Previous work by our group showed that supplementing diets with Ca salts containing fish oil fatty acids improved pregnancy per AI (P/AI) in dairy cows. Objectives were to determine the effects of supplementing DHA by feeding algae on lactation and reproductive performance of Holstein cows. The hypothesis was that feeding DHA improves P/AI in dairy cattle. Weekly cohorts of cows were blocked by parity and randomly assigned at 27 DIM to a control [CON; n = 372, 115 primiparous and 258 multiparous] or an algae supplemented (ALG; n = 366, 105 primiparous and 261 multiparous) diet. Cows were fed the same TMR; however, ALG received 100 g/cow/d of a 17% DHA supplement top-dressed and hand-mixed onto the TMR for 120 d. Milk yield was recorded daily and sampled every 3 wk for analysis. Cows were subjected to the Presynch-Ovsynch protocol starting at 44 ± 3 DIM and those in estrus after 58 ± 3 DIM were inseminated on the same day, otherwise, they received timed AI at 80 ± 3 DIM. Pregnancy was diagnosed on d 60 after AI. Data were analyzed by ANOVA, logistic regression or the Cox's proportional hazard model using the GLIMMIX and PHREG procedures of SAS. Intake of DM did not differ between treatments (ALG = 24.8 vs. CON = 25.5 ± 0.6 kg/d). Milk yield was greater ($P = 0.01$) in ALG than CON (43.6 vs. 42.5 ± 0.3), but yield of energy-corrected milk was similar between treatments and averaged 39.2 ± 0.2 kg/d. Feeding ALG reduced ($P = 0.03$) content and yield of milk fat (3.08 vs. 3.23 ± 0.03% and 1.30 vs. 1.34 ± 0.01 kg/d); however, ALG increased ($P < 0.01$) yields of protein (1.23 vs. 1.20 ± 0.01 kg/d) and lactose (2.07 vs. 2.02 ± 0.01 kg/d). Feeding ALG increased ($P = 0.04$) the proportion of primiparous cows that resumed estrous cyclicity by 58 DIM (77.6 vs. 65.9%) and P/AI at first AI (47.6 vs. 32.8%). Feeding ALG increased ($P < 0.01$) P/AI at all AI in all cows (41.4 vs. 30.8%). Cows fed ALG became pregnant 21 d (103 vs. 124 d) sooner ($P < 0.01$) than those fed Control (adjusted HR = 1.38; 95% CI = 1.13 to 1.69). Supplementing DHA by feeding ALG did not affect intake of DM, increased yields of milk and protein, but reduced milk fat content and yield. Cows fed ALG had improved estrous cyclicity, P/AI, and reduced interval to pregnancy.

288 Assessment of acute pain during and after knife and band castration of beef calves at three different industry-relevant ages.

Daniela M. Meléndez*[1,2], Sonia Marti[1], Eugene D. Janzen[2], Diego Moya[1,2], Ed Pajor[2], and Karen S. Schwartzkopf[1], *[1]Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada, [2]University of Calgary, Calgary, Alberta, Canada.*

The aim of this study was to identify which age and method of castration causes less acute pain and distress in beef calves. One hundred five Angus bull calves were blocked by age and body weight, and randomly assigned to 1 of 3 treatments: control (C; n = 12); band castration (B; n = 12); and surgical castration (S; n = 12); at 1 wk, 2 and 4 mo of age. Physiological and behavioral parameters were collected before, during and after castration to assess acute pain. Physiological measures included blood count, salivary cortisol, haptoglobin, substance P and infrared thermography. Behavioral measures consisted of visual analog score, stride length, hobo data loggers and behavioral scoring of walking, standing, lying, tail flick, foot stamping and head turning. Overall, no physiological or behavioral parameters differed significantly for calves castrated at 1 wk of age. Salivary cortisol tended ($P = 0.07$) to differ at 1 wk of age when S calves had greater concentrations than B calves. Conversely, both physiological and behavioral indicators of pain/distress were clearly observed when calves were castrated at 2 and 4 mo of age regardless of the method used. A time × treatment interaction ($P < 0.0001$) was observed for salivary cortisol in 4 mo old calves, with B and S calves having greater concentrations than C calves 60 min after castration, while B had greater concentrations than S and C calves 120 min after castration. Based on behavioral data, S calves at 2 and 4 mo of age, stood ($P < 0.0001$) and walked ($P = 0.04$) more but lie down and ate less ($P = 0.01$; $P = 0.002$) compared with B and C only at 2 mo of age. At 4 mo of age, S calves tail flicked more ($P = 0.0006$) and had shorter stride length ($P = 0.036$) than B and C calves. The indicators of acute pain/discomfort assessed in this study suggest that the most welfare-friendly age and method of castration is band castration at 1 wk of age.

Key Words: castration, pain, beef

289 The influence of dietary strong ions on rumen ion concentrations.

Tracy L. Catterton* and Richard A. Erdman, *Department of Animal and Avian Sciences, University of Maryland, College Park, MD.*

Dietary cation-anion difference (DCAD) is being used as a basis for diet formulation in the dairy industry. While extensive research has been conducted on the effects of DCAD concentration on animal performance and rumen characteristics, the effects of the individual strong ions that contribute to DCAD have yet to be determined. In addition to DCAD, there is evidence that cation source (Na vs. K) affects animal performance (Iwaniuk et al., 2015). We hypothesized that dietary strong ion concentrations (Na, K, and Cl) would affect the rumen ion concentrations. Our objective was to determine if rumen Na, K, and Cl concentrations were affected by dietary mineral content. Literature data were collected from 2 dairy cattle studies (Bailey, 1961; Bennink et al., 1978) that included 11 different diets with (mean ± SE) concentrations of 47 ± 35, 358 ± 312, and 108 ± 188 mEq/kg dietary Na, K, and Cl, respectively. Rumen samples, collected by rumen cannula, were taken between 0 to 9 h (Bennink et al., 1978) and 1 to 14 h post-feeding (Bailey, 1961). Principal components analysis (PCA) suggested that rumen Na and K were PCA negative, while rumen Cl and diet K clustered together. Subsequent multiple regression analysis (PROC GLMSELECT) showed that dietary K and Cl were significant factors ($P < 0.01$) associated with changes in rumen Na, K, and Cl, and diet Na was associated ($P \leq 0.06$) with changes in rumen Na and K. As rumen K increased, rumen Na decreased ($P < 0.001$). We concluded that manipulation of diet strong ion concentrations could be used to alter rumen Na, K, and Cl concentrations and, thus, alter the rumen environment.

Table 1 (Abstr. 289).

290 Disbudding and dehorning practices in dairy calves among Ontario bovine veterinarians.

Charlotte B. Winder*[1], Stephen J. LeBlanc[1], Derek B. Haley[1], Kerry D. Lissemore[1], M. Ann Godkin[2], and Todd F. Duffield[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]Ontario Ministry of Agriculture, Food and Rural Affairs (OMAFRA), Guelph, Ontario, Canada.*

An online survey was conducted in the fall of 2014 to explore current practices, including analgesic use, in the disbudding or dehorning (D/D) of dairy calves by veterinarians in Ontario. Members of the Ontario Association of Bovine Practitioners (n = 238) were invited to participate. Ninety-three veterinarians (39%) from 51 clinics (63%) responded, with 94% of clinics reporting veterinarians or veterinary technicians (VT) performing D/D for an estimated mean of 29% (SD = 20) of their dairy clients. Twenty-five percent of clinics employed VT to perform this service. Of these clinics, VT accounted for an estimated mean of 69% (SD = 29) of the clinic's total D/D. Veterinarians who perform D/D were asked to report calf age at time of D/D. Seventy-five percent of veterinarians disbudded calves < 4 weeks of age. Of these veterinarians, 99% used local anesthetic, 56% used a sedative, and 50% used an NSAID. Ninety-one percent of veterinarians disbudded calves 4–8 weeks of age. Of these veterinarians, 99% used a local anesthetic, 61% used a sedative, and 54% used an NSAID. Finally, 76% of vets performed D/D in calves > 8 weeks of age. Of these veterinarians, 97% used a local anesthetic, 66% used a sedative, and 59% used an NSAID. Injectable meloxicam accounted for 89% of all NSAIDs given in all age groups. Common reasons for NSAID use were: pain control, known withdrawal time, and reasonable cost. Common reasons for the lack of NSAID use

were: objections to cost, and client requests excluding cost. Nearly all (98%) veterinarians practicing for at least 10 years reported changing D/D practices over this time period. Common changes included: use or increased use of an NSAID (60%), use or increased use of sedation (34%), and use or increased use of local anesthetic (29%). Reasons for changes included: concern for the welfare of the calf, information from continuing education, and improved calf handling. Use of NSAID in this survey is higher than previously reported, as was the proportion of calves disbudded < 4 weeks of age. This indicates a trend toward improved analgesia and adoption of best practices for welfare in the D/D of dairy calves.

Key Words: calf, disbud, welfare

291 Identification of early pregnancy and fetal landmarks via transabdominal ultrasound in sheep.

Amanda K. Jones*[1], Rachael E. Gately[2], Katelyn K. McFadden[1], Steven A. Zinn[1], Kristen E. Govoni[1], and Sarah A. Reed[1], *[1]Department of Animal Science, University of Connecticut, Storrs, CT, [2]Department of Environmental and Population Health, Tufts Cummings School of Veterinary Medicine, North Grafton, MA.*

Field application of small ruminant ultrasound is primarily used for pregnancy detection and fetal number beginning at mid-gestation. Efforts to estimate fetal age and number early in small ruminant pregnancies are limited. We hypothesized that detection of pregnancy and fetal landmarks before d 45 via transabdominal ultrasound is reliable in the sheep, and may be used to determine fetal age during early in sheep. To test this hypothesis, 106 Western Whiteface ewes were exposed to 1 of 4 rams. The day a ewe was marked by a ram was considered d 0 of pregnancy. Transabdominal ultrasound (Easi-Scan, BCF Technology, Rochester, MN) was performed 3 times/wk with a 5 MHz rectal transducer in the right non-haired abdominal region of the ewe starting at d 26.0 ± 0.3 (range d 22 to d 30). Pregnancy was confirmed in 88 ewes, with the remaining identified as non-pregnant. Fluid-filled uterine cross-sections provided first evidence of pregnancy from d 26.0 ± 2.9 onward. Pregnancy was confirmed by the presence of a fetus with a heartbeat on d 28.5 ± 0.4. Singleton pregnancies were detected later than multiple pregnancies (singletons: d 31.2 ± 0.9, twins: d 27.6 ± 0.9, triplets: d 26.3 ± 1.0, $P < 0.01$). The uterine horn of fetal origin had no effect on identifying singleton pregnancies ($P = 0.52$). Placentome evagination was first observed at d 33.8 ± 0.4, separation of limb buds at d 35.2 ± 0.7, fetal genitalia spots at d 37.9 ± 0.7, mature placentomes at d 40.6 ± 0.4, and ribs at d 42.9 ± 1.4. Additionally, 3 fetal losses were identified by d 40.0 ± 0.7 of pregnancy (3.4% early embryonic loss rate). Accuracy of counting fetuses (77.6%) increased with decreasing number of offspring. That is, identification of singletons, twins and triplets was 95, 80 and 41%, respectively. Pregnancy detection via transabdominal ultrasound was accurate as early as d 28 in sheep and sensitive enough to consistently identify early embryonic developments before d 45. Distinguishing these fetal landmarks may allow for estimating fetal age to improve early detection of pregnancy and breeding management of sheep.

Key Words: ultrasound, pregnancy, sheep

292 Isolation and characterization of chemical components of *Leucaena leucocephala* with anti-methanogenic properties by using in vitro gas production technique.

D. Dineshkumar*[1], A. L. Abdalla[1], C. L. Linander[1], A. P. Massarioli[2], A. L. Abdalla Filho[1], P. P. Santos[1], A. S. Natel[1], S. M. Alencar[2], and H. Louvandini[1], *[1]Centre for Nuclear Energy in Agriculture, University of Sao Paulo, Piracicaba, Sao Paulo, Brazil, [2]College of Agriculture "Luiz de Queiroz," University of Sao Paulo, Piracicaba, Sao Paulo, Brazil.*

Studies emphasized that group of plant secondary metabolites (saponins, flavonoids and tannins) seems to present the ability to manipulate rumen fermentation lessening the CH_4 formation. The purposes of this research were to find out individual bioactive compound with anti-methanogenic activity. However, we anticipate that advances technology such as GC-MS will provide unprecedented data on the distribution of component existing in plant extracts. *Leucaena leucocephala* plant samples were extracted with methanol solvent using ultra sonication. Crude solvent free extract (8.58 g) was then extracted with different organic solvent with increasing polarity provided extracts of hexane (1.03 g), chloroform (0.34 g), ethyl acetate (0.48 g), butanol (0.77 g) and residual crude fractions (1.99 g) respectively. Assessment of phytoconstituents in such organic extracts was subjected to find out individual bioactive compound with the modified GC–MS (Shimadzu gas chromatography-mass spectrometer (GCMS-QP2010) method. 38 components were identified from the chromatograms of the different organic solvent extracts. Dried 0.5g of ground leucena plant, alfafa plant (positive control) and the different crude methanolic extracts with 3 different levels (125, 250, and 500 µg/mL) were tested for anti-methanogenic properties in terms of in vitro gas production and nutrient degradability. We found significant organic solvent effects for CH_4 production. Hexane extract reduces Net CH_4/OMD ($P < 0.001$) compared with other solvent extracts tested. Nutrient degradability, ruminal parameters and VFA production were non-significantly differed between the treatment groups. But, there was an improvement on nutrient degradability compared with *Leucaena leucocephala* and control plants. However, we found no doses and interaction between solvent and dose effects among the treatment groups. This study explained hexane extract from whole plant methanolic extract is effective against anti-methanogenic activity in modifying ruminal degradation of nutrients. The most active components still have to be identifying by fractionation of hexane extract.

Key Words: *Leucaena leucocephala*, anti-methanogenic properties, GC-MS

293 Immune cells populate mesenteric adipose tissues of Holstein Friesian cows.

Bridget A. Aylward*[1], Megan Clark[1], Amanda Barnard[1], Jen Wilson[1], Candice Gittens[1], Tanya Gressley[1], Erin Brannick[1], Marie Fecteau[2], and Robert Dyer[1], *[1]Department of Animal and Food Sciences, College of Agricultural and Natural Resources, University of Delaware, Newark, DE, [2]Department of Clinical Studies, New Bolton Center, University of Pennsylvania, School of Veterinary Medicine, Kennet Square, PA.*

In many animal species, anti-inflammatory immune cells are normal residents of lean adipose depots and produce a barrier of related cytokines that protect against metabolic syndrome. Our objective was to determine if similar immune cells reside in mid-jejunum mesenteric adipose tissue (MAT) of randomly selected lean Holstein Friesian cows from an abattoir. Body condition scores were determined before slaughter (mean BCS = 2.74). Stromal cell fractions (SCF) were prepared from washed, minced MAT digested with type I collagenase. Following digestion and cleaning of the sample, cells were stained with bovine immune cell marker specific monoclonal antibodies expressed on macrophages, dendritic cells, T lymphocytes and T regulatory lymphocytes (T regs). Background controls consisted of cells stained with irrelevant, isotype-matched control antibodies. SCF composition was analyzed across 10,000 cells/sample using a Becton Dickson FACS Calibur Flow Cytometer. Marker specific fluorescence was compared with background fluorescence in controls by ANOVA. Marker expression is summarized

in the table below. Results from this work indicate that populations of innate (macrophage and dendritic cells) and adaptive (lymphocytes and T regs) immune response cells do in fact reside in MAT of lean cows (Table 1). Furthermore, expression of MHC class II in the context of dendritic cells or macrophages and T lymphocytes suggests adaptive immune responses do occur in MAT. Subpopulations of FoxP3$^+$ regulatory T lymphocytes were the dominant effector lymphocyte, implying that anti-inflammatory functions could contribute to MAT homeostasis in lean cows and potentially protect against development of metabolic disease.

Table 1 (Abstr. 293). Presence of immune cells mesenteric adipose tissue (MAT) of Holstein Friesian cows

Presumptive cell type	Marker	Percent of SCF
Macrophages	CD11b (n=9)	8.71 ± 0.75*
	CD172 (n=8)	12.57 ± 1.20*
	CD11b/CD172 (n=8)	6.74 ± 0.84*
	CD3/CD11b (n=4)	2.48 ± 0.62
Dendritic cells	MHC II (n=5)	10.62 ± 0.86*
	CD11c (n=9)	9.43 ± 0.57*
	MHC II/CD11c (n=5)	2.59 ± 0.52
	CD11c/CD3 (n=4)	1.76 ± 0.44
T lymphocytes	CD3 (n=17)	8.99 ± 0.33*
	CD8 (n=4)	3.58 ± 0.89
	CD3/CD8 (n=4)	1.07 ± 0.27
T regulatory lymphocytes	FoxP3 (n=6)	8.00 ± 0.56*
	CD4/FOXP3(n=6)	0.04 ± 0.12

294 Effects of under- and over-feeding during gestation on organ development of offspring at days 45 and 90 of gestation.

Sambhu M. Pillai*, Joseline S. Raja, Maria L. Hoffman, Amanda K. Jones, Katelyn K. McFadden, Sarah A. Reed, Steven A. Zinn, and Kristen E. Govoni, *University of Connecticut, Storrs, CT.*

Poor maternal nutrition during gestation can lead to intrauterine growth restriction resulting in offspring with low birth weight and altered organ development, negatively affecting production. We hypothesized that poor maternal nutrition during gestation would alter fetal body weight and organ mass of lambs during gestation. Western Whiteface ewes (n = 82) were bred to 1 of 4 rams and confirmed pregnant by ultrasound. Ewes were fed 100%, 60%, or 140% of NRC requirements for TDN beginning at d 30.2 ± 0.2 of gestation and offspring from these ewes will be referred to as CON, RES, and OVER, respectively. Fetal weights and organs were collected at d 45, 90, and 135 of gestation and within 24 h of birth. To date, organ weights have been collected from d 45 and 90. Data are expressed as percent of fetal weight and were analyzed using PROC MIXED in SAS. At d 45, fetal weight tended to be different ($P = 0.067$) between treatments with OVER offspring smaller than CON ($P = 0.021$) and RES intermediate (CON = 11.0 ± 0.6 g; RES = 10.1 ± 0.5 g; OVER = 9.2 ± 0.5 g). Liver weight at d 45 tended to be different ($P = 0.055$) with RES offspring larger than OVER ($P = 0.017$) and CON intermediate (CON = 6.7 ± 0.5%; RES = 7.6 ± 0.5%; OVER 6.1 ± 0.4%). We did not observe a difference in the weight of heart and kidney at d 45 ($P \geq 0.148$). Although fetal weights were not different at d 90 ($P = 0.329$) liver weights were greater in OVER offspring vs CON and RES ($P \leq 0.05$; CON = 5.5 ± 0.2%; RES = 5.7 ± 0.2%; OVER = 6.3 ± 0.2%). At 90 d an effect of maternal diet was not observed for kidney, heart, pancreas, adrenal, or renal fat weights ($P \geq 0.153$). In conclusion, maternal under- and over-feeding affects liver development during early gestation, a period of rapid liver growth, which may lead to altered health and growth of the offspring later in life.

Key Words: maternal nutrition, sheep, organ development

Lactation Biology I

295 CLOCK regulation of mammary epithelial cell growth.

Theresa Casey*[1], Jennifer Crodian[1], Aridany Suárez-Trujillo[2], Emily Erickson[1], Bethany Weldon[1], Kristi Crow[1], Avi Shamay[3], Sameer Majbeesh[4], and Karen Plaut[1], *[1]Purdue University, West Lafayette, IN, [2]Universidad de Las Palmas de Gran Canaria, Arucas, Canary Islands, Spain, [3]Agriculture Research Organization, Volcani Center, Bet Dagan, Israel, [4]The Hebrew University of Jerusalem, Rehovot, Israel.*

The circadian timing system (CTS) influences virtually all physiological processes, including lactation. However, the manner that the multitude of molecular clocks that make up the CTS both centrally and peripherally affect lactation performance is currently not understood. Preliminary studies from our lab led us to hypothesize clocks in the mammary play an important role in regulation of gland development. The objective of this study was to determine if decreasing abundance of CLOCK, a core component of the circadian clock mechanism, affects growth of mammary epithelial cells. For this study a mouse mammary epithelial cell line, HC11, was transfected with shRNA that targeted *Clock* or a negative control scramble sequence. Cells transfected with sh*Clock* expressed 70% less *Clock* mRNA than wild-type (WT) HC11 cultures, which resulted in significantly depressed levels of CLOCK protein ($P < 0.05$). Scramble had no effect on mRNA or CLOCK protein levels. Six-day growth curve analysis revealed HC11 lines carrying sh*Clock* had 4-fold higher growth rates ($P < 0.05$) and reached at least 2-fold higher cell density than scramble transfected or WT HC11 cultures. To understand how CLOCK regulates growth, sh*Clock* transfected and WT HC11 cells were plated in growth medium, serum starved for 24 h, returned to growth medium and then collected every 4 h over a 48-h period. Cell cycle analysis of propidium iodide stained cells showed sh*Clock* significantly increased response to serum starvation (90.1 ± 1.1% of sh*Clock* versus 71.3 ± 3.6% of WT-HC11 in G1 phase), and affected progression through cell cycle. Two-way ANOVA showed time and cell line had significant effects ($P < 0.0001$) on relative expression levels of the cell cycle regulators, *Ccnd1* (regulates transition from G1 to S phase), *Wee1* (regulates transition from G1 to S and G2 to M phase) and *Tp63* (a tumor suppressor gene). Moreover, basal mean expression of *Ccnd1* was 43% greater ($P = 0.002$) in sh*Clock* versus WT cell lines, and *Tp63* expression was depressed by ~3-fold in sh*Clock* cultures ($P < 0.0001$). These data support circadian clocks play a role in regulation of epithelial cell growth in the mammary gland.

Key Words: circadian, clock, mammary

296 CLOCK regulates mammary differentiation and output.

Aridany Suárez Trujillo*[2], Jennifer Crodian[1], Emily Erickson[1], Avi Shamay[3], Sameer Majbeesh[4], Karen Plaut[1], and Theresa Casey[1], *[1]Purdue University, West Lafayette, IN, [2]Universidad de Las Palmas de Gran Canaria, Arucas, Canary Islands, Spain, [3]Agriculture Research Organization, Volcani Center, Bet Dagan, Israel, [4]The Hebrew University of Jerusalem, Rehovot, Israel.*

Circadian clocks synchronize internal physiology to the environment, thus understanding role in regulation of lactation may lead to development of noninvasive approaches to improve production efficiency of dairy animals. Circadian clocks are present in all mammalian cells. The *BMAL1* and *CLOCK* genes are core components of clocks, functioning together as a transcription factor. In the mammary gland, abundance of BMAL1-CLOCK increases during the transition from pregnancy to lactation and upon lactogen-induced differentiation of mammary cells in culture. We hypothesize that in the mammary BMAL1-CLOCK regulates differentiation and milk synthesis. Our objective was to elucidate the effect of decreasing CLOCK abundance on expression of markers of differentiation (e-cadherin- CDH1) and metabolic output (fatty acid synthase- FASN; β-casein- CSN2) in a mouse mammary epithelial cell line, HC11. To decrease CLOCK abundance, HC11 cells were transfected with shRNA specific for *Clock* or a scramble sequence (negative control), and clonal lines were established. Cells transfected with sh*Clock* had a 70% reduction in *Clock* mRNA, which resulted in significantly reduced ($P < 0.05$) CLOCK protein abundance relative to wild-type cultures. Abundance of CLOCK in scramble-line was not different from wild-type. RNA and protein were collected from undifferentiated cultures, and cultures treated 96 h with dexamethasone, insulin and prolactin (differentiated). Gene expression was analyzed using RT-qPCR. Two-way ANOVA showed cell line (wild-type, scramble, sh*Clock*) and state of differentiation had a significant effect ($P < 0.05$) on relative expression of *Fasn, Csn2* and *Cdh1*. Post-hoc analysis revealed *Fasn* was significantly reduced by 2-fold ($P < 0.05$) in sh*Clock* treatments relative to wild-type cultures. *Cdh1* was also reduced more than 3-fold in sh*Clock* lines relative to wild-type cultures ($P < 0.05$). Moreover, Western blot analysis showed abundance of CDH1 protein was significantly reduced in cultures transfected with sh*Clock*. sh*Clock* sequence did not have a significant effect on *Csn2* expression. In conclusion CLOCK regulates differentiation markers and *Fasn*, future studies are needed to understand how factors affect mammary clocks and the relationship to dairy performance.

Key Words: mammary, circadian, differentiation

297 Expression of putative stem cell marker, hepatocyte nuclear factor 4 alpha, in mammary gland of water buffalo.

Ratan K. Choudhary*[1], Harmanjot Kaur[1], Shanti Choudhary[1], and Devendra Pathak[2], *[1]School of Animal Biotechnology, Guru Angad Dev Veterinary and Animal Science University, Ludhiana, Punjab, India, [2]Department of Veterinary Anatomy, College of Veterinary Sciences, Guru Angad Dev Veterinary and Animal Science University, Ludhiana, Punjab, India.*

Buffaloes account for more than 56% of total milk production in India. Cyclic remodeling of mammary glands of human, mice, cow, sheep and goat is determined by mammary stem cells. It is logical to assume that buffalo mammary gland will have mammary stem/progenitor cells. Thus far, no report exists on identification of buffalo mammary stem cells. Hepatocyte nuclear factor 4 α (HNF4A) is a candidate marker for hepatic progenitor cells and has recently been suggested as a marker of bovine mammary stem/progenitor cells. We hypothesized that (1) HNF4A identifies putative buffalo mammary stem/progenitor cells and (2) the number of mammary stem/progenitor cells increases during mastitis. Thirteen buffalo mammary samples were collected from a local slaughterhouse. Hematoxylin and eosin staining were performed on 5-μm-thick sections. Based on histomorphology of mammary glands, physiological stages were estimated to be nonlactating ($n = 4$ animals) and mastitis ($n = 9$ animals). In total, ~22,000 cells were counted (10 microscopic fields/animal; $n = 13$ animals), of which 40% cells were mammary epithelial cells (MEC) and 60% cells were the stromal cells. The percentage of MEC in nonlactating animals was higher compared with that in mastitic animals (47.3 vs. 37.3%), which was likely due to loss of MEC caused by infection. HNF4A staining was observed in nuclei of MEC of ducts, alveoli and stromal cells. Basal location and low frequency of basally located HNF4A positive cells (ranges from 0.4 to 4.5%) was consistent with characteristics of mammary stem cells. HNF4A-positive MEC (basal and luminal; light and dark stained) tended to be higher during nonlactating stage than mastitis (8.73 ± 1.71 vs. 4.29 ± 1.19%; $P = 0.07$). MEC proliferation (assessed by immunohistochemical expression of Ki67) was higher in mastitic glands in comparison to nonlactating glands (15.3 ± 5.7% vs. 0.53 ± 0.1%; $P = 0.03$). This is the first report outlining the expression of HNF4A as a putative mammary stem/progenitor cells of buffalo mammary gland; and evaluation of MEC proliferation in naturally infected mastitic buffaloes.

Key Words: buffalo, mammary stem/progenitor cell, HNF4A

298 Optimization of transfection and real-time monitoring of fluorescent proteins in bovine cells: An untapped molecular biology approach for dairy sciences.

J. S. Osorio* and M. Bionaz, *Oregon State University, Corvallis, OR.*

The study of nuclear receptor activation by specific dietary compounds via gene reporter technology (GRT) is essential in nutrigenomics research. The GRT requires inserting into cells an artificial plasmid containing a promoter region with the response element for the nuclear receptor of interest and DNA coding for luciferase or a fluorescent protein. The main challenge of using GRT is the low efficiency and high variability of plasmid transfection; thus limiting the sensitivity and increasing intra-essay variability. To investigate the efficiency of transfection in immortalized (MacT) and primary mammary bovine (BMEC) cells we have tested several concentrations of transfection reagents in combination with several concentrations of a plasmid for the constitutively expressed enhanced green fluorescent protein (EGFP). Cells were seeded 24 h prior transfection at 30,000 cells/well in a 96-well plate and treated with a nuclear staining (NucBlue Live). The transfection reagents Lipofectamine 2000, Lipofectamine LTX, and TransIT-X2 were used at 0.2, 0.3, 0.4, or 0.5 mL/well with 50, 100, 200, or 300 ng/well of EGFP. Using a robotic inverted fluorescent microscope for live imaging (Leica DMI6000B), 2 pictures/well were taken every hour for 30 h post-transfection. Cell number, viability, and quantification of transfection efficiency were assessed using the CellProfiler sotfware. Data were analyzed using GLIMMIX of SAS. EGFP protein was visualized as early as 4 h after transfection and plateau expression was observed >7 h post-transfection. We observed high variability in transfection efficiency ranging from 1 to 30%. Transfection efficiency was best using Lipofectamine 2000 in BMEC and Lipofectamine LTX in MacT. In general we observed that high dose of transfection reagent and plasmid provided best results; however, high dose of transfection reagent tend also to kill the cells. Overall, our data confirmed the large intra- and inter-cells variation in transfection efficiency and prompt for a more precise approach to obtain high reliable data for nutrigenomics studies in dairy cows.

Key Words: mammary epithelial cell, nutrigenomics, transfection

299 Palmitate and peroxisome proliferator-activated receptor (PPAR)γ synthetic agonists, but not *trans*-10,*cis*-12 CLA, activatePPAR in MacT and primary goat mammary cells.

J. S. Osorio* and M. Bionaz, *Oregon State University, Corvallis, OR.*

The peroxisome proliferator-activated receptors (PPAR) can play pivotal nutrigenomics roles in ruminants owing their capacity to be activated by long-chain fatty acids (LCFA). Data on expression of putative PPARs target genes suggested that palmitate (PA) is a potent PPARs activator in cows and goats whereas *trans*-10,*cis*-12 conjugated linoleic acid (CLA) is not or is a very weak PPAR agonist. Furthermore, previous in vivo data in goats and cows suggested that 2,4-thiazolidinedione (TZD) is a weak activator of PPARγ. To test if palmitate, *trans*-10,*cis*-12-CLA, and TZD are PPAR agonists we have transfected immortalized MacT and primary mammary goat (PMG) cells with a PPRE-X3-TK-Luc plasmid. Prior transfection cells were seeded at 10^4 cells/well in a 96-well plate. We have used as transfection reagents Lipofectamine 3000 with PMG and TransIT-X2 with MacT at 0.3 µL/well with 200 ng/well of plasmid in OptiMEM deprived of fetal bovine serum (FBS). Transfected cells were treated for 24h in quadruplicates with 10% FBS or 0.1 m*M* of ethanol (control), rosiglitazone (ROSI), PA, and CLA as well as 2 doses of TZD (0.1 m*M* and 1 m*M*) in medium without FBS. All were supplemented with 10 µ*M* of 9-*cis*-retinoic acid. Cell number and transfection efficiency was obtained via CellProfiler software and luciferase was measured using luminometer and normalized by number of viable cells. Data were analyzed using GLIMMIX of SAS and significance was declared with $P < 0.05$. Transfection was higher with MacT (24 ± 3%) compared with PMG (6 ± 4%). In MacT cells, all treatments with exception of CLA activated PPAR compared with control with the highest activation observed with TZD followed by PA, ROSI, and FBS. In PMG the PPAR activation was observed with FBS, PA, and TZD, while CLA and ROSI did not affect luciferase. Overall our data confirmed that TZD is a PPARγ synthetic agonist in ruminant mammary cells. In addition, the data confirmed that PA but not CLA is a PPAR activator and that blood serum in ruminants contains potent natural PPAR agonists, likely LCFA. These findings underscore the nutrigenomics importance of PA and confirmed the PPARγ responsiveness of mammary cells in ruminants.

Key Words: nutrigenomics, PPAR, transfection

300 Protection of bovine mammary epithelial cells from hydrogen peroxide-induced oxidative cell damage by resveratrol.

X. L. Jin*[1,3], Kai Wang[2], H. Y. Liu[1,3], F. L. Hu[2], F. Q. Zhao[1,4], and J. X. Liu[1,3], [1]*Institute of Dairy Science, College of Animal Sciences, Zhejiang University, Hangzhou, China,* [2]*Institute of Sericulture and Apiculture, College of Animal Sciences, Zhejiang University, Hangzhou, China,* [3]*MOE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, China,* [4]*Laboratory of Lactation and Metabolic Physiology, Department of Animal Science, University of Vermont, Burlington, VT.*

Knowledge in the effects of oxidative stress and antioxidants on bovine mammary epithelial cells (bMEC) is limited. The objectives of this study were to investigate the oxidative damaging effects of hydrogen peroxide (H_2O_2) and the cytoprotective effects of resveratrol, a well-known natural product rich in grape seeds, against oxidative stress in cultured bMEC (MAC-T). To establish an oxidative stress model in bMECs, 500 µ*M* H_2O_2 was added to MAC-T cells. The CCK-8 assay was applied to detect cell viability and flow cytometry method was used to detect intracellular production of reactive oxygen species. Pretreatment of MAC-T cells with resveratrol could rescue the decrease in cell viability and resulted in lower intracellular accumulation of reactive oxygen species after H_2O_2 exposure. Using qRT-PCR, we found that resveratrol helped MAC-T cells to prevent H_2O_2-induced endoplasmic reticulum stress, indicated by significantly decreased abundance of endoplasmic reticulum stress marker GRP78 and CHOP mRNA ($P < 0.01$). Resveratrol also inhibited mitochondria-related cell apoptosis by downregulating the expression of pro-apoptotic Bax gene ($P < 0.01$) and upregulating expression of anti-apoptotic Bcl-2 gene ($P < 0.01$) compared with H_2O_2 group. Moreover, resveratrol increased the abundance of multiple antioxidant defense genes (HO-1, xCT, Txnrd1, and NQO-1) in MAC-T cells under normal/oxidative conditions. It is confirmed that Nrf2 was required for the cytoprotective effects on MAC-T cells by resveratrol, because knockdown of Nrf2 abolished resveratrol-induced cytoprotective effects against oxidative stress, accompanied by no significant differences in gene expression of Nrf2, HO-1, Txnrd, and CHOP between resveratrol+H_2O_2 and H_2O_2 groups in Nrf2 knockdown MAC-T cells. Finally, by using selective inhibitors, we confirmed that the induction of Nrf2 by resveratrol was mediated through the activation of the PI3K/Akt and ERK/MAPK pathways, but negatively regulated by p38/MAPK pathway. In conclusion, our study provided evidence that resveratrol may be potentially used as a therapeutic agent for cytoprotection of bMEC against oxidative stress.

Key Words: resveratrol, oxidative stress, mammary epithelial cell

301 Stabilization of Nrf2 by tBHQ attenuates heat shock-induced cell damage in bovine mammary epithelial cells.

X.L. Jin*[1,2], H.Y. Liu[1,2], and J.X. Liu[1,2], [1]*Institute of Dairy Science, College of Animal Sciences, Zhejiang University, Hangzhou, China,* [2]*MOE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, China.*

Nrf2-ARE signaling plays a key role in cellular antioxidant-defense system, but whether Nrf2 activation has protective effects against heat shock (HS) stress remains unclear. The objective of the present study was to determine whether the Nrf2 activator, tBHQ, could attenuate the heat stress-induced responses in bovine mammary epithelial cells (bMECs). MAC-T cells were exposed to HS (42.5°C for 1 h) followed by recovery at 37°C to mimic HS stress. Compared with cells consistently cultured at normothermia (37°C), cell viability was dropped after HS treatment ($P < 0.01$), and arrived at the lowest (64.5 ± 7.68%) after 12 h recovery. Accordingly, mRNA abundance of cell-apoptosis marker genes (Bax and CHOP, $P < 0.01$) and cellular antioxidant defense genes (HO-1 and Txnrd1, $P < 0.01$) increased time-dependently in HS challenged cells and reached to the highest level after 12 h recovery, compared with normothermic cultured MAC-T cells. When the MAC-T was pretreated with tBHQ (10 μ*M*) for 2 h and performed HS following 12 h recovery, pre-incubation of tBHQ significantly prevented loss of cell viability and downregulated mRNA expression of Bax and CHOP ($P < 0.01$) than HS treated MAC-T cells in the absence of tBHQ. The presence of tBHQ also significantly blocked accumulation of reactive oxygen species induced by HS in MAC-T cells after recovering for 2 h ($P < 0.01$). More importantly, tBHQ pre-treated cells showed stronger activation of Nrf2-ARE signaling compared with the HS group, including more nuclei-accumulations of Nrf2 and higher upregulations of Nrf2-ARE driven gene expressions (including Nrf2, HO-1 and Txnrd1, $P < 0.01$). RNA silencing of Nrf2 in HS-treated MAC-T cells almost abolished the cytoprotective effects of tBHQ. These results indicated that HS could cause oxidative stress in bMECs, and stabilization of Nrf2 by tBHQ could attenuate HS-induced bMECs damage.

Key Words: heat shock, Nrf2, tBHQ

Nonruminant Nutrition: Amino acids and minerals

302 Long-term leucine and branched-chain amino acid supplementation in a protein and energy deficient diet increases muscle mTORC1 activation in neonatal pigs.

Rodrigo Manjarín*, Daniel A. Columbus, Agus Suryawan, Hanh V. Nguyen, Adriana Hernández-García, Rosemarie D. Parada, Marta L. Forotto, and Teresa Davis, *USDA-ARS, Children's Nutrition Research Center, Houston, TX.*

Suboptimal nutrient intake represents a limiting factor for growth and long-term survival of low-birth weight infants and runt pigs. The objective of this study was to determine if enteral leucine or branched chain amino acid (BCAA) supplementation will upregulate the mammalian target of rapamycin complex 1 (mTORC1) pathway in skeletal muscle and lead to an increase in protein synthesis in neonates who consume only 70% of their protein and energy requirements. Twenty-two 4-d-old piglets were fed by gastric tube 1 of 4 diets, containing (kg body weight$^{-1}\cdot$d^{-1}) 15 g protein and 215 kcal (CON; n = 5), 10.5 g protein and 156 kcal (R; n = 5), 10.5 g protein + 1.19 g leucine and 156 kcal (RL; n = 6), or 10.5 g protein + 1.67 g BCAA (n = 6) at 4-h intervals for 21 d. On d 21, plasma AA and insulin levels were measured during 6 post-feeding intervals, whereas muscle protein synthesis rate and mTORC1 activation were determined at 120 min post-feeding. Data were analyzed by ANOVA using a linear mixed model with repeated measures. *P*-values for pre-planned pairwise comparisons were calculated using Student's *t*-tests. Compared with CON, the RL and BCAA diets increased plasma leucine levels ($P \leq 0.01$), whereas RL decreased isoleucine and valine ($P \leq 0.01$) between 0 and 120 min post-feeding. At 120 min insulin was higher in CON compared with R ($P \leq 0.01$). Compared with CON, BCAA, RL and R decreased ($P < 0.01$) body weight gain (3.5, 2.9, 3.0 and 2.9 ± 0.01 kg, respectively), protein synthesis (19.3, 14.2, 15.2 and 14.6 ± 1.3%$\cdot$d^{-1}), phosphorylation of S6 kinase (p-S6K1; 0.6, 0.4, 0.4 and 0.2 ± 0.01 AU) and 4E-binding protein (p-4EBP1; 0.4, 0.2, 0.2 and 0.1 ± 0.03 AU), and activation of eukaryotic initiation factor 4 complex (eIF4E$\cdot$eIF4G; 1.5, 1.1, 1.1, and 0.4 ± 0.02 AU). BCAA and RL increased ($P \leq 0.01$) p-S6K1, p-4EBP1 and eIF4E$\cdot$eIF4G compared with R. In conclusion, when protein and energy intakes are restricted, leucine or BCAA supplementation increases muscle mTORC1 activation but does not improve body weight gain or skeletal muscle protein synthesis in neonatal pigs.

Key Words: leucine, neonate, muscle

303 Effect of fermentation on ileal digestibility of nutrients and amino acids in soybean meal with low solubility in growing pigs.

S. D. Upadhaya*[1], J. H. Ryu[2], K. I. Kang[2], S. J. Cho[2], and I. H. Kim[1], [1]*Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea,* [2]*CJ Food Ingredients R&D Center, Seoul, South Korea.*

Fermentation of soybean meal with microbes has been reported to increase digestibility of nutrients. The objective of this study was to evaluate the effects of fermentation on digestibility of soybean meal with protein solubility below optimal range. Apparent ileal digestibility (AID) and standardized ileal digestibility (SID) of GE, DM, N and amino acids were evaluated in 5 cannulated [(Landrace × Yorkshire) × Duroc)] barrows with an average initial BW of 27.05 kg. The pigs were used in a 5 × 5 Latin square design with treatments of soybean meal (SBM) with protein solubility of 84% and fermented soybean meal (FSM) with protein solubility of 52%, 62% and 72% and designated as FSMA, FSMB and FSMC, respectively. A purified diet without protein was used to determine basal endogenous losses of CP and amino acids. Data were analyzed using the Mixed procedure of SAS with pig as the experimental unit for all analyses. Tukey's test was used to determine significant differences among treatments. The AID of DM and N was greater ($P < 0.05$) in FMSC (75.9% and 73.7%) and tended to improve in FSMA (74.4% and 71.3%) and FSMB (73.7% and 71.8%) compared with SBM (71.1% and 69.1%). The AID of Ile, Phe and Val was greater in all fermented soybean meal whereas that of Lys was greater ($P < 0.05$) in FSMC (76.19%) compared with SBM (69.05%). Likewise, the AID of Asp and Pro was greater ($P < 0.05$) in FSMA and FSMC than SBM. The SID of CP and Lys was higher ($P < 0.05$) in FSMC (85.03% and 83.86%) and tended to improve in FSMA (82.4% and 81.08%) and FSMB (83.11% and 82.23%) compared with SBM (80.68% and 77.72%) whereas the SID of Ile was higher ($P < 0.05$) in FSMA (87.47%), FSMB (84.86%) and FSMC (86.75%) compared with SBM (80.29%). In conclusion, fermentation of soybean meal showed better digestibility compared with SBM regardless of its protein solubility values.

Key Words: amino acid, ileal digestibility, fermented soybean meal

304 Requirement of valine and optimal valine:lysine ratio in diets for 8- to 18-kg pigs.

John K. Htoo*[1] and Georg Dusel[2], [1]*Evonik Industries AG, Hanau-Wolfgang, Germany,* [2]*University of Applied Sciences Bingen, Bingen am Rhein, Germany.*

A 28-d experiment was conducted to estimate the optimal SID Val:Lys in diets for starter pigs. A total of 192 weaned pigs (Topigs; initial BW of 8.5 ± 0.12 kg) were randomly assigned to 8 dietary treatments with 6 pen replicates (2 barrows and 2 gilts/pen) per treatment. A corn-wheat-soybean meal-based basal diet was formulated using analyzed ingredient AA contents and published SID coefficients to meet requirements of AA other than Val and Lys. Valine was first limiting (0.69% SID Val) and Lys was second limiting (1.15% SID Lys). Graded levels of L-Val were added to the basal diet to obtain 5 SID Val:Lys ratios (60, 64, 68, 72 and 76%). In addition, diets 6, 7 and 8 were produced to be adequate in SID Lys (1.34%) but varied in SID Val (0.86, 0.91 and 0.97%). All diets contained 2,474 kcal/kg NE. Based on analyzed AA contents, the corrected SID Val:Lys ratios in diets 1 to 5 were 63, 66, 72, 76 and 78%, and corrected SID Val contents in diets 6 to 8 were 0.86, 0.94 and 1.01%, respectively. Data were analyzed by ANOVA using the GLM procedure of SAS. Orthogonal-polynomial contrasts were used to determine linear and quadratic effects of SID Val:Lys ratios (diets 1–5) on response criteria. Increasing dietary SID Val:Lys from 63 to 78% (Diet 1 to 5) increased ($P = 0.046$) the final BW quadratically, and tended to increase ($P = 0.075$) the ADG (d 0–28) quadratically. The greatest final BW (16.47 vs. 15.55 kg) and ADG (284 vs. 258 g/d) in comparison to the basal diet were achieved at a SID Val:Lys ratio of 66%. The FCR (d 0–28) tended to improve ($P = 0.078$; quadratic) and the best FCR (1.377 vs. 1.545) in comparison to the basal diet was achieved at a SID Val:Lys ratio of 72%. Feed intake was not affected by dietary treatments. A 2-slope broken-line regression estimated the SID Val:Lys ratio of 67% to optimize both the ADG and FCR. When containing adequate Lys (diets 6 to 8), increasing the SID Val from 0.86 to 0.94% (SID Val:Lys from 66 to 71%) improved FCR ($P = 0.011$) but did not affect ADG ($P = 0.148$). Based on these results an optimal SID Val:Lys ratio of at least 67% is recommended in diets for 8 to 18 kg pigs.

Key Words: lysine, pig, valine

305 Effects of dietary fiber on the optimum threonine:lysine ratio for 25- to 50-kg gilts.

John K. Mathai*[1], John K. Htoo[2], John Thomson[3], Kevin J. Touchette[4], and Hans H. Stein[1], *[1]University of Illinois, Urbana, IL, [2]Evonik Industries AG, Hanau-Wolfgang, Hesse, Germany, [3]Evonik Degussa Corporation, Kennesaw, GA, [4]Ajinomoto Heartland Inc., Chicago, IL.*

Two experiments were conducted to determine the effect of dietary fiber on the ideal Thr:Lys ratio for 25 to 50 kg gilts. In Exp. 1, 192 gilts (26.3 ± 4.64 kg) were used with 2 pigs/pen and 8 pens/trt. A 2 × 6 factorial arrangement was used to determine the effect of dietary fiber (low and high) and standardized ileal digestible (SID) Thr:Lys ratios 45, 54, 63, 72, 81, and 90:100. At both fiber levels, ADG and G:F increased quadratically ($P < 0.05$), as the concentration of Thr increased in the diets. For pigs fed low-fiber diets, broken-line analyses estimated the optimum SID Thr:Lys ratio for ADG and G:F, respectively, as 0.60 and 0.59, quadratic analyses as 0.76 and 0.73, and combined linear-quadratic analyses as 0.66 and 0.63. For pigs fed high fiber diets, broken-line analyses estimated the optimum SID Thr:Lys ratio for ADG and G:F, respectively, as 0.66 and 0.55, quadratic analyses as 0.80 and 0.75, and combined linear-quadratic analyses as 0.71 and 0.63. In Exp. 2, pigs were fed either low-fiber or high-fiber diets that were very deficient (0.45 SID Thr:Lys) or marginally deficient (0.60 SID Thr:Lys) in Thr. Thirty-six gilts (29.0 ± 0.74 kg) were housed in metabolism crates with 9 replicate pigs per diet. Output of N in feces was greater ($P < 0.05$) from pigs fed high-fiber diets, whereas output of N in urine was greater ($P < 0.05$) from pigs fed low-fiber diets. The ATTD of N and retention of N were greater ($P < 0.05$) in pigs fed low-fiber diets. There was a lower ($P < 0.05$) N output in urine and a greater ($P < 0.05$) N retention in pigs fed high-Thr diets with 0.60 SID Thr:Lys compared with pigs fed low-Thr diets containing 0.45 SID Thr:Lys. There was also an interaction ($P < 0.05$) between fiber level and Thr for output of N in feces with N output increasing ($P < 0.05$) as Thr in the high-fiber diet increased. Results of these experiments indicate that increased fiber levels in diets fed to growing gilts increase the requirement for Thr, and diets with higher fiber levels should, therefore, include a greater concentration of Thr.

Key Words: pig, fiber, threonine

306 Evaluation of L-methionine bioavailability in piglet diets.

Helvio C. Ferreira Júnior*[1], Melissa I. Hannas[1], Luiz F. T. Albino[1], Horácio S. Rostagno[1], Lyssa Otani[2], and Lília T. Lopes[1], *[1]Federal University of Viçosa, Viçosa, Minas Gerais, Brazil, [2]CJ of Brazil Ltda, São Paulo, São Paulo, Brazil.*

The objective of this trial was to evaluate the bioavailability of L-Met considering DL-Met as the standard source (100% availability) based on average daily gain (ADG) and feed conversion (FC) of piglets. A total of 135 barrows (14.77 ± 1.46 kg) 24 d old were distributed in a completely randomized block design into 5 treatments with 9 replicates and 3 animals per pen. The treatments were a basal diet (BD) formulated to meet or exceed the nutritional recommendations of all nutrients (except for methionine), BD + 0.041% DL-Met; BD + 0.082% DL-Met; BD + 0.041% L-Met and BD + 0.082% L-Met. The calculated content of Met and Met+Cys in basal diet were 0.206% and 0.441% respectively. The experimental period lasted 28 d and individual pig body weight and feed intake were recorded to calculate performance: ADG, average daily feed intake (ADFI) and FC. Multiple regression model was obtained from linear regression analysis using SAS PROC MIXED procedure at probability level of $P < 0.05$ was regarded as statistically significant. The regression coefficient ratios were utilized to determine bioavailability of L-Met considering that both equations had the same intercept. A linear increase was observed in ADG ($P < 0.05$) with the supplementation of both DL-Met and L-Met. DL-Met supplementation levels increased ADFI linearly ($P < 0.05$). However there was a linear decrease ($P < 0.05$) in ADFI with supplemental sources of L-Met. The L-Met bioavailabilities estimated by ADG and FC were 105.48 and 130.94%, respectively.

Table 1 (Abstr. 306). Performance and bioavailability (BV) of L-Met for piglets from 15 to 30 kg[1]

	BD	DL-Met			L-Met			
Item	0.0%	0.041%	0.082%	*P*-value	0.041%	0.082%	*P*-value	s
ADG, g	581	648	714	0.001	664	715	0.001	0.246
ADFI, g	1121	1275	1368	0.003	1320	1312	0.052	0.487
FC, g/g	2.085	1.975	1.916	0.001	1.990	1.839	0.001	0.427

l-Met BV	Intercept	b^D	b^L	Bioavailability

307 Oral tryptophan supplementation to nursing piglets increases serotonin synthesis and improves performance after weaning under social mixing stress.

T. J. Pasquetti*[1,2], I. Park[1], J. Y. Guo[1], P. C. Pozza[2], and S. W. Kim[1], *[1]Department of Animal Science, North Carolina State University, Raleigh, NC, [2]Departamento de Zootecnia, Universidade Estadual de Maringá, Bolsista do Ciências sem Fronteiras / CNPQ, Maringá, PR, Brazil.*

This study was to evaluate the effect of oral Trp supplementation to nursing piglets on serotonin (5-HT) metabolism, growth performance, and behavior during nursing (from 14 to 21 d of age) and nursery (from 21 to 56 d of age) periods under social mixing stress at weaning (from 21 to 22 d of age). Eighty piglets from 10 sows (4 males and 4 females per litter) at 14 d of age were randomly allotted to 2 treatments based on sex. Treatments (Trp, 0.46 g/kg BW/d; or Ala + glucose, 0.38 + 0.42 g/kg BW/d, respectively) were orally given to piglets during nursing period. At weaning on d 21, 6 piglets from each treatment were euthanized to collect hypothalamus to analyze 5-HT and 5-hydroxyindoleacetic acid (5-HIAA) concentrations. Remaining 68 piglets were weaned and moved to nursery pens. Pigs within a treatment, same sex, but from different litters were paired and housed together (2 pigs/pen, 17 pens/treatment). Normal and aggressive behaviors were recorded from 21 to 22 d of age immediately after weaning and mixing. All pigs were fed the same diet during nursery period. Growth performance was measured during nursing and nursery periods. Data were analyzed using Proc Mixed of SAS with treatment and sex as fixed effects. Oral Trp feeding during nursing period increased ($P \leq 0.05$) hypothalamic concentration of 5-HT and 5-HIAA (2.84 to 5.94 and 59.1 to 104.6 ng/mg of protein, respectively), tended to increase the frequency of visits to the feeders ($P = 0.057$, 0.42 to 0.83%) during mixing period and G:F ratio ($P = 0.094$, 0.440 to 0.514) during the first week of nursery period. Collectively, oral Trp feeding during nursing period increased hypothalamic serotonin affecting eating behavior and potentially enhancing feed efficiency immediately after weaning.

Key Words: mixing stress, pig, tryptophan

308 Concentrations of nitrogen-corrected apparent metabolizable energy and amino acid digestibility in soybean meal from Argentina, Brazil, China, Thailand, and the United States fed to broilers.

Kelly M. Sotak-Peper*[1], Rommel C. Sulabo[2], Carl M. Parsons[1], and Hans H. Stein[1], *[1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]University of the Philippines Los Banos, Los Banos, Luzon, Philippines.*

The Philippines import soybean meal (SBM) from many different countries, but the quality of the SBM from the different sources is not known. Therefore, 2 experiments were conducted using SBM from Argentina (ARG 1 and ARG 2), Brazil, China, Thailand, and the U.S (US1, US2, and US3) that was collected at feed mills in the Philippines. The objective was to determine concentrations of nitrogen-corrected apparent metabolizable energy (AMEn) and standardized ileal digestibility (SID) of AA in each source of SBM. In both experiments, ANOVA was used with the PROC MIXED function in SAS. In Exp. 1, 72 d-old male broilers were allotted to 1 of 9 treatments using a completely randomized design with 8 broilers per treatment. Treatments included a corn-SBM based basal diet and 8 diets that were formulated by mixing 70% basal diet and 30% of each SBM source. Broilers were placed in individual metabolism crates equipped with an aluminum tray for total collection of excreta. Excreta were collected for 3 d after a 10 d adaptation period. The AMEn (2,762 kcal/kg) of Chinese SBM was greater ($P < 0.05$) than in ARG 1 (2,699 kg/kcal) and ARG2 (2,737 kcal/kg), but not different from the other sources. No differences in BW gain were observed, but there was reduced ($P < 0.05$) feed intake and improved ($P < 0.05$) G:F for birds fed US1 SBM compared with birds fed Argentinian or US2 SBM. In Exp. 2, 48 cecectomized roosters were allotted to 1 of 8 treatments using a completely randomized design with 6 roosters per treatment. The cecectomized roosters were tube fed 30 g of SBM and excreta were collected for 48 h following feeding. There was a tendency for greater ($P < 0.10$) SID of indispensable AA for US3 SBM than for the other sources of SBM. The SBM from US3 had greater ($P < 0.05$) SID of Lys compared with Brazilian SBM. The SBM from US3 also had greater ($P < 0.05$) SID of dispensable AA and total AA than SBM from China, Thailand, US1 and US2. These studies demonstrated that differences in energy and AA digestibility exist among different SBM sources.

Key Words: amino acid, energy, soybean meal

309 Effect of dietary cation-anion difference during late gestation and lactation on blood and urine parameters of sow.

J. Y. Guo*[1], D. E. Axe[2], and S. W. Kim[1], *[1]Department of Animal Science, North Carolina State University, Raleigh, NC, [2]Granco Minerals, Disputanta, VA.*

The experiment was conducted to evaluate the effect of dietary cation-anion difference (DCAD) on pH of blood and urine, mineral concentrations in serum, and hypocalcemia for sows during late gestation and lactation. A total of 22 pre-parturient sows (average parity of 4.5 ± 2.9 and BW of 224.1 ± 38.7 kg) were initially allotted to 2 dietary treatments in a completely randomized design: a control diet with positive DCAD (100 mEq/kg) and a diet with negative DCAD (−100 mEq/kg) with supplemental anionic salt (Cad-mate, Granco Minerals, Disputanta, VA) which were fed from d 93 of gestation to d 18 of lactation. Each sow had a daily access to 2 kg feed during gestation and had ad libitum access to feed during lactation. Feed with positive DCAD was provided during the subsequent parity. The pH of blood and urine were determined at d 93, 108 of gestation, d 1, 9 and 18 of lactation. At d 1 and 18 of lactation, Ca concentration in urine and milk and serum concentrations of Na, K, Mg, Ca, P, and Cl were measured. Data were analyzed using Proc Mixed of SAS with treatment as a fixed effect. Feed intake and BW loss in current lactation, and litter performance in current as well as subsequent lactations were not affected by changing DCAD. At d 1 of lactation, decreasing DCAD reduced ($P < 0.05$) blood pH (7.83 to 7.72). Urinary pH was reduced ($P < 0.05$) by decreasing DCAD at d 108 of gestation, d 1, 9, and 18 of lactation (6.18 to 5.28; 6.38 to 5.47; 6.47 to 5.10; 6.23 to 5.04). Reducing DCAD increased ($P < 0.05$) Ca concentrations in serum (9.23 to 9.71 mg/dL) and colostrum (66.11 to 79.34 mg/dL) at d 1 of lactation and increased ($P < 0.05$) serum Ca concentration (9.74 to 10.14 mg/dL) at d 18 of lactation. Reducing DCAD tended to increase Mg concentration in serum at d 1 of lactation ($P = 0.097$, 18.73 to 19.84 mg/L) and at d 18 of lactation ($P = 0.087$, 22.11 to 23.97 mg/L). At d 1 of lactation, reducing DCAD increased ($P < 0.05$) Cl concentration in serum (101.8 to 104.7 mEq/L). Collectively, negative DCAD increased Ca mobilization and decreased potential risk of urine tract infection without affecting litter performance.

Key Words: sow, dietary cation-anion difference, Ca

310 Effects of copper sources and levels on growth performance and carcass traits in wean-finishing pigs.

Ferdinando N. Almeida*[1], Jeffery Escobar[1], Gary Allee[2], Junmei Zhao[1], Yulin L. Ma[1], and Mercedes Vazquez-Anon[1], *[1]Novus International Inc., St Charles, MO, [2]Porktech LLC, Columbia, MO.*

A study was conducted under commercial conditions to compare the effects of 2 different Cu sources [tri-basic copper chloride ($Cu_2[OH]_3Cl$) or $Cu(HMTBa)_2$] on growth performance and carcass traits in pigs and to evaluate a step-down feeding strategy when supplementing pigs with $Cu(HMTBa)_2$. $Cu(HMTBa)_2$ is a chelated Cu with 2-hydroxy 4-methylthio butanoic acid (HMTBa) at 1:2 ratio (Novus International Inc., St. Charles MO). A total of 2,300 weaned pigs (initial BW = 6.60 ± 0.34 kg, 21 d of age, mixed sex) were randomly allotted to 1 of 4 feeding programs with 23 replications and 25 pig/pen. Treatments included 1) control (16 mg/kg Cu in the premix); 2) ($Cu_2[OH]_3Cl$) at 150 mg/kg (wean-finishing); 3) $Cu(HMTBa)_2$ at 150, 80, and 60 mg/kg (Nursery-Phase-I, Nursery-Phases-II-III, and grow-finishing phases, respectively) and 4) $Cu(HMTBa)_2$ at 150 mg/kg in Nursery-Phase-I and 80 mg/kg from Nursery-Phase-II to finishing phase. Copper levels were chosen based on current industry practices. Data were analyzed using the Mixed Procedure of SAS. The model included treatment as fixed effect and replication as random effect. From d 7 to 21 post-weaning, the ADG and GF was greater ($P = 0.03$) for pigs fed $Cu(HMTBa)_2$ than that of the control pigs. Pigs fed ($Cu_2[OH]_3Cl$) were intermediate. From d 0–42, ADG tended ($P = 0.11$) to be greater for pigs fed $Cu(HMTBa)_2$ than control pigs. In the grow-finishing phase (d 42–153), by d 111, the BW of pigs fed $Cu(HMTBa)_2$ at 80 mg/kg was heavier ($P < 0.05$) than control pigs and pigs fed ($Cu_2[OH]_3Cl$) or $Cu(HMTBa)_2$ at 60 mg/kg were intermediate. Overall (d 42–153) the GF was greater ($P < 0.05$) for both (60 and 80 mg/kg) $Cu(HMTBa)_2$ treatments compared with control (0.377 and 0.378 vs. 0.370, respectively). Pigs fed ($Cu_2[OH]_3Cl$) were intermediate. On average, the hot carcass weight (HCW) of pigs fed both levels of $Cu(HMTBa)_2$ was 101.48 and 101.49 (60 and 80 mg/kg, respectively) vs. 100.44 kg in pigs fed control, whereas the HCW of pigs fed ($Cu_2[OH]_3Cl$) was 101.34 kg. In conclusion, growth performance was improved by $Cu(HMTBa)_2$ supplementation to a greater extent than ($Cu_2[OH]_3Cl$). Supplementing $Cu(HMTBa)_2$ either at 60 or 80 mg/kg resulted in similar performance in terms of feed efficiency.

Key Words: chelated trace mineral, copper, pig growth performance

Physiology and Endocrinology: Nutrition, reproduction and metabolism

311 Dietary omega-3 supplementation alters gene expression in equine endometrial and embryonic tissues. Robert D. Jacobs*[1], Alan D. Ealy[1], Parker M. Pennington[2,3], Budhan Pukazhenthi[2], Lori K. Warren[4], Ashley L. Wagner[5], Tanja M. Hess[6], and Rebecca K. Splan[1,7], *[1]Virginia Polytechnic Institute and State University, Blacksburg, VA, [2]Smithsonian Conservation Biology Institute, Front Royal, VA, [3]George Mason University, Fairfax, VA, [4]University of Florida, Gainesville, FL, [5]Cooperative Research Farms, Richmond, VA, [6]Colorado State University, Fort Collins, CO, [7]Virginia Tech MARE Center, Middleburg, VA.*

Adverse maternal events around the time of conception influence embryonic development. Thus, aberrations in the uterine environment during early pregnancy, such as maternal metabolic or nutritional disruption, can alter gene expression in the developing embryo, leading to alteration in its developmental trajectory. Dietary supplementation of long-chain omega-3 polyunsaturated fatty acids (LCPUFA) improves metabolic and reproductive health across species. The objective of this study was to evaluate effects of peri-conceptual LCPUFA supplementation on endometrial and embryonic gene expression in overweight horses. Light horse mares (n = 13; mean age = 13.56 ± 0.11 yr; mean BCS = 7.07 ± 0.21) were supplemented with concentrate (n = 6) or an isocaloric, isonitrogenous diet containing 0.06 mg/kg BW marine-derived omega-3 LCPUFA (n = 7) 60 d before first sample collection. Four consecutive ovulatory cycles were monitored and uterine endometrial samples were obtained 12 d post-ovulation 1, 3 and 4. Mares were bred to one stallion on ovulatory cycles 2, 3 and 4, and embryos were flushed 12 d post ovulation. Candidate genes essential to inflammation, prostaglandin synthesis and embryonic development were evaluated by quantitative PCR. Data were log-transformed and analyzed using the GLM procedure in SAS (v9.3). When examining the data independent of breeding and pregnancy status, samples from LCPUFA supplemented mares contained reduced ($P = 0.04$) *IL6* mRNA abundance and tended to have increased transcript abundance for Uterocalin ($P = 0.09$), *SAA* ($P = 0.06$) and *IL10* ($P = 0.06$). Mares fed LCPUFA pregnant in cycle 3 contained greater *IL10* ($P < 0.001$) and *PLA2G3* mRNA ($P = 0.009$) and had a tendency for increased *SAA* abundance ($P = 0.08$). Supplemented mares bred but not pregnant in cycle 3 had a tendency for reduced expression of *PTGER2* ($P = 0.100$). In the conceptus, relative transcript abundance of *GATA4* and *GATA6*, markers of endoderm differentiation, along with *GATA3* and *ELF3*, markers of trophectoderm differentiation were greater ($P < 0.05$) in embryos from LCPUFA supplemented mares (n = 5), than controls (n = 5). These results indicate that LCPUFA supplementation during the peri-conceptual period may alter the post-ovulatory uterine environment and early embryonic development in the horse.

Key Words: fatty acid, pregnancy, fetal programming

312 Omega-6 fatty acid-rich sunflower oil supplements in diet affect uterine health, ovarian function and oocyte characteristic in heat-stressed dairy cows. Chainarong Navanukraw*[1,2], Aree Kraisoon[1], Vilaivan Khanthusaeng[1], Suthipong Uriyapongson[1], and Chuchart Kamollirt[3], *[1]Department of Animal Science, Khon Kaen University, Khon Kaen, Thailand, [2]Agricultural Biotechnology Research Center for Sustainable Economy, Khon Kaen University, Khon Kaen, Thailand, [3]Department of Anatomy, Faculty of Veterinary Medicine, Khon Kaen, Thailand.*

The objective was to examine effects of plant oil supplement on uterine health, ovarian function, and oocyte characteristic in heat-stressed dairy cows. Prepartum cows (n = 36) were randomly allocated to one of 3 dietary treatments; control, 4% refined palm oil (PO), and 4% refined sunflower oil (SO). ANOVA using the general linear model procedure was performed to determine treatments effect. All variables were analyzed with a nested ANOVA with treatment, animal (treatment), and time included in the model. Differences between specific means were evaluated by least significance difference. Placental expulsion and uterine involution in cows fed oil supplements occurred earlier than control cows (3.4 h and 33.2 d for cows fed SO, 4.9 h and 42.0 d for cows fed PO, and 21.0 h and 50.4 d for control cows; $P < 0.05$). Numbers of class 1 (2–5 mm) and class 3 (≥10 mm) follicles of cows fed oil supplements were greater than those of control cows ($P < 0.05$). In the second experiment, lactating cows (n = 42) were hormonally synchronized and were randomly offered diets supplemented either with 4% PO or 4% SO for 42 d. Follicle and oocyte numbers and corpus luteum (CL) volume were determined on d 5, 9, and 13 of the estrous cycle and morphologic quality assessed. Neither follicle nor oocyte characteristics were affected by the dietary treatment, however volume of CL and progesterone concentrations on d 13 in cows fed SO were greater ($P < 0.05$) than those fed PO diet (8,290 vs. 7,875 mm^3 and 5.0 vs. 3.9 ng/mL). The data support the beneficial effects of SO supplement in diet on reproductive function in dairy cows

Key Words: plant oil, ovarian function, dairy cow

313 Effects of excess dietary MP from corn gluten meal or soybean meal on ovarian function of beef cows consuming low quality forage. Taylor C. Geppert*[1], George A. Perry[2], and Patrick J. Gunn[1], *[1]Department of Animal Science, Iowa State University, Ames, IA, [2]Department of Animal Sciences, South Dakota State University, Brookings, SD.*

The objective of this study was to determine the effects of feeding excess MP from feedstuffs differing in rumen degradability on ovarian function of beef cows. Non-pregnant, nonlactating beef cows (n = 18) were stratified by age, BCS, and BW to 1 of 2 isocaloric, isonitrogenous diets: (1) corn gluten meal (CGM) or (2) soybean meal (SBM), supplemented at 150% of MP requirements with ad libitum access to corn stalks for 58d. After a 20d supplement adaptation period, cows were synchronized for ovulation using the 5-d CO-Synch + CIDR protocol. Ten d after synchronization completion, 100 µg of GnRH was administered to reset follicular growth. Starting at GnRH administration and daily thereafter until spontaneous ovulation, transrectal ultrasonography was performed to diagram ovarian follicular growth, and blood samples were collected for hormone and metabolite analyses. Seven d after visual detection of estrus, corpus luteum (CL) size was determined and supplements were terminated. Data were analyzed using the MIXED procedures of SAS. Body weight and BCS, ovulatory follicular wavelength, antral follicle count, size of ovulatory follicle at dominance and duration of dominance were not different ($P = 0.13$) between treatments. Cows supplemented with CGM had greater ($P < 0.01$) post-dominance dominant follicle growth, larger ($P = 0.03$) dominant follicles at spontaneous luteolysis, shorter proestrus (36 vs. 68 h; $P < 0.01$) and larger (15.4 vs. 13.5 mm; $P = 0.03$) ovulatory follicles than SBM cows. No differences ($P = 0.11$) in estradiol, ratio of estradiol to ovulatory follicle volume, or plasma urea nitrogen concentrations were observed between treatments. Although CL volume and the ratio of progesterone to CL volume were not affected by treatment ($P = 0.24$), CGM treated cows tended to have lesser (4.7 vs. 5.7 ng/mL; $P = 0.07$) concentrations of circulating progesterone 7d post-estrus than SBM. In summary, these data illustrate that excess MP when supplemented to cows consuming a low quality forage may differentially affect ovarian function depending on rumen degradability of the protein source.

Key Words: follicle, ovary, RUP

314 Effects of supplementing excess amounts of MP from a moderately abundant RUP source on ovarian function of beef cows consuming low quality forage.

Taylor C. Geppert*[1], George A. Perry[2], and Patrick J. Gunn[1], *[1]Department of Animal Science, Iowa State University, Ames, IA, [2]Department of Animal Sciences, South Dakota State University, Brookings, SD.*

The objective of this experiment was to determine the effects of excess MP supplementation from a moderately abundant RUP source on ovarian function in beef cows consuming low quality forage. Non-pregnant, nonlactating mature beef cows (n = 16) were allocated by age, BW and BCS to 1 of 2 isocaloric supplements designed to maintain BW for 60 d. All cows were offered ad-libitum access to corn stalks and individually offered a corn gluten meal-based supplement at (1) 125% (MP125) or (2) 150% (MP150) of NRC MP requirements. After a 20-d supplement adaptation period, cows were synchronized for ovulation using the 5-d CO-Synch + CIDR protocol. Ten days after synchronization, 100 µL of GnRH was administered to reset follicular growth. Starting at GnRH administration and daily thereafter, transrectal ultrasonography was performed to diagram follicular waves, and blood samples were collected for hormone and metabolite analyses. Seven days after observation of estrus, corpus luteum (CL) size was determined via ultrasound and supplementation was terminated. Data were analyzed using the MIXED procedures of SAS. There were no differences ($P \geq 0.21$) between BW and BCS. Preovulatory ovarian follicle characteristics including size at dominance, duration of dominance, post-dominance growth, size at spontaneous luteolysis, post-luteolysis growth, length of proestrus, and wavelength were not different between treatments ($P \geq 0.11$). However, ovulatory follicles were larger ($P = 0.04$) and average antral follicle count was greater ($P = 0.01$) in the MP150 than MP125 treatment. Estradiol concentrations and the ratio of estradiol to ovulatory follicle volume was not affected ($P \geq 0.51$) by treatment. Although CL volume 7 d post-estrus was greater ($P < 0.01$) in MP150 than MP125, circulating progesterone 7 d post-estrus and the ratio of progesterone to CL volume was not different ($P \geq 0.21$). In conclusion, supplementation of CP at 150% of NRC MP requirements from a moderately undegradable protein source may enhance growth of the ovulatory follicle and subsequent CL compared with MP supplementation at 125% of NRC requirements.

Key Words: crude protein, follicle, ovulation

315 Effect of top-dressing rumen-protected methionine in lactating Holstein cows II: Fertility and embryo development.

Mateus Z. Toledo*[1], Giovanni M. Baez[1], Eduardo Trevisol[1], Nelson E. Lobos[1], Alvaro Garcia-Guerra[1], Jerry N. Guenther[1], Daniel Luchini[2], Randy D. Shaver[1], and Milo C. Wiltbank[1], *[1]University of Wisconsin-Madison, Madison, WI, [2]Adisseo, Alpharetta, GA.*

Experimental objectives were to evaluate the effects of supplementation with rumen-protected methionine (RPM) from 31 ± 2 to 127 ± 2 DIM (61 d after timed AI; TAI) on fertility and embryo development of dairy cows. Holstein cows (n = 309) were housed in a free-stall barn, milked twice daily, fed a basal diet formulated to 16.7% CP to deliver 2521 g of metabolizable protein (MP) with 6.93 lysine as % of MP and randomly assigned to once daily top-dressing with either (1) RPM, 21.2 g of Smartamine M mixed with 38.8 g of dry distillers grains (2.34 methionine as % of MP) or (2) Control (CON), 60 g of dry distillers grain (1.87 methionine as % of MP). All cows were synchronized using a Double Ovsynch protocol (GnRH-7d-PGF-3d-GnRH-7d-GnRH-7d-PGF-56h-GnRH-16h-TAI) to receive first TAI at 66 ± 3 DIM. Pregnancy diagnosis was done at 28 d (pregnancy-specific protein B) and at 32 and 61 d (ultrasound) after TAI. Embryo size and amniotic vesicle volume were determined by ultrasound on d 33 of pregnancy. Binomial data were analyzed by parity using Chi-squared or Fisher's exact test. Continuous outcomes were analyzed by *t*-test or Wilcoxon sum-rank test. Only synchronized cows (92.1%, determined by progesterone concentrations) were used in the final analysis (n = 285). There was no effect of treatment on pregnancies per AI at 28 (65.5 vs. 66.7%; CON vs. RPM), 32 (58.6 vs. 61.4%), or 61 (54.4 vs. 58.3%) d after TAI. However, pregnancy loss was greater in multiparous cows for CON compared with RPM cows from 28 to 61 d (19.6 vs. 6.1%; $P = 0.04$) or from 32 to 61 d (8.9 vs. 0.0%, $P = 0.03$). However, there was no effect of treatment on pregnancy loss in primiparous cows (28 to 61 d, $P = 0.50$; 32 to 61 d, $P = 0.50$). Consistent with data on pregnancy loss, RPM increased embryonic size in multiparous cows (RPM vs. CON; amniotic vesicle volume, 592 vs. 472 mm^3, $P = 0.03$; embryo abdominal diameter, 11.0 vs. 10.5 mm, $P = 0.01$; crown-rump length, 5.8 vs. 5.4 mm, $P = 0.13$), but had little effect on embryonic size in primiparous cows. Thus, top-dressing RPM increased embryo size and pregnancy maintenance in multiparous cows.

Key Words: methionine, dairy cattle, reproduction

316 Intravenous glucose infusion in early postpartum dairy cows: Effects on plasma metabolites, milk production, and interval to first ovulation.

Stephen Butler*[1], Shane Leane[1], Francis Curran[1], Stephen Moore[1], Mark Crowe[2], and Matthew Lucy[3], *[1]Teagasc Moorepark-Animal & Grassland Research and Innovation Centre, Fermoy, Ireland, [2]School of Veterinary Medicine, University College Dublin, Dublin, Ireland, [3]Department of Animal Sciences, University of Missouri, Columbia, MO.*

Glucose supply is less than required during early lactation. The glucose deficit affects the homeorhetic mechanisms that coordinate milk production and also impinges upon reproduction. The effect of glucose infusion during early lactation was tested. Postpartum dairy cows (n = 22) that calved in either the autumn (n = 11) or spring (n = 11) were treated with either glucose (GLUC; n = 11) or saline (SAL; n = 11). The GLUC cows received 750 g of glucose per day via continuous intravenous infusion of 40% dextrose solution (0.52 g glucose/min). The SAL cows received an equal volume of 0.9% saline. Infusions began during the second week postpartum (7.9 ± 1.9 d) and continued for 14 d. Blood was collected 4 times daily. Data were analyzed by using PROC MIXED of SAS. Compared with SAL, the GLUC cows had greater blood glucose concentrations (69.7 ± 1.5 vs. 61.7 ± 1.5 mg/dL; $P < 0.01$). There was a tendency ($P < 0.11$) for a treatment by season interaction for plasma glucose (spring: 71.6 ± 2.3 vs. 60.0 ± 2.5 ng/mL, $P < 0.01$; autumn: 67.7 ± 2.0 vs. 63.4 ± 1.8 mg/mL, $P > 0.10$; GLUC vs. SAL) and there was a treatment by season interaction ($P < 0.01$) for plasma insulin (spring: 4.4 ± 0.4 vs. 3.1 ± 0.4 ng/mL, $P < 0.05$; autumn: 3.4 ± 0.5 vs. 3.1 ± 0.5 ng/mL, $P > 0.10$; GLUC vs. SAL). GLUC cows had lesser plasma nonesterified fatty acids (NEFA; 448 ± 39 vs. 580 ± 39 µEq/L; $P < 0.03$) and lesser plasma β hydroxybutyrate (BHBA; 0.63 ± 0.10 vs. 1.15 ± 0.10 mM; $P < 0.01$). Insulin sensitivity (RQUICKI) was less in spring cows compared with autumn cows (0.50 ± 0.01 vs 0.53

± 0.01; $P < 0.05$). There was no effect of treatment on milk produced (27.8 ± 1.1 vs. 27.8 ± 1.1 kg/d; GLUC vs. SAL) or as-fed consumption of total mixed ration (44.1 ± 1.6 vs. 45.1 ± 1.7 kg/d; GLUC vs. SAL). The number of cows with first ovulation during the infusion was not affected by treatment [5/11 (45%) for GLUC and SAL] and interval to first ovulation was similar (13.7 ± 0.9 d postpartum). There was a tendency ($P < 0.10$) for more autumn cows [7/11 (64%)] compared with spring cows [3/11(27%)] to ovulate during infusion. Glucose infusion affected plasma hormone and metabolite concentrations but did not affect milk production or interval to first ovulation.

Key Words: glucose, dairy, reproduction

317 Intravenous glucose infusion during pregnancy in dairy cows: Effects on plasma hormones, metabolites, milk production, and conceptus growth.

Matthew Lucy*[1], Shane Leane[2], Francis Curran[2], Stephen Moore[2], Mark Crowe[3], and Stephen Butler[2], *[1]Department of Animal Sciences, University of Missouri, Columbia, MO, [2]Teagasc Moorepark-Animal & Grassland Research and Innovation Centre, Fermoy, Ireland, [3]School of Veterinary Medicine, University College Dublin, Dublin, Ireland.*

Glucose supply in postpartum dairy cows may impinge upon early pregnancy by affecting maternal and placental endocrinology as well as substrate availability to the developing conceptus. The objective was to test the effect of glucose infusion from d 32 to 45 of pregnancy on plasma hormones and metabolites, milk production and conceptus growth. Dairy cows (n = 10) were assigned to glucose (GLUC; n = 5) or saline (SAL; n = 5)]. The GLUC cows received 750 g of glucose per d via continuous intravenous infusion of 40% dextrose (0.52 g glucose/min). The SAL cows were infused with an equal volume of 0.9% saline. Infusions began on d 32 of pregnancy (98 ± 15 d postpartum) and ended on d 45 of pregnancy. Blood was collected twice daily during the infusion. Fetal and amniotic vesicle length and width were measured on d 31 (1 d before infusion) and d 33, 35, 37, 39, 41, 43 and 45. Data were analyzed by using PROC MIXED of SAS. Compared with SAL, the GLUC cows had greater blood glucose (81.7 ± 2.1 vs. 74.2 ± 2.1 mg/dL; $P < 0.05$). Plasma progesterone (P4; 9.5 ± 1.3 vs. 9.5 ± 1.3 ng/mL), insulin (7.7 ± 1.7 vs. 7.0 ± 1.7 ng/mL), IGF1 (159 ± 27 vs. 143 ± 27 ng/mL), β hydroxybutyrate (0.93 ± 0.08 vs. 1.02 ± 0.08 m*M*), nonesterified fatty acids (280 ± 10 vs. 264 ± 10 μEq/L) and pregnancy-associated glycoproteins (PAG; 64 ± 21 vs. 73.2 ± 21% of assay control) were not affected ($P > 0.10$; GLUC vs. SAL). There was no effect of treatment on milk yield (26.8 ± 2.4 vs. 24.6 ± 2.2 kg/d; GLUC vs. SAL) or as-fed consumption of total mixed ration (63 ± 4 vs. 67 ± 3 kg/d; GLUC vs. SAL). There was an effect of day of pregnancy ($P < 0.001$) but no effect of treatment on length, width, or volume of the fetus or amniotic vesicle. All hormone and metabolic data were provided as independent variables to explain variation in conceptus measurements using backward elimination (GLMSELECT of SAS). The only significant effects remaining were day ($P < 0.001$) and plasma progesterone (P4; $P < 0.001$; positive association for P4 with all conceptus measurements). Glucose infusion from d 32 to 45 of pregnancy increased plasma glucose but did not affect growth of the conceptus. Greater plasma P4 was associated with larger conceptuses.

Key Words: glucose, pregnancy, dairy

318 Rumen-protected methyl donors during late pregnancy: 1. Maternal Smartamine M and its association with neonatal Holstein calf blood immunometabolic biomarkers.

Carolina Bespalhok Jacometo*[1], Zheng Zhou[2], Erminio Trevisi[3], Daniel Luchini[4], Marcio Nunes Corrêa[1], and Juan J. Loor[2], *[1]Universidade Federal de Pelotas, Pelotas, Rio Grande do Sul, Brazil, [2]University of Illinois, Urbana, IL, [3]Università Cattolica del Sacro Cuore, Piacenza, Italy, [4]Adisseo NA, Alpharetta, GA.*

The aim was to evaluate the effect of supplementing pregnant cows with rumen-protected methionine (MET) on growth and blood biomarkers of hepatic and energy metabolism, inflammation and oxidative stress. Forty Holstein calves born to cows receiving during the last ~4 wk of pregnancy MET (Smartamine M, Adisseo NA.; ~2.9:1 Lys:Met; n = 20) or control (CON, ~3.35:1 Lys:Met, n = 20) were used. Immediately after birth calves were separated from the dam, fed first colostrum (3.8 L with minimum IgG concentration of 50 g/L), housed individually and fed a common milk replacer (25% CP, 17% fat) twice daily. Calves were bled at birth (before colostrum), 24 h after first colostrum, at 14, 28 and 50 (~1 wk post-weaning) d of age. Data were analyzed as repeated measures using the MIXED procedure of SAS. No maternal diet effect ($P > 0.05$) was observed in calf growth (body weight and withers height) from birth through weaning. MET calves had lower glucose at birth (4.05 vs. 4.73 mmol/L, $P > 0.01$), but there was no overall maternal diet effect ($P = 0.18$). Regardless of maternal diet, glucose, AST and GGT increased markedly ($P < 0.01$) from birth to 24 h after colostrum intake, then decreased ($P < 0.01$) at 14 d and remained unchanged until 50 d. NEFA and creatinine concentrations had a sharp decrease after birth ($P < 0.01$) while BHBA concentrations increased ($P < 0.01$) over time. Paraoxonase, albumin and ceruloplasmin concentration increased ($P < 0.01$) over time. MET calves had lower albumin (30.1 vs. 30.9 g/L, $P = 0.09$) and ceruloplasmin tended to be lower (1.58 vs. 1.85 μmol/L, $P = 0.11$). IL1-B and IL-6 had a marked decrease ($P < 0.01$) from birth to 24 h after colostrum intake. Tocopherol (1.31 vs. 2.19 μg/mL), myeloperoxidase (466 vs. 544 U/L) and ROMt (12.4 vs. 15.5 mg H_2O_2/100 mL) were lower ($P < 0.05$) in MET calves at 14 d of age. Retinol increased over time ($P < 0.01$). Overall, data suggest that maternal supplementation with MET during the last ~4 wk of gestation affected some biomarkers of metabolism and oxidative stress, hence, seemed to elicit a beneficial effect on the neonatal calf.

Key Words: dairy cattle, fetal programming, nutrition

319 Rumen-protected methyl donors during late pregnancy: 2. Maternal Smartamine M and its association with hepatic gene expression in neonatal Holstein calves.

Carolina Bespahok Jacometo*[1], Zheng Zhou[2], Daniel Luchini[3], Marcio Nunes Corrêa[1], and Juan J. Loor[2], *[1]Universidade Federal de Pelotas, Pelotas, Rio Grande do Sul, Brazil, [2]University of Illinois, Urbana, IL, [3]Adisseo NA, Alpharetta, GA.*

The aim was to evaluate the effect of supplementing pregnant cows with rumen-protected methionine (MET) on neonatal calf liver expression of genes related to energy/lipid metabolism, insulin signaling, growth hormone signaling and inflammation. Forty Holstein calves born to cows receiving during the last ~4 wk of pregnancy MET (Smartamine M, Adisseo NA; ~2.9:1 Lys:Met; n = 20) or control (CON, ~3.35:1 Lys:Met, n = 20) were used. Immediately after birth calves were separated from the dam, fed first colostrum within 6 h (3.8 L with minimum IgG concentration of 50 g/L), housed individually and fed a common milk replacer (25% CP, 17% fat) twice daily. Liver biopsies were harvested (n = 8/group) at 4, 14, 28 and 50 (~1 wk post-weaning) d of age. Data were analyzed as repeated measures using the MIXED procedure of SAS. No maternal diet effect ($P > 0.05$) was observed on calf growth (body weight and withers height) from birth through weaning. Expression of genes related to lipoprotein metabolism (*APOB, MTTP*) and growth hormone signaling (*IGF1, GHR1A*) were not ($P > 0.05$) affected by maternal diet, but increased in expression over time ($P < 0.05$). *PCK1* and *FBP1* expression was greater ($P = 0.05$ and 0.02) in MET calves and increased ($P < 0.001$) over time in both groups. *PC* expression, however, was lower ($P = 0.007$) in MET calves and decreased ($P < 0.001$) over time in both groups. Lower ($P = 0.001$) *ACOX1* expression was observed in MET, while *CPT1A* was greater ($P < 0.001$). The insulin-signaling related genes *AKT2* and *SLC2A2* had greater ($P < 0.01$) expression in MET calves. Except for *FOXO1* and *SLC2A2*, all other genes evaluated in this pathway (*INSR*, *IRS1*, *AKT2*, *SREBF1*) increased ($P < 0.05$) expression over time regardless of maternal diet. MET calves had higher *NFKB* ($P = 0.009$) and *SOD2* ($P < 0.001$) expression, and also a trend ($P = 0.08$) for higher *SOD1*. Overall, the data suggest that maternal supplementation with MET during the last ~4 wk of gestation elicited changes in calf hepatic gene expression and, as such, might have led to functional differences in improving neonatal energy metabolism.

Key Words: fetal programming, nutrition, nutrigenomics

320 Rumen-protected methyl donors during late pregnancy: 3. Maternal Smartamine M and its association with neonatal Holstein calf neutrophil gene network expression.

Carolina Bespalhok Jacometo*[1], Zheng Zhou[2], Erminio Trevisi[3], Daniel Luchini[4], Marcio Nunes Corrêa[1], and Juan J. Loor[2], *[1]Universidade Federal de Pelotas, Pelotas, Rio Grande do Sul, Brazil, [2]University of Illinois, Urbana, IL, [3]Università Cattolica del Sacro Cuore, Piacenza, Italy, [4]Adisseo NA, Alpharetta, GA.*

The aim was to evaluate the effect of supplementing pregnant cows with rumen-protected methionine (MET) on calf neutrophil expression of genes related to cell adhesion and chemotaxis, oxidative stress and inflammation. Forty Holstein calves born to cows receiving during the last ~4 wk of pregnancy MET (Smartamine M, Adisseo NA; ~2.9:1 Lys:Met; n = 20) or control (CON, ~3.35:1 Lys:Met, n = 20) were used. Immediately after birth calves were separated from the dam, fed first colostrum within 6 h (3.8 L with minimum IgG concentration of 50 g/L), housed individually and fed a common milk replacer (25% CP, 17% fat) twice daily. Blood neutrophils were isolated at birth (before receiving colostrum), 24 h after first colostrum and at 14, 28 and 50 (~1 wk post-weaning) d of age. Data were analyzed as repeated measures using the MIXED procedure of SAS. Neutrophil phagocytosis was not affected ($P > 0.05$) by maternal MET supplementation, but increased ($P < 0.01$) over time in both groups. Regardless of maternal diet *SELL*, *CADM1*, *LCP1* and *CYBA* expression increased ($P < 0.05$) from birth to 24 h after colostrum intake, then decreased ($P < 0.05$) until 28 d. *ZBP1* increased ($P < 0.01$) from birth to 28 d. *SELL* expression was overall greater ($P = 0.04$) in MET than CON calves. Expression of genes related to oxidative stress (*MPO*, *NOS2*, *SOD1*, *SOD2*, *NFE2L2*) was not affected ($P > 0.05$) by maternal diet. Similarly, blood biomarkers related to oxidative stress (ROMt, myeloperoxidase, retinol, tocopherol) were not affected ($P > 0.05$) by diet. *TLR2* had lower ($P = 0.04$) expression in MET calves, but other inflammatory mediators (*TLR4*, *MYD88*, *IRAK1*, *TRAF6*, *NFKB*, *TNF*, *IL1B, SLAMF7*) and blood IL-1B and IL-6 concentrations were not affected ($P > 0.05$). A marked decrease ($P < 0.01$) in both cytokines from birth to 24 h after colostrum intake was observed regardless of diet. Overall, the data suggest that maternal supplementation with MET during the last ~4 wk of gestation had a minor effect on calf neutrophil gene network expression and blood biomarkers of oxidative stress and inflammation.

Key Words: fetal programming, nutrition, nutrigenomics

321 Chromium supplementation alleviates heat stress in growing pigs.

Fan Liu*[1], Jeremy J Cottrell[1], Danni Wijesiriwardana[1], Fletcher W. Kelly[1], Pietro Celi[2,1], Brian J. Leury[1], and Frank R. Dunshea[1], *[1]Facultry of Veterinary and Agricultural Sciences, the University of Melbourne, Parkville, VIC, Australia, [2]Faculty of Veterinary Science, the University of Sydney, Camden, NSW, Australia.*

Reduced insulin sensitivity is a characteristic of heat stress (HS) in pigs. Therefore the aim of the experiment was to investigate the effect of chromium (Cr) supplementation in ameliorating HS due to its properties augmenting insulin sensitivity. Thirty-six gilts (Large White × Landrace, 29 ± 4 kg) were randomly assigned to 2 diets containing 0 (control) or 3200 ppb Cr picolinate (400 ppb Cr). After 14 d supplementation pigs were allocated to 8 d thermoneutral (20°C; TN) or cyclic HS (8h/d 35°C) (n = 9/group). Production performance was recorded in the thermal exposure period. Respiration rate (RR) and rectal temperature (RT) were measured at 0900, 1300 and 1600h daily, and blood gas was measured on d 7. Area under the curve (AUC) of glucose and NEFA was studied in an intravenous glucose tolerance test (n = 6/group) on d 8. Data were analyzed by ANOVA in Genstat. In TN pigs fed Cr diet had higher ADFI (2.0 vs. 2.3 kg, $P < 0.05$), but ADG was not improved (0.63 vs. 0.69 kg, $P = 0.26$). Heat stress decreased ADFI by 35% and ADG by 84% (both $P < 0.001$) and no effect of Cr was observed. Heat stress increased RT (38.8 vs. 40.0°C, $P < 0.001$) and RR (34 vs. 155 breaths/min, $P < 0.001$). The increased RR led to reductions in blood CO_2, bicarbonate and base excess in HS (all $P < 0.05$). Collectively the results indicate that heat treatment resulted in a “heat stressed” state. Besides, HS increased glucose and decreased NEFA AUC (both $P = 0.05$), suggesting reduced insulin sensitivity. Compared with control diet, Cr pigs had lower RT (40.2 vs. 39.9, $P < 0.05$) and RR (173 vs. 136, $P < 0.01$) under HS, indicating an amelioration in the level of HS experienced in Cr pigs. Chromium did not alter the glucose AUC in HS, although Cr reduced the glucose “basal to peak” increment in TN (4.15 vs. 2.55 m*M*, $P < 0.05$). Besides, Cr tended to increase NEFA recovery (20 to 90 min) rate and AUC in HS (both $P = 0.09$), indicating that Cr facilitated lipid mobilization in HS. In summary, pig growth performance was not improved by Cr during HS, possibly because of the severe reduction in ADFI. However, dietary Cr mitigated the physiological responses to HS, including lipid mobilization. Therefore, an inclusion of 400 ppb Cr may reduce HS in growing pigs.

Key Words: chromium, pig, insulin

322 Metabolome-based relationships of four biofluids from dairy cows.

H. Z. Sun*[1,2], L. L. Guan[3], and J. X. Liu[1,2], *[1]Institute of Dairy Science, College of Animal Sciences, Hangzhou, China, [2]MoE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, China, [3]Department of Agricultural, Food & Nutritional Science, University of Alberta, Edmonton, Canada.*

To date, most studies have focused on the improvement of dairy nutritional management strategies to enhance milk production and quality, whereas the physiological and metabolic mechanisms involved have not been well examined. This study was conducted to investigate the relationships of 4 biofluids from lactating dairy cow to identify mechanisms and potential biomarkers as well as key pathways involved in potential regulation of lactation. Eight multiparous Holstein dairy cows with similar lactation stage (164 ± 19.6 d, mean ± SD) and milk yield (30.4 ± 2.29 kg, mean ± SD) were offered a diet with 16.7% (DM basis) of crude protein and 1.57 Mcal/kg of net energy for lactation.

Rumen fluid, serum, milk, and urine were collected after 65-d feeding to identify the metabolome using gas chromatography–time of flight/mass spectrometry. A total of 165, 195, 218 and 156 metabolites were identified from rumen fluid, milk, serum, and urine, respectively, with 29 metabolites detected in all 4 biofluids. The TIC chromatograms showed a clear discrimination among 4 biofluids; and principal component analysis of the relative concentration of mutual metabolites revealed 4 separated metabolite profile clusters of 4 biofluids. The clusters derived from the rumen fluid, milk, and serum partly overlapped with each other, whereas the cluster from the urine was separated from the other 3 biofluids. The dendrogram of hierarchical clustering analysis revealed different subclusters containing varying numbers of metabolites within each biofluid; and the subclusters from rumen fluid and serum were grouped together and highly correlated with each other, but were separated from milk. Based on metabolomic profiles, urine is the most different biofluid, compared with other 3 biofluids. When the mutual metabolites were used for pathway analysis, the impact values of the pathway were 0.29, 0.28, and 0.11 for glycine, serine and threonine metabolism, glycerolipid metabolism, and tyrosine metabolism, respectively. These 3 pathways may play important roles in improvement of lactation performance. Our results suggest that all the 4 biofluids represent the comprehensive metabolism of dairy cow that can be further used for metabolic pathway analysis.

Key Words: biofluid, metabolomics, dairy cow

Physiology and Endocrinology Symposium: Progesterone as an endocrine regulator of fertility in cattle

323 The role of progesterone in uterine biology of ruminants. Thomas E. Spencer*, *University of Missouri, Columbia, MO.*

This review integrates established and new information on the role of progesterone in uterine biology of ruminants. Establishment of pregnancy in ruminants occurs during the peri-implantation period and involves growth of the blastocyst, elongation of the conceptus (embryo and extraembryonic membranes), and suppression of the endometrial luteolytic mechanism to maintain progesterone production by the ovary. Conceptus elongation involves exponential increases in length and weight of the trophectoderm and onset of extraembryonic membrane differentiation, including gastrulation of the embryo and formation of the yolk sac and allantois that are vital for embryonic survival and formation of a functional placenta. Antiluteolytic effects of the elongating conceptus are due to production of interferon tau (IFNT) by the trophoblast that has a paracrine effect to inhibit upregulation of oxytocin receptors in the endometrial epithelia, thereby disrupting uterine release of luteolytic prostaglandin $F_{2\alpha}$ (PGF) pulses. Survival of the blastocyst and elongation of the conceptus requires embryotrophic factors (ions, amino acids, carbohydrates, proteins, lipids, and other substances) from the epithelia of the uterus, and those embryotrophic factors are primarily regulated by progesterone. Available results from studies in sheep support the idea that the individual, interactive, and coordinated actions of progesterone, IFNT, prostaglandins, and cortisol regulate expression of elongation- and implantation-related genes in the endometrial epithelia and are essential regulators of conceptus elongation. The outcome of these gene expression changes is alterations in endometrial epithelial secretions that govern conceptus elongation. Elevated concentrations of circulating progesterone immediately after conception have been associated with an advancement of conceptus elongation, an increase in IFNT production and, in some studies, higher pregnancy rates in cattle. An increased knowledge of progesterone biology and conceptus-endometrial interactions is necessary to understand and elucidate the causes of recurrent pregnancy loss and to provide a basis for new strategies to improve pregnancy outcome and reproductive efficiency in ruminants.

Key Words: uterus, conceptus, progesterone

324 Cellular and molecular mechanisms controlling corpus luteum function and progesterone concentrations in cattle. Milo Wiltbank*[1], Giovanni Baez[1], Julian Ochoa[1,2], Joao Ferreira[2], Eduardo Trevisol[2], Wenxiang Luo[1], and Roberto Sartori[3], *[1]University of Wisconsin-Madison, Madison, WI, [2]São Paulo State University, Botucatu, SP, Brazil, [3]University of São Paulo, Piracicaba, SP, Brazil.*

Steady-state, circulating progesterone (P4) concentrations are determined primarily by 2 factors: the rate of P4 production, principally by the corpus luteum (CL), and the rate of P4 metabolism, mainly by the liver. Rate of P4 production is primarily related to number of large luteal cells (LLC), differentiation state of LLC, and provision of substrate for P4 production. Steroid production increases 1000-fold from estrus to d 7 with growth of the follicular granulosa cells from 10 mm diameter to 38 mm LLC, a 50-fold increase in cellular volume. The LLC of ruminants are distinguished by a large number of mitochondria and high constitutive P4 production meaning that luteotrophic hormones are not required for P4 production. Nevertheless, cholesterol substrate, primarily in the form of high-density lipoprotein (HDL) is essential for high P4 production by ruminant LLC. Circulating HDL is not limiting in well-fed cattle but may be manipulated by diet. One limiting factor is number of granulosa cells in the follicle and therefore number of LLC. Ovulation of larger follicles or ovulation of multiple follicles can produce greater quantity of luteal tissue and therefore increased luteal P4 production. Regression of the CL is marked by decrease P4 production due to decreased transport of cholesterol to the inner mitochondrial membrane of the LLC. The rate-limiting step in cholesterol transport is StAR protein. Other steroidogenic enzymes remain active as P4 production by the CL plummets. Thus, luteal P4 production can be increased or decreased by hormonal, dietary, and management manipulations. Metabolic clearance rate (MCR) of P4 has been found to vary substantially between cows in different physiological conditions. For example, P4 MCR more than doubles in cows during high milk production as compared with similar size and age nonlactating cows. The P4 metabolism enzymes are concentrated in the liver. Thus, MCR of P4 and other steroids is primarily related to the rate of liver blood flow, which has been related to dry matter intake in dairy cattle. In conclusion, manipulation of P4 production and metabolism appear to be fertile areas for future research aimed at improving fertility in cattle.

Key Words: P4, corpus luteum, fertility

325 Novel concepts on the role of prostaglandins on luteal maintenance and maternal recognition of pregnancy in ruminants. Joe A. Arosh*[1], JeHoon Lee[1], Jone A. Stanley[1], John A. McCracken[2], and Sakhila K. Banu[1], *[1]Department of Veterinary Integrative Biosciences, College of Veterinary Medicine and Biomedical Sciences, Texas A&M University, College Station, TX, [2]Department of Animal Science, University of Connecticut, Storrs, CT.*

In ruminants, the corpus luteum (CL) of early pregnancy is resistant to luteolysis. PGE_2 is considered as a luteoprotective mediator. Early studies indicate that during the establishment of pregnancy in sheep, a factor(s) from the conceptus or gravid uterus reaches the ovary locally through the utero-ovarian plexus (UOP) and protects the CL from luteolysis. The local nature of the embryonic antiluteolytic or luteoprotective effect precludes any direct effect of a protein transported or acting between the gravid uterus and CL in ruminants. At the time of establishment of pregnancy, interferon tau (IFNT) secreted by the trophoblast of the conceptus inhibits endometrial pulsatile release of PGF2a and increases endometrial PGE2. Our recent studies indicate that (1) luteal PG biosynthesis is selectively directed toward PGF2a at the time of luteolysis and toward PGE_2 during establishment of pregnancy; (2) the ability of CL of early pregnancy to resist luteolysis is likely due to increased intraluteal biosynthesis of PGE_2 and signaling; (3) IFNT protein is not transported from the uterus to the CL through the UOP vascular route; and (4) a large proportion of endometrial PGE_2 is transported from the uterus to the CL through the UOP vascular route during the establishment of pregnancy in sheep. Our ongoing studies indicate that intrauterine co-administration of IFNT and PGES-1 inhibitor inhibits IFNT action and IFNT fails to rescue the CL in cyclic sheep. By contrast, intrauterine co-administration of IFNT and PGES-1 inhibitor along with intraovarian administration of PGE2 rescues the CL in cyclic sheep. These results suggest that IFNT may prolong the lifespan of the CL by increasing endometrial secretion of PGE_2 which in turn increases luteal PGE_2 biosynthesis and signaling and promotes luteal resistance. Together, our studies provide compelling evidence that PGE2 produced by the CL in response to endometrial PGE2 may protect the CL, as a component of luteoprotective mechanisms, at the time of maternal recognition of pregnancy in ruminants. These novel findings may offer therapeutic strategies to target PGE2 biosynthesis and signaling selectively in the endometrium and/or CL to improve reproductive efficiency in ruminants.

326 The role of progesterone receptor on control of ovulation and oviductal transport in mammals.

Rebecca Robker*, Darryl Russell, and Lisa Akison, *University of Adelaide, Adelaide, South Australia, Australia.*

Progesterone is critical for many aspects of female reproduction such as ovulation, oviductal transport, implantation, and maintenance of pregnancy. Its effects are mediated by the progesterone receptor (PGR), which occurs in both PGR-A and PGR-B isoforms, acting as nuclear hormone transcription factors. In the ovary, PGR is transiently expressed, specifically in granulosa cells of preovulatory follicles in response to the luteinizing hormone (LH) surge that triggers ovulation. To identify PGR regulated genes that are responsible for these key reproductive events we conducted microarray analyses of mRNA from granulosa cells and oviducts comparing progesterone receptor null mice (PRKOs) and heterozygous littermates. Microarray results confirmed that proteases Adamts1 and Cathepsin L are expressed at greatly reduced levels in PRKO granulosa cells, and identified novel gene products involved in cellular migration and invasion processes that are likely to mediate the dynamic tissue remodeling that facilitates ovulation. In the oviduct, PGR is expressed predominantly in luminal epithelial cells but also muscle cells. A large number of oviductal genes were also dysregulated in PRKO mouse oviducts during the peri-ovulatory period and we identified and subsequently validated several that have potential roles in cumulus-oocyte capture and transport following ovulation. The majority were genes associated with adhesion and muscular contractility including integrin α 8, endothelin 3, myocardin and angiotensin II receptor. Thus, the actions of PGR play key roles in coordinating the functions of multiple tissues, including the important peri-ovulatory events of oocyte release and acquisition of oocyte developmental competence, as well as subsequent oviductal transport of the newly formed embryo and immunological events at implantation.

Key Words: progesterone receptor, ovulation, oviduct

327 Contrasting effects of progesterone on fertility of dairy and beef cows.

Jeffrey S. Stevenson*[1] and G. Cliff Lamb[2], *[1]Kansas State University, Manhattan, KS, [2]University of Florida, Marianna, FL.*

Role of progesterone in maintaining pregnancy is well known in the bovine. Subtle differences exist between dairy (milked) and beef (suckled) cows because of differing concentrations of progesterone during recrudescence of postpartum estrous cycles, rate of follicular growth and maturation, proportions of 2- and 3-follicular wave cycles, and other effects on pregnancy outcomes per AI (P/AI). Because proportions of anovulatory cows at the onset of the AI period are greater and more variable in beef (usually ranging from 30 to 70%) than dairy (25%) cows, AI programs were developed to accommodate anovulatory and cycling beef cows enrolled therein. Incorporating a progestin as part of an AI program in beef cows improved P/AI by reducing the proportion of cows having premature luteal regression and short post-AI luteal phases. Two- vs. 3-follicle wave cycles are more common in beef cows (86 vs. 14%) than in dairy cows (68 vs. 32%), respectively, even though P/AI may not differ in 2- vs. 3-wave beef cows (82 vs. 100%), but differed in dairy cows (63 vs. 81%). When dominant follicles matured in subluteal-phase progesterone concentrations compared with those matured in luteal-phase concentrations, P/AI increased in beef cows, but were reduced in dairy cows when the first dominant follicle (matured in sub-luteal milieu) was induced to ovulate compared with cows ovulating a second-wave dominant follicle. Further, supplementing progesterone during growth of the first-wave dominant follicle improved fertility in dairy cows. Initiating timed AI programs in dairy cows in a greater progesterone environment and during cycle d 5 through 12 enhanced fertility. In contrast, progesterone status in beef cows at the onset of synchronization does not seem to be related to P/AI in multiparous cows, whereas P/AI were suppressed in primiparous cows that began a timed AI program in a low-progesterone environment. Pregnancy losses after AI between 35 and 60 to 70 d are less than 5% in beef cows and are not associated with pre-AI progesterone or cycling status, whereas losses in dairy cows (6 to 20%) are inversely related to progesterone and adversely affected in anovular dairy cows.

Key Words: beef and dairy cattle, progesterone, fertility

328 The influence of progesterone (P4) during follicle development on endometrial and conceptus biology and fertility in dairy cows.

Rafael S. Bisinotto*, Eduardo S. Ribeiro, Leandro F. Greco, Natalia Martinez, Leticia D. P. Sinedino, Fabio S. Lima, William W. Thatcher, and Jose E. P. Santos, *Department of Animal Sciences, University of Florida, Gainesville, FL.*

The effects of P4 concentrations during follicle growth on fertility responses in dairy cows were evaluated. In study 1, pregnancy per artificial insemination (P/AI) increased ($P < 0.01$) in cows initiating the timed AI program in diestrus compared with anovular and cyclic cows without a corpus luteum (CL; 36.9, 25.1, 28.1%); however, pregnancy loss was smaller ($P = 0.08$) in cyclic cows without CL, followed by cows in diestrus, and anovular cows (10.0, 13.5, 15.0%). In study 2, concepti on d 15 after AI were longer ($P < 0.05$) in anovular compared with cyclic cows (47.8 ± 8.8 vs. 9.4 ± 5.8 mm). Concepti transcriptome analysis depicted 417 genes differentially expressed in response to cyclic status, mostly involved with embryonic development. In study 3, cyclic cows were induced to ovulate the dominant follicle from the first wave (FW; P4 = 1.2 ± 0.3 ng/mL), first wave supplemented with P4 (FWP4; P4 = 4.3 ± 0.3 ng/mL), or second wave (SW; P4 = 5.4 ± 0.2 ng/mL). Cows in FW had ($P < 0.05$) larger ovulatory follicles (19.6 ± 0.6, 15.6 ± 0.6, 15.2 ± 0.5 mm), greater estradiol concentrations during proestrus (8.0 ± 0.6, 7.0 ± 0.7, 5.9 ± 0.6 pg/mL), and a faster P4 rise after AI. Concepti on d 17 after AI were longer ($P = 0.05$) for FW compared with FWP4 and SW (16.6 ± 2.3, 9.8 ± 2.2, 9.6 ± 2.0 cm); however, major changes on transcriptome were not observed. Treatment did not affect any biological process in the endometrium on d 17 of gestation. In studies 4 and 5, a single ultrasound evaluation identified a low-fertility cohort based on the absence of CL at the initiation of the timed AI program. Increasing P4 concentrations to at least 2.0 ng/mL improved ($P \leq 0.01$) P/AI in cows lacking CL similar to those in diestrus in the 5-d timed AI (No CL = 28.6, 2CIDR = 43.7, Diestrus = 47.3%) and the Ovsynch protocols (No CL = 28.9, 2CIDR = 37.2, Diestrus = 33.9%). Low concentrations of P4 during the development of the ovulatory follicle impair fertility and a minimum of 2.0 ng/mL seems to be needed to restore P/AI. Lack of differences on conceptus and endometrium on d 17 suggest that effects occur early in gestation.

Key Words: anovulation, embryo, progesterone

329 Effect of manipulating progesterone before timed artificial insemination on reproductive and endocrine parameters in Irish Holstein-Friesian dairy cows. Paul M. Fricke*[1], Paulo D. Carvalho[1], Matthew C. Lucy[2], Francis Curran[3], Mary M. Herlihy[3], and Stephen T. Butler[3], [1]*University of Wisconsin - Madison, Madison, WI,* [2]*University of Missouri, Columbia, MO,* [3]*Teagasc Moorepark-Animal & Grassland Research and Innovation Centre, Fermoy, Ireland.*

Irish Holstein-Friesian dairy cows managed in a seasonal calving, grazing-based dairy system were randomly assigned to 2 treatments to manipulate progesterone (P4) before timed AI (TAI). Cows in the first treatment (High P4; n = 30) were submitted to a Double Ovsynch protocol [Pre-Ovsynch protocol (GnRH; 7 d, $PGF_{2\alpha}$; 3 d, GnRH) followed 7 d later by an Ovsynch-56 protocol (GnRH (G1); 7 d $PGF_{2\alpha}$ (PGF); 24 h, $PGF_{2\alpha}$; 32 h, GnRH (G2); 16 h, TAI)]. Cows in the second treatment (n = 30; Low P4) received the same protocol with an additional PGF injection 24 h after G1. Data were analyzed using PROC MIXED and PROC GLIMMIX of SAS. Overall, synchronization rate was 92% (55/60) and did not differ between treatments. As expected, High P4 cows had more ($P < 0.001$) CL at PGF (1.93 ± 0.09 vs. 1.04 ± 0.04), and P4 (ng/mL) did not differ between treatments at G1 (3.8 ± 0.3 vs. 4.1 ± 0.4). Circulating P4 was greater ($P < 0.001$) for High vs. Low P4 cows at PGF (8.5 ± 0.9 vs. 1.6 ± 0.4) and G2 (0.30 ± 0.04 vs. 0.08 ± 0.02). Although diameter (mm) of the preovulatory follicle was greater ($P < 0.001$) for Low vs. High P4 cows at G2 (17.1 ± 0.4 vs. 15.6 ± 0.4), neither CL diameter nor volume differed between treatments 15 d after TAI. The proportion of pregnant cows 39 and 60 d after TAI did not differ between treatments (63%; 17/27 vs. 61%; 17/28 for Low P4 vs. High P4 cows), and no pregnancy loss occurred. Both treatment ($P = 0.006$) and time ($P < 0.001$) affected P4 concentrations in pregnant cows from 1 to 39 d after TAI with Low P4 cows having greater P4 than High P4 cows. Treatment did not affect plasma pregnancy-associated glycoprotein (PAG) concentrations for cows diagnosed pregnant 39 d after TAI; however, pregnant primiparous cows had greater ($P = 0.02$) PAGs from 20 to 39 d after TAI than pregnant multiparous cows. We conclude that although low P4 before TAI increased follicle growth before TAI and P4 concentrations in pregnant cows after TAI compared with high P4, low P4 before TAI did not negatively affect fertility, pregnancy loss, or PAGs after TAI in Irish Holstein-Friesian dairy cows.

Key Words: progesterone, timed AI, dairy cow

Ruminant Nutrition: General

330 Effect of trace minerals and different levels of starch on digestibility and ruminal fermentation in diets for dairy heifers.

Felipe Pino* and Jud Heinrichs, *The Pennsylvania State University, State College, PA.*

Eight rumen cannulated dairy heifers (15.4 ± 0.8 mo of age and 438.31 ± 18.08 kg of BW) were fed a high forage diet with 4 different levels of starch (3.5, 12.9, 22.3, and 31.7%) and 2 types of trace minerals (TM; organic and inorganic; OTM and ITM). Inorganic TM were provided as sulfates and organic TM as proteinates (Bioplex; Alltech, Inc.). The TM analyzed were Cu, Mn, Se, and Zn. Heifers were subject to a split-plot, 4 × 4 Latin square design with 19-d periods; 15 d adaptation and 4 d sampling. The whole-plot factor was TM, and the subplot was starch concentration. Total collection of feces and urine were completed on d 15 to 19 to determine digestibility and TM excretion. Rumen contents were sampled (d 18 to 19) from 5 different locations in the rumen at 0, 1, 2, 4, 8, 12, 16, 20, and 22 h after feeding to measure pH and VFA concentrations. Plasma samples were collected to evaluate TM concentrations. Data were analyzed with the mixed procedure of SAS. Trace mineral intake was lower for OTM compared with ITM. No effect of TM on digestibility was detected, but as level of starch increased, DM digestibility increased ($P = 0.08$). Rumen pH was lower for diets with OTM ($P = 0.01$), which is consistent with higher total VFA production and butyrate proportion ($P = 0.03$) observed for OTM diets. These variables may be explained by the higher bioavailability of OTM and faster utilization and fermentation by rumen microorganisms. Heifers that consumed ITM had higher moisture in feces and urine excretion, which increased total manure production ($P < 0.01$). Excretion of TM was not different by treatment. Blood plasma was not different between treatments except for Mn that was higher for OTM. Because mineral intake was reduced and blood mineral levels were not different, these results suggest enhanced absorption of OTM compared with ITM. In conclusion, based on pH, VFA production and plasma TM concentration, OTM may be more ruminally bioavailable and absorbed in a greater extent than ITM. Also, the form of TM affects fecal moisture and urine excretion suggesting that ITM might stimulate water intake.

Key Words: trace mineral, starch digestibility, heifer

331 Small intestinal starch digestion in cattle is linearly increased by duodenal glutamic acid flow.

Ethan J. Blom*[1], Derek W. Brake[1], and David E. Anderson[2], [1]*South Dakota State University, Brookings, SD,* [2]*University of Tennessee Knoxville, Knoxville, TN.*

Postruminal infusion of glutamic acid has been shown to increase small intestinal starch digestion in cattle. Our objective was to determine response among small intestinal starch digestion in cattle provided increasing amounts of postruminal glutamic acid. Five ruminally, duodenally, and ileally cannulated steers (351 ± 11 kg BW) were fed (5.1 ± 0.06 kg DM/d) a soybean hull-based diet that contained only slight amounts of starch (0.8% DM) and placed in a 5 × 5 Latin square with 12-d periods. Cattle received (DM basis) continuous duodenal infusion of raw cornstarch (1.5 ± 0.08 kg/d), and either 0 (control), 30.9 ± 0.6, 62.4 ± 1.2, 120.4 ± 3.4 g/d glutamic acid or 407 ± 18.3 g/d casein (a positive control). Ileal and fecal nutrient flows were measured during the last 4 d of each period and CrEDTA served as an indigestible marker. Amounts of starch infused did not differ ($P = 0.46$). Casein increased ($P = 0.05$) small intestinal starch digestion. Similarly, small intestinal starch digestion increased linearly ($P = 0.02$) with increasing amounts of glutamic acid. Ileal flow of ethanol soluble starch tended to decrease (linear = 0.16) with greater amounts of glutamic acid, but ileal flow of ethanol soluble starch was not affected by casein ($P = 0.42$). Ileal flow of glucose was small (8.5 ± 3.0 g/d); however, greater glutamic acid flow tended (quadratic = 0.08) to decrease ileal glucose flow. Fecal starch flow decreased in response to casein ($P = 0.01$) and glutamic acid (linear = 0.04; cubic = 0.04); however, fecal flow of ethanol soluble starch and glucose were not affected by casein or glutamic acid. Postruminal starch digestion was increased by both casein ($P = 0.02$) and glutamic acid (linear = 0.05; cubic = 0.03). Our data indicate that small intestinal starch digestion is linearly increased by postruminal glutamic acid flow.

Key Words: cattle, small intestinal starch digestion, glutamic acid

332 Protein chemical profile, energy values, protein fractions, and rumen degradation characteristics of the newly developed yellow and brown carinata lines for dairy cattle compared with commercial canola seeds.

Yajing Ban*, David A. Christensen, John J. McKinnon, and Peiqiang Yu, *Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, SK, Canada.*

Brassica carinata (Yellow: AAC A110; Brown: 110915EM) are newly developed oil crop lines for bio-fuel industry. However, there is little research on chemical profile, nutritive value and biodegradation characteristics of seeds as a feed source for animal diets. The objectives of this study were to systematically determine (1) chemical composition, (2) energy values, (3) protein fractions, (4) rumen protein degradation kinetics of the new yellow and brown carinata lines in comparison with brown commercial canola seeds, and to provide detailed information for feed registration in Canada. The 2 carinata lines were bred by Agriculture and Agri-Food Canada, and 2 sources of seeds were combined for each line. Four cannulated lactating dairy cows were used for rumen degradation trial. Protein fractions were partitioned based on Cornell Net Carbohydrate and Protein System (CNCPS). Statistical analyses were performed using PROC MIXED procedure of SAS 9.3 with significance declared at $P \leq 0.05$. The results showed that yellow carinata seeds were higher than canola seeds in crude protein, non-protein nitrogen but lower in neutral detergent insoluble crude protein and acid detergent insoluble crude protein ($P \leq 0.05$). Yellow carinata seeds were not significantly different from canola seeds in total digestible nutrient (TDN) and energy values, while brown carinata seeds had the lowest TDN and energy values. Results from CNCPS indicated that yellow carinata seeds were lower in unavailable protein C fraction and higher in true protein ($P \leq 0.05$), while brown carinata seeds had no significant difference with canola seeds in protein subfractions. Yellow carinata seeds had more rumen undegraded feed crude protein (RUP) and effective degradability of feed crude protein (EDCP) than canola seeds. In conclusion, *Brassica carinata* have potential to be utilized as a good feed protein source compared with commercial canola seeds, and the yellow carinata line had a higher protein supply than the brown line.

Key Words: carinata seed, protein fractions, rumen degradation

333 Effect of an increased ruminal ammonia supply on lysine utilization by growing steers.

A. H. Hussein*[1], E. D. Batista[1,2], M. D. Miesner[3], and E. C. Titgemeyer[1], [1]*Department of Animal Sciences and Industry, Kansas State University, Manhattan, KS,* [2]*Departamento de Zootecnia, Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil,* [3]*Department of Clinical Sciences, Kansas State University, Manhattan, KS.*

Six ruminally cannulated Holstein steers (202 ± 15 kg) were used to study effects of ruminal ammonia loading on whole-body lysine utilization. Steers were housed in metabolism crates and used in a 6 × 6 Latin square design. All steers received 2.52 kg of DM/d of a diet (10.1% CP) containing 82% soybean hulls, 8% wheat straw, and 5% cane molasses, and 10 g/d of urea was ruminally infused continuously to all steers to ensure adequate ruminal ammonia concentrations. All steers were ruminally infused continuously with 200 g/d acetic acid, 200 g/d propionic acid, and 50 g/d of butyric acid and abomasally infused with 300 g/d of glucose continuously to increase energy supply without increasing microbial protein supply. Steers were also abomasally infused continuously with an excess of all essential amino acids except lysine to ensure that lysine was the only limiting amino acid. Treatments were arranged as a 3 × 2 factorial with 3 levels of urea (0, 40, or 80 g/d) continuously infused ruminally to induce ammonia loading and 2 levels of lysine (0 or 6 g/d) continuously infused abomasally. Treatments did not affect fecal N output ($P \geq 0.37$). Lysine supplementation decreased ($P < 0.01$) urinary N excretion from 51.9 g/d to 44.3 g/d (SEM = 1.3), increased ($P < 0.01$) retained N from 24.8 to 33.8 g/d (SEM = 1.2), and tended ($P = 0.09$) to reduce plasma urea. Urea infusions linearly increased retained N (27.1, 29.3, and 31.5 g/d; SEM = 1.5; $P = 0.05$) and also linearly increased ($P < 0.01$) urinary N excretion (31.8, 48.1, and 64.4 g/d; SEM = 1.6), urinary urea-N (21.9, 37.7, and 54.3 g/d; SEM = 1.5), urinary ammonia-N (1.1, 1.4, and 1.9 g/d; SEM = 0.1), and plasma urea (2.7, 4.0, and 5.1 m*M*; SEM = 0.5). Assuming that retained protein is 6.25 × retained N and contains 6.4% lysine, the incremental efficiencies of infused lysine utilization were 51, 59, and 69% for steers receiving 0, 40, and 80 g/d of urea, respectively, suggesting that ruminal ammonia loads might improve efficiency of lysine utilization; this is supported by the observed increases in whole body protein deposition in response to ammonia loading of our steers that were, by design, lysine deficient.

Key Words: ammonia, lysine, cattle

334 Relationship between antioxidant capacity, oxidative stress, and feed efficiency in beef steers.

J. R. Russell*[1], W. J. Sexten[2], M. S. Kerley[2], and S. L. Hansen[1], [1]*Iowa State University, Ames, IA,* [2]*University of Missouri, Columbia, MO.*

The objective was to evaluate the relationship between feed efficiency (FE), antioxidant activity (ANTI) and oxidative stress (OXI) in feedlot steers representing phenotypic extremes for FE. Steers (n = 182) were fed a 70 d growing phase (GP) diet of whole shell corn (GCorn) or roughage (GRough) in GrowSafe bunks at University of Missouri, then shipped to Iowa State University where the 12 greatest (HFE) and 12 least (LFE) efficient steers from each diet (n = 48; 467 ± 48 kg) were selected for evaluation. Steers received diets similar to GP diets and 3 d after arrival, blood was sampled to evaluate ANTI and OXI markers for GP. Steers were transitioned to finishing phase (FP) corn (FCorn) or byproduct-based diets (FByp) and on FP d 97, blood samples for FP were collected. Data for GP were analyzed as a 2 × 2, and data for FP as a 2x2x2 using PROC MIXED of SAS. Looking at GP diet effects, GRough had greater ($P = 0.04$) GP plasma protein carbonyl concentrations (PC) and a tendency for greater ($P = 0.06$) FP total blood lysate superoxide dismutase activity (SOD) than GCorn. The FByp had greater ($P < 0.01$) PC during FP than FCorn and no other FP diet effects were noted ($P > 0.2$). Analyzing FE group effects, during GP the HFE had greater ($P < 0.04$) PC and ratio of oxidized:reduced blood lysate glutathione concentrations than LFE. There were GP diet x FE group interactions, as LFE-GRough had greater ($P \leq 0.03$) GP total SOD and greater ($P \leq 0.05$) FP glutathione peroxidase activity (GPX) compared with LFE-GCorn and HFE-GRough; HFE-GCorn was intermediate. During GP, the LFE-GRough had greater ($P < 0.01$) GPX than other treatments and had greater ($P = 0.03$) plasma malondialdehyde concentrations than LFE-GCorn. No GP diet x FP diet, FP diet x FE group, or 3-way interactions were noted ($P > 0.3$). The GP diet and FE groups had stronger relationships with ANTI and OXI markers measured during the GP than the FP. Antioxidant activity may play a role in FE as LFE, driven largely by LFE-GRough, had greater SOD and GPX than HFE, potentially using a greater proportion of energy otherwise utilized for tissue accretion.

Key Words: antioxidant, feed efficiency, oxidative stress

335 Efficiency of lysine utilization by growing steers.

Erick D. Batista*[1,2], Ali H. Hussein[1], Matt Miesner[1], Edenio Detmann[2], and Evan C. Titgemeyer[1], [1]*Kansas State University, Manhattan, KS,* [2]*Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

This study evaluated the efficiency of lysine utilization by growing steers. Five ruminally cannulated Holstein steers (165 kg ± 8 kg) housed in metabolism crates were used in a 6 × 6 Latin square design. Data from a sixth steer was excluded due to erratic feed intake. All steers were limit-fed (2.46 kg DM/d) twice daily diets low in RUP (81% soybean hulls, 8% wheat straw, 6% cane molasses, and 5% vitamins and minerals). Treatments were: 0, 3, 6, 9, 12, and 15 g/d of L-lysine abomasally infused continuously. To prevent amino acids other than lysine from limiting performance, a mixture providing all essential amino acids in excess was continuously infused abomasally. Additional continuous infusions included 10 g urea/d, 200 g acetate/d, 200 g propionate/d, and 50 g butyrate/d to the rumen and 300 g glucose/d to the abomasum. These infusions provided adequate ruminal ammonia and increased energy supply without increasing microbial protein supply. Each 6-d period included 2 d for adaptation and 4 d for total fecal and urinary collections for measuring N balance. Blood was collected on d 6 (10 h after feeding). Plasma urea-N was decreased ($P = 0.01$) by lysine supplementation, but plasma glucose was unaffected ($P = 0.73$). Diet DM digestibility was not altered ($P = 0.94$) by treatment and averaged 72.2%. Increasing lysine supplementation from 0 to 9 g/d decreased urinary N excretion ($P < 0.01$) from 32.3 to 24.3 g/d with no further reduction when more than 9 g/d of lysine was supplied. Changes in total urinary N excretion were due to changes in urinary urea-N, which decreased ($P < 0.01$) from 21.6 to 14.8 g/d as supplemental lysine increased from 0 to 9 g/d. Urinary ammonia-N was not affected by treatment ($P = 0.48$). Increasing lysine supply from 0 to 9 g/d increased ($P < 0.01$) N retention from 20.7 to 29.9 g/d with no further increase observed beyond 9 g/d of lysine. Breakpoint analysis estimated maximal N retention at 9.0 g/d supplemental lysine. Over the linear response surface of 0 to 9 g/d lysine, assuming that retained protein is 6.25 × retained N and contains 6.4% lysine, the efficiency of lysine utilization for protein deposition was 40%.

Key Words: cattle, lysine, efficiency

336 Effects of preweaning nutrient supply on growth and pre and post-weaning glucose tolerance test in male Holstein calves.

Isabela Pena Carvalho de Carvalho*, Leonel Neto Leal, Harma Berends, and Javier Martín-Tereso, *Nutreco Ruminant Research Center, Boxmeer, the Netherlands.*

Perinatal nutrient supply can affect metabolism of mammals with effects that persist later in life. We hypothesized that pre-weaning calf milk replacer (CMR) supply can alter energy homeostasis in later growth phases. One hundred twenty male Holstein calves (20 ± 3.2 d old and 48.4 ± 2.2 kg BW) were assigned to a low (LP) or high (HP) plane of nutrition, in a randomized block design with 12 blocks of 2 pens. LP received 25 kg and HP 50 kg of the same CMR (18% fat, 23% protein) for 7 weeks before weaning. Throughout the 12 weeks of experiment, calves were offered ad libitum calf starter and straw. Body weight (BW) was recorded weekly. A glucose tolerance test (GTT) was conducted before (d 42, PW) and after (d 84, AW) weaning in 24 calves (1 calf randomly selected per pen). After a 12h fasting period, glucose was infused at 180 mg/kg of BW through a venous catheter. Blood was collected at −15, −5, 0, 5, 10, 15, 20, 25, 30, 35, 45, 60, and 90 min relative to glucose infusion. Data were analyzed using PROC MIXED in SAS. BW and average daily gain (ADG) were affected ($P < 0.01$) by treatment, week and treatment × week interactions. HP calves were heavier from wk 2 leading to a final BW of 131.3 ± 1.88 and 140.0 ± 1.88 for LP and HP at wk 12, respectively. ADG was greater for HP on wk 1 ($P < 0.01$), 2 ($P < 0.01$), 3 ($P < 0.01$), 10 ($P = 0.05$) and 12 ($P = 0.04$) although on wk 7, LP presented a higher ($P = 0.01$) ADG. Consequently, overall ADG was lower ($P < 0.01$) for LP (0.969 ± 0.029 vs. 1.089 ± 0.029 kg/d). Glucose responses PW or AW did not differ ($P = 0.78$ and $P = 0.32$, respectively) between the treatments. Serum insulin presented no treatment *x* time interactions ($P = 0.24$ and $P = 0.06$, for PW and AW, respectively). In the PW test, insulin did not differ ($P = 0.89$) between treatments. In the AW test, however, plasma insulin was greater ($P < 0.01$) in HP calves 5, 10, 15, 20, 30 35 and 45 min following glucose infusion. Nutrient supply to calves in early life affects post weaning insulin response, supporting the importance of perinatal nutritional stimuli for later life metabolism.

Key Words: calf milk replacer, insulin, metabolic programming

337 Effects of hemp seed oil on serum antioxidant indicators in dairy water buffalo.

Cai-xia Zou*[1], Sheng-ju Wei[1], Dan Wan[1,2], Xin Liang[1], Li-Li Li[1], Bo Lin[1], Xian-wei Liang[1], Bing-zhuang Yang[1], and Zhong-sheng Xia[1,2], *[1]Key Laboratory of Buffalo Genetics, Breeding and Reproduction technology, Ministry of Agriculture and Guangxi, Buffalo Research Institute, Chinese Academy of Agricultural Sciences, Nanning, China., [2]College of Animal Science and Technology, Guangxi University, Nanning, China.*

The aim of the present study was to investigate the effects of hemp seed oil supplementation on serum antioxidant indicators in dairy water buffalo. Eighteen dairy water buffaloes were randomly assigned to 3 treatments: (1) 0 g/d hemp seed oil supplement, (2)100 g/d hemp seed oil supplement, and (3) 200 g/d hemp seed oil supplement. The whole feeding experiment duration was 6 weeks with 2 weeks for adaptation and measurements were made at the end of whole feeding experiment. The results showed that, compared with group 1, hemp seed oil supplementation tended to increase the activity of total antioxidative capacity (T-AOC), glutathione peroxidase (GSH-PX) and catalase (CAT), and group 3 reached significance level ($P < 0.05$). Group 2 resulted in significantly decreased activity of peroxidase (MDA) compared with group 1, while group 3 had no significant effect. On the other hand, no significant differences were found between group 1 and the other treatments in the activity of peroxidase (POD) and superoxide dismutase (SOD). In conclusion, these results of this study indicated that supplement hemp seed oil would increase the antioxidant capacity of serum and enhance the immune function in organism of dairy water buffalo.

Key Words: dairy water buffalo, hemp seed oil, antioxidant indicator

338 Effects of maternal metabolizable protein supply during late gestation on maternal and fetal intestinal development in sheep.

G. Q. Jia*, J. S. Caton, K. A. Vonnahme, T. J. Swanson, L. A. Lekatz, P. P. Borowicz, S. T. Dorsam, A. M. Meyer, and L. P. Reynolds, *North Dakota State University, Fargo, ND.*

We hypothesized that metabolizable protein (MP) supply during late gestation would affect maternal and fetal intestinal development in sheep. In Exp. 1, multiparous ewes (n = 45) were allotted randomly to 1 of 3 treatments, 60% (MP60), 80% (MP80), or 100% (MP100) of MP requirements fed from d 100 to d 130 of gestation. In Exp. 2, multiparous singleton pregnant ewes (n = 18) were randomized to receive 1 of 3 diets that were similar in energy and formulated to supply 60% (MP60), 100% (MP100), or 140% (MP140) of MP requirements during late gestation (d 100 to 130). Pregnant ewes and fetuses were euthanized and necropsied on d 130 ± 1 of gestation, and maternal and fetal intestinal tissues were collected. Data were analyzed with GLM and means separated using PDIFF of SAS. In Exp. 1, as previously reported, maternal BW of MP80 was greater ($P = 0.05$) than MP60 and MP100 which were not different, whereas fetal BW was not altered by treatment. Neither maternal nor fetal small intestinal mass or % proliferating jejunal crypt cells (labeling index) were affects by dietary MP supply during late gestation. Fetal large intestinal mass in MP80-fed ewes tended ($P = 0.08$) to be greater than MP60 and MP100 fetuses when examined as a proportion of eviscerated BW. Likewise, in Exp. 2, crypt cell proliferation in fetal jejunal samples was unaltered by maternal MP supply. Thus, maternal MP supply did not affect maternal and fetal intestinal development during late gestation; however, fetal large intestinal weight appeared to be increased when dams were supplied MP80 compared with MP100. Additional research is needed to confirm and extend these results. We hypothesized that metabolizable protein (MP) supply during late gestation would affect maternal and fetal intestinal development in sheep. In Exp. 1, multiparous ewes (n = 45) were allotted randomly to 1 of 3 treatments, 60% (MP60), 80% (MP80), or 100% (MP100) of MP requirements fed from d 100 to d 130 of gestation. In Exp. 2, multiparous singleton pregnant ewes (n = 18) were randomized to receive 1 of 3 diets that were isocaloric and formulated to supply 60% (MP60), 100% (MP100), or 140% (MP140) of MP requirements during late gestation (d 100 to 130). Pregnant ewes and fetuses were euthanized and necropsied on d 130 ± 1 of gestation, and maternal and fetal intestinal tissues were collected. In Exp. 1, as previously reported, maternal BW of MP80 was greater ($P = 0.05$) than MP60 and MP100 which were not different, whereas fetal BW was not altered by treatment. Neither maternal nor fetal small intestinal mass nor % proliferating jejunal crypt cells (labeling index) were affected by dietary MP supply during late gestation. Fetal large intestinal mass in MP80-fed ewes tended ($P = 0.08$) to be greater than MP60 and MP100 fetuses when examined as a proportion of eviscerated BW. Likewise, in Exp. 2, crypt cell proliferation in fetal jejunal samples was unaltered by maternal MP supply. Thus, maternal MP supply did not affect maternal and fetal intestinal development during late gestation; however, fetal large intestinal weight appeared to be increased when dams were supplied MP80 compared with MP100. Additional research is needed to confirm and extend these results.

339 Effects of supplementation to steers consuming green chopped wheat pasture on energy losses and nitrogen balance.

Adam L. Shreck*[1], Pake J. Ebert[3], Eric A. Bailey[3], Jenny S. Jennings[2], Ken D. Casey[2], and N. Andy Cole[1], [1]*USDA-ARS, Bushland, TX,* [2]*Texas Agrilife Research, Amarillo, TX,* [3]*West Texas A&M University, Canyon, TX.*

British cross steers (n = 10; initial BW: 206 ± 10.7 kg) were studied using respiration calorimetry chambers to evaluate energy losses, N balance, and nutrient digestibility of greenchop wheat forage as affected by energy supplementation. The study was designed as a 2 × 2 factorial arrangement of treatments. Eight steers were assigned to one of 2 BW blocks (4 steers per block) with factors consisting of either dietary treatment [no supplementation (CON) vs. supplemented with a corn-based energy supplement that contained 150 mg monensin sodium per steer/daily) at 0.5% of BW daily (SUP)] and NE_m intake level [(1-times (1×) vs. 1.5-times (1.5×) maintenance]. Wheat forage was harvested daily and fed as green chop to steers continuously during the 56-d study. No difference ($P \geq 0.29$) was observed between CON and SUP for apparent digestibility of OM (79.6% vs. 79.6%), NDF (68.7% vs. 64.7%), or N (82.2% vs. 80.4%). No difference was observed for DE (2.90 Mcal/kg), heat production (8.54 vs. 8.29 Mcal), or retained energy (4.98 vs. 4.06 Mcal) between dietary treatments when fed at 1.5× maintenance. CON steers had greater ($P = 0.01$) O_2 consumption (1,790 vs. 1,711 L/d), tended to have ($P = 0.06$) greater CH_4 production (78 vs. 65 L/d), and had similar CO_2 production (1,704 vs. 1,627 L/d; $P = 0.62$) compared with SUP. Methane, as a proportion of GE intake, was 6.50% and 6.00%, for CON and SUP, respectively, but was not significantly different ($P = 0.60$) between treatments. No difference ($P = 0.69$) was noted in retained energy as a proportion of GE intake (24.8 vs. 23.0%) between treatments. We determined that the CON treatment (wheat forage alone) contained 1.61 Mcal/kg NE_m and 0.98 Mcal/kg NE_g and the SUP treatment contained 1.78 Mcal/ kg NE_m and 0.95 Mcal/kg NE_g. By difference, supplementation improved the calculated NEm of wheat forage by 10.6% but decreased NEg of wheat forage by 3.1%. Under the conditions of this study, supplementation of wheat forage with a corn-based supplement did not affect losses of energy and resulted in similar NE values.

Key Words: methane, net energy, wheat forage

340 Supplement and undegradable protein influence on beef calf performance grazing stockpiled tall fescue.

Dylan L. Hamlin*, Robert L. Kallenbach, and William J. Sexten, *University of Missouri, Columbia, MO.*

ABSTRACT: Ninety crossbred beef calves (277.7 ± 7.1 kg) were utilized in a completely randomized design to determine supplement and rumen undegraded protein (RUP) influence on calf performance while grazing stockpiled tall fescue. Calves were supplemented at 1.15% of BW DM with dried distillers grains w/solubles (DDGS); 80.7% DDGS, 19.3% AminoPlus (DDG19); 80.7% soybean hulls (SBH), 19.3% AminoPlus (SBH19); 61.7% SBH, 38.3% AminoPlus (SBH38), or unsupplemented control (CON). We hypothesized supplement would increase ADG, and supplements with increased RUP would improve performance. Calves were stratified by BW, source, color, and sex, and then randomly assigned to a pasture. Pasture replicates (n = 15) were fertilized with nitrogen at 24.4 kg/ha on 25 August 2014 and at experiment initiation were blocked by percent endophyte infection. Weekly forage allocations were based on 3.25% BW DM $hd^{-1}d^{-1}$. Supplement and forage DM allocations were adjusted every 21 d using interim BW. Forage DM substitution was set at 0.5 times average supplemental DMI. Forage allocations were adjusted to maintain 509 kg DM/ha residual. Proc Glimmix procedure of SAS was used for ANOVA. Supplement increased ($P < 0.01$) ADG and final BW compared with CON (0.68 vs. −0.03 kg/d; 336.0 vs. 276.7 kg). ADG did not differ ($P > 0.05$) between DDG19 and SBH38 (0.78 vs. 0.73 kg/d), however DDG19 increased ($P < 0.05$) ADG compared with SBH19 (0.62 kg/d) and DDGS (0.59 kg/d). ADG was not different ($P > 0.05$) between SBH38, SBH19, and DDGS. Forage DM disappearance was not different ($P > 0.05$) between CON (6.7 kg/d), DDG19 (6.5 kg/d) and SBH38 (6.2 kg/d). SBH19 (5.5 kg/d) forage DM disappearance did not differ ($P > 0.05$) from DDG19, SBH38 whereas DDGS (4.3 kg/d) decreased ($P < 0.01$) forage DM disappearance compared with CON, DDG19, and SBH38. DDG19 improved ($P < 0.05$) supplemental G:F compared with DDGS, (0.23 vs. 0.18 kg/kg). SBH38 (0.22 kg/kg) and SBH19 (0.19 kg/kg) supplemental G:F did not differ ($P > 0.05$) compared with DDG19 or DDGS. DMI did not differ ($P > 0.05$) between DDG19 (10.0 kg/d), SBH38 (9.7 kg/d), and SBH19 (8.9 kg/d), and was least for DDGS (7.8 kg/d). Supplementation increased ADG, while additional RUP improved ADG and supplemental G:F.

Key Words: supplementation, grazing, DDGS

341 Performance and economics of supplementing calves with distillers grains or fertilization of smooth bromegrass pastures.

Cody A. Welchons*, Terry J. Klopfenstein, James C. MacDonald, Andrea K. Watson, and Robert G. Bondurant, *University of Nebraska-Lincoln, Lincoln, NE.*

Ten years of performance data were summarized to evaluate distillers grains supplementation and smooth bromegrass fertilization on cattle performance and economics. Each year, 45 steer calves (321 kg, SD = 21 kg) were assigned to 1 of 3 treatments with 3 replications per treatment. Treatments included non-fertilized control pasture (CON), fertilized pasture (89.75 kg N/ha; FERT), or non-fertilized and supplemented with distillers grains plus solubles (DGS) at 0.6% of BW daily for an average of 152 d (SUPP). Cattle on FERT and SUPP were stocked at 9.88 AUM (308 kg of forage)/ha while CON cattle were stocked at 6.82 AUM/ha. Pastures had 5 test animals and put and take animals were used to maintain similar grazing pressure among treatments. Cattle on CON and FERT treatments gained the same through the grazing period (0.77 kg/d; $P = 0.67$); however, fertilized pastures had greater gain per hectare. Supplemented cattle gained 0.31 kg/d more than FERT or CON ($P < 0.01$), resulting in 45.4 kg more BW at the end of the grazing season. Utilizing performance data from this 10 year period, 3 corn prices ($3, $4, and $5/25.4 kg) and 3 DGS prices (95, 105, and 115% price of corn) were used in a partial budget to compare profit potential of these treatments. To account for the greater BW of SUPP cattle at the end of grazing, a $10/45.4 kg price slide was used to calculate SUPP cattle revenue. At all prices, CON cattle were set to breakeven for profit comparisons. Across all scenarios, fertilizer costs were offset by savings in land rent, resulting in a $16.71/animal profit for FERT relative to CON ($P < 0.01$). As price of corn increased, profit of SUPP relative to CON decreased; however, SUPP cattle had greater profit than CON and FERT ($P < 0.01$) at all prices evaluated. For every 10% increase in DGS price relative to corn, SUPP profit decreased $5.32, $7.09, and $8.86 per animal for $3, $4, and $5/25.4 kg corn, respectively. Using an average DGS price of 105% the value of corn, SUPP cattle were $80.76, $62.14, and $43.52/animal more profitable than CON ($P < 0.01$) at corn prices of $3, $4, and $5/25.4 kg, respectively. In these scenarios, supplementing cattle grazing smooth bromegrass pasture with DGS increased ADG and profitability.

Key Words: beef cattle, grazing, supplementation

Ruminant Nutrition Symposium: Time required for diet adaptation and minimization of carry-over effect in ruminants: Evidence-based decisions

342 Time required for adaptation of rumen fermentation and the rumen microbiome. Timothy Hackmann*, *University of Florida, Gainesville, FL.*

Dietary shifts disturb microbiota and fermentation of the rumen, and varying amounts of time are required for them to re-stabilize. Shifts from high-forage to high-grain diets have been studied for over 60 years. During these shifts, abundance of total and cultured bacteria generally increases and then stabilizes. For some shifts in some studies, stabilization was complete within 24 h, but in others, it was incomplete even after 3 wk. Specific groups of bacteria (cellulolytics, amylolytics, lactate-utilizers) and protozoa also require varying amounts of time to stabilize. The time required for methanogens and fungi to stabilize has seldom been studied. Stabilization of fermentation (pH, short-chain fatty acid concentration) does not necessarily coincide with stabilization of the microbiota. For diets with very high (>70%) grain, abundance of protozoa and cultured bacteria vacillates greatly and stabilizes slowly, if at all. More recent studies have employed culture-independent methods, such as qPCR and 16S rDNA sequencing, to investigate taxonomic composition of bacteria and methanogens during dietary shifts. These studies confirm that taxonomic composition does change during dietary shifts, but more frequent sampling is required to resolve at what exact point it stabilizes. Other culture-independent methods, such as whole-genome or transcriptome sequencing, need to be deployed to resolve changes in microbial function, not just taxonomic composition. Changes in microbial communities, whether assessed by culture-independent or dependent methods, need to be better related to variables of interest in feeding trials (e.g., diet intake and digestibility).

Key Words: dietary adaptation, microbiota, rumen

343 Time required for adaptation of behavior, feed intake, and dietary digestibility in cattle. Richard J. Grant*, Heather M. Dann, and Melissa E. Woolpert, *William H. Miner Agricultural Research Institute, Chazy, NY.*

Experimental designs such as Latin square, crossover, and switchback have been used extensively in nutritional studies to assess behavioral, intake, and digestibility responses to diet. A critical consideration when using these designs is the necessary length of an adaptation period to accurately measure treatment effect and to minimize potential confounding influence of carry-over from previous treatment. The objective of this review was to determine typical time required for adaptation of these responses based on research evidence primarily with dairy cattle. We focused on (1) eating, ruminating, and resting behavior, (2) dry matter intake (DMI), and (3) total-tract nutrient digestibility. Animal response to dietary treatment integrates response to physicochemical properties of the diet being studied as well as the feeding environment, and so the environment must be similar among treatments. For example, competition for feed can profoundly affect eating behavior and DMI. Response to diet for eating, ruminating, and resting behaviors usually stabilizes within 1–7 d. Consequently, DMI response to diet reflects the pattern of change in eating behavior. This time course is affected by physical and chemical attributes of the diet such as particle size, carbohydrate fermentability, and fat or protein content and characteristics. Most research indicates that ruminant total-tract digestibility ordinarily adjusts to diet within 10 to 14 d. Meta-analysis reveals that change-over designs are as accurate as continuous designs in assessing DMI. However, diets of extremely high or low digestibility may cause lingering effects on digestive and metabolic processes related to ruminal function or dynamics of body fat and protein that may confound interpretation of response to diet in subsequent experimental periods. Examples of expected time to adaptation and potential carryover in lactating dairy cattle will be illustrated using Latin square studies that evaluated diets with considerable range in forage amount and carbohydrate fermentability. In summary, adaptation periods of approximately 7–14 d are usually adequate for measuring response in eating behavior and DMI, but potential consequences of carryover effects in change-over designs are less clear.

Key Words: adaptation, carryover

344 Time required for adaptation of protein metabolism. G. I. Zanton*, *USDA, Agricultural Research Service, US Dairy Forage Research Center, Madison, WI.*

Animals that can appropriately adjust to varying environmental and nutritional conditions possess a survival advantage. Maintaining homeostasis and homeorhesis in response to changing nutritional conditions requires flexibility in nutrient partitioning and use efficiencies. This is especially the case for protein metabolism because there is no dedicated pool of amino acids held in reserve for times of changing dietary protein availability. Research on the adaptation in protein metabolism to changing dietary conditions could have potential implications on experimental design and on basic and applied ruminant nutrition. However, experiments directly evaluating the metabolic characteristics and appropriate timing of dietary adaptation are very limited. This is especially the case when compared with the number of experiments that have evaluated a response to a nutritional change after the period of adaptation is presumed to be complete, although rarely verified. Factors affecting the adaptive responses in protein metabolism in the ruminant are multiple and likely interacting, although the time required for adaptation appears to depend most on factors such as the duration and level of the previous nutritional condition, the difference from the current nutritional condition, the timing of these dietary changes with respect to the physiological state of the animal, the priority of the metabolic demand, and the productive state of the animal (i.e., the respective combinations of maintenance, growth, and/or lactation). As a consequence of these varied factors, from an experimental perspective, the time required for adaptation may depend on the response variables of interest, productive state of the animal, and the treatments under investigation. Existing literature will be reviewed to highlight time-related adaptive responses to diet changes on protein digestion, post-absorptive metabolism, and production and to emphasize areas where this understanding is incomplete.

Key Words: protein nutrition, adaptation, ruminant

345 Time required for diet adaptation and minimization of carry-over effect in ruminants: The perspective of an experimental researcher. Kevin J. Harvatine*, *Penn State University, University Park, PA.*

The ideal experimental design depends on the biological mechanisms and physiology under investigation. Classical metabolic data provides insight into clearance of specific metabolic pools, but recent discoveries in epigenetic provide the opportunity for long-term responses to diet. Arguably, the most complete experimental design would determine the effect of a dietary treatment over entire lactations, multiple lactations, and possibly over multiple generations. However, these approaches are not practical and arguably other interactions are of greater importance. Experimentally the time course of response to a treatment is very important to provide mechanistic insight into the primary mechanism and secondary adaptations. Both primary mechanisms and secondary adaptations are biologically relevant and application of time-series analysis in experiments may provide key insight in understanding theses mechanisms. In our own work with milk fat depression we have determined the time course of rumen response to diet changes and mammary response to bioactive fatty acids. This information has been invaluable to efficient experimental design and increasing confidence in mechanisms. Lastly, a common goal is to determine the expected response to a treatment. Temporal adaptation is one factor to consider, but many other interactions such as composition of the basal diet (e.g., high vs. low fiber) and physiological state of the cow (including level of intake and production) are also extremely important factors. Arguably, testing treatments over several conditions with adequate, but not excessive, treatment durations would optimize the accuracy of the predicted response when a treatment is applied in practice.

Key Words: time-course, milk fat depression

346 The perspectives of a beef cattle nutritionist. Shawn L. Archibeque*[1] and Gerald B. Huntington[2], *[1]Department of Animal Sciences, Colorado State University, Fort Collins, CO, [2]Department of Animal Science, North Carolina State University, Raleigh, NC.*

There are numerous changes in beef cattle in both their symbiotic and physiological aspects as they are adjusted to various diets associated with varying production states and research needs. Within the beef industry, there is a need to address changes within diet types as well as across diet types (i.e., high roughage vs. high concentrate). These changes will influence our understanding of how nutrients are used during varying production states. These variations in treatments that deal with source more than daily supply will allow for minimal variation in measurements within a shorter period of time than those studies with large changes in particularly nutrients or overall plane of nutrition. In particular, these adaptations are greatly varied in the literature. This is of particular interest in studies that use a study design that minimizes animal-to-animal variation through the repeated use of animals in the study, such as a Latin square or crossover design. To highlight the significance of this issue, over 35% of the articles in the ruminant nutrition section of the *Journal of Animal Science* used these research techniques and had a range in adaptation periods from 9 to 27 d, with an average of 14.6 d. There is a need for greater understanding and homogeneity in these adaptation periods for future understanding of data, particularly those that will be happening over a fixed period of time.

Key Words: homeorhetic adaptation, ruminal adaptation, variance

347 Algae meal for ruminants: I. Nutrient digestibility in finishing lambs. Rebecca S. Stokes*, Megan L. Van Emon, Daniel D. Loy, and Stephanie L. Hansen, *Department of Animal Science, Iowa State University, Ames, IA.*

Heterotrophic microalgae combined with soyhulls forms an algae meal (ALG) which contains partially deoiled microalgae (DMA; 57% DM basis) and soyhulls (43%). Eight whiteface wethers (23.02 ± 0.54 kg) were used in a 4 × 4 Latin square design to determine the effect of the DMA portion of ALG on total-tract nutrient digestibility. Lambs received 1 of 4 isonitrogenous dietary treatments (2 sheep$\cdot$diet$^{-1}\cdot$period^{-1}) where ALG was added at the expense of soyhulls: a soyhulls-based control (CON; 53% soyhulls), 10% DMA from ALG (DMA10), 20% DMA from ALG (DMA20), and 30% DMA from ALG (DMA30). There were 4 periods, with 10 d of adaptation and 5 d of total fecal and urine collection. Prior to each collection period was a 14 d washout period where all lambs were fed a common diet. Data were analyzed using Proc Mixed of SAS, and pooled LSMEANS and SEM are reported. Intake of OM and fecal OM output were similar ($P \geq 0.11$) between CON and ALG-fed lambs. Urine output linearly increased ($P = 0.02$) as DMA increased in diets (0.57, 0.72, 0.77, and 0.87 ± 0.08 L/d for CON, DMA10, DMA20, and DMA30, respectively). Digestibility of OM (73.6, 72.9, 71.0, and 69.1 ± 1.01% for CON, DMA10, DMA20, and DMA30, respectively) linearly decreased ($P < 0.01$) as DMA increased in diets. Also, NDF (65.5, 61.3, 53.6, and 39.0 ± 2.36% for CON, DMA10, DMA20, and DMA30, respectively) and ADF (65.0, 60.7, 50.9, and 30.2 ± 1.94% for CON, DMA10, DMA20, and DMA30, respectively) digestibility linearly decreased ($P < 0.01$) as DMA increased in diets. Ether extract digestibility did not differ ($P = 0.24$) between CON and DMA-fed lambs. Nitrogen digestibility linearly decreased ($P = 0.05$) as DMA increased in the diet (60.2, 58.9, 58.0, and 57.2 ± 1.10% for CON, DMA10, DMA20, and DMA30, respectively). Also, N balance linearly decreased ($P < 0.01$) as DMA increased in the diet (10.1, 8.4, 8.9, and 6.8 ± 0.64 g/d for CON, DMA10, DMA20, and DMA30, respectively). These results suggest that the DMA portion of ALG may be less digestible than soyhulls, and even though the ALG had minimal effects on OM digestibility the differences in N balance may suggest an effect on growth in sheep, under the conditions of this study.

Key Words: algae, digestibility, sheep

348 Algae meal for ruminants: II. Growth and carcass characteristics of finishing steers. Rebecca S. Stokes*, Daniel D. Loy, and Stephanie L. Hansen, *Department of Animal Science, Iowa State University, Ames, IA.*

De-oiled microalgae from large-scale production of heterotrophic microalgae can be combined with soyhulls to form a novel feedstuff called algae meal (ALG). To determine the effects of replacing corn in a finishing diet with ALG on growth and carcass characteristics, crossbred steers (168) were blocked by BW (432.2 ± 30.8 kg) into pens of 6 steers (7 pens per treatment) and assigned to 1 of 4 diets: a corn-based control (CON), 14% ALG (ALG14), 28% ALG (ALG28), and 42% ALG (ALG42). Corn was replaced by ALG on a DM basis. Steer BW were taken on d 0, 1, 28, 56, 74, 101, and 102, and steers were harvested on d 103. Pen was the experimental unit and DMI, ADG, and G:F data were analyzed as repeated measures. Two steers per pen were selected for sampling of blood and liver (d −1 and 96), and collection of rib facings at harvest. Overall DMI linearly increased ($P < 0.01$) as ALG increased in the diet (12.7, 13.4, 13.8, and 14.4 ± 0.15 kg/d for CON, ALG14, ALG28, and ALG42, respectively). There was a treatment by time effect for ADG ($P < 0.01$), with ADG linearly decreasing ($P \leq 0.03$) in the first and third month, not differing ($P = 0.95$) in the second month, and linearly increasing ($P < 0.01$) in the fourth month as ALG increased in the diet. Final BW did not differ ($P = 0.74$) between CON and ALG-fed cattle. There was a treatment by time effect for G:F ($P < 0.01$), with G:F linearly decreasing ($P < 0.01$) in the first 3 mo as ALG increased in the diet, while G:F linearly increased ($P < 0.01$) in

the fourth month. Yield grade linearly decreased ($P = 0.02$), and there was a tendency for dressing percent and 12th rib backfat to linearly decrease ($P \leq 0.10$) as ALG increased in the diet. Plasma Cu, Fe, and Mg concentrations were not different ($P \geq 0.31$) in CON vs. ALG cattle; however, plasma Zn concentrations linearly increased ($P = 0.03$) as ALG increased in the diet. Total lipid, SFA, MUFA, and PUFA concentrations in the longissimus thoracis did not differ ($P \geq 0.13$) between CON and ALG-fed cattle. It appears ALG has less energy than corn; however, minimal effect on carcass performance suggests ALG may serve as a potential replacement for corn in feedlot diets.

Key Words: algae, performance, cattle

Animal Health: Lactating cows

T1 Health and productive responses of dairy cows treated with reduced doses of recombinant bovine somatotropin during the periparturient period. Paula R. B. Silva*[1], Henrique F. Soares[1], Gabriel D. Bombardelli[1], Wagner D. Braz[1], Daniela N. Liboreiro[1], and Ricardo C. Chebel[1,2], [1]*University of Minnesota, St Paul, MN,* [2]*University of Florida, Gainesville, FL.*

The objectives were to evaluate the effects of treatment of dairy cows with recombinant bovine somatotropin (rbST) during the periparturient period on health and production. Holstein (HO, n = 302) and Jersey (JS, n = 522) cows were enrolled in the experiment 21 d before calving. Cows were assigned randomly to the control and rbST (125 mg of rbST every 7 d from −21 to 21 d relative to calving) treatments. At −21, 0, 30, and 60 d relative to calving, BCS was recorded. Occurrence of retained placenta (RP) was recorded and cows were examined for diagnosis of metritis 4, 7, 10, and 14 d postpartum (DIM). Acute metritis (metritis and fever and/or anorexia) was recorded in the JS herd. Blood was sampled 7 and 14 d postpartum to determine ketosis incidence. Cows were milked thrice daily. In the HO herd, milk yield and composition were determined weekly until 21 d postpartum; thereafter, monthly milk yield was recorded. In the JS herd, milk yield and composition were recorded monthly. Dichotomous data were analyzed by logistic regression and continuous data were analyzed by ANOVA. Incidence of RP tended to be affected by treatment (HO-control = 14.4%, rbST = 6.1%; JS-control = 1.5%, rbST = 1.2%; $P = 0.10$). Incidence of metritis was reduced by rbST treatment (HO-control = 26.2%, rbST = 16.8%; JS-control = 19.9%, rbST = 13.3%; $P < 0.01$). Treatment tended to affect the incidence of ketosis (HO-control = 8.2%, rbST = 10.0%; JS-control = 8.4%, rbST = 13.1%; $P = 0.09$). Postpartum BCS was ($P < 0.05$) lower for rbST treated cows (HO-control = 3.08 ± 0.03, rbST = 2.99 ± 0.03; JS-control = 2.83 ± 0.03, rbST = 2.80 ± 0.03). Yield of energy corrected milk (ECM) in the first 3 weeks postpartum in the HO herd was greater for rbST cows (control = 33.0 ± 1.3, rbST = 36.3 ± 1.3kg/d; $P = 0.05$) but yield of ECM in the first month postpartum was not affected by treatment in the JS herd (control = 26.6 ± 0.6, rbST = 27.7 ± 0.6 kg/d; $P = 0.15$). Milk yield in the first month postpartum was ($P = 0.05$) increased by rbST treatment (HO-control = 35.0 ± 0.9, rbST = 37.9 ± 0.8kg/d; JS-control = 26.9 ± 0.8, rbST = 28.1 ± 0.8kg/d). Treatment of periparturient cows with small doses of rbST improved postpartum health and increased milk yield.

Key Words: transition cow, recombinant bovine somatotropin, health

T2 Reduction in hepatic functionality can delay resumption of ovarian activity postpartum in dairy cows. Paula Montagner*[1,2], Rubens A. Pereira[1,2], Ana Rita T. Krause[1,2], Marina M. Weschenfelder[1,2], Elizabeth Schwegler[1,2], Fernanda M. Gonçalves[1,2], Carolina B. Jacometo[1,2], Cássio C. Brauner[1,2], and Marcio N. Corrêa[1,2], [1]*Federal University of Pelotas, Pelotas, RS, Brazil,* [2]*Center for Research, Teaching and Extension in Animal Science (NUPEEC), Pelotas, RS, Brazil.*

After calving, the liver undergoes a metabolic overload due to high energetic and nutritional demand caused by milk synthesis and these challenges can induce inflammation and impair liver function. Several studies demonstrate that inflammation around calving is responsible for decreased productive efficiency and fertility. For this a composite index based on multiple variables associated with inflammation, the liver functionality index (LFI), can be promising for aid in the diagnosis of diseases and reproductive problems on dairy farms. The LFI is determined utilizing 3 biomarkers of hepatic function: albumin, total cholesterol and bilirubin, measured on 3 and 28 d after calving. The aim of this study was to evaluate the resumption of postpartum ovarian activity of dairy cows with low LFI. Twenty cows Holstein were evaluated from d 21 prepartum until 30 d postpartum. The cows were divided into 2 groups: Low LFI (LLFI: ≤ −7 to −12; n: 10) and High LFI (HLFI; > −7 to −4; n: 10). Serum concentration of progesterone (P4) was analyzed on d 16, 23, 30, 37 and 44 postpartum to predict the resumption of ovarian activity. The cows which had P4 concentration higher than 1ng/mL in 2 consecutive assays were considered ovulatory, while cows with P4 concentration below 1ng/ml during same period were considered anovulatory. The statistical analyses were performed using SAS 9.0 software. The statistical model CATMOD (Categorical Data Analysis Procedures) was used for analysis of categorical data of ovulation. $P < 0.05$ was considered significant. The proportion cows that resumed ovarian activity to 44 d postpartum was lower (29%; 3/10; $P < 0.05$) in the LLFI, compared with HLFI group (86%, 9/10). In conclusion, dairy cows with reduced hepatic functionality after calving have delayed resumption of ovarian activity, which demonstrates that the LFI can be a useful index to predict problems in resumption of ovulation in dairy cows.

Key Words: liver functionality index, ovarian activity, progesterone

T3 Organic trace minerals during the transition period. 4. Corium gene expression profiling reveals a beneficial effect of supplementing Zn, Mn, and Cu from Availa Mins and Co from CoPro on hoof health of peripartal dairy cows. J. S. Osorio*[1], E. F. Garrett[1], M. M. Elhanafy[1], E. Trevisi[2], J. K. Drackley[1], M. T. Socha[3], and J. J. Loor[1], [1]*University of Illinois at Urbana-Champaign, Urbana, IL,* [2]*Università Cattolica del Sacro Cuore, Piacenza, Italy,* [3]*Zinpro Corporation, Eden Prairie, MN.*

Lameness remains a major health problem and cause of death, in dairy cows. The negative effects of the transition period may make cows prone to become lame. Positive effects of supplementation of organic trace minerals (AAC) on hoof health have been reported. A hoof biopsy method to study the transcriptome of corium tissue has been published (Osorio et al., J. Dairy Sci. 95:6388–6396). Objective was to evaluate corium mRNA expression of genes related to claw conformation, oxidative stress, chemotaxis, inflammation, and transcription regulation in peripartal cows supplemented with AAC or inorganic (INO) trace minerals. Twenty Holstein dairy cows received a common prepartal (1.5 Mcal/kg DM, 15% CP) and postpartal (1.76 Mcal/kg DM, 18% CP) diet. Both diets were partially supplemented with an INO mix of Zn, Mn, and Cu to supply 35, 45, and 6 ppm, respectively, of the total diet DM. Cows were assigned to treatments in a randomized complete block design, receiving an oral bolus daily with a mix of INO (n = 10) or AAC (n = 9) containing Zn, Mn, Cu, and Co to achieve 75, 65, 11, and 1 ppm, respectively, in total diet DM. Treatments began on −30 d and continued until 30 d postpartum. Inorganic trace minerals were provided in sulfate form and AAC were supplied via Availa Zn, Availa Mn, Availa Cu, and CoPro (Zinpro Corp., Eden Prairie, MN). Hoof biopsies were harvested at 30 d postpartum from the sole of the rear right lateral claw in the right rear limb. Data on 31 genes were analyzed using the MIXED procedure of SAS. Expression of keratin 5 (*KRT5*) was lower ($P < 0.01$) and biotinidase (*BTD*) was greater ($P < 0.01$) in AAC cows, suggesting that AAC cows had a lower requirement of keratins for hoof tissue repair, while having additional biotin for claw conformation. In contrast, a concomitantly greater ($P < 0.06$) expression of toll-like receptor 2 (*TLR2*), tumor necrosis factor (*TNF*), and interleukin 1 β (*IL1B*) in INO cows suggested a greater inflammatory status in hoof tissue. Overall, data suggest that peripartal AAC supplementation ameliorates the negative effect of transition period on hoof health.

Key Words: hoof biopsy, trace mineral, transition cow

T4 Effects of postpartum uterine diseases on milk yield, milk components, and culling in dairy cows under certified organic management.

J. M. Piñeiro*[1], M. G. Maquivar[2], A. A. Barragan[1], J. S. Velez[3], H. Bothe[3], and G. M. Schuenemann[1], *[1]The Ohio State University, Columbus, OH, [2]Washington State University, Pullman, WA, [3]Aurora Organic Farms, Boulder, CO.*

The objective was to assess the effect of postpartum uterine diseases on milk yield (kg), milk components (SCC and percent fat and protein), and culling. Cows (n = 3,227) from 2 dairy herds were screened for retained placenta (RP; > 24 h after parturition), metritis (within 20 d in milk [DIM]), and purulent vaginal discharge (PVD) at 26 ± 3 DIM. Milk yield and components from the DHIA test-days and cows culled from farm records up to 300 DIM were collected. Weekly, a list of cows by DIM was obtained using on-farm computer records and screened for RP (presence of fetal membranes outside the vulva), metritis (fetid brown-red watery vaginal discharge and fever), and PVD (gloved hand technique). PVD was defined as any cow presenting a score of 2 or 3 (0–3 scale; mucopurulent or worse vaginal discharge) at the time of exam. Parity (lactations 1, 2 and ≥ 3) of cows was considered for milk yield, milk components, and culling. The statistical analyses were performed using MIXED (milk yield and components) and GLIMMIX (culling) procedures of SAS. Cows with metritis, RP or PVD had an additive effect on milk yield, milk components, and culling. Regardless of parity, lactating cows diagnosed with uterine diseases (all combined) had significantly reduced milk yield (by 2–3.9 kg/cow/d) for at least one of the first 4 DHIA test-days ($P < 0.05$), but was not different at later tests. For the first 2 DHIA test-days, lactating cows diagnosed with uterine disease (all combined) had significantly higher SCC (232×10^3 cells/mL) and fat content (3.7%) compared with cows without uterine diseases (164×10^3 cells/mL and 3.5%, respectively; $P < 0.05$). Milk protein content (%) was not different between cows with or without uterine diseases. Cows with uterine diseases had higher ($P < 0.05$) culling within 60 DIM and significantly lower ($P < 0.05$) pregnancy hazard up to 300 DIM compared with cows without uterine diseases, regardless of parity. Uterine diseases decreased milk yield and changed milk components (SCC and fat) early in lactation; and these diseases were a substantial risk factor within 60 DIM for culling.

Key Words: organic, dairy cattle, uterine disease

T5 Cows diagnosed with metritis showed blood alterations related to innate immunity and carbohydrate and lipid metabolism during early dry off period.

Guanshi Zhang, Dagnachew W. Hailemariam, Elda Dervishi, Qilan Deng, Tran H. Lam, Seyed A. Goldansaz, Suzanna M. Dunn, and Burim N. Ametaj*, *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

The objective of this study was to search for screening biomarkers of metritis in transition dairy cows. Blood samples were collected from the coccygeal vein once per week before morning feeding from 100 multiparous Holstein dairy cows during −8, −4, disease diagnosis, and +4 and +8 wk relative to parturition. Six healthy cows (CON) and 6 cows that showed clinical signs of disease were selected for intensive serum analyses. Concentrations of interleukin-1 (IL-1), interleukin-6 (IL-6), and tumor necrosis factor (TNF); haptoglobin (Hp), serum amyloid A (SAA), and lipopolysaccharide binding protein (LBP); and nonesterified fatty acids (NEFA) and β-hydroxybutyrate (BHBA) were measured in serum by ELISA or colorimetric methods. Health status, feed intake, and milk yield were monitored for each cow during the whole experimental period. Data were processed statistically by MIXED procedure of SAS 9.2. Results showed that cows affected by metritis had greater concentrations of lactate (2,901 vs 2,251 ± 183 µmol/L, $P = 0.04$), IL-6 (111 vs 27 ± 13 pg/mL, $P = 0.01$), TNF (0.72 vs 0.19 ± 0.11 ng/mL, $P = 0.01$), and SAA (13,441 vs 8,517 ± 1,517 µg/mL, $P = 0.03$) in the serum vs CON. Most interestingly, elevated concentrations of all 4 variables were observed at −8 (lactate: 3,902 vs 2,455 µmol/L, $P = 0.03$; IL-6: 87 vs 19 pg/mL, $P = 0.05$; TNF: 0.77 vs. 0.34 ng/mL, $P = 0.09$; SAA: 17,960 vs 8,448 µg/mL, $P = 0.02$) and −4 (lactate: 3,311 vs 2,162 µmol/L, $P = 0.03$; IL-6: 166 vs 48 pg/mL, $P = 0.02$; TNF: 1.02 vs 0.27 ng/mL, $P = 0.03$; SAA: 6,003 vs 3,461 µg/mL, $P = 0.03$) wk before the occurrence of metritis compared with those of CON cows. The disease also lowered the overall milk production (38.18 vs 42.16 ± 1.48 kg/d, $P = 0.01$) and feed intake (36.87 vs 39.81 ± 1.30 kg/d) as well as milk fat (3.56 vs 3.88 g/kg, $P = 0.10$) and fat:protein ratio (1.10 vs. 1.38, $P = 0.05$) and was associated with greater SCC (44,700 vs. 29,250 ± 4,880 cells/mL, $P = 0.05$). In conclusion, metritis affected serum concentrations of several variables related to innate immunity and carbohydrate metabolism that might serve to monitor health status of transition dairy cows. More research is warranted to validate these data.

Key Words: dairy cow, metritis, innate immunity

T6 Activation of innate immunity ahead of occurrence of ketosis.

Guanshi Zhang, Dagnachew W. Hailemariam, Elda Dervishi, Qilan Deng, Tran H. Lam, Seyed A. Goldansaz, Suzanna M. Dunn, and Burim N. Ametaj*, *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

The objective of this study was to evaluate alterations in blood variables related to innate immunity, carbohydrate and lipid metabolism in transition dairy cows with ketosis. Multiparous Holstein dairy cows (n = 100) were involved in the study. Five blood samples were collected from the coccygeal vein during the −8 to +8 wk around parturition, once per week before the morning feeding. Serum samples collected at −8, −4, time of diagnosis of disease, +4 and +8 wk relative to parturition from 6 healthy control cows (CON) and 6 cows with ketosis were selected for analyzes. Samples were analyzed for β-hydroxybutyrate (BHBA), lactate, nonesterified fatty acids (NEFA), interleukin-1 (IL-1), interleukin-6 (IL-6), tumor necrosis factor (TNF), haptoglobin (Hp), and serum amyloid A (SAA). Health status, feed intake, and milk yield data were monitored for each cow during the whole experimental period. Data were processed statistically by MIXED procedure of SAS 9.2. Results revealed that cows with ketosis had greater concentrations of serum BHBA (1,014 vs 504 ± 140 µmol/L, $P = 0.04$), lactate (4,236 vs 2,240 ± 351 µmol/L, $P < 0.01$), IL-6 (255 vs 27 ± 55 pg/mL, $P = 0.03$), TNF (0.47 vs 0.19 ± 0.07 ng/mL, $P = 0.03$), and SAA (24,107 vs 8,550 ± 3,457 µg/mL, $P = 0.01$) in comparison with the CON animals. Enhanced serum concentrations of BHBA (483 vs 312 ± 19 µmol/L at −4 wk, $P = 0.02$), lactate (5,795 vs 2,455 ± 349 µmol/L at −8 wk, $P = 0.01$; and 4,478 vs 2,162 ± 185 µmol/L at −4 wk, $P = 0.01$), IL-6 (183 vs 19 ± 6 pg/mL at −8 wk, $P < 0.01$; and 330 vs. 48 ± 18 pg/mL at −4 wk, $P < 0.01$) and TNF (0.64 vs 0.27 ± 0.05 ng/mL at −4 wk, $P = 0.03$) at −4 or −8 wks before parturition were identified in cows with ketosis compared with the CON group.

Cows with ketosis also had overall lower feed intake (35.70 vs 39.81 ± 1.74 kg/d, $P = 0.03$) and milk production (32.25 vs 42.16 ± 2.53 kg/d, $P < 0.05$) vs CON animals. Overall results indicate that cows affected by ketosis displayed an activated innate immunity and altered carbohydrate and lipid metabolism several weeks before diagnosis of disease. More research is warranted to better understand the agent(s) that contribute(s) to ketosis in transition dairy cows and to validate utilization of these blood variables to predict disease state in cows.

Key Words: dairy cow, ketosis, blood variable

T7 Effects of repeated oral administration of lipopolysaccharide and lipoteichoic acid either alone or in combination with subcutaneous exposure on metabolite responses in periparturient dairy cows. Emily F. Eckel*, Dagnachew W. Hailemariam, Grzegorz Zwierzchowski, Guanshi Zhang, Suzanna M. Dunn, and Burim N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

Recent investigations implicate bacterial lipopolysaccharide (LPS) and lipoteichoic acid (LTA) in the pathogenesis of multiple diseases currently affecting transition dairy cows. The objective of this investigation was to evaluate the effect of repeated oral administration of LPS and LTA alone or with subcutaneous injections on carbohydrate and lipid metabolism which are associated with the immune response to LPS and LTA. Two hundred dairy cows were randomly assigned to one of 4 treatments (n = 50 per group) which they received on d −28, −25, −21, −18, and −14 before the expected calving date: 1) 2 mL oral sterile saline (CON), 2) Flat doses of oral LPS and LTA (TRT1), 3) Flat doses oral LPS and LTA plus subcutaneous (sc) injection on d −18 and −14 (TRT2), 4) Oral increasing doses of LPS at 6.5μg (d −28 and −25), 32.5μg (d −21 and −18) and 65μg (d −14), all with flat doses of LTA (TRT3). Flat doses of LPS and LTA were 100 and 120 μg/cow, respectively, in 2 mL sterile saline. Blood samples from the coccygeal vein were collected during d −28, −14, 0, +7, +14, and +28 and analyzed for insulin, glucose, cholesterol, nonesterified fatty acid (NEFA), lactate, and β-hydroxybutyric acid (BHBA). Preliminary statistical analysis showed a significant effect of treatment on serum insulin ($P = 0.02$). In general, TRT2 had lower serum insulin concentrations than TRT1 and TRT3 while TRT1 had higher concentrations than CTR. A tendency for treatment to affect serum cholesterol ($P = 0.10$) was observed with TRT3 lowering cholesterol compared CTR and TRT1, but not TRT2. Results also showed a tendency for TRT2 to increase NEFA ($P = 0.06$) compared with all other treatments. No effect of treatment was observed for serum glucose ($P = 0.11$), lactate ($P = 0.13$), or BHBA ($P = 0.21$). Overall, preliminary results of this study suggest that repeated oral administration of LPS and LTA alone or in combination with sc injections were associated with minimal changes to lipid and carbohydrate metabolism.

Key Words: transition dairy cow, vaccine, serum metabolite

T8 Effect of repeated oral administration of lipopolysaccharide and lipoteichoic acid either alone or in combination with subcutaneous exposure on humoral immunity in periparturient dairy cows. Emily F. Eckel*, Dagnachew W. Hailemariam, Grzegorz Zwierzchowski, Guanshi Zhang, Suzanna M. Dunn, and Burim N. Ametaj, *University of Alberta, Edmonton, AB, Canada.*

Transition dairy cows experience a high incidence of metabolic and infectious diseases immediately after calving. Recent research implicates bacterial lipopolysaccharide (LPS) and lipoteichoic acid (LTA) in their pathogenesis. Minimal knowledge exists of the periparturient dairy cow immune response to oral endotoxin exposure while other routes have been extensively explored. The objective of this study was to evaluate the humoral immune response of periparturient dairy cows to repeated oral administration of LPS and LTA alone or in combination with subcutaneous injections. Two hundred dairy cows were randomly assigned to one of 4 treatments (n = 50 per group; administration d −28, −25, −21, −18, and −14 before expected calving date): 1) 2 mL oral sterile saline (CON), 2) Flat doses of oral LPS and LTA (TRT1), 3) Flat doses of oral LPS and LTA plus subcutaneous (sc) injection d −18 and −14 (TRT2), 4) Oral increasing doses of LPS at 6.5 μg (d −28 and −25), 32.5 μg (d −21 and −18) and 65 μg (d −14), all with flat doses of LTA (TRT3). Flat doses of LPS and LTA were 100 and 120 μg/cow, respectively, in 2 mL sterile saline. Blood samples collected from the coccygeal vein at d −28, −7, +7, and +28 were analyzed for lipopolysaccharide binding protein (LBP), interleukin 1 (IL-1), transforming growth factor-β (TGF-β), immunoglobulin M (IgM), and immunoglobulin G (IgG). Statistical results showed there was no effect of treatment on serum concentrations of LBP ($P = 0.82$), IL-1 ($P = 0.50$), TGF-β ($P = 0.75$), IgG ($P = 0.25$), or IgM ($P = 0.40$). Overall, preliminary results suggest that repeated oral administration of LPS and LTA or in combination with sc injections did not modulate humoral immunity in periparturient dairy cows.

Key Words: transition dairy cow, vaccine, humoral immunity

T9 Blood alterations indicate subclinical mastitis diagnosed postpartum might start during early dry-off period. Guanshi Zhang, Dagnachew W. Hailemariam, Elda Dervishi, Qilan Deng, Seyed A. Goldansaz, Suzanna M. Dunn, and Burim N. Ametaj*, *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

The objective of this study was to identify alterations in innate immunity reactants, carbohydrate and lipid metabolites in the blood of transition dairy cows with subclinical mastitis (SM). Multiparous Holstein cows (n = 100) were involved in the study and the experimental period lasted 16 wk starting at −8 wk before until +8 wk postpartum. Health status, feed intake, and milk yield and composition were monitored for each cow during the whole experimental period. Blood samples were collected from the coccygeal vein once/week before the morning feeding. Six healthy cows (CON) and 6 cows with SM were selected for intensive blood analyses. Serum concentrations of lactate, nonesterified fatty acids (NEFA), β-hydroxybutyrate (BHBA), interleukin-1 (IL-1), interleukin-6 (IL-6), tumor necrosis factor (TNF), haptoglobin (Hp), and serum amyloid A (SAA) were determined. Feed intake, milk production and composition also were determined. Data were processed using the MIXED procedure of SAS 9.2. Results indicated that concentrations of lactate (3,043 vs 2,243 ± 149 μmol/L, $P < 0.01$), TNF (0.52 vs 0.19 ± 0.04 ng/mL, $P < 0.01$) and SAA (23,915 vs 8,514 ± 2,518 μg/mL, $P < 0.01$) were greater in cows with SM than CTR cows. Moreover, serum lactate (3,478 vs 2,455 μmol/L at −8 wk, $P = 0.03$; 3,467 vs 2,162 μmol/L at −4 wk, $P = 0.04$) and TNF (1.29 vs 0.27 ng/mL at −4 wk, $P < 0.01$) in cows with SM were different from CTR cows starting at about −8 and −4 wks before diagnosis of disease. Overall feed intake (36.18 vs 39.81 ± 1.55 kg/d, $P = 0.01$) and milk production (33.76 vs 42.16 ± 2.52 kg/d, $P = 0.04$) was lower in SM-affected cows. Additionally, milk fat (3.32 vs 5.08 g/kg, $P = 0.02$) and fat:protein ratio (1.11 vs 1.69, $P < 0.01$) were lower, whereas SCC (1,867,000 vs 28,330 cells/mL, $P = 0.02$) and milk urea N (18.70 vs 15.39 mg/dL, $P = 0.03$) were greater in SM cows at diagnosis of disease vs CON. In conclusion cows affected by SM showed enhanced concentrations of indicators of innate immunity and metabolites related to carbohydrate metabolism weeks before diagnosis of SM. More research is warranted to validate these data and better understand the reasons for activation of innate immune responses to SM in transition dairy cows.

Key Words: dairy cow, subclinical mastitis, innate immunity

T10 The effect of lipopolysaccharide (LPS) and phorbol 12-myristate 13-acetate (PMA) on whole blood oxidative response as assessed by luminol-amplified chemiluminescence in dairy cows.

Y. Qu*[1], S. Kahl[2], T. H. Elsasser[2], E. E. Connor[2], and K. M. Moyes[1], [1]*University of Maryland, College Park, MD,* [2]*Agricultural Research Service, US Department of Agriculture, Beltsville, MD.*

The differences between lipopolysaccharide (LPS) and phorbol 12-myristate 13-acetate (PMA) on whole blood oxidative response using luminol-amplified chemiluminescence (CL) are currently unknown in cattle. Luminol-dependent CL measures the amount of reactive oxygen species released from leukocytes after stimulation with LPS and/or PMA. The objective of this study was to compare in vitro the effect of PMA and LPS on oxidative response in whole blood of dairy cows during lactation as a rapid means of assaying the oxidative response of blood leukocytes. Jugular blood (20 mL) was collected from 6 healthy multiparous Holstein dairy cows in mid-lactation (>90 DIM) using EDTA Vacutainer tubes. For each cow, 500 µL of blood was incubated at final concentrations of either 0, 200, 800 or 1,600 ng/mL of PMA or LPS for 15 min at 37°C using a heating block. After incubation, oxidative response of whole blood was measured using a chemiluminometer. Data were analyzed by ANOVA using the PROC MIXED procedure of SAS. Overall, whole blood incubated with PMA resulted in higher ($P < 0.001$) CL values (800 ng/mL; 2635 relative units) than LPS (800 ng/mL; 777 relative units). In PMA, a significant dose response relationship was observed where incubation with 200, 800 or 1,600 ng/mL resulted in progressively higher CL values than 0 ng/mL. In addition, incubation with PMA resulted in a higher CL values when compared with LPS. In conclusion, although both LPS and PMA both generated an oxidative response measurable by CL, PMA elicited a CL response greater than that of LPS. The data suggest that PMA stimulation of cells in whole blood may serve as a rapid test of oxidative burst responsiveness to assess a vital aspect of immune function in dairy cows.

Key Words: chemiluminescence, cow, endotoxin

T11 Efficacy of a novel antimicrobial post-milking teat dip on rate of new intramammary infections with an experimental bacterial challenge against contagious mastitis organisms.

David M. Galton[1] and Leo L. Timms*[2], [1]*Cornell University, Ithaca, NY,* [2]*Iowa State University, Ames, IA.*

Study objective was to determine efficacy of a novel antimicrobial solution containing citrate ion, methylene blue, parabens and emollients (ZuraLac^{SD}, Zurex PharmAgra) used as a post-milking teat dip against a positive and negative control in reducing the incidence of new quarter intramammary infections (QIMI) during a period of experimental exposure of teats to contagious mastitis organisms, *Streptococcus agalactiae* and *Staphylococcus aureus*. 120 Holstein cows were used in an 8-wk trial with 40 cows/ treatment. Cows were 66–122 DIM and free of IMI. Three treatments were experimental dip - ZuraLac^{SD} containing 10.0% trisodium citrate with 5.0% emollients used as a post-milking teat dip; positive control – Theratec^{R} (GEA Farm Technologies Inc.) containing 0.5% iodine with a 3% triple emollient system used as a post-milking teat dip; and a negative control where no post-milking teat dipping occurred. All teats were dipped immediately after machine removal at morning milking with broth suspensions of *Streptococcus agalactiae* (ATCC 55194) and *Staphylococcus aureus* (ATCC 12600). Teats were post dipped with appropriate teat dip between 2 and 5 min after teats dipped with culture broth. Duplicate quarter samples were taken aseptically weekly (and when clinical mastitis occurred) to determine quarter bacteriological status (3rd sample when results differed). Infection data were analyzed using Student *t*-statistics based on percent eligible quarters becoming infected with respective mastitis pathogens. Novel germicide post milking teat dip (3.3% quarter IMI) significantly ($P < 0.01\%$) reduced the number of new infections of *Streptococcus agalactiae* and *Staphylococcus aureus* compared with both the negative control (53.7% QIMI; 95.3% reduction) and positive control (13.1% QIMI; 80.9% reduction). Incidence of clinical mastitis with a bacteriological positive identification of one of the challenge organisms was 40, 4, and 0 for negative control, positive control and novel germicide dips, respectively. Novel germicide dip was significantly better than positive and negative controls.

Key Words: postmilking teat dipping, intramammary infection, germicide

T12 Effects of a 6-week duodenal supplementation of quercetin on metabolic stress and liver health in peripartal dairy cows.

Ann-Kathrin Stoldt[1], Manfred Mielenz[1], Alexander Starke[2], Siegfried Wolffram[3], and Cornelia C. Metges*[1], [1]*Institute of Nutritional Physiology, Leibniz Institute for Farm Animal Biology, Dummerstorf, Germany,* [2]*Faculty of Veterinary Medicine, University of Leipzig, Leipzig, Germany,* [3]*Institute of Animal Nutrition and Physiology, Christian-Albrechts University of Kiel, Kiel, Germany.*

The periparturient period poses metabolic challenges for dairy cows resulting in negative energy balance often followed by fatty liver disease, a typical periparturient metabolic disorder, and further health problems. Quercetin (Q), a polyphenolic compound found in plants, has hepatoprotective and antioxidative potential, and can reduce hepatic lipid accumulation in rodents. In ruminants, knowledge on metabolic effects of Q is scarce. Thus, we investigated whether Q affects lipid metabolism, oxidative stress defense, and has hepatoprotective effects in periparturient dairy cows. Because Q is degraded in rumen, 5 cows were given 100 mg Q dihydrate per kg BW daily in 0.9% NaCl solution into a duodenal fistula while control (CTR; n = 5) cows received NaCl only, starting 3 wk antepartum (ap) to 3 wk postpartum (pp). Twice-weekly blood samples were collected and liver was biopsied twice ap and once pp. Selected hepatic transcript abundances were determined by quantitative real-time PCR. Effects of Q were analyzed using repeated-measure ANOVA (SAS PROC MIXED). Duodenal supplementation of Q resulted in higher ($P < 0.05$) plasma flavonoid levels in Q than in CTR cows. In Q cows pp plasma values of aspartate aminotransferase (AST) were lower ($P < 0.05$) whereas glutamate dehydrogenase (GLDH) and BHBA levels tended to be lower ($P = 0.1$). Liver fat content tended ($P = 0.1$) to be lower in Q cows pp, although groups did not differ ($P = 0.7$) in fat mobilization indicated by plasma NEFA. We could not show group differences of hepatic mRNA abundance of genes related to lipid metabolism and oxidative stress defense (fatty acid synthase, carnitine palmityltransferase 1A, peroxisome proliferator-activated receptors α and γ, paraoxonase, superoxide dismutase, catalase and glutathione peroxidase). In conclusion, when Q is systemically available during the peripartal period there is potential that metabolic stress and liver damage in dairy cows can be reduced. However, these results should be verified in a larger number of cows and mechanisms of action of Q in cows need to be clarified. Eventually a rumen-protected form of Q has to be developed.

Key Words: transition dairy cow, quercetin, liver health

T13 Effects of manipulated insulin and glucose plasma concentrations on glucagon secretion during intramammary LPS challenge in dairy cows. Mousa Zarrin*[1,2], Olga Wellnitz[1], and Rupert Bruckmaier[1], [1]*Veterinary Physiology Vetsuisse Faculty, University of Bern, Bern, Switzerland,* [2]*Department of Animal Science, Yasouj University, Yasouj, Iran.*

Insulin and glucagon are glucoregulatory hormones that contribute to glucose homeostasis which is also critical during immune reaction. Intramammary LPS challenge causes an immune reaction, which is accompanied by metabolic and endocrine changes. The objective of the present study was to investigate effects of intramammary LPS challenge concomitantly with elevated insulin concentrations on glucagon concentration during simultaneous hypoglycemia or euglycemia in dairy cows. Animals were randomly assigned to 3 treatment groups: an intravenous insulin infusion (HypoG, $n = 5$) to decrease plasma glucose concentration (2.5 mmol/L), a hyperinsulinemic euglycemic clamp to maintain plasma glucose at pre-infusion level to study effects of insulin at simultaneously normal glucose concentration (EuG, $n = 6$), and a 0.9% saline solution infusion (Control, $n = 8$). Glucose was measured in blood at 5-min intervals to allow adjustments of glucose infusion rate. Plasma insulin and glucagon concentrations were analyzed hourly. Area under the curve was evaluated by ANOVA with treatment as fixed effect. Data are presented as means ± SEM. The mean of insulin infusion rate before LPS challenge (48 h), was 0.6 mU/kg BW /min in HypoG and EuG. In EuG the glucose infusion rate was 2.20 ± 0.04 mmol/kg/min to keep plasma glucose concentrations at a pre-infusion level and it unchanged during the LPS challenge. In response to LPS challenge, plasma insulin and glucose increased. Plasma glucose concentration increased in EuG (4.4 ± 0.1 mmol/L) compared with concentrations before the LPS challenge (3.8 ± 0.2 mmol/L; $P < 0.01$), and HypoG (2.6 ± 0.1 mmol/L; $P < 0.01$). Intramammary LPS challenge caused an increase of plasma glucagon in HypoG and control compared with basal level, 48 h infusions period, and EuG, but the increase of glucagon was more pronounced in control (219.7 ± 17.3 pg/mL; $P < 0.001$). In conclusion, intramammary LPS challenge induces increases of glucose, insulin, and glucagon concentrations. The results show that glucagon concentrations dramatically increased in the absence of insulin infusion. This is in agreement with previous reports that suggested a general inhibitory effect of insulin on glucagon secretion.

Key Words: glucagon, insulin, glucose

T14 Total immunoglobulin concentration in colostrum produced by dairy cows in Costa Rica. J. A. Elizondo-Salazar*[1], D. Benavides-Varela[2], and A. Vargas-Ramírez[1], [1]*Estación Experimental Alfredo Volio Mata. Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, San José, Costa Rica,* [2]*Alimentos del Norte S.A-DIPCR, Costa Rica.*

The objective of this study was to determine total immunoglobulin (Ig) concentration in colostrum produced by dairy cows and establish the effect that breed and parity can have on Ig concentration. The data presented correspond to determinations of total Ig concentration determined by a colostrometer in 537 colostrum samples obtained in 50 dairy farms in the provinces of San José, Alajuela, Heredia, and Cartago. Cow breeds were classified into Holstein, Jersey, Holstein × Jersey, and other. Farm size ranged from 10 to 300 milking cows. To determine breed and parity number effect on colostrum Ig concentration, MIXED procedure was used, where dam was considered as a random effect. For the purposes of this study, good quality colostrum was considered when Ig concentration was ≥50 mg/mL. Immunoglobulin concentration ranged from 10 to 140 mg/mL with an average of 85 mg/mL. Of all the samples analyzed, 13.2% had an inadequate concentration of Ig. When considering breed effect on Ig concentration, no significant differences were found ($P > 0.05$). Parity number significantly ($P < 0.05$) influenced Ig concentration and it was found that Ig concentration increased with parity number. Based on the current study, Ig concentration was adequate for calf feeding in 87% of colostrum samples.

Table 1 (Abstr. T14). Effect of dam breed on total Ig concentration in 537 colostrum samples from 50 dairy farms in Costa Rica

Dam breed	Number	Ig (mg/mL)	SEM
Holstein	270	88.8	1.9
Holstein × Jersey	64	85.9	2.5
Jersey	146	85.5	2.6
Other	57	85.6	4.2

Key Words: passive immunity, colostrometer, immunoglobulin

T15 Risk factors associated with milk fever occurrence in Costa Rican dairy cattle. Alejandro Saborío-Montero*[2], Bernardo Vargas-Leitón[1], Juan José Romero-Zúñiga[1], and Jorge M. l. Sánchez[2], [1]*Programa de Investigación en Medicina Poblacional, Escuela de Medicina Veterinaria, Universidad Nacional, Heredia, Costa Rica,* [2]*Centro de Investigaciones en Nutrición Animal y Escuela de Zootecnia, Universidad de Costa Rica, San José, Costa Rica.*

The aim of this study was to determine risk factors associated with milk fever (MF) occurrence in dairy cows in Costa Rica. A total of 69,870 cows from 127 dairy herds were included in the study. Data were collected in the VAMPP (Veterinary Automated Management and Production Control Program) software by the Population Medicine Research Program of the Veterinary Medicine School, National University of Costa Rica; from 1985 to 2014. To determine the risk factors, 2 logistic regression mixed models were evaluated. The first model used breed (B), month of calving (M), quinquennium of calving (Y) ecological life zones (Z) and calving number (N) as fixed effects. The second model excluded first lactation animals and cows without productive information, had the same fixed effects of the first model plus: previous MF case (C), previous lactation length (L), previous dry period length (D), previous corrected 305d milk yield (P), and calving interval length (I) as fixed effects. Both models used animal (a) and herd (h) as random effects. Of the 235,971 recorded lactations, 4,312 (1.83%) reported MF event. The significantly associated ($P < 0.05$) risk factors for MF occurrence, ranked by their highest odds ratio (OR) are listed on Table 1. The findings of this study are the first data reported for a population study on risk factors for MF in Costa Rica. Some of these results might be used to improve preventive management practices at the farms to reduce the incidence of this metabolic disease.

Contd.

Table 1 (Abstr. T15). Risk factors associated with milk fever (MF) occurrence ranked by odds ratio (OR) in Costa Rican dairy cattle[1]

Risk factor	Riskiest category	Reference category	OR	95% CI
Calving number	6th or more calving	1st calving	52.40	40.94–67.08
Breed	Jersey	Brown Swiss	2.88	1.66–4.98
Previous MF case	Previous case reported	No previous case reported	2.39	2.17–2.63
Quinquennium of calving	1990-1994	2005-2009	2.33	2.00–2.78
Month of calving	July	December	1.37	1.16–1.61
Previous 305-d milk yield	1,000 kg over µ	µ for 305-d milk yield	1.17	1.14–1.21
Previous lactation length	30 d over µ	µ for lactation length	1.06	1.03–1.09

[1] µ = population mean; 6,021 kg for previous 305-d milk yield, 316 d for previous lactation length.

Key Words: milk fever, risk factor, dairy cattle

T16 Serum calcium concentration during the peripartum period in a Jersey herd grazing tropical pastures and supplemented with a low calcium grain mixture.

Jorge M. l. Sánchez* and Alejandro Saborío-Montero, *Centro de Investigaciones en Nutrición Animal y Escuela de Zootecnia, Universidad de Costa Rica, San José, Costa Rica.*

The aim of this study was to analyze the serum Ca concentration in a Jersey herd during the peripartum period in a tropical production system, to compare Ca status in young (≤2nd parity) and adult (≥3rd parity) cows. The study was conducted on a dairy farm located in Cartago, Costa Rica, during a 6-mo period (January–June, 2014) and comprised 161 cows (62 young cows; 99 adult cows). During the close-up period cows grazed lush kikuyu grass (*Kikuyuocloa clandestina*) (14.8% DM, 23.4% CP, 0.35% Ca, 0.31% Mg and 3.5% K) and were supplemented with 4 kg/cow/d of a low Ca grain mixture (88% DM, 14% CP, 0.2% Ca, 0.42% Mg and 1.38% K) and 1 kg of hay (82.3% DM, 5.1% CP, 0.4% Ca, 0.35% Mg and 1.8% K)/d. After calving, cows were fed 1 kg of grain mixture (87.5% DM, 18.6% CP, 0.90% Ca, 0.42% Mg and 1.38% K)/2.5 to 3.0 kg of milk. A total of 752 blood samples were taken from 4d before calving until 5d postpartum and were analyzed for total calcium. Data were analized as a repeated measures with the fixed effect of parity class and cow nested within parity was the subject of the repeated measure of time. Statistical analysis showed significant effect for category, not so for day and day x category interaction. Means across the 2 categories were compared by Student's *t*-test (Table 1). Serum Ca concentrations in young cows were usually greater than concentrations in adult cows. Starting at 1 d before calving through 1 d post calving, serum Ca in adult cows was depressed reaching its nadir at 1 d in milk. Results show that adult cows were subclinically hypocalcemic (serum Ca <8.0 mg/dl) from d 2 before calving until 5 d in milk, requiring feeding practices designed to improve Ca metabolism in the periparturient adult cows.

Contd.

Table 1 (Abstr. T16). Serum Ca concentration (mg/dl) from 4 d before to 5 d after calving for young (1 and 2 parities) and adult (3 or more parities) Jersey cows grazing lush tropical pastures

T17 Bacterial diversity and pathogen load in recovered dairy cows bedding materials following an aerobic composting of dairy manure.

Maral Rahmani*, Hooman Derakhshani, Hein M. Tun, Jacqueline Donogh, Shadi Sepehri, and Ehsan Khafipour, *University of Manitoba, Winnipeg, MB, Canada.*

The FAN bedding recovery system consists of a solid separator and an in-vessel aerobic composting system, allowing the treatment of dairy manure into separate liquid and solid streams, with the solid stream later used within the barn as dairy cows bedding. The objective was to evaluate the effect of composting on the microbiota profile and pathogen load of recovered bedding material (RBM). Manure (MAN), liquid stream (LS), solid stream undigested (SSU) and solid stream digested (SSD) samples were collected on a weekly basis for a 2-mo period during summer and winter seasons (n = 36/category). Genomic DNA was extracted and subjected to bacterial 16S rRNA gene sequencing for community analysis and qPCR for absolute quantification of generic *Escherichia coli*, *E. coli* O157:H7, *Staphylococcus aureus*, *Mycobacterium avium* ssp. *paratuberculosus* (MAP); *Arcanobacterium pyogenes,* and *Klebsiella pneumoniae.* On average, 29,982 high-quality sequences were generated per sample. The α-diversity of SSD microbial communities was found to be lower ($P < 0.001$) than other treatment groups, with the MAN samples showing the most diverse microbiota followed by LS and SSU. The proportion of phylum Firmicutes (members of the family Bacillaceae) was greater ($P < 0.05$) in SSD group, and the relative abundances of several members of the phyla Proteobacteria (family Moraxellaceae and genus *Acinetobacter*) and Bacteroidetes (family Sphingobacteriaceae) were found to be significantly ($P < 0.05$) higher in SSU compared with other groups. The proportions of several members of the phylum Proteobacteria were also found to be higher in SSU compared with LS, suggesting that, in the absence of composting process, separation of the solid and liquid part of the RBM may increase the proportion of the opportunistic microorganism in the solid fraction. *E. coli* O157:H7, MAP and *S. aureus* were present only in a limited number of samples and only 2 SSD samples found to be MAP, O157:H7 or *S. aureus* positive. Aerobic composting had limited effect on the population of *E. coli, A. pyogenes,* and *K. pneumonia.*

Key Words: aerobic composting, microbial community, pathogen load

T18 Massive shotgun metagenomic sequencing reveals the potential mode of action of *Saccharomyces cerevisiae* fermentation product (SCFP) on rumen microbiome during subacute ruminal acidosis (SARA) in dairy cows.

H. M. Tun*[1], S. Li[1], I. Yoon[2], M. Scott[2], J. C. Plaizier[1], and E. Khafipour[1], [1]*Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada,* [2]*Diamond V, Cedar Rapids, IA.*

The effects of *Saccharomyces cerevisiae* fermentation product on rumen microbiome composition and function were studied in 8 rumen-cannulated lactating cows in a crossover study with two 5-wk periods. Each period consisted of a 4-wk normal feeding and a 1-wk grain-based SARA challenge. A 3-wk washout period separated the experimental periods. During each period, 4 cows received 14 g/d of SCFP (Original XPC, Diamond V) mixed with 126 g/d ground corn and the other 4 received 140 g/d ground corn as control. Rumen fluid was collected during wk 4 and 5 of each period. Genomic DNA was extracted and subjected to shotgun metagenomic sequencing using a MiSeq Illumina platform. Host genomic sequences were removed before analysis. Taxonomies were annotated against Greengenes database and functional genes were annotated against SEED subsystems in the MG-RAST pipeline. Both compositional and functional differences among treatments were analyzed by the linear discriminant analysis effect size. In total, 103.4 GB sequences were obtained from 32 shotgun metagenomic samples with an average of 10 millions sequences per sample. The SCFP supplement altered the β-diversity of rumen functional metagenome under both control and SARA conditions ($P < 0.05$). The SCFP supplement restored several cellulolytic populations, including *Fibrobacteres*, *Paenibacillaceae* and *Spirochaetaceae*, as well as *Burkholderiales* that were suppressed during SARA ($P < 0.05$). The SCFP supplement also tended to increase the population of *Eubacteriaceae*, *Coriobacteriaceae* and unclassified *Clostridiales* observed during SARA ($P < 0.05$). Several enzymatic pathways were downregulated during SARA. The SCFP supplement increased the abundance of formate dehydrogenase and methylmalonyl-CoA mutase (MCM) that were suppressed during SARA ($P < 0.05$). The MCM is a vitamin B12-dependent enzyme constantly found in methanol-utilizing bacteria, such as members of *Burkholderiales*. Data reveals potential mechanisms through which SCFP supplement contributes to the resilience of the rumen microbiome, especially during SARA.

Key Words: shotgun metagenomic, *Saccharomyces cerevisiae* fermentation product, subacute ruminal acidosis

T19 Effects of *Saccharomyces cerevisiae* fermentation product (SCFP) on the predicted functional profiles of rumen microbiome in lactating dairy cows with subacute ruminal acidosis (SARA).

S. C. Li*[1], H. M. Tun[1], P. Azevedo[1], I. Yoon[2], M. Scott[2], J. C. Plaizier[1], and E. Khafipour[1], [1]*Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada,* [2]*Diamond V, Cedar Rapids, IA.*

The effects of *Saccharomyces cerevisiae* fermentation product (SCFP) on the rumen bacterial function were studied in 8 rumen-cannulated lactating cows in a crossover study with 2 5-wk periods. Each period consisted of 4 wk of normal feeding and a 1-wk grain-based SARA challenge. A 3-wk washout period separated the experimental periods. During each period, 4 cows received 14 g/d of SCFP (Original XPC, Diamond V) mixed with 126 g/d ground corn and the other 4 received 140 g/d ground corn as control. Rumen fluid was collected during wk 4 and 5 of each period. DNA was extracted and V1-V3 region of 16S rRNA gene was amplified and subjected to pyrosequencing. Phylogenetic Investigation of Communities by Reconstruction of Unobserved States (PICRUSt) was used to impute metagenomic information based on 16S rRNA sequencing data. The SARA challenge and SCFP supplementation did not affect the α-diversity of the predicted functional gene families of rumen bacterial communities. However, the β-diversity was affected by SARA ($P < 0.01$), but not by SCFP. A total of 9 out of 36 level-2, and 39 out of 254 level-3 KEGG Orthology groups were found to be affected by SARA challenge ($P < 0.01$). At the KEGG level-2, pathways upregulated during SARA included cell motility, membrane transport, signal transduction and transcription, while pathways involved in the metabolism of terpenoids and polyketides, biosynthesis of other secondary metabolites, amino acid metabolism, signaling molecules and interaction, transport and catabolism were downregulated. However, SCFP supplementation and interaction between SARA challenge and SCFP supplementation were not significant. The relevance and accuracy of PICRUSt application to predict the function of microbiome in the rumen need further validation using shotgun sequencing approach.

Key Words: dairy cow, SARA, *Saccharomyces cerevisiae* fermentation product

T20 Effect of milk yield genotype on response to repeated lipopolysaccharide (LPS) administration to lactating Holstein cows.

Georgina Cousillas*[1], Wanda J. Weber[1], Stanislaw Kahl[2], Bruce Walcheck[1], Ricardo Chebel[1], David Kerr[3], Theodore H. Elsasser[2], and Brian A. Crooker[1], [1]*University of Minnesota, St. Paul, MN,* [2]*USDA-ARS, Beltsville, MD,* [3]*University of Vermont, Burlington, VT.*

Cows (n = 12/genotype) from unselected (stable milk yield since 1964, UH) and contemporary (CH) Holsteins that differed by more than 4,500 kg milk/305 d were fed the same diet ad lib and housed together for more than 4 mo before being blocked (2/genotype) by DIM and randomly assigned within genotype to receive saline or 0.25 µg LPS (*Escherichia coli* 055:B5) per kg BW. Cows were synchronized to be at d 8 of their estrous cycle for the first challenge (C1) at 70–84 d in milk. Jugular catheters were implanted 24 h before C1. Blood samples were collected at −1, −0.5, 0, 1, 2, 3, 4, 6, 8, 12, and 24 h relative to treatment administration and plasma harvested. Body temperatures (BT) were determined at these times and at 5 and 7 h. Liver biopsies and blood for flow cytometry and hemogram assays were obtained at 0, 4, and 24 h. A second identical challenge (C2) and sampling was conducted 4 d later. Data were analyzed by repeated measures using PROC MIXED (SAS). Means differed when $P < 0.05$. Pre-challenge glucose and IGF-1 were greater ($P < 0.01$) and BT was less ($P < 0.01$) in UH than CH. Glucose response to LPS was greater ($P < 0.01$) in UH than CH, but IGF-1 and BT response was similar in both genotypes. TNFα and cortisol response to LPS was greater during C1 than C2 ($P < 0.02$). TNFα response to LPS was greater ($P < 0.05$) in UH than CH in C1 but similar in C2. Cortisol response to LPS increased in both genotypes but returned to baseline earlier in CH than UH ($P < 0.05$). LPS decreased white blood cell count ($P < 0.01$) but response did not differ between genotypes or challenge. Neutrophil oxidative burst was greater ($P < 0.05$) and phagocytic capacity tended ($P = 0.07$) to be greater in UH than CH. CD11b expression increased ($P < 0.05$) in response to LPS at 4h, was less in CH than UH at 24h and did not differ between C1 and C2. L-selectin decreased in response to LPS at 4hr but did not differ between challenge or genotype. Results indicate that genotype affects bovine response to LPS and this effect differs among the response variables assessed.

Key Words: innate immunity, Holstein genotype, lipopolysaccharide

T21 Use of chitosan microparticles to prevent metritis in lactating dairy cows.

Rodolfo Daetz*[2], Federico Cunha[2], Yosuke Maeda[3], Carlos A. Risco[2], Kwang C. Jeong1,4, Jose Eduardo P. Santos[1], and Klibs N. Galvao[2], [1]*Department of Animal Sciences, University of Florida, Gainesville, FL,* [2]*Department of Large Animal Clinical Sciences, University of Florida, Gainesville, FL,* [3]*School of Veterinary Medicine, Kitasato University, Towada, Japan,* [4]*Emerging Pathogens Institute, University of Florida, Gainesville, FL.*

The objective was to determine the efficacy of chitosan microparticles (CM) in preventing metritis in dairy cows. Holstein cows (n = 101) from a 4,500-cow commercial herd that had risk factors for metritis (dystocia, twins, stillbirth, retained placenta) were randomly assigned to one of 2 treatments 1 d postpartum (DPP): CM (n = 51) = intrauterine (i.u.) infusion of 8 g of CM dissolved in 40 mL of sterile water for 5 d; Control (n = 50) = i.u. infusion of 40 mL of sterile saline solution for 5 d. Metritis prevalence was analyzed by logistic regression using the LOGISTIC procedure of SAS using a one-side test in accordance with sample size calculation for reduction in metritis prevalence using CM. Continuous outcomes were analyzed by ANOVA for repeated measures using the MIXED procedure of SAS. Models included the effects of treatment, parity, specific risk factor, body condition score at enrollment and interaction between treatment and other covariates. The effect of time and interaction between treatment and time was also included in repeated measures analyses. Treatment with CM resulted in decreased incidence of metritis at 7 DPP compared with Control (45.1 vs. 64.0%, respectively; $P = 0.03$); however, there were only numerical differences at 4 (11.8 vs. 18%, respectively; $P = 0.23$), 10 (60.1 vs. 72%, respectively; $P = 0.12$), and 14 (62.7 vs. 72.0%, respectively; $P = 0.16$). Treatment with CM resulted in decreased NEFA plasma concentrations at 10 DPP (464.2 ± 57.2 vs. 639.5 ± 57.2 μEq/L; $P = 0.04$); however, there were no differences at 4 (813.8 ± 56.7 vs. 780.4 ± 56.7 μEq/L; $P = 0.67$), 7 (669.9 ± 56.7 vs. 692.9 ± 56.7 μEq/L; $P = 0.77$), and 14 (527.6 ± 57.7 vs. 420.7 ± 57.7 μEq/L; $P = 0.18$). The uterine discharge pH was lower in Control than in CM cows (6.84 ± 0.03 vs. 6.93 ± 0.03; $P = 0.02$). BHBA (647.4 ± 30.0 vs. 589.3 ± 30.0 μmol/L; $P = 0.36$), temperature (39.2 ± 0.04 vs. 39.1 ± 0.04°C; $P = 0.62$) and milk production (29.3 ± 1.0 vs. 28.8 ± 1.0 L/d; $P = 0.69$) were not different between CM and Control groups. In conclusion, CM may be a viable alternative for treatment of metritis; however, the duration of treatment may have to be extended to maintain differences in the incidence of metritis.

Key Words: chitosan microparticle, metritis, dairy cow

T22 The role of Bacteroidetes and *Bacteroides* species in the development of metritis and fever in dairy cows.

Soo Jin Jeon*[2], Achilles Vieira-Neto[1], and Klibs N. Galvão[2], [1]*Department of Animal Sciences, University of Florida, Gainesville, FL,* [2]*Department of Large Animal Clinical Sciences, University of Florida, Gainesville, FL.*

Objective was to evaluate if uterine microbiota was associated with the presence of fever in metritic cows. Uterine swabs were collected at 6 ± 2 d postpartum (DPP) from 92 cows. Uterine swabs from 11 metritic cows that had a fever (rectal temperature ≥ 39.5°C) at the time of metritis diagnosis (MF), 12 metritic cows that did not have a fever at the time of metritis diagnosis (MNF), and 11 cows that remained healthy (Healthy) were used for metagenomic sequencing of the 16S rRNA gene using the Illumina MiSeq platform. Data were analyzed by ANOVA using the GLM procedure of SAS. Rectal temperature was 38.97 ± 0.12, 38.96 ± 0.08, and 39.89°C ± 0.11 for Healthy, MNF, and MF, respectively. At the phylum level, Bacteroidetes were found to have lower ($P < 0.01$) relative abundance in Healthy than in MNF and MF (27.3 vs. 51.1 vs. 53.3%), whereas there was no difference ($P > 0.25$) in Fusobacteria (23.9 vs. 28.6 vs. 24.6%), Actinobacteria (1.2 vs. 0.5 vs. 1.1%), and Firmicutes (18.6 vs. 12.4 vs 15.6). Proteobacteria in Healthy was similar ($P = 0.13$) to MNF but greater ($P = 0.05$) than MF (16.6 vs. 6.5 vs. 2.9%). Tenericutes was lower ($P < 0.04$) in Healthy than in MNF and MF (10.6 vs. 0.7 vs. 2.0%). At the species level, principal coordinates analysis showed that MNF were clustered together with MF, whereas Healthy were mostly separated from metritic cows. Relative abundance of *Bacteroides heparinolyticus* in Healthy was lower ($P = 0.01$) than in MNF and tended ($P = 0.06$) to be lower than in MF (7.0 vs. 20.3 vs. 16.8%). *Bacteroides pyogenes* was lower ($P \leq 0.05$) in Healthy and MNF than in MF (4.0 vs. 3.8 vs. 10.0%), but similar between Healthy and MNF. There was no difference in the relative abundance of *Fusobacterium necrophorum* ($P = 0.68$) or other 10 most prevalent bacteria ($P > 0.15$). In conclusion, Bacteroidetes is more abundant, whereas Firmicutes and Tenericutes are less abundant in metritic cows. Furthermore, *B. heparinolyticus* is an important species for the development of metritis, whereas *B. pyogenes* seem to be involved in the development of fever in metritic cows.

Key Words: Bacteroidetes, *Bacteroides* species, metritis

T23 Incidence of health treatments among pure Holsteins of 8 high-performance dairies in Minnesota.

M. R. Donnelly*[1], A. R. Hazel[1], B. J. Heins[2], and L. B. Hansen[1], [1]*University of Minnesota, St. Paul, MN,* [2]*West-Central Research and Outreach Center, Morris, MN.*

Health treatments of pure Holstein cows (n = 3,936) were evaluated in 8 high-performance Minnesota dairies. Cows calved from March 2008 to February 2013, and 16 types of health treatments were defined uniformly across herds. For analysis, treatments were grouped into 5 categories: mastitis, reproduction (cystic ovary, retained placenta, and metritis), hoof, metabolic (milk fever, displaced abomasum, ketosis, and digestive), and miscellaneous (respiratory, injury, and other). Excluded from analysis were California Mastitis Test/culture, hoof trimming, palpation, reproductive aid, and abortion. Parity was coded as 1 (n = 2,285), 2 (n = 2,529), or 3 to 5 (n = 3,842), and later lactations were deleted. Observations were recorded for entire lactations and coded as treated (1) or not treated (0) during a lactation. Independent variables for statistical analysis of all 5 treatment categories were the fixed effects of herd, year-season nested within herd, parity, and interaction of herd and parity. Cow was considered a repeated measure. For all 5 treatment categories, herd and year-season nested within herd were highly significant ($P < 0.01$). Parity was significant ($P < 0.05$) for all 5 categories of health treatments, except parity was not significant ($P = 0.71$) for miscellaneous. Interaction of herd and parity was significant ($P < 0.05$) for all categories. Least squares means increased with advancing parity for all 5 treatment categories except for the miscellaneous category. Treatment rates for parities 1, 2, and 3 to 5, respectively, for each health treatment category were 0.25, 0.34, and 0.42 (mastitis); 0.12, 0.13, and 0.16 (reproduction); 0.32, 0.39, and 0.40 (hoof); 0.07, 0.13, and 0.18 (metabolic); 0.14, 0.13, and 0.14 (miscellaneous). Across herds and parities, the largest treatment rate was for the hoof category followed by mastitis, and the other 3 treatment categories had similar treatment rates.

Key Words: health, treatment, mastitis

T24 Rumination behavior alert indexes for detecting health disorders during early lactation.

Sushil Paudyal[1], Fiona Maunsell[2], Carlos Risco[2], Arthur Donovan[2], Albert De Vries[3], John Richeson[1], and Pablo Pinedo*[4,5], [1]*West Texas A&M University, Canyon, TX,* [2]*Department of Large Animal Clinical Sciences, College of Veterinary Medicine, University of Florida, Gainesville, FL,* [3]*Department of Animal Sciences, University of Florida, Gainesville, FL,* [4]*Texas A&M AgriLife Research, Amarillo, TX,* [5]*Department of Veterinary Pathobiology, College of Veterinary Medicine & Biomedical Sciences, Texas A&M University System, College Station, TX.*

Monitoring of health disorders during early lactation is a key component in the management of dairy systems. Electronic systems that allow for monitoring of rumination are now available. The objective was to evaluate the association between changes in rumination time (RT) and early stages of disease within the prepartum and early lactation. Two weeks before the due date, 198 cows at the University of Florida (UF) Dairy Unit were affixed with a neck collar containing rumination loggers (Hr-Tag rumination monitoring system, SCR Engineers Ltd., Netanya, Israel), providing rumination time (RT) for each 2-h interval. Occurrence of health disorders [mastitis (MAS), metritis (MET), clinical hypocalcemia (HYC), digestive disorders (DIG), lameness (LAM), and ketosis (KET),] were assessed until 60 DIM by UF veterinarians and farm personnel. Two indices were developed to explore the association between RT and disease: i) Cow Index (CI) = 24-h RT on the day of diagnosis (d0) minus average RT on d −3 to −5 relative to d0 (0to3–5RT), divided by the −3 to −5 d RT average; ii) Mates Index (MI) = (0to3–5RT - pen mates 0to3–5RT)/pen mates d0 RT. Subsequently an alert value (ACI and AMI) was determined for both indices when the value was lower than −0.1. Alert indices were evaluated by ROC curve analyses. Average CI in healthy cows ranged from 0.0491 to 0.0495 while CI in sick cows were −0.165, −0.029, −0.513, −0.022, −0.098, and −0.081 for MAS, MET, HYC, DIG, LAM, and KET, respectively. Average MI in healthy cows ranged from 0.0001 to 0.001 while MI in sick cows were −0.183, −0.101, −0.424, −0.101, −0.148, and −0.147 for MAS, MET, HYC, DIG, LAM, and KET, respectively. Sensitivity/specificity (%) of ACI were 56/72, 39/73, 100/72, 44/72, 67/72, and 61/72 for MAS, MET, HYC, DIG, LAM, and KET, respectively. Sensitivity/specificity (%) of AMI were 63/71, 42/72, 100/72, 48/72, 55/72, and 67/72 for MAS, MET, HYC, DIG, LAM, and KET, respectively. Area under the curve for our proposed cut-off value ranged from 0.56 (KET) to 0.87 (HYC) for CI and from 0.51 (MET) to 0.87 (HYC) for MI. Consistent negative changes in rumination activity, both within cow (CI) and compared with cohorts (MI), were observed on the day of diagnosis for each postpartum disease.

Key Words: rumination, disease, alert index

T25 OmniGen-AF alters rectal temperature (RT) and leukocyte profiles in dairy cows exposed to heat stress (HS) following acute activation of the stress axis. Nicole C. Burdick Sanchez*[1], Jeffery A. Carroll[1], Paul R. Broadway[1], Matthew L. McBride[2], Xavier A. Ortiz[2], Jayne L. Collier[2], James D. Chapman[3], Derek McLean[3], and Robert J. Collier[2], *[1]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX, [2]University of Arizona, Department of Animal Science, Tucson, AZ, [3]Phibro Animal Health Corp., Quincy, IL.*

Differences in the response of OmniGen-AF (OG) supplemented dairy cows to a corticotropin releasing hormone (CRH) and vasopressin (VP) or an adrenocorticotropic hormone (ACTH) challenge when housed at different temperature-humidity indices (THI) were studied. Holstein cows (n = 12; 162 ± 1 DIM) were balanced by milk yield, BW and DIM into 1 of 2 trts: 1) OminGen-AF, supplemented with OG at 4.54 g/kg BW for 70d; or 2) Control (CON), no supplement. Cows were moved to individual tie stalls in 1 of 2 temperature controlled chambers on d51 and fitted with indwelling RT devices and jugular catheters on d52. Initially THI was cycling at thermoneutrality (TN; THI < 72 for 24 h/d) for 7d, followed by HS (THI > 72 for 12h/d) for 10d. Cows were challenged with CRH (0.3 µg/kg) and VP (1 µg/kg) at 1000h on d4 of TN and d1 of HS, and with ACTH (0.1 IU/kg) at 1000h on d5 of TN and d2 of HS. Blood samples were collected from −2 to 8h at 30-min intervals relative to each challenge and analyzed for leukocyte profiles. There was a THI × time interaction ($P \leq 0.01$) for RT such that RT was greater during HS than TN (2 to 9h, and at 11h for CRHVP and 4 to 9h and 11 to 13h for ACTH). Also, RT was greater ($P \leq 0.02$) in OG than CON cows regardless of challenge. Total white blood cells (WBC) and neutrophils (NT) increased ($P < 0.01$) in response to CRHVP and ACTH. There was a trt × THI interaction ($P < 0.01$) for WBC during both challenges. Specifically, WBC were decreased in CON during HS compared with TN in response to CRHVP, while WBC were greatest in CON during TN and least in OG during HS in response to ACTH. There was a trt x THI interaction ($P = 0.02$) for NT in response to CRHVP challenge; NT decreased in CON cows during HS compared with TN. Also, NT were decreased during HS ($P < 0.01$) compared with TN and decreased in OG compared with CON ($P < 0.01$) following ACTH. Lymphocytes were decreased during HS compared with TN ($P < 0.01$) and in OG compared with CON cows ($P < 0.01$) regardless of challenge. These data suggest supplementing cows with OG can reduce the negative effects of HS on leukocyte profiles following activation of the stress axis.

Key Words: heat stress, immune, OmniGen-AF

T26 Altered microbiomes in bovine digital dermatitis lesions, and the gut as a pathogen reservoir. Martin Zinicola*[1], Fabio Lima[1], Svetlana Lima[1], Vinicius Machado[1], Charles Guard[1], Dörte Döpfer[2], and Rodrigo Bicalho[1], *[1]Cornell University, Ithaca, NY, [2]University of Wisconsin, Madison, WI.*

Bovine digital dermatitis (DD) is the most relevant infectious disease associated with lameness affecting cattle worldwide. Notwithstanding decades of research, the pathogenesis of this disease and the potential reservoir of pathogenic microbes involved in DD remain unclear. Here, we characterize the microbiome of healthy skin (HS) and lesions from dairy cows affected with different stages of DD and we also identified DD-causing *Treponema* spp. in rumen and fecal samples. A total of 140 biopsy samples (BS) (51 HS and 89 DD lesions) were collected from Holstein dairy cows housed in 3 different dairy farms. BS were trimmed in 2 different layers, resulting in 280 samples. Rumen fluid (n = 8) and fecal (n = 14) samples were also collected. DNA was extracted and the microbiome was determined by shotgun and 16S metagenomic techniques using Illumina MiSeq platform. Discriminant analysis revealed that microbiomes of HS, active and inactive DD lesions were completely distinct. The differences in microbiomes between the superficial and deep strata were found to be minor. *Treponema* spp. were found in greater ($P < 0.05$) relative abundance in active DD lesions when compared with HS and inactive DD lesions and these *Treponema* spp. were nearly ubiquitously present in rumen and fecal microbiomes. *Candidatus amoebophilus asiaticus,* a bacterium not previously reported in DD lesions, was encountered in high ($P < 0.05$) relative abundance in active and inactive lesions but not in HS. In conclusion, our data support the concept that DD is a polymicrobial disease, with active DD lesions having a markedly distinct microbiome dominated by *T. denticola*, *T. maltophilum*, *T. medium*, *T. putidum*, *T. phagedenis* and *T. paraluiscuniculi*. Furthermore, these *Treponema* species are nearly ubiquitously found in rumen and fecal microbiomes, suggesting that the gut is an important reservoir of microbes involved in DD pathogenesis. Further investigation into the potential role of the gut microbiome as a reservoir for pathogens leading to DD development and of prophylactic measures to control the potential environmental shedding of these pathogens is needed.

Key Words: bovine digital dermatitis, dairy cow, microbiome

T27 Characterization of the leukocyte transcriptome in cows challenged with *Mycobacterium bovis* and healthy controls.

Robmay Garcia*, Dianelys Gonzalez-Pena, and Sandra L. Rodriguez-Zas, *University of Illinois at Urbana Champaign, Urbana, IL.*

Mycobacterium bovis (*M. bovis*) is a pathogenic bacteria that generates approximately $3 billion worldwide production loss for the cattle industry, in terms of animal value and productivity. To help understand the response to this pathogen, the objective of this study was to characterize the transcriptome of cows infected with *M. bovis* relative to healthy controls. Cows positive for *M. bovis* were identified using the single intradermal comparative tuberculin test, and in vitro ELISA-based interferon-gamma. The transcriptome of peripheral blood leukocytes from Holstein cows detected positive was compared with healthy control cows (n = 8/group) using individual RNA-Seq libraries. Single-end reads were mapped to the *Bos taurus* reference genome (UCSC_bosTau7) using Tophat v2.0.12. In total, 8,309 isoform transcripts pertaining to 8,127 genes were identified and 2,620 isoform transcripts pertaining to 2,608 genes were identified as differentially expressed (false discovery rate-adjusted *P*-value <0.05) using Cufflinks v2.2.1. Among the top 25 differentially abundant transcripts using log fold change, 76% were overexpressed in the infected group relative to control cows including polo-like kinase 3 (PLK3), atypical chemokine receptor 3 (CXCR7), and nuclear factor of kappa light polypeptide gene enhancer in B-cells inhibitor delta (NFKBID). PLK3 participates in the tuberculosis response pathway, activating the nuclear factor-κB, which in turn stimulates transcription of the inducible nitric oxide synthase as well as pro-inflammatory cytokines. CXCR7 is an innate immune gene reported in leukocytes infected with *M. bovis*. Also, NFKBID may regulate the expression of cytokines by regulating nuclear factor-κB activity. Functional analysis of the differentially expressed genes using DAVID identified 14 enriched functional category clusters (enrichment score >3) including leukocyte mediated immunity, leukocyte activation and proliferation, cellular apoptosis, together with cytokines and chemokines production. The majority of the genes in these clusters were overexpressed in the infected group relative to control cows. These results offer insights on leukocyte transcriptome changes in response to *M. bovis* infection.

Key Words: transcriptome, tuberculosis, production

T28 Evaluation of antimicrobial activity of chitosan microparticles in different matrices from dairy cows.

Zhengxin Ma*[1,2], Lin Teng[1,2], Donghyeon Kim[1], Klibs N. Galvão[3], Corwin D. Nelson[1], Adegbola T. Adesogan[1], and K. Casey Jeong[1,2], [1]*Department of Animal Sciences, University of Florida, Gainesville, FL,* [2]*Emerging Pathogens Institute, University of Florida, Gainesville, FL,* [3]*Department of Large Animal Clinical Sciences, University of Florida, Gainesville, FL.*

The objective of this study was to evaluate antimicrobial activity of chitosan microparticles (CM) in different matrices from dairy cows. CM was prepared by cross-linking of chitosan solution to enhance antimicrobial activity. Chitosan is biocompatible, natural antimicrobial biopolymer and considered Generally Recognized As Safe in many countries. Although CM shows strong antimicrobial activity in vitro, antimicrobial activity of CM in different animal matrices is not understood. We assayed antimicrobial activity of CM in cow uterine fluids (n = 3), milk samples (n = 5) and rumen fluids (n = 4) that were collected from metritic, subclinical mastitic, and fistulated dairy cows, respectively. To evaluate antimicrobial activity in the rumen fluids, we inoculated 5×10^4 cfu/mL *E. coli* O157:H7 into the fluids, but we used endogenous microorganisms for milk and uterine samples. Concentrations of CM ranging from 0.1% to 0.8% were tested in these matrices. Efficacy of antimicrobial activity of CM was measured by direct plating of treatments to measure the concentration of pathogens. Milk and uterine fluid samples were plated on LB agar, but the rumen fluids were plated on CT-SMAC agar after 0, 2, 4 and 6 h incubation to select *E. coli* O157:H7. The experiment in each fluid was conducted as a completely randomized design independently and in triplicate. Data were analyzed using the GLIMMIX procedure of SAS (SAS Institute Inc., Cary, NC). Treatment with CM effectively reduced the concentration of pathogens in all of the tested samples, even though the antimicrobial activity varied depending on matrices and CM concentrations. In milk, naturally occurring pathogens were completely eliminated within 4 h with 0.1% CM ($P < 0.001$). Regarding the cow uterine fluid, although the growth of naturally occurring pathogens was inhibited at 0.1% ($P < 0.001$), higher concentration (0.6%) of CM was required to eradicate pathogens ($P < 0.001$). Finally, 0.2% CM reduced *E. coli* O157:H7 by 2 log cfu/mL in spiked rumen samples ($P < 0.001$). These data demonstrate that a natural antimicrobial agent, CM, retains antimicrobial activity in different matrices from dairy cows.

Key Words: chitosan microparticle, antimicrobial activity

T29 Targeted oxylipid analyses of milk obtained from periparturient dairy cows.

Jeffery C. Gandy*, Vengai Mavangira, and Lorraine M. Sordillo, *Michigan State University, East Lansing, MI.*

Dysfunctional mammary gland inflammatory responses around the time of parturition contribute to immunopathology associated with mastitis. Oxylipids are bioactive lipid mediators that restore tissue homeostasis following injury by orchestrating the initiation and resolution of inflammation. The objective of this study was to develop a method to detect milk oxylipid concentrations and profile changes with respect to lactation stage. Milk samples were obtained from 11 multiparous cows at the time of calving and again at approximately 80 and 220 d in milk. Analytes in milk were obtained using solid-phase column extraction and then measured using liquid chromatography with tandem mass spectrophotometry (LC/MS/MS). The amount of oxylipids in each sample were quantified relative to internal standard abundance and calibrated against standard curves. Using this newly developed extraction and analytical methodology, a total of 31 of the 63 total oxylipids species targeted for analyses could be detected in milk samples within the limits of detection. Linoleic acid (2,419 μM) was the predominant polyunsaturated fatty acid detected in milk samples regardless of lactation state followed by arachidonic (743 μM), docosahexaenoic (89.9 μM), and eicosapentaenoic (82.14 μM) acids. The linoleic acid-derived oxylipids were the most abundant found in milk with significant increases ($P < 0.05$) in several hydroxyl products including 9,10-dihydroxy-octadecenoic acid during late (109.6 n*M*) when compared with milk samples obtained in early lactation (0.01 n*M*). Lipoxin A4 is an arachidonic acid-derived oxylipids with known anti-inflammatory functions that was higher ($P < 0.05$) in milk samples obtained at the time of calving (0.01 n*M*) when compared with late lactation samples (0.002 n*M*). These are the first observations of how oxylipids profiles change with respect to lactation stage and in response to changing concentration of fatty acid substrates in milk. A better understanding of how individual milk oxylipids affect mammary gland immunity may provide new insight of how to better control dysfunctional inflammatory responses during disease.

Key Words: oxylipid, eicosanoid, inflammation

T30 Prevalence and antimicrobial resistance of mastitis pathogens in cattle dairy in a region of Colombia.

Maria del P. Sanchez*, Norma P. Gutierrez, and Ivan J. Posada, *Universidad Cooperativa de Colombia Sede Ibagué, Ibagué, Tolima, Colombia.*

Bovine mastitis is the most common and major economic problem in the dairy industry worldwide, with a wide variety of microorganisms involved. Identification of mastitis pathogens is important for the selection of appropriate antimicrobial therapies. Antimicrobial agents are used to treat these infections caused by bacteria in particular but in recent years some bacteria have demonstrated full or partial resistance to different antibiotics. This phenomenon called antimicrobial resistance is a rising concern in both public and animal health and in this case, dairy science. The objective of the research was to determine the prevalence and antimicrobial resistance of pathogens involved in bovine mastitis in a region of Colombia. 1392 quarters of 348 cows from Anaime Colombia region were tested, using the California mastitis test (CMT). The positive samples to CMT were cultured for bacteriological isolation and were tested for antibiotic susceptibility and resistance by disk diffusion method and performed according to CLSI guidelines in Mueller-Hinton agar. Analysis of the results was made through descriptive statistics and prevalence ratio. 190 (54,6%) cows were considered mastitis free. One hundred fifty-eight cows (45,4%) were positive for CMT and bacteriological culture. Clinical mastitis in 20 (5,74%) cows characterized by milk abnormalities and subclinical mastitis in 138 (39,65%) were found. Coagulase-negative staphylococci (CoNS) was the main pathogenic agent with 44,79% of the total isolations, followed by *Staphylococcus aureus* (CoNP) 30.73% and *Streptococcus* spp. 22.39%, both *Klebsiella pneumoniae* and *E. coli* with 1.1%. CoNS and *S. aureus* exhibited the highest degree of resistance to penicillin G, *S. aureus* and *Streptococcus* spp. showed a high resistance to streptomycin and erythromycin respectively. The most prevalent organism was CoNS considered currently a worldwide emerging mastitis and it was mainly evidenced as a cause of subclinical mastitis with high degree of resistance to penicillin.

Key Words: clinical mastitis, subclinical mastitis, coagulase-negative staphylococci

T31 Variation in clinical mastitis detection frequency and etiology among milkers.

Paulo Cesar Duque-Madrid[1,3], Cedric Blanc[2], and Alfonso Lago*[3], [1]*Universidad de Caldas, Manizales, Colombia,* [2]*GTV Dairies, Tipton, CA,* [3]*DairyExperts Inc., Tulare, CA.*

Early detection of clinical mastitis cases is considered key for the success of therapy and to maintain milk quality. Our objectives were to describe variation in 1) clinical mastitis detection frequency among milkers; and, 2) etiology of clinical mastitis among low and high detection milkers. Clinical mastitis records were from 712 cases from one California Central Valley large dairy herd where cows were milked twice a day in 2 separate parlors. Milking procedures included forestripping with observation of milk appearance on the parlor floor. When abnormal milk was observed a milk sample was collected, labeled with the milker ID, and cultured on-farm following the Minnesota Easy Culture system. Culture results were classified as no-growths, gram-negatives, gram-positives, and, mixed culture when gram-negatives and gram-positives were isolated. The total number of cases detected among 10 milkers ranged from 21 to 113 and the number of working hours from 817 to 987. Milkers 1 to 5 detected 2 to 7 cases per 100 h and were classified as low detection milkers. Conversely, milkers 6 to 10 detected 9 to 12 cases per 100 h and were classified as high detection milkers. The percentage of samples from which bacteria were isolated ranged from 38% to 71% among milkers. However, milker's clinical mastitis detection rate did not affect the percentage of samples with bacterial growth ($P = 0.93$) - it was 58% for the 2 clinical mastitis detection rate groups. Gram-positives were the bacteria most commonly isolated from both groups with 32% of the samples; gram-negative bacteria represented 21% and 16% of isolates in groups low and high, respectively; and, mixed cultures 5% and 10% in groups low and high, respectively. In conclusion, there was a large variation among milkers in clinical mastitis detection rate and in the percentage of samples with bacterial growth. However, neither the percentage of samples with bacterial growth nor the etiology were influenced by the level of detection. Therefore, it appears that high clinical mastitis detection rates can be achieved without increasing the percentage of cases without bacterial growth.

Key Words: clinical mastitis, mastitis detection, milkers

T32 The effect of concentrate allocation strategy on the metabolic and immune function of high genetic merit dairy cows offered a grass silage based diet.

Mark W. Little*[1,2], Niamh O'Connell[2], Jason Barley[3], Michael D. Welsh[3], and Conrad P. Ferris[1], [1]*Agri-Food and Biosciences Institute, Hillsborough, UK,* [2]*School of Biological Sciences, Queens University Belfast, Belfast, UK,* [3]*Agri-Food and Biosciences Institute, Veterinary Sciences Division, Belfast, UK.*

The impact of concentrate allocation strategy on metabolic and immune function has received little attention. This 140-d study (commencing at calving) examined the effect of either a group fed (GF) or individual cow fed (ICF) concentrate allocation strategy on hematology, biochemistry, inflammatory and immune competence of Holstein Friesian dairy cows (n = 72). With GF, cows were offered a total mixed ration comprising grass silage and concentrates (50: 50 DM ratio) plus 0.35 kg chopped straw/cow/day throughout the study. With ICF, cows were offered a basal ration consisting of grass silage, concentrates (6 kg/cow/day) and chopped straw (0.35 kg/cow/day), with this diet designed to meet the cows energy requirements for maintenance plus 24 kg milk/cow/day. With this treatment additional concentrates were offered 'feed-to-yield' via an out-of-parlor feeding system (0.45 kg concentrate/kg milk) based on each individual cow's milk yield during the previous week. Blood samples were obtained from the coccygeal vein or artery of each cow at wk 2, 4, 6, 8, 10, 12, 16 and 20 (± 3 d) post-calving. Data were analyzed using a residual maximum likelihood (REML) mixed model analysis using GenStat (Version 16.2). Cows on the GF treatment had a higher mean hemoglobin ($P = 0.009$) and packed cell volume ($P = 0.018$), higher lymphocyte ($P = 0.020$) percentage and lower neutrophil percentage ($P = 0.018$) than cows on the ICF treatment. Cows on the GF treatment had lower serum NEFA concentrations ($P = 0.028$) and tended to have a higher serum albumin concentration ($P = 0.055$) than cows on the ICF treatment. There was no effect of concentrate allocation strategy on serum haptoglobin ($P = 0.356$) or interferon gamma production of whole blood incubated with pokeweed mitogen ($P = 0.115$). Allocating concentrates on a group basis resulted in small physiological improvements to metabolic function, but had no effect on immunological function, compared with offering the same amount of concentrates on an individual cow basis.

Key Words: concentrate allocation, metabolic function, immune function

T33 Evaluation of experimental novel germicide postmilking teat dips and a commercial iodine barrier postmilking teat dip on teat end and teat skin health and integrity.

Rae Sires, Kia Knutson, and Leo L. Timms*, *Iowa State University, Ames, IA, 50011.*

Study objective was to evaluate prototype novel germicide post milking teat dips versus a control commercial iodine barrier post milking teat dip on overall teat end (TE) and teat skin (TS) health and integrity. Control dip was Bovi-Kote (1% iodine with 10% multiple emollient system (low drip): Boumatic, Inc.) and treatment dips were a novel germicide dip with 10% citrate, parabens, and varying methylene blue (MB) (0.1, 0.25, and 0.4%) and emollient (5, 10, and 11%) concentrations (Zurex Pharma Inc.). Trial used a split pen and split udder design. Twenty-four early- mid lactation Jersey cows in a single pen were used with 12 cows having a blue leg band (BLB group) to designate them as trial group 1 while the other 12 had no leg band (NLB group). Left teats of all 24 cows were post dipped with Bovi-Kote (control) while right teats were were initially dipped with a 0.1% methylene blue dip (1/29) but differed in emollient % (5 v 11%). Dips changed to .25% MB (2/10) to enhance coloration. NLB teats switched to a 0.4% MB with 11% emollients (2/19), while BLB teats switched to a higher emollient (10 v 5%) no drip teat dip (2/20). Trial was 5 weeks in duration (Jan –Feb). TS and TE scoring were performed 1st 4 trial days, then 3×/week using Goldberg and Timms methods (1–5 scoring for both, 0.5 increments for TE scores). Mixed procedure of SAS with repeated measures (quarter within cow as a repeated measure) were used to analyze TS and TE data and GENMOD procedures of SAS with repeated measures was used to analyze % rough teat ends or dry/chapped teat skin, with $P < 0.05$ considered significant. Results of experimental vs commercial control dip were similar across groups so data were combined. No significant differences in TS score were seen (99+% excellent). TE scores and % rough teats were not significantly different during weeks. One and 4, but were significantly higher [1.6, 13% (Exp) v 2.1, 27% (Con) $P < 0.01$] and compromised in control teats during wks. 2–3, corresponding to temperature change (30°F (−1C) to −4°F (−20C)). Experimental dip showed significantly better TE during colder weather and temperature changes.

