In vitro digestion (IVD) techniques can evaluate digestibility of energy and energy-yielding nutrients in feedstuffs or complete diets for pigs and other monogastric species. These techniques can mimic the conditions of the gastro-intestinal tract and may have advantages compared with in vivo models of digestion. For example, IVD analyses require less sample material and less time, and are cheaper than in vivo digestibility analyses. Therefore, IVD provides the possibility to screen many samples and support the development of feedstuff databases and rapid feed quality evaluation systems. However, one critical step for IVD analyses is rigorous validation of in vitro digestibility data using the target animal model. For pigs, considerable validation efforts have been made. Using purified enzymes, buffers, and controlled pH, a 3-step IVD model, mimicking digestion in the stomach, small intestine, and large intestine, respectively can estimate the apparent total-tract digestibility (ATTD) of energy. The impact of evaluating the ATTD of energy is clear instantly, because it relates strongly to the DE value of feedstuffs or diets. Similarly, kinetics of glucose release during in vitro digestion of starch is an excellent indicator of net portal appearance of glucose in pigs. Kinetics of fiber degradation can be characterized by in vitro fermentation models, but these models not been validated quantitatively in the pig model. Nevertheless, kinetics of both starch digestion and fiber fermentation are related to important aspects of metabolism of nutrients, gut physiology, and health. In summary, IVD techniques can be a valuable tool to describe the ATTD of energy and kinetics of starch digestion and fiber fermentation of feedstuffs in swine.

Key Words: in vitro digestion, energy, pig

549 Nature's pet food: Energy of raw meat-based and whole prey diets. Katherine Kerr*[1] and Cheryl Morris[2], [1]*University of Florida, Gainesville, FL,* [2]*Iowa State University, Ames, IA.*

Raw and cooked meat-based and whole prey diets for pets have seen increased popularity in past decades. This rise has been attributed to owner perceptions of increased control of dietary ingredients and processing along with feeding more biologically appropriate foods that contributes to the human animal bond. Nutritional therapy with these diet types can play an integral role in maintaining pet health and, for some pets, in mitigation of disease, such as allergy, gastroenteric diseases, kidney disease and obesity. Meat-based and whole prey diet formulations can mimic the natural history of pets with positive implications for pet health; that is, distribution of energy among macronutrients, dilution of energy and nutrients with moisture – while providing opportunities for modulations that optimize health (i.e., addition of animal or plant fibers). Felines have evolutionarily lacked the need for rapid adaptation to a variety of diet types, and are metabolically prepared for protein and fat energy, with less emphasis on carbohydrate utilization. Similar to the wild type diet of the cat, meat-based and whole prey diets provide > 90% of metabolizable energy (ME) from protein and fat, with little contribution to ME from digestible carbohydrates. Meat-based and whole prey diets also mimic the high moisture of wild type diets (~20 to 30% DM), diluting energy concentration compared with extruded diets (~90% DM). Isocalorically (DM basis), an owner may need to feed 4 times more whole prey on an as-fed basis to provide the same amount of ME as the extruded diet. In wild type diets, fermentable and non-fermentable animal (hide, hair, etc.) and plant fibers play an important role in energy metabolism and gut health: addition of plant and animal fibers, dilutes ME concentrations, decreases inflammation, and beneficially modulates gut bacterial populations. Meat-based and whole prey diets have been underutilized, undervalued, and under-researched as pet foods or as nutritional therapy options. Research has predominately focused on microbial contamination and public health concerns and health implication research are lacking. The flexibility and ingredient control of meat-based diets paired with proper formulations can provide palatable, highly digestible energy sources and targeted nutrient concentrations for pets.

550 Bioenergetics of pet obesity. Dennis Jewell*, *Hill's Pet Nutrition Inc., Topeka, KS.*

Most pet owners in the United States fulfill their pet's nutritional needs through feeding commercially prepared pet foods. These are supplied with suggested feeding amounts which individual pet-parents adjust to maintain body weight and influence body composition. Significant research efforts have been expended to develop methods for estimating energy concentration of pet foods; however, even the poorest estimates of pet food energy are less variable than the variation of energy need between pets. For example, the estimate for canned cat food has an average difference of 9% and including 2 standard deviations, still had an estimate within 20% of the measured value. The variation of dogs and cats, which are living in the same environment, shows that dogs on average maintain weight consuming 121 kcal/kg$^{3/4}$ daily, while the cat uses 73. There is a greater than 2-fold difference between the dog or cat using the least or most amount of energy. Therefore, although the relationship between dietary energy and the bioenergetics of pet food starts with the energy concentration of pet food it is most significantly concerned with the energy use associated with life. Obese dogs and cats use less energy to maintain weight than do their lean counterparts. However, the amount of energy needed to maintain weight in obese pets is subject to change and may be influenced to equal or even exceed the energy needed by normal pets to maintain weight. It has been shown that when dogs were fed a food with increased amounts of fiber there was spontaneous reduction in ad libitum energy intake and repartitioning of energy away from fat so that the energy deficit was completely balanced by energy mobilization from fat. This is also the normal response to food restriction. However, in both dogs and cats a feeding program with controlled weight loss, followed by weight maintenance, when consuming a nutritionally enhanced food, resulted in a significant change in body composition and a significant change in energy needed to maintain weight. This suggests that the bioenergetics of pet obesity is established by the food being eaten, the individual pet, and the feeding regimen.

Key Words: bioenergetics, pet, obesity

Contemporary and Emerging Issues and International Animal Agriculture Symposium: Ahead to 2050—Global livestock production challenges: Current status, future needs, production obstacles

551 Global livestock production challenges: Current status, future needs, and production obstacles—North America. Michael Galyean*, *Texas Tech University, Lubbock, TX.*

Feeding a rapidly growing global population is an enormous challenge. Livestock ownership and production is common in all economies, and demand for animal products grows as economic standards rise, suggesting that livestock will remain an integral component of worldwide food production systems. To achieve global food security, resources used for livestock production must be managed efficiently and sustainably. Current North American (NA) livestock numbers are decreasing or stable, reflecting greater market weight and production efficiency of individual animals and stable or decreased demand for products in NA. Exports of NA livestock products, largely to middle- or upper-income countries, have increased steadily in recent years. Rebuilding animal numbers in some NA livestock segments (e.g., beef cows) will be challenging, which could diminish growth potential. Consolidation in the NA livestock industry has been extensive, which could limit or redirect investments in production infrastructure. Urbanization of agricultural land, increasing regulation, consumer concerns for food safety and environmental effects of livestock production, and a general backlash against technology-based approaches to increase animal growth and efficiency are obstacles to increased production in NA. Challenges associated with climate (e.g., increased drought, decreasing water for irrigation, and shifts in crop production and availability of traditional feedstuffs) are likely but difficult to predict. With these obstacles and challenges, what role will NA livestock production systems play in meeting global food needs? Exporting livestock products should remain an important feature of the NA role, but expansion could be limited by trade issues and will likely continue to focus on developed countries. A potentially significant role for NA to play in meeting worldwide food production needs is to provide leadership in research and development related to sustainable livestock production systems that fit economies and cultures in developing nations. This will require renewed national commitments to support agricultural research and a recognition of the historical and cultural importance of livestock production.

Key Words: livestock production, research and development, sustainability

552 Opportunities and challenges in animal nutrition. Leo A. den Hartog*[1,2], [1]*Nutreco, Boxmeer, the Netherlands,* [2]*Wageningen University, Animal Nutrition Group, Wageningen, the Netherlands.*

The global livestock sector is characterized by differences in dynamics. In developing economies, the livestock sector is evolving in response to rapidly increasing demand for livestock products. In developed economies, demand for animal products is stagnating. Livestock production will increasingly be affected by external factors. These include surging demands for animal products and struggling supplies of feed raw materials, resulting from the competition for natural resources and trade barriers. Simultaneously, there is growing concern about food and its impact on health, and the effect of production systems on animal welfare and the environment. Optimization of productivity and efficiency within such constraints are important objectives, as well as maximization of the profit for all stakeholders. Animal feed and nutrition are the essential link in the livestock production chain, i.e., between crop cultivation and animal protein production and processing. It is usually the biggest cost factor in livestock production. Several indicators demonstrate that further optimization of animal feed and nutrition is potentially possible. The genetic potential is only partially utilized. The utilization of most nutrients appears to be low and there is a huge variation in performance among farms and within farms, among animals. In addition, environmental performance can be improved significantly. New science and technologies seem to offer many opportunities for innovation in animal feed and nutrition. Key drivers for future innovation are basically (gen)omics, microsystem- and nanotechnology and information and communication technology (ICT). These mainstream technologies are the foundation of many application technologies of relevance for animal feed and nutrition. Acceptance by consumers and society is a critical success factor. In conclusion, animal feed and nutrition are crucial in livestock production. Innovations have the potential to meet the challenges and to result in resource efficiency, healthy livestock and people, responsible production systems and optimal profit throughout the value chain.

Key Words: animal nutrition, livestock production, innovation

553 The future of feed business and live animal production in Asian and Chinese markets to year 2050. Genfeng (Ian) Yi*, *Aquaculture Science & Technology Group of Beijing Dabeinong (DBN) Technology Group Co. Ltd., Beijing, China.*

By 2050, the world's population will be 9 to 10 billion people, with at least 40% from Asia. Currently, the feed production volume of Asia contributes about 40%, with Chinese production of 190 million metric tonnes (MMT). The major live animal production countries include China, Indonesia, Thailand, Vietnam, India, Malaysia, and Japan. China is the dominant animal producer, with live pork production about 53 MMT, aquaculture 46 MMT, egg 27 MMT, white and yellow poultry 6 MMT, and ruminant (lamb, sheep, and beef) 5 MMT. With fast economic growth and increasing revenue, urbanization, a growing middle-class population, food safety concerns, environmental pressures, and progress of science and technology, the Asian market, especially the Chinese market, faces numerous development opportunities and challenges. The major challenges for Asian feed and live animal production are as follows: (1) how to supply sufficient safe animal protein and milk to the growing demands of consumers; (2) how to run large-scale and high-input farms efficiently; (3) how to train and attract professionals for live animal production; (4) how to find financial resources for modern agribusiness; (5) how to ensure biosecurity and disease control; (6) how to deal with the conflict of the environment and increased live animal production; (7) how to control soaring feed ingredient costs and reduce overall live animal production cost; (8) how to solve international trading interests and conflicts; (9) how to upgrade and use Internet and "web of things" technology for modern agribusiness; (10) how to integrate and consolidate industry chains and face international competition; (11) molecular and disease-resistance breeding technology; (12) how to innovate and apply new science and technology; (13) organic animal production; (14) antibiotic residue issues; (15) impact of climatic change on animal and aquaculture production (Asia accounts for 90% of world aquaculture production); (16) limited water and land resources; (17) GMO and transgenic issues of plants and their effect on animal production; (18) nanotechnology; (19) bioactive substances and biotechnology application; and (20) local governmental policies and regulations. The future of live animal production must include high production efficiency, low carbon production, organic foods, and minimal production cost and maximal production profitability. Asian live animal production needs to be more environmentally friendly, health-oriented, nutritious, safe, sustainable, and affordable to consumers.

554 Ahead to 2050—Latin American livestock production challenges.

Fernando Rutz*, *Universidade Federal de Pelotas, RS, Brazil.*

According to FAO, the world's population will be over 9 billion people and food production will need to be increased by 70% by the year 2050. Latin America (LA) has the potential to be an important player in providing food to fulfill this requirement, having the largest global fresh water reservoir, and one third of the world's available land for sustainable livestock production. With a wide range of climate zones, LA has diversified agriculture capabilities, ranging from tropical- to temperate-zone products. However, there is a lot of productivity variation among countries and even among different regions within a country. From the ruminant side, LA has suitable production conditions for increased beef, dairy and sheep production. From the monogastric point of view, the swine, poultry and aqua industries are well developed and constantly growing. This capability is exemplified by the fact that Brazil is now the largest beef and chicken meat exporter in the world. The dairy industry has also been experiencing significant growth and development during the last 2 decades. In almost all LA regions, milk (M) and milk-derivatives (MD) are increasing and diversifying into more complex products. In addition, M and MD export have been increasing in some LA countries. In spite of that, within some countries in LA and Caribe the average consumption of milk is below 25% of requirement. This fact shows the need to stimulate production and consumption of milk in some regions. To cope with the demands of food production, LA needs to increase the efficiency of production. To do this it can use technologies to supplement on pasture, increase grazing-tillage integration, and use more intensive livestock systems to shorten the time to slaughter. Use of tools like predicting feed efficiency with in vitro fermentation, development of DNA technology, exploring gene expression (nutrigenomics), genetic improvement and crossbreeding, artificial insemination, embryo transfer and sexed semen, can improve production capabilities too. Improvements in livestock health, product safety and quality, and control global warming gas emissions are also essential. Increased LA livestock production efficiency will result in decreased land degradation, and natural resource conservation.

Key Words: ruminant, monogastric, climate

555 Global livestock production challenges: Current status, future needs, production obstacles in Africa—The Uganda example.

L. Okedi*[1], Y. Baguma[2], J. M. Kabirizi[1], and J. Kungu[1], [1]*National Livestock Resources Research Institute, Tororo, Uganda,* [2]*National Agricultural Research Organization Secretariat, Entebbe, Uganda.*

The livestock sector in Uganda contributes 5.2% to the national gross domestic product and 18% to the overall agricultural GDP. National livestock numbers consist of 12.8 million cattle, 12.5 million goats, 4 million sheep, 3.6 million pigs and 42 million chickens. A total of 5 million households in Uganda own livestock (UBOS, 2008). Farming households that include livestock in their enterprise mix tend to have higher incomes than those involved only in crop farming. This is a result of livestock ownership and also improved crop productivity in that livestock manure improves nutrient availability to plants and increases soil organic matter. Economic benefits of including livestock production within farming enterprises are the greater accumulation of assets and the ability to secure credit. Uganda leads Africa in pork consumption, but cattle, goats, poultry and fish still provide significant sources of dietary animal protein. The expansion of meat and milk production in Africa has been disappointing despite efforts to stimulate increased production. Constraints cut across socioeconomic, technological, institutional and financial sectors. As well, little attention has been given to the development of the livestock value chain due to uncertainty in feed availability, reproductive inefficiency, the lack of livestock genetic improvement, public and animal health issues, and the prevailing policy environment.

Dairy Foods: Cheese and chemistry

556 Release of bioactive peptides and essential amino acids as affected by sodium chloride reduction and substitution in Akawi cheese. Akanksha Gandhi* and Nagendra P. Shah, *The University of Hong Kong, Hong Kong.*

The aim of this study was to evaluate the effects of sodium chloride reduction and its substitution with potassium chloride on selected probiotic bacteria and their functionality in Akawi cheese during storage for 30 d at 4°C. The survival of selected probiotic bacteria (*Lactobacillus acidophilus*, *Lactobacillus casei* and *Bifidobacterium longum*) and starter bacteria (*Streptococcus thermophilus* and *Lactobacillus delbrueckii* ssp. *bulgaricus*), the angiotensin-converting enzyme-inhibitory and antioxidant activities, and the concentrations of essential amino acids as affected by storage in different brine solutions [10% NaCl, 7.5% NaCl, 7.5% NaCl+KCl (1:1), 5% NaCl and 5% NaCl+KCl (1:1)] were investigated. Peptide profiles of cheese extracts, from different salt concentrations, were observed by RP-HPLC and in vitro bioactivities of the peptide fractions were evaluated using Caco-2 cell line. Survival of probiotic bacteria increased significantly in cheeses with low salt after 30 d, and after 20 d for starter bacteria. No significant difference in texture profile of cheeses during 30-d storage was observed except for fracturability and gumminess, which was found to be lesser in cheeses brined with only NaCl solutions. No significant changes were observed in ACE-inhibitory activity and antioxidant activity of the cheeses during storage. Interestingly, concentrations of 4 essential amino acids (phenylalanine, tryptophan, valine and leucine) increased significantly during storage in brine solutions containing 7.5% (w/v) total salt. The study revealed that at total salt concentration of 7.5% (w/v), 50% substitution of NaCl with KCl in Akawi cheese would not affect the activities of potential bioactive peptides, and would lead to increased release of essential amino acids.

Key Words: salt reduction, cheese, essential amino acids

557 Generation of highly antioxidative peptides from purified bovine α_{S2}-casein. Zahur Z. Haque* and Xue Zhang, *Department of Food Science, Nutrition and Health Promotion, Mississippi State University, Mississippi State, MS.*

Alpha$_{s2}$-casein is particularly rich in π electron rich aromatic amino acids that, in the absence of structural constraints, partake in π-π stacking and interact with positively charged residues (cation-π) resulting in electronic continuity required for rapid quenching of lone-pairs of oxidative radicals. This study investigated isolation of α_{s2}-casein from bovine milk, standardization of its chymotryptic hydrolysis, visualization of resulting peptide profiles by tricine-SDS-polyacrylamide gel electrophoresis (TSDS-PAGE) and size-exclusion high performance liquid chromatography (SE-HPLC), and determination of the antioxidative efficacy of the fractions. Alpha$_{s2}$-casein was isolated from whole casein by a 2-step 1-proponal-precipitation method and hydrolyzed using chymotrypsin (EC 3.4.21.1) because it selectively cleaves peptide bonds adjacent to aromatic residues, increasing the chances for inter-peptide aromatic-stacking. Five mg/mL of α_{s2}-casein was hydrolyzed with chymotrypsin (50 µg/mL) for 5–60 min at 37°C. A novel fixing method with sodium hypochlorite was used to fix the highly amphipathic peptides after TSDS-PAGE and visualization was by silver staining. The original protein was complete hydrolyzed to smaller peptides within 5 min. Peptide profiles determined by SE-HPLC, using a Superdex Peptide 10/300 GL column and 30% acetonitrile (v/v) as the eluent, substantiated the effectiveness of the peptide fixation following TSDS-PAGE peptide profiling. Average molecular weight of each fraction was determined by comparing its retention time with those of molecular weight standards. Data depicted an inverse relationship between molecular weight and the duration of enzymatic hydrolysis. Average molecular weight of the smallest fraction at 5 min of hydrolysis was 981 Da, and it was gradually reduced to 130 Da after 60 min of hydrolysis. As expected all hydrolyzates had oxygen radical absorbance capacity values (2000–3000 µ*M* TE) that were significantly ($P < 0.05$) higher than that of the original protein (580 µ*M* TE). Correlation of the antioxidative efficacy with residual secondary structural constraints and intensity of association tendency of the peptide fractions is presently being investigated.

Key Words: milk protein, reactive oxygen species, oxygen radical absorbance capacity

558 Efficacy of Cheddar whey combined with chitosan in edible coatings to reduce protein-fat oxidation and accumulation of reactive oxygen species in retail-cut catfish fillet. Zahur Z. Haque* and Dipaloke Mukherjee, *Department of Food Science, Nutrition and Health Promotion, Mississippi State University, Mississippi State, MS.*

Retail-cut muscle foods are especially susceptible to oxidative degradation and formation of harmful reactive oxygen species (ROS) owing to exposure to oxygen, bright lights and contact with metal counters. Due to extended cooking at temperatures near the pH optima of most of starter culture proteases during its Cheddar cheese manufacture, the resulting whey (CW) is naturally rich in antioxidative peptides and Maillard reaction products. In the present study, we report the antioxidative efficacy of CW when used in an edible coating, with and without chitosan (Ch), to reduce protein and fat degradation in stored farm-raised retail-cut catfish and the accumulation of ROS in the muscle. Fresh catfish fillet of uniform thickness were cut into cubes of unvarying weight (5g) and geometry, and immersed in dispersions of CW (2% w/v), Ch (1%, w/v) or mixture of both (CW+Ch) in 0.2 *M* McIlvaine's iso-ionic buffer (pH 7) at 22°C for 2 min. Protein and lipid oxidation [evident from carbonyl contents (CC) and peroxide values (PV)] of the samples were determined after storage at 4°C for nil, 1, 3, 5 and 7 d . Accumulation of ROS at cellular level was studied using a fluorogenic molecular probe (CellROX Deep Red Reagent, Life Technologies). Results showed significantly ($P < 0.05$) superior efficacy of the coatings in reducing overall oxidative degradation of samples for most of the storage periods compared with control (immersed only in the buffer). The CW+Ch mixture showed dramatic effects in alleviating lipid oxidation and ROS accumulation. It also reduced CC by ~60% compared with control after 3 d of storage, thus indicating a considerable extension in shelf life. The PV was reduced to ~22 and 16% in the samples immersed in CW+Ch and CW, respectively, after 5 d of storage compared with control. The same samples also exhibited 28 and 21% reduction in ROS accumulation relative to control after the same number of days of storage. The results indicated a vivid potential of this combined approach for combating oxidative degradation of foods and prevention of the formation/accumulation of harmful ROS in foods.

Key Words: reactive oxygen species, muscle food, sweet whey.

559 Influence of fish oil alone or in combination with hydrogenated palm oil on sensory characteristics and fatty acid composition of bovine cheese. Einar Vargas-Bello-Pérez*[1], Gonzalo Íñiguez-González[1], Karen Fehrmann-Cartes[1], Paula Toro-Mujica[1], and Philip C. Garnsworthy[2], *[1]Pontificia Universidad Católica de Chile, Santiago, Chile, [2]The University of Nottingham, Loughborough, UK.*

The objective of the present study was to evaluate the effect of dietary supplementation of fish oil (FO) alone or in combination with hydrogenated palm oil (FOPO) on the fatty acid (FA) profile of milk and cheese from dairy cows and the sensory characteristics of cheese. Nine Holstein cows (173 ± 21 DIM) were used in a replicated 3 × 3 Latin square design with 21-d periods. Dietary treatments consisted of a basal diet (Control; no fat supplement), and fat-supplemented diets containing fish oil (FO; salmon oil; 500 g/d/cow) and FO (250 g/d/cow) + hydrogenated palm oil (PO; palm oil; 250 g/d/cow). Milk collected on d 21 was pooled from 3 cows within the same treatment and period and made into cheese. Three cheeses per treatment per period at 14 d of aging were used for sensory evaluation. Cheese color measurements were determined according to the CIE L*, a*, and b* LAB color system. Sensory evaluation considered the following attributes: color homogeneity, holes, overall odor, ripe cheese odor, cow milk odor, salty, acid, bitter, overall flavor, ripe cheese flavor, sharpness, toughness, graininess, screeching, moisture and greasiness. Except for milk lactose yield, milk and cheese components were not affected by dietary treatments. Milk and cheese contents of C6:0, C8:0, C10:0 and C14:0 and atherogenicity index were lower ($P < 0.05$) with FO and FOPO diets than control diet. Compared with control and FOPO, FO increased ($P < 0.05$) C18:1 trans 11 and C22:6n3 content in milk and cheese. The color obtained from cheeses elaborated from cows given FO resulted in a more ($P < 0.05$) intense yellowness than control and FOPO. Compared with control and FOPO, FO resulted in higher ($P < 0.05$) notes for color homogeneity, whereas in comparison with control and FO, FOPO resulted in higher ($P < 0.05$) tough texture. In conclusion, supplementation of dairy cow diets with FO alone or in combination with hydrogenated palm oil can enhance the FA profile of milk and cheese without deleterious effects on sensory characteristics of cheese. This study was sponsored by a research grant from FONDECYT 11121142 (Fondo Nacional de Desarrollo Científico y Tecnológico, Chile).

Key Words: cheese, fatty acids, fish oil

560 Comparison between whey dilution during cheese-making and standardization of milk lactose by ultrafiltration on the properties of low and reduced fat Gouda cheese. Rodrigo A. Ibáñez*[1,2], Selvarani Govindasamy-Lucey[3], John J. Jaeggi[3], Mark E. Johnson[3], Paul L. H. McSweeney[1], and John A. Lucey[2,3], *[1]University College Cork, Cork, Ireland, [2]University of Wisconsin-Madison, Madison, WI, [3]Wisconsin Center for Dairy Research, Madison, WI.*

In recent years, the consumption of cheeses with reduced fat content has experienced growth due to health concerns. However, these products are associated with a hard and rubbery texture, poor melting properties and excessive development of acidity. In the manufacture of Gouda cheese, some whey is removed and replaced with water to decrease the residual lactose content and hence to control pH. This step is also known as whey dilution (WD) and may be a cause of high variability depending on the amount of water added, temperature, holding times and stirring rates. As an alternative, the standardization of lactose content in cheesemilk by ultrafiltration (UF) prior cheese manufacture could potentially reduce the residual lactose content in cheese and thus control the final pH. This study aimed to compare the effect of WD during cheese manufacture, with the alternative approach of adjustment of the lactose content of cheesemilk using UF, on the composition, texture, functionality and sensory properties of reduced-fat (RF) and low-fat (LF) Gouda-type cheeses during 6 mo of ripening. A stirred curd direct-salted cheese manufacture was used, differing in the levels of WD at 30, 15 and 0% (WD$_{30}$, WD$_{15}$ and WD$_{0}$, respectively). The RF and LF milks used in WD$_{30}$ and WD$_{15}$ had a lactose-to-casein (L:C) ratio of ~1.8, which is the typical ratio found in milk. The WD$_{0}$ treatments were made with UF standardized milks to L:C ratio of ~1.1. Similar trends between treatments were observed in both RF and LF treatments. WD$_{0}$ exhibited lower residual lactose and lactic acid contents than WD$_{30}$ and WD$_{15}$, leading to higher pH values ($P < 0.05$). WD$_{0}$ had softer texture and were more meltable ($P < 0.05$), probably due to a lower proportion of insoluble Ca caused by the addition of water required to achieve the lower L:C ratio in UF milks. Sensory analysis also indicated that WD$_{0}$ cheese had lower acidity and softer texture. These results suggest that UF standardization of the L:C ratio of cheesemilk could be a useful alternative to WD to reduce the acidity, improve texture and functionality of reduced- and low-fat Gouda cheese.

Key Words: Gouda cheese, lactose standardization, whey dilution

561 Growth and gas formation by a novel obligatory heterofermentative nonstarter lactic acid bacterium in cheese made using a *Streptococcus thermophilus* starter. Fatih Ortakci*[1], Jeffery Broadbent[1], Craig Oberg[2,1], and Donald McMahon[1], *[1]Utah State University, Logan, UT, [2]Weber State University, Ogden, UT.*

A novel slow-growing obligatory heterofermentative nonstarter lactic acid bacterium, *Lactobacillus wasatchii* sp. nov, was studied for growth and gas production in Cheddar cheese made using a *Streptococcus thermophilus* starter. Cheesemaking trials were conducted using starter *St. thermophilus* alone or in combination with *Lb. wasatchii* deliberately added to cheese milk at a level of ~10^4 cfu/ml. Then cheeses were ripened at 6 or 12°C. At d 1, starter streptococcal numbers were similar in both cheeses (~10^9 cfu/g) and nonstarter lactic acid bacteria (NSLAB) counts were below detectable levels (<10^2 cfu/g). As expected, *Lactobacillus wasatchii* counts were 3×10^5 cfu/g in cheeses inoculated with this bacterium. Starter streptococci decreased over time at both ripening temperatures but fell more rapidly at 12°C, especially in cheese with *Lb. wasatchii* ($P < 0.05$). Populations of NSLAB and *Lb. wasatchii* reached 5×10^7 and 2×10^8 cfu/g, respectively after 16 wk of ripening at 12°C, and their emergence was correlated with ~0.5% reductions in galactose concentrations. Levels of galactose at 6°C had also similar decrease after 16 wk storage. Gas formation and textural defects were only observed in cheese with added *Lb. wasatchii* ripened at 12°C. Results demonstrate that, *Lb. wasatchii* can contribute to late gas blowing in Cheddar cheese made with *St. thermophilus*, especially when the cheese is ripened at elevated temperature.

Key Words: cheese late blowing, nonstarter lactic acid bacteria, *Streptococcus thermophilus*

562 Late blowing of Cheddar cheese induced by accelerated ripening and ribose and galactose supplementation in presence of a novel obligatory heterofermentative nonstarter lactobacilli species. Fatih Ortakci*[1], Jeffery Broadbent[1], Craig Oberg[2,1], and Donald McMahon[1], *[1]Utah State University, Logan, UT, [2]Weber State University, Ogden, UT.*

A novel nonstarter lactic acid bacterium, *Lactobacillus wasatchii* sp. nov. has been studied for growth and gas formation in a control Cheddar cheese and in cheese supplemented with 0.5% ribose, 0.5% galactose, or 0.25% ribose plus 0.25% galactose using regular and accelerated cheese ripening temperatures of 6 and 12°C. Cheese milk along with starter lactococci was inoculated with *Lb. wasatchii* at a level of 10^4 cfu/mL, whereas a control vat was inoculated with starter lactococci only. Starter numbers in both cheeses decreased from 10^7 to $\sim10^3$ cfu/g at 23 wk of ripening at both temperatures, except the control cheese at 6°C which had one log higher final cell counts. Unlike starter bacteria, nonstarter lactic acid bacteria started at $<10^2$ cfu/g in the cheese and reached 10^6 to 10^7 cfu/g with higher numbers observed at 12°C. *Lactobacillus wasatchii* grew to $\geq10^8$ cfu/g in cheese supplemented with ribose (alone or with galactose) at elevated temperature which was ~1-log higher compared with the control and galactose-supplemented cheeses. In all cheeses with adjunct *Lb. wasatchii*, highest growth and gas formation was observed at 12°C although most gas production occurred at ≥16 wk. Adding both ribose and galactose provided substantially higher growth and gas formation because of the ability of *Lb. wasatchii* to co-utilize both sugars; producing gas from galactose as a result of the obligatory heterofermentative nature of the bacterium. Even without sugar supplementation, gas was observed in the presence of adjunct *Lb. wasatchii* after 16 wk. We have observed that *Lb. wasatchii* can grow to high cell densities when grown in carbohydrate-restricted broth containing lactococcal cell lysate. During cheese ripening, lysis of starter bacteria would provide sufficient substrate (such as ribose) to allow growth of *Lb. wasatchii* during cheese ripening and the presence of any hexoses in cheese would allow *Lb. wasatchii* to produce gas. We conclude that *Lb. wasatchii* is a previously undetected contributor to late gas formation in Cheddar cheese and the defect is more pronounced when elevated ripening temperatures are used.

Key Words: nonstarter lactic acid bacteria, gas, cheese

563 Demonstration of pH micro-heterogeneity in cheese matrices by fluorescence microscopy.

Zuzana Burdikova[1], Zdenek Svindrych[2], Jan Pala[3], Cian D. Hickey[1,4], Martin G. Wilkinson[4], Jiri Panek[5], Mark A. E. Auty[1], Ammasi Periasamy[2], and Jeremiah J. Sheehan*[1], *[1]Teagasc Food Research Centre Moorepark, Fermoy, Co. Cork, Ireland, [2]Department of Biology, University of Virginia, Charlottesville, VA, [3]Third faculty of Medicine, Charles University, Prague, Czech Republic, [4]Dept of Life Sciences, University of Limerick, Ireland, [5]Institute of Macromolecular Chemistry, Academy of Sciences of the Czech Republic, Prague, Czech Republic.*

Cheese, a product of microbial fermentation, may be defined as a protein matrix entrapping fat, moisture, minerals and solutes as well as dispersed bacterial colonies. The growth and physiology of bacterial cells in these colonies may be influenced by the microenvironment around the colony, or alternatively the cells within the colony may modify the microenvironment (e.g., pH, redox potential) due to their metabolic activity. To date there remains a significant knowledge gap relating to the degree of micro-heterogeneity in compositional and biochemical parameters such as pH within the cheese matrix and its relationship with microbial, enzymatic and physiochemical parameters and ultimately with cheese quality, consistency and ripening patterns. The objective of this study was to investigate whether pH micro-heterogeneity exists in cheese matrices. For the first time and arising from the development of a method using fluorescent lifetime imaging (FLIM) microscopy with Oregon green 488 dye, it is now possible to examine cheese for localized differences in pH. A ripened, semi-hard, dry salted cheese manufactured with thermophillic cultures was analyzed. Our study showed micro-heterogeneity in pH within the matrix of that cheese with pH ranging between 4.0 and 5.5. This is particularly interesting as it shows, contrary to previous assumptions, that the pH of a cheese matrix is not homogenous at micro-scale but contains localized variation. This may be due to localized differences in the aqueous phase or concentrations of constituents of the aqueous phase including lactose, lactate, minerals or salt. It may also be influenced by variations in buffering capacity of the surrounding cheese matrix. It is envisaged that future work using this method will focus on determining whether manufacture processes influence pH at local level within different cheese matrices and whether different cheese types may have different patterns of micro heterogeneity. It is also envisaged that this methodology will be employed to examine a broad range of food matrices in differing food products.

Key Words: pH, micro-heterogeneity, cheese

564 Evaluation of X-ray fluorescence spectroscopy for determination of minerals in process cheese.

Catherine Shawl*[1], Jordan S. Rose[2], and David R. McCoy[3], *[1]Kraft Foods Group, Glenview, IL, [2]Oxford Instruments, Concord, MA, [3]Dairy Management Inc., Rosemont, IL.*

X-ray fluorescence spectroscopy (XRF) has been demonstrated to have the ability to rapidly and directly measure sodium in a variety of cheeses by Stankey et al. Their rapid and simple method used a disk of cheese as the sample. However, inaccuracies may result from the formation of a thin layer of butter oil forming between the cheese and the surface of the holder and from using cheese samples that do not have a uniform surface such as shredded or ground cheeses. It is also important in process cheese manufacture to control the concentration of chloride, phosphorus and potassium as well as sodium. This study investigated various modifications to the sample preparation procedures for XRF technology that would remove the mentioned limitations, expand the minerals assayed, and evaluate the feasibility of using XRF in a manufacturing situation. The optimum sample preparation was created by homogenizing process cheese into 0.1 *N* nitric acid at 50o C. The homogenate was then centrifuged for 2 min in a microcentrifuge to separate the sample into a solids, an aqueous, and an oil layer. Two to 3 mL of the aqueous layer was removed from the centrifuge tube and assayed in an Oxford Instruments X-Supreme8000 Energy Dispersive X-Ray Fluorescence (EDXRF) spectrometer. Instrument assay time was 3 min, which allowed simultaneous measurement of the minerals of interest. Total time from sample submission to result was 15 min, making it rapid enough for in-plant quality control use. Relative standard deviation for multiple trials with the same block of process cheese product was 3.0% for sodium, 6.5% for phosphorus, 0.9% for chlorine, and 1.4% for potassium in preliminary studies. The instrument calibration to a reference ICP method has an R2 of 0.915 for sodium using a straight line fit. The modified XRF method extends the range of minerals assayed and addresses the causes of the inaccuracies that had limited the desirability for industrial use.

Key Words: sodium, cheese, assay

565 Novel sample preparation for smear ripened cheese rinds evaluated by powder X-ray diffractometry.

Gil F. Tansman*[1], Paul S. Kindstedt[1], and John M. Hughes[2], *[1]Department of Nutrition and Food Sciences, University of Vermont, Burlington, VT, [2]Department of Geology, University of Vermont, Burlington, VT.*

Recently we developed methods to evaluate surface crystals in Cheddar and hard Italian-style cheeses, and internal crystals in Cheddar, Gouda, and Parmigiano Reggiano cheeses by powder X-ray diffraction (PXRD). However, new sample preparation techniques are needed to analyze surface crystals of washed rind cheeses because of the complex nature of the surface smear. Our objectives were to develop repeatable sample preparation protocols for smear evaluation by PXRD and to validate the protocols by single crystal X-ray diffraction (SCXRD). Initial efforts to evaluate crystalline inclusions in smears involved scraping the surfaces of 3 washed rind cheeses with a spatula and loading them onto PXRD slides. Fresh samples were used deliberately because ikaite ($CaCO_3 \cdot 6H_2O$), which in cheese has thus far only been observed in surface smears, decomposes in the presence of acetone. Diffraction patterns showed limited repeatability between repeated measures when data collection was performed in succession at roughly 25 min intervals. The lack of repeatability was found to be an artifact of sample desiccation during data collection. To prevent drying during data collection, 2 modifications were investigated; sample slides were coated in a thin layer of immersion oil, and alternatively allowed to air-dry before pulverization in a mortar. PXRD data collected using both PXRD method modifications revealed that all 3 smears contained ikaite and that one of the smears also contained struvite ($NH_4MgPO_4 \cdot 6H_2O$). The presence of ikaite and struvite was confirmed by single crystal x-ray diffraction (SCXRD) in the corresponding cheeses. It appears that smear material used in PXRD requires additional prep due to its extensive loss of volume upon drying, which causes diffraction artifacts. As confirmed by SCXRD, both modified PXRD methods provide valid diffraction data on the identities of crystals present in smear samples. Although SCXRD is a superior method for identifying the single crystals from surface smears, a reliable PXRD method is useful because powder diffractometers are typically less expensive, more widely available, and require less training to operate.

Key Words: cheese, crystals, PXRD

Dairy Foods Symposium: Recent developments in manufacturing and applications of lactose and lactose derivatives

566 Overview of technological advances in manufacture and applications of lactose and lactose derivatives: Present and future. Shantanu Agarwal*, *Dairy Management Inc., Rosemont, IL.*

Lactose is a major component of milk and has been extensively studied over the years. Much work has focused on the manufacture and application of lactose. Lactose and it derivatives have wide physico-chemical and bioactive properties making it appropriate for a wide range of applications food, animal feed, and pharmaceuticals. Primary uses of lactose in the food industry are largely based on its relatively low sweetness, protein stabilizing ability, great crystallization attributes, ability to accentuate flavor/ color and significant nutritional value. Extensive research continues on various fronts as to how to bring added value to lactose and it derivatives in various food and nutraceutical applications. In this presentation, technological advancements and challenges in manufacture of lactose from various product streams (e.g., permeate, acid whey) will be reviewed. The presentation will also review latest research in understanding drivers and inhibitors for lactose crystallization. The role of lactose and its derivatives in various food applications will be discussed with regards to attributes such as product quality and sensory attributes (color, texture, mouthfeel, and sweetness). Nutritional significance of lactose and it derivatives will be discussed in relation to glycemic index, dietary fiber, and mineral absorption. Last, this presentation will focus on the future growth opportunities for lactose and it derivatives.

Key Words: lactose, permeate, crystallization

567 Lactose and lactose derivatives: More than prebiotics? Michael Gänzle*, *University of Alberta, Edmonton, AB, Canada.*

Commercially available lactose derivatives include lactulose (β-4’galactosylfructose), lactosucrose (β-4’galactosylsucrose), and galacto-oligosaccharides. 3-, 4-, and 6-Galactobiose, allolactose, and 6-, 3-, and 4-galactosyllactose are the major components of commercial galacto-oligosaccharide preparations. Commercial processes for lactose conversion generally employ enzymatic transglycosylation with fructose, sucrose, and lactose, respectively, as galactosyl acceptors. Because human β-galactosidase is specific for lactose, enzymatic transgalactosylation coverts lactose, a disaccharide that is indigestible in about 75% of human adults, to oligosaccharides that are indigestible in all human infants and adults. Galacto-oligosaccharides and other lactose derivatives are fermented by colonic microbiota. Galacto-oligosaccharides increase the abundance of bifidobacteria in intestinal microbiota and are thus recognized as prebiotic compounds. However, the increase of bifidobacteria in human microbiota depends on the individual composition of the microbiota and is observed in most but not in all individuals. Health benefits of consumption of galacto-oligosaccharides are predominantly derived from intestinal fermentation to short chain fatty acids and may be independent of the stimulation of specific taxa in the human gut. In analogy to lactose intolerance, over-consumption of galacto-oligosaccharides results in intestinal discomfort and osmotic diarrhea. In addition to their prebiotic activity, galacto-oligosaccharides have been shown to prevent the adhesion of enteric pathogens to mucosal surfaces. Their activity is likely mediated by specific interaction with bacterial glycan recognition proteins that are involved in early steps of pathogenesis. The prevention of pathogen adhesion is a complementary mechanism of galacto-oligosaccharides to specifically benefit host health. The concept of preventing pathogen adhesion was validated in vivo with swine models; anti-adhesive glycans may be used as functional food ingredient but also in animal production to reduce the use of antimicrobial growth promoters.

Key Words: lactose β-galactosidase galacto-oligosaccharide, pathogen adhesion

568 Role of lactose in dairy and food products: State of understanding. Tonya C. Schoenfuss*, *University of Minnesota, St. Paul, MN.*

Lactose is the most abundant nonfat solid in milk and its properties present both opportunities and challenges for its presence in food and dairy products. Important properties that affect dairy ingredient use due to lactose are crystallization, stickiness, hygroscopicity, and reactions it participates in. Positive attributes of lactose include its low sweetness, low cost, and the ability to participate in non-enzymatic (Maillard) browning reactions because it is a reducing sugar. It is also important as a solids replacer to balance mouth feel and the solution properties in beverages, ice cream mixes, and the liquid phase during baking. The effect of lactose on the viscosity of the solution phase can alter the ability to hold gas during baking, and maintain ice crystal stability during the storage of frozen products. Thermodynamic parameters that are measured such as the glass transition (T_g), melting temperature (T_m) and temperature of crystallization (T_{cr}) are useful to evaluate the effects of processing and other ingredients on lactose state and stability. But in formulated food systems, it can be complicated to attribute the functional attributes entirely to these measured properties. This objective of this symposium talk is to focus on the challenges of using lactose in formulated foods, and what is understood about the important chemical, physical and thermodynamic properties involved in caking and crystallization. Challenges with using lactose in beverages, chocolate, frozen desserts and bars will be highlighted, as will methods to avoid undesirable changes to texture, viscosity and handling characteristics.

Key Words: lactose, food

569 Industry perspective on managing quality and yield of lactose: From food to pharmaceutical grade. A. Kent Keller*, *Keller Technologies Inc., Mantorville, MN.*

Lactose has been commercially produced since the early part of the twentieth century. Worldwide production increased phenomenally in the 1940s when it was found that lactose was the best substrate for penicillin production. Further increases in lactose production resulted when mothers started to use infant formula, which contains lactose as the major constituent. Late in the twentieth century, confectioners found many reasons to use crystalline lactose in chocolates. Today chocolates are second only to infant formulae as the major use of lactose. In this presentation, the author shares some of his 40 years of experience operating and designing commercial-scale lactose production systems. Each unit operation for lactose production is discussed with a focus of how each unit operation can affect lactose quality and yield. The following unit operations are covered: raw material supply, concentration (RO and evaporation), crystallization, refining, drying and packaging. Particular attention will be given to the current state of the art, which is not typically covered in various textbooks. Finally, a review of traditional and new methods for producing pharmaceutical grade lactose are discussed.

Key Words: lactose, lactose production

570 Processing and stability of high lactose powders . Thom Huppertz*[1,2], Inge Gazi[1], and Hasmukh Patel[2], *[1]NIZO food research, Ede, the Netherlands, [2]South Dakota State University, Brookings, SD.*

Lactose strongly affects the stability of dairy products on drying and storage. In skim milk powder, WPC35 and infant formula, lactose represents >50% of dry matter and forms an amorphous matrix in which other constituents are dispersed. When temperature and water activity exceed critical values, the amorphous lactose matrix changes to a rubber-like state, where the powder can become sticky. Lactose crystallization and Maillard reactions can also occur as self-propagating reactions due to water release from amorphous lactose on crystallization and the reaction between the carbonyl and the amino group, thus further increasing water activity. Hence strict control of heat-load and drying conditions and prevention of moisture gradients (e.g., in dry-blending ingredients) are needed to maintain powder properties. Otherwise, lumping, caking and other handling properties can occur. Moisture sorption isotherms and glass transition temperatures can be predicted based on composition and can be used as input parameters for optimization of processing conditions. For powders with even higher lactose content, e.g., permeate or whey powder, pre-crystallization of lactose in the concentrate before drying is required to avoid development of excessive stickiness during drying. Pre-crystallization is achieved by (flash) cooling and addition of seeding crystals. Optimization of pre-crystallization conditions (temperature and solids content) in relation to crystallization rate and viscosity is needed to attain sufficient crystallization within an acceptable time. Typically, up to 75% of lactose can be crystallized by pre-crystallization. Post-crystallization after drying can further increase crystallization levels, up to 95%. Failure to attain sufficiently lactose crystallization (i.e., >75%) can lead to caking, lumping and browning when powders are stored. Other constituents also influence the behavior of lactose during processing and storage. Lactose-phosphate, formed during fermentation, is a potent inhibitor of lactose crystallization, whereas lactate salts present can add considerable hygroscopicity to powders. Overall, careful control of composition, processing and storage conditions is paramount to attain and maintain high-lactose powders of desirable properties.

Key Words: lactose, powder, processing

Nonruminant Nutrition: Feed ingredients

571 Nutrient profile and digestibility of agro-industrial coproducts as determined using an in vitro model of swine. Utsav P. Tiwari*, Halina M. Zaleski, and Rajesh Jha, *University of Hawaii at Manoa, Honolulu, HI.*

Market availability and price of some conventional feedstuffs, such as corn, wheat, and soybean meal, are highly variable because of high demand for food, feed and fuel. Exploring alternative feedstuffs that can either completely or partially replace these feedstuffs is very important to ensure the sustainability of the swine industry. Use of these alternative feedstuffs in pig diets can be optimized by characterizing their nutrient profile and digestibility. To explore the nutritional value, 3 agro-industrial coproducts, barley brewers grain (BBG), okara and wheat millrun (WMR) were analyzed for basic nutrients, fiber and GE content. Digestibility of DM and GE was determined using an in vitro 3-step enzymatic assay using pepsin, pancreatin and viscozyme (which mimics the digestion occurring in the gastrointestinal tract of swine) with 4 replicates of each sample digested over 2 batches. All replicates were used to determine DM digestibility while 2 replicates from each batch of each feedstuff were used to determine GE digestibility. On a DM basis, nutrient profile were as follows. GE: 4073 (BBG), 4736 (WMR) and 4824 kcal/kg (okara); CP: 11.7 (BBG), 15.9 (WMR) and 22.7% (okara); NDF: 31.0 (okara), 35.0 and 42.0% (BBG); ADF: 19.7 (okara), 24.2 and 34.0% (BBG), and hemicellulose: 8.0 (BBG), 10.8 and 11.2% (okara). The DM digestibility of okara (74.1%) was higher ($P < 0.05$) than BBG (61.3%), WMR was in between (69.9%). Similarly, GE digestibility of okara (66.2%) was higher ($P < 0.05$) than BBG (43.0%), WMR was in between (53.1%). Okara is not merely a good source of protein and energy, but also had fairly high in vitro DM and GE digestibility in swine. In conclusion, some agro-industrial coproducts can be potential substitute for common ingredients used as energy sources in pig diets, especially for small farms where these coproducts are widely available.

Key Words: coproduct, in vitro digestibility, swine

572 Feeding liquid dairy derivatives (whey) to nursery pigs. Laura Eastwood, Mike R. Deibert, Dakota L. Wightman, and Denise Beaulieu*, *Prairie Swine Centre Inc., Saskatoon, SK, Canada.*

Two experiments were conducted to examine the feeding value of liquid whey for newly weaned pigs. The experiments used pigs weaned at 26 ± 2 d of age, housed 2 per pen. A water/whey mix was provided in buckets suspended above each pen allowing accurate measurement of intake. No additional water source was provided. Pig body weights, and liquid and feed intakes were calculated weekly. In Expt. 1, 72 pigs received 0, 8 or 16% sweet whey (vol/vol) in their drinking water (providing 0, 16.4 or 24.6 g solids/L). Pigs were acclimated for 7 d, followed by 14 d data collection, and fed a standard pre-grower diet. In Expt. 2, 160 pigs were assigned to 1 of 7 treatments (3 × 2 factorial + control). Treatments consisted of 0% whey (control; n = 20), and sweet (pH 5.8, 20.5% DM) or acid (pH 2.9, 29.9% DM) whey at levels providing 16.4, 24.6 and 32.8 g solids/L (8, 12 or 16% inclusion (vol/vol) in drinking water for sweet whey, and 5.5, 8.2 and 10.9% for acid whey; n = 10/whey level). Diets were adjusted to account for expected nutrient intakes from the whey, based on intakes from Expt. 1. Data for both experiments were analyzed as a randomized complete block with treatment as a fixed effect, and block and pen as random effects. Effects of whey level were determined using linear and quadratic polynomial contrasts and an orthogonal contrast was used in Expt. Two to test the effect of whey type. $P < 0.05$ was considered significant. In Expt. 1, liquid intake and the intake of DM and calories from the whey increased with increasing whey concentration ($P < 0.01$), Total caloric intake (2.64 Mcal DE/d), and piglet ADG (0.32 kg/d) were not affected by treatment. In Expt. 2, whey type (sweet vs. acid) had no effect on growth or nutrient intake. Liquid, nutrient and energy intake increased, and ADG and G:F ratios were improved with increasing whey regardless of whey type (linear $P < 0.05$). Diet ADFI was unaffected by type or amount of whey (0.50 kg/d). Pigs compensated for the nutrients in the whey by decreasing feed intake (Expt. 1) or consuming similar amounts of a less nutrient dense diet (Expt. 2). Depending on the price of the whey, cost savings could therefore be achieved.

Key Words: swine, nursery, whey

573 Growth performance, serum lipids, and intestinal volatile fatty acids contents in growing pigs fed flaxseed meal- and oat hulls-containing diets. Saymore P. Ndou*[1], Elijah Kiarie[1,2], and Charles M. Nyachoti[1], *[1]Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada, [2]DuPont Industrial Biosciences-Danisco Animal Nutrition, Marlborough, UK.*

The objective of the study was to determine growth performance, serum lipids, and intestinal volatile fatty acids (VFA) concentrations in pigs fed flaxseed meal (FM)- and oat hulls (OH)-containing diets. Forty-eight Genesus [(Yorkshire-Landrace) × Duroc] barrows with initial BW of 25.0 ± 0.32 kg were penned in pairs. Pigs were allotted to 3 experimental diets: (corn-soybean meal-based diet (Control), 12% FM- and 10% OH-containing diets, in a completely randomized design, to give 8 replicates per treatment. Diets were formulated to be iso-energetic. However, incorporation of FM and OH increased the soluble fiber (sDF) and insoluble fiber (iDF) content of the diets, respectively. Feed intake and BW of pigs were measured weekly for 28 d. On d 28, blood samples were collected via jugular vein puncture for measuring concentration of serum lipids. Pigs were subsequently slaughtered for ileal, cecal and colonic digesta collection for VFA analysis. Pigs fed the control and OH-containing diet had greater final BW ($P < 0.01$), feed intake ($P = 0.01$) and weight gain ($P < 0.01$) than FM-containing diets-fed pigs. Feed efficiency was reduced by 15.6% in pigs fed FM-based diets compared with the control ($P = 0.01$). Total cholesterol was reduced ($P < 0.01$) more in pigs fed OH-containing diets (1.99 mmol/L) than in FM-containing diets (2.25 mmol/L), compared with the control (2.36 mmol/L). Pigs fed FM- and OH-containing diets had greater ($P < 0.01$) cecal pooled VFA concentration (135 and 126 mmol/L) than those fed the control diet (87.5 mmol/L). Dietary inclusion of FM and OH increased the cecal ($P < 0.01$) and colonic ($P < 0.01$) concentration of acetate by more than 100% and 20%, respectively. A similar trend was observed in the colon in which case pigs fed the FM- and OH-containing diets tended to have highest concentrations of valerate ($P = 0.09$) and pooled VFA ($P = 0.10$). In conclusion, iDF reduced serum cholesterol more than sDF and the former depressed growth performance by reducing feed intake. However, both sDF and iDF induced variable effects on VFA concentrations depending on intestinal segment.

Key Words: dietary fiber, growth performance, hindgut fermentation

574 Effects of feeding increasing inclusion of canola press-cake on diet nutrient digestibility and growth performance of weaned pigs.

X. Zhou*[1], E. Beltranena[1,2], and R. T. Zijlstra[1], [1]*University of Alberta, Edmonton, AB, Canada,* [2]*Alberta Agriculture and Rural Development, Edmonton, AB, Canada.*

Canola press-cake (CPC) is a co-product from biodiesel production in small-scale processing plants that mechanically press oil from cleaned canola seed without seed conditioning or solvent extraction. The CPC contains 37% CP and 20% remaining oil; thus, CPC could be a source of AA and energy in pig diets. However, growth responses to increasing inclusion of CPC have not been evaluated in pigs. To evaluate the feeding value of CPC, 240 pigs (7.5 kg) starting 1 wk after weaning at 19 d of age were fed 5 wheat-based diets containing 0, 5, 10, 15, or 20% CPC to replace soybean meal in 2 phases (Phase 1 and 2). Diets were formulated to contain 2.45 and 2.41 Mcal NE/kg and 5.02 and 4.20 g standardized ileal digestible (SID) Lys/Mcal NE, respectively, and were fed for 2 wk for phase 1 (d 0–14) and 3 wk for phase 2 (d 15–35). Feed added and left and pig BW were measured weekly to calculate pen ADFI, ADG, and G:F. Freshly-voided feces were collected on d 12–13 and d 33–34 for phase 1 and 2, respectively, to determine diet apparent total-tract digestibility (ATTD) of DM, GE, and CP and diet DE using the index method. The diet NE value was predicted by Eq. 1–8 in NRC (2012). Data were analyzed using the MIXED procedure in SAS by orthogonal contrasts tested the linear or quadratic effects of CPC inclusion. Increasing dietary inclusion of CPC linearly reduced ($P < 0.05$) the ATTD of GE by 1.3% and CP by 2.3% and diet DE and NE values in phase 1 and 2. Increasing dietary inclusion of CPC did not affect overall (d 0–35) ADFI and ADG of pigs but linearly reduced ($P < 0.01$) ADFI for d 29–35, linearly increased ($P < 0.05$) ADG for d 15–21, and linearly reduced ($P < 0.05$) ADG for d 29–35. Increasing CPC inclusion linearly increased ($P < 0.05$) feed efficiency for d 15–21 and overall. In conclusion, feeding up to 20% of CPC reduced ATTD of nutrients but did not reduce overall growth performance of weaned pigs when diets were balanced for NE and SID Lys/NE ratio. The CPC may be used as an alternative feedstuff to soybean meal to reduce feed cost while maintaining performance.

Key Words: canola press-cake, performance, weaned pig

575 Apparent and true ileal and total-tract digestibility of fat in diets including canola press-cake or canola oil and endogenous fat loss in growing pigs.

X. Zhou*[1], E. Beltranena[1,2], and R. T. Zijlstra[1], [1]*University of Alberta, Edmonton, AB, Canada,* [2]*Alberta Agriculture and Rural Development, Edmonton, AB, Canada.*

Residual oil in canola press-cake (CPC) and extracted oil (CO) are both sources of dietary fat for pigs. However, fat digestibility may be lower in cake as oil remains trapped in the crushed seed matrix. Dietary fat source may affect endogenous fat losses that must be determined to calculate true fat digestibility. To test these hypotheses, 9 ileal-cannulated pigs (25.4 kg BW) were fed 9 diets in a 9 × 8 Youden square. A basal diet of wheat and barley grains and canola meal was formulated. Eight test diets were prepared by mixing 10, 20, 30, and 40% CPC or 1.5, 3.0, 4.5, and 6.0% CO with basal diet, respectively, to match dietary fat content. Apparent total-tract digestibility (ATTD) and apparent ileal digestibility (AID) of acid-hydrolyzed ether extract (EE) were calculated for each diet using TiO2 as marker. True total-tract digestibility (TTTD) and true ileal digestibility (TID) of EE in CPC and CO and endogenous loss of EE were estimated by regressing apparent digested EE (g/kg of DM intake) against dietary EE intake (g/kg of DM). The ATTD and AID of EE in CPC diets were 61.5 and 78.9% and were lower ($P < 0.01$) than the 63.4 to 81.9% in CO diets, respectively. Apparent total-tract and ileal digested EE content in CPC and CO diets increased linearly ($P < 0.01$) with increasing EE intake. Endogenous loss of EE was greater ($P < 0.05$) for the total-tract (−23.4 g/kg of DM intake) than by the ileum (−9.4 g/kg of DM intake). Dietary fat source did not affect ($P > 0.05$) total-tract or ileal endogenous EE loss. The TTTD and TID of EE in CPC were 94.5 and 92.3% and were lower ($P < 0.01$) than 100 and 96.5% in CO, respectively. In conclusion, CPC had reduced ATTD, AID, TTTD, and TID of EE compared with CO. Dietary fat source did not affect endogenous losses of EE. The reduced fat digestibility of CPC compared with CO indicates that fat digestibility of CPC should be considered to predict its nutritional value accurately before diet formulation.

Key Words: canola oil, fat digestibility, pig

576 Nutrient profile and digestibility of macadamia nut cake as determined using an in vitro model of swine.

Utsav P. Tiwari and Rajesh Jha*, *University of Hawaii at Manoa, Honolulu, HI.*

Highly variable price and market availability of some conventional feedstuffs, such as corn, wheat, soybean meal (SBM) make imperative to explore alternative feedstuffs to be used in swine diets. Macadamia nut cake (MNC), a coproduct from macadamia nut oil extraction process, is available and can serve as a potential feedstuff. However no or limited information of its nutrient profile and digestibility value limit its use in swine diets. To explore the nutritional value, MNC was analyzed for its basic nutrients, fibers, GE, AA and fatty acids content using standard methods. Digestibility of DM and GE of MNC was determined using an in vitro 3-step enzymatic assay using pepsin, pancreatin and viscozyme (which mimics the digestion occurring in the gastrointestinal tract of swine) with 4 replicates of sample digested over 2 batches. All replicates were used to determine DM digestibility while 2 replicates from each batch were used to determine GE digestibility. The MNC sample contained 93.1% DM. On DM basis, Ash, CP, crude fat, NDF, ADF, lignin and GE were found to be 3.7%, 25.5%, 11.9%, 35.8%, 28.0%, 16.0% and 5581 kcal/kg, respectively. In vitro DM and GE digestibility were found to be 76.7 and 71.4%, respectively. The concentration of Lys, the first limiting AA in swine, was found to be 0.7%. Linoleic and linolenic acid content were 2.5 and 0.2%, respectively. Gross energy content in MNC is comparable with that of corn and higher than SBM, due to high residual oil content, while protein content is twice as high as corn but lower than SBM. However, high fiber and presence of potential antinutritional factors like tannin and phytic acid need to be considered while using MNC in swine diets. In conclusion, MNC is not merely a good source of protein and energy but also had fairly high DM and GE digestibility when studied using an in vitro model of swine. Hence, it may serve as a potential alternative of some conventional sources of protein and energy in swine diets.

Key Words: in vitro digestibility, macadamia nut cake, swine

577 Effect of duck grease on growth performance, carcass characteristics, and meat quality in growing-finishing pigs.

Jie Yu*, Li Zhu, Bing Yu, Jun He, Ping Zheng, Xiangbing Mao, Quyuan Wang, Zhiqing Huang, Junqiu Luo, and Daiwen Chen, *Animal Nutrition Institute, Sichuan Agricultural University, Chengdu, Sichuan, China.*

Duck grease (DG), a by-product of the duck industry, is abundant and inexpensive as a potential energy feed source because more than 60% of global ducks are produced in China. However, the nutritive value of DG in swine diet has not been assessed. In our previous study, the apparent digestible energy and metabolizable energy have been evaluated. The present study addressed the effects of DG compared with soybean oil (SO) on growth performance, carcass characteristics and meat quality in a 82 d feeding program. A total of 72 growing barrows (31.62 ± 2.31 kg initial body weight) were randomly assigned into 2 dietary treatment groups in 6 replicates/pens utilizing a completely randomized design. The pigs were fed a corn-soybean meal based diet containing same amount (2% in growing diet, 1% in finishing diet) of SO or DG. One pig at average body weight in each pen was electrically stunned and slaughtered at the end of the feeding experiment, and carcass characteristics and pork quality were measured. Unpaired *t*-test was applied to evaluate the comparisons between 2 groups. Growth performance and carcass characteristics were not different ($P > 0.05$). Pigs fed DG improved the apparent total-tract digestibility of dry matter (DM; 82.19 vs. 86.46%, $P < 0.05$) and gross energy (GE; 81.22 vs. 84.17%, $P < 0.05$). Visual color, ultimate pH, marbling score, and driploss were not different between DG and SO treatment. The intramuscular fat (IMF) content (2.77 vs. 3.67%, $P < 0.05$) and muscle fiber density (1112.82 vs. 1389.97 fiber number /mm^2, $P < 0.05$) in longissimus dorsi (LM) were increased, while slice shear force was decreased in DG fed pigs (5.94 vs. 4.54 kg, $P < 0.05$). In conclusion, dietary DG improved pork quality without negatively influencing growth performance and carcass characteristics in growing-finishing pigs.

Key Words: duck grease, pork quality, growing-finishing pigs

578 Feeding layer hens with a new type of defatted green microalgae produced dose-dependent enrichments of eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) in their egg yolk and tissues. Theodore Derksen, Meghan Manor, and Xin Gen Lei*, *Cornell University, Ithaca, NY.*

There is little EPA or DHA present in the yolks of eggs produced by hens fed corn-soybean meal-based diets. The purpose of this experiment was to enrich these n-3 fatty acids in the egg yolk by feeding hens with defatted green microalgae. A total of 50 White Leghorn hens (46-wk old, 1.70 ± 0.27 kg BW) were housed individually in cages, divided into 5 groups (n = 10), and fed a corn-soybean meal-based diet containing 0, 2.9, 5.8, 11.5, or 23% of a new type of defatted green microalgae (*Nannochloropsis oceanica,* Cellana, Kailua-Kona, HI) for 6 wk. Data were analyzed by one-way ANOVA with or without time-repeated measurements (SAS Version 9.1, SAS Institute, Inc., Cary, NC). The *P*-values for multiple regression analyses were adjusted using a Bonferroni correction procedure (significance at $P \leq 0.01$). The microalgae supplementation produced dose-dependent linear ($P < 0.01$) enrichments of EPA, DHA, and total n-3 fatty acids consistently in egg yolk ($R^2 > 0.9$) assayed biweekly and of DHA in Liver ($R^2 = 0.78$), breast ($R^2 = 0.82$), and thigh ($R^2 = 0.66$) assayed at wk 6. Concentrations of EPA + DHA in egg yolk, liver, breast muscle, and thigh muscle of hens fed 11.5 and 23% microalgae were 1.4–2.1, 0.6–1, 3.3–5.3, and 6–7-fold greater ($P < 0.001$) than those in the controls (0% microalgae), respectively. Supplemental microalgae showed no effect on body weight, egg production rate, or tibia dimensions, but produced linear increases ($P < 0.05$) in tibia bone strength ($R^2 = 0.71$), egg shell weight ($R^2 = 0.58$), and egg yolk redness ($R^2 = 0.71$) and linear decreases ($P < 0.05$) in ADFI ($R^2 = 0.88$), egg yolk lightness ($R^2 = 0.97$), and egg yolk yellowness ($R^2 = 0.80$). In conclusion, this new type of defatted green microalgae was very effective in elevating EPA and DHA in the egg yolk, liver, and muscle tissues of layer hens. Eggs produced by hens fed the 23% defatted green microalgae diet may serve as a major food source of EPA and DHA to meet human needs. Supported in part by USDA/DOE Biomass R&D Initiative Grant, a Hatch Grant of Cornell University, and a Hatch Grant Supplement from Cornell University for Undergraduate Research.

Key Words: egg, EPA/DHA, microalgae

579 Moderate levels of supplemental defatted green microalgae in broiler diets had no adverse effect on bone properties. Eleanore O'Neil, Stephanie Gatrell, Meghan Manor, and Xin Gen Lei*, *Cornell University, Ithaca, NY.*

Two experiments were conducted to determine if supplementing broiler diets with defatted green microalgae (*Nannochloropsis oceanica,* 0.69% phosphorus, Cellana, Kailua-Kona, HI) affected bone properties and phosphorous nutrition. Data were analyzed using one-way ANOVA and(or) linear regression procedure (SAS Version 9.1, SAS Institute, Inc., Cary, NC). In Experiment 1, day-old male Ross broiler chicks (total = 180) were fed a corn-soybean meal basal diet (BD) containing 0 (Control), 2, 4, 8, or 16% of the defatted microalgae for 6 wk. Chicks were housed in cages (6/cage) and each treatment consisted of 6 cages. Supplemental microalgae had no effect on tibial maximum load, maximum slope, extension at maximum load, energy to maximum load, or weight. However, tibial length of birds fed the 16% microalgae diet was 6.9% shorter (113 ± 0.3 mm vs. 105 ± 4.6 mm, $P < 0.05$) than that of those fed the control diet. This decrease was consistent with a 10.2% lower BW of birds fed the 16% microalgae compared with the control (2817 ± 70.6 vs. 2528 ± 75.8 g, $P < 0.01$). There were dose-dependent increases ($P < 0.01$) in soluble inorganic phosphorous retention, and decreases ($P < 0.05$) in soluble inorganic phosphorous excretion with elevated microalgal inclusions. Plasma inorganic phosphorous concentrations were not affected by the diet treatments. In Experiment 2, 3-wk old male Cobb chicks (total = 120) were fed the control, BD + 10% microalgae, BD +10% microalgae + high vitamin E (DL-α-tocopheryl acetate, 150 IU/kg), or BD + 10% microalgae + high selenium (selenium-enriched yeast, 0.5 mg Se/kg) for 3 wk. Chicks were housed in cages (5/cage) and each diet treatment consisted of 6 cages. Compared with the control (BD), the other 3 diets produced no differences in all the tibial measures (including length) as described in Experiment 1. In conclusion, feeding broiler chicks with the defatted green microalgal biomass up to 10% in their diets did not show any adverse effect on bone health, but seemed to improve dietary phosphorus retention. Supported in part by a USDA/DOE Biomass R&D Initiative Grant, a Hatch Grant of Cornell University, and a Morley Student Research Fund Award of Cornell University.

Key Words: broiler, microalgae, tibial strength

580 Low concentrations of supplemental defatted microalgae affect egg and tissue fatty acid composition differently in layers fed diets containing corn and flaxseed oils. Jonggun Kim and Xin Gen Lei*, *Cornell University, Ithaca, NY.*

Our laboratory previously showed that high concentrations of supplemental defatted microalgae (DMA, 10–15%) or flaxseed oil (FO,5%) altered fatty acid profiles of egg yolk and tissues of layers. This experiment was to determine if and how lower concentrations of these supplementations affected fatty acid composition of egg yolk, liver, adipose tissue, and plasma of layers. A total of 60 Shaver leghorn layer hens (individually caged, 20 wk old) were allotted into 6 groups (n = 10) and fed a corn soybean meal-basal diet containing 0, 3, or 5% DMA (*Nannochloropsis oceanica*, Cellana, Kailua-Kona, HI) and 0 (1.5% corn oil) or 1.5% FO (Dyets, Bethlehem, PA) for 6 wk. Data were analyzed by 2-way

(2 by 3 factorial) ANOVA with or without time-repeated measurements using PC-SAS (Version 9.1, SAS Institute, Inc., Cary, NC).Although BW, ADFI, egg production rate, egg weight, or egg albumen, yolk, and shell were not affected by any of the dietary treatments at various time points, egg yolk color was changed ($P < 0.05$) from 7 to 13 (Roche color fan) with increasing concentrations of DMA. There was no diet effect on plasma concentrations of triglyceride, cholesterol, or uric acid. While concentrations of n-3 fatty acids in egg yolk and plasma were elevated by FO up to 9-fold ($P < 0.05$) starting at wk 1 or 2, such improvements by DMA were only 39 to 83% ($P < 0.05$). Although DMA also improved ($P < 0.05$) n-6/n-3 fatty acid ratios in egg yolk and plasma from 13 to 23 to 7–13, this effect was seen only in hens fed diets without FO. In the presence of 1.5% FO, only 5% DMA produced 8–9% increase ($P < 0.05$) in n-3 fatty acid concentration of egg yolk at wk 2 and 3. Fatty acid profiles of liver and adipose tissue (collected at wk 6) displayed responses to supplemental DMA and FO similar to those of egg yolk or plasma. In conclusion, supplemental 2.5 or 5% DMA caused moderate enrichments of n-3 fatty acids and decreases of n6/n3 fatty acid ratios of egg yolk and tissues in hens fed diets containing corn oil. The DMA effects on these measures were very limited in hens fed diets containing FO. Supported in part by a USDA/DOE Biomass R&D Initiative Grant and a Hatch Grant of Cornell University.

Key Words: eggs, microalgae, n-3 fatty acid

581 Supplemental defatted green microalgae and phytase improve hemoglobin repletion in weanling pigs.

Meghan L. Manor, Theordore J. Derksen, Rebecca L. Schwartz, Carol A. Roneker, and Xin Gen Lei*, *Cornell University, Ithaca, NY.*

Our previous studies demonstrated that supplementing 7.5% defatted microalgae in diets for weanling pigs improved their blood hemoglobin concentrations over the controls (11.0 ± 1.5 vs.13.0 ± 1.4 g/dL). This experiment was to determine if a lower concentration of microalgae alone or in combination with phytase produced similar improvements. A total of 30 weanling pigs (Hampshire × Yorkshire × Landrace crossbred, 7.5 ± 0.4 kg BW, hematocrit: 27.5 ± 1.7%, and hemoglobin: 9.4 ± 0.6 g/dL) were allotted to 5 dietary treatment groups (n = 6/group). The 5 diets included (1) a corn-soybean meal basal diet (BD) without supplemental inorganic iron (negative control), (2) BD + 50 mg Fe/kg (as $FeSO_4$, positive control), (3) BD + 0.5% defatted green microalgae (*Nannochloropsis oceanica,* Cellana, Kailua-Kona, HI), (4) BD + 500 units/kg of phytase (OptiPhos, Huvepharma, Peachtree City, GA), and (5) BD + defatted microalgae + phytase. The trial lasted for 6 wk and growth performance and hematology of pigs were measured biweekly. Individually penned pigs were considered the experimental unit. All data were analyzed by one-way ANOVA with or without time-repeated measurements using PC-SAS (Version 9.1, SAS Institute, Inc., Cary, NC). Blood hemoglobin concentrations and hematocrit of pigs fed the negative control diet were lower ($P < 0.05$) than those fed the positive control diet at wk 4 and(or) 6, whereas pigs fed the 3 diets containing microalgae and(or) phytase had similar values to the positive control group for both measures at both time points. The experimental diets exerted effects on BW, ADG, ADFI, and gain/feed ratio similar to those on hemoglobin and hematocrit. However, the diets had no effect on plasma lipid or glucose profiles of pigs. In conclusion, supplementing 0.5% defatted green microalgae alone or with 500 units of phytase/kg was very effective in improving iron utilization for hemoglobin repletion in the weanling pigs. Supported in part by USDA/DOE Biomass R&D Initiative Grant, a Hatch Grant of Cornell University, and a Morley Student Research Fund Award of Cornell University.

Key Words: iron, microalgae, phytase

Physiology and Endocrinology: Gametes and stress

582 The effects of coenzyme Q10 supplementation on in vitro fertilization in porcine oocytes.

Caitlin A. Streacker* and Brian D. Whitaker, *The University of Findlay, Findlay, OH.*

Polyspermic penetration as a result of in vitro fertilization (IVF) has shown to be a major obstacle in the production of porcine embryos. The objective of this study was to reduce the incidence of polyspermic penetration by supplementing coenzyme Q10 during oocyte maturation. Oocytes (n = 50/well) were maturated in tissue culture media 199 supplemented with 0, 10, 50 or 100 m*M* of coenzyme Q10 during the last 24 h of maturation. Frozen thawed semen from a single boar was used for fertilizing groups of approximately 30 oocytes in a concentration of 200 sperm/oocyte. Approximately 12 h after IVF, oocytes were evaluated for fertilization kinetics and subsequent embryonic development. A total of 600 oocytes over 3 replications were used in this study with one well/treatment/replicate. Data were analyzed using ANOVA with the main effects including treatment well and replicate. Chi-squared analysis was used to determine percentages of embryos reaching the different developmental states for each treatment. Oocytes supplemented with 50 m*M* coenzyme Q10 had significantly higher ($P < 0.05$) penetration rates (100 ± 14.97%) and pronuclear formation (MPN; 58.33 ± 19.54%) compared with 100 m*M* coenzyme Q10 supplementation. There was no difference between not supplementing coenzyme Q10 and 10 m*M* supplementation with respect to penetration and MPN formation rates. There was no difference between the treatments groups when considering the incidence of on polyspermic penetration. Cleavage at 48 h after IVF and blastocyst formation at 144 h after IVF were evaluated. Supplementing 100 m*M* coenzyme Q10 during oocyte maturation significantly decreased ($P < 0.05$) the percentage of embryos cleaved by 48h after IVF (3.33 ± 19.06%) and the percent of embryos at the blastocyst stage of development by 144 h after IVF (0.00 ± 15.76%) compared with all the other treatment groups. There was no difference between the other treatment groups with respect to cleavage and blastocyst formation rates. These results indicate that 50 m*M* coenzyme Q10 supplementation during oocyte maturation will not be detrimental to IVF and embryo culture in pig oocytes.

Key Words: coenzyme Q10, IVF, swine

583 Melatonin supplementation during oocyte maturation improves embryonic development in pigs.

Rachel L. Lane* and Brian D. Whitaker, *University of Findlay, Findlay, OH.*

High levels of reactive oxygen species (ROS) in and around maturing oocytes lead to oxidative stress, which decrease fertilization success rates. Melatonin reduces levels of ROS during in vitro fertilization in swine. The objective was to determine the effects of melatonin during oocyte maturation on: IVF kinetics and embryonic development. Oocytes (n = 50/well) were supplemented during the last 24 h of maturation with 0, 75, 100, or 150 n*M* melatonin and then subjected to IVF and embryo culture. Frozen-thawed semen from a single boar was used (approximately 30 oocytes/well, 200 sperm/oocyte). A total of 600 oocytes over 3 replicates were used in this study with one well/ treatment/ replicate. Post IVF, a percentage of the embryos were evaluated for penetration, polyspermy, and male pronuclear formation rates. The remaining embryos were evaluated 48 h after IVF for cleavage and 144 h for blastocyst formation. Data were analyzed using ANOVA with the main effects including treatment, well and replicate. Chi-squared analysis was used to determine percentages of embryos reaching the different developmental stages for each treatment. There were no differences between treatment groups with respect to penetration and polyspermy. Supplementation of 150 n*M* melatonin produced a significant ($P < 0.05$) percent of embryos with MPN (25. 93 ± 21.17%) compared with those supplemented with 75 n*M* (66.67 ± 21.17%) or 100 n*M* (79.17 ± 21.17%). There was no difference between the 75 n*M* and 100 n*M* treatment groups. Supplementation of 150 n*M* (22.00 ± 21.37%) produced significantly ($P < 0.05$) less of cleavage between all of the other treatment groups 48 h after IVF. Embryo supplementation of 75 n*M* melatonin during maturation had significantly higher ($P < 0.05$) percentage of blastocyst formation by 144 h after IVF compared with those supplemented with 150 n*M* (10.00 ± 17.32%) of melatonin. There was no difference in the percent of embryos reaching the blastocyst stage of development by 144 h after IVF between no supplementation, 100 n*M*, and 75 n*M* of melatonin. These results indicate that the supplementation of 75 n*M* melatonin during the later stages of maturation improves embryo development by increasing cleavage and blastocyst rates 48 and 144 h after IVF, respectively.

Key Words: melatonin, IVF, swine

584 Cumulus-oocyte complex gene expression in bovine preovulatory follicles after administration of porcine luteinizing hormone.

Amir Behrouzi*[1], Marcos G. Colazo[1], Ana Ruiz-Sanchez[2], and Divakar J. Ambrose[1,2], *[1]Alberta Agriculture and Rural Development, Livestock Research Branch, Edmonton, AB, Canada, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, AB, Canada.*

In previous work, the use of porcine luteinizing hormone (pLH) in lieu of gonadotropin releasing hormone (GnRH) for synchronizing ovulation improved pregnancy rates in lactating dairy cows. Later, we found that pLH treatment not only altered the LH profile, but also influenced expression of the BMP-15, GDF-9 and TGF-β1 proteins known to promote cumulus expansion and oocyte competence in nonlactating cows. We currently hypothesized that pLH would alter the expression of target genes in the cumulus-oocyte complexes (COC), which regulate oocyte competence. Cyclic nonlactating Holstein cows (n = 8) were subjected to ovarian stimulation with 200 mg FSH. Follicles = 10 mm were aspirated at 21 ± 1 h after giving either 100 µg GnRH or 25 mg pLH im, and COC recovered and frozen until qRT-PCR analysis. Serial blood samples were collected from before giving GnRH/pLH until 20 h after, for plasma LH analysis using an anti-bovine LH monoclonal antibody that cross-reacts equally with both bovine and porcine LH. Plasma LH concentrations and qRT-PCR data were analyzed using MIXED and GENMOD procedures of SAS, respectively. When LH concentrations (ng/mL) were compared in GnRH- and pLH-treated cows, effects of time and time-by-treatment interactions were detected ($P < 0.01$) with mean LH being higher in GnRH than pLH cows (2.8 ± 0.2 vs. 2.0 ± 0.2) from 30 min until 4 h post-treatment. However, mean plasma LH from 5 to 20 h post-treatment was greater ($P < 0.01$) in pLH- than in GnRH-treated cows (1.1 ± 0.2 vs. 0.4 ± 0.1). Treatment with pLH altered *HAS-2* and *GREM-1* mRNA abundance ($P < 0.01$) by about 26- and 7-fold, in COC of pLH- and GnRH-treated cows, respectively. Whereas the relative expression of *AREG* abundance tended ($P = 0.06$) to increase in GnRH-treated cows, *EREG*, *BTC*, *PGr*, *COX-2* and *PTX-3* mRNA expression were not affected by treatment. This study provides evidence that a prolonged, higher-than-basal LH profile in pLH-treated cows increased the expression of *HAS-2* and *GREM-1*, genes known to improve oocyte competence, which may explain the higher pregnancy rates previously reported when pLH was used to induce ovulation.

Key Words: cumulus-oocyte complex, porcine LH, GnRH

585 α-Lipoic acid improves the post-thaw quality and survival of Nili-Ravi buffalo bull sperm.

Muhammad Hammad Fayyaz[1], Sajid Iqbal[1,2], Muhammad Binyameen[3], Nasim Ahmad*[1], and Mushtaq Ahmad[1], *[1]Department of Theriogenology, University of Veterinary and Animal Sciences, Lahore, Pakistan, [2]Semen Production Unit, Qadirabad, Sahiwal, Pakistan, [3]Buffalo Research Institute, Kasur, Pakistan.*

Cryopreseravation exerts damages to sperm including crystal formation, oxidative stress, osmotic shock and lipid peroxidation. α-Lipoic acid (ALA); an antioxidant that plays a role in ATP production and breakdown of free radicals thus reduces oxidative stress. The aim of this study was to optimize the concentration and effect of ALA on post-thaw quality and survival at 37°C of buffalo (*Bubalus bubalis*) bull sperm. Semen of 3 mature Nili Ravi breeding bulls was collected twice a week using artificial vagina. The ejaculates of 3 bulls were pooled bull wise (replicates = 6), divided into 6 aliquots, diluted with the Tris-citrate-egg yolk extender supplemented with different concentrations of ALA (0, 0.5, 1, 1.5, 2 and 2.5mM) and cryopreserved in 0.5-mL French straws using standard procedure. Two straws per replicate were thawed and pooled and incubated in modified synthetic fluid (mSOF) at 37°C in a humidified CO_2 incubator. Semen was evaluated for motility, plasma membrane integrity (PMI; hypo-osmotic swelling test), viability and acrosomal integrity simultaneously (FITC-PNA/PI assay) and DNA integrity using acridine orange assay; at 0, 1.5, 3 and 4.5h of incubation. The data were presented as Mean ± SEM and analyzed 6 × 4 factorial repeated measure ANOVA for 6 concentrations and 4 times using MIXED procedure in SAS Enterprise Guide (version 4.2) taking time as repeated measure. The results revealed that extender supplemented 0.5 m*M* and 1 m*M* ALA resulted in higher ($P < 0.05$) sperm motility (55 ± 1.3% and 55.5 ± 1.3% respectively than control; 48.5 ± 1.37%, 1.5 m*M*; 49 ± 1.37% and 2 m*M*; 43.5 ± 1.37%), PMI (59.8 ± 1.8% and 60 ± 1.8% respectively), viability (67.3 ± 1.5% and 68.5 ± 1.5% respectively) and DNA integrity (99.29 ± 0.48% and 99.39 ± 0.48%) than control and other groups after thawing. The survival of sperm was also recorded higher ($P < 0.05$) due to 0.5 and 1 m*M* ALA resulting in motility (23.5 ± 1.3% and 25.5 ± 1.3%), PMI (34.3 ± 1.8% and 37.8 ± 1.8%), viability (38.6 ± 1.5% and 42.6 ± 1.5%) and DNA integrity (97.34 ± 0.48%and 98.0 ± 0.48%) than control and other groups at 4.5 h of incubation. In conclusion, α-lipoic acid enhances the post-thaw quality and survival of buffalo bull sperm.

