Received 8 April 2010; accepted 3 May 2010

Key indicators: single-crystal X-ray study; $T = 298\text{ K}$; mean $\sigma(\text{C}-\text{C}) = 0.006\text{ \AA}$; R factor = 0.035; wR factor = 0.072; data-to-parameter ratio = 142.9.

In the title half-sandwich compound, $[\text{Ni}(\text{C}_6\text{H}_{15}\text{N}_3)(\text{H}_2\text{O})_3]\text{-Br}(\text{NO}_3)$, the central Ni^{II} ion, lying on a threefold rotation axis, is six-coordinated by three amine N atoms from the face-capping triaza macrocycle and three water O atoms in a slightly distorted octahedral geometry. In the crystal, $\text{O}-\text{H}\cdots\text{O}$ hydrogen bonding and weak $\text{O}-\text{H}\cdots\text{Br}$ interactions associate the Ni^{II} cations and the counter-ions into a three-dimensional supramolecular network.

Triaqua(1,4,7-triazacyclononane- κ^3N^1,N^4,N^7)nickel(II) bromide nitrate

C. Wen, J. Lu and Z. Zhang

Comment

The coordination chemistry of 1,4,7-triazacyclononane (TACN) has been extensively studied for its applications in the simulation of metalloenzymes and metalloproteins (Chaudhury *et al.*, 1985; Deal *et al.*, 1996; Hegg & Burstyn, 1995; Hegg *et al.*, 1997; Lin *et al.*, 2001; Williams *et al.*, 1999) as well as in constructing molecule-based magnetic materials (Berseth *et al.*, 2000; Cheng *et al.*, 2004; Poganiuch *et al.*, 1991). In general, TACN ligand can form stable sandwich complexes with many transition metals (Stranger *et al.*, 1992; Zompa & Margulis, 1978) or functions as a terminal chelator for the assembly of binuclear/polynuclear species and coordination polymers supported by bridging ligands (Bencini *et al.*, 1990; Wang *et al.*, 2005; Wang *et al.*, 2003). In this paper, a half-sandwich type Ni^{II} complex with TACN has been synthesized and characterized.

In the selected crystal, the title compound (I) crystallizes in a chiral space group *P*2₁3 and Flack parameter of 0.01 (3) indicates that a spontaneous resolution has been achieved during crystallization. As depicted in Fig. 1, the Ni^{II} center in the complex cation lies on a three-fold rotation axis and three amine N atoms from facially coordinated TACN and three water molecules complete the slightly distorted octahedral arrangement. Upon coordination, three five-membered Ni—N—C—C—N chelating rings subtended at metal center adopt ($\lambda\lambda\lambda$) conformation, which is the source of the chirality of the crystal. Ni—N [2.091 (3) Å] and Ni—O [2.089 (3) Å] bond lengths are both in the normal ranges, meanwhile N—Ni—N bond angle is smaller than that of O—Ni—O due to the small size of TACN ring. Counter-ions NO₃⁻ and Br⁻ interconnect neighbouring cations by O—H···O hydrogen bond and O—H···Br⁻ weak interaction (Table 1) into three-dimensional supramolecular network (Fig. 2).

Experimental

1,4,7-Triazacyclononane trihydrobromide (TACN·3HBr) was prepared by following a modified published method (Koyama & Yoshino, 1972).

To a solution of 0.074 g (0.02 mmol) of TACN·3HBr in water (10 ml), 0.1 M NaOH was added to adjust the pH to 6. Then aqueous solution (5 ml) of 0.058 g (0.02 mmol) of Ni(NO₃)₂·6H₂O was added and the resulting mixture was stirred under reflux for 6 h. After cooling, the mixture was filtered, and the filtrate was allowed to standing at ambient temperature. Plate-like green single crystals suitable for X-ray crystallographic analysis were collected by slow evaporation of the filtrate within two months.

supplementary materials

Refinement

All methylene H atoms were placed at calculated positions and refined as riding on their parent atoms [C—H = 0.97 Å and $U_{\text{iso}}(\text{H}) = 1.2 U_{\text{eq}}(\text{C})$]. The H atoms of amine groups and water molecules were located in a difference Fourier map as riding atoms, with $U_{\text{iso}}(\text{H}) = 1.5 U_{\text{eq}}(\text{N})$ and $1.5 U_{\text{eq}}(\text{O})$.

Figures

Flack parameter: 0.01 (3)

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R -factor wR and goodness of fit S are based on F^2 , conventional R -factors R are based on F , with F set to zero for negative F^2 . The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R -factors(gt) etc. and is not relevant to the choice of reflections for refinement. R -factors based on F^2 are statistically about twice as large as those based on F , and R -factors based on ALL data will be even larger.