Key Words: postmilking teat dip, germicide, teat health

T34 Study of the activity of soluble and nanostructured IFNγ and metalloproteinases as a new tool for the optimization of the dry-off of dairy cows.

Francesc Fabregas[1], Olivia Cano[2,3], Sandra Genís*[1], Silvia Parés[1], Joaquim Seras-Franzoso[2,3], Alex Bach[1,4], Antonio Villaverde[2,3], Elena Garcia-Fruitos[2,3], and Anna Aris[1], *[1]Department of Ruminant Production, Institute of Research in Agriculture and Technology, Caldes de Montbui, Spain, [2]Department of Genetics and Microbiology, Institute of Biotechnology and Biomedics, Universitat Autonoma de Barcelona, Bellaterra, Spain, [3]CIBER de Bioingenieria, Biomateriales y Nanomedicina, Bellaterra, Spain, [4]ICREA, Barcelona, Spain.*

The use of bovine metalloproteinases and IFNγ to hasten mammary gland involution and the stimulation of immune system response has been proposed to accelerate the dry off period and diminish the risk of intramammary infections. The protein nanoparticles technology has shown to be an economically viable production strategy of recombinant proteins. The objective of this work was to study the activity of bovine metalloproteinase 2 and 9 (MMP-2, MMP-9) and IFNγ produced in *Lactococcus lactis* either as nanoparticles (Lu et al. Mol. Biotechnol. 2013 54:170–176) or soluble recombinant proteins. The activity of IFNγ was tested using a macrophage activation test along with an assay of induction of nuclear factor kappa-β (NF-κβ) expression in mammary epithelial cells. Monocytes were isolated from cow blood, differentiated to macrophages, and treated with IFNγ for 24 h at 37°C, 5% CO_2 while primary culture of mammary gland epithelial cells were treated with IFNγ for 4 h at 37°C, 5% CO_2. Cell samples were taken to analyze the expression of NF-κβ by qPCR. Activity of MMP-2 and MMP-9 soluble or as nanoparticles was tested by both zymography and ex vivo. For the ex vivo assay, mammary gland explants were incubated with MMP for 7 h at 37°C and 5% CO_2. Then, apoptotic and proliferation gene expression was assessed by qPCR (PCNA, SPC25, CASP3 and BNIP). The sensitivity of NF-κβ assay was greater than the macrophage activity test (detection limit of 19.6 µg and 140 µg IFNγ, respectively; $P < 0.05$). Soluble IFNγ upregulated ($P < 0.05$) NF-κβ, whereas similar amounts of IFNγ nanoparticles had no significant effect. Metalloproteinase activity was detected for MMP-2 and MMP-9 in both forms by zymography. As expected, the soluble form was more active than the nanostructured form ($P < 0.05$). Only soluble MMP9 activity was detected ex vivo, stimulating ($P < 0.001$) the expression of SPC25 and PCNA proliferative genes. In conclusion, the bovine recombinant MMP and IFNγ proteins elicited the expected biological response and thus they can be used in further in vivo dry-off studies in dairy cows.

Key Words: dry period, nanoparticle, metalloproteinase

T35 Metabolic parameters of cows with different status for bovine leukemia.

Irina V. Vinogradova*[1], Elena A. Gladyr[1], Ludmila A. Ivanova[2], Alexandr S. Kramarenko[1], Igor V. Gusev[1], Roman V. Rykov[1], Michael I. Guljukin[2], and Natalia A. Zinovieva[1], *[1]L.K. Ernst Institute of Animal Husbandry, Dubrovitsy, Moscow, Russia, [2]Y.R. Kovalenko Institute of Experimental Veterinary Medicine, Moscow, Russia.*

Increased susceptibility of high-productive dairy cows to infectious diseases is associated with metabolic stress which is developed on the background of a negative energy balance. The objective of our study was to determine the differences in metabolic parameters and blood leukocyte profiles in cows infected by bovine leukemia virus (BLV+) compared with non-infected cows (BLV−). The blood samples were collected from 150 cows of the Russian Black-and-White breed. The cows were housed at identical environmental conditions in one free-stall facility and were fed by the same diets. BLV status was determined by immune diffusion reaction and confirmed by enzyme immune assay. The blood serum concentrations of carbohydrate, protein and lipid metabolites were measures and the blood leukocyte profile was evaluated. The experimental data were analyzed using logistic regression analysis of binary data, (http://www.statistica-help.ru/node/28) (p_1) and linear model ANOVA (p_2), where the BLV status and correlation coefficient were taken as a random factor. Student *t*-test was perform to evaluate the statistical significance of differences between the groups. The serum concentrations of albumin, creatinine and ALT did not differ significantly between the groups, but the concentrations of the total protein (+6.89 g/L, $p_1 \leq 0.0001$, $p_2 \leq 0.0141$), globulin (+6.95 g/L, $p_1 \leq 0.0002$, $p_2 \leq 0.0483$), urea (+1.02 m*M*/L, $p_1 \leq 0.0020$, $p_2 \leq 0.0006$) and bilirubin (+2.01 m*M*/L, $p_1 \leq 0.0162$, $p_2 \leq 0.0016$) were significantly higher among BLV+ cows compared with non-infected cows, but the concentrations of glucose (−0.50 m*M*/L, $p_1 \leq 0,0007$, $p_2 \leq 0.0940$), triglycerides (−0.04 m*M*/L, $p_1 \leq 0,0384$, $p_2 \leq 0.0065$), alkaline phosphatase (−63.1 IE/L, $p_1 \leq 0,0384$, $p_2 \leq 0.0065$) and AST enzyme (−1.56 IE/l, $p_2 \leq 0.0713$) were significantly decreased. According to clinical indicators of blood (WBC, RBC, HGB, HCT, MCV, MCH, MCHC, RDW) significant differences between the groups were not found. The data obtained confirm the assessment that bovine leukemia has effect on the biochemical parameters of carbohydrate, lipid, protein metabolism.

The research was supported by the Russian Science Foundation, project number 14–16–00046.

Key Words: dairy cattle, bovine leukemia virus, biochemical paramete

T36 High forage diet alters feeding behavior, health, and milk production in fresh Holstein dairy cows.

Juliana M. Huzzey*[1,2], Hesam A. Seifi[1,3], Muhammad A. Khan[1,4], Marina A. G. von Keyserlingk[1], and Daniel M. Weary[1], [1]*Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada,* [2]*Animal Science Department, California Polytechnic State University, San Luis Obispo, CA,* [3]*Department of Clinical Sciences, School of Veterinary Medicine, Ferdowsi University of Mashhad, Iran,* [4]*AgResearch, Grasslands Research Centre, Palmerston North, New Zealand.*

High-forage diets for close-up dairy cows are gaining popularity and are increasingly perceived to provide health and production advantages. After calving cows are typically transitioned to a high-energy diet but it is not clear how this transition affects their health and behavior. Our objective was to test the effect of maintaining cows on a high-forage diet for 3 wk after calving, versus switching to the conventional high-energy diet. Sixty-eight Holstein dairy cows (21 primiparous and 47 multiparous cows) were all fed the same high-forage prepartum diet. After calving, cows were moved to a postpartum pen for 21 d and randomly assigned to feed bins according to their respective treatments (Straw TMR: STMR vs. Control TMR: CTMR). After 21 d, all cows were moved to a new pen and fed CTMR. An electronic feeding system continuously monitored individual feeding behavior and intake. Rumination time was recorded using data loggers. Blood was sampled twice per week and tested using the β-hydroxybutyrate (BHBA) Precision Xtra kit. Cows were considered subclinically ketotic (SCK) if BHBA was ≥1.0 mmol/L in the first wk postpartum or ≥1.2 mmol/L from d 7 to 35 postpartum. Milk yield was recorded daily. Data were analyzed using the Mixed and Genmod procedures of SAS; cow was treated as a random effect and period (wk or d) as the repeated measure. Fresh cows fed STMR had lower DMI, fewer meals, spent more time at the feed bunk and had a slower feeding rate ($P \leq 0.02$). Rumination time of cows fed STMR was higher than cows fed CTMR ($P = 0.04$). Cows fed STMR had higher BHBA concentrations during wk 3 ($P = 0.03$) and were 4.9 times more likely than the CTMR group to develop SCK by wk 3 (odds ratio = 4.9, 95% confidence interval = 0.95 - 25.47, $P = 0.06$). Over the first 35 d of lactation, cows fed CTMR produced more milk than those fed STMR (33.3 ± 1.0 vs. 30.7 ± 1.0 kg/d; $P = 0.03$). These results indicate that maintaining cows on a high-forage diet after calving can have detrimental effects on energy balance and cow health.

Key Words: transition cow, nutrition, welfare

T37 Prepartum rumination patterns in dairy cows that develop health disorders in the early postpartum period.

Matias L. Stangaferro*, Robert Wijma, Miranda M. Medrano, Mohammed A. Al Abri, and Julio O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

The objective of this study was to compare prepartum rumination patterns of lactating dairy cows that developed health disorders (HD) versus cows that did not develop HD (NoHD) up to 30 DIM. A total of 559 Holstein cows (222 primiparous and 337 multiparous) were fitted with a rumination and activity monitoring tag (HR Tags, SCR Dairy) from −28 to 30 DIM. Rumination time (RT) was recorded in minutes per 2 h intervals and summarized in 24 h periods. After calving, farm personnel examined cows daily for signs of clinical disease following farm standard operating procedures. From 1 to 10 DIM, personnel evaluated: appetite, rectal temperature, ketone bodies in urine, rumen fill and movements, retained placenta, vaginal discharge, daily milk weights, and milk conductivity. Milk culture was performed for all mastitis cases. Number of cows suffering HD was displaced abomasum (DA) 17, ketosis (KET) 16, indigestion (IND) 5, metritis (MET) 171, retained placenta (RP) 49, and mastitis (MAST) 36. Rumination time for the 7 d preceding calving was evaluated for cows with HD or NoHD within 30 DIM. Also, data were evaluated for all metabolic and digestive diseases (MDZ = DA, KET, IND) combined and RP, MET, and MAST individually. Data were analyzed by ANOVA with repeated measurements using PROC MIXED of SAS. For all HD combined, RT was less ($P = 0.02$) for cows with HD (439.1 ± 2.8 min) than for cows with NoHD (455.9 ± 2.0 min). Rumination time was lowest ($P < 0.01$) on the day of calving (391.3 ± 4.3 min) than the 6 d preceding calving (mean range = 457.5 ± 4.0 – 462.6 ± 4.1 min) for all cows. Cows with MDZ had reduced RT ($P < 0.01$) than NoHD cows (409.6 ± 7.3 vs 455.9 ± 2.0 min). Cows with RP had similar RT ($P = 0.25$) than NoHD cows (440.2 ± 5.0 vs 455.9 ± 2.0 min). Cows with MET tended to have reduced RT ($P = 0.05$) than NoHD cows (440.5 ± 3.1 vs 455.9 ± 2.0 min). Cows with MAST had similar RT ($P = 0.82$) than NoHD cows (452.4 ± 6.1 vs 455.9 ± 2.0 min).We conclude that starting 7 d prepartum, rumination patterns are altered in cows that suffer health disorders within 30 DIM. Rumination time is reduced in cows that suffer MDZ (DA, KET, IND) and MET but not in cows with RP and MAST

Key Words: rumination, dairy cow, disease

T38 Plasma phosphatidylcholine and lysophosphatidylcholine profiling of heat-stressed lactating dairy cows.

He Tian[1], Jianbo Cheng[2], Yangdong Zhang[1], Nan Zheng*[1], and Jiaqi Wang[1], [1]*Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*College of Animal Science and Technology, Anhui Agricultural University, Hefei, China.*

Heat stress (HS) is a global challenge for the dairy industry; however, its abnormal physiological alterations still remain elusive. Here, a LC-MS-based study on lysophosphatidylcholine (lysoPC) and phosphatidylcholine (PC) in plasma of HS dairy cows was performed to explore HS-induced metabolic alterations. LysoPCs or PCs exist in 2 forms/isomers, with the fatty acyl groups at positions 1 (sn-1) or 2 (sn-2) on the glycerol backbone. First experiment, the LC-MS-based method of discriminating isomers of lysoPCs or PCs was constructed. The isomeric lysoPCs or PCs can be differentiated by chromatographic separations and relative intensities of their characteristic fragments. Second experiment, the enrolled 2 groups of Holstein cows were in second parity, mid-lactation stage, had similar milk yield (both around 40 kg/day), and fed the same diet. The HS-free group consisted of 22 cows, with plasma samples obtained in spring season, after temperature-humidity index (THI) was around 50–55 for 1 mo. The HS group consisted of another 22 cows, with samples obtained in summer season, after THI gradually increased from 68 to 80 over 1 mo. LC-MS in combination with multivariate analyses on plasma profiling of HS-free and HS groups was conducted to discover HS-induced discriminating metabolites ($P < 0.05$), from which isomeric lysoPCs or PCs were identified by the constructed method in first experiment. The results revealed that concentrations of 14 lysoPCs and 17 PCs were significantly up- or downregulated in HS compared with in HS-free group, indicating HS-induced alterations of lysoPCs and PCs. Of these 31 discriminating metabolites, concentrations of sn-1 lysoPC 14:0, sn-2 lysoPC 15:0, sn-1 lysoPC 18:0, and sn-2 lysoPC 22:4 were upregulated in HS group ($P < 0.05$), concentrations of sn-1 PC 14:0/18:3, sn-1 PC 14:0/18:2, sn-2 PC 15:0/17:1, sn-1 PC 14:0/20:4, sn-1 PC 18:0/15:1, sn-1 PC 18:0/15:0, and sn-2 PC 15:0/20:4, were downregulated in HS group ($P < 0.05$); whereas, concentrations of their respective isomers remained unchanged, suggesting isomers of these lysoPCs and PCs have different biological functions played in lactating dairy cows under HS states.

Key Words: lactating dairy cow, heat stress, phosphatidylcholine and lysophosphatidylcholine profiling

T39 Assessment of an application to collect calving-related events in dairy herds. A. A. Barragan*, J. D. Workman, S. Bas, K. L. Proudfoot, and G. M. Schuenemann, *The Ohio State University, Columbus, OH.*

Calving-related losses (survival, health, and productivity of cows and calves) are known challenges for the dairy industry worldwide, and poor management practices can increase the risk of these losses. It is common to observe large variation within and between herds on the quality and quantity of calving-related records. The objective of the present study was to assess an application (APP) for hand-held smart devices to capture defined calving-related events in dairy herds. Calving events collected by personnel (n = 23) from 6 large dairy operations (range: 900–5,000 cows) were recorded. Calving personnel received the same training on calving management and use of the APP before collecting events. Immediately after training, personnel recorded calving events (n = 448) using the APP for 7 d. Personnel satisfaction with the APP and knowledge gained from the training were assessed. Calving personnel reported that the information provided during the training was relevant (agree = 14.3% and strongly agree = 85.7%) and of great immediate use (agree = 33.3% and strongly agree = 66.7%). The presented materials and demonstrations substantially increased ($P < 0.05$) the knowledge level of the participants by 23.7 percentage points from pre- to post-test scores. The APP accurately captured (100%) calving events and integrated multiple metrics with personnel performance (accounting for the effect of shift change) such as the dam (e.g., date-time of calving), colostrum (e.g., timing, quality, and quantity) and newborn calf (e.g., presentation, vigor). The follow-up assessment with participants revealed that the APP was easy to use (91.3%) and that they would like to keep using it (100%). Dairymen, consultants, and veterinarians often trouble-shoot calving related losses within-herd; however, the lack of meaningful records makes it difficult to implement effective corrective measures. It is important to note that the timing and accuracy of data is always dependent on the willingness of the individual recording the information. However, this effective and easy-to-use tool requires minimal personnel training. These findings showed that decision-makers can monitor calving events and losses (magnitude and time) at the farm level accounting for the effect of management.

Key Words: dairy cattle, calving, application

T40 Difructose anhydride III supplementation promotes passive calcium absorption in the small intestine immediately after calving in dairy cows. Makoto Teramura*[1,2], Syaw Wynn[1], Maimaiti Reshalaitihan[3], Wakana Kyuuno[2], Tadashi Sato[2], Masayuki Ohtani[2], Chiho Kawashima[3], and Masaaki Hanada[3], *[1]United Graduate School of Agricultural Sciences, Iwate University, Morioka, Iwate, Japan, [2]Nippon Beet Sugar Manufacturing Co., Ltd., Obihiro, Hokkaido, Japan, [3]Obihiro University of Agriculture and Veterinary Medicine, Obihiro, Hokkaido, Japan.*

Difructose anhydride (DFA) III is an indigestible oligosaccharide. It has been shown to reach the duodenum without being degraded by ruminal bacteria and to promote the intestinal calcium (Ca) absorption via paracellular pathway in cattle, but these studies did not mention DFA III's effectiveness during early postpartum (pp) period. The objective of this study was to determine whether DFA III could promote intestinal paracellular Ca absorption during early pp period. Seventy-four multiparous Holstein cows were separated into the DFA and control groups based on their parity (3.7 ± 0.3 and 3.7 ± 0.3, respectively). The DFA group was fed 40 g/d of DFA III from −14 d to 6 d relative to calving and the control group was not fed DFA III. At calving (0 h pp), the serum Ca declined below 9 mg/dL in both groups. However, the serum Ca was significantly greater in the DFA group than in the control group at 6 h, 12 h, 24 h, and 48 h pp ($P < 0.05$) and the time interval for serum Ca recovery to ≥9 mg/dL during the pp period was shorter in the high-parity cows of the DFA group than in those of the control group. The serum parathyroid hormone (PTH) increased at 0 h pp in both groups and was significantly greater in the control group than in the DFA group at 12 h and 24 h pp ($P < 0.05$). The serum 1,25-dihydroxyvitamin D [1,25-$(OH)_2D$] increased at 0 h and 12 h pp in both groups and was significantly greater in the control group than in the DFA group at 72 h pp ($P < 0.01$). The serum bone-resorption marker cross-linked N-telopeptide of type I collagen (NTX) was not significantly different between the groups during peripartum period, and the serum NTX in all of the cows was lesser at 0 h, 6 h, 12 h, 24 h, 48 h, and 72 h pp than at −21 d, 4 d, and 5 d relative to calving ($P < 0.05$). These results suggest that the DFA group had rapid recovery of serum Ca, although bone resorption was restrained and active intestinal Ca absorption via transcellular pathway was impaired. In conclusion, DFA III promotes intestinal passive Ca absorption via paracellular pathway during early pp period, which is unaffected by aging.

Key Words: hypocalcemia, dairy cow, DFA III

T41 Supplementation with *Bacillus pumilus* 8G-134 enhances expression of T cell markers in dairy cows during early lactation. Megan Duersteler*[1], Mike Brouk[2], and Elizabeth Galbraith[1], *[1]DuPont, Waukesha, WI, [2]Kansas State University, Manhattan, KS.*

Infectious disease during transition and early lactation periods has the potential to decrease production performance and increase morbidity and mortality in dairy cows. Enhanced adaptive immunity through nutritional supplementation may counter immunosuppression that occurs naturally during the periparturient and early lactation periods. The objective of this study was to evaluate the effect of a direct-fed microbial, *Bacillus pumilus* 8G-134, on systemic immunity in dairy cows through flow cytometric analysis of peripheral blood mononuclear cells. Thirty cows were fed a control diet or a diet including 5×10^9 cfu/head/day *B. pumilus* 8G-134 from 3 weeks prepartum to 22 weeks postpartum. Peripheral blood mononuclear cells were collected at 60 d in milk and analyzed by flow cytometry. Leukocytes and lymphocytes were gated based on forward and side scatter, and relevant cell surface markers were examined in each population. *B. pumilus* 8G-134 supplementation increased ($P < 0.05$) expression of T cell surface markers CD4, CD8, CD62L, CD25, and CD45RO, but did not affect proportions of T cell subsets. There was no effect on expression of cell surface markers on innate immune cells (Mono, CD14, CD45, CD172a, and CD62L) or B cells (Bcell, and CD21). Feeding *B. pumilus* 8G-134 induced expression of T cell surface markers that are naturally suppressed during parturition. By targeting the adaptive immune system, *B. pumilus* 8G-134 was able to enhance T cell marker expression without activating a systemic immune response that would adversely affect energy balance. This may help dairy cows recover faster from periparturient immunosuppression.

Key Words: dairy, direct-fed microbial, immunology

T42 A stochastic estimate of the economic impact of oral calcium supplementation in postparturient dairy cows.

J. A. A. McArt[1] and G. R. Oetzel*[2], [1]*Department of Population Medicine and Diagnostic Services, Cornell University, Ithaca, NY,* [2]*Department of Medical Sciences, University of Wisconsin-Madison, Madison, WI.*

Stochastic models were developed to estimate the economic impact in the first 30 d in milk of oral calcium supplementation (Bovikalc, Boehringer Ingelheim Vetmedica Inc., St. Joseph, MO) to multiparous postparturient dairy cows using 4 different strategies: 1) supplementation of cows with a high previous lactation mature equivalent milk yield, 2) supplementation of lame cows, 3) supplementation of cows that either have a high previous lactation mature equivalent milk yield or are lame, and 4) supplementation of all cows. Data from current literature was used to model input variables associated with the costs and risks related to milk production, postparturient disease, and culling. The mean net herd impact per 1,000 calvings for each of the 4 supplementation strategies was \$4,425, \$5,812, \$8,313, and \$3,065 respectively. Return on investment was 6.5 to 1 for supplementation of lame cows, 1.8 to 1 for high milk yield and lame cows, 1.1 to 1 for high milk yield cows, and 0.3 to 1 for supplementation of all multiparous postpartum cows. A herd's average milk yield at first test had the highest influence on the net impact of oral calcium supplementation to all multiparous cows and accounted for 30% of the variation in net herd financial impact of oral calcium administration. Other variables that explained at least 5% of the variation in financial impact included decreased risk of health events in lame cows, herd prevalence of lameness, and milk price. Whereas supplementation of all postpartum multiparous cows returned a positive net herd impact approximately 80% of the time, if a herd was willing to devote time to mature-equivalent milk yield calculations and locomotion scoring, supplementation of this subpopulation of postpartum cows with oral calcium was estimated to have a positive economic impact in all iterations. Depending on the supplementation strategy chosen and baseline milk yield and immediate postpartum lameness prevalence in a herd, a herd with 1,000 calvings per year can expect to see an average net impact ranging from approximately \$3,000 to \$8,000 after postpartum supplementation of oral calcium in multiparous animals.

Key Words: dairy cow, oral calcium, economic impact

T43 Mastitic cows management practices on California dairies.

Pau Pallarés*[1], Arnau Espadamala[1], Alfonso Lago[2], and Noelia Silva-del-Rio[1], [1]*UC Davis School of Veterinary Medicine, VMTRC, Tulare, CA,* [2]*DairyExperts, Tulare, CA.*

Minimizing the risk of antibiotic resistant organisms and antibiotic residues in dairy and dairy beef products is a topic of nationwide interest. However, to design an effective outreach program on judicious use of antibiotics, it is imperative to describe the actual practices on dairies. Thus, our objective was to summarize management and treatment practices for mastitic cows on 15 California dairies as a first step in that outreach effort. Herds ranged in size from 600 to 9,500 cows. Data were collected by 2 bilingual veterinarians during the milking of mastitic cows, based on cow-side observation and responses from dairy employees. Cows identified with mastitis were kept in the same pen ($n = 1$) or moved to the hospital pen ($n = 14$). The hospital pen housed mastitic cows ($n = 5$); mastitic, sick and lame cows ($n = 3$); or mastitic, sick, lame and fresh cows ($n = 6$). Four of the 10 herds housing mastitic and non-mastitic cows in the hospital pen did not clean milking units in between cows. Five dairies were fitted with a milking parlor just for fresh and mastitic cows. Dairies with a single parlor milked the mastitic cow pen last. Mastitic cows were identified during regular milking based on quarter inflammation ($n = 2$) and quarter inflammation and milk appearance ($n = 13$). Two dairies used California Mastitis Test (CMT) for confirmation. Cows with abnormal milk were sampled as soon as they were identified ($n = 2$) or after they were moved to the hospital pen ($n = 8$). Milk culture results were used for selective treatment of mastitis ($n = 4$). The first treatment options were intramammary cephapirin [1 d ($n = 1$), 3 d ($n = 2$), 4 d ($n = 1$) or 5 d ($n = 1$)], ceftiofur [2 d ($n = 1$), 3 d ($n = 4$) or 4 d ($n = 3$)], hetacillin [3 d ($n = 1$)] or intravenous oxytetracycline and sulfamides [5 d ($n = 1$)]. If after treatment completion cows showed abnormal milk ($n = 13$) or positive CMT ($n = 2$) the antibiotic therapy was continued with the same ($n = 10$) or a different ($n = 5$) drug. Milk culture was used on some dairies as a treatment decision tool. Although the antibiotic drug of choice was similar across dairies, the length of treatment varied widely across dairies.

Key Words: dairy cattle, mastitis, intramammary treatment

T44 Concentrations of saturated fatty acids in whole raw milk of dairy cows under different management systems and country of origin: A meta-analytical study.

Grzegorz Zwierzchowski* and Burim Ametaj, *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

The objective of this meta-analytical study was to investigate concentrations of milk saturated fatty acids (SFA) including C4, C6, C8, C10, C12, C14, C15, C16, C17, and C18 in whole raw dairy cow milk from different production systems (conventional [CVN] vs organic (ORG)] and several countries of origin. Data from 18 studies and 13 countries were used to create a data set, which was used for statistical analyses. Data are reported in milk fat percent. The average concentrations of C15 and C17 in the raw milk from ORG system were greater (1.49 vs 1.12 and 1.17 vs 0.61%, respectively) than those from CVN farms ($P < 0.05$). However, no differences were found with regards to concentrations of C4 (3.21 vs 3.17%), C14 (10.70 vs 10.13%), and C16 (28.69 vs 26.82%), in the raw milk between ORG and CNV systems. Also no differences were obtained in the concentration of C6, C8, C10, C12, and C18. On the other hand, country of origin affected concentrations of SFA ($P < 0.05$). For example, raw milk from Ireland had lower amounts of C4 compared with milk from Belgium (1.33 vs 6.26%; $P < 0.05$). Additionally, the greatest concentrations of C6, C8, C10, and C14 were reported in Norway (3.11, 1.95, 4.43, and 13.88%, respectively), whereas the lowermost levels of those fatty acids were reported in Germany (0.82%), Switzerland (0.95%), Mexico (0.91%), and United Kingdom (7.13%), respectively ($P < 0.05$). Average C12 levels varied from 1.97% (Mexico) to 4.83% (Netherlands) ($P < 0.05$). Likewise, milk originating from US had lower means of C15 (0.63 vs 2.53%) and C17 (0.33 vs 1.61%) compared with milk from Germany ($P < 0.05$). Additionally milk form Germany had greater C16 levels compared with milk from UK (15.84 vs 41.31%) ($P < 0.05$). Means of C18 varied from 5.49 to 13.12% (China, $P < 0.05$). In conclusion, data from this meta-analytical study indicated that ORG farms were characterized by greater concentrations of some of the SFA compared with CVN system of management. This study also showed high variability in concentrations of SFA in the raw milk with regards to the country of origin.

Key Words: whole raw milk, saturated fatty acid, meta-analysis

T45 Concentrations of unsaturated fatty acids in the whole raw milk of dairy cows under different management systems and country of origin: A meta-analytical study.

Grzegorz Zwierzchowski* and Burim Ametaj, *Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada.*

The objective of this meta-analytical study was to investigate concentrations of milk unsaturated fatty acids (UFA), including C14:1, C18:1, C18:2, CLA, C18:3, C20:1, C20:2, C20:4, docosapentaenoic (DPA), and eicosapentaenoic acid (EPA) in whole raw bovine milk from different production systems (conventional (CNV) vs organic (ORG)) and countries of origin. Data from 18 studies and 13 countries were used to create a data set, which was used for statistical analyses. Data are reported in milk fat percent. The average concentrations of C18:2 and C18:3 in the raw milk from CNV system were greater (1.94, and 0.60 respectively) than those coming from ORG farms (1.90, and 0.54%, respectively), but difference reached no significance. In addition, there were greater concentrations of C20:4 (0.14%) in the raw milk from CNV vs ORG system (0.11%) ($P < 0.05$). Lower ($P < 0.05$) amounts of C14:1 (0.76%), C20:1 (0.17%), C20:2 (0.03%), and EPA (0.04%) were reported for milk originating from ORG vs CNV (0.97, 0.26, 0.13, and 0.10%, respectively). In addition, no differences with regards to C18:1 ($P = 0.90$), CLA ($P = 0.31$), and DPA ($P = 0.07$), were reported for milk from the ORG vs CNV system. Country of origin had significant effect on concentrations of UFA ($P < 0.05$). The lowermost concentrations of C18:1, C18:2, and C20:4 were reported in Germany ($P < 0.04\%$), whereas the greatest levels of those UFA were reported in Belgium and US ($P < 0.05$). Milk from Poland had lower amounts of C14:1 and C20:1 compared with milk from Germany and Norway, respectively ($P < 0.05$). Average DPA levels varied from 0.01% (Norway) to 0.19% (Switzerland). Moreover, milk from UK had greater means of C18:3 and CLA compared with milk from Norway and Netherlands, respectively ($P < 0.05$). Norwegian milk had greater EPA levels compared with milk from China ($P < 0.05$).In conclusion, data from this meta-analytical study indicated that ORG farms were characterized by greater concentrations of n-3 FA (CLA, DPA, EPA) in the milk compared with milk from the CNV system. This study also showed high variability in concentrations of UFA in raw milk with regards to the country of origin.

Key Words: whole raw milk, unsaturated fatty acid, meta-analysis

T46 Owner and veterinarian involvement on fresh cow health management on California dairies.

Pau Pallarés*[1], Arnau Espadamala[1], Alfonso Lago[2], and Noelia Silva-del-Rio[1], *[1]UC Davis School of Veterinary Medicine, VMTRC, Tulare, CA, [2]DairyExperts, Tulare, CA.*

Minimizing the risk of antibiotic resistant organisms and antibiotic residues in dairy and dairy beef products is a topic of nationwide interest. However, to design an effective outreach program on judicious use of antibiotics, it is imperative to describe the actual practices on dairies. Thus, as a first step in that outreach effort, our objective was to evaluate the involvement of owners and veterinarians on fresh cow (FC) evaluations and to identify who FC evaluators requested advice from. Herds (n = 15) ranged in size from 600 to 9,500 cows. Cow-side observation and responses from FC evaluators were collected by 2 bilingual veterinarians during FC evaluations. Dairy owner conducted FC evaluations (n = 2), supervised FC evaluations (n = 4) or delegated FC evaluations (n = 9). The dairy veterinarian identified and treated cows once a week (n = 2) or every other week (n = 2), provided occasional advice on treatments (n = 7) or they were not involved on FC evaluations (n = 4). Dairies with minimum veterinarian involvement relied on pharmaceutical sales representatives (PSR) and other consultants for advice on herd health. During FC evaluations a single individual identified sick cows and decided on treatments [dairy owner (n = 2), herdsman (n = 5), herdsman assistant (n = 8)]. Evaluators had < 1 yr (n = 2), 1–5 yr (n = 3), > 5 yr (n = 10) of experience. New knowledge was acquired based on formal training [<1 year (n = 4) or 1–5 yr (n = 1) ago], communication with other dairies workers (n = 7), working with more experienced employees at the dairy (n = 7) or through self-teaching (n = 3). Based on FC evaluators, treatments were decided by the owner (n = 8) or manager (n = 7). And, when advice on treatments was needed, the owner (n = 6), the veterinarian (n = 8), or the PSR (n = 1) were consulted. Information on new drugs and treatments came through veterinarians (n = 8), and/or PSR (n = 13). Veterinarians involvement on FC evaluations can be strengthen. Furthermore, many FC evaluators relied on their peers to learn and discuss work related issues. This information suggested that teaching tools that promote peers networking might be of relevance for fresh cow employees.

Key Words: dairy cattle, fresh-cow evaluation, veterinarian

T47 Fresh cow evaluations and treatments on California dairies.

Arnau Espadamala*[1], Pau Pallares[1], Alfonso Lago[2], and Noelia Silva-del-Rio[1], *[1]UC Davis School of Veterinary Medicine, VMTRC, Tulare, CA, [2]DairyExperts, Tulare, CA.*

Minimizing the risk of antibiotic resistant organisms and antibiotic residues in dairy and dairy beef products is a topic of nationwide interest. To design an effective outreach program on judicious use of antibiotics, it is imperative to describe the actual practices on dairies. Thus, our objective was to summarize management and treatment practices for fresh cows (FC) on 15 California dairies (600 to 9,500 cows) as a first step in that outreach effort. Data were collected by 2 bilingual veterinarians during the FC evaluations, based on cow-side observations and responses from dairy employees. Daily (n = 14) or thrice a week (n = 1) FC evaluations and treatments administrations lasted [median (range)] 13.8 (1.5 to 45) s/cow. To identify sick cows evaluators relied on thermometer (n = 1), stethoscope (n = 7) or both (n = 3). All dairies visually inspected cows for abnormal uterine discharge. Twelve dairies evaluated 2 to 5 signs of diseases [rumen fill (n = 7), eyes-ears (n = 7), milk yield / udder fill (n = 7), appetite (n = 7), feces (n = 5), temperature (n = 5)]. Antibiotic therapy was given systematically after eutotic (n = 2), twinning (n = 7) and dystotic calvings [all FC (n = 5), primiparous FC (n = 1), severe cases (n = 7)]. Cows with retained placenta were treated at 24 (n = 8), 48 (n = 4) and 72 (n = 3) h postpartum with systemic ceftiofur (n = 9), penicillin (n = 1) or ampicillin (n = 3), or intrauterine urea or essential oils (n = 2). Cows with foul-smelling vaginal discharge were treated for metritis with NSAIDs (n = 3) and systemic antibiotics [ceftiofur (n = 12), penicillin (n = 2) or ampicillin (n = 1)], as well as with antiseptic (n = 1) or antibiotic (n = 2) uterine flushing. Two dairies used antibiotic uterine flushings if systemic antibiotics were ineffective. Non-foul-smelling abnormal vaginal discharge was treated with uterine antiseptic flushings (n = 4). On 2 dairies, antibiotics were the treatment of choice for sick cows with an unknown disease. In this study we have observed that some dairies used antibiotics either as prophylactic therapy or to treat sick cows with unspecific diagnose. Sick cows identification, disease classification, and treatments were not consistent across dairies.

Key Words: dairy cattle, fresh cow, metritis

T48 Association among gestation length with health, reproduction, and production in Holstein cows. Achilles Vieira-Neto*, Klibs N. Galvao, and Jose E. P. Santos, *University of Florida, Gainesville, FL.*

Objectives were to evaluate the association between gestation length (GL) and incidence of diseases, reproduction, and milk production. The data were screened to eliminate cows with GL longer or shorter than 3 SD from the population mean, resulting in 104 cows excluded from the analyses. Holstein cows (n = 6,254) on a farm using only artificial insemination (AI) were evaluated. Responses measured included the incidences of stillbirth, retained placenta (RP), metritis, mastitis, and other diseases within 90 d in milk (DIM). Pregnancy at first AI and interval to pregnancy were evaluated. Milk yield and removal from the herd by death or culling were recorded for the first 300 DIM. Gestation length was categorized as short (S; at least 1 SD below the population mean; group mean = 266, range 256 to 269), normal (N; population mean ± 1 SD; group mean = 276, range 270 to 282 d), and long (L; > 1 SD above the population mean; group mean = 285, range 283 to 296 d). Data were analyzed by ANOVA, logistic regression, and the Cox's proportional hazard model using the GLIMMIX and PHREG procedures of SAS. Models included the fixed effects of GL category (S, N, L), gender of calf (female, male, twin), parity (1 or >1), season of calving (cool or hot), and all 2-way interactions. Gestation length affected ($P < 0.01$) the incidences of stillbirth (S = 11.4, n = 7.3, L = 6.7%), RP (S = 32.7, n = 10.3, L = 9.4%), metritis (S = 51.1, n = 36.5, L = 33.9%), but not ($P = 0.85$) that of mastitis (S = 4.7, n = 4.0, L = 5.2%). The rate of removal from the herd by culling or death was faster ($P < 0.01$) for S than N (adjusted hazard ratio [HR] = 1.32; 95% CI = 1.10–1.58) and tended ($P = 0.10$) to be faster for L than N (adjusted HR = 1.12; 95% CI = 0.98–1.29). Pregnancy at first AI did not differ ($P = 0.94$) among groups (S = 33.2, n = 34.3, L = 33.5%). The rate of pregnancy was greater ($P < 0.05$) for N than L (adjusted HR = 1.11; 95% CI = 1.02–1.21), but it did not differ between N and S or L and S. Daily milk yield was greater ($P < 0.01$) for N than S or L (S = 35.2, n = 38.1, L = 35.8 ± 0.4 kg/d). Cows with GL within 1 SD of the population mean (range 270 to 282 d) had improved health, reproduction, and production.

Key Words: dairy cow, gestation length, health

T49 Hepatic mRNA expression of genes related to inflammatory and immune responses of dairy cows treated with recombinant bovine somatotropin during the periparturient period. Paula R. B. Silva*[1], Wanda Weber[1], Brian Crooker[1], and Ricardo C. Chebel[1,2], [1]*University of Minnesota, St Paul, MN,* [2]*University of Florida, Gainesville, FL.*

Objectives were to determine the effects recombinant bovine somatotropin (rbST) treatment during the peripartum period on hepatic mRNA expression of genes related to inflammation and immune response. Holstein cows were assigned randomly to receive no treatment (control; n = 10), 87.5 mg (rbST87.5; n = 12), or 125 mg (rbST125; n = 10) of rbST every 7 d from −21 to 21 d relative to calving. Liver biopsies were collected −21, −7, and 7 d relative to calving. Twenty-four genes were assessed by direct molecular counts using NanoString technology. Continuous data were analyzed by ANOVA. Gene expression on d −21 was used as a covariate for analyses of mRNA expression on d −7 and 7. No differences in mRNA expression were observed among treatments on d −21 for any of the genes except SOCS3, which had lower ($P \leq 0.05$) mRNA expression in control cows compared with rbST87.5 cows. On d −7, expression of mRNA for ANGPTL4 and SCARB1 was higher ($P \leq 0.05$) in rbST87.5 and rbST125 than control cows. The rbST87.5 cows had higher ($P \leq 0.05$) mRNA expression for HP, ICAM1, SOCS2 and XBP1 on d −7 than control and rbST125 cows. Control cows had higher ($P \leq 0.05$) mRNA expression for HIF1A than rbST125 cows on d −7. On d 7, control cows had higher ($P \leq 0.05$) mRNA expression for CXCL1, IL1RN, MYD88, NFKBIA, and SOCS3 compared with rbST87.5 and rbST125 cows. Control cows had higher ($P \leq 0.05$) mRNA expression for ICAM1 and XBP1 than rbST125 cows and had higher mRNA expression for HIF1A than rbST87.5 cows. Expression of mRNA for NR3C1 and SOCS2 was lower ($P \leq 0.05$) in control cows than rbST125 and rbST87.5 cows, respectively. Treatment did not affect hepatic expression of CEBPD, JUN, M-CSF1, NFKB1, PPARGC1A, STAT5B, TLR2, TNF, TNFRSF1 and TNFRSF5. Weekly treatment of periparturient cows with rbST regulates liver mRNA expression of genes related to inflammation and immune response during the prepartum and postpartum periods. These rbST-induced changes in gene expression have resulted in improved neutrophil function, antibody production, and reduced incidence of retained placenta and metritis.

Key Words: periparturient cow, recombinant bovine somatotropin, hepatic gene expression

T50 Changes in serum triacylglycerols may indicate disease risk for retained placenta and mastitis in multiparous dairy cows. Fereshteh Zandkarimi, Massimo Bionaz, Jan S. Stevens, Claudia S. Maier, and Gerd Bobe*, *Oregon State University, Corvallis, OR.*

Compromised liver function has been proposed to be involved in the etiology of many diseases in early lactation dairy cows. Examining changes in individual serum triacylglycerols (TAG) may identify previously unknown metabolic pathways involved in the etiology of disease in early lactation. We used ultraperformance liquid chromatography (UPLC) in conjunction with high-resolution accurate mass spectrometry to comprehensively and quantitatively profile individual TAG in serum. The objective of this study was to examine whether individual TAG in serum may serve as disease risk indicators of mastitis, retained placenta, or both. Serum samples were collected from 161 multiparous cows 3, 2, and 1 week before calving and at calving. For this nested case-control study, serum samples of 3 groups of cows that either developed after calving retained placenta (RP; n = 8), mastitis (MA; n = 8), or remained healthy (Healthy; n = 9) were selected and serum levels of individual TAG were measured. Using PROC MIXED, overall and individual TAG levels in serum were compared between groups. The mass spectrometry-driven strategy resulted in the identification and comparative quantification of 24 individual saturated and unsaturated TAG between C48:1 and C54:4. Total TAG levels decreased until calving ($P < 0.0001$). Cows that subsequently developed RP had and tended to have lower TAG levels than cows that subsequently developed mastitis ($P = 0.03$) or remained healthy ($P = 0.12$). Similarly, RP cows had lower TAG with 4 double-bonds compared with Healthy cows ($P = 0.04$) and MA cows ($P = 0.0006$), which could serve as potential RP indicator. In contrast, both diseased groups had lower saturated TAG levels compared with Healthy cows (MA: $P = 0.03$; RP: $P = 0.05$). Consequently, the ratio between TAG with 4 double bonds to saturated TAG was higher in MA cows compared with Healthy ($P = 0.007$) and RP cows ($P = 0.01$), which, thus, could be a potential MA indicator. These findings suggest changes in serum TAG levels are an early indicator for the development of retained placenta and mastitis in multiparous dairy cows.

Key Words: dairy cow, early disease indicator, triacylglycerols

T51 Changes in serum nonesterified fatty acids precede retained placenta and mastitis in multiparous dairy cows.

Fereshteh Zadnkarimi, Massimo Bionaz, Jan S. Stevens, Claudia S. Maier, and Gerd Bobe*, *Oregon State University, Corvallis, OR.*

We previously documented that elevated serum nonesterified fatty acids (NEFA) before calving are a general disease risk indicator in dairy cows. Examining changes in individual or subclasses of NEFA may improve disease risk detection. Untargeted lipid profiling using ultra performance liquid chromatography-high resolution mass spectrometry (UPLC-MS) is a comprehensive technique that allowed simultaneous analysis of individual NEFA in complex biological samples. The objective of this study was to examine the association between serum levels of individual or subclasses of NEFA and subsequent development of diseases. Serum samples were collected from 161 multiparous cows 3, 2, and 1 week before calving and at calving. For this nested case-control study, serum samples of 3 groups of cows that either developed after calving retained placenta (RP: $n = 8$), mastitis (MA: $n = 8$), or remained healthy (Healthy: $n = 9$) were selected and serum levels of individual NEFA were measured. Using PROC MIXED, serum NEFA levels were overall and individually compared between groups. Levels of 22 individual NEFA between C14:0 and C26:0 were above the limit of detection. Overall levels of NEFA identified by UPLC-MS analysis were in good agreement with chemical analysis of total NEFA concentrations. Cows that developed RP and MA in early lactation had 1 week before calving ($P = 0.05$) and at parturition ($P = 0.005$) elevated overall NEFA levels compared with Healthy cows. Similar directional changes were observed for C14:0, C16:0, C16:1, C18:1, as well as the C18:1 to C18:0 ratio, which could serve as general disease risk indicators. In contrast, cows that subsequently developed diseases had lower elongation and/or very long chain fatty acid (≥C20) desaturation indices compared with Healthy cows. MA cows had greater ≥ C20 n6 to ≥ C20 n3 and C20:1 to C20:0 ratios and lower ≥ C20:0 levels compared with Healthy and RP cows, which could be used as potential MA indicators. These findings suggest changes in very long chain fatty acids levels and their ratios are an early indicator for the development of retained placenta and mastitis in multiparous cows.

Key Words: dairy cow, early disease indicator, nonesterified fatty acids

T52 Distribution of most common coagulase-negative species over parity and lactation in Canadian dairy herds.

Larissa A. Z. Condas*[1], Diego B. Nobrega[2,1], Domonique Carson[1], Jeroen De Buck[1], and Herman W. Barkema[1], [1]*University of Calgary, Calgary, AB, Canada,* [2]*Universidade Estadual de Campinas, Campinas, SP, Brazil.*

Coagulase-negative staphylococci (CNS) are the most frequently isolated group of microorganisms from the bovine udder. Research has shown that certain CNS species can be protective, while other species are prone to decrease milk quality and production. Our objective was to describe the distribution of CNS species for the lactation period and parities in Canadian herds, as an initial effort to understand the disease. Cows were sampled randomly across Canada in 2007 and 2008. In total, 1965 cows had udder infection with CNS, being compared with a total of 6067 cows sampled in the study. Chi-squared was used to test different prevalences ($P < 0.05$). The 5 most common CNS species identified in were *S. chromogenes* (49%), *S. simulans* (17%), *S. xylosus* (11%), *S. haemolyticus* (7%) and *S. epidermidis* (4%). Parity and lactation prevalences are presented in Table 1. *S. chromogenes* was predominant in heifers, and its prevalence increased during the lactation. *S. epidermidis* was mostly isolated from older cows and the prevalence did not increase as lactation progressed. *S. haemolyticus* isolated equally often in all parities; its prevalence increased during lactation. *S. simulans* seems to be more isolated in heifers, and its prevalence did not increase over the lactation. *S. xylosus* fluctuates over parities and its prevalence increased during the lactation. The distribution of these CNS species differed over parities and lactation period. The prevalence of species such as *S. chromogenes,* which maybe less pathogenic, was very high in heifers compared with older cows. Throughout lactation, it seems that most species can persist or reinfect udder. Understanding the distribution of CNS species will possibly lead to selective management practices and may lead to identification of species or genotypes that act as protective udder pathogens.

Table 1 (Abstr. T52). Relative frequency (%) of CNS species distribution over parity and over lactation thirds

	Parity				Lactation thirds			
CNS species	1	2	3	≥4	1	2	3	>305 d
S. chromogenes	60	23	24	26	8	8	11	11
S. epidermidis	1	3	3	5	1	1	0.5	1
S. haemolyticus	5	5	6	5	1	1.2	2	2
S. simulans	15	9	10	13	4	2	2	3
S. xylosus	6	9	7	10	1	1	2	3

Key Words: coagulase-negative staphylococci, intramammary infection

T53 Phospholipids are potential early risk indicator for retained placenta and mastitis in multiparous dairy cows.

Fereshteh Zandkarimi, Massimo Bionaz, Jan S. Stevens, Claudia S. Maier, and Gerd Bobe*, *Oregon State University, Corvallis, OR.*

Phospholipids such as phosphatidylcholines (PC), phosphatidylethanolamines (PE), phosphatidylinositols (PI), and phosphatidylserines (PS), have been proposed to be involved with compromised liver function in dairy cows. Examining changes in individual phospholipids may identify potential therapeutic targets of diseases in early lactation. We employed an untargeted mass spectrometry-based lipid profiling strategy to analyze simultaneously individual phospholipids in serum. The objective of this study was to examine whether individual phospholipids in serum may serve as disease risk indicators of mastitis, retained placenta, or both. Serum samples were collected from 161 multiparous cows 3, 2, and 1 week before calving and at calving. For this nested case-control study, serum samples of 3 groups of cows that either developed after calving retained placenta (RP; $n = 8$), mastitis (MA; $n = 8$), or remained healthy (Healthy; $n = 9$) were selected and serum levels of individual phospholipids were measured. Using PROC MIXED, serum levels of phospholipid classes and subclasses were compared between groups. Total PC, lysoPC, and lysoPE levels decreased until calving (all $P < 0.0001$). At calving, cows that subsequently developed mastitis had lower lysoPC, lysoPE, and inositol phosphate levels than cows that subsequently developed RP or remained healthy (lyso PC: both $P = 0.03$; lyso PE: both $P = 0.02$; inositol phosphate: $P = 0.04$ and $P = 0.03$) and thus, could be used as MA indicators. In contrast, RP cows had lower levels of highly unsaturated PS (PS with 4 double bonds) than MA or Healthy cows (both $P = 0.02$), which could serve as RP indicator. These findings suggest changes in phospholipids are an early indicator for the development of retained placenta and mastitis in multiparous cows and may be potential therapeutic targets for diseases in early lactation.

Key Words: dairy cow, early disease indicator, phospholipids

T54 Hoof measurements before and after hoof trimmer intervention on dairy lame cows on California dairies. Marc Pineda*[1], Ibrahim Akin[2], and Noelia Silva-del-Rio[1], [1]*Veterinary Medicine Teaching and Research Center. UC Davis, Tulare, CA,* [2]*Adnan Menderes University Veterinary Faculty Department of Surgery, Aydin, Turkey.*

The objective of this study was to describe lame cow hoof measurements before and after hoof trimmer intervention on California dairies. A total of 17 dairies ranging in size from 1,000 to 10,000 were enrolled in the study. Hoof trimmers were dairy workers (n = 11) or outside service providers (n = 6). Researchers collected information from rear hooves from 10 (n = 15) or 9 (n = 2) lame cows per dairy (dorsal wall length, hoof angle, heel height, and abaxial groove length) before and after the hoof trimmer intervention. Descriptive statistics were analyzed with PROC MEANS, PROC UNIVARIATE and PROC CORR of SAS 9.4. Before the hoof trimmer intervention 10.1% of the hooves had a desirable dorsal wall length (>7 to <8.5 cm). After the hoof trimmer intervention, at least 70% (n = 7) or less than 30% (n = 4) of the hooves were within the desirable range. Dorsal wall length of hooves of the same claw differed by >0.5 cm at least 5% of the time (n = 8). Dorsal wall angle was within a desirable range (³45° to <50°) on 52.2% and 50.9% of the hooves before and after hoof trimmer intervention respectively. After the hoof trimmer intervention, at least 60% (n = 4) or less than 30% (n = 3) of the hooves were within the desirable range. Dorsal wall angle of hooves of the same claw differed by 3° at least 25% of the time (n = 11). Heel height was within > 3.4 to < 4.4 cm on 20.0 and 36.8% of the hooves before and after hoof trimmer intervention respectively. After the hoof trimmer intervention, 5 herds had at least 50% (up to 65%) of hooves with heel height within > 3.4 to < 4.4 cm. Heel height of hooves of the same claw differed by >0.5 cm at least 25% of the time (n = 9). The abaxial groove length was >4.5 cm on 93.5 and 90.8% of the hooves before and after hoof trimmer intervention respectively. The correlation between heel height and abaxial groove length was significant (*P* < 0.01) but with a low correlation coefficient before (r = 0.47) and after (r = 0.20). Our data indicates that there is an opportunity to improve hoof angle of lame cows after hoof trimmer intervention on California dairies.

Key Words: lameness, hoof trimmer, dairy cow

T55 Correlation of ACTH test results with hormonal, metabolic and cardiac stress responses during stress challenge in dairy cows. Lea Fieguth[1], Lena Locher[1], Anja Schacht[1], Akos Kenez[2], Asako Kinoshita[1], Ulrich Meyer[3], Sven Dänicke[3], and Juergen Rehage*[1], [1]*Clinic for Cattle, University of Veterinary Medicine Hannover, Hannover, Germany,* [2]*Department of Physiology, University of Veterinary Medicine Hannover, Hannover, Germany,* [3]*Department of Animal Nutrition, Friedrich-Loeffler-Institute, Braunschweig, Hannover.*

Cows react to stressors with release of cortisol and catecholamines after activation of the hypothalamic-pituitary-adrenal axis (HPA) and of the hypothalamic-adrenal medullary axis, respectively. Increases in heart rate, hyperglycemia, and hyperlipidemia are typical metabolic responses. The extent of the individual stress response depends on individual experience and stress responsiveness. ACTH-test results are assumed to reflect the individual HPA reactivity. The aim of the study was to compare results of the ACTH test with hormonal, metabolic and cardiac stress responses of cows on claw trimming as a typical acute non-painful stressor. In 18 pluriparous German HF cows claw trimming (CT) was performed in lateral recumbency 40 d postpartum (pp). Blood level of cortisol, glucose, and nonesterified fatty acids (NEFA) and heart rate (HR) and heart rate variability (HRV; standard deviation of R-R intervals: SDNN, root mean square of successive differences: RMSSD) were measured at T1: 30 min before CT in the herd, T2: standing at the surgical table, T3: end of claw trimming, T4: 30 min after CT in the herd. ACTH tests were performed on d 110 pp (80 µg/cow ACTH; repeated blood samples for cortisol measurement over 120 min) from which the area under the cortisol time curve (AUC) were assessed. AUC was correlated (SPEARMAN, SAS package) with cortisol, glucose and NEFA blood concentrations as well as HR and HRV at T1-T4and with differences between time points during the CT procedure. AUC correlated positively with T3 cortisol (r: 0.76, *P* = 0.002) and Diff$_{T4\text{-}T1}$ cortisol (r: 0.75, *P* = 0.002), and negatively with T$_4$ NEFA (r: −0.64, *P* = 0.014), T$_4$ HR (r: −0.64, *P* = 0.014), T$_4$ SDNN (r: −0.59, *P* = 0.027), Diff$_{T4\text{-}T3}$ glucose (r: −0.56, *P* = 0.037), Diff$_{T4\text{-}T1}$ NEFA (r:-.73, *P* = 0.003), Diff$_{T4\text{-}T1}$ HR (r:-.71, *P* = 0.005), Diff$_{T4\text{-}T1}$ SDNN (r: −0.65, *P* = 0.012). High ACTH test reactivity was associated with high cortisol level during but a quick decrease to baseline values in blood NEFA and glucose concentrations and in HR, and HRV after CT, which may indicate a close association between individual stress responsiveness and metabolic and cardiac adaptability to stress challenges in cows.

Key Words: ACTH test, stress reactivity, dairy cow

T56 Weather-related cold stress on conception rates in Sim-Angus cattle. Jessica A. Stone* and Julie D. Weathers, *Southeast Missouri State University, Cape Girardeau, MO.*

The purpose of this study was to determine how much correlation there was, if any, between temperature, wind chill factor, and pregnancy results. It has been well documented that weather patterns and temperature will affect reproductive efficiency in cattle, as well as other species. The study was conducted in 2013 and again in 2014, using the similar methods. Because of a change in management, 2012 was not eligible for the study because of inconsistency from the following years. The same population of similarly bred Sim-Angus cattle was inseminated using a fixed timed artificial insemination program of a 14-d CO-Synch + CIDR protocol at the David M. Barton Agriculture Research Center in Gordonville, Missouri. In 2013, 41 Sim-Angus cows participated in the study and in 2014, 17 Sim-Angus cows were used. Only 17 were used in 2014 because the entire herd was split equally to create a fall and spring calving herds. By studying the weather patterns 14 d before and after the day of breeding and comparing the pregnancy results of 2013 and 2014, a correlation was found between the temperature, wind chill factor, and pregnancy results ($r = -0.6$). In 2013, the animals were bred on December 6, where the average temperature was −5°C with a wind chill of −12.94°C at 8:53 a.m. In 2014, the day of breeding was December 12, with an average temperature of 3.88°C and a wind chill of 0.05°C at 8:53 a.m. After comparison of blood samples each year for pregnancy (BioPryn; Moscow, ID), 16 out of 41 animals were pregnant in 2013, giving a conception rate of 39%. In 2014 however, 14 of the 17 animals were bred, giving a conception rate of 82%. More research is forthcoming to determine if this correlation holds true for a larger sample of cattle and more repetitions of the experiment.

Key Words: conception, cold stress, temperature

T57 Number of pigs born alive in parity-1 sows associated with lifetime performance and removal hazard in high- or low-performing herds in Japan. Satomi Tani*, Ryosuke Iida, and Yuzo Koketsu, *Meiji University, Kawasaki, Kanagawa, Japan.*

We compared reproductive performance across parity, lifetime performance and removal hazard of sows in commercial Japanese herds categorized into 3 sow reproductive performance groups and 2 herd productivity groups. The sow group categories were based on the lower and upper 25th percentiles of the number of pigs born alive (PBA) in parity 1, as follows: 8 pigs or fewer, 9–12 pigs and 13 pigs or more. The herds were classified into high- and low-performing herds on the basis of the 50th percentile of pigs weaned per mated female per year. We analyzed 213,514 parity records and 47,024 lifetime records of females entered into 96 herds. Multivariate and single response models were applied to reproductive performance across parity and lifetime performance, respectively, and a proportional hazard model was applied to removal hazard. Sows having 13 or more PBA in parity 1 had 1.0–1.4 more PBA in subsequent parities than sows having 8 or fewer PBA. However, there were no such differences between sow groups for weaning-to-first-mating interval across parity ($P > 0.05$). Also, sows having 13 or more PBA in parity 1 had 3.4–3.7 higher lifetime average PBA than sows having 8 or fewer PBA in both the herd groups ($P < 0.05$). Furthermore, the sows in the low-performing herds with 13 or more PBA in parity 1 also had 2.3 fewer lifetime average nonproductive days than sows having 8 or fewer PBA ($P < 0.05$), although again no similar difference was found for high-performing herds ($P > 0.05$). The removal hazards for a sow having 13 or more PBA in parity 1 were lower than those for a sow having 8 or fewer PBA ($P < 0.05$), with no difference in hazards between the 2 herd groups ($P = 0.62$). In conclusion, PBA in parity 1 can be used to predict a prolific or a low PBA sow. Also, producers in low-performing herds should pay particular attention to sows having low PBA in parity 1 to reduce nonproductive days.

Key Words: cohort study, fertile sow, hazard model

T58 Beneficial effects of a short-term provision of forage to intensively reared broiler chickens. Oluwaseun S. Iyasere, Toluwatope O. Sodipo, and Anuoluwapo V. Subulokun*, *Federal University of Agriculture, Abeokuta, Ogun State, Nigeria.*

Poultry production plays a major role in bridging the protein gap in developing countries. However, the productivity of poultry in the tropics has been limited by scarcity and high prices of the conventional protein and energy sources. In modern day free-range poultry farming, it is generally assumed that the contribution of foraging to nutritional intake is negligible despite the fact that birds still obtain some of their feed requirements from forage. It became imperative to study the effect of the provision of forage on a short-term to broilers reared intensively on deep litter. Thirty-two 5-wk-old broilers (average weight of 1.2kg) of mixed sex were divided into 2 treatments namely concentrate and concentrate-pasture fed birds, each treatment had 4 replicates. Each replicate of birds were housed in separate pens (1.2 × 2.0 cm). Birds were offered either concentrate (200g) or concentrate-pasture (100 g concentrate and 100 g *Tridax procumbens*) every other day for 30 min. The behavior of the birds was scanned at 5 min interval for 30 min, 4 times a week for 2 weeks and the percentage of birds feeding or drinking was recorded. Feed intake and water intake was monitored during the 30 min period. Weight gain was determined at the end of the 2 weeks experimental period. After checking for normality, data were analyzed using independent *t*-test of SPSS statistical package (version 16). Result showed that a greater percentage of birds offered concentrate displayed higher ($P < 0.001$) drinking behavior and drank more water ($P < 0.001$) compared with birds offered concentrate-pasture. The percentage of birds feeding was greater ($P < 0.001$) in birds offered concentrate-pasture feed than those offered only concentrate feed. In conclusion, a short-term provision of broilers with forage (*Tridax procumbens)* alongside their concentrate feed enhanced their feeding behavior and reduced their concentrate intake by 34% without having a negative effect on their body weight gain. Hence, farmers could consider this as a strategy for conserving their expensive feed resources.

Key Words: behavior, body weight gain, broiler

T59 Inosine 5′-monophosphate increases glutamic acid induced cholecystokinin release from bovine proximal small intestine. Erin L. Doherty*, Derek W. Brake, and George A. Perry, *South Dakota State University, Brookings, SD.*

Cholecystokinin (CCK) is a hormone secreted by the proximal small intestine and mediates pancreatic exocrine secretions in response to luminal nutrient flows. Glutamic acid and other amino acids can increase secretions of CCK among mice, dogs, and STC-1 cells. Further, inosine 5′-monophosphate (IMP) can increase amino acid induced CCK release from murine proximal intestine. Our objective was to quantify effects of

IMP on glutamic acid induced CCK release from bovine small intestine. Small intestines were collected at slaughter from 2 steers (638 ± 3.2 kg BW) fed a common dry rolled corn-based diet. The small intestine was measured after removal of digesta, and 1-m sections of duodenum, jejunum and ileum were collected. Each small intestinal section was cut longitudinally, rinsed and serosa was removed before collection of mucosa. Mucosal explants (1-cm in diameter) were incubated (37°C) in HBSS (containing 1.26 m*M* Ca^{2+}) with 20 m*M* HEPES (pH 7.4) and supplemented with 0, 10, 20, or 30 m*M* glutamic acid and 0 or 2.5 m*M* IMP. After 1 h, incubation buffer was collected, centrifuged to remove cellular debris, and frozen (−80°C) before analyses. Cholecystokinin secretions were quantified by radioimmunoassay. Cholecystokinin release was greater ($P < 0.01$) from duodenum (68.5 ± 5.0 p*M*) than from jejunum (8.5 ± 4.9 p*M*) and ileum (2.3 ± 4.9 p*M*). Release of CCK was 529% greater (glutamic acid × IMP <0.01) when proximal small intestine was supplemented with glutamic acid and IMP (2.79 p*M* CCK released / m*M* glutamic acid) than when proximal small intestine was supplemented with glutamic acid alone (0.53 p*M* CCK released / m*M* glutamic acid). Cursory comparisons to previous data suggest that glutamic acid induced CCK release by proximal intestine is less in cattle than in mice; however, IMP enhanced glutamic acid induced CCK release in cattle to a greater extent than previously reported in mice.

Key Words: cattle, cholecystokinin, glutamic acid

T60 Overexpression and inhibition of specificity protein 1 (SP1) affect milk fat formation in goat mammary epithelial cells.

Jiangjiang Zhu* and Jun Luo, *Shaanxi Key Laboratory of Molecular Biology for Agriculture, College of Animal Science and Technology, Northwest A&F University, Yangling, Shaanxi, China.*

The objectives of the present study are to explore the function of SP1 in regulating triglyceride accumulation, droplet formation and the expression of genes associated with fat metabolism in goat mammary epithelial cells (GMECs). Adenovirus was used for SP1 overexpression, siRNA and mithramycin A were used for SP1 silencing and inhibition respectively. GC-MS was used for fatty acid composition analysis. Three repeats was used for qPCR and fatty acid determination. Six repeats were used for triglyceride determination and oil red O staining. The results were expressed as mean ± SD. Data of qPCR were analyzed using the 2^{-DDCt} method. Group data for multiple comparisons were analyzed by ANOVA followed by Tukey's test. Significance was established at a $P < 0.05$. The results showed that overexpression and interference of SP1, using adenovirus and siRNA respectively, significantly reduced the content of cellular triglyceride and suppressed the accumulation of lipid droplets, and altered the expression of genes related to lipid metabolism. These data indicated that PPARγ and LXRα might have affected the role of SP1 in regulating other genes related to fatty acid uptake (CD36 and LPL), de novo fatty acid synthesis (FASN and ACACA), fatty acid elongation and desaturation (EVOLV6, SCD and FADS2), fatty acid transport (ACSL1, ACSS2 and FABP3), triglyceride synthesis (AGPAT6, LPIN1, DGAT1 and DGAT2), lipid droplet formation and secretion (TIP47, ADFP and XDH), and triglyceride hydrolysis (ATGL and HSL). But expression of SREBP1 was not affected by manipulation of SP1 despite of the crucial role in regulating de novo fatty acid synthesis. To support the results on triglyceride accumulation, adenovirus and mithramycin A, an inhibitor of SP1, was used to treat GMECs. The result showed that, similar to the decrease of triglyceride accumulation, both inhibition and overexpression of SP1 increased the relative content of saturated fatty acids, including C16:0, C14:0 and decreased the content of C18:1 which is important for triglyceride synthesis in GMECs. In conclusion, the findings provide a novel insight of SP1 function in regulating lipid metabolism in GMECs, and also provide novel method for dairy goat breeding.

Key Words: dairy goat, specificity protein 1 (SP1), milk fat metabolism

T61 Effects of plant-derived compounds on *Staphylococcus aureus* infection of primary bovine mammary epithelial cells.

Ellen V. Valley*[1], Devi Jaganathan[1], Kumar Venkitanarayanan[1], Gary W. Kazmer[1], Lynn Kuo[2], Yu Bo Wang[2], and Kristen E. Govoni[1], *[1]Department of Animal Science, University of Connecticut, Storrs, CT, [2]Department of Statistics, University of Connecticut, Storrs, CT.*

Mastitis is an inflammation of the mammary gland which results in losses to the dairy industry due to discarded milk, poor milk quality and culling. Plant-derived antimicrobials (PDA) have inhibitory effects on *Staphylococcus aureus*, an economically important cause of mastitis, and have less potential to induce bacterial antimicrobial resistance. We hypothesized that (1) eugenol (EG) and *trans*-cinnamaldehyde (TC) would reduce *S. aureus* adhesion to and invasion of primary bovine mammary epithelial cells (MEC), and (2) EG and TC would alter the expression of virulence factors in *S. aureus* and immune response genes in MEC. Mammary epithelial cells were collected from a lactating dairy cow at slaughter and isolated by selective trypsinization. Four strains of *S. aureus*, Thorn 17, S35, M9175, and Thorn 15, were obtained from the Connecticut Veterinary Medical Diagnostic Laboratory. Before inoculation, MEC and *S. aureus* were incubated at 37°C for 12 and 5 h, respectively, with sub-inhibitory concentrations (SIC, concentrations not inhibiting bacterial growth) of EG (0.03%) and TC (0.006%). Mammary epithelial cells were challenged with *S. aureus* in mid log phase and incubated for 2 h at 37°C. To quantify adhesion, cells were washed with PBS to remove unadhered bacteria and lysed with Triton-X. Lysed cells were serially diluted and plated on mannitol salt agar, and colonies were counted after 48 h. To quantify invasion, cells were incubated for 1 h with gentamycin before washing, lysing, and plating as performed for the adhesion assay. Experiments included MEC and *S. aureus* as controls, MEC or *S. aureus* pre-treated with PDA, and MEC and *S. aureus* both pre-treated with PDA (9 treatments). Experiments were performed in duplicate and repeated 3 times. Data were analyzed using PROC MIXED in SAS. For all strains, adhesion was reduced 0.2 to 0.8 $\log_{10}$ cfu/mL ($P \leq 0.05$) and invasion was reduced 1.7 to 3.8 $\log_{10}$ cfu/mL ($P \leq 0.05$). Gene expression analysis is currently underway. In conclusion, SIC of EG and TC effectively reduced *S. aureus* infection of MEC.

Key Words: bovine, mastitis, plant-derived antimicrobial

T62 Extended-spectrum cephalosporin, carbapenem, and fluoroquinolone-resistant gram-negative coliform bacteria present on equine environmental surfaces.

Rachael Adams*[2], Dixie Mollenkopf[1], Dimitria Mathys[1], Joshua Daniels[1], and Thomas Wittum[1], *[1]The Ohio State University College of Veterinary Medicine, Columbus, OH, [2]The Ohio State University College of Food, Agricultural, and Environmental Sciences, Columbus, OH.*

Antimicrobial resistant bacteria are a rapidly growing concern in human and veterinary medicine. The rising prevalence of extended spectrum β-lactamase (ESBL), AmpC β-lactamase, carbapenemase (CRE), and fluoroquinolone-resistant *Enterobacteriaceae* continually decreases the efficiency of vital antibiotics. Moreover, antibiotic resistant enteric bacteria are zoonotic and can be transmitted between horses and people. Our objective was to evaluate the prevalence of antibiotic resistant bacteria on human contact surfaces in equine environments. Environmental surfaces in 20 Ohio equine barns were sampled using 2 electrostatic cloths (Swiffer), yielding a total of 242 samples. Samples were phenotypically screened for AmpC, ESBL, CRE, and fluoroquinolone resistance using selective media. To select for cephalosporinase phenotypes, samples were incubated at 37°C in nutrient broth with 2 μg/mL cefotaxime. This broth was aseptically inoculated to MacConkey agar with 8 μg/mL cefoxitin, 4 μg/mL cefepime, and 1 μg/mL meropenem to detect AmpC, ESBL, and CRE phenotypes, respectively. Additionally, samples were incubated in nutrient broth with 16 μg/mL naladixic acid and then inoculated to MacConkey agar with 16 μg/mL naladixic acid and 2 μg/mL ciprofloxacin to detect fluoroquinolone resistance phenotypes. Genotypes were confirmed using standard PCR techniques. Of the coliform bacteria isolated from each surface, 49 (24.5%) were cefoxitin resistant, 25 (12.5%) were naladixic acid resistant, 13 (6.5%) were cefepime resistant, and 9 (4.5%) were ciprofloxacin resistant. Drains and wash stalls were most commonly contaminated at 17 resistant isolates, followed by handles of mucky equipment at 15 resistant isolates. These results indicate that equine environmental surfaces are contaminated with resistant bacteria that can potentially be transmitted between human and horse populations. Furthermore, detecting these bacteria on common human contact surfaces suggests that the environment can serve as a reservoir for antibiotic resistance genes. Identifying interventions to lower the prevalence of antibiotic resistant bacteria in equine environments will protect both animal and public health.

Key Words: antibiotic resistance, equine, environmental

T63 Interleukin-6, tumor necrosis factor-α, insulin-like growth factor-1 and fibroblast growth factor-2 alter proliferation and differentiation of equine satellite cells.

Emma K. LaVigne*[1], Alfredo Sanchez Londoño[2], and Sarah A. Reed[1], [1]*Department of Animal Science, University of Connecticut, Storrs, CT,* [2]*Department of Environmental and Population Health, Cummings School of Veterinary Medicine at Tufts University, North Grafton, MA.*

Muscle growth in young horses occurs by hypertrophy of individual muscle fibers, which can be accomplished through the activation and differentiation of satellite cells. Satellite cells are muscle stem cells that reside between the sarcolemma and the basal lamina of the muscle fiber and can be stimulated or inhibited in response to different cytokines and growth factors. We hypothesized that interleukin (IL)-6, tumor necrosis factor (TNF)-α, insulin-like growth factor (IGF)-1 and fibroblast growth factor (FGF)-2 would alter proliferation and differentiation in satellite cells isolated from young horses. Satellite cells obtained from 10 d old foals (n = 4) were cultured individually in the presence of 10 ng/mL IL-6, 20 ng/mL TNF-α, 25 ng/mL IGF-1 or 10 ng/mL FGF-2 to determine the effects on proliferation and differentiation (3 wells per treatment group per horse). Proliferation was measured by incorporation of 5-ethynyl-2'-deoxyuridine (EdU) into cells in S phase. Differentiation was measured by quantifying the fusion index (the number of nuclei present in multinucleated myofibers divided by the total number of nuclei). Data were analyzed using the MIXED procedure in SAS; $P < 0.05$ was considered significant. Interleukin-6 and TNF-α decreased satellite cell proliferation compared with control cells (14.9% and 11.5%, respectively; $P \leq 0.01$). Fusion into myotubes was increased 6.2% in the presence of IL-6 ($P = 0.001$) but decreased 8.7% by TNF-α ($P < 0.0001$). Satellite cell proliferation was increased 28.8% in the presence of IGF-1 ($P < 0.0001$) and 73.0% in the presence of FGF-2 ($P < 0.0001$) compared with controls. Insulin-like growth factor-1 increased fusion 3.5% ($P = 0.0087$) and FGF-2 decreased fusion 13.1% ($P < 0.0001$). By differentially stimulating or inhibiting proliferation and fusion of satellite cells, IL-6, TNF-α, IGF-1 and FGF-2 significantly affect muscle hypertrophy. Dysregulation of these cytokines or growth factors, therefore, can lead to detrimental muscle degradation, inflammation, and impaired growth.

Key Words: satellite cells, horse, inflammation

T64 Effects of varying anthelmintic formulations on hindgut microflora in horses.

John Rowe*, Katelyn Barnhart, Elizabeth Share, John Mark Reddish, and Kimberly Cole, *The Ohio State University College of Food, Agricultural, and Environmental Sciences, Columbus, OH.*

Horses house a dynamic population of microbes within their hindgut that can be disrupted by diet, stress, and medication. Horses are routinely given anthelmintic drugs to reduce internal parasite loads and although their modes of action are well known, there is a lack of knowledge of their effect on the gastrointestinal microflora in horses. The objective of this study was to monitor changes in hindgut microflora after treatment with 2 pyrantel anthelmintic formulations. Ten non-pregnant Quarter Horse mares (8.0 ± 6.0 yr) were randomly assigned to 1 of 2 treatment groups: Paste or Pellet. Throughout the study, all mares continued to receive their basal diet of 0.5% BW of a 12% CP pelleted concentrate with mixed grass hay and water ad libitum. Mares in the Paste group received one dose (0.9 g per 136 kg BW) of pyrantel pamoate paste. Fecal samples were collected immediately before treatment (d 0) and on d 1, 2, 3, 7, 10, and 14 post-treatment. Mares in the Pellet group received pyrantel tartrate pellets (28.3 g per 113 kg bw) once daily for 14 d. Fecal samples were collected immediately before treatment (d 0) and on d 1, 2, 3, 7, 10, and 14 of treatment as well as d 1, 2, 3, 7, 10, and 14 post-treatment. Pooled fecal samples from d 0 served as the untreated controls. DNA was extracted from fecal samples and subjected to PCR-DGGE with universal primers specific to the V2-V3 region of the 16S rRNA gene. PCR-DGGE images were analyzed with BioNumerics software to generate dendrogram comparisons based on the position and number of bands with further evaluation using principal coordinate analysis (PCA). Dendrograms and PCA revealed clustering by time in both groups indicating that pyrantel anthelmintic treatment influenced hindgut microbial diversity. Additional research identifying specific changes in the microbial profiles is needed to better understand the influence of anthelmintic products on the hindgut microflora of horses.

Key Words: equine, microflora, anthelmintic

T65 Effects of poor maternal nutrition during gestation on protein expression in the liver of lambs.

Katelyn K. McFadden*, Maria L. Hoffman, Kristen N. Peck, Sarah A. Reed, Steven A. Zinn, and Kristen E. Govoni, *Department of Animal Science, University of Connecticut, Storrs, CT.*

Poor maternal nutrition during gestation can reduce growth and circulating growth factors secreted by the liver, as well as alter lipid metabolism; however, the mechanisms involved are not well understood. Previously, we reported that poor maternal nutrition altered liver expression of genes involved in lipid metabolism and the somatotropic axis in the offspring. Therefore, we hypothesized that poor maternal nutrition during gestation would alter expression of key proteins involved in lipid metabolism and the somatotropic axis in the liver of offspring. Multiparous ewes (n = 36) were individually housed and fed 100, 60, or 140% of NRC requirements beginning at d 31 ± 1.3 of gestation. Lambs were euthanized within 24 h of birth (1 d; n = 18) or at 3 mo of age (n = 15). Lambs from ewes fed 100, 60, or 140% will be referred to as CON, RES, and OVER, respectively. At euthanasia, whole livers were harvested, weighed and tissue samples collected. Protein was determined by Western immunoblot. Proteins were imaged using an Odyssey CLx Imaging System and quantified using Image Studio Lite program. Data were analyzed using PROC GLM. As previously reported, BW were 13% greater in OVER vs. CON at 1 d and 3 mo. Liver weight was 43% greater in OVER vs. CON at 1 d when adjusted for BW, but not at 3 mo. Based on previously determined changes in gene expression in the liver, sterol-regulatory element binding protein-I (SREBP-I), a regulatory gene of hepatic lipogenesis, IGF binding protein-4 (IGFBP-4) and IGFBP-3 were evaluated. At 3 mo, IGFBP-3 expression increased 16% in OVER vs. CON ($P = 0.03$) and IGFBP-4 tended to increase 88% in RES vs. CON ($P = 0.08$). Maternal diet did not affect protein expression of IGFBP-3 or −4 at 1 d or SREBP-I at either time point ($P \geq 0.11$). The observed increase in IGFBP-3 protein expression in OVER parallels previously determined increases in gene expression and circulating concentrations of IGFBP-3. In conclusion, poor maternal nutrition alters gene, protein, and circulating concentrations of key growth factors, such as IGFBP-3, which may contribute to altered growth of offspring.

Key Words: IGF binding protein, liver, maternal nutrition

T66 Effects of rubber covers for concrete slats on lameness in confined feedlots.

Bryant R. Chapman*, Derrick S. Smith, Colleen N. Curtiss, Monica J. Atkin, Steven R. Rust, and Daniel L. Grooms, *Michigan State University, East Lansing, MI.*

The second most significant health issue for fed cattle in the US is lameness and is viewed as a major welfare issue in animal agriculture. Lameness tends to be more problematic for cattle housed in facilities with slatted floors. The objective of this study was to evaluate the effectiveness of rubber covered slatted floors for reduction of lameness, tail injury incidence, and improvement of overall performance. Angus-based steers (250 to 300 kg) were assigned randomly to pens with non-covered concrete slats (NC;n = 4) or concrete slats covered with rubber (RC;n = 4). Each pen contained 7 steers at a stocking density of 6.9 m^2/steer. Cattle were on feed for 110 to 131 d. Locomotion scores, tail lesions, left carpal joint circumference, and hoof dimensions were recorded. Average daily gain, feed conversion efficiency, cleanliness, and carcass traits were collected and reported in a companion abstract. Hide cleanliness was graded on a scale of 0 to 9, with 0 being less than 5% soiled and 9 being completely soiled. Locomotion scores were recorded on a 0 to 3 scale, where 0 was a normal gait and 3 was severely lame. Tail tip injury was recorded on a scale of 0 to 3, where 0 had no visible lesions and 3 had open wounds. Locomotion scores, left carpal joint circumference, and tail lesions did not differ between treatments. The toe length of cattle housed on the RC was longer than NC (77.3 vs. 84.0; $P < 0.01$). A trend for sharper angle of the hoof was observed for cattle on NC compared with RC (55.5 vs. 52.5; $P < 0.16$). A positive correlation was detected between the angle of the front hoof and the carpal joint circumference ($r = 0.77$; $P < 0.03$). Positive correlations were detected between hide soiling vs. the front toe length ($r = 0.71$; $P < 0.05$) and angles between the front and rear hooves ($r = 0.62$; $P < 0.10$). In summary, provision of rubber covers for concrete slats had minor effects on overall cattle lameness.

Key Words: lameness, welfare, tail lesion

T67 Associations between animal performance measures and rumen pH of growing feedlot steers in drought simulated conditions.

Sara E. Place[1], Michelle S. Calvo-Lorenzo[1], Clint R. Krehbiel[1], Christopher J. Richards[1], Douglas L. Step[2], Kristi Allwardt[1], Catherine L. Haviland[1], Emily A. Andreini[1], Jacob Reed[1], Andrew Grimes[1], Ashley Broocks[1], Justin L. Lyles[1], Kyre E. Larrabee*[1], Kimberly Branham[1], Megan M. Rolf[1], *[1]Department of Animal Science, Oklahoma State University, Stillwater, OK, [2]Veterinary Clinical Sciences, Oklahoma State University, Stillwater, OK.*

Located in the drought stricken Southern Great Plains, Oklahoma is an ideal site to investigate the associations between decreased water availability and cattle performance. The objectives of this research were to investigate the effects of restricted water intake (WI) on animal performance, and associations between animal performance and rumen pH. These data are part of a larger 5 yr project that will develop selection and management tools to adapt cattle to drought conditions. The data were collected from 117 cross-bred steers (*Bos taurus*) that were blocked by BW upon arrival to the Willard Sparks Beef Research Center at Oklahoma State University in Stillwater. Steers were housed in 4 identical pens each equipped with an Insentec feed and water intake system consisting of 6 feed bunks and 1 waterer per pen, which allowed for individual DMI and WI collection. Following a 21 d adaptation, a 70 d feed and WI collection trial was conducted to establish baseline WI for each individual steer. Following the 70 d trial, steers had their WI reduced 10% of baseline weekly for 4 wks to achieve a 50% of baseline WI restriction. After 1 wk of adaptation, cattle were maintained at 50% WI restriction for 35 d to simulate reductions of WI due to decreased water quality, quantity, and increased temperature that cattle would experience during drought events. Steers were weighed every 14 d. Prior to and after water restriction, rumen fluid was collected for each steer via rumenocentesis and the pH was immediately measured. Associations between DMI, WI, ADG, and rumen fluid pH before and after water restriction and the effects of water restriction on ADG were investigated using Proc Corr and Proc GLM procedures in SAS (SAS Institute, Cary, NC), respectively. Rumen fluid pH was not associated with any steer performance measures ($P > 0.05$). Water restriction significantly reduced steer ADG and DMI by 23% and 19% ($P < 0.001$), respectively, and rumen pH was increased during restriction ($P = 0.0141$). These data suggest drought conditions negatively affect steer performance, emphasizing the importance of selection and management tools to adapt beef cattle production to drought conditions.

Key Words: climate adaptation, drought, cattle

T68 Macrominerals requirements for growth of Canindé goats.

Luana P. S. Ribeiro*[1], Ariosvaldo N. Medeiros[2], Francisco F. R. Carvalho[3], Elzânia S. Pereira[4], Anaiane P. Souza[5], José Maurício S. Neto[5], Cláudio G. S. Junior[2], Gabriel C. L. Branco[2], and Andreia B. Bezerra[2], *[1]Federal University of Bahia, Salvador, Bahia, Brazil, [2]Federal University of Paraíba, Areia, Paraiba, Brazil, [3]Federal University Rural of Pernambuco, Recife, Pernambuco, Brazil, [4]Federal University Ceará, Fortaleza, Ceara, Brazil, [5]State University Sao Paulo, Jaboticabal, Sao Paulo, Brazil.*

Minerals are important constituents of structural tissues, metabolism and body fluids; however, the mineral nutritional requirements remain poorly quantified in goats. In fact, the values are estimated from other species. Therefore, the objective of this study was to predict the net requirement of Ca, P, Mg, Na, and K for growth of Canindé kids. Thirty 3 castrated kids (15.65 ± 0.41 kg of initial BW) were used, 5 of which were slaughtered at the beginning of the experiment to determine the initial body composition. The 28 remaining goats were distributed in a completely randomized design, kept in individual pens, and fed 4 levels (treatments) of intake: 1) ad libitum (100%), 2) 80%, 3) 60%, and 4) 40%. The diet consisted of 55% forage (Tifton) and 45% concentrate. The goats were slaughtered when the animals fed ad libitum reached 26.55 ± 0.65 kg of BW. The carcasses and organs were weighed, homogenized and sampled for chemical analysis. A comparative slaughter method for assessing body composition and estimation of nutritional requirements was used (Garret et al., 1959). The data were analyzed by the REG procedure of SAS. Body composition were estimated from the predicted equation obtained by regressing the logarithm of the weight of each mineral in the empty body, for animals with 15 to 25 kg. The values (g kg-1 EBW) for Ca, P, Mg, K and Na ranged from 10.49 to 12.59, 8.08 to 7.16, 0.18 to 0.44, 1.63 to 1.37, and 1.59 to 4.09, respectively. The net requirements for growth were estimated by the first derivative of the allometric equations. The values (g kg-1 EBW) for Ca, P, Mg, K and Na ranged from 10.91 to 13.83, 5.00 to 4.67, 0.36 to 0.93, 1.40 to 1.75 and 3.34 to 9.06, respectively. This study indicates that indigenous goats have lower requirements of Ca, Mg and Na, and greater requirements of P and K when compared with current feeding system recommendations.

Key Words: body composition, goat, nutrition

T69 Back to basics: Are beef cattle good at showing estrus? An assessment of estrus response, length of sexual receptivity, follicular growth, and pregnancy rate in beef cattle following a 5-day CO-Synch + CIDR estrus synchronization program.

Victoria Morrow*, Shannon Edwards, Stephanie Webb, Jeremy Hemmer, Jennifer Bouland, Steve Parish, and Martin Maquivar, *Washington State University, Pullman, WA.*

The development of estrus synchronization protocols that facilitate fixed time artificial insemination (FTAI) in beef cattle has resulted in variable pregnancy rates. This variability has been attributed to different factors such as expression of sexual behavior, and follicular dynamics. The objective of the present study was to assess the onset of estrus response, estrus length, follicular growth, and size at AI using the 5 d-CO-Synch + CIDR program. One hundred and 3 females (81 cows and 22 heifers) were synchronized with an administration of 100 µg of GnRH IM and an intravaginal controlled internal drug release (CIDR) at d −5. At d 0, the CIDR was withdrawn and 2 doses of PGF2-α (25 mg) were administered via IM 6 h apart. Animals were observed continuously for behavioral signs of heat after CIDR removal until either 56 h (FTAI for heifers) or 72 h (FTAI for cows). At AI all animals received 100 µg of GnRH IM. Pregnancy diagnosis was performed approximately 60 d after FTAI. Results were analyzed by PROC MIXED procedure using a 2 × 2 factorial arrangement (pregnancy status and expression of heat). No differences where observed between heifers and cows. Overall, the proportion of animals showing sexual behavior was 45% (46/103), where 22% (10/46) did not get pregnant. No differences ($P > 0.05$) were detected between animals that showed estrus and became pregnant (n = 36) or showed estrus and were non pregnant (n = 10) at onset of sexual receptivity (52:09 h vs 46:30 h) and length of estrus (6:05 h vs 6:36 h) respectively. Non pregnant animals without estrus expression had the smallest follicle size at AI ($P = 0.04$), however no differences were observed in follicular growth. Pregnancy rate at FTAI was similar among animals regardless expression of estrus. In conclusion, the lack of reproductive response in animals submitted to a FTAI synchronization program can be related to a reduction in follicular size at FTAI and absence of estrus behavior.

Key Words: estrus expression, beef cattle, reproductive management

T70 Single nose ringed swine behavior in free-range production system.

Patrícia M. Gomes*[1], Amanda R. R. Cabral[1], Jacqueline N. Paiva[1], Karoline M. Silva[1], Frederico L. Silva[1], Felipe H. Soares[1], Carlos A. Silva Júnior[1], Julia E. G. N. Perini[2], Jessica M. Araujo[1], Angela P. Santana[1], and Luci S. Murata[1], *[1]University of Brasilia, Brasilia, Federal District, Brazil, [2]Brasilia Federal Institute, Brasilia, Federal District, Brazil.*

Single nose ring is commonly used in free-range swine production to control pasture and soil degradation. To evaluate the behavior frequency in multiparous non-pregnant sows, a trial was carried out with 2 treatments, ringed and control, with 4 sows each. The trial was divided based on cicatrization process: inflammation, proliferation and remodeling, during 23 d. The chosen method to evaluate the behavior after nose ring insertion was scan, consisting in observation every 10 min, 6 h a day (morning and evening). Twelve categories of behavior were used in scan sampling: rooting, tree rubbing, tree bark chewing, digging, wallowing, grazing, alert, resting, positive social interaction, negative social interaction, drinking and sniffing. Each group of sows were allocated in a 1000-m^2 paddock, limited with solar electric fences, in exotic *B. decumbens* pasture and with push-lever bowl drinker. Sows were fed with commercial regular mash diet twice a day. Results showed that ringed sows spend 60.65% of the time resting, while control group spend 47.46% ($P < 0.01$). Rooting behavior was not observed in the ringed group, whereas control group demonstrated it for 0.63% of the time. Digging was seen in ringed group, in a frequency of 0.24%, and was not observed in control sows. Sniffing in ringed group was seen in 3.52% of the time and 13.17% in the control group ($P < 0.01$). During inflammation phase, rooting, tree rubbing and tree bark chewing were seen in control group (0.57%, 0.43%, 0.14% respectively) and were not observed in ringed group. In proliferation phase the ringed group already showed tree bark chewing and tree rubbing (both with 0.33%) whereas for the control group the frequencies were 0.55% and 0.22% (ns). In remodeling phase control group showed 0.88% for rooting, 0.88% for tree rubbing and 1.1% for tree bark chewing, while ringed sows were not observed with the first 2 behaviors and with 0.22% (ns) of the last. The trial showed that the ring insertion changed the behavior of the sows, resulting in more time resting. Rooting behavior was absent in ringed group during observations and signals of adaptations were seen, because digging was a behavior not seen in control group and present in ring inserted sows.

Key Words: sustainability, rooting, welfare

T71 Conception rates of beef heifers and cows based on facilities.

Miriam A. Snider* and Julie D. Weathers, *Southeast Missouri State University, Cape Girardeau, MO.*

Two breeding experiments conducted over a 2-year period were conducted to determine if conception rates in beef heifers and cows were affected in response to breeding facilities. The study compared the traditional squeeze chute and the insemination barn with timed artificial insemination programs. The heifer groups were given the 14 d CIDR-PG and cow groups the 7 d CO-Synch + CIDR protocol to determine whether conception rates are affected by insemination within a squeeze chute or insemination within an insemination barn. In Experiment 1, 17 beef heifers at the Barton Agricultural Research Center in Gordonville, Missouri were artificially inseminated following standard protocols. Cattle numbers were selected at random to determine which animals would be bred in the insemination barn or within the squeeze chute. Technicians were alternated so that each technician inseminated half of the animals in each facility setting. Ultrasound technology was used to determine which heifers were pregnant. Results indicated that 87.5% of heifers bred in the squeeze chute became pregnant as compared with 37.5% ($P \leq 0.05$) of heifers bred in the insemination barn. Experiment 2 largely consisted of the same process. This time, however, 17 beef cows were inseminated. BioPryn (Moscow, ID) blood tests were used to confirm pregnancy within the cow population 30 d following insemination.

Results indicated that 88.89% of the cows bred in the squeeze chute became pregnant whereas only 75% ($P \leq 0.10$) in the insemination barn became pregnant. This indicates on average a 31.94% ($P \leq 0.05$) higher rate of pregnancy from breeding in a traditional squeeze chute compared with the insemination barn. Future studies will include larger sample sizes of cattle and take into account technician preferences.

Key Words: conception, insemination barn, squeeze chute

T72 A comparison of Dorper and Blackface lambs in growth and carcass performance.

Kayley R. Wall* and Chris R. Kerth, *Texas A&M University, College Station, TX.*

To determine the suitability of a purebred Dorper as a meat animal in a production setting, the growth and carcass traits of Blackface April–born lambs (n = 8) grown on a concentrate diet were compared with Dorper September–born lambs (n = 8). All lambs were fed a concentrate diet (16% CP, 3% crude fat, 9% crude fiber) ad libitum in separate pens for 18 d before the start and for the duration of the study (62 d). The initial (0 d) and final (62 d) BW, percent change in BW, ADG, and G:F were measured. One Blackface lamb died during the feeding trial. All of the lambs were harvested on d 62 and placed into the blast chiller (4°C) for 15 h after hot carcass weights were recorded. Carcass data were collected 16 d postmortem. The carcasses were ribbed and allowed to bloom for 1 h before marbling, fat thickness, LM area, leg confirmation score, KPH %, flank streaking, and lean color (L*, a*, and b*) were collected. Data were analyzed using a one-way ANOVA of a completely randomized design with animal as the experimental unit and α set at 5%. Average daily gain and G:F were not affected ($P > 0.47$) by lamb breed, but percentage change in BW tended ($P = 0.099$) to be higher in Dorper sheep compared with Blackface sheep. Fat thickness, marbling, flank streaking and KPH % were higher ($P < 0.014$) in the Blackface than Dorper lambs. The Blackface lambs also had heavier ($P < 0.001$) live and hot carcass weights than the Dorper lambs; however, there were no significant differences ($P > 0.13$) between the breeds in LM area and dressing percentage, despite the age difference of the lambs. Dorper lambs had lighter (higher L* values; $P = 0.001$) and less red (lower a* values; $P = 0.041$) lean, but b* values were not affected ($P = 0.62$) by breed. Although the Blackface lambs were fatter and had higher BW and HCW compared with the Dorper lambs, they did not outperform them in growth, dressing percent, or LM area. We believe the Dorper could be a suitable competitor to the Blackface in a production system as a meat-producing animal.

Key Words: Dorper, lamb

T73 Gait score of broilers supplemented with vitamin D (25-OHD$_3$).

Grace Alessandra Araujo Baldo*[1], Ibiara Correia de Lima Almeida Paz[1], Edivaldo Antônio Garcia[1], Andréa Britto Molino[1], and Marlon Sávio Amadori[2], [1]*School of Veterinary Medicine of Animal Science, UNESP, Botucatu, SP, Brazil,* [2]*School of Agricultural Sciences, UFGD, Dourados, MS, Brazil.*

The aim of this study was evaluated the gait score of broilers supplemented with vitamin D. For this, we used 2400 broilers distributed in a randomized blocks allocated in factorial design 2 × 2 × 2, being males and females, strains Cobb 500 and Ross 308, supplemented or not with vitamin D (25-OHD$_3$). The diets were formulated following the requirements of each phase and added to 69 mg of 25-OHD$_3$/t of feed in the supplemented treatments. After 41 d evaluated the gait score and, for this, 100% of the birds were put to walk in the path of a bounded linear meter inside the boxes. The way the birds walked was ranked scores ranging from 0 to 2, being gait score 0 bird that walked normally, gait score 1 bird which was difficult to walk and gait score 2 bird that walked with difficulty. We used the Chi-Square at a significance level of 5%. Females had higher ($P < 0.05$) frequency of gait score 0 (88.41%) and males had a higher frequency of gait score 1 (16.26%). The Cobb 500 strain of birds had higher ($P < 0.05$) incidence of gait score 0 (87.79%) when compared with the Ross 308 (83.10%). Supplementation with vitamin D (25-OHD$_3$) did not affect ($P > 0.05$) the gait score of birds. Therefore, it was concluded that vitamin D (25-OHD$_3$) did not improve the way of walking (gait score) of broilers.

Key Words: animal welfare, poultry production, way of walking

T74 Effects of corn particle size and diet form on nursery pig growth performance.

Ashton D. Yoder*, Grace E. Bokelman, and Cassandra K. Jones, [1]*Kansas State University, Manhattan, KS.*

A total of 180 nursery pigs (PIC 327 × 1050; 36 d of age; initially 16.1 kg) were utilized in a 35-d experiment to determine the effects of corn particle size and pelleting on nursery pig growth performance. All diets were nutritionally similar, but processing parameters created 4 experimental treatments in a 2 × 2 factorial with 2 corn particle sizes (500 µm vs. 750 µm) and 2 diet forms (mash vs. pelleted). Pigs were weaned on d 26 of age, blocked by initial BW, and fed a pelleted acclimation diet for 10 d. On d 0 of the experiment, pigs were randomly assigned to pens in a randomized complete block design with 5 pigs per pen and 9 replications per treatment. Experimental diets were fed in 2 phases: d 0 to 14 and d 14 to 35. Data were analyzed using the GLIMMIX procedure of SAS. Reducing particle size from 750 to 500 µm did not affect growth performance ($P > 0.44$). Pelleting reduced ($P < 0.05$) feed intake compared with feeding mash diets during each phase and overall, but did not affect ADG or G:F ($P > 0.11$). The interaction between particle size and diet form affected G:F from d 0 to 14, where finely ground mash diets or coarsely ground pelleted diets had greater feed efficiency than finely ground pelleted diets or coarsely ground mash diets ($P = 0.04$; 0.72, 0.68, 0.68, and 0.74 for 500 µm mash, 500 µm pelleted, 750 µm mash, and 750 µm pelleted diets, respectively). Additionally, the interaction tended to affect ADG from d 0 to 14 and overall where pigs fed finely ground mash diets had greater ADG than those fed finely ground pelleted diets ($P = 0.06$; 0.46 vs. 0.40 kg/d for d 0 to 14 and $P = 0.10$; 0.53 vs. 0.48 kg/d for d 0 to 35, respectively). However, this was offset by a tendency for the interaction to affect ADFI from d 14 to 35 as pigs fed finely ground mash diets had greater feed disappearance than those fed finely ground pelleted diets ($P = 0.08$; 1.18 vs. 1.08 kg/d, respectively). These findings are similar to recently published research in both nursery and finishing pigs that suggest there is little advantage of pelleting diets with a fine particle size.

Key Words: mash, pellet, nursery pig

T75 Effect of herbal liniment on equine back pain over time: a preliminary study.

Shannon M. Heibeck*[1], Kelly W. Walter[1], Jay A. Altman[2], Brady J. Karren[2], Miriam B. Altman[3], and Kevin K. Haussler[4], [1]*Agricultural Science Department, Truman State University, Kirksville, MO,* [2]*Arenus, Fort Collins, CO,* [3]*Organic Exchange Ltd., Fort Collins, CO,* [4]*Clinical Sciences Department, Colorado State University, Fort Collins, CO.*

Previous research established pressure algometry as a quantitative and repeatable method of assessing induced musculoskeletal back pain in horses; however there is no data evaluating large areas over time in response to pain-mitigating products. Stock-type horses (n = 18) were

used in a completely randomized 44 d trial to investigate the efficacy of an herbal liniment solution to mitigate musculoskeletal back pain. Horses began the study after a 30 d rest and all were maintained in similar daily light work through use in university horsemanship classes and equestrian team practices for the entire 44 d. Horses were randomly assigned to treatment groups which consisted of a commercially available herbal liniment gel solution (SoreNoMore Ultra, Arenus) or a control gel solution (identical gel solution minus active ingredients) applied to the back daily following exercise at 0.02 cc per square cm. Evaluation of back pain was standardized by dividing the back into 4 equal quadrants lengthwise beginning at the highest point of the withers and ending at the sacroiliac joint. Quadrants extended 17.78 cm ventrally from the spine. The third quadrant (on left and right side) was selected as the area of interest and was clipped to maintain consistency over time. Nine data points in this quadrant were selected (top-left, mid-left, bottom-left, top-mid, center, bottom-mid, top-right, mid-right, bottom-right) for weekly evaluation using a force gage pressure meter (by a single nonblinded examiner). A negative pain response was classified as no reaction to the application of 5.9 kg pressure. Data was inverted to create a 0 to 13 pain score based on the amount of pressure applied. Data were analyzed using the PROC MIXED procedure of SAS with main effects tested being treatment, time, and treatment × time interaction. Treated horses decreased mean pain score from beginning to end of trial (2.87 decrease; $P < 0.001$) compared with control horses (0.72 decrease; $P \leq 0.18$). In summary, standardized evaluation procedure using pressure algometry suggests the herbal liniment gel solution was able to mitigate pain response when applied daily over a 44-d period.

Key Words: horse, back pain, liniment

T76 Evaluation of inter-day variation of horses on total fecal collection. Elizabeth F. Miller*[1], Francesca R. Melgar[2], Trevor D. Morgan[2], Shanna L. Ivey[2], Clint L. Loest[2], Laura M. White[2], and Kelly W. Walter[1], [1]*Agricultural Science Department, Truman State University, Kirksville, MO,* [2]*Department of Animal and Range Sciences, New Mexico State University, Las Cruces, NM.*

Environmental changes and stress may influence passage rate and therefore digestibility in horses participating in a total fecal collection where they are individually housed and fitted with fecal collection harnesses. Existing equine research methods sections frequently do not include descriptions of adaptation periods to allow horses to acclimate to the potential stressors of total fecal collections. Utilization of collection harnesses and confined housing could impact data collection of horse nutrition trials. Therefore, the objective of the current study is to evaluate inter-day variation of dry matter intake (DMI), output (DMO), and resulting calculation of digestibility (DMD) of horses on a 5-d total fecal collection. Twelve mature Quarter horse geldings (13.8 ± 5.6 y; 514.4 ± 38.9 kg) were utilized in a completely randomized design. Horses were fitted with fecal collection harnesses and housed individually in 3.7 m × 3.7 m stalls with ad libitum access to water and mineral block. All horses were fed 1.85% BW coastal bermudagrass hay (AF; 8.92% CP and 33.47% ADF) and 1 kg (AF) of a pelleted concentrate supplement (divided into 2 equal meals) beginning 21 d before the start of total fecal collection and continuing through the 5 d collection. Individual daily intake was recorded, and fecal weights were obtained every 6-h during each day of collection. Subsamples of feed and feces were obtained to determine dry matter using standard AOAC methods. Individual days of collection were separated by all possible pairwise comparisons using PROC MIXED of SAS. Day of collection affected DMO, with increased DMO on d 1 compared with d 3 and 4 ($P < 0.05$), and a tendency ($P \leq 0.07$) for increased DMO on d 1 compared with d 2 and 5. This suggests the start of fecal collection may have altered passage rate to increase DMO. The differences of d 1 DMO affected calculated DMD between days (d 1 and 3, $P \leq 0.04$; d 1 and 5, $P \leq 0.09$). This highlights the importance of adapting horses to collection techniques before data collection regardless of diet or treatments to be applied, and warrants adequate description within the methods section of research reports.

Key Words: fecal collection, horse

Breeding and Genetics: Application and methodology in animal breeding—Beef

T77 Genetic parameters for breeding phase in Hereford x Aberdeen Angus crosses in grazing system of Uruguay. Ana C. Espasandin*[1], Diego Gimeno[2,1], Jorge Urioste[1], and Fernando Pereyra[1], *[1]Udelar, School of Agronomy, Bernardo Rosengurtt Experimental Station, Cerro Largo, Uruguay, [2]Uruaguayan Wool Secretariat, Montevideo, Uruguay.*

A diallelic experiment between Hereford (HH) and Aberdeen Angus (AA) beef breeds, developed between 1994 and 2002 at the Bernardo Rosengurtt Experimental Station, College of Agriculture-University of the Republic, Uruguay (32°35′ S, 54°15′ W, and 94 of altitude). The data set totalized a set of 57 sires and 1365 dams. The individual ($g^{i}_{A} - g^{i}_{H}$) and maternal ($g^{m}_{A} - g^{m}_{H}$) breed differences, as well as individual (h^{i}_{AH}) and maternal (h^{m}_{AH}) heterosis were estimated using additive linear models for cow body condition score at calving (BCS), calf birth weight (BW) and weaning weight (WW), and generalized linear models for weaning percentage (%W). Effects of genetic group, year and month(year) at birth, dam age, and calf sex were included as fixed effects, and individual or sire as random effects. The effect of the difference between individual breed genetic ($g^{i}_{A} - g^{i}_{H}$), as well the heterosis were not significant for BW ($P > 0.05$). For WW, the difference between maternal effects ($g^{m}_{A} - g^{m}_{H}$) was positive, with 4.87 ± 1.01 kg ($P < 0.0001$), and individual heterosis was 5.12 ± 1.24 kg ($P < 0.0001$). The h^{i}_{AH} for %W was 0.22 ± 0.03. The h^{m}_{AH} was significant for WW (11.58 ± 1.48 kg, $P < 0.0001$). Crossbred dams were higher than pure breed by 0.04 points in BCS (3.79 vs. 3.75), being different HH and HA vs. AA and HA ($P < 0.05$). At birth, calves HH, AH and HA were heavier than AA. For %W, crossbred dams averaged 24.7 points higher than pure breeds (85.0% vs. 60.3%). Crossbred breed dams weaned calves significantly heavier (means 159.1 ± 4.1 kg) to purebred cows. Hereford breed dams weaned calves with significantly less weight (means 143.3 ± 2.7 kg). The estimations of breed genetic effects show reductions in birth weight related to a Angus breed (g^{i}), as well an increment in weaning weight due to a maternal Angus effect (g^{m}). Superiority in crossbred dams were evidenced in individual and maternal heterosis.

Key Words: breed effect, crossbreeding, heterosis

T78 Estimates of genetic parameters for reproductive traits in Brahman cattle breed. Ligia Cavani*[1], Diogo Anastácio Garcia[2], Luis Orlando Duitama Carreño[2], Rafael Keith Ono[2], Henrique Torres Ventura[3], and Ricardo Fonseca[1], *[1]São Paulo State University (Unesp), Dracena, São Paulo, Brazil, [2]São Paulo State University (Unesp), Jaboticabal, São Paulo, Brazil, [3]Brazilian Association of Zebu Breeders (ABCZ), Uberaba, Minas Gerais, Brazil.*

This study was designed to estimate genetic parameters for the following traits of Brahman cattle in Brazil: age at first calving (AFC), calving interval (CI), rebreeding (REB), and stayability (STAY). The data were provided by Brazilian Association of Zebu Breeders (ABCZ), and included Brahman cattle that were born between 1994 and 2012. For REB, the value 1 was assigned to heifers that rebreed and calved after first calving, and the value 0 was assigned to heifers that failed to rebreed after first calving. Likewise, for STAY, the value 1 was assigned to heifers that calved at least 3 times when they were 6-yr-old; otherwise, the value 0 was assigned. We utilized bivariate analysis using linear-threshold animal model to estimate co-variances components by using the software GIBBSF90 and THRGIBBS1F90 from BGF90. The model included fixed effects, random effects that represented additive genetic direct effects of each animal, permanent environmental effects, included as random, and residuals. For AFC and STAY, the fixed effects were composed only by contemporary group. Besides that, for REB and CI, the fixed effects were composed by contemporary group, calf birth year and calf birth season. Also, the covariate dam age at calving was included for CI. The permanent environmental effects only were included in the model for CI. The contemporary groups were composed from farm, type of gestation (AI or natural service) and birth year of dam; and in addition, only for STAY, birth season of dam (rainy or dry). The mean h^2 were 0.10, 0.02, 0.22, and 0.10 for AFC, CI, REB, and STAY; respectively. The genetic correlations were −0.13 between AFC and CI, −0.35 between AFC and REB, −0.57 between AFC and STAY, and 0.32 between REB and STAY, which reveal that cows that remain productive for longer periods in the herd, also start breeding younger and present greater chances to REB; however, heifers that calved too young may present problems, such as calving difficulty, that may increase CI. The selection of Brahman cattle for reproductive traits, such as AFC, CI, REB, and STAY, will render low magnitude and long-term responses.

Key Words: heritability, rebreeding, stayability

T79 Assessment of genetic variability of Brazilian Brahman cattle raised either on pasture or stabled by pedigree analysis. Ligia Cavani*[1], Rafael Medeiros de Oliveira Silva[2], Michel Marques Farah[3], Rafael Keith Ono[2], Luis Orlando Duitama Carreño[2], Henrique Torres Ventura[4], and Ricardo Fonseca[1], *[1]São Paulo State University (Unesp), Dracena, São Paulo, Brazil, [2]São Paulo State University (Unesp), Jaboticabal, São Paulo, Brazil, [3]Brazilian Agricultural Research Corporation (Embrapa), Juiz de Fora, Minas Gerais, Brazil, [4]Brazilian Association of Zebu Breeders (ABCZ), Uberaba, Minas Gerais, Brazil.*

The aim of this study was to assess the genetic variability of Brahman cattle in Brazil by analyzing information obtained by genealogical records. The pedigree data were obtained from the Brazilian Association of Zebu Breeders and was formed by 207,747 Brahman animals from different regions of Brazil. In this data set, cattle were born between 1994 and 2012 and they were analyzed in 3 ways: considering all the pedigree information (Pt), and dividing the pedigree data according to animals raised either on pasture (Ppt) or stabled (Pst). The software R was used for data consistency and to generate the file with the following information: animal, sire, dam, birth date, and sex. The software Pedig was used to determine the inbreeding, generation intervals and the results of the parameters based on the probability of gene origin: number of founders (Nf), effective number of founders (fe), effective number of ancestors (fa) and founder genome equivalents (fg). Average inbreeding coefficients (F) were 0.31%, 0.30% and 0.22% for Pt, Ppt and Pst, respectively. However, mean F values for inbred animals were 5.94%, 5.13% and 6.52% for Pt, Ppt and Pst, respectively. In addition, average generation intervals were 4.73, 4.65 and 4.81 years for Pt, Ppt and Pst, respectively. For Pt, the results based on probability of gene origin were 13,764, 101.4, 97.07, 75.02, 1.04, 0.74 for Nf, fe, fa, fg, fe/fa and fg/fe; respectively. For Ppt, the results based on probability of gene origin were 6,906, 94.4, 91.57, 72.93, 1.03, 0.80 for Nf, fe, fa, fg, fe/fa and fg/fe; respectively. For Pst, the results based on probability of gene origin were 2,407, 68.8, 66.36, 58.42, 1.04, 0.88 for Nf, fe, fa, fg, fe/fa and fg/fe; respectively. The number of ancestors to explain 50% of the genetic variability in Pt was 46, in Ppt was 41 and in Pst was 24. The results showed a reduction in genetic variability, because fe > fa > fg. Values close to 1 observed for fe/fa and fg/fe showed no genetic bottleneck and a small process of genetic drift. Thus, genetic variability has been reduced in Brahman cattle population, especially on those from Pst.

Key Words: ancestor, inbreeding

T80 Use of a robust Bayesian regression model in genome-wide association study of growth traits in Brangus heifers.

Sunday O. Peters*[1], Kadir Kizilkaya[2], Dorian J. Garrick[3], Rohan L. Fernando[3], Ikhide G. Imumorin[4], and Milton G. Thomas[5], [1]*Berry College, Mount Berry, GA,* [2]*Adnan Menderes University, Aydin, Turkey,* [3]*Iowa State University, Ames, IA,* [4]*Cornell University, Ithaca, NY,* [5]*Colorado State University, Fort Collins, CO.*

When alternative models are used for genome-wide association studies (GWAS), not a single one of them has been recognized as universally best across all traits. One explanation is that different traits may have different genomic architecture characterized by different distributions for marker effects. Further, it is known that results from BayesA and BayesB models can be heavily influenced by the value of hyperparameters assumed known, namely pi, the scale factor and degrees of freedom. Our objective was to use a robust Bayesian regression model for GWAS that treated these hyperparameters as unknown and apply this model to 3 growth traits in Brangus (3/8 Brahman × 5/8 Angus) heifers. Genotypes for each heifer were obtained from BovineSNP50 Infinium beadchips. Phenotypes included data on birth weight (BW), weaning weight (WW) and yearling weight (YW) from 830 individuals from 67 sires. Simultaneous association of all SNP for each of BW, WW and YW were tested in a robust model that treated SNP effects as random. Fixed effects included cohort groups as class effects (defined for animals with the same calving season, location, and trait contemporary group) and dam age (in years) as classes. Several genomic locations were associated with variation in these growth traits in heifers. The top 10 regions by SNP effects were found on chromosomes 1, 2, 5, 6, 14 and 26 for BW, chromosomes 1, 2, 3, 5, 6, 16 and 28 for WW and chromosomes 5, 6, 7, 11, 12, 14, 16, 18, 20 and 29 for YW. Results confirm many previously reported regions associated with variation in these growth traits in both taurine and indicine cattle breeds but also included new associations. Results demonstrated the utility of regression models with unknown hyperparameters of pi, scale and degrees of freedom in GWAS of growth traits in Brangus heifers.

Key Words: robust Bayesian regression, genome-wide association, growth

T81 Genetic parameter estimates for fatty acid profile of *longissimus thoracis* beef from Nellore cattle finished in feedlot.

Carolyn A. Santos[1], Angélica S. C. Pereira[2], Fabieli L. B. Feitosa[1], Marcos V. A. Lemos[1], Hermenegildo L. J. Chiaia[1], Mariana P. Berton[1], Adrielle M. Ferrinho[2], Lenise F. Mueller[3], Joyce M. Furlan[2], Monica R. Mazalli[3], and Fernando S. Baldi*[1], [1]*Universidade Estadual Paulista, Faculdade de Ciências Agrárias e Veterinárias, Departamento de Zootecnia, Jaboticabal, São Paulo, Brazil,* [2]*Universidade de São Paulo, Faculdade de Medicina Veterinária e Zootecnia, Departamento de Nutrição e Produção Animal, Pirassununga, São Paulo, Brazil,* [3]*Universidade de São Paulo, Faculdade de Zootecnia e Engenharia de Alimentos, Pirassununga, São Paulo, Brazil.*

The present study aimed to estimate (co)variance components and genetic parameters for beef fatty acid (FA) composition in 937 Nellore bulls, finished in feedlot (period of 90 d) and slaughtered with an average age of 24 mo, weighing 500–550 kg. The FA profile was analyzed in *Longissimus thoracis* samples using a gas chromatography, with a 100-m capillary column. The contemporary groups (CG) were organized based on farm and year of birth, and management group at yearling. The following 14 FAs were quantified: C16:0, C18:0, C18:1 *cis*-9, C18:2 *cis*-6, C18:2 *cis*-9,*trans*-11 and C18:2 *trans*-10,*cis*-12, C18:3n-3, C14:0, C14:1, C18:1n-9 *trans*, 18:1 *trans*-11, C20:3n-6 *cis*-8,11,14, C20:3n-3 *cis*-11,14,17, and C20:4. The (co)variance components were estimated using an animal model which included random additive genetic effects, fixed effects (CG), and the slaughter age as a covariable (linear and quadratic effect). The restricted maximum likelihood method was used (REMLF90 computer program) and 2 multi-trait analysis were performed, one including 14 individual FA and the other the total SFA, MUFA, PUFA, n-3, n-6 and n-9. The individual FAs with the highest heritability estimates were C18:2 *trans*-10,*cis*-12 (0.38) and C18:3n-3 (0.41). The C18:0, C16:0, C18:1 *cis*-9, 18:1 t11, C18:2 *cis*-9,*trans*-11 and C20:4 FAs resulted in low heritability estimates, indicating that these FAs should respond slowly to selection. With the exception of the C18:2 *trans*-10,*cis*-12 FA, the genetic associations between individual PUFAs were high and positive. The genetic correlation estimates between the total of SFA with PUFA and n-6 were high and negative (−0.84 and −0.88), and with n-3 were moderate (−0.62). It is expected that the response to direct selection for polyunsaturated, n-3 and n-6 fatty acids would be fast. In general, the correlations between the most important fatty acids are favorable and therefore indirect selection may be used to improve the fatty acid profile. This study revealed the existence of genetic variation and hence the possibility of genetic improvement of meat fatty acid composition in zebu cattle.

Key Words: *Bos indicus*, genetic variation, meat

T82 Genetic evaluation of growth traits in Brahman cattle.

A. M. Mariorano[2], M. E. Z. Mercadante[3], J. N. S. G. Cyrillo[3], L. A. L. Chardulo[1], and J. A. V. Silva*[1], [1]*Universidade Estadual Paulista, Botucatu, SP, Brasil,* [2]*Universidade Estadual Paulista, Jaboticabal, SP, Brasil,* [3]*Instituto de Zootecnia, Sertãozinho, SP, Brasil.*

The aim of this study was to estimate genetic parameters and determine ratio efficiency of selection for weaning weight (W205), weight at 450 d (W450) and weight gain from weaning to 450 d (PWG450) in Brahman cattle. Traits were studied through multivariate analyses. Variance components were estimated by restricted maximum likelihood performed by the software MTDFREML. The Statistical model included the fixed effects of contemporary group (composed by farm, crop and birth season, sex, and weaning and yearling management groups) and the linear covariate age, the random effect of animal and residual. For weaning weight, the management group at yearling was excluded from the contemporary group and the fixed effect of dam at calving age (3 to 9 years and more than 9 years) and the effect of permanent environmental were included. Purpose of ratio efficiency was verifying the efficiency of genetic gain as a function of indirect selection. Observed means of W205, W450 and PWG450 were 197 ± 34, 320 ± 74, 118 ± 59. Estimated heritability of W205, W450, and PWG450 were 0.18, 0.16 and 0.12. W205 and W450 had very high genetic correlation (0.89). GPW450 had high genetic correlation with W450 (0.79), but relatively lower correlation with W205 (0.43). For all traits, the direct selection was more efficient. Information obtained suggests slow genetic gain for W205, W450 and GPW450. GPW450 was appropriate to use as selection criteria because it showed less influence of weaning weight, and high correlation with W450.

Key Words: beef cattle, genetic correlation, weaning weight

T83 Effect of prediction method and cross-validation approach on accuracy of DGV for feed efficiency traits.

Rafael M. O. Silva*[1], Daniela A. L. Lourenco[2], Breno O. Fragomeni[2], Luciana Takada[1], Rafael Espigolan[1], Maria E. Z. Mercadante[3], Fernando Baldi[1], Guilherme C. Venturini[1], Joslaine N. S. G. Cyrillo[3], Ignacy Misztal[2], Roberto Carvalheiro[1], and Lucia G. Albuquerque[1], *[1]Univ Est Paulista Julio de Mesquita Filho,FCAV-UNESP, Jaboticabal, SP, Brazil, [2]The University of Georgia, Athens, GA, [3]APTA Center for Beef Cattle, Animal Science Institute, Sertaozinho, SP, Brazil.*

Accuracies of direct genomic values (DGV) for feed efficiency traits obtained with different methods and cross-validation approaches were compared. After quality control 437,197 SNP genotypes were available for 761 Nellore cattle provided by the Institute of Animal Science, SP, Brazil. Methods of analysis were traditional BLUP, ssGBLUP, GBLUP, and BayesCPi. The traits were residual feed intake (RFI), feed conversion ratio (FCR), average daily gain (ADG) and dry matter intake (DMI). Model included fixed effects of contemporary groups (sex, year of birth, and pen), month of birth, and the covariable age of dam (linear and quadratic effects); and, as random, the additive animal effects. Three cross-validation approaches were considered: WPRO – validation was done on animals that did not have progeny; UNREL – the data set was split into 3 less related subsets; RAN – the data set was randomly divided into 4 subsets and the validation was done in each subset at a time. The accuracy of DGV was calculated as the Pearson correlation between corrected phenotype and the DGV divided by square root of heritability. Accuracies ranged from 0.01 (with UNREL) to 0.78 (with RAN) for studied traits. The inclusion of genomic information increased more than 10% of the average accuracy of predictions over traditional BLUP; on average, GBLUP showed more accurate predictions of DGV than BayesCPi (0.33 and 0.29, respectively). For the RAN cross-validation approach, accuracies were 50% higher with ssGBLUP than GBLUP, especially for traits with high heritabilities (ADG- $h^2 = 0.55$, and DMI – $h^2 = 0.58$). The most accurate predictions were obtained using RAN, ranging from 0.28 to 0.78. On the other hand, the UNREL cross-validation approach provided the less accurate predictions, ranging from 0.001 to 0.29. With WPRO accuracies of DGVs were from 0.12 to 0.69. These results show that accurate genomic prediction can be obtained for all analyzed traits, especially for those with high heritability. Accuracies of DGV are higher when animals in validation are more related to those in training. São Paulo Research Foundation (FAPESP) grant 2013/01228-5 associated to 2009/16118-5.

Key Words: beef cattle, genomic selection

T84 Genetic correlation estimates between the profile of individual beef fatty acids of meat and carcass traits and meat in Nellore cattle finished in feedlot.

Fabieli Loise Braga Feitosa, Carolyn Aboujaoude, Marcos Vinícius Antunes de Lemos, Mariana Piatto Berton, Guilherme Costa Venturini, Rafael Lara Tonussi, Rafael Espigolan, Bianca Ferreira Olivieri, Lucia Galvão de Albuquerque, and Fernando Baldi*, *Universidade Estadual Paulista, FCAV-UNESP, Jaboticabal, São Paulo, Brasil.*

The aim of this study was to evaluate the genetic-quantitative relationships between the beef fatty acid profile with carcass and meat traits and meat in Nellore cattle. Data from 1616 Nellore bulls finished in feedlot (90 d), aged around 2 years old were used. Samples were taken from the *Longissimus thoracis* muscle in the region of the 12th to 13th ribs of the left half-carcasses 48 h after slaughter. The backfat thickness (BF) was measured using a caliper. The percentage of lipids (LIP) was determined by the Bligh and Dyer method. The fatty acid profile was quantified using SP-2560 capillary column (100 m × 0.25 mm diameter with 0.02 mm thickness, Supelco, Bellefonte, PA). After quality control for genotypes, a total of 470,007 SNPs from 1,556 samples remained. The (co)variances and genetic parameters were estimated using the restricted maximum likelihood method, considering an animal model (ssGBLUP). The heritability estimates for fatty acids were from low to high, ranging from 0.06 to 0.65 for saturated fatty acids, from 0.07 to 0.14 for the monounsaturated fatty acids and 0.05 to 0.62 for polyunsaturated fatty acids. Carcass and meat traits showed low to moderate heritability estimates, ranging from 0.06 (SF) to 0.17 (EGS). Estimates of genetic correlation between BF with (C14:0), (C18:0), (C18:1n-9 *cis*), (C18:2n-6 *cis*), (C18:3n-3), CLA *cis*-9,*trans*-11 and CLA *cis*-10,*trans*-12 were low to moderate, being 0.38, −0.15, −0.44, 0.18, −0.22, 0.19 and −0.10, respectively. The estimates of genetic correlations between SF with previous fatty acids were low to moderate (0.16, 0.04, 0.04, 0.02, −0.40, 0.35 and 0.60). Estimated genetic correlations between the LIP with C14:0, C18:0, C18:1n-9 *cis*, C18:2n-6 *cis*, C18:3n-3, CLA *cis*-9,*trans*-11 and CLA *cis*-10,*trans*-12 were low to high, being 0.75, 0 70, −0.02, −0.93, −0.62, −0.04 and −0.60, respectively. It is expected that selection for increasing the concentration of mono and polyunsaturated fatty acids by direct selection for carcass and meat traits is less likely to occur.

Key Words: lipid composition, meat quality, *Bos indicus*

T85 Genetic parameter estimates for carcass and meat quality traits in Nellore cattle finished in feedlot.

Bianca Ferreira Olivieri[1], Fabiele Loise Braga Feitosa[1], Hermenegildo Lucas Justino Chiaia[1], Guilherme Costa Venturini[1], Carolyn Aboujaoude[1], Marcos Vinícius Antunes de Lemos[1], Mariana Piatto Berton[1], Rafael Lara Tonussi[1], Rafael Espigolan[1], Joyce de Jesus Mangini Furlan[2], Angélica Simone Cravo Pereira*[2], Lucia Galvão de Albuquerque[1], and Fernando Baldi[1], *[1]Universidade Estadual Paulista, FCAV-UNESP, Jaboticabal, São Paulo, Brazil, [2]Universidade de São Paulo, FMVZ-USP, Pirassununga, São Paulo, Brazil.*

The aim of this study was to estimate genetic parameters for beef fatty acids profile, carcass and meat traits in Nellore cattle. A total of 1616 Nellore bulls finished in feedlot (90 d), and slaughtered with an average of 24 mo of age were used. Samples from the *Longissimus thoracis* muscle were collected 48 h after slaughter. The proportion of saturated (SFA), monounsaturated (MUFA) and polyunsaturated fatty acids (PUFA), n-3 and n-6 were calculated. The total lipid concentration (LIP) was quantified using the Bligh and Dyer (1959) method. Fatty acids were quantified by gas chromatography (GC-2010 Plus - Shimadzu AOC 20i autosampler) using SP-2560 capillary column. The backfat thickness (BF) was measured using a caliper. Shear force (SF) was measured by the method of Wheeler et al. (1995). The (co)variances and genetic parameters were estimated using the restricted maximum likelihood method, considering an animal model (ssGBLUP), applying the remlf90 software. The animals were genotyped with the BovineSNP BeadChip (High-Density Bovine BeadChip) that contained 777,962 SNP markers. After quality control for genotypes, a total of 470,007 SNPs from 1,556 samples remained. The heritability estimates were low for SFA (0.09), MUFA 0.005, and moderate for PUFA (0.20), n3 (0.08) and n6 (0.20). For SFA, the genetic correlation estimates with SF (0.04) with BF (0.30), and LIP (0.27) were low. The genetic correlation estimates

between MUFA with carcass and meat traits were low to high, being −0.05 with SF, −0.64 with BF, and 0.88 with LIP. The genetic correlation estimates between PUFA were low with SF (0.22), moderate with BF (−0.41) and LIP (−0.64). For n3, the genetic correlation estimates with were low with BF (−0.17) moderate with SF (−0.37) and with LIP (−0.40). The genetic correlation estimates between omega 6 with BF and SF were low (0.05 and 0.10, respectively), and high with LIP (−0.86). It is expected that the selection for carcass and meat traits would change the beef fatty acid composition.

Key Words: *Bos indicus*, heritability, genetic correlation

Breeding and Genetics: Applications and methodology in animal breeding—Dairy

T86 Genetic and phenotypic trends for age at first calving and milk yield in daughters from imported and Thai Holstein sires. Tawirat Konkruea[1], Skorn Koonawootrittriron*[1], Thanathip Suwanasopee[1], and Mauricio A. Elzo[2], [1]*Kasetsart University, Bangkok, Thailand,* [2]*University of Florida, Gainesville, FL.*

Age at first calving (AFC) and milk yield (MY; accumulated 305-d milk yield) are important traits for the dairy cattle industry. To genetically improve these traits under tropical conditions in Thailand, both imported Holstein (IH) and Thai Holstein (TH; purebred and crossbred Holstein-Other Breeds) sires have been used for mating with Holstein purebred and Holstein-Other Breeds crossbred cows. The objective of this study was to compare genetic changes in AFC and MY from 1991 to 2014 in first-lactation daughters of IH and TH sires. The data set included AFC and first-lactation MY from 5,390 daughters of 507 IH and 232 TH sires that calved from 1991 to 2013 in 481 dairy farms. The bivariate animal model considered herd-year-season and Holstein fraction as fixed effects, and animal and residual as random effects. Variance components were estimated using an average information restricted maximum likelihood procedure. Variance component estimates were used to compute heritabilities and correlations. Mean estimated breeding value (EBV) for daughters of IH and TH sires were computed for each calving year. Regressions of mean EBV for AFC and MY on calving years were computed to assess genetic trends. Heritability estimates were 0.19 ± 0.04 for AFC and 0.13 ± 0.04 for MY. Near zero genetic (0.09 ± 0.18) and phenotypic (0.07 ± 0.02) correlations were estimated between AFC and MY. Overall genetic trends were negative for AFC (−0.013 ± 0.003 mo/yr; $P < 0.001$) and positive for MY (1.16 ± 0.30 kg/yr; $P < 0.001$). However, non-significant negative AFC genetic trends existed for daughters of IH sires (−0.006 ± 0.003 mo/yr; $P = 0.06$) and TH sires (−0.020 ± 0.004 mo/yr; $P < 0.001$). Conversely, significant positive MY genetic trends occurred for progeny of IH sires (1.14 ± 0.43 kg/yr; $P = 0.008$) and TH sires (4.40 ± 0.46 kg/yr; $P < 0.001$). These results indicated that there was genetic improvement in the appropriate direction (negative for AFC and positive for MY) in this Thai dairy population, and that TH sires brought larger changes than IH sires, primarily for MY.

Key Words: dairy, selection, tropics

T87 Genomic-polygenic evaluation for milk yield and fat yield in a multibreed dairy cattle population in central Thailand. Bodin Wongpom[1], Skorn Koonawootrittriron*[1], Mauricio A. Elzo[2], and Thanathip Suwanasopee[1], [1]*Kasetsart University, Bangkok, Thailand,* [2]*University of Florida, Gainesville, FL.*

Milk yield (MY) and fat yield (FY) are economically important traits for Thai dairy businesses. Genetic prediction for MY and FY in Thailand uses only pedigree and phenotypic information. Combining SNP genotypes of individual animals with pedigree and phenotypes would be expected to increase the accuracy of genetic predictions and speed up selection progress. The objectives of this study were to estimate the fraction of the genetic variance accounted for by 8,257 SNP from GeneSeek GGP-LD BeadChip and to compare the rankings of animals evaluated with a genomic-polygenic (GP), genomic (G), and polygenic (P) models for MY and FY. The data set consisted of first-lactation MY and FY records from 600 cows from 56 farms in Central Thailand collected from 2000 to 2013. The mixed model contained herd-year-season, Holstein fraction and age at first calving as fixed effects (all models). Random effects were SNP genomic (GP and G), animal polygenic (GP and P) and residual. Variance components were estimated using GS3 software (option VCE; GP and P). Additive genetic predictions were computed with GS3 (option BLUP) for all models. The fraction of additive genetic variances explained by the 8,257 SNP from GGP-LD and computed with the GP model were 46% for MY and 45% for FY. Heritability estimates with the GP model were higher (0.37 for MY and 0.40 for FY) than those with the P model (0.28 for MY and 0.30 for FY). Rank correlations between GP and G models were the highest (0.99 for both MY and FY; $P < 0.0001$), followed by correlations between GP and P models (0.91 for MY and 0.75 for FY), and the lowest correlations were between G and P models (0.89 for MY and 0.73 for FY; $P < 0.0001$). Thus, SNP from GeneSeek GGP-LD not only accounted for a sizeable fraction of the additive genetic variance for MY and FY, but they also yielded animal genomic EBV whose ranking was highly correlated with rankings of both genomic-polygenic and polygenic EBV. These results indicated that utilization of GGP-LD, and perhaps higher density genotyping chips, would be advantageous for genomic-polygenic evaluation and selection in Central Thailand.

Key Words: dairy, genomic, tropics

T88 Genomic evaluation, breed identification, and population structure of North American, English and Island Guernsey dairy cattle. Tabatha A. Cooper*[1], Sophie A. E. Eaglen[2], George R. Wiggans[1], Janez Jenko[2], Heather J. Huson[3], David M. Morrice[2], Maurice Bichard[4], William G. Luff[5], John A. Woolliams[2], and Brian P. Van Doormaal[7], [1]*Animal Genomic and Improvement Laboratory, Agricultural Research Service, USDA, Beltsville, MD,* [2]*The Roslin Institute & R(D)SVS, University of Edinburgh, Easter Bush, United Kingdom,* [3]*Department of Animal Science, Cornell University, Ithaca, NY,* [4]*English Guernsey Cattle Society, Launceston, United Kingdom,* [5]*World Guernsey Cattle Federation, Castel, Guernsey, United Kingdom* [6]*Select Sires, Plain City, OH,* [7]*Canadian Dairy Network, Guelph, ON, Canada.*

Genomic evaluations of dairy cattle in the United States have been available for Brown Swiss, Holstein, and Jersey since 2009 and for Ayrshire since 2013. As of February 2015, 2,281 Guernsey bulls and cows had genotypes from collaboration between the United States (USA), Canada (CAN), England (E), and the Island of Guernsey (I). The E /I contributions were made possible by the European Commission project, Gene2Farm. Of those genotyped, 431 were males with traditional evaluations. Evaluation accuracy was assessed using 4-fold cross-validation using males only. The cross-validation was repeated 10-fold and gains in reliability over parent average were averaged. Twenty-two traits were analyzed including 5 yield traits, 3 functional traits and 14 conformation traits. Mean gain in reliability over parent average for all traits was 13.8 percentage points. The highest gains were for strength (26.7), rump width (23.6), fore udder attachment (23.2) and fat percent (21.1). Traits with the lowest gains were daughter pregnancy rate (1.0) and somatic cell score (−0.9). The average 13.8-point gain for Guernsey can be compared with averages of 9, 24, 40, and 31 for Ayrshire, Brown Swiss, Holstein, and Jersey respectively. Twenty-one single nucleotide polymorphisms were useful for Guernsey breed determination and are used in routine genotype quality control to confirm breed and identify crossbreds. Genetic differences between E/I animals and USA/CAN animals from an admixture study using principal component analysis will be presented. No haplotypes that affect fertility were identified from the current data set however; monthly assessments are conducted. These results are expected to lead to routine genomic evaluation of Guernseys in the USA and E/I.

Key Words: Guernsey, genomic evaluation, single nucleotide polymorphism

T89 Genetic relationship between final score and production traits in Brazilian Holstein cattle. Victor B. Pedrosa*[1], Pedro G. Ribas Neto[2], Silvano F. Valoto[2], Luis F. B. Pinto[3], and Gabrieli S. Romano[3], *[1]Universidade Estadual de Ponta Grossa, Ponta Grossa, Parana, Brazil, [2]Associacao Paranaense dos Criadores de Bovinos da Raca Holandesa, Curitiba, Parana, Brazil, [3]Universidade Federal da Bahia, Salvador, Bahia, Brazil.*

Dairy cattle farmers seek to have animals that stay longer in the herd and still produce more milk and solids with each generation. In this regard, the final score has been used as a selection criterion to be related to many linear type traits and possibly present positive correlation with dairy yield traits. Thus, this study aimed to evaluate the genetic correlations between final score, milk, fat and protein yield and thus prove the positive relationship between them to better conduct dairy cattle programs in Brazil. The database contained information on 83,176 first lactation cows born between 1991 and 2011, with 148,534 records on pedigree file. The considered final score was 50 to 97, wherein the lower score represents a weak classification and the highest score excellent. Genetic parameters estimation were obtained based on the animal model using the VCE software. Analyses were performed considering the contemporary group (same herd-year) as fixed effect and the age of cow as a covariate. The average of final score and production of milk, fat, and protein were respectively 81.50 points, 8,531.50 kg, 287.90 kg, 270.74 kg. The genetic correlation between final score and production traits were 0.12, 0.02 and 0.14, respectively for milk, fat and protein. Hence, the correlation among milk and fat, milk and protein and lastly fat and protein were 0.49, 0.84 and 0.55, respectively. The results showed that there is a low, but positive correlation between final score and production traits, demonstrating that the selection for this type feature can improve dairy production. The results of relationship between production traits are consistent with findings in the literature in Holstein breed, in which the selection to increase milk or solids will benefit other production traits, specialty among milk and protein yields. Therefore, the final score should be included in the Brazilian Holstein breeding programs because it is widely known to be positive associated with legs, feet and udder, besides genetically contributing to increase dairy production.

Key Words: dairy cattle, linear type trait, milk yield

T90 Genetic trends in dairy production of Brazilian Holstein cow. Victor B. Pedrosa*[1], Altair A. Valloto[2], Jose A. Horst[2], Avelino M. Figueiredo[2], and Adriana S. Martins[1], *[1]Universidade Estadual de Ponta Grossa, Ponta Grossa, Parana, Brazil, [2]Associacao Paranaense dos Criadores de Bovinos da Raca Holandesa, Curitiba, Parana, Brazil.*

Production and pedigree monitoring in Holstein cattle is carried out for many years but a only a few farmers effectively use breeding programs in Brazil. In the year 2014, the Holstein Association of Paraná State in partnership with the State University of Ponta Grossa created the State breeding program of cows, to accelerate genetic progress and consequently increase dairy production. Therefore, this study aimed to evaluate the genetic trend obtained in the last 10 years for milk, fat, and protein yield and thus increase the genetic evaluation of female population in the country. The database contained information on 54,224 first lactation cows born between 2001 and 2011, with 81,336 records on pedigree file. Genetic trends were estimated from the linear regression of annual averages of breeding values. Estimates of breeding values were obtained based on the methodology of mixed models through BLUP solutions using the PEST software. Analyses were performed considering the contemporary group (same herd-year) as fixed effect and the age of cow as a covariate. The average production of milk, fat, and protein were respectively 8,693.17 kg, 286.51 kg and 264.28 kg. The estimated genetic trend was 6.62 kg/yr for milk, 0.44 kg/yr for fat and 0.34 kg/yr for protein. The results show that even with low adherence to animal breeding programs by dairy farmers there was a significant genetic progress for the 3 studied traits. This result might be explained by the use of imported genetic material of quality bulls from markets such as the United States, Canada and the Netherlands. However, it is essential to mention the importance of the farmers to increase selection based on genetic values estimated in a national selection program, reducing possible negative effects caused by the use of imported genetic material, selected in a different environment. Thus, it is expected that the new breeding program of cows provide greater genetic and productive advances for Brazilian herds.

Key Words: breeding program, milk yield, selection

T91 Association between genomic SNPs and dairy production traits in Thai multibreed dairy cattle. Pimchanok Yodklaew[1], Skorn Koonawootrittriron*[1], Mauricio A. Elzo[2], and Thanathip Suwanasopee[1], *[1]Kasetsart University, Bangkok, Thailand, [2]University of Florida, Gainesville, FL.*

Genomic chips containing large number of single nucleotide polymorphisms (SNPs) have been widely used to study marker-trait associations in dairy cattle. Identification of genes associated with economically relevant traits close to significant SNPs are subsequently identified in genomic databases. The objective of this study was to find significant SNPs and genes that were associated with milk yield (MY), initial yield (IY), peak yield (PY), day to peak (DP), persistency (PS) and age at first calving (AFC) in a Thai Holstein-Other multibreed dairy population. The data set contained 2,409 first-lactation records from 295 dairy farms located in Central, Northern, Western, and Southern Thailand that were collected between 1997 and 2014. Animals were genotyped with 1 of 4 GeneSeek Genomic Profiler BeadChips (9K, 20K, 26K, or 80K). Thus, a set of 7,357 SNPs from autosomes in common among the 4 chips were used in this study. Association between SNPs and traits were analyzed using QXPAK.5 software. The mixed model included herd-year-season, Holstein fraction, age at first calving and SNPs as fixed effects, and animal and residual as random effects. The number of significant SNPs associated with MY, IY, PY, DP, PS and AFC were 649, 491, 627, 477, 527, and 381 at $P < 0.05$, and 342, 225, 301, 215, 259 and 156 at $P < 0.01$, respectively. All significant SNPs were checked for their association to 5,320 genes in the NCBI database obtained using Map2NCBI (R package). No gene was related to all traits. However, 8 genes were associated with 5 traits (*C3H1orf87, LOC100848063, NR5A2, PCDH15, WWO30, NCAM1, GLI2* and *LOC784126*) at $P < 0.05$, and 7 genes were associated with 4 traits at $P < 0.01$ (*NR5A2, KCNIP1, INSC, LOC784126, EEF1E1, ATRNL1 and LOC100294923*) at $P < 0.01$. Results from this research emphasized the need to validate SNP-dairy trait associations under Thai tropical environmental conditions to optimize the benefits of genomic selection.

Key Words: SNP, multibreed, tropics

T92 Accuracy of genomic prediction using principal component analysis on an imputed high -density SNP panel in Italian Holstein cattle.

Antonio Puledda[1], Giustino Gaspa[1], Ezequiel L. Nicolazzi[2], Corrado Dimauro[1], Paolo Ajmone Marsan[3], Alessio Valentini[4], and Nicolo PP Macciotta*[1], *[1]Dipartimento di Agraria, Università di Sassari, Sassari, Italy, [2]Fondazione Parco Tecnologico Padano, Lodi, Italy, [3]Istituto di Zootecnica, Università Cattolica del Sacro Cuore, Piacenza, Italy, [4]Dipartimento per l'Innovazione dei sistemi biologici, agroalimentari e forestali, Università della Tuscia, Viterbo, Italy.*

In this study, the effect of predictor dimensionality reduction using Principal Component analysis (PCA) on the accuracy of Direct Genomic Values (DGV) for of 2,822 Italian Holstein bulls was tested. A subset of animals (916) were genotyped with high density (HD, 800K) beadchip; the remaining were imputed from medium density (MD, 50K) to HD. Several 617,166 markers were retained after data editing. A MD panel was simulated for all animals by merging the HD panel with the BovineSNP50v2. A total of 40,669 markers were retained for the analysis. PCA were carried out both genome and chromosome wide for the MD (MD_GW and MD_CHR respectively), only by chromosome for the HD (HD_CHR) panel. Several PC explaining 90% of the total variance was retained: 1,436 (MD_GW) 4,829 (MD_CHR) and 5,321 (HD_CHR) respectively. PC score effects for 32 productive, functional and conformation traits were estimated on 2,301 training bulls born before 2004. DGVs were computed for the remaining 521 validation bulls born after 2003. Accuracy of prediction (rDGV) was computed as correlation between DGVs and phenotypes. Average rDGV across 32 traits were 0.29 ± 0.13, 0.31 ± 0.13, 0.36 ± 0.14 for MD_GW, HD_CHR and MD_CHR, respectively. Such an increase may be explained by the reduction of asymmetry between the number of predictors and observations. In particular, the shrinkage of the total variance of different SNP panel size in a quite similar number of PCs occurring during PCs extraction, could be seen as possible explanation of a better repartition of variance that resulted in a gain of rDGVpassing from genome to chromosome wide and from high to medium density. This research was supported by Italian Ministry of Agriculture, grant INNOVAGEN.

Key Words: genomic selection, principal component analysis, high-density SNP panel

T93 Estimation of genetic parameters for calving ease of Holstein cattle in Korea.

Mahboob Alam, Kwang Hyeon Cho*, Tae Jeong Choi, Chung Il Cho, and Yun Ho Choy, *National Institute of Animal Science, Rural Development Administration, Cheonan-si, Chungcheongnam-do, Republic of Korea.*

Calving ease (CE) is a complex reproductive trait of economic importance for dairy cattle. This study was aimed to estimate the genetic parameters of CE for Holsteins in Korea. A total of 978,674 records of CE, collected from 1992 to 2014, from first 5 parities of Holstein cows were analyzed. Age of cows at first 5 parities were ranged within 18–42 mo, 30–54 mo, 42–66 mo, 54–78 mo, and 66–90 mo, respectively. Calving ease was recorded as ordered categories ranged from 1 to 5, indicating 1 = normal (not assisted), 2 = moderate assistance (extraction by 1 person), 3 = moderate assistance (extraction by 2/3 persons), 4 = difficult (extraction by > 3 persons), and 5 = surgical assistance calving. All CE categories were converted to a continuous scale through Snell score transformation procedure. The derived Snell scores for all parities were 0.01, 3.92, 6.288, 7.485, and 8.825 for category 1 through 5, respectively. A single trait sire-maternal grandsire model (S-MGS) was considered for ANOVA and covariance components from each parity cows using ASREML 3.0 software package. Age at calving was fitted as fixed covariate, and herd-year-season, sire and maternal grandsires of the recorded cows were fitted as random effects in the S-MGS model. Estimated direct heritabilities for parity 1 through 5 were 0.06 ± 0.01, 0.08 ± 0.01, 0.10 ± 0.01, 0.07 ± 0.01, and 0.06 ± 0.02, respectively. Maternal heritabilities from the models were 0.02 ± 0.01, 0.04 ± 0.02, 0.03 ± 0.01, 0.01 ± 0.01, and 0.04 ± 0.01, respectively. Genetic correlations between direct and maternal genetic components were moderately to strongly negative for first 5 parities, such as −0.51 ± 0.15, −0.50 ± 0.16, −0.89 ± 0.10, −0.97 ± 0.30, and −0.81 ± 0.17, respectively. This study being the first report on CE of Korean Holsteins, we expect that the estimated genetic parameters derived in the study would be valuable for their calving ease improvement.

Key Words: calving ease, genetic parameter, Holstein cattle

T94 Modeling for estimation of genetic parameters of milk production traits using random regression models in Korean Holstein cattle.

Chung Il Cho, Tae Jeong Choi*, Kwang Hyeon Cho, Mahboob Alam, Yun Ho Choi, and Jae Gu Lee, *National Institute of Animal Science, Rural Development Administration, Cheonan-si, Chungcheongnam-do, Republic of Korea.*

The study was aimed to estimate genetic parameters for milk production traits of Holstein using random regression models (RRM), and compare the goodness of various RRM with homogeneous and heterogeneous residual variances. A total of 126,980 test-day milk production records of the first parity Holstein cows between 2007 and 2014, from the Dairy Cattle Improvement Center of National Agricultural Cooperative Federation in South Korea, were used in this purpose. These records were milk yield (MILK), fat yield (FAT), protein yield (PROT) and solids-not-fat yield (SNF). The statistical models included random effects of genetic and permanent environments using Legendre polynomials of third to fifth order (L3-L5), fixed effects of herd-test day, and year-season at calving and, a fixed regression for the test-day record (third to fifth order). The residual variances in the models were either homogeneous (HOM) or heterogeneous (15 classes, HET15; 60 classes, HET60). Total 9 models (3 orders of polynomials × 3 types of residual variance) such as L3-HOM, L3-HET15, L3-HET60, L4-HOM, L4-HET15, L4-HET60, L5-HOM, L5-HET15, and L5-HET60 were compared using AIC and/or BIC statistic to find the best fitted model(s) for particular traits. The AIC and BIC estimates were different among models for traits. The lowest BIC value was observed for the model L5-HET15 (MILK; PROT; SNF), and L4-HET15 (FAT), and those fitted the best. The BIC value of HET15 model for a particular polynomial order was lower than that of HET60 model in most cases. The estimated heritabilities from the best-fitted models in the study ranged from 0.08 to 0.15 for MILK, 0.06 to 0.14 for FAT, 0.08 to 0.12 for PROT, and 0.07 to 0.13 for SNF according to days in milk of first lactation. Genetic variances for studied traits tend to decrease at earlier stage of lactation, which then followed by an increase in the middle, and a further decrease at the end of lactation. Estimated RRM parameters can be used in Korean national genetic evaluation system instead of lactation models.

Key Words: random regression model, milk production trait, heritability

T95 Estimation of genetic trends and profitability of dairy herds using different reproductive and genetic culling strategies with a stochastic simulation model which includes multitrait genetics. K. Kaniyamattam* and A. De Vries, *University of Florida, Gainesville, FL.*

The objective of the study was to estimate the genetic and phenotypic performance of the herd when voluntary culling of heifers was based on estimated breeding value (EBV) of milk (1st criteria) or Net Merit (NM$) (2nd criteria). A daily dynamic stochastic model that simulates 5000 milking dairy cows, heifers and embryos over time and which included multitrait genetics was used. Heifers were inseminated with conventional (CS) or sexed semen (SS). Surplus dairy cows were culled based on the same criteria used to rank heifers. Genetic and economic changes were measured by the changes in true breeding values (TBV) of milk and NM$, as well as actual phenotypic milk production and profit in a decade. Each of 5 experiment was run 5 times. In the first set of experiments, only CS was used with criteria 1 and 2. The increases in mean ± SE of TBV of milk in first parity cows were 1,243 ± 9 and 1,223 ± 12 kg for criteria 1 and 2 respectively. The corresponding increases in annual milk yield/milking cow were 1,628 ± 31 and 1,607 ± 41 kg. The increases in mean ± SE of TBV of NM$ in first parity cows were $925 ± 10 and $951 ± 6 for criteria 1 and 2, respectively. The corresponding increases in profit/milking cow/yr were $752 and $763. In the second set of 3 experiments SS was used in the first 2 inseminations in heifers with culling of the lowest 20%, 30% and 40% heifers ranked on EBV for DPR. The increases in mean ± SE of TBV of milk in first parity cows were 1090 ± 11, 1084 ± 15 and 1060 ± 4 kg for the 3 heifer cull rates respectively. The corresponding increases in annual milk yield were 1245 ± 44, 1197 ± 42 and 1087 ± 30 kg. The increases in mean ± SE of TBV of NM$ in first parity cows were $975 ± 6, $980 ± 3 and $974 ± 6 for the 3 heifer cull rates respectively. The corresponding increases in profit/milking cow were $680, $685 and $618. In conclusion, the results showed that genetic trends and profitability depended on the genetic culling and reproductive strategies. Future studies will determine optimal combinations of genetic selection and reproductive strategies.

Key Words: multitrait genetics, phenotype, profit

T97 Genetic parameters and trends for dairy traits in Holstein Friesian under North African conditions. Salem Abdalla-Bozrayda[1], Emhimad A. E. Abdalla[1], and Mauricio A. Elzo*[2], *[1]University of Benghazi, Benghazi, Libya, [2]University of Florida, Gainesville, FL.*

Few studies have investigated the performance of Holstein Friesian cattle under North African conditions. Thus, the objectives of this research were to estimate genetic parameters for milk yield (MY, kg), true herd life (THL, d), and age at first calving (AFC, mo), and to compute genetic and environmental trends for MY using information from the Ghot Al-Sultan dairy farm near Benghazi, Libya. The data set contained MY, THL, and AFC records from 1,968 Holstein Friesian first-lactation cows collected from 1986 to 2002. There were 96 sires and 1,511 dams represented in the data set. Genetic parameters were estimated using restricted maximum likelihood procedures using a 3-trait mixed model. Fixed effects were year-season (all traits) and the covariates of age at first calving (MY, THL) and lactation period (MY). Random effects were cow and residual. The relationship matrix included 2,935 animals. Computations were carried out using the AIREMLF90 program. Milk yield genetic trends for cows, sires, and dams were estimated using means of breeding values for cows, sires and dams per year as regressions of average cow, sire, and dam mean breeding values on years. The estimates of heritability for MY (0.17 ± 0.04) and AFC (0.14 ± 0.03) were low, whereas the value for THL (0.05 ± 0.04) was close to zero. The estimates of genetic correlations between MY and THL (0.22 ± 0.01), and between MY and AFC (0.19 ± 0.04) were low, and the correlation between THL and AFC was near zero (0.07 ± 0.04). The MY genetic trends were 4.11 ± 0.92 kg/yr for cows, 5.70 ± 1.12 kg/yr for sires, and 2.32 ± 0.81 kg/yr for dams. Although low, the positive MY genetic trends for cows, sires and dams suggested the existence of an effective selection program and utilization of sires with superior breeding values under Libyan conditions. Conversely, environmental trends were negative for cows, sires, and dams suggesting deterioration of nutrition and management practices during the period covered in this study.

Key Words: dairy cattle, genetic trends, North Africa

T98 Genetic parameters for production traits and age at first calving in Gyr dairy cattle. Marco Prata*[1,2], Francesca Malchiodi[2], Filippo Miglior[3,2], Lenira El Faro[4], Aníbal Vercesi Filho[5], and Vera Cardoso[1], *[1]Departament of Genetics, Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto, SP, Brazil., [2]Centre for Genetic Improvement of Livestock, University of Guelph, Guelph, ON, Canada, [3]Canadian Dairy Network, Guelph, ON, Canada, [4]Centro Avançado de Pesquisa Tecnológica do Agronegócio de Bovinos de Corte, Instituto de Zootecnia, Sertãozinho, SP, Brazil, [5]Centro Avançado de Pesquisa Tecnológica do Agronegócio de Bovinos de Leite, Instituto de Zootecnia, Nova Odessa, SP, Brazil.*

The selection of Gyr cattle in Brazil has been focused mostly on improving milk yield. However, after the implementation of the Brazilian Agriculture Ministry regulation polices in 2002, which established new parameters for milk quality, producers have shown an interest in increasing fat and protein yield, as well as fat and protein content of milk. Other traits of interest for producers included age at first calving, known to be elevated in Gyr cattle, and which has an important economic impact on dairy farms. The objective of this study was to estimate genetic parameters for 305d milk, fat and protein yield, fat and protein content, and age at first calving for Gyr dairy cattle. The data set consisted of 10,977 records from 8,571 Gyr dairy cows in 245 herds in Brazil. Production traits were analyzed through a linear animal model including the fixed effects of contemporary groups (herd - calving year - calving season - parity) and age at calving as covariable (linear and quadratic effects). Direct additive genetic and permanent environmental effects were included as random effects. The model for age at first calving included the effect of contemporary group (herd - year and season of birth). Estimated heritabilities (SE) for milk, fat and protein yield were 0.23 (0.02), 0.18 (0.04), and 0.13 (0.07), respectively. Fat and protein content showed heritabilities of 0.12 (0.05) and 0.08 (0.07) respectively. Furthermore, the estimated heritability of age at first calving was 0.14 (0.02). The results indicated that the selection for these traits is possible in Brazilian Gyr. However, the low heritability values suggest that environmental factors (i.e., management strategies) could have the highest potential impact on the improvement of these traits. Further analysis should be performed to build a multi-trait selection index for Gyr dairy cattle breeding program in Brazil, to obtain desirable genetic gain for these traits.

Key Words: Gyr cattle milk, production, age at first calving

T99 Evaluation of genetic diversity of three indigenous Russian cattle breeds using whole-genome scanning. Elena A. Gladyr[1], Alexander A. Sermyagin*[1], Tatiana E. Deniskova[1], Alexey A. Traspov[1], Veronika R. Kharsinova[1], Gottfried Brem[2], Natalia A. Zinovieva[1], and Alexey V. Shakhin[1], *[1]L.K.Ernst Institute of Animal*

Husbandry, Dubrovitsy, Moscow, Russia, [2]Institute of animal breeding and genetics, University of Veterinary Medicine, Vienna, Austria.

Whole-genome analysis opens the new possibilities to characterize the genetic structure of population and to evaluate the biodiversity in agriculture animal species. The aim of our study was to investigate genetic diversity for local cattle breeds from Central and Northeast European parts of Russia and Siberia in comparison with dairy cattle breeds using the whole-genome SNP data. The total of 57 animals from 5 different breeds were genotyped by 50K Illumina BeadChip including Yaroslavlskaya (n = 5), Kholmogorskya (n = 8) and Yakutian cattle (n = 7) as well as widespread Russian Black-and-White (n = 6) and Holstein (n = 30). Quality control and analysis was performed using PLINK (1.07), while 1119 loci with > 10% of missing data were excluded, 7069 SNPs failed test frequency minor alleles (MAF < 0.01) and one bull was removed with missingness rate > 10%. 46596 SNPs were left for further analysis. A total of 2660 heterozygous haploid genotypes with the genotyping rate 0.992 were revealed. All local breeds characterized by deficient of SNP heterozygotes. Values of index fixation (F) were positive and ranged from 0.57% in the Russian Black-and-White breed to 17.56% in the Yakutian cattle. The genomic inbreeding coefficient was 3.99%, 4.17% and 10.39% for Holstein, Kholmogorskya and Yaroslavlskya breeds, respectively. Runs of homozygosity (ROH) in all investigated animals were 7.64Mb in average wherein minimal ROH was observed for Kholmogorskya, Yakutian and Yaroslavlskya breeds (6,65Mb, 7.25Mb and 7.39Mb,respectively) while for Holsteins and Russian Black-and-Whites were characterized by the maximum value of ROH in 7.97–8.00Mb. Linkage disequilibrium in the data set was $r^2 = 0.40$. The principal component analysis based on pairwise identity-by-state distances confirmed that there was the clear clusterisation among animals of Russian local cattle breeds and the group of Black-and-White and Holstein breeds. The greatest genetic difference was shown between Yakutian, Yaroslavlskya, and Kholmogorskya breeds as well as between Yakutian and the populations, which were assigned to branch of Holstein cattle. Supported by the Federal Agency for Scientific Organizations, Theme number 19.3 and Russian Scientific Foundation, project number 14–36–00039.

Key Words: cattle, biodiversity, whole-genome analysis

T100 Exploring methodology for application of genomic information in South African dairy breeds.

Bernice E. Mostert[1], Robert R. Van der Westhuizen[2], Este Van Marle-Köster*[1], and Brian Van Doormaal[3], *[1]Department of Animal and Wildlife Sciences, University of Pretoria, Pretoria, South Africa, [2]SA Stud Book and Animal Improvement Association, Bloemfontein, South Africa, [3]Canadian Dairy Network, Guelph, ON, Canada.*

The establishment of reference populations for genomic selection for Holstein and Jersey breeds in South Africa (SA) is underway. SA breeders have been using direct genomic values (DGVs) based on foreign reference populations, depending on base year definitions and units of measurement of foreign countries to make within herd selection decisions. Due to extensive linkage with international dairy populations, potential exists for utilizing DGVs originating from foreign reference populations to provide SA breeders with genomic information, comparable to SA breeding values. International collaboration was sought for foreign genomic profiles. Genomic profiles of SA Holstein and Jersey animals were generated based on either the GGPHD78K or GGPLD23K chips and DGV on the Canadian scale were estimated, using the North American Consortium's reference population. These were converted to the SA scale using Interbull conversion equations and blended with the SA Parent Averages (PAs), based on performance of SA cows. This blending was done according to weightings determined by the reliabilities of the DGV and SA PAs. To account for genotype × environmental interactions between Canada and SA, the reliability of the DGV was multiplied by the correlation coefficient between SA and Canada for the specific trait, thereby ensuring that DGV from traits with lower correlations received less weight in the blending with local estimated breeding values (EBV). The weighting for the blending was determined as: EBV weight = EBV reliability/(EBV reliability + DGV reliability). These blended EBVs have been released as genomically enhanced breeding values (GEBVs) and serves as the official breeding values for these animals in the genetic evaluation, which are directly comparable to EBVs of the same breed in SA. Significant increases in the reliability with implementation of this methodology have been observed, with an average increase of 27% for milk yield and 23% for functional herd life. This approach has resulted in the release of GEBVs for production, udder health, fertility, longevity and conformation traits for SA Holstein and Jersey breeders.

Key Words: dairy, genomic information, reliability

T101 Genetic parameters of fertility indicators in Holstein.

Dianelys Gonzalez-Pena*[1], Pablo J. Pinedo[2], Jose E. P. Santos[3], Gustavo M. Schuenemann[4], Guilherme J. M. Rosa[5], Robert Gilbert[6], Rodrigo C. Bicalho[6], Ricardo C. Chebel[3], Klibs N. Galvão[3], Christopher M. Seabury[2], John Fetrow[7], William W. Thatcher[3], and Sandra L. Rodriguez-Zas[1], *[1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]Texas A&M University, College Station, TX, [3]University of Florida, Gainesville, FL, [4]The Ohio State University, Columbus, OH, [5]University of Wisconsin, Madison, WI, [6]Cornell University, Ithaca, NY, [7]University of Minnesota, Saint Paul, MN.*

Reproductive performance of lactating dairy cows influences the annual calving frequency, replacement heifers available, and milk yield. The goal of this study was to estimate the genetic parameters of fertility indicators in dairy cattle. Measurements from 953 Holstein cows from one farm in Texas across 2 calving years were analyzed. Three fertility indicators were evaluated: probability of cycling at d45 post-calving (Pr_Cyc), probability of disease diagnosis at 45d post-calving (Pr_Sck), and probability of pregnancy after 2 AIs (Pr_Prg). These indicators were estimated using a logistic model including the covariables: dystocia, retained placenta, body condition score at 7d and 35d post-calving (BCS7 and BCS35, respectively), and blood β-hydroxybutyrate (BHBA) indication of subclinical ketosis. Univariate sire models including the effects of contemporary group and lactation number were used to estimate the genetic parameters of days open (DO), BCS7, BCS35, Pr_Cyc, Pr_Sck, and Pr_Prg. The percentage of cows cycling, diagnosed with a disease, and pregnant after 2 AIs were 69.7%, 14.9%, and 64.6%, respectively. The marginal probabilities indicated that cows diagnosed with dystocia, retained placenta, metritis, and mastitis were 1.7%, 6.0%, 11.4%, and 7.3% less likely to be cycling than healthy cows, respectively. Cows were 2.7% and 4% less likely to be cycling per unit increase in mucus score and BHBA, respectively. The heritability estimates (and standard errors) for Pr_Cyc, Pr_Sck, Pr_Prg, DO, BCS7, and BCS35 were 0.23 (0.15), 0.29(0.17), 0.58(0.19), 0.19(0.13), 0.25(0.16), and 0.25(0.18), respectively. Our results indicate that the fertility traits considered in this study have an important genetic component and that they could be used as effective indicators of fertility in breeding and management decisions. These findings could be the foundation to develop novel fertility indices that combine the fertility indicators hereby studied to improve the accuracy of pregnancy prediction and selection for improved fertility in dairy production. These findings contribute to

a long-term multistate project database (USDA-NIFA-AFRI-003542) for direct measures of fertility.

Key Words: heritability, fertility, dairy cattle

T102 Selection signature analysis in Holstein cattle identified genes known to affect reproduction.

Li Ma[1], Tad, S. Sonstegard[2], Curtis Van Tassell[2], John B. Cole[2], George R. Wiggans[2], Brian A. Crooker[3], F. Abel Ponce de Leon[3], and Yang Da*[3], [1]*Department of Animal and Avian Sciences, University of Maryland, College Park, MD,* [2]*Animal Genomics and Improvement Laboratory, ARS-USDA, Beltsville, MD,* [3]*Department of Animal Science, University of Minnesota, Saint Paul, MN.*

Using direct comparison of 45,878 SNPs between a group of Holstein cattle unselected since 1964 and contemporary Holsteins that on average take 30 d longer for successful conception than the 1964 Holsteins, we conducted selection signature analyses to identify genome regions associated with dairy fertility. Several genes known to affect reproduction were located in or near genome regions with strong selection signals. These genes include the fibroblast growth factor 1 gene (*FGF1*) on Chr07; the follicle stimulating hormone receptor gene (*FSHR*) and the luteinizing hormone choriogonadotropin receptor gene (*LHCGR*) on Chr11; the KIT ligand gene (*KITLG* or *KITL*), the fibroblast growth factor 6 and 23 genes (*FGF6* and *FGF23*) and the cyclin D2 gene (*CCND2*) on Chr05; the placental growth factor gene (*PGF* or *PLGF*) and the estrogen-related receptor β gene (*ESRRB*) 2Mb downstream of *PGF* on Chr10; and the prolactin receptor gene (*PRLR*) on Chr20. The selection signal for the region containing *FGF1* was among the strongest selection signals we observed. According to the literature on these genes, *FGF1* is involved in broad mitogenic and cell survival activities including embryonic development, *PGF* plays a key role in embryogenesis, *ESRRB* plays an essential role in placenta development, *FSHR* is necessary for follicular development and is expressed on the granulosa cells that are closely associated with the developing female gamete in the ovary of mammals, and *LHCGR* is necessary for follicular maturation and ovulation. Mouse knockout models showed that *FSHR*, *KITLG*, *CCNG2*, and *PRLR* were involved in female fertility proteins. These known gene functions related to reproduction and the fact that these genes were in or near chromosome regions with strong selection signals indicate that these genes could be involved in the vast difference in fertility between contemporary Holsteins and the 1964 Holsteins.

Key Words: fertility, selection signature, Holstein

T103 Genetic interactions for heat stress and herd yield level: predicting foreign genetic merit from domestic data.

Janice R. Wright* and Paul M. VanRaden, *Animal Genomics and Improvement Laboratory, Agricultural Research Service, US Department of Agriculture, Beltsville, MD.*

Genetic-by-environmental interactions were estimated from national data by separately adding random regressions for heat stress (HS) and herd yield level (HL) to the US all-breed animal model to improve predictions of future records and genetic rankings in other climates and production situations. Yield data included 79 million lactation records of 40 million cows; somatic cell score, productive life, and daughter pregnancy rate were also tested but had fewer records. Coefficients for HS were the state's July average temperature-humidity index; coefficients for HL were management-level weighted means for energy-corrected milk (ECM) divided by breed-year mean ECM. Coefficients were standardized to a mean of 0 and variance of 1. Predictions of current (August 2014) from historical (August 2011) records were tested with a model that included herd management group (absorbed), sire estimated breeding value (EBV), dam EBV, and an interaction term (HS or HL) from the truncated data; records were weighted by lactation length for records in progress and by herd heritability using the same weights as in national evaluations. Estimated regression coefficients for sire EBV and dam EBV were always near their expected values of 0.5 and did not change when HS or HL interactions were added to the model. Estimated regressions for interaction terms, expected to be near 1, were 0.80 to 0.93 for HS and 0.61 to 0.72 for HL in yield traits. Squared correlations increased by < 0.0003 for both HS and HL; increases for nonyield traits were even smaller. An additional test used multitrait across-country EBV to predict rankings of the same bulls in the United States and 14 other countries with somewhat different environments. The HS coefficient was significant ($P < 0.05$) in 9 of 14 countries for milk and protein and in 10 for fat; the HL coefficient was significant in 8 countries for milk, 5 for protein, and 1 for fat. Squared correlations after adding an interaction term increased by < 0.004 for HL and < 0.01 for HS. The small changes in rank and correlation gains when HS and HL interactions were included in national evaluations indicate that current genetic predictions perform very well in a variety of environments.

Key Words: heat stress, environmental interaction, random regression

T104 Application of milk mid-infrared (MIR) spectrometry in the dairy cattle industry in Canada.

Saranya Gunasegaram*[1], Allison Fleming[1], Astrid Koeck[1], Francesca Malchiodi[1], Mehdi Sargolzaei[1,2], Milena Corredig[3,4], Flavio Schenkel[1], Bonnie Mallard[5], Ayesha Ali[7], and Filippo Miglior[1,7], [1]*CGIL,University of Guelph, Guelph, ON, Canada,* [2]*Semex Alliance, Guelph, ON, Canada,* [3]*Gay Lea, Guelph, ON, Canada,* [4]*Department of Food Science, University of Guelph, Guelph, ON, Canada,* [5]*Department of Pathobiology, OVC, University of Guelph, Guelph, ON, Canada,* [6]*Department of Mathematics and Statistics, University of Guelph, Guelph, ON, Canada,* [7]*Canadian Dairy Network, Guelph, ON, Canada.*

In Canada, many projects are aiming to integrate milk MIR spectra to develop predictions of milk components and cow status. A proportion of milk spectral data from FOSS MIR machines at Canadian DHI partners, CanWest DHI (Guelph, ON) and Valacta (Sainte-Anne-de-Bellevue, QC), have been saved and transferred to the Canadian Dairy Network, since early 2013. With addition of roughly 60,000 milk spectra every month; from approximately 700,000 cows enrolled in milk recording programs in Canada; the database is nearing 1.8 million. These spectra will be merged with recorded cow reproduction and health events (including hoof health). Currently, University of Guelph is analyzing approximately 2,000 milk samples for their fatty acid profile, milk fat globule and casein micelle size, lactoferrin, calcium, casein, and phospholipid content to use as a reference for developing MIR prediction equations. Genetic and genomic evaluation of Canadian dairy cows and bulls will be done using these MIR predicted milk component traits, with the objective of improving the nutritional value of milk and milk products for human consumption. Use of milk MIR spectra will be incorporated in a pending Canadian project, measuring feed efficiency and methane emissions in dairy cattle as a possible means for prediction. Information available to improve both cow management and genetic evaluation in Canadian dairy industry will be increased with the implementation of MIR prediction of a variety of new milk component and cow traits.

Key Words: milk infrared spectra, genomic, dairy cattle

T105 Development of a daily stochastic dynamic dairy simulation model including the 12 traits in the Net Merit Index. K. Kaniyamattam*, M. A. Elzo, and A. De Vries, *University of Florida, Gainesville, FL.*

We are interested in predicting changes in genetics and profitability of dairy herds when different reproductive strategies are combined with genetic selection. Our objective was to incorporate 12 correlated genetic traits included in Net Merit Index in a dynamic, stochastic model. An existing dynamic, stochastic model that mimics the biology and management of a herd of individual young stock and cows over time was adapted as follows. A true breeding value (TBV) for each trait was calculated as the average of the sire's and dam's TBV, plus a fraction of the inbreeding and Mendelian sampling. TBV were calculated from the Cholesky decomposed genetic covariance matrix of an average unselected Holstein population given as input, multiplied with by a 12 × 1 matrix of standard normal deviates. Similarly, an environmental component for each trait was calculated based on the Cholesky decomposition of the environmental covariance matrix of the same population. The environmental component was partitioned into a permanent and a daily temporary effect. The combined effect of TBV and the environmental component was converted into an effect on the phenotypic performance of each animal for 6 of the 12 traits, for example effects on milk production, fertility, and risk of culling. Hence, genetics and phenotypic performance were associated. Estimated breeding values (EBV) were calculated using a normal inverse function based on correlated random numbers, the animal's TBV and a standard deviation depending on the reliability of the estimate. The EBV were updated 3 times a year, with reliabilities depending on the age of animals. Complete technical and economic measures were calculated by the model over a period of time. Preliminary validation resulted in similar genetic changes per decade as predicted by USDA-AGIL when using the Net Merit index. The model is suitable to estimate the economic and genetic effects from using different reproductive strategies in dairy herds.

Key Words: multitrait genetics, stochastic modelling

T106 Genetic correlations between days open and milk, fat, and protein yields for the Uruguayan Holstein. Nicolas Frioni*[1], Jorge I. Urioste[1], Ignacio Aguilar[2], and Gabriel Rovere[1], [1]*Facultad de Agronomia Universidad de la Republica, Montevideo, Montevideo, Uruguay,* [2]*Instituto Nacional de Investigacion Agropecuaria Las Brujas, Rincon de Colorado, Canelones, Uruguay.*

This study aims to estimate the additive genetic correlations (RA) among days open (DO), milk (MY), fat (FY) and protein yield (PY) in lactations 1 to 3 of Holstein herds on pastures-based production systems. The database used had 546,659; 367,774 and 247,158 observations for 1st, 2nd, and 3rd lactation. Data were edited to set records to DO greater than 42 d. Traits for each lactation were considered different and they were analyzed using 6-variate models, with DO and a production trait. The fixed effects were the age at calving and the combined effect of the herd-year-season and the random additive genetic effect of the animal. Estimations were obtained via Gibbs sampling with Gibbs2f90 program. Heritabilities obtained for each lactation of DO ranged from 0.04 to 0.06, for MY the range was 0.23 to 0.22, for PY from 0.09 to 0.28 and for FY from 0.06 to 0.28. The RA between DO ranged from 0.68 to 0.96, although they were different from 1, most of the values were very high to consider them as different traits. The RA between DO and production traits is presented in Table 1. Results suggest that DO can be considered as one trait, adjusting the model with a fixed effect accounting for different lactations. Unfavorable relationship between DO and production traits may be confirmed, thus is necessary the inclusion of fertility in selection programs, and further estimation of RA analyzing all traits together with a repeatability model.

Table 1 (Abstr. T106). Additive genetic correlations among days open, milk yield (MY), fat yield (FY), and protein yield (PY) in lactations 1 to 3 of Holstein herds

		Days open		
		1	2	3
MY	1	0.39 (0.0375)	0.56 (0.0338)	0.51 (0.0638)
	2	0.49 (0.0357)	0.58 (0.0314)	0.59 (0.0640)
	3	0.40 (0.0335)	0.54 (0.0393)	0.63 (0.0581)
PY	1	0.43 (0.0456)	0.53 (0.0471)	0.78 (0.0282)
	2	0.44 (0.0425)	0.53 (0.0375)	0.69 (0.0372)
	3	0.46 (0.0601)	0.55 (0.0535)	0.67 (0.0543)
FY	1	0.41 (0.0751)	0.51 (0.0907)	0.69 (0.0565)
	2	0.54 (0.0604)	0.66 (0.0434)	0.80 (0.0345)
	3	0.34 (0.0620)	0.46 (0.0520)	0.63 (0.0493)

T107 Angiotensin-converting enzyme inhibitory activity of whey proteins obtained from the manufacture of traditional Mexican cheeses. Yuridia S. Tarango-Hernandez, Alma D. Alarcon-Rojo, Nestor Gutierrez-Mendez, and Jose C. Rodriguez-Figueroa*, *Universidad Autonoma de Chihuahua, Chihuahua, Mexico.*

Traditional Mexican cheese production has been increasing in recent years. Thus, the increase in cheese whey volume must be carefully dealt with. Because of its high BOD (27–60 g L^{-1}) and DOQ (50–102 g L^{-1}), cheese whey represents a potential pollutant to the environment. However, studies have demonstrated the bioactivity of whey proteins. Therefore, this research aimed to evaluate the angiotensin-I-converting enzyme (ACE)-inhibitory activity of Fresco, Asadero and Chihuahua cheese whey. Samples corresponded to 3 different traditional cheese-making times. The <1 and 3–1 kDa whey fractions were obtained by ultrafiltration. The ACE-inhibitory activity was evaluated by standardized RP-HPLC methodology. Results showed that all cheese whey fractions were able to inhibit ACE activity. The highest ACE-inhibitory activity (67.3 ± 2.0%) was found in the < 1 kDa Fresco cheese whey fraction, however it was not significant different ($P > 0.01$) from the Asadero cheese whey fraction (65.3 ± 3.6%). In contrast, the <1 kDa Chihuahua cheese whey fraction presented the lowest ($P < 0.01$) activity (29.3 ± 7.5%). The 3–1 kDa Asadero cheese whey fraction showed high ($P < 0.01$) ACE-inhibitory activity value (66.1 ± 3.6%). In conclusion, Asadero and Fresco cheese whey presented relevant ACE-inhibitory activity. Therefore, whey obtained from the manufacture of these traditional Mexican cheeses may have a potential to be used as functional ingredients.

Key Words: ACE-inhibitory activity, traditional Mexican cheese, whey

T108 The effect of partially hydrolyzed different milk species on xanthine oxidase activity of fetal enterocyte culture. Hristina Kocic*, *Medical Faculty University Maribor, Maribor, Slovenia.*

Introduction of enteral nutrition in early life may lead to autoimmune, inflammatory and allergic reactions. Oxidative damage is a contributing factor in inflammatory bowel disease, necrotizing enterocolitis and ulcerative colitis. Xanthine oxidase (XO) plays an important role in oxidative injuries, because of the generation of free radical hydrogen peroxide (H_2O_2). It can induce oxidative modification and may activate redox-sensitive transcription factors (NF-κB) and proinflammatory cytokines. This study was conducted with the aim to compare the effect of hydrolyzed milk samples, β-casein (CS) and β-casomorphin-7 (CSM-7) on XO activity in culture of fetal human enterocytes (commercial H4 cells). During exposure of H4 cells to hydrolysed milk species, XO activity (U/g prot) decreased significantly treated with hydrolyzates of human colostrum (85.28 ± 7.31*), mature human milk (80.34 ± 5.40*), donkey colostrum (91.82 ± 4.47*), mature donkey milk (71.73 ± 3.89*) vs 165.33 ± 3.40 of control H4 cells. The activity did not change significantly by using cow colostrum (182.20 ± 5.88), but decreased with mature cow milk (101.84 ± 11.56*). Significant decrease was observed for Bebelac formula 0 (96.35 ± 8.89*), but not of Bebelac formula for 12 mo (139.36 ± 5.88). Both, CS and CSM-7decreased XO activity (66.80 ± 6.48* and 67.98 ± 5.32*). Observed activities correlated positively with NF-kB activity, but negatively with proliferative (mitotic activity) of H4 cells. Exclusive breast-feeding has been associated with a reduction in the incidence of chronic inflammatory conditions, including autoimmune diseases, allergies, asthma, atopic dermatitis and inflammatory bowel diseases, what may correlate with decreased oxidative stress. The use of donkey milk seems to be a promising strategy against allergic and other immune-related reactions, regarding oxidative injury and XO activity. Well-documented antioxidative properties of CS may be due to decreased XO activity. Well-documented toxic effects of CSM-7 may not depend on XO activity.

Key Words: donkey milk, breast milk, cow milk

T109 Case study: Comparison of biologically active compounds in milk from organic and conventional dairy herds. Diane L. Van Hekken*[1], Michael H. Tunick[1], Hubert J. Karreman[2], Elaine R. Ingham[2,3], and Peggy M. Tomasula[1], *[1]USDA, ARS, Wyndmoor, PA, [2]Rodale Institute, Kutztown, PA, [3]Soil Foodweb Inc., Corvallis, OR.*

Conflicting reports of the quantities of biologically active compounds present in milk from organic grass-fed and conventional herds show that more research is required, especially as these compounds are linked to human health benefits and can improve the health value consumers place on dairy products. In collaboration with the Rodale Institute, Kutztown, Pennsylvania, a 3-year study evaluated the composition of milk obtained from 2 farms adjacent to the Rodale experimental farm: one herd transitioned to certified organic in the first year; cows averaged over 50% dry matter intake from pasture during the grazing season. The other herd was on a confined conventional farm with no access to pasture. This study provided a unique opportunity to compare milk from farms of similar soil types, climate, and weather. Over a 150-week period (3 grazing seasons), weekly milk samples were collected and assayed for composition and physical traits, and profiled for fatty acids (FAs) and proteins-peptides. The overall protein, lactose, ash, minerals, total solids contents, pH, water activity, titratable acidity, and protein profiles of the milk samples from both farms were similar ($P < 0.05$). Fat content was more variable in the milk from the organic herd, especially after the seasonal grazing was implemented, with higher fat levels ($P < 0.05$) obtained during the winter months. The FA profiles were the major difference between the milk from the 2 herds. Compared with the confined herd, the grazing herd milk had considerable variation in the FA profiles, which generally stabilized after 4 mo, and had higher levels ($P < 0.05$) of α-linolenic acid (omega-3 FA) after the second month. Once certified, the organic herd produced milk that contained 36% more omega-3 FA and had lower linoleic acid (omega-6):omega-3 FA values throughout the year, and 25–30% more conjugated linoleic (CLA) during the grazing seasons than the confined herd. Because higher CLA and omega-3 FA levels and a low omega-6:omega-3 value have been linked to being beneficial to human health, the importance of pasture grazing must be considered in supplying milk and dairy products that address consumers' demand for foods that support human health and wellness.

Key Words: milk, organic, omega-3 fatty acids

T110 Evaluation of the effect of diets containing grape seed and linseed on milk fatty acid composition in Sarda sheep by principal component analysis. Fabio Correddu, Anna Nudda*, Giustino Gaspa, Gianni Battacone, and Giuseppe Pulina, *Dipartimento di Agraria, University of Sassari, Sassari, Italy.*

This work aimed was to study the effect of the dietary inclusion of grape seed and linseed, on milk fatty acid (FA) composition in Sarda dairy sheep. Milk samples were collected weekly from 24 Sarda ewes assigned to 4 dietary treatments: control diet (CON), containing 300 g/d of grape seed (GS), a diet containing 220 g/d of linseed (LIN) and a diet containing both lin- and grape seed (MIX). Samples were analyzed for FA profile with GC. Data of major classes of FA were analyzed by principal component analysis (PCA) and the first 2 PC were retained for further analysis based on the proportion of variance explained by PC. The first and second PC accounted for about 90% of the total variability (78.3% and 12%, PC1 and PC2, respectively). Elements of eigenvector of PC1 were positively associated with unsaturated (0.246), monounsaturated, long, *trans* FA and CLA (0.244, 0.243, 0.233, 0.231), whereas groups characterized by short, medium chain FA, saturated FA showed negative association with PC1 (−0.231, −0.238, −0.246). PC2 loadings were positively correlated with n-6 and n-6/n-3 ratio (0.455, 0.559), and negatively with n-3 (0.470). Furthermore, PC1 presented negative loadings for atherogenic index and thrombogenic index (−0.238, −0.236). It was supposed that PC1 was positively associated with the PUFA intake, which progressively increased in CON, GS, LIN and MIX. PC2 could be related to the different source of PUFA (grape seed or linseed) and consequently, with the ratio PUFA n-6/n-3 in the diet. The observations plotted on the new system of variables defined by PC1 and PC2, revealed definite clusters for each of the 4 dietary treatments. Incremental scores in PC1 were observed for CON, GS, LIN and MIX, (−5.8, −0.3, 1.5, 4.5, respectively); PC2 discriminated only GS (positive scores, 1.9) from LIN (negative scores, −2.0). Overall, the results suggest that the inclusion of grape seed and linseed in the diet of lactating ewes could be useful to improve the quality of milk FA, especially when used in combination. The PCA has shown to be a useful tool for understanding the effect of different dietary treatments on milk FA profile.

Key Words: grapeseed, milk fatty acid, multivariate analysis

T111 Interaction between whey protein and inulin in model system.

Cuina Wang[1], Hao Wang[1], and Mingruo Guo*[1,2], [1]*Jilin University, Changchun, Jilin, China,* [2]*University of Vermont, Burlington, VT.*

Effects of protein concentration (4–8%, w/v), inulin concentration (1–5%, w/v) and ionic strength (10–50 m*M*) on Ca^{2+}-induced interactions between whey protein (WP) and inulin mixture (pH 7.0) heated at 85°C for 30 min were investigated. The interactions were analyzed for turbidity, particle size, zeta potential, apparent viscosity, and texture profile. Interaction properties were also compared with mixture of polymerized whey protein (PWP) and inulin in which whey protein was heated first and then mixed with inulin. Results indicated that the dispersion became more opaque with increasing protein but no significant difference was detected regarding the way inulin added ($P < 0.05$). Three peaks at about 40, 900 and 5000 nm were observed in size distribution by volume. Compared with the control, there was a small shift toward larger size with increasing inulin level in the width of peak corresponding to denatured whey protein. Zeta potential values for all samples fell in the ranges of −10 to −30 mV independent of the manner in which inulin added. Increasing inulin resulted in less negative zeta potential and smaller repulsive force between particles for both types of mixtures. As protein and inulin increased, apparent viscosity increased and combination of PWP and inulin showed significant higher values ($P < 0.05$) than WP and inulin mixture. It was not sufficient to form cold gels for all samples at the level of 10 m*M* Ca^{2+}. Compared with the control, the mixtures of PWP with inulin showed higher water holding capacity may due to the ability of occluding water of inulin microcrystals ($P < 0.05$). WP/inulin mixture showed significant higher hardness ($P < 0.05$) than PWP/inulin due to possible microcrystal seeds maintained in solutions when heated at 80°C for 30 min. Results indicated that interactions maybe occurred between whey protein and inulin in the model system.

Key Words: whey protein isolate, polymerized whey protein, inulin

T112 Characterizing the dissolution behavior of whey protein concentrate with an ultrasonic flaw detector.

Mary Hauser* and Jayendra Amamcharla, *Kansas State University, Manhattan, KS.*

Current methods used in the dairy industry to characterize the dissolution process are difficult to reproduce and subjective. Low-intensity ultrasound spectroscopy has the advantage of being rapid and precise, but the equipment is expensive. An ultrasonic flaw detector (UFD) is an economical alternative and allows for rapid data collection at a single frequency. This study focused on characterizing the dissolution behavior of whey protein concentrate (WPC) with an UFD. The experimental setup included an UFD (Epoch LTC) in pulse-echo mode and a 1MHz immersion transducer. Two batches of WPC80 from a commercial manufacturer were stored at 25°C and 40°C for 3 weeks. 19.74g of WPC was gradually added to 375g water. The tests were performed in duplicate. During dissolution, ultrasonic (US) data from UFD, chord length distribution from focused beam reflectance measurement (FBRM), and solubility index were collected at regular intervals for 1800s. US relative velocity and attenuation were calculated from A-scan data obtained from the UFD. The relative velocity was defined as the ratio of the US velocities of WPC solution and water at 40°C. It was observed that fresh WPC had a relative velocity of 1 after 1800s. The relative velocity at 1800s increased for powders stored at 25°C and decreased for powders stored at 40°C. After 3 weeks of storage at 25°C and 40°C, the relative velocities were 1.015 and 0.98, respectively. Attenuation had a general trend of increasing and then gradually decreasing. The storage temperature of WPC influenced the time to reach the peak and the area under the attenuation curve. Fresh powders reached the peak after 1440s. Three weeks of storage at 25°C and 40°C caused the peak time to increase to 1658s and decrease to 986s, respectively. The area had a similar trend. Fresh powders had an area of 60Np*s/m. Powders stored at 25°C and 40°C for 3 weeks had areas of 47Np*s/m and 91 Np*s/m, respectively. Storage temperature significantly ($P < 0.05$) effected relative velocity at 1800s, peak time, and area. FBRM data showed that powders stored at 40°C for 3 weeks had larger particles. Overall, a UFD can be a useful tool when characterizing the dissolution behavior of WPC.

Key Words: ultrasonic flaw detector, whey protein concentrate

T113 Effect of pH and Ca-ion activity on the heat stability of reconstituted reduced Ca milk protein concentrate dispersions.

Gopinathan H. Meletharayil[1], Anil Kommineni*[1], Chenchaiah Marella[2], and Lloyd E. Metzger[1], [1]*Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings, SD,* [2]*Idaho Milk Products, Jerome, ID.*

The purpose of this study was to investigate the heat stability and calcium ion activity of the reconstituted MPC dispersions. Reduced calcium MPC (RCMPC) powders were produced from skim milk subjected to CO_2 treatment before and during the process of ultrafiltration. The CO_2 injection was controlled to obtain 0, 20, 30, and 40% reduction in Ca levels of MPC powders. RCMPC powders were reconstituted to 10% protein in deionized water. These dispersions were tested for heat stability in a rocking oil bath at 140°C at unadjusted, 6.5, 6.7, 6.9, and 7.1 pH. Calcium ion activity (CIA) and ionic strength measurements on Ca-standards and all dispersions were carried out using a Ca ion-selective electrode and conductivity meter. The unadjusted pH of the dispersions varied from 6.8 in control to 5.95 in 40% RCMPC dispersions. This pH difference had an effect on the CIA of the dispersions and ranged from 1.31mM in control to 18.39mM in 40% RCMPC dispersions. Differences in the heat stability were observed in the unadjusted pH dispersions with the control MPC having the highest heat stability that decreased as the percentage of Ca reduction increased. The heat stability of control MPC dispersions showed a minimum at pH 6.7 and maximum at pH 6.9 with a decrease observed at pH 7.1. The CIA of RCMPC dispersions decreased with an increase in pH. A steady increase in the heat stability of 30 and 40% RCMPC dispersions was observed with increase in pH which correlated with decrease in the calcium ion activity. Dispersions from 20% RCMPC showed a heat stability profile similar to the control MPC dispersion but had higher heat stability values at all adjusted pH values. The CIA activity had a direct correlation on the heat stability of the unadjusted MPC dispersions, but at a higher pH of 7.1, no correlation was evident, even though, all the dispersions had a low CIA. Heat stability of 30 and 40% RCMPC dispersions increased with an increase in the pH showing highest heat stability at a pH of 7.1. From this study, it can be concluded that pH and ca-ion activity influences the heat stability of RCMPC dispersions.

Key Words: milk protein concentrate, Ca ion activity, heat stability

T114 Rennet coagulation and cold gelation properties of recombined highly concentrated micellar casein concentrate and cream.

Ying Lu*[1], Donald McMahon[1], Lloyd Metzger[2], Anil Kommineni[2], and Almut Vollmer[1], *[1]Western Dairy Center, Utah State University, Logan, UT, [2]Midwest Dairy Foods Research Center, South Dakota State University, Brookings, SD.*

Highly concentrated micellar casein concentrate (HC-MCC), a potential ingredient for cheese making, containing ~20% casein with ~70% of whey proteins removed by microfiltration, and diafiltration of skim milk, and then further concentrated by vacuum evaporation. Our objective was to investigate rennet coagulation and cold gelation properties of recombined thawed frozen HC-MCC and cream under different conditions. The HC-MCC was recombined with cream using low shearing at 50°C for 30 min, followed by rheological measurements. Cold gelling temperature [the temperature at which storage modulus (G′) = loss modulus (G″)], was positively correlated with casein levels from 8.6% to 11.5% ($R^2 = 0.71$) and pH from 6.6 to 7.0 ($R^2 = 0.96$). Gelation occurred at ~35, ~26 and ~13°C with 11%, 10% and 9% casein concentration, respectively. This process was reversible with a hysteresis effect observed depending on whether the mixture was being heated or cooled. Rennet coagulation of HC-MCC and cream mixture at rennet level of 20 mg/100 g was studied by testing coagulation time (CT, the time when G′ = G″) and curd firming rate (the ratio of G’ at 1.5 times of coagulation time and at coagulation time). Increasing casein level from 3.3 to 10.9% significantly increased ($P < 0.001$) G’ from 0.1 to 2 Pa, and slightly reduced CT ($P < 0.05$) by 1.3 min from casein level from 3.3% to 5.7%, without change of CT at higher casein level. Decreasing pH of mixture from 6.6 to 6.2 significantly reduced CT ($P < 0.001$) by 5.5 min, and increased firming rate ($P < 0.05$) from 35 to 107. Decreasing coagulation temperature from 31 to 25°C significantly decreased firming rate ($P = 0.001$) from 160 to 76, increased CT ($P < 0.001$) by 2 min, and G’ ($P < 0.05$) from 2 Pa to 4 Pa. Addition of citrate to the mixture significantly decreased ($P < 0.05$) firming rate from 35.2 to 4.6, increased G’ ($P < 0.05$) from 3 Pa to 6 Pa, with no significant effect ($P > 0.05$) on CT. Therefore, decreasing coagulation temperature, or adding citrate may make rennet coagulation properties of recombined HC-MCC and cream at high casein level more suitable for cheese making by increasing coagulation time and reducing curd firming rate. Understanding rennet coagulation and cold gelation properties can help potentially use recombined HC-MCC and cream for cheese making.

Key Words: rennet coagulation, micellar casein, microfiltration

T115 Formation of sodium caseinate-maltodextrin conjugates and the rheological properties of acid gels.

Shuwen Zhang*[1,2], Yuansheng Gong[1], Som Khanal[1], Yanjie Lu[1], and John A. Lucey[1], *[1]Department of Food Science, University of Wisconsin-Madison, Madison, WI, [2]Institute of Agro-Product Processing Science and Technology, Chinese Academy of Agricultural Sciences, Beijing, China.*

Conjugation of polysaccharides to proteins utilizing the Maillard reaction leads to significant improvement in the functional properties of proteins, such as solubility, emulsification, and thermal stability. However, no gelation properties of conjugates have previously been reported. In this study, we studied the conjugation reaction between sodium caseinate (NaCN) and maltodextrin100 (Md100) in aqueous solutions via the initial stage of the Maillard reaction. The rheological properties of acid-induced gels made from NaCN-Md conjugates prepared by Maillard reaction were investigated. Acidification was performed by the addition of glucono-delta-lactone at 30°C. Covalently linked conjugates of NaCN and Md100 were produced by incubating aqueous solutions containing 5% NaCN and 5% Md100 at 90°C for 10 h. The covalent attachment of Md100 to NaCN was confirmed by SDS-PAGE with both protein and carbohydrate staining. The Schiff base formation of NaCN-Md conjugates was monitored by maximum absorbance peak at □300 nm using UV spectroscopy. Conjugation resulted in faster gelation (higher pH) but lower storage modulus and shear stress values of acid gels compared with gel made with NaCN only. An increase of loss tangent was also observed in acid gel made with conjugates. These results indicate that conjugates modify protein gelation and a potential use for these NaCN-Md could be as specialty functional food ingredients.

Key Words: sodium caseinate, maltodextrin, conjugate

T116 Edible packaging films from calcium-caseinate and citric pectin.

Laetitia M. Bonnaillie* and Peggy M. Tomasula, *USDA/ARS/NEA/ERRC, Wyndmoor, PA.*

Casein-based films have excellent gas-barrier properties and strength appropriate to form a variety of edible food packaging, but do not constitute strong moisture barriers. In prior work, we used humidity-controlled DMA (DMA-RH) to show that solvent-cast films from calcium caseinate (CaCas, 75% dry basis) and glycerol plasticizer (Gly, 25% dry basis) of 0.03–0.05 mm thickness are extremely sensitive to ambient relative humidity (RH) and temperature (T) and melt around Tm~45°C at 50% RH, or RHm~67% at 20°C; Tm also decreases at higher RH, which limits the usefulness of CaCas packaging films in warm and/or humid conditions. Citric pectin (CP, 0.1 to 2% dry basis) was explored as an edible additive to crosslink CaCas/Gly films with the objective to improve their environmental resistance. CP was added to water/Gly solutions, stirred for 1h, then CaCas was added and stirred for 1 h. Dynamic T-ramps (10–70°C) with an AR2000 rheometer showed that at 25°C, CP% strongly increased the viscosity and storage modulus, G′, of the solutions near-exponentially, signifying strong binding of CP with CaCas; in addition, new crosslinks were activated between ~42–60°C for 1–2% CP. DMA-RH (Q800) T-ramps of dried films at 50% RH showed that 0.1–0.5% CP softened the films and reduced G′ due to steric hindrance of isolated CP particles throughout the CaCas network, while

1 to 2% CP increased G′, demonstrating a higher crosslink-density in the films. Tm increased to ~50°C with 1% CP and ~60°C with 2% CP. Optical microscopy imaging confirmed strong changes in the CaCas/Gly/CP network as a function of CP content. Moisture sorption RH-ramps at 20°C (Q5000SA) indicated that CaCas films absorb ~10% of their weight in water at 50% RH and up to ~28% at 80%RH; adding up to 2% CP reduced water-sorption by up to 15% at high RH. High CP% (0.75–2%) slowed dissolution kinetics of the films in water at 20°C, while low CP% (0.1–0.5%) accelerated solubilization slightly. CaCas films strengthened with > 1–2% CP are more environmentally-resistant and have the potential to replace or improve some synthetic food packaging to reduce waste and/or add functionality and nutrition to food products.

Key Words: casein, hydrophilic film, dynamic rheology

T117 Changes in volatile compounds in whey protein concentrate stored at elevated temperature and humidity.

Michael H. Tunick*[1], Diane L. Van Hekken[1], Susan K. Iandola[1], Russell Bazemore[2], Caitlin Allison[2], and Katherine M. Bazemore[2], *[1]USDA, ARS, Eastern Regional Research Center, Dairy & Functional Foods Research Unit, Wyndmoor, PA, [2]2Volatile Analysis Corporation, Grant, AL.*

Whey protein concentrate (WPC) has been recommended for use in emergency aid programs, but it is often stored overseas without temperature and relative humidity (RH) control, which may cause it to be rejected because of yellowing, off-flavors, or clumping. Therefore, the volatile compounds present in 14.0-kg bags of WPC34 (36% protein) and 18.7-kg bags of WPC80 (79% protein) were analyzed during storage over 18 mo in environmental chambers at 25, 30, and 35°C at RH levels of 70, 80, and 90%. An ambient chamber at around 21°C and 45–65% RH served as the control. The concentrations of dimethyl disulfide increased with time as the sulfur-containing amino acids cysteine and methionine were degraded. Five aldehydes (hexanal, heptanal, octanal, nonanal, and benzaldehyde) and 2 ketones (2-butanone and 2-heptanone) appeared as a result of lipid oxidation. Lactose breakdown led to the presence of butanol, hexanol, and furaneol. The levels of volatiles were higher in the WPC80 and tended to increase with temperature and RH. Although the color and flow properties were affected by the conditions, the generation of volatile compounds did not have a noticeable effect on product odor.

Key Words: whey protein concentrate, volatile compounds

T118 Characterization of milk, soymilk, and almond milk through consumer affective and emotional responses.

Hayley L. Potts*, Kristen A. Leitch, Laurie M. Bianchi, and Susan E. Duncan, *Virginia Polytechnic Institute & State University, Blacksburg, VA.*

Plant-based milk beverages, notably soymilk and almond milk, are competing with dairy milk in the refrigerated retail case. It is unknown if product sensory differences affect consumer behaviors and purchasing decisions. Dairy and plant-based milk beverages were evaluated for acceptability and characterization of product attributes and emotional response for dairy milk, almond milk, soymilk, and soymilk with added titanium dioxide for whitening. We hypothesized that appearance would affect acceptability; soymilk treatments and almond milk, with a darker visual appearance, would have different acceptability and emotional characterization than dairy milk. Untrained panelists (n = 49) received each product for evaluation of overall acceptability, just-about-right (JAR) scale, and check-all-that-apply (CATA) emotional terminology (EsSense) ballot. Mean acceptability of all treatments was between "neither like or dislike" and "like slightly" on a 9-point hedonic scale (mean = 5.33); however, all products appeared to have bimodal distributions. CATA emotional terms calm, content, good, and mild were chosen by >20% of panelists (frequently selected terms) for all treatments. Of the frequently selected terms across products, calm was selected less for soymilk, good was chosen more for almond milk, and the terms happy and pleasant were not chosen for dairy milk. Mild (almond, soymilk with titanium dioxide, and dairy milk) and quiet (soymilk, soymilk with titanium dioxide) terms were associated with decreased hedonic score based on penalty life analysis. Pleased (soymilk) and satisfied (dairy milk) were most closely associated with high hedonic scores. Dairy milk had a more optimal appearance than all plant-based milk products based on JAR characteristics. Almond milk and soymilk have different product characteristics than dairy milk, based on JAR, that influence acceptability. Plant-based beverages, while competing for shelf-space in the dairy retail case, do not match consumer just-about-right expectations for sensory quality as well as dairy milk. Understanding consumer emotional perception of dairy milk compared with plant based milk beverages can add value to marketing and promotion of fluid milk in a competitive beverage market.

Key Words: milk, emotions, just-about-right scale

T119 Effect of storage temperature on physico-chemical and sensory attributes of ready-to-drink breakfast smoothie.

Dipakkumar Mehta*[1], Latha Sabikhi[2], Sathish Kumar[2], and Hasmukh Patel[1], *[1]South Dakota State University, Brookings, SD, [2]National Dairy Research Institute, Karnal, Haryana, India.*

Shelf-life is an important consideration for ready-to-drink (RTD), long-shelf-life beverages such as smoothie. For any new product, product developer would be interested to know the shelf-life of the products when stored at different temperature. The objective of the present study was to determine the physico-chemical and sensory stability of formulated smoothie at 3 different temperatures (4°C, 30°C and 40°C). Sensory analysis using trained panel as well as physico-chemical attributes such as expressible serum (ES), acidity, pH, viscosity were studied to determine the shelf-life. An expert panel consisting 10 member evaluated the products for its color and appearance (C&A), flavor, consistency, sweetness and overall acceptability (OA) based on 9-point hedonic scale at the interval of every 15 d. Effect of storage period on acceptability of smoothie at 3 different temperatures was analyzed using IBM SPSS 20 software and study was done in triplicate. ES and acidity values were increased significantly ($P < 0.05$) at all temperatures during storage and highest increment for both parameters were found at 40°C while lowest increment were at 4°C. Viscosity was increased during storage at 4°C but reduction was found at rest of 2 temperatures ($P < 0.05$). pH of product decreased at all temperatures significantly ($P < 0.05$). Sensory attributes; C & A, flavor, sweetness and OA scores were significantly ($P < 0.05$) reduced during storage at all temperatures. Highest reduction in scores was found at 40°C while lowest reduction was at 4°C. In case of consistency, score was increased during storage at 4°C while reduction in score was observed at 30°C and 40°C ($P < 0.05$). Shelf life studies revealed that the product remained an acceptable up to 90, 75 and 60 d at 4°C, 30°C and 40°C respectively.

Key Words: ready-to-drink, smoothie, storage study

T120 Physico-chemical profile and mineral content of yogurts and whey beverages available in the Brazilian market.

Thaiza Serrano, Simone Lorena, Adriano Cruz, and Renata Raices*, *Federal*

Institute of Science and Technology of Rio de Janeiro (IFRJ), %%Rio de Janeiro, Brazil.

The physico-chemical profile and the minerals content in yogurt and whey beverage marketed in Brazilian market were investigated. Twenty samples (Ten yogurt and 10 whey beverages) presented in the label Federal Inspection Service (SIF) were submitted to physicochemical analysis (moisture, proteins and lipids levels) minerals contents (Ca, Fe, K, Mg, Na, Cd, Cr, Cu, Mn and Pb) being the latter identified and quantified from Inductively Coupled Plasma Optical Emission Spectrometry (ICP-OES). Absence of difference was noted in moisture content, as the yogurt samples presented mean value 82.12 ± 0,21% while and the dairy beverages presented 83.08 ± 0,06% w/w ($P > 0.05$). Both products presented protein content of yogurt above the minimum required by the legislation (4.87 ± 0.42% w/w and 2.72 ± 0.13% w/w, yogurt and whey beverage, respectively) which present an advantage on the nutritional point of view. Regards the lipid levels, the yogurt presented high values compared with whey beverages (2.00 ± 0.07 and 1.23 ± 0.06% w/w, respectively, $P < 0.05$). Calcium was the mineral with the highest concentration in both product categories (mean values 1.36 ± 0.36 and 1.07 ± 0.36 mg/ g, respectively, $P < 0.05$), followed by potassium (mean values 1.60 ± 0.29 and 1.41 ± 0.21 mg/g, respectively, $P > 0.05$), sodium (mean values 0.74 ± 0.15 and 0.68 ± 0,09 mg/g, respectively, $P > 0.05$), magnesium (mean values 0.16 ± 0.04 and 0.11 ± 0.01 mg/g, respectively, $P > 0.05$) and iron (0, 01 ± 0.00 mg/g for both products categories). It was not detected minority constituents (Cd, Cr, Cu, Mn and Pb), in both products.

Key Words: yogurt, whey beverage, characterization

T121 Probiotic fermented milk with banana flour: Understanding the prebiotic effect.

Aline Silva, Renata Raices, Marcia Cristina, Luciana Nogueira, and Adriano Cruz*, *Federal Institute of Science and Technology of Rio de Janeiro (IFRJ), Rio de Janeiro, Brazil.*

This study aimed to investigated the effect of adding increased amounts of banana flour (0, 0.5, 1.5 e 3 w/w %, I, II, III, IV) in probiotic fermented milk processing. Microbiological (*Streptococcus thermophilus, Lactobacillus acidophilus* and *Bifidobacterium* counts), Physicochemical analysis (gross composition, resistant starch, pH, proteolysis and firmess) were performed weekly along 21 d. While *S. thermophilus* presented always values about 8 log cfu/g for all samples, probiotic microrganisms presented different behavior. While *L. acidophilus* presented a decrease in the viable counts in the samples added with 3 w/w % banana flour (from 8.03, d 1, to 7.14 log cfu/g, d 21, $P < 0.05$), *Bifidobacterium* present increase along the storage time (6.78, d 1 to 7.14 log cfu/g, d 21, $P < 0.05$). Toward the physic-chemical parameter, pH did not present difference among the samples and related to storage time (values ranged 4.60 to 4.67, $P > 0.05$), while increased proteolysis level was observed at the fermented milks added with intermediate levels of banana flour (values ranged from 0.430 to 0.667, sample II and 0.455 to 0.662, sample III) in relation to sample III (values ranged from 0.345 to 0.378, $P < 0.05$). For the firmness, it was observed direct relation with the banana flour addition (values ranged to 1.23, sample I to 1.88 N, sample IV) without relation to the storage time. The gross composition reported absence of difference among the fat and proteins levels while for resistant starch content, sample III presented increased decrease (30.11%) compared with sample IV (20.07%), respectively. Our findings suggest the need to adjust the banana flour dosage during probiotic fermented milk processing as well as the probiotic culture to be added at the formulation to obtain the prebiotic effect.

Key Words: banana flour, probiotic fermented milk

T122 Probiotic yogurt with glucose oxidase: Performance with commercial products and potential advantages.

Aline Batista, Marcia Silva*, Renata Raices, Luciana Nogueira, and Adriano Cruz, *Federal Institute of Science and Technology of Rio de Janeiro (IFRJ), Rio de Janeiro, Brazil.*

The quality parameters of probiotic yogurt with addition of glucose oxidase (250 and 500 ppm, GOXI and GOXII) compared with commercial products available in the Brazilian market were investigated. Microbiological (probiotic bacteria count), physical-chemical (pH, proteolysis) and metabolic activities (production of organic acids, flavor and aroma compounds and fatty acid profile) were performed. High counts were observed for all microorganisms, with values above 9 log cfu/mL for *S. thermophilus,* and 8 log cfu/mL for *L. bulgaricus*, *L. acidophilus,* and *Bifidobacterium* ($P > 0.05$). In addition, they presented lower post-acidification values and the highest proteolysis values, which ranged from 4.17 to 4.21 and 0.796 to 0.788, respectively, $P < 0.05$), as well as exhibited similar results for lactic acid and acetic acid (from 1.34 to 1.37, and 0.72 to 0.79 mg/mL, $P > 0.05$), and higher values for diacetyl and acetaldehyde. Regards the fatty acid profile, it were observed intermediate values for short- and medium-chain fatty acids (SCFA and MCFA, in the range of 1.82 to 2.20, and 16.3 to 17.07 g/100 g lipids, $P < 0.05$) and higher values for long-chain fatty acids especially for the yogurt GOX1 (LCFA, in the range of 80.73 to 81.92 g/100 g lipids, $P > 0.05$). In addition the yogurt GOX1, presented higher values for monounsaturated and polyunsaturated fatty acids (MUFA and PUFA, in the range of 30.14 to 34.26, and 4.04 to 4.12 g/100 g lipids, $P < 0.05$), as well as, higher values for trans-vaccenic acid and for linolenic and conjugated linoleic acids (C18:1t, C18:2 and CLA, in the range of 3.71 to 3.72, 2.84 to 2.89, and 1.28 to 1.27 g/100 g lipids, respectively, $P > 0.05$). In a functional food perspective, the addition of glucose oxidase to probiotic yogurts may be an interesting technological option for small and medium-size dairy enterprises to enter to the market of functional dairy foods.

Key Words: probiotic yogurt, glucose oxidase

T123 Physical characteristics of set-type probiotic yogurt produced from mixtures of cow and sheep milk.

Felipe S. Vianna, Celso Fasura Balthazar*, and Adriana C. O. Silva, *Department of Food Technology, Veterinary College, Federal Fluminense University, Niterói, Rio de Janeiro, Brazil.*

Bovine milk is the most important from commercial and industrial point of view, because the milk supplied from cows is cheaper and more plentiful than sheep milk. Thus, large-scale industrialization of the dairy sheep sectors in many countries is limited by low volume and seasonal cyclicity of individual milk production. As well, it is known that milk is more rich in milk total solid than bovine milk and has interesting features concerning texture technological aspects, thus this milk is used to produce dairy products. To combine the benefits of sheep milk plus the more affordable bovine milk, the purpose of this study was to develop a functional set-type probiotic yogurt from the mixture of cow and sheep milk, to establish a comparison among the mixtures (25/75; 50/50; 75/25 v/v sheep/cow milk) and control treatments trough evaluation of yogurt physical composition. Sheep milk yogurt (SMY) obtained the highest ($P < 0.05$) firmness value. Thus, an increase in the amount of sheep milk for yogurt increased the firmness of mixtures. Different sheep milk ratios in cow milk did not influence ($P < 0.05$) the apparent viscosity of the yogurt mixtures. Concerning the water-holding capacity, SMY obtained the highest values, whereas CMY exhibited the lowest values ($P < 0.05$). The yogurts produced with mixed milk (50/50 v/v) presented an intermediate value when compared with the other treatments. All treatments presented significant differences in syneresis index and the greater the amount of sheep milk in the yogurt resulted in lower index of syneresis. Thus intermediate mixed milk yogurts showed satisfactory results for physical analyses.

Key Words: firmness, sheep milk, water-holding capacity

T124 Physical characteristics of set-type yogurts produced using milk from different ruminants species. Felipe S. Vianna, Celso Fasura Balthazar*, and Adriana C. O. Silva, *Department of Food Technology, Veterinary College, Federal Fluminense University, Niterói, Rio de Janeiro, Brazil.*

Most published studies involving dairy products used cow milk because of large volume and economic importance, however, many countries with specific climatic (desert) and terrain features (mountainous terrain) favor dairy goat and sheep farming, making this activity essential for national economy. The present study purpose was to compare physical properties of yogurts obtained from sheep (SMY), cow (CMY) and goat (GMY) milk for 28 d of storage. This research found that SMY were firmer ($P < 0.05$) than those of CMY and GMY. The firmness of CMY was greater ($P < 0.05$) than GMY in the 14th and 28th day of storage. In most of cases, the firmness was not altered by the storage time. Apparent viscosity varied depending on the type of milk used to produce yogurts. The apparent viscosity (AV) of SMY was higher ($P < 0.05$) than CMY and GMY at 14th and 28th day. Moreover, CMY had greater ($P < 0.05$) levels of viscosity than GMY. There was not, however, a significant difference during storage ($P < 0.05$) for each yogurt type. The water-holding capacity (WHC) of GMY were lower ($P < 0.05$) than that obtained from CMY and SMY, which had the highest levels. Furthermore, there was no influence in this ratio during the storage time ($P < 0.05$). The syneresis index (SI) was significantly affected by the milk type, however it was not altered by the storage time ($P < 0.05$). In contrast with WHC, the lowest syneresis was observed in SMY than in CMY and GMY. Therefore, SMY achieved the greater firmness, AV and WHC, with lower SI than CMY and GMY. On the other hand, despite the proximate composition of CMY being similar to GMY, GMY generally had the lowest firmness, AV and WHC, but highest SI.

Key Words: cow milk, goat milk, sheep milk

T125 Fatty acid profile in prebiotic sheep milk yogurt. Celso Fasura Balthazar*[1], Jeremias Moraes[2], Hugo Leandro A. Silva[1], Renata S. L. Raices[2], and Adriano G. Cruz[2], [1]*Department of Food Technology, Veterinary College, Federal Fluminense University, Niterói, Brazil,* [2]*Instituto Federal de Educação, Ciência e Tecnologia do Rio de Janeiro, Rio de Janeiro, Brazil.*

The fatty acids (FA) present in sheep milk have beneficial compounds, which might prevent cardiovascular diseases. Inulin fiber was added to sheep milk to enhance the prebiotic biological effects to this milk. This study aimed to verify the FA profile, atherogenic (AI) and thrombogenic indices (TI) in prebiotic sheep milk yogurt (PSMY) with added inulin (0, 2, 4 and 6%) during 28 d of storage. Thus, CLA *trans*-10,*cis*-12 were detected, but below qualification limit, meaning they were in low amounts in PSMY. The predominant FA were palmitic, oleic, myristic and capric. There was an increase ($P < 0.05$) of saturated fatty acids (SFA) during storage in PSMY. Therefore, palmitic appeared with approximately 33% (C16:0 and SFA: $r = 0.582$), myristic with approximately 20% (C14:0 and SFA: $r = 0.894$) and capric with approximately 16% (C10:0 and SFA: $r = 0.929$). Oleic acid indicated an antiatherogenic (C18:1n9 and AI: $r = -0.845$) and antithrombotic (C18:1n9 and TI: $r = -0.897$) properties and represented around 92% of MUFA. CLA *cis*-9,*trans*-11 represented approximately 78% of PUFA and 2% of FA, which indicated that PSMY are a great source of it. There could be a direct link between CLA and oleic acid ($r = 0.978$), as well CLA increased ($P < 0.05$) along storage. Still, ALA was present in low levels, corresponding to about 22% of PUFA and 1% FA. There was a drop ($P < 0.05$) in ALA level at the first storage measure, which was maintained until the last storage measurement. ALA has nutritional importance due to its anti-thrombogenetic effect. PSMY might be considered a food with low atherogenic and thrombogenic risk, because of the low levles of AI and TI. Plus, sheep milk yogurt may have benefitial prebiotic effects with inulin addition.

Key Words: CLA, fermented milk, inulin

T126 Acidity in sheep milk yogurt: The inulin effect. Celso Fasura Balthazar*[1], Rodrigo B. A. Oliveira[1], and Adriano G. Cruz[2], [1]*Department of Food Technology, Veterinary College, Federal Fluminense University, Niterói, Brazil,* [2]*Instituto Federal de Educação, Ciência e Tecnologia do Rio de Janeiro, Rio de Janeiro, Brazil.*

The widespread inulin use in food industry is based on their technological and nutritional properties. This study analyzed pH, titratable acidity (TA), lactose and lactic acid in prebiotic sheep milk yogurt (PSMY), with different inulin content (0, 2, 4 and 6%) immediately after incubation and during 28 storage days at 4 ± 2°C. The bacteriological count was performed at the 1st and 28th days of storage. On the 1st day, *Streptococcus thermophilus* counts were: 9 log, 10 log, 11 log, 11 log cfu.mL^{-1}, whereas *Lactobacillus delbrueckii* subs. *bulgaricus* were 8 log, 8 log, 8 log, 9 log cfu.mL^{-1}. On the 28th day, *S. thermophilus* were 8 log, 8 log, 8 log, 9 log cfu.mL^{-1}, and *L. bulgaricus* were 6 log, 7 log, 7 log, 7 log cfu.mL^{-1} for PSMY treatments, respectively. There was a significant decrease ($P < 0.05$) in both lactic acid bacteria during storage, due to inulin protective effect. As expected, the pH decreased and TA increased significantly (pH and TA: $r = -0{,}835$; $P < 0.05$) of PSMY during storage. There was a significant difference ($P < 0.05$) between PSMY with different inulin content, being 0% the most acidic and 6% the less acidic. As well, pH values were not significantly influenced ($P < 0.05$) by the inulin addition. Lactose had a significant decrease ($P < 0.05$) expected through storage ($r = -0.759$) in PSMY. Inulin content had a significant impact ($P < 0.05$) in lactose concentration, because lactose amount was higher in PSMY 6%, dropping in each treatment until PSMY 0%, which had a significantly lower concentration ($P < 0.05$) of lactose during measurement days. This statement suggested that the acid lactic bacteria consumed inulin instead of lactose proportionally with inulin amounts, meaning that lactose was proportionally degraded by lactic acid bacteria into lactic acid (lactose and lactic acid: $r = -0.826$). Thus, lactic acid concentration of PSMY 0% was higher ($P < 0.05$) compared with others. Lactic acid had a significant increase during storage ($r = +0.936$; $P < 0.05$) in PSMY. Moreover, inulin amount delayed the acidity increase in PSMY (lactic acid and TA: $r = +0{,}919$), suggesting that inulin fiber retarded the acidity growth in yogurts, which is pleasant for consumer and dairy industry.

Key Words: ferment milk, inulin, lactic acid.

T127 A clean label approach for manufacture of yogurts using tailored milk protein interactions. Gopinathan H. Meletharayil* and Hasmukh A. Patel, *South Dakota State University, Brooking, SD.*

Tailoring protein interactions can be used as a strategy to improve textural properties that can potentially replace stabilizers in yogurts. The objective of the present study was to investigate the influence of functionalized milk proteins in yogurt formulations of varying protein content on the rheological and textural properties of yogurt. Functionalized retentate (FUR) was obtained by injecting CO_2 prior to and during the ultrafiltration of skim milk (SM) at ~10°C. Control and test yogurt formulations containing 3.0, 4.0 and 5.0% w/w of total protein were prepared with control containing proteins from SM and test formulations containing proteins from SM and FUR at 1:1 protein ratio. Formulations were heated at 90°C for 10 min, followed by cooling to 42°C. Following inoculation with yogurt culture, formulations were incubated at 42°C for 4 h in cups. After overnight storage at 4°C, the samples were analyzed for hardness using a texture analyzer and flow behavior using a rheometer. Experimental data were tested for ANOVA and statistical significance ($P < 0.05$) was determined, using statistical software SAS. The hardness values significantly increased ($P < 0.05$) from 189, 305 and 426 g in control yogurts to 236, 351 and 511 g in yogurts containing functional proteins at 3.0, 4.0 and 5.0% protein respectively. Similarly, the consistency coefficient, K, increased significantly ($P < 0.05$) from 6.1, 10.3 and 18.7 Pa.S^n in control yogurts to 10.68, 21.2 and 25.80 in yogurts containing functionalized milk proteins. Apparent viscosity (η70) significantly increased ($P < 0.05$) from 0.45, 0.67 and 1.1 Pa.S in control yogurts to 0.51, 1.08 and 1.25 Pa.S in yogurts containing functional milk proteins at 3, 4, and 5% protein respectively. These results showed that there was an increase in the hardness, consistency coefficient and apparent viscosity of yogurts containing functionalized milk protein at all the three protein levels, which could be attributed to greater protein interactions in the serum phase. The results of the present study clearly indicate that the use of functionalized milk in yogurt formulation can be used as a potential approach to replacing stabilizers such as gelatin in yogurts and thus achieving a step towards clean label products

Key Words: clean label, yogurt, carbon dioxide

T128 Application of computing technology in simulation of consumer acceptance of typical hard ice creams during storage Maryam Bahram-Parvar*[1,2], Fakhreddin Salehi[2], and Seyed Razavi[2], *[1]University of Guelph, Guelph, ON, Canada, [2]Ferdowsi University of Mashhad, Mashhad, Khorasan Razavi, Iran.*

Sensory evaluation is widely used in the food industry, especially for quality inspection, product design and marketing. Ice cream acceptability by consumers is mainly perceived by means of texture and flavor. Various ingredients contribute to ice cream's complex colloidal structure and make its perception difficult. In addition, it requires training the judges and proper environmental conditions during assessment. Furthermore, one distinctive characteristic of sensory responses is that they are ambiguous and imprecise; that is, they are fuzzy. Then, by normal statistical analysis of sensory data obtained through subjective evaluation, a complex idea of a product quality is often generated, which makes it nearly impossible to determine the strength and weakness of the product concerning its sensory attributes. Therefore, application of fuzzy set concept could be useful in this area. Combination of fuzzy concept and artificial neural network is of great importance among various combinations of methodologies in soft computing. There are some reports dealing with the sensory evaluation of ice cream based on texture perception. However, there are no or few studies available concerning the use of computing technology for prediction of consumer acceptance of ice cream. Hence, the objectives of this work were to investigate the efficiency of genetic algorithm–artificial neural network (GA-ANN) and adaptive neuro-fuzzy inference system (ANFIS) simulations for predicting acceptability of hard ice creams during storage. For this purpose, GA-ANN and ANFIS were fed with 4 inputs of flavor, iciness, wateriness and creaminess for prediction of overall acceptability of ice cream. Both models were trained with experimental data. The developed GA–ANN, which included 16 hidden neurons, could predict total acceptance with correlation coefficient of 0.93. The overall agreement between ANFIS predictions and experimental data was also very good ($r = 0.92$). Results of present research showed that both GA-ANN and ANFIS models' predictions agreed well with testing data sets and could be useful for understanding and controlling factors affecting palatability of ice cream.

Key Words: ice cream, quality, storage

T129 Evaluation of textural property changes in three types of low-fat goat milk ice creams during 8 weeks of frozen storage. Christopher E. McGhee, Brittany I. Davis, Krishna P. Bastola*, Jolethia O. Jones, and Young W. Park, *Fort Valley State University, Fort Valley, GA.*

Although ice cream is a popular frozen food around the world, low-fat ice creams have problems of low flavor and low textural quality compared with traditional ice creams. Three types of low-fat soft-serve goat milk ice creams were manufactured using whole milk (3.64% fat), 2% fat and skim (0.71% fat) goat milk, and stored at −18°C for 0, 2, 4, 8 weeks to evaluate the effect of extended frozen-storage on textural properties of the caprine products. A commercial cow milk based powdered vanilla flavor pre-mix containing 2.5% fat (Alpha Freeze, Tampa, FL) was formulated into the 3 types of fluid goat milk base for ice cream manufacture, where the final fat contents of the whole, 2% and skim milk mixes were 5.31, 3.84, 1.87%, respectively. Textural characteristics of the ice cream were evaluated using a texture analyzer (TA-XT2 Texture Technologies Corp., Scarsdale, NY). A cylindrical probe, which was made of acrylic material and 2.5 cm in diameter and 3.5 cm in height, was used for detecting shear force (g). The results showed that mean values (g force) of firmness and consistency for freshly made soft serve whole milk, 2% and skim milk goat ice creams were: 208.7, 297.3; 182.8, 261.8; 183.5, 255.0, respectively. There were significant increases ($P < 0.001$) in firmness and consistency of all 3 types of soft-serve low-fat goat ice creams after 1 d frozen-storage. The similar trend of increase was observed in cohesiveness and index of viscosity for all tested products, probably due to the hardening of the texture of the frozen products after 1 d storage. Regardless of fat level of the low-fat caprine milk ice creams, all tested textural properties after 56 d frozen-storage revealed substantial increases ($P < 0.0001$), especially in firmness and consistency traits compared with those of the original soft-serve goat ice creams with extreme high variations. It was concluded that all textural properties of the experimental low-fat goat milk ice creams were very significantly increased after 8 weeks extended frozen-storage.

Key Words: goat ice cream, frozen storage, textural property

T130 Dulce de leche: Characterization by physicochemical and instrumental methods. Leonardo Gaze[2], Carlos Conte-Junior[2], Adriano Cruz[1], Renata Raices*[1], and Monica Freitas[2], *[1]Federal Institute of Science and Technology of Rio de Janeiro (IFRJ), Rio de Janeiro, Brazil, [2]Federal University Fluminense, Rio de Janeiro, Brazil.*

The physicochemical profile of dulce de leche (DL) was determined by both routine analysis and others techniques (HPLC, GC-MS and ICP-OES). Seven Brazilian commercial brands were characterized for moisture content, protein, fat, ash, pH and titratable acidity, mineral content (sodium, potassium, calcium, and phosphorus) and instrumental analysis (carbohydrates content and volatile compounds). Protein, lipid, ash, moisture, lactic acid content and pH ranged respectively from 3.51 to 7.12; 3.56 to 6.99; 1.31 to 2.05; 17.49 to 29.67; 0.23 to 0.50; and 6.14 to 6.37 w/w ($P < 0.05$), with a significant variability in all parameters. Regards the mineral content, it is also reported difference between these parameters was observed for all samples, ranging from 0.12 to 0.16 g/100 g; 0.28 to 0.40 g/100 g; 0.19 to 0.36 g/100 g; 0.14 to 0.24 g/100 g for sodium, calcium, potassium and phosphorus, respectively ($P < 0.05$). In concordance, a great variation was observed for glucose content, which ranged from 0.09 to 0.75 g/100 g for all the samples, suggesting heterogeneity of the technological processing of DLs. 32 volatile compounds were identified belonging to 10 different chemical families of which only 2 were not present in all samples. In this sense, an increase of intrinsic quality of DL is related closely the standardization of operational parameters using during the manufacture.

Key Words: dulce de leche, quality, control quality

Dairy Foods: Microbiology

T131 *Lactobacillus plantarum* L67 suppresses allergic inflammation. Sooyeon Song*[1], Anna Jeong[1], Geun-Bae Kim[2], Dong-June Park[3], and Sejong Oh[1], *[1]Div. of Animal Science, Chonnam National University, Gwangju, South Korea, [2]Dept. Animal Science, Chung-Ang University, Anseong, South Korea, [3]Korea Food Research Institute, Seongnam, South Korea.*

Bisphenol A (BPA) is a widely used monomer of polycarbonate plastics and epoxide resin that has been implicated in allergy related disease. Allergy is an abnormal immune response to an allergen. Type I hypersensitivity is an immunoglobulin (Ig) E-mediated allergic disorder. This study investigated the inhibitory effect of the *Lactobacillus plantarum* L67 extract on BPA induced allergic inflammatory response in RBL-2H3 cells. RBL-2H3 cells were treated with bisphenol A (50 μ*M*/mL) and co-treated with the *L. plantarum* L67 extract (5–100 μg/mL) for 30 min. histamine releasing, β-hexosaminidase and intracellular Ca^{2+} level were estimated in the medium. IgE production and activities of PKC, iNOS were measured ELISA and Western blotting separately. Also IL-4 and TNF-α were measured by RTq-PCR. The histamine releasing of treatment with the *L. plantarum* L67 extract considerably decreased in a concentration dependent manner. When the cells were treated with the 100 μg/mL *L. plantarum* L67 extract, the values of histamine releasing decreased 0.48-fold compared with the BPA treatment alone. The addition of BPA caused a 1.43-fold increase in IgE levels compared with control, while the values of IgE amounts decreased by 1.31, 1.28, 1.14, 1.08 and 1.04 at addition *L. plantarum* L67 extract (5–100 μg/mL) in the presence of BPA, compared with that for the BPA treatment alone. Our results showed that *L. plantarum* L67 extract inhibited the histamine releasing, β-hexosaminidase, productions of IgE, the intracellular Ca^{2+} level, and activity of iNOS in BPA treated RBL-2H3 cells but also the results indicated that the *L. plantarum* L67 extract inhibits expression of cytokines related to allergy such as TNF-α and IL-4 on the degranulation stage of mast cell. The *L. plantarum* L67 extract can inhibit to occur allergy caused by environmental hormone such as BPA.

Key Words: bisphenol A, β-hexosaminidase, *Lactobacillus plantarum*

T132 Metal-chelating and ACE-inhibitory activity of a milk fermented with bacteria isolated from double cream cheese of Chiapas, Mexico. Claudia Y. Figueroa*, Gustavo F. Gutiérrez, and Humberto Hernández, *Escuela Nacional de Ciencias Biológicas-IPN, México City, México.*

During the fermentation of milk with lactic acid bacteria, biologically active sequences, known as bioactive peptides, can be produced. Among the most important biological activities attributed to these peptides are metal-chelating (mainly iron and calcium) and ACE-inhibitory activities. Three probiotic strains (*Lactobacillus plantarum*, *Lb. pentosus* and *Lb. acidipiscis*) were isolated from double cream cheese produced in Chiapas (Mexico). This study aims to assess the metal-chelating (iron and calcium) and ACE-inhibitory activity during the milk fermentation by each microorganism and by a mixed culture. Fermentations were performed using reconstituted skim milk powder. Milks were inoculated with 2% of each of the microorganisms or mixed culture. Fermentations were performed at 37°C for 48 h. Samples were taken every 8 h for measurement of microbial growth, protein concentration, degree of proteolysis (TNBS method), metal-chelating (calcium and iron) and ACE-inhibitory activity. Variations on free amino group concentration with respect to the initial concentration that could indicates proteolysis during fermentation were observed. The initial iron-chelating activity was high (68 ± 2%), and was attributed to the fact that some milk proteins have the ability to bind iron. However, during the fermentation the iron-chelating activity increased (99 ± 0.6% of iron-chelating activity in *Lb. plantarum* fermentation). The other fermentation batches showed a lower percentage of iron-chelating activity. In the case of the calcium-chelating activity, an initial activity of 5 μ*M* Ca^{2+}/mg protein which increased up to 18 μ*M* Ca^{2+}/mg protein in *Lb. acidipiscis*, *Lb. plantarum* and the mixed fermentations could be measured. *Lactobacillus plantarum* fermentation showed the lowest ACE inhibitory activity (its maximum value is 78 ± 2.3% of ACE-inhibition) while other fermentations reached 97 ± 3% of ACE-inhibition activity. The initial ACE-inhibition activity was 35 ± 3%. All the fermentation batches performed generated metal-chelating (calcium and iron) and ACE-inhibitory activities in these in vitro tests which could be important for the production of functional dairy products.

Key Words: bioactive peptides, metal-chelating activities, ACE-inhibitory activity

T133 Virulence and regulator gene expression in *Bacillus* spp. from ultrapasteurized organic milk. Alyssa Grutsch* and John McKillip, *Ball State University, Muncie, IN.*

We isolated a *Bacillus amyloliquefaciens* strain present in ultra-high temperature (UHT) pasteurized organic whole milk to ascertain virulence determinants present in this species, as well as the pattern of virulence gene expression over time in a model food (UHT milk) system compared with the type strain *Bacillus cereus* ATCC14579. The overall goal of this project was to genotypically and phenotypically characterize thermoduric *B. amyloliquefaciens* virulence potential and the presence of the global regulator effector PlcR. Recovery of bacteria from milk required an enrichment in brain-heart infusion broth, incubated aerobically for >24 h, after which time samples were spread-plated onto tryptic soy agar (TSA) plates to recover *Bacillus* spp. Resulting colonies were streak plated onto TSA to ensure purity of culture before catalase testing, Gram and spore-staining to presumptively identify to the genus level. Pure cultures were biochemically identified to the species level using the Microgen *Bacillus* ID system (Hardy Diagnostics), yielding an identification of *Bacillus firmus*, and validated further using fatty acid profiling and 16S rDNA sequencing, which revealed the isolate to be a strain of *B. amyloliquefaciens*. To confirm presence of the target genes in each isolate, DNA was extracted from pure cultures during late log phase. Quantified DNA template was used in real-time (SYBR Green-based) PCR with primers specific for each of the target genes: *plcR*, *codY*, *nheA* and *hblC*, and the16S rRNA gene as a control. PCR results indicated no significant difference existed between average melting temperatures (T_m) of 16s rRNA ($P = 0.435$) and *plcR* ($P = 0.341$) of *B. amyloliquefaciens* and *B. cereus*. The applications of this project will be to determine if parameters regarding shipment, storage, and shelf life of UHT organic milk should be revisited, to ensure quality before consumption of product that may harbor thermoduric toxigenic *Bacillus* spp.

T134 Sequencing and annotation of novel plasmids from *Lactobacillus curvatus*. Jordan Hendricks[1], Craig Oberg*[1], Michele Culumber[1], Taylor Oberg[2], Donald McMahon[2], and Jeff Broadbent[2], *[1]Weber State University, Ogden, UT, [2]Utah State University, Logan, UT.*

Lactobacillus curvatus, a nonstarter lactic acid bacteria (NSLAB), is rapidly becoming the most prevalent NSLAB strain isolated from aged Cheddar cheese. Plasmids often carry genes that confer advantageous traits, which provide a survival advantage to the organism. Understanding the genotype of *Lb. curvatus* plasmids could provide important information concerning genes that provide *Lb. curvatus* an advantage in the cheese environment. Plasmids were isolated from 2 different strains of *Lb. curvatus*, WSU-1 and LFC-1. These strains were isolated from distinct geographical areas. WSU-1 contained 7 plasmids while 4 plasmids were detected in LFC-1. Similarities, at least in size, exist between the largest (40kb) and smallest (1240 bp) plasmids in both *Lb. curvatus* strains. The genomes of both strains have been sequenced and several putative plasmid contigs identified. These sequences were paired with similarly sized plasmids isolated from the organisms and the identified open reading frames compared. Each strain contained a plasmid, of different sizes, with nearly identical genes that coded for an anti-toxin part of a toxin-antitoxin system. Plasmid contigs also coded for cation transport proteins that could promote survival in aging cheese. Variation in plasmid profiles between the 2 *Lb. curvatus* strains also suggests multiple strains may be circulating in cheese plants. WSU-1 and LFC-1 strains carry a greater complement of plasmids than are typically found in dairy lactobacilli. Maintaining a large set of plasmids has a high metabolic cost to the cell, indicating these plasmids contain genes of value to the organism.

Key Words: NSLAB, plasmids, *Lactobacillus curvatus*

T135 Comparative analysis of prebiotics on growth kinetics, fermentation, and antioxidant activity of probiotics.

Evelyn Puspitasari*[1], Chi Kong Yeung[2], and Marie Yeung[1], [1]*Biological Sciences Department, California Polytechnic State University, San Luis Obispo, CA,* [2]*Dairy Science Department, California Polytechnic State University, San Luis Obispo, CA.*

Prebiotics are nondigestible oligosaccharides that selectively stimulate the growth of beneficial bacteria in the human intestine. Fructooligosaccharide (FOS) and inulin are among the most common prebiotics used in food products and dietary supplements. Previous studies examining the bioactivity of lactulose suggest that it also has a prebiotic potential. Lactulose is a derivative of lactose in which the glucose moiety is isomerized to fructose in the presence of heat; and hence can be found in heated milk. The goal of this study was to establish growth kinetics of common probiotics cultured in FOS, inulin or lactulose as the sole carbohydrate source. Fermentation of the prebiotics and the antioxidant activity of spent medium were also characterized. Dextrose and non-probiotic species were included for comparison. Eight commercial and ATCC strains were cultured in a semi-defined modified MRS, modified MRS plus L-cysteine-HCl, or peptone medium containing 1% carbohydrate. When incubated at 37°C in aerobic condition, except for *Lactobacillus casei*, probiotic strains cultured in prebiotics did not reach maximum growth rate or yield compared with dextrose. Multiple pairwise comparisons showed that lactulose tended to produce better growth than FOS and inulin in *L. rhamnosus* and *L. acidophilus*. In anaerobic condition, non-probiotic species were able to catabolize all carbohydrate sources, but displayed weaker lactic acid production (0.13 ± 0.06%) relative to *Bifidobacterium* spp. (0.30 ± 0.09%) or *Lactobacillus* spp. (0.56 ± 0.27%), as measured by titratable acidity. Antioxidant activity, with Trolox as the reference standard, was inversely correlated with the pH of the spent medium after fermentation ($P = 0.022$). Among the 3 prebiotic substrates, lactulose yielded the lowest pH in *L. acidophilus* and *B. infantis*, while FOS appeared to be preferred by *L. casei* and *B. bifidum*. Antioxidant activity was overall the highest from lactulose fermentation. In conclusion, lactulose is a promising prebiotic ingredient that can be incorporated in functional food products.

Key Words: prebiotic, probiotic, lactulose

T136 Heat tolerance of *Lactococcus lactis* with prior subjection to mild heat stress.

Ingrid Osorio* and Kayanush J. Aryana, *School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge, LA.*

Lactococcus lactis has been associated with cheese manufacturing. It is important that the cultures used are able to survive to adverse heat conditions in manufacturing of probiotic process cheese. The hypothesis was whether prior exposure to mild heat would enhance heat tolerance of *L. lactis.* The objective was to evaluate the effect of prior exposure to mild heat on the growth of *Lactococcus lactis*. *L. lactis* R-604 was subjected to heat shock at 40 or 50°C for 1 h. Control was not subjected to heat shock. Cultures were subsequently incubated for 24 h at 30°C followed by subjecting them to batch pasteurization (for ice cream mix) at 71.11°C for 30 min. M17 Agar with 10% w/v lactose was used for plating. Plates were incubated aerobically at 30°C for 48 h. Each experiment was conducted 3 times. Counts observed after subjecting mildly heat treated *L. lactis* to batch pasteurization were 4.4 Log for 40°C, 4.3 Log at 50°C, and 1 Log for the control. Exposure of *L. lactis* R-604 to mild heat enhanced its tolerance to heat (batch pasteurization).

Key Words: heat tolerance, dairy culture

T137 Effect of ultraviolet light exposure and mild heat shock on the salt tolerance of *Lactococcus lactis*.

Ernesto E. Gonzalez-Duran* and Kayanush J. Aryana, *School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge, LA.*

Lactococcus lactis is a dairy culture bacterium widely used in dairy products which contain salt (NaCl) such as cheese and salted butter. Osmotic conditions generally hinder the growth of both pathogen and desirable bacteria. It has been observed that exposure to an environmental stress can develop resistance to several stresses. Some studies have shown that short UV (UV) light exposure build up resistance to acid, ethanol, hydrogen peroxide and heat induced stress. There are many proteins and low molecular weight compounds that are produced under more than one stress condition which protects the cell. If salt tolerance is enhanced in desirable bacteria they would survive better compared with pathogens in salty environments. The hypothesis was whether salt tolerance of *Lactococcus lactis* can be enhanced. The objective was to study the influence of UV light and heat shock on salt tolerance of *L. lactis*. *L. lactis* R-604 cells were exposed to mild stresses of UV light (245 nm) for 5 min or a heat shock at 50°C for 25 min. A control sample was run without any stress. Samples were transferred to M17 broth with 5 concentrations of NaCl (0, 1, 3, 5 and 7% w/v) and incubated aerobically at 30°C for 5 d. Plating was conducted immediately after inoculation and every 24 h for 5 d in M17 agar with 0.5% of lactose and incubated aerobically at 30°C for 48 h. Three replications were conducted. On d 1 and 2 no differences were observed for either UV light or heat shock treated cells when exposed to 0, 1 and 3% w/v NaCl, however growth inhibition was observed using UV light or heat shock at 7% w/v NaCl. On d 1,2 and 3, resistance to salt was improved using UV light or heat shock treated cells when exposed to 5% w/v NaCl compared with control. On d 5, mild heat shock and UV light exposure had no effect on salt tolerance. Until d 4, different amount of NaCl and days of salt exposure had a differential effect on growth of *L. lactis* R-604.

Key Words: salt tolerance, dairy culture

T138 Influence of osmotic adaptation and lactose deprivation on the salt tolerance of *Lactococcus lactis*.