Key Words: α-lipoic acid, buffalo sperm, in vitro incubation

586 Comparison of fertility of liquid and frozen semen when varying the interval from CIDR removal to insemination.

Brittany N. Richardson*[1], Erin L. Larimore[1], Julie A. Walker[1], Matthew D. Utt[2], J. Mel DeJarnette[2], and George A. Perry[1], *[1]Department of Animal Sciences, South Dakota State University, Brookings, SD, [2]Select Sires Inc., Plains City, OH.*

Cryopreservation allows for long-term storage of semen. However, cryopreservation and thawing imposes stress on spermatozoa, and prematurely initiates the process of capacitation; possibly decreasing sperm lifespan. Liquid semen is not exposed to these stressors, leading to a potential longer lifespan in the female reproductive tract and thus increasing the window for successful insemination. The objective of this study was to compare fertility of liquid and frozen semen when varying the interval from CIDR removal to insemination using the 7-d CO-Synch + CIDR protocol. Within age group cows (n = 389) were randomly assigned to insemination at 36 or 60 h after CIDR removal with either liquid (36L and 60L) or frozen semen (36F and 60F). Cows were monitored for estrus activity from CIDR removal to 60 h after CIDR removal. Cows that failed to exhibit estrus received an injection of GnRH (100 µg) and a blood sample was collected for analysis of estradiol concentration. Data were analyzed using the GLIMMIX procedure of SAS with sire and herd as random variables. There was no difference in pregnancy rates between liquid or frozen semen (53% and 52%), but cows inseminated at 60 h had greater ($P < 0.01$) pregnancy rates than cows inseminated at 36 h (72% and 31%). There was no interval by semen type interaction ($P = 0.57$). Estrus was detected in 63%, 61%, 56%, and 62% of 36F, 36L, 60F, and 60L, respectively (only 5% and 1% of 36F and 36L were detected in estrus before insemination). Overall cows that exhibited estrus had greater pregnancy rates compared with cows that did not ($P < 0.01$; 79% and 24%). Among cows that did not exhibit estrus, those inseminated with liquid semen tended to have greater pregnancy rates than those inseminated with frozen semen ($P = 0.06$), and ones that became pregnant had elevated ($P < 0.01$) concentrations of estradiol at 60 h (10.7 ± 1.9 vs 7.9 ± 2.9 pg/mL). In summary, there was no difference in pregnancy success between liquid and frozen semen. However, cows that exhibited estrus and inseminated at 60 h after CIDR removal had greater pregnancy success compared with cows that did not exhibit estrus.

Key Words: pregnancy, liquid semen, estrus

587 The effects of seasonal heat stress on sperm nuclear shape in boars.

Teyanna M. Loether, Ricky L. Monson, Cathy Miller-Gaudette, and John J. Parrish*, *University of Wisconsin-Madison, Madison, WI.*

Negative effects on germ cell development have been correlated with elevated scrotal temperatures in domestic livestock species, including the boar. To fully comprehend the effect of environmental heat stress on male fertility, a total of 1,181 boar ejaculates, with an average of 49.2 ± 1.7 per week, were collected during June–November 2012 from a commercial boar stud. Boars were housed in facilities equipped with cool cell technology and facility temperature was measured every 30 min in 2012. Environmental temperature data were obtained from the National Oceanic and Atmospheric Administration for 2012 and 2014, and expressed as a weekly average of the maximum daily temperature. Sperm were assessed using Fourier Harmonic Amplitude (FHA) analysis to determine sperm nuclear shape and harmonic values were generated (HA0–5). Using the first collection week as the control, a GLM procedure with Dunnett's mean separation test was performed to measure changes occurring in HA0-HA5. Changes were found in HA0 and HA2 for wk 8–21, or the weeks of July 25-October 24 ($P < 0.05$). The HA0 at week one was 2.80 ± 0.01 µm and peaked during wk 14 at 2.87 ± 0.01 µm. Effects on HA0 appeared 3 weeks after external temperatures rose above 90°F (facility temperature = 82°F); this corresponds to when affected round spermatids first appear in the ejaculate as mature sperm. Fluctuations in HA0 followed the oscillations in temperature until the average maximum external and internal temperature fell below 68°F. To confirm these results, samples from the same facility were collected in 2014 3 weeks after external temperatures rose above 90°F. A period of heat stress was effectively captured as changes in HA0 and HA4 were again found 3 weeks post-heat event ($P < 0.05$). Increases seen in HA0, which is a reflection of the overall size of the sperm head, indicate that boar sperm nuclei enlarge during seasonal heat stress. Fourier Harmonic

Amplitudes, particularly HA0, 2, and 4, can be utilized as an effective tool in predicting specific periods where nuclear shape may be affected by heat stress. Furthermore, FHA analysis could be utilized in the future to correlate changes in nuclear shape as a result of heat stress to fertility.

Key Words: boar reproduction, seasonal heat stress, sperm nuclear shape

588 Expressional regulation of chemerin and its receptors in the liver and adipose tissues of young cattle by weaning and nutrition.

Yutaka Suzuki*[1], Daichi Kato[1], Mitsuhiko Kondo[1], Hizuru Hatanaka[1], Satoshi Haga[1,2], Takafumi Gotoh[3], and Sanggun Roh[1], [1]*Graduate School of Agricultural Science, Tohoku University, Sendai, Miyagi, Japan,* [2]*Grassland Management Research Division, NARO Institute of Livestock and Grassland Science, Nasushiobara, Tochigi, Japan,* [3]*Kuju Agricultural Research Center, Kyushu University, Takeda, Oita, Japan.*

Chemerin is highly expressed and secreted from liver and adipose tissues, and acts through its receptors in an endocrine, paracrine, autocrine manner in ruminant. We previously reported the administration of chemerin analog peptide induced insulin secretion in vivo. However, there are currently no data on the expressional regulation of chemerin and its receptors depending on weaning and nutrition. In the present study we investigated the expressional levels of chemerin and its receptors (CMKLR1 and CCRL2) gene in the liver and adipose tissue of weaning calves and young cattle fed with different diets. Japanese Black calves were divided into (1) pre-weaning and post-weaning group (euthanized before and after weaning; 1.5 or 3.5 mo of age, respectively), or (2) concentrate-fed group received concentrate (CP 12%, TDN 73%; 2.5% of BW daily) plus Italian ryegrass (CP 9.4%, TDN 55.3%; ad libitum) and hay-fed group received Italian ryegrass ad libitum from 3 to 10 mo of age. The liver and/or adipose tissue (subcutaneous, mesenteric, perirenal and epididymal) samples were collected from cattle to quantitate mRNA expressional levels of chemerin, CMKLR1 and CCRL2 by qRT-PCR. Statistical analysis was performed by Mann-Whitney U test (significant difference; $P < 0.05$). Chemerin mRNA level was higher in mesenteric adipose tissue of post-weaning group and CCRL2 mRNA level was higher in the liver of post-weaning group, compared with pre-weaning group. Chemerin mRNA level in liver was higher in the concentrate-fed group than in hay-fed group at 10 months of age. This study revealed the effects of weaning and dietary energy source on gene expression of chemerin and CCRL2, suggesting the role of chemerin in the regulation of insulin secretion in cattle around weaning and in different nutritional states.

Key Words: chemerin, weaning, nutrition

589 Modulation of the metabolic response to vaccination in naïve beef steers using an acute versus chronic stress model.

Nicole C. Burdick Sanchez*[1], Jeffery A. Carroll[1], Nathan D. May[2], Shelby L. Roberts[2], Heather D. Hughes[2], Paul R. Broadway[1], Kate P. Sharon[1,3], Michael A. Ballou[3], and John T. Richeson[2], [1]*USDA-ARS, Livestock Issues Research Unit, Lubbock, TX,* [2]*West Texas A&M University, Department of Agricultural Sciences, Canyon, TX,* [3]*Texas Tech University, Department of Animal and Food Sciences, Lubbock, TX.*

Available energy plays a critical role in the initiation and maintenance of an immune response to a pathogen a process that is further altered by activation of stress system. This study was designed to determine the effect of an acute versus chronic stress model on the metabolic response to vaccination in naïve beef steers. Steers (n = 32; 209 ± 8 kg) were blocked by BW and assigned to 1 of 3 treatments: (1) Chronic stress (CHR), 0.5 mg/kg BW dexamethasone (DEX) administered i.v. at 1000h on d 3 to d 6; (2) Acute stress (ACU), 0.5 mg/kg BW DEX administered i.v. at 1000h on d 6; or (3) Control (CON), no DEX. On d 2, steers were fitted with jugular vein catheters and moved into individual stanchions in an environmentally controlled facility. Blood samples were collected at −74, −50, and −26 h, at 0.5-h intervals from −4 h to 6 h, and at 12, 24, 36, 48, and 72 h relative to vaccination with Pyramid 5 + Presponse SQ at 1200h on d 6. Data were analyzed by the MIXED procedure of SAS specific for repeated measures. Feed intake was not different ($P = 0.44$) between CON (4.9 ± 0.2 kg), ACU (4.9 ± 0.2 kg) and CHR steers (5.1 ± 0.2 kg). There was a treatment × time interaction ($P < 0.001$) for serum glucose concentrations. Specifically, glucose concentrations increased at −50 h in CHR steers and at 12 h in ACU steers, and remained elevated through 72-h post-vaccination period compared with CON steers. The change in NEFA concentrations was affected by treatment ($P < 0.001$) and time ($P < 0.001$) such that the change in NEFA was greater in CHR (0.06 ± 0.01 mmol/L), followed by CON (−0.01 ± 0.01 mmol/L) and ACU steers (−0.04 ± 0.01 mmol/L). Blood urea nitrogen (BUN) was affected by treatment ($P < 0.001$) and time ($P < 0.001$) such that BUN concentrations were greatest in CHR (12.0 ± 0.1 mg/dL) followed by ACU (10.4 ± 0.1 mg/dL) and CON steers (9.6 ± 0.1 mg/dL). These data demonstrate that activation of the stress and immune axes using an acute or chronic stress model can increase energy mobilization before and following vaccination in naïve steers, potentially affecting energy availability needed to mount an adequate antibody response to vaccination.

Key Words: cattle, metabolism, vaccination

590 Mimicking acute and chronic stress exposure in naïve beef steers alters the acute phase response (APR) associated with vaccination.

Jeffery A. Carroll*[1], Nicole C. Burdick Sanchez[1], Nathan D. May[2], Shelby L. Roberts[2], Heather D. Hughes[2], Paul R. Broadway[1], Kate P. Sharon[1,3], Michael A. Ballou[3], and John T. Richeson[2], [1]*USDA-ARS, Livestock Issues Research Unit, Lubbock, TX,* [2]*West Texas A&M University, Department of Agricultural Sciences, Canyon, TX,* [3]*Texas Tech University, Department of Animal and Food Sciences, Lubbock, TX.*

This study was designed to determine the effect of an acute versus chronic stress model on the APR associated with vaccination in naïve beef steers. Steers (n = 32; 209 ± 8 kg) were blocked by BW and assigned to 1 of 3 treatments: (1) Chronic stress (CHR), 0.5 mg/kg BW dexamethasone (DEX) administered i.v. at 1000h on d 3 to d 6; (2) Acute stress (ACU), 0.5 mg/kg BW DEX administered i.v. at 1000h on d 6 only; or (3) Control (CON), no DEX. On d 2, steers were fitted with indwelling rectal temperature (RT) devices and jugular catheters, and then moved into individual stanchions in an environmentally controlled barn. Blood samples were collected and serum isolated at −74, −50, and −26 h, at 0.5-h intervals from −4 h to 6 h, and at 12, 24, 36, 48, and 72 h relative to vaccination with Pyramid 5 + Presponse SQ at 1200 h on d 6. A second blood sample was used to measure complete blood cell counts. Data were analyzed using the Mixed procedure of SAS specific for repeated measures. There was a treatment × time interaction ($P < 0.01$) for RT such that DEX treatment in CHR and ACU steers decreased RT on d3 and d6, respectively, compared with CON steers. Vaccination on d 6 increased RT in CON but not in CHR or ACU steers with RT remaining elevated in CON for the remainder of the study. There was a treatment × time interaction ($P < 0.01$) for total white blood cells (WBC), neutrophils, lymphocytes, and monocytes. Specifically, DEX increased WBC and neutrophils in CHR and ACU steers, yet decreased lymphocytes in CHR steers. Monocytes initially increased in response to DEX treatment in CHR and ACU steers. Also, eosinophils were greater ($P < 0.01$) in CON than ACU and CHR steers. There was a treatment × time interaction ($P < 0.01$) for interferon-γ (IFN-γ) such that IFN-γ was greater in CON and CHR than ACU steers. Concentrations of tumor necrosis factor-α were elevated ($P < 0.01$) in CHR compared with ACU and CON steers. These data suggest that ACU stress may prime, while CHR stress may cause hyper-activation, of the APR associated with vaccination in naïve beef calves, thus potentially negatively affecting the overall immunological response to vaccination.

Key Words: cattle, immunity, vaccination

Production, Management, and the Environment II

591 Global impact of improving feed efficiency and technology transfer efficacy.

Robin R. White*[1,3], Todd J. Applegate[2], Gary L. Cromwell[3], Donald C. Beitz[4], Michael L. Galyean[5], Mary Beth Hall[6], Phillip S. Miller[7], Jack Odle[8], William P. Weiss[9], and Mark D. Hanigan[1], *[1]National Animal Nutrition Program, Virginia Tech, Blacksburg, VA, [2]Purdue University, West Lafayette, IN, [3]University of Kentucky, Lexington, KY, [4]Iowa State University, Ames, IA, [5]Texas Tech University, Lubbock, TX, [6]USDA/ARS, Madison, WI, [7]University of Nebraska, Lincoln, NE, [8]North Carolina State University, Raleigh, NC, [9]The Ohio State University, Columbus, OH.*

Providing protein for the expanding population is an imperative challenge to which animal nutrition research is vital. The objective of this work was to model how improving livestock feed efficiency and adoption of agricultural technologies would affect the number of people's annual protein requirements that could be met from a constant feed base. Global production data from FAOStat and occupation statistics from World Bank were collected to estimate the meat, milk and eggs (food) produced by an average farmer. Increasing feed efficiency was modeled as a % reduction in the feed required to produce 1 kg of food. Technology transfer efficiency was also accounted for. Net improvement in food produced was modeled as the sum of food produced from the proportion of farmers adopting the technology and food produced from the proportion of farmers not adopting the technology. Conversion of meat live weight to retail weight was based on dressing percentages (sheep/goat, 50%; beef, 63%; pork 70%) and a 50% conversion of dressed to retail weight. Retail milk and eggs were assumed 90% of produced weights. Protein production was calculated based on protein content. Meat protein (125 g/kg to 183 g/kg) and milk or egg protein (33 g/kg to 126 g/kg) varied by species. Protein produced by the system was divided by an average human's protein requirement (45 g/d) multiplied by 365 d. Assuming a 30% efficiency in technology transfer, a 34% improvement in feed efficiency would be required to meet the protein needs of an additional 0.5×10^9 people. A myriad of combinations of improved feed efficiency and improved technology transfer could result in sufficient protein to feed 2×10^9 people. In general, feed efficiency improvements of over 50% were required and technology transfer efficiencies between 50 and 70% greatly improved practicality of meeting the protein requirements of 2×10^9 billion people. Both biological research aimed at improving feed efficiency, and social research aimed at understanding factors influencing technology adoption rates will be required to improve global food security. Supported by USDA NIFA and State Agricultural Experiment Stations.

Key Words: food security, nutrition, feed efficiency

592 Nutrient cycling on dairy farms: Status and opportunities.

Andrew Henderson[1], Ying Wang*[2], Karin Veltmank[3], and Olivier Jolliet[3], *[1]University of Texas, Houston, TX, [2]Innovation Center for US Dairy, Rosemont, IL, [3]University of Michigan, Ann Arbor, MI.*

Nutrient management represents both a challenge and opportunity to dairy and other livestock industries. Current practices may lead to lost nutrients from feed, manure, and commercial fertilizers, possibly impairing water bodies or affecting air quality. These losses may have direct economic implications for dairy farms, via possible phosphorus supply shortages [Van Vuuren et al., 2010. Glob. Environ. Change 20:428–439] or future nutrient regulation (for eutrophication or greenhouse gases). Losses also present an opportunity for improvement, if farmers can take advantage of nutrient cycling. Using a combination of literature meta-analysis and case study modeling, this research outlines and estimates the potential scale of improved nutrient cycling on dairy farm. For the meta-analysis, we compiled ~300 research articles for nutrient flows on dairy farms. We cataloged the variety of nitrogen, phosphorus, and potassium flows crossing the farm boundary (e.g., purchased feed) and internal to the farm (e.g., manure application to crops). Some flows had large coefficients of variation (CV), such as total excretion of nitrogen (CV = 2.3, n = 43) and total intake of nitrogen (CV = 2.7, n = 94). To complement this analysis, we compared modeled nutrient flows on a commercial dairy farm, using the process-based models Integrated Farm System Model [IFSM; Rotz et al., 2014; The Integrated Farm System Model (IFSM): Reference Manual Version 4.1, USDA] and ManureDNDC [Manure De-Nitrification De-Composition; Li et al., 2012. Nutr. Cycl. Agroecosys. 93:163-200]. Field N_2O emissions differed between the models (3.8–11.3 t of N_2O/yr), but other emissions predicted P and N losses to (ground)water through leaching, run-off and erosion are comparable across models. Whole-farm ammonia emissions are comparable across models (87.6 – 122.1 t NH_3/yr). The variation among farms, in the literature and modeled, represents a potential for improvement. This study compares and contrasts these variations, identifying the magnitude of potential nutrient cycling efficiencies on farm.

Key Words: dairy, nutrient cycling, environmental impact

593 Comparing climate impacts of grass-finished beef production strategies in the upper Midwest using a partial life cycle analysis.

Jason E. Rowntree*[1], Rebecca Ryals[2], Marcia S. DeLonge[3], Marilia B. Chiavegato[4], W. Richard Teague[5], and Peter Byck[6], *[1]Michigan State University, East Lansing, MI, [2]University of Hawaii, Honolulu, HI, [3]Union of Concerned Scientists, Washington, DC, [4]University of São Paulo, Piracicaba, São Paulo, Brazil, [5]Texas A&M Agrilife Research, Vernon, TX, [6]Arizona State University, Tempe, AZ.*

Cattle grazing management strategies can vary widely and have important effects on ecosystem carbon storage, greenhouse gas (GHG) emissions and land requirements. Existing GHG life cycle assessments of beef production often lack refined details about grazing strategies and their associated impacts on ecosystem carbon and greenhouse gas dynamics. A partial life cycle analysis was conducted on an upper Midwest grass finishing beef production system that compared 2 different grazing management strategies. The approaches were: 1) a non-irrigated, high-density grazing system stocked at 1.0 AU/ha (100,000 kg LW/ha; SysA) and 2) an irrigated, low-density grazing system stocked at 2.5 AU/ha (30,000 kg LW/ha; SysB). Our life cycle boundary only included the grass-finishing portion of beef production. Steers were born in April, weaned in November, backgrounded for 6 mo and grazed until slaughter in November, the following year, with an average age at slaughter of 19 mo and a 295 kg HCW. We included GHG associated with enteric methane (CH_4), soil nitrous oxide and CH_4 emissions, alfalfa and mineral supplementation and farm energy use. We used 2 years of on-farm corrected data for soil and enteric emissions and animal performance from Lake City Research Center, Lake City, MI. The assumed boundaries for potential soil C loss or gain ranged from an emission of 3 Mg C/ha/yr to a positive sink of 3 Mg C/ha/yr. Enteric CH_4 emissions had the largest effect on overall GHG flux and this varied by year and grazing system. In years 2012 and 2013, enteric CH_4 was 89 and 49% of the overall flux for SysA compared with 72 and 65% for SysB, respectively. Both systems are net GHG sources when soil

C sequestration is excluded. When soil C sequestration is considered, each grazing strategy has potential to be an overall sink. These results indicate SysA and SysB would have to sequester up to 1.0 and 2.0 Mg C/ha/yr to have a net zero GHG footprint, respectively.

Key Words: grass-finished, methane, carbon

594 Predicting methane emission of dairy cows using fatty acids and volatile and non-volatile metabolites in milk.

Sanne van Gastelen*[1,2], Elsa C. Antunes-Fernandes[1,3], Kasper A. Hettinga[3], and Jan Dijkstra[2], *[1]Top Institute Food and Nutrition, Wageningen, the Netherlands, [2]Animal Nutrition Group, Wageningen University, Wageningen, the Netherlands, [3]Food Quality Design Group, Wageningen University, Wageningen, the Netherlands.*

The objective of this study was to develop prediction equations for methane (CH4) emission of dairy cows using fatty acids (FA), volatile metabolites, and non-volatile metabolites in milk. Data from a randomized block design experiment with 32 multiparous Holstein Friesian cows and 4 diets was used. All diets had a roughage:concentrate ratio of 80:20 based on dry matter. Roughage consisted of grass silage only, corn silage only, or mixtures of both silages. Methane emission was measured in climate respiration chambers, and expressed per unit dry matter intake (DMI) and per unit fat- and protein-corrected milk (FPCM). Milk samples were analyzed for FA by gas chromatography, volatile metabolites by gas chromatography-mass spectrometry, and non-volatile metabolites by nuclear magnetic resonance. A multivariate model was developed using a stepwise procedure with selection of FA, volatile, and non-volatile metabolites. Only variables with $P < 0.05$ entered the model, and variables with $P < 0.10$ were retained in the final model. Multivariate analysis, using only FA (g/100g total FA), resulted in equations: CH4 (g/kg DMI) = 29.5 (±1.33) – 2.13 (±0.98) × C18:2n-6 – 5.37 (±1.31) × total CLA (adjusted R2 = 0.53), and CH4 (g/kg FPCM) = 11.7 (±2.13) + 42.7 (±7.55) × C15:0iso – 9.88 (±3.23) × C17:0 (adjusted $R^2 = 0.51$). Multivariate analysis, using FA, volatile metabolites (peak area) and non-volatile metabolites (area change), resulted in equations: CH4 (g/kg DMI) = 28.6 (±0.97) – 6.33 (±1.00) × total CLA – 6.21 (±1.65) × N-acetyl sugar + 2.46 (±0.83) × choline (adjusted R2 = 0.69), and CH4 (g/kg FPCM) = 7.2 (±2.32) + 1.23 × 10–6 (5.26 × 10–7) × 3-nonanone + 22.1 (±5.69) × C15:0iso – 205.1 (±66.21) × uridine diphosphate hexose + 62.7 (±28.17) × Unknown (adjusted R2 = 0.68). The potential of milk FA only to predict CH4 emissions was moderate. Including volatile and non-volatile metabolites enhanced the predictive power, suggesting that these metabolites, in combination with milk FA, hold potential to predict CH4 emission of dairy cows.

Key Words: methane emission, milk fatty acids, milk volatile and non-volatile metabolites

595 Methane prediction equations for beef cattle fed low forage diet.

Paul Escobar-Bahamondes*[1,2], Masahito Oba[1], and Karen A. Beauchemin[2], *[1]University of Alberta, Edmonton, AB, Canada, [2]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

The goal of this study was to develop equations to predict CH_4 emissions from beef cattle fed low forage diets (≤20% DM basis) and compare their predictions with IPCC 2006. A dietary forage ≤20% DM database was constructed with treatment means from 17 beef studies published between 2000 and 2014. Criteria for inclusion in the database were: intake, diet composition and enteric CH_4 production. To overcome the limited size of the database (n = 34) each study was resampled 1,000 times using a Monte Carlo technique to create a new virtual data set. Outliers were excluded by Mahalanobis procedure. Three steps were used to obtain new equations: 1) variables associated with CH_4 production were detected by Principal Component Analysis, 2) stepwise forward multiple regression was used with the original database to obtain prediction equations with study included as a random effect using the Mixed procedure, and 3) stepwise forward regression and K-fold cross validation (n = 5) was used with the Monte Carlo data set (n = 34,000). Observed-predicted values were used to evaluate model performance using the concordance correlation (r_c) and root mean square prediction error (RMSPE, g/d). Statistical analysis was performed using JMP v.11. The best-fit equation using the original database was: CH_4 (g/d) = −26.4(±20.17) + 0.21(±0.04) × BW(kg) + 38.1(±11.83) × CP(kg/d) - 70.5(±25.48) × fat^2(kg/d) + 10.1(±5.12) × $(NDF\text{-}ADF)^3$(kg/d) with $P < 0.05$, r_c: 0.91 and RMSPE: 13.74; where BW = body weight, CP = crude protein, NDF = neutral detergent fiber, and ADF = acid detergent fiber. The best-fit Monte Carlo equation was: CH_4 (g/d) = −10.1(±0.62) + 0.21(±0.001) × BW(kg) + 0.36(±0.003) × DMI^2(kg/d) - 69.2(±1.65) × fat^3(kg/d) + 13.0(±0.45) × (CP/NDF) - 4.9(±0.07) × (starch/NDF) with $P < 0.001$, r_c: 0.92 and RMSPE: 12.6 where DMI = dry matter intake. These new prediction equations had greater r_c and lower RMSPE than IPCC 2006 (r_c:0.29; RMSPE:43.2), indicating greater prediction accuracy. Using the Monte Carlo equation data set improved accuracy of prediction compared with the original equation database. Both equations specifically developed for cattle fed low forage diets increase the accuracy of predicting CH_4 emissions compared with IPCC (2006).

Key Words: methane, beef cattle, equation

596 Evaluating extant empirical models for predicting enteric methane emissions from lactating dairy cows.

J. A. D. R. N. Appuhamy* and E. Kebreab, *Department of Animal Science, University of California, Davis, CA.*

Empirical models are widely used to estimate enteric methane (CH_4) emissions from dairy cows worldwide. The objective of this study was to evaluate extant models for predicting CH_4 emissions from dairy cows using literature data. Thirty-nine extant models developed based on dairy cow data were evaluated using measurements from 47 studies published after 2000. The data containing dietary, production and animal information included 50, 83, and 41 enteric CH_4 measurements of lactating dairy cows from North America (NA), Europe (EU), and Australia and New Zealand (AUNZ), respectively. The models were evaluated using root mean square prediction error (RMSPE), concordance correlation coefficient, and Nash-Sutcliffe efficiency statistics. An index including equally weighted statistics was used to rank the models within each region. For NA, the 5 top ranked models were those by Hristov et al. (2013), Moe and Tyrrell (1979), Ellis et al. (2007), Moraes et al. (2014), and Moate et al. (2011) [Ref 1–5, respectively, in Table 1] and had RMSPE 15–17% of the average observed value. The majority of the best performing models in NA were developed on data from NA cows. A completely different Set of models performed best on both EU (RMSPE = 11–13%) and AUNZ (RMSPE = 11–15%) data. The best performing models were those by FAO (2010), IPCC (1997), Storlien et al. (2014), Yan et al. (2000), and Nielsen et al. (2014) [Ref I–V respectively in Table 1]. Regional origin and perhaps diet type of the data on which models have been developed need to be considered when selecting a model to predict CH_4 emissions successfully.

Table 1 (Abstr. 596). Top ranked models for predicting enteric CH_4 (MJ/cow/d) emissions[1]

NA	Ref	EU and AUNZ	Ref
= [2.54 + 19.14 × DMI] × 0.05565	1	(0.0975 – 0.0005 × DMd) × GEI	I
= 3.14 + 0.51 × NSC + 1.74 × HC + 2.65 × C	2	0.065 × GEI	II
= 4.08 + 0.068 × MEI	3	1.47 + 1.28 × DMI	III
= –9.311 + 0.042 × GEI + 0.094 × NDF% – 0.381 × FA% + 0.008 × BW + 1.621 × MilkF	4	3.234 + 0.0547 × GEI	IV
= [exp(3.15 – 0.0035 × FA)] × DMI × 0.05565	5	1.26 × DMI	V

[1] DMI, NSC, HC = hemicellulose, C =cellulose (all in kg/d), FA and FA%= dietary fat (g/kg of DM and % of DM), DMd = diet DM digestibility (%), GEI and MEI = gross and metabolizable energy intake (MJ/d), NDF% (% of DM), BW (kg), MilkF = milk fat %.

597 Comparison between the GreenFeed system and the sulfur hexafluoride tracer technique for measuring enteric methane emissions from dairy cows.

Joonpyo Oh*[1], Fabio Giallongo[1], Tyler Frederick[1], Mike T. Harper[1], Holley Weeks[1], Antonio F. Branco[2], Alexander N. Hristov[1], William J. Price[3], Peter J. Moate[4], Matthew H. Deighton[4], S. Richard O. Williams[4], Maik Kindermann[5], and Stephane Duval[6], *[1]The Pennsylvania State University, University Park, PA, [2]Universidade Estadual de Maringá, Maringá, Paraná, Brazil, [3]University of Idaho, Moscow, ID, [4]Agriculture Research Division, Ellinbank Centre, Ellinbank, Victoria, Australia, [5]DSM Nutritional Products, Base, Switzerland, [6]DSM Nutritional Products France, Saint Louis Cedex, France.*

The objective of this study was to compare 2 commonly used techniques for measuring CH_4 emissions from ruminant animals, the GreenFeed (GF) system and the sulfur hexafluoride (SF_6) technique. The study was part of a larger experiment, in which a CH_4 inhibitor, 3-nitrooxypropanol (3NOP), fed at 4 application rates (0, 40, 60, and 80 mg/kg feed DM) decreased enteric CH_4 emission by 25 to 32% in a 12-wk experiment with 48 lactating Holstein cows. The larger experiment used a randomized block design and was conducted in 2 phases (Feb-May, phase 1 and Jun-Aug, phase 2), with 24 cows in each phase. Methane emissions using GF were measured during experimental wk 2, 6, 9, and 12. During each GF measurement, 8 spot samples of gas emissions were collected from each cow, staggered over a 3-d period (a total of 0.67 h/cow). Emission data using the SF_6 technique were collected for 3, 24 h periods (a total of 77 h/cow) during wk 2, 6 or 9, and 12. An outlier analysis removed 1 observation from the GF data set (1,271 observations) and 6 observations from the SF6 data set (451 observations). Methane yield data (g/kg DMI) were averaged per cow for the statistical analysis. The mean CH_4 yield, SD, lower and upper 95% CL, CV, and min and max values for the GF data set were (g CH_4/kg DMI or as indicated): 12.8, 3.63, 12.8 and 13.9, 27.2% (18.1 and 21.2%; control and 3NOP cows, respectively), and 6.7 and 26.4. For the SF6 data set these values were: 14.7, 5.60, 14.7 and 17.0, 35.3% (30.4 and 29.9%, control and 3NOP cows), and 7.2 and 36.5. Data were analyzed within experimental phase, sampling week, and treatment to compare CH_4 yield between GF and SF_6. The difference between the 2 methods (SF_6 – GF) within treatment was 1.9 to 4.1 g CH_4/kg DMI ($P < 0.001$ to 0.06) for phase 1 and 1.1 to 2.4 g/kg DMI ($P = 0.06$ to 0.38) for phase 2. In the conditions of this experiment, the SF_6 technique produced larger variability in CH_4 yield than the GF method. The difference between the 2 methods was not consistent over time, perhaps influenced by barn ventilation and background CH_4 and SF_6 concentrations.

Key Words: methane, GreenFeed, sulfur hexafluoride

598 Breed and lactation stage affect rumen methanogens in co-housed primiparous dairy cattle.

L. M. Cersosimo*[1], M. Bainbridge[1], J. Kraft[1], and A.-D. G. Wright[2], *[1]University of Vermont, Burlington, VT, [2]University of Arizona, Tucson, AZ.*

Rumen methanogens are anaerobic, methane-producing archaea that decrease feed efficiency in dairy cattle and contribute to global warming. The objective of this study was to determine if breed or lactation stage affect the rumen methanogen diversity and density. Seven Holstein (H), 8 Jersey (J), and 7 Holstein-Jersey crossbreeds (X) were co-housed in a free stall on a total mixed ration, and whole rumen digesta samples were collected at 3, 93, 183, and 273 d in milk (DIM). To determine the methanogen diversity, the V1-V3 region of the 16S rRNA gene was amplified. Sequences were generated using Illumina MiSeq v.3 and all bioinformatics analyses were performed using Mothur. Real-time PCR amplified the methanogen-specific mcrA gene and the mcrA copy numbers per mL rumen digesta were calculated. Data were analyzed using PROC MIXED in SAS. The model included the effects of breed (B), lactation stage (LS), and B x LS. A total of 1,683,569 16S sequence reads were classified to species-level taxa by B and LS. The *Methanobrevibacter* (*Mbr.*) *smithii-gottschalkii-millerae-thaueri* and *Mbr. ruminantium-olleyae* clades did not differ. Notably, the mean % abundance of the species *Mbr. thaueri* differed ($P < 0.01$) by LS. At 93 DIM, *Mbr. thaueri* abundance was higher in J (35.0%) compared with both H (24.5%, $P < 0.05$) and X (19.4%, $P < 0.01$), while no significance was observed at 183 and 273 DIM, respectively. Differences by LS were seen in less abundant species (<5%), *Mbr. woesei* ($P < 0.001$), *gottschalkii* ($P < 0.05$), *millerae* ($P < 0.05$), and *Methanosphaera stadtmanae* ($P < 0.01$). The top operational taxonomic units (OTU) from a 2% cutoff were related to *Mbr. smithii*, *Mbr. thaueri*, *Mbr. ruminantium*, and *Mbr. millerae*. There were no differences in methanogen density, the number of OTUs (18–37 per breed), or Shannon and Inverse Simpson indices. Chao values differed by LS ($P < 0.01$). Our data suggest that LS may have had a greater effect on the methanogen diversity than B and that core rumen methanogens persist over a lactation period.

Key Words: archaea, diversity, *Mbr. thaueri*

599 Aerodynamic design of a TMR feed bin to measure gaseous emissions from cattle.

Scott Zimmerman*[1], John Roche[2], and Pat Zimmerman[1], *[1]C-Lock Inc., Rapid City, SD, [2]Dairy NZ, Hamilton, New Zealand.*

The need to measure methane (CH_4) and carbon dioxide (CO_2) emissions from cattle in production environments is increasing. Previously, CH_4 and CO_2 emissions have been accurately measured for short-term repeated periods using a supplemental feeding station (GreenFeed, C-Lock Inc.). Considering the interest in residual feed intake, there is an opportunity to combine the measurement of feed intake with the measurement of CH_4, by incorporating this technology into a TMR-feeder. To do this effectively, it is necessary to design a feed bin that has desirable airflow characteristics, that ensure a high capture of emitted gasses and produces a fast response time to emitted gasses. The purpose of this study was to design a TMR feeder with optimal airflow characteristics. A TMR bin, 92 × 92 × 81 cm was constructed (dead-volume = 710 L). An opening for the cow's head of 30 × 6 cm was made and the lid was sealed. Bin dimensions enabled adequate TMR to be offered, while allowing the cow to reach all corners. Airflow was extracted from the bin at a rate of 45 L/s using a fan. From the outlet gas, CO_2 concentrations were measured. Artificial smoke was used to visualize flow patterns inside the TMR bin and results were recorded on video. Separately, CO_2 gas was injected into the TMR bin at 7 g/min until the system reached equilibrium, at which point the CO_2 was removed. The T-90 equilibrium time of CO_2 disappearance was analyzed. Three gas extraction methods were tested: (m1) a 10-cm-diameter circular outlet, (m2) a manifold with 36 evenly spaced 1.27-cm-diameter holes in only the upper half of the bin, (m3) a manifold with 72 evenly spaced 1.27-cm-diameter holes throughout the bin. There was no observed sample loss from the head opening with any outlet configuration. However, m2 and m3 produced a significantly longer T-90 equilibrium time compared with m1 (24, 33, and 66 s, respectively). The multiple air outlets in m2 and m3 produced improved airflow characteristics. Although m3 produced the fastest equilibrium time, the air holes at the bottom of the bin could become plugged with TMR; therefore, manifold 2 is likely the optimal option. In conclusion, a well-designed TMR bin can produce acceptable airflow characteristics for the measurement of gaseous emissions from cattle while they are feeding.

Key Words: methane, emissions, cattle

600 Predicting nitrogen excretion from lactating dairy cattle.

Kristan F. Reed*[1], Luis E. Moraes[1], Alexa Johnson[1], David P. Casper[2], and Ermias Kebreab[1], *[1]University of California, Davis, Davis, CA, [2]South Dakota State University, Brookings, SD.*

A genetic algorithm was implemented to select models to predict fecal, urinary, and total manure nitrogen (N) excretion by lactating dairy cows. Akaike's Information Criterion was used as the criteria for model selection. Data for model development consisted of 1,047 indirect calorimetry observations on lactating cows collected at the USDA's Energy and Metabolism laboratory from 1963 to 1995. Two tiers of model classes based on model input requirements were developed resulting in 6 models. Tier 1 selects a single covariate model to estimate N excretion and the Tier 2 selects models from many potential dietary and animal covariates including BW, DIM, CP, NDF, ash content, and proportion of concentrate in the diet. Animal and study were designated as cross-classified random effects and the final selected mixed models were fit using restricted maximum likelihood in R statistical software with the lme4 package. The root mean square prediction error (RMSPE) was used to evaluate the models in 3 ways: (1) K-fold cross validation based on all data, (2) evaluation with the most recent 6 years of data, and (3) evaluation with N balance data collected from literature published from 1996 to 2014. The number of published studies reporting covariates required for tier 2 models was not sufficient for model evaluation. Results listed in Table 1 for tier 1 models show better prediction for total manure N and fecal N compared with urinary N excretion. Tier 2 models had lower RMSPE than Tier 1 models across all forms of excretion.

Table 1 (Abstr. 600). Model selection and evaluation reported in the RMSPE (% mean N excretion); parameter estimates with standard errors in parentheses

Model estimates	USDA cross-validation	USDA 1990-1995	Literature data 1995-2014
UN = 12.0(5.80) + 0.333(0.0106) × NI	23.7	12.7	23.8
FN = −18.5(3.59) + 10.1(0.169) × DMI	12.6	18.2	16.2
TN = 20.3(4.72) + 0.654(0.00926) × NI	9.80	8.14	10.8

UN = urine nitrogen, FN = fecal nitrogen, TN = total manure nitrogen, NI = nitrogen intake (g/d).

Key Words: dairy, nitrogen, prediction

601 Checks and balances: Evaluating reliability of dairy nutrient management data to better protect groundwater resources.

Christine Miller* and Deanne Meyer, *University of California, Davis, Davis, CA.*

To protect groundwater from further nitrate contamination, California regulations require dairy farmers to follow a strict nutrient management plan. The regulations require copious annual reporting of crop field management, farm infrastructure, and animal population. The data collected in these annual reports could be integral to evaluating and improving both farm practices and the regulations themselves. The objectives of this project were to (1) assess the reliability and accuracy of annual report data to allow the information to be used responsibly and (2) to suggest promising methods of improving data quality. Annual reports from 18 dairies were obtained to assess data reliability. Mass balance calculations were preformed to check the self-consistency of data within a facility. The results of mass balance calculations show that the annual reports do not account for a remarkably large percentage of the nutrients being produced on the farms. Literature suggests that over 60% of nitrogen (N) and 90% of phosphorus (P) should be recovered; however, a median of only 25% of both N and P in cattle manure was recovered based on annual reports. This could be due to many different causes including inaccurate nutrient sampling and analysis techniques or fraudulent reporting. It is likely that the sampling and analysis methods are a significant source of error because the accuracy of the majority of the protocols has not been assessed. The results of this study have led to projects that should improve data collection protocols in both the short and long-term. In the short term, online decision trees are being developed in collaboration with extension agents and consultants to help farmers self-assess their current data collection practices, and provide personalized suggestions for improvement. Suggestions are currently based on the recommendations of experts, but will be improved in the long term using a statistical modeling approach paried with field experiments to examine the uncertainty in each of the recommended protocols. With more reliable data, we can identify regulations and management practices that are more protective of groundwater quality.

Key Words: dairy waste management, nitrate leaching

602 Economic and environmental implications of wheat crop rotations on organic dairy farms.

D. C. Abreu*[1,3], A. K. Hoshide[2], E. B. Mallory[2], A. S. Oliveira[1], R. J. Kersbergen[2], R. P. Lana[3], and C. P. Ghedini[4], *[1]Universidade Federal de Mato Grosso, Sinop, MT, Brazil, [2]University of Maine, Orono, ME, [3]Universidade Federal de Viçosa, Viçosa, MG, Brazil, [4]University of New Hampshire, Durham, NH.*

Our objective was to determine the sustainability for 8 crop rotation sequences of 3-yr rotations in a long-term (25-yr) well-managed organic dairy farm in Maine. A medium-sized organic dairy farm was simulated with the Integrated Farm System Model (version 3.6) to evaluate crop rotation (management) effects on crop performance, environmental impacts and profitability. The 9 cropping strategies included continuous ryegrass/red clover (continuous grass), corn harvested early followed by winter wheat (corn-wwheat-grass), corn followed by spring wheat (corn-swheat-grass), ryegrass/red clover rotated with winter wheat (grass-wwheat-grass), ryegrass/red clover in rotation with spring wheat (grass-swheat-grass), soybean rotated with both winter wheat (soybean-wwheat-grass) and spring wheat (soybean-swheat-grass), corn double cropped (corn-corn-grass) and soybean followed by corn (soybean-corn-grass). Wheat was harvested as a cash crop in all simulated years and sold at an organic premium price. All rotations were in long rotation with perennial ryegrass/red clover over the 3 yr period. When the continuous grass-based system was simulated, farm net return was higher ($742.15/cow). Under crop rotation, the option of growing and selling winter wheat instead of spring wheat improved farm profitability when the results were compared with other wheat cropping rotations. The higher winter wheat yields for soybean-wwheat-grass resulted in 7% more income from feed sales ($1,027) and 1% more in total revenue ($1,065). Also, winter wheat should be encouraged to reduce soil nutrient accumulation, particularly soybean replaced with cash crop wheat (soybean-wwheat-grass). Here the major reductions in nutrient flows were a 0.8 kg/ha/yr decrease in both P runoff and leachate losses and K accumulation (−17%); there was also a 4% reduction in water footprint (kg/kg FPCM). Use of corn harvested as silage in place of grass or/and soybean in the first year or winter/spring wheat in the second year provided relatively less profitability to the farm. In general, there were lower economic and more favorable environmental benefits to shifting land from continuous grass-based production to specified small grain cropping rotations.

Key Words: dairy, wheat, integrated farm system model

Ruminant Nutrition: Manipulating rumen function

603 The effects of Megalac and a fatty acid prill containing high levels of palmitic acid supplementation on milk fatty acid composition with early lactation dairy cows. Guiling Ma[1], Elliot Block[2], Limin Kung[3], Joe Harrison*[1], and C. Merrill[2], *[1]Washington State University, Puyallup, WA, [2]Arm & Hammer Animal Nutrition, Princeton, NJ, [3]University of Delaware, Newark, DE.*

The objective of this study was to compare 2 fat sources, Megalac (Church & Dwight Co. Inc., Princeton, NJ;) and a high palmitic acid prill (Guarantee-palmitate (min) 80%) on composition of milk fatty acids of early lactation cows in a feeding trial lasting 12 wks. Thirty multiparous Holstein cows were randomly assigned to 1 of 2 diets. Except for the fat products, other feeding ingredients were identical in the diets. Fat products were supplemented at 1.2% (DMI). Milk components were assessed from AM and PM milkings. Milk fatty acids were analyzed with Proc Mixed. The interaction between time and treatment was also analyzed. There were no differences in the composition of short chain fatty acids (C6:0, 8:0, 10:0, 11:0, 12:0, 14:1T, 14:1, 15:0 and 15:1T) between treatments ($P > 0.05$). Palmitic supplementation increased palmitic acid in milk (37.2 ± 0.5 vs. 40.7 ± 0.6, $P < 0.05$), while there was a fat source x week interaction ($P < 0.05$). Megalac supplementation increased the concentration of stearic acid (10.1 ± 0.3 vs. 8.8 ± 0.3, $P < 0.05$), and no interaction between fat source and time ($P > 0.05$). MEGALAC^{TM} supplementation also increased ($P < 0.05$) unsaturated fatty acids C18:1–8T (0.081 ± 0.004 vs. 0.067 ± 0.004), C18:1–9T (0.31 ± 0.03 vs. 0.21 ± 0.03), C18:2 (2.5 ± 0.1 vs.2.2 ± 0.1), C20:1–8-eicosenoate (0.054 ± 0.003 vs. 0.042 ± 0.004), and there was no time interaction ($P > 0.05$). Megalac supplementation increased ($P < 0.05$) C18:1–11T (1.13 ± 0.08 vs.0.89 ± 0.08, $P < 0.05$), tended to increase C18:1–12C (0.34 ± 0.01 vs. 0.31 ± 0.01, $P < 0.07$), increased C18:2-*cis*-9,*trans*-11 (0.45 ± 0.02 vs. 0.38 ± 0.03, $P < 0.06$), and there was a time interaction. There was no difference ($P > 0.05$) between fat sources for C16:1T, C16:1, C17:0, C17:1–10-heptadecenoate, C18:1–10-T, C18:1, C18:1–11-C, C18:3-γ, C18:3-α, C18:2CLA, and C18:2- *trans*-10,*cis*-12, in milk. Except for C18:1–12C, there was no difference between AM and PM sampling times ($P > 0.05$). Our findings suggest that in the future, it is not necessary to separately analyze the AM, PM samples for milk fatty acid analysis. Feeding of Megalac appears to promote the T 11 vs. T 10 pathway of biohydrogenation.

Key Words: milk, fatty acid, dairy

604 Effects of different levels of supplementation of a molasses and crude glycerol mixture on ruminal fermentation parameters of beef steers. Francine M. Ciriaco*, Darren D. Henry, Vitor R. G. Mercadante, Tessa M. Schulmeister, Martin Ruiz-Moreno, G. Cliff Lamb, and Nicolas DiLorenzo, *North Florida Research and Education Center, University of Florida, Marianna, FL.*

We determined the effects of feeding different levels of a 50:50 molasses:crude glycerol supplement on ruminal fermentation and blood parameters. Eight ruminally cannulated Angus crossbred steers (323 ± 42 kg BW) were used in a 4 × 4 duplicated Latin square design. In each of the 4 28-d periods, animals were housed in individual pens at the University of Florida Feed Efficiency Facility, had ad libitum access to Tifton 85 bermudagrass hay, and were randomly assigned to one of 4 treatments: 0, 0.45, 1.36, and 2.27 kg/d (as fed) of a 50:50 liquid mixture of molasses:crude glycerol. Ruminal fluid and blood samples were collected before supplement feeding (0 h) and every 3 h postfeeding for 24 h. Immediately after each collection, ruminal pH was measured. Plasma was analyzed for blood urea nitrogen (BUN) and ruminal fluid for VFA and NH_3-N concentrations. Data were analyzed as repeated measures and orthogonal polynomial contrasts were used to determine the effects of supplementation level on ruminal fermentation and blood parameters. As the level of supplementation increased, mean ruminal pH (6.73, 6.83, 6.74, 6.65 for 0, 0.45, 1.36, and 2.27 kg/d, respectively; $P = 0.03$) and concentrations of BUN and NH_3-N ($P < 0.001$) decreased linearly. Molar proportions of acetate decreased ($P < 0.001$) whereas molar proportions of propionate ($P < 0.001$) and butyrate ($P = 0.007$) increased linearly as the level of supplementation increased. Total VFA concentrations were affected cubically ($P = 0.005$) by liquid supplementation. Feeding up to 2.27 kg/d of the liquid supplement to steers consuming bermudagrass hay caused a decrease in ruminal pH; however, values were not below 6.0, which is the threshold known to affect fiber digestion. Therefore, we concluded that the inclusion of up to 2.27 kg/d of a 50:50 mixture molasses:crude glycerol in forage based diets fed to growing steers, positively affected ruminal fermentation, increasing propionate concentrations at the expense of acetate, which should improve animal performance.

Key Words: crude glycerol, forage, molasses

605 Total-tract pdNDF digestibility in heifers fed with TMR or pelleted ration. Elena Bonfante*, Mattia Fustini, Nicola Negri, Alberto Palmonari, Giorgia Canestrari, and Andrea Formigoni, *DIMEVET, University of Bologna, Ozzano Emilia, Italy.*

The aim of this study was to evaluate the total-tract pdNDF digestibility (TTdpdNDF) in heifers fed with the same ration as TMR or pellet. Eight tie-stall heifers (age 336 ± 30d, BW 346 ± 35kg) were used in a 12 weeks study (4 periods of 3 weeks: 2 adaptive and 1 for data collection). Diets had the same ingredients (hay 41.8%, barley straw 27.4%, sunflower 13.7%, grain 16.4%, NaCl 0.7%) but fed in 2 physical forms: TMR and PELLET (Ø = 8mm), thus differing in structure, evaluated through the physical effective factor (pef = 38.73% in pellet, 66.12% in TMR). Heifers, divided in 2 groups, were fed ad libitum, individually, with the 2 diets in alternate periods, and dry matter intake (DMI), DMI/BW, water intake, rumination time, rumen temperature and pH were evaluated daily. Fecal samples for TTdpdNDF determination were collected and average daily gain (ADG) was calculated at the end of each period. Data of the third week of each period were statistically analyzed with ANOVA for repeated measures, while ADG and TTdpdNDF by *t*-test (Statistica v10). The DMI and DMI/BW was higher ($P < 0.001$) in pelleted diet (11.49 ± 1.72 vs. 9.03 ± 1.33 kg) (3.05 ± 0.33 vs. 2.40 ± 0.24%) and water intake increased ($P < 0.01$) during pellet administration (52.0 ± 13.0 vs. 41.0 ± 9.0 L/d). ADG at the end of the study was 1.0 ± 0.45 kg/d. The rate for the pellet diet was greater but not significantly different (1.07 ± 0.32 vs. 0.90 ± 0.54 kg/d). Rumination time was considerably lower ($P < 0.001$) with pellet than TMR (256 ± 58 vs. 521 ± 66 min/d). Diet had no effect on rumen temperature or pH. TTdpdNDF, evaluated using uNDF$_{240\ h}$ as a marker, was statistically different between pellet and TMR (87.88 ± 3.72 vs. 91.45 ± 1.92%). The results of this study suggest that a complete pelleted diet was well accepted by animals, as showed by higher DMI. Moreover, even if rumination time dropped with the pelleted diet, ruminal pH was maintained similar to those with TMR. TTdpdNDF, despite the difference between 2 diets was significant, maintained high values in both diets. In conclusion, a complete pelleted diet, designed to provide sufficient amount of physically effective fiber, could be fed to growing ruminants without generating digestive disorders.

Key Words: TTdpdNDF, physical effective fiber, heifer nutrition

606 Rumen degradability of wheat straw is related to changes in lignin properties after fungal treatment.

Sandra J. A. van Kuijk*[1], Anton S. M. Sonnenberg[2], Johan J. P. Baars[2], Wouter H. Hendriks[1], and John W. Cone[1], *[1]Animal Nutrition Group, Wageningen University, Wageningen, the Netherlands, [2]Plant Breeding, Wageningen University, Wageningen, the Netherlands.*

The aim was to improve the rumen degradability of wheat straw (WS), which has relatively high cell wall content. Plant cell walls consist of hemicellulose and cellulose that are bound to lignin. These carbohydrates can be an important source of energy for rumen microbes. However, rumen microbes cannot degrade lignin, which blocks the availability of the carbohydrates. The availability of carbohydrates can be increased when lignin is removed in a pre-treatment. In nature, dead plants can be degraded by fungi. Some fungal species degrade lignin without consuming cellulose during vegetative growth. One of the selective lignin degrading fungi, *Lentinula edodes* was used to test the improvement in rumen degradability of WS. Two conditions were tested in triplicate: autoclaved WS inoculated with *L. edodes* and autoclaved WS as control. After 12 weeks of incubation at 24°C, rumen degradability was determined with the in vitro gas production (IVGP) technique (Cone et al., 1996). Lignin, hemicellulose and cellulose content were determined according to the methods described by Van Soest et al. (1991). Changes in chemical composition and IVGP upon fungal treatment were compared with the control, using the generalized linear model method in SAS (v9.3). To test the effect of changes in lignin structure and properties, pyrolysis gas chromatography-mass spectrometry (py-GC/MS) was done on fungal treated WS and the control. *L. edodes* treatment for 12 weeks increased ($P < 0.05$) IVGP of WS compared with untreated WS. Cellulose content was unchanged, while hemicellulose and lignin content decreased ($P < 0.05$). In addition to a decrease in total lignin, py-GC/MS showed an increasing amount of lignin degradation products. Upon *L. edodes* treatment not only a total degradation of lignin occurred, but the composition of lignin also changed. Lignin in WS consists of syringyl (S) and guaiacyl (G) units in a 1:1 ratio. *L. edodes* degraded more S than G units, since the S/G ratio decreased. This decrease in S/G ratio was correlated to an increase in IVGP. We conclude that the *L. edodes* treatment increased the IVGP of WS, which was correlated to both lignin content and composition.

Key Words: rumen degradation, plant cell wall, fungal pretreatment

607 Inoculant effects on silage fermentation and aerobic stability of sorghum wet ethanol co-product/roughage blends.

Pedro R. B. Campanili*, Jhones O. Sarturi, Michael L. Galyean, Sara Trojan, Lauren A. Ovinge, Barbara J. M. Lemos, Alex Thompsom, David Klein, Mendu Venugopal, and Bradley Johnson, *Texas Tech University, Lubbock, TX.*

Anaerobic storage of blends containing sorghum wet distillers grains plus solubles (WDGS) and low-quality roughages with or without microbial inoculants (DeLaval Manufacturing) on fermentation, losses, and aerobic stability were evaluated. Experimental silos (n = 90; 18.9-L plastic containers) were assigned randomly to 1 of the 15 treatments using a 3 × 3 + 6 treatment arrangement as follows: 65:35 blend of WDGS and one of the following roughage sources: wheat straw (WS), corn stalks (CS), and alfalfa hay:cottonseed hull (CSH) blend, with or without inoculant (n = 5; inoculant A and B, all roughages; C, D, and E only for CSH); roughages with no inoculants (cotton burrs (CB), and corn dry DGS:WDGS blend (52:48; DGS-blend); and pure WDGS. Data were analyzed using GLIMMIX procedures of SAS with d 0 as a covariate. Regardless of inoculation, pure WDGS showed greater ($P < 0.01$) total DM losses (8 vs. 2%), and less acetate (0.44 vs. 0.80%, DM basis) than silage blends. Low acetate concentration (0.13% of DM) was observed on d 0, regardless of treatment. Disappearance of fiber fractions was greater ($P < 0.01$) for blends than for pure WDGS. Inoculation tended ($P = 0.07$) to increase ADF digestibility for the CSH blend, and increased ($P < 0.01$) fiber disappearance for WS blends. Greater ($P < 0.01$) disappearance of NDF and ADF was observed for the WS blend plus inoculants A or B than for the average of other roughage treatments (16.80 *vs*. 4.57%, and 12.27 *vs*. 0% for NDF and ADF, respectively). Blends of CSH and CS had less ($P \leq 0.04$) fat loss when inoculant A or B was applied vs. those without inoculant. The CSH blends took more time ($P = 0.04$; 6 h) to lose aerobic stability than other treatments. Independent of inoculation, pH and losses increased ($P < 0.01$) during the aerobic stability for WS, but was less for CSH, with CS blends being intermediate. Inoculation positively affected fermentation profile of ensiled WDGS/low-quality roughage blends, although this depended on type of roughage. Silo post-opening management of blends must be considered once it can account as an important source of loss.

Key Words: distillers, ensiling, stability

609 Effects of urea and fibrolytic enzymes on chemical composition, in vitro digestibility, in vitro degradability, and gas production of cotton gin trash.

Alexandro Pereira Andrade[1,2], Mauro Pereira de Figueiredo[2], Danilo Gusmao de Quadros*[1], Joel Queiroga Ferreira[2], and Yann Santos Luz[2], *[1]Bahia State University, Barreiras, Bahia, Brazil, [2]Southwest Bahia University, Vitoria da Conquista, Bahia, Brazil.*

The objective of this study was to evaluate the effects of treatment with urea (0 and 6%) and fibrolytic enzymes (0, 2, 4 and 6%; 75% cellulase and 25% hemicellulase) on chemical composition, IVDMD, dry matter in vitro degradability (IVDEG), and gas production of cotton gin trash. A completely randomized design in a 2 × 4 factorial design was used, with 4 replications. Two kilograms of residue were treated by 60 d with urea dissolved in water, applied to raise the moisture to 25%. The enzymes were sprayed, acting for 24 h. There was significant interaction between urea and fibrolytic enzymes for DM, EE, CP, and ADF ($P < 0.05$). Urea treatment increased CP in 157% ($P < 0.05$). Enzymatic hydrolysis affected quadratically CP in the untreated residue, but positively linear when it was ammoniated. Urea and enzymes were an effective way in reducing cell wall constituents ($P < 0.05$). The IVDMD was greater with ammoniation and when the enzymes doses were increased ($P < 0.05$). There was no significant interaction between urea and fibrolytic enzymes on IVDEG ($P < 0.05$). Although the values of the fraction *a* decreased from 19.1% to 13.6%, ammoniation increased *b* and *c* fractions from 34.2% to 40.4%, and from 0.038 to 0.045, respectively ($P < 0.05$). Using 5% of passage rate, the addition of urea reduced the effective degradability from 33.9% to 32.6%. No effect of urea was observed for potential degradability ($P > 0.05$). Fibrolytic enzymes did not affect the soluble fraction ($P > 0.05$); however, they increased linearly all other IVDEG parameters. Urea did not affect the rate of digestion of K_{d1} and K_{d2} ($P > 0.05$), while the enzymes just decreased linearly K_{d2}. The Vf_1 and Vf_2 were greater with ammoniation ($P < 0.05$), increasing from 16.2 to 51.2 and 51.2 to 62.4 mL/g, respectively, and they were increased linearly with the enzymes doses. The lag time was affected by the interaction between urea and enzymes ($P < 0.05$), being

different in the ammoniated material without or with 2% of enzymes. Urea and fibrolytic enzymes associated treatment enhanced nutritional value of cotton gin trash.

Key Words: ammoniation, cellulase, hemicellulase

610 Effects of *Saccharomyces cerevisiae boulardii* supplementation during the receiving period on growth efficiency, and behavioral and health responses in newly weaned beef heifers.

Monica L. Jenks*[1], Gordon E. Carstens[1], Abbey G. Cupples[1], Jason E. Sawyer[1], William E. Pinchak[2], Kerry S. Barling[3], and E. Chevaux[3], *[1]Department of Animal Science, Texas A&M University, College Station, TX, [2]Texas A&M AgriLife, Vernon, TX, [3]Lallemand Animal Nutrition, Milwaukee, WI.*

Objectives of this study were to evaluate the effects of live yeast (LY; *Saccharomyces cerevisiae boulardii* strain I-1079; 0.35×10^9 cfu/g ProTernative) supplementation during the receiving period on growth efficiency, feeding behavior, activity and vaginal temperature in 72 newly weaned beef heifers (initial BW of 203 ± 22 kg). Immediately upon weaning, heifers were vaccinated (Pyramid 5) and ship stressed (800 km) before being returning to the research center. Upon arrival, heifers were allotted to 1 of 4 pens each equipped with 3 GrowSafe feed bunks, and pens to 1 of 2 treatments (n = 36) consisting of standard receiving diet (ME 2.36 Mcal/kg, CP 16.5% DM) without LY, and control diet containing LY (5 g ProTernative/kg diet; Lallemand Animal Nutrition). Temperature sensors (iButton) were placed intra-vaginally (CIDR) to record temperature, and HOBO devices attached (hind leg) to measure physical activity for the first 14 d (n = 18). LY treatment did not affect morbidity rate (10.4%), vaginal temperature (39.2 ± 0.2°C), or frequency (16.6 ± 2.2 events/d) and duration (46 ± 5 min/event) of standing bouts. ADG tended ($P < 0.1$) to be greater for LY heifers during the first 28 d (0.625 vs. 0.432 ± 0.08 kg/d), but was not affected by LY treatment during the 56-d study. LY treatment did not affect DMI, but DMI increased as the study progressed from 2.06 ± 0.22 (first 14 d) to 2.91 ± 0.19% of BW during the 56-d study. LY heifers consumed more ($P < 0.05$) meals (16.8 vs. 14.6 vs. ± 1.1 events/d) that were shorter ($P = 0.08$) in length (12.8 vs 14.9 ± 1.2 min/event) and smaller ($P < 0.05$) in size (0.48 vs 0.55 ± 0.04 kg/event) and at a slower ($P < 0.05$) meal-eating rate (4.61 vs. 5.54 ± 0.39 g DM/min) compared with control heifers. Moreover, heterogeneities of DMI (SD = 0.59 vs. 0.92 kg/d) and RFI (SD = 0.48 vs. 0.73 kg/d) were less ($P < 0.05$) in LY than control heifers. While the LY treatment did not affect growth efficiency or health status, supplementation with live-yeast may have favorably affected meal patterns of newly weaned beef heifers.

Key Words: live yeast, morbidity, feeding behavior

611 Direct addition or pre-incubation of exogenous xylanase affects in vitro gas production kinetics, degradability and ruminal fermentation activities of three fibrous feeds.

M. M. Y. Elghandour[1], A. E. Kholif[2], S. Lopez[3], A. Z. M. Salem*[1], and T. A. Morsy[2], *[1]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma del Estado de México, Toluca, Estado De México, Mexico, [2]Dairy Science Department, National Research Centre, Giza, Egypt, [3]Instituto de Ganadería de Montaña (IGM) CSIC-Universidad de León, Departamento de Producción Animal, Universidad de León, León, Spain.*

The use of exogenous fibrolytic enzymes (EFE) technology to improve the utilization of fibrous feeds is a novel approach for enhancing feed utilization ruminants performance. The effects of EFE xylanase on in vitro fermentation characteristics of maize stover (MS), oat straw (OS) and sugarcane bagasse (SCB) were examined using an in vitro gas production (GP) technique. Three doses of xylanase plus EFE (Dyadic PLUS, Dyadic International Inc., Jupiter, FL) in liquid form were used at 0 (control), 60 (low), 120 (medium) and 240 (high) µg/g DM of substrate. Ruminal GP, CH_4 and CO_2 concentrations were recorded at 2, 4, 6, 8, 10, 12, 14, 24, and 48 h of incubation at 2 methods of application (direct or 72-h pre-incubation). Separate ANOVA was performed for each feedstuff (maize stover, oat straw and sugarcane). Each experiment was laid down in a 2 (mode of EZ application either by pre-treatment or directly) × 3 (rates of application of 60, 120, and 240 µg xylanase/g DM) factorial plus one control (no enzyme additive) completely random design, for a total of 7 experimental treatments. The analysis was performed using the PROC MIXED of SAS for factorial arrangements of treatments plus one control. Increased ($P < 0.05$) GP at different incubation times was observed with EFE doses addition for the incubated fibrous feeds versus control. The pre-incubation versus direct addition of EZ increased GP of the 3 feeds. However, the direct addition of EFE improved ($P < 0.05$) DM, neutral detergent fiber (NDF), and acid detergent fiber (ADF) degradabilities. Substrates incubated with higher doses of EFE increased ($P < 0.05$) GP, DM, NDF, and ADF degradabilities versus low and medium doses. Enzyme decreased ($P < 0.05$) rumen pH of MS and SCB compared with control. Ammonia-N and total volatile fatty acids (VFA) was unaffected ($P > 0.05$) by EFE application, doses, and application methods in MS and OS. However, total and individual VFA increased ($P < 0.05$) when SCB was incubated with xylanase and this was EZ dose dependent ($P < 0.05$). Methane and CO_2 concentrations were not affected ($P > 0.05$) with EZ application methods or its doses in MS and OS. However, increasing EFE doses with SCB increased CH_4 ($P = 0.013$) and CO_2 concentrations ($P = 0.006$). It could be concluded that application of xylanase enzyme improved GP and rumen fermentation activities. However, the effects were substrate, application methods, and EFE doses dependent, and increasing EZ doses had more effects than low doses.

Key Words: enzyme, fibrous feed, gas production

612 Effects of essential oils and exogenous enzymes for finishing Nellore cattle in feedlot.

Murillo Alves Porto Meschiatti[1], Lucas Agostinho Pellarin[1], João Ricardo Rebouças Dórea[2], Tiago Sabella Acedo[2], Luis Fernando Tamassia[2], Cristina Simões Cortinhas[2], and Flávio Augusto Portela Santos*[1], *[1]University of São Paulo, Piracicaba, SP, Brazil, [2]DSM Produtos Nutricionais Brasil SA, São Paulo, SP, Brazil.*

The objective with this experiment was to evaluate the combination of essential oils and exogenous enzymes on performance of Nellore bulls finished in feedlot. Three hundred Nellore bulls (initial BW = 330 ± 33 kg) were fed during a total period of 90 d with diets containing 82.5% corn, 8.5% sugarcane bagasse, 5% soybean meal, 3% mineral, 1% urea and were randomly allocated to 50 pens. Animals were blocked based on initial BW. The treatments were MON (Monensin, Tortuga – 26 mg/kg DM), CRINA (Essential Oils: Crina Ruminants, DSM – 90 mg/kg DM), CRINA+MON (90 and 26 mg/kg DM, respectively), CRINA+RUM (CRINA + α-amylase: Ronozyme RumiStar, DSM – 90 and 560 mg/kg DM, respectively) and CRINA+RUM+P (CRINA+RUM+Protease: Ronozyme Proact, DSM – 90; 560 and 840 mg/kg DM, respectively). Response variables included: dry matter intake (DMI), average daily gain (ADG), feed efficiency (ADG/DMI), final body weight (final BW), hot carcass weight (HCW) and dressing. The data were analyzed using PROC MIXED of SAS and means were compared by Tukey test considering the block as random effect and treatments as fixed effects.

The DMI, ADG, final BW, HCW were greater for CRINA+RUM in comparison with MON, CRINA+MON and CRINA+RUM+P (Table 1). Cattle fed CRINA+RUM had improvements 9.4% in DMI, 12.2% in ADG, 3.7% in final BW and 4,6% HCW compared with cattle fed MON diets. In conclusion, Nellore bulls fed diets containing amylase and essential oils were slaughtered heavier than bulls fed monensin diets.

Table 1 (Abstr. 612). Combination of essential oils and exogenous enzymes on feedlot performance of finishing Nellore bulls

Item	MON	CRINA	CRINA+ MON	CRINA+ RUM	CRINA+ RUM+P	*P*-value	SEM

613 Effect of supplementing grazing cattle with *Saccharomyces cerevisiae* on fiber digestibility and rumen cellulolytic bacteria population.

D. O. Sousa*[1], M. A. Arcari[1], M. V. Biehl[1], A. V. Pires[1], E. Chevaux[2], L. J. Mari[2], and L. F. P. Silva[1], [1]*University of São Paulo, Pirassununga, São Paulo, Brazil,* [2]*Lallemand Animal Nutrition, Aparecidada de Goiânia, Goiás, Brazil.*

The aim of this study was to evaluate the effect of live yeast (*Saccharomyces cerevisiae* CNCM I-1077) supplementation on fiber digestibility and rumen population of cellulolytic bacteria of grazing Nellore cattle, throughout the 4 seasons of the year. Eight rumen cannulated steers were used in a completely randomized design in a 2 × 4 factorial arrangement of treatments: with or without yeast and seasons of the year (spring, summer, fall, and winter). The live yeast product (Levucell SC Farm, Lallemand, Brazil) was given daily, in capsules, via the rumen cannula, to achieve 8×10^9 cfu per animal. Animals were kept on an intensive rotational grazing system throughout the year, receiving similar mineral supplementation. Every 45 d, in situ rumen NDF degradability (NDFD) of 5 reference forages was determined after 24 and 48 h incubation: (1) corn silage, (2) bermudagrass hay, (3) sugarcane silage, (4) marandugrass, and (5) guinea grass (mombaça-grass). In addition, a composite sample representing the liquid and solid phases of the ruminal content was collected for DNA extraction and real-time PCR quantification of 4 rumen cellulolytic bacteria species (*Butyrivibrio fibrisolvens*, *Fibrobacter succinogenes*, *Ruminococcus flavefaciens* and *Ruminococcus albus*). On average, live yeast supplementation increased 24 h-NDFD by 6.8% throughout the year (40.7 vs. 38.1%, $P < 0.01$), without a yeast × season interaction ($P = 0.45$), or yeast × roughage interaction ($P = 0.39$). When analyzed after 48h of rumen incubation, there was a yeast × season interaction ($P = 0.08$). Live yeast supplementation increased 48h-NDFD only during the autumn months ($P = 0.01$). Among the 4 species evaluated, *R. flavefaciens* was the most prevalent cellulolytic bacteria, and yeast supplementation increased by 78% ($P < 0.01$) the relative population of *R. flavefaciens* in the rumen, and this effect was more pronounced during the summer and spring months (yeast × season interaction, $P = 0.10$). Supplementation with live *Saccharomyces cerevisiae* increased fiber digestibility of roughages in steers grazing tropical grasses, and this effect was related to the greater population of *R. flavefaciens* in the rumen.

Key Words: cellulolytic bacteria, fiber digestibility, yeast

614 Effects of enzymatically hydrolyzed yeast supplementation and supplementation frequency on immune parameters among periparturient beef cows and calves.

Janine E. Swartz*, Derek W. Brake, Elaine E. Grings, Eric A. Nelson, Cody L. Wright, Julie A. Walker, Ethan J. Blom, and George A. Perry, *South Dakota State University, Brookings, SD.*

We evaluated effects of enzymatically hydrolyzed yeast (EHY) and supplementation frequency (FREQ) on immune parameters among beef cows and calves. Eighty multiparous (parity = 4.2 ± 0.3) cows were fed a common brome hay-based diet (CP = 8.0 ± 0.1%). Cows were blocked by expected calving date and stratified by BCS within block before random assignment to treatment. Beginning 88 ± 5 d prior and up to parturition, cows were provided 1 kg daily or 3 kg every 3 d of a soybean hull-based supplement that contained 0 or 3 g/kg EHY. The daily supplement was designed to meet ruminal N requirements. Cows were vaccinated against rotavirus at 62 and 48 ± 5 d before parturition. Jugular blood was collected from cows at 62, 48, 40, 24 and 14 d before parturition. At parturition, colostrum was milked from cows before feeding to calves and jugular blood was collected from cows and calves. Subsequently, calf plasma was collected at 2 and 14 d after parturition. Calf plasma IgG concentration increased (*Quadratic* < 0.01) as age increased and the passive transfer status among calves was 'excellent' (i.e., calf 2 d plasma IgG = 37 ± 1.9 g/L; APHIS, 2010). Nonetheless, plasma IgG was greater ($P = 0.03$) among calves born to cows supplemented EHY; FREQ had no effect on plasma IgG in calves. Despite differences among calf plasma IgG concentrations, there was no effect of EHY or FREQ on colostrum yield, colostrum concentration of IgG or calf intake of colostrum. Similarly, apparent efficiency of IgG absorption and sera rotavirus neutralization titers among calves aged 14 d was not affected by treatment ($P \geq 0.36$). Cow plasma IgG decreased (*Quadratic* = 0.02) as cows neared parturition and was not affected by EHY ($P = 0.56$) or FREQ ($P = 0.14$). We observed a quadratic increase in rotavirus neutralization titers in cow sera in response to vaccination, as expected. Sera rotavirus neutralization titers were not affected by EHY ($P = 0.70$) nor FREQ ($P = 0.42$). These data suggest that EHY but not FREQ may affect passive transfer of IgG.

Key Words: immunity, cattle, supplementation

Ruminant Nutrition: Protein metabolism

615 Water partitioning in lactating Holstein cows fed two levels of dietary forage and crude protein contents. J. A. D. R. N. Appuhamy*[1], M. Niu[1], A. Leytem[2], R. Dungan[2], and E. Kebreab[1], *[1]Department of Animal Science, University of California, Davis, CA, [2]USDA-ARS, Northwest Irrigation Research Lab, Kimberly, ID.*

Knowledge on relationships between diet composition and water kinetics of dairy cows will assist in understanding water utilization and determining water footprint. The objective of the study was to investigate the effects of dietary forage and CP contents on water partitioning in lactating dairy cows. Twelve Holstein cows were randomly assign to a 2 × 2 factorial arrangement of 2 forage levels [38 (LF) vs. 53% (HF)] and 2 CP levels [15.2 (LP) vs. 18.5% (HP)] in a 4 × 4 Latin square design with 4 periods. Cows were kept in metabolic cages indoors, where drinking water intake (dWI), DMI, urine weight, feces weight, and milk yield were measured over 3 d. The dietary treatment effects were analyzed in mixed-effect models including random cow effect. Average DMI, dWI, water via feed (fWI), milk yield, and ambient temperature (T) were 20.0 ± 2.2, 100.6 ± 14.3, 2.5 ± 0.2 and 31.4 ± 5.8 kg/cow/d, and 25.9 ± 1.4°C, respectively. Drinking water intake was positively related to DMI ($P < 0.01$). Independent of DMI, dWI increased respectively by 5.0 ± 2.1 and 5.9 ± 2.2 kg/cow/d ($P < 0.05$) for the increases in dietary fiber and CP contents. Irrespective to DMI and the diet composition, dWI increased by 2.2 ± 0.8 kg/cow/d ($P = 0.02$) for unit increase in T. Fecal water output (fWO) increased as DMI increased ($P < 0.01$). Regardless of DMI, fWO increased (FL = 27.2 vs. FH = 30.4 kg/cow/d) as dietary fiber content increased ($P < 0.01$). Urinary water output (uWO) was positively related to dWI ($P < 0.01$). When adjusted for dWI, HP and HF diets were associated with greater uWO (by 3.4 ± 1.1 and 2.0 ± 1.1 kg/cow/d, respectively) than LP and LF diets ($P < 0.08$). Each dietary nutrient modification independently and equally increased total manure water output (fWO+uWO) by 4.7 ± 1.2 kg/cow/d ($P < 0.01$). Water in milk (mWO) and BW were not affected by the dietary treatments. Overall, 26.8 ± 5.4, 28.1 ± 5.7, and 23.5 ± 6.8% of total water intake (fWI+dWI) were partitioned to mWO, fWO, and uWO, respectively. The majority of the rest (21.6 ± 10.7%) may be respiratory-cutaneous water losses. Forage content, dietary composition and temperature should be included for a better estimate of water utilization and partitioning in dairy cows.

Key Words: diet composition, lactating cow, water balance

616 Milk yield and composition responses to changes in supply of net energy and metabolizable protein: A meta-analysis. Jean-Baptiste Daniel*[1,2], Nicolas C. Friggens[1], Patrick Chapoutot[1], Harmen Van Laar[2], and Daniel Sauvant[1], *[1]INRA-AgroParisTech UMR791, Paris, Îles-de-France, France, [2]Nutreco R&D, Boxmeer, North Brabant, the Netherlands.*

This study aimed to quantify, through a meta-analysis of literature data, average milk yield, milk composition and energy balance responses to changes in supply of: net energy (NE_L), metabolizable protein (MP), and their interaction, for dairy cows. Experiments with designs focused on the effects of protein and/or energy levels on milk performance were selected. The dietary NE_L and MP supplies were estimated for all treatments using the updated digestive model from INRA (Sauvant and Nozière, 2013). From all studies included in the database, 308 experiments (917 treatments) with experimentally induced variations in either NE_L or MP supplies were kept for this analysis. These treatments covered a wide range of diet characteristics and therefore a large part of the plausible NE_L and MP supplies that can be expected in practical situations. The average predicted MP supply was (mean ± SD) 2080 ± 467 g/d and average NE_L supply was 143 ± 25 MJ/d. The majority of those studies used multiparous Holstein-Friesian cows between 50 and 200 d in milk. Between and within-experiment variations were split to estimated milk responses. Linear and quadratic effects of NE_L and MP supplies and their interaction on milk responses were systematically tested, and removed from the model when non-significant ($P > 0.05$). Increasing either NE_L or MP supplies resulted in positive responses for milk, lactose, protein and fat yields. Interactions between NE_L and MP supplies were significant ($P < 0.01$) for milk yield, milk protein yield and milk lactose yield. Greater responses were found with increasing NE_L at higher MP supply, and vice versa. Energy balance was related, positively with NE_L supply, and negatively with MP supply. The negative interaction found between NE_L and MP supply diminished the effect of MP on energy balance at high NE_L supply. The current meta-analysis provides accurate estimation of milk yield (RMSE = 1.04 kg) and milk composition responses to change in supply of NE_L and MP. This study also found significant interactions between NE_L and MP supply for milk, protein and lactose yields.

Key Words: dairy cow, milk composition, meta-analysis

617 Updating protein requirements and responses of metabolizable protein efficiency in dairy cows and goats. Daniel Sauvant*[1], Gonzalo Cantalapiedra-Hijar[2], and Pierre Noziere[2], *[1]AgroParistech-INRA, Paris, France, [2]INRA-VetagroSup, Theix, France.*

One of the major target of renewing the INRA feed evaluation system for ruminants was to update their metabolizable protein (MP) requirements as well as their responses to changes in protein supply. These updates have been made from meta-analyses of large databases of INRA and of literature. For the requirements, the nitrogen losses observed in practical situations were quantified. The 3 main routes of losses, which result in non-productive protein requirements, are, in decreasing order of importance (1) metabolic fecal protein (MFP) which was calculated from non-digestible organic matter intake, (2) urinary endogenous nitrogen losses (NUE) which was the NU losses corresponding to digestible N intake = 0 and corrected for purine-N derivative from rumen microorganisms, (3) loss of protein from phaneres (PPH). After, the values of "non-productive" MP requirements were applied to 873 treatments of 296experiments performed on lactating cows or goats with the aim to study the milk response to MP supply. MP supply was calculated using the renewed INRA model (Sauvant and Nozière, 2013). The efficiency of available MP utilization (EffMP%) was determined with an iterative calculation, assuming the same common EffMP value not only for milk protein synthesis but also for MFP, for PPH as well as for the accretion or mobilization of body proteins which was related to the calculated energy balance. This leaded to the most accurate prediction of EffMP in response to the dietary concentration of MP (g/kg DM). EffMP presented the same decreasing function to the MP concentration for cows and goats. Moreover, for a given MP content, inter-experiments variations were significantly explained, positively by actual or potential milk protein yield (MPY, g/d) and negatively by the level of dry matter intake (DMI, kg/d). Therefore, for dairy cows, the following regression was calculated: $\text{EffMP} = 68.3 - 0.54\ (\text{MP}-100) + 0.029\ (\text{MPY}-1000) - 1.04\ (\text{DMI} - 21)$ [$n = 873$, $R^2 = 0.83$, RMSE = 2.9]. In conclusion, the major novelties of these updates were the fecal and urinary nitrogen losses and the common value of EffMP for all the functions of proteosynthesis.

Key Words: protein requirement, efficiency, dairy

618 The effect of concentration allocation strategy on the performance, health and fertility of high-genetic-merit dairy cows offered a grass silage-based diet.