Ernesto E. Gonzalez-Duran* and Kayanush J. Aryana, *School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge, LA.*

Lactococcus lactis is often used in cheese and salted butter manufacture. Mediterranean cheeses can have up to 7% NaCl. Osmotic conditions generally slow down the growth of both pathogen and desirable bacteria. Studies have shown that vegetative cells exposed to a mild stress become more resistant to lethal doses of the same stress since the first exposure starts the defense mechanisms of the cells creating an effect of cross-protection. The hypothesis was whether salt tolerance of *Lactococcus lactis* can be enhanced. The objective was to study the influence of lactose deprivation and osmotic adaptation on salt tolerance of *L. lactis*. *L. lactis* R-604 was subjected to mild stress induced by lactose deprivation (grown with no lactose in M17 broth) or prior osmotic adaption (grown with 3% w/v NaCl in M17 broth) for 24 h aerobically at 30°C. A control was run without stress (grown in M17 broth with lactose and no NaCl and incubated aerobically for 24 h at 30°C). Lactose deprived or osmotic adapted cells were transferred to M17 broth with 5 concentrations of NaCl (0, 1, 3, 5 and 7% w/v) and incubated aerobically at 30°C for 5 d. Plating was conducted immediately after inoculation and every 24 h for 5 d in M17 agar with 0.5% of lactose and incubated aerobically at 30°C for 48 h. Three replications were conducted. After the 24 h incubation in M17 broth with no lactose or 3% NaCl an increase in 4 log cfu/mL was observed. Lactose deprived cells exposed to 0, 1,3 and 5% w/v salt had a stationary phase at 11 logs for d 1 and 2. While use of 7% w/v salt reduced cells by 2 logs by d 2. On d 5 there were no differences in counts of lactose deprived cells exposed to all salt concentrations. Osmotic adapted cells exposed to 5% salt had a stationary phase at 11 logs for d 1 and 2, while cells exposed to 0,1,3 and 7% NaCl slowly declined until d 5. On d 5 there were no differences in counts of osmotic adapted cells exposed to all salt concentrations. Different amount of NaCl and days of salt exposure had a differential effect on growth of *L. lactis*. From d 3 until d 5, prior exposure to either mild stress did not have an effect on salt tolerance of *L. lactis* R-604.

Key Words: salt tolerance, dairy culture

T139 *Lactobacillus wasatchii* WDC04 associated with late gas production in aged Cheddar cheese.

Lauren Montierth[1], Craig Oberg[1], Michele Culumber*[1], Donald McMahon[2], Fatih Ortakci[2], and Jeff Broadbent[2], [1]*Weber State University, Ogden, UT,* [2]*Utah State University, Logan, UT.*

A new species of nonstarter lactic acid bacteria (NSLAB), called *Lactobacillus wasatchii* WDC04, was identified in aged Cheddar cheese manufactured in northern Utah. This bacterium has been linked to gas formation in the latter stages of Cheddar cheese ripening. It is an obligate heterofermentative NSLAB shown to produce gas in broth cultures under the conditions of cheese aging. WDC04 prefers growth on ribose at low pH (5.0–5.5). It grows slowly at cold temperatures, which could play a role in its ability to create gas defects during cheese ripening. In aging cheese, gas formation causes swelling of the packaging and splitting of the cheese, making it unfit for consumer use. Twenty-seven aged Cheddar cheeses from around the world were tested for WDC04 using MRS medium (pH 5.2) amended with 1.5% ribose and incubated for 1 to 4 weeks. Isolates were identified using 16S rRNA gene sequencing then compared with the GenBank database and to the 16S rRNA gene from *Lb. wasatchii* WDC04. No *Lb. wasatchii* were detected in cheeses without gas defects. WDC04 was found, however, in several distinct aged commercial Cheddar cheeses produced in facilities geographically distant from the original isolation location. These results indicate *Lb. wasatchii* is more widespread than previously thought, and appears to be a causative agent of late gas defect in aged Cheddar cheeses.

Key Words: NSLAB, gas production, cheese

T140 The effect of xenon pulsed-light technology on biofilm adhered to stainless steel surfaces.

Stephanie Jacquez* and Rafael Jimenez-Flores, *California Polytechnic State University, San Luis Obispo, CA.*

In food processing, inadequate sanitation procedures lead to the formation of biofilms, in which bacteria attach to surfaces and aggregate in a hydrated polymeric matrix of their own synthesis. Formation of these sessile communities and their inherent resistance to existing sanitation agents are at the root of the risk of bacterial infections for consumers. Based on this evidence, an effective method for reducing biofilm formation in dairy processing equipment is necessary. UV pulsed light technology has proven effective in eliminating microorganism populations on food products. The objective of this work is to evaluate the effect of pulsed light technology on a biofilm consisting of different dairy media (e.g., whey protein concentrate (WPC) and pure lactose) as well as 3 strains of spore forming *Bacillus* species (*B. subtilis*, *B. coagulans*, and *B. licheniformis*) adhered to square, 2.5 × 2.5, ASI 304, stainless steel coupons . Four treatment levels (no treatment, 5 bursts, 10 s, and 20 s) were applied to the coupon surfaces using the Xenon model RC847 machine. Each coupon was placed at a distance of 10.5 cm away from the UV lamp. The pulsed light effect was evaluated using the pour plate technique with 0.2% (w/v) starch TSA and incubated for 48h at 55 C. The adhesion of Bacillus to stainless steel in water as matrix was 1000 to 3000/cm^2 as measured in our laboratory. When compared with the No treatment group, there was a maximum of a 3.96 delta log kill rate in the biofilm created with whey protein concentrate when exposed to 20 s of pulsed UV light. Results indicate a difference between kill rates at 20 s with biofilms created with 5% whey protein concentrate and 5% lactose.

T141 Slime production by *Bacillus* strains affects biofilm formation on dairy separation membranes.

Nuria Garcia-Fernandez*[1,2], Ashraf Hassan[1], and Sanjeev Anand[1,2], [1]*Dairy Science Department, South Dakota State University, Brookings, SD,* [2]*Midwest Dairy Foods Research Center, South Dakota State University, Brookings, SD.*

Our previous research showed that the hydrophobicity of the extracellular polysaccharides produced by lactic acid bacteria plays an important role in biofilm formation on dairy separation membranes. Thermoduric bacilli possess a major challenge for the dairy industry, due to their resistance to heat and cleaning agents. The objective of this study was to evaluate the effect of slime production by *Bacillus* spp. on biofilm formation on separation membranes. Two slime-producing strains; *Bacillus mojavensis* (Bc) and *Bacillus licheniformis* (K1), isolated from dairy powder and one non-slime producing variant from each of the 2 strains (K1–1 from K1 and Bc-1 from Bc) produced by spontaneous mutation were used to study attachment (in the absence of growth) and biofilm formation on polyamide RO membrane pieces. Parameters related to bacterial adhesion (cell charge, capsule production, and hydrophobicity) were evaluated to determine their contribution to differences in biofilm formation among strains. The number of viable cells on biofilm formed by the hydrophobic Bc was more than 1 log cfu/cm^2 greater that its less hydrophobic slime-negative mutant (Bc-1) ($P < 0.05$). However, counts lower by about 0.7 log cfu/cm^2 were found in biofilm formed by the hydrophilic K1 than its slime-negative mutant ($P > 0.05$). Bc and K1 slime precipitated by ethanol contained only 3.6

and 6.5% of total carbohydrates. Bacterial cell surface hydrophobicity was the only parameter that strongly related to both attachment and biofilm formation on RO membranes. To confirm its role, cell surface hydrophobicity was modified by surfactants with different hydrophilic lipophilic balance (HLB) values and attachment of the altered cells was then studied. Tween 20 (high HLB) resulted in lower attachment of Bc while Span 80 (low HLB) improved biofilm formation by K1 ($P < 0.05$). In conclusion, hydrophobic slime produced by *Bacillus* enhanced attachment and biofilm formation on RO membranes. Cleaning strategies that decrease cell hydrophobicity or increase membrane hydrophilicity would reduce risk of biofilm formation by the potential spoilage and disease-causing *Bacillus* strains.

Key Words: biofilm, *Bacillus*, slime

T142 Identification of gram-negative bacteria in cooling tanks of dairy farms. Magali Soares Santos Pozza*[1], Gilberto Henrique Simões[2], Maximiliane Alarvase Zambom[2], Maichel Lange[2], and Grasiele Scaramal Madrona[1], *[1]Universidade Estadual de Maringá, Maringá, Brazil, [2]Universidade Estadual do Oeste do Paraná, Marechal Cândido Rondon, Paraná, Brazil.*

The main parameter to verify the quality of milk is the microbiological profile and microbial contamination index. The aim of this study was to isolate and identify gram-negative proteolytic bacteria in different dairy production systems in western Paraná, Brazil. Thirty-five milk samples collected directly from milk tanks evaluated for flow cytometry by somatic cells count (SCC) and total bacteria count (TBC). Samples were diluted in peptone water and seeded in caseinate agar. The colonies were inoculated into *Escherichia coli* broth for 48 h at 35°C. Subsequently were inoculated Eosin Methylene Blue Agar (EMB) and inoculated in Bactray I and II Kit, for the purpose of identification of gram-negative oxidase negative bacteria. Twenty 7 samples showed isolation and identification of some kind of agent, with 77.1% of bacteria isolated. The mean values obtained for TBC and SCC were 1.867.000 cfu/mL and 944.000 cels/mL respectively, values considered above the current legislation. The frequencies of isolated species were *Escherichia coli* (8.6%), *Escherichia fergusoni* (8.6%), *Klebsiella oxytoca* (8.6%), *Yersinia enterocolitica* (8.6%), *Hafnia alvei* (5.7%), *Serratia liquefaciens* (5.7%) *Serratia odorifera* (5.7%), *Citrobacter freundi* (2.85%), *Klebsiella ornithinolytica* (2.85%), *Klebsiella pneumoniae* (2.85%), *Proteus mirabilis* (2.85%), *Providencia rustigiani* (2.85%), *Providencia Stuart* II (2.8 5%), *Salmonella* (2.85%), *Serratia rubidaea* (2.85%) and *Shigella flexneri* serogroup B (2.85%). Of isolates identified 42.85% of them belonged to the family *Enterobacteriaceae*, poor hygiene indicators in manufacturing processes. Proteinases produced by this microbiota are thermostable, remains intact and active after heat treatment, and the considerable economic losses, and one should trace their sources of contamination as hazards to public health.

Key Words: isolating, microorganisms, milk

T143 Can probiotic bacteria survive in a beverage made from "acid whey" from Greek yogurt? Alexis Duferene*, Dasom Park, Douglas Olson, and Kayanush J. Aryana, *School of Animal Sciences, Louisiana State University Agricultural Center, Baton Rouge, LA.*

Over the last 2 years, Greek yogurt sales and consumption have grown very rapidly leading to a $2 billion per year industry. The by-product of Greek yogurt manufacture is "acid whey," in which the industry needs to decide its utilization. For every 3 parts of milk, 1 part of Greek yogurt and 2 parts of acid whey are formed. The probiotics industry is rapidly growing since the health benefits of probiotics are widely known. Typically, probiotic bacteria do not thrive in acidic conditions. In a product such as acid whey, which naturally contains proteins, amino acids and sugars (lactose) that are needed for lactic acid bacterial growth, it will be beneficial to determine if the lactic acid probiotic *Lactobacillus acidophilus* can survive. The objectives were 1) to manufacture a probiotic acid whey beverage, 2) to determine the growth of the probiotic *Lactobacillus acidophilus* in the acid whey beverage and 3) to study any changes in pH, viscosity and titratable acidity over 5 wk of refrigerated storage. Plain yogurt was manufactured, and whey was separated from the plain yogurt to yield Greek yogurt and acid whey. Acid whey was batch pasteurized, cooled, sweetened, flavored with pineapple flavoring, inoculated with *Lactobacillus acidophilus* to 10^7 cfu/mL and stored at 4°C for 5 wk. The *L. acidophilus* counts declined from 3.2×10^7 immediately after manufacture to 1.4×10^3 at wk 3 and 90 cfu/mL at wk 5. There were no changes in pH, TA and viscosity of the flavored probiotic acid whey over storage for 5 wk which is desirable as it indicates product stability over shelf life. *L. acidophilus* survived in the flavored acid whey, although counts rapidly declined over 5 weeks. This suggests future research on methods to enhance acid tolerance of probiotic *L. acidophilus*.

Key Words: acid whey, probiotic

T144 Evaluation of microbial quality of raw goat and ewe's milk produced in Sabrata, Libya. Yahiah Abojnah[1], Nahed Khatabi[2], Said Gnan[2], and Marvin Moncada*[3], *[1]University of Tripoli, Tripoli Libya, [2]School of Science, Academy of Graduate Studies, Tripoli, Libya, [3]School of Animal Sciences, Louisiana State University, Baton Rouge, LA.*

The objective of this project was to evaluate the microbial quality of the raw goat and ewe's milk in the region of Sabrata, Libya. One hundred random samples of bulk tank raw ewe's and goat's milk (50 samples each) were collected from different farms in Sabrata. All samples were subjected to microbiological tests which included total plate counts (TPC), total coliform counts, yeast and mold counts, *Staphylococcus aureus*, psychotrophic, thermophilic, proteolytic and lipolytic bacteria counts as well as pH measuring. There was a significant ($P < 0.05$) differences between all samples analyzed on total plate counts, thermophilic, coliform and lipolytic bacteria counts. The obtained results showed that the mean TPC log cfu/mL were 6.36 and 4.62 respectively. Psychrotrophic and thermophilic counts were detected in 90 and 88%; 88 and 76% of the samples with mean values in log cfu/mL of 3.67 and 3.18; 2.79 and 3.56 respectively. Results also indicated that *Staphylococcus aureus* and coliforms were present in 100 and 100%; 98 and 98% of the samples with mean values in log cfu/mL 2.82 and 3.28; 3.63 and 3.18 respectively. On the other hand proteolytic and lipolytic bacteria were present in 100 and 100%; 98 and 94% of the samples with mean values in log cfu/mL 2.88 and 3.17; 2.61 and 2.61 respectively. Yeast and mold were detected in 88 and 88% of the samples with mean values in log cfu/mL < 1.17 and < 1.17. The mean values of pH in all samples analyzed were 6.46 and 6.5. In conclusion, the relatively high microbial count reflecting the poor sanitation and hygienic practices in the region evaluated.

Key Words: microbial, goat-ewe, milk

T145 Quantification of spoilage and contaminants bacteria in samples of raw milk. Magali Pozza*[1], Gilberto Simões[2], Maximiliane Zambom[2], Marcelo Neumann[2], and Paulo Pozza[1], *[1]Universidade*

Estadual de Maringá, Maringá, Brazil, [2]Universidade Estadual do Oeste do Paraná, Paraná, Brazil.

The majority of the mesophilic bacteria found in raw milk, has a big involvement in the refrigerated milk degradation and its dairy products producing enzymes with proteolytic and lipolytic action. This research was conducted in the state of west region of Parana- Brazil. The milk samples from 35 properties were collected directly from the cooling tanks and analyzed by flow cytometry for TBC and SCC. The proteolytic and lipolytic microorganisms were plated on caseinate agar and tributyrin agar both incubated at 35°C for 48 h. For all milk samples was also evaluated in the presence of Staphylococcus spp. at 3 critical points of production: from milking, hands-of-milkers, milk cooling tank and plated on Baird Parker agar being held coagulase test. It was possible to stratify the milk samples into 4 distinct treatments according to the values of somatic cells count and total bacteria count: Treatment 1 (>600.000 cells/mL), Treatment 2 (>600.000 cfu/mL), Treatment 3 (>600.000 cells/mL and cfu/mL) and Treatment 4 (<600.000 cells/mL and cfu/mL). The treatments showed mean values of proteolytic microorganisms: 2.7×10^3 cfu/mL, 1.8×10^4 cfu/mL, 1.9×10^4 cfu/mL, 1.4×10^4 cfu/mL and lipolytic microorganisms 1.0×10^5 cfu/mL, 2.1×10^5 cfu/mL, 2.0×10^5 cfu/mL, 6.2×10^4 cfu/mL, with no significant difference by Tukey test ($P > 0.05$). The dairy production systems had unsatisfactory hygienic conditions. Moderate contamination were obtained from *Staphylococcus* 9.6×10^3 cfu/mL, 2.2×10^3 cfu/mL, 1.4×10^4 cfu/mL and 3.8×10^3 cfu/mL cfu/mL; for milking, hands-of-milker, cooling tank and milk respectively. The results show the presence of *Staphylococcus* agent in dairy production systems.

Key Words: microbiology, milking, cooling tank

T146 The identification of lactic acid bacteria in the traditional Carpathian ewe's cheese.

Orysysa Tsisaryk*[1], Iryna Slyvka[1], and Tomasz Bocer[2], [1]*Lviv National University of Veterinary Medicine and Biotechnology, Ukraine,* [2]*Rzeszow University, Poland.*

Our purpose was to isolate and identify lactic acid bacteria (LAB) from the traditional ewe's cheese from the Carpathian region (Ukraine), which were unknown. The objective of the study was to determine LAB from ewe's cheese by molecular genetic methods. 95 pure cultures of LAB were isolation from 3 samples of cheese. Culture media MRS and M17 were used for following isolation of pure cultures of LAB. Genomic DNA was prepared by using a set of Genomic Mini according to the instructions. Primer 1254 was used for RAPD-PCR. Primers EGE1 and 1492R were used for RFLP-PCR (Sigma-Aldrich). Two endonucleases were used for digestion amplification product: *Rsa*I and *Hinf*I (Roche). Taxonomic position of LAB strains was established under the complex cultural, morphological and biochemical properties. Seven strains of LAB of genera *Enterococcus*, 9 strains of genera *Lactobacillus*, 6 strains of genera *Lactococcus* and 6 strains of genera Leuconostoc were isolated from cheese N1. Twenty-eight strains of genera *Lactococcus* and 8 strains of genera *Enterococcus* were isolated from sample N2. Twenty-six strains of genera *Lactococcus* and 5 strains of genera *Enterococcus* were isolated from sample N3. Sixteen groups of LAB with heterogeneous properties were obtained by the method RAPD-PCR. Thirteen groups of LAB were obtained using endonuclease *Rsa*I and 11 groups of LAB using endonuclease *Hinf*I. Thirty-five cultures of LAB for heterogeneous differences were selected to determine their nucleotide sequences of the 16S rRNA gene. Taxonomic position of 20 isolates of LAB of 98-99% homology, 4 isolates of LAB with 96-94% homology, 1 isolates with 93% and 1 isolate with 90% were established by the results of the 16S rRNA gene sequencing. Taxon belonged to 7 species of *Lactobacillus plantarum* ssp., *Leuconostoc mesenteroides* ssp., *Lactococcus lactis* ssp. *lactis*, *Lactococcus garvieae* ssp., *Enterococcus faecium* ssp., *Enterococcus faecalis* ssp., *Enterococcus durans* ssp. The results of the LAB identification demonstrated a complex LAB population of Carpathian ewe's cheeses. Our examinations of LAB populations in raw ewe's milk products from Carpathian cheeses revealed 7 distinct species, some of which could be used in the dairy industry.

Key Words: Carpathian cheese, LAB, PCR-RFLP

T147 Studies of microbiological parameters of cultured butter during storage.

Orysya Tsisaryk* and Lubov Musiy, *Lviv National University of Veterinary Medicine and Biotechnology, Ukraine.*

The aim of this work was to study the stability and growth ability of probiotic strains *Lactobacillus acidophilus* (*La-5*) with *Lac. lactis* ssp. *cremoris*, *Lac. lactis* ssp. *lactis*, *Lac. lactis* ssp. *diacetylactis* and *Leu. mesenteroides* spp. *cremoris*, as Flora Danica (FD) Chr. Hansen commercial starters. Four groups of cultured butter (CB) were produced: 1 – the cream fermented at 30°C by *FD* (CB1), 1:1 *FD* and *La-5* (CB2) and *La-5* (CB3); 2 – the cream fermented at 37°C by *FD* (CB4), 1:1 *FD* and *La-5* (CB5) and *La-5* (CB6); 3 (Alnarps Winter method) – 8 °→ 20 °→ 12 ° and added starter *FD* (CB7), 1:1 *FD* and La-5 (CB8) and *La-5* (CB9); 4 – added starter *FD* (CB10), 1:1 *FD* and *La-5* (CB11) and *La-5* (CB12) to the butter grain. The initial concentration of starter cultures in cream was 6 log cfu/mL. The experiment was replicated 3 times. Cultured butter was packed in polystyrene cups and stored in a refrigerator at the temperature of 4–6°C for 42 d. The cell viability of Flora Danica and *Lactobacillus acidophilus La-5* was analyzed during storage on the d 1, 7, 14, 21, 28, 35, and 42. Viable cell counts were performed by preparing serial decimal dilution in 0.1% peptone water. The *Flora Danica* strains were subsequently counted by plating (in duplicate) into M17 agar (Merck). The plates were incubated aerobically for 72 h, at 30°C. The *La-5* strains were subsequently counted by plating (in duplicate) into MRS agar (Merck). The plates were incubated aerobically for 72 h, at 37°C. The results were recorded as colony forming units (cfu) per g of product. During 14 d of storage at 4–6°C the number of viable cells *Flora Danica* and *La-5* has increased. After 14 d all samples showed a drastic decrease of the number of viable cells. The samples CB1 (7.1 log cfu/g) and CB2 (7,3 log cfu/g) possessed the best viable cells *Flora Danica* properties after 35 d of storage. The sample CB2 (7.7 log cfu/g) possessed the best viable cells *La-5* properties after 35 d of storage. The best combination with a significant growth of probiotic strains *Lactobacillus acidophilus La-5* was observed in CB2. We recommend the storage period of cultured butter less than 35 d at 4–6°C for ensure the survival the probiotic strains.

Key Words: cultured butter, Flora Danica, La-5

Extension Education

T148 Utilization of fixed-time artificial insemination (TAI) to reduce breeding season length and its effects on subsequent calf value: A case study. Vitor R. G. Mercadante*, Darren D. Henry, Francine M. Ciriaco, Guilherme H. L. Marquezini, Tera E. Black, Kalyn M. Waters, Pedro L. P. Fontes, Nicolas DiLorenzo, and G. Cliff Lamb, *North Florida Research and Education Center, University of Florida, Marianna, FL.*

The development of TAI protocols has resulted in the opportunity for increased application of AI in commercial cattle operations. However, the long-term production and economic impact of implementing a TAI protocol in beef cattle operations has not been evaluated. Therefore, during an 8-yr period we evaluated the impacts of TAI to reduce the length of the breeding season (BS) and its effects on subsequent calving distribution, calf value, and BS pregnancy rates. The North Florida Research and Education Center consists of a beef herd containing 300 cows of Angus, Brangus, and Braford breed origin. During the 2006 and 2007 BS, the cows were exposed to a 120 d BS by natural service. In 2008, and every subsequent BS to 2013, all females were exposed to TAI using either the 5-d or 7-d CO-Synch+CIDR protocols. Initially, calving season length resulted in cows being inseminated in 3 TAI groups (in the 2008 and 2009 BS), subsequently reduced to 2 TAI groups (in the 2010 and 2011 BS), and eventually to a single TAI group (in the 2012 and 2013 BS). Following the initial TAI for each group, females were detected for estrus and inseminated artificially after an observed estrus until d 23 after TAI. On d 23 after TAI, bulls were introduced and cows were naturally mated for the remainder of the BS. All bulls passed a breeding soundness examination before being introduced to cows. The BS length was reduced from 120 to 70 d between the 2008 and 2013 BS. Calf distribution and subsequent weaning performance were determined. Overall pregnancy rates increased from 81% and 86% in the 2006 and 2007 BS, respectively, to 94% and 93% in 2012 and 2013, respectively. Mean calving date from the first calf born during each calving season was reduced from 80.9 d from the 2007 BS to 38.9 d from the 2013 BS. Utilizing a similar calf value across years of $0.91/kg, the mean value per calf increased by $87 per calf resulting from the 2008 BS to $169 per calf resulting from the 2013 BS. We conclude that exposing beef females to TAI and reducing the BS length for 6 years altered calving distribution, increased breeding season pregnancy rates, and increased calf value.

Key Words: fixed-time artificial insemination, economics, calving distribution

T149 Silage safety issues for large-scale bunker silos and drive-over piles: Avalanches. Ruth E. Bolsen and Keith K. Bolsen*, *Kansas State University, Manhattan, KS.*

Few farming operations invite as many different opportunities for injury or fatality as a silage program. One of these is an avalanche or collapsing silage. It only takes a fraction of a second for part of a silage face to silently break off and fall, and the result can be deadly for anyone located beneath it. Two silage avalanche tragedies are documented and 5 common sense ways they can be avoided are presented. In October 2013, Matthew Winkelbauer was buried in a silage avalanche on a feedlot near Norfolk, Nebraska. Winkelbauer, who owned the feedlot, was pronounced dead at the scene. He was standing in front of the feedout face, which was about 4 m tall, and the avalanche pushed the falling silage more than twice that distance from the face. In January 2014, Jason Leadingham, a silage haul-back driver, was working alone in a bunker silo near Roswell, New Mexico, when 10 to 15 tons of corn silage collapsed on him. Leadingham's body was not recovered from the silage until 2 h later, and the cause of his death was mechanical asphyxia. Many bunkers and piles are too large to be safe for the crew filling them and the one feeding the silage out. Common sense tells us that a 6-m-tall silage face is far more dangerous than one that is only 3 m tall. Here are guidelines that can decrease the chance of having a fatality or serious accident caused by a silage avalanche: (1) Never allow people to stand near the feedout face, (2) a rule-of-thumb is never stand closer to the feeding face than 3 times its height, (3) suffocation is a primary concern and a likely cause of death in any silage avalanche, so follow the "buddy rule" and never work alone in a bunker or pile, (4) post warning signs, "Danger! Silage Face Might Collapse", around the perimeter of bunkers and piles, and (5) avoid being complacent and never think that an avalanche cannot happen to you. We cannot stop avalanches from happening, and they are impossible to predict, but we can prevent people from being under them. Every feedlot and dairy should have safety policies and procedures for their silage program, and they should schedule regular meetings with all their employees to discuss safety.

Key Words: silage, avalanche, fatality

T150 Production system characteristics related to technology transfer facility to improve milk quality of small dairy farms. Luiz C. Roma Jr*, Marcia S. V. Salles, Fernando A. Salles, and Lenira El Faro, *APTA, Ribeirao Preto, SP, Brazil.*

The milk production by small-scale farmers has great importance in Brazilian agribusiness, however this sector is deficient in terms of technology to ensure minimum quality standards. Many aspects are needed to achieve these quality criteria, but among these, an important factor is the transfer of technology through technical assistance programs. The study was conducted in State of São Paulo, Brazil, and had the objective of identify the characteristic of small-scale dairy farms that are related to technology transfer facility to improve milk quality. During 12 mo, 60 farms were monitored for milk composition, somatic cell count and total bacterial count, and received technical assistance. At the beginning of the study, the producers were interviewed with the use of a semi-structured questionnaire. After 12 mo, the farms were divided into 2 groups: greater improvement and lesser improvement of milk quality, and a multiple correspondence analysis was performed to identify the characteristics that differentiate the groups. The results show that properties had average herd of 38 cattle, 180 L/d milk, total area of 30 ha and use of direct family manpower. Multivariate analysis enabled to identify some characteristics that helped in improvement of milk quality. The group with greater improvement used artificial insemination without technical advice with the choice of bulls, were in quality-based payment programs, used formulated diets with no silage. These characteristics were evaluated at the beginning of the study, and altered according to the needs of each property, resulting in improvement of milk quality. The changes suggested by the extensionists in nutrition, mastitis control, and milking hygiene had great importance, however the participation of quality-based payment programs had the greatest impact on improvement of milk quality. These information are useful and could help to develop and guide technical assistance programs and the transfer of technology to small-scale milk producers. Financial support: FAPESP.

Key Words: extension program, milk production, small-scale dairy farming

T151 Participation in the 2015 Margin Protection Program by Idaho dairy producers.

Richard J. Norell*[1] and Benjamin M. Eborn[2], [1]*University of Idaho, Idaho Falls, ID,* [2]*University of Idaho, Driggs, ID.*

A mail-in survey was conducted to evaluate participation in the Margin Protection Progam (MPP) and to gather producer input for future MPP education. The survey was mailed to every registered dairy in Idaho (n = 515) and 107 surveys were returned (20.7% response rate). Survey data were compared with Proc GLM and Proc Freq in SAS (SAS Inst. Inc., Cary, NC). Dairies were categorized by annual milk sales: small (<1,814 tonnes, 40.2%), medium (1,814 to 5,443 tonnes, 23.3%), large (5,444 to 11,399 tonnes, 19.6%) or very large (>11,399 tonnes, 16.8%). Eighty-two percent of respondents described their MPP knowledge as moderate to very high and their decision to participate as not difficult to somewhat difficult. On-line MPP decision tools were used by 30% of respondents and 28% calculated an average historical margin basis (herd margin - MPP margin) for their dairy. Sixty-eight percent of respondents elected to participate in MPP and 31 out of 73 elected to buy up coverage over basic ($4.00/45 kg). Participation rate was greater ($P < 0.01$) for dairies producing >11,399 tonnes but the percentage of producers buying up coverage was higher ($P < 0.01$) for those producing <5,443 tonnes. The overall mean margin and coverage rate were $5.03 ± 0.16 and 84 ± 2%, respectively, and averaged $6.42 ± 0.16 and 76 ± 4% for those purchasing higher coverage. Mean buy up coverage was similar ($P > 0.20$) between herd size categories. Producers indicated an interest in learning how to calculate and interpret margin basis plus training on how to use and interpret the on-line MPP decision tools. Producers preferred future MPP training with the following methods: producer meetings (76 ± 4%), newsletters (70 ± 4%), magazine articles (60 ± 4%), web based materials (48 ± 4%), and webinars (24 ± 4%). Preference for educational method did not differ between herd size categories ($P > 0.25$). We conclude that the MPP is an important management tool for Idaho dairy producers and further MPP training is desired by the industry.

Key Words: Margin Protection Program, risk management

T152 Comparing lying behaviors on commercial Croatian dairy farms.

Nicole L. Eberhart*[1], Pero Mijic[2], Goran Vuckovic[2], and Peter D. Krawczel[1], [1]*Department of Animal Science, University of Tennessee, Knoxville, TN,* [2]*Faculty of Agriculture, Josip Jurai Strossmayer University of Osijek, Osijek, Croatia.*

Lying behavior can be a useful tool for evaluating the suitability of dairy cows' housing environment. The objective of this study was to evaluate the lying behavior of high-producing Holstein dairy cows on commercial Croatian farms with different management systems. Data were collected from 303 dairy cows across 4 farms in eastern Croatia for at least 3 d. There were some general differences in farm management. One farm used bedded pack housing and a parallel parlor (BP), one used older freestalls (>30 yrs. old) and a herringbone parlor (FH), one was a forced-traffic robotic farm with freestalls (FRb), and one used new freestalls (built in 2013) and a rotary parlor (FRt). Behaviors (lying times (min/d), lying bout duration (min/bout), lying bouts (n/d) and laterality of lying) were recorded by dataloggers recording at 1-min intervals. Acceleration data were summarized into lying behaviors for each individual cow using SAS (v9.3) and the MIXED procedure was used to determine differences in lying behavior across farms. Lying times differed ($P < 0.001$) with values ranging from (farm mean ± SE) 735.1 ± 17.2 (BP) to 623.7 ± 22.8 (FRb) min/d. Lying duration values ranged from 95.7 ± 5.2 (FH) to 60.1 ± 5.4 (FRt) min/bout, differing across farms ($P < 0.01$). Lying bouts differed ($P < 0.001$) with values from 13.4 ± 0.4 (FRt) to 9.1 ± 0.6 (FRb) n/d. Right side lying duration differed ($P < 0.001$) with values from 87.7 ± 3.9 (FH) to 58.1 ± 4.1 min/bout (FRt). Right side lying bouts ranged from 6.7 ± 0.3 (FRt) 4.1 ± 0.3 (FH) n/d and differed ($P < 0.001$). Left side lying times differed ($P = 0.01$) ranging from 381.1 ± 15.8 (BP) to 291.7 ± 21.1 (FRb) min/d. Left side lying duration ranging from 92.3 ± 5.7 (FH) to 63.3 ± 6.0 (FRt) min/bout differed ($P = 0.006$). Left side lying bouts differed ($P < 0.001$) ranging from 6.7 ± 0.3 (FRt) to 4.5 ± 0.5 (FRb) n/d. BP had longer daily lying times than any of the farms with freestalls suggesting greater cow comfort. FRt had more lying bouts per day and the shortest lying durations suggesting reduced comfort. These data suggest there may be differences among farm systems to be addressed when developing standards for cow comfort.

Key Words: lying behavior, dairy cow, dairy management

T153 A demonstration on the use of small ruminants for unwanted vegetation management.

Enrique N. Escobar*[1], Jorge J. Rodriguez[2], and Harry Taylor[2], [1]*University of Maryland Extension-1890 Program, University of Maryland Eastern Shore (UMES), Princess Anne, MD,* [2]*Department of Agriculture, Food and Resource Sciences, University of Maryland Eastern Shore (UMES), Princess Anne, MD.*

The practice of using small ruminants to manage unwanted vegetation (noxious weeds, invasive species, weeds, etc.) is considered an environment favorable practice. Sheep and goats have a small environmental footprint and combined with their size and maneuverability allure their use as tools to manage unwanted vegetation. The main objective of this extension demonstration project was to develop a module with multiple components to propose solutions for management of unwanted vegetation using sheep and goats on Delmarva. During the spring and summer of 2014, 2 groups of sheep and goats were selected to be part of a vegetation management demonstration at the University of Maryland Eastern Shore. The animals were confined using cattle panels and steel posts to 2 main targeted areas. Area 1 consisted of 2 drain canal sites with a total area of 2160.24 m^2 and contained mixed understory, predominantly multiflora rose (*Rosa multiflora*). Area 2 consisted of steep banks in 2 lagoons with a combined target area of 1,670.97 m^2. The vegetation was predominantly horseweed (*Coniza canadensis*). To estimate dry matter available for consumption, vegetation samples were collected from random sites (1 m^2). The collected samples were weighed, air-dried and sent to a laboratory for analysis. The vegetation's total digestible nutrients for the ditch and lagoon locations were 54.25% and 51.40%, respectively. Percent protein was higher in Area 1 than the lagoon location, 9.25% and 4.98%, respectively. Acid detergent fiber percentage was similar, 45.90% for the canals and 45.98% for the lagoon banks. In Area 1 there were 419.3 kg Dry Matter (DM) available for consumption and 1019.3 kg DM on Area 2. The results obtained showed that in Area 1 it took 29 d to obtain an average disappearance of unwanted vegetation of 83% using 10 does and 10 ewes (average BW 35.6 kg). While in Area 2, it took 40 sheep and goat wethers (average BW 41.3 kg) 28 d remove 95% of unwanted vegetation. The measurement of vegetation disappearance is a key component for future studies to estimate the number of sheep and goats necessary to manage vegetation in targeted areas.

Key Words: unwanted vegetation, small ruminant, environmental impact

T154 Bedding characteristics are associated with milk quality in Illinois dairy farms: A Dairy Focus Team approach.

Maria I. Rivelli*[1], Katie J. Haerr[1], Sarah Y. Morrison[1], Saige A. Sulzberger[1], Cassandra S. Skenandore[1], Leo L. Timms[2], and Felipe C. Cardoso[1], [1]*University of Illinois, Urbana, IL,* [2]*Iowa State University, Ames, IA.*

The ultimate goal of this project is to improve Illinois dairy farms through education, accomplished through the science based innovation of the University of Illinois research and extension. The specific aim of this study was to investigate the association between bedding material and milk quality of dairy cows. Twenty dairy farms in Illinois located in the central (C), north (N), and south (S) regions were visited. During the visits, a questionnaire, DHI records along with the individual farm data set (PCDART or DAIRYCOMP305) were collected and a final data set with the combined information was built in excel for analysis. Cow's bedding sample was a composite sample made from 3 different spots in the bed (front, center, and back). Bedding quality was evaluated by quantifying dry matter (DM) percentage, organic matter (OM) percentage, and particle size (PS). Dry matter analysis was performed in all types of bedding; OM and PS analyses were performed only in sand bedded farms (n = 12). Three replications for each sample were performed for PS to obtain particle size (µm), standard deviation, and particles per gram (p/g). Statistical analysis was performed using the UNIVARIATE and GLM procedures of SAS (v9.4). Sixteen farms (80%) used sand bedding; 32% of those farms combined sand with a different type of bedding such as straw or compost. Among the other 4 farms (20%), there were 2 farms (10%) with straw bedding, 1 farm (5%) was using sawdust, and only one farm (5%) had their cows on pasture. Differences for DM and OM were found between and within regions. On average the 12 farms that used sand as bedding had a 92 ± 8% of DM, 3 ± 2.7% of OM, milk yield per cow/d was 35.17 ± 6kg, and somatic cell count (SCC) tank was 204 ± 91 cells/mL. However there was a linear correlation ($P = 0.05$, $R^2 = 0.32$, SCC = 16.28OM +134.1) between OM and SCC, and no correlation ($P = 0.3827$) between DM and SCC, Southern IL had lower DM (88.4 ± 9) and OM (1.9 ± 0.8) percentage and higher somatic cell count (261.2 ± 179) than N or C. In conclusion, our results confirm the premise that farms with high OM bedding are associated with higher milk tank SCC.

Key Words: sand, bed, organic matter

T155 On-farm field days as a tool to demonstrate and educate about dairy waste management practices.

Mario E. de Haro-Marti*[1], Mireille Chahine[2], Lide Chen[2], and Howard W. Neibling[3], [1]*University of Idaho, Gooding, ID,* [2]*University of Idaho, Twin Falls, ID,* [3]*University of Idaho, Kimberly, ID.*

Teaching best management practices (BMP) or introducing new agricultural waste management practices to dairy producers and crop farmers is a challenge. A series of on-farm field days were designed to deliver information and demonstrate several waste management techniques. During these field days, extension personnel presented each technique and offered written information on how to apply them. Presentations by the livestock producers and farmers who are already applying the techniques and hosted each field day at their farms were a powerful tool to spark interest and conversations with attendees. Five field days were delivered in 2012 and 2013. The objectives were to demonstrate techniques aimed to reduce ammonia, greenhouse gases, and odor emissions, increase nitrogen retention from manure, reduce run-off risks, manage mortalities, and generate usable by-products from livestock and other agricultural wastes. Topics addressed on each field day were (a) dairy manure collection and composting; (b) dairy slurry manure land application using a drag hose and injection system; (c) two field days on grape vine prunings and dairy manure composting; (d) mortality and offal on-farm composting at a sheep and goat dairy farm. A total of 142 individuals attended the field days. In all cases, farm owners and their managers presented and were available to answer attendees' questions, sharing their experience, and opinions regarding the demonstrated practices. Many attendees expressed their interest and willingness to adopt some of the demonstrated practices. On-farm field days are an excellent tool to increase understanding and adoption of BMP and new technologies. Hearing experiences first hand from producers applying the techniques and being able to see them in action are excellent outreach tools. On-farm field days also fit the fast pace, busy schedule of modern producers who can later visit with extension, industry, and other institutions personnel if they need more details, information, and help on how to adopt the techniques they are interested in.

Key Words: extension, field day

T156 Reproductive performance in dairy farms throughout Illinois: A Dairy Focus Team approach.

Maria I. Rivelli*[1], Tonja Egan[1], Diego A. Velasco Acosta[1,2], Katie J. Haerr[1], Sarah Y. Morrison[1], Saige A. Sulzberger[1], Cassandra S. Skenandore[1], and Felipe C. Cardoso[1], [1]*University of Illinois, Urbana, IL,* [2]*Universidade Federal de Pelotas, Pelotas, Brazil.*

The ultimate goal of this project is to improve Illinois dairy farms through education. This is accomplished through the science-based innovation of the University of Illinois research and extension, and also gives students hands-on experience evaluating commercial dairy farms. Fertility in dairy cows has been declining in recent years. Therefore, the specific aim of this study was to survey the association between milk yield and reproductive status of dairy cows in selected dairy farms in Illinois. Twenty dairy farms in Illinois located in the central (C), north (N), and south (S) regions were visited. During the visits, a questionnaire, DHI records along with the individual farm data set (PCDART or DAIRYCOMP305) were collected and a final data set with the combined information was built in Excel for analysis. Yearly pregnancy rates (PR), first service conception rate (FSC), and services per conception (SC) were assessed on cows and heifers from 12 farms. Statistical analysis was performed using the UNIVARIATE procedure in SAS (v9.4). Heifer's PR average overall was 14 ± 8.4%, and cow's PR was 16.7 ± 4.9%. As expected, FSC was higher for heifers (56.5 ± 16.5%) than cows (40.8 ± 9.0%). Heifer's SC was 2.2 ± 1.4, and cow's was 2.6 ± 0.6, and average milk yield per cow/d was 35.3 ± 6.1kg. In Northern Illinois, heifer's PR was higher (20.2 ± 4.3%) than Central Illinois (13.5 ± 8%). Furthermore, in Northern Illinois cow's PR was higher (19.2 ± 4.9%) than Central Illinois (17.7 ± 2.6%). Moreover, similar differences were found for FSC, and SC. Average milk yield per cow/d was 38.0 ± 6.6 kg for N; 32.9 ± 5.6 kg for C; and 36.2 ± 6.4 kg for S. In conclusion, there were differences for PR, FSC, and SC percentages between and within regions. These results collectively, although limited in sample size, suggest that geographical aspects may play a role in reproductive success in Illinois dairy farms. The results of this study would imply customized recommendations to each farm to improve its reproductive status.

Key Words: reproductive success, Illinois, pregnancy rate

T157 Evaluation of seed corn hybrids to provide nutrients that are highly digestible for South Dakota livestock operations. David P. Casper*, Sara Sontag, Laura McMartin, William Weich, and Jonathan Kleinjan, *South Dakota State University, Brookings, SD.*

South Dakota cropping operations are historically well known historically, as is the SD State University (SDSU) Crop Performance Testing (CPT) program, for focusing on grain production. Recent expansion of the SD dairy industry has created interest in selecting the right seed hybrid for either corn silage and/or grain production. A unique SDSU relationship developed to expand the CPT program to evaluate hybrids for forage production and quality. This information will be crucial for the Interstate-29 SD dairy industry to compete globally. In the 2013 growing season, 45 grain hybrids were evaluated for both corn silage and grain. Hybrids were planted in 4 row field test plots at the SDSU Volga research farm. Corn plants from the center rows were hand harvested at a min of 15 cm from the ground. The plants were weighed, chopped (chipper/shredder), inoculated with Silo King (0.55 kg/ton), packed in duplicate 18.9 L buckets, sealed, weighed, and allowed to ensile for >90 d at which time, buckets were weighed, opened, and samples submitted for measurement of nutrient concentrations and digestibility (Analab Inc.). In the 2014 growing season, 31 silage specific silage hybrids were evaluated. Procedures were the same, except buckets were opened at 60 and 90 d. In the 2013, the grain hybrids were drier at harvest (range: 28.7 – 56.5; mean = 39.1 ± 3.21% DM), compared with 2014 hybrids being wetter (range: 21.8 - 39.6: mean = 29.9 ± 2.62% DM). For the 2013, the hybrids varied in digestible DM (range: 60.6 – 74.3; mean = 69.8 ± 3.21% DM), while 2014 hybrids were (range: 65.4 – 72.5: mean = 69.6 ± 2.54%) were less variable. The 2014 DM silage yield (range: 18.4 - 23.8; mean = 20.2 ± 2.51 t/ha) varied dramatically, while digestible DM yield (range: 12.4 - 16.8; mean = 14.1 ± 2.02 t/ha) varied as well. Selecting the appropriate seed corn hybrid can improve corn silage yield and digestibility, thereby the right hybrid being able to meet a great percentgae of the nutrient requirements of the lactating dairy cow.

Key Words: hybrid, corn silage, forage

Food Safety

T158 Consumer perception regarding beef quality and food safety. Maribel Ruiz-Leon, Karina Leon-Lucio, Gilberto Aranda-Osorio*, and Agustin Ruiz-Flores, *Universidad Autonoma Chapingo, Chapingo, Texcoco, Mexico.*

The aim of this study was to evaluate consumers' perception and attitude regarding beef quality and food safety and the characteristics that are taken into account for purchasing, considering socio-economic factors such as income and education level. A survey integrated by 70 questions, grouped into 6 sections, was applied to 347 administrative and academic staff belonging to the University of Chapingo. The sample population was divided into 4 monthly income levels (strata): 1) Low (less than 7,000 pesos), 2) Medium (from 7,000 to 14,000 pesos), 3) High (from 14,000 to 21,000 pesos) and 4) Very high (more than 21,000 pesos). USD exchange ratio: 1USD = 13.50 pesos. Data were processed by discriminatory canonical analysis to identify the main factors that affect beef consumption; after that, association tests between the income level and beef consumption variables were performed using the ANOVA and the statistic Chi-squared of SPSS. The results showed dependence ($P < 0.05$) between income and education level to: preference for purchasing place (butcheries > supermarkets > street markets) and meat type (poultry > beef > pork) according to the conservation method (chilled > not chilled > frozen); perception and preference for TIF (Federal Inspection Type) seal (42%); preference for the amount of fat (60%, low) and beef color (80%, bright red); knowledge about the use of clenbuterol on finishing cattle (90%) and its negative effect on consumer health (62%); willingness for purchasing beef-free of clenbuterol (100%); knowledge about the concept of food safety (35%); perception of the importance of safe beef and its relation to human health (32%). In conclusion, the awareness about beef safety positively grows with the income and education levels of the consumers, encouraging them to search for safe markets, which ensure beef safety and quality.

Key Words: beef quality, food safety, consumer characteristic

T159 Levels of aflatoxin M$_1$ in dairy products from Londrina supermarkets and its estimated daily intake. Joice Sifuentes dos Santos*, Ana Beatriz C. Ribeiro, Vanessa R. França, Shiguedy Katto, and Elsa Helena W. Santana, *University North of Paraná, Londrina, Paraná, Brazil.*

Aflatoxins are fungi secondary metabolites that contaminate cereals and other products of vegetable origin. Aflatoxin B$_1$ (AFB$_1$) is the most common and the most toxic aflatoxin. After the ingestion of AFB$_1$ contaminated feeds, a part is degraded in the rumen, resulting in the formation of aflatoxicol. The remaining fraction is absorbed in the digestive tract by passive diffusion and is hydroxylated in the liver to aflatoxin M$_1$ (AFM$_1$). Circulating AFM$_1$ can be excreted in the urine or appear in milk. AFM$_1$ excretion is also observed in human milk. AFM$_1$ was originally classified as a Group 2B – possibly carcinogenic to humans, in 1993, but subsequent evidence of its cytotoxic, genotoxic and carcinogenic effects led to a new categorization of AFM$_1$ as Group 1. The occurrence of aflatoxin M$_1$ (AFM$_1$) was evaluated in 42 milk (pasteurized, ultra-high treated (UHT) milk and milk powder) randomly collected in July 2014 from supermarkets in Londrina, Paraná State, Brazil and this rate of occurrence was used to estimate AFM$_1$ exposure. AFM$_1$ determination was carried out by ELISA. AFM$_1$ was detected in 100% samples, with levels ranging from 0.01 to 0.81 µg/kg, and a mean of 0.13 µg/kg. Differences were observed in AFM$_1$ levels in milk powder samples (0.61 µg/kg) compared with pasteurized (0.02 µg/kg) and UHT milk (0.04 µg/kg; $P < 0.05$). None of the samples presented AFM$_1$ above the maximum permitted level by Brazilian Legislation (0.5 µg/kg for fluid milk and 5 µg/kg for milk powder). Determination of the exposure degree is one of the most important parameters to assess risk from chemical compounds. The Estimated Daily Intake (EDI) of AFM$_1$ from fluid milk and milk powder was obtained using the amount of food consumed and the corresponding mean concentrations of AFM$_1$ detected in each food group, taking into account the mean body weight of the age groups. The estimated daily intake (EDI) of AFM$_1$ was evaluated, and the average intake was 0.468 ng/kg body weight (BW) for adolescents, 0.384 ng/kg BW for adults and 0.559 ng/kg BW for the elderly, values that pose a toxicological risk to the population investigated.

Key Words: mycotoxin, dairy product, ELISA

T160 Occurrence of aflatoxin M$_1$ and somatic cell count in milk from farms in São Paulo, Brazil. AF Rosa[1], MS Miranda[1], JRP Arcaro[1], R. Braghini[2], E. Pinatti[3], and CR Pozzi*[1], [1]*Instituto de Zootecnia, Nova Odessa, São Paulo, Brazil,* [2]*Instituto de Ciências Biomédicas, São Paulo, São Paulo, Brazil,* [3]*Instituto de Economia Agrícola, São Paulo, São Paulo, Brazil.*

Milk needs to be of good quality and a low somatic cell count (SCC) and absence of contaminants such as aflatoxin M$_1$ (AFM$_1$) are important factors in the assessment of the health status of herds. The objective of this study was to evaluate the presence of aflatoxin M$_1$ and SCC in milk and to determine the correlation between aflatoxin M$_1$ and SCC. Fifteen lactating cows were monitored at intervals of 15 d over a period of 45 d (n = 4) on 9 dairy farms in the state of São Paulo (n = 540). Milk samples were collected from the glass collecting jars (n = 15) and refrigeration tanks (n = 38). Aflatoxin M$_1$ was determined on immunoaffinity columns using separation and quantification by high-performance liquid chromatography (HPLC). Somatic cell counting was performed by flow cytometry in a Somacount 300. Data were analyzed using a one-way ANOVA with Tukey's test ($P \leq 0.05$). Pearson correlation test was used between AFM$_1$ and CCS. Aflatoxin M$_1$ was detected in 12% (n = 64) of the milk samples collected from the glass bottles. Mean contamination of the samples ranged from 0.03 ± 0.09 to 0.746 ± 1.85 µg/kg, with a maximum level of 9.83 µg/kg. Of the 38 milk samples obtained from the refrigeration tanks, 16% (n = 6) were contaminated with aflatoxin M$_1$, with levels ranging from 0.44 to 2.65 µg/kg; 83% (n = 4.98) of these samples contained levels that exceeded the limit permitted by the Brazilian legislation (0.5 µg/kg). Mean SCC in the glass collecting bottles ranged from 283.78 (±1,302.12) to 1,124.58 (±1,844.9) x 1,000 cells/mL. Mean SCC in the refrigeration tanks ranged from 452.75 (±220.7) to 2,057.75 (±1,233) x 1,000 cells/mL. All farms had tanks with SCC above the limit permitted by the current Brazilian legislation (500 × 1,000 cells/mL). There was no correlation between the detection of aflatoxin M$_1$ and SCC in milk samples from the glass collecting jars or refrigeration tanks. The presence of aflatoxin M$_1$ and high SCC indicate deficiency in the sanitation management of the farms and highlight the need for public policies to improve these patterns.

Key Words: aflatoxin M$_1$, somatic cell count, milk

T161 Risk assessment of seven toxic elements residues in raw milk in China. XueYin Qu[1,2], Nan Zheng[1,2], JiaQi Wang*[1,2], XueWei Zhou[1,2], and SongLi Li[1,2], [1]*Ministry of Agriculture-Laboratory of*

Quality & Safety Risk Assessment for Dairy Products (Beijing), Beijing, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.

The pollution of toxic elements has been serious since the rapid development of industrialization in China. There were no data about toxic element levels in raw milk in China. The object of this study was to survey the levels of 7 toxic elements residues in raw milk in China and assess the potential health risk of those residues. The 178 raw milk samples were collected from 8 main milk-producing provinces and from 3 types of milk stations in China, and were analyzed for arsenic (As), lead (Pb), cadmium (Cd), chromium (Cr), mercury (Hg), aluminum (Al) and nickel (Ni) using inductively coupled plasma-mass spectrometry (ICP-MS). Al, Pb, Hg, Ni, Cr, As were detected in 47.8% 29.2%, 28.1%,23.6%, 12.4% and 9.0% of total milk samples, respectively, and Cd was not detected in any samples. The levels of detected toxic elements were all below China's regulated limits of As ≤0.1 mg/kg, Pb ≤0.05 mg/kg, Cr ≤0.3 mg/kg, Hg ≤0.01 mg/kg. The residue levels of the samples from the processing plants were lower than that from the large-scale farms and small farm cooperatives by the results of Nemerow pollution index analysis method and this could be related with the different manufacturing practices. The regional difference analysis results indicate that the raw milk samples from heavy industry provinces have relative high residue levels. The need for further attention to the raw milk of heavy industry regions is crucial. In all detected samples, the risks of the concentrations were far below the reference values. The HQ analysis showed that the residues of As, Pb, Hg, Cr, Al and Ni in the raw milk samples were not presenting potential risk to Chinese adult, if the daily intake was 300 mL.

Key Words: raw milk, toxic elements, China

T162 Concentration of 22 elements in milk, feed and water of dairy cow, goat, and buffalo from different regions of China.

Xuewei Zhou[1,2], Xueyin Qu[1,3], Nan Zheng[1,3], Fadi Li[2], and Jiaqi Wang*[1,3], [1]*Ministry of Agriculture Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*College of Animal Science and Technology, Gansu Agriculture University, Lanzhou, Gansu, China,* [3]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Milk is the most diversified natural food contained more than 20 trace elements that are necessary for human health. However, metals such as Pb, Cr, Hg, As and so on, may contaminate the environment and thus the feed and water, passing into milk and causing health problems. In our study, the content of 22 elements, including Fe, Mn, Cu, Zn, Co, Al, V, Cr, Ni, Ga, As, Se, Rb, Sr, Ag, Cd, Cs, Ba, Hg, Tl, Pb and U, in cow milk (40), goat milk (40) and buffalo milk (20) in China were analyzed. These 22 elements in their corresponding feed and water were also examined using inductively coupled plasma-mass spectrometry (ICP-MS) after microwave-assisted acid digestion. Significant differences ($P < 0.05$) with mean values were analyzed by Tukey's HSD test in SPSS 17.0. The mean spiked recovery of analytical method was 70.96–113.41% in milk, 71.2–114.8% in feed, and 86.50–123.30% in water. In milk, the mean content of Rb and Zn showed high levels (>1000μg/L), followed by Al, Fe, Sr and Ba (100–1000 μg/L), and then Mn, Cu, Se and Cs (10~100μg/L). The mean values of V, Cr, Co, Ni, Ga, As, Ag, Cd, Hg, Tl, Pb and U were less than 10 μg/L. Co, Rb, Sr, Cs and Tl levels showed significant difference ($P < 0.05$) among cow, goat and buffalo milk. The content of Rb, Sr, Pb, Cs, As, Ni, Tl in drinking water were significant ($P < 0.05$) correlated with those in milk. However, elements in feed were not ($P > 0.05$) related to milk. It suggested that elements in water might contribute the content of elements in milk. The levels of As, Cd, Hg and Pb were under the MRL of China and did not pose threat to consumers.

Key Words: element, milk, ICP-MS

T163 Effect of HTST and UHT processing on the stability of cephalosporin residues in milk.

Meixia Chen[1,2], Nan Zheng[1,2], Fang Wen[1,2], Hui Wang[1,2], Songli Li[1], and Jiaqi Wang*[1,2], [1]*Ministry of Agriculture Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*Ministry of Agriculture-Milk and Dairy Product Inspection Center, Beijing, China,* [3]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Presence of antibiotics in raw milk threatens human health and dairy production. Heat treatments are expected to inactivate various pathogens or reduce the amount of other undesired substances such as antibiotics before milk reach consumers. As a common part of cephalosporins' molecular structure, β-lactam ring makes cephalosporins susceptive to chemical reaction. Hence, cephalosporins are very likely to experience decrease once heated. To date, few information about cephalosporins' stability during conventional dairy process such as high temperature short time pasteurization (HTST) and ultrahigh temperature process (UHT) has been reported. This study was designed to study the effects of HTST and UHT on cephalosporins. So heat treatment were performed on raw milk samples spiked with 5 cephalosporins—cefoperazone (PER), cefquinome (QUI), cephapirin (PIR), ceftiofur (TIO), cefazolin (ZOL)—on the level of maximum residues limits (MRLs). Of these treatments, 65°C/15s was used for preheating raw milk, 20M Pa for homogenization, 75°C/15s for HTST and 140°C/4s for UHT. Concentration of 5 cephalosporins in milk was determined by UPLC-MS/MS simultaneously before and after heat treatment. Recovery test was conducted to validate the analytical methods used in this study for determination of 5 cephalosporins in our lab. SAS 9.2 statistical software package were applied to carry out the statistical analysis. Data of recovery ranges from 85.8% to 99.8% with RSD lower than 10%, which demonstrates good recovery was obtained. Degradation percentages of cephalosporins obtained after HTST is as following: 2.6% for ZOL, 8.6% for PIR, 12.2% for QUI and 12.3% for TIO with the highest 20.5% for PER. Whereas UHT process showed higher reduction level of cephalosporins in all cases. As is shown, cephalosporins' loss is 15.7% for PIR, 36.3% for PER, 43.9% for QUI, 50.0% for TIO with the highest 77.4% for ZOL after UHT. It is noteworthy that degradation results obtained in our work is higher than the previous data predicted by M. Roca (2011) using the prediction model based on the kinetic equation. In addition, the effect of HTST and UHT displays significant difference ($P < 0.01$). In conclusion, cephalosporins studied in this work is resistant to HTST but is unstable in UHT.

Key Words: cephalosporins, HTST, UHT

T164 Toxins in milk of cows fed with transgenic maize.

Geraldo Neto Balieiro*[1,3], Keila Maria Roncato Duarte[2], Roberto Botelho Ferraz Branco[1], and Acyr Vanderley de Paula Freitas[1], [1]*São Paulo State Agency Agribusiness Technology, Ribeirão Preto, São Paulo, Brazil,* [2]*São Paulo State Agency Agribusiness Technology, Nova Odessa, São Paulo, Brazil,* [3]*Research Supported by FAPESP, São Paulo, Brazil.*

The goal of this study was to evaluate the presence Cry toxin in milk of cows feeding transgenic maize hybrids. Twenty-four Jersey cows were allotted into 2 groups: control (n = 12), feeding conventional diet, or test, consuming grain and silage from maize with *cry* gene from *Bacillus thuringiensis* (n = 12). A paired *t*-test was used to determine whether there were significant differences between the 2 treatments. Were used 0.5 g of maize leaves transgenic lyophilized, macerated in liquid nitrogen, resuspended in 1 mL of methanol (80%) and diluted with 4 mL of PBS buffer as immunoassay antigen. Two female New Zealand rabbits were used to produce polyclonal antibodies against Cry1A105, Cry2Ab2, Cry1F, Cry1Ab and VP3Aa20 toxins from DKB 390 VT Pro II, AG 8088 Pro II, Biomatrix 2B655 Hx, Syngenta Impacto TL TG and Syngenta 7205 Viptera, respectively, to be used as a screening for maize-derived food products, by plate-trapped antigen (PTA)-ELISA. Immunogen was prepared bioconjugating Cry toxin to carbodiimides. Immunizations were performed each 15 d. At the end of 5 immunizations the rabbits were bled and sera were kept at –80°C. Antibodies were purified in immunoaffinity columns between 50 and 100 kDa. Milk samples, collected 3 time each 14 d during 56 d, were frozen and lyophilized. Antigen (100 mL) were placed into micro wells in triplicates and incubated 1 h at 37°C. Blocking were done using 200 mL of PBS buffer added to 1% BSA for 1 h 37°C. Plates were dried and 100 mL of anti-sera dilution (1:500) were placed, for 1 h at 37°C. Plates were washed (PBS) and anti-rabbit conjugated HRP sera dilution (1:1000) was added. After 1 h at 37°C, plates were washed (PBS-T-G) and PNPP (*p*-nitrophenyl phosphate) revealed, at 450 nm. The presence Cry toxin analysis did not differ between milk of cows fed by transgenic maize hybrids and its nonbiotech counterpart. Results showed that the milk system production using silage and ration with transgenic maize hybrids that contains cry gene is safe and the antibodies produced through leaves as antigen are highly sensitive and specific to Cry toxin and can be used on an enzyme immunosorbent with low cost, high sensibility and specificity.

Key Words: GMO, food security, plate-trapped antigen (PTA)-ELISA

T165 Aflatoxin B_1 and aflatoxin M_1 induced cytotoxicity and DNA damage in differentiated and undifferentiated Caco-2 cells.

Jie Zhang[1,2], Nan Zheng[1,3], Fadi Li[2], Songli Li[1,3], and Jiaqi Wang*[1,3], [1]*Ministry of Agriculture Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, China,* [3]*State Key Laboratory of Animal Nutrition, Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, Beijing, China.*

Aflatoxin B1 (AFB_1) and aflatoxin M_1 (AFM_1) are natural mycotoxins that frequently found in food and feed. Numerous reports have indicated that these toxins pose serious risks to human and animal health. However, there are few data in the literature regarding the impairment of AFB_1 and AFM_1 on intestine. The present study therefore was undertaken to investigate the cytotoxic effect and DNA damage of these toxins on human colon carcinoma cell line Caco-2, especially the differentiated cells that resemble mature small intestinal enterocytes. Both undifferentiated (UC) and differentiated (DC) cell were treated with AFB_1 and AFM_1 at various concentrations for 24, 48 and 72 h. Cell viability, lactate dehydrogenase (LDH) release and reactive oxygen species (ROS) production were determined, and DNA damage was accessed by comet assay. Statistical analysis of data was carried out using SAS9.2, statistical software package. Data showed that AFB_1 and AFM_1 inhibited UC and DC cell growth and increased the LDH release in a time- and dose-dependent manner. Besides, AFB_1 treatment resulted in an evident increase in cytotoxicity over AFM_1 at the high dosage ($P < 0.05$). Moreover, DC were more sensitive to toxins compared with UC ($P < 0.05$), particularly after exposure of 72 h at the dose of 1 μg/mL, as indicated from the lower cell viability(48% vs. 67%, AFB_1 treatment) and the higher LDH release (118% vs. 186%, AFM_1 treatment; 142% vs. 194%, AFB_1 treatment). Marked impacts in the genetic damage were observed after treatment with 2 toxins on UC and DC, even higher than those of H_2O_2 treatment (positive control). Compared with UC, DC also had more DNA damage ($P < 0.05$), which might due to the alteration of cells during differentiation. All these cytotoxic effects might associate with the strong intracellular ROS generation in the presence of toxins. The present study provided the first experimental evidence of the in vitro DNA damage of DC induced by AFB1 and AFM1.

Key Words: aflatoxin B_1, aflatoxin M_1, DNA damage

T166 Interaction of aflatoxin M1, ochratoxin A, zearalenone, and α-zearalenol combinations on Caco-2 cells.

Yanan Gao[1,2], Nan Zheng[1,2], Songli Li[1,2], Yangdong Zhang[1,2], and Jiaqi Wang*[1,2], [1]*Ministry of Agriculture Laboratory of Quality & Safety Risk Assessment for Dairy Products (Beijing), Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*State Key Laboratory of Animal Nutrition, Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, Beijing, China.*

It is common to find the co-occurrence of aflatoxin B_1 (AFB_1), ochratoxin A (OTA), zearalenone (ZEA) in feed. These mycotoxins can be metabolized or transferred to raw milk in the forms of Aflatoxin M1 (AFM_1), ochratoxin A (OTA), ZEA, and α-zearalenol (α-ZOL), which are stable in processing of dairy products. The aim of the present study is to investigate the cytotoxicity of combined mycotoxins of AFM1, OTA, ZEA, and α-ZOL on the human colon adenocarcinoma cell lines (Caco-2) by using the tetrazolium salt (MTT) assay and the isobologram analysis. Statistical analysis of data was carried out using SAS9.2 statistical software package. Our results demonstrated the significant cytotoxic effects ($P < 0.05$) of the 2-toxin, 3-toxin and 4-toxin combination on Caco-2 cells in a time- and concentration-dependent manner. The results from MTT assay demonstrated that AFM_1 had the similar cytotoxicity as OTA ($IC_{50} = 4.10$ μM) upon exposure for 72 h, which was much higher than that of ZEA and α-ZOL. The cytotoxic effect of the all the mycotoxin combinations increased in the following order: OTA+α-ZOL < ZEA+α-ZOL < OTA+ZEA < AFM_1+ZEA < AFM_1+α-ZOL < AFM_1+OTA < OTA+ZEA+α-ZOL < AFM_1+ZEA+OTA < AFM_1+ZEA+α-ZOL < AFM_1+OTA+α-ZOL < AFM_1+ZEA+OTA+α-ZOL. Isobologram analysis was further indicated that the existence of AFM1 brought additive effect at IC_{50} and even synergism at IC_{25}. The synergistic effect of the 4-toxin group is the highest of all mytotoxin combinations investigated (Combination Index = 0.17 ± 0.05 at IC_{25}). Other cell lines will be further studied in the future to obtain an appropriate health risk assessment of milk.

Key Words: aflatoxin M_1, cytotoxicity, interaction

T167 Clean-in-place cleaning validation at lower temperatures with alkaline chlorinated detergent Cool CIP.

Gary Smith*, John Partridge, and Zey Ustunol, *Michigan State University, East Lansing, MI.*

Traditionally removal of organic soils in a clean-in-place (CIP) cleaning cycle by alkaline, chlorinated detergents is carried out at temperatures ranging from 50 to 65°C. The objective of this research was to determine the cleaning efficiency of a newly formulated CIP solution called Cool CIP, a chlorinated alkaline cleaner developed by DeLaval Cleaning Solutions designed to function at low temperatures. Cool CIP is formulated to function at temperatures ranging from 32 to 40°C. The study was conducted over a 1-year period at the Michigan State University Dairy Plant. CIP cleaning cycles of a raw milk tanker truck and receiving lines, raw milk lines, and raw milk storage tanks were chosen to be included in the study. Effectiveness of Cool CIP was evaluated on each cleaning cycle by analysis of solution temperature, chlorine level, pre-wash and post-wash turbidity, Adenosine Tri-Phosphate (ATP) bioluminescence counts, as well as visual confirmation of overall cleanliness. Samples were collected at the beginning and end of the chemical recirculation step of each CIP cycle. ATP swabs were taken inside the vessel of each cycle, before and after each complete cleaning cycle. The results showed that Cool CIP was able to clean effectively at temperatures as low as 30°C as careful visual inspection of all systems passed after each cleaning cycle. The results also showed that all ATP tests were passable post-cycle on tests at 30°C. The raw line tanker truck receiving lines (n = 14) had 1011.6 ± 943.4 ATP units pre-cleaning, and 0 ± 0 ATP units post-CIP cleaning cycle. The raw milk lines (n = 7) had 10611.3 ± 25620.2 ATP units pre-cleaning, and 1.5 ± 4.8 ATP units post-CIP cleaning cycle. The raw milk tanks (n = 12) had 1381.1 ± 1116.2 ATP units pre-cleaning, and 0 ± 0 ATP units post-CIP cleaning cycle. This paper will present Cool CIP as an effective substitute for traditionally accepted high-temperature alkaline CIP cleaning regimens.

Key Words: clean-in-place (CIP)

T168 Metagenomic evidence of the prevalence and distribution patterns of antimicrobial resistant genes in dairy agroecosystems.

Dipti Pitta*, Sanjay Kumar, Nagaraju Indugu, Zhengxia Dou, John Toth, Bonnie Vecchiarelli, and Bhima Bhukya, *Department of Clinical Studies, School of Veterinary Medicine, New Bolton Center, University of Pennsylvania, Kennett Square, PA.*

Antimicrobial resistance (AR) is a global problem with serious implications for public health. AR genes are prevalent on animal farms but little is known about their origin and distribution patterns in animal farm agroecosystems. In this study, a total of 20 resistomes (collections of AR genes), 5 each from animal feces, manure, near and far soil, on dairy farms were analyzed using shotgun approach. Antimicrobial resistance genes were detected on all 5 farms and only 2% was annotated to AR genes, but varied with sample type ($P < 0.05$). Despite variations in abundance, majority of AR genes (*acr*B, *bcr*A, *mac*B, *mdt*F, *pbp*1a, *tet*L, *tet*M, *tet*O, *tet*Q, *tet*S, *tet*W, *vanr*A, *vanr*B) that conferred resistance to multiple antibiotics, including macrolides, β-lactams, amphenicols, and tetracyclines, were common to all samples. Additionally, fecal and manure resistomes contained AR genes specific for quinolones, sulfonamides and aminoglycosides. Across all farms, manure was identified as a "Hot Spot" with the greatest abundance and diversity of AR genes. We compared AR genes from present data set with publically available data sets using hierarchal clustering. Multidrug resistant AR genes were prevalent across different animal species and humans, implicating an exchange of AR genes between unrelated microbial niches that may be potentiated by human activities. This study reports the prevalence of AR genes across different farm sectors and identifies potential pathways for horizontal transmission of AR genes (animal-manure-soil) in dairy agroecosystems.

Key Words: antimicrobial resistance, agroecosystems, antimicrobial resistance (AR) genes

T169 Antimicrobial resistance of *Escherichia coli* isolates from cheese made from unpasteurized milk in Brazil.

Laryssa Freitas Ribeiro*[1,2], Mayhara Martins Cordeiro Barbosa[3], Fernanda de Rezende Pinto[4], Renato Pariz Maluta[5], Mônica Costa Oliveira[2], Viviane de Souza[6], Maria Izabel Merino de Medeiros[7], Lucimara Antonio Borges[2], Priscila Arrigucci Bernardes[1], Luiz Augusto do Amaral[2], and John Morris Fairbrother[1], *[1]Faculté de Médecine Vétérinaire, Université de Montréal, Saint-Hyacinthe, QC, Canada, [2]Universidade Estadual Paulista, Jaboticabal, São Paulo, Brazil, [3]Instituto Federal de Educação, Ciência e Tecnologia do Ceará, Quixadá, Ceará, Brazil, [4]Universidade Federal de Pelotas, Pelotas, Rio Grande do Sul, Brazil, [5]Universidade de Campinas, Campinas, São Paulo, Brazil, [6]Embrapa Caprinos e Ovinos, Sobral, Ceará, Brazil, [7]Instituto Tecnológico de Alimentos, Campinas, São Paulo, Brazil.*

The production of cheeses from unpasteurized milk is a public health problem, due to the use of raw milk and the associated poor hygienic conditions. Contamination may occur from several sources, involving several different pathogenic microorganisms, including *Escherichia coli*. The use of antimicrobials in animals has led to emergence of resistant microorganisms, contributing to the ineffectiveness of these products. The purpose of the current study was to investigate the presence of antimicrobial resistance in *E. coli* isolates in raw milk cheese in Brazil and to identify the potential risk to public health. A total of 83 cheeses from 3 different cities, Uberaba, Minas Gerais (30), Ribeirão Preto, São Paulo (22) and Aracaju, Sergipe (31) were cultured. From each cheese, 5 colonies were examined and a total of 169 *E. coli* isolates, 51, 25, and 93 from Uberaba, Ribeirão Preto, and Aracajú respectively were obtained. Ninety-five randomly selected isolates were tested for susceptibility to the 15 antimicrobials: amoxicillin + clavulanic acid (20 + 10 µg), ceftiofur (30 µg), ceftriaxone (30 µg), ciprofloxacin (5 µg), amikacin (30ug), ampicillin (10 µg), cefoxitin (30 µg), gentamicin (10 µg), kanamycin (30 µg), nalidixic acid (30 µg), streptomycin (10 µg), tetracycline (30 µg), chloramphenicol (30 µg), sulfisoxazole (0.25 mg) and trimethoprim + sulfamethoxazole (1.25 + 23.75 µg) used for testing generic *E. coli* in the Canadian Integrated Program for Antimicrobial Resistance Surveillance (CIPARS), by the disk-diffusion (Kirby-Bauer) method. The greatest number of isolates with a resistance pattern (one antimicrobial class or more) was observed in Uberaba, most being resistant to 1–2 antimicrobial classes. Multidrug resistance (resistance to 3 or more classes of antimicrobial agents) was much more frequently observed in isolates from Uberaba and Ribeirão Preto (12 to 14%) than in those from Aracaju (2%). The highest prevalence of resistance in all regions was to tetracycline. Strikingly, prevalence of resistance to ampicillin and amoxicillin/clavulanic acid was much higher in Uberaba than in Ribeirão Preto and Aracajú. For example, 58.85% of Uberaba samples were amoxicillin/clavulanic acid resistant while Ribeirão Preto and Aracaju were 18.18% and 3.57% respectively. For ampicillin, the prevalence in samples were 61.54%, 27.27% and 14.29% to Uberaba, Ribeirão Preto and Aracaju repectively. All 95 isolates were susceptible to ceftriaxone, amikacin, gentamicin, and chloramphenicol. Resistance to ceftiofur was found in Ribeirão Preto, suggesting the therapeutic use this antimicrobial.For statistics analysis, the sample was considered resistant to the antimicrobial when at least one of the isolates demonstrated resistance and it was used exact chi-squared. So, with the test, *P*-value was 0.001571 and it showed that the city is not resistant independent, thus they do not have the same resistance. And it showed that Uberaba was different from Ribeirão Preto and Aracaju and Aracaju and Ribeirão did not differ ($P < 0.05$). The variation of resistance to antimicrobials between regions observed in the present study indicates that the cheese made with unpasteurized milk in Brazil may contain *E. coli* that can be a risk for public health.

Key Words: public health, microbiology, antimicrobial resistance

T170 Ecoepidemiology of *Staphylococcus* spp. in small-scale goat milk dairy plants in northeastern Brazil.

Candice de Leon[1], Celso Oliveira*[1], Iara Siqueira[2], Maria G. Carvalho[2], and Denis Spricigo[3], [1]*Federal University of Paraiba (UFPB), Brazil, Areia, PB, Brazil,* [2]*Federal University of Campina Grande, Patos, PB, Brazil,* [3]*LANAGRO, Porto Alegre, RS, Brazil.*

The microbiological quality of goat milk needs to be monitored to ensure the milk and milk products are safe for consumers. Our previous studies have demonstrated high contamination of goat milk by coagulase-positive and coagulase-negative *Staphylococcus* spp. that frequently harbor enterotoxin-producing genes. Staphylococci have been associated with food-poisoning outbreaks in humans and because staphylococci are commonly isolated from goat milk and are have an important effect on public health, these organisms are used as indicators of contamination in goat dairy plants. Therefore, this study aimed to evaluate the epidemiology of *Staphylococcus* spp. at different points of small-scale processing plants of goat milk in northeastern Brazil, the leading goat milk-producing region in the country. A longitudinal study was performed in 2 goat milk processing plants; samples of raw and pasteurized milk and swabs of the inner surface of equipment, walls, and handlers' hands were collected. Samples were collected in the morning before milk processing to detect residual contamination. *Staphylococcus* spp. isolates (n = 36) were subjected to genotyping by REP-PCR using the primer RW3A. Indistinguishable genotypic profiles were observed among *Staphylococcus* spp. collected from milk samples, equipment, and handlers' hands, indicating the presence of residual contamination during milk processing and the need to improve cleaning and disinfection procedures. The *Staphylococcus* spp. isolates from handlers' hand swabs had high genotypic relatedness with isolates from equipment and pasteurized milk, indicating that workers can play a role in the cross-contamination by *Staphylococcus* spp. in milk processing plants.

Key Words: food safety, genotyping, pathogen

T171 Effects of purple prairie clover (*Dalea purpurea* Vent.) on feed intake, nutrient digestibility and fecal shedding of *Escherichia coli* O157: H7 in lambs.

Qianqian Huang1,2, Long Jin[1], Zhong Xu[1], Ruth Barbieri[1], Surya Acharya[1], Tianming Hu[2], Tim McAllister[1], Kim Stanford[3], and Yuxi Wang*[1], [1]*Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada,* [2]*College of Animal Science and Technology, Northwest A&F University, China,* [3]*Alberta Agriculture and Rural Development, Lethbridge Agriculture Centre, Lethbridge, AB, Canada.*

This study was conducted to assess the effects of purple prairie clover (PPC, *Dalea purpurea* Vent.) on feed intake, nutrient digestibility, fecal shedding of *Escherichia coli* O157: H7 and blood metabolites of lambs. Three groups of lambs (6 per group)were individually fed green chop alfalfa (Alf), a mixture of Alf and PPC in a ratio of 40:60 (DM basis; Mix) and Mix supplemented with polyethylene glycol (Mix-P) for 45 d. Polyethylene glycol (PEG) was included to neutralize the biological activity of condensed tannins (CT) in PPC. Total-tract digestibility was determined using AIA as an indigestible marker. Blood samples were collected to measure serum metabolites and activity of antioxidant enzymes. All lambs were orally inoculated with a 5-strain mixture of *E. coli* O157:H7 after determination of diet digestibility and fecal samples were enumerated for *E. coli* O157:H7 after 1, 2, 3, 4, 7, 14, 21 and 28 d of inoculation. Feed intake was similar among lambs fed the 3 diets. The OM digestibility of Mix ($P < 0.05$) and CP digestibility of both Mix and Mix-P ($P < 0.01$) were lower than Alf. However, the 3 diets had similar NDF digestibility. After inoculation, lambs fed Mix shed less *E. coli* O157:H7 than lambs fed Alf between d 1 and d 7 ($P < 0.05$ to 0.006), and lambs fed Mix-P between d 1 and d 3 ($P < 0.05$ to 0.012). Lambs fed Alf shed more *E .coli* O157:H7 than lambs fed Mix ($P < 0.001$) or Mix-P ($P < 0.01$) over the 28-d post-challenge period. Lambs fed Mix had lower levels ($P < 0.05$) of serum creatinine and urea nitrogen than Alf, but both Mix and Mix-P had higher ($P < 0.05$) levels of serum P. Mix fed lambs had greater ($P < 0.05$) serum total antioxidant capacity but lower ($P < 0.05$) serum superoxide dismutase activity than lambs fed Alf. Incorporation of PPC in lamb diets at 60% of DM reduced fecal shedding in lambs challenged with *E. coli* O157:H7 as compared to Alf. The fact that shedding of *E. coli* O157:H7 was also reduced with Mix-P suggests that the anti- *E. coli* O157:H7 response of PPC is not solely due to CT.

Key Words: purple prairie clover, *E. coli* O157: H7, condensed tannins

T172 Reduction of biological hazards in animal feed mills via a decontamination protocol.

Anne R. Huss*, Roger A. Cochrane, Aiswariya Deliephan, Charles R. Stark, and Cassandra K. Jones, *Kansas State University, Manhattan, KS.*

Animal feed and ingredients have been shown to be potential vectors of pathogenic bacteria in to the human food chain. Introduction of contaminated materials can lead to facility contamination, which can be easily spread to non-contaminated materials, including finished feeds. Upon detection of contamination, facility decontamination is necessary to prevent potential cross-contamination to feedstuffs. The purpose of this experiment was to evaluate a standardized protocol to decontaminate an animal feed manufacturing facility using *Enteroccoccus faecium* (ATCC 31282) as an indicator. A pelleted swine diet inoculated with *E. faecium* was manufactured at the Kansas State University Feed Safety Research Center. Environmental samples including swabs, RODAC plates and air samples were collected and consisted of: 1) baseline before inoculation, 2) after inoculated feed production, 3) after production physical clean using pressurized air, 4) after chemical clean with a quaternary ammonium-glutaraldehyde blend, 5) after chemical clean with sodium hypochlorite, 6) after facility heat-up to 60°C for 24 h, 7) 48 h, and 8) 72 h. Air samples collected on the exterior of the facility confirmed pathogen containment as *E. faecium* concentrations were equal to or lower than baseline levels at each sample location. Decontamination step and its associated interactions were the only factors that affected *E. faecium* incidence ($P < 0.0001$ vs. $P > 0.22$). After production of the inoculated diet, 85.7% of environmental samples were positive for *E. faecium*. Interestingly, physical cleaning had no effect on contamination ($P = 0.32$). Chemical cleaning with a quaternary ammonium-glutaraldehyde blend and sodium hypochlorite each reduced ($P < 0.0001$) *E. faecium* contamination to 28.6% and 2.4% of tested surfaces. All samples were negative after 48 h of heating. In summary, both wet chemical cleaning and facility heating resulted in substantial *E. faecium* decontamination, but not physical cleaning. In addition, this experiment confirmed both successful containment and decontamination of biological pathogens in the tested pilot-scale feed mill.

Key Words: feed safety, pathogen, decontamination

T173 Evaluation of select bacterial populations in poultry excreta and potential treatments for their disinfection.

C. Arzola*[1], J. Corrales[1], R. Anderson[2], M. Hume[2], O. Ruiz[1], A. Corral[1], C. Rodriguez-Muela[1], Y. Castillo[3], J. L. Guevara[1], and R. Lechuga[1], *[1]Universidad Autonoma de Chihuahua, Chihuahua, Chihuahua, Mexico, [2]ARS,USDA, SPARC, College Station TX, [3]Universidad Autonoma de Ciudad Juarez, Casas Grandes, Chihuahua, Mexico.*

Because poultry litter has been used as feed supplement for cattle, there is interest in learning more about any unwanted bacteria present in poultry excreta. The objective of this study was to test for the presence of select bacterial populations in UACH poultry excreta for total aerobes, *Salmonella* spp., *E. coli* and coliforms, and *Campylobacter* spp. Additionally, sodium chlorate and nitroethane were evaluated as bactericidal agents to reduce bacterial concentrations. Approximately 45 kg of poultry excreta were mixed with 16 L of water and distributed equally to 9 buckets. Treatments were sodium chlorate (10 mM concentration), nitroethane (12 mM concentration) and a control. Excreta temperature and pH were measured. Samples were collected at 0, 6 and 24 h and processed for bacteriological enumeration. Enumeration of total aerobes, *Salmonella* spp., *E. coli* and coliforms, and *Campylobacter* spp. were performed with 3M Petrifilm Total Aerobe Count Plates, brilliant green agar supplemented with novobiocin, 3M Petrifilm E.coli/Coliform Count Plates and Campy-Cefex Agar, respectively. Data were analyzed by means of an ANOVA design, with time and treatments as main effects and their interactions. There was found a main effect of time ($P < 0.0001$) but not treatment or an interaction ($P > 0.05$) on litter temperature and pH. A main effect of time ($P < 0.0001$) was observed but treatment and the time x treatment interaction ($P > 0.05$) for litter temperature and pH was not significant. A main effect of time ($P < 0.01$) but not treatment or the interaction ($P > 0.10$) on total aerobes or on *Salmonella* spp. was observed. A treatment x time interaction ($P = 0.05$) on *E. coli* and total coliforms was observed. *Campylobacter* spp. was present but no effects of treatment or time ($P < 0.15$) on incidence of culture-positive samples was observed. *Campylobacte*r concentrations were not sufficient across all samples to perform quantitative analysis. In conclusion, modest effects of chlorate and nitroethane treatment were observed on *E. coli* and total coliforms but not on total aerobes or *Salmonella.*

Key Words: poultry excreta, *Salmonella* and *E. coli*, chlorate nitroethane

T174 *Trypanorhyncha* cestodes in *Brachyplatystoma rousseauxii*, *Cynoscion leiarchus*, *Cichla* spp., and *Colossoma macropomum*, captured in coast of Amazon/Brazil.

Raquel L. Salgado*[1] and Josemir S. Gonçalves[2], *[1]Universidade Federal Fluminense, Niterói, Rio de Janeiro, Brazil, [2]Universidade Federal Rural do Semi Árido, Mossoró, Rio Grande do Norte, Brazil.*

Fish consumption in the Amazon region is one of the world's largest; however, many species of fish commonly show high parasitism rates in muscles, making them unfit for consumption. In this context, the aim of this study was to evaluate the diversity of the parasitic fauna of 4 different species of fish captured in the northern coast of Amazon/Brazil. During the months from January to December 2009, 60 specimens of each species (*Brachyplatystoma rousseauxii*, *Cynoscion leiarchus*, *Cichla* spp., and *Colossoma macropomum*) were weighed, measured, and identified according their anatomic traits. They were filleted and with the aid of a candling table, their muscles were evaluated for the presence of parasites. The *Trypanorhyncha* larvae were released from their blastocysts, placed in Petri dishes containing distilled water for 24 h in the refrigerator. Subsequently, they were fixed in A.F.A. (95 parts of 70% alcohol, 5 parts of formalin, 2 parts of acetic acid) for 24 h. The cestodes identification was based in their morphologic traits. The amount of parasites in each specimen and overall were used to calculate the prevalence (P), infection intensity (I), mean infection intensity (MI) and mean abundance (MA). Of the 60 specimens of *B. rousseauxii* analyzed, 2 were infested by cetodes parasites, one by *Poecilancistrium caryophyllum*, P (1.60%), I (1), MI (1.00), MA (0.02) and one by *Pterobothrium heteracanthum* P (1.60%), I (1), MI (1.00), MA (0.02). Three specimens of *Cynoscion leiarchus* exhibited multiple parasitism by *Anisakis* spp. and *Poecilancistrium caryophyllum* P (7.50%), I (1–2), MI (1.50), MA (0.10). Six specimens of *Cichla* spp. were infested by *Clinostomum complanatum*, P (10.00%), I (2–3), MI (2.50), MA (0.92) and 2 are also infested by *Contracecum* spp. P (17.00%), I (1–3), MI (1.70), MA (0.27). No specimen of *Colossoma macropomum* was infested by any parasites. Despite they do not have zoonotic potential, the high prevalence of *Trypanorhyncha* represents a serious risk to human health, through the possibility of causing allergic reactions in humans.

Key Words: fish, human health, parasite

T175 Helminth with zoonotic potential in fish of Amazon/Brazil.

Raquel L. Salgado*[1] and Josemir S. Gonçalves[2], *[1]Universidade Federal Fluminense, Niterói, Rio de Janeiro, Brazil, [2]Universidade Federal Rural do Semi Árido, Mossoró, Rio Grande do Norte, Brazil.*

Among the parasites with zoonotic potential, nematodes from the family Anisakidae are most involved in cases of infection due to the consumption of fish. The aim of this study was to evaluate the presence of parasites with zoonotic potential in *Brachyplatystoma rousseauxii*, *Cynoscion leiarchus*, *Cichla* spp., and *Colossoma macropomum* captured in the northern coast of Amazon/Brazil. During the months from January to December 2009, 60 specimens of each specie were weighed, measured, and identified according their anatomic traits. They were filleted and with the aid of a candling table, their muscles were evaluated for the presence of parasites. Nematode larvae were placed in Petri dishes containing distilled water and subsequently fixed in A.F.A. (95 parts of 70% alcohol, 5 parts of formalin, 2 parts of acetic acid) for 24 h. The nematodes identification was based in their morphologic traits. The amount of parasites in each specimen and overall were used to calculate the prevalence (P), infection intensity (I), mean infection intensity (MI) and mean abundance (MA). Nematodes of the genus *Anisakis* spp. were observed parasitizing 15 specimens of *Cynoscion leiarchus* P (37.50%), I (3–42), MI (18.06), MA (6.77). Three specimens exhibited multiple parasitism by *Anisakis* spp. and *Poecilancistrium caryophyllum* P (7.50%), I (1–2), MI (1.30), MA (0.10). Twelve specimens of *Cichla* spp. were infested, of which, 10 by nematodes of the genus *Contracecum* spp. P (17.00%), I (2–12), MI (2.50), MA (0.92) and 2 by *Contracecum* spp. and by *Clinostomum complanatum* P (17.00%), I (1–3), MI (1.70), MA (0.27). Nine specimens of *B. rousseauxii* were infested by *Anisakis* spp. P (15.00%), I (4–32), MI (12.00), MA (1.80). No parasite species were found in the 60 specimens of *C. macropomum* analyzed. The parasites found may be responsible for allergic and gastric reactions and may even lead to death in humans. The high prevalence of parasites with zoonotic potential combined with the small number of studies on the parasite fauna of the Amazon fish, represents a serious risk to human health, and reinforce the need for a larger number of studies in this area.

Key Words: Anisakidae, human health, parasite

Forages and Pastures: Silages and forages in beef and sheep production systems

T176 Tiller population stability index from the spring in palisadegrass previously used in deferred grazing. Simone Pedro da Silva*[1], Manoel Eduardo Rozalino Santos[2], Bruno Humberto Rezende Carvalho[2], Ludiêmilem Keith Parreira da Costa[2], Denis Douglas Pessoa[2], Heron Alves de Oliveira[2], Róger Carvalho Cardoso[2], Miriã Gonçalves Simplício[2], and Dilermando Miranda da Fonseca[3], *[1]Instituto Federal Goiano, Hidrolândia, Goias, Brazil, [2]Universidade Federal de Uberlândia, Uberlândia, Minas Gerais, Brazil, [3]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

We evaluated the effect of pasture condition previously deferred and on late winter on regrowth of *Brachiaria brizantha* 'Marandu' (palisadegrass). From October 2013 to January 2014, the palisadegrass pastures were evaluated at the Federal University of Uberlândia, located in the State of Minas Gerais, Brazil. The experimental site was located at 776 m altitude, 18°30′ S and 47°50′ W. Annual precipitation was around 1.584 mm. Medium temperature was 22.3°C. The tiller dynamics was evaluated in deferred pastures with 4 conditions to late winter. The pastures conditions were low (15.1 cm), medium (23.2 cm), high (31.4 cm) and high/cutting (31.3 cm and cutting to 8.0 cm). The experiment was carried out using a randomized completely design with 3 repetitions and subdivided plots. In each experimental unit (paddocks), all tillers inside the 3 frames with 0.0625 m^2 were counted and marked with colored plastic. Every 30 d, all tillers were recounted and new tillers were marked with a different wire color. The collected data were used to calculate the tiller population stability index (SI). During spring and early summer, all pastures were kept with 30 cm in continuous stocking, with sheep. There were interactions ($P < 0.05$) of months with pasture conditions for SI. In October, the low (2.3) and high/cutting (2.2) pastures showed ($P < 0.05$) higher SI, followed by medium (1.7) and high (1.4) pasture, respectively. For other months, there was no effect of pasture conditions on SI. The SI was higher in low and high/cutting pastures, due to high tillering these pastures. The SI was less than or equal to one unit only in November (0.9) and December (1.0). The high development of shoots in tillers in October may have generated higher shading at plant base in November and December, causing decrease in SI. The lower and deferred palisadegrass pastures in late winter have a higher SI from early spring, compared with higher pastures. We conclude that cutting of high palisadegrass pasture in late winter improves the tiller population stability index from the spring.

Key Words: grazing, seasons of the year, sward height

T177 Performance of crossbred cows on Tanzania grass pastures subjected to two pasture-management strategies. Alberto Magno Fernandes*[1], Ricardo Augusto Mendonça Vieira[1], Tadeu Silva de Oliveira[1], and Fermino Deresz[2], *[1]Universidade Estadual do Norte Fluminense, Campos dos Goytacazes, Rio de Janeiro, Brazil, [2]EMBRAPA-Gado de Leite, Juiz de Fora, Minas Gerais, Brazil.*

The objective of this study was to evaluate nutrient intake and yield and components of milk from Holstein × Zebu cows on Tanzania grass using a fixed resting period (FR) or according to 95% light interception (LI, by accuparLP-80) for managing Tanzania-grass pastures. As the LI of the herbage mass reached 95%, the animals were allowed to graze each paddock for 3 d; and (2) 30 d defoliation interval with a 3-d grazing period (FR). Experimental unit consisted of 11 paddocks grazed by 5 Holstein-Gir cows allowing for 2 replicates per defoliation treatment in the first year with the same areas assigned to the same treatment the following year grazed by 4 Holstein-Gir cows per experimental unit. Intake and digestibility were estimated using the external marker chromic oxide (Cr_2O_3). Each grazing animal received 5 g of Cr_2O_3 administered orally in paper cartridges twice daily at 12-h intervals for 12 d. The cows were milked twice daily, at 06.00 and 15.00 h. Milk samples were analyzed every 14 d to determine protein, fat, lactose, energy, and total solids (TS) contents. The management strategies imposed on the Tanzania-grass pasture did not affect ($P > 0.05$) the intake or digestibility of nutrients. Milk yield and milk components were not affected ($P > 0.05$) by the management strategies, but treatment LI95 yielded 2,067 ± 288 kg milk/ha while FR was less at 1,861 ± 288 kg milk/ha ($P < 0.05$). In conclusion, adopting forage management utilizing a 95% light interception defoliation interval improves milk production per land unit and efficiency of land resources.

Key Words: grass, intake, milk

T178 Performance of cows and calves grazing limpograss pastures as affected by creep-feeding protein supplements. J. M. D. Sanchez*[1], J. M. B. Vendramini[1], P. A. Lancaster[1], J. K. Yarborough[1], F. A. Kuwahara[2], and V. C. Gomes[3], *[1]Range Cattle Research and Education Center, University of Florida, Ona, FL, [2]Faculdade de Medicina Veterinaria e Zootecnia, Universidade Estadual Paulista, Botucatu, Sao Paulo, Brazil, [3]Instituto de Zootecnia, Nova Odessa, Sao Paulo, Brazil.*

Creep-feeding soybean meal (SBM) to suckling calves grazing limpogras (*Hemarthria altissima*) pastures has been an effective management practice to improve calf average daily gain (ADG); however, it is not clear if the positive effect is result of a greater CP and energy intake or specifically the additional rumen degradable protein (RDP) supplied by the SBM. The objective of this study was to investigate the effects of creep-feeding different amounts of RDP to cow-calf pairs grazing limpograss pastures. The experiment was conducted at the Range Cattle Research and Education Center, Ona, FL from May to August 2014. Treatments were 400 g/d of SBM (65% RDP) or SoyPlus (40% RDP) distributed in a randomized complete block design with 4 replicates. Brangus crossbred cow-calf pairs (n = 16; calf initial BW = 160 ± 5 kg) were randomly assigned to 8 limpograss pastures (1.0 ha/pasture; 2 pairs/pasture). Average daily gain of cows and calves was recorded every 28 d. Body condition scores (BCS) of cows was measured at the beginning and ending of the experiment. Herbage mass (HM) and CP concentration were measured every 14 d. Data were analyzed using the Proc Mixed of SAS with treatment and month as fixed effects and block as random effect. There were no differences in HM ($P = 0.48$, 6800 ± 1200 kg DM/ha) and CP ($P = 0.20$, 12.2 ± 3.2% CP) between treatments. The CP concentration decreased ($P < 0.01$) from May to July and was similar in July and August (from 15 to 10% CP). There was no difference in ADG of cows ($P = 0.71$, 0.12 ± 0.14 kg/d) and calves ($P = 0.24$, 0.74 ± 0.03 kg/d) between treatments. Calf ADG decreased from May to August ($P < 0.01$, from 1.03 to 0.30 kg/d). There were no differences in the final cow BCS ($P = 0.90$, 5.34 ± 0.30) and change in BCS ($P = 0.73$, 0.51 ± 0.31) during the experimental period. In conclusion, the increase in performance of calves creep-fed with SBM observed in previous studies may be due to increase in CP and energy intake rather than the additional RDP provided by the SBM.

Key Words: soybean meal, SoyPlus, limpograss

T179 Decreased reproductive rates in sheep fed a high selenium diet.

Thomas Z. Davis*[1], Bryan L. Stegelmeier[1], Kip E. Panter[1], and Jeffery O. Hall[2], [1]*United States Department of Agriculture-Agricultural Research Service, Poisonous Plant Research Laboratory, Logan, UT,* [2]*Utah State University Veterinary Diagnostic Laboratory, Logan, UT.*

High Se-containing forages grow on seleniferous soils in many parts of the United States and throughout the world. Selenium is an essential trace element that is required for many physiological processes but can also be either acutely or chronically toxic to livestock. Anecdotal reports of decreased reproductive rates in livestock grazing seleniferous forages have been reported and it has been speculated that reproductive failure is one of the initial changes of Se poisoning. The objective of this study was to determine the effect of high Se forages on reproductive rates in sheep. The study was conducted in 2 phases. Phase 1, the ewes ($n = 3–5$) were fed a Se-containing alfalfa pellet (made by adding western aster containing approximately 2000 ppm Se) that contained <0.3 (control),10, 20, 30, 45, or 60 ppm Se for 12 weeks. Feeding of the pellets began 6 weeks before exposing the ewes to rams. Each ewe was exposed to 2 rams twice each day for 2 complete reproductive cycles. At 35 to 45 d post-exposure the pregnancy status of the ewes was determined by ultrasound imaging. Each group fed Se-containing pellets had fewer pregnant ewes than the control group (pregnant ewes/ewes exposed): control (3/3), 10 ppm Se (3/5), 30 ppm Se (0/5), 45 ppm Se (1/5), 60 ppm Se (1/5). Throughout the study hair samples, blood samples, liver biopsies, and muscle biopsies were collected to monitor the Se status of the ewes. In phase 2, ewes were divided into 3 groups ($n = 10$) and were fed Se-containing pellets containing <0.3 (control), 10, and 30 ppm Se in the same manner and for the same period. However liver and muscle biopsies were not performed. After the first cycle, significantly ($P < 0.05$) more ewes were pregnant in the control group (10/10) than in the 10 ppm Se (6/10) and 30 ppm Se (6/10) groups. After a second cycle 9/10 and 6/10 were pregnant in the 10 and 30 ppm Se groups, respectively. None of the ewes in either phase of the study demonstrated any clinical signs of chronic Se poisoning during the study. In summary, high selenium forages containing 10 ppm Se or greater decreased reproduction rates in ewes when fed for 6 weeks before exposure to rams.

Key Words: selenium, sheep, reproduction

T180 Total nitrogen in Marandu-grass pastures under different grazing intensities in southeast Brazil.

Mariana Vieira Azenha*[1], Liziane Figueiredo Brito[2], Andre Alves Oliveira[2], Elisamara Raposo[2], Estella Rosseto Janusckiewicz[2], Ricardo Andrade Reis[2], and Ana Claudia Ruggieri[2], [1]*EMBRAPA Pecuaria Sudeste, São Carlos, Sao Paulo, Brazil,* [2]*UNESP / FCAV, Jaboticabal, Sao Paulo, Brazil.*

Pasture productivity relies heavily on exchange of several different compounds between roots and shoots. The study aimed to evaluate nitrogen content on Marandu-grass pasture managed under 3 grazing management heights. The heights of 15, 25 and 35 cm were managed by beef steers grazing under continuous stocking and occurred from January to November, 2011. Data were analyzed by repeated measurements with grazing intensity, period and interactions. Roots and shoots samples were collected monthly. The collected samples were washed, dried and ground for further analysis. Total nitrogen concentration in the shoots was higher during the summer (14.77 g kg^{-1} DM) and lower during the drier seasons (7.47 g kg^{-1} DM) ($P < 0.05$). This decrease in concentration was more marked for the 35 cm pasture height ($P < 0.05$). Total nitrogen concentration in the roots followed the opposite pattern, increasing in drier seasons (7.29 g kg^{-1} DM), and had no consistent correlation with pasture height. Root nitrogen content was also negatively correlated with precipitation and temperature, while shoot nitrogen was positively correlated ($P < 0.05$). During the summer, fertilizer application along with temperature, precipitation and insolation favor plant growth. With a higher quantity of new leaves in this season there was an increase in shoot nitrogen content. During the winter, limited growth favors nitrogen storage in roots. Our results indicate that roots provide a storage site for nitrogen during drier, less favorable seasons. These reserves were directed to shoot regrowth during the summer. We found a negative linear association between pasture heights and shoot nitrogen content in autumn and winter ($P < 0.05$). In more intensely managed pastures, greater tissue renewal occurs as tillers develop in an environment with reduced competition for light. Indeed, intensely managed palisadegrass pastures have higher rates of tiller appearance and death, and higher defoliation frequency of individual tillers. In addition, taller pastures carry a higher proportion of stem and dead material in relation to shorter pastures, contributing to lower nitrogen concentrations. Root nitrogen did not show a consistent response pattern in relation to pasture height.

Key Words: pasture management, roots, shoots

T181 Effects of conservation method on condensed tannin content, ruminal and intestinal digestion characteristics of purple prairie clover.

Qianqian Huang1,2, Tianming Hu[1], Long Jin[2], Surya Acharya[2], Tim McAllister[2], Alan Iwaasa[3], Mike Schellenberg[3], and Yuxi Wang*[2], [1]*College of Animal Science and Technology, Northwest A&F University, Yangling, Shaanxi, China,* [2]*Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada,* [3]*Agriculture and Agri-Food Canada,Semiarid Prairie Agricultural Research Centre, Swift Current, SK, Canada.*

Purple prairie clover (PPC, *Dalea purpurea* Vent.) is a forage that contains high levels of phenolics including condensed tannins (CT) and exhibits anti- *Escherichia coli* O157: H7 activity. The objectives of this study were to evaluate the effects of forage conservation method on the CT content, ruminal and intestinal digestion characteristics of PPC. Whole PPC was harvested at the full flower stage and either immediately freeze-dried to represent green chop (FG), ensiled in mini-silos for 45 d (Silage), or sun cured in the field to DM >85%, baled and stored under shed for 45 d (Hay). In situ DM, NDF and CP degradabilities were determined by incubating the conserved forage in 3 rumen cannulated heifers for 0, 1, 2, 4, 8, 12, 24, 48 and 72 h, and analyzing data for Degradability = $a + b\,(1 - e^{-c(t-L)})$ and effective degradability (ED) = $a + [bc/(c + k)]\,e^{-(c+k)L}$. Intestinal DM and CP digestion were estimated by incubating 12-h ruminal in situ residues in a modified 3-step in vitro procedure. Silage exhibited decreased ($P < 0.001$) extractable CT, but increased ($P < 0.001$) protein and fiber–bound CT, whereas Hay only increased ($P < 0.01$) protein-bound CT. The ED of FG was greater ($P < 0.01$) than Silage or Hay, with ED of Hay being lower ($P < 0.01$) than Silage. However, the ED of NDF and CP as influenced by conservation method ranked as Silage > FG > Hay ($P < 0.01$). Conservation method did not affect intestinal DM digestion of 12-h in situ residues, but the CP intestinal digestion of Silage was higher ($P < 0.01$) than FG and Hay. Ensiling increased proportions of protein- and fiber-bound CT, but also increased ED of both CP and NDF as well as in vitro intestinal digestibility of CP. These findings indicate that the biological activity of CT and the formation of CT-protein complexes were altered by the ensiling process. Silage is a better conservation method than sun cured hay for PPC in terms of ruminal and intestinal digestion of DM, NDF, and CP while the biological activity of CT is higher in Hay than in Silage.

Key Words: purple prairie clover, forage conservation, condensed tannins

T182 Nutrient content of *Atriplex canescens* (Pursh Nutt) as a function of soil electrical conductivity.

Aracely Zúñiga*[1], Luz M. Tejada[1], Juan C. Martínez-Alfaro[2], and Miguel Mellado[1], [1]*Autonomous Agrarian University Antonio Narro, Saltillo, México,* [2]*Regional Academic Center UAAAN, Chiapas, México*.

Arid and semi-arid areas of northern Mexico are characterized for having little availability of fodder. Another limitation in some desert areas is the presence of soils with high amounts of salts, which limits the development of crops. Four-wing saltbush (*Atriplex canescens*) is a shrub of arid and semi-arid areas adapted to soils with high salinity, it remains green throughout the year, and has a high nutritional content, which represents a good forage for herbivores in these areas. For this study, *A. canescens* samples (leaves) from 20 plots (3 × 3 m) were collected during November in northern Mexico (24°N) and the nutrient content was analyzed. Soil samples near stems of these shrubs were also collected, at depths of 0–30 cm. Crude protein of this fodder shrub was 9.87%. Soil testing showed slight levels of salinity, with an electrical conductivity of 2 to 4 mMhos/cm. The association between nutrient content of *Atriplex canescens* and electrical conductivity of soil were analyzed by nonlinear regression with the CurveExpert program. It was found that the crude protein of *A. canescens* was positively affected by ascending levels of electrical conductivity ($y = 10.9 \times 0.092^{1/x}$; $r^2 = 0.17$). Calcium levels increased with electrical conductivity ($y = 4.85 + 0.34x – 0.32/x^2$; $r^2 = 0.31$). The association between electrical conductivity and phosphorous was weak ($y = 7.29 −0.94x −0.5/x^2$; $r^2 = 22$). The variable with the highest association with electrical conductivity was potassium ($r^2 = 0.44$). It was concluded that neither dry matter digestibility nor structural carbohydrates are associated with electrical conductivity of soil and that the increase in electrical conductivity of soil mainly affect the mineral content of this fodder shrub.

Key Words: *Atriplex canescens*, electrical conductivity, crude protein

T183 Nutritional composition of a *Musa* sp. fodder bank located in the central part of Costa Rica.

Pablo Chacon Hernandez*, Carlos Boschini Figueroa, and Ricardo Russo Andrade, *Universidad de Costa Rica, San Pedro, San José, Costa Rica.*

Bananas are widely grown in tropical areas and a large proportion of the production is related to the pseudo-stem which is not normally utilized. We hypothesized that this material could be used depending on its nutritional quality. Using a completely randomized block design with 3 replicates, the nutritional composition was evaluated on a *Musa* sp. fodder bank located at the University of Costa Rica's Alfredo Volio Mata Experimental Station during the rainy season of 2012. Five adult plants were harvested on each block at 20–25 cm above ground and divided into 5 sections for sampling (base, center and tip of the pseudo-stem and blades and petioles of the leaves). For the whole plant mean values of 9.22% of DM, 8.57% of CP, 58.02% of NDF, 37.59% of ADF, 9.25% of LIG, 28.34% of CEL, 20.42% of HEMI, 2.35% of EE, 14.17% of ASH, 6.91% of NDICP and 6.91% of NFC were obtained; also, statistical differences among plant parts were found ($P < 0.05$). Despite the low dry matter content, banana plant portions may be utilized as ingredient in ruminant diets, especially in areas where the crop is commonly grown.

Table 1 (Abstr. T183). Nutritional composition of the *Musa* sp. plant

T184 Litter lignin and phosphorus content in different grazing intensities of Marandu-grass pasture in Southeast Brazil.

Mariana Vieira Azenha[1], Elisamara Raposo[2], Andre Alves Oliveira[2], Liziane Figueiredo Brito[2], Estella Rosseto Janusckiewicz[2], Ricardo Andrade Reis[2], and Ana Claudia Ruggieri*[2], [1]*EMBRAPA Pecuaria Sudeste, São Carlos, Sao Paulo, Brazil,* [2]*UNESP/FCAV, Jaboticabal, Sao Paulo, Brazil.*

The objective of this study was to evaluate lignin and phosphorus content in a Marandu-grass pasture managed under 3 heights of pasture. The pastures were managed by beef steers grazing under continuous stocking. Evaluations of litter decomposition occurred in 2011, at Jaboticabal, SP, Brazil. The litter bag technique was used to evaluate the decomposition of senescent plant material. Incubation times were 4, 8, 16, 32, 64, 128 and 256 d. Nylon bags were used. At the end of each incubation period, the bags were and analyzed. The lignin and phosphorus content was analyzed and compared using Proc Mixed from SAS. Polynomial models were used to fit the curves for each pasture stubble height according to incubation times. A significant linear increase in litter lignin with increasing pasture stubble height was observed in the litter incubated ($P < 0.01$), with means of 16.32, 18.50, and 19.84%, respectively, for pasture stubble heights 15, 25, and 35 cm. A relative increase in litter lignin (67%) with decomposition time was observed. Since increasing pasture stubble height is associated with stem elongation, hence higher cell-wall and lignin content than leaves, this could explain the positive association observed between litter lignin and pasture stubble height. The magnitude of differences in lignin content according to pasture stubble height is, however, expected to decrease over the course of the incubation period as the relative content of other components becomes progressively lower while lignin remains undecomposed, since it is chemically very insoluble. Since more soluble components, such as cellulose and hemicelluloses, are primarily used by microorganisms as energy source, a relative increase in litter lignin with incubation time is expected. Phosphorus in the incubated litter was 0.02% on average, and did not differ among pasture stubble heights ($P > 0.05$). The relative increase in litter phosphorus content with incubation time ($P < 0.01$) was expected. As phosphorus immobilization occurs when C/P ratio is higher than 200, this process prevailed throughout the incubation period, when C/P ratios ranged from 1600 to 825.

Key Words: litter decomposition, height, pasture management.

T185 Adding medium quality hay to the diet of stocker calves grazing annual ryegrass did not improve beef production.

Guillermo Scaglia*[1], Cathy Williams[2], and Ashley Dolesji[2], [1]*LSU AgCenter, Iberia Research Station, Jeanerette, LA,* [2]*LSU AgCenter, School of Animal Sciences, Baton Rouge, LA.*

Strategic use of hay may allow increasing the stocking rate of small areas of high nutritive value pastures, benefiting producers by keeping a greater number of calves for stocker programs. The objective was to compare performance and blood metabolite concentrations of beef steers continuously stocked on annual ryegrass (*Lolium multiflorum* Lam. 'Marshall') or grazing and strategically receiving bermudagrass (*Cynodon dactylon* 'Jiggs') hay (CP = 9.6%; TDN = 50%; NDF = 67%). For 3 consecutive years, 54 steers (BW = 229 ± 2.9 kg) were used. Treatments (3 replicates; n = 6 steers) evaluated were: 1) steers (CON) continuously stocked on ryegrass (1.33 ha; 4.5 steers/ha; 1040 kg BW/ha); 2) steers grazed 50% of the area assigned to CON (0.67 ha; 9 steers/ha; 2081 kg BW/ha) on alternate days (HAY24) and fed hay in a barn; 3) steers grazed 50% of the area assigned to CON (0.67 ha; 9 steers/ha; 2079 kg BW/ha) for 96 h, then were hay-fed in the barn for 72 h (HAY72). Steers were individually fed hay using Calan gates. Blood samples were obtained on 4 consecutive days (d1 after 24 h on ryegrass). Data were analyzed using Proc mixed. Pastures grazed by HAY24 and HAY72 steers had greater ($P < 0.05$) forage mass than CON from d 28 until the end of the grazing season. Concentrations of ADF (27 and 23%) and NDF (41 and 37%) were greater and IVDMD (74 and 78%) was lower ($P < 0.05$) in ryegrass grazed by HAY72 vs. CON, respectively. Production (kg/ha) and ADG (kg) were greater ($P < 0.05$) for CON (498 and 1.2, respectively), intermediate for HAY24 (418 and 0.8, respectively), and lowest for HAY72 (352 and 0.6). Plasma urea nitrogen (PUN) concentration was greatest ($P < 0.001$) for CON (28 mg/dL), intermediate for HAY24 (24 mg/dL), and lowest for HAY72 (21 mg/dL). NEFA were similar for CON and HAY24 (0.32 mEq/L) but lower ($P < 0.001$) than HAY72 (0.47 mEq/L). Concentration of PUN decreased (26 to 23mg/dL) and NEFA increased (0.31 to 0.45 mEq/L) linearly ($P = 0.003$; $P < 0.001$, respectively) from d1 to d4 of sampling. Steers in HAY72 consumed 13% less hay ($P < 0.05$) than those on HAY24. In the present experiment, hay feeding strategies negatively affected animal performance.

Key Words: hay, ryegrass, stocking rate

T186 Cow-calf performance and gain per ha from bermudagrasses overseeded with 'Apache' arrowleaf clover or 'TAM-90' annual ryegrass and stocked at three intensities.

Francis M. Rouquette Jr.*, Joel L. Kerby, Kelli D. Norman, and Gerald R. Smith, *Texas A&M AgriLife Research, Overton, TX.*

From 2002 through 2013, both Coastal (COS) and common (COM) Bermudagrass (C*ynodon dactylon*) (BER) pastures were overseeded in Oct each year with either 'Apache' arrowleaf clover (*Trifolium vesiculosum*) (CLV) without N-fertilization or 'TAM-90' annual ryegrass (*Lolium multiflorum*) (RYG) plus N for the 7-mo stocking period. F-1 (Hereford × Brahman) cows with fall-born Simmental-sired (SIM) calves were stocked on all pastures from late Feb. to early June (SPG), and with winter-born SIM calves from mid-June to late Sept. (SUM). All pastures were stocked continuously at 3 intensities (STK) to achieve different forage mass. Proc Mixed was used to determine treatment differences. Calf (steers and heifers) ADG was greater ($P < 0.01$) during growth of CLV and RYG in SPG compared with SUM. During SPG, calf ADG was greater ($P < 0.01$) from RYG (1.24 kg d^{-1}) compared with CLV (1.05 kg d^{-1}); and ADG was different ($P < 0.01$) at all 3 STK for low (LO) 1.40 kg d^{-1}, medium (ME) 1.20 kg d^{-1}, or high (HI) 0.83 kg d^{-1}; and no difference for BER. During SUM, calf ADG ($P < 0.01$) was different at all STK at LO (1.05 kg d^{-1}), ME (0.81 kg d^{-1}), and HI (0.58 kg d^{-1}). Cow ADG during SPG was greater ($P < 0.01$) for RYG (0.40 kg d^{-1}) vs CLV (0.20 kg d^{-1}), and all 3 STK were different ($P < 0.01$) for LO (0.74 kg d^{-1}), ME (0.30 kg d^{-1}), and HI (−0.15 kg d^{-1}). In SUM, cow ADG was affected by STK ($P < 0.01$), BER ($P < 0.04$), and STK x BER ($P < 0.04$). Cows lost weight on COM at all 3 STK (−0.19, −0.53, and −0.87 kg d^{-1}); whereas cow ADG on COS was different at each STK of LO, ME, and HI, respectively, at 0.15, −0.47, and −0.89 kg d^{-1}. Calf gain ha^{-1} for combined SPG and SUM was greater ($P < 0.01$) from COS (720 kg ha^{-1}) than COM (638 kg ha^{-1}); and from either HI or ME STK (758, 724 kg ha^{-1}) compared with LO STK (557 kg ha^{-1}). The RYG + N resulted in total calf gains of 804 kg ha^{-1} compared ($P < 0.01$) to CLV + no N at 556 kg ha^{-1}. This 11 yr study showed calf gains per ha of more than 550 kg ha^{-1} on BER with CLV and no-N. Apache CLV proved to be a reliable, productive legume for overseeding BER in the southeastern US without use of N.

Key Words: cow-calf, clover, ryegrass

T187 Performance of steers raised on pastures of elephant and mombasa grasses.

Alberto Magno Fernandes*[1], Ricardo Augusto Mendonça Vieira[1], Tadeu Silva de Oliveira[1], and Fermino Deresz[2], [1]*Universidade Estadual do Norte Fluminense, Campos dos Goytacazes, Rio de Janeiro, Brazil,* [2]*EMBRAPA-Gado de Leite, Juiz de Fora, Minas Gerais, Brazil.*

The performance of steers raised on elephant and mombasa grass pastures was evaluated from October to December 2006. A rotational grazing system with a regulated forage offer was adopted. The experimental area consisted of 2 block containing 18 paddocks of 0.25 ha divided into 9 paddocks with elephant grass and 9 with mombasa grass. Forage species, area block, the interaction among these effects, paddocks within the interaction, and the experimental error were the effects of the treatments. This model was used to analyze pasture attributes. For analyses of intake, digestibility and gain, 24 steers were randomly assigned to the respective interactions among forage vs. block vs. grazing system, totaling 3 animals per triple interaction. The grazing systems consisted of ad libitum (AL) and restricted (PR) grazing. Elephant-grass showed the highest ($P < 0.05$) total dry matter biomass (TB) and green leaf dry matter biomass (GLDM). There were no differences ($P > 0.05$) among forage plants for production of biomass of green leaf dry matter; however, leaf proportion was the greatest ($P < 0.05$) in mombasa grass. Extrusas showed similar ($P > 0.05$) bromatological composition. Only crude protein intake, which was the highest for mombasa pasture, differed ($P < 0.05$) among forage plants. Ad libitum feeding enabled a higher ($P < 0.05$) intake of all nutrients from both pastures. Digestibility of nutrients was higher for elephant-grass but it did not differ ($P > 0.05$) among feeding levels:restricted grazing allowed for greater plant crude protein concentration while ad libitum grazing resulted in greater gross energy consumption. In conclusion, despite qualitative and quantitative differences among forage plants, differences of weight gain per animal and per area were not found. For animal with ad libitum feeding, average body mass gain was 850 g/day and gain per area was 246 kg/ha during the experimental period. Funded by CAPES, CNPq, FAPEMIG, and FAPERJ.

Key Words: digestibility, growth, intake

T188 Diurnal time to move animals to a new paddock: Forage nonstructural carbohydrates concentration, grazing patterns, and performance of beef cattle. F. C. Leite de Oliveira*[1], C. O. Rocha[1], J. M. D. Sanchez[2], R. S. Ferigato[3], L. E. T. Pereira[1], C. G. Lima[1], P. H. C. Luz[1], and V. R. Herling[1], *[1]University of São Paulo, Faculty of Animal Science and Food Engineering, Department of Animal Science, Pirassununga, Sao Paulo, Brazil, [2]Range Cattle Research and Education Center, University of Florida, Ona, FL, [3]Anhanguera Faculties, Department of Veterinary, Leme, Sao Paulo, Brazil.*

Although the physiology of substances produced in photosynthesis is known, few studies with tropical forage species have been done to provide information about animal grazing patterns and performance. The objective of this study was to investigate the effects of diurnal time of allocating animals to a new paddock on ingestive behavior, forage nonstructural carbohydrates concentration (NSC: sugar and starch) and performance of beef heifers grazing *Brachiaria brizantha* 'Marandu'. The experiment was conducted in southeastern Brazil (21° 59′ N; 47° 26′ W). Treatments were daily time of allocating animals to new paddocks at 0600 h (AM) and 1500 h (PM) in a randomized complete block design with 3 replicates. Heifers (n = 60, initial BW = 230 kg) were managed by 78 d in rotational stocking, with 1 d grazing period and 25 d resting period during the summer of 2012/2013. All variables were measured every 26 d. Treatments had similar forage allowances ($P > 0.05$, 3.7 ± 0.1 kg DM/kg BW). Times spent grazing, ruminating and other activities were acoustically recorded during a 24 h period. Animals were weighed after a 14–16 h fasting. NSC was determined in forage samples hand-plucked at 0600 and 1500 h, in both treatments. Data were analyzed with Proc Mixed of SAS, with treatment and month as fixed effects and block as a random effect. Total daily grazing time was greater for AM ($P < 0.05$, 490 vs. 450 ± 5.4 min), however, PM concentrated diurnal grazing time in the afternoon ($P < 0.05$, ~66%), whereas AM did not concentrate grazing activities in the morning when compared with the afternoon ($P > 0.05$, ~50% in each period). There was no difference of NSC between treatments for a given time of the day ($P > 0.05$, 36 and 79 ± 2.7 g/kg DM at 0600 and 1500 h, respectively), although PM had 50 g NSC/kg DM more than AM at 1500 h ($P < 0.05$). Thus, compensating between grazing time and forage NSC throughout the day resulted in similar ADG (0.75 ± 0.04 kg/d). The schedule for allocating beef cattle in new paddocks may be done according to the convenience of each farm, as it does not affect performance.

Key Words: daytime, ingestive behavior, sugar

T189 Sequential and mixed grazing of stockpiled toxic tall fescue by fall-calving Angus cows and Katahdin ewes. Taylor N. Drane*, Richard E. Daugherty, James D. Caldwell, Bruce C. Shanks, Chris L. Boeckmann, Cindy A. Deornellis, Amy L. Bax, Abbey J. Kempker, and Jason D. Walker, *Lincoln University, Jefferson City, MO.*

There are many potential benefits with multi-species grazing including possible performance improvements for one or both species involved. For this reason, there is renewed interest in evaluating mixed versus sequential grazing schemes; however, little research has been done in hair sheep and cattle especially grazing stockpiled toxic tall fescue [*Lolium arundinaceum* (Schreb.) Darbysh; E+]. Therefore, the objective of this study was to determine performance and reproductive measurements by fall-calving Angus cows and Katahdin ewes grazing stockpiled E+ under a mixed or sequential grazing scheme. Over 3 consecutive yr, fall-calving Angus cows (n = 60; 499.8 ± 56.4 kg initial BW; 5.7 ± 0.7 initial BCS) and Katahdin ewes (n = 121; 26.1 ± 6.9 kg initial BW; 2.9 ± 0.4 initial BCS) were stratified by BW and age within species and allocated randomly to 1 of 4 groups representing 2 treatments: 1) sequential grazing (SG; 6 replications) or 2) mixed grazing (MG; 6 replications). Each year, a total of 8.16 ha (0.68-ha per group) were grazed 40 d for yr 1 and 2 and 42 d for yr 3. In SG, cows always followed ewes and all groups were rotated based on available forage. Initial weight, initial BCS, end weight, end BCS, total gain, and ADG did not differ ($P \geq 0.15$) between treatments. Cow and ewe pregnancy rates did not differ ($P \geq 0.96$) between treatments. Calf birth date and calf birth weight did not differ ($P \geq 0.33$) between treatments. Calf start weight was heavier ($P = 0.03$) for MG vs. SG, but calf end weight, total gain, and ADG were similar ($P \geq 0.13$) between treatments. Lamb birth date, birth weight, and number of lambs born did not differ ($P \geq 0.12$) between treatments. Therefore, sequential grazing compared with mixed grazing may not improve performance and reproductive measurements in fall-calving Angus cows and Katahdin ewes. Thus, the extra labor associated with a multi-species, sequential grazing scheme may not be justified.

Key Words: fescue, mixed grazing, sequential grazing

T190 Performance and reproductive measurements by spring-born Katahdin ewes grazing stockpiled toxic tall fescue, non-toxic tall fescue, or Persist orchardgrass. H. L. Bartimus*[1,2], B. C. Shanks[1], J. D. Caldwell[1], A. L. Bax[1], L. S. Wilbers[1], A. J. Kempker[1], J. D. Walker[1], C. A. Clifford-Rathert[1], and A. K. Busalacki[1], *[1]Lincoln University, Jefferson City, MO, [2]University of Arkansas, Fayetteville, AR.*

Stockpiled forages are an alternative to expensive feedstuffs and may extend the grazing season through the winter months for small ruminant producers. Our objective was to evaluate the effects of stockpiled endophyte-infected tall fescue [*Lolium arundinaceum* (Schreb.) Darbysh; E+], novel endophyte-infected tall fescue (NE+), and Persist orchardgrass (*Dactylis glomerata* L.; OG) on performance and reproductive measurements by spring-born Katahdin ewes. Over 2 consecutive years, Katahdin ewes (n = 116; 27.7 ± 0.57 kg initial BW, 2.8 ± 0.05 initial BCS) were stratified by weight and BCS and allocated randomly to 1 of 3 treatments consisting of: 1) E+ (5 replications), 2) NE+ (5 replications), 3) OG (5 replications). Each year, excess forage was grazed in early August, 54 kg N/ha was applied in mid-September, and beginning in early November grazing was initiated. Data were analyzed using PROC MIXED of SAS with 2 preplanned orthogonal contrast statements to evaluate ewe performance and reproductive measurements: 1) the mean of E+ vs. the mean of NE+ and OG and 2) the mean of NE+ vs. the mean of OG. Pregnancy rates and percentage of multiple births were analyzed by the Chi-squared procedure of SAS. Ewe BW, BCS, total gain, and ADG did not differ ($P \geq 0.12$) across treatments at the initiation of the study, at breeding, end of breeding, or end of the study. Pregnancy rates did not differ ($P \geq 0.19$) across treatments. Percentage of multiple births tended ($P = 0.07$) to be greater from NE+ and OG compared with E+ (19 vs. 0%, respectively) and tended ($P = 0.07$) to be greater from NE+ compared with OG (19 vs. 0%, respectively). Therefore, grazing spring-born Katahdin ewes on stockpiled endophyte-infected tall fescue, novel endophyte-infected tall fescue, or Persist orchardgrass during the winter months may result in similar performance and pregnancy rates. However, grazing ewes on stockpiled novel endophyte-infected tall fescue may result in more multiple births.

Key Words: Katahdin, grazing, performance

T191 Characteristics of cheese powders and the role of color on consumer perception of cheese flavor. Ni Cheng*, Yeijin Jo, and M. A. Drake, *Southeast Dairy Foods Research Center, North Carolina State University, Raleigh, NC.*

Cheese powder is applied in many food applications including sauces and snacks. Cheese flavor is a consumer expectation of these applications. The objective of this study was to characterize the properties of cheese powders and to explore the role of color on consumer perception of cheese flavor on cheese powder applications. Duplicate samples of 11 commercial cheese powders were collected. Proximate analyses (moisture, fat, salt, color, pH) were conducted. Cheese powders were rehydrated and evaluated with a trained panel using an established cheese flavor lexicon. Volatile compounds were extracted by solid phase micro-extraction (SPME) followed by gas chromatography-mass spectrometry (GC-MS). Seven representative powders were selected from trained panel sensory results, applied to potato chips, and evaluated by 113 consumers. Consumers evaluated expected liking and cheese flavor before tasting (visual only) and after tasting. Moisture, fat, salt and pH of cheese powders varied (1.40–4.73%, 0.77–47.74%, 1.68–13.99% and 4.56–6.88, respectively). Color varied from white to dark orange. Cheese powders were characterized by a variety of natural cheese flavor attributes including milky, whey, diacetyl, sulfur, brothy, nutty, and free fatty acid and basic tastes. The major aroma-active volatile compounds in cheese powders were dimethyl sulfide, dimethyl disulfide, dimethyl trisulfide, methional, 2/3-methylbutanal, guaiacol, 1-octen-3-ol, diacetyl and volatile free fatty acids. Consumers associated orange color with higher cheesy color liking and higher expected cheese flavor compared with white cheese powders ($P < 0.05$). Diacetyl and whey flavors with salty and sour tastes were perceived as "cheesy" by consumers. Orange color in cheese powders enhanced consumer cheese flavor expectations while diacetyl and whey flavors and salty and sour tastes increased cheese flavor on potato chips.

Key Words: cheese powder, cheese flavor, color

T192 The effect of raw milk cooling on sensory perception and shelf life of pasteurized skim milk. Andy Lee*[1], D. M. Barbano[2], and M. A. Drake[1], [1]*Southeast Dairy Foods Research Center, North Carolina State University, Raleigh, NC,* [2]*Cornell University, Ithaca, NY.*

The cooling rate of raw milk may influence sensory properties and pasteurized shelf life. Under the Pasteurized Milk Ordinance (PMO) for grade A milk, raw milk may be cooled instantaneously by on-farm heat exchangers but is also acceptable if "cooled to 10°C or less within four (4) hours of the commencement of the first milking." The objective of this study was to determine the effect of raw milk cooling on consumer perception and shelf life. Raw milk (18–21°C) was obtained and transported within 1 h of milking to North Carolina State University. After comingling, the batch was split and a plate heat exchanger was used to quickly cool one treatment to <6°C for all milkings. The second treatment was stored in a jacketed bulk tank and slowly cooled over 4 h to <10°C. Three consecutive milkings were collected every 12 h with subsequent milkings added to the previous collections. The bulk milk was kept below 10°C while adding milk for the slow cool milk treatment. After 72 h, each whole milk was separated, pasteurized at 73 or 78°C for 20 s, homogenized, and held at 4°C. Difference tests (n = 75) and consumer acceptance tests (n = 100) were conducted to determine if consumers could detect differences among milks. Descriptive analysis (DA) and microbial testing for aerobic, psychrotrophic, and spore counts were conducted through shelf life. The entire experiment was repeated in triplicate. Raw milks averaged 4.29 Log cfu/mL by aerobic plate count, 52 cfu/mL coliforms, 300,000 SCC and 3.15 ± 0.7% protein. Spores were < 20 cfu/mL in raw milk. After processing, consumers could not detect differences ($P < 0.05$) between cooling treatments of the same pasteurization temperature nor between different temperatures of the same cooling treatment. Milks reached sensory failure 35–42 d after processing, and aerobic counts were between 5 and 7 log cfu/mL. Higher pasteurization temperature decreased shelf life. Cooling treatment had no effect on shelf life. These results suggest that pasteurized milk quality is due to a combination of many factors. Raw milk cooling rate is not the largest effect on milk quality.

Key Words: fluid milk, cooling, quality

T193 Reducing protein bar hardening via whey protein-polyphenol ingredients. Margaret Schneider*, Mary Ann Lila, and E. Allen Foegeding, *Department of Food, Bioprocessing and Nutrition Sciences, North Carolina State University, Raleigh, NC.*

Whey proteins serve as a structural component and source of protein in foods. When used in protein bars, whey proteins can contribute to a reduction in shelf life as a consequence of bar hardening. Bar hardening has been associated with water migration between phases and formation of a protein network in bars over time. One approach to ameliorate bar hardening is to form whey protein meso-structures that are not susceptible to water migration or protein network formation. We hypothesize such structures can be formed by using berry polyphenols to initiate whey protein aggregation that leads to formation of inert particles. Whey protein-cranberry polyphenol (WP-CP) particles were formed by adding 200 g of whey protein isolate (WPI) to 1 L of cranberry juice during continuous stirring. After mixing for 4 h, particles were pelleted (7,000 x g for 40 min), re-suspended at 0.01 g/mL in water, and spray dried. Bars were made with WP-CP particles or unmodified WPI. Textural properties were assessed using transient creep-recovery testing which measured the maximum compliance (J_{max}, indicating bar firmness) and percent creep-recovery (bar viscoelasticity). The WP-CP particles contained up to 2 mg/g of total phenolics, and the particle size ranged from 10 to 100 µm. Bars produced with WPI had a smaller J_{max} (more rigid) of 0.000053 Pa^{-1} compared with 0.0023 Pa^{-1} J_{max} for bars formulated with WP-CP particles. Bars formed with the WP-CP had a reduced percent recovery of 2.5% compared with 28.6% for bars made with WPI. Greater percent recovery indicates a more elastic system and possible network formation. Bars were placed in accelerated shelf life tests that imitate 3 weeks of storage at room temperature. The bars with WP-CP particles remained less rigid and more viscous (J_{max} of 0.0039 Pa^{-1} and 10.9% creep recovery) than control whey protein bars (J_{max} 0.000012 Pa^{-1} and 57.5% creep recovery). All differences between bars were found to be statistically significant at the $P < 0.01$ level. Rheological properties are consistent with WP-CP particles acting as inactive fillers and preventing formation of a protein network. These results suggest that WP-CP particles can be used to extend shelf life of protein bars and offer additional health benefits from plant polyphenols.

Key Words: whey protein, polyphenol, protein bar

T194 Development and characterization of whey protein nanoparticles for beverage applications.

Ty B. Wagoner*[1], Loren S. Ward[2], Chris W. Pernell[1], and E. Allen Foegeding[1], [1]*North Carolina State University, Raleigh, NC,* [2]*Glanbia Nutritionals, Twin Falls, ID.*

Whey protein consumption has been linked to several health benefits including increased satiety and metabolic regulation; therefore, there is interest in increased consumption of foods rich in whey proteins. Meal replacement beverages and sports drinks are categories of foods that contain whey proteins. However, low thermal stability—especially near the protein isoelectric point (pI)—limits the pH range and protein concentrations at which beverages can be formulated. Studies have shown that at a narrow pH range close to the pI, whey proteins and pectin self assemble into soluble complexes (SCs) that have improved colloidal stability. Our objectives were to 1) determine the conditions required to form stable whey protein-pectin SCs, 2) characterize physical properties of the SCs, and 3) evaluate the effect of SCs on bulk rheological properties. Soluble complexes were formed at various protein concentrations (1, 4, 5 and 6% wt/wt) with a constant protein to pectin ratio of 8:1 by adjusting the pH from 7 to 5. After complexation, particles were stabilized by heating at 85°C for 25 min. The properties of unheated and heat-set SCs were characterized via intrinsic viscosity, particle size distribution, and rheological analysis. Laser diffraction particle size analysis revealed that heating shifted sizes toward a monomodal distribution with mean diameter of ~100 nm for all protein concentrations. Heat-stabilization significantly reduced intrinsic viscosity of SCs from 93.6 mL/g to 79.5 mL/g ($P < 0.05$), suggesting conformational changes that favor a smaller hydrodynamic size. Decreased viscosity of heat-set SCs was consistent with intrinsic viscosity and particle size results. Increasing protein concentration had very little effect on size of heat-set SCs, suggesting applications in beverages where a high protein concentration is desired. Heat-set SCs remained as 100 nm particles and did not aggregate over the pH range of 3–6. Moreover, they remained stable in this pH range after thermal processing. These results indicate that whey protein-pectin SCs can be heat-set into 100 nm particles with enhanced colloidal stability for applications in beverages.

Key Words: whey protein, beverage, thermal stability

T195 Casein and exopolysaccharide degrading activities of *Bacillus* strains isolated from the dairy environment.

Dipakkumar Mehta*[1], Hasmukh Patel[1], Ashraf Hassan[2], and Brandon Nelson[2], [1]*South Dakota State University, Brookings, SD,* [2]*Daisy Brand, Garland, TX.*

Milk proteins and exopolysaccharides (EPS) play an important role in texture formation and stabilization of yogurt. Many *Bacillus* strains have the ability to breakdown proteins and degrade polysaccharides. To our knowledge, the ability of the *Bacillus* spp. to degrade EPS from starter cultures has not been tested. The objective of this study was to quantify proteolytic and the EPS-degrading activity of *Bacillus* strains. Twenty-five *Bacillus* strains isolated from the pasteurizer balance tank of a dairy company were pre-screened for their proteolytic ability using skim-milk agar (SMA) at 42°C. The strains that showed proteolytic activities were inoculated individually at 10^3 cfu/mL in heated (90°C for 10 min) rehydrated nonfat dry milk (11% w/v) which was then incubated at 42°C for 48h. The evidences of proteolytic activity were quantified by SDS-PAGE and measuring the non-casein nitrogen (NCN). To study EPS degradation, 2 *Bacillus* strains that were able to degrade a wide range of polysaccharides in a previous study were selected. The reduction in viscosity of a whey protein concentrate (WPC) solution (10% w/v) fermented with yogurt cultures producing high, medium, or low EPS in the presence of the test *Bacillus* strains (10^3 cfu/mL) indicated positive results. The viscosity of the fermented media was measured using the Stress-Tech rheometer at 42°C and a shear rate of 100 s^{-1}. Out of the 25 *Bacillus* strains, 20 stains showed proteolytic activities on SMA. Of these 20 strains, 8 strains showed significant ($P < 0.05$) 30–50% degradation of caseins (predominantly β- and κ-CN) as determined by SDS-PAGE and 4 fold increase in NCN contents. Highly proteolytic strains also caused sweet curdling in skim milk. Used Two *Bacillus* strains showed 20–30% reduction in viscosity was observed in the WPC medium containing the low EPS producing culture whereas only 8–10% decrease in viscosity was found in the medium fermented with the high EPS-producing culture. The results of the present study showed the potential of *Bacillus* strains to degrade EPS and reduce viscosity of the fermented dairy products. It also provided useful information on the prevalence of highly proteolytic *Bacillus* strains in a relatively large number of isolates from a dairy plant.

Key Words: *Bacillus*, protein, EPS

T196 Chemosensory analysis of light-emitting diode and fluorescent light on fluid milk volatiles.

Kemia N. Amin*, Maria A. Hadley, Susan E. Duncan, and Kumar Mallikarjunan, *Virginia Polytechnic Institute State University, Blacksburg, VA.*

Fluid milk deteriorates rapidly under lighted storage, affecting milk sensory and nutritional quality before purchase. Energy conservation efforts have shifted commercial retail cases from fluorescent to light emitting diode lights (LED). The effect of LED lights on milk quality has not been determined. Efficient milk freshness validation methods are needed in the dairy industry to predict sensory quality. The purpose of this study was to determine volatile differences of 2% milk under LED and fluorescent lights using a commercial conducting polymer electronic nose (ENose). This study focused on changes in volatiles within 72 h of storage under refrigerated retail case conditions. Fresh 2% milk (half gallon high density polyethylene; n = 60) was purchased from a local grocery store immediately upon delivery. Bottles (treatments: light protected control [LP; foil overwrap); light-exposed (LE)] were randomly placed in a commercial retail case with LED and fluorescent lighted sections. Milk was tested on receipt and at 4, 8, 24, 48, and 72 h. Samples (n = 3 bottles per LP and LE treatment) were collected at each time interval and tested with the ENose and thiobarbituric acid reactive substances (TBARS). Canonical distribution ($P < 0.05$) of volatile changes showed 100% separation of volatiles components detected by ENose, for each time under each light treatment for LE milk compared with LP control. As time increased, separation between LED and fluorescent clustered ENose data moved further away from the control and each light treatment resulting in greater differences. By 72 h, LED LE cluster data were farther from the ideal fresh milk than the fluorescent cluster. This suggests that milk under LED may have more differences in volatiles than milk under fluorescent light at 72 h. TBARS values were not significantly different ($P > 0.05$) between the interval light treatments. ENose technology could be more sensitive to volatile changes than TBARS. The volatile differences detected through the ENose may affect product integrity and consumer response. Understanding different light effects on milk and ENose application in the dairy industry could improve sensory and quality testing of milk.

Key Words: electronic nose (ENose), milk, light oxidation

T197 Inactivation of thermoduric bacterial endospores in milk by combined effect of cavitation and thermal treatment. Dikshi Bawa*, Sanjeev Anand, Harsh Dahiya, and Hasmukh Patel, *South Dakota State University, Brookings, SD.*

Bacillus endospores can survive milk pasteurization, and later germinate and grow during further processing of milk. Their resistance to various physical and biochemical treatments, dormancy, ability to adhere to the surfaces of process equipment resulting in biofilm formation, and prompt germination under favorable conditions, make them important contaminants in dairy processes. The objective of this research was to investigate the effect of hydrodynamic cavitation in a continuous mode, and its combination with thermal treatment, to reduce *Bacillus* spores in milk. We hypothesized that cavitation would induce germination of spores and any post cavitation heat treatment would lead to their inactivation. Spores of *Bacillus licheniformis* (ATCC 6634) were produced in lab by incubating on brain-heart infusion (BHI) agar plates for about 2 weeks, and were harvested from plates by washing and centrifugation. The vegetative cells in spore suspension were inactivated by heating at 85°C for 10 min. The resulting spores were inoculated in sterile skim milk to a level of log 2 cfu/mL. Inoculated milk samples at 10°C were passed through APV Cavitator (SPX, Denmark) at 60 Hz frequency using 4-row rotor in 6-mm housing. The exposure time of 22 s per pass was provided at 200 L/h flow rate with a back pressure of 120 kPa. The milk containing endospores was recirculated for 25 min (a total exposure time of 183 s) with a temperature rise to 99°C. Samples were cooled and held for 3 h at 30°C to let the germination process occur. Samples were then heated at 85°C for 15 min, and were plated on BHI agar medium. Experiments were conducted as replicates of 2, and were repeated thrice. Statistical significance of the data at $P < 0.05$ was determined using the SAS software. A significant difference was observed in the endospore counts after the treatments. Heat treatment alone did not result in inactivation of the spores. Whereas, cavitation with holding followed by heat treatment caused a reduction with only 0.60 log survivors. In conclusion, it was evident that a combined process with cavitation effect, holding for germination, followed by thermal treatment can be effectively used to inactivate thermoduric endospores.

Key Words: cavitation, endospore, germination

Graduate Student Competition: ADSA Production Division Graduate Student Poster Competition, PhD

T198 Effects of estrus number on milk yield and estrus expression in Holstein cows managed for extended lactation. Charlotte Gaillard*, Mogens Vestergaard, and Jakob Sehested, *Aarhus University, Foulum, Tjele, Denmark.*

Cows managed for a 16-mo extended lactation have, at least, 8 estrus periods before being inseminated. The aims were to determine the effect of estrus number on milk yield and estrus expression, and to compare conception rates with the rates obtained during the previous 10 mo lactation. It was hypothesized that (1) milk yield will decrease during the day of estrus, and this loss will diminish with increasing estrus number; (2) postponing the insemination (AI) will increase the expression of estrus leading to a better detection and a higher conception rate. A total of 62 Holstein cows (30% 1st parity) were managed for 16 mo extended lactation. The 8 first estrus periods were determined by milk progesterone levels (<3 ng/L) and the day of estrus by visual observations (mucus consistency, blood in genital area, cow jump/stand/lay). Milk yield at 'estrus day' was compared with 'normal day' yield (average yield of d −4, −5 and −6 before 'estrus day'). The percentage of cows expressing estrus was calculated using the behaviors mounting, being mounted or standing as criteria. Milk yield was analyzed using a linear mixed effects model while a chi-squared test was used for evaluating estrus expression and conception rate. The results showed a milk loss of 0.56 ± 0.19 kg per estrus day ($P < 0.001$) with no differences between the 8 estruses ($P = 0.3$). This negative estrus effect on milk yield is small compared with the well-known pregnancy effect. Moreover, 70% of the cows expressed the 8th estrus compared with 37% for the 1st estrus ($P = 0.02$) and 40% for the 2nd estrus ($P = 0.06$). However, the conception rates of the 1st and 2nd AI did not differ from those of the previous 10 mo lactation (respectively + 2.9%, $P = 0.8$ and + 3.4%, $P = 0.7$). To conclude, milk yield decreases similarly during each of the 8 estrus days studied whereas the proportion of cows expressing estrus nearly doubles from the 1st and 2nd to the 8th estrus.

Key Words: estrus number, milk yield, mounting

T199 Effects of canola meal as a source of rumen-undegraded protein on ruminal fermentation using a dual-flow continuous-culture system. Eduardo Marostegan de Paula*[1], Lorrayny Galoro da Silva[1], Pedro Del Bianco Benedeti[1,2], Hugo Monteiro[1,3], Yenling Yeh[1], Teshome Shenkoru[1], Glen A. Broderick[4], and Antonio Faciola[1], *[1]University of Nevada, Reno, NV, [2]Federal University of Viçosa, Viçosa, MG, Brazil, [3]Maringa State University, Maringa, PR, Brazil, [4]Broderick Nutrition & Research, Madison, WI.*

Previous research indicated that there were significant differences in rumen-undegraded protein (RUP) among canola meals (CM). These differences could influence the nutritional value of CM. The objective of this study was to evaluate the effects of feeding CM with different RUP on ruminal fermentation, nutrient digestion, and microbial growth using a dual-flow continuous-culture system. Diets were randomly assigned to 6 fermenters in a replicated 3 × 3 Latin square with three 10-d experimental periods consisting of 7-d for adaptation and 3-d for sample collection. Treatments were solvent soybean-meal (SBM); low-RUP CM (LCM); and high-RUP CM (HCM). Fermenters were fed 72 g/d, divided in 4 feedings. Diets were prepared as 3 concentrate mixes that were combined with orchardgrass hay and wheat straw. Liquid and solid flow rates were adjusted to 11 and 5.5%/h, respectively. Samples were collected for digestibility, ruminal fermentation, and microbial growth. Statistical analyses were performed using SAS. Orthogonal contrasts were used to compare effects of different protein sources (SBM vs. LCM + HCM), and (LCM vs. HCM). Partial data are presented in the table below. Ruminal NH_3-N, total VFA concentration, molar proportion of acetate, propionate, butyrate, and isobutyrate were not affected by treatments. Molar proportion of valerate was greater when SBM was fed, whereas molar proportions of isovalerate, and total BCVFA were lower for CM diets (Table 1). Isovalerate, an intermediate product of leucine degradation, is associated with protein degradation; therefore, this may indicate that CM diets had higher RUP than SBM.

Table 1 (Abstr. T199). Effects of feeding canola meals (with different RUP LCM and HCM) on ruminal fermentation

	Treatment				Contrast *P*-values	
Item	SBM	LCM	HCM	SEM	SBM vs. LCM + HCM	LCM vs. HCM

T200 Comparison of lying times of lame versus sound dairy cattle using a leg-based accelerometer. Barbara A. Wadsworth*, Lauren M. Mayo, Nicky I. Tsai, Amanda E. Stone, Denise L. Ray, Joey D. Clark, and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

Lameness is a painful disease that affects cattle performance. Lame cattle may lay down longer than sound cattle. The objective of this study, conducted at the University of Kentucky Coldstream Dairy from March 18 to December 10, 2014, was to determine lying times of lame cows versus sound cows using a leg-based accelerometer. All cows (n = 96) were housed in 2 freestall barns and were balanced for parity and days in milk. Each individual freestall barn stocking density never exceeded 100%. One barn was equipped with sawdust covered Dual Chamber Cow Waterbeds (Advanced Comfort Technology, Reedsburg, WI) and another with sawdust covered rubber-filled mattresses (Promat Inc., Woodstock, Ontario, Canada). All cows were equipped with an AfiAct Pedometer Plus (Afimilk, Kibbutz Afikim, Israel), which recorded daily lying time. The AfiMilk milking system (Afimilk) recorded daily milk yield. The Hobo U23 Pro V2 External Temperature Relative Humidity Data Logger (Onset, Bourne, MA) determined temperature and relative humidity (THI) in each barn every 15 min. Ambient conditions were categorized as low and high if THI was below or above 68, respectively.

Cows gait was assessed weekly using a 1 (sound cow) to 5 (severely lame cow) scale for general symmetry, speed, head bobbing, spine curvature, tracking, and abduction and adduction. Final gait score was calculated as the mean of all gait aspects for each cow. Cows scored ≥3 were determined as lame. The MIXED procedure in SAS (Version 9.3, Cary, NC) was used to evaluate factors influencing lying times. Stepwise backward elimination was used to remove non-significant interactions ($P \geq 0.05$). Lying times of lame cows were greater than sound cows ($P < 0.01$; 10.96 h/d and 9.51 h/d, respectively). All cows lied down longer in the cold season versus the warm season ($P < 0.01$; 10.43 h/d and 10.04 h/d, respectively). Milk yield was not different ($P \geq 0.05$) between lame and sound cows.

Key Words: lying time, lameness, accelerometer

T201 Survey of management of reproduction on Canadian dairy farms.

José Denis-Robichaud*[1], Ronaldo L. A. Cerri[2], Andria Jones-Bitton[1], and Stephen J. LeBlanc[1], [1]*Department of Population Medicine, University of Guelph, Guelph, ON, Canada,* [2]*Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada.*

The objective of this study was to survey attitudes and management practices for reproduction in a representative sample of Canadian dairy farms. A questionnaire was distributed online and by mail to Canadian dairy farmers from March to May 2014. Respondents were asked to give their percentage of artificial inseminations (AI) based on visual heat detection, timed artificial insemination (TAI) program, or automated activity monitoring (AAM), for first and subsequent AI separately. The main management practice was the one that used for >50% of inseminations, or "combined" if no one practice was used for >50% of AI. Out of the approximate 9,000 invitations to participate to the survey, a total of 833 surveys were completed (response rate estimated at 9%). The average number of lactating cows per herd was 77 (median = 55, interquartile range = 40–88), and the herds were located in all Canadian provinces. Lactating cows were housed in tie stall (61%) and freestall barns (39%). Visual heat detection was reported to be the main management practice in 51% and 44% of herds for first and subsequent AI, respectively. Respondents reported observing cows for heat signs 3.3 times per day for a total of 36 min, on average. Timed AI was the main management practice in 21% and 22% of herds for first and subsequent AI, respectively. Although 74% of respondents agreed that reproductive hormones were safe for consumers of dairy products, fewer (64%) agreed that routine use of synchronization programs was acceptable to them, or to consumers (44%). Ten percent of respondents, mainly housing lactating cows in free stall barns, reported using AAM as their main management practice for all AI. They reported using the system to flag cows in heat, but also using observed signs of estrus to decide to inseminate. Sixteen and 20% of all respondents used combined practices for first and subsequent inseminations, respectively. Bulls were used by 4% of respondents. These results suggest that visual heat detection is the principal management practice in many Canadian herds, but that TAI and AAM systems are also important in the management of reproduction.

Key Words: dairy cow, reproduction management, survey

T202 Lactational performance of early lactation, high-producing dairy cows fed corn silage produced by different seed corn hybrids.

Ishwary Acharya*[1], Mark Kirk[2], and David Casper[1], [1]*Dairy Science Department, South Dakota State University, Brookings, SD,* [2]*Masters Choice, Anna, IL.*

Twenty-one (6 primiparous and 15 multiparous) high producing early lactation Holstein cows were fed one of 3 experimental corn silages harvested from the planting of 3 different seed corn hybrids from wk 4 through wk 14 postpartum. Corn hybrids (Control (C): Dekalb and Masters Choice: MC1 and MC2) were planted and harvested as corn silage during the 2012 growing season. Corn silage was harvested using a kernel processor silage harvester, inoculated, and ensiled in either a bunker or individual Ag Bags. Total mixed rations were formulated to be isonitrogenous at 17.5% CP consisting of 15.9% alfalfa hay, 35.1% concentrate mix and 48% of the respective experimental corn silage (DM basis). Cows were blocked by calving date and parity and randomly assigned to 1 of 3 treatments in a randomized complete block design. Data collected the third wk postpartum was used as a covariate in least squares analysis of covariance via the PROC MIXED procedure (SAS Institute). Dry matter intake (22.9, 23.5, and 22.4 kg/d for C, MC1, and MC2, respectively), milk yield (35.6, 34.8, and 36.1 kg/d), 3.5% fat-corrected milk (FCM) yield (38.7, 36.5, and 37.6 kg/d), energy corrected milk yield (38.2, 36.1, and 38.1 kg/d), feed efficiency (1.79, 1.61, and 1.67 kg/kg; 3.5% FCM/ DMI), milk fat (4.17, 3.94, and 3.71%), milk protein (3.12, 3.09, and 3.03%), lactose (4.93, 4.92, and 4.92%), solid-not-fat (8.96, 8.92, and 8.85%), body weight change (−0.10, −0.06, and −0.08 kg/d), and body condition score change (−0.05, −0.04, and −0.05 score/d) were similar for early lactation dairy cows fed all corn silage hybrids. Milk urea nitrogen was significantly ($P < 0.05$) lower for cows fed C (13.64) compared with cows fed MC1 and MC2 corn silage (15.0, and 15.0 mg/dL). This study demonstrated that different seed corn hybrids for the production of corn silage were similar in lactational performance.

Key Words: corn silage, corn hybrid, high-producing dairy cow

T203 Nitrogen utilization and growth effects in Holstein dairy calves fed a moderately high protein or conventional milk replacer.

Colleen E. Chapman*[1], Thelton M. Hill[2], and Peter S. Erickson[1], [1]*University of New Hampshire, Durham, NH,* [2]*Provimi North America, Brookville, OH.*

Studies have shown that calves fed milk replacers (MR) with crude protein (CP) concentrations greater than 20% typically found in conventional MR have higher dry matter intakes (DMI) and greater average daily gains (ADG), but consume less starter which can lead to stress during weaning and reduced rumen development. The greater amount of CP being fed to preweaned calves may alter their nitrogen (N) balance and excess N may be excreted in the urine. The objective of this study was to determine N utilization in preweaned calves fed diets varying in the amount of CP and MR fed. This study used 24 newborn dairy heifer calves blocked by birth and randomly assigned to 1 of 3 treatments: (1) 454 g of a conventional MR (C; 20% CP, 20% fat), (2) 680 g of a moderately high protein MR (MMR; 26% CP, 17% fat), or (3) 908 g of a MMR (HMR; 26% CP, 17% fat). All calves had free choice access to starter and water. Both MR and starter were medicated with decoquinate. During weaning (d 43–49), AM MR feeding ceased. On d 50, all MR feedings ended; however, starter and water intakes were continuously recorded until d 56. At 5 wk of age, urine was collected using urinary catheters for 3 d and chromium oxide was administered by bolus at 2 g/d for 7 d to estimate N efficiency. Calves fed MMR and HMR had similar starter intakes, feed efficiencies (FE), and ADG; with the combined treatments having reduced starter intakes (258 g/d vs. 537 g/d), greater ADG (674 g/d vs. 422 g/d), and improved FE (0.57 vs. 0.45) compared with the C calves preweaning ($P < 0.05$). However, DMI and water intake were similar across all treatments. Results from the N utilization phase showed that MMR and HMR treatments had

similar but lower N efficiency than C calves (45.5% vs 52.7%; $P < 0.05$). This could be due to MMR and HMR fed calves having greater urine volume; and thereby, greater combined urine N output compared with C calves (17.6 g/d vs 12.1 g/d; $P < 0.05$). In summary, feeding a moderately high protein MR increased ADG and improved FE during the preweaning period, but reduced starter intake and lowered N efficiency.

Key Words: high protein, milk replacer, nitrogen efficiency

T204 Blood calcium changes after prophylactic subcutaneous treatment with calcium.

Cynthia L. Miltenburg*, Elizabeth Scholtz, Dorothee Bienzle, Todd F. Duffield, and Stephen J. LeBlanc, *University of Guelph, Guelph, ON, Canada.*

Prophylactic calcium supplementation immediately after calving is a common strategy to prevent clinical and subclinical hypocalcemia in parturient dairy cows. The objective of this study was to evaluate the effect of prophylactic administration of Theracalcium on blood calcium concentration at 24 and 48 h after treatment, in cows without clinical hypocalcemia. Cows (n = 128) from 4 farms were blocked by parity and randomly assigned to receive either calcium gluconate (35% w/v) in combination with calcium glucoheptonate (10% w/v; Theracalcium, Vétoquinol Canada Inc., Lavaltrie, Quebec) or a placebo (medication vehicle solution with no calcium) at first contact with each cow after calving and again 12–24 h later when available for lockup. Each dose was 120mL injected subcutaneously over 2 sites. Total serum calcium concentration (tCa) was measured from coccygeal blood samples before (time 0) and 24 and 48 h after first treatment. There was no significant difference in tCa at time 0 (2.05 ± 0.02) between groups ($P = 0.18$). Serum tCa at time 0 was highly correlated with parity (r = −0.7) therefore pre-treatment tCa but not parity was used as a covariate in the models. A mixed model was constructed to measure tCa at 24 h after first treatment. For cows that had received 1 injection of calcium before the blood sample at 24 h (n = 95), tCa was significantly higher in the treated cows ($P = 0.01$): mean ± SE 2.03 ± 0.03 versus 1.90 ± 0.03 mmol/L, accounting for tCa at time 0 and a treatment by tCa at time 0 interaction. At 48 h there was no significant difference in tCa between treatment and control (mean ± SE 2.12 ± 0.02 and 2.10 ± 0.03 mmol/L, respectively) accounting for tCa at time 0 and farm as a fixed effect. With this subcutaneous prophylactic calcium treatment regimen, blood calcium levels were temporarily increased at 24 h after treatment. Further studies of disease and production in the postpartum period are required to determine if such a rise in blood calcium translates into improvements in transition cow health.

Key Words: calcium supplementation, hypocalcemia

T205 Moved to Ruminant Nutrition: General II (page 475)

T206 Quantification of select ruminal bacterial in Holstein bull calves treated with daily oral sodium bicarbonate.

Taylor T. Yohe*[1,2], Rene R. Delgado-Peraza[1], Hannah L. M. Tucker[1,2], and Kristy M. Daniels[1,2], [1]*The Ohio State University, OARDC, Wooster, OH,* [2]*Virginia Tech, Blacksburg, VA.*

Dairy calves commonly have a rumen pH below 5.5 and it is unknown if this is problematic or normal for rumen development. The objective was to test if oral administration of sodium bicarbonate ($NaHCO_3$) to young calves can affect ruminal: pH, lactate concentration, and populations of select ruminal bacteria. We hypothesized that administration of $NaHCO_3$ would increase rumen pH, decrease lactate concentration, and affect populations of lactate-producing (*Lactobacillus* spp.) and lactate-utilizing (*Megasphaera elsdenii*) bacteria. Twelve Holstein bulls (40.2 ± 1.6 kg BW) were randomized into treatments, arranged factorially. The factorials were treatment and route of treatment. The treatments were: CON-drench (water), BICARB-drench (1 *M* $NaHCO_3$ in water), CON-bolus (gelatin capsule), BICARB-bolus ($NaHCO_3$ gelatin capsule). $NaHCO_3$ was administered twice daily, adjusted weekly, and reached a maximum of 48 g/d. Calves were fed 543g DM/d of a 22% CP, 20% fat milk replacer and 20% CP starter. Rumen contents were sampled at wk 1 and 8 for pH, lactate, and bacteria measurement. Rumen pH did not depend on treatment or route, but was different by week (wk 1, pH = 6.00 ± 0.15; wk 8 pH = 5.19 ± 0.14; $P = 0.007$). Overall *D*- and *L*- lactate concentrations did not differ (7.45 ± 2.15 m*M* and 7.33 ± 1.98 m*M*, respectively); although, concentrations of each were numerically higher at wk 8 as opposed to wk 1. Populations of *Lactobacillus* spp. and *M. elsdenii* were calculated as a percentage of total 16S rDNA gene copies. *Lactobacillus* spp. abundance was unaffected by treatments or their interactions, but abundance of *M. elsdenii* was affected by the interaction of treatment and week (wk 1 CON = 0.05%, wk 1 BICARB = 0.00%, wk 8 CON = 0.19%, wk 8 BICARB = 0.26% of total bacteria, respectively; $P = 0.05$). Administration of $NaHCO_3$ by one of 2 oral routes did not affect rumen pH, lactate, or *Lactobacillus* spp. numbers, but in combination with time, did have an effect on *M. elsdenii* abundance. This suggests that *M. elsdenii* was able utilize lactate as a substrate and can withstand low rumen pH. These results support the idea that low rumen pH may be part of the normal rumen development of a dairy calf.

Key Words: dairy calf, rumen, bacteria

T207 Cost of days open equations accounting for variable market and dairy herd conditions.

Karmella A. Dolecheck* and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

The objective of this study was to develop equations for estimating farm-specific cost of days open. The equations were constructed using a whole farm stochastic simulation model previously described by Bewley et al. (2010) and Liang (2013). Ten thousand iterations were run for lactations 1 to 5 with the mean cost per day open as an output. Stochastic variables expected to have potential effects on cost per day open were collected from each iteration. Those variables included: rolling herd average milk production, age at first calving, mature cow live weight, heifer calf value, bull calf value, semen cost, days in milk dictating an open cow as a reproductive cull, milk production level dictating an open cow as a production cull, veterinarian costs, discount rate, milk price, feed price, replacement price, cull cow price, voluntary waiting period, estrus detection rate, and conception rate. The GLMSELECT procedure of SAS 9.3 (SAS Institute, Inc., Cary, NC) was used to analyze the effect of stochastic variables and 2-way interactions on the mean cost per day open for each lactation. Variables remained in the model when significant at $P < 0.05$. The R^2 of the resulting models were 0.57, 0.54, 0.64, 0.85, and 0.63 for lactations 1 to 5, respectively. The models were used to develop deterministic, lactation-specific equations for cost of days open. These equations are available in an online spreadsheet at: http://afsdairy.ca.uky.edu/CostOfDaysOpen. To demonstrate use, mean US Holstein herd data from 2015 DairyMetrics (Dairy Records Management Systems, Raleigh, NC), 2014 Food and Agricultural Research Policy Institute (Columbia, MO), and published literature were entered into each equation. Mean cost per day open for lactations 1 to 5 was $2.44, $2.82, $4.42, $4.54, and $3.32, respectively. These new, robust regression equations for cost of days open account for the complexities of varying market and herd conditions. The equations can estimate cost of days open in partial budgets without the costs or computing time required for stochastic simulations.

Key Words: days open, cost of days open, stochastic model

T208 Checks and balances: Evaluating reliability of dairy nutrient management data to better protect groundwater resources. Christine Miller* and Deanne Meyer, *University of California, Davis, Davis, CA.*

To protect groundwater from further nitrate contamination, California regulations prohibit dairy producers from applying more than 140% of the nitrogen (N) that their crops remove. The regulations require copious annual reporting of crop field management, farm infrastructure, and animal population. The data collected in these annual reports could be integral to evaluating and improving both farm practices and the regulations themselves. Data reliability and accuracy must be assessed to use the information responsibly. Annual Reports from 18 dairies were obtained to assess reliability. Mass balance calculations were preformed to check the self-consistency of data within a facility. The results of mass balance calculations show that the data do not account for a remarkably large percentage of the nutrients being produced on the farms. Literature suggests that over 60% of N and 90% of P should be recovered; however, a median of only 25% of both N and P in cattle manure was recovered based on annual report data. This could be due to many different causes including inaccurate nitrogen sampling and analysis techniques, systematic reporting errors, or fraudulent reporting. Given that the accuracy of the majority of the recommended sampling and analysis protocols has not been assessed, it is likely that these methods are a significant source of error. Projects that should improve data collection protocols in both the short and long-term are in progress. Online decision trees are being developed to help farmers self-assess their current data collection practices, and provide personalized suggestions for improvement. Additionally, I will use a statistical modeling approach paired with in-field measurements to examine the uncertainty in these recommended protocols (and thereby the overall uncertainty in regulations). By separating the various sources of measurement error, the model will identify the best ways to improve data collection and regulation efficacy. Results of this and future studies will influence future nutrient management regulations in California and other states with active livestock industries.

Key Words: dairy waste management, nitrate leaching

T209 Distribution of quarter-level SCC across the dry and early post-partum period. Stephanie A. Metzger*, Laura L. Hernandez, and Pamela L. Ruegg, *University of Wisconsin, Madison, WI.*

The aim of this study was to characterize changes in quarter-level SCC for cows at dry off and the first 2 weeks postpartum. Milk samples were collected at dry off (S1) and postpartum wk 1 (S2) and wk 2 (S3) from quarters (n = 660) of 185 cows at the UW dairy farm. Microbiological analysis of milk samples was performed at the UW Milk Quality Laboratory. The SCC at each sampling period was used to determine postpartum categories: (1) Healthy (SCC < 150,000 at S1,S2,S3), (2) DryCure (S1 $\geq$ 150,000; S2 & S3 < 150,000), (3) Chronic (S1,S2,S3 all $\geq$ 150,000), (4) PostChronic (S < 150,000; S2 & S3 $\geq$ 150,000), (5) LateCure (S1 & S2 $\geq$ 150,000, S3 < 150,000), (6) LateInf (S1 & S2 < 150,000, S3 $\geq$ 150,000),(7) ShortNew (S1 & S3 < 150,000, S2 $\geq$ 150,000). Univariate analyses were performed to determine risk factors associated with Chronic quarters. Average DIM was 6.1 and 13.6 for S1 and S2, respectively. Median SCC were 117,000, 42,000, and 18,000 cells/mL for S1, S2 and S3, respectively. The prevalence of SCC $\geq$ 150,000 cells/ml was 43.6%, 13.5%, and 9.4% for S1, S2, and S3, respectively. The distribution of quarters was: Healthy (n = 321; 48.6%), DryCure (221; 33.5%), Chronic (20; 3.0%), PostChronic (13, 2.0%), LateCure (33, 5.0%), LateInf (29, 4.4%), and ShortNew (23, 3.5%). The occurrence of a clinical case in the lactation before dry off was associated with postpartum category ($P = 0.004$). Fewer quarters that had previously experienced a clinical case were categorized as healthy and a greater proportion were categorized as LateCure and PostChronic. Parity was associated with postpartum category ($P < 0.001$). As compared with younger cows, quarters of cows in parity $\geq$ 3 were 10.9 (3.6–34.6) times more likely to be categorized as chronic (rather than healthy). The number of days dry was greater for quarters categorized as Chronic (66.8d) and LateCure (66.4) as compared with quarters categorized as DryCure (59.1), PostChronic (57.6), LateInf (54.2), Healthy (53.1), or ShortNew (50.5) ($P < 0.001$). Only 8.6% of Chronic quarters were microbiologically positive at dry off. Results of this study demonstrate the dynamic nature of quarter SCC values during the dry and immediate postpartum period.

Key Words: dryoff, fresh cow, SCC

T210 Protein nutrient supply and feed milk value of two newly developed genotypes of transgenic alfalfa compared with non-transgenic alfalfa in dairy cattle. Xinxin Li*[1,2], Yonggen Zhang[2], and Peiqiang Yu[1], *[1]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Saskatchewan, Canada, [2]College of Animal Science and Technology, Northeast Agricultural University, Harbin, China.*

Two newly developed transgenic alfalfa with transformed *TRANSPARENT TESTA 8* (*TT8*) and *HB12* genes were developed by scientists at Agriculture and Agri-Food Canada. Our study was conducted to (1) predict the extent of ruminal and intestinal digestion of protein, (2) evaluate the nutrient supply to dairy cattle and (3) determine the feed milk value in dairy cattle. *HB12* transgenic alfalfa, *TT8* transgenic alfalfa and unmodified control genotype alfalfa were cultivated and harvested from the greenhouse of Agriculture and Agri-Food Canada. There were 2 experimental samples for each treatment. Total rumen degraded protein (TRDP), total rumen undegraded protein (TRUP) and intestinal digestible protein fractions were predicted. The parameters evaluated included: truly absorbed rumen microbial protein (AMCP), truly absorbed rumen undegraded feed protein in the small intestine (ARUP), endogenous protein loss in the small intestine (ENDP), total metabolizable protein (DVE) and degraded protein balance (OEB). The PROC MIXED procedure of SAS 9.3 was used for data analysis. Significance was declared at $P < 0.05$ and trends at $P \leq 0.10$. The results showed that *TT8* alfalfa had highest TRDP value compared with HB12 and control alfalfa ($P < 0.05$). *TT8* alfalfa trended to be higher in TRUP than *HB12* alfalfa, with control alfalfa intermediate ($P < 0.10$). Intestinal digestible PB1 was higher in *TT8* alfalfa than the other 2 alfalfa plants ($P < 0.05$). *TT8* alfalfa had a greater content of microbial protein production (MCP_{RDP}, $P < 0.05$). No significant difference of OEB value was found between *HB12* alfalfa and control alfalfa, but the OEB value was higher in *TT8* alfalfa ($P < 0.05$). No significant differences in DVE and feed milk value (FMV) were found among 3 different genotypes of alfalfa plants ($P > 0.05$). In conclusion, altering the expression of lignin-related *TT8* and *HB12* genes in alfalfa plant could affect its nutrient supply to dairy cattle.

Key Words: lignin-related gene, alfalfa, feed milk value

T211 Probiotic *Enterococcus faecium* increased the propionate and total volatile fatty acids on in vitro rumen fermentation.

Lovelia L. Mamuad, Ashraf A. Biswas, and Sang Suk Lee*, *Sunchon National University, Suncheon, Jeonnam, South Korea.*

Enterococcus faecium had been widely used as direct fed microbial due to their capability to produce antibacterial compounds. Thus, this study was conducted to determine the beneficial effects of *E. faecium* on in vitro rumen fermentation, methane concentration, microbial diversity and population. Ruminal samples were collected from ruminally cannulated Holstein Friesian cattle and 40:60 rice straw to concentrate ratio were used as substrate at 1g dry matter (DM) per 100mL buffered rumen fluid. Fresh culture of *E. faecium* (7.5×10^8 cfu/ml) at different inclusion rates were investigated using in vitro rumen fermentation. The following treatments were non addition, 0.1%, 0.5% and 1.0% of *E. faecium* and, hereafter referred to as control, treatments 1, 2, and 3, respectively. Increased in total gas production and ammonia nitrogen concentration over time were found in control and all treatments while the opposite was observed in pH. Addition of *E. faecium* had significant effect on total gas production after 48h of incubation having the highest ($P < 0.05$) in T2 followed by T4, T3 and control with 93.33, 91.75, 89.50 and 82.20 ml, respectively. pH was not affected by addition of *E. faecium* and lactate was only detected at 0h and was not detected after 12, 24 and 48h of incubation. Propionate was found highest ($P < 0.05$) in T1 after 12h of incubation with 14.15 mM/L. Higher ($P < 0.05$) concentrations in treated than control were found in acetate after 12h, propionate after 48h, butyrate after 12, 24 and 48h and total volatile fatty acids (TVFA) after 12 and 48h of incubations. Pyrosequencing, methane concentration, and methanogen quantity are still on going. So far, addition of *E. faecium* did not affect the pH but increased the propionate and TVFA concentrations.

Key Words: *Enterococcus faecium*, in vitro, pyrosequencing

T212 Effects of replacing soybean meal with canola meal or treated canola meal on performance of lactating dairy cows.

E. M. Paula*[1], M. A. C. Danes[2], N. E. Lobos[2], G. I. Zanton[3], G. A. Broderick[4], and A. Faciola[1], [1]*University of Nevada, Reno, NV,* [2]*University of Wisconsin, Madison, WI,* [3]*USDA-Agricultural Research Service, US Dairy Forage Research Center, Madison, WI,* [4]*Broderick Nutrition & Research, Madison, WI.*

Canola meal (CM) has been shown to be a more effective CP source than soybean meal (SBM) for lactating dairy cows. Treating CM may increase its RUP fraction and improve the amount of absorbable AA. The objective of this study was to evaluate the effects of feeding treated CM (TCM) on performance of dairy cows. Forty-five Holstein cows were blocked by parity and DIM and used in a study of randomized complete block design. Cows were fed a control diet for a 2-week covariate period and then switched to the experimental diets for a 12-week study. Treatments differed only in CP source and were SBM, CM, and TCM. All diets contained (DM basis) 30% alfalfa silage, 30% corn silage, 4% soy hulls, 2.4% mineral-vitamin premix and 16% CP. SBM diets contained 25% high moisture corn (HMC) and 8.6% SBM; CM diets contained 22% HMC and 11.4% CM. Data were analyzed using the mixed procedure of SAS. Orthogonal contrasts were used to compare effects of different protein sources (SBM vs. CM + TCM) and (CM vs. TCM). There were no statistical differences in DMI and milk yield among diets; however, CM diets had numerically higher milk yields (Table 1). Compared with SBM both CM diets decreased MUN concentration ($P = 0.02$). There were no significant differences in milk composition and yields among treatments. Results from this study suggest that CM diets may improve N utilization, as indicated by reduced MUN. Although the large numeric differences in milk production were not statistically significant, these differences may be important from a practical standpoint.

Table 1 (Abstr. T212). Dry matter intake, milk production, and composition results

	Treatment				Contrast probability	
Item	SBM	CM	TCM	SEM	SBM vs. CM + TCM	CM vs. TCM

T213 Transport of a fluorescent analog of glucose (2-NBDG) by rumen bacteria.

Junyi Tao*, Rebecca K. Diaz, and Timothy J. Hackmann, *University of Florida, Gainesville, FL.*

Our objective was to determine if cultured strains of rumen bacteria would transport a fluorescent analog of glucose (2-NBDG) with the same specificity and kinetics as glucose. Our rationale was that 2-NBDG could be used to identify uncultured, glucose-utilizing bacteria if it were transported similarly to glucose. Pure cultures of bacteria were harvested in the mid-to-late log phase, washed, and dosed with 2-NBDG or radiolabeled sugar (0 to 100 μM). Transport was halted by adding −5°C stop buffer and filtering through a membrane. The membrane was taken for fluorometry or liquid scintillation counting. Transport of 2-NBDG could be detected within 2 s of 2-NBDG addition for *Streptococcus bovis* and *Selenomonas ruminantium* (2 strains each), but it was not detected at any time for 6 other glucose-fermenting species. Genomes of *S. bovis* and *S. ruminantium* strains were found to possess genes for the mannose phosphotransferase system, whereas the other species had genes for other glucose transporters. For *S. bovis* JB1, the Michaelis constant (K_m) for 2-NBDG transport was 10.6-fold lower than that for [^{14}C]-glucose transport ($P = 0.006$). The maximum velocity (V_{max}) was 2.9-fold lower than that for [^{14}C]-glucose, but this difference was not significant ($P = 0.100$). In another set of experiments, transport of 2-NBDG at a single concentration (100 μM) was compared with that of [^{14}C]-glucose, [^{3}H]-mannose, and [^{14}C]-deoxy-2-glucose. For *S. bovis* JB1, transport of 2-NBDG was 3.2-fold lower than that of [^{14}C]-glucose ($P = 0.002$) but similar to that for [^{3}H]-mannose ($P = 0.992$) and [^{14}C]-deoxyglucose ($P = 0.955$). 2-NBDG could identify uncultured, glucose-utilizing bacteria, but only those with a mannose phosphotransferase system (not other glucose transporters). Its transport may more closely reflect that of mannose and deoxy-2-glucose than glucose.

Key Words: rumen bacteria, 2-NBDG, transport

T214 Characteristics of dairy cows with a greater or lower risk of subacute rumen acidosis: Volatile fatty acid absorption, rumen digestion kinetics and consistency of the risk.

Xiaosheng Gao* and Masahito Oba, *University of Alberta, Edmonton, AB, Canada.*

The objectives of this study were to examine if lactating dairy cows with a greater or lower risk of subacute ruminal acidosis (SARA) have differences in volatile fatty acid (VFA) absorption rate, rumen digesta passage rate, and in situ rumen digestion, and determine if cows identified to have a greater risk of SARA in mid-lactation consistently have lower rumen pH in late-lactation than cows with a lower risk of SARA. Fourteen ruminally-cannulated dairy cows (DIM = 119 ± 47.2; BW = 640 ± 47.9 kg) were fed a high-grain diet consisting of 30% forage to induce SARA. Eight cows with the lowest acidosis index (area below pH 5.8 normalized for DMI; 0.10 ± 0.16 pH·min/kg) and 5 with the highest acidosis index (3.72 ± 0.19 pH·min/kg) were classified as animals with lower (LOW) and higher (HIGH) risk of SARA, respectively. All response variables were evaluated for the group effect using the PROC TTEST procedure of SAS (version 9.2, SAS Institute Inc., Cary, NC). Minimum (5.75 vs. 5.33; $P < 0.01$) and mean ruminal pH (6.33 vs. 5.98; $P < 0.01$) was higher for LOW compared with HIGH animals. However, there were no differences in VFA absorption rate, rumen digesta passage rate, and in situ runminal digestibility of starch and NDF between HIGH and LOW cows. Nine of these 14 animals (4 HIGH and 5 LOW) were fed the same high-grain diet at a later stage of lactation (DIM = 243 ± 19.6) for 21 d. Similar to the mid-lactation, minimum (5.73 vs. 5.32; $P = 0.02$) and mean ruminal pH (6.32 vs. 6.07; $P = 0.01$) was higher for LOW compared with HIGH animals. These results suggested that variable risk of SARA among lactating dairy cows fed a high grain diet cannot be attributed to the differences in VFA absorption rate, rumen digesta passage rate, and ruminal digestibility, and that stage of lactation does not affect the risk category of animals in developing SARA.

Key Words: acidosis, VFA absorption, rumen digestion kinetics

T215 Systems nutrition in dairy cattle: Integrating hepatic metabolomics and transcriptomics in late pregnancy to better understand postpartal ketosis.

Khuram Shahzad*[1], Johan Osorio[2], Daniel Luchini[3], and Juan J. Loor[1], *[1]University of Illinois, Urbana, IL, [2]Oregon State University, Corvallis, OR, [3]Adisseo NA, Alpharetta, GA.*

'Omics' and bioinformatics were used to identify unique signatures characterizing liver of cows with postpartal ketosis relative to healthy cows fed rumen-protected methionine during late-pregnancy. Transcriptomics and metabolomics data were generated from liver tissue (n = 8/group, d −10 relative to parturition) of cows overfed a higher-energy diet during the dry period and classified as follows based on postpartal health: healthy (OVE), ketosis (K), or OVE plus Smartamine M (SM) or MetaSmart (MS). Data integration was via Ingenuity Pathways Analysis. Network construction included transcription regulators (TR) within the transcriptomics database and metabolites obtained through GC/MS-LC/MS. By comparing the different groups we obtained 21, 6, 10, 3, 11 and 15 transcription regulators (TR) out of 2908, 832, 1261, 922, 1573 and 1033, respectively, differentially expressed genes from K vs. OVE, K vs. SM, K vs. MS, SM vs. OVE, MS vs. OVE and SM vs. MS. Out of 313 known biochemical compounds, we detected 25, 34, 33, 20, 21, and 48 affected metabolites in the respective comparisons. As an example, using the TR (*HIF1A, HIF3A, SIRT1, HDAC4*) along with affected metabolites (cholic acid, D-erythro-dihydrosphingosine, lactic acid, malic acid, xylitol) in K vs. OVE the bioinformatics analyses revealed alterations in pathways related to tissue growth, and glucose and lipid metabolism. In regards to the methionine-supplemented groups, using the TR (*HDAC2, SOX10, STAT1*) along with affected metabolites (arginine, inosine) in SM vs. OVE the bioinformatics analyses revealed alterations in pathways related to regulation of liver regeneration and metabolism. Unique patterns also were detected between SM and MS, analysis of the TR (*CREBBP, GATA2, NFKB2, STAT1*) along with affected metabolites (arachidonic acid, arginine, chenodeoxycholic acid, docosahexaenoic acid, oleic acid) revealed alterations in pathways involved in cell signaling, immune response, and cholesterol synthesis. Results indicate that 'omics' data integration could be helpful in better understanding the link between nutrition and incidence of disorders after calving.

Key Words: systems biology, ketosis, network reconstruction

T216 Laboratory validation of a prototype cow-side instrument for the measurement of blood ionized calcium concentrations in dairy cattle.

Rafael C. Neves*, Tracy Stokol, and Jessica A. A. McArt, *Department of Population Medicine and Diagnostic Sciences, Cornell University, Ithaca, NY.*

There is currently no efficient and inexpensive method for field measurement of blood calcium concentrations. Ionized calcium (iCa) is the homeostatic form of the mineral and is thought to have greater biological relevance over that of total calcium. The objective of this study was to evaluate the linearity and precision of a prototype cow-side instrument (Horiba, Japan) for measuring blood iCa concentrations. Blood (300 mL) was collected from the right jugular vein of a multiparous dairy cow (4 d-in-milk) into lithium heparin tubes immediately before (T0) and 5 min after (T5) intravenous administration of 500 mL of 23% calcium borogluconate. The iCa concentrations were determined using a blood-gas analyzer (ABL-800 FLEX, Radiometer) as a gold-standard. The T0 sample was diluted using 0.9% saline to create a sample with low iCa (reference interval = 1.10 to 1.35 μmol/L). The diluted T0 sample was then mixed with the T5 sample in different ratios (100/0, 75/25, 50/50, 25/75, 0/100) to obtain 5 levels of iCa concentrations (0.69, 1.0, 1.28, 1.58, and 1.82 μmol/L). Each mixture was then analyzed in triplicate using 3 different prototypes under one-point (1P) and 2-point (2P) calibration with the means compared with results from the blood-gas analyzer. Cumulative sum tests for linearity from Passing and Bablok regressions showed no deviation from linearity for the combined results of all 3 prototypes under 1P vs. the gold-standard ($P = 0.19$) and under 2P vs. the gold-standard ($P = 0.19$). Instrument precision (coefficient of variation; CV) was determined by 10 repeat measurements of the diluted T0 sample, T0, and T5 samples under 1P and 2P calibrations. The CV ranged from 1.3 to 5% for the 3 prototypes. Laboratory results indicate good accuracy and precision for a cow-side instrument at the tested iCa concentrations. Investigation of the instrument under field conditions is warranted.

Key Words: ionized calcium, cow-side instrument, dairy cattle

T217 Validation of a hand-held meter for measuring β-hydroxybutyrate in plasma and serum of dairy cows.

Arnulfo Pineda* and Felipe C. Cardoso, *University of Illinois, Urbana, IL.*

The aim of this study was to compare serum (sBHBA) and plasma (pBHBA) BHBA concentrations analyzed using either a laboratory method (Randox Laboratories Ltd., UK, Cat # RB1007 as "gold standard"; LM) or a hand-held meter (PX; Precision Xtra). Results from 187 samples taken from Holstein cows from 11 d before to 5 d after parturition were used for the analysis. Statistical analysis was performed using the MIXED, REG, and LOGISTIC procedures of SAS (v9.4). A linear mixed model with repeated measures was performed for LM and PX. A regression analysis was completed to estimate the relationship between the 2 methods. Cross-validation by randomly splitting the data in model building and validation sets was performed to estimate and validate the equation that predicted the LM results using PX. Receiver operation characteristic (ROC) curves were made to estimate the sensitivity and specificity of PX at different threshold levels. The PX yielded higher ($P < 0.01$) pBHBA and sBHBA than LM, 1.45 vs. 0.95 and 1.63 vs. 1.00 mmol/dL, respectively. Adjusted R^2 between both methods for pBHBA was 97.1% and 97.8% for sBHBA. The equation from the model building data set that predicted pBHBA results using PX was $y = -0.05353 + 0.67842x$, while the equation that predicted sBHBA results was $y = 0.05542 + 0.56862x$, where y = predicted LM BHBA and x = PX BHBA. Mean square error (MSE) yielded by the model building data set for pBHBA and sBHBA were 0.006 and 0.005, respectively. Mean squared predictor error (MSPR) from the validation data set was 0.007 for pBHBA and 0.006 for sBHBA. Highest sensitivity and specificity for PX was achieved when threshold was set to 1.8 for pBHBA and 2.1 mmol/dL for sBHBA. The area under ROC curve (AUC) was 0.97 for pBHBA and 0.96 for sBHBA. In conclusion, the small difference between MSE and MSPR suggest that PX can be used to predict pBHBA and sBHBA by using the aforementioned equations. However, the threshold for ketosis requests to be higher than the commonly used in the field (1.2 mmol/dL) when using PX. The AUC close to 1 suggests greater ability of PX in predicting ketosis under the indicated thresholds.

Key Words: BHBA, dairy cow, Precision Xtra

T218 Effects of feeding calcium hydroxide-treated corn stover on milk production and milk composition in lactating Holstein cows.

Brittany A. Casperson*[1], Aimee E. Wert-Lutz[2], and Shawn S. Donkin[1], [1]*Purdue University, West Lafayette, IN,* [2]*ADM Alliance Nutrition, Quincy, IL.*

Chemical treatment may improve the nutritional value of corn stalk residues and their potential use as an alternative forage source for lactating dairy cows. The objectives of this study were to determine the effect of prestorage hydration and treatment with 6.6% $Ca(OH)_2$ on feeding value of corn stalks as an alternative forage source on milk production, milk composition, and DMI. Mid-lactation multiparous Holstein cows (n = 30) were stratified by parity and milk production and randomly assigned to 1 of 3 diets. Corn stalks were chopped, hydrated, and treated with 6.6% $Ca(OH)_2$ (DM basis) and stored in Ag-bag silos. Treated corn stover was fed in a TMR at 0, 15, and 30% of the diet DM. Treated corn stover replaced either alfalfa haylage (15% stover diet) or replaced alfalfa haylage and an additional portion of corn silage (30% stover diet). Cows were individually fed in tie stalls for 10 weeks. Milk production was not altered by treatment ($P = 0.80$). Compared with 0% stover diet, DMI was reduced when the 15% stover diet was fed (25.9 vs. 22.7 ± 0.88 kg/d, $P < 0.05$) and tended to be reduced (25.9 vs. 23.1 ± 0.88 kg/d, $P = 0.08$) when cows were fed the 30% stover diet. Milk production per unit DMI (kg/kg) tended to increase for cows fed 15% stover diet compared with the 0% stover diet (1.41 vs. 1.62 ± 0.07, $P = 0.08$) but was not different between cows fed the 0% and 30% stover diets (1.41 vs. 1.50 ± 0.07, $P = 0.62$). Milk composition, energy corrected milk production, and energy corrected milk produced per unit of DMI (kg/kg) was not different ($P > 0.05$) among treatments for the 10-week feeding period. Cows fed the 15% and 30% diets had stable DMI and daily milk production over the 10-week treatment period but DMI for cows fed 0% stover increased slightly (time x treatment effect, $P < 0.05$). These data indicate that corn stover processed through prestorage hydration with $Ca(OH)_2$ results in an alternative forage source for lactating dairy cows that when fed to mid-lactation cows tends to improve the efficiency of conversion of feed to milk without altering milk production or milk composition.

Key Words: corn stover, alternative forage, milk fat

T219 Increased stocking density at the feed bunk may affect the welfare and productivity of dairy cows and growth of their heifer calves.

Jessica A. Pempek*, Maurice L. Eastridge, Kathryn L. Proudfoot, Gregory G. Habing, Lohendy M. Muñoz Vargas, and Danielle N. Coleman, *The Ohio State University, Columbus, OH.*

Overstocking the feed bunk during late-gestation has behavioral and physiological consequences, both of which negatively affect the welfare of the cow. However, it is unknown as to whether overstocking the dam may also affect the growth of the developing calf. The aim of the present study was to investigate the effect of increased stocking density at the feed bunk during different stages of the dry period on metabolic health and productivity of dairy cows, as well as the postnatal growth of their calves. One hundred twenty nonlactating Holstein dairy cows were blocked and assigned to 1 of 4 treatment groups with different stocking densities at the feed bunk (Overstocked (OS): 0.88 headlocks/cow; Understocked (US): 1.17 headlocks/cow). The 4 treatments were: OS from 60 to 1 d (OS), OS from 60 to 26 d and US from 25 to 1 d (OS-US), US from 60 to 26 d and OS from 25 to 1 d (US-OS), and US from 60 to 1 d (US) before calving. The heifer calves' treatment reflected the treatment assignment of their dam (n = 13, 18, 16, and 11, respectively). Blood samples were obtained from the cow at −60, −30, −14, −7, and +7 d relative to calving to determine concentrations of nonesterified fatty acids (NEFA). Colostrum quantity and quality were recorded from the cow's first milking. Calf body weight (BW) was measured once per wk through weaning at 5 wk of age. Data were analyzed using repeated measures and the Mixed model procedure of SAS (2012). NEFA concentrations were similar among treatment groups across periods (0.36, 0.42, 0.37, and 0.42 mEq/L, respectively; $P > 0.05$). There was a tendency for colostrum quantity to differ among treatments (7.52, 5.70, 7.03, and 8.76 kg, respectively; $P = 0.11$), primarily due to the difference between OS–US and US. However, there was no difference in colostrum quality (weighted Brix value of 7.24%). Using initial BW as a covariate, calf BW was similar among treatment groups (53.7, 51.9, 52.2, and 54.1 kg, respectively; $P > 0.05$), and there was no treatment by week interaction. In conclusion, moderate increases in stocking density at the feed bunk did not appear to compromise the metabolic status of dairy cows or the growth of their heifer calves.

Key Words: stocking density, feed bunk, dry period

T220 Unraveling the mechanisms that regulate activation of β-defensin antimicrobial peptide responses in cattle.

Mercedes F. Kweh*, Kathryn E. Merriman, and Corwin D. Nelson, *University of Florida, Gainesville, FL.*

Bovine β-defensin peptides exhibit antimicrobial properties against bacterial pathogens, and expression of several β-defensin genes has been reported in the udder during mastitis. In cattle, toll-like receptor (TLR) and vitamin D signaling pathways induce expression of multiple β-defensin genes; however, β-defensin expression in mammary epithelial cells is only activated via the TLR pathway and is much lower compared with neutrophils and macrophages. The β-defensin gene cluster on bovine chromosome 27 contains multiple potential DNA methylation sites, suggesting the hypothesis that epigenetic mechanisms contribute to induction of the β-defensin response in cattle. The objective of this

study was to investigate the effects of DNA methylation and histone deacetylation inhibitors, 5-aza-2’-deoxycytidine (5-Aza) and Trichostatin A (TSA), respectively, on TLR and 1,25-dihydroxyvitamin D_3 (1,25D)-induced expression of β-defensins in primary bovine mammary epithelial cells (bMEC). Primary bMEC cultures obtained via mammary biopsy were treated with 5-Aza (1uM, 72 h), TSA (80 nM, 16 h) or control in combination with lipopolysaccharide (LPS; 100 ng/mL; 16 h) and 1,25D (10 nM, 16 h). Expression of β-defensin 3 (*BNBD3*), *BNBD4, BNBD7, BNBD10,* and lingual antimicrobial peptide (*LAP*) genes was determined using qPCR. The 5-Aza treatment resulted in a > 10-fold increased expression of each gene ($P < 0.001$). There was also an interaction between LPS and 5-Aza for expression of *BNBD3, BNBD10*, and *LAP* genes ($P < 0.001$). The TSA treatment also increased expression of the *BNBD7, BNBD10,* and *LAP* genes approximately 5-fold compared with control ($P < 0.01$), and there was TSA by LPS interaction for each of the genes ($P < 0.05$). In contrast, there were not interactions between 1,25D and 5-Aza or TSA for any of the β-defensin genes. These data suggest that DNA methylation and histone acetylation both contribute to β-defensin expression, and that epigenetic mechanisms may affect TLR activation of the β-defensin antimicrobial response of mammary epithelial cells.

Key Words: β-defensins, mammary immunity, vitamin D

T221 Ellipsoid equation improves accuracy and efficiency of estimating protozoal volume. Benjamin A. Wenner*, Brooklyn K. Wagner, and Jeffrey L. Firkins, *Department of Animal Sciences, The Ohio State University, Columbus, OH.*

Previous observations of protozoa in cultures treated with essential oils or ionophores indicated possible cell shrinkage due to deleterious effects on cell function. Cell volume reduction by formaldehyde preservation combined with visually flattened or tapered morphology of rumen protozoa limited our ability to detect volume differences using common cylindrical derivations for protozoa. The advent of affordable, high definition imaging equipment enables recording of live protozoa from cultures treated with various additives that potentially shrink cells. We hypothesized that using still frames from video of protozoa swimming would improve accuracy of volume predictions by optimizing an approach to measure one maximal longitudinal measurement and both minimum and maximum diameter measurements perpendicular to the longitudinal axis, thus yielding a 3-dimensional estimation of protozoal volume. An ellipsoid formula (E, $^4/_3\pi abc$) was compared with previously published estimations using cylindrical (C, $L\pi(^W/_2)^2$) or species coefficient (SP, XLW^2) calculations. Testing this method on inanimate objects shaped similarly to protozoa demonstrated that the ellipsoid is more accurate in predicting volume as measured by displacement. True displacement was 11.8 mL for 10 large particles, and estimated volumes were 12.7 to 27.1, 7.7 to 16.6, and 12.3 mL for C, SP, and E, respectively. For smaller particles with more surface area, true displacement was 4.5 mL, and estimated volumes were 5.6 to 13.1, 3.2 to 7.5, and 5.6 for C, SP, and E, respectively. Rumen fluid sampled from 2 lactating Jersey cows was flocculated and wet-mounted on a microscope fitted with an HD (1080p) camera. Mean entodiniomorphid (ENTO) volumes were 109,665 (±55,912), 99,145 (±51,704), and 79,830 (±39,859) μm^3 for C, SP and E, respectively. Mean epidinium (EPI) volumes were 1.74×10^5, 2.47×10^5, and 1.45×10^5 for C, SP, and E, respectively. Regression of SP on E demonstrated that SP more likely overestimates volume for ENTO ($Y = 1.187X + 0.8567$) or EPI ($Y = 1.467X + 38528$) than for teardrop-shaped isotrichids ($Y = 0.833X + 346,973$). This ellipsoid method offers potential to advance prediction of treatment effects on protozoal viability and volume.

Key Words: protozoa, imaging, rumen

T222 Milk yield at dry-off and other factors affecting risk of intramammary infections at calving. Paige N. Gott*[1], Päivi J. Rajala-Schultz[1], Gustavo M. Schuenemann[1], and Joseph S. Hogan[2], *[1]The Ohio State University, Columbus, OH, [2]The Ohio State University, Wooster, OH.*

Increased milk yield at dry-off has been associated with increased risk of intramammary infections (IMI) at calving. Abrupt cessation of milking is widely practiced although gradual cessation has been shown to significantly decrease milk yield. The objective of this study was to evaluate the effect of milk cessation method (MilkCess) and Dairy Herd Improvement Association final test day (FTD) milk yield on IMI at calving. Cows in 8 Ohio dairy herds were enrolled 7 to 14 d before expected dry-off and randomly assigned either to ABRUPT or to GRADUAL cessation of milking. The GRADUAL group was milked once daily for the final week of lactation while the ABRUPT group kept the farm’s normal milking schedule. Aseptic quarter foremilk samples were collected at enrollment, at the final milking (DRY), and within 7 d of calving (CALV). Samples were cultured following NMC guidelines. Isolation of ≥ 10 colonies of similar morphology was considered an IMI while isolation of ≥ 3 morphologies was called contamination. Coagulase-negative staphylococci and *Corynebacterium* spp. were considered minor (MIN) pathogens. Other species were considered major (MAJ) pathogens. The association between quarter IMI status at CALV and MilkCess and FTD milk yield was evaluated using PROC GLIMMIX in SAS. Separate models were run with MAJ and MIN IMI at CALV as the outcomes. Data from 392 cows were analyzed. MilkCess was not significant, but was forced into each model. For every 4.5-kg increase in FTD milk yield, the odds of IMI at CALV increased (MAJ = 39%, $P = 0.0007$; MIN = 18%, $P = 0.0498$). The odds of MAJ IMI at CALV for quarters with MAJ IMI at DRY were 17.2 times the odds of quarters uninfected at DRY ($P < 0.0001$). The odds of MIN IMI at CALV for quarters with MIN IMI at DRY were 1.9 times the odds of quarters uninfected at DRY ($P = 0.0316$). For every 7d increase in DIM at dry-off above 305 DIM, the odds of MIN IMI at CALV increased 3.1% ($P = 0.0328$). On average, dry periods lasted 58 d and for every 7-d increase in days dry above 58 d, the odds of MIN IMI increased 28% ($P = 0.0125$). In conclusion, decreasing milk yield before dry-off could help improve udder health at calving.

Key Words: milk yield, IMI, dry-off

Growth and Development I

T223 Exogenous estradiol decreases relative endometrial gene expression for *ERα* and *ERβ* in pre-pubertal dairy heifers. Chelsee T.L. Holloway*[1], Adam J. Geiger[1], Jennifer Malkus[1], Alan D. Ealy[2], Rebecca R. Cockrum[1], and Robert M. Akers[1], [1]*Virginia Polytechnic Institute and State University, Department of Dairy Science, Blacksburg, VA,* [2]*Virginia Polytechnic Institute and State University, Department of Animal and Poultry Sciences, Blacksburg, VA.*

The objectives of this study were to determine (1) the effect of early nutrition on reproductive development and (2) response of reproductive tissues to estradiol (E_2) in pre-pubertal heifers. Holstein heifer calves (n = 23; 7 d of age) were fed either a restricted milk replacer diet (20% CP, 20% fat, 454 g/d) or accelerated diet (28% CP, 25% fat 1,333 g/d) for 8 wks. After the initial 8 wks, heifers were partitioned into a 2 × 2 factorial design and treated for an additional 2 wks accordingly: restricted diet + placebo implant (CON; n = 6), accelerated diet + placebo (ACC; n = 5), restricted diet + E_2 implant (CONEST; n = 6) and accelerated diet + E_2 (ACCEST; n = 6). Estrogen receptor α (*ERα*) and β (*ERβ*) gene expression was determined from RNA isolated from harvested endometrial, ovarian, and hypothalamic tissues using Real-Time qPCR. Fold changes were analyzed using the GLM procedure in SAS with treatment used as a fixed effect and initial body weight used as a covariate. The main effect of diet did not differ ($P \geq 0.127$) for any of the tissues. However, E_2 treatment differed for the endometrium ($P \leq 0.001$), but not for the ovary or hypothalamus ($P \geq 0.528$). In the endometrium, *ERα* was upregulated ($P \leq 0.024$) in ACC heifers (8.44 ± 1.21) as compared with ACCEST (2.69 ± 1.43), and CONEST heifers (2.63 ± 1.22). Gene *ERβ* was also upregulated more ($P \leq 0.052$) in ACC heifers (4.16 ± 0.52) than ACCEST (2.11 ± 0.61) or CONEST heifers (1.46 ± 0.52) in the endometrium. Additionally, *ERβ* was upregulated ($P < 0.001$) in CON heifers (4.56 ± 0.52) as compared with CONEST heifers, and tended ($P = 0.071$) to be upregulated in ACCEST heifers. Overall, results indicated that diet alone did not affect expression of *ERα* or *ERβ* in reproductive tissues of pre-pubertal heifers. However, treatment with E_2 in pre-pubertal heifers affected relative gene expression of key genes within the hypothalamic-gonadal pathway. Determining the effect of estrogen on the development of reproductive tissues is key to understanding signaling pathways that activate the onset of puberty.

Key Words: estradiol, gene expression, nutrition

T224 Plane of nutrition affects muscle fiber hypertrophy and satellite cell activity in neonatal bull calves. Jennifer S. Bradley*, Meghan E. MacGhee, Sarah R. McCoski, Amanda M. Reeg, Alan D. Ealy, and Sally E. Johnson, *Virginia Polytechnic Institute and State University, Blacksburg, VA.*

Muscle growth in newborn calves is a product of protein accretion concomitant with addition of nuclei to the muscle fiber. The objective of the experiment was to examine the effect of diet on live animal performance, muscle fiber hypertrophy and satellite cell activity in young calves. Neonatal Holstein bull calves were fed either a high nutritional plane (HNP; 27% CP, 10% fat) or low nutritional plane (LNP; 20% CP, 20% fat) milk replacer. Daily intake of GE for the LNP group was 50% of HNP, but exceeded the NRC requirement for NEm and NEg. Groups of HNP (n = 4) and LNP (n = 4) were slaughtered at 2, 4 and 8 wk. The LM was removed for fiber morphometric evaluation and satellite cell isolations. Data were analyzed by ANOVA using PROC GLM for the main effects of diet and time and their interaction. Calves fed HNP gained more ($P < 0.05$) BW at 2, 4 and 8 wks than LNP with the largest difference at 8 wks (HNP = 749 g/d, LNP = 134 g/d, pooled SEM = 0.05). Fiber cross-sectional area was larger ($P < 0.05$) in HNP than LNP at 8 wk (1502 ± 242 μm^2 vs. 356 ± 25 μm^2). The numbers of Pax7 immunopositive satellite cells per fiber did not differ ($P > 0.05$) between the groups with time or diet. Satellite cell isolates were cultured in growth media and pulsed for 2 h with EdU, a thymidine analog, to measure proliferation rate. Isolates from HNP at 2 wks contained a greater ($P < 0.05$) percentage of proliferating cells during log phase growth than LNP at equal cell densities (51.7 and 35.2%, respectively, SEM = 2.1). At 4 wks, the percentage of proliferating HNP satellite cells was less ($P < 0.05$) than that of LNP isolates (21.5 vs. 39.1%, SEM = 1.6) and tended ($P = 0.10$) to remain lower at 8 wk. No differences were observed in the numbers of myofibers formed from HNP or LNP satellite cell isolates. These results demonstrate that calves fed a higher plane of nutrition gain more weight and experience greater muscle fiber hypertrophy than calves fed at a lower level. The larger HNP fiber may be attributed to greater satellite cell proliferation and their subsequent fusion into the adjacent fiber.

Key Words: muscle fiber, hypertrophy, Pax7

T225 Effects of heat-treatment of colostrum on absorption and gut development in neonatal bull calves during the first 12 hours of life. Coral Kent-Dennis[1] and Thomas McFadden*[2], [1]*University of Alberta, Edmonton, AB, Canada,* [2]*University of Missouri, Columbia, MO.*

Heat-treatment of colostrum reduces transmission of pathogens to neonatal calves but may alter the bioactivity of colostrum. The objective was to determine the effects of heat-treating colostrum on absorptive function and gut development in neonatal calves. First-milking colostrum was collected in batches and stored at −20°C. Batches were thawed, pooled, mixed thoroughly, and divided into equal volumes. Half was re-frozen in 1L aliquots and the other half was heat-treated at 60°C for 60 min then re-frozen in 1L aliquots. Holstein bull calves were enrolled in the study as they were born and received 2L of either heat-treated (n = 9) or unheated (n = 8) colostrum via esophageal tube feeder within 1.5h of birth. Blood samples were taken at 0 (pre-colostrum), 3, 6, 9 and 12h after birth for analysis of IgG and β-lactoglobulin (BLG) concentrations. Six calves from each treatment group were euthanized at 12h after birth and ileal tissue was collected for analysis of villus height, crypt depth, and goblet cell count. Statistical analysis was conducted using PROC MIXED of SAS with batch as a random effect and repeated measures where appropriate. Colostral IgG concentration did not differ between heated and unheated pools. Plasma IgG concentration tended to be higher in calves fed unheated versus heated colostrum at 9 h and the difference was significant at 12h (15.8 ± 1.4 versus 12.9 ± 1.4 mg/mL; $P = 0.02$). Plasma BLG concentrations were significantly higher in calves fed unheated versus heat-treated colostrum at 6 h (324.3 ± 52 versus 239.9 ± 51.0 mg/mL; $P = 0.04$) and 9h (258.2 ± 52.0 versus 126.3 ± 51.9 mg/mL; $P = 0.002$). By 12 h, there was no difference between the 2 treatment groups. These data suggest that different colostral proteins have different rates of absorption and biological half-lives. Villus height and crypt depth did not differ significantly between treatment groups. The average number of goblet cells on ileal villi was higher in calves fed heat-treated versus unheated colostrum (63.4 ± 3.3 versus 48.8 ± 3.3; $P = 0.02$). Results indicate that heat-treatment of colostrum altered absorption of colostral proteins and stimulated development of mucus-producing cells but did not affect mucosal growth.

Key Words: colostrum, pasteurization, calf health

T226 Direct-fed microbial efficacy and milk plan: Effect on heifer growth in an automated feeding system.

Melissa C. Cornett* and Amy L. Stanton, *University of Wisconsin-Madison, Madison, WI.*

Automated feeding systems (AF) offer flexible nutrition programs for pre-weaned dairy calves. The technology offers the option of changing daily milk allotment as calves grow and providing feed additives, such as direct-fed microbial (DFM). This study determined the effect of DFM efficacy and 2 milk plans (SLW, FST) on growth. Holstein heifers (n = 104) from a commercial Wisconsin herd were enrolled at birth in a 2 × 2 factorial design. Factor 1 was a DFM protocol versus a placebo (PLAC) from birth to weaning. Factor 2 compared 2 feeding plans (SLW and FST) offering 543L pasteurized whole milk over 53 feeder days (FD). The SLW initially offered (7L/d), and peaked milk at 28 FD (13L/d). The FST initially offered 11L/d, and peaked milk at 21 FD (15L/d). Both plans stopped milk at 53 FD. Rate of passive transfer was 86%. Calves were housed individually before AF. Ability of calf to drink milk unassisted triggered AF move. During AF, ad libitum Ampli-Calf (Land O' Lakes, MN) calf starter was provided in a bunk. No individual starter intakes were recorded. Calf weight (WT) was measured 2×/wk from age 3 ± 2 d (Mean ± SD) until 1 wk post-weaning. The effect of treatments on WT was evaluated using PROC MIXED in SAS, controlling for initial WT, age, and study period, study month was a random effect and calf nested in treatment for repeated measure. Study period was divided into 4 times: Period 1 birth to AF (P1), Period 2 FD1 – FD28 when FST offered more milk/d than SLW (P2), Period 3 FD29-FD53 (P3), and Period 4, the 7 d post-weaning (P4). Average milk consumption was 430.9 ± 89.0L for SLW and 378.5 ± 78.7L for FST. Initial feeder enrollment age was 7 ± 2 d. Milk plan, DFM, and study period interacted ($P = 0.03$). In P2, FST DFM calves weighed 3.6 ± 1.5 kg (LSM ± SEM) more than FST PLAC ($P < 0.02$). In P3, FST DFM calves weighed 3.2 ± 1.5 kg more than FST PLAC ($P < 0.04$). In P3, SLW PLAC weighed 3.0 ± 1.5 kg more than FST PLAC ($P < 0.05$). In P4, FST DFM tended to weigh 2.9 ± 1.6 more than FST PLAC ($P = 0.07$). These results suggest DFM effectively improves growth in dairy calves on a rapid increase milk plan. Calves provided peak milk at 28FD had higher growth than calves with peak milk at 21FD. Growth can be optimized by AF and DFM.

Key Words: calves, growth, probiotic

T227 Anti-oxidative status and inflammatory response in neonatal calves fed quercetin with or without colostrum.

Harald M. Hammon*[1], Jeannine Gruse[1], Manfred Mielenz[1], and Siegfried Wolffram[2], [1]*Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany,* [2]*Christian Albrechts University, Kiel, Germany.*

Flavonoids such as quercetin are known to exert anti-inflammatory and anti-oxidative effects that could improve neonatal health. We hypothesized that quercetin feeding during the first week of life may improve anti-inflammatory and antioxidative status in neonatal calves and that quercetin feeding compensates for an inadequate colostrum supply. Twenty-eight new-born male Holstein calves were randomly assigned to 2 feeding groups receiving same amounts of either colostrum (C; n = 14) or a milk-based formula (F; n = 13) with same nutrient density as C, but no biologically active factors (e.g., growth factors), during the first 2 d of life. From d 3 to d 7, all calves were fed milk replacer at 12% of BW. From d 2 on, groups were subdivided each into a treatment group receiving 150 µmol quercetin/(kg BW × d) as quercetin aglycone with milk and a control group without quercetin. For characterization of anti-oxidative status, trolox equivalent antioxidative capacity (TEAC), ferric reducing ability of plasma, thiobarbituric acid reactive substances (TBARS) and prostaglandin-like substances were analyzed in blood plasma taken on d 1, 4, and 7. Liver biopsy was taken 2 h after morning meal on d 8 to determine mRNA abundances of anti-oxidative enzymes (catalase; glutathione peroxidase; superoxide dismutase) and inflammation markers (tumor necrosis factor, TNFα; serum amyloid A2, SAA2; C-reactive protein, CRP) using quantitative real-time PCR. Data were evaluated by Proc Mixed (blood) or Proc GLM (mRNA) of SAS with milk and quercetin as fixed effects. TEAC and TBARS were greater in C- than in F-fed calves ($P < 0.05$). Relative mRNA abundance of TNFα was greater in quercetin-fed groups ($P < 0.05$); CRP was greater ($P < 0.05$) and SAA2 tended to be greater ($P < 0.1$) in F- than in C-fed calves. Absence of C feeding was associated with a reduced anti-oxidative status and increased hepatic mRNA abundance of acute phase proteins, which underlines the importance of C feeding for neonatal health. Results further indicate that quercetin supplementation barely affects the anti-inflammatory and antioxidative status in neonatal calves.

Key Words: calf, quercetin, antioxidative status

T228 Effect of milk aroma flavor on starter consumption, growth, and feed conversion in female Holstein calves.

Yaqi Wu, Yanliang Bi, Shengli Li*, Yajing Wang, and Zhijun Cao, *College of Animal Science and Technology, China Agriculture University, Beijing, China.*

Milk aroma flavor (Luctarom1866, Lucta, Spain) was added to calf starter to investigate its effects on starter consumption (SC), growth and feed conversion in dairy calves. Forty-four female Holstein calves (6 wk of age; 56 ± 6 kg of BW) were randomly assigned to 2 groups, which were fed with 2 g or 0 g milk aroma flavor per kg starter. All calves consumed the same milk and starter from birth to the beginning of the experiment (wk 0–6). The experiment lasted 4 weeks (wk 7–10) and calves were provided same milk from the beginning of the experiment (wk 7) and weaned at 8 wk of age. SC was recorded daily and each calf was weighed weekly. The data were analyzed by ANOVA and LSD test at 5% and 1% probability utilizing SAS statistical program. The results indicated that SC of calves fed flavor had no significant differences in wk 7, 8, 9 and during the entire experimental period, while it increased by 0.38 kg per day ($P < 0.05$) in wk 10. Compared with the calves fed starter with no flavor, the calves fed flavor gained more weight in wk 9 (0.2 kg per day ($P < 0.05$)), wk 10 (0.3 kg per day ($P < 0.01$)), and during the whole experimental period (0.1 kg per day ($P < 0.05$)). From wk 9 to wk 10, the ratio of weight gain to SC was 0.42 and 0.38 for calves fed with and without flavor ($P > 0.05$). Overall, milk aroma flavor in starter could improve SC and average daily gain (ADG) in dairy calves and tend to encourage feed conversion.

Key Words: milk aroma flavor, average daily gain, weight gain:starter consumption

T229 Caloric restriction reduces protein accretion in skeletal muscle by attenuating IGF-I signaling in young calves.

Yue Lu[1], Jennifer S. Bradley[1], Sarah R. McCoski[1], John M. Gonzalez[2], Adam J. Geiger[1], R. Michael Akers[1], Alan D. Ealy[1], and Sally E. Johnson*[1], [1]*Virginia Polytechnic Institute and State University, Blacksburg, VA,* [2]*Kansas State University, Manhattan, KS.*

Caloric restriction decreases skeletal muscle mass in mammals, principally due to a reduction in fiber size. This study examined the consequences of reduced caloric intake on the metabolic properties of skeletal muscles in young Holstein heifer calves. Newborn heifers were assigned to a control (CON, n = 5; 28% CP, 25% fat) or caloric restricted (CR, n = 5; 20% CP, 20% fat) milk replacer diet from birth to 8 wks of age. Grain (25% CP, 4% fat) was pair-fed beginning at wk 5. Diets supported ADG of 771 g/d and 220 g/d for CON and CR calves, respectively. Heifers were euthanized at 8 wks and the LM was collected for muscle morphometry, gene expression and metabolic signal transduction measurements. The effect of diet was exained using by Student *t*-test with $\alpha = 0.05$. Results revealed that CR heifers had smaller ($P < 0.05$) LM fiber cross-sectional area and a greater percentage of oxidative type I and IIA fibers. The oxidative fiber type of the CR LM was not associated with elevated expression of *PGC1α*, a mitochondria biogenesis factor. Reverse transcription-qPCR revealed *PGC1α* mRNA levels were 40% lower in CR than CON LM. Western blot analysis detected reduced ($P < 0.05$) amounts of PGC1α4, a PGC1a splice variant, in CR LM. The PGC1α4 target gene, *IGF-I*, was 40% lower ($P < 0.05$) in CR than CON. Downstream mediators of autocrine IGF-I signaling are attenuated in CR by comparison to CON. The amount of phosphorylated AKT was lower ($P < 0.05$) in CR than CON. However, activated components of the AKT/mTOR signaling axis, p70 S6 kinase, ERK1/2 and 4E-BP1, were equivalent or unaffected ($P > 0.05$) by CR. Activation of the energy sensor, AMP kinase, was not detected in either CON or CR lysates indicating that a block to mTOR-controlled protein synthesis is absent. Protein lysates from CR LM contained less ($P < 0.05$) total and phosphorylated, inactive GSK3β than CON LM. Elevated GSK3β activity is associated with inhibition of protein synthesis as well as induction of atrogin. Reverse transcription-qPCR demonstrated no differences ($P < 0.05$) in atrogin expression levels between CON and CR. These results indicate that CR suppresses a hypertrophic PGC1α4/IGF-I/AKT pathway in young heifer calves through an undiscovered mechanism.

Key Words: skeletal muscle, metabolism, IGF-I

T230 Use of ultrasound for assessment of muscle area and depth in postmortem preweaned Holstein calves.

Jessica H. Davis*[1], Heidi A. Rossow[1], and Chris M. Barker[2], [1]*Veterinary Medicine Teaching and Research Center, University of California, Davis, Tulare, CA,* [2]*Center for Vectorborne Diseases, University of California, Davis, Davis, CA.*

The prewean period is one of the most important stages of dairy calf development. A tool is needed to more accurately assess calf growth, specifically muscle development. The objective was to determine if ultrasound can be used to predict *longissimus dorsi* (ribeye) linear depth and *external carpi radialis* (front) and *semitendinosus* (hind) area in postmortem preweaned Holstein calves. Postmortem bull and heifer calves (n = 191, age 17.3 ± 20.67 d, body weight 37.9 ± 19.07 kg) were obtained from 2 calf ranches between April and July 2013. Ultrasound images of the ribeye, front, and hind muscles were collected using an Aloka 500V equipped with a 5-cm 7.5-MHz linear transducer. Ultrasound ribeye linear depth and front and hind areas were calculated using the Ultrasound Image Capture System. The ribeye was dissected and measured for linear depth. The front and hind muscles were dissected and the cross-sectional planes were traced onto transparency paper. The transparency paper was photocopied and individual paper muscle tracings were cut out and weighed. The weights of the paper muscle tracings were then converted to areas using the known area of a standard 8.5 × 11 inch paper. Means were calculated using PROC GLM in SAS (version 9.2). Mean dissected values for the ribeye, front, and hind muscles (1.65 ± 0.44 cm, 6.23 ± 1.83 cm^2, 9.05 ± 2.37 cm^2) were greater than the respective mean ultrasound values (1.46 ± 0.37 cm, 5.41 ± 1.49 cm^2, 8.60 ± 2.40 cm^2) indicating ultrasound underestimated the true linear depth and area values consistently. The relationship between the dissected and ultrasound measurements was tested using Pearson correlation coefficient (PROC CORR). Overall, there was a strong, positive relationship between both the dissected and ultrasound measurements for the ribeye ($r = 0.55$, $P < 0.01$), front ($r = 0.65$, $P < 0.01$), and hind muscle ($r = 0.80$, $P < 0.01$). The weight, age, and sex of the calf and the operator of the ultrasound may explain some of the variability not accounted for by the correlation coefficient. The *semitendinosus* muscle displayed the highest correlation coefficient and may be used in future studies to assess calf muscle growth and guide implementation of dynamic feeding changes on both dairy farms and calf ranches.

Key Words: ultrasound, dairy calf, muscle

T231 Increasing the metabolizable protein supply enhanced growth performance and humoral immune response of preconditioning beef steers.

Philipe Moriel[1], Luis Felipe Arelaro*[1], Matt Poore[2], Rodrigo Marques[3], and Reinaldo Cooke[3], [1]*North Carolina State University, Waynesville, NC,* [2]*North Carolina State University, Raleigh, NC,* [3]*Oregon State University, Burns, OR.*

We evaluated the effects of metabolizable protein (MP) supply on growth performance, and post-vaccination measurements of humoral immune response of beef steers. Angus steers (n = 36; 231 ± 21 kg; 184 ± 18 d) were weaned on d 0, stratified by weight and age on d 7, and randomly assigned into 1 of 18 drylot pens (2 steers/pen). Treatments were assigned to pens (6 pens/treatment), and consisted of isocaloric, corn silage-based diets formulated to provide 85, 100 or 115% of the daily MP requirements. Diets were offered at 2.1% of BW (DM basis) from d 7 to 49. Steers were vaccinated on d 21 and 35 with modified-live and killed vaccines (Select-Vac, Zoetis). Blood samples were collected from jugular vein on d 0, 21, 35 and 49 to determine the plasma cortisol concentrations, and serum titers against bovine viral diarrhea virus-1b (BVDV1b), infectious bovine rhinotracheitis (IBR) and *Mannheimia haemolytica* leukotoxin. Data were analyzed using GLIMMIX procedure of SAS, and pen(treatment) as random effect. Body weight differed only on d 49, and was greatest ($P \leq 0.05$) for 115MP, least for 85MP and intermediate ($P \geq 0.21$) for 100MP steers (297, 278 and 290 ± 7 kg, respectively). From d 7 to 49, 100MP and 115MP steers had similar ADG ($P = 0.13$), but both had greater ($P < 0.001$) ADG than 85MP steers (1.20, 1.35 and 0.83 ± 0.068 kg/d, respectively). Plasma cortisol concentrations were greater ($P \leq 0.03$) for 85MP vs. 100MP and 115MP steers on d 21 and 35. Serum BVDV1b titers were greatest ($P \leq 0.02$) for 115MP, and similar ($P = 0.37$) between 85 and 100MP steers (5.8, 3.7 and 3.0 ± 0.60 base 2 log, respectively). Mean serum *M. haemolytica* leukotoxin titers were greater ($P = 0.05$) for 85MP vs. 100MP and 115MP steers (3.12, 2.39 and 2.49 ± 0.21 ng/antibody bound, respectively). Hence, a 15% MP deficiency increased plasma cortisol, and both factors may have suppressed innate immune system leading to greater multiplication of endogenous *M. haemolytica* and a compensatory greater production of serum *M. haemolytica* leukotoxin titers. In contrast, 15% MP excess enhanced growth performance and increased serum BVDV1b titers of beef steers.

Key Words: metabolizable protein, steer, immune

T232 Characterization of key factors constraining lamb survival in marginal environments. Francisco A. Sales*[1], Sue A. McCoard[2], and Raúl J. Lira[1], [1]*Instituto de Investigaciones Agropecuarias, Punta Arenas, Chile,* [2]*AgResearch, Palmerston North, New Zealand.*

Sheep farming normally occurs in areas with limited vegetation. Climate change is placing more pressure on farming in these challenging environments. There is limited research on factors limiting lamb survival in marginal environments. The objective of this study was to characterize fetal and maternal factors associated with low (<80%) lamb survival in Patagonia. Corriedale ewes, synchronized, superovulated and mated to Suffolk rams and managed under commercial grazing conditions were used. Single- (n = 8) and twin-bearing (n = 8) ewes were euthanized at d 140 of gestation and mass of the fetal and placental components and ewe carcass traits were obtained. The effect of litter size (single vs twin) on maternal and fetal characteristics was analyzed using ANOVA. Maternal live weight was similar between twin- and single-bearing ewes (60.4 ± 1.6 vs 61.4 ± 1.6 kg, $P = 0.7$), while twin-bearing ewes had lower carcass weight compared with single-bearing ewes (18.9 ± 0.6 vs 20.7 ± 0.6 kg, $P = 0.05$), associated with a trend for reduced loin area (11.8 ± 0.7 vs 13.8 ± 0.7 kg, $P = 0.07$), but similar carcass fat depth (Fat GR: 4.5 ± 1.1 vs 4.12 ± 1.1 mm, $P = 0.8$; Fat C: 3.8 ± 0.6 vs 3.8 ± 0.6 mm, $P = 1.00$). Twin fetuses were lighter (3.24 ± 0.11 vs 4.18 ± 0.14 kg, $P < 0.01$), with proportionally lighter organ and leg muscle weight ($P < 0.05$), a tendency for less perirenal fat (9.15 ± 0.64 vs. 10.99 ± 0.78, $P = 0.07$) and disproportionately lighter adrenal glands ($P = 0.05$), *M. adductor* ($P = 0.02$) and *M. gluteus* ($P = 0.03$) compared with singletons. Total placentome weight (256.2 ± 10.6 vs 391.5 ± 14.9 g, $P < 0.01$) and number (49.6 ± 4.0 vs 75.6 ± 5.7, $P < 0.01$) were lower in twin- comparer to single-bearing ewes. Reduced placental mass and reduced fetal weight in twins compared with singletons is consistent with prior studies. The greater mobilization of skeletal muscle but not fat in twin-bearing ewes is likely a mechanism to enhance protein supply to the fetuses. Compared with studies in less marginal environments, the fetuses (both singles and twins) in this study had a higher percentage of perirenal fat (0.3% vs 0.2%), which may indicate an adaptive response, to enhance fetal survival.

Horse Species

T233 Velocity-related changes in stride variables of the intermediate gait of the Irish Draught horse of North America.

Molly Nicodemus*[1], Rachel Fletcher[1], and Jeannette Beranger[2], [1]*Mississippi State University, Mississippi State, MS,* [2]*Livestock Conservancy, Pittsboro, NC.*

Although originating as a farming breed having a gait derived from the bloodlines of the extinct ambling Irish Hobby horse, the Irish Draught horse today is bred to excel in the sport-horse industry. With around 500 in North America, the breed is on the Livestock Conservancy's (LC) watch list. Study objectives were to determine the relationship between trotting velocities and stride variables. Ten Irish Draught horses selected by the LC and Irish Draught Horse Society of North America were worked at a slow velocity (SV) and fast velocity (FV) at the trot (SV = 4.5 ± 0.2 m/s; FV = 5.2 ± 0.1 m/s). Frame-by-frame analysis using the Ariel Performance Analysis System was performed documenting hoof contact and lift-off for 10 strides for each horse at each velocity with stride variables given as a % of stride duration. Means (SD) were calculated and student's paired *t*-tests were performed ($P = 0.05$). Both velocities demonstrated a leaping diagonal footfall sequence with diagonal limb pairs at hoof contact and periods of bipedal support (FV = 79 ± 4, SV = 87 ± 3%). While neither velocity demonstrated a 4-beat rhythm at hoof contact, the diagonal limbs disassociated at lift-off (4 ± 1%) at the SV with the hind lifting first creating a period of forelimb unipedal support (9 ± 1%). Along with limb support and coupling of diagonal limbs, fore stance duration (FV = 41 ± 3, SV = 48 ± 1%), stride length (FV = 3.8 ± 0.1, SV = 3.2 ± 0.1 m/s), and length of suspension (FV = 21 ± 4, SV = 4 ± 2%) distinguished between velocities ($P < 0.05$). Stride duration (FV = 0.70 ± 0.01, SV = 0.74 ± 0.02 s) and rate (FV = 1.41 ± 0.02, SV = 1.37 ± 0.01 strides/sec) and hind stance duration (FV = 41 ± 4, SV = 43 ± 2%) remained consistent between velocities. The North American Irish Draught horse did not demonstrate an ambling gait at velocities measured. Nevertheless, pattern and timing of the disassociated limbs and resulting limb support are unique compared with breeds that are today used in the breeding of the Irish Draught horse such as the Thoroughbred and Warmblood, and thus, potentially reflecting gait characteristics of the extinct Irish Hobby horse.

Key Words: stride variable, trot, velocity

T234 Influence of fibrolytic enzymes and yeast addition in horse's diet on digestibility, blood chemistry and fecal coliform.

M. M. Y. Elghandour[1], A. E. Kholif[2], A. Z. M. Salem*[1], J. C. Vázquez Chagoyán[1], J. S. Martínez Castañeda[1], L. M. Camacho[3], R. Montes de Oca[1], and T. A. Morsy[2], [1]*Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma del Estado de México, Toluca, Estado De México, Mexico,* [2]*Dairy Science Department, National Research Centre, Giza, Egypt,* [3]*Unidad Académica de Medicina Veterinaria y Zootecnia, Universidad Autónoma de Guerrero, Altamirano, México.*

Improving fibrous feeds utilization ensures low consumption of high-starch grains and may reduce various pathologies. Fibrolytic enzymes (FE) like cellulase and xylanase, and yeast addition can improve fibrous feeds utilization. Therefore, the current study aimed to study the effect of FE (Exp. 1) and yeast (Exp. 2) on the utilization of diet with 11.2% CP and 51.1% NDF. Thirty-two mares of Quarter Horse (450-500 kg BW) were used in a complete randomize design for 15 d, with 10 d for adaptation and 5 d for samples collection. For Exp. 1, mares (n=16) were distributed onto 4 treatments to be fed on the basal diet without FE (control), or plus cellulase at 10 mL/mare/d (CELL), plus xylanase at 10 mL/mare/d (XYL), or plus mixture cellulase and xylanase at 5 ml of each enzyme/mare/d (CX). For Exp. 2, mares (n=16) were distributed onto 4 treatments to be fed on the basal diet without yeast (control), or fed the control diets plus Procreatin 7 (1.5×10^{10} cfu/g *S. cerevisiae*) at 15 g/mare/d (P7), plus Biocell F53 (2×10^{10} cfu/g *S. cerevisiae*) at 11 g/mare/d (F53), or plus Biosaf SC47 (1.5×10^{10} cfu/g *S. cerevisiae*) at 15 g/mare/d (SC47); yeast products were in powder form. Both of enzyme and yeast doses were mix with the 1 kg of concentrate diet at 0400 h. Mares were fed the concentrates twice daily at 0400 and 1600 h, while the forage of oat straw was offered ad libitum at 0500 and 1700 h. Acid insoluble ash concentrations in feed and fecal samples were used for digestibility determination. No effects for FE and yeast were obtained in blood alanine transaminase, aspartate aminotransferase, urea, creatinine, total protein and glucose. Addition of CELL, XYL and CX increased ($P = 0.001$) nutrient intakes from oat straw versus control. Moreover, CELL, XYL and CX increased ($P < 0.05$) digestibilities of DM, OM, NDF and ADF. Enzymes decreased ($P < 0.05$) concentration of fecal coliform. In the contrary, F53 increased nutrients intake of oat and nutrients digestibility ($P < 0.05$) without difference compared with other treatments. Yeast had no effect on fecal coliform concentration. It could be concluded that addition of FE at 10 mL/mare/d or addition of Biocell F53 at 11 g/mare/d improved feed intake and nutrients digestibility without affecting mare's blood parameters.

Key Words: enzyme, horse, yeast

T235 Changes in salivary IgA and nasopharyngeal leukocyte populations in response to prolonged head elevation.

Jill M. Bobel*, Megan R. Di-Lernia, Jeffrey R. Abbott, Maureen T. Long, and Lori K. Warren, *University of Florida, Gainesville, FL.*

Prolonged head elevation is thought to be a major contributor to the increased risk of respiratory disease associated with transportation in horses. Prior investigations have focused on immunological changes in the lower respiratory tract. The aim of this study was to characterize the response to head elevation in the upper respiratory tract. Twelve horses (mean ± SEM, 552 ± 10 kg; 11.5 ± 1.4 y) were tethered for 12 h with their heads elevated at a height of 1.5 m to induce physiological stress. While tied, horses had unlimited access to bermudagrass hay and were offered water every 2 h. Each horse underwent head elevation on 4 occasions, each separated by 30 d. When not tied, horses were maintained on pasture forage. Nasopharyngeal flush (NPF) and saliva samples were obtained before head elevation, immediately after (0 h), and 12, 24, and 72 h post head elevation. Mucus content and leukocyte populations were quantified in NPF and IgA was measured in saliva. Data were compared using mixed model ANOVA with repeated measures. NPF samples contained more mucus at 0 h post ($P < 0.02$) compared with pre-head tie samples. Percentage and number of neutrophils in NPF increased at 0 h post ($P < 0.0001$) and the number remained elevated through 72 h ($P = 0.04$). Lymphocytes, monocytes, and eosinophils in NPF increased in number ($P < 0.05$) but decreased in percent ($P < 0.05$) in response to head elevation. While the proportion of these cells normalized by 72 h, the numbers declined to levels lower than pre-head tie values. Percentage of CD8+ T cells and B cells in NPF were lower at 0 h post ($P < 0.05$) and returned to baseline by 12 h. Percentage of CD4+ and the ratio of CD4+ to CD8+ cells increased at 0 h post ($P < 0.01$) and remained elevated through 72 h ($P < 0.05$). Salivary IgA

increased at 0 h post ($P < 0.0001$), then decreased below baseline at 12 h post ($P < 0.0001$) and remained lower than pre-head elevation values through 72 h ($P < 0.05$). The immunological changes observed in the upper respiratory tract agree with those reported for lower tract, and highlight increased risk of disease following prolonged head elevation.

Key Words: immunosuppression, upper respiratory disease, horse

T236 Utilization of the equine SNP 70 beadchip in monitoring inbreeding and describing the genetic background in an Arab horse herd.

Mohammed Al Abri*[1], Samantha Brooks[2], and König von Borstel[3], [1]*Cornell University, Ithaca, NY,* [2]*University of Florida, Gainesville, FL,* [3]*Göttingen University, Göttingen, Germany.*

Horse breeders rely heavily on the accurate identification of individual ancestry through pedigrees. Errors in such pedigrees may inaccurately assign horses to false lineages or breed memberships, and can result in inaccurate estimates of inbreeding. Discrepancies in pedigree records can lead horse owners into making misguided purchasing and breeding decisions. Genome-wide SNP data provide a robust and precisely quantitative tool to resolve many lineage assignments and provide genomic measures of inbreeding values. The aim of this project was to pilot a comparison between pedigree and genomic relatedness measures. Here, we describe a herd of 36 pedigreed Egyptian Arabian horses genotyped using the Equine SNP70 (Geneseek, Inc.) Genomic inbreeding values and pair-wise relatedness between horses within the herd were estimated from the genotypic data. Pedigree derived inbreeding values were significantly correlated with the genomic inbreeding values across the population ($r = 0.44$, $P = 0.007$), although within an individual the 2 values could differ substantially. Genomic inbreeding values were also positively correlated with the year of birth ($r = 0.29$, $P = 0.086$), demonstrating a trend in inbreeding over the years. A multi-dimensional scaling analysis (MDS), a phylogenic analysis and a clustering analysis were preformed to compute the relationships between the horses and the results were compared with the pedigree information. These same analyses were also conducted for the herd among US, Polish, and Egyptian Arabian horses to examine their Arabian ancestry. The within herd analysis was successful in recapturing much of first-degree relationships, although more distant relationships were not entirly reconstructed. The herds' Egyptian lineage was successfully assigned among Arabian horse sub-groups. It can be concluded that genome-wide genotypes are good alternatives to compute inbreeding and verify the integrity of pedigrees in horses in cases where records are unavailable or in doubt. Although costly, application of this tool in a breeding program can enable informed mating decisions and assess inbreeding in lines of horse already at risk of loosing genomic diversity.

Key Words: Arabian horse, pedigree inbreeding, genomic inbreeding

T237 Evaluation of single nucleotide polymorphisms effects on injury predisposition in a population of multi-discipline athletically trained horses.

Sarah Mercer[1], Neely Walker[2], and Matthew Garcia*[1,2], [1]*Louisiana State University, Baton Rouge, LA,* [2]*LSU AgCenter, Baton Rouge, LA.*

Tendon and ligament injuries (TLIs) in the performance horse represent a significant burden to the equine industry. Furthermore, treatment is often unsuccessful and re-injury common, prevention of TLIs is a major goal. The objective of the current study was to evaluate a population of athletically trained horses from multiple disciplines for SNP located 5 candidate genes in association with increased injury predisposition or injury resistance. A total population of 63 performance horses with documented injury history or injury resistance was utilized for the current study. Specifically, the study was comprised of 25 horses of various ages with at least one injury and 33 horses of various ages with no injury history. A 5mL blood sample collected from all horses via jugular venipuncture and DNA was subsequently extracted from white blood cell buffy coats for SNP genotyping. The 5 candidate genes selected for evaluation included the Angiotensin 1 converter enzyme gene (ACE), the ATPase α 2 peptide gene (ATP1A2) the Bradykinin receptor B2 gene (BDKRB2), the Collagen type 1 α 1 gene (COL1A1) and the Collagen type 5 α 1 gene (COL5A1). Candidate genes in the current study have been previously reported to be associated with jumping ability (ACE), racing ability (ATP1A2), and ligament and tendon injuries (BDKRB2, COL1A1 and COL5A1). A total of 64 single nucleotide polymorphisms (SNP) were selected across all candidate genes (ACE = 11, ATP1A2 = 14, BDKRB2 = 9, COL1A1 = 14, COL5A1 = 16). A mixed model analysis was utilized for the current data set with independent variables of sex, breed, age, discipline, training start age, first competition age, first age of injury, and number of years in competition. Independent effects included injury status (injured or not injured) and inherited SNP genotype for each unique SNP located on the previously described candidate genes. Although multiple SNP were identified in the current study as being associated with injury susceptibility/resistance, these SNP and a greater number of candidate genes must be evaluated in larger more diverse populations before implementation into selection strategies.

Key Words: equine, injury, SNP

T238 Effect of oil supplementation on milk IgG, serum insulin, glucose, placental efficiency, and immune status of foals.

Lauren B. Hodge*, Brian J. Rude, Caleb O. Lemley, and Toree L. Bova, *Mississippi State University, Starkville, MS.*

The objective of this research was to evaluate the effects of supplementing pregnant mares with omega-3 fatty acids and how this may affect the suckling foal. Pregnant mares ($n = 18$) were randomly assigned to 1 of 3 diets beginning 28 d before their expected foaling date until 84 d after foaling. Diet 1 was a commercial feed fed to meet NRC requirements, based on forage analysis; diet 2 was diet 1 plus a blended fish oil; and diet 3 was diet 1 plus a blend of fish and soybean oil. Blood samples were collected 28 d before their expected foaling date, and at 14 d increments. Placental efficiency was calculated as a ratio of placenta weight:foal weight. Milk samples were obtained at foaling and on remaining blood collection days. Body weights were recorded the same day blood samples were collected. Placentas were weighed and ~5 g sample taken. No differences were found for mare plasma IgG ($P = 0.1318$), serum insulin ($P = 0.3886$), plasma glucose ($P = 0.2407$), or milk IgG ($P = 0.1262$) concentrations for treatment or time period of sampling. Mare packed cell were not different ($P = 0.0885$) among treatments; however, decreased ($P < 0.0001$) as the trial progressed. Mare body weight and body weight change were not different ($P = 0.5704$; $P = 0.08265$, respectively) among treatments, or relative to time of sampling. Mare body weight change did differ ($P < 0.0001$) relative to time. Foal plasma IgG ($P = 0.2767$), serum insulin ($P = 0.4843$), or plasma glucose ($P = 0.1204$) were not affected by treatment or time of collection. Foal packed cell was not different ($P = 0.6275$) among treatments, however, there was a difference ($P = 0.0005$) relative to time of sampling. Foal body weight change and total gain were not different among treatments ($P = 0.6825$; $P = 0.8220$, respectively); however foal body weight were least ($P = 0.0041$) for foals consuming diet 1 and greatest for foals consuming diet 3, with foals consuming diet 2 being intermediate. Foal body weight change decreased as the trial progressed ($P < 0.0001$). Placental efficiency and nitrites were not different ($P =$

0.1631; $P = 0.5604$, respectively) among treatments. Research should be conducted to evaluate supplementation earlier in gestation.

Key Words: horse nutrition, fat, supplementation

T239 Testis tissue explant culture supports the viability of equine spermatogonial stem cells.

Kyle C. Caires*[1], Louie Y. Chen[2], Rachel A. Lemcke[1], and Laurie A. Seigler[1], [1]*Berry College, Department of Animal Sciences, Mount Berry, GA,* [2]*RDBL, National Institute of Environmental Health Sciences, National Institutes of Health, Research Triangle Park, NC.*

Spermatogenesis is a stem-cell dependent process that supplies an indefinite supply of spermatozoa during adult male life. Sperm production is well characterized in rodents and depends on a milieu of endocrine and growth factors, but little is known regarding the regulation of male fertility and spermatogonial stem cells (SSC) in other domestic animals. The objective of the present study was to develop an organ culture system to investigate spermatogenesis in horses. To accomplish this aim we obtained testicular parenchyma from pre- and post-pubertal stallions (n = 3 for each age group) and cultured those tissues upon 0.4-μm membranes in XC medium (DMEM supplemented with 1-, 5- and 10% fetal bovine serum) over a weeklong period with alternate-day media changes. All data sets were evaluated using ANOVA and differences between means were considered significant at $P < 0.05$. Immunohistochemical analysis of *PLZF*, *GFRA1*, and *DDX4* expression were used to confirm the identity of undifferentiated spermatogonia, differentiated spermatogonia and meiotic germ cells, whereas *GATA4* was used as a marker for Sertoli cell and Leydig cell populations. Histological analysis of fresh and cultured testis tissue indicates the survival of germ-line stem cells and somatic cells populations within morphologically normal seminiferous tubules at 24, 48, and 72 h during the culture period with different levels of serum. Sertoli cell and Leydig cell populations remained stable ($P > 0.05$) throughout the culture period, but the appearance of pyknotic nuclei in germ and somatic cells observed following 120 h of culture indicates limitations of our approach for long-term tissue maintenance, and this notion is confirmed by TUNEL analysis of apoptosis. Investigating the effect of specific growth factor and hormone treatment combinations on the biological activity and stem cell behavior of undifferentiated spermatogonia is ongoing. Collectively, these results demonstrate successful culture of equine spermatogonial stem cells, and provide a useful ex-vivo model for investigating spermatogenesis in stallions without the costs typically associated with whole-animal experimentation.

Key Words: equine testis, stem cells, spermatogonial stem cells

T240 Valerenic acid detection in equine urine after administration of calming supplement.

Celina M. Checura*[1], Nikki McGreevey[1], Travis J. De Wolfe[1], Simon F. Peek[1], Greg A. Barrett-Wilt[1], Richard G. Godbee[2], and Benjamin J. Darien[1], [1]*University WI-Madison, Madison, WI,* [2]*Central Garden & Pet, Phoenix, AZ.*

Valerian root (*Valeriana officinalis*) is an herbal tranquilizer used in horses. However, many plants and herbs are classified as forbidden by the USEF Equine Drugs and Medications Rule due to their potential to affect performance. The aim of this study was to establish a reliable withdrawal period before competition for trainers considering valerenic acid supplements as a training aid. Ten mares between 10 and 20 years of age were administered an oral paste of valerian root extract (36 mg) daily for 5 consecutive days. Urine samples were collected by sterile catheterization before the first and all subsequent treatments. Urine was also collected at 4, 8, 24, 48, and 72 h after the last treatment. Urine samples were coded for blinding and stored at 4°C until testing. Valerenic acid in urine was analyzed using a triple-quadrupole mass spectrometer coupled to an Agilent 1100 capillary HPLC system. Quantitation of urine valerenic acid was done by generating a calibration curve using the peak areas of 3 replicate injections for each calibration point. Two different calibration curves for quantitation of valerenic acid in urine were created. One curve was generated by spiking valerenic acid at 0 (blank), 25, 50, 100, 200, and 400 ng/mL into known blank urine before protein precipitation and solid-phase extraction. A second curve was generated for later samples by pooling 2 mL from each of 4 blank urine samples and then adding valerenic acid as described. Regression analysis of a representative calibration curve generated from these standards yielded a linearity of $R^2 = 0.9969$. Based on the signal-to-noise ratio of the 25 ng/mL calibration standard, the limit of quantitation was estimated at 20 ng/mL. From a total of 90 post-valerenic acid treatment urine samples, 3 samples were positive. Urine samples obtained from one horse was positive for valerenic acid on d 2 (21 ng/mL) and 3 (29.5 ng/mL) of treatment. A different mare tested positive (67.8 ng/mL) 4 h after the last dosage (d 5). Based on our results, horses should be withdrawn from competition for at least 5 d after the oral administration of 36 mg valerenic root extract.

Key Words: valerian, herbal, tranquilizer

T241 Influence of α-linolenic acid supplementation in mature horses at maintenance: Body composition.

Jessica L. Leatherwood*[1], Emily D. Lamprecht[2], Mark J. Anderson[1], Kyle J. Stutts[1], Marcy M. Beverly[1], and Stanley F. Kelley[1], [1]*Sam Houston State University, Huntsville, TX,* [2]*Cargill Incorporated, Elk River, MN.*

Twenty mature horses (455 to 457 kg and 5 to 10 yr) were utilized in a randomized complete block design to evaluate incorporation of α-linolenic acid into plasma and the effects of supplementation on performance variables in mature horses. Horses were blocked by BW, age, and sex and randomly assigned to treatment within block for a 112 d trial. Dietary treatments included control (no α-linolenic acid; CON) or 150 mg/kg BW/d α-linolenic acid (ALA) derived from a flaxseed oil (TRT; Clear Valley Omega 3 Oil; Cargill, Inc., Eddyville, IA). Diets consisted of CON horses (n = 10) fed 0.25% BW (as-fed) concentrate only or TRT horses fed (n = 10) the same concentrate with additional ALA offered at 12 h intervals. Horses were housed by block and maintained in adjacent dry lots with ad libitium access to coastal Bermudagrass (Cynodon dactylon) hay. Body weight and BCS were obtained every 14 d and concentrate was adjusted accordingly. Rump fat (RF), longissimus dorsi area (LD), and longissimus dorsi fat thickness (LDF) were obtained every 28 d via ultrasonography. Blood samples were collected on d 0, 56, and 112 to determine plasma fatty acid concentrations by gas chromatography. Data were analyzed using the PROC MIXED procedure of SAS. Fatty acid levels in the oil supplement remained stable over the course of the trial. Plasma concentrations of ALA were greater ($P \leq 0.01$), and plasma levels of arachidonic acid were lower ($P \leq 0.01$) in TRT compared with CON beginning at d 56 to d 112 of the study. Body weight and BCS were not influenced ($P = 0.96$ and $P = 0.14$, respectively) by dietary treatment; however, all horses gained BW and BCS throughout the trial ($P \leq 0.01$). Rump fat, LD and LDF were not influenced ($P \geq 0.54$) by dietary supplementation although, performance variables increased ($P \leq 0.01$) over time across treatments. These results indicate that this source of ALA is stable and will incorporate into circulation through targeted supplementation; however, further studies are needed to fully elucidate effects of dietary ALA supplementation to mature horses.

Key Words: equine, α-linolenic acid, longissimus dorsi

T242 In vitro evaluation of protein content on forage digestion using equine fecal inocula.

Tayler L. Hansen*, Brooke M. Eubanks, Emily K. Rizzo, and Lori K. Warren, *University of Florida, Gainesville, FL.*

Previous research has indicated crude protein (CP) and neutral detergent fiber (NDF) concentrations are related to forage digestibility by horses. However, it is unclear if greater CP concentrations are simply correlated with higher quality forage or if CP amounts influence digestion and microbial fermentation in the hindgut by increasing nitrogen substrates to cellulolytic bacteria. The objective of this study was to determine the influence of varying amounts of CP on forage digestibility using an in vitro hindgut fermentation model. We hypothesized increasing CP presence would increase in vitro dry matter digestibility (IVDMD), NDF digestibility (NDFD), and acid detergent fiber digestibility (ADFD). Quadruplicate 0.5 g forage samples (alfalfa, bermudagrass, and orchardgrass) and cellulose (Sigma-Aldrich) were incubated at 37.5°C for 48 h in an ANKOM DaisyII Incubator. Casein (Sigma-Aldrich) was added to the digestion jars at 1 of 4 levels (no added casein, 66.1, 125.9, and 188.8 g) to represent control, NRC CP recommendations, industry-typical diets, and 3× NRC recommendations, after adjusting for 51% prececal CP digestibility. Freshly voided fecal samples were collected on 4 separate days from mature horses with ad libitum access to bermudagrass hay to serve as microbial inoculum for DaisyII runs (n = 4). Data were analyzed using ANOVA (SAS, v 9.3) as a split-plot design with the main plot as casein level and subplot as forage type with an error term of casein level × block. Means were separated using LSD comparisons. In vitro DMD decreased ($P < 0.0001$) as added casein increased. Control IVDMD across all forage types (47.5 ± 9.6%, mean ± SE) was greater than ($P < 0.05$) IVDMD for all added casein treatments (30.7 ± 13.0, 32.3 ± 13.6, 28.0 ± 11.2%, as casein level increased). Both NDFD and ADFD were greater ($P < 0.0001$) in control compared with casein-added treatments. In vitro DMD, NDFD, and ADFD differed ($P < 0.0001$) by forage type. Casein as a protein source may have affected results with this closed-system in vitro model. Further evaluations are needed to determine the relationship between protein in the equine hindgut and fiber digestion in vivo.

Key Words: DaisyII, fiber, horse

T243 Changes in plasma calcium and phosphorus concentrations in mares fed decreasing amounts of dietary Ca and P just prior to weaning.

Ashley L. Fowler*, Brittany E. Harlow, Morgan B. Pyles, Susan H. Hayes, Andrea D. Crum, and Laurie M. Lawrence, *University of Kentucky, Lexington, KY.*

During lactation, the concentrations of Ca and P in milk are highly conserved, frequently at the expense of bone mineral. Replacement of bone mobilized during lactation and dietary changes in the post- weaning period may further alter Ca and P metabolism, but it is unknown if these changes influence the ability to achieve Ca and P homeostasis. The objective of this study was to examine changes in plasma Ca and P in lactating mares fed decreasing amounts of Ca and P just before weaning. Four mares in late lactation (12 ± 5.7 yr; 527 ± 26 kg) were transitioned to a diet containing Ca and P in amounts appropriate for nonlactating mares for 14 d, weaned and then maintained on the same diet for 7 d. Four nonlactating mares (11 ± 4 yr; 552 ± 33 kg) received the same diet and served as the controls. We hypothesized that low mineral intake during late lactation would stimulate bone resorption (increasing blood Ca and P) and that in the post-weaning period there would be bone deposition (decreasing blood Ca and P). Blood samples for P and Ca analysis were obtained 14 d before weaning (dietary Ca and P equal to or exceeding requirements), at 2 d before, and 7 d after weaning (dietary Ca and P adequate for nonlactating mares). Saliva samples were taken 7 d post-weaning for P analysis. Data were analyzed using ANOVA with repeated measures with group (lactating or nonlactating) and sample date as main effects. Plasma P increased from baseline to pre-weaning ($P < 0.05$) across groups and did not change further post-weaning. The increase in plasma P at 2 d pre-weaning might reflect an increase in bone resorption as a result of decreasing amounts of dietary P, but a decrease in plasma P 7 d post-weaning was not observed. Salivary P was not different between groups post-weaning. Plasma Ca decreased from baseline to pre-weaning ($P = 0.053$) across groups, but did not change further post-weaning. The Ca:P ratio in the blood decreased from 3.7:1 at baseline to 2.8:1 at pre-weaning ($P < 0.05$). From these data, it appears that changes in Ca and P intakes influence blood Ca and P more than the physiological change of lactation cessation.

Key Words: horse, lactation, mineral

T244 Relationship between training difficulty and aggression in horses.

M. J. Anderson*, J. L. Leatherwood, K. Jones, K. J. Stutts, M. M. Beverly, and S. F. Kelley, *Sam Houston State University, Huntsville, TX.*

Training of horses involves a balance of trust and dominance between animal and trainer. Yet in a herd, horses will establish a social hierarchy, which lends to antagonistic behaviors. The objective of this research was to characterize behavior and interactions between horses and determine the implications on the trainability of the horse by trainers of varying skill levels. To accomplish this test, horses (n = 10) from the Sam Houston State University behavior and training course were randomly selected and individually introduced in 9.14-m round pens to control horses (n = 5) over a 2-wk period. The interaction between the horses was recorded by 3 independent observers and scored on a 15 cm line scale ranging from submissive (1) to aggressive (15). Horses were individually worked by one of 5 trainers of varying skill levels. Activities included ground work only, and maneuvers began with haltering and leading to advanced maneuvering through obstacle courses. Horses were blindly scored by the same 3 observers using a 15 cm line scale ranging from obedient (1) to resistant (15). Horses were then placed into 2 groups (Difficult, Easy) based on average difficulty of training, and the aggression scores were compared across the 2 groups using the PROC GLM procedure in SAS 9.2. Correlations were calculated between the average aggression and training scores for all test horses. Results from the training scores showed a difference ($P < 0.01$) between the 2 selected groups, indicating that the separation of the groups was valid. However, no difference was detected ($P = 0.22$) in aggression scores between the Difficult and Easy training groups. This illustrates that the aggression of a horse in a herd or in establishing a social order may not be a good indicator of the difficultly to subsequently train the horse. This is further demonstrated in the weak correlation (r = 0.408) between the average aggression and training scores for the test horses. While in establishing social order aggression may be observed, but it is not the sole factor in determining dominance in a herd. Most likely the trait of dominance may be more important in terms of trainability than aggression and should be the focus of future behavior research.

Key Words: horse, behavior, training

T245 The occurrence of different mycotoxins (aflatoxins, fumonisins, zearalnenone, ochratoxin, deoxynivalenol, ergot alkaloids) in horse feed.

Nicole Reisinger*[1], Paula Kovalsky[2], Verena Starkl[2], Simone Schaumberger[2], Michael Sulyok[3], and Ursula

Hofstetter[2], [1]*Biomin Research Center, Tulln, Austria,* [2]*Biomin Holding GmbH, Herzogenburg, Austria,* [3]*Center for Analytical Chemistry, Department for Agrobiotechnology (IFA-Tulln), University of Natural Resources and Life Sciences (BOKU), Tulln, Austria.*

Mycotoxins are toxic secondary metabolites of fungi, which can be found in cereal grains and animal feeds. The occurrence of mycotoxins in feed of livestock animals is well investigated. In contrast, only limited information is available on the occurrence of mycotoxins in horse feed as well as on their effects on horse health. The aim of this study investigate the occurrence of the mycotoxins aflatoxins (Afla), fumonisins (FUM), zearalenone (ZEN), ochratoxin A (OTA), deoxynivalenol (DON) and ergot alkaloids in horse feed in Europe. Hay, straw and concentrate feed samples (n = 135) were collected from different countries of Europe in 2014. Samples were analyzed by liquid chromatography – tandem mass spectrometry (Streit et al., 2013). In total, mycotoxins could be found in 83% of all tested samples. Ergot alkaloids (e.g., ergotamine, festuclavine) were detected in 63% of the samples and therefore represented the most frequently occurring mycotoxin in our survey. In the individual samples, concentrations up to 1,230 µg/kg were determined. In addition, a high prevalence of DON (60%) and ZEN (54%) was observed. Maximum concentrations of 3,800 µg/kg and 200 µg/kg were measured for DON and ZEN, respectively. FUM was detected in 16% of the feed samples, maximum concentration measured was 330 µg/kg. In contrast, Afla (1.5%) and OTA (3%) were detectable in only a few of the feed samples. Results of this study clearly show that mycotoxins are frequent contaminants of horse feed, although usually only high quality feed is given to horses. There are only scattered reports on the effects of mycotoxins on horses. However, it is known that horses are extremely sensitive to FUM (Caloni et al., 2011) and also negative effects of ZEN have been reported (Minervini et al., 2006). Furthermore, ergot alkaloids are described to induce dystocia, agalactia and lameness in horses (Cross et al., 1995; Douthit et al., 2012). Therefore, an effective mycotoxin risk management program can help to protect horses against negative effects of mycotoxins.

Key Words: horse, equine, mycotoxins

T246 Effectiveness of a brewer's yeast supplement with or without fat for performance horses.

Jeneva R. Seidl*[1], Toree L. Bova[1], J. Latham Brister[1], Lauren B. Hodge[1], Angela R. Mays[2], and Brian J. Rude[1], [1]*Mississippi State University, Starkville, MS,* [2]*F.L. Emmert Company, Cincinnati, OH.*

The objective of the current trial was to evaluate the effect of additional fat to a brewer's yeast supplement on hoof, coat, and body condition of performance horses. Twelve performance geldings randomly allotted to one of 3 dietary treatments: 1) a commercially available horse feed (10% CP, 4.5% fat) at 0.9% BW/d; 2) diet 1 plus a brewer's yeast product at 113g/d; 3) diet 2 plus vegetable oil at 5% of the diet. Diet 1 was given to meet basic nutrient requirements of 10% CP and 0.6% LYS. All geldings were fed half of their diet treatment twice a day for 84 d. Geldings had ad libitum access to bermudagrass pasture and hay throughout the trial. Body weight (BW) measurements and body evaluations were collected at initiation of the trial and every subsequent 28 d until 84 d. Body evaluations included coat condition, body condition score (BCS), and hoof condition. Coat and hoof condition were evaluated on scale ranging from 1 to 5 (1 reflecting poor or damaged and 5 reflecting glossy) accounting for condition, texture and appearance. Body condition was based on the standard BCS scale of 1 to 9. Four total evaluations were taken during the experiment, an initial evaluation and then every 28 d. Data were subjected to ANOVA using the GLM procedures of SAS. No effect of diet was found for hoof (3.5, 3.4, and 3.1; $P = 0.6207$), coat (3.3, 3.3, and 3.3; $P = 0.0826$), or BCS (5.3, 5.6, and 5.6; $P = 0.9967$) for diets 1, 2, and 3, respectively. Body weights were not different (509, 524, and 560 kg; $P = 0.4602$) among diets 1, 2, and 3, respectively, nor was the change in body weight during the trial different (1.9, −6.8, and 4.5 kg, respectively; $P = 0.6815$). Addition of fat to brewer's yeast supplement did not enhance body scores or weight change. Diet 1 (basal diet fed to all treatments) was a concentrate based supplement containing a large amount of available energy. Feeding diet 1 at 0.9% BW/d may have masked the effects of increased energy from fat. Further research should be conducted to evaluate brewer's yeast product and fat with horses while being fed a less nutritious basal diet.

Key Words: equine, brewer's yeast, fat supplementation

T247 Effectiveness of a brewer's yeast supplement with or without fat for weanling horses.

J. Latham Brister*[1], Toree L. Bova[1], Jeneva R. Seidl[1], Lauren B. Hodge[1], Angela R. Mays[2], and Brian J. Rude[1], [1]*Mississippi State University, Starkville, MS,* [2]*F.L. Emmert Company, Cincinnati, OH.*

The objective of this study was to evaluate the effect of additional fat to a brewer's yeast supplement on hoof, coat, and body condition of weanling horses. Twelve Quarter Horse weanlings (7 colts and 5 fillies) were utilized in an 84 d feeding trial using 3 dietary treatments: 1) a commercially available horse feed (10% CP, 4.5% fat) at 0.9% BW; 2) diet 1 plus a brewer's yeast product at 113g/d; 3) diet 2 plus vegetable oil at 5% of the diet. Weanlings were fed half of their ration twice daily (0600 and 1800 h) with all 3 treatments receiving the diet 1 portion of their treatment at 0.9% BW/d, to meet NRC requirements based on forage analysis. Body weight (BW) measurements and body evaluations were collected at initiation of the trial and every subsequent 28 d until 84 d. Body evaluations included coat condition, BCS, and hoof condition. Coat and hoof condition were evaluated on a scale ranging from 1 to 5 (1 reflecting poor or damaged and 5 reflecting glossy), with coat evaluation scale accounting for condition, texture, and appearance. Body condition score was based on the standard BCS scale of 1 to 9. During the first 7 d post weaning, weanlings were divided into groups of 3 (1 weanling randomly assigned to each treatment) and housed together in open lot to reduce stress. Weaned groups were offered ad libitum access to hay and water while introduced to the diet 1 portion of their dietary treatment. Diets were determined as a percent of the weanling's BW, which was adjusted every 28 d. Weanlings were also provided ad libitum access to grass, bermudagrass hay, and water. Data were analyzed through ANOVA using the GLM procedures of SAS. As expected, BW increased throughout the trial for all 3 treatments. After 28 d foals on diet 2 and 3 had increased BW ($P = 0.0102$; 211 and 207 kg, respectively) compared with foals on diet 1 (194 kg). There were no differences for BCS ($P = 0.2768$), coat score ($P = 0.3243$), or hoof score ($P = 0.5014$). Supplementation with brewer's yeast increased BW gains, but additional fat did not affect horses on the concentrate diet. In conclusion, added fat did not increase brewer's yeast affects in weanling horses.

Key Words: equine, brewer's yeast, fat supplementation

International Animal Agriculture

T248 Proposal for standard methods and procedure for guinea pig carcass evaluation, jointing, and tissue separation. Davinia Sánchez-Macías*[1], Noemi Castro[2], Miguel Rivero[3], Anastasio Argüello[2], and Antonio Morales-delaNuez[4], [1]*Department of Agro-industrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Chimborazo, Ecuador,* [2]*Animal Science Department, Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain,* [3]*Department of Veterinary Histology and Pathology, Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain,* [4]*Facultad de Ciencia Pecuarias, Escuela Superior Politécnica de Chimborazo, Riobamba, Chimborazo, Ecuador.*

The South American guinea pig rodent has become a livestock animal acceptable for human consumption in different parts of the world. Its white meat has a great potential as a new protein source, and its social and economic importance for different human populations is considered key for development. Scarce data are found in the literature when the statistical livestock information is checked, and few researches have been done about morphological characteristics of guinea pigs carcasses. These works do not follow the same procedures, using different criteria, overall the jointing, making it difficult to compare different studies. The aim of the present study is to suggest a practical and normalized method to analyze the guinea pig carcass characteristics allowing their evaluation. It describes the main traits to be considered from the birth of the animal to the carcass analysis. This work concerns (1) growth, feeding, pre-slaughter and slaughter processing, (2) method for the definition, hanging and presentation of the carcass, (3) carcass morphological characteristics, (4) jointing procedure based on 4 anatomically defined regions, (5) methods for 20 evaluating meat pH and color and (6) method for tissue separation. This proposal could be useful to compare data of these animals under different conditions.

Key Words: guinea pig, carcass, jointing

T249 Cow-calf production performance under different management systems in Thailand. Jirayut Khemsawat[1], Skorn Koonawootrittriron*[1], Thanathip Suwanasopee[1], and Mauricio A. Elzo[2], [1]*Kasetsart University, Bangkok, Thailand,* [2]*University of Florida, Gainesville, FL.*

The numbers of beef cattle and cow-calf producers in Thailand are decreasing every year due to a sharp increase in demand and high prices offered for all types of cattle by neighboring countries. To help evaluate the extent of this problem, an assessment of the current status of cow-calf production in Thailand is needed. Thus, the objective of this study was to compare the cow-calf production performance and profitability in 3 regions of Thailand (UN = upper Northeast region; LN = lower Northeast region, CT = Central region). The factors considered were number of cows per farm, paddock size, number of laborers, birth weight, weaning weight, sale age, calving interval, costs and profits. Data for these factors were gathered from 501 cow-calf producers (130 producers in UN, 341 producers in LN, and 30 producers in CT) using questionnaires, interviews, visits, and seminars. Means and SD were used to describe factors. Least squares means (LSM) for all factors in each region were computed using a linear model that included region (UN, LN, CT) and farm size (small: less than 10 cows; medium: 11 to 20 cows; large: more than 20 cows) as fixed effects, and residual as a random effect. Cow-calf producers had from 7.7 (UN) to 12.9 (CT) cows per farm, paddock size ranged from 1.3 (UN) to 2.1 (CN) ha, and hired 1.9 (LN) to 2.2 (UN) laborers for their operations. Calf birth weights ranged from 24.3 (UN) to 29.9 (CT) kg, weaning weights ranged from 151.9 (LN) to 193.4 (CT) kg, weaning ages from 7.8 (CT) to 8.6 (UN) mo, and sale ages ranged from 11.7 (CT) to 13.5 (LN) mo. Calving intervals were from 12.6 (LN) to 13.7 (UN) mo. Factor LSM differed among regions ($P < 0.05$), except for weaning age, sale age and calving interval. Cow-calf producers in CT had higher profits and lower costs than UN and LN ($P < 0.05$). These results suggested the need for different cow-calf production strategies would need to be implemented in each Thai region improve productivity and profitability in a sustainable manner.

Key Words: cattle, cow-calf production, cost

T250 Chemical composition, physical parameters and cholesterol status of fertile and unfertile eggs from chicken and quail birds. Patience Olusola Fakolade*, *Osun State University, Ejigbo, Osun State, Nigeria.*

A study to compare the chemical composition, physical parameters and cholesterol status of fertile and unfertile eggs from chicken and quail bird was evaluated. One hundred twenty Harco black and 120 Japanese quail birds were used for the study. Birds were fed with compounded feeds and divided into 2 groups, group A had 60 birds each from chicken and quail to produce unfertile eggs while group B had 55 hen and 5 cocks each from chicken and quail, to produce fertile eggs. All the birds were subjected to appropriate vaccination and medication procedures. Both eggs (fertile and unfertile) were evaluated for their variations in chemical composition, physical status and cholesterol levels in a 3 × 3 factorial design. Results for chemical composition, showed that, unfertile chicken eggs had highest significant values ($P < 0.05$) of (Ca, P, Na, Zn, Fe and K), than for fertile chicken eggs, unfertile quail eggs, and fertile quail eggs. The fertile quail eggs had significant higher value for (Na, Zn and Fe) but lower value for (Ca, P, and K) than the unfertile eggs. In this study, the physical characteristics measured followed the same trend as that of the chemical composition except for the shell weight and yolk color. Quail eggs for both fertile and unfertile eggs had lowest significant value ($P < 0.05$) for cholesterol (10 mg/100 g and 36.49 mg/100 g) and viscosity level (16.20 mL/s and 28.90 mL/s), than for chicken eggs with (1150 mg/100 g and 1291.20 mg/100 g) and the viscosity level had (55.60 mL/s and 69.20 mL/s). Quail eggs had lower cholesterol level than chicken eggs and as such could be incorporated into human diet to increase protein intake and reduces cholesterol accumulation in the diet, through consumption of egg.

Key Words: chicken egg, quail egg, fertile egg

T251 Correlation between the guinea pig tissue composition and carcass measurements. Iván Barba[1], Lida Barba*[1,2], César Hernández[1], Julio Palmay[1], Nibaldo Rodríguez[2], and Davinia Sánchez Macías[1], [1]*Department of Agroindustrial Engineering. Universidad Nacional de Chimborazo, Riobamba, Chimborazo, Ecuador,* [2]*School of Informatics Engineering. Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile.*

Combining carcass measurements, such as weights, conformation and fat classes and carcass dimensions would lead to moderate predictions of muscle, fat or bone content in carcass. A correlation analysis of these parameters is necessary to build up potential prediction equations. This study was performed to establish correlations between guinea pig carcass composition and measurements. The carcasses of 40 guinea pigs, males and females of 3 and 12 mo age (fattening and discarded animals, respectively) with similar management previous to slaughter were used. Seventeen measurements consistent in weight, yield, and the length of carcass pieces were analyzed to identify the major correlation with the 9 variables of tissue composition. The tissue composition is represented as subcutaneous fat (SF), intermuscular fat (IF), muscle (M), bone (B), skin (S), waste (W), and 3 combined variables SF-IF, B-W, and muscle plus freeze loss (M-FL). In all the cases, an important positive correlation with live weight at slaughter (LWS), empty body weight (EBW), hot carcass weight (HCW), and cold carcass weight (CCW) was found. The variables related to fat were highly correlated with the measurement perirenal and pelvic fat (PPF). The linear measurements internal carcass length (L), external carcass length (ECL), lumbar circumference (LC), and thorax circumference (ThC) showed high correlation with the tissue composition variables that are not related to fat. The major correlation was found in the relation M-LWS, M-EBW, M-HCW, M-CCW with a Pearson Coefficient of R = 95%, followed by the relation S-LWS, S-EBW, S-HCW, S-CCW with R = 94%. Some measurements that are not correlated with any variable are hid limb length (F), buttock width (BW), and thorax width (ThW).

Key Words: guinea pig, carcass composition, correlation

T252 Prediction of guinea pig carcass tissue composition from weight and linear normalized measurements.

Lida Barba*[1,2], Iván Barba[1], Julio Palmay[1], César Hernández[1], Nibaldo Rodríguez[2], and Davinia Sánchez Macías[1], [1]*Department of Agroindustrial Engineering. Universidad Nacional de Chimborazo, Riobamba, Chimborazo, Ecuador,* [2]*School of Informatics Engineering. Pontificia Universidad Católica de Valparaíso, Valparaíso, Chile.*

The evaluation of carcass composition makes possible to assign a value for the carcass. It is possible to predict carcass composition by measurements taken on the carcass: weights, carcass yield, fatness, conformation and other non-invasive methods. The use of these measurements offers an advantage over joint dissection, as they are faster and easier to make and do not involve any loss of carcass tissue. The aim of this work is to develop equations to predict the tissue composition of guinea pig carcasses, by using weight, yield and linear measurements. The data were obtained after a practical and normalized method to measure the guinea pig carcass, based on anatomical guidelines. The carcass measurements of 40 South American Guinea pigs, males and females of 3 and 12 mo age (fattening and discarded animals, respectively) were used for multiple regression analysis; which was implemented from the correlation matrix of dependent and independent variables and the significance test. The independent variables or predictors used were live weight at slaughter (LWS), hot carcass weight (HCW), perirenal and pelvic fat (PPF), external carcass length (ECL), and thorax circumference (ThC). The accuracy of the predictions was evaluated with root mean square error (RMSE) and coefficient of determination (R^2). The prediction equations for carcass composition in grams were more accurate than those related to composition proportion. In the prediction of some variables in grams such as total muscle (TM), skin (S) and muscle + freeze-thawing loss (MpFL) were obtained values of $R^2 = 95\%$, for total bone (TB) was obtained an $R^2 = 90\%$, and for subcutaneous fat (SF) and total fat (TF) were obtained $R^2 = 78\%$ and 76%, respectively. Lean (or muscle) and fatness are both the most important commercial components of a carcass. In this case, PPF was a good predictor for guinea pig carcass fatness, whereas HCW and ThC were good predictors of lean content.

Key Words: guinea pig, carcass composition, prediction

T253 Comparison between a method based upon the anatomical structure and a method based upon standardized butchering practice of guinea pig carcass.

Julio Palmay[1], César Hernández[1], Iván Barba[1], Roberto Remache[1], Antonio Morales de la Nuez[2], Anastasio Argüello[3], Noemí Castro[3], and Davinia Sánchez Macías*[1], [1]*Department of Agroindustrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Chimborazo, Ecuador,* [2]*Facultad de Ciencia Pecuarias, Escuela Superior Politécnica de Chimborazo, Riobamba, Chimborazo, Ecuador,* [3]*Animal Science Department, Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain.*

A diversity of methods for jointing meat animal carcasses exists in the literature and in the technical regulations in different countries. Standardized methods with good repeatability are needed for researching works. The objective of this work is to determine a representative cut for tissue carcass composition of guinea pig from 2 different jointing methods. Forty guinea pig carcasses were selected: 20 from 3-mo-age fattening animals (10 males and 10 females) and 20 from 12-mo-age breeding discarded animals (10 males and 10 females). Each carcass was divided into 2 half carcasses; the right half carcass was jointed in 2 cuts following a technical standard commercial regulation from Peru (forequarter and hindquarter), and the left half carcass was jointed in 4 cuts following anatomical points (neck, shoulder, hind leg and ribs). Each cut was dissected in skin, muscle, sub-cutaneous fat, inter-muscular fat, waste and bone. Total fat was calculated as the sum of sub-cutaneous and inter-muscular fat, inedible section as the sum of bones and remainder, and muscle + freeze-thawing loss. All results are presented in proportion to the cut. A factorial ANOVA procedure was used with the statistical program SAS (v. 11), for each tissue comparing the different cuts and total tissue in the carcass, and second, the effect of the animal group. In some animal groups, the neck differed from the carcass in terms of proportion for sub-cutaneous and inter-muscular fat tissues, total fat and bones. On the other hand, the muscle proportion in the hindquarter cut in 12 mo-age female guinea pigs was higher respect to the muscle proportion in the whole carcass. The other studied cuts were similar in terms of proportions of the different tissues respect to the whole carcass composition. However, it is noted that the closest cut to the tissue composition of the guinea pig carcass, in percentage values, was the hind leg cut. We conclude that the most representative cut of guinea pig carcass is the hind leg, and thus the jointing method proposed in 4 cuts is the most appropriated for these animals.

Key Words: carcass tissue composition, guinea pig, jointing

T254 Carcass tissue composition in fattening or discarded guinea pigs.

Julio Palmay[1], Iván Barba[1], César Hernández[1], Erick Ureña[1], Antonio Morales de la Nuez[2], Noemí Castro[3], Anastasio Argüello[3], and Davinia Sánchez Macías*[1], [1]*Department of Agroindustrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Chimborazo, Ecuador,* [2]*Facultad de Ciencia Pecuarias, Escuela Superior Politécnica de Chimborazo, Riobamba, Chimborazo, Ecuador,* [3]*Animal Science Department, Universidad de las Palmas de Gran Canaria, Arucas, Las Palmas, Spain.*

The development of tissue composition during growth may be reflected in the carcass tissue composition due to age at slaughter and sex. For this reason, the aim of this work is to analyze the carcass composition in 6 different carcass cuts, in males and females fattening or discarded guinea pigs. Forty guinea pig carcasses were selected: 20 from 3-mo-age fattening animals (10 males and 10 females) and 20 from 12-mo-age breeding discarded animals (10 males and 10 females). Each carcass was divided into 2 half carcasses; the right half carcass was jointed in 2 cuts following a technical standard commercial regulation from Peru (forequarter and hindquarter), and the left half carcass was jointed in 4 cuts following anatomical points (neck, shoulder, hind leg and ribs). Each cut was dissected in skin, muscle, sub-cutaneous fat, inter-muscular fat, waste and bone. Total fat was calculated as the sum of sub-cutaneous and inter-muscular fat, inedible section as the sum of bones and remainder, and muscle + freeze-thawing loss. All results are presented in tissue weights of the cut or whole carcass. A factorial ANOVA procedure was used with the statistical program SAS (v. 11), comparing among the different cuts, and analyzing the effect of age and sex. For the whole carcass composition, 3 mo-age guinea pigs showed the lowest fat content and female 12 mo-age animals the highest value. For muscle, bones, skin and waste, 12 mo-age guinea pigs had higher values in carcass than the younger animals, and no differences were found due to the sex. Into the 4 cuts jointing method, long leg and ribs cuts had the higher values of fat, muscle, bones and skin, while ribs presented the highest waste content. And into the commercial jointing method, the forequarter showed the highest contents of all the analyzed tissues. We conclude that tissue composition in the whole carcass is different in fattening or discarded guinea pigs, except for the fat content, in this case, 3 mo-age females have similar values than discarded guinea pigs.

Key Words: carcass tissue composition, guinea pig, jointing

T255 Substitution of commercial concentrate by mulberry forage (*Morus alba* 'Linn') in the ration of fattening tropical Pelibuey lambs.

Andrés Alpízar-Naranjo[1], Javier Arece-García[2], Marcos Esperance[2], Yoel López[1], Michael Molina[2], and Eliel González-García*[3], *[1]Escuela de Ciencias Agrarias, Facultad de Ciencias de la Tierra y el Mar, Universidad Nacional de Costa Rica, Heredia, Costa Rica, [2]Estación Experimental de Pastos y Forrajes "Indio Hatuey," Matanzas, Cuba, [3]INRA UMR868, Systèmes d'Elevage Méditerranéens et Tropicaux (SELMET), Montpellier Cedex 2, France.*

The effects of substituting concentrate by chopped and fresh home-ground mulberry forage were evaluated in an experiment with fattening lambs lasting 126 d from weaning. The basal forage diet was composed by *Pennisetum purpureum*, *Panicum maximun* 'Likoni' and sugarcane. Forty-eight entire Pelibuey lambs (initial BW 20.6 kg) were randomly allocated in 4 experimental groups according to treatments which consisted on the level of supplementing (or not) the basal diet with mulberry forage: M-1: mulberry at 1% of BW (DM basis); M-0.75: mulberry at 0.75% plus 0.1 kg/lamb/d of concentrate; M-0.50: mulberry at 0.50% plus 0.2 kg of concentrate; and M-0: supplementing basal diet with 0.3 kg of concentrate (Control). Average daily gain (ADG, g/d) was significantly affected ($P < 0.01$) by the supplementation regimen with M-1 lambs yielding the lowest ADG (100.2 g/d). No differences in ADG among the other groups were observed (124.7; 125.4 and 128.9 g/d for the treatments M-0.75, M-0.50 and M-0, respectively). Feed conversion was 11.6, 9.9, 10.3 and 9.7 kg DM/ kg of BW gain for M-1, M-0.75, M-0.50 and M-0 lambs, respectively. Differences in final BW at slaughtering and hot or cold carcass yields were coherent with those found in growth performance. Supplementing with mulberry forage at 0.75% of BW was the feeding alternative showing the best productive response. Results are shown in Table 1.

Table 1 (Abstr. T255). Performance data

Item	Diet				SEM
	M-1	M-0.75	M-0.50	M-0	
Initial BW, kg	20.5	20.7	20.7	20.7	0.38
Final BW, kg	29.6^{b}	32.2^{a}	32.3^{a}	32.8^{a}	0.57
BW change, kg	9.1^{b}	11.5^{a}	11.6^{a}	12.1^{a}	—
ADG, g/lamb/d	100.2^{b}	124.7^{a}	125.4^{a}	128.9^{a}	3.08
Total feed intake, g DM/lamb/d	835.8^{b}	908.2^{a}	953.7^{a}	930.0^{a}	7.0
Average feed intake, g DM/kg BW	33.4	34.3	36.0	34.8	—
Average feed intake, g DM/kg BW$^{0.75}$	74.6	77.9	81.7	79.1	—
Feed conversion, kg DM/kg BW gain	11.6^{a}	9.9^{c}	10.28^{b}	9.70^{c}	—
Hot carcass weight, kg	11.5^{b}	13.3^{ab}	13.5^{a}	13.7^{a}	0.30
Cold carcass weight, kg	11.2^{b}	13.0^{ab}	13.2^{a}	12.8^{ab}	0.28

T256 Carcass quality of guinea pigs: Sex effect on fattening or discarded animals.

César Hernández[1], Iván Barba[1], Julio Palmay[1], Lisbeth Medina[1], Antonio Morales de la Nuez[2], Noemí Castro[3], Anastasio Argüello[3], and Davinia Sánchez Macías*[1], *[1]Department of Agroindustrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Chimborazo, Ecuador, [2]Facultad de Ciencia Pecuarias, Escuela Superior Politécnica de Chimborazo, Riobamba, Chimborazo, Ecuador, [3]Animal Science Department, Universidad de las Palmas de Gran Canaria, Arucas, Las Palmas, Spain.*

Guinea pigs are used for meat production in South America, Africa, and Asia. The increased interest in this product is due to the low production price, and because of their relatively rapid reproduction and the large litter size. The objective of the present study was to evaluate the effect of age and sex on weight, yield, drip loss and pH evolution in guinea pig carcasses. Forty guinea pigs (10 male and 10 female of 3 mo age, and 10 male and 10 female of 12 mo age discarded animals) were used. The animals were fasted during 14 h before slaughter. Live weight at slaughter (LWS), empty body weight (EBW), and hot and cold carcass weights (HCW and CCW) were recorded. pH evolution was measured at 15, 45 min and 24 h after slaughter in *Longissimus dorsi* (LD) and *Psoas major* (PM) muscles. Four different carcass yields and drip loss (in grams and percentage) were calculated. Twelve mo-age animals showed higher LWS, EBW, HCW and CCW than 3 mo-age guinea pigs. The lowest values of hot or cold carcass yields (HCY, CCY) were observed in 3 mo-age male guinea pigs and no differences were found among the other groups. CCY was lower than HCY in all cases, due to the drip loss during the chilling time (24h at 4°C). When yields were presented related to empty body weight, the values were higher than the yields that used live weight at slaughter, as expected. Discarded animals had higher drip losses, but expressed in percentage, 3 mo-age females had the highest losses, while the 12 mo guinea pigs showed the lowest losses. pH declined significantly during 24h in both muscles and all the animals, with the exception of 12 mo-age female guinea pigs. At 15 and 45 min LD did not show differences due to sex or age. After 24h, 12 mo-age females had the highest pH values (6.37) and 3 mo-age females had the lowest (5.54). When pH in PM was analyzed, the results revealed different behavior than LD. At 15 min and 24 h, 12 mo females presented the lowest pH (6.29 and 6.30, 15 min and 24 h, respectively), while the in the other groups pH ranged from 6.70 to 6.44 at 15 min, and was near to 6 after 24h postmortem.

Key Words: carcass quality, sex, guinea pig

T257 Comparison of linear carcass measurements in male or female fattening and discarded guinea pigs.

César Hernández[1], Julio Palmay[1], Iván Barba[1], Jairo Espinoza[1], Antonio Morales de la Nuez[2], Noemí Castro[3], Anastasio Argüello[3], and Davinia Sánchez Macías*[1], [1]*Department of Agroindustrial Engineering, Universidad Nacional de Chimborazo, Riobamba, Chimborazo, Ecuador,* [2]*Facultad de Ciencia Pecuarias, Escuela Superior Politécnica de Chimborazo, Riobamba, Chimborazo, Ecuador,* [3]*Animal Science Department, Universidad de las Palmas de Gran Canaria, Arucas, Las Palmas, Spain.*

Linear carcass measurements (LCM) are important variable of carcass quality. Several studies describe a relationship between LCMs and body live weight and other parameters of carcass and meat quality in different species. Guinea pigs are an important source of protein in numerous undeveloped countries and currently they are introducing in developed countries. The present study analyzes the effect of sex and fattening or discarded guinea pigs on LCMs carcass. Forty guinea pig carcasses after 24 h of chilling were selected: 20 from 3months-age fattening animals (10 males and 10 females) and 20 from 12 mo-age breeding discarded animals (10 males and 10 females). The following measurements in carcasses after chilling for 24 h at 4°C were recorded: carcass length (L), loin length (Lo), hind limb length (F), width of the buttocks (G), lumbar circumference (LC), thorax circumference (ThC) and thorax width (ThW). Furthermore carcass compactness (CarC) and leg compactness (LegC) were calculated. L, Lo, LC and ThC were higher in 12 mo-age than 3 mo-age guinea pigs. Sex did not affect the described measurements, and G values were similar (7 cm) in all studied animals. F was higher in 12 mo-age males (12 cm), while 3 mo-age females showed the smaller value (9 cm). There was a sex effect on F for 12 mo animals, being higher in males than in females (12 *vs* 10 cm, respectively). When CarC was analyzed an age effect was evident in 12 mo-age animals, which showed 40g cm-1 of carcass weight vs 25–30g cm-1 for the 3 mo-age guinea pigs. So, after 3 mo the animals not only increased their length, but they also increased their body mass. Sex had an important effect on LegC of fattening guinea pigs: males had higher values than females (67% and 55%, respectively). However, in discarded guinea pigs, males showed smaller compactness than females (50% and 60%, respectively).

Key Words: linear carcass measurement, carcass quality, guinea pig

T258 Fatty acid composition of fats from female and male muskoxen (*Ovibos moschatus)* living in western Greenland.

Susana P. Alves[1], Angelo Cabo[1], Katrine Raundrup[2], Rui J. B. Bessa[1], and André M. de Almeida*[3], [1]*CIISA/FMV - Centro Interdisciplinar de Investigação em Sanidade Animal, Faculdade de Medicina Veterinária, Universidade de Lisboa, Lisboa, Portugal,* [2]*Greenland Institute of Natural Resources, Nuuk, Greenland,* [3]*Instituto de Biologia Experimental e Tecnológica, Oeiras, Portugal,*

Muskoxen (*Ovibos moschatus*) are large ruminants living in Arctic habitats, and their diet is usually dominated by grasses, sedges and dicots. Muskoxen have an exceptional ability to fatten during spring and summer to support their energy needs during the arctic winter. However, little is known about the fatty acid (FA) composition of muskox meat, adipose tissue and liver. The objective of this study is to characterize the FA composition in samples from muskox females and males from Western Greenland. Muskox samples (muscle, adipose tissue and liver) from adult female (n = 12) and male (n = 8) were collected around Kangerlussuaq (West Greenland) during the winter hunting season of 2014. Samples were freeze-dried and lipids were extracted using dichloromethane and methanol (2:1, v/v). Total lipids were measured gravimetrically. Fatty acid methyl esters (FAME) were prepared from the lipid extracts with sodium methoxide in methanol followed by hydrochloric acid in methanol. FAME were quantified by GC-FID using a Shimadzu GC-2010 Plus (Shimadzu, Kyoto, Japan) equipped with a TR-CN100 capillary column (100 m, 0.25 mm i.d., 0.20 µm film thickness, Teknokroma, Spain). FAME were expressed as g/100 g of total peaks and data were analyzed using the PROC MIXED of SAS (SAS Institute Inc., Cary, NC) with a model that included the sex (female vs. male) as the single effect. Muskox muscle, adipose tissue and liver contained about 396, 916 and 150 mg/g DM of total lipids, respectively. Females showed the highest fat content ($P = 0.046$) compared with males, which might be an additional energy reserve for the late-winter lactation. More than 60 FA were detected in muskoxen samples, however, the 18:1*cis*-9 was the dominant FA in muscle and adipose tissue, presenting more than 43% and 32% of total FA, respectively. The great oleic acid concentration in muskoxen fats might indicate a higher lipogenic activity in these animals. Differences between sexes on the FA composition were minor in liver and more pronounced in adipose tissues. In general, males presented more levels of branched-chain FA, while female presented more oleic acid.

Key Words: musk ox, fatty acid profile

T259 Body condition score, subcutaneous fat and reproductive performance relationship in *Bos indicus* cows in a tropical region of Mexico.

Ivette Rubio, Victoria Blas, Manuel D. Corro*, Clara Murcia, and Carlos S. Galina, *Faculty of Veterinary Medicine and Zootechnics National Autonomous University of Mexico, Mexico, DF, Mexico.*

With the aim of evaluate the relationship between body condition, subcutaneous fat and reproductive performance in *Bos indicus* cattle in the Mexican tropics. Sixty multiparous cows were selected, with an average of 186.5 ± 90.8 d postpartum, synchronized with intravaginal device with natural progesterone. Body condition (BCS) scale 1–9, subcutaneous body fat (BF) by ultrasonography and live weight (LW) were measurement at 3 different times during a 90 d breeding period in all cows. The BF was defined as the subcutaneous layer of fat between the skin and fascia of the *longisimus dorsi* muscle and measured between the 2nd and 3rd spinous of the lumbar vertebrae. We assessed the level of progesterone blood at the beginning of the breeding season. The cows were grouped, according to the BCS, group1 (n = 25) cows with less than 4.5 and group 2 (n = 35) more than 4.5. An ANOVA was used to determine the differences between BCS, BF and LW. A linear correlation was performed to assess the association between BCS, BF and LW. At the beginning of the breeding season a larger ($P < 0.05$) proportion of cows in group 2 were cycling, and responded to synchronization than those in group 1. BF was higher ($P < 0.05$) in group 2 than group 1, 0.995 ± 0.091mm and 0.847 ± 0.114 mm, respectively. Although, there was a moderate positive relationship between BCS and BF, BCS can be a predictor of fat thickness as an indicator of body energy stored to maintain reproductive function. Because of this, Bos indicus cows with higher BF, at beginning of breeding season, would have a greater chance to become pregnant by the end of breeding season.

Key Words: body condition, subcutaneous fat, reproduction

T260 Effects of diet type and a yeast product in performance, nutrient digestibility, intestinal morphology, carcass composition and visceral organ mass by guinea pigs.

Andres E. Idrobo, Karina M. Boada, Patricia X. Falconi, and Christian H. Ponce*, *Departamento de Ciencias de la Vida y Agricultura, Universidad de las fuerzas Armadas ESPE, Sangolqui, Ecuador.*

An experiment was conducted to evaluate the effects of a yeast culture/enzymatically hydrolyzed yeast product (Celmanax; Varied Industries Corp. Inc., Mason City, IA) and a diet type on performance, nutrient digestibility, intestinal morphology, carcass composition and visceral organ mass by guinea pigs. Eighty-eight guinea pigs (initial BW = 453.21 g ± 21.90 g) were group fed in 24 pens during a 69 d feeding period. Treatments were arranged in a 2 × 2 factorial and included a concentrate diet (C) or a mixture of forage and concentrate diet (M) and supplementation of Celmanax (Ce, 0 or 0.1% of diet DM). No type of diet × addition of Ce interactions were detected in any variable measured ($P \geq 0.157$). Animals fed the M treatment had greater CMS, ADG, and improved G:F during the feeding period ($P < 0.001$). Supplementation of Ce had greater CMS and improved G:F during the first 49 d of the experiment ($P \leq 0.048$). However, overall performance was not altered by Ce supplementation ($P \geq 0.247$). Fat digestibility was greater for C ($P < 0.001$), and crude fiber digestibility was decreased ($P = 0.004$) compared with M. Nutrient digestibilities were not altered by Ce supplementation ($P \geq 0.285$). Feeding M increased dressing percent, empty body weight, fractional mass of: liver, large intestine, portal drained viscera, and total splanchnic tissue ($P \leq 0.019$) compared with C. Carcass characteristics and visceral organ mas were not altered by Ce supplementation. Fatty acid profile from adipose tissue was not different across treatments ($P \geq 0.053$). The relation between n-3:n-6 fatty acids was greater for animal fed M compared with C ($P = 0.019$). Villus height and crypt depth were increased by Ce supplementation ($P \leq 0.019$). Animals fed M diet had greater crypt depth ($P = 0.05$). Results indicate that feeding a mixture of forage and a concentrate diet results in positive effects in performance and carcass characteristics, and supplementation of Celmanax may have positive effects on performance and intestinal characteristics under both feeding regimens.

Key Words: diet type, guinea pig, yeast product

T261 Energy flow analysis on dairy farms in North Carolina and Malawi.

Shalimbala Chizonda* and Jonathan C. Allen, *North Carolina State University, Raleigh, NC.*

Milk production in developing and tropical countries is subject to different constraints than in the US. Even large, advanced dairies in Malawi have different inputs of energy and materials to optimize their milk output compared with moderate sized dairy farms in the US The objective of this study was to compare energetic inputs, outputs, and efficiencies of dairy farms in Malawi (southeast Africa) and North Carolina to assess sustainable milk production. Feed consumption and milk production data were collected from Katete Dairy herd in Lilongwe, Malawi, consisting of 408 cattle with 108 lactating cows, and the NCSU Dairy Research and Teaching Farm, housing 245 Holstein and 55 Jersey cows and 170 lactating cows. Both are teaching farms that employ extensive record keeping. Milk production averaged 34 and 19.5 kg/cow/day at NCSU and Katete, respectively. Feed energy intake was 85.8 Mcal/cow/d at NCSU and 135 Mcal/cow/d at Katete. Thus, return of feed energy as milk energy was 24.7% efficient at NCSU and 11.3% efficient in the lower producing cows at Katete. Manure is recycled for crop production at Katete, and is processed with a solids separation and lagoon system at NCSU. Additional factors that impact the overall farm efficiencies include inputs of petroleum fuels and electricity, and the number of calves, heifers and dry cows fed. The project identifies factors in dairy production that should be considered to improve efficiency, sustainability, and milk supply. Both farms had a substantial portion of the energy fed to the cows lost to the environment as composted manure in soils or lagoons that did not capture the heat or methane generated.

T262 Nestlé China Dairy Farming Institute: Development of collaborative, science-based, practical, sustainable courses.

Karen Nielsen*, Pamela Ruegg, and David Combs, *University of Wisconsin, Madison, WI.*

The Chinese dairy industry has expanded rapidly as the growing middle class demands higher protein diets. However, because there were not many dairy farms in China's traditional agricultural system, few farmers and farm managers have the knowledge and experience to run dairy farms using modern, science-based practices. To improve dairy science knowledge, Nestlé opened a comprehensive, collaborative, science-based Dairy Farming Institute (DFI) in 2014 that includes farms, laboratories, classrooms, living quarters, offices, and cafeteria in Shuangcheng, Heilongjiang Province, in northeastern China. The University of Wisconsin-Madison was chosen to lead DFI course development. Faculty, staff and affiliates of the UW-Madison work on all elements of curriculum design, program planning, establishment of learning objectives and core competencies, and evaluation of training programs and trainers. Courses are developed by teams of UW subject matter experts, industry partners and DFI trainers, and include instruction at basic, intermediate, and advanced levels for farm workers, supervisors and managers, and for dairy professionals such as veterinarians and nutritionists. Courses developed are practical, hands-on, and science-based with a goal of consistency in content, evaluation, and excellence in course delivery. Courses are offered many times and the trainers delivering the lectures, and leading the group case study work and hands-on activities in the barns or laboratories may be different from one course to the next. Therefore, materials must include clear instructions for future trainers and train the trainer sessions are provided before every new course. New trainers are evaluated, suggestions and advice are provided, and those who receive favorable evaluations continue to teach the DFI courses, making the program sustainable. Participating DFI partners include Alltech, Alta Genetics, Avery Weigh-Tronix, Boehringer Ingelheim, Eastrock, Elanco, Foester Technik, GEA, Goke/Storti, IFCN, Land O'Lakes, SCR, Zoetis, and Northeast Agricultural University in Harbin.

Key Words: dairy course development, university-industry partnerships

Lactation Biology II

T263 Risk factors for undergoing lactations >15 months in high-producing Holstein cows in a hot environment. Jessica María Flores-Salas*[1] and Miguel Mellado[2], *[1]Universidad Autonoma Agraria Antonio Narro Unidad Laguna, Torreón, Coahuila, México, [2]Universidad Autonoma Agraria Antonio Narro, Saltillo, Coahuila, México.*

An epidemiological study of risk factors for involuntary extended lactations (15 to 40 mo) using a multiple variable logistic regression was carried out on 3278 high-yielding dairy cows in an intensive well-managed Hostein herd, milked 3 times daily in northern Mexico. Additional objectives were to assess the association of lactation length (15 to 40 mo) with milk yield and to assess the effect of multiple services (4 to $\geq$14) on pregnancy per artificial insemination. Also, a survival analysis was performed using the Cox proportional hazards model to test how the occurrence of pregnancy affects lactation length. Retained placenta (odds ratio (OR) = 1.3), metritis (OR = 1.8), ketosis (OR = 1.4), peak milk yield (<50 vs > 50 kg, OR = 1.4), temperature-humidity index at 60 d postpartum (<82 vs > 82 units, OR = 1.4), and 305-d milk yield (<11,000 vs > 11,000 kg, OR = 1.6) significantly increased the risk for lactations > 15 mo. Primiparous cows had less than half the risk of extended lactations (OR = 0.3) compared with multiparous cows. Once a cow had conceived, her risk of having a prolonged lactation dropped sharply ($P < 0.01$). A strong linear association was found between lactation length and total milk yield for primiparous (450 to 1349 d in milk, maximum milk yield 37,852 kg; r = 0.71) and pluriparous (450 to 1221 d in milk, maximum milk yield 38,021 kg; r = 0.75). Pregnancy per artificial insemination (P/AI) in cows with extended lactation decreased linearly as number of services increased (P/AI = 50.5% for 4 services and 12.8% for $\geq$14 services). The data showed that well-managed Holstein cows milked 3 times daily were capable of lactating up to 40 mo with remarkable high persistency and with high milk yield at dry-off. Additionally, this study supports previous findings indicating that reproductive and metabolic disorders associated with calving are important risk factors for extended lactations, derived from the link of periparturient diseases withdepressed reproduction in dairy cows.

Key Words: milk production, hot environment, extended lactations

T264 Enhanced pre-weaning nutrition stimulates mammary gland development in dairy heifer calves. Adam J. Geiger*[1], Robert E. James[1], Catherine L. Parsons[1], Anthony V. Capuco[2], and Robert M. Akers[1], *[1]Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, VA, [2]United States Department of Agriculture-Agricultural Research Service, Beltsville, MD.*

It is established that feeding heifers a high plane of nutrition post-weaning but before puberty negatively affects mammary gland (MG) development and milk yield. The mass of the MG parenchyma (PAR) increases up to 60-fold from birth until 3 mo of age. Interestingly, enhanced nutrition during this time (pre-weaning) does not appear to negatively affect MG development and may in fact be beneficial. Therefore, the objectives of this study were to clarify the effects of feeding a higher plane of nutrition pre-weaning to Holstein heifer calves on MG growth, and particularly PAR and fat pad (MFP) development. Thirty-six Holstein heifer calves (<1 wk old) were reared on 1 of 2 dietary treatments to create 2 physiologically diverse groups of animals. Diets included (1) a control milk replacer (MR) fed at 454 g powder per day (CON; 20% crude protein [CP], 20% fat), or (2) an accelerated MR fed at 1,135 g powder per day (ACC; 28% CP, 25% fat). Milk replacer mixed at 15% solids was fed as indicated until the 8th week when feeding was reduced 50% to induce weaning. Calves were housed individually with ad libitum access to water. Starter feeding was initiated at wk 5 and balanced between treatments. Udders were examined visually and by palpation with teats measured weekly. At weaning, a subset of calves were killed (n = 6/diet). Whole MG were removed, dissected, and weighed. ACC calves consumed more MR liquid pre-weaning (4575 vs 3199 mL MR/day; $P < 0.01$). At wk 8, ACC calves had longer front (1.3 vs 0.9 cm; $P < 0.01$) and rear (1.2 vs 0.8 cm; $P < 0.01$) teats. Whole untrimmed udders of ACC-fed calves were heavier (255 vs 66 g; $P < 0.01$). Differences were more pronounced after skin was trimmed (198 vs 38 g; $P < 0.01$). Dissected PAR and MFP were both greater for ACC calves (10.5 vs 1.4 g and 173 vs 29 g, respectively; $P < 0.01$). Overall differences remained if expressed on a body weight basis ($P \leq 0.05$). Results provide compelling evidence that pre-weaning nutrition markedly affects MG development in dairy calves. Efforts in our lab are underway to uncover the cellular and molecular mechanisms responsible for these differences.

Key Words: mammary gland, milk replacer, parenchyma

T265 Bovine, caprine and ovine serotonin receptors expression in the mammary gland during lactating and dry off by immunohistochemistry. Aridany Suarez-Trujillo*[1], Miguel A. Rivero[2], Anastasio Argüello[1], Juan Capote[3], and Noemi Castro[1], *[1]Department of Animal Science, Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain, [2]Department of Morphology, Universidad de Las Palmas de Gran Canaria, Arucas, Las Palmas, Spain, [3]Canarian Agronomic Science Institute, La Laguna, Tenerife, Spain.*

Serotonin (5-HT) functions as a feedback inhibitor of lactation. This action is mediated by 5-HT receptors (5-HTR). In situ hybridization studies showed 5-HTR subtypes are expressed in bovine mammary epithelial and myoepithelial cells as well as blood vessels, and vary by receptor subtype. The aim of this study was to determine the distribution of the 5-HTR subtypes (1B, 1E, 2A, 2B, 4 and 7) in cattle, goat and sheep mammary glands using immunohistochemistry, and to compare distribution among lactating and dry udders. Hypothalamus and mammary gland samples were taken at slaughter from 3 lactating and 3 nonlactating animals of each species. Hypothalamal tissue was used as positive control. Tissues were fixed, paraffin embedded and 5-μm sections were placed on slides. Immunohistochemical staining was performed using rabbit primary antibodies against 5-HTR for the 1B, 1E, 2A, 2B, 4 and 7 subtypes. Anti-rabbit secondary antibody was conjugated with streptavidin peroxidase, and visualization of binding was realized using diaminobenzidine substrate. Tissues were counterstained with hematoxylin. Myoepithelial cells were identified in serial sections by positive immunohistochemical staining for calponin. All 6 receptor subtypes were expressed in mammary epithelial cells in the 3 species studied. Furthermore, 5-HTR 1E was expressed in the myoepithelial cells in all 3 species, and in the blood vessels of cows. Receptor subtype 4 was found in myoepithelial cells of cows and sheep. In all 3 species blood vessels were positively stained for receptors 1B, 2A and 2B. In the lactating animals, receptor distribution in the mammary epithelial cells was cytoplasmatic. However, in mammary tissue from nonlactating animals, distribution changed to the apical membrane in all species. In conclusion, 5-HTR are expressed in epithelial, myoepithelial and blood vessels within mammary tissue of cattle, sheep and goats, with distribution of subtype varying by cell-type and species. Furthermore, distribution of the receptors on mammary epithelial cells changes between lactating and nonlactating states.

Key Words: serotonin receptors, mammary gland, immunohistochemistry

T266 Effect of the supplementation of a functional additive in prepartal cows of two breeds on the level of IgG in colostrum.

Angela Moreno and Claudia Ariza-Nieto*, *Corporacion Colombiana de Investigacion Agropecuaria CORPOICA, Bogota, Colombia.*

The purpose of this study was to estimate the effect of supplementation of a functional additive during the last third of gestation in cows on the level of IgG in colostrum. Twenty-eight (28) Holstein and White Orejinegro (WON) cows were assigned to a randomized complete block design with 2 factors (breed and supplementation) with repeated measures (i.e., days of lactation). The supplementation factor included 3 treatments: CTL) Control without supplementation, S0) Supplement without additive, S1) Supplement with additive. Colostrum samples were obtained during the first 3 d of lactation for the determination of crude protein (CP), immunoglobulin G (IgG) and Brix grades. A correlation analysis between Brix grades an IgG was performed. Concentrations of IgG determined by the ELISA technique were strongly correlated with the percentages of Brix grades (n = 82, r = 0.954, $P < 0.0001$), indicating that it can be used as an estimate of the concentration of IgG. The concentration of crude protein in colostrum was affected by the breed × day interaction ($P < 0.05$), it was lower in WON cows (10.3%) than Holstein cows (11.5%) on d 1, whereas on d 2 and 3 WON cows had greater concentrations of protein (5.9% and 6.5%, respectively) compared with Holstein cows (4.8% and 4.1%, respectively). There was a breed × day × supplementation interaction on colostral IgG ($P < 0.05$). On d 1, S1 cows of both Holstein (55.1 mg/mL) and WON breeds (47.3 mg/mL) had greater concentrations of colostral IgG than CTL Holstein (44.4 mg/mL) and WON (32.5 mg/mL) cows. The decrease in colostral IgG from d 1 to d 3 was greater in Holstein (95%) than in WON (86%) cows. It can be concluded that dietary supplementation with functional additives increased the colostral concentration of IgG in both cow breeds.

Key Words: feed additive, cow, colostrum

T267 The effects of cabergoline administration at dry-off of lactating cows on udder engorgement, milk leakages, lying behavior, and udder health at calving.

Alex Bach*[1,3], Naomi Isaka[2], Audrey Deflandre[2], and Anna Arís[3], [1]*ICREA (Institució Catalana de Recerca i Estudis Avançats), Barcelona, Spain,* [2]*CEVA Santé Animale, Libourne, France,* [3]*Department of Ruminant Production-IRTA, Caldes de Montbui, Spain.*

Cabergoline is an ergot-derivative with high affinity for the D_2 dopamine receptors whose dopaminergic effects cause inhibition of prolactin (PRL) secretion, and thus it could be considered a molecule that acts as a potential dry-off facilitator. One hundred ninety-nine Holstein cows (102 primiparous; 97 multiparous) producing ≥ 18 kg/d at dry-off were split in 2 treatments with the objective of evaluating the effects of cabergoline at dry-off (between 70 and 50 d before the expecting calving date) on PRL secretion, udder engorgement, milk leakages, udder health at calving, and cow wellbeing after dry-off. Treatments consisted of a single i.m. injection of 5 mL of a solution containing 5.6 mg of cabergoline (CAB) or 5 mL of saline solution as a placebo (CTRL). Each animal was evaluated for presence or absence of milk leakages during the 4 d following drying-off and udder engorgement determined using a digital algometer. Lying behavior was recorded during 10 d after drying-off. Twenty-five cows from each treatment were randomly chosen and blood sampled at 3 and 15 d after dry-off and at 5 and 3 d before the expected calving date to determine serum PRL concentrations. Data were analyzed using a mixed-effects model for repeated measures. Cows on CTRL had greater ($P < 0.05$) serum PRL concentrations than cows on CAB at 3 and 15 d after dry-off. Cows on CTRL had a greater ($P < 0.01$) udder engorgement (24.0 ± 0.33 Newtons) than cows on CAB (22.4 ± 33 Newtons) throughout the 4 d following dry-off, and it decreased ($P < 0.05$) as days since dry-off increased. The overall incidence of milk leakage in cows on CAB (3.1 ± 0.88%) was 73.5% of that obtained in cows on CTRL (11.7 ± 1.64%); and cows on CAB had 0.2 lesser odds ($P < 0.001$) to incur in milk leakage than cows on CTRL. The day following dry-off, CTRL cows lied about 1.5 h/d less ($P < 0.05$) than cows on CAB. It is concluded that an i.m. administration of 5.6 mg of carbegoline at dry-off effectively reduces PRL secretion, udder engorgement, milk leakages, and improves lying time the day following dry-off.

Key Words: involution, mammary gland, prolactin

T268 Dry-off facilitator cabergoline hastened the GLUT-1 decrease and lactoferrin increase in the mammary tissue during drying-off in dairy cows.

Marion Boutinaud*[1,2], Naomi Isaka[3], Audrey Deflandre[3], Sandra Wiart[1,2], Philippe Lamberton[1], Ana Isabel De Prado Taranilla[3], and Vanessa Lollivier[1,2], [1]*INRA UMR1348, Saint Gilles, France,* [2]*Agrocampus Ouest UMR1348, Rennes, France,* [3]*CEVA Santé Animale, Libourne, France.*

In ruminants, the early phase of drying-off is a period of mammary gland involution where lactose secretion is inhibited and lactoferrin is stimulated. GLUT-1 is a glucose transporter that has a key role in supplying substrate for lactose synthesis. The analysis of the changes in lactose and lactoferrin contents in mammary secretions and in GLUT-1 and lactoferrin contents in the udder can provide valuable information about the speed of the mammary involution. To assess the effect of prolactin inhibition by cabergoline on udder involution, 14 Holstein dairy cows were injected with a single i.m. administration of 5.6 mg cabergoline (n = 7) or placebo (n = 7) within 4 h after the last milking the day of drying off (D0). After D0, hay and water ad libitum was supplied to the cows for 10 d. Mammary secretion samples, collected during lactation (D-6) and at D1, D2, D3, D4, D8 and D14 after the drying-off, were used for lactose and lactoferrin analysis. Mammary biopsy samples, collected at D-6, D1 and D8, were used for GLUT-1 mRNA and lactoferrin analyses. Lactose content of mammary secretions progressively decreased during involution, whereas their lactoferrin content increased. The change in lactose content was associated with paralleled change in GLUT-1 mRNA level in the udder. These decreases were faster in cabergoline treated cows compared with controls with lower lactose content in cabergoline treated cows already by D1 than in controls ($P < 0.05$) and significant decrease in GLUT-1 mRNA levels at D1 and D8 respectively for cabergoline and control treatments compared with D-6 ($P \leq 0.05$). The rise of lactoferrin content in mammary secretions was significant starting at D4 in the cabergoline treated cows ($P \leq 0.05$) whereas it only happened at D8 in controls ($P < 0.05$). Overall, cabergoline treatment decreased GLUT-1 mRNA level ($P < 0.05$) and increased lactoferrin content ($P = 0.10$). Similarly, lactoferrin immunostaining intensity in the mammary tissue was higher at D1 than at D-6 in cabergoline treated cows ($P \leq 0.05$), whereas it tended to be higher only at D8 in controls ($P < 0.10$). Our results indicate that cabergoline treatment was efficient to hasten the udder involution and therefore facilitates the dry-off.

Key Words: cow, drying-off, prolactin

T269 Transcriptome analysis of the mammary gland reveals new insights for the role of serotonin in lactation. Jimena Laporta*[1], Francisco Peñagaricano[1], and Laura L. Hernandez[2], [1]*University of Florida, Gainesville, FL,* [2]*University of Wisconsin-Madison, Madison, WI.*

Serotonin (5-HT) in the mammary gland is known to regulate processes such as calcium homeostasis, tight junction permeability, and milk protein gene expression. The rate-limiting enzyme in the synthesis of non-neuronal 5-HT is tryptophan-hydroxylase (TPH1). Our objective was to further explore the roles of 5-HT in the mammary gland during lactation. We used whole body TPH1 knockout dams (KO; 5-HT deficient, n = 4) and compare them to wild-type (WT; n = 4) and rescue (RC; KO + 100 mg/kg 5-hydroxytryptophan injected daily, n = 4) dams. Mammary tissues were collected on d 10 of lactation. Total RNA extraction, amplification, library preparation, and sequencing were performed following the Illumina mRNA-seq protocol. Sequencing reads were mapped to the mouse reference genome using Tophat. The resulting alignments were used to reconstruct transcript models by Cufflinks. Differential gene expression was analyzed using Cuffdiff. Overall, 97 and 204 genes (false discovery rate, FDR ≤ 0.01) showed at least a 2-fold expression difference between WT and KO and between WT and RC, respectively. Most of the differentially expressed genes (DEG) are related to calcium homeostasis, regulation of apoptosis, cell cycle and cell differentiation, proliferation, and the immune response, among others. Additionally, enrichment analysis using Gene Ontology (GO) and Medical Subject Headings (MeSH) databases revealed the alteration of several biological processes (FRD ≤0.01) including fat cell differentiation and lipid metabolism, regulation of extracellular signal-related kinases and mitogen-activated kinase cascades, insulin resistance, nuclear transport, regulation of membrane potential, release of calcium from the endoplasmic reticulum into the cytosol. The majority of the biological processes and metabolic pathways altered in the KO dams are required for mammary gland homeostasis. Our study reveals the importance of non-neuronal 5-HT for normal mammary gland function and lactation. The potential modes of regulation of the bovine mammary gland during lactation by 5-HT should be further investigated.

Key Words: RNA sequencing, tryptophan-hydroxylase 1, lactation

T270 Lactation performance of dairy cows milked 3 times per day and supplemented with two different formulations of bovine somatotropin. Jozivaldo P. G. Morais*, Andressa P. da S. Cruz, Natalia S. Minami, Luiz P. Veronese, Tiago A. Del Valle, and Simone D. Sartorio, *Universidade Federal de São Carlos, UFSCAR, Araras, SP, Brazil.*

The aim of this randomized field study was to evaluate the lactation performance of dairy cows supplemented with 2 different 500-mg bovine somatotropin (bST) formulations. Sixty Holstein cows were allocated to a control, 90 Holstein cows to a somatotropin fast release formulation (FR-bST, Boostin-S, LG Life Science), and 90 Holstein cows to a somatotropin slow release formulation (SR-bST, Lactotropin, Elanco Animal Health). Treatments (TRT) were delivered every 14 d starting at 57–70 d post calving until the end of lactation, or 17 injections. Before TRT assignment, animals were paired by milk yield, lactation number, and randomly assigned to one of the 3 TRT. Evaluated parameters were milk production, milk protein, milk fat, milk SCC, and BCS. Somatotropin treatment increased milk yield ($P < 0.001$). SR-bST treated cows, yielded 1.6 kg/day more milk than FR-bST treated cows ($P = 0.008$). Somatotropin increased milk protein % ($P = 0.002$), decreased BCS ($P < 0.001$), and had no effect on milk fat % ($P = 0.120$) and SCC ($P = 0.964$). Results are shown in Table 1.

Table 1 (Abstr. T270). Production variables of cows milked 3 times per day without bST and with 2 different bST formulations[1]

	Treatment				P-value[2]	
Item	No bST	FR-bST	SR-bST	SEM	C1	C2

[1] FR-bST = Boostin-S, LG Life Science; SR-bST = Lactotropin, Elanco Animal Health. Starting on d 63 bovine somatotropin was administered at 14-d intervals to cows on the groups to receive bst.

[2] C1 = control vs. bST; C2 = FR-bST vs. SR-bST.

Key Words: milk composition, milk yield, recombinant bST

T271 Effects of milking frequency and prolactin on milk production and expression of prolactin receptors in the mammary gland of dairy cows. Izabella Thompson*[1], Severine Ollier[1], Xin Zhao[2], and Pierre Lacasse[1], [1]*AAFC-Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada,* [2]*Department of Animal Science, McGill University, Sainte-Anne-de-Bellevue, QC, Canada.*

A better understanding of how biological processes affect milk production in dairy cows is important to improve lactation persistence. The present study investigated the sensitivity of the mammary gland to prolactin. Eleven mid-lactation cows were milked twice daily during the first 2 experimental weeks. During wk 3–10 cows were differentially milked; the right quarters being milked thrice daily (3×), while the left were milked once daily (1×). During wk 11–14, all quarters were milked twice daily. After 4 weeks of differential milking, cows received daily i.m. injections of the dopamine antagonist domperidone (300 mg; DOMP; n = 6) or DMSO (CTL: n = 5) for 8 weeks (wk 7–14). Blood and milk samples were collected weekly for measurement of prolactin (PRL) as well as milk components for the latter. Milk was also collected from front quarters every 2 weeks and RNA was extracted from milk fat fraction. Expression of PRL receptors (long; PRLRL and short; PRLRS) were measured by real-time RT-PCR. Mammary gland biopsies were taken from rear quarters on wk 2, 6, 10 and 14 for subsequent gene and protein analyses. Differential milking improved milk production in the 3× quarters compared with the 1× quarters ($P < 0.01$). Increases in fat ($P = 0.04$), protein ($P = 0.05$) urea ($P = 0.01$) and lactose ($P < 0.01$) were observed in the 1× quarters, while greater SSC ($P < 0.01$) was observed in the 3× quarters. Blood PRL concentrations were greater for DOMP than CTL cows (24.8 ± 2.3 vs 13.9 ± 2.5 ng/mL; $P < 0.01$). There was no effect of injections on milk production, but milk from DOMP cows had greater concentrations of lactose ($P = 0.02$) than CTL. Interestingly, DOMP cows had greater expression of both forms of PRLR ($P < 0.01$) in milk fat compared with CTL. Additionally, greater PRLR expression was observed in the 3× than 1× quarters ($P < 0.01$). Results show that milk frequency improves milk production and alters composition and expression of PRLR in the mammary gland. Moreover, administration of domperiodone increased PRL concentration and is related to greater expression of both forms of PRLR in the mammary gland.

Key Words: milk production, mammary gland, prolactin

T272 Effects of inhibiting the lactogenic signal at calving on milk production and metabolic perturbations in cows.

Noémie Vanacker*[1], Ollier Séverine[1], Blouin Richard[2], and Lacasse Pierre[1], [1]*AAFC-Dairy and Swine Research and Development Centre, Sherbrook, Québec, Canada,* [2]*Département de Biologie, Université de Sherbrooke, Sherbrooke, Québec, Canada.*

During the periparturient period, the abrupt increase in energy demand for milk production induces metabolic disorders. Our previous work has shown that reducing milk output by milking once a day or partially in the first days of lactation reduces these disorders. The aim of this study was to reduce metabolic disorders by limiting milk production during the first week of lactation through inhibition of the lactogenic signal driven by prolactin. Twenty-two late gestation cows were assigned into 2 groups based on parity and milk production of the first 100 d of the previous lactation. Both groups received 8 i.m. injections of either quinagolide (Quin; 2mg of an inhibitor of prolactin release) or water (CTL) just after calving, and the subsequent 7 injections were given every 12h. Milk production was measured until d 28 post-calving. Blood samples were taken from d 1 (calving) to 5 and then on d 7, 10, 14, 21 and 28 to measure concentrations of urea, phosphorus, calcium, glucose, non-esterified fatty acids (NEFA), β-hydroxybutyrate and prolactin (PRL). Prolactin concentrations were lower ($P < 0.01$) in Quin cows from d 2 to d 5. Interestingly, between d 10 and d 28, PRL concentrations were greater ($P < 0.05$) in Quin than CTL cows. Milk production was lower in Quin cows from d 2 to d 6 than in control (24.3 ± 6.4 kg/d vs 34.8 ± 4.1 kg/d; $P < 0.05$). There was no residual effect of quinagolide on milk production after d 6. The blood glucose and calcium concentrations were greater ($P < 0.05$) in Quin cows whereas the concentration of β-hydroxybutyrate was greater ($P < 0.05$) in CTL cows during the first week of lactation. Blood NEFA, urea and phosphorus were not affected by treatment. In conclusion, reducing the prolactin peak at calving is effective to reduce milk production during the first week of lactation without compromising the global productivity of the dairy cow. This reduction in milk production allows a reduction of the metabolic stress during this period.

Key Words: prolactin, quinagolide, energy balance

T273 Effect of increased milking frequency in early lactation on milk production, proliferation and apoptosis of mammary cells in dairy cow.

Juliana Mergh Leão*[1], Juliana Aparecida Mello Lima[1], Sandra Gesteira Coelho[1], José Reinaldo Mendes Ruas[2], Anilton César Vasconcelos[1], Ângela Maria Quintão Lana[1], Ronaldo Braga Reis[1], and Helton Mattana Saturnino[1], [1]*Universidade Federal de Minas Gerais-UFMG, Belo Horizonte, Minas Gerais, Brazil,* [2]*Empresa de Pesquisa Agropecuária de Minas Gerais-EPAMIG, Felixlândia, Minas Gerais, Brazil.*

The objectives of the present study were to evaluate the effect of increased milking frequency (IMF) during early lactation on milk yield, proliferation and apoptosis in mammary epithelial cells of F_1 Holstein × Zebu cows. Fourteen cows F_1 Holstein × Zebu cows were randomly distributed into 2 groups. The control group (2×) was milked twice a day up to 210 d in milking (DIM), and the group subjected to IMF (4×) was milked 4 times a day from 2 to 21 DIM, and twice a day from 22 to 210 DIM. Milk production was measured daily from 4 to 30 DIM and then each 15 d until 210 d. Mammary biopsies were performed on d 2, 7, 14, 21, and 28 postpartum. Biopsies were obtained using a biopsy needle (12 g × 12). Mammary tissue was used to measure rates of cell proliferation and apoptosis using Ki-67 nuclear proliferation antigen localization and terminal deoxynucleotidyl transferase nick-end labeling (TUNEL), respectively. Data were analyzed with a repeated measures design and means were compared by Tukey›s test ($P < 0.05$). During IMF, the 4× produced 2.6 ± 0.2 kg/d more milk than the 2× ($P < 0.05$). After IMF phase, milk production from the 4× decreased and was similar to 2× up to 210 DIM ($P > 0.05$). Mammary cell proliferation and apoptosis were not affected by milking frequency ($P > 0.05$). Rates of proliferation and apoptosis were influenced by days of lactation ($P < 0.05$). On the second day of lactation, the highest apoptosis rate (0.3%) was observed. Days 7 (0.16%), 14 (0.13%), 21 (0.11%) and 28 (0.06%) had similar and lower rates in comparison with the second day of lactation. There was a higher percentage of proliferation in mammary epithelial cells on d 2 (2.12%). On d 7 (0.99%) and 14 (0.87%), the proliferation rate dropped to about half the value observed on d 2 and in the following week (0.47%) it was observed another reduction which remained until the 28th of lactation (0.43%). Changes in milking frequency during early lactation did not alter milk yield after IMF and mammary cell population dynamics suggesting that maybe the mammary biopsy procedure used in the current study influenced these responses negatively.

Key Words: biopsy, Ki-67, terminal deoxynucleotidyl transferase nick-end labeling (TUNEL)

T274 Effect of cortisol on mammary epithelial cell turnover: milk synthesis, proliferation and apoptosis.

J. A. Negrao*, G. M. Krempel, S. A. Oliveira, G. F. Bomfim, H. Z. Polato, and F. C. Lahr, *Basic Science Department, FZEA/USP, Pirassununga, SP, Brazil.*

Cortisol is essential for copious synthesis of milk components, and cortisol administration delayed the decline of milk yield in late lactation. However, the effect of cortisol in proliferation, activity, and survival of the epithelial cells remains controversial. The objective of this study was to evaluate the effect of cortisol on the survival and proliferation of epithelial cells. Twenty-four Saanen goats were submitted to administration of ACTH (Cortisol group) or placebo (Control group). Milk yield and milk quality (fat, protein, lactose, and CCS) were measured daily and weekly, respectively. Cortisol concentrations in plasma were measured before and after ACTH or Placebo administration at 60, 90, and 120 d of lactation. All mammary biopsies were conducted 1 h after ACTH or placebo administration. Biopsies were taken of 4 goats submitted to ACTH and 4 goats submitted to placebo at 60, 90 and 120 d of lactation. Apoptosis was determined using terminal deoxynucleotidyl transferase dUTP nick-end labeling (TUNEL) kit, and proliferating cell was determined using a proliferating cell nuclear antigen (PCNA) kit. The mRNA levels of Bax and Bcl-2 were analyzed by RT-PCR. At the same time, Bax and Bcl-2 synthesis were measured by ELISA kit. Statistical analysis was performed by ANOVA using mixed model, and the level of significance was set at $P < 0.05$ for main effects and interactions. Although, cortisol increased significantly after ACTH administration milk yield, milk quality, casein and lactose in milk were similar for both groups. Furthermore, percentage of apoptotic cells measured by TUNEL, percentage of proliferation measured by PCNA, and the expression and synthesis of Bax (promoter of apoptosis) were similar in ACTH and placebo groups (control). However, the expression and synthesis of Bcl-2 (inhibitor of apoptosis) were significantly higher after ACTH administration when compared with placebo administration. Furthermore, the relationship between Bax/Bcl-2 was significantly lower after ACTH administration when compared with placebo administration.

These results support the hypothesis that cortisol can delay apoptosis in the mammary gland.

Key Words: mammary gland, Bax, Bcl-2

T275 Effects of growth hormone and insulin-like growth factor on synthesis and secretion of β-casein, β-lactalbumin and lactoferrin in mammary epithelial cells.

J. A. Negrao*, G. M. Krempel, S. A. Oliveira, G. F. Bomfim, F. C. Lahr, and H. Z. Polato, *Basic Science Department, FZEA/USP, Pirassununga, SP, Brazil.*

Growth hormone (GH) and insulin-like growth factor (IGF-I) are associated to milk production traits, however the mechanism how GH and IGF-I increase the milk synthesis remains unclear. The objective of this study was to evaluate the effect of GH and IGF-I on the synthesis and secretion of β-casein, β-lactalbumin, and lactoferrin by mammary epithelial cells. Twenty-four Saanen goats were used, and 5 goats were biopsied. Milk yield and milk quality (fat, protein, lactose and CCS) were measured daily and weekly, respectively. Growth hormone and insulin-like growth factor-I concentrations in plasma were measured once a day, at 30 and 60 d of lactation. All mammary biopsies were conducted just after blood samples. Biopsies were taken of 5 goats at 30 and 60 d of lactation. Epithelial cells were isolated and cell culture was used to study expression and synthesis of β-casein, β-lactalbumin, and lactoferrin. Four treatments were imposed to epithelial cell culture: (1) control (basal medium); (2) GH (10 ng/mL); (3) IGF-I (10 ng/mL); (4) GH + IGF-I (10 ng/mL + 10 ng/mL). The mRNA levels of β-casein, β-lactalbumin, and lactoferrin were analyzed by RT-PCR. At the same time, the synthesis of β-casein, β-lactalbumin, lactoferrin, and lactose in were measured by ELISA kit in culture medium. Statistical analysis was performed by ANOVA using mixed model, and the level of significance was set at $P < 0.05$ for main effects and interactions. Growth hormone (GH) and insulin-like growth factor (IGF-I) were associated with milk yield, and goats classified as higher producing (4 from 24 experimental goats) presented high GH and IGF-I levels. β-Casein expression and synthesis were significantly higher for IGF-I and GH + IGF-I treatments when compared with control. Lactoferrin expression and synthesis were significantly higher for GH and GH + IGF-I treatments when compared with control. However, β-lactalbumin expression and synthesis were not change by hormone treatments when compared with control. These results support the hypothesis that GH and IGF-I can modulate directly the synthesis of milk.

Key Words: growth hormone (GH), insulin-like growth factor (IGF-I), milk synthesis

T276 The barrier integrity of bovine mammary epithelial cells in vitro in response to lipopolysaccharide (LPS) and lipoteichoic acid (LTA) treatment.

Christina Zbinden*[1,2], Rupert M. Bruckmaier[1], and Olga Wellnitz[1], *[1]Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland, [2]Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, Switzerland.*

The blood-milk barrier of the bovine mammary gland prevents an intermixture of blood and milk. During mastitis, the permeability of the blood milk barrier is increased, which is reflected by an exchange of blood constituents into milk, and vice versa. The aim of this study was to investigate the role of mammary epithelial cells in the regulation of blood-milk barrier alteration during mastitis induced by cell wall components of *Escherichia coli* (LPS) and *Staphylococcus aureus* (LTA). Low passage primary bovine mammary epithelial cells (bMEC) from 3 different cows were grown separately on Transwell inserts. The level of integrity of the epithelial barrier was measured by means of transepithelial electrical resistance (TEER), as well as by diffusion of the fluorophore Lucifer Yellow (LY) across the cell layer. The formation of tight junctions between adjacent epithelial cells was examined by immunofluorescence staining of zona occludens-1 and by transmission electron microscopy. The cultured cells formed tight cell layers sealed by tight junctions. The barrier integrity was reduced after 3 h ($P < 0.05$; paired *t*-test relative to unchallenged cells) in response to 500 µg/mL LPS from *E. coli*, and after 7 h in response to 20 mg/mL LTA from *S. aureus*. At these dosages, the fluorescence values of LY in the apical compartment of the Transwell insert dropped within 24 h from 5386 to 560 ± 235 RFU in response to LPS, and from 5386 to 1416 ± 144 RFU in response to LTA. No significant changes in barrier permeability were observed in response to 200 µg/mL LPS, or to 2 mg/mL LTA Although LPS and LTA affected the barrier permeability most likely due to an opening of the tight junctions, LPS additionally caused considerable cell damage reflected by increased LDH concentrations in cell culture medium ($P < 0.05$). These results confirm a pathogen-specific impairment of the blood-milk barrier during mastitis, which involves differences in cell degradation.

Key Words: bovine mastitis, blood-milk barrier, tight junction

T277 Intravenous challenge with lipopolysaccharide does not induce a mammary immune response in dairy cows and does not affect the blood-milk barrier.

Olga Wellnitz*[1,2], Emmanouil Kalaitzakis[1,2], Heinrich Bollwein[2], and Rupert M. Bruckmaier[1], *[1]Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland, [2]Clinic of Reproductive Medicine, Vetsuisse Faculty University of Zurich, Zurich Switzerland.*

An intramammary challenge with lipopolysaccharide (LPS) from *Escherichia coli* is known to induce a considerable immune response of the mammary gland and an impairment of the blood-milk barrier. The aim of the current study was to investigate a potential immune reaction in the mammary gland and potential changes of the integrity of the blood-milk barrier in response to an intravenous, i.e., systemic challenge, with LPS. Ten lactating dairy cows in wk 3 of lactation were challenged intravenously (V. jugularis) with 0.5 µg/kg BW *E. coli* LPS (O26:B6). Rectal temperature was measured hourly. Milk samples of one udder quarter were taken immediately before and then every 30 min until 5 h after challenge. Mammary gland biopsies of one quarter were taken immediately before and 8 h after LPS challenge for RT-qPCR of immunorelevant factors. Rectal temperature increased ($P < 0.001$) within 1 h of LPS administration from 38.3 ± 0.1 to 39.2 ± 0.1°C and stayed elevated throughout the 5 h of experiment. The milk somatic cell count was $83.3 \pm 19.1 \times 10^3$/mL immediately before challenge and did not change throughout the experiment. Lactate-dehydrogenase concentrations in milk as a marker for blood-milk barrier impairment was 48.1 ± 6.0 U/L immediately before challenge and did not change throughout the experiment. Relative mRNA expression of immunorelevant factors; that is, the cytokines TNF-α and interleukin-1β in mammary gland tissue did not change in response to intravenous LPS injection. In conclusion, in contrast to intramammary injections, an intravenous injection of 0.5 µg/kg BW LPS induces a systemic immune response shown by an increase in rectal temperature, but has obviously no effects on factors of mammary gland immune response which typically change during LPS-induced mastitis. Also the blood-milk barrier integrity does not appear to be influenced by systemic LPS.

Key Words: intravenous lipopolysaccharide, mammary gland, blood-milk barrier

T278 Characterization of mammary glucose metabolism during milk fat depression.

Natalie L. Urrutia*[1], Kevin J. Harvatine[1], and Dale E. Bauman[2], [1]*The Pennsylvania State University, University Park, PA,* [2]*Cornell University, Ithaca, NY.*

Milk fat synthesis requires butyrate, acetate, and reducing equivalents (NADPH) as substrates. NADPH is provided from glucose through the pentose phosphate pathway and isocitrate dehydrogenase (IDH1). During milk fat depression (MFD), reduced milk fat synthesis may result in decreased uptake of nutrients by the mammary gland, including glucose. The objective of this study was to characterize expression of glucose metabolism and NADPH synthesis enzymes in mammary tissue during MFD using tissue from a previously published experiment. Cows were arranged in a 3 × 3 Latin square design with 14-d experimental periods. Treatments were control (CON), CLA-induced MFD (CLA; 3 d i.v infusion of 10 g/d of *trans*-10,*cis*-12 CLA in an intralipid emulsion), and a low forage, high oil diet (LF/HO; 45.9% forage, 3.0% soybean oil, and 1.5% fish oil). Milk fat yield was decreased 24% by CLA and 38% by LF/HO. Mammary biopsies were performed 1 to 3 h after milking at the end of each treatment. Gene expression of enzymes involved in glucose metabolism and NADPH synthesis were determined by Real-Time PCR and analyzed relative to the geometric mean of housekeeping genes (18S ribosomal subunit, ribosomal protein S9 and β2-microglobulin). Data were analyzed using the fit model procedure of JMP Pro and the model included fixed effects of treatment and geometric mean of housekeeping genes and random effects of cow and period. Glucose transporter 1 (GLUT1) and IDH1 were significantly reduced by the LF/HO treatment when compared with CON (28 and 36%, respectively; $P < 0.05$). Phosphogluconate dehydrogenase expression was lower in the LF/HO treatment when compared with CLA ($P < 0.05$), but not different compared with CON. Other genes involved in glucose metabolism such as HK2, ACLY, G6PDH and GLUT8 were not affected by treatments.These results suggest that during diet-induced MFD the reduction in glucose uptake coincides with decreased expression of GLUT1 and that the decrease in use of NADPH corresponds to a downregulation of the isocitrate pathway. The smaller decrease in milk fat in the CLA treatment may have limited the ability to observe a treatment effect during CLA-induced MFD.

Key Words: glucose, NAPDH, isocitrate

T279 Transcriptome adaptation of the bovine mammary gland to a diet supplemented with linseed oil.

Eveline M. Ibeagha-Awemu[1], Ran Li[1], Adolf A. Ammah[1], Nathalie Bissonnette*[1], Chaouki Benchaar[1], and Xin Zhao[2], [1]*Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, Quebec, Canada,* [2]*Department of Animal Science, McGill University, Ste-Anne-De-Bellevue, Quebec, Canada.*

Diets rich in unsaturated fatty acids (UFA) have been shown to increase the contents of some milk beneficial fatty acids (FA) including conjugated linoleic acid (CLA). The mechanism by which UFAs modulate cow's genetics resulting in increased milk CLA content is not clear. This study examined the transcriptome of the bovine mammary gland following dietary supplementation with linseed oil. Twelve Holstein cows (35±10 kg milk; 150±50 DIM) were used in a complete randomized block design and fed a total mixed ration (control diet) for 28 d (d 1-28; control period, CP) followed by a treatment period (TP; d 29-56) consisting of control diet + 5% linseed oil (57% α-linolenic acid). Milk samples were collected weekly for fat, protein and individual FA determination. Mammary gland biopsies were performed on 6 cows on d 14 (CP) and d 35 and 56 (TP). Global transcriptome was analyzed using RNA-sequencing. Milk fat percent decreased ($P < 0.0001$) from 3.62% (CP) to 2.52% (TP) while protein percent was unchanged by treatment. The proportions of C4:0, C8:0, C14:0, C16:0 and C14:1 decreased ($P \le 0.0003$) while C18:1n-11t, C20:3n-3, C20:5n-3, C22:5n-3, CLA10t12c and CLA9c11t increased ($P \le 0.035$) during the TP. RNA-sequencing generated 459 million reads out of which 89% mapped to unique positions on the bovine genome. Eight genes (*CSN2*, *CSN1S1*, *CSN1S2*, *LGB*, *CSN3*, *LALBA*, *COX1*, and *GLYCAM1*) out of 11121 expressed constituted 73.70% of mapped reads. One hundred seventy-nine genes were significantly regulated (79 up- and 100 down-regulated) after FDR correction. Most affected genes were *FBP2* (11-fold up-regulated) and *MROH2B* (4-fold down-regulated). Further regulated genes with roles in FA synthesis/uptake included *LPIN1*, *SREBF1*, *INSIG1*, *FASN*, *BDH1*, *ACSS1*, *ACADVL*, *SLC25A34*, *SLC39A11*, *TIEG2*, and *CYP2B6*. Differentially expressed genes were significantly enriched in several KEGG pathways including PPAR and insulin signaling pathways. This study has provided a broader picture of the transcriptomics events that are involved in mammary gland adaptation to a diet rich in UFA. Our study provides further knowledge on mammary lipogenesis and data that can be used to develop new nutritional strategies for a better management of milk increased beneficial FAs.

Key Words: bovine mammary gland transcriptome, linseed oil, lipogenesis

Nonruminant Nutrition: General II

T280 Chemical treatment of corn stover with calcium hydroxide increases its energy value for swine.

Victor G. Perez*, Lester Pordesimo, Amanda Knorr, and Terry Radke, *ADM Animal Nutrition, Quincy, IL.*

The objective was to estimate DE and ME content in corn stover (CS) and CS treated (CST) with $Ca(OH)_2$ for swine. The $Ca(OH)_2$ was added to CS in the amount of 6.6% of the DM in CS, with enough water to raise moisture content in CST to 50% (wet basis). After 7 d, CST was sun dried and both CS and CST were pelleted (9 mm). Dietary treatments were a basal diet (97.28% corn), and the basal diet with 30% of either CS or CST added at the expense of corn. The experiment was a RCBD based on initial BW, and each treatment had 8 block replicates (barrows; 90 ± 0.7 kg BW). Feed was offered to provide 2.5 times the energy maintenance requirement. It was assumed that CST had 10% more energy than CS, based on preliminary data from an in vitro organic matter digestibility (Boisen and Fernandez, 1997). Pigs were placed in metabolic crates and allowed 7 d of adaptation, followed by 4 d of total collection of feces and urine. The DE and ME values in ingredients were calculated by the difference procedure. Data were analyzed using the PROC GLM procedure of SAS. Pairwise comparisons were used for treatment means separation. Measured DE and ME values in corn (Table 1) were 2% smaller or less than published values (NRC, 2012). Feed intake was not different between CS and CST. Chemical treatment of CS increased ($P \leq 0.06$) its DE and ME by 43 and 34%, respectively (Table 1), perhaps because it increased ($P < 0.05$) digestibility of dietary NDF (17.7 vs. 29.2%; SEM = 3.22) and ADF (17.5 vs. 35.7%; SEM = 2.20). In conclusion, chemical treatment of CS with $Ca(OH)_2$ increases its energy value in swine.

Table 1 (Abstr. T280). Energy value (kcal/kg DM) of corn, corn stover (CS), and CS treated with $Ca(OH)_2$ (CST) in pigs (90 ± 0.7 kg BW)

Item	Corn	CS	CST	SEM	CS vs. CST, kcal (%)
DE	3,864^a	914^b	1,306^c	106	392 (43%)
ME	3,758^a	917^b	1,229^c	105	312 (34%)

$^{a–c}$Within rows, means with different superscript differ ($P \leq 0.06$)

Key Words: corn stover, sow, metabolizable energy

T281 Hammer status in hammer mill affects feed particle size and piglet performance after weaning.

David Solà-Oriol, Laia Blavi*, and Roser Sala, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Hammers of hammer mill are changed when working edges are worn but, often this is not decided according to the quality standards of feed and their possible effects on performance. The aim of the present work was to study the effect of different hammer status (new; N or worn; W) on particle size distribution of ground diets and the performance of weaned piglets. One hundred sixty 28-d-old piglets [Pietrain × (Landrace × Large White)] were distributed into 16 pens according to their initial BW following a RCBD. A pre-starter (PS; 0 to 14d) and a starter (ST; 14 to 35d) diet was formulated to contain 2.63 Mcal/kg NE, 20.2% CP, 1.37 Lys and 2.48 Mcal/kg NE, 15.1% CP, 1.20 Lys, respectively. Two experimental treatments were performed according to the hammer status N or W. PS and ST diets were ground at Ø = 2 and Ø = 3 mm, respectively. Feed was offered ad libitum in mash form. Individual animal weight and feed disappearance were recorded at 0, 14, and 35 d post-weaning to calculate average daily feed intake (ADFI) and average daily gain (ADG). Data were analyzed with ANOVA taking into account block of BW and hammer status as main factors. Feed particle size distribution was determined as % of particles ≥1 mm, ≥0.75 mm, ≥0.5 mm and <0.5 mm. Different size distribution was mainly observed for ST. The W diets showed 21% and 3.7% more particles of ≥ 1mm and ≥ 0.5mm, but 8.5% and 9.3% less of ≥0.75 mm and <0.5 mm, respectively than N diet. For PS period, no different BW, ADG and ADFI was observed ($P > 0.05$). However, higher ADFI (666 vs 619 g/d; $P = 0.03$) and a tendency to higher ADG (418 vs 387 g/d: $P = 0.10$) were observed for the animals fed the N diet for ST period. Considering the entire period (0 to 35d), higher BW (18.9 vs 18.1 kg; $P = 0.03$), ADFI (505 vs 471 g/d; $P = 0.01$) and ADG (318 vs 295 g/d: $P = 0.03$) were observed for the animals fed the N diets. It is concluded that hammer status affects particle size and piglet performance in weanling diets in a larger extend in ST than PS diets.

Key Words: hammer mill, particle size, piglet

T282 Effect of salt particle size and extended mixing times on the mixing uniformity of a corn-soy swine diet.

Marut Saensukjaroenphon*[1], Cassandra K. Jones[1], Charles H. Fahrenholz[2], Kessinee Chitakasempornkul[1], and Charles R. Stark[1], *[1]Kansas State University, Manhattan, Kansas, [2]Phibro Animal Health Corporation, Manhattan, Kansas.*

The uniformity of a feed mixture is determined from the coefficient of variation (CV) of 10 samples in a single batch of feed. The feed industry standard is a CV of <10% using a single source tracer such as salt, trace minerals, or iron filings. The uniformity of mix can be affected by many factors, including mixer design, particle size of the ingredients, and mixing time. Previous research has determined the minimum mix time to maximize the mixing efficiency, but some hypothesize that over-mixing may lead to ingredient segregation. However, there is limited data regarding the effects of extended mixing or of the analytical marker appropriate for maximum precision of the assay. The objectives of this experiment were to determine (1) the effects of extended mix time, and (2) particle size of the marker on the CV in a corn-soy swine diet. Treatments were arranged in a 3 × 7 factorial design with 3 salt particle sizes: fine (350 µm), medium (464 µm), and coarse (728 µm) and 7 mix times: 2, 3, 5, 15, 30, 45 and 60 min. There were 3 replicates per treatment and 10 samples per replicate. Salt concentrations were determined using a Quantab Chloride Titrator. Data were analyzed using the GLIMMIX procedure of SAS. There was no interaction between mix time and salt particle size ($P > 0.60$). The extended mix time did not result in segregation ($P > 0.30$; 9.6, 11.5, 11.8, 11.2, 12.50, 10.6, and 10.1% CV for 2, 3, 5, 15, 30, 45, and 60 min, respectively). Particle size of the salt significantly affected the uniformity of mix ($P < 0.01$; 20.7, 8.4, and 7.7% CV for the coarse, medium, and fine salt, respectively). These results indicate that feed did not segregate after mixing for one hour and that greater number of particles per gram increased the precision of the analysis, likely due to an increased probability that the tracer was present in proportionate quantities in the sample tested. More research is needed to determine if sample size or number of samples per batch should be increased, as well as the effect of diet particle size on uniformity of mix.

Key Words: mixing uniformity, mixing time, particle size

T283 Optimization of different probiotics on improving the quality of cottonseed meal fermentation using response surface methodology. X. M. Liu[1], C. W. Yang*[2], Z. Y. Li[3], Z. B. Yang[1], and Y. Wang[4], [1]*College of Animal Science, Shandong Agricultural University, Shandong, China,* [2]*College of Life science, Shandong Agricultural University, Shandong, China,* [3]*CRVAB Bio-tech Group, Shanghai, China,* [4]*Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada.*

Central composite design of response surface methodology (RSM) was employed to optimize *Lactobacillus* content (X_1: 4.5×10^6 to 5.5×10^6 cfu/g), *Bacillus subtilis* content (X_2: 9.0×10^6 to 1.1×10^7 cfu/g) and yeast content (X_3: 5.50×10^6 to 7.0×10^6 cfu/g) of solid-state fermentation (SSF) cottonseed meal with low pH value, high dry matter recovery (DMR) and high the reducing-sugar content. Results indicated that the data were adequately fitted into 3 s-order polynomial models. The *Lactobacillus* content, *Bacillus subtilis* content, and yeast content were found to have significant linear, quadratic and interaction effects on pH value, the DMR and the reducing-sugar. The optimal extraction conditions were predicted to be lactobacillus content of 5.50×10^6 cfu/g, *Bacillus subtilis* content of 1.08×10^7 cfu/g and yeast content of 6.08×10^5 cfu/g. The pH value, DMR and the reducing sugar predicted by RSA were 5.01, 91.8% and 1.69%, respectively. The detection index obtained experimentally was close to its predicted values. The establishment of such model provides a good experimental basis employing RSM for optimizing the quantity of inoculation of *Lactobacillus*, *Bacillus subtilis*, and yeast on fermentation.

Key Words: quantity of inoculation, pH, dry matter recovery

T284 Effects of ginger root, star anise, and *Salvia miltiorrhiza* on growth performance, antioxidant status and serum metabolites in growing pigs. Z. B. Yang*[1], X. Y. Li[1], S. Z. Jiang[1], and C. W. Yang[2], [1]*College of Animal Science, Shandong Agricultural University,* [2]*College of Life Science, Shandong Agricultural University.*

To compare the effects of ginger root (*Zingiber officinale*), star anise (*Illicium verum*) and dan-shen root (*Salvia miltiorrhiza*) that were processed to particle sizes of 300 μm on growth performance, serum antioxidant status and serum metabolites of growing pigs, 24 Laiwu pigs at 70-d old were randomly allocated to 4 treatments with 6 replicates in a complete randomized design. The 4 treatments (TRT) were (1) TRT 1, pigs were fed corn-soybean meal based diets; (2) TRT 1 + 10 mg/kg ginger; (3) TRT 1 + 5 g/kg star anise; (4) TRT 1 + 10 g/kg dan-shen. ADG, ADFI and feed conversion rate of each replicate were measured weekly. At d35 of the experiment, blood samples were obtained from 6 pigs per treatment to determine antioxidant enzymatic activities and metabolites in the serum. All dates were subjected to ANOVA using the one-way of SAS program software (version 9.2). Differences among treatments were tested using Duncan's multiple-range test. All pigs had similar ADFI, ADG, feed conversion rate and concentrations of malondialdehyde in serum over the entire experimental period. However, comparing to TRT 1, supplementation of ginger, star anise and dan-shen increased activities of total antioxidant capacity and superoxide dismutase ($P = 0.003$, $P < 0.001$, respectively). The activity of superoxide dismutase in TRT 2 was higher ($P < 0.05$) than TRT 4. Concentration of glutathione in serum was higher ($P < 0.05$) with dietary supplementation of star anise and dan-shen than TRT 1 and TRT 2. As compared with that of TRT 1, supplementation of 3 botanical additives reduced ($P < 0.05$) concentrations of total cholesterol but had same concentrations of total protein, globulin and low density lipoprotein in serum of growing pigs. Supplementation of star anise increased ($P < 0.05$) concentrations of albumin and high-density lipoprotein comparing to TRT 1. Concentration of high-density lipoprotein in serum of ginger-supplemented pigs was higher ($P < 0.05$) compared with that of TRT1. Dietary supplementation of ginger, star anise and dan-shen may improve serum antioxidant status and serum metabolites of growing pigs in a certain degree.

Key Words: ginger, star anise, dan-shen root (*Salvia miltiorrhiza*)

T285 Effect of oregano essential oil supplementation on oxidative stability of eggs enriched with polyunsaturated fatty acids during storage. Ronnal E. Ortiz*[1,2], Germán Afanador-Tellez[2], Diana R. Vásquez[1], and Claudia Ariza-Nieto[1], [1]*Corporación Colombiana de Investigación Agropecuaria, Bogotá, Cundinamarca, Colombia,* [2]*Universidad Nacional de Colombia, Bogotá, Cundinamarca, Colombia.*

This study evaluated the inclusion of oregano essential oil (OEO) *Lippia origanoides* Kunth in diets enriched with polyunsaturated fatty acids (PUFA) on oxidative stability of eggs during storage. A total of 144 Babcock Brown hens 48-week-old were assigned to a completely randomized factorial design 2 × 2; Factor A oil type (palm and fish), Factor B OEO level (0 and 100 g/Ton) with the repeated measures of days of storage (0, 30, 60 d). The statistical model included the fixed effects of oil type, OEO level, day of storage and their interactions. At the end of the period (8 weeks) 6 eggs per replicate were collected; 2 eggs were analyzed as fresh, the remaining 4 were storage at 4°C; 2 for 30days and 2 for 60 d. Egg yolks were used for the analysis of PUFA and thiobarbituric acid reactive substances (TBARS) that measures malonaldehyde concentration (MDA). Results showed no significant interactions effect ($P > 0.05$). In fish oil groups, the concentration of PUFA and docosahexaenoic acid (DHA) increased (+16.8 and +1.4%, respectively) ($P < 0.05$). The concentration of MDA was higher in fish oil groups (41.6 ng/g yolk) compared with palm oil groups (32.6 ng/g yolk). The groups supplemented with OEO improved oxidative stability during storage (MDA 31.1 ng/g yolk) compared with the groups without supplementation (MDA 34.1 ng/g yolk). Concentration of MDA showed an effect on storage time ($P < 0.05$); on day zero egg yolks had lower MDA (28.3 ng/g yolk), whereas on d 30 and 60 of storage MDA increased (31.4 and 38 ng/g yolk, respectively). The OEO showed potential as a natural antioxidant in the diet of layers hens improving the oxidative stability of eggs stored at 4°C up to 60 d.

Key Words: layer hen, lipid peroxidation, egg yolk

T286 Effects of dietary inclusion of *Lactobacillus acidophilus* on growth performance, health, and carcass traits of growing-finishing pigs. A. S. Loftus*, I. Park, N. E. Manzke, and S. W. Kim, *Department of Animal Science, North Carolina State University, Raleigh, NC.*

The objective of this study was to determine the effect of a single strain direct-fed microbial (DFM, *Lactobacillus acidophilus* 1×10^9 cfu/g) on growth performance and carcass traits of growing-finishing pigs. Sixty pigs (30 gilts and 30 barrows) with initial BW of 44.4 kg ± 1.8 kg were allotted to 2 dietary treatments in a randomized complete block design with sex and initial BW as blocks. Experimental diets met the NRC 2012 nutrient requirements. The inclusion levels of DFM were 0.28, 0.24, and 0.20% during phase 5 (d 0 to 28), phase 6 (d 28 to 49), and phase 7 (d 49 to 70), respectively. Growth performance was measured for 10 wk. Blood samples were collected at wk 9 to measure TNFα and blood urea nitrogen (BUN). At wk 10, pigs were slaughtered at a local abattoir to evaluate carcass and loin quality including HCW, CCW, backfat thickness (1st, 10th, and last rib), loin weight, loin color (Minolta colorimeter), loin marbling score (1 to 10, NPPC scale), drip loss (48 h), loin eye area, and chemical composition. Data were analyzed using Proc Mixed of SAS with treatment and sex as fixed effects and initial BW block as a random effect. P value less than 0.05 was considered significant and less than 0.10 tendency. The ADG, ADFI, and G:F were not different between treatments. Backfat thickness of pigs with DFM was smaller ($P < 0.05$, 24.5 vs. 29.6 mm) at the last rib and tended to be smaller ($P = 0.088$, 30.1 vs 34.4 mm) at the 1st rib than pigs without DFM. Loin of pigs with DFM tended to be redder ($P = 0.084$, a* value for redness: 7.22 vs. 6.35) than pigs without DFM. Chemical composition, drip loss, TNFα, BUN, and intestinal morphology did not differ between treatments. Collectively, dietary supplementation of a single strain DFM, *Lactobacillus acidophilus* to grower-finisher feeds reduced backfat thickness of pigs without affecting growth performance and loin quality.

Key Words: direct-fed microbial, growing-finishing pig, carcass trait

T287 Nutrient digestibility of high oleic soybean meal by broilers.

Guilherme Hosotani*, Monty S. Kerley, and Marcia C. Shannon, *University of Missouri, Columbia, MO.*

Two 21-d experiments were conducted to compare soybean meal (SBM) from high oleic to parent soybean cultivars on growth performance, ileal AA (IAA) digestibility, and apparent metabolizable energy (AME). Soybean meal was prepared by laboratory-scale mechanical extraction. In Exp. 1, growth performance was evaluated. Fifty 1-d-old male broilers (Ross 308) were randomly placed in battery cages and allocated to 2 dietary treatments with 5 replicates and 5 birds per replicate. The SBM sources consisted of cold-pressed conventional SBM (CON) and cold-pressed high oleic SBM (HO). All SBM sources were heated in a forced-air oven at 120°C for 20 min. Diets were formulated to meet or exceed NRC (1994) requirements. Broilers were weighed and feed disappearance measured on d 7, 14, and 21. In Exp. 2, IAA digestibility and AME were estimated using 100 one-d-old broilers randomly allotted to 3 dietary treatments with 10 replicates and 5 birds per replicate. Chicks were fed a corn-SBM based diet for 17 d, and a diet was developed by substituting the soybean cultivars at 48% in a corn starch-dextrose basal diet and fed from d 18 to 21. A nitrogen-free diet was fed to determine ileal endogenous AA losses. Titanium dioxide (0.5%) was included in all diets as a digesta flow marker. Excreta were collected from d 19 to 21 and ileal content at d 21. Statistical analyses were performed as a randomized complete block design using PROC GLM of SAS with significance level set at $P \leq 0.05$. Chicks fed diets containing HO had decreased ADG ($P < 0.05$; 25.3 vs. 29.4 g) and increased feed conversion ratio ($P < 0.05$) from d 0 to 14 (1.71 vs. 1.56) and d 0 to 21 (1.54 vs. 1.47), compared with CON. Amino acid digestibility did not differ among all essential AA. There were no differences in AME (kcal per g) from SBM indirectly calculated between CON and HO, with values of 2,330 and 2,161, respectively. In conclusion, although there were no differences in nutrient digestibility, broilers fed HO had impaired performance compared with CON.

Key Words: broiler, soybean, high oleic acid

T288 Effect of dietary quercetin and oregano essential oil on growth performance, carcass characteristics, meat quality and antioxidant properties in pigs under transport stress conditions.

Yi Zou, Yuanfei Zhou*, Hongkui Wei, and Jian Peng, *Department of Animal Nutrition and Feed Science, College of Animal Science and Technology, Huazhong Agricultural University, Wuhan, Hubei, China.*

The current study was conducted to investigate the effects of dietary oregano essential oil and quercetin supplementation on growth performance, meat quality and antioxidant property in transported pigs. A total of 336 finishing pigs (Large White × Landrace) with an initial body weight of 72 ± 4.0 kg were randomly allotted to 4 groups (5 replicate pens per treatment, 17 pigs per pen). Animals in these 4 groups consumed basal diet (control), basal diet supplemented with 100 mg/kg of vitamin E (VE), or 25 mg/kg of oregano essential oil (OEO) or 25 mg/kg quercetin for 4 wk, respectively. After 4 wk feeding period, 144 pigs were transported for 7 h by high stocking density (275kg/m^2). Pigs were slaughtered to determine meat quality at 45 min and 24 h postmortem from the M. longissimus dorsi muscles. Blood samples were also collected for measurement of glutathione peroxidase (GSH-Px), total superoxide dismutase (T-SOD), malondialdehyde (MDA) and reactive oxygen species (ROS) levels. Statistical analysis was performed using the GLM procedure (SAS Inst. Inc., Cary, NC). Pen was the experimental unit, and the mean differences were determined using Fisher's test of LSD. The level of statistical significance was taken at $P < 0.05$ or $P < 0.01$. Compared with control group, both OEO and quercetin groups had significant higher average daily gain (ADG), whereas only OEO group had higher final body weight and lower feed intake/gain ($P < 0.05$). Hot carcass weights and dressing percentage was higher in OEO group than those in control and VE groups ($P < 0.05$). The OEO and quercetin groups had significant ($P < 0.05$) lower drip loss and MDA levels but higher ($P < 0.01$) pH value and lightness value in meat compared with control group. In serum, compared with the control group, OEO and quercetin group had increased activation of GSH-Px and T-SOD ($P < 0.01$), and decreased MDA and ROS levels ($P < 0.01$). Moreover, compared with quercetin and VE groups, OEO group had a higher GSH-Px activity in serum. In general, dietary OEO and quercetin may protect against transport stress and improve redox status in transported pigs.

Key Words: finishing pig, transport stress, meat quality

T289 Effect of vitamin E supplementation on performance of male broiler chickens—A meta-analytic approach.

M. A. Pompeu*[1], L. F. L. Cavalcanti[2], and F. L. B. Toral[1], [1]*Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brazil,* [2]*CNPq, RHAE, Seva Engenharia, Projeto Intergado, Contagem, MG, Brazil.*

Vitamin E (VE) is broadly recognized by its effects on immune response and meat quality of broiler chickens. However, studies have presented controversial results of VE effects on broiler performance. A meta-analysis was conducted to estimate the linear effect of VE supplementation on body weight (BW, 39–49 d of age), daily weight gain (DWG), daily feed intake (DFI) and feed conversion ratio (FCR) of male broiler chickens, using a data set composed by 33 peer-reviewed journal articles from 2010 to 2014. Data were analyzed by linear mixed models approach, where studies (s) were assumed as random effect whereas VE total amount on diet as fixed effect. VE levels in the database were: mean = 91.89 ± 106.6 mg/kg, min = 0 mg/kg, max = 400 mg/kg, while the response variables presented the following averages and observations: BW = 2.16 ± 0.66 kg, n = 41, s = 12; DWG = 61.6 ± 16.02 g, n = 44, s = 13; DFI = 91.7 ± 19.6 g, n = 49, s = 13; FCR = 1.78 ± 0.18 g/g, n = 56, s = 16. The necessity to model error heteroscedasticity was evaluated based on Akaike's information criterion and Schwarz criterion. Significance was declared at $P \leq 0.05$. None of the analyzed variables was linearly influenced by VE supplementation, where the estimated slopes were not different from zero with P-values equal to: 0.99, 0.80, 0.22, 0.40, for BW, DWG, DFI and FCR, respectively. The absolute value of correlation between random terms (i.e., intercept and slope) was never greater than 0.27, what indicates that VE effect is independent of variables' values range, with the exception of DFI ($r = -0.86$). Although 33 studies were evaluated in this research, few of them presented all performance variables simultaneously, what could have reduced the meta-regression power of analysis. Moreover, most studies presented a small range and few VE levels (i.e., less than 4 levels). More standardized and integrated research should be conducted to investigate possible effects of VE on broilers performance; nevertheless, there is not yet, in the current literature, any evidence indicating that the non-effect hypothesis should be rejected.

Key Words: meta-regression, nutrition, poultry

T290 The duration required to detect differences in bone mass accumulation in young pigs fed diets with varied vitamin D, Ca, and P concentrations.

Lynzie M. Miller*, Laura A. Amundson, and Thomas D. Crenshaw, *University of Wisconsin, Madison, Wisconsin.*

The time course for accumulation of bone mass was established in 49 pigs (~28 d of age) fed diets with either low (LCaP; 75% Ca; 95% P) or high (HCaP; 150% Ca; 120% P) Ca and P (expressed as a percentage of requirements) each formulated without (-D; 0 IU D/kg) or with (+D; 280 IU D/kg) supplemental vitamin D_3. Bone mass was measured by dual-energy x-ray absorpitometry (DXA). Accumulation of skeletal mass was calculated from DXA scans at weekly intervals for the first 3-wk period, then at 2-wk intervals for the next 4 wk. Animals were fed a recovery diet (+D HCaP) during the last 4 wk. Growth and skeletal mass traits were analyzed as randomized block design for each weekly interval with inferences about diet differences based on orthogonal contrasts for main effects of CaP or vitamin D and the CaP × D interaction. Differences ($P < 0.01$) in skeletal mass due to dietary Ca and P were detected after 1 wk, but differences ($P < 0.01$) due to vitamin D effects were not detected until 2 wk. However, during the recovery phase the initial dietary vitamin D treatments affected recovery responses, not dietary Ca and P. Pigs fed diets without vitamin D failed ($P < 0.01$) to regain skeletal mass over the 4-wk recovery period, but pigs previously fed diets supplemented with vitamin D recovered skeletal mass equal to that of control pigs. In conclusion, DXA provides an effective method to detect differences in bone mineral content gain (gBMC, g/d). Young pigs responded to dietary depletions of Ca and P earlier than to vitamin D, but recovery from a vitamin D depletion was not detected after a 4-wk period.

Table 1 (Abstr. T290). Whole-body bone mineral content gain, g/d

Days	−D LCaP	−D HCaP	+D LCaP	+D HCaP	SEM
0 to 8[a]	0.72	2.43	1.03	2.74	0.33
0 to 16[abc]	1.14	2.84	3.01	6.20	0.30
0 to 24[abc]	1.15	2.58	5.22	8.48	0.30
0 to 55[b]	11.98	12.39	17.92	18.22	0.66

a = CaP effect, $P < 0.01$; b = D effect, $P < 0.01$; c = CaP × D effect, $P < 0.02$.

Key Words: bone mineral, DXA, recovery

T291 Comparison of response criteria used to assess dietary vitamin D_3 requirements in young pigs.

Laura A. Amundson* and Thomas D. Crenshaw, *University of Wisconsin, Madison, WI.*

Recent concerns for increased mortality of young pigs attributed to hypovitaminosis D have focused attention on response criteria used to assess vitamin D requirements. The objective of the current experiment was to determine the dose-response relationships between dietary vitamin D_3 and skeleton mineral accumulation and serum 25-OH D_3 in growing pigs. All pigs were fed diets with 95% of the recommended Ca and P, but no supplemental vitamin D for 1 wk post-weaning. At 1 wk after weaning (~25 d), 84 crossbred pigs (n = 4 pigs/pen, 3 pens/diet) were randomly assigned to 1 of 7 diets formulated to supply 95% of the recommended Ca and P concentrations with either 0, 50, 100, 200, 400, 800 or 1,600 IU D_3/kg. Sows that produced the litters were fed the UW Swine Research and Teaching Center standard gestation and lactation diets, both formulated to supply 325 IU vitamin D_3/kg. A segmented 2-phase linear model was applied to regress variables to vitamin D intake. Growth (ADG, kg/d), whole body bone mineral content (BMC, g) and bone mineral density (BMD, g/cm^2) via dual energy x-ray absorpitometry (DXA) scans, femur mechanical properties (bending force, yBM, kg-cm; stress, kg/cm^2) responses at the end of the 28-d trial (n = 6 pigs/diet, 2 pigs/pen) peaked at diet concentrations between 50 to 100 IU vitamin D_3 ($P < 0.05$), but serum 25-OH D_3 concentrations continued to increase as concentrations of dietary vitamin D_3 increased to 1,600 IU Intersections of the 2 regression slopes were 81, 84, and 77 IU vitamin D_3/d for ADG, BMD, and yBM respectively. Slopes for the upper range were not significantly different. No plateau was detected in serum 25-OH D_3 concentrations. Although limited by the number of groups in the lower range, diets with 100 IU vitamin D_3/kg appear adequate to meet requirements of young pigs for growth and skeletal traits. No benefit was attributed to the increased serum 25-OH D_3 concentrations.

Table 1 (Abstr. T291). Effects of supplemental vitamin D_3 on performance

	Vitamin D_3 (IU/kg diet)							
Trait	0	50	100	200	400	800	1,600	SEM
ADG, kg/d	0.338	0.385	0.452	0.472	0.485	0.434	0.486	0.024
BMD, g/cm^2	0.289	0.327	0.371	0.380	0.397	0.366	0.370	0.014
yBM, kg-cm	278	318	463	434	473	451	405	50

Nonruminant Nutrition: Sows and piglets

T292 Meta-analysis of the influence of live yeast addition on feed intake in lactating sows. Eric Chevaux*[1], David Guillou[1], and Ernest Keith[2], [1]*Lallemand Animal Nutrition, Blagnac, France,* [2]*Lallemand Animal Nutrition, Milwaukee, WI.*

Increasing the lactating sow feed intake is generally considered beneficial, but high inter-individual variability of the measurements makes difficult designing the trials on this subject. A meta-analysis of 10 trials (1111 sows, 8 genetics lines, parity 1–8, lactation duration 19–31d) was undertaken, comparing "control" diets (n = 12) to diets supplemented with the same strain of live yeast *Saccharomyces cerevisiae* boulardii CNCM I-1079 (LY) at 1.0 or 2.0 × 10^9 cfu/kg (n = 12), to increase the chance to detect feed intake differences. In these trials, individual feed intake of sows (ranging 3.9 to 8.5 kg/d) was measured; trials were performed in commercial farms or close situation, in Europe or North America. Measurements of litter weight at weaning and number of piglets weaned could be retrieved from all 10 trials, but not changes of sow weight or P2 backfat thickness. Data were analyzed by ANOVA (SPSS 19.0) incorporating a random effect of trial, the treatment effect being considered weighted or not for experimental power or measurement variability. Effect of location of the experiment, year (1999 to 2013), lactation length, or duration of pre-treatment with live yeast were incorporated in the model, then excluded because of lack of significance ($P > 0.20$). Litter size, litter weight at weaning, parity or backfat thickness were included as covariate, and then discarded from final model as neither significance nor correlations were found. Live yeast added to sows diets stimulated appetite overall (Table 1), leading to a significant increase of feed intake ranging between +200 (weighted by number of replicates) and +300 g/d (un-weighted). Feed intake difference higher than the mean standard error of measurement was found in 6 trials out of 10. Nonetheless, factors affecting the magnitude of yeast effect could not be elucidated with only 10 trials in the compilation. Subsequently, the present results deserve being confirmed with new studies including accurate measurements of sows DMI and body condition.

Table 1 (Abstr. T292). DMI (kg) per treatment according to the statistical model

Weighted	Control	LY	SEM	*P*-value
None	5.714	5.997	0.346	0.03

T293 Effects of palm kernel expellers on productive performance, nutrient digestibility, and white blood cells of lactating sows. J. Kim*[1], Y. Jang[1], S. Kim[1], W. Kim[1], K. Jang[1], K. Kim[1], B. Kim[1], S. Park[1], I. Park[1], Y. H. Kim[2], J. C. Park[2], J. Seo[3], Y. Kim[4], S. Seo[1], M. Song[1], [1]*Chungnam National University, Daejeon, Republic of Korea,* [2]*National Institute of Animal Science, Cheonan, Republic of Korea,* [3]*Pusan National University, Miryang, Republic of Korea,* [4]*Chonbuk National University, Jeonju, Republic of Korea.*

A preliminary study was conducted to investigate the effects of palm kernel expellers on productive performance, nutrient digestibility, and changes in white blood cells (WBC) of lactating sows. A total of 14 sows (200 ± 12 kg BW; 2.5 parity) were randomly assigned to 2 dietary treatments: a diet based on corn and soybean meal (CON) and CON + 20% palm kernel expellers (PKE). Sows were fed the treatments for 28 d (weaning) after farrowing. Blood was collected from each sow and randomly selected 4 piglets in each sow before farrowing or on d 3, 7, or 14 of lactation. Sows were fed respective treatments containing 0.2% chromic oxide from d 15 to 21 of lactation. Fecal samples were collected daily for the last 3 d after the 4-d adjustment period. Measurements were performances and WBC changes of sows and litter, nutrient digestibility of sows, and daily diarrhea of litter. Data were analyzed using the PROC GLM procedure of SAS. The statistical model for every measurement except frequency of diarrhea included dietary effect and parity as a covariate. The chi-squared test was used for the frequency of diarrhea. Sows fed PKE had greater ADFI (7.38 vs. 7.10 ± 0.06 kg/d; $P < 0.05$) and lost less BW (−6.85 vs. −8.54 ± 0.51 kg; $P < 0.05$) and backfat depth (−0.42 vs. −0.71 ± 0.09 mm; $P < 0.05$) than those fed CON. However, there were no differences on digestibility of dry matter, nitrogen, and energy and weaning to estrus interval of sows fed either CON or PKE. Piglets from sows fed PKE gained more BW (203 vs. 181 ± 7.62 g/d; $P = 0.08$) and had less frequency of diarrhea (6.80 vs. 8.56%; $P = 0.07$) than those from sows fed CON. However, no difference was found on preweaning mortality of piglets from sows fed either CON or PKE. Sows fed PKE had lower number of WBC (9.57 vs. 11.82 ± 0.83 × 10^3/µL; $P = 0.09$) before farrowing than those fed CON, but no difference on d 3 and 7. Similarly, piglets from sows fed PKE had lower number of WBC (7.86 vs. 9.80 ± 0.62 × 10^3/µL; $P < 0.05$) on d 14 of lactation than those fed CON, but no difference on d 3 and 7. In conclusion, PKE increased ADFI and decreased changes of BW and backfat depth of lactating sows compared with CON, but no differences were found on other measurements.

Key Words: lactating sow, palm kernel expellers, performance

T294 Effects of the level of bovine plasma in pregnant gilts on the birth weight of the litter. Bárbara V. Freitas*, Simone M. M. K. Martins, Jose A. R. Ulloa, Gustavo A. Campos, and Lúcio F. Araújo, *University of São Paulo, Pirassununga, São Paulo, Brazil.*

Plasma is considered an important ingredient in animal feed for high quality, functional protein. In piglets, it has been associated with causing a reduction in inflammation and immune stimulation. The use of the ingredient is growing in sows during the pregnancy to improve weight and homogeneity at birth and the body condition of the sow at the end of lactation, reducing the number of "days open" before conception. The study aimed to evaluate the effect of different plasma levels in the diet of gilts on the birth weight of piglets. Twenty-four pregnant, primiparous females (Topigs Norsvin) aged 215 ± 9.46 d and weighing 127 ± 8.0 kg were used. The compositions of the diets were based on corn and soybean meal, in accordance with NRC recommendations (2012). The experimental design was completely randomized, with 4 treatments: 0, 0.5, 1.0 and 2.0% of plasma added to the feed. Six repetitions per treatment were used and the experimental unit was one primiparous pregnant sow. During the gestational period, from 1 to 3 d after insemination, the gilts consumed a mean 1.200 kg of feed per day, from 4 to 79 d, a mean of 1.800 kg per day and from 80 to 110 d, a mean of 2.800 kg of feed per day. Blood plasma was added to the diet formulation according to treatment. After birth, all the live piglets, placentas, stillbirths, and mummies were weighed. The mean weight of the complete litter, including mummies and stillbirths, was 16.85 kg, 17.36 kg, 17.63 kg and 18.52 kg for the treatments 0, 0.5, 1.0 and 2.0% of added plasma, respectively. The characteristics of total litter weight, live births weight, fetal membrane weight and number of live-born, stillborn and mummified piglets were not affected by the inclusion of plasma in the diet of sows. The characteristics of the total litter weight, live births weight, fetal membrane weight and number of live-born piglets were analyzed using PROC REG (SAS, 2012), while stillborn and mummified piglets were analyzed using PROC GLIMMIX, Poisson distribution (SAS, 2012). Level of significance $P < 0.05$.

Key Words: primiparous pregnancy, gestation, blood plasma.

T295 Effect of dietary supplementation of oregano essential oils to sows on oxidative stress status, lactation feed intake and reproductive performance.

Chengquan Tan[1], Jiangtao Ao[1], Guang Long[1], Haiqing Sun[1,2], and Jian Peng*[1], [1]*Department of Animal Nutrition and Feed Science, College of Animal Science and Technology, Huazhong Agricultural University, Wuhan, Hubei, China,* [2]*YangXiang Joint Stock Company, Guigang, Guangxi, China.*

The aim of the current study was to evaluate the effects of supplementing sow diets with oregano essential oils (OEO) during gestation and lactation on oxidative stress status, lactation feed intake and reproductive performance of sows. Sixty multiparous large white sows were randomly assigned to 1 of 2 dietary treatments within 24h after service to weaning: control (C) or C+ 300mg/kg of OEO (OEO). Serum samples collected from sows on d 10, 60, 90 and 109 of gestation and d 1, 3, 7 and 21 of lactation were used to determine reactive oxygen species (ROS), glutathione peroxidase (GSH-Px) and oxidative stress markers [malondialdehyde (MDA), 8-hydroxy-deoxyguanosine (8-OHdG)] levels. Data were analyzed using GLM procedure. The average daily gain (ADG) of suckling piglets was subjected to analysis of covariance with the piglet weight after cross-foster as the covariate. Variations of oxidative stress parameters were using the procedure for repeated measurements, which included the effects of treatment, physiological stage and replicate. Differences between means were significant at $P < 0.05$ and trends identified when $P > 0.05$ but ≤ 0.10. The results showed that serum levels of ROS, MDA and 8-OHdG were higher ($P < 0.05$) during gestation (d 90, 109) and lactation (d 1, 3) than early gestation (d 10). Sows fed OEO diet elevated serum concentration of GSH-Px on d 60 of gestation ($P = 0.08$), and d 1 ($P = 0.07$) of lactation than C group, while serum concentrations of MDA on d 1 of lactation ($P < 0.01$), 8-OHdG on d 109 of gestation ($P = 0.09$), d 1 ($P = 0.06$) and d 3 ($P = 0.10$) of lactation and ROS on d 1 ($P = 0.10$) and d 3 ($P = 0.10$) of lactation were lower in sows treated with OEO dietary than C group. Dietary OEO treatment increased sow feed intake in the third week of lactation (6.46 vs 6.03 kg/d, $P = 0.07$), accordingly, had higher ADG (252.36 vs 233.61 kg/d, $P < 0.01$) of suckling piglets of entire lactation than C group. In conclusion, our results demonstrated that there was an increased systemic oxidative stress during late gestation and early lactation of sows. Nevertheless, OEO dietary supplementation attenuated oxidative stress in sows.

Key Words: oxidative stress, oregano essential oil, sow

T296 Sow productivity at farrowing was not affected when 50% of a co-product combination was included in the gestation diet.

Elizabeth Magowan[1], Paul McMullen[1], Aishling O’Connell[2], Rosanna Wregor[2], and Wallace Henry*[3], [1]*Agri-Food and Biosciences Institute, Hillsborough, United Kingdom,* [2]*JMW Farms, Tynan, United Kingdom,* [3]*Rektify Limited, Gilford, United Kingdom.*

This study, aimed to compare the performance of sows offered a diet containing a high level of co-products during gestation (d5–112). A control (cereal/soy) gestating diet was compared with one containing 50% of a co product (a blend of potato skins, whey permeate, and residual grains and effluent from the production of an alcoholic beverage). A total of 176 sows (88/treatment), penned in groups of 8, were group fed over 11 time periods (each group was balanced for weight, parity and condition score). Individual sows were used as the experimental unit when assessing effects on litter performance. Lactation feed intake was measured for 10 pairs of sows per treatment. The DE, CP, lysine and CF content of the diets were formulated to be 2.77 and 2.96 Mcal/kg, 17.7 and 14.4%, 0.7 and 0.7%, 9.1 and 7.4% for the co product and control diets respectively. Sows were offered feed once a day during gestation using a feed curve that offered sows 8.60 Mcal/d from d 7–34, 6.69 Mcal/d from d 35–83 and 8.60 Mcal/d from d 84–112 of gestation. Sows were fed ad lib during lactation they farrowed. Changes in sow condition score and weight and litter performance were measured. Sow dirtiness was scored on a 0–3 point scale. Statistical analysis used ANOVA with period as a blocking factor. There was no difference in sow parity (3.85), weight (204 kg) or condition scoring (2.9) on d 5 of gestation. Due to the lower energy content of the co product diet, total sow intake was numerically higher when it was offered (245 vs. 229 kg). There was no effect of diet on sow weight at farrowing (266 kg), condition score (3.2), litter size (13.6), number born alive (12.7), dead (0.73) or mummified (0.17). When the co-product diet was offered, sows were dirtier ($P < 0.001$) (2.09) compared with when the control diet was offered (1.03). The average daily lactation feed intake of sows was statistically similar when the co product diet (5.97 kg/d) was offered compared with when the control diet was offered (6.62 kg/d). In conclusion, the inclusion of 50% of the blended co product had no significant impact on sow weight, condition score or productivity at farrowing.

Key Words: dry sow, co-product, performance

T297 Effect of supplying a nucleotide product (Harv-con NT) to sow diets on the reproductive performance and the health status of the offspring.

I-Fen Hung*[1], Fuguei Li[2], Shigeng Zou[3], and Merlin D. Lindemann[1], [1]*University of Kentucky, Lexington, KY,* [2]*Interflavor Ltd., Zhongshan City, Guangdong, China,* [3]*WENS Group, Yunfu City, Guangdong, China.*

Nucleotides have demonstrated their ability to improve several biological responses during stress periods, including parturition. This experiment was conducted in a commercial farm (WENS Groups) in China. Around d 87 of gestation, sows (n = 316) were assigned to 2 dietary treatments based on their housing unit: 1) the standard farm gestation diets provided by WENS Group or 2) the standard diets top dressed with 3.5 g/sow/d of a nucleotide product (Harv-con NT, NT; Interflavor Ltd., China). Approximately 1 week before expected parturition, sows were moved to farrowing facilities and assigned to 2 dietary treatments: (1) the standard farm lactation feed; or (2) the standard diet top dressed with 8 g/sow/d (on the day of moving to 7 d post-farrowing) and 12 g/sow/d (7 d post-farrowing till weaning) NT in the lactation diet, which resulted in a 2 × 2 factorial arrangement. The data were analyzed using GLM program of SAS with the housing unit as the experimental unit, 4 units per treatment. Supplying NT to sow diets during late gestation had no effect on the total litter size at birth as expected (11.5 vs. 11.9, $P = 0.19$), but reduced the “healthy” pig litter size (9.9 vs. 10.8, $P = 0.01$) as determined by the farm. Litter weight of the healthy pigs at birth was not affected by the treatments (14.4 vs. 14.4, $P = 0.88$), thus the individual birth weight was increased in NT sows (1.4 vs. 1.3kg, $P = 0.01$). In the units with diarrhea, less diarrhea was observed in litters from sows fed NT in gestation compared with those from Control sows (25 vs. 69%, $P = 0.07$). Also, more sows in the gestation NT treatment returned to heat within 7 d post weaning compared with control sows

(95 vs. 82%, $P = 0.01$). Neither NT treatment in gestation or lactation had an effect on colostrum and d13–17 milk nutrient composition (i.e., fat, protein, and lactose) or immunoglobulin profile. In conclusion, adding NT to the sow diets during late gestation increased healthy pig birth weight and ratio of returning heat within 7d post weaned. It also reduced diarrhea incidence during the suckling period in the units that experienced diarrhea. However, supplying NT to the sow diets during lactation had no effects on these observations. Supplying NT to sow diet during gestation or lactation had no effects on milk composition as well.

Key Words: nucleotide, sow, piglet

T298 The effect of coated sodium butyrate supplementation in sow and nursery diets on reproductive performance and nursery pig performance. Young Dal Jang*, Merlin D. Lindemann, H. James Monegue, and James S. Monegue, *University of Kentucky, Lexington, KY.*

The experiment was conducted to evaluate the effect of coated sodium butyrate (CSB) supplementation to peripartal and lactating sows and nursery pigs on reproductive performance and nursery growth performance. In Exp. 1, a total of 43 gestating sows (d 81–90 of gestation) were allotted to 0 (n = 15), 500 (n = 16), and 1,000 (n = 12) ppm of CSB (CM3000, Hangzhou King Techina Feed Co., Ltd., China) based on breed, parity and BW, and then fed treatment diets until weaning. In Exp. 2, a total of 72 weanling pigs were selected from the 0 (n = 5 sows) and 1,000 (n = 4 sows) ppm CSB treatments in Exp. 1 and allotted within the sow treatment to 0, 500, and 1,000 ppm of CSB in nursery diets for 3 replicates with 4 pigs per pen as a split plot design (SPD) for a 35-d growth study. All pigs were injected with ovalbumin at weaning and d 14 postweaning as an immune challenge. All data were analyzed by ANOVA using GLM procedure of SAS as a completely randomized design in Exp. 1 and a SPD in Exp. 2. In Exp. 1, there was no difference on sow BW, litter size, litter weight, lactation feed intake or milk composition. However, colostral IgG ($P = 0.06$; 2,447, 3,337, and 2,723 mg/dl for 0, 500, and 1,000 ppm of CSB treatments, respectively) and IgA ($P = 0.09$; 406, 540, and 464 mg/dl) concentrations tended to increase quadratically as CSB supplementation levels increased. In Exp. 2, pigs from the 1,000 ppm CSB sow treatment had greater BW ($P < 0.01$; 23.1 vs. 21.6 kg), ADG ($P < 0.01$; 0.462 vs. 0.418 kg/d), ADFI ($P < 0.01$; 0.776 vs. 0.684 kg/d) and F:G ratio ($P = 0.07$; 1.67 vs. 1.64) than those from the 0 ppm CSB sow treatment at d 35 postweaning. For the nursery treatments, ADG ($P < 0.05$; 0.428, 0.428, and 0.463 kg/d for 0, 500, and 1,000 ppm CSB, respectively) and ADFI ($P = 0.06$; 0.707, 0.717, and 0.767 kg/d) during the 35-d period increased linearly as CSB supplementation levels increased whereas F:G ratio had a quadratic response ($P = 0.10$; 1.64, 1.68, and 1.64). In summary, CSB supplementation increased colostral IgG and IgA concentrations of sows when supplemented in the sow diet and improved growth performance of nursery pigs under an immune challenge when supplemented in the nursery diet.

Key Words: coated sodium butyrate, reproductive performance, sow

T299 Nucleotide supplementation improves growth performance of weaned piglets. Gabriela de Mello Miassi*[1], Luan Sousa Santos[2], Livea Maria Gomes[1], Patrícia Nardin Berto[1], Mayra Dib Saleh[1], Alessandro Borges Amorin[3], Marcos Livio Panhoza Tse[1], and Dirlei Antonio Berto[1], *[1]Faculdade de Medicina Veterinária e Zootecnia, FMVZ/UNESP, Botucatu, São Paulo, Brazil, [2]Faculdade de Ciências Agrárias e Veterinárias, FCAV/UNESP, Jaboticabal, São Paulo, Brazil, [3]Instituto de Ciências Agrárias e Tecnológicas, ICAT/UFMT, Rondonópolis, Mato Grosso, Brazil.*

This study was conducted to evaluate effects of dietary supplementation of nucleotide (disodium 5 guanylate and disodium 5 inosinate) on the growth performance and plasmatic lipid profile of weaned piglets. Eighty-four weaned piglets of 21 d of age (6.04 ± 0.25 kg average initial BW) were allotted to 4 dietary treatments with 7 pens per treatment and 3 pigs per pen, in a randomized complete block design. The treatments were dietary supplementation with 0% (control); 0.2%; 0.4% or 0.6% nucleotide of diet during 34 d. Performance was determined from 21 to 36, 21 to 48 and 21 to 55 d of age. Blood samples were collected to determinate lipid profile (triglycerides, total cholesterol, HDL cholesterol and LDL+VLDL cholesterol) on 21 and 55 d of age. Data were submitted to ANOVA using PROC GLM of SAS and the effects of supplementation levels of nucleotide were studied through regression analysis. During the first period (21 to 36 d of age) no differences were detected on the performance. During the second period (21 to 48 d of age) a quadratic effect ($P < 0.01$) of the levels of nucleotide was verified on average daily feed intake and average daily weight gain, with optimal response to the levels of 0.31% and 0.32%, respectively . During the whole experimental period (21 to 55 d of age) there was a quadratic effect of the levels of nucleotide ($P < 0.01$) on average daily weight gain with optimal response to the level of 0.31%. There was no significant effect on triglycerides, total cholesterol, HDL cholesterol and LDL+VLDL cholesterol. The overall results suggest that dietary nucleotide supplementation at 0.32% improves the performance of weaned piglets.

Key Words: disodium 5 guanylate, disodium 5 inosinate, pig

T300 Effect of nucleotide supplementation in high soybean meal inclusion diets on weight gain and inflammatory process in weanling pigs. David Solà-Oriol[1], Wellington Coloma[1], Elisabet Borda*[2], and José Francisco Pérez[1], *[1]Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]R&D Animal Nutrition, Bioibérica, Palafolls, Spain.*

Soybean protein ingredients (SB as soybean meal; SBM and soya protein concentrates; SBP) are widely used in pig diets; however they may also promote acute intestinal inflammation and affect gut mucosal integrity and performance. Several beneficial effects of nucleotide supplementation on gut immune function, inflammation and diarrhea has been reported, which could reduce the negative effects SB in piglets. The aim of the present work was to study the effect of including nucleotides (Nucleoforce Piglets, Bioibérica, SA) in diets containing different levels of SB on acute inflammation process and early performance of weaned piglets. Two hundred forty 28-d-old piglets [Pt × (LD × LW)] were distributed into 24 pens (10 pigs/ pen) according to the initial BW following a RCBD. Two pre-starter diets differing in the SB content as protein source (Low or High) formulated to contain 10.3 MJ/kg of NE, 19.5% CP and 1.28% Lys were supplemented with or without nucleotides (500 mg/kg) following a 2 × 2 factorial arrangement. High SB diet contained 15% of extruded soybeans, 6.82% SBM and 5.62% SBP; while Low SB diet was obtained by partly replacing SB ingredients with fish meal (8.44%) and animal plasma (2.5%) according to their protein content. Feed was offered ad libitum in mash form. Individual animal weight and feed disappearance were recorded at d 28 and 42 of live. Blood samples were collected on d 7 to determine TNFα as inflammation marker. Data was analyzed with ANOVA following a 2 × 2 factorial arrangement with GLM procedure of SAS. Higher BW (9.59 vs 9.09 kg; $P = 0.03$), ADFI (205 vs 167 g/d; $P = 0.002$) and ADG (140 vs 103 g/d: $P = 0.04$) was observed for Low SB diet than high SB diet, independently of the nucleotide supplementation. An interaction between SB inclusion in the diet and nucleotide supplementation was observed ($P = 0.04$) reflecting that nucleotides promote a decrease of TNFα in High SB group (95.1 vs 67.4 pg/mL) but not in Low SB group (60.3 vs 70.1 pg/mL) without and with nucleotides, respectively. It is concluded that nucleotide supplementation in diets containing high inclusion of soybean meal and soybean protein products reduces acute inflammation process.

Key Words: soybean meal, nucleotide, inflammation

T301 Effects of palm kernel expellers on growth performance, nutrient digestibility, and blood profiles of weaned pigs.

Y. Jang*[1], J. Kim[1], S. Kim[1], W. Kim[1], K. Jang[1], K. Kim[1], B. Kim[1], S. Park[1], I. Park[1], Y. H. Kim[2], J. C. Park[2], J. Seo[3], Y. Kim[4], S. Seo[1], M. Song[1], *[1]Chungnam National University, Daejeon, Republic of Korea, [2]National Institute of Animal science, Cheonan, Republic of Korea, [3]Pusan National University, Miryang, Republic of Korea, [4]Chonbuk National University, Jeonju, Republic of Korea.*

A study was conducted to investigate the effects of palm kernel expellers on growth performance, nutrient digestibility, and blood profiles of weaned pigs. A total of 88 weaned pigs (6.94 ± 0.76 kg BW; 28 d old) were randomly allotted to 2 dietary treatments (4 pigs/pen; 11 replicates/treatment): a typical nursery diet based on corn and soybean meal (CON) and CON + 20% of palm kernel expellers (PKE). Pigs were fed for 6 wk using a 3-phase feeding program with declining diet complexity and with phases of 1, 2, and 3 wk, respectively. Blood was collected from randomly selected 2 pigs in each pen before weaning and on d 7 after weaning. Pigs were fed dietary treatments containing 0.2% chromic oxide from d 29 to 35 after weaning. Fecal samples were collected from randomly selected 2 pigs in each pen daily for the last 3 d after the 4-d adjustment period. Measurements were growth performances, nutrient digestibility, blood profiles, and incidence of diarrhea. Data were analyzed using the PROC MIXED procedure of SAS. The statistical model for every measurement except frequency of diarrhea included dietary effect as a fixed effect and sex as a random effect. The chi-squared test was used for the frequency of diarrhea. The PKE tended to increase ADG (246 vs. 215 g/d; $P = 0.06$), increased ADFI (470 vs. 343 g/d; $P < 0.05$), and decreased G:F (0.522 vs. 0.628 g/g; $P < 0.05$) during phase 2 compared with CON, but did not affect growth performance during phase 1 and 3. During overall experimental period, PKE tended to increase ADG (383 vs. 362 g/d; $P = 0.05$) and increased ADFI (549 vs. 496 g/d; $P < 0.05$) compared with CON, but did not affect G:F. However, no differences were found on digestibility of dry matter, nitrogen, and energy between CON and PKE. The PKE tended to reduce frequency of diarrhea (15 vs. 25%; $P = 0.08$) for the first 2 wk after weaning compared with CON. Similarly, PKE tended to decrease white blood cells (8.19 vs. 9.56×10^3/μL; $P = 0.07$), red blood cells (2.92 vs. 3.25×10^6/μL; $P = 0.09$), and packed cell volume (11.1 vs. 12.6%; $P = 0.06$) on d 7 after weaning compared with CON. In conclusion, PKE had no negative effects on growth performance, nutrient digestibility, and blood profiles of weaned pigs.

Key Words: growth performance, palm kernel expellers, weaned pig

T302 Beneficial effects of a prebiotic supplement on growth and performance of weaned piglet.

Edi Vianello, Anne-Kathrin Blässe*, and Bernhard Eckel, *Dr. Eckel GmbH, Niederzissen, Germany.*

Weaning is a crucial phase in piglet rearing as the change from milk to solid feed in combination with external stressors such as regrouping may be related to an impaired gut and animal health. Villus atrophy and a limited activity of digestive enzymes can lead to an accumulation of undigested feed in the lower intestinal segments followed by increases in the count of pathogenic bacteria such as *E. coli* and subsequent diarrhea. Prebiotics are non-digestible feed components that selectively stimulate the growth of positive bacteria such as lactobacilli and may thus reduce pathogens. The present study investigated the potential of a specific prebiotic acid and salt mixture including formic and lactic acid and their salts as well as butyrate and gluconate (PreAcid, Dr. Eckel GmbH, Niederzissen, Germany) in increasing piglet growth and performance. Twenty weaned crossbred piglets each [Pietrain x (Large White x German Landrace)] with an initial BW of 8 ± 1 kg were randomly allocated to a control group and a treatment group. The animals were individually fed a diet based on wheat, barley and soybean meal for a period of 6 wk and the treatment group received the basal diet supplemented with 1% PreAcid. Statistical analyses were performed using SAS (fixed factors: mother, sex, treatment, group). Energy efficiency (6,139 kcal/kg weight gain vs 6,330 kcal/kg weight gain, $P < 0.05$) and energy conversion (39 g/kcal vs 38 g/kcal, $P < 0.05$) were significantly improved by the treatment. In conclusion, the present trial demonstrated that the inclusion of the specific prebiotic acidifier in diets for weaned piglets increased feed efficiency indicating an improved energy utilization.

Key Words: prebiotic, piglet, growth performance

T303 Effect of dietary melatonin supplementation on growth performance and behavior, and their correlations in weaned pigs.

Kyeongsu Chae*[1], Junseung Choi[2], Jonggun Kim[1], and Kwang-Youn Whang[1], *[1]Department of Biotechnology, Graduate School, Korea University, Seoul, Korea, [2]Dodram Swine Service, Gyeonggi, Korea.*

Some behaviors such as roaming and fighting observed in weaned pigs have been considered to be unhelpful to growth performance. Melatonin (MEL) secreted from the pineal gland has a sedative effect on human behavior. In this study, MEL was supplemented in the weaned pig diets to determine the effect of MEL on growth performance and behaviors, and correlation between them. Two hundred twenty-five 21-d-old pigs were allotted into 4 treatments (9 or 10 pigs per pen) with 6 replications and fed diets containing MEL at doses of 0, 25, 50 and 100 mg/kg of diet (M0, M25, M50 and M100) for 35 d. By using closed-circuit television cameras, the behavior of pigs was recorded to score resting (RT), roaming (RM), feeding (FD) and fighting (FT) states for 24 h on d 3, 10, 17, 24 and 31. The BW and feed intake were measured every week to calculate ADG and feed efficiency (FE). The data were analyzed by ANOVA, followed by the Duncan's new multiple range test. Correlations between growth performance and the behaviors were analyzed with reference to the Pearson correlation coefficients. The BW was higher in M25 group (not different from M0) than M50 and M100 groups on d 28 ($P < 0.05$) but there was no difference at the end of experiment. The ADG was higher in M25 group than the other groups during d 21–28 ($P < 0.05$). There were no differences in ADFI and FE throughout the experiment. The RT was lower and RM was higher in M50 group (not different from M0) than M25 and M100 groups on d 10 ($P < 0.05$) but there were no differences on the other days. The MEL did not alter FD and FT throughout the experiment. Correlations between growth performance and behavior were found in M0 group but not in MEL-treated groups (M25, M50 and M100) during d 7–14. Therefore, it is concluded that MEL at dose of 25 mg/kg of diet may affect BW in weaned pigs on d 28 according to the improved ADG during d 21–28 but MEL does not affect ADFI and FE. This study also suggests that MEL affects RT and RM within 14 d. However, the behaviors affected by MEL are not correlated with growth performance.

Key Words: pig, melatonin, behavior

Physiology and Endocrinology: Environment, metabolism and physiological processes

T304 Effect of the environmental conditions over the vaginal temperature and respiration rate on wild type and slick-haired Puerto Rican Jersey cows. Amneris M. Castro-Ramos*, Gladycia C. Muñiz-Colón, Jaime E. Curbelo-Rodríguez, Melvin Pagán-Morales, Alexander Mesonero-Morales, Adalberto de Jesus-de Jesus, Neftalí Lluch-García, and Héctor L. Sánchez-Rodríguez, *University of Puerto Rico at Mayagüez Campus, Mayagüez, Puerto Rico.*

The slick hair phenotype is associated with enhanced thermoregulation in Holstein cows; however, no such data are available in slick-haired Jersey cows. The relationship between hair coat type (phenotypically determined), vaginal temperature (VT; as an index of core body temperature), respiration rate (RR), and thermal humidity index (THI) was evaluated in 10 Puerto Rican Jersey cows [5 wild type-haired (WT; 111.2 ± 0.8 d in milk (DIM); 1.2 lactations) and 5 slick-haired (SLICK; 171.6 ± 1.5 DIM; 1.2 lactations)]. Cows were exposed to solar radiation from 1030 to 1130 h and to artificial shade from 1130 to 1030 h during 5 consecutive days. Data loggers recorded VT (TidbiT v2), air temperature, and relative humidity (HOBO Pro v2) every 5 min and the THI was determined. Daily THI ranged from 63.47 – 81.77. The RR was recorded at 0600, 0800, 0900, 1000, 1100, 1200, 1300, 1400, and 1500 h daily. Data were analyzed using the GLIMMIX and CORR procedures of SAS. There were no differences in VT between hair type groups either under sun or shade exposure ($P = 0.43$). From 1030 to 1130 h (direct solar radiation exposure) mean VT values of 39.08 ± 0.02 and 39.26 ± 0.02°C were observed in SLICK and WT cows, respectively. During the 1130–1030 h (shade period), SLICK and WT cows presented mean VT values of 38.80 ± 0.01 and 38.89 ± 0.01°C, respectively. However, SLICK cows presented lower RR than their WT counterparts ($P = 0.004$). Mean daily RR values of 56.0 ± 5.2 and 77.6 ± 5.0 breaths per minute were observed in the SLICK and the WT cows, respectively. Correlation coefficients of 0.68 ($P < 0.0001$) and 0.47 ($P < 0.0001$) were observed between the VT and the RR in WT and SLICK cows, respectively. However, VT was less associated with THI in WT than in SLICK cows [$r = 0.24$ ($P < 0.0001$) and $r = 0.50$ ($P < 0.0001$), respectively]. In conclusion, slick-haired Jersey cows were able to maintain similar vaginal temperature than their wild type-haired counterparts, but with a lower respiration rate. These findings suggest that wild type-haired Jersey cows' body temperature regulation requires greater heat dissipation through evaporation than their slick-haired counterparts.

Key Words: slick-haired Jersey cow, thermoregulation, solar radiation

T305 Effects of the thermal humidity index on vaginal temperature of slick- and wild type-haired Puerto Rican Holstein cows. Héctor L. Sánchez-Rodríguez*, Amneris M. Castro-Ramos, Melvin Pagán-Morales, Jaime E. Curbelo-Rodríguez, Alexander Mesonero-Morales, and Gladycia C. Muñiz-Colón, *University of Puerto Rico at Mayagüez Campus, Mayagüez, Puerto Rico.*

The slick hair phenotype has been suggested as an alternative for dairy production in tropical and subtropical countries. The present study evaluated the relationship between hair coat type (phenotypically determined), vaginal temperature (VT) and thermal humidity index (THI) in lactating Puerto Rican Holstein cows. In trial 1, 4 wild type-haired (WT; 169.8 ± 3.8 d in milk (DIM) and 3.8 ± 2.2 lactations) and 5 slick-haired (SLICK; 146.6 ± 63 DIM and 3.0 ± 2.1 lactations) cows were used. In trial 2, 5 WT (173.2 ± 42.3 DIM and 3.0 ± 2.1 lactations) and 5 SLICK (163.8 ± 43.0 DIM and 2.8 ± 1.7 lactations) cows were evaluated. Data loggers recorded VT (TidbiT v2), air temperature, and relative humidity (HOBO Pro v2) every 5 min for 8 consecutive days and the THI was determined. The THI presented daily ranges from 63.72 to 80.63 and 61.79–81.47 on trial 1 and trial 2, respectively. Data were analyzed by the GLIMMIX and CORR procedures of SAS. In trial 1 there were no differences in VT between SLICK and WT cows (38.71 ± 0.08 and 38.71 ± 0.09°C, respectively; $P = 0.96$). Daily VT in SLICK and WT cows began to increase ($P < 0.001$) at similar THI values (68.49 and 65.02, respectively; $P = 0.82$). In this first trial, correlation coefficients of 0.27 ($P < 0.0001$) and 0.36 ($P < 0.0001$) were found between the VT and THI in SLICK and WT cows, respectively. In trial 2, hair coat type and time of the day interacted to affect VT ($P < 0.001$). During the 1900–2100 h WT cows presented VT values 0.25°C greater than SLICK cows ($P = 0.02$). From 2200 to 1800 h WT and SLICK cows presented similar VT values (38.68 ± 0.10 and 38.60 ± 0.07°C, respectively; $P = 0.39$). Also in trial 2, daily VT began to increase ($P < 0.001$) in both hair type groups when THI reached 70.08. In this second trial, correlation coefficients of 0.32 ($P < 0.001$) and 0.42 ($P < 0.001$) were found between the VT and THI in SLICK and WT cows, respectively. In general, environmental conditions had a greater association with the vaginal temperature in wild type cows than in their slick-haired counterparts, and in trial 2 than in trial 1. However, vaginal temperature only differed between hair type groups during a limited period.

Key Words: slick-haired Holstein cow, thermoregulation, thermal humidity index

T306 Relationship between daily milk production and core-body temperature of lactating Holstein cows. E. O. S. Batista*[1,2], C. Collar[1], P. D. Carvalho[3], N. Silva-Del-Rio[1], P. S. Baruselli[2], and A.H. Souza[1], *[1]University of California, Tulare, CA, [2]University of Sao Paulo, Sao Paulo, SP, Brazil, [3]University of Wisconsin, Madison, WI.*

Our objective was to study the daily variation in the core-body temperature (CBT) of lactating dairy cows under heat stress. Holstein cows (8 multiparous and 5 primiparous) producing 37.1 ± 2.9 kg/d and at 234 ± 15 DIM were used in the study. Cows were milked twice daily and located in a commercial dry-lot facility in California. The CBT of all cows was synchronously measured at every 10 min throughout 7 d from August 7 to August 13, 2014, using a temperature data logger (iButton, Maxim Integrated) attached to an intravaginal CIDR device. Body condition scores were recorded at device insertion. Environmental temperature was collected at 10 min intervals throughout the experimental period (Average = 29.0°C; Max = 38.9°C; Min = 18.3°C). Individual milk production was recorded daily and extracted from the herd's management software (Dairy Comp-305). Two cows lost their device and records were not used. Data were analyzed by repeated measures using the GLIMMIX procedure of SAS. In some analysis, cows were categorized into 2 milk production categories (high and low) based on milk production average. Parity, days in milk, and body condition score were not associated with CBT ($P > 0.10$). In contrast, time of the day and milk production influenced CBT ($P < 0.01$). Although large individual CBT variations were observed, further analysis comparing cows with high vs. low milk production indicated that maximal CBT was reached later in the afternoon and was greater for high compared with low producing cows ($P = 0.04$). More importantly, high producing cows remained for a longer period (45.1% of their daily time budget, $P < 0.01$) with their CBT above the 39.9°C threshold compared with the low producing cows (27.1% of their daily time budget). In conclusion, cows with greater daily milk production seem to be more susceptible to heat stress. Thus, cooling systems should be designed to match milk production requirements.

Key Words: milk production, heat stress, body temperature

T307 Effect of castration and multi alleviation treatment on growth and physiological responses in Korean cattle. Seung Ju Park, Min Yu Piao, Hyun Jin Kim, Hyeok Joong Kang, and Myunggi Baik*, *Seoul National University, Gwanak-gu, Seoul, Republic of Korea.*

This study was performed to determine the effects of castration and multi alleviation treatment (MAT) on growth and physiology in Korean cattle male calves. Forty Korean cattle calves (BW = 197.0 kg; 188 d of age) were allocated to 4 treatments (n = 10/group): castration with MAT (12 ml of 2% lidocaine hydrochloride injection for local anesthesia in the scrotum and 2 mg/kg body weight of 50 mg/ml flunixin meglumine injection for antiinflammation in the muscle of the buttock immediately before castration), castration without MAT, no castration with MAT, and no castration without MAT. Surgical castration was performed using a Newberry knife and Henderson castrating tool. The 0.9% NaCl solution was used for non-drug groups instead of MAT. Blood was collected immediately before castration and drug injection (0 h) and 0.5 h, 6 h, 1 d, 3 d, 7 d, and 14 d after castration, body temperature was measured at same time points. Food intake was recorded daily, and body weight was measured at 0 d before castration and 14 d. Average daily gain was analyzed using 2-way ANOVA, using mixed model procedure of SAS. Other variables were analyzed in a repeated measures model using PROC GLIMMIX of SAS. Castration tended to decrease ($P = 0.07$) average daily gain (castration group 0.58 kg/d vs. non-castration group 0.79 kg/d), but MAT did not affect weight gain. Castration increased ($P < 0.001$) body temperature only at 1 d after castration, but not at other time points. Castration increased ($P < 0.001$) plasma cortisol concentrations (castration group 102 ng/mL vs. non-castration group 49 ng/mL) only at 0.5 h after castration, but not at other time points. MAT did not affect cortisol concentrations. Castration increased ($P < 0.05$) plasma nonesterified fatty acid (NEFA) concentrations at 0.5 h, 1 d, and 14 d after castration, but MAT did not affect NEFA concentrations. In conclusion, castration of bulls increased temporally circulating cortisol and NEFA concentrations and tended to decrease forage intake and retard animal growth, but neither increased cortisol concentration nor retarded growth caused by castration were alleviated by MAT.

Key Words: alleviation treatment, castration, cortisol

T308 The effect of exercise in pregnant Holstein heifers on fitness and heat tolerance. Jessica Winkler* and Timothy G. Rozell, *Kansas State University, Manhattan, KS.*

Heat stress negatively affects milk production and feed intake of dairy cows resulting in efforts to find ways of reducing heat stress. A possible avenue could be implementing an exercise regimen to improve thermoregulatory capacity. Our objective was to determine if exercising late gestation heifers in a warm climate could physiologically improve thermoregulation. Pregnant Holstein heifers (n = 25) were randomly assigned to 3 treatment groups: exercise (EX; n = 8), exercise control (EC; n = 8; walked with exercise heifers to exerciser but held in a holding pen), and sedentary control (SC; n = 9). Exercise regimens were implemented 4–5 d per wk in the morning for approximately 30–45 min for 8 wk using a motorized panel walker to control duration and speed. Data were collected on fitness test d 0, 28, and 56 of the experiment in which heifers were pushed to reach their maximum speed and time before exhaustion. Pre- and post-exercise blood samples, intra-vaginal temperature, duration, final speed, and heart rate were collected. During wk 2 and wk 6 of the experiment, intra-vaginal temperature devices recorded temperature for 2–4 d and all data were analyzed using PROC GLIMMIX. Duration (min) and final speed (kph) were significantly greater ($P = 0.04$, $P = 0.009$) at d 28 for the EX compared with the SC (duration = 19.31 vs. 13.81; final speed = 6.65 vs. 5.20), implying fitness was achieved. During wk 6, EX heifers spent a smaller percentage of time in Zone 3 (temperature > 39.17°C) than EC during the hottest h of a d (7% vs. 76%; $P = 0.045$), and both EX and EC heifers also spent less time in Zone 3 compared with the SC during the cooler part of a d (4.16e^{-}17% vs. 20%; $P = 0.02$). During the first wk of lactation, milk protein tended ($P = 0.06$) to be greater in EX than in SC heifers (3.88 vs. 3.57). There was no significant difference between pre- and post-serum samples (Na^+, base excess, ionized Ca, glucose, lactate, pCO_2, pO_2) and heart rate collected on fitness days. Based on results from our pilot study, it appears that heifers undergoing an exercise regimen may be able to improve their ability to regulate a homeostatic body temperature.

Key Words: heat acclimation, cattle exercise

T309 Comparative efficacy of dexamethasone or corticotropin releasing hormone and vasopressin administration as a model to induce chronic physiological stress in beef cattle. Nathan D. May*[1], Jeff A. Carroll[3], Nicole C. Burdick Sanchez[3], Shelby L. Roberts[1], Heather D. Hughes[1], Paul R. Broadway[3], Kate P. Sharon[2,3], Michael A. Ballou[2], and John T. Richeson[1], *[1]Department of Agricultural Sciences, West Texas A&M University, Canyon, TX, [2]Department of Food and Animal Sciences, Texas Tech University, Lubbock, TX, [3]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

The objective of this study was to delineate a model for chronic stress by evaluating physiological and hematological alterations in cattle administered: 1) 0.5 mg/kg BW dexamethasone (DEX) once daily at 10am for 3 d consecutively, or 2) 0.3 μg/kg BW corticotropin releasing hormone (CRH) and 1 μg/kg BW vasopressin (VP) twice daily at 10am and 10pm for 3 d consecutively. Twelve (n = 6) beef steers (BW = 389 ± 11kg) were stratified by BW, assigned randomly to treatment, and fitted with indwelling rectal temperature (RT) devices and jugular catheters, before relocation into individual stanchions in an environmentally-controlled facility. Blood samples were collected at 0.5-h intervals from −2 to 6 h relative to each 10am challenge. Serum was analyzed for cortisol concentration and whole blood samples were evaluated to profile hematological responses via automated hemocytometer. All data were analyzed using PROC MIXED with repeated measures and steer was the subject. A trt × time interaction ($P < 0.001$) was observed for RT, which increased transiently in both treatments following the 10am challenge time each d. However, the magnitude of the febrile response was greater ($P < 0.001$) for DEX. Likewise, serum cortisol increased transiently in response to both challenges, yet the cortisol increase was more pronounced for CRH-VP (trt × time; $P < 0.001$). On d 1, cortisol was 24.8 and 30.4 ng/mL for DEX and CRH-VP, respectively (trt × d; $P < 0.001$). Total peripheral blood leukocytes (PBL) were increased in both treatments; however, the PBL concentration was greater for DEX vs. CRH-VP from h 5 to 54 (trt × d; $P < 0.001$). The total PBL was associated with a corresponding increase in circulating neutrophils observed for DEX, but not CRH-VP on d 2 (12.2 vs. 7.2 × 103/μL) and 3 (11.7

vs. 6.6 × 103/µL; trt × d; $P < 0.001$). In contrast, eosinophils decreased ($P < 0.001$) sharply for DEX on d 1 and remained undetectable through d 3. These data suggest that exogenous administration of both DEX and CRH-VP alter RT and cortisol variables indicative of stress, while DEX may more strongly inhibit neutrophil translocation from peripheral blood, a key component of stress-induced immunosuppression.

Key Words: cattle, immunosuppression, stress

T310 Intraperitoneal administration of lipopolysaccharide induces differential expression of mRNA encoding inflammatory mediators in the oviducts of mice.

Katheryn L. Cerny* and Phillip J. Bridges, *University of Kentucky, Lexington, KY.*

Infection with gram-negative bacteria is a major cause of aberrant inflammation in the oviduct; consequences can include tubal infertility and/or ectopic pregnancy. Understanding inflammatory responses due to bacterial infection is necessary for the development of novel treatment options that specifically target inflammatory responses. Our objective was to test the hypothesis that intraperitoneal (IP) administration of *E. coli*-derived lipopolysaccharide (LPS) induces the expression of inflammatory mRNAs in the mouse oviduct. On the day of estrus, 6–8 week old CD1 mice (n = 4/treatment) were treated IP with 0 (control), 2 µg (low dose) or 10 µg (high dose) of LPS from *E. coli* serotype 055:B5 in 100 mL of PBS. Mice were killed 24 h later and the oviducts collected for determination of inflammatory gene expression by a targeted nanostring approach using the nCounter GX Mouse Inflammation Kit (Nanostring Technologies, Seattle, WA). Real-time PCR was used to validate selected mRNAs. The effect of LPS was evaluated by one-way ANOVA and treatment means of differentially expressed mRNA ($P < 0.05$) were separated using a post-hoc LSD test. In total, 56/179 targeted genes were affected by treatment ($P < 0.05$). Pairwise comparison revealed 8 mRNA differentially expressed in control vs. low dose, 50 mRNAs in control vs. high dose and 43 mRNAs in low vs. high dose ($P < 0.05$). These results indicate that systemic treatment with LPS induces inflammation in the oviducts of mice; this study provides evidence of a new model to investigate the regulation of oviductal inflammation in the future.

Key Words: oviduct, inflammation, immune response

T311 Effects of lipopolysaccharide (LPS)-induced inflammatory response on early embryo survival in ewes.

M. R. Graham*[1], E. C. Bowdridge[1], S. A. Bowdridge[1], I. Holásková[1], T. H. Elsasser[2], and R. A. Dailey[1], [1]*West Virginia University, Morgantown, WV,* [2]*United States Department of Agriculture-Agricultural Research Service (USDA-ARS), Beltsville Agricultural Research Center (BARC), Beltsville, MD.*

The effects of proinflammatory pathway triggers on pregnancy success was assessed in early pregnant ewes. Effects of endogenous cytokine activation (via LPS), direct exogenous tumor necrosis factor-α (TNF-a) and TNF-a+Dexamethasone (TNF-a+Dex) administration were compared in regard to pregnancy rate. Dorset × Texel ewes (n = 38) were synchronized for estrus and bred to fertile rams (d 0). On d 6, ewes were assigned to receive via the jugular 2.5 mL containing either PBS (n = 9), 2.5 µg/kg LPS (n = 9), 1 µg/kg TNF-a (n = 10) at 0 and 30min, or 2.5 µg/kg of LPS after 3.5 mL containing 0.14 mg/kg BW im Dex (n = 10) at −12h and 0h. Behavioral changes and rectal temperatures (BT) were recorded before challenge and hourly for 12 h. Jugular blood was collected before challenge, every 30 min for 3 h, hourly until 12 h, at 24, 36, and 48 h, and on d 10 and d 26 for progesterone. At d 26, pregnancy was examined using ultrasonography. The proportion of ewes pregnant was analyzed by Chi-squared and Fisher's exact test with preplanned contrasts. Other data were analyzed by repeated measures ANOVA. Treatment with LPS resulted in peak BT at 4 h (40°C; control 38°C; $P < 0.05$), increased lethargy, mucosal response, white blood cell (WBC) count (9.8×10^6; control 9.1×10^6; $P < 0.05$), serum TNF-a (0.9 ng/mL; control 0.2 ng/mL; $P < 0.05$). Treatment with LPS+Dex resulted in peak BT at 4 h (39°C), but was blunted by Dex. Additionally, Dex blocked mucosal and lethargic responses and attenuated LPS-induced increases in TNF-a and did not improve pregnancy rate compared with LPS alone ($P > 0.05$). TNF-a treatment increased BT at 1 h (39°C), did not induce lethargy; 5/10 ewes showed a mucosal response; and WBC counts did not change but high concentrations of TNF-a were not sustained. More control and TNF-a ewes (15/19) were pregnant than LPS or LPS+Dex ewes (9/19; $P = 0.045$). In summary, an inflammatory response was elicited by LPS and resulted in reduced proportion of ewes pregnant regardless of Dex administration. Treatment with TNF-a did not affect proportion of ewes pregnant, perhaps due to low serum TNF- a levels or different pathway components stimulated by LPS. These data show that a sustained inflammatory response to LPS decreased pregnancy rate and may involve a complex cascade of inflammatory mediators elicited by LPS.

Key Words: LPS, embryonic loss, sheep

T312 Intramammary lipopolysaccharide induces increased luteal mRNA abundance of tumor necrosis factor alpha and toll-like receptor 2 but not luteolysis in dairy cows.

Johannes Lüttgenau[1], Olga Wellnitz[1,2], David Kradolfer[3], Christina Zbinden[2], Susanne E. Ulbrich[3], Rupert M. Bruckmaier*[2], and Heiner Bollwein[1], [1]*Clinic of Reproductive Medicine, Vetsuisse Faculty, University of Zurich, Zurich, Switzerland,* [2]*Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland,* [3]*ETH Zurich, Animal Physiology, Institute of Agricultural Sciences, Zurich, Switzerland.*

Recently, we observed that the application of *Escherichia coli* lipopolysaccharide (LPS) into the mammary gland induce severe clinical symptoms (pyrexia, increased cardiac and respiratory frequencies), an intense stress, and systemic immune response (increased plasma cortisol and haptoglobin concentrations). However, no obvious suppression of luteal size, blood flow, and progesterone secretion in lactating dairy cows were detectable. To investigate possible effects of intramammary LPS challenge on gene expression in luteal tissue, biopsies of the corpus luteum (CL) were analyzed. On d 9 of the estrous cycle (d 1 = ovulation), 8 lactating dairy cows received once 200 µg LPS (dissolved in 10 mL NaCL) and 6 cows received once 10 mL saline (control) into one quarter of the mammary gland. Luteal tissue was collected for biopsy 24 h before and 6 h after treatment, using an ultrasound-guided semi-automatic high-speed biopsy needle. RT-qPCR was applied to assess the mRNA expression of toll-like receptors (*TLR2*, *TLR-4*), tumor necrosis factor α (*TNFα*), steroidogenic factors (*STAR*, *3βHSD*), and factors related to apoptosis (*CASP3*) and prostaglandin synthesis (*PGES*, *PGFS*, *FP*). Data were normally distributed (Shapiro-Wilk-test) and Student's *t*-test was used for dependent comparisons of repeated measures. LPS challenge increased ($P \leq 0.05$) mRNA abundance of *TNFα*, *TLR2* and *CASP3*, whereas *TLR4*, *STAR*, *3βHSD*, and prostaglandin-related factors did not change significantly. In control cows, only mRNA expression of *CASP3* was increased ($P \leq 0.05$) at 6 h after compared with 24 h before treatment. Our results indicate that LPS-induced mammary immune response increases luteal TNFα and TLR2 synthesis but do not induce luteolysis in the bovine CL.

Key Words: lipopolysaccharide, mammary gland, corpus luteum

T313 Different weaning age changes piglets blood parameters related to stress prior anxiety test.

Patricia M. Ramos*[1,2], Maicon Sbardella[1,2], Marcelo A. S. Coutinho[1,2], Valdomiro S. Miyada[1,2], and Eduardo F. Delgado[1,2], *[1]"Luiz de Queiroz" College of Agriculture, Piracicaba, SP, Brazil, [2]University of São Paulo, São Paulo, Brazil*

This study aimed to identify behavior and metabolites changes in piglets after different weaning when submitted to anxiety test. Thirty-two piglets were separated in 2 homogeneous groups, regarding sex and weight, within 2 pairs of sows based on same parturition date. Half of each sow litter was submitted to different weaning ages (days): 23 (early weaning - EW) and 30 (normal weaning - NW). One week after the NW date, piglets at the same age were submitted to an anxiety test (ATest) in elevate plus maze. Piglets were weighed and blood sampled on the day before and at weaning and also before and after the maze. Blood glucose (mg/dL), lactate (mg/dL) and protein (g/dL) concentrations were measured. ATest was recorded for 3 min and analyzed. GLM was run and means compared by Tukey's test at 0.05. Average daily gain during the week after early weaning were greater ($P < 0.01$) for NW animals, that were still suckling, compared with EW animals. This scenario was inverted in the week after NW date. The blood glucose before weaning was greater ($P < 0.01$; SEM ± 2.26) for the EW (127.62) than for NW (114.28) piglets. Those differences were still present ($P < 0.01$; ± 3.11) in the blood before ATest for EW and NW at 115.92 and 101.54, respectively. Differences were not observed neither after weaning nor after ATest. Likewise, lactate was greater ($P < 0.05$; ± 4.48) in EW vs NW animals before weaning and ATest, with 53.55 vs 38.48 and 66.21 vs 35.09 (SEM ± 6.32), respectively. Inverted after weaning, where NW (52.85) animals presented greater ($P < 0.05$; ± 4.43) lactate compared with EW (39.87). Lactate did not change between groups after ATest. Total protein was different ($P < 0.05$; ±0.12) between EW and NW animals only after weaning, with 5.48 and 5.06, respectively. There was no difference between the EW and NW on the variables recorded in ATest. After anxiety test blood glucose was negatively correlated (−0.35; $P < 0.01$) to the entry in open arms. Early weaning changes blood parameters at weaning and when animals are submitted to novel environmental challenges. Blood glucose concentration is negatively associated with more active and less anxious animals in maze test.

Key Words: early weaning, metabolites, maze

T314 Conjugated linoleic acid (CLA) isomers strongly improves the redox status of bovine mammary epithelial cells (BME-UV1).

Loredana Basiricò[1], Arnoulf Troscher*[2], Daniele Dipasquale[1], Patrizia Morera[1], Andrea Serra[3], Marcello Mele[3], and Umberto Bernabucci[1], *[1]Dipartimento di scienze e tecnologie per l'Agricoltura, le Foreste, la Natura e l'Energia, Università degli Studi della Tuscia, Viterbo, Italy [2]BASF-SE, Ludwigshafen, Germany, [3]Dipartimento di Scienze Agrarie, Alimentari e Agro-ambientali, Università di Pisa, Pisa, Italy.*

To date, there is no information available concerning the relationship between administration of CLA and changes in oxidative status of bovine mammary gland. The aim of this study was to assess in vitro the role of CLA in cell protection against the oxidative stress of bovine mammary cells. The uptake rates of CLA in BME-UV1 cells at 3 h and 48 h were tested using DAD HPLC analysis. BME-UV1 cells were treated with complete medium containing 50 μM of *cis*-9,*trans*-11 CLA (c9,t11), *trans*-10,*cis*-12 CLA (t10,c12) and CLA Mixture (50% c9,t11 and 50% t10,c12). After 48 h from addition of CLA, cell samples were collected for determining oxidative markers such as nicotinamide adenine dinucleotide phosphate (NADPH), glutathione (GSH/GSSG), thiobarbituric acid reactive substances (TBARS), cytoplasmic superoxide dismutase (SOD), glutathione peroxidase (GPx1), glutathione S-transferase (GST) and glutathione reductase (GR) using commercial kits. The mRNAs quantification of antioxidant enzymes (SOD, GPx1, GST and GR) was performed by rt-PCR. The potential protection of CLA against H_2O_2-induced oxidative stress was assessed by XTT assay after 48h of pre-treatment with CLA and 3h with H_2O_2. The data were analyzed by ANOVA and differences were declared significant at $P < 0.05$. The results showed that the uptake rates of CLA in cells increased from 3 (26.54%) to 48h (73.95%). CLA increased ($P < 0.01$) the concentration of reduced GSH (CLA 17.25 vs control 11.73 μM) and NADPH (CLA 0.28 vs control 0.20 μM), mostly in cells treated with t10,c12 (0.50 μM). The enzymatic antioxidant activity of GR (CLA 7.00 vs control 11.82 U/L) was decreased ($P < 0.01$) whereas GSPx1($P < 0.01$), GST ($P < 0.05$) and SOD ($P < 0.01$) activities (CLA 19.85, 0.70, 0.05 vs control 7.07 U/L, 0.61 U/mL, 0.02 U/mL, respectively) were increased in cells treated with CLA. Lower levels of TBARS (CLA 1.50 vs control 1.96 μM/MDA equivalent) were observed in cells treated with CLA. CLA had not any substantial effect on gene expression of antioxidant enzymes. All CLA isomers were able to enhance ($P < 0.01$) cell resistance against oxidative stress (CLA 2.85 vs control 2.65 O.D.). Findings of the present study corroborate the antioxidant role of CLA, in particular of t10,c12 isomer, by improving of redox status in cells, and might be of help during physiological oxidative stress situations such as the periparturient period in dairy cow. This work was funded by BASF-SE.

Key Words: conjugated linoleic acid, bovine mammary cell, oxidative stress

T315 Antioxidant potential in the gut of juvenile fish fed with lyophilized bovine colostrum.

Debora B. Moretti*, Wiolene M. Nordi, Thaline M. P. Cruz, Jose Eurico P. Cyrino, and Raul Machado-Neto, *University of São Paulo, Piracicaba, São Paulo, Brazil.*

Bovine colostrum is a rich source of immunological factors and contains a large concentration of antioxidant components that can affect gut physiology. Thus, the antioxidant potential was evaluated in the gut of juvenile pacu (*Piaractus mesopotamicus,* Holmberg, 1887), an omnivorous fish, and dourado (*Salminus brasiliensis,* Cuvier, 1816), a carnivorous fish, fed with diets containing 0, 10 and 20% of lyophilized bovine colostrum (LBC) for either 30 or 60 d. The antioxidant capacity in the intestinal tissue was assessed by the determination of superoxide dismutase (SOD), catalase (CAT), glutathione peroxidase (GPx) and by the oxygen radical absorbance capacity (ORAC value expressed as equivalent trolox in μM/mg of protein). Experimental design was completely randomized with treatments arranged as a 3 × 2 factorial, considering the 3 diets and the 2 periods as main effects. If F value was significant, Tukey test was used for comparisons between means ($P < 0.05$). In pacu, interaction between diet and period was observed to SOD ($P < 0.05$), juveniles fed 0 and 10% LBC did not change enzyme activity at 30 (423 ± 27 and 692 ± 42 U/mg of protein, respectively) and 60 d (504 ± 14 and 890 ± 57 U/mg of protein, respectively), whereas juvenile fed 20% LBC showed higher enzyme activity at 60 d (1122 ± 71 U/mg of protein) compared with 30 d (595 ± 61 U/mg of protein). GPx was not influenced by diet and period ($P > 0.05$) and CAT was

affected only by period ($P < 0.05$), showing higher activity at 60 d (891 ± 86 U/mg of protein) compared with 30 d (437 ± 99 U/mg of protein). The ORAC was affected by diet and period ($P < 0.05$); the juveniles fed 10% LBC (505 ± 100 μM/mg) had greater oxygen absorbance capacity than the juveniles fed 20% LBC (348 ± 104 μM/mg), and the value was greater at 30 (628 ± 61 μM/mg) than at 60 d (234 ± 31 μM/mg). In dourado, GPx was affected by period ($P < 0.05$), showing greater activity at 30 (224 ± 30 U/mg of protein) than at 60 d (94 ± 19 U/mg of protein). SOD, CAT and ORAC value were not affected by diet and period ($P > 0.05$). Inclusion of lyophilized bovine colostrum improved SOD activity in the gut of juvenile pacu, an omnivorous fish, indicating a possible protective action of this lacteal secretion.

Key Words: colostrum, antioxidant enzyme, oxygen radical absorbance capacity (ORAC)

Physiology and Endocrinology: Reproductive tissues, gametes, and embryo development

T316 Stem cell factor (SCF) activates AKT-p70RSK-S6 signaling in porcine trophoblast cells. Yurina Choi*, Wooyoung Jeong, Heejo Bang, Yujin Sung, and Jinyoung Kim, *Dankook University, Cheonan, Korea.*

During early pregnancy, a well-coordinated network between the conceptus and maternal uterus is especially crucial in pigs which involve a prolonged pre-attachment phase. This network is regulated by an astonishing amount of molecules such as growth factors. SCF (Stem Cell Factor) is a multipotent growth factor that elicits diverse biological actions on various types of tissues. In pig, SCF and their receptors are expressed in the uterine endometrium and conceptus during early pregnancy, but little is known about the biological role of SCF in the conceptus. Therefore, the aim of present study was to access SCF-induced intracellular signaling and cellular activities in porcine trophectoderm (pTr) cells. The effects of SCF were studied using pTr cells isolated from Day 12 pig conceptuses. Abundance of phosphorylated (p)-proteins relative to total proteins were determined by Western blot analyses of whole cell extracts 3 times and subjected to least squares using SAS software. In vitro cultured pTr cells were incubated with different concentrations of recombinant SCF (0–50 ng/mL). SCF dose dependently increased AKT phosphorylation, reaching 3.3-fold at 20 ng/mL. Within 30 min after 20 ng/mL of SCF treatment, levels of p-AKT, p-p70RSK and p-S6 proteins increased by 3.0-, 3.1- and 4.0-fold, respectively, and then returned to basal levels by 120 min. To ensure stimulatory effect of SCF on AKT signaling, cells were pre-incubated with AKT blocker (LY294002) 1 h before SCF treatment. Twenty μM of LY294002 decreased SCF-induced p-AKT, p-p70RSK and p-S6 proteins. Also immunofluorescence analyses found that p-S6 were localized abundantly within the cytoplasm of SCF-treated cells, but p-S6 was present at basal levels in the presence of LY294002. Furthermore, SCF increased pTr cell migration by 200%, but LY294002 significantly reduced this stimulatory effect to basal level. In conclusion, results of the present study suggest that SCF activates migration of trophectoderm through AKT signaling and supports the hypothesis that SCF is a critical regulatory factor of conceptus development during early pregnancy in pigs.

Key Words: SCF, early pregnancy, trophectoderm

T317 In vitro fertilization (IVF) from low or high antral follicle count pubertal beef heifers using semi-defined culture conditions. C. C. Chase, Jr.*[1], R. A. Cushman[1], A. K. McNeel[1], E. C. Wright-Johnson[1], O. L. Amundson[2], E. L. Larimore[2], B. N. Richardson[2], G. A. Perry[2], S. C. Tenley[3], J. R. Wood[3], A. S. Cupp[3], J. L. Vallet[1], D. D. Sypherd[1], and J. L. Miles[1], *[1]USDA, ARS, US Meat Animal Research Center, Clay Center, NE, [2]Dept. of Animal Science, South Dakota State Univ., Brookings, SD, [3]Dept. of Animal Science, University of Nebraska, Lincoln, Lincoln, NE.*

Our objective was to compare the in vitro maturation and fertilization of oocytes collected from low and high antral follicle count (AFC) heifers. Trans rectal ultrasonography was performed on 120 heifers to determine AFC and presence of a corpus luteum (i.e., pubertal). Those 10 heifers with the lowest AFC (avg. 14.2) and those 10 heifers with the highest AFC (avg. 29.9) all with evidence of estrous cyclicity (i.e., pubertal) were synchronized with 2 injections of $PGF_{2\alpha}$ and killed over 4 d; on d 5 to 6 of the estrous cycle. Nineteen heifers (n = 9 low and n = 10 high AFC) were at the appropriate stage of the estrous cycle. The IVF procedures and media were as described (P. J. Hansen's Laboratory, IVP Protocol). Cumulus-oocyte complexes (COCs) from follicles less than 8 mm in diameter were cultured in maturation medium (5% CO_2; 38.5°C) for 24 h. Matured COCs were fertilized using thawed frozen semen from a crossbred bull that was purified using Percoll separation procedures. Motile spermatozoa were added to COCs in fertilization medium at a final concentration of $1x10^6$ spermatozoa per mL. About 24 h later, presumptive zygotes were placed in micro drops of development medium under oil, and cultured (5% CO_2; 5% O_2; 38.5°C). On d 3 and 8 after fertilization, cleavage and blastocyst development, respectively, were assessed. Data were analyzed using the MIXED procedure of SAS and the model included the effects of collection d, group, and their interaction. Percentage data were analyzed using the GLIMMIX procedure with a binomial distribution and a logit link. Neither collection d nor the interaction differed ($P \geq 0.13$). High compared with low AFC heifers had greater numbers of COCs ($P < 0.01$; 27.0 ± 3.79 vs. 9.6 ± 3.97 per heifer), oocytes that cleaved ($P < 0.04$; 15.2 ± 2.63 vs. 6.1 ± 2.76 per heifer), and developed to blastocysts ($P < 0.007$; 4.08 ± 0.662 vs. 0.83 ± 0.695 per heifer). There was no difference ($P > 0.9$) in the percentage of COCs that cleaved (low = 52.3 ± 8.37%, high = 53.6 ± 7.98%) or in the percentage of COCs that developed to blastocysts ($P < 0.13$; low = 6.6 ± 2.79% vs. high = 13.7 ± 2.66). These results agree with our previous findings, high AFC heifers had greater numbers of COCs, oocytes that cleaved, and blastocysts compared with low AFC heifers; however, AFC does not appear to affect oocyte development and maturation through the blastocyst stage.

Key Words: heifer, IVF, antral follicle count

T318 Effect of L-carnitine in serum-supplemented IVM medium on mitochondrial membrane potential, ROS levels and subsequent embryo development of bovine oocytes. Beatriz C. S. Leao*, Nathália A. S. Rocha Frigoni, Priscila C. Dall'Acqua, and Gisele Z. Mingoti, *Laboratory of Physiology of Reproduction, School of Veterinary Medicine, Sao Paulo State University, Araçatuba, Sao Paulo, Brazil.*

This study aimed to evaluate the effects of supplementation with different concentrations of L-carnitine (L-car) during in vitro maturation (IVM) of bovine oocytes on their mitochondrial membrane potential (MMP), reactive oxygen species (ROS) levels, and subsequent embryonic development. Cumulus-oocyte complexes (COC) were matured for 22 h at 38.5°C, 5% CO_2 in air, on IVM medium (TCM-199 with bicarbonate, hormones and 10% FCS) supplemented with 0 (Control), 1, 5 or 10 m*M* of L-car. Matured and immatured oocytes (0 h) were stained with 500 n*M* of MitoTracker Red (Molecular Probes, Invitrogen), or with 5 m*M* of H_2DCFDA (Molecular Probes, Invitrogen). Stained oocytes (MMP: n = 191; and ROS: n = 250) were evaluated under an epifluorescence inverted microscope (excitation 579/495nm and emission 599/404nm, respectively) and the images analyzed by Q-Capture Pro image software to measure the arbitrary fluorescence units. The fluorescence intensity values were subtracted from mean values of "background" in the images. The 0h group was chosen as the calibrator, and each treatment value was divided by the mean of the 0h. In a second trial, COC (n = 1875) were IVM as above and then fertilized. The presumptive zygotes were cultured in SOF medium at 38.5°C, 5% CO_2 in air, for 7 d (Day 0 = IVF), when the blastocysts (Bl) rates were evaluated. The averages were compared by ANOVA followed by the Tukey's test and data are presented as mean ± SEM. It was found a reduction ($P < 0.05$) on MMP after IVM with L-car 10mM (0.4 ± 0.0^{c}) in comparison to 1 m*M* (1.1 ± 0.1^{ab}) and 5 m*M* (1.0 ± 0.0^{ab}), as well as to 0h (1.0 ± 0.1^{a}); however, no treatment differed from the Control (0.8 ± 0.0^{abc}). In respect to ROS levels, we found an increase ($P < 0.05$) in oocytes matured with 10 m*M* (2.3 ± 0.1^{c}), in comparison to Control (1.8 ± 0.1^{b}), 1 m*M* (1.9 ± 0.1^{b}), 5 m*M* (2.0 ± 0.1^{b}) and 0 h (1.0 ± 0.0^{a}). Bl rates were similar ($P > 0.05$) in all treatments (25.2% ± 3.7 to 37.1% ± 2.7). In conclusion, the reduction on MMP after IVM of bovine oocytes with L-car 10 m*M* was followed by an increase of ROS level. However, there was no influence on their acquisition of capacity to Bl development. Financial support: FAPESP (#2012/10084–4 and #2013/07382–6)

Key Words: L-carnitine, mitochondrial membrane potential, ROS level

T319 Cell proliferation in ovarian follicles in nonpregnant ewes: Effects of plane of nutrition and arginine.

Anna T. Grazul-Bilska*, Samantha L. Kaminski, Casie S. Bass, Kaitlyn K. Ebel, and Dale A. Redmer, *North Dakota State University, Fargo, ND.*

The aim of this study was to investigate the role of the NO system in ovarian function by determining if Arg supplementation affects cell proliferation in ovarian follicles in nutritionally compromised ewes. Ewes were stratified by weight and randomly assigned into either control (C; n = 35), overfed (O; 2xC; n = 37), or underfed (U; 0.6xC; n = 36) groups 8 weeks before Arg-treatment. Ewes from each nutritional group were randomly assigned to one of 2 i.v. treatments: saline (~10 mL) or Arg (L-Arg-HCl, 155 µmol Arg/kg of BW) which was initiated on d 0 of the estrous cycle and administered 3 times per day (0700, 1400, 2100 h) until ovary collection at the late-luteal stage of the first estrous cycle, or early or mid-luteal stages of the second estrous cycle. Ovaries were fixed in formalin solution followed by immunohistochemical localization of Ki67 (a marker of proliferating cells), and image analysis of granulosa (G) and thecal (T) layers. Data were analyzed by ANOVA using SAS. During nutritional treatment, C maintained BW, O gained 6 ± 1.2 kg, and U lost 14 ± 1.3 kg. Ki67 was detected in G and T layers, and other ovarian compartments. Cell proliferation in G and T of healthy follicles was affected by stage of the estrous cycle, but not plane of nutrition or Arg-treatment. Cell proliferation was 1.3–1.5-fold greater ($P < 0.001$) at early and mid than late luteal phase. For G and T of healthy follicles, interactions ($P < 0.05$) between plane of nutrition, Arg-treatment and/or stage were detected, demonstrating stimulatory effects of Arg-treatment on cell proliferation at the early luteal phase in O and U, and inhibitory Arg-effects at the mid-luteal phase in O ewes. Cell proliferation was greater ($P < 0.001$) in healthy antral than atretic follicles in all groups (14.4 ± 0.4 vs. 1.9 ± 0.1%). These data show that cell proliferation in G and T layers is affected by plane of nutrition, Arg-treatment and/or stage of the estrous cycle that likely affects follicular function. The mechanism of regulation of ovarian cell proliferation by diet and Arg remains to be elucidated. Supported by USDA-AFRI grant 2011–67016–30174, and Hatch Projects ND01748 and ND01754 to ATGB and DAR.

Key Words: plane of nutrition, arginine, ovary

T320 Comparison of mRNA expression of dominant follicle and follicular cyst in lactating dairy cows.

Diego A. Velasco Acosta*[1,2], Tonja Egan[2], Cassandra Skenandore[2], Saige Sulzberger[2], Augusto Schneider[2], Fabio Lima[2], Marcio Corrêa[1], and Felipe Cardoso[2], [1]*Universidade Federal de Pelotas, Pelotas, Rio Grande do Sul, Brazil,* [2]*University of Illinois, Urbana, IL.*

Follicular cysts are an important disorder affecting 5 to 30% of dairy cows that leads to abnormal estrous cycle behavior and economic losses due to infertility. The aim of this study was to compare the mRNA expression in follicular cells of cows classified either as having a follicular cyst or cycling with dominant follicle (DF). Lactating dairy cows (n = 22) were examined weekly by ultrasound and 11 cows (Holstein, n = 7; Jersey n = 3; and Shorthorn n = 1) were classified as having a follicular cystic (CYS, follicle >25 mm with absence of corpus luteum) whereas 11 cows (Holstein, n = 11) were classified as cycling with a dominant follicle (CON, presence of corpus luteum and dominant follicle, n = 11). Cows were at 94.4 (30 – 382) DIM, milk yield 37.9 ± 12 kg /d, and parity 2.6 ± 1.3. Cows in CON had follicle diameter of 14.10 ± 3 mm whereas cows in CYS had follicle diameter of 35.73 ± 10.2 mm. Follicular fluid from each cow was aspirated and follicular cells were retrieved immediately by centrifugation, frozen in liquid nitrogen and stored at −80°C until RNA extraction. The mRNA expression for *LHCGR, STAR, 3β-HSD, P450scc, CYP19A1, IRS1, IGF, TLR4, TNF, IL1- β, IL8* and *IL6* was measured by real-time PCR. Statistical analysis was performed using the MIXED procedure of SAS. *LHCGR, 3β-HSD, CYP19A1, IRS1* mRNA expression was higher ($P < 0.05$) in CON (1.37 ± 0.4, 5.58 ± 1.2, 1.33 ± 0.2, 1.41 ± 0.3, respectively) than CYS (0.69 ± 0.3, 3.24 ± 0.9, 0.24 ± 0.01, 0.74 ± 0.2, respectively) with breed effect ($P < 0.07$). Expression of mRNA for *IGF, TLR4, TNF* and *IL8* was lower ($P < 0.05$) in CON (0.55 ± 0.07, 0.61 ± 0.2, 0.54 ± 0.3, 0.12 ± 0.01, respectively) than in CYS (4.62 ± 0.7, 3.40 ± 0.5, 1.58 ± 0.3, 0.52 ± 0.04, respectively), with no breed effect ($P > 0.20$). There was no difference ($P > 0.05$) for *STAR, P450scc, IL6* and *IL1-β* mRNA expression between CYS and CON. In conclusion, cows in CYS had lower expression of genes related to steroidogenesis and energy metabolism and greater expression of genes related to inflammation than CON. It seems that an inflammatory response may be involved in the follicular cyst etiology.

Key Words: follicle, cystic, inflammation.

T321 Colony-stimulating factor 2 affects development of the bovine preimplantation embryo differently for females than males.

Luiz G. B. Siqueira*[1,2] and Peter J. Hansen[1], [1]*University of Florida, Department of Animal Sciences, Gainesville, FL,* [2]*Embrapa Gado de Leite, Juiz de Fora, MG, Brazil.*

Colony-stimulating factor 2 (CSF2) regulates early embryonic development by modifying the epigenome, reducing apoptosis, and altering ratio of cells in the trophectoderm (TE) and inner cell mass (ICM) of the blastocyst. Previously, CSF2 reduced trophoblast elongation in female embryos but increased elongation in males. Here it was tested whether sexual dimorphism in response to CSF2 can be observed as early as the blastocyst stage. Embryos were produced in vitro using X- or Y-sorted sexed semen (n = 1612 putative zygotes). On d 5 of culture, droplets were supplemented with 5 µL vehicle (control) or 10 ng/mL bovine CSF2. Blastocysts (n = 210) were collected at Day 7 and labeled with a nuclear dye (Hoescht 33342; total cells) and a TE cell marker (CDX2). Number of ICM cells was calculated by subtraction. Statistical analysis was performed using the Proc Mixed procedure of SAS; data represent least squares means ± SEM. Treatment of female embryos with CSF2 increased the proportion of zygotes ($P = 0.0213$) and cleaved embryos ($P = 0.0252$) to become a blastocyst but there were no effects in males ($P > 0.10$). The percent of zygotes becoming blastocysts on Day 7 was 14.7 ± 2.1 vs 21.5 ± 2.1% for control and CSF2 in females and 16.2 ± 2.0 vs 16.3 ± 2.0% in males. There was no effect of CSF2 treatment, sex, or the interaction on the total cell number or number of TE ($P > 0.10$). There was a tendency ($P = 0.0934$) for ICM number to be less in females (56.2 ± 3.1 vs 61.0 ± 2.9) and the TE:ICM ratio was greater (P

= 0.0217) for females (1.64 ± 0.91) compared with males (1.45 ± 0.09). Numerically (but not significantly), CSF2 tended to decrease ICM in females (53.9 ± 3.6 vs 58.6 ± 3.7) but not in males (60.4 ± 3.5 vs 61.5 ± 3.4). There was a tendency for a CSF2 by sex interaction ($P = 0.0955$) for TE:ICM ratio. In females CSF2 increased ratio (1.73 ± 0.11 vs 1.55 ± 0.11), but no effect was observed in males (1.41 ± 0.10 vs 1.50 ± 0.10). In conclusion, CSF2 exerts different responses on development of female and male preimplantation embryos. Consequences of actions of CSF2 on ICM and TE cell differentiation require further investigation. Support: NIH HD080855.

Key Words: embryo, colony-stimulating factor 2, sex

T322 Effect of fertility stressors on transcriptome of peripheral blood leukocytes (PBL) in dairy cows at the onset of conceptus implantation.

Eduardo S. Ribeiro*[1,2], Rafael S. Bisinotto[1,2], Fabio S. Lima[1,2], Natalia P. Martinez[1,2], Leandro F. Greco[1,2], William W. Thatcher[1,2], and José E. Santos[1,2], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]D.H. Barron Reproductive and Perinatal Biology Research Program, University of Florida, Gainesville, FL.*

Objectives were to investigate changes in transcriptome of PBL occurring at the onset of implantation and how they are affected by fertility stressors. Lactating cows (n = 481) had estrous cycle and ovulation synchronized to receive their first insemination (AI) postpartum. On d 19 after AI, PBL were isolated and mRNA extracted. A subsample of PBL mRNA from 36 cows was subjected to transcriptome analysis using the Affymetrix platform. Pregnancy was diagnosed on d 34 after AI. Two fertility stressors were evaluated, progesterone concentration during development of the ovulatory follicle and clinical uterine diseases (UTD). At the onset of synchronization, experimental design was established to have cows ovulating follicles that grow under low (LP) or high (HP) concentrations of progesterone. In addition, cows were evaluated daily on the first 10 d postpartum for diagnosis of UTD. Statistics was performed using Limma on R and FDR adjustment was used. LP during development of the ovulatory follicle reduced pregnancy per AI (P/AI; 34 vs 53%) and altered the transcriptome of PBL. In the HP group, pregnancy resulted in upregulation of classical interferon stimulated genes (e.g., *IFI6*, *ISG15*, *OAS1Y*); whereas in the LP group, pregnancy resulted in downregulation of a large number of inflammatory response genes (e.g., *HP*, *JUN*, *MYD88*). Particularly distinct transcriptome was observed in LP cows that failed to become pregnant, which indicated an inflammatory state. Cows that suffered from UTD also presented reduced P/AI (33 vs 50%) but only subtle differences in transcriptome, although potentially important. In pregnant cows previously diagnosed with UTD, expression of *OAS1X* was downregulated whereas *CD244* was upregulated compared with pregnant cows not diagnosed with UTD. Fertility stressors were associated with altered PBL transcript profiles at the onset of implantation. Differences observed might represent either a primary cause of subfertility or a consequence of impaired developmental potential of their conceptus and its ability to secrete signaling molecules to modulate the maternal immune system.

Key Words: cow, fertility, leukocyte

T323 Circulating concentrations of bovine pregnancy associated glycoproteins and late embryonic mortality in lactating dairy herds.

Ky G. Pohler*[1], Marcos H. Pereira[2], Francisco R. Lopes[2], Jose L. M. Vasconcelos[2], Michael F. Smith[1], and Jon A. Green[1], *[1]Division of Animal Sciences, University of Missouri, Columbia, MO, [2]FMVZ–UNESP, Botucatu, SP, Brazil.*

In cattle, the incidence of late embryonic mortality (EM) has been reported to range from 3.2 to 42.7%. In some cases, the economic consequences of late EM are reported to be greater than that of early EM, because late EM can cause a significant delay in conception date. Although considerable effort has been directed toward understanding the causes of early EM, relatively little is known about the causes or mechanisms associated with late EM. The objectives of this experiment were as follows: (1) to determine the association between circulating concentrations of pregnancy associated glycoproteins (PAGs) and late EM in lactating dairy cattle following fixed-timed artificial insemination (TAI) on d 0 or fixed-timed embryo transfer (TET) on d 7, and (2) to identify a circulating concentration of PAGS on d 30 below which late EM would be likely to occur. Cows were diagnosed pregnant on d 30 of gestation based on presence of a fetal heartbeat and reconfirmed on d 60 of gestation. Late EM occurred when a cow had a viable embryo on d 30 of gestation but not on d 60 following TAI or TET. Only pregnant cows were included in the analysis (TAI-maintained, n = 413; TAI-EM n = 77; TET-maintained, n = 238; TET-EM, n = 47) which was subjected to Proc Glimix procedures of SAS. Cows that were pregnant at d 30 of gestation and maintained the pregnancy until d 60 had significantly greater ($P < 0.05$) circulating concentrations of PAGs at d 30 of gestation compared with cows that experienced late EM between d 30 and 60 of gestation in both TAI and TET. A receiver-operating characteristic curve was generated using MedCal Software to determine circulating concentration of PAGs on d 30 that should predict EM with ≥95 accuracy in both TAI and TET. Based on positive and negative predicative value analysis, a circulating concentration of PAGs below 1.4 ng/mL (TAI) and 1.85 ng/mL (TET) was 95% accurate in predicting EM (between d 30 - d 60) at d 30 of gestation. In summary, PAGs may provide a good marker for predicting EM between d 30 to 60 of gestation and may be able to accurately predict cows that will undergo late EM for the purpose of investigating mechanisms leading to late EM.

T324 Etiology of early pregnancy losses in Holstein dairy cows based on serum pregnancy-associated glycoprotein and progesterone concentrations.

Maria J. Fuenzalida*, Paulo D. Carvalho, Milo C. Wiltbank, Pamela L. Ruegg, and Paul M. Fricke, *University of Wisconsin-Madison, Madison, WI.*

Our objective was to describe the mechanism and timing of pregnancy losses (PL) in cows after the first timed artificial insemination (TAI). A total of 136 cows that experienced PL were included in a matched case-control study. Cases were obtained from 3,164 cows from 4 dairy farms enrolled in a prospective cohort study. Cows with pregnancy-specific protein B (PSPB) ≥ 0.3 ng/mL on d 25 after TAI and were open based on transrectal ultrasonography 27 to 32 d (PG1) were defined as early PL (n = 49 cows). Cows that were pregnant at PG1 but open at subsequent evaluations were considered later PL (n = 87 cows). Cows that remained pregnant during the study period (from TAI to 90 d after TAI) were defined as Controls (n = 266 cows). Two Control cows were matched to each PL cow based on days in milk and parity. Progesterone (P4) and PSPB were measured weekly from 10 d before TAI until a cow was diagnosed open or remained pregnant and reached 90 d after TAI. Week of PL and cause of PL (embryonic death [ED] or corpus luteum regression [CLR]) was determined from weekly PSPB using a cutoff of the lowest PSPB concentrations of Controls (from 25 to 88 d after TAI) and weekly P4 concentrations. Data were analyzed by *t*-test, chi-squared and linear regression. For early PL, 30.6% (15/49), 16.3% (8/23) and 53.1% (26/49) were due to ED, CLR and undefined causes, respectively. For cows with later PL, 37.9% (33/87), 48.3% (42/87), and 13.8% (12/87) were due to ED, CLR and undefined causes ($P = 0.04$). Mean average days for occurrence of PL based on PSPB concentration cutoff for ED was 48.6 (ranging from 28 to 88) and for CLR was 45.3 (ranging from 24 to 86) ($P = 0.29$). For early PL, P4 concentrations on d 25 were 5.8 ± 3.4 ng/mL and on d 32 were 6.6 ± 2.3 ng/mL ($P > 0.05$). PSPB concentrations on d 25 were 0.6 ± 0.6 ng/mL and on d 32 were 1.9 ± 1.5 ng/mL ($P < 0.05$). In conclusion, the occurrence of pregnancy loss due to ED occurred with more frequency in early PL near 32 d, whereas later PL were more likely due to CLR. Supported by AFRI Competitive Grant no. 2010–85122–20612.

Key Words: pregnancy loss, progesterone, pregnancy-associated glycoprotein

T325 Supplementation with insulin-like growth factor-1 during in vitro culture protects bovine embryos from deleterious actions of menadione. Nathália A. S. Rocha-Frigoni*, Beatriz C. S. Leão, Priscila C. Dall'Acqua, and Gisele Z. Mingoti, *Laboratory of Physiology of Reproduction, School of Veterinary Medicine, University of Sao Paulo State (UNESP), Araçatuba, Sao Paulo, Brazil.*

The objective of this study was to evaluate the protective effect of insulin-like growth factor (IGF-1) under oxidative stress condition induced by menadione (MD) on bovine embryos in vitro cultured (IVC). Cumulus-oocyte complexes were matured in TCM-199 with bicarbonate, hormones and 10% FCS for 22 h at 38.5°C in 5% CO$_2$ in air. After fertilization, the presumptive zygotes were IVC in SOF medium supplemented with 100 μM IGF-1, at 38.5°C in 5% CO$_2$ in air, for 7 d. On Day 6 the culture medium was supplemented with 5 μM MD. The cleavage rates and embryonic development were evaluated at Day 3 and Day 7, respectively (IVF = d 0). At d 7 blastocysts were stained to quantify the reactive oxygen species (ROS) levels with 5 μM H$_2$DCFDA (Molecular Probes, Invitrogen), the caspase activity (Image iT LIVE Red Caspase-3 and-7 Detection Kit, Molecular Probes) or the apoptotic index using TUNEL (In Situ Cell Death Detection Kit, Fluorescein, Roche Applied Science). Stained embryos were evaluated under an epifluorescence inverted microscope (excitation 495/550–510–550nm and emission 404/595/590 nm, respectively for ROS, caspase and TUNEL). The images were analyzed by Q-Capture Pro image software for determining the fluorescent intensity. The results were compared by ANOVA followed by Student *t*-test ($P < 0.05$) and are presented as mean ± SEM. The cleavage rates did not differ ($P > 0.05$) among groups (77.1% ± 1.9 to 82.7.5% ± 2.2). The blastocyst rates were 38.1% ± 2.50^{ab} (Control), 38.9% ± 1.97^{a} (IGF), 21.39% ± 2.93^{c} (MD) and 25.7% ± 3.32^{bc} (IGF+MD). The intracellular levels of ROS were 111.1 ± 1.7^{b} (Control), 118.3 ± 2.1^{a} (IGF), 118.8 ± 2.1^{a} (MD) and 112.1 ± 3.6^{ab} (IGF+MD). The caspase activity did not differ ($P > 0.05$) among groups (28.2 ± 2.7 to 41.1 ± 3.2). Although, the rates of apoptosis were 12.8% ± 1.0^{b} (Control), 9.1% ± 0.75^{c} (IGF), 22.3% ± 2.3^{a} (MD) and 15.6% ± 1.6^{b} (IGF+MD). In conclusion, the supplementation with IGF-1 during IVC reversed the detrimental effects of MD on embryonic levels of ROS and apoptosis, as well as improved the embryo development.

Key Words: IGF-1, reactive oxygen species, apoptosis

T326 Menadione induces oxidative stress and reduces embryo development. Priscila C. Dall'Acqua*, Nathália A. S. Rocha-Frigoni, Beatriz C. S. Leão, and Gisele Z. Mingoti, *1Laboratory of Physiology of Reproduction, School of Veterinary Medicine, University of Sao Paulo State (UNESP), Araçatuba, São Paulo, Brazil.*

Oxidative stress during the in vitro production of embryos culminates with a rise in reactive oxygen species (ROS) levels and apoptosis. Menadione (MD) induces ROS generation and can be used as a tool to understand the actions of oxidative stress on embryo development. This study evaluated the effects of different MD concentrations during in vitro culture on bovine embryo development, intracellular levels of ROS and apoptosis rate. Cumulus-oocyte complexes were matured in vitro in TCM-199 with bicarbonate, hormones and 10% FCS during 22 h at 38.5°C in 5% CO$_2$ in air. After fertilization, zygotes were cultured in SOF medium at 38.5°C in 5% CO$_2$ in air, for 7 d (IVF = Day 0). On Day 6, SOF was supplemented with 0 (Control group), 2.5 μ*M* MD (MD 2.5) or 5.0 μ*M* MD (MD 5.0), The cleavage and blastocyst rates were evaluated at Days 3 and 7, respectively. Day-7 blastocysts were stained with H$_2$DCFDA (Molecular Probes, Invitrogen) or with TUNEL (in situ cell death detection kit, Roche Life Science) to evaluate the ROS levels and the apoptotic rates, respectively. Stained embryos were evaluated under epifluorescence (excitation 495/510–550 nm and emission 520/590 nm, respectively for H$_2$DCFDA and TUNEL) and the images were analyzed by Q-Capture Pro Image Software to determine the fluorescence intensity. Data were analyzed by ANOVA followed by Tukey's test ($P < 0.05$) and are presented as Mean ± SEM. The cleavage rates were similar ($P > 0.05$) among groups (78.2% ± 1.14 to 80.5% ± 0.88). The blastocyst rates were lower ($P < 0.05$) in MD 5.0 (25.9% ± 2.06^{b}) compared with Control (36.4% ± 1.51^{a}), and both were similar ($P > 0.05$) to MD 2.5 (32.5% ± 1.94^{ab}). The ROS levels were higher in MD 2.5 (0.75 ± 0.05^{b}) and MD 5.0 (1.11 ± 0.07^{b}) compared with Control (0.72 ± 0.04^{a}). The rates of apoptosis were higher ($P < 0.05$) in MD 5.0 (19.24% ± 0.69^{c}) compared with MD 2.5 (13.28% ± 0.71^{b}) and Control (10.0% ± 0.45^{a}). In conclusion, MD concentrations of 2.5 and 5.0 μ*M* were effective in inducing oxidative stress in bovine embryos produced in vitro and the detrimental effects were dose-dependent. The higher the oxidative stress, the more detrimental were the effects, causing reduction in the embryonic development, increasing on the intracellular ROS levels and apoptosis.

Key Words: menadione, oxidative stress, apoptosis

T327 Antioxidants improve membrane integrity and acrosome and sperm mitochondrial activity in ram sperm after cryopreservation. Elenice A. Moraes*[1], Wildelfrancys L. Souza[1], Jonathan M. S. Costa[1], and James K. Graham[2], *[1]Federal University of San Francisco Valley, Petrolina, PE, Brazil, [2]Colorado State University, Fort Collins, CO.*

There has been a renewed interest in the effects of oxidative damage to human sperm, as this damage to mitochondrial DNA and membrane architecture may explain the impaired fertility of the cryopreserved sperm. Different antioxidants have been tested to improve sperm quality but distinct and consistent beneficial effects are lacking. The objective was to determine if adding a combination different antioxidants improved ram sperm quality after cryopreservation. Thirty ejaculates, from 3 rams, were split and diluted into an egg-yolk-tris diluent containing different antioxidant treatments: control; 100 μ*M* melatonin (MEL) plus 0.05% ascorbic acid (MEL+AA); 100 μ*M* MEL plus 90 μL Trolox-C (MEL+TRO); 90 μL TRO plus 0.05% AA (TRO+AA); and 100 μ*M* MEL plus 0.05% AA plus 90 μL of TRO (MEL+AA+TRO); to final concentration 200 × 10^{6} sperm/mL. The samples were cooled to 5°C/2 h, packaged into 0.5-mL straws, and frozen in static liquid nitrogen vapor for 15 min before being plunged into liquid nitrogen. Straws were thawed (37°C/30 s). The motility was determine using CASA, and to plasma membrane integrity the samples were stained with 2 L of Hoechst 33342 and 2 μL PI and incubated at 37°C/8min. Acrosomal integrity was determined, visually, after staining the sperm with 50 μL FITC-PNA at 37°C/20min. The sperm mitochondrial function was assessed using Rhodamine and PI (samples were incubated at 37°C/8 min with at 2 μL Rhodamine and 2 μL PI) and the samples assessed for the proportion of viable spermatozoa with high mitochondrial activity. Variables were determined by ANOVA using a Tukey test. Sperm treated with MEL+AA (29.1%) and MEL+AA+TRO (28.9%) maintained higher percentages of cells with intact plasma membranes after thawing ($P < 0.05$) than other treatments. The antioxidant combination (MEL+AA+TRO) resulted in the highest percentages of sperm with intact acrosomes (84.5%) and mitochondrial activity (96.4%) compared with other treatments ($P < 0.05$). All antioxidant treatments exhibited higher motility (61.4% versus 53%), acrosome integrity (78.1% versus 68.2%) and mitochondrial activity (92.7% versus 88.6%), than control ($P < 0.05$).Therefore, adding a combination of MEL+AA+TRO to ram sperm improved cell cryosurvival. Supported by FACEPE/CAPES.

Key Words: melatonin, Trolox-C

T328 Testosterone enhances basal, FSH- and IGF-I-stimulated aromatase gene expression in porcine granulosa cells in vitro.

Leon J. Spicer*, John R. Evans, and Nicole B. Schreiber, *Oklahoma State University, Stillwater, OK.*

Ovarian follicular development is regulated by systemic as well as autocrine and paracrine factors such as estradiol (E2). E2 is produced by growing follicles via aromatase conversion of androgens into estrogens. Both FSH and IGF-I induce aromatase activity in granulosa cells (GC) of several species. To further evaluate the effects of FSH, IGF-I and testosterone on abundance of aromatase (*CYP19A1*) mRNA, GC from small porcine follicles (1 to 5 mm) were cultured for 2 d in medium containing 5% fetal bovine serum and 5% porcine serum followed by 48 h in serum-free medium containing control (no addition), FSH (30 ng/mL), or FSH plus IGF-I (30 ng/mL) in the absence or presence of 500 ng/mL of testosterone in a 2 × 3 factorial design. Cellular RNA was isolated and relative *CYP19A1* mRNA abundance was measured using real-time PCR with *18S* rRNA as a housekeeping gene. Data were analyzed via GLM procedure of SAS. Alone, FSH increased ($P < 0.05$) *CYP19A1* mRNA abundance 63-fold. Addition of IGF-I to FSH-treated cells increased *CYP19A1* mRNA abundance 6.5-fold above that seen with FSH alone. Testosterone alone increased ($P < 0.05$) *CYP19A1* mRNA abundance 30-fold and further amplified both FSH- and FSH plus IGF-I-induced *CYP19A1* mRNA abundance by 3- to 4-fold. In a second experiment, GC were cultured as in the first experiment except that medium (containing 500 ng/mL of testosterone as E2 precursor) was collected after 1 and 2 d of treatment for E2 measurement via RIA. FSH increased ($P < 0.05$) E2 production by 1.3- and 1.5-fold after 1 d and 2 d of treatment, respectively. IGF-I increased ($P < 0.05$) FSH-induced E2 production by 4.7- and 9.2-fold after 1 d (0.19 vs. 0.94 ± 0.06 ng/10^5 cells) and 2 d (0.21 vs. 1.94 ± 0.09 ng/10^5 cells) of treatment, respectively. In conclusion, testosterone-amplified basal and hormone-induced aromatase gene expression indicates that androgens produced by theca cells may act as a paracrine factor to increase aromatase activity in GC in addition to serving as E2 precursors for GC. This intra-ovarian regulatory mechanism may be vital for optimal follicular growth in pigs.

Key Words: aromatase, granulosa cells, pig

T329 Ovarian follicular dynamics in early- and late-maturing Brahman cows.

Rui A. d'Orey Branco*[1,2], Thomaz H. Welsh[2], Don Neuendorff[1], and Ron D. Randel[1], [1]*Texas A&M AgriLife Research, Overton, TX,* [2]*Department of Animal Science, Texas A&M University, College Station, TX.*

Age at first calving is greater in *Bos indicus* than in *Bos taurus* cattle. Two different populations of Brahman cows exist based on age at first calving. Specifically, cows that are capable of calving by 26 mo of age are defined as early maturing (EM). Conversely, those cows that must be over 33 mo of age to calve are considered late maturing (LM). The objective of this trial was to compare follicular dynamics of EM and LM cows. This study's herd (located near Overton, Texas) was comprised of 120 pure bred Brahman cows. The EM group (n = 7) calved before 26 mo of age and the LM group (n = 7) calved at 33 mo of age or later. Cow BCS was between 4.5 and 7.5 and all of the cows calved at least 60 d before the trial began. Follicular evaluation was performed by transrectal ultrasound (US; Medison Co. SA-600; 7.5 mHz probe) and began after a naturally occurring estrus detected by a heat check bull. Cows were examined daily by US until signs of a new estrus were detected. During this second estrus the cow was examined by US every 4 h. Data were analyzed using PROC GLM of SAS. The EM and LM groups did not differ ($P > 0.1$) with respect to the diameter of the pre-ovulatory follicle or the time elapsed from the onset of estrus to ovulation. There were 3 follicular waves in 85.7% (6/7) of the LM and 14.3% (1/7) in EM cows (chi-squared; $P < 0.05$). The size of the largest subordinate follicle on the day before estrus was greater ($P < 0.01$) in EM (10.42 ± 2.38 mm) than in LM (5.23 ± 2.31 mm) cows. The number of subordinate follicles (>4mm) one day before estrus in EM cows (4.28 ± 2.55) was greater than in the LM cows (1 ± 0.76; $P < 0.01$). The total of follicular diameters one day before estrus was greater ($P < 0.01$) in EM (32.43 ± 5.63 mm) than in LM (7.43 ± 5.63 mm) cows. These results suggest that early and late maturing cows have differing aspects of follicular dynamics such as the number of follicular waves, the number of subordinate follicles, and the diameter of the second largest follicle. Further studies to determine whether this phenotypic difference is present in cows of other breeds are warranted.

Key Words: follicular dynamics, early maturing, late maturing

Production, Management and the Environment II

T330 Influence of egg holding time on hatchability of Hubbard broiler eggs. Modupe Orunmuyi*[1] and Chidiebere Livinus Akanwa[2], [1]*Federal University, Oye-Ekiti, Ikole-Ekiti, Ekit State, Nigeria,* [2]*Ahmadu Bello University, Zaria, Kaduna State, Nigeria.*

In a study to determine the influence of egg storage time on hatchability in Zaria, northern guinea savannah of Nigeria, 1,634 Hubbard broiler breeder eggs stored for 1 to 7 d at 16°C were set in 8 batches when the birds were 42–49 weeks of age to determine the maximum egg holding time. Birds were raised on deep litter at a mating ratio of 1 rooster to 6 hens in a pedigree hatching involving 12 sire families. Data collected were subjected to ANOVA (GLM PROCEDURE) using SAS 2008. There were significant ($P < 0.05$) differences in all parameters studied namely; set weight, transfer weight, fertility%, hatchability of all eggs set (%hatch), hatchability of fertile eggs (% hatchability) and chick weight except egg weight at collection. Average initial egg weight before storage ranged from 68.08 to 69.57g. The range of values for set weight, transfer weight, %fertility, %hatch, %hatchability and chick weight at hatch were 64.88- 68.08g, 55.19–58.87g, 54.63–70.92%, 26.50–39.81%, 41.58–62.92% and 41.13–44.77% respectively. Set weight was highest at 1 d storage and lowest at 7 d storage. Transfer weights were similar from1 d to 5 and were different from d 6 and 7. Although fertility % was lowest for 1 d storage, it was not significantly different from d 3 and 7. Percentage hatch was lowest for 7 d storage (26.50%) while % hatchability was highest for 1 d storage (62.92%). Chick weight at hatch was similar on all days except d 4. Fertility % was lowest (54.63 ± 0.06%) for eggs stored for 7 d. Eggs meant for hatching may not be stored for more than 5 d in this environment.

Key Words: Hubbard broiler, egg storage, hatchability

T331 Performance of dual-purpose cows supplemented with two sources of energy in subtropical conditions. Isela Salvador-Loreto[1], Benito Albarran-Portillo*[1], Fernando Vicente-Mainar[2], Isela G. Salas-Reyes[1], Carlos M. Arriaga-Jordan[1], and Julieta G. Estrada-Flores[1], [1]*Universidad Autonoma del Estado de Mexico, Toluca, Mexico, Mexico,* [2]*Servicio Regional de Investigación y Desarrollo Agroalimentario, Villaviciosa, Asturias, España.*

The aim of this study was to assess the performance of lactating dual purpose cows (milk and calves), supplemented with 2 sources of energy: molasses (Mo) or ground corn (Gc) during the dry season under subtropical conditions in Mexico. In the subtropical regions of Mexico, during the dry season there is a lack of quality and quantity of fodders to support lactating cows and their suckling calves under grazing systems. Therefore, farmers supplement their cows to maintain milk production and calves weight gain. Supplements are based on cracked corn, cob and husk (CCH), soybean meal and urea (70 g/cow/d). The CCH processing method reduced ruminal starch digestibility, limiting the potential energy cows could obtained from the supplement. Treatments (TX) consisted of molasses or ground corn at 6% inclusion in CCH supplement (5 kg of DM cow/d). Response variables were recorded every 2 weeks, considered as experimental periods (EP). Milk, milk components, body weight, calves weight and body condition score, were subjected to a mixed model procedure from SAS 9.0 for a complete randomize experimental design. Cow was defined as a random effect. There were no significant differences among response variables due to TX (milk yield 7.1 vs 7.0 kg/cow/d, molasses and ground corn TX, respectively), but there were differences ($P < 0.05$) for EP on milk yields which increased by the end of the experiment with milk yields of 6.5 and 8.6 (kg/cow/d, EP 1 and 5, respectively). There were no differences on animal response variables when molasses or ground corn at 6% inclusion were added to supplements as an extra source of energy.

Key Words: supplement, molasses, ground corn

T332 Evaluation of the feedlot performance, carcass yield, and production costs of finishing beef cattle supplemented with β-agonists. Silvia Larios-Cueto, Gilberto Aranda-Osorio*, Rodolfo Ramirez-Valverde, Hermilo Suarez-Dominguez, and Jose M. Monzon-Armenta, *Universidad Autonoma Chapingo, Chapingo, Texcoco, Mexico.*

The objective of the this study was to evaluate the effect of β-agonists (zilpaterol and ractopamine hydrochloride) supplementation on finishing beef cattle performance and carcass quality. These agonists are approved in Mexico. There were used 50 7 commercial crossbred (*Bos taurus* × *Bos indicus*) young bulls, initially weighing 446.3 ± 9.0 kg, from the tropical region (Veracruz State), and allotted to 3 pens (19 each) of the Experimental Feedlot Facilty of the University of Chapingo (Mexico State a temperate region), each pen was randomly assigned to the following treatments: 1) Control (no supplement added), 2) Ractopamine (0.91 mg/kg of body weight (BW) per day) and 3) Zilpaterol (0.15 mg/k of BW per day). All animals received the same finishing diet, which has the following calculated nutritional composition: 14.48% CP; 1.79 and 1.16 Mcal/kg of NEm and NEg, respectively, 11.16% CF, and 2.2 Ca:P. At the moment that cattle arrived to the feedlot they received a prophylactic management (identified, weighed, vaccinated, dewormed, vitamined and implanted). The β-agonists were supplemented at least 35 d at the end of the finishing period. The variables evaluated were: dry matter intake (DMI), average daily gain (ADG), feed:gain (F:G), gain:feed (G:F), hot carcass yield (HCY), trimmed carcass fat (TCF) and benefit/cost (B/C) ratio. Data were analyzed under a completely randomized design with the GLM procedure of SAS, and to compare means the Tukey Test was performed. The only variable that was not statistically analyzed was DMI because it was calculated collectively. Cattle performed very similarly and no differences ($P > 0.05$) were found among treatments, the mean values being 11.88 kg/animal per day for DMI, 1.80 kg for ADG, 7.35 kg for F:G, 143 g/kg for G:F, 57.7% for HCY and 2.2% for TCF. Although, the B/C ratio was better for ractopamine treatment (1.13 vs. 1.05 for control and zilpaterol, respectively). Under the conditions of this study, the supplementation of β-agonists (ractopamine or zilpaterol hydrochloride) during the finishing period of young bulls showed a tendency to increase animal performance and carcass traits, but only ractopamine demonstrated to be profitable.

Key Words: bullock, ractopamine, zilpaterol

T333 Physiological responses in Santa Ines ewes submitted to stressful conditions of management. Monalissa de Melo Stradiotto*[1,2], Alice Deléo Rodrigues[1,2], and João Alberto Negrão[1,2], [1]*University of Sao Paulo–USP, Pirassununga, SP, Brazil,* [2]*University of Sao Paulo State–UNESP, Jaboticabal, SP, Brazil.*

Literature data suggest that although there is a great variability of stress responses, animals maintain a pattern of response to different stressful factors. In this context, the objective of this experiment was to verify the different physiological responses of Santa Ines ewes to management conditions considered stressful to the animals. For that, 50 Santa Ines ewes were submitted to 3 different impositions of stress (1: weaning; 2: first milking, 3: change of milker). Cortisol levels of experimental ewes were monitored along lactation and after weaning, 60 d after birth. Plasma samples were collected through jugular puncture in 5 times at −20 min (20 min before the stressful stimulus), 0 min (at the moment of the stressful stimulus) and 60, 120 and 300 min after the stimulus. Hormonal analyses were done using immunoenzymatic kits with readings at 450nm in ELISA equipment at the Laboratory of Animal Physiology of FZEA/USP. Hormonal levels were analyzed in subdivided parcels, which means as repeated measures in time, through MIXED procedure. Means were compared by Tukey test with a significance level of 0.05. For the change of milker stimulus, it were observed greater values in cortisol levels in 0, 60 and 120 min after stress imposition (31.557 ng/mL ± 26.153; 30.106 ng/mL ± 18.138 and 23.989 ng/mL ± 15.982, respectively; $P = 0.0069$), statistically different from the other times of measurement. In the stress of the first milking, it were observed greater values of cortisol levels 60 min after milking (48.274 ng/mL ± 60.07; $P = 0.001$) and almost 5 h later, the basal levels were reestablished. Therefore, the pattern of cortisol release in the first milking and weaning differed where in the last, it remained elevated until 300min after stress imposition (40.334 ng/mL ± 59.971), showing that this type of stress can influence the productive life of Santa Ines ewes.

Key Words: cortisol, milking, stress

T334 Goal structure and reasons for selecting a goat enterprise by US meat goat producers.

Narayan P. Nyaupane*[2], Jeffrey M. Gillespie[1], and Kenneth W. McMillin[1], [1]*Louisiana State University, Agricultural Center, Baton Rouge, LA*, [2]*The Samuel Roberts Noble Foundation Inc., Ardmore, OK.*

The US meat goat industry has expanded rapidly in recent years; however, the US continues to rely on goat meat imports due to a rise in demand associated with increased immigration. US meat goat industry leaders need to know the current direction and drivers of production so that necessary measures can be taken for establishing a sustainable and competitive industry. We seek to determine US meat goat producers' goal structure and their perceived reasons of farming. Survey data from 584 US meat goat producers was used for this study. Using the fuzzy pair-wise comparison method, the hierarchy of 7 major goals that a meat goat producer could have were determined and ordinary least squares regressions were conducted to analyze the factors affecting producer goal structure. To determine the producer's reasons of farming, the following question was asked with a list of 14 possible reasons in a 5 point Likert-scale: "To what extent do you agree or disagree that your selection of a goat enterprise as opposed to other agricultural enterprises is because of the following reasons"? Ordered probit regressions were conducted for factors affecting reasons of farming. Results show that *Maximize Profit* was the primary goal of US meat goat producers with the mean score of 0.51, followed by *Have Family Involved in Agriculture* (0.50), *Avoid Years of Loss/Low Profit* (0.49) and *Have Time for Other Activities* (0.48), *Increase Net Worth* (0.46), *Control Weeds/Vegetation* (0.40), and *Increase Farm Size* (0.33). Means of producer agreements showed that the most frequently cited reasons for producers selecting goat enterprise were: *I enjoy working with goats* (4.59), *goat production fits well into my land management plan* (4.30), *I can raise goats on a relatively small acreage* (4.25), and *goat grazing preferences are different from other species* (4.17). Regression results show that producer demographics, farm characteristics, regional variables, and other economic indicators affect producer goal structure and enterprise selection.

Key Words: goat, goal structure, reasons for farming

T335 Managing variability in decision making in swine growing-finishing units.

P. S. Agostini[1], E. G. Manzanilla[2], C. de Blas[3], A. G. Fahey[4], C. A. Silva*[5], and J. Gasa[1], [1]*Universitat Autònoma de Barcelona, Bellaterra, Spain,* [2]*Animal and Grassland Research and Innovation Centre, Teagasc, Fermoy, Ireland,* [3]*Universidad Politécnica de Madrid, Madrid, Spain,* [4]*University College Dublin, Dublin, Ireland,* [5]*Universidade Estadual de Londrina, Londrina, Brazil.*

Analysis of data from pig producing companies may be useful for the optimization of farm management. However, obtaining these data and drawing conclusions from them presents several challenges. In the present study, information from 686 batches of growing-finishing (GF) pigs from 404 GF farms integrated in 7 Spanish companies was obtained. Management and facility factors affecting feed conversion ratio (FCR) and mortality (MORT) were studied by multivariate linear mixed regression analysis in each single company (A to G) and in an overall database (OD). Factors studied were geographic location of the farm, trimester the pigs entered the farm, genetics, sex, use of circovirus vaccine, number of pig origins the pigs were obtained from, age of the farm, percentage of slatted floor, type of feeder, drinker and ventilation, number of phases and form of feed, antibiotic administration system, water source, and number and initial weight of pigs. The variability among companies was much higher than within companies and some factors presented no variability within companies. In most companies and in the OD batches had better FCR and/or lower MORT ($P \leq 0.05$) when animals: 1) were placed between April and September, 2) came from a unique sows farm origin and 3) had lower initial body weight, 4) were originated from a Pietrain pig-sire, presence of males and segregated in pens (only for FCR), 5) were housed in farms less than 10 years old (only for FCR), 6) were housed in farms where the drinking water was properly treated (only for MORT) and 7) were raised in farms with less than 800 pigs (only for MORT). Age of the farm, antibiotic administration system, and water source were provided by only some companies and were not included in the OD model. However, when analyzed in particular companies, these 3 variables had an important effect and may be of interest even for the companies that do not record them. In general, models developed for each company were more accurate than those obtained from the OD.

Key Words: grow-finishing pig, facilities, management

T336 The production performance of egg layers in different rearing systems.

Bilgehan Yilmaz Dikmen*, Aydin Ipek, Ümran Sahan, and Arda Sözcü, *Department of Animal Science, Faculty of Agriculture, University of Uludag Bursa, Turkey.*

Today alternative rearing systems for caged hen egg production has gained importance. The objective of this study was to determine the production performance of laying hens kept in different rearing systems (conventional, enriched cages and free-range system). A total of 480 egg layer strain *(Lohmann Brown) w*ere weighed and randomly allocated into 3 rearing system (n = 160, 4 replicates of 40 hen per group) as conventional cage, enriched cage and free range pen at 17 wk of age. The 3 rearing systems were located on a single farm and experienced identical seasonal temperature fluctuations and photoperiod (16L:8D). Feed and water were given ad libitum until 66 wk of age. Live weight was measured at the beginning and at the end of the study. Egg production as hen day, number of damaged eggs, dirty eggs and mortality were monitored daily. Feed intake and egg weight were recorded on weekly basis. The data were analyzed with using ANOVA, and significant means were separated using Duncan Multiple Range Test. The final live weight of hens were found similar in conventional and enriched cage system (1.95 vs. 1.94 ± 0.03 kg, respectively), but was higher in free-range system (2.09 ± 0.02 kg; $P < 0.001$). The earliest 5% egg production age was found in enriched cage system (138.3 ± 1.75 d; $P < 0.05$). The latest 50% egg production age was found in free-range system (159.25 ± 1.75 d; $P < 0.01$). The highest mean egg production ratio was found in free range rearing system (89.27 ± 0.87%; $P < 0.05$). The egg mass was higher in free-range system, but was similar in conventional and enriched cage systems (59.76, 56.80 vs. 56.66 ± 0.34 g/d/hen, respectively; $P < 0.001$). The feed intake was found to be higher in free-range system, but similar between conventional and enriched cage systems (124.58, 117.06 and 118.06 ± 0.56 g/d/hen, respectively; $P < 0.001$). The damaged egg ratio was low but dirty egg ratio was higher in free-range systems (0.35 ± 0.07% vs. 3.30 ± 0.15%, respectively; $P < 0.001$). The mortality ratio was higher in enriched cage system (6.25%; $P < 0.05$). It was concluded that free-range system has a positive effect on egg production and egg weight, but feed intake and dirty egg ratio were higher than the caged system.

Key Words: rearing system, egg production, egg layer

T337 Effect of a single dose of injectable trace minerals on measurements of performance, innate and humoral immune responses of beef heifers. Luana S. Caramalac*[1], Philipe Moriel[2], Luis F. A. Artioli[2], and John D. Arthington[3], [1]*Mato Grosso do Sul State University, Aquidauana, MS, Brazil,* [2]*North Carolina State University, Waynesville, NC,* [3]*University of Florida, Ona, FL.*

Injectable trace minerals (ITM) administered simultaneously to novel antigens of porcine red blood cells (PRBC) affects trace mineral status, innate and humoral immune responses of weaned beef heifers. Angus heifers (n = 22; 234 ± 39 kg of BW; 225 ± 19 d of age) were stratified by BW and age, and randomly assigned to receive a 2.5-mL s.c. injection of sterile saline (SAL; 0.9% NaCl), ITM (MultiMin 90; Multimin USA, Inc. Fort Collins, CO; 60, 10, 15 and 5 mg/mL of Zn, Mn, Cu and Se), or a squalene-based oil-in-water adjuvant (ADJ; AddaVax; InvivoGen, Inc. San Diego, CA) that promotes humoral immune response. Thereafter (d 0), heifers were immunologically challenged with a 10-mL i.m. injection of PRBC solution (25% PRBC; 75% sterile PBS), allocated to drylot pens (2 pens/treatment) and limit-fed a fescue hay-based diet at 2.2% of BW for 28 d. Shrunk BW was recorded on d 0 and 28, blood samples collected on d 0, 3, 7, 15, 21 and 28, and liver samples collected on d 14. Body weight on d 28 (263, 262 and 258 ± 19 kg) and mean ADG (0.81, 0.98 and 0.96 ± 0.180 kg/d for SAL, MM and ADJ heifers) did not differ among treatments ($P \geq 0.72$). But, treatment effects were detected ($P \leq 0.05$) for concentrations of liver Se, plasma ceruloplasmin (Cp) and serum PRBC titers. Liver Se was greater for MM vs. ADJ and SAL heifers (2.21, 1.36 and 1.45 ± 0.177 mg/kg, respectively), whereas plasma Cp was greater for ADJ vs. SAL (26 vs. 20 ± 1.6 mg/dL; $P = 0.02$), and intermediate for ITM heifers (23 ± 1.6 mg/dL; $P \geq 0.17$). Likewise, serum PRBC titers were greater for ADJ vs. SAL (1.6 vs. 0.7 ± 0.28 log 2 base; $P = 0.02$), and intermediate for ITM heifers (1.1 ± 0.28 log 2 base; $P \geq 0.13$). Treatment x time effect was detected for plasma haptoglobin (Hp) concentrations ($P < 0.0001$), which did not differ from d 0 to 28 ($P \geq 0.18$), but were greater for ADJ vs. SAL and ITM heifers on d 3 (0.71, 0.05 and 0.07 ± 0.032 mg/mL). Hence, although injectable trace mineral injection enhanced liver Se concentrations, the magnitude of the innate and humoral immune responses to novel antigen were less compared with a water-in-oil adjuvant.