Mark W. Little*[1,2], Niamh O'Connell[2], and Conrad P. Ferris[1], [1]*Agri-Food and Biosciences Institute, Hillsborough, UK,* [2]*School of Biological Sciences, Queens University Belfast, Belfast, UK.*

Few studies have examined the effect of concentrate allocation strategy on the performance high yielding cows (approximately 40 kg/day). This 140-d study (commencing at calving) examined the effect of concentration allocation strategy: group fed (GF) or individual cow fed (ICF) on feed intake, milk production and composition, tissue changes, energy balance, health and fertility of Holstein Friesian dairy cows (n = 72). With GF, cows were offered a total mixed ration comprising grass silage and concentrates (50:50 DM ratio) plus 0.35 kg chopped straw/cow/day throughout the study. With ICF, cows were offered a basal ration consisting of grass silage, concentrates (6 kg/cow/day) and chopped straw (0.35 kg/cow/day), with this diet designed to meet the cows energy requirements for maintenance plus 24 kg milk/cow/day. With this treatment additional concentrates were offered 'feed-to-yield' via an out-of-parlor feeding system (0.45 kg concentrate/kg milk) based on each individual cow's milk yield during the previous week. Production data were analyzed using a Residual Maximum Likelihood (REML) mixed model analysis; fertility and health data were analyzed using generalized linear model regression analysis with the logit link function, using GenStat Version 16.2. Total concentrate intakes were 1616 kg/cow and 1635 kg/cow for GC and ICF, respectively. Neither silage DM intake ($P = 0.059$) nor total DM intake (22.4(GF), 22.2(ICF) kgDM/day: $P = 0.243$) was affected by allocation strategy. Similarly, concentrate allocation strategy had no effect on milk yield (39.3 (GF), 38.0 (ICF) kg DM/day: $P = 0.113$), milk fat content ($P = 0.819$), milk protein content ($P = 0.308$), somatic cell score ($P = 0.125$), BCS loss to nadir ($P = 0.521$) or mean daily energy balance ($P = 0.356$). Concentrate allocation strategy has no effect on the numbers of cows with mastitis ($P = 0.617$), lameness ($P = 0.144$) or pneumonia ($P = 0.451$). Cows on the ICF treatment tended to have more abomasal disorders ($P = 0.096$), and an improved pregnancy rate to first and second service ($P = 0.014$). Offering concentrates according to milk yield had no effect on cow performance or health, while improving fertility performance.

Key Words: concentrate allocation, performance, fertility

619 How the efficiency of utilization of histidine varies with supply in dairy cows.

Helene Lapierre* and Daniel R. Ouellet, *Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada.*

To determine the effect of a limited supply of His, 5 multiparous Holstein cows fitted with catheters were used in a 4×4 Latin square plus one cow, with 14-d periods. Cows were fed a diet balanced to supply 103% of NE_L and 72% of MP requirements (1610 g/d; NRC, 2001). Treatments were abomasal infusion of His at 0, 7.6, 15.2 or 22.8 g/d plus a mixture of AA (595 g/d, CN profile; from Ajinomoto). At each period, 6 sets of blood samples were collected from arterial, portal, hepatic and mammary sources. Splanchnic plasma flow was calculated by downstream dilution of deacetylated para-amino-hippurate and mammary plasma flow, using the Fick principle. Results are given in Table 1. Mammary plasma flow was not affected ($P = 0.75$) by His deletion, averaging 690, 644, 682, and 690 ± 34 L/h, for incremental doses of His. Portal absorption accounted for 108% of the infused His at the highest dose suggesting very little catabolism of His across the gut. The mammary uptake:ouput ratio did not differ from unity across infusion rates. However, the splanchnic release was not sufficient to account for MG uptake at the 0 dose, in line with decreased muscle carnosine (a labile pool of His dipeptide) concentration at low His supply (JDS 97 E-Suppl.1:757). The increased hepatic removal observed as His supply increases was the sole responsible of the decreased His efficiency and was directly related to liver inflow of His.

Table 1 (Abstr. 619).

	His infused (g/d)					*P*-value

Key Words: histidine, metabolism, dairy cow

620 Effects of rumen-protected methionine, lysine, and histidine on lactation performance of dairy cows.

F. Giallongo*[1], J. Oh[1], M. Harper[1], J. Lopes[1], A. N. Hristov[1], H. Lapierre[2], R. A. Patton[3], I. Shinzato[4], J. Tekippe[4], and C. Parys[5], [1]*Department of Animal Science, The Pennsylvania State University, University Park, PA,* [2]*Dairy and Swine Research and Development Centre, Agriculture and Agri-Food Canada, Sherbrooke, QC, Canada,* [3]*Nittany Dairy Nutrition Inc., Mifflinburg, PA,* [4]*Ajinomoto Co. Inc., Tokyo, Japan,* [5]*Evonik Industries AG, Hanau, Germany.*

The objective of this study was to evaluate the effects of rumen-protected (RP) Met, Lys and His supplementation to a metabolizable protein (MP)-deficient diet on performance of dairy cows. The experiment was a 9-wk randomized complete block design with 36 Holstein cows (DIM, 132 ± 30 d; BW, 611 ± 81 kg). After a 2-wk covariate period, cows were blocked by DIM, milk yield, and parity, and randomly assigned to 1 of the following 6 treatments: control [AMP; +245 g/d of MP over NRC (2001) requirements]; MP-deficient diet (DMP; −118 g/d of MP); DMP supplemented with RPMet (30 g/d of Mepron; Evonik Industries AG; DMPM); DMP supplemented with RPLys (130 g/d of AjiPro-L; Ajinomoto Co., Inc.; DMPL); DMP supplemented with RPHis (120 g/d of an

experimental product; DMPH); and DMP supplemented with RPMet, RPLys and RPHis (DMPMLH). The AMP and DMP diets consisted of (DM basis): 42% corn and 21% alfalfa silages and 37% concentrates and contained 16.5 and 14.5% CP, respectively. DMI tended to be decreased ($P = 0.07$) by DMP compared with AMP (28.0 vs. 29.4 kg/d). Milk and energy-corrected milk yields were decreased ($P < 0.03$) by DMP (40.5 and 36.1 kg/d) vs. AMP (44.1 and 42.1 kg/d). Milk protein content was increased ($P \leq 0.03$) by DMPH and DMPL (3.17 and 3.20%) compared with DMP and AMP (3.01%), and tended ($P = 0.06$) or was numerically higher ($P \leq 0.15$) for DMPMLH and DMPM (3.15 and 3.12%) vs. DMP and AMP. Milk fat content was decreased by DMP vs. AMP (3.33 and 3.90%; $P = 0.04$) and was increased by DMPH and DMPMLH (3.93 and 4.01%; $P \leq 0.03$) compared with DMP. Yields of milk protein and milk fat were decreased ($P = 0.01$) by DMP vs. AMP (by 10 and 20%, respectively). Cows fed AMP had higher MUN (11.7 mg/dL; $P < 0.01$) compared with cows fed the DMP diets (on average 8.09 mg/dL). Overall, feeding an MP-deficient diet decreased DMI and yields of milk, protein, and fat. Addition of RPAA to the DMP diet generally increased milk protein content but did not affect protein yield. Supplementation of RPHis alone or in combinations with RPMet and RPLys also increased milk fat content.

Key Words: methionine, lysine, histidine

621 Evaluation of a rumen-protected methionine product for lactating dairy cows at 2 concentrations of dietary crude protein. Shane M. Fredin*[1], Heather M. Dann[1], Kurt W. Cotanch[1], Catherine S. Ballard[1], Richard Paratte[2], Kai Yuan[3], and Rick J. Grant[1], [1]*William H. Miner Agricultural Research Institute, Chazy, NY,* [2]*Vetagro S.p.A, Reggio Emilia, Italy,* [3]*Vetagro Inc., Chicago, IL.*

This study evaluated the effect of a supplemental rumen-protected Met product (Timet; VETAGRO S.p.A.; Reggio Emilia, Italy) on lactation performance and rumen measures of dairy cows fed 2 concentrations of dietary CP. Sixteen multiparous Holstein cows (8 ruminally-cannulated) were used in a replicated 4 × 4 Latin square design with 28-d periods. Cows were fed 1 of 4 diets: (1) a control diet containing (DM basis) 40.8% corn silage, 9.5% hay crop silage, and 49.7% grain mix (CON); (2) the CON diet plus Timet (TMT); (3) the CON diet plus Smartamine (Adisseo USA Inc.; Alpharetta, GA; SMT); and (4) a reduced-CP diet plus Timet (TMT-RCP). The TMT, SMT, and TMT-RCP were balanced to contain the same supply of metabolizable Met and Lys, and contained (DM basis) 16.2, 16.2, 15.9, and 13.7% CP, respectively. All diets contained 30.9% NDF and 26.8% starch. Dry matter intake and milk yield were measured on d 22–28. Milk samples were collected d 26–27 to determine composition. Rumen NH_3-N concentrations were measured on d 26–27 at 4-h intervals. Data were analyzed by ANOVA using the MIXED procedure of SAS. Dry matter intake was unaffected by diet, averaging 26.8 kg/d ($P > 0.10$). Milk yield was unaffected by diet and was 45.6, 46.8, 44.4, and 44.9 kg/d for the CON, TMT, SMT, and TMT-RCP diets, respectively ($P > 0.10$). Milk protein percentage was increased for cows fed SMT (3.33%) compared with the other 3 diets (3.24%; $P = 0.01$), but protein yield was unaffected by diet and was 1.44, 1.49, 1.45, and 1.46 kg/d for the CON, TMT, SMT, and TMT-RCP diets, respectively ($P > 0.10$). Milk lactose percentage was decreased for cows fed SMT (4.55%) compared with the other 3 diets (4.61%; $P = 0.01$). Consistent with reduced CP, MUN (mg/dL) was decreased for cows fed TMT-RCP (11.3) compared with the other 3 diets (13.5; $P \leq 0.01$), and ruminal NH_3-N (mg/dL) was decreased for cows fed TMT-RCP (3.4) compared with the other 3 diets (6.9; $P = 0.001$). In conclusion, milk and protein yields were unaffected by sources of rumen-protected Met products. Supplementation of Timet maintained the lactation performance of cows fed reduced CP diets.

Key Words: amino acid, reduced CP, rumen measure

622 Milk protein yield and plasma concentration of methionine increase in dairy cows fed field peas supplemented with rumen-protected amino acids. Andre B. D. Pereira*, Andre F. Brito, Kayla M. Aragona, Simone F. Reis, and Kelsey A. Juntwait, *University of New Hampshire, Durham, NH.*

Previous studies showed that diets with more than 15% field peas (FP; DM basis) resulted in reduced milk and milk protein yield in dairy cows. We hypothesize that decreased yields were caused by limited supplies of MP-Lys and MP-Met due to extensive degradation of FP RDP in the rumen. The objective of this study was to evaluate diets with 25% of FP supplemented with rumen-protected (RP) Lys (AjiPro-L) and Met (Smartamine-M) as a substitute for corn meal (CM) and soybean meal (SBM). Twelve multiparous and 4 primiparous lactating Holstein cows were blocked by DIM, milk yield and parity, and randomly assigned to 1 of 4 diets in a replicated 4 × 4 Latin square design. Diets were 35.5% corn silage, 15.5% grass-legume haylage, 5.9% roasted soybean, and: (1) 36% CM and 1.3% urea (3.59:1 MPLys:MPMet ratio; negative control: NC), (2) 29.7% CM, 9.8% SBM, and RPLys-Met (3.07:1 MPLys:MPMet ratio; positive control: PC), (3) 25% FP, 12.3% CM, and 2.4% SBM (3.88:1 MPLys:MPMet ratio; PEAS), and (4) 25% FP, 12.2% CM, 2.4% SBM, and RPLys-Met (3.13:1 MPLys:MPMet ratio; PEASAA). Data were analyzed using the MIXED procedure of SAS and Tukey adjustment for means separation ($\alpha = 0.05$). All dietary treatments had 15.1% CP and 1.58 Mcal/kg. As expected, cows fed NC had decreased DMI, milk protein yield and total concentration of ruminal VFA and increased excretion of MUN. Cows fed NC and PEAS had decreased plasma concentration of Met. Feeding cows PC, and PEASAA mitigated these negative responses. Results showed that plasma Lys was higher for diets fed FP, suggesting that Met is the first limiting AA in FP-based diets.

Table 1 (Abstr. 622). Feeding field peas to dairy cows

	Diet					
Item	NC	PC	PEAS	PEASAA	SEM	*P*-value
DMI, kg/d	23.30^{b}	24.96^{a}	24.63^{a}	25.00^{a}	0.39	<0.01
Milk, kg/d	41.79	42.93	42.69	42.71	1.04	0.53
Milk fat, kg/d	1.40	1.41	1.45	1.49	0.04	0.09
Milk protein, kg/d	1.15^{b}	1.25^{a}	1.21^{ab}	1.24^{a}	0.03	<0.01
MUN, mg/dL	9.85^{c}	7.93^{a}	9.09^{b}	8.77^{b}	0.27	<0.01
Ruminal total VFA, m*M*	103.08^{c}	113.23^{b}	111.92^{b}	120.92^{a}	1.84	<0.01
Plasma Lys, m*M*	67.20^{b}	69.94^{b}	77.21^{a}	76.97^{a}	3.96	0.03
Plasma Met, m*M*	19.92^{c}	27.71^{b}	19.63^{c}	31.89^{a}	1.06	<0.01

Key Words: field peas, dairy cow, rumen-protected amino acid

623 Increased pre-wilting increases metabolizable protein concentration in grass-clover silage.

Marianne Johansen* and Martin R. Weisbjerg, *Department of Animal Science, AU Foulum, Aarhus University, Tjele, Denmark.*

In organic dairy farming supply with metabolizable protein (MP) is often limited. Therefore, the potential for increased MP concentration by increased pre-wilting of grass-clover before ensiling was investigated. Spring growth and first regrowth grown by 2 Danish organic farmers were cut and pre-wilted to a planned dry matter (DM) content of 35% and 70%, respectively, giving in total 8 silages with DM contents ranging from 28.3 to 72.5%. Four rumen, duodenal and ileal fistulated Holstein dairy cows (551 ± 33 kg body weight, 216 ± 23 d in milk, mean ± SD) were fed ad libitum with the silages in a crossover design, with 5 periods of 3 weeks. No concentrate was offered, but minerals and vitamins were offered daily. Three markers (Cr_2O_3, TiO_2 and $YbCl_3 \cdot 6H_2O$) were dosed in the rumen twice a day for measurement of flow at duodenum and ileum. In the last week of each period daily feed intake was registered and 12 subsamples from duodenum and ileum, respectively, were collected over 94 h to cover the diurnal variation, pooled, and subsequently analyzed. Microbes were isolated from the rumen and analyzed for amino acids (AA) and purines to estimate the flow of microbial protein at the duodenum. Statistical analyses were done in R using a linear random regression model with DM content as fixed effect, cow and growth x farmer as random intercepts and with a growth x farmer random slope. Results given below are per 10% units increase in DM content of grass-clover silage. The absorption of AA in the small intestine was increased ($P = 0.03$) with 5.59 g/kg DM intake. The increased absorption was caused by a higher small intestinal digestibility of AA (1.27 g/100g AA, $P = 0.03$) and a higher flow of AA in the duodenum (5.63 g/kg DM intake, $P = 0.08$). The higher flow of AA in the duodenum derived from both a higher flow of microbial AA (2.12 g/kg DM intake, $P = 0.06$), and a lower true rumen degradation of AA from the silage (−4.04 g/100g AA, $P = 0.04$). In conclusion, the MP concentration in grass-clover silage can be improved by pre-wilting to a higher DM content before ensiling.

Key Words: pre-wilting, metabolizable protein, grass-clover silage

624 Precision-feeding dairy heifers different levels of dietary fiber and high rumen undegradable protein.

Louisa Bowen*[1], Ashley Bowyer[1], Sonya Weeks[1], Gustavo Lascano[1], and N. A. Gomez[2], [1]*Clemson University, Clemson, SC,* [2]*The California Polytechnic State University, San Luis Obispo, CA.*

The objective of this experiment was to determine the effects of feeding a high rumen undegradable protein (RUP) diet when dietary fiber level is manipulated within differing forage to concentrate ratio (F:C) on nutrient utilization of precision-fed dairy heifers. Six rumen cannulated Holstein heifers (555.4 ± 31.4 kg BW) were randomly assigned to 2 levels of concentrate, HC [55%] and LC [40%] and to a fiber level sequence [100% oat hay and silage OA, 0% wheat straw WS (low fiber); 83% OA, 17% WS (medium fiber); and 67% OA, 33% WS (high fiber)] administered according to a split-plot 3 × 3 Latin square design (21-d periods). Similar levels of N intake (1.70 g N/kg $BW^{0.75}$) and RUP (55% of CP) were provided. All dependent variables were analyzed as a 3 × 3 Latin square using the PROC MIXED procedure of SAS. No differences were observed for dry matter (DM), neutral detergent fiber (NDF), and acid detergent fiber (ADF) apparent digestibility (AD) between HC and LC-fed heifers. Heifers receiving HC diets had greater starch AD ($P < 0.01$) than LC heifers. Increasing the fiber level through WS addition resulted in a linear reduction of organic matter AD ($P = 0.05$). There was a linear interaction for DM AD ($P = 0.05$) with a concurrent linear interaction in NDF AD. Nitrogen intake, AD, and retention were not different among treatments, however, urine N excretion increased linearly ($P = 0.03$) with added fiber. Uric acid excretion differed among F:C treatments ($P < 0.01$) but total purine derivatives (PD), microbial CP, and protozoa did not differ between F:C treatments. Microbial CP flow and PD quadratically increased ($P < 0.05$) with WS inclusion. Mean rumen fluid pH quadratically increased ($P = 0.04$) with WS addition, although no F:C effect was detected. Ruminal ammonia concentration did not differ among treatments. Apparent digestibility, purine excretion, and ruminal pH were affected differently as dietary fiber was added through the addition of WS in the diet, suggesting that high RUP can have differential effects on nutrient utilization as dietary fiber is manipulated in precision-fed dairy heifers.

Key Words: fiber level, protein degradability, precision-feeding

625 Dietary fiber and crude protein contents can be modified to minimize enteric methane emissions and nitrogen excretions from dairy cows simultaneously.

M. Niu*[1], J. A. D. R.N. Appuhamy[1], A. Leytem[2], R. Dungan[2], and E. Kebreab[1], [1]*Department of Animal Science, University of California, Davis, Davis, CA,* [2]*USDA-ARS, Northwest Irrigation and Soils Research Lab, Kimberly, ID.*

Simulation of enteric methane (CH_4) emissions and nitrogen (N) excretion from cows fed grass silage-based diet indicated that there may be a trade-off between reduced N excretions and increased CH_4 emissions when certain dietary manipulations were considered. The study aimed to examine effects of changing dietary forage and CP contents on CH_4 emissions and N excretions from lactating dairy cows. Twelve post-peak lactating Holstein cows were randomly assigned to a 2 × 2 factorial arrangement of 2 forage (alfalfa hay) levels [37 (LF) vs. 53% (HF)] and 2 CP levels [15.2 (LP) vs. 18.5% (HP)] in a 4 × 4 Latin square design with 4 periods. Cows were fed and milked twice daily. During the first 14 d, cows were housed in a free-stall barn, where enteric CH_4 emissions were measured using the GreenFeed system from d 8 to 14 in each period. Cows were then moved to metabolic cages, where total feces and urine output (kg/cow/d) were measured using total collection approach for 3 d. Treatment effects were analyzed by a mixed model with the random effect of cow. Dietary forage content was negatively associated with DMI ($P = 0.09$) and milk yield (MY, $P = 0.02$) and positively related ($P < 0.05$) to CH_4 emission per unit of DMI (HF = 20.4 (0.83) vs. LF = 17.8 (0.84) g/kg) and MY (HF = 13.7 (0.80) vs. LF = 11.6 (0.80) g/kg). Dietary CP content did not affect CH_4 emissions but was positively related to milk urea nitrogen content, urine, urine N (UN), and total manure N outputs (MN) per kg of DMI or MY ($P < 0.01$). Dietary forage content was positively associated with only UN (HF = 170 (8.5) vs. LF = 152 (8.5) g/cow/d, $P < 0.01$). Fecal N output was not affected by dietary CP levels. Dietary forage content was positively associated with only UN (HF = 170 (8.5) vs. LF = 152 (8.5) g/cow/d, $P < 0.01$). The enteric CH_4 emissions and MN per unit of milk yield were positively correlated (r = 0.67, $P < 0.01$). There were no interactions between dietary CP and forage contents on CH_4 emissions or N excretion. Overall, increasing dietary forage and CP contents independently increased CH_4 emissions (g/kg of MY) and total manure N excretions (g/kg of MY), respectively.

Key Words: dairy cow, methane emissions, nitrogen excretions

626 Effects of substituting true protein with non-protein nitrogen in Holstein dairy heifers precision-fed different forage to concentrate ratios.

Prabha G. Ranasinghe*[1], Noe A. Gomez[2], Krystina Rowland[1], Ashley Caprio[1], and Gustavo J. Lascano[1], [1]*Clemson University, Clemson, SC,* [2]*California Polytechnic State University, San Luis Obispo, CA.*

The objective of this experiment was to determine the effects of feeding different combinations of true protein (TP) and non-protein nitrogen (NPN) when forage to concentrate (F:C) is manipulated on nutrient utilization in precision-fed dairy heifers. Eight ruminally fistulated Holstein heifers (386 ± 9.1 kg BW) were randomly assigned to 2 concentrate levels: HC (25% forage) and LC (75% forage) and to a combination of TP and NPN sequence [U:C; 0% from urea U, 100% casein C (0% U, 100% C; 33% U, 67% C; 67% U, 33% C; 100% U, 0% C)] within concentrate level administered according to a split-plot, 4 × 4 Latin square design (21 d periods). Data were analyzed using the PROC Mixed procedure from SAS. Intake of N was similar and use U and C to provide 1.80 g N/kg BW 0.75. Neutral detergent fiber (NDF) and acid detergent fiber (ADF) apparent digestibility (AD) were positively affected in HC diets ($P \leq 0.05$). ADF AD linearly increased ($P < 0.01$) in HC, and the opposite occurred in the LC group. Fecal N, urine N, and total excreted N were reduced ($P \leq 0.05$) in the HC treatment (TRT) which resulted in an increased retained N. No U:C effects were observed in AD of DM, OM, and NDF, but N AD, N (% of intake), N (% of digested) decreased linearly as U level increased ($P < 0.05$). A quadratic interaction ($P < 0.01$) was observed; decreasing total excreted N and retained N (g/d) in the HC and the opposite in LC. Total purine derivatives (PD) were positively affected by the HC group ($P = 0.04$) but did not affect microbial protein flow. There was a positive quadratic ($P < 0.01$) response in total PD as U increased in both F:C TRT. Protozoa numbers were higher in the HC diets (3.3 × 105 vs. 2.8 × 103; $P < 0.01$) and increase quadratically ($P < 0.01$) with U inclusion. No effects for ruminal NH3N between F:C TRT was observed, but there was a linear increase ($P < 0.01$) as U level increased. Ruminal pH was lower for HC diets (6.3 vs. 6.6) and there was a quadratic interaction as U increased. Nutrient utilization was significantly affected by manipulation of F:C and U:C.

627 Use of a staphylococcal vaccine to reduce prevalence of mastitis and lower somatic cell counts in a registered Saanen dairy goat herd. Felicia Kautz, Stephen Nickerson*, and Lane Ely, *University of Georgia.*

The purpose of this investigation was to evaluate the efficacy of a staphylococcal bacterin in reducing the prevalence of staphylococcal mastitis and somatic cell counts (SCC) in a commercial dairy goat herd. Does were vaccinated or left as controls, and the levels of mastitis and SCC monitored over 18 mo. *Staphylococcus caprae* (42.5%), *S. xylosus* (15.1%), and *S. simulans* (10.0%) were the predominant causes of intramammary infections (IMI). The new infection rate was 1.64 IMI/doe among vaccinates, which tended to be lower ($P < 0.12$) than controls (2.67 IMI/doe). The spontaneous cure rate of existing IMI after immunization was 1.28 cures/doe in vaccinates, which was higher than that observed in controls (0.6 cures/doe; $P < 0.043$). Average SCC of milk samples from vaccinates showed a tendency to be lower than that of controls (1274×10^3/mL vs. 1529×10^3/mL, respectively; $P < 0.10$). Results support the continued study of mastitis vaccines for use in managing staphylococcal mastitis and SCC in dairy goats.

Key Words: dairy goat, mastitis, vaccination

628 Keeping trends and practices for various exotic, crossbred, and indigenous sheep breeds in sub-tropical highlands of Pakistan. Muhammad Abdullah*[1], Muhammad Mudassir[1], Jalees Ahmed Bhatti[1], Abu Saeed Hashmi[2], Nisar Ahmad[1], and Umair Younas[1], [1]*Department of Livestock Production, University of Veterinary & Animal Sciences, Lahore, Punjab, Pakistan,* [2]*Department of Biochemistry, Institute of Biochemistry and Biotechnology, Lahore, Punjab, Pakistan.*

Northern areas of Pakistan are rich in natural resources including livestock as a major source of income for local residents and landless herders. The study objective was to fulfill the knowledge gap about herder's perception toward the relative performance and ecological adaptability of different sheep breeds and their crosses. The herds of 150 pastoralists were considered as case study to investigate their herds. The study was conducted at Kaghan valley of Mansehra district and Haripur according to availability of landless farmers during summer and winter season, respectively. Three pastoral units were selected each from Naran upland and Haripur/Attock lowlands. Herders (n = 20) were interviewed using questionnaire from each unit. The collected information were entered in to Epi-info software program (version 6.04b) for descriptive statistics. Various sheep breeds found in northern areas were Afghani, Kaghani, Crossbreed and Rambouillet. Average number of sheep belonging to Kaghani, Rambouillet (exotic), Ramghani (crossbreed) and Afghani sheep per herd were found to be 41%, 6%, 29% and 29%, respectively. Trends for keeping Kaghani, Afghani, Crossbreed and Rambouillet ram as an animal with beauty was among 28%, 40%, 26% and 16% herders. Kaghani sheep was found to be preferred by majority of population for its mutton quality. Highest replacement preference (44.3%) for ram was given to Kaghani breed as compared with Rambouillet which was given least preference (16.78%) due to its low disease resistance against our local conditions. Herders (92%) suggested that high disease resistance was noted in Kaghani breed. In conclusion, such survey studies helped in better understanding of landless farmer's preferences about keeping herd among indigenous, cross and exotic sheep breeds.

Key Words: Kaghani, Rambouillet, sheep

629 Motility of Boer buck spermatozoa stored fresh for 72 hours. Olumide A. Ajao*, Daniel M. Barry, and Kow K. Benyi, *University of Venda, Thohoyandou, Limpopo Province, South Africa.*

This study was aimed at evaluating the effects of Biladyl and Triladyl extenders, ambient and refrigerated temperatures (5°C, 12°C and 17°C) on the motility of Boer buck spermatozoa stored for 72 h period of storage. Four (n = 4) healthy Boer bucks aged 3.12 ± 0.55 years were ejaculated using artificial vagina (AV) once every 4 d for 6 replicates. The semen samples were pooled and divided into 2 equal halves. One half was extended in a 2-step Biladyl extender (semen sample plus Biladyl Fraction A made up half of the final volume) and the other with Triladyl, both at ratio 1: 5 v/v (semen to extender). Each of the extended semen divisions was further divided into 4 equal parts; one of the 4 was stored at ambient temperature and the others at 5°C, 12°C and 17°C. Data were analyzed by ANOVA for a $2 \times 4 \times 6$ factorial in a completely randomized design, using the GLM procedure of Minitab (Minitab 2013). Spermatozoa motility was evaluated using Sperm class Analyzer (SCA) after every 12 h for 72 h. Extender type (E) and storage temperature (T) had highly significant effects ($P < 0.01$) on the total motility (TM) of Boer buck spermatozoa kept at the refrigerated temperatures after 72 h of storage compared with the TM of spermatozoa stored at ambient temperature which were the lowest in both extenders. Biladyl had 68% TM on spermatozoa kept at ambient temperature, 85% TM at 5°C, 89% TM at 12°C and 90% TM at 17°C; and Triladyl had 64% TM at ambient temperature, 88% TM at 5°C, 89% TM at 12°C and 90% TM at 17°C. The highest progression obtained after the 72 h was 34% as observed from the semen kept at 17°C in Biladyl and 45% in the semen kept at 17°C Triladyl. With suitable protocol, both extenders can maintain goat sperm motility at specific refrigerated temperatures when kept fresh for up to 72 h.

Key Words: Boer buck, ambient, artificial vaginal

630 *Salix babylonica* as a phytogenic anthelmintic alternative on sheep and goat farms in México. A. Z. M. Salem*[1], M. M. Y. Elghandour[1], A. E. Kholif[2], J. C. Vázquez-Chagoyán[1], R. M. de Oca-Jiménez[1], A. B. Pliego[1], and T. A. Morsy[2], [1]*Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma del Estado de México, Toluca, Estado De México, Mexico,* [2]*Dairy Science Department, National Research Centre, Giza, Egypt.*

There is an increased interest in screening phytogenic extracts and medicinal plants as alternatives to the traditional drugs. The efficacy of *Salix babylonica* (SB) extract as a alternative control of gastrointestinal and pulmonary parasites in sheep and goats at the commercial scale was tested. A sample of 20% of the population of 8 sheep and 7 goat farms was included. About 20 mL of SB extract was orally administered weekly at 0700–0900 h before morning feeding for 60 d. A fecal egg or oocyst count technique was performed after 0 (pre-extract administration), 1, 20, 40 and 60 d after the extract administration. Fecal samples were evaluated for the presence of coccidian oocysts, cestode and nematode eggs by a salt flotation technique. Afterward, oocysts or eggs were counted using the McMaster method. Significantly differences ($P < 0.01$) in the fecal oocyst and egg output of *Eimeria*, *Dictyocaulus*, and *Moniezia* were observed between sheep and goats. The treatment influenced ($P < 0.05$) egg outputs of *Cooperia*, *Dictyocaulus* and *Trichuris*. The fecal egg or oocyst counts of *Haemonchus contortus*, *Eimeria*, *Cooperia*, *Chabertia*, *Dictyocaulus*, *Moniezia* and *Ostertagia* were time-dependent ($P < 0.05$). For sheep, administration of SB decreased ($P < 0.05$) the fecal eggs count of *H. contortus, Cooperia*, *Chabertia*, *Dictyocaulus*, *Moniezia* and *Trichuris*. After 20 d of treatment, no *H. contortus*, *Cooperia* or *Moniezia* were detected. For goats, only a few species were affected ($P < 0.05$) after the SB administration. The SB reduced ($P < 0.05$) the fecal eggs count of *H. contortus*, *Cooperia*, *Chabertia* and *Moniezia*. Quadratic decreases were observed ($P < 0.05$) for *Chabertia*, *Trichostrongylus* and *Ostertagia*. Eggs of *H. contortus* and *Moniezia* were not present in the feces of goats after one day of treatment; in contrast to the egg output of *Trichostrongylus* and *Ostertagia*. It is therefore concluded that weekly administration of SB at 20 mL weekly can be a promising alternative to the use of synthetic anthelmintics to treat gastrointestinal and lung nematodes of small ruminants in organic and conventional production systems.

Key Words: anthelmintic, *Salix babylonica*, small ruminants

631 A comparison of ewe colostrum and a colostrum alternative (Volostrum) as a colostrum source for artificially reared triplet lambs.

Tommy M. Boland*[1], Fiona M. McGovern[1], Francis P. Campion[1], and Jessica Cooke[2], [1]*School of Agriculture and Food Science, University College Dublin, Dublin, Ireland*, [2]*Volac International Ltd., Orwell, Royston, UK.*

Prolificacy is a key driver of output and profitability in sheep-meat production systems. An increase in multiple births is associated with increasing prolificacy. Litter sizes of 3 or more lambs can potentially increase sheep meat production if managed appropriately however such litters are often associated with increased mortality and low post natal growth. Potential mechanisms to reduce these performance bottlenecks include artificially rearing one lamb of each triplet set. The objective of this study was to compare the pre-weaning, post-weaning and slaughter performance of triplet lambs, removed from their dams at birth. Animals were subjected to one of 2 treatments (n = 15 per treatment) for the first 24 h of life. Lambs received either ewe colostrum at one, 10 and 18 h postpartum (C) or they received a commercial colostrum alternative (Volostrum; V). From 24 h postpartum until weaning (at 6 weeks of age) all lambs received artificial milk replacer ad libitum (Lamlac). Concentrate feed was introduced at 10 d of age and lambs were weaned to an all concentrate diet, once daily concentrate intakes reached 250 g FW. Pre-weaning lamb growth rate averaged 384 g/d and did not differ with treatment. Post weaning lamb growth rate tended to be higher for lambs offered ewe colostrum in the first 24 h of life (412 vs. 325 g/d; $P = 0.06$). The C lambs had higher live weights at 10, 11 and 12 weeks of age ($P < 0.05$). There was a tendency for higher lifetime growth rates for the lambs offered ewe colostrum (392 vs. 324 g/d: $P = 0.07$). Lambs offered ewe colostrum during the first 24 h of life reached target slaughter weight (44 kg) 24 d earlier (109 d) than lambs offered Volostrum ($P < 0.01$) however other slaughter and carcass parameters did not differ with treatment. In conclusion, a colostrum alternative supports high pre-weaning and post-weaning lamb growth rates, however performance advantages in terms of post weaning growth rate and reduced days to slaughter are conferred when lambs consume ewe colostrum during the first day of life.

Key Words: colostrum, colostrum alternative, lamb

632 The relationship of body linear measurements and body weight with real-time ultrasound body composition measurements in Boer x Spanish yearling goats.

Flavio R. B. Ribeiro*, Louis C. Nuti, Shaye K. Lewis, William B. Foxworth, Yoonsung Jung, Bianca Garza, Brandi Owens, Rosemarie Somers, and Gary R. Newton, *Cooperative Agricultural Research Center, Prairie View A&M University, Prairie View, TX.*

The objective of this study was to determine the relationship of body linear measurements such as hip height (HH), girth circumference (GC), point of the shoulder to hip length (HipShL), forearm circumference (FntLC) and BW with real-time ultrasound (RTU) measurements of body composition, in Boer × Spanish cross yearling goats (n = 90; n = 48 wethers and n = 42 doelings). The body composition traits measured by RTU were 12–13th rib longissimus lumborum muscle area (uLMA), 12–13th rib fat thickness (uBF), and rump fat thickness (uRUMP). Ultrasound measurements were taken using an Aloka 500 with a 12 cm 3.5 MHz transducer, hair was clipped and vegetable oil was used as a coupling agent to enhance image quality. Data were analyzed by gender and also pooled using the Proc CORR and Proc REG procedures of SAS. BW was highly correlated ($P < 0.0001$) to HH, GC, HipShL, FntLC, uLEA, uBF, and uRUMP (0.65, 0.85, 0.62, 0.70, 0.89, 0.75, and 0.70, respectively) with the pooled data. Similar results were observed when data were analyzed by gender. However, a lower correlation was observed between BW and HIpShL and FntLC with the doelings (0.46 and 0.48, respectively) and between BW and HH, uBF and uRUMP for the wethers (0.35, 0.38, and 0.36, respectively). Prediction equations were also developed to predict uLEA, and uBF. Predictions of uLEA had an R^2 of 0.75, 0.64, and 0.65 for the pooled, wether and doelings data, respectively, with BW and HipShL included in the pooled and doelings model and BW and FntLC in the wether model. Predicitons of uBF had an R^2 of 0.59, 0.23, and 0.68 for the pooled, wether and doelings data, respectively, with BW and HipShl included in the pooled and wether models and BW and HH in the doeling model. Results showed that RTU body composition traits are highly correlated to body linear measurements in yearling Boer × Spanish yearling goats and that different measurements within gender accounted for more variation within the RTU traits. More research is needed to refine the models and improve accuracy of prediction.

Key Words: ultrasound, body composition, goat

633 An investigation in to the interaction between ewe BCS and litter weights at key times of the production cycle.

Francis P. Campion*[1], Fiona M. McGovern[1], Philip Creighton[2], Alan G. Fahey[1], and Tommy M. Boland[1], [1]*University College Dublin, Dublin, Ireland*, [2]*Teagasc Athenry, Co. Galway, Ireland.*

Ewe body reserve accumulation and mobilization is an essential part of the production cycle. The interaction between breed, ewe body condition score (BCS) and animal performance is an area that warrants investigation. Using 3 commercial flocks which are part of a national progeny testing scheme, BCS data was collected from twin bearing ewes at mating, mid-pregnancy, mid-lactation (~d 40 of lactation) and weaning (~d 100 postpartum). This data was then combined with ewe breed, maternal age, and litter weight at birth (BW), d 40 of lactation (D40) and weaning (WE) data. The objective of this study was to investigate if litter weight from birth to weaning of twin bearing ewes was influenced by ewe BCS. Lamb weights collected from each lamb at BW, D40 and WE were summed to calculate litter weight. Regression coefficients were estimated using PROC MIXED (SAS v9.4). The model included the fixed effects of flock, breed, time point and maternal age, and previous years litter size along with the continuous variables of lambing date and lambing difficulty, and BW, D40 or WE. Variables with a P-value > 0.10 were removed from the final model. Initially a correlation analysis was carried out on BCS and weight. Mid-lactation BCS and weaning BCS had a correlation of 0.63; all other time points had correlations less than 0.40. There was strong correlation between D40 and WE litter

weight (0.80) but not between BW and D40 (0.40) or BW and WE (0.23) litter weights. Changes in BW and WE litter weight were influenced by mid-pregnancy BCS ($P < 0.05$) and there was a tendency toward a relationship between D40 litter weight and BCS at mid-pregnancy and weaning ($P < 0.10$). There was no relationship between litter weight at any stage during the first 14 weeks of life and mating or mid-lactation BCS ($P > 0.10$). Farm, ewe maternal age and breed, time point and breed by time point interaction all had a significant effect on the relationship between BCS and litter weight ($P < 0.05$). These findings show that mid pregnancy BCS is the key BCS measurement linked to litter weight of twin bearing ewes at birth and weaning.

Key Words: BCS, litter weight, lamb.

634 Development of a low-density single nucleotide polymorphism panel for prolificacy in sheep. Thaisa Lacerda[1], Harvey Blackburn[2], Michel Yamagishi[3], Concepta McManus[1], Alexandre Caetano[4], and Samuel Paiva*[5,2], [1]*Universidade de Brasilia, Brasilia, DF, Brazil,* [2]*USDA-ARS National Center Genetic Resources Preservation, Fort Collins, CO,* [3]*Embrpa Informatica Agropecuaria, Campinas, SP, Brazil,* [4]*Embrapa Recursos Geneticos e Biotecnologia, Brasilia, DF, Brazil,* [5]*Embrapa Secretaria de Relacoes Internacionais, Brasilia, DF, Brazil.*

High-density SNP panels (e.g., 50,000 and 600,000 SNPs) have been used in exploratory population genetic studies with commercial and minor sheep breeds. Routine genetic diversity evaluations of large numbers of samples and panels are in general cost-prohibitive for gene banks. Lower cost panels based mostly on SNPs known to be associated with production traits of interest and may be more efficient for genetic diversity assessment and improvement of gene bank collections. The first phase of the study was to develop and validate a small SNP panel (29 SNPs) based on known prolificacy genes. SNP selection was based on known polymorphisms in major genes affecting sheep prolificacy (*GDF9*, *BMP15* and *BMPR1B*), as well as new polymorphisms mined from whole genome resequencing data from *GDF9* and *BMP15* by the International Sheep Genome Consortium. A total of 125 animals from 15 breeds with litter size information collected by the National Animal Germplasm Program were tested. Genotyping was performed with PCR-based KASP chemistry and 27 SNPs had a call rate higher than 98%. All *BMP15* and *BMPR1B* SNPs were monomorphic. In *GDF9* 8 SNPs were polymorphic - 3 are located in introns and 5 in exons. Three SNPs were non-synonymous AA changes. No significant allele frequency differences were found for GDF9_G4:E241K among from single or multiple births. The GDF9_G6:V332I allele was related to high prolificacy in 5 breeds with the following frequencies: Lincoln (0.416), Polypay (0.32), Navajo Churro (0.27), St Croix (0.125) and Suffolk (0.083). Allele GDF9_G7:V371M was found only in Polypay at a frequency of 0.35 which agrees with recent studies with the hyper-prolific Norwegian White Sheep. The other 10 breeds did not differ significantly. Our results suggest that the developed panel will be useful to identify possible genes/mutations associated with prolificacy in worldwide sheep breeds. Additional SNPs will be included as more information becomes available. In the next phase of this study, SNPs related to other economically important traits will be added to the panel to improve the characterization and management of gene bank sheep collections.

Key Words: *Ovis aries*, conservation genetics, gene bank

635 Influence of surgical castration on biochemical profile of rams. V. M. Storillo[1], M. B. R. Alves[1], E. C. C. Celeghini[1], B. Barcelos*[2], D. B. Birgel[2], V. F. P. Ríspoli[2], W. C. Garcia[2], P. S. Silva[2], and E. H. Birgel Junior[2], [1]*Faculdade de Medicina Veterinária e Zootecnia da Universidade de São Paulo, São Paulo, São Paulo, Brazil,* [2]*Faculdade de Zootecnia e Engenharia de Alimentos da Universidade de São Paulo, Pirassununga, São Paulo, Brazil.*

Castration is often used in male sheep to prevent losses in meat palatability, improve subcutaneous adipose tissue and prevent undesirable pregnancies. But, there is insufficient research on how long for the changes in biochemical profile to take place and finally stabilize as well as which parameters are definitely altered after castration in adult rams. To elucidate this issue, this research was carried on using 31 White Dorper males at 36 mo of age, when biochemical changes are not expected, since they reached adulthood. Animals were surgically castrated, with removal of the scrotum apex, under tranquilization, local anesthesia and using sterile materials. Antibiotic and analgesia treatments were performed for 3 d. Blood samples for measurement of urea, creatinine, albumin, total protein, GGT, AST, CK, HDL, LDL, VLDL, cholesterol, β-hydroxybutyrate (BHB), NEFA and triglycerides, were collected days before castration (D0) and, after that, on d 1, 3, 7, 15, 30, 60 and 9 mo. Castration had no influence on GGT, creatinine, total protein and cholesterol. Up until 15 d after castration, the others parameters were altered because of stress and surgery. Urea increased ($P < 0.0001$) from 19,85 (D0) to 32,43mg/dL (9 mo). Albumin decreased after surgery, possibly due to exudation, and returned to the same values as D0 on D60. AST increased after surgery, then decreased gradually and returned to normal on D15. CK decreased ($P < 0.0001$) from 230,1 to 103,4 U/L, which can be explained for the tranquil temper of rams after surgery, with the absence of fights, that used to be common. The HDL, BHB and NEFA decreased on D3 and remained low. Triglycerides and VLDL decreased on D1 until D15, then raised on D30 to the same values as before castration. The LDL values only increased on D1and on D3 they were similar to D0. The results showed that surgical castration, even under ideal surgical conditions, causes important changes in biochemical profile, especially in the first 15 d after surgery, with stabilization of values in 30 d. The castration alters the behavior of rams, decreases HDL, BHB and NEFA values and raises urea amounts.

Key Words: orchiectomy, sterilization, metabolism

636 Effects of dairy slurry application and bale moisture concentration on voluntary intake and digestibility of alfalfa silage by sheep. Jessica K. Clark*[1,2], Bruce C. Shanks[1], James D. Caldwell[6], Ken P. Coffey[2], Wayne K. Coblentz[3], R. E. Muck[4], Dirk Phillip[2], M. A. Borchardt[3], Robert T. Rhein[2], Ashley N. Young[2], Marshal D. Basham[2], W. E. Jokela[3], Elizabeth A. Backes[2], Keith A. Center[2], M. G. Bertram[5], [1]*Lincoln University, Jefferson City, MO,* [2]*University of Arkansas, Fayetteville, AR,* [3]*USDA-ARS, Marshfield, WI,* [4]*USDA-ARS, Madison, WI,* [5]*University of Wisconsin, Arlington, WI,* [6]*Land O' Lakes.*

Dairy slurry is used commonly as a fertilizer in agriculture. However, residual effects of slurry application on intake and digestibility of alfalfa silage from subsequent harvests are not well known. The objective of this study was to determine if moisture concentration of alfalfa silage and timing of dairy slurry application relative to subsequent harvest affect intake and digestibility by sheep. Pregnant crossbred ewes (n = 18; 3–5 yr old; 47.6 ± 5.34 kg) were stratified by BW and allocated randomly each period to 1 of 6 treatments arranged in a 2 × 3 factorial consisting of high (HM; 46.8%) or low (LM; 39.7%) moisture at baling after no slurry application (NS), slurry applied to stubble immediately after removal of the previous cutting (S0), or slurry applied 14 d after the previous cutting (S14). Period 1 consisted of a 14-d adaptation and a 7-d fecal collection. Period 2 immediately followed period 1 and consisted of an 11-d adaptation with a 7-d fecal collection. Ewes were housed individually in 1.4 × 4.3-m pens equipped with rubber mats and feces were swept from the floor twice daily, weighed, and dried at 50°C. Ewes had ad libitum access to water, were offered chopped silage based on 10% refusal, and were offered commercial sheep mineral (14 g) daily. Intake (g/d) of DM and OM and NDF digestibility (%) did not differ ($P \geq 0.13$) across moisture or slurry application treatments. However, DM and OM digestibility (%) tended ($P < 0.10$) to be greater from LM vs. HM. Total white blood cell concentrations, hematocrits, and red blood cell concentrations were greater ($P < 0.05$) from S0 and S14 vs. NS. Lymphocytes were greater ($P < 0.05$) from LM vs. HM and from NS vs. S0 and S14. Serum urea N concentrations did not differ ($P > 0.13$) across treatments. Therefore, moisture level of alfalfa silage and time of dairy slurry application may not affect voluntary intake or NDF digestibility, but moisture concentration may have a slight effect on DM and OM digestibility. Also, moisture concentration of alfalfa silage and time of dairy slurry application may affect specific blood hemograms.

Key Words: digestibility, silage, dairy slurry

637 Comparison of delayed weaning and mineral form on lamb growth and parasitism.

Jefferson McCutcheon*, David Clevenger, Gary Lowe, and Francis Fluharty, *The Ohio State University, Columbus, OH.*

The objectives were to 1) compare a 60 d of age and a 120 d of age weaning on lamb growth and parasitism on pasture and lamb growth in a feedlot and 2) compare form of mineral (BLOCK and LOOSE) offered ad libitum on pasture on lamb growth and parasitism in lambs. Each weaning treatment consisted of 4 replicate fields/pens of 6 lambs per field/pen blocked by gender and initial starting weight. Twin lambs were used with one randomly weaned (WEAN) and one left with its mother for the pasture phase (NURSE). Subdivided perennial pastures were rotationally stocked. Paddocks size matched stocking density between ewes with lambs and weaned lambs. Mineral form was randomly assigned to both weaning groups. After the 63 d pasture phase, nursing lambs were weaned and intact groups were placed in feedlot pens and fed an alfalfa haylage based diet to a pen average final live weight of 54 kg. Statistics were run using SAS Proc Mixed with PDIFF for mean separation. At the end of the pasture phase lamb final live weight was greater for the NURSE lambs (LSM ± SEM) (39.64 ± 0.57 kg) compared with the WEAN lambs (30.26 ± 0.57 kg) ($P < 0.05$). The pasture ADG was greater for the NURSE (254 ± 6 g/d) than the WEAN (100 ± 6 g/d) lambs ($P < 0.05$). Packed Cell volumes were lesser for the WEAN lambs (2.6 ± 0.6) at 63 d than the NURSE lambs (1.1 ± 0.6) ($P < 0.05$). Log-transformed fecal egg counts were greater for the WEAN lambs (3.42 ± 0.29) at 42 d compared with the NURSE lambs (1.88 ± 0.29) ($P < 0.05$). Mineral form revealed greater ADG for the LOOSE lambs (195 ± 6 g/d) compared with (159 ± 6 g/d) for the BLOCK lambs ($P < 0.05$). Lamb ADG in the feedlot was similar ($P > 0.05$) for the WEAN (217 ± 6 g/d) and NURSE (233 ± 6 g/d) lambs, while days on feed was greater for the WEAN (71 ± 5 d) than the NURSE (96 ± 5 d) lambs ($P < 0.05$). Weaning at 120 d produced greater gains and lower measures of parasitism on pasture compared with weaning at 60 d. In the feedlot this translated to shorter time to final weight. Loose mineral produced greater ADG than block mineral when offered on pasture.

Key Words: lamb, growth, weaning

Teaching/Undergraduate and Graduate Education Symposium: Teaching graduate students to teach and be successful at teaching

638 Engaging introductory animal science students through free-range learning. Frank E. Robinson*, Dana C. Penrice, and Martin J. Zuidhof, *University of Alberta, Edmonton, Alberta, Canada.*

Student success in post-secondary education is largely assessed by their competency assessed by exams and written reports. Curricula may be updated frequently or not. In some cases students are active learners, while in others, a lecture lab format leaves the students learning what they are told to. Often, first year students take primarily large basic science or arts classes with little direct connection to agriculture. An animal science course could serve to "warm-up" the first year for agriculture students. For 11 years, the introductory animal science class at the University of Alberta has carried about 50% of the marks though open-ended project work, known to us as "free-range learning." Through a series of individual and group projects, over 1,100 students have learned the basics of animal science. Lectures, lab tours and exams are still held. The value-added part of the courses have been the offering of 2 to 4 projects per term, designed to allow creativity, embrace the arts, allow opportunity for in depth science discovery and to construct and maintain a learning community. In these projects, students become the experts, with encouragement to contact local individuals as well as those at other universities for up-to-date information. Student deliverables have included videos, live drama presentations, and in-class presentations. For some students, success in this environment can be a challenge so we have senior undergrad alumni return as "learning coaches." Some projects have focused on tools and technologies used in animal production and processing and value-added food production. The program "There's a Heifer in Your Tank" provided groups of students opportunity to answer "questions you didn't know you had about food production" in a public venue reminiscent of an agriculture-based show. In an effort to build ag-fluency, a Rural Café provided 78 students a chance to converse one-on-one with 18 farmers in a speed-dating format. In our experience, engaging students as active learners has improved student satisfaction and retention and resulted in a stronger student-institution bond.

Key Words: student engagement, undergraduate learning, teaching

639 Teaching graduate students to teach: An integrated approach. Donald L. Gillian-Daniel*, *University of Wisconsin-Madison, Madison, WI.*

A key leverage point for improving undergraduate education is preparing graduate students and post-doctoral researchers to teach effectively. In this session, I will present a model professional development program for future faculty. I'll discuss the conceptual basis behind the program and its effects on the local institution. The Center for the Integration of Research, Teaching and Learning Network (CIRTL) is a national association of research universities collaborating to change graduate education by training graduate students and post-docs to teach. Three core ideas form CIRTL's conceptual framework: Teaching-As-Research – using disciplinary research skills to address questions about student learning; Learning Communities – engaging participants in shared learning around effective teaching; and Learning through Diversity – viewing diversity as an asset that can enrich learning. The Delta Program in Research, Teaching and Learning (Delta) at the University of Wisconsin-Madison is CIRTL programming. It involves credit-based graduate courses, facilitated discussion groups, workshops, community events, a Teaching-As-Research Internship and a Certificate. Delta's use of CIRTL's conceptual framework has affected the campus. For example, (1) curricular innovations are developed and evaluated through Teaching-As-Research projects, which also promote cross-institutional collaborations (Gillian-Daniel and Walz, 2015). This type of capstone program has common elements that can be replicated at different institutions (Gillian-Daniel et al., 2015; submitted); (2) grant proposals that leverage Delta programming for broader impacts receive more research funding; (3) interdisciplinary STEM learning communities develop and thrive; (4) program graduates experience improved hiring and early-career success. CIRTL future faculty learn to apply research-based, high-impact teaching practices and to acquire data about student learning to advance their teaching (Pfund et al., 2012; Benbow et al., 2011). CIRTL's conceptual framework provides a solid foundation for training graduate students and post-docs how to teach effectively to promote learning.

Key Words: graduate education, teaching

640 Assessing teaching skills when hiring new faculty members, and rewarding faculty and graduate students for teaching well. Kenneth G. Odde*, *Kansas State University, Manhattan, KS.*

Outstanding teaching has long been a priority for animal science departments. Sustaining excellence in teaching has become a challenge for animal science departments because of declining state funding, the changing nature of our student bodies, loss of livestock units that support teaching, and increased emphasis on extramurally funded research. Excellence in teaching requires that the organization has a culture that respects teaching equal to other mission areas. Attributes of outstanding teachers include compassion for students, a commitment to helping students learn and grow, excellent listening and communication skills, and competence in the subject matter. When recruiting new faculty with teaching responsibilities, it is essential that the evaluation process include the potential for effective teaching. Most candidates for new faculty positions do not have extensive teaching training or experience. Therefore, the evaluation of teaching is primarily one of assessing teaching potential. Many departments use a teaching demonstration as part of the interview for faculty positions that have teaching responsibilities. Properly rewarding faculty and graduate students for excellence in teaching requires a reward system where teaching is effectively evaluated and respected. Student evaluation of teaching is a useful tool, but it has limitations. Peer evaluation of teaching can also be an effective tool in improving teaching quality.

Key Words: assessing teaching potential, rewarding teaching

641 Scholarship of teaching: What are the best methods of conducting research in teaching? Michel A. Wattiaux*, *University of Wisconsin, Madison, WI.*

Instructors are encouraged to bring some level of scholarship of teaching and learning (SoTL) to their instructional activities. Although years of experience may serve as a basis for scholarship, the informal or formal but purposeful collection of data, which is core to SoTL, provides a way to document efforts to improve teaching quality (which may contribute to reward system). However, the ultimate goal of research in teaching is student learning (i.e., achievements). Classroom assessment techniques

(CAT) are informal and formative tools providing instructors with an opportunity to modify instruction based on students' feedback (i.e., perception) when it matters the most (within a semester). Research has shown, however, that people are poor at evaluating their own learning. In contrast, a systematic data collection protocol can be deployed to generate replicated data addressing specific issues with the goal of producing generalizable knowledge. Unfortunately measuring learning outcomes is extremely complex demanding high level of expertise and investment in educational research. Reviewing a large body of literature, Carl Weiman (Nobel laureate in physics) and a colleague have proposed recently a simple teaching practice inventory tool, which they claim can be used as a proxy for students learning outcomes (measured as improvement in grades). This tool may serve as a pedagogical framework to initiate research projects. Evidently, innumerable factors influence the type of research an instructor can realistically engage in successfully. The literature abounds with examples of qualitative (words as data) or quantitative (numbers as data) approaches, experimental designs (pre- and posttest, survey) and statistical methods (parametric, non-parametric). Regardless of challenges and limitations inherent to research in teaching, it is essentially a goal-oriented discovery process that has the potential to transform profoundly one's own teaching practice. Thus, the "best" research methods might be the ones that that the instructor deems most adequate to shed light on the degree to which the learning environment of their classes promotes student achievements.

Key Words: undergraduate education

642 Is *Natural Sciences Education* the journal for you? Ken Barbarick*, *Colorado State University, Fort Collins, CO.*

Natural Sciences Education (NSE) is a peer-reviewed international journal published online continuously during the year. Articles are written by and for educators in the areas of animal science, ecology, natural resources, agronomy, the environment, entomology, and more. Articles cover extension, university, industry, administration, and grades K-12 education. NSE is published by the American Society of Agronomy. NSE provides quick turnaround (49 d from submission to first decision in 2014) and an editorial board that represents all cooperating societies and that works closely with authors to improve the chances for publication (76% acceptance rate on 29 submissions in 2014). We welcome pedagogical studies that include supporting data replicated in time or space, review papers, philosophical discussions, K-12 activities, and profiles of legendary scientists/teachers. We hope members of ADSA and ASAS will consider NSE as their outlet for educational papers.

Key Words: teaching

Animal Behavior and Well-Being II

W1 The relationship between equine temperament and behavior as affected over time by the skill level of the rider. Taylor Huffman and Katherine Koudele*, *Andrews University, Berrien Springs, MI.*

The goal of this study was to determine if there was a relationship between horse temperament and incidence of misbehavior due to the stress of being ridden by riders with a wide range of ability during the course of a camp season (9 weeks). It was hypothesized that horses with a social or aloof temperament would be able to adjust more easily while those with a fearful or challenging temperament would have higher incidence of misbehavior. At the beginning of the summer season at Timber Ridge Camp, Spencer, Indiana, the temperament of each horse (n = 15) was determined using on a rubric based on criteria developed by Barteau (2007). During the camp season, each rider was evaluated for riding skill level, and each incidence of equine misbehavior on trail rides was recorded as were the lengths of the trail rides. The scale for misbehavior was 0–4 with 0 = was not ridden, 1 = no incidents, 2 = annoyance (i.e., head tossing, ear-pinning, moving out of line), 3 = disruptive (i.e., balking, kicking, moderate shying), 4 = hazardous (i.e., bucking, bolting, rearing). The rider skill level was evaluated using a rubric based on Blokhuis et al. (2008) with a scale of 1–4, 1 = an advanced rider and 4 = total novice. The skill level of the rider was multiplied by the length of the rides in minutes to develop a stress index. One-way ANOVA showed a highly significant relationship ($P < 0.0001$) between the stress index and incidence of misbehavior. The behavior scale data for misbehaviors were combined due to lower frequency of severe misbehaviors 3–4. Horses with a challenging temperament exhibited significantly more misbehavior ($P = 0.007$) as did horses with a fearful temperament ($P < 0.0001$). Horses with social or aloof temperaments did not show any significant increase in misbehavior. The results support that in a summer camp horse program a positive relationship exists between stress and misbehavior of horses which varies with their temperament ($P = 0.02$). Horses with fearful or challenging temperaments appeared to be more stressed than horses with a social or aloof temperament based on their greater incidence of misbehavior. It is therefore recommended that horses be temperament tested before entering a summer camp program.

Key Words: horse temperament, rider skill level, misbehavior

W2 Better welfare outcomes in lambs subjected to gradual weaning when compared with abrupt weaning. Cristiane G. Titto*[1], Fábio L. Henrique[1], Evaldo A. L. Titto[1], Adroaldo J. Zanella[2], Henrique B. Hooper[1], Lina F. P. Rodriguez[1], Ana Luisa S. Longo[1], Thays M. C. Leme-dos Santos[1], Raquel F. Calviello[1], Jessica C. Veronezi[1], and Alfredo M. F. Pereira[3], [1]*Faculdade de Zootecnia e Engenharia de Alimentos, Universidade de São Paulo, Pirassununga, São Paulo, Brazil,* [2]*Faculdade de Medicina Veterinária e Zootecnia, Universidade de São Paulo, Pirassununga, São Paulo, Brazil,* [3]*Instituto de Ciências Agrárias e Ambientais Mediterrânicas, Universidade de Évora, Évora, Alentejo, Portugal.*

Weaning is a stressful process during the early-life of lambs. The aim of this study was to compare 2 types of weaning on cortisol levels and rectal temperature of 47 crossbreed lambs. During gradual weaning (GW, n = 12 males, n = 10 females), for 6 d, from d 39 to 44, the mothers were removed from the paddock at 7:00AM, and the lambs were kept separated from them until 17:00h. During the GW the same animal groups were maintained and lambs had free access to clean and fresh water, pasture and concentrate. On d 45, the lambs were placed in the feedlot and blood samples for cortisol levels evaluation were taken at 3 different moments: the first during the last contact with the mother (T1), the second 60 min after entering the feedlot (T2) and the third 180 min after entering the feedlot (T3). On d 46 and 47, the samples were taken once a day, 24 h and 48 h after the entry into the feedlot, respectively. The abrupt weaning (AW, n = 9 males, n = 15 females) began at d 45 of age, and the samples were collected in a similar way as reported for GW. Statistical analyses of variance were divided in 2 steps: the first at d 45 for both GW and AW, with fixed effects of sex, type of weaning and sample time and interactions; the second one analyzed the d 45, 46 and 47 and had fixed effects of sex, days of total separation of the mother and type of weaning as their interactions. Means were compared by F test and *t*-test (PDIFF). On d 45, AW lambs had higher cortisol levels ($1.74\ \mu g \cdot dL^{-1}$) compared with GW lambs ($0.93\ \mu g \cdot dL^{-1}$; $P < 0.05$), and time had no effect on type of weaning. However, the first sample, just after the separation, was 66.6% higher than the T2 and 76.2% higher than T3 ($P < 0.05$). GW lambs had lower cortisol levels ($1.38\ \mu g \cdot dL^{-1}$) than AW lambs ($2.22\ \mu g \cdot dL^{-1}$) on d 45, 46 and 47 ($P < 0.05$) when they were in the feedlot. Sex had no effect on cortisol levels ($P > 0.05$). When weaning is done early and lambs are allowed to have a period to adapt to solid feed and to the absence of their mother, there is less activation of the stress axis after total separation and on the beginning of the feedlot period.

Key Words: cortisol, sheep, stress

W3 Assessing cow-calf welfare. Gabrielle E. Simon*[1], Bruce R. Hoar[2], and Cassandra B. Tucker[1], [1]*University of California, Davis, Davis, CA,* [2]*University of Wyoming, Laramie, WY.*

Certification programs are one way beef producers can assess and communicate information about animal welfare to the public. Programs have been created to monitor cattle all the way through production (e.g., Global Animal Partnership) or at individual stages (e.g., slaughter; American Meat Institute), but to date, there is no certification program addressing welfare specifically at the cow-calf level. The objectives of this study were to gather animal-based prevalence information, describe management practices and facility characteristics, and identify welfare risk factors on cow-calf operations. A welfare assessment was designed using features of similar programs in the beef and dairy industries and was applied to 25 California ranches that varied in herd size (mean ± SD, range: 669 ± 751, 28 – 2450 cows), specialization (i.e., commercial, purebred, grass-finished), and geographic location. Cow health and behavior and stockperson handling measures were collected during a chute-side procedure, management practices were evaluated through an interview-guided questionnaire, and facility characteristics were recorded at the chute and water access points. Cattle health problems were rare and only seen on specific ranches (e.g., prevalence of lame cattle: 1.5 ± 1.6, 0 – 7.1%). Conversely, cattle behavior and stockperson handling varied between ranches (e.g., cattle balking prevalence: 16.5 ± 16.2, 1.6 – 71.4%, electric prod use: 21.5 ± 21.1, 0 – 73.0%). Although some management characteristics were shared by all (e.g., all producers reported having a veterinary/client/patient relationship), a variety of practices were reported (e.g., weaning age: 8.1 ± 1.5, 6 - 11 mo). Likewise, some facility features were common (e.g., 20 curved head gate stanchions vs. 4 straight) and other aspects varied (e.g., 14 restraints without louvers vs. 10 with louvers). A risk factor evaluation will identify which inputs (i.e., stockperson handling, management practices, facility design) influence welfare on cow-calf operations.

Key Words: welfare assessment, cow-calf, risk factor

W4 Identifying the principal problems of animal welfare on intensive dairy farms in the central zone of Chile.

Maria Sol Morales*, Lorena Carmona, Tamara Tadich, and Carlos Alvear, *Facultad de Ciencias Veterinarias y Pecuarias, Universidad de Chile, Santiago, RM, Chile.*

Animal welfare (AW) on 19 intensive dairy farms (DF) from the central zone of Chile was studied using Welfare Quality protocol (WQP); 18 were qualified between acceptable and enhanced, one as non-classified, and none as excellent. The objective of the present study was identify the specific problems of AW on these DF using the data on which the evaluations were made. WQP assesses AW on animal-based observations (cow or herd level) and on indirect information from farm records. For each observation or record, an average value/DF was obtained and compared with the alarm value (AV) for each indicator; AV is considered as the minimum value acceptable. For some indicators, AV was provided by WQP, otherwise this was calculated as 25% of the distance between maximum and minimum value found on the evaluation. Then the percentages of DF that exceeded the AV for each indicator were obtained and ranked to identify the principal problems. Problems were related to animal health, where 78.9, 52.6, 53, 40 and 40% of DF exceeded the AV on: % cows with areas of hairless patch, Total % of lame cows, % of cows with dystocia, mortality and downer cows, respectively; although some sanitary indicators as: % of cows with oral, nasal or vulvar secretions, as well % of cows with diarrhea did not show problems at all. Housing problems are mainly related to dirtiness (68.5, 57.9, 52.6% of DF had problems on: % of cows with udder dirty, % of cows with flank/upper leg dirty and % of cows with dirty lower legs, respectively). With regard to animal behavior, social interaction among cows did not seem to be a major problem; however, at human-cow interaction there is poor AW: 64.7 and 58.8% of DF showed problems with flight zone and % of cows that can be touched, respectively. Good feeding aspects did not appear as a major AW problem. The results show diverse aspects of management and housing, which affect the AW of dairy cows. This study has identified those problems that deserve greater attention in training of farm workers. Funded by project No. FOOD-CT-2004–506508 and CONICYT.

Key Words: animal welfare, dairy cow

W5 Identifying farm-level factors affecting milking attendance and productivity in automated milking systems.

Meagan T. M. King*[1], Ed A. Pajor[2], Stephen J. Leblanc[3], and Trevor J. DeVries[1], [1]*Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada,* [2]*Faculty of Veterinary Medicine, University of Calgary, Calgary, AB, Canada,* [3]*Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

The objective of this study was to determine how barn design, herd management, and lameness prevalence relate to automated milking system (AMS) attendance and productivity. Data were collected from 26 AMS farms in Eastern Ontario, Canada. Farms averaged 108 ± 13 (mean ± SE) lactating cows and 2.3 ± 0.3 AMS units. The majority of farms used free-flow cow traffic (n = 24), while 2 farms employed a mixture of free-flow and milk-first traffic for different groups. Physical barn characteristics and stocking densities were recorded, and complemented by a questionnaire regarding feeding and bedding management. At each farm, 40 cows were gait scored (or 30% for herds > 130 cows) using a 5-point numerical rating system (1 = sound to 5 = lame). Cows were defined as lame with gait scores ≥ 3 (28.4 ± 2.8%) and severely lame as ≥ 4 (2.9 ± 0.7%). For a 6-d period, milking activity and production parameters for all cows at each farm were extracted from the respective AMS computers. Data were summarized across all cows and the 6-d observation period for each farm and analyzed in multivariable mixed-effect regression models. Milking frequency (2.9 ± 0.1 milkings/cow/d) increased with herds of greater average parity ($P = 0.04$; mean = 2.2 ± 0.4 lactations), greater frequency of feed push up/d ($P = 0.04$; mean = 9 ± 1.2 ×/d), and when stalls were raked ≥ 3×/d vs. 2×/d ($P = 0.01$), while it decreased with a greater prevalence of severe lameness ($P = 0.008$). Milk yield (32.6 ± 0.5 kg/d) increased with herd size ($P = 0.01$) and feed space/cow ($P < 0.001$; mean = 70.4 ± 2.6 cm/cow). Lying time (706 ± 11.8 min/d) was greater with concrete flooring ($P = 0.045$) as opposed to rubber flooring, and tended to decrease with lying stall neck rails placed further from the back curb ($P = 0.07$; mean = 172.0 ± 1.6 cm). Lying bouts (8.9 ± 0.3 no./d) were less frequent with a greater prevalence of lameness ($P = 0.01$), and tended to be less frequent with longer stall lengths ($P = 0.07$; mean = 248.9 ± 3.4 cm). These results demonstrate that behavior and productivity in AMS herds may be positively affected by modifiable housing and management practices and are negatively affected by a higher prevalence of lameness.

Key Words: automatic milking, dairy cow, behavior

W6 Differences in cow comfort between traditional bedded pack and compost bedded pack for dairy housing systems.

Anna Fernández, Eva Mainau, Xavier Manteca, Cinta Sol*, and Lorena Castillejos, *Animal Nutrition and Welfare Service, Animal and Food Science Departament, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

The objective of this research was to compare cow welfare between 2 different types of dairy cattle housing systems, compost bedded pack (CB) and traditional bedded pack (TB), using the Welfare Quality protocol. Both behavior indicators (time needed to lie down) and health indicators (dirtiness of the cows, body condition, hairless patches, lesions and swellings, lameness, nasal and ocular discharge, hampered respiration, diarrhea, and vulvar discharge) were evaluated as indicators of cow welfare. The study was conducted on 2 commercial dairy farms (816 and 394 lactating cows) between the spring 2013 and the summer 2014. Data from behavior and health indicators were collected from 451 lactating cows (11.28 ± 0.29 cows for each farm, season and treatment) and 1222 lactating cows (30.5 ± 0.6 for each farm, season and treatment) respectively. Statistical analyses were carried out with the SAS 9.2 software applying a MIXED procedure for behavior and GLIMMIX procedure for health data. Regarding behavior, cows took a similar amount of time to lie down in CB and TB (4.8 ± 0.08 and 4.7 ± 0.07 s; $P > 0.05$). For health indicators, the percentage of cows with dirtiness on the udder was higher ($P < 0.05$) in CB (50.7 ± 2.61) than TB (44.0 ± 3.33) in summer and spring. Conversely, in winter, the percentage of cows with dirtiness on the hindquarters was higher ($P < 0.05$) in TB (61.7 ± 2.93) than CB (50.3 ± 2.99). Cows allocated in TB showed higher prevalence of hairless patches on the flank, side and udder than in CB (10.8 ± 1.57 and 9.6 ± 1.55; $P < 0.05$) in summer. There were no other differences in health measures between cows housed in CB and TB throughout the year. Most of the welfare parameters evaluated did not differ between the 2 loose housing systems, with the exception of dirtiness and hairless patches.

Key Words: compost bedded pack, cow comfort, lactating cow

W7 Behaviors of Holstein heifers associated with large follicles during the estrous cycle.

Cassandra S. Skenandore* and Felipe C. Cardoso, *University of Illinois, Urbana, IL.*

Estrus detection in heifers is pivotal for reproductive success. The objective of this study was to identify behaviors associated with 2 different periods of the estrous cycle of Holstein heifers. Eighteen heifers at breeding age were selected, balanced by age, BW, and BCS (average 13.7 ± 1 mo, 394 ± 32 kg, and 3.43 ± 0.1 respectively), and observed for 6 wk. The experimental period was divided into 3 periods of 14 d each. All heifers received the same basal diet to meet requirements (NRC 2001), fed once daily. Visual observations were performed in 30 min segments every 2 h from 6AM to 6PM. Video recordings were used to confirm observations. Twelve behaviors were recorded (Social Lick, Rump Lick, Tail Paint Lick, Body Butt, Head Butt, Push, Chin Rest, Anogenital Sniff, Play Rub, Winner, Mount, and Attempt Mount). A synchronization protocol starting on d 1 of each period (Ovsynch: 100mg GnRH at d 1, 25mg PGF2α at d 7, and 48 h later an application of 100mg of GnRH) was used to stimulate periods of high and low interactions. Observations were summarized to daily counts of interactions for each behavior. Ovaries were examined via ultrasound imaging on d 1, 8, and 10 of each period. The presence of follicles or a corpus luteum (CL) was recorded with their respective sizes. Lying time, standing time, and bouts /d were recorded using accelerometers (Onset HOBO Pendant G) at 1 min intervals for 14 d. Statistical analyses were performed using the GLIMMIX procedure of SAS (v9.3). During periods of low activity per the synchronization protocol, social ($P < 0.01$) and paint ($P < 0.05$) licking were more likely to be expressed than estrus-related behaviors such as rump licking ($P < 0.05$), chin resting ($P < 0.002$), and mounting ($P < 0.003$). The aforementioned estrus related behaviors were also performed in more frequency than other behaviors when a large follicle is present ($P < 0.03$). Heifers spent more time standing and less time lying per day when they had a large follicle ($P < 0.006$) compared with a small follicle. In conclusion, increased activity and specific behaviors may be used in the future to facilitate estrus detection in heifers.

Key Words: heifer, behavior, heat detection

W8 Behavioral responses of periparturient Jersey cows treated with recombinant bovine somatotropin during the periparturient period.

Henrique F. Soares[1], **Daniela N. Liboreiro***[1], Gabriel D. Bombardelli[1], Paula R. B. Silva[1], and Ricardo C. Chebel[1,2], *[1]University of Minnesota, St Paul, MN, [2]University of Florida, Gainesville, FL.*

Objectives were to determine the effects of recombinant bovine somatotropin (rbST) treatment of Jersey cows from −21 to 21 d relative to calving on rumination, activity, and lying behavior. Cows were assigned randomly to control and rbST (125 mg of rbST every 7 d from −21 to 21 d relative to calving) treatments. Cows (n = 50) were fitted with rumination/activity collars (SCR) and lying behavior loggers (HOBO) from −21 to 21 d relative to calving. Rumination and activity were recorded every 2 h and lying behavior was recorded every 1 min. Data were analyzed in 24 h intervals. Continuous data were analyzed by ANOVA using the PROC MIXED procedure for repeated measures with cows as the experimental unit. The model included treatment (control vs rbST), time (days relative to calving), and the interaction between treatment and time. Daily rumination time was not ($P = 0.74$) different between treatments in the prepartum, but rbST cows had reduced daily rumination time in the postpartum (rbST125 = 428.5 ± 17.0, control = 484.3 ± 16.7 min/d, $P = 0.03$). The interaction between treatment and time affected ($P < 0.01$) daily rumination time because from 0 to 7 d postpartum treatments did not differ, but in most days from 8 to 21 d postpartum control cows had greater daily rumination time. Treatment did not affect activity during the prepartum ($P = 0.97$), but control cows tended to have greater activity during the postpartum (540.3 ± 33.7 vs 499.1 ± 36.1 arbitrary units; $P = 0.12$). Lying time was not affected by treatment (prepartum-$P = 0.34$, postpartum-$P = 0.72$). Treatment by time interaction affected number of lying bouts in the prepartum ($P < 0.01$) and rbST cows tended to have greater number of lying bouts in the postpartum (rbST = 7.2 ± 1.1, control = 6.5 ± 1.6 bouts/day). Lying bout duration was not different in the prepartum ($P = 0.86$), but rbST cows tended to have shorter lying bout duration in the postpartum (rbST = 83.9 ± 3.8, control = 93.5 ± 3.7 min/bout; $P = 0.08$). Reduced rumination and increased lying bouts during the postpartum period among rbST treated cows may be associated with changes in metabolic and health status resulting from rbST treatment.

Key Words: Jersey cow, behavior, recombinant bovine somatotropin

W9 Preference of flavored concentrate premixes by dairy cows.

Michael T. Harper*[1], Joonpyo Oh[1], Fabio Giallongo[1], Juliana C. Lopes[1], Alexander N. Hristov[1], and Joelle Faugeron[2], *[1]The Pennsylvania State University, University Park, PA, [2]Pancosma, Geneva, Switzerland.*

Flavor preferences may stimulate feed intake in dairy cows, which may improve energy balance in early lactation and lead to increased milk production. A cafeteria experiment was designed to determine if dairy cows have flavor preferences. Sixteen lactating Holstein cows averaging 197 ± 32 DIM, 1.9 ± 0.8 lactations, 27.8 ± 4.2 kg/d DMI, and 41.5 ± 7.4 kg/d milk yield were involved in the experiment. Cows were offered 7 flavored and a control concentrate premixes (FCP). The FCP flavors were: anise, fenugreek, honey, orange, thyme, molasses, vanilla, and the absence of flavor acted as a control. The inclusion rate of the flavors in FCP was 250 to 300 g/t, as-is basis. Cows were not adapted to the flavors before the experiment. Cows were housed in a tie-stall barn and were offered each d 4 different FCP of 1 kg each in plastic bins placed in front of each cow. The duration of the experiment was 6 consecutive days. Each FCP was presented to each cow once every 2 d, 2 h after the morning feeding. Thus, each flavor was presented to each cow 3 times during the experiment. Flavors and position of the bins in front of the cows were randomized. Each cow had access to the FCP for 5 min from the time they started eating. Eating times were recorded. Amount consumed and rate of FCP consumption were analyzed using the MIXED procedure of SAS with cow as random effect. The vanilla and fenugreek FCP were consumed the most ($P = 0.03$) at 408 and 371 g per 5 min offering, respectively, while the orange and anise FCP were consumed the least at 264 and 239 g, respectively. Similarly, cows spent the most ($P = 0.002$) time eating the vanilla and fenugreek FCP at 99 and 75 s, respectively, and the least amount of time eating the orange and anise FCP at 49 and 50 s, respectively. There was an effect of bin position with the 2 center FCP being consumed more ($P < 0.001$) than the outer 2 FCP. There was a trend for flavor by bin position interaction ($P = 0.07$) for the amount consumed, but not ($P = 0.11$) for the time spent eating. Flavor had no effect on consumption rate. In conclusion, dairy cows may prefer vanilla or fenugreek flavors, when offered a novel choice.

Key Words: feed intake, flavor preference, dairy cow

W10 Sorting of TMR by dairy calves is affected by availability of an alternative source of grain.

Joao H. C. Costa*, Nicola A. Adderley, Daniel M. Weary, and Marina A. G. von Keyserlingk, *Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada.*

We performed 2 trials on sorting behavior in individually raised dairy calves (n = 18). For both, calves were provided free access to TMR [49.1 ± 1.5% DM (Mean ± SD); chemical composition shown as % of DM, CP 16.9 ± 0.95%, NDF 31.8 ± 2.68%, ADF 20.4 ± 1.77] and calf starter [with an overall DM of 89.5%; chemical composition shown as % of DM, CP 20.6 ± 1.13%, NDF 16.5 ± 0.39%, ADF 7.84 ± 0.45%] for the first 2 mo of life. Sorting was assessed at 65 d, when calves still had access to calf starter, and again at d70 when starter was no longer available. On each day, sorting was measured by comparing diets before feeding with orts after 24 h of feed access. Particle sizes were measured using the Penn State Particle Separator with 3 screens (19, 8, and 1.18 mm) and a bottom pan to separate the TMR into long, medium, short, and fine fractions respectively. The predicted intake of each particle size fraction in the orts was tested between treatment for a difference from 100 using *t*-tests. When able to access the calf starter, calves sorted the TMR selecting for long particles (133 ± 9%; $P = 0.0038$) and against small particles (92 ± 3%; $P = 0.0240$), with no differences for the remaining particle fractions (99 ± 5% [$P = 0.90$] for medium; 107 ± 5% [$P = 0.14$] for fine). When calves no longer had access to the starter these preferences reversed; calves preferentially selected the fine particles (113 ± 4%; $P = 0.01$), with no selection for the other fractions (101 ± 11% [$P = 0.94$] for long; 99 ± 6% [$P = 0.80$] for medium; 97 ± 4% [$P = 0.51$] for short). These results indicate that young dairy calves are capable of sorting TMR and adjust their sorting behavior in response to changes in feed offered.

Key Words: feeding behavior, sorting behavior, motivation

W11 Predicting filching: A logistical approach. Kristina A. Weld*, Louis E. Armentano, and Amy L. Stanton, *University of Wisconsin, Madison, WI.*

Understanding the feeding behavior of dairy cattle in greater detail can lead us to broader conclusions about animal welfare. One feeding behavior of interest is filching, in which cows steal feed from an automatic gate which they do not have access to, rather than taking the easier route and eating out of a gate that they have access to. The objective of this study was to determine factors that predict filching behavior. Sixty-three cows (28 primiparous, 35 multiparous, average 76 DIM) were assigned to 4 mixed parity groups. All cows were in the same physical pen containing 32 Insentec Roughage Intake Control feed gates (Insentec BV, Marknesse, the Netherlands), but each group had access to a different set of 8 randomly assigned gates. For the first 6 weeks, cows were fed a common diet, followed by a second 3 week period in which cows were fed 1 of 2 diets that differed only in the variety of soybean that they contained. Data were analyzed with logistic regression (Proc Glimmix) in SAS 9.4. For the first 6 weeks, filching at or above 0.5% of diet was positively associated with hip height ($P = 0.01$). Cows that filched above 1% in the second period consumed 92% (Confidence Interval 89–95%) of their filched feed from their unassigned diet which is significantly above the amount that would be predicted if they filched randomly from unassigned gates (67%). Hip height was positively associated with filching and meal length was shorter for cows that filched in the second period ($P < 0.05$). Filching in period 1 was not predictive of filching during period 2. Filching was not associated with the number of bunk displacements. These models indicate that height is a requirement for filching in this gate arrangement. However, competition does not necessarily drive filching indicating that filching may not be driven by necessity. Because cattle are willing to work for a novel feed, regardless of competition, this may indicate that cattle are willing to work to experience novelty. This might indicate that provision of novelty, in the form of alternative feeds, plays a larger role in cattle welfare than previously thought.