Key Words: trace minerals, heifer, humoral

T338 Pre-weaning injections of bovine somatotropin enhanced post-weaning growth performance and puberty attainment of beef heifers. Philipe Moriel[1], Luis F. A. Artioli*[1], Phillip Lancaster[3], John D. Arthington[3], and Reinaldo F. Cooke[2], [1]*North Carolina State University, Waynesville, NC,* [2]*Oregon State University, Burns, OR,* [3]*University of Florida, Ona, FL.*

Effects of injections of bovine somatotropin (bST) to suckling beef heifers on pre- and post-weaning growth performance and puberty achievement. Angus × Brangus heifers (n = 30; BW = 140 ± 20 kg; age = 132 ± 15 d) were stratified by BW and age, and randomly assigned to receive s.c. injections of saline (SAL; 5 mL; 0.9% saline) or half-dose of bST (250 mg of sometribove zinc; Posilac, Elanco, Greenfield, IN) on d 0, 14 and 28 (15 heifers/treatment). Then, cow-calf pairs were grazed on 4 bahiagrass pastures (7 to 8 pairs/pasture) from d 0 until weaning (d 126). Unshrunk BW and blood samples were collected on d 0, 14, 28 and 126. From d 126 to 350, heifers were grazed on bahiagrass pastures (1 pasture/treatment) and fed blackstap molasses-based concentrate at 1.1% BW (DM basis). Unshrunk post-weaning BW was obtained every 28 d, and blood samples every 10 d to determine plasma progesterone (P4) concentrations. Heifers were considered pubertal when 2 consecutive plasma samples had P4 ≥ 1.5 ng/mL. During the pre-weaning phase, bST injections increased ADG from d 0 to 42 (1.2 vs. 1.1 ± 0.04 kg/d; $P = 0.03$), but not ADG from d 42 to 126 or weaning BW (0.89 vs. 0.84 ± 0.028 kg/d and 266 vs. 261 ± 7 kg; $P \geq 0.28$). Also, bST injections increased pre-weaning mean plasma IGF-1 (97 vs. 85 ± 3.7 ng/mL; $P = 0.02$), and tended to decrease plasma leptin on d 42 (5.2 vs. 5.9 ± 0.24 ng/mL; $P = 0.06$). Pre-weaning bST injections increased post-weaning mean ADG and BW on d 350 (0.30 vs. 0.22 ± 0.02 kg/d and 329 vs. 311 ± 3 kg; $P < 0.01$), tended to increase overall puberty achievement (49 vs. 30 ± 6.9% of total heifers; $P = 0.06$) and decrease age at puberty (402 vs. 435 ± 13 d; $P = 0.08$), but did not affect BW at puberty (287 vs. 288 ± 7 kg; $P = 0.95$). Hence, 3 half-dose injections of bST administered to suckling beef heifers at 14-d intervals, between 132 and 160 d of age, did not affect body weight at weaning or puberty, but enhanced post-weaning ADG, tended to increase puberty attainment and decrease age at puberty.

Key Words: somatotropin, heifer, puberty

T339 Feed intake and feed conversion ratio in integrated pig fattening farms are affected by management practices and barn conditions. Caio Abércio Silva*[1], Piero da Silva Agostini[2], and Josep Gasa[2], [1]*Universidade Estadual de Londrina. Departamento de Zootecnia, Londrina, Paraná, Brazil,* [2]*Universidad Autônoma de Barcelona, SNiBA, Depto. de Ciencia Animal y Alimentos, Barcelona, Calatuña, Spain.*

This study aims to investigate the effect of some in-farm management and facility factors on the average daily feed intake (ADFI) and feed conversion ratio (FCR) of grow-finishing pigs. Information from 1,532 batches from 216 grow-finishing farms consisting of 1,025,385 pigs (22.6 to 116.7 kg of live weight) belonging to 4 integrated pig companies (located in southwest of Parana State, Brazil) were collected by survey during 2010 and 2012. Risk factors obtained included 13 management practices and 9 facilities factors. A multivariate linear mixed regression model was used including factors that presented a $P < 0.20$ in a univariate model for ADFI and FCR. The "company" and "farms within the company" were considered as random factors whereas "batches within the farm and company" as the residual factor. Risk factors in the multivariable model were considered to have a significant effect if $P \leq 0.05$ and a trend effect if $0.05 < P \leq 0.10$. The mean ADFI was 2.14 ± 0.10 kg and FCR was 2.45 ± 0.12 kg/kg. Lower ADFI and/or better

FCR ($P < 0.01$) were found in batches with (a) ≤ 20 pigs per pen vs >20 pigs (respectively 3.4 and 4.1 points), (b) linear feeder vs plastic conic (2.6 points, both), (c) females vs barrows or mixed (4.1 and 4.9 points), (d) pigs coming from other farms vs those coming from own integrated farms (1.3 point, both), (e) absence of water depth area in pens vs presence of water depth (1.8 point, just ADFI, $P = 0.06$) and (f) barns built in masonry vs barns built in wood or mixed (2.5 points, just FCR). For each 1-kg of increase of initial and final body weight the ADFI was, respectively 0.007 and 0.010 kg higher ($P < 0.001$) and FCR 0.03 poorer and 0.012 better, respectively ($P < 0.001$). FCR was also 0.015 poorer per additional day of the fattening duration. Total variability explained by the models was 41% for ADFI and 55% for FCR. This study indicates that ADFI and FCR were influenced by some farm facilities and management practices that could be modified considering that some of them do not demand great investments.

Key Words: grow-finishing pig, management, performance

T340 Modeling and simulation for beef cattle stocker-finishing systems analysis.

Julio Otavio Barcellos*[1], Leonardo C. Canellas[1], Vinicius N. Lampert[2], Fernanda G. Moojen[1], Marcela Kuczynski Rocha[1], Eduardo T. Azevedo[1], Gabriel R. Pereira[1], Silvio R. O. Menegassi[1], and Eduardo Antunes Dias[1], [1]*NESPRO/UFRGS, Porto Alegre, RS, Brazil,* [2]*EMBRAPA/CPPSUL, Bagé, RS, Brazil.*

The purpose of this study was to present a management model for stocker-finishing cattle systems through modeling and simulation results from intervening the different levels of intensification, serving as a Decision Support System (DSS) for ranchers. Model was developed and operated in Microsoft Excel spreadsheets, with data collected in the field and literature reviews. The system allows to individually manipulated the animal feeding in the herd throughout the production cycle. This approach will measure the results quantitatively, through the existing stocking rate, and qualitative, through the daily weight gain from each diet administered to animals. DDS spreadsheets support the individual management for up to 500 animals in a period of analysis of maximum 53 mo. The model is operated in a single spreadsheet, divided into 3 components: Feeding Systems; Animal Performance; and Summary & Economic Analysis, being all levels interconnected. Model validation was simulated based on the Pasture-Based System (PBS) within 2 situations: Pasture/Feedlot-Based System for Finishing Cattle (FBSF) and Pasture/Feedlot-Based System for Stocker Cattle (FBSS). There was an increase in productivity for FBSF and FBSS (321 and 314 kg/hectare/year, respectively) and a decrease in slaughter age (21 and 23 mo, respectively) compared with PBS, 274 kg/hectare/year and 26 mo ($P < 0.05$). In the economic analysis, PBS (119.23 U$) showed higher annual gross margin per hectare, followed by FBSF (79.65 U$) and FBSS (57.25 U$) ($P < 0.05$). The model provides an overview of integrated management, showing major results during herd's feeding, purchase and selling prices, and animal performance of stocker-finishing systems in beef cattle production. The intensification observed in our study decreases the economic return in the evaluated system. Intensification is not indicated regarding biological and economic parameters used in this simulation. Scenario studies simulating purchase and selling prices, costs and another management interventions are necessary to better support the decision making process.

Key Words: intervention assessment, decision-making, beef-cattle production

T341 Performance and profitability on beef cattle in intensive tropical pasture in Amazon biome.

Fabiano Alvim Barbosa*[1], Vando Telles Oliveira[2], Filipe Lage Bicalho[3], Luciano Bastos Lopes[4], Juliana Mergh Leão[1], and Lucas Luz Emerick[1], [1]*Universidade Federal de Minas Gerais, UFMG, Belo Horizonte, Minas Gerais, Brazil,* [2]*Instituto Centro de Vida, ICV, Alta Floresta, Mato Grosso, Brazil,* [3]*Soluções Integradas ao Agronegócio, SIGA, Alta Floresta, Mato Grosso, Brazil,* [4]*Empresa Brasileira de Pesquisa Agropecuária, Embrapa, Sinop, Mato Grosso, Brazil.*

To avoid deforestation in the Amazon rainforest is necessary to increase productivity and profitability in beef cattle. So the aim of this study was to evaluate economic efficiency and productivity of 5 intensive pasture systems (IPS) on beef cattle production in Mato Grosso, Amazon biome, January 2013 to December 2014, part of the Livestock Low Carbon Integrated Project-ICV. Production and economic data were collected using control software (Prodap Professional GP) and analyzed by electronic spreadsheets (Microsoft Excel). The total of IPS was 177.7 ha (ha) and 1,877 cattle. The average of pasture was 35.5 ha/farm and 125 animals/IPS. The IPS was established with *Panicum maximum* 'Mombaça', with limestone, potassium chloride, triple phosphate and urea as soil analysis. During the rainy season were placed urea according stocking rate. The systems was developed exclusively on a grazing system with a base herd comprised of Zebu (Nelore) and crossbred *Bos taurus* × *Bos indicus* cattle. The zootechnical and economic indexes were compared in 3 periods, April–September 2013, October–2013 to March 2014, April–September 2013, by Duncan test, besides Person correlations, with significance level of 5%. During rainy season, October–2013 to March 2014, stocking rates (5.15 animals/ha), live weight/ha (1,553 kg), body weight produced (404 kg/ha) and total operating costs (US$ 248.18/ha) were higher than other periods ($P < 0.05$). There was no statistical difference to net margin of 155.49 US$/ha ($P > 0.05$). High correlations were found (0.76) between body weight produced (kg/ha) and total operating costs (US$/ha) ($P < 0.05$). High correlations were found (0.898) between body weight produced (kg/ha) and net margin (US$/ha) ($P < 0.05$) indicating that higher productivity is related to higher net margin, despite the higher cost per area. The period had influence on production of beef cattle and on costs in intensive pasture system, but the net margin indicated that the activity of beef cattle in Amazon biome can be profitable and had high correlation with animal production.

Key Words: cost, productivity, sustainability

T342 Carcass quality of grain-finished first-calf heifers.

Jose A. Arce*[1], Shawn L. Archibeque[1], Jason K. Ahola[1], Richard K. Peel[1], Dale R. Woerner[1], Jack C. Whittier[2], and George E. Seidel[3], [1]*Department of Animal Sciences, Colorado State University, Fort Collins, CO* [2]*Department of Animal Science and Panhandle Research and Extension Center, University of Nebraska, Scottsbluff, NE,* [3]*Department of Biomedical Sciences, Colorado State University, Fort Collins, CO.*

Single-calf beef production systems require harvesting females after early weaning their first calf; these systems reduce the share of energy destined for maintenance of adult cows. However, pregnancy hormones accelerate bone ossification, which may negatively affect carcass value. The objective of this study was to evaluate preliminary data on estimated lean maturity (LE), bone maturity (BM), overall maturity (OM), marbling (MA) and Warner Bratzler shear force (WBSF) of carcasses from primiparous females approximately 30 mo of age. A set of 53 Angus-based yearling heifers (BW = 352 ± 38.9 kg) were synchronized and inseminated with sexed semen to calve at approximately 24 mo of age; calves were early weaned at 106 ± 21 d postpartum. First calf heifers (n = 42) were taken to a feedlot to be fed acclimating, set up, and finishing diets for 6, 22, and 60 d, respectively. Diets were 12.7, 13.8 and 12.5% CP; and 0.84, 1.15 and 1.39 Mcal·kg^{-1} NEg, respectively. At harvest, carcasses were scored for LE and BM to estimate OM in which A, B and C maturities corresponded to scores of 100, 200 and 300, respectively. Also MA was evaluated (slight = 300, small = 400, modest = 500 and moderate = 600) and a LM sample was removed for WBSF measurement. Given the large decrease in quality grade with OM ≥ 300 and that according to approximate age few heifers were supposed to fall into that category, carcasses were sorted by OM as <300 or ≥300, and the resulting means for LE, BM, MA and WBSF were compared with a *t*-test. Means ± SD for the 64% of carcasses classified as < 300 OM were: 170 ± 14 LE, 248 ± 29 BM 220 ± 15 OM, 470 ± 80 MA and 4.87 ± 1.10 kg WBSF. Remaining carcasses were classified as ≥ 300 OM with 169 ± 15 LE, 342 ± 37 BM, 301 ± 3 OM, 485 ± 70 MA and 4.98 ± 0.64 kg WBSF. No differences were detected between the 2 maturity groups for LE (P = 0.76), MA (P = 0.53) or WBSF (P = 0.67); meanwhile significant differences were found for BM and OM (P < 0.001). Therefore, differences in ossification did not affect characteristics related to meat palatability of carcasses of previously pregnant heifers slaughtered at about 30 months of age.

Key Words: bone ossification, carcass maturity, shear force

T343 Occurrence of mycotoxins in corn samples collected in the United States in 2014. Simone Schaumberger*[1], Paula Kovalsky[1], Michael Sulyok[2], and Ursula Hofstetter[1], [1]*Biomin Holding GmbH, Herzogenburg, Austria,* [2]*University of Natural Resources and Life Sciences, Department IFA Tulln, Vienna, Austria.*

Mycotoxin occurrence in agricultural commodities is a worldwide phenomenon and poses a risk to human and animal health. A mycotoxin survey was conducted to raise awareness of the incidence of mycotoxins in cereals intended for animal feed. The focus of this study is to compare the extent of mycotoxin contamination in corn samples from 27 states in the United States in 2014. During harvest 507 corn samples were collected and analyzed for aflatoxins (Afla), zearalenone (ZEN), deoxynivalenol (DON), fumonisins (FUM), T-2 toxin (T-2) and ochratoxin A (OTA). Samples were analyzed using liquid chromatography-tandem mass spectrometry, high performance liquid chromatography and enzyme-linked immunosorbent assay.In total, 87% of samples tested were positive for the major mycotoxins mentioned above and out of those 36% were co-contaminated with more than one mycotoxin. The most frequently occurring mycotoxin was DON with a prevalence of 62% and an average value of 1,441 ppb. DON concentrations exceeding the respective FDA threshold (1,000 ppb; 8%) could be predominantly found in samples deriving from several northern states, California and Florida. FUM occurred in 55% of all samples tested with average value of 4,512 ppb. The FDA threshold for FUM (5,000 ppb) was exceeded in 4% of the samples. Afla and ZEN were detected in about 20% of the samples with average contamination levels of 35 and 484 ppb, respectively. Compared with the other mycotoxins, prevalence of T-2 toxin was low (13%), whereas OTA was not detected at all. Our results demonstrate a significant mycotoxin contamination of US corn harvested in 2014. Overall, the most frequently occurring mycotoxin was DON. FUM ranked second among the 6 mycotoxins analyzed. Owing to the fact that both DON and FUM have the potential to cause subclinical health effects in animals even at comparably low levels in feed (Antonissen et al., 2014), these 2 mycotoxins can be regarded as relevant threat for US livestock productivity. Occurrence of more than one mycotoxin was observed in around one third of the samples. Hence, due to potential additive and synergistic effects, special attention should be paid to co-occurrence of mycotoxins in animal feed (Grenier and Oswald, 2011).

Key Words: mycotoxin, survey, corn

T344 Antibiotic resistance gene abundance in feces of calves fed pirlimycin-containing whole milk. Tiffany Casteel*, Heather Littier, Partha Ray, Amy Pruden, and Katharine Knowlton, *Virginia Tech, Blacksburg, VA.*

Non-saleable (waste) milk containing antibiotics is commonly fed to dairy calves. Effects of ingestion of antibiotics at an early age on the gut microbiome and the development of antibiotic resistance genes (ARG) in the naïve gut are unknown. Pirlimycin, a lincosamide active against gram-positive bacteria, is commonly used as mastitis therapy. Lincosamides are considered highly important in human medicine, with applications in *S. aureus* and *C. difficile* infections. Resistance to pirlimycin is emerging and is of concern for both animal and human health. The objective was to determine the effect of early antibiotic exposure on the abundance of ARG in feces of milk-fed calves. Eight female Holstein calves were assigned to pasteurized whole milk (control; n = 4) or milk containing 0.2 mg/L of pirlimycin (treatment; n = 4). Calves were enrolled after receiving 2 colostrum feedings, were blocked by age, and paired by block. Calves were fed 5.68 L of pasteurized whole milk, treatment or control, divided into 2 daily feedings, from d 1 to d 50 of age. After weaning at the age of 50 d, calves were fed *ad libitum* non-medicated starter grain. Fecal samples were collected weekly until 85 d of age and freeze-dried. DNA was extracted from all samples using QiaAmp Fast DNA Stool Mini Kit and qPCR was used to quantify the abundance (gene copies/g of wet feces) of *Tet*W and 16S rRNA. Data were analyzed using PROC GLIMMIX in SAS. Differences were declared significant at $P < 0.10$, and trends at $P < 0.15$. Abundance of 16S rRNA was not different between control and pirlimycin-fed calves (mean = 9.81 log gene copies/g wet feces). Abundance of *Tet*W tended to be higher (9.51 log gene copies/g wet feces; $P = 0.13$) in pirlimycin-fed calves compared with control calves. The relative abundance of *Tet*W (0.49 gene copies/16S rRNA) in feces of calves was not influenced by treatment. Feeding pirlimycin-containing non-saleable milk to growing calves may increase environmental loading of *Tet*W. Additional research is needed on effects on other ARG and on the post-excretion fate of these genes following application of manure from calves fed waste milk.

Key Words: antibiotic resistance, waste milk, dairy calf

T345 Endocrine profiles during early gestation are affected by breed: Suffolk versus Cheviot dams. Ana Meikle*[1], Milena Sequeira[1], L. M. Fermin[2], Sarah Pain[2], Paul Kenyon[2], and H. T. Blair[2], [1]*Veterinary Faculty, Montevideo, Uruguay,* [2]*University of Massey, New Zealand.*

Previous studies have shown that Cheviot embryos are shorter than Suffolk embryos at d 19 of gestation, even when uterine capacity is not a limiting factor for embryo growth, evidence of the role the maternal uterine environment plays in embryo development. We determined if there were differences in the circulating concentrations of progesterone (P4), IGF-1, insulin and adiponectin between Cheviot and Suffolk dams during early gestation. Ewes (Cheviot, n = 8 and Suffolk, n = 6; 58.6 vs. 78.2 kg live weight, $P < 0.05$, with no differences in body condition score) were inseminated (d 0) laparoscopically with fresh semen from rams of the same breed. Blood samples were taken from the ewes every other day from d 0 to 21. Hormone concentrations were analyzed by repeated measures including using the fixed effects of maternal breed, day of sampling and their interaction; the covariance structure was first-order autoregressive AR(1), and for P4 concentrations the number of corpora lutea was used as a covariable. Cheviot dams had a higher P4 concentration than Suffolk dams from d 6 to 21 of pregnancy (6.82 ± 0.31 vs. 5.84 ± 0.33 ng/mL, $P < 0.05$) and P4 was also affected by ovulation rate ($P < 0.001$) as animals presenting with 2 corpora lutea had greater P4 than those with a single ovulation. No effect of ovulation rate was found for the rest of the hormones. Insulin concentrations were also greater in Cheviot dams compared with Suffolk dams (27.0 ± 2.0 vs. 20.4 ± 2.3 µUI/ mL, $P < 0.05$), while IGF-I concentrations did not differ among breeds. Suffolk ewes tended to present greater adiponectin concentrations than Cheviot ewes (4.4 ± 1.0 vs. 2.1 ± 0.8 ng/mL, $P = 0.099$). The greater P4 concentration found in Cheviot dams is consistent with their higher insulin concentration, as insulin stimulates granulosa cell P4 production. The opposite profile was found for adiponectin concentration, with the higher levels found in Suffok dams potentially associated with adiponectin inhibition of insulin-induced progesterone secretion by granulosa cells, as has been found in other species. The differences in hormone concentrations according to breed could explain the distinct embryo growth found during early gestation.

Key Words: sheep, gestation, hormone

T346 Gene expression in the kidneys of broilers fed dietary ochratoxin A for different time periods.

C. P. Zeferino*[1], K. D. Wells[1], A. S. A. M. T. Moura[2], G. E. Rottinghaus[1], and D. R. Ledoux[1], [1]*University of Missouri, Columbia, MO,* [2]*São Paulo State University, Botucatu, São Paulo, Brazil.*

Consumption of ochratoxin A (OTA) contaminated diets results in economic losses to the poultry industry. The objective of the current study was to evaluate the effects of quantity and time of exposure to dietary OTA on performance, organ weights, serum biochemistry, and gene expression in the kidneys of chicks. One hundred eighty day-old male broiler chicks (Ross 308) were randomly assigned to a 3 × 3 factorial arrangement of treatments (3 levels of OTA: 0, 1 and 2 mg OTA/kg diet and 3 time periods: 7, 14 and 21 d) with 4 replicate pens of 5 birds each per treatment. Birds fed 2 mg OTA/kg diet had decreased feed intake, body weight gain and increased serum uric acid levels at 14 and 21 d, and also poorer feed conversion and increased relative kidney weight. Birds fed 1 mg OTA/kg diet had decreased serum total protein. At 21 d, birds fed 1 mg OTA/kg diet had decreased albumin, and aspartate aminotransferase concentrations. For RNA-Sequencing analysis (RNA-Seq), kidney samples were collected weekly from 3 controls and 3 chicks fed 1 mg OTA/kg. NextGENe software was used for read alignment and transcript quantification. Reads per kilobase of target per million tiled reads (RPKM) were used in the Student's t test ($P < 0.05$, fold change >2). A total of 27,638,976 50-bp RNA-Seq reads were produced over the 3 time periods. Transcripts (40,782) were assembled de novo and annotated by homology to either *G. gallus* or *H. sapiens*. Genes associated with carbohydrate and amino acid metabolism were downregulated and genes associated with the immune system were upregulated at 7 and 14 d. Genes associated with lipid metabolism and xenobiotics biodegradation and metabolism were also downregulated at 14 d. These metabolic changes disappeared at 21 d, suggesting that damage to the kidney and other related organs was repaired or the damage was contained. In conclusion, the decreased performance and increased kidney weight and serum uric acid levels in birds fed 2 mg OTA/kg confirmed the nephrotoxic effects of OTA. The supplementation of 1 mg OTA/kg diet caused time-dependent alterations in renal gene expression in chicks.

Key Words: chicken, mycotoxin, RNA-sequencing

T347 Maintenance energy requirements of gestating beef cows and effects on cow reproduction and performance of calves.

Brit H. Boehmer* and Robert P. Wettemann, *Oklahoma Agricultural Experiment Station, Stillwater, OK.*

Spring calving, Angus cows were used to evaluate the repeatability of maintenance energy requirements (MR) during subsequent gestations, and the effects of MR on reproduction in cows and performance of calves. A total of 62 cows (5 to 11 yr of age, 150 ± 2 d of gestation) were individually fed a complete diet to meet MR (Model 1, NRC 1996) during 1 or more yr. Body weights were obtained twice weekly and daily feed intake was adjusted every 2 wk until constant BW was achieved for 30 d (regression analyses). Cows were classified by MR as low (L; < 0.5 SD less than yearly mean), moderate (M; ± 0.5 SD of mean) or high (H; > 0.5 SD more than mean). Cows (n = 26) were selected for repeatability analyses when MR was determined on 2 sequential years. The influence of MR on metabolic body weight, DMI, and pregnancy rate of cows and WW and ADG of calves was determined by ANOVA (PROC MIXED; SAS Inst. Inc.). Repeatability of individual cow MR in sequential years was determined using Pearson correlations with year in the model (PROC CORR; SAS). Pregnancy rate was analyzed by Chi-squared test (PROC FREQ; SAS). Mean MR of cows was 88.79 ± 0.89 kcal/kg BW $^{0.75}$/d. Mean yearly difference between cows with the greatest and least MR was 26.9%. Year influenced MR of cows ($P < 0.001$) but cow age did not affect MR ($P = 0.99$). Maintenance energy requirement of cows was repeatable ($r = 0.30$, $P = 0.02$) between sequential years. Repeatability of MR was determined when cows were fed to maintain a constant body weigh rather than estimates of MR. Metabolic body weight at maintenance was greater in L cows ($P = 0.01$; 117.1 ± 1.1 kg$^{0.75}$) compared with H cows (111.8 ± 1.1 kg$^{0.75}$) and M cows tended to be intermediate ($P < 0.09$; 114.45 ± 1.1 kg$^{0.75}$). At maintenance, DMI was greater in H cows ($P < 0.001$) compared with M and L cows. Subsequent pregnancy rate of cows conceiving to AI was not influenced by MR ($P = 0.11$). Maintenance energy requirement of cows did not influence performance of calves before weaning ($P = 0.92$). Production efficiency of beef cows may be improved by identifying cows that require less energy input and maintain performance.

Key Words: beef cow, maintenance, cow-calf performance

T348 Activation and deactivation of renal genes of chicken associated with induced ochratoxicosis at different exposure times.

C. P. Zeferino*[1], K. D. Wells[1], A. S. A. M. T. Moura[2], G. E. Rottinghaus[1], and D. R. Ledoux[1], [1]*University of Missouri, Columbia, MO,* [2]*São Paulo State University, Botucatu, São Paulo, Brazil.*

This study investigated the expression of genes that were turned on or off in renal cells of chicks as a result of different exposure times to ochratoxin A (OTA). One hundred and 80 d-old male broiler chicks (Ross 308) were randomly assigned to a 3 × 3 factorial arrangement of treatments (3 levels of OTA: 0, 1 and 2 mg OTA/kg diet and 3 time periods: 7, 14 and 21 d) with 4 replicate pens of 5 birds each per treatment. For RNA-Sequencing analysis (RNA-Seq), kidney samples were collected weekly from 3 controls and 3 chicks fed 1 mg OTA/kg. Birds fed 2 mg OTA/kg diet were not used because their reduced feed intake could affect gene expression. The libraries were constructed by Illumina's TruSeq RNA protocol. NextGENe software was used for alignment and transcript quantification. Reads per kilobase of target per million tiled reads (RPKM) were used in the Binary test analysis ($P < 0.05$). A total of 27,638,976 50-bp RNA-Seq reads were produced over the 3 time periods. Transcripts (40,782) were assembled de novo and annotated by homology to either *G. gallus* or *H. sapiens*. The interleukin 9 (*IL9*) and tubby like protein 1 (*TULP1*) genes were activated at 7 d, the growth hormone secretagogue receptor (*GHSR*) gene was activated at 14 d, and the G protein-coupled receptor kinase 6 (*GRK6*) and glyceraldehyde-3-phosphate dehydrogenase (*GAPDH*) genes were activated at 21 d. The preprogastrin (*LOC396365*) was activated during all time periods. The sperm associated antigen 4 (*SPAG4*), sperm-associated antigen 4 protein-like (*LOC100857131*) and V-region-like B-G antigen, and MHC class IV antigen (*B-G*) were deactivated at 7 d, the zinc finger B-box domain-containing protein 1-like (*LOC771469*), NK2 homeobox 1, variant 2, and NK2 homeobox 8 (*NKX2–1* and *NKX2–8*), forkhead box O1 (*FOXO1*), myosin heavy chain (*MyHC*) and claudin 18 (*CLDN18*) genes were deactivated at 14 d and finally, the V-region-like B-G antigen (*B-G*) and xeroderma pigmentosum, complementation group C (*XPC*) genes were deactivated at 21 d. The turning on and off of the genes may be a response to the carcinogenic and tumorigenic effects of OTA in birds.

Key Words: broiler, nephrocarcinogenicity, ochratoxin A

T349 Evaluation of models for predicting acidosis risk of barley grain in finishing beef cattle .

Uchenna Y. Anele[1], Mary-lou Swift[2], Tim A. McAllister[1], and Wenzhu Yang*[1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Alberta Agriculture & Rural Development, Lethbridge, Lethbridge, AB, Canada.*

A model to predict acidotic risk of barley grain was developed from a batch culture consisting of 50 barley samples varying in bulk density (BD), processing method (standard vs. precision processing: sieving grains into large versus small kernels and rolling based on kernel size), processing index (BD after rolling/BD before rolling), processing (ground vs. dry-rolled), geographical and agronomic origin. The objective of this study was to develop a model that can predict the relative 'hotness' of individual barley samples. Of all the independent variables (pH, starch content, dry matter disappearance (DMD), neutral detergent fiber, acid detergent fiber, in vitro gas kinetics, total and molar proportions of individual short-chain fatty acids at different incubation times) considered, dry matter disappearance at 6 h of incubation (DMD6) accounted for 90.5% of the variation in acidosis index with a root mean square error (RMSE) of 4.46%. When the new model ($-0.7826 + 2.5536 \times$ DMD6) was applied to 3 independent data sets to predict acidosis, it accounted for 33.4, 90.9 and 25.6% of the variation in calculated acidosis index. Significant ($P < 0.01$) mean bias was evident in 2 of the data sets and it under-predicted acidosis index by 26.1 and 5.35%. There were marked similarities in the acidosis index ranking of barley samples by the models as shown by the result of a correlation analysis between calculated and predicted acidosis index ($R^2 = 0.67$, $P < 0.01$). We observed variations in the acidosis index ranking of samples that were processed differently (processing index of 75 versus 85% and precision processing versus control). Results suggest that our model which is based on DMD6 has the potential to predict acidosis risk and can rank different barley samples based on their acidotic risk; however, the model would benefit from further refinement.

Key Words: acidosis, barley, prediction

T350 Influence of growth-promoting implants on endocrine factors and efficiency of replacement beef heifers.

Laura R. Meyer*[1], Thomas L. Devine[1], Michael L. Looper[1], Dirk Philipp[1], Donald S. Hubbell III[2], Rick W. Rorie[1], and Charles F. Rosenkrans Jr.[1], *[1]Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville, AR, [2]Livestock and Forestry Research Station, Division of Agriculture, University of Arkansas, Batesville, AR.*

Anabolic steroid implants are commonly used in the beef industry to increase BW gain in feedyard cattle. However, there are a limited number of implants approved for use in replacement heifers. Objectives were to use growth-promoting implants to add value to low-BW heifers, and to determine the relationships among hormones and cow efficiency. Charolais × Balancer heifers (n = 65; 179 ± 30 kg; 255 ± 12 d of age) were used to determine the influence of androgenic and(or) estrogenic implants on serum concentrations of insulin-like growth factor-I (IGF-I), prolactin (PRL), cortisol (CORT), and reproduction. Heifers were blocked by BW and assigned to 1 of 4 implant treatment groups: 1) control, no implant (CON; n = 16); 2) trenbolone acetate (TBA; 200 mg of TBA; n = 15); 3) trenbolone acetate plus estradiol (TBA+E2; 40 mg TBA and 8 mg E2; n = 17); or 4) zeranol (ZER; 36 mg ZER; n = 17). Heifers were implanted on d 0, and blood samples collected on d 0 (15 Nov), 106 (1 Mar), and 195 (29 May) of the experiment. Heifers were AI on d 220 and exposed to an Angus bull for 28 d starting 12 d after AI. Calf birth date, and birth weight were recorded. At weaning, dam and calf weights were determined and cow efficiency was calculated by dividing calf adjusted 205 d weight by dam weight at weaning. Treatment did not influence ($P > 0.10$) calving rate (41.5%), Julian calving date (96.8 ± 2.5 d), cow efficiency (0.47 ± 0.23), concentrations of IGF-I (78.4 ± 3.9 ng/mL), PRL (83.5 ± 5.81 ng/mL), CORT (36.3 ± 9.9 ng/mL), or PRL:CORT (ratio = 2.19 ± 0.24). Serum PRL and IGF-I increased ($P < 0.01$) from d 0 to 195. Serum cortisol increased ($P < 0.01$) from d 0 to 106, and concentrations were similar from d 106 to 195. Multiple regression analyses indicated PRL and IGF-I at d 195 described 30% of variation in adjusted 205 d calf weights; 35% of variation in cow weight at weaning was explained by PRL at d 0 and 106; and PRL:CORT at d 0 and IGF-I at d 195 accounted for 44% of variation in cow efficiency. Anabolic implants did not affect heifer reproduction. Serum PRL, CORT, and IGF-I of heifers at weaning, yearling, and pre-breeding may serve as biomarkers of cow efficiency.

Key Words: cortisol, IGF-I, prolactin

Ruminant Nutrition: Beef II

T351 Effect of monensin inclusion on intake and digestion in *Bos indicus* and *Bos taurus* steers consuming bermudagrass hay.

Natasha L. Bell*1,2, Todd R. Callaway[3], Robin C. Anderson[3], Marcia O. Franco[4], and Tryon A. Wickersham[1], [1]*Texas A&M University, College Station, TX,* [2]*Texas A&M University-Kingsville, Kingsville, TX,* [3]*Southern Plains Agricultural Research Center, Agricultural Research Service, USDA, College Station, TX,* [4]*Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Effects of monensin inclusion and the subspecies of cattle on utilization of bermudagrass hay (13.7% CP) were evaluated using ruminally cannulated steers (5 *Bos indicus*, BI and 5 *Bos taurus*, BT; 398 kg BW). Subspecies were concurrently subjected to a 2 period, 2 treatment crossover design. Treatments consisted of 0 (CON) or 200 (MON) $mg \cdot hd^{-1}$ monensin (Rumensin 90; Elanco Animal Health, Greenfield, IN) fed daily in 0.91 kg DDGS. Steers were group housed during adaptation periods and moved to individual covered pens to facilitate sampling. Periods were 70 d in length: 20 d adaptation, 5 d sample collection, 17 d continuation of treatment application (for ruminal sampling), and 28 d withdrawal between periods. Hay, ort, and fecal grab samples were collected d 21–25 for determination of intake and digestion. Data were analyzed using the MIXED procedure of SAS 9.3 (SAS Inst. Inc., Cary, NC) with terms in the model including treatment, subspecies, subspecies × treatment and period, with animal as a random effect. No subspecies × treatment interactions were observed ($P \geq 0.21$). Monensin tended to increase forage OM intake (FOMI; $P = 0.08$) from 19.5 to 20.3 g/kg BW and total OM intake (TOMI; $P = 0.07$) from 21.3 to 22.2 g/kg BW. No effect of subspecies ($P \geq 0.16$) was observed for FOMI or TOMI. Organic matter digestibility was not affected by monensin ($P = 0.97$; 60.6 and 60.7 for CON and MON, respectively) and was not different ($P = 0.28$) between subspecies (58.0 and 63.3% for BI and BT, respectively). When the combined effects of TOMI and OMD were evaluated as total digestible OM intake (TDOMI), no response ($P = 0.71$) was observed from monensin supplementation. *Bos taurus* steers had greater ($P = 0.04$) TDOMI than BI steers (14.3 vs 12.2 g/kg BW). Monensin tended to increase forage NDF intake (FNDFI; $P = 0.07$) from 16.5 to 17.2 g/kg BW and total NDF intake (TNDFI; $P = 0.08$) from 17.4 to 18.1 g/kg BW, but had no effect ($P \geq 0.73$) on NDF digestibility (NDFD; 66.4 and 66.0% for CON and MON, respectively) or total digestible NDF intake (TDNDFI; 11.7 and 11.9 g/kg BW for CON and MON, respectively). Although FNDFI, TNDFI, and NDFD were not different ($P \geq 0.16$) between subspecies, total digestible NDF intake was greater ($P = 0.02$) for BT than BI steers (12.7 vs 10.9 g/kg BW). Overall, monensin increased FOMI and FNDFI and had no effect on OMD or NDFD. *Bos taurus* had greater TDOMI and TDNDFI compared with BI steers.

Key Words: cattle subspecies, ionophore, digestibility

T352 Effect of rumen protected B vitamins supplementation during the receiving period on the productive performance of beef cattle.

Helene Leclerc*[1], Diana A. Espinosa[2], Essi Evans[3], Roberto Zambrano Gaytan[2], and Juan de Dios Garza Flores[2], [1]*Jefo Nutrition, St-Hyacinthe, QC, Canada,* [2]*Rancho El 17, Hermosillo, Sonora, Mexico,* [3]*Technical Advisory Services, Bowmanville, ON, Canada.*

A study was conducted to evaluate the performance of beef cattle given a rumen protected B vitamins blend during a 21-d receiving period. Twelve loads of cattle (899 head) were equally split based on weight and shrink and were assigned to 15 pens/treatment. The test treatment consisted of 2g/head/day of rumen protected B vitamins (folic acid, pyridoxine, pantothenic acid and biotin; Jefo Nutrition, St-Hyacinthe, Quebec, Canada). No added B vitamins were given to control cattle, and a common diet was provided to both groups. Receiving ration consisted of 38% alfalfa hay, 30% steam flaked corn, 10% corn distillers grain, 2% soybean meal, 11% sugar cane molasses, 3% wheat straw and 6% minerals and vitamins. Animals were weighted individually on d 1 and d 21 of the trial to calculate total and daily gain weights. Animals were fed twice daily. Daily pen feed intakes were measured. All data were analyzed as a randomized complete block, using pens as experimental units. The general linear model included treatment as fixed and block as random effects. Days to recover shrink were reduced (15.36 vs. 16.63 d; $P < 0.05$), for the group of cattle fed the protected B vitamins blend. No significant difference was observed between the control and treatment group, for morbidity status (2.16 vs. 1.52%) and mortality rate (0.43 vs.0.87%). The inclusion of the protected B vitamins blend in the diet significantly improved total gain weight (46.26 vs. 42.40 kg; $P < 0.05$), average daily gain (2.20 vs. 2.01 kg; $P < 0.05$), and feed/gain (3.90 vs. 4.33; $P < 0.05$); without affecting average daily feed intake. It is concluded that addition of the protected B vitamins blend in the diet improves the productivity of beef cattle during the receiving period, without affecting feed intake and the morbidity rate.

Key Words: protected B vitamins, beef cattle, receiving

T353 Effects of including virginiamycin in feedlot diets containing monensin under commercial conditions in Mexico.

Jorge R. Kawas[2], Rene Alvarado[2], Milton A. Gorocica-Buenfil*[1], and Francis L. Fluharty[3], [1]*Phibro Animal Health de Mexico, Queretaro, Qro. Mexico,* [2]*MNA de Mexico, San Nicolas de los Garza, NL, Mexico,* [3]*The Ohio State University, Wooster, OH.*

A trial was conducted in a commercial feedlot in northeastern Mexico to determine the effects of supplemental virginiamycin (Vm) in combination with monensin (Mn) on finishing cattle performance. Upon arrival, 2,256 crossbred heifers (BW = 276.0 ± 3.33 kg) were dewormed, vaccinated against respiratory and clostridial pathogens and implanted with a trenbolone acetate (TBA) implant (200 mg TBA + 20 mg estradiol benzoate). At processing, animals were allotted to 22 pens (approx. 100/pen) using a randomized complete block design. Two treatment groups were evaluated, both receiving a high-concentrate (+90%) diet. One treatment group (MN) had the basal diet supplemented with 400 mg/hd/d of Mn; the other treatment group (VM) diet was supplemented with 250 mg/hd/d of Vm and 300 mg/hd/d of Mn. Cattle were gradually adapted to their final diet (15.5% protein, 1.51 Mcal NEg/kg) over a 21–28 d period. When cattle had 44 d on feed (DOF), they were reimplanted with the same TBA implant. Zilpaterol chlorhydrate was provided to all cattle at 0.15 mg/kg BW for 30 d and was withdrawn 4 d before harvest. Cattle were harvested after 100 DOF. At harvest, HCW was recorded. Data were analyzed using the PROC MIXED analysis of SAS for a randomized complete block design. Pen was used as the experimental unit and block was included in the model as a random factor. After 44 DOF when cattle were reimplanted, the VM group had greater ADG (1.51 vs. 1.38; $P < 0.05$). At harvest, total ADG was 6% greater in the VM group (1.40 vs. 1.32; $P < 0.05$), and G:F was improved 7% in the VM group (0.179 vs. 0.167; $P < 0.05$). Hot carcass weight was 4.9 kg greater ($P < 0.01$) in the VM group than in the MN group (251.7 kg vs.

246.8 kg). These results agree with previous research in commercial feedlots in Mexico and Brazil. Under the parameters of this study, virginiamycin inclusion in a feedlot diet containing monensin improved feedlot performance and carcass weight.

Key Words: feedlot, virginiamycin, performance

T354 Growth performance of yellow cattle in southern China weaned at different ages.

C. Wang*[1], Y. F. Xia[1], H. L. Mao[1], Y. Tu[2], C. G. Jiang[2], H. F. Wang[1], Q. Y. Diao[2], and D. X. Ren[3], [1]*College of Animal Science and Technology, Zhejiang A & F University, Hangzhou-Lin'an, Zhejiang Province, China,* [2]*Feed Research Institute, Chinese Academy of Agricultural Sciences, Beijing, China,* [3]*Institute of Dairy Science, Zhejiang University, Hangzhou, Zhejiang Province, China.*

This study was conducted to examine the effects of weaning ages on performance of a small-type yellow cattle in southern China. Thirty female calves were selected according to birth weight, and stratified into 10 blocks of 3 and allocated within block to 3 treatments that the calf was considered weaned when it consumed 1000 (W1000), 750 (W750), or 500 (W500) g of starter for 2 consecutive days. All calves had colostrum within 4 h after born, and then were fed milk up to 3 L/d until d 7. Liquid feed composed of half whole milk and half milk replacer (MR, 93.2% DM, 23.9% CP, and 13.1% EE) were fed to calves at 3L/d until d 13 and 3 L/d MR for the remainder of the study. Starter (17.9% CP, 10.9 MJ/kg ME) was fed ad libitum from d 10, and grass hay and water were available ad libitum. Milk, MR, starter, and hay intakes were recorded daily. All Claves were weighted and body height, body length, circumference of cannon bone were measured after birth and every 30 d until d 150. Data except for weaning age and BW change were analyzed using the Proc MIXED of SAS while weaning age and BW change were analyzed using the Proc GLM of SAS. The results showed that average weaning age was 49 ± 4.8, 58 ± 4.4, and 63 ± 4.6 for W500, W750, and W1000, respectively. Calves in W500 and W750 had higher starter intake than that of W1000 ($P < 0.05$). The body measurements were not significant different between groups ($P > 0.05$), however, calves in W1000 tend to have a low body height and body length ($0.05 < P < 0.15$). There was no significant difference in BW and ADG on d 30 when any of the calves was weaned ($P > 0.05$). On d 60, BW of calves in W1000 was higher than that of W500 ($P < 0.05$) and tend to be higher than that of W750 ($P = 0.10$). However, calves in W1000 lost their BW advantage on d 90. Calves in W750 and W500 had higher ADG from 1 to 150 d compared with that of W1000. It is concluded that starter-dependent weaning can help to enhance the adaptation to the solid feed with advantages on weight gain and feed intake.

Key Words: weaning, yellow cattle, growth performance

T355 Decreasing the frequency of energy supplementation to beef steers impairs growth and antibody production against bovine viral diarrhea virus 1b.

Luis F. Artioli*[1], Philipe Moriel[1], Rodrigo S. Marques[2], and Reinaldo Cooke[2], [1]*North Carolina State University, Waynesville, NC,* [2]*Oregon State University, Burns, OR.*

We evaluated the effects of decreasing the frequency of energy supplementation on growth performance and measurements of innate and humoral immune response of preconditioning beef steers. At weaning (d −7), Angus steers (n = 24; BW = 221 ± 31 kg; age = 177 ± 19 d) were allocated to a single drylot pen with free-choice access to fescue hay. On d 0, steers were stratified by BW and age, and randomly assigned to 1 of 8 drylot pens (3 steers/pen). Steers were provided daily ad libitum access to ground fescue hay (17% CP and 58% TDN; DM basis) and similar weekly concentrate offer (12 kg/steer) from d 0 to 42. Treatments were randomly assigned to pens (4 pens/treatment) and consisted of dividing and providing the weekly concentrate offer either 3 (S3; 3.8 kg on Mondays, Wednesdays and Fridays) or 7 times (S7; 1.7 kg daily) per week. Supplements included 50% soyhulls and 50% corn gluten feed (17% CP and 72% TDN; DM basis). Steers were vaccinated using the SelectVAC protocol (Zoetis) on d 7 and 21. Shrunk BW was obtained on d 0 and 42, and blood samples from jugular vein collected on d −7, 0, 7, 8, 9, 10, 14, 21, 22, 23, 24, 28, 35 and 42. Although BW did not differ from d 0 to 42 ($P \geq 0.33$), S7 steers had greater mean ADG (1.3 vs. 1.0 ± 0.07 kg/d; $P = 0.01$), mean hay DMI (2.8 vs. 2.2 ± 0.08 kg/d; $P < 0.01$) and total DMI from d 0 to 42 (190 vs. 165 ± 4 kg; $P = 0.02$), but similar G:F compared with S3 steers ($P = 0.14$; 0.29 vs. 0.26). Plasma concentrations of glucose, insulin, cortisol and ceruloplasmin did not differ ($P \geq 0.33$) between treatments. However, S3 steers had greater plasma haptoglobin concentrations on d 8 (1.95 vs. 1.20 ± 0.13 mg/mL; $P < 0.01$) and 10 (1.39 vs. 0.84 ± 0.13 mg/mL; $P < 0.01$), and less mean serum bovine viral diarrhea virus-1b (BVDV1b) titers than S7 steers (1.5 vs. 2.5 ± 0.31 log 2 base; $P = 0.03$). Therefore, decreasing the frequency of energy supplementation from 7 to 3 times weekly during a 42-d preconditioning period decreased hay and total DMI, growth and antibody production against serum BVDV-1b, and increased plasma haptoglobin concentrations of beef steers.

Key Words: supplementation frequency, immune, steer

T356 Pre- and postpartum herbage allowances of grasslands affected productive and reproductive performances of primiparous beef cows.

Mariana Carriquiry*[1], Martín Claramunt[2], Ana L. Astessiano[1], and Pablo M. Soca[3], [1]*Facultad de Agronomía, Montevideo, Uruguay,* [2]*Facultad de Veterinaria, Paysandú, Uruguay,* [3]*Facultad de Agronomía, Paysandú, Uruguay.*

The aim of this work was to evaluate the effect of herbage allowance of grasslands (Campo biome) during the prepartum and postpartum on productive and reproductive responses of primiparous beef cows. Fifty-four Hereford cows (5.9 ± 0.5 BCS in a 1–8 scale and 472 ± 35 kg BW) were used in a randomized block design with 2 spatial replications and a factorial arrangement of prepartum (fall;high vs. low, PREH vs. PREL) and postpartum (spring-summer; high vs. low, POSTH vs. POSTL) herbage allowance (4 vs. 2.5 kgDM/kgBW of annual mean for high vs. low). Cows were in a continuous grazing system. Cow BW, BCS, and calf BW were determined monthly and at calving and milk production and composition were determined using a milking machine at 130 d postpartum. Calving to conception interval (CCI) and early (during first month of mating period) and total pregnancy were registered using ultrasound. Means from a mixed model were considered to differ when $P \leq 0.05$. Cow BW and BCS were greater from mid-winter to the end of summer (last third of gestation to weaning) for PREH than PREL cows and during the postpartum for POSTH than POSTL cows. Milk energy output was between 1.2 and 1.6 ± 0.8 Mcal NEL/d greater for PREH than PREL cows and for POSTH than POSTL cows. Calf BW did not differed at birth but at weaning was 30 ± 5 kg greater for POSTH than POSTL cows. The CCI tended ($P = 0.10$) to be shorter for PREH than PREL cows (129 vs. 139 ± 6 d) and was shorter for POSTH than POSTL cows (126 vs. 141 ± 6 d). Early pregnancy was greater for POSTH than POSTL cows (54 vs. 39%) while total pregnancy did not differed among treatments (averaged 77%). Cow BCS at calving affected CCI, early and total pregnancy (1 unit of BCS at calving decreased CCI by 21 d and increased early and total pregnancy by 50%). Effects of PRE and

POST herbage allowances had an additive effect on productive and/or reproductive responses of primiparous beef cows grazing native pastures.

Key Words: beef cattle, rangeland, forage allowance

T357 The effects of adding 3-nitrooxypropanol and monensin to a finishing diet on methane production using the rumen simulation technique (Rusitec).

A. Romero-Perez*[1,2], E. K. Okine[2], L. L. Guan[2], S. M. Duval[3], M. Kindermann[4], and K. A. Beauchemin[1], *[1]Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada, [3]DSM Nutritional Products France, Research Centre for Animal Nutrition and Health, Saint Louis Cedex, France, [4]DSM Nutritional Products, Basel, Switzerland.*

3-Nitrooxypropanol (NOP), an enzymatic inhibitor that has consistently reduced methane (CH_4) emissions in sheep, dairy and beef cattle (up to 59% reduction on a long-term basis), and monensin (MON), an ionophore that has a moderate, and sometimes transitory, effect on CH_4 reduction were used in this study. The objective was to evaluate the effect of NOP, MON and the combination of both on CH_4 production when added to a finishing diet (85% barley grain, 10% barley silage, and 5% vitamin-mineral supplement; DM basis) using Rusitec fermenters. Two Rusitec apparatuses each equipped with 8 fermenters were used in a completely randomized block design with 2 blocks (apparatus) and 4 treatments: Control, NOP (2 mg), MON (2 mg) and NOP+MON (2 mg+2 mg). Within each apparatus, 2 fermenters were randomly assigned to a treatment. Treatments were supplied daily with 10 g of diet. The experiment included an adaptation period without treatment supplementation (8 d), a treatment period (7 d), and a recovery period where treatments were discontinued (3 d). During the treatment period, DM digestibility was not affected. Total VFA and molar proportion of propionate and butyrate were not affected ($P > 0.05$) but acetate was reduced ($P < 0.01$) with addition of NOP (8.3%) and NOP+MON (14.9%). Methane production was reduced ($P < 0.01$) by 69.4 and 68.2% with NOP and NOP+MON respectively, while H_2 production was increased ($P < 0.01$) by 76.7 and 75.2% respectively for the same treatments compared with Control. Treatments had no effect on the copy number of the 16S rRNA gene for total bacteria ($P > 0.21$); however, that for methanogens was reduced ($P < 0.01$) with NOP and NOP+MON treatments. During the recovery period on d 18, no effect ($P > 0.20$) was observed for CH_4 and H_2 production; however, a trend for lower acetate concentration with NOP and NOP+MON was still observed ($P = 0.08$). Treatments including NOP were effective in reducing CH_4 production in vitro using a finishing diet with a concomitant increase in H_2 production; however, the combination of NOP and MON did not lead to greater CH_4 reduction than NOP alone.

Key Words: 3-nitrooxypropanol, monensin, methane

T358 Nutritional performance and metabolic characteristics of cattle fed tropical forage with nitrogen and starch supplementation.

Marcia de Oliveira Franco*, Edenio Detmann, Alexandre Ribeiro Lopes, Luana Marta de Almeida Rufino, and Erick Darlisson Batista, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Effects of nitrogen supplementation with and without starch supplementation on nutritional performance and metabolic characteristics of cattle fed low and medium-quality tropical forages were evaluated using ruminal and abomasal cannulated steers. Four European × Zebu bulls (381 kg BW) were distributed according to a 4 × 4 Latin square. Each experimental period of 28 d was divided into 2 sub-periods: in the first sub-period 2 animals received low-quality hay and 2 animals received medium-quality hay (*Brachiaria decumbens*); the following supplementation schemes were evaluated in the second sub-period: low-quality hay with nitrogen supplementation (300 g CP/d); low-quality hay with nitrogen (300 g CP/d) and starch (225 g/d) supplementation; medium-quality hay with nitrogen supplementation (300 g CP/d); and medium-quality hay with nitrogen (300 g CP/d) and starch (225 g/d) supplementation. In the absence of supplementation, the medium-quality forage provided higher ($P < 0.05$) intake, digestibility, nitrogen balance (NB), and efficiency of nitrogen utilization (EFNU). The greater performance of animals fed medium-quality forage was attributed to anabolic stimuli, supported by higher ($P < 0.05$) serum concentration of IGF1. Comparing sub-periods, the supply of supplements depressed ($P < 0.05$) medium-quality forage intake, but did not affect ($P > 0.05$) low-quality forage intake. There was no effect ($P > 0.05$) of supplementation on NDF digestibility as compared with the sub-period without supplementation. However, comparison between supplements indicated depression ($P < 0.05$) in NDF digestibility when starch was included. Supplementation increased ($P < 0.05$) NB, EFNU, and serum concentration of IGF1 in animals fed low-quality forage. Nitrogen supplementation increases nitrogen retention in animals, an effect attributed mainly to anabolic stimuli. However, this effect is more prominent when animals are fed low-quality forages. No positive impact on animal metabolism was obtained with the combination of supplemental nitrogen and starch.

Key Words: *Brachiaria decumbens*, digestibility, nitrogen balance

T359 Nutritional performance and metabolic characteristics of cattle fed low-quality tropical forage and supplemented with nitrogen associated with different starch proportions.

Marcia de Oliveira Franco*, Edenio Detmann, Marcília Medrado Barbosa, Gabriel Cipriano Rocha, and Claudia Batista Sampaio, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Effects of nitrogen supplementation associated with different starch proportions on nutritional performance and metabolic characteristics of cattle fed low-quality tropical forage (*Brachiaria decumbens* hay, 7.4% CP) were evaluated using ruminal and abomasal cannulated steers. Five European × Zebu young bulls (186 kg BW) were distributed according to a 5 × 5 Latin square. The following treatments were evaluated: control (only forage), supplementation with 300 g CP/d (0:1), supplementation with 300 g starch/d and 300 g CP/d (1:1), supplementation with 600 g starch/d and 300 g CP/d (2:1), and supplementation with 900 g starch/d and 300 g CP/d (3:1). Supplements increased ($P < 0.05$) DM intake, but did not affect ($P > 0.05$) forage intake. There was a cubic effect ($P < 0.05$) of starch, which was attributed to the highest forage intake (g/kg BW) when using the 2:1 starch:CP ratio. Supplements increased ($P < 0.05$) OM digestibility, but did not affect ($P > 0.05$) NDF digestibility. There was a positive linear effect ($P < 0.05$) of the amount of starch supplemented on OM digestibility. Total NDF digestibility was not affected ($P > 0.05$) by the amount of starch supplemented. Ruminal ammonia nitrogen concentrations were higher ($P < 0.05$) in supplemented animals, however, a negative linear effect ($P < 0.05$) of amount of starch was observed. Supplements increased ($P < 0.05$) the nitrogen balance (NB) and efficiency of nitrogen utilization. These effects were attributed to increased body anabolism, supported by higher ($P < 0.05$) serum concentration of IGF1. Increasing the amount of starch tended to linearly increase the NB ($P < 0.06$) and serum concentration of IGF1 ($P < 0.05$). However, comparison of NB means between treatments with supplementation showed a higher value for the 2:1 starch:CP ratio.

Nitrogen supplementation in cattle fed low-quality tropical forage increases nitrogen retention in the animal body. Additional supply of starch increases nitrogen retention by increasing energy availability for both rumen and animal metabolism.

Key Words: fiber, nitrogen balance, Zebu

T360 Effect of rumen protected carbohydrate supplementation on performance in feedlot finishing steers during heat stress.

Juan P. Russi*[1,3], Patricio Davies[4], Nicolas DiLorenzo[2], and Alejandro E. Relling[1], [1]*Facultad de Cs Veterinarias, UNLP, La Plata, Buenos Aires, Argentina,* [2]*University of Florida, Mariana, FL,* [3]*RUPCA LLC, Merced, CA,* [4]*INTA, Gral Villegas, Buenos Aires, Argentina.*

Finishing steers during the summer can be challenging due to the effects of high temperatures and humidity on DMI. The objective of this study was to evaluate the inclusion of a rumen-protected carbohydrate (RUPCA; US Patent # 8,507,025) on performance of finishing steers during heat stress. Temperature-humidity index average measured every day during the experiment was 72 ± 4.9. Crossbred steers (n = 135; 355 ± 20kg) were used in a 62-d experiment. Steers were blocked by initial BW and placed into 15 pens. Steers within blocks were randomly assigned to 3 treatments: T0 = fed 91.4% of a basal diet (% DM), 22.3% corn silage, 65.9% dry corn, 0.6% sunflower meal, 0.5% urea, 2% minerals and vitamins and 8.6% of a supplement containing (% DM) 58.1% soybean meal, 38.9% soluble carbohydrates, 2% urea and 1% minerals salts; T1 = fed the basal diet plus 4.3% supplement and 4.3% RUPCA; and T2 = fed basal diet plus 8.6% RUPCA. The supplement and RUPCA consisted of the same ingredients, differing on the processing of the carbohydrate (i.e., protected or not from ruminal degradation). Body weight was measured on d 0, 15, 39 and 62 relative to the beginning of treatments feeding (d 0). Pen DMI was measured on d 10, 18, 25, 31, 35, 46, 51, 56, 60 and 62. Back-fat on the 12th rib (BF) and LM area were measured on d 1 and 62. Data were analyzed as a randomized complete block design with repeated measures using a mixed model of SAS. Initial BW was used as a covariate. There were no differences between treatments on final BW, BF or LM area on d 62 ($P > 0.10$). Treatment × day interactions were observed for G:F, ADG and DMI ($P < 0.05$) suggesting a different response to treatments during periods of heat stress (Table 1). Feeding RUPCA may be beneficial for finishing steers under heat stress.

Table 1 (Abstr. T360).

	Treatment				*P*-value

T361 Partially replacing corn with glycerin increases total VFA, propionate, and ruminal NH$_3$-N concentrations in finishing beef diets evaluated in a dual-flow continuous culture system.

Pedro Del Bianco Benedeti[1,2], Lorrayny Galoro da Silva[1], Eduardo Marostegan de Paula[1], Teshome Shenkoru[1], Hugo Monteiro[1], Brad Amorati[1], Yehling Yeah[1], Marcos Marcondes[2], and Antonio Faciola*[1], [1]*University of Nevada, Reno, NV,* [2]*Federal University of Viçosa, Viçosa, MG, Brazil.*

Glycerin, the main biodiesel production by-product, has the potential to partially replace corn as an energy source for cattle. The objective of this study was to evaluate the effects of partially replacing dry ground corn (DGC) with glycerin on ruminal fermentation using a dual-flow continuous culture system. Six fermenters were used in a replicated 3x3 latin square arrangement with 3 periods of 10 d each, with 7 d for diet adaptation and 3-d for sample collections. Three dietary inclusion levels of glycerin were tested (0, 15, and 30% on DM basis). All diets contained 75% concentrate and were formulated to meet NRC (2000) recommendations. Fermenters were fed 72 g of DM/d equally divided in 2 meals per day. Liquid and solid dilution rates were adjusted to 11 and 5.5%/h, respectively. On d 8, 9, and 10, samples of digesta effluent were collected for ruminal NH$_3$-N and VFA analyses. Nutrient flow and digestibility, N balance, and microbial growth were also measured. Data were analyzed using the MIXED procedure in SAS. Ruminal traits are presented in Table 1. Concentrations of total VFA, propionate, and NH$_3$-N increased linearly ($P < 0.05$) and concentrations of acetate, butyrate, *iso*-valerate, and BCVFA, as well as the acetate: propionate ratio decreased linearly ($P < 0.05$) as glycerin replaced DGC. These results suggest that partially replacing DGC with glycerin may change ruminal fermentation, increasing total VFA, propionate, and NH$_3$-N concentrations, which may increase energy status and microbial yield in beef cattle.

Table 1 (Abstr. T361). Ruminal traits

T362 Herbage allowance of grasslands during calf fetal and early life: Effects on body weight and composition.

Mariana Carriquiry*[1], Martín Claramunt[2], Alberto Casal[1], Ana L. Astessiano[1], and Pablo M. Soca[3], [1]*Facultad de Agronomía, UdelaR, Montevideo, Uruguay,* [2]*Facultad de Veterinaria, UdelaR, Paysandú, Uruguay,* [3]*Facultad de Agronomía, Paysandú, Uruguay.*

Fifty-four Hereford calves (31 males, 23 females) were used in a randomized block design (2 spatial replications) to evaluate the effect of herbage allowance of grasslands during their fetal and early life (130 d of gestation to weaning) on calf BW and body composition during the first year of age. Their dams (primiparous, 5.9 ± 0.5 BCS 1–8 scale, 472 ± 35 kg BW) were allocated in a factorial arrangement of prepartum (fall, 130 ± 12 d of gestation to calving; high vs. low, PREH vs. PREL) and postpartum (spring-summer, birth to weaning; high vs. low, POSTH vs. POSTL) herbage allowance (4 vs. 2.5 kgDM/kgBW of annual mean). Males were castrated at birth. Calf BW was determined at birth and monthly thereafter until the first year of age (390 ± 12 d). Body composition was determined at 200 (weaning) and 390 d using the urea dilution technique. Means from a mixed model repeated analysis were considered to differ when $P \leq 0.05$. Calf birth weight was not affected by PRE and was greater in male than female calves (33.7 vs. 32.5 ± 0.2 kg). Calf BW at 200 and 390 d or pre and postweaning average daily gains (ADG) were not affected by PRE but calf BW at 200 and 390 d was 30 ± 3 kg greater in POSTH than POSTL calves due to a greater preweaning ADG (+152 ± 0.02 g/d). Carcass fat increased (10.7 vs. 14.2 ± 1.2%) while water (62.4 vs. 60.1 ± 0.7%) and protein (19.1 vs. 18.3 ± 0.3%) decreased from 200 to 390 d. Body composition was affected by the interaction between PRE and POST as carcass fat was greater while water and protein percentages were less in PREL-POSTH than PREL-POSTL calves, being intermediate in PREH-POSTL and PREH-POSTH calves (10.3, 15.2, 12.2 and 12.6 ± 1.2% for fat, 62.7, 59.6, 61.6 and 61.0 ± 0.7% for water and 19.2, 18.2, 18.8 and 18.8 ± 0.3% for protein for PREL-POSTL, PREL-POSTH, POSTH-PREL, and POSTH-POSTH, respectively). Improve forage allowance during calf lactation period modified body composition of calves born from cows grazing low herbage allowance during gestation, as the increase in calf BW was associated with increased fat in detriment of protein deposition.

Key Words: beef cattle, rangeland, developmental programming

T363 Effects of a standardized blend of phytomolecules on performance of beef cattle in two distinct dietary contexts using multiple trial analysis method. Clementine Oguey[1] and Christian Bruneau*[2], [1]*Pancosma SA, Le Grand Saconnex, GE, Switzerland,* [2]*Pancosma, St Hyacinthe, QC, Canada.*

The optimization of performance of naturally fed beef cattle and the replacement of monensin (MON) are concerns constantly looked after by producers. Many phytomolecules have been reported to influence production efficiency of dairy and beef animals. Objective was to assess the effect of a standardized protected blend of cinnamaldehyde, eugenol and capsicum oleoresin (XT, XTRACT Ruminant, code X60–7065, Pancosma) on performance of beef cattle in 2 distinct commercial contexts: on top of a blank diet or as a substitute to MON, by 2 multiple trial analyses. A first set of data regrouped 10 trials organized in 7 studies (1290 growing cattle; mean initial BW of 276 kg; mean duration of 88 d, mean XT dose of 1.1 g/hd/d). All trials reported side by side comparisons of an unsupplemented control void of ionophore to the inclusion of XT in beef cattle. A second set of data regrouped 4 trials organized in 4 studies, all reporting side-by-side comparisons of the use of MON vs. XT (1004 growing cattle; mean initial BW of 215 kg; mean duration of 85 d, mean XT dose of 950 mg/hd/d; mean MON dose of 265 mg/hd/d). Outcomes selected were DMI, ADG and feed to gain ration (F:G). For each set of data, data were analyzed using a mixed model with the TRIAL variable as a random effect and the TRT variable as a fixed effect. Mean values were calculated using the LSMEANS procedure of XLstat, weighting the data for the variance among trials. Results showed that when added on top to a blank diet, XT did not affect DMI of beef cattle (mean: 7.18 kg/hd/d, $P = 1.0$), but increased ADG by 108 g/hd/d ($P < 0.05$) and reduced F:G by 7.5% ($P < 0.05$). The second analysis showed that XT numerically increased ADG and DMI compared with MON by respectively 2.4 and 4.7% ($P = 0.2$) without altering F:G (mean 4.82 g/g, $P = 0.7$). These findings are in line with available data on MON, and suggest that the addition of XT on top of a basal diet improves performance of beef cattle and can be safely used to replace MON.

Key Words: phytomolecule, beef cattle performance, multiple analysis

T364 Nutrient intake and productive performance of beef cattle fed diets containing soybean, corn, or sorghum silages. Lilian Oliveira Rosa*[1], Odilon Gomes Pereira[1], Karina Guimarães Ribeiro[1], Sebastião de Campos Valadares Filho[1], Stefanie Alvarenga Santos[2], Rilene Ferreira Diniz Valadares[2], and Andressa Fernanda Campos[3], [1]*Viçosa Federal University, Viçosa, Minas Gerais, Brazil,* [2]*Bahia Federal University, Salvador, Bahia, Brazil,* [3]*Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil.*

The aim of this work was to evaluate the nutrient intake and productive performance of Nellore cattle fed with diets containing soybean, corn, or sorghum silages as forage sources. The experimental diets was composed for: 1 - soybean silage (SS); 2 - corn silage (CS); 3 - sorghum silage (SOS); 4 - 50% SS:50% CS; and 5 - 50% SS:50% SOS, on dry matter basis. Diets consisted of 60% silage and 40% concentrate (corn, soybean meal, urea, and mineral mixture), formulated to be isonitrogenous (12% CP, DM basis). Forty-five crossbred Holstein-Zebu bulls none castrated, with initial live weight of 360 kg were allotted in a randomized blocks design with 5 treatments and 9 replicates. The animals were kept in individual pens of approximately 10 m^2, with protected feeders and waterier. The experiment lasted 99 d, divided in 15 d of initial adaptation plus 3 periods of 28 d each. All data were analyzed using MIXED procedure of SAS and differences between means were determined using the DIFF, which differentiates means based on Tukey's test. Significance was declared at $P < 0.05$. The dry matter (DM) intake was affected by the silages ($P < 0.01$), being SS silage that got lowest value among silages. The soybean silage (SS silage) provided lowest values of organic matter (OM), crude protein (CP), neutral detergent fiber (NDF) and non-fibrous carbohydrate (NFC) intakes, kg/d. The ether extract (EE) intake was highest in soybean silage, as only forage source or associated with CS or SOS. The maximum NDF intake, in % BW, was found to animals fed diets with sorghum silage as only forage source (0.88% BW) or associated with soybean silage (0.74% BW). The average daily gain (ADG) was lower in animals fed diets with soybean silage (0.433 kg/d) compared the others diets, that were not different statistically, with average to 1.163 kg/d. However, no effect of different silages ($P > 0.05$) was observed on dressing percentage, on average 54.5%. Our results suggest that soybean silage, as only forage source, results in lower animal performance. However, when this silage was associated with corn and sorghum silages, it has similar animal performance that of animals fed corn and sorghum silages as only forage sources.

Key Words: average daily gain, carcass dressing, forage source

T365 Nutrient intake, total digestibility, ruminal pH, and ammonia concentration of beef cattle fed diets containing soybean, corn, or sorghum silages. Lilian Oliveira Rosa*[1], Odilon Gomes Pereira[1], Karina Guimarães Ribeiro[1], Sebastião de Campos Valadares Filho[1], Stefanie Alvarenga Santos[2], Rilene Ferreira Diniz Valadares[2], and Andressa Fernanda Campos[3], [1]*Viçosa Federal University, Viçosa, Minas Gerais, Brazil,* [2]*Bahia Federal University, Salvador, Bahia, Brazil,* [3]*Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil.*

The aim of this work was to evaluate the nutrient intake, total digestibility and ruminal pH and ammonia concentration of beef cattle fed diets containing soybean, corn, or sorghum silages as forage sources. The experimental diets was composed for: 1 - soybean silage (SS); 2 - corn silage (CS); 3 - sorghum silage (SOS); 4 - 50% SS:50% CS; and 5 - 50% SS:50% SOS, on dry matter basis. Diets consisted of 60% silage and 40% concentrate (corn, soybean meal, urea, and mineral mixture), formulated to be isonitrogenous (12% CP, DM basis). Five adult crossbred Holstein-Zebu bulls, male no castrated, rumen-cannulated with an initial weight of 442 kg were distributed in a 5 × 5 Latin square design. The animals were kept in individual pens of approximately 10 m^2, with protected feeders and waterier. Effects of diets ($P < 0.01$) were observed on the intakes of all nutrients, with the lowest intakes ($P < 0.05$) of dry matter (DM), organic matter (OM), crude protein (CP), neutral detergent fiber (NDF) and neutral detergent fiber corrected to ash and protein (NDFap) being observed in the animals fed with soybean silage as only forage source. For TDN intake, the highest values were found for diets containing corn silage and it associated with soybean silage. For most nutrients, the highest digestibilities values were found with the diets containing corn silage as only forage source or when it was associated with soybean silage. There was effect to collection time ($P < 0.05$) for ruminal pH (T, hours), adjusting quadratic model ($Y = 6.0452 + 0.2648 \times T - 0.09955 \times T^2$, $r^2 = 83{,}4\%$), but no effects were observed to diets (D) and collection times and diets interaction (T × D) for the same parameter. However, no effects were detected to diets (D), collection time (T) and collection time and diets interaction (T × D) for ruminal ammonia concentration, with average of 6.25 mg/dL. Our results suggest that soybean silage, as only forage source, results in lower nutrients intake. However, animals fed with this silage had similar ruminal parameters compared the others diets.

Key Words: dry matter intake, forage source, ruminal parameter

T366 Enteric methane emissions in cattle fed diets containing sugar cane or corn silage. Lays Mariz[1,4], Stefanie Alvarenga Santos[2], Laura Franco Prados[1], Paloma de Melo Amaral*[1,4], Diego Zanetti[1], Gustavo Chamon de Castro Menezes[1], Sebastiao Valadares Filho[1], Antonio Faciola[4], and Luiz Gustavo Pereira[3], *[1]Federal University of Vicosa, Vicosa, MG, Brazil, [2]School of Veterinary Medicine and Animal Science of the Federal University of Bahia (UFBA), Salvador, BA, Brazil, [3]Embrapa Dairy Cattle, Juiz de Fora, MG, Brazil, [4]University of Nevada, Reno, NV.*

The objective of this study was to evaluate enteric methane emissions in cattle fed diets containing sugar cane or corn silage. Five rumen-cannulated steers (336 ± 16.6 kg of initial BW) were used in a 5 × 5 Latin square arrangement. The study lasted 105 d and consisted of 5 periods of 21-d each. Animals were housed and fed individually. The 5 experimental diets contained 60% forage and 40% concentrate. Treatments consisted of 5 different forage sources: corn silage (CS), fresh sugar cane (FSC), regular sugar cane silage (SCS0%), sugar cane silage treated with 0.4% calcium oxide (SCS0.4%), and sugar cane silage treated with 0.8% calcium oxide (SCS0.8%). Forage CP levels were adjusted to 11% using a mixture of urea/ammonium sulfate (9:1). Sulfur hexafluoride tracer gas technique was used to measure methane emissions. Feed intake and refusals were measured daily and methane emissions were measured for 5 consecutive days. Data were analyzed using the MIXED procedure in SAS. Data is presented in Table 1. Animals fed CS had higher DMI ($P < 0.01$) than animals fed sugar cane. Methane emissions when expressed in g/d or in g/kg of DMI did not change among treatments. However, when expressed in g/kg of digestible NDF (DNDF) was lower for CS diet ($P = 0.05$). Methane energy loss did not change among diets; however, it was numerically lower for the CS diet. Treated SCS did not improve intake and did not reduce methane emissions. The results from this study suggest that compared with sugar cane diets, corn silage diets may reduce methane emissions per unit of DNDF, which may lead to higher energy efficiency.

Table 1 (Abstr. T366). Mean values for intake and enteric methane emissions in steers

	Treatment						
Item	CS	FSC	SCS 0%	SCS 0.4%	SCS 0.8%	SEM	*P*-value

T367 Effects of oscillating dietary crude protein on nutrient intake, digestibility, performance, and carcass traits of finishing crossbred bulls in feedlot. Paloma de Melo Amaral*[1,3], Stefanie Alvarenga Santos[2], Laura Franco Prados[1], Lays Mariz[1,3], Lyvian Cardoso Alves[1], Ana Clara Baiao Menezes[1], Faider Alberto Castano Villadiego[1], Flavia Adriane de Sales Silva[1], Sebastiao Valadares Filho[1], and Antonio Faciola[3], *[1]Federal University of Vicosa, Vicosa, MG, Brazil, [2]School of Veterinary Medicine and Animal Science of the Federal University of Bahia (UFBA), Salvador, BA, Brazil, [3]University of Nevada, Reno, NV.*

Protein is a costly nutrient and excessive dietary N is an important environmental concern. The finishing period may offer the possibility of reducing dietary CP without negatively affecting beef-cattle production. This reduction may be achieved by oscillating dietary CP during the finishing period. Therefore, the goal of this study was to evaluate the effects of fixed or oscillating dietary CP on nutrient intake, digestibility, performance, and carcass traits of crossbred bulls in the finishing period. Twenty-four bulls (417 ± 54 kg of initial BW) were used in a complete randomized block design in a 2 × 2 factorial arrangement with 6 replications per treatment. The treatments were: Constant 11% CP (11–11), constant 13% CP (13–13), oscillating 11–13% CP (11–13), and oscillating 13–11% CP (13–11). The experiment lasted 72 d and oscillating treatments switched diets at d 37. Animals were housed and fed individually. Data were analyzed using the MIXED procedure in SAS and significance was declared at $\alpha = 0.05$. Partial data are presented in Table 1. There were no interactions ($P > 0.05$) between fixed and oscillating CP level. There were no effects ($P > 0.05$) of CP levels on intakes of DM, OM, NFC, and TDN. There were no effects ($P > 0.05$) of CP levels on ADG or in carcass traits. We concluded that there were no benefits of oscillating dietary CP levels for crossbred bulls with ADG of approximately 2 kg/d in feedlots. There were no performance or carcass traits benefits of feeding more than 11% CP in the diets of crossbred bulls in feedlots.

Table 1 (Abstr. T367). Effects of constant or oscillating CP levels on intake, performance, and carcass traits

	Dietary CP					*P*-value

T368 Identification and removal of outliers in feed databases for beef cattle.

Huyen Tran*[1], William Weiss[2], Galen Erickson[3], and Phillip S. Miller[3], *[1]National Animal Nutrition Program, University of Kentucky, Lexington, KY, [2]The Ohio State University, Wooster, OH, [3]University of Nebraska, Lincoln, NE.*

Accurate feed composition data are critical for diet formulation and determination of nutrient requirements of animals. Large feed databases are available; however, they often contain misidentified feed names and can have biased nutritive values. The first 2 objectives of this project were to identify and characterize outliers in feed databases and to develop feed composition tables for beef cattle. Approximately 1.5 million feed composition records provided by 3 commercial laboratories were sorted, screened, and reclassified. Histograms were used to visualize sample distribution. For most forages, feeds were classified as haylage or hay when DM <70 or ≥70, respectively. Grains were classified as high moisture (DM <80%) and dry grains (DM ≥80%). Any nutrient with a value outside mean ± 3.5 SD was removed (method A). Data were analyzed by laboratory before individual means and variance were weighted for sample size for calculation of the overall mean and SD. The third objective was to compare performance of method A to a combination of univariate and multivariate approaches for identifying outliers. Fifteen feeds were randomly selected representing grains, forages, byproducts, and oilseeds and screened for outliers. Feeds with missing key nutrients were removed. Principal component and clustering analyses of SAS were used in the multivariate approach. Among 1.5 million data classified as 352 feeds, 45.7% of the data seemed to be misidentified, leaving 196 feeds for analysis. Outliers were characterized as inaccurate DM classification, transformation of data, decimal point issues, erroneous data, or terminology inconsistency. Method A removed 1.4% of samples and decreased means by 0.9% and SD by 15.2% for CP. The multivariate analysis removed a larger percentage of samples (33.3%) and decreased means by 1.6% and SD by 38.8% for CP. Clustering analysis defined 8 of 15 feeds with >1 cluster. The multivariate method was powerful in decreasing the SD and clustering feeds. Removing outliers based on 3.5 SD (Method A) was simple to use; but this method was inefficient in clustering feeds classified by economic values or maturity. A National Research Support project supported by USDA-NIFA and the State Agricultural Experiment Stations.

T369 Effects of energy and nitrogen supplementation of cheatgrass on ruminal fermentation using a dual-flow continuous culture system.

Lorrayny Galoro da Silva*[1], Farnaz Malekjahani[1,4], Pedro Del Bianco Benedeti[1,2], Eduardo Marostegan de Paula[1], Teshome Shenkoru[1], Paloma de Melo Amaral1[,2], Lays Mariz[1,2], Hugo Monteiro[1,3], and Antonio Faciola[1], *[1]University of Nevada, Reno, NV, [2]Federal University of Viçosa, Viçosa, MG, Brazil, [3]Maringa State University, Maringa, PR, Brazil, [4]Ferdowsi University, Mashhad, Iran.*

Cheatgrass (CG; *Bromus tectorum*), an annual grass that is one of the main components of sagebrush community in Western US contributes to the fuel-load for wild fires. One fuel-reduction strategy is livestock grazing. The objective of this study was to determine the effects of molasses and urea supplementation on a CG-based diet on ruminal digestibility, rumen microbial fermentation and bacterial N synthesis. Diets were randomly assigned to 8 dual-flow continuous culture fermenters in a 2 × 2 factorial arrangement of treatments (urea and molasses) in a 4 × 4 Latin square design with four 10-d experimental periods consisted of 7 d for diet adaptation and 3 d for sample collection. Fermenters were fed 72 g/d of DM divided in 4 portions of 1 of 4 diets: CG, CG plus urea (CGU), CG plus molasses (CGM), and CG plus urea and molasses (CGUM). Liquid and solid flow rates were adjusted to 10 and 5%/h; respectively. A 500-mL sample was taken on d 8, 9, and 10 and analyzed for rumen traits, nutrient digestibility, and microbial growth. Data were analyzed in SAS. Partial data are presented in the table. The NH_3-N concentration was higher in the diets containing urea, indicating a higher N availability for microbial growth. Total VFA concentration was not increased by molasses; however, it was lower when urea alone was added. Acetate molar proportion decreased when molasses alone was added. However, propionate molar proportion was increased when molasses was added. Results from this experiment indicate that CG utilization is improved by a combination of N and energy supplementation, which may reduce CG fuel-load in areas where CG is widely spread.

Table 1 (Abstr. T369).

T370 Interactions between physical form of the feed and previous experience on concentrate spillage in Holstein calves.

Maria Devant*[1], Alex Bach[2,1], Josep Ribó[3], and Anna Solé[1], *[1]IRTA-Ruminant Production, Animal Nutrition, Management, and Welfare Research Group, Caldes Montbui, Spain, [2]ICREA, Barcelona, Spain, [3]Grup Alimentari Guissona, Guissona, Spain.*

Twenty-four Holstein bulls (137 ± 2.9 kg of BW and 117 ± 3.02 d old) were housed individually in pens (1.2 m × 1.45 m), and fed concentrate and straw in separate feeders. During the first 2 wk, half of the calves

were fed the same concentrate either in meal (MF) or pellet (PF) form. After these first 2 wk, half of the MF calves continued to be fed MF (MFMF) and half received pellet (MFPF), whereas half of the PF calves were MF (PFMF) and the other half pellet (PFPF) for 3 additional weeks. During the entire 5 wk concentrate and straw intake were recorded daily, attendance (number of visits and duration) at the feeder (concentrate and straw) were recorded through a sensor placed at the access door to the feeder, and concentrate spillage around the feeder was collected weekly. Data were analyzed using a mixed-effects model with repeated measures split in 2 analyses; the first model for the first 2 wk contrasted MF vs PF, and a second model for the last 3 wk analyzed the data as a 2 × 2 factorial design (MFMF, MFPF, PFMF, PFPF). During the first 2 wk of study, apparent mean concentrate (4.90 ± 0.128 kg/d) and straw (0.30 ± 0.30 kg/d) intakes were not affected by treatments, however concentrate spillage was doubled ($P < 0.05$) in MF (5.9 ± 0.70%) than in PF (2.8 ± 0.70%) calves. Number of daily visits did not differ between treatments (14.3 and 15.4 ± 0.48, for MF and PF, respectively), but time devoted to each visit tended ($P = 0.10$) to be lesser in PF (9.2 ± 0.83 min) than in MF (11.1 ± 0.83 min). In the last 3 wk of study, previous experience did not affect apparent concentrate or straw intake. Previous experience had a positive impact on feed spillage when previous presentation form was PF; thus, concentrate spillage was similar between PFMF (2.5 ± 0.87%) and PFPF (2.6 ± 0.87%). In contrast, previous experience did not affect concentrate spillage when calves were initially exposed to MF, and MFMF calves spilled more concentrate (6.8 ± 0.87%) than MFPF calves (2.3 ± 0.87%). In conclusion, feeding calves a pellet upon arrival to a grower facility could have long-lasting positive effects due to a reduction on concentrate spillage.

Key Words: beef, feed spillage, feed presentation form

T371 Effect of zinc amino acid complex on growth performance and carcass characteristics of finishing beef steers fed ractopamine hydrochloride.

C. K. Larson and M. E. Branine*, *Zinpro Corporation, Eden Prairie, MN.*

Ractopamine hydrochloride (RAC) is fed to cattle before slaughter to improve growth performance and carcass lean meat yield. Zinc (Zn) is required for RAC function; however, Zn level and source required to optimize RAC response is unknown. The objective of this research was to evaluate the response of Zn provided as an amino acid complex (Zn-AAC) on growth, feed efficiency, and carcass merit in growing-finishing beef steers. Two well-controlled studies were conducted at commercial feedlot research facilities in TX and OK. At the TX and OK sites, 3,849 (initial BW = 344 ± 2.3 kg) and 2,105 (initial BW = 311 ± 3.5 kg) steers, respectively, were randomized across 8 pens/treatment. Common treatments at each site were: (1) Control (CON) = basal diet with no Zn-AAC or no RAC;(2) RAC = 320 mg RAC$\cdot$hd$^{-1}\cdot$d^{-1} (TX) and 200 mg RAC$\cdot$hd$^{-1}\cdot$d^{-1} (OK);(3) Zn-AAC + RAC = RAC plus 360 mg Zn-AAC$\cdot$hd$^{-1}\cdot$d^{-1}. At both sites, RAC was fed for the final 28-d before slaughter. Basal diets provided steam-flaked corn as the primary grain source. Total dietary Zn concentration in CON diets was 62 and 76 mg Zn$\cdot$kg^{-1}DM for OK and TX, respectively. Individual and combined study analyses were conducted using SAS on growth performance and carcass data. Pen was the experimental unit. Combined study analyses indicated RAC increased carcass-adjusted final BW ($P \leq 0.02$), ADG ($P \leq 0.01$, feed efficiency ($P \leq 0.01$), HCW ($P \leq 0.03$) and ribeye area ($P \leq 0.01$) compared with CON. Adding Zn-AAC to RAC produced additional improvements in carcass-adjusted final BW ($P \leq 0.09$); ADG ($P \leq 0.01$ and HCW ($P \leq 0.11$). Marbling score, back fat thickness and calculated yield grade were not affected by treatment. Incidence and severity of liver abscesses were reduced ($P \leq 0.02$) with Zn-AAC + RAC compared with CON and RAC. Feeding Zn-AAC to cattle fed RAC produced additional improvements in growth and carcass yield and reduced prevalence of total and severe (A^+) liver abscesses.

Key Words: feedlot, ractopamine, zinc

T372 Sources of nonfiber carbohydrate in sugarcane silage based diets.

Viviane B. Ferrari*, Nara R. B. Consolo, Rafael T. Sousa, Frederich D. Rodriguez, and Luís Felipe P. Silva, *University of São Paulo, São Paulo, Brazil.*

The aim of this study was to evaluate sources of nonfiber carbohydrates (NFC) and levels of concentrate, in sugarcane silage based diets, on intake, ADG, final body weight (FBW) and G:F ratio. The trial was repeated in 2 years: 2012 and 2013, to increase the power of the experiment. In each year, 54 Nellore young bulls, with initial body weight of 365 kg, were randomly distributed in 18 pens, with 3 animals per pen. The experimental design was a randomized block design, with 6 replicates, in a 2 × 3 factorial arrangement of treatments. Treatments were 2 levels of concentrate (diets 60% or 80% concentrate on DM basis) and 3 sources of NFC: steam-flaked corn (SFC), pelleted citrus pulp (PCP), or ground corn (GC). Steam-flaked corn and PCP replaced 70% of the ground corn in the diet, and all diets had sugarcane silage as the roughage source. Animals were weighted at the beginning of the experiment and at the end of each period (4 periods of 21 d). Intake was regulated for pen by daily weighting of diet and orts, allowing for 5 to 10% of orts. Samples of feedstuffs and orts were weekly collected for chemical analyses and determination of nutrients intake. There was a NFC x Diet interaction on DMI ($P = 0.01$), as substituting GC for SFC and PCP decreased DMI, but only at the 60% concentrate diet ($P < 0.01$). There was also a NFC × Diet interaction for NDFI ($P = 0.02$). At the 60% concentrate diet, SFC decreased NDFI when compared with GC and PCP ($P < 0.05$). At the 80% concentrate diet, NDFI was higher for PCP than for GC and SFC ($P < 0.01$). Substituting PCP for GC decreased FBW ($P < 0.01$), with no difference between GC and SFC ($P = 0.26$). Similarly, PCP decreased ADG compared with GC (1.27 vs. 1.40; $P = 0.04$), independently of diet. Increasing the concentrate level in the diet improved G:F ratio (0.149 vs. 0.137; $P < 0.01$), but there was no effect of NFC sources on G:F ratio ($P = 0.74$), nor there was a NFC × Diet interaction ($P = 0.21$). Pelleted citrus pulp as main carbohydrate source decreased performance of young bulls compared with ground and steam-flaked corn.

Key Words: average daily gain, steam-flaking, feed intake

T373 Effects of starch content on in vitro ruminal fermentation of ground and dry-rolled barley grain.

Uchenna Y. Anele[1], Basim Refat[1,4], Mary-Lou Swift[2], Yanli Zhao[1,3], Tim McAllister[1], and Wenzhu Yang*[1], [1]*Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada,* [2]*Alberta Agriculture & Rural Development, Lethbridge, AB, Canada,* [3]*Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China,* [4]*Zagazig University, Zagazig, Egypt.*

Rapid digestion of barley starch in the rumen is hypothesized that starch content of barley grain can influence both rates of gas production (GP) and dry matter disappearance (DMD). Rumen fermentation of ground and dry-rolled barley grain differing in starch content was evaluated using a batch culture technique. The study was arranged in a 2 starch contents (low vs. high) × 2 processing (ground vs. dry-rolled) factorial design. Barley samples were collected monthly from 10 different feedlots in southern Alberta during one year. Samples were ranked according to the starch content into low (<60%) and high (>60% of DM). Ten barley samples with 5 low (57.1 ± 1.7%) and 5 high (66.0 ± 0.7% of DM) starch were either ground 2 mm or dry-rolled with processing index (PI) of 75%. Gas production and DMD were estimated at 3, 6, 12 and 24 h of incubation using rumen fluid from 3 fistulated beef heifers fed diet containing 70% barley silage and 30% barley grain (DM basis). Cumulative GP (mL/g DM) was fitted to a model $GP = B(1-e^{-c(t-lag)})$. Starch content × processing interaction was not significant for in vitro GP kinetics. Rate of GP (%/h) was greater ($P < 0.01$) in both high starch (18.3) and ground (20.6) versus, respectively, low starch (16.1) and rolled (13.9) barley samples. Similarly, both high starch (40.0) and ground (44.9) samples had greater ($P < 0.01$) absolute initial GP during the first hour of incubation compared with, respectively, low starch (34.6) and rolled (29.7) barley. Data from DMD at different times of incubation were fitted to a model $DMD = a + b(1-e^{-c(t-L)})$. Starch content × processing interactions were noted for the b fraction ($P < 0.03$) and rate of DMD ($P < 0.01$). Consistently, both high starch and ground barley had greater ($P < 0.05$) a, b and c of DM versus low starch and dry-rolled barley. However, the a, b, and c of starch did not differ between low and high starch barley. Ground barley had greater ($P < 0.01$) c (ground vs. rolled; 8.9 vs 6.1%) compared with rolled barley. The results indicated that starch content of barley had significant effect on in vitro rate of GP and the rate of DMD; processing (ground vs. dry-rolled) increased the extent and rate of DMD and starch.

Key Words: barley starch content, in vitro fermentation, grain processing

T374 Effect of sainfoin hay and pomegranate peel extracts on in vitro fermentation and protein degradation using the Rusitec technique.

Basim Refat[1,2], Uchenna Y. Anele[1], Zhixiong He*[1,3], S. M. Bassiony[2], G. A. Abdel-Rahman[2], and Wenzhu Yang[1], *[1]Agriculture and Agri-Food Canada, Research Centre, Lethbridge, AB, Canada, [2]Faculty of Agriculture, University of Zagazig, Zagazig, Egypt, [3]Institute of Subtropical Agriculture, The Chinese Academy of Science, Changsha, Hunan, China.*

Pomegranate peel extracts (PPE) have been found to exert beneficial effects on animal health due to their antioxidant, antibacterial and immunological effects. Sainfoin hay that contains moderate to high content of condensed tannins, was reported the reduced rumen proteolysis and decreased urine N excretion in beef cattle. The objective of this study was to determine the effect of sainfoin hay extract (SHE) and PPE supplementation on in vitro rumen fermentation and protein metabolism of high-protein finishing diet using rumen simulation technique (Rusitec). The experiment was a completely randomized design with 3 treatments: Control (10% barley silage, 60% barley grain and 30% wheat distillers grain), and control supplemented with SHE (4.1 g catechin equivalent/kg DM) or with PPE (2.8 g tannic acid equivalents/kg DM). The experiment consisted of 10 d of adaptation and 7 d of data collection. Concentration of volatile fatty acid (VFA) was lower (44.1 or 41.6 vs. 48.2 mM; $P < 0.02$) but molar proportion of acetate was higher (37.2 or 37.4 vs. 34.9%; $P < 0.01$) with SHE or PPE vs. control. Branched-chain VFA decreased ($P < 0.01$) with PPE (0.9%) compared with control. Concentrations (mg/100 mL) of large (10.1) and small peptides (6.1) were not affected but that of NH_3-N was lower ($P < 0.01$) with PPE (6.3) vs. control (8.1). Digestibility of DM, starch and crude protein decreased ($P < 0.02$) with SHE (58.7, 74.7 and 43.0%, respectively) and PPE (55.5, 68.9 and 43.4%, respectively) supplementation compared with control (63.3, 83.2 and 51.0%, respectively). Bacterial N production (averaged 52 mg/d) and bacterial efficiency (averaged 10.3 g bacterial N/kg digested OM) were not affected by SHE or PPE supplementation. Overall, there were no differences in VFA concentrations, N fractions and nutrient digestibility between SHE and PPE except for the concentrations of branched-chain VFA and NH_3-N which were higher ($P < 0.01$) with SHE versus PPE supplementation. These results indicated that supplementation of high-grain diet with SHE or PPE increased rumen by-pass protein; however, suppression of feed fermentation may decrease the feeding value of high-grain diet.

Key Words: tannins extracts, fermentation, Rusitec

T375 Effects of starch content and processing method on in situ rumen digestibility of barley grain in beef heifers.

Yanli Zhao[1,2], Sumei Yan[2], Uchenna Y. Anele[1], Mary-Lou Swift[3], Tim A. McAllister[1], and Wenzhu Yang*[1], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]College of Animal Science, Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China, [3]Alberta Agriculture and Rural Development, Lethbridge, AB, Canada.*

The inherent variability in barley chemical composition leads to differences in animal performance. The objective of this study was to investigate the effects of starch content of barley grain and processing method on in situ rumen digestion of DM and starch. Barley samples (n = 120) were collected monthly from 10 feedlots in Southern Alberta for one year. Samples were ranked according to their starch content into low (<60%) and high (>60% of DM). Ten barley samples with 5 low (57.1 ± 1.7%) and 5 high (66.0 ± 0.7% of DM) starch were either ground 2 mm or dry-rolled with processing index (PI) of 75% (PI = 100 × bulk density processed/bulk density whole). Three beef heifers (650 BW) fitted with rumen cannulas and fed diet consisting of 70% barley silage and 30% barley grain were used for in situ incubation. The study was arranged in a 2 (low and high starch) × 2 (ground and rolled) factorial design. Digestion kinetics of DM after 0, 3, 6, 12, 24, and 48 h of incubation was estimated using the model: $y = a + b(1\text{-}e^{-ct})$. Effective rumen digestibility (ED) was estimated using $ED = a + bc/(c + k)$ with k = 6%/h. Particle size distribution of rolled barley differed between low and high starch barley; the particles retained on the 3.35-mm sieve was less (17.8 vs. 25.3%; $P < 0.01$) but the particles on 2.36-mm sieve was greater (40.5 vs. 32.1%; $P < 0.01$) for low vs. high starch barley. Starch content × processing interactions were not noted. Low starch barley had less ($P < 0.01$) a (12.2 vs. 14.8%) and ED of DM (60.4 vs. 64.8%) versus high starch barley. The low starch barley also had less ($P < 0.01$) a (14.2 vs. 23.1%) and ED of starch (68.4 vs. 74.6%) but had greater ($P < 0.03$) b (75.5 vs. 70.5%) compared with high starch barley. As expected, rumen digestion kinetics of DM and starch differed between ground and dry rolled (PI = 75%) samples. Ground samples had greater ($P < 0.01$) a (21.6 vs. 5.4%), c (33.1 vs. 10.1%/h) and ED (71.6 vs. 53.6%) of DM but smaller b (59.8 vs. 77.8%; $P < 0.01$) compared with rolled barley. These results indicated that starch content of barley grain and manipulating processing method could effectively alter rumen digestion of barley grain.

Key Words: barley starch content, in situ rumen digestion, beef heifer

T376 Effect of physical form of concentrate on performance, eating pattern, and behavior in Holstein bulls fed finishing high-concentrate diets.

Marçal Verdú*[1], Alex Bach[2,1], and Maria Devant[1], *[1]IRTA-Ruminant Production, Animal Nutrition, Management, and Welfare Research Group, Caldes Montbui, Spain, [2]ICREA, Barcelona, Spain.*

Pelleting concentrate is one of the predominant grain processing methods in Mediterranean beef feeding systems. A good pellet quality is related to improvements in performance and feed efficiency, but it involves an extra cost at manufacturing. One hundred twelve bulls (272 ± 4.4 kg of BW and 216 ± 1.0 d of age) were randomly allocated in 6 pens provided with a concentrate single feeder with lateral protections, a straw feeder, and a water bowl. Pens were assigned to 1 of 2 dietary treatments according to the physical form of concentrate: pellet (PF), and crumble (CF) to simulate a worse pellet quality. The experimental design was 3 Latin Squares with periods of 28 d replicated twice. Concentrate intake and eating pattern were recorded daily, and concentrate wastage and animal BW every 14 d. Behavior was registered on d 20 of each period by scan sampling to analyze the general activity and social behavior. Data were analyzed using a mixed-effects model. The PF bulls consumed more concentrate ($P < 0.01$), but had lesser ($P < 0.01$) waste and day-to-day CV of concentrate intake compared with CF (7.0 and 6.7 ± 0.08 kg of DM/d, 0.06 and 0.11 ± 0.004 kg of DM/d, 16.7 and 21.3 ± 0.99%, respectively). However, ADG ($P = 0.11$) and feed efficiency were not affected by physical form. The eating pattern of PF bulls was characterized ($P < 0.01$) by a lesser meal size and meal duration, but a greater meal frequency and eating rate than CF bulls (630.9 and 668.4 ± 17.32 g/meal, 3.6 and 4.2 ± 0.18 min/meal, 11.8 and 10.9 ± 0.32 meals/d, 193.0 and 174.4 ± 11.79 g/min, respectively). Social behavior was not influenced by physical form. In conclusion, the decrease of pellet quality modified eating behavior increasing meal duration and decreasing concentrate intake, may be bulls fed crumbles were sorting avoiding fines. A long-term study is necessary, as it could be hypothesized that the effects of decreased pellet quality on decreased concentrate intake could impair performance.

Key Words: bull, eating pattern, physical form of concentrate

T377 Carcass and sensory traits and free amino acid contents among quality grades in loin and rump of Korean cattle steer.

MinYu Piao, Cheorun Jo, Hyun Joo Kim, Hyun Jung Lee, Hyun Jin Kim, and Myunggi Baik*, *Department of Agricultural Biotechnology, College of Agriculture and Life Science, Seoul National University, Seoul, Republic of Korea.*

This study was performed to compare carcass traits, sensory characteristics, physiochemical composition, and contents of nucleotides, collagen, and free amino acids among quality grades (QG) and to understand the association between QG and above parameters in loin and rump of Korean cattle steer. Loin and rump samples were obtained from 48 Korean cattle steers with each of 4 quality grades (QG 1++, 1+, 1, and 2; average 32 mo of age). Carcass weight and marbling score (MS) were highest in QG 1++, whereas texture score measured by a meat grader was highest in QG 2. A correlation analysis revealed that MS ($r = 0.98$; $P < 0.01$) and fat content ($r = 0.73$; $P < 0.01$) had strong positive correlations with QG and that texture had a strong negative correlation ($r = -0.78$) with QG. Fat content in loin was highest but protein and moisture contents were lowest in QG 1++. Our results confirmed that a major determinant of QG is the MS; thus, intramuscular fat (IMF) content. The CIE L*, a*, and b* values in loin were highest in QG 1++. Numeric values of shear force in loin were lowest in QG 1++, whereas those of tenderness, juiciness, and overall acceptability tended to be highest in QG 1++ without statistical significance. QG was strongly correlated with juiciness ($r = 0.81$; $P < 0.01$) and overall acceptability ($r = 0.87$; $P < 0.001$). All sensory characteristics were higher ($P < 0.05$) in loin than those in rump. Adenosine-5′-monophosphate (AMP) and inosine-5′-monophosphate (IMP) contents in both loin and rump did not differ among QGs. No nucleotide (AMP, IMP, inosine, hypoxanthine) was correlated with any of the sensory traits. Total, soluble, and insoluble collagen contents in loin were higher in QG 1++ than those in QG 1. All 3 collagens had lower content in loin than that in rump. All 3 collagens were positively correlated with tenderness, juiciness, and overall acceptability. Glutamic acid content did not significantly differ among the 4 QGs in either loin or rump. In conclusion, it is confirmed that QG is associated with sensory traits but nucleotide contents in beef may not be a major factor determining meat palatability in the present study.

T378 Plasma creatinine concentration of beef heifers fed with different lipid sources and frequency supplementation.

Marcia Cristina A. Santana*[1], Ricardo A. Reis[2], Gabriel M. P. Melo[2], Viviane C. Modesto[3], Telma T. Berchielli[2], Jucilene Cavali[4], and Juliana F. H. Rodrigues[4], *[1]EMATER, Goiania, Goias, Brazil, [2]Unesp, Jaboticabal, Sao Paulo, Brazil, [3]Unesp, Ilha Solteira, Sao Paulo, Brazil, [4]UNIR, Presidente Médici,Rondônia, Brazil.*

This research aims to evaluate urea plasma responses under different lipid sources and supplementation frequencies. The experiment was conducted throughout a 4-mo period during the dry season. The experiment was completely random, using a 3 × 2 factorial arrangement (3 supplements and 2 supplementation frequencies). The supplements were derived from 3 different sources, soybean grains, soybean oil and protected fat (Megalac-E), the 2 supplement frequencies were (D) daily or 3 d of week (Monday, Wednesday and Friday) called "alternate" (A). In the 4-mo experimental period, August–November, blood samples were taken from the jugular vein 4 h after the morning feeding. In all treatments, no creatinine levels differences were observed during August, October and November ($P > 0.05$). However, on September were observed lower values of creatinine for Megalac-E daily and soybean oil alternately supplied. Therefore, the highest creatinine plama levels observed for all treatments were on September and the lower showed on November. Overall, these data indicated that the creatinine plama level can be influenced according to the feeding strategy during the dry season.

Table 1. Plasma creatinine concentration of heifers supplemented with different lipid sources at two different frequencies (mg/dL) [1]

	D-SG	A-SG	D-SO	A-SO	D-ML	A-ML
August	$1.2^{A,b}$	$1.2^{A,b}$	$1.0^{A,b}$	$1.1^{A,bc}$	$1.2^{A,b}$	$1.3^{A,b}$
September	$2.8^{A,a}$	$2.8^{A,a}$	$2.6^{A,a}$	$2.2^{B,a}$	$2.4^{AB,a}$	$2.6^{A,a}$
October	$1.1^{A,b}$	$1.4^{A,b}$	$1.2^{A,b}$	$1.4^{A,b}$	$1.1^{A,b}$	$1.3^{A,b}$

T379 Efficacy of supplying lasalocid sodium via a self-fed trace mineralized salt block supplement to growing beef calves grazing warm season grass.

Brandon Stewart*[1], Paul Beck[1], John Tucker[2], Tom Hess[2], and Don Hubbell[2], *[1]University of Arkansas SWREC, Hope, AR, [2]University of Arkansas LFRS, Batesville, AR.*

Two experiments were conducted at the University of Arkansas Southwest Research and Experiment Station (Hope, AR) and Livestock and Forestry Branch Station (Batesville, AR) in northern Arkansas. Growing beef calves (n = 96 steers at the Hope site and 48 steers and 48 heifers at the Batesville site, BW = 215 ± 14.5) grazed 0.8 ha warm-season grass based pastures (n = 24/site, predominantly bermudagrass) during a 56-d summer grazing study to determine the effects of supplementation of growing steers grazing warm-season perennial grass pastures with Lasalocid via self-limited block (Bovatec 2.2 Block, Zoetis Animal Health, Inc.) on growth performance. Pastures were stocked with 4 calves/pasture with 24 total pasture replicates/treatment. Because of drought conditions this study was initiated on June 12 and terminated on August 8 at the Batesville site and was initiated on June 27 and terminated on August 22 at the Hope site. At the Hope site, lack of grazable forage made it necessary to offer grass hay (10% CP and 55% TDN) and soybean hulls at 2 lb/head/d to all pastures for the duration of the study. Beginning and ending weights were collected full on 2 consecutive days, and interim weights were collected full on 28-d intervals. Calves in each pasture were offered free-choice access to either a non-medicated control trace mineralized salt block (Control) or Bovatec 2.2 block (Bovatec). Daily block intakes at the Hope site averaged 12 ± 8.1 g/calf with an average Bovatec dose of 59 ± 39 mg/head/day. At Batesville, daily intake of control averaged 28 ± 12 g/calf and intake of Bovatec averaged 20 ± 5.3 g /head/day (supplying 100 ± 25 mg Bovatec). There was no treatment × site interaction ($P = 0.44$) for performance in this study. At the end of the study there was no difference ($P \geq 0.16$) between Control and Bovatec treatments for BW (267 vs 269 ± 3.9 kg, respectively) or ADG (0.75 vs. 0.81 ± 0.0435 kg/d, respectively). The results of this study indicate that Bovatec offered in a self-fed trace mineralized salt block supplement did not supply a large enough dose of lasalocid to increase growth rate of beef calves grazing warm-season grass pastures.

Key Words: growing calves, lasalocid, bermudagrass pasture

Ruminant Nutrition: Dairy II

T380 Dietary grain source and oil supplement: Milk fat synthesis and milk fatty acid profile of Holstein cows. Shahryar Kargar*[1], Gholam Reza Ghorbani[2], Veerle Fievez[3], and David J. Schingoethe[4], *[1]Shiraz University, Shiraz, Iran, [2]Isfahan University of Technology, Isfahan, Iran, [3]Ghent University, Melle, Belgium, [4]South Dakota State University, Brookings.*

Effects of grain type and dietary oil supplement on milk fat depression, milk fatty acid (FA) profile, and lactational performance of dairy cows were evaluated using 8 multiparous Holstein cows in a duplicated 4 × 4 Latin square design with a 2 × 2 factorial arrangement of treatments. Experimental diets contained either ground barley or ground corn supplemented with either fish oil or soybean oil at 2% of dietary dry matter (DM). Experimental diets contained 28.5 and 31.2% of cereal grain in corn- and barley-based diets, respectively, as the sole source of grain. The forage component of the experimental diet was a mixture of corn silage (19.0% of DM) and alfalfa hay (21.0% of DM). Treatment periods were 25 d, with the final 7 d used for sample and data collection. Data were composited within period and subjected to MIXED MODEL procedure of SAS (SAS Institute, 2003) to account for effects of square, period within square, cow within square, treatments (grain type and oil supplement), and the interaction between grain type and oil supplement. Total FA intake was greater in corn-based diets and also in soybean oil supplemented diets ($P \leq 0.05$). Fish oil decreased intake of all 18-carbon FA but increased intakes of other FA including C16:0, C20:5, and C22:6 ($P \leq 0.05$). No significant differences existed in the DM intake and yield of milk or milk components between barley- and corn-based diets ($P > 0.05$). Fish oil negatively affected feed intake and yields of milk and milk components as compared with soybean oil ($P \leq 0.05$). Although milk fat yield was not affected ($P > 0.05$), the barley-based diets increased the concentration and yield of medium-chain FA but decreased the concentration of long-chain FA as compared with corn-based diets ($P \leq 0.05$). Corn-based diets increased concentration and yield of both *trans*-11 C18:1 and *cis*-9, *trans*-11 C18:2 which was a reflection of greater intake of *cis*-9, *cis*-12 C18:2 (25.1 g/d) as substrate for rumen biohydrogenation ($P \leq 0.05$). Severity of MFD was greater for fish oil- vs. soybean oil which evidenced by the increased concentration and yield of biohydrogenation intermediates associated with MFD (especially *trans*-10 C18:1) in milk fat ($P \leq 0.05$). However, fish oil increased concentration and yield of both *trans*-11 C18:1 and *cis*-9, *trans*-11 C18:2 as compared with soybean oil ($P \leq 0.05$). Results indicated that there was no interaction between the type of grain and oil supplement on induction of MFD and milk fat yield. Although milk fat yield was not affected, milk fat composition was differently modified in barley- vs. corn-based diets. Observed lower milk fat yield for fish oil supplemented diets was coincided with the increased concentration and yield of biohydrogenation intermediates associated with MFD in milk fat.

Key Words: grain and oil, milk fat depression, dairy cow

T381 Effect of biotin and pantothenic acid supplementation on performance and concentration of avidin-binding substances (ABS) in lactating dairy cows. Gonzalo Ferreira, Alston N. Brown*, and Christy Teets, *Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, VA.*

We hypothesized that pantothenic acid reduces the absorption of biotin in lactating dairy cows. Twenty-four Holstein cows (8 primiparous and 16 multiparous) were assigned to a 4 × 4 replicated Latin square design with 18-d periods. Cows were 109 ± 30 d in milk and weighed 591 ± 70 kg at the beginning of the experiment. Treatments consisted of a control diet (CON) containing 53% concentrate and 47% forage, CON supplemented with 20 mg/d biotin (BIO), CON supplemented with 475 mg/d pantothenic acid (PAN), and CON supplemented with 20 mg/d biotin + 475 mg/d pantothenic acid (BIOPAN). Data were analyzed with a Proc Mixed model that included the effects of square (fixed, 5 df), treatment (fixed, 3 df), treatment × square interaction (fixed, 15 df), period (random, 3 df), cow within square (random, 18 df), and the residual error (51 df). No differences among treatments were observed for dry matter intake ($P < 0.46$), milk yield ($P < 0.68$), fat concentration ($P < 0.85$) and yield ($P < 0.88$), protein concentration ($P < 0.28$) and yield ($P < 0.07$), lactose concentration ($P < 0.90$) and yield ($P < 0.25$), and milk urea nitrogen ($P < 0.49$). Biotin supplementation increased the concentration of avidin-binding substances (ABS) in milk ($P < 0.03$). This increase was similar for BIOPAN ($P < 0.01$). Relative to CON, pantothenic acid did not reduce the concentration of ABS in milk ($P < 0.99$). In conclusion, under the conditions of this experiment, pantothenic acid did not affect the absorption of biotin in lactating dairy cows.

T382 Assessment of in vitro ruminal fermentation characteristics of lactation dairy diets supplemented with slow-release urea using continuous cultures. F. Mason[1], K. Neal[2], S. Y. Yang[2], J.-S. Eun*[2], and M. Spanghero[1], *[1]Department of Agricultural and Environmental Science, University of Udine, Udine, Italy, [2]Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, UT.*

The present study investigated the effects of supplementing slow-release urea (SRU; Optigen, Alltech, Nicholasville, KY) in 3 lactation dairy diets with different forage-to-concentrate ratios (F:C) on in vitro ruminal fermentation characteristics. The experiment was performed in a 3 (F:C) × 2 (without vs. with SRU supplementation) factorial design with 4 independent runs of continuous cultures (n = 4). The 3 F:C included high-forage (HF; 64:36), medium-forage (MF; 51:49), and low-forage diet (LF; 34:66) on a DM basis, and alfalfa hay and cone silage were forage sources at equal proportions. Supplementing SRU considerably reduced dietary concentrations of mixture of soybean meal and canola meal (50:50 on a DM basis) in the SRU supplemented diets. Continuous culture apparatus consisted of 700-mL working volume fermentation vessels to measure major fermentation end products. Each culture was offered a diet of 20 g DM/d in 2 equal portions at 0800 and 2000 h. Decreasing forage proportion reduced ruminal pH ($P < 0.01$), but supplementing SRU did not influence ruminal pH. Manipulating F:C did not affect total VFA concentration; however, under HF supplementing SRU increased total VFA concentration, while SRU supplementation in MF decreased total VFA concentration, leading to an interaction between F:C and SRU ($P = 0.02$). Decreasing forage proportion decreased acetate proportion, but increased propionate proportion, resulting in a tendency to decrease acetate-to-propionate ratio ($P = 0.09$). In contrast, SRU supplementation did not affect individual VFA proportions. Decreasing F:C decreased ammonia-N concentration, whereas supplementation of SRU tended to increase concentration of ammonia-N ($P = 0.08$). While methane production decreased with decreasing F:C ($P < 0.01$), supplementing SRU tended to increase methane production ($P = 0.07$) mainly due to its sizable increase in MF, leading to a tendency of F:C × SRU interaction ($P = 0.06$). Overall results in the current study indicate that supplementing SRU would be more beneficial in HF with enhanced ruminal fermentation evidenced by increased total VFA concentration.

Key Words: forage-to-concentrate ratio, ruminal fermentation, slow-release urea

T383 Ruminal fermentation characteristics of lactation dairy diets with different forage-to-concentrate ratios without or with lipid extract algae in continuous cultures.

S. Y. Yang*[1], K. Neal[1], J.-S. Eun[1], A. J. Young[1], and R. C. Sims[2], [1]*Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, UT,* [2]*Department of Biological Engineering, Utah State University, Logan, UT.*

The current in vitro experiment was performed to test the effects of supplementing lipid extract algae (LEA) in lactation dairy diets on ruminal fermentation in a 2 (level of forage in diets) × 2 (without vs. with LEA) factorial design with 4 independent runs of continuous cultures (n = 4). Diets with LEA completely replaced mixture of soybean meal and canola meal (50:50 in a DM basis). The data in this experiment were analyzed using the Proc Mixed procedure of SAS using a model that included fixed effects of level of forage, LEA supplementation, and their interaction and a random effect of fermentor within independent run. Feeding LEA decreased culture pH, regardless of level of forage, but the decrease of culture pH was greater under high-forage diet compared with low-forage diet, resulting in an interaction between level of forage and LEA. Under high-forage diet, total VFA concentration increased with feeding LEA, but it was not affected in low-forage diet, leading to a tendency ($P = 0.08$) of level of forage and LEA interaction. Adding LEA decreased ammonia-N concentration both in high- and low-forage diet. Overall results in this experiment indicate that feeding LEA in lactation dairy diets did not interfere with in vitro ruminal fermentation. The decreased ammonia-N concentration due to feeding LEA may have resulted from less degradation of N fraction in LEA compared with mixture of soybean meal and canola meal.

Contd.

T384 In vitro ruminal metabolism of a lactation dairy diet supplemented with virgin coconut oil and pine bark extract in continuous cultures.

S. Y. Yang*[1], R. W. S. Ningrat[2], K. Neal[1], B. R. Min[3], and J.-S. Eun[1], [1]*Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, UT,* [2]*Faculty of Animal Sciences, Andalas University, Padang, Indonesia,* [3]*Department of Agricultural and Environmental Sciences, Tuskegee University, Tuskegee, AL.*

The present study investigated effects of virgin coconut oil (VCO; 7.0% C8:0, 5.4% C10:0, 48.9% C12:0, and 20.2% C14:0) and pine bark extract (PBE; 75% condensed tannins), either separately or in combination as supplements to a lactation dairy diet on in vitro ruminal fermentation profiles. The experiment was performed in a completely randomized design with 4 independent runs of continuous cultures. Four dietary treatments included: 1) control (CONT; TMR without supplement), 2) TMR with 3% VCO (VCOT), 3) TMR with 3% PBE (PBET), and 4) TMR with 3% VCO and 3% PBE (VPT). Each culture of 700-mL working volume fermentation content was offered a diet of 20 g DM/d in 2 equal portions at 0800 and 2000 h. The data in this study were analyzed using the Proc Mixed procedure of SAS using a model that included fixed effect of dietary treatments (CONT, VCOT, PBET, and VPT) and a random effect of fermentor within independent run. Culture pH was maintained at least at 6.13 across dietary treatments, and supplementing VCO and/or PBE did not influence culture pH. Total VFA concentration was similar in response to the supplements. Supplementation of VCO decreased acetate proportion, but did not affect propionate proportion, resulting in a tendency to decrease acetate-to-propionate ratio ($P = 0.10$). In contrast, PBE supplementation increased acetate proportion, while it did not influence propionate proportion, leading to a tendency to increase acetate-to-propionate ratio ($P = 0.10$). Cultures offered VCOT and VPT increased butyrate proportion ($P = 0.01$). Supplementing PBE decreased ($P < 0.01$) ammonia-N concentration both in PBET and VPT, whereas VCO supplementation resulted in no effect on ammonia-N concentration. Cultures offered VCO and PBE supplementation, either separately or in combination, showed no response on methane production, although feeding VCOT numerically decreased methane production by 13.5% compared with CONT. The decrease in ammonia-N concentration when PBE-containing diets (PBET and VPT) were offered is likely attributed to condensed tannins in PBE; however, their concentration would not be enough to lessen ruminal methanogenesis. In addition, the concentration of VCO used in this study may have not been enough to manipulate ruminal fermentation.

Key Words: continuous culture, pine bark extract, virgin coconut oil

T385 Methane production from dairy cows fed regular or brown midrib corn silage.

Fadi Hassanat*[1], Rachel Gervais[2], and Chaouki Benchaar[1], [1]*Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada,* [2]*Département des Sciences Animales, Université Laval, Québec, QC, Canada.*

This study investigated the effects of feeding dairy cows regular (RCS) or brown midrib corn silage (BMCS) based diets on enteric CH_4 emissions. In a crossover design (35-d periods), 16 lactating multiparous Holstein cows (BW = 691 ± 77 kg; DIM = 119 ± 27; milk yield = 43.5 ± 6.4 kg/d) were fed (ad libitum; 5% orts on as-fed basis) a TMR (65:35 forage:concentrate ratio) containing 59% (dry matter basis) RCS or BMCS. Production of CH_4 was measured (3 consecutive days) using respiration chambers. Rumen fermentation characteristics were assessed over 2 consecutive days, and milk performance and nutrient apparent-total-tract digestibility were determined over 6 consecutive days. Effects of dietary corn silage cultivar were determined using the MIXED Procedure of SAS and significance was declared at $P \leq 0.05$. Compared with feeding RCS, feeding BMCS increased ($P \leq 0.01$) dry matter intake (+ 1.6 kg/d), milk yield (+ 3.2 kg/d) without affecting milk fat (3.87% ± 0.11) and milk protein (3.50% ± 0.05) contents. Dietary treatment did not affect ruminal pH, protozoa numbers, volatile fatty acid profile and apparent total-tract digestibility of organic matter, including its fiber fraction. Daily enteric methane emission averaged 476 g/d (±21) and was not affected by dietary treatment. Methane energy losses (proportional to gross energy intake) were 7% lower ($P = 0.05$) in cows fed BMCS (5.16%) compared with cows fed RCS (5.52%). Similarly, CH_4 emitted per kg of milk was lower ($P = 0.02$) in cows fed BMCS (12.7 g/kg) than in cows fed RCS (14.3 g/kg). It is concluded that replacing RCS with BMCS in dairy cow diets has the potential to lower CH_4 production per unit of energy consumed or unit of milk produced. Possible influence of feeding RCS or BMCS-based diets on gaseous emissions from manure needs to be evaluated.

Key Words: CH_4 production, dairy cow, brown midrib corn silage

T386 Determination of in vivo and in situ bioavailability of a rumen-protected lysine product, AjiPro-L.

Makoto Miura*[1], Atsushi Haruno[1], Hiroyuki Sato[1], Yuki Miyazawa[1], Eri Ikegami[1], Takeshi Fujieda[1], and Izuru Shinzato[2], [1]*Research Institute for Bioscience Products & Fine Chemicals, Ajinomoto Co. Inc., Kawasaki, Kanagawa, Japan,* [2]*Ajinomoto Heartland Inc., Chicago, IL.*

Past studies indicated that the 2nd generation AjiPro-L (A2G, Ajinomoto Co., Inc.) has higher bioavailability than the 1st generation product (A1G) based on in vivo plasma lysine technique (Whitehouse et al., 2014; Tucker et al., 2014). The objective of this study was to compare the other characteristics between A2G and A1G. Three ruminally fistulated lactating cows fed a diet composed of corn silage, grass silage and concentrates were used to determine in situ rumen stability. A1G and A2G were placed in Nylon bags (1 g per bag, 5 × 7 cm, pore size 53 ± 10 μm) and incubated in the rumen for 6, 12 and 24 h, respectively. After washing and drying bags, lysine (Lys) content in the residual products was analyzed. Three dry cows, fistulated both ruminally and duodenally and fed a corn silage based diet, were used to determine rumen-bypassed and fecal excreted Lys from each product. A1G or A2G was ruminally administrated along with the highly protected L-arginine (HP-Arg; Robinson et al., 2011) as a control marker. Duodenal digesta was collected every 2 or 3 h for 48 – 54 h and was homogenized to extract free Lys and Arg. Changes of Lys and Arg concentrations in digesta were plotted to calculate the area under the curve (AUC). The proportion of AUC of Lys to Arg was defined as the bypass rate of AjiPro-L. To determine the fecal excretion, feces from each cow were collected for 72 h after ingestion of AjiPro-L. Feces were homogenized with hot water to extract free Lys from the products. Amounts of Lys excreted in feces were calculated by analyzing free Lys concentration in the extract. Statistical differences were tested by an ANOVA. In situ ruminal protection of A2G was lower ($P < 0.01$) than A1G (97 vs. 99% at 6 h, 94 vs 97% at 12 h and 84 vs 90% at 24 h, respectively), but still reasonably high. The bypass rate of Lys from A2G (75 ± 11%) was not different ($P = 0.45$) from A1G (82 ± 14%), but fecal excreted Lys from A2G (33 ± 6%) was significantly less ($P < 0.01$) than A1G (51 ± 1%). Our results indicate that higher bioavailability of A2G than A1G was attributed to improved intestinal digestibility, supporting the results obtained by the in vivo plasma Lys response method.

Key Words: rumen-protected lysine, dairy cow, bioavailability

T387 Handling characteristics of AjiPro-L in the practical use.

Makoto Miura*[1], Yuki Miyazawa[1], Eri Ikegami[1], Mizuki Tanida[1], Takeshi Fujieda[1], and Izuru Shinzato[2], [1]*Research Institute for Bioscience Products & Fine Chemicals, Ajinomoto Co. Inc., Kawasaki, Kanagawa, Japan,* [2]*Ajinomoto Heartland Inc., Chicago, IL.*

When choosing a rumen-protected lysine product (RPL), not only the product efficacy but also handling stability in the practical use should be paid attention to. The 2nd generation AjiPro-L (A2G; Ajinomoto Co., Inc.) has been proven to possess higher bioavailability than the 1st generation product (A1G) based on in vivo plasma lysine technique (Whitehouse et al., 2014; Tucker et al., 2014). The objective of this study was to compare handling characteristics between A1G and A2G. A1G or A2G was mixed in a concentrate mix, and the mixing homogeneity was examined. The mix was loaded into a feed truck, transported for 160 km, unloaded into a feed bin, and was discharged. Samples were collected at the time of loading into the truck and discharging from the feed bin. The samples were sieved to separate the particles of A1G or A2G to calculate the inclusion rate. Results showed the inclusion rate of A2G remained unchanged between before and after transportation ($P > 0.05$) while that of A1G decreased after transportation (4.0 vs. 3.6%, $P < 0.05$), suggesting superior mixing homogeneity of A2G over A1G probably thanks to a smaller particle size of A2G (1 – 2 mm in diameter) than A1G (6 – 7 mm). Next, TMR mixing stability was evaluated with the same procedure as Ji et al. (2012). Dacron bags containing 1 g of RPL were mixed with TMR for 6 min in a Super Data Ranger. Then, bags were incubated in the rumen of 3 fistulated cows for 6, 12, and 24 h. After incubation, bags were washed and dried. Amounts of Lys in the residual product were analyzed for calculation of in situ protection. In situ protection of A2G mixed with TMR was slightly lower than A1G (97 vs. 99% at 6 h, 93 vs. 97% at 12 h and 85 vs. 91% at 24 h, respectively, $P < 0.01$). The protection of both RPLs was not affected by mechanical mixing ($P > 0.05$). Finally, storage stability of A2G was examined under −22 to 104°F by using the in vitro procedure (Miyazawa et al., 2014). In vitro ruminal protection or intestinal dissolution was not deteriorated at least for 6 mo under the ambient temperature tested.

Results demonstrate that A2G possesses sufficient handling stability for a use under practical conditions.

Key Words: rumen-protected lysine, handling, stability

T388 Effects of corn silage hybrids on metabolic parameters and lactational performance of transition dairy cows.

A. W. Kelley, K. Neal, J.-S. Eun*, and A. J. Young, *Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, UT.*

Developing solutions to lessen metabolic stress experienced by transition dairy cows is very critical to improve lactational performance. The objective of this study was to determine metabolic parameters [concentrations of nonesterified fatty acids (NEFA) and β-hydroxybutyric acid (BHBA) and lactational performance of dairy cows fed brown midrib corn silage (BMRCS)-based diets during the transition period when compared with conventional corn silage (CCS)-based diets. At 4 wk before parturition, 40 dry multiparous Holstein cows were randomly assigned treatments. The treatment groups consisted of 2 close-up transition diets (CCS-based and BMRCS-based diets) offered to 2 groups of 20 cows each. After calving, 10 cows from each prepartum group were individually fed either a CCS-based lactation diet or a BMRCS-based lactation diet. Four dietary treatments tested postpartum included: 1) CC = CCS-based close-up diet + CCS-based lactation diet; 2) CB = CCS-based close-up diet + BMRCS-based lactation diet; 3) BB = BMRCS-based close-up diet + BMRCS-based lactation diet; and 4) BC = BMRCS-based close-up diet + CCS-based lactation diet. Statistical analysis during the pre- and postpartum period parameters were performed by a split-plot-in-time design with repeated measures procedure using the Proc Mixed procedure of SAS with a model that included effects of treatment and week and their interaction and a random effect of cow within treatment. During the dry period, there was a tendency ($P = 0.09$) for a diet × test week interaction for DMI; initially, CCS-based diet had greater DMI, but as parturition neared, BMRCS-based diet increased DMI, resulting in greater DMI than CCS-based dirt at parturition. Postpartum concentrations of BHBA and NEFA were lower for BB and BC diets, with CC and CB diets having the greatest concentrations of both BHBA and NEFA ($P < 0.05$). In contrast, cows fed BB and BC diets increased milk yield compared with those fed CC and CB diets. There was a tendency for BB to have greater milk yield than CB on wk 1 (32.7 vs. 27.9 kg/d, $P = 0.09$) and greater milk yield on wk 4 (45.1 vs. 38.5 kg/d). Overall data in the present study indicate that cows fed BMRCS-based diet in the dry period but CCS-based diet in lactation had positive carry-over effects on metabolic parameters and lactational performance possibly due to a consistent pattern of feed intake during dry period.

Key Words: brown-midrib corn silage, dairy cow, transition period

T389 Effects of thermal processed clay in nonmedicated rations in Japanese dairy farms.

Fang Chi*[1], Fumiaki Atarashi[2], Kenji Wada[2], Hiroshi Endo[2], San Ching[1], and LeAnn Johnston[1], *[1]Amlan International, Chicago, IL, [2]Okitama Food Animal Clinic, Federation of Agricultural Mutual Aid Association, Yamagata Prefecture, Japan.*

Calibrin-Z (CZ), a thermally processed calcium montmorillonite, has been shown to enhance dairy productivity due to its barrier function in the digestive tract. Two classic dairy farms from different locations in Yamagata Prefecture, Japan, were used in this on-farm feeding trial. The objective was to investigate the effects of CZ feeding on lactating cow performance under a common dairy feeding regimen in Japan. Concentrate feed was purchased from local feed companies, corn and grass silage was produced on-farm, and CZ was added to the Total Mixed Ration (TMR) with 20 g/cow/d for 3 mo. The TMR was formulated to meet Japanese nutrients requirements standard, and collected for mycotoxin analyses. Milk yield and quality and fecal firmness were recorded daily. Blood was drawn before and 30 d after CZ was fed, and albumin, BUN, GGT, hematocrit, and white blood cell counts were determined. Disease incidence and general health were recorded. Analysis of variance was used to determine the effects of CZ. Mycotoxin concentrations, such as aflatoxin, DON, fumonisin, and zearalenone were detectable in the TMR, but were below Japanese regulations. Manure firmness was numerically increased on one farm, but no changes were found on the other farm over the 3 mo feeding period. There were no differences in general blood chemistry; however, CD4+ and CD14+ were higher ($P < 0.05$) after CZ was fed for 30 d. In addition, CD3+ and CD335+ were numerically higher ($P > 0.05$) when CZ was included in the ration. Interestingly, a 47% (Farm A) or 40% (Farm B) reduction of disease incidences was observed as compared with the same period of the prior year. Among them, mastitis decreased 60% on Farm A, and enteritis decreased 100% on Farm B. Milk production was increased ($P < 0.05$) on both farms (Farm A, 25.0 vs. 26.4 kg; Farm B, 27.0 vs. 28.4 kg/cow/d) after CZ was fed; while milk fat, protein, lactose, bacteria count, urea nitrogen, and somatic cell count remained unchanged. In conclusion, addition of Calibrin-Z to Japanese non-medicated rations may enhance general health in lactating cows; consequently, increased milk production and a reduction of disease occurrence were observed on the studied farms.

Key Words: dairy milk production, white blood cells, calcium montmorillonite

T390 Associations of behavior and production in lactating dairy cows.

Carleigh Johnston and Trevor J. DeVries*, *Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

Identification of the associations of cow behavior with productivity is important for supporting recommendation of strategies that optimize milk quality, efficiency, and yield. Thus, the objective of this study was to collate data from studies of the behavior of lactating dairy cows and identify associations between measures of behavior of dairy cattle and milk production and efficiency. A database containing behavior and production data for 132 dairy cow-week observations (mean of 7 d of consecutive data per cow) was assembled from 5 studies. Cows averaged (mean ± SD) 1.8 ± 0.9 lactations, 108.4 ± 42.7 DIM, and 654.6 ± 71.4 kg BW during each observation week. Production data included: DMI (27.0 ± 3.1 kg/d), milk yield (43.0 ± 7.0 kg/d), milk fat content (3.60 ± 0.49%), milk fat yield (1.53 ± 0.30 kg/d), milk protein content (3.05 ± 0.25%), milk protein yield (1.29 ± 0.17 kg/d), and production efficiency (1.60 ± 0.22 kg milk/kg DMI). Behavioral data included: feeding time (230.4 ± 35.5 min/d), feeding rate (0.13 ± 0.03 kg/min), meal frequency (9.0 ± 2.0 meals/d), meal size (3.2 ± 0.9 kg/meal), daily mealtime (279.6 ± 51.7 min/d), rumination time (516.0 ± 90.7 min/d), and lying time (621.5 ± 142.8 min/d). Data were analyzed in multivariable mixed-effect regression models to identify which behavioral variables, when accounting for other cow-level factors (DIM, parity, BW), were associated with measures of production. DMI was associated with feeding time (+0.02 kg/min; $P = 0.002$) and tended to be associated with rumination time (+0.003 kg/min; $P = 0.1$) and meal frequency (+0.2 kg/meal; $P = 0.06$). Similarly, milk yield was associated with feeding time (+0.03 kg/min; $P = 0.005$) and rumination time (+0.02 kg/min; $P < 0.001$), and tended to be associated with meal frequency (+0.3 kg/meal; $P = 0.1$). Milk fat yield was associated with meal frequency

(+0.02%/meal; $P = 0.05$). Efficiency of production was associated with rumination time (+0.0006/min; $P < 0.001$) and tended to be associated with meal time per day (+0.0005/min; $P = 0.09$). Overall, our results indicate that nutrition, management, and housing factors that improve time spent feeding, in more frequent meals, and time spent ruminating may have a positive impact on milk yield and component production, as well as production efficiency.

Key Words: behavior, production, rumination

T391 Growth performance and sorting behavior of heifers offered diets with forage dilution. Wayne Coblentz*[1], Nancy Esser[2], Patrick Hoffman[3], and Matt Akins[3], *[1]US Dairy Forage Research Center, Marshfield, WI, [2]University of Wisconsin, Marshfield, WI, [3]University of Wisconsin, Madison, WI.*

Dairy heifers consuming high-quality forage diets are susceptible to excessive weight gains and over-conditioning, which often has been controlled by dilution with straw that is sortable by dairy heifers. Our objectives were: i) to compare the growth performance of dairy heifers offered a high-quality forage diet (CONTROL) with diets containing 1 of 3 diluting agents that included eastern gamagrass haylage (EGG), chopped wheat straw (STRAW), or chopped corn fodder (FODDER); and ii) evaluate sorting behaviors of heifers offered these forage diets. Holstein heifers (n = 128) were stratified (32 heifers/block) on the basis of initial BW (heavy, 560 ± 27.7 kg; medium-heavy, 481 ± 17.7 kg; medium-light, 441 ± 22.0 kg; and light, 399 ± 14.4 kg), and then assigned to 1 of 16 identical research pens (4 pens/block; 8 heifers/pen) in a randomized complete block design with the 4 research diets as treatments. Diets were offered in a 118-d feeding trial with heifers crowded to 133% of capacity at the feed bunk. Compared with CONTROL, inclusion of low-energy forages was effective in reducing DMI (11.06 vs. 10.04 kg/d; $P < 0.01$) and energy intake (7.39 vs. 5.95 kg TDN/d; $P < 0.01$). Concentrations of physically effective fiber (pef) particles did not change during the 24-h period following feeding for either the CONTROL ($P \geq 0.56$) or EGG ($P \geq 0.75$) diets; however, this response for pef particles masked the competing (and cancelling) responses for individual large and medium particles comprising pef, which heifers sorted with discrimination and preference, respectively. Sorting against pef particles was detected for STRAW as a linear ($P < 0.01$) function of time from feeding, and much more severely for the FODDER diet, which exhibited linear, quadratic and cubic effects ($P < 0.01$). Sorting of forage particles by heifers could not be related directly to heifer performance. Compared with CONTROL, ADG was reduced by dilution in all cases (1.16 vs. 0.91 kg/d; $P < 0.01$), but ADG for STRAW was approximately 0.2 kg/d less than EGG (0.98 kg/d) or FODDER (0.97 kg/d), despite exhibiting sorting characteristics intermediate between those diets.

Key Words: heifer, sorting, dilution

T392 Response of lactating cows to a blend of essential oils and pepper extract. Rayana B. Silva[1], Renata A. N. Pereira[3,2], Rafael C. Araújo[4], and Marcos N. Pereira*[1,2], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Better Nature Research Center, Ijaci, MG, Brazil, [3]Empresa de Pesquisa Agropecuária de Minas Gerais, Lavras, MG, Brazil, [4]GRASP Ind. e Com. LTDA, Curitiba, PR, Brazil.*

Secondary plant compounds can modify rumen fermentation, cutaneous blood flow, sweat secretion, diet digestibility, and feeding behavior of dairy cows. Twenty-eight, individually fed Holsteins (181 ± 102 DIM) received a standard diet for 2 wk and 2 dietary treatments for 8 wk, in a covariate adjusted randomized block design. Treatments were: Control (CTL) or a microencapsulated blend of essential oils and pepper extract (BEO. Carvacrol, cinamaldehyde, eugenol, and capsaicin. Activo Premium. 150 mg/kg DM). BEO decreased DMI (20.1 vs. 19.5 kg/d; $P = 0.05$) and increased milk yield (30.1 vs. 30.8 kg; $P = 0.04$), improving the milk to feed ratio (1.53 vs. 1.63; $P < 0.01$). Milk fat content tended to increase with BEO ($P = 0.10$), but protein, lactose, total solids, MUN, and SCC did not differ ($P > 0.21$). BCS and BW were similar ($P > 0.39$). BEO reduced ruminal acetate (57.8 vs. 51.4% of VFA; $P = 0.01$) and increased propionate (26.1 vs. 31.3% of VFA; $P = 0.02$), decreasing the A/P ratio (2.3 vs. 1.7; $P = 0.03$). Total-tract digestibility of DM, OM, and NDF were similar ($P > 0.20$), but there were trends for increased non-NDF OM digestibility ($P = 0.07$) and digestible OM intake ($P = 0.06$) on BEO. Cows on BEO ingested a greater proportion of the daily feed intake from 6AM to 12PM ($P = 0.02$) and tended to have longer duration of the first meal ($P = 0.08$), whereas CTL cows tended to ingest more from 7PM to 6AM ($P = 0.06$). BEO induced selective sorting in favor of small feed particles ($P < 0.01$) and refusal of large particles ($P < 0.03$) in the morning. Ingestion and rumination times were similar ($P > 0.19$). Viscosity of manure was reduced by BEO ($P = 0.04$). Treatments had no effect on PUN along the day, plasma glucose content, and the urinary secretion of allantoin ($P > 0.42$). BEO increased the concentration of O_2 in jugular blood ($P < 0.01$), but had no effect on pH, pCO_2, HCO_3^-, total CO_2, and base excess ($P > 0.46$). Sweating rate at d 14 was increased by BEO ($P = 0.05$). No difference was detected in rectal and skin temperatures and in respiratory frequency ($P > 0.21$). The supplementation of dairy cows with BEO affected feeding behavior, reduced the A/P ratio in rumen fluid, and improved feed efficiency.

Key Words: capsaicin, essential oil, feeding behavior

T393 Supplementation of herbage-based diets with corn meal or liquid molasses changes the milk fatty acids profile in grazing dairy cows. S. F. Reis[1], A. F. Brito*[1], P. Y. Chouinard[3], K. J. Soder[2], and S. Ross[1], *[1]University of New Hampshire, Durham, NH, [2]USDA-Agricultural Research Service, University Park, PA, [3]Université Laval, Québec City, Québec, Canada.*

Previous studies showed that feeding carbohydrate sources with different NSC profiles (e.g., starch vs. sucrose) and rates of ruminal degradation altered the milk fatty acids (FA) profile in dairy cows. This study evaluated the impact of corn meal (CM) or liquid molasses (MOL) on the milk FA profile of organically certified Jersey cows fed herbage-based diets. Ten multiparous (107 DIM) and 10 primiparous (131 DIM) lactating cows were blocked by parity, DIM, and milk yield and randomly assigned to 1 of 2 dietary treatments: CM or MOL. Diets were formulated to contain (DM basis): 74% herbage, 12% grass-legume mix hay, 12% CM or MOL, and 2% minerals and vitamins premix. The study lasted 110 d (June to September). Cows had access to pasture with mixed botanical composition (41.2% grass and 20% legume) for approximately 16 h daily in a strip grazing management system and were milked twice daily. Milk samples were collected monthly for 4 consecutive milkings, pooled by cow/period, and analyzed for milk FA using GLC. Herbage averaged (DM basis) 18.5% CP and 56.3% NDF, and 20% linoleic acid and 41.5% α-linolenic acid (% total FA). Milk FA was expressed as % total milk FA. Milk proportions of most saturated and unsaturated FA were affected by month, which are explained by variation in herbage botanical and FA composition, and milk yield. The milk proportion of total saturated FA was highest in cows fed MOL (71.8 vs. 71%). Milk proportions of α-linolenic acid (0.88 vs. 0.77%), *trans*-10,*cis*-12 CLA (0.090 vs. 0.078%), and PUFA (4.57 vs. 4.43%) were highest in cows fed MOL. Conversely, milk linoleic acid (1.12 vs. 1.72%), *trans*-10 18:1

(0.16 vs. 0.19%), *trans*-11 18:1 (2.62 vs. 2.76%), *cis*-9,*trans*-11 CLA (0.83 vs. 0.87%), and MUFA (22.8 vs. 23.7%) were lowest with MOL. The proportion of n-3 FA was highest (1.19 vs. 1.03%), whereas that of n-6 FA (1.30 vs. 1.35%) was lowest in cows fed MOL. Supplementing herbage-based diets with energy sources containing different NSC profiles resulted in marked changes in milk FA composition.

Key Words: milk fatty acids, molasses, herbage

T394 Health, milk, milk components, milk quality and reproduction evaluated in Holstein cows fed OmniGen-AF from dry-off through 120 days in milk. Amanda E. Holland*[1], Frank E. Rivera[1], James D. Chapman[1], and Lane O. Ely[2], [1]*Phibro Animal Health Corporation, Quincy, IL,* [2]*University of Georgia, Athens, GA.*

Three hundred sixty-one multiparous late lactation cows were selected using DC305 and randomly assigned to 1 or 2 diet additives before dry-off; basal diet + placebo (PL, n = 181) or basal diet + OmniGen-AF (OG, n = 180). Diet groups were balanced by parity, DIM, calving date, 305ME, milk and health history. Both additives were fed at 56g/h/d, added directly to the dry and lactation TMR's. Cows were fed the assigned diet additives from dry-off through 120 d in milk (DIM) and health, milk, milk quality and reproduction evaluated. Data were analyzed by PROC GLM with significance tested at $P < 0.05$ and only cows completing 120 DIM were included. Average parity and days dry for cows fed the PL and OG were 3.7, 59.3 d and 3.6, 58.3 d, respectively. Cows fed OG had fewer retained placenta (−6.6%, $P = 0.023$) and metritis (−5%, $P = 0.044$) cases than PL fed cows. Mastitis cases were similar, however cows fed OG tended to have fewer repeat cases ($P = 0.107$). No differences were detected in the other recorded health metrics. Individual milk and milk components were recorded and were used to calculate week-4 milk (W4), energy and fat corrected milks (ECM, FCM). No differences were detected between PL and OG fed cows for test-day (TD) milk 1–4 (44.6kg vs. 45.5kg), W4 (43.5kg vs. 44.7kg) or peak milk (49.9kg vs. 50.4kg). OG fed cows produced more ECM (+1.5kg, $P = 0.008$) and FCM (+1.7kg, $P = 0.007$) through TD 1–4 than PL cows. OG cows had higher % milk fat (MF) at TD 1 (+0.3) and kg MF at TD 1 (+0.13), 2 (+0.09) and 3 (+0.09) and 0.05 kg more milk protein (MP) at TD 2 than PL cows. Compared with PL, the OG cows made milk with more kg MF (1.5 vs. 1.6, $P = 0.002$), kg MP (1.3 vs. 1.5, $P = 0.053$) and % MF (3.45 vs. 3.56, $P = 0.032$). TD 1–4 SCC's were not different. All reproductive measures were not different, however OG cows tended to have fewer days to first breeding ($P = 0.12$) and greater days carried calf ($P = 0.088$) than PL cows. In conclusion, feeding OG to multiparous cows from dry-off through 120 DIM resulted in differences in peripartum disease incidence, milk and milk components.

Key Words: OmniGen-AF, health, components

T395 Supplementing lactating cow diets with long chain fats has minimal effects on total-tract NDF digestibility: A quantitative review. Kristina A. Weld* and Louis E. Armentano, *University of Wisconsin-Madison, Madison, WI.*

Supplementing fat to lactating cows may reduce total-tract NDF digestibility (ttNDFd). The objective was to analyze the effects of different types of fat across studies. The numerical difference between ttNDFd and dry matter intake (DMI) for the supplemented minus control diet were calculated within study and these differences were analyzed in SAS 9.4 using Proc Mixed (Table 1). Studies were weighted based on the inverse of the standard error of ttNDFd squared. The model contained the fixed effect of fat type and study as a random effect. Fatty acid content of treatment diets never exceeded 10% of DM (mean = 6.2, SD = 1.4). Supplementation of fats containing 12 and 14 carbon chain fatty acids (C12, C14) decreased both DMI and ttNDFd. Oil decreased ttNDFd by 2.1 percentage units, but the DMI decrease was not significant. No other type of fat consistently decreased ttNDFd, though calcium salts (n = 13 of palm oil, n = 6 of unsaturated C18) increased ttNDFd by 2.2 percentage units and decreased DMI by 1.45 kg/day. A regression analysis across all types of fat, using Proc Glm in SAS 9.4, of the difference in ttNDFd versus the difference in DMI within study shows a positive relationship. This suggests that the increase in ttNDFd for calcium salts is not explained through the decrease in DMI. Overall, these results indicate that the addition of a fat supplement, in which the fatty acids are C16 or greater in length, has minimal effects on ttNDFd. Feeding calcium salts in place of free oils would likely increase ttNDFd, but decrease DMI.

Table 1 (Abstr. T395). Effects of fat supplemented diets compared with control diets by fat type

Fat type	No. of studies	ΔttNDFd percentage units	SE	*P*-value	ΔDMI, kg/d	SE	*P*-value	ΔFA content of diet %DM	SE
C12/C14	6	−11.32	1.67	0.0001	−4.04	0.66	0.0001	3.8	0.72

T396 Sodium and potassium carbonates added to continuous cultures of ruminal microorganisms had similar effects on reducing biohydrogenation intermediates linked to milk fat depression. Kaylin Young[1], Elliot Block[2], Joseph Harrison[3], and Thomas Jenkins*[1], [1]*Clemson University, Clemson, SC,* [2]*Arm and Hammer Animal Nutrition, Princeton, NJ,* [3]*Washington State University, Puyallup, WA.*

In previous studies, the addition of potassium carbonate to continuous cultures of ruminal microorganisms decreased the production of *trans*-10 18:1 and *trans*-10,*cis*-12 conjugated linoleic acid (CLA), consistent with in vivo reports of higher milk fat percentages in lactating cows fed supplemental potassium carbonate. This experiment compared sodium carbonate to potassium carbonate to determine if they had similar effects on biohydrogenation intermediates. A single basal diet was fed (60 g/d) to 4 dual-flow continuous fermenters for four 10-d periods divided into 7 d for adaptation and 3 d for collection of samples. The diet consisted of alfalfa pellets and concentrate mix (47/53, DM basis), and contained 3.3% (DM basis) soybean oil. At each feeding (0800 and 1600 h), 16 mL were injected into each fermenter containing either only distilled water (CON), 1.4 g carbonate as K_2CO_3, 1.4 g carbonate as Na_2CO_3, or 1.4 g carbonate as a 50:50 mixture of K_2CO_3 and Na_2CO_3 (MIX). The experiment was analyzed as a randomized block design with differences among treatments determined by 3 orthogonal contrasts: (1) control vs. carbonate; (2) MIX vs. both single carbonates; and (3) K_2CO_3 vs. Na_2CO_3. Carbonate sources did not differ ($P > 0.05$) so MIX, K_2CO_3, and Na_2CO_3 means were averaged to give a single combined carbonate value. CON and carbonate values differed ($P < 0.05$) respectively for culture pH (6.05 and 6.36), acetate (58.9 vs. 65.5 mol/100 mol), propionate (27.2 vs. 22.3 mol/100 mol), acetate/propionate (2.12 and 3.19), and production of *trans*-10 C18:1 (504.1 and 251.7 mg/d), *trans*-11 C18:1 (253.6 and 355.5 mg/d), and *cis*-9, *trans*-11 CLA (8.4 and 11.7 mg/d). CON and carbonate also differed ($P < 0.10$) in production of *trans*-10, *cis*-12 CLA (19.7 and 12.8 mg/d). The results showed that sodium carbonate was equally effective as potassium carbonate in reducing the production of biohydrogenation intermediates that have been linked to the cause of milk fat depression.

Key Words: lipid, biohydrogenation, carbonates

T397 Effects of starch content and fermentability, and culture pH on biohydrogenation of unsaturated fatty acids and NDF digestibility in batch culture.

Yan Sun*, Michael S. Allen, and Adam L. Lock, *Michigan State University, East Lansing, MI.*

Effects of starch content (SC) and fermentability (SF), and culture pH on biohydrogenation (BH) of unsaturated fatty acids (FA) and NDF digestibility (NDFD) in batch culture were evaluated. Cultures (4 replicates/treatment/time point) were incubated at pH 5.8 or 6.2 for 0, 12, and 24 h and included alfalfa hay (55 or 70% of DM), and either dry ground corn (DC) or high moisture corn (HMC) as starch sources (30 or 45% of DM) for a SC of 22 or 33% DM. The alfalfa hay was treated with corn oil (2% of DM) to increase the total unsaturated FA content of cultures. Effects of SC, SF, culture pH, and their interactions were determined. BH extent for *cis*-9,*cis*-12 18:2 and NDFD increased over time across all treatments (both $P < 0.001$). For main effects of treatments, 33% SC compared with 22% SC and pH 5.8 compared with pH 6.2 reduced BH extent of *cis*-9,*cis*-12 18:2 (35 vs. 39% and 23 vs. 51%, respectively; both $P < 0.001$) and NDFD (13 vs. 16% and 8 vs. 21%, respectively; both $P < 0.001$). Compared with DC, HMC decreased NDFD (13 vs. 16%; $P < 0.001$). HMC increased BH extent of *cis*-9,*cis*-12 18:2 at pH 5.8, and decreased it at pH 6.2 compared with DC (interaction $P < 0.001$) with no overall effect of SF ($P = 0.90$). Contents of *trans*-10,*cis*-12 18:2 (CLA) and *trans*-10 18:1 increased over time for all treatments (both $P < 0.001$). Overall, 33% SC compared with 22% SC and pH 5.8 compared with pH 6.2 increased content of CLA by 20 and 67% respectively (both $P < 0.001$). Although SF did not affect CLA content overall ($P = 0.13$), it interacted with time (interaction $P < 0.001$); HMC increased CLA at 12 h, and decreased it at 24 h compared with DC. The 33% SC compared with 22% SC, HMC compared with DC, and pH 5.8 compared with pH 6.2, increased content of *trans*-10 18:1 by 17, 28, and 43% respectively (all $P < 0.001$). In conclusion, higher SC and lower culture pH decreased BH of *cis*-9,*cis*-12 18:2 and NDFD, and increased formation of CLA and *trans*-10 18:1. Compared with DC, HMC increased formation of *trans*-10 18:1, decreased NDFD, and interacted with culture pH and time for BH of *cis*-9, *cis*-12 18:2 and the formation of CLA.

Key Words: biohydrogenation, starch, conjugated linoleic acid

T398 The effect of replacing corn silage with sugarcane on milk yield and intake of lactating dairy cows: An analysis using CNCPS v6.5.

Edgar A. Collao-Saenz*[1], Andreas Foskolos[2], Ryan J. Higgs[2], Vera L. Banys[1], Marcos N. Pereira[3], and Michael E. Van Amburgh[2], [1]*Universidade Federal de Goiás, Jatai, GO, Brazil,* [2]*Cornell University, Ithaca, NY,* [3]*Universidade Federal de Lavras, Lavras, MG, Brazil.*

Sugarcane is an option for feeding dairy cattle in the tropics. Reductions in DMI and milk yield (MY) are frequently reported when sugarcane replaces corn silage in dairy rations, due to the low NDF digestibility. This meta-analysis was conducted to evaluate DMI and MY response of dairy cows to the replacement of corn silage with sugarcane. A database was compiled from 13 Brazilian publications involving 50 treatments from the last 12 years. The nutrient composition of the diets was calculated using CNCPS v. 6.5 feed library. Treatments were stratified in 3 categories: no replacement (SC0), 25–75% replacement (SCA) and 100% replacement (SCB) and the outcomes and predictions were analyzed with a mixed effects model (random: study; fixed: replacement level). Then, a mixed model regression analysis was used to investigate the potential relationships among reported nutrient composition of the diets (CP, NPN, NDF, NFC, Lignin and CNCPS estimated fractions) and MY and DMI as dependent variables. The best models were selected based on the highest BLUP (R^2_{BLUP}) correlation coefficient and the lowest root mean square error (RMSE). Total replacement reduced MY (21.9 vs. 18.6 kg/d) and DMI (19.1 vs. 16 kg/d). DMI was the single most important factor explaining MY ($R^2_{BLUP} = 0.973$; RMSE = 0.865. When CP and RUP (%CP) were included into the DMI model, accuracy and precision were increased ($R^2_{BLUP} = 0.979$; RMSE = 0.75. Total NDF of the diet did not affect MY, but sugarcane NDF content affected it negatively. Sugar (CHOA4; $R^2_{BLUP} = 0.948$; RMSE = 0.66) and sugarcane peNDF ($R^2_{BLUP} = 0.941$; RMSE = 0.68) were the 2 primary factors negatively related to DMI. The replacement of corn silage with sugarcane reduced MY and DMI of dairy cows, diet sugarcane NDF content was the nutrient most related to the response.

Key Words: DMI, corn silage, NDF

T399 Effect of dietary energy source and protein supply on dairy cow performance.

Helio Rezende Lima Neto[1], Helene Lapierre[2], and Lorraine Doepel*[1], [1]*University of Calgary, Calgary, Alberta, Canada,* [2]*Agriculture and Agri-Food Canada, Sherbrooke, Quebec, Canada.*

This study examined the interaction of dietary energy source and metabolizable protein (MP) supply on cow performance. Eight Holstein cows were used in a double 4 × 4 Latin square design with 21-d periods, with dietary energy source and MP supply tested in a factorial arrangement: high fiber, high protein (HFHP); high fiber, low protein (HFLP); high starch, high protein (HSHP); and high starch, low protein (HSLP). Diets were formulated to supply 100% of the NE_L requirement, and 100% (HP) or 70% (LP) of MP requirement. There were no interactions between energy source and MP supply on the parameters measured. Intakes of NE_L (Mcal/d) and MP (g/d) were: HFHP: 31.5, 2148; HFLP: 29.5, 1492; HSHP: 37.8, 2699; HSLP: 36.2, 2007. Milk yield (34.4 vs. 29.9 kg/d) and DMI (22.6 vs. 18.4 kg/d) were higher in cows fed HS compared with those fed HF, whereas DMI tended to be lower in cows fed LP vs. HP (19.9 vs. 21.1). Milk protein (3.04 vs. 2.85%) and lactose (4.62 vs. 4.56%) concentrations were higher in cows fed HS than those fed HF, but milk fat concentration was higher with HF compared with HS (4.22 vs. 3.49%). Milk protein (1.04 vs. 0.85 kg/d) and lactose (1.59 vs. 1.36 kg/d) yields were higher in cows fed HS than those fed HF. Milk protein yield tended to be higher with HP than with LP (962 vs. 925 g/d), and milk urea-N was higher with HP than LP (14.5 vs. 7.9 mg/dL). Dietary energy affected milk yield and composition more than protein supply did. Although diets were formulated to be iso-energetic, the large decrease in DMI in cows fed HF mainly drove the effect of HS vs. HF. The smaller effects of protein supply were not affected by energy source.

T400 Effect of dietary energy source and protein supply on mammary amino acid metabolism of dairy cows. Helio Rezende Lima Neto[1], Helene Lapierre[2], and Lorraine Doepel*[1], *[1]University of Calgary, Calgary, AB, Canada, [2]Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada.*

The objective of this study was to determine the interaction of dietary energy source and metabolizable protein (MP) supply on AA arterial concentration and mammary arterial-venous difference (AVdiff). Eight Holstein cows were used in a double 4 × 4 Latin square design with 21-d periods. Energy source and MP supply were tested in a factorial arrangement with the following dietary treatments: high fiber, high protein (HFHP); high fiber, low protein (HFLP); high starch, high protein (HSHP); and high starch, low protein (HSLP). Diets were formulated to supply 100% of the NE_L requirement, and 100% (HP) or 70% (LP) of MP requirement. Arterial concentrations of Ile, Leu, Phe, and the branched-chain AA (BCAA) were higher with HF compared with HS, regardless of MP supply, whereas concentrations of His, Leu, and BCAA were higher, or tended to be higher, with HP compared with LP. Group 1 AA-N (His, Met, Trp, Phe+Tyr) concentration tended to be higher with HP than LP but Group 2 AA-N (Ile, Leu, Ly, Val) concentration was not different between HP and LP. Metabolizable protein supply did not affect AVdiff except for Ile, Leu and BCAA, in which it was greater for HP than LP ($P < 0.10$). Energy source did not affect AVdiff. The concentration of total essential AA-N (TEAAN) was higher with HF and HP relative to HS and LP, but AVdiff was not affected by treatment. Protein supply had a greater influence on AVdiff than did energy source, whereas energy source and MP supply influenced essential AA concentrations. Dietary energy source and MP affected several production variables; those data are presented in a companion abstract.

T401 Effect of supplemental level of Optigen on the milk performance and plasma biochemical indices of dairy goat. Wang Hui[1], Xue Neil[2], and Luo Jun*[1], *[1]Alltech-NWAFU Animal Science Research Alliance, Northwest A&F University, Yangling, Shaanxi, China, [2]Alltech China, Chaoyang District, Beijing, China.*

The experiment was conducted to investigate the effects of different levels of Optigen, a new slow-release non-protein product, on milk performance and plasma biochemical indices of Xinong Saanen dairy goat, thus to select the optimum supplemental level in the diet. Forty-eight healthy lactating Xinong Saanen dairy goats with average BW of 60 ± 8.98 kg were assigned to 4 groups with 12 goats in each group. Goats in the 4 groups were fed experimental diets containing 0, 0.25, 0.5, or 0.75% Optigen, respectively. There was a pretrial period of 1 wk followed by an experimental period of 16 wk. The results showed that (1) the dietary Optigen level did not significantly affect average daily feed intake ($P > 0.05$); (2) goats in the group with dietary Optigen level of 0.5% have a significantly high average daily milk yield ($P < 0.05$); (3) the dietary Optigen level had significant influences on milk fat ($P < 0.05$), but there was no significant difference among 3 experimental group containing 0.25, 0.5, and 0.75% Optigen in the diet ($P > 0.05$); milk protein percentage, milk lactose percentage and SNF percentage were all unaffected ($P > 0.05$) by the supplementation of Optigen; (4) the dietary Optigen level had significant influences on plasma urea nitrogen ($P < 0.05$), goats with 0.5% Optigen supplement in the diet demonstrated the lowest plasma urea nitrogen content, and followed by that with 0.75% and 0.25% Optigen supplement in the diet. Plasma triglyceride, total cholesterol and total protein were unaffected ($P > 0.05$) by the supplementation of Optigen. In conclusion, dietary supplementation of Optigen can increase milk fat content and reduce plasma urea nitrogen content. 0.5% supplementation of Optigen in the diet can obtain a higher fat content and milk production.

Key Words: Optigen, milk performance, dairy goat

T402 A sensory additive increases milk and protein responses to concentrate supplementation in grazing dairy cows. R. Pulido[1], M. Ruiz[1], F. Bargo*[2], G. Tedó[2], R. Cussen[3], J. Acuña[3], J. R. Roche[4], and I. R. Ipharraguerre[2], *[1]UACh, Valdivia, Chile, [2]Lucta SA, Barcelona, Spain, [3]BestFed, Osorno, Chile, [4]Down to Earth Advice Ltd., Hamilton, New Zealand.*

Forty 5 Holstein dairy cows (62 DIM, 501 kg BW) were assigned to a 3 × 2 incomplete Latin square (LS) design replicated 15 times to evaluate the effect of a sensory additive (ProEfficient, PE) on milk response to concentrate supplementation on pasture. Cows were blocked by parity in 15 blocks and within blocks randomly assigned to 3 concentrate treatments: 1 kg/d mineral concentrate (MC); 7 kg/d starch-based concentrate (CC); and 7 kg/d of CC with 30 g/d of PE (PEC). Cows grazed a perennial ryegrass pasture during 56 d divided into 2 28-d periods. Targeted herbage allowance and pre grazing herbage mass were 25 kg DM/cow and 2400 kg DM/ha, respectively. Concentrates were fed twice daily at milking. The MC was composed of 60% wheat/barley/oat mix, 10% rapeseed meal, and 30% of a mineral premix, and averaged 10.4% CP, 17.2% NDF, and 64.3% in vitro DM digestibility (IVDMD). The CC and PEC were composed of 65% corn, 13.5% triticale/oat/wheat mix, 10% soybean meal, 5% rapeseed meal, 2% sugar beet molasses, and 4.5% mineral premix, and averaged 14.1% CP; 14.7% NDF, 88.4% IVDMD. Ryegrass pasture averaged 22.3% CP, 41.9% NDF, and 77.7% IVDMD. Data were analyzed using a mixed model that included the fixed effects of treatment, block, period, their 2-way interactions, and the random effect of cow within block. On average, supplementation with the starch-based concentrate increased ($P < 0.05$) milk yield 4.4 kg/d compared with MC (24.3 vs. 28.7 kg/d, SEM 0.284). However, cows supplemented with PEC produced more ($P < 0.05$) milk than CC cows (29.0 vs. 28.4 kg/d, respectively; SEM 0.284) because the milk production response to concentrate supplementation was improved 16% ($P < 0.05$) by the addition of PE into the concentrate (0.79 kg vs. 0.68 kg milk/kg concentrate for PEC and CC, respectively). Supplementation with PEC also increased ($P < 0.05$) milk protein percentage (3.74 vs. 3.43%, SEM 0.11) and yield (1.084 vs. 0.978 kg/d, SEM 0.039) compared with CC. The milk and protein responses triggered by PE might be associated with a reduction in the substitution rate of CC for pasture or changes in the concentration of the orexigenic hormone ghrelin.

Key Words: sensory additive, milk response to supplementation, grazing dairy cow

T403 Effect of intensified milk feeding on immune status and hepatic energy metabolism of calves.

Christine T. Schäff*[1], Tadeusz Stefaniak[2], Paulina Jawor[2], and Harald M. Hammon[1], *[1]Leibniz Institute for Farm Animal Biology (FBN), Dummerstorf, Germany, [2]Faculty of Veterinary Medicine, Wroclaw University of Environmental and Life Science, Wroclaw, Poland.*

Ad libitum milk feeding of neonatal calves improves growth, which is reflected by increased plasma concentrations of glucose, insulin, and IGF-I. Thus, we hypothesized that ad libitum milk replacer feeding during the first 5 wk of life affects hepatic energy metabolism and immune status before weaning in neonatal calves. Holstein calves were fed colostrum for 3 d followed by milk replacer (MR) feeding (125 g/l water) until wk 9 either restricted to 6 l/d all the time (RES; n = 14) or ad libitum until d 35 and then stepwise reduced in wk 6 to 6 l/d and fed like RES thereafter (ADLIB; n = 14). Calves had free access to concentrate and hay and were slaughtered at d 60 ± 2. Blood samples were taken on d 1, 2, and 7, then weekly until wk 8 for determination of plasma concentrations of immunoglobulin (Ig) G1, G2, M, haptoglobin, and fibrinogen. Liver samples were taken at slaughter to determine glycogen concentration and mRNA abundance of IGF-I, IGF and insulin receptor, IGF binding proteins 2, 3, and 4, glucose-6-phosphatase, pyruvate carboxylase, cytosolic phosphoenolpyruvate carboxykinase (*PCK1*), and glucose transporter GLUT 2 by quantitative real-time PCR. Data were analyzed by Mixed Model (plasma data) and General Linear Model (mRNA and glycogen data) of SAS. Plasma concentrations of all Ig equally increased ($P < 0.05$) after first colostrum intake in both groups. Plasma concentrations of fibrinogen ($P < 0.05$) increased during 1st wk in both group and tended to be greater ($P < 0.1$) in RES than in ADLIB, whereas plasma haptoglobin concentrations were not affected by feeding. Hepatic glycogen concentration and mRNA abundance were unaffected by feeding except abundance of *PCK1* was greater ($P < 0.05$) in ADLIB than in RES indicating possible influence of intensified milk feeding on gluconeogenesis. The hepatic somatotropic axis was not influenced at slaughter by different early feeding. Therefore, intensive milk feeding for 5 wk had no long-lasting effects on hepatic energy metabolism and Ig status in blood plasma, but may partly affect hepatic acute phase protein response in milk-fed calves.

Key Words: calf, ad libitum feeding, energy metabolism

T404 Effect of lactation stage and rate of increase of concentrate allowance on rumen adaptation in dairy cows.

Kasper Dieho*[1], André Bannink[2], Thomas J. Schonewille[3], and Jan Dijkstra[1], *[1]Animal Nutrition Group, Wageningen University, Wageningen, the Netherlands, [2]Animal Nutrition, Wageningen UR Livestock Research, Wageningen, the Netherlands, [3]Department of Farm Animal Health, Faculty of Veterinary Medicine, Utrecht University, Utrecht, the Netherlands.*

We studied the effects of lactation stage and postpartum rate of increase of concentrate allowance on daily fermentable organic matter (FOM) intake, rumen papilla surface area, and fractional VFA absorption rate (k_aVFA). The concentrate treatment aimed to create a transient difference in daily FOM intake. Twelve rumen-cannulated, Holstein-Friesian cows had free access to either a dry period ration or a basal lactation ration. Starting at 4 DIM, concentrate allowance increased at a high (1.0 kg DM/d; HIGH, n = 6) or a low rate (0.25 kg DM/d; LOW, n = 6) up to a maximum of 10.9 kg DM/d. On sampling days (−50, −30, −10, 3, 9, 16, 30, 44, 60, and 80 DIM), the rumen contents were evacuated and papilla biopsies taken. Thereafter, k_aVFA was measured using the empty washed rumen technique with 46 L McDougall buffer (pH 6.0, 39°C), containing 120 m*M* VFA (60% acetic, 25% propionic, and 15% butyric acid) and a marker (Co-EDTA). From −50 to 3 DIM, FOM intake was 5.7 ± 0.3 kg/d ($P = 0.29$), papilla surface area decreased from 34.4 to 28.0 ± 2.0 mm^2 ($P = 0.02$) and k_aVFA decreased from 0.51 to 0.33 ± 0.03 /h ($P < 0.01$), with no differences between future treatment groups HIGH and LOW ($P \geq 0.33$). From 3 to 80 DIM, FOM intake, papilla surface area, and k_aVFA increased to 15.0 ± 0.3 kg/d, 63.4 ± 2.0 mm^2, and 0.75 ± 0.03 /h respectively (all $P < 0.01$). A treatment by DIM interaction occurred for daily FOM intake ($P < 0.01$), which was greater in group HIGH at 16 DIM (12.3 vs. 10.1 ± 0.3 kg/d, $P < 0.01$), and for papilla surface area ($P = 0.01$), which was greater in group HIGH from 16 DIM (46.0 vs. 33.2 ± 2.0 mm^2, $P < 0.01$) through to 44 DIM (60.5 vs. 49.7 ± 2.0 mm^2, $P = 0.01$). However, a treatment by DIM interaction did not occur for k_aVFA ($P = 0.28$), which was similar for group HIGH and LOW at 16 DIM (0.60 vs. 0.56 ± 0.03 /h, $P = 0.53$) and 44 DIM (0.69 vs. 0.69 ± 0.03 /h, $P = 0.95$). In conclusion, lactation stage but not concentrate treatment affected k_aVFA. This suggests k_aVFA increases with, but is not limited by, papilla surface area during the first weeks of lactation, which was affected by the rate of increase of concentrate allowance.

Key Words: VFA absorption, rumen papillae

T405 Breed and stage of lactation affect the content of bioactive fatty acids in milk.

Melissa L. Bainbridge*[1], Laura M. Cersosimo[1], André-Denis G. Wright[2], and Jana Kraft[1], *[1]University of Vermont, Burlington, VT, [2]University of Arizona, Tucson, AZ.*

Dairy products are a significant contributor to the fat intake of the American diet and contain several bioactive fatty acids (FA) that possess health benefits. The objective of this study was to compare the content and profile of bioactive FA in milk between Holstein (HO), Jersey (JE), and F_1 HO × JE crossbreds (CB). Twenty-two primiparous cows (n = 7 HO, n = 7 CB, n = 8 JE) were followed across a lactation. All cows were fed a consistent TMR at a 70:30 forage to concentrate ratio. Sample periods (SP) were defined as 3 d in milk (DIM), 93 DIM, 183 DIM, and 273 DIM. Milk sample and data collection occurred on days −2 to 2 relative to the SP. Data were analyzed using a repeated measures general linear mixed model in SAS. HO and CB, had a higher content of n-3 FA in milk fat than JE (0.60 and 0.63 vs. 0.47 g/100g FA; $P < 0.01$) and a lower n-6/n-3 ratio (3.2 and 3.1 vs. 3.8; $P < 0.01$). SP had an effect on the n-6/n-3 ratio of milk fat, with the lowest value observed at 3 DIM (2.6; $P < 0.01$) and the highest at 183 DIM (3.9; $P < 0.01$). The content of conjugated linoleic acids (CLA) in milk fat was affected by breed and SP. HO and CB had a higher proportion of CLA than JE (0.50 and 0.48 vs. 0.37 g/100g FA; $P < 0.01$). Overall, CLA content decreased over lactation (0.54, 0.45, 0.40, and 0.40 g/100g FA for 3, 93, 183 and 273 DIM, respectively; $P < 0.01$). Breed had no effect on content of total branched-chain fatty acids (BCFA) in milk fat, however, breed affected individual BCFA. Content of *iso* 14:0 in milk fat was lower in HO than in JE (0.10 vs. 0.13 g/100g FA; $P < 0.05$) and content of *iso* 17:0 was higher in HO and CB than in JE (0.33 and 0.31 vs. 0.27g/100g FA; $P < 0.01$). Total BCFA were affected by SP, with 93 and 183 DIM (1.51 and 1.59 g/100g FA) having a lower proportion of BCFA than 3 and 273 DIM (1.71 and 1.74 g/100g FA; $P < 0.01$). In conclusion, HO and CB exhibited a higher content of bioactive FA in milk than JE. Across a lactation, the greatest content of bioactive FA in milk occurred postpartum.

Key Words: branched-chain fatty acids, n-3 fatty acids, CLA

T406 Rumen microbial protein outflow, and plasma amino acid levels, in early lactation multiparity Holstein cows on commercial California dairy farms.

Nadia Swanepoel*[1,2], Peter H. Robinson[1], and Lourens J. Erasmus[2], [1]*Department of Animal Science, University of California, Davis, CA,* [2]*Department of Animal and Wildlife Sciences, University of Pretoria, Pretoria, South Africa.*

Metabolic models are unlikely to accurately predict microbial crude protein outflow (MCP) from the rumen and amino acid (AA) limitations since they are generally based on static values of unknown accuracy. Practical and reliable methods to identify MCP and AA limitations are required to evaluate nutritional limitations in commercial groups of dairy cows in ‘real time’. Our objective was to determine normal ranges of plasma AA, and MCP, in early lactation multiparity Holstein dairy cows fed a range of rations as a benchmark to determine high, low and normal levels. Multiparity high cow groups on 19 commercial dairies in California were selected. One load of total mixed ration (TMR) was collected at feeding, and milk yields were obtained from monthly milk tests on each dairy. Spot urine samples were collected from voluntarily urinating cows between 38 and 151 d in milk (DIM) to focus on early lactation. Specific gravity of each urine sample was determined to estimate urine flow. Urine samples from each dairy were analyzed for allantoin, which was used, with estimated urine volume, to calculate MCP. Blood was collected from the tail vein of 12 cows/dairy (65 to 76 DIM) and assayed for AA. Group averages among the dairies were 33.6 to 52.5 kg/d milk yield, 1309 to 2149 g/d MCP, 2.8 to 4.4, 8.4 to 13.9, 5.9 to 9.7, 22.9 to 38.5, 16.9 to 27.5 and 11.3 to 18.6 µg/mL for Met, Lys, His, Val, Leu, and Ile respectively. Correlation analysis was performed using the STEPWISE Procedure of SAS with a backward elimination of parameters. Milk and DIM were poor MCP predictors ($r^2 < 0.01$ and 0.05 respectively) and neutral detergent fiber (NDF; $P = 0.02$, $r^2 = 0.23$) was the only TMR nutrient that was predictive of MCP, with higher diet NDF levels leading to increased MCP flow. Multiple correlation with all TMR nutrients (% DM) created the best fit model: MCP (g/d) = −5793.1 + (118.8 × NDF) + (150.1 × Fat) + (87.0 × Starch) + (74.0 × nonfiber carbohydrate) [$r^2 = 0.50$]. Results show that plasma AA (from 6 cows) and MCP (from 8 cows) are sufficient to determine whether plasma AA and/or MCP values in a group of cows are low, high, or normal thereby suggesting changes in rations to address the identified issue(s).

Key Words: allantoin, spot urine samples

T407 Evaluating different physical concentrate forms in preweaned calves.

Marta Terré[1], Maria Devant*[1], and Alex Bach[2,1], [1]*IRTA, Caldes de Montbui, Spain,* [2]*ICREA, Barcelona, Spain.*

In Experiment 1, 37 crossbreed calves were used in a cafeteria study to evaluate calves preferences for different physical form presentation of concentrates. The same concentrate with 4 different physical presentations: meal (ML), pellet (PL), pellet and whole cereal grains (WHL), and pellet and flaked cereal grains (FLK) were simultaneously available from 4 to 45 d age (weaning). A preference diet ratio was calculated: daily concentrate DM intake for each concentrate presentation divided by daily total DM intake divided by the total number of concentrate offered, and an ANOVA with repeated measures was used to analyze the preference ratio. In Experiment 2, 63 Holstein calves were randomly distributed in 2x2 factorial design to evaluate performance of calves fed 2 different protein sources in the milk replacer (MR) and 2 concentrates with different presentation form: calves received either a MR containing dried whey as a protein source, and a pellet concentrate with whole grains of corn and barley or corn and barley flakes; or calves received a MR with dried skim milk as protein ingredient, and a pellet concentrate with whole grains of corn and barley or corn and barley flakes. Animals were weighed weekly, and intakes were recorded daily. Data were analyzed with an ANOVA with repeated measures. In Experiment 1, during the first week of study, calves had a lower ($P < 0.01$) preference for FLK than for WHL; however, thereafter calves showed the greatest ($P < 0.01$) preference for FLK at 2, 4, and 5 week of study. In Experiment 2, there were no differences between milk replacer types, and starter concentrate intake was greater ($P < 0.05$) in whole-grain than in flaked-grain concentrates from the 5 wk of study until weaning. However, no differences in growth or gain to feed ratio were observed. It is concluded that preweaned calves prefer concentrates based on pellets and flaked-grains, and when flaked-grains are compared with whole-grains, lower concentrate intake is observed, but their performance was not impaired.

Key Words: calves, physical form, preference

T408 Fetal programming on dairy cows: Effect of dam’s parity and days in milk at conception on first-lactation milk yield in dairy cows.

Ayelen Chiarle[1], Ramiro Rearte[1], Santiago Corva[1], R. Luzbel de la Sota[1,2], Mauricio Giuliodori[1], and Alejandro Relling*[1,3], [1]*Fac. Cs Veterinarias, UNLP, La Plata, Argentina,* [2]*CCT La Plata, CONICET, Argentina,* [3]*IGEVET, CCT La Plata, CONICET, Argentina.*

Fetal programming is defined as nutritional and/or endocrine changes that happen in the cow during gestation that may change expression of some genes on the adult life of the progeny. These changes may have an impact on the progeny’s performance. Therefore, the objective of the current study was to evaluate the effect of dam’s parity (1 through 8) and days in milk (DIM) at conception on the daughter`s first lactation milk yield accumulated up to 150 d (MY150, kg). Data from dairy cows (n = 159.886) and their daughters (n = 201.547) from 1131 Argentinean dairy herds from ARPECOL (La Plata, BA, Argentina) were included in the study. Data were analyzed as completely randomized block design with a mixed model (SAS 9.3). The model included the fixed effects of parity (1 through 8) and DIM at conception, divided into quartiles (1st: >77 d, 2nd: 77–115 d; 3rd: 115–190 d; 4th: <190); and the random effects of dam and dairy herd (block). Mean DIM for each quartile were 57, 94, 148 and 296 d. Linear, quadratic and cubic polynomial contrasts were used for mean separation. The daughters' MY150 decreases (*P*-value Linear < 0.01, Quadratic < 0.01, Cubic > 0.10) when parity number increases. Mean MY150 were 2915, 2879, 2862, 2853, 2844, 2846, 2837 and 2835 kg for 1st, 2nd, 3rd, 4th, 5th, 6th, 7th and 8th parity, respectively. In addition, daughters' MY150 increases (*P*-value Linear < 0.01, Quadratic < 0.05, Cubic > 0.10) when DIM at conception increases. Mean MY150 were 2851, 2858, 2863, and 2863 kg for those conceived on average at 57, 94, 148 and 296 DIM, respectively. In summary, physiological changes related to parity and DIM at conception have an impact on progeny's MY150.

Key Words: dairy cattle, fetal programing, progeny milk yield

T409 Transcriptome profile in cows resistant to milk fat depression.

Adriana Siurana[1], Sergio Calsamiglia*[1], David Gallardo[3], and Angela Canovas[2], [1]*Animal Nutrition and Welfare Service, Universitat Autonoma de Barcelona, Bellaterra, Spain,* [2]*Servei Veterinari de Genetica Molecular, Universitat Autonoma de Barcelona, Bellaterra, Spain,* [3]*Departament de Genetica Animal, Centre de Recerca en Agrigenomica, Universitat Autonoma de Barcelona, Bellaterra, Spain.*

Feeding linseed to dairy cows results in milk fat depression (MFD), but there is a wide range of sensitivity among cows. The objectives of this study were (1) To compare the mRNA expression of transcripts expressed in milk somatic cells in cows resistant or sensitive to MFD; (2) to identify metabolic pathways and transcription factors affected by MFD in resistant cows under different dietary conditions (no fat supplemented or linseed rich-diet). Four cows were selected from a dairy farm after a switch from a control diet to a linseed-rich diet. Among them, 2 cows (R-MFD) were resistant to MFD showing high milk fat content in both control (CTR) (4.06%) and linseed-rich diet (LIN) (4.36%); and 2 cows (S-MFD) were sensitive to MFD decreasing milk fat content after the change into the LIN diet (3.56 to 2.54%). Fresh milk samples were collected from each cow the week before and 2 weeks after the diet change. Transcriptome analysis was performed using RNA-sequencing technology with a HiSeq2000 platform. Differential expression analysis between cows S-MFD vs. R-MFD allowed to detect a large number of genes differentially expressed (DE) in both diets, CTR (n = 1,111) and LIN (n = 1,669). In addition, 726 genes were differentially expressed between CTR and LIN diets in cows R-MFD whereas only 38 genes were identified in cows S-MFD. Results showed an overexpression in genes and pathways related to fatty acid synthesis and lipid metabolism such as TR/RXR and PPARα/RXRα Activation pathways in cows R-MFD (CTR vs. LIN). Several genes and transcription factors such as *FOXO3, MTOR, PPARA, PPARG, SREBF1* and *MYC* were identified acting as key regulators in R-MFD cows with linseed-rich diet. These results suggest that R-MFD cows could be activating a compensatory mechanism to increase the fatty acid synthesis in linseed-rich diets. It would be interesting to combine these results with the study of the structural variation in the whole transcriptome of S-MFD and R-MFD cows to contribute to the better understanding of molecular mechanisms affecting the MFD in cows.

Key Words: milk fat depression, fatty acid synthesis, RNA-sequencing

T410 Apparent synthesis of vitamin B_6 and folates in the rumen of lactating dairy cows fed alfalfa or orchardgrass silages.

D. S. Castagnino*[1,2], M. Seck[1,2], K. L. Kammes[3], J. A. Voelker Linton[3], M. S. Allen[3], R. Gervais[2], P. Y. Chouinard[2], and C. L. Girard[1], [1]*Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada,* [2]*Département des Sciences Animales, Université Laval, Québec, QC, Canada,* [3]*Department of Animal Science, Michigan State University, East Lansing, MI.*

Effects of forage family (legume vs. grass) on apparent ruminal synthesis and post-ruminal supply of vitamin B_6 and folates were evaluated in 2 experiments. Diets containing either alfalfa (AL) or orchardgrass (OG) silages as the sole forage were offered to ruminally and duodenally cannulated lactating Holstein cows in crossover design experiments. Experiment 1 (E1) compared diets containing AL and OG (~27% total NDF) offered to 8 cows in 2 15-d treatment periods. Experiment 2 (E2) compared diets containing AL and OG (~30% total NDF) offered to 13 cows in 2 18-d treatment periods. Intake, duodenal flow and apparent ruminal synthesis (ARS) for each vitamin were analyzed using SAS mixed procedure. The experiments were analyzed separately. Differences were declared significant at $P < 0.05$. Vitamin B_6 intakes were greater for AL than OG in E1 (368 vs. 236 ± 18.2 mg/d; $P < 0.01$) and E2 (180 vs. 77 ± 5.1 mg/d; $P < 0.01$). In contrast, folates intakes were lower for AL than OG in E1 (7.6 vs. 9.2 ± 0.51 mg/d; $P = 0.02$) and E2 (8.7 vs. 10.2 ± 0.29 mg/d; $P < 0.01$). In E1, duodenal flows of vitamins were not affected by treatment (vitamin B_6, 72 ± 6.2 mg/d, $P = 0.63$; folates, 33 ± 4.2 mg/d, $P = 0.15$). In E2, duodenal flows of vitamin B_6 were greater for AL than OG (59 vs. 31 ± 5.2 mg/d; $P < 0.01$) but the duodenal flows of folates were not affected by treatment (39 ± 2.7 mg/d; $P = 0.78$). Alfalfa increased the apparent ruminal degradation of vitamin B_6 compared with OG in E1 (−294 vs. −167 ± 14.5 mg/d; $P < 0.01$) and E2 (−121 vs. −46 ± 4.9 mg/d; $P < 0.01$). The ARS of folates were not affected by treatment in either experiment (E1: 25 ± 3.9 mg/d, $P = 0.19$; E2: 30 ± 2.5 mg/d, $P = 0.81$). Combining data from both experiments, vitamin B_6 intake was correlated positively with its duodenal flow ($r = 0.68$, $P < 0.01$) but negatively with ARS synthesis of the vitamin ($r = -0.98$, $P < 0.01$). Folates intake was correlated positively with its duodenal flow ($r = 0.68$, $P < 0.01$) and its ARS ($r = 0.59$, $P < 0.01$). Forage family affected the ruminal balance of vitamin B_6 but had little or no effect on the post-ruminal supply of vitamin B_6 and folates.

Key Words: dairy cow, vitamin B_6, folates

T411 Noninvasive indicators to identify lactating dairy cows with the greater risk of subacute rumen acidosis.

Xiaosheng Gao* and Masahito Oba, *University of Alberta, Edmonton, Alberta, Canada.*

The objective of the study was to evaluate if milk urea nitrogen (MUN) and milk fat content could be used as the noninvasive indicator to identify cows with a greater or lower risk of subacute ruminal acidosis (SARA). Our hypothesis was that cows greatly very in their risk to develop SARA even if they are fed a common diet, and that cows with lower MUN and milk fat content would have a greater risk of SARA while cows with higher MUN and milk fat content would have a lower risk of SARA. In a screening study, 35 late-lactating Holstein cows (DIM = 250 ± 71.1; BW = 601 ± 45.4 kg) were fed a high grain diet containing 35% forage and 65% concentrate mix ad libitum for 21 d. Concentration of MUN ranged from 5.7 to 13.9 mg/dL among the 35 cows, and the average milk fat content was 3.5%. Then, 5 cows with highest MUN concentrations with milk fat higher than 3.5% were selected as animals that presumably have a low risk of SARA (LOW), and 5 cows with lowest MUN concentrations with milk fat less than 3.5% were selected as animals that presumably have a high risk of SARA (HIGH). Then these 10 animals were ruminally cannulated during the subsequent dry period. As one LOW cow was culled due to fatty liver, 9 animals (DIM = 122 ± 33.2; BW = 615 ± 49.1 kg) were used for the subsequent study in the following lactation. All cows were fed a high grain diet consisting of 35% forage and 65% concentrate mix ad libitum for 21 d. Ruminal pH was measured every 30 s for 72 h. All response variables were evaluated for the group effect using the PROC TTEST procedure of SAS (version 9.2, SAS Institute Inc., Cary, NC). Minimum (5.75 vs. 5.30; $P = 0.02$) and mean ruminal pH (6.35 vs. 6.04; $P = 0.02$) was higher for LOW compared with HIGH animals. In addition, duration of rumen pH below 5.8 was shorter in LOW animals (52.5 vs. 395 min/d; $P = 0.04$). These results suggested that MUN and milk fat content in late-lactating cows fed a high grain diet may be used to identify cows that have a higher or lower risk of SARA.

Key Words: subacute ruminal acidosis, milk urea nitrogen, milk fat

T412 Effects of different dosages of *Saccharomyces cerevisiae* fermentation product on lactation performance of dairy cows under heat stress. Wen Zhu*[1], B. X. Zhang[1], K. Y. Yao[1], I. Yoon[2], Ruby Chung[2], J. K. Wang[1], J. A. Ye[1], and J. X. Liu[1], [1]*Institute of Dairy Science, College of Animal Science, Zhejiang University, Hangzhou, China,* [2]*Diamond V, Cedar Rapids, IA.*

The objective of this study was to evaluate the effects of different dosages of *Saccharomyces cerevisiae* fermentation product (SCFP; Original XP; Diamond V, Cedar Rapids, IA) on lactation performance of mid-lactation dairy cows under heat stress. Eighty-one multiparous Holstein lactating dairy cows were divided into 27 blocks of 3 cows each based on milk yield (23.6 ± 0.20 kg/d), parity (2.88 ± 0.91) and days in milk (204 ± 46 d). The cows were randomly assigned within blocks to one of 3 dietary treatments: 0 (control), 120, or 240 g/d of SCFP mixed with 240, 120, or 0 g of corn meal, respectively. The experiment lasted for 9 weeks, using the first week as adaption period. All data were analyzed through the PROC MIXED program of SAS with the covariance type AR (1) for repeated measures. Means were separated using the PDIFF option in the LSMEANS statement. Linear and quadratic effects of treatment were tested using orthogonal polynomial contrasts. During the experimental period, average daily Temperature-Humidity Index (measured at 08:00, 14:00 and 20:00) was above 72 for 47 out of 56 d (84%). Rectal temperatures tended to decrease linearly ($P = 0.07$) for cows supplemented with SCFP compared with control cows at 14:30, but were not different at 06:30 ($P > 0.05$). Dry matter intake was not affected ($P > 0.05$) by SCFP supplementation. Milk yield increased linearly ($P = 0.02$) with increasing dosage of SCFP. Feed efficiency (milk yield/dry matter intake) was highest ($P = 0.04$) for cows fed 240 g/d SCFP. Net energy balance also increased linearly ($P < 0.01$) with increasing dosage of SCFP. Cows supplemented with SCFP gained ($P < 0.01$) body weight, while control cows lost body weight. Concentrations of milk urea nitrogen decreased linearly ($P < 0.01$) with increasing dosage of SCFP, while no difference was observed among the treatments in conversion of dietary N to milk N. In summary, supplementation of SCFP alleviated the negative effect of heat stress in lactating Holstein dairy cows and allowed cows to maintain higher milk production, feed efficiency and net energy balance. Effects of SCFP were dose-dependent and greater effects were observed from higher doses.

Key Words: heat stress, yeast culture, lactation performance

T413 Effects of *Saccharomyces cerevisiae* fermentation products on lactation performance, rumen fermentation and microbial communities in dairy cows fed a diet containing low quality forages. Wen Zhu*[1], Z. H. Wei[1], N. N. Xu[1], Fan Yang[1], I. Yoon[2], Ruby Chung[2], J. K. Wang[1], J. A. Ye[1], and J. X. Liu[1], [1]*Institute of Dairy Science, College of Animal Science, Zhejiang University, Hangzhou, China,* [2]*Diamond V, Cedar Rapids, IA.*

The objective of this study was to evaluate the effects of various dosages of *Saccharomyces cerevisiae* fermentation product (SCFP; Original XP; Diamond V) on lactation performance, rumen microbial communities and rumen fermentation in mid-lactation dairy cows fed a total mixed ration containing low quality forages. Eighty multiparous Holstein dairy cows were blocked based on days in milk (180 ± 45 d), parity (3.24 ± 1.06) and milk yield (26.6 ± 0.79 kg/d), and were randomly assigned to one of 4 treatments. Treatments consisted of 0, 60, 120, or 180 g/d of SCFP per head mixed with 180, 120, 60, or 0 g of corn meal, respectively. The forage in the basal diet was comprised (DM basis) of 15% corn stover, 7% Chinese wild ryegrass, and 17.3% corn silage. The experiment lasted for 10 weeks, with the first 2 weeks for adaption. The data were analyzed using the PROC MIXED program of SAS with the covariance type AR (1) for repeated measures. Means were separated by using the PDIFF option in the LSMEANS statement. Orthogonal polynomial contrasts were used for linear and quadratic effects testing. Dry matter intake decreased linearly ($P = 0.02$), while milk yield increased linearly ($P = 0.05$) with the increasing dosage of SCFP, resulting in improved ($P < 0.01$) feed efficiency compared with the control. Contents of milk components were similar ($P > 0.05$) among the treatments. Neither rumen pH ($P = 0.70$) nor ammonia-nitrogen concentration ($P = 0.82$) was affected by SCFP supplementation. Increasing dosage of SCFP linearly increased ($P < 0.05$) concentrations of ruminal total volatile fatty acids, acetate, propionate and butyrate, with no difference ($P > 0.05$) in molar proportion of individual acids. The population of fungi and cellulolytic bacteria increased linearly ($P < 0.01$), but those of lactate-utilizing and lactate-producing bacteria decreased linearly ($P < 0.01$) with increasing dosage of SCFP. The estimated microbial protein yield in the rumen increased linearly ($P < 0.01$) in response to SCFP supplementation. In summary, supplementation of SCFP improved the lactation performance of dairy cows consuming diets containing low quality forages by optimizing rumen fermentation through manipulating rumen populations. Effects of SCFP were dose-dependent and greater effects were observed from higher doses.

Key Words: low-quality forage, yeast culture, lactation performance

T414 Response of dairy cows to monensin on diets differing in starch content and source. Eugenio F. Barbosa[1], Julia D. L. Dias[1], Fabiana F. Cardoso[1], Túlio H. R. Souza[1], Lucas C. Resende[1], Ozana F. Zacaroni[1], Renata A. N. Pereira[3,2], and Marcos N. Pereira*[1,2], [1]*Universidade Federal de Lavras, Lavras, MG, Brazil,* [2]*Better Nature Research Center, Ijaci, MG, Brazil,* [3]*Empresa de Pesquisa Agropecuária de Minas Gerais, Lavras, MG, Brazil.*

The response of dairy cows to monensin can interact with diet composition. We evaluated the response of lactating cows to monensin supplementation of diets differing in rumen fermentable starch. Twenty-eight Holsteins (157 ± 76 DIM) were individually fed a standard TMR for 3 wks and monensin (MON. 300 mg/d) or control (CTL) for 9 wks, in a covariate adjusted randomized block design. A low-starch diet (LS. 25.8% starch in DM) was offered from d 1 to 35 and a high-starch diet (HS. 30% starch in DM) from d 36 to 63. HS was formulated by replacing whole cottonseed and finely ground mature corn by an isonitrogenous mixture of soybean meal and high moisture corn. Data were collected daily or after adaptation to LS and HS, and were analyzed as repeated measures with PROC MIXED of SAS. The mean square for cow nested within treatment (MON vs. CTL) was the error term for the treatment effect. Digestible OM intake (DOMI) was increased by HS (15.3 vs. 14.4 kg/d. $P < 0.01$), but was similar for MON (14.6 kg/d) and CTL (15.1 kg/d. $P = 0.41$). Milk yield did not respond to MON (32.3 kg/d. $P = 0.32$). MON reduced DMI and increased Milk/DMI, ECM/DMI, and ECM/DOMI only when HS was fed ($P < 0.01$ for the interaction of treatment and wk/diet). Plasma glucose content was increased by MON and the response interacted similarly with wk/diet ($P < 0.05$). MON reduced the A/P ratio in rumen fluid in both diets (2.43 vs. 1.81. $P < 0.01$) and HS reduced ruminal pH ($P < 0.01$) and increased protozoa content ($P < 0.01$). MON reduced total-tract NDF digestibility more in LS (52.1 vs. 41.3% of intake) than in HS (57.0 vs. 52.0. $P < 0.05$ for the interaction). The daily urinary allantoin excretion did not respond to MON ($P = 0.40$), neither PUN at 0, 1.5, and 3 h post feeding ($P > 0.27$). MON induced lower degree of refusal of long feed particles and of preferential intake of short particles in the afternoon than CTL ($P < 0.05$). Ingestion time (min/d and min/kg of DMI) and the number of daily meals were reduced by HS ($P < 0.05$). HS increased pCO_2, HCO_3^-, total CO_2, and base excess of jugular blood ($P < 0.04$) and tended to reduce blood pH ($P = 0.10$). The positive effect of MON on feed efficiency occurred only when ruminally available starch was increased in the diet.

Key Words: monensin, starch, feed efficiency

T415 Growth performance of dairy heifers fed reduced-fat distillers grains in replacement of forage in limit-fed rations.

Angela K. Manthey*[1], Jill L. Anderson[1], and George A. Perry[2], [1]*Dairy Science Department, South Dakota State University, Brookings, SD*, [2]*Department of Animal Science, South Dakota State University, Brookings, SD.*

Our objective was to determine the maximum inclusion rate of reduced-fat distillers dried grains (RFDDGS) in dairy heifer rations. A 16-wk randomized complete block design study was conducted using 48 Holstein heifers (199 ± 2 d of age) to evaluate effects of diet on growth performance. Treatments were 30% RFDDGS (30DG), 40% RFDDGS (40DG), and 50% RFDDGS (50DG) with the rest of the diets consisting of grass hay and 1.5% mineral mix. Using Calan gates rations were limit-fed at 2.65, 2.50, and 2.35% of BW (DM basis) for 30DG, 40DG, and 50DG, respectively to have similar intakes of CP and energy among treatments. Frame sizes, BW, and BCS were measured on 2 consecutive days during wk 0, 2, 4, 6, 8, 10, 12, 14, and 16 of the feeding period. Data were analyzed using the MIXED procedures with repeated measures in SAS 9.4. Changes per day were analyzed by regression analysis. There were no interactions of treatment by wk. Heifer DMI linearly decreased ($P < 0.01$) with increased dietary concentrations of RFDDGS (6.49, 6.21, and 5.84 kg/d; SEM = 0.117 for 30DG, 40DG, and 50DG, respectively). Body weights (264.1, 266.2, and 266.4 kg; SEM = 4.98) and ADG (0.89, 0.94, and 0.97 ± 0.083 kg/d) were similar ($P > 0.05$) among treatments. Gain to feed (0.14, 0.16, and 0.18 kg; SEM = 0.0034) linearly increased ($P < 0.01$). Hip height (124.8, 124.7, and 124.8 cm; SEM = 0.36) and hip width (35.6, 35.8, and 35.8 cm; SEM = 0.57) were similar ($P > 0.05$) among treatments. Body length (112.5, 112.9, and 113.1 cm; SEM = 0.18) tended ($P = 0.06$) to linearly increase across treatments. There was a quadratic effect ($P < 0.05$) for withers height (120.9, 121.7, and 121.6 cm; SEM = 0.29), paunch girth (172.5, 173.9, and 172.5 cm; SEM = 1.29), and BCS (3.11, 3.12, and 3.07; SEM = 0.018), and a quadratic tendency ($P = 0.08$) for heart girth (140.9, 140.6, and 140.9 cm; SEM = 0.41). Limit-feeding diets with greater inclusion rates of RFDDGS resulted in improved gain to feed ratios and maintained frame growth without increasing BCS, demonstrating that replacing forage with RFDDGS does not negatively affect heifer growth performance.

Key Words: distillers grains, dairy heifer, growth performance

T416 Ruminal degradation and intestinal digestibility of camelina and carinata meal compared with other protein sources.

Rhea D. Lawrence* and Jill L. Anderson, *Dairy Science Department, South Dakota State University, Brookings, SD.*

Our objective was to determine DM and CP ruminal degradability and intestinal digestibility of camelina meal (CM) and carinata meal (CR) compared with other oilseed meals, soybean meal (SBM) and reduced-fat distillers dried grains (DG). In situ measurements were done using 3 multiparous, ruminally-cannulated Holstein cows (BW 848.6 ± 94.7 kg). Six feeds were evaluated: CM, CR, canola meal (CN), linseed meal (LN), DG, and SBM. Duplicate 5 g samples were weighed into 10 × 20 cm nylon bags and ruminally incubated for 0, 2, 4, 8, 12, 24 and 48 h. Six additional bags of each feed were incubated at 12 h for use in determination of in vitro intestinal digestibility of CP. Residues were incubated with pepsin and pancreatin solutions for 1 h and 24 h, respectively. Rumen degradation constants for DM and CP were estimated using the NLIN procedures in SAS 9.3. Intestinally digestible protein (IDP), intestinally absorbable dietary protein (IADP = ruminally undegradable protein (RUP) × IDP), and total digestible protein (TDP = ruminally degradable protein (RDP) + IADP) were evaluated using MIXED procedures in SAS. Ruminally degradable DM (RDDM) was greatest in CM, CR, and SBM. The CM and CR had the greatest RDP and least RUP of the feeds. The IDP was less in CM and CR compared with SBM and LN, but greater than CN and DG. The CR and CM had less IADP compared with the other feeds. The TDP was similar for CM and CR compared with SBM and LN, but greater than CN and DG. Overall, results indicate that CM and CR are highly degradable in the rumen and are comparable protein sources to SBM and LN for total digestibility.

T417 The decline in digestive efficiency of US dairy cows during the last 44 years.

Sarah B. Potts*, Melissa Shaughness, and Richard A. Erdman, *University of Maryland, College Park, MD.*

Since 1970, US milk production per cow has more than doubled resulting in large increases in feed intake. It is well established that increasing feed intake reduces diet digestibility. Our objective was to determine if the digestive efficiency of US dairy cows has also changed in the last 44 years. We assembled a data set consisting of diet digestibility measured via total collection or iNDF procedures with lactating dairy cows from studies published in the *Journal of Dairy Science* from 1970 to 2014. The data set contained 121 treatment means from 38 studies conducted at 16 US institutions. Based on regression analysis, milk yield and DMI increased by 20 kg/d and 8 kg/d between 1970 and 2014, respectively. Temporal effects on digestibility (DM, CP, or NDF) were determined using the regression model: Digestibility = $YEAR_{1970}$ + CP + NDF; where $YEAR_{1970}$ is the publication year minus 1970 and CP and NDF are diet constituents (% of diet DM) included to account for their effects on digestibility. DM digestibility decreased 0.13 percentage units per year ($P < 0.01$) for a total reduction of 5.7 percentage units since 1970. However, there were no temporal effects on CP and NDF digestibilities ($P > 0.3$). To account for the potential effect of feed intake on digestibility, DMI as a percentage of BW (DMI_{BW}) was included in the regression model. With DMI_{BW} in the model, DM digestibility decreased 0.08 percentage units per year ($P = 0.03$) for a total reduction of 3.5 percentage units. This suggests that only a portion (39%) of the decline in digestibility was due to level of feed intake. In contrast, CP digestibility was unchanged over time ($P = 0.94$), and NDF digestibility increased 0.14 percentage units per year ($P = 0.05$) when the model included DMI_{BW}. Increased NDF digestibility was likely due to the use of more highly digestible NDF sources in more recent studies. These results suggest that digestive efficiency has decreased by nearly 6 percentage units over the last 44 years. Perhaps genetic selection of cows for high milk production has inadvertently resulted in cows with high feed intake capacity irrespective of effects on digestive efficiency.

Key Words: digestibility, digestive efficiency, dairy cow

T418 Ruminal degradation and intestinal digestibility of microbially treated soybean meal and dried distillers grains compared with the original feeds.

Jennifer L. Casperson[1], Jill L. Anderson*[1], Jason R. Croat[2], and William R. Gibbons[2], [1]*Dairy Science Department, South Dakota State University, Brookings, SD*, [2]*Department of Biology and Microbiology, South Dakota State University, Brookings, SD.*

Our objective was to determine if microbial (fungal) treatment of soybean meal (SBM) and dried distillers grain with solubles (DG) affected ruminal degradation and intestinal digestibility of DM and CP. In situ measurements were done using 3 mid-lactation, multiparous, ruminally-cannulated Holstein cows (BW 847 ± 96). Four feeds were evaluated: SBM, treated SBM (TSBM), DG, and treated DG (TDG). Duplicate 5 g samples in nylon bags (10 × 20 cm) were incubated in the rumen for 0, 1, 2, 4, 8, 12, 24 and 48 h. Rumen degradation constants for DM and CP were estimated using the NLIN procedures in SAS 9.3. Six additional bags of each feed were ruminally incubated for 12 h. Residues were used to determine in vitro intestinal digestibility of CP via incubation with pepsin and pancreatin solutions for 1 h and 24 h, respectively. Intestinally digestible protein (IDP), intestinally absorbable dietary protein (IADP = Rumen undegradable protein (RUP) × IDP), and total digestible protein (TDP = Rumen degradable protein (RDP) + IADP) were compared using MIXED procedures in SAS. Total CP was more in TSBM and TDG compared with original feeds. Ruminally degradable DM (RDDM) was less in TSBM and DG than in SBM, TDG. The RDP was increased in TDG versus DG and decreased in TSBM versus SBM. Effects were opposite for RUP. The IDP, IADP were less in DG and TDG compared with SBM and TSBM. The TDP was greatest in SBM and least in DG. Results indicate that microbial-treatment increased protein content of SBM and DG. Digestibility of CP was increased for TDG versus DG, but was not increased in TSBM versus SBM.

T419 Meta-analysis of feeding trials to estimate energy requirements of dairy cows under tropical conditions.

André S. Oliveira*, *Universidade Federal de Mato Grosso, Campus Sinop, Sinop, Mato Grosso, Brazil.*

A meta-analysis of feeding trials was conducted to determine the metabolizable energy requirements for the maintenance (ME_m) and efficiency of metabolizable energy intake (MEI) for the milk production (k_L) of *Bos taurus* and *Bos taurus* × *Bos indicus* crossbreds dairy cows in the tropics. The database contained 236 means treatments from 60 feeding trial studies. The data set was classified by genotype: *Bos taurus* (37 studies; n = 150 treatments means; MEI = 45.9 ± 6.6 Mcal/d; BW = 570 ± 45 kg; BW variation = 0.30 ± 0.37 kg/d; BCS = 2.7 ± 0.2; milk production = 22.3 ± 5.0 kg/d; milk fat = 3.64 ± 0.37%; milk protein = 3.23 ± 0.25%; milk lactose = 4.43 ± 0.21%; and milk energy = 0.70 ± 0.04 Mcal/kg) and *Bos taurus* × *Bos indicus* crossbred (23 studies; n = 86 treatments means; MEI = 31.6 ± 7.2.6 Mcal/d; BW = 487 ± 48 kg; BW variation = 0.07 ± 0.52 kg/d; BCS = 3.2 ± 0.5; milk production = 13.7 ± 2.0 kg/d; milk fat = 3.63 ± 0.55%; milk protein = 3.11 ± 0.28%; milk lactose = 4.49 ± 0.20%; and milk energy = 0.70 ± 0.06 Mcal/kg). A linear regression of MEI (Mcal/kg $BW^{0.75}$/d) with the milk energy output adjusted to a zero energy balance ($E_{L(0)}$, Mcal/kg $BW^{0.75}$/d) was fitted using a mixed model with the study as the random effect and the genotype as the fixed effect. The ME_m was calculated as the intercept and k_L as the reciprocal of the slope of the regression. The dairy cow genotype affected the ME_m ($P = 0.013$) and k_L ($P = 0.033$). *Bos taurus* MEI (Mcal/kg $BW^{0.75}$/d) = 0.180 (±0.022, $P < 0.001$) + 1.546 (±0.153, $P < 0.001$) × $E_{L(0)}$, $R^2 = 0.675$, MSPE = 0.0007; and *Bos taurus* × *Bos indicus* MEI (Mcal/kg $BW^{0.75}$/d) = 0.147 (±0.024, $P < 0.001$) + 1.771 (±0.288, $P < 0.001$) × $E_{L(0)}$, $R^2 = 0.859$, MSPE = 0.0004. *Bos taurus* × *Bos indicus* crossbred dairy cows have ($P < 0.05$) an ME_m requirement that is 18% lower (0.147 ± 0.024 vs. 0.180 ± 0.022 Mcal/kg $BW^{0.75}$/d), but a k_L that is 12% lower (0.57 ± 0.09 *vs*. 0.65 ± 0.06) than that of *Bos taurus* cows. These results support the hypothesis that *Bos taurus* × *Bos indicus* crossbred dairy cows have a lower ME_m requirement but lower energetic efficiency for milk production than do *Bos taurus* dairy cows under tropical conditions.

Key Words: *Bos indicus,* maintenance, metabolizable energy

T420 Effect of a ration change from a TMR to a pasture-based ration on rumen bacteria in dairy cows.

Melanie Schären*[1], Ulrich Meyer[1], Sven Dänicke[1], and Gerhard Breves[2], [1]*Friedrich Loeffler Institut (FLI)-Federal Research Institute for Animal Health - Institute for Animal Nutrition, Braunschweig, Germany*, [2]*University of Veterinary Medicine Hannover, Foundation - Institute for Physiology, Hannover, Germany.*

In spring, dairy cows are often gradually transitioned from a TMR to a pasture-based ration. This study aims to investigate how the populations of the liquid (LAB), particle (PAB) and epithelium (EAB) associated bacteria in the rumen are influenced by this nutritional change. A 10-wk trial (w1–10) was performed in spring 2014, including 10 rumen-fistulated dairy cows of the German Holstein breed (182 ± 24 d in milk, 23.5 ± 3.5 kg milk/day, means ± SD). The cows were divided into a pasture- and a confinement group (PG and CG, n = 5). The CG stayed on a TMR-based ration (35% corn silage, 35% grass silage, 30% concentrate; DM basis), while the PG was gradually transitioned from a TMR- to a pasture-based ration (w1: TMR-only, w2: 3 h/day on pasture, w3 and 4: 12 h/day on pasture, w5–10: pasture-only).

In w1, w5 and w10 of the trial samples of solid and liquid rumen contents were taken and after emptying the rumen, papillae biopsies were taken from the ventral rumen sac. The bacterial DNA was isolated from each sample and a SSCP-analysis was performed. Similarity and cluster analysis was done using GelComparII. Data were analyzed as repeated measures using PROC MIXED of SAS Enterprise Guide 6.1. Cluster analysis displayed a clustering of LAB, PAB and EAB in both ration types and all three points in time. LAB and PAB had a similarity of 82 ± 5% (means ± SD) and differ strongly from the EAB with a similarity of 39 ± 8% EAB compared with LAB, and 37 ± 8% EAB compared with PAB (p < 0.001). When comparing the samples of the different bacteria populations in w5 and w10 to their reference sample in w1, a significant greater decrease in similarity over time in all three bacteria populations was observed for the PG compared with the CG (p < 0.01; illustrated in Table 1). To further identify the different bacterial populations 16S DNA sequencing of all samples is currently being performed.

Table 1 (Abstr. T420). Change in bacterial populations of the LAB, PAB, and EAB over time expressed in average similarity (in %) of samples compared with their reference sample in week 1 (means ± SD)

	LAB CG	PAB CG	EAB CG	LAB PG	PAB PG	EAB PG
Week 5	93 ± 6%	97 ± 2%	91 ± 4%	76 ± 10%	86 ± 8%	82 ± 8%
Week 10	91 ± 3%	94 ± 2%	88 ± 4%	61 ± 13%	85 ± 8%	67 ± 8%

Key Words: dairy cow, pasture, rumen microbiota

T421 Morphology change and expression of genes related to tight junctions, cytokines, proliferation and apoptosis in the rumen of lactating dairy cows fed corn stover or rice straw replacing alfalfa as forage source.

Bing Wang*[1,3], Mei Liu[1,3], X. B. Huang[1,3], J. S. Wu[2], and J. X. Liu[1,3], [1]*Institute of Dairy Science, College of Animal Sciences, Zhejiang University, Hangzhou, China,* [2]*Department of Veterinary Science, College of Animal Sciences, Zhejiang University, Hangzhou, China,* [3]*MOE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, China.*

The objective of this study was to characterize the morphology and expression of the genes related to tight junction protein, cytokines, proliferation, and apoptosis in the gastrointestinal tracts (GIT) of lactating cows. Eighteen multiparous Holstein dairy cows were individually fed, and randomly assigned into 1 of 3 treatments. Isonitrogenous diets with forage-to-concentrate ratio at 45:55 contained similar concentrate and 15% corn silage, with 3 forage sources (DM basis): 23% alfalfa hay and 7% Chinese wild rye hay (AH); 30% corn stover (CS); and 30% rice straw (RS). The portion with length above 19 mm was the largest in RS, followed by AH, least in CS. After 14-wk feeding, all the cows were slaughtered. The digesta, tissue, and relevant epithelium of the GIT were collected immediately after dissection. The morphology of the GIT tissues was analyzed according to the hematoxylin-eosin stained method and the histomorphometric analysis was performed using Image J Plus software (Media Cybernetics, Bethesda, MD). The qRT-PCR reaction of the related genes in rumen epithelium was performed using the 2 × SYBR Premix Ex Taq (Tli RNaseH Plus) kit (Takara, Otsu, Japan). The variance of the data was analyzed as a completely randomized design using PROC MIXED of SAS. The DM of rumen digesta was heavier in diet RS than in AH ($P < 0.01$). The thickness of ruminal mucosa was greater in RS than in AH ($P < 0.05$) or CS ($P < 0.05$), but the thickness of mucous epithelium was greater in AH ($P < 0.05$) or RS ($P < 0.05$) than in CS. The rumen butyrate concentration was greater in diet CS than RS ($P < 0.01$) or AH ($P < 0.01$), and had a negative correlation with the mRNA abundance of BCD ($P = 0.01$). Abundance of mRNA of IGF-1R was upregulated in AH compared with CS ($P = 0.047$). Abundance of mRNA of claudin-1 ($P = 0.09$), claudin-4 ($P = 0.10$), and ZO-1 ($P = 0.07$) tended to increase in AH compared with CS. The expression of gene related to cytokines showed no difference among the treatments. The expression of IGF-1 tended to increase in AH ($P = 0.066$) compared with CS. Our finding suggested that feeding of rice straw to dairy cow caused the change in ruminal mucosa mostly related to cell proliferation and apoptosis, which may be not only attributed to the physically effective fiber effects but also the butyrate factor.

Key Words: cow, gastrointestinal tract, morphology

T422 Effect of a calcium oral bolus administered after calving on the metabolic parameters of dairy cows.

J. M. Béguin*[1], R. P. Dagorne[1], and P. Courty[2], [1]*Néolait, Yffiniac, France,* [2]*ESITPA, Mont-Saint-Aignan, France.*

The objective of this study was to evaluate the effect of postpartum administration of a calcium bolus (Dietevit Flash, Néolait, Yffiniac, France), on the metabolic parameters of multiparous dairy cows. Holstein cows (n = 38) from 3 commercial dairy farms in Western France, were randomly assigned to a control group (group A) and a trial group (group B). Cows in group B received at calving 2 boluses and 2 boluses at 12–18 h after calving. The 4 boluses supplied calcium (65 g as calcium formiate and calcium propionate), magnesium (5 g), vitamin E (4,000 IU), vitamin D3 (50,000 IU) and niacin (12 g). Blood samples were taken 12 d before calving, 12 and 28 h after calving and 10 d after calving. Blood serum was then analyzed for calcium, magnesium and vitamin E at the Frank Duncombe's Lab, France. The metabolic profiles of the 2 groups were compared using repeated measures ANOVA (SPSS v18). The incidence of cows with postpartum hypocalcemia (calcium < 80mg/L) in both groups was compared using the Pearson Chi-squared test. Compared with group A, cows in group B had higher calcemia at 12 h postpartum (87.3 vs. 79.1 mg/L, $P = 0.02$) and 28 h postpartum (86.3 vs. 76.4 mg/L, $P = 0.01$), lower magnesemia at 28 h postpartum (19.0 vs. 22.1 mg/L, $P = 0.03$) and higher blood levels of vitamin E at 28 h postpartum (2.2 vs. 1.4 µg/L, $P = 0.04$). Prevalence of hypocalcaemia was significantly decreased in group B (7.1% vs. 37.5 and 25% vs. 56.2%, $P = 0.01$) at respectively 12 and 28 h postpartum. In conclusion, the Dietevit Flash bolus significantly improves calcemia in postpartum multiparous dairy cows. The Dietevit Flash helps secure the difficult peripartum phase by decreasing the prevalence of subclinical hypocalcaemia in a significant way during the first 2 d of lactation.

Key Words: dairy cow, bolus, subclinical hypocalcemia

T423 Urea kinetics in dairy cows fed soybean meal (SBM), canola meal (CM), corn high protein dried distillers grains (HPDDG) or wheat dried distillers grains with solubles (WDDGS).

D. R. Ouellet*[1], G. Maxin[2], and H. Lapierre[1], [1]*Dairy and Swine R&D Centre, Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada,* [2]*INRA UMR 1213 Herbivores, Saint-Genès-Champanelle, France.*

Inclusion of CM in dairy rations decreases plasma urea concentration (Martineau et al., J. Dairy Sci. 97:1603).The objective of this study was to compare the effects of feeding diets containing SBM, CM, HPDDG or WDDGS as single protein supplement on urea kinetics. Eight rumen-fistulated Holstein cows were used in a replicated 4 × 4 Latin square with 14-d periods. Dietary treatments consisted of inclusion of these protein in diet: SBM (13.7%), CM (20.8%), HPDDG (20.4%) or WDDGS (22.8%). The 4 diets were isonitrogenous (17.2%CP) and isoenergetic (1.56 Mcal NE_L/kg DM; NRC 2001), with a fixed forage:concentrate ratio of 62:38. From d 10–13, total collection of urine was performed. On d 12, cows were infused in a jugular vein $^{15}N_2$-urea (0.5 mmol/h) and urine spot samples were collected after 24 h of infusion; enrichment of $^{15}N_2$-urea was determined to estimate urea kinetics. Differences among treatments were analyzed using adjusted Tukey-Kramer multiple comparisons test. Results are given as LSM ± SEM for SBM, CM, HPDDG and WDDGS, respectively. The N intake and milk N were similar between treatments (659, 660,657, and 665 ± 23 g/d and 1.13, 1.15, 1.15, and 1.13 ± 0.01 kg/d; Maxin et al., JDS 96:7806). The RDP supply (NRC 2001) averaged 2622, 2672, 2110 and 2959 g/d. Urea production (UER) tended (P = 0.08) to be lower for WDDGS vs. SBM (353 vs. 409 ± 18 g urea-N/d) whereas CM (391) and HPDDG (405) were intermediate. Urea gut entry rate (GER) averaged 265, 272, 267 and 210 ± 18 g urea-N/d, with only WDDGS being lower ($P < 0.05$) than the other diets. The proportion of GER/UER was also lower ($P < 0.05$) for WDDGS: 0.65, 0.69, 0.65, and 0.59 ± 0.02. Urinary N excretion was lower ($P < 0.06$) for CM (118 ± 6 g urea-N/d) than HPDDG (139), WDDGS (144) and SBM (144). Cows fed WDDGS had a lower urea production and GER, but urinary excretion was similar to HPDDG and SBM, in disagreement with estimated higher RDP supply. The intermediate urea production for the CM supplement coupled with the numerically higher proportion returned to the gut lead to a lower urinary urea-N excretion which can explain the decreased plasma urea concentration also observed in this study: 8.5, 7.8, 8.8, and 8.9 ± 0.4 m*M* (Maxin et al., J. Dairy Sci. 96:7806).

Key Words: urea kinetics, protein supplement, dairy cow

T424 Determining bioavailability of Lys in rumen-protected Lys products using the plasma free AA dose-response technique.

Nancy L. Whitehouse*[1], Andre B. D. Pereira[1], Adam C. Crowther[1], Devan L. Chirgwin[1], Andre F. Brito[1], Charles G. Schwab[2], and Jack E. Garrett[3], [1]*University of New Hampshire, Durham, NH,* [2]*Schwab Consulting, LLC, Boscobel, WI,* [3]*QualiTech Inc, Chaska, MN.*

Two experiments were conducted using the technique to determine the bioavailability of Lys in rumen-protected (RP)Lys supplements manufactured by QualiTech Inc. Bioavailability estimates are calculated by dividing the slope of the regression line relating changes in plasma Lys concentrations from feeding an RPLys supplement by the slope of the regression line obtained by continuous abomasal infusion of Lys. Experiment 1 examined the efficacy of the company's first generation product. Experiment 2 was to determine the effect of changes in core/matrix composition and amount of encapsulation on Lys availability. Six multiparous ruminally-cannulated Holstein cows were used in Exp. 1 in a replicated 3 × 3 Latin square (193 DIM). Treatments were 1) 0 g/d Lys, 2) 60 g/d infused Lys from Lys-HCl (80% Lys), and 3) 60 g/d fed Lys from RPLys (56% Lys). Five multiparous ruminally-cannulated cows were used in Exp. 2 in a 5 × 5 Latin square (108 DIM). Treatments were 1) 0 g/d Lys, 2) 60 g/d infused Lys from Lys-HCl (80% Lys), 3) 60 g/d fed Lys from product A (30.4% Lys), 4) 60 g/d fed Lys from product B (47.4% Lys), and 5) 60 g/d fed Lys from product C (37.3% Lys). Before feeding, the products were mixed with 2 kg of the Lys-adequate basal TMR, placed in ziploc bags, and stored for 8 h at 4°C. Fed treatments were offered to cows 30 min before each of 3 daily feedings. Fed treatments not consumed after 15 min were placed in the rumen. Tail vein samples were collected 2, 4, 6 and 8 h after the morning feeding the last 3 d of each period. Deproteinized plasma samples were composited by cow/d and stored (−80°C) until AA analysis. Lysine concentrations (µ*M*) were expressed as a proportion of total AA before regression analysis. Data were analyzed using the PROC MIXED and REG procedures of SAS. Lysine was the only plasma AA that increased linearly in response to treatments ($P < 0.02$). Calculated Lys bioavailability estimates were 27.1% in Exp. 1, and 17.0, 24.5, and 28.5%, respectively, for Products A, B, and C in Exp. 2. The technique was sensitive enough to confirm differences between Product A vs. products B and C in Exp. 2.

Key Words: amino acid, lysine, bioavailability

T425 Blood ketone bodies incidence and concentration from intensively housed early-lactation dairy cows in Brazil.

Rafahel C. Souza[1], Rogério C. Souza[1], Breno M. Sousa[2], and Andre B. D. Pereira*[3], [1]*Pontifícia Universidade Católica de Minas Gerais, Betim, MG, Brazil,* [2]*Centro Universitário UniBH, Belo Horizonte, MG, Brazil,* [3]*University of New Hampshire, Durham, NH.*

Ketosis is a metabolic syndrome that can increase farm costs and result in milk production losses during a lactation. This syndrome mostly affects high production cows and causes are usually associated with negative energy balance during early to mid-lactation. The objective of this study was to evaluate the concentration of ketone bodies in the blood of 732 early-lactation [25.2 ± 15.8 d in milk (DIM)] high producing Holstein cows (32.98 kg/d of milk yield) from 10 intensively managed farms in Brazil. A portable electronic diagnosis equipment (Ketovet, TaiDoc technology, Taiwan, China) was used for measurement of blood ketone bodies and results are expressed in m*M*. Blood was sampled from the tail's artery or vein, and the volume of 1 drop was added to a reagent strip set for β-hydroxybutyrate (BHBA) analysis and 5 s was the average time needed for the equipment to yield results. Animals with values of blood BHBA of less than 1.1 m*M* were considered normal and free of metabolic syndrome. Animals with values between 1.2 and 3.5 m*M* were diagnosed with subclinical ketosis, and animals with values above 3.5 were diagnosed with clinical ketosis. Animals were blocked by days in milk (0–15, 16–30, 31–45, >46) and farm was used as a random effect. Data were analyzed using a t student test of least square difference and significance was declared as $P < 0.05$. From the 732 animals evaluated, 448 (47.85%) were considered free from the syndrome, 279 (38.11%) had subclinical ketosis and 5 (0.68%) had clinical levels of BHBA. Similar BHBA levels were found for cows between 0 and 15 DIM (1.07 m*M*), between 16 and 30 DIM (1.15 m*M*) and between 31 and 45 DIM (1.06 m*M*), but were significantly higher for cows with more than 46 DIM (1.34 m*M*, SEM = 1.34, $P < 0.01$). Results of this experiment suggest that cows with more than 46 DIM had subclinical ketosis and values of BHBA that were higher than for all cows with less than 45 DIM.

Key Words: transition period, metabolic syndrome, ketone bodies

T426 Evaluation of camelina meal as a feedstuff for growing dairy heifers.

Rhea D. Lawrence* and Jill L. Anderson, *Dairy Science Department, South Dakota State University, Brookings, SD.*

Our objective was to evaluate growth performance of dairy heifers fed camelina meal (CM) compared with linseed meal (LN) or reduced-fat distillers dried grains with solubles (DG). A 12-wk randomized complete block design study was conducted using 33 Holstein and 9 Brown Swiss heifers (144.8 ± 22 d of age; body weight (BW) 171.8 ± 24.3 kg) with 3 treatments. Treatments were 10% of the diet as CM, LN, or DG (DM basis). Concentrate mixes also included corn and soybean meal, at slightly different inclusion rates to make diets isocaloric and isonitrogenous. All diets contained 60% grass hay and 40% concentrate mix. Diets were limit-fed to 2.65% of BW (DM basis) using a Calan gate feeding system. Frame sizes, BW, and body condition scores (BCS) were measured on 2 d during wk 0, 2, 4, 6, 8, 10, and 12. Data were analyzed using MIXED procedures with repeated measures and ADG was found using REGRESSION procedures of SAS 9.4. Heifer DMI was similar between CM and LN, but greater ($P = 0.03$) for DG (4.83, 4.82, and 5.03 kg/d; SEM = 0.17 for CM, LN, and DG, respectively). Body weights (199.5, 210.9, and 205.1 kg; SEM = 2.86) were found to be less ($P < 0.01$) for heifers fed CM and greatest for LN, which could be due to unequal initial BW. Treatments had similar ($P > 0.05$) ADG (0.67, 0.75, 0.71 kg/d; SE = 0.15). Gain to feed was similar for CM and DG, but greater ($P < 0.05$) for LN (0.14, 0.17, 0.15 kg/d; SEM = 0.006). Hip height (116.3, 115.8, and 115.4 cm; SEM = 0.67), withers height (112.3, 112.3, and 112.4 cm; SEM = 0.47), and heart girth (128.6, 128.3, and 128.9 cm; SEM = 0.81) were similar ($P > 0.05$) among treatments. Hip width (31.7, 31.3, and 31.4 cm; SEM = 0.27) and body length (105.2, 102.0, and 103.3 cm; SEM = 0.77) were greater ($P < 0.05$) for CM compared with LN and DG. Body condition score (3.16, 3.10, and 3.17; SEM = 0.02) was greater ($P < 0.01$) for CM and DG compared with LN. Feeding CM maintained frame growth and ADG but decreased gain to feed compared with DG and LN. The decreased feed efficiency may be related to glucosinolates in the CM. Further research should be conducted before implementing CM as a primary protein source for growing heifers.

Key Words: camelina meal, dairy heifer

T427 Evaluation of the incidence of subclinical ketosis for F_1 Gir x Holstein lactating dairy cows supplemented with medium-chain fatty acids.

Rafahel C. Souza[1], Rogério C. Souza[1], Vanessa A. Teixeira[1], Joaquim H. C. M. Souza Junior[1], Igor C. Leal[1], Andre B. D. Pereira*[2], and Maria I. V. Melo[1], [1]*Pontifícia Universidade Católica de Minas Gerais, Betim, MG, Brazil,* [2]*University of New Hampshire, Durham, NH.*

The use of medium-chain fatty acids (MCFA) during the periparturient period can alleviate the effects of negative energy balance and improve animal health in early lactation dairy cows. The objective of this study was to evaluate blood β-hydroxybutyrate (BHBA) of 30 early-lactation F_1 Gir × Holstein cows supplemented with MCFA. Diets were formulated according to the NRC (2001) model and contained 50% forage as corn silage and chopped sugar cane. Concentrate was based on ground corn, soybean meal, citrus pulp and minerals in 2 treatments: (1) no addition of MCFA (0FA); and (2) addition of 40 g of MCFA [40FA, 0.186% of dry matter as toplac rumacel (Nutrifarma, Taio, PR, Brazil)]. The experiment was a completely randomized design and cows were supplemented with MCFA during the periparturient period (from 21 d before parturition until 21 d after). A portable electronic diagnosis equipment (Ketovet, TaiDoc technology, Taiwan, China) was used for measurement of BHBA and results are expressed in m*M*. Blood was sampled from the tail artery or vein, and the volume of 1 drop was added to a reagent strip set for BHBA analysis. Samples were collected and analyzed at the day of parturition and then again after 42 and 70 d in milk. Animals with values above 1.2 m*M* were diagnosed with subclinical ketosis. Data were analyzed using the MIXED procedure of SAS and significance was declared at $P < 0.05$. At the day of parturition, 73.4% of cows in 0FA (11 out of 15) had subclinical ketosis while only 6.6% (1 out of 15 cows) of cows on 40FA had subclinical ketosis ($P < 0.05$). The proportion of cows with subclinical ketosis was reduced to 40% for 0FA and slightly increased to 13.4% for 40FA after 42 d in milk and this proportion remained for after 70 d in milk, being significantly different between treatments ($P < 0.05$). Results of this study suggests that F_1 Gir × Holstein cows receiving diets based on corn silage and chopped sugar cane supplemented with MCFA may have lower incidence of subclinical ketosis when compared with non-supplemented cows.

Key Words: dairy cow, medium-chain fatty acids, subclinical ketosis.

T428 Milk production and composition of F_1 Gir x Holstein lactating cows supplemented with medium-chain fatty acids during the periparturient period.

Rafahel C. Souza[1], Rogério C. Souza[1], Vanessa A. Teixeira[1], Igor G. Leal[1], Joaquim H. C. M. Souza Junior[1], Andre B. D. Pereira*[2], and Maria I. V. Melo[1], [1]*Pontifícia Universidade Católica de Minas Gerais, Betim, MG, Brazil,* [2]*University of New Hampshire, Durham, NH.*

Subclinical ketosis is usually associated with negative energy balance in early lactation. The use of medium-chain fatty acids (MCFA) during the periparturient period can alleviate the negative energy balance and improve animal health. The objective of this study was to evaluate 30 F_1 Gir × Holstein lactating dairy cows for milk production and composition when supplemented with MCFA during the periparturient period. Diets were formulated according to the NRC (2001) model and contained 50% forage as corn silage and chopped sugar cane. Concentrate was based on ground corn, soybean meal, citrus pulp and minerals in 2 treatments: (1) No addition of MCFA (0FA) and (2) Addition of 40 g of MCFA (40FA, 0.186% of DM) as Toplac Rumacel (Nutrifarma, Taio, PR, Brazil). The experiment was a completely randomized design and cows were supplemented with MCFA during the periparturient period (from 21 d before parturition until 21 d after). Analyses of milk yield and composition were done weekly and collections were made on d 7, 14, 21, 28, 35, 42, 49, 56, 63 and 70 after parturition for each cow. Data were analyzed using the MIXED procedure of SAS and means were compared using the Tukey adjustment with significance declared as $P < 0.05$. Milk yield was higher for cows on 40FA (26.97 kg/d) when compared with cows on 0FA (25.50 kg/d, $P < 0.05$), but this trend only happened from 35 d after parturition until 70 d. Milk fat and protein yields were not different between treatments and days sampled. Somatic cell count was lower (64,260 cells/mL) for cows on treatment 40FA compared with 0FA (98,800 cells/mL, $P < 0.05$) suggesting that MCFA can improve mammary health. Results of this study suggest that supplementation of MCFA improved milk production and composition of F1 Gir x Holstein cows when compared with non-supplemented cows.

Key Words: dairy cow, milk production and composition, medium-chain fatty acids

T429 Effects of casein, glucose, and acetate infused into the abomasum of feed-restricted cows on milk and milk components yield.

Marina A. C. Danes*[1], Michel A. Wattiaux[1], and Glen A. Broderick[2], [1]*University of Wisconsin-Madison, Madison, WI.* [2]*Broderick Nutrition & Research LLC.*

Amino acids and glucose have been shown to regulate protein synthesis in the mammary gland through cell signaling. Acetate might also have an effect through AKT pathway, since it is the main energy source for the mammary secretory cell. Six Holstein multiparous cows, averaging 55 kg milk/d, were used in a 6x6 Latin square with 14-d periods. In each period, cows were fed the same diet for 10 d, after which they were feed-restricted for 4 d to 85% of ad libitum intake and abomasally infused for 1 of 6 treatments: acetate (A), glucose (G), each at 5% of ad libitum metabolizable energy intake (Mcal/d), casein (C) at 15% of ad libitum metabolizable protein intake (g/d), A+C (AC), G+C (GC), or a saline solution (S, negative control). Data from d 13 and 14 of each period were analyzed with Proc Mixed of SAS, using data from the d 9 and 10 as covariate. LS means are reported in the table. Casein by itself had no effect on any of the variables, compared with the negative control. This could be a consequence of lack of energy due to feed restriction, since glucose infused with casein numerically increased milk protein yield by 121 g/d. Glucose increased milk yield and nitrogen use efficiency, as indicated by the lowest MUN. Acetate had no effect on any of the variables, rejecting our hypothesis that it would enhance milk protein synthesis by improving energy status of the cell. Instead, acetate was used for fat synthesis as shown by the numerically greater fat yield for the acetate treatments. Interestingly, the infusion of casein along with acetate increased milk fat secretion more than acetate alone, which might be related to the effect of specific AA on fat synthesizing enzymes recently reported in the literature.

Table 1 (Abstr. T429).

Item	A	AC	C	G	GC	S	SEM	*P*-value
Milk, kg/d	37.2^{B}	39.2^{AB}	38.4^{AB}	42.2^{A}	41.3^{AB}	37.1^{B}	1.8	<0.10

T430 The effect of pelletized corn stover replacing alfalfa hay on lactation performance, blood parameters and rumen fermentation in mid-lactation dairy cows.

H. Z. Sun*[1,2], Z. H. Wei[1,2], Wen Zhu[1,2], X. Xie[1,2], J. K. Wang[1,2], L. L. Guan[3], and J. X. Liu[1,2], *[1]Institute of Dairy Science, College of Animal Sciences, Zhejiang University, Hangzhou, China, [2]MoE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, China, [3]Department of Agricultural, Food & Nutritional Science, University of Alberta, Edmonton, Canada.*

This study was conducted to investigate the effect of pelletized corn stover replacing alfalfa hay on lactation performance, blood parameters and rumen fermentation dairy cows. Twenty multiparous Holstein dairy cows were blocked based on days in milk (219 ± 49.5 d, mean ± SD) and milk yield (25.4 ± 4.03 kg, mean ± SD), and were randomly assigned into one of 2 dietary treatments with similar concentrate mixture, but different forage ingredients (as DM basis): 15% of pelletized corn stover pellets (CS) or 12.2% of alfalfa hay (AH). Two diets had similar content of net energy for lactation (1.57 vs. 1.58 Mcal/kg DM), but differed in crude protein content (15.8 vs. 16.7 for CS and AH). After feeding for 3 weeks, the rumen fluid and blood samples were collected. The data were analyzed using MIXED procedure of SAS software. The DM intake of diet did not differ ($P = 0.72$) between 2 diets, with an average of 16.5 kg/d. Milk yield in AH-fed cows was 0.87 kg/d higher than the CS-fed, though the difference was not significant ($P = 0.53$). No difference was observed between 2 diets in milk protein (3.37 vs. 3.38%, $P = 0.97$), milk fat (4.15 vs. 4.25%, $P = 0.76$), lactose (4.78 vs. 4.76%, $P = 0.83$), total solid (13.7 vs.12.9%, $P = 0.16$), milk urea nitrogen (16.0 vs. 13.9%, $P = 0.19$), and somatic cell counts (206 vs. 325×10^3/mL, $P = 0.39$). The concentration of plasma glucose was significantly lower in the CS-fed cows than in AH-fed animals (1.82 vs. 2.23 m*M*, $P = 0.02$), whereas the other blood parameters (NEFA, BHBA, Ca and P) were not different ($P > 0.05$). The concentrations of ruminal total and individual volatile fatty acids showed no difference between 2 groups. From the above results, it is indicated that the pelletized corn stover can be used to replace alfalfa hay in the diet for mid-lactation dairy cows without adverse effects on lactation performance and rumen fermentation.

Key Words: pelletized corn stover, alfalfa hay, dairy cow

T431 Supplementation with artificial sweetener improves milk yield and composition and alters nutrient partitioning in lactating dairy cows.

Emma H. Wall*[1,2] and David M. Bravo[2], *[1]Pancosma, Geneva, Switzerland, [2]InVivo Animal Nutrition & Health, Saint-Nolff, France.*

Supplementation with Sucram (SUC, Pancosma, Geneva, Switzerland) increases intestinal expression of sodium-glucose co-transporter 1, glucose uptake, and mucosal growth in ruminants. This trial aimed to determine the productive implications of this response in dairy cows. Primi- and multiparous lactating Holstein dairy cows were housed together in a freestall pen and were milked using an automated milking system (AMS). For 8 weeks, SUC was blended with a carrier and was dispensed at the AMS for SUC cows (n = 91) at a rate of 2.72 kg/d (SUC dose: 2g/cow/d); control cows received no additive (n = 89). Individual cow milk production and composition, milking frequency, and BW were recorded daily. Average DMI of the pen was monitored daily and did not change throughout the study. A treatment by stage of lactation interaction was observed: in cows that were greater than 100 DIM, there was no effect of SUC on any variables measured ($P > 0.20$). In contrast in cows less than 100 DIM, SUC enhanced milk production (44.5 vs. 45.6 kg/d; $P \leq 0.10$). Milk fat (1.62 vs. 1.71 kg/d) and protein (1.41 vs. 1.46 kg/d) yields were also improved with SUC ($P < 0.02$); therefore, energy-corrected milk production was greater for SUC cows (46.0 vs. 48.0 kg/d; $P < 0.01$). There was a parity by treatment interaction for BW such that primiparous cows maintained condition regardless of treatment ($P > 0.50$) whereas multiparous cows supplemented with SUC lost BW during the trial ($P < 0.001$). Interestingly, there was also a parity by treatment interaction for number of daily milkings, which was increased by SUC in primiparous animals only ($P < 0.001$). This indicates that the increase in milk yield in those animals may have been due to greater frequency of milk removal whereas in multiparous cows it was due to mobilization of body reserves. These findings reveal that in early to mid-lactation, supplementation with SUC improves milk production performance and optimizes nutrient partitioning.

Key Words: automated milking system, feed additive, Sucram

T432 Effect of fish oil on transportation of fatty acids in plasma lipoproteins of lactating and nonlactating cows.

Einar Vargas-Bello-Pérez*[1], Gonzalo Íñiguez-González[1], Philip C. Garnsworthy[2], and Juan J. Loor[3], *[1]Pontificia Universidad Católica de Chile, Santiago, Chile, [2]The University of Nottingham, Loughborough, UK, [3]University of Illinois, Urbana, IL.*

The aim of this study was to elucidate the effect of dietary fish oil (FO) and a blend of FO and hydrogenated palm oil (PO) on transportation of fatty acids (FA) in plasma lipoproteins of lactating and nonlactating cows. Three lactating and 3 nonlactating Holstein cows (fitted with rumen cannulas) were used in 2 different 3 × 3 Latin square designs that included 3 periods of 21 d. Dietary treatments for lactating cows consisted of a basal diet (Control; no fat supplement), and fat-supplemented diets containing FO (500 g/d/cow) and FOPO (250 FO + 250 PO g/d/cow hydrogenated palm oil). For nonlactating cows dietary treatments consisted of a basal diet (Control; no fat supplement), and fat-supplemented diets containing FO (170 g/d/cow) and FOPO (85 FO + 85 PO g/d/cow). Compared with control and FOPO, FO increased plasma contents of C16:0, C16:1, C17:1, C18:2n6t, C18:2 c9t11 and C20:5n3. Nonlactating cows had higher plasma contents of C18:1t11, C18:1n9c, C20:3n6, C18:2n6c, C23:0 and C22:6n3. Only C18:2n6c was higher in lactating than nonlactating cows (37 vs. 26 g/100g). Compared with control and FOPO, FO increased HDL contents of C18:1t11, C18:2n6t, C18:2 c9t11 and C20:5n3, and increased LDL contents of C18:1t9, C18:1t11 and C20:5n3. Nonlactating cows had higher LDL contents of C18:1t9 and C18:1t11 (1.98 vs. 0.89 g/100g and 2.7 vs. 1.14 g/100g) than lactating cows. In plasma, nonlactating cows had higher contents of total SFA (46 vs. 43 g/100g), MUFA (16 vs. 11 g/100g) and C18:1 tFA (5 vs. 3 g/100g) and lower content of total PUFA (39 vs. 46 g/100g) than lactating cows. Total content of C18:1 tFA was higher in nonlactating cows than in lactating cows (7 vs. 3 g/100g). Overall, results demonstrate clear differences in plasma transport of FA, which depend on dietary FA source and lactation state.

Key Words: fish oil, plasma, lipoprotein

T433 Development and evaluation of predictive models of intake for crossbred Holstein-Zebu dairy cows.

V. L. Souza*[1], T. Z. Albertini[1], R. Almeida[2], G. B. Mourão[1], J. K. Drackley[3], and D. P. D. Lanna[1], *[1]Esalq/USP, Piracicaba, SP, Brazil, [2]Universidade Federal do Paraná, Curitiba, PR, Brazil, [3]University of Illinois, Urbana, IL.*

Equations to predict dry matter intake (DMI) of crossbred Holstein-Zebu dairy cows were developed and compared by using data of 161 treatment means from 38 Brazilian studies (n = 446 cows, milk production average = 16.60 ± 5.70 kg/d). A data set was developed of Holstein × Zebu lactating dairy cows of different degrees of breeding in confinement or pasture systems. The data were evaluated using mixed nonlinear models including study as a random effect. Body weight (BW), 4% fat corrected milk (4% FCM) and weeks of lactation (WOL) were used as independent variables in the model. The proposed model to estimate DMI (kg/d) of crossbred cows was: $[0.5552\ (\pm 0.06636) \times 4\%\ \mathrm{FCM} + 0.06332\ (\pm 0.009455) \times \mathrm{BW}^{0.75}] \times [1 - e^{(-0.7732\ (\pm 0.7019) \times (\mathrm{WOL}\ -\ 1.629\ (\pm 1.913)))}]$. The accuracy of the model was compared with 4 previously published equations by use of an independent data set. The mean square error of prediction (MSEP), mean bias, concordance correlation coefficient (CCC), and analysis of linear regression were used for evaluating models. The new model showed the lowest values of MSEP and highest CCC and r^2 compared with the other 4 equations (Table 1). The Brazilian model from Freitas et al. (2006), despite being developed in tropical conditions, showed the highest value of the MSEP. The new equations to predict DMI can be used in the formulation of diets for crossbred dairy cows under tropical conditions.

Table 1 (Abstr. T433).

Variable	DMI (kg/d)	New model (2015)	NRC (2001)	Fox et al. (2004)	Traxler (1997)	Freitas et al. (2006)
Mean, kg	16.10	16.88	16.11	15.05	16.95	15.85
Mean bias, Y – X, kg	—	−0.78	−0.01	1.05	−0.85	0.25
MSEP, kg × kg	—	1.64	2.45	2.73	2.76	6.98
MSEP Decomposition, %

T434 Soil contamination in forages: Estimation and geographical distribution.

J. R. Knapp*[1], W. P. Weiss[2], R. T. Ward[3], and K. R. Perryman[4], *[1]Fox Hollow Consulting LLC, Columbus, OH, [2]Dept. of Animal Sciences, The Ohio State University, Wooster, OH, [3]Cumberland Valley Analytical Services, Hagerstown, MD, [4]Micronutrients Inc., Indianapolis, IN.*

Titanium (Ti) concentration in forages is considered by agronomists to be the gold standard in determining soil contamination of herbaceous materials. However, Ti is not measured in routine nutrient analysis of feed ingredients. Soil contamination of forages reduces the concentration of all nutrients, and soil Fe can decrease the absorption and utilization of dietary copper and perhaps other minerals. The objectives of this study were to determine the relationship between Fe and ash concentrations and to estimate soil contamination from available analytes in commonly used forages in US dairy operations. Data from Cumberland Valley Analytical Services covering the period from 2009 to 2014 for corn silage, legume hay, mixed mostly legume (MML) silage, and mixed mostly grass (MMG) silage were used. Soil contamination was estimated using 2 independent measures, residual ash and Fe enrichment. Residual ash (RA) was calculated according to Cary et al. (1986). Fe enrichment was calculated using the measured forage Fe concentrations and soil Fe concentrations obtained from a US Geological Survey database for the matching location. Linear regression analysis was used to evaluate relationships between total ash, RA, and forage Fe concentrations. As expected, RA was highly correlated with total ash with $R^2 > 0.90$ ($P < 0.001$). Fe was also highly correlated with RA and total ash with R^2 ranging from 0.47 to 0.63 ($P < 0.001$). The relationships between Fe and ash concentrations is good across forages, and 1% or greater soil contamination occurs in a significant portion of forages (Table). Level of soil contamination was associated with geographic location. In particular, corn silages grown in the western US had higher ($P < 0.001$) levels of total ash, RA, and Fe than corn silages from the eastern and midwestern US.

Contd.

Table 1 (Abstr. T434). Level of soil contamination (% DM), percentage of samples (Prop), total ash (% DM), and Fe concentrations (mg/kg) of commonly used dairy forages, given as mean ± SD

Soil contamination		Corn silage	Legume hay	MML silage	MMG silage

T435 Comparison of two methods to quantify free amino acids in cow plasma.

Nelson Lobos*[1], Glen Broderick[2], Nancy Whitehouse[5], Daniel Luchini[3], Michel Wattiaux[1], and Peter Crump[4], *[1]Department of Dairy Science, University of Wisconsin-Madison, Madison, WI, [2]Broderick Nutrition & Research LLC, Madison, WI, [3]Adisseo S.A.S., Alpharetta, GA, [4]Department of Computing and Biometry, University of Wisconsin-Madison, Madison, WI, [5]Department of Biological Sciences, University of New Hampshire, Durham, NH.*

The objective was to determine how measurements of plasma free AA by gas chromatography (GC) after chloroformate derivatization compared with values obtained by ion-exchange chromatography (HPLC) followed by ninhydrin derivatization. Plasma was obtained from lactating dairy cows (mean DIM = 148) part of a trial were Met was abomasally infused (12 or 24 g Met/d) or fed in rumen-protected form (15 or 30 g Met/d). Blood samples (n = 89) were collected from coccygeal vessels into evacuated tubes. After centrifugation, plasma was split into 2 aliquots and stored frozen at −80°C. Each set was analyzed either by HPLC in a commercial laboratory, or in-house by GC using a kit (EZ:faast, Phenomenex). This method involved deproteinization with TCA, AA collection using solid phase extraction, derivatization with chloroformate, GC separation in a capillary column and flame ionization detection. Quantitation was based on area under the curve, using the internal standard ratio method (Norvaline). Data were analyzed by Pearson correlation (r; Table 1). However Bland-Altman posited that correlation is misleading to compare methods and instead proposed the inspection of differrence plots and limits of agreement. Calculation of concordance correlation coefficients provided a quantitative alternative (CCC; Table 1). Overall correlation between methods was 0.95 ($P < 0.001$); nevertheless, correlations varied greatly for individual AA from 0.97 for Met to 0.15 for Glu. For Met, most data were within the limits of agreement established by Bland-Altman approach. Furthermore among all AA, CCC for Met was the closest to 1 (indicating almost total agreement between methods; Table 1). For research focusing on Met, GC offers a cheaper and faster alternative to HPLC.

Contd.

Table 1 (Abstr. T435). Free AA (except Arg and Trp) in plasma measured by two methods

Amino acid	GC (μ*M*)	HPLC (μ*M*)	r	CCC

T436 Fecal starch and starch digestibility: An indirect interrelationship.

C. E. Owens[1], R. A. Zinn[2], and F. N. Owens*[3], *[1]Duke University, Durham, NC, [2]University of California, El Centro, CA, [3]DuPont Pioneer, Johnston, IA.*

Published equations to calculate total-tract starch digestibility (SD) from the concentration of starch in fecal dry matter (FS) have regression slopes that differ by more than 5 fold. Why these slopes differed and methods to improve the accuracy and precision of prediction were explored. Mathematically, SD and FS are correlated. However, 2 additional factors, starch content of dietary DM (DS) and indigestibility of diet DM (IDM = 100 – DMD, %) alter this relationship. Published literature data (204 diets fed to lactating dairy cows; 191 diets fed to feedlot cattle) that provided or allowed SD, FS, DS, and IDM to be calculated were compiled to examine this relationship. When DS and IDM were ignored, the relationship was imprecise (SD, % = 99.16 – 1.07 FS %; $R^2 = 0.81$ for lactating cows; SD, % = 99.98 – 0.44 × FS %; $R^2 = 0.88$ for feedlot cattle). Including DS improved precision (SD, % = 100.13 – 0.341 × FS%/DS%, $R^2 = 0.92$ for lactating cows; SD, % = 100.29 – 0.257 × FS%/DS%, $R^2 = 0.91$ for feedlot cattle); adding IDM increased precision further (SD, % = 100 – 1 × FS%/DS% × IDM%; $R^2 = 1.00$; $P = 1/\infty$ for all cattle). Because starch is a component of dietary DM, as SD increases IDM will decrease; hence the relationship of SD to FS is curvilinear, not linear unless the digestibility of non-starch components increases when SD increases. Knowledge of IDM and the dietary and fecal concentrations of any component of the diet including NDF allows apparent digestibility to be computed directly and avoids the need to predict digestibility from in vitro assays. Direct measurement often proves more economical analytically than in vitro procedures and avoids dependence on tabular feedstuff values in publications or computerized diet formulation programs. Combined with intake of DM, direct digestibility measurement can quantify the amount of digested energy available for production by ruminants. As with all analytical procedures, accuracy of digestibility estimates relies on representative sampling and appropriate analyses of diets and feces.

Key Words: starch digestibility, fecal starch, equation

T437 Starch and NDF digestibility by high-producing lactating cows: A field study.

B. Powel-Smith, L. J. Nuzback, W. C. Mahanna, and F. N. Owens*, *DuPont Pioneer, Johnston, IA.*

In vivo measurements are the gold standard against which in vitro procedures digestibility estimates must be judged. To quantify the relationships of in vitro ruminal disappearance to total-tract digestibility of starch and NDF, samples were obtained from the top string of lactating cows from 32 commercial herds in the Upper Midwest. Silage, TMR, grain, and fecal samples were assayed at a commercial laboratory for some of the following: starch, 7h in vitro starch digestion, NDF digestibility at 24 and 240 h, and lignin at. For calculating in vivo digestibility, lignin and UNDF served as indigestible markers. All cows were fed kernel processed corn silage (25 to 40% DM) plus dry ground or high moisture ear corn or grain; diets averaged 26% starch and 31% NDF. Except for 2 herds, starch digestibility exceeded 95% being related closely to fecal starch concentration ($R^2 = 0.98$). However, in vitro starch disappearance at 7 h was not related to total-tract starch digestibility ($R^2 = 0.00$). Total-tract digestion averaged 55% for NDF or 60% for available NDF (NDF minus UNDF240). In vivo NDF digestibility of the TMR tended to decline as its UNDF content increased ($R^2 = 0.21$), but 24 h in vitro NDF disappearance of the TMR proved to be poorly related to NDF digestibility in vivo ($R^2 = 0.13$). Kernel processing score was not related to starch digestibility, but all silage had fermented more than 6 mo before feeding. Processing score tended to be greater and presence of whole and half kernels in silage was less with shredlage than conventional kernel processing rolls but total-tract starch digestibility was not altered by processing roll type. Dry matter digestibility calculated from UNDF differed by as much as 10% from digestibility calculated from lignin. Total-tract starch digestibility was not correlated with surface area of particles or mean particle size of the dry ground corn fed. To obtain reliable and accurate estimates of energy availability for ruminants, nutritionists should rely on total-tract digestion measurements.

Key Words: in vivo digestibility, NDF, starch

T438 Effects of diets with different energy levels on growth performance and rumen environment of heifer.

Yan Tu*[1,2], Xiang Cui[1], Tao Ma[1,2], Bing-wen Si[1,2], Nai-feng Zhang[1,2], and Qi-yu Diao[1,2], [1]*Feed Research Institute of Chinese Academy of Agricultural Sciences, Key Laboratory of Feed Biotechnology of the Ministry of Agriculture, Beijing, China,* [2]*Beijing Key Laboratory for Dairy Cow Nutrition, Beijing, China.*

Thirty-two Chinese Holstein heifers (98 d old) were randomly divided into 4 groups with 8 heifers each (8 replications). Each group was subjected to one of the following 4 total mixed rations (TMR) with 2.52 (A), 2.82 (B), 2.99 (C), and 3.21 (D) Mcal of metabolic energy (ME) per kg (dry matter basis) diet for 82 d. The energy gradient was adjusted by changing the composition of concentrate and adding rumen bypass fat. The concentrate to roughage ratio of the TMR was fixed at 59.52:40.48. Growth performance was determined at 98, 120, 150, and 180 d of age, and rumen fermentation parameters were determined at 98, 120, 150, and 180 d of age, and microbial populations in rumen fluid from 181-d-old heifers were determined by real time polymerase chain reaction analysis. During 98 to 180 d of age, the average daily gain (ADG) did not differ among the groups ($P > 0.05$). However, during 151 to 180 d of age, ADG of the heifers of group D (1.11 kg/d) were greater ($P < 0.05$) than those of group A (0.77 kg/d). Feed utilization efficiency was improved in groups C and D ($P < 0.05$) when compared with that in group A. Dietary ME did not influence ruminal pH value and NH_3-N concentration ($P > 0.05$). Increasing level of ME significantly increased ruminal proportion of propionate ($P < 0.01$) and reduced that of acetate ($P < 0.05$) and the ratio of acetate to propionate ($P < 0.01$). Dietary treatments had no significant effect on the concentration of total volatile fatty acid ($P > 0.05$). *Lachospira multipara* of group C tended to be higher than that of group D ($P < 0.10$), and the numerical quantity of protozoan, *R. flaefaciens*, *R. albus*, *B. fibrisolvens* and *P. ruminicola* of group C were greater than the other groups ($P < 0.05$). Current study suggested that heifers supplemented with 2.99 Mcal of ME per kg of diet (group C) had better feed utilization efficiency and more abundant microbial flora compared with those fed other levels of ME.

Key Words: heifer, rumen fermentation parameter, ruminal microorganism

T439 Effect of tallow and soybean oil addition to calf starters fed to dairy calves from birth to four months of age on calf performance and digestion.

T. Mark Hill*, H. Gale Bateman II, James M. Aldrich, James D. Quigley, and Rick L. Schlotterbeck, *Nurture Research Center, Provimi North America, Brookville, OH.*

Energy demands for calves can increase during periods of heat and cold stress. One way to potentially increase energy intake is to increase the energy density of the feed with fat. Trial 1a compared a control starter with no added fat or oil (CON) to starters with 2% tallow (TAL) and 2% soybean oil (SOY). Starters were 20% CP and 45 to 47% starch. Male Holstein calves (n = 48) that were initially 3 to 5 d of age were fed a 27% CP, 17% fat milk replacer at 0.66 kg DM daily and fully weaned by 42 d of a 56-d trial. Trial 1b estimated the digestion of the diets (employed chromic oxide as an indigestible digesta flow marker) using a subset of 5 weaned calves per treatment between d 52 and 56. Trial 2 used 48 Holstein calves initially 59 to 61 d of age fed starters CON and SOY blended with 5% chopped grass hay over a 56-d trial. Trial 3 used 48 Holstein calves initially 59 to 61 d of age fed starters CON and TAL blended with 5% chopped grass hay over a 56-d trial. Treatments were compared in a randomized ANOVA using repeated measures. In Trials 1a and 1b, pre-planned contrasts compared CON vs. TAL and CON vs. SOY ($P < 0.05$) Compared with CON, calves fed SOY had reduced starter intake, ADG, and digestion of DM, OM, and CP vs. CON before 8 weeks of age ($P < 0.05$). Compared with CON, calves fed SOY had reduced ($P < 0.05$) ADG and change in hip width from 2 to 4 mo of age. Compared with CON, calves fed TAL had reduced ($P < 0.05$) ADG and tended ($P < 0.1$) to have reduced change in hip width from 2 to 4 mo of age. Calculated ME intake was not increased in any trial by added fat or oil. Tallow and soybean oil inclusion at 2% of the starter feed was not advantageous for calf growth before 4 mo of age.

Key Words: fat, oil, digestion

T440 Relationships between udder resistance and dietary levels of copper and zinc.

Alfredo J. Escribano[1], Juan Jose Mallo*[1], Luis Miguel Jiménez[2], and Nuria Roger[2], [1]*NOREL Animal Nutrition, Madrid, Spain,* [2]*Servet Talavera S.L., Talavera de la Reina, Toledo, Spain.*

Mastitis constitutes the main health issue in dairy cows farms, because it is widespread and leads to high economic loses. Copper and especially zinc have shown to increase cows' resistance to mammary infections. However, the levels of these minerals in rations varies greatly, and then, there is a gap of knowledge with regard to the relationship between the levels of trace minerals in the diets used to feed dairy cows, and the incidence of mammary diseases. To contribute in this sense, we carried out this study, with the objective to evaluate the relationship between the level of zinc and copper and udder health parameters. For this purpose, 55 farms representative of the Spanish production systems were selected. The statistical procedure followed was based on bivariate correlation analysis and ANOVA. Results showed that negative and significant correlations existed between the level of dietary copper and the following indicators: Somatic Cell Counts (R2 = 0.138, $P = 0.008$) and monthly rate of clinical mastitis (R2 = 0.093, $P = 0.031$). However, no significant correlations were found with the rest of indicators: mastitis prevalence, new infections rate, curation rate in lactation, curation rate in the dry period, and new infections rate at calving. Regarding zinc levels, a significant correlation was found with the curation rate in the dry period ($R^2 = 0.136$, $P = 0.008$). As it can be observed, weak and few correlations were found. Surprisingly and contrary to most of the scientific knowledge, the effect of zinc had a low impact on udder health and resistance. These results could be showing interactions between minerals levels and other dietary compounds. Also, as levels of zinc were above the recommendations, a low response to increasing zinc levels was found. On the contrary, as not all diets were satisfying animals' needs for copper, higher responses to the level of this mineral were found. Further research is needed to have a deeper knowledge about both minerals interactions and the levels of minerals above which host's resistance do not increase significantly.

Key Words: dairy, mastitis, mineral

T441 Use of a fermented ammoniated condensed whey product in lactating dairy cattle. John P. McNamara*[1], Drina Huisman[1], Heather M. Hastings[1], and Gerald Poppy[2], [1]*Washington State University, Pullman, WA,* [2]*Packerland Whey Product Inc., Luxemburg, WI.*

An existing fermented ammoniated condensed whey product (LactoWhey) has been in use in dairy rations for more than 30 years; however the last published studies were almost 30 years ago. It was of interest to test the efficacy of using this product in more modern dairy rations typical of the northwestern US dairy region which contain a wide variety of protein sources and by-product feeds. Therefore, a field trial was conducted at 3 commercial dairies and one university dairy. Lactowhey is liquid fermented ammoniated condensed whey containing 44% CP equivalent and 38% lactic acid equivalent from ammonium lactate. Lactowhey was added to the ration to replace other protein sources (primarily SBM and Canola meal) on a CP equivalent basis. Rations were balanced and fed to meet requirements to multiple pens on each commercial dairy (or through individual feeding gates on the university dairy) starting from an average of 66 DIM for 90 d. On the commercial dairies, milk tank weights and composition were recorded as well as DHIA test day milk and composition. A subset of 18 to 20 cows in each pen was followed for individual milk and composition, and rumen fluid and blood was sampled at 0, 3 and 13 wk of treatment (at the university dairy all cows (n = 20 per treatment group) were also sampled at 6 wk of treatment. Milk production ranged from 35.9 to 45.5 kg/d at start of trial and 41.7 to 35.2 kg/d during treatment period, with no effect of treatment. Milk composition averaged 3.80% and 3.21% and 12.3 mg/dl for fat and protein and MUN across the period and farms, with no effect of treatment. There were no differences due to treatment in BW or BCS change, or rumen pH or in blood NEFA, glucose or BUN. The proportion of rumen bacterial DNA as measured by microbiome analysis was primarily *Prevotella* species, with a variety of other species represented. Species proportions varied among the 4 dairies and among individual cows, with a generally consistent pattern within dairies and individual cows. There was no consistent effect of the fermented whey on bacterial proportions. The work confirms the utility of this fermented whey product to support high milk production in commercial herd when used to replace other protein sources.

Key Words: ammoniated whey, protein substitution, lactation

T442 Evaluating varying dietary protein and energy levels for economical productive performance of Nili-Ravi buffalo heifer calves. Zeeshan Muhammad Iqbal*[1], Muhammad Abdullah[1], Khalid Javed[1], Makhdoom Abdul Jabbar[1], and Juan J. Loor[2], [1]*University of Veterinary and Animal Sciences, Lahore, Pakistan,* [2]*University of Illinois at Urbana-Champaign, Urbana, IL.*

The optimal dairy management programs are based on rearing of heifers at a low cost without compromising growth rate. The aim of this study was to investigate the effect of dietary protein and energy level on growth and metabolic parameters of Nili-Ravi buffalo heifers. The experiment was conducted with 30 female buffalo calves (6–8 mo age) divided randomly into 3 treatment groups (n = 10/group). The animals in treatment A, B and C were offered 3 different levels of concentrate (CP 17% and 2.6 Mcal ME/kg) at 0.5%, 1% and 1.5% of body weight, respectively. In addition to this, all animals were given chopped green fodder (sorghum and maize) and fresh water ad libitum. All data were collected on individual animals for a total of 8 mo. As designed, the average daily protein and energy (585.94 ± 15.36 g, 13.08 ± 0.34 MJ/kg) intake was greater in treatment C and lower (374.70 ± 10.09 g, 9.56 ± 0.26 MJ/kg) in treatment A. The differences in intake did not affect ($P > 0.05$) average daily gain of heifers (497.32.69 ± 17.92, 503.63 ± 19.09 and 532.77 ± 20.67 g/d). Thus, feed efficiency estimates were greater for treatment A (0.135 ± 0.004) as compared with treatments B and C (0.113 ± 0.003, 0.108 ± 0.004). Dietary treatments did not affect ($P > 0.05$) blood profile but serum urea concentration was greater in treatment B and C (50.08 ± 2.05, 51.41 ± 2.29) compared with treatment A (42.34 ± 1.59). Increasing nutrient intake had no effect ($P > 0.05$) on the digestibility of organic matter, fat, ash, ADF. However, the digestibility of diet DM, crude protein and ADF was greater in treatment C (71.14 ± 0.96, 65.85 ± 0.88, 56.09 ± 1.02%) as compared with treatment A (66.06 ± 2.32, 61.21 ± 1.72, 51.43 ± 2.13%) and B (67.22 ± 1.09, 62.01 ± 1.20, 52.91 ± 1.32%). The cost for production (USD) of per kg gain was higher in treatment C ($2.42) and lower in lower in treatment A ($1.34) and B ($1.96), respectively. As increasing dietary concentrate intake had no effect on growth rate, the estimated efficiency of utilization of nutrients was better and cost per kg gain was lower with the 0.5% concentrate inclusion. Thus, this level of concentrate in the diet at a rate of 0.5% of body weight appears most economical for rearing Nili-Ravi buffalo heifers from 6 to 14 mo of age.

Key Words: protein, energy, heifer

T443 Trace mineral variation in dairy forages: Where are the hot spots? J. R. Knapp*[1], W. P. Weiss[2], R. T. Ward[3], and K. R. Perryman[4], [1]*Fox Hollow Consulting LLC, Columbus, OH,* [2]*Dept. of Animal Sciences, The Ohio State University, Wooster, OH,* [3]*Cumberland Valley Analytical Services, Hagerstown, MD,* [4]*Micronutrients Inc., Indianapolis, IN.*

The objectives of this study were to quantify the variation in trace mineral (TM) concentrations in forages, evaluate the contribution of US geographical location and harvest season to the TM variation, and identify areas where high variation in TM concentrations would preclude using standard reference concentrations. Trace minerals of interest were Cu, Mn, Zn, and Fe. Data from Cumberland Valley Analytical Services covering the period from 2009 to 2014 with concentrations of major nutrients as well as mineral concentrations were used. Data were statistically filtered to remove outliers based on macronutrient concentrations and misidentified feeds before analyses of TM variation. As expected, TM concentrations for corn silage, legume hay, mixed mostly legume (MML) silage, and mixed mostly grass (MMG) silage displayed skewed distributions. TM values were log normalized before ANOVA with location, season, and their interaction as independent effects and total ash concentration as a covariate. Variation in TM concentrations due to location and total ash were significant ($P < 0.0001$) and the largest sources. Season was often non-significant ($P > 0.20$), while the interaction between location and season was significant ($P < 0.05$). Whereas forages in some US locations have consistently low TM concentrations, forages in other areas have both high concentrations and high variation. These results support sampling and analysis of forages and formulation of dairy rations for TM based on analytical results rather than reference values. Recommendations for sampling frequency will vary by location as a function of the observed variation in TM concentrations.

Table 1 (Abstr. T443). Lowest and highest variation in observed Cu and Zn concentrations among U.S. geographical locations, given as median and 5th (p5) to 95th (p95) percentiles in mg/kg

	Lowest variation			Highest variation		
Item	Median	p5	p95	Median	p5	p95

Key Words: copper, zinc, mineral variation

T444 Evaluating carbon and oxygen flux variability and heat production in dairy cows using a portable automated gas quantification system.

Andre B. D. Pereira*[1], Andre F. Brito[1], Santiago A. Utsumi[2], Brianna J. Isenberg[1], and Kelly S. O'Connor[1], *[1]University of New Hampshire, Durham, NH, [2]Michigan State University, W. K. Kellogg Biological Station, Hickory Corners, MI.*

The objectives of this study were (1) to evaluate the variability in spot short-term measurements of CO_2 ($Q\text{CO}_2$) CH_4 ($Q\text{CH}_4$) emissions and O_2 consumption ($Q\text{O}_2$), and (2) estimate heat production (HP) from dairy cows fed diets with different RDP and NSC profiles. Eight multiparous and 4 primiparous lactating Holstein cows were blocked by days in milk and milk yield into replicated 4 × 4 Latin squares. Cows received corn silage, grass-legume haylage, roasted soybean, and (1) corn meal and urea (negative control), (2) corn meal, soybean meal, and rumen-protected Lys-Met (positive control), (3) field peas, corn meal, and soybean meal, or (4) field peas, corn meal, soybean meal, and rumen-protected Lys-Met. Gas measurements were performed using a portable automated gas quantification system (Greenfeed, C-Lock Inc., Rapid City, SD) fitted with sensors for CO_2, CH_4 and O_2. Cows were sampled 3 times daily (about 8 h apart) for 7 d, with sampling points advanced 2 h in the following day to account for diurnal variation of gas flux. Heart rate was monitored for 4 d to calculate $Q\text{O}_2$/heartbeat (n = 4 cows). Heat production was calculated according to Kaufmann et al. (2011): [(4.96 + 16.07/respiratory quotient) × $Q\text{CO}_2$]. Filtering of gas sampling by variable head position or low visitation to the gas quantification system (n = 2) resulted in lower number of gas flux points than anticipated (316 valid measurements of 1,008 possible). Each gas sampling lasted, on average, 3.7 min. For all treatments, the within animal CV averaged 25.5% ($Q\text{CH}_4$), 15.4% ($Q\text{CO}_2$), and 22.3% ($Q\text{O}_2$) and the between animal CV averaged 7.0% ($Q\text{CH}_4$), 4.3% ($Q\text{CO}_2$), and 5.8% ($Q\text{CO}_2$). There was no difference between treatments for $Q\text{CH}_4$ (mean = 373.5 g/d), $Q\text{CO}_2$ (mean = 6,293 L/d), $Q\text{O}_2$ (mean = 7,307 L/d), HP (mean = 149 MJ/d), $Q\text{O}_2$/heartbeat (mean = 66.1 L/heartbeat), and HP/heartbeat (mean = 20.7 MJ/heartbeat). Short-term spot measurements of gas flux can be used to estimate HP in dairy cows. However, sampling rate needs to be optimized, when using the automated gas quantification system, to reduce variability.

Key Words: carbon emission, oxygen consumption, heat production

T445 Influence of a grape seed and grape marc meal extract (GSGME) on performance parameters, hepatic expression of pro-inflammatory and ER stress-related genes and antioxidant status in dairy cows.

Denise K. Gessner[1], Christian Koch[2], Franz-Josef Romberg[2], Anne Winkler[3], Georg Dusel[3], Eva Herzog[1], Erika Most[1], Anne-Kathrin Blässe*[4], Bernhard Eckel[4], and Klaus Eder[1], *[1]Justus Liebig University Giessen, Giessen, Germany, [2]Lehr- und Versuchsanstalt Hofgut Neumühle, Neumühle, Germany, [3]University of Applied Sciences Bingen, Bingen, Germany, [4]Dr. Eckel GmbH, Niederzissen, Germany.*

At the onset of lactation, inflammation and stress of the endoplasmic reticulum (ER) occurs in the liver resulting in impaired hepatic function with undesirable effects on the health status of high yielding dairy cows. The present study investigated the hypothesis that feeding a polyphenol-rich grape seed and grape marc extract (GSGME) has the potential to suppress the inflammatory process and ER stress in the liver during early lactation. Twenty-eight German Holstein cows received either a total mixed ration (TMR, control group) or the same TMR supplemented with 1% GSGME (polyphenol content: 43 mg/g; Anta Ox, Dr. Eckel GmbH) from wk 3 ap to wk 9 pp (experimental unit: single cow). Milk, blood, and liver samples were taken. Data were statistically evaluated by the linear mixed-effects model of R. Dry matter intake of the cows did not differ between the 2 groups. However, the GSGME group had a greater milk performance (Δ milk yield: + 3.7 kg/d; $P < 0.05$; Δ energy corrected milk: + 2.9 kg, $P < 0.05$) from wk 2 to 9 of lactation. Cows of the GSGME group had lower hepatic mRNA concentrations of FGF21, a key marker of ER stress ($P < 0.05$) and a tendency toward lower hepatic levels of triglycerides and cholesterol ($P < 0.15$). A reduction of mRNA concentrations of various other ER stress response-related and pro-inflammatory genes could be observed in the GSGME group. Feeding GSGME had no effect on the antioxidative status (α-tocopherol, β-carotene, TBARS and total antioxidant capacity in plasma). In conclusion, the study suggests that feeding polyphenol-rich plant extracts during early lactation could be a useful strategy to prevent inflammatory processes and ER stress in the liver and thus improve milk yield and animal health in dairy cows.

Key Words: grape seed extract, grape seed meal extract, dairy cow

T446 Effects of *Saccharomyces cerevisiae* fermentation products on dairy calf: I. Pre-weaning performance and post-weaning stress.

G. M. Alugongo*[1], J. X. Xiao[1], R. Chung[2], S. Z. Dong[1], S. L. Li[1], I. Yoon[2], and Z. J. Cao[1], *[1]State Key Laboratory of Animal Nutrition, Department of Animal Nutrition and Feed Sciences, China Agricultural University, Beijing, China, [2]Diamond V, Cedar Rapids, IA.*

The aim of the study was to evaluate the effects of *Saccharomyces cerevisiae* fermentation products (SCFP) on performance and health of calves during the first 63 d of age. New Zealand Holstein calves (30 male and 30 female) at 2 d of age were blocked by sex and date of birth then randomly assigned within blocks to one of 3 treatments. A texturized grain starter was fed ad libitum containing 0 (Control), 0.5 or 1% SCFP (Original XPC, Diamond V) of DM. The basal diet contained steam-flaked corn (33.1%), wheat bran (7.6%), Soybean meal (14.3%), Extruded soybean (4.2%), canola meal (8.0%), and DDGS (16.0%) and was without antibiotics. In addition, the supplemented calves were fed 1 g/d SCFP (SmartCare, Diamond V) in milk from d 2 to 30. All calves were fed 4 L of colostrum within 1 h of birth and were subsequently fed milk twice daily until weaned at 56 d of age. Performance and health of all weaned female calves were monitored until 63 d of age to determine the effect of pre-weaning treatment of SCFP on weaning stress. Starter intake, fecal score and medical treatment were recorded daily. Body weight measures and blood samples were collected on d 2, 28, 56, and 63. Serum was analyzed for BUN, NEFA, IGF-1, glucose, albumin, total protein and oxidative biomarkers. Data were analyzed by MIXED procedure in SAS with contrast statement to declare Control vs. all SCFP, and 0.5% SCFP vs. 1% SCFP in starter grains. Calf was the experimental unit. Body weight, DMI, blood parameters and oxidative biomarkers did not differ. Supplementation of SCFP lowered ($P < 0.05$) fecal scores, and diarrhea frequency. Number of medical treatments and medication costs were also lower ($P < 0.05$) with SCFP. After weaning, SCFP reduced diarrhea in a dose-dependent manner with greater effect seen with 1% SCFP in starter grain. Overall, SCFP reduced diarrhea and pre-weaning medical costs and helped calves better manage weaning stress. The effects of SCFP were greater with the higher dosage of SCFP in starter grain.

T447 Fibrolytic enzyme and corn silage differing in particle size for lactating dairy cows.

Gilson S. Dias Júnior*[1], Alan S. Pereira[1], Fabiana F. Cardoso[1], Renata A. N. Pereira[3,2], and Marcos N. Pereira[1,2], [1]*Universidade Federal de Lavras, Lavras, MG, Brazil,* [2]*Better Nature Research Center, Ijaci, MG, Brazil,* [3]*Empresa de Pesquisa Agropecuária de Minas Gerais, Lavras. MG, Brazil.*

The majority of Brazilian dairy farms use pull-type, one row forage harvesters for ensiling corn. For such machines, a kernel processor (KP) was developed (MU9000462–0 U2 INPI patent). We evaluated the response of cows to corn silage (CS) short particles-no KP (S, 3 mm theoretical cut) compared with long particles-KP (L, 8.5 mm). The supplementation of fibrolytic enzyme (F, Fibrozyme, Alltech) was evaluated in a 2 × 2 factorial. Sixteen individually fed Holsteins (110 ± 62 DIM) received treatments in 28-d periods, 4 × 4 LS. Corn was harvested at half milk line maturity and ensiled in 3 m diameter bag silos for 138 d. Silage S had 44.8% of particles below the 8 mm screen and L had 25.3%. Diets contained 31.6% of DM as the treatment CS, 17.1% of a standard CS, 1.9% Tifton hay, and 31.7% starch. Diet S had 1.9% of DM as NDF above the 19 mm screen, 12.3% from 8 to 19 mm, and 17.8% below 8 mm, and L had 3.0%, 15.6%, and 13.9%, respectively. The TMR was mixed manually twice per day immediately before feeding to avoid particle size reduction. Silage L increased 4% FCM (29.5 vs. 28.2 kg/d, $P = 0.09$) and fat yield ($P = 0.04$), and had no impact on DMI (22.0 kg/d, $P = 0.50$). There were trends for reduced milk fat content and yield in response to F ($P < 0.15$). Silage S reduced ruminal fluid pH and the proportion of acetate in VFA, but increased butyrate and protozoa content ($P < 0.05$). Total-tract OM and NDF digestibility tended to be increased by F only when S reduced nutrient digestibility ($P = 0.09$ for interaction of CS and F).The daily urinary allantoin secretion was increased only when F supplemented S ($P = 0.03$ for interaction of CS and F). Fecal viscosity and DM content were also reduced when F was added to S ($P < 0.02$ for interaction of CS and F). The loss of visible damaged corn kernels in feces was reduced by F ($P = 0.05$), but the excretion of intact kernels was similar ($P = 0.92$). Silage L tended to increase rumination bouts/bolus ($P = 0.10$) and the duration of the first daily meal ($P = 0.08$), and increased chewing activity per day and per unit of DMI ($P < 0.03$). There was a trend for reduced PUN on F ($P = 0.07$). Fibrolytic enzyme was beneficial to digestion only when fiber digestibility was reduced by short particles CS. Long particles CS increased lactation performance and chewing activity.

Key Words: fibrolytic enzyme, corn silage, particle size

T448 Meta-analysis to examine the effect of supplemental sugar on dairy cow performance as influenced by diet nutrient components.

Stephen M. Emanuele*[1], Mary Beth de Ondarza[2], and Charles J. Sniffen[3], [1]*Quality Liquid Feeds, Dodgeville, WI,* [2]*Paradox Nutrition LLC, West Chazy, NY,* [3]*Fencrest LLC, Holderness, NH.*

A data set was compiled from published research (n = 85) that tested the effect of supplemental dietary sugar. Forage NDF ranged from 17 – 29% DM and calculated total sugar from 2.3 - 11% DM. Mixed model analysis was conducted using JMP statistical software (SAS Inst. Inc., Cary, NC) with nutrient parameters (CNCPS 6.1 with NDS platform, RUM&N Sas, Italy) as main effects. Model fit used treatment (Control vs. 1.5–3% added sugar vs. 3–5% added sugar vs. 5–7% added sugar), DIM (<150 or >150 DIM) within treatment, and Milk Yield (<33 or >33 kg/d) within treatment as independent factors with experiment as the random effect. Responses were analyzed with the following nutrients (%DM) in the model: starch, soluble fiber, forage NDF, ammonia, RDP, and Protein B2. Protein B2 is true protein that can contribute to dietary RUP. Number of cows per treatment was included as a weighting factor. Nutrients with a positive effect on 3.5% FCM yield were sugar (+1.45 kg) ($P < 0.04$), starch ($P < 0.01$) and soluble fiber ($P < 0.05$). Higher producing cows (>33 kg milk/d) had a greater response (2.14 kg FCM/d) to sugar than cows producing <33 kg of milk ($P < 0.0001$). Nutrients with a positive effect on milk protein yield were sugar (+0.07 kg; $P < 0.05$) and starch ($P < 0.0001$). Cows producing > 33kg milk had a greater milk protein response to sugar (0.09 vs. 0.05 kg/d than cows producing <33 kg milk/d, ($P < 0.001$). Sugar did not affect milk fat yield ($P = 0.16$), although starch and soluble fiber had a positive effect ($P <= 0.05$). Sugar alone did not affect feed efficiency but starch ($P = 0.04$), soluble fiber ($P = 0.01$), and Protein B2 ($P = 0.03$), all had a positive effect with a mean increase of 0.06 units with 3–5% supplemental sugar. Nonlinear statistical analysis using JMP Neural Net function determined optimal total calculated sugar to be 6.75% of diet DM. Optimal range for starch when feeding supplemental sugar was 20 – 25% of diet DM. Sugar did not affect milk fat or protein percent. In conclusion, 3 to 5% supplemental sugar (6 to 8% total sugar (%DM)), and starch (%DM) increased FCM (kg/d), and milk protein yield. To optimize response to supplemental sugar, the diet should contain >17% forage NDF, 10 −11% RDP and less than 30% starch.

Key Words: sugar, meta-analysis, dairy

T449 Pre- and post weaning performance and health of dairy calves fed milk replacers with plant and milk protein by-product sources balanced for selected amino acids. Hugh Chester-Jones*[1], Dustin Dean[2], David Ziegler[1], and Kevin Halpin[2], *[1]University of Minnesota Southern Research and Outreach Center, Waseca, MN, [2]International Ingredients Corporation, St. Louis, MO.*

One-hundred three (9 to12 d old) individually fed Holstein heifer calves (41.8 ± 0.66 kg) were randomly assigned to 1 of 4 treatments to evaluate pre- (d 1–35) and post-weaning (d 36 to 49) calf performance and health when fed milk replacers (MR) with alternative protein sources. The study was conducted between April and August, 2014. All calves were fed a common all-milk non-medicated 22% CP:18% fat as-fed MR before the study was initiated. Calves were fed the non-medicated 22% CP:18% fat MR with either (1) All milk protein; (2) 33% of the protein replaced with dried partially hydrolyzed vegetable protein, partially autolyzed yeast and dairy solids; (3) 33% of the protein replaced with a milk extender made from dairy ingredients, edible lard, hydrolyzed vegetable proteins and yeast; or (4) 25% proteins from co-drying cheese and whey by-products. Milk replacers were formulated to be equivalent in lysine and sulfur amino acids. The MR were fed at 0.284 kg in 1.99 L water (12.5% solids) 2× daily from d 1 to 28 and 1× daily from d 29 to weaning at d 35. Calf starter (CS; 18% CP) and water were fed free choice d 1 to 49. During the first 7d of the study, calves were fed 1 part neomycin to 1 part oxytetracycline added to the MR solution to provide 22 mg/kg BW daily. There were no pre- or post weaning ADG differences ($P > 0.05$). Calves averaged 0.74 kg/d gain for the 49 d study. There were no differences ($P > 0.05$) in CS or total DMI intake which averaged 53.0 and 69.4 kg for the 49-d study, respectively. There were no differences in pre- and post weaning gain/feed. Gain/feed averaged 0.52 kg for the 49 d study. There were no differences in number of scouring d (d ≥ fecal score 3) pre- and post weaning. Days with fecal scores = 4 were higher ($P < 0.05$) for Treatment 2 calves vs. those fed Treatments 3 and 4. Health treatment costs did not differ ($P > 0.05$). Under the conditions of this study, replacing the total milk protein in MR with alternative sources resulted in calf performance and health similar to those fed an all milk protein MR.

Key Words: calf performance, milk replacer, alternative protein

T450 The effect of biochemical fulvic acid (BFA) on heat stress and lactation performance in lactating cows. Yifan Fan*, Xiaoming Zhang, and Zhijun Cao, *State Key Laboratory of Animal Nutrition, Department of Animal Nutrition and Feed Sciences, China Agricultural University, Beijing, China.*

There was almost all cows suffered heat stress in hot and humid climate in most regions of China during summer. The objective of this study was to investigate the effect of biochemical fulvic acid (BFA) on heat stress and lactation performance in lactating cows. BFA is an aromatic nitrogen compound (Shenzhoulvyuanmuye Co., Hebei Province, China). Its molecular construction determined it can be chelated trace elements. Thirty multiparous Holstein dairy cows were blocked into 2 groups by parity, days in milk, milk yield (MY) and somatic cell counts (SCC). This research was conducted from July through August 2014 (49 d). Two groups were fed same TMR. One was control group (CG) without BFA; the treatment group (TG) was added 25g BFA per cow per day. The quantity of different cows' parities is same in 2 groups (3 preparious cows, 7 s lactation cows and 5 third lactation cows). The averaged days in milk of TG versus CG were 150 ± 35 d vs. 149 ± 38 d (Mean ± SD). The MY of TG and CG was 38.4 ± 4.8, 37.9 ± 6.6 kg, respectively. The SCC of TG was 4.17×10^4 compared with CG (5.06×10^4). Cows were milked 3 times per day at 0430, 1230, and 2030 h. The MY, composition of milk, body temperature, blood samples, and respiratory rate were recorded. Data were statistically analyzed using the two-sample paired *t*-test for means procedure of SAS (version 9.2, SAS Institute Inc., Cary, NC). Although lactose, milk urea nitrogen (MUN), SCC, body temperature, and respiratory rate did not differ between TG and CG, milk yield (37.30 vs. 35.73 kg; $P < 0.01$) and concentration of milk fat (3.54 vs. 3.13%; $P < 0.05$) were significantly higher for TG compared with CG. However, the milk CP (3.29 vs. 3.18%; $P < 0.01$) of CG was higher than TG. In the meanwhile, concentration of serum GSX-px (356 vs 207 μmol/L, $P < 0.05$) was higher for TG compared with CG. These results suggested that adding BFA to lactating dairy cows during summer might increase milk yield, milk fat, relieve heat stress and not change the yield of milk CP.

Key Words: fulvic acid, heat stress, milk production

T451 Pre- and post-weaning performance and health of dairy calves fed all-milk protein milk replacers or partially replacing milk protein with plasma and plant proteins in varying combinations. . Bruce Ziegler*[1], David Ziegler[2], Hugh Chester-Jones[2], Daniel Schimek[1], Mary Raeth[3], and David Cook[4], *[1]Hubbard Feeds, Inc., Mankato, MN, [2]University of Minnesota Southern Research and Outreach Center, Waseca, MN, [3]University of Minnesota Department of Animal Science, St. Paul, MN, [4]Milk Products, Chilton, WI.*

One-hundred seven (2–5 d old) individually fed Holstein heifer calves (39.8 ± 0.70kg) were randomly assigned to 1 of 4 treatments to evaluate pre- (d 1–42) and post weaning (d 43–56) calf performance and health when fed milk replacers (MR) with alternative protein sources. The study was conducted between February and April, 2014. Calves were assigned to non-medicated 24% CP:20% fat MR with (1) All milk protein, (2) 25% of total protein from plasma, (3) 25% of total protein from plant peptide proteins, or (4) 12.5% plasma,12.5% peptide proteins. All calves were fed a non-medicated 24% CP:20% fat MR at 0.34 kg in 2.39 L water (12.5% solids) 2× daily for the first 35 d and 1× daily d 36 to weaning at 42 d. Day 1 to 14, 1:1 neomycin:oxytetracycline was added to the MR solution to provide 22 mg/kg BW/d. Calf starter (CS; 18% CP as-fed) and water were fed free choice from d1. Milk replacer feeding rate was adjusted if ambient temperatures taken 0800 h were −23.3 to −28.3°C (+ 20% volume) or > −28.9°C (+ 40% volume). During the study, average minimum temperatures were - 21.1, - 9.6 and 0.6°C for February (22 d < -17.8°C), March (3 d < -17.8°C) and April respectively. There were no pre- or post weaning ADG differences ($P > 0.05$). Calves averaged 0.73 kg/d gain for the 56-d study. Milk replacer intake was similar for all treatments, averaging 25.1 kg. There were no differences ($P > 0.05$) in CS or total DMI intake which averaged 51.5 and 76.7 kg for the 56-d study, respectively. There were no differences in pre- and post weaning gain/feed. Gain/feed averaged 0.58 kg for the 56 d study. Across treatments, calves doubled their initial BW and gained an average of 11.7 cm in frame growth. There were no differences in number of scouring d pre- and post weaning and health treatment costs. Under the conditions of this study, replacing 25% of the total milk protein in MR with alternative sources resulted in calf performance and health similar to those fed an all milk protein MR.

Key Words: calf performance, milk replacer, alternative protein

T452 Flow of microbial crude protein out of the rumen when dairy cattle are supplemented with 2-hydroxy-4-methylthio-butanoic acid (HMTBa).

C. J. R. Jenkins[1], S. C. Fernando[1], C. L. Anderson[3], N. D. Aluthge[2], E. Castillo-Lopez[4,1], H. A. Tucker[5], G. I. Zanton[5], D. Hostetler*[6], and P. J. Kononoff[1], [1]*Department of Animal Science, University of Nebraska-Lincoln, Lincoln, NE,* [2]*Food Science and Technology Department, University of Nebraska-Lincoln, Lincoln, NE,* [3]*School of Biological Sciences, University of Nebraska-Lincoln, Lincoln, NE,* [4]*Instituto de Investigaciones Oceanológicas, Universidad Autónoma de Baja California, Ensenada, México,* [5]*Novus International Inc., St. Charles, MO,* [6]*The School of Veterinary Medicine and Biomedical Sciences, University of Nebraska-Lincoln, Lincoln, NE.*

Four multiparous, lactating Holstein cows (average DIM 169.5 ± 20.5 d), fitted with ruminal and duodenal cannulas, were used in a 4 × 4 Latin square with a 2 × 2 factorial arrangement of treatments to investigate the effects of 2-hydroxy-4-methylthio-butanoic acid (HMTBa; Alimet, Novus International, St. Charles, MO) when fed with diets deficient or in excess of metabolizable protein (MP) on milk production and composition, rumen microbial activity and protein flow out of the rumen, and rumen microbial community composition. Cows were housed in individual tiestalls and fed diets designated as "Low MP" or "High MP," which were top dressed once daily with 250 g of a corn carrier or 250 g of a corn carrier containing 10% Alimet yielding 25 g of Alimet/hd/d .No interactions were observed between HMTBa and level of dietary MP, with the exception of ruminal acetate to propionate ratio ($P = 0.04$). Milk yield was not affected by treatment and averaged 23.8 ± 2.06 kg. There was a tendency ($P = 0.06$) for increased milk protein percent in cows receiving Low MP diets, averaging 3.30 ± 0.09% and 3.21 ± 0.09% for Low MP and High MP, respectively. The DM, OM, NDF, total-tract digestibilities were greater ($P \leq 0.03$) in cows consuming the Low MP diet. Rumen pH was lower ($P = 0.05$) in cows consuming High MP diets as well as in those consuming HMTBa ($P < 0.01$). Rumen ammonia concentrations tended to be greater ($P = 0.06$) in cows consuming HMTBa. Rumen VFA concentrations were greater ($P = 0.02$) in cows consuming HMTBa. Duodenal DM flow, N flow, and bacterial N flow did not differ between treatments ($P \geq 0.15$). The microbial community structure of cows receiving HMTBa was affected at the phylum level, as the relative abundance of *Fibrobacteres* was increased ($P = 0.04$). Several correlations ($P \leq 0.05$) between microorganisms and metadata were observed, including animal, HMTBa supplementation, level of dietary MP, DMI, digestibility, rumen ammonia, microbial N flow, and milk production. Results suggest that HMTBa affects rumen microbial activity, irrespective of level of MP. Consequently, further investigation is warranted into the mechanism of these effects in the rumen.

Key Words: 2-hydroxy-4-methylthio-butanoic acid, microbial protein, rumen

T453 Differences in microbial community structure associated with metabolizable protein and 2-hydroxy-4-methylthio-butanoic acid (HMTBa) supplementation when using in vitro and in vivo methods.

C. J. R. Jenkins[1], N. D. Aluthge[2], C. Anderson[3], S. C. Fernando*[1], H. A. Tucker[4], G. I. Zanton[4], D. Hostetler[5], and P. J. Kononoff[1], [1]*Department of Animal Science, University of Nebraska-Lincoln, Lincoln, NE,* [2]*Food Science and Technology Department, University of Nebraska-Lincoln, Lincoln, NE,* [3]*School of Biological Sciences, University of Nebraska-Lincoln, Lincoln, NE,* [4]*Novus International Inc., St. Charles, MO,* [5]*The School of Veterinary Medicine and Biomedical Sciences, University of Nebraska-Lincoln, Lincoln, NE.*

The objective of the study was to investigate the effects of 2-hydroxy-4-methylthio-butanoic acid (HMTB; Alimet, Novus International, St. Charles, MO) and metabolizable protein, (Low MP or High MP) as observed in vitro and in vivo. Four multiparous, lactating Holstein cows (average DIM 169.5 ± 20.5 d), fitted with a ruminal and duodenal cannula were used in a 4 × 4 Latin square with a 2 × 2 factorial arrangement of treatments. Experimental periods were 28 d in length and cows received a top dress with either 0 or 25 g of HMTBa. On d 23 of each period and 4 h after feeding, 5 kg of whole ruminal contents were collected from all cows and rumen fluid was collected. Inoculum containing rumen fluid from each cow was added to tubes according to treatment and 0.5 g of each dietary treatment placed in a 100 mL fermentation tubes.. After 24 h of fermentation, the fermentation was stop by snap freezing and a microbial pellet was isolated. DNA was isolated from the microbial pellet and was used for microbial community analysis. The Operational Taxonomic Unit(s) (OTU) based analysis of OTU in the Core Measureable Microbiome (CMM), revealed that the relative abundance of *Firmicutes* decreased ($P = 0.01$) from the Low MP diet to the High MP diet (41.3 ± 4.9% and 30.2 ± 1.25%, respectively). In contrast, the proportion of *Tenericutes*, and *Spirochaetes* increased ($P \leq 0.05$) from the Low MP to the High MP diet while an interaction between MP and HMTBa was observed ($P \leq 0.05$) in *Bacteroidetes*, *Fibrobacteres*, and *Verrucomicrobia*. The relative abundance of phyla also differed ($P \leq 0.01$) by method (in vitro vs in vivo) in *Firmicutes, Bacteroidetes*, *Proteobacteria*, TM7, *Tenericutes*, *Spirochaetes*, SR1, and *Verrucomicrobia*. The proportion of *Actinobacteria* tended to be higher ($P = 0.02$) in vivo. Comparison of methods revealed differences in the average proportion of most phyla suggesting that in vitro fermentation after 24 h was not completely representative of that which was observed the in vivo.

Key Words: 2-hydroxy-4-methylthio-butanoic acid, rumen, bioinformatics

T454 The effect of long-day photoperiod on behavior of lactating dairy cows.

Kira Macmillan*, Santiago Espinoza, and Masahito Oba, *University of Alberta, Edmonton, Alberta, Canada.*

The objective of this study was to evaluate effects of photoperiod management on behavioral responses in lactating dairy cows. Thirty lactating cows (days in milk = 115 ± 33, body weight = 617 ± 70 kg) were subjected to a long-day photoperiod (LP; 16 h/d light) or a short day photoperiod (SP; 8 h/d light) in a tiestall barn (n = 15 per treatment). Data and samples were collected before animals were assigned to treatments and after a 21-dadaptation period. Feeding behavior data were summarized for 4 time periods based on light management: Period 1 (7 p.m. to 3 a.m.; both treatments had no light), Period 2 (3 a.m. to 8 a.m.; only LP treatment had light), Period 3 (8 a.m. to 4 p.m.; both treatments had light), and Period 4 (4 p.m. to 7 p.m.; only LP treatment had light). All response variables were analyzed using a model including fixed effect of treatment, time, and treatment by time interaction with FIT Model Procedure of JMP. Period by treatment interaction was not observed for DMI, milk yield, lying time, or overall feeding behavior. However, in Period 2 (3 a.m. to 8 a.m.), there was a time by treatment interaction for lying time ($P = 0.015$); LP treatment decreased lying time by 5.5 min/h while SP treatment did not. There was also tendency of an interaction for eating time ($P = 0.064$); LP treatment increased eating time by 5.1 min/h while SP treatment did not. In addition, tendency for period by treatment interaction was observed for sorting behavior ($P = 0.08$). The LP cows sorted, to a less extent compared with SP cows, against long particles (sorting index for particles on the screen with 19-mm pores: 91.4 vs. 78.0), and for small particles (sorting index for particles through the screen with 1.18-mm pores: 101.5 vs. 104.2). These results suggest that the provision of supplementary light may reduce sorting and modulate behavior in dairy cows, and that the behavior response to LP may differ depending on time of day in which supplementary light is given.

Key Words: long-day photoperiod, feeding behavior, sorting

T455 Effects of *Saccharomyces cerevisiae* fermentation products on dairy calf: II) rumen fermentation and gastrointestinal development. Jianxin Xiao*[1], Gibson Maswayi Alugingo[1], Ruby Chung[2], Dongshuang Zhao[1], Shengli Li[1], Ilkyu Yoon[2], and Zhijun Cao[1], [1]*State Key Laboratory of Animal Nutrition, Department of Animal Nutrition and Feed Sciences, China Agricultural University, Beijing, China,* [2]*Diamond V, Cedar Rapids, IA.*

The aim of the study was to evaluate the effects of *Saccharomyces cerevisiae* fermentation products (SCFP) in calf starter and milk on rumen fermentation and gastrointestinal tract development in the first 56 d of age. Fifteen Holstein bull calves were randomly assigned to one of 3 groups: a texturized calf starter containing 0 (Control), 0.5 or 1% SCFP (Original XPC, Diamond V) of DM from d 4 to 56. In addition, the supplemented calves were fed 1 g/d SCFP (SmartCare, Diamond V) in milk from d 2 to 30. All calves were fed 4 L of colostrum within 1 h of birth and were subsequently fed milk twice daily until weaned at d 56. Rumen fluid was collected by an esophageal tube 4 h after the morning feeding on d 28 and 56 to determine ruminal pH, ammonia N, and volatile fatty acids (VFA). At d 56, all 15 calves were harvested for slaughter weight, and rumen and intestinal morphological parameters. Papilla length (PL) and width (PW) were measured from 5 locations of rumen. Villus height (VH) and width (VW), crypt depth (CD) and villus height to crypt depth ratio (VCR) were measured in duodenum, jejunum and ileum. Data were analyzed by MIXED procedure in SAS with contrast statement to declare Control vs. all SCFP, and 0.5% SCFP vs. 1% SCFP in starter grains. Ruminal pH and ammonia N were not altered by SCFP. However, SCFP supplementation exhibited higher ($P < 0.05$) ruminal butyrate concentration than Control at d 56. Supplementation of SCFP stimulated ($P < 0.05$) PL in the rumen. Although SCFP had limited effect on VH, it reduced ($P < 0.01$) the CD in jejunum, and increased ($P < 0.05$) VCR in all segments of small intestine, especially when supplemented at a higher dosage in starter. In conclusion, SCFP improved gastrointestinal development, possibly due to increased butyrate production, and greater effect was observed with higher dosage of SCFP.

Key Words: calf, *Saccharomyces cerevisiae* fermentation product (SCFP), gastrointestinal morphology

T456 Effects of exogenous C16:0 and C18 fatty acids (FA) on milk lipid metabolism in bovine mammary epithelial cells. N. Dan*[1], H. Zhang[2], C. J. Ao[1], and Khas-Erdene[1], [1]*College of Animal Science, Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, China,* [2]*College of Animal Science, Inner Mongolia University for the Nationalities, Tongliao, Inner Mongolia, China.*

The objective of this study was to examine the regulatory effects of C16:0, C18:0, C18:1c9, C18:2n6, and C18:3n3 on lipid metabolism of bovine mammary epithelial cells. After plating for 48h, bovine mammary epithelial cells cultured from Chinese Holstein cows were bathed in one of the 6 treatments: 100 μM of C16:0 + 5 μM of C18:0 + 100 μM of C18:1c9 + 25 μM of C18:2n6 + 1.2 μM of C18:3n3 as Control; C18:0 + C18:1c9 + C18:2n6 + C18:3n3 as C16:0 absent treatment(A-C16:0); C16:0 + C18:1c9 + C18:2n6 + C18:3n3 as C18:0 absent treatment (A-C18:0); C16:0 + C18:0 + C18:2n6 + C18:3n3 as C18:1 absent treatment (A-C18:1); C16:0 + C18:0 + C18:1c9 + C18:3n3 as C18:2 absent treatment (A-C18:2); C16:0 + C18:0 + C18:1c9 + C18:2n6 as C18:3 absent treatment (A-C18:3). Key lipogenic genes were analyzed using quantitative PCR, and the FA composition in cells was quantified with gas chromatography. Data were analyzed by the ANOVA procedure of SAS. Cellular triglyceride contents in cells treated with A-C18:0, A-C18:2, A-C18:3 ($P < 0.01$) and A-C18:1 ($P < 0.05$) were decreased compared with the control. Absence of C16:0 induced greater level of LPL ($P < 0.05$). The level of ACSL1 in A-C18:3 was higher ($P < 0.05$) than that of A-C16:0 and A-C18:2. The mRNA abundance of FABP3 was enhanced by A-C18:3 ($P < 0.05$). The expression of SCD was reduced by A-C18:1 ($P < 0.05$). The abundance of CD36 showed reduction in A-C16:0, A-C18:1, and A-C18:2 ($P < 0.05$). Expression of SREBP-1 in A-C18:0, A-C18:1 and A-C18:2 were lower than that of A-C18:3 ($P < 0.05$). No effects of the treatments on ACACA and FASN were observed ($P > 0.05$). Furthermore, C18:2n6 and C18:1c9 compositions in cells were increased by A-C16:0 and A-C18:0 ($P < 0.05$), respectively. Percentage of C16:0 in A-C18:1, and that of C16:0 and C18:0 in A-C18:3 were enhanced ($P < 0.05$), respectively. Cells in A-C18:3 had greater SFA and lower UFA compared with other treatments ($P < 0.05$). In general, extracellular C18 FA availability has a strong effect on cellular triglyceride synthesis; different exogenous long-chain FAs showed no difference on inhibition of de novo FA synthesis, but greatly influence expression of lipogenic genes and milk FA composition.

Key Words: milk fat, lipid metabolism, gene expression

T457 Does ruminal pH affect flow of N fractions in high-producing dairy cows? Danilo Domingues Millen*[1], Charles Schwab[2], and Sergio Calsamiglia[3], [1]*Sao Paulo State University, Dracena, Sao Paulo, Brazil,* [2]*Department of Animal and Nutritional Sciences, University of New Hampshire, Durham, NH,* [3]*Animal Nutrition and Welfare Service, Universidad Autonoma de Barcelona, Bellaterra, Spain.*

There is continuous culture (Calsamiglia et al., 2008) and in situ (Devant et al., 2001) evidence that nonammonia nonmicrobial N (NANMN) flow from the rumen is increased under high concentrate-low pH conditions commonly found in high producing dairy cows. The objective of this study was to evaluate the effect of dietary conditions, including rumi-

nal pH, on the ruminal outflow of N fractions in lactating dairy cows. Peer-reviewed published studies (n = 45 papers; n = 176 data points) designed to investigate flow of N fractions to the small intestine in dairy cows were used. Rumen pH, organic matter truly digested in the rumen (OMTDR), efficiency of microbial protein synthesis (EMPS), and intakes of RUP (RUPI), N (NI), OM (OMI), DM (DMI), and concentrate (CONCI) were the independent variables. Microbial N (MN) NANMN, and nonammonia N (NAN) were the dependent variables in the analysis. Study was included as random effect. The relationship among variables was subjected to multivariate regression analysis by MIXED procedure of SAS. The contribution of each independent variable to the changes observed in each dependent variable was assessed by calculating semipartial correlations (pR^2). The RUPI ($P < 0.0001$; $pR^2 = 0.47$), OMTDR ($P < 0.0001$; $pR^2 = 0.10$), EMPS ($P = 0.003$; $pR^2 = 0.02$) and CONCI ($P = 0.05$; $pR^2 = 0.01$) explained 60% of the variation in NANMN. The contribution of rumen pH to the changes in NANMN was close to, but not significant ($P = 0.13$). The average flow of NANMN at pH <5.8 (n = 14) was 325 g N/d compared with 241g N/d at pH >5.8 (n = 162), with residuals showing some degree of lack of fit at low pH. However, the small number of data at pH <5.8 limits the power of the test. The EMPS ($P < 0.0001$; $pR^2 = 0.37$), OMTDR ($P < 0.0001$; $pR^2 = 0.31$), and DMI ($P < 0.0001$; $pR^2 = 0.19$) explained 87% of the variation in MN. The RUPI ($P < 0.0001$; $pR^2 = 0.27$), EMPS ($P < 0.0001$; $pR^2 = 0.21$), OMI ($P < 0.0001$; $pR^2 = 0.09$) and NI ($P = 0.01$; $pR^2 = 0.01$) explained 58% of the variation in NAN flow. The limited in vivo data does not allow to confirm the hypothesis that pH affects the flow of NANMN, but suggests that its flow is increased at low pH.

Key Words: pH, microbial, nonammonia

Ruminant Nutrition: General II

T205 Effects of prophylactic subcutaneous calcium treatment at calving on macro mineral status and health in Holstein cows. Hamid Amanlou[1], Ahmad Pourakbari[1], Noelia Silva del Rio*[2], and Najme Eslamian Farsuni[1], [1]*Zanjan University, Zanjan, Zanjan, Iran,* [2]*University of California, Davis, CA.*

The objective of this study was to evaluate the effects of prophylactic subcutaneous (SC) Ca treatment at calving on DMI at 1 DIM, serum concentrations of Ca, P, Mg and subclinical hypocalcemia (SHC) and metritis incidence on a commercial HO herd. Cows were blocked based on parity [first (n = 143), second (n = 108) and third or greater (n = 124)], and randomly assigned to treatments after calving. Treatments were no treatment (Control; n = 190); 250 ml of 40% Ca borogluconate (CB) by SC injection at calving (1SC$_{250}$; n = 72); 500 ml of 40% CB by SC injection at calving (1SC$_{500;}$ n = 63); 250 ml of 40% CB by SC injection at calving and at 12 to 18 h after the first injection (2SC$_{250;}$ n = 50). Blood samples were collected immediately after calving and at 1, 2, 4, and 7 DIM. Dry matter intake was measured for 24 h after calving in individual calving pens. Intake was analyzed with GLM procedure, including treatment, parity, and their interactions in the model. Serum Ca, P and Mg were analyzed as repeated measures with mixed procedure of SAS. Metritis (foul-smelling uterine discharge with fever) and SHC (Ca ≤8.5 mg/dl) were analyzed with PROC GENMOD with binomial distributions and logit link functions including treatment, parity, Ca status (≤8.5 vs >8.5 mg/dl) and their interactions. At 1 DIM, intake was greater ($P = 0.004$) for 1SC$_{250}$ (13.5 kg), 1SC$_{500}$ (15.0 kg) and 2SC$_{250}$ (15.6 kg) relative to control (12.4 kg). Compared with control (8.4 mg/dl), postpartum serum Ca was greater for 1SC$_{250}$, 1SC$_{500}$ and 2SC$_{250}$ with 8.9, 9.2 and 9.0 mg/dl respectively. No treatment effect was found on serum P and Mg. The odds of SHC were 3.7, 3.0 and 14.0 times greater ($P = 0.01$) for control than 1SC$_{250}$, 1SC$_{500}$ and 2SC$_{250}$ respectively. The odds to develop metritis tended to be 1.7 times higher for control than 2SC$_{250}$ ($P = 0.07$; 95% CI = 0.9- 3.3). These results suggest that prophylactic SC injections of Ca at calving can improve postpartum Ca status in HO cows and DMI at 1 DIM. Given the reduction on metritis and SHC with treatment, the evaluation of immune status warrant further investigation.

Key Words: calcium status, subcutaneous injection, metritis

T458 Effect of time of gestation on fatty acid transporter and receptor mRNA concentration in bovine placenta. Ramiro Desantadina[1], Silvina Quntana[2], Mariana Recavarren[2], Luis Fazzio[1], and Alejandro Relling*[1,3], [1]*Fc Cs Veterinarias, UNLP, La Plata, Argentina,* [2]*Lab. Farestaie, Mar del Plata, Argentina,* [3]*IGEVET CCT La Plata, CONICET, Argentina.*

The aim of the study was to evaluate the effect of time of gestation on fatty acid transporter and receptor mRNA concentration in maternal and fetal bovine placenta. Placentas from 12 cows at different thirds of gestation (n = 4 per third) were sampled at slaughter to measure FATP-1, FATP-4, FABP-1 mRNA concentration in maternal (caruncles) and fetal (cotyledons) side. Once the placenta was removed, 1cm2 was dissected and, divided into caruncles and cotyledons, stored in sterile tubes, dropped into liquid nitrogen and kept at −80°C until rtPCR analysis. Extraction of RNA was performed with TRIzol. Fetal and maternal placenta cDNA was subjected to qPCR assays using EvaGreen as intercalating dye (KAPA FAST, Biosystems, Woburn). Quantitative PCR was performed in a Rotor Gene Q thermocycler (Qiagen). Relative mRNA concentration was calculated by ddCt method using β actin as housekeeping gene. Data were analyzed as a complete randomized design with a 3 × 2 factorial arrangement, using the mixed procedure (SAS 9.3) with repeated measurements on space. Time of gestation, size of the placenta and their interaction were fixed factors, whereas animal was a random factor. There was a time by treatment interaction ($P < 0.01$) on FATP-1 mRNA expression of due to a greater mRNA expression in cotyledons on the first third of gestation as compared with the concentration in caruncles (Table 1). On the second and third thirds of gestation, the mRNA concentration in cotyledons decreased, reaching a similar concentration to that observed in caruncles (Table 1). FATP-4 and FABP-1 mRNA concentration were not different ($P > 0.1$, Table 1). We conclude that FATP-1 would play an important role in fatty acid transport during early fetal development.

Table 1 (Abstr. T458). Relative mRNA concentration of FATP-1, FATP-4, FABP-1 mRNA in different thirds of gestation on maternal (caruncles-M) and fetal (cotyledons-F) side on bovine placenta

	M			F				*P*-value		
Item	1	2	3	1	2	3	SEM	Side	Third	Side × Third

T459 Ensiling carinata meal with forages to decrease glucosinolate concentrations. Karla Rodriguez-Hernandez*[1,2], Jill L. Anderson[1], and Mark A. Berhow[3], [1]*Dairy Science Department, South Dakota State University, Brookings, SD,* [2]*CIRNOC, INIFAP, Matamoros, Mexico,* [3]*USDA, ARS, NCAUR, Peoria, IL.*

Carinata meal (CM) has high quality protein, but it also has high concentration of sinigrin, a glucosinolate, which limits its use as a feedstuff. Our objective was to determine if ensiling CM with forages would decrease sinigrin concentration without compromising fermentation. Two trials were conducted, one on ensiling CM with alfalfa haylage (AH) and one with corn silage (CS). For both trials 3 blends of CM and forage were made of 0:100, 25:27, and 50:50 on a DM basis. In both approximately 637 g of DM for each the 3 blends were packed in 942 cm^3 microsilos in quadruplicate for 0, 7, 21 and 60 d of ensiling. Sinigrin was greatest ($P < 0.01$) in the 50:50 and decreased over time ($P < 0.01$) in the 25:75 and 50:50 in both trials. There was no treatment by d interaction for AH blends, but there was a treatment by d interaction for the CS blends for sinigrin. The pH decreased in all blends over time, but was greater in the 50:50 compared with the other blends. Acetic acid and lactic acid increased over time in all blends. Acetic acid was less in the AH blends with increased CM. There was no treatment effect on acetic acid for the CS blends. Lactic acid was less in both trials with increased inclusion of CM. In both trials, CP increased with inclusion of CM. The CP was similar over d of ensiling in AH blends, but tended ($P = 0.05$) to decrease over d in CS blends. In both trials, NDF was less with the addition of the CM and there was a treatment by d interaction ($P < 0.01$) in CS, and a tendency ($P = 0.08$) for interaction in the AH trial. Ensiling CM with forage decreases sinigrin concentration, without major detriment to silage fermentation.

T460 Double-layered S/O/W emulsions as rumen delivery system for potential site-selective delivery of lysine in cows. Yongguang Guan and Qixin Zhong*, *Department of Food Science and Technology, University of Tennessee, Knoxville, TN.*

Essential amino acids such as lysine are deficient in most ingredients fed to cows. Direct supplementation of lysine in cow diets however is questionable because the residence time of diets in the rumen is as long as 12 h and lysine can be hydrolyzed by some rumen microorganisms. Safe rumen delivery systems are therefore highly demanded to utilize essential amino acids. The objective of the present work was to study solid/oil/water (S/O/W) emulsions as a potential rumen delivery system that can release most lysine post-rumen. Spray-dried lysine solid particles were prepared and were suspended in soybean oil. The S/O suspension was emulsified in neutral aqueous suspensions with 2, 10, and 30% whey protein concentration (WPC), which was then acidified to pH 3.0 and mixed with a 0.5% sodium alginate solution at pH 2.0 to prepare double-layered emulsion droplets. The emulsion was then spray-dried. The dimension and morphology of droplets were studied using a laser diffraction particle size analyzer, optical microscopy, and scanning electron microscopy. The amount of unencapsulated lysine and the amount of lysine released from spray-dried powder after incubation in simulated rumen, abomasum, and intestinal juices at 37°C were determined using high performance liquid chromatography. All experiments were carried out at least in triplicate. ANOVA was carried out to determine significant differences between treatments at a significance level of 0.05. Results showed that increasing WPC concentration significantly ($P < 0.05$) improved the encapsulation efficiency of lysine, up to 78.5% for the 30% WPC treatment. The particle dimension was around 10 µm based on particle size analysis and microscopy. About 10% lysine was released after 12-h incubation in the simulated rumen juice containing proteases. After an additional 3-h incubation in the simulated abomasum juice at pH 2 with pepsin, the cumulatively released lysine was less than 18%. After further in vitro digestion in the simulated intestinal juice at pH 7.0 with pancreatin, pepsin, and bile salt, the cumulatively released lysine was up to 56%. Therefore, the S/O/W emulsion can be developed as delivery systems to release most lysine post-rumen to supply important amino acids for cows.

Key Words: rumen delivery system, lysine, solid/lipid/water emulsions

T461 Effects of dietary n-6 and n-3 fatty acid sources on intake, digestibility, rumen microbes and fatty acid profile in sheep. Sardar M. Amanullah[1,3], Sam Churl Kim*[1], Dong Hyeon Kim[1], Hyuk Jun lee[1], Young Ho Joo[1], and Eun Tae Kim[2], *[1]Division of Applied Life Science (BK21Plus, Insti. of Agric. & Life Sci.), Gyeongsang National University, Jinju, Gyeongsangnam-do, South Korea, [2]Dairy Science Division, National Institute of Animal Science, RDA, Cheonan, Chungcheongnam-do, South Korea, [3]Bangladesh Livestock Research Institute, Dhaka, Bangladesh.*

A study was conducted to know the effects of dietary oil sources rich in n-6 and n-3 FA on nutrient intake, digestibility, rumen microbial population and fatty acid (FA) profile in sheep. Four pre-pubertal female sheep (48.03 ± 3.69 kg) were housed individually in digestion crates in 4 × 4 Latin square design. Timothy hay and concentrate mixture (3:7 ratio) was the basal diet which was supplied at 2% of live weight on DM basis. Treatments were control (CON), corn oil (CO: n-6), linseed oil (LSO; n-3), and calcium salt of FA (Ca-Salt; protected n-6). Oil sources were pre-mixed with concentrate at 3% of fresh weight. Each period consisted with 10 d of adaptation and 5 d of sample collection. The orts, feces and urine were collected daily before morning feed during the collection period. Blood sample was collected on collection d 4 after 1 h of morning feed, while rumen fluid sample was collected on d 5 at 3 h after morning feed by stomach tube. Data were analyzed using the GLM procedure of SAS. It was observed that intake and digestibility of nutrients were not affected by the supplementing oil sources ($P > 0.05$). Real Time PCR revealed no differences in DNA concentration of methanogenic archaea ($P = 0.047$), *Fibrobacter succinogens* ($P = 0.307$) and *Ruminococcus falvefacience* ($P = 0.327$) among treatments. On the other hand, DNA concentration of rumen ciliate (*Entodinium*) was reduced ($P = 0.018$) by Ca-Salt, while *Ruminococcus albus* was reduced ($P = 0.028$) by LSO compared with the others. The ruminal concentration of C18:0 was highest ($P = 0.012$), but C16:0 ($P = 0.001$) and C16:1n-9 ($P = 0.018$) were lowest in LSO treatment. Other major 18-carbon FAs remained unaffected ($P > 0.05$) in rumen contents. Plasma FA profile showed that, not only C18:3n-3 ($P < 0.001$), but also C20:5n-3 ($P = 0.033$) were increased by LSO supplementation. Consequently, n-6 to n-3 FA ratio ($P = 0.007$) was decreased by LSO treatment. Results indicated that, increased concentration of n-3 FA and decreased n-6 to n-3 FA ratio in plasma can be achieved by supplementing linseed oil in ruminant's diet without affecting intake and digestibility of nutrients.

Key Words: fatty acid profile, oil source, rumen microbe

T462 Approaches to confidence intervals for the energy requirements of beef cattle. Hugo Colombarolli Bonfá*, Edenio Detmann, Paulo Roberto Cecon, Sebastião de Campos Valadares Filho, and José Gilson Louzada Regadas Filho, *Universidade Federal de Minas Gerais, Viçosa, Minas Gerais, Brazil.*

The objective of this study was to propose approaches to the confidence intervals for the net and metabolizable energy requirements for maintenance and for the efficiency of utilization of metabolizable energy for maintenance and weight gain in beef cattle. A simulated population of 100,000 animals was used to demonstrate the distributional properties of the energy requirements. One hundred random samples (n = 100) were taken from a simulated population (n = 100,000). From those samples it was obtained through the Qui-Square and Kolmogorov-Smirnoff tests that net and metabolizable energy requirements for maintenance can be studied by using the properties of the normal distribution ($P > 0.05$). This condition can be reinforced by the sigmoid pattern showed by the upper limits of the confidence intervals when plotted in a scatter graph. The confidence intervals approaches were proposed and demonstrated using the properties of the normal distribution, and using approaches based on anamorphosis techniques and on utilization of a Taylor's series. A data set of 158 animals was used to demonstrate and validate the proposed approaches. The methods that were developed in this study allow obtaining the variance information and confidence intervals for the energy requirements of cattle more affordable by ruminant nutrition researchers, who can obtain confidence intervals for both energy requirements and efficiency of energy utilization based on information from one single experiment. The results demonstrated the feasibility of use of such approaches, which are relevant tools for the practice of inductive statistics and for the inter- and intra-experimental comparisons.

Key Words: efficiency of use of metabolizable energy, nutrient requirements of cattle, statistical inference

T463 Predicting ruminal methane inhibition by condensed tannins using nonlinear exponential decay regression analysis.

Harley D. Naumann[1], Mozart A. Fonseca*[2], and Luis O. Tedeschi[2], *[1]University of Missouri, Columbia, MO, [2]Texas A&M University, College Station, TX.*

Methane (CH_4) is a potent greenhouse gas that is normally produced by microbial fermentation in the rumen and released to the environment during the eructation process. Prediction of ruminal CH_4 is important for ruminant nutrition, especially for determination of ME intake. Equations have been developed to predict ruminal CH_4 production based on dietary constituents, but none have considered condensed tannins (CT). Our objective was to develop an equation to predict ruminal CH_4 inhibition by CT. We gathered CH_4 production data from 24- to 48-h in vitro fermentation of diverse forages containing different concentrations of CT over the course of 3 years. Our analysis included 113 observations. The predictor variable CT was regressed on the response variable CH_4 using PROC NLIN of SAS and the Gauss-Newton method to converge the parameters of the nonlinear regression. We used the following exponential decay model to express the relationship between CT and CH_4: $Y = span \times e^{(-KxX)} + plateau$, where Y is CH_4, g/kg FOM; *span* is the difference between Y when CT equals zero and the *plateau* (Y value at infinite), g/kg FOM; K is the fractional rate of decline, 1/% DM; and X is CT concentration, % DM. The following nonlinear exponential decay regression equation was developed: $CH_4 = 113.6 \times e^{-0.1751 x CT} - 2.18$ ($r^2 = 0.52$; $P < 0.0001$). This equation predicted that CH_4 production could be reduced by 50% when CT is about 3.85% DM. We used several statistics to evaluate the adequacy of this equation, including precision and accuracy. We determined that this equation is more accurate when screening CT-containing forages for their potential ability to mitigate CH_4 production by ruminants when the CT concentration is greater than 5% DM. We concluded that despite the large degree of variability in ruminal CH_4 production, this equation can be used as a tool for predicting potential ruminal CH_4 inhibition that occurs when feeding CT-containing forages to ruminants. Future research should focus on the development of predictive equations when other potential reducers of ruminal CH_4 are used in conjunction with CT.

Key Words: forage, greenhouse gas, modeling

T464 Effect of lipid sources with different fatty acid profiles on intake and nutrient digestion of feedlot Nellore steers.

Juliana Duarte Messana*, Giovani Fiorentini, Isabela P. C. Carvalho, Pablo S. Castagnino, and Telma T. Berchielli, *UNESP - Univ. Estadual Paulista, Jaboticabal, São Paulo, Brazil.*

The present study was conducted to determine the effect of lipid sources with different fatty acid profiles on intake and nutrient digestion. Ten rumen and duodenal fistulated Nellore steers (268 body weight ± 27 kg) were distributed in a double 5 × 5 Latin square (5 periods of 20 d, including 15 d for diet adjustment and 5 d for sample collection). Dietary treatments were: without fat (WF), palm oil (PO), linseed oil (LO), protected fat (PF; Lactoplus), and whole soybeans (WS). The roughage feed was corn silage (600 g/kg on a DM basis) plus concentrate (400 g/kg on a DM basis). Throughout the entire experimental period, the allowance was adjusted to allow refusals of approximately 100 g/kg in relation to the total amount consumed on the previous day. Feed refusals were collected and weighed before feeding for the first 5 d of each experimental period. Feces were collected for 5 d to estimate the digestibility of dietary constituents. Data were analyzed using the PROC MIXED of SAS. The higher intake ($P < 0.001$) of DM, OM was found in animals on the diet with PF and WF. Animals fed with WS had intermediate intake, whereas the diet PO had the lowest intake. The intake of DM and OM of animals fed with LO did not differ from PO and WS diets. The higher EE intake ($P < 0.001$) occurred in animals receiving PF. However, animals fed PO, showed intake similar to that of animals fed WF. There were no differences for the NDF intake ($P > 0.05$). The treatments with PO and LO decreased total digestibility of DM ($P = 0.021$), OM ($P = 0.048$) and EE ($P < 0.001$). Animals fed with the WF diet had lower ($P < 0.001$) EE digestibility than other diets. The addition of LO resulted in the lowest NDF digestibility ($P = 0.047$; 0.40 kg/kg), and the NDF digestibility was not different among the other diets. These observations may be linked to the number of double bonds in the fatty acid molecules and to the high availability of this source (LO), which tends to reduce cellulolytic bacteria proportion. Diets with lipid sources with different fatty acid profiles affected intake and nutrient digestion.

T465 Experimental design and data-reporting needs to help support the advancement of nutrition research and nutrient requirement models.

C. Roselina Angel[7], Mark Hanigan[2], Ermias Kebreab[3], Brian Kerr[4], John P. McNamara[5], Nathalie Trottier[1], Luis O. Tedeschi[6], Mike J. Vandehaar[1], and Robin R. White*[2], *[1]Michigan State University, East Lansing, MI, [2]Virginia Tech University, Blacksburg, VA [3]University of California Davis, Davis, CA, [4]ARS USDA, Ames, IA, [5]Washington State University, Pullman, WA. [6]Texas A&M, College Station, TX, [7]University of Maryland, College Park, MD.*

The National Animal Nutrition Program, National Research Support Project 9, supports efforts in livestock nutrition, including the National Research Council's committees on the Nutrient Requirements of Animals. Our objective was to review the current status of experimentation and data reporting in animal nutrition literature and to provide suggestions for the advancement of animal nutrition research and the ongoing improvement of field-applied nutrient requirement models. Improved data reporting consistency and completeness represent a substantial opportunity to improve nutrition-related mathematical models. A body of nutrition research was reviewed and common phrases used to describe diets, animals, housing and environmental conditions were recorded and equivalent numerical data that could be reported were proposed. With the increasing availability of online supplementary material sections available in journals, a comprehensive checklist of data that should be included in publications was developed. To continue to improve our research effectiveness, studies utilizing multiple research methodologies to address complex systems and measure multiple variables will be necessary. From the current body of animal nutrition literature, a series of opportunities to integrate research focuses (nutrition, reproduction and

genetics) to advance the development of nutrient requirement models were identified. Examples of possibilities to integrate research methodologies include analysis of the energy cost of ionic gradients in cells and protein turnover in tissues. From our survey of experimentation and data reporting in animal nutrition, 4 key opportunities to advance animal nutrition knowledge were identified: 1) coordinated experiments must be designed to employ multiple research methodologies; 2) publication guidelines and restrictions should be updated to allow more complete data sets to be made available; 3) systems-oriented research approaches should be encouraged and supported; and 4) such new data should be more rapidly be integrated into our knowledge bases, research programs and practical applications

T466 Oxygen uptake by splanchnic tissues of sheep infused with different N compounds into the mesenteric vein.

Simone Stefanello, Gilberto V. Kozloski*, Mariana P. Mezzomo, Alsiane S. Capelesso, Tiago Orlandi, Fernanda Hentz, and Diego Zeni, *Universidade Federal de Santa Maria, Santa Maria, RS, Brazil.*

Gluconeogenesis and ureagenesis might be integrated and energy expensive processes and, thus, a trial was conducted to measure the impact of the mesenteric infusion of different N compounds on oxygen uptake by splanchnic tissues of wethers. The trial was conducted with 4 multicatheterized wethers as a 4 × 4 Latin square with 210-min daily periods. The blood flow through portal-drained viscera (PDV) and liver was determined by downstream dilution of 15 g/L *p*-aminohippurate (PAH) infused continuously (1.5 mL/min) into the mesenteric vein. In parallel, wethers were continually infused into the mesenteric vein with a saline (0.15 *M* NaCl) solution during 90 min followed by the infusion, during more 120 min, of either: saline (control), 0.25 *M* NH_4HCO_3, 0.25 *M* L-alanine or 0.125 *M* L-arginine, all of them infused at a rate of 1.5 mL/min to provide 375 µmol N/min. Throughout infusion periods simultaneous arterial, portal and hepatic blood samples were taken at 30 min interval and analyzed for PAH and oxygen concentration. The PROC MIXED of SAS was used for variance analysis, which generated a residual error. The oxygen uptake during treatment infusion (i.e., 90 to 210 min) was compared with that of control period (i.e., first 90 min) within each treatment by F test. Oxygen uptake by PDV during treatment infusion was not different from that observed during saline infusion for any treatment, whereas only NH_4HCO_3 infusion increased oxygen uptake by liver (Table 1). In conclusion, increased ammonia load increased energy expenditure by liver of wethers.

Table 1 (Abstr. T466). Oxygen uptake (mL/h) by portal-drained viscera (PDV) and liver of wethers infused with saline (NaCl) or with 375 µmol N/min of different N compounds into the mesenteric vein

T467 Net flux of metabolites by liver of sheep infused with different N compounds into the mesenteric vein.

Simone Stefanello, Gilberto V. Kozloski*, Renato N. Libardoni, Gabriela P. Coradini, Sabrina Bäumer, Marta L. R. Leal, and André V. Soares, *Universidade Federal de Santa Maria, Santa Maria, RS, Brazil.*

Ureagenesis and gluconeogenesis might be integrated processes and, thus, a trial with 4 multicatheterized wethers was conducted to measure the impact of the mesenteric infusion of different N compounds on liver net flux of urea and glucose. The trial was conducted as a 4 × 4 Latin square with 210-min daily periods. The blood flow through portal-drained viscera (PDV) and total splanchnic tissues (ST) was determined by downstream dilution of 15 g/L *p*-aminohippurate (PAH) infused continuously (1.5 mL/min) into the mesenteric vein. In parallel, wethers were continually infused into the mesenteric vein with a saline (0.15 *M* NaCl) solution during 90 min followed by the infusion, during more 120 min, of either: saline (control), 0.25 *M* NH_4HCO_3, 0.25 *M* L-alanine or 0.125 *M* L-arginine, all of them infused at a rate of 1.5 mL/min to provide 375 µmol N/min. Throughout infusion periods simultaneous arterial, portal and hepatic blood samples were taken at 30 min interval and analyzed for PAH, urea and glucose. Liver net flux was the difference between TS and PDV values. The PROC MIXED of SAS was used for variance analysis, which generated a residual error. The hepatic net flux obtained during treatment infusion (i.e., 90 to 210 min) was compared with that of control period (i.e., first 90 min) within each treatment by F test. Hepatic net flux of urea was increased only for NH_4HCO_3 whereas glucose net flux was increased only when alanine was infused into the mesenteric vein (Table 1). In conclusion, no clear relationship between ureagenesis and gluconeogenesis was observed in wethers.

Table 1 (Abstr. T467). Hepatic net flux (mg/h) of metabolites by wethers infused with saline (NaCl) or with 375 µmol N/min of different N compounds into the mesenteric vein

		Infusion treatments				
Item	Time (min)[1]	NaCl	Ammonia	Alanine	Arginine	SEM
Urea	0-90	431	437	585	538	68.9
	90-210	450	752	602	519	89.1
*P**		0.796	0.044	0.888	0.889	
Glucose	0-90	2817	4220	3042	3799	540.5
	90-210	3825	4648	5502	4306	395.5
*P**		0.194	0.757	0.018	0.556	

[1] Saline solution was used through the first 90 minutes in all treatments.

T468 Evaluation of dairy and beef farm greenhouse gas emissions in different areas of Spain.

Ibidhi Ridha and Sergio Calsamiglia*, *Animal Nutrition and Welfare Service, Universitat Autonoma de Barcelona, Bellaterra, Spain.*

Ruminants are recognized sources of greenhouse gas (GHG) emissions. The objective of this paper was to estimate the carbon footprint of dairy and beef farms in different production systems in Spain. Component models for predicting all important sources of CH4, N_2O, and CO_2 from primary and secondary sources in dairy and beef production were estimated with the Integrated Farm System Model (IFSM) and reported in CO_2 equivalent (eCO_2/kg of energy-corrected milk (ECM) or kg body weight (BW)). The IFSM and Cornell Net Carbohydrate and Protein System (CNCPS) were used to evaluate dairy and beef farms in Spain for

GHG emissions and diet evaluation on methane production, respectively. Three dairy farms from each of 3 regions were selected: Mediterranean (Catalonia, Valencia and Murcia), Cantabric area (Galicia, Asturias and Cantabria) and Central zone (Castilla-La Mancha, Castilla-Leon and Madrid). The average carbon footprint (kg eCO_2/kg of ECM) of all dairy farms was 0.83, with the Mediterranean farms being highest ($P < 0.01$); 0.98) compared with the Central Zone (0.84) and the Cantabric area (0.67). Two extreme farms were selected for further simulations: the first one had the highest carbon footprint and non-enteric methane, while the second had the lowest carbon footprint and the highest enteric methane. These farms were simulated by the IFSM model using different management change scenarios (higher productivity, manure type collection, bedding type, anaerobic digester and storage type of manure) and dietary changes (modification of the ratio forage:concentrate, improved forages quality, inclusion of fat, use of ionophore). Management changes reduced methane emission up to 30% while dietary change reduced it up to 5%. Two beef farms fed 90:10 concentrate:straw and one fed with corn silage were used to simulate GHG emissions using the same models. The carbon footprint (eCO_2/kg BW) was 6.98 in beef fed corn silage and 6.90 in beef fed without corn silage. Management strategies provided a greater potential to reduce methane emissions compared with dietary scenarios changes.

Key Words: carbon footprint, dairy and beef farm, Integrated Farm System Model (IFSM)

T469 Detect the association of protein structures to protein nutrient utilization and availability of co-products from bio-fuel and bio-brewing processing. Xuewei Zhang[1], Limei Chen[2,1], Yajing Ban[2], and Peiqiang Yu*[2,1], *[1]Department of Animal Science, Tianjin Agricultural University, Tianjin, China, [2]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

The objective of this study was to identify the correlation between protein molecular structures and protein nutritional profiles of co-products from cereal grains after bio-fuel and bio-brewing processing in terms of (1) protein chemical profiles; (2) protein subfractions; (3) total digestible protein; (4) protein degradation and estimated intestinal CP digestibility. Five kinds of corn DDGS and 2 kinds of barley DDGS were collected from different manufactures in the north of China from 2012 to 2013. The protein molecular structure spectral feature were analyzed using advanced molecular spectroscopy technique at University of Saskatchewan. The protein subfractions were partitioned using CNCPS system. Total digestible protein, protein rumen degradation and intestinal digestion were determined using dry Holstein dry cows at University of Saskatchewan. Statistical analysis was performed using the PROC MIXED of SAS 9.3. The results showed that the co-products from corn and barley grains differed in both protein nutritional profiles and protein molecular structures in terms of α-helix, β-sheet spectral intensity and their ratio and amide I, amide II spectral intensity and their ratio. Protein amide II height had a positive correlation with ($P < 0.05$) PB2 fraction with R = 0.53, but that other protein amide parameters had no correlation with ($P > 0.05$) PA, PB1, PB3 and PC fractions. Protein amide II height had a positive correlation with ($P < 0.05$) TDN with R = 0.74. Protein amide II height has a negative correlation with ($P < 0.05$) protein degradability (R_DCP) with R = −0.67, and a positive correlation with ($P < 0.05$) intestinal protein digestibility (I_DCP) with R = 0.60 and total-tract available protein (T_ACP) with R = 0.58. For protein secondary structure, the α-helix to β-sheet ratio was negatively correlated with ($P < 0.05$) total protein digestibility (T_DCP) with R = −0.56 and positively correlated with ($P < 0.05$) total digestible crude protein (tdCP) with R = 0.55. In conclusion, protein molecular spectral parameters in the co-products are association with protein nutritional profiles and protein degradation and digestion.

Key Words: protein nutritive value, protein molecular structure, molecular spectroscopy

T470 Effects of essential oils from wormwood hybrids on *in vitro* digestibility, microbial diversity and rumen fermentation of bermudagrass hay and soybean meal . Seong Shin Lee*[1], Hee Yoon[1], Hyuk Jun Lee[1], Dong Hyeon Kim[1,3], Sardar M. Amanullah[1], Young Ho Joo[1], Eun Tae Kim[2], Adegbola T. Adesogan[3], and Sam Churl Kim[1], *[1]Division of Applied Life Science (BK21Plus, Insti. of Agri. & Life Sci.), Gyeongsang National University, Jinju, Gyeongsangnam-do, South Korea, [2]Dairy Science Division, National Institute of Animal Science, RDA, Cheonan, Chungcheongnam-do, South Korea, [3]Department of Animal Science, Institute of Food and Agricultural Sciences, University of Florida, Gainesville, FL.*

Effects of wormwood essential oil (EO) supplementations on in vitro digestibility and rumen fermentation characteristics of soybean meal (SBM) or bermudagrass hay (BH) were examined. Rumen fluid was collected from 2 cannulated Holstein cows, filtered through 2 layers of cheese cloth and mixed with Van Soest medium (1:2 ratio). Exactly 0.5 g of SBM or BH was treated with nothing or with 200 mL of wormwood EO from Ganghwa (GA), Injin (IN) or San (SA) wormwood hybrids grown at the Research Unit, Gyeongsang National University, South Korea. Three replicates of each treatment with 3 blanks were incubated at 39°C for 72 h in buffered-rumen fluid (40 mL). In vitro DM digestibility (DMD), pH, ammonia-N and volatile fatty acids (VFA) were measured. The population of certain rumen microbes was measured by Real-time PCR. Data were analyzed using the GLM procedure of SAS (SAS Inst., Cary, NC). Total VFA concentration (m*M*) of SBM was decreased ($P < 0.05$) by GA and SA (157 vs. 143, and 146) but not IN (149). Other fermentation or digestibility measures and the methanogenic archaea population were unaffected by EO. However, the fold change of *Fibrobacter succinogens* was reduced ($P < 0.05$) by GA, IN and SA (18.8 vs. 9.13, 2.36, 2.63), that of *Ruminococcus albus* was increased ($P < 0.05$) by SA (10.8 vs. 24.5), that of *Streptococcus bovis* was increased ($P < 0.05$) by GA and SA though greatest by SA ($P < 0.05$) and that of *R. flavefaciens* was increased ($P < 0.05$) by GA and IN. The DMD of BH was not increased by EO but GA decreased NDF digestibility. Ammonia-N concentration was increased ($P < 0.05$) by SA (17.7 vs. 19.9 mg N/dl). Total VFA concentration was reduced ($P < 0.05$) by GA (136.1 vs. 119.8 m*M*) but pH and VFA molar proportion did not differ among treatments ($P > 0.05$). Adding the EO to SBM or BH had no beneficial effects on the fermentation or digestibility despite altering the ruminal bacteria population.

Key Words: essential oil, fermentation indices, rumen microbe

T471 Dry matter intake and feeding behavior of cattle fed cottonseed and vitamin E. Ricardo Galbiatti Sandoval Nogueira*, Flavio Perna Jr, Eduardo Cuellar Orlandi Cassiano, Lizbeth Collazo Paucar, Mariane Cheschin Ernandes, Diana Carolina Zapata Vasquez, Adrielle Matias Ferrinho, Romulo Germano de Resende, Felipe Bispo Mendonça, Renata Gardenalli, Angélica Simone Cravo Pereira, and Paulo Henrique Mazza Rodrigues, *University of São Paulo, Pirassununga, São Paulo, Brazil.*

The objective of this study was to evaluate the dry matter intake and feeding behavior of cattle fed cottonseed and vitamin E. The experiment was conducted University of São Paulo, Campus Pirassununga. Six cannulated non-pregnant, nonlactating cows were distributed in a replicated 3 × 3 Latin square design. Feed was offered ad libitum twice daily. Feeding behavior was observed during 24 h 5 by 5 min. Treatments were: Control; Cottonseed (CS): 30.47% cottonseed included; vitamin E (VitE): 30.47% cottonseed plus 500 IU VitE included. Diets were isoenergetic and isonitrogenous. The ether extract content was 3.74, 8.32 and 8.32% for the Control, CS and VitE diets. Data were analyzed by SAS (v9.3) and significance declared at $P < 0.05$. Dry matter intake, dry matter intake in relation to body weight and per unit of metabolic size, total time and average time per event eating, ruminating, free and chewing (eating plus ruminating) were compared through orthogonal contrasts, where contrast 1 = CS and VitE vs. control, and contrast 2 = CS vs. VitE. Both diets provided ($P > 0.05$) similar amounts of dry matter intake (15.44 and 15.40 vs. 14.64 kg animal day^{-1}), dry matter intake in relation to body weight (1.74 and 1.74 vs. 1.66) and per unit of metabolic size (95.10 and 95.25 vs. 90.69). Treatments CS and VitE had greater time eating (219.1 and 215.0 vs. 190.8 min), ruminating (437.5 and 430.0 vs. 291.6 min), chewing (656.6 and 645.0 vs. 482.5 min) but less time free (775.0 and 786.9 vs. 947.5) compared with control. The average eating time per event was not different among treatments (33.1 and 36.9 vs. 32.4 min), but the average ruminating time per event (29.12 and 24.58 vs. 20.62 min) and chewing (30.0 and 27.3 vs. 24.16 min) was greater for CS and VitE compared with control. The average free time per event was less for CS and VitE than control (40.5 and 38.4 vs. 49.5 min). Including cottonseed in a diet at 30% did not decrease dry matter intake and the animals spent more time eating, ruminating, and chewing with less free time. Vitamin E did not affect dry matter intake parameters and feeding behavior.

Key Words: dry matter intake, feeding behavior, lipid

T472 In situ degradability, rumen bacteria population, and in vitro gas production in cannulated steers fed diets with and without HMTBa.

Y. Liang, S. E. Bettis, M. Wehmeyer, G. I. Zanton, H. A. Tucker*, and M. Vazquez-Anon, *Novus International Inc., St. Charles, MO.*

The objective of this study was to investigate changes in rumen environment when animals are fed a diet containing 2-hydroxy-4-(methylthio) butanoate (HMTBa). Six cannulated Holstein steers were utilized in a crossover design trial with two 42-d periods (28 d adaptation, 14 d sampling) and were fed a ration with hay, corn, and soyhulls with HMTBa (0.1%, DM basis) or without (CON). Whole rumen contents (WRC), rumen solids (RS) and rumen liquid (RL) samples were taken 3 h pre- and post-feeding on d 29 of each period. Samples were analyzed for bacteria sequencing. Additional rumen fluid, collected 3 h post-feeding was used to measure gas production using the ANKOM gas production system and alfalfa hay as substrate. On d 36 of each period, the effect of HMTBa supplementation on dry matter and NDF digestibility of alfalfa and grass hays were evaluated using in situ methods. In vitro gas production at 24 h was greater ($P = 0.002$) in rumen fluid from steers fed HMTBa than CON. Supplementing HMTBa increased DM digestibility of alfalfa hay at 4 ($P = 0.001$) and 12 h ($P = 0.025$) of incubation and increased ($P = 0.013$) that of grass hay at 24 h of incubation. In situ NDF digestibility was greater at 12 h of incubation for alfalfa hay ($P = 0.005$) and 24 h of incubation for grass hay ($P = 0.006$) with HMTBa supplementation. Feeding steers HMTBa tended ($P = 0.074$) to increase Proteobacteria in RS and ($P = 0.039$) Actinomycetales in RL. Supplementing HMTBa resulted in *Ruminococcaceae* accounting for a greater proportion of bacteria at the family level in RL ($P = 0.048$), RS ($P = 0.054$) and WRC ($P = 0.037$). Furthermore, feeding steers HMTBa increased ($P = 0.028$) *Ruminococcus* in WRC, and tended to increase in RL ($P = 0.054$) and RS ($P = 0.052$). Greater population of *Ruminococcus* sp. was detected in WRC ($P = 0.022$), RL ($P = 0.031$), and RS ($P = 0.025$) in HMTBa fed steers. In conclusion, supplementing HMTBa increases fibrolytic bacterial species, resulting in a greater gas production in vitro, and greater in situ DM and NDF digestibility of selected hays.

Key Words: 2-hydroxy-4-(methylthio) butanoate (HMTBa), rumen bacteria, NDF digestibility

T473 Effect of sustained-release mineral dietetic feed bolus on plasma trace minerals status in grazing heifers.

J. M. Beguin*[1], R. P. Dagorne[1], and R. Lecrubier[2], *[1]NEOLAIT, Yffiniac, France, [2]ESA, Angers, France.*

The objective of this study was to evaluate, in grazing dairy heifers, the effect of an oral bolus on plasma trace mineral status. Heifers (n = 74, initial BW = 427 kg, age = 445 d) from 4 dairy farms in Western France, were randomly assigned to a control group (CONTROL) and a trial group (TEST). Heifers in TEST received 2 boluses (Dietevit Excell, Néolait, Yffiniac, France), at the start of grazing season. Boluses supplies zinc, manganese, copper, iodine, cobalt, selenium, vitamin A, vitamin D3 and vitamin E. Blood samples were taken before turn out in April (d 0), in July (d 106), and at the end of the grazing season in November (d 245). Plasma trace minerals analysis was carried out by ICP-MS (LEA Vendée, France). Glutathione peroxidase was also measured (LDH, Oniris, France). Metabolic profiles were compared using Repeated Measures ANOVA (SPSS v18). Samples of grass were taken from the grazing plots and were analyzed by ICP-MS (Sciantec Analytical Services Ltd., United Kingdom). Grass trace mineral content per kg DM was zinc (25.4 mg), manganese (84 mg), iron (72 mg), copper (5.3 mg), cobalt (0.10 mg) and selenium (0.03 mg). Compared with CONTROL, heifers in TEST had the same trace minerals levels in d 0, higher selenium levels (42.6 vs. 25.7 μg/L in d 106 and 36.4 vs. 26.6 μg/L in d 245, $P = 0.01$ and $P = 0.03$), higher glutathione peroxidase levels (205 vs. 114 μg/L in d 106 and 205 vs. 129 μg/L in d 245, $P = 0.01$ and $P = 0.02$) and higher iodine levels (79 vs. 48 μg/L in d 106 and 62 vs. 56 μg/L in d 245, $P = 0.01$ and $P = 0.07$). There was no difference in plasma level for zinc (1064 vs. 999 μg/L in d 106 and 954 vs. 922 μg/L in d 245), manganese (2.8 vs. 2.8 μg/L in d 106 and 3.3 vs. 3.4 μg/L in d 245), copper (892 vs. 916 μg/L in d 106 and 995 vs. 1017 μg/L in d 245) and cobalt (1.4 vs. 1.2 μg/L in d 106 and 1.1 vs. 0.9 μg/L in d 245). Administration of 2 Dietevit Excell boluses to dairy heifers before turn out maintains healthy selenium, glutathione peroxidase and iodine plasma levels over a period of at least 245 d. Results show that Dietevit Excell gradually dissolves providing a sustained release of minerals over the grazing season.

Key Words: heifer, trace mineral, bolus

T474 Crambe meal (*Crambe abyssinca*) inclusion in feed of Santa Inês crossbred lambs on blood serum urea.

Kariny Ferreira Moreira, Darcilene Maria Figueiredo*, Adriano Oliveira Cruz, Ronald Matos dos Santos, Juscilene Aparecida Silva Pacheco, Cassiane Gomes dos Santos, Daniela Cordeiro Rocha, Marianne Schorer, and Aldrin Vieira Pires, *Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, MG, Brazil.*

The objective of this study was to evaluate the effect of increasing levels of crude protein of crambe meal (*Crambe abyssinca*) (0, 25, 50, and 75%) on blood serum urea levels of lambs. Twenty-four Santa

Inês crossbred male lambs, with an average weight and age of 18 kg of body weight, and 4 mo, respectively. The experiment was conducted in a completely randomized design with 4 treatment and 6 replicates each. Animals remained 7 d for adaptation, and 3 periods of 28 d for data collection. Lambs were kept in individual pens (1.5 m x 1.0 m), equipped with trough and drinker. Animals received diets with 19% crude protein (% DM), and 65.4% total digestible nutrients (% DM), based on average daily gain of 200 g head^{-1} with forage: concentrate ratio of 50:50. Lambs were fed ad libitum, twice a day, always at 0700 and 1500 h, allowing leftovers of approximately 20%. Sampling of urea serum in the lambs were through blood samples taken by puncture of the jugular vein at 13th day of the second experimental period immediately at 0, 3, 6 and 9 h after the morning feeding. Data were subjected to ANOVA and regression, at 5% probability. The blood serum urea level did not differ ($P > 0.05$) among treatments and 25.96, 25.65, 24.23, and 21.70 g day^{-1}, respectively, for diets with 0, 25, 50, and 75% crude protein inclusion of crambe meal. This result demonstrates the appropriateness of the use of nitrogen compounds in the rumen due to the availability of degradable organic matter. Therefore the use of crambe meal on diet has satisfactory effect with regard in lamb blood serum urea.

Key Words: alternative feed, protein feed, sheep breeding

T475 Crambe meal (*Crambe abyssinica*) inclusion in food of Santa Inês crossbred lambs on urea nitrogen.

Kariny Ferreira Moreira, Darcilene Maria Figueiredo*, Adriano Oliveira Cruz, Ronald Matos dos Santos, Juscilene Aparecida Silva Pacheco, Cassiane Gomes dos Santos, Daniela Cordeiro Barbosa, Marianne Schorer, and Aldrin Vieira Pires, *Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, MG, Brazil.*

The objective of this study was to evaluate the increasing levels of crude protein of crambe meal (*Crambe abyssinica*) (0, 25, 50, and 75% DM) in lambs diets on the urinary excretion of urea nitrogen (UEUN). Twenty-four Santa Ines crossbred male sheep, with an average weight and age of 18 kg of body weight, and 4 mo, respectively. The experiment was conducted in a completely randomized design with 4 treatment and 6 replicates each. Animals remained 7 d for adaptation, and 3 periods of 28 d for data collection. Lambs were kept in individual pens (1.5 m x 1.0 m), equipped with trough and drinker. Animals received diets with 19% crude protein (% DM), and 65.4% total digestible nutrients (% DM), based on average daily gain of 200 g head^{-1} with forage: concentrate ratio of 50:50. Lambs were fed ad libitum, twice a day, always at 0700 to 1500 h, allowing leftovers of approximately 20%. For determination of UEUN spot urine samples were collected by spontaneous urination on the 13th day of the second experimental period immediately at 0h, 3h, 6h and 9h after morning feeding. Data were subjected to ANOVA and regression, at 5% probability. There was no effect ($P > 0.05$) between diets on the UEUN, and 2.49, 2.41, 2.47 and 2.66 g day^{-1}, respectively for diets containing 0, 25, 50 and 75% of crude protein inclusion of crambe meal indicating low amount of nitrogen without being fully utilized by the animal. Therefore the inclusion of crude protein from the crambe meal for lambs feeding had a beneficial effect in relation to UEUN.

Key Words: alternative food, protein food, sheep breeding

T476 Induction of subacute ruminal acidosis affects gene expression in rumen epithelial tissue.

J. C. McCann*, S. Alqarni, S. Luan, F. C. Cardoso, and J. J. Loor, *University of Illinois at Urbana-Champaign, Urbana, IL.*

Subacute ruminal acidosis (SARA) negatively affects the dairy industry by decreasing dry matter intake, milk production, profitability, and increasing culling rate and death loss. These consequences are related to a loss of barrier function in the rumen epithelial tissue associated with a reduction in ruminal pH. Six lactating Holstein cows were used in a replicated 2 × 2 Latin square design to determine the effects of SARA induction on the rumen epithelial tissue. Experimental periods were 10 d with d 1 to 3 for ad libitum intake of control diet, followed by 50% feed restriction on d 4, and ad libitum access on d 5 of the control diet (control) or control diet + 4.6 kg of a 50:50 wheat/barley pellet (challenge). Ruminal papillae biopsies were collected on d 1 and 6 of each period and stored at −80 C. Quantitative RT-PCR was used to determine expression genes related to barrier function with all reactions run in triplicate. Three reference genes (*CMTM6*, *ERC1*, and *MRPL39*) were selected due to stable expression across animals and times. Data were analyzed using the MIXED procedure of SAS with day, treatment, period, and square as fixed effects and cow as a random effect. Of the evaluated barrier function genes, the greatest relative abundance was observed for *CLDN1* followed by *CLDN4*. Expression of *CLDN1*, *CLDN4*, and *JAM2* was upregulated on d 6 ($P < 0.1$). Greater expression of *TJP1*/*ZO-1* was observed for the control treatment ($P = 0.086$). A treatment × day effect was observed for *OCLN* ($P = 0.07$) as expression was upregulated on d 6 for the challenge treatment but downregulated for the control. No treatment effect ($P > 0.1$) was observed for *CLDN1*, *CLDN4*, *JAM2*, *CAR*, *TLR2*, *TLR4*, and *IGFBP3*. Toll-like receptors recognize bacterial components and are capable of upregulating barrier function of epithelial tissue. Both *TLR2* and *TLR4* were downregulated on d 6 ($P = 0.05$ and $P = 0.1$, respectively). Collectively, results suggest feed restriction and subsequent refeeding caused a greater effect on expression of barrier function genes than the additional starch in the challenge treatment. However the results may still be indicative of the rumen epithelium tissue response to SARA.

Key Words: acidosis, rumen, epithelium

T477 Effects of monensin and essential oils from some Nigerian spices on methane production and ruminal fermentation in vitro.

Musibau A. Bamikole[1,2], Ibukun M. Ogunade*[1], Felipe Amaro[1], Yun Jiang[1], Thiago F. Bernardes[1], Darren D. Henry[3], F. O. Ugiagbe[2], U. J. Ikhatua[2], Nicolas DiLorenzo[3], and Adegbola T. Adesogan[1], [1]*University of Florida, Gainesville, FL,* [2]*University of Benin, Benin city, Nigeria,* [3]*North Florida Research and Education Center, University of Florida, Marianna, FL.*

Plant extracts may be potential replacements for antibiotic feed additives used in livestock production and they are considered safer. Effects of essential oils (EO) extracted from rosemary (*Rosimarinus officcinalis*; REO) leaves and clove (*Syzgium aromaticum*; COE) flower on in vitro rumen fermentation parameters including methane production were examined. A corn silage-based TMR (0.5 g; CP 16.6%; NDF 35.9%) was treated with CEO or REO at rates of 0 (Control), 10 (Low), 20 (Med) and 30 (High) μL/50 mL of rumen fluid-buffer inoculum (ratio 1:2) and with monensin (0.6 mg/50 mL). Each suspension was incubated in a 120-mL gas-tight culture bottle in triplicate at 39oC for 24 h in each of 2 runs. Fermentation parameters, gas and methane production, in vitro DM digestibility (DMD), and fermentation efficiency (FE; DMD g kg-1/gas volume) were measured. Data for each EO were separately analyzed with the Glimmix procedure of SAS. The DMD was reduced ($P < 0.05$) by monensin, Med REO and High CEO (526, 531 and 513 vs. 555 g/kg). Gas volume (mL/g DM) was increased ($P < 0.05$) by Low REO or CEO (84.5 vs. 92.4 and 96.2) and decreased ($P < 0.05$) by their High rates or monensin (76.7, 63.6 and 66.8), respectively. The

FE was increased ($P < 0.05$) by High REO or CEO or monensin (7.27, 8.69 and 7.92 vs. 6.58) and reduced ($P < 0.05$) by Low REO (5.85), respectively. Methane production (mg/g DM digested) was reduced ($P < 0.05$) by High REO and CEO and monensin (8.65, 8.02, and 7.10 vs. 11.44). The pH was increased ($P < 0.05$) by monensin (5.75 vs. 5.66) but not by EO. Ammonia-N and VFA concentrations were unaffected by treatment except that monensin reduced ($P < 0.05$) acetate concentration and increased valerate concentration. Also, monensin and Med and high CEO increased ($P < 0.05$) butyrate concentration. High doses of essential oils from clove and rosemary decreased methane production and increased fermentation efficiency in a manner comparable to monensin

Key Words: essential oil, spice, in vitro fermentation

T478 Effect of heating method on alteration of protein molecular structure in flaxseed: Relationship with changes in protein subfraction profile and digestion in dairy cows.

Nazir A. Khan[1], Helen Booker[2], Yajing Ban[1], and Peiqiang Yu*[1], *[1]Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada, [2]Department of Plant Sciences, University of Saskatchewan, Department of Plant Sciences, University of Saskatchewan, Saskatoon, SK, Canada.*

This study evaluated the effect of heating methods on alteration of protein structure in flaxseed (*Linum usitatissimum* L.) in relation to changes in protein subfraction profile and digestion in dairy cows. Seeds from 2 flaxseed varieties, sampled from 2 replicate plots at 2 locations, were evaluated. The plots (n = 4) were used as replicates. The seeds were either maintained in their raw state or heated in an air-draft oven (dry heating) or autoclave (moist heating) for 60 min at 120°C or by microwave irradiation (MIR) for 5 min. Compared with raw seeds, moist heating decreased ($P < 0.05$) soluble protein (SP) content (56.5 ± 5.55 to 25.9 ± 6.16% crude protein) and increased ($P < 0.05$) rumen undegraded protein (RUP) content (36.0 ± 5.19 to 46.9 ± 2.72% CP) and intestinal digestibility of RUP (61.0 ± 2.28 to 63.8 ± 2.67% RUP). Dry heating did not alter ($P > 0.05$) the protein subfraction profile and rumen degradation kinetics, whereas MIR increased ($P < 0.05$) the RUP content from 36.0 ± 5.19 to 40.4 ± 4.67% CP. The MIR and dry heating did not alter ($P > 0.05$) the amide I to amide II ratio, but moist heating decreased ($P < 0.05$) both the amide I to amide II ratio and α-helix-to-β-sheet ratio. Regression equations based on protein molecular spectral intensities provided high prediction power for estimation of heat-induced changes in SP ($R^2 = 0.62$), RUP ($R^2 = 0.71$), and intestinal digestibility of RUP ($R^2 = 0.72$). Overall, heat-induced changes in protein nutritive value and digestion were strongly associated with heat-induced alteration in protein molecular structures.

Key Words: heat processing method, protein molecular structure, protein subfraction

T479 Investigation of protein digestion kinetics in vitro using ^{15}N-labeled timothy and red clover.

Merko Vaga*, Kerstin Huss-Danell, Mårten Hetta, and Pekka Huhtanen, *Dept. of Agricultural Research for Northern Sweden, Swedish University of Agricultural Sciences, Umeå, Sweden.*

An in vitro method based on ^{15}N-labeled forage N was developed to study ruminal protein degradation of timothy and red clover. Timothy and red clover were grown on the same field with 2 replicate plots, 2 m^2 each. One replicate plot was fertilized with ^{15}N-enriched NH_4NO_3 while the other received non-enriched fertilizer. Labeled timothy and red clover had average enrichment of 2.37 and 1.23 atom % excess ^{15}N, respectively. Forages from the first-cut were preserved either as hay (TH, RCH), untreated (T, RC) or formic acid-treated silage (TF, RCF). Rumen fluid was collected from 2 Swedish red cows fed on grass silage:concentrate diet (60:40 DM basis). Samples of 1 g were incubated in 60 mL of buffered rumen fluid at 39°C for 48 h. For non-labeled forages NH_3-N in the inoculum was labeled with ^{15}N enriched $(NH_4)_2SO_4$. Vessels containing labeled forages received the same amount of non-enriched $(NH_4)_2SO_4$. Liquid samples were collected every hour at 0 to 10 h, after 12, 16, 24, 30 and 48 h, and later analyzed for NH_3-N and ^{15}N. Degraded CP was calculated as a sum of appearance of ^{15}N from labeled forages and disappearance of ^{15}N from labeled NH_3-N. Degradation parameters were estimated by the 2 pool exponential model using the SAS NLIN procedure. Timothy forages had higher rapidly degradable fraction (b1). Slowly degradable fraction (b2) was smaller in formic acid treated silages and in red clover silages. Hay had slower degradation rates (kd) than silages. Total degraded CP (a+b) was higher for timothy and for hay. It is concluded that incubating ^{15}N labeled feeds or feed fractions simultaneously with corresponding unlabeled feeds by labeling ammonia pool with ^{15}N can be a useful tool in investigating kinetics of ruminal protein degradation.

Table 1 (Asbtr. T479). CP concentration and degradation parameters of timothy (T) and red clover (RC)

	TF	RCF	T	RC	TH	RCH
CP, g/kg DM	155	147	166	133	144	137
CP degradation[1]						
b1, g/kg	495	418	335	334	473	391
b2, g/kg	380	362	594	507	490	452
kd1, 1/h	0.696	1.250	1.263	1.200	0.815	0.818
kd2, 1/h	0.189	0.132	0.139	0.161	0.055	0.091
a+b, g/kg	875	780	929	841	963	843

[1]b1 = rapidly degradable, b2 = slowly degradable, kd1 = degradation rate of b1, kd2 = degradation rate of b2.

T480 Effects of yam (*Dioscorea opposite*) supplementation on *in vitro* digestibility and rumen fermentation characteristics of ground corn and perennial ryegrass.

Jin Yeon Park*[1], Tea Hyeon Kim[1], Hyuk Jun Lee[2], Young Ho Joo[2], Sardar M. Amanullah[2], Dong Hyeon Kim[2], In Hak Choi[3], and Sam Churl Kim[1,2], *[1]Department of Animal Science, Gyungsang National University, Jinju, Gyeongsangnam-do, South Korea, [2]Division of Applied Life Science (BK21Plus, Insti. of Agric. & Life Sci.), Gyungsang National University, Jinju, Gyeongsangnam-do, South Korea, [3]Department of Companion Animal & Animal Resources Sciences, Joongbu University, Geumsan, Chungcheongnam-do, South Korea.*

This study was carried out to investigate the effect of yam (*Dioscorea opposite*) supplement levels on in vitro digestibility, gas production and rumen fermentation characteristics of ground corn and perennial ryegrass using a novel wireless automated gas production system. Rumen fluid was collected from 2 cannulated Hanwoo heifers, filtered by 2 layers of cheese cloth and mixed with Van Soest medium at 1:2 ratio. The rumen fluid mixture (40 mL) added to the incubation bottles containing ground corn or perennial ryegrass (0.5 g) with 4 levels of Yam supplement (0, 5, 25 and 50 mg). Four replicates in each treatment with 2 blanks were incubated at 39°C for 48 h and 72 h for ground corn and perennial ryegrass, respectively. After incubation, the bottle content was used for the analyses of in vitro digestibilities of dry matter (IVDMD) and neutral detergent fiber (IVNDFD), pH, ammonia-N and volatile fatty acid (VFA). Data were analyzed using the GLM procedure of SAS (SAS Inst., Cary, NC). The pH (Linear, $P < 0.001$) and the concentrations of iso-butyrate (Quadratic, $P = 0.025$) and iso-valerate (Quadratic, $P < 0.001$) of ground corn decreased with increasing yam supplementation level, while the concentrations of total VFA (Linear, $P = 0.01$) and butyrate (Quadratic, $P = 0.001$) increased. However, the fermentation kinetic of ground corn was not affected by Yam supplementation level. With increasing yam supplementation level, IVDMD (Linear, $P < 0.001$), IVNDFD (Linear, $P = 0.002$), the potentially fermentable fraction (Linear, $P = 0.057$) and the total fermentable fraction (Linear, $P = 0.018$) of perennial ryegrass increased. Results indicated that yam (*Dioscorea opposite*) supplementation can increase not only total VFA concentration of ground corn, but also in vitro digestibilities of perennial ryegrass.

Key Words: digestibility, rumen fermentation, yam (*Dioscorea opposite*)

T481 In vitro study of yeast cell-wall b-glucans behavior in ruminal fluid.

Nadia Yacoubi[1], Jean Philippe Marden[3], and Corine Bayourthe*[2], [1]*INRA UR1268 Biopolymers Interactions Assemblies, Nantes, France,* [2]*Université de Toulouse, INRA, UMR 1388 INRA-INPT GenPhySE, Castanet-Tolosan, France,* [3]*Phileo Lesaffre Animal Care, Marcq en Baroeul, France.*

Behavior of β-(1,3/1,6)-glucans (BG) of yeast cell-wall (*Saccharomyces cerevisiae*) in ruminal milieu was evaluated in vitro. The solubility of BG, pH, and production of VFA were measured after 4, 8, and 16 h of incubation in ruminal fluid. Two yeast cell-wall products were used: brewer's yeast (BrYBG) and baker's yeast (BaYBG), containing 15.1 and 26.3% DM of BG, respectively. Ruminal fluid was collected 3h post-feeding from a ruminally fistulated Holstein dairy cow fed a hay-based diet and strained through a metal sieve (2 mm). Within 45 min of sampling, 60 mL of ruminal fluid and 60 mL of degassed buffer solution (pH 7, 39°C) were added to 250-mL flasks, containing 5 g of yeast cell-wall product, flushed with O_2-free CO_2, and capped. For each incubation time, 5 flasks were prepared: 2 replicates each for BrYBG, and BaYBG, and one without product, used as control. Flasks were kept from light and air at 39°C in a waterbath rotary shaker. The pH was recorded at the start of incubation (0 h), 4 h, 8 h, and 16 h. Once the pH was measured, batch culture was centrifuged (4,500 × *g* for 10 min). Supernatants were taken to determine VFA contents. Total VFA produced was calculated by subtracting the initial total VFA concentration from the final concentration. The sediment BG content was determined (enzymatic kit, Megazyme). BG solubility was calculated by subtracting residual BG in sediment at the end of each incubation time from the starting concentration at 0 h. This batch culture experiment was repeated on 3 different days. At 4 h, the percentage of soluble BG was 3 times higher ($P < 0.0001$) for BaYBG than for BrYBG. At 16 h, it reached 96.4% and 92.5 for BaYBG and BrYBG, respectively. Amount of soluble BG increased ($P < 0.0001$) linearly with time ($r^2 = 0.916$ for BrYBG and 0.993 for BaYBG). Total VFA contents at 16 h differ ($P = 0.0007$): 95.2 vs. 110.7 m*M,* for BaYBG and BrYBG, respectively. The pH fall was less important ($P < 0.0001$) for BaYBG than for BrYBG. The decrease in pH and increase in total VFA production suggested that ruminal microflora would be potentially capable of degrading some soluble components in the yeast cell-wall products. But at 16h, 70% of DM BaYBG and 56% of DM BrYBG escape the ruminal degradation suggesting bioavailability in post-ruminal digestive tract.

Key Words: beta-glucan, yeast, in vitro

T482 Effect of different sources of glycerol on in vitro fermentation parameters of corn silage.

E. H. C. B. van Cleef*[1,2], E. S. Castro Filho[1], M. T. C. Almeida[1], J. R. Paschoaloto[1], I. Monsignati[1], S. F. B. Buzinaro[3], and J. M. B. Ezequiel[1], [1]*São Paulo State University, Jaboticabal, São Paulo, Brazil,* [2]*FAPESP, São Paulo, Brazil,* [3]*University of São Paulo, Pirassununga, São Paulo, Brazil.*

Two studies were conducted to evaluate the effect of sources of glycerol on in vitro fermentation, and dry matter and neutral detergent fiber digestibilities of corn silage. In the first trial, rumen content was collected from 2 ruminally cannulated male sheep (68.5 kg BW) fed diet composed of 40% corn silage and 60% concentrate (corn, soybean hulls, soybean meal, urea, and minerals). Substrates tested were (1) corn silage, (2) corn silage + 20% crude glycerin (86% glycerol), (3) corn silage + dry glycerin (68% glycerol), and (4) corn silage + pure glycerin (99% glycerol). Substrates (200 mg) and buffered rumen fluid (20 mL McDougall's buffer and 10 mL rumen fluid) were placed into 60-mL bottles (n = 20), purged with helium gas and sealed. Gas production, pH, ammonia nitrogen (NH_3-N) and DM disappearance were evaluated after 24 h of incubation at 39°C. In the second trial, Ankom Daisy^{II} fermenter was used to evaluate in vitro digestibility of DM and NDF. Filter bags (n = 25) were filled with substrates, and incubated for 48 h (39°C) into vessels containing a solution composed of 400 mL rumen fluid, 1330 mL buffer A and 266 mL buffer B. After 48-h incubation, 40 mL of 6 *N* HCl and 8 g of pepsin was added to each digestion vessel, and incubated for another 24 h. Substrates and residues were evaluated for DM and NDF content. All the procedures were replicated for both trials. There was no effect of treatments on 24-h pH (6.1) and NH_3-N (38.4 mg/dL), nor for production of total gas (51.2 mL), CH_4 (8.9 mL), and CO_2 (39.7 mL). When DM disappearance. When the dry matter disappearance was taken into account, corn silage produced more gas (total gas) and more CO_2 than glycerol treatments ($P = 0.01$ and $P = 0.003$, respectively), and no difference was observed among treatments for CH_4, and among glycerol treatments for CO_2. Glycerol, regardless the source, increased IVDMD of corn silage ($P < 0.0001$), and no changes were observed among glycerol treatments (71.7%). IVDMD was unaffected by treatments (41.7%). All sources of glycerol (crude, dry or pure) do not alter neither rumen fermentation nor in vitro digestibility, when inoculated at 20% with corn silage, thus any of these sources are suitable to improve IVDMD of corn silage.

Key Words: glycerol, in vitro dry matter digestibility, methane

T483 Quality evaluation of corn silage prepared with microbial inoculants.

Luiz Keller*[1,4], Marcos Aronovich[3], Christiane Perali[2,4], Eliane Rodrigues[3], Airton Castagna[3], and Carlos Rosa[2,4], [1]*Universidade Federal Fluminese (UFF), Rio de Janeiro, RJ, Brazil,* [2]*Universidade Federal Rural do Rio de Janeiro (UFRRJ), Rio de Janeiro, RJ, Brazil,* [3]*Empresa de Desenvolvimento Agropecuário do Estado do Rio de Janeiro (PESAGRO-RJ), Rio de Janeiro, RJ, Brazil,* [4]*Conselho Nacional de Pesquisas Científicas (CNPq), Belo Horizonte, MG, Brazil.*

Silage is a common widespread practice to preserve forages in Brazil. One of the main problems encountered is the high value of rations and raw materials, so use mainly corn, sorghum and agro-industrial sub products. Being reviewed mycobiota present in the ensiled material and mycotoxins levels are an indicator of quality, because the poor storage conditions can lead contamination and toxins production. The research evaluated the quality of silages preserved with biological inoculants on mycobiota, mycotoxins levels and nutritional assessment parameters. Two dosages of commercial inoculant product, with 10 replications was used on corn silage and evaluated at 0, 30, 60 and 90 d. Fungal counts were done by surface-spread method and toxigenic ability of isolates strains was evaluated with in vitro conditions. Aflatoxins (AFs), ochratoxin A (OTA), fumonisin B1 (FB1) and deoxinivalenol (DON) natural contamination was determined with immunoaffinity columns extracts in HPLC. Total fungal counts were generally high (range 1.0 × 10^6 to 1.0 × 10^2 cfu g^{-1}). *Aspergillus flavus, Penicillium citrinum,* and *Fusarium verticillioides* were the prevalent toxigenic strains isolated. Mycotoxins levels differed ($P < 0.001$) from pre and post-fermentation samples, probably due to mold growth. Dry matter, carbohydrates, lipids, protein, volatile fatty acids, and fiber content not differed ($P < 0.001$) from pre and post-fermentation samples and were not different from literature. The inoculants does not helped in reducing the count of fungal propagules but decreased the biodiversity of the toxigenic strains presents in the treated silos. So, the use of microbial inoculant on silage production should be recommended to reduce some toxigenic strains contamination. However, each product must be evaluated and the applying process must be carefully conducted. The mycotoxin binding and nutritional quality increase related on literature was not observed on the present study.

Key Words: aflatoxin, corn silage, feedstuffs

T484 Utilization of equations to predict carbohydrate fractions in some tropical grasses. Romualdo S. Fukushima*, Carolina B. Bacha, Adriana P. Fuzeto, Ana C. R. Port, Valdo R. Herling, and Alejandro V. Velasquez, *Sao Paulo University, Pirassununga, SP, Brazil.*

The chemical composition of 5 tropical grasses, divided into stalk and leaf, at 3 maturity stages, was used to predict carbohydrate fractions by equations of the Cornell Net Carbohydrate and Protein System (CNCPS) or equations from our research group. Carbohydrate fraction A is a rapidly fermented pool that is primarily composed of sugars, some organic acids and short oligosaccharides. Fraction B1 is constituted mainly of starch and pectin. Fraction B2 has a slower rate of degradation and is available cell wall carbohydrates. The C pool is unavailable cell wall, which includes lignin. These carbohydrates fractions are estimated based on NDF analysis. However, NDF does not recover pectic substances and other ND soluble oligosaccharides such as β-glucans, fructans, galactans, etc. that are part of the cell wall matrix. Structurally, NDF is not complete plant cell wall. Then, a crude cell wall (CW) preparation, which represents plant cell wall matrix more completely because it preserves those carbohydrates that otherwise would be solubilized by the ND solution, was used in equations to predict carbohydrate fractions. By substituting NDF for CW, it was found that pectin and other ND soluble oligosaccharides (soluble fiber - SF) actually appeared in the fraction A of CNCPS, the rapidly degradable carbohydrate pool, instead of fraction B1, as proposed in the original CNCPS model. However, location of SF in the fraction A seems inadequate because degradation rate of SF is lower than fraction A components; thus, an alternative could be to place SF in a specific carbohydrate fraction (B2). This B2 fraction, soluble fiber, can be estimated by subtracting NDF from CW preparation. Because in the original CNCPS model the slowly degradable cell wall carbohydrates were assigned as fraction B2, we suggest naming this carbohydrate pool a new fraction, B3. With this arrangement, the fraction B1 would be constituted only by starch. These fractions are expressed on total carbohydrate basis, here suggested as: CHO = 100 - (CP + EE + MM + Lignin). This equation excludes lignin from the CHO compartment.

Key Words: cell wall, Cornell, soluble fiber

T485 Analysis of microbial populations in Rusitec fermenters fed diets of variable composition. Ivan Mateos[2], Maria Jose Ranilla*[2,3], Cristina Saro[2], Alexey Díaz[2], Maria Gracia De Garnica[2], Jairo Garcia[2], and Maria Dolores Carro[1], *[1]Technical University of Madrid, Madrid, Spain, [2]University of León, León, Spain, [3]IGM (CSIC-ULE), Grulleros, León, Spain.*

Fermenters are widely used to study ruminal fermentation, but information on microbial populations developing in fermenters over the incubation period is limited. Four Rusitec fermenters were fed 2 diets representative of those administered to dairy sheep (DAI; 50:50 alfalfa hay:concentrate) and fattening lambs (FAT; 15:85 barley straw:concentrate) in a crossover design with 2 14-d incubation periods to assess the evolution of the microbial populations. There were 4 fermenters per diet. The fermenters received daily 30 g of diet DM and samples from liquid (LIQ) and solid (SOL) digesta were taken on d 3, 8 and 14, and stored frozen at −80ºC until DNA extraction. Concentrations of bacterial and protozoal DNA and relative abundance of fungi and methanogenic archaea to total bacterial DNA concentration were determined by real time PCR using previously validated primers and DNA from bacteria and protozoa isolated from sheep rumen as standards. Data were analyzed as a mixed model with repeated measures using the PROC MIXED of SAS. The model included diet, incubation run, time, and diet × time as fixed effects, and fermenter as a random effect. Diet x sampling time interactions ($P > 0.05$) were detected for bacterial and protozoal DNA concentrations in both digesta phases. The bacterial DNA concentrations in SOL did not change ($P = 0.002$) over the incubation period, whereas concentrations in LIQ increased ($P < 0.001$) by 1.5 and 1.8 times for DAI and FAT diets by the end of the incubation, respectively. Protozoal DNA concentrations on d 14 were 37.8 and 8.0 times lower ($P < 0.001$; means across diets) than those on d 3 for SOL and LIQ phases, respectively. Relative abundance of fungi decreased ($P < 0.05$) with time in both phases, and that of methanogenic archaea remain unchanged in LIQ and increased ($P = 0.021$) in SOL. Concentration of bacterial and protozoal DNA and the relative abundance of methanogenic archaea were greater in the fermenters fed the DAI diet ($P < 0.05$) compared with FAT diet. The results show that microbial populations in Rusitec fermenters are affected by the incubated diet and change over the incubation period.

Key Words: Rusitec fermenter, microbial populations, real-time PCR

T486 Influence of inoculum preparation method on in vitro methane production by ruminal microorganisms. Mireia Ramos[1], Ivan Mateos[2], Cristina Saro[2], Alexey Díaz[2], Maria Jose Ranilla*[2,3], and Maria Dolores Carro[1], *[1]Technical University of Madrid, Madrid, Spain, [2]University of León, León, Spain, [3]IGM (CSIC-ULE), Grulleros, León, Spain.*

The characteristics of the inoculum are recognized as one of the most relevant factors influencing the results of in vitro fermentations in batch cultures of ruminal microorganisms. Four rumen-fistulated sheep fed a 66:34 alfalfa hay:concentrate diet were used as donors to investigate the effect of rumen contents' processing on in vitro methane (CH_4) and volatile fatty acid (VFA) production from 3 substrates of variable composition. Rumen contents were sampled from each individual sheep and subjected to the following treatments: SQ) squeezed through 4 layers of cheesecloth; FIL) SQ treatment and further filtration through a 100-µm nylon cloth; STO) treated with a Stomacher for 3 min at 230 rev min^{-1} and followed by SQ. The resulting fluids were used as inoculum for batch cultures containing alfalfa hay, concentrate, or a 50:50 mixture of both feeds. Cultures were incubated at 39°C for 8 and 24 h, and CH_4 and VFA production was measured. There were no treatment × substrate interactions ($P > 0.05$) for any variable at any incubation time, excepting for the molar proportion of acetate at 24 h ($P = 0.019$). The method of processing the rumen contents did not affect ($P > 0.05$) either total VFA and CH_4 production or molar proportions of individual VFA at any time. At both incubation times, increasing the amount of concentrate in the substrate increased CH_4 production ($P < 0.001$, quadratic) and molar proportion of butyrate ($P < 0.001$, linear), but decreased acetate proportion ($P < 0.001$, quadratic) without affecting ($P > 0.05$) proportions of propionate. Whereas total VFA production was linearly decreased ($P = 0.007$) by increased amounts of concentrate in the substrate at 8 h of incubation, it was quadratically increased ($P < 0.001$) after 24 h of incubation. There were clear differences in CH_4 and VFA production among inocula from different sheep, which persisted across substrates. The results show that the tested methods of processing rumen contents did not affect in vitro fermentation characteristics of good quality substrates, but studies analyzing their possible influence on fermentation of low-quality substrates are required.

Key Words: Rumen content treatment, methane, volatile fatty acids

T487 Microbial rDNA sequences as markers to determine microbial synthesis in Rusitec fermenters: A comparison with ^{15}N.

Cristina Saro[2], Maria Jose Ranilla*[2,3], Ivan Mateos[2], Alexey Díaz[2], Jairo Garcia[2], Maria Gracia de Garnica[2], and Maria Dolores Carro[1], [1]*Technical University of Madrid, Madrid, Spain,* [2]*University of León, León, Spain,* [3]*IGM (CSIC-ULE), Grulleros, León, Spain.*

Microbial rDNA sequences have been proposed as potential internal markers to determine microbial synthesis in the rumen. The objective of this experiment was to compare values of microbial growth determined using ^{15}N as external marker with concentrations of microbial DNA in fermenters, and to assess if both procedures detected similar differences between diets and solid (SOL) and liquid (LIQ) digesta phases. Four Rusitec vessels were used in a crossover trial with 2 14-d periods. In each period, 2 fermenters received a 50:50 alfalfa hay:concentrate diet (MC) and 2 were fed a 15:85 barley straw:concentrate diet (HC). A solution of $^{15}NH_4Cl$ was infused for 5 d before taken samples of SOL and LIQ digesta and isolation of bacterial pellets from both digesta phases to estimate microbial protein synthesis. Samples of SOL and LIQ digesta were simultaneously taken for DNA extraction and analysis of concentrations of total bacterial and protozoal DNA by quantitative PCR. Total microbial N (TMN) was calculated from the ^{15}N enrichment in digesta and isolated bacterial pellets, and total microbial DNA (TMDNA) was calculated as the sum of bacterial DNA and protozoal DNA in both digesta fractions. There were no diet × digesta phase interactions ($P > 0.05$) with any marker. Both TMN and TMDNA were greater ($P < 0.001$) in MC-fermenters than in HC-fermenters (1.5 and 2.0 times greater for TMN and TMDNA, respectively). Values of TMN were greater ($P = 0.004$) in SOL than in LIQ digesta (108 and 89.7 mg N, respectively), whereas the opposite was found for TMDNA (3.37 and 13.1 mg DNA, respectively). There was no difference between diets ($P > 0.05$) in the contribution of SOL digesta to TMN (53.8 and 55.7% for MC and HC diets, respectively), but contribution of SOL digesta to TMDNA was greater in MC than in HC diet ($P = 0.039$; 24.5 and 11.5%, respectively). There was no relationship ($P > 0.05$) between TMN and TMDNA values, but a significant relationship was observed when only values in the LIQ digesta were considered ($P = 0.024$; r = 0.821). In summary, both markers detected similar differences between diets, but not between digesta phases.

Key Words: microbial growth, ^{15}N, qPCR

T488 Comparison of Roche 454 and Ion Torrent Personal Genome Machine sequencing on the rumen bacterial profiles of dairy cows.

Nagaraju Indugu*, Sanjay Kumar, Bonnie Vecchiarelli, and Dipti Pitta, *Department of Clinical Studies, School of Veterinary Medicine, New Bolton Center, University of Pennsylvania, Kennett Square, PA.*

Next generation sequencing (NGS) is a widely accepted technology used by microbial ecologists for metagenomic analysis of complex microbial communities. As technologies continue to improve, it is necessary to compare data sets obtained from different platforms and analyze their effect on community structure. In the present study, we compared the 454 data set with that of Ion Torrent Personal Genome Machine (PGM) on the same DNA samples (n = 14) obtained from the rumen of dairy cows during their transition period. Despite the substantial difference in number of reads and length of reads, the platforms provided a similar community structure. The weighted UniFrac distances between the samples that were sequenced on both 454 and PGM were significantly correlated, as determined by Procrustes analysis of principal coordinate matrices (M2 = 0.319; Monte Carlo $P < 0.001$). Though similar major abundant phyla were detected by both platforms, PGM recovered 4 additional phyla. At the genus level, there was no substantial variation between the 454 and PGM data sets for each animal except for *Prevotella*, *Cyanobacteria* YS2 and *Succiniliclasticum* ($P < 0.05$; chi-squared test). However, there was variation in the abundance of genera between different animals, irrespective of the platform used. Collectively, the present study will be useful for microbiologists/ecologists to compare the microbial community structure obtained from different platforms; particularly with the expectation 454 will be completely replaced by PGM and/ or Illumina.

Key Words: Ion Torrent PGM, microbial community, 454-Roche

T489 Effect of chitosan in dairy cows diets on ruminal fermentation and milk yield and composition.

Carlos Eduardo Cardoso Consentini[1], Elmeson Ferreira de Jesus[2], Pablo Gomes de Paiva*[2], Tiago Antonio Del Valle[1], Gustavo Ferreira de Almeida[1], Artur Gabriel Brao Vilas Boas Costa[1], Fernanda Carolina Ramos dos Santos[1], Victor Chiaroni Galvão[1], and Francisco Palma Rennó[1], [1]*School of Veterinary Medicine and Animal Science of USP, Pirassununga, São Paulo, Brazil,* [2]*School of Agricultural and Veterinary Sciences of UNESP, Jaboticabal, São Paulo, Brazil.*

In this study, we evaluate the effects of chitosan level for cows in late lactation on ruminal fermentation and milk yield and composition. Eight Holstein cows cannulated in the rumen (215.4 ± 60.9 DIM, 22.07 ± 5.32 kg of milk yield and 641.6 ± 41.06 kg of BW) in replicated 4 × 4 Latin squares, were fed the following diets: (CTR) control diet without addition of chitosan, CHI75 mg/kg, CHI150 mg/kg and 225 mg/ kg of chitosan addition per kg BW. Each period had 14 d adaptation and 7 for collection data. Ruminal fluid was collected on 20th day of each period at 7 times to evaluate the effect of the diets on ruminal fermentation. Sampling of milk was done on 16 to 18th day of each period to evaluate the composition. The results of milk composition was subjected to ANOVA, while ruminal fermentation data were analyzed as repeated measures by PROC MIXED of SAS. Chitosan changed ruminal fermentation profile, increasing rumen propionate ($P < 0.05$) without shift acetate and total VFA concentrations ($P > 0.05$). However, chitosan decreased linearly acetate:propionate ratio ($P < 0.05$) similarly to butyrate and AGCR concentrations ($P < 0.05$). Chitosan increased milk yield ($P < 0.05$). Furthermore, dietary chitosan linear increased protein and lactose milk production ($P < 0.05$). Chitosan as feed additive improve animal performance and ruminal fermentation with increased ruminal propionate concentration.

Key Words: additive, antimicrobial, performance

T490 Method to measure production of volatile fatty acids and gases in vitro.

Latisha M. Judd* and Richard A. Kohn, *University of Maryland, College Park, MD.*

In vitro methods have been developed to measure digestibility, but such methods may not accurately estimate methane or volatile fatty acid (VFA) production. Methane emissions are stoichiometrically linked with VFA profiles. For example, a shift from acetate to propionate may decrease CO_2 and H_2 production, and in turn decrease conversion of CO_2 and H_2 to methane. The objective of this study was to determine the effect of different conditions of in vitro procedures on VFA and gas profiles in comparison with in vivo measurements. Experimental design was a 4 × 2 × 2 factorial CRD with 4 replicates. Treatments were 4 ratios of rumen fluid to buffer by volume (95/5, 75/25, 50/50, 25/75), 2 concentrations (w/v) of added timothy hay (0.5% or 1%), and with or without sodium acetate addition (50 mmol final concentration). Statistical analysis was conducted using a mixed model that included all fixed effects and interactions. Total volume of broth (rumen fluid and buffer) was 10 mL per tube. Measurements of gas production and VFAs were recorded at 0, 4, 16, 24, and 48 h. Total gas was proportioned into CO_2 and non-CO_2 after collection at 48 h. Higher hay concentration averaged more ($P < 0.0001$) total gas than the lower hay concentration (12.1 vs. 6.7 mL gas/tube; SE = ± 0.23), and more ($P < 0.0001$) non-CO_2 gas (0.28 vs. 0.15 mL; SE = ± 0.046). Total gas production increased ($P < 0.001$) with higher buffer concentration, and averaged 6.1, 9.1, 11.2 and 11.2 mL per tube (SE = ± 0.32 mL) as buffer concentration increased. The acetate/propionate (A/P) concentration decreased over time ($P < 0.0001$). The initial rumen fluid A/P ratio was 3.7 but the A/P ratio of produced VFA averaged 2.5 (SE = ± 0.14). The addition of acetate did not affect gas production or A/P ratio of produced VFA. This could mean that adding acetate to a system does not necessarily shift production away from acetate. A/P ratio differed for VFA produced in vitro compared with initial rumen fluid, but no tested treatments were identified as a cause of the difference.

Key Words: in vitro digestion, volatile fatty acids, methane

T491 A rapid mold and yeast enumeration technique is comparable to a conventional technique for animal feedstuffs.

Lauren Meyer*[1] and John Goeser[1,2], [1]*Rock River Laboratory, Watertown, WI,* [2]*University of Wisconsin-Madison, Madison, WI.*

Feedstuff and TMR yeast and mold enumerations (cfu/g) have grown in popularity to diagnose opportunities on farm. Turnaround time with conventional enumeration (CON) limits utility, requiring 5 d incubation, extending total time from sampling to reporting to 7d or more. More recent human food grade, rapid yeast and mold enumeration techniques (RAP) offer faster turnaround and may have utility for production agriculture. The objective here was to determine if RAP, tested under 2 incubation lengths, was equivalent to CON. Corn silage (n = 17), TMR (n = 3), alfalfa silage (n = 15), high moisture corn or snaplage (n = 6), small grain silages (n = 6), and concentrate (n = 6) samples submitted for CON in late February 2015 were further assayed using RAP, with both 48-h and 5-d incubation. When samples arrived, roughly 5g feed was blended and stored at 1C for later plating. At plating, 1g wet feed was subsampled and diluted to 100mL in sterile buffer, shaken and then serially diluted 1:1000, 1:10,000 and 1:100,000 for most probable number enumeration. For CON, subsamples of each dilution were taken with sterile glass pipette and plated on potato-dextrose agar using spread-plate method. For RAP, subsamples of each dilution taken with an electronic pipette were plated on Petrifilm, using a Petrifilm flat spreader (3M, St. Paul, MN). For RAP plates were aerobically incubated at 28C for both 48h and 5d and CON for 5d. Post incubation, enumeration was done by direct microscopy. Yeast and mold count mean/median across feeds and techniques were $1.69 \times 10^6/1 \times 10^3$ and $2.53 \times 10^5/1 \times 10^4$, respectively. Raw and log-transformed data were determined not normally distributed, hence data were fit using one-way analysis option of SAS JMPv11.0. Technique (CON, RAP-48h, and RAP-5d) and feed main effects were compared using non-parametric Wilcoxon/Kruskal-Wallis test. Significance was declared if resulting Chi-squared statistic p-value was < 0.05. For both mold and yeast enumeration, techniques did not differ ($P > 0.05$) while feed types differed ($P < 0.01$). Our results suggest both yeast and mold enumeration results are comparable across the techniques tested here.

Key Words: feed, mold, yeast

T492 Comparison of acetyl bromide lignin with acid detergent lignin and relationship with in vitro forage degradability.

Romualdo S. Fukushima*[1,2], Monty Kerley[2], Marcelo H. Ramos[2], James H. Porter[2], and Robert L. Kallenbach[2], [1]*Sao Paulo University, Pirassununga, SP, Brazil,* [2]*University of Missouri, Columbia, MO.*

The spectroscopic acetyl bromide lignin (ABL) and the gravimetric acid detergent lignin (ADL) methods were compared with in vitro forage dry matter degradability (IVDMD) and neutral detergent fiber degradability (IVNDFD) assays of 73 grass and legume samples, and a conjecture was made with the lignin component of the Cornell Net Carbohydrate and Protein System (CNCPS) equations. The slopes and intercepts of regressions were declared different when there was an interaction effect among forages within each lignin method (MIXED procedure of SAS). Regression curves of ADL values with forage IVDMD (grass: $y = -7.929x + 901.8$; legume: $y = -3.663x + 853.6$) and IVNDFD (grass: $y = -3.289x + 916.0$; legume: $y = -1.051x + 697.8$) revealed different slopes, with steeper curves for grasses. Grass and legume samples assayed with the ABL procedure, exhibited similar slopes, with parallel lines for both IVDMD (grass: $y = -3.847x + 886.7$; legume: $y = -3.638x + 789.8$) and IVNDFD (grass: $y = -3.636x + 1117.7$; legume: $y = -3.454x + 889.9$) assays. Steeper inclination of curve for grasses relative to legumes in the ADL method has been attributed to grass lignin being more inhibitory to degradation than legume lignin. Similar and parallel curves of ABL method suggests that grass lignin is no more inhibitory than legume lignin. However, the steeper inclination may be attributed to partial loss of grass lignin during the ADL procedure. We hypothesize that this loss is around 2.4, that is, the residual ADL multiplied by 2.4 would yield the actual lignin content. This number is the same used in the Cornell equations to estimate the B2 and C carbohydrate fractions (NDF x Lignin x 2.4). When we multiplied the grass ADL values by 2.4, forage IVDMD regressions were: (grass: $y = -3.690x + 934.7$; legume: $y = -3.663x + 853.6$), which originated parallel lines and were strikingly similar to the ones obtained with the ABL method. After correcting IVNDFD, the regressions were: (grass: $y = -1.744x + 962.9$; legume: $y = -1.737x + 805.8$), also yielding parallel curves. At this moment we can speculate that grass and legume lignins have the same effect on cell wall degradation and that ABL method seems a promising procedure for lignin quantification.

Key Words: lignin methods, Cornell carbohydrate equations

T493 What roles do viruses play in the rumen? Christopher Anderson, Galen Erickson, and Samodha Fernando*, *University of Nebraska, Lincoln, NE.*

Viruses are the most abundant biological entity on earth. However, the role of viruses within ecosystems are poorly understood. As an attempt to better understand the role and functional relationships of viruses and their influence on rumen bacterial communities, we investigated viral and bacterial community relationships using culture independent metagenomic approaches under 4 different dietary conditions (55% corn silage, 27% condensed distillers plus solubles (CDS), 40% modified distillers grains plus solubles (MDGS), corn based control diet) in a Latin-square design with 5 fistulated steers. Rumen samples were collected after total rumen evacuation and mixing following a 21-d adaptation period. Tangential flow filtration was performed to enrich for viral particles from the rumen sample. The enriched viral metagenome and the total metagenome were sequenced using the Ion Torrent Personnel Genome Machine (PGM) to identify species composition, interactions between viruses and bacteria, and to identify the role of virus auxiliary genes within rumen metabolism. The metagenome analysis displayed the total metagenome contained 118 differentially abundant genes and the viral metagenome 309 differentially abundant genes based on diet. Interestingly, the metagenomes and metaviromes contained different metabolic profiles. To better understand the role of the virome in ecosystem function, we mapped the genes identified to a community metabolic network. Using the metabolic networks we compared topological features of enzyme nodes to identify the roles of differentially abundant genes. The nodes that were differentially abundant in the total metagenome and virome had significantly higher betweenness centrality ($P < 0.05$) and a lower average shortest path length compared with non-differential genes in the network ($P < 0.05$). In addition, differential viral genes had a significantly higher total degree and in-degree compared with non-differential genes and the differential genes in the total metagenome ($P < 0.05$). Currently, we are applying network approaches to understand the ecological roles of viruses within energy metabolism in the rumen environment.

Key Words: metagenome, virome, metabolic network

T494 Effects of short-term inclusion of mixed fish and sunflower oils in finishing diet on carcass characteristics and performance of fat tailed Afshari lambs. H. R. Mirzaei Alamouti*, T. Khademi, M. H. Shahir, and M. Hajilo, *Department of Animal Science, University of Zanjan, Iran.*

An experiment was conducted to determine the effects of unsaturated fatty acids supplementation on growth performance and carcass characteristics of finishing lambs. Thirty-two finishing Afshari lambs (initial weigh 58 ± 5 kg and 8 mo age) were used in a completely randomized design with 4 treatments (slaughtered in time series) and 8 lambs/treatment for the final 30 d before slaughter. The slaughter times were d 0 (first day after adaptation period), 10, 20 and 30 after beginning of experiment. The lambs individually fed to the basal diet (80% concentrate; 65% barley grain and 11% soybean meal and 4% mineral and vitamin supplement, and 20% alfalfa hay) and daily fed with 60 g sunflower oil and 40 g fish oil. Body weight changes and daily feed intake were recorded. Blood samples, ultrasonography (back fat and Longissimus muscle thickness) and rumen fluid was taken on the last day of each periods. Cold and warm slaughter weight, dressing percentage, fat yield, pH, moisture loss, chemical composition, and visceral organs mass were measured. The results of this study were revealed that body weight, back fat and Longissimus muscle thickness, for d 0, 10, 20 and 30 after allocating to high oil supplemented diets was 59.20, 62.45, 65.26, and 69.07 kg; 4.8, 5.09, 5.36, and 4.79 mm; 24.41, 24.28, 25.90, and 30.38 mm; respectively. Warm and cold carcass weight and rumino-reticlum mass increased during time. Oil supplementation decreased tail weight to carcass weight ratio from 0.17 to 0.12 and also improved feed conversion ratio. Plasma concentration of cholesterol was highly increased by oil supplementation and was significantly different among the experimental diets ($P < 0.01$). This experiment showed that short-term inclusion of mixed fish and sunflower oils in final days of finishing lambs diet can improve carcass characteristics and performance of lambs.

Key Words: unsaturated fatty acid, carcass characteristic, finishing lamb

T495 Growth, hepatic enzymes and carcass characteristics of lambs fed diets containing increasing levels of crude glycerin. D. M. Polizel[1], R. S. Gentil[1], E. M. Ferreira[1], R. A. Souza[1], A. P. A. Freire[1], M. C. A. Sucupira[2], and I. Susin*[1], [1]*Escola Superior de Agricultura Luiz de Queiroz (ESALQ)/USP, Piracicaba, SP, Brazil,* [2]*Faculdade de Medicina Veterinária e Zootecnia (FMVZ)/USP, São Paulo, SP, Brazil.*

Crude glycerin is a high energy by-product of biodiesel production. However, some impurities may be present in it including methanol and salts. Methanol can impair liver function.The objectives of this trial were to determine the effects of partial replacement of corn by crude glycerin on growth, hepatic enzymes and carcass characteristics of lambs fed high-concentrate diets. Fifty (40 males and 10 females) White Dorper × Santa Ines lambs were assigned to a randomized complete block design, defined by initial BW, sex and age. Lambs were penned individually and fed, during 56 d (2 periods of 28-d), a TMR composed of 90% concentrate. Diets were isonitrogenous (15.7 ± 0.3% CP, DM basis) and the increasing levels of crude glycerin (83.6% glycerol and 397 mg of methanol/kg, DM basis) were 0, 5, 10, 15 or 20%. Lambs were weighted and blood samples were collected on d-0, d-28 and d-56. Average daily gain (ADG), feed efficiency (FE) and dry matter intake (DMI) were determined in each period. At the end of the 56-d, all ram lambs were slaughtered for carcass characteristics evaluation. Data were analyzed using the MIXED procedure (SAS Inst. Inc.). Orthogonal polynomials for diet responses were determined by linear and quadratic. Replacing corn by crude glycerin did not affect ADG (0.29, 0.29, 0.30, 0.31 and 0.28 kg), DMI (1.03, 1.02, 1.04, 1.08, 1.00 kg/d), FE (0.28, 0.28, 0.29, 0.28, 0.28) and body weight on d-28 (29.3, 29.3, 29.3, 29.2, 28.4 kg) and d-56 (38.9, 38.7, 39.0, 39.2, 38.2 kg). There was a diet and period interaction for DMI. In the second period (d28-d56) a quadratic effect for DMI (1.11, 1.15, 1.18, 1.25, 1.11, kg/d) was observed. Hepatic enzymes (aspartate aminotransferase and gamma glutamyltransferase) activity and carcass characteristics were not affected by crude glycerin addition to the diet. Crude glycerin can be used to replace up to 20% of corn (DM basis) in high-concentrate diet of lambs without detrimental effects on performance, hepatic enzymes and carcass characteristics.

Key Words: co-product, glycerol, sheep

T496 Effect of supplementation with dried citrus pulp, urea, and DDGS on reproductive performance of goats. Mayra A. Liñan Gonzalez[1], Hugo Bernal Barragan*[1], Fernando Sanchez Davila[1], Rogelio A. Ledezma Torres[1], Miguel Cervantes Ramirez[2], and Braulio Valles de la Mora[3], [1]*Universidad Autonoma de Nuevo Leon, San Nicolas de los Garza, Nuevo Leon, Mexico,* [2]*Universidad Autonoma de Baja California, Mexicali, Baja California, Mexico,* [3]*Universidad Nacional Autonoma de Mexico, Martinez de la Torre, Veracruz, Mexico.*

The objective of this study was to evaluate the effect of supplementation with 2 agroindustrial byproducts and urea, on body weight, serum glucose and BUN, as well as reproductive performance and blood progesterone of 56 goats of a commercial farm in Northeastern Mexico, grazing mixed thornscrub vegetation, including browse species, grass, forbs and Opuntia spp. (3.6 to 15.5% crude protein (CP) and 27.0 to 69.3% NDF), with daily access to shelter. Goats were blocked by breed (Nubian, Alpina and Saanen), age (1.5 to 2.5 years), parity (1 to 3), and body weight, and were randomly assigned among blocks either to T1: No supplementation; or to individually receiving 300 g/d of T2: dried citrus pulp (DCP, 4.9% CP, 20.0% NDF); or T3: DCP+Urea+DDGS (17.7% CP, 26.0% NDF); or T4: DCP+DDGS (15.4% CP, 29.2% NDF; n = 14 goats/treatment). Supplementation lasted 28 d in July–August 2014 (outside the natural breeding season). Beginning on d 13, a 9-d oestrus synchronization protocol was conducted applying 50 µg GnRH on d 13 and 22, and 75 µg PGF2α on d 20. Oestrus was observed utilizing teaser bucks, and goats were fixed-time transcervically inseminated 16 h after the second GnRH dose, using fresh processed and evaluated semen of 2 randomly assigned sires. Blood samples were collected by venipuncture of jugular vein on d 1, 6, 12, 20, 22 and 26. Glucose and BUN were colorimetrically analyzed. Progesterone was measured by ELISA. Results were analyzed by ANOVA and Chi-squared. Supplemented goats lost less BW ($P < 0.05$) than control animals. Serum glucose (42.3 ± 0.7 mg/dL) was similar ($P > 0.05$) among treatments. Goats in T1 and T4 had higher BUN values than T2 (mean 27.6 *vs* 25.2 mg/dL; $P < 0.05$). No differences were detected among treatments in oestrus appearance. Fertility rate of T2 and T3 (53 – 57%) was numerically better than in T1 and T4 (35 - 43%). Goats in T1 had on d 22 higher ($P < 0.05$) progesterone values than others. In conclusion, supplementing 300 g of DCP and DCP+Urea+DDGS during 28 d helped avoid loss of BW and improved fertility of goats.

Key Words: goat, dried citrus pulp, dried distillers grains with solubles

T497 Effect of feed restriction on protein metabolism of Saanen goats of different sexes.

Nhayandra C. D. Silva*, Izabelle A. M. A. Teixeira, Carla J. Härter, Simone P. Silva, Amélia K. Almeida, Diogo C. Soares, and Kléber T. Resende, *Unesp Univ Estadual Paulista, Jaboticabal, São Paulo, Brazil.*

The objective of this study was to evaluate the effect of feed restriction on protein metabolism of 84 Saanen goats (26 intact males, 27 castrated males and 31 females) with initial BW of 30,3 ± 0,87 kg. At the beginning of the experiment 8 intact males, 9 castrated males and 13 females were slaughtered with 30 kg of BW to estimate their initial body composition. The remaining 18 goats of each sex were assigned to 3 levels of feed restriction (ad libitum, 25% and 50% of feed restriction), with 6 goats per sex-feeding level (3 × 3 factorial). Animal sets (1 goat per sex-feeding level) were slaughtered when BW of ad libitum goats was 45 kg. Blood samples were collected every 14 d, in a total of 7 blood collections (98 d of experimental period). In these samples we evaluated total protein, albumin, urea, creatinine, triiodothyronine (T3) and IGF-1. Data were analyzed using Proc Mixed of SAS. Intact males presented lower body protein retention (kg) regardless the level of feed restriction ($P = 0.020$). Intact males fed ad libitum and with 50% of feed restriction had greater serum levels of creatinine in the blood (0.88 mg/dL and 1.28 mg/dL respectively; $P = 0.014$). Females fed ad libitum had lower urea levels (42.08 ± 1.83 mg/dL) than intact (51.1 ± 1.83 mg/dL) and castrated males (48.2 ± 1.81 mg/dL) however, when subjected feed restriction (25% and 50%), females increased serum levels of urea, whereas males had an opposite behavior. The feed restriction and sex did not affect serum albumin and total protein levels ($P > 0.05$). Intact males fed ad libitum and 25% feed restriction showed greater plasma levels of IGF-1 than females and castrated males ($P = 0.018$), but when fed 50% restriction, the IGF-1 concentration were similar between all sexes (85.0 ± 9.89 ng/mL). Plasma levels of T3 were similar in females and castrated males (1.57 ng/mL) and greater than in intact males (1.43 ng/mL; $P = 0.001$). The levels of IGF-1 and T3 in the blood showed a linear decrease with the increase of feed restriction ($P < 0.0001$). The feed restriction changed the protein metabolism in females and males. Pubertal males were not able to keep protein synthesis during feed restriction.

Key Words: dairy goat, gender, metabolic profile

T498 Female goat kids change their energy metabolism when subjected to feed restriction.

Nhayandra C. D. Silva*[1], Izabelle A. M. A. Teixeira[1], Carla J. Härter[1], Fernanda O. M. Figueiredo[1], Rafael F. Leite[1], Moaceli M. Freire[2], and Kléber T. Resende[1], *[1]Unesp Univ Estadual Paulista, Jaboticabal, São Paulo, Brazil, [2]Universidade Federal de Alagoas, Maceió, Alagoas, Brazil.*

The objective of this study was to evaluate the effect of sex and feed restriction on energy metabolism of 72 Saanen goat kids (24 intact males, 24 castrated males and 24 female) with initial BW of 15.8 ± 0.17 kg. At the beginning of the experiment 6 animals of each sex were slaughtered with 15 kg of BW to estimate their initial body composition. The remaining 18 kids of each sex were assigned to 3 levels of feed restriction (ad libitum, 25% and 50% of feed restriction), with 6 kids per sex-feeding level (3 × 3 factorial). Animal sets (1 kid per sex-feeding level) were slaughtered when BW of ad libitum kids was 30 kg. Blood samples were collected from all animals every 10 d, in a total of 7 blood collections (70 d of experimental period). In these samples, we evaluated glucose, cholesterol, NEFA, β-hydroxybutyrate (B-HB) and aspartate aminotransferase (AST). Data were analyzed using Proc Mixed of SAS. Females presented greater fat deposition (31.6 ± 0.36% EBW) than castrated males (24.7 ± 0.36% EBW) and intact males (11.5 ± 0.36% EBW) regardless the level of feed restriction ($P < 0.0001$). Serum glucose was similar in intact and castrated males throughout the experiment (67.4 ± 4.59 mg/dL). As the feed restriction level increased, serum AST activity of castrated males decreased ($P = 0.0251$) in a ratio of 4.3% for those subjected to 25% of feed restriction and 15.8% for those under 50% feed restriction compared with castrated fed ad libitum. In females, AST activity was higher in those subjected to 50% feed restriction (83.83 ± 4.96 U/L), whereas in intact males remained unchanged regardless of the restriction regimen (80.9 ± 4.95 U/L). The highest B-HB concentration was observed when animals were subjected to the maximum level of feed restriction (0.129 mmol/l) followed by those fed ad libitum (0.103 mmol/L) and restricted by 25% (0.090 mmol/L; P < 0.0149). Sex and feed restriction did not influence NEFA and cholesterol blood levels ($P > 0.05$). Goat kids of different sex act physiologically different when subjected to feed restriction. Females changed all their glycolytic metabolism to keep the fat deposition even when they are subjected to feed restriction.

Key Words: growth, metabolic profile

T499 Effects of restricted diet access on intake and performance by dairy goats in mid- to late lactation.

Nhayandra C. D. Silva*[1,2], Ryszard Puchala[1], Terry A. Gipson[1], Yoko Tsukahara[1], Tilahun Sahlu[1], and Arthur L. Goetsch[1], *[1]American Institute for Goat Research, Langston University, Langston, OK, [2]UNESP, Universidade Estadual Paulista, Department of Animal Science, Jaboticabal, SP, Brazil.*

Restricting periods of dietary access of lactating dairy goats could influence level or efficiency of production and offer different management options. Therefore, objectives of the experiment were to determine effects of offering feed at different times of the day and for various lengths on intake and milk yield and composition of 50 Alpines (15, 25, and 10 of parity 1, 2, and ≥3, respectively) with initial BW of 55.2 kg (SE = 0.95) and 125 d-in-milk (SE = 3.0). A 40% forage diet (20% alfalfa pellets, 10% cottonseed hulls, and 10% coarsely ground grass hay) was given free-choice in Calan gate feeders during a 2-wk covariate period and subsequent 12-wk experiment. Treatments were feed access continuously (C), during the day for 8 h (D) or night for 16 h (N), and for 2 or 4 h/d with equal lengths after milking in the morning and afternoon (2H and 4H, respectively) (10 animals/treatment). Neither DMI (2.05, 1.87, 2.08, 1.91, and 1.87 kg/d; SE = 0.107) nor milk yield (1.77, 1.75, 1.67, 1.64, and 1.68 kg/d for C, D, N, 2H, and 4H, respectively; SE = 0.098) were influenced by treatment ($P > 0.05$), with milk yield (1.83, 1.84, 1.60, and 1.54 kg/d in periods 1, 2, 3, and 4, respectively; SE = 0.051) but not DMI differing among periods. Treatment also did not influence ADG (32, 22, 49, 9, and 20 g; SE = 13.0) or body condition score during the study (2.35, 2.32, 2.24, 2.26, and 2.34; SE = 0.052) and at the end (2.49, 2.39, 2.32, 2.33, and 2.42; SE = 0.054). However, there were treatment effects on milk concentrations of fat (3.78, 3.64, 3.54, 3.75, and 3.21%; SE = 0.126) and protein (2.91, 2.88, 2.88, 2.84, and 2.58% for C, D, N, 2H, and 4H, respectively; SE = 0.049). Energy-corrected milk (3.5% fat, 3.2% protein) in kg/d (1.70, 1.66, 1.58, 1.53, and 1.52 kg/d; SE = 0.101) and relative to DMI (0.79, 0.84, 0.78, 0.81, and 0.81 kg/kg for C, D, N, 2H, and 4H, respectively; SE = 0.073) were similar among treatments. In conclusion, dairy goats in mid- and late lactation possess considerable flexibility in eating behavior that may allow for incorporation of limited feed access regimens in management systems for most efficient facility utilization.

Key Words: dairy goat, feed access, milk production

T500 Effect of sodium monensin on rumen metabolism in lambs fed high-forage diets.

Mariana F. Westphalen*[1], Daniel M. Polizel[2], Marcelo H. Santos[2], Renan G. Silva[2], Analisa V. Bertoloni[1], Gabriela B. Oliveira[1], Thiago S. Andrade[2], Vinicius N. Gouvea[2], Marcos V. Biehl[2], and Alexandre V. Pires[1,2], *[1]University of São Paulo, Piracicaba, São Paulo, Brazil, [2]University of São Paulo, Pirassununga, São Paulo, Brazil.*

The objectives of this trial were to determine the effects of increasing doses of sodium monensin on rumen metabolism of lambs fed high-forage diets. Five wethers (BW 70.5 ± 2.8 kg), cannulated in the rumen, were used in 5 × 5 Latin Square design. Animals were fed daily and diet was composed of coastcross hay. Sodium monensin were offered twice a day and doses were 0 (control), 8, 16, 24 or 32 mg/kg DM, corresponding to 0, 40, 80, 120 and 160 mg of Rumensin 200. The delivery vehicle of the set dosage of monensin was 20 g of ground corn per 1 kg DM intake. Every period of experiment lasted 20 d and rumen fluid was collected in the last day, every 3 h, starting prior feeding, 3, 6, 9 and 12 h after feeding. Short-chain fatty acids (SCFA) and pH were analyzed as repeated measures over time. Protozoa concentration was determined only 3 h after feeding. Data were analyzed using MIXED procedure (SAS Inst. Inc.) and LSMEANS option was used to generate individual means. Orthogonal polynomials for diets responses were determined by linear and quadratic effect. There was a quadratic response for acetate (78.22, 78.25, 78.65, 77.62, 76.27 m*M*/100 m*M*, $P = 0.03$), propionate (14.81, 14.59, 15.07, 15.60, 16.90 m*M*/100 m*M*, $P = 0.02$), isobutyrate (0.66, 0.59, 0.53, 0.56, 0.64 m*M*/100 m*M*, $P = 0.02$) and acetate:propionate ratio (5.30, 5.35, 5.24, 5.02, 4.54, $P = 0.02$). However, there was an interaction ($P < 0.05$) between diet × hour for acetate:propionate ratio. The inclusion of sodium monensin decreased acetate:propionate ratio during 9 and 12 h. There was a linear response for valerate (0.76, 0.66, 0.59, 0.60, 0.59 m*M*/100 m*M*, $P = 0.03$) and pH (6.57, 6.61, 6.46, 6.43, 6.49, $P = 0.05$). Butyrate (4.42 ± 0.06 m*M*/100 m*M*), isovalerate (1.01 ± 0.04 m*M*/100 m*M*), total SCFA (85.58 ± 1.14 m*M*/L) and protozoa concentration ($1.88 \pm 0.22 \times 10^5$/mL) were unaffected ($P > 0.05$) by the experimental diets. Sodium monensin doses above 16 mg/kg DM provided an increase in the molar proportion of propionate over acetate, consequently reducing the acetate-to-propionate ratio and pH.

Key Words: ionophore, propionate, acetate:propionate ratio

T501 Either intramuscular or submucous vulvar administration of HCG positively affects the reproductive outcomes of anovulatory Alpine goats in Northern Mexico.

Karen Isabel Tapia-Robles*[1], Cesar Alberto Meza-Herrera[2], Jessica Maria Flores-Salas[1], Alan Sebastian Alvarado-Espino[1], Vicente Homero Gonzalez-Alvarez[1], Evaristo Carrillo-Castellanos[3], Juan Manuel Guillen-Muñoz[1], Francisco Gerardo Veliz-Deras[1], and Rafael Rodriguez-Martinez[1], *[1]Universidad Autonoma Agraria Antonio Narro, Torreon, Mexico, [2]Universidad Autonoma Chapingo, Unidad Regional Universitaria de Zonas Aridas, Bermejillo, Durango, Mexico, [3]Instituto Tecnologico de Torreon, Torreon, Mexico.*

This study was performed to determine whether vulvar administration HCG, either intramuscular (IM) or submucous (SM), influence the reproductive response of goats during the natural anestrous season in Northern Mexico. Anovulatory Alpine goats (n = 30) under intensive conditions were divided in 3 homogeneous groups (n = 10, each) based on body weight (BW; 37.36 ± 8.48 kg) and body condition (BC, 1.96 ± 0.32). On June 29th, 20 mg of progesterone was applied to all of the goats; 24-h later (d 0), 7.5 mg of $PGF_{2\alpha}$ IM was also applied. Group 1; (GC) received 0.5 ml of isotonic saline solution IM, group 2 (GIM) received 100 UI of hCG of IM and group 3 (GSM) received 100 UI of HCG SM. Estrous activity was registered twice per day from d-0 to d-5 using a male; females accepting mating were considered to be in estrus. Ovulation activity was assessed on d-10 by detecting the presence of at least one corpus luteum while gestation was determined on d-45 both throughout a transrectal ultrasonographic scanning (7.5 MHz). The percentages of females in estrous, ovulating and pregnant were compared with chi^2. While the control group did not depict any response in either variable, treated groups depicted an important reproductive response without differences ($P > 0.05$) between treated groups regarding estrus behavior (GIM 100% *vs* GSM 100%), ovulatory activity (GIM 70% *vs* GSM 100%), and pregnancy rate (GIM 70% *vs* GSM 100%). To conclude, regardless of the administration route of 100 IU of HCG, either i.m. or s.m., both treatments were equally efficient to induce sexual activity with significant reproductive outcomes in Alpine goats during the natural anestrous season in northern Mexico (25°N).

Key Words: anestrous goats, HCG, administration route

T502 Performance of Santa Inês meat lambs receiving cactus pear (*Nopalea cochenillifera*) in substitution of Tifton hay with or without access of water.

Alma V. Cordova Torres[1], Leonardo S. Knupp[2], Antonello Cannas*[2], Giustino Gaspa[2], José T. Araújo Filho[1], Ariosvaldo N. Medeiros[1], Neymar L. Alves[3], and Roberto G. Costa[1], *[1]Programa de Pós Graduação em Ciência e Tecnologia de Alimentos, Universidade Federal da Paraíba, João Pessoa, Paraíba, Brasil, [2]Dipartimento di Agraria, University of Sassari, Sardinia, Italy, [3]Departamento de Zootecnia, Universidade Federal de Alagoas, Rio Largo, Alagoas, Brasil.*

This work aimed to study the performance of Santa Inês meat lambs receiving different levels of inclusion of cactus pear (*Nopalea cochenillifera*) in substitution of Tifton (*Cynodon* dactylon) hay. The trial was conducted using 48 Santa Inês male lambs at 100 d of age, with average initial weight of 18.75 ± 0.46 kg. Diets were formulated to be isoproteic and isoenergetic. Animals had ad libitum access to feed. The experiment was carried out as a completely randomized factorial design (3 × 2), with 3 levels of substitution of Tifton hay with cactus pear (30%, 50% and 70%), subdivided in 2 groups, with or without access of water, and a control treatment. DMI significantly differed among treatments ($P < 0.001$) and the interaction among levels of cactus and access of water were not significant for all variables ($P > 0.05$). The equations to estimate DMI and the ADG in the diets with cactus pear were: $DMI = 1572.3 - 17.8x - 112.8y + 0.07x^2 + 1.78xy$ ($R^2 = 0.63$); $ADG = 145.3 + 1.2x + 15.5y - 0.02x^2 - 0.10xy$ ($R^2 = 0.29$), being x = level of inclusion of cactus pear in the diet (30, 50, 70%) and y = animals with (1) or without (0) access of water. In contrast, the equations to predict the DMI and the ADG including the control treatment with the group that had access of water were: $DMI = 897.3 + 7.8x - 0.16x^2$ ($R^2 = 0.40$); $ADG = 109.2 + 3.2x - 0.04x^2$ ($R^2 = 0.43$), being x = diet control and levels of cactus (0, 30, 50, 70%). The maximum value of DMI was 1.1 kg/day and the minimum was 0.7 kg/day, obtained for the group receiving 30% of cactus without access of water and 70% without access of water, respectively. The ADG was different among treatments ($P < 0.05$) ranging between 177.8 g to 106.8 g for the group with 30% of cactus in the diet with access of water and the control treatment, respectively. Feed efficiency was affected only by treatments, being the group that received 70% of

cactus in the diet with access of water the most efficient (0.19 g). In conclusion, cactus pear is recommended at 30% (with access of water) or 50% (without access of water) of substitution of Tifton hay, resulting in ADG of 178 or 157 g/day, respectively.

Key Words: cactus, dry matter intake, weight gain

T503 Influence of supplementing lamb with dried algae + live yeast product on growth and blood metabolites during summer.

Ekin Sucu*[1], Duygu Udum Küçüksen[2], and Nazmiye Günes[2], [1]*Department of Animal Science, Faculty of Agriculture, Uludag University, Bursa, Turkey,* [2]*Department of Biochemistry, Faculty of Veterinary Medicine, Uludag University, Bursa, Turkey.*

Endocrine and immune system stimulation by Algae is an active area of research. Thus, the current case conducted to examine the impact of an dried algae (Schizochytrium limacinum) and live yeast product (*Saccharomyces cerevisiae* CBS 493.94; 3.0×10^{10} cfu) on lamb performance and blood metabolites during summer (mean temperature humidity index 75.5). Lambs were blocked by weight and randomly assigned to receive either control ration (n = 20) based on wheat grain and sunflower meal or a algae derived supplement with live yeast product (n = 20) in a crossover design with two 21-d experimental periods. Supplement top dressed 1×/d at a rate of 5 g/head/d. Daily pen dry matter intake were recorded and lambs were weighed weekly throughout the trial to determine daily weight gain and feed efficiency. Blood samples were collected from the individual animals during both periods at the beginning of the treatment period (d 0) and on the last day (d 21) of trial. Data were analyzed with the repeated measures PROC MIXED procedure of SAS (SAS Inst. Inc. Cary NC). Overall, Algae+ live yeast supplement increased final live weight and average daily gain ($P < 0.05$). However, no differences were noted between treatments for average dry matter intake ($P = 0.24$) or feed efficiency ($P = 0.23$). Plasma glucose (98.47 vs. 84.97 mg/dl) and insulin (64.14 vs. 29.26 ng/mL) concentrations were higher ($P < 0.05$) while total plasma cholesterol concentration tended to be lower ($P = 0.09$; 58.22 vs. 61.68 mg/dL) in Algae+ live yeast-fed lambs relative to control animals. However, plasma non-ester fatty acid ($P = 0.68$), total protein ($P = 0.55$), blood urea nitrogen ($P = 0.58$), lipopolysacharide binding protein ($P = 0.89$), diamine oxidase ($P = 0.17$), malondialdehyde ($P = 0.49$) and glutathione peroxidase ($P = 0.44$) concentrations were unaffected by supplementation. Results of this study indicate that algae supplement influences productivity and alter bioenergetics in growing lambs during summer. This study was supported by the Scientific Research Project Council of Uludag University, Project Number: KUAP(Z)-2013/46.

Key Words: algae, blood metabolite, lamb performance

T504 Net energy and protein requirements for growth of Moxotó goats grazing in the semiarid region of Brazil.

Marcos J. Araújo*[1], Ariosvaldo N. Medeiros[2], Carlo A. T. Marques[1], Roberto G. Costa[2], Francisco F. R. Carvalho[3], and Jacira N. C. Torreão[4], [1]*Federal University of Piauí, Bom Jesus, Piauí, Brazil,* [2]*Federal University of Paraíba, Areia, Paraíba, Brazil,* [3]*Federal Rural University of Pernambuco, Recife, Pernambuco, Brazil,* [4]*Colégio Técnico de Bom Jesus, Bom Jesus, Piauí, Brazil.*

Indigenous goats play an important role in the semiarid region of Brazil as a biological resource with great genetic variability and historical value. They are raised in the traditional manner because they are rustic animals, commonly used for milk and meat production. Therefore, understanding their nutritional requirements is important for a successful nutrition system because animals fed properly will more efficiently convert the nutrients ingested in products. The objective of this study was to determine net energy (NE_g) and protein (NP_g) requirements for growth of 36 male Moxotó goat kids (15.69 ± 0.78 kg initial BW), grazing in the semiarid region of Brazil. Four kids were slaughtered at the beginning of the experiment (baseline group, 15.37 ± 0.30 kg BW) and the remainder (n = 32) were allocated randomly to one of the 4 levels of concentrate supplementation (treatments groups: 0, 0.5, 1.0 and 1.5% BW), with 8 kids per group. When the animals in the 1.5% BW treatment group reached 25 kg BW, the animals in the other treatment groups were also slaughtered. The individual whole empty body was weighed, ground, mixed and sampled for chemical analyses. We used the comparative slaughter method to assess body composition and calculate the nutritional requirements. Linear regressions were used to determine the relationship between the shrunk BW and the empty body weight (EBW). The allometric equations were calculated using the relationship between the amount of fat, energy and protein and the EBW. Body composition varied from 156.40 to 171.52 g of protein, from 65.20 to 138.44 g of fat and from 1.56 to 2.51 Mcal of energy per kg of EBW. The ratio of EBW/BW was 0.81. The NE_g requirements to gain ranged from 2.85 to 4.58 Mcal/kg EBW gain and NP_g to gain ranged from 181.36 to 198.78 g/kg EBW gain for the castrated indigenous goat kids weighing between 15 and 25 kg. This study has indicated that castrated Moxotó goat kids have different protein and energy requirements in relation to those values commonly recommended by feeding system for other breeds.

Key Words: body composition, caatinga, comparative slaughter

T505 Reproductive outcomes of anovulatory females exposed to males treated with either i.m. or s.c. testosterone.

Andrea González-Tavizón*[1], Cezar A. Meza-Herrera[2], Alan Sebastián Alvarado-Espino[1], Vicente Homero González-Álvarez[1], M. de los Angeles de Santiago-Miramontes[1], M. Guadalupe Calderón-Leyva[1], Juan Manuel Guillen Muñoz[1], Fernando Arrellano-Rodríguez[1], and Francisco Gerardo Véliz-Deras[1], [1]*Universidad Autónoma Agraria Antonio Narro, Torreón Coahuila, México,* [2]*Universidad Autónoma Chapingo, Unidad Universitaria de Zonas Aridas, Bermejillo Durango, México.*

The aim of this study was to evaluate the reproductive response of anovulatory goats exposed to bucks treated with either intramuscular (i.m.) or subcutaneous (s.c.) testosterone in April in northern Mexico (25°N, 103°W). Anovulatory female goats (n = 60) were divided in 3 homogeneous groups regarding body weight and condition (20 goats each) and exposed to 2 of 6 multiracial bucks. Males were randomly selected to receive different treatments: (1) 50 mg testosterone i.m. (TIM, n = 2), (2) 50 mg testosterone s.c. (TSC, n = 2) and (3) 0.5 mL of physiological saline (CONT, n = 2). Treatments lasted 21 d, with treatments every 3 d. Thereafter, each group of males was exposed to 20 females to evaluate the male effect. Response variables considered the latency (interval between introduction of the males and estrus initiation) and sexual activity of females twice daily (0700 and 1900 h), for 10 d. The percentages of females in heat, ovulated (10-d post-male introduction) and pregnant (45-d post-treatment) were also considered. Ovulation and pregnancy response were evaluated by transrectal ultrasonographic scanning (7.5 MHz, HS-2000, Honda Electronic CO, LTD). The proportions of females showing estrus, ovulation and pregnancy were compared using an exact Fisher probability test, while latency considered the Student *t*-test (SYSTAT 5.03 software). Results suggest that males treated with either SC or IM testosterone depicted similar reproductive outcomes, with the TIM depicting the highest estrus response ($P < 0.05$) yet without differences regarding ovulation and pregnancy rates (Table 1).

Table 1 (Abstr. T505). Reproductive outcomes in anovulatory goats exposed to the male effect with mix-breed bucks treated either with s.c or i.m. testosterone during the anovulatory season in northern Mexico (May, 25°N)

Groups	Latency	Estrus %	Ovulation %	Gestation %
CONT	50 ± 3.8^a	65 (14/20)^a	50 (10/20)^a	10 (2/20)^a
TIM	38.4 ± 5.4^a	100 (20/20)^b	65 (14/20)^a	55 (12/20)^b
TSC	42 ± 3.9^a	65 (14/20)^a	47.5 (9/20)^a	45 (8/20)^b

Values with different superscripts within column differ ($P < 0.05$).

Key Words: seasonal reproduction, female goat, testosterone

T506 Mineral requirements for growth and maintenance of F$_1$ Boer × Saanen male kids.

Izabelle A. M. A. Teixeira*[1], Carla J. Härter[1], José M. Pereira Filho[2], Américo G. Silva Sobrinho[1], and Kleber T. Resende[1],. *[1]UNESP, Universidade Estadual Paulista, Department of Animal Science, Jaboticabal, SP, Brazil, [2]Universidade Federal De Campina Grande, Patos, PB, Brazil.*

The objective of this study was to determine the net requirements of minerals for the growth and maintenance of intact male F$_1$ Boer × Saanen goat kids in the initial phase of growth. The following 2 experiments were performed: Exp.1 was performed to determine the net growth requirements of Ca, P, Mg, Na and K of F$_1$ Boer × Saanen goat kids from 5 to 25 kg of BW; Exp.2 was performed to determine the maintenance requirements for F$_1$ Boer × Saanen goats from 15 to 25 kg BW. In Exp.1, 32 intact male goat kids were distributed in a completely randomized design and its mineral body composition were fitted by an allometric equation in the form of nonlinear model. To determine the mineral requirements for maintenance of Exp. 2, 21 intact male goat kids were distributed in a randomized-block design, where the goat kids were subjected to 3 levels of feed restriction (0, 30, and 60% feed restriction). At the onset of the Exp.2, 7 goat kids were harvested and used to estimate the initial body composition (15 kg BW). Initial body composition was used to calculate the retention of minerals. The maintenance requirements were estimated by regressions obtained from the retention of minerals in the empty body and the intake of the mineral. The concentration of Ca, P, Na, and K in the empty BW decreased by 11, 13, 26, and 23% with the increase in BW from 5 to 25 kg ($P < 0.01$). As a consequence, our results showed that net requirements of Ca, P, Mg, Na, and K for weight gain decreased by 27.5, 27.8, 4.25, 43.2, and 39.7%, respectively, with the increase in BW from 5 to 25 kg ($P < 0.01$). The net requirements (in g/kg of ADG) decreased from 9.7 to 7.0 for Ca, 6.5 to 4.7 for P, 0.38 to 0.36 for Mg, 0.88 to 0.50 for Na, and 1.9 to 1.2 for K when BW increased from 5 to 25 kg. The daily net requirements for maintenance per kg of BW were 38 mg of Ca, 42 mg of P, 1.6 mg of Mg, 5.0 mg of Na, and 19 mg of K. These results for the nutritional requirements of minerals may help to formulate more balanced diets for F$_1$ Boer × Saanen goat kids in the initial growth phase.

Key Words: body composition, comparative slaughter, crossbred goat

T507 Analysing the diversity of five Spanish sheep breeds by combining massive genotyping and RNA-seq data.

Antonia Noce[1], Arianna Manunza[1], Ángela Cánovas[1], Silvia Adán[2], Luis A. Bermejo[3], Juan Capote[4], Juan Vicente Delgado[5], Jordi Jordana[6], Vincenzo Landi[5], Agueda Pons[7], Armand Sánchez[1], Oriol Vidal[8], Amparo Martínez[5], Marcel Amills[1], Joaquim Casellas*[6], *[1]Centro de Investigación en Agrigenómica, Bellaterra, Spain, [2]Federación de Razas Autóctonas de Galicia, Coles, Spain, [3]Universidad de La Laguna, San Cristóbal de la Laguna, Spain, [4]Instituto Canario de Investigaciones Agrarias, San Cristóbal de la Laguna, Spain, [5]Universidad de Córdoba, Córdoba, Spain, [6]Universitat Autònoma de Barcelona, Bellaterra, Spain, [7]Serveis de Millora Agrària i Pesquera, Son Ferriol, Spain, [8]Universiat de Girona, Girona, Spain.*

The objective of this research was to characterize the genetic diversity in 5 Spanish sheep breeds from high throughput data. We have used the OvineSNP50 Genotyping BeadChip to genotype 54,241 single nucleotide polymorphisms (SNPs) in 5 endangered Spanish ovine breeds (Xisqueta, Ripollesa, Roja Mallorquina, Canaria de Pelo o Pelibuey and Gallega) with the intention of investigating their genetic relationships and population structure. Multidimensional scaling plot and Admixture analyses revealed that the 2 insular breeds, i.e., Canaria de Pelo (Canary Islands) and Roja Mallorquina (Majorca Island), are the 2 most differentiated populations. African influences and prolonged geographic isolation may partly explain these observations. In contrast, the 3 peninsular breeds showed a weak level differentiation (FST = 0.01–0.03). We have also investigated the variability of the 5 Spanish breeds mentioned above through a RNA-seq approach. More specifically, we sequenced muscle mRNA from pools of 10 individuals by using a Hiseq 2000 platform (Illumina). Our main goal was to find out which percentage of the variation of these populations is breed-specific. Around 300 million reads were obtained per breed, and approximately 70% of them were sucessfully mapped to the latest version of the sheep reference genome. The total number of SNPs retrieved per breed ranged from 147,262 SNPs (Gallega) to 368,661 SNPs (Xisqueta). Obviously, genotyping experiments in a broader sample of individuals will be necessary to confirm the population-specificity of these SNPs. As a whole, our data suggest that ovine breeds share a substantial amount of variability, probably due to the combined effects of recent divergence and gene flow. However, we have also obtained evidence that thousands of variants appear to segregate specifically in particular breeds, a finding that reinforces the need of making every effort to conserve these unique genetic resources.

Key Words: genetic diversity, RNA sequencing, sheep breed

T508 Body condition as a reference for slaughter of feedlot lambs fed sunflower cake.

Flavio Monção[2], Euclides Oliveira[1], Andréia Gabriel[1], Rodrigo Sousa[1], Jefferson Gandra*[1], Mariana Santos[1], Lais Moura[1], Luiz Henrique Silva[1], Leandro Silva[1], Loan Silva[1], Thais Pereira[1], and Vadim Carbonari[1], *[1]Faculdade de Ciências Agrárias, Universidade Federal da Grande Dourados, Dourados, MS, Brazil, [2]Universidade Estadual Julio de Mesquita, Jaboticabal, SP, Brazil, Jaboticabal, SP, Brazil.*

The aim of this study was to evaluate the qualitative and quantitative carcass traits of lambs fed different levels of sunflower cake. For this experiment 28 lambs, crossbred Suffolk, non-castrated males, with an average weight of 21 kg, aging 4 mo were used. The animals were divided into weight classes (4 treatments) and 7 animals per treatmen in a randomized block design. The lambs stayed in the feedlot for a period 70 d. The study treatments were: T 1 - Treatment control, 0% of sunflower cake (84.56% DM; 17.45% CP; 60.22% NDF; 1,34% Fat; 56.60% TDN); T 2 - Treatment with 10% sunflower cake; T 3 - Treatment with 20% sunflower cake; T 4 - Treatment with 30% of sunflower cake. The roughage: concentrate ratio of 50:50 was used on the dry matter basis (DM). When the lambs from each treatment reached the body condition in the range of (2.5 to 3.5), the animal was slaughtered and determined the following parameters: SW- slaughter weight; HCY - Hot carcass yield; CCY- Cold carcass yield; ICL- Internal carcass length; SFT- Subcutaneous fat thickness; TEX- Texture; MARB- Marbling.

The statistical analyses were performed by the SAEG program. In this trial the correlation analysis of the variables allowed to verify that SW (slaughter weight) of lambs was not significantly correlated with HCY, CCY, ICL, SFT, COLOR, MARB and AEL However, it displayed a negative correlation with TEX (texture) of the meat. The HCY was highly correlated with the CCY, in other words, the greater the HCY lower losses occurred during cooling of the carcass, the better CCY. The CCY also showed a positive correlation with TEX and AEL, ICL also showed a positive correlation with the SFT. It was verified that the color and marbling of the meat showed no significant correlations with the other traits. Therefore, it was expected that animals with higher slaughter weight presented positive correlation with marbling, which did not happen in this study that could be justified by the period of confinement of the animals. About the color and texture, no significant difference was noticed. In conclusion, the sunflower cake can be used in supplements for lambs in intensive production systems in partial substitution of soybean meal up to 20%.

Key Words: body condition, sunflower cake, lamb

T509 Performance of Santa Inês meat lambs receiving cactus pear (*Opuntia ficus indica* Mill) in substitution of forage with or without access of water.

José Matias Porto Filho[1], Leonardo S. Knupp[2], Antonello Cannas*[2], Alberto S. Atzori[2], Ariosvaldo N. Medeiros[1], George R. B. Cruz[1], Genilson B. Silva[1], and Roberto G. Costa[1], [1]*Programa de Pós Graduação em Ciência e Tecnologia de Alimentos, Universidade Federal da Paraíba, João Pessoa, Paraíba, Brazil,* [2]*Dipartimento di Agraria, University of Sassari, Sardinia, Italy.*

This work aimed to study the performance of Santa Inês meat lambs receiving different levels of inclusion of cactus pear (*Opuntia ficus indica* Mill) in substitution of Tifton (*Cynodon dactylon*) hay. The trial was conducted using 48 Santa Inês male lambs at 180 d of age, with average initial weight of 21.64 ± 0.48 kg. Diets were formulated to be isoproteic and isoenergetic. Animals had ad libitum access to feed. The experiment was carried out as a completely randomized factorial design (3 × 2) with 3 levels of substitution of Tifton hay with cactus pear (30%, 50% and 70%) subdivided in 2 groups, with or without access of water and a control treatment. DMI significantly differed among treatments ($P < 0.001$) and the interaction among levels of cactus and access of water were not significant for all variables ($P > 0.05$). The equations to estimate DMI and the ADG in the diets with cactus pear were: $DMI = 1776.9 – 26.3x + 96.6y + 0.14x^2 - 2.08xy$ ($R^2 = 0.86$); $ADG = 34.4 + 7.9x - 106.5y - 0.09x^2 - 1.74xy$ ($R^2 = 0.57$), being x = level of inclusion of cactus pear in the diet (30, 50, 70%) and y = animals with (1) or without (0) access of water. In contrast, the equations to predict the DMI and the ADG including the control treatment with the group that had access of water were: $DMI = 1094.3 + 5.3x - 0.19x^2$ ($R^2 = 0.87$); $ADG = 242.3 + 1.77x - 0.047x^2$ ($R^2 = 0.76$), being x = diet control and levels of cactus (0, 30, 50, 70%). The maximum value of DMI was 1.1 kg/day and the minimum was 0.5 kg/day, obtained for the group receiving 30% of cactus with access of water and 70% with access of water, respectively. The ADG was different among treatments ($P < 0.05$) ranging between 245.1 g to 134.4 g for the group with 30% of cactus in the diet with access of water and those that received 70% of cactus with access of water, respectively. Feed efficiency was affected by treatments, being the group that received 50% of cactus in the diet more efficient (0.27 g). In conclusion, cactus pear is recommended at 30% (with access of water) or 50% (without access of water) of substitution of Tifton hay, resulting in ADG of 253 or 205, respectively.

Key Words: cactus, dry matter intake, weight gain

T510 Effects of oral glycerol dosage on short duration transportation shrink in goats.

Amy L. Bax*[1], James D. Caldwell[1], Taylor N. Drane[1], Kelsey L. Basinger[2], Haley L. Bartimus[2], Jessica K. Clark[2], Cindy A. DeOrnellis[1], Jeri D. Rippeto[1], Abbey J. Kempker[1], Mikel J. Thompson[1], Blake E. Koelling[1], and Bruce C. Shanks[1], [1]*Lincoln University, Jefferson City, MO,* [2]*University of Arkansas, Fayetteville, AR.*

The use of various osmolyte products as a means for increasing blood glucose and mediating effects of shrink have been shown to be effective in different livestock species, but have been examined very little in goats. Therefore, the objective was to evaluate the effects of oral glycerol dosage on short duration transportation shrink in goats. On January 19, 2015, a total of 27 (23.4 ± 0.4 kg BW) intact and castrated male goat kids were stratified by sex and BW, and allocated randomly to 1 of 3 treatments: 1) control (C; n = 9); 2) 1 mL oral dose of glycerol per 0.45 kg of BW (n = 9); or 3) 2 mL oral dose of glycerol per 0.45 kg of BW (n = 9). Goats had ad libitum access to mixed-grass pasture and water until initiation of the study. At 0830, goat kids were gathered, bled, weighed, and dosed with glycerol according to treatment. Goats were then transported in a livestock trailer for approximately 4.5 h with an average ambient temperature of 12°C. After transport, goats were unloaded, bled, re-weighed, and returned to their pasture for the night. After a 24-h recovery time, goats were bled and weighed a final time. Data were analyzed using PROC MIXED of SAS with 2 preplanned orthogonal contrast statements: (1) the mean of control vs the mean of 1 mL and 2 mL, and (2) the mean of 1 mL vs 2 mL. Beginning weight, final weight, 24-h recovery weight, shrink, and recovery weight change did not differ ($P \geq 0.31$) across treatments. Beginning white blood cell, final monocyte, basophil, and platelet, and 24-h monocyte counts were higher ($P \leq 0.05$) and beginning neutrophil and eosinophil, and final red blood cell and white blood cell counts and mean corpuscular volumes tended ($P \leq 0.10$) to be higher for 2 mL vs 1 mL. The 24-h neutrophil counts were higher ($P = 0.05$) and 24-h lymphocyte counts and white blood cell counts change tended ($P \leq 0.08$) to be higher for C vs 1 mL and 2 mL. There were no differences ($P \geq 0.13$) in the other blood measurements. Therefore, oral glycerol dosage may affect some blood measurements, but ultimately kid goats in this study did not shrink; thus, the effects of this treatment on short duration transportation shrink in goats were undetermined.

Key Words: glycerol, goat, shrink

T511 Effects of breed and resistance classification of sire on progeny growth performance and response to artificial infection with *Haemonchus contortus* in a central performance test.

Yoko Tsukahara*[1], Terry A. Gipson[1], Steven P. Hart[1], Lionel J. Dawson[1,2], Zaisen Wang[1], Ryszard Puchala[1], Tilahun Sahlu[1], and Arthur L. Goetsch[1], [1]*American Institute for Goat Research, Langston University, Langston, OK,* [2]*Center of Veterinary Health Sciences, Oklahoma State University, Stillwater, OK.*

Fifteen Dorper (D; 3.8 mo of age, 29 kg), 14 St. Croix (C; 3.9 mo, 18 kg), 14 Kiko (K; 4.0 mo, 19 kg), 13 Boer (B; 3.2 mo, 22 kg), and 17 Spanish (S; 3.1 mo, 18 kg) males were used to investigate effects of classification for resistance to *Haemonchus contortus* of sire and among and within breed differences in the second year of a central test at Langston University (LU) for growth performance and response to artificial infection with infective larvae. In the first year of the test, males were randomly selected from 4 commercial farms in KS, MO, and OK and LU B and S goat herds. Animals used in this study were progeny of the sires (i.e., High and Moderate, with no progeny of susceptible males) selected in the first year. For both years, the test entailed an adjustment period of

2 wk followed by 8 wk of data collection. Animal groups were housed separately in adjacent pens with automated feeders allowing free-choice access to a 15% CP (DM) and 50% concentrate pelletized diet. During adaptation, anthelmintic treatment resulted in low fecal egg count (FEC; < 600/g), after which 10,000 larvae were administered orally. Packed cell volume (PCV) was measured weekly and FEC was determined 4 times in wk 6–8. For analysis, initial BW, PCV, and FEC were covariates, and the logarithmic transformation $\ln(x + 2{,}000)$ was used for mean FEC. Breed affected ($P \le 0.01$) ADG (307, 286, 159, 247, and 142 g; SEM = 13.8), DMI (2.2, 1.6, 1.3, 1.5, and 1.3 kg; SEM = 0.12), FEC (2,098, 1,278, 1,419, 1,335, and 716 eggs/g, original scale; SEM = 80.9), and PCV (27.2, 31.7, 31.6, 28.1, and 25.6% ; SEM = 0.76 for D, C, K, B, and S, respectively). Means of resistance classification of sires were similar ($P > 0.10$) for FEC, PCV, ADG, and DMI. Correlation coefficients of sire and progeny FEC within breed were nonsignificant ($P > 0.10$). In conclusion, with only one generation of selection, there was no detectable relationship in resistance to internal parasite between selected sires and progeny based on FEC after an artificial challenge with *H. contortus* larvae in a standardized environment.

Key Words: goat, internal parasitism, sheep

T512 Growth performance and resistance to internal parasitism of small ruminant males from the south-central US in a centralized test. Yoko Tsukahara*[1], Terry A. Gipson[1], Steven P. Hart[1], Lionel J. Dawson[1,2], Zaisen Wang[1], Ryszard Puchala[1], Tilahun Sahlu[1], and Arthur L. Goetsch[1], *[1]American Institute for Goat Research, Langston University, Langston, OK, [2]Center of Veterinary Health Sciences, Oklahoma State University, Stillwater, OK.*

Various breeds of young male sheep and goats from commercial farms in Arkansas, Kansas, Missouri, and Oklahoma and of Langston University (LU) were used in a centralized test at LU, which included artificial infection with *Haemonchus contortus*, to investigate growth performance and genetic resistance to internal parasitism. Year 1 included 2 Katahdin flocks (KS-A, n = 17, 3.5 mo of age, 35 kg; KS-B, 18, 4.0 mo, 19 kg), 20 Dorper (DS; 8.2 mo, 45 kg), 13 St. Croix (CS; 4.4 mo, 21 kg), 2 Boer herds (BG-A; 16, 3.8 mo, 21 kg; BG-B, 17, 19 kg) 16 Kiko (KG; 3.1 mo, 20 kg), and 14 Spanish (SG; 4.4 mo, 19 kg). In year 2, animals were progeny from breeding groups classified in year 1 as of high and moderate resistance, with 15 DS (3.8 mo, 29 kg), 14 CS (3.9 mo, 18 kg), 14 KG (4.0 mo, 19 kg), 13 BG-A (3.2 mo, 22 kg), and 17 SG (3.1 mo, 18 kg). There was 2 wk for adaptation and an 8-wk test period, with automated feeders allowing free-choice access to a 50% concentrate pelletized diet. During adaptation, anthelmintic treatment resulted in low fecal egg count (FEC; < 600/g), after which 10,000 infective larvae were administrated orally. Packed cell volume (PCV) was measured weekly and FEC was determined 4 times in wk 6 to 8. Breed affected ($P \le 0.01$) FEC in year 1 (1,512, 2,196, 3,072, 1,229, 1,069 2,713, 3,575, and 1,182 eggs/g for KS-A, KS-B, DS, CS, BG-A, BG-B, KG, and SG, respectively; SE = 100.0) and year 2 (2,621, 1,368, 1,413, 1,669, and 884 eggs/g for DS, CS, BG-A, KG, and SG, respectively; SEM = 48.1). Animals were placed in 3 categories of resistance (i.e., high, moderate, low) within flocks/herds based primarily on FEC but also considering residual feed intake and ADG using cubic clustering criterion. Resistance category means were similar ($P > 0.05$) for ADG and ADG:DMI in both years. In conclusion, based on FEC after an artificial challenge with *H. contortus* larvae in a standardized environment, there was considerable variability among flocks/herds of small ruminants in resistance to internal parasitism due to multiple factors such as species, breed, and genetic differences within breed.

Key Words: goat, internal parasitism, sheep

T513 The *FecG*^{E} allele of the ovine *GDF9* gene in the Pelibuey breed in México and its effects on prolificacy. Felipe A. Rodríguez-Almeida*, Claudia P. Pérez-Camacho, María E. Burrola-Barraza, and Joel Domínguez-Viveros, *Facultad de Zootecnia y Ecología, Universidad Autónoma de Chihuahua, Chihuahua, México.*

The *FecG*^{E} allele of the ovine *GDF9* gene, reported previously in the Santa Inés breed in Brazil, is segregating in Pelibuey, another hair type sheep breed in México. To determine allelic and genotypic frequencies, as well as effects on prolificacy and potential for marker assisted selection, 160 Pelibuey ewes from 4 flocks in different regions of México [Jalisco 1 (n = 34), Jalisco 2 (n = 62), Tabasco (n = 30) and Chihuahua (n = 34)] were genotyped by RT-PCR (StepOnePlus) using the FAMACTTCAAACAGTTTCTTTTTMGBNFQ and VICTCAAACAGTGTCTTTTTMGBNFQ probes (Applied Biosystems). Pearson's Ji-squared was used to test genotypic frequencies for Hardy-Weinberg equilibrium. After discarding data of lambings that resulted from synchronized estrous with hormones, 631 records of the Poisson variable prolificacy were analyzed using a generalized linear model with PROC GLIMMIX of SAS (SAS Institute Inc., Cary, NC.). The model included fixed effects of year, season, flock, genotype, 2-way interactions and age as a covariate, as well as the random effect of ewe within flock and genotype. The average frequency of the *FecG*^{E} allele was 0.48 (0.48 to 0.54 for the flocks in Jalisco and Chihuahua, and 0.35 for the flock in Tabasco, which is in most challenging environment). Genotypic frequencies were as expected under Hardy-Weinberg equilibrium ($P > 0.10$). Back transformed estimated means for litter size for ewes of the different genotypes were 1.43 for +/+, 1.73 for +/E, and 1.78 for E/E ($P < 0.05$). For genotypes +/+, +/E, and E/E, frequencies of litters with more than 2 lambs were 0.5, 11.4, and 15.2%, respectively; frequencies of litters with a single lamb were 56.0, 37.6, and 35.6%, respectively. Homozygous E/E ewes reproduced normally, in agreement with results from Brazil, but in contrast to the sterility of homozygous ewes reported for other *GDF9* mutations in European breeds. Potential for marker assisted selection exists, especially to produce homozygous rams to be used in low-prolificacy commercial flocks and(or) in crossbreeding with low-prolificacy well-adapted maternal breeds under harsh environments to obtain F_1 ewes.

Key Words: fecundity gene, hair sheep, litter size

T514 Methane concentration and degradation profile of broom sorghum based-diets for sheep. M. A. Cerrillo-Soto[1], A. L. Abdalla[2], R. C. Lucas[2], A. Estrada-Angulo[3], F. G. Rios-Rincón[3], and M. Guerrero-Cervantes*[1], *[1]Universidad Juárez del Estado de Durango, Durango, Dgo, México, [2]Centro de Energia Nuclear na Agricultura, Piracicaba, Sâo Paulo, Brasil, [3]Universidad Autónoma de Sinaloa, Culiacán, Sin., México.*

Broom sorghum (BS) represents a suitable alternative in sheep nutrition practices in Northwest Mexico. Moreover, concerns on rumen methane production support the search for feeds to minimize environmental impacts. This in vitro assay evaluated rumen methanogenesis and degradability characteristics of mixed sheep diets with increasing levels (0, 20, 40, 60 and 80%) of broom sorghum substituting sorghum grain. Diets included soybean meal, Sudan and molasses as well. A semi-automated system for gas production (GP) using a pressure transducer was used. Ground samples (500 mg DM) were weighed into filter bags and further placed into 160-mL glass bottles. A mixture of incubation medium- rumen inoculum was added to the bottles and sealed. Nine Santa Inês cannulated sheep fed tropical grass were used as donors. Head space gas pressure was measured at 4, 8, 12 and 24 h. The CH_4 concentration was determined using gas chromatography. The truly degraded organic matter (TDOM) was estimated after 24 h incubation by refluxing the filter bags with NDF solution. The partitioning factor was calculated as the ratio of TDOM (mg) and gas volume (mL). Data were analyzed using ANOVA (GLM, SAS). Values for CP, NDF and ADF of the diets varied ($P < 0.05$) from 11 to 13%, 54 to 66% and 16 to 39%, respectively. Gas production (GP) varied among treatments ($P < 0.05$). Increasing levels of BS promoted a reduction in GP from 171 mL/g DM in the 0% (control) to 125 mL/g DM in the 80% treatment. Methane production calculated per unit of TDOM varied from 9.4 to 7.5 mL/g TDOM, although no differences were detected ($P > 0.05$). Nonetheless, methane production calculated per unit of degraded NDF resulted in significant variations ($P < 0.05$). Treatment containing no broom sorghum (0%) resulted in the highest methane production (4.7 mL/g DNDF), whereas 60% treatment showed the lowest (1.9 mL/g DNDF). No differences were detected in TDOM among treatments (mean = 351 g/kg DDM). Similarly, no effect was found in the partitioning factor (mean = 1.24). Results suggested that increasing levels of BS did not affect OM digestibility, although that might promote a reduction in methane concentration. However, further studies are to be performed to elucidate stronger effects.

Key Words: sheep, methane concentration, broom sorghum

T515 Effect of timing of $PGF_{2\alpha}$ administration in a short-term progesterone-based estrous synchronization protocol on fertility in ewes.

Callayn D. Paul*, Erin N. Greenleaf, Adam K. Redhead, Abiodun E. Adebiyi, and Marlon Knights, *West Virginia University, Morgantown, WV.*

Traditionally, prostaglandin F2α ($PGF_{2\alpha}$) has been included in short-term progesterone-based estrous synchronization (STPBES) protocols but its inclusion has been associated with a reduction in fertility at the synchronized estrus. To determine if there is an effect of timing of prostaglandin administration relative to the progesterone pre-treatment on fertility, ewes (n = 442) on 4 farms located in WV and PA were randomly assigned to receive controlled internal drug-releasing devices (CIDR-g, 0.3 g progesterone) for 5 d alone (n = 123; treatment 4), in combination with $PGF_{2\alpha}$ (5 mL Lutalyse; 25 mg Dinoprost) at CIDR insertion (n = 103; treatment 1) or removal (n = 100; treatment 2), or 25 mg $PGF_{2\alpha}$ alone (n = 116; treatment 3) before being joined with sexually mature rams. Data were analyzed using ANOVA with the model consisting of the main effects of treatments, farms and their interactions and additionally, least squares means for treatment effects were determined. Ewes receiving only $PGF_{2\alpha}$ had a lower estrous response than other treatments (58.7 ± 3.7% vs. 74.6 ± 37.6%; $P < 0.0001$) but tended to have a higher conception rate than ewes receiving combination treatments of PGF at insertion (78.8 ± 8.9% vs. 61.2 ± 4.9%; $P = 0.08$) or removal (78.8 ± 8.9% vs. 59.8 ± 5.0%; $P = 0.06$). $PGF_{2\alpha}$ ewes also had a significantly lower pregnancy rate to 1st service than ewes receiving the combination treatment with $PGF_{2\alpha}$ at insertion (41.6 ± 4.4% vs. 54.1 ± 4.5%; $P < 0.05$) and ewes receiving CIDR only (41.6 ± 4.4% vs. 58.5 ± 4.1%; $P < 0.005$). There were no effects of treatment on any other measures of reproductive performance. In conclusion, inclusion of $PGF_{2\alpha}$ at the beginning or end of progesterone pretreatment did not enhance synchrony of estrus or other reproductive outcomes. Furthermore, synchronization of estrus with a 5 d treatment of progesterone was sufficient to synchronize estrus with high fertility in ewes.

Key Words: progesterone, prostaglandin, fertility

T516 Method of zilpaterol hydrochloride supplementation on meat quality of feedlot lambs.

Horacio Davila-Ramos*, Karla Hildeliza Leyva-Medina, Salvador Garcia-Sandoval, Jessica Berenice Zuñiga-Villegas, and Juan Carlos Robles-Estrada, *Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico.*

Zilpaterol hydrochloride (ZH) is a β-adrenergic agonist was approved in México (2002) and the United States (2006) to promote growth and carcass dressing in beef cattle. Forty Dorper × Katahdin (45.4 ± 4.5 kg) crossbred male lambs were used in a 27-d feeding trial (5 pens/treatment) to evaluate the influence of method of zilpaterol supplementation on growth performance and carcass characteristics. Lambs were fed twice daily with a cracked corn based (64%) experimental diet (1.39 Mcal/kg of NE_g and 14.0% CP). The animals were allotted to individual pens (6 m^2) with full shade and ad libitum water. Treatments were (1) control (CON), no zilpaterol supplementation; (2) total dose of zilpaterol was offered only in morning feeding (AM), (3) total dose of zilpaterol was offered in morning and afternoon feeding (PPM), and (4) total dose of zilpaterol consisted in offering one day and suspended the next day, like intermittent supplementation (INT). Zilpaterol was supplemented at a rate of 0.20 mg/kg of live weight d^{-1} (as zilpaterol chlorhydrate, Zilmax). The lambs were slaughtered in a local slaughterhouse. The data were analized at complete randomized design, with orthogonal contrast and means compare with LSD. Zilpaterol supplementation (CON vs AM, PPM) decreased the redness index (a^*) (10.9%; $P < 0.04$), yellowness index (b^*) (15.5%; $P < 0.03$) and chromaticity (13.6%; $P < 0.02$). Shear force values of zilpaterol supplementation tended to be greater ($P = 0.08$) than shear force values of CON. There were not differences on pH values between treatments. Zilpaterol intermittent supplementation (CON vs INT) reduced luminosity (L^*) (10.3%; $P = 0.05$), no statistical difference was found with the remaining variables ($P \geq 0.12$), similarly, the contrast (INT vs. AM) showed no significant differences ($P \geq 0.33$) in all variables evaluated.

Key Words: zilpaterol supplementation, lamb, meat quality

T517 Effect of weaning on rapid rebreeding in Katahdin ewes.

Erin N. Greenleaf*, Callayn D. Paul, Abiodun E. Adebiyi, Kyle J. Powell, Adam K. Redhead, and Marlon Knights, *West Virginia University, Morgantown, WV.*

To increase the frequency of lambing, ewes must be mated during seasonal anestrus and while lactating. The present study investigated the effect of lactation and season on the fertility of Katahdin ewes rebred while lactating. Fall-lambing ewes (n = 57, 2 mo postpartum, experiment 1) and spring-lambing ewes (n = 40, 3 mo postpartun, experiment 2) were randomly assigned within birth type to be weaned approximately 3 weeks before breeding or to continue to suckle their lambs for an additional 3 mo. In experiment 1, all ewes were treated with a controlled internal drug releasing (CIDR-g; 0.3 g progesterone) device for 5 d and introduced to rams. In experiment 2, half of the ewes in each lactation status group were treated with an estrus induction protocol consisting of a pre-treatment with a CIDR device for 5 d and an injection with 3 mL P.G. 600 (240IU eCG and 120 IU hCG) at insert removal or received no further treatment. In experiment 1, the mean estrous response, conception rate, pregnancy rate to the first and second service period, proportion of ewes lambing and prolificacy was 64.9, 89.2, 57.9, 91.2, 67.3 and 129% respectively and was not affected by lactation status. In experiment 2, estrous response tended to be higher in suckling compared with weaned ewes (50 vs 11.1%, $P = 0.08$) but lactation status did not affect any of the other variables measured. Ewes receiving the estrous induction protocol had a higher ($P < 0.01$) estrous response, conception rate, pregnancy rate to the first and second service period, proportion of ewe lambing to the first service period and overall and lambing rate (84.2 vs 33.3%; 81.3 vs 0; 80 vs 0; 94 vs 23.8; 61.1 vs 0; 72.2 vs 30 and

111.1 vs 40%, respectively). Lambs suckling their dams gained more weight and grew faster (19.6 vs 14.1 kg; 13.1 ± 0.68 vs 11.3 ± 0.85 kg and 183 ± 0.6 vs 131 ± 0.6 g/d; 128.2 ± 0.7 vs 110.4 ± 0.8 g/d, ($P <$ 0.001 and $P < 0.1$ for experiments 1 and 2, respectively). In conclusion, weaning depressed growth of lambs and did not improve the ability of Katahdin ewes to rebreed in the postpartum period. However, treatment with an estrous induction protocol is necessary for early rebreeding of Katahdin ewes during seasonal anestrus.

Key Words: Katahdin, postpartum period, estrous

T518 Effect of supplementation with propylene glycol and lactation period on energy metabolism of lactating ewes.

Simone Pedro da Silva*[1], Gilberto de Lima Macedo Junior[2], Rogério Pereira dos Santos[3], Jhone Talisson Lira de Sousa[3], Marina Elizabeth Barbosa de Andrade[4], Érica Beatriz Schultz[2], Luciano Fernandes de Sousa[3], Adriano Santana Crozara[2], and Nhayandra Christina Dias e Silva[4], *[1]Instituto Federal Goiano, Hidrolândia, Goias, Brazil, [2]Universidade Federal de Uberlândia, Uberlândia, Minas Gerais, Brazil, [3]Universidade Federal do Tocantins, Araguaína, Tocantins, Brazil, [4]Universidade Estadual Paulista, Jaboticabal, São Paulo, Brazil.*

The objective of this study was to evaluate the effect of supplementation with propylene glycol (PG) in water and the lactation period on energy metabolism of 19 lactating ewes Santa Ines with initial body weight (BW) 58.67 ± 0.80 kg, from calving to weaning (0–90 d), organized into 4 treatments (0.0, 1.5, 3.0 and 4.5% PG) in a completely randomized in a split plot design. The experiment was conducted at sheep sector in Federal University of Uberlândia, Minas Gerais, Brazil. The animals were fed a total mixed ration consisting relation roughage concentrate 67:32. Blood samples were collected every 7 d, totaling 12 blood collections. In these samples we evaluated triglycerides, cholesterol, very low density lipoprotein (VLDL), high density lipoprotein (HDL), low density lipoprotein (LDL), LDL/HDL, β-hydroxybutyrate and enzyme gamma glutamyl transferase (GGT). The supplementation with propylene glycol not affected the levels serum of triglycerides, VLDL, LDL, and LDL/HDL in the blood ($P > 0.05$). The triglycerides and VLDL levels in the blood showed a linear decrease with the advancing lactation ($P <$ 0.01). The cholesterol and HDL levels in the blood showed quadratic response with maximum cholesterol concentration at 61, 70, 68 e 53 d of lactation and maximum HDL concentration at 58, 86, 58 e 85 d of lactation according with supplementation of 0.0, 1.5, 3.0 and 4.5% propylene glycol, respectively. The β-hydroxybutyrate level showed a linear decrease with the increase of propylene glycol ($P < 0.05$). There was no effect of lactation period on the levels serum β hydroxybutyrate on the blood ($P > 0.05$). The level of enzyme gamma glutamyl transferase (GGT) in the blood was not affected by the inclusion of propylene glycol ($P > 0.05$), but was affected by lactation period ($P < 0.01$). With 36 d of lactation, sheep showed the maximum concentration of GGT (80.36 IU/L). Supplementation with propylene glycol improved the energy status of the sheep and, thus, caused a reduction in the levels of ketone bodies. We concluded that supplementation with propylene glycol reduces the adverse effects of negative energetic balance in sheep during the lactation.

Key Words: energetic balance, metabolic profile

T519 Crude glycerin added into low-starch diets improved fatty acid profile of lamb meat.

V. B. Carvalho*, J. M. B. Ezequiel, R. F. Leite, M. T. C. Almeida, J. R. Paschoaloto, H. L. Perez, E. A. Oliveira, A. C. Homem Junior, E. B. Carvalho, and E. S. Castro Filho, *Universidade Estadual Paulista, Jaboticabal, São Paulo, Brazil.*

The objective was to evaluate replacement of corn with crude glycerin (CG) in high-concentrate, low starch diets on fatty acid profile of meat. Forty Santa Ines lambs (23.5 ± 1.35 kg BW) were assigned to a randomized block design with 5 treatments: 0, 7.5, 15, 22.5, and 30% of CG (DM basis). The diet with 30% of CG promoted total replacement of corn. The diets consisted of Tifton-85 hay, corn, CG (83% glycerol), corn gluten meal, corn oil, urea, sunflower meal, soybean hulls and mineral. All diets had around 18% roughage and 82% concentrate. The animals were housed in individual pens and fed ad libitum twice daily at 0700 and 1600 h. The experimental period had 72 ± 7 d of duration and animal harvest was performed when the animals had reached 38 kg BW. Orthogonal contrasts were used to determine the linear and quadratic effects of CG and also constrast of 0% CG vs. CG treatments was used. Odd-chain fatty acids (C15:0, C17:0 and C17:1), oleic (C18:1), palmitoleic (C16:1), total monounsaturated, total unsaturated fatty acids, and their ratios to saturated fatty acids increased linearly within increasing CG. The concentration of all these fatty acids and the ratios, except C16:1, were greater in animals fed any concentration of CG compared with animals fed without CG ($P < 0.01$). The CLA tended to increase in glycerin-fed lambs ($P = 0.06$). The CG decreased linearly the stearic (C18:0), palmitic (C16:0), transvaccenic (C18:1 t11) and total saturated fatty acids ($P < 0.01$). The myristic acid (C14:0) tended to decrease quadratically with increasing CG ($P = 0.06$). The concentration of C18:0, C16:0, C14:0 and total saturated fatty acids decreased when CG was added, regardless of concentration ($P \leq 0.02$). The C18:1 t11 tended to be present in greater concentrations in animals fed without CG compared with animals fed CG ($P = 0.09$). Crude glycerin can be a viable alternative as an energy source in the diet of lambs fully replacing corn into low-starch diets, providing meat with healthier fatty acid profile.

Key Words: corn, glycerol, high-concentrate

T520 Detection of gene expression and location of receptors activated by the oral administration of lithium chloride for conditioned taste aversion in sheep.

Katariina Vara[1], Ahmed K. K. Salama[1,2], Carmen L. Manuelian[1], Maristela Rovai*[1], Juan J. Loor[3], Elena Albanell[1], Xavier Such[1], and Gerardo Caja[1], *[1]Group of Ruminant Research (G2R), Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Animal Production Research Institute, Dokki, Giza, Egypt, [3]Department Animal Science. University of Illinois, Urbana, IL.*

The emetic system activation (nausea and vomiting) plays a key role in the negative postingestive feedback. Lithium chloride (LiCl) is a nonlethal gastrointestinal drug that stimulates the chemoreceptor trigger zone, activating the emetic center and generating conditioned taste aversion (CTA) without other side-effects. There is scarce information on the pathways involved in the CTA mechanism by using LiCl. The aim of this study was to determine changes in gene expression of 4 genes (*CNR1*, *GCG*, *GLP1R*, *HTR3A*) involved in food intake and nausea. A total of 9 Manchega dry ewes, orally dosed with 225 mg LiCl/kg BW, were allocated into 3 euthanasia groups (0, 12 and 24 h after LiCl administration). Brain (area postrema), distal small intestine and colon tissue samples were collected, snap-frozen in liquid nitrogen, and stored at −80°C until analysis. The total RNA was extracted and purified using miRNeasy Mini Kit, and concentration and integrity determined by NonoDrop ND-1000 Spectrophotometer and Agilent 2100 Bioanalyzer, respectively. Gene expressions were determined by RT-qPCR with designed primers and 3 internal control genes. Data were normalized using the geometric mean of internal control genes, and expression values calculated using base-10 logarithm. As results, expressions of CNR1 and GLP1R were detected in all 3 tissues, and GCG was only detected in the distal small intestine and colon. The overall expressions of CNR1 and GLP1R differed by time and tissue, whereas GCG differed by time points. The CNR1 expression showed a linear regression in distal small intestine (decrease) and colon (increase) when comparing expression levels before and after Li administration. The GCG expression increased in distal small intestine and GLP1 expression decreased in colon 24 h after euthanasia. In conclusion, LiCl administration for a CTA treatment revealed changes in the expression of the genes *CNR1*, *GCG* and *GLP1R* in brain, distal small intestine and colon. Acknowledgments: Spanish Plan Nacional I+D+I (Project AGL2010–22178-CO2–01).

Key Words: *CNR1*, *GCG*, food aversion

T521 Conditioned taste aversion generalization by aroma in sheep. Carmen L. Manuelian[1], Elena Albanell[1], Maristela Rovai*[1], Ahmed K. K. Salama[1,2], and Gerardo Caja[1], *[1]Group of Ruminant Research (G2R), Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain, [2]Animal Production Research Institute, Dokki, Giza, Egypt.*

Neophobia is an innate protective mechanism that allows animals to learn from postingestive consequences of eating a new and potentially toxic feed before being harmed by it. Small ruminants usually begin to eat an edible feed that they have not previously encountered by ingesting small amounts; thereafter, if there is no negative feedback, they will gradually increase the intake. On the other hand, if there is a negative feedback, they will associated feed characteristics (taste, odor, texture and sight) with the gastrointestinal discomfort and develop rejection for that feed (food aversion, AV). Despite odor, taste and flavor have been used to increase feed intake; however, few studies have examined its effect in AV. The AV occurs to both the taste and odor of a food (flavor); however, if odor is conditioned in compound with taste, potentiation of the odor will occur. Therefore, when the odor is tested by itself, it becomes a highly potent cue for AV. The aim of this study was to evaluate the ability of 2 breeds of sheep (Manchega, n = 10; Lacaune, n = 10) to generalize the induced AV against a concentrate with strawberry odor to barley and grass flavored with the same aroma. The odor was selected after a preliminary test of acceptability between chocolate and strawberry odors with no taste cues. Ewes were allocated into 2 groups/breed and treatment consisted in: Control (C, water) and Aversion (AV, 225 mg LiCl/kg BW). For AV induction, 100 g of concentrated with strawberry odor was offered individually during 5 min and thereafter orally administered the treatment (water or LiCl). The AV induction lasted 3 d, and redosing when necessary (intake > 75 g). On d 6, 100 g of concentrated, barley and grass with strawberry odor were offered individually during 5 min each food. The 80% of the animals needed ≥ 2 LiCl doses to establish the AV. No differences between breeds were observed in the AV behavior. Generalization of the AV toward barley and grass with strawberry odor was not observed. In conclusion, the use of a flavor instead of an odor could be more effective in the AV generalization. Acknowledgments: Spanish Plan Nacional I+D+I (Project AGL2010–22178-CO2–01) and Lucta (Montornés del Valles, Spain).

Key Words: lithium chloride, flavor, neophobia.

T522 Microbial population and in vitro gas production of sheep fed diets with starch and neutral detergent-soluble fiber. Josemir S. Gonçalves*[1], Jane M. B. Ezequiel[1], Eric H. C. B. Van Cleef[1], Antonio C. Homem Junior[2], and Raquel L. Salgado[3], *[1]UNESP - Univ Estadual Paulista, Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, São Paulo, Brazil, [2]UNESP - Univ Estadual Paulista, Faculdade de Engenharia, Ilha Solteira, São Paulo, Brazil, [3]UFERSA - Federal University of Semi-arid, Mossoró, Rio Grande do Norte, Brazil.*

Six ruminally cannulated male sheep (Santa Ines × Dorper; 35 ± 0.9 kg BW) were used to evaluate the effects of diets containing different levels of starch and neutral detergent-soluble fiber on protozoa and bacterial fractions, as well as methane and carbonic gases productions. Lambs were assigned to a replicated 3 × 3 Latin square design. Each experimental period consisted of 20 d adaptation and 1 d sampling. Diets consisted of 30% corn silage and 70% concentrate (corn grain, citrus pulp, sunflower meal, soybean hulls, sunflower oil, urea and minerals), providing one diet with high starch content (26.7%), one with same content of starch and neutral detergent-soluble fiber (18.4%) and one with high neutral detergent-soluble fiber (24.3%). Ruminal content were sampled on d 21of each experimental period, at 1.5; 6.5 and 11.5 h after the morning feeding. Samples were strained through a nylon filter to separate liquid and solid phases. Liquid-associated protozoa (LAP) and bacteria (LAB) were obtained using series of filtrations, dilution with salt solution and centrifugations. Particle-associated bacteria (PAB) were obtained using agitation with a salt solution, as well as filtrations and centrifugations. Data were analyzed using the MIXED procedure of SAS, with repeated measures. In vitro fermentation was performed using 250-mL flasks in a completely randomized design with 3 treatments and 6 replicates to evaluate the methane and carbonic gasses production. Samples of diets were added at 1.25 g DM/flask, and consisted of same diets fed to ruminal fluid donor. Data were analyzed using the GLM procedure of SAS. There were no effect ($P > 0.05$) of diets on LAP (980.4 mg/kg DM), LAB (858.9 mg/kg DM) or PAB (1237.7 mg/kg DM). The methane production was unaffected by diets (7.1 L/kg DM; $P > 0.05$) but the high-starch diet decreased carbonic gas production ($P < 0.05$). The starch or neutral detergent-soluble fiber diets do not affect ruminal microbial populations nor methane production.

Key Words: bacteria, fermentation, methane

T523 Effects of replacement of soybean meal with handmade fish meal on productive performance of Pelibuey ewes and their suckling kids. Jose L. Loya-Olguin*[1], Yissel S. Valdes-Garcia[1], Lilia E. Nuñez-Gonzalez[1], Alberto Barreras[2], Alejandro Plascencia[2], Francisco Escalera-Valente[1], and Alejandro A. Gomez-Danes[1], *[1]Posgrado en Ciencias Biológico Agropecuarias/Unidad Académica de Medicina Veterinaria y Zootecnia de Universidad Autónoma de Nayarit, Tepic, Nayarit, Mexico, [2]Instituto de Investigaciones en Ciencias Veterinarias, Universidad Autónoma de Baja California, Mexicali, Baja California, Mexico.*

Thirteen Pelibuey ewes (38 ± 7 kg) were used to evaluate the effect of replacing soybean meal (SBM) with a handmade product of fish (HMF). The experimental period lasted 6 weeks which comprised the last 3 weeks of gestation, where the change of body weight in pregnancy was individually evaluated, and the first 3 weeks of lactation, where changes in body weight, feed intake and milk production and composition were evaluated in sheep, and changes in body weight was evaluated on 22 of their kids (initial wt = 2.52. ± 0.05 kg). Control diet and the test diet used in both phases were formulated to be isonitrogenous and isocaloric. The level of inclusion of SBM and HFM in diets was 7 and 3.5%, respectively. HFM was elaborated with marine fish by-products (whole fish, heads, tails, and backbone). The chemical composition of HMF averaged: 50.8 ± 7.7% CP, fat 9.4 ± 0.8 and 22.7 ± 5.9% ash. There were no differences on DM intake, BW changes and milk production;

however, as a result of an increase (<0.01) in the percentage of protein in milk with HFM treatment, was obtained greater final weight (19%, $P < 0.01$) of their suckling kids. It was concluded that HFM is a suitable substitute of SBM in gestating and lactating ewes. Replacing of SBM with HFM did not altered DM intake and milk performance in ewes. However, changes in the concentration of protein in milk in ewes that received HFM may be reflected in a greater weight gain of lambs in the first 21 d of age.

Key Words: lactating ewes, soybean meal, fish

T524 Ruminal kinetics on sheep fed diets with starch and neutral detergent-soluble fiber.

Josemir S. Gonçalves*[1], Jane M. B. Ezequiel[1], Eric H. C. B. Van Cleef[1], Antonio C. Homem Junior[2], and Raquel L. Salgado[3], [1]*UNESP - Univ Estadual Paulista, Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, São Paulo, Brazil,* [2]*UNESP-Univ Estadual Paulista, Faculdade de Engenharia, Ilha Solteira, São Paulo, Brazil,* [3]*UFERSA-Federal University of Semi-arid, Mossoró, Rio Grande do Norte, Brazil.*

The objective of this study was to evaluate the effects of different soluble carbohydrates (starch and neutral detergent-soluble fiber - NDSF) types and proportions on ruminal degradability and fermentation parameters in crossbred sheep. Six ruminally cannulated male sheep (Santa Ines × Dorper; 35 ± 0.9 kg BW) were housed in metabolism cages, assigned to a replicated 3 × 3 Latin square design. During 63 d, lambs were fed with 3 isonitrogenous and isoenergetic diets (30% corn silage and 70% concentrate): D1 - high starch concentration (26.6%) and low NDSF concentrations (13.4%); D2 - similar concentrations (18.4%) of starch and NDSF, D3 - high NDSF concentration (24.3%) and low starch concentration (8.3%). To formulate concentrates were used corn, citrus pulp (only orange), soybean hulls, soybean meal, sunflower meal, sunflower oil and urea. The dried ground samples were incubated in nylon bags (7 × 14 cm) into the rumen for 3, 6, 12, 24, 48 and 72 h. The fraction "a" was determined by washing the bags in water and the residue after 72 h incubation was considered the fraction "c." The potential and effective degradabilities were calculated with the models: $P = a + b\ (1 - e^{kt})$, and $P = a + b * [k / (k + K_p)]$, respectively. Ammonia nitrogen (AN), volatile fatty acids (VFA), and pH were determined at 1 h pre-prandial and 0, 1, 2, 4, 6, and 8 h after morning feeding. Data were analyzed using the MIXED procedure of SAS, with repeated measures. The degradation parameters were not affected by diets ($P > 0.05$). The corn OM presented potential degradability of 81.7% and degradation rate of 10.7%/h, while citrus pulp OM showed 90.5% and 8.4%/h, respectively. Total VFA, acetic, propionic and butyric acids were unaffected ($P > 0.05$) by dietary treatments (79.3, 50.9, 18.8, and 9.6 mM, respectively). The diets did not alter ruminal pH values (averaging 6.3; $P > 0.05$), but AN concentrations (15.87%) were higher ($P < 0.05$) in D3. Diets with different types and proportions of soluble carbohydrates do not affect neither ruminal degradation kinetics nor VFA concentrations, however the ruminal AN concentration increases in NDSF diets.

Key Words: fermentation, rumen, soluble carbohydrate

T525 Relationship between body condition score and body fat depots in Pelibuey ewes.

Gamaliel Antonio-Molina[1], Alfonso Chay-Canul*[1], Juan Ku-Vera[2], Armando Gomez-Vazquez[1], and Aldenamar Cruz-Hernandez[1], [1]*División Académica de Ciencias Agropecuarias, Universidad Juárez Autónoma de Tabasco, Tabsco, Mexico,* [2]*Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma de Yucatán, Yucatán, Mexico.*

Twenty-eight nonlactating and non-pregnant adult Pelibuey ewes, ranging in body condition score (BCS) from 1 (thin) to 5 (obese) were used to study the relationship between body condition score and body fat depots. The animals were humanely slaughtered following the Mexican Official Norms; before slaughter, shrunk BW and BCS were measure after feed and water deprivation for 24 h. The BCS was evaluated using palpation by 2 trained evaluators. Data recorded at slaughter were weights of viscera and carcass. Internal fat (IF, internal adipose tissue) was dissected, weighed and grouped as mesenteric (MF), omental (OF) and kidney knob and channel fat (KKCF). Carcass was then split at the dorsal midline in 2 equal halves, weighed, and chilled at 1°C during 24 h. After refrigeration, the left half of the carcass was completely dissected into subcutaneous and intermuscular fat (carcass fat, CF), muscle, bone and each component weighed separately. Dissected tissues of the left carcass were adjusted as whole carcass. The relationships between BCS and with body fat depots were investigated using regression analysis, with PROC REG of SAS. The BW and BCS at slaughter were highly correlated (r = 0.92). The regression equation for estimating BW from BCS was BW (kg) = 23.46 (±1.62)+ 6.34 (±0.54) × BCS (r^2: 0.84; RSD: 3.41; P: < 0.0001 and n = 28). All equations for relationship between BCS and body fat depots were significant (<0.0001) and the r^2 ranged from 0.87 for CF (RSD = 1.016 kg) to 0.96 for IF (RSD = 1.206). Because the intercept of equations that involved BCS and IF, OF, MF and KKCF were no significant, we fitted a linear regression trough the origin. The regression equation for estimating total body fat (TBF) from BCS were TBF (kg) = −2.64 (±0.911)+ 4.29 (±0.302) × BCS (r^2: 0.89; RSD: 1.916; P: < 0.0001 and n = 28). These results indicated that BCS could be used as a predictor of the main body fat reserves in Pelibuey ewes.

Key Words: body condition, body energy reserves, energy balance

T526 The sexual behavior of male goats treated with exogenous testosterone is affected by the feeding level.

Ma de Santiago Miramontes*[1], J. F. Alvarado-Espinosa[1], F. G. Véliz-Deras[1], O. Ángel-García[1], A. Gonzalez-Tavizón[1], M. G. Calderón-Leyva[1], L. I. Vélez-Monroy[2], J. D. Hernández-Bustamante[1], and M. Mellado[1], [1]*Universidad Auonoma Agraria Antonio Narro,* [2]*Instituto Nacional de Investigaciones Agricolas y Pecuarias.*

A successful male effect is supported on sexually active bucks, therefore the aim and the present study were to determine the effect of feeding level + testosterone (T_4) treatment, on search and consummation behaviors in bucks (mixed-breed in arid region of Mexico; 26° N) during the sexual rest. Four groups were used (n = 5 c/u; Body condition Score, 2.5 ± 0.12 points, 1–4 scale). On February 2nd, one group: NT$_4$ (Normal feeding + T_4) received 0.5 kg of alfalfa hay, 1.1 kg of oaten hay and 0.2 kg of molasses/animal + 25 mg of T_4 IM; NC group (Normal feeding, no T_4) received a same feeding +1 mL of NaCl (as placebo); LT$_4$ group (Low feeding + T_4) received 0.3 kg of alfalfa hay, 0.5 kg of oaten hay and 0.15 kg of molasses per animal + 25 mg of T_4, the LC group (Low feeding, no T_4) received a same feeding + 1 mL of NaCl. T_4 and NaCl was applied every 3rd day for 3 weeks. On April 14, the sexual behaviors (search; ano-genital sniffs, approaches, vocalizations, flehmen. Consummation; attempts to mount, mounts, mounts with a scabbard, mounts with ejaculation) were individually registered using a estrogenized female. The behaviors were compared with a χ^2 test (MYSTAT 12).The Body Condition Score at the end of the study was: LT$_4$ & LC = 1.7 ± 0.2 and: NT$_4$ & NC = 2.4 ± 0.13. The search behaviors showed statistical differences ($P < 0.05$) for all groups (NT$_4$, 53%; LT$_4$, 24%; LC, 15%; NC, 8%), Likewise, on consummation ($P < 0.05$) for all groups (NT$_4$, 54%; LT$_4$, 32%; LC, 10%; NC, 4%). We conclude that an appropriate feeding, improves the sexual behaviors of search and consummation in male goats treated with exogenous testosterone. These sexually active bucks would stimulate through the "male effect" the estrous behavior in mixed-bred anovulatory goats in the arid region of northern Mexico.

Key Words: goat, testosterone, male effect

T527 Pre-weaning and post-weaning growth performance of F_1 intact male Kiko × Boer goat kids from does divided into high and low lines for parasite resistance—One year summary.