Key Words: filching, welfare, novel feed

W12 Validation of methodology for assessing heat abatement strategies in dry-lot cattle. Grazyne Tresoldi*[1], Karin Schütz[2], and Cassandra Tucker[1], [1]*Center for Animal Welfare, Department of Animal Science, University of California, Davis, Davis, CA,* [2]*Farm Systems North, AgResearch Ltd., Ruakura Research Centre, Hamilton, New Zealand.*

Identifying dairy cattle experiencing heat stress can improve welfare and profitability. However, it is unclear how often we need to observe the animals for this purpose, nor the relevance of specific aspects of the heat stress response, particularly in terms of panting (e.g., closed vs. open mouth panting). Our objectives were to refine and validate methodology used to assess heat load in dairies by (1) determining sampling intervals to measure usage of heat abatement resources (HAR; sprayed water or shade); and (2) evaluating the relationship between respiration rates (RR) and panting characteristics (PC; drooling, open mouth, and tongue outside the mouth). High-producing lactating cows (>40 kg milk/d) were chosen from 4 California dry-lot dairies (8 cows/dairy, n = 32) and observed for at least 6 h (1000 to 1800 h, excluding milking) when air temperature, humidity and the combined index averaged 33°C, 30% and 79, respectively. Use of HAR by individual cows was recorded continuously. Every 5 min, RR and presence/absence of PC (observed for 10 s at a time) were recorded. For use of HAR, estimates from different sampling intervals (1, 5, 10, 15, 20, 30, 60, 90 and 120 min) were derived from continuous data. Linear regression was used to compare these estimates against the continuous measurements. Sampling intervals were considered accurate if they met 3 criteria: $R^2 \geq 0.9$, intercept = 0 and slope = 1. The relationship between RR and each PC was analyzed using mixed models with random effects for cow and cow × PC, to generate appropriate error degrees of freedom. When the sampling interval for HAR was ≤ 60 min, R^2 values were ≥ 0.9 and both the intercept and slope did not differ from 0 and 1, respectively ($P > 0.05$). RR was higher when PC were present (least squares means ± standard error, breaths/min: with vs. without drool present, 97 ± 3 vs. 74 ± 3; open vs. closed mouth, 100 ± 4 vs. 80 ± 3; tongue outside vs. inside the mouth, 96 ± 4 vs. 81 ± 3; $P < 0.001$). In summary, use of HAR is best measured when using sampling interval ≤60 min. Panting was accompanied by higher RR, and further analysis is planned to determine appropriate sampling intervals for these measures.

Key Words: well-being, behavior, cooling

W13 Infrared thermography as a tool to diagnose foot rot and digital dermatitis in feedlot cattle. Sonia Marti[1], Randy E. Wilde[1], Diego Moya*[1,2], Eugene D. Janzen[2], Michael J. Jelinski[3], Craig L. Dorin[3], Karin Orsel[2], Ed Pajor[2], Jan Shearer[4], Suzanne T. Millman[4], Johann F. Coetzee[4], Dan Thomson[5], and Karen S. Schwartzkopf-Genswein[1], [1]*Agriculture and Agri-Food Canada, Lethbridge, AB, Canada,* [2]*University of Calgary, Faculty of Veterinary Medicine, Calgary, AB, Canada,* [3]*Veterinary Agri-Health Services Ltd., Airdrie, AB, Canada,* [4]*Iowa State University, College of Veterinary Medicine, Ames, IA,* [5]*Kansas State University, College of Veterinary Medicine, Manhattan, KS.*

Diagnosis of lameness due to infectious claw lesions in beef cattle can be extremely challenging under commercial feedlot conditions resulting in inappropriate medical treatment and unnecessary drug and labor costs.

The objective of this study was to determine if infrared thermography could be used to make a differential diagnosis between foot rot (FR) and digital dermatitis (DD) based on claw area temperatures. Over a 16-mo period, 470 lame cattle from the same commercial feedlot in Southern Alberta were examined while restrained in a squeeze chute. Thermographic images were taken using a Flir i40 infrared camera, and processed with ThermCam QuickView 1.3 (Flir Systems Inc., Burlington, ON, Canada) from the anterior and posterior views of each affected hoof, and the laterally adjacent unaffected hoof within the same animal, to obtain temperature differentials. Limb position (fore or hind) of the imaged hoof was also recorded. Temperatures from the underside view of the affected limb were also measured. Ambient temperature and relative humidity within the examination barn were recorded using a Hobo U23 Pro v2 logger (Onset Computer Corporation, Bourne, MA). After images were obtained, the affected hoof and lesion were cleaned with a brush and a physical exam was conducted to determine the actual cause of lameness. Data were analyzed using a mixed effect model with diagnosis, affected limb and their interaction as a main effects, and ambient temperature and relative humidity as covariates. No differences were observed in temperatures of unaffected and affected hooves for either FR or DD cases (−1.3 ± 0.22°C and −0.7 ± 0.37°C, respectively ($P = 0.15$) for the anterior view, and −0.9 ± 0.16°C and −1.2 ± 0.24°C, respectively ($P = 0.41$) for the posterior view). In addition, temperatures from the underside view were not different ($P = 0.67$) between FR (35.9 ± 0.12°C) and DD (35.8 ± 0.18°C). Under the conditions of this study, infrared thermography was not a useful tool for differentiating between beef feedlot cattle diagnosed with foot rot and digital dermatitis.

Key Words: lameness, feedlot, cattle

W14 Continuous recording versus scan-sampling in behavioral studies with growing heifers fed high-concentrate diets.

Ana Madruga*[1], Alfred Ferret[1], María Rodríguez[1], Eva Mainau[1], Jose Luis Ruiz de la Torre[1], Luciano Gonzalez[2], and Xavier Manteca[1], [1]*Animal Nutrition and Welfare Service (SNIBA), Universitat Autonòma de Barcelona, Bellaterra, Spain,* [2]*Centre for Carbon, Water and Food, The University of Sydney, Camden, NSW, Australia.*

Continuous observation is an accurate method for behavioral measurements in ruminants but is very time-consuming. An alternative is scan-sampling (SC), in which behavior is recorded at regular intervals. The aim of this study was to compare the loss of information when different SC intervals were chosen to record heifer behavior. Behavior of 8 growing heifers fed a high-concentrate diet was recorded on 6 non-consecutive days. Continuous sampling (CS) was considered the control treatment and was used to evaluate scan-sampling intervals of 2, (SC2), 5 (SC5), 10 (SC10), 15 (SC15), 20 (SC20) and 30 (SC30) min. Two additional sampling techniques were considered: a time sampling of the first 10 min of every hour (TS), and the continuous observations during 4 h post-feeding (4PF). Behaviors were expressed as a percentage of the total daily activity. A square root-arcsine transformation was applied to achieve normal distribution. Differences were analyzed by using the GLIMMIX procedure of SAS. The model contained the fixed effect of treatment, and the random effects of heifer and day. Pearson correlations were used to compare CS with SC treatments. Daily time in each behavioral activity using the SC and TS treatment did not differ from CS ($P > 0.10$). In contrast, 4PF affected behavioral measurements. Time spent ruminating, social behavior and self-grooming were 50, 41 and 38% lower ($P < 0.001$), while eating and resting times were 28 and 17% higher ($P < 0.001$) in 4PF than CS. For all behaviors, high correlations were observed between CS and SC2 ($r > 0.93$; $P < 0.001$) and between CS and SC5 ($r > 0.75$; $P < 0.001$). For eating, drinking, social, self-grooming, tongue-rolling, licking and biting fixtures, and rummaging in wood shavings, the longer the scan interval, the lower was the correlation. For ruminating and resting, correlations between CS and SC30 were greater than 0.90 ($P < 0.001$). In conclusion, the use of SC or the TS treatment did not result in any loss of information. However, 4PF is not an accurate technique for measuring behavioral activities in ruminants.

Key Words: beef cattle, behavior, scan-sampling method

W15 Evaluation of technologies to predict the onset of calving in Holstein dairy cows.

Véronique Ouellet*[1], Elsa Vasseur[2], Wolfgang Heuwieser[3], Onno Burfeind[3], Xavier Maldague[4], and Édith Charbonneau[1], [1]*Département des Sciences Animales, Université Laval, Québec, QC, Canada,* [2]*Organic Dairy Research Center, University of Guelph, Alfred, ON, Canada,* [3]*Clinic for Animal Reproduction, Faculty of Veterinary Medicine, Freie Universität Berlin, Berlin, Germany,* [4]*Département de Génie électrique et de Génie Informatique, Université Laval, Québec, QC, Canada.*

Dystocias are common in dairy cows and are known to have labor, production, reproduction, welfare and economic implications. A technology that would accurately predict the onset of calving would help minimize the effects of dystocia by allowing producer intervention in a timely matter. The aim of this study was to assess the performances to predict calving using a decrease in vaginal temperature, rumination time, and lying time or an increase in number of lying bouts measured by 3 technologies. The combination of technologies allowing simultaneous measure of the variables was also tested. Forty 2 multiparous Holstein cows housed in tie-stall were fitted with a temperature logger, a rumination sensor and an accelerometer 7 ± 2 d before their expected calving date. Data collected during the last 120 h before calving were summarized per day and in 6 h periods. Differences between days and between periods were analyzed using proc GLIMMIX of SAS. Test performances (sensitivity, specificity, predictive values) were conducted to predict calving within the next 24, 12 or 6 h. Vaginal temperature were 0.3°C lower ($P < 0.05$) whereas rumination and lying time were respectively 41 and 52 min lower ($P < 0.05$) on calving day compared with the 4 d precalving. Cows had 2 more lying bouts on calving day ($P < 0.05$). While comparing tested variables, a decrease of vaginal temperature achieved the best performance to predict calving within the next 24, 12, and 6 h. Between those periods, the best performance was achieved for a prediction within the next 24 h with a sensitivity, specificity, positive and negative predictive values respectively of 74, 74, 51, and 89%. Combining the technologies enhanced the performance to predict calving with best results obtained by the combination of the 3 technologies for a prediction within the next 24 h (sensitivity: 77%, specificity: 77%, positive and negative predictive values: 56 and 90%). These results suggest that technologies are better at identifying events during which the cow did not calve than calving events. Therefore, a device that would be able to measure the 4 variables may not be able to accurately predict calving time but would provide insightful information for calving monitoring.

Key Words: technologies, calving, dystocia

W16 Barrow behavioral reactivity to a human or novel object when fed low versus high fiber diets.

Jessica D. Colpoys*[1], Nicholas K. Gabler[1], Caitlyn E. Abell[2], Aileen F. Keating[1], Suzanne T. Millman[1], Janice M. Siegford[3], and Anna K. Johnson[1], [1]*Iowa State University, Ames, IA,* [2]*DNA Genetics, Columbus, NE,* [3]*Michigan State University, East Lansing, MI.*

Low energy, higher fiber diets (HFD) are becoming more prevalent in the US swine industry due to fluctuating corn-soy diet prices. In sows, HFD are reported to increase satiety and reduce stereotypic behavior, aggression, and activity. However, little is known about how fiber content in diets contributes to behavioral reactivity in grow-finish pigs. Therefore, the objective of this study was to determine if diet influences behavioral reactivity using a human approach test (HAT) and novel object test (NOT). We hypothesized that pigs reared on HFD would be less reactive to HAT and NOT compared with pigs reared on high energy, low fiber corn-soy diets (CD). Forty Yorkshire barrows (48 ± 8 kg BW) were randomly allocated to 2 treatments: HFD (n = 20) and CD (n = 20). The barrows were evaluated once using HAT and once using NOT utilizing a crossover experimental design. Each pig was individually tested within a 4.9 × 2.4 m test arena for 10 min between 1300 and 1900 h. Behavior was evaluated using live and video observations. The video was watched continuously by one trained observer for latency, frequency, and duration of human and novel object (orange traffic cone) touches, frequency of escape attempts, frequency of freezing postures, activity (number of arena line crossings), urination, and defecation. Data were analyzed using the Glimmix procedure of SAS with fixed effects of diet and test week, covariate of body weight, and random effect of pen. Diet did not alter latency to first touch, touch frequency, or duration of touches with the human or novel object ($P > 0.10$). Similarly, frequency of escape attempts, freezing, activity, and urination did not differ between diets during HAT or NOT ($P > 0.10$). Barrows fed HFD defecated more during NOT ($P = 0.01$), and tended to defecate more during HAT compared with CD barrows ($P = 0.06$). Differences in defecations are likely due to high fiber content of HFD resulting in more waste excretion. These results suggest that feeding high fiber diets did not alter grow-finisher barrow behavioral reactivity.

Key Words: approach, fear, high fiber diet

W17 A novel objective chute score interacts with monensin to affect growth of receiving cattle. Kelsey A. Bruno*, Eric S. Vanzant, Alex W. Altman, Monoj Kudupoje, and Kyle R. McLeod, *University of Kentucky, Lexington, KY.*

Temperamental animals often have lower gains associated with reduced intake and/or efficiency. Temperament is ill defined. Thus, different temperament measures may relate differently to production traits. Also, hepatic oxidation theory (HOT) suggests that propionate can exacerbate intake depression in stressed cattle. To examine relationships between diet, temperament, growth, and health, 160 crossbred steers were used in a 56-d RCBD experiment with a 2 × 2 x 2 factorial treatment structure. The experimental unit was pen (5 pens/treatment). Steers were pen fed a corn silage-based diet with or without monensin, ad lib. Temperament treatments (assigned on d −7) were exit velocity (EV; slow vs. fast) and objective chute score (OCS; low vs. high), a novel temperament measure, the CV of weights collected at 5 Hz for 10 s while an animal's head was restrained in a chute. Both were measured on d −7, 1, 14, 28, 55, and 56. Subjective chute scores (SCS) were measured on d −7 and d 56 by 4–5 observers. Jugular blood samples were analyzed for antibody response to leptospirosis vaccine. There was a positive correlation between SCS and OCS ($P < 0.01$; $R^2 = 0.38$) and SCS was moderately repeatable among observers (Krippendorff's $\alpha = 0.58$ to 0.67). Treatment x day effects ($P < 0.10$) for EV and OCS indicated that initial measures may be better proxies of growth than average measures. There were no interactions between EV and OCS ($P \geq 0.24$) and no interactions between treatments ($P \geq 0.12$) on intake (%BW). Monensin decreased intake ($P < 0.01$) without effect of temperament. Thus, our hypothesis regarding HOT was not supported. Gains, antibody titer, and gain:feed responses to monensin depended on OCS ($P < 0.10$) but not ($P \geq 0.34$) EV. Gain was reduced ($P < 0.10$) by monensin with low, but not high OCS and gain:feed was increased ($P < 0.10$) and titer response decreased ($P < 0.10$) by monensin on high, but not low OCS. Gain and intake tended ($P \leq 0.15$) to be reduced in fast, compared with slow EV steers. Results provide novel indications that certain temperament measures can interact with dietary manipulation to influence animal performance.

Key Words: temperament, growth, monensin

W18 Could forming uniform body weight groups at entrance result in improved performance, behavior, health and carcass in fattening Holstein bulls? Marçal Verdú*[1], Alex Bach[2,1], Armando Pérez[3], and Maria Devant[1], *[1]IRTA-Ruminant Production, Animal Nutrition, Management, and Welfare Research Group, Caldes Montbui, Spain, [2]ICREA, Barcelona, Spain, [3]Grup Alimentari Guissona, Guissona, Spain.*

The purpose of the present study is related to the criterion that should be followed to form animal groups according to BW, and to evaluate the effect of this practice on productive, behavior, or health outcomes when animals are mixed at the onset of fattening. A total of 160 Holstein bulls (162 ± 0.3 kg BW and 124 ± 1.1 d age) were allocated in 8 pens with similar mean BW, and were randomly assigned to 1 of 2 treatments: homogeneity of initial BW that corresponded to a CV of BW within a pen of 7% (HO), and heterogeneity with a CV of BW within a pen of 21% (HE). Concentrate intake and health incidences were recorded daily, straw consumption weekly, and BW every 14 d. Animal behavior was registered on d 0, 1, 3, 5, 8, 14, 28 and every 28 d by scan sampling. Animals were slaughtered after 206 d, and HCW and carcass quality were recorded. Data were analyzed using a mixed-effects model with repeated measures. Performance and carcass data were not affected by the BW uniformity of the groups at the onset. However, while the CV of BW within HO was maintained ($P > 0.10$) throughout the study (6.1 ± 0.73%), the CV of BW within HE was reduced ($P < 0.01$) from 21.5 to 10.7 ± 0.86% at the beginning and at the end, respectively. During the 1st month HO exhibited ($P < 0.05$) lesser completed mounts than HE (0.5 and 1.0 ± 0.09 times/15 min). Throughout the study HO tended ($P = 0.10$) to perform more self-grooming compared with HE (13.6 and 11.6 ± 0.13 times/15 min). Whereas 80% of veterinary therapies applied in HE were chronic (≥3 consecutive treatments in the same animal), 90% of therapies in HO were acute (≤2 consecutive treatments in the same animal, $P < 0.05$). Moreover, 6 HE bulls were removed from the study for health reasons. In conclusion, even if bulls from pens with a non-uniform BW at the onset had greater frequency in completed mounts and worse health status than bulls from pens with uniform BW at the onset, animal growth and carcass was not impaired.

Key Words: bull, BW uniformity, performance

W19 Effect of housing on the leukocyte transcriptome of beef calves. Robmay Garcia*, Dianelys Gonzalez-Pena, and Sandra L. Rodriguez-Zas, *University of Illinois at Urbana-Champaign, Urbana IL.*

Movement of beef calves from a pasture to a housing environment induces a stress response including changes in leukocyte physiology. Understanding the molecular profiles underlying these changes can help to develop better management practices and treatments to minimize the deleterious effects of stress. The objective of this study is to characterize the leukocytes transcriptome changes during housing stress after moving claves from outdoor to indoor environments. Transcriptome of blood leukocytes from 6 beef calves in outdoor pasture (d 0) was compared with that of d 1, 2 and 7 after being moved indoors. Individual calf RNA-seq libraries were sequenced using Illumina HiSeq analyzer platform. Single-end reads were mapped to the *Bos taurus* reference genome (UCSC_bosTau7) using Tophat v2.0.12. In total, 26,163 isoform transcripts pertaining to 8,606 genes were identified and 1,636 isoform transcripts pertaining to 1,320 genes were differentially expressed at d 1, d 2 and d 7 relative to d 0 (False Discovery Rate-adjusted P-value <0.05) using Cufflinks v2.2.1. The number of differentially expressed genes increased with time indoors: d 0 vs d 1 (32 genes), d 0 vs d 2 (434 genes), and d 0 vs d 7 (1170 genes). Among the top 50 differentially abundant transcripts CCAAT/enhancer binding protein C/EBP epsilon (CEBPE) and Dual Specificity Phosphatase 1 (DUSP1) were overexpressed in leukocytes collected on d 1, d 2, and d 7, relative to d 0. DUSP1 plays a role in the cellular response to environmental stress, and CEBPE is essential for terminal differentiation and functional maturation of leukocyte cells. Functional analysis of the differentially expressed genes using DAVID identified 8 enriched functional category clusters pertaining to Biological Processes, Molecular functions and KEGG Pathways (Enrichment score >2): protein synthesis and transport, cell regulation and reorganization, RNA transport, leukocyte activation, proliferation and differentiation. These categories confirm that housing stress elicits changes in the leukocyte transcriptome associated with inflammatory response. The permanency of these changes and the impact on inflammatory response to other stress sources including infection and management requires further evaluation.

Key Words: transcriptome, stress, leukocyte

W20 Short-term α-tocopherol treatment during neonatal period modulates pro-inflammatory response to endotoxin (LPS) challenge in the same calves several months later. S. Kahl* and T. H. Elsasser, *USDA, ARS, Animal Biosciences and Biotechnology Laboratory, Beltsville, MD.*

Vitamin E, a major natural antioxidant, has been previously shown to attenuate pro-inflammatory response to immune challenge in cattle. Our objective was to evaluate the effect of short-term treatment with α-tocopherol in newborn calves on selected elements of the pro-inflammatory response to LPS challenge in the same calves ~8 mo later. In 2 separate trials (T_1, T_2), newborn Angus × Hereford calves (T1, n = 41; T2, n = 17) were assigned to α-tocopherol (E, 1000 IU/d, ~1 g, i.m.) or control (C, placebo, canola oil, ~1 g) treatments. Injections of E/placebo (21/20, 8/9, in T_1 and T_2, respectively) started on the day of birth and were repeated every other day for the first 14 d of life. At the age of 237 ± 3 d (BW 276 ± 5 kg) all calves were challenged with 2 consecutive LPS injections (LPS1, LPS2) 4 d apart (0.25 µg *E. coli* 055:B5/kg BW, i.v.). Blood samples were obtained at 0, 1, 2, 3, 4, and 24 h relative to each LPS injection. In T_1, plasma concentration of tumor necrosis factor-α (TNF-α) was determined by RIA with TNF-α response to LPS calculated as area under the time × concentration curve (AUC). In T_2, plasma total antioxidative capacity (TAC), xanthine oxidase activity (XO), as well as concentration of acute phase proteins, haptoglobin (Hg) and serum amyloid-A (SAA), were measured. No differences between treatment groups were found after LPS1 and LPS2 in plasma XO and Hg, and after LPS1 in TNF-α and SAA responses. However, compared with C, E treatment decreased plasma TNF-α AUC (5.9 vs. 9.3 ng/mL × h, $P < 0.05$) and increased SAA concentration (246 vs.151 µg/mL, $P < 0.01$) after LPS2. Plasma TAC declined 4 d after LPS1 in all calves (116 vs. 168 µmol/L, $P < 0.01$) although the overall values during LPS2 were greater in E than C calves (125 vs. 106 µmol/L, $P < 0.05$). The data suggest that the i.m. treatment of calves with E during a critical first 14 d of life may serve to condition the animals toward a modified immune response later in life. Weather this implies a potential to alter the development of the immune system to improved life-long health remains to be determined.

Key Words: beef calves, endotoxin, α-tocopherol

W21 Influence of a feed additive on support of calves during initial growth phase. Jorge A. Saltijeral Oaxaca[1], Luis Galicia[1], Juan E. Guerra[2], and H. I. Rogge*[3], *[1]Universidad Autónoma Metropolitana, Mexico, DF, Mexico, [2]Universidad Autónoma de Sinaloa, Culiacan, Sinaloa Mexico, [3]Phytobiotics Futterzusatzstoffe GmbH, Eltville, Germany.*

The objective of this study was to analyze the effect of Sangrovit CS, plant-derived quaternary benzophenanthridine and protopine alkaloids (QBA+PA) on growth performance and health status of calves. A total of 160 Holstein Friesians calves obtained from 2 commercial farms of Tizayuca/Mexico were randomly assigned into 2 groups: a) control, b) Treatment (control + 5 g/meal of QBA+PA product added into the milk replacer (MR) from the 3rd until the 23rd day of life). Calves were fed twice daily 2 L of MR/meal and concentrate and alfalfa ad libitum. Colostrum, MR, bacteriological and parasitic fecal analysis were conducted. The coproparasitoscopic analyses were performed on 3 and 23 d of age of each calf. In the treatment group no antibiotic of any kind was used, whereas in control the routine farm protocols including antibiotic treatments (ATB) were conducted. The following management factors that influence the health status of the calves were considered: birth management, colostrum and feeding management, housing and hygiene of the calves. Overall, morbidity and mortality rates were 21.8% and 5.66%, respectively, both below the national benchmark parameters, with no significant differences among the groups. In the control group, 2 calves died from diarrhea whereas in the treatment no deaths were observed. The average duration of diarrhea tended to be lower in the treatment group with 2.4 d vs. 3.2 d in the control group (SD 1.25; $P = 0.07$). Parasitized calves were lower in treatment group ($P < 0.01$; Table 1). The starting weight was 38.83 kg (±SD 6.12 kg). Weight gain during the trial was 5.596 and 4.045 kg for treatment and control groups respectively ($P = 0.07$). The QBA+PA had a positive influence on the well-being and weight gain of the calves. Furthermore, it supported to remedy intestinal disorders leading to lower persistence of diarrhea and no death due to diarrhea.

Table 1 (Abstr. W21). The most common pathogens found in feces

Species	Control	Experimental
Entamoeba spp.	21	17
Eimeria spp.	3	0
Cyptosporidium parvum	0	1
Giardia spp.	1	0
Bacillus spp.	6	3
Escherichia coli	6	6

Key Words: calves, feed additive

W22 Influence of sex and temperament on response to *Salmonella* Newport extract vaccine in crossbred beef calves.

Anita M. Snell*[1,2], Jason P. Banta[2], Brittini P. Littlejohn[1,2], Sara D. Lawhon[3], Tom H. Welsh Jr.[1], Ron D. Randel[2], and Rhonda C. Vann[4], *[1]Department of Animal Science, Texas A&M, College Station, TX, [2]AgriLife Research and Extension Center, Texas A&M, Overton, TX, [3]Department of Veterinary Pathobiology, Texas A&M, College Station, TX, [4]MAFES-E.G. Morrison Brown Loam Exp. Station, Mississippi State University, , Raymond, MS.*

The effect of sex and temperament on response of crossbred beef calves to a commercially available *Salmonella* vaccine was studied. Exit velocity (m/s) and pen score (1 = calm and 5 = excitable) data collected from calves 28 d before weaning were used for assignment to 1 of 3 temperament classes (calm, n = 31; intermediate, n = 44; temperamental, n = 31). Calves, stratified by temperament class and sex, were assigned to non-vaccinated (control, n = 54) and vaccinated (n = 52) groups. Vaccinated calves received 2 mL of *Salmonella* Newport extract vaccine (Zoetis, Florham Park, NJ) twice: at weaning (d 0) and 28 d after weaning. Body weights were recorded on d 0, 28, and 56 and blood samples were taken at 7-d intervals to determine serum cortisol concentration by RIA and Ig ratio specific to the vaccine by ELISA (Epitopix, MN). Weight and age data were analyzed with mixed model procedures of SAS; sex, temperament class, and vaccine group were included as fixed effects. Average age at weaning did not differ between treatments ($P = 0.2$; 200 ± 3.9 d). Vaccination did not affect weight gain from d 0 to 28 ($P = 0.33$; 7.21 ± 0.9 kg) or d 0 to 56 ($P = 0.4$; 24.61 ± 1.1 kg). As there was no difference in performance due to vaccination only vaccinated calves were used in the remaining analysis. A specific Ig profile of each calf was assessed for maximum height for both initial (Ig1; d 0 to 21) and booster vaccination (Ig2; d 28 to 56). Neither sex ($P > 0.19$) nor temperament ($P > 0.07$) influenced peak Ig1 (0.34 ± 0.06), peak Ig1d (15 ± 1.5 d), peak Ig2 (0.70 ± 0.03), or peak Ig2d (41 ± 2.7 d). Cortisol and Ig ratio during the study were analyzed as repeated measures; the models included temperament, sex, and day as fixed effects. Temperament did not affect average cortisol ($P = 0.29$) or average Ig ratio ($P = 0.50$). Male relative to female calves had lower average cortisol ($P < 0.01$; 31.5 ± 2.8 vs 55.7 ± 2.8 ng/mL) and greater average Ig ratios ($P = 0.04$; 0.44 ± 0.03 vs 0.34 ± 0.03). Sex of calf influenced the adaptive immune response to *Salmonella* Newport extract vaccine.

Key Words: *Salmonella*, cortisol, calves

W23 Passive transfer of immunity in dairy heifer calves on Costa Rican dairy farms.

J. A. Elizondo-Salazar*[1], D. Benavides-Varela[2], A. Vargas-Ramírez[1], and C. M. Campos-Granados[3], *[1]Estación Experimental Alfredo Volio Mata, Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, San José, Costa Rica, [2]Alimentos del Norte S.A-DIPCR, Costa Rica, [3]Centro de Investigación en Nutrición Animal, Facultad de Ciencias Agroalimentarias, Universidad de Costa Rica, San José, Costa Rica.*

The objective of this study was to determine the transfer of passive immunity of dairy heifer calves in 4 provinces of Costa Rica. The data presented correspond to total serum protein (TSP) measurements obtained in 50 dairy farms. A total of 2500 heifer calves were sampled. Dam breeds were classified into Holstein, Jersey, Holstein × Jersey and other. Blood samples were collected between d 1 and 7 of age into serum Vacutainer tubes, refrigerated overnight, centrifuged, and the serum separated from clot within 24 h of collection. A hand-held refractometer was used to measure TSP. For the purpose of this study, failure of passive immunity was considered when TSP concentration was less than 5.5 g/dL. GLM procedure was used to establish differences between parity and breed of the dams. Descriptive statistics were generated to define percentage of failure of passive transfer by breed and parity of the dam. TSP concentration ranged from 2.0 to 10.0, with an overall mean of 5.9 g/dL. Of all the calves evaluated, 38.8% presented failure of passive transfer of immunity. Calves born to Jersey and Holstein × Jersey crosses had significantly ($P < 0.05$) higher TSP concentrations than calves born to Holstein and other breeds. When considering parity of the dam, there were no significant differences ($P > 0.05$) on TSP concentration; however, offspring born to first lactation heifers showed the lowest percentage of animals with inadequate transfer of immunity. Calves that were allowed to suckle their dams showed a 44% failure of passive immunity against 33% of calves that were given colostrum by bottle. The findings of this study suggest that minimizing the risk of calves with failure of passive transfer of immunity is an important task to perform in dairy herds of Costa Rica.

Table 1 (Abstr. W23). Effect of dam breed over total serum protein (TSP) concentration in 2500 heifer calves from 1 to 7 days old in 50 dairy farms located in four provinces of Costa Rica[1]

Dam breed	n	TSP, g/dL	Animals with FPTI, %
Holstein	769	5.8 ± 0.06^b	39^b
Holstein × Jersey	287	6.4 ± 0.09^a	25^a
Jersey	743	6.3 ± 0.07^a	27^a
Other	740	5.4 ± 0.07^c	55^c

[1] n = number of animals; FPTI = failure of passive transfer of immunity.

Key Words: total serum protein, colostrum, passive immunity

W24 Prevalence of bovine respiratory disease in pre-weaned dairy calves in Northern California.

Betsy M. Karle*[1], Sasha A. Dubrovsky[2], William J. Love[3], Deniece R. Williams[3], Jeffery W. Stackhouse[4], Randall J. Anderson[5], Alison L. Van Eenennaam[2], Terry W. Lehenbauer[3,5], and Sharif S. Aly[3,5], *[1]University of California Cooperative Extension, Orland, CA, [2]University of California Department of Animal Science, Davis, CA, [3]UC Davis Veterinary Medicine Teaching and Research Center, Tulare, CA, [4]University of California Cooperative Extension, Eureka, CA, [5]California Department of Food and Agriculture, Animal Health Branch, Sacramento, CA, [6]Department of Population Health and Reproduction, School of Veterinary Medicine, University of California, Davis, Davis, CA.*

Bovine respiratory disease (BRD) is one of the most important diseases affecting the health of dairy calves. The objective of this cross-sectional study was to estimate the prevalence of BRD in pre-weaned dairy calves and identify management practices that may be risk factors for BRD. A total of 31 dairies in 3 regions in Northern California were surveyed by convenience sample. Represented counties included Humboldt and

Del Norte (Region 1, average herd size 788, n = 10), Sonoma, Marin and Mendocino (Region 2, average herd size 305, n = 11), and Glenn, Tehama and Yuba (Region 3, average herd size 1,010, n = 10). A comprehensive questionnaire focusing on calf management practices and relevant demographic information was administered via in-person interviews at each dairy. Calves currently raised on each dairy were randomly sampled and evaluated using the California BRD scoring system. A total of 1,438 calves were evaluated, and mean BRD prevalence was 10.2% (95% CI 8.7, 11.6), which did not differ significantly across regions ($P = 0.67$; 10.7% Region 1, 8.9% Region 2 and 12.5% Region 3). Overall BRD prevalence was 10.5% on organic dairies and 10.8% on conventional dairies ($P = 0.93$). Herd size, volume of colostrum fed within 12 h of birth, testing colostrum for IgG concentration or age that calves were moved to group pens were not significantly associated with BRD prevalence at the herd level. Additionally, age, sex, and airborne ammonia concentrations within 1 foot of the hutch or housing floor were not significantly associated with BRD in calves. Group housing of pre-weaned calves was common in Northern California, with pens containing between 2 to 40 calves, and significantly increased the odds of BRD (OR 1.07, $P < 0.001$). Additionally, the prevalence of BRD in Jersey calves was 2.2 times higher than in Holstein calves ($P < 0.001$). Respiratory disease clearly affects calves throughout Northern California. While factors affecting the prevalence of BRD are apparent, further research is needed to identify additional management practices that affect prevalence of respiratory disease in pre-weaned dairy calves.

Key Words: BRD, preweaned calves, scoring system

W25 Risk factors for diarrhea and pneumonia in Holstein calves offered colostrum of different quality in a hot environment. Edir Torres-Rodriguez*[1], Miguel A. Mellado-Bosque[2], Jose E. Garcia-Martinez[2], and Francisco G. Veliz-Deras[1], *[1]Universidad Autonoma Agraria Antonio Narro, Torreon, Coahuila, Mexico, [2]Universidad Autonoma Agraria Antonio Narro, Saltillo, Coahuila, Mexico.*

Intake of non-contaminated and high immunoglobulin content colostrum by neonatal calves is an important factor in successful calf programs. The objectives of this study were to determine the risk factors for the occurrence of diarrhea and pneumonia by evaluating colostrum quality (Ig content determined with colostrometer and refractometry) and bacterial contamination in 300 Holstein calves born in June 2014. A second objective was to describe the effect of feeding colostrum of different quality on growth and physiological parameters in neonatal calves. Calves were removed from their dams shortly after parturition and fed 2.8 L of colostrum by bottle; calves were placed in individual portable roofed pens. Colostrum variables were total bacterial counts, coliform bacteria counts, refractometry values, and Ig content. Multivariable logistic-regression analyses were performed. None of the variables included in the model affected the occurrence of diarrhea. The calves with highest odds of pneumonia were those receiving colostrum with total standard plate counts >15,000/mL (odds ratio = 1.8). Calves fed colostrum with < 15,000 counts/mL (n = 145) had greater weaning weights (66.3 kg ± 6.7 vs. 63.4 kg ± 6.7; $P < 0.01$) and preweaning daily weight gain (0.515 kg/d ± 116 vs. 0.477 kg/d ± 123; $P < 0.01$) than calves fed colostrum with >15,000 counts/mL (n = 155). Calves fed colostrum with the highest bacterial counts presented higher ($P < 0.01$) values for fecal consistency (1.5 ± 0.8) than calves receiving colostrum with low bacterial counts (1.2 ± 0.5; scale 1 to 4, with 1 being normal feces to 4 being severe diarrhea; $P < 0.01$). Calves receiving colostrum with higher Ig content (>85 mg/mL, measured with colostrometer) presented feces more solid ($P < 0.01$) than calves receiving colostrum with Ig < 85 mg/mL (1.2 ± 0.6 vs 1.5 ± 0.9). There was no difference between groups when examining the effect of different characteristics of colostrum on height to withers, respiration condition and rectal temperature. Given the conditions of this trial, feeding colostrum with <15,000 total bacterial counts/ml reduced the odds of pneumonia and enhanced growth rate of Holstein calves in a hot environment.

Key Words: colostrum, total standard plate count, calves

W26 Preweaning plane of nutrition and *Mannheimia haemolytica* dose influence metabolic responses to a combined bovine herpesvirus-1 and *Mannheimia haemolytica* challenge in post-weaned Holstein calves. K. P. Sharon*[1,2], Y. L. Liang[1], N. C. Burdick Sanchez[2], J. A. Carroll[2], P. R. Broadway[2], and M. A. Ballou[1], *[1]Texas Tech University, Department of Animal and Food Sciences, Lubbock, TX, [2]USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

To determine whether previous plane of milk replacer nutrition (PON) and *M. haemolytica* (MH) dose influences metabolic responses to a combined viral-bacterial respiratory challenge, Holstein calves (1d of age; n = 30) were assigned to treatments in a 2 × 3 factorial with preweaned PON and dose of MH as main effects (n = 5/treatment). Calves were fed either a low (LPN; n = 15) or a high PON (HPN; n = 15) from birth through weaning. Calves fed the LPN were fed 445g DM/d of milk replacer until weaning, and HPN calves were fed 830g DM/d of milk replacer from 1 to 10d and 1080g from 11d until weaning. Calf starter and water were offered ad libitum. Calves were step-down weaned beginning at 54d and moved into an enclosed barn at 70d. Indwelling jugular catheters were inserted at 80d. Calves were challenged with 1.5×10^8 PFU/mL/nostril of bovine herpesvirus-1 (BHV-1) at 81d and with 10^6, 10^7, or 10^8 cfu of MH at 84d. Blood samples were collected at varying intervals respective to BHV-1 and MH challenges. Body weights at 70d were different ($P < 0.01$) between LPN and HPN calves (62.2 vs 81.2 ± 2.67 kg, respectively). Although HPN calves consumed more calf starter ($P < 0.01$) during the challenge, there were no differences ($P \geq 0.42$) in ADG or when intake was expressed per kg $BW^{0.75}$. Glucose concentrations were greater ($P \leq 0.02$) in HPN compared with LPN calves during both BHV-1 (61.1 vs 57.5 ± 1.01 mg/dL, respectively) and MH challenges (57.8 vs 53.5 ± 1.13 mg/dL, respectively). Following the MH challenge, calves receiving 10^8 MH had the greatest ($P = 0.05$) NEFA concentrations. During the BHV-1 challenge, there was a time × PON interaction ($P = 0.02$) for plasma urea N concentrations, where LPN calves had greater ($P = 0.02$) concentrations at 72 h. Glucose concentrations were reduced among LPN calves throughout the respiratory challenge, and calves receiving 10^8 MH mobilized more lipid reserves after the MH challenge suggesting calves fed a LPN during preweaning and calves receiving a 10^8 MH dose results in a more severe response to a viral-bacterial respiratory challenge.

Key Words: health, nutrition, respiratory

W27 Effect of repeated intravenous LPS infusions in endometrium gene expression and inflammatory response in Holstein heifers. Artur C. C. Fernandes*[1,2], Juliana S. Souza[1], Douglas Veira[1], Audrey Nadalin[1], Lúcio E. H. Melo[2], and Ronaldo L. A. Cerri[1], *[1]Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada, [2]Federal Rural University of Pernambuco, Recife, Pernambuco, Brazil.*

This study aimed to evaluate the effect of repeated intravenous lipopolysaccharide (LPS) stimulus in endometrial gene expression of candidate transcripts of nonlactating heifers on late luteal phase. Heifers (n = 22; 11 mo of age) were synchronized by the ovsynch protocol and enrolled into control group (CON; n = 11) that received sterile saline solution i.v., or LPS group (LPS; n = 11) submitted to repeated LPS injections i.v. (0.1; 0.25; 0.5; 0.75; 1.0; 1.25 μg/kg WB) starting 2 d (d) after AI (d0), then every other d. At each injection, rectal temperatures were measured during 6 h. Blood samples were collected from the d-1 to d13, for analyses of TNF-α, haptoglobin, progesterone, and WBC count and differential. On d15, endometrium tissue biopsies were taken and kept at −80°C until qRT-PCR analysis of 30 target genes related to immune system, adhesion molecules and endometrium receptivity. Data were checked for normality and analyzed by ANOVA for repeated measures using proc MIXED and UNIVARIATE. After each injection, temperature was greater in the first 6h in the LPS compared with CON group ($P < 0.05$). Both TNF-α ($P = 0.05$) and haptoglobin ($P < 0.01$) were increased in the LPS group with significant ($P < 0.05$) treatment by d interactions. Total leukocyte count was not different between treatments ($P = 0.29$), but differential count was increased for neutrophils, band cells and monocytes, but decreased for lymphocytes and eosinophil in LPS compared with CON group ($P < 0.01$). Progesterone concentrations during the experimental period were not different between treatments. Out of the 30 target genes analyzed, only 3 transcripts were differentially expressed. IDO ($P = 0.04$; Fold = 0.48) and PTX3 ($P = 0.01$; Fold = 0.38) were downregulated, whereas MX1 ($P = 0.02$; Fold = 2.85) was upregulated in the LPS group. Sequential LPS injections was able to induce a systemic pro-inflammatory state with limited, but strong effect in gene expression of transcripts related to the immune system, suggesting a possible explanation for sub-fertility related to health disorders in dairy cows.

Key Words: gene expression, heifer, LPS

W28 Performance of Jersey calves born from dams treated with recombinant bovine somatotropin during the periparturient period. Paula R. B. Silva*[1], Henrique F. Soares[1], Gabriel D. Bombardelli[1], and Ricardo C. Chebel[1,2], [1]*University of Minnesota, St Paul, MN,* [2]*University of Florida, Gainesville, FL.*

Objectives of the current experiment were to evaluate the performance of Jersey calves born from Jersey dams treated with recombinant bovine somatotropin (rbST) during the periparturient period. Jersey dams were assigned randomly to control (n = 264) and rbST (125 mg of rbST every 7 d from −21 to 21 d relative to calving; n = 258) treatments. A sub-sample (control = 19, rbST = 19) of cows had colostrum samples collected at calving to determine IgG concentration. Male Jersey calves were sold at birth, leaving 199 and 173 calves from control and rbST cows. Calves born from cows enrolled in this experiment were fed pooled colostrum (4 L) twice within 6 h of birth, were housed in individual hutches from birth to 21 d of age, and in group pens with automated calf feeders from 22 d of age to weaning (60 d of age). Calves were weighed individually at birth (control = 198, rbST = 172) and at weaning (control = 122, rbST = 107) and average daily gain in the first 60 d of life was calculated. Calves were observed daily for diagnosis of diarrhea and respiratory illness. Data referent to health and performance to 60 d of age is reported herein. Continuous data were analyzed by ANOVA and dichotomous data were analyzed by logistic regression. Colostrum IgG concentration was not different between treatments (control = 87.6 ± 6.4, rbST = 94.5 ± 6.4 g/L; $P = 0.45$). Treatment did not affect birth weight (control = 27.9 ± 0.4, rbST = 27.4 ± 0.5 kg; $P = 0.24$), weaning weight (control = 70.5 ± 1.8, rbST = 71.1 ± 1.8 kg; $P = 0.60$) or average daily gain (control = 0.74 ± 0.03, rbST = 0.74 ± 0.03 kg/d; $P = 0.88$). There was a greater likelihood of calves born from rbST cows to be diagnosed with diarrhea (control = 1.0, rbST = 4.6%; $P = 0.05$) but treatment did not affect the likelihood of pneumonia (control = 25.6, rbST = 27.8%; $P = 0.61$) and death (control = 10.6, rbST = 13.3%; $P = 0.41$) within the first 60 d of life. Treatment of periparturient Jersey cows with small doses of rbST did not affect performance and health of calves up to 60 d of life.

Key Words: recombinant bovine somatotropin, Jersey calves, performance

W29 Supplementation of *Saccharomyces cerevisiae* fermentation products for the prevention of geophagia in Holstein female calves fed milk in buckets. Sonia Vazquez-Flores*[1], Stephany Barrera-Almanza[1], María de Jesús Guerrero[2], Kristy Dorton[3], Mark Scott[3], and William Sanchez[3], [1]*Tecnológico de Monterrey, Querétaro, Querétaro, México,* [2]*Universidad Autónoma de Querétaro, Querétaro, Querétaro, México,* [3]*Diamond V, Cedar Rapids, IA.*

The objective of the study was to compare 2 nutritional complements delivered in feed to diminish geophagia in neonatal calves with or without concurrent gastrointestinal diseases. Ruminal acidosis has been extensively studied in adult ruminants, and neglected in neonatal calves. Under certain feeding systems like bucket feeding milk, a common practice in most dairies in Mexico; it becomes the main factor for nutritional behavioral changes. Sand eating (geophagia) leads to tympanism, bruxism, depression, enterotoxemia, and sudden deaths. 60 Holstein female calves were randomly assigned at birth to 1 of 3 treatments: maltodextrin (C); BIOMOS (T1); and Smartcare/XPC (T2). Treatments were delivered in colostrum and in both whole UV purified milk and calf starter for up to 60 d in the morning feeding. Urine, blood and fecal samples (6, 2 and 8 respectively) were collected from each calf during the neonatal period. Analysis for bacteriological, parasitological and pH determination were performed. Binomial and repeated measures were determined by Welch ANOVA test, Duncan's test for multiple comparisons, Bartlett and Logistic Fit, nonparametric tests and odds ratio. Urine pH showed a range from 5 to 9, stratification was made taking 3 parameters from Oetzel, 2003: acid pH (5–6.9); neutral pH (7–7.9) and alkaline pH (8–9). See Table 1 for results. A statistical correlation was found with least squares means analysis for geophagia cases and days in diarrhea for the C group. No differences were found in diarrhea and *E. coli*, *Salmonella* spp., *Campylobacter* spp. and *Cryptosporidium* spp. with Tukey-Kramer test. Supplementation of T2 to neonatal calves' diet allowed the neonate to control best the metabolic acidity, being twice as often the need for buffers in the C group.

Table 1 (Abstr. W29).

Treatment group	Acid urine pH (5-6.9)	Geophagia mean (SD)	Odds ratio (95% CI) for no geophagia cases
C	61.7% (74)	0.23 (0.44)	
T1	73.3% (88)	0.2 (0.41)	vs. control: 0.54 (0.15–1.9)[a]
			vs. control: 0.12 (0.028–0.53)[a]
T2	72.5% (87)	0.1 (0.31)[b]	vs. T1: 0.25 (0.04–0.97)[b]

[a]Significant difference (*P*-value = 0.05); [b]highly significant difference (*P*-value = 0.006).

Key Words: neonatal, calves, acidosis

W30 Comparison of the effect of LongRange (eprinomectin) versus Dectomax (doramectin) and fly tags on growth of post-weaned grazing dairy heifers. M. W. Sahar[1,2], J. E. Tower[1], T. S. Dennis[1], A. M. Mosiman[1], H. F. P. Schmitz[1], R. K. Tessman[3], and T.

D. Nennich*[1,4], [1]*Purdue University, West Lafayette, IN,* [2]*Kabul University, Kabul, Afghanistan,* [3]*Merial, Hallsville, MO,* [4]*Famo Feeds, Freeport, MN.*

Limited information is available on gain and structural growth of young grazing dairy heifers when treated with different parasiticides. The objective of this study was to compare the effects of LongRange (eprinomectin) (LGR) against Dectomax (doramectin) and pyrethroid impregnated fly tags (DFT) on gain, structural growth, and fecal egg counts (FEC) of grazing, post-weaned Holstein dairy heifers. Forty-eight heifers were randomly grouped into 12 paddocks according to BW (169.5 ± 8.5 Kg of BW and 149.8 ± 13.8 d of age) and assigned to 1 of 2 treatments: 1) LGR or 2) DFT. The BW, hip height (HH), withers height (WH), hip width (HW), body condition score (BCS), heart girth (HG), blood samples, and fecal samples were collected every 4 wk from June until August 2014. Face flies (FF) and horn flies (HF) were counted twice/wk. Water consumption for each paddock was recorded 2 times/wk. Temperature and relative humidity were recorded hourly. Data were analyzed using PROC MIXED in SAS as repeated records using pen within treatment as a random variable. Daily midday temperatures (1200 to 1500 h) averaged 26.9 ± 0.14°C during the study. The ADG did not differ between treatments (mean ADG = 0.92(0.02) Kg/d; $P = 0.79$) with BW at the end of the study averaging 210.2 and 208.9(1.02) Kg ($P = 0.38$) for LGR and DFT, respectively. The HH and WH ($P = 0.61$) averaged 117.4(0.29) and 112.3(0.39) cm, respectively, at the end of the study. The HG ($P = 0.38$), HW ($P = 0.34$), and BCS ($P = 0.86$) were also similar between treatments. However, PUN values tended to be greater ($P = 0.06$) for LGR compared with DFT (12.7 and 11.4(0.28) mg/dL, respectively). Water intakes averaged 18.8 L/d for DFT and 20.1(2.07) L/d for LGR ($P = 0.67$). Fecal egg counts were lower ($P = 0.02$) for heifers treated with LGR compared with DFT (95.2 and 246.7(60.7) epg, respectively) and HF counts tended ($P = 0.08$) to be lower for DFT than LGR (9.7 and 17.2(0.08) flies/heifer, respectively) with no differences in FF counts ($P = 0.24$). Treating post-weaned grazing Holstein dairy heifers with either LGR or DFT resulted in similar growth performance; however, LGR reduced FEC and DFT reduced the presence of horn flies.

Key Words: doramectin, dairy heifer, eprinomectin

W31 Associations between fecal pathogens, growth, and clinical signs of diarrhea in dairy heifer calves.

Elizabeth S. Binversie*, Melissa C. Cornett, Catie C. Cramer, and Amy L. Stanton, *University of Wisconsin-Madison, Department of Dairy Science, Madison, WI.*

Diarrhea can affect the health, performance, and welfare of preweaned dairy calves. The objectives for this project were to determine (1) associations between a positive test for a fecal pathogen and the probability of a calf showing clinical signs of diarrhea and (2) the impact of number of positive fecal tests on calf growth. The study population included dairy heifer calves (n = 54) on a commercial dairy that were enrolled in a 2 × 2 factorial study design examining a direct fed microbial and 2 milk programs. Feces were collected weekly for the first 4 weeks of life and tested for presence of 4 fecal pathogens: Rotavirus (ROT), Coronavirus (COR), *E. coli* K99 (F5) (ECO) and *Cryptosporidium* (CRP) (Enterichek). Clinical diarrhea was identified using a standardized fecal score that combined observations of odor, consistency, fluidity and color. Calves were weighed at birth (BW) and 5 weeks of age (WT5). The association between pathogen and diarrhea was evaluated with a logistic regression model (PROC GLIMMIX, SAS) with calf as a random effect and an autoregressive covariance structure. The association between weight at 5 weeks and number of positive fecal tests was evaluated using a linear regression model (Proc Mixed), controlling for initial weight and calf age. At 2 weeks of age calves were 5.8 times [95% CL: 2.2 to 15.3] as likely to test positive for at least one fecal pathogen compared with 4 ($P < 0.001$). Controlling for age, calves that tested positive for CRP were 2.8 times [95% CL: 1.2 to 6.4] as likely to show clinical signs of diarrhea ($P < 0.05$). Rotavirus and ECO were not associated with clinical signs of diarrhea. *E. coli*, CRP, and COR were not significantly associated with WT5. Rotavirus was associated with WT5 ($P < 0.05$). Calves with ROT at 1 or 2 time points weighed 5.1 ± 1.9 kg (LSM ± SEM) and 5.3 ± 1.9 kg (LSM ± SEM) less than calves that never tested positive, respectively ($P < 0.001$). In conclusion, although considered to be associated with a single diarrheal complex, specific pathogens may have different effects on growth, and knowledge of pathogens present may provide greater insight into treatment and management of calves with diarrhea.

Key Words: calves, growth, diarrhea

W32 Efficacy of feeding First Day Formula CR versus maternal colostrum on calf serum immunological parameters.

Alfonso Lago*[1], Claudia Leonardi[1], Cedric Blanc[2], David Cook[3], Michael Socha[4], and Humberto Rivera[5], [1]*DairyExperts Inc., Tulare, CA,* [2]*Pacific Rim Dairy, Corcoran, CA,* [3]*Milk Products Inc., Chilton, WI,* [4]*Zinpro Corporation, Eden Prairie, MN,* [5]*Accelerated Genetics, Baraboo, WI.*

Commercially available colostrum replacers (CR) are commonly used for convenience, when maternal colostrum (MC) is unavailable, of questionable quality or in disease control programs. The objective was to determine the efficacy of a colostrum-derived CR, First Day Formula CR (Accelerated Genetics, Baraboo, WI), versus raw MC on immunological parameters. A total of 1,220 female and male Jersey and crossbred calves born in a California Central Valley dairy were systematically assigned to either CR or MC based on birth order. Calves assigned to CR were tube fed the CR product, reconstituted with 1.9 L of water and calves assigned to MC were tube fed 2.8 L of MC at 1 h ± 5 min after the calf was born. Every sixth calf born between 1:00 to 7:00 and 9:00 to 15:00 h that was enrolled was weighed and bled before first feeding and all calves born during those time intervals were bled at 22 to 28 h after birth. Immunoglobulin G (IgG) concentration was determined in serum samples using a radial immunodiffusion kit (Triple J Farms, Bellingham, WA). IgG was also measured in MC fed to every sixth calf born during the previously mentioned time intervals. The CR provided ~150 g IgG per dose and MC contained an average of 63.6 mg/mL of IgG. Outcome variables included serum IgG at 22 to 28 h after birth (n = 592), failure of passive transfer (FPT) defined as serum IgG < 10 mg/ml (n = 592), and apparent efficiency of absorption (AEA) (n = 96), calculated as grams of IgG absorbed into blood circulation. Only one calf in each treatment group (CR and MC) experienced FPT. The mean serum concentration of IgG was 19.8 mg/mL for calves fed CR and 23.4 for MC ($P < 0.05$). However, AEA of IgG did not differ between treatments and was 34.4% for CR and 35.9% for MC ($P = 0.52$). Therefore, the slightly higher mean blood concentration of IgG for calves fed MC was due mainly to a higher IgG intake. Overall, IgG absorption and serum concentration of calves were within acceptable ranges when fed either CR or MC. In this study the parameters measured indicated that the CR used was comparable to MC in eliciting passive transfer.

Key Words: calves, colostrum, immunoglobulin

W33 Relationship between serum total proteins and immunoglobulin G for calves fed either First Day Formula CR or maternal colostrum.

Alfonso Lago*[1], Claudia Leonardi[1], Cedric Blanc[2], David Cook[3], Michael Socha[4], and Humberto Rivera[5], *[1]DairyExperts Inc., Tulare, CA, [2]Pacific Rim Dairy, Corcoran, CA, [3]Milk Products Inc., Chilton, WI, [4]Zinpro Corporation, Eden Prairie, MN, [5]Accelerated Genetics, Baraboo, WI.*

Total serum proteins concentration (TP) is frequently measured in calves to evaluate adequacy of passive transfer of immunoglobulin G (IgG) from colostrum. However, calves fed some commercially available colostrum-derived colostrum replacers (CR) may have lower serum TP at equal IgG concentrations than calves fed maternal colostrum (MC). This can be due to removal of some proteins during manufacturing of CR. The objective was to determine the linear relationship between TP and IgG for CR and MC. Serum IgG and TP measurements from blood collected at 22 to 28 h after birth were available from 299 calves fed CR (First Day Formula CR, Accelerated Genetics, Baraboo, WI) and 292 calves fed MC. Concentration of IgG was determined using a radial immunodiffusion kit (Triple J Farms, Bellingham, WA) and TP using a digital refractometer (Misco, Model DD-2, Solon, OH). The linear relationship between TP and IgG was investigated for MC and CR using the Reg procedure of SAS (SAS Institute Inc., Cary, NC). The following are the linear relationships between IgG and TP in serum for the CR [IgG mg/mL = $-9.87(\pm1.88) + 5.77(\pm0.36) \times$ TP g/dL] and MC [IgG mg/mL = $-45.30(\pm2.58) + 12.45(\pm0.44) \times$ TP g/dL]. For both CR and MC, a linear relationship between TP and IgG was observed ($P < 0.01$). However, for CR, a smaller percentage of the variability in IgG was accounted by TP ($R^2 = 0.465$ for CR and $R^2 = 0.738$ for MC). The TP value that resulted in IgG equal to 10 mg/mL (90% CI) was 3.44 g/dL (2.48, 4.38) for CR and 4.44 g/dL (3.65, 5.23) for MC. The 90% CI for MC includes the classical reference value of 5.2 g/dL indicating that the value estimated in the present study is not significantly different from the classical reference. Only one calf fed CR and one calf fed MC had a serum IgG value less than 10 mg/mL, making the estimation of the TP cut point for failure of passive transfer potentially inaccurate. In conclusion, lower serum TP values at equal IgG concentrations were found when feeding CR compared with MC. Therefore, a lower TP cut point indicative of successful passive transfer of IgG should be used when using CR.

Key Words: calves, replacer, total protein

W34 Prophylactic efficacy of an engineered biotherapeutic fusion protein against *Cryptosporidium parvum* in experimentally challenged neonatal calves.

Travis J. De Wolfe*[1], Sheila M. McGuirk[1], Nicholas S. Keuler[1], Robert D. Bremel[2], Jane Homan[2], Michael Imboden[2], Deborah A. Schaefer[3], and Benjamin J. Darien[1], *[1]University of Wisconsin-Madison, Madison, WI, [2]ioGenetics, Inc., Madison, WI, [3]University of Arizona, Tucson, AZ.*

Cryptosporidium parvum is a parasitic pathogen that causes gastroenteritis in cattle and humans. The host innate immune response to *C. parvum* infection is associated with expression of enteric antimicrobial peptides that may represent a useful prophylactic to prevent *C. parvum* infection. The aim of this study is to evaluate a model of *C. parvum* infection and to evaluate the prophylactic efficacy of a *C. parvum*-specific monoclonal antibody, 4H9, fused to the human cathelicidin LL-37 (4H9-G1-LL37) in *C. parvum* challenged calves. Holstein bull calves (n = 18) were randomly assigned to receive either 0 mg (control), 20 mg, or 100 mg of fusion protein 4H9-G1-LL37 orally upon birth. Approximately 36–44 h later, calves were challenged with 1×10^7 *C. parvum* oocysts. Fecal consistency, daily total fecal volumes, daily oocyst concentration (oocysts/mL), and total daily oocysts shed were assessed over a 10-d post-challenge period. Prior to experimental *C. parvum* challenge all calves tested negative for *C. parvum* and by d 3 post-challenge all calves were shedding *C. parvum* oocysts in feces and had developed diarrhea. The control calves exhibited features of a natural infection, with diarrhea occurring between 4 and 7d post-challenge. The daily oocyst concentration was determined by immunofluorescence microscopy. Enumeration of total daily oocysts shed, was calculated as the product of the oocyst concentration and the total fecal volume collected for the corresponding day. The daily oocyst concentration was highly correlated with total daily oocysts shed for d 2–10 in the control calves, validating both quantification methods as robust measures of shedding even during peak oocyst production. Prophylactic treatment (20 mg) of calves before challenge tended to reduce total oocyte shedding on d 6 compared with control calves ($P = 0.085$). These results validated the oocyst quantification technique and demonstrate the potential efficacy of the prophylactic fusion protein 4H9-G1-LL37 in reducing *C. parvum* shedding. These results also suggest that additional studies with a larger sample size are warranted.

Key Words: *Cryptosporidium parvum*, cathelicidin, fusion protein

W35 Association between plasma haptoglobin concentration and bovine respiratory disease status in preweaned dairy calves.

Sonia J. Moisá*[1], Sharif S. Aly[2], William J. Love[2], Terry W. Lehenbauer[2], Alison L. Van Eenennaam[3], and Lindsey E. Hulbert[1], *[1]Department of Animal Sciences and Industry, Kansas State University, Manhattan, KS, [2]School of Veterinary Medicine, University of California-Davis, ,Tulare, CA, [3]Department of Animal Sciences, University of California-Davis, Davis, CA.*

The objective of this case-control study was to assess the association between bovine respiratory disease score, determined by a scoring system (BRDs), and plasma Haptoglobin concentration (Hp). Four dairy operations located in the central San Joaquin Valley of California participated in this study (A, B, C, D) during the months of April to September, 2013. At each location, heifer or bull dairy calves were identified using as treatments BRDs-positive (n = 150); and randomly chosen calves within the same age group, sex, and breed (Jersey or Holstein) served as controls (Con; n = 356). Whole blood was collected, and plasma Hp concentrations were measured using a colorimetric method base on peroxidase activity. In addition, each calf had a respiratory examination via thoracic auscultation (Au) and Ultrasound (Us). Haptoglobin data were analyzed using the MIXED procedure of SAS using age as a covariate with BRDs as the fixed effect in the statistical model with breed, sex, Au, Us, or location analyzed separately. Some Con calves had abnormal Au (n = 22; 15%) and some of the BRDs calves had normal Au (n = 113; 32%). Preliminary results showed that BRDs-positive calves with abnormal Au and Us tended to have higher Hp ($P = 0.10$ and $P = 0.13$ respectively). Location accounted for variation in Hp ($P = 0.01$); Control calves at D had greater concentrations of Hp than Con calves at the other locations. In addition, BRDs-positive calves at A had lower Hp than BRDs-positive calves at the other locations. Further investigation is needed to determine if Hp can serve as a biological marker for respiratory disease in BRDs-positive or negative calves with abnormal Au and Us. Also, baseline concentrations for haptoglobin may need to be established for specific locations.

Key Words: bovine respiratory disease, haptoglobin, preweaned dairy calves

W36 Cosinor analysis of CRT in heifers.

Alexander W. Altman*[1], Nicole C. Burdick-Sanchez[2], Jeffery A. Carroll[2], Ty B. Schmidt[3], Kyle R. McLeod[1], Glen E. Aiken[4], and Eric S. Vanzant[1],

[1]*Department of Animal and Food Sciences, University of Kentucky, Lexington, KY,* [2]*Livestock Issues Research Unit, USDA-ARS, Lubbock, TX,* [3]*Department of Animal Science, University of Nebraska-Lincoln, Lincoln, NE,* [4]*Forage Animal Production Research Unit, USDA-ARS, Lexington, KY.*

Cosinor analysis can detect changes in phase, amplitude, or means of circadian rhythm of body temperature (CRT). Two experiments (E1: 22 Angus heifers, 292 ± 9 kg BW; E2: 16 Angus and 8 Hereford × Angus heifers, 335 ± 11 kg BW) evaluated changes to CRT due to a minor, chronic stressor (endophyte) and a major, acute stressor (LPS). Diets, starting 10 d before LPS challenge and fed at 1.8 × NE_m in individual stalls (3.0 × 3.7 m), contained 20% of either endophyte-free (E-) or endophyte-infected (E+) fescue seed, 30% cottonseed hulls, 36% cracked corn, and 14% supplement and were balanced to meet protein and mineral requirements. E2 included MGA (0.5 mg/hd/d) and evaluation of weaning exit velocity (wEV).Vaginal (E1 and E2) and rectal (E2 only) temperature probes recorded body temperature every 5 min. Cosinor analysis was used to analyze data in each of 4 phases: pre-treatment diet (P1), treatment diet, pre-LPS (P2), post-LPS temperature spike 1 (P3), post-LPS temperature spike 2 (P4). Disruption to CRT occurred during P2 of both experiments, as evidenced by 39% of curves failing to fit a cosine model (i.e., less than 40% R^2) compared with only 5% of curves failing to meet inclusion criteria for all other phases, suggesting that abrupt dietary shifts can affect temperature regulation. Amplitude differences across days ($P = 0.05$) occurred in P1 of E1, when mean temperatures did not differ ($P > 0.10$). Amplitude ($P = 0.80$) and mean temperature ($P = 0.66$) between treatment groups in P3 of E1 were similar, but shifts in timing of the peak ($P = 0.09$) occurred. Endophyte affected vaginal temperature amplitudes in P2 ($P = 0.07$) and P4 ($P = 0.08$) of E2 without influencing mean temperatures. Shifts in timing of peak vaginal temperatures during P1 ($P = 0.01$) of E2 across days may indicate adaptation of CRT to shifts in environment. Treatment × wEV interactions were significant for mean rectal, but not vaginal, temperatures during P1 ($P = 0.10$), P2 ($P = 0.10$), and P3 ($P = 0.04$) of E2, indicating different temperature responses between sites. These data demonstrate that cosinor analysis can be used to detect shifts in CRT responses that would not be detected by evaluation of mean temperature responses alone.

Key Words: endophyte, LPS, CRT

W37 Effect of bovine genotype on heifer response to repeated lipopolysaccharide (LPS) administration.

Georgina Cousillas*[1], Aimee Benjamin[2], Wanda J. Weber[1], David Kerr[2], Theodore H. Elsasser[3], Stanislaw Kahl[3], and Brian A. Crooker[1], [1]*University of Minnesota, St. Paul, MN,* [2]*University of Vermont, Burlington, VT,* [3]*USDA-ARS, Beltsville, MD.*

Heifers (n = 4/genotype) from unselected (stable milk yield since 1964, UH) and contemporary (CH) Holsteins that differed in milk yield (6,200 and 11,100 kg milk/305 d) or from Red Angus cows (RA) were fed the same diet ad lib and housed together for 47 d before being challenged with 0.5 µg LPS/kg BW. Heifers were 20 mo old and pregnant except for 2 CH heifers that were synchronized to be at d 8 of their cycle at the first LPS challenge (C1). Progesterone exceeded 3.5 ng/mL at C1. Jugular catheters were implanted 24 h before LPS (*Escherichia coli* O111:B4). Blood samples were collected at −1, −0.5, 0, 1, 2, 3, 4, 6, 8, and 24 h relative to LPS administration and plasma harvested. Body temperatures (BT) were determined at these times and at 5 and 7 h. A second identical LPS challenge (C2) was administered 4 d later. Data were analyzed by repeated measures using PROC MIXED (SAS). Means differed when $P < 0.05$. Cortisol, interleukin-6 (IL-6), xanthine oxidase (XO), and tumor necrosis factor α (TNFα) were greater ($P < 0.01$) in C1 than C2, BT and IGF-1 were less ($P < 0.01$) and glucose and nitric oxide (NOX) did not differ ($P > 0.11$) between C1 and C2. There were genotype x challenge x time interactions ($P < 0.05$) for BT, glucose and TNFα. During C1, BT increased earlier and peaked higher in RA than UH or CH, glucose increased less in RA than UH or CH, and TNFα increased more in CH than UH and RA. Glucose, TNFα, and BT did not differ ($P > 0.10$) among genotypes during C2. There was an interaction of genotype and challenge for IL-6 as response in UH was greater than in CH or RA in C1 but there was no effect of genotype on IL-6 in C2. There was a trend for NOX ($P = 0.10$) to be less in RA than in UH or CH and a trend ($P = 0.10$) for a genotype × challenge interaction for XO as XO was greater in UH than in CH and RA in C1 but not in C2. Results indicate the reduced response during a repeated challenge decreases the ability to detect an effect of genotype on LPS. Regardless, results indicate genotype affects bovine response to LPS and that the effect of genotype differs among the response variables assessed in this study.

Key Words: innate immunity, bovine genotype, lipopolysaccharide

W38 The effects of plane of milk replacer nutrition on the health and performance of high-risk Holstein bull calves from a commercial calf ranch.

K. P. Sharon*[1,3], L. E. Hulbert[2], J. A. Carroll[3], and M. A. Ballou[1], [1]*Department of Animal and Food Sciences, Texas Tech University, Lubbock, TX,* [2]*Department of Animal Sciences and Industry, Kansas State University, Manhattan, KS ,* [3]*Livestock Issues Research Unit, USDA-ARS, Lubbock, TX.*

To determine if preweaning plane of milk replacer nutrition (PON) influences health and performance of high risk Holstein bull calves, 36 Holstein bull calves (1d of age) from a commercial calf ranch were assigned to either a high (HPN; n = 18; 20% and 28% DM lipid and protein) or a low plane of milk replacer nutrition (LPN; n = 18; 20% DM lipid and protein) through weaning. Total serum protein concentrations confirmed that 72 and 76% of calves had failure of passive transfer (<5.2g/dL) in HPN and LPN, respectively. All calves were bottle fed twice daily, the LPN were fed 445 g DM/d of milk replacer until weaning, and the HPN calves were fed 830 g DM/d of milk replacer during the first 10 d and 1080 g from 11 d until weaning. Calf starter and water were offered ad libitum. Calves were step-down weaned beginning at 51 d and ending on 57 d. Data are reported as HPN vs. LPN throughout, respectively. Two of the 18 calves died in both treatments. There was a tendency ($P = 0.100$) for more HPN calves to bloat during the study (29.4 vs 6.7%). The HPN calves had greater ($P = 0.007$) incidence of scouring (66.7 vs. 22.2%), but there was no difference ($P = 0.688$) in the percentage of calves that received systemic antibiotics (47 vs. 40%). There was a time × PON interaction ($P < 0.001$) in weekly starter intake, where LPN ate more ($P \leq 0.004$) starter during wk 6, 7, 8, and 9. There was a time × PON interaction ($P = 0.017$) in water intake, where LPN had greater ($P \leq 0.001$) water intake throughout the study (3.6 vs. 2.3 ± 0.21L). There was a time × PON interaction ($P < 0.001$) in ADG, whereas HPN had greater ($P \leq 0.001$) ADG from 0 to 25 d (0.53 vs. 0.08 ± 0.040kg/d), 0 to 49 d (0.60 vs. 0.23 ± 0.040kg/d), and 0 to 68 d (0.58 vs. 0.33 ± 0.049kg/d). There was also a time × PON interaction ($P < 0.001$) in F:G, whereas HPN had greater ($P \leq 0.054$) efficiency from 0 to 25 d (1.7 vs. 5.8 ± 0.38), 0 to 49 d (1.8 vs. 3.7 ± 0.38), and 0 to 68 d (2.2 vs. 3.3 ± 0.38). Risk for bloat and scouring were greater for calves fed the HPN, but there was no difference in antibiotic treatment or mortality. Further, the HPN calves had greater performance over the preweaning period.

Key Words: calf, health, nutrition

W39 The effect of diarrhea, fever, and respiratory disease on post-weaning weight of Holstein dairy heifers in an automated feeding system. Gabriela A. Zaldumbide*, Melissa C. Cornett, and Amy L. Stanton, *University of Wisconsin-Madison, Madison, WI.*

Automated feeder systems (AFS) are gaining popularity in the dairy industry. Considering that calves intermingle in this system, it is important to evaluate and understand the risk of diseases and their impact on calf weight. This study examined the effect of cumulative health events (HE), respiratory disease (BRD), fever (F), and diarrhea (D), on 1-wk post-weaning weight (FWT) in calves. Holstein heifers (n = 96) from a 2 × 2 factorial study were used for this trial. Factorials were direct-fed microbial (DFM) efficacy and 2 pasteurized milk feeding plans that offered 543 L over 53 feeder days (FD). Plan 1 offered (7L/d) and peaked at 28 FD (13L/d). Plan 2 offered (11L/d) and peaked at 21 FD (15L/d). Both plans weaned calves at 53 FD. Researchers conducted complete health exams twice weekly from birth until FWT. Calves were weighed at 3 ± 2 d (Mean ± SD) of age and at FWT 66 ± 3 d. The effect of HE on FWT was evaluated by PROC MIXED in SAS, controlling for initial weight, age, and milk plan with study month as a random effect. The HE of calves were categorized into a score of 0, 1, 2, or 3 based on number of HE for each of the following: F, BRD, and D. A score of 0 indicated no HE, a score of 1 was 2–3 HE, a score of 2 was 4–5 HE, and a score of 3 was 6+ HE. For F, D, and BRD 22%, 20.8%, 19.8% of calves had a score of 0, respectively. For F, 52.1%, 18.8%, and 7.2% were categorized as 1, 2, and 3, respectively. For D, 53.1%, 24.0%, and 2.1% of calves scored 1, 2 and 3, respectively. For BRD 41.7%, 29.1%, and 9.4% of calves scored 1, 2, and 3, respectively. Final post weaning weight was 93.6 ± 12.9 kg (LSM ± SEM). Initial weight and final age were significantly associated with FWT ($P < 0.0001$), ($P < 0.0001$), respectively. For every increase in D HE score, FWT were lowered by −1.54 ± 0.62 kg ($P < 0.02$). For every additional F HE, FWT was lowered −1.05 ± 0.50 kg ($P < 0.04$). Final weight was not influenced by BRD ($P = 0.54$). Results suggest that diarrhea and fever have a cumulative effect on growth in dairy calves reared in AFS.

Animal Health: Monogastric health

W40 Changes in liver and white adipose tissue metabolism induced by postnatal nutritional restriction in piglets with intrauterine growth restriction. Liang Hu*, Xie Peng, Fali Wu, Chuan Yan, Qin Xu, Yan Liu, De Wu, Shengyu Xu, Yan Lin, Zhengfeng Fang, and Lianqiang Che, *Institute of Animal Nutrition, Sichuan Agricultural University, Chengdu, Sichuan, China.*

It is well known that intrauterine growth restricted (IUGR) neonates lead to escalation in the incidence of metabolic syndrome due to postnatal early catch up growth. We hypothesized that postnatal nutritional restriction may improve metabolic status of liver and white adipose tissue (WAT) in IUGR neonates. Piglets with a birth weight near the mean litter birth weight (SD 0.5) were defined as normal-birth weight (NBW), whereas those with at least 1.5 SD lower birth weight were defined as IUGR. Twelve pairs of NBW and IUGR piglets at 7 d of age were randomly assigned to adequate nutrient intake (ANI) or restricted NI (RNI) for a period of 21 d, which produced 4 experimental groups as NBW-ANI, IUGR-ANI, NBW-RNI and IUGR-RNI (n = 6 per group). The NBW-ANI and IUGR-ANI piglets had free access to formula milk, the NBW-RNI piglets were provided the same amount of formula as the IUGR-ANI piglets, and the IUGR-RNI piglets were provided approximately 70% of the formula intake of the IUGR-ANI piglets. At d 28, blood, liver and WAT samples were collected at necropsy and analyzed for hormone, metabolites and gene expressions. Data were analyzed by SPSS software using the MIXED procedure. The results indicated that IUGR significantly increased leptin concentration ($P < 0.01$). Compared with NBW piglets, the mRNA abundance of glucose-6-phosphatase and acetyl-CoA carboxylases were significantly decreased ($P < 0.05$) while sterol regulatory element-binding protein-1c (*SREBP1c*) was markedly increased ($P < 0.01$) in the liver of IUGR piglets; moreover, the mRNA abundances of *CD36*, hormone-sensitive lipase, adipose triglyceride lipase and carnitine palmitoyltransferase-1A in WAT were significantly decreased by IUGR ($P < 0.05$). Irrespective of BW, the hepatic mRNA abundances of *SREBP1c*, glucose transporter 4, phosphoenolpyruvate carboxykinase, lipoprotein lipase and peroxisome *proliferator activated receptor α* were significantly increased by RNI ($P < 0.05$). In summary, postnatal nutritional restriction changed blood metabolites and hormone concentrations by the metabolic related genes in piglets with IUGR.

Key Words: nutritional intake, metabolism, white adipose tissue

W41 MicroRNA expression profile of the mouse lung infected with a virulent avian H5N2 virus. M. K. Shim*[1], E. J. Choi[2], S. H. Hong[1], Y. K. Choi[2], and H. B. Kim[1], *[1]Dankook University, Cheonan, Chungnam, Republic of Korea, [2]Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.*

The aim of this study was to investigate the differences of the microRNA (miRNA) expression profiles in mouse lungs infected with wild type low pathogenic H5N2 avian influenza A (w81) or mouse-adapted virulent H5N2 avian influenza A (ma81) virus. Different sensitivities of influenza A virus strains to the hosts cause variations in miRNA expression. Therefore, some of miRNAs can be used as potential prognostic targets during the avian influenza A virus infections in mammalian hosts. Five-week-old C57BL/6 female mice were inoculated with 30 ul of 10^4 $TCID_{50}$ of w81 or ma81. Lung tissues from 3 mice per group were harvested at 1 and 3 dpi. A small RNA library was constructed from the total RNAs of lung samples and sequenced using the Solexa platform. Sequence reads were normalized to determine the number of transcripts per million, and fold changes of miRNAs were evaluated. *P*-value was calculated using following formula as previously described. $p(x|y) = (N2/N1)\ (x+y)!/x!y!(1 + N2/N1)(x + y + 1)$ where x, y, N1, and N2 represent number of miRNAs surveyed, number of homologous miRNAs in controls, total number of clean reads in controls, and total number of clean reads in treatments, respectively. Gene ontology analysis was conducted by miRanda and DAVID. The w81 virus induced a higher number of differentially expressed miRNAs compared with the ma81 virus. It is interesting to see that only 9 miRNAs (miR-100-5p, miR-130a-5p, miR-146b-3p, miR-147-3p, miR-151-5p, miR-155-3p, miR-223-3p, miR-301a-3p, and miR-495-3p) were significantly upregulated in both lungs infected either with the w81 or ma81 strain at both time point ($P < 0.05$). Especially, expression levels of 4 miRNAs were higher in the lungs of mice infected with the ma81 virus than those infected with the w81 virus ($P < 0.05$). These 4 miRNAs have been implicated in immune responses (miR-223-3p and miR-147-3p), viral infection (miR-155-3p), and cell migration (miR-151-5p). Our results suggest that the mammalian adaptation of avian influenza A virus results in a different miRNA expression pattern in lungs of virus-infected mice compared with its parental strain. Thus these might be used as potential prognostic targets during the avian influenza A virus infections in mammalian hosts.

Key Words: influenza A virus, microRNA, virulence

W42 Relationship between *Salmonella* translocation patterns and immune responses in orally inoculated pigs. Paul R. Broadway*[1], Jeffery A. Carroll[1], Nicole C. Burdick Sanchez[1], E. V. Gart[2], L. K. Bryan[2], R. M. Gold[2], C. Yang[2], and Sara D. Lawhon[2], *[1]Livestock Issues Research Unit, USDA-ARS, Lubbock, TX, [2]Department of Veterinary Pathobiology, College of Veterinary Medicine and Biomedical Sciences, Texas A&M University, College Station, TX.*

Salmonella is a pathogen of interest with broad implications ranging from animal health to food safety. Translocation patterns of *Salmonella* from the gastrointestinal tract to peripheral tissues have not been fully elucidated. Also, the mechanisms by which immunological responses influence translocation and fecal shedding are not fully understood. The objective of this study was to determine the translocation patterns of orally inoculated *Salmonella* in response to changes in immune biomarkers. Male pigs (n = 12; 6.1 ± 2 kg) were orally inoculated with 4.7×10^9 cfu of *Salmonella* Typhimurium. Whole blood samples were collected and analyzed for serum cortisol concentrations and complete blood counts. Fecal samples were collected daily from −1 to 3 d relative to the bacterial challenge on d 0. At 72 h post-inoculation, animals were humanely euthanized and tissues were collected to determine the presence of the inoculated *Salmonella* [mesenteric lymph node (LN), subiliac LN, liver, spleen, kidney, and gallbladder]. There was a tendency ($P = 0.06$) for fecal shedding quantity to be similar to mesenteric LN *Salmonella* concentrations at 72 h. There was no interaction ($P > 0.05$) between the presence of *Salmonella* in LN and any of the immune parameters measured. Subiliac LN *Salmonella* concentrations were highly correlated ($P = 0.0001$; r = 0.99) with liver *Salmonella* concentrations. Fecal shedding at d 3 was negatively correlated with kidney and gallbladder *Salmonella* concentrations ($P = 0.04$). Cecum concentrations of *Salmonella* were negatively correlated with white blood cell ($P = 0.02$ r = −0.72) and neutrophil ($P = 0.0003$) counts. These data suggest that orally inoculated *Salmonella* may translocate to tissue not only within the gastrointestinal tract but to organs and peripheral tissues such as musculoskeletal LN. Additionally, negative correlations between immune biomarkers and *Salmonella* migration suggest that translocation of *Salmonella* may be inhibited following the peak immunological response. Further information is needed to fully elucidate the mechanisms by which pathogens interact with their host and how an immune response alters migration patterns.