Kelsey L. Basinger*[1,2], Bruce C. Shanks[1], Jason K. Apple[2], James D. Caldwell[1], Luke S. Wilbers[1], Chevise L. Thomas[1], Whitney M. Haslag[1], Shelby N. Kleithermes[1], and Amy L. Bax[1], *[1]Lincoln University, Jefferson City, MO, [2]University of Arkansas, Fayetteville, AR.*

Goats are becoming increasingly popular because of their potential economic benefits and their ability to compliment other livestock enterprises. However, gastrointestinal parasites are a serious constraint in goat production; one solution may be selection for parasite resistance. Therefore, the objective of this study was to evaluate pre-weaning and post-weaning growth performance of F_1 intact male Kiko × Boer goat kids from does divergently grouped based on parasite resistance. Intact male F_1 Kiko × Boer progeny (n = 57; 3.0 ± 0.70 kg birth weight) from 2 lines of does with either a high resistance to internal parasites (HL; n = 34) or low resistance to internal parasites (LL; n = 23) were compared. Goat kids were born and managed on pasture with ad libitum access to creep feed until weaning at approximately 100 d of age. Kids were then placed in a drylot with ad libitum access to water, commercial goat mineral, a high-concentrate finishing diet, and were offered mixed-grass hay at approximately 10% of their total diet daily. Pre- and post-weaning weights did not differ ($P \geq 0.16$) between HL and LL; however, weights across pre- and post-weaning weigh periods collectively tended ($P = 0.10$) to be heavier for LL than HL. As expected, weight differed ($P < 0.0001$) across all weigh periods. Weight was regressed over all weigh periods using linear equations to graphically display differences in kid growth rate. Kids from LL had lower birth weights than HL, but, by weaning, weights of LL kids tended to increase at a greater rate (slope difference, $P = 0.15$) than that of HL kids (pre-wean $\text{weight}_{LL} = 2.99776 + [0.13235 \times \text{weigh d}]$, $R^2 = 0.45$ vs. $\text{weight}_{HL} = 4.3369 + [0.1045 \times \text{weigh d}]$, $R^2 = 0.46$). Yet, after weaning, weights of LL and HL kids increased at virtually the same rate (slope difference, $P = 0.81$). Maternal contributions to weaning weight differences are typically attributed to dam's milking ability; thus, these preliminary results indicate that HL does may not have the same milk production as LL does when grazing parasite-infected pastures.

Key Words: goat, parasite, growth

T528 Effect of adding zeolite (*clinoptilolite*) on growth performance and carcass characteristics in hair lambs fed a finishing diet.

Luis Antonio Rojas Roman[1], Beatriz Isabel Castro Perez*[1], Francisco Coronel Burgos[1], Alfredo Estrada Angulo[1], Alejandro Plascencia Jorquera[2], Andrea Cerrillo Soto[3], Carlos Raul Rivera Mendez[1], Francisco Gerardo Rios Rincon[1], and German Contreras Perez[1], *[1]Universidad Autonoma de Sinaloa, Culiacan, Sinaloa, Mexico, [2]Universidad Autonoma de Baja California, Mexicali, Baja California, Mexico, [3]Universidad Juarez del Estado de Durango, Durango, Durango, Mexico.*

Mexican sheep meat production covers only 56.52% of its demand; thus, an alternative to the national sheep production shortage is intensive completion based on the supply of potential of byproducts, additives and minerals that could be included in the diets for intensive fed sheep to reduce the finishing time. Clinoptilolite zeolite are hidrated alcaline aluminosilicates with known capacity of increasing digestion time, thus increasing the digestive efficiency of feed nutrients. To determine the effect of the addition of 4 increasing levels of zeolite (0, 1.5, 3.0, 4.5%) in completely mixed diets for sheep on growth performance and carcass characteristics, 40 male sheep 1/4 Kathadin × 3/4 pelibuey were used. According to a randomized complete block design, sheep were grouped into 5 blocks with 4 pens each and each treatment randomly sorted into each block. The test lasted 75 d and weighings were carried at 28, 56 and 75 d respectively. The treatments used were: T1) 0% Zeolite (16.5% CP and 1.38 Mcal / kg ME), T2) 1.5% Zeolite (16.0% CP and 1.35 Mcal / kg ME), T3) 3% Zeolite (16.5% CP and 1.32 Mcal / kg ME) and T4) 4.5% zeolite (15.1% CP and 1.29 Mcal / kg ME). The feed was offered in twice a day at 8:00 and 14:30, adjusted to 3.0% of their initial body weight amount and gradually adjusted based on the excess or shortage of existing food the next day. Feed was served in a 40:60 ratio in the morning and afternoon respectively. At the end of the trial animals were killed, and 24 h after slaughter carcass data were obtained. In the productive performance data, no effect in final weight ($P = 0.50$), daily weight gain ($P = 0.50$) and dry matter intake ($P = 0.08$) was observed due to the effect of addition of zeolite. Also, no effect owed to zeolite added to diet was observed in HCW ($P = 0.98$) or rib-eye area ($P = 0.64$). It is concluded that clinoptilolite zeolite can be replaced up to 4.5% in substitution of corn and soybean, ingredients of high economic impact, with no significant effect in productive of carcass variables.

Key Words: additive, mineral, ruminant nutrition

T529 Indices of enzyme activities and atherogenicity of lamb meat fed high levels of crude glycerin.

R. F. Leite*, V. B. Carvalho, J. M. B. Ezequiel, M. T. C. Almeida, J. R. Paschoaloto, H. L. Perez, E. A. Oliveira, A. C. Homem Junior, E. B. Carvalho, E. S. Castro Filho, and E. M. O. D'Aurea, *Universidade Estadual Paulista, Jaboticabal, São Paulo, Brazil.*

The objective was to evaluate the effects of corn replacement by crude glycerin (CG) in diets with high-concentrate diets and low starch on enzyme activities and atherogenicity index of lamb meat. Forty Santa Ines lambs (23.5 ± 1.35 kg BW) were assigned to a randomized block design with 5 treatments: 0, 7.5, 15, 22.5, and 30% of CG on dry matter basis. The diet with 30% of CG promoted total replacement of corn. Diets consisted of Tifton-85 hay, corn, crude glycerin (83% glycerol), corn gluten meal, corn oil, urea, sunflower meal, soybean hulls and mineral. All diets had around 18% roughage and 82% concentrate. The Animals were housed in individual pens and fed ad libitum twice daily at 0700 and 1600 h. The experimental period had 72 ± 7 d of duration and the animals were slaughtered when reached 38 kg BW. The indices of enzyme activities Δ^9-desaturase on C16 and C18 fatty acids and enlogase, as well as atherogenicity index (indicator of the risk of cardiovascular disease) were calculated using the concentration of fatty acids from *Longissimus* muscle. Orthogonal contrasts were used to determine the linear and quadratic effects of CG and also contrast of 0% CG vs. CG treatments were used. The enzymatic activity indexes for elongase and Δ^9 desaturase 16 and 18 increased linearly with increasing dietary crude glycerin ($P \leq 0.02$). Activity indexes were also higher in the meat from animals fed CG, regardless of concentration, when compared with meat from animals fed without CG ($P \leq 0.04$). Increasing CG linearly reduced the meat atherogenicity index ($P < 0.01$). Moreover, the index was lower in animals fed CG, regardless of concentration, in comparison to animals fed CG ($P < 0.01$). The CG can provide higher activity of enzyme linked to production of CLA and oleic fatty acid in lamb meat. The CG has potential to decrease the risk of cardiovascular disease.

Key Words: cardiovascular disease, CLA, glycerol

T530 Performance of lambs fed corn stalk silages plus pig excreta, poultry litter and urea, or cane molasses and bakery by-products. Daniel Trujillo-Gutiérrez[1], José L. Bórquez-Gastelum[1], Sergio S. González-Muñoz*[2], Mario A. Cobos-Peralta[2], and Ignacio A. Domínguez-Vara[1], [1]*Universidad Autónoma del Estado de México, Toluca, Estado de México, México,* [2]*Colegio de Postgraduados, Montecillo, Estado de México, México.*

This experiment was carried out to evaluate the effect of corn stalk (CS) silage diet (145 g CP/kg DM; 2.4 Mcal/kg DM) plus 3 nitrogen sources (pig excreta, PE; poultry litter, PL; urea, UR) and 2 energy sources (sugar cane molasses, CM; bakery by-products, BBP). Composition (g/kg DM) of silages was (1) 384. Six CS; 384.6 PL; 230.8 CM or BBP; (2) 294.1 CS; 529.4 PE; 176.5 CM or BBP; (3) 630.0 CS; 30 UR; 340 CM or BBP. Diet contained (g/kg DM) silage 400:600 supplement (corn grain, soybean meal, wheat bran, fish meal, vitamins and minerals). The experimental design was completely randomized, using 30 Criollo lambs (24.05 ± 3.68 kg initial BW) housed in individual cages during 60 d. Data were analyzed with PROC MIXED for average daily gain (ADG) and dry matter intake (DMI) utilizing initial body weight as covariable, whereas PROC GLM and Tukey test ($P < 0.05$) were used for carcass variables. Qualitative variables (color of meat and fat) were analyzed by U-Mann-Withney test. No differences ($P > 0.05$) were found for ADG (161, 175, 163, 160, 161, 150 g/day), DMI (792, 856, 894, 962, 961, 767 g DM/day) for PL-CM, PL-BBP, PE-CM, PE-BBP, UR-CM and UR-BBP, respectively. Rib eye area was larger for lambs fed PE-BBP (14.26 cm^2), as compared with UR-CM (9.34 cm^2). Empty BW was lower ($P < 0.05$) for lambs fed corn stalk silage plus UR and CM (27.7 kg), as compared with those fed CS, PE and CM (34.8 kg). Corn stalk silage plus UR and CM decreased ($P < 0.05$) carcass width (23.04 cm), as compared with corn stalk silage plus PE and BBP. No differences were found for the qualitative variables among treatments ($P > 0.05$). Therefore, it may be concluded that lambs fed corn stalk silage plus pig excreta and bakery by-products showed better carcasses.

Key Words: corn stalk, waste and by-product, lamb

Teaching/Undergraduate and Graduate Education

T531 Instructors' perceptions of the importance and adequacy of "high-impact educational practices" in the animal science undergraduate curriculum in the United States. Sanjeewa D. Ranathunga*[1], Michel A. Wattiaux[1], and Peter Crump[2], *[1]Department of Dairy Science, University of Wisconsin, Madison, WI, [2]Department of Computing and Biometry, University of Wisconsin, Madison, WI.*

High-impact educational practices (HIP) correlated positively with students' educational outcomes and can be an approach to address achievement gaps. A survey was conducted in 2012 and 2013 to evaluate the perception of animal sciences instructors on the importance (1 = not at all to 5 = a great deal) and adequacy (need more, good as it is, need less) of 16 educational practices which included 7 HIP: internships (INT), capstone courses or projects (CCP), collaborative assignments and projects (CAP), undergraduate research (URS), writing-intensive courses (WIC), diversity/global learning (DGL), and service learning, community-based learning (SCL). The analyzed data set included 148 instructors from 68 academic institutions. Rankings and scores (mean ± SD) for the 7 HIP were INT (3, 4.44 ± 0.64), CCP (4, 4.37 ± 0.79), CAP (5, 4.26 ± 0.68), URS (6, 4.25 ± 0.79), WIC (7, 4.21 ± 0.76), DGL (10, 3.88 ± 0.88), and SCL (15, 3.54 ± 0.86). Except for DGL, demographic factors affected HIP scores as follows: types of colleagues (animal scientists vs. others; INT, $P = 0.010$), academic position (assistant, associate, full professor, others; INT, $P = 0.008$; CAP, $P = 0.026$), graduate program completed in the US (yes or no; CAP, $P = 0.011$), teaching experience (no, limited, some experience, taught full-semester courses; CAP, $P = 0.031$), type of university (Carnegie basic classification, 2010; URS, $P = 0.034$), survey year (2012 vs. 2013; WIC, $P = 0.006$), first generation to attend college (yes or no; SCL, $P = 0.022$), and ethnicity (minority vs. Caucasian; SCL, $P = 0.040$). Percentage of respondents who indicated "need more" of the HIP in the curriculum in their institutions were: WIC:55, URS:53, CCP:53, SLC:53, CAP:48, INT:46, and DGL:46%; whereas the percentages for "good as it is" were 34, 38, 34, 37, 41, 43, and 47%, respectively. Multiple demographic factors influenced animal science instructors' perceptions of the importance of HIP. Furthermore, most instructors recognized the need to include more HIP in the curriculum.

Key Words: high-impact educational practices, survey, curriculum

T532 Effect of volunteer activities on the students' understanding of equine assisted therapy. Molly Nicodemus*, Toree Bova, and Jennifer Lockhart, *Mississippi State University, Mississippi State, MS.*

The Professional Association of Therapeutic Horsemanship International certification requires applicants not only to have a strong background in horsemanship activities, but also to have a history of volunteering at an equine-assisted therapy program. Nevertheless, the equine assisted therapy course, ADS 3233, at Mississippi State University has only consisted of a laboratory dedicated to developing horsemanship skills. This school year, volunteer hours performed at a local equine-assisted therapy program were required of students, and thus, the study objective was to evaluate whether volunteering assisted in the development of the students' understanding of equine-assisted therapy. Researcher-developed, 22 forced-choice question survey was given at the start (S) and end (E) of the semester to students taking ADS 3233 in 2013 ($n = 15$) and 2014 ($n = 15$). While in both years students participated in a riding laboratory, only students in 2014 were required to volunteer a minimum of 10 h with a local equine-assisted therapy program. Each question on the survey was a statement concerning activities associated with working in various aspects of equine-assisted therapy programs with students rating from 1 to 5 their agreement to the statements. Lower scores indicated a stronger disagreement with the statement given concerning the aspect of the equine-assisted therapy program covered in the statement, while a higher score indicated a stronger agreement. Differences between S and E answers were calculated for each year and these differences were compared between years using a 2-sample Student's *t*-test ($P = 0.05$). No question resulted in a score of 5. While both years demonstrated improvements on all 22 questions after completing the course, 5 of the questions demonstrated significant difference between years ($P < 0.05$). These questions focused on the ability of the students to work with various experts in the industry and setting up riding programs for specific groups. By volunteering, students were able to get a more thorough understanding of equine-assisted therapy programs by working firsthand with those participating in these programs.

Key Words: equine-assisted therapy, volunteering

T533 Students' perceptions of learning effectiveness in a capstone dairy management course. Lisa A. Holden*, *Pennsylvania State University, University Park, PA.*

Animal Science 410 is an advanced dairy management course in a capstone series for graduating seniors. The course is team-taught by a group of instructors, has an on-farm evaluation component, and integrates production information with financial and business management concepts. For the past 4 years, students were asked to provide course feedback and complete a short supplemental survey about "learning effectiveness." This survey was in addition to the regular online course evaluation data gathered for all courses. The objective of this supplemental survey was to better understand the impact of a team taught course with real world examples had on the quality of student learning. From 2011 to 2014, a total of 80 students completed the course and 76 responses were gathered in the short supplemental survey about 3 key areas of course structure: team taught format, farm evaluation experience and integration of production and financial data. Students were asked to rank the learning effectiveness of each area on a Likert scale of 1 to 5 where 1 = poor for learning and 5 = excellent for learning. Students were also asked to provide feedback about course structure, either verbally with an instructor or as written comments as part of the short supplemental survey. Average ratings for the team taught format were 3.8 ($n = 74$) with a range of 2 to 5, for farm evaluation 4.2 ($n = 76$) with a range of 2 to 5 and for integration of production and financial information 4.7 ($n = 75$) with a range from 3 to 5. Key areas for improvement from student comments included information about "linking" classroom concepts to the farm evaluation, "standardizing" information and testing across instructors, and the need for "real world" financial data. Key areas that appeared to positively affect student learning were the use of classroom examples to explain concepts, interactive classroom discussion, and the quality of data available from farm evaluations. Based on results of this data set, consistency of information among instructors in a team-taught course and the use of high quality data in classroom examples can have positive benefits on student learning.

Key Words: student, learning, effectiveness

T534 Ever wonder what they're thinking? Using a reflective academic journal to gauge learning in a content heavy classroom.

Douglas Vincent*, *University of Hawaii at Manoa, Honolulu, HI.*

As instructors of content classes, we often lack real-time data on how our students are progressing in class. The objective is to present a teaching technique, Reflective Academic Journal, which provides for a 2-way conversation between student and instructor. The student uses the journal to summarize their learning in class; to ask questions they might not in the classroom. The instructor benefits because he/she receives real-time feedback on the content being presented. Learning involves 3 components: (1) the actual knowledge–what it is you know; (2) your skills or ability to apply the knowledge in a particular context; and (3) your feelings–what you think about (1) and (2). Students in junior/senior classes in animal physiology and reproduction are required to write weekly reflective journals beginning after the third week of the semester. A journal can include a description of what happened in class; a constructive criticism of the learning media; a summary of what the student learned that week; a personal response to a class discussion; a reflection on what the student enjoyed about the class and even an expression of fear about an upcoming exam. In practice, the students benefit because they can open up a conversation with the instructor in a non-threatening manner, ask questions, and clear up misconceptions. The instructor benefits because they can obtain real time data on the student learning in that particular week. Questions raised in the journal can be addressed in the next class period. If general misconceptions exist among students, the instructor can trace back and repeat critical information. Student feedback from final journals and end-of-semester course evaluations indicate that writing journals help student learning. Reflective academic journals are an effective tool to improve student learning.

Key Words: learning, academic journal, assessment

T535 Retention of concepts related to beef palatability from classroom experience of an informal consumer sensory panel in conjunction with discussion.

Jay A. Daniel*[1], George R. Gallagher[1], and T. Dean Pringle[2], [1]*Berry College, Mount Berry, GA,* [2]*University of Georgia, Athens, GA.*

We have previously reported use of an informal consumer sensory panel in conjunction with discussion as an effective means of teaching concepts related to beef palatability. In this experience, students evaluate steak samples for tenderness, juiciness, beef flavor and overall desirability. The samples serve to demonstrate the impact of cut and degree of doneness on beef palatability. After sampling the steak, results of the students' evaluation and other factors affecting beef palatability are discussed. To evaluate retention of concepts related to beef palatability, students ($n = 37$) enrolled in ANS 422 Beef Systems were asked to complete a 10 question quiz on concepts related to beef palatability. Five questions on the quiz were related to the informal consumer sensory panel experience (experience), and 5 were related to only the discussion which followed (lecture). All students had completed the informal consumer sensory panel (steak lab) as part of ANS 120 Introduction to Animal Science. In addition to the 10-question quiz, students were asked when they had completed ANS 120 (year), who their instructor was for ANS 120 (instructor, $n = 2$), and if the steak lab affected their steak purchasing habits. Overall scores on the quiz were tested for effect of instructor, year and instructor × year interaction by ANOVA with JMP software (version 10, SAS Inst. Inc., Cary, NC). There was no effect of instructor ($P = 0.31$), year ($P = 0.60$) or instructor × year interaction ($P = 0.56$) on quiz score. Furthermore, student scores on experience questions were compared with scores on lecture questions using ANOVA. Student scores on experience questions were greater than scores on lecture questions ($81 \pm 2\%$ vs. $60 \pm 2\%$ respectively, $P < 0.0001$). Additionally, 65% of students agreed or strongly agreed that the steak lab influenced their choices in steak purchases. These results indicate use of an informal consumer panel is an effective means of teaching concepts related to beef palatability.

T536 Relationship between course performance and graduation rates of animal science majors.

M. J. Anderson*, J. L. Leatherwood, M. M. Beverly, K. J. Stutts, and S. F. Kelley, *Sam Houston State University, Huntsville, TX.*

Student success in completing a degree and graduating is dependent on course performance. Additionally, courses in a student's major will not only affect graduation, but also determine the aptitude of that student for their chosen career path. The objective of this study was to investigate the relationship between graduation rates and the grade earned in specific animal science courses. To accomplish this, course grades and graduation rates of students receiving those specific grades were collected for animal science courses over a 10-year period at Sam Houston State University. The courses included Animal Science, Anatomy and Physiology of Domestic Animals, Animal Nutrition, Meat Science, Equine Science, Animal Breeding and Genetics, Range Management, Animal Reproduction, and Animal Feeds and Feeding. Animal Science is an introductory course for freshmen-level students and prerequisite for other courses evaluated. Anatomy and Physiology of Domestic Animals, Equine Science, and Animal Nutrition are commonly composed of sophomore-level students, while the remaining courses are generally composed of upperclassmen. When graduation rates are reviewed across courses, there is a steady decline in graduation rate of students in the Animal Science course as the final course grade moves from a B (74%), to a C (51%), to a D (30%), and, last, to an F (0%). This pattern does not continue with the sophomore- and upper-level courses. In those courses, over 77% of students graduate when earning a final course grade of C or better. This illustrates that the introductory Animal Science course at Sam Houston provides the necessary rigor to the program and adequately prepares students for the advanced courses in animal science. This also demonstrates that students who receive a lower grade in the introductory Animal Science course may be able to continue in the program, but their likelihood of graduating is significantly lower. Therefore, the introductory Animal Science course at Sam Houston provides an early indicator of student success in reaching graduation.

Key Words: graduation rate, education, animal science

T537 *Fine Focus*: A new international undergraduate microbiology research journal.

John L. McKillip*, *Ball State University, Muncie, IN.*

Fine Focus is the first product-based course of its kind at Ball State University, and is poised to meet the AAAS recent call to action for transformative learning in biology. In utilizing the skill sets of 12 undergraduate students spanning 4 departments, *Fine Focus* has developed a peer-reviewed academic digital and print journal whose mission is to publish findings of undergraduate research internationally. We hypothesize that this "immersive learning" course provides participating students direct experience in double-blind peer-reviewed manuscript management, copy editing, and marketing/advertising available nowhere else. Participating students gain a multitude of experiences through collaborations with professionals from the American Society for Microbiology (ASM), National Institutes of Health (NIH), and the Council on Undergraduate Research (CUR). Such experiences include acquisition of a working knowledge on scientific writing, editing, peer review, graphic design, and advertising, and professional correspondence with authors and reviewers, as they relate to dissemination of microbiological research data through an academic journal with an international scope. This multifaceted learning impact is assessed through student surveys, progress report notebooks, and self-evaluation exercises, which consistently indicated that *Fine Focus* offered exposure to techical aspects of manuscript review and data analyses not available in traditional content courses. After 4 semesters, *Fine Focus* has established an Editorial Board of more than four dozen experts in microbiology and is publishing the first issue in January 2015 that includes 6 published articles on original undergraduate research. Students leave the course having also established permanent career-relevant contacts in varied subdisciplines of microbiology worldwide, and the leadership development skills necessary to serve their profession in the realm of peer-reviewed research, a vital skill in today's community of scientists.

Key Words: undergraduate research, microbiology, journal

ADSA Production Division Symposium: Production efficiency of the dairy cow

349 Genetics of productive life.

Chad Dechow*, *Penn State University, University Park, PA.*

Historic selection for yield has improved the efficiency of dairy production for individual cows and current interest in direct selection for feed utilization aims to further increase productive efficiencies. However, herd efficiency will improve only marginally if selection practices reduce cow fitness levels and increase herd replacement rates. US genetic evaluations for productive life were introduced in 1994 and remain a robust general indicator of cow fitness levels. Productive life credits are limited to a cow's lactation cycle with early lactation weighted more heavily than late lactation. There is considerable variation in herd-life with a genetic standard deviation of 5 mo despite a relatively low heritability (8%). Factors that influence herd life vary across herds and have shifted over time as herd management has evolved. The relationship of productive life with body size has become increasingly antagonistic over time, whereas the relationship with yield has gone from a moderately favorable to a low association. Given the current US Holstein population structure, productive life is strongly correlated with higher cow fertility and lower somatic cell score. Deriving the economic value of longer productive life is complicated by shifts in milk price, heifer rearing and replacement costs, and cull cow value. This has led to varying degrees of emphasis on productive life in different countries and across time. The evaluation of productive life is also complicated by the necessity of a cow's life-cycle to be completed before her true productive life is known. Despite such challenges, higher sire productive life has been demonstrated to be associated with lower rates of daughter mortality and early lactation culling across a range of management systems. As dairy cattle breeders continue to emphasize productive and economic efficiencies, the need to consider traits related to cow fitness levels are of increasing importance to ensure that selection for cow-level efficiencies do not diminish productive efficiency at the herd level.

Key Words: productive life, genetic, efficiency

350 Economics of production efficiency: Nutritional grouping.

Victor E. Cabrera*, *University of Wisconsin-Madison, Madison, WI.*

Nutritional grouping of lactating cows under TMR feeding systems has been discussed in the literature since the 70s. Most of the studies have concluded that using multiple, more-homogeneous TMR feeding groups is economically beneficial because of either or both nutrient cost savings or improved productivity. Nonetheless, there is not yet an absolute consensus or wide adoption. Latest studies using optimal basis for grouping and optimal diet specifications are reporting consistently greater income over feed cost ($/cow per yr) with multiple TMR groups compared with 1 TMR (3 TMR = 46 to 77 and 2 TMR = 21 to 45). Critical factors that determine the economic value of nutritional grouping are (1) basis for grouping, (2) diets' specifications, (3) effects on milk production, and (4) additional costs. It has been strongly documented that grouping cows according to their simultaneous nutritional requirements (a.k.a., cluster grouping) is optimal. Cluster grouping is superior to other methods such as grouping by DIM, milk production, or production and BW combined. However, the dairy industry still uses less than optimal grouping bases. Using cluster grouping would enhance the positive economic impacts of multiple TMR. Next, groups diets' specifications seem not to be optimal either. The concept of lead factors, which are only based on group average milk production are heavily used. Nonetheless, diets should be more precise following overall group nutrient requirements. Providing more precise diets will also be in favor of grouping economics. Next, an area that requires further attention is the potential negative effects of grouping on milk production because of either or both social interactions or diet concentration changes. Although the literature is inconclusive on this, latest studies indicate that multiple TMR largely outperform economically 1 TMR even after considering plausible potential milk losses of grouping. Finally, additional costs of management, labor, facilities, and equipment required for grouping are farm specific. The few studies that integrated these factors in their analyses found that multiple TMR would still be economically superior to 1 TMR.

Key Words: nutritional feeding, feed efficiency, cluster

351 Potential benefits of nutrition on reproductive performance of high-efficiency dairy cows.

Milo Wiltbank*[1], Paulo Carvalho[1], Alex Souza[1], Paul Fricke[1], Mateus Toledo[1], Roberto Sartori[2], Jose Santos[3], Guilherme Pontes[2], Daniel Luchini[4], Francisco Penagaricano[3], Hasan Khatib[1], Katherine Hackbart[1], and Randy Shaver[1], *[1]University of Wisconsin-Madison, Madison, WI, [2]University of Sao Paulo, Piracicaba, SP, Brazil, [3]University of Florida, Gainesville, FL, [4]Adisseo, Alpharetta, GA.*

During the last century, increasing milk production has been associated with decreasing reproductive performance. However during the last decade, there has been a dramatic improvement in reproduction even as milk production continues to increase. The reasons for improving reproduction are multifactorial with dramatic improvements in reproductive management programs, advances in cow comfort and health management programs, and a turn-around in the genetics of reproduction underlying some of these gains. In addition, older research and many recent studies indicate that gains in reproductive performance require optimized nutritional programs including 4 specific areas that will be emphasized in this presentation. First, nutritional deficiencies in the prepartum diet can affect reproduction. As an example, recent research indicates that supplementation during the last month before calving with vitamin E in marginally-vitamin E deficient dairy cattle decreased retained placenta and stillbirths and increased subsequent reproductive performance. Second, nutritional deficiencies near calving and during the first 21 d after calving can have substantial effect on subsequent reproduction. In a recent retrospective study and consistent with previous results, we observed changes in BCS during the first 21 d after calving were associated with dramatic differences in fertility in high-producing lactating dairy cows. Third, increased insulin during the week before AI, potentially due to diets with high non-fiber carbohydrates, can have negative effects on fertilization and reproductive performance of ruminants. Thus, reducing insulin by targeted but subtle changes in feed intake or energy composition of the diet could be used to improve reproduction. Fourth, optimization of amino acid composition of diets may improve reproductive efficiency. Our recent research demonstrates that supplementing rumen-protected methionine altered gene expression in early preimplantation embryos and reduced subsequent pregnancy loss in lactating dairy cows. Thus, inadequate nutritional programs can reduce reproductive performance and optimized nutrition may augment reproduction even in herds with enhanced genetics and reproductive management strategies.

Key Words: fertility, nutrition

352 Providing facilities to improve health, welfare, and productive life.

Trevor J. DeVries*[1], Marina A. G. von Keyserlingk[2], and Daniel M. Weary[2], *[1]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [2]Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada.*

Poorly designed and managed facilities cause injuries and increase the risk of health problems, including lameness and other infectious and metabolic diseases, whose high prevalence is a welfare challenge facing the dairy industry. Massive capital expenditures are made on housing systems for dairy cattle, with the aim of providing a comfortable environment for these animals–one that ensures adequate rest, protection from climatic extremes, and free access to an appropriate, well-balanced diet. Despite these laudable aims, housing systems do not always function well from the perspective of the cow—poorly designed and maintained facilities can reduce feeding and lying time, increase competitive interactions, cause injuries, and increase the risk of health disorders. This review will focus on examples from empirical work on the feeding, standing, and lying areas utilized by dairy cattle, and show how these can be better designed and managed to meet the behavioral needs of dairy cattle, and thus improve welfare, health, and in some cases, productivity. Much of the research reviewed has evaluated housing systems from the cow's perspective by asking how the housing affects cow health, what elements of the housing environment the cow prefers, and how the these elements affect behavior and welfare. This presentation will focus primarily on free-stall housing and will first, identify science-based solutions that result in improved health and welfare of dairy cows and, second, identify gaps where further research is needed.

Key Words: dairy cow, housing, welfare

353 Precision dairy monitoring technologies as tools to improve dairy production efficiency.

J. M. Bewley*, R. A. Russell, A. E. Stone, B. A. Wadsworth, K. A. Dolecheck, M. R. Borchers, M. E. Weatherly, L. M. Mayo, I. C. Tsai, M. C. Hardy, and J. M. Klefot, *University of Kentucky, Lexington, KY.*

Technologies are changing the shape of the dairy industry across the globe. In fact, many of the technologies applied to the dairy industry are variations of base technologies used in larger industries such as the automobile or personal electronic industries. Undoubtedly, these technologies will continue to change the way that dairy animals are managed. This technological shift provides reasons for optimism for improvements in both cow and farmer well-being moving forward. Many industry changes are setting the stage for the rapid introduction of new technologies in the dairy industry. Dairy operations today are characterized by narrower profit margins than in the past, largely because of reduced governmental involvement in regulating agricultural commodity prices. The resulting competition growth has intensified the drive for efficiency resulting in increased emphasis on business and financial management. Furthermore, the decision making landscape for a dairy manager has changed dramatically with increased emphasis on consumer protection, continuous quality assurance, natural foods, pathogen-free food, zoonotic disease transmission, reduction of the use of medical treatments, and increased concern for the care of animals. Lastly, powers of human observation limit dairy producers' ability to identify sick or lame cows or cows in heat. Precision dairy management may help remedy some of these problems. Precision dairy management is the use of automated, mechanized technologies toward refinement of dairy management processes, procedures, or information collection. Precision dairy management technologies provide tremendous opportunities for improvements in individual animal management on dairy farms. Although the technological "gadgets" may drive innovation, social and economic factors dictate technology adoption success.

Key Words: precision dairy, monitoring, technology

Animal Health: Transition cow health

354 Characterizing critical thresholds of subclinical ketosis using the in-line milk monitoring system Herd Navigator. Elizabeth R. Ellis*, Tom C. Wright, John P. Cant, and Vern R. Osborne, *Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

Sub-clinical ketosis (SCK) refers to a state of elevated β-hydroxybutyrate (BHBA) without visual signs of acute disease. With a prevalence of 26 to 60% (dependent on BHBA level used to define disease), this costly metabolic disorder often goes undetected. Innovative in-line milk testing technology, Herd Navigator (DeLaval), enables automated milk BHBA analysis of individuals in a herd. The objective of this study was to characterize SCK as it affects milk production using Herd Navigator technology. The study comprised 3 hundred and 56 Holstein cows from 5 dairy farms in Ontario, operating herd-specific SCK treatment protocols based on BHBA thresholds ranging from 1.2 to 1.7 mmol/L. Individual cow data were collected from June 2013 to July 2014 for daily milk yield, days to peak BHBA level, days to peak milk, peak milk yield; total predicted milk yield to 60 d and 305 d were generated for all cows. Based on the maximum BHBA level attained within 60DIM, cows were assigned to 1 of 5 groups (G1 ≥ 1.7 mmol/L, G2 ≥ 1.5 mmol/L, G3 ≥ 1.4 mmol/L, G4 ≥ 1.2 mmol/L, G5 < 1.2 mmol/L) for analysis. Data were analyzed by ANOVA using the maximum BHBA value as covariate and farm as a random effect. Results showed that first-lactation cows in G1 had higher milk yield at 60 DIM (165 kg ± 91, $P < 0.05$) than first-lactation cows in G5. In second-lactation cows, there were no differences in milk yield between groups. Third-lactation cows in G2 had higher milk yield at 60 DIM than those in G4 (431 kg ± 153, $P < 0.05$) G5 (295 kg ± 125, $P < 0.05$). Predicted milk yield at 305 DIM of third lactation cows in G1 was lower (−2505 kg ± 1318, $P < 0.05$) than in G2. Across farms, elevated (≥1.4mmol/L) milk BHBA values were associated with higher milk production for mature cows at 305DIM, but not for first- and second-lactation cows. Results of this study indicate that farm-level milk BHBA data from Herd Navigator coupled with available on-farm milk production records could be used to refine the effectiveness of SCK treatment protocols and identify different BHBA treatment thresholds by parity to improve milk yield.

Key Words: ketosis, milk production, Herd Navigator

355 Monitoring rumination in transition dairy cows for the early detection of subclinical ketosis. Emily I. Kaufman*[1], Stephen J. LeBlanc[2], Brian W. McBride[1], Todd F. Duffield[2], and Trevor J. DeVries[1], [1]*Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada,* [2]*Department of Population Medicine, University of Guelph, Guelph, ON, Canada.*

The objective of this study was to characterize the relationship between rumination and subclinical ketosis (SCK) in transition dairy cows. A study was conducted on 4 commercial dairy farms in Eastern Ontario, Canada. A total of 339 dairy cows (107 primiparous and 232 multiparous) were monitored for rumination activity and SCK from 14d before calving until 28d after calving. Rumination was recorded daily using an automated monitoring system. A blood sample was taken from the coccygeal vein of each cow for the measurement of β-hydroxybutyrate (BHBA) 1x/wk throughout the 6-wk observation period. Cows with a BHBA concentration ≥ 1.2mmol/L postpartum were considered to have SCK. Cases of retained placenta, metritis, milk fever, or mastitis during the study period were also recorded. Cows were categorized into 1 of 3 groups: healthy (H) cows had no SCK or any other health issue (n = 139); SCK (K) cows with no other health problems during transition (n = 97); or ketotic plus (K+) cows that had SCK and one or more other health problems (n = 53). Data were summarized by wk and analyzed in a repeated measures general linear mixed model. From 2 wk before (−2) calving to 4 wk after calving (+4), there was no difference in daily rumination time (409 ± 9.8 min/d; mean ± SE) among H, K, and K+ cows in their first lactation ($P = 0.5$). Multiparous cows in H spent an average of 459 min/d ruminating from wk −2 to wk +4. Multiparous K cows ruminated 25 ± 12.8 min/d less ($P = 0.05$) than H cows, while K+ cows ruminated 44 ± 15.6 min/d less ($P = 0.005$) than H cows. The largest differences in rumination time between H and K+ cows were seen during wk −1, +1 and +2, when K+ cows ruminated 48 ± 17.2 min/d, 73 ± 16.0 min/d, and 65 ± 19.4 min/d less ($P \leq 0.005$) than H cows, respectively. These results suggest that rumination monitoring across the transition period might contribute to identification of SCK and other health issues in multiparous cows.

Key Words: transition cow, rumination, subclinical ketosis

356 Use of a rumination and activity monitoring for the identification of dairy cows with health disorders. Matias L. Stangaferro*, Robert Wijma, Cristian E. Quinteros, Miranda M. Medrano, Magdalena Masello, and Julio O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Objectives were to evaluate: 1) the ability of a commercial rumination (Rum) and activity (Act) monitoring system (HR Tags, SCR Dairy) to identify cows with health disorders and 2) the interval between the day of diagnosis of disease and day of alert by the HR system (HR). Holstein cows (n = 1,118; 449 nulliparous and 669 multiparous) were fitted with an HR tag from −28 to 80 DIM. Every 12 h after 1 DIM, an individual cow Health Index (HI) was generated based on Rum and Act. Cows with a HI value < 86 points were flagged by HR. Farm personnel examined cows for signs of clinical disease (CDZ) daily. From 1 to 10 DIM, personnel evaluated: appetite, rectal temperature, ketone bodies in urine, rumen fill and movements, vaginal discharge, daily milk weights, and conductivity. Data from 1,099 cows was available. Number of CDZ events included was: displaced abomasum (DA) 41, ketosis (KET) 57, indigestion (IND) 9, metritis (MET) 360, and mastitis (MAST) 74. Sensitivity (Se) of HR to flag cows with CDZ (farm personnel diagnosis as gold standard) and the interval between day of CDZ diagnosis and the day a cow was flagged by HR was evaluated with PROC FREQ and PROC TTEST of SAS, respectively. The Se of HI was: 97.6% (CI 93–100%) for DA, 84.2% (CI 75–94%) for KET, 88.9% (CI 68–100%) for IND, 45.6% (CI 40–51%) for MET and 49.7% (CI 42–57%) for all MAST. For all DA, KET, and IND combined, Se of HR was 89.7% (CI 84–95%). Sensitivity of HR by MAST pathogen was 66.7% (CI 50–83%) for *E. coli* and *Klebsiella*, 52.6% (CI 37–68%) for *Streptococcus* and *Staphylococcus* spp. combined, and 22.2% (CI 0–49%) for *Staph. aureus*. Mean and 95% CI for interval between day of CDZ to day flagged by HR (cows flagged only) was: −3 (−3.7- −2.3; $P < 0.01$), −1.6 (−2.3- −1.0; $P < 0.01$), −0.5 (−1.5- 0.5; $P = 0.28$), −0.8 (−1.2- −0.44; $P < 0.01$), −0.8 (−1.2- 0.3; $P < 0.01$), for DA, KET, IND, MET, and all MAST, respectively. We conclude that the HR system is most effective to identify cows suffering metabolic and digestive disorders. A relatively lower Se to identify cows with MET and MAST might be explained by less severe systemic illness and type of mastitis-causing pathogen. The HR system identified cows with DA, KET, MET and MAST earlier than farm personnel.

Key Words: rumination, activity, dairy cow

357 Development of a ketosis prevalence tool in Holstein dairy cows based on milk component data and cow test-day information.

Tawny L. Chandler*[1], Ryan S. Pralle[1], Garrett R. Oetzel[1], Robert H. Fourdraine[2], and Heather M. White[1], [1]*University of Wisconsin-Madison, Madison, WI,* [2]*AgSource Cooperative Services, Verona, WI.*

Subclinical ketosis affects between 40 and 60% of dairy cows and negatively affects cow productivity and health. Although cowside ketone testing strategies are available, many lack sufficient accuracy, are labor-intensive, and can be costly. The objective of this study was to validate the use of multiple regression models to predict blood β-hydroxybutyrate (BHBA) from milk components and continuous test-day variables in early lactation cows for determining ketosis prevalence. Blood samples were collected on the same day as milk test from 658 Holstein cows 5 to 20 DIM on 10 dairy farms. Blood serum was analyzed for concentration of BHBA by colorimetric assay (Stanbio, Boerne, TX). Milk samples were analyzed for milk BHBA and acetone concentrations by Fourier transform infrared spectrometry (FOSS Analytical A/S, Eden Prairie, MN), in addition to standard milk analysis variables. Continuous test-day variables were collected from DairyComp305 (Valley Agricultural Software, Tulare, CA) records. Models were built in the REG procedure of SAS 9.4 (SAS Institute Inc., Cary, NC) using stepwise, forward selection by excluding variables with a P-value < 0.15 and selection criterion of Akaike's information criterion. Data interrogation justified development of separate models for primiparous and multiparous cows, as well as cows 5 to 11 DIM and cows 12 to 20 DIM. Additionally, disease etiology allowed for unique models for the 5 to 11 and 12 to 20 DIM ranges. Significant variables were milk BHBA, acetone, and fat:protein ratio; parity, previous days dry, previous lactation length, and age at first calving; and DIM and milk production on test day. Overall, model accuracy was 88% for multiparous cows 5 to 11 DIM ($R^2 = 0.57$), 83% for multiparous cows 12 to 20 DIM ($R^2 = 0.67$), 96% for primiparous cows 5 to 11 DIM ($R^2 = 0.74$), and 97% for primiparous cows 5 to 20 DIM ($R^2 = 0.66$). These results suggest that modeling blood BHBA based on milk component data and cow test-day information can serve as a valuable diagnostic tool for monitoring herd-level ketosis prevalence.

Key Words: ketosis, linear regression, model

358 Evaluation of recurrence of frequent diseases and disorders in early postpartum dairy cows.

Achilles Vieira-Neto*[1], Ana Carolina Parize[3], Carlos A. Risco[2], José Eduardo P. Santos[1], and Klibs N. Galvão[2], [1]*Department of Animal Sciences, University of Florida, Gainesville, FL,* [2]*Department of Large Animal Clinical Sciences, University of Florida, Gainesville, FL,* [3]*Escola de Veterinária e Zootecnia, Universidade Federal de Goiás, Goiánia, GO, Brazil.*

Objective was to evaluate if having disease in one lactation (Lac1) would affect the risk of developing disease and calving related problems in the subsequent lactation (Lac2). Holstein cows (n = 1351) from 2 herds in North Florida were used to create 2295 lactation pairs from 4590 lactations occurring between 2006 and 2013. Data were collected within 60 DIM. Data were evaluated using the LOGISTIC procedure of SAS. Having dystocia in Lac1 increased the risk of having it in Lac2 (37.0 vs. 23.7%; $P < 0.01$). Dystocia in Lac2 was also increased by induced parturition and twins in Lac2. Having twins in Lac1 increased the risk of having it in Lac2 (4.6 vs. 2.4%; $P < 0.02$). Twins in Lac2 tended ($P = 0.09$) to be increased in parity > 2 vs. parity 2 in Lact2. Having stillbirth in Lac1 did not affect the risk of having it in Lac2 (5.7 vs. 3.2%; $P = 0.12$). Stillbirth in Lac2 was increased ($P < 0.05$) by dystocia and twins in Lac2. Having milk fever in Lac1 increased the risk of having it in Lac2 (38.9 vs. 2.6%; $P < 0.01$). Milk fever in Lact2 was also increased ($P < 0.05$) by dystocia and parity ≥ 2 in Lac2, but was decreased by induced parturition in Lac2. Having retained placenta in Lac1 increased the risk of having it in Lac2 (13.1 vs. 6.2%; $P = 0.01$). Retained placenta in Lact 2 was also increased ($P < 0.05$) by twins and induced parturition in Lac2. Having metritis in Lac1 increased the risk of having it in Lac2 (20.4 vs. 10.4%; $P < 0.02$). Metritis in Lact2 was also increased ($P < 0.05$) by dystocia, induced parturition, twins, stillbirth, retained placenta and ketosis in Lact2. Having ketosis in Lac1 increased the risk of having it in Lac2 (41.9 vs. 17.0%; $P = 0.01$). Ketosis in Lact2 was also increased ($P < 0.05$) by induced parturition, metritis, and parity > 2 in Lac2. Having displaced abomasum in Lac1 had a tendency to increase the risk of having it in Lac2 (10.5 vs. 2.1%; $P = 0.06$). Displaced abomasum in Lact 2 was increased ($P < 0.05$) by ketosis in Lac2. Having mastitis in Lac1 had a tendency to increase the risk of having it in Lac2 (22.9 vs. 9.3%; $P = 0.09$). Mastitis in Lact2 was increased ($P < 0.05$) by parity > 2. In conclusion, with the exception of stillbirth, disease in Lac1 affected the incidence of disease in Lac2.

Key Words: dairy cow, postpartum diseases, disease recurrence

359 Early lactation disease incidence in Holstein cows across multiple US regions.

Pablo Pinedo*[1,6], Jose Santos[2], Gustavo Schuenemann[3], Rodrigo Bicalho[4], Ricardo Chebel[2], Klibs Galvao[2], Robert Gilbert[4], Sandra Rodrigez-Zas[5], Guilherme Rosa[6], Christopher Seabury[7], John Fetrow[8], and William Thatcher[2], [1]*Texas A&M AgriLife Research, Amarillo TX,* [2]*University of Florida, Gainesville, FL,* [3]*The Ohio State University, Columbus, OH,* [4]*Cornell University, Ithaca, NY,* [5]*University of Illinois, Urbana-Champaign, IL,* [6]*University of Wisconsin, Madison, WI,* [7]*Texas A&M University, College Station, TX,* [8]*University of Minnesota, Saint Paul, MN.*

The objective was to assess the incidence of transition cow diseases in Holstein cows (n = 10,959 in 16 herds) calving during the warm (WS: May–Aug) and cool (CS: Oct – Jan) seasons. Cows were enrolled at parturition and monitored weekly for multiple diseases until 60 DIM. Disease included retained fetal membranes (RFM), metritis (MET, 7 ± 3 DIM; foul-smell, watery, brownish vaginal discharge), subclinical ketosis (SKT, 7 ± 3 DIM; serum BHBA >1.0 mmol/L), mastitis (MAS; farm records), left displaced abomasum (LDA), pneumonia (PN; farm records), clinical endometritis (CE 28 ± 3 DIM; from mucopurulent to fetid vaginal discharge) and lameness (LAM 35 ± 3 DIM; score > 3). Study locations included the Northeast (NE; 4 herds), Midwest (MW; 6 herds), Southeast (SE; 1 herd), and the Southwest (SW; 5 herds) regions. Disease incidence was estimated by region and season (top part of Table 1). Associations between disease occurrence and region, calving season, and parity (1, ≥ 2) were tested by logistic regression. The effect of region on disease occurrence was only significant for LAM ($P < 0.05$). Contrarily, season of calving and parity were significantly associated with the risk of transition diseases in all the disorders analyzed (bottom part of Table 1). This project was funded by USDA-NIFA-AFRI (2013–68004–20361).

Contd.

Table 1 (Abstr. 359). Incidence (%) of transition cow diseases by region and season of calving (top) and odds ratios (OR) for the risk of disease by region, season of calving, and parity (bottom); references are SW, WS, and parity ≥2

360 Association between dry matter intake pre- and postpartum and postpartum diseases in dairy cows.

Johanny Perez Baez*[2], Carlos A. Risco[2], Jorge A. Hernandez[2], Gabriel C. Gomes[2], Leandro F. Greco[1], Sha Tao[1,3], Izabella Thompson[1,4], Bruno do Amaral[1,5], and Charles Staples[1], Jose Eduardo P. Santos[1], and Klibs N. Galvão[2], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]Department of Large Animal Clinical Sciences, University of Florida, Gainesville, FL, [3]Department of Animal and Dairy Science, University of Georgia, Tifton, GA, [4]Agriculture and Agri-Food Canada, Ottawa, Ontario, Canada, [5]Land O'Lakes, Inc., St. Paul, MN.*

The objectives of this retrospective observational study were to determine the association between dry matter intake (DMI) pre- (−14 d to −1) and postpartum (1 to 28 d) and postpartum diseases [retained placenta (RP), metritis (MET), mastitis (MAST), ketosis (KET), and displaced abomasum (DA)] within 28 d postpartum; and to estimate the risk of disease postpartum based on DMI prepartum. Data involving 294 cows from 7 studies were collected. The data were analyzed with the MIXED and GLIMMIX procedures of SAS. Random and repeated variables were cow and day relative to calving, respectively. Models were adjusted for parity, BCS, treatment, study, and interaction between disease and other covariates. Variables with $P \leq 0.05$ were considered significant. Cows that had RP ate less on d −3 (RP × day $P = 0.01$) and on d 5, 7, 8, 12, and 19 (RP × day $P = 0.10$). Cows that had MET ate less on d −3 and −2 (MET × day $P = 0.03$) and ate less postpartum ($P < 0.01$). Cows that had MAST ate less prepartum ($P = 0.02$) and in the first 14 d postpartum (MAST × day $P < 0.01$). Cows that had KET ate less pre- and postpartum ($P < 0.01$). Intake of cows that had DA did not differ prepartum ($P = 0.70$) but they ate less postpartum ($P < 0.01$). Cows with at least one disease ate less pre- and postpartum ($P < 0.01$). Moreover, for each kg decrease in DMI in the last week prepartum, there was an increase of 28% in the odds of having KET (OR = 1.28; CI = 1.15–1.41; $P < 0.01$), and 24% in the odds of having at least one disease (OR = 1.24; CI = 1.13–1.34; $P < 0.01$) postpartum. However, DMI was not associated with the odds of having MAST (OR = 1.09; CI = 0.95–1.23; $P = 0.23$), RP (OR = 1.04; CI = 0.86–1.22; $P = 0.66$), MET (OR = 1.08; CI = 0.97–1.19; $P = 0.14$), or DA (OR = 1.07; CI = 0.82–1.32; $P = 0.6$). Collectively, these data suggest that there is an association between DMI pre- and postpartum and postpartum diseases, and that a reduction in DMI prepartum predisposes cows to disease postpartum.

Key Words: postpartum disease, dry matter intake, dairy cow

361 Laboratory validation of a prototype cow-side instrument for the measurement of blood ionized calcium concentrations in dairy cattle.

Rafael C. Neves*, Tracy Stokol, and Jessica A. A. McArt, *Department of Population Medicine & Diagnostic Sciences, Cornell University, Ithaca, NY.*

There is currently no efficient and inexpensive method for field measurement of blood calcium concentrations. Ionized calcium (iCa) is the homeostatic form of the mineral and is thought to have greater biological relevance over that of total calcium. The objective of this study was to evaluate the linearity and precision of a prototype cow-side instrument (Horiba, Japan) for measuring blood iCa concentrations. Blood (300 mL) was collected from the right jugular vein of a multiparous dairy cow (4 DIM) into lithium heparin tubes immediately before (T0) and 5 min after (T5) intravenous administration of 500 mL of 23% calcium borogluconate. The iCa concentrations were determined using a blood-gas analyzer (ABL-800 FLEX, Radiometer) as a gold-standard. The T0 sample was diluted using 0.9% saline to create a sample with low iCa (reference interval = 1.10 to 1.35 μmol/L). The diluted T0 sample was then mixed with the T5 sample in different ratios (100/0, 75/25, 50/50, 25/75, 0/100) to obtain 5 levels of iCa concentrations (0.69, 1.0, 1.28, 1.58, and 1.82 μmol/L). Each mixture was then analyzed in triplicate using 3 different prototypes under one-point (1P) and 2-point (2P) calibration with the means compared with results from the blood-gas

analyzer. Cumulative sum tests for linearity from Passing and Bablok regressions showed no deviation from linearity for the combined results of all 3 prototypes under 1P vs. the gold-standard ($P = 0.19$) and under 2P vs. the gold-standard ($P = 0.19$). Instrument precision (coefficient of variation; CV) was determined by 10 repeat measurements of the diluted T0 sample, T0, and T5 samples under 1P and 2P calibrations. The CV ranged from 1.3 to 5% for the 3 prototypes. Laboratory results indicate good accuracy and precision for a cow-side instrument at the tested iCa concentrations. Investigation of the instrument under field conditions is warranted.

Key Words: ionized calcium, cow-side instrument, dairy cattle

362 Assessment of daily activity patterns in lactating dairy cows diagnosed with metritis. Santiago Bas*, Adrian A. Barragan, Juan M. Piñeiro, Gustavo M. Schuenemann, Päivi J. Rajala-Schultz, and Troy A. Brick, *Department of Veterinary Preventive Medicine, College of Veterinary Medicine, The Ohio State University, Columbus, OH.*

Metritis (MET) is a prevalent uterine disease that affects dairy cows, and causes substantial economic losses due to reduced milk yield, delayed pregnancy, cost of treatments, and increased culling and death rates. The objective was to assess changes in daily activity patterns (i.e., number of steps, number of lying bouts, standing time and lying time) of lactating dairy cows diagnosed with MET using activity monitors (IceQube, IceRobotics, Edinburgh, UK). Lactating dairy cows (n = 60) from one commercial dairy herd were enrolled. Primiparous (PRIM; n = 12) and multiparous (MULT; n = 48) cows were housed in the same pen and were milked 4 times daily. Cows diagnosed with MET (n = 30) were matched by lactation number and DIM to cows without MET (noMET; n = 30). On study d 1, MET was confirmed (using a metricheck device) by the presence of watery, reddish or brownish foul smelling vaginal discharge. In addition, activity monitors were placed on the hind legs of MET and noMET cows and were kept until study d 7. The daily number of steps (n/d), number of lying bouts (n/d), standing time (min/d) and lying time (min/d) were recorded. Cows showing any other signs of disease (e.g., lameness, mastitis) were not included. Data were analyzed using the MIXED procedure of SAS. Preliminary results showed no difference in the number of steps ($P = 0.30$), number of lying bouts ($P = 0.93$) standing time ($P = 0.89$), or lying time ($P = 0.89$) between MET and noMET cows. However, a different pattern of behavioral activity was observed between PRIM and MULT cows regardless of the MET status. PRIM cows had more steps ($P < 0.0001$; PRIM = 1921; MULT = 1728), more lying bouts ($P < 0.0001$; PRIM = 14; MULT = 11), spent more time standing ($P = 0.01$; PRIM = 860; MULT = 779) and less time lying ($P = 0.01$; PRIM = 580; MULT = 660) than MULT cows. Previous studies have reported differences in activity patterns between cows with and without MET. In the present study, PRIM and MULT cows were housed together and were milked 4 times daily; thus, on-farm management may affect daily behavioral activity patterns of lactating dairy cows regardless of the uterine health status postpartum.

Key Words: dairy, metritis, activity

363 The effect of ketosis on milk production in early lactation. Khaled Gohary*, Todd Duffield, and Stephen LeBlanc, *Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, Ontario, Canada.*

The objective of this study was to evaluate the effect of ketosis on milk production in early lactation. Data from 1,156 cows enrolled in a previous study from 5 commercial dairy herds in Southern Ontario were analyzed. Blood samples from all cows were obtained 1 week before calving and once a week for the first 2 weeks following calving. Sera were submitted to the laboratory at the University of Guelph to measure blood analytes including β-hydroxybutyrate (BHBA). Results were categorized from 1.0 to 2.0 mmol/L in 0.2 mmol/L increments. Daily milk production for all cows was recorded until 63 d in milk (DIM). Using weekly milk production as an outcome, for each of the selected thresholds, 3 linear mixed models that accounted for repeated measures within cow were fitted to test the effects of ketosis in wk 1 or wk 2 postpartum, or both. The analyses were performed with farm as a random effect or as a fixed effect. Overall, as the concentration of BHBA increased, milk yield was lower in cows with ketosis compared with cows without ketosis. Ketotic cows produced less total milk to 63 DIM when ketosis persisted for the first 2 weeks after calving than if present in wk 1 or 2 (at BHBA ≥ 1.4 mmol/L: −97, −37, and −62 kg, for first 2 weeks after calving, wk 1, and wk 2 after calving, relative to cows without ketosis, respectively, $P < 0.0001$). Cows ketotic at wk 2 only produced more milk in wk 1 than cows without ketosis (at BHBA ≥ 1.4 mmol/L: 25.9 ± 1.3 kg/d and 23.9 ± 1.2 kg/d, respectively, $P = 0.004$). When farm was included as a fixed effect, there was a significant interaction between farm and ketosis in wk 2 alone for BHBA ≥ 1.2 mmol/L, and in wk 1 and 2 for BHBA ≥ 1.6 mmol/L. The effect of ketosis on yield varied among farms from no significant difference to 7.3 kg/d ($P < 0.0001$). The degree and duration of ketosis were negatively associated with milk yield in early lactation, but the timing of onset of ketosis affects the association. The threshold at which ketosis reduces milk production in early lactation may vary among farms and this should be explored in a large data set from many herds.

Key Words: dairy cattle, ketosis, milk production

364 Estimating glucose requirements of an activated immune system in lactating Holstein cows. Sara K. Stoakes*, Erin A. Nolan, David J. Valko, Mohannad Abuajamieh, Edith J. Mayorga, Jake Seibert, Maria V. Sanz Fernandez, Patrick J. Gorden, and Lance H. Baumgard, *Iowa State University, Ames, IA.*

Activated immune cells are obligate glucose utilizers; thus, study objectives were to estimate the quantity of whole body glucose utilization during an IV endotoxin challenge. Fasting lactating Holstein cows (718 ± 16 kg; 169 ± 7 DIM) were jugular catheterized and assigned 1 of 3 bolus treatments: control (CON; 5 mL saline; n = 6), lipopolysaccharide infused (LPS; 1.5 μg/kg BW; *E. coli* 055:B5; n = 6), and LPS + euglycemic clamp (LPS-Eu; 1.5 μg/kg BW; 50% dextrose infusion; n = 6). After infusion, blood glucose was determined every 10 min and dextrose infusion was adjusted in LPS-Eu cows to maintain euglycemia. Blood samples were obtained 3, 6, 9, and 12 h post-bolus for further analysis. Cows were milked 6 and 12 h post-bolus. Milk yield decreased in LPS and LPS-Eu cows relative to CON (80%, $P < 0.01$). Milk SCC was increased in LPS relative to CON (48%, $P = 0.02$) while LPS-Eu did not differ from either treatment. LPS and LPS-Eu cows were hyperglycemic for 3 h post-bolus, but thereafter glucose content decreased in LPS relative to LPS-Eu and CON cows (30%, $P < 0.01$). Circulating insulin was and tended to be increased in LPS-Eu (80%, $P = 0.01$) and LPS (72%, $P = 0.06$) relative to CON. Plasma NEFA, BHBA, and Ca were decreased ($P < 0.01$) in LPS and LPS-Eu relative to CON (46, 53, and 46%, respectively). Plasma haptoglobin and L-lactate were increased ($P < 0.01$) in LPS and LPS-Eu cows relative to CON (72 and 62%, respectively). Serum amyloid A was increased in LPS (47%, *P*

= 0.01) and tended be increased in LPS-Eu (34%, $P = 0.09$) compared with CON cows. White blood cells were decreased in LPS and LPS-Eu relative to CON cows ($P < 0.01$). Total glucose deficit during the 12 h post-bolus was calculated as the decrease in the amount of glucose required to synthesize milk (relative to pre-infusion levels) plus the amount of glucose infused to maintain euglycemia (in LPS-Eu cows only). Glucose deficit for CON, LPS, and LPS-Eu cows was 483, 1259, and 1553 g, respectively. If this model is a proxy of glucose demands during an immune response, our data indicates an intensely activated immune system uses at least 90 g glucose/h and maintaining euglycemia does not rescue the decrease in milk synthesis.

Key Words: lipopolysaccharide

365 DNA methylation patterns in peripheral blood leukocytes as a marker of uterine function. Caroline Walker*[1], Barbara Kuhn-Sherlock[2], Susanne Meier[2], John Roche[2], and Murray Mitchell[3], *[1]DairyNZ, Auckland, New Zealand, [2]DairyNZ, Hamilton, New Zealand, [3]University of Queensland, Queensland, Brisbane, Australia.*

The objective of this study was to assess the suitability of using DNA methylation patterns in peripheral blood leukocytes as a marker of uterine function in the dairy cow. Peripheral blood and endometrial tissues were obtained at 29 d postpartum from cows with subclinical endometritis (SCE, n = 6) and control cows (CON, n = 6). DNA was extracted from peripheral blood leukocytes and endometrial tissues and DNA methylation was measured using Methylated DNA immunoprecipitation (MeDIP) in combination with microarrays. Genome-wide DNA methylation was assessed using a custom 400K Agilent microarray (GPL16270). The agreement between DNA methylation measured in leukocytes and in uterine tissue was assessed using Pearson correlation between log ratio in leukocytes and log ratio in intercaruncular and caruncular endometrium. Correlations were considered high if either of the 2 correlation coefficients was greater than 70%. All analyses were performed using SAS 9.2. Genes that were highly correlated between leukocytes and endometrial tissue were submitted for pathway enrichment analysis using PANTHER (Protein Analysis THrough Evolutionary Relationships). 9,733 DNA methylation probes had high (>70%) correlation between blood and endometrial tissue. These probes mapped to a total of 3,329 genes. Enrichment analysis identified several pathways of which the top 5 pathways were; gonadotropin releasing hormone receptor pathway (1.85 fold enrichment, $P = 1.5 \times 10^{-4}$), oxytocin receptor mediated signaling pathway (2.7 fold enrichment, $P = 3.17 \times 10^{-3}$), heterotrimeric G-protein signaling pathway-Gq α and Go α mediated pathway (1.9 fold enrichment, $P = 4.2 \times 10^{-3}$), PI3 kinase pathway (2.5 fold enrichment, $P = 4.3 \times 10^{-3}$), and Wnt signaling pathway (1.5 fold enrichment, $P = 5 \times 10^{-3}$). DNA methylation in the blood is highly correlated with DNA methylation status in endometrial tissue. In genes that were highly correlated, there was significant enrichment for several biological pathways that regulate the reproductive and immune systems. This study provides support for the efficacy of peripheral blood leukocytes as a marker of uterine function. Further research will establish if any of these markers are associated with improved reproductive function.

Key Words: epigenetics, reproduction

ARPAS Symposium: Reproductive efficiency of beef cows—Current status and new technologies

366 Nutrition and management of cows—Supplementation and feed additives. Richard J. Rasby*[1] and Rick N. Funston[2], [1]*University of Nebraska, Lincoln, NE,* [2]*University of Nebraska West Central Research and Extension Center, North Platte, NE.*

Reproductive efficiency is the primary factor affecting profitability of a cow/calf enterprise. The objective is to review how nutrition affects reproduction in beef females and subsequent calf performance. Nutrition has profound effects on reproduction in beef females. Body condition is an indicator of nutritional status and when used in conjunction with BW change can provide a useful method to assess reproduction. Body energy reserve at calving is the most important factor influencing pregnancy rate in beef females. Energy and protein are the nutrients required in the greatest amounts and are the first priority in nutritional programs to optimize reproduction. Beef females underfed and/or in poor body condition lack ovarian activity as a result of suppression of pulsatile release of LH under the control of GnRH. Factors affecting the postpartum interval and pregnancy rate include breed type, suckling status, age, dystocia, energy and protein supplementation pre and post calving, and BCS pre and post calving. Using management strategies to influence when a beef female calves during the calving season affects future productivity of both dam and offspring. Feeding an ionophore results in earlier return to estrus postpartum. The effect of feeding fat pre or postpartum on reproductive performance in beef females has been extensively researched but results are inconclusive. Recent research has evaluated how energy restriction after AI affects embryo development and survival. Nutritional considerations and effects on reproduction have focused on postnatal development; however, prenatal nutrition appears to have potential effects on subsequent reproductive performance in beef cattle. No feed ingredient exists that will compensate for a diets deficient in any nutrient or poor body condition score.

Key Words: beef cow, nutrition, reproduction

367 Selection of a calving season. R. N. Funston*[1], E. E. Grings[2], A. J. Roberts[3], and B. T. Tibbitts[4], [1]*University of Nebraska West Central Research and Extension Center, North Platte, NE,* [2]*South Dakota State University, Brookings, SD,* [3]*Fort Keogh Livestock and Range Research Laboratory, Miles City, MT,* [4]*University of Nebraska West Central Research and Extension Center, North Platte, NE.*

Calving date affects cost and timing of production events. Due to the polyestrous nature of beef females, producers can choose a calving date that fits their production system and geographic region. Any time an entire production system is considered, decision making becomes complex. Any calving system, regardless of date, should address the relationship between nutritional requirements of beef females and the quality and quantity of available feed. Nutritional status of beef females is influenced by stage of production, and the environment, including; length of growing season, forage species, day length, topography, forage quality and availability, ambient temperature, annual rainfall, and weather extremes. These differences cause grazing and feeding strategies to vary across regions. Ideally, high nutrient demand at parturition and peak lactation overlaps with optimal weather conditions and seasonal peaks in forage quality, and lowest nutrient demand overlaps with lowest quality forage, to minimize supplemental feed cost. Calving systems that do not match nutritional demand with forage quality must address potential nutrient deficits faced by breeding females, likely occurring in late gestation and early lactation. Alternative calving systems with higher feed costs need to justify alternative dates through increased revenue generated from higher market value, increased calf performance, or improved reproductive performance. Heat stress, resulting from high temperature and humidity, can reduce calf performance and negatively affect reproductive performance in both the male and female. Hot and humid regions may favor a breeding season during seasonally lower temperatures to minimize poor reproductive performance. Additionally, regions prone to freezing temperatures, heavy snowstorms, or other severe weather events, must consider such risks when choosing a calving date. Many differences exist across regions in regard to environment, production systems, and marketing strategies that contribute to the complexity of choosing a calving date; therefore, beef producers must make site-based decisions according to conditions present on their operation.

Key Words: calving date, calving season, reproduction

368 Advantages of current and future reproductive technologies for beef cattle production. G. Cliff Lamb*, Vitor R. G. Mercadante, Darren D. Henry, Pedro L. P. Fontes, and Nicolas DiLorenzo, *North Florida Research and Education Center, University of Florida, Marianna, FL.*

The refinement of current and development of new technologies aimed at increasing the productivity of the resources while minimizing the environmental impact will be critical to meet the global food demand in the near future. During the past 50 years assisted reproductive technologies have been developed and refined to increase the prolificacy and quality of calves from beef females. Artificial insemination (AI), estrous synchronization and fixed-time AI (TAI), semen and embryo cryopreservation, multiple ovulation and embryo transfer (MOET), in vitro fertilization, sex determination of sperm or embryos, and nuclear transfer are technologies that are used to enhance the production efficiency of beef systems. Development and implementation of these technologies is responsible for significant changes to world production of beef. Sales of beef semen for AI increased from 3.3 to 13.0 million units between 1993 and 2010 in Brazil, whereas that in the US has increased from 2.9 to 4.4 million units during the same period, likely as a result of the development of practical TAI systems that have allowed beef producers the opportunity to eliminate detection of estrus in their AI programs with a high degree of success. Similarly, the quantity of in vivo produced embryos transferred worldwide has increased from 361,000 in 1997 to 506,000 in 2012. In addition, during the last 15 years the transfer of in vitro produced embryos has increased more than 300%. Incorporating applied reproductive technologies continues to affect beef cattle production systems by providing producers opportunities to enhance genetics, reduce transfer of disease, advance fertility, and ultimately increase offspring value. Improvements in fertility and technology, reductions in cost, and improvements in ease of application will ensure that more cattle producers will adopt applied reproductive technologies in future years. However, incorporation of applied reproductive technologies into production systems will vary worldwide depending on cattle markets, infrastructure, production systems, and climate.

Key Words: beef cattle, reproductive technology, fertility

369 Use of ultrasonography to make management decisions.

George A. Perry*[1], Olivia L. Amundson[1], and Robert A. Cushman[2], *[1]Department of Animal Sciences; South Dakota State University, Brookings, SD, [2]USDA, ARS, US Meat Animal Research Center, Clay Center, NE.*

Transrectal ultrasonography has been available for making management decisions since the mid 1980s. This technology allows for the real-time visualization of internal structures (i.e., ovary and fetus) that are otherwise difficult to evaluate. The use of this technology in making reproductive management decisions can be divided into 3 key areas: (1) selection of animals to be kept in the breeding herd, (2) increasing the likelihood of reproductive success, and (3) pregnancy determination. When selecting replacement animals, ultrasonography can be utilized to assess antral follicle counts in females. Antral follicle counts have a direct impact on animal fertility. Around the start of the breeding season transrectal ultrasonography can be utilized to determine puberty status, reproductive tract score, and estrous cycling status. In addition it can be used to determine response to synchronization protocols (presence of a dominant follicle, ovarian cyst, and follicle diameter), or if other assisted reproductive technologies are being utilized it can be used to predict success (superovulation response or presence of a CL for embryo transfer). Following insemination this technology can be used to determine pregnancy status as early as 28 d after insemination, fetal age and sex, and presence of multiple offspring. The largest limitations to the use of ultrasonography include the time and technical skills required, and the strain on the arm and shoulder. While handles can be used for pregnancy diagnosis exams, measurements on the ovary require consistent placement of the transducer that to date can only be accomplished manually. Future improvements that may overcome some of these limitations include better imaging software, larger hard drives allowing the storage of video clips, and improved diagnostic capabilities of the machine (i.e., software that will be able to use pixel density to categorize ovaries). Color doppler images are being explored for earlier pregnancy diagnosis by blood flow to CL. Thus transrectal ultrasonography has and will have a role in the successful reproductive management of cattle herds. USDA is an equal opportunity provider and employer.

Key Words: ultrasonography, reproductive management

Beef Species Symposium: Keeping beef in the center of the plate—Meeting consumer demand in a period of reduced cattle numbers and increased prices

370 Reducing antibiotic use in cattle: Making healthier cattle starting at conception. Daniel Thomson*, *Kansas State University, Manhattan, KS.*

Antibiotic use creates antibiotic resistance. Claims and concerns suggest that modern animal agriculture is dependent on antibiotic usage to compensate for poor hygiene, poor health and poor management of animals. Regardless, there is still much debate in the scientific communities on how antibiotics in food animal production contribute to antibiotic resistance in humans. Many countries have increased antibiotic regulation in hopes of decreasing antibiotic usage to decrease antibiotic resistance. Producers and veterinarians will need to make a paradigm shift from antibiotic residue avoidance alone to prevention of both antibiotic residues and antibiotic resistance in our production units. The beef industry will need to develop antibiotic stewardship programs that monitor antibiotic usage on farms, antibiotic resistance in target pathogens and antibiotic resistance in foodborne pathogens. Complete removal of antibiotics from use in animal agriculture would not be prudent or practical for animal health and well-being. The antibiotics used in food animal medicine and important for human medicine recognized as potential resistance issues are macrolides, cephalosporins and fluoroquinolones. The most important foodborne pathogens in antibiotic resistance in human medicine are *Salmonella*, *E. coli* and *Campylobacter* species. The most common reasons for use of antibiotics in beef and dairy beef cattle production are bovine respiratory disease, neonatal calf scours, mastitis, foot rot and pink eye. The most common use of feed-grade antibiotics in beef cattle is prevention of liver abscesses and control of bovine respiratory disease. In the end, strategies that improve animal health will decrease antibiotic usage, which by theory will decrease antibiotic resistance. Antibiotic usage can be decreased in modern beef production systems if focus is applied to improvements in pre- and perinatal nutrition, neonatal calf housing and management, weaning calf management, marketing systems, transportation, receiving calf programs and nutritional management of finishing cattle.

Key Words: beef cattle, health, antibiotics

371 Can we produce more with less? A critical look at technology in the feedlot sector. Clint R. Krehbiel*[1], Casey L. Maxwell[1], Bryan C. Bernhard[2], Blake K. Wilson[1], Cathy L. Haviland[1], Michelle S. Calvo-Lorenzo[1], Sara E. Place[1], Deb L. VanOverbeke[1], Gretchen G. Mafi[1], Chris J. Richards[1], and D. L. Step[1], *[1]Oklahoma State University, Stillwater, OK, [2]Texas Tech University, Lubbock, TX.*

Adoption of technologies has enhanced beef cattle production and efficiency. With the increasing world population, use of technologies that are economically, environmentally, and socially sustainable is needed to meet protein demand. Long-term use of growth-enhancing technologies (implants, ionophores, β-adrenergic agonists) in the feedlot sector has proven that compounds enhance lean-tissue deposition, and changes in performance result in an economic benefit to both consumers and producers. Land needed and environmental impact is decreased when growth technologies are used. We determined the effects of feedlot production systems with the use of growth technologies compared with an all-natural program on cattle performance and carcass characteristics. Treatments consisted of an all-natural treatment (NAT; no technologies), a conventional treatment (CONV; ionophore and implant), and a CONV treatment with the addition of a β-adrenergic agonist (CONV-Z). There was a 35.7% increase in carcass gain and a 32.6% improvement in carcass efficiency for CONV-Z steers compared with NAT steers. Hot carcass weight was increased by 46 kg for CONV-Z steers compared with NAT steers. An increase in yield grade (YG) 1 and a decrease in YG 3 carcasses was observed for CONV-Z compared with CONV steers. Based on per capita beef consumption of 37.2 kg, added HCW for a single CONV-Z steer compared with a NAT steer would feed 1.2 more US Citizens per year. As society has concern over technologies used in animal production, it is imperative to communicate how increased animal productivity, reduced environmental impact and improved animal well-being are interrelated. Our results suggest that growth promoting products do not affect behavior, mobility, or the overall observed health and well-being of finishing beef steers. Food security depends on developing technologies for improving production efficiencies of beef cattle while adapting to climate change, protecting animal health, and improving the nutritional quality and safety of meat products for consumers. Developing technologies that can improve beef cattle production while minimizing environmental impact, enhancing animal well-being, and ensuring the health and safety of consumers should be our goal.

Key Words: beef cattle, growth-enhancing technologies, production

372 Keeping the eating experience enjoyable: Postmortem management of heavy carcasses. Chris Calkins*, *University of Nebraska, Lincoln, NE.*

Tenderness is one of the most important palatability traits for beef. As beef prices rise, the importance of palatability also increases. Consumer demand is a reflection of perceived value (including eating quality) compared with price. Although demand is increasing, consumers indicate that beef does not always perform on tenderness. Thus, postmortem changes that influence tenderness are critical to understand and control. The improvement in tenderness that occurs during cooler aging is well known and cannot be overlooked. Identifying carcasses with desirable tenderness characteristics offers the opportunity to assure consumers of beef quality. Many studies have shown the consumers are willing to pay a premium for beef that performs in tenderness. The USDA recently approved a marketing claim for beef tenderness, reflecting increased consumer interest. The ability to identify beef that meets consumer expectations is of increasing interest to the industry and may hold the key to sustained customer satisfaction. Branded beef is an attempt to provide that assurance. Similarly, optimal use of individual muscles increases the likelihood of a desirable eating experience. Projects such as muscle profiling have helped to identify potential value upgrade opportunities. Intermediately priced cuts provide the chance for consumers to continue to eat beef in the face of rising costs. Success is most likely when the marketplace puts a premium on tenderness and systems are in place to reward its presence. Clear links between consumer demands and producer compensation help to encourage production of high-quality, tender beef.

Key Words: beef, palatability, tenderness

Breeding and Genetics: Application and methods—Dairy I

373 Montbéliarde × Holstein and Viking Red × Holstein crossbreds compared with pure Holsteins during first lactation in eight high-performance dairies in Minnesota: I. Production. A. R. Hazel*[1], B. J. Heins[2], and L. B. Hansen[1], [1]*University of Minnesota, St. Paul, MN,* [2]*West Central Research and Outreach Center, Morris, MN.*

Montbéliarde × Holstein crossbred cows (MH, n = 484) and Viking Red × Holstein crossbred cows (VH, n = 510) were compared with pure Holstein cows (HO, n = 887) for 305-d milk, fat, and protein production and somatic cell score (SCS) during first lactation. A designed crossbreeding study was initiated in 8 commercial dairy herds in Minnesota in 2008. The first generation cows (MH, VH, and HO) calved for the first time from December 2010 to November 2013. Best Prediction was used to calculate production and SCS for 305-d lactations with adjustment for age at calving, and records less than 305 d were projected to 305 d. Independent variables for statistical analysis of all traits included the fixed effects of herd-year-season of calving, breed, interaction of herd-year-season and breed group, and random sire effect nested within breed. The MH, VH, and HO did not differ significantly for age at first calving (23.8 mo, 23.7 mo, and 23.8 mo, respectively). The MH and HO did not differ significantly ($P = 0.81$) for milk volume (11,304 kg vs. 11,272 kg, respectively); however, VH had significantly less ($P < 0.01$) milk volume (−495 kg) than HO. Fat solids production was similar ($P > 0.17$) for MH (429 kg) and VH (423 kg) compared with HO (423 kg). However, the MH had significantly greater ($P < 0.01$) protein production (355 kg vs. 344 kg) and fat plus protein production (784 kg vs. 767 kg) compared with HO. The protein production and fat plus protein production of VH (344 kg and 767 kg, respectively) were similar ($P > 0.94$) to pure HO. The MH (2.2), and VH (2.2) were also similar ($P > 0.27$) to HO (2.1) for SCS. The results have potential effect on the calculation of lifetime profit of cows because revenue from milk solids is the largest component of total revenue in many regions of the world.

Key Words: crossbreeding, Montbéliarde, Viking Red

374 Montbéliarde × Holstein and Viking Red × Holstein crossbreds compared with pure Holsteins during first lactation in eight high-performance dairies in Minnesota: II. Fertility, survival, and conformation. A. R. Hazel*[1], B. J. Heins[2], and L. B. Hansen[1], [1]*University of Minnesota, St. Paul, MN,* [2]*West Central Research and Outreach Center, Morris, MN.*

Montbéliarde × Holstein crossbred cows (MH) and Viking Red × Holstein crossbred cows (VH) were compared with pure Holstein cows (HO) for fertility, survival, and conformation during first lactation. A designed crossbreeding study was initiated in 8 commercial dairy herds in Minnesota in 2008. The first-generation cows (MH, VH, and HO) calved for the first time from December 2010 to November 2013. Cows (n = 451, 487, and 794 for MH, VH, and HO, respectively) were required to have at least 250 DIM for days open (DO), and cows with DO greater than 250 d were truncated to 250 d. For survival to second calving (n = 415, 450, and 697 for MH, VH, and HO, respectively), cows had at least 20 mo of opportunity to calve a second time. Conformation was scored once between 4 and 150 d on a linear, 9-point scale. Independent variables for the analysis of DO and conformation traits included herd-year-season, breed, interaction of herd-year-season and breed, and random sire effect nested within breed. Chi-squared was used to test survival to second calving. The MH (116 d) had significantly fewer DO ($P < 0.05$) than HO (126 d); however, VH (122 d) were similar to HO for DO. The MH (86%) had significantly greater ($P < 0.01$) survival to second calving compared with HO (80%), but VH (83%) were similar to HO. The MH and VH had greater udder depth than HO (Table 1); however, culling for udder conformation did not differ for breed groups. The MH and VH had less stature, angularity, and body depth than HO (Table 1), indicating they had smaller body size with more body condition.

Table 1 (Abstr. 374). Least squares means of conformation scores for Montbéliarde × Holstein crossbred cows (MH) and Viking Red × Holstein crossbred cows (VH) compared with pure Holstein cows (HO) in 8 high-input dairies in Minnesota

Trait	HO (n = 1,137)	MH (n = 523)	VH (n = 564)
Stature (9 = tall)	5.4	4.7**	3.9**
Angularity (9 = angular)	5.6	2.6**	4.2**
Body depth (9 = deep)	5.1	4.1**	4.4**
Foot angle (9 = steep)	5.6	6.6**	5.5
Udder depth (9 = shallow)	6.9	5.4**	6.2**

**Difference from HO ($P < 0.01$).

Key Words: crossbreeding

375 Milk production and fertility performance of Holstein, Friesian, Jersey, Holstein x Jersey, and Friesian x Jersey crossbred cows on commercial Irish farms. E. L. Coffey*[1,2], B. Horan[1], R. D. Evans[3], K. M. Pierce[2], and D. P. Berry[1], [1]*Teagasc Moorepark, Fermoy, Co. Cork, Ireland,* [2]*School of Agricultural and Food Science, UCD, Dublin, Ireland,* [3]*Irish Cattle Breeding Federation, Bandon, Co. Cork, Ireland.*

There is renewed interest in dairy crossbreeding as a means to further augment farm productivity and profitability. Research experiments have demonstrated the benefits of crossbreeding on animal performance and financial efficiency, exploiting both additive and non-additive genetic effects. The objective of this study was to compare the biological performance of Holstein, Friesian, Jersey, Holstein × Jersey and Friesian × Jersey crossbred cows using commercial dairy herds practicing crossbreeding over a 5-year period. Milk production and fertility information from the national database on 11,808 cows from 40 spring calving dairy herds that adopted crossbreeding between Holstein and Jersey breeds from 2008 to 2012 inclusive were available. Obvious data errors were removed. Least squares means for traits of interest were estimated for purebred and crossbred animals using linear mixed models. Holstein-Jersey first cross cows produced more ($P < 0.001$) milk solids (heterosis = 6.5%), calved earlier ($P < 0.001$) as heifers (heterosis = 1.6%), had a shorter ($P < 0.001$) calving interval (heterosis = 2.1%) and had a higher ($P < 0.05$) submission rates in the first 21 d of the breeding season (heterosis = 4.5%) relative to their purebred parent breeds. Friesian-Jersey first cross cows had a lower ($P < 0.001$) somatic cell count (heterosis = 4%), a shorter ($P < 0.05$) calving interval (heterosis = 2.5%) and a higher ($P < 0.01$) submission rate in the first 21 d of the breeding season (heterosis = 1.2%) relative to their purebred parent breeds. Results were consistent with findings from controlled experiments. Breed complementarity and heterosis attainable from crossbreeding resulted in superior performance in crossbreds relative to their purebred parents.

Key Words: crossbreeding, Jersey, heterosis

376 Fertility and production of 3-breed and third-generation Holstein-sired crossbreds compared with pure Holstein cows in a seasonal pasture production system.

Bradley J. Heins*[1,2], Amy R. Hazel[2], and Leslie B. Hansen[2], [1]*University of Minnesota, West Central Research and Outreach Center, Morris, MN,* [2]*University of Minnesota, Saint Paul, MN.*

Three-breed crossbred cows (Montbéliarde × Jersey × Holstein (HO) and Jersey × Montbéliarde × HO, n = 64); and HO-sired crossbred cows HO × Montbéliarde × Jersey × HO and HO × Jersey × Montbéliarde × HO, n = 87) were compared with pure HO cows (n = 138) for 305-d milk, fat, and protein production; SCS; and days open (DO) during their first 3 lactations. Cows were housed at the University of Minnesota West Central Research and Outreach Center, Morris, Minnesota, a grazing herd, and calved from March 2007 to May 2014. Best Prediction was used to calculate actual production (milk, fat, protein, and SCS) for 305-d lactations with adjustment for age at calving, and records less than 305 d were projected to 305 d. The DO was measured as actual DO for cows and cows were required to be at least 250 d in milk and those with greater than 250 DO were truncated to 250 d. Independent variables for statistical analysis were the fixed effects of season of calving, genetic group (HO, versus 3-breed crossbred versus Holstein-sired crossbred), parity nested within genetic group, and cow nested within genetic group, which was a random effect. Across the first 3 lactations, the 3-breed crossbred (485 kg) cows and Holstein-sired crossbred (499 kg) cows were not different ($P > 0.05$) from pure HO (495 kg) cows for fat plus protein production. Across lactations, 3-breed crossbred cows (2.78) and HO-sired crossbreds (2.92) were similar to pure HO cows (2.90) for SCS. The 3-breed crossbred cows (111 d) and HO-sired crossbreds (125 d) had significantly ($P < 0.05$) fewer DO than pure HO (150 d) cows during first lactation. During second lactation, the DO for the pure HO cows increased to 162 d, and the 3-breed crossbred ($P < 0.05$) and Holstein-sired crossbreds ($P < 0.10$) had a fewer DO (130 d and 136 d, respectively) compared with the pure HO cows. Mating 3-breed crossbreds to HO bulls may have advantages in a rotational crossbreeding system. Three distinct breeds is likely optimum for a rotational crossbreeding system.

Key Words: crossbreeding, days open, pasture

377 Relationships between yield, fitness, and type traits in US Brown Swiss.

Keith D. Gibson* and Chad D. Dechow, *The Pennsylvania State University, State College, PA.*

Genetic parameters have often been estimated for the US Holstein population, but infrequently for Brown Swiss. The objective of this research was to evaluate heritabilities and correlations of fitness with yield and type traits for Brown Swiss cattle born in 2000 and later. The data consisted of 105,164 first through fifth lactation yield and somatic cell score (SCS) records from 45,464 cows with 82,761 d open (DO) and 31,105 productive life (PL) records. Approximately 52,250 of the records had values for 17 type traits and 41,074 had values for milking speed. These data were analyzed using a series of 3 trait models in ASREML that included fixed effects for lactation, age, and herd-calving cluster. Random effects were animal, permanent environment, and residual. The heritabilities of milk, fat, and protein yield were 0.30, 0.20, and 0.20, respectively. The heritabilities of PL, DO, SCS, and milking speed were 0.11, 0.03, 0.12, and 0.26, respectively. Yield traits had strong positive correlations with PL (0.63 to 0.71), whereas DO (−0.69) and SCS (−0.60) had strong negative correlations with PL. Milking speed had a moderate positive correlation with PL (0.26) and DO (0.19) and a slight negative correlation with SCS (−0.10). Yield traits had a slight unfavorable genetic correlation with DO (0.11 to 0.18). However, rear udder width (0.55), final score (0.45), body depth (0.43), dairy form (0.43), rear udder height (0.32), and stature (0.27), were more unfavorably correlated with DO than was yield. Yield was positively correlated with rear udder height (0.19 to 0.25) and rear udder width (0.34 to 0.48), and negatively correlated with udder depth (−0.40 to −0.24) and fore udder attachment (−0.21 to −0.04). However, udder depth (−0.26) and fore udder attachment (−0.14) were more favorably correlated with SCS than rear udder height and rear udder width (−0.02 and 0.18, respectively). Of the udder traits, fore udder attachment, rear udder width, rear udder height, and udder cleft were most favorably correlated with PL (0.31 to 0.44). These updated genetic parameters will allow for improved genetic selection in the Brown Swiss breed.

Key Words: Brown Swiss, correlation, productive life

378 Genetic disorders in Indian dairy cattle.

Prasad Dinkar Deshpande*, Marimuthu Swaminathan, Jayant Ramchandra Khadse, Hemant Dasharath Kadam, Ashok Bhaskarrao Pande, Sumit Prakashrao Totade, and Priyanka Shivaji Garad, *BAIF Development Research Foundation, Central Research Station, Urulikanchan, Pune, Maharashtra, India.*

The advancements in cattle genetics and genomics have widened the scope of understanding number of hereditary diseases in cattle, leading to the development of early diagnostic techniques to detect presence of lethal or mutant allele for a specific phenotype. Bovine Leukocyte Adhesion Deficiency decreases host resistance and increases susceptibility to fatal illnesses. Citrullinemia is a disorder of urea cycle and this condition leads to increase levels of ammonia accumulation in blood and tissues, and subsequent death. Deficiency of uridine monophosphate synthase (DUMPS) causes prenatal embryonic mortality before d 40 of gestation. Factor XI results in a bleeding disorder and the affected animals (homozygotes) have hemophilia-like disorder. Although the frequency of these alleles in the population is usually very low, it can be easily increased if heterozygous (carrier) sires are used for large scale breeding through artificial insemination program resulting in increase in the proportion of lethal alleles. As per minimum standard protocol laid down by Government of India, it is mandatory to screen each stud bull before its entry to semen collection to rule out genetically transmitted diseases. All the stud bulls were screened by single nucleotide polymorphism (SNP) genotyping for BLAD, citrullinemia, DUMPS by Custom Designed Assays from Life Technologies (a brand of Thermo Fisher Scientific) and temperature melting curve for Factor XI. BAIF Development Research Foundation has a regular genetic disorder-screening program for its own stud bull farm. To date, 400 stud bulls have been screened and not a single male carrier for such genetic disorders has been found (Table 1).

Table 1 (Abstr. 378). Screening for disorders in Indian stud bulls

Sr. No.	Breed	Tests carried out	No. of stud bulls screened
1	Indigenous cattle and buffaloes	Factor XI, BLAD, citrullinemia	150
2	HF and HF crossbreeds	Factor XI, BLAD, citrullinemia, DUMPS	150
3	Jersey and Jersey crossbreeds	Factor XI, BLAD, citrullinemia	100

Key Words: genetic disorder, stud bull

380 SNP-analysis solves questions on the genetic background of the rare Dutch breed of Red Friesian cattle.

Kor Oldenbroek*[1], Ina Hulsegge[2,3], Jack Windig[2,3], and Mario Calus[2,3], [1]*Centre for Genetic Resources the Netherlands, Wageningen, the Netherlands,* [2]*Animal Breeding and Genomics Centre, Wageningen, the Netherlands,* [3]*Wageningen UR Livestock Research, Wageningen, the Netherlands.*

The Red Friesian cattle population went through a severe bottleneck around 1990. It revived due to the availability in the Dutch genebank of semen from bulls born between 1960 and 1970. Nowadays, it counts approximately 500 females and together with the bulls in the genebank, some 50 bulls are available for breeding. Three questions were put forward by the breeding organization: (1) is the Red Friesian cattle a unique breed or is it strongly related to the Black and White Dutch Friesian? (2) Is it relevant to distinguish the 5 different sire lines within the breed? (3) Are 2 herds of non-registered Red Friesian Cattle related to the registered population? DNA samples were extracted from 25 genebank bulls and 43 females from the 5 sire lines and 2 non-registered herds from semen and hair roots. These were analyzed with the BovineSNP50 BeadChip. After editing 42552 SNP's remained from the 54609 observed. Genetic relationships were evaluated by analyzing admixture using STRUCTURE and analyzing the average relatedness within and between lines. These revealed that (1) the Red Friesian Cattle is a breed in its own right, strongly related to the Black and White Dutch Friesian, (2) a large overlap in genetic variation exists between the 5 sire lines, and (3) the 2 non-registered herds although highly related to the registered population, contain genetic diversity not present in the 5 lines. For one of these herds this diversity originated from some Holstein Friesian sires used in the past. The other herd had been bred in isolation from the rest of the breed leading on the one hand to a high amount of inbreeding (25%) and associated loss of diversity, but on the other hand to conservation of diversity not present in the rest of the breed.

Key Words: SNP, genetic variation, genetic relatedness

381 Genetic variation and breeding values of casein in Holstein cattle using novel FTIR predictive modeling.

Herwin Eding[1], Gerben de Jong*[1], Hiemke Knijn[1], Jan Rademaker[2], and Nisha Shetty[2], [1]*CRV, Arnhem, the Netherlands,* [2]*Qlip, Zutphen, the Netherlands.*

Based on reference method measurements and Fourier transform infrared (FTIR) spectra, prediction equations for casein in raw milk were calculated. Subsequently casein content was predicted from multiple milk samples of 1.3 million cows from March 1, 2012, until February 23, 2013. After editing 8.5 million test-day records were available for analysis. The average casein content observed in milk was 2.77% (m/m), 77 percent of the total milk protein, with a standard deviation of 0.37% (m/m). Genetic parameter estimation was carried out on 61 000 Holstein cows, with 480 000 test days. The found heritability was 0.30, 0.34 and 0.39 for first, second and third lactation, respectively. The genetic correlation among the lactations ranged from 0.52 to 0.60. Genetic correlation with overall protein was 0.982. The genetic standard deviation for casein:protein ratio was 1.36 percent, with an heritability of 29 percent. The genetic correlation between casein:protein ratio and casein and protein yield was 0.23 and 0.35 respectively, while the phenotypic correlation was 0.01 lower, showing the ratio trait is independent from the yield traits. A genetic evaluation for protein yield and content, casein yield and content and casein:protein ratio was carried out on the whole population. This showed that selection for casein:protein ratio increases casein content but decrease casein and protein yield. In conclusion, casein yield showed to be a promising parameter in a cheese merit index. Efficient assessment of casein using the novel FTIR prediction equation allowed for access to sufficient data being available. This research was supported by the EU and the province of Gelderland, the Netherlands.

Key Words: dairy cattle, FTIR, infrared

382 Use of infrared spectroscopy to enhance technological and nutritional quality of milk: Genetic components of FTIR spectra and breeding values estimates in Italian Simmental cattle.

Valentina Bonfatti*[1], Daniele Vicario[2], Lorenzo Degano[2], Andrea Lugo[3], and Paolo Carnier[1], [1]*Department of Comparative Biomedicine and Food Science, University of Padova, Legnaro, Italy,* [2]*National Simmental Cattle Breeders Association, Udine, Italy,* [3]*Friuli Venezia Giulia Milk Recording Agency, Codroipo, Italy.*

The aim of this study was to develop a general procedure for routine estimation of breeding values in the Italian Simmental cattle population for several innovative FTIR-predicted traits, using a direct prediction method, where breeding values estimation is directly conducted on milk FTIR spectral variables instead of FTIR-predicted traits. Breeding values for all new traits are then derived from the genetic component of the spectra. The investigated traits were: detailed milk fatty acid composition measured by 2D-GC, milk coagulation properties assessed by renneting meter analysis, pH, contents of major casein and whey protein fractions measured by RP-HPLC, cheese yield, curd composition and recovery rates of protein and fat in the curd, measured in individual micro-cheese making procedures, contents of major minerals by ICP-OES and of lactoferrin quantified by ELISA. FTIR calibrations were developed using more than 1,000 milk samples for all traits, with the exception of minerals (820 samples) and lactoferrin (635 samples). The calibration set included approximately 90% Simmental and 10% Holstein Friesian cows. A total of 100,272 milk spectra from 11,216 Italian Simmental cows were collected during the routine milk recording and stored. Principal component analysis of the unprocessed spectral data resulted in 8 latent traits that explained 99% of the total spectral variability. Restricted maximum likelihood was used to estimate (co)variance components of the latent variables. Heritability for these 8 latent traits ranged from 0.09 to 0.40. Variance ratios of the permanent environmental effect were between 0.10 and 0.25 and residual variance ratios ranged from 0.39 to 0.81. Variance components and the breeding values of original spectral transmittances were obtained by back transformation. Breeding values for the new milk traits were then predicted through FTIR calibrations as values correlated with the genetic component of the FTIR spectra. The procedure yielded estimates of breeding values for all the investigated traits for more than 10,000 Simmental animals.

Key Words: spectroscopy, breeding value, milk quality

383 Association between *INHA* A192G polymorphism and dairy traits in Holstein cattle of Antioquia-Colombia.

Stephania Madrid*, Albeiro López, and Julián Echeverri, *Universidad Nacional de Colombia, Medellín, Antioquia, Colombia.*

Productive and reproductive performance are some of the most important parameters in dairy cattle because they affect profitability of these systems. Marker-assisted selection is a useful tool to improve efficiency of dairy herds, because it allows identification of genetic differences related to a higher productive potential. Inhibin protein belongs to the transforming growth factor β super family, and its function is to modulate the secretion and action of the FSH. The goal of this research was to determine the effect of A192G polymorphism on productive and reproductive traits in Antioquia Holstein cows. The PCR-RFLP technique was used to amplify a segment of 249bp of the bovine inhibin α gene (*INHA*), and then digested with the enzyme *Msp*I. It was analyzed 1240 lactations from 356 dairy cows. The effect of the INHA genotypes on the traits was determinate by a mixed linear model and Tukey test was used to establish significant differences between means for the 3 genotypes. The effect of allelic substitution was made through a linear regression model where the genotypes AA, AG and GG were transformed into a quantitative scale of 0, 1 and 2, according to the number of G alleles. In Antioquia Holstein cattle the most common genotype was AG (0.529), followed by AA (0.269) and GG (0.201). Allele frequencies were 0.534 for A and 0.466 for G. The INHA genotypes did not exerted a significant effect on the principal productive parameters, except for fat percentage, where GG animals presented the highest value for this trait. Despite it was not a significant effect of this polymorphism on reproductive parameters, Tukey test showed that G allele tended to have a detrimental effect on female fertility, increasing the calving interval and the number of services per conception, decreasing the reproductive efficiency of the herds. Further studies are required to determine whether this SNP may be used as a molecular marker.

Key Words: inhibin, PCR-RFLP, SNP

384 Genome-wide association studies for fertility traits in Brown Swiss cattle using single SNP regression and Bayesian approaches applied to high-density SNP array information.

Beat Bapst*[1], Christine F. Baes[1,2], Franz R. Seefried[1], Marlies A. Dolezal[5], Christine Flury[2], Heidi Signer-Hasler[2], Dorian Garrick[3], Christian Stricker[4], Johann Sölkner[7], Alessandro Bagnato[6], Ingolf Russ[8], Klemen Potocnik[9], and Birgit Gredler[1], *[1]Qualitas AG, Zug, Switzerland, [2]Bern University of Applied Sciences, Zollikofen, Bern, Switzerland, [3]Iowa State University, Ames, IA, [4]agn Genetics, Davos, Graubünden, Switzerland, [5]University of Veterinary Medicine Vienna, Vienna, Austria, [6]Dept. Vespa University of Milan, Milan, Italy, [7]University of Natural Resources and Life Sciences, Vienna, Austria, [8]Tierzuchtforschung e.V. (TZF), Poing, Bavaria, Germany, [9]University of Ljubljana, Ljubljana, Slovenia.*

Large-scale, in-depth, genome-wide analyses of various economically important traits are now possible due to the availability of medium (50K; 54,609 SNP) and high-density (HD; 777,962 SNP) SNP arrays. Genome-wide association studies (GWAS) provide a powerful tool for identifying associations between phenotypes and variants in the underlying genome. Here we present GWAS results for 5 fertility traits in Brown Swiss cattle. Traits analyzed included non-return-rates in heifers (NRR_H) and cows (NRR_C), days to first service (DFS), and intervals between first and last insemination in heifers (IFL_H) and in cows (IFL_C). Imputation from 50K to HD was carried out with FImpute. After filtering out SNPs with minor allele frequency <0.05, a total of 654,847 imputed SNPs on 29 bovine autosomes remained. Deregressed breeding values of 1,502 (IFL_H) to 3,379 (NRR_C) progeny-tested bulls were used as phenotypes. Single SNP GWAS (M1) were conducted with the SNP & Variation Suite package GoldenHelix. The Efficient Mixed-Model Association expedited (EMMAX) algorithm was applied to account for population stratification. Additionally, bulls with more than 75% Original Braunvieh pedigree background were excluded. Significance levels were determined by false discovery rates. Multi-SNP GWAS (M2) using Bayesian methodology implemented in GenSel were also conducted. In those analyses, all SNPs were fitted simultaneously. A 1 Mb non-overlapping window approach that accumulated contributions of adjacent SNPs was used to identify associated genomic regions. The M1 analyses using genome-wide significance levels showed that regions on BTA3, 17, and 25 were associated with NRR_C, a region on BTA29 was associated with DFS, and a region on BTA8 was associated with IFL_C. The significant SNPs in these regions were also represented in the 1 Mb windows accounting for the largest proportion of genetic variance in the corresponding traits from M2. The promising results presented here provide evidence that specific regions of the genome are associated with fertility traits in Brown Swiss cattle.

Key Words: GWAS, fertility, dairy cattle

Cell Biology Symposium: Regulation of growth through amino acid sensing

385 Role of amino acid transporters in amino acid sensing. Peter M. Taylor*, *College of Life Sciences, University of Dundee, Dundee, UK.*

Amino acid (AA) transporters have functional importance in nutrient sensing as well as in delivering tissue nutrient supplies. These transmembrane proteins mediate AA transfer and exchange between extracellular and various intracellular fluid compartments. AA transporters at the cell surface, particularly those for large neutral AA such as leucine, interact functionally with intracellular AA sensors and nutrient-signaling pathways which regulate metabolism; for example, the mTORC1 pathway which promotes cell growth and the GCN pathway activated by AA starvation. Upregulated expression of these AA transporter; for example, the leucine transporter SLC7A5 (System L1; LAT1), is required under some circumstances to initiate AA-dependent activation of the mTORC1 pathway. Transporter activity for leucine and other essential AA may be an important determinant of baseline insulin-sensitivity. Gastrointestinal-endocrine interactions contribute to dietary regulation of AA transporter expression and activity in the intestine. Certain AA transporters (e.g., SLC38A2, SLC38A9) may have dual receptor-transporter functions, operating as “transceptors” to sense extracellular (or intracellular) AA availability upstream of intracellular signaling pathways. SLC38A2 (System A; SNAT2) at the cell surface provides a repressive signal for gene transcription during AA sufficiency, thus echoing AA sensing by transceptor orthologs in yeast (e.g., Gap1). Expression and activity of SLC38A2 is upregulated by AA starvation by a mechanism dependent on both SLC38A2 gene transcription and enhanced stabilization of SLC38A2 protein. This forms part of an integrated cellular stress response to availability of nutrients, including unsaturated fatty acids which promote SLC38A2 protein degradation via the ubiquitin-proteasome system. SLC38A9 at the lysosomal membrane may act as the endosomal AA sensor for mTORC1 activation by glutamine and arginine. New opportunities for nutritional therapy may include targeting of AA transporters (or mechanisms which regulate their expression) to promote protein-anabolic signals for growth or retention of lean-tissue mass. Research funded by the Wellcome Trust, BBSRC UK and RERAD (Scottish Government).

Key Words: amino acid, membrane transport, cell signaling

386 Integration of amino acid signaling and metabolism in the mTORC1 pathway. John Blenis*, Gwen Buel, Anders Mutvei, Alfredo Csibi, Jing Li, Gina Lee, Sang Gyun Kim, and Andy Choo, *Sandra and Edward Meyer Cancer Center, Department of Pharmacology, Weill Cornell Medical College, New York, NY.*

The mTOR complex 1 (mTORC1) signaling pathway has evolved to sense and respond to amino acid availability, cellular energy status, surrounding oxygen concentrations and stress conditions. In addition, mTORC1 can be further activated by mitogen- and hormone-stimulated kinases including Akt, ERK, and RSK, and suppressed by mTORC1-regulated S6K1 via a variety of negative feedback loops. The integration of these multiple inputs control the strength and duration of downstream signaling, which is important in differentially regulating mTORC1-dependent processes such as protein synthesis and cellular metabolism. Importantly, amino acid-mediated regulation of mTORC1 is reportedly dominant over mitogen-dependent activation of mTORC1 signaling and therefore has attracted much interest as a therapeutic target in mTORC1-driven diseases such as obesity, diabetes, aging, and cancer. The molecular basis for amino acid signaling is complex but many gaps in our knowledge of this regulatory system remain. We will discuss our recent observations regarding amino acid-dependent regulation of mTORC1 and the ability of mTORC1 to regulate cellular metabolism.

Key Words: mTOR complex, amino acid signaling, cellular metabolism

387 Integration of signals generated from nutrients, hormones, growth factors, and exercise. Scot R. Kimball*, *Penn State College of Medicine, Hershey, PA.*

The stimulation of protein synthesis that occurs in skeletal muscle in response to either nutrient intake or a bout of resistance exercise requires activation of the protein kinase known as the mechanistic (a.k.a. mammalian) target of rapamycin in complex 1 (mTORC1). The activation state of mTORC1 is controlled by several upstream signaling pathways that function in a combinatorial manner to integrate positive (e.g., re-feeding and/or resistance exercise) or negative (e.g., inactivity or glucocorticoid treatment) inputs to the kinase. For example, amino acids and insulin act through independent pathways to activate mTORC1 in an additive manner. In contrast, hindlimb immobilization attenuates the stimulatory effect of leucine on mTORC1 activity in muscle. A growing body of evidence implicates a protein known as REDD1 (regulated in development and DNA damage response 1) as a critical regulator of mTORC1 signaling, and in a variety of studies REDD1 expression has been shown to be inversely proportional to the activation state of mTORC1. For example, REDD1 abundance is reduced and mTORC1 signaling is elevated after a bout of resistance exercise, but the opposite effects are observed after endurance exercise. Moreover, compared with freely fed rats, REDD1 abundance is elevated and mTORC1 signaling is reduced after an overnight fast, and re-feeding rapidly reverses both effects. The important role played by REDD1 in controlling mTORC1 activity is emphasized in studies demonstrating that both re-feeding and muscle contraction activate mTORC1 signaling to a significantly greater extent in muscle of REDD1 deficient mice compared with wildtype mice. This presentation will focus on the signaling pathways through which amino acids, insulin, and resistance exercise act to activate mTORC1 as well as the role of REDD1 in governing the stimulatory effect of these inputs on the kinase. Work in the author’s laboratory is supported by NIH grants DK13499, DK15658, and DK094141.

388 Distributed nutrient sensing in the integrated control of energy balance. Gary J. Schwartz*, *Albert Einstein College of Medicine, Bronx, NY.*

The presence of nutrients in the gut following ingestion of a meal gives rise to multiple neural and humoral signals that depend on the mechanical and chemical properties of the ingested food. Specialized sensors within the gut are able to transduce these properties to activate a central brainstem-forebrain network that includes the brainstem dorsal vagal complex as well as forebrain hypothalamic and striatal sites. Both extrinsic nerves supplying the gut as well as nutrient stimulated, gut secretory factors mediate the transmission of gut of meal-related stimuli to this central network. Once activated, this network engages multiple effector systems that drive behavioral and physiological responses to peripheral gut nutrient availability to determine energy balance. These effectors include the negative feedback control of food intake, hepatic glucose production, thermogenesis, and food seeking behavior for palatable diets. Activity in effector pathways can limit body weight gain and adiposity, as well as improve glucose tolerance and insulin sensitivity. The responsiveness of this sensory-motor network to meal-related signals is modulated by the neuroendocrine metabolic context in which signals are received and processed, depending on the adiposity of the organism. We have identified important roles for vagal and non-vagal gut afferents linking gut nutrient availability to activation of the brainstem-forebrain network. Furthermore, growing evidence suggests that local nutrient sensing at both hindbrain and forebrain sites is acutely engaged to drive behavioral and physiological effectors. Results from neuroanatomical and neurochemical studies of each effector response suggest distinct yet overlapping neurohumoral circuits linking the gut to the brain network can be identified to modulate each distinct effector systems. As gut nutrient stimuli drive each of these pathways simultaneously during gut–meal related meal stimulation, major challenges for the field are (1) to understand the temporal and spatial patterns of neural activity during simultaneous activation of these pathways, and (2) how or whether they interact during a meal to coordinate effector responses.

Key Words: feeding, nutrient sensing, neurobiology

Companion Animals: Nutrition and behavior

389 Evaluation of pelleted diets targeted for grazing ruminants housed in zoological institutions. Katherine R. Kerr*[1,2], Marcos Zenobi[2], Rodrigo Gardinal[2], Jorge Zuniga[2], Adegbola Adesogan[2], Charles Staples[2], and Eduardo Valdes[1], *[1]Disney's Animal Kingdom, Lake Buena Vista, FL, [2]University of Florida, Gainesville, FL.*

Objective was to evaluate the apparent digestibility of 2 commercially prepared pellets targeted for herbivores housed in zoological institutions (Mazuri Wild Herbivore Hi-Fiber Diet, Purina Mills International, Brentwood MO). The pellets, differing primarily in ether extract concentration, were designated low fat (LF; DM basis: 91% OM, 29% ADF, 46% NDF, and 5.9% EE) and high fat (HF; DM basis: 92% OM, 30% ADF, 48% NDF, and 10% EE). Dietary treatments consisted of 30% chopped Bermuda grass hay (*Cynodon dactylon*) and 70% commercial pellets. Using a crossover design, 13 male lambs (45.0 ± 4.8 kg BW) served as a model for ex situ ruminant herbivores. Lambs were offered diets at 90% of ad libitum intake for a 7-d adaptation and the subsequent 7-d fecal collection period. Ten percent of wet feces were retained, dried at 55 C, ground, and chemically analyzed. Daily intake of pelleted feed tended ($P = 0.06$) to be greater in sheep fed LF pellets (1040 vs. 1003 g DM/d); however, intake of total DM did not differ due to treatment (1434 ± 183 g DM/d). Apparent digestibility coefficients of DM (57 ± 1.8%) and OM (57 ± 1.8%) did not differ ($P > 0.10$) due to treatment. Apparent digestibility coefficients of NDF, ADF, and EE were greater ($P < 0.01$) for lambs fed HF pellets (42, 45, and 94%, respectively) compared with those fed LF pellets (36, 42, and 90%, respectively). Blood was collected via jugular vein approximately 4 h after feeding. Plasma concentrations of glucose (70 ± 2.0 mg/dL) and urea nitrogen (21.3 ± 1.1 mg/dL) were not affected ($P > 0.10$) by diet. To provide proper care and ensure optimal health of ex situ wildlife species, a clear understanding of the diet utilization by these species is necessary. Use of appropriate model species (i.e., closely related domestic counterparts) allows researchers to measure physiological data that might be otherwise unattainable due to research limitations when working with ex situ wildlife species (e.g., low numbers, control of variation, and sampling limitations). Herein, we utilized the sheep as a model for ruminants housed in zoological institutions.

Key Words: captive exotic, fiber digestibility, herbivore

390 Serum metabolite profiling to identify biomarkers and mechanistic insight into the metabolic changes associated with weight loss in overweight cats. Marissa R. Pallotto*[1], Maria R. C. de Godoy[2], Kirk L. Pappan[3], Preston R. Buff[4], and Kelly S. Swanson[1,2], *[1]Division of Nutritional Sciences, University of Illinois, Urbana, IL, [2]Department of Animal Sciences, University of Illinois, Urbana, IL, [3]Metabolon, Durham, NC, [4]The Nutro Company, Franklin, TN.*

Previous studies have shown that obese and overweight models have increased oxidative stress and lipid metabolism dysregulation. Thus, the objective of this study was to identify metabolite changes and potential biomarkers during weight loss that could be used as indicators of reestablished health. During a 4-wk baseline period, 8 adult neutered male cats were fed to maintain BW. For 18 wk following baseline, cats were fed to lose weight at a targeted rate of 1.5% BW/wk. As expected, mean BW (7.7 ± 0.4 vs. 6.2 ± 0.4 kg) and mean BCS (7.6 vs. 6.0) decreased ($P < 0.05$) at wk 18 vs. wk 0. Daily food intake, twice-weekly BW, and weekly BCS were recorded throughout the study. Fasted (~15 h) blood samples were collected at wk 0, 1, 2, 4, 8, 12, and 16. Serum was stored at −80°C until GC-MS and LC-MS/MS analyses. A total of 535 named biochemicals were identified, with up to 269 metabolites altered (P- and q- values <0.05) at wk 16 vs. wk 0. Principal component analysis showed a continual shift as weekly weight loss progressed. Component 1 and 2 explained 14.3% and 10.3% of the variability, respectively. There was a significant and dramatic reduction of bile acids (cholate; taurocholate; deoxycholate) with weight loss. A reduction in numerous free fatty acids (FFA) and an increase in ketones (acetoacetate; 3-hydroxybutryate) and monoglycerides suggest a shift toward lipolysis and hepatic FFA oxidation. Decreased markers of inflammation and oxidative stress were indicated by reduced pro-inflammatory oxylipids, eicosanoids, and oxidized biomarkers following weight loss. Markers of collagen degradation, such as proline-hydroxyproline and proline-glycine, and muscle protein turnover, such as 1-methylhistidine, increased. Mevalonate was significantly decreased after wk 8 compared with baseline, which agrees with the reduced bile acids without altering cholesterol. This may suggest upregulation of hepatic ketogenesis through activation of HMG-CoA lyase. Considering these results, global metabolomics was useful to potentially identify biomarkers of systemic changes in response to caloric restriction of a high-protein, high-fiber diet.

Key Words: feline, metabolomics, obesity

391 Behavior assessment of dogs fed soybean hulls. Mariana Scheraiber*[1], Tabyta Tamara Sabchuk[1], Tatiane Ramos[1], Juliana Regina da Silva[2], Lidiane Priscila Domingues[1], Ana Vitória Fischer da Silva[1], and Ananda Portella Felix[1], *[1]Federal University of Paraná, Curitiba, Paraná, Brazil, [2]Federal University of Santa Catarina, Florianópolis, Santa Catarina, Brazil.*

The behavior of dogs is influenced by dietary effects on satiety. Dietary fiber may prolong the gastric emptying time, slow the absorption of nutrients and dilute the energy of the diet. Thus, the development of strategies to increase satiety may be desirable to help to increase socialization and decrease undesirable behaviors of the animals. Soybean hulls (SH) is an alternative fiber source for dog food, due to the soluble and insoluble fiber portions resulting in benefits in the animal's health. Thus, this study aimed to evaluate the behavior of dogs after ingestion of diets without (0%SH) and with 16%SH. Twelve adult Beagle dogs (6 males and 6 females) in a completely randomized design were used. Dogs were individually housed in concrete kennels with solarium (2 m wide × 5 m long) and received the diets for 28 d. The behavior of dogs was evaluated on the 28th day, for 24 h continuously, at intervals of 10 min between each observation. The behaviors assessed were: alert, walking, scratching, sleeping, stereotypies, hygiene, lying idle, standing idle, sitting leisure and socialization. The results were expressed as the behavior occurrence frequency (%) (number of observations of the behavior / total number of observations × 100). Data were analyzed using the Mann-Whitney-Wilcoxon test, with $P < 0.10$. There was a decrease in the behavior of scratching ($P < 0.05$; 9,3% 0%SH to 3.7% 16%SH) and stereotypy ($P < 0.10$; 8,3% 0%SH to 4.8% 16%SH) in dogs fed 16%SH, in comparison with the 0%SH diet. The other behaviors did not differ ($P > 0.05$) between diets. Diets with SH, as fiber source, can decrease stereotypy behaviors of dogs.

Key Words: dog nutrition, feeding behavior, fiber

392 Evidence for a cat pheromone that modulates kitten scratching.

John J. McGlone*[1,2] and Rebekkah R. Plummer[2], *[1]Laboratory of Animal Behavior, Physiology and Welfare, Texas Tech University, Lubbock, TX, [2]McGlone Enterprises Inc., Lubbock, TX.*

Inappropriate scratching is a behavioral problem among kittens and cats in homes. Tools to modulate (increase or decrease) scratching would be valuable for cat owners and cats. Anecdotal literature suggests that cats have pheromones in their paws or claws, or in their saliva that they transfer to their claws. These pheromones are reportedly used to mark territory or objects. Through evaluation of cat scratchers, we noticed effects over time that suggested saliva, claw, or paw pheromones may modulate kitten scratching. We used the highly preferred S-shaped cardboard scratcher and 6 kittens (<3 mo of age) per study in 2 studies with the objective of finding evidence that supports pheromones may be present. In study 1, we compared kitten scratching with paired access to a previously used cat scratcher compared with a new cat scratcher. Using a 20-min evaluation period, kittens spent more ($P < 0.05$) time interacting (scratching and playing) with a previously used cat scratcher than with a new cat scratcher (33.1 vs. 20.6 ± 6.3 s). In study 2, new S-shaped cardboard scratchers were evaluated alone or with catnip, catnip oil, or cat hair added (clipped from adult donor cats and allowed to fall between the cracks of the cardboard scratcher). Kittens spent more ($P < 0.05$) time interacting with the S-shaped cardboard scratcher with added cat hair than with a control scratcher (16.0 vs. 8.3 ± 2.7 s). Adding dried catnip plants or catnip oil did not cause a change in scratching compared with the control (5.0, 10.2 vs. 8.3 ± 2.7 s). In conclusion, we provide evidence that kittens touching cardboard cause future kittens to interact more with that material. Second, we show that catnip plants and oil are not effective at increasing use of a scratcher by kittens. Finally, we show that cat hair (odor) induces enhanced interactions (scratching and play) with a cardboard scratcher. These findings can be used as a basis to discover new pheromones that modulate kitten and cat behavior.

Key Words: cat, behavior, scratch

393 The use of varying strengths of gelatin and the effect on physical properties of extruded pet food.

Analena E. Manbeck*, C. Greg Aldrich, and Sajid Alavi, *Department of Grain Science and Industry, Kansas State University, Manhattan, KS.*

Previous work with low-bloom gelatin demonstrated an increase in hardness and durability when incorporated into extruded kibbles. The objective of this experiment was to determine the effect of gelatin bloom strength on extruded kibble physical properties. Four nutritionally complete diets (30% protein) were formulated with no gelatin (control) or with 10% gelatin from 50, 175 and 250 bloom strength sources (Pro-Bind 100, PigSkin 175, and PigSkin 250) exchanged with chicken by-product meal. All diets were produced on a Wenger X-20 extruder through a circle die (3mm diameter) then a triangle die (5.3mm base × 4.9mm height). Products were analyzed for bulk and piece density, throughput, cross-sectional expansion, hardness, and pellet durability index (PDI). Experimental treatments were arranged as a factorial with main effects separated using statistical software (SAS 9.4). Kibble shape had an effect on hardness, cross-sectional expansion, and piece density, but this was likely due to a slight difference in die open area. The interaction of gelatin strength and kibble shape also had effects on hardness, PDI, and density, but these can be attributed to changes in bloom strength. Relative to the control, hardness increased with 50 bloom gelatin but decreased with 175 and 250 bloom gelatin ($P < 0.05$; 5.93, 7.38, 4.57, 3.59kg, respectively). Relative to the control, PDI was the same for 50 bloom but decreased with both 175 and 250 bloom gelatin (88.49%, 87.57%, 64.55%, and 30.01%, respectively). The main effect means of cross-sectional expansion and specific length increased with bloom strength (3.05, 3.54, 4.29, 4.92mm^2/mm^2 expansion and 4.27, 4.26, 4.49, 4.74cm/g length for 0, 50, 175, 250 bloom, respectively). The main effect means for bulk and piece density became lighter with increasing bloom (0.56, 0.48, 0.39, 0.33g/cm^3 piece density and 347.6, 310.7, 242.4, 212.3g/L bulk density for 0, 50, 175, 250 bloom, respectively). There were no treatment effects on throughput. Low-bloom gelatin may improve expansion while increasing product hardness and durability, making it a potential structure-enhancing ingredient.

Key Words: pet food, gelatin, extrusion

394 Digestibility and palatability of diets containing crude corn oil in dogs.

Tabyta T. Sabchuk*[1], Daniele C. Lima[1], Cleusa B.M. Brito[1], Larissa Barrile[2], Ananda P. Félix[1], Simone G. Oliveira[1], and Alex Maiorka[1], *[1]Federal University of Paraná, Curitiba, Paraná, Brazil, [2]Cargil Agricola SA, Uberlândia, Minas Gerais, Brazil.*

Crude corn oil (CCO) has large amount of linoleic acid, an essential fatty acid for dogs. Furthermore, CCO has less variation in composition and quality than animal fats. The objectives were to evaluate the apparent total-tract digestibility (ATTD), ME, and palatability of diets containing CCO in dogs. Four diets were evaluated: a control diet (with 12% poultry fat, PF), and 3 diets containing: 4, 8, and 12% CCO, replacing the PF. Diets were sprayed with the fat sources. Eight Beagle dogs were assigned in a replicated Latin square (4 × 4), totaling 8 replicates per treatment. The experimental diets were offered for a 5-d adaptation period, followed by 5 d of total fecal collection per period. The results were submitted to analysis of regression and orthogonal contrasts (PF vs. CCO). Palatability tests were performed using 2 pair-wise comparisons: 12% PF vs. 12% CCO, both diets with (Test 1) or without (Test 2) palatability enhancer (liquid chicken liver hydrolyzed). Palatability was determined by measuring intake ratio (IR) between the foods offered to 15 adult dogs. Each test was repeated for 3 d (n = 45). The IR data were analyzed by Student's *t*-test. The ATTD of DM (80.0, 80.4, 78.2, and 79.2%), CP (80.8, 81.7, 79.4, and 80.0%), GE (84.2, 83.7, 82.3, and 83.5%), and ME (15.68, 15.58, 15.32, and 15.55 MJ/kg DM) of diets 12% PF, 4, 8, and 12% CCO, respectively, did not differ ($P > 0.05$). The IR did not differ ($P > 0.05$) between diets with palatability enhancer (0.53 to 12% CCO vs. 0.47 to 12% PF) and without palatability enhancer (0.52 to 12% CCO vs. 0.48 to 12% PF). The use of CCO as a lipid source in diets for dogs does not change the digestibility and the palatability of the diet, even in diets without palatability enhancer, when compared with the PF.

Key Words: companion animal nutrition, fat source, food preference.

395 Effects of androstenone on reduction of leash pulling in dogs.

Glenna M. Pirner* and John J. McGlone, *Texas Tech University, Lubbock, TX.*

Behavioral problems are the primary reason owners relinquish dogs to animal shelters. Interomones are olfactory cues produced by one species that elicit a response in another species. The objective of this study is to determine the effects of androstenone acting as an interomone to reduce leash-pulling behavior using a model of dog walking. Androstenone is a swine sex pheromone capable of eliminating jumping and barking in dogs; as such, it may also reduce leash pulling. This study took place at a local animal shelter using adoption dogs surrendered by owners due to behavioral issues, providing an exceptional model for this study. A researcher walked each dog on a standard nylon neck collar and leash 53 m around an enclosed yard (average time 76.0 ±

11.6 s). Leash pulling was defined as pressure exerted on the leash by the dog resulting in the researcher's inability to walk comfortably. Each dog was walked twice with 90 min of rest between walks. On the first walk the researcher did not respond to leash pulling (NOT). On the second walk the researcher responded to each leash pull by spraying the designated treatment 46 cm from the dog's head. Treatments were water (H_2O, n = 8), androstenone+water (ANH, n = 9), or InteroSTOP (Meridian Animal Health, Omaha, NE) (INT, n = 10). The study was designed so each dog was walked twice: once with NOT, and once with H2O, ANH or INT. Walks were video recorded and observed by researchers blind to the treatments. The observers counted number of leash pulls during each walk and noted reactions to sprays. Data were analyzed using a 2-tailed Student's *t*-test, with number of leash pulls during the walk with NOT as the control for each treatment. ANH and INT reduced the number of leash pulls by 84% and 86%, respectively, compared with H_2O ($P < 0.001$). There was no difference in reduction of leash pulling between ANH and INT ($P > 0.05$). INT reduced leash pulling; however, the compressed air sound accompanying the spray frightened many dogs when sprayed from behind. These findings may be beneficial in developing behavioral modification training tools for dogs, thereby improving the human-animal bond and possibly reducing the desire of owners to relinquish ownership of dogs.

Key Words: behavior, canine, interomone

396 Effects of graded dietary HP 300 concentrations on apparent total-tract macronutrient digestibility, fecal characteristics, and fecal fermentative end-products in healthy adult dogs.

Alison N. Beloshapka*[1], Maria R. C. de Godoy[1], Katelyn B. Detweiler[1], Ingmar S. Middelbos[3], George C. Fahey Jr.[1,2], and Kelly S. Swanson[1,2], [1]*University of Illinois at Urbana-Champaign Department of Animal Sciences, Urbana, IL,* [2]*University of Illinois at Urbana-Champaign Division of Nutritional Sciences, Urbana, IL,* [3]*Hamlet Protein Inc., Findlay, OH.*

Animal proteins, such as poultry by-product meal (PBM), are commonly used in extruded dog foods. Plant-based proteins have a more consistent nutrient profile than animal sources but may contain anti-nutritional factors (ANF), including trypsin inhibitors and oligosaccharides. The test protein, HP 300, is a proprietarily processed soy-based product with very low ANF concentrations and high nutritional value. The objective was to evaluate if HP 300 can be an effective PBM replacement in pet food and if there are practical limits to its use. We tested the effects of 0% (control), 4%, 8%, 12%, 24%, and 48% HP 300 on apparent total-tract macronutrient digestibility, fecal characteristics, and fecal fermentative end products in healthy adult dogs. All 6 diets were formulated to meet AAFCO nutrient profiles with approximately 30% crude protein and 16% fat. Forty-eight healthy adult beagle dogs (20 females, 28 males; mean age: 3.4 y; mean BW: 10.0 kg) were studied in a completely randomized design. The treatment period consisted of a 10-d diet adaptation phase followed by a 4-d fresh and total fecal collection phase. Stool output (both on as-is and dry matter basis [DMB]) did not differ from control until 48% HP 300 ($P < 0.01$). Fecal output per unit food intake (DMB) differed ($P < 0.01$) from control only at the 24% and 48% HP 300 inclusion rates. Notably, no effect of HP 300 inclusion was found for stool consistency scores. Digestibility of DM, organic matter and energy did not differ from control at any inclusion rate, except for a decrease ($P < 0.01$) at 48% HP 300, which is likely due to increased dietary fiber concentrations. Crude protein digestibility was not affected by treatment and ranged from 82.9 – 86.2%. Short-chain fatty acid production increased ($P < 0.01$) compared with control only at 24% and 48% HP 300. Conversely, branched-chain fatty acids were reduced ($P < 0.01$) compared with control at inclusion rates of HP 300 of 8 – 48%. Overall, these data suggest that HP 300 is a suitable replacement for PBM in canine diets up to at least a 24% inclusion rate.

Key Words: canine, digestibility, soy protein

397 Characterization of hindgut microbiota during the onset of obesity in adult domestic cats.

Maria R. C. de Godoy*[1] and Kelly S. Swanson[1,2], [1]*Department of Animal Sciences, University of Illinois, Urbana, IL,* [2]*Department of Veterinary Clinical Medicine Sciences, University of Illinois, Urbana, IL.*

In humans, gastrointestinal microbiota of obese subjects harbor a less diverse bacterial community and a lower ratio of Bacteriodetes:Firmicutes phyla. However, these relationships have not been examined in the domestic cat. Thus, the objective of this study was to characterize the hindgut microbiota of domestic cats transitioning from a lean to an obese phenotype. Nine domestic male cats (mean age = 8 ± 0.3 yr; mean BW = 4.5 ± 0.4 kg, mean BCS range = 5.0 ± 0.5) were ad libitum fed a complete and balanced experimental diet for 36 wk. Food intake was measured daily, while BW and BCS were measured weekly, fresh fecal samples were collected at 0, 6, 12, 24 and 36 wk. Amplification of fecal bacterial DNA was performed using targeted primers and a Fluidigm Access Array. Illumina sequencing was performed utilizing a MiSeq2000 using v3 reagents. High quality (quality value >25) sequence data derived from the sequencing process were analyzed using QIIME 1.8.0. Resulting sequences were clustered into operational taxonomic units (OTU) using closed-reference OTU picking against the Greengenes 13_8 reference OTU using a 97% similarity threshold. Data were analyzed as repeated measurements, with post-hoc Tukey adjustment. A $P < 0.05$ was considered statistically significant. A total of 9,145,663 reads were generated in the current data set, with an average of 203,236 reads per sample used to provide diversity estimates. Cats incrementally changed from a lean phenotype (mean BCS = 5.0) at baseline to an overweight phenotype with a mean BCS of 7.5 at 36 wk. Similar to previously observed in humans, overweight cats had a lower ratio of Bacteriodetes (e.g., Bacteroides; Prevotella) to Firmicutes (e.g., Lactobacillus) phyla. However, microbial diversity and species richness was not altered by BW gain (~250 species). Body weight gain resulted in a gut microbiota shift depicted by unweighted UniFrac-based PCoA analysis between cats at baseline and 6 wk vs. 24 and 36 wk. Proteobacteria (e.g., Succinivibrionaceae) and Fusobacteria (Fusobacteriaceae) were decreased ($P < 0.05$) by BW gain. These data demonstrate the transition from a lean to an overweight phenotype alters the GI microbiota in cats.

Key Words: feline, microbiome, obesity

398 Evaluation of cat scratcher efficacy.

John J. McGlone*[1,2] and Rebekkah R. Plummer[2], [1]*Laboratory of Animal Behavior, Physiology and Welfare, Texas Tech University, Lubbock, TX,* [2]*McGlone Enterprises Inc., Lubbock, TX.*

Inappropriate scratching is a behavioral problem among kittens and cats in homes. Many models of cat scratchers are available but there is little objective work that evaluates efficacy of cat scratchers. A model was developed to evaluate cat scratching using kittens in a controlled setting. Four studies were conducted. The first study used 12 kittens (<3 mo of age) in a completely random design with 2 scratcher types per study. A power test revealed 6 kittens gave sufficient power for a scratcher evaluation; therefore, studies 2 to 4 used 6 unique kittens each. In a given study, a kitten was given simultaneous access to 2 cat scratchers for 20 min. Kittens spent an average of 95 s scratching and playing with cat scratchers. Preference studies examined cat scratchers. The key measure was the time kittens spent interacting (scratching and playing) with each scratcher. In study 1a, kittens spent more ($P < 0.05$) time with a cardboard bed than with a hemp post (99.3 vs. 14.9 ± 15.9 s) while in study 1b, a carpeted tall post and cardboard bed induced similar scratching (24.2 vs. 20.2 ± 23.3 s). In studies 2a-c, a screen was placed in either horizontal or vertical positions. In study 2a, kittens spent more ($P < 0.05$) time with the screen in the horizontal compared with the vertical position (21.7 vs. 10.5 ± 2.8 s). In study 2b, kittens spent similar time with the horizontal screen compared with the cardboard scratcher (25.0 vs. 29.8 ± 8.6 s). In 2c, kittens preferred ($P < 0.05$) the cardboard scratcher to horizontal bubble wrap (31.0 vs. 9.0 ± 5.1 s). In study 3a, kittens spent more ($P < 0.05$) time with cardboard than with screen (37.5 vs. 7.8 ± 7.9 s) and in 3b more time with cardboard vs. carpet (37.5 vs. 5.0 ± 6.7 s). In studies 4a-c, kittens spent more ($P < 0.05$) time with an S-shaped cardboard than with long-flat, rectangular-flat, or boat-shaped cardboard scratchers (20.6, 6.2, 6.3, 11.3 ± 3.9 s). In conclusion, kittens prefer cardboard and carpet over screen, bubble wrap, or hemp-type scratchers. Second, kittens had a clear preference to play and scratch with cardboard scratchers in an S-shape. Finally, scratchers vary considerably in their ability to interest kittens in scratching.

Key Words: cat, kitten, behavior

399 Evaluation of pork and pork by-products in raw meat diets for African wildcats.

Cayla J. Iske*[1], Cheryl L. Morris[1,2], and Kelly Kappen[2], [1]*Iowa State University, Ames, IA,* [2]*Omaha's Henry Doorly Zoo and Aquarium, Omaha, NE.*

Primarily, only 2 protein sources (beef or horse) are commercially used for raw meat diets fed to carnivores managed in zoos. An additional protein source such as pork has potential to mitigate some gastrointestinal issues and provide dietary variety. Concerns with high levels of microbial populations in raw meat diets and possible zoonoses also have been expressed. The objectives of this study were to determine if a pork-based diet had similar apparent total-tract macronutrient digestibility and fecal scores in African wildcats as standard zoological carnivore diets formulated with either horse or beef and to characterize the microbial counts among the diets. Four African wildcats were used (2 males, 2 females) in a randomized crossover design consisting of 4 raw meat diets: horse (H), beef (B), beef/horse blend (HB), and pork (P) all fed isocalorically to maintain body weight. Data were analyzed using the Mixed models procedure of SAS. All diets were highly digestible, especially for fat where digestibiltiy values ranged from 98.58 (H) to 99.73% (HB) and were not different. Digestibility of OM was higher ($P < 0.05$) when cats consumed HB (97.15%) compared with P (93.10%). Crude protein digestibility was highest ($P < 0.05$) for HB (98.08%) and lowest for B (93.44%). Fecal scores (1 = hard, dry feces to 5 = liquid/watery feces) were higher ($P < 0.05$) for cats fed B (2.63) compared with cats fed H (1.55) or P (1.91). Microbial counts varied and included E. Coli ranging from 110 to 10,000 cfu/g for HB and B diets, respectively; total coliforms from 150 to 28,000 cfu/g for HB and B diets, respectively; yeast from 20 to 4,000 cfu/g for P and HB, respectively; mold counts were not detectable for all diets except B that contained 10 cfu/g and aerobic plate counts ranged from 23,000 to 26,000,000 cfu/g for H and HB diets, respectively. Staphylococcus aureus was not detected in any of the diets. *Salmonella* was presumptive positive in the P and HB diets; however,these values were not enumerated or quantified for specific strains. In conclusion, a pork-based diet can be utilized by exotic small cats and included among dietary options for felid management. Raw meat diets do contain variable levels of microbes and should be handled and managed appropriately.

Key Words: raw meat diet, cat, exotic animal

Dairy Foods: Microbiology

400 Development of an anaphylactic model of buckwheat using B-type CpG oligodeoxynucleotides from lactic acid bacteria. Yoshinari Yamamoto*[1], Suguru Shigemori[1,2], Kazushi Oshiro[3], Pengfei Wang[1], Yeqin Wang[1], Takashi Sato[4], and Takeshi Shimosato[1,5], [1]*Interdisciplinary Graduate School of Science and Technology, Shinshu University, Kamiina, Nagano, Japan,* [2]*Research Fellow of the Japan Society for the Promotion of Science (JSPS), Chiyoda, Tokyo, Japan,* [3]*Graduate School of Agriculture, Shinshu University, Kamiina, Nagano, Japan,* [4]*Graduate School of Medicine, Yokohama City University, Yokohama, Kanagawa, Japan,* [5]*Institute for Biomedical Sciences, Shinshu University, Kamiina, Nagano, Japan.*

Anaphylaxis is an acute systemic allergic reaction (severe type I hypersensitivity) to a specific allergen and occurs in human and other mammals. Food anaphylaxis is most frequently triggered by peanut, buckwheat, milk, egg, and wheat allergens. Anaphylactic mouse models against ovalbumin and peanut allergens have been established by repeated exposure to small amounts of allergen with adjuvant via subcutaneous (s.c.) and intraperitoneal (i.p.) routes. When immunity is established, the animals are challenged with a large quantity of allergens via an i.v. route to induce anaphylaxis. However, i.v. sensitization is a relatively complicated procedure, and establishing an anaphylactic model requires considerable time. In addition, the i.p. method for allergen delivery is simpler than i.v. routes, has lower risk for failure, and can shorten sensitization duration. Here, we attempted to develop a simple anaphylactic shock model by exposing mice to a B-type CpG-oligodeoxynucleotide (ODN), termed MsST, which had the immune ability to induce IL-33 and IFN-γ production from the *lac* Z gene of *Streptococcus thermophilus* ATCC19258 with allergen via an i.p. route. After the allergen challenge for inducing anaphylactic shock, IgG_{2a}-production and IFN-γ-positive cells were markedly increased in mice that received B-type CpG-ODN. In contrast, IL-33-positive cells in the model mice were only slightly increased. Generally, IFN-γ supports Th1 cell responses that suppress allergic disease. However, it was previously reported that IFN-γ enhances platelet-activating factor, which is a bioactive lipid mediator that plays a role in the onset of inflammatory diseases such as asthma, anaphylaxis and atherosclerosis, and is involved in the generation of $CD11b^+$ and $CD11c^+$ cells. The anaphylactic shock model described here is expected to contribute to the development of anaphylaxis treatment strategies.

Key Words: anaphylactic model, buckwheat, B-type CpG-oligodeoxynucleotide (ODN)

401 Construction of genetically modified *Lactococcus lactis* expressing buckwheat protein Fagag1 with strong allergenicity. Suguru Shigemori*[1,2], Yoshinari Yamamoto[1], Kazushi Oshiro[3], Pengfei Wang[1], Yeqin Wang[1], Takashi Sato[4], and Takeshi Shimosato[1,5], [1]*Interdisciplinary Graduate School of Science and Technology, Shinshu University, Kamiina, Nagano, Japan,* [2]*Research Fellow of the Japan Society for the Promotion of Science (JSPS), Chiyoda, Tokyo, Japan,* [3]*Graduate School of Agriculture, Shinshu University, Kamiina, Nagano, Japan,* [4]*Graduate School of Medicine, Yokohama City University, Yokohama, Kanagawa, Japan,* [5]*Institute for Biomedical Sciences, Shinshu University, Kamiina, Nagano, Japan.*

Buckwheat (*Fagopyrum esculentum*) is consumed as a pseudocereal in Asia and Western countries, and is recognized as a functional food. However, several proteins from buckwheat have strong allergenicity and cause severe symptoms, such as an anaphylaxis, in hypersensitive patients. Here, we engineered strains of *Lactococcus lactis* NZ9000 (NZ9000) that express Fagag1, a major allergenic storage protein of buckwheat, fused with or without green fluorescent protein (GFP). Codon-optimized sequences of Fagag1 and GFP-Fagag1 were individually cloned into the *L. lactis* expression vector pNSH, containing a nisin-inducible promoter and 6x histidine-tag sequence. The resulting plasmids were separately introduced into NZ9000, and nisin-dependent expression of recombinant Fagag1 (rFagag1) and rGFP-Fagag1 was confirmed by Western blotting and confocal laser scanning microscopy. rFagag1 and rGFP-Fagag1 were individually purified by immobilized metal-ion affinity chromatography techniques, and the allergenicity of the purified proteins was then evaluated in *in vitro* cultures of splenocytes isolated from buckwheat crude protein-immunized mice. Treatment of splenocytes with rFagag1 markedly induced the mRNA expression of interleukin (IL)-4, IL-13, and IL-17F, which are known mediators of allergic inflammation. Similar expression levels of IL-4 and IL-17F mRNA were observed in the splenocytes stimulated with purified rGFP-Fagag1; however, the increases from baseline were significantly lower than those observed in rFagag1-treated cells. Recent evidence suggests that the mucosal (i.e., oral or intranasal) application of lactic acid bacteria genetically modified to produce allergen is a promising strategy for allergy therapy. Therefore, our present results suggest that NZ9000 expressing immunoreactive rFagag1 or rGFP-Fagag1 may be a powerful candidate for the prevention and therapy of buckwheat allergy. However, the future application of prophylactic and therapeutic strategies based on NZ9000 strains first requires a clear demonstration of efficacy in in vivo trials.

Key Words: buckwheat, *Lactococcus lactis*, food allergy

402 Production of recombinant β-lactoglobulin in *Lactococcus lactis* and generation of a bioactive peptide with incretin-inactivation activity. Kazushi Oshiro*[1], Suguru Shigemori[2,3], Yoshinari Yamamoto[2], Pengfei Wang[2], Yeqin Wang[2], Takashi Sato[4], and Takeshi Shimosato[2,5], [1]*Graduate School of Agriculture, Shinshu University, Kamiina, Nagano, Japan,* [2]*Interdisciplinary Graduate School of Science and Technology, Shinshu University, Kamiina, Nagano, Japan,* [3]*Research Fellow of the Japan Society for the Promotion of Science (JSPS), Chiyoda, Tokyo, Japan,* [4]*Graduate School of Medicine, Yokohama City University, Yokohama, Kanagawa, Japan,* [5]*Institute for Biomedical Sciences, Shinshu University, Kamiina, Nagano, Japan.*

β-Lactoglobulin (BLG) is the most abundant protein in cow's milk whey. Peptides prepared from BLG digested with the gastrointestinal (GI) proteases pepsin and trypsin strongly inhibit dipeptidyl peptidase-IV (DPP-IV) activity. DPP-IV is a ubiquitously expressed serine protease that cleaves N-terminal dipeptides from incretins, which are insulinotropic GI hormones. Recently, genetically modified lactic acid bacteria have emerged as efficient cell factories for the production and safe delivery of heterologous proteins to the GI tract. Here, we engineered a strain of *Lactococcus lactis* to secrete recombinant BLG (rBLG) and evaluated the DPP-IV-inhibiting activity of trypsin-digested rBLG. To construct rBLG-producing *L. lactis*, a codon-optimized bovine BLG gene was inserted into the lactococcal secretion vector pNZ8148#2:SEC, containing a nisin-inducible promoter and signal peptide sequence from USP45 protein. The constructed rBLG secretion vector was transformed into *L. lactis* NZ9000 (NZ9000) as a host strain for gene expression. The secretion of rBLG by NZ9000 was confirmed by Western blotting. The DPP-IV-inhibitory activity of trypsin-digested rBLG was examined by comparative analysis with trypsin-digested commercial BLG (cBLG) using a DPP-IV Drug Discovery Kit. Results from the assay revealed that the inhibitory activity of trypsin-digested rBLG against DPP-IV was similar to that of cBLG. In conclusion, we successfully engineered a strain of NZ9000 that efficiently secretes rBLG, and clearly demonstrated that trypsin-digested rBLG has strong inhibitory activity against DPP-IV enzyme. In future studies, we plan to evaluate the potential of rBLG-secreting NZ9000 as a therapeutic agent for type 2 diabetes.

Key Words: β-lactoglobulin, *Lactococcus lactis*, dipeptidyl peptidase-IV

403 Sodium chloride induced stress responses in dairy probiotic bacteria. Akanksha Gandhi* and Nagendra P. Shah, *The University of Hong Kong, Hong Kong.*

The study focused on possible mechanisms of salt stress injury and responses of selected probiotic bacteria to salt stress. The effects of varying NaCl/KCl concentrations on viability, membrane integrity and metabolic activity of *Lactobacillus acidophilus*, *Lactobacillus casei* and *Bifidobacterium longum* were studied using flow cytometry. Furthermore, the changes in surface functional groups, morphology and membrane fatty acid composition of these bacteria were investigated using Fourier-transform infrared (FTIR) spectroscopy, transmission electron microscopy and gas chromatography. The effect of NaCl/KCl stress on the in vitro adhesion ability of stressed bacteria to Caco-2 cells was also evaluated. Cell viability as evaluated using conventional culture technique was compared with the findings from flow cytometric analysis on metabolic activities of the cells and it was revealed that there was a correlation between culturability and dye extrusion ability of *Lb. casei* and *B. longum*. However, a certain population of *Lb. acidophilus* was viable as per the plate count method but the efflux activity was compromised. The metabolic activity of *Lb. casei* was found to be highest among the 3-probiotic bacteria. The FTIR spectral analysis also highlighted the shifts that occurred mainly in the amide regions upon increasing the NaCl concentration. Significant changes in the morphology of all bacteria were observed at higher salt concentrations. Shrinkage of the cytoplasmic content and irregularities in cell wall on exposure to high NaCl concentrations (10% w/v) were observed in all bacteria. Membrane fatty acid composition was affected by salt stress, and the ratio of unsaturated to saturated fatty acids was altered on exposure to NaCl stress. Adhesion ability of stressed bacteria to Caco-2 cell lines was also reduced at higher NaCl concentrations (10% w/v). Comparing the responses among the selected bacteria, *Lb. casei* appeared to be most robust to NaCl stress. Overall, the study revealed the impact of salt stress on membrane characteristics and adhesion capability of selected probiotic bacteria.

Key Words: sodium chloride, lactic acid bacteria, cell membrane

404 Potential role of *Bacillus* strains isolated from the dairy environment as defect-causing organisms in yogurt. Dipakkumar Mehta*[1], Ashraf Hassan[2], Brandon Nelson[2], and Hasmukh Patel[1], [1]*South Dakota State University, Brookings, SD,* [2]*Daisy Brand, Garland, TX.*

Bacillus spp. can cause spoilage of milk and dairy products due to their ability to produce heat resistant enzymes and spores. Milk proteins, fat, and stabilizers (such as gelatin, amylopectin (AP), xanthan, and pectin) play an important role in structure formation and stability of yogurt. Possible sources of *Bacillus* spp. in these products include raw milk, ingredients such as dairy powders, and processing equipment. The objective of this study was to test the proteolytic, lipolytic, and phospholipase activities as well as stabilizer-degrading characteristics of 25 *Bacillus* strains isolated from the dairy environment. Proteolysis, lipolysis, and phospholipase activity were tested using skim-milk agar, spirit blue agar, and lecithin agar, respectively. A basic agar medium containing AP, xanthan, or pectin and gelatin agar were used to study the stabilizer-degradation activities of the various *Bacillus* strains. All experiments were conducted in triplicate at 42°C and under mesophilic conditions. Many of the tested *Bacillus* strains were highly proteolytic and could degrade various stabilizers (AP, pectin, xanthan and gelatin). It was found that the majority (92%) of *Bacillus* strains were able to degrade AP while only 20% showed lipolytic activities. All proteolytic strains showed gelatin degradation activities. The xanthan, phospholipid, and pectin degradation activities were found in 68%, 40% and 24% *Bacillus* strains, respectively. Generally, *Bacillus* spp. exhibited higher activities at 42°C than at mesophilic temperatures. Based on these results, it can be concluded that the order of susceptibility of the different tested components to *Bacillus* strains was AP > protein = gelatin > xanthan > phospholipids > pectin > fat, suggesting their ability to induce texture defects in yogurt.

Key Words: *Bacillus,* yogurt, stabilizer

405 Inactivation of thermoduric sporeformers in milk by combined effect of cavitation and pasteurization. Dikshi Bawa*, Sanjeev Anand, Harsh Dahiya, and Hasmukh Patel, *South Dakota State University, Brookings, SD.*

Thermoduric sporeformers show resistance to the commonly applied thermal treatments and later produce spores during further processing of milk. They survive pasteurization and can cause spoilage defects in dairy foods. The objective of this study was to investigate the application of controlled hydrodynamic cavitation in a continuous mode, and its combination with thermal treatments on the inactivation of thermoduric sporeformers in milk. We hypothesized that the high shear created by the cavitation shock waves and the resulting friction would cause rupturing of the bacterial cell wall, resulting in cell death. Mid exponential phase vegetative cells of *Bacillus coagulans* (ATCC 12245) were inoculated in sterile skim milk at log 5 cfu/mL. Inoculated milk samples were passed at 60 Hz frequency and 200 L/h flow rate with 120 kPa back pressure, using APV Cavitator (supplied by SPX, Denmark) fitted with 4 row rotor in 6mm housing, resulting in exposure time of 22 s per pass. The inoculated milk at 10°C was recirculated until 6 passes or 6 cavitation effects (a total exposure time of 132 s) with an average inlet and outlet temperature rise up to 68°C and 82°C respectively after the 6th pass. Samples were kept in an ice bath during the treatments for temperature control. For studying the combined effect, post cavitation, samples were exposed to lab pasteurization (63°C for 30 min). Brain Heart Infusion Agar was used to plate the survivors. Experiments were conducted as replicates of 2, and were repeated thrice. Statistical significance of the data was determined using SAS software. A significant reduction ($P < 0.05$) was observed in the bacterial counts after the treatments. The 6-pass cavitation effect alone, resulted in 1.56 log survivors. Additionally, the combined effect of cavitation and pasteurization further reduced the survivors to only 0.64 log. The results revealed that 6-pass cavitation effect alone and in combination with pasteurization was very effective in inactivating thermally resistant vegetative cells of *Bacillus coagulans* by 99.963 and 99.996% respectively.

Key Words: cavitation, thermoduric sporeformers, pasteurization

Extension Education

406 Optimal dairy farm management subject to greenhouse gas emissions constraints. Di Liang*, Thomas F. Rutherford, and Victor E. Cabrera, *University of Wisconsin-Madison, Madison, WI.*

Dairy farm feed allocation decisions seek to maximize farm profit. We present a nonlinear programming model that chooses a robust policies among a set of dairy farm management strategies. In the optimal policy, animal feed may be produced or purchased to meet nutrition and production demands of cow groups in the herd. Nutrition requirements are calculated according to the National Research Council equations, production level, cow group, and lactation number. Farm-produced feed quantity and quality (e.g., total DM, CP, NDF, NE_L, RDP) are simulated with the Integrated Farm System Model using daily weather data. The quality of purchased feeds is established from published research. Based on these, milk sales, the farm-produced feed costs, purchased feed costs and the greenhouse gas emissions from manure and enteric fermentation are calculated. The optimal solution addresses the dual objective of maximizing profit (milk income over feed cost) while limiting greenhouse gas emissions. Farm characteristics (e.g., breed, production level, culling rate, reproductive performance, cropping strategy), feeding strategies (e.g., high or low forage, grazing, CP content, grouping strategy, seasonal diets which address heat stress), and manure management options (e.g., direct field application, lagoon, manure pile) provide detailed control of the dairy management strategies, which characterize an optimal policy. Consequently, the optimal solution provides a list of best feeding strategies and manure management practices according to farm-specific characteristics that maximize profit and minimize greenhouse gas emissions.

Key Words: profitability and environment, feed allocation, optimization modeling

407 A decision support tool for *Escherichia coli* bacterin mastitis vaccine use in dairy cows. Amanda E. Stone*, Tyler B. Mark, and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

The objective of this study was to create a producer-friendly decision support tool to evaluate the economic decision of implementing *Escherichia coli* (0111:B4) bacterin vaccination as a management practice. A partial budget analysis was conducted in Excel (Microsoft Corporation, Redmond, WA) and a producer-friendly dashboard was created (SAP America, Inc. Newtown Square, PA; the dashboard is available at http://afsdairy.ca.uky.edu/J5MastitisVaccine). Farm-specific inputs adjustable by the end user included herd size, milk price, milk yield, vaccine cost, labor cost, feed cost, culling rate from mastitis, coliform prevalence, replacement cow cost, and cull cow value. To demonstrate model sensitivity and utility, 3 example scenarios were evaluated. In all scenarios, vaccine cost was estimated at $4.74 per cow and the rate of clinical mastitis in vaccinated cows was estimated at 8.6%. In the first scenario, a 100-cow herd was modeled with an average clinical mastitis prevalence (48%/year) and milk price ($17.65, calculated from Food and Agricultural Policy Research Institute for years 2015 to 2025). In the second scenario, a 100-cow herd was modeled with an average clinical mastitis prevalence (48%/year) and greater than average milk price ($25.70/cwt, calculated from years 2005 to 2015). In the third scenario, a 1,000 cow herd was modeled with an average clinical mastitis prevalence (48%/year) and average milk price ($17.65/cwt). Labor costs, cull cow price, and replacement cow price were $10/h, $1,000/cow, and $1,500/cow for all scenarios, respectively. The benefit:cost ratio of using a *Escherichia coli* bacterin vaccine was $7.52:$1, $8.51:$1, and $7.53:$1, for scenarios 1, 2, and 3, respectively. The benefit was $8,719/herd/year, $11,552/herd/year, and $87,191/herd/year, for scenarios 1, 2, and 3, respectively. All scenarios evaluated in this project were positive investments. Dairy producers considering investing in a coliform bacterin vaccine may use this as a decision support tool. This work was supported by a grant award from USDA-NIFA-AFRI (2013–68004–20424).

Key Words: economic dashboard, coliform mastitis vaccine, decision support tool

408 The Missouri Show-Me-Select Replacement Heifer Program: Improving heifer development practices and increasing technology utilization through economic incentives. Jordan M. Thomas*, Brianne E. Bishop, Jillian M. Abel, Jared E. Decker, Scott E. Poock, Douglas S. Brown, Michael F. Smith, and David J. Patterson, *University of Missouri, Columbia, MO.*

The Show-Me-Select Heifer Program has resulted in improvements in development programs for replacement beef heifers and increased utilization of technology among participating beef operations across Missouri. Enrollment of heifers in the program has increased steadily in recent years, from 3,020 heifers enrolled in 2010 to 5,867 heifers in 2014. Enrolled heifers undergo a prebreeding evaluation that includes pelvic measurement and a reproductive tract score (RTS). Producers may elect to expose heifers for breeding via AI or natural service (NS), and the proportion of heifers exposed for AI service has increased steadily. In 2010, 68% of enrolled heifers were exposed for AI rather than serviced exclusively with NS; whereas, AI serviced heifers accounted for 91% of enrolled heifers in 2014. Use of ultrasound (US), as opposed to palpation per rectum for pregnancy diagnosis, has also increased in the program. In 2010, 59% of heifers were diagnosed for pregnancy using US, increasing to 72% of heifers in 2014. Use of US facilitates a more accurate determination of whether a pregnancy resulted from AI or NS and may also allow for determinations of fetal sex. Lastly, differences in average sale price among Show-Me-Select heifers indicate a growing awareness among buyers of the value associated with genetically elite females. Heifers meeting the minimum requirements for enrollment are classified as Tier 1. Heifers may be further distinguished as Tier 2 if the sire of the heifer meets minimum accuracy requirements for specified traits at the time of sale, including: calving ease direct, calving ease maternal, weaning weight, carcass weight, and marbling. From 2010 to 2014, Tier 2 heifers carrying AI sired pregnancies ($2,279) sold on average for $213 more per heifer than Tier 1 heifers carrying NS sired pregnancies ($2,066). In summary, continued growth in the Show-Me-Select Heifer Program highlights the importance of economic incentives to drive technology utilization and improve heifer development practices statewide.

Key Words: heifer development, reproductive management, beef cattle

409 Engaging industry personnel in an agricultural education program. Angela R. Mays*, *F.L. Emmert Company, Cincinnati, OH.*

Typically inter-dependent departments usually exist within animal agricultural products businesses. Those personnel in billing, sales, maintenance, production and other areas may not have knowledge or understanding of end product usage in this industry. Consequently, the F.L. Emmert Company recently initiated an agricultural education program, Emmert Educates, to engage and educate its employees. The program is voluntary, occurs once a month, and lasts for approximately one hour. Attendees are provided lunch, followed by a 10–15 min presentation, and then open discussion among the group. Supplemental printed materials and the opportunity for employees to suggest future topics have also been made available. A survey was recently conducted to evaluate the progress and staying power of the program, and allowed participants the opportunity to express themselves anonymously. The survey was conducted during the February 2015 Emmert Educates program and included all attendees, for a total of 10 participants. Of those surveyed, 100% were interested in the program continuing through 2015, with changes occurring in the frequency in which meetings are held. When asked if the program was informative and if the format was adequate 100% of those surveyed responded yes to both questions. Seventy percent of individuals surveyed did not feel as though the program interfered with their daily schedules, while 20% felt as though it did and 10% were unsure. The most impactful response came from the question addressing if employees had gained information from this program they would not have obtained elsewhere, with a 100% positive response rate. Therefore, the capability of the program to progress and evolve has been made available and confirmed through the positive responses from the survey. Overall, the ability to communicate and connect with employees through an agricultural education program has provided many benefits beyond the sharing of knowledge regarding this industry. Employees have been able to interact with one another in a work-free environment, learn from one another, and begin to understand their role as an employee in this industry, as well as a consumer of agricultural goods.

Key Words: education, industry, personnel

410 Using video for consumer attitude inoculation about beef animal slaughter.

Katherine E. Powers and Traci L. Naile*, *Oklahoma State University, Stillwater, OK.*

In the face of increasing consumer demands for transparency in agricultural production, decreasing literacy about agriculture, and increasing needs for trustworthy information sources for consumers, methods of communicating information about agriculture need to be examined for their effectiveness. Specifically, concerns about beef cattle slaughter need to be addressed through creative and effective channels of communication. However, few studies have been conducted to determine whether consumers can be inoculated through specific mediums against negative messages about slaughter. As visual media platforms have been demonstrated to increase learning, this study was conducted to determine the success of video in educating consumers about the slaughter process. To accomplish this purpose, an online questionnaire was administered to control and treatment groups drawn from a population of university faculty and staff. Both groups responded to series of questions designed to measure their attitudes toward beef consumption and beef cattle slaughter. The treatment group also watched a video of the humane beef cattle slaughter process immediately after answering the first series of questions, which was designed to capture attitudes about raising beef cattle for consumption. The American Meat Institute originally produced the video for the Glass Walls Project and permitted its use in this study. Consumers in the treatment and control groups had positive attitudes toward raising cattle for human consumption, humane beef cattle slaughter, education about slaughter, and consumption of beef. Consumers who viewed the video had significantly ($P < 0.05$) more positive attitudes about humane beef cattle slaughter, transparency about the slaughter process, and education about slaughter. These attitudes demonstrate that viewing a video of humane beef cattle slaughter is a successful method for educating consumers about the slaughter process. Using this method of communication is effective in inoculating consumers to negative messages that could influence consumers' attitudes about humane beef cattle slaughter.

Key Words: beef, slaughter, video

411 A high percentage of beef bull pictures in semen catalogs have obscured feet and legs.

March K. Franks and Temple Grandin*, *Colorado State University, Fort Collins, CO.*

To assist semen buyers in evaluating conformation, bull photos should have fully visible feet and legs. A total of 1,379 beef bull pictures were surveyed to determine visibility of feet and legs from 4 American semen company websites. Five different breeds were represented: Angus, Red Angus, Hereford (polled and horned), Simmental, and Charolais. In addition to visibility, other variables were surveyed to establish frequencies and correlations. These included breed, color, material that obscured visibility such as grass, picture taken at livestock show or outside, semen company, photographer, video, age of bull, and semen price. A visibility score was given to each bull picture. The results showed that 19.4% of the pictures scored a visibility score of one, where the bull's feet and legs were fully visible. In the rest of the pictures, the bull's feet and legs were hidden to some degree, 42.9% hid the hooves (visibility score 2), 32.5% hid both the hooves and the dewclaws (visibility score 3), 1.5% covered the entire legs up to the brisket (visibility score 4); and 3.8% hid 2 feet or legs while the other 2 were fully visible (visibility score 5). Correlation (Spearman's test) between the bull's age and the first 4 visibility scores was statistically significant $P < 0.001$. As age increased the feet and legs were more likely to be visible in the bull's picture. Semen price and visibility score correlation was also statistically significant $P = 0.0143$. Higher semen cost was associated with higher percentage of pictures with hidden feet and lower legs. The results show that many bull semen catalog pictures need to have greater leg and foot visibility.

Key Words: bull, cattle, hoof

Food Safety

412 Residue of three fluoroquinolone (ciprofloxacin, norfloxacin, and ofloxacin) in commonly consumed meat products. Adekunmbi B. Omotoso[1] and Andrew B. Omojola*[2], [1]*University of Ibadan, Ibadan, Oyo State, Nigeria,* [2]*University of Ibadan, Ibadan, Oyo State, Nigeria.*

The study was conducted to investigate residue of 3 fluoroquinolone (ciprofloxacin, norfloxacin, and ofloxacin) in commonly consumed meat products in the study area. Microbiological assay, followed by HPLC, was used to screen market-ready meat for residues of 3 fluoroquinolones. Three hundred twenty samples, comprising 80 each of beef, chicken, pork, and chevon (goat) were collected from open markets. Initial screening by microbiological assay revealed that 50%, 55%, 40% and 40% of beef, chicken, pork and chevon respectively were positive for residues of antibiotics to which *Escherichia coli* was susceptible. Further analysis revealed the presence of ciprofloxacin, norfloxacin and ofloxacin and varying concentrations in the different meat types. Overall mean concentration of ciprofloxacin was 242.50 µg/kg, which differed significantly ($P < 0.05$) from the means of 80.86 µg/kg and 33.46 µg/kg for norfloxacin and ofloxacin respectively. Mean ciprofloxacin was highest in chevon (345.62 µg/kg); beef had the highest concentration of norfloxacin and ofloxacin at 173.40 µg/kg and 79.28 µg/kg respectively. Ofloxacin was the least in frequency and abundance in all meat types. Results obtained in this study have practical implications for public health and will lead to steps that will further enhance the safety of foods originating from animals to protect the animal production industry.

Key Words: fluoroquinolone, meat, residue

413 Abattoir waste management practices in Ibadan metropolis. Olubunmi Olufemi Olusola[1,] Adenike Olubunmi Ajanaku*[2], and Andrew Babatunde Omojola,[1] [1]*University of Ibadan, Ibadan, Oyo State, Nigeria,* [2]*Federal College of Forestry, Ibadan, Oyo State, Nigeria.*

The study evaluated waste management practices in 2 major abattoirs in Ibadan, South West, Nigeria, through investigative survey/questionnaire, to educate dwellers in the vicinity of the danger abattoir operations pose to health and to assess the ethical practices of abattoir operators. Water samples taken from well water around the abattoirs were assessed for selected physical, chemical and microbiological properties. General Linear Model (GLM) procedure was used for statistical analysis. The survey showed that 100% of abattoir operators in both abattoirs disposed waste manually using spade, 90% sweep and wash the waste into open drainage, eventually flowing into streams and rivers around, 90% do not treat waste in any way before dumping at sites. All these give rise to the offensive odor and stench characteristic of the abattoir environment, leading to eutrophication. Study further showed that though the residents of the two abattoirs were aware of the danger abattoir operations pose to their health, majority of them (63%) were not ready to move from this vicinity. Water samples from the wells taken for analysis for physical, chemical and microbiological properties showed that heavy metal concentration-Cu (0.00) and Pb (0.00) at both abattoirs, Fe-0.00 at Bodija, 0.05± 0.01 at Akinyele, Zn-0.03 ± 0.03 and 0.16 ± 0.03 at Bodija and Akinyele respectively were not significantly different from each other, and were below the maximum permissible limit. Turbidity, total dissolved solids (TDS) and total suspended solids (TSS) were significantly different from each other in the two abattoirs. Total aerobic count (TAC) and coliform count (TCC) were 2.1×10^6 and 6.3×10^5, respectively, in the well water at Bodija, while TAC and TCC were $1.7 \text{ x } 10^6$ and 7.6×10^5 in wells at Akinyele. High biochemical oxygen demand (BOD) of 7.05 ± 0.25, dissolved oxygen (DO) 6.30 ± 0.14 and TAC of 2.8×10^6 obtained on Wednesdays in both locations, significantly differed from those of Fridays. The high microbial load and its health implications further confirm the need to treat abattoir waste rather than discharge them to the environment. Portable water should be provided for operators.

Key Words: abattoir, waste management, food safety

414 Bioaccumulation of heavy metals, phenol, and polycyclic aromatic hydrocarbons in differently singed, skin-on, red Sokoto buck goats. Andrew B. Omojola*[1], John O. Oluwole[1], Olubunmi O. Olusola[1], and Worlah Y. Akwetey[2], [1]*University of Ibadan, Ibadan, Oyo State, Nigeria,* [2]*Kwame Nkrumah University of Science and Technology, Kumasi, Ghana.*

The safety of skin-on meat obtained from singed carcasses is a matter of public health concern. This study was therefore carried out to investigate the concentration of heavy metals [lead (Pb), cadmium (Cd), zinc (Zn), manganese (Mn) and copper (Cu)], phenol and polycyclic aromatic hydrocarbons (PAH) in red Sokoto buck goat carcasses singed using fire wood, kerosene, scrap tire and liquefied gas (LG). A total of 24 good grade red Sokoto buck goats weighing between 18 and 20 kg were randomly distributed into each of the 4 treatments in a completely randomized design. Each treatment was replicated 6 times. The total PAH and phenol contents were determined by HPLC, whereas the minerals were measured by atomic absorption spectroscopy (AAS). PAH levels were highest ($P < 0.05$) in scrap tire singed carcasses (0.040 mg/kg) and least in LG singed carcasses (0.001mg/kg). Pb and Mn were below detectable limit in carcasses singed with LG while the concentrations were similar ($P > 0.01$) in the other treatments. Cd was not detected in any of the treatments. Zn concentration was highest ($P > 0.05$) in carcasses singed with kerosene (0.005mg/kg). The level of phenol ranged from 0.02 Gae/kg in LG singed carcasses to 0.38 Gae/kg when scrap tire was used. Material used in singeing was found to have profound effect on heavy metal, phenol, and PAH depositions on skin-on meat from red Sokoto buck goats.

Key Words: skin-on, singed carcass, heavy metal

415 Antibiotic resistance of bacteria from commercial silages in Israel. Zwi Weinberg*, Shlomo Sela, Yaira Chen, Vladislav Volchinski, Judith Kraut-Cohen, and Eddie Cytryn, *ARO, The Volcani Center, Rishon Le Zion, Israel.*

Antibiotic resistance has become a major issue in health care treatment with the emergence of multidrug resistant pathogens, which is attributed to the excessive use of antibiotics in medicine and in agriculture. Accumulating evidence suggests that agricultural sources such as sewage effluents, biosolids and animal manure are potential sources of antibiotic resistant bacteria and resistance genes. The objective of the current study was to determine the magnitude of antibiotic resistance in lactobacilli and enterobacteria in commercial wheat and corn/sorghum silages in Israel. Mixed corn-sorghum silage and wheat silage were sampled at 2 commercial cattle feeding centers in Israel. Grab samples were taken at a depth of 10 cm from the center (pH = 3.9 in both silages) and shoulders (pH = 6.8 and 4.4, respectively) of each bunker silo. Isolates

of *Enterobacteriaceae* and *Lactobacillus* were screened on ampicillin, tetracycline, ciprofloxacin, ceftriaxone, erythromycin kanamycin and vancomycin. Surprisingly, in both types of silage, the vast majority of lactobacilli isolates were resistant (based on EUCAST MIC clinical breakpoint values) to all the 7 tested antibiotics. These isolates are currently being screened for the presence of clinically relevant antibiotic resistance genes to determine the potential for horizontal-transfer to other bacteria. The resistance of the enterobacterial isolates was significantly lower than that of the lactobacilli, however all of the isolates were resistant to at least 2 of the 5 tested antibiotics, and some isolates were resistant to all 5. Interestingly, isolates from the corn-sorghum silage (sewage irrigation) were significantly more resistant than those isolated from the wheat silage (rain irrigated) (resistant to 3.25 of the screened antibiotics vs.2.5, respectively). This study demonstrates the vast scope of antibiotic resistance in silage, which may contribute to antibiotic resistance propagation through the food chain.

Key Words: silage, antibiotic resistance

Forages and Pastures Symposium: Implications of climate change on the resiliency of forage and pasture production systems

416 Managed grassland resiliency to climate change: Shifting species composition buffers climate change effects on plant production and forage quality. Rebecca L. McCulley*[1], A. Elizabeth Carlisle[1], Allison L. Cooke[2], Matthew M. Conley[3], Bruce A. Kimball[3], and Jim A. Nelson[1], *[1]University of Kentucky, Lexington, KY, [2]Metabolic Disease Institute, University of Cincinnati, Cincinnati, OH, [3]US Arid-Land Agricultural Research Center, USDA-ARS, Maricopa, AZ.*

Managed grasslands cover significant acreage in the eastern half of the United States, and are dominated by non-native grass species that may or may not respond to climate change similarly to native species. It is important to understand how plant species composition, plant production, and forage quality will respond to predicted warming and alterations in precipitation because managed grasslands can improve environmental quality and provide the forage base for animal production in the region. We hypothesized that warming would cause species shifts (increased relative abundance of C_4 vs. C_3 species) and would reduce plant production and forage quality, but increases in precipitation would ameliorate these effects. We tested this hypothesis using a field-based, climate manipulation, located in central Kentucky. In a mixed species pasture, we established 5 replicate plots of 4 climate treatments: an ambient control, increased temperature, increased precipitation, and the combination of increased temperature and precipitation. Treatments were applied for 5 consecutive years (2009–2013), and species composition, plant biomass, and forage quality were measured seasonally in all years. Warming significantly increased the relative abundance of C_4 grasses, especially in summer and fall. However, in the spring, C_3 grasses remained the dominant plant functional type in all plots. Climate treatment effects on production varied by year, but when harvested biomass was summed across the 5-year experiment, no significant effect was observed. Effects of climate treatments on forage quality metrics (% crude protein and lignin) also varied by year and season, but were less dramatic than effects on plant production and species composition. Increased temperature and precipitation did not substantially alter plant production or forage quality, but did promote C_4 vs. C_3 grass dominance, illustrating the potential of species compositional changes to buffer ecosystem response to climate change. This result suggests that although dominant plants will differ, managed grasslands of the eastern United States will continue, from an animal forage production perspective, to function similarly to today.

Key Words: pasture, climate change, forage production

417 Carbon sequestration potential for forage and pasture systems . Vern S. Baron*[1], R. Howard Skinner[2], and Gilles Bélanger[3], *[1]Agriculture and Agri-Food Canada, Lacombe, AB, Canada, [2]USDA-ARS, University Park, PA, [3]Agriculture and Agri-Food Canada, Quebec City, QC, Canada.*

Grassland soils are a reservoir of organic and inorganic carbon. Regionally, grasslands are CO_2 sources or sinks depending on management, soil organic carbon (SOC) concentration and climate. Land management changes (LMC) affect SOC sequestration rate, duration and C-store at steady state. A common hypothesis is that higher grassland productivity increases SOC sequestration to a higher steady state. High SOC-sequestration rates occur for 5 to 10 yr after LMC, but continue slowly up to 50 yr. Permanent grasslands are at steady state for CO_2 exchange. The most significant LMC for SOC accumulation is conversion from cropland to grassland where C-inputs from perennial roots and residues are higher than annual crops. Residue- and root-C inputs for Alberta perennial forage systems were 2.3 to 3 times greater, than barley silage. SOC sequestration rates for improved pastures on degraded soils in South-Eastern US were up to 1.4 Mg SOC ha^{-1} yr^{-1}. Applications of fertilizer-N, manure and using legumes increased SOC through higher root-C inputs, but not always permanently, due to the increased degradable-C fraction. Manure-C application effectively replaces surface soil-C on Quebec dairy farms. But, micro-meteorological studies on net ecosystem exchange (NEE) on old pastures in Pennsylvania, and Alberta (>6% soil organic matter), indicated that when harvested forage-C was removed from NEE, net Biome-C loss occurred in 90% of the years. Increasing productivity through N-application in Pennsylvania resulted in lost SOC, but a 5-species forage mixture increased productivity and sequestered more SOC than a 2-species mixture. Specific LMC in this grassland was less important to sequestration rate than initial SOC content. Quebec studies show that grass and legume species respond differently to increased atmospheric temperature and CO_2 concentration. Elevated temperature and CO_2 caused a higher root C: N ratio, resulting in a lower in vitro degradation rate, indicating that reduced SOC-degradation rates under future climates might be possible. How a concomitant change in species mixture affects SOC and what effects changing moisture and temperature regimens have on potential SOC-sequestration at a regional level can only be speculated.

Key Words: C-sequestration, forage management

418 Climate-related risk management in agriculture: Its importance for coping with current and future climate changes in the southeastern United States. B. V. Ortiz*[1], C. Fraisse[2], D. Dourte[2], W. Bartels[2], D. Zierden[3], and P. Knox[4], *[1]Auburn University, Auburn, AL, [2]University of Florida, Gainesville, FL, [3]Center for Ocean-Atmospheric Prediction Studies, Tallahassee, FL, [4]University of Georgia, Athens, GA.*

Agricultural food and feed production is extremely important to the southeastern (SE) United States, because it not only provides quality food and feed for residents but also contributes to the region’s economy. However, the stability and sustainability of the SE agriculture is affected by the interannual and seasonal variability of the climate, and could be at much higher risk under the projected future climate. Currently, El Niño Southern Oscillation (ENSO), especially El Niño and La Niña phases, makes important contributions to the year-to-year variations in conditions. ENSO has the strongest influence in the SE climate during the winter and spring months. During those months El Niño phase brings wet and cold conditions and La Niña phase results on dry and warm conditions. Several research studies have shown the relationship of ENSO phases and changes in row crops and forages yield, pest, and diseases; therefore the importance of the use of the ENSO forecast as a risk management strategy. The impact of weather and climate conditions on livestock farming (e.g., milk yield and composition, beef productivity) and, especially extreme events have been also documented. The current US National Climate Assessment released in 2014 report data of the effect of future climate scenarios on rainfall, ambient temperature, extreme events, among other variables. By 2050 in the SE, compared with the period 1971–2000, SE summer rainfall is expected to decline

up to 20%, the number of days per year with maximum temperature above 95°F, heat waves, is expected to be in the range of 25 to 35 d, summer ambient temperature could increase in the range of 4°F to 8°F. Projections of future precipitation patterns are less certain than projections for temperature increases; however, tropical storms are projected to be to be fewer in number globally, but stronger in force, and extreme precipitation events are expected to increase in number. Several climate research, education, and extension regional projects funded by USDA-NIFA are currently implemented to help stakeholders with adoption of new or adaptation of current management strategies to increase resilience and reduce potential impacts. The Southeast Climate Extension project (http://www.agroclimate.org/seclimate/), a multi-state and multi-institution project, is using a participatory approach toward engaging producers, extension specialists and agents, and farmers associations on the identification, development and evaluation of climate adaptation strategies. Hand-on workshops on the use of and awareness of web-based climate decision support tools hosted in www.Agroclimate.org are also very popular among the SE clientele. Awareness of the future climate projections and potential adaptation strategies should be considered into the risk management package.

Key Words: adaptive capacity, climate variability, climate change

876 Intensive grazing systems can enhance carcass production with the same methane emissions. A. Berndt*[1], L. S. Sakamoto[2], A. P. Lemes[3], A. F. Pedroso[1], J. R. M. Pezzopane[1], T. C. Alves[1], D. F. Vilas Boas[4], R. Ruegger[5], P. P. A. Oliveira[1], *[1]Embrapa Southeast Livestock, Sao Carlos, Brazil, [2]Animal Productivity and Quality Program, FZEA/USP, Pirassununga, Brazil, [3]Veterinarian Medicine, FCAV/UNESP, Jaboticabal, Brazil, [4]FAPED, Brazil, [5]CAPES/EMBRAPA, Brazil.*

Enteric methane emissions are significant from countries with considerable livestock production, including Brazil. Various strategies exist for the mitigation of greenhouse gas emissions and, in general, the intensification of production systems reduces emissions intensity; that is, emissions of CO_2 equivalents per unit of product (meat or milk). The objective of this trial was to measure CH_4 emissions and animal performance in beef cattle in 4 Brazilian grazing systems with different levels of intensification. The study was conducted at EMBRAPA Southeast Livestock, in São Paulo State, Brazil. Twenty-four Nellore steers were distributed across 4 representative grazing systems: (1) irrigated pasture with high stocking rate (IHS); (2) dryland pasture with high stocking rate (DHS), planted with *Panicum maximum*; (3) dryland pasture with moderate stocking rate (DMS); and (4) degraded pasture (DP), planted with *Brachiaria decumbens*. The HIS and DHS systems were composed of 12 paddocks each, and the DMS system consisted of 6 paddocks, all under rotational grazing. The DP system was managed under continuous stocking. Animals were kept in the same grazing systems from weaning until slaughter. Methane measurements were taken during 4 seasons using the SF_6 tracer technique and gases were analyzed by Shimadzu GC 2014. Data were analyzed using the SAS MIXED procedure and averages were compared using the Tukey test and considered significant at $P < 0.05$. The animals finished in the DP system presented the lowest ($P < 0.01$) carcass weights (265.5 ± 15.6 kg), whereas those finished in the IHS system presented the highest (328.3 ± 10.2 kg). The average daily methane emissions were similar at 202.7 ± 38.6 g/d, as were emissions per kilogram of live weight at 409.1 ± 59.7 (g of CH_4/kg of live weight). At the end of the experimental period, total methane emissions were similar at 66.9 ± 12.7 kg, whereas carcass gain over the period was significantly lower ($P = 0.0234$) for the DP group at 73.2 ± 18.0 kg, versus 105.8 ± 25.0 kg in the other intensified systems. The use of technologies that permit increased production favors animal performance, increases carcass production, and dilutes the emissions per kilogram of carcass produced.

Key Words: intensive grazing, Brazil, methane

Growth and Development I

419 Growth, intake, and health of Holstein heifer calves fed an enhanced diet pre-weaning with or without exogenous estradiol immediately post-weaning. Adam J. Geiger*[1], Robert E. James[1], Catherine L. Parsons[1], Anthony V. Capuco[2], and Robert M. Akers[1], *[1]Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, VA, [2]United States Department of Agriculture-Agricultural Research Service, Beltsville, MD.*

Enhanced feeding (HP) of heifers post-weaning but before puberty can reduce mammary gland (MG) development and milk yield. Better pre-weaning (PW) nutrition is likely beneficial. Our objectives were to determine effects of PW HP and exogenous estradiol (E_2) on growth, intake, and health. Thirty-six Holstein heifer calves were reared on: 1) a control milk replacer (MR) fed at 454 g powder/day (CON; 20% crude protein [CP], 20% fat), or 2) an accelerated MR fed at 1135 g powder/day (ACC; 28% CP, 25% fat). MR feeding was reduced 50% at wk 8. Starter was offered after wk 4 but balanced between treatments. BW and frame measures were taken weekly with intakes and health monitored daily. At weaning a subset of calves were killed (n = 6/diet). Remaining calves received E_2 implants and were killed at wk 10. The 4 treatments were: 1) CON, 2) CON + E_2 (EST), 3) ACC, and 4) ACC + E_2 (ACCEST). Data were analyzed using PROC GLIMMIX in SAS and treatment differences were separated with the PDFIFF function. Significance was declared when $P < 0.05$ and tendencies when $0.10 > P > 0.05$. ACC calves were heavier at weaning (75 vs 51 kg, $P < 0.01$). E_2 did not influence BW. ACC calves had greater average daily gain (ADG) between wk 1 to 7 ($P < 0.01$). Post-weaning ADG was similar between CON, ACC, and ACCEST calves, but greater in EST calves ($P < 0.05$) than ACC calves. At first slaughter, ACC calves had greater carcass, MG, thymus, liver, and spleen weights ($P < 0.01$). EST calves had heavier MG than CON calves ($P < 0.01$) and ACCEST calves heavier reproductive tracts and uteri compared with ACC calves ($P < 0.01$). ACC calves consumed more MR DM, CP, fat, and ash PW ($P < 0.01$). CON calves consumed more starter DM, CP, fat, NDF, ADF, and ash PW ($P < 0.01$). These differences were not observed post-weaning. Fecal scores (FS) were greater for ACC calves (1.7 vs 1.5; $P < 0.01$) PW. FS were lower for EST calves post-weaning. Results show that PW HP increases weight and frame measures pre and post-weaning. PW HP increased ADG PW, but not post-weaning. E_2 may elicit beneficial responses in some calves. Analysis of collected samples will allow us to determine cellular and molecular processes responsible for tissue differences.

Key Words: mammary gland, estradiol, milk replacer

420 Plane of nutrition affects Holstein bull calf growth, bone mineral density and organ size. Meghan E. MacGhee*, Sarah R. McCoski, Camilla H. K. Hughes, Sally E. Johnson, and Alan D. Ealy, *Virginia Polytechnic Institute and State University, Blacksburg, VA.*

Early postnatal milk replacer diet affects ADG and feed efficiency and can have long-term consequences on calf growth, health and productivity. This study examined how plane of nutrition affects calf body weight, height, bone mineralization, and organ size. On postnatal d 1, Holstein bull calves (n = 4–5/diet/time point) were assigned randomly to a low plane of nutrition (LPN; 20% CP, 20% fat; 441 g DM/d) or high plane of nutrition (HPN; 27% CP, 10% fat; 882 g DM/d during wk 1 and 1131 g DM/d thereafter). Starter grain (25% CP, 4% fat) was offered at 1% BW beginning at wk 3. At 2, 4, or 8 wk of age, calves were euthanized and bone mineralization and body composition were determined with Dual Energy x-ray Absorptiometry (DEXA). Visceral organs were removed and weighed, and empty carcass weight (ECW) was recorded. Data were analyzed by least squares ANOVA. Final BW and ADG were greater ($P < 0.05$) in calves fed HPN at each time point. Hip heights and bone mineral densities were greater ($P < 0.05$) for HPN calves than LPN calves at 8 wk but not at 2 or 4 wk. ECW-adjusted organ weights also were affected by diet. Thymus weight was greater ($P < 0.05$) in HPN calves than LPN calves at 4 and 8 wk (0.37% vs. 0.13% and 0.64% vs. 0.22%, respectively; SEM = 0.03). Spleen weight was greater ($P < 0.05$) in HPN calves than LPN calves at 8 wk (0.93% vs. 0.46%; SEM = 0.05). Also, kidney and liver weights were greater ($P < 0.05$) in HPN calves at 4 wk, and lung weights were reduced ($P < 0.05$) in HPN calves at 2 wk. Weights of the heart and pancreas did not differ based on plane of nutrition within each time point. Calf ECW was greater ($P < 0.01$) in the HPN group at each time point. In summary, deviations in growth rates, bone mineralization, and organ weights were evident between calves fed HPN and LPN diets. These outcomes are consistent with the contention that HPN feeding accelerates growth and improves health in young calves. The beneficial effects of HPN on bone mineral density and immune-centric organs provide new possibilities for understanding the effects of early nutrition on calf immune responses and productive lifespan of the cow.

Key Words: milk replacer, organ growth, bone density

421 Daily growth rate in Holstein Friesian heifers is affected by fasting insulin levels as newborn calves. M. Van Eetvelde*, M. M. Kamal, H. Bogaert, and G. Opsomer, *Department of Reproduction, Obstetrics and Herd Health, Faculty of Veterinary Medicine, Ghent University, Merelbeke, Belgium.*

Body growth and reproduction traits were followed in 51 female Holstein Friesian calves at one herd in Flanders (Belgium). After an overnight fast, 3-d-old calves were weighed and blood samples were taken to determine fasting glucose (GLU_F) and insulin (INS_F) levels. All calves were kept indoors during the first year of life, and were fed according to their requirements for maintenance and growth. Every 3 mo until their first calving, body weight was recorded, as well as insemination dates and date of calving. Calves weighed 39.1 ± 4.26 kg at birth and were classified in 3 categories dependent on their daily growth rate during the first 6 mo of life: slow (<750 g/day; n = 6); moderate (750 to 950 g/day; n = 40) and fast growing (>950 g/day; n = 5). Analysis of variance was used to compare Glu_F and body weight between categories and the differences in Ins_F were assessed by the Kruskal-Wallis test. GLU_F was 6.0 ± 0.63 mmol/L without significant differences between the 3 groups ($P = 0.16$). INS_F was 7.2 ± 4.76 mU/L in moderately growing calves. Slow growing calves had higher INS_F of 12.9 ± 9.10 mU/L in comparison to the fast growing ones (4.3 ± 2.39 mU/L, $P < 0.05$). Calves were inseminated at 14.9 mo. Heifers that were growing > 950 g/day weighed 472 ± 45 kg at first insemination, which was significantly more than the moderately and slow growing calves (respectively 414 ± 42 and 378 ± 29 kg, $P < 0.05$). The effect of early growth was still visible at first calving, as the fastest growing heifers weighed 734 ± 144 kg, which was significantly more than the heifers with a moderate growth rate (615 ± 72 kg, $P < 0.05$). In human medicine, low INS_F is seen in newborns that are small for gestational age, which is indicative for an increased insulin sensitivity to glucose and resembles conditions of prolonged fasting. Although in our research, no difference in birth weight was observed, the association of low insulin levels with subsequently high daily growth rates resembles the human situation of catch up growth. Based on these preliminary results, we suggest that low fasting insulin levels in newborns could be the result of a suboptimal environment during gestation and could be a forecast of catch-up growth during early life.

Key Words: catch-up growth, insulin, Holstein Friesian heifers

422 Maternal obesity (MO) during ovine pregnancy leads to increased collagen content and cross-linking in the myocardium of adult F_1 but not F_2 offspring.

Adel Bashir Ghnenis*, John F. Odhiambo, Richard J. McCormick, and Stephen P. Ford, *Department of Animal Science, University of Wyoming, Laramie, WY.*

There is accumulating evidence that MO increases offspring risk of obesity and cardiovascular disease in later life. Utilizing a well-established (J. Anim. Sci. 2010. 88:3546) ovine model of diet-induced MO from conception through gestation, we reported that gestational d 135 fetal heart left ventricle weight and collagen content were markedly increased by MO. Further, in a Langendorff system, the d 135 fetal heart from MO fetuses could not sustain high work levels (FASEB J. 2010. 24:2066). Here we examined the effect of MO on increasing collagen content and crosslinking in the adult F_1 and F_2 offspring myocardium. Ewes were assigned randomly as controls (CON) and fed at 100% of NRC recommendations or to an MO group fed 150% of NRC from 60 d before conception to term. Left ventricular free wall myocardial samples were collected from adult (22 mo old) male F1 and F2 offspring of CON and MO ewes at necropsy following a 12-week ad lib feeding challenge. Myocardial tissue was either snap frozen in liquid nitrogen for collagen analyses or fixed and paraffin embedded for histological evaluation. Collagen concentration was determined by colorimetry as hydroxyproline equivalents. Collagen crosslinking was also determined by measuring the amount of hydroxylysylpyridinoline by immunoassay (Microvue, PYD EIA Kit, Quidel, San Diego, CA). Data were analyzed by mixed procedures of SAS. Myocardial collagen concentration was greater ($P < 0.05$) in MOF1 compared with CON F1 offspring (1.73 ± 0.10 vs. 1.42 ± 0.07 µg/mg, n = 6). The differences in OBF1 and CONF1 collagen concentration were confirmed by visualizing trichrome stained sections of myocardial tissue. Myocardial collagen crosslinking was 11% greater ($P < 0.05$) in OBF1 vs. CONF1 offspring. In contrast, myocardial collagen content and crosslinking did not differ between MOF2 and CONF2 offspring. These data provide evidence for programming of increased myocardial fibrosis in adult MOF1 offspring, which potentially results from MO-induced changes in fetal life and might impair cardiac muscle function in postnatal life.

Key Words: maternal obesity, myocardium, collagen

423 Growth and lactation during gestation decrease placental efficiency in cattle.

M. Van Eetvelde*, M. M. Kamal, H. Bogaert, and G. Opsomer, *Department of Reproduction, Obstetrics and Herd Health, Faculty of Veterinary Medicine, Ghent University, Merelbeke, Belgium.*

In adult pregnancy, the gravid uterus receives a high priority status for nutrient partitioning. A shift in this hierarchy in favor of maternal tissues, as seen in adolescent pregnancy, compromises placental growth and fetal development. This situation occurs during gestation in growing heifers and lactating cows, as a high priority status of respectively maternal tissue growth and lactation is then observed. To assess the effect of dam lactation and growth on placental and fetal development, placentas of 49 multiparous (MP) Holstein Friesian (HF) cows and 43 growing heifers [27 HF and 16 Belgian Blue (BB)] were compared with afterbirths of 27 non-growing, nonlactating MPBB cows. Placentas were weighed and cotyledons were removed, after which their surface was calculated by the formula area(ellips) = πab; with a = half of major diameter and b = half of minor diameter. Placental efficiency (PE) was assessed by the calf weight:cotyledonary surface ratio. Analysis of variance was used to compare placental weight and cotyledonary surface, differences in cotyledon number and PE were assessed by the Kruskal-Wallis test. Placentas of MPBB dams weighed 5.9 ± 1.79 kg with a cotyledonary surface of 0.53 ± 0.110 m^2. Placentas of MPHF dams were 0.9 kg lighter ($P < 0.01$) but tended to have a larger total cotyledonary surface (0.58 ± 0.106 m^2, $P = 0.05$). Placentas of heifers were smaller (4.7 ± 1.34 kg and 0.48 ± 0.085 m^2, $P < 0.05$), without significant breed effect. The number of cotyledons in MPBB placentas (91 ± 27.2) was lower than in placentas of heifers and MPHF (respectively 114 ± 29.0 and 115 ± 28.2, $P < 0.05$). In addition, MPHF dams had a greater proportion of small (<60 cm^2) cotyledons; as mentioned in nutrient-restricted ewes. MPBB cows had the highest PE of 107 ± 25.1 kg/m^2, compared with 74 ± 13.5 kg/m^2 in MPHF dams ($P < 0.01$). BB and HF heifers had a similar PE of 96 ± 23.0 and 84 ± 18.0 kg/m^2 respectively. These preliminary findings suggest maternal growth and lactation during gestation to have a similar nutrient restrictive effect on placental development, which may result in a lower PE. This could be, at least partly, responsible for the differences in size of the offspring. Further research is necessary to assess the influence on organ development and future health of the calves.

Key Words: growth, lactation, placental development

424 Effects of GH and IGF-I on proliferation and apoptosis of bovine mammary epithelial cells.

Hongrong Wang*, Yun Ji, Xueyan Pang, Qing Tian, Mengzhi Wang, and Lihuai Yu, *College of Animal Science and Technology, Yangzhou University, Yangzhou, Jiangsu Province, China.*

Growth hormone (GH) may exert its function through direct activation of the the growth hormone receptor (GHR) in mammary gland or through stimulating insulin-like growth factor-I (IGF-I). We hypothesized that the reduction of milk yield caused in part by apoptosis of mammary epithelial cells depends on the ratio of GH and IGF-I which could be influenced by nutrition, however, evidence to support this suggestion is lacking. Therefore, the purpose of this study was to investigate the effects of GH and IGF-I alone and in combination on proliferation and apoptosis of bovine mammary epithelial cells cultured in vitro. Mammary epithelial cells isolated from bovine mammary tissue were identified by cytomorphology, immunocytochemistry and specific gene expression. Subcultured and purified cells were treated with GH (100 ng/mL) and IGF-I (100 ng/mL) alone or a combination of GH and IGF-I (each 100 ng/mL) in growth medium without fetal calf serum for 24 h. The mRNA abundance was quantified by RT-qPCR, cell proliferation was determined with a CCK-8 kit, and apoptosis was identified by an FITC-Annexin V/PI kit. Statistical analysis was carried out by using ANOVA procedure of SAS 9.1 software with Duncan's multiple-range test. Cell proliferation was not enhanced by adding GH alone ($P > 0.05$) while it was promoted by IGF-I at about 6 h ($P < 0.05$). The combination of GH and IGF-I increased cell proliferation from 4 to 24 h ($P < 0.05$), which had no significant difference with IGF-I group ($P > 0.05$); The supplementation of GH or IGF-I individually had no significant effect on the early apoptosis rates of cells ($P > 0.05$), however, the late ($P < 0.01$) and total apoptosis rates ($P < 0.05$) were reduced. The late and total cell apoptosis rates were decreased by adding GH and IGF-I together ($P < 0.01$). In addition, adding GH or IGF-I alone tended to decreased the mRNA abundance of IGFBP-5 ($P < 0.1$) compared with the control, and the inhibitory effect was strongest when GH was combined with IGF-I

($P < 0.05$). This study demonstrated that GH and IGF-I can regulate the number and activity of bovine mammary epithelial cell through promoting cell proliferation and inhibiting cell apoptosis to stimulate lactation.

Key Words: mammary epithelial cell, growth hormone, insulin-like growth factor-I

425 Effects of recombinant bovine somatotropin (bST) administration at breeding on the cow, conceptus, and subsequent offspring performance of beef cattle. Vitor R. G. Mercadante*, Francine M. Ciriaco, Darren D. Henry, Pedro L. P. Fontes, Danilo D. Demeterco, Pedro H. S. Pereira, Nicolas DiLorenzo, and G. Cliff Lamb, *North Florida Research and Education Center, University of Florida, Marianna, FL.*

To determine the effects of administration of a low dose of slow-release bST (Posilac, Elanco, Greenville, IN) on hormone concentration and conceptus development, a total of 190 suckled beef cows were exposed to the 7-d CO-Synch+CIDR fixed-time AI (TAI) protocol. Cows were blocked by days postpartum, BCS, breed and randomly assigned to receive one of the following treatments: (1) 2 injections of 325 mg bST, one at TAI and a second injection 14 d after TAI (D-bST, n = 40); (2) 1 injection of 325 mg bST at TAI and a placebo (saline) injection 14 d after TAI (TAI-bST, n = 48); (3) a placebo injection at TAI and one injection of 325 mg bST 14 d later (14D-bST n = 49); and (4) 2 injections of placebo, one at TAI and a second injection 14 d after TAI (Ctrl, n = 53). Pregnancy was determined via transrectal ultrasonography 35 d after TAI and conceptus development was assessed by measuring crown to rump length (CRL) on d 35 and crown to nose length (CNL) on d 65 after TAI. Blood samples were collected on d 0, 7, 14, 21, 35 and 65 relative to TAI to determine concentrations of and IGF-1. Plasma concentrations of pregnancy-specific protein B (PSPB) were also assessed on d 35 and 65 after TAI. Individual calf birth weight and sex were determined at birth. Procedure GLIMMIX of SAS was used to analyze all data with the appropriate models. There were no differences ($P = 0.767$) among treatments on pregnancy to TAI (48.7 ± 0.5%). Administration of bST at TAI increased ($P < 0.01$) plasma concentration of IGF-1 on d 7, 14 and 21. However, CRL and CNL (12.11 ± 0.4 mm and 17.09 ± 0.2 mm, respectively) did not differ ($P = 0.231$) among treatments. Concentration of PSPB did not differ ($P = 0.18$) among treatments and between days ($P = 0.30$; 2.69 ± 0.11 ng/mL), and gestation length (282 ± 9 d) did not differ ($P = 0.49$) among treatments. In addition, calf birth weight was similar ($P = 0.52$) among treatments. We conclude that administration of 325 mg bST during the time of TAI to suckled beef cows enhanced concentrations of IGF-1, but failed to improve pregnancy rates, fetal size, PSPB concentrations, and had no effect on calf birth weight.

Key Words: bovine somatotropin, fetal programming, IGF-1

Horse Species Symposium: Exercise physiology of the horse

426 The effect of oxidative stress during exercise in the horse.

Carey A. Williams*, *Rutgers, The State University of New Jersey, New Brunswick, NJ.*

Oxidative stress is an imbalance of the oxidant to antioxidant ratio in the body. In the following presentation, I will highlight studies from my laboratory along with other pertinent studies of oxidative stress in exercising horses. An increase in oxidative stress and changes in anti-oxidant status has been shown during endurance, intense exercise, and eventing competition in horses. Antioxidants are vitamins, minerals, and protein that must be synthesized in the body or obtained from the diet. Therefore, exercise level and diet are both factors that play a role in influencing the oxidative stress and antioxidant status of the equine athlete. Along with exercise intensity, duration and diet, age and conditioning program also have affected oxidative stress in the horse. The "free radical theory of aging" states that long-term effects of the degenerative changes associated with aging may create oxidative stress. However, in old horses (22 ± 2 yr), the amount of lipid peroxidation and blood antioxidant concentrations were similar to those found in mature but younger (12 ± 2 yr) horses. Same as older horses that may require dietary intervention to help combat oxidative stress so might young growing exercising horses. Studies have shown that yearlings (18 ± 2.4 mo) did not begin their exercise training with higher levels of oxidative stress in muscle or blood than mature mares (13 ± 2.1 yr). Prior to exercise conditioning, yearlings had lower lipid peroxidation and higher antioxidants than mature mares. Conditioning reduced oxidative stress and improved antioxidant status in mares, while few effects were seen in yearlings. This suggests that age alone was the biggest defense against oxidative stress after exercise. Other studies during competition (endurance, jumping, eventing, and racing) have investigated the influence on oxidative stress with varying results. These results will be expanded upon during the presentation. Even though there have been many studies examining the levels of lipid peroxidation, antioxidant status and other related metabolites in the horse during exercise, we still have a long way to go before we fully understand the large variation in results both with and without antioxidant supplementation.

Key Words: equine, antioxidant, oxidative stress

427 Effects of aging on mitochondrial function in skeletal muscle of Quarter Horses.

Chengcheng Li*[1], Sarah H. White[2], Lori K. Warren[1], and Stephanie E. Wohlgemuth[1], [1]*Department of Animal Sciences, University of Florida, Gainesville, FL,* [2]*College of Health Sciences, University of Kentucky, Lexington, KY.*

Abstract. Research in human and rodents has shown an age-associated decline in physical function, aerobic capacity and skeletal muscle mitochondrial function, which in humans begins around the age of 50 yr. On the other hand, many horses can still actively work or compete beyond 20 yr of age, an age equivalent to a 65-year-old human. The purpose of the present study was to determine the age-related changes in fiber type composition and mitochondrial function in equine skeletal muscle. Muscle biopsies of right gluteus medius and triceps brachii from young (1.8 ± 0.1 yr; n = 24) and aged (20 ± 5 yr; n = 10) Quarter Horses were compared. High-resolution respirometry was performed on freshly sampled and subsequently permeabilized muscle fibers. Remaining tissue was frozen in liquid nitrogen and stored at −80°C for measurement of fiber type composition and enzyme activities. Statistical differences were analyzed using one-way ANOVA and Holm-Sidak post hoc analysis (Sigmaplot 12.0). We found that aged horses had a higher percentage of oxidative type I myosin heavy chain (MHC) isoform in both gluteus ($P < 0.001$) and triceps ($P = 0.024$) compared with young horses. The proportion of glycolytic type IIX MHC isoform tended to decrease with advancing age, particularly in triceps ($P = 0.061$). The proportion of intermediate fiber type IIA MHC isoform was not affected by age. Age had no effect on mitochondrial respiration in gluteus; but *triceps* from aged compared with young horses had greater leak respiration ($P = 0.038$), electron transport system capacity ($P = 0.032$), and a tendency for a lower respiratory control ratio ($P = 0.076$). Cytochrome *c* oxidase activity in both triceps ($P < 0.001$) and gluteus ($P < 0.001$) was lower in aged compared with young horses. Using citrate synthase activity as a marker, mitochondrial density increased by 26.8% in the gluteus of aged horses ($P = 0.034$), but was unaffected by age in the triceps ($P = 0.183$). Our data suggest that aging resulted in an increased percentage of oxidative type I fibers, increased mitochondrial density, and impaired mitochondrial function in Quarter Horse skeletal muscle.

Key Words: myosin heavy chain isoform, cytochrome c oxidase, high-resolution respirometry

428 Bones and muscles in endurance horses—Physiology, pathology, and clinical issues.

Katja F. Duesterdieck-Zellmer*, *Oregon State University, Corvallis, OR.*

Adaptation of muscle or bone to endurance exercise in the horse is of great interest, as specific training and nutrition regimens may maximize performance and prevent injury. Medical manipulation of muscle or bone, while ethically questionable, may also impact the fitness of these tissues. The speed in endurance competitions has increased in recent years, as has the incidence of fractures in endurance horses. The bones of endurance horses experience repetitive loading, resulting in microdamage, which can be repaired or may accumulate into stress fractures that can be catastrophic. This phenomenon is well known in flat-racing horses, but has received less attention in endurance horses. Apparently, front limb fractures are more common than hind limb fractures and most fractures occur in the metacarpal/metatarsal or proximal phalangeal regions in endurance horses, most of which were metatarsal/metacarpal condylar fractures. Information about specific training regimens directed towards prevention of certain bony injuries is available only for flat-racing horses, indicating a need for research in this field to benefit endurance horses. Additionally, bisphosphonate medications that have the potential to significantly affect bony remodeling have been recently approved for use in equines in many countries. While there is no information on specific effects of bisphosphonates on the skeleton in endurance horses, they may be less safe for them, compared with other equine athletes. Genetics determine the predominant muscle fiber types, total fiber number and relative size of fast and slow twitch fibers in horses, favoring certain breeds over others to be successful endurance athletes. Elite endurance horses have a high ratio of type I (slow twitch) and IIA (fast-oxidative glycolytic) muscle fibers and endurance training stimulates transition from fast twitch (type IIX) to slower twitch fibers (type IIA and I). Endurance training also causes hypertrophy of type I and IIA fiber types, resulting in increased aerobic and decreased anaerobic capacity of the muscle. On a cellular level, these changes are induced by quantitative and qualitative alterations in gene expression of both regulatory and structural genes.

Key Words: horse, muscle, bone

429 Biomechanics of the exercising horse. Hilary Clayton*[1,2], *[1]Sport Horse Science LLC, Mason, MI, [2]Michigan State University, East Lansing, MI.*

Horses have long been used for athletic pursuits due to their superb physiological and biomechanical abilities. This talk explores structural and functional specializations of the equine limbs in relation to athletic performance. During locomotion the limbs cycle back and forth relative to the trunk moving primarily in the sagittal plane. Protraction and retraction are facilitated by morphological adaptations that reduce limb mass, especially in the distal limb, and allow a more proximal location of the moment of inertia. The joint angulations and muscle architecture of the hind limbs facilitate the generation of forward and upward propulsion of the center of mass, whereas the more strut-like forelimbs control speed and direction of movement. During a stride each limb has stance and swing phases. During swing the limb is rapidly protracted and then there is a final period of retraction that reduces hoof velocity relative to the ground at impact. During the first 50 ms after hoof contact with the ground, the hoof is rapidly decelerated and brought to rest with the effects of deceleration being mitigated if the hoof can slide a little forward and sink downward into the footing. The forces associated with hoof impact are damped within the hoof and distal limb so their effects are progressively attenuated in the more proximal parts of the limb. Vibrations associated with impact are damped by the digital flexor tendons. During the stance phase the limb is loaded by the mass of the horse (and rider). It is during this phase of the stride that stretching and recoil of elastic tendons makes a significant contribution to the exchange between kinetic and potential energy in the gaits that have a suspension phase. In the terminal part of the stance phase, tension applied to the third phalanx by the deep digital flexor tendon eventually exceeds the counteracting ground reaction force causing the heels to lift. During locomotion dynamic balance is maintained by the interactions between momentum that carries the horse forward, gravity that pulls the body downwards, and the propulsive forces from the limbs. As each limb contacts the ground it 'catches' the body, raises it and provides propulsion to maintain the forward progression.

Lactation Biology II

430 Glucose activates translation factors in muscle but not in mammary glands of lactating dairy cows when essential amino acids are in excess supply.

Kelly Nichols*[1], Michelle Carson[2], Julie J. M. Kim[1], John A. Metcalf[2], John P. Cant[1], and John Doelman[2,1], *[1]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [2]Nutreco Canada Agresearch, Guelph, ON, Canada.*

To determine how glucose modulates protein synthesis when essential amino acids (EAA) are supplied in excess, 5 early-lactation Holstein cows (78 ± 13 DIM) were abomasally infused for 5 d with EAA and glucose in a 5 × 5 Latin square design, and abundances and phosphorylation states of ribosomal S6 kinase 1 (S6K1), eukaryotic initiation factor 4E binding protein-1 (4EBP1) and eukaryotic initiation factor 2α (eIF2α) in mammary tissue and longissimus dorsi were assayed. Treatments were saline, 844 g/d EAA in the profile of casein, 1126 g/d EAA, 844 g/d EAA + 1000 g/d glucose, or 1126 g/d EAA + 1000 g/d glucose. Cows were fed a diet containing 6.96 MJ/kg NE_L and 12% crude protein. Measurements were subjected to ANOVA using PROC MIXED in SAS, where cow was a random effect. While no differences were observed between levels of EAA, compared with saline, infusion of EAA increased arterial concentrations of EAA 3- to 4-fold ($P < 0.01$), increased mammary uptake of EAA from plasma 66% ($P < 0.01$), and led to 256 g/d higher milk protein yield ($P < 0.01$). The addition of glucose to EAA infusions decreased Ile, Leu and Val concentrations by 29% ($P < 0.01$), but did not affect mammary uptake of any amino acids ($P > 0.40$) or milk protein yield ($P = 0.32$). Infusion of EAA increased the mammary abundance of S6K1 ($P = 0.01$) and tended to increase phosphorylated S6K1 abundance ($P = 0.09$), indicating activation of mRNA translation. Infusion of glucose tended to increase the mammary abundance of phosphorylated eIF2α ($P = 0.09$) and decrease the total abundance of eIF2α ($P = 0.07$), both of which are inhibitory to mRNA translation. In muscle tissue, EAA infusion increased the phosphorylation state of 4EBP1 ($P = 0.02$), which is stimulatory to mRNA translation. When glucose was added, the phosphorylation state of 4EBP1 increased ($P = 0.11$), and total S6K1 abundance tended to increase ($P = 0.11$). Thus, EAA activated regulators of mRNA translation in both mammary glands and skeletal muscle, while the addition of glucose activated pathways of mRNA translation in muscle tissue but not in the mammary glands.

Key Words: protein synthesis, mammary, muscle

431 Early postnatal plane of nutrition of Holstein calves has an effect on milk production and feed intake during their first lactation.

Steffi Wiedemann*[1], Patricia Holz[2], Hans-Juergen Kunz[3], and Martin Kaske[4], *[1]Animal Health, Institute of Animal Breeding and Husbandry, Kiel University, Kiel, Germany, [2]Clinic for Cattle, University of Veterinary Medicine Hannover Foundation, Hannover, Germany, [3]Chamber of Agriculture of Schleswig-Holstein, Blekendorf, Germany, [4]Department for Farm Animals, University of Zurich, Zurich, Switzerland.*

The objective of the study was to assess the effect of 2 different feeding strategies during the very early postnatal life of Holstein calves on subsequent first lactation milk production and feed intake. During the first 4 wk of life, calves were fed either ad libitum (AdL; ad libitum feeding of whole milk during wk 1 and milk replacer ([MR], 160 g/L) from d 8–28; n = 38) or according to a restrictive feeding protocol (RES; 4 L milk/d during wk 1, 6 L MR (120 g/L) from d 8–28; n = 30). Feeding was similar in both groups after the 4th wk of life. All animals were kept individually during the first wk of life and in groups thereafter. The feed intakes were analyzed during the first 10 wk of life in all animals and during first lactation in 37 animals. Daily milk yield and monthly milk composition were recorded. Total energy intake during the first 4 wk was higher in AdL-calves compared with RES-calves (16.6 MJ ME/d vs. 10.2 MJ ME/d, respectively; $P < 0.01$). Thereafter, no difference in energy intake was observed until the 10th wk of life. In AdL-calves the average daily gain was higher compared with RES-calves during the first 4 wk of life (0.72 vs. 0.45 kg/d; $P < 0.001$), while age at first calving did not differ (765 vs. 777 d; $P = 0.30$). In the AdL- and RES-group, 21 and 26 animals remained on the farm for a full 305-d first lactation, respectively. The FCM yield was higher in AdL-animals compared with RES-animals (29.2 ± 0.4 vs. 28.0 ± 0.4 kg FCM/d; $P < 0.05$); but milk composition did not differ. The higher FCM yield was accompanied by a higher feed intake in AdL-animals (19.3 kg DM/d vs. 18.8 kg DM/d; $P < 0.01$). The results indicate that an increased feeding intensity during early life has positive long-term effects on the milk production potential in the first lactation, which could be the result of an improved girth or height or of an enhanced development of mammary parenchyma.

Key Words: calf feeding, feed intake, milk production

432 Interrelation of somatic cell count, lactate dehydrogenase, and immunoglobulin G during mastitis caused by different pathogens.

Lorenzo E. Hernández-Castellano*[1], Samantha K. Wall[1], Roger Stephan[2], and Rupert Bruckmaier[1], *[1]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [2]Institute for Food Safety and Hygiene, Vetsuisse Faculty, University of Zurich, Zürich, Switzerland.*

Somatic cell count (SCC) is the most widely used mastitis indicator. However, immunoglobulin G (IgG), part of the specific immune system, is transferred from blood to milk, and the extent of this transfer appears to be pathogen specific. As IgG measurement is not available for farmers, milk lactate dehydrogenase (LDH) activity has been considered a suitable mastitis indicator and a marker for the presence of IgG in milk. This study aims to analyze the correlation and linear regression of the variables SCC, LDH and IgG in mastitis produced by different bacteria, and to determine if LDH can be used as an indicator for elevated IgG. Four quarters of 38 cows on 2 dairy farms with automatic milking systems were sampled. Selection criteria was based on the composite milk SCC (>100,000 cell/mL) from each cow. Samples were measured for SCC, LDH, IgG and cultured for bacteriology. SCC, LDH and IgG data were analyzed using the CORR and GLM procedures of SAS. When milk samples were not grouped by bacterial population, IgG and LDH were the highest correlated variables (r = 0.49) compared with IgG and SCC (r = 0.41) or LDH and SCC (r = 0.41). Prediction equations for all variables had an R-square ≤0.24. After quarter milk samples were classified by bacteria (control, *S. aureus*, *C. bovis*, *E. coli*, other *Staphylococcus* spp. and *S. uberis*), different correlations and regression patterns were observed. Control and infected quarters showed a positive correlation between LDH and SCC, with the exception of those infected with *E. coli* and *S. uberis*. A positive correlation between SCC and IgG was observed in quarters where *C. bovis* was identified. LDH/SCC regression slopes differed from the control group. Several differences between LDH/SCC and LDH/IgG regression slopes were observed among bacterial infections. In conclusion, LDH appears to be a good indicator for some bacterial infections (namely *C. bovis*); however the use of both SCC and

LDH may increase the mastitis detection rate, particularly infections caused by *C. bovis*, other *Staphylococcus* spp. and *S. aureus.*

Key Words: mastitis, lactate dehydrogenase, SCC

433 The innate immune response of bovine mammary epithelial cells to live or heat-inactivated *Mycoplasma bovis*.

Christina Zbinden*[1,3], Paola Pilo[2], Joachim Frey[2], Rupert M. Bruckmaier[1], and Olga Wellnitz[1], *[1]Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland, [2]Institute for Veterinary Bacteriology, Vetsuisse Faculty University of Bern, Bern, Switzerland, [3]Graduate School for Cellular and Biomedical Sciences, University of Bern, Bern, Switzerland.*

Although *Mycoplasma bovis,* an emerging etiological agent of bovine mastitis, lack classical virulence factors, they induce an immune reaction and inflammation in the host. Because effects on the bovine mammary immune system are not yet well characterized, this study aimed to investigate the immunogenic effects of *M. bovis* on the mammary gland in an established primary bovine mammary epithelial cell (bMEC) culture system. Primary bMEC in 4th passage of 4 different cows were challenged with live or heat-inactivated *M. bovis* strain JF4278 isolated from acute bovine mastitis in Switzerland with a multiplicity of infection (MOI) of 108, as well as with the type strain PG45 with a MOI of 30. The immune response of bMEC was evaluated after a co-incubation with mycoplasmas for 6, and 24 h at 37°C by measuring the relative mRNA expression of important immune factors by quantitative PCR. Live JF4278 *M. bovis* triggered a considerable immune response in bMEC ($P < 0.05$), reflected by the upregulation of relative mRNA expression (ΔΔCT) of tumor necrosis factor (TNF)-α (6 h: 4.5 ± 0.9; 24 h: 4.9 ± 0.4 threshold cycles [CT]), interleukin (IL)-1β (6 h: 7.9 ± 1.0; 24 h: 8.1 ± 0.7 CT), IL-6 (24h: 2.1 ± 0.4), IL-8 (6 h: 5.6 ± 0.9; 24 h: 7.1 ± 1.1 CT), lactoferrin (after 24 h: 4.4 ± 1.0 CT), Toll-like receptor (TLR)-2 (6 h: 1.9 ± 0.3 CT), and serum amyloid A (SAA; 24 h: 8.5 ± 0.7 CT). For live type strain PG45, very similar results were obtained; that is, a significant induction of TNF-α (6 h: 4.9 ± 0.4; 24 h: 4.4 0.5 CT), IL-1β (6 h: 7.9 ± 1.1; 24 h: 9.2 ± 0.5 CT), IL-8 (6 h: 5.6 ± 0.3; 24 h: 7.6 ± 1.0 CT), lactoferrin (6 h: 1.1 ± 0.2; 24 h: 4.0 ± 1.4 CT), TLR-2 (24 h: 2.3 ± 0.7 CT), and SAA (24 h: 8.5 ± 0.7 CT). Interestingly, this cellular reaction was only observed in response to live, but not to heat-inactivated *M. bovis*. This study provides evidence that bMEC exhibit a strong inflammatory reaction in response to live *M. bovis*. The lack of a cellular response to heat-inactivated *M. bovis* may indicate that its intracellular localization or secondary metabolites are involved in *M. bovis* pathogenesis.

Key Words: bovine mastitis, *Mycoplasma bovis*, innate immune response

434 Heat stress and amino acid supplementation affected dramatically the expression of genes related to mammary cell activity and number.

A. A. K. Salama*[1], M. Duque[2], K. Shahzad[3], and J. J. Loor[3], *[1]Grup de Recerca en Remugants (G2R), Departament de Ciència Animal i dels Aliments, Universitat Autónoma de Barcelona, Bellaterra, Spain, [2]Grupo de Investigación Biogénesis and GRICA. Facultad de Ciencias Agrarias, Universidad de Antioquia, Medellín, Colombia, [3]Department of Animal Sciences, University of Illinois, Urbana; IL.*

Heat stress (HS) causes reductions in milk yield and content of fat and protein. It is not clear whether these losses are due to reduced number or activity (or both) of mammary epithelial cells. To test mechanisms by which mammary metabolism is impaired by HS, MAC-T cells were incubated in different ambient temperature conditions: thermo-neutral (TN; 37°C) and heat stress (HS; 42°C). In both conditions, 3 mediums varying in amino acid (AA) concentrations were used. These media were: optimal amino acid profile as control (Con), control plus methionine (Met), and control plus arginine (Arg). Consequently, there were 6 treatment combinations: TN-Con, TN-Met, TN-Arg, HS-Con, HS-Met and HS-Arg. After incubation, cells were harvested and RNA was extracted for the study of gene expression by quantitative RT-PCR. Both HS and AA increased ($P < 0.01$) the expression of heat shock proteins (HSP70A1A), transcription and translation factors (RPS6KB1, JAK2, AKT2), and AA transporters (SLC1A5, SLC7A1). The expression of PPARG (fat transcription regulation), FASN (de novo fatty acids synthesis), BCL2L1 (anti-apoptotic), and AKT1 (cell survival) decreased ($P < 0.05$) with HS, but increased ($P < 0.05$) with AA. Furthermore, HS downregulated ACACA (de novo fatty acids synthesis) and upregulated BAX (apoptotic). Supplementation with Met or Arg upregulated ($P < 0.05$) genes related to transcription and translation (MAPK1, MTOR, SREBF1), cell proliferation (MKI67), and insulin signaling (IRS1). The expression of EIF4EBP1 (inhibitor of protein synthesis) was upregulated by HS, but downregulated by Met. Results suggest that heat stress exerts its negative effect on milk production at least in part by inhibiting mammary synthetic capacity as well as increasing apoptosis of mammary cells without affecting cell proliferation. Supplementation with AA (especially Met) increased mammary synthetic activity and had a positive effect on cell number by increasing proliferation and decreasing apoptosis. This raises the possibility that supplemental rumen-protected Met during heat stress might have a positive effect on mammary metabolism.

Key Words: mammary cells, gene expression, heat stress

435 Effects of different lysine/methionine pattern and glucose level on expression of the key genes involved in milk protein transcription and translation in bovine mammary epithelial cells.

F. Wang[1], J. Q. Wang[1], D. P. Bu*[1,2], X. M. Nan[1,3], and S. Lian[1], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]CAAS-ICRAF Joint Laboratory of Agroforestry and Sustainable Animal Husbandry, World Agroforestry Centre, East and Central Asia, Beijing, China, [3]Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China.*

The synthesis of milk protein requires the availability of amino acids and a large supply of energy. Lysine, methionine and glucose regulate milk protein production of lactating dairy cows in vivo. Moreover, the content and ratio of lysine to methionine can regulate milk protein synthesis via cellular signaling pathways involving JAK2-STAT5 and mammalian target of rapamycin (mTOR). This study was conducted to investigate the effects of different lysine/methionine pattern and glucose level on milk protein synthesis in vitro, mainly focused on genes related to JAK2-STAT5 and mTOR. Primary bovine mammary epithelial cells (BMEC) were obtained from Holstein dairy cows and cultured in Dulbecco's modified Eagle's medium-F12 medium containing 10% fetal bovine serum. BMEC were subjected to 4 treatments arranged in a 2 × 2 factorial design with lysine/methionine ratio (3: 1 vs. 2.3: 1, namely balanced vs. unbalanced) and glucose level (17.5 m*M* vs. 2.5m*M*, namely high vs. low) as 2 factors. In this experiment, total casein content, cell proliferation and genes expression related to JAK2-STAT5 and mTOR pathways were measured. Compared with low level of glucose groups, casein content and cell proliferation increased in groups with high level of glucose ($P < 0.05$). Casein content was also higher in lysine/methionine balanced groups than in unbalanced groups

($P < 0.01$). Expression of *CSN1S2, CSN2, LALBA, STAT5, ELF5, mTOR* ($P < 0.01$) and *CSN1S1* ($P < 0.05$) were upregulated in groups with high level of glucose compared with low level groups. The upregulation of *CSN1S2, CSN2, LALBA, JAK2, STAT5, ELF5, mTOR* ($P < 0.01$) and *CSN1S1, CSN3* ($P < 0.05$) were also observed in Lysine/Methionine balanced groups compared with unbalanced groups, while *EIF4EBP1* was downregulated ($P < 0.05$). In conclusion, proper ratio of Lysine to methionine and high level of glucose may directly accelerate the BMEC proliferation and regulate the expression of genes related to milk protein transcription and translation, which can increase milk protein synthesis.

Key Words: mammary epithelial cell, glucose, amino acid

436 *Trans*-10,*cis*-12 CLA regulates SREBP1 activation in bovine mammary epithelial cells through proteasomal degradation of Insig1. Liang Chen*, Andrea Lengi, and Benjamin Corl, *Virginia Tech, Blacksburg, VA.*

trans-10,*cis*-12 conjugated linoleic acid (t10,c12-CLA) was linked to milk fat depression in dairy cows; transcription factor sterol response element binding protein-1 (SREBP1) regulates fatty acid synthesis. SREBP1 activation and migration to the nucleus requires the removal of Insig1, a protein that anchors SREBP1 in the endoplasmic reticulum membrane. The molecular basis orchestrating the effect of t10,c12-CLA on bovine SREBP1 activation has not yet been elucidated. We hypothesize that t10,c12-CLA reduces SREBP1 activation through delay of Insig1 degradation. In the present study, we employed a bovine mammary epithelial cell line (Mac-T) and found that, mRNA and protein levels of SREBP1 declined over 56% when cells were treated with 60 μ*M* or greater t10,c12-CLA for 24 h ($P < 0.05$). Similar dose effects were observed in the mRNA expression of SREBP1-regulated genes including FAS, SCD1, and Insig1. Compared with 0 μ*M* t10,c12-CLA, 60 μ*M* or higher CLA increased Insig1 protein expression over 2-fold in cells transfected with FLAG-tagged Insig1 ($P < 0.05$). The effect was greater with t10, c12-CLA than other fatty acids including cis9, trans11-CLA, linoleic acid, or oleic acid when cells were treated with 75 μ*M* for 6 h. Further investigation revealed that increased FLAG-Insig1 was due to the inhibitory effect of t10,c12-CLA on the proteasomal degradation of Insig1. Cells treated with 75 μ*M* t10,c12-CLA or 10 μ*M* MG132, a proteasome inhibitor, for 6 h had 2.5-fold greater accumulation of FLAG-Insig1 compared with 0 μ*M* t10,c12-CLA ($P < 0.05$). The degradation of FLAG-Insig1 was delayed when cells were treated with 75 μ*M* t10,c12-CLA for 6 h. These findings suggest that t10,c12-CLA plays a role in regulating SREBP1 activation by reducing proteasomal degradation of Insig1. We conclude that stabilized Insig1 retains SREBP1 in the ER preventing activation and migration to nucleus, thus reducing lipogenic gene transcription.

Key Words: conjugated linoleic acid, SREBP1, Insig1

Milk Protein and Enzymes Symposium: High milk protein foods—Challenges and opportunities in structures and digestion

437 The role of milk proteins in the development of high protein foods. Harjinder Singh*, *Riddet Institute, Massey University, Palmerston North, New Zealand.*

The global demand for milk protein has increased significantly in recent years due to better understanding of its nutritional value, physiological and bioactive properties. A growing body of research shows that a greater intake of protein may be beneficial in sports performance, weight management, lean muscle mass retention, satiety and general wellbeing. Much of the evidence regarding many of these health benefits focuses on milk proteins, particularly whey proteins. As a result, the demand for milk protein-enriched food and beverage products has increased enormously over the last 5 years. Several milk protein products, such as milk protein concentrates, whey protein concentrates and whey protein isolates, are now available and can be added to beverages, yogurt, soups, desserts and bars. However, some functional properties of milk proteins, such as aggregation and viscosity, pose challenges to developing acceptable food formulations at high protein concentrations. For example, the addition of protein will typically cause a food product to become excessively thick and will create stability issues during processing. In addition to maintaining suitable stability and texture, protein at high concentration has a marked impact on the taste and flavor profile of the product. Although some solutions to these problems have been developed by the food industry, we need to have better understanding of the fundamental behavior of proteins at high concentrations in various food formats.Recent studies indicate that beneficial effects of protein on health are not just dependent on sufficient protein intake; the rate at which amino acids are released and absorbed, as well as the generation of bioactive peptides influence biological potency. Thus, the interactions of milk proteins in the food and in the gastro-intestinal tract can play an important role in modulating the efficiency of protein digestion and the magnitude of its biological effects. In the future, it may be possible to design structures based on milk protein preparations to optimize the delivery of amino acids, hence modulating the postprandial physiological responses.

Key Words: milk protein, functionality, digestion

438 Structuring food for improving nutrient bioavailability: The case of dairy gels. Didier Dupont*[1], Florence Barbe[1], Steven Le Feunteun[2], Olivia Menard[1], Yann Le Gouar[1], Amelie Deglaire[1], Juliane Floury[1], Didier Remond[3], and Beatrice Laroche[4], *[1]INRA-Agrocampus Ouest, Rennes, France, [2]INRA-AgroParisTech, Grignon, France, [3]INRA-Université Clermont 1, Clermont-Ferrand, France, [4]INRA, Jouy-en-Josas, France.*

The food matrix structure is one of the key drivers to control the fate of food in the digestive tract and, consequently, the kinetics of nutrient release. Milk is "the" perfect raw material to build a wide variety of structures and can be really seen as a "Lego box" from which all the constituents can be separated (cracking) and re-assembled into different structures. The behavior in the gastrointestinal tract of milk protein matrices of identical composition but different micro and macrostructures was investigated in the present study. Six multi-cannulated and catheterized mini-pigs were fed 6 different dairy matrices (raw and heat-treated milks, acid and rennet gels). Effluents from the duodenum and mid-jejunum as well as plasma from the abdominal aorta were collected over 7h. Structure was shown to drive the time of residence of food in the stomach. The liquid-gel transition led to a significant increase in the gastric emptying time. Liquid matrices generated a fast and intense peak of proteins in the intestine and amino acids in the bloodstream. Peptidomic analysis showed different patterns between intestinal samples. Finally, rennet gels had a different behavior than the acid ones forming a compact coagulum in the stomach that slowed down the gastric emptying and delayed the release of amino acids. A mathematical model of digestion was built from these data. Therefore, controlling the time of residence of food in the stomach by playing on its structure should allow to design products with a fast release of nutrients particularly adapted for elderlies, athletes etc… whereas foods persisting in the stomach should induce satiety and be dedicated to overweight people. As an example, 2 isocaloric yogurts with 3.3 and 8.4g of protein /100g respectively were manufactured and given to 11 pigs. Gastric emptying followed by scintigraphy was significantly slowed down for the protein-enriched yogurt leading to different kinetics of proteolysis. Ongoing experiments using biophysical methods will help us in understanding the mechanisms of gel particle breakdown in the stomach to design dairy products of new generation perfectly adapted to the nutritional needs of specific populations

Key Words: digestion, dairy, bioavailability

439 Dairy protein and soluble fiber complexation: Effect on digestion and healthfulness of high protein foods. Bongkosh Vardhanabhuti*, *University of Missouri, Columbia, MO.*

Through controlled assembly of protein and polysaccharide, especially anionic soluble fibers, biopolymer particles with desirable functional properties can be created. The majority of research has focused on fabrication conditions under associative interaction (e.g., at pH < isoelectric point of protein) where they form complex coacervates. Much less attention has been given to their interactions under limited thermodynamic compatibility (e.g., at neutral or near neutral pH) where the positively charged patches of protein can form electrostatic attraction with negatively charged polysaccharides. Research has shown that unheated and heated soluble complexes between whey protein and anionic soluble fibers can be formed under limited thermodynamic compatibility. At optimum conditions, structuring of these complexes improves functional properties of whey protein, leading to enhanced texture and stability of food products. Using *in vitro* digestion model, recent studies have revealed that high protein beverages containing whey protein and anionic soluble fiber complexes can form intragastric gel when entering the simulated gastric environment. The transformation of liquid (e.g., beverages) to gel results in slow gastric emptying and slower protein degradation. Formation of intragastric gel also traps other ingredients including sugar, resulting in delayed sugar-release from the gel network. Potentially, intragastric gelation behavior could lead to the development of high protein food products with healthy blood sugar or high satiety claims. As the demand for high protein products continues to grow, complexes between dairy protein and soluble fibers could be utilized to improve the quality and healthfulness of high protein foods and beverages.

Key Words: dairy protein, digestion, soluble fiber

440 Milk protein ingredients for controlling hardening of protein bars.

Thom Huppertz*[1,2] and Sean Hogan[3], [1]*NIZO food research, Ede, the Netherlands,* [2]*South Dakota State University, Brookings, SD,* [3]*Teagasc Dairy Products Research Centre, Moorepark, Fermoy, Ireland.*

Demand for high-protein snack bars as meal replacers and by consumers engaged in sports and dieting has grown significantly in recent years. These products provide healthy alternatives to conventional snacks because of the inclusion of high levels of protein (15–35%, w/w) and other nutritionally beneficial ingredients. Inclusion of high levels of protein in bars may result in adverse quality effects, in particular bar hardening, the degree of which is dependent on the ingredients and process used to produce the bars. Particularly water migration to the protein powder particles is a strong contributor to hardening of protein bars due to subtraction of water from different constituents, which can lead to hardening due to crystallization of carbohydrates. Protein bars containing whey protein isolate as the protein source generally developed less hardness than those containing caseinate. Part of these differences can be related to differences in moisture sorption of the protein powder particles in the water activity region of the protein bars (~0.5–0.7). For understanding protein functionality in bars, it is important to keep in mind that at these water activities, proteins should not be considered as fully hydrated proteins, but as partially hydrated. A further strong contributor to protein ingredient behavior in protein bars is powder particle size and microstructure. A broad particle size distribution and agglomeration were found to be beneficial to reduce development of hardness. Such effects can be attributed to the fact that less dense packing of powder particles is achieved in polydisperse systems, as a result of which hardness is reduced. The use of protein blends can also be beneficial from this perspective. Overall, initial hardness of protein bars can be described initially as a function of volume fraction of suspended powder particles and the efficiency of packing thereof. During storage, water migration and partial hydration and swelling of protein particles further contribute to hardness development. Hence, control of water sorption of powder particles and powder particle size and structure are prime routes to control the development of hardness in protein bars.

Key Words: whey protein, casein, protein bar hardening

441 Technological challenges of high milk protein formulations.

Juan M. Gonzalez*, *Global Technology at Mead Johnson Nutrition, Evansville, IN.*

The formulation and processing of high protein nutritional dairy products present several challenges. Two product formats to be discussed: powder products to be consumed as reconstituted beverages, and ready-to-eat (RTE) liquid products. Regarding powder products, the challenges are related to the consumer experience. Regarding the RTE liquid product, the challenges are related to processing and stability. High dairy protein powder products processed via powder blending face consumer experience challenges related to preparation, such as hydration, and to the sensory perception. The use of agglomeration technologies may provide a fast wetting of the powder. However, the hydration of the proteins may become a challenge as the proteins would compete for water available for hydration. The sugars and salts that may be present in the formulation would also compete for the bulk water available for hydration. Regarding the sensory experience, the presence of insufficient bulk water may lead to a perceived graininess in the beverage. The high protein content may produce a thick beverage more suitable to be spooned or chewed rather than swallow. RTE liquid products present challenges of hydration and thermal stability of the high protein matrix through processing. The processing stability of RTE high protein liquid beverages is related to the protein components. Whey based formulations are more stable than casein based formulations. The target pH, presence of salts, carbohydrates, and the buffering capacity of the high protein slurry would present formulation and processing challenges, as is in the case of concentrated infant formulas. The presence of reducing sugars at pH > 7 would encourage the formation of Maillard reaction color and flavor compounds that may or may not be desirable. This reaction also compromises the nutritional value of the protein as it makes unavailable amino acids, such as lysine, arginine and glutamine. The use of the shockwave steam injection technology allows for the processing of high protein dairy slurries. The viscosity observed in these shockwave-processed slurries is considerably lower than the one observed in traditionally heat-treated systems. Lower protein denaturation has been observed and this may be attributed to thermodynamic relationships within the process.

Physiology and Endocrinology: Reproduction in cattle

442 Comparison of TAI at GnRH injection and delayed insemination of non-estrus beef heifers. Hazy R. Nielson*[1], Dan J. Kelly[2], and Rick N. Funston[1], *[1]University of Nebraska, West Central Research and Extension Center, North Platte, NE, [2]Kelly Ranch, Sutherland, NE.*

A study evaluated the effect of a 16-h delayed AI following GnRH administration in a hybrid estrus detection and time AI protocol in heifers not in estrus at the time of scheduled AI. Angus-based, crossbred heifers (n = 453) of the same origin were managed at the Kelly Ranch (Sutherland, NE) or the University of Nebraska West Central Research and Extension Center (North Platte, NE). Estrus was synchronized utilizing the melengestrol acetate (MGA)-PG protocol; heifers received MGA for 14 d. Nineteen d later, on d 33 of the protocol, heifers received a PG injection and estrus detection aids (Estrotect) were applied. Heifers were considered to have expressed estrus when greater than 50% of the rub off coating was removed from the Estrotect. Heifers (n = 319) were then removed from the herd and AI 12 h later (ESTRUS). Seventy-two hours following the PG injection, heifers whose Estrotect were less than 50% activated were administered GnRH, and randomly assigned to 1 of 2 treatment groups; 1) immediately AI (n = 70, GNRH1) or 2) AI 16 ± 1 h following GnRH injection (n = 64, GNRH2). Data were analyzed using the GLIMMIX procedure of SAS (SAS Inst. Inc., Cary, NC) and the proportion of pregnant heifers was found using an odds ratio utilizing the ILINK function. Pre-breeding BW was similar ($P = 0.58$) between ESTRUS, GNRH1, and GNRH2 (351, 346, and 349 ± 6 kg, respectively). Furthermore, pregnancy diagnosis BW among the treatments was similar ($P = 0.48$; 376, 380, and 377 ± 6 kg; ESTRUS, GNRH1, and GNRH2, respectively). Heifers who were AI on their estrus, as determined by an activated Estrotect, had significantly higher ($P < 0.01$) pregnancy rate compared with heifers in both GNRH1 and GNRH2 groups (70 vs. 56, 47 ± 6%). Pregnancy rates did not differ ($P = 0.56$) between GNRH1 and GNRH2 (56 vs. 47 ± 6%). Heifers in all groups reached a similar ($P = 0.59$) percentage of mature BW before the breeding season (63 ± 1%). Final pregnancy rate was not different ($P = 0.54$) for ESTRUS, GNRH1, and GNRH2 heifers (92, 89, 91 ± 4%). There was no significant benefit to delayed AI of non-estrus beef heifers compared with traditional timed AI at the time of GnRH injection.

Key Words: beef heifer, delayed insemination, estrus synchronization

443 Bee Synch for synchronization and fixed-time AI of *Bos indicus*-influenced cows: An update. Gary L. Williams*[1,3], Randy L. Stanko[2], and Marcel Amstalden[3], *[1]Texas A&M AgriLife Research, Beeville, TX, [2]Texas A&M University-Kingsville, Kingsville, TX, [3]Texas A&M University, College Station, TX.*

Synchronization methodologies that are successful in straight-bred English and Continental breeds have proven less successful in *Bos indicus*-influenced cattle, with fixed-time AI (FTAI) pregnancy rates of 35 to 40%. Because of these poor outcomes, few commercial cattlemen who utilize these types of cattle employ synchronization technologies and FTAI. Research has indicated that variation in the rate of maturation of the dominant follicle after CIDR removal in *Bos indicus*-influenced females is a major contributor to reduced pregnancy potential at FTAI. Herein, we provide an updated report on the use of a modification of the standard 5-day CO-Synch + CIDR protocol, the 5-day Bee Synch + CIDR (Bee Synch) which has been termed PG-5-Day + CIDR by the Beef Reproduction Task Force. The protocol was designed to eliminate mature corpora lutea at the onset of synchronization, thus reducing circulating concentrations of progesterone, minimize variation in the rate of follicle maturation, and improve FTAI pregnancy rates. Initial studies evaluated the 5-Day CO-Synch + CIDR protocol alone (n = 100; Trial 1) or in comparison with Bee Synch (Bee Synch, n = 133; 5-Day CO-Synch, n = 136; Trial 2) at one location with mature cows. Subsequently, Bee Synch was evaluated at 4 additional locations utilizing Braford, Brangus, and Nelore crossbred cows. The 5-d protocol involved insertion of a controlled internal drug releasing device (CIDR) and i.m. injection of GnRH (100 µg; Factrel) on d 0. On d 5, the CIDR was removed and cows were treated i.m. with prostaglandin $F_{2\alpha}$ (PGF; Lutalyse, 50 mg). Cows were inseminated at 66–72 h after CIDR removal and treated with 100 µg GnRH. Bee Synch employed a similar sequence except that all cows were treated with 25 mg PGF at the time of CIDR insertion. Pregnancy rate to FTAI in Trial 1 (5-Day CO-Synch + CIDR) was 33%. In trial 2, Bee Synch markedly improved FTAI pregnancy rates compared with the standard 5-day protocol (51.8 ± 0.9 vs 40.9 ± 5.7%; $P < 0.04$). Cumulative FTAI pregnancy rates in cows (n = 702) treated with Bee Synch at 5 locations averaged 51.9 ± 3.1% (range = 40 to 59.3). Bee Synch appears to improve FTAI feasibility in *Bos indicus*-influenced cows.

Key Words: synchronization, *Bos indicus*-influenced, Bee Synch

444 Effect of MGA versus CIDR estrus synchronization on estrus response and pregnancy rates in 311-d-old beef heifers. Hazy R. Nielson*[1], Rosemary V. Anderson[2], and Rick N. Funston[1], *[1]University of Nebraska, West Central Research and Extension Center, North Platte, NE, [2]Anderson Ranch, Whitman, NE.*

A study compared the effect of melengestrol acetate (MGA)-PG and 14-d controlled internal drug release (CIDR)-PG estrus synchronization protocols on estrus response and pregnancy rates of 311-d-old Angus-based, crossbred heifers (n = 153). Fall-born heifers, at 10 mo of age, were randomly assigned to 1 of 2 estrus synchronization protocols in the spring (2 replications/treatment). Heifers in the MGA protocol received MGA for 14 d fed through the diet beginning on d 0 of the synchronization treatment period. Heifers in the CIDR treatment received the same diet as MGA heifers and were implanted with a CIDR (Eazi-breed CIDR) on d 2 of the treatment period and removed on d 16. Following estrus synchronization, heifers from both treatments were combined and received a single PG (Lutalyse) injection on d 32. Heifers with activated heat detection aids (Estrotect) were AI 12 h following observation. All data were analyzed with the GLIMMIX procedure of SAS (SAS Inst. Inc., Cary, NC). Group BW was measured at weaning (198 kg) and before breeding (273 kg). Pre-breeding BW was 50.1% of predicted mature BW. Heifer age at breeding was not different ($P = 0.12$) between MGA and CIDR treatment groups. Percentage of heifers demonstrating signs of estrus was similar ($P = 0.42$) between synchronization treatment groups (CIDR vs. MGA, 71.5 vs. 77.4 ± 1.0%). Heifers not expressing estrus were not given an opportunity to become pregnant and removed from the herd. Pregnancy rates to AI of heifers expressing estrus (n = 115) were similar ($P = 0.27$) between CIDR and MGA synchronization treatment (46.3 vs. 36.1 ± 6.8%). Bulls were placed with heifers at a 1:25 ratio 10 d following AI. Final pregnancy rate was also similar ($P = 0.96$) between CIDR and MGA treatment groups (51.0 vs. 51.5 ± 7.4%). Heifer BW at pregnancy diagnosis was not different ($P = 0.45$) between CIDR and MGA treatment groups (325 vs. 321 ± 3.4 kg). The numerical 10% decrease in AI pregnancy rate in MGA compared with CIDR synchronization is not significant but is of interest. Approximately half of these 311 d old heifers exposed to AI and bulls became pregnant.