Key Words: *Salmonella,* swine, immune

W43 Isolation and characterization of *Clostridium tertium* in poultry feces.

S. H. Hong*, S. A. Seok, M. K. Shim, and H. B. Kim, *Dankook University, Cheonan, Chungnam, Republic of Korea.*

The aim of this study was to isolate and characterize *Clostridium tertium* from chicken feces. *C. tertium* is found in soil as well as gastrointestinal tracts of humans and other animals. *C. tertium* is an anaerobic, motile, gram-positive, rod-shaped bacterium that forms highly resistant endospores without generating an exotoxin. Although it is considered an uncommon pathogen and its pathogenicity is often unclear, this bacterium has been implicated in bacteremia, pneumonia, enterocolitis, septic arthritis and abscess in humans and animals. Even though there is no direct evidence that *C. tertitum* can be transmitted from animals to humans, it is of importance to see the prevalence and distribution of *C. tertium* in animal feces. Chicken feces samples were collected from the research farm at Dankook University, South Korea. Ten chickens per cage were housed together and 10 chicken droppings per cage (a total of 10 cages) were collected using sterile disposable culture loops starting when chickens were 1 week of age then at one-week interval until they were 4 weeks of age. After ethanol treatment (50% ethanol for 1 h), dropping samples were streaked onto TCCFA agar plates with 5% sheep blood, and incubated in anaerobic jars at 37°C for 72 h. The isolates were identified based on morphological criteria. Then identification was confirmed by the Gram staining and sequencing of the V1-V3 of 16S rRNA gene. After 72 h incubation in an anaerobic jar, a pure culture of colonies was recovered. A Gram stained smear of colonies showed weak-staining, gram-positive rods. These rod-shaped bacteria were detected from all chicken feces. The cloning and subsequent sequencing of the 16S rRNA genes from 2 representative isolates identified them as *C. tertium* with a probability of 99%. To our knowledge, this is the first isolation of *C. tertium* from chicken droppings. In depth studies on pathogenesis of *C. tertium* will be needed to better understand potential roles of *C. tertium* in poultry health.

Key Words: *Clostridium tertium*, chicken, feces

W44 Antimicrobial resistance strategy and effect on the veterinary feed directive regulation.

David B. Edwards*, Dragan Momcilovic, Sharon A. Benz, and Jo W. Gulley, *Division of Animal Feeds, Center for Veterinary Medicine, Rockville, MD.*

On December 12, 2013, the Food and Drug Administration (FDA) proposed to change its animal drug regulations to improve the efficiency for stakeholders using veterinary feed directive (VFD) drugs while continuing to protect human and animal health. The VFD drug class was created in 1996 by the Animal Drug Availability Act, and they are intended for use in or on animal feed under a veterinarian's order and professional supervision. The FDA established the VFD program in 2000. Changes to the VFD regulation are important as FDA implements the judicious use principles for medically important antimicrobial new animal drugs approved for use in food-producing animals, based on the framework set forth in Guidance for Industry (GFI) #209 issued April 13, 2012 and the process and timeline in GFI #213 issued December 13, 2013. Antimicrobials must continue to be available to combat disease in animals, including treatment, control, and prevention, while preserving availability of effective drugs. The primary concern is the continued effectiveness of "medically important" drugs. One important change in GFI #213 is to include veterinary involvement in the use of these antimicrobials by changing the drug marketing status of antimicrobial drugs from over the counter to prescription or VFD drugs to be used for therapeutic uses only. This means a VFD order from a licensed veterinarian will be needed to obtain medicated feeds containing VFD drugs. This order must include information on the number and type of animals to be treated. This keeps veterinarians included in the decision-making process to use medically important antimicrobials. FDA has secured the cooperation of drug manufacturers to change the drug marketing status and remove the production uses from these drug approvals. To improve the VFD process, FDA proposed several key changes in the proposed rule such as removing the federally defined veterinarian-client-patient-relationship requirement, eliminating the automatic classification of VFD drugs as Category II, and modifying recordkeeping requirements. FDA received about 2000 comments on the proposed rule and is reviewing those comments to publish a final rule.

Key Words: antimicrobial, veterinary feed directive, regulation

W45 Estimating glucose requirements of an activated immune system in growing pigs.

Sara K. Stoakes*, Erin A. Nolan, Mohannad Abuajamieh, Maria V. Sanz Fernandez, and Lance H. Baumgard, *Iowa State University, Ames, IA.*

Activated immune cells are obligate glucose utilizers and a large lipopolysaccharide (LPS) IV dose causes severe hypoglycemia. Therefore, study objectives were to use the quantity of glucose needed to maintain euglycemia following an endotoxin challenge as a proxy of immune cell glucose requirement. Fifteen fasted crossbred gilts (30 ± 2 kg) were jugular catheterized bilaterally and assigned one of 2 IV bolus treatments: control (CON; 10 mL sterile saline; n = 7) or LPS-infused + euglycemic clamp (LPS-Eu; *E. coli* 055:B5; 5 μg/kg BW; 50% dextrose infusion to maintain euglycemia; n = 8). Following infusion, blood glucose was determined every 10 min and dextrose infusion rates were adjusted in LPS-Eu pigs to maintain euglycemia for 8 h. Rectal temperature was increased in LPS-Eu pigs relative to control (39.8 vs 38.8°C, $P < 0.01$). After 3 h, blood glucose content gradually declined for CON pigs while LPS-Eu glucose levels remained unchanged ($P = 0.01$). Plasma insulin, BUN, BHBA, and L-lactate were increased in LPS-Eu pigs compared with CON (69, 57, 21, and 60%, respectively; $P < 0.05$). By 8 h, plasma LPS binding protein was increased 24% in LPS-Eu pigs relative to controls ($P < 0.01$). Plasma NEFA increased with time in CON pigs, but remained unchanged in the LPS-Eu pigs ($P < 0.01$). White blood cells, lymphocytes, monocytes, eosinophils, and basophils were decreased in LPS-Eu pigs relative to CON ($P < 0.01$). Additionally, the neutrophil-to-lymphocyte ratio was increased in LPS-Eu pigs relative to CON (72%, $P < 0.01$). During the 8 h, 232 ± 16 g of infused glucose was required to maintain euglycemia. If the amount of glucose required to maintain euglycemia can be used as a proxy, then the glucose requirements of an activated immune system are approximately 29 g/h.

Key Words: lipopolysaccharide, immune challenge, glucose homeostasis

W46 The influence of sodium alendronate on performance and bone densitometry of broilers at 42 days of age.

Thays Cristina Olveira Quadros*[1], Sarah Sgavioli[1], Giuliana Milan de Andrade Rocha Garcia[1], Liliana Longo Borges[1], Elaine Talita Santos[1], Diana

M. Correa Castiblanco[1], Albaraa Hisham Sarsour[2], Lizandra Amoroso[1], Joao Batista Matos Junior[1], Joao Paulo M. Chiquini[1], Otto Mack Junqueira[1], and Silvana Martinez Baraldi Artoni[1], *[1]Paulista State University Julio de Mesquita Filho, Jaboticabal, Sao Paulo, Brazil, [2]North Carolina State University, Raleigh, NC.*

Sodium alendronate (SA) is a drug that shows effects on bone mass, which may contribute to better bone development of animals, allowing for more efficient production performance. This study was conducted to evaluate the influence of SA on performance and bone mineral density of Cobb broilers at 42 d of age. Twelve hundred broilers used in this study were derived from 2 treatments that included injection or no vitamin D injection during incubation. After the eggs hatched, the broilers received water containing different levels of sodium alendronate (0, 2, 4, 6 or 12 mg/mL). The water solution with SA was supplied through esophageal inoculation in broilers chicken once a week for 3 weeks. One milliliter of solution was given to each bird on 7, 14 and 35 d of age, to ensure that all animals ingested the treatment. Experimental design was completely randomized in a 2 × 5 factorial for a total of 10 treatments (injected or not × sodium alendronate level). Broiler performance was evaluated by calculating feed intake, body weight gain and feed conversion. Bone density of the tibiotarsus was analyzed at 42 d using DEXA equipment. Data were analyzed using the JMP program for ANOVA. For the performance parameters of the broilers there was no significant effect ($P > 0.05$), as well as for the densitometry results, though one can observe an increased bone density value (0.242 g/cm2) in broilers derived from eggs injected with vitamin D and subsequently treated with 4mg of SA level. Treatments with SA can increase total skeletal mass, but the data suggest that despite the non-significant results of SA in this experiment, a numerical increase in bone density was observed, hence an improvement in bone development. It was concluded there was no influence on broiler performance ($P = 0.798$) and for bone mineral density the level of 4 mg of SA was numerically ($P = 0.246$) better when compared with other treatments, which encourages us to continue our research to establish a significant level of SA. SA may enable us to increase bone mineral density, and possibly contribute to weight gain of broilers.

Key Words: bone development, chicken, densitometry

W47 Potential of a new probiotic strain, *Bifidobacterium longum* ssp. *infantis* CECT 7210, to improve health status of weaning piglets orally inoculated with *Salmonella* Typhimurium or ETEC K88.

E. Barba-Vidal[1], L. Castillejos[1], C. Sol*[1], M. Rivero[2], JA Moreno[2], and SM Martín-Orúe[1], *[1]Animal Nutrition and Welfare Service, Animal and Food Science Department, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Laboratorios Ordesa S. L., Parc Científic de Barcelona, Barcelona, Spain.*

A new probiotic strain of *Bifidobacterium longum* subsp *infantis* CECT 7210 (Laboratorios Ordesa, S.L.) was evaluated in 2 oral challenges against *Salmonella* Typhimurium or enterotoxigenic *E. coli* (ETEC) K88. Seventy-two piglets, 21 and 24 (±2) days old were used in each trial. Animals were distributed in 24 pens and 4 groups in a 2 × 2 design: with and without probiotic and oral challenge. The animals were fed a plain diet and the probiotic was administered orally on a daily basis (10^9 cfu/d). After a 1-week adaptation, a double oral inoculation was done with *Salmonella* Typhimurium (2×10^9 and 6×10^9 cfu/day) (trial 1) or ETEC K88 (5×10^9 and 6×10^{10} cfu/day) (trial 2). Intake, live weight, fecal excretion of the pathogen, fecal consistency and rectal temperature were registered. Results were analyzed with a GLM and adjusted by Tukey. Microbiological frequencies were analyzed by Fisher. On d 4 and 8 post inoculation (PI), blood samples were obtained from one animal from each pen to assess inflammatory response (TNF-α and Pig-Map), being euthanized afterward for intestinal content and ileal scrapings sampling for microbiological and fermentation products analysis. Performance parameters were affected by the *Salmonella* challenge with reductions in feed intake and gains (ADG 118 g challenge animals vs. 209 g, $P < 0.001$), but not by *E. coli* (ADG 114g challenge animals vs. 120 g, $P = 0.801$). No significant differences were found related to the probiotic. The challenge also got worse fecal consistency ($P < 0.001$) and increased plasma TNF-α levels ($P < 0.05$). Although the probiotic did not ameliorate these clinical signs it was able to reduce fecal excretion of *Salmonella* (especially at d 3 PI; $P = 0.043$) and diminished the percentage of animals with countable ($>10^5$cfu/g) coliforms in ileal scrapings at d 4 PI (58 vs. 91%; $P = 0.010$). A consistent interaction was seen in both trials for colonic short chain fatty acids (SCFA), were the probiotic increased their concentration in the control animals but not in the challenged ones. Results indicate administration of the probiotic can reduce intestinal colonization by *Salmonella* and ETEC K88 in mild enteric processes.

Key Words: probiotic, *Salmonella*, ETEC K88

W48 A comparison for IgG absorption between Minpig and Landrace piglets.

Shiquan Cui*[1,2], Yuan Xu[1], Xuankai Huang[1], Xibiao Wang[1], and Yuzhi Li[2], *[1]Northeast Agricultural University, Harbin, Heilongjiang, China, [2]West Central Research and Outreach Center, Morris, MN.*

The levels of IgG in colostrum is responsible for the natural passive immunity of piglets, so effectively obtaining colostrum is important to survival and growth of newborn piglets. A study was conducted to evaluate the ability of newborn Minpig piglets to obtain IgG from colostrum. Four pairs of Minpig and Landrace sows (3–5 parity), with each pair farrowing their first piglet within an hour, were used. The 6 first born piglets were removed from their dam immediately after birth to prevent them from suckling colostrum. Then 3 out of 6 piglets in each litter were cross-fostered to a sow of another breed, resulting in 4 treatment groups: MM (Minpig piglets nursed by Minpig sows), ML (Landrace nursed by Minpig), LM (Minpig nursed by Landrace), and LL (Landrace nursed by Landrace), with 12 piglets in each group. Blood samples were collected from all piglets at 12 h, 24 h, 36 h, 48 h, 72 h, and 7 d after birth to determine concentrations of IgG using ELISA. Serum IgG concentrations for MM, ML, LM, and LL groups were 58.95 ± 3.33, 53.81 ± 3.64, 54.03 ± 3.11, and 48.89 ± 2.60 mg/ml, respectively, at 24h after birth. Compared with Landrace piglets, Minpig piglets had higher IgG concentrations ($P < 0.05$) regardless of being nursed by Minpig or Landrace sows. To further verify the efficiency of Minpig piglets to absorb IgG, a piglet from each 5 litters of Minpig and Landrace were tube-fed bovine IgG (1000mg/kg·BW) at 0 h, 6 h, 12 h, 24 h, 36 h, 48 h, and 72 h after birth, respectively. Blood samples were collected from the piglets at 6h after eating BIgG, and the absorption efficiency of BIgG was calculated for each piglet based on: {[serum BIgG concentration × BW × 0.10 × (1 − hematocrit)]/BIgG consumed} × 100%. Results indicate that Minpig piglets had higher absorption efficiency of exogenous BIgG than Landrace piglets (19.82 ± 1.55 vs. 17.07 ± 1.18 at 24 h, $P < 0.05$; 17.25 ± 1.63 vs. 14.43 ± 1.43 at 36 h, $P < 0.05$). These results suggest that Minpig piglets had a stronger capability to obtain passive immunity through milk and feed compare with Landrace piglets during the suckling period.

Key Words: Minpig, piglet, IgG

Beef Species

W49 Characterization of growth traits of Senepol heifers and bulls from birth through a year of age in the tropics. Robert W. Godfrey* and Henry C. Nelthropp, *Agricultural Experiment Station, University of the Virgin Islands, St Croix, VI.*

Senepol is a *Bos taurus* breed of beef cattle that is well suited to the tropics. This study was conducted to evaluate growth of Senepol bull and heifer calves from birth to a year of age using calves born in spring of 2012 (n = 11 heifers and 10 bulls) and 2013 (n = 17 heifers and 16 bulls). Hip height (HHT) and BW were measured at weaning and yearling. Pelvic area (PA) of heifers and scrotal circumference (SC) of bulls were measured at yearling. Average daily gain (ADG) was calculated from birth to weaning and weaning to yearling. Data were analyzed using year and sex of calf in the model with sire as a covariate due of unequal representation of sires across years. Age of dam was not significant ($P > 0.10$) for any trait. There was no effect of year or sex on birth weight ($P > 0.10$). Bulls had a greater 205-d adjusted weaning weight ($P < 0.008$) than heifers (242 ± 6 vs. 217 ± 6 kg, respectively) but there was no effect of year ($P > 01.0$). Bulls had a greater ADG from birth to weaning than heifers (0.96 ± 0.03 vs. ± 0.83 ± 0.03 kg/d, respectively) but there was no effect of year ($P > 0.10$). Weaning HHT was greater ($P < 0.003$) in bulls than in heifers (111.5 ± 0.7 vs. 108.3 ± 0.7 cm, respectively) and greater ($P < 0.002$) for calves born in 2012 than in 2013 (111.9 ± 0.8 vs. 107.8 ± 0.6 cm, respectively). Bulls had a greater 365-d adjusted yearling weight ($P < 0.01$) than heifers (293 ± 7 vs. 268 ± 7 kg, respectively) but there was no effect of year ($P > 0.10$). Calves born in 2012 had lower ADG from weaning to yearling ($P < 0.004$) than calves born in 2013 (0.28 ± 0.02 vs. 0.37 ± 0.02 kg/d, respectively) but there was no effect of sex ($P > 0.10$). Bulls had greater ($P < 0.0008$) yearling HHT than heifers (118.8 ± 0.7 vs. 115.4 ± 0.7 cm, respectively) and calves born in 2013 had greater HHT ($P < 0.0002$) than those born in 2012 (118.9 ± 0.6 vs. 115.2 ± 0.7 cm, respectively). Yearling SC of bulls was not different ($P > 0.10$) between years (24.7 ± 1.3 vs. 24.4 ± 0.9 cm, respectively). The PA of heifers was not different ($P > 0.10$) between years (145.5 ± 7.7 vs. 136.4 ± 5.5 cm2, respectively). These data show that there are differences in the growth traits between Senepol bull and heifer calves reared under tropical conditions.

Key Words: heifer, bull, cattle

W50 Association of skin thickness and resistance to *Rhipicephalus microplus* in Simmental heifers. J. A. II V. Silva*[1], A. M. Maiorano[2], A. C. Verdugo[3], Rogerio A. Curi[1], and L. A. L. Chardulo[1], [1]*Universidade Estadual Paulista, Botucatu, SP, Brasil,* [2]*Universidade Estadual Paulista, Jaboticabal, SP, Brasil,* [3]*University of Saskatchewan, Saskatchewan, Canada.*

The aim of this study was to verify association among skin thickness (ST) and resistance to the *Rhipicephalus microplus* ticks on Simmental animals, artificially infested with ticks. Eighteen Simmental heifers, with about to 450 age days and belonging a farm in the Avaré/SP/Brazil were used. ST was measure on the left side behind the shoulder of animal by a tuberculin caliper. Three artificial infestations were performed using approximately 20,000 *R. microplus* larvae on each animal. Counts female ticks were measured in the 19th and 23th range days after infestations, what only left side of the animal and engorged females with sizes larger than 4.5 mm were considered. Total tick counts (TTC) and payback percentages (PP) variables were transformed, respectively, in $\log_{10}$ (n + 1) and $PP^{0.25}$. MIXED procedure of SAS considering repeated measurements was used. Models considering the skin thickness group (STG), divided into thin leather and thick leather, infestation (IN) and their interactions as fixed effects were used in the analyzes for both variables. Mean comparisons were performed using Tukey-Kramer test ($P < 0.05$). Repeatability coefficient (R) of the variables was estimated by intraclass correlation between the same animal measures. The IN effect was significant ($P < 0.05$) for the studied variables. The STG mean were 7.11 ± 0.74 and 11.24 ± 0.86 for thin leather and thick leather, respectively. Means values observed, in chronological order, were 0.33 ± 0.29, 1.98 ± 0.22 and 2.36 ± 0.38 to TTC and 1.61 ± 1.35, 6.64 ± 0.83 and 8.40 ± 1.64 for PP. It is probably that the amount of detached female of animals significantly increased the infesting larval on pastures, caused significantly increased ($P < 0.05$) of TTC and PP in the following counts. Value of R were 0.61 for both variables, suggesting that resistance to ticks measures observed in the same animal have similar values in artificial infestations data. There was no significant effect of STG, indicating that the ST trait is not an attribute that influences in cattle resistance to ticks.

Key Words: artificial infestation, beef cattle, repeatability

W51 The effect of selection using residual average daily gain and marbling EPD on growth performance and carcass traits in Angus steers. J. B. Wells*, J. R. Segers, J. Duggin, J. K. Bertrand, R. Rekaya, and T. D. Pringle, *University of Georgia, Athens, GA.*

Steers (n = 68) were produced at the NW Georgia REC from the mating of Angus bulls selected for high and low residual ADG (RADG) EPD and high and average marbling (MARB) EPD to Angus cows. The resulting 2 × 2 factorial design contained 2 Angus sires in the following treatments: high RADG, high MARB (Hi/Hi); high RADG, average MARB (Hi/Avg); low RADG, high MARB (Lo/Hi); and low RADG, average MARB (Lo/Avg). Steers from the matings were used to determine the effects of RADG and MARB selection on growth performance and carcass traits. Steer weights were recorded and composition was determined via ultrasound at weaning (229 d) and yearling (391 d) ages. Steers entered the feedlot and were fed ad libitum for 2 wk before completing a 65-d GrowSafe Beef feed test to measure DMI, ADG, and residual feed intake (RFI). Steers were slaughtered at approximately 1.3 cm of backfat and USDA yield and quality grade data were collected after 24 h at 4C. Data were analyzed using ANOVA with the main effects of RADG and MARB EPD levels in the sire. Significant interactions were found for weaning and yearling weights and ultrasound REA, while DMI tended to be affected ($P < 0.10$). The Hi/Hi steers were heavier ($P < 0.05$) than Lo/Hi and Hi/Avg steers at both ages, while Hi/Hi and Lo/Avg steers had larger REA than Hi/Avg steers. There was a tendency ($P = 0.07$) for yearling ultrasound IMF to be higher in steers from high MARB sires. Hi/Avg steers consumed less feed than Lo/Avg, with the Hi/Hi and Lo/Hi steers being intermediate. No RADG effects were observed for ADG ($P = 0.96$); however, RFI tended to be lower ($P = 0.11$) in steers from the high RADG sires. Slaughter weights were higher ($P < 0.01$) for high vs low RADG groups, however, HCW and dressing percentage were not affected. USDA yield and quality grades did not differ ($P > 0.10$) across RADG or MARB groups; however, carcass REA was larger ($P < 0.05$) in Hi/Hi compared with Lo/Hi steers. In conclusion, selection using RADG appears to improve growth efficiency in Angus cattle, however, further work is needed to fully characterize the potential for this trait as a selection tool in beef production systems.

Key Words: residual ADG, RFI, carcass

W52 Relationship of grazing activities with residual feed intake measured in female Angus cattle carrying different genetic marker.

Ana Ines Trujillo*, Alberto Casal, Mariana Carriquiry, and Pablo Chilibroste, *Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay.*

A significant difference in residual feed intake (RFI, −1.02 vs. 1.02 kg of DM) measured under grazing conditions in beef heifers carrying different genetic marker (presence – V group or absence – C group of 3 allelic variants of the genes neuropeptide Y (NPY), IGF-1 and leptin) was reported. The objective of this study was to explore if grazing activities would be associated with the RFI measured in 2 beef cattle groups: carrying the genetic marker associated with low RFI or not carrying the genetic marker. Grazing activities were measured in beef heifers (370 ± 28 d, 294 ± 37.4 kg of BW, n = 18) grazed on unrestricted and high quality temperate pasture. Grazing activities (grazing, ruminating and idling) were determined using behavior recorders in 2 sequential moments (wk 4 and wk 5) during herbage dry matter intake (DMI) determinations. Intake rate was obtained as the ratio between herbage DMI and actual grazing time of each animal. Data were analyzed as repeated measures. The model included genetic marker group (V or C), week and their interaction as fixed effects and paddock as random effect. More efficient heifers under grazing condition (V group) tended ($P \leq 0.14$) to spent 45 min less in grazing time and to graze at a lower intake rate than less efficient heifers. Our results suggest that grazing activities would contribute to the biology behind RFI in growing heifers at grazing condition. Further experiments are needed to uncover drivers for better understanding the variation in RFI under grazing condition

Key Words: residual feed intake, beef cattle, grazing

W53 Reproducibility of estimators and validity of feed efficiency models.

Carl A. Old*[1], Heidi A. Rossow[2], and Thomas R. Famula[2], *[1]A3 Cattle Co., LeGrand, CA, [2]University of California, Davis, Davis, CA.*

A residual feed intake (RFI) equation (ADFI = a + b_1 x $BW^{0.75}$ + b_2 x ADG), used to estimate ADFI in individual animals, was evaluated to determine if specification was correct and if predicted ADFI was equal to observed ADFI (validity). We evaluated 2 data sets of growing beef cattle using ordinary least squares (OLS), bootstrapping (BS) or a first order (FO) model in which final BW (BW_f) was a function of initial BW (BW_0) and cumulative DMI (DMI_c). The FO equation was $BW_f = BW_0 e^{kDMIc}$. The RFI model was improperly specified ($P < 0.10$), predicted ADFI, both OLS and BS, differed from observed ($P < 0.05$), OLS and BS parameter estimates within and among data sets were not unique ($P < 0.05$) and the model failed all tests of external validity ($P < 0.05$). Functional forms of the variables were inconsistent with published classical energetic relationships among ADFI, BW and ADG. The intercept term, a, was either 0, negative or positive. The latter are inconsistent with biology; when BW and ADG are 0, a must likewise be 0. Parameter estimate b_1 indicated that ME intake at $NE_g = 0$ (ME_m) was either 0.280 x $BW^{0.75}$ or 0.165 x $BW^{0.75}$; both of these are greater ($P < 0.05$) than the NAS/NRC estimate of 0.131 x $BW^{0.75}$. Parameter estimate b_2 indicated that efficiency of ME utilization for gain was either outside or within the range of biological possibility. The FO model was internally and externally invalid for both data sets ($P < 0.05$) although R^2 were > 0.90. It appears that initial and final BW, as state variables, improve model fit in describing the relationship among ADFI, BW_0 and BW_f. Improper specification for the RFI model, parametric instability, lack of internal and external validity, irreproducibility of estimators between data sets and among published studies, and the random nature of residuals indicate the linear RFI model is a poor predictor of ADFI and of animal efficiency, for the data sets examined. A first order function (nonlinear) better describes relationships between BW change and ADFI. However, regardless of model, BW change and ADFI may be inadequate descriptors of efficiency.

Key Words: efficiency, beef cattle, residual feed intake

W54 The effect of selection using residual average daily gain EPD on growth and reproductive performance in Angus heifers.

J. B. Wells*, J. R. Segers, J. Duggin, J. K. Bertrand, R. Rekaya, and T. D. Pringle, *University of Georgia, Athens, GA.*

Forty-five heifers were produced at the Northwest Georgia Research and Education Center in Calhoun from the random mating of commercial Angus cows to Angus bulls selected for high and low residual ADG (RADG) EPD and high and average marbling EPD. The experimental design was a 2 × 2 factorial design with 2 Angus sires represented in each of the following treatments: high RADG, high marbling (Hi/Hi); high RADG, average marbling (Hi/Avg); low RADG, high marbling (Lo/Hi); and low RADG, average marbling (Lo/Avg). Heifers from the matings were studied to determine the effects of selection for RADG and marbling on growth and reproductive performance. Heifer weights were recorded and composition was determined via ultrasound scanning at 229 d (weaning) and 391 d (yearling) of age. There were no differences observed in weaning and yearling weights between the groups ($P > 0.19$). Weaning 12th rib fat levels were different with low RADG animals having greater fat depth ($P = 0.01$) than high RADG. Interactions between RADG and marbling were present in yearling 12th rib fat ($P = 0.04$), weaning IMF ($P = 0.07$), and yearling IMF ($P = 0.08$) with Lo/Avg heifers having greater values than Hi/Avg heifers. Blood samples were drawn at 8 mo, 10 mo, and 12 mo of age to directly quantify the level of progesterone present using the Siemens Coat-A-Count Progesterone RIA procedure. At 10 mo of age, 26% of low RADG heifers had reached puberty while no high RADG heifers had reached puberty. By 12 mo of age, 37% of low RADG and 19% of high RADG heifers had reached puberty. At approximately 14 mo of age, heifers were synchronized and artificially inseminated using the 14-d CIDR-PG & TAI protocol. Heifers that returned to estrus within 30 d were bred a second time by AI before exposure to a bull. Overall AI conception rates were Hi/Hi: 82%, Hi/Avg: 53%, Low/Hi: 89%, and Low/Avg: 80%. The average age at calving (714 d) was not different between groups ($P = 0.73$). In conclusion, selection using RADG may negatively effect early reproductive performance in Angus heifers, however, further work is needed to fully characterize the potential for this trait as a selection tool in beef production systems.

Key Words: residual ADG, heifer, reproduction

W55 Evaluation of serum 25-hydroxyvitamin D concentrations of beef calves during the spring and summer seasons.

Jessica L. Powell*[1], Deborah M. Price[1], Matthew J. Hersom[1], Joel V. Yelich[1], G. Allen Bridges[2], Scott Bird[2], Mary E. Drewnoski[3], and Wade A. Sutton[4], *[1]University of Florida, Gainesville, FL, [2]University of Minnesota, Grand Rapids, MN, [3]University of Nebraska, Lincoln, NE, [4]University of Idaho, Moscow, ID.*

Vitamin D is known to be critical for the growth and development of young calves and contributes to activation of innate immune defenses of cattle. The 25-hydroxyvitamin D (25D) metabolite is the precursor to the active vitamin D hormone and its concentration in serum serves as an indicator of an animal's vitamin D status. Normal serum 25D concentrations originally described for cattle are between 20 and 50 ng/mL, but recent evidence has indicated that serum 25D concentrations below 30 ng/mL are insufficient for adequate health. Because little information is available regarding vitamin D status of beef calves, the objective of this study was to evaluate serum 25D concentrations of beef calves born during the spring calving season. Four separate cohorts of calves were studied where serum samples were collected at birth and again 3–4 weeks after birth or in mid to late summer. Serum 25D concentrations were determined by using a 25D ELISA. In the first cohort, the average (±SD) concentrations of 16 Angus and Brangus calves born in Florida were 25.6 ± 12.1 ng/mL at birth in February and 26 ± 10.3, 53.8 ± 12.9, and 59.5 ± 17.2 ng/mL in March, July, and September, respectively. In the second cohort, the average serum 25D concentrations of 12 Angus and Brangus calves born in Florida were 16.4 ± 11.1 ng/mL at birth in April and 29.4 ± 9.7, 43.8 ± 11.8, and 51.0 ± 12.6 ng/mL in June, July, and September, respectively. In the third cohort, the average serum concentrations of 20 Angus calves born in Minnesota were 13.2 ± 6.4 ng/mL at birth in April and 45.9 ± 7.6 ng/mL in July. In the fourth cohort, the average serum 25D concentrations of 15 Charolais calves born from January to April in Idaho were 3.0 ± 2.2 ng/mL at birth and 10.5 ± 7.7 ng/mL at 3 weeks of age. Averages of the serum 25D concentrations for the dams of the calves in cohorts 2, 3, and 4 at calving were 69.5 ± 16.0, 57.7 ± 8.2, and 53 ± 8.2 ng/mL, respectively. In summary, this study indicates that vitamin D insufficiency (serum 25D < 30 ng/mL) is prevalent in newborn beef calves, and that potential opportunities exist to improve health of newborn calves through vitamin D supplementation.

Key Words: beef calves, vitamin D, health

W56 Equations to predict chemical body composition in Nellore cattle. A. M. Castilhos[1], R. H. Branco[2], C. L. Francisco*[1], M. E. Z. Mercadante[2], S. F. M. Bonilha[2], C. M. Pariz[1], M. B. Silva[1], and A. M. Jorge[1], *[1]Universidade Estadual Paulista-FMVZ, Botucatu, SP, Brazil, [2]Centro APTA Bovinos de Corte, Instituto de Zootecnia, Sertãozinho, SP, Brazil.*

Multiple linear regressions equations were developed to predict the chemical composition of the empty body of Nellore cattle. Thirty-tree young bulls (Control Nellore, n = 11; Selected Nellore, n = 22) of 339 ± 35 kg initial weight and 448 ± 26 d of age were used. The characteristics used to develop the prediction models were: empty body weight (EBW), age (days), hip height (HH), and ultrasound measurements [backfat thickness (uBF), rump fat (RF) and longissimus muscle area (uLMA)]. Ultrasound measurements were collected at the end of the trial period (d 110). Chemical composition (protein, ether extract, water and ash) was performed on samples obtained after grinding and homogenization of all body tissues. No interaction ($P > 0.05$) was observed between chemical components and genetic groups. Mallows Cp values were close to the ideal value of number of independent variables in the prediction equations plus one. Precise predictions ($R^2 > 0.72$) were obtained for protein, ether extract, and water, whereas poor prediction for ash ($R^2 = 0.67$) was revealed. Protein, ether extract, and water percentage can be calculated using the following equations: % Protein = 52.011 − 1.415 × RF + 0.179 × EBW − 32.122 × HH ($R^2 = 0.91$; SE = 2.24); % Ether Extract = 11.300 + 2.096 × RF + 0.157 × EBW − 0.061 × age ($R^2 = 0.72$; SE = 4.47); % Water = −34.156 − 2.327 × RF + 0.550 × EBW + 0.103 × age ($R^2 = 0.96$; SE = 5.81). In conclusion, multiple linear regressions were detected between non-invasive measurements and chemical composition of the empty body. The equations developed can be used to estimate chemical body composition characteristics as protein, ether extract and water body percentages of Nellore cattle. Supported by FAPESP Process#2005/60042–2.

Key Words: empty body, equation, Nellore cattle

W57 Effect of maternal body weight gain during mid-gestation on progeny skeletal muscle microRNA. J. C. McCann*, T. B. Wilson, D. W. Shike, and J. J. Loor, *University of Illinois at Urbana-Champaign, Urbana, IL.*

The objectives were to investigate the effects of maternal body gain during mid-gestation on skeletal muscle microRNAs expressed in the progeny. Post-transcriptionally, microRNAs downregulate gene expression by degrading target mRNA or translational repression. Spring-calving, multiparous cows (n = 26) were pen fed a diet consisting of 52% corn silage, 24% soy hulls, and 24% alfalfa haylage for 82 d during mid-gestation. Cows were classified into 3 groups (Hi-gain, Med-gain, and Low-gain) based on BW gain during the feeding period. After calving, all calves were managed similarly as a single contemporary group. Longissimus muscles biopsies were taken on 99, 197, and 392 d of age. Quantitative RT-PCR was used to determine mature microRNA in LM with all reactions run in triplicate. Three reference microRNAs (let-7a, miR-191a, and miR-103) were selected due to stable expression across animals and times. Data were analyzed using the MIXED procedure of SAS with cow BW gain, biopsy time, sex, and sire as fixed effects and pen as the random effect. Pairwise comparisons were implemented to separate means. MiR-381 expression in progeny born to Med-gain BW gain cows was greater ($P = 0.01$) than Low-gain with Hi-gain being intermediate. A cow BW gain × time interaction was observed for miR-181a ($P = 0.02$); while all groups decreased over time, calves from Hi-gain dams were greatest at d 392. A tendency ($P = 0.08$) for a cow BW gain × time interaction was observed for miR-26a. Despite all groups increasing from d 99 to 197, only the Hi-gain group maintained a similar level of miR-26a at d 392 while Med-gain and Low-gain were downregulated. Relative abundance of microRNAs was greatest for known muscle-specific microRNAs, miR-1 and −133a. All measured microRNAs changed ($P < 0.01$) over time. Expression of miR-23a and miR-29a increased with age, while miR-376d and miR-381 decreased at each subsequent time point. Additionally, expression of miR-133a and let-7g was greatest at d 197. Overall, results suggest microRNAs have a role in the robust and coordinated regulation of skeletal muscle development and some may be regulated by epigenetic factors.

Key Words: fetal programming, microRNA, muscle

W58 Physical and chemical analysis of the longissimus thoracis muscle of Nellore cattle selected for production. Jessica Moraes Malheiros*[1], Rogério Abdallah Curi[2], Josineudson Augusto Vasconcelos Silva[2], Henrique Nunes de Oliveira[1], Lúcia Galvão Albuquerque[1], and Luis Artur Loyola Chardulo[2], *[1]College of Agriculture and Veterinary Science, College of Agriculture and Veterinary Science, São Paulo State University (UNESP), Jaboticabal, São Paulo, Brazil, [2]College of Veterinary and Animal Science, College of Veterinary and Animal Science, São Paulo State University (UNESP), Botucatu, São Paulo, Brazil.*

Tenderness is one of the main characteristics in the producer and consumer market. Identifying and selecting beef cattle that have genetic propensity for quality meat production is necessary for zebu animals.

The aim of this study has been to evaluate the qualitative aspects of meat in *Longissimus thoracis* muscle of 2 selected contrasting groups of 718 Nellore animals finished in feedlot and from herds that are part of breeding programs. Samples were collected between the 12th and 13th ribs to perform the physical-chemical analysis of shear force (SF), rib eye area (REA), backfat thickness (BFT), visual scale of marbling scores (marbling) and cooking losses (Cl). The contrasting groups were selected by SF: animals with tender meat (n = 15) and animals with tough meat (n = 15). Statistical analyzes were performed using the GLM procedure, CORR and the averages were compared using the Tukey test. The values found in the groups of animals with tender meat and animals with tough meat were, respectively to SF (3.8 ± 1.17 and 6.8 ± 1.4 kg), REA (74.8 ± 8.52 and 62.6 ± 6.55 cm^2) and Cl (24.2 ± 3.02 and 28.8 ± 3.81%), showed significant differences ($P < 0.01$). REA has a good relationship with the amount of this muscle in the carcass and thus contributes to the prediction of meat cuts and product yield. Meat with SF values below 5.5 kg may be considered potentially tender. The difference to REA between previously selected groups for meat tenderness establishes the possibility of obtaining Nellore more efficiently in production, coupled with achieving superior products. Samples of tough group showed higher values for Cl, impairing the tenderness. The BFT values (3.4 ± 1.11 and 3.6 ± 0.73 mm) and marbling (2.5 ± 0.24 and 2.5 ± 0.36) for groups of tender and tough meat respectively showed no significant difference ($P > 0.05$). Therefore, in animals of Nellore breed for production the ability to produce meat observed through REA, BFT and marbling, has to be satisfactory. However, the wide variation in SF of the animals selected in breeding programs, sorts the final product with lower added value on meat quality characteristics.

Key Words: quality beef cattle, rib eye area, shear force

W59 Characterization and identification of MyHC and their association with quality beef cattle Nellore. Jessica Moraes Malheiros*[1], Ivan José Vechetti-Junior[2], Maeli Dal-Pai-Silva[2], Henrique Nunes de Oliveira[1], Lúcia Galvão Albuquerque[1], and Luis Artur Loyola Chardulo[3], *[1]College of Agriculture and Veterinary Science, College of Agriculture and Veterinary Science, São Paulo State University (UNESP), Jaboticabal, São Paulo, Brazil, [2]Institute of Biosciences, Institute of Biosciences, São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [3]College of Veterinary and Animal Science, College of Veterinary and Animal Science, São Paulo State University (UNESP), Botucatu, São Paulo, Brazil.*

The study of myosin protein is directly related to the tenderness, growth, development and muscle contraction, and expresses different isoforms, where the way it operates has great influence on meat quality. This study aimed to relate the Nellore meat (*Bos indicus*) separating 2 contrasting groups through the identification and quantification of heavy chain isoforms of myosin (I, IIa, IIx and IIb). A total of 718 samples of the *Longissimus thoracis* from animals slaughtered in commercial abattoir were used in the shear force analysis (SF) to determine tenderness. According to SF were selected 2 groups: (1) Group of tender meat (n = 15) and (2) Group of tough meat (n = 15) who underwent extraction, identification and quantification of heavy chain isoforms myosin (MyHC) by electrophoresis (SDS-PAGE) and photo documentation of gels. Statistical analyzes were performed using the GLM procedure, CORR and averages were compared using the Tukey test using Statistical Analysis System. For MyHC was identified and quantified 3 isoforms (I, IIa and IIx), the presence of MyHC IIb isoform has not been identified. Mean values of the optical density index (IOD) in relative percentage of MyHC isoforms were observed in the tender meat group and tough respectively MyHC-I (18.2 ± 3.54 and 16.9 ± 3.14), MyHC-IIa (16.7 ± 3.09 and 14.0 ± 3.38) and MyHC-IIx (64.9 ± 3.79 and 66.3 ± 5.05). It can be seen a greater amount of type II isoform (fast) compared with type I (slow). There were no differences ($P > 0.05$) between the extreme groups of type I and IIx, unlike IIa ($P < 0.05$), with the highest relative percentage in tender meat group and reported a significant negative association with SF ($rp = -0.34$; $P < 0.05$). It is concluded from the results that the Nellore have good relationship between the hypertrophy of the *Longissimus thoracis*, as measured by the concentration of MyHC IIa, and meat tenderness, measured by the SF. The study of MyHC isoforms is an appropriate type of muscle fibers identification tool having a good correlation with the meat tenderness feature.

Key Words: quality beef cattle, shear force, skeletal muscle

W60 Effects of pre- and post-breeding supplementation of a ruminally protected lipid on subsequent beef cow performance. Darren D. Henry*[1], Francine M. Ciriaco[1], Vitor R. G. Mercadante[1], Danilo D. Demeterco[1], Pedro L. P. Fontes[1], Elliot Block[2], Neil Michael[2], Nicolas DiLorenzo[1], and G. Cliff Lamb[1], *[1]North Florida Research and Education Center, University of Florida, Marianna, FL, [2]Arm & Hammer Animal Nutrition, Princeton, NJ.*

We determined the effects of supplementation of a ruminally protected lipid (Megalac-R, Church & Dwight Co., Princeton, NJ) on subsequent beef cow reproductive performance. Sixty primiparous cows (428 ± 42 kg of BW) were used in a completely randomized design. Cows were stratified by breed, BCS and the previous year's calving date, and assigned to one of 2 treatments: control (CTRL; 1.36 $kg \cdot d^{-1}$ of corn gluten feed) and treatment (MLAC; 1.36 $kg \cdot d^{-1}$ of corn gluten feed and 0.23 $kg \cdot d^{-1}$ of Megalac-R). Cows grazed a mixed winter forage pasture of rye (*Secale cereale*) and ryegrass (*Lolium multiflorum*) and had ad libitum access to water. Supplementation of CTRL and MLAC occurred from 30 d before AI until 7 d post-AI. Daily, cows were individually penned and received their respective supplementation. Cow BW and BCS were recorded 35 and 28 d before AI and 35 and 60 d after AI. At initiation of the breeding season cows were exposed to the 7-d CO-Synch+CIDR ovulation synchronization protocol. Pregnancy was diagnosed on d 30, 60, and 90 after AI. Cows pregnant to AI were monitored until calving to determine length of gestation and calf birth weight. Treatment did not affect ($P > 0.05$) mean cow BW (491 ± 2.9 kg) or change in cow BW. There was no effect ($P > 0.05$) of treatment on pregnancy rates to AI (53 ± 0.5%) or at 90 d after AI (94.5 ± 0.5%). Length of gestation was greater ($P = 0.0234$) for MLAC (285 ± 1.3 d) than for CTRL (281 ± 1.1 d). No effect of treatment was observed for calf birth weight (34 ± 3 kg; $P > 0.05$). Supplementation of 0.23 $kg \cdot d^{-1}$ of a ruminally protected lipid to primiparous cows did not enhance subsequent cow reproductive performance.

Key Words: ruminally protected, supplementation, beef cow

W61 Effects of prepartum supplementation of a rumen fermentation enhancer on subsequent beef cow performance. Darren D. Henry*[1], Francine M. Ciriaco[1], Vitor R. G. Mercadante[1], Danilo D. Demeterco[1], Pedro L. P. Fontes[1], Elliot Block[2], Neil Michael[2], Nicolas DiLorenzo[1], and G. Cliff Lamb[1], *[1]North Florida Research and Education Center, University of Florida, Marianna, FL, [2]Arm & Hammer Animal Nutrition, Princeton, NJ.*

We determined the effects of a prepartum negative dietary cation-anion difference (DCAD) supplement on subsequent performance of beef cows. Forty-three multiparous cows (568 ± 73 kg of BW) were used in a completely randomized design. Prepartum cows were stratified by breed, BCS, and the previous year's calving date and assigned to one of 2 treatments: control (CTRL; 1.75 $\text{kg}\cdot\text{d}^{-1}$ of 50:50 corn gluten feed (CGF):soybean meal (SBM) mixture, DM basis) and treatment (BCLR; 0.57 $\text{kg}\cdot\text{d}^{-1}$ of an anion source [Bio-Chlor, Church & Dwight Co., Princeton, NJ] and 1.13 $\text{kg}\cdot\text{d}^{-1}$ of 50:50 CGF:SBM mixture, DM basis). Cows had ad libitum access to bermudagrass hay (*Cynodon dactylon*) and water. Daily, cows were individually penned and received supplement (CTRL and BCLR were fed for 21.8 ± 9.3 and 24 ± 9.5 d, respectively) until calving. After calving, cows and calves were weighed within 12 h of parturition and blood samples were collected from the cow. Weekly, blood samples were collected from cows, and BW of cows and calves and BCS of cows were recorded. On d 28, 84, and 140 postpartum, milk yield was recorded and milk samples were analyzed to determine energy corrected milk (ECM). Calculated DCAD of CTRL was 469.61 $\text{mEq}\cdot\text{kg}^{-1}$ DM whereas BCLR was −1295.89 $\text{mEq}\cdot\text{kg}^{-1}$. Cow weight and calf weight was not affected by treatment ($P = 0.1154$ and $P = 0.9598$, respectively). The ADG of cows (0.1 ± 0.043 kg), ADG of calves (1.0 ± 0.04 kg), and BCS of cows (4.97 ± 0.05; 1 to 9 scale) was not different between treatments ($P > 0.05$). Similarly, ECM did not differ between CTRL and BCLR ($P > 0.05$). Supplemental DMI was greater ($P < 0.001$) for CTRL (1.60 ± 0.031 $\text{kg}\cdot^{-1}$) than for BCLR (1.23 ± 0.033 $\text{kg}\cdot\text{d}^{-1}$). Concentrations of plasma Ca (10.67 ± 0.51 $\text{mg}\cdot\text{dL}^{-1}$) and β-hydroxybutyrate (173.0 ± 9.18 $\text{mmol}\cdot\text{L}^{-1}$) did not differ ($P > 0.05$) between treatments. Prepartum supplementation of 0.57 $\text{kg}\cdot\text{d}^{-1}$ of an anion source to beef cows did not enhance subsequent cow or calf performance.

Key Words: dietary cation-anion difference, prepartum diet, supplementation

W62 Performance effects related to administration of long-acting eprinomectin or oxfendazole near calving in spring-calving cows over a 230-d grazing period.

Elizabeth A. Backes*[1], Jeremy G. Powell[1], Donald S. Hubbell III[2], John D. Tucker[2], William L. Galyen[1], and Laura R. Meyer[1], [1]*Department of Animal Science, Division of Agriculture, University of Arkansas, Fayetteville, AR,* [2]*Livestock and Forestry Research Station, Batesville, AR.*

Internal parasites have been reported to flourish in Southern states and cause detrimental economic effects to the beef cattle industry. The objective was to evaluate the effects of anthelmintic therapy administered at recommended dose to spring-calving cows approximately 5 d before the initiation of the calving season. Eighty-two (563 ± 8.1 kg) cows located at the Livestock and Forestry Research Station in Batesville, AR, were stratified by BW, BCS, and fecal egg counts (FEC), then allocated randomly to 1 of 3 treatments representing: Control (CON; no anthelmintic administered; n = 27); Oxfendazole (OXF; n = 27); or Long-acting eprinomectin (LAE; n = 28). Cows were rotationally grazed within individual treatment on 2.4-ha mixed grass pastures. Body weight, BCS, FEC were taken on d 0, 14, 91, 154, and 230 and hair coat scores (HCS) taken on d 0, 91, 154. Beginning May 15, 2015, one bull was placed in each pasture for a 60 d breeding season. Performance data were analyzed using PROC MIXED of SAS, with individual cow being the experimental unit and conception rates were analyzed using Chi-squared. Body weight on any sampling date (d 230 BW 568, 573, 574 kg for CON, LAE, OXF, respectively), BCS on d 0, 14, 154, and 230, and HCS on d 0 and 154 did not differ ($P \geq 0.25$) across treatments; however, BCS were greatest ($P = 0.03$) for OXF (6.0), CON intermediate (5.9), and lowest for LAE (5.8) on d 91, and HCS were greater ($P < 0.01$) for LAE (3.5) versus OXF (1.7) and CON (2.8) on d 91. Similar ($P \geq 0.16$) overall ADG were reported (0.00, 0.08, and 0.05 kg/d for CON, LAE, OXF, respectively). Cow FEC did not differ ($P \geq 0.11$) on d 0 or 91; however, were greater for CON on d 14 and 154 versus OXF and LAE; were greater ($P = 0.02$) for LAE versus CON and OXF on d 230. Conception rates did not differ ($P = 0.17$) across treatments (78, 61, 81%, for CON, LAE, OXF, respectively). In this study, anthelmintic therapy did not improve BW, BCS, HCS, FEC, or conception rate, in spring-calving cows rotationally grazed over a 230-d grazing period.

Key Words: fecal egg counts, spring-calving cows, anthelmintic

W63 The effects of weight gain, carcass characteristics, temperament, and Brahman influence on estrus behavior and conception rate in heifers.

Brittney L. Ivey*, Allison C. Vail, William A. Storer, and C. Edward Ferguson, *McNeese State University, Lake Charles, LA.*

Heifers from southwest Louisiana were dry-lotted and evaluated for factors influencing estrus and conception. In October, spring born heifer calves (n = 121, 259 ± 150 kg) were received and processed with routine procedures before beginning a 120 d feeding trial. Heifers were visually assessed for temperament and percentage of Brahman influence. Temperament was evaluated as individual chute scores (CS) and denoted as 1–4 increasing with increased heifer excitability. Temperament was also evaluated as chute exit velocity (EV) using a rodeo event timer to calculate the speed of each animal exiting the squeeze chute. Brahman influence (BI) was determined by the phenotype and/or genotype of the heifers. Criteria for phenotype assessment were ear length and shape, hair type, coat color, and length of sheath. Individual BW and ADG were assessed monthly. Heifers were scanned by ultrasound at d 120 to determine RF, REA, and IMF. Intramuscular fat and RF decreased ($P < 0.05$) in heifers with greater BI. Cattle that were greater than 25% BI had lower ($P < 0.05$) ADG and final BW than did heifers with 0 to 25% BI. During 2 rounds of estrus detection, females were fitted with electronic estrus detection transmitters and monitored for estrus behavior. In round 1 (n = 121), BI did not make a difference ($P > 0.1$) in the duration of estrus or the estrous cycle length. Temperament, as assessed by CS and EV, did not influence ($P > 0.1$) duration of estrus or estrus cycle length. In the second round of estrus detection (n = 59), there was no relationship ($P > 0.1$) between conception and estrous cycle length, duration of estrus, RF, REA, ADG, or BW. Temperament and breed also did not affect ($P > 0.1$) conception rate. This aided in clarifying the relationships of weight gain, carcass characteristics, temperament and BI on estrus behavior and conception rates in heifers.

Key Words: temperament, Brahman, estrus

W64 Effect of breed on the sale price of beef calves sold through video auctions from 2010 through 2014.

Michael E. King[1], Kevin L. Hill[2], Glenn M. Rogers[3], and Kenneth G. Odde*[1], [1]*Kansas State University, Manhattan, KS,* [2]*Merck Animal Health, Kaysville, UT,* [3]*Grassy Ridge Consulting, Aledo, TX.*

The objective of this study was to quantify the effect of breed description on the sale price of beef calves marketed through video auctions while adjusting for all other factors that significantly influenced price. Information on descriptive characteristics of lots of beef calves were obtained from a livestock video auction service. Data were available on 33,811 lots of calves (3,345,826 total calves) that sold in 116 video auctions between 2010 and 2014. All lot characteristics that could be accurately quantified or categorized were used to develop a multiple regression model that evaluated the effects of independent factors on sale price using a backward selection procedure. A value of $P < 0.05$ was used to maintain a factor in the final model. Breed description of the calves in the lot was 1 of 18 factors included in the original model and was categorized into 5 groups: English, English crosses (EX), English-Continental crosses (ECX), Black Angus sired out of dams with no Brahman influence (AN), Red Angus sired out of dams with no Brahman influence (AR), and Brahman influenced (BR). Breed of the lot affected the sale price of beef calves ($P < 0.0001$), and was 1 of 15 independent factors that remained in the final model. The number of lots in each breed group was 3,521, 9,022, 10,744, 1,373, and 9,151 for the EX, ECX, AN, AR, and BR breed groups, respectively. Lots of AR calves sold for a higher price ($P < 0.01$, $366.32/100 kg) than all other breed groups. Black Angus sired calves had the second highest sale price at $362.09/100 kg, and this price was higher ($P < 0.01$) compared with the EX ($359.04/100 kg), the ECX ($358.36/100 kg), and the BR ($350.05/100 kg) groups. The EX and the ECX breed groups sold for similar prices ($P = 0.55$), but both of these breed groups sold for higher prices ($P < 0.01$) than the BR lots. Breed composition of lots of beef calves selling through video auctions significantly influenced sale price.

Key Words: beef calves, breed, sale price

W65 Economic aspects of rebreeding non-pregnant cows. Aline Gomes da Silva*[1,2] and Rick N. Funston[1], [1]*University of Nebraska-Lincoln, West Central Research and Extension Center, North Platte, NE,* [2]*Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

A study was conducted to evaluate the economic aspects of retaining ownership and rebreeding open spring-calving cows to be sold as pregnant fall-calving cows. Composite Red Angus × Simmental females diagnosed as non-pregnant after regular spring breeding season were utilized over a 2-yr period (Yr 1, n = 61; Yr 2, n = 72). Hay and supplement were fed from November to February. Cows diagnosed as non-pregnant after a second breeding season were sold in March. Pregnant cows grazed Sandhills meadow pastures until April, when they were sold. Cows were synchronized with a 7-d controlled internal drug release (CIDR)-PG protocol before a 60 d natural service breeding season beginning in November, utilizing a 1:25 bull to cow ratio. Pregnancy diagnosis was determined by ultrasound 30 d after bull removal. A partial budget analysis was performed for Yr 1 to compare the economics of selling non-pregnant cows immediately after pregnancy diagnosis or retaining ownership and rebreeding them to sell as pregnant cows in more favorable market prices. Total cost was calculated by adding the purchase price (cull cow value at first pregnancy diagnosis), feeding costs, meadow grazing and management cost, breeding cost, and 6% annual interest rate on the purchase price. The net cost of 1 pregnant cow was calculated as the difference between total cost and cull value, divided by the number of pregnant cows. The overall rebreeding pregnancy rate was 90.2% for Yr 1 and 81.9% for Yr 2, the percentage of the pregnant cows that conceived in the first 21 d of the breeding season was 89.1% for Yr 1 and 79.7% for Yr 2. The total cost/female was $1,186.38. Subtracting the cull value of the open cows sold in March, the net cost of one pregnant cow was $1,185.08. The pregnant cows were sold for $1,638.00, resulting in a $452.92 net gain/pregnant cow. While conventional wisdom has held open cows should be sold after pregnancy detection, we conclude rebreeding a non-pregnant cow to be sold at higher market prices may be an economic alternative.

Key Words: budget analysis, cull cow, rebreeding

Breeding and Genetics: Genomic methods and application—Beef

W66 GWAS between single nucleotide polymorphisms with beef fatty acid profile in Nellore cattle using the single-step procedure. Marcos V. A. Lemos*[1], Hermenegildo L. J. Chiaia[1], Mariana P. Berton[1], Fabiele L. B. Feitosa[1], Carolyn Aboujaoude[1], Adrielle M. Ferrinho[2], Lenise F. Mueller[2], Joyce J. M. Furlan[2], Angelica S. C. Pereira[2], Lucia G. Albuquerque[1], and Fernando Baldi[1], *[1]State University of São Paulo, Jaboticabal, São Paulo, Brazil, [2]University of São Paulo, Pirassununga, São Paulo, Brazil.*

The aim of this study was determine genomic regions associated with the profile of beef fatty acid (FA) of Nellore cattle finished in feedlot using the single-step method. A total of 1,616 genotypes and 963 phenotypes were used. The FA profile was analyzed in *Longissimus thoracis* samples using a gas chromatography, with a 100-m capillary column. The following fatty acids were analyzed: lauric (C12:0), palmitic (C16:0), stearic (C18:0), oleic (C18:1 *cis*-9), linoleic (C18:2 *cis*-6), CLA (C18:2 *cis*-9 *trans*-11), CLA (C18:2 trans10 cis12), linolenic (C18:3 n3), myristic (C14:0), myristoleic (C14:1), docosahexaenoic (C22:6 n3), elaidic (C18:1 n9t), vaccenic (C18:1 t11), arachidonic (C20:4 n-6) eicosatrienoic (C20:3 n6 cis-8,11,14) and alfa-linolenic (C18:3 n6). The animals were genotyped with the BovineSNP BeadChip (High-Density Bovine BeadChip). After quality control of genotypes, a total of 470,000 SNPs and 1,556 samples remained. The model used for the (co)variance and genetic parameter estimation included the random genetic additive direct effect, the fixed effect of the contemporary groups, and the animal's slaughter age as a covariable. To determine the areas of QTL, segments that were $\geq 1\%$ of the additive genetic variance were chosen. For identification and positioning of these segments, the database available in the "National Center for Biotechnology Information" and Ensembl Genome Browser were used. A total of 115 genomic regions (1-Mb SNP windows) associated with the FA profile were identified many of these regions were previously detected in other cattle breeds, like the gene *ELOVL5* (fatty acid elongase 5) associated with the C20:4 n-6 FA, the *ESRRG* (estrogen receptor-related gamma gene) was associated with the C12:0 FA and the *PCYT1A*, TCTEX1D and *GALNTL6* were associated with C18:2 cis-9 cis-12 n-6, C14:0 and C16:0 FA. The genes present in these regions may help to explain the genetic basis of FA profile in Bos indicus cattle, contributing to better selection of these traits associated with improvement of human health.

Key Words: *Bos indicus*, fatty acid composition, genetic markers

W67 Genotype imputation and haplotype-phase inference using trio based reference panel in Hanwoo (Korean cattle). Dajeong Lim*, Jung-Woo Choi, Hyung-Chul Kim, Han-Ha Chai, and Yong-Min Cho, *National Institute of Animal Science, Suwon, South Korea.*

In recent years, large numbers of cattle have been genotyped with SNP arrays from 3K to 800K. These platforms can be available to increase the efficiency and accuracy of breeding programs by implementing genomic selection. As for cattle, there are currently several imputation/phasing methods used in genomic selection, genome-wide association (GWA) studies, or genetic diversity analysis. Currently, many imputation and phasing methods are introduced to reduce the number of missing genotypes and to infer the haplotypes from these genotype data. Despite these efforts, imputation or phasing errors are still present. Next-generation sequencing (NGS) price has been consistently dropped, various population genomic theories and breeding program can be now applied to the sequencing data obtained from population of each breed of interest. For example, long-range haplotype sequencing technology can phase 99% of single-nucleotide variants (SNVs) in sequencing data without imputation process; current technologies typically phase ~95–97% in human. Therefore, we describe the phasing study using Hanwoo trio sample. First, we selected the representative trio sample from pedigree analysis in Hanwoo population. Genotyping was performed based on the Illumina 800K. Imputations for genotype data in this study were done using BEAGLE and FIMPUTE, genotype imputation tools that use a reference panel of haplotypes to estimate phase and impute missing genotypes in trio data. Second, We sequenced the trio data using Illumina Long-read haplotyping technology known as Moleculo. The short sequence reads producing from each molecule are assembled into synthetic long-reads. These fragments assign haplotype to homologous chromosomes in the phasing application. Finally, we compared accuracy of imputation/phasing based on the SNP array and sequencing data of an optimal reference panel of maternal/paternal haplotypes. These results help in improving selection and breeding value estimation and in avoiding imputation errors from SNP information.

Key Words: phasing, imputation, Hanwoo

W68 Genome-wide association study analysis for meat traits of beef cattle. Hoyoung Chung*, *National Institute of Animal Science, Suwon, KY, Korea.*

To identify genomic loci with an effect on meat quality traits in Hanwoo cattle, 3,000 animals with carcass phenotypes were genotyped with a customized 56K Affymetrix SNP chip. Genome-wide association studies (GWAS) were performed for marbling (MAR), maturity (MAT), backfat thickness (BFT), loin eye area (LEA), carcass weight (CAW), meat quality grade (MQG), and meat yield grade (MYG). Multiple statistically significant SNP were identified for MAT (674 SNP), MAR (595), CAW (754), LEA (506), BFT (440), MYG (496), and MQG (2,850) with chromosomes 14 and 23 having extreme significant associations for CAW and MYG, respectively. A 66-bp insertion in *ADIPOQ* from 81966364 to 81966419 was genotyped by agarose gel electrophoresis in 3,000 animals to verify the associations of GWAS loci located in the *ADIPOQ* region. The *ADIPOQ* insertion was significantly associated with MAR ($P = 0.034$), BFT ($P = 0.004$), LEA ($P = 0.014$), CAW ($P = 0.002$), and MYG ($P = 0.003$). This study's significant SNP may be used in marker-assisted selection programs to improve meat quality traits in beef cattle.

Key Words: GWAS, SNP, meat trait

W69 Admixture analysis in Brazilian synthetic cattle. Marcos E. Buzanskas*[1], Ricardo V. Ventura[2], Tatiane C. S. Chud[1], Daniel J. A. Santos[1], Priscila A. Bernardes[1], Thiago B. R. Silva[1], Mauricio A. Mudadu[3], Luciana C. A. Regitano[3], Marcos V. G. Barbosa da Silva[4], Changxi Li[5], Flavio S. Schenkel[2], Maurício M. Alencar[3], and Danísio P. Munari[1], *[1]UNESP – Univ Estadual Paulista, Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, SP, Brazil, [2]University of Guelph, Guelph, ON, Canada, [3]Embrapa Southeast Livestock, São Carlos, SP, Brazil, [4]Embrapa Dairy Cattle, Juiz de Fora, MG, Brazil, [5]University of Alberta, Edmonton, AB, Canada.*

The development of synthetic breeds in Brazil from crosses between *Bos taurus indicus* (Bti) and *Bos taurus taurus* (Btt) is very useful when it is desired to combine the fitness and carcass yield. The Canchim breed (CA), which has expected proportions of 62.5% Charolais and 37.5% zebu (Nellore breed), have been the focus of several studies because this breed has high carcass quality and adaptability to extensive production system. The aim of this study was to estimate the genetic composition in the Canchim breed using single nucleotide polymorphism (SNP) data. Canchim animals (285 individuals) were genotyped with the Illumina BovineHD BeadChip (777962 SNPs). To estimate the genetic contribution of Btt and Bti, 814 animals from the Nellore breed (NE) and 405 animals from the Charolais breed (CH) were genotyped with the Illumina BovineHD BeadChip and BovineSNP50 BeadChip (54609 SNPs), respectively. The PLINK v.1.9 software was used to combine the data, perform genotype quality control, and estimate the linkage disequilibrium (r^2). The ADMIXTURE software was used to estimate the genetic contributions. Genotype quality control resulted in 283, 811, and 405 animals from the CA, NE, and CH breeds and 29716 SNPs. The genetic contributions of Btt and Bti in the Canchim breed were, in average, 72.5% and 27.5%, respectively. Minimum and maximum proportions of Btt and Bti ranged from 66.0% to 89.0% and 11.0% to 34.0%, respectively, in Canchim cattle. The differences between the expected proportions and the estimated proportions of Btt and Bti were due to the patterns r^2, which are greater in shorter distances (0–0.04 Mb) for CH (0.20), followed by CA (0.16), and NE (0.15). When the r^2 between adjacent SNPs are high, recombination rates should be low, which may be indicative of greater contribution of CH animals in the composition of CA breed. The maximum proportion of 16.0% of Btt was observed for NE, indicating remote crossbreeding, which could have contributed to higher Btt proportion in CA animals.

Key Words: beef cattle, genomics, genetic structure

W70 Genome-wide association analysis and gene ontology enrichment of meat tenderness in Polled Nellore cattle in Brazil.

Leticia M. Castro[1,4], Claudio U. Magnabosco[2,3], Fernando B. Lopes[2,4], Roberto D. Sainz*[2,5], and Guilherme J. M. Rosa[6], *[1]Federal University of Goias, Goania, GO, Brazil, [2]Embrapa-Brazilian Agricultural Research Corporation, Brasilia, DF, Brazil, [3]CNPq-National Council for Scientific and Technological Development, Brasilia, DF, Brazil, [4]Capes-Coordination for the Improvement of Higher Education Personnel, Brasilia, DF, Brazil, [5]University of California, Davis, CA, [6]University of Wisconsin, Madison, WI.*

Brazil has the largest commercial cattle herd worldwide, but its meat quality is highly variable. The national herd is largely composed of *Bos indicus* breeds, which in general have less tender meat than *Bos taurus* cattle, decreasing the product value. This study was carried out to identify genomic regions and biological relevant pathways associated with meat tenderness in Polled Nellore cattle. Data consisted of Warner-Bratzler shear force (WBSF) values of *Longissimus* muscle after 7 d of aging, from 326 Polled Nellore animals born in 3 breeding seasons (2002, 2005 and 2009) at the OB ranch, located in the State of Mato Grosso, Brazil. The animals were genotyped using either the Bovine HD Chip (777k) or the GGP-Indicus Chip (77k). The imputation from the GGP to the HD Chip was performed using FImput software. SNPs were excluded when GenCall <0.7, Call rate <0.90, EHW $P < 0.01$ (using Bonferroni adjustment), and MAF <0.05. Due to large dispersion of sires (progenies' parents), the population stratification was controlled by the 3 first genomic principal components. Genome-wide association analysis (GWAS) was performed using the Efficient Mixed-Model Association (EMMA) method. The GWAS was complemented with a gene set enrichment analysis of Gene Ontology (GO) terms using the FatiGO procedure. The most significant markers ($P < 0.0001$) were located on chromosomes 2, 3, 7, 10, 11, 17, 20, 21, 24 and 25, indicating several QTLs associated with meat tenderness throughout the genome. Additionally, 48 GO terms were deemed enriched. Several of these functional categories can be related to WBSF in Polled Nellore cattle, such as activities of ion channels, membrane cell transportation, growth factors, and protein serine/threonine phosphatase complex, which participate in processes that inactivate apoptosis components. These results help to elucidate the metabolic pathways related to this trait, which is of extreme economic and social importance to Brazil as Nellore is the dominant beef cattle breed in the country. Financial support: EMBRAPA, CNPq, CAPES.

Key Words: shear force, GWAS, pathway

W71 Genomic-polygenic and genomic predictions of direct and maternal effects for growth traits in a multibreed Angus-Brahman cattle population.

Mauricio Elzo*[1], Milton Thomas[2], Dwain Johnson[1], Carlos Martinez[1], Cliff Lamb[1], Owen Rae[1], Jerry Wasdin[1], and Joseph Driver[1], *[1]University of Florida, Gainesville, FL, [2]Colorado State University, Fort Collins, CO.*

The objectives of this research were to compare variance components, genetic parameters, and EBV rankings for birth weight (BW) direct and maternal, weaning weight (WW) direct and maternal, and postweaning gain from 205 d to 365 d (WG) direct using 3 genomic-polygenic and one polygenic model. In addition, trends in EBV were evaluated for each trait and model as Brahman fraction increased from 0% to 100%. The Angus-Brahman multibreed data set included 5,264 animals born between 1987 and 2013. Genomic-polygenic models 1 (GP1; pedigree relationships for all animals; genomic relationships for genotyped animals), 2 (GP2; pedigree relationships for non-genotyped animals only; genomic relationships for genotyped animals), and 3 (GP3; no pedigree relationships; genomic relationships for genotyped animals) used actual and imputed genotypes from 46,768 SNP markers. Variance components and genetic parameters were estimated using REML procedures. Estimates of variance components and genetic parameters from GP1 were the most similar to those from the polygenic model, followed by those from GP2, and the least similar (particularly for maternal traits) were those from GP3. Similarly, the highest rank correlations were those between animal EBV from the polygenic model and GP1 (0.98 to 0.99), followed by those from GP1 and GP2 (0.82 to 0.94) and lastly by those from the polygenic model and GP2 (0.81 to 0.94). Model GP3 performed poorly for maternal traits due to ignoring calf-dam relationships (−0.12 to 0.23). These results indicated that the polygenic model and genomic-polygenic model 1 should be preferred. High genotyping costs could still make the polygenic model preferable for commercial beef cattle operations. Brahman animals tended to have higher EBV for BW direct and WW direct, and lower EBV for WG direct, BW maternal, and WW maternal. However, low regression coefficients for EBV on Brahman fraction ensured that high, medium, and low EBV animals from all breed compositions existed for all growth traits in this multibreed population.

Key Words: cattle, genomic, growth

W72 Genomic regions associated with beef fatty acid profile in Nellore cattle.

R. Espigolan*[1], M. V. A. Lemos[1], H. L. J. Chiaia[1], M. P. Berton[1], F. L. B. Feitosa[1], D. G. M. Gordo[1], R. L. Tonussi[1], A. F. B. Magalhães[1], A. M. Ferrinho[3], L. F. Mueller[3], M. R. Mazalli[3], J. J. M. Furlan[3], A. S. C. Pereira[3], L. G. Albuquerque[1,2], F. Baldi[1], *[1]Universidade Estadual Paulista, Faculdade de Ciencias Agrarias e Veterinarias, Jaboticabal, SP, Brazil, [2]Conselho Nacional de Desenvolvimento*

Cientifico e Tecnologico (CNPq), Brasilia, DF, Brazil, [3]Universidade de Sao Paulo, Faculdade de Zootecnia e Engenharia de Alimentos, Pirassununga, SP, Brazil.

The objective of this study was to identify genomic regions associated with beef fatty acid profile (FA) in Nellore males finished in feedlot using the single-step method. A total of 1,616 genotypes and 963 phenotypes were used. Animals were genotyped using the high-density Bovine-HDBeadChip panel, which contains 777,962 SNP markers distributed throughout the genome. Quality control (QC) criteria were: i) SNPs with minor allele frequency ≤5%, call rate ≤90% (CR); ii) Only samples with CR ≥90% were considered. A total of 470,007 SNPs and 1,556 samples remained in the data set. The FA profile was measured in *Longissimus thoracis* muscle using a gas chromatography, with a 100 m capillary column. The following FA were analyzed: total saturated FA (SFA), total monounsaturated FA (MUFA), total polyunsaturated FA (PUFA), omega-3 (n-3) and omega-6 (n-6). Contemporary groups (CG) were defined as farm, year of birth, and yearling management group. Variance components estimation model included random additive direct genetic effects, fixed effects of CG, and animal's slaughter age as a covariable (linear and quadratic effect). For SFA, MUFA, PUFA, n-3 and n-6, a total of 31, 19, 40, 6 and 6 genomic regions that explain 1% or more of the additive genetic variance were found, respectively. Preliminary studies showed that many of these regions were not previously detected in other cattle breeds. Genes like *PRKAR1A* (protein kinase), *ELOVL5* (fatty acid elongase 5), *FASN* (fatty acid synthase) and *SCD* (esterol-CoA desaturase) were also identified. This study found several genomic regions associated with meat fat acidy profile in Nellore cattle that can be used for further studies to contribute for the production of healthier meat. This work was supported by Sao Paulo Research Foundation (FAPESP) grant #2009/16118-5 and grant #2011/21241-0.

Key Words: fatty acid composition, molecular marker, SNP

W73 An SNP association study evaluating Brahman and Brahman-influenced steers for growth and carcass traits.

Amanda Royer[1], Chris Shivers[3], David Riley[4], Mauricio Elzo[5], and Matthew Garcia*[1,2], *[1]Louisiana State University School of Animal Sciences, Baton Rouge, LA, [2]LSU AgCenter, Baton Rouge, LA, [3]American Brahman Breeders Association, Houston, TX, [4]Department of Animal Science, Texas A&M University, College Station TX, [5]Department of Animal Science, University of Florida, Gainesville, FL.*

Brahman cattle are important in tropical regions due to the breed's ability to tolerate excessive heat and parasite presence. However Brahman cattle exhibit lower yielding, lower quality carcasses as compared with *Bos taurus* breeds. The objective of the current study was to evaluate potential SNP associations on 4 candidate genes for growth and carcass traits in a population of Brahman and Brahman-influenced steers. A total of 42 Brahman and Brahman-influenced steers born between 2009 and 2014, at Louisiana State University Central Research Station in Baton Rouge, Louisiana, were utilized. Steers were evaluated through the American Brahman Breeders Association (ABBA) carcass evaluation project in Gonzales, Texas, for growth, feedlot performance, and carcass quality and composition traits. Growth traits measured at the Central Research Station beef unit before shipment to the feedlot include birth weight, weaning weight, and hip height. Traits measured in Gonzales, Texas, included feedyard entrance weight, harvest weight, and average daily gain. Carcass traits measured include hot carcass weight, ribeye area, marbling score, yield grade, quality grade, dressing percent, and Warner-Bratzler shear force score. A mixed model design with growth, carcass traits and individual SNP genotype fit as dependent variables and breed type, year, dam fit as independent variables was utilized to evaluate potential SNP associations. Sire was fit as a random variable in the model. Four known candidate genes were chosen for SNP analysis based on previous association with growth and carcass traits. Candidate genes include calpastatin (CAST), calpain (CAPN), thyroglobulin (TG), and adiponectin (ADIPOQ). A total of 20 SNP were chosen for each CAST and CAPN, and a total of 30 SNP were chosen for each TG and ADIPOQ. All SNP were selected equidistantly spaced across each candidate gene. Although multiple SNP in the current study were significantly ($P < 0.05$) associated with growth and carcass traits, they must first be validated in much larger and diverse populations before implementation into selection strategies.

Key Words: *Bos indicus*, carcass trait, growth

W74 Major loci associated with growth traits on BTA14 in Hanwoo (Korean cattle).

Seung Hwan Lee*[1,3], Ki Yong Chung[1], Cedric Gondro[2], Chang Gwan Dang[1], Hyeong Cheul Kim[1], Sidong Kim[1], and Hee Ceol Kang[1], *[1]National Institute of Animal Science, Pyeongchang, Gangwon, Korea, [2]University of New England, Armidale, NSW, Australia, [3]Chungnam National University, Daejeon, Chungnam, Korea.*

Genome-wide single marker regression using Bovine 50K BeadChip was performed on growth traits from 1,012 Hanwoo steers in Hanwoo (Korean Cattle). SNPs were excluded from the analysis if they failed in over 5% of the genotypes, had median GC scores below 0.6, had GC scores under 0.6 in less than 90% of the samples, deviated in heterozygosity more than 3 standard deviations from the other SNPs and were out of Hardy-Weinberg equilibrium for a cutoff *P*-value of $1E^{-5}$. Unmapped and SNPs on sex chromosomes were also excluded. A total of 32,696 SNPs were used in this analysis. To test an association between SNP and QTL, single marker regression analysis was implemented in this study. SNP was assumed to be in LD with QTL in close proximity and the effect evaluated was additive effect (QTL allele substitution effect). The Bonferroni-corrected genome wide significant association ($P < 1.5 \times 10^{-6}$) was applied to detect significant SNPs for the GWAS. The GWAS identified one major QTL for body weight at 6, 12, 18 and 23 mo ranging 23Mb to 25Mb on BTA14. The most significant SNP was Hapmap32241-BTC-054753 (24Mb, $P = 1.8 \times 10^{-6}$) for BW6, Hapmap27934-BTC-065223 (25Mb, $P = 1.2 \times 10^{-10}$) for BW12, BW18 and BW23 in Hanwoo. The most significant SNPs accounted for 8 to 10% of additive genetic variance, which is quite large proportion against total additive genetic variance. The Hapmap27934-BTC-065223 has 12.97 kg of allele substitution effect in body weight at 12 mo (BW12). The results revealed that growth traits was affected by major QTL with large effect and many other SNP with small effects with the normal distribution.

Key Words: genome-wide association study, major loci, BTA14

W75 Identification of shared copy number variation among Spanish beef cattle.

T. B. R. da Silva*[1], A. González-Rodríguez[3], E. Mouresan[3], J. J. Cañas-Álvarez[5], L. Varona[3], D. P. Munari[1], M. J. Carabaño[2], C. Avilés[4], P. Martínez-Camblor[6], and C. Díaz[2], *[1]Univ Estadual Paulista, Jaboticabal, SP, Brazil, [2]Instituto Nacional de Investigacion y Tecnologia Agraria y Alimentaria, Madrid, MD, Spain, [3]Univ de Zaragoza, Zaragoza, AR, Spain, [4]Univ de Cordoba, Córdoba, AN, Spain, [5]Univ Autonoma de Barcelona, Barcelona, CT, Spain, [6]Univ De Valladolid, Valladolid, CL, Spain.*

Copy number variations (CNV) are defined as structural variation with 1 kb or larger, and are present in the genome in several forms. Gene expression and gene dosage can be affected by CNV, therefore it can be associated with diseases and livestock economic traits. Local Spanish breed such as Asturiana de los Valles (AV); Avileña Negro-Ibérica (ANI); Morucha (Mor); Pirenaica (Pi) and Retinta (Ret) breeds play an important role in the beef market in Spain. The aim of this paper was to identify CNVs being shared among the 5 breeds and verify the functional annotation of the genes within these CNVs. The 366 animals were genotyped with the Illumina BovineHD BeadChip, which 75 are from AV; 74 from ANI; 75 from Mor; 74 from Pi and 68 from Retinta. Each breed had 25 families composed by father-mother-offspring, exception those breeds that had not 75 individuals, which had 25 incomplete families (mother-offspring). The families within breed were selected to have greater genetic variability. The Penncnv software was applied to detect and filter the CNVs, which considers the BAF (B Alelle Frequency) and LRR (Log R Ratio) signals. We used the trio calling option to identify the CNVs, which consider the pedigree information after the individual CNV calling. We found CNVs being shared among breeds, varying from 87 between Pi and Ret to 514 between AV and Mor. These results suggest evidence that the formation of these breeds may be connected to common ancestry. We found the same CNV in different copy number between breeds, which means, one CNV that is a deletion in certain breed, is an insertion in another one and some of these CNVs encompassed genes. Those genes were WC1.8, PRAME, HSFY2, OAS1X, CD163L1, BOLA-DQA2, OR4P4, OR5J2, TRAC, and they are related to immune system, MHC (Major Histocompatibility Complex) and Olfactory System. Our findings speculate that some CNVs seem to be species specific and the difference of gene copy number among breeds can influence the response to environmental and pathogens challenges.

Key Words: genomic, single nucleotide polymorphism, structural variant

W76 Whole-genome resequencing analysis for identifying genome-wide SNPs and signatures of selection.

Dajeong Lim*, Jung-Woo Choi, Bong-Hwan Choi, Won-Hyong Chung, and Seung-Soo Lee, *National Institute of Animal Science, Suwon, South Korea.*

Over the last 30 years, Hanwoo has been selectively bred to improve economically important traits. Hanwoo is currently the representative Korean native beef cattle breed, and it is believed that it shared an ancestor with a Chinese breed, Yanbian cattle, until the last century. However, these 2 breeds have experienced different selection pressures during recent decades. Here, we whole-genome sequenced 10 animals each of Hanwoo and Yanbian cattle (20 total) using the Illumina HiSeq 2000 sequencer. A total of approximately 3.12 and 3.07 billion sequence reads were mapped to the bovine reference sequence assembly (UMD 3.1) at an average of approximately 10.71- and 10.53-fold coverage for Hanwoo and Yanbian cattle, respectively. A total of 17,936,399 single nucleotide polymorphisms (SNPs) were yielded, of which 22.3% were found to be novel. By annotating the SNPs, we further retrieved numerous nonsynonymous SNPs that may be associated with traits of interest in cattle. Furthermore, we performed whole-genome screening to detect signatures of selection throughout the genome. We located several promising selective sweeps that are potentially responsible for economically important traits in cattle; the *PPP1R12A* gene is an example of a gene that potentially affects intramuscular fat content. These discoveries provide valuable genomic information regarding potential genomic markers that could predict traits of interest for breeding programs of these cattle breeds.

Key Words: whole-genome sequencing, Hanwoo, Yanbian

W77 Genome-wide association on growth traits in Nellore Cattle.

Rafael M. O. Silva*[1], Daniela A. L. Lourenco[2], Breno O. Fragomeni[2], Luciana Takada[1], Rafael Espigolan[1], Maria E. Z. Mercadante[3], Fernando Baldi[1], Guilherme C. Venturini[1], Joslaine N. S. G. Cyrillo[3], and Lucia G. Albuquerque[1], *[1]Univ Est Paulista Julio de Mesquita Filho–FCAV-UNESP, Jabiticabal, SP, Brazil, [2]The University of Georgia, Athens, GA, [3]APTA Center for Beef Cattle, Animal Science Institute, Sertaozinho, SP, Brazil.*

The purpose of this study was to identify genomic regions which could explain the genetic variation in growth traits in a Nellore cattle population. The data set contained 8702, 8004, 3828, and 3942 records for birth weight (BW), weaning weight (WW), one year weight (YA) and yearling weight (YW), respectively. The animals were genotyped using panels of high-density SNP (Illumina High-Density Bovine BeadChip, 700k). After genomic data quality control, 437,197 SNPs for 631, 635, 342, and 299 animals for BW, WW, YA, and YW, respectively, were also available. SNP solutions were estimated by genome-wide association study using a single-step BLUP approach (ssGWAS). Before the ssGWAS the data was analyzed by a single-step genomic BLUP. Variances were calculated for windows of 200 SNP. Fixed effects in the model included month of birth, age of dam (linear and quadratic effect), contemporary group (sex, year of birth, and pen), plus animal and maternal additive random effects. Moreover, maternal permanent environmental effects were considered as random for all traits but BW. The results showed the top 10 SNP windows for each trait explained a total of 7%, 2.5%, 1.5%, and 3.5% of variance of BW, WW, YA, and YW, respectively. For all of analyzed traits the SNP windows with greatest influences were at chromosome number 14 (BTA14). In all regions of top SNP windows many genes that have been associated with growth in beef cattle were found. Various authors have recommended caution to interpret the results. Even though many SNP windows explained part of variance of all studied traits, it does not necessarily mean those regions cause the phenotypic variation. These results suggest that there are many regions on chromosome 14 associated with growth traits in Nellore cattle. São Paulo Research Foundation (FAPESP) grant 2013/01228-5 associated to grant #2009/16118-5

Key Words: beef cattle, GWAS

W78 Genome-wide association study for flight speed in Nellore cattle.

Tiago S. Valente*, Fernando Baldi, Aline C. Sant'Anna, Lucia G. Albuquerque, and Mateus J. R. Paranhos Da Costa, *São Paulo State University, Faculty of Agriculture and Veterinary Sciences, Jaboticabal, São Paulo, Brazil.*

The aim of this study was to identify single nucleotide polymorphisms (SNPs) that are significantly associated with temperament, measured by flight speed (FS), in Nellore cattle using the single step procedure (ssGWAS). Temperament was assessed by the speed (m/s) at which each animal exited the crush after yearling weighing. Data were from 16,119 animals with phenotypes and a pedigree file with 162,644 animals. A total of 1,405 animals were genotyped with BovineHD BeadChip. Quality control was performed to exclude SNP markers with unknown genomic position, located on sex chromosomes, monomorphic, MAF < 1%, call rate < 90%, and animal call rate (with less than 90% of SNPs called). After edits, 455,374 SNPs and 1,384 genotyped animals remained. The association analyze was performed by ssGBLUP, a modification of BLUP with numerator relationship matrix $\mathbf{A}^{-1}$ matrix replaced by $\mathbf{H}^{-1}$, that uses the GEBV to estimate the SNPs effects. Variance components and genetic parameters were estimated by Bayesian inference via Gibbs sampling using the softwares GIBBS2F90, PREGSF90 and POSTGSF90, assuming a linear animal model for FS which included

direct additive genetic and residual effects as random effects and contemporary groups as fixed effect. The effects were calculated to segments of 10 sequential SNPs and results interpreted as the percentage (%) of total genetic variance explained by each SNP window. Segments that explained 1% or more of the total genetic variation were considered as canditade region associated with FS. Ten regions were associated with FS: one on BTA1 (1:73354330–73406566, 2.07%), 2 on BTA5 (5:22596661–22604723, 3.04% and 5:119291684–119306475, 1.44%, respectively), one on BTA9 (9:98759214–98767952, 3.33%), BTA11 (11:67385287–67404876, 1.39%), BTA15 (15:16598639–16662233, 1.45%), BTA17 (17:639678–671693, 4.62%), BTA18 (18:34146668–34168795, 1.22%) BTA22 (22:32886184–32904212, 1.08%) and BTA26 (26:47061401–47095621, 1.86%). This result confirms the polygenic architecture related to expression of cattle temperament, resulting from the influence of numerous genes interacting with each other and with environmental factors. Future approaches are required to identify the gene expression associated with the SNP windows found in this study.

Key Words: GWAS, temperament

Breeding and Genetics: Genomic methods and application—Dairy

W79 Common copy number variation regions affecting dairy traits in Gyr cattle. Gerson A. Oliveira Junior*[1], Adriana S. Carmo[2], Adam T. H. Utsunomiya[3], Tatiane C. S. Chud[3], Fernando S. B. Rey[3], Jose Bento S. Ferraz[1], and Marcos Vinicius G. B. da Silva[2], *[1]University of São Paulo, Pirassununga, São Paulo, Brazil, [2]Embrapa Dairy Cattle, Juiz de Fora, Minas Gerais, Brazil, [3]São Paulo State University, Jaboticabal, São Paulo, Brazil.*

The Gyr cattle (*Bos indicus*) is a very important dairy breed in tropical countries like Brazil, mainly due to its tolerance to heat stress and parasites infestations as well as their use in crossbreeding schemes with other specialized dairy breeds, such as Holstein. In addition to the single nucleotide polymorphism (SNP), genomic structural variants such as copy number variants (CNV) have been revealed to be a substantial source of genetic and phenotypic variation in cattle, being an alternative to explain the missing heritability of complex traits. The aim of this work was to investigate common CNV regions associated with dairy traits in Gyr cattle. The Log R ratio profiles of 481 Gyr animals were determined using a high density SNP chip (Illumina BovineHD BeadChip assay), and the phenotypes evaluated were: age at first calving (AFC), milk (MY), fat (FY), protein (PY) and total solids yields (TSY), and protein (PP), fat (FP) and total solids percentage (TSP). The Log R ratio, predicted from Genome Studio software, was used in Golden Helix SNP & Variation Suite (SVS) 8.1, and the copy number analysis module (CNAM – multivariate algorithm) was used to identify common CNVs among animals. Linear regression was employed to identify CNVs associated with each production trait with significance level of FDR >0.05. A total of 47 CNV regions were detected that affected at least one trait, with 22 regions affecting 3 or more traits where one of them, located at chromosome 7, affected all traits except MY. Under these 22 regions, 38 structural variation, 18 genes and one pseudo-gene annotated in bovine genome (Biomart tool of Ensembl) were observed. The Panther Classification System divided these genes into 10 biological process categories highlighting localization, immune system and metabolic processes. The results suggest that common CNV regions can be biologically involved with more than one dairy trait.

Key Words: structural variant, genomics, dairy cattle

W80 Genome-wide association study on conception rate, milk production, and SCS in different stages of lactation for first three parities in US Holsteins. Shogo Tsuruta*[1], Daniela A. L. Lourenco[1], Ignacio Aguilar[2], and Ignacy Misztal[1], *[1]University of Georgia, Athens, GA, [2]INIA, Las Brujas, Canelones, Uruguay.*

The objectives of this study were to conduct genome-wide association studies (GWAS) on conception rate (CR), production traits, and SCS for Holstein cows and determine if the genetic architecture of these traits is different in 3 stages of lactation for the first 3 parities in US Holsteins. Genome-wide association studies were conducted for conception rate (CR), test-day milk, fat and protein yields, and test-day SCS. The data were split into 3 sets: early (<14wk), middle (14wk ≤ DIM ≤ 29wk), and end (29wk <). Heritability estimates for CR were lowest (0.03) in the middle and highest (0.05 to 0.08) in the end of lactation in all parities. Genetic correlations of CR with other production traits were low and all negative (−0.1 to −0.5). The SNP marker effects were divided into equal segments of 30 SNP. A segment on chromosome 14 was associated with CR only in early and middle stages of lactation in the third parity; the proportion of the total genetic variance explained by this segment for CR were 2.7% and 2.5%, respectively. The proportions for test-day milk and fat yields were highest in the middle of lactation (7% for milk and 8% for fat) in all 3 parities, whereas the proportions for test-day protein and SCS were low (<2%). The results suggest that gene expression for CR and milk production traits is stronger in early and middle lactation stages and similar over the lactations.

Key Words: GWAS, conception rate, US Holsteins

W81 Single nucleotide polymorphisms associated with thermoregulation in lactating dairy cows exposed to heat stress. Serdal Dikmen*[1,3], Xian-zhong Wang[2,3], and Peter J. Hansen[3], *[1]Department of Animal Science, Faculty of Veterinary Medicine, University of Uludag, Bursa, Turkey, [2]College of Animal Science and Technology, Southwest University, Chongqing, China, [3]Department of Animal Sciences, University of Florida, Gainesville, FL.*

Dairy cows with increased rectal temperature during heat stress experience lower milk yield and fertility. Given that rectal temperature during heat stress is heritable in dairy cattle, genetic selection for regulation of body temperature should reduce effects of heat stress on production. One goal of the study was to validate the relationship between genotype and heat tolerance for SNPs previously related to resistance to heat stress. A second goal was to identify new candidate gene SNPs related to resistance to heat stress. Thermotolerance was assessed in 625 lactating Holstein cows during the hottest part of the day in summer by measuring rectal temperature (a direct measurement of body temperature regulation), respiration rate (an indirect measurement body temperature regulation) and sweating rate (the major evaporative cooling mechanism in cattle). Specific genetic markers and candidate genes responsible for genetic variation in these variables were identified. For SNPs previously related to heat tolerance in genome-wide analysis, a region of BTA6 was related to rectal temperature and 3 closely-located genetic markers on BTA24 and another on BTA29 were associated with sweating rate. New candidate gene SNPs were identified for rectal temperature (n = 7), respiration rate (n = 9), and sweating rate (n = 6). The largest effect on rectal temperature was for *PGR,* which explained 2.1% of the phenotypic variation after adjustment for dry bulb temperature. This SNP could affect heat loss via cutaneous cooling because progesterone regulates vasodilation in the skin during local heating. *ACAT2* (involved in lipid metabolism) explained the largest variation in respiration rate (3.3%) and *SERPINE2*, which regulates the enzyme thrombin that regulates epithelial cells in sweat glands, explained the largest variation in sweating rate (2.1%). These genetic markers could prove useful in genetic selection for heat tolerance in Holstein cattle.

Key Words: heat stress, thermoregulation, SNP

W82 Multi-generational imputation of SNP genotypes and accuracy of genomic selection. Sajjad Toghiani* and Romdhane Rekaya, *The University of Georgia, Athens, GA.*

Superiority of genomic selection (GS) is possible only when high density single nucleotide polymorphism (SNP) panels are used to track QTLs affecting traits. Even with the continuous decrease in genotyping costs, only a small fraction of the population has been genotyped with these high-density panels. To reduce the cost of GS, it is often the case that a larger portion of the population is genotyped with low-density SNP panels and then imputed to a higher density. Accuracy of SNP genotype imputation tends to be high when minimum requirements are met. Nevertheless, a certain rate of errors is unavoidable. Such rate of errors tends to increase with the increase of the generational interval between reference and testing generations. Thus, it is reasonable to assume that accuracy of GEBVs will be affected by imputation errors. To evaluate the impact of multi-generational selection on the accuracy of SNP genotypes imputation on the reliability of resulting GEBVs, a simulation was carried out under varying updating of the reference population, distance between training and validation sets, and the approach used for the estimation of GEBVs. Using fixed reference populations, imputation accuracy decayed by around 0.5% per generations. In fact, after 25 generations, the accuracy was only 7% lower than the first generation. When the reference population was updated by either 1% or 5% of the top animals in the previous generations, decay of imputation accuracy was substantially reduced. These results indicate that low-density panels are useful, especially when the generational interval between reference and testing population is small. As the generational interval increases, the imputation accuracies decay, although not at an alarming rate. In absence of updating of the reference population, accuracy of GEBVs decays substantially in 1 or 2 generations with a decrease rate of around 20–25% per generation. When the reference population is updated by 1 or 5% every generation, the decay in accuracy was only 8 to 11% after 7 generations. These results indicate that imputed genotypes provide a viable alternative, as long the reference and training populations are appropriately updated.

Key Words: genotype imputation, genomic selection, accuracy

W83 Genome-wide association study for milk production traits in Russian dairy cattle.

Alexander A. Sermyagin*[1], Elena A. Gladyr[1], Sergei N. Kharitonov[1], Alexander N. Ermilov[1,2], Ivan N. Yanchukov[2], Nikolai I. Strekozov[1], and Natalia A. Zinovieva[1], *[1]L.K.Ernst Institute of Animal Husbandry, Dubrovitsy, Moscow, Russia, [2]Regional Information Selection Center, Noginsk, Moscow, Russia.*

Genome-wide association study has been proven as a powerful tool for identifying genomic variants associated with economically important traits in domestic animal breeds. Our study is the first step toward the creating the reference population of Russian Holsteins to utilize the genomic information in the dairy cattle breeding programs in Russia. The objective of our study was to evaluate the association between SNPs and estimated breeding values (EBVs) for milk production traits. The genomic data were obtained by genotyping 195 progeny-tested and 61 young bulls using the Illumina Bovine SNP50 v2 BeadChip. The SNP's quality control was performed by using Plink (1.07) software. BLUP AM approach has been used to estimate the marker effects which were applied then to calculate the genomic EBVs for young bulls to increase the prediction reliability of the associations. Direct genomic and genomic EBVs (by GBLUP) were estimated for 305-d milk yield (MY), milk fat yield (FY), milk protein yield (PY), fat percent (FP) and protein percentage (PP). After the quality control, 41370 SNPs were selected for the association analysis. The average number of daughters per sire was about 240 and the reliability of EBVs amounted 87%. The linkage disequilibrium was $r^2 = 0.41$. The Bonferroni correction for detection significant associations was applied as $P < 1.2 \times 10^{-6}$. Two SNPs which had the most significant effect for MY were identified: ARS-BFGL-NGS-50172 on BTA17 ($P = 7.6 \times 10^{-8}$) and Hapmap54246-rs29017970 on BTA13 ($P = 1.7 \times 10^{-7}$). The association analysis for milk components revealed 3 SNPs significantly associated with FP: BTA-104917-no-rs on BTA9 ($P = 4.1 \times 10^{-8}$), ARS-BFGL-NGS-107379 on BTA14 ($P = 6.0 \times 10^{-7}$) and BTB-01604502 on BTA9 ($P = 1.1 \times 10^{-6}$). The effect on PP was shown for SNP Hapmap43278-BTA-50082 on BTA20 ($P = 8.0 \times 10^{-7}$). Few SNPs were found to have the effects on FY and PY traits. The significant effects of SNPs explained from 9.0 to 11.3% of additive genetic variances. Supported by the Russian Ministry of Education and Science (RFMEFI60414X0062).

Key Words: genome-wide association, breeding value, milk production

W84 Identification of copy number variable gene families in Holstein and Jersey cattle.

Derek M. Bickhart*[1], Lingyang Xu[2,1], Jana L. Hutchison[1], Harris A. Lewin[3], and George E. Liu[1], *[1]United States Department of Agriculture, Agricultural Research Service, Animal Genomics and Improvement Laboratory, Beltsville, MD, [2]University of Maryland, Department of Animal and Avian Sciences, College Park, MD, [3]University of California, Department of Evolution and Ecology, Davis, CA.*

Copy number variants (CNV) represent a large proportion of genetic variation within the cattle genome that has yet to be accurately characterized by SNP genotyping arrays. While significant progress has been made in the identification of CNVs within individual animals using next generation sequence data, CNV frequencies within larger populations have not yet been estimated in cattle. In this study, we sequenced 28 individual bulls from 2 dairy breeds of cattle (22 Holstein bulls; 6 Jersey bulls) to identify dairy breed-specific copy number variation. Using a read depth method of CNV detection, we identified 1359 non-redundant CNV regions within all 28 animals. The number of variable bases contained within these CNV regions accounts for ~2% of the cattle genome, and the average CNV region frequency was 37.67%. This high average frequency suggests that a large proportion of CNVs were present in the ancestral population of both breeds of cattle rather than as a result of a large number of de novo events arising in subsequent generations after breed formation. We also assigned copy number values to each gene within each individual sequenced using the normalized sequencing read depth of non-overlapping genomic windows. Using a Vst approach on these gene copy number values, we identified 27 gene families with breed specific copy number expansions/contractions. We identified a Jersey-exclusive expansion of the CLEC5A gene, which is a regulator of osteoclastogenesis. Additionally, we identified a Holstein-exclusive duplication of the ASAP1 gene, which may be involved in cell membrane trafficking and the differentiation of fibroblasts into adipocytes. CNVs identified by this survey intersected gene families that may play a role in productive traits in dairy cattle and are therefore good candidates for novel genetic marker design.

Key Words: copy number variant, genomics, sequencing

W85 Single nucleotide polymorphisms in specific candidate genes are associated with phenotypic differences in days open for first lactation in Holstein cows.

M. Sofia Ortega*[1], Anna C. Denicol[1], Daniel J. Null[2], John B. Cole[2], and Peter J. Hansen[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]Animal Genomics and Improvement Laboratory, Agriculture Research Service, United States Department of Agriculture, Beltsville, MD.*

Previously, a candidate gene approach identified 51 single nucleotide polymorphisms (SNP) associated with genetic merit for reproductive traits and 26 associated with genetic merit for production in dairy bulls. We evaluated association of these 77 SNP with days open (DO) for first lactation in a population of Holstein cows grouped based on predicted transmitting ability for daughter pregnancy rate (DPR): ≤ -1 (n = 1220) and ≥ 1.5 (n = 1053), and located on 11 farms in Florida and California. Cows were genotyped using a Sequenom MassARRAY assay. To evaluate phenotypes, farm records were retrieved from on-farm computers and combined with records from the national genetic evaluation system. The association of the genetic variants with DO was evaluated using the MIXED procedure of SAS V9.4 (SAS Institute, Inc., Cary, NC). The model included farm, number of copies of the minor allele, and the numerator relationship matrix to account for (co)variances among animals. For each SNP, the genotype was treated as a categorical variable to estimate additive and heterosis effects. Days open was lower ($P < 0.0001$) for cows in the high DPR group as compared with the low DPR group (97.8 ± 2.6 d vs 163.0 ± 2.9 d). There were 6 SNP with significant additive effects ($P < 0.05$) on DO (*COQ9, FCER1G, FST, GPLD1, MRGPRF* and *OCLN*) and an additional 6 SNPS with a tendency ($P < 0.10$) for an association (*ACAT2, CD14, PCCB, PMM2, RABEP2* and *SREBF1*). For example, DO for cows with 0, 1, or 2 copies of the minor allele for *COQ9* averaged 139.4 ± 3.5, 134.3 ± 2.8, and 123.6 ± 3.5 d, respectively. The DO for cows with 0, 1, or 2 copies of the minor allele for *FST* averaged 124.9 ± 3.3, 134.8 ± 2.6 and 135.8 ± 4.4 d, respectively. For 9 of 12 genes, the favorable allele for DO was also the favorable allele in the earlier report based on bulls. The SNP related to genetic and phenotypic estimates of fertility are likely to be informative markers for genetic selection. Moreover, the study of the role of these genes could provide new insights into the physiological regulation of fertility in dairy cattle (USDA AFRI 2013–68004–20365).

Key Words: single nucleotide polymorphism, days open, dairy cattle

W86 Animal selection for whole-genome sequencing by quantifying the unique contribution of homozygous haplotypes sequenced.

Jana L. Hutchison*, John B. Cole, and Derek M. Bickhart, *United States Department of Agriculture, Agricultural Research Service, Animal Genomics and Improvement Laboratory, Beltsville, MD.*

Major whole-genome sequencing projects promise to identify rare and causal variants within livestock species; however, the efficient selection of animals for sequencing remains a major problem within these surveys. The goal of this project was to develop a library of high accuracy genetic variants found within diverse haplotypes that were in a homozygous state identified from animal genotypes in the national database. An inverted weight function that calculated the value of sequencing an animal based on the sum of the rarity of the haplotypes it had in its SNP-based genotype was used to calculate the estimate, as more common haplotypes would likely be represented within animals already sequenced in subsequent iterations. A weight value was assigned to each 75-SNP haplotype based on the inverse of its frequency within genotyped animals in the national database. Each individual's haplotype weights were summed, and the highest scoring animal was selected for sequencing. Haplotypes from selected animals were removed from future consideration, and the cumulative scores of all remaining animals were recalculated in the absence of those selected haplotypes. This iteration continued until all haplotypes above a frequency threshold of 4% had been selected for sequencing. There were a total of 3,680 75-SNP haplotypes above a frequency of 4% in the national database and 484,522 genotyped Holstein animals. We compared this method against the selection of animals for sequencing based on 3 additional algorithms: (1) an ascending relatedness weight function, (2) an unbiased predictor of imputation accuracy, and (3) a random selection of animals from the population. By calculating an iterative summed score based on the inverse value of an animal's unsequenced haplotypes, one can quickly determine the value of sequencing a new individual and avoid data redundancy that plagues projects that focus on sequencing highly related individuals in a population.

Key Words: sequencing, haplotype

W87 A GWAS on heat tolerance phenotypes for Italian Holstein bulls.

Stefano Biffani[1], Umberto Bernabucci[2], Nicola Lacetera[2], Andrea Vitali[2], Paolo Ajmone Marsan[3], Nicolo PP Macciotta*[4], and Alessandro Nardone[2], [1]*IBBA-CNR, Lodi, Italy,* [2]*Dipartimento di Scienze e Tecnologie per l'Agricoltura, le Foreste, la Natura e l'Energia Università degli Studi della Tuscia, Viterbo, Italy,* [3]*Istituto di Zootecnica, Università CAttolica del Sacro Cuore, Piacenza, Italy,* [4]*Dipartimento di Agraria, Università di Sassari, Sassari, Italy.*

Heat stress is a key factor that negatively affects livestock productive and reproductive performance. A genome-wide scan was performed on a sample of 1,592 Italian Holstein bulls using 2 different measures of heat tolerance for milk yield and protein percentage. The first was a temperature-humidity index breeding value (THI EBV) recently proposed for the Italian Holstein breed. The latter was obtained by a principal component analysis carried out on milk test-day records corrected for environmental effects except for THI. Only the second principal component (PC2), which describes the individual patterns of corrected production data across different THI levels, was considered. Animals were genotyped with the Illumina BovineSNP 50 BeadChip. Monomorphic SNPs (7,140) and SNPs with a call-rate <95% (1,045) were discarded. In total, 45,546 SNPs were retained for the analysis. All bulls had a THI EBV, whereas the PC2 was available only for a sub-sample of bulls (423). Genome-wide scan was performed fitting the GRAMMAR approach through the GenABEL R package. Then, a Gene discovery analysis was carried out considering windows of 0.5 Mb surrounding the significant marker (0.25Mb up and down stream respectively). No significant associations were detected for milk THI EBV, apart from a weak signal on BTA 2 at about 32 Mb. In this region is located the solute carrier family 38, member 11 (SLC38A11) gene, reported to be involved in folliculogenesis in cattle. For PC2, 3 SNPs were detected on BTA 6, 16 and 26, respectively. The SNP on BTA26 is located in a region that hosts genes involved in the ovarian activity (FGF8). An interesting candidate for the SNP located on BTA16 at approximately 42.1 Mb is the dehydrogenase/reductase member 3 (DHRS3), involved in the embryonic development in humans. No significant associations were found for protein percentage THI EBV. However, 3 significant markers were detected for PC2 on BTAs 20, 14 and 8. Interestingly the BTA14 region hosts the junctophilin 1 (JPH1) gene, whose expression has been found to be upregulated in the hypothalamus of chickens subjected to heat stress. These preliminary findings suggest potential genomic regions linked to heat stress resistance in dairy cattle.

Key Words: heat stress, GWAS, principal component analysis

W88 A genome-wide association study of mastitis in US Holstein and the relationship to mammary microbiome profile identifies novel QTL.

Heather Huson*[1] and Rodrigo Bicalho[2], [1]*College of Agriculture and Life Sciences, Cornell University, Ithaca, NY,* [2]*College of Veterinary Medicine, Cornell University, Ithaca, NY.*

One of the most prevalent and costly obstacles facing dairy producers is the occurrence of mastitis. Mastitis is a worldwide endemic disease causing both short and long-term cow health and economic repercussions with production losses in terms of reduced milk yield, clinical treatment, culling of animals, and discarded milk. The objective of this study was

to conduct a genome-wide association study (GWAS) for mastitis and explore the use of milk microbiome profiles to identify novel mastitis QTL using the Illumina Bovine High-Density (777K SNPs) Beadchip on a cohort of US Holstein dairy cows. To this end, 2 GWAS were run comparing Holstein cows; the first compared cows phenotypically characterized as having clinical mastitis (CM) or healthy based on their somatic cell score (SCS) and the second GWAS used a linear score based on their mammary microbiome profile. The mammary microbiome profile was generated sequencing 16S rRNA of the milk microbiota, directly correlated with mastitis incidence, to generate a cow specific profile. Four genomic regions demonstrating significant association to CM incidence were identified on BTA 5, 16, 26, and 29 using SCS and 5 regions on BTA 5, 9, 16, 26, and 29 were significantly associated with microbiome profile GWAS (corrected P-value < 0.05). Of particular interest to this study was to identify regions of similar association and those different between the 2 trait GWAS, CM as opposed to microbiome profile. Regions on BTA 5, 9, and 26 validated previous mastitis QTL findings. Both GWAS approaches in this study identified novel QTL on BTA 16 and 29 potentially being the product of a more generalized immune response to infection. In contrast, marker associations on BTA 1, 2, and 11 show more variation between the 2 GWAS and may reflect a genetic predisposition to specific microbiota. In all, the study validated previously discovered QTL and identified novel QTL with both similarities and variation in the comparison of the 2 trait GWA studies. Further studies are required to validate specific candidate genes and their influence on mastitis and the potential identification of diagnostic markers for the selection of mastitis resistant dairy cows.

Key Words: mastitis, GWAS, microbiome

W89 The accuracy of genomic predictions for Japanese Holsteins using by GBLUP and ssGBLUP methods. Yusaku Gotoh*[1], Toshimi Baba[1], Satoshi Yamaguchi[2], and Takayoshi Kawahara[1], [1]*Holstein Cattle Association of Japan, Hokkaido Branch, Sapporo, Japan,* [2]*Hokkaido Dairy Milk Recording and Testing Association, Sapporo, Japan.*

Several strategies including GBLUP and ssGBLUP methods have been proposed to predict genomic breeding values (GEBV) for dairy cattle. Many studies have reported that the accuracy of GEBV predicted from ssGBLUP was higher than from GBLUP. There is no report applying same analysis to Japanese Holsteins. The objective of this study was to compare the accuracies of GPI predicted by GBLUP and ssGBLUP. The traits used in this analysis were 305-d milk, fat and protein yields, and feet and legs, udder and final score. In total, 3,787 bulls genotyped by the Illumina BovineSNP50 BeadChip were used. Validation bulls were prediction bulls with no daughters in 2009 data but more than 20 daughters in 2013 data. In multistep evaluation, training bulls were required to have 10 daughters in 2009 data. Number of training bulls were 517 and 554 for the analysis of milk and type traits, respectively. For multistep evaluation, GPI were estimated by selection index blending after calculating DGV by linear GBLUP. Coefficients of determination (R^2) by regression analysis of GPI for 2009 data on deregressed EBV for 2013 data were used as indicator of accuracy. The R^2 ranged from 0.19 (protein) to 0.27 (milk) and from 0.17 (feet and legs) to 0.28 (milk) for DGV and GPI predicted by GBLUP and from 0.21 (protein) to 0.30 (milk) for GEBV predicted by ssGBLUP, respectively. Hence, it is suggested that the GEBV predicted by ssGBLUP is higher accuracy than DGV and GPI predicted by GBLUP.

Key Words: GBLUP, ssGBLUP, accuracy

W90 Identification of loci associated with fertility in Holstein heifers. Joao G. N. Moraes*[1], Joseph Dalton[2], Thomas E. Spencer[1], Jennifer N. Kiser[1], Gregory W. Burns[1], Andrzej Wojtowicz[1], Mahesh Neupane[1], and Holly L. Neibergs[1], [1]*Department of Animal Science, Washington State University, Pullman, WA,* [2]*Department of Animal and Veterinary Sciences, University of Idaho, Caldwell, ID.*

Selection for higher milk production in United States dairy cattle has been very successful during the past 50 years, however modern lactating dairy cows exhibit a high incidence of subfertility and infertility with a national pregnancy rate of only 15 to 20%. The objective of this study was to identify genomic loci associated with fertility in nulliparous Holstein heifers. Breeding and health records of Holstein heifers (n = 2,333) were analyzed from a commercial heifer raising facility in Southern Idaho. Of these, 1,114 heifers were classified as highly fertile (conceived on first AI service) and 209 were identified as subfertile (did not conceive until after the fourth AI service or culled due to failure to conceive). Blood samples were obtained from the fertility-classified heifers, and DNA was extracted from 497 high fertile and 209 subfertile heifers. The DNA was genotyped with the Illumina Bovine HD Genotyping BeadChip. Quality control consisted of removing SNPs with < 90% call rate, and a MAF < 1% and removing heifers with a genotyping rate < 90%, leaving 575,959 SNPs and 470 fertile and 189 subfertile heifers for analysis. A genome wide association analysis (GWAA) and heritability estimate was conducted with the Efficient Mixed-Model Association expedited (EMMAX) software. This mixed model program empirically estimated a genomic relationship matrix and used it to model the correlation between the fertility phenotypes. Correction for population stratification was done by variance components and resulted in $\lambda_{GC} = 1.0$. The GWAA identified a QTL on BTA4 with a strong association with fertility ($P = 2.9 \times 10^{-9}$), while loci on BTA1, BTA2, BTA5, BTA6, BTA10, BTA11, BTA18, BTA23, BTA26, BTA27 and BTA28 were identified with a moderate association with fertility ($P < 5.0 \times 10^{-5}$). The heritability estimate for fertility in Holstein heifers was 0.52. These results indicate that there is ample opportunity to make significant gains in fertility in nulliparous Holstein heifers with genomic selection. This project was supported by Agriculture and Food Research Initiative Competitive Grant no. 2013–68004–20365 from the USDA National Institute of Food and Agriculture.

Key Words: genomics, fertility, heifer

W91 Accuracy of genomic imputation in a Thai multibreed dairy cattle population. Danai Jattawa*[1,2], Skorn Koonawootrittriron[1], Mauricio A. Elzo[2], and Thanathip Suwanasopee[1], [1]*Kasetsart University, Chatuchak, Bangkok, Thailand,* [2]*University of Florida, Gainesville, FL.*

The objective of this study was to investigate the accuracy of imputation from low (LDC) to moderate density SNP chips (MDC) in a Thai Holstein-Other multibreed dairy cattle population. Dairy cows with complete pedigree information (n = 1,110) from 129 dairy farms were genotyped with GeneSeek GGP20K (n = 570) and GGP26K (n = 540) BeadChips. After checking for genotypic quality, 16,387 SNP in common between the GGP20K and GGP26K were used to represent MDC in this study. Cows were divided into 2 groups, a reference group (n = 778) and a test group (n = 332). The SNP genotypes chosen for the test group were those SNP located in positions corresponding to GeneSeek GGP9K (n = 7,356). The LDC to MDC genomic imputation was carried out using 3 different methods, namely a population-based algorithm in the Beagle software (PBG), a population-based algorithm in the FImpute software (PFI), and a combined family and population-based algorithm in FImpute (CFI). Imputation accuracies within and across chromosomes were calculated as ratios of correctly imputed genotypes to overall imputed genotypes. Imputation accuracy for the 3 methods ranged from 76.31% to 93.91%. The CFI had slightly higher imputation accuracy (93.91%) than PFI (93.56%) and both methods were substantially more accurate than PBG (76.31%). Noticeably most chromosomes that showed either high or low imputation accuracies were the same chromosomes that had high and low average linkage disequilibrium (defined here as the correlation between pairs of adjacent SNP within chromosomes less than 5 MB apart). This suggested that choosing sets of SNP with high levels of average linkage disequilibrium would improve imputation accuracy. Results clearly indicated that FImpute software (population or combined family-population) were more suitable than Beagle for genotype imputation in this Thai multibreed population. Perhaps additional increments in imputation accuracy could be achieved by discarding SNP with low levels of average linkage disequilibrium, and by increasing the completeness of pedigree information.

Key Words: imputation accuracy, linkage disequilibrium, multibreed dairy cattle

W92 Identification of copy number variation in Brazilian synthetic dairy cattle breed.

T. C. S. Chud[1], M. V. G. B. da Silva[2], A. S. Carmo[2], T. B. R. Silva*[1], G. A. Oliveira Junior[3], F. S. Baldi Rey[1], and D. P. Munari[1], *[1]Univ Estadual Paulista "Júlio de Mesquita Filho," Jaboticabal, SP, Brazil, [2]Embrapa - Brazilian Corporation of Agricultural Research, Juiz de Fora, MG, Brazil, [3]Universidade de São Paulo, Pirassununga, SP, Brazil.*

Copy number variation (CNV) refers to genomic segments that present a type of structural variation, such as duplications or deletions. CNVs have been observed as an important source of genetic and phenotypic variation for production traits and animal health. The aim of this work was to identify CNVs in a synthetic breed (Gyr × Holstein) dairy cattle population (Girolando cattle). The data set contained 417 animals genotyped with the Illumina 50K SNP panel (~54.609 SNPs). An algorithm based on the Hidden Markov Model was implemented using PennCNV software (Wang et al., 2007) for CNV identification. PennCNV perl script was used to eliminate calls from low quality samples, based on the standard deviation of LRR (<0.30), the BAF drift (<0.01) and waviness factor (less than 0.05). The final data set was composed of 384 animals. Gene content of cattle CNV was assessed using Ensembl genes. We used the PANTHER classification system for testing the hypothesis ($P < 0.05$) that the GO terms of the molecular function, biological process, and pathway terms were under or overrepresented in the CNV. An account of 1,986 CNVs were found along the genome, of which 84% were duplications and 16% were deletions. The chromosomes BTA3, BTA17 and BTA23 presented higher frequencies (10.52%, 11.53%, 8.30%, respectively) of CNV. Chromosomes that showed lower frequency of CNV (<1%) were BTA27, BTA14 and BTA29. A total of 861 genes were found within these regions and they are involved in biological processes, such as development (105 genes), growth (2 genes), immune system (83 genes), metabolism (343 genes) and reproduction (12 genes). This study showed evidences of structural variations in the genome of Girolando cattle and the genes found in CNV may be involved in the expression of production and animal health traits.

Key Words: genomics, single nucleotide polymorphism, structural variation

W93 Linkage disequilibrium in a Thai dairy cattle population with different Holstein fractions.

Thawee Laodim[1], Skorn Koonawootrittriron*[1], Mauricio A. Elzo[2], and Thanathip Suwanasopee[1], *[1]Kasetsart University, Bangkok, Thailand, [2]University of Florida, Gainesville, FL.*

Linkage disequilibrium (LD) is important for gene mapping, accuracy of genomic prediction, and understanding of recombination biology in dairy cattle populations. The level of LD can vary among populations depending on their genetic structure, selection and recombination rates. The objective of this study was to estimate and compare levels of LD in dairy cattle with different Holstein fractions under tropical conditions. Blood samples of 2,643 dairy cattle (89 bulls and 2,554 cows) from 304 farms located in Central, Northern, Western and Southern Thailand were extracted for DNA. The DNA samples were genotyped with one of 4 GeneSeek Genomic Profiler BeadChips (9K, 20K, 26K, or 80K). Only SNPs from autosomes in common among the 4 chips were considered. In addition, SNPs with a minor allele frequency (MAF) lower than 0.01 and a call rate lower than 90% were excluded. This resulted in a set of 7,123 SNPs used in this study. Animals were classified into 7 groups based on their Holstein fraction (HF): HF <75%, 75% ≤ HF <80%, 80% ≤ HF <85%, 85% ≤ HF <90%, 90% ≤ HF <95%, 95% ≤ HF <100%, and purebred HF. Distribution of MAF and estimation of LD were done using Haploview. All HF groups had similar patterns of MAF across autosomes (fraction of SNPs increased with an increase in MAF). However, means of MAF across autosomes differed among HF groups and it tended to decrease with an increase in H fraction (from 0.376 for HF <75% to 0.362 for purebred HF). Conversely, the mean r^2 across autosomes tended to increase as HF increased from 0.081 for HF <75% to 0.109 for purebred HF. Results from this study will be useful for genome wide association studies and for genomic prediction and selection of crossbred Holstein cattle in tropical regions.

Key Words: linkage disequilibrium, Holstein, tropics

W94 Improving the genotyping-by-sequencing (GBS) approach for the identification of SNPs associated with Johne's disease.

Émilie Constant[1,2], Eveline M. Ibeagha-Awemu[1], Filippo Miglior[3,4], Gilles Robitaille[5], and Nathalie Bissonnette*[1,2], *[1]Dairy & Swine Research and Development Centre Agriculture and Agri-Food Canada, Sherbrooke, Quebec, Canada, [2]Department of Biology, Université de Sherbrooke, Sherbrooke, Quebec, Canada, [3]Canadian Dairy Network, Guelph, Ontario, Canada, [4]CGIL, University of Guelph, Guelph, Ontario, Canada, [5]Food Research and Development Centre, Agriculture and Agri-Food Canada, Saint-Hyacinthe, Québec, Canada.*

Bovine paratuberculosis is a disease caused by *Mycobacterium avium* ssp. *paratuberculosis* (MAP). Most infected cows are culled before they reach clinical stage, leading to the premature slaughter of many animals and significant economic losses. Several genetic variants have been reported associated with host susceptibility to MAP. The objective of this study was to validate a whole genome genotyping-by-sequencing (GBS) method to identify single nucleotide polymorphisms (SNPs) associated with bovine paratuberculosis. Animals were selected from 10 farms in the province of Quebec. Fecal and blood samples were collected to identify 24 MAP infectious status by fecal culture and serum ELISA and 24 healthy cows. Two GBS methods were compared: a conventional (restriction enzymes *Pst*I and *Msp*I at 5′/3′ used to construct DNA libraries) method (CM) and CM with more selective primers to reduce the complexity of the libraries (RM). DNA was extracted from isolated peripheral blood monocyte cells. Multiplexed libraries (48 libraries per lane) were subjected to 100-bp single-end sequencing on an Illumina HiSeq 2000 system. Reads that passed all filtering criteria were mapped to the bovine genome (Bta_4.6.1). The SNPs were called using the Universal Network-Enabled Analysis Kit and 30,266 and 82,593 passed the quality control steps for the CM and the RM methods, respectively. Using the SVS GoldenHelix software, 3,653 (CM) and 17,413 (RM) SNPs were associated with regions that are not intergenic. Associated genes are linked to biological processes related to the immune system and to responses to stimuli, such as defense responses to bacteria. Analysis confirmed that 8 (CM) and 19 (RM) SNPs were associated with MAP infectious status ($P < 0.05$). Validation of their genetic association with bovine paratuberculosis are currently performed by SEQUENOM mass spectrometry using a larger group of animals (n = 800). The reduction of the complexity of the genome produced a larger number of qualified genotypes compared with the conventional method suggesting that this GBS strategy provides a greater reading depth, which increases the quality of each genotype.

Key Words: genotyping-by-sequencing, *Mycobacterium avium* ssp. *paratuberculosis*, genetic predisposition to disease

Companion Animals: Nutrition

W95 Identifying sources of *Salmonella* contamination in animal feed and pet food facilities. Andrea M. Jeffrey*[1], Cassandra K. Jones[1], Greg Aldrich[1], Anne R. Huss[1], and Carl Knueven[2], *[1]Kansas State University, Manhattan, KS, [2]Jones-Hamilton, Walbridge, OH.*

Salmonella is a potential biological hazard in animal food, and may contaminate livestock feed and pet food through cross contamination at manufacturing facilities. The FDA has evaluated *Salmonella* concentrations in classes of feed ingredients, but has not evaluated pathogen concentrations based on location throughout a facility. The objective of this experiment was to investigate sources of *Salmonella* contamination from various equipment and environmental locations in 2 livestock feed manufacturing plants and 2 pet food manufacturing plants on a specific sampling day. Up to 40 environmental swab samples were collected at each facility using sterile, prepackaged swab vials containing buffered peptone water. Samples were collected from a variety of equipment and structural surfaces, including concrete, dust, plastic, rubber, and broom bristles and analyzed for qualitative *Salmonella* determination as described by FDA's Bacteriological Analytical Manual. Data were categorized by facility (1 to 4), type (equipment or structural), and surface (concrete, metal, plastic, rubber, or dust) and analyzed using the GLIMMIX procedure of SAS. There were no interactions, so all were removed from the model ($P > 0.05$). There were no differences in *Salmonella*-positive samples among facilities, but facility 1, a livestock feed manufacturer, doubled the locations testing positive for *Salmonella* as compared with the other 3 facilities ($P = 0.11$; average positive-*Salmonella* concentration of 44.1, 20.1, 19.0, and 20.1% for facilities 1, 2, 3, and 4, respectively). There were no differences in percentage of *Salmonella* samples testing positive based on location of swab ($P = 0.57$; average *Salmonella* concentration of 22.9 and 28.7% for equipment and structural, respectively). Finally, there was a tendency for rubber and concrete to have greater *Salmonella*-positive samples than plastic, dust, or metal ($P = 0.10$; 40.9, 35.2, 24.4, 20.4, and 8.2%, respectfully). With these results in mind, it may be important to consider the types of surfaces present and the appropriate sanitation to best control *Salmonella* in livestock and pet food manufacturing facilities to prevent cross-contamination into animal food.

Key Words: *Salmonella*, animal feed, pet food

W96 Dog ownership increases the richness of the cutaneous microbiome. Celia S. Sobelman*[1], Jessica K. Suagee[2], and Cristina Caldari[1], *[1]Centenary College of Louisiana, Shreveport, LA, [2]The Ohio State University, Wooster, OH.*

Maintaining a normal microflora is imperative for the modulation of immune responses by the host and prevents the overgrowth of opportunistic microorganisms. Changes in cutaneous microflora could result in skin diseases. It has been shown that individuals that co-habitate harbor similar cutaneous microbial communities. The purpose of this study was to determine if humans that co-habitate with dogs have different cutaneous microbial richness compared with humans that are rarely exposed to dogs. Microbial richness was defined as the number of morphologically distinct colonies in a sample. Humans that co-habitate with dogs (dog owners) were defined as humans living with ≥1 indoor dogs. Humans having rare contact with dogs (non-dog owners) were defined as humans that were in contact with dogs ≤ once a week. Cutaneous microbial samples were obtained by using a sterile cotton swab to swab the top of the hands, forearms and foreheads of humans and the dorsal thoracic area, nose area, and chest of dogs. The cotton swabs were stored in sterile phosphate buffered saline (PBS) for 24 h after which time 100 mL of the PBS were plated onto a tryptic soy agar plate with 5% sheep blood. After a 48-h incubation period at 37°C, distinct microbial colonies were counted. Distinctness of the colonies was determined based on colony morphology, cell morphology and Gram staining. Microbial richness varied among dogs, dog-owners, and non-dog owners (Levene's test, P-value = 0.007), with dogs having the most variation and non-dog owners having the least variation. The average cultured cutaneous microbial richness was significantly higher in dogs and dog owners (6.73 ± 4.23 and 5.60 ± 3.20 microbial species, respectively) compared with non-dog owners (2.73 ± 0.96 microbial species; dog vs. non-dog owner: $P = 0.0001$, dog owner vs non-dog owner: $P = 0.002$). There was no significant difference in the cutaneous microbial richness of dogs and dog-owners. These results suggest that frequent contact with dogs leads to an increase in cutaneous microbial richness compared with infrequent contact with dogs. The implications of these findings on health and disease warrant further investigation.

Key Words: cutaneous microbiome, dog, dog ownership

W97 Effects of thiamine type, species meat versus livers, and sulfite addition on water-soluble B-vitamins in a canned cat diet. Shelby D. Trible*, Charles G. Aldrich, and Cassandra K. Jones, *Kansas State University, Manhattan, KS.*

There has been little work published concerning the effect of processing on the degradation of water-soluble B-vitamins in canned pet foods. The objectives of these experiments were to evaluate the effect of thiamine type (mononitrate vs hydrochloride), protein type (species meat and livers), and sulfite (yes or no) addition on B-vitamin retention. All diets were produced at a batter temperature of 60°C and moisture of 78%. The cook time was one hour at 121°C and 21psi. In Exp. 1 ($n = 26$) thiamine type tended ($P = 0.12$) to influence retention, wherein thiamine mononitrate retention (140.68 mg/kg) was higher than that of thiamine hydrochloride (128.37 mg/kg). In Exp. 2 ($n = 14$), protein type had an effect on retention of several B-vitamins. Thiamine retention was highest in fish relative to chicken or liver diets ($P < 0.05$; 202.26 vs 140.72, and 131.19 mg/kg, respectively). Riboflavin retention was highest in diets containing liver, intermediate with fish, and lowest for chicken ($P < 0.05$; 200.83, 153.46, and 113.66 mg/kg, respectively). Niacin was at its lowest retention in diets containing chicken compared with fish and liver diets ($P < 0.0015$; 238.42, 327.90, and 444.64 mg/kg, respectively). Pyridoxine retention was highest in diets containing fish versus those with liver or chicken ($P < 0.05$; 135.89 vs 113.34, and 100.59 mg/kg, respectively). Cobalamin retention was at its lowest in diets containing chicken, and intermediate for fish and highest for liver ($P < 0.05$; 0.45, 0.62, and 1.53 mg/kg, respectively). The addition of sulfites indirectly from dehydrated potatoes in Exp. 2 had a negative effect on pantothenic acid ($P < 0.05$; 234.80 mg/kg vs 360.29 mg/kg), and pyridoxine ($P < 0.05$; 108.02 mg/kg vs 134.34 mg/kg) relative to the controls, respectively. The dehydrated potatoes with sulfites tended to influence thiamine retention ($P = 0.07$; 137.80 mg/kg vs 188.22 mg/kg) and riboflavin retention ($P = 0.09$; 147.89 mg/kg vs. 188.25 mg/kg) relative to the control. Vitamin form, protein type, and presence of sulfites may influence their retention in canned pet foods.

Key Words: B-vitamin, wet pet food, sulfites

W98 Chemical composition, nutrient digestibility, and true metabolizable energy of commercially available protein sources using the precision-fed cecectomized rooster assay. Ping Deng*[1], Pamela Utterback[1], Carl Parsons[1], and Kelly Swanson[1,2], *[1]Department of Animal Sciences, University of Illinois, Urbana, IL, [2]Department of Veterinary Clinical Medicine, University of Illinois, Urbana, IL, [3]Division of Nutritional Sciences, University of Illinois, Urbana, IL.*

A wide variety of animal protein-based ingredients are commonly used in the pet food products. The raw ingredients and processing procedures used may greatly affect protein quality and digestibility. Testing the quality of alternative protein sources is necessary and contributes to the sustainability of pet foods. The objective of this study was to determine the chemical composition, nutrient digestibility, and nitrogen-corrected true metabolizable energy (TMEn) of 4 protein sources intended for use in dog and cat foods (pork peptone, calamari meal, chicken meal, and duck meal) using the precision-fed cecectomized rooster assay. Calamari meal and pork peptone had lower ash [4.4% and 3.6% of dry matter (DM), respectively], but greater crude protein (CP; 88.1% and 80.5% of DM, respectively) and gross energy (GE; 5.55 and 5.32 kcal/g of DM, respectively) compared with chicken meal (11.8% ash; 65.9% CP; 4.79 kcal/g) and duck meal (17.3% ash; 60.8% CP; 4.62 kcal/g). Acid-hydrolyzed fat (AHF) was lower in calamari meal (8.7% of DM) compared with the other proteins tested (15.5–15.9% of DM). Nutrient digestibility was variable among the protein sources [64 to 79% of DM, 76 to 83% of organic matter (OM), 86 to 92% of AHF, 83 to 89% of GE] with pork peptone having the highest DM, AHF, and GE digestibility, and calamari meal having the highest OM digestibility. Essential amino acid (AA) true digestibility was highest for calamari meal, with all AA having a digestibility greater than 90%. Except for histidine, all essential AA had a digestibility over 85% for pork peptone. All essential AA had a digestibility over 80% for duck meal, but chicken meal had 3 essential AA with digestibilities less than 80%. The TMEn of calamari meal (4.82 kcal/g DM; 86.8% of GE) was greater ($P > 0.05$) than that of pork peptone (3.83 kcal/g DM; 71.9% of GE), chicken meal (3.46 kcal/g DM; 72.2% of GE), and duck meal (3.46 kcal/g DM; 74.9% of GE). This study demonstrates the considerable variability that exists not only in the chemical composition, but also the nutrient digestibility, among protein sources intended for use in dog and cat foods.

Key Words: protein source, nutrient digestion, rooster assay

W99 The effect of low-bloom gelatin on physical properties of extruded pet food. Analena E. Manbeck*, C. Greg Aldrich, and Sajid Alavi, *Department of Grain Science and Industry, Kansas State University, Manhattan, KS.*

Gelatin is an animal-based protein that has been used to improve pellet quality. Previous work with low-bloom gelatin in extruded kibble demonstrated improved hardness and durability but decreased expansion. The objective of this experiment was to clarify the relationship of expansion on product hardness and durability resulting from gelatin inclusion. Two complete diets (30% protein) were produced: a control with no gelatin (OG) and another with 10% low-bloom gelatin (10G) added at the expense of chicken by-product meal. Diets were produced on a Wenger X-20 extruder through a circular die (4.6mm diameter). The extruder screw speed and throttle valve opening were adjusted to achieve 2 densities (HD and LD). Products were analyzed for bulk and piece density, radial expansion, specific length, hardness, and pellet durability index (PDI). Results were summarized with the aid of statistical analysis software (SAS 9.4). Hardness was not affected by treatment ($P > 0.05$). The main effect means of PDI decreased 33% with the inclusion of gelatin ($P < 0.05$; 77.57% v 52.25%) and decreased 20% between HD and LD ($P < 0.05$; 72.17% v 57.65%). The main effect means of radial expansion and specific length increased with gelatin inclusion ($P < 0.05$; 2.86 v 3.56mm^2/mm^2 expansion and 4.12 v 4.47cm/g length), but were unaffected by HD or LD. The main effect means of piece and bulk density were lower with gelatin inclusion (0.52 v 0.39g/cm^3 piece density and 351.8 v 280.7g/L bulk density) and also reduced from HD to LD (0.46 v 0.44 g/cm^3 piece density and 345.8 v 266.7g/L bulk density). The means for PDI were affected by the interaction of gelatin level and target density. PDI decreased from HD to LD within the OG diet ($P < 0.05$; 92.0% v 63.14%) and continued to decrease with the 10G diets. However, there was no difference between HD and LD for the 10G diets ($P > 0.05$; 52.34% v 52.16% for HD and LD, respectively). The decrease in PDI between 0G and 10G may be due to the increased expansion, but the gelatin may prevent a further decrease in PDI between HD and LD. Low-bloom gelatin may improve the physical properties of high protein pet food without compromising expansion.

Key Words: pet food, gelatin, extrusion

W100 Effects of age and diet on colonic mucosa microbiota of dogs. Ana Paula J. Maria*[1], Ping Deng[2], Hannah D. Holscher[2], Franz N. Yoshitoshi[3], Thaila C. Putarov[1], Kelly S. Swanson[2], and Aulus C. Carciofi[1], *[1]São Paulo State University (UNESP), Jaboticabal, SP, Brazil, [2]University of Illinois at Urbana-Champaign, Urbana, IL, [3]Endoscopet-Endoscopy and Surgery, São Paulo, SP, Brazil.*

The objective of this study was to identify the effects of age and diet, with particular focus on carbohydrate and protein sources, on the colonic mucosa microbiota of dogs. Thirty-six healthy beagles were used in a 3x2 factorial design. Dogs were separated in 2 age groups, young adult (2.6 ± 0.9 yr) and geriatric (10.2 ± 1.1 yr), and were assigned to 3 isonutritive kibble dietary groups containing: (1) a non-fermentable insoluble fiber (IF; 34% poultry meal; 8% sugarcane fiber); (2) a fermentable fiber (FF; 35% poultry meal; 10% beet pulp); and (3) soybean meal (SM; 30% SM; 11% poultry meal; no additional fiber source). Dogs were fed the experimental diets for 30-d, followed by sample collection on d 31. Mucosal biopsies from the colon were performed by colonoscopy procedure with dogs under anesthesia. DNA was extracted and the V4 region of the 16S rRNA gene was amplified and subjected to Miseq Illumina sequencing. Data analysis was performed using QIIME 1.8.0. The resulting operational taxonomic units (OTU) were aligned to the Greengenes 13_8 database (97% similarity threshold). Firmicutes (44.1%) was the predominant bacterial phylum, followed by Bacteroidetes (39.2%), Fusobacteria (6.5%), Proteobacteria (5.6%), Actinobacteria (4.3%) and Deferribateres (0.2%). There was an interaction between age and diet ($P < 0.05$) for *Prevotella*, *Sutterella*, and an undefined genus in the Mogibacteriaceae family. The abundance of *Slackia*, *Bacteriodes*, *Plesiomonas,* and an undefined genus in the Paraprevotellaceae family were lower ($P < 0.05$) in geriatric dogs compared with the young adult dogs. *Peptococcu*s and *Slackia* genus were in a higher ($P < 0.05$) abundance in dogs fed the IF and FF diets than those fed the SM diet. Dogs fed the IF diet had lower ($P < 0.05$) colonic mucosa *Megamonas* and *Suturella* abundance when compared with the dogs fed FF and SM diets. In conclusion, both dietary fiber fermentability and age may impact the microbial communities present on the colonic mucosa of dogs. More research is needed to identify the relevance of these microbial shifts in regards to gastrointestinal health.

Key Words: age, carbohydrates, microbiota

W101 Digestibility of the crude corn oil in dogs. Tabyta T. Sabchuk*[1], Karoline Vanelli[1], Larissa Barrile[2], Fabiane Y. Murakami[1], Alex Maiorka[1], Simone G. Oliveira[1], and Ananda P. Félix[1], *[1]Federal University of Paraná, Curitiba, Paraná, Brazil, [2]Cargil Agricola SA, Uberlândia, Minas Gerais, Brazil.*

There are many fat sources used in dog nutrition, such as poultry fat, beef tallow, and soy oil. In addition, there are several factors that can determine the choice of the fat source, such as price, availability, fatty acid profile, chain saturation. One alternative fat source can be the crude corn oil (CCO) that is a co-product of maize, produced worldwide. Besides, CCO has a large amount of linoleic acid, an essential fatty acid for dogs. Thus, the objective was to evaluate the apparent total-tract digestibility (ATTD) and ME of CCO in adult dogs. Three diets were evaluated: a control diet (with 8% beef tallow, CD), and 2 diets containing 92% of the ingredients of the CD and 8% of CCO and another with 8% poultry fat (PF). Diets were sprayed with the fat sources. Nine Beagle dogs were randomly assigned in 2 blocks (2 periods), totaling 6 replicates per treatment. The experimental diets in kibble form were offered for a 5-d adaptation period, followed by 5 d of total fecal collection per period. The ATTD and ME of the tested ingredients (CCO and PF) were calculated according to the substitution method. The results were submitted to Student's t-test ($P < 0.05$). The ATTD of DM (98.7% *vs* 96.0%), acid-hydrolyzed fat (AHF, 98.6% *vs* 97.4%), GE (99.7% *vs* 98.6%), and ME (38.08 MJ/kg *vs* 37.93 MJ/kg) of CCO and PF, respectively, did not differ ($P > 0.05$). Normally we evaluate the digestibility of diets and not the digestibility of the ingredient itself, such as in this study. Consequently, specific information on the nutritional quality of ingredients is lacking, particularly in fat sources to dogs. We found that the digestibility and ME of CCO was similar to the PF, which is the most frequently used fat source in dog nutrition. Thus, the CCO has high digestibility and can be a co-product with potential use in diets for dogs.

Key Words: companion animal nutrition, fat source, ingredient digestibility.

W102 A high protein intake allows the preservation of lean mass and prevents the increase of fat mass, compared with a moderate protein intake, in neutered cats. Agnès André[1], Isabelle Leriche[2], Gwendoline Chaix[3], and Patrick Nguyen*[1], *[1]Nutrition & Endocrinology Unit, National College of Veterinary Medicine, Nantes, France, [2]Virbac Nutrition, Vauvert, France, [3]Virbac Medical Department, Carros, France.*

Cats are strict carnivores and have a high dietary protein requirement. Rich-protein diets are often intended to prevent obesity or manage weight loss, as they help preserve the lean body mass. The aim of this study was to assess the effect of an experimental high-protein low-carbohydrate maintenance dry diet (HP) on body composition (BC), compared with a commercial moderate-protein high-carbohydrate dry diet (MP) in neutered cats. Twelve (12) young adult neutered cats (19.6 ± 0.4 mo old; 3.56 ± 0.2 kgBW) were randomized in 2 groups and received, for 20 weeks, either a HP (3,320 kcal/kg of DM; 50.2 CP %DM) or a MP (3,590 kcal/kg of DM; 33.7 CP %DM) diet. Main protein sources and amino acid content (DM basis) were: HP diet: meat meal, pea; Lys 2.3%, Met 1.0%, Try 0.4%, Thr 1.7%; MP diet: poultry meal, corn gluten meal, corn; Lys 2.0%, Met 1.0%, Try 0.3%, Thr 1.3%. Animals were fed according to their estimated energy requirement to maintain their BW. Body composition (BC) was determined using deuterium oxide dilution at the beginning then at the end of the study. Tukey's test was used to detect the effect of each diet and a Wilcoxon test to evaluate the differences between groups, with a 5% significance level. The mean protein intake during the study was 7.2 ± 0.6 g/kgBW/d in the HP group, and 4.6 ± 0.3 g/kgBW/d in the MP group. On d 1, the 2 groups were similar regarding their BW and BC. In both groups, no change in BW was observed. BC was unchanged in the HP group whereas body fat mass increased ($P < 0.05$) and lean body mass decreased ($P < 0.01$) in the MP group. The lean mass/fat mass ratio changed from 74/26 to 75/25 and from 77/23 to 69/31, in the HP and MP groups respectively. Although the protein content of the MP diet was higher than the recommended allowance (20% ME according to NRC 2006), it appeared not high enough to maintain lean body mass in these cats. Our results are in accordance with another study showing that adult cats would require at least 5.2 g protein/kg BW/d to maintain their lean body mass.

Key Words: cat nutrition, protein intake, body composition

W103 The effect of processing and elevated storage temperatures on omega-3 fatty acid stability in pet food. Alaina K. Mooney*, C. G. Aldrich, C. K. Jones, and S. Alavi, *Kansas State University, Manhattan, KS.*

Essential fatty acid research has shown that omega-3 fatty acids such as eicosahexaenoic acid (EPA) and docoshexaenoic acid (DHA; 22:6n3) may help maintain normal body structure, function and aid in long-term health and wellbeing. Common sources of omega 3 fatty acids include flax seed, fish oil, fishmeal, and more recently, purpose grown algae. This commercially produced source of omega 3 fatty acids has been evaluated as a supplement to animal diets and for its impact on metabolism; however, questions regarding the effect of processing and storage in pet foods are unanswered. The objective was to determine the effect of processing on stability of an algal source of DHA, (DHAgold S17-B; DSM Nutritional Products) added to the diet by premix, extrusion-drying processing, and extended storage. Three nutritionally complete pet diets at protein levels 21.7, 25, and 30% CP (Low, Medium and High, respectively) were produced with equal levels of DHA supplied by DHAgold S17-B, fishmeal and fish oil. Diets were produced on a Wenger X-20 single screw extruder (Wenger Mfg, Sabetha, KS) and dried at 104°C for 10 min at each pass in a triple pass dryer (Wenger Mfg, Sabetha, KS). Samples from each treatment were analyzed immediately following production for moisture and fatty acids. Shelf-life samples were collected in whirlpaks with a pin-hole and stored at 40°C and 75% relative humidity for analysis at 3, 6, 12, 18 and 24 weeks following production. Retention of EPA and DHA at production time was not affected by CP level ($P > 0.05$), but was impacted by DHA source ($P < 0.05$). The total omega 3 fatty acids were affected by DHA source and CP level ($P < 0.05$). As time in storage progressed through 0, 3, 6, 12, 18 and 24 weeks EPA ($P < 0.05$; 12.53, 10.45, 10.19, 8.9, 8.4, and 8.2 mg/kg, respectively) and DHA ($P < 0.05$; 7.7, 7.2, 6.9, 6.1, 6.4, and 6.0 mg/kg, respectively) declined slightly; but, total omega 3 fatty acids ($P < 0.05$; 35.6, 47.7, 47.9, 44.4, 43.3, and 41.8 mg/kg, respectively) were greater at all times than the start. These results suggest that elevated temperatures during storage for 24 weeks could result in slight EPA and DHA sacrifice. DHAgold S17-B appears to be a stable source of DHA when compared with fish oil and fishmeal.

Key Words: extrusion, pet food, omega-3 fatty acid

W105 The impact of rendered protein meal level of oxidation on shelf life and acceptability in extruded pet foods. Morgan N. Gray*, Charles G. Aldrich, Cassandra K. Jones, and Michael W. Gibson, *Kansas State University, Manhattan, KS.*

Increasing pressure has been put on ingredient suppliers to assure a low level of oxidation, as measured by a low peroxide value. Our objective was to determine the effect of increasingly oxidized protein meals on the shelf life of extruded pet foods. Approximately one metric ton each of unpreserved chicken by-product meal (C) and unpreserved beef meat and bone meal (B) were collected and left unpreserved (U) or preserved with either ethoxyquin (E), or mixed tocopherols (T). These were allowed to oxidize at ambient conditions (25°C and 51% RH) while being monitored for peroxide value (PV) and anisidine value (AV) until they plateaued (41 and 63 d, respectively) at a PV of 88.44, 4.43, 2.22 mEq/kg and AV of 1.08, 0.55, 0.00 g/g for CU, CT, CE, respectively and at a PV of 86.42, 8.88, 2.23 mEq/kg and AV of 12.23, 7.14, 0.00 g/g for BU, BT, BE, respectively. Each meal was then incorporated into a model extruded cat food diet (~30% protein). Samples of kibble for each treatment were collected and stored at an elevated temperature and humidity (40°C and 70%) for 18 weeks. At time 0, PV and AV were greater for CU and BU ($P < 0.05$; 14.41, 10.07 mEq/kg and 15.56, 10.08 g/g, respectively) versus the preserved treatments CT, CE, BT, and BE (2.78, 2.22, 2.22, 2.22 mEq/kg and 3.85, 1.79, 9.62, 3.03 g/g, respectively). At elevated storage temperatures, the PV for CE remained low (4.44 mEq/kg), CT was intermediate (23.21 mEq/kg) and CU increased to 53.15 mEq/kg by 18 weeks ($P < 0.05$). The AV for C followed a similar pattern. The PV of B under elevated temperatures behaved differently; wherein, BE was low (3.33 mEq/kg), but BT had the highest PV (15.48 mEq/kg) and BU was intermediate (6.66 mEq/kg) by 18 weeks ($P < 0.05$). BE had the lowest ($P < 0.05$) AV and BT and BU were greater, but did not differ from each other (average 16.75 g/g) at 18 weeks. The results from this study demonstrate that oxidation occurred regardless of treatment; but, was rapid and extensive in meals without preservative. The ingredient oxidation levels were diluted by food production and their oxidation may not completely account for later food product deterioration.

Key Words: pet food, oxidation, rendered protein meals

Comparative Gut Physiology

W106 Effect of complex and prebiotic diets on intestinal health of nursery pigs inoculated to porcine circovirus 2 (PCV2).

Marco M. Lima*[1,2], Dana M. van Sambeek[2], Huyen Tran[2], Daniel C. Ciobanu[2], Phillip S. Miller[2], and Thomas E. Burkey[2], *[1]Univesidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil, [2]University of Nebraska, Lincoln, NE.*

To investigate the effects of complex and prebiotic diets on nursery pigs inoculated for or vaccinated against porcine circovirus 2 (PCV2) on the intestinal health, 96 weaned barrows (age 27 to 40 d; BW 7.1 kg) were housed (4 pigs/pen) in an environmentally controlled nursery with ad libitum access to feed and water over a 28-d study. Forty-eight pigs were vaccinated (VAC) for PCV2 before arrival, while remaining pigs (PCV) were inoculated for PCV2 on d 0. Pigs were randomly assigned to 1 of 3 diets: complex (CO; lactose, spray-dried plasma, spray-dried whey), simple (SI; corn and SBM), or simple + 2.5% Grobiotic-S (GS). After 28 d of experiment, 1 pig per pen was euthanized by exposure to CO_2 for collection of samples. Two-cm segments of duodenum and ileum were collected for the determination of villous height (VH), villous area (VA), crypt depth (CD), and villous height:crypt depth (VH:CD) ratio. Images were recorded using an Olympus DP71camera (Olympus, Center Valley, PA). The VH, CD, VH:CD ratio, and VA were measured using Cell Sense standard software (Olympus, Center Valley, PA). For each intestinal sample, a minimum of 10 to 15 full villi and crypts were measured and averaged for statistical analysis. All data were analyzed as a completely randomized design using the MIXED procedure of SAS. Pen was considered the experimental unit and the model included treatment as a fixed effect. All measurements were performed without treatment awareness. No significant PCV-status effects were observed in the duodenum histological measurements; however, a significant diet × PCV-status interaction ($P = 0.0251$) on VH:CD in duodenal samples was observed. The highest VH:CD result observed was in pigs fed GS and inoculated with PCV. Diet had an effect ($P = 0.0066$) on duodenal CD, with deeper crypts being observed for GS pigs. With respect to VH and CD, a tendency for a diet × PCV-status interaction ($P < 0.07$) was observed whereby PCV inoculated pigs and fed simple or GS diets had greater CD and VH, respectively. No significant effects were observed for ileum histological measurements. Results indicate that diet complexity may affect duodenal health in pigs inoculated with PCV.

Key Words: diet, health, intestine

W107 Mitotic and apoptosis rate of intestinal cells of nursery pigs fed with a blend of organic acids and medium chain fatty acids.

Marco M. Lima*[1], Maria C. Thomaz[1], Fabricio F. Castro[1], Rosemeire S. Filardi[2], Daniela J. Rodrigues[1], Maryane S. F. Oliveira[1], Manuela V. Marujo[1], Everton Daniel[1], Antonio C. Laurentiz[2], and Thomas E. Burkey[3], *[1]Univesidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil, [2]Univ Estadual Paulista, Ilha Solteira, Sao Paulo, Brazil, [3]University of Nebraska, Lincoln, NE.*

To investigate the effects of a blend of organic acids and medium chain fatty acids on gut health, 96 weaned barrows (21 d; BW 5.2 kg) were housed (3 pigs/pen) with ad libitum access to feed and water over a 28-d study. The diets were comprised primarily of corn, soybean meal and a source of lactose, with inclusion of 0, 0.15, 0.30 and 0.45% of a mixture of acetic acid, citric acid, formic acid, lactic acid, caprylic acid and caproic acid (BLEND). Piglets (n = 4 pigs/treatment/time point) were euthanized on d 14 and 28 for sample collection. Two-cm segments of duodenal and jejunal tissue were collected for analysis of apoptotic and mitotic rates. Rate of apoptosis and mitosis were evaluated immunohistochemically in paraffin wax-embedded tissue sections using polyclonal antibodies (anti-Caspase 3 and anti-PCNA, respectively; Biocare Medical, Concord, CA).The immunohistochemical procedure was conducted per the manufacturer's instructions. Images were recorded using an Olympus BX41 camera. For each intestinal sample, a minimum of 20 to 30 full villi and crypts were measured. ANOVA was generated using the mixed-model procedure of SAS. Linear, quadratic, and cubic polynomials were used to detect the response to dietary inclusion of the BLEND. All measurements were performed without treatment awareness. A cubic effect was observed with respect to the number of cells in mitosis in duodenal ($P < 0.0001$) and jejunal ($P = 0.0062$) tissue segments obtained on d 14 with the greatest rate of mitosis observed in tissues obtained from pigs fed 0.30% BLEND. In addition, a quadratic effect in mitosis:apoptosis ($P = 0.0171$) ratio was observed in duodenal tissue obtained from piglets on d 14 with minimal inflection point at 0.18% inclusion of BLEND. No significant effects were observed with respect to mitotic or apoptotic rates in tissues obtained on d 28. In conclusion, feeding a blend of organic acids and medium chain fatty acids may have a short-term positive effect on mitosis and apoptosis, possibly contributing to intestinal epithelial restitution and gut health.

Key Words: apoptosis, intestine, mitosis

W108 Effects of organic acids and medium-chain fatty acids on gut health of nursery pigs.

Marco M. Lima*[1], Maria C. Thomaz[1], Fabricio F. Castro[1], Rosemeire S. Filardi[3], Daniela J. Rodrigues[1], Maryane S. F. Oliveira[1], Manuela V. Marujo[1], Dana M. van Sambeek[2], and Thomas E. Burkey[2], *[1]Univesidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil, [2]University of Nebraska-Lincoln, Lincoln, NE, [3]Universidade Estadual Paulista, Illha Solteira, Sao Paulo, Brazil.*

To investigate the effects of a blend of organic acids and medium chain fatty acids on gut health, 96 weaned barrows (21 d; BW 5.2 kg) were housed (3 pigs/pen) with ad libitum access to feed and water over a 28-d study. The diets were comprised primarily of corn, soybean meal and a source of lactose, with inclusion of 0, 0.15, 0.30 and 0.45% of blend (acetic acid, citric acid, formic acid, lactic acid, caprylic acid and caproic acid). For sample collection, piglets (n = 16) were euthanized at 14 and 28-d study. Two-cm segments of duodenum and jejunum were collected for the determination of villous height (VH), crypt depth (CD), villous height:crypt (VH:CD) depth ratio and count goblet cell by methods of Schiff-PAS and Alcian Blue. Images were recorded using an Olympus BX41 camera. Cell Sense standard software was used for measurement of the respective morphological aspects. For each intestinal sample, a minimum of 20 to 30 full villi and crypts were measured and in assessing the number of goblet cells, 15 counts were performed. ANOVA was generated using the mixed-model procedure of SAS. Linear, quadratic and cubic polynomials were used to detect the response to dietary inclusion of the blend. Was observed a cubic effect in duodenal VH:CD ($P < 0.0001$) ratio and jejunal goblet cell count ($P = 0.0034$) by method of Schiff-PAS at 14-d study. Was observed a cubic effect on CD ($P = 0.0009$), goblet cell count ($P = 0.0014$) by method of Schiff-PAS, goblet cell count ($P = 0.006$) by method of Alcian Blue, and an increasing linear effect on the VH:CD ($P = 0.0006$) ratio in jejunum of pigs at 28-d study. Results indicate the blend had little effect at 14-d study; however,

positive effects of blend were observed at 28-d of study. In conclusion, the blend may contribute to intestinal restitution.

Key Words: health, organic acid, pig

W109 Effect of turmeric, ginger and garlic extracts on performance, microbial load, and gut morphology of weaned pigs.

Olufemi A. Adebiyi*[1], Isaac A. Adejumo[2], Oluremi A. Adeniji[1], Olusegun D. Oshibanjo[1], and Muyiwa B. Falana-Williams[1], [1]*Department of Animal Science, University of Ibadan, Ibadan, Nigeria,* [2]*Department of Animal Science, Landmark University, Omu Aran, Kwara state, Nigeria.*

Producing swine without in-feed antibiotics requires a combination of different strategies. Some of the approaches that are available to improve the pigs ability to reduce the impact of intestinal pathogens are phytogenic, which improve intestinal health and promote productivity. Therefore, the objective of this experiment was to assess the effect of turmeric, ginger and garlic extracts on performance, microbial loads and gut morphology of weaned pigs. A total number of 20 weaned pigs were randomly allotted into 4 treatments with 5 replicates arranged in a completely randomized design. The treatments are: T1 (control), T2 (2g turmeric extract/kg feed), T3 (2g ginger extract/kg), T4 (2g garlic extract/kg). The feed was formulated to contain 19% crude protein and 2950 kcal/kg ME which meets the nutritional requirements of the weaner pigs. The experiment lasted for 49 d. No significant ($P < 0.05$) difference was observed in the performance attributes of the weaned pig that were fed the different diets. The feed conversion ratio ranges from 3.59 in pigs fed T2 diet to 3.92 in pigs fed the control diet. Enterobacter count was significantly ($P < 0.05$) higher in pigs fed T1 (6.38 cfu), T2 (6.29 cfu) and T3 (6.27 cfu) diets, compared with their counterpart on T4 (5.12 cfu). The least value of 6.63 cfu for total bacteria count was also observed in pigs fed T4 (garlic extract) diet. The ileum section of the gastro-intestinal tract of the pigs revealed significant ($P < 0.05$) increase in the villus height for pigs on T4 (1419.75 µm) than what was observed on pigs fed other diets (709.25 µm, 1156.50 µm and 1068.00 µm in T1, T2 and T3 respectively. However, no significant ($P > 0.05$) variations was observed in the villus width and crypt depth despite the different treatments. It can be concluded that inclusion of garlic extract at 2g/kg feed resulted in improved intestinal morphology and reduction in the microbial load in weaned pig.

Key Words: pig, extract, performance

W110 Effect of heat stress on endogenous intestinal loss of amino acids in growing pigs.

Adriana Morales[1], Lorenzo Buenabad[1], Lisbeth Hernández[1], Misael Pérez[1], Pedro Castro[1], Gilberto Castillo[1], Lance Baumgard[2], and Miguel Cervantes*[1], [1]*ICA, Universidad Autónoma de Baja California, Mexicali, BC, México,* [2]*Department of Animal Science, Iowa State University, Ames, IA.*

Heat stress (HS) appears to increase intestinal cell death in pigs, which in turn may increase endogenous intestinal losses (EIL) of proteins and amino acids (AA). Experimental objectives were to analyze the effect of HS on the AA composition of intestinal endogenous proteins and the EIL of AA in pigs. Eight pigs (24 kg initial BW) were surgically implanted with T-type cannulas at the end of the small intestine. After surgery recovery, all pigs were adapted to a protein-AA-free diet and trained to consume the same amount of feed twice a day for 7d in thermo-neutral (TN) conditions (22 ± 2°C). On d 8 of TN conditions ileal content was collected during 12 consecutive h. On d 9 pigs were exposed to natural HS conditions (31 to 37°C) for 8 d. During the HS period ileal content was collected again on d2 (HSd2) and d8 (HSd8). Chromic oxide was used as indicator of the intestinal digesta flow. Data were analyzed using PROC MIXED of SAS; the model considered the TN pigs as no HS and the fixed effect of HS-sampling day was used to compare TN with HSd2 and HSd8. The AA composition of endogenous intestinal protein was not affected by HS ($P > 0.10$). The EIL of indispensable AA of TN, HSd2 and HSd8 pigs were: Arg, 314, 345, 335; His, 144, 163, 153; Ile, 169, 196, 173; Leu, 378, 434, 387; Lys, 238, 275, 250; Met, 099, 113, 110; Phe, 298, 337, 296; Thr, 489, 533, 481; Val, 335, 354, 343 mg/d, respectively. The EIL of dispensable AA of TN, HSd2and HSd8 pigs were: Ala, 377, 423, 383; Asp, 639, 684, 621; Glu, 478, 553, 509; Gly, 977, 838, 872; Pro, 763, 892, 1,941; Ser, 375, 394, 422; Tyr, 219, 251, 227 mg/d, respectively. The EIL of Thr and Phe tended to be increased ($P \leq 0.10$), and Arg and His were enhanced at HSd2 ($P < 0.05$), and Pro increased at HSd8 ($P = 0.01$) compared with TN conditions. The EIL of the remainder AA was not affected by HS. Although HS increased the EIL of Arg and His within the first 2 d, it appears that normal EIL of AA is quickly reestablished. In summary, HS does not appear to affect the AA composition of intestinal endogenous proteins and suggest that the EIL of AA may not be critical in chronic HS pigs.

Key Words: pig, heat stress, endogenous amino acids loss

W111 Effect of dietary fiber and a multicarbohydrase enzyme blend on net glucose and lactate fluxes, insulin production, and oxygen consumption by the portal-drained viscera and by the whole animal in growing pigs.

Atta K. Agyekum*[1], Elijah Kiarie[2,1], and Charles M. Nyachoti[1], [1]*Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada,* [2]*DuPont Industrial Biosciences, Marlborough, Wiltshire, UK.*

The objective was to determine the effects of supplementing a high-fiber (HF) diet with a multicarbohydrase enzyme (MC; 4000 units/g xylanase, 1000 units/g α-amylase, 500 units/g protease, 150 units/g β-glucanase) on net portal fluxes of glucose and lactate, insulin production and oxygen consumption by the portal-drained viscera (PDV) and whole animal (WAOC) in growing pigs. Three isocaloric/nitrogenous diets based on corn and soybean meal (SBM) with either 0% (CTRL) or 30% distillers dried grains with solubles (DDGS; 1:1 corn and wheat mixture; HF) were used; the third diet was supplemented with MC in addition to the 30% DDGS (HF+MC). Five 22.8 ± 1.6 kg gilts fitted with permanent catheters in the portal vein, ileal vein (to infuse para-amino hippuric acid to measure blood flow rate) and carotid artery were fed the 3 diets at 4% BW once daily at 0900 h for 7 d in a replicated 3 × 3 Latin square design. On d 7, pigs were placed in an open-circuit indirect calorimeter to measure WAOC and sample blood for 7 h postprandial. Net glucose and insulin production were calculated from portal-arterial differences × flow and PDV O_2 consumption was calculated as arterial-portal O_2 differences × flow. Diet had no effect ($P > 0.10$) on postprandial WAOC, flow rate, and lactate flux. Also, diet had no effect ($P > 0.10$) on overall postprandial PDV O_2 consumption, but altered ($P < 0.05$) postprandial PDV O_2 consumption from 240 to 360 min postprandial. Pigs fed CTRL had higher ($P < 0.05$) portal insulin and glucose fluxes, from 90 to 300 min, and net glucose flux from 90 to 240 min postprandial. However, pigs fed CTRL and HF+MC had similar ($P > 0.10$) postprandial net glucose flux, which was higher ($P < 0.05$) than pigs fed HF. Therefore, it was concluded that adding MC to the HF diet improved net glucose portal flux in pigs.

Key Words: high-fiber diet, multicarbohydrase, net portal flux

W112 Effect of a post-weanling diet supplemented with gut health-enhancing feed additives on ileum transcriptome activity and serum cytokines in piglets challenged with lipopolysaccharides (LPS).