Key Words: beef heifers, estrus synchronization, heifer development

445 Variation in timed-AI pregnancy rates in beef sires.

Bo R. Harstine*[1], Rodrigo A. C. Martins[2], Adnan D. P. Rodrigues[4], Leandro H. Cruppe[1,3], Matthew D. Utt[3], Lon D. Peters[3], José L. M. Vasconcelos[4], Mel DeJarnette[3], and Michael L. Day[1], [1]*The Ohio State University, Department of Animal Sciences, Columbus, OH,* [2]*RM Reprodução Animal, Brasilia, Brazil,* [3]*Select Sires Inc., Plain City, OH,* [4]*Faculdade de Medicina Veterinária e Zootecnia, UNESP, Botucatu, SP, Brazil.*

Differences between timed-AI (TAI) pregnancy rates (PR) of beef bulls and collections within bull are difficult to determine due to limited number of females per breeding group. PR to TAI between 6 Angus bulls and between collections (combined 2 ejaculates) within bull were examined in large Brazilian beef herds. In 4 bulls, 3 collections obtained in a 2-week period were packaged in different colored straws. In 2 bulls, a single collection was packaged in 3 straw colors as controls. Straws contained 20 million total spermatozoa (0.5 ml). Nelore females (n = 6003) in 75 groups on 4 farms were synchronized for TAI. Every bull was represented in each group, and collection within bull was randomized across groups. Parity and body condition score (BCS) were recorded at TAI. Pregnancy was diagnosed approximately 35 d post-TAI (5614 complete records). Data were analyzed using GLIMMIX procedure of SAS with main effects of sire, collection(sire), farm, parity(farm), and BCS ($\leq$2.75 or $\geq$3 on a scale of 5). Estrotect patches were used on a subset of cows (n = 3334; 2 farms) to assess estrus activity. PR was greater ($P < 0.05$) when BCS was $\geq$3 and if females displayed estrus. PR differed ($P < 0.05$) between sires and tended to differ between collections within sire ($P = 0.09$; Table 1). The numeric range in PR was similar among straw colors for both individual collections and a control (Sire 3), illustrating that the impact of binomial variation, even within large sample sizes such as these, cannot be ignored. In conclusion, large and economically significant differences in fertility exist between bulls used for TAI, and knowledge of bull fertility is crucial for the consistency and success of beef TAI programs.

Table 1 (Abstr. 445). Pregnancy rates (PR; %) to timed-AI (TAI) for bulls and individual collections within bull

	TAI PR per bull		SEM	TAI PR by straw color		
Bull	n	TAI PR	(%)	Purple	Red	Yellow
1	828	46.1^{a}	2.7	47.7	44.8	45.8
2	1,109	44.7^{a}	2.4	47.3	40.4	46.6
3[1]	735	41.3^{ab}	2.9	42.3	44.7	36.8
4	1,026	39.2^{ab}	2.6	31.8	42.3	43.7
5[1]	841	35.7^{bc}	2.6	35.5	35.8	35.7
6	1,075	30.6^{c}	2.1	26.5	34.5	30.7

[a–c] Means within the same column not sharing a common superscript differ significantly, $P < 0.05$.

[1] All straws from sire are from the same collection.

Key Words: fertility, AI, bull

446 Effect of decreasing the duration of a PRID-synch protocol and addition of a second prostaglandin $F_{2\alpha}$ treatment on fertility after resynchronization of ovulation in lactating Holstein cows.

V. G. Santos*[1,2], P. D. Carvalho[1], C. Maia[3], B. C. Carneiro[3], A. Valenza[4], E. M. Bettencourt[2], and P. M. Fricke[1], [1]*Department of Dairy Science, University of Wisconsin-Madison, Madison, WI,* [2]*Departamento de Medicina Veterinária, Escola de Ciências e Tecnologia, Instituto de Ciências Agrárias e Ambientais Mediterrânicas, Instituto de Investigação e Formação Avançada, Universidade de Évora, Núcleo da Mitra, Évora, Portugal,* [3]*Diessen Servicos Veterinarios Lda, Évora, Portugal,* [4]*CEVA Sante Animale, Libourne, France.*

Our objective was to evaluate the effects of (1) decreasing the interval between the first GnRH treatment (G1) and the $PGF_{2\alpha}$ (PGF) treatment and (2) a second PGF treatment 24 h after the first during hormonal protocols for resynchronization of ovulation and timed artificial insemination (TAI). Lactating Holstein cows (n = 249) from 3 commercial dairy farms were randomly assigned at a nonpregnancy diagnosis to 1 of 3 hormonal protocols for resynchronization of ovulation: (1) a 7-d PRID-synch protocol with 1 PGF injection (7D1P: d 0; GnRH +PRID; d 7, PGF -PRID; 56 h, GnRH; 16 h, TAI); (2) a 7-d PRID-synch protocol with 2 PGF injections (7D2P: d 0, GnRH +PRID; d 7, PGF -PRID; 24 h, PGF; 32 h, GnRH; 16 h TAI); and (3) a 5-d PRID-synch protocol with 2 PGF injections (5D2P: d 0, GnRH +PRID; d 5, PGF -PRID; 24 h, PGF; 32 h, GnRH; 16 h, TAI). Ovaries of all cows were examined at G1 using transrectal ultrasonography, and cows were classified as either having or lacking a CL. Data were analyzed by logistic regression using PROC GLIMMIX of SAS. Pregnancy diagnosis was conducted 32 d after TAI using transrectal ultrasonography. Overall, P/AI 32 d after TAI did not differ ($P = 0.83$) between primiparous and multiparous cows [47% (35/75) vs. 44% (77/174), respectively]. At 32 d after TAI, P/AI tended to differ ($P = 0.09$) among treatments and was least for 7D1P cows, intermediate for 5D2P cows, and greatest for 7D2P cows [39% (35/89) vs. 44% (34/77) vs. 52% (43/83), respectively]. Furthermore, P/AI did not differ ($P = 0.20$) between cows classified as having or lacking a CL at G1 of the resynchronization protocols [48% (83/174) vs. 39% (22/56), respectively]. Based on these preliminary data, addition of a second PGF injection to a 7-d PRID-synch protocol increased ($P = 0.03$) P/AI 32 d after TAI by 13 percentage points (7D2P vs. 7D1P cows), whereas decreasing the interval between G1 and the PGF injection (5D2P vs. 7D2P cows) did not increase ($P = 0.62$) P/AI 32 d after TAI in resynchronized Holstein cows. Supported by CEVA Sante Animale.

Key Words: timed AI, dairy cow, resynchronization

447 Evaluating blood perfusion of the corpus luteum in beef cows during fescue toxicosis.

Garrett F. Cline*[1], Ashleigh M. Muth-Spurlock[1], Benjamin E. Voelz[2], Caleb O. Lemley[1], and Jamie E. Larson[1], [1]*Mississippi State University, Mississippi State, MS,* [2]*Kansas State University, Manhattan, KS.*

The aim of this study was to determine if fescue toxicosis altered blood perfusion in the corpus luteum (CL), and peripheral concentrations of progesterone (P4) in cattle. In 2 replicates, the estrous cycles of 36, non-pregnant Angus or Charolais cows were synchronized using the CO-Synch+CIDR protocol. Seven d after initiation of the protocol, cows were assigned (d 0) to 1 of 2 treatments: 2.5 kg of (1) Kentucky-31 endophyte-infected (E+; n = 14), or (2) MaxQ novel endophyte (NE; n = 12) tall fescue seed. On d 7 ovaries were examined using ultrasonography and only cows that had 1 CL present remained on the study (n = 26). Images of blood perfusion of CL, blood samples, rectal temperatures, and blood pressure of tails were collected on d 10, 13, 15 and 18. Images of CL blood perfusion were analyzed using ImageJ software for pixel density, and scored visually (0 to 9 with 0 = no perfusion, 9 = complete perfusion) by 2 independent technicians. The MIXED procedure of SAS was used with day as a repeated measure. LSMeans and pooled SEM are reported. Cows receiving E+ had greater rectal temperatures ($P = 0.02$; 38.73 ± 0.08°C) than those receiving NE (38.46 ± 0.08°C), providing evidence the cows treated with E+ were influenced by fescue toxicosis. Pulse pressure and mean arterial pressure were decreased ($P < 0.01$) in cows receiving E+ (54.08 ± 3.21 and 80.06 ± 2.71 mmHg, respectively) than NE (67.12 ± 3.11 and 91.37 ± 2.93 mmHg, respectively). Concentrations of P4 were similar ($P = 0.54$) between cows receiving E+ (6.04 ± 0.53 ng/mL) or NE (6.36 ± 0.63 ng/mL). Pixel densities ($P = 0.14$) and visual perfusion scores were similar ($P = 0.11$) between cows receiving E+ (1,477.20 ± 655.62 pixels and 2.23 ± 0.34, respectively) or NE (2,934.70 ± 718.20 pixels and 3.00 ± 0.36, respectively). Mean CL volume was similar ($P = 0.39$) between treatments. In conclusion, blood perfusion of CL or peripheral concentrations of P4 were not altered at the onset of fescue toxicosis, indicating that a decrease in blood perfusion of the CL may not be a primary mechanism involved in decreased reproductive efficiency of cattle during fescue toxicosis.

Key Words: blood perfusion, corpus luteum, fescue toxicosis

448 Improved fertility of cows failing to respond to resynchronization of ovulation through presynchronization of ovulation or progesterone supplementation.

Julio O. Giordano*[1], Mark J. Thomas[2], Grace Cuatucuamba[2], Mathew D. Curler[2], Robert Wijma[1], and Matias L. Stangaferro[1], *[1]Department of Animal Science, Cornell University, Ithaca, NY, [2]Dairy Health & Management Services, Lowville, NY.*

Our objective was to evaluate treatments to increase fertility of timed-AI (TAI) services of lactating dairy cows without a corpus luteum (CL) at the time of the PGF injection of Resynch initiated 32 ± 3 d after AI (RD32; GnRH-7d-PGF-56h-GnRH-16h-TAI). In Exp1, blood collection and ovarian ultrasound was conducted (n = 555) at the PGF of RD32 to define a cutoff value for CL size that allows creating groups of cows with low and high fertility after TAI. P/AI were analyzed by logistical regression using PROC GLIMMIX of SAS. Based on P/AI, the CL size selected was 15 mm [CL ≥ 15 mm = 33.2%; (165/497) vs. NoCL or CL < 15 mm = 10.3% (6/58); $P < 0.01$]. In Exp2, cows without a CL or a CL < 15 mm (NoCL) were randomly assigned to (1) Ovsynch plus progesterone (P4) [OvP4; GnRH (G1) and CIDR-7d-PGF and CIDR removal-56h-GnRH-16h-TAI; n = 212] or (2) presynchronization with GnRH (PreG) 7 d before Ovsynch [PreGOv; GnRH-7d-GnRH(G1)-7d-PGF(P)-56h-GnRH-16h-TAI; n = 192]. Cows with a CL > 15mm (CLPG) at PGF of RD32 (n = 1,797) completed RD32 to receive TAI. Binary data were analyzed by logistical regression using PROC GLIMMIX whereas quantitative data were analyzed by ANOVA using PROC MIXED of SAS. At 39 d after AI, overall P/AI were similar ($P = 0.13$) for cows in OvP4 (34.4%), PreGOv (35.9%), and CLPG (31.1%). Cows inseminated in estrus had similar ($P = 0.32$) P/AI [41.4% (n = 29) OvP4, 24.4% (n = 41) PreGOv, and 34.1% (n = 173) CLPG] but P/AI tended ($P = 0.06$) to differ for TAI cows (33.3% OvP4, 39.1% PreGOv, and 30.8% CLPG). Pregnancy losses were similar ($P = 0.29$) for cows in OvP4 (2.9%), PreGOv (8.7%), and CLPG (11.6%). Ovulatory response to PreG was 86.0%. At G1, cows with a CL (86.6 vs. 16.4%; $P < 0.01$), cows with P4 > 1ng/mL (82.8 vs. 31.8%; $P < 0.01$), P4 concentrations (3.7 vs. 1.1 ng/mL; $P < 0.01$), and cows with a follicle > 10 mm (94.9 vs. 80.9%; $P < 0.01$) was greater in PreGOv than OvP4 group. Ovulatory response to G1 was 71.9 vs 58.3% for OvP4 and PreGOv ($P = 0.03$). At the PGF before TAI, more cows had a CL in PreGOv than OvP4 (92.1 vs. 77%; $P < 0.01$), cows with P4 > 1 ng/mL was similar (79.1 vs. 82.7%; $P = 0.50$), but P4 concentrations were greater in PreGOv than in OvP4 (4.1 vs. 2.6 ng/mL; $P < 0.01$). We conclude that presynchronization with GnRH 7 d before Ovsynch or Ovsynch plus P4 are 2 feasible alternatives to increase P/AI of cows without a CL at the PGF injection of RD32. Supported by New York Farm Viability Institute project AOR12–012.

Key Words: corpus luteum, resynchronization, dairy cow

449 Interferon-tau and progesterone down-regulate cytochrome P450 1A and 2C in bovine endometrial epithelial cells.

Caleb O. Lemley* and Christa L. Gilfeather, *Mississippi State University, Mississippi State, MS.*

The objective of the current study was to examine cytochrome P450 1A (CYP1A) and 2C (CYP2C) activity in bovine endometrial cell cultures following exposure to oxytocin (OT), interferon-tau (IFN), estradiol (E2), and/or progesterone (P4). Bovine endometrial epithelial cells were cultured to 80% confluence in 6-well plates. For experiment 1, cells were treated with 1 μg/mL OT, 10 ng/mL IFN, a combination of OT+IFN, or control (CON) media for 24 h. For the second experiment, cells were treated with 1 ng/mL E2, 15 ng/mL P4, a combination of E2+P4, or CON media for 24 h. Following the hormone treatment, endometrial cells were harvested in lysis buffer containing protease and phosphatase inhibitors and frozen at −80°C until further analysis. Treatments were performed in triplicate and the experiment was repeated 4 times (n = 12 per treatment). The activity of CYP1A and CYP2C were determined using specific luminogenic substrates and expressed relative to mg of cellular protein. Data were analyzed using MIXED procedure of SAS and the model statement included hormone and replicate. Treatment with OT alone did not alter activity of CYP1A ($P = 0.55$) or CYP2C ($P = 0.46$) compared with CON cells. Activity of CYP1A was decreased in cells exposed to IFN ($P < 0.01$) or OT+IFN ($P < 0.01$) compared with CON. Similarly, activity of CYP2C was decreased in cells exposed to IFN ($P < 0.01$) or OT+IFN ($P < 0.01$) compared with CON. Treatment with E2 alone did not alter activity of CYP1A ($P = 0.64$) or CYP2C ($P = 0.06$) compared with CON cells. Activity of CYP1A was decreased ($P < 0.01$) in P4 versus CON, while E2+P4 was not different ($P = 0.38$) from CON. Activity of CYP2C was decreased in cells exposed to P4 ($P < 0.01$) or E2+P4 ($P < 0.01$) compared with CON cells. In summary, both interferon-tau and progesterone exposure decreased CYP1A and CYP2C activity. The mixed function monooxygenase enzymes, CYP1A and CYP2C, have been implicated in synthesizing embryotoxic compounds; therefore, down-regulation in the endometrium may be necessary during maternal recognition of pregnancy.

Key Words: cytochrome P450, endometrium, interferon-tau

450 Epidermal growth factor promotes interferon-tau expression in bovine trophectoderm.

Sarah R. McCoski* and Alan D. Ealy, *Virginia Tech, Blacksburg, VA.*

Significant pregnancy loss occurs in cattle during the early stages of embryogenesis and placentation. Several critical events occur in the first 3 to 4 weeks of gestation, and aberrations in any one of these events will prompt pregnancy loss. One such event is maternal recognition of pregnancy, when interferon-tau (IFNT) must be produced in sufficient quantities from the conceptus to prevent luteolysis and modify uterine function to favor pregnancy. Epidermal growth factor (EGF) is produced by the uterus and is a recognized embryotrophic factor. Specific activities in bovine embryos include improving rates of bovine embryo development and increasing trophectoderm (TE) proliferation. This study examined whether EGF affects *IFNT* expression. A stable bovine TE cell line (CT1) was maintained in Dulbecco's Modified Eagle's Medium (DMEM). Cells were serum-starved and then exposed to various concentrations of human recombinant EGF. Total cellular RNA was extracted, and quantitative reverse transcription PCR was completed using *IFNT*-specific primers and ribosomal protein S9 (*RPS9*; internal control). Data were analyzed by ANOVA. In the first study, a 6 h dose response was completed (n = 3 replicate studies). Supplementation with 100 ng/mL EGF increased ($P < 0.05$) *IFNT* transcript abundance when compared with controls (2.3 ± 0.8 fold effect). Exposure to 1 or 10 ng/mL EGF did not affect *IFNT* transcript abundance. In the second study, a 24 h dose-response was completed (n = 3 replicate studies). A trend in increased *IFNT* mRNA abundance was evident ($P = 0.07$) when CT1 cells were supplemented with 1 ng/mL EGF (2.0 ± 1.5 fold vs. controls). Incubation with either 10 or 100 ng/mL EGF increased ($P < 0.05$) *IFNT* transcript abundance when compared with controls (2.6 ± 0.8 and 3.6 ± 1.4 fold effect, respectively). Moreover, the 100 ng/mL effect was more pronounced than the 1 ng/mL effect ($P = 0.06$; 1.75 ± 0.7 fold). These outcomes implicate EGF as a mediator of *IFNT* expression, and provide further evidence of how the maternal system may control IFNT production and other developmental events during early pregnancy in ways that dictate pregnancy retention or failure.

Key Words: interferon-tau, embryo, trophectoderm

451 Effects of label-dose permethrin administration on reproductive function in superstimulated beef heifers.

Tyler M. Dohlman*[1,2], Marianna M. Jahnke[1], James K. West[1], Patrick E. Phillips[1], and Patrick J. Gunn[2], [1]*Veterinary and Diagnostic Production Animal Medicine, Iowa State University, Ames, IA,* [2]*Department of Animal Science, Iowa State University, Ames, IA.*

The objective was to study the effects of a commercial pyrethroid-based pour-on product, permethrin, on reproductive performance in superovulated beef heifers by assessing steroid biosynthesis and embryo quality. Nonpregnant, yearling beef heifers (n = 10; 417 ± 33 kg; 5.5 ± 0.2 BCS) were assigned by BW and breed to either 1) saline control (CON) or 2) permethrin pour-on administered at label dose (PYR). Superstimulation was achieved on all heifers utilizing a timed, 17-d, CIDR-based protocol with GnRH and PGF_{2a} and decreasing total dosage of 240mg FSH administered twice daily for 4 d. Heifers were AI twice (at onset of estrus and 12 h later) by the same technician with frozen semen from single bull collection. To determine short and long-term effects of permethrin on embryo quality and steroid biosynthesis, superstimulation was initiated twice with collection of embryos occurring at 17 and 51 d post-treatment. Embryos were recovered 6.5 d after first AI via non-surgical flush and were evaluated by International Embryo Transfer Society standards. Blood was collected at standing estrus and d of embryo recovery. Estrogen (E_2) and progesterone (P_4) concentrations were analyzed via RIA. MIXED and GLIMMIX procedures of SAS were used to analyze continuous and categorical data, respectively. Heifer per flush was the experimental unit. Total embryos recovered did not differ due to treatment ($P = 0.30$), but did decrease in flush 2 compared with flush 1 ($P = 0.02$). Quality grade, total transferrable quality embryos (TQE), and overall flush success did not differ due to treatment ($P = 0.16$). However, TQE was decreased in flush 2 compared with flush 1 ($P = 0.05$). Total unfertilized oocytes was greater in CON ($P = 0.04$). The PYR heifers tended to have less total P_4 ($P = 0.15$) and P_4 per corpus luteum ($P = 0.06$) at recovery. E_2 per ovulated follicle and E_2 per total ovarian structure was greater in flush 2 ($P = 0.03$) but did not differ due to treatment ($P = 0.23$). In summary, these data indicate that permethrin administration at label dose in superstimulated beef heifers has a tendency to reduce $P_{4,}$ but embryo quality is not affected.

Key Words: permethrin, embryo, progesterone

452 Effects of tamoxifen on pre-pubertal heifer reproductive tissues: Potential for disruption of tract development through alteration of related signaling pathways.

Abdullah Al Naib*[1], Ali.Y. Wood[1], Hannah.L. M. Tucker[1], Catherine.L. M. Parsons[1], Victoria.L. McCracken[1], Abigail.L. Zezeski[1], Stacie.E. Deaver[2], Britni.M. Brown[1], Mike.M. Akers[1], and Michelle.L. Rhoads[1], [1]*Virginia Polytechnic Institute and State University, Blacksburg, Virginia,* [2]*Virginia Western Community College, Roanoke, Virginia.*

Pre-pubertal exposure of the developing reproductive tract (RT) to estrogen or xenoestrogens can have long-term consequences that compromise the reproductive performance of dairy cattle. This research examined the effects of the selective estrogen receptor modulator, tamoxifen (TAM), on gene and protein expression in the pre-pubertal RT with particular focus on signaling pathways that affect RT morphology. Tamoxifen was administered to heifer calves (n = 7) daily (0.3 mg/kg subcutaneously) from 28 to 120 d of age. Control calves (CON; n = 7) received an equal volume of excipient. Weight, gross measurements and samples of RT tissues were collected upon sacrifice at 120.7 ± 0.3 d of age. Protein and mRNA were extracted from snap frozen samples of vagina, cervix, uterine body, ovary and oviduct. Data were analyzed using the proc mixed procedure of SAS version 9.1.3 (SAS Institute Inc., Cary, NC) followed by the Tukey-Kramer test as a multiple comparison test. As we previously reported, overall weight of the RT was dramatically decreased following TAM treatment ($P = 0.01$). Both estrogen receptor α (ERα) protein and gene expression were dramatically reduced in the uterus, cervix and vagina ($P < 0.01$). In oviduct, ERα protein was reduced in the TAM treated animals ($P < 0.01$) while ERα gene expression was not affected. Similarly, the phosphorylated form of ERα protein was reduced in the cervix and vagina ($P < 0.01$) and tended to be reduced in the uterus ($P = 0.09$) of the TAM group. In contrast to other RT tissues, phosphorylated ERα protein abundance was greater in the ovaries of the TAM animals ($P < 0.05$). Even though insulin-like growth factor-I (IGFI) gene expression was higher in the uterus, oviduct and vagina of the TAM group ($P < 0.01$), IGFI receptor protein and gene expression did not differ. Total mitogen-activated protein kinases (MAPK) protein was higher in the oviduct, vagina and ovary ($P < 0.01$) but was lower in the uterus of TAM treated heifers ($P < 0.01$). The phosphorylated form of MAPK protein was similarly increased in the ovary but was decreased in the cervix of the TAM group ($P < 0.05$). In conclusion, the bovine pre-pubertal RT is affected by TAM treatment. Further research is needed to determine if these effects have long-term consequences for reproductive performance.

Key Words: reproductive tract, tamoxifen, estrogen

453 Effects of label-dose permethrin administration on reproductive function and testicular histopathology in yearling bulls.

Tyler M. Dohlman*[1,2], Darin M. Madson[1], Patrick E. Phillips[1], Chris A. Clark[3], and Patrick J. Gunn[2], [1]*Veterinary and Diagnostic Production Animal Medicine, Iowa State University, Ames, IA,* [2]*Department of Animal Science, Iowa State University, Ames, IA,* [3]*Armstrong Research and Demonstration Farm, Iowa State University, Lewis, IA.*

The objective of this experiment was to study the effects of a commercial, pyrethroid-based pour-on product, permethrin, on reproductive parameters and testicular histopathology of yearling beef bulls. Black Angus bulls (n = 60; 369 ± 17 d of age; 509 ± 33 kg; 6.2 ± 0.5 BCS) were assigned to either (1) saline control (CON) or (2) permethrin pour-on administered at label dose (PYR). All bulls had blood samples collected and were subjected to an industry standard breeding soundness exam (BSE) via electroejaculation at both 5 d before and 14 d post-treatment. Progressive motility and Eosin-Nigrosin stained morphology were analyzed using high power magnification with phase contrast microscopy. Plasma testosterone concentrations were analyzed via RIA. At 34 d post-treatment, bulls were slaughtered and one testicle per bull was collected for histopathological examination. Categorical and continuous data were analyzed with the GLIMMIX and MIXED procedures of SAS, respectively. Change in motility between BSEs was not different due to treatment ($P = 0.69$). Although morphology improved across treatments between BSEs, PYR bulls had less improvement in percent of head ($P < 0.001$) and tailless sperm ($P = 0.05$) abnormalities compared with CON, resulting in less improvement of primary abnormalities ($P = 0.04$). Nonetheless, morphological differences did not change the overall outcome for satisfactory breeder status ($P = 0.82$). Change in testosterone concentration did not differ due to treatment ($P = 0.22$). Histopathological examination determined that testicular degeneration and tubule diameter did not differ as a result of treatment ($P \geq 0.19$). It should be noted, however, that degeneration score (higher score having more degeneration) was positively correlated with primary abnormalities ($P < 0.01$; $r = 0.35$) and negatively correlated with normal sperm cells ($P < 0.001$; $r = -0.43$). In summary, these data indicate that a single use of permethrin at label dose in yearling Angus bulls results in minimal detrimental effects on semen morphology, but not to a degree that affects the ability of bulls to pass a standard BSE.

Key Words: permethrin, breeding soundness exam (BSE), sperm

Ruminant Nutrition: Amino acids and metabolism

454 Energy requirements for pregnant and nonpregnant Nellore cows. Mateus P. Gionbelli*[1], Marcio S. Duarte[2], Sebastiao C. Valadares Filho[2], Edenio Detmann[2], Tathyane R. S. Gionbelli[1], Diego Zanetti[2], and Luiz H. P. Silva[2], *[1]University of Lavras, Lavras, Minas Gerais, Brazil, [2]University of Viçosa, Viçosa, Minas Gerais, Brazil.*

Forty-nine adult Nellore cows (32 pregnant and 17 nonpregnant) with average initial body weight of 451 ± 10 kg were used in a comparative slaughter study aiming to describe equations and relationships for prediction of net, metabolizable and dietary energy requirements for adult, pregnant and nonpregnant, *Bos indicus* cows. Feeding control was measured individually and cattle were fed either HIGH (ad libitum) or LOW (restricted feeding 1.2 times maintenance according to the NRC). The 32 pregnant cows were separated at random into 4 groups of 8 cows each (4 cows per each feeding level) and harvested at 136 ± 1, 189 ± 1, 239 ± 1 and 269 ± 1 d of pregnancy. The nonpregnant cows were harvested at different times of the experiment (85 to 216 d of feeding control) to keep them in experiment for a similar amount of time as the pregnant cows. The digestible energy and losses of energy as methane and urine were directly measured to establish the relations between GE, DE and ME. Energy content was analyzed in empty body and pregnant compounds. A set of relationships and equations based in the factorial method from ARC was used to estimate the nutrient requirements. The net energy requirement for pregnancy (NE_p) estimated in this study was about 3/4 of those estimated by NRC. When estimated by a logistic model, the daily requirements for pregnancy showed an exponential increase up to 250 d of gestation and then decreased. However, when an allometric model was used to estimate the daily requirements for pregnancy, the maximum daily requirements were at birth. There were no differences in the dynamics of energy ($P = 0.388$) in the cow's empty body weight pregnant free (EBW_{np}) suggesting that the pregnancy does not affect the requirements for accretion of body reserves in cows. The partial efficiencies for use of metabolizable energy for maintenance, weight gain and pregnancy (k_m, k_g and k_c) were respectively 70, 53 and 12%. The efficiency of transformation of DE in ME was 0.80.

Key Words: *Bos indicus*, conceptus, metabolizable energy

455 Rumen-protected methyl donors during the transition period: 1. Better postpartal performance in dairy cows supplemented with rumen-protected methionine (Smartamine M) than choline (ReaShure). Z. Zhou*[1], M. Vailati Riboni[1], E. Trevisi[2], J. K. Drackley[1], D. N. Luchini[3], and J. J. Loor[1], *[1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]Università Cattolica del Sacro Cuore, Piacenza, Italy, [3]Adisseo NA, Alpharetta, GA.*

The objective of this study was to evaluate the efficacy of supplemental rumen-protected methionine (MET) and choline (CHO) on performance and health of transition cows. Eighty-one multiparous Holstein cows were used in a randomized complete block design with 2 × 2 factorial arrangement of MET (Smartamine M, Adisseo NA) and CHO (ReaShure, Balchem Inc.) level (with or without). Treatments (20–21 cows each) were control (CON), no MET or CHO; CON+MET (SMA); CON+CHO (REA); and CON+MET+CHO (MIX). From −50 d to −21 d before expected calving, all cows received the same diet (1.24 Mcal/kg DM) with no MET or CHO. From −21 d to calving, cows received the same close up diet (1.54 Mcal/kg DM) and were assigned randomly to treatments (CON, SMA, REA, or MIX). From calving to 30 DIM, cows were on the same postpartal diet (1.69 Mcal/kg DM) and continued to receive the same treatments through 30 DIM. MET supplementation was adjusted daily at 0.08% DM of diet and REA was supplemented at 60 g/cow/d. No differences ($P = 0.34$ or greater) were detected for pre- or postpartal body weight and body condition score. However, MET supplementation (SMA, MIX) led to greater ($P < 0.05$) DMI compared with other treatments (CON, REA) in both close-up (14.40 vs. 13.13 kg/d, SEM 0.40) and first 30 d postpartum (19.30 vs. 17.15 kg/d, SEM 0.63). Milk yield in MET-supplemented cows (SMA, MIX) also was greater ($P < 0.05$) compared with other (CON, REA) treatments (44.32 vs. 40.32 kg/d, SEM 1.29). Milk fat % did not differ in response to MET ($P = 0.91$; 3.72% vs. 3.74%, SEM 0.11%) or CHO ($P = 0.46$; 3.78% vs. 3.68%, SEM 0.10%). However, milk protein % was greater in MET-supplemented ($P < 0.01$; 3.32% vs. 3.14%, SEM 0.05%) but not CHO-supplemented ($P = 0.23$; 3.27% vs. 3.19%, SEM 0.05%) cows. CHO led to greater ($P = 0.02$) blood glucose. No MET or CHO effects were detected for blood NEFA ($P = 0.56$ or greater) or BHBA ($P = 0.11$ or greater), but a MET × time effect ($P = 0.10$) was observed for NEFA due to lower concentrations on d 4. Results from the present study indicate peripartal supplementation of rumen-protected methionine has positive effects on cow performance.

Key Words: methionine, choline, transition cow

456 Rumen-protected methyl donors during the transition period. 2. Biomarkers of inflammation and oxidative stress reveal better liver and immune function in cows supplemented with rumen-protected methionine (Smartamine M) than choline (ReaShure). Z. Zhou*[1], M. Vailati Riboni[1], E. Trevisi[2], F. C. Cardoso[1], D. N. Luchini[3], and J. J. Loor[1], *[1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]Università Cattolica del Sacro Cuore, Piacenza, Italy, [3]Adisseo NA, Alpharetta, GA.*

The objective of this study was to evaluate the efficacy of supplemental rumen-protected methionine (MET) and choline (CHO) on alleviating inflammation and oxidative stress through their use for synthesis of antioxidants or other methyl-group requiring compounds. Forty-eight multiparous Holstein cows were used in a randomized complete block design with 2 × 2 factorial arrangement of MET (Smartamine M, Adisseo NA) and CHO (ReaShure, Balchem Inc.) level (with or without). Treatments (12 cows each) were control (CON), no MET or CHO; CON+MET (SMA); CON+CHO (REA); and CON+MET+CHO (MIX). From −50 d to −21 d before expected calving, all cows received the same diet (1.24 Mcal/kg DM) with no MET or CHO. From −21 d to calving, cows received the same close-up diet (1.54 Mcal/kg DM) and were assigned randomly to each treatment. From calving to 30 d, cows were on the same postpartal diet (1.69 Mcal/kg DM) and continued to receive the same treatments until 30 d. MET supplementation was adjusted daily at 0.08% DM of diet and CHO was supplemented at 60 g/cow/d. Blood was collected at −10, 4, 8, 20, and 30 d for profiling of 16 biomarkers. Neutrophil and monocyte phagocytosis and oxidative burst were assessed at d 1, 3, 7, 14, and 28 d. MET (SMA, MIX) led to greater ($P = 0.04$; 36.55 vs. 35.53 g/L, SEM 0.35) albumin, lower ($P = 0.08$; 0.35 vs. 0.47 g/L, SEM 0.05) haptoglobin, and greater ($P = 0.07$, 93.09 vs. 84.54 U/ml, SEM 3.20) paraoxonase (antioxidant) compared with other treatments. This suggests a more pronounced inflammatory state in cows without supplemental MET. MET-supplemented cows had greater ($P < 0.01$; 60.43 vs. 54.88%, SEM 1.65) neutrophil phagocytosis capacity. Both SMA and REA had greater ($P < 0.01$) monocyte (SMA, 26.93 vs. 16.96%, SEM 2.71; REA, 25.96 vs. 16.96%, SEM 2.52) and neutrophil (SMA, 59.19 vs. 43.32%, SEM 4.58; REA, 53.89 vs. 43.32%, SEM 4.25) oxidative burst activity compared with CON. Data suggest that supplementing rumen-protected methionine peripartal has positive effects on immune and liver function at least in part by reducing oxidative stress and inflammation.

Key Words: methionine, choline, inflammation

457 Rumen-protected methyl donors during the transition period: 3. Hepatic one-carbon metabolism flux in response to supplemental Smartamine M or ReaShure.

Z. Zhou*[1], T. A. Garrow[1], M. Vailati Riboni[1], F. C. Cardoso[1], D. N. Luchini[2], and J. J. Loor[1], [1]*University of Illinois at Urbana-Champaign, Urbana, IL,* [2]*Adisseo NA, Alpharetta, GA.*

Nutrients such as methionine (MET), choline (CHO), folate, and betaine are vital for provision of methyl groups required by various cellular pathways in tissues such as liver. In the context of dietary methyl-donors, the peripartal dairy cows are characterized by negative MET and CHO balance, both of which can play a role in allowing cows to achieve optimal performance while maintaining good health. Although studies of 1-carbon metabolism and MET cycle in ruminant liver already were performed in sheep, similar data are not available for high-producing Holstein dairy cows. Objectives were to measure activity of enzymes governing S-adenosyl MET formation (methionine adenosyltransferase 1), the transsulfuration pathway (Cystathionine β synthase), and endogenous synthesis of MET via CHO (betaine homocysteine S-methyltransferase, BHMT). Forty multiparous Holstein cows were used in a randomized complete block design with 2 × 2 factorial arrangement of MET and CHO level (with or without). Treatments (10 cows each) were control (CON), no MET or CHO; (SMA), CON+Smartamine M, Adisseo NA; (REA) CON+ReaShure, Balchem Inc.; and (MIX) CON+SMA+REA. From −50 d to −21 d before expected calving, all cows received the same diet (1.24 Mcal/kg DM) with no MET or CHO. From −21 d to calving, cows received the same close-up diet (1.54 Mcal/kg DM) and were assigned randomly to each treatment. From calving to 30 d, cows were on the same postpartal diet (1.69 Mcal/kg DM) and continued to receive the same treatments through 30 d. MET supplementation was adjusted daily at a rate of 0.08% (DM basis) of diet and CHO was supplemented at 60 g/cow/d. Liver samples were harvested at −10, 10, 20 and 30 d relative to calving. Compared with −10 d, liver BHMT activity increased ($P < 0.01$) by 2-fold postpartum regardless of treatment and remained high through at least 30 d. CHO supplementation had no affect ($P > 0.05$). Although no main effect of MET was detected ($P > 0.05$), a significant MET × Time interaction ($P < 0.01$) occurred due to higher BHMT activity in MET vs. CON cows on d 20. Data underscore the high demand for endogenous MET synthesis and increased flux through the MET cycle during early lactation.

Key Words: methionine, choline, betaine homecysteine S-methyltransferase (BHMT)

458 Supplemental Smartamine M in high-energy diets during the peripartal period improves production and hepatic biomarkers of oxidative status in Holstein cows.

Mario Vailati Riboni*[1], Johan S. Osorio[2], Erminio Trevisi[3], James K. Drackley[1], Daniel Luchini[4], and Juan J. Loor[1], [1]*University of Illinois at Urbana-Champaign, Urbana, IL,* [2]*Oregon State University, Corvallis, OR,* [3]*Università Cattolica del Sacro Cuore, Piacenza, Italy,* [4]*Adisseo S.A.S., Alpharetta, GA.*

Feeding higher-energy prepartum is a common practice in the dairy industry. However, recent data underscore how it could reduce performance, deepen negative energy balance, and augment inflammation and oxidative stress in fresh cows. We tested the effectiveness of rumen-protected methionine in preventing the negative effect of feeding high-energy prepartum. Twenty-one multiparous Holstein cows were fed a controlled-energy diet (CON, n = 7; 1.24 Mcal/kg DM; high-straw) during the whole dry period (~50 d), or switched to a higher-energy (OVE, n = 7; 1.54 Mcal/kg DM), or OVE plus Smartamine M® (OVE+SM, n = 7; Adisseo NA) during the last 21 d before calving. Afterward cows received the same lactation diet (1.75 Mcal/kg DM). Smartamine M was top-dressed on the OVE diet (0.07% of DM) from −21 through 30 d in milk (DIM). Liver samples were obtained via percutaneous biopsy at −10, 7 and 21 DIM. Expression of genes associated with energy and lipid metabolism, hepatokines, methionine cycle, antioxidant capacity and inflammation was measured. Although prepartal dry matter intake (DMI) was not affected ($P = 0.21$) by diet, it was lower ($P < 0.005$) in OVE than CON and OVE+SM. Milk yield and ECM were lower ($P < 0.10$) in OVE than CON and OVE+SM. Milk protein and fat percentages were lower ($P < 0.05$) in CON and OVE compared with OVE+SM. Feeding OVE compared with CON led to lower ($P < 0.05$) *PCK1* and *PPARA*. At 7 DIM, *GSR* was greater ($P < 0.05$) in OVE than CON-fed cows, suggesting a greater antioxidant demand. Feeding OVE+SM resulted in similar expression of *GSR* compared with CON. Expression of *SAHH*, *STAT5B* and *MTR* was greater ($P < 0.05$) prepartum in OVE+SM compared with both CON and OVE, and at 7 DIM ($P < 0.05$) for CON and OVE+SM compared with OVE. *FGF21* was lower ($P < 0.05$) prepartum in OVE than CON and OVE+SM, and increased ($P < 0.05$) postpartum only in OVE. Expression of *DMT3A* was greater ($P < 0.05$) in OVE and OVE+SM, while *MTTP* was lower in OVE+SM than CON or OVE. Data suggest, supplemental Smartamine M was able to compensate the negative effect of prepartal energy-overfeeding by increasing production and alleviating the demand for intracellular antioxidants.

Key Words: methionine, transition period, nutrigenomics

459 Effect of strategic ration balancing with use of Prolak, MetaboLys, and Smartamine M on the efficiency of milk protein production and environmental impact in primiparous cows.

Yanting Chen*[1], Joe Harrison[1], Pius Ndegwa[1], Deb Wilks[2], Lynn VanWieringen[1], and John Azzone[3], [1]*Washington State University, Puyallup, WA,* [2]*EPL Feeds, Lynden, WA,* [3]*H J Baker, Fayetteville, PA.*

The objective of this study was to evaluate the effect of reduced CP on milk production and environmental impact in a commercial dairy herd. Primiparous cows were completely randomized to 2 groups with 84 cows each, and each group had similar DIM (181 ± 7.14 vs. 195 ± 7.85) before initiation of the study. The control diet was the current general herd ration. The reformulated diet was supplemented with Prolak, MetaboLys and Smartamine M, reduced the dietary CP (17.7 ± 0.65 vs. 16.7 ± 0.7% DM), and increased methionine (1.8 vs. 2.2% MP) and lysine (6.6 vs. 6.9% MP) concentrations. Diets were fed in a 6-wk switch back design trial with 2 periods. DMI was recorded daily (1 pen per treatment), and milk yield and composition of individual cows were measured weekly. Urine and feces samples were mixed together and used in a closed chamber incubation to determine NH_3 emission. Feeding the reformulated diet numerically decreased DMI 0.4 kg (19.3 ± 0.49 vs. 18.9 ± 0.58 kg), however milk yield ($P = 0.91$), protein yield ($P = 0.74$), % protein ($P = 0.49$), fat yield ($P = 0.19$), % fat ($P = 0.09$), and lactose yield ($P = 0.28$) did not differ. Lactose % and MUN ($P < 0.001$) decreased when cows were fed the reformulated diet. Cows fed the reformulated diet had higher Met ($P = 0.09$) and less Tyr ($P = 0.06$) in blood plasma than control cows. Feeding the reformulated diet numerically increased feed efficiency (1.62 vs. 1.66 ± 0.01) and milk true protein efficiency (28.4 vs. 30.8 ± 0.01%). Cows fed the reformulated diet consumed 7.2% less N, produced 0.6% more milk total N, excreted 9.9% less predicted urinary N and 18.0% less calculated fecal N than control cows. The difference in income over feed cost for the reformulated diet was \$0.15 and \$0.18 based on the milk price of Washington State in 2013 and 2014, respectively. The emitted NH_3 flux rates of manure were numerically similar (122.6 ± 10.26 vs. 124.1 ± 11.99 $mg \cdot h^{-1} \cdot m^{-2}$) between diets. These results illustrated that feeding low CP with balanced AA diet could improve the efficiency of nitrogen utilization and reduce the environmental impact without compromising the profitability of milk production in primiparous cows.

Key Words: bypass lysine, methionine, milk production

460 Sodium salicylate alters ruminal digestion in vitro and in situ. Abigail J. Carpenter*, Claudio F. Vargas-Rodriguez, Jacob A. B. Jantz, and Barry J. Bradford, *Kansas State University, Manhattan, KS.*

Although sodium salicylate (SS) administration after calving increases 305-d milk production, it is associated with hypoglycemia in some circumstances. We hypothesized that this may be in part due to decreased glucogenic substrate supply from fermentation. Six heifers were drenched once daily for 3 d with either 62.5 g of SS in water (SS) or an equal volume of water (CON). A series of batch cultures were performed the day before the start of treatment and 1, 13, and 35 d following. Strained fluid from each heifer was combined in a 2:1 ratio with McDougall's buffer, and 150 mL of the inoculum was added to each flask (n = 4/heifer) with 2.5 g substrate. Gas production was measured with the ANKOM^{RF} Gas Production System. Following each rumen fluid collection, Dacron bags containing approximately 1 g of substrate DM were inserted into the rumen of each heifer in duplicate at 2, 8, 16, 24, and 48 h time points to estimate rate of DMD. The 48-h time point was used to estimate rumen-undigested substrate. Measurements from the pre-treatment batch culture and in situ experiments were used as covariates for statistical analysis but were removed from the model if they were not significant ($P > 0.05$). Overall, there was no effect of treatment on batch culture final pH across time ($P = 0.70$), although dry matter disappearance (DMD) was decreased across time due to treatment ($P < 0.01$; treatment × day: $P = 0.01$). One day following treatment, SS had no effect on DMD ($P = 0.70$); however, DMD was decreased ($P < 0.01$) in batch culture 13 d after SS treatment (45.0 vs. 38.9 ± 0.9% of DM for CON vs. SS, respectively), and it remained lesser for the SS treatment 35 d after the end of treatment ($P < 0.01$, 44.0% vs. 40.3 ± 0.9% of DM for CON vs. SS, respectively). No differences were observed due to treatment for volume, rate, or lag in gas production ($P \geq 0.60$). For the in situ experiment, no differences were detected in any 48-h time points ($P \geq 0.17$). Treatment with SS tended to decrease DMD rate ($P = 0.10$; treatment × day: $P = 0.50$). Given the sustained effect of SS drenches on in vitro DMD, it is likely that SS modifies the rumen microbiota to impair ruminal digestion.

Key Words: salicylate, fermentation, rumen modification

461 Effect of rumen acidosis and short-term feed restriction on short-chain fatty acid concentrations and permeability of the bovine gastrointestinal tract. Rae-Leigh A. Pederzolli*[1], Steve Hendrick[2], John Campbell[1], Katie M. Wood[1], and Gregory B. Penner[1], *[1]University of Saskatchewan, Saskatoon, Saskatchewan, Canada, [2]Coaldale Veterinary Clinic, Lethbridge, Alberta, Canada.*

The objective of this study was to identify whether ruminal acidosis (RA) or feed restriction (FR) differentially affect permeability of the gastrointestinal tract (GIT). Twenty-one Holstein steers were randomly assigned to 1 of 3 treatments: control (CON); ruminal acidosis (ACID), and feed restriction (REST). Steers were fed a common diet with a 50:50 F:C ratio once daily at 0800 h for a 5-d baseline period followed by a challenge period. Rumen acidosis was induced by restricting feed to 25% DMI for 1 d and then offering pelleted barley (30% DMI:BW) the next day. Steers on the REST treatment were restricted to 25% DMI for 5 d. Steers were killed and tissues were collected from the rumen, omasum, duodenum, jejunum, ileum, cecum, and proximal and distal colon for measurement of ^{14}C-mannitol and ^{3}H-inulin flux in Ussing chambers as markers for gut permeability. Data were analyzed as a randomized complete block design using Proc Mixed. Rumen pH was recorded throughout the study. During baseline, there were no differences for DMI or rumen pH (7.1 kg/d and 6.53, respectively; $P > 0.1$), but DMI and pH during the challenge were 1.7 kg/d and 6.94, and 7.9 kg/d and 5.86 for REST and ACID calves, respectively. The proportion of acetate in the proximal colon from CON (56.8%) was greater (treatment × region, $P = 0.01$) than for FR (31.0%) and ACID (31.0%). Butyrate concentration was less in the proximal colon of CON (16.0%; interaction $P < 0.01$) than ACID (31.0%). There were no region × treatment interactions or treatment effects ($P > 0.10$) for inulin or mannitol flux. However, inulin flux ($nmol/(cm^2 \times h)$) was greater ($P < 0.01$) in rumen (21.1), omasum (26.9), and duodenum (21.3) than ileum (4.2), cecum (7.5), and distal colon (2.4). Mannitol flux ($nmol/(cm^2 \times h)$) was greatest ($P < 0.01$) in rumen (36.9), duodenum (59.5), jejunum (48.2), and proximal (41.4) and distal colon (33.0) relative to ileum (13.0). These data indicate that feed restriction and ruminal acidosis do not appear to differentially affect permeability of the GIT. The duodenum and rumen are likely regions with greatest permeability.

Key Words: acidosis, feed restriction, permeability

462 Effect of gluconeogenic precursors on blood metabolites and milk yield in Chilean transition Holstein cattle. Pedro Melendez*[1], Katherine Severino[2], Maria P. Marin[2], Patrick Pithua[1], and Pablo Pinedo[4,5], *[1]Department of Veterinary Medicine and Surgery, College of Veterinary Medicine, University of Missouri-Columbia, Columbia, MO, [2]College of Veterinary Medicine, University Santo Tomas, Viña del Mar, Chile, [3]3Department of Animal Sciences, College of Veterinary Medicine, University of Chile, Santiago, Chile, [4]Texas A&M AgriLife Research, Amarillo, TX, [5]5Department of Veterinary Pathobiology, College of Veterinary Medicine & Biomedical Sciences, Texas A&M University System, College Station, TX.*

The objective of this study was to determine the effect of feeding a gluconeogenic precursor containing calcium propionate, propylene glycol, and glycerol on serum concentrations of β-hydroxybutyrate (BHBA), nonesterified fatty acids (NEFA), and milk yield in transition Holstein cows under Chilean conditions. The study was conducted in a commercial dairy farm located in central Chile. Cows were housed in a freestall system with headlocks, milked 3 times per day and fed a total mixed ration containing alfalfa hay, corn silage, and concentrate to meet or exceed the requirements proposed by the National Research Council (2001). At 21 d before expected parturition 40 multiparous cows were assigned at random to either a control or a treated group to achieve at least 15 cows per group at 30 DIM. The cows in the control group received the default periparturient TMR diet. Cows in the treatment group received 300 g of a supplement containing 70 g of calcium propionate, 95 g of propylene glycol and 330 g of glycerol top dressed on the TMR during morning feedings when cows were head-locked. This feeding protocol was continued into the postpartum period until 30 d in milk. Seventeen and 18 cows completed the protocol in the control and the treatment group, respectively. Blood samples were collected at calving for NEFA quantitation and later at 7, 14 and 21 d postpartum for BHBA determination. The average daily milk yield up to 60-d of lactation was significantly higher (2 kg per day) in the treated than the control group ($P < 0.05$). NEFA (mEq/L) at calving were higher in the control (0.75 ± 0.1) than the treated group (0.55 ± 0.1; $P < 0.05$). The concentration of serum BHBA at 14 d postpartum was lower in control (0.60 ± 0.11 mmol/L) than treated cows (0.98 ± 0.11 mmol/L; $P < 0.05$). In conclusion, supplementing the default diet with gluconeogenic precursors during the pre- and postpartum period improved milk yield during the first 60 d of lactation and maintained a moderated metabolic energy status in Chilean dairy cattle.

Key Words: transition cow, metabolite, dairy cattle

463 Expression of G-protein coupled fatty acid receptors during the transition period.

Alea Agrawal*, Johan S. Osorio, and Juan J. Loor, *University of Illinois at Urbana-Champaign, Urbana, IL.*

G-protein coupled receptors (GPR) have been widely studied within human medicine as drug targets for metabolic disorders. They play central roles in many cell signaling processes, and also have application within dairy nutrition as targets for specific dietary components; for example, omega-3 fatty acids. To combat metabolic disorders prevalent in dairy cows during the transition period, which often co-occur with negative energy balance and lipid mobilization, it may be helpful to identify locations, activities, and roles of free fatty acid receptors (FFAR) and other members of the GPR family. To provide insight on tissue-specific differences in gene expression, and therefore, potential downstream pathways of fatty acid-sensing GPR in bovine, quantitative RT-PCR (qPCR) of subcutaneous adipose, liver, and polymorphonuclear leukocyte (PMN) samples during the transition period (−15, +10, and +30 d) were used for expression profiling of medium- (MCFA) and long-chain fatty acid (LCFA) receptors *GPR120* and *GPR40*, MCFA receptor *GPR84*, and niacin receptor *GPR109A*. Results were analyzed in SAS to examine differences in expression over time ($P < 0.05$). In adipose tissue, *GPR120* expression was highest at −15 d, decreased at +10 d, and further decreased at +30 d. *GPR40* expression was highest at +10 d relative to other time points, and *GPR109A* expression was lower prepartum than both postpartum time points. *GPR84* was undetectable. In liver tissue, *GPR84* and *GPR109A* were nearly undetectable and did not differ ($P > 0.05$) across time. *GPR40* had lower expression at +30 d than −15 or +10 d. *GPR120* was undetectable. In PMN, *GPR120* expression was increased between +10 and +30 d but neither were significantly different from −15 d. *GPR84* expression was higher at +10 d relative to other time points. Neither *GPR40* nor *GPR109A* were altered in PMN. The data suggest that there is likely not a direct role for the selected GPR in the liver during the transition period, but they do play variable roles in adipose and PMN. Dietary supplementation or exclusion of LCFA and/or niacin may provide a method of regulating GPR function during the prepartal or early postpartal periods.

Key Words: transition cow, fatty acid, G-protein coupled receptor (GPR)

464 Effects of prepartal dietary intake and calving on blood neutrophil transcriptome in Holstein cows.

Alea Agrawal*, Muhammad J. Khan, Daniel E. Graugnard, Sandra L. Rodriguez-Zas, and Juan J. Loor, *University of Illinois at Urbana-Champaign, Urbana, IL.*

In the dairy industry, cow health and farmer profits depend on the balance between diet (i.e., nutrient composition, daily intake) and metabolism. This is especially true during the transition period, where dramatic physiological changes foster vulnerability to immunosuppression, negative energy balance, and clinical and subclinical disorders. Using an Agilent microarray platform, the present study examined changes in the transcriptome of bovine PMNL, a representative cell of the immune system, due to time relative to parturition, prepartal dietary intake, or the combination. Sixteen Holstein cows were fed a high-straw, control diet (S; NEL = 1.34 Mcal/kg) or overfed a moderate-energy diet (M; NEL = 1.62 Mcal/kg) during the dry period. Blood for PMNL isolation and metabolite analysis was collected at −14 and +7 d relative to parturition. At an ANOVA false discovery rate (FDR) < 0.05, time (7 vs. −14 d) significantly influenced expression of 1758 genes, energy intake (M vs. S) influenced 3062 genes, and the interaction had an effect on 1673 genes. Dynamic Impact Approach (DIA) bioinformatics analysis classified effects on KEGG pathways, including: activated carbohydrate metabolism due to time and interactions, and activated amino acid (AA) biosynthesis and ribosome activity with dietary treatment. In contrast, DIA analysis revealed inhibition of riboflavin and fatty acid (FA) metabolism, unsaturated FA synthesis, and calcium reabsorption due to energy intake. These analyses suggest that processes critical for energy metabolism and immune function (e.g., calcium reabsorption, FA and vitamin metabolism, and AA synthesis) were affected by energy overfeeding with mixed results, but overall, strong effects from either main effect were mitigated by the interactions. Ingenuity Pathway Analysis (IPA) of genes significantly affected at an FDR <0.10 also revealed 50 upstream regulators for each main effect and interaction comparison. The widespread, transcriptome-level changes captured here confirm the importance of dietary energy adjustments around calving on the immune system.

Key Words: transition cow, PMNL, intake

465 A cow mammary epithelial cell-free system based on crude lysosomes and cytosol proteins: Leucine activating mTOR at Ser2448.

Wen-ting Dai[1,2], Nan Zheng[1,3], and Jia-qi Wang*[1,3], [1]*Ministry of Agriculture Laboratory of Quality & Safety Risk Assessment for Dairy Products, Beijing, China,* [2]*Jilin University, Changchun, China,* [3]*Ministry of Agriculture-Milk and Dairy Product Inspection Center, Beijing, China.*

Essential amino acids, especially leucine, initiated the signaling of the mammalian target of rapamycin complex-1 (mTORC1) and protein synthesis in cow mammary epithelial cells (CMEC). CMEC-H is an immortalized cow mammary epithelial cell line. We established a cell-free system, which was based on crude lysosomes and cytosol proteins from CMEC-H. By trypan blue dye exclusion assay, we found passing through gauge-26 needle was a good cell lysis method of CMEC-H. Crude lysosomes were extracted by lysosome isolation kit and cytosol proteins (supernatant-100) were obtained by ultracentrifugation at 1×10^5 *g* about 1 h Supernatants 100, which contained all the cytosolic soluble proteins, were identified by SDS-PAGE. Raptor, mTOR and mLST8, the essential components of mTORC1, played a vital role in regulating protein synthesis; Lamp2 represented lysosome. All these proteins were testified by western blots. The constructed cell-free model stimulated by 1× essential amino acids was regarded as positive control,

the cell-free model stimulated by no amino acids was regarded as negative control, and the cell-free model stimulated by 1× leucine was seen as the treatment group. The cell-free models stimulated by 1× leucine readded 20 nmol rapamycin and stimulated by 1× essential amino acids readded 20 nmol rapamycin were both regarded as the corresponding inhibition groups. The results showed that the model can partially duplicate aspects of amino acids signaling mTOR program in vitro; the addition of 1× leucine solely and 1× essential amino acids led mTOR to be activated, phosphorylated and then moved towards the crude lysosome fractions in the cell-free system. However, combined with 1× leucine or 1× essential amino acids, 20 nmol rapamycin was not able to completely prevent mTOR from being phosphorylated. This study may provide some directions for further construction of cell-free system duplicating amino acid signaling mTOR. Furthermore, the method may be applied to cell-free models of other cell lines.

Key Words: cell-free system, crude lysosomes, leucine

Ruminant Nutrition: Dairy

466 Effects of including supplemental fat in low and high starch diets on milk production and energy partitioning.

Joshua L. Garver*, Jonas De Souza, Michael J. VandeHaar, and Adam L. Lock, *Michigan State University, East Lansing, MI.*

Effects of low or high starch diets with or without supplemental fat on the yield of milk and milk components and energy partitioning were evaluated. Thirty-two Holstein cows (172 ± 35 DIM) were assigned randomly to treatment sequence in replicated 4 × 4 Latin squares with a 2 × 2 factorial arrangement of treatments. Treatment diets contained 16% (LS) or 32% (HS) starch and 0.0% (LF) or 1.5% (HF) palmitic acid-enriched fat supplement (BergaFat F-100). Dietary starch was altered by varying the proportion of ground corn, cottonseed, and soyhulls, with LS and HS diets containing 17 and 21% forage NDF and 42 and 29% NDF, respectively. Treatment periods were 21 d in length with the final 5 d used for data and sample collection. The statistical model included the random effects of cow and period and the fixed effects of dietary starch level, fat supplementation, and their interaction. Compared with LF, the HF treatment increased DMI in the LS diet (26.8 vs. 25.8. kg/d) and decreased DMI in the HS diet (25.9 vs. 26.5 kg/d; interaction $P < 0.01$). The HF treatment increased milk fat yield in the LS diet (1.57 vs. 1.51 kg/d) but not in the HS diet (1.49 vs. 1.51 kg/d; interaction $P = 0.06$). Compared with LF, the HF treatment also increased milk protein concentration and yield in the LS diet (3.40 vs. 3.35% and 1.31 vs. 1.26 kg/d), but not in the HS diet (interaction $P = 0.10$ and $P < 0.05$, respectively). There was no effect of treatments on milk fat and lactose concentrations or lactose yield. Compared with LF, the HF treatment increased 3.5% FCM (42.2 vs. 41.0 kg/d) in the LS diet but not in the HS diet (40.4 vs. 41.1 kg/d; interaction $P = 0.07$). Similarly, the HF treatment increased ECM (42.3 vs. 41.0 kg/d) in the LS diet but not in the HS diet (40.5 vs. 41.2 kg/d; interaction $P < 0.05$). The milk to feed ratio (ECM/DMI) was not affected by treatments. There was a trend for HS diets to increase change in BCS compared with LS diets ($P = 0.08$). However, fat supplementation did not affect change in BCS. Results demonstrate that under the dietary conditions tested, a palmitic acid-enriched fat supplement fed to mid and late lactation dairy cows maximized yield of milk and milk components when fed in a low starch diet.

Key Words: body condition, milk fat, palmitic acid

467 Effect of breed, energy level of diet, and lactation stage on the evolution of milk lipolysis in dairy cow.

Elise Vanbergue*[1,2], Luc Delaby[1], Ségolène Colette[3], Yves Gallard[3], and Catherine Hurtaud[1], [1]*INRA-Agrocampus Ouest UMR1348 Pegase, Saint-Gilles, France,* [2]*Institut de l'Elevage, Le Rheu, France,* [3]*INRA, Domaine du Pin-au-Haras, Exmes, France.*

Spontaneous lipolysis is the result of the activity of a native milk enzyme, the lipoprotein lipase. Lipolysis leads to a release of free fatty acids (FFA) that cause rancid flavor in milk products. A trial was carried out to study the effects of breed, energy levels, and lactation stage on milk spontaneous lipolysis in dairy cows. Sixty-four cows were used through a year of lactation. Cows were divided into 4 homogenous groups according to their breed [Holstein (HO) or Normande (NO)] and to their feeding system: the intensive system, with a high energy diet (HED) (in winter, corn silage with 30% concentrate; otherwise, pasture with 4 kg/d of concentrate) and the grass system (GS) (in winter, conserved grass with no concentrate; otherwise, pasture with no concentrate). The period of calving was synchronized between January and March. Individual milk samples were collected every month from both morning and evening milkings. The FFA levels were determined by the difference between the FFA levels after milking and the FFA after 24 h of storage at 4°C. Data were analyzed using SAS mixed procedure. We showed that FFA levels were higher in the evening milks (0.45 vs. 0.25 mEq/100 g of fat, $P < 0.001$) and that evening milks were more susceptible to lipolysis variations. HO cows were more susceptible to lipolysis than NO (0.34 vs. 0.20 mEq/100 g of fat, in morning milks; 0.62 vs. 0.33 mEq/100 g of fat in evenings milks, $P < 0.001$). There was no effect of the feeding system on morning milks lipolysis but GS had a tendency to increase milk lipolysis in evening milks (0.41 vs. 0.55 mEq/100 g of fat, $P = 0.06$). Lipolysis was higher in early and late lactation stage, particularly in the GS group. Conserved grass may also affect the lipolysis rate. The energy status in early and late lactation stage is frequently negative so the cows may be more susceptible to a low energy diet. No correlation was found between lipolysis and milk fat content. Poor correlations ($r < 0.4$, $P < 0.001$) were found between lipolysis and milk production, fat globule size, proportion of fatty acid and protein composition, body condition and weight.

Key Words: spontaneous milk lipolysis, production factors

468 Direct and indirect transfer of omega-3 fatty acids to milk fat in dairy cows.

Natalie L. Urrutia*, Jackie Y. Ying, Samantha R. McKinney, Michael H. Green, and Kevin J. Harvatine, *The Pennsylvania State University, University Park, PA.*

Transfer of dietary fatty acids (FA) to milk has been proposed to fit a 2-pool model with a fast pool representing direct transfer by chylomicrons and a slow pool representing indirect transfer through tissue recycling. The objective of this experiment was to quantify direct and indirect transfer of omega-3 (n-3) FA to milk after an abomasal bolus infusion of n-3 FA. Ten ruminally cannulated multiparous Holstein cows (247 ± 113 DIM; mean ± SD) were used in a crossover design with 7 d periods. Cows were milked 4 times daily (6 h intervals) starting 2 d before initiation of the experiment. Treatments were abomasal infusion of 120 g (infused over 1 h) of a free FA mixture enriched in α-linolenic acid (18:3 n-3; EALA) or in very long chain n-3 (>18C n-3; EVLC). The EALA and EVLC treatments provided 80.2 g and 87.6 g of n-3 FA, respectively. Milk was sampled at each milking for determination of milk fat yield and FA profile. The day before bolus infusion was used as a baseline. Total transfer of n-3 FA was analyzed in a model that included random effects of cow nested in sequence, sequence and period and fixed effect of treatment and milk yield (JMP Pro). Time course data was analyzed as repeated measures in SAS and resulting least squares means were fit to a double exponential decay function by nonlinear curve fitting (JMP Pro). Total transfer of n-3 FA to milk differed between treatments ($P < 0.001$) and was 48.2 and 32.7% of the bolus for EALA and EVLC, respectively. Milk n-3 FA concentration and yield peaked at 12 h and returned to baseline at 138 h post infusion in both treatments. Time course of n-3 FA transferred to milk fit a biexponential model ($R^2 = 0.99$). The area (% of total) under the first exponential representing direct transfer was 83.9 and 42.2% and the second exponential representing indirect transfer was 16.1 and 57.8% of the total n-3 FA transferred for EALA and EVLC, respectively. In conclusion, n-3 FA differed greatly in their transfer efficiency mainly due to differences in their direct transfer rates. These differences presumably occur due to trafficking of very long chain n-3 FA into plasma lipid pools unavailable to the mammary gland.

Key Words: omega-3, milk fat

469 2-Hydroxy-4-(methylthio)butanoate (HMTBa) supplementation increases milk fat and decreases synthesis of alternate biohydrogenation intermediates in diets with risk for milk fat depression.

Michel Baldin*[1], Yun Ying[1], Geoff I. Zanton[2], Heather A. Tucker[2], Mercedes Vazquez-Anon[2], and Kevin J. Harvatine[1], *[1]Penn State University, University Park, PA, [2]Novus International Inc., St. Charles, MO.*

We recently reported that supplementation of 2-hydroxy-4-(methylthio) butanoate (HMTBa) reduced the shift to the alternate biohydrogenation pathway and maintained higher milk fat yield in high producing cows fed diets lower in fiber and higher in unsaturated fatty acids (FA). The objective of this experiment was to verify the effect of HMTBa (Alimet, Novus International, Inc., St. Charles, MO) on biohydrogenation intermediates and milk fat synthesis. Twenty-two rumen cannulated high-producing Holstein cows [168 ± 66 DIM; 42 ± 7 kg milk/d (Mean ± SD)] were used in a randomized design performed in 2 blocks (1 = 14 cows, 2 = 8 cows). Treatments were control (corn carrier) and HMTBa (0.1% of diet DM). The experiment included a 7-d covariate period followed by 3 phases that fed diets with increasing risk of milk fat depression (MFD). The diet during the covariate and low-risk phase (7 d) was 32% NDF with no additional oil. The diet during the moderate-risk phase (17 d) was 29% NDF with 0.75% soybean oil. Soybean oil was increased to 1.5% for the last 4 d. Milk yield and DMI were measured daily. Milk was sampled every 7 d and analyzed for fat, protein and FA profile. Data were analyzed using PROC Mixed with repeated measures and the effect of treatment was tested at each time point. There was no effect of block or interaction of block and other fixed effects. There was no overall effect of treatment or treatment by time interaction for DMI ($P = 0.4$), milk yield ($P = 0.4$), and milk protein concentration ($P = 0.9$) and yield ($P = 0.6$). There was an effect of treatment, but no treatment by dietary phase interaction on milk fat with HMTBa increasing milk fat percent (3.2 vs. 3.6%, $P < 0.01$) and yield (1342 vs. 1543 g/d, $P = 0.02$). Additionally, HMTBa decreased the concentration (1.29 vs. 0.81 g/100 g of total FA, $P = 0.02$) and yield (14.7 vs. 10.9 g/d, $P = 0.01$) of *trans*-10 18:1 in milk across the entire feeding period. In conclusion, HMTBa prevented the increase in *trans* FA associated with MFD and maintained milk fat yield when cows were fed a diet with moderate risk of diet-induced MFD.

Key Words: 2-hydroxy-4-(methylthio)butanoate (HMTBa), milk fat

470 Meta-analysis of the effect of plant oils rich in 18:2n-6 on milk fatty acid composition in lactating dairy cows.

Mina Vazirigohar*, Mehdi Dehghan-Banadaky, Kamran Rezayazdi, and Ardeshir Nejati-Javaremi, *Department of Animal Science, Campus of Agriculture and Natural Resources, University of Tehran, Karaj, Alborz, Iran.*

The objective of this study was to evaluate the effect of dietary plant oils rich in 18:2n-6 (POLA; including safflower, sunflower, corn, soybean and cottonseed oils) on milk fatty acid (FA) profile in lactating dairy cows, using meta-analysis and meta-regression methods. A total of 20 studies were identified with 27 comparisons between treatment and control groups, which met the selection criteria and included in the analysis. Two levels of POLA supplement (less and more than 30 g/kg diet DM) were evaluated in this meta-analysis. Supplementation of cows with 20 g POLA/kg diet DM reduced milk fat 6:0–16:0, enhanced 18:0, *cis* (Δ9–12, and 15) and *trans* 18:1 (Δ6−14), 18:2n-6, *cis*-9,*trans*-11 CLA and *trans*-10,*cis*-12 CLA concentrations. The weighted mean differences for milk fat content of 16:0, *cis*-9 18:1, 18:2n-6 and *cis*-9,*trans*-11 CLA were –5.687 (95% confidence interval (CI) = –7.558 to –3.816), 3.194 (95% CI = 1.139 to 5.249), 0.810 (95% CI = 0.384 to 1.236) and 0.467 g/100 g total FA (95% CI = 0.281 to 0.653), respectively. Inclusion of 20 g/kg DM POLA had no effect on milk 4:0 and 18:3n-3 concentrations. Results of meta-regression showed that dietary 18:2n-6 content explained more than 55% of the variation in 8:0–15:0 results. Dietary FA content, amount of grain in the basal diets and parity were the sources of heterogeneity for milk *cis*-9 18:1. Milk *trans*-11 18:1 increased with increased dietary 18:2n-6 content and forage level of basal diets. Estimated effect size of milk 18:2n-6, *trans*-10,*cis*-12 CLA and 18:0 were greater in safflower > sunflower > corn > soybean and > cottonseed oils. In conclusion, feeding 20 g POLA/kg diet DM lowered milk fat 16:0, increased *cis*-9 18:1, 18:2n-6, *cis*-9,*trans*-18 CLA, without any changes on 4:0 and 18:3n-3.

Key Words: meta-analysis, milk fatty acid, plant oil

471 Prediction of blood nonesterified fatty acid (NEFA) by FTIR analysis of individual cow milk samples.

David M. Barbano*[1], Patrick Cree[3], Tom R. Overton[1], Heather M. Dann[2], and Rick J. Grant[2], *[1]Cornell University, Ithaca, NY, [2]William H. Miner Agricultural Institute, Chazy, NY, [3]Delta Instruments, Drachten, the Netherlands.*

Our objective was to develop and validate a Fourier transform mid-IR-based milk analysis method to estimate blood NEFA concentrations in lactating dairy cows. High blood NEFA indicates that a cow is mobilizing body fat and increases the risk of metabolic disorders. Milk and blood samples were collected from 60 lactating Holsteins once per week for the first 3 weeks of lactation. Cows were milked 3 times per day. Within + or – one milking of the time of blood collection, a milk sample was analyzed using a Delta Instruments (model FTA) mid-IR milk analyzer. A Wako NEFA HR test kit was used as an in vitro enzymatic colorimetric method for the quantitation of NEFA in blood serum and these values were used as reference values for development of a partial least squares (PLS) regression model to predict blood NEFA from the mid-IR milk spectra. There are no NEFA in milk, so a model to predict blood NEFA from a milk sample uses differences in the milk spectra from sample to sample that are correlated with changes in blood NEFA. The final PLS model had 9 factors, used wavelengths in the following ranges (3000 to 2800, 1800 to 1700, 1585 to 1000 cm^{-1}) with a standard error of cross validation of 172 μEq/L. Validation milk and blood sample pairs (n = 53) were collected from Holstein cows from a different herd. The mean value for the blood reference test was 713 μEq/L of serum and the mean value for the milk based blood NEFA prediction was 703 μEq/L of serum with a standard deviation of the difference (SDD) of 218 μEq/L for the 53 validation samples. Blood NEFA measured on blood is a snapshot of the NEFA concentration at an instant in time, while blood NEFA predicted from milk analysis represents a time average for the total time between milkings. The FTIR milk analysis to estimate blood NEFA is rapid (about 10 s), done simultaneously with all other milk component measures, and uses no reagents. This approach could be useful for rapid evaluation of risks of ketosis and reproductive disorders.

Key Words: blood NEFA, FTIR, milk analysis

472 Increased NEFA availability promotes plasma ceramide accumulation in Holstein cows. J. Eduardo Rico[1], Luciano S. Caixeta[2], Yves R. Boisclair[2], and Joseph W. McFadden*[1], *[1]West Virginia University, Morgantown, WV, [2]Cornell University, Ithaca, NY.*

An increase in plasma NEFA can impair insulin sensitivity in dairy cows by unknown mechanisms. In monogastrics, excess saturated fatty acids can upregulate the hepatic synthesis and secretion of ceramide, a sphingolipid that inhibits insulin action in muscle and adipose tissue. Our objective was to determine whether an increase in plasma NEFA can augment ceramide levels in cows. Six nonpregnant, nonlactating Holstein dairy cows (682 kg ± 22), were used in a crossover design with treatments consisting of i.v. infusion (100 mL/h) of either saline (control) or triacylglycerol (TG) emulsion (Intralipid 20%; Frasenius Kabi) for 16 consecutive hours. The feeding level was set at 120% of estimated energy requirement with meals offered every 2 h. Blood was collected at regular intervals and liver was biopsied at 16 h. LC/MS was used to profile 25 ceramides (Cer), monohexosylceramides (GlcCer), and lactosylceramides (LacCer) in plasma. Data were analyzed using a mixed model with repeated measures (fixed effects of treatment and time). Nonparametric correlations were analyzed. TG infusion increased plasma NEFA by 454% at 3 h relative to control ($P < 0.01$) with no further increase at 16 h. Liver TG were elevated 321% in TG vs control by end of TG infusion ($P < 0.01$). Before infusion, C24:0-Cer, C24:0-GlcCer, and C16:0-LacCer represented 52, 47, and 83%, respectively, of plasma Cer, GlcCer and LacCer. Plasma total Cer increased 149 and 235% by 3 and 16 h of TG infusion, relative to control ($P < 0.01$). Plasma C20:0-, C22:0-, C24:0-, and C26:0-Cer levels increased during TG infusion ($P < 0.01$). Although TG infusion did not modify plasma C16:0-Cer level at 16 h, C16:0-Cer abundance (% of total) was lower at 16 h ($P < 0.01$). TG infusion increased plasma C16:0-, C20:0-, C22:0-, and C24:0-GlcCer levels ($P < 0.01$). Plasma LacCer levels were not modified by TG infusion. Cer levels were positively correlated with NEFA (e.g., C24:0-Cer, r = 0.80; $P < 0.01$). Our data indicate that plasma Cer accumulation occurs in dairy cows concomitantly with increases in plasma NEFA and liver TG. Research is needed to determine whether NEFA-induced insulin resistance is mediated by Cer.

Key Words: ceramide, dairy cow, insulin resistance

473 An acute increase in circulating NEFA does not lower total plasma sphingomyelin levels in Holstein cows. J. Eduardo Rico*[1], Luciano S. Caixeta[2], Yves R. Boisclair[2], and Joseph W. McFadden[1], *[1]West Virginia University, Morgantown, WV, [2]Cornell University, Ithaca, NY.*

Insulin resistance in rodents is characterized by inflammation-mediated activation of sphingomyelinase and the transformation of sphingomyelin (SM) into ceramide (Cer), an effect provoked by saturated fatty acids. Our objective was to determine whether an acute increase in circulating NEFA lowers plasma SM levels in cows. Six nonpregnant, nonlactating Holstein dairy cows (682 kg ± 22), were used in a crossover design with treatments consisting of i.v. infusion (100 mL/h) of either saline (control) or triacylglycerol (TG) emulsion (Intralipid 20%; Frasenius Kabi) for 16 consecutive hours. The feeding level was set at 120% of estimated energy requirement with meals offered every 2 h. Blood was collected at regular intervals. LC/MS was used to profile SM in plasma. Data were analyzed using a mixed model with repeated measures (fixed effects of treatment and time). Nonparametric correlations were analyzed. TG infusion increased plasma NEFA by 454% at 3 h relative to control ($P < 0.01$) with no further increase at 16 h. Total plasma Cer concentrations increased in TG-infused cows, relative to control ($P < 0.01$). Before infusion, C16:0- and C18:1-SM represented 30 and 21%, respectively, of plasma SM. Plasma C16:0-SM levels increased 10% by 16 h of TG infusion, relative to control ($P < 0.05$). Plasma C20:1-SM concentrations were lower in TG-infused cows, relative to control ($P < 0.05$). Plasma C16:1-, C18:0-, C18:1-, C22:0-, C24:0-, and C24:1-SM, as well as total plasma SM were not modified with TG infusion. Before infusion, C20:0-dihydro-SM (DHSM) represented 89% of total plasma DHSM. Plasma C20:0- and C18:0-DHSM increased 79 and 14%, respectively, by 16 h of TG infusion, relative to control ($P < 0.01$). Plasma C18:1- and C20:1-SM were negatively correlated with NEFA (e.g., C20:1-DHSM, r = −0.47; $P < 0.01$). In contrast, plasma C18:0- and C20:0-DHSM, as well as total DHSM were positively correlated with NEFA (e.g., C20:0-DHSM, r = 0.77; $P < 0.01$). An acute increase in plasma NEFA does not appear to promote sphingomyelin hydrolysis in dairy cows thus suggesting that plasma Cer accumulations occurred due to enhanced de novo Cer synthesis.

Key Words: dairy cow, insulin resistance, sphingomyelin

474 Temporal changes in plasma sphingolipids during the transition from pregnancy to lactation in Holstein cows. J. Eduardo Rico*, Sina Saed Samii, Alice T. Mathews, and Joseph W. McFadden, *West Virginia University, Morgantown, WV.*

Ceramide (Cer) and sphingomyelin (SM) are sphingolipids associated with conserved cellular processes; however, their involvement in the homeorhetic adaptation to lactation in cows is unknown. Our objectives were to characterize temporal responses in plasma sphingolipids during the periparturient period and determine whether these changes were related to adiposity and lipolysis. Multiparous Holstein cows were grouped by BCS at d −28 prepartum: lean (BCS 2.9 ± 0.13; n = 7) or overweight (OVER; BCS 4.0 ± 0.21; n = 7), fed a balanced diet. Blood samples were collected routinely from d −21 to 21. LC/MS was used to profile 37 Cer, monohexosylceramides (GlcCer), lactosylceramides (LacCer), and SM in plasma. Data were analyzed as repeated measures under a mixed model (fixed effects of BCS and day). Nonparametric correlations were analyzed. Plasma NEFA increased around calving and was higher in OVER from d −5 to 21 ($P < 0.05$). OVER lost more BCS and BW ($P < 0.01$). C16:0-Cer concentration decreased by 40% during transition and was higher in OVER prepartum ($P < 0.05$). C24:0-Cer increased 50% and was 33% higher in OVER at d 21 ($P < 0.05$). C22:0-Cer increased 49 and 66% at d 14 and 21, respectively, in OVER ($P < 0.05$). C24:0-GlcCer increased 52% during transition ($P < 0.05$) and tended to be higher in OVER at d 0 ($P < 0.1$). C16:0-GlcCer increased by 145% at d 4 ($P < 0.01$). C22:0-GlcCer increased over time and was higher in OVER at d 14 ($P = 0.05$). C24:1-GlcCer tended to increase by 100% in OVER during transition ($P < 0.1$). C16:0-LacCer increased postpartum and peaked at d 14 ($P < 0.01$). C18:1- and C24:1-LacCer levels increased during transition and were higher in OVER from d 4 to 21 ($P < 0.01$). Abundant C16:0-, C18:1- and C20:1-SM decreased over time and reached nadir around parturition ($P < 0.01$). C18:1- and C20:1-SM were higher in OVER pre- and postpartum ($P < 0.05$). C20:0-dihydro-SM decreased around calving ($P < 0.01$) and was higher in OVER at d −5 ($P < 0.05$). Cer, GlcCer and LacCer were positively correlated to NEFA and negatively to SM during transition ($P < 0.001$). Our results support a model of NEFA-induced ceramide synthesis during peripartum.

Key Words: dairy cow, transition, sphingolipid

475 Elevations in milk yield from palmitic acid feeding are associated with reduced estimated insulin sensitivity and glucose-stimulated NEFA disappearance.

Alice T. Mathews*, J. Eduardo Rico, Neil T. Sprenkle, and Joseph W. McFadden, *West Virginia University, Morgantown, WV.*

The ability of saturated fatty acids (SFA) to enhance milk yield in dairy cows may be due to shifts in glucose utilization by reducing insulin sensitivity in adipose and muscle tissues. Our objective was to evaluate the effects of palmitic acid (PA) on milk production and insulin sensitivity in cows. Twenty multiparous mid-lactation Holstein cows were enrolled in a 68-d study consisting of 3 sequential periods: 5-d covariate, 49-d treatment, and 14-d post. All cows received a sorghum silage-based diet pre- and post-treatment, and were randomly assigned to a common diet (control; no fat, n = 10; 138 ± 45 DIM) or PA at 4% of ration DM (98% PA; Palmit 98; Global Agri-Trade; n = 10; 136 ± 44 DIM). Blood and milk were collected at routine intervals. Intravenous glucose challenges (0.3 g/kg BW; GTT) were performed at d −1, 21, and 49 relative to start of treatments. Data were analyzed as repeated measures using a mixed model (fixed effects of treatment and time), and milk yield served as a covariate. Effects of PA are presented as changes relative to control. PA increased milk yield by wk 7 (30.8 vs. 24.6 kg/d, $P < 0.05$). PA increased milk fat yield (+22 and +18%; $P < 0.05$) and 3.5%-FCM (+19 and +18%; $P < 0.05$) by wk 3 and 7, respectively. PA had no effect on milk protein or lactose content, MUN, SCC, or BW, but increased milk protein yield by wk 7 ($P = 0.05$). PA tended to increase estimated energy balance by wk 7 ($P = 0.06$). PA increased feed efficiency (+10%; 3.5%-FCM/DMI; $P < 0.05$). By d 68, 3.5%-FCM remained elevated in PA cows ($P < 0.05$), while milk yield and components were not different. PA increased plasma NEFA by 48, 93, and 60% by d 4, 6, and 8 ($P < 0.05$), respectively, and had no effect thereafter. PA did not modify plasma insulin or glucose, but reduced estimated insulin sensitivity wk 1 (e.g., −35% on d 8; $P < 0.01$). PA did not modify glucose disposal following GTT; however, PA reduced glucose-stimulated NEFA disappearance by wk 7 ($P < 0.05$). Our data suggest that increased milk yield with PA supplementation may be due in part to alterations in insulin sensitivity.

Key Words: insulin sensitivity, milk production, palmitic acid

476 Effects of timing of chromium propionate supplementation on metabolic and production responses of Holstein cows in early lactation.

Michael S. Allen* and Richard Longuski, *Michigan State University, East Lansing, MI.*

Forty-eight multiparous Holstein cows were used in a randomized block design experiment with 4 treatments and 12 cows per treatment to determine effects of timing of chromium propionate (CrPr) supplementation on metabolic and production responses in early lactation. Treatments were chromium propionate (C) or control (N), supplemented according to 4 schedules: 1 to 65 d PP (CC); 1–22 d PP (CN); 23–65 d PP (NC); no CrPr supplementation (NN). Supplements were top-dressed at 20 g per cow/d to provide 8 mg of chromium per cow/d for C (KemTRACE Chromium, 0.04% chromium, Kemin Animal Nutrition and Health) or no additional chromium for N (feed-grade limestone). Cows were blocked by calving date, body condition score (BCS) and previous milk yield, and randomly assigned to treatment. Cows were offered a fresh diet (FR) from 1 to 22 d PP and a peak diet (PK) from 23 to 68 ± 3 d PP. CrPr increased daily DMI (2.75 kg/d) and milk yield (4.5 kg/d, both $P < 0.01$), tended to decrease milk fat concentration ($P = 0.07$), and did not affect fat yield compared with control when supplemented during FR only. There were no interactions of the main effects of timing of CrPr supplementation; effects of CrPr supplementation were sustained through most of the experiment when supplementation ceased at 22 d PP and starting supplementation at 23 d PP did not benefit production. Although CrPr supplementation during FR increased milk yield, the effect diminished by 68 d PP, even when supplementation continued during PK. Plasma metabolites and hormones indicate possible effects of CrPr on insulin sensitivity with a reduction in plasma concentrations of NEFA ($P = 0.08$) and BHBA ($P = 0.02$), lower milk fat concentration ($P = 0.07$), and greater BCS over time (interaction $P = 0.06$) during FR compared with control. Supplementation of CrPr during FR increased DMI and milk yield but effects on production diminished over time with no effects of CrPr by 10 weeks PP, even when supplementation continued during PK. Initiating supplementation at 23 d PP did not benefit production in this experiment.

Key Words: postpartum, chromium, insulin sensitivity

477 The effects of dietary niacin supplementation on FoxO1 and genes involved in hepatic glucose production in dairy cows during the transition period.

Asako Kinoshita*[1], Kathrin Hansen[3], Lena Locher[1], Ulrich Meyer[2], Sven Dänicke[2], Korinna Huber[3], and Jürgen Rehage[1], [1]*Clinic for cattle, University of Veterinary Medicine Hannover, Hannover, Lower Saxony, Germany,* [2]*Institute of Animal Nutrition, Friedrich-Loeffler-Institute, Braunschweig, Lower Saxony, Germany,* [3]*Department of Physiology, University of Veterinary Medicine Hannover, Hannover, Lower Saxony, Germany.*

Forkhead box protein O1 (FoxO1) promotes the hepatic glucose production (HGP) by activating the transcription of gluconeogenic enzymes. As a main target of insulin signaling, FoxO1 is phosphorylated by insulin, leading to inhibition of HGP. Dietary niacin supplementation could affect HGP; for example, by modifying the expression of genes or by inhibiting lipolysis. The objective of this study was to investigate the effects of dietary niacin supplements on protein expression of hepatic FoxO1 and mRNA expression of genes involved in HGP in dairy cows during the transition period. Twenty-one pluriparous German Holstein cows were used for 2 × 2 factorial analysis. Cows received diets containing 0 g (C) or 24 g (N) niacin supplementation from −42 d related to calving (d −42) to d 24. Each group was further divided and received diets with 30% (L) or 60% (H) of concentrate on dry matter basis from d-42 to d0. Dietary concentrate proportion was set to 30% at d 0 for all, and then increased up to 50% within 16 d for CL and NL and within 24 d for CH and NH. Liver biopsies were taken at d −42, d 3, and d 21. Protein expression of FoxO1 and phosphorylated FoxO1 at serine 256 (pFoxO1) was measured semiquantitatively by Western blotting. Real-time RT-PCR was performed to measure the mRNA of FoxO1, glucose-6-phosphatase (G6P), pyruvate carboxylase (PC), cytosolic phosphoenolpyruvate carboxykinase (PCK1), propionyl CoA carboxylase (PCCA), glucose transporter 2 (GLUT2). Data were evaluated by mixed model for repeated measures to test the effect of time, niacin and prepartal concentrate proportion. The protein and mRNA expression of FoxO1 and the protein expression of pFoxO1 were affected neither by time nor by diet. In cows fed with niacin, the relative quantities of mRNA of G6P, GLUT2, PCCA were higher at d 21 and that of GLUT2 was lower at d 1 ($P < 0.05$). Dietary niacin supplements altered the gene expression, increasing HGP in the transition period of cows. However, the regulation of HGP by FoxO1 seemed to be of less importance on the levels of mRNA, protein and phosphorylation.

Key Words: FoxO1, hepatic glucose production, cow

478 “Pre-Veterinary Academy” course exposes and inspires.

Andrew Fidler*, *University of Arkansas, Fayetteville, AR.*

In the competitive environment of professional school admissions, and with the massive time, effort, and financial commitment of a professional school program, students benefit from experiences that either reinforce their decision to pursue a professional degree or cause them to change their career path. The “Pre-Veterinary Academy” course exposes students to a veterinary school-like learning experience and delivers a range of subject matter for students to evaluate their interest in and preparation for veterinary school. The course utilizes a condensed 9-d intersession period, providing a unique opportunity to present a large-volume, fast-paced curriculum. Having the full academic attention of the students allows for more intensive lectures, case studies, and hands-on opportunities that are less practical to achieve during a full semester course. The condensed schedule also allows for visiting veterinary college faculty to provide several lectures in a single day, giving the students a more realistic veterinary school-like learning environment. All 10 students enrolled in the course in January 2015 completed a survey following conclusion of the course. All 10 students were either planning on or considering attending veterinary school, with no significant change following completion of the course. All 10 students believed they had at least “some,” with 7 believing they had “most,” and 1 believing (s) he had “all” of the skills, knowledge, and dedication to be successful in veterinary school. All 10 students indicated at least some improvement in their ability to perform and analyze a clinical examination of a veterinary patient as well as their ability to understand and apply research and clinical evidence to a medical case following completion of the course. Seven of 10 students described at least some improvement in their ability to understand and analyze lecture material as well as their ability to work with classmates to achieve learning objectives. The “Pre-Veterinary Academy” course provides students a brief taste of a veterinary curriculum to inspire commitment to and confidence in their pre-veterinary education.

Key Words: veterinary, education, teaching

479 SafeAssign as a tool for student identification of potential plagiarism.

Sarah A. Reed*, *Department of Animal Science, University of Connecticut, Storrs, CT.*

As writing across the curriculum becomes more common in higher education, the need for instruction about plagiarism is growing. Several plagiarism detection technologies identify matching text in student writing and published work. These technologies have been used to assist instructors in detecting plagiarism and to deter students from committing plagiarism. However, they may also be useful as an instructional tool to assist students to self-identify potential areas of plagiarism in their writing and make appropriate revisions before submission. The hypotheses of this study were that student use of SafeAssign would decrease percent of matching text from first to final submission and improve student awareness of plagiarism. To test these hypotheses, students (n = 20) in an upper level, writing intensive Animal Science physiology course were required to submit their first submission of a 15-page literature review to SafeAssign and write a short reflective piece on how they would improve their writing for the final submission based on the results. Students then completed an anonymous online survey to gauge the perceived usefulness of the assignment. Final submissions were also analyzed by SafeAssign and compared with first submissions. The percent of matching text identified by SafeAssign ranged from 0 to 22% in each submission and was not different between submissions (first: 8.1 ± 1.5%, final: 7.5 ± 1.6%, $P = 0.6$). However, much of the text flagged were false positives, including common phrases and citations. Of 5 papers with true plagiarism, 2 were appropriately revised for the final draft and had fewer incidences of plagiarism. Students reported that use of the program was helpful in identifying potential areas of plagiarism (n = 69%) and increased understanding of what is considered plagiarism (n = 54%). Due to inclusion of false positives, the report generated by SafeAssign must be carefully interpreted by both the instructor and student; however, the report provides an additional opportunity for dialog about plagiarism. Use of plagiarism detection programs may be beneficial when used formatively by students during the writing process when supported by other mechanisms of instruction.

Key Words: plagiarism, writing, animal science

480 Using animal sciences courses to teach general university learning goals.

John P. McNamara and Martin Maquivar*, *Washington State University, Pullman, WA.*

At many universities, there are broad learning goals expected of all undergraduates; including critical and creative thinking, information and scientific literacy, communication, quantitative reasoning, diversity; and depth, breadth and integration of learning. Department often align their learning goals as much as possible, to these goals. To gain an assessment of Animal Science student’s broad abilities, we conducted a survey in 2 semesters to gain a qualitative assessment of student learning related to these broad goals. The classes included Intro. Anim. Sci. (101); Comp. Anim. Nutrition (a university General Biology course open to all majors); AS 285, Rights and Welfare; AS 350, Anim. Reproduction and AS 464 Comp. Anim. Management, a university Capstone course (primarily AS majors with others). The approximately 200 students were more than 80% under 24 years of age, female, Caucasian, with an even distribution of grade levels. For learning information literacy, over 90% of students went to the Internet first to find information, 40 to 55% to textbooks, 20 to 30% to scientific journals, 50% to notes, and only 10% to experts. For information literacy, approximately 55 to 75% self-identified as being comfortable (C) or very comfortable (VC) on using Internet sites from general, university, government agencies, and companies. For scientific and quantitative literacy AS students reported 67, 78, 77, and 65% C and VC on finding and reporting quantitative data, comparing data from graphs and tables, making conclusions from data and preparing graphs and tables. For general communications, on average, AS students reported C and VC at 69, 78, 68 and 56% for communication using verbal conversations, essays, presentations and long papers, with an improvement from start to end of semester of 7, 5, 12 and 13%. For communication on specific AS topics; for writing, oral, using social media, engaging in discussion and explaining complex issues, they reported C and VC at an average of 73, 61, 57, 63 and 56%. Improvement in during the semester was 6, 6, 11, 7 and 17% (a 35% improvement in “explaining complex issues”). Animal science courses can be used effectively to teach broadly applicable skills as well as subject specific skills.

Key Words: teaching, undergraduate learning goals, animal science students

481 Perceptions and effectiveness of teaching methods and technology in animal sciences classes.

John P. McNamara* and Martin Maquivar, *Washington State University, Pullman, WA.*

New learning styles and careers demand new teaching pedagogies and technologies. Lecture/test, videos, online materials (video, PowerPoints, text, web searches); group projects, and homework may be used to a variety of effects. Different students learn in different ways and a variety of teaching methodologies may lift all students, at the least give them a more diverse skillset. Animal sciences teachers must also adapt to learning styles and technologies, however we should understand their effectiveness. To assess the effectiveness of various teaching technologies, we conducted a survey of animal sciences students over the course of 2 semesters and different grade levels to gain a qualitative assessment of perceptions and effectiveness of methods and technologies on student learning. The classes included Intro. Anim. Sci. (101); Comp. Anim. Nutrition (a university General Biology course open to all majors); AS 285, Rights and Welfare; AS 350, Anim. Reproduction and AS 464 Comp. Anim. Management, a university Capstone course (primarily AS majors with others). The approximately 200 students were more than 80% under 24 years of age, female, Caucasian, with an even distribution of grade levels. The students reported that lectures (with or without slides) and videos, pictures, or other media were their preferred methods of learning at 67 and 50%. In fall semester the percentage choosing lectures as their preferred methodology increased from 60 to 77% and videos decreased from 52 to 42%. When asked about the use of various teaching methods or technology, overwhelmingly 87 to 89% of students responded that in class lectures had the most positive effect on learning, while technologies such as clickers, interactive software, “flipped classroom” (students do work outside class and discuss/work in class) all were fairly neutral to slightly positive (25 to 40% “no effect” and 36 to 53% positive or very positive). Using on line search engines were a positive and very positive for 75% of the students. At this stage it may be concluded that students are most familiar and comfortable with in class lectures and on line searches but other technologies and methods are at least positively affecting learning.

Key Words: teaching technology, student perceptions, undergraduate education

482 Closing the gap between society and university: Effect of teaching animal welfare and animal rights course to animal sciences students at Washington State University.

Martin Maquivar*, Kristen Koenig, and John McNamara, *Washington State University, Pullman, WA.*

There is increased scrutiny and concern for the welfare of animals used in research, education, food production, and companionship. Animal sciences departments have an opportunity and responsibility to provide education and expertise regarding animal welfare. Our general University learning goals include critical and creative thinking, quantitative reasoning, scientific and information literacy, communication skills, global diversity and integration of learning. The overall objective of the present study was to assess the effect of animal welfare and animal rights course on university learning goals of critical, creative thinking and communication skills related to animal welfare issues. A survey was conducted at the beginning and at the end of the semester. A total of 61 students (84% female and primarily third year) voluntarily answered the survey (questions ranked in a 5-point Likert scale) to assess perceptions and effectiveness of the course to achieve these goals. The course included discussions, assigned readings, term papers and a team project where students prepared a topic related to animal welfare and presented it to community groups (seniors, elementary school students, and high school students). At the end of the semester students agreed or strongly agreed that “this course increased their ability to define, analyze and solve problems” (90.2%, 55/61); “understand diverse philosophical viewpoints and cultural perspectives” (92%, 56/61); “evaluate arguments based on evidence” (88.5%, 54/61); “tailor messages to audiences” (90.2%, 55/61); “express concepts and beliefs in a coherent, concise and technically correct form” (98.3% 59/61) and “speak with comfort in front of groups” (95%, 58/61). Students felt this course improved and increased their ability to solve problems, engage in discussions with members of the society and also increased their ability to effectively learn.

Key Words: animal welfare, undergraduate education, teaching

483 The relationship between delivery and discovery skills and student performance in animal science courses.

A. Ahmadzadeh*, J. M. Falk, D. T. Masser, and M. E. Doumit, *University of Idaho, Moscow, ID.*

Different courses require different types of skills by students. The objective was to investigate the relationship between 2 types of students’ personal skills and their performance as measured by course grade. The population consisted of 55 students in 2 animal science courses (Animal Reproduction and Animal Products) at the University of Idaho. A 20-question survey was used to assess an individual’s delivery skills (planning, attention to detail, implementing, and self-discipline) and discovery skills (questioning, observing, networking, and experimenting). Discovery and delivery types were measured (scale of 0 to 50) and based on the score, the skill scores for each type were categorized into 3 levels: high (H; 43–50), moderate (M, 33–42), or low (L; ≤ 32). Data were analyzed using ANOVA. The model tested the effects of skill level, course, and their interaction. There was no interaction between course type and skill level. There was a moderate association between delivery skills and exam scores ($r^2 = 0.4$, $P < 0.01$). However, overall delivery skill level influenced ($P < 0.01$) the total exams grades. Grades were 88.1 ± 3.1, 79.5 ± 2.3, and 71.5 ± 3.6 for H, M, and L delivery skill, respectively. Discovery skills and exam scores had little association ($r^2 = 0.1$, $P > 0.5$). Discovery skill level did not influence ($P > 0.2$) the total exam scores. Grades were 87.8 ± 5.1, 78.6 ± 2.1, and 82.1 ± 3.1 for H, M, and L discovery skills, respectively. Overall, when exam scores of delivery skills were compared, students with H delivery skill earned the highest grades, whereas discovery skills had little influence on exam scores in these 2 courses. Students with high levels of Delivery skills tend to excel at planning, attention to detail, executing, and self-discipline. If course content is structured for memorization and fact acquisition, then instructors are encouraged to help students develop delivery skills. If course content requires exploration and innovation, then instructors should encourage discovery skills (like questioning, networking and experimenting), and provide feedback on these skills using course grades and assignments.

Key Words: discovery and delivery skills, performance, undergraduates

484 Gender differences in species and career interests among students in first-year seminar courses.

Cody L. Wright, Sara L. Mastellar, Michael G. Gonda*, and Andie B. Vsetecka, *South Dakota State University, Brookings, SD.*

Changing demographics of students in Animal Science programs have created some uncertainty as to whether traditional curricula adequately address the needs of such a diverse body of students. This study was designed to identify gender differences in species and career interests among students in first-year seminar courses in both Animal Science (AS 109) and Veterinary and Biomedical Sciences (VET 199). Students were surveyed using an instrument that included demographic questions and a series of 4-point, Likert-type scales for each species and career interest. Eighty-seven students in AS 109 and 45 in VET 199 completed the survey. Animal Science majors comprised 98.5% of the survey respondents, 1.5% had not declared a major. Of the 132 respondents, 68.2% were female and 31.8% were male. The majority of respondents were freshmen (86.4%), 6.8% were sophomores, and 6.8% were upperclassmen. Half of the students (50.8%) either came from a small hobby farm or had no farm or ranch background. Gender differences were analyzed using a Pearson Chi-Square test. Males had greater ($P = 0.019$) interest in feedlot cattle, while females had greater interest in goats ($P < 0.001$), horses ($P < 0.001$), pets ($P < 0.001$), and zoo animals ($P = 0.021$). Interest in cow-calf, dairy, poultry, sheep, swine, and wildlife between genders were not different. Career fields related to agronomy and the feed industry were of more interest to males ($P = 0.021$ and $P = 0.016$, respectively). Females had greater interest in both hands-on and support careers related to horses ($P = 0.003$ and $P < 0.001$, respectively) and in working with zoo animals ($P = 0.020$). Veterinary medicine tended ($P = 0.059$) to be of greater interest to females than males. Interest in careers related to animal breeding, animal reproduction, banking, Extension, farming/ranching, food production, government, meats, teaching, or veterinary technician between genders were not different. These data suggest that more females than males may be pursuing degrees in animal science. Furthermore, females clearly have greater interest in some species that may not be commonly included in traditional animal science curricula.

Key Words: animal science, students, gender

485 Factors affecting first-year academic success in a large animal science program.

Amanda L. Robinson*, Heather A. Jennings, Jodi A. Sterle, Cheryl L. Morris, Kenneth J. Stalder, David G. Acker, and Howard D. Tyler, *Iowa State University, Ames, IA.*

This study was designed to determine if student's background, interests or non-academic skills affect their grade point average (GPA) during their first year at a large 4-year Animal Science program. All new students (n = 344) entering the Department of Animal Science at Iowa State University in the fall of 2013 completed assessments (TalentSmart's Emotional Intelligence (4 categories)) of non-academic skills at the beginning of their first semester. Demographic surveys were used to collect additional data (sex, residency status, entry status (transfer/freshman), species interest, career goals, and home background). Student records were accessed to provide data on previous and current academic performance that included high school rank, ACT scores, first year ISU GPA, and retention data. All data were analyzed using general linear model methods (PROC GLM, SAS Version 9.3). Fixed effects included sex, residency status, entry status, species interest, career goals, and background as well as ACT and overall Emotional Intelligence (EI) scores. For ACT and Emotional Intelligence assessments, students were separated into group quartiles by their scores. Of the higher order fixed effects, only ACT scores significantly affected end-of-first-year GPA. There was no interaction between Emotional Intelligence quartile scores and ACT quartile scores on end-of-first-year GPA. For incoming students in the ISU animal science program, ACT scores are the best predictors of first year grade point average.

Key Words: student success, emotional intelligence, demographics

486 Integration of an immersive experience in public policy and governmental affairs into agricultural sciences PhD training programs.

Catherine W. Ernst*[1], Lowell Randel[2], Mary Malaspina[3], Kaitlyn R. Perry[1], Deborah Velez-Irizarry[1], Camille Scott[1], and Ronald O. Bates[1], *[1]Michigan State University, East Lansing, MI, [2]The Randel Group LLC, Washington, DC, [3]Michigan State University, Washington, DC.*

With the increasing dependency on extramural funding to define the direction of animal sciences research, changes in policy at the federal level heavily influence the discoveries that will improve animal production. Yet few scientists are familiar with this process. Internship opportunities in governmental affairs or science policy are usually summer or full-year programs, and are typically available to advanced graduate students or post-doctoral scientists. Few opportunities exist for students early in their graduate program to explore governmental agencies or interact with policymakers. To address this limitation, we designed an immersive experience for PhD students supported by a USDA NIFA National Needs Fellowship Grant. Three students spent 4 weeks in Washington, DC in June 2014. Students were housed in a local university dormitory, using week 1 to acclimate to the area including familiarization with local transportation systems and locating destinations for subsequent weeks' activities. Weeks 2 to 4 were set up on a rotational basis with each student individually pursuing a different weekly activity. Students spent 1 week on Capitol Hill in the office of a US Congressman (a different congressional office for each student). They also spent 1 week visiting various USDA agencies (a different agency each day). For the third week, students shadowed a professional in either an agriculture-related non-governmental organization or a governmental agency, selected to fit with their individual interests. Through these experiences, students interacted with scientists in federal agencies involved with research and/or policy development, and scientists in trade or commodity organizations, as well as attended congressional hearings, briefings and other meetings on agriculture-related topics. This opportunity not only reinforced the interconnectedness of science, industry, and policy, but also exposed students to many unique scientific careers. This immersive experience in public policy, and its impact on the agricultural industry, greatly influenced the students' professional development.

Key Words: science policy, graduate education

487 Changes in emotional intelligence scores following a peer mentor experience.

Amanda L. Robinson*, Heather A. Jennings, Jodi A. Sterle, Cheryl L. Morris, and Howard D. Tyler, *Iowa State University.*

This study was designed to determine if participating in a full-year peer mentor experience affects their emotional intelligence (EI) scores. Students selected to the peer mentor program for the Department of Animal Science at Iowa State University (n = 34) completed TalentSmart's Emotional Intelligence assessment before starting the program (January, 2014) and then completed the EI reassessment after completing the program (December, 2014). All data were analyzed using paired *t*-tests (PROC TTEST, SAS Version 9.3) to determine potential differences between each student's beginning and ending EI scores (4 distinct categories and 3 composite categories with possible scores ranging from 50 to 100). Scores for self-awareness, self-management, social awareness, and relationship management all significantly increased for peer mentors. The associated composite categories of personal management and social management also were significantly increased, as was the composite for overall EI. Students that were new to the peer mentor program and started with initial overall EI scores that were below the group average score experienced the largest increase in all scores, with over a 14-point increase in self-awareness scores and over a 12-point increase in social awareness scores. Students showed improvements in all aspects of their EI as a result of completing the peer mentor program in the animal science program at ISU.

Key Words: peer mentor, emotional intelligence

ADSA Production Division Symposium: The rumen and beyond—Nutritional physiology of the modern dairy cow

488 Harnessing the physiology of the modern dairy cow to continue improvements in feed efficiency. Michael VandeHaar*[1], Diane Spurlock[2], and Louis Armentano[3], [1]*Michigan State University, East Lansing, MI,* [2]*Iowa State University, Ames, IA,* [3]*University of Wisconsin, Madison, WI.*

Feed efficiency, as defined by the fraction of feed energy captured in products, has more than doubled for the US dairy industry in the past 100 years. This increased feed efficiency resulted from increased milk production per cow achieved through genetics, nutrition, and management with the desired goal being greater profitability. With increased milk production per cow, more feed is consumed per cow but a greater portion of the feed is partitioned toward milk instead of maintenance and body growth. The dilution of maintenance has been the overwhelming driver of enhanced feed efficiency in the past, but its impact diminishes with each successive increment in production relative to body size. In the future, we must focus on new ways to enhance digestive and metabolic efficiency. One way to examine variation in efficiency among animals is residual feed intake (RFI), a measure of efficiency that is independent of the dilution of maintenance. Cows that convert feed energy to net energy more efficiently, or have lower maintenance requirements than expected based on BW, use less feed than expected and thus have lower RFI. Cows with low RFI likely digest and metabolize nutrients more efficiently and should have overall greater efficiency and profitability if they are also healthy, fertile, and produce at a high multiple of maintenance. Genomic technologies will help to identify these animals for selection programs. Nutrition and management also will continue to play a major role in farm-level feed efficiency. Helping all farms achieve the efficiency of the best farms would have a major effect on feed efficiency for the industry. Management practices such as TMR-feeding and grouping improve rumen function and efficiency, but they have decreased our attention on individual cows. Perhaps new computer-driven technologies will enable us to optimize efficiency for each individual cow within a herd, or to optimize animal selection to match management environments. In the future, availability of feed resources may shift as competition for land increases. New approaches combining genetic, nutrition, and other management practices will help optimize feed efficiency, environmental sustainability, and profitability.

Key Words: efficiency, dairy cow, genetics

489 Development and physiology of the rumen and the lower gut: Targets for improving production efficiency. Michael A. Steele*[1], Greg B. Penner[2], Frédérique Chaucheyras-Durand[3], and Leluo Guan[1], [1]*Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada,* [2]*Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada,* [3]*Lallemand Animal Nutrition, Blagnac, France.*

It has been estimated that the gastrointestinal tract accounts for 30% of metabolic and protein synthesis activities of the cow and calf, and thus, plays an important role in animal energetics. Diet and microbiota can positively and negatively affect gut function and the ability to modulate gut function has created an applied interest relevant to improved dairy cow and calf productivity. The mechanisms that govern growth and barrier function of gut tissues have received particular attention, especially with the advancements of molecular based techniques over the past decade. The rumen has been the focal point of dairy cow and calf nutritional physiology research, yet the intestinal tract has received less attention. Three key areas requiring more discovery-based and applied research: (1) early-life intestinal gut barrier function and growth; (2) how the weaning transition affects gut health of rumen and intestine; and (3) gastrointestinal adaptations during the transition to high energy diets in early lactation. Nutrients are not only seen as substrates, but also as signals that can alter gastrointestinal growth and barrier function. Nutrients can act directly, affecting epithelial cell gene expression, and in concert with somatotropic axis hormones, insulin-like growth factor (IGF) and growth hormone where they have been shown to play a pivotal role in gut tissue growth. For example, IGF-1 can mediate other hormones involved in cell growth, such as glucagon-like peptide 2 (GLP-2), whereas, intestinal GLP-2 is secreted upon nutrient ingestion causing a stimulation of intestinal growth. The latest research suggests that total-tract barrier function in calves and cows in early life, at weaning and in early lactation is compromised. A major factor for gut health is maintaining proper gastrointestinal barrier function, which is highly influenced by the presence of metabolites (butyrate) and resident microbiota and/or direct fed microbials within the gut. In the first studies that investigated barrier function in cows and calves, it was determined that the expression of genes encoding mucin and tight junction regulating proteins, such as claudins, occludins and desmosomal cadherins, are regulated by diet. Additionally, recent evidence suggests that the upper and lower gut can communicate, but the exact mechanisms of gastrointestinal cross-talk have not been studied in detail. A deeper understanding of how diet and microbiota can affect growth and barrier function of the intestinal tract would provide knowledge of what specific management regimens could effectively impact gut function.

490 The contribution of the lower gut to altered nutrient partitioning during stress. Lance H. Baumgard*[1], Sara K. Stoakes[1], Mohannad Abuajamieh[1], and Robert P. Rhoads[2], [1]*Iowa State University, Ames, IA,* [2]*Virginia Tech University, Blacksburg, VA.*

Increased animal productivity and production variability are due to changes in nutrient partitioning. The coordination of nutrient trafficking is an incredibly complex system and how tissues/systems are reprioritized or de-emphasized during different physiological states is controlled by homeostatic and homeorhetic adaptations that probably incorporate every tissue and physiological system. There are a variety of situations in an animal's life-cycle that challenges homeostasis. The metabolic adaptations that cows utilize to copiously synthesize milk following parturition are unfortunately often referred to as "metabolic stress." Metabolic maladaptation to lactation results in ketosis and this is in part either caused by inadequate feed intake or causes reduced feed intake. Regardless, although heavily researched for the last 3 decades the specific etiology of periparturient ketosis remains elusive as it unclear why a small percentage of cows are susceptible (or predisposed?) to metabolic imbalances following calving. Heat stress (HS) compromises efficient animal production and jeopardizes animal welfare and HS animals also have a unique metabolic and physiological fingerprint that is uniquely different than their nutritional status predicts. The origin of both ketosis and HS issues may lie at the gastrointestinal tract. Increased intestinal permeability to lipopolysaccharide (LPS) and other luminal contents results in local and systemic inflammatory responses. LPS interferes with hepatic lipid trafficking, stimulates insulin secretion and influences systemic fuel selection. We demonstrated that both ketotic and HS animals have markedly increased circulating markers of leaky gut. We have also shown that reduced feed intake (a conserved response to stress) compromises intestinal integrity in both thermal-neutral monogastrics and ruminants. Thus, stressors that physically prevent ad libitum feed intake or cause voluntarily reductions in feed take may share a common mechanism(s). Defining the physiology and mechanisms that underlie how intestinal barrier dysfunction jeopardizes animal performance is critical for developing approaches to ameliorate current production issues.

Key Words: nutrient partitioning, intestine

491 Nutritional strategies to optimize dairy cattle immunity.

Lorraine M. Sordillo*, *Michigan State University, East Lansing, MI.*

Dairy cattle are susceptible to increased incidence and severity of both metabolic and infectious diseases during the periparturient period. Health problems occurring around the time of parturition are especially problematic because they greatly affect the productive efficiency of cows in the ensuing lactation. A major contributing factor to increased health disorders is alterations in bovine immune mechanisms. Indeed, uncontrolled inflammation is a major contributing factor and a common link among several economically important diseases including mastitis, retained placenta, metritis, displaced abomasum, and ketosis. The nutritional status of dairy cows and the metabolism of specific nutrients are critical regulators of immune cell function. There is now a greater appreciation that certain mediators of the immune system also can have a reciprocal impact on the metabolism of nutrients. Thus, any disturbances in nutritional or immunological homeostasis can provide deleterious feedback loops that can further enhance health disorders, increase production losses, and decrease the availability of safe and nutritious foods for a growing global population. This review will discuss the complex interactions between nutrient metabolism and immune functions in periparturient dairy cattle. Details of how either deficiencies or overexposure to macro- and micronutrients can contribute to immune dysfunction and the subsequent development of health disorders will be presented. Specifically, the ways in which altered nutrient metabolism and oxidative stress can interact to initiate and promote uncontrolled inflammatory responses in transition cows will be discussed. Understanding more about the underlying causes of dysfunctional inflammatory responses may facilitate the design of nutritional regimens that will reduce disease susceptibility in early lactation cows. Given the critical role that nutrition plays in supporting all immune functions, nutritional-based management strategies should have a central position in any disease prevention program.

Key Words: immunity, inflammation, oxidative stress

492 Managing complexity: Dealing with systemic cross-talk in bovine physiology.

Barry J. Bradford*, *Kansas State University, Manhattan, KS.*

Dairy producers rely heavily on advisors with deep expertise in nutrition, reproduction, and health. However, a shift is occurring, driven by both farm size and advances in biology. Larger dairy businesses can investigate management options with a degree of precision never before possible; simultaneously, the lines between the metabolic, immune, and reproductive systems are becoming blurred. For example, new research has revealed a surprising role for immune cells in regulating metabolism and documented the nutrient requirements of the immune system. The gut epithelium has garnered new attention as a tissue that actively manages the commensal microbiome, entrains the responses of the neonatal immune system, and provides a barrier limiting movement of molecules from the gut lumen. New hormone discoveries have added adipose tissue, bone, and muscle to the list of endocrine organs. Finally, nutrients are now seen not only as substrates and cofactors, but also as signals that can alter cellular function. What does all of this mean for the dairy industry? Consultants increasingly need to reach across disciplinary boundaries to best support the physiology of the cow. However, research is needed to move beyond proof-of-principle findings toward applications in dairy cattle. Key unanswered questions include: the degree to which roles of the hindgut in monogastrics translate to ruminants; whether host/microbe crosstalk also occurs in the rumen; whether hormone release by storage organs during a catabolic state affects reproductive function; and the degree to which immunostimulation by dietary signals enhances or disrupts health and productivity. It is critical to address these questions with a 2-pronged approach. Mechanistic studies provide a nuanced understanding of signal interactions, but large-scale commercial studies are also needed to evaluate effects on multiple production outcomes in the environment of interest. Incorporating all aspects of animal health and productivity in management decisions will remain an art for the foreseeable future, but this should not dissuade the industry from pursuing a more holistic approach to management of the cow.

Key Words: physiology, endocrinology, dairy cow

Animal Behavior and Well-Being I

493 Development of a behavior-based screening tool for disease detection in preweaned group-housed dairy calves. Mary C. Cramer* and Amy L. Stanton, *University of Wisconsin- Madison, Madison, WI.*

Producers report bovine respiratory disease (BRD) and diarrhea as the 2 most common diseases in preweaned calves, both of which can affect calf performance and welfare. Group housing has the potential to improve calf welfare, but only if producers are able to detect disease. To reduce time evaluating individual calves, there is a need for a group level health-screening tool to identify potentially sick calves that require further examination. The objective of this study was to develop a screening tool using behavioral measures to detect disease in preweaned group-housed dairy calves. This cross-sectional study included the evaluation of preweaned group-housed calves (n = 206) on 4 farms in Wisconsin. Calves were scored for behaviors that were hypothesized to be indicative of illness: abnormal posture when lying or standing, isolation, lethargy, and the willingness to approach a stationary person (2 approach tests were performed and each was scored separately). Each behavior category was scored as normal (0 points) or abnormal (1 point) and then categories were summed to obtain a total behavior score for each calf. Following the behavior scoring, calves underwent an individual health assessment for BRD, diarrhea, and umbilical infections. Total behavior scores ranged from 0 (normal) to 5 (severely abnormal) and reflect the number of abnormal behaviors observed. The highest sensitivity and specificity of the behavior score for disease identification occurred at score cut points of 2 and 3. Therefore, scores of 2 or greater or scores of 3 or greater were considered a positive test result for disease and were further examined. Outcomes of a positive or negative behavior score for cut points of 2 and 3 were analyzed using PROC LOGISTIC in SAS and all models were controlled for calf age and farm. A score of 2 or greater tended to be significant for the detection of diarrhea ($P = 0.05$), but was not significant for BRD ($P > 0.05$). At a cut point of 3 or greater, calves without BRD were 0.24 (95% CI: 0.10 to 0.59) times as likely to have a positive behavior score, compared with calves with BRD ($P < 0.01$). Utilizing a cut point of 3 or greater on this behavior-based screening tool may be useful to identify calves with BRD.

Key Words: behavior, BRD, calves

494 Milk replacer plane of nutrition influences calf nutritive and non-nutritive oral behaviors. Lindsey E. Hulbert[1], Sophia C. Trombetta*[1], Kate P. Sharon[2], and Michael A. Ballou[2], *[1]Department of Animal Sciences and Industry, Kansas State University, Manhattan, KS, [2]Department of Animal and Food Science, Texas Tech University, Lubbock, TX.*

The objectives of the study were to (1) determine if milk replacer (MR) plane of nutrition (PN) influences Holstein bull-calf daily duration of non-nutritive sucking (NNS) as well as daily calf starter (CS) and water intake from ages 6–64 d and, (2) determine if automated NNS measures can be used as an additional measure to CS intake to determine if calves are ready for weaning. At age 1 d, calves were randomly assigned to MR treatments of either High (HPN; n = 18; 20:28 DM fat:protein; 830g and 1080 g DM/d from ages 1 to 10 and 11to 51 d, respectively) or Low (LPN; n = 15; 20:20 fat:protein; 445 g DM/d ages 1–51 d) PN. All calves were fed milk bottles twice daily at 0700 and 1600 h until step-down weaning. Weaning was initiated at age 51 d by removal of the PM-MR feeding and completed at age 57 d with the removal of the AM-MR feeding. Water and CS were offered ad libitum and measured once daily. Daily-NNS was measured by event-loggers (1 Hz, HOBO State Data Logger UX90–001M) that recorded when each calf manipulated a dummy-nipple. Repated data were analyzed using REML PROC MIXED procedure in SAS. Throughout the experiment, LPN-calves drank 1.5 × more water than HPN-calves ($P < 0.05$). Prior to weaning, LPN-calves consumed more CS than HPN-calves ($P < 0.01$), except for ages 32–41 d. During and after weaning the LPN calves consumed over 18% more CS than HPN ($P < 0.01$). After weaning was completed, HPN-calves doubled CS intake compared with pre-weaning ($P < 0.05$). The LPN-calves performed more daily NNS at ages 13–17 d ($P < 0.01$). Around weaning, HPN-calves tripled NNS from pre-weaning measures ($P < 0.05$), while LPN calves nearly stopped their NNS behaviors ($P < 0.01$). These results indicate that PN influences nutritive and non-nutritive oral behaviors. Calves fed LPN are not motivated to perform NNS once one MR feeding is removed from their diet. In contrast, weaning-initiation increases NNS in HPN-calves, but full-removal of MR stimulates CS intake in HPN-calves. In addition, HPN-calves may not acclimate as easily as LPN-calves to step-down weaning; therefore, alternate weaning strategies for HPN calves may need to be considered and tested utilizing NNS measures.

Key Words: behavior, calf, nutrition

495 Evaluation of pelleting a feed-through larvicide on dairy calf behavior and fly control. Randi Black*[1], Christa Kurman[1], David Paulsen[2], Rebecca Trout Fryxell[2], and Peter Krawczel[1], *[1]Department of Animal Science, University of Tennessee, Knoxville, TN, [2]Department of Entomology and Plant Pathology, University of Tennessee, Knoxville, TN.*

Dipteran pests affect dairy calves through rapid transmission of pathogens and reduction in calf well-being. A feed-through larvicide may effectively manage fly pressure and improve well-being. The objective of this study was to determine the effect of pelleting a feed through larvicide on calf lying behavior. Holstein dairy calves (n = 12) were divided into 4 pens and assigned to one of 2 treatment sequences: control (CON)-washout (WAS)-larvicide (LAR) (n = 6) or LAR-WAS-CON (n = 6). CON and LAR lasted 4 d and WAS lasted 10 d. The control pellet was fed during CON and WAS and the experimental pellet was fed during LAR. Dataloggers recorded lying bouts and posture at 1-min intervals from d 0 to d 24. Fecal samples, collected on d 2, 4, 11, 20, and 14, were seeded with house (n = 25), stable (n = 25), face (n = 25), and horn fly eggs (n = 25) to assessed daily emergence of pupae and adults. Data were analyzed using PROC GLM of SAS to determine the effect of treatment period, sequence, and treatment period × sequence interaction. No effects on lying bouts were evident ($P \geq 0.26$). Calves laid down longer during CON (17.1 ± 0.2 h/d) and LAR (17.2 ± 0.2 h/d) compared with WAS (14.4 ± 0.1 h/d; $P < 0.0001$). Further, calves laid down less frequently during WAS (11.6 ± 0.2 bouts/d) compared with CON (16.5 ± 0.4 bouts/d) and LAR (16.0 ± 0.4 bouts/d; $P < 0.0001$). Calves on the LAR-WAS-CON sequence had a tendency to stand longer (8.0 ± 0.2 h/d) than CON-WAS-LAR sequence calves (7.5 ± 0.2 h/d; $P = 0.08$). Fewer pupae emerged during the WAS period of the LAR-WAS-CON sequence (5.8 ± 1.5 pupae) compared with CON in CON-WAS-LAR (18.0 ± 1.0 pupae) and LAR-WAS-CON (19.1 ± 1.0 pupae), LAR in CON-WAS-LAR (18.8 ± 1.0 pupae) and LAR-WAS-CON (16.3 ± 1.0 pupae), and WAS in CON-WAS-LAR (13.7 ± 1.5 pupae; $P < 0.0001$). This indicates there may be a delayed response of larvicide. Further, fewer adults emerged during the LAR period (1.6 ± 0.8 adults) compared with the CON period (7.9 ± 0.8 adults) of the LAR-WAS-CON sequence ($P < 0.01$). These data suggest a pelleted feed through larvicide may be an effective fly management option for producers without negatively affecting calf behavior.

Key Words: dairy calf, larvicide, behavior

496 An outdoor method of housing dairy calves in groups using individual calf hutches.

Lisa M. Wormsbecher*[1], Renée Bergeron[1], Derek B. Haley[2], Anne Marie B. de Passillé[3], Jeff Rushen[3], and Elsa Vasseur[1], [1]*Organic Dairy Research Centre, University of Guelph, Alfred Campus, Alfred, ON, Canada,* [2]*Ontario Veterinary College, University of Guelph, Guelph, ON, Canada,* [3]*UBC Dairy Education and Research Centre, University of British Columbia, Agassiz, BC, Canada.*

Housing dairy calves in groups allows natural social interactions between conspecifics. Many farms still house dairy calves individually and feed them milk by hand. Some dairy operations have implemented group-housing using an automated milk feeding system even if the initial set up is expensive. To evaluate the feasibility of using calf hutches in a novel, low input cost group-housing method, we compared individually- and pair-housed calves kept in hutches and examined differences in growth rate, activity level, and competition of paired calves at feeding. Individual calves were given a hutch with an outdoor area (total 6.87 m^2); 2 hutches were placed side by side with a shared outdoor area for paired calves (6.87 m^2 total per calf). Eighteen Holstein heifer calves were purchased and arrived on farm between the ages of 5–12 d. Calves were assigned to treatments and balanced for age and weight within pairs and across treatments. Over 7 weeks, calves had free-access to milk (up to 16 L/day/calf), calf starter, water and hay. Activity loggers were used to record daily lying time and calves were weighed each week to monitor growth. To evaluate competition in pairs and use of space for all calves, behavioral observations were completed 1 d/wk (7 non-consecutive h/d) and included recording calf location within pen, and for paired calves: displacements at the nipple (indicative of competition between calves), cross sucking (sucking on conspecific), and social grooming (grooming/licking another calf). Over 7 weeks of milk feeding the average feed conversion was 0.10 ± 0.005 kg weight gain/kg milk intake (mean ± SE) for paired and individual calves. Social interactions by paired calves did not change across weeks (Wilcoxon sign rank tests; $P > 0.1$): 5.5 ± 1.62% social grooming, 1.4 ± 0.84% cross sucking, and 6.5 ± 3.60% displacements at the nipple. Data for growth, resting time, and space usage are being analyzed while milk and competition data are undergoing further analysis. A 6-week winter replicate of this research is in progress to determine whether the housing method can be utilized in various climatic conditions.

Key Words: dairy, calf, housing

497 The use of single measurements to assess growth of dairy calves and the effect of management practices on calf BW variability.

Guilherme B. Bond*[1], Daniel M. Weary[2], Marina A. G. von Keyserlingk[2], Lorraine Doepel[1], Karin Orsel[1], Herman W. Barkema[1], and Edmond A. Pajor[1], [1]*University of Calgary, Calgary, AB, Canada,* [2]*University of British Columbia, Vancouver, BC, Canada.*

Bridging the gap between research methods and application on commercial farm settings is necessary to stimulate producers to use new management practices that promote better calf welfare. Our objectives were to evaluate the association between a single measurement of calf BW and management practices and identify practices related to higher BW residuals. Farms (n = 82) were selected through convenience sampling, had at least 80 Holstein lactating cows and used DHI recording systems. Visits occurred once from June 2010 to August 2012 in AB and BC, Canada. Producers were interviewed about their pre-weaning calf management practices and heart girth was measured for all available calves from 0 to 8 weeks of age. The final database contained data from 865 calves from 57 farms in AB (567 calves) and 25 farms from BC (298 calves). Calf BW was regressed against age and the resulting line equation was $BW = 40.56 + 4.649 \times Age$ (wk). Calf BW residuals were calculated by subtracting the actual BW from the expected BW at each age. Individual animal BW residuals were averaged by farm to represent calf growth on each farm. Average farm BW residuals ranged from −16.5 kg to +16.7 kg. The association between management practices and calf BW residuals was tested at calf-level using mixed models in SAS 9.4. Management variables significant in a univariable model ($P < 0.20$) were included in the final multivariable model ($P < 0.05$). Feeding more than 5 L of milk per day through a teat was associated with higher BW. Conversely, calves fed less than 5 L of milk by bottle had the lowest BW when compared with the other feeding strategies. Feeding milk by bucket, regardless of the amount, was associated with lower BW. Calves introduced to water at an earlier age had higher BW than calves introduced to water later than 2 mo of age. Calves housed in groups had lower BW when compared with calves housed in individual pens; mixed housing (using 2 or more different types of housing) resulted in the lowest BW compared with other systems. The growth measurement used in this study was successful in describing differences of calf growth among farms. These differences were related to practices such as feeding more milk by teat and early introduction to water.

Key Words: welfare, feeding, water

498 Reflective calf hutch covers improve antibody response and decrease panting, but not gain, during hot conditions.

Jade Haberman, Theodore Friend*, and Thomas Hairgrove, *Texas A&M University, College Station, TX.*

Previous research found reflective hutch covers reduced hutch temperature during hot weather, but the biological significance is unknown. This study determined the effect of reflective covers on calves' immune response, body weight, and respiration rate. The study was conducted from June to August, on 2 farms: one near Stanfield, Arizona (10,000 cows) and one near Plainview, Texas (6,000 cows). Agri-Plastic hutches were used in Arizona and Calf-Tel in Texas. Covers were 3.0 mil (aluminized on the external side) white LDPE overlaying the top, sides, and back of the hutches; leaving the front exposed. At each farm, 5 covered and 5 uncovered (control) hutches were also fitted with temperature loggers that recorded internal hutch temperature every 30 min. Calves were given a commercial IBR vaccine at 21-d of age and antibody titer differences at 21 and 42 d determined immune response. Titers were determined using virus neutralization with logarithmic transformation to normalize data. Treatment effects were analyzed with ANOVA and LSD. Calves in covered hutches in AZ (n = 50) had a higher ($P < 0.05$) titer responses (25%) than control calves (n = 54). Respiration rates taken during sunny conditions at 16:00 at AZ were significantly lower (8 bpm, $P < 0.01$) for covered calves (n = 43) than controls (n = 50). Body weight was not significantly influenced by treatments at either farm ($P > 0.05$). Covered hutches were 3.03°C cooler than controls at the hottest time of the day at AZ ($P < 0.01$) and 0.7°C warmer ($P < 0.05$) during the coolest 2 h period at night. TX was much cooler than average with cloud cover and rain, and daily highs averaged 7.9°C lower than AZ over the study period, so the cover were not advantageous in

TX. In conclusion, the reflective covers were most effective during sunny and hot conditions, resulting in increased antibody response and decreased respiration rate.

Key Words: heat, stress, dairy

499 Lameness score, pain threshold, temperature and type of lesion of severely lame dairy cows before and after trimming. Vivian Fischer*[1], Lorena Teixeira Passos[1], Eduardo Augusto da Cruz[1], Marcelo Tempel Stumpf[2], Elissa Forgiarini Vizzotto[1], Daise Wernck e[1], Mateus Wanderer[1], Andress Sopelsa[1], and Isabella Dias Barbosa da Silveira[3], *[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil, [2]Universidade Federal do Rio Grande, São Lourenço, RS, Brazil, [3]Universidade Federal de Pelotas, Pelotas, RS, Brazil.*

This study aimed to verify the effect of corrective trimming and the type of lesion on lameness score (LS), nociceptive pain threshold and temperature close to the lesion of lame cows. Six Jersey and 28 Holstein cows were used. The day before trimming (day −1), cows were gait scored using a 1-to-5 numerical rating system where 1 = perfect gait and 5 = severely lame. Cows showing LS of 4 or 5 were selected. On d 0 (trimming), cows were restrained in a tilt chute and before they were hoof trimmed, they were evaluated for pain threshold, temperature close to the lesion and type of hoof lesion, which were classified as dermatitis (digital and interdigital) or ulcers (sole and wall ulcers). Temperature close to the lesion was measured with a thermograph. Pain threshold was measured utilizing an algometer, applying a pressure stimulus at the regions close to the lesion of both rear legs, and observing the foot-lift response. Cows with dermatitis were given an antibiotic and a bandage, those with ulcers received glueing shoes and none received analgesic. After trimming, on d 6, cows were evaluated for LS and on d 7, cows were evaluated for pain threshold and temperature close to the lesion. Data were submitted to variance analysis according to a completely randomized design, considering in the model the effect of trimming, type of lesion and their interaction. Twenty-six cows had dermatitis, 8 cows had sole and wall ulcers. There was no interaction between type of lesion and trimming (Table 1). Trimming decreased LS and increased pain threshold but did not affect temperature close to the lesion. Cows dermatitis showed lower pain threshold than those with ulcers. Type of lesion did not affect LS nor the temperature close to the affected region. Trimming improved cow’s welfare.

Table 1 (Abstr. 499). Effect of trimming and type of lesion on lesion pain and temperature

	Corrective trimming (T)			Type of hoof lesion (L)		
Trait	Before	After	$P > F$	Dermatitis	Ulcers	$P > F$
Pain threshold (kgf)	7.0^{a}	9.3^{b}	<0.01	6.8 ^{a}	9.5^{b}	<0.01
Lameness score (1 – 5)	4.5^{a}	2.9^{b}	<0.01	3.5 ^{a}	3.9^{a}	NS
Temperature of affected region (°C)	29.6^{a}	29.8^{a}	NS	29.7 ^{a}	29.8^{a}	NS

Key Words: lameness, pain sensitivity, trimming

500 Assessment of calving personnel performance and stillbirth in dairy herds. G. M. Schuenemann*, J. M. Piñeiro, A. A. Barragan, S. Bas, and J. D. Workman, *The Ohio State University, Columbus, OH.*

It is common to observe large between- and within-herd variation in calving personnel performance (CPP) and turnover (TO). The objectives were to assess (1) the association of self-reported conflicts (e.g., lack of communication) on knowledge, skills, and performance of personnel; and (2) the association of CPP and TO on stillbirth and economics. A total of 70 personnel (18 dairy herds and approximately 18,100 cows) who participated in a 2 yr calving training program designed to improve calving management practices and reduce stillbirth were assessed. The educational content was delivered through oral presentation with group discussion and demonstration with supervised practice (skills). Pre- and post-tests of knowledge were used to assess knowledge gain. Participants evaluated the program and provided qualitative feedback about their working environment. Data were analyzed using GLIMMIX. Unresolved conflicts was significantly associated ($P < 0.05$) with personnel performance (determined by proportion of stillbirth) regardless of any differences in knowledge and skills. For the economic simulation, CPP (determined by compliance with calving protocol) was set to either 85% or 95%. Calf loss (stillbirth) was set at 1 preventable death due to late or no intervention at calving, assuming 18% of births need assistance. The overall risk performance percentage (RP) was estimated taking into account the CCP and TO. Costs were set at $280/head for calf loss, $1,000 for herd audit, and $1,000 for training (4 sessions/yr). For a 2,000-cow herd, calf losses were higher ($43,490 or $21 per cow/yr) for RP 85% with 30% TO (166 calves lost/yr) compared with RP 95% with 5% TO (19 calves lost/yr). The return on investment (ROI) for high performance teams (RP 95% and TO 5%) was $21 for every $1 invested (herd audit and training). The estimated ROI assumes that facilities are adequate, participants are willing to learn and apply newly learned concepts, and the herd audit correctly identifies and addresses the needs with the appropriate training program. Unresolved conflicts (interpersonal issues) within herd are associated with both TO and CPP, which in turns compromise the welfare of cows and calves around parturition.

Key Words: dairy personnel, stillbirth, welfare

501 Do improvements in housing and management voluntarily applied by producers following a cow comfort assessment reduce cow injuries in tie-stall dairies? Santiago Palacio*[1], Renée Bergeron[1], Jeff Rushen[2], Anne Marie de Passillé[2], Doris Pellerin[3], Derek Haley[4], Trevor DeVries[5], and Elsa Vasseur[1], *[1]University of Guelph- Alfred Campus, Alfred, ON, Canada, [2]University of British Columbia- Dairy Education and Research Center, Agassiz, BC, Canada, [3]Université Laval, Quebec, QC, Canada, [4]University of Guelph, Guelph, ON, Canada, [5]University of Guelph-Kemptville, Kemptville, ON, Canada.*

Cow welfare is an increasing concern for consumers. In Canada new standards on the care and handling of dairy cattle have been established and are currently being enforced. Injuries to hocks, knees, and neck are common in dairy cows and are accepted as being painful and a welfare concern. The objective if this study was to evaluate how voluntary improvements applied by producers in housing and management following a cow comfort assessment with recommendations would lead to improvements in cow welfare in tie-stall farms. The 4 most reported modification made to the tie-stall were: adding new rubber mats, adding or adjusting the brisket board, pushing up and/or out the tie-rail, and/or increasing the chain length. Hock and knee injuries were scored on a scale of 0–3 were scores 2 (swelling 1 – 2.5 cm and/or a lesion) and 3 (swelling >2.5 cm) represent major injuries. Neck injuries were scored on a scale of 0–2 were 2 represents swelling and/or lesions. Forty cows/farm from a total of 19 farms (2 groups: 10 that applied modifications, 9 that did not) visited in the summer were scored during 2 assessments (2011 and 2014). Kruskal-Wallis test was used to compare, between farm groups, the difference in prevalence of injuries between both assessments. Both groups of producers who reported to have made modifications and those that did not had reduced prevalence of major hock injuries by 23.8 and 21.4% (SEM 3.14), major knee injuries by 27.0 and 25.3% (SEM 3.89) and major neck injuries by 32.9 and 34.8% (SEM 4.56) respectively. There were no differences observed in improvement of injury prevalence between both groups of producers (hock: $X^2 = 0.3$, $P < 0.1$; knee: $X^2 = 0.2$, $P < 0.1$; neck: $X^2 = 0.0$, $P < 0.1$). Between the time producers received results of the assessment of their farm, and the new assessment, the level of cow injury decreased indicating that when equipped with knowledge, producers took action to improve cow comfort. Besides the ones reported, producers may have applied other modifications in cow housing or management that could explain the reduction in cow injuries between both assessments.

502 Social dominance affects body growth, follicle development, and age at puberty in dairy heifers.

Carolina Fiol*[1,2], Annie dos Santos[1,2], Augusto Lacava[1,2], Ana Maverino[1,2], Mariana Carriquiry[3], and Rodolfo Ungerfeld[2], [1]*Departamento de Bovinos, Facultad de Veterinaria, Montevideo, Uruguay,* [2]*Departamento de Fisiología, Facultad de Veterinaria, Montevideo, Uruguay,* [3]*Departamento de Producción Animal y Pasturas, Facultad de Agronomía, Montevideo, Uruguay.*

The aim of our study was to determine the effects of social dominance in dairy heifers during the prepuberal period on body growth, follicle development and age of onset of cyclic activity. Sixteen Holstein dairy heifers (8.2 ± 0.3 mo-old, 208.5 ± 13.9 kg BW) were homogeneously allocated according to age and BW to 8 dyads. Each dyad was housed in a different pen separated by electrical fences, had access to only one feeder and received a total mixed ration on a 5% restriction of their potential total dry matter intake to promote competition between heifers. Social dominance (dominant-DH, subordinate-SH) was determined every 30 d in each dyad during the 120 d of the experiment. Heifers were weighed every 20 d, and the number of follicles, the maximum follicle diameter (MFD) and presence of corpus luteum (CL) were determined every 7 d by transrectal ultrasound. Puberty onset was defined as the first day in which a CL—confirmed in the following observation—was recorded. Body weight and follicular parameters were analyzed with an ANOVA for repeated measures, while age at puberty was compared with a paired *t*-test. At the end of the experiment, DH were heavier than SH heifers (312.4 ± 2.5 vs. 304.0 ± 2.5 kg for DH and SH respectively, $P = 0.006$). In addition, DH reached puberty earlier than SH (318.0 ± 17.5 vs. 330.0 ± 23.3 d, for DH and SH, respectively; $P < 0.05$), and presented greater MFD from d 53 until the end of the experiment (10.0 ± 0.5 vs. 8.3 ± 0.5 mm, DH and SH heifers; $P = 0.04$). There was an interaction between social dominance and day of the study for total number of follicles: SH had more follicles than DH heifers on d 70 (4.8 ± 1.1 vs. 8.6 ± 1.1, DH and SH, $P < 0.01$), 79 (4.3 ± 1.1 vs. 7.7 ± 1.1, DH and SH, $P < 0.01$) and 86 (4.2 ± 1.1 vs. 6.8 ± 1.1, DH and SH, $P = 0.04$). No differences were found on the number of follicles >6 mm between groups (1.7 ± 0.3 vs. 2.0 ± 0.3, DH and SH, respectively; $P > 0.05$). In conclusion, with a slight restriction of food availability, dominant heifers presented greater body growth and reproductive development than subordinate ones. Financial support: CSIC, Uruguay.

Key Words: dominance, replacement heifer, puberty

503 Association between social ranking and health of transition dairy cows.

Karen M. Lobeck-Luchterhand*, Paula R. B. Silva, Ricardo C. Chebel, and Marcia I. Endres, *University of Minnesota, St. Paul, MN.*

The objective of this study was to determine whether social ranking was associated with health of transition dairy cows. A total of 953 Jersey cows were used in the analysis. Cows were examined on DIM 1, 4, 7, 10, and 13 for the diagnosis of retained fetal membranes (RP) and metritis. Metritis was defined as cows with watery, pink or brown, and fetid uterine discharge; acute metritis included cows that had a fever (>39.5°C). Cows were classified with subclinical ketosis when BHBA concentration was ≥1200 µmol/L. Cows were observed once daily for displacement of abomasum (DA) and thrice daily for mastitis. Displacements from the feedbunk were measured continuously for 3 h after fresh feed delivery 4 d/wk during the 4 wk before calving for determination of social rank. A displacement index (DI) was calculated for each cow as the number of displacements as actor (cow initiated the displacement) divided by total displacements as actor or reactor (cow received the displacement). Displacement index was used on a continuous scale (method 1) and also categorized into social rankings (method 2); cows with a DI <0.4 were considered low-ranking, 0.4 to 0.6 were considered middle-ranking, and >0.6 were considered high-ranking. Additionally, the top and bottom 10th percentile for DI were selected to examine cows on the extreme ends of DI (method 3). Cows were categorized into bottom (DI <0.19), middle (0.19–0.71), and top 10th percentile (DI > 0.71). Proc Logistics in SAS was used to investigate the association between social ranking (defined by each of the 3 methods above) and health. Displacement index was associated with RP (AOR = 1.02, 95% CI 1.00–1.03), metritis (0.99, 0.97–1.00) and incidence of mastitis up to 60 DIM (0.99, 0.97–1.00). High-ranking cows were 2.0 times (1.08–3.70) more likely to have RP than low-ranking cows with no differences between low- and middle-ranking cows. The bottom 10th percentile DI cows were 4.7 times (1.6–13.4) more likely to have a case of metritis than the top 10th percentile ranking cows. A cow's ability to displace another cow from the feedbunk during the prepartum period as a determinant of her social rank was not very consistent in predicting the odds of having a transition health disorder.

Key Words: social rank, transition cow, displacement index

Animal Health: Beef cattle health, lameness and mastitis

504 Evaluating the metagenome of nasal samples from cattle with bovine respiratory disease complex (BRDC). Tara G. McDaneld*, Larry A. Kuehn, and John W. Keele, *US Meat Animal Research Center, Clay Center, NE.*

Bovine respiratory disease complex (BRDC) is a multi-factor disease, and disease incidence may be associated with an animal's commensal microbiota (metagenome). Therefore, evaluation of the animal's resident microbiota in the upper nasal cavity may help us to understand the effect of the metagenome on incidence of BRDC in cattle. Nasal swabs from approximately 600 calves were collected at various time points including preconditioning, weaning, and when the animal enters the feedlot and is diagnosed with BRDC. Samples from healthy cohorts were also collected for each time point evaluated in the feedlot to compare metagenome profiles of healthy and sick animals. Samples from animals diagnosed with BRDC in the feedlot were pooled in groups of 10 based on when the animal was diagnosed with BRDC (one week, 3 weeks, or 4 weeks after weaning). Samples from these same animals were also evaluated at the time points previous to entering the feedlot (preconditioning and weaning) to evaluate changes in the metagenome across time. Additionally, samples from the preconditioning and weaning time points were pooled in groups of 10 based on location origin of the animals before entering the feedlot, as calves came from 4 pasture locations before being weaned and comingled in the feedlot. To evaluate and compare the metagenome of each pooled sample, the variable region (approximately 1,500 bp) along the 16S ribosomal RNA gene was amplified by PCR to include v1-v8. These amplified products were then sequenced using next-generation sequencing (Pacific Biosciences RSII instrument) and sequence reads were analyzed by WebMGA and GreenGenes to identify subfamilies for the bacterial populations present. Overall, *Mannheimia haemolytica* (34–87%) was the predominant bacterial subfamily present in all pools evaluated at the feedlot, compared with preconditioning and weaning time points. Additionally, metagenome profiles differed across animal location origin before entering the feedlot. These results demonstrate a change in the metagenome of the nasal cavity across different time points of production and confirm the likely role of *Mannheimia haemolytica* in BRDC.

Key Words: bovine respiratory disease complex, metagenome, 16S sequence

505 Acute and chronic stress models differentially affect the inflammatory and antibody titer responses to respiratory vaccination in naïve beef steers. Nathan D. May*[1], Jeff A. Carroll[2], Nicole C. Burdick Sanchez[2], Shelby L. Roberts[1], Heather D. Hughes[1], Paul R. Broadway[2], Kate P. Sharon[3], Michael A. Ballou[3], and John T. Richeson[1], [1]*West Texas A&M University, Department of Agricultural Sciences, Canyon, TX,* [2]*USDA-ARS, Livestock Issues Research Unit, Lubbock, TX,* [3]*Texas Tech University, Department of Food and Animal Sciences, Lubbock, TX.*

The objective of this research was to determine the effect of an acute vs. chronic stress model on serum antibody titer and acute phase responses. Seronegative beef steers (n = 32; 209 ± 8 kg) were stratified by BW and assigned randomly to 1 of 3 treatments (1) Chronic stress (CHR), 0.5 mg/kg BW dexamethasone (DEX) administered i.v. at 1000h on d −3 to 0; (2) Acute stress (ACU), 0.5 mg/kg BW DEX administered i.v. at 1000h on d 0 only; or (3) Control (CON), no DEX. On d −4, steers were fitted with jugular catheters and placed into individual stanchions in an environmentally controlled facility. At 1200h on d 0, steers were administered a modified-live virus respiratory vaccine containing isolates of infectious bovine rhinotracheitis virus (IBRV), bovine viral diarrhea virus (BVDV), bovine respiratory syncytial virus (BRSV) and parainfluenza-3 virus (PI3V). On d 4, cattle were transported (177 km) to an isolated facility and housed in a single pen. Serum was harvested from d 0, 7, 14, 21, 28, 35, 42, and 56 and subsequently used to determine IBRV-, BVDV-, BRSV-, and PI3V-specific antibody titers. Additionally, serum from d −2, 0, 1, 3, 7, and 14 was used to quantify haptoglobin (Hp) and ceruloplasmin (Cp) concentrations. There was a trt × d interaction ($P < 0.01$) such that CHR steers had a greater ($P \leq 0.07$) BVDV antibody titer from d 14 to 28; whereas, CHR was greater ($P = 0.06$) than ACU on d 56. Moreover, IBRV antibody titers were increased beginning on d 14 for CHR and d 28 for ACU, and remained elevated through d 56 compared with CON ($P \leq 0.03$). Stress treatment altered Hp such that CON exhibited a greater ($P < 0.01$) Hp concentration than CHR but was not different from ACU ($P = 0.16$). On d 3, Cp was greatest for CON, intermediate for ACU, and least for CHR (trt × d; $P \leq 0.01$). Results suggest that immunosuppressive conditions in CHR and ACU may have allowed enhanced viral replication from the vaccine, resulting in a greater antibody titer response. Data further indicate that DEX administration blunted the acute phase response and these alterations were particularly evident in the CHR stress model.

Key Words: cattle, stress, vaccination

506 Effect of injectable trace mineral administration on health, performance and vaccine response of newly received beef cattle. Shelby L. Roberts*[1], Nathan D. May[1], Casey L. Brauer[2], Wes W. Gentry[2], Caleb P. Weiss[2], Jenny S. Jennings[2], and John T. Richeson[1], [1]*Department of Agricultural Sciences, West Texas A&M University, Canyon, TX,* [2]*Texas A&M AgriLife Research, Amarillo, TX.*

Previous research has established that trace minerals are necessary for optimal animal health and performance. The objective of this study was to evaluate the effect of an injectable trace mineral supplement containing copper, zinc, selenium, and manganese (Multimin 90) on vaccine response, growth performance and morbidity of beef calves upon entry into a feedlot. A total of 128 crossbred bull (n = 40) and steer (n = 88) calves were utilized. Cattle were stratified by initial BW (276 ± 3 kg) and gender, then assigned randomly to treatment pens (n = 8/treatment). Treatment protocols were (1) negative control (CON), or (2) Multimin 90 (MM) administered at 1 mL/45.5 kg BW subcutaneously on d 0. Cattle were also administered a pentavalent modified-live respiratory vaccine, anthelmintic, and metaphylaxis with tilmicosin phosphate on d 0. Individual BW data and blood were collected on d 0, 14, 28, and 42. Harvested serum was used to determine bovine viral diarrhea virus (BVDV) type 1a antibody titer as a proxy for vaccine response. Health was monitored daily by trained personnel blinded to treatment pen assignment. Calves were pulled when assigned a clinical illness score of ≥ 2, and considered morbid and administered antimicrobial treatment if rectal temperature was ≥ 39.7°C or if lung auscultation score was ≥ 3 on a 1 to 5 scale. Overall DMI was not different ($P = 0.82$) between CON and MM. Also, no difference in overall ADG ($P = 0.21$) was detected between CON (1.36 kg/d) and MM (1.25 kg/d) steers. The overall morbidity rate observed for this study was low (14%). There was no statistical difference ($P = 0.71$) in morbidity between treatments, which averaged 15.6 and 12.5%, for CON and MM, respectively. There was a treatment x d effect ($P = 0.09$) for BVDV-specific antibody titer. On d 14, the MM group had a greater ($P = 0.02$) BVDV antibody titer than the CON group. This data suggests that while administration of an injectable trace mineral did not improve performance or morbidity rate when disease incidence was low, the BVDV-specific antibody response to a respiratory vaccine developed faster for Multimin 90 treated animals.

Key Words: cattle, trace mineral, vaccine

507 Effect of different combination viral-bacterial respiratory vaccines on serum leukotoxin antibody, acute phase response, and performance in beef heifer calves.

Heather D. Hughes*[1], Sjoert Zuidhof[2], Shelby L. Roberts[1], Joelle L. Pillen[1], Garrett D. Bigham[1], and John T. Richeson[1], *[1]Department of Agricultural Sciences, West Texas A&M University, Canyon, TX, [2]Boehringer Ingelheim Vetmedica, St. Joseph, MO.*

Vaccination of newly received cattle against respiratory pathogens is a common practice in the stocker or feedlot setting; however, this practice may induce an acute inflammatory or febrile response that could affect clinical presentation or transiently reduce performance. Our objective was to determine if different combination viral-bacterial respiratory vaccines affect the leukotoxin (LKT) antibody concentration, acute phase response, rectal temperature (RT), or gain performance. A total of 30 clinically healthy beef heifer calves (BW = 222.3 ± 27.1 kg) were stratified by pre-trial serum antibody against *Mannheimia haemolytica* (MH) whole cell wall, then assigned randomly to 1 of 3 vaccine treatment regimens consisting of (1) Pyramid 5 + Presponse SQ (P5PS; n = 10), (2) Bovi-shield Gold One Shot (BGOS; n = 10), or (3) unvaccinated control (CON; n = 10). Heifers were housed in a single pen, and blood, BW and RT were collected on d 0, 4, 7, 14, 28, 42 and 56. A treatment x d interaction was observed for MH-specific LKT ($P < 0.001$). Cattle administered either of the vaccines had greater LKT antibody concentrations than CON on d 14 and 28 ($P \leq 0.04$), whereas BGOS was greater than CON on d 7 ($P = 0.03$) but did not differ from P5PS ($P = 0.49$). No differences were detected for RT ($P = 0.85$) or ADG ($P \geq 0.33$), which averaged 1.17, 1.11 and 1.23 kg/d for P5PS, BGOS, and CON, respectively from d 0 to 56. Respiratory vaccination affected serum haptoglobin (Hp) concentration; P5PS exhibited greater Hp concentrations than CON ($P = 0.01$) but was not different from BGOS ($P = 0.53$). No difference in serum ceruloplasmin was observed ($P = 0.88$). Results indicate that either vaccine produced a greater LKT antibody and Hp response compared with CON, but RT and performance were not affected. Respiratory vaccines may have slight inflammatory effects when administered to clinically healthy cattle, yet further research is warranted to elucidate vaccine-induced inflammation in highly stressed cattle.

Key Words: acute phase response, cattle, vaccine

508 Prebiotic supplementation improves performance, neutrophil function, and antibody responses of post-weaned Holstein heifers during the commingling phase.

Caleigh E. Payne*, Luis G. D. Mendonça, Lucas D. S. Rocha, Sophia C. Trombetta, Suzy Q. Fowler, Juan C. Gordienko, Sonia J. Moisá, and Lindsey E. Hulbert, *Kansas State University, Manhattan, KS.*

The risk of disease increases for post-weaned calves when they are transitioned from individual housing to group housing (commingling). Therefore, this study was conducted to determine if prebiotic supplementation of mannan-oligosaccharide (MOS) and b-glucan (BG) would assist calves in the transition from individual hutches to groups of 3. Feed intake, body weight gain, in vivo adaptive immune responses, and ex vivo neutrophil responses were measured from 60, weaned Holstein heifer calves (age 52 ± 4.0 SD d; 83 ± 14.7 SD kg). One week before commingling (−1 wk), calves were randomly assigned to either a daily bolus dose of oral prebiotics (3 g; 10% MOS, 18% BG) dissolved in 15 mL of molasses or control (15 mL molasses only) for 7 weeks. Daily DMI was collected and calves were weighed weekly. Whole blood was collected via jugular venipuncture on wk −1, 1, 2, and 6 relative to commingling. In addition, all calves were administered an innocuous protein injection, ovalbumin (OVA; subQ; 0.5 mg/mL), at commingling and 4 weeks after commingling. All blood samples were measured via flowcytometry for peripheral neutrophil phagocytosis (PG) and oxidative burst (OB) responses to heat-killed *E. coli* (8739). Plasma OVA-specific IgG and IgA were measured at 2 weeks after each OVA injection. Two weeks after commingling, prebiotic-treated calves had neutrophils with greater OB intensity than control calves ($P = 0.005$). Prebiotic-calves also had greater primary IgA ($P < 0.01$) and IgG ($P = 0.04$) responses to OVA than control calves, as well as greater secondary IgA response ($P < 0.01$) than control calves. One week after commingling, prebiotic-calves had greater ADG (1.07 vs. 0.90 ± 0.059 kg/d; $P = 0.04$) and as well as lower F:G (2.61 vs. 3.60 ± 0.204; $P = 0.001$) than control calves. Prebiotic supplements enhanced innate and adaptive immune measures and performance during the commingling phase. This supplementation may help reduce the risk of disease and improve vaccination response during commingling in post-weaned dairy heifers.

Key Words: prebiotic, immunology, bovine

509 Shotgun metagenomic analysis of bovine digital dermatitis.

Martin Zinicola*, Hazel Higgins, Svetlana Lima, Vinicius Machado, Charles Guard, and Rodrigo Bicalho, *Cornell University, Ithaca, NY.*

Metagenomic methods amplifying 16S ribosomal RNA genes have been used to describe the microbial diversity of healthy skin (HS) and lesion stages of bovine digital dermatitis (DD) and to detect critical pathogens involved with disease pathogenesis. In this study, we characterized the microbiome and for the first time, the composition of functional genes of HS, active (ADD) and inactive (IDD) lesion stages using a whole-genome shotgun approach. A total of 16 biopsy samples (HS, n = 8; ADD, n = 4; IDD, n = 4) were collected from Holstein dairy cows housed in one dairy farm. DNA was extracted and the microbiome was determined by shotgun techniques using Illumina MiSeq platform. Metagenomic sequences were annotated using MG-RAST pipeline. Six phyla were identified as the most abundant. *Chordata*, *Firmicutes* and *Actinobacteria* were the predominant phyla in the microbiome of HS, while *Spirochetes*, *Bacteroidetes* and *Proteobacteria* were highly abundant in ADD and IDD. *T. denticola-like, T. vincentii-like* and *T. phagedenis-like* constituted the most abundant species in ADD and IDD. Recruitment plots comparing sequences from HS, ADD and IDD samples to the genomes of specific *Treponema* spp., supported the presence of *T. denticola* and *T. vincentii* in ADD and IDD. Comparison of the functional composition of HS to ADD and IDD identified a significant difference ($P < 0.05$) in genes associated with motility/chemotaxis and iron acquisition/metabolism. We also provide evidence that the microbiome of ADD and IDD compared with that of HS had significantly higher ($P < 0.05$) abundance of genes associated with resistance to copper and zinc, which are commonly used in footbaths to prevent and control DD. In conclusion, the results from this study provide new insights into the HS, ADD and IDD microbiomes, improve our understanding of the disease pathogenesis and generate unprecedented knowledge regarding the functional genetic composition of the DD microbiome. Additionally, an increase in the abundance of copper and zinc resistance genes has been reported, suggesting that further research is necessary to optimize the foot bathing technique for the control and treatment of DD.

Key Words: bovine digital dermatitis, dairy cow, metagenomic

510 Comparison of milking and lying behavior between lame and sound cows on dairy farms with automated milking systems.

Meagan T. M. King*[1], Ed A. Pajor[2], Stephen J. Leblanc[3], and Trevor J. DeVries[1], [1]*Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada,* [2]*Faculty of Veterinary Medicine, University of Calgary, Calgary, AB, Canada,* [3]*Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

To develop better ways to use behavioral data to detect lame cows, comparisons of milking visit behavior, milk yield, and lying behavior were made between lame and sound cows on automated milking system (AMS) farms. Data were collected for 30 cows, over a 6-d period, from each of 26 AMS farms in Eastern Ontario, Canada. Cows were gait scored using a 5-point numerical rating system (1 = sound to 5 = lame). Cows with gait scores < 3 were classified as sound (n = 527) while those with gait scores ≥ 3 were classified as lame (n = 245). Milking visit behavior was extracted from the AMS computer at each farm, while lying behavior was measured continuously using electronic data loggers. Body condition and hygiene were also scored, and were compiled with other cow-level variables such as parity and DIM. Data were summarized across the 6-d observation period/cow and analyzed in multivariable general linear mixed models. When controlling for DIM, milking frequency (#/d; mean ± SE) was lower ($P < 0.001$) for lame cows (2.8 ± 0.1) compared with sound cows (3.1 ± 0.1). Milk yield was lower ($P = 0.05$) for lame cows (32.0 ± 0.9 kg/d) compared with sound cows (33.4 ± 0.8 kg/d), while accounting for parity, DIM, and body condition. Compared with sound cows, lame cows had fewer AMS refusals/d (1.0 vs. 1.8; SE = 0.2; $P < 0.001$). Lameness status did not affect the frequency of AMS failures/d (0.1 ± 0.01). Overall, lame cows made fewer visits to the AMS than sound cows (4.0 vs. 5.0 visits/d; SE = 0.3; $P < 0.001$). When accounting for parity and DIM, lying time was greater ($P = 0.002$) for lame cows (728.2 ± 13.7 min/d) compared with sound cows (693.8 ± 12.0 min/d). These results demonstrate the differences in behavior and resulting productivity between lame and sound cows, indicating the potential use of behavioral indicators to identify lame cows on AMS farms.

Key Words: automatic milking, dairy cow behavior, lameness

511 Comparing the prevalence of hoof lesions in dairy cattle classified as high, average or low antibody and cell-mediated immune responders.

Shannon L. Cartwright*[1], Kathleen Thompson-Crispi[1,2], Marlene Paibomesai[1], Filippo Miglior[2,3], and Bonnie Mallard[1,2], [1]*Department of Pathobiology, University of Guelph, Guelph, ON, Canada,* [2]*Center of Genetic Improvement of Livestock, University of Guelph, Guelph, ON, Canada,* [3]*Canadian Dairy Network, Guelph, ON, Canada.*

Several studies have shown cattle classified as high immune responders have lower incidence of disease, however the occurrence of hoof lesions has yet to be evaluated in dairy cattle classified for immune response. Therefore the objective of this study was to compare the prevalence of hoof lesions in dairy cattle classified as high, average or low antibody (AMIR) and cell-mediated immune responders (CMIR). Cattle (n = 190) from a commercial dairy farm in Ontario were evaluated for immune response (IR) using a patented protocol that captures both AMIR and CMIR. They were classified as high, average and low responders based on Estimated Breeding Values for AMIR and CMIR. Hoof health data was collected by the farm's hoof trimmer using Hoof Supervisor software. Only the first trim date for each animal was included in this data set, and multiple lesions per cow were considered. All lesions were analyzed both as individual lesion types and grouped into infectious (digital dermatitis) and horn (sole hemorrhage, sole ulcer, toe ulcer, interdigital hyperplasia and white line). The trimmer scored each lesion for severity as: 1 = least, 2 = middle, 3 = most. Data was analyzed using a SAS mixed model, which included the effects of parity and IR category (high, average and low). Data is presented as number of cases per cows within IR category, and significance is reported at $P < 0.05$ with trends at $P < 0.10$. Results showed that high antibody responders had significantly less digital dermatitis (20%) compared with average (36%) and similarly significantly less severe digital dermatitis (3%) compared with low (16%). Conversely, high antibody responders (50%) had significantly more non-infectious horn lesions compared with average (25%) and low (21%). High cell-mediated responders had a trend toward less interdigital hyperplasia (0%) compared with average (8%). Therefore, not only do cows classified as high immune responders have lower disease incidence, but this study suggests they also have lower prevalence of infectious hoof lesions, a critical problem facing dairy producers.

Key Words: hoof health, immune response, dairy cattle

512 Calf macrophages exhibit a robust response to LPS which is not affected three weeks after an early life challenge with LPS in vivo.

Filiz T. Korkmaz*, Aimee L. Benjamin, and David E. Kerr, *University of Vermont, Burlington, VT.*

Genetic and epigenetic factors may contribute to animal-to-animal variation in innate immune response to infection with epigenetic effects being imposed by differences in early life environment. To evaluate lasting effects of a severe early-life infection on innate immune response capability we exposed 6 pairs of Holstein bull calves, at 8d of age, to either a 0.5 µg/kg intravenous dose of LPS or saline. Three weeks later we established cultures of monocyte-derived-macrophages (MDMs) from 100 mL blood samples by culturing monocytes for 8 d. The cells were then challenged for 24h with 100 ng/mL of LPS. The LPS treated calves demonstrated clinical signs of endotoxin challenge and markedly elevated ($P < 0.05$) plasma levels of TNF-α (3.2 ± 1.0 ng/mL) and IL-6 (14.4 ± 2.8 ng/mL) at 2h post-challenge. Although there was no significant difference ($P > 0.05$) between cells from LPS or saline treated calves, the MDMs produced considerable quantities of IL6 and TNF-α in response to LPS, which averaged 2.3 ± 0.4 ng/mL and 190 ± 81 pg/mL, respectively. Likewise, there was a large LPS-mediated induction of IL8 and IL1-β (88.1 ± 37.6 and 1954.9 ± 1166.5 fold change, respectively). Readily detectable expression of TLR4 and CD14 was measured with minor induction due to LPS. No differences ($P > 0.05$) were measured between groups in LPS-induced gene expression. Relatively large inter-animal variation was found in most parameters with a significant correlation between expression of IL1-β and IL8 ($R^2 = 0.68$, $P < 0.01$) and TLR4 and CD14 ($R^2 = 0.57$, $P < 0.01$). Dermal fibroblasts were also isolated from 10 calves to determine how their response to LPS compared with that of the MDMs. Fibroblast TLR4 expression was less than MDM TLR4 expression and this was reflected in lower LPS-induced induction of IL8 and IL-6 gene expression. In conclusion, LPS response in MDMs and fibroblasts is variable between animals, lower in fibroblasts, and is not affected in MDMs 3-wks after a single exposure to LPS at 8d of age. Future studies are needed to determine genetic and epigenetic components which may be influenced by early life environment.

Key Words: innate immunity, epigenetic

513 Dysbiosis of the fecal microbiota in cattle infected with *Mycobacterium avium* ssp. *paratuberculosis*. Marie-Eve Facteau, Raymond Sweeney, Sanjay Kumar, Nagaraju Indugu, Bonnie Vecchiarelli, Bhima Bhukya, and Dipti Pitta*, *Department of Clinical Studies, School of Veterinary Medicine, New Bolton Center, University of Pennsylvania, Kennett Square, PA.*

Johne's disease (JD) is a chronic gastrointestinal infection of cattle caused by *Mycobacterium avium* ssp. *paratuberculosis* (MAP). In the US, more than 68% of dairy herds are infected with MAP, leading to considerable financial losses for producers. We hypothesized that cattle naturally infected with MAP have a reduction in gastrointestinal microbial biodiversity and gastrointestinal dysbiosis may play a role in the pathogenesis of JD. In the present study, fecal samples from 20 naturally infected (positive group); 25 JD-negative herdmates (exposed group); and 25 JD-negative cows from a MAP-free herd (negative group) were obtained from New Bolton Center, JD repository. All fecal samples were processed for genomic DNA and amplified for the V1-V2 regions of the 16S rDNA gene. Sequencing was performed on a 454 Roche Platform and sequences were analyzed using QIIME. Approximately 252,380 reads were analyzed from 70 bacterial communities with an average of 2,843 reads per sample. Approximately 34,606 operational taxonomic units (OTUs) were produced by clustering at 97% sequence similarity. Weighted and unweighted Unifrac distances by principal coordinate analysis showed a substantial difference ($P < 0.001$; Permanova test) in the bacterial community composition of the positive group verses the exposed and negative groups. Taxonomic assignment of the OTUs identified a total of 18 bacterial phyla across all samples. Across negative and exposed groups, *Bacteroidetes* and *Firmicutes* constituted more than 95% of the total bacterial population. However, in the positive group, lineages of *Actinobacteria* and *Proteobacteria* increased and those of *Bacteroidetes* and *Firmicutes* decreased ($P < 0.001$). *Actinobacteria* was highly abundant (30% of the total bacteria) in the positive group compared with <0.1% in exposed and negative groups. Therefore, it is apparent that bacterial communities in exposed and negative groups were homologous whereas significant variation in positive samples was observed. Bacterial diversity in positive group was compromised compared with negative and exposed groups.

Key Words: dysbiosis, fecal, Johne's disease

514 Use of a novel adjuvant to enhance the protective effect of a commercial vaccine against *Staphylococcus aureus* mastitis in dairy heifers. Charles Hall, Stephen Nickerson*, David Hurley, Lane Ely, and Felicia Kautz, *University of Georgia, Athens, GA.*

Use of a novel adjuvant (Immunoboost) to enhance antibody titers in response to a commercial vaccine (Lysigin) against *Staphylococcus aureus* mastitis in dairy heifers was evaluated in a 2-phase trial. Heifers 5 to 12 mo of age were used in both study phases and blood samples were collected weekly for processing (ELISA) to determine anti-*S. aureus* antibody levels; baseline titers before each phase did not exceed 1:1600. In phase 1, hyper-immunization with Lysigin to enhance the level and duration of titers did not result in titers that consistently exceeded conventional immunization. In phase 2, anti-*S. aureus* titers in heifers immunized with Lysigin + 2 mL Immunoboost tended to be elevated ($P = 0.10$) over those of heifers immunized conventionally with Lysigin alone by d 7 after initial immunization, a trend that continued through d 14. By d 21, titers in the Immunoboost group were elevated ($P = 0.05$) over conventional vaccinates and remained significantly elevated through d 35, returning to baseline by d 42. After receiving booster injections on d 42, the Immunoboost group experienced an increase ($P = 0.05$) in titers over conventional vaccinates on d 49 of the trial, and titers remained significantly elevated through d 63. Titers in the Immunoboost group remained elevated over conventional vaccinates through d 84 of the trial, but the difference was not significant, and titers in both groups were approaching baseline values. Findings suggest that Immunoboost is capable of enhancing the antistaphylococcal titer response to the commercial vaccine Lysigin, albeit in the short term. These studies indicate that continued study of using immunization to control *S. aureus* mastitis in dairy heifers is justified.

Key Words: antibodies, heifer, mastitis

515 The efficacy of PlyC endolylsin as an alternative therapy for *Streptococcus uberis* mastitis in vitro. Sara Linden[1], Parimala Sharma[1,2], Kasey M. Moyes*[2], and Daniel C. Nelson[1,3], *[1]University of Maryland, College Park, MD, [2]Institute for Bioscience and Biotechnology Research, Rockville, MD, [3]Department of Veterinary Medicine, College Park, MD.*

The bacteriophage endolysin, PlyC, displays antimicrobial activity against select streptococcal species and may be a promising new therapy for *S. uberis*-associated mastitis. This study investigated the antimicrobial activity of PlyC against a broad spectrum of *S. uberis* isolates, established an in vitro dose response, measured ex vivo binding and antimicrobial efficacy in *S. uberis* infected milk, and assessed safety and response to antibodies. For antimicrobial activity, 2 µg/mL of PlyC was incubated with 7 different strains of *S. uberis* isolated from cows with mastitis as well as ATCC 27958 and BAA-854 (strain 0140J). For dose-response studies, PlyC (0–16 µg/mL) were incubated with 27958. The linear proportion of the initial lytic velocity was measured using a spectrophotometric turbidity reduction assay for both antimicrobial activity and dose-response assays. To demonstrate streptococcal-specific binding in raw cow's milk, 20 µg of AlexaFluor-555-labeled PlyC was incubated with milk containing BAA-854 and binding was visualized via fluorescent microscopy. Finally, polyclonal antibodies against PlyC (pre-immune sera and hyper immune sera [titer ranging from 1:10–1:10,000]) were mixed with 32 µg/mL of PlyC and activity was measured using the spectrophotometric turbidity reduction assay. All data were statistically analyzed using the Student's *t*-test. Our results showed that PlyC possessed potent lytic activity ($P < 0.01$) against all strains of *S. uberis* tested. The dose-response profile demonstrated lytic activity ($P < 0.01$) at concentrations ranging from 1 to 16 µg/mL. Microscopy results indicated that PlyC specifically labeled cell walls of BAA-854 in raw milk ($P < 0.01$). In addition, PlyC retains full lytic activity ($P < 0.01$) against 27958 in the presence of high titer anti-PlyC antibodies, suggesting that even if antibodies are present, they are non-neutralizing. Taken together, the results indicated PlyC has the potential to be used as a novel therapeutic against *S. uberis*-associated bovine mastitis via its specificity against several strains of *S. uberis*, the components in milk do not interfere with activity, and it is not inhibited in the presence of antibodies.

Key Words: mastitis, PlyC, treatment

Beef Cattle Nutrition Symposium: Feeding Holstein steers

516 Neonatal and young (<205 kg) feeding programs in calf-fed Holsteins. Luis O. Burciaga-Robles*, *Feedlot Health Management Services, Okotoks, Alberta, Canada.*

The limited supply of beef cattle is one of the greatest challenges facing the beef industry globally and is a factor reflected in the annual decline in fed cattle harvest. Calf-fed Holsteins (CFH) represent an opportunity to fill the void in beef cattle supply; however, because of the differences that exist compared with beef cattle, a science based approach is required to optimize production and profitability. The CFH often is overlooked in academic research. The research based on dairy heifer calves or beef cattle is often extrapolated to CFH. The objective of this presentation is to discuss the implications of Neonatal Nutrition Programs (NNP) on health and lifetime performance in CFH. The success of NNP (birth to <205 kg) should take into consideration the environment, genetics, immune status, and inherent variation that exist in CFH populations. During NNP, the greatest contributor to the feed-only cost of gain is the milk feeding program. More research is required to optimize growth and production goals without compromising the well-being of the calf. Understanding how NNP affects the immune status/response of the calf and implications on lifetime health and growth is pivotal. Nutrigenomics is an avenue of research that could expand the understanding of how clinical or subclinical disease change nutrient requirements and potentially allowing for development of mitigation strategies. Another area of research required in the CFH encompasses determining the effects of lifetime feeding of CFH through understanding the potential interactions between NNP at the calf ranch and the eventual feeding program at the feedlot. Research regarding grain type, grain processing, by-product use, protein sources and concentrations, and roughage level at the calf ranch is critical. Understanding the biology of the CFH across all growth stages is needed so that economic models can be developed. Understanding the economic contribution of different aspects of biology allows for sensitivity determination of key economic variables that should help identify research priorities. A multidisciplinary research approach to understanding the CFH is required to meet the increasing demand for animal protein without compromising the overall well-being and sustainability of this industry.

Key Words: nutrition, calf-fed, feedlot

517 Morphological, microbiological, and biochemical development of ruminant gastrointestinal tract. Carl J. Yeoman and Glenn C. Duff*, *Department of Animal and Range Sciences, Montana State University, Bozeman, MT.*

It is well recognized that morphological development of the rumen is dependent on diet and microbiota. For example, dietary concentrates stimulate the microbial production of VFA, including butyrate. Butyrate is the primary form of energy to the developing rumen wall and promotes development of ruminal papillae. Microbial colonization of the ruminant gut is complex and begins at birth. Microbes found on the teat and in the colostrum rapidly replace early colonizers from the vagina and a dynamic succession takes place until a mature climax community forms between 180 to 360 d of age. By using direct-fed microbials, including live cultures of *Lactobacillus acidophilus, L. bulgaricus, Streptococcus thermophilus,* and *Aspergillus oryzae* in place of colostrum, we found no loss ($P > 0.05$) in ADG or increase ($P > 0.05$) in intake in neonatal lambs. In Holstein calves supplementation of *L. acidophilus* and *Propionibacterium freudenreichii* resulted in increased ($P < 0.05$) gastrointestinal villus height, crypt depth, and total height (crypt plus villus) before weaning with average ruminal papillae width greater ($P < 0.01$) in calves fed the live cultures versus control calves after weaning. Genus populations of *Bacteroides*, *Roseburia*, and *Eubacterium* were greater ($P < 0.05$) in fecal samples collected in nonscouring calves versus scouring calves. Using serum β-hydroxybutyrate as a marker in serum for ruminal development, milk feeding regimen (bottle versus trough) and housing (group versus individual) did not appear ($P > 0.10$) to affect ruminal development. Alterations of microbiota in the rumen to hasten ruminal development deserves attention to potentially improve animal health and performance.

Key Words: ruminant, gastrointestinal, development

518 Genetic, epigenetic, and management factors contribute to the risk of morbidity and mortality of Holstein feeder calves. Michael A. Ballou*[1], David E. Kerr[2], Kate P. Sharon[1], and Aimee L. Benjamin[2], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, TX, [2]Department of Animal Science, The University of Vermont, Burlington, VT.*

Holstein steers contribute significantly to US beef production. Healthy feeder calves are more efficient and produce carcasses with greater value. Holsteins have the genetic capability to produce carcasses with comparable quality to many common beef breeds, but there are unique challenges to feeding Holsteins. Genetic differences between Holsteins and common beef breeds influence health. Additionally, early life management and other environmental factors can have long-term effects on the health and productivity of Holstein feeder calves. Holstein heifers had greater inflammatory responses than Angus heifers when evaluated in both ex vivo fibroblast and in vivo lipopolysaccharide challenge models. In both models, the Holstein heifers produced approximately 3 times more inflammatory mediators than the Angus heifers. The greater inflammatory capacity is likely due to a combination of genetic and epigenetic factors. In fact, pre-weaning nutrition influenced the risk of morbidity and mortality to a combined bovine herpesvirus-1 and *Mannheimia haemolytica* respiratory disease challenge in Holstein calves a month after weaning. Calves fed a restricted quantity of milk replacer, a common management strategy, had greater ($P \leq 0.05$) mortality (4/15) compared with calves fed 2.5 times more milk replacer (0/15). In agreement, the restricted fed calves had greater measures of systemic inflammation, increased peripheral blood neutrophil:lymphocyte ratio and plasma haptoglobin concentrations. In contrast, many management strategies that are common among Holstein calves improve their health in a feed yard. These management strategies include: vaccination (viral and bacterial antigens), weaning, castration, dehorning, and feed bunk and water trough training. Implementing these management strategies to calves will reduce stress and its negative effects on immunity during arrival at the feed yard. Taken together, management decisions of Holsteins during the calf phase are important as they can have either positive or negative effects on future health.

Key Words: beef, calf, health

519 Nutrition and management of calf-fed Holstein steers. Richard Zinn*, *University of California, Davis, CA.*

This presentation provides a brief review of feedlot nutrition and management considerations for Holstein steers. Calf-fed Holstein steers typically enter the commercial feedlot at 100 to 120 d of age, with a full purchase weight of approximately 137 ± 16 kg. On a shrunk-to-shrunk basis (full purchase and final weights reduced 4%), harvest weight, ADG, and days on feed of implanted calf-fed Holstein steers average 588 ± 16 kg, 1.31 ± 16 kg, and 349 ± 10 d, respectively. Rate of gain and gain efficiency are markedly influenced by harvest weight and placement month. Due to high summer temperatures, late summer and fall close-outs are least efficient for feedlots located in the desert southwest. Calf density should be regulated to achieve an average surface moisture level of roughly 20%. Because water consumption is greater (20 to 30%) in Holsteins than conventional beef breeds, they require more pen and shade space. In commercial practice, calf-fed Holsteins are fed a single growing-finishing diet throughout the duration of the feedlot period. A characteristic diet may contain 12–13% crude protein (urea the sole source of supplemental N), 0.70–0.80% calcium, 0.35–0.40% phosphorus,0.20 to 0.28% magnesium, 0.3 to 0.4% tracemineral salt, and 8% forage NDF. Due to very high growth potential during the initial 112 d on feed, this diet will not meet the calf's metabolizable amino acid requirements, resulting in a predictable decrease (15 to 20%) in energetic efficiency during that phase. The rather high incidence of liver abscess frequently observed among lots of calf-fed Holsteins may warrant continued low-level antibiotic supplementation. Good feedbunk management is particularly important with Holsteins. The high energy content of the diet fed over a protracted period of time poses added threat to the possibility of acidosis.

Key Words: Holstein, feedlot, nutrition

520 Feedlot: Liver abscesses.

T. G. Nagaraja*, *Kansas State University, Manhattan, KS.*

Abscesses in the liver of cattle are focal infections resulting from entry and establishment of pyogenic bacteria. There are several routes by which bacteria reach the liver, but entry via portal blood is by far the most frequent, because it drains the gastrointestinal tract, a source of bacteria. Liver abscesses can occur at all ages and in all types of cattle, but are most common in feedlot cattle fed high-grain finishing diets. The generally accepted pathogenesis of liver abscess includes chronic ruminal acidosis that leads to rumenitis, which then allows bacteria, primarily *Fusobacterium necrophorum,* to cross the epithelial barrier to enter the portal circulation. Bacteria from the portal circulation are filtered by the liver, leading to growth, production of virulence factors, particularly leukotoxin, damage to hepatic parenchyma, and abscess formation. *Trueperella* (formerly *Arcanobacterium*) *pyogenes* is the second most common bacterial species isolated from liver abscesses. Another bacterial species that has been recently isolated from liver abscesses is *Salmonella enterica.* Liver abscesses in cattle are of significant economic concern to the feedlot industry because of liver condemnation, reduction in performance and carcass yield. Liver abscess data collected from several packing plants have indicated a higher incidence of liver abscesses, particularly of the A+ score (most severe), in Holstein steers than the traditional beef cattle. Holstein steers raised for beef production are different from traditional beef breeds. Among the differences include more digestive and metabolic disorders and death losses in Holstein steers compared with beef breeds. The generally accepted reason for the increased digestive disorders, liver abscesses and death loss is the greater number of days Holsteins are on feed. However, it is not known whether the bacterial flora of liver abscesses of Holstein steers is in any way different from abscesses of the traditional beef cattle. In a recent study, liver abscesses in Holstein steers had a more diverse bacterial flora compared with traditional beef cattle. However, the prevalence of the major bacterial species, *F. necrophorum,* and *T. pyogenes* were similar between the 2 cattle types.

Key Words: liver abscess, Holstein steers, etiology

521 Methods of estimating empty body composition, energy retention, and grading characteristics of calf-fed Holstein steers.

T. J. McEvers*[1], N. D. May[1], J. A. Reed[1], L. J. Walter[1], J. P. Hutcheson[2], and T. E. Lawrence[1], [1]*West Texas A&M University Beef Carcass Research Center, Canyon, TX,* [2]*Merck Animal Health, Summit, NJ.*

A serial harvest trial investigating growth characteristics of calf-fed Holstein steers (n = 115; initial BW = 449.2 ± 19.9 kg) was conducted in 28 d intervals starting at 226 d on feed (DOF) and ending at 534 DOF. Five steers were slaughtered on d 226 and utilized as a point for growth modeling. Remaining cattle (110 steers) were randomly allocated to harvest endpoint (10 cattle per slaughter day; 254, 282, 310, 338, 366, 394, 422, 450, 478, 506, and 534 DOF) with one-half of each group receiving zilpaterol hydrochloride (ZH) for 20 d followed by a 3 d withdrawal. Shrunk BW (SBW, kg) and hot carcass weight (HCW, kg) were utilized to predict empty body weight, kg (EBW). Feeding performance {dry matter intake (DMI, kg), net energy for gain, (NEG, Mcal/kg of diet dry matter), and ZH supplementation} variables were utilized to estimate EBW and empty body fat (EBF, %). For prediction of HCW, a 2 variable equation was developed with an R^2 of 0.946 ($P < 0.01$) and root mean square error (RMSE) of 20.13 {$HCW = -41.44 + (0.6637 \times SBW) + (12.974 \times ZH)$; 1 = 20-d supplementation, 0 = 0-d supplementation}. For prediction of EBW, an equation with an R^2 of 0.942 ($P < 0.01$) and RMSE of 29.9 was developed {$EBW = 57.6232 + (1.39280 \times HCW) - (11.0994 \times ZH)$}. Utilizing feeding performance data, a model with an R^2 of 0.919 ($P < 0.01$) and RMSE of 35.2 was developed for prediction of EBW {$EBW = -1547.34 + (1.19 \times DOF) + (21.13 \times DMI) + (1005.73 \times NEG) + (18.87 \times ZH)$}. To predict EBF using feeding performance variables, a 4 variable equation was developed with an R^2 of 0.621 ($P < 0.01$) and RMSE of 2.9 {$EBF = 0.7769 + (0.0003 \times DOF) + (0.0046 \times DMI) - (0.4346 \times NEG) - (0.0167 \times ZH)$}. Several variables available to calf-fed Holstein producers may be implicated for use in predictive models related to finishing performance and composition of gain for calf-fed Holstein steers.

Key Words: Holstein, body composition, carcass characteristics

Breeding and Genetics: Feed efficiency and methods

522 Definition and implementation of a breeding value for feed efficiency. Jennie E. Pryce*[1,2], Oscar Gonzalez-Recio[1], Gert Nieuwhof[1], Bill Wales[1], Michael P. Coffey[3], Ben J. Hayes[1,2], and Michael E. Goddard[1,4], *[1]Department of Economic Development, Jobs, Transport and Resources, Bundoora, VIC, Australia, [2]La Trobe University, Bundoora, VIC, Australia, [3]SRUC, Edinburgh, Midlothian, UK, [4]The University of Melbourne, Melbourne, VIC, Australia.*

The objective was to describe how a new estimated breeding value (EBV) for feed efficiency is calculated. From April 2015, the Australian Dairy Herd Improvement Scheme (ADHIS) has published a new breeding value, called feed saved, that is the amount of feed saved through improved metabolic efficiency and reduced maintenance requirements. The breeding value includes a genomic component for residual feed intake (RFI) combined with either a genomic or pedigree EBV for body weight (BW) predicted using conformation traits. The RFI component of the feed saved EBV has 2 parts: Australian calf RFI and Australian lactating cow RFI. Genomic breeding values for RFI were estimated in a multi-trait analysis (3 traits) that included including Australian growing heifer and lactating cow RFI in addition to overseas (UK and Dutch) lactating cow RFI. The reference population included 50k single nucleotide polymorphism (SNP) genotypes and phenotypes for 234 Australian lactating cows and 843 heifers (approximately 6 mo old) and 958 UK and Dutch lactating cows. In all cases, the RFI phenotypes were trait deviations that were calculated by correcting dry matter intake for bodyweight, growth and yield (in the case of lactating cows). Effects for each SNP were calculated from the output of genomic best linear unbiased prediction and used to predict breeding values of 4,416 sires that were genotyped, but did not have RFI phenotypes themselves. These bulls already had BW breeding values calculated from type traits, from which maintenance requirements in kg of feed per year were inferred. Finally, RFI and the feed required for maintenance (through BW) were combined to construct a feed saved breeding value. Animals with EBVs that are one standard deviation above the mean are predicted to eat 65 kg dry matter less per year at the same level of milk production. The mean reliability associated with the feed saved breeding value was 0.37 in the data set of 4416 genotyped Holstein sires. From April 2015, feed saved has also been included as part of the Australian national selection index published by ADHIS.

Key Words: feed efficiency, residual feed intake, genomic

523 Indices to improve feed efficiency. Kelli J. Retallick*[1], Jennifer M. Bormann[1], Robert L. Weaber[1], Michael D. MacNeil[3], Heather L. Bradford[1], Harvey C. Freetly[2], Daniel W. Moser[1], Warren M. Snelling[2], Richard M. Thallman[2], and Larry A. Kuehn[2], *[1]Kansas State University, Manhattan, KS, [2]USDA-ARS Meat Animal Research Center, Clay Center, NE, [3]Delta G, Miles City, MT.*

Evaluating feed efficiency of beef cattle has evolved from relying on single trait selection for increased gain to extensive use of multiple trait selection combining measures of gain and intake. Postweaning gain (difference between 365-d and 205-d age adjusted weights) is analyzed as part of National Cattle Evaluation programs and could be used in an index with shorter intake tests (currently >70d to accurately measure gain) to select animals for improved feed efficiency. Under this paradigm, producers could decrease costs per animal and increase genetic change by testing a greater number of animals per year. Objectives of this study were to compare 2 alternative indices for feed efficiency and to quantify the genetic response to selection for feed efficiency combining an intake test with PWG data. Strong genetic correlation estimates for steers and heifers between average daily gain (ADG) and postweaning gain (PWG) (0.81, 0.65) suggest PWG is a reliable proxy for ADG. On-test ADFI, on-test average daily gain ADG, and postweaning daily gain (PWG) records on 5,606 growing steers and heifers were obtained from the US Meat Animal Research Center in Clay Center, NE. Genetic (co)variances and EBV were estimated using a 6 trait animal mixed model with ADG, ADFI, and PWG as dependent variables for both steers and heifers. Indices combining EBVs for ADFI and ADG and for ADFI and PWG were evaluated. For each index, the weighting of gain was arbitrarily set to 1.0 and the weighting for ADFI was the negative of the average of the intra-contemporary group ratio of mean gain divided by mean ADFI. Values were combined with EBV to compute 2 index values per animal. Pearson correlations for steers (0.96) and heifers (0.45) indicated a strong relationship for steers between the indices. For steers, using the index with PWG rather than with ADG effectively results in the same genetic gain without additional intake records. Because more animals can be measured for intake, using PWG increases relative annual progress of selection for feed efficiency by 15%. These findings support using PWG data in combination with ADFI to determine efficient steers, lessen costs, and increase feed efficiency genetic change per year.

Key Words: beef, index, efficiency

524 Comparison of actual versus predicted feed intake phenotypes for genetic evaluation of feed efficiency in beef cattle. Kimberly A. Branham*[1], Jonathan E. Beever[2], Dan B. Faulkner[10], Holly L. Neibergs[3], Kris A. Johnson[3], Christopher M. Seabury[4], Dorian J. Garrick[5], Daniel D. Loy[5], Stephanie L. Hansen[5], Harvey C. Freetly[6], Matt L. Spangler[7], Monty S. Kerley[8], Robert L. Weaber[9], Daniel W. Shike[2], Robert D. Schnabel[8], J. E. Decker[8], Jerry F. Taylor[8], and Megan M. Rolf[1], *[1]Oklahoma State University, Stillwater, OK, [2]University of Illinois, Champaign, IL, [3]Washington State University, Pullman, WA, [4]Texas A&M University, College Station, TX, [5]Iowa State University, Ames, IA, [6]USDA- Meat Animal Research Center, Clay Center, NE, [7]University of Nebraska, Lincoln, NE, [8]University of Missouri, Columbia, MO, [9]Kansas State University, Manhattan, KS, [10]University of Arizona, Tucson, AZ.*

Feed efficiency is expensive to measure in beef cattle because of the technology it requires to measure individual animal dry matter intakes (DMI). One potential solution is to develop methods to effectively utilize pen feed intake data for genetic evaluation. Genetic correlations between predicted DMI (pDMI) and actual DMI reported in the literature indicate that pDMI may be useful as an indicator trait. Therefore, the objective of this study is to evaluate whether quantitative trait loci (QTL) mapping approaches identify the same regions of the genome for pDMI and DMI. Because average daily gain (ADG) is a primary driver of the prediction models, the overlap of pDMI and DMI QTL regions with QTL for ADG will also be evaluated. To achieve these objectives, individual animal feed intake, weight, and carcass data was obtained on 849 Hereford steers and heifers fed within a GrowSafe (GrowSafe Systems Ltd.) feed intake system. The Cattle Value Discovery System (CVDS) growth and carcass data model was utilized to obtain pDMI from DMI pooled within pens and reallocated to individual animals. Phenotypic correlations were 0.64 ($P < 0.0001$) and 0.56 ($P < 0.001$) between pDMI and DMI and pDMI and ADG, respectively. Genotypes were collected using the Illumina BovineHD Beadchip assay (Illumina Inc., San Diego, CA), and after data filtering, a final data set of 648,625 single nucleotide polymorphisms (SNP) were available for analysis. The SNP effects for ADG, pDMI, and DMI were estimated utilizing a BayesB0 model in GenSel. The 5-SNP windows surrounding the 100 largest SNP effects for each phenotype were compared with determine overlap between QTL regions. Concordance of QTL regions was 50% between pDMI and ADG, 26% between pDMI and DMI, and 19% between DMI and ADG. Seven of the QTL regions in common between pDMI and DMI were independent of ADG QTL regions. These results show that there is concordance between genomic regions for pDMI and DMI independent of the model drivers (ADG), and additional research will be conducted to characterize these regions of interest in genomic prediction for feed efficiency.

Key Words: beef cattle, feed efficiency, genomics

525 Hierarchical Bayesian inference on genetic and non-genetic components of partial efficiencies determining feed efficiency in dairy cattle.

Yongfang Lu*[1], Mike Vandehaar[1], Diane Spurlock[2], Kent Weigel[3], Louis Armentano[3], Charles Staples[4], Erin Connor[5], Zhiquan Wang[6], Mike Coffey[7], Roel Veerkamp[8], Yvette Haas[8], Nora Bello[9], and Robert Tempelman[1], [1]*Michigan State University, East Lansing, MI,* [2]*Iowa State University, Ames, IA,* [3]*University of Wisconsin, Madison, WI,* [4]*University of Florida, Gainesville, FL,* [5]*U.S. Department of Agriculture, Beltsville, MD,* [6]*University of Alberta, Edmonton, AB, Canada,* [7]*Scottish Agricultural College, Easter Bush, Midlothian, UK,* [8]*Animal Breeding and Genomics Centre, Wageningen UR Livestock Research, Lelystad, the Netherlands,* [9]*Kansas State University, Manhattan, KS.*

Dairy cattle feed efficiency (FE) can be defined as the ability to convert DMI into milk energy (MILKE) and maintenance or metabolic body weight (MBW). In other words, FE is DMI conditional on MILKE and MBW (i.e., DMI|MILKE,MBW). These partial regressions or partial efficiencies (PE) of DMI on MILKE and MBW can be separately partitioned into genetic or residual PE; furthermore, either PE category might be heterogeneous across various environmental or management factors. We develop a hierarchical Bayesian multivariate mixed model to infer upon such heterogeneity in PE as well as that of variance components (VC) of FE by modeling genetic and residual components of PE and of VC as mixed model functions of various factors such as station (fixed), parity (fixed), days in milk (fixed), and ration within station (random). After validating our proposed model with a simulation study, we applied it to analysis of a dairy consortium data set involving 5,088 Holstein cows from 13 research stations in 4 countries. Although no significant differences were detected across stations for the genetic PE of DMI|MILKE (0.38 kg/Mcal) and of DMI|MBW (0.10 kg/kg$^{0.75}$), as well as the residual PE of DMI|MILKE (0.33 kg/Mcal), the residual PE of DMI|MBW significantly differed across stations ($P < 0.05$), ranging from 0.05 kg/kg$^{0.75}$ to 0.18 kg/ kg$^{0.75}$. Substantial heterogeneity in genetic and residual VC in FE across stations, rations, and parities was also inferred. Estimated heritabilities of FE ranged from 0.16 to 0.46 across stations, whereas the overall estimated heritability of FE was 0.23. These results suggest that FE is more complex than what is currently considered in most quantitative genetic analyses.

Key Words: dairy cattle, feed efficiency, heterogeneity.

526 Thermal imaging as an indicator of feed efficiency in mid-lactation Holstein cows.

Lydia C. Hardie* and Diane M. Spurlock, *Iowa State University, Ames, IA.*

Genetic improvement of feed efficiency in dairy cattle through direct selection is a challenge because of costs associated with measuring feed intake on individual cows. The identification of an easy to measure indicator trait of feed efficiency would help alleviate this problem. The objective of this study was to characterize the genetic variability and determine the relationship between surface body temperature and internal body temperature with feed efficiency in mid-lactation Holstein cows. Feed efficiency was measured as residual feed intake (RFI), defined as the difference between the actual intake and predicted intake based on milk energy, body weight change, and maintenance requirements. Individual daily feed intakes and milk production were recorded for 8 weeks on 124 primiparous cows between 50 and 200 d in milk. Weekly body weight and milk component data were also collected, and average RFI throughout the measurement period was calculated. Surface body temperature was measured weekly by thermal images taken of the lower right rear leg using a Fluke hand-held Thermal Imaging Scanner. The mean temperature in a defined region on the image was averaged across days for each cow. Rectal body temperatures were taken on imaging days and averaged for each cow. The ability of the body temperatures to explain variation in RFI was analyzed with a linear model, which included the fixed effect of replicate along with body temperature (surface or rectal) as a covariate. Heritabilities for body temperatures were estimated in ASReml. Rectal temperature did not significantly explain variation in RFI while surface leg temperature accounted for 2.8% of the total variance in RFI ($P < 0.10$). Average leg surface temperatures for the top and bottom quartiles for RFI were 25.3 and 24.9 C (SE 0.3) for high and low RFI, respectively. Rectal temperatures did not differ between high and low RFI quartiles. Leg surface temperature was moderately heritable (0.32 ± 0.32) while the heritability estimate of rectal temperature was 0.16 ± 0.26. This research demonstrates surface leg temperature is a heritable trait that explains a small portion of variation in RFI.

Key Words: feed efficiency, residual feed intake, thermal imaging

527 Genetic correlations of lower gastrointestinal tract microflora taxonomic groups with animal intake and gain.

Larry A. Kuehn*[1], Warren M. Snelling[1], Rohita Sinha[2], James E. Wells[1], James L. Bono[1], Harvey C. Freetly[1], Min Seok Kim[1], Jennifer Clarke[2], Stephen D. Kachman[2], Etsuko Moriyama[2], Danielle F. Wells[2], and Andrew K. Benson[2], [1]*USDA, ARS, U.S. Meat Animal Research Center, Clay Center, NE,* [2]*University of Nebraska-Lincoln, Lincoln, NE.*

Diversity and composition of microorganisms in the lower gastrointestinal tract have been shown to affect health and weight in humans and other mammalian species. At least a portion of the microbial diversity is likely under host genetic control. Our objective was to determine whether animal feed intake and growth were genetically correlated with microbial taxonomic groups as measured in fecal samples from the lower gastrointestinal tract through metagenomic analysis. Fall born animals (n = 905) of various breed composition (crosses of 18 different breeds) had individual animal feed intake recorded during a 63d period. Steers (n = 491) received a high energy concentrate (finishing) ration, and heifers (n = 414) received a roughage (growing) ration. During these feeding trials, animals were weighed on 2 consecutive days both when feed intake collection began and ended with additional weights recorded at least every 3 weeks. Fecal samples were collected prior (once), during (at least 3 times), and after (once) the feed intake trial period and pooled as a composite sample by animal. Taxonomic composition of the fecal microbiome was quantified from shotgun metagenomic sequencing of total DNA. Common contigs within and among animals were pooled by phylogeny yielding a reference metagenome assembly of 87 taxonomic groups. These groups (each present in at least 75% of the animals) were quantified by mapping reads from individual animals onto the reference assembly. Genetic (co)variance components for feed intake, gain, and individual taxonomic groups were estimated using REML. Data were modeled with fixed effects of contemporary group (sex, year, season) and breed composition covariates. Random effects were animal direct genetic effect (pedigree derived relationships) and error. Seven taxonomic groups were estimated to be heritable ($P \leq 0.10$). Genetic correlations were detected ($P \leq 0.10$) for *Blautia* with feed intake (r = 0.61) and *Cellulosilyticum* with weight gain (r = −0.68). Ration (or sex) specific correlations were not estimable; however, it is likely that ration affects the lower gastrointestinal tract microbial composition. The USDA is an equal opportunity provider and employer.

Key Words: beef cattle, feed efficiency, metagenomics

528 Evaluating residual feed intake in dairy cattle using marker × environment interaction genomic selection model.

Chen Yao*[1], Gustavo de los Campos[2], Michael J. Vande Haar[3], Diane M. Spurlock[4], Lou Armentano[1], Yvette de Haas[5], Roel Veerkamp[5], Mike Coffey[6], and Kent A. Weigel[1], *[1]University of Wisconsin, Madison, WI, [2]University of Alabama, Birmingham, AL [3]Michigan State University, East Lansing, MI [4]Iowa State University, Ames, IA [5]Wageningen UR Livestock Research, Lelystad, the Netherlands, [6]Scottish Agricultural College, Easter Bush, Midlothian, UK.*

Feed efficiency in dairy cattle has gained much attention recently. To obtain residual feed intake (RFI), a measure of feed efficiency, individual feed intakes must be measured, which is usually cost prohibitive. Combining data from multiple countries could enlarge the reference population, but in this scenario it is essential to model genotype × environment (G × E) interactions when making inferences about feed efficiency or selecting efficient cattle. In this study, we constructed an interaction model that allowed marker effects to be peculiar to each environment (marker × environment interaction). As a benchmark, a standard genomic selection model that assumes marker effects are constant across environments was also fitted. We applied these models to data from 3,656 cows measured in 3 environments, North America (NAM), the Netherlands (NLD), and Scotland (SAC). The RFI phenotype was calculated as the deviation of an animal's feed intake from its expected intake based on milk energy output and metabolic body weight. Genotypic data included 57,574 SNPs per animal. The proposed model was used to estimate environment-specific genomic heritabilities, marker effects and breeding values. Genomic correlations between environments can also be computed using the variance component estimates from the model. For prediction purposes, the interaction model gave comparable accuracies to the standard model. The interaction model provides a novel way to evaluate traits measured in multiple environments in which G × E may exist, and it allows the user to distinguish markers with effects that are stable across environments versus markers for which interactions exist.

Key Words: genomic selection, marker × environment interaction, residual feed intake

529 Validating your validation: A consistency check for the R^2 found in a validation to calculate correct reliabilities for genomic EBV in a multi-trait setting.

W. Marianne Stoop*, H. Eding, and G. de Jong, *CRV, Arnhem, the Netherlands.*

In 2014, the Netherlands and Flanders implemented a new genomic system, in which direct genomic values (DGV) are used as pseudo-observations to directly affect the conventional trait. For most trait groups, this pseudo-record system is a multi-trait animal model, where the added R^2 from a validation study is used as correlation between DGV and conventional trait, and a covariance matrix holding partial correlations is derived from it. However, validation of the DGV is done in a single trait setting, where a relatively young –and unreliable- group of bulls is used as validation set, often resulting in unstable added R^2, depending on which set of bulls you select as validation set. When the added R^2 of traits within a multi-trait system are not consistent to each other, the multi-trait system is unbalanced, even if the defined covariance matrix is positive definite, resulting in incorrect reliabilities. In this study, a consistency check is done on the validation results of a set of fertility traits (nonreturn56, interval-calving-1st-insemination, calving interval, interval-first-last-insemination, conception rate, conception rate heifers, and age at first insemination) used in a multi-trait animal model, to assess the correctness of the added R^2, the used correlations and the reliability calculated for the GEBV. This consistency check is based on the coefficient of multiple correlations (MCC); where the expectation is that the diagonal of the matrix containing MCC is equal to the corresponding R^2 from the validation. Data of the EuroGenomics consortium was used. The training set varied between 6,000 bulls (for traits with national data only) to 26,000 bulls. Bulls born after 20040630 were considered as validation set. The added R^2 ranged from 0.21 for age-at-first-insemination to 0.64 for interval-first-last-insemination. When the set of added R^2 was consistent, the reliabilities for the validation bulls estimated in the multi-trait model were similar to realized reliabilities. In conclusion, the consistency check is a valuable tool to assess genomic validation.

Key Words: dairy cattle, genomics, validation

530 Genomic heritabilities and SNP associated with lower gastrointestinal tract microflora taxonomic groups and *E. coli* O157:H7 shedding.

Warren M. Snelling*[1], Larry A. Kuehn[1], Rohita Sinha[2], James E. Wells[1], James L. Bono[1], Elaine D. Berry[1], Min Seok Kim[1], Jennifer Clarke[2], Stephen D. Kachman[2], Etsuko Moriyama[2], Danielle F. Wells[2], and Andrew K. Benson[2], *[1]USDA-ARS-US Meat Animal Research Center, Clay Center, NE, [2]University of Nebraska-Lincoln, Lincoln, NE.*

Risk of beef contaminated by *E. coli* O157:H7 is affected by prevalence of O157:H7 in cattle feces. Host genetics may influence O157:H7 shedding and overall microbial diversity in the lower gastrointestinal tract. Objectives of this study were to determine influence of animal genotypes on measures of O157:H7 shedding and relative abundance of different taxa in cattle feces, and identify regions of the bovine genome associated with O157:H7 prevalence and microbial diversity. Feces were sampled from fall born animals (n = 1,099) of various breed composition (crosses of 18 different breeds) undergoing trials to measure individual animal intake over 63 to 90 d periods. Steers (n = 574) received a high-energy finishing ration and heifers (n = 525) a high-roughage breeding development diet. Feces were sampled once before, at least thrice during, and once after the feed intake trial period. Individual samples were assessed for enumerable O157:H7. Taxonomic composition of the fecal microbiome was quantified from shotgun metagenome sequencing of total DNA pooled for each animal. Reads were assembled for each animal individually and contigs pooled within and across animals by phylogeny, yielding a reference metagenome assembly of 87 different taxonomic groups that were detected across > 75% of the animals. These taxa were quantified by mapping reads from each sample onto the reference assembly. Heritability for relative abundance of each taxa and O157:H7 prevalence measure was estimated with REML, using genomic relationships described by imputed BovineHD SNP genotypes. Individual SNP effects were solved from animal solutions after REML converged. Heritability estimates ranged from 0.00 for 35 taxa to 0.21 for *Butyrivibrio,* and were greater than 0.05 for 19 taxa. For O157:H7 traits, estimates were 0.10 for the number of times the animal was prevalence positive, and 0.07 for $\log_{10}$ of the average O157:H7 level. Correlations between SNP effects on O157:H7 and individual taxa were near zero, although a cluster of SNP between *TMEM20* and *PLCE1* on BTA26 was associated with $\log_{10}$[0157:H7] and 11 taxa having heritabilities >0.05.

Key Words: beef cattle, metagenomics, *E. coli* O157:H7

531 Utilizing cattle genetic trends to evaluate the long-term use of gene bank collections.

Harvey D. Blackburn*[1], Carrie S. Wilson[1], Samuel Paiva[2], Scott Spiller[1], and Phil H. Purdy[1], [1]*ARS/USDA, Fort Collins, CO,* [2]*EMBRAPA, Brasilia, Brazil.*

The National Animal Germplasm Program has developed substantial germplasm collections (>800,000 samples) for more than 300 unique livestock populations or breeds. Gene bank utilization is relatively new to the livestock sector and the long-term genetic relevance of such collections has not been documented in terms of how far into the future the captured diversity might be commercially useful. Comparing the annual average PTA or EPD for various traits computed by the respective breed associations with the collection's PTA/EPD statistics (mean, standard deviation, and extremes) may be a comparison that provides insight as to how well the collection mirrors the in situ population. Six breeds selected for comparison were Holstein (n = 5393), Jersey (n = 873), Angus (n = 703), Hereford (n = 252), Charolais (n = 86), and Brangus (n = 70). Birth years for the bulls in each breed spanned: 50, 60, 55, 60, 45, and 35 years, respectively. Trends for PTA or EPD for each trait computed by the respective associations were developed. Breed average (in situ population) vs. collection: average, standard deviation and minimum and maximum values for the respective breeds were compared. The collection average across breeds and traits closely mirrored the in situ populations' PTA or EPD estimates over time. When comparing the repository PTA or EPD outliers of any breed to the mean of its in situ counterpart across traits it was determined that it would take the in situ average PTA/EBV estimates, for a given birth year, 25 to 35 years to reach the collection's maximum or minimum value. This finding was consistent across all breeds regardless of collection size and age. These results demonstrate that animals with samples in gene bank collections could produce progeny that are commercially competitive for at least a quarter century (post collection) and demonstrates that gene bank collections are sufficient to provide protection for the various breeds in the collection. These results demonstrate that continued targeted sampling by gene banks over time will further ensure collection utility. In addition to the issue of genetic security, these findings suggest genetic progress has not advanced as quickly in cattle populations as might have been assumed.

Key Words: genetic resource, cattle, gene bank

532 Estimating the heritability of gene expression profiles using RNAseq data.

Deborah Velez-Irizarry*[1], Catherine W. Ernst[1], Ronald O. Bates[1], Pablo Reeb[1], Yeni Bernal Rubio[2], Nancy E. Raney[1], and Juan P. Steibel[1], [1]*Michigan State University, East Lansing, MI,* [2]*University of Buenos Aires, Buenos Aires, Argentina.*

Estimation of heritability is crucial for breeding purposes and for understanding the genetic basis of phenotypic traits. For the specific case of expression traits, heritability estimates can be used to prioritize expression quantitative trait loci (eQTL) genes. Estimates of heritability are usually obtained by linking phenotypic records with the estimated relationship matrix. The relationship matrices can be derived from pedigree, marker information or both. We propose an approach to estimate heritability of gene expression that takes full advantage of next generation sequencing platforms. A GBLUP-based animal model was used to fit all genetic markers simultaneously to each gene expression profile individually. A preliminary study using longissimus muscle (LM) transcriptome sequence data (RNaseq) for 24 animals from the Michigan State University pig resource population (MSUPRP) showed that more power was needed to identify significant genetic effects when using gene expression profiles as a trait phenotype. A subsequent study involving LM RNaseq for 144 MSUPRP animals was conducted using a similar GBLUP-based model. Results showed great improvement in the detection of significantly heritable expression traits (HET). A total of 226 statistically significant HET were discovered at FDR = 1%. The range of heritability estimates for these significant expression traits was between 0.27 and 1.00. Furthermore, 3 gene expression profiles showed extremely high heritability ($h^2 > 0.99$, with GBV q-values $<1 \times 10^{-8}$). Pathway Analyses of the significant HET revealed multiple genes involved in organismal development and transcriptional regulation emphasizing cellular growth and proliferation. The top genes involved in these molecular processes include *TGFB3*, *BMPR1A* and *MCM8*, the former 2 associated with weight gain. This research shows that genomic prediction models can be effectively used to elucidate the molecular mechanisms driving variations in heritable expression traits and to identify important regulatory gene networks.

Key Words: heritability, RNAseq, quantitative genetics

533 Exploitation of population-wide whole-genome genotyping to identify the founder of a deleterious mutation in cattle.

Andreas Kromik[1], Phillip Widmann[1], Frieder Hadlich[1], Dierck Segelke[2], Rosemarie Weikard[1], and Christa Kühn*[1,3], [1]*Leibniz Institute for Farm Animal Biology (FBN), Institute for Genome Biology, Dummerstorf, Germany,* [2]*Vereinigte Informationssysteme Tierhaltung w.V. (vit), Verden/Aller, Germany,* [3]*University Rostock, Faculty of Agricultural and Environmental Sciences, Rostock, Germany.*

Genomic selection programs generate deep pedigrees with whole genome genotyping data, which can also be used for the analysis of genetic defects. Recently, studies highlighted the relevance of novel mutations for human health. The use of non-progeny tested very young sires in genomic selection programs increases the danger of an unnoticed, rapid spread of novel mutations, if no respective precautions are taken. Recently, we identified a novel defect (spinal and vertebral malformation, VSD) and its causal mutation in Holstein cattle. Based on 50K SNP data, in our project 73 offspring of a carrier sire for VSD (41 VSD affected, 31 VSD unaffected) were haplotyped using CRIMAP options, and the paternal haplotype carrying the VSD mutation was identified. To further trace the origin of the haplotype associated with VSD, we subsequently haplotyped 50K SNP genotypes of a total of 55,384 individuals from the German Holstein population including all available relatives of the carrier sire using BEAGLE. Genotypes were provided by VIT Verden, the central database for genomic evaluation in German Holstein cattle. Tracking of haplotypes and haplotype breakpoints through the pedigree excluded the father of the carrier sire as potential source of the mutation and indicated that the mutation was located on the paternally inherited haplotype of the dam. Sequencing of the bovine *brachyury* gene in the maternal grandsire, the dam and the carrier sire itself revealed that the mutation developed de novo in the dam, because the haplotype of the maternal grandsire that was transmitted to the dam contained the wild type allele, whereas the respective haplotype in the dam showed the mutated allele. Additional genotyping of 94 offspring of the maternal grandsire revealed that none of those offspring showed the mutated allele. In conclusion, population-wide SNP genotyping and haplotype tracking enabled exclusion of a major Holstein blood line as source for VSD and confirmed the origin of the defect. Due to the recent de novo mutation and the confirmed knowledge about the founder, the defect can easily be eradicated from the Holstein population before any further outspread.

Key Words: genetic defect, cattle, vertebro-spinal dysplasia

Breeding and Genetics: Genomic methods

534 Use of genomic recursions in single-step genomic BLUP with a large number of genotypes. Breno D. Fragomeni*[1], Daniela A. L. Lourenco[1], Shogo Tsuruta[1], Yutaka Masuda[1], Ignacio Aguilar[2], Andres Legarra[3], Thomas J. Lawlor[4], and Ignacy Misztal[1], *[1]Department of Animal and Dairy Science, University of Georgia, Athens, GA, [2]Instituto Nacional de Investigacion Agropecuaria, Las Brujas, Canelones, Uruguay, [3]INRA, UMR1388 GenePhySE, Castanet Tolosan, France, [4]Holstein Association USA Inc., Brattleboro, VT.*

The purpose of this study was to evaluate accuracy of genomic selection in single-step genomic BLUP (ssGBLUP) when the inverse of the genomic relationship matrix (G) is derived by the APY (algorithm for proven and young animals). This algorithm implements genomic recursions on a subset of "proven" animals. Only a matrix due to the subset needs to be inverted and extra costs of adding "young" animals are linear. Analyses involved 10,102,702 Holsteins with final scores on 6,930,618 cows. A total of 100k animals with genotypes included 23k sires (16k with more than 5 progenies), 27k cows, and 50k young animals. Genomic EBV (GEBV) were calculated with a regular inverse of G, and with the G inverse approximated by APY. Initially, animals in the "proven" subset included only sires or cows. Later, animals in the "proven" subset were randomly sampled from all genotyped animals in sets of 5k, 10k, and 20k; each sample was replicated 4 times. Genomic EBV with APY were accurate when the number of animals in the "proven" subset was ≥10k, with little difference between the ways of creating the subset. Numerical properties as shown by the number of rounds to convergence were best with random subsets. The ssGBLUP with APY can accommodate a large number of genotypes at low cost and with high accuracy.

Table 1 (Abstr. 534). Correlations (or range of correlations) between genomic EBV with regular and APY ssGBLUP for young genotyped animals and rounds to convergence for different subset of animals used in recursions

Definition of subset	Animals in subset	Correlation	Rounds to convergence
All	100,000	1.00	567
Sires	23,174	0.99	432
Cows	27,215	0.99	797
2k random	2,000	0.94	356
5k random	5,000	0.97	360
10k random	10,000	0.99	396
20k random	20,000	0.99	420

Key Words: single-step method, genomic selection, genomic recursion

535 Genomic predictions with approximated G-inverse for a large number of genotyped animals. Yutaka Masuda*[1], Ignacy Misztal[1], Shogo Tsuruta[1], Daniela A. L. Lourenco[1], Breno Fragomeni[1], Andres Legarra[2], Ignacio Aguilar[3], and Tom J. Lawlor[4], *[1]University of Georgia, Athens, GA, [2]INRA, Castanet-Tolosan Cedex, France, [3]Instituto Nacional de Investigación Agropecuaria, Canelones, Uruguay, [4]Holstein Association USA Inc., Brattleboro, VT.*

The objective of this study was to compare the accuracy of genomic predictions in final score for young Holstein bulls calculated from single-step GBLUP models with the regular G^{-1} and approximated G^{-1} ($G^{-1}{}_{ap}$) matrices. The $G^{-1}{}_{ap}$ was calculated with recursions on a small subset of animals. The regular G^{-1} has a quadratic memory cost and cubic computational cost as the number of genotyped animals increases, whereas $G^{-1}{}_{ap}$ has a linear cost for animals outside the subset. The predictor data set consisted of 77,066 genotyped animals, 9,009,998 pedigree animals, and 6,384,859 classified cows born in 2009 or earlier. For calculation of $G^{-1}{}_{ap}$, 9,406 high accuracy bulls or 16,828 high accuracy bulls and cows were used as the small subset. Genomic predictions (GEBV2009) were calculated for predicted bulls that had no classified daughters in 2009 but did in 2014. The validation data set contained phenotypes and pedigree recorded up to March 2014. Daughter yield deviations (DYD2014) were calculated for the predicted bulls with at least 30 daughters in 2014 (n = 2,948). Coefficient of determination (R^2), calculated from a linear regression of DYD2014 on GEBV2009, was 0.44 with the regular G^{-1} and 0.45 with $G^{-1}{}_{ap}$ for either subset. Genomic predictions using all available 569,404 (570K) genotypes were also calculated with $G^{-1}{}_{ap}$ on 9,406 bulls. The computation was performed using 16 CPU cores and 61 G bytes of working memory. Setting up $G^{-1}{}_{ap}$ took 1.8 h, setting up matrices associated with $A_{22}{}^{-1}$ took 7 min, and iterations took 4.6 h, resulting in 6.4 total hours. In contrast, BLUP computations without genotypes took 1.6 h in total. The R^2 value from 570K genotypes was similar to the result from GEBV2009. Genetic predictions can be obtained with substantially less computational cost but without loss of reliability using $G^{-1}{}_{ap}$. The single-step GBLUP with $G^{-1}{}_{ap}$ is applicable to very large genotyped populations.

Key Words: computing, Holstein, single-step genomic BLUP (ssGBLUP)

536 Theoretical aspects of the APY algorithm for inverting a large genomic relationship matrix. Ignacy Misztal*, *University of Georgia, Athens, GA.*

The algorithm for proven and young animals (APY) implements the inverse of the genomic relationship matrix by recursion on a subset of animals. If the subset is small, storage and computations are approximately linear with the number of genotyped individuals, allowing for processing of practically an unlimited number of animals. The APY algorithm was tested with many subsets, including proven bulls, bulls and cows, cows only and random subsets. GEBVs calculated with APY were accurate when the number of animals in the subset was ≥10k, with little difference between different subsets. Best convergence rates when solving equations with APY were obtained with subsets composed of randomly chosen animals. The properties of the APY algorithm can be explained using the concept of a finite number of independent chromosome segments. Assume that each segment has a fixed value, that a fraction of each segment has a value proportional to the length of that segment (infinitesimal model), and that a genome of an individual is composed of a fraction of each segment. Subsequently, in the absence of confounding, n animals allow for identification of a population with n segments. Assuming some errors, lowest estimation errors are with heterogeneous animals. For traits where genes are distributed unequally across the genome, a conceptual division of segments into smaller segments with quasi-equal distribution would result in a larger subset required for the same accuracy of GEBV. If genome sequencing allows for identification of all m QTN, each QTN may be treated as one segment and, assuming a purely additive model, a recursion on m sufficiently heterogeneous animals will capture all variability in the genome. Computation in APY assume ability to compute parts of such a genomic relationship matrix that reflects the genetic architecture for each trait. The APY algorithm may allow routine genomic evaluation for any number of genotyped animals with any model at a cost not much above BLUP.

Key Words: genome selection, genomic recursion, genomic relationship matrix

537 Effect of increasing the number of single nucleotide polymorphisms from 60,000 to 85,000 in genomic evaluation of Holsteins. George R. Wiggans*, Tabatha A. Cooper, Paul M. VanRaden, Curt P. Van Tassell, Derek M. Bickhart, and Tad S. Sonstegard, *Animal Genomics and Improvement Laboratory, Agricultural Research Service, USDA, Beltsville, MD.*

The periodic need to restock reagent pools for genotyping chips provides an opportunity to increase the number of single nucleotide polymorphisms (SNP) on a chip. As an improved replacement for the GeneSeek Genomic Profiler HD for dairy cattle, a set of >140,000 SNP was selected that included all SNP on the current chip, all SNP used in genomic evaluations, SNP that are possible functional mutations, and other informative SNP. Most added SNP were selected from the Illumina Bovine HD Genotyping BeadChip based on the magnitude of effects on evaluated traits. Some SNP with lower minor allele frequency were considered because of their potential for better tracking of causative variants. Genotypes already available from other chips were used to impute and evaluate the SNP set. Effects for 134,511 usable SNP were estimated for all breed-trait combinations; SNP with the largest absolute values for effects were selected (5,000 for Holsteins, 1,000 for Jerseys, and 500 each for Brown Swiss and Ayrshires for each trait), which resulted in 78,032 SNP after removing duplicates. An additional 9,130 SNP with many parent-progeny conflicts after imputation were removed, which resulted in 72,843 SNP. Of those, 38,515 were among the 60,671 SNP currently used in genomic evaluation. To minimize possible accuracy loss,12,094 of the SNP currently used but not already selected and with the largest effects were added for a total of 84,937 SNP. Three cutoff studies were conducted with 60,671, 84,937, and 134,511 SNP to determine gain in reliability over parent average when evaluations based on data from August 2011 were used to predict genetic merit from December 2014. Across all traits, mean gains were 32.5, 33.4, and 32.0 percentage points, respectively. Previous experience indicates that gains from the highest number of SNP will increase as the number of genotypes from the new SNP set increases. The gain of 0.9 percentage points from adding nearly 25,000 SNP justifies the extra computation time needed. However, the gain may be overestimated because data used to select the most informative SNP were also the data used to determine gain.

Key Words: dairy cattle, genomic evaluation, single nucleotide polymorphisms

538 Genome-wide association study of fertility traits in dairy cattle using high-density single nucleotide polymorphism marker panels. Kristen L. Parker Gaddis[1] and John B. Cole*[2], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]Animal Genomics and Improvement Laboratory, ARS, USDA, Beltsville, MD.*

Unfavorable genetic correlations between production and fertility traits are well documented. Genetic selection for fertility traits is slow, however, due to low heritabilities. Identification of single nucleotide polymorphisms (SNP) involved in reproduction could improve reliability of genomic estimates for these low heritability traits. Additionally, high-density marker panels can increase the power of resultant GWAS by providing increased coverage and stronger linkage disequilibrium between markers and causal variants. The objective of this study was to identify SNP associated with 3 fertility traits in dairy cattle, daughter pregnancy rate (DPR), heifer conception rate (HCR), and cow conception rate (CCR), using high-density marker panels. Deregressed predicted transmitting abilities were available for 10,000 bulls sampled from the National Dairy Database that had high-density genotypes. Of those, 725 had been genotyped with the Illumina BovineHD Genotyping BeadChip. The remaining bulls had genotypes from various chip densities that were imputed up to the same level. After editing, 312,614 markers were included in the analyses. Univariate analyses were performed for DPR, HCR, and CCR using REMLF90 (version 1.79) with genomic options. postGSf90 (version 1.170) was used to calculate SNP effects and 10-SNP window variances. The largest proportion of variance explained for DPR (0.126%) was located on chromosome 6. Peaks were also identified on chromosomes 5, 18, and 28 associated with DPR. For HCR, the region explaining the largest proportion of variance (0.155%) was located on chromosome 1. Large peaks were also identified for HCR on chromosomes 6, 8, 14, and 17. The largest proportion of variance explained for CCR (0.181%) was located on chromosome 18. Large peaks associated with CCR were also identified on chromosomes 6, 15, and 19. Numerous markers and regions aligned with those previously identified. Significant SNPs could be used in genomic selection programs as well as in identification of genes and networks involved with fertility.

Key Words: fertility, genomic evaluation, high-density genotype

539 Segment-based methods to calculate weights for weighted single-step GBLUP. Xinyue Zhang*, Daniela A. L. Lourenco, and Ignacy Misztal, *University of Georgia, Athens, GA.*

The purpose of this study was to explore additional options for calculating weights in weighted single-step GBLUP (WssGBLUP). In GWAS by ssGBLUP, GEBV are converted to marker (SNP) effects. Unequal variances for markers are then derived from SNP solutions and subsequently incorporated into a weighted genomic relationship matrix. Improvements on the SNP weights were obtained iteratively by recomputing both the SNP effects and the GEBV. Six options were used to calculate the weights: (1) proportional to u_i^2 where u_i is the effect of the i-th SNP; (2) proportional to u_i^2 + constant; (3) weights as $\nu^{|s-2|}$, where ν is a scale standing for the departure from normality, and s is number of standard deviation from mean for each u_i^2 where p_i is frequency of the second allele; (4) as the largest effect (u_i^2) among every 20 SNP; (5) as the mean effect of every 20 SNP; (6) as the summation of effects of every 20 SNP. A simulated data set was used that included 15,600 animals in 5 generations, of which 1,540 were genotyped for 50k SNP. The simulation involved phenotypes for a trait with heritability of 0.5 and affected by 5, 100, and 500 QTL. Accuracy between TBV and GEBV for genotyped animals in the last generation was used for evaluation. Comparisons also involved BayesB and BayesC with deregressed proofs or EBV from BLUP, and $\pi = 0.99$, 0.9 or 0.5. In single-step, SNP effects were tracked along 10 iterations and weights were equal to 1.0 in the first iteration. Option 5 was the best in identifying simulated QTL without background noise and with precision in most of the regions. Option 2 kept accuracy of GEBV at the plateau after 2 iterations and was 0.81 as opposed to 0.70 for BayesC and 0.48 for BayesB under 500 QTL scenario. All methods reached better accuracies than BayesB and BayesC when number of QTL approached or exceeded 100 (0.2% of all SNP) due to automatically including PA in GEBV. Weights based on a sum of SNPs may be superior to those based on individual SNPs.

540 Multi-allelic haplotype model based on genetic partition for genomic prediction and variance component estimation.

Yang Da*, *Department of Animal Science, University of Minnesota, Saint Paul, MN.*

Functional genomic information has been growing rapidly but remains largely unused in genomic selection. Genomic prediction and estimation using haplotypes in genome regions with functional elements such as all genes of the genome can be an approach to integrate functional genomic information with genomic selection. Toward this goal, a multi-allelic haplotype model treating each haplotype as an 'allele' was developed for genomic prediction and estimation based on the partition of a multi-allelic genotypic value into additive and dominance values. Each additive value is expressed as a function of h-1 additive effects, where h = number of alleles or haplotypes, and each dominance value is expressed as a function of h(h − 1)/2 dominance effects. For a sample of q individuals, the limit number of effects is 2q − 1 for additive effects and is the number of heterozygous genotypes for dominance effects. Additive values are factorized as a product between the additive model matrix and the h − 1 additive effects, and dominance values are factorized as a product between the dominance model matrix and the h(h-1)/2 dominance effects. Genomic additive relationship matrix is defined as a function of the haplotype model matrix for additive effects, and genomic dominance relationship matrix is defined as a function of the haplotype model matrix for dominance effects. Based on these results, a mixed model implementation for genomic prediction and variance component estimation that jointly use haplotypes and single SNPs is established, including 2 computing strategies for genomic BLUP (GBLUP) and genomic REML (GREML) with identical results. The multi-allelic genetic partition fills a theoretical gap in genetic partition by providing general formulations for partitioning multi-allelic genotypic values and provides a haplotype method based on the quantitative genetics model toward the utilization of functional genomic information for genomic selection.

541 Revisiting allelic frequencies estimation: A decision theory approach to derive Bayes, minimax, and admissible estimators.

Carlos A. Martinez*[1,2], Kshitij Khare[2], and Mauricio A. Elzo[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]Department of Statistics, University of Florida, Gainesville, FL.*

Decision theory was used to derive point estimators of allelic frequencies with optimal statistical properties. Uniparameter (2 alleles) and multiparameter (multiple alleles) estimation problems were addressed for an arbitrary locus, then results were extended to multiple loci. First, estimators satisfying the Bayes principle of average risk optimality were obtained using a multinomial sampling model, a Beta (biallelic loci) and a Dirichlet (multiallelic loci) prior and 3 different loss functions: Squared Error Loss (SEL), Kullback-Leibler Loss (KLL) and a Quadratic Error Loss (QEL). Second, these Bayes estimators were used to obtain minimax estimators by finding values of the hyperparameters such that the frequentist risk functions were constant, a condition that implies minimaxity. Finally, the admissibility of the estimators was checked using standard theorems from decision theory. The frequentist risk function of the Bayes estimator derived from KLL involved a finite sum without a closed form, hence this risk function could not be written as a simple algebraic expression. However, this does not prevent its computation. Under SEL and QEL it was possible to find Bayes-minimax-admissible estimators (BMAE). Sufficient conditions for the usual maximum likelihood estimator to be BMAE and for the risk functions tending to infinite or converging to zero were also found. In addition to optimal statistical properties, these estimators have the appealing feature of taking into account random variation in allelic frequencies. The impact of using these estimators in different areas of quantitative and population genetics needs be assessed either empirically or theoretically and this poses a problem for further research.

Key Words: admissibility, allele frequency, minimaxity

542 Strategies for estimating hyperparameters based on single-step Bayesian models.

Lei Zhou* and Robert J. Tempelman, *Michigan State University, East Lansing, MI.*

Single-step BLUP (SS-BLUP) genomic prediction has the advantage of combining phenotypic information on both genotyped and nongenotyped animals. Recently developed single-step Bayesian regression models (SSBR) provide potentially even greater flexibility (e.g., heavy-tailed or variable selection alternatives) for modeling the prior distribution of SNP markers in tandem with polygenic effects. We discuss and present strategies for inferring upon these hyperparameters, particularly when data from either category (i.e., genotyped or nongenotyped) of animals is limiting. For example, when most animals in a genetic evaluation are not genotyped, inferences on key hyperparameters (i.e., marker variance, scale parameters) are compromised if these inferences are primarily based on marker data from genotyped animals only (strategy 1) whereas information on these hyperparameters might be readily borrowed from polygenic inferences involving nongenotyped animals as well (strategy 2). To compare these 2 strategies, a simulation study with 10 replicates was conducted. Five generations and a total of 2000 animals were simulated in each replicate. The heritability of the trait was 0.5 based on 1500 SNPs. The proportion of animals genotyped ranged from 10 to 90%. Results showed that strategy 2 estimated hyperparameters with greater accuracy than strategy 1 (Table 1), particularly when the proportion of animals that were genotyped was low (i.e., 10%). Nevertheless both strategies lead to similar accuracies of estimated breeding values for both genotyped and non-genotyped animals under the various genotyping rate scenarios. We also present methodology for both strategies using REML to infer upon these hyperparameters based on Gaussian specifications as well as how to infer upon hyperparameters in heavy-tailed (BayesA) and/or variable selection (BayesB) specifications. In conclusion, our proposed strategy had some advantage upon inferring hyperparameters, and further research is necessary for SSBR models.

Table 1 (Abstr. 542). Genetic variance by scenario and strategy

Scenario	Strategy	Total genetic variance (mean ± SD)
		24.60 ± 4.48 (True)
10% genotyped	1	24.92 ± 5.64
	2	25.70 ± 4.33
50% genotyped	1	22.35 ± 4.70
	2	24.05 ± 2.87
90% genotyped	1	20.73 ± 7.81
	2	24.26 ± 3.22

543 Reassessing hierarchical Bayesian genome-wide association analyses.

C. Chen*, J. P. Steibel, and R. J. Tempelman, *Michigan State University, East Lansing, MI.*

Genomic best linear unbiased prediction (GBLUP) analyses have been increasingly adapted for genome-wide association (GWA) analyses. A currently popular modification of GBLUP for GWA, which we label as classic GBLUP, is to treat all genetic markers as random, except for the marker being tested; conversely, shrinkage GBLUP treats all markers as random in a whole genome prediction (WGP) analysis. The classic GBLUP modification has been demonstrated to preserve Type I error rates whereas shrinkage GBLUP leads to a very conservative GWA test. Nevertheless, shrinkage estimation has recently been shown to have GWA properties under alternative prior specifications. Some popular WGP model specifications are heavy-tailed (i.e., BayesA) or involve variable selection (i.e., BayesSSVS) that do not shrink large marker effects as much as shrinkage GBLUP. Given that MCMC implementations of these models are computationally onerous, we propose inferences under these alternative priors based on the EM algorithm (i.e., EMBayesA and EMBayesSSVS). In a simulation involving 10 replicated data sets, each involving about 2000 individuals and 5000 SNP markers with average pairwise LD $r^2 = 0.30$ across 5 chromosomes, we discovered that EMBayesA and EMBayesSSVS shrink the majority of the posterior *z*-score based *P*-values to be larger relative to classic GBLUP, whereas markers in QTL regions tend to have substantially smaller *P*-values in EMBayesA and EMBayesSSVS compared with classic GBLUP. In an application involving backfat data from a Duroc-Pietrain F2 cross, we determined that EMBayesSSVS inferred SNP effects in albeit fewer putative QTL regions compared with classical GBLUP, although GWA using EMBayesA did not detect any such association. We suggest that EMBayesSSVS or other hierarchical variable selection models represent promising alternatives for GWA analyses of complex traits for which null marker effects might not appropriately represent a global null hypothesis; however, we also demonstrate that recently developed regularization techniques are vitally important in helping avoid posterior multimodality concerns in large dimensional EM-based inferences as well.

Key Words: expectation maximization, genome-wide association (GWA)

544 Approximating realized additive relationships in absence of genomic information.

Romdhane Rekaya*, Sajjad Toghiani, and L. Y. Chang, *The University of Georgia, Athens, GA.*

Superiority of genomic selection is due to the use of the realized relationships. Unfortunately, only a small portion of animals included in the evaluation are genotyped. Consequently, the majority of animals will still be evaluated based on their expected relationships. With the availability of genomic information, it is possible to assess the variation of expected co-ancestry coefficients for different orders (degrees) of relationships. Thus, this available information represents a good prior and could be used to better assess the Mendelian sampling in absence of genomic data. Furthermore, a sizeable portion of non-genotyped animals are already phenotyped for several traits with moderate to high heritabilities. Phenotypic records contain information about the true genetic relationship between animals. Using these 2 sources of information, we can improve the pedigree based relationship without using genomic data. A simulation was carried out to investigate the ability to infer realized additive relationships in absence of genomic information. A single trait with heritability of either 0.5 or 0.8 was simulated. A pedigree with large number of full (FS) and half (HS) sibs reflective of a chicken population was also simulated. All animals in the pedigree were assigned 60K SNP genotypes. The average (A) and the realized (G) matrices were computed using the pedigree and the genomic information, respectively. Using our procedure a realized relationship matrix (G*) was computed without use of the simulated genomic information. The results showed that the similarity between G and G*, measured by the absolute value of difference between corresponding elements of both matrices, was greater than between G and A. The average difference between G and A was 0.07 compared with 0.03 between G and G*. The realized relationships for FS and HS estimated using our proposed method overlap largely with those obtained using genomic information. Additionally, the similarity between G and G* increased, as expected, with the increase of heritability. The fact that the difference between G and G* is smaller than between G and A indicate that the matrix G* is a better approximation of G than A.

Key Words: realized, relationship, genomic

545 Imputation using whole-genome sequence data in Brown Swiss and Original Braunvieh.

Christine F. Baes*[1,2], Beat Bapst[2], Franz R. Seefried[2], Heidi Signer-Hasler[1], Christine Flury[1], Dorian Garrick[3], Christian Stricker[4], and Birgit Gredler[2], *[1]Bern University of Applied Sciences, Zollikofen, Bern, Switzerland, [2]Qualitas AG, Zug, Zug, Switzerland, [3]Iowa State University, Ames, IA, [4]agn Genetics, Davos, Grison, Switzerland.*

The distinct half-sib population structure common in dairy cattle populations permits imputation of array-based genotypes up to sequence level using sequence information of key ancestors. This approach provides a cost-effective alternative to sequencing all animals. The process works well in single breeds (e.g., Holstein), however it is less accurate when validation and reference animals are not of the same breed or population (e.g., Brown Swiss or Original Braunvieh). The objective of this study was therefore to investigate imputation strategies for composing reference and validation sets using Brown Swiss (BS) and Original Braunvieh (OB) animals. Whole genome sequence information (WGS) of 70 BS, 17 BS × OB and 8 OB animals was available for analysis. WGS was masked to mimic medium (50K; 54,609 SNP), and high-density (HD; 777,962 SNP) SNP arrays and then imputed back up to sequence level. Imputation was conducted using fimpute, which employs an overlapping sliding window approach to exploit haplotype similarities between validation and reference animals. Principal component analysis was used to determine which animals constituted reference and validation sets; scenarios involving various breed compositions were compared. The accuracy of imputation from 50K and HD to WGS was evaluated for each scenario by calculating the number of correctly imputed genotypes and concordance between true and imputed genotypes. Furthermore, imputation accuracy when the reference population was solely comprised of the breed to be imputed was compared with results obtained when the reference population was comprised of multiple breeds. Validation of OB genotypes resulted in 64.6–69.6% (50K to WGS) and 79.5–83.8% (HD to WGS) correctly imputed genotypes. BS validation resulted in 78.0–78.9% (50K to WGS) and 85.5–86.1% (HD to WGS) correctly imputed genotypes. Validation of intermediary animals using both BS and OB as reference resulted in the highest percentage of correctly imputed genotypes (79.1–79.6% for 50K to WGS and 86.5–86.7% for HD to WGS). Results show that breed composition of reference and validation sets has a considerable effect on imputation accuracy, and that imputation quality is improved if reference animals from similar populations are included.

Key Words: imputation, whole-genome sequence, accuracy

Companion Animal Symposium: Bioenergetics of pet food

546 Pet obesity and bioenergetics of pet food. Kelly Swanson*, *University of Illinois at Urbana-Champaign, Urbana, IL.*

It is estimated that 30 to 40% of dogs and cats in the United States are overweight or obese. Pet obesity increases the risk of several diseases and disorders, including insulin resistance, diabetes mellitus, hyperlipidemia, cancers, and many others, and results in a shorter life span. Although genetics, a sedentary lifestyle, and neutering contribute to weight gain, the over-consumption of energy-dense foods is a major driver. There are many challenges to preventing pet obesity, including owner beliefs and feeding tendencies, estimation of energy density, and development of appropriate feeding guidelines. Owner education, especially as it pertains to body condition scoring and feeding guidelines, is a critical need. Feeding guidelines are required on all pet foods, but many owners either do not read them carefully and/or do not understand the importance of adjusting intake based on body condition score. Ad libitum feeding and excessive feeding of table scraps and treats contribute to overfeeding. Estimating caloric content of ingredients or pet foods may also be difficult and quite different depending on the methodology used. Numerous equations are used to estimate the caloric density of diets based on proximate analysis, but they are all based on assumptions pertaining to the digestibility and metabolism of nutrients. The use of crude fiber, a highly inaccurate method of fiber estimation, also contributes to inaccuracies in determining digestible carbohydrate content and consequent caloric density estimates. In vitro assays that estimate nutrient digestibility have been developed, but in vivo tests are by far the most accurate method by which metabolizable energy content of diets may be determined. Even when an accurate caloric density has been determined, developing accurate feeding instructions are difficult because a large variation among pet animals exists, including differences in physical activity level, age, life stage, and metabolism. Fortunately, AAFCO regulations will be requiring a calorie statement on all pet foods in the near future. Given the issues listed above, however, it is questionable whether that requirement will aid in obesity prevention or provide false hope to veterinarians and pet food professionals.

Key Words: pet obesity

547 Bioenergetics of pet food. Ellen Kienzle* and Britta Dobenecker, *Chair of Animal Nutrition and Dietetics, Ludwig-Maximilians-Universität München, Oberschleissheim Germany.*

Energy of pet food is evaluated as metabolizable energy (ME). To determine ME heat of combustion in food (gross energy, GE), feces and urine is analyzed. Losses by gases are negligible. GE of the food can be calculated by standard values for heat of combustion of nutrients. Given a typical pet food potential errors in the standard values for heat of combustion of nutrients can add up to a deviation of a maximum of about 8% between GE as analyzed and GE as calculated. In practice there are often deviations of up to 30% between analyzed and calculated GE, mostly due to pitfalls of bomb calorimetry. Five repetitions with an intra-analysis variation coefficient of < 0.4% are necessary to ensure quality. To predict digestibility a fixed value for the digestibility of each nutrient can be used. This works well in a group of rather homogenous foods. Examples are unmodified Atwater factors for homemade western diet type foods for humans and pets. If digestibility is variable within a group of foods it is either necessary to make subgroups of foods with similar digestibilities or to use equations which adjust digestibility such as the prediction of digestibility by fiber in dry matter. For this crude fiber is the analysis of choice because in pet foods it detects mostly unfermentable fiber, which has a stronger impact on energy digestibility than fermentable fiber. Even so subgrouping the foods may present an advantage. The depressive effect of fiber on digestibility is stronger for carbohydrates than for fat, thus subgrouping according to carbohydrate or fat content may increase accuracy of prediction. Subgrouping of foods could even be done by in vitro tests such as an HCl-pepsin test to identify reducing diets with low digestibility of protein. There is little data on renal energy excretion in pets. So far the prediction of renal losses is done by a factor linked to protein intake, which is lower for cats than for dogs in most equations. Presumably the species difference reflects a difference in renal excretion of high energy nitrogen compounds such as hippuric acid, which is derived from phenolic food compounds. Both the content of such compounds in the diet and the ability to degrade these compounds to hippuric acid may contribute to the difference.

Key Words: pet food, bomb calorimetry, prediction of digestibility

548 Animal and in vitro digestion models for estimates of value of energy and energy-yielding nutrients. R. T. Zijlstra* and L. F. Wang, *University of Alberta, Edmonton, AB, Canada.*