Nathalie Bissonnette*[1], Xian-Ren Jiang[1,4], Jacques J. Matte[1], Guylaine Talbot[1], Frédéric Guay[2], Joshua Gong[3], Qi Wang[3], Valentino Bontempo[4], and Martin Lessard[1], *[1]Dairy & Swine Research and Development Centre Agriculture and Agri-Food Canada, Sherbrooke, Quebec, Canada, [2]Département des Sciences Animales, Université Laval, Québec, Québec, Canada, [3]Guelph Food Research Centre, Agriculture and Agri-Food Canada, Guelph, Ontario, Canada, [4]Department of Health, Animal Science and Food Safety, University of Milan, Milan, Italy.*

This study aimed to evaluate the impact of dietary feed additives with supplemental vitamins and trace minerals (DS) on the ileum and on systemic immune responses to a LPS challenge in low- (LW) and high-weight (HW) weaned piglets. At 20 ± 1 d of age (weaning), litters (12 piglet each) from 32 sows were randomly assigned to 4 dietary groups: control diet (CTL), CTL diet + chlortetracycline (ATB) or + DS, or DS + bovine colostrum instead of spray-dried animal plasma (DS-BC). Within each litter, 2 LW, 2 medium-weight (MW) and 2 HW piglets were identified. At 37 d, LW and HW piglets received intra-peritoneal LPS injection (200 µg). Piglets were bled before the injection (T0) and at slaughter, 4 h (T4; 1 LW and 1 HW) and 18 h (T18; 1 LW and 1 HW) post-injection. Microarray analysis was performed on LW, MW, and HW ileal tissues. The dietary feed treatments had no effect on the basal transcriptome level of the in MW piglets or on blood concentrations at T0 of tumor necrosis factor-α (TNF-α), IL-8, and IL-10. At T4, LW piglets secreted more TNF-α ($P = 0.05$) and more (tendency) IL-8 ($P = 0.11$) and IL-10 ($P = 0.10$) than HW piglets. LPS altered the expression of 3,078 ileal genes with the false discovery rate (FDR) at 0.05.

There was no diet × LPS interaction on ileal gene expression on T4 vs T18 vs unchallenged MW piglets. However, a diet effect was observed on gene expression for LW piglets using fold change > 1.5 for the T4/MW ratio. Confirmed by QPCR, T4/MW in DS+BC ileal tissue of the apoptotic *CD163* gene was lower than in ATB's for LW piglets ($P = 0.02$), whereas the corresponding effect in HW was a tendency ($P = 0.07$). The T4/MW ratio of the acute phase (*SAA2* and *S100A12*), *SOD2*, and heat shock protein (*DNAJB1* and *HSP90AA1*) genes was also lower in DS than ATB ($P < 0.05$) for LW piglets. The chemokine (*CXCL9*) T4/MW ratio was lower in both DS and DS+BC than ATB's ($P < 0.02$) for LW and HW piglets. In conclusion, LW piglets developed a more pronounced inflammatory response than HW piglets and dietary feed additives supplemented with micronutrients attenuated the ileal gene response to LPS challenge.

Key Words: weaned swine feeding, gut health-enhancing feed additive, intestinal disease

W113 Chitooligosaccharide improves intestinal barrier function in the jejunum of weaning piglets.

Y. Yao*, G. Tian, D. W. Chen, B. Yu, X. H. Song, J. Yu, P. Zheng, X. B. Mao, J. He, and Z. Q. Huang, *Animal Nutrition Institute, Sichuan Agricultural University, Chengdu, Sichuan, China.*

The recognition that chitooligosaccharide (COS) possess potent anti-inflammatory, antioxidant and antimicrobial properties has prompted studies investigating its efficacy for animal growth and intestinal health. The objective of this study was to examine the effect of COS on growth and jejunal barrier function of weaning piglets. A total of 18 piglets (6.55 ± 0.32 kg) at 21 d of age, were randomly assigned to 1 of 3 groups (n = 6/group). Piglets in group 1 continued to be nursed by sows, while piglets in groups 2 and 3 were weaned to a corn and soybean meal–based diet that was supplemented with 0 mL or 10 mL COS (5 ml/time, 2 times/d). At 28 d of age, growth performance, jejunal structure and epithelial integrity were examined. Data were analyzed by ANOVA procedure of SPSS. Differences between means were determined by using the Duncan multiple comparison method. The results indicated that final BW and ADG were markedly reduced in weanling piglets when compared with suckling piglets ($P < 0.05$), while supplementation with COS restored ADFI, final BW and ADG in the weaned piglets ($P < 0.05$). Weaning stress did not affect villous height but increased crypt depth and decreased the ration of villous height: crypt depth ($P < 0.05$), whereas, this alteration can't be reversed by COS supplementation. Peripheral D-lactate concentration and diamine oxidase activities were not affected by weaning stress or COS supplementation. Weaning stress led to greater jejunal cell apoptosis index and sIgA content ($P < 0.05$), and COS supplementation partially restored this changes ($P < 0.05$). Jejunal gene abundance of occludin was not affected by weaning or COS supplementation, while the weaning-induced decrease in jejunal ZO1 ($P < 0.05$) and ZO2 mRNA levels were elevated by COS supplementation ($P < 0.05$). Collectively, our results support an important role of COS in regulating jejunal barrier function of weaning piglets.

Key Words: chitooligosaccharide, weaning stress, piglet

W114 Exogenous enzymes blend (DigeGrain Delta) improve growth performance and gut health of weanling pigs fed corn-soybean based diet in absence of antibiotic growth promoters.

Y. H. Kim[1], S. L. Ingale*[2], P. C. Rathi[2], S. H. Lee[1], and B. J. Chae[1], *[1]College of Animal Life Sciences, Kangwon National University, Chuncheon, Gangwon-do, Republic of Korea, [2]Advanced Enzyme Technologies Ltd., Thane, Maharashtra, India.*

The present study investigated the effects of dietary supplementation of an exogenous enzyme blend (DigeGrain Delta; a blend of amylase, protease, β-mannanase, xylanase and phytase) on growth performance, apparent total-tract digestibility (ATTD) of nutrients, and gut health of weanling pigs. A total of 192 weaned piglets (Landrace × Yorkshire × Duroc, initial body weight: 7.3 ± 0.7 kg) were randomly allotted to 4 treatments on the basis of body weight (4 pens per treatment with 12 pigs in each pen). The dietary treatments included corn-SBM based basal diet supplemented with 0 (control), 0.025, 0.050, or 0.075% exogenous enzyme blend. The experimental diets were fed in a meal form for 2 phases (d 0–14, phase I and d 14–28, phase II). Pigs fed dietary increasing levels of enzyme blend had linear improvement ($P < 0.05$) in overall (d 0–28) average daily gain (ADG), gain:feed (G:F), and ATTD of dry matter, gross energy, and crude protein. Also, overall ADG and G:F of pigs fed diets supplemented with 0.050 and 0.075% enzyme blend were greater ($P < 0.05$) than pigs fed the control diet. The ATTD of Ca and P was tended to increase ($P < 0.10$) with dietary increase in enzyme blend. At d 21, pigs fed dietary increasing levels of enzyme blend had greater (linear, $P < 0.05$) *Lactobacills* spp. (ileum and cecum) and fewer (linear, $P < 0.05$) *Clostridium* spp. (ileum and cecum) and coliform (ileum) populations. On d 28, villus height of the jejunum and ileum were linearly increased ($P < 0.05$) with dietary increase in enzyme blend. In addition, crypt depth (duodenum and ileum) and villus height:crypt depth (duodenum, jejunum and ileum) tended to increase (linear; $P < 0.10$) with increase in dietary level of enzyme blend. Results obtained in the present study indicates that dietary supplementation of amylase, protease, β-mannanase, xylanase, and phytase blend had potential to improve the growth performance, ATTD of nutrients, and gut health of weanling pigs fed a corn-SBM based diet in the absence of antibiotics growth promoters.

Key Words: exogenous enzyme blend, performance, weanling pig

W115 Endoplasmic reticulum stress pathway is involved in weaning stress induced jejunum cell apoptosis in piglets.

Y. Yao*, G. Tian, D. W. Chen, B. Yu, X. H. Song, J. Yu, P. Zheng, X. B. Mao, J. He, and Z. Q. Huang, *Animal Nutrition Institute, Sichuan Agricultural University, Chengdu, Sichuan, China.*

Unresolved endoplasmic reticulum (ER) stress can lead to cell apoptosis. We therefore tested the role of ER stress in intestinal epithelial barrier disruption in piglets post-weaning. A total of 24 piglets (21 d of age and 6.52 ± 0.29 kg) from 4 litters were randomly continued to be nursed by sows (suckling piglets, 3 piglets/sow) or weaned to a corn and soybean meal–based diet. On d 3 and 7 post-weaning, blood and jejunum tissue were collected at necropsy. Thus, this produced 4 experimental groups (management/time) as suckling/3 d, suckling/7 d, weaning/3 d and weaning/7 d (n = 6/group). Data were analyzed by ANOVA procedure of SPSS including management, time, interaction between management and time as the main factors. Differences between means were determined by using the Duncan multiple comparison method. Weaning stress induced significant elevations in plasma cortisol level, D-lactate content and diamine oxidase (DAO) activity ($P < 0.001$). Moreover, this management-related increase in blood index was higher in 3 d than in 7 d ($P = 0.03$ for cortisol, $P = 0.03$ for D-lactate and $P = 0.02$ for DAO). Enterocyte apoptosis index in jejunum was increased in weanling piglets ($P < 0.001$), this alteration was accompanied by increasing jejunal gene expression of caspase3 ($P = 0.03$), without any difference between piglets at different time. Weaning stress did not affect Bcl-2 expression but decreased caspase9 expression ($P = 0.04$). Meanwhile, weaning stress upregulated mRNA expression of fas and caspase8 that were related to death receptor signal ($P = 0.03$ and $P < 0.001$). Marked weaning modifications were also observed for gene expression of ER stress pathway (glucose regulated protein 78kDa, +16%, $P = 0.02$; eukaryotic translation initiation factor 2-subunit 1 α, +17%, $P = 0.02$; activating transcription factor 4, +16%, $P = 0.002$; x-box binding protein1, −19%, $P = 0.004$; ER degradation enhance- mannosidase α like 2, −11%, $P = 0.10$). However, most of these genes were not affected by time or interaction between management and time. In conclusion, weaning stress induced jejunal enterocyte apoptosis and barrier disruption possibly via regulation of ER stress pathway and death receptor signal.

Key Words: endoplasmic reticulum stress, weaning stress, apoptosis

W116 The expression of genes encoding gastrointestinal enzymes, microbial populations, and volatile fatty acids in pigs differing in feed efficiency.

Stafford Vigors*, Torres Sweeney, Cormac J. O'Shea, and John V. O'Doherty, *College of Agriculture, Food Science and Veterinary Medicine, Dublin, Ireland.*

The objective of this study was to examine the effect of divergent selection for feed efficiency using residual feed intake (RFI) as a model on nutrient digestibility, bacterial populations, enzyme gene expression and volatile fatty acid (VFA) production. Male pigs (n = 75; initial BW 22.4 kg were fed a standard finishing diet (9.21 g/kg of standard ileal digestible lysine and 14 MJ/kg digestible energy) for 43 d before slaughter to evaluate feed intake and growth for the purpose of calculating RFI. Phenotypic RFI was calculated as the residuals from a regression model regressing average daily feed intake (ADFI) on average daily gain (ADG) and mid-test metabolic BW0.75 (MWT). Data were analyzed using the GLM procedure of SAS. Sixteen pigs (85 kg, SEM 2.84 kg), designated as high RFI (HRFI; n = 8) and 8 low RFI (LRFI) were killed and digesta was collected from the cecum and colon to determine microbial populations and VFAs. Digesta was collected from the ileum and rectum to measure coefficient of apparent ileal (CAID) and total-tract nutrient digestibility (CATTD). Mucosal scrapings from the duodenum, jejunum and ileum were used for RNA extraction and subsequent analysis of mRNA expression of several enzymes using RT-PCR. As expected LRFI pigs had lower ADFI (2.44kg vs. 1.87kg, + 0.07) and improved feed conversion ratio (1.96 vs. 2.48, SEM 0.02) than HRFI pigs ($P < 0.001$) with no difference in ADG or MWT. The LRFI pigs had improved CAID of GE ($P < 0.05$). Similarly, LRFI pigs had improved CATTD of GE, while also having improved CATTD of nitrogen and dry matter ($P < 0.05$). In the jejunum RFI was correlated ($r = -0.46$; $P < 0.10$) with the gene expression of the enzyme sucrase-isomaltase which is located in the intestinal brush border cells. In the colon HRFI pigs had increased concentration of acetic acid ($P < 0.05$). In the cecum LRFI pigs had increased molar proportions of butyric acid ($P < 0.10$). LRFI pigs had increased cecal lactobacillus ($P < 0.05$) compared with HRFI pigs. In conclusion differences in GE digestibility, sucrase-isomaltase gene expression, and populations of lactobacillus may contribute to differences in feed efficiency between RFI groups.

Key Words: feed efficiency, pig, RFI

W117 Diets containing flaxseed-meal and oat hulls modulate fat digestibility, production, and excretion of bile acids and neutral sterols in growing pigs.

Saymore P. Ndou*[1], Elijah Kiarie[1,2], Sijo J. Thandapilly[3], Nancy Ames[3], and Charles M. Nyachoti[1], [1]*Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada,* [2]*DuPont Industrial Biosciences-Danisco Animal Nutrition, Marlborough, Wiltshire, United Kingdom,* [3]*Richardson Centre for Functional Foods and Nutraceuticals, Agriculture and Agri-Food Canada, Winnipeg, MB, Canada.*

Effects of dietary fiber type on fat digestibility, intestinal and fecal concentrations of bile acids and plant sterols were determined. Forty-eight Genesus [(Yorkshire-Landrace) × Duroc] barrows (25.0 ± 0.32 kg BW) were housed in pairs and assigned to 3 diets; corn-soybean meal-based diet (control), 12% flaxseed meal (FM)- and 10% oat hulls (OH)-containing diets. All diets were replicated 8 times in a completely randomized design. Titanium oxide was added in the diets as an indigestible marker. Diets were formulated to be iso-energetic; FM and OH were used as sources of soluble and insoluble fiber, respectively. The analyzed dietary NDF content (% as fed) was 9.4, 18.0 and 18.7% in the control, FH and OH, respectively. After 28 d of ad libitum feeding, fecal samples were collected from each pen, and then pigs were slaughtered to sample ileal and cecal digesta for the assessment of fat, bile acids and sterols concentrations. Fat digestibility in pigs fed FM-based diets was 24% lower ($P = 0.02$) than the control, whereas that of OH-based diets fed pigs was intermediate. The ileal deoxycholic acid concentrations in pigs fed OH- and FM-containing diets were increased ($P < 0.01$) by 46.3% and 30.1%, respectively, compared with the control. In the cecal contents, the total bile acids concentration was increased ($P < 0.01$) by 114 and 75% in pigs fed FM- and OH-containing diets, respectively. The total bile acids excreted in feces of pigs fed FM- and OH-rich diets were respectively 2.47- and 2.03-fold higher than in control fed pigs. Compared with the control, intestinal bioconversion of cholesterol (coprostanol: cholesterol) was enhanced more in pigs fed FM- and OH-containing diets ($P = 0.05$). Pigs fed FM- and OH-containing diets had higher cecal ($P < 0.01$) and fecal ($P = 0.002$) cholesterol concentrations than control fed pigs. In summary, soluble fiber reduces fat digestibility more than insoluble fiber, and malabsorption of fat can be attributed to deconjugation of bile acids.

Key Words: dietary fiber, fat digestibility, bile acids

W118 The gut and vaginal microbiota profile of pregnant sows and their contribution to neonatal piglet gut microbiota development.

Alessi A. Kwawukume*, Hein M. Tun, Martin C. Nyachoti, and Ehsan Khafipour, *University of Manitoba, Winnipeg, Manitoba, Canada.*

The establishment of an initial gut microbiota is identified as a critical stage in neonatal development and is believed to influence health throughout life. Neonates are believed to receive their first bacterial colonizers while passing through the birth canal, from the environment as well as from milk during suckling; however, the relationship between maternal microbiota and development of neonatal gut microbiota is not clearly understood. To establish the contribution of maternal microbiota (gut and vaginal) to neonatal gut microbiota development, swab samples were taken from the posterior and anterior vagina 4 d before expected farrowing in pregnant sows housed on concrete slatted floors (CSF) (n = 12) and on straw (ASF) (n = 15). Fecal samples were obtained from sows at the same time as vaginal sampling, and from 5 piglets born to each sow (n = 135 piglets) on d 0, 1 and 3 after birth. DNA was extracted and subjected to V3-V4 bacterial 16S rRNA Illumina sequencing. Firmicutes (46.5%) and Bacteroidetes (24.8%) dominated the vaginal bacterial community of pregnant sows while Proteobacteria were in low numbers (14.5%). Among Firmicutes, Clostridia (34.6%) were found to predominate while Lactobacilli (3.8%) were few. No differences in β-diversity ($P = 0.447$) of bacterial communities were observed between the anterior and posterior vagina in sows from the 2 housing types. Firmicutes and Bacteroidetes dominated sows fecal microbiota (48.7% and 37.13% respectively) with relatively low numbers of Proteobacteria (0.9%). Fecal samples of piglets differed in percent composition during the first 3 d after birth. Proteobacteria were found to be predominant on d 0 (63.8%), Firmicutes on d 1 (55.2%), and Firmicutes and Bacteroidetes on d 3 (60.1% and 15.15% respectively). Although piglet fecal microbiota was significantly different from both sow vaginal, and fecal microbiota ($P = 0.001$), the principal coordinate analysis showed a moving trend of piglet microbiota toward the sow vaginal microbiota as piglets grew from d 1 to d 3. Results indicate that maternal microbiota may contribute to piglet gut microbiota development.

Key Words: piglet, sow, vaginal and fecal microbiota

W119 Enteral bile acids modulate intestinal immune response and gut microbiota in early-weaned piglets challenged with LPS.

Alessandro Mereu*[1], Nuria de Diego-Cabero[2], Jose Javier Pastor Porras[1], David Menoyo[2], and Ignacio Ipharraguerre[3,1], [1]*Lucta SA, Montornés del Valles, Barcelona, Spain,* [2]*Departamento de Producción Animal, Universidad Politécnica de Madrid, ETS Ingenieros Agrónomos, Madrid, Spain,* [3]*Institute of Human Nutrition and Food Science, University of Kiel, Kiel, Germany.*

Bile acids (BA) have recently emerged as regulators of intestinal immune homeostasis and mucosal integrity. We examined the effects of administering enterally deoxycholic acid (DCA) to early-weaned pigs challenged with lipopolysaccharide (LPS) on gut BA profile, immune response and microbiota. Twenty-four piglets were weaned at 21 d, acclimatized for 14 d, and subsequently grouped (n = 8) to be intragastrically infused with either deionized water (C+, C−) or 15 mg of DCA·kg^{-1} initial BW (DCA) daily during 14 d. On d 28, C+ and DCA piglets were injected i.p. with 150 µg LPS·kg^{-1} BW. Three h later, all animals were bled and killed for organ measurement and sampling. Blood samples were analyzed for endotoxin (EDT), interleukin (IL)-6, and tumor necrosis factor α (TNF-α). Expression of occludin, IL-6 and IL-10 genes and the concentration of individual BA were measured in the ileal mucosa. Colonic microbiota was characterized by sequencing bacterial 16S ribosomal-RNA. Individual BW and feed intake were recorded weekly. Data were analyzed with a mixed-effects model in which pig was treated as random effect and treatment as fixed effect. Compared with C-, LPS decreased total BA concentration ($P < 0.01$) and increased plasma TNF-α ($P < 0.01$) and EDT ($P < 0.02$) as well as hepatic ($P < 0.01$) and intestinal ($P < 0.03$) weight. Interestingly, DCA infusion increased the proportion of BA with the greatest ability to induce BA-signaling pathways ($P < 0.05$), prevented alterations ($P > 0.10$) in plasma EDT and intestinal weight, decreased expression of IL genes ($P < 0.04$) in the ileum, and enhanced ($P < 0.05$) feed intake. In addition, treating pigs with DCA increased ($P < 0.05$) *Peptostreptococcaceae* and *Clostridiaceae* whereas decreased ($P < 0.05$) *Lactobacillaceae* in the colon. In conclusion, DCA acted locally to prevent LPS-induced inflammation and barrier disruption of the intestinal mucosa. These effects were associated with changes in the intestinal BA signature.

Key Words: deoxycholic acid, bile acid signaling, gut permeability

W120 Impact of xylanases on gut microbiome of growing pigs fed with corn-based and wheat-based diets.

H. M. Tun*[1], R. Li[1], E. Kiarie[1,2], M. Nyachoti[1], and E. Khafipour[1], [1]*University of Manitoba, Winnipeg, MB, Canada,* [2]*DuPont Industrial Biosciences-Danisco Animal Nutrition, Marlborough, Wiltshire, UK.*

This study was carried out to assess the effects of exogenous xylanases on production performance and gastrointestinal microbiota of growing gilts fed corn-based or wheat-based diets. A total of 96 individually penned gilts (22.7 ± 0.65 kg initial BW) were used in a CRD experiment with 2 × 6 factorial arrangement and fed experimental diets for 42 d. Gilts (n = 8 per treatment) received one of the 2 basal diets: (a) corn with 40% corn distillers dried grains, or (b) wheat with 25% wheat co-products, each without or with one of the 5 xylanases (XA, XB, XC, XD and XE). Xylanases were supplemented at 75 mg/kg of feed and all diets contained phytase. All xylanases were produced by different fungal organisms, except for xylanase-C, which originated from bacteria. On d 42, all pigs were euthanized to obtain ileal and cecum digesta for microbiome analysis using pyrosequencing of V1-V3 regions of 16S rRNA and downstream bioinformatic analyses using QIIME. Spearman's correlation was used to correlate microbiome composition data with performance characteristics, apparent total-tract digestibility (ATTD), and colon digesta volatile fatty acids (VFA) concentration. The XA yielded the best growth performance in both corn and wheat based diets ($P < 0.05$) when compared with other xylanases. Based on PERMANOVA analysis on UniFrac distances, XA significantly affected the β-diversity of ileum microbiota compared with other xylanases and controls ($P < 0.05$). Furthermore, xylanases influenced ATTD and colonic digester volatile fatty acids diet dependently ($P < 0.05$). The XA increased *Lactobacillus* species in the cecum in both diets, whereas other xylanases drastically decreased *Lactobacillus* species when compared with control ($P < 0.05$). In the wheat-based diet with xylanases, cecal bacterial community composition changes significantly correlated with ATTD of DM ($r = -0.5$), gross energy digestibility ($r = -0.49$) and colon VFA concentrations ($r = -0.67$) ($P < 0.02$). However, in the corn-based diet with xylanases, ileal bacterial community changes correlated with ATTD of DM ($r = -0.4$) and gross energy digestibility ($r = -0.43$), whereas cecal bacterial community changes correlated with

ATTD of fat digestibility (r = −0.58) and colon VFA concentration (r = −0.41) ($P < 0.03$).

Key Words: pig, xylanases, gut microbiome

W121 Effects of sulfur amino acids to lysine ratio on the expression of selected genes from piglets challenged with enterotoxigenic *Escherichia coli* K88.

Roseline Kahindi*[1], Alemu Regassa[1], John Htoo[2], and Martin Nyachoti[1], [1]*University of Manitoba, Winnipeg, MB, Canada,* [2]*Evonik Industries AG.*

The sulfur AA (SAA; methionine and cysteine):Lys ratio for protein accretion is 55% for 7 to 11 kg pigs (NRC, 2012). The use of SAA to support immunity in addition to accretion of lean tissue may exert additional requirements in immune stimulated pigs. Moreover, due to negative whole body protein balance resulting from muscle wasting during an immune challenge, performance responses may not be suitable response criteria for determining SAA requirements. A study was conducted to determine the standardized ileal digestible (SID) SAA:Lys ratio of weaned pigs under an enterotoxigenic *Escherichia coli* (ETEC) challenge using gene expressions of methionine adenosyltransferase 1 and 2-α (MAT1A and 2A), 5-methyltetrahydrofolate-homocysteine methyltransferase (MTR), and cystathionine γ-lyase (CTH) as response criteria. Thirty-five [Duroc × (Yorkshire × Landrace)], 7-kg piglets were assigned to 5 dietary treatments in a completely randomized design. The corn-wheat-soybean-meal based antibiotic-free diets had graded SID SAA:Lys ratios (48, 54, 60, 66, and 72%) and 1.18% SID Lys. Feed was offered at 4% BW and fed twice a day at 08.00 and 16.00 h. Piglets had a 6-d diet adaptation period and were all orally challenged with 6 and 15 mL of ciprofloxacin-resistant ETEC K88+ (5×10^9cfu/mL) on d 7 and 10, respectively. Blood samples were collected before and after challenge. On d 13 all pigs were killed to collect liver and ileal tissues for gene expression of MAT1A and 2A, MTR, and CTH using quantitative real-time PCR. Serum TNF-α concentration 6 h after inoculation was higher ($P < 0.05$) than pre-challenge and was improved with increasing SAA:Lys ratio. Data were subjected to ANOVA using Proc Mixed of SAS 9.2. Increasing SAA:Lys ratio linearly decreased ($P < 0.01$) liver MTR, while quadratically increasing ($P < 0.01$) CTH and MAT1A gene expression. Ileal expression of MTR and MAT2A linearly increased, whereas, CTH and MAT2A were quadratically increased ($P < 0.05$) with increasing SAA:Lys ratio. Maximum transmethylation, transulfuration, and remethylation was at SAA:Lys ratio of 60% indicating that this ratio was enough to support piglets during an immune challenge.

Key Words: pig, *Escherichia coli* K88, SAA:Lys ratio

W122 Messenger ribonucleic acid abundance of intestinal enzymes and nutrient transporters in chickens fed with vitamin D_3 and 1,25-dihydroxycholecalciferol.

Cristiane R. A. Duarte*, Alice E. Murakami, Ana F. Q. M. Guerra, and Iván C. Ospina-Rojas, *Departamento de Zootecnia, Universidade Estadual de Maringá, Maringá, Paraná, Brazil.*

Vitamin D plays an essential role in regulating the bone formation and mineral balance in chickens and it is also related to functional development of the small intestine in rats. This study compared the effects of cholecalciferol and 1,25-dihydroxycholecalciferol on gene expression of vitamin D receptor, intestinal enzymes and nutrient transporters in chickens in the starter phase (1 to 21 d). A total of 1,008 1-d-old male Cobb chicks were used, distributed in a completely randomized factorial design 2 × 3 (2 sources of vitamin D_3: D_3 and $1,25(OH)_2D_3$ x 3 levels: 200; 950; 1,700 IU/kg feed) with 6 replicates and 28 birds each one. Relative mRNA abundance of vitamin D receptor (VDR), aminopeptidase N (APN), maltase, sucrase-isomaltase (SI) complex, vitamin D-1-α-hydroxylase, sodium/glucose cotransporter 1 (SGLT1), glucose transporter 2 (GLUT2), peptide transporter 1 (PEPT1), sodium/phosphate cotransporter type IIb (NaPi-IIb), plasma membrane Ca^{2+} ATPase (PMCA-1b) were assayed using real-time PCR. All data were analyzed by SAS GLM and differences among means were separated using Tukey's multiple range tests. There was an interaction ($P < 0.05$) between sources and levels of vitamin D_3 only for mRNA abundance of SI. The mRNA abundance of maltase, NAPi-IIb, PMCA-1b, PEPT1 and GLUT2 were higher ($P < 0.05$) in jejunal mucosa of animals fed with vitamin D_3, while the mRNA abundance of 1-α-hydroxylase and SGLT1 were lower ($P < 0.05$) in these animals. The levels of vitamin D (independently of source) affected the mRNA abundance of 1-α-hydroxylase, PEPT1 and SGLT1. The mRNA abundance of 1-α-hydroxylase in jejunal mucosa of animals fed with 200 IU/kg feed of vitamin D was higher ($P < 0.05$) compared with 950 IU/kg feed. The mRNA abundance of PEPT1 was higher ($P < 0.05$) with 200 IU/kg feed of vitamin D compared with other levels, while the mRNA abundance of SGLT1 was higher ($P < 0.05$) in animals fed with 200 IU/kg feed of vitamin D compared with 1,700 IU/kg feed. It can be concluded that vitamin D and $1,25(OH)_2D_3$ can differently influence the gene expression of intestinal enzymes and nutrient transporters in chicken.

Key Words: cholecalciferol, gene expression, intestine

W123 Early supplementation of alfalfa to starter diets altered electrophysiological properties and permeability of the gastrointestinal tracts in growing lambs.

Bin Yang*[1], Shan-shan Wang[1], Bo He[1], Jian-xin Liu[1,2], and Jia-kun Wang[1], [1]*Institute of Dairy Science, Hangzhou, Zhejiang, China,* [2]*Zhejiang University, Hangzhou, Zhejiang, China.*

To investigate the effects of early supplementation of starter pellets with alfalfa in pre-weaning period on the permeability, expressions of tight junction (TJ) proteins and cytokines of gastrointestinal tract during the pre- and post-weaning period, 6 of 66 male Hu lambs at the age of 10 d were slaughtered as control, and the other 60 lambs were randomly allocated to 2 dietary treatments: milk replacer and starter pellets without (STA) or with free-choice provision of chopped alfalfa (S-ALF). The animals were offered 300-g/d concentrate mixture and had free access to alfalfa after weaning at the end of wk 4 (age of 38 d). The plasma concentrations of D-lactic acid, lipopolysaccharides, IgA, IgM and IgG were measured by ELISA kit (RB). Ruminal epithelium and duodenal mucosa were subjected to Ussing chamber to measure the transepithelial electrical resistance (TER) and conductance. The mRNA expressions of TJ proteins and cytokines of gastrointestinal tract were determined with qRT-PCR. Results were analyzed as a completely randomized design. All data were analyzed by 2-way ANOVA using PROC GLM SAS (version 9.2; SAS Institute Inc., Cary, NC). Data of TER and conductance showed that alfalfa supplementation increased or decreased permeability of ruminal epithelium and duodenal mucosa numerically in pre- or post-weaning period, respectively, while the plasma concentrations and the morphological appearance of duodenum were not different between 2 treatments ($P > 0.05$). Compared with STA group, alfalfa supplementation increased ($P = 0.057$) the ruminal occludin expression, enhanced ($P < 0.01$) the duodenal expression of claudin-1, and numerically enhanced ileal expression of claudin-1 and claudin-4 during the pre-weaning period, and inhibited ($P < 0.05$) the weaning-caused compensatory increase in ruminal epithelial expression of claudin-4. The change in ruminal expression of TNF-α with weaning was similar to claudin-4. In summary, early supplementation of alfalfa to starter diet could maintain the normal function of the gastrointestinal barrier, and helped to release the stress from weaning and feed transition in growing lambs.

Key Words: alfalfa, weaning, gastrointestinal tract

W124 Heat-treated colostrum feeding promotes beneficial bacteria colonization in the small intestine of neonatal calves. Nilusha Malmuthuge*, Guanxiang Liang, Yanhong Chen, Laksiri Goonewardene, and Le L. Guan, *University of Alberta, Edmonton, AB, Canada.*

The feeding of heat-treated colostrum is a common practice to increase passive transfer of immunity and decrease enteric infections in calves. However, its influence on gut microbial colonization has not been well studied. The present study investigated the effect of heat-treated colostrum feeding on the bacterial colonization in calf small intestine, within the first 12 h of life. Newborn Holstein bull calves (n = 32) were removed from dams and fed with either fresh colostrum (FC, n = 12) or heat-treated colostrum (HC, n = 12) soon after birth, while the control (NC, n = 8) group did not receive colostrum. Small intestinal samples (tissue and contents) were collected from proximal jejunum, distal jejunum and ileum at 6 and 12 h after birth, following euthanasia. Quantitative real time PCR was used to explore the colonization of total bacteria, lactobacilli, and bifidobacteria. The feeding of colostrum soon after birth increased total bacteria density (FC-1.4 ± 0.7 × 10^{10} 16S rRNA copy/g of sample, HC-9.8 ± 3.4 × 10^9 16S rRNA copy/g of sample) in calf gut within the first 12 h compared with NC (5.3 ± 2.2 × 10^8 16S rRNA copy/g of sample). Although there were bacteria in FC (1.8 × 10^3 16S rRNA gene copy/mL), bacteria were not detectable in HC. In contrast, the prevalence of lactobacilli was lower in HC (0.007 ± 0.004%) and FC (0.014 ± 0.008%), comparing to NC (0.031 ± 0.015%). Remarkable changes in the prevalence of small intestinal tissue-attached bifidobacteria were observed with the feeding of HC soon after birth, but not that in gut contents. The prevalence of bifidobacteria was 3.2-fold and 5.2-fold higher in HC (28.6 ± 10.3%) than FC (8.9 ± 2.5%) and NC (5.5 ± 1.5%), respectively, at 6 h. The feeding of FC increased the prevalence of tissue-attached bifidobacteria gradually, reaching to that of HC at 12 h. Thus, the present study suggests that feeding of HC enhances the colonization of bifidobacteria on small intestinal tissue immediately postpartum compared with that of FC and NC, which may prevent the colonization of enteric pathogens, and thereby decrease enteric infections in neonatal calves.

Key Words: newborn calves, gut colonization, bifidobacteria

Dairy Foods: Cheese

W125 Determining economic feasibility for artisan cheese companies. Cathy Durham[2], Andrea Bouma[1], and Lisbeth Goddik*[1], *[1]Department of Food Science, Oregon State University, Corvallis, OR, [2]Food Innovation Center, Oregon State University, Portland, OR.*

Artisan cheese makers lack access to valid economic data to help them evaluate business opportunities and make important business decisions such as determining cheese pricing structure. An economic model was developed in Excel following close collaboration with current and future artisan cheese companies. The objective of this study was to utilize this economic model to evaluate the net present value (NPV), internal rate of return, and pay back period for artisan cheese production at different annual production volumes for a given cheese type. The model is also used to determine the minimum retail price necessary to assure positive NPV for 5 different cheese types produced at 4 different production volumes. These 2 scenarios demonstrate important business considerations facing artisan cheese makers. For example, a small size cheese maker with annual production volume at 3,401 kg (7,500 lb) cannot be economically viable (negative NPV) if selling cow milk Gouda for $48.50/kg ($22/lb); by doubling the production size, the business would obtain a positive NPV. Due to differences in cheese yield, investment in aging facility, labor required during aging, and raw milk purchase price, fresh cow milk cheeses such as fresh mozzarella can be sold for about half the price of hard, aged, goats' milk cheeses at the largest volume or about 2-thirds the price at the lowest volume examined. For example, for the given model assumptions, at an annual production of 13,608 kg cheese (30,000 lb), a fresh cows' milk mozzarella should be sold at a minimum retail price of $27.29/kg ($12.38/lb) while a goats' milk gouda needs minimum retail price of $49.54/kg ($22.47/lb) for the business to have NPV at or above zero. The model is utilized within the OSU Extension program and has gone through 2 major updates. The observations derived from the model are consistent with the current business situation for artisan cheese companies.

W126 Effect of *terroir* for raw and pasteurized milk Cheddar on nonstarter lactic acid bacteria. Christopher Baird, Lisbeth Goddik*, Gregory Turbes, Elizabeth Tomasino, Juyun Lim, and Joy Waite-Cusic, *Department of Food Science, Oregon State University, Corvallis, OR.*

Terroir is a connection to the land and producer that influences the organoleptic properties in many products including cheese. Non-starter lactic acid bacteria (NSLAB), which are present in the environment, are thought to be one driving component of terroir in cheese. The effect of *terroir* was explored through differences in NSLAB between Cheddars made from different milk source locations. The effects of heat treatment on the importance of *terroir* on NSLAB present in cheddar was also investigated. Cheddar was produced with raw and low-temperature long-time (LTLT) pasteurized milk at Oregon State University. Milk was sourced from 3 individual farms, and 2 commingled sites in different eco-regions of Oregon. All milk was collected within 5 weeks while the Jersey herds were on a pasture-based diet. Cheddar was aged at 5°C and 2 samples per cheese were extracted at 5 and 9 mo. Samples were homogenized and grown anaerobically on MRS at 30°C for 48 h. Five random colonies were selected per for further identification. Isolates were speciated using API50 fermentation test kits. At 5 mo, the majority of isolates identified in raw and LTLT pasteurized cheddar were *Lactobacillus paracasei* and *Lactobacillus plantarum* respectively. Fermentation patterns between similar identifications showed wide variation at 5 mo with no overlap between regions. *L. paracasei* remained the dominant NSLAB in raw cheeses after 9 mo of aging. Each Cheddar showed reduced variety in NSLAB fermentation patterns at 9 mo. The unique fermentation patterns suggest that milk source location influenced the NSLAB profile of Cheddars. Further variability of isolates will be performed by pulsed field gel electrophoresis (PFGE). The NSLAB profile of cheddar is a reflection of the milk source location. This connection between NSLAB and location demonstrates one facet of *terroir* that affects Cheddar.

Key Words: nonstarter lactic acid bacteria, Cheddar, *terroir*

W127 Effect of *terroir* on flavor for raw and pasteurized milk Cheddar. Gregory Turbes, Lisbeth Goddik*, Christopher Baird, Juyun Lim, Joy Waite-Cusic, and Elizabeth Tomasino, *Department of Food Science, Oregon State University, Corvallis, OR.*

Terroir is a term that in the United States has come to be known as "taste of place." It builds off the idea that a food's organoleptic properties are defined by the environment, climate, and production practices. The effect of *terroir* and heat treatment effect on *terroir* to Oregon Cheddar flavor were explored. Cheddar was produced with raw and low-temperature long-time (LTLT) pasteurized milk at Oregon State University. Milk was sourced from 3 individual farms, and 2 commingled sites in different eco-regions of Oregon. Dairy farms were selected with similar herd management styles. Collection of milk occurred within a 5-week period while the Jersey herds were on a pasture-based diet. Cheddar was aged at 5°C and 2 samples per cheese were extracted at 5 and 9 mo of aging. Flavor compounds were analyzed using gas chromatography-mass spectrometry (GCMS). A total of 54 flavor compounds were detected. At 5 and 9 mo 46 and 30 flavor compounds were identified respectively, consisting of acetates, alcohols, aldehydes, alkanes, alkenes, esters, fatty acids, ketones, lactones, nitrogen compounds, sulfur compounds, and terpenes. Principal component analysis (PCA) was performed for all samples. At 5 mo, samples separated based on milk source location and at 9 mo samples separated based on heat treatment. Results suggest that the flavor of Cheddar is affected by both *terroir* and LTLT pasteurization; 5 mo cheddar flavor is best characterized by *terroir* and 9 mo Cheddar flavor is best characterized by heat treatment. This connection between Cheddar flavor and milk source location suggest that *terroir* is part of what characterizes a Cheddar.

Key Words: flavor, Cheddar, *terroir*

W128 The effects of *terroir* and heat treatment on consumers' perception of Cheddar cheese flavor. Gregory Turbes, Lisbeth Goddik*, Tyler Linscott, Elizabeth Tomasino, Joy Waite-Cusic, and Juyun Lim, *Department of Food Science, Oregon State University, Corvallis, OR.*

The objective of this research was to investigate the effect of *terroir* (geographical location of milk source) on Cheddar cheese flavor. Milk from 5 locations, including single dairy farms and commingled sites, were collected from around the state of Oregon: 3 individual dairy farms from the mid-valley and 2 commingled sites at coastal and high desert plateau. These farms/sites were selected based on their representation of Oregon's dairy industry as well as similarities in herd and herd management characteristics. Using raw and pasteurized counterparts of the standardized milk, Cheddar cheese was made and aged. At 5 and 9 mo into aging, Cheddar cheese consumers were asked to sort the samples based on perceived similarity/dissimilarity of cheese flavor and also to describe the characteristics of each cheese groups. Grouping data were subjected to multidimensional scaling and subsequent cluster analysis. Correspondence analysis was also performed on consumer descriptions as a simplified exploratory approach to discover underlying characteristics. Results at 5 mo into aging revealed that consumers could differentiate cheese samples based on dairy farm origin, while cheeses produced from commingled milk samples were perceived to be similar. At 9 mo into aging, consumers differentiated the cheeses based on heat treatment; that is, raw vs. pasteurized milk cheeses. These data suggest that for younger cheeses, the geographical location of the milk source has a significant effect on the flavor of Cheddar cheese but that the practice of milk commingling may overcome the effects of geographical location. Thus we can source cheese flavor to individual farms and thereby demonstrate the existence of *terroir*. In contrast, the older cheeses are primarily characterized by their history of heat treatment.

Key Words: *terroir*, cheese, sensory

W129 Sensory and functional properties of cheese across three storage temperatures.

Ni Cheng*[1], P. D. Gerard[2], and M. A. Drake[1], *[1]Southeast Dairy Foods Research Center, North Carolina State University, Raleigh, NC, [2]Dept. Mathematical Sciences, Clemson University, Clemson, SC.*

Cheese quality influences sales and applications. Storage time and temperature affect cheese quality and may play a crucial role in cheese designated for export markets as optimum quality must be maintained. A mild flavor profile is expected in export markets concurrent with optimum functional properties. The objective of this study was to evaluate sensory and functional properties of 4 cheese types across different storage temperatures. Triplicate lots (18 kg blocks)of cheeses (Cheddar, Monterey Jack, Mozzarella and Gouda) were obtained from 2 commercial facilities and assigned to 4°C, −1°C and −18°C storage. Cheeses were evaluated every 3 mo through 1 year storage. At each time point, sensory evaluation (flavor and texture) and functional tests (moisture, pH, shreddability, sliceability, color, melting, viscosity, and fork stretch) were conducted. Two-way ANOVA (storage time, temperature) as well as multivariate analyses were applied to evaluate the data. Time and storage temperatures had no practical effects on cheese composition or color ($P > 0.05$). Storage time increased shreddability and melt and decreased sliceability, viscosity and fork stretch values ($P < 0.05$). Storage at −18°C resulted in smaller increases in shreddability and melt than −1°C or 4°C. There were no differences in shreddability and melt properties for cheeses stored at 4°C or −1°C ($P > 0.05$). Across storage time, cheeses increased in intensities of typical aged cheese flavors (sulfur and brothy), cheeses stored at lower temperatures maintained young/undeveloped cheese flavors (cooked, whey, milkfat and diacteyl) longer than cheeses stored at 4°C. Texture properties by sensory analysis were unchanged through 6 mo storage, regardless of temperature. These results indicate that a lower temperature (−1°C) may be applied to cheeses for up to 6 mo to maintain sensory quality (young, mild flavor) without detrimental effects on functional properties.

Key Words: cheese, storage, quality

W130 Microstructural arrangements observed using electron microscopy during the manufacture of cheese and the influence of cheese pH.

Almut H. Vollmer*, Nabil N. Youssef, and Donald J. McMahon, *Western Dairy Center, Utah State University, Logan, UT.*

It is known that the texture of cheese changes as a function of pH. Our objective was to determine the differences in the arrangements of protein and fat between a medium pH cheese (Cheddar cheese) and a low pH cheese (feta cheese). Cheese was made using 16-kg aliquots of milk and the make procedure modified to produce cheddar cheeses with a range of pH values as well as making a feta cheese. Samples of curd were collected throughout the cheese making processing, starting from before cutting the curd and during cheese storage. Samples were fixed in glutaraldehyde, then dehydrated, heavy metal stained, embedded and sectioned, and multiple fields observed using transmission electron microscopy. During initial curd formation the characteristic fine stranded network of aggregated casein micelles was observed with fat globules entrapped between the protein strands. As the cheese manufacture continued, and the curd particles contracted and whey was expelled, the initial protein strands apparently coalesced into thicker strands and the casein micelles tended to lose their individual identity. This same general pattern continued throughout manufacture and into the storage period. After 3 mo of aging the cheddar cheeses ranged from pH 4.9 to pH 5.2. There were variations in protein arrangements observed within individual cheese samples as is typical in microstructure of dairy foods. No observable differences in structural arrangements outside this natural variability were apparent between the Cheddar cheese of lowest pH to the highest pH. In contrast, the microstructure arrangements of the proteins in feta cheese were very different to those in Cheddar cheese. In feta cheese, there is a more openness present in the protein network with the appearance of the protein regions having a looser nature; that is, not having large coherent regions of connected protein. This was related to feta cheese having a pH below that at which the caseins are acid precipitated and as they become less soluble in the surrounding serum phase of the cheese. These differences in protein arrangements observed using electron microscopy helps explain the crumbly texture associated with low pH rennet-set cheeses.

Key Words: Cheddar, feta, microstructure

W131 Effect of salting pH, salting rate, and stretching temperature on proteolysis in Mozzarella cheese.

Ananya C. Biswas*[1], Anil Kommineni[1], Praveen Upreti[2], and Lloyd E. Metzger[1], *[1]Dairy Science Department, South Dakota State University, Brookings, SD, [2]Nestle R&D Center Inc., Solon, OH.*

The level of proteolysis during refrigerated storage of Mozzarella cheese can have an effect on functionality including stretching and melting characteristics. Proteolysis in Mozzarella cheese could be influenced by several manufacturing parameters including: salting pH (SP), salting rate (SR), and stretching temperature (ST). The objective of this study was to evaluate the effects of SP, SR and ST on Mozzarella cheese proteolysis during storage. Thirty-two batches of Mozzarella cheese were manufactured using a partial split plot design that included a range of protein-to-fat ratios (1 to 4.5) in the main plot. In the sub plot, 2 salting pH (5.2 and 5.6), 2 salting rates (1.5% and 2.2%), and 2 stretching temperatures (65°C and 85°C) were used. After manufacture Mozzarella cheese was vacuum packed and stored at 4°C for 28 d. After storage, proteolysis was determined by measuring the soluble protein at pH 4.6 as a percentage of total protein content. Proteolysis and composition data were analyzed using simple linear regression analysis to establish potential relationships among the cheese compositions (moisture, fat, and protein), SP, SR, ST and proteolysis. Linear regression analysis indicated that proteolysis was primarily influenced by ST and cheese manufactured with the high ST always resulting in less proteolysis as compared with the low ST. Subsequently the GLM procedure of SAS was utilized to conduct an ANOVA. The results determined that milk fat and protein content, and ST had a significant effect ($P < 0.05$) on cheese proteolysis, whereas no significant effects were observed for SP and SR. These results demonstrate that in this study milk composition and stretching temperature were the primary factors influencing proteolysis of mozzarella cheese. This information can be used by cheese manufacturers to control the level of proteolysis in Mozzarella cheese.

Key Words: milk protein-to-fat ratio, Mozzarella cheese, proteolysis

W132 Effect of selenium supplementation on Se status and Mozzarella quality in dairy cattle feed. Weizheng Zhu, Hongyun Liu*, Daxi Ren, and Jianxin Liu, *Institute of Dairy Science, College of Animal Science, Zhejiang University, Hangzhou, Zhejiang, China.*

Selenium (Se) is an important trace element and its deficiency has been associated with human and animal health. The human recommended dietary allowance (RDA) for adult Se intake is about 55 µg per day; however, many places in the world are lower than that level so need a dietary supply. The objective of this study was to research the effect of feed Se supplementation on Se status in milk and mozzarella cheese quality. Thirty multiparous Holstein dairy cows (3 groups) with similar condition were raised in local dairy farm. First group of dairy cow was fed with selenium yeast (0.5 mg Se/kg dry matter), second group was fed with sodium selenite at the same Se concentration, third group without Se supply as control. After 2 mo feeding, milk samples were collected for Se analysis and cheese-making. Data were analyzed by one-way ANOVA using SAS 9.3. Results showed that the Se content in milk was increased to 47.9 µg/L by selenium yeast group, significantly higher than the 25.6 µg/L in sodium selenite group when both supplied with 0.5 mg Se/kg DM. The fat, casein and whey protein of Se-milk were seperated by ultracentrifuge and the Se content was determined by atomic absorption spectroscopy. The results were 9.82%, 45.56% and 44.62% respectively. When Se-enriched mozzarella cheese was made from high Se-milk and compared with control, no significant difference was found in composition or texture. But the functional properties (meltability, flowability and stretchability) were better in Se-cheese after 8 weeks storage. Additionally, the pH and a_w were lower in Se-cheese, leading to lower total plate count. The Se content increased more than 4 times in mozzarella cheese than milk, and additional Se was found in whey, hot water and brine collected during cheese-making. Organic and inorganic Se was found in Se-cheese after 8 weeks storage. Most of the Se-peptide produced during the storage was SeMet (215 ng/g) and SeCys (123 ng/g). The results of this study showed that the Se content in milk and cheese can be increased by dietary Se supplement, and the mozzarella cheese quality was not affected by feed Se supply.

Key Words: selenium status, Mozzarella cheese

W133 Microbiological characteristics and mineral content of probiotic low sodium Minas cheese with added arginine. Taissa Felicio, Marcia Cristina, Renata Raices, Luciana Nogueira, and Adriano Cruz*, *Federal Institute of Science and Technology of Rio de Janeiro (IFRJ), Rio de Janeiro, Brazil.*

The objective of the present study was to develop technology for the production of probiotic fresh Minas cheese with a reduced sodium content and the addition of arginine, and evaluate any changes in the quality parameters occurring throughout the shelf life. Gross composition and mineral content (moisture, protein, lipid, sodium, calcium and potassium). With the exception of the lipid content, differences were observed between the treatments during the storage period ($P > 0.05$) for all the parameters evaluated. Cheese QIII (50/50 NaCl/KCl reduction plus 1% w/w arginine) showed the highest moisture content (variation of 60 to 61.6% w/w, $P < 0.05$) and a progressive decrease in protein during storage (variation from 17.1 to 16.6% w/w, $P < 0.05$). With respect to the sodium and potassium levels, there was a progressive reduction in sodium in relation to the substitution level, that is, between the treatments, varying from 315 to 275 mg/100g (Qc, 100% NaCl) and from 193 to 215 mg/100g (QIII, 50/50 NaCl/KCl plus 1% arginine, $P > 0.05$). With respect to the calcium content, the addition of arginine resulted in a higher calcium content with an average value of 735.3 mg/100g (cheese QIII), whereas the value for the cheese containing only NaCl was 587.3 mg/100g ($P < 0.05$). Similarly, the concentration decreased throughout storage (variation from 591 to 566 mg/100g for cheese Qc with 100% NaCl, and from 744 to 660 mg/100g for QIII, with 50/50 NaCl/KCl added with arginine. The values observed were relevant and considerably lower than those reported on the labels of fresh Minas cheeses available on the Brazilian market, which show mean values of 437.4 mg/100g and in this context probiotic cheese with arginine seems an interesting option to functional cheese market.

Key Words: probiotic cheese, arginine, low sodium cheese

W134 Probiotic Minas Frescal cheese with *Lactobacillus casei* Zhang. Ramon Silva, Marcia Cristina, Luciana Nogueira, Renata Raices, and Adriano Cruz*, *Federal Institute of Science and Technology of Rio de Janeiro (IFRJ), Rio de Janeiro, Brazil.*

The addition of *Lactobacillus casei* Zhang in the manufacture of Minas Frescal cheese was investigated. Minas Frescal cheeses were produced by enzymatic coagulation and direct acidification, supplemented with probiotic bacteria (*L. casei* Zhang) and subjected to microbiological (probiotic and lactic bacteria counts) and physicochemical analysis (pH, proteolysis, lactic acid, and acetic acid level). Adequate *L. lactis* and *L. casei* Zhang counts were observed in both cheeses, and as previously discussed, the highest values were observed in all cheeses throughout the refrigerated storage (about 8 log cfu / g for *L. lactis*, ranging from 8.14 to 9.02 log cfu / g, $P < 0.05$, respectively. However, the addition of *L. casei* Zhang provided lower pH and high proteolysis indexes during storage (from 5.38 to 4.94 and 0.470 to 0.702, $P < 0.05$, respectively), and these changes were more significant in the cheese produced by enzymatic coagulation. In addition, with respect to the organic acids, regardless the treatment the addition of *L. casei* Zhang led to higher lactic acid and acetic acid levels (ranging from 1.75 to 2.98 and 0.45 to 0.84 µg/mL, $P < 0.05$). Consumer test reported improved overall liking for the control sample produced by direct acidification, (7.83, $P < 0.05$), while the cheeses containing *L. casei Zhang* presented lower values for all sensory attribute. The optimization of *L. casei Zhang* dosage during the manufacturing of probiotic Minas Cheese should be performed.

Key Words: probiotic cheese, *Lactobacillus casei* Zhang

W135 Effect of inulin and lactulose on characteristics of Iranian probiotic ultrafiltration feta cheese. Maryam Enteshari[1], Mahshid Azizi*[2], Bahram Jirsaraei[3], and Mohammadreza Dolatkhahnejad[4], *[1]Department of Food Science and Technology, Shahid Beheshti University of Medical Sciences, Tehran, Iran, [2]Islamic Azad University of Birjand, Chemical Engineering and Food Industries Department, Tehran, Iran, [3]Azad University of Varamin, Faculty of Agriculture, Department of Food Science and Technology, Tehran, Iran, [4]Islamic Azad University of Ayatollah Amoli, Food Industries and Scientific Engineering Department, Tehran, Iran.*

Nowadays, consumers' demands for foods with health effect, desirable organoleptic and mouth feel characteristics, low-caloric and low fat content have greatly increased. Meanwhile, consumption of synbiotic products (simultaneous presence of probiotic and prebiotic) has revealed functional properties. In this study, effects of prebiotic compounds including inulin (I), lactulose (L), and inulin-lactulose (IL) on physicochemical, sensorial and survival of *Lactobacillus casei* in ultrafiltration (UF) probiotic cheese in different storage days (1, 15, 30, 45 and 60) have been evaluated. Obtained results revealed that changes in pH values for all of cheese samples during storage were significant with a descending trend; the pH of IL sample declined significantly from initial value of 4.71 to 4.48 at the end of storage ($P < 0.05$). In other ways, amounts of acidity for all of cheese samples increased significantly during storage ($P < 0.05$); at the initial and final days of storage, the IL sample exhibited the highest acidity values (1.66 and 2.03 g/100g, respectively) while the L sample presented the lowest ones (0.98 and 1.23 g/100g, respectively). At the first and final days of storage time, the highest (65.11 and 64.8%, respectively) and lowest amounts of moisture content (63.27 and 63.12%, respectively) pertained to the C (control) and I samples, correspondingly. The cheese samples of I and IL presented the highest sensory scores. At the end of storage, the highest numbers of *Lactobacillus casei* were observed in the samples of I and L (in the range of 7.83–7.9 Log cfu/g) and the lowest one belonged to the C sample (6.63 Log cfu/g). Therefore, in this research the final synbiotic cheese which contained more than 10^7 cfu/g viable *Lactobacillus casei* at the end of storage, is being proposed as probiotic product and the inulin or lactulose prebiotic compounds in the single mixture (I or L samples) have protective effect on the survival of *Lactobacillus casei.*

Key Words: ultrafiltration cheese, probiotic, prebiotic

W136 Volatile compounds formation in Prato cheese. Lígia Dozena Domingos, Lilian Regina Barros Mariutti, Neura Bragagnolo, and Walkiria Hanada Viotto*, *University of Campinas (UNICAMP), Campinas, São Paulo, Brazil.*

Prato cheese is a washed curd and semi-hard cheese produced from pasteurized cows' milk acidified by a mesophilic starter containing citrate-positive bacteria, and matured for a minimum period of 25 d. Volatiles play an important role in flavor perception of cheese and they are result of compounds formed by glycolysis, citrate metabolism, proteolysis and lipolysis. The aim of this work was to evaluate the formation of volatile compounds in Prato cheese after 30 d of refrigerated storage at 12°C. The compounds were determined by gas chromatography-solid phase micro extraction coupled to a mass spectrometer detector (GC-SPME-MS). Two grams of a mixture of cheese sample and sodium phosphate saline solution (1:3, w/v) were incubated in a sealed 20 mL vial for 15 min at 40°C and after that, the DVB/CAR/PDMS fiber was exposed to the headspace for 30 min. The fiber was desorbed in the injector (splitless mode) at 250°C for 1 min. Compounds were separated in a RTX-Wax (30 m × 0.25 mm × 0.20 µm, Restek). Electron ionization source was set at 70 eV and 250°C. MS data were acquired in SCAN mode (*m/z* 35–350). Identification was carried out by comparison with mass spectra of authentic standards or Wiley 9 library and Kovats retention index. Volatile compounds found were organic acids ($C_{4:0}$ to $C_{10:0}$), esters (ethyl butyrate, ethyl hexanoate), ketone (2-pentanone, 2-heptanone, 2-undecanone), alcohols (ethanol, 1-pentanol, 1-butanol, 1-hexanol, 3-methyl-1-butanol, 1-heptanol, 1-octanol) and aldehydes (hexanal, heptanal, nonanal, decanal, benzaldehyde) as a result of cheese glycolysis, lipolysis and proteolysis. From the citrate metabolism, we found acetoin, 2,3-butanediol, 2-butanone and diacetyl, which is associated with characteristic butter flavor of Prato cheese.

Key Words: cheese ripening, GC-MS, flavor compound

W137 Consumer perception of reduced-fat fresh cheese in Brazil. Juliana Zara Brondi Mendes, Jorge Herman Behrens, and Walkiria Hanada Viotto*, *University of Campinas (UNICAMP), Campinas, São Paulo, Brazil.*

Minas Frescal, the most consumed reduced-fat cheese in Brazil, is a fresh and soft white cheese produced by the enzymatic coagulation of pasteurized milk, with high moisture content (>55%). It is industrially produced by 3 different processes that result in cheeses with different sensory characteristics, particularly texture. Cheeses manufactured by the traditional process (addition of starter) or direct acidification (by replacing the starter by lactic acid) have firmer texture than those produced by ultrafiltration which presents a gel texture, due to the incorporation of whey proteins. This work aimed to assess Brazilian consumers' perceptions regarding reduced-fat Minas Frescal cheese manufactured by three different technological processes (traditional, direct acidification, and ultrafiltration). A grocer's shop and a consumer research center in São Paulo, Brazil, served as settings for consumer test with 151 individuals. Respondents were characterized by a demographic questionnaire and purchasing habits. Conjoint analysis based on complete profile was conducted with eight different product concepts derived from a factorial design of relevant variables in local consumers' choices: texture (firm or soft), size of the pack (family or individual) and nutritional information (light or light + 40% less fat). The majority of consumers participating in the study were female, on high income and over 35 years old, and the main reason reported for consuming light cheeses was the concern for health. Conjoint Analysis revealed that texture (41.1%) was the most important attribute followed by portion size (36.2%) and nutritional information (22.7%). Consumers positively rated the firm texture, the individual portion, and the "light + 40% less fat." These results favor cheeses obtained by traditional process or direct acidification, due to their characteristic firmness that leads to higher purchase intention by the consumers. Findings of this study can assist cheese industries in adjusting process conditions, labels and packaging in order to enhance local consumers' willingness to purchase reduced fat cheese.

Key Words: fresh cheese, consumer, purchase intention

W138 Effect of myrrh essential oil as a highly effective antimicrobial agent in processed cheese spreads. A. G. Mohamed*, J. M. Kassem, and H. M. Abbas, *National Research Centre, Dokki, Giza, Egypt*

There is a new approach to prevent the proliferation of food microorganisms using of plant essential oils. *Commiphora myrrha* is considered as highly effective, natura, and safe antimicrobial. Therefore, the current study aimed to evaluate the effects of *Commiphora myrrha* on (1) pathogenic positive bacteria including *Listeria monocytogenes*, *Staphylococus aureus*, and *Bacillus cereus* as well as gram-negative bacteria including *Escherichia coli* O157:H7 and *Salmonella typhimurium*, and (2) the sensory properties of processed cheese spreads at 5 different levels of usage. Moreover, processed cheese spread (PCS) samples were prepared by using 5 different ratios of *Commiphora myrrha* essential oil at 0.2, 0.4, 0.6, 0.8, 1 w/w to evaluate its organoleptic acceptability. The PCSs was made by heating and mixing the ingredients at 85°C for 10 min. Gross chemical composition and some physical characteristics were estimated through 3 mo of storage at 5 ± 1°C. Oil separation, penetration, melting point and color parameters were also determined through the storage period. Results showed that all tested microbes were susceptible to *Commiphora myrrha* at minimum inhibitory concentration of 2–5 µL of oil/mL. Moreover, results showed that using 0.2% (w/w) *Commiphora myrrha* essential oil gave satisfactory sensory properties. The appearance was shiny; gumminess and oil separation were absent. The overall preference of preferable ratio was "like very much" comparing to the other treatments. Color was more acceptable without significant differences ($P > 0.05$) and it spread well compared with control. The penetration values were 33.5, 32.0 and 31.2 mm versus 33.0, 30.5 and 26.5 mm for treated PCS versus control PCS ($P > 0.05$) when fresh, and after 1 mo and 3 mo of storage. Moreover, meltability 85.4, 81.6 and 80.0 mm versus 81.6, 80.5 and 78.7 mm for treated PCSs compared with control when fresh, and after 1 moand 3 mo of storage. *Commiphora myrrha* essential oil can be used successfully as antimicrobial agent during preparing of PCS with acceptable properties and satisfied sensory behavior.

Key Words: *Commiphora myrrha*, processed cheese spread, antimicrobial agent

W139 Effects of storage temperature and period on textural properties of cholesterol reduced and control Cheddar-type goat milk cheeses.

Binod P. Gupta, Brittany I. Davis, Krishna P. Bastola*, Jolethia O. Jones, and Young W. Park, *Fort Valley State University, Fort Valley, GA.*

Consumption of fat and cholesterol reduced food products has been increasingly popular among health conscientious consumers due to its association with health problems including heart diseases and stroke. The objective of this study was to evaluate textural properties of cholesterol reduced (CR) and control (CC) caprine milk cheeses during storage. Three batches each of CR and CC Cheddar-type caprine milk cheeses were manufactured, and stored at 3 different temperatures (−18, 4 and 22°C) for 0, 3 and 6 mo. β-Cyclodextrin (β-CD) was used to remove cholesterol from milk and cream before manufacture of the CR cheeses. Textural properties of all experimental cheeses were evaluated using a texture analyzer (Model TA.XT2i, Texture Technology Corp., Scarsdale, NY). The pooled means (g force) of hardness, adhesiveness, resilience, cohesiveness, springiness, gumminess, and chewiness across batches, storage temperatures and periods of CC and CR cheeses were: 851.1, 2750.1; 11.4, 0.92; 19.3, 46.6; 0.45, 0.65; 69.9, 84.6; 388.3, 1976.2; 320.8, 1867.8, respectively. CR cheese had significantly ($P < 0.01$) higher hardness, resilience, cohesiveness, springiness, gumminess, and chewiness, but lower adhesiveness compared with CC counterparts. These results may account for the difference in moisture contents (55.3 and 50.8%) in CC and CR cheeses, respectively. For 3 main factors, cheese type was significant ($P < 0.01$) for all textural traits, while storage temperature and storage period were significant ($P < 0.05$ or 0.01) except for springiness and gumminess. For 2-way interactions, cheese type × storage temperature and cheese type × storage period were significant ($P < 0.05$ or 0.01) for most properties, whereas none of 3-way interactions were significant. It was concluded that textural properties of the experimental caprine cheeses were significantly affected by cheese type (cholesterol removal), followed by storage temperature and periods.

Key Words: goat milk cheese, cholesterol-reduced, texture

W140 Identification of crystalline entities in the rinds of white mold ripened cheese and smear ripened cheese with powder X-ray diffractometry.

Gil F. Tansman*[1], Paul S. Kindstedt[1], and John M. Hughes[2], [1]*Department of Nutrition and Food Sciences, University of Vermont, Burlington, VT,* [2]*Department of Geology, University of Vermont, Burlington, VT.*

Curd softening in wheels of surface ripened cheese occurs radially from the surface toward the center and is the result of chemical changes including decalcification. It has been theorized that calcium is removed from the system by depositing as calcium phosphate crystals in and beneath the rind. Although researchers have observed calcium-containing crystals under the bloomy rind in several cheese varieties, no work has adequately determined the identity of the crystals. The present study was conducted to identify the crystals in bloomy rind (white mold ripened) cheeses and compare them to crystals that form in the smears of washed rind cheeses. Four varieties of Vermont soft ripened cheese were obtained from a commercial source; 2 of these were bloomy rind cheeses and 2 were washed rind cheeses. Powder X-ray diffraction (PXRD) patterns were generated for each cheese from fresh samples extracted from 1mm below the curd surface. Diffraction patterns were also generated from the smear material and surface hyphae scraped from the surfaces of washed rind and bloomy rind cheeses, respectively. The PXRD patterns revealed that small quantities of calcite ($CaCO_3$) form below the rinds of both cheese classes, but the diffraction patterns were very weak, due to the limited quantity of crystalline material present. Strong PXRD patterns from smear material revealed the presence of large concentrations of crystalline material. The smear from one cheese contained crystalline ikaite ($CaCO_3 \cdot 6H_2O$) and the other contained both ikaite and struvite ($NH_4MgPO_4 \cdot 6H_2O$). Powder diffractions from the bloomy hyphae produced very weak diffraction patterns with characteristic peaks of calcite, which may represent crystalline material that adhered to the hyphae from the cheese-hyphae interface.

Key Words: cheese, crystals, powder X-ray diffraction (PXRD)

W141 Characterization of single crystals in the rinds of white mold and smear ripened cheeses with single crystal X-ray diffractometry.

Gil F. Tansman*[1], Paul S. Kindstedt[1], and John M. Hughes[2], [1]*Department of Nutrition and Food Sciences, University of Vermont, Burlington, VT,* [2]*Department of Geology, University of Vermont, Burlington, VT.*

Calcium-containing crystals that form in the rinds of soft surface-ripened cheeses are thought to contribute to cheese softening through the removal of calcium from the aqueous and colloidal states. Several researchers have observed crystals near the surface of bloomy rind cheeses but none have succeeded in identifying them. The present work was conducted in parallel with a powder X-ray diffraction (PXRD) study in which fresh cheese samples were analyzed for total crystalline composition. In contrast, this study used single crystal X-ray diffraction (SCXRD) and polarized light microscopy to identify individual crystals isolated from cheese rinds and surface smears to obtain chemical information about crystal structure and atomic uniformity. Four Vermont soft surface ripened cheeses were obtained from commercial sources; 2 of these cheeses were bloomy rind (white mold) varieties and 2 were smear ripened varieties. Samples from 1mm below the rinds of all 4 cheeses as well as scrapings of the washed rind surface smears were mounted on glass microscope slides and observed with a petrographic polarized light microscope. Rotation of the circular microscope stage allowed crystal extinction to be observed. Three distinct crystals were observed by comparing crystal morphologies and extinction variability. Two different crystals were observed in the smears (one smear exhibited only one of the crystals) and one entity was observed 1mm beneath the rind in all 4 cheeses. Nearly all crystals that had not been damaged in the mounting process exhibited uniform extinction indicating that they were single crystals. Single crystals from the smears and from beneath the fungal bloom were isolated with a dissection needle and mounted on a goniometer head for analysis with a single crystal diffractometer. Structures for crystals in the smears were determined for ikaite ($CaCO_3 \cdot 6H_2O$) and struvite ($NH_4MgPO_4 \cdot 6H_2O$), and a crystal structure for calcite ($CaCO_3$) was determined from a bloomy rind crystal, thereby corroborating the results of the parallel PXRD study. This is the first observation of single crystals in cheese.

Key Words: cheese, crystal, single crystal x-ray diffraction (SCXRD)

Dairy Foods: Processing

W142 Improved heat stability of whey protein isolate by dry-heating with inulin. Yue He and Bongkosh Vardhanabhuti*, *University of Missouri, Columbia, MO.*

Dry-heating whey protein with reducing saccharides via Maillard reaction has been shown to improve heat stability. Selecting proper saccharides that offer technological and nutritional benefits could create new protein ingredients that have better functional properties and are more attractive to the consumers. The aim of this study was to develop heat stable whey protein ingredients by dry-heating with inulin, a non-digestible carbohydrate with known health and technological benefits. The effects of biopolymer ratio and heating conditions on heat stability, physicochemical properties, and nutritional qualities of the conjugates were determined. Whey protein isolate (WPI) and inulin at weight ratios of 1:1 to 6:1 were dissolved in deionized water, freeze-dried, and incubated at 70 to 80°C for 12 – 72 h without or with controlled relative humidity (RH) at 44 or 80%. Heat stability was measured by heating 6% w/w protein solutions, pH 6.0 at 85°C for 15 min and the absorbance was measured at 630 nm. Particle size, zeta potential, rheological properties, and lysine content were determined. WPI or mixed WPI-inulin (no dry-heating) turned very opaque after heating. Dry-heating of WPI-inulin clearly increased heat stability as shown by a significant reduction ($P < 0.05$) in turbidity (e.g., from A630 of 1.9 for WPI control to 0.8 for 12 h dry-heated 6:1 WPI-inulin) and particle size (from 160 nm in z-average diameter to 107 nm). Decreasing WPI:inulin weight ratio and increasing dry-heating temperature, incubation time, as well as RH resulted in increased heat stability; however, brown color intensity also increased. Rheological analysis revealed that all samples maintained Newtonian behavior with no significant difference in flow behavior index and consistency index. Dry-heated WPI-inulin had higher surface charge compared with WPI. The loss of lysine content ranged from 2.6% in 6:1 WPI-inulin after 12 h dry-heating to 19.2% in 2:1 WPI-inulin after 72 h dry-heating. In conclusion, dry-heating WPI with inulin creates new ingredient with improved heat stability. The new ingredient has great potential to be used in high protein beverages or other applications that require heat stability.

Key Words: whey protein, inulin, heat stability

W143 Heat treatment effect on hydrolysis of sodium tripolyphosphate in milk. Diogo Maus, Alviclér Magalhães, and Walkiria Hanada Viotto*, *University of Campinas (UNICAMP), Campinas, São Paulo, Brazil.*

Sodium phosphate salts are widely used in the manufacture of processed cheese for the stabilization of casein, as well as to improve the texture and functionality of the final cheese. The essential role involves calcium sequestering and pH control leading to the hydration and dispersion of casein, which in turn allows it to act as emulsifying agent resulting in the formation of a homogeneous cheese structure. During the processing phosphates may undergo hydrolysis due to heat treatment, pH and ionic environment. The formation of short chain phosphates increases the buffering capacity of the medium and therefore affects the final pH of the processed cheese. The objective of this study was to investigate the impact of temperature on the hydrolysis of sodium tripolyphosphate (STPP) in milk. Milk with 2.3% STPP was heated to 90°C and cooled to 5°C and the nuclear magnetic resonance (NMR) spectra were obtained at 5°C intervals. ^{31}P NMR spectroscopy was performed using a double resonance probe, fitted with a field gradient in the Z direction, coupled to a Bruker AVANCE III, operating at 14.1 T static magnetic field (500 MHz for ^{1}H). The spectra were processed with the aid of TOPSPIN 3.1 software. STPP hydrolysis occurred for the entire temperature range during milk heating and cooling and was significantly more intense from 80°C. At 90°C, 20.5% of STPP was hydrolyzed resulting in a 33.5% increase in the amount of pyrophosphate and orthophosphate. The spectra also showed a shift from left to right, indicating that the STPP hydrolysis resulted in a more acidic environment, which can affect the rate of hydrolysis. Knowledge of the phosphates behavior during processing can lead to a better understanding of the changes associated with the protein matrix of processed cheeses and its functional properties. Acknowledgment: São Paulo Research Foundation (FAPESP), grant 14/07291–3.

Key Words: phosphate, hydrolysis, NMR

W144 Inactivation of thermoduric sporeformers in milk by continuous ultrasonication. Dikshi Bawa*, Sanjeev Anand, and Steve Beckman, *South Dakota State University, Brookings, SD.*

Thermoduric sporeformers can survive milk pasteurization and cause spoilage in dairy foods. Our previous studies established that batch ultrasonication combined with pasteurization inactivated thermally resistant vegetative cells of spore forming *Bacillus* spp. This study investigates the effect of a continuous ultrasonication process to reduce thermoduric sporeforming bacilli in milk. We hypothesize that ultrasonication causes increase of cell membrane permeability leading to leakage of cell components thus causing cell death. Mid exponential phase vegetative cells of thermoduric *Bacillus coagulans* (ATCC 12245) were inoculated in sterile skim milk at log 5 cfu/mL. Their thermal stability was validated by exposing them to batch pasteurization (63°C for 30 min). Inoculated skim milk was passed through a continuous ultrasonicator with 22-mm sonotrode, 20 kHz frequency, and 1000 W power input (UIP1000hd, Hielscher USA, Inc.), at 86% (91.2 µm) amplitude and a flow rate of approximately 7.5 L/h and back pressure of 345 kPa resulting in an exposure time of 80 s per pass. Ultrasonicated samples were batch pasteurized to study the combined effect. Brain Heart Infusion agar was used for plating the survivors. Experiments were conducted as replicates of 2, and were repeated thrice. Statistical significance of the data was determined using SAS enterprise guide 7.1 software. A significant ($P < 0.05$) reduction was found in the log counts after treatments. Lab pasteurization alone reduced the vegetative cells by 25%, while ultrasonication alone resulted in a greater inactivation of 92% after 12 passes (16 min total exposure time). Inactivation was further increased to 99.98% by combining ultrasonication and pasteurization. It can thus be concluded that a continuous ultrasonication process followed by pasteurization is highly effective to inactivate thermoduric vegetative cells of sporeformers such as *Bacillus coagulans.*

Key Words: ultrasonication, pasteurization, thermoduric sporeformer

W145 Effect of ultrasound treatment on reconstituted deproteinized whey prior to lactose crystallization. Steve Beckman, Lee Alexander*, Sanjeev Anand, and Lloyd Metzger, *South Dakota State University, Brookings, SD.*

Ultrasonication (US) is an emerging technology being applied to dairy streams. The objective of this study was to determine the effect of US on reconstituted deproteinized whey (DPW) before crystallization and isolation of lactose. Commercial DPW was reconstituted to 65% TS (wt/wt) at 80°C. Solutions were then seeded (0.027 g/100 g solution) with lactose crystals, or treated with US (10 min, 22.5 Hz) and then seeded. Each sample was then stirred for one min and transferred into a 1 L glass crystallizer (CST). The CST was immersed into a temperature controlled bath and cooled from 80 to 18°C (rate = −0.0479°C/min). Constant agitation (100 rpm) was applied to the CST by an overhead stirrer and agitator. After crystallization, approx. 225 g of solution was transferred to a centrifuge bottle. The solution was centrifuged at 10,000 × *g* for 30 min at 5°C. The supernatant was decanted, weighed, and a mass of deionized water (<4.0°C) equivalent to the supernatant was added to resuspend the crystals before centrifugation. The resuspended crystals were centrifuged, decanted, and resuspended 3 more times using the previous procedure (4 washes total). Recovered lactose crystals (>75 crystals) were measured microscopically (10×) to determine mean crystal size. Total solids of commingled supernatants, and of isolated crystals were measured to assess yield. Each treatment was repeated in triplicate. Mean crystal size, and lactose yield data were analyzed for statistical significance with replicate and treatment as categorical explanatory variables. Mean crystal size was larger ($P < 0.01$) for the US treatment, 85.0 μm, than for the control treatment, 74.4 μm. Lactose yields, 78.7 and 78.9%, for control and US, respectively, were not different ($P > 0.05$). Theoretical yield for lactose at the conditions used is 88%. Yields may be overestimated due to non-lactose impurities. Ultrasonication with seeding of reconstituted DPW before crystallization increased lactose crystal size, but did not increase lactose yield.

Key Words: lactose, crystallization, ultrasound

W146 Evaluation of a Centritherm evaporator for concentrating micellar casein.

Anil Kommineni, Dustin Grossbier*, Steven Beckman, Ananya C. Biswas, and Lloyd E. Metzger, *Midwest Dairy Foods Research Center, Dairy Science Department, South Dakota State University, Brookings, SD.*

Micellar casein is produced by micro-filtering skim milk. In a typical skim milk microfiltration (MF) process the retentate produced has approximately 10% protein and 12% total solids. After MF this retentate can be further concentrated before spray drying. In previous research we determined that micellar casein could be concentrated to approximately 25% solids using a falling film vacuum evaporator. However, concentration beyond 25% solids was challenging due to the high water binding and film forming characteristics of micellar casein. As compared with falling film evaporation, a Centritherm evaporator (CTE) is a thin film vacuum evaporator that can be used to concentrate highly viscous products. In a CTE the feed tube distributes product on the underside of a rotating heating cone through a feed nozzle. Steam is injected on the opposite side of the cone thereby heating the product stream through conduction. Centrifugal force of the rotating cone creates a thin, turbulent layer, which gives a residence time of 1sec with a high heat transfer coefficient. The objective of this study was to evaluate the CTE for concentrating micellar casein. In this study, 3 replicates of micellar casein with 12% solids were manufactured by micro filtration of skim milk and then used as feed for the CTE. Initial trails were conducted to find the optimum evaporation conditions for minimal fouling. The heating temperature of 80°C, boiling temperature of 50°C and feed rate of 50 L/h were determined as optimal. Each replicate of micellar casein was passed through the CTE 3 times. The average water evaporation rate in each pass and the total solids of the concentrate was determined. The total solids content of the final micellar casein for each replicate was 22.49, 21.92, and 22.93%. The mean water evaporation of each pass was 6.17, 5.92, and 3.83% respectively for pass one, 2, and 3. The decreasing water evaporation rate with each pass may be a result of increased water binding as the solids content of the micellar casein increased. The results indicate that the CTE concentrated micellar casein similar to falling film evaporation.

Key Words: micellar casein, Centritherm evaporator

W147 Novel microfiltration process for the manufacture of soluble casein isolate from acidified milk.

Yanjie Lu*, Michael Molitor, and John Lucey, *Wisconsin Center for Dairy Research, University of Wisconsin-Madison, Madison, WI.*

Caseinates are traditionally manufactured by precipitating caseins using acid, thoroughly washing the precipitate and then neutralizing the casein curd with alkali, which requires very specialized equipment. The objective of this study was to develop an innovative process utilizing spiral filtration to produce a soluble casein product that would act as a caseinate alternative. Stable casein dispersions were prepared by sufficient acidification of pasteurized skim milk to solubilize the colloidal calcium phosphate (CCP), but avoid aggregating the caseins. The acidified skim milk was processed at ambient temperature using microfiltration /diafiltration to remove serum proteins, lactose, and the soluble minerals. Next the soluble casein product was neutralized with 40% NaOH and spray dried. Compositional analysis, SDS-PAGE, and turbidity measurement were used to characterize the casein product. Our results showed that acidification to pH ~5.3 solubilized the majority of CCP and allowed the removal of calcium during membrane processing. Acidification of the diafiltration water helped to maintain the narrow target pH range throughout the extensive diafiltration. The microfiltration process, temperature and pH were all optimized to promote casein retention and avoid temperature and /or pH-induced casein aggregation. The casein isolate powder had ~93% of crude protein (dry basis), 0.08% calcium, 0.37% lactose, 1.60% fat and casein accounted for 97% of the crude protein. When rehydrated to a total solids content of 5% (w/v), our casein product was less turbid compared with commercial sodium caseinate. This novel process looks promising for the production of a soluble casein product.

Key Words: caseinate, membrane filtration, acidification

W148 Effect of some operating parameters on the hydraulic resistance developed during milk protein concentration by ultrafiltration.

Stephanie Methot-Hains*, Alain Doyen, Laurent Bazinet, and Yves Pouliot, *STELA Dairy Research Center, Institute of Nutrition and Functional Foods, Université Laval, Québec, Canada.*

Milk protein concentrates are increasingly used as enrichment ingredients in cheese manufacturing. Ultrafiltration (UF) membranes with a molecular weight cut-off of 10 kDa are typically used for concentrating skim milk proteins content up to 57 to 84% (dry basis). However, some operating parameters such as transmembrane pressure control, temperature or multistage design have important impacts on process efficiency and functional properties of the concentrates. The objective of this work was to investigate the effect of transmembrane pressure (TMP) on the membrane performance and the protein retention by UF on skim milk using a 10 kDa polyethersulfone membrane. Skim milk was concentrated by a 4X volumic concentration factor at 50°C. Three operating modes were investigated: constant transmembrane pressure, 90 and 53 psi, and constant flux. Fouling of the membrane system was characterized using the resistance-in-series approach. It was found that operating at constant flux increases ($P < 0.05$) the reversible fouling and consequently increases the energy requirement necessary to produce

milk concentrate in comparison with to operating at lower constant transmembrane pressure. Our results showed that transmembrane pressure control does not affect the irreversible fouling during milk protein concentrate production, 66.5 ± 0.6% protein. Also, the protein retention was not affected ($P < 0.05$) by changes in transmembrane pressure. This study demonstrates that milk protein concentration by UF at low transmembrane pressures limits the formation of cake layer (reversible fouling) and this improves the efficiency of the process by reducing the energy consumption during filtration and its environmental footprint.

Key Words: transmembrane pressure, fouling, energy

W149 Comparative performance of two membrane configurations for the separation of casein from bovine milk by microfiltration. Daniel Tremblay-Marchand[1], Alain Doyen[1], Michel Britten[2], and Yves Pouliot*[1], *[1]STELA Dairy Research Center, INAF, Université Laval, Québec, QC, Canada, [2]Agriculture & Agri-Food Canada, FDRC, St-Hyacinthe, QC, Canada.*

Microfiltration (MF) is increasingly used for the separation of casein micelles from serum or whey proteins (SP) in milk, using a 0.1–0.2 µm pore size membrane. One of the processing benefits of casein concentration by MF is that the co-product generated is considered as native or ideal whey. Ceramic graded permeability (GP) MF membranes ensuring long-term permeation flux and membrane selectivity have been successfully used for the separation of caseins from milk. Polymeric spiral wound (SW) MF membrane elements have also been reported to perform casein separation from milk but their performance has not yet been fully characterized. The objective of the present study was to compare the performance of 2 MF membranes configurations (SW vs GP) for the separation of casein from skim milk. The first membrane studied was a ceramic Membralox GP (model EP1940, Pall Corp.) with a 0.1-µm pore size and a surface area of 0.72 m^2 while the second was a polymeric polyvinylidene fluoride (PVDF) spiral-wound membrane (model V0.2–2B-3838, Synder filtration) with a 0.2 µm pore size and a surface area of 14.12 m^2 (2 elements). Both membranes were mounted on a Model 393 pilot-scale system (Tetra Pak, Champlin, MN). Experiments were performed at 50°C up to a concentration factor of 2×, 3×, and 4×. Permeation flux and changes in membrane resistance during MF were compared. Membrane selectivity (separation of caseins from whey proteins) was determined by chemical analysis (TN, NCN, NPN) and validated by SDS-PAGE electrophoresis. It was found that GP membrane had an average permeation flux 3 times higher than that of SW. The CN/TP ratio of the final retentates were similar for both membranes. The water flux of fouled membranes (before cleaning) was 40% and 60% of the initial water flux for SW and GP membrane respectively. Although casein separation could be achieved using the 2 membrane configurations (GP and SW), our observations suggest that the GP MF membrane offers better process control by maintaining a higher permeability and preventing severe membrane fouling upon casein separation from milk.

Key Words: microfiltration, casein, membrane

W150 Characterization of the early stages of biofouling during ultrafiltration of dairy fluids using polyethersulfone membranes in a model system. Julien Chamberland*, Marie-Hélène Lessard, Steve Labrie, and Yves Pouliot, *STELA Dairy Research Center, Institute of Nutrition and Functional Foods, Université Laval, Quebec, QC, Canada.*

Bacterial biofilms are known to affect operational performance of membrane filtration, but little knowledge is available concerning the mechanisms and factors involved in their formation. The present work aimed to characterize pioneer colonizer bacteria involved in biofilm formation on filtration membranes during dairy fluids treatments. In this context, a laboratory-scale crossflow filtration model system has been designed consisting in an assembly of 4 parallel filtration units (CF042, Sterlitech) each equipped with a UF membrane of 42 cm^2 flat polyethersulfone (PES) sheet with a molecular weight cut-off of 10 kDa. The dairy fluids studied were raw and pasteurized skim milk, unpasteurized cheese whey and pasteurized cheese whey from the same batch of raw milk. UF separations were performed in full-recycle mode at 40°C for 5 h. After UF operations, membranes were collected before and after cleaning procedure (pH 10.5, 150 ppm of free chlorine, 45°C, 30 min.) for DNA extraction (phenol-chloroform extraction). All experiments were performed in duplicate. A high correlation ($R^2 = 0.93$) was found between DNA recovery on UF membranes after water flush (before cleaning) and the initial microbial load of the fluid; whey pasteurization reduced significantly the amount of DNA recovered on the membrane coupons before cleaning ($P < 0.05$). After cleaning, genomic DNA was still detectable on membranes coupons. Indeed, preliminary results showed that even with a higher initial microbial load, unpasteurized cheese whey left the lowest amount of DNA (2.76 ng DNA/cm^2) compared with both milk samples (3.86 and 4.71 ng DNA/cm^2). Sequencing of the extracted metagenomic DNA is currently in preparation (MiSeq, Illumina) to establish the portrait of the rising bacterial ecosystem located on PES membranes. Our results will translate into designing processing conditions for a better control of biofouling and consequently process efficiency.

Key Words: dairy processing, biofouling, metagenomic

W151 In situ monitoring of lactose crystallization using focused beam reflectance measurement (FBRM). Karthik Pandalaneni* and Jayendra Kumar Amamcharla, *Kansas State University, Manhattan, Kansas.*

Lactose is the second most abundant component present in milk. It is commercially produced from whey or whey permeate or milk permeate by crystallization. The current problem is lack of efficient tool to monitor crystal sizes and chord lengths during industrial lactose crystallization (LC). The objective of this study was to use focused beam reflectance measurement (FBRM) as a tool for in situ monitoring of LC. A 2 × 3 factorial design was used, with temperature (20°C and 30°C) and concentration (w/w) (50%, 55% and 60%) as independent variables. Desired concentrations of lactose were obtained by dissolving commercial grade lactose in distilled water. The FBRM was placed in a batch crystallizer consisting of an overheard stirrer and a temperature-controlled waterbath. LC was monitored for 630 min using an in situ FBRM system to obtain chord length distributions (CLD) and crystal size distributions (CSD). CLD obtained from FBRM were recorded in the ranges of < 50 µm (fine crystals) and 50–300 µm (coarse crystals). At regular intervals, lactose concentration was measured using a refractometer to deduce extent of crystallization. The extent of crystallization increased rapidly during the first one hour of crystallization. The time required to reach 90% extent of crystallization at 30°C was found to be 300, 360, and 420 min for 60%, 55%, and 50% solutions, respectively. As the extent of crystallization increased, the fine crystal counts obtained from FBRM were also increased. It was observed that fine crystal counts increased with increasing supersaturated concentration (65,000 for 50% and 84,000 for 60% at 30°C) and temperature (59,000 at 20°C and 65,000 at 30°C for 60%). Square weighted CLD obtained from FBRM helped demonstrate that, as concentration increased there was a substantial decrease in chord lengths at 20°C. Mean chord lengths of lactose crystals as observed by FBRM for 60, 55, and 50% at 20°C were 39.09, 40.52, and 57.64 µm, respectively at 630 min. In conclusion, FBRM in conjunction with refractometer could be used as a potential tool for in situ monitoring of LC process.

Key Words: lactose crystallization, focused beam reflectance measurement (FBRM)

W152 Influence of magnetic field exposure and clay mineral addition on the fractionation of Greek yogurt whey components.

Clinton R. Kyle* and Jayendra K. Amamcharla, *Kansas State University, Manhattan, KS.*

Greek style yogurt in the United States is one of the largest growing sectors in the dairy industry. Greek yogurt is produced by removing a part of water and water-soluble components from yogurt. Consequently, a large quantity of Greek yogurt whey (GYW) is being produced as a co-product. The GYW is compositionally different from cheese whey, and thus posing economic and environmental challenges to the dairy industry. The objective of the present work was to evaluate the use of magnetic fluid treatment (MFT) and addition of sepiolite (IMV Nevada, NV), a clay mineral, as alternative methods for separating valuable GYW components. The MFT chamber was designed using 4 pairs of neodymium magnets arranged to produce a magnetic field strength of 0.6 Tesla. The GYW was pumped through the MFT chamber at a flow rate of 7.5 L/min. Three batches of GYW each from 2 manufacturers were procured. A 2 × 3 factorial design was used with MFT or no MFT and the addition of 0, 2, or 4 g of sepiolite for 100g of GYW. The pH of GYW was adjusted to 7.2 using 5 *N* NaOH, and processed in the MFT chamber. The sample was split into 3 sub-samples, heated to 80°C, and sepiolite was added as per the experimental design. Subsequently, the samples were centrifuged at 1000g for 5 min. The supernatant aqueous layer was separated and analyzed for total solids, ash, lactose, protein, calcium, phosphates, sodium, and color. Data were analyzed separately for each manufacture using the MIXED procedure in SAS software. MFT and its interaction did not significantly ($P > 0.05$) influence the analyzed whey components except for lactose. However, the addition of sepiolite significantly ($P < 0.001$) influenced the protein content, a*, and b* for the top aqueous layers. Both levels of sepiolite addition resulted in about a 50% decrease in protein compared with original GYW. Adding 2g of sepiolite per 100g of GYW form manufacturer 1 resulted b* decreasing from 25.99 to 8.16 compared with treated GYW with no sepiolite. Sepiolite was found to have possible applications in the removal of proteins and color pigments in Greek yogurt whey.

Key Words: Greek yogurt whey, magnetic treatment, sepiolite

W153 Characterization and oxidative stability of oleic acid-modified chitosan/milk protein nanoparticle containing docosahexaenoic acid.

Ho-Kyung Ha*[1], Ji-Young Hong[1], Jae-Young Hwang[1], Won-Jae Lee[1], and Mee-Ryung Lee[2], [1]*Department of Animal Bioscience (Institute of Agriculture and Life Science), Gyeongsang National University, Jinju, Gyeongnam, Republic of Korea,* [2]*Department of Food and Nutrition, Daegu University, Gyeongsan, Gyeongbuk, Republic of Korea.*

The application of docosahexaenoic acid (DHA) to nonfat food is often challenging due to its poor bioavailability and susceptibility to oxidative rancidity. The aim of this study was to investigate how manufacturing variables, such as degree of substitution (DS) of oleic acid-modified chitosan and sub-ambient temperature treatment, affected the physicochemical properties of oleic acid-modified chitosan/milk protein nanoparticle (OPN) and reduction in oxidative rancidity. Oleic acid-modified chitosan with various DS ranging from 0 to 7.4% were prepared using a carbodiimide coupling method. OPN was manufactured at various sub-ambient temperature from 5 to 25°C. The morphology and size of OPN were investigated using atomic force microscopy and particle size analyzer, respectively. Encapsulation efficiency, oxidative rancidity, and off-flavor compounds of DHA were determined by high performance liquid chromatography, peroxide value, and gas chromatography/mass spectrometry, respectively. Globular shaped particles with the size of ~190 nm were observed indicating the successful formation of OPN. As DS increased from 0 to 7.4%, a significant ($P < 0.05$) increase in the size of OPN and encapsulation efficiency of DHA was observed. During storage, the peroxide value for OPN containing DHA was significantly ($P < 0.05$) decreased with an increase in DS. A decrease in sub-ambient temperature from 25 to 5°C resulted in a significant ($P < 0.05$) decrease in the size of OPN and increase in the encapsulation efficiency of DHA. The peroxide value for OPN containing DHA was significantly ($P < 0.05$) lower in comparison to free DHA although it was not significantly affected by sub-ambient temperature treatment. No significant ($P < 0.05$) off-flavor developments were observed in OPN containing DHA while free DHA exhibited a significant ($P < 0.05$) increase in off-flavor development during storage. In conclusions, DS and sub-ambient temperature treatment were crucial factors affecting the physicochemical properties of OPN and oxidative stability.

Key Words: milk protein, nanoparticle, docosahexaenoic acid

W154 Electrospinning casein-based fibrous mats for food applications.

Peggy M. Tomasula*[1], Shih-Chuan Liou[2], Ran Li[3], Laetitia M. Bonnaillie[1], and LinShu Liu[1], [1]*USDA/Agricultural Research Service, Eastern Regional Research Service, Dairy and Functional Foods Research Unit, Wyndmoor, PA,* [2]*Chung Shan Medical University, Taichung City, Taiwan,* [3]*State Key Laboratory of Hollow Fiber Materials and Processes, School of Materials Science and Engineering, Tianjin Polytechnic University, Tianjin, China.*

Electrospinning is a process that produces fibrous mats from fibers with diameters on the micron or nano scales from an electrified jet of a polymer solution. If produced by electrospinning biopolymer solutions, the fibrous mats may have the same potential as edible films for protecting foods and improving food quality but also allow for preservation of sensitive nutrients. Electrospinning aqueous solutions of dextran, pullulan (PUL) and gelatin are known to result in homogeneous fibers. However, little information is available on electrospinning other food grade biopolymers. The objective of this study was to create fibers for food use from electrospinning aqueous solutions containing calcium (CaCAS) or sodium caseinate (NaCAS). A nanofiber electrospinning unit was used to generate the fibers at 40°C using voltage of 23 KV and flow rate of 0.5 mL/h. Fibers were not produced by electrospinning 5, 10, or 20% (w/w) solutions of either CAS, possibly because of little interaction among the CAS chains, but were produced when either of the 20% CAS solutions were blended with 15% or 30% (w/w) aqueous solutions of PUL in volume ratios from (2:1) to (1:4), using PUL as a spinnable carrier. The morphologies of the fibrous mats were determined using scanning electron microscopy equipped with software to sample 100 of the constituent fibers to calculate mean diameters. Electrospinning 15% PUL solutions resulted in fibers with diameters of 190 ± 50 nm. CaCAS:PUL solutions in volume ratios of (1:1) and (1:2) resulted in fibers with average diameters of 160 ± 40 nm and 1020 ± 600 nm, respectively. NaCAS:PUL solutions in volume ratios of (1:1) and (1:2) resulted in fibers with average diameters of 320 ± 30 nm and 340 ± 150 nm, respectively. The mean diameter of the CaCAS:PUL (1:1) fibers was not significantly different from the pure PUL fibers, but the increase in size of the CaCAS:PUL (2:1) fibers and the NaCAS:PUL(1:1) and (1:2) fiber sizes may stem from changes in hydrogen bonding and thus the degree of entanglement of the PUL chains in the presence of CAS, compared with pure PUL solutions. This is the first example of CAS nano- and micro-fibers prepared using a polysaccharide carrier, rendering a new dairy product with potential use in food and packaging applications.

Key Words: fibers, nanoscale, polysaccharide

W155 Isolation of milk fat globule membrane (MFGM) from buttermilk.

Liza Ivanov*[1], Vladimir Shritz[1,2], and Vitaly L. Spitsberg[1,3], [1]*Astrazemcal, Raanana, Israel,* [2]*Baemek Advanced Technology, Afula, Israel,* [3]*Biovita Technologies, Bat Yam, Israel.*

Due to a great interest in application of bovine MFGM as a nutraceutical (J. Dairy Sci. 88:2289–2294, 2005), we developed a new protocol for isolation of large amounts of MFGM from buttermilk. The protocol includes the following steps: precipitation of casein and MFGM at pH 4.6, treatment of the precipitated complex casein-MFGM with sodium phosphate at pH 4.6–8.0 or with polyphosphate (Calgon) at pH 7.1 and differential centrifugation (1000–2000 × *g* to get a pellet of casein and 32,000 × *g* (Strator centrifuge) to collect a pellet of MFGM. Maximum dissociation of MFGM from casein was achieved at pH 7.1–7.4. Yield of MFGM from 1 L of buttermilk treated with sodium phosphate at pH 7.2 was 789 mg of protein and treatment with Calgon at pH 7.1 also provided a high yield of MFGM, 725 mg/L. Treatment of precipitated casein with 0.1 *M* Na-citrate or Na-oxalate at pH 7.1 led to the isolation of MFGM in amount of 234 mg/L and 106 mg/L, correspondingly. Treatment of precipitated casein with 0.1 *M* NaCl or 0.1 *M* Na_2SO_4 did not produce a noticeable amount of MFGM. Recovery of MFGM from buttermilk allowed us to suggest that MFGM in buttermilk is present in association with casein through Ca- bridges between phospholipids of MFGM and phosphate groups of casein, primarily with k-casein as a peripheral protein of casein micelles. For production of large amount of MFGM on industrial scale the use of continuous-flow centrifuge and microfiltration were suggested. Baemek Advanced Technology supported this work.

Key Words: milk fat globule membrane (MFGM), nutraceutical, buttermilk

W156 Effects of surface modification on bacterial and spore adhesion in dairy handling materials.

Garrett T. Walsh* and Rafael Jimenez-Flores, *California Polytechnic State University, San Luis Obispo, CA.*

The objective of this work was to demonstrate how stainless steel microstructure, material processing and surface treatment affect the attachment of spores, and the subsequent development of biofilms on the surface of AISI 316L Stainless steel, the typical milk handling and processing material. Stainless steel coupons with different surface finishes were prepared (as received, 220 grit, 400 grit and 800 grit) and characterized by contact profilometry and scanning electron microscopy. In addition, autogenously welded samples were produced for each surface roughness. Samples were exposed to both sterile and bioactive solutions for 5 and 20 h periods. Corrosion resistance was subsequently measured using cyclic polarization testing in each surface and solution pairing. Samples were examined using scanning electron microscopy and epifluorescence microscopy. The former was used to characterize surface damage, identify film presence, and examine spore attachments. The latter was used to quantify attachment of *Bacillus licheniformis* and to estimate the thickness of biofilms formed. The work has demonstrated that surface preparation had a significant effect on attachment and proliferation ($P < 0.05$). Furthermore welding had a significant effect on attachment and electrochemical reactivity ($P < 0.05$). The electrochemical reactivity of the material as measured by stable pitting potential and measured passive current is also affected by both surface roughness and by bioactivity of the solution. Metastable pitting is common in all solutions, stable pitting potential is lower in bioactive solutions and the passivation current is greater in bioactive solutions. Microstructure of the material is critical to its behavior, as is the complexity of the solution. Planktonic populations are not a direct indication of the sessile populations.

W157 The impact of milk hauling practices on overall raw milk quality.

Emily Darchuk, Joy Waite-Cusic, and Lisbeth Goddik*, *Department of Food Science, Oregon State University, Corvallis, OR.*

Historically, milk tankers were cleaned after every load. Consolidation of the industry has led to longer routes and use of tankers for up to 24 h in between cleans. This study focused on the effect of frequent tanker use hauling on raw milk quality. Standard tanker use, (CIP once per 24 h) served as our control and incremental cleaning treatments (water rinse after each load, water rinse after each load with a 12 h sanitizer treatment, and 12 h sanitizer treatment) were added to the study to understand if any effect could be mitigated by more frequent cleans. Two trucks were isolated for this study, which utilized a mix model with repeated measures design. Each truck was utilized for up to 9 routes per day. To understand the effect of seasonality, the 8-d study was repeated in both summer and winter. Producer samples were collected from the farm bulk tank before loading raw milk into the tanker as well as sampling the same milk directly out of the tanker truck before unloading at the manufacturer. Milk quality was quantified through commonly utilized microbiological tests: total bacteria count, thermophilic spore count and preliminary incubation count. Within our study, we defined a negative effect on milk quality as a statistically significant ($P < 0.05$) difference between the producer and tanker sample in any of the 3 microbial tests conducted. Results did not identify a negative effect on raw milk quality due to hauling neither in summer nor in winter conditions. Therefore, the addition of cleaning treatments did not appear to provide a positive impact on milk quality. Based on this study, current practices appear to be effective in mitigating any measurable negative effect due to hauling.

Key Words: hauling, milk, quality

Forages and Pastures: General forages and forage systems

W158 Chemical composition, digestibility and fermentation characteristics of sorghum ensiled with soybean crop residue.

Larissa de A. Lima, Marcia Dias, Nayara D. de Carvalho, Vinicio A. Nascimento, Vera L. Banys, and Edgar A. Collao-Saenz*, *Universidade Federal de Goiás, Jatai, GO, Brazil.*

The fermentation of silage process depends on the initial balance of nutrients in the ensiled forage and must minimize nutritional losses. Agricultural regions have high quantities of crop residues, and sometimes these residues have nutritional value and are used as co-products like soybean hulls but stalks, leaves and broken grains are frequently lost. The objective of this assay was to evaluate the effects of the soybean crop residue inclusion (0, 3 and 6% as fed basis) on sorghum silage quality. Sorghum was harvested at 30% dry matter (DM), mixed with the residues and ensiled targeting density between 600 and 650 kg as fed/m^3 using 6 silos/treatment. The nutritional value was evaluated after 50 d of ensiling. There was a significant effect of the soybean residue inclusion for crude protein (CP) (5.59, 6.50 and 6.74% DM), and neutral detergent insoluble protein (NDIP)/CP (42.46, 35.24 and 32.60%). The soybean residue inclusion reduced the non-fiber carbohydrates (34.51, 31.77 and 29.93% DM) and total carbohydrates (85.84, 84.84 and 83.79% DM) which caused decreases in in vitro DM digestibility (63.49, 63.35 and 59.71%) and in vitro OM digestibility (65.77, 61.64 and 59.05%). Linear increase in gas production (75.50, 101.62 and 129.22 mm^3/gDM/h) was observed. The pH close to 3.8 at the moment of opening the silo, the constant ammonia-N concentration (72.8 g/kg total N), and the high recovery of DM 86.87% and OM 85.74% indicate heterolactic fermentation favoring acetic acid production which promotes aerobic stability of silage. An inclusion of soybean crop residue up to 6% as fed basis in sorghum silage is possible without effects on the fermentation characteristics of the silage.

Key Words: gas production, pH, silage

W159 Effect of reduced lignin alfalfa on forage quality at three harvest intervals.

Zhiqiang Li*[2], Zhenzhen Li[2], David Combs[1], and Daniel Undersander[1], [1]*University of Wisconsin, Madison, WI,* [2]*China Agricultural University, Beijing, China.*

The present study investigates the effect of reduced lignin on alfalfa quality. Two alfalfa cultivars [Roundup Ready (RR) and double stacked Roundup Ready and Reduced Lignin (RR/RL)] were harvested at intervals of 28, 33, and 35 d. All replicated plots were harvested for 2 regrowth periods in July and August, 2014. CP, aNDF, lignin, NDFD48 value of samples on DM basis were analyzed with NIRS method (FOSS 6500) using NIRSC 2012 Alfalfa Hay Equation. Statistical analysis was done as a 2 way ANOVA using SPSS 22. CP content was not different between RR and RR/RL (27.5 vs 28.0, $P > 0.05$) and declined with advancing maturity ($P < 0.05$). aNDF content was higher in RR than RR/RL (31.6 vs 30.1, $P < 0.05$) though differences among harvest intervals were not significant (30.8 vs 30.5 vs 31.1, $P > 0.05$. Lignin content was not significantly different between RR and RR/RL (5.6 vs 5.5, $P > 0.05$) or among harvest intervals (5.6 vs 5.6 vs 5.5, $P > 0.05$). The NDFD48 of RR/RL was significantly higher than RR (52.2 vs 50.5, $P < 0.05$) and that of 28d harvest interval was significantly higher than 33d and 35d levels (53.1 vs 50.2 vs 50.8, $P < 0.05$). No significant interaction occurred between variety and harvest interval for any of the above 5 indices. The iNDF, kd and total-tract NDF digestibility (TTNDFD) are shown in the table below. The reduced lignin alfalfa tended to be lower in iNDF and higher in kd though differences were not significant, but was significantly higher in TTNDFD ($P < 0.012$). It appears that RR/RL variety reduces the NDF content and improves NDFD48, and TTNDFD.

Table 1 (Abstr. W159).

Item	Interval	RR	RR/RL	Mean	*P*-value Forage	*P*-value Harvest interval	*P*-value Forage harvest × interval

W160 Characterization of novel polymers for alkaloid adsorption.

Manoj B. Kudupoje*[1,2], Eric S. Vanzant[1], Alexandros Yiannikouris[2], Karl A. Dawson[2], and Kyle R. McLeod[1], [1]*University of Kentucky, Alltech-University of Kentucky Research Alliance, Lexington, KY,* [2]*Center for Animal Nutrigenomics & Applied Animal Nutrition, Alltech Inc., Nicholasville, KY.*

A methacrylic acid-based molecularly imprinted polymer (MIP) was evaluated for physical and isothermal adsorption properties. Polymers were synthesized by suspension polymerization with (MIP) or without (NIP) ergotamine tartrate (ETA) as template. Polymer morphology was characterized by light scattering diffraction, SEM and BET. Polymer-template interactions were characterized by FT-IR, 1H NMR and isotherms. For each of 4 alkaloids evaluated, adsorption difference between MIP and NIP interacted ($P < 0.01$) with alkaloid concentration, but product differences were generally consistent across concentrations. With bromocryptine and methylergonovine, average adsorption was greater ($P < 0.01$) for MIP than NIP (62.9 vs 37.1 and 35.8 vs 24.7%, respectively). NIP adsorption was greater ($P < 0.01$) for ETA (93.1 vs 96.7%), and no difference ($P > 0.05$) existed between products for lysergol adsorption (38.1 vs 37.7). The Freundlich model (R2 = 0.99) indicated similar adsorption intensity to ETA for MIP (n~1.025) and NIP (n~1.011) and the Qmax estimate from the Langmuir model (R2 = 0.99) was 388.7 and 435.4 n*M*/mg for MIP and NIP, respectively. Both polymers had IR spectra at ~3500 (carboxyl stretch), ~1730 (carbonyl stretch), and ~1260 cm-1 (C-O stretch) indicating similarities in backbone structure. Spectral shifts observed in polymer-ETA complex samples suggest the interaction with amine groups was via H-bonding, which was confirmed using ^{1}H NMR. SEM demonstrated compactness of implanted polymer, which, after template removal turned microporous with microvoids. BET analysis showed NIPs to have a smooth surface with few pore structures, whereas MIPs exhibited greater surface area and porosity; implying that MIPs have a larger surface for adsorption. Light scattering diffraction suggests bimodal particle size distribution for both polymers with larger percentage in 30–80 μm range. These imprinted polymers could be utilized as SPE material, or for extraction of ergot alkaloids from complex materials. Furthermore, the described MIP is a candidate for application as a feed adsorbent to reduce bioavailability of certain alkaloid compounds in the gut.

Key Words: molecularly imprinted polymer, ergotamine D-tartrate, isothermal adsorption

W161 Nutritive value and in vitro degradability of Marandu palisade grass at different locations within the pasture in silvopastoral systems with different babassu palm densities.

Rosane Cláudia Rodrigues, Michelle de Oliveira Maia Parente, Xerxes de Moraes Tosta, Ana Paula Ribeiro de Jesus, Henrique Nunes Parente, Jocélio dos Santos Araújo, Sâmara Stainy Cardoso Sanchês*, Ivone Rodrigues Araújo, Clésio dos Santos Costa, and Ivo Guilherme Ribeiro Araújo, *Universidade Federal do Maranhão, Chapadinha, Maranhão, Brazil.*

The objective of this study was to evaluate the nutritive value and "in situ" degradability of Marandu grass at different locations within the pasture in silvopastoral systems with different densities of babassu palm (Low density:39, Medium density:72 and High density:92 palm/ha). The silvopastoril system consisted of *Brachiaria brizantha*, the forage specie and Babassu palm *Orbignia phalerata* Martius, tree species. Pre-dried samples of forages were used for determination of dry matter (DM), organic matter (OM), neutral detergent fiber (NDF), acid detergent fiber (ADF), lignin, crude protein (CP), cellulose and hemicellulose. One Santa Inês male sheep, castrated, cannulated in the rumen, with an average body weight of 63 kg was used for ruminal incubation. Samples of forages (5 g) were incubated in the rumen in nylon bags. For each incubation time, 4 bags were used. The experimental design was a completely randomized design with factorial arrangement 3 × 3 (3 incubation times: 6, 24 and 96 h and 3 sampling sites within the pasture: no interference of shadow - NS, an intermediary INT and shadow interference - SI). There was no effect ($P \geq 0.05$) of the density of palm trees or locations within the pasture on the content of NDF, ADF, lignin, cellulose and hemicellulose. The densities in grassland Palm did not influence the chemical composition of grass Marandu only DM content. The sampling sites influenced ($P \leq 0.05$) content of CP and DM. Higher rates of disappearance of DM (RDDM) was observed in 96 h. At all densities, NS and SI had higher RDDM. Pastures with low density of palm (LDP), the location INT showed higher degradation rate and higher digestibility for passages rates 2, 5 and 8%. Locations within the SSPs reviews had a little influence on the nutritive value of grass Marandu, however, the local NS, at higher densities showed the higher protein content. In all pastoral environments, the NS and SI locations had higher DMS and location INT in SSPs with LDP and MDP smaller DMS, but higher degradation rate and effective digestibility, respectively.

Key Words: *Attalea speciosa* Mart, *Brachiaria brizantha*, protein

W162 Effect of the cytokinin BAP on growth, senescence and in vitro degradation of *Lolium perenne* L.

Hilda A. Zavaleta-Mancera*, Sergio S. González-Muñoz, Ángel H. Soto-Urano, and Omar Hernández-Mendo, *Colegio de Postgraduados, Montecillo, Estado de México, México.*

The cytokinin 6-benzylaminopurine (BAP) is a growth promoter that can delay leaf senescence. Therefore, the objective of this study was to study the effect of BAP on growth, senescence and in vitro degradation of *Lolium perenne* L. (var. Linn). The experimental design was completely randomized with 4 treatments: 3 concentration of BAP (T:0.1 mM; T2:0.01 mM; T3: 0.001 mM); and a control without BAP (T0). Plants were grown from seed at 25 kg/ha on 68 pots containing a mix of soil:agrolite:peat-moss (1:1:1), in a greenhouse. Plants of 8 mo were cut at 5 cm above substrate. At 21 d of regrowth, plants were sprayed weekly during 65 d (7 times). The variables evaluated were: leaf growth and senescence during 112 d; soluble proteins and photosynthetic pigments during 84 d; chemical and morphological composition and in vitro degradation of the cell wall (6, 12, 24 and 48 h). Means were compared using the Tukey test ($P < 0.05$). All BAP treatments increased net leaf growth (T1: 32%; T2: 18%; T3: 39%) with respect to the control, but leaf senescence and photosynthetic pigments were not significantly different ($P > 0.05$). BAP 0.1 mM promoted accumulation of leaf soluble protein (3.55 mg/gFW) and reduction of acid detergent fiber by 6%, as compared with the control. In vitro degradation was increased only with 0.001 mM BAP at 60 d of regrowth (T0:0.50; T1:0.43; T2: 0.52; T3:0.53). It may be concluded that BAP increased growth and leaf protein of *Lolium perenne* L. and reduced cell wall components.

Key Words: *Lolium perenne* L., 6-benzylaminopurine, senescence

W163 Effect of supplementation strategy and forage quality on in vitro digestibility of Kentucky 31 tall fescue and Tifton 85 bermudagrass.

Jeferson M. Lourenço*[1], Matthew W. Studstill[1], Cathy A. Bandyk[2], Dennis W. Hancock[1], and Robert L. Stewart Jr[1], [1]*The University of Georgia, Athens, GA,* [2]*Westway Feed Products.*

A 3 × 3 factorial experiment was conducted to evaluate IVDMD of Kentucky 31 tall fescue (KY-31) and Tifton 85 bermudagrass (T-85) with or without supplementation. The main effects included relative forage quality (RFQ) and type of supplement. Each forage type was harvested at different intervals during the yr of 2013 and 2014 to represent grazing and hay production scenarios in the state of Georgia. After harvested, the nutritive values of forages were assessed via near-infrared spectroscopy, and samples were stratified by RFQ. Forage samples were selected to represent high (HIG), medium (AVG), or poor (LOW) RFQ for KY-31 (171, 111, and 78, respectively) and T-85 (142, 101, and 80, respectively). Supplemental treatments included: 1) commercial molasses-urea based supplement (MUR) or 2) corn gluten feed (CGF) to provide the equivalent of 0.36 kg of supplemental CP; or 3) no supplement (CON). The forage-supplement mixtures were subjected to 48-h in vitro digestion to evaluate the digestibility characteristics. Two in vitro incubations were conducted and bottles (n = 140 in each incubation) were considered the experimental units. Across forage type, IVDMD increased as the incubation time was extended, and it was greatest ($P < 0.001$) when samples were incubated for 48 h. The same response was observed for NDF and ADF digestibilities. No supplement × RFQ interaction was observed for KY-31 ($P = 0.55$). Across RFQ for KY-31, 48-h IVDMD increased ($P = 0.008$) with the addition of LIQ and CGF compared with CON (49.9, 49.6, and 47.7%, respectively). Across supplementation, IVDMD of KY-31was greatest ($P < 0.001$) for HIG and AVG compared with LOW (62.5, 50.2, and 34.5%, respectively). A supplement × RFQ interaction was observed for T-85 ($P < 0.003$). In vitro dry matter disappearance was lowest for LOW × CON compared with all other supplement × RFQ combinations. These results suggest that forage quality is the main factor affecting IVDMD. However, the addition of LIQ and CGF can increase IVDMD of KY-31 and low RFQ T-85.

Key Words: bermudagrass, in vitro, tall fescue

W164 Herbage accumulation of palisadegrass with variable heights in beginning of deferment period. Manoel Eduardo Rozalino Santos*[1], Laryssa Avelino Luz[1], Pedro Henrique Marçal Rodrigues[1], Lucas Coelho Alves[1], Wirley Duarte de Souza[1], Simone Pedro da Silva[2], and Dilermando Miranda da Fonseca[3], *[1]Universidade Federal de Uberlândia, Uberlândia, Minas Gerais, Brazil, [2]Instituto Federal Goiano, Hidrolândia, Goias, Brazil, [3]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The experiment was conducted to evaluate 2 different strategies for managing *Brachiaria brizantha* (palisadegrass) under deferred grazing. From January to June 2014, the palisadegrass pastures were evaluated at the Federal University of Uberlândia, located in the State of Minas Gerais, Brazil. The experimental site was located at 776 m altitude, 18°30′ S and 47°50′ W. Annual precipitation was around 1.584 mm. Medium temperature was 22.3°C. The experimental area was made up of 6 paddocks (experimental units) of 800 m^2. Two pasture heights in the beginning of deferment period were evaluated: 15 cm and 45 cm. Before the deferment period, the pastures were managed in continuous stocking with sheep. The deferment period was 90 d. The experiment was carried out using a randomized completely design with 3 repetitions and subdivided plots. On 1, 45 and 90 d of deferment period, the tillers number m^{-2} was quantified. In each experimental unit, 15 tillers were marked. The lengths of live portions of leaf blades and stems of tillers were measured weekly. The collected data were used to calculate the growth, senescence and herbage accumulation rates. The conversion factors were generated to transform the measures in cm tiller^{-1} day^{-1} to kg ha^{-1} day^{-1} of dry matter. The growth rate (GR) was higher at the beginning (87.1 kg ha^{-1} day^{-1}) than at the end (11.4 kg ha^{-1} day^{-1}) of deferment period. Deferred pasture with 45 cm (73.5 kg ha^{-1} day^{-1}) also showed higher GR, compared with deferred with 15 cm (34.9 kg ha^{-1} day^{-1}). Leaf senescence rate (LSR) was higher at end (78.0 kg ha^{-1} day^{-1}) than at the beginning (24.7 kg ha^{-1} day^{-1}) of deferment period in the pasture with 45 cm. The herbage accumulation rate (HAR) was higher at the beginning (37.6 kg ha^{-1} day^{-1}) than at end (−13.5 kg ha^{-1} day^{-1}) of deferment period. Deferred pasture with 45 cm showed greater HAR (22.1 kg ha^{-1} day^{-1}) of that with 15 cm (2.0 kg ha^{-1} day^{-1}). We conclude that the reduction in palisadegrass height at the beginning of deferment period results in pasture with lower growth, senescence and herbage accumulation.

Key Words: growth, senescence, tiller

W165 Balance between the emergence and mortality of tiller in *Brachiaria brizantha* under variable heights in winter. Manoel Eduardo Rozalino Santos*[1], Ludiêmilem Keith Parreira da Costa[1], Bruno Humberto Rezende Carvalho[1], Denis Douglas Pessoa[1], Heron Alves de Oliveira[1], Roger Carvalho Cardoso[1], Miriã Gonçalves Simplício[1], Simone Pedro da Silva[2], and Dilermando Miranda Fonseca[3], *[1]Universidade Federal de Uberlândia, Uberlândia, Minas Gerais, Brazil, [2]Instituto Federal Goiano, Hidrolândia, Goias, Brazil, [3]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The experiment was conducted to evaluate 3 different defoliation strategies of *Brachiaria brizantha* (palisadegrass) in winter. From April 2013 to March 2014, the palisadegrass were evaluated at the Federal University of Uberlândia, located in the State of Minas Gerais, Brazil. The experimental site was located at 776 m altitude, 18°30′ S and 47°50′ W. Annual precipitation was around 1.584 mm. Medium temperature was 22.3°C. The experimental area was made up of 12 plots (experimental units) of 9 m^2. In one management strategy, palisadegrass was maintained at 30 cm high during all the trial. In the other, the palisadegrass was kept at an average of 15 cm during the winter (July to September 2013), and at 30 cm from the early spring until the summer (October 2013 to March 2014). At last, the palisadegrass was kept at an average of 45 cm during the winter and at 30 cm from the early spring until the summer. The experiment was carried out using a randomized completely design with 4 repetitions and subdivided plots. The defoliation strategies correspond to plots. The year seasons were the subplots. In each experimental unit, all tillers inside the 2 frames with 0.0625 m^2 were counted and marked with colored plastic. Every 30 d, all tillers were recounted and new tillers were marked with a different wire color. The collected data were used to calculate the balance between the emergence and mortality of tiller (BAL). The tillers number was quantified in each season year. The BAL was ($P < 0.05$) lower in winter (−7.2%) and later spring (−5.0%), intermediate in summer (11.6%) and higher in early spring (26.2%). This response pattern was due to unfavorable weather conditions in winter. On the other hand, the high development of shoots in tillers in early spring may have generated higher shading at plant base in late spring, causing negative BAL. The defoliation strategies did not affect the BAL. We conclude that palisadegrass keep with 15 cm in winter showed higher tiller number during all experimental period, when compared with grass with 30 and 45 cm in winter.

Key Words: defoliation, tiller density population, seasons of the year

W166 Effects of exogenous fibrolytic enzymes on in vitro digestibility and gas and methane production of corn silage. Vania R. Vasconcelos*[1,2], Kathy G. Arriola[2], Andressa Campos[2], Felix X. Amaro[2], Rafael M. Martins[2], Musibau A. Bamikole[2,3], and Adegbola T. Adesogan[2], *[1]Universidade Federal do Piauí, Campus Agrícola da Socopo, Teresina, Piauí, Brazil, [2]Department of Animal Sciences, University of Florida, Gainesville, FL, [3]Department of Animal Science, University of Benin, Benin City, Nigeria.*

This study examined effects of enzyme type and duration of the enzyme-substrate interaction (preincubation) period before in vitro fermentation on the in vitro digestibility and gas and methane production of corn silage (CS). Exactly 1 mL of 0.1 *M* citrate phosphate buffer (pH 6.0; Control) or the buffer and either xylanase (XYL; 1 mg/g) or xylanase-cellulase (MIX 3.4 mg/g) fibrolytic enzyme preparations were incubated with 0.5 g of dried, ground CS at room temperature for 0, 12, 24 and 48 h in a 120-mL culture bottle. Subsequently, 40 mL of buffered-rumen fluid was added to each bottle and the contents were incubated for 24 h at 39°C. At least 3 replicates of each treatment combination were examined in each of 5 runs. Total gas and methane production, volatile fatty acids (VFA), pH and in vitro digestibility of dry matter (DMD) and neutral detergent fiber (NDFD) were measured. The data were analyzed as a completely randomized design with a 3 × 4 factorial treatment arrangement using the GLIMMIX procedure of SAS (SAS Inst. Cary, NC). There were no ($P > 0.10$) enzyme by time interactions for any measure except DMD ($P = 0.09$). Preincubating MIX for 12 or 24 h with CS resulted in less ($P < 0.05$) DMD than that at 0 h but similar DMD to that at 48 h. Preincubating XYL with CS for 12 h resulted in greater ($P < 0.05$) DMD than that at 0, 24 or 48 h. Both MIX and XYL increased NDFD but MIX had the greatest value ($P < 0.05$; 58.6 and 53.6 vs 51.0%, respectively). Compared with CON, MIX increased gas production (40.1 vs. 42.9 mL) and decreased methane production ($P < 0.05$; 0.023 vs. 0.019 mg/mL) but XYL had similar values to the other treatments (41.4 mL and 0.021 mg/mL, respectively). Across enzyme treatments, pH was greater after 12 h of preincubation (6.34 vs. 6.28) and gas production was greater after 48 h (45.5 vs. 40.17 mL) compared with other incubation times. The MIX enzyme was more effective than the XYL enzyme at increasing the fermentation and digestion of CS. Enzyme-substrate preincubation period had enzyme-specific effects on DMD and no effects on NDFD or other fermentation measures.

Key Words: fibrolytic enzyme, gas production, digestibility

W167 Use of two natural antimicrobial additives in solid-state fermentation of apple bagasse.

J. L. Guevara-Valdez*, C. Rodriguez-Muela, L. A. Duran-Melendez, D. Diaz-Plascencia, E. Santellano-Estrada, and R. Marquez-Melendez, *Universidad Autonoma de Chihuahua, Chihuahua, Chihuahua, Mexico.*

The objective of this study was to evaluate the antimicrobial effect of oregano essential oil and zeolite in solid state fermentation (SSF) of apple bagasse using 5% clinoptilolite zeolite (ZEO), oregano essential oil (0.1% OEO) and both additives (ZXA), compared against the traditional method including apple bagasse, urea, ammonium sulfate and mineral mix as control (CTL). The experiment included 3 replicates per treatment in laboratory plastic containers of 1 L, with sampling at 0, 6, 12, 24, 48, 72 and 96 h. Data were analyzed by repeated measures over time and multiple means comparison. Variables analyzed were aerobic mesophiic bacteria by plate count, pH with a potentiometer, and yeast count by improved Neubauer chamber. Results showed that maximum growth of yeast were obtained at 48 h in ZXA (462×10^6 cells/g), while CTL achieved it at 96 h (470.5×10^6 cells/g), thereby reducing the fermentation time and optimizing the process by the oregano extract antimicrobial activity and the capacity of the zeolite to regulate the concentration of nitrogen compounds. The count of aerobic mesophilic bacteria was decreased significantly ($P < 0.01$) at 48 h, from 0.70×10^6 cfu/g in CTL to 0.25×10^6 cfu/g in ZXA, being OEO the lower bacterial count treatment (0.11×10^6 cfu/g). There was a higher pH ($P < 0.01$) in ZEO (4.80) and ZXA (4.62) versus CTL (4.06) and OEO (4.03), indicating that the adsorptive capacity of the zeolite allowed a slow and adequate release of the ammonia in the zeolite to the fermentation medium, resulting in a most efficient use of ammonia by yeasts, also regulating the pH and preventing volatile loss. We conclude that the use of both additives provides microbiological advantages over traditional SSF, reducing the fermentation time since yeasts have more available nitrogen compounds, and less foreign bacterial contamination, which could compete for substrates, production of secondary metabolites or modify pH. This guarantees a clean and free microbiological contaminants process.

Key Words: yeast, mesophilic bacteria, apple bagasse

W168 In vitro fermentation and digestion characteristics of shrubs *Crotton cortesianus* and *Leucophyllum frutescens* browsed by white-tailed deer (*Odocoileus virginianus*).

M. S. Alvarado[1], M. A. Cerrillo-Soto[1], M. Guerero-Cervantes*[1], A. S. Juárez-Reyes[1], R. G. Ramírez[2], H. Rodriguez[2], and T. G. Dominguez[1], [1]*Universidad Juárez del Estado de Durango, Durango, Mexico,* [2]*Universidad Autónoma de Nuevo León, San Nicolás de los Garza, Nuevo León, México,* [3]*Universidad Autónoma de Nuevo León, Linares, Nuevo León, México.*

Native vegetation in northeastern Mexico is mainly composed of shrubs and small trees, which are commonly selected by white-tailed deer. The aim of the study was to determine, seasonally, the in vitro fermentation profiles of *Croton cortesianus* and *Leucophyllum frutescens*. Foliage was sampled from summer 2004 to spring 2005 for a total of 4 consecutive seasons in Los Ramones in the state of Nuevo Leon, Mexico. In vitro gas production was recorded at 3, 6, 9, 12, 24, 48, 72 and 96 h. As inoculum, rumen fluid from fistulated sheep was utilized. Kinetic parameters such as the asymptotic gas production (B), rate of gas production (k) and lag phase (L) were estimated by the exponential model $G = b \times (1 - e^{-k(t-L)})$. Microbial protein synthesis, ME content and in vitro organic matter digestibility (IVOMD) were also evaluated. Data were analyzed using ANOVA for a completely randomized design. The asymptotic gas production (B) ranged from 151 mL/g DM in *L. frutescens* in spring to 220 mL/g DM in *C. cortesianus* in winter. The rate of gas production (c) was the lowest in *C. cortesianus* in summer (0.050%/h) while the highest (0.082%/h) in *L. frutescens* collected in winter. Values regarding lag phase (L) ranged from 0.43 to 22.06 h; in general, this variable was superior in *C. cortesianus* during summer, autumn and winter (2.06, 1.60 and 1.23 respectively). Microbial protein synthesis measured as purines was similar among shrubs and seasons. Mean values ranged from 4.04 in to 7.80 µmol in *C. cortesianus* in spring and winter. Estimates of ME were highest in *C. cortesianus* among seasons (summer 1.73; autumn, spring 1.70 and winter 1.66 Mcal/kg DM). The same scenario was registered with the IVOMD content where values varied from 55 to 84%. Highest digestibility values were registered in *C. cortesianus*. Data suggest that *C. cortesianus* represents a better feed reserve for white-tailed deer in the semiarid regions of northeastern Mexico.

Key Words: gas production, white-tailed deer, native shrubs

W169 Effect of lactic acid bacteria with bacteriocinogenic activity on the microbial populations and fermentation of alfalfa silage in tropical conditions.

V. P. Silva, O. G. Pereira*, K. G. Ribeiro, T. C. Da Silva, M. C. N. Agarussi, L. D. A. Rufino, R. M. Martins, F. X. Amaro, and A. M. Corrêa, *Universidade Federal de Vicosa, Vicosa, Minas Gerais, Brazil.*

Lactic acid bacteria (LAB) are used as silage additives to ensure the conservation of the nutritive value of forage by reducing the pH through acid production and inhibition of undesirable microorganisms in the epiphytic flora. The objective of this work was to evaluate the effect of a commercial inoculant and 2 strains of LAB with potential bacteriocinogenic activity on the microbial populations and the fermentation of alfalfa silage. The alfalfa was harvested 82 d after sowing and was wilted for 6 h. After, it was chopped into a 1.5 cm particle size and packed in bags, with 3 replications. A 4 × 6 factorial arrangement (4 inoculants and 6 fermentation periods) was used in a completely randomized design. The inoculants (I) were: 1) Control; 2) Sil All (CI; Alltech, Brazil); 3) Strain 10.4 (S-10.4; *Pediococcus acidilactici*); and 4) Strain 6.16 (S-6.16; *P. pentosaceus*). These strains have potential bacteriocinogenic activity and were isolated from Stylosanthes silage. The fermentation periods (P) were: 1, 3, 7, 14, 28 and 56 d after ensiling. The concentration of lactic acid and propionic acid were not affected by the interaction I × P ($P > 0.05$). There was effect of I on the DM, pH, ammonia, lactic acid and acetic acid. Silages treated with S-10.4 and S-6.16 resulted in the lowest pH. After 56 d, all silages treated with inoculants had lower ($P < 0.05$) pH compared with the control. The silage treated with S-6.16 showed the highest ($P < 0.05$) concentration of lactic acid (3.07% of DM) at 56 d. There was no effect ($P > 0.05$) of I on the concentrations of CP, NDF, ADIN, and lignin at 56 d. Only the population of enterobacteria was affected ($P < 0.05$) by P, showing a decrease overtime and the lowest number on d 14 (1.05 cfu/g). The strains evaluated improved the fermentation of alfalfa silage in tropical conditions by reducing the concentration of ammonia nitrogen, and increasing the concentration of lactic acid, leading to a faster pH drop and control of undesirable microorganisms.

Key Words: inoculant, lactic acid bacteria, strain

W170 Effect of wilting and inoculant on microbial populations and fermentation profile of alfalfa silage in tropical conditions. M. C. N. Agarussi, O. G. Pereira*, A. M. Corrêa, V. P. Silva, A. N. Rodrigues, T. C. Silva, L. D. A. Rufino, and K. G. Ribeiro, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The objective of this study was to evaluate the effects of wilting (W) and microbial inoculant (I) on the fermentation characteristics and microbial populations of alfalfa silage. Data were analyzed as a 2 × 2 × 6 factorial arrangement with the effects of wilting (absence or presence), microbial inoculant (with and without) and period of fermentation (P) (1, 3, 7, 14, 28 and 56 d), and their interaction in a completely randomized design with 3 replications. Alfalfa was harvested at 56 d of regrowth and chopped into particles of 1.5 cm. Alfalfa was wilted for 6 h in the field before ensiling, in the material submitted to this treatment. The inoculant used was Sil-All 4x4 W.S. (Alltech, Brazil), applied at the rate of 10^5 cfu/g of fresh forage. After applying treatments the forage was packed in plastic bags of 25 × 35 cm and sealed by using vacuum sealer. Wilting increased the DM content of the fresh alfalfa from 133.9 g/kg to 233.4 g/kg DM and the population of lactic acid bacteria (LAB) from 5.28 log cfu/g to 6.88 log cfu/g before ensiling. The number of enterobacteria and yeasts were affected ($P < 0.05$) by P, registering a higher number of these microorganisms on the first day of ensiling. The pH and ammonia nitrogen concentration were affected by the interaction W × P ($P < 0.05$), recording the lowest values on wilted-alfalfa silages from the 7th day of ensiling. There was effect of the interaction W × P ($P < 0.05$) on the concentrations of lactic, acetic and propionic acids. Except for the first day of fermentation, we observed higher concentrations of lactic acid in the wilted silages, however in both wilted and non-wilted silages the values decreased from the 7th day of ensiling. The concentration of acetic acid in the wilted alfalfa was lower than non-wilted alfalfa in all period of fermentation. The wilting of alfalfa was not enough to promote adequate silage fermentation in presence or absence of microbial inoculant.

Key Words: pH, organic acid, microbial inoculant

W171 Seeding rate affects performance of ball clover mixed with annual ryegrass in North Florida. Hiran M. S. Silva*, Jose C. B. Dubeux Jr., Ann Blount, Cheryl Mackowiak, Erick R. S. Santos, Nicolas DiLorenzo, and Martin R. Moreno, *University of Florida, North Florida Research and Education Center (NFREC), Marianna, FL.*

Legumes have the capacity to associate with rhizobia strains and fix atmospheric N_2. Ball clover (*Trifolium nigrescens* Viv.) has reseeding ability and when planted in mixtures with annual ryegrass (*Lolium multiflorum* Lam.) contributes to add N to the systems and to expand the grazing season. This experiment tested 3 seeding rates of ball clover (0.9, 1.8 and 2.7 kg ha^{-1}) in a mixture with annual ryegrass compared with annual ryegrass in monoculture, fertilized (50 kg N ha^{-1}) or not with N. Response variables included percentage of ball clover, dry matter yield (DMY) annual ryegrass, DMY ball clover, total DMY, percentage of plant N derived from atmosphere (%Ndfa) and N fixed contained in the shoot (N_{fix}). The study was performed in a complete randomized block design with 4 replicates. Ball clover proportion in the mixture increased ($P = 0.02$) from 32% (at 0.9 kg ha^{-1} seeding rate) to 47% (at 1.8 kg ha^{-1} seeding rate), with no significant differences ($P > 0.05$) observed between the 2 higher seeding rates (1.8 and 2.7 kg ha^{-1}). Ball clover DMY increased linearly ($P = 0.02$) with increasing seeding rates, with DMY of 711, 1,117, and 1,165 kg ha^{-1} for 0.9, 1.8, and 2.7 kg ha^{-1} seeding rates, respectively. Annual ryegrass DMY ($P < 0.0001$) and total DMY ($P = 0.0007$) were greater in the N fertilized treatment (3,810 kg DM ha^{-1}). Average %Ndfa was 95% for ball clover and there was no difference among treatments ($P > 0.05$). The N_{fix} showed linear increase with seeding rate ($P = 0.02$) with values ranging from 18 to 28 kg N ha^{-1}. Treatments including seed rates of 1.8 and 2.7 kg ha^{-1} were similar in botanical composition, DMY ball clover, DMY ryegrass, total DMY, and N_{fix}. From the producer perspective, it is more economical to use 1.8 kg seeds of ball clover ha^{-1}. Increasing seed rates of ball clover in annual ryegrass mixtures allowed greater legume contribution in the pasture, improving forage N without decreasing yield.

Key Words: botanical composition, legume, N-fixation

W172 Effects of hybrid and inoculant application on chemical composition and fermentation indices of barley silage. Dong Hyeon Kim*[1,3], Hyuk Jun Lee[1], Sardar M. Amanullah[1], Young Ho JOO[1], Hee Yoon[1], In Hag Choi[2], Adegbola T. Adesogan[3], and Sam Churl KIM[1], [1]*Division of Applied Life Science (BK 21Plus, Inst. Agric. & Life Sci.), Gyeongsang National University, Jinju, Gyeongsangnam-do, South Korea,* [2]*Department of Companion Animal & Animal Resources Sciences, Joongbu University, Geumsan, Chungcheongnam-do, South Korea,* [3]*Department of Animal Sciences, University of Florida, Gainesville, FL.*

This study examined the effect of hybrid and inoculant application on the chemical composition, fermentation indices and fatty acid profile of barley silage. Two Korean barley hybrids (Yuyeon, YU and Youngyang, YO) were harvested at dough stage, which were 24.9% and 27.1% of dry matter, respectively. The forages were chopped to 4–6cm lengths and treated with or without inoculant at the ratio of 1.2×10^4 cfu/g of *L. plantarum* on fresh weight basis. Treatments had a 2 × 2 factorial arrangement with 4 replicates. Each replicate was ensiled in a 10-L mini silo for 100 d and analyzed for chemical composition and in vitro DM digestibility. Data were analyzed with a model including hybrid, inoculant and the interaction using the GLM procedure of SAS. The YU silage had greater ($P < 0.01$) ash, acid detergent fiber and in vitro dry matter digestibility and mold counts than YO silage, but lower ($P < 0.01$) lactate and acetate concentrations. For YU but not YO, inoculation decreased the NDF concentration ($P = 0.002$), lactic to acetic acid ratio ($P = 0.004$), lactic acid bacteria ($P = 0.007$) and yeast counts ($P < 0.001$) and increased the pH ($P = 0.032$) and ammonia-N concentration ($P = 0.026$) (hybrid × inoculant interaction). The YU silage had greater ($P < 0.005$) C14:0, C16:0, C18:3n-3 and saturated fatty acid concentrations than YO silage, but lower ($P = 0.001$) C18:2n-6 concentration. Inoculation decreased ($P < 0.05$) C18:3n-3 concentrations, but increased ($P < 0.05$) C18:2n-6 and saturated fatty acid concentrations. For YU but not YO, inoculation decreased total fatty acid ($P = 0.034$) and polyunsaturated fatty acid ($P = 0.003$) concentrations but increased C18:0 ($P = 0.011$), C18:1n-9 ($P = 0.044$), monounsaturated fatty acid ($P = 0.033$) concentrations (hybrid × inoculant interaction). The PCR analysis followed by gel electrophoresis showed higher concentration of *L. plantarum* DNA in the inoculated silage. In conclusion, YU silage was more digestible but it had greater mold counts than YO silage. Inoculation did not improve the fermentation but it reduced the acetate and 18:3n-3 fatty acid concentrations and increased the C18:2n-6 and saturated fatty acid concentration.

Key Words: barley silage, fatty acid profile, inoculant

W173 Comparison of in situ digestion of corn stover treated by two alkali methods to untreated corn stover and soyhulls. Derek M. Donnelly*, David E. Cook, and David K. Combs, *University of Wisconsin-Madison, Madison, WI.*

The objective of this study was to evaluate the in situ NDF digestibility of corn stover treated at ambient temperature with a solution of sodium hydroxide and ethanol co-solvent. The treatment process is patented by Cellulose Sciences International (CSI) of Madison, WI. Digestion kinetics were evaluated in situ for untreated corn stover, corn stover treated with CaOH at 70g kg^{-1}, corn stover treated by the CSI process and untreated soyhulls. All materials were ground through a 2 mm screen in a Wiley mill and 0.5 g was sealed into Ankom F57 bags. Bags were placed in the rumens of 2 fistulated cows for 0h, 12h, 24h, 30h, 36h, 42h, 48h, 96h, 120h, and 240 h in reverse order. Bags were then washed, dried and contents analyzed for residual NDF. The 240h time point was used as the estimate of indigestible NDF (iNDF). The rate of digestion of potentially digestible NDF (pdNDF) was determined from the slope of the natural log of the pdNDF residue verses time. The fraction of iNDF and the rate of pdNDF degradation between forages were compared by ANOVA (PROC Mixed, SAS, v 9.3) as a randomized design with cows as replicates. Least square treatment means were compared by PDIFF. The digestion rate of pdNDF (kd,) of CSI-treated corn stover (5.36%/h) was higher than CaOH-treated stover (2.27%/h, $P < 0.01$), and untreated corn stover (1.76%/h, $P < 0.001$). The kd of soyhulls (4.93%/h) was similar CSI-treated stover ($P = 0.56$). The iNDF proportions in CSI-treated stover and soyhulls, were similar (2.8 and 3.6% of NDF, respectively, $P = 0.26$). The CSI-treated stover had lower iNDF than CaOH-treated stover or untreated stover (2.8, 27.3 and 35.1% of NDF, respectively, $P < 0.0001$). Results indicate that the CSI-treatment process improved rate and extent of digestion of corn stover to a greater degree than the CaOH treatment process. The CSI treatment process appears to convert corn stover into a source of highly digestible fiber with digestion characteristics similar to soyhulls.

Key Words: in situ, NDF, NaOH

W174 Effects of different source additive and wilt condition on the pH value, aerobic stability, and carbohydrate and protein fractions of alfalfa silage.

Lian Tao[1], He Zhou[2], Nai-feng Zhang[1], Bing-wen Si[1], Yan Tu[1], Tao Ma[1], and Qi-yu Diao*[1], *[1]Feed Research Institute, Chinese Academy of Agricultural Sciences, Key Laboratory of Feed Biotechnology of the Ministry of Agriculture, Beijing, China, [2]Institute of Grassland Science, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

To improve alfalfa silage quality and reduce additive cost, the potential of applying the fermented juice of epiphytic lactobacillus (FJEL) as an additive was evaluated. The experiment was designed as a 5 × 3 2-factor (wilt condition and additive) test. The second cut alfalfa at the budding stage was harvested, exposed to sunlight for 0 (20.04% DM; type 1), 5.2 (34.15% DM; type 2) or 8.5 h (54.58% DM; type 3). Alfalfa stuff were harvested in the next morning, exposed to sunlight and then natural rainfall for 1 h (33.20%DM; type 4) or 3 h (24.58% DM; type 5) before cutting. Alfalfa forage of each type was cut to 1–2 cm, then treated with distilled water (control), FJEL, or commercial lactobacillus product (CLP) at 10 ml/kg fresh weight (FW). The FJEL was made from alfalfa juice that was anaerobically stored for 2 d. The treated forages (approximately 500 g) were ensiled in vacuum-sealed polyethylene bags for 45 d, with 3 replicates for each treatment. The statistical significance of the effects of additive, wilt condition, and additive × wilt condition on silage quality were analyzed using a repeated measures one-way ANOVA. The application of FJEL decreased ($P < 0.01$) the pH value (4.44 vs. 4.93 or 4.66) and volatile fatty acid (VFA; 38.32 vs.49.55 or 44.82) content and increased ($P < 0.01$) the concentrations of lactic acid (LA; 68.99 vs.51.84 or 63.29) compared with those of the control and CLP treatment. However, the FJEL treatment had the lower ($P < 0.01$) aerobic stability (254 vs. 274 h), soluble fiber (148.89 vs. 154.85 g/kg DM), available NDF (145.39 vs. 154.25 g/kg DM), rapidly rumen degradable CP (59.91 vs. 62.33 g/kg DM) than CLP treatment. A higher pH and lower LA, sugar, starch and soluble fiber contents were found in the rain treatments compared with those of the no-rain treatments ($P < 0.01$). In conclusion, the application of FJEL could improve silage quality compared with the control; in addition, its effect as a fermentation stimulant may be comparable to or even better than CLP.

Key Words: alfalfa silage, wilt condition, epiphytic lactic acid bacteria

W175 Yield and nutritive value for ruminants of organic winter cereals–bard vetch intercrops.

Alexey Díaz[1,4], Marîa Dolores Carro[2], Carlos Palacios[3], Cristina Saro[1], Iván Mateos[1], Marîa Luisa Tejido[4], and Marîa José Ranilla*[1,4], *[1]Animal Production Department, University of León, León Spain, [2]Agriculture Production Department, Technical University of Madrid, Madrid, Spain, [3]Construction and Agronomy Department, University of Salamanca, Salamanca, Spain, [4]IGM (CSIC-ULE), Finca Marzanas s/n, Grulleros, León, Spain.*

Organic livestock in the European Union must be fed with organic feed, and forage should be at least 60% of the diet of herbivorous animals. However, the productivity of crops in organic farming is frequently lower than that in conventional farming, and organic cultivation of winter cereals often reduces forage CP content. Intercropping of winter cereals with legumes can provide both higher forage yield and quality compared with winter cereal monocultures, but the results may differ with cultivation conditions. The objective of this study was to investigate the potential of winter oats and barley intercropping with bard vetch (*Vicia articulata*) to enhance forage yield and quality as compared with cereals as a monoculture. The experiment was carried out in the province of Zamora (Spain) in 2014, as a randomized complete block design with 4 replications. Whole-plant DM yield was determined in June and chemical composition and in vitro DM digestibility (IVDMD) of harvested forages were analyzed. In addition, samples (500 mg) of each forage were incubated with 50 mL of buffered sheep rumen fluid at 39°C for 24 h and VFA production was measured. Intercropping with bard vetch increased ($P < 0.05$) forage yield by 25 and 18% for oats and barley, respectively, compared with monoculture. Intercropping also increased CP contents ($P < 0.05$; mean values 629 vs. 949 g/kg DM), and decreased ($P < 0.05$) NDF and ADF contents. The IVDMD was also higher ($P < 0.01$) for intercrops than for cereal monocultures. The presence of bard vetch in the cultures increased total VFA production ($P < 0.001$) by 27 and 15% for oats and barley, respectively. This was due to an increase in the production of acetate, propionate and butyrate ($P < 0.05$), but no effects ($P > 0.05$) of intercropping were detected for the acetate:propionate ratio or the molar proportions of individual VFA. The results indicate that forage yield and quality of oats and barley can be enhanced by intercropping with bard vetch under the cultivation conditions of this study. These results should be confirmed in multi-year studies before drawing up guidelines for organic farmers.

Key Words: organic cultivation, cereal, legume intercropping

W176 Comparison of total tract neutral detergent fiber digestibility of different varieties of barley silage selected on the basis of in vitro NDF degradability.

Natalie G. Preston*[1,2], Jayakrishnan Nair[1], Peiqiang Yu[1], David A. Christensen[1], John J. McKinnon[1], and Timothy A. McAllister[2], *[1]University of Saskatchewan, Saskatoon,* *SK, Canada, [2]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

Selecting forages with increased neutral detergent fiber (NDF) digestibility has been hypothesized to increase dry matter intake (DMI) in ruminants, but this hypothesis has not being tested using barley (*Hordeum vulgare*) silage. The objective of this study was to compare the total-tract NDF digestibility of different barley silage varieties selected for increased in vitro NDF degradability at 30 h using rumen cannulated sheep. Nine cannulated wethers in a triplicated 3 × 3 Latin square design were fed a 50:50 barley silage: concentrate pellet ration on a dry matter (DM) basis. Varieties of barley silage ensiled and fed included; CDC Cowboy, CDC Copeland, and Xena, based on selection for high, intermediate, and low NDF degradability, respectively. Of the 7 ensiled barley varieties tested, NDF degradability after 30 h incubation in an ANKOM fiber analyzer, CDC Cowboy had the highest NDF degradability at 34.2% of DM, CDC Copeland and Xena were selected based on their intermediate and lower degradability of 28.3% and 26.2%, respectively ($P < 0.05$). Lambs were fed ad libitum during a 12 d adaptation period. On d 12–14, lambs were restricted to 95% intake during which ruminal pH was recorded over 48 h using rumen pH loggers set to record pH every minute. On d 18, lambs were restricted to 90% intake, and housed in metabolic crates for total fecal collection over 4 d. Data were analyzed using the Proc Mixed procedure of SAS as a triplicate Latin square with day as a repeated measure within period. Lambs fed Xena had higher ($P < 0.01$) DMI (773 g/d) as compared with those fed Cowboy (667 g/d), both of which did not differ from Copeland (714 g/d). Digestibility of DM was greater ($P < 0.05$) for Copeland (69.3%) than Cowboy (65.6%) both of which did not differ from Xena (67.5%). Ruminal pH was reported as mean, max, min, and time < 5.8. Treatment did not affect mean, max, or min pH ($P > 0.05$), but time pH < 5.8 was longer ($P < 0.05$) for Xena, 301 min/d, than Cowboy, 123 min/d. Based on DM digestion and intake it can be inferred that selecting varieties based on improved in vitro NDF degradability does not improve DMI or total-tract digestibility of barley silage in sheep.

Key Words: barley silage, neutral detergent fiber, digestibility

W177 Effect of reduced lignin alfalfa on forage quality at 3 harvest intervals.

Zhiqiang Li*[1,2], Dan J. Undersander[1], David K. Combs[1], and Zhenzhen Li[1,2], *[1]University of Wisconsin, Madison, WI, [2]Department of Grassland Science, China Agricultural University, Beijing, China.*

The present study investigated the effect of reduced lignin alfalfa on forage quality. A 2 × 3 factorial design was used. Two alfalfa cultivars (Roundup Ready (RR) and double stacked RR and Reduced Lignin (RR/RL)) were harvested at intervals of 28d, 33d, and 35d. All replicated plots were established in June and harvested for 2 regrowth periods in July and August in 2014. Four replicates were used. Statistical analysis was a 2-way ANOVA using SPSS 22. Crude Protein (CP), Neutral Detergent Fiber (aNDF), Lignin, NDF Digestibility in 48 h (NDFD48) were analyzed by NIRS (FOSS 6500 using NIRSC 2012 Alfalfa Hay Equation). CP content was not significantly different between RR and RR/RL (27.5 vs 28.0, $P > 0.05$) and declined with advancing maturity ($P < 0.05$). aNDF content of RR was significantly higher than RR/RL (31.6 vs 30.1), though differences among harvest intervals were not significant (30.8 vs 30.5 vs 31.1). Lignin content was not significantly different between RR and RR/RL (5.6 vs 5.5) or among harvest intervals (5.6 vs 5.6 vs 5.5). The NDFD48 of RR/RL was significantly higher than RR (52.2 vs 50.5). Indigestible NDF (iNDF), Rate of fiber digestion (K_d), and Total-tract NDF Digestibility (TTNDFD) had not been reported for the RL germplasm and were shown in the table below. The reduced lignin alfalfa tended to be lower in iNDF and higher in K_d though differences were not significant, but was significantly higher in TTNDFD. It appears that RR/RL reduced the aNDF content and improved NDFD48 and TTNDFD.

Table 1 (Abstr. W177). Comparison between RR and RR/RL in iNDF, Kd and TTNDFD

Item		RR	RR/RL	Average	*P*-value Forage	 Harvest interval	 Forage × harvest interval

W178 Microbial counts, fermentation, and aerobic stability of oats with and without combo inoculant ensiled in vacuum bags and plastic bucket silos.

Juan J. Romero*[1], Jinwoo Park[2], Youngho Joo[2], Yuchen Zhao[3], Axel Gonzalez[1], Marco A. Balseca-Paredes[1], and Miguel S. Castillo[1], *[1]Department of Crop Science, North Carolina State University, Raleigh, NC, [2]Department of Animal Science, Gyeongsang National University, Jinju, Korea, [3]Department of Animal Nutrition and Feed Science, China Agricultural University, Beijing, China.*

The objective was to evaluate the use of 2 types of experimental silos to characterize microbial counts, fermentation, and aerobic stability of oats ensiled with and without addition of a homolactic and heterolactic inoculant. From each of 6 sections in a field, whole-plant oats at heading stage were harvested, wilted, chopped, treated (INO) or not (CON) with inoculant, packed into 20L plastic bucket silos (BKT) or 15.2 × 30.5cm nylon-polyethylene embossed vacuum bags (BAG), and ensiled for 217d. The inoculant added contained *Lactobacillus buchneri* and *Pediococcus pentosaceus* (4×10^{5} and 1×10^{5} cfu/g of fresh oats, respectively). Experimental design was a complete randomized design replicated 6 times. Treatment design was the factorial combination of 2 silo types × 2 inoculation treatments. At d 0 there were no differences between BAG and BKT, and between INO and CON on DM (44.0 ± 1.0, %), pH (6.11 ± 0.07), and counts of lactic acid bacteria (9.28 ± 0.13), yeasts (4.88 ± 0.09), and molds (3.97 ± 0.08). At opening (d 217) there was no difference in DM (42.9 ± 0.9, %) among treatment combinations. There was a lower pH (4.25 vs. 4.41 ± 0.02), yeasts (1.10 vs. 4.13 ± 0.34), and NDF (65.0 vs. 67.0 ± 0.40) for INO compared with CON, respectively ($P \leq 0.05$). Lactic acid bacteria count (6.39 vs. 5.65 ± 0.17), DM recovery (96.1 vs. 92.9 ± 0.43, %), and aerobic stability (565 vs. 133 ± 29, h) were greater in INO compared with CON, respectively ($P \leq 0.05$). Molds were similar when INO was applied to BKT (1.68) and BAG (1.42) but higher in BKT (2.82) compared with BAG (0.80 ± 0.41) for CON (silo type × inoculation, $P \leq 0.05$). In summary, differences due to silo type were only significant for mold count at opening. The combo inoculant used increased lactic acid bacteria, decreased pH and NDF, and improved aerobic stability by decreasing yeast count of oats silage. Silo bags are an alternative technique to buckets to adequately characterize lactic acid bacteria, yeasts, and fermentation of ensiled oats.

Key Words: silo, microbe, inoculant

W179 Change in chemical and microbial composition during aerobic challenge of maize silage with and without *L. buchneri* inoculation.

Ida K. Hindrichsen*, Nina Milora, Marianne Richelieu, and Asger Geppel, *Chr. Hansen A/S, Hørsholm, Denmark.*

Inoculation of *L. buchneri* (LB) is well recognized for extending aerobic stability of silage during feed out. The effect is mainly documented by measuring temperature change during small scale aerobic challenge. The objective of the current study was to investigate the microbial and chemical changes occurring during re-exposure of air to mini-silos inoculated with or without *L. buchneri* (LB). Newly harvested maize was collected from a farm in Denmark in September 2013. The maize was inoculated with tap water or LB and vacuum packed in 1-kg bags and stored at 25°C for 2, 7 or 15 weeks (n = 5 per treatment). For the aerobic challenge, the silage was divided into 2 containers (1.2 L; 274 kg/m^3) with a 1 cm hole in the top and bottom, and kept at room temperature for 156 h. After aerobic challenge for 0, 3 and 7 d chemical and microbial analysis were performed on all samples. Data were statistically analyzed as a randomized complete block by using GLM procedure by SAS. The none-fermented maize was highly contaminated with yeast and mold of log 6 and log 5, respectively. Aerobic stability and number of yeast was not significantly ($P > 0.05$) improved by inoculating with LB after 2 weeks, but LB inoculation improved the aerobic stability and reduced number of yeast significantly ($P < 0.05$) compared with control, when the silage was kept anaerobic for 7 or 15 weeks. During the aerobic challenge both the microbial and chemical composition changed. Yeast enumeration significantly ($P < 0.05$) increased during the aerobic challenge, except for the LB inoculated silage after 15 weeks of anaerobic fermentation, where yeast count was lower than detection level (log 2). Acetate, ethyl acetate, lactate, and ethanol levels decreased significantly ($P < 0.05$) during aerobic challenge for both treatments and anaerobic fermentation time points. Considerable chemical changes occur during aerobic challenge and with increased anaerobe fermentation the effect on aerobic stability by inoculation with LB improves.

Key Words: volatile organic compound, maize silage, aerobic stability

W180 Biological N_2 fixation and performance of cool-season legumes mixed with annual ryegrass.

Jose C. B. Dubeux Jr.*[1], Lynn E. Sollenberger[2], Ann R. S. Blount[1], Cheryl Mackowiak[1], Erick R. S. Santos[1], Hiran M. S. Silva[1], and Martin Ruiz-Moreno[1], [1]*North Florida Research and Education Center, University of FloridaMarianna, FL,* [2]*Agronomy Department, University of Florida, Gainesville, FL.*

Symbiotic association between forage legumes and N_2-fixing microorganisms reduces the need for pasture N fertilization and increases forage N concentration. Pastures of cool-season legumes mixed with annual ryegrass (*Lolium multiflorum* Lam.) are an option to extend the grazing season in subtropical regions. We investigated the association of 4 cool-season legumes with annual ryegrass and contrasted with annual ryegrass in monoculture. Clovers tested included balansa (*Trifolium michelianum* Savi), ball (*Trifolium nigrescens* Viv.), berseem (*Trifolium alexandrinum* L.), and crimson (*Trifolium incarnatum* L.). Treatments were replicated 4 times in a randomized complete block design. Response variables analyzed included total dry matter yield (DMY), clover DMY, annual ryegrass DMY, ^{15}N grass, ^{15}N legume, botanical composition, N concentration of grass and legume components, shoot N yield for grass and legume, percentage of N derived from atmosphere (%Ndfa), and N_2-fixation by the legume. Legume/annual ryegrass mixtures yielded more biomass (average of 2,590 kg DM ha^{-1}) compared with unfertilized annual ryegrass (980 kg DM ha^{-1}). Among mixtures, crimson clover/annual ryegrass was the most ($P < 0.01$) productive one (4,580 kg DM ha^{-1}). Crimson (2,230 kg DM ha^{-1}) and berseem (1,720 DM ha^{-1}) clovers were the 2 most productive legumes. Annual ryegrass yielded more biomass ($P < 0.001$) when mixed with crimson clover compared with other clover mixtures. Clover percentage in the mixtures ranged from 26 to 74%, with berseem showing the highest proportion. Total shoot N yields were 29, 41, 49, 88, and 11 kg N ha^{-1} for balansa, ball, berseem, crimson, and unfertilized ryegrass, respectively. The %Ndfa for all clovers were high, varying from 67 to 98%. N_2-fixation ranged from 11 to 52 kg N ha^{-1}, with crimson fixing the greatest amount. Crimson clover presented the best overall performance when mixed with annual ryegrass in North Florida.

Key Words: balansa, ball, berseem

W181 Rumen papillae size and blood serum enzymatic cofactors concentration of bulls fattened under two feeding systems at the Mexican dry tropic.

Carlos Rodríguez-Muela*, Nilda E. Ruiz-Holguin, Gabriela Corral-Flores, José A. Ramírez-Godínez, Alberto Flores-Mariñelarena, Pablo F. Mancillas-Flores, and Claudio Arzola-Alvarez, *Universidad Autónoma de Chihuhua, Chihuahua, México.*

The objective was to evaluate the effect of the feeding system on rumen papillae (RP) development and the animal welfare. The feeding systems used were: Intensive Silvopastoril (SPI) with grazing leukaena and Tanzania and African star grasses; Feedlot system (FLT) with a diet based on 70% of concentrate and 30% of corn stover. Eighty bulls of 2 breeding groups Brahman×Charolais (Bh×Ch) and Brahman×Brown Swiss (Bh×Ps) randomly distributed at both systems were used. The study lasted 195 d. Blood samples were taken at 0, 71, 132, and 195 d. Initial animal's body weight was 195 kg. Animals were killed at 450kg body weight. Tissue samples of rumen were taken during slaughter of animals. Evaluated variables were length and width of RP using a Vernier caliper. The concentration of Cu, Zn and Mn in blood serum was measured by atomic absorption spectrophotometry. Data were analyzed with a completely randomized design with factorial arrangement 2 × 2. Measures repeated in time and 0d as a co-variable for the blood serum enzymatic cofactors concentration (SEC) were used. SPI favored ($P < 0.01$) RP development, with values of 1.16 ± 0.05 and 1.11 ± 0.05; 0.38 ± 0.03 and 0.36 ± 0.03 cm in length and width of RP of Bh×Ch and Bh×Ps respectively (Table 1). There were a decrease ($P < 0.01$) in Cu, Mn and Zn concentration for sampling day, with lowest values at 132d, due to a possible caloric stress for environmental high temperature and relative humidity. There was effect of system for SEC ($P < 0.05$), with increase for Cu and Mn but decrease of Zn in SPI. We concluded that SPI allowed to a better RP development by the quality of the fiber consumed in the diet, no matter the breed group, and a larger serum concentration of Cu and Mn, although with a significant reduction of Zn concentration.

Contd.

Table 1 (Abstr. 181). Length and width of RP[1] and SEC of bulls fattened under two feeding systems

Variable	FLT	SPI
RP length (Bh×Ch)	0.63 ± 0.09^b	1.16 ± 0.05^a
RP length (Bh×Ps)	0.76 ± 0.07^b	1.11 ± 0.05^a
RP width (Bh×Ch)	0.20 ± 0.05^b	0.38 ± 0.03^a
RP width (Bh×Ps)	0.22 ± 0.04^b	0.36 ± 0.03^a
Cu (mg/L)	0.108 ± 0.004^b	0.124 ± 0.004^a
Mn (mg/L)	0.379 ± 0.010^b	0.424 ± 0.011^a
Zn (mg/L)	0.533 ± 0.030^a	0.406 ± 0.032^b

[1] Length and width of RP are expressed in cm.

Key Words: papillae, enzymatic cofactors, feeding system

W182 Effect of kernel processor and theoretical length of cut on physical characteristics of forage corn harvested with one row harvester. Gilson S. Dias Júnior*[1], Nilson N. Morais Júnior[1], Ronaldo F. Lima[1], Fabiana F. Cardoso[1], Ozana F. Zacaroni[1], Renata A. N. Pereira[3,2], and Marcos N. Pereira[1,2], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Better Nature Research Center, Ijaci, MG, Brazil, [3]Empresa de Pesquisa Agropecuária de Minas Gerais, Lavras, MG, Brazil.*

Adequate kernel breakage and sufficient particle size are desirable in corn silage (CS). Most Brazilian dairy farms use one-row forage harvesters. For such machines, a kernel processor (KP) was developed (MU9000462–0 U2 INPI patent). We evaluated the effect of theoretical length of cut (TLOC) and KP on CS particle size and kernel damage. Corn (Dow 2B587 Hx) was harvested at half milk line maturity (36.4% DM, 52.1% NDF, 30.0% starch). Treatments were a factorial combination of TLOC (3, 4.5, 6, 8.5 mm) and KP (with or without), and 50 m rows were harvested in triplicate. Statistical model had effects of TLOC, KP, and their interaction. Particle size distribution was measured with the Penn State Particle Separator. Visible kernels were quantified and classified in extreme (E), poor (P) or intact (I) breakage. Kernel in situ degradation in 12 h was 24.4% for E, 12.6% for P, and 11.5% for I, in 24 h 39.5%, 26.2%, and 23.6% ($P < 0.05$ E vs. P and E vs. I), and the residue of 72 h 25.2%, 39.4%, and 48.3% (all differ at $P < 0.05$), respectively. The KP reduced visible kernels in forage (44.2 vs. 70.5 g/500 g forage, $P < 0.01$) and the proportion of P+I (23.2 vs. 41.0 g/500 g forage, $P < 0.01$). The TLOC 3 mm without KP (traditional in practice) had more visible kernels (56 g/500 g forage) than 8.5 mm with KP (44 g/500 g forage). The reduction in visible kernels with smaller TLOC was larger when KP was not used ($P < 0.01$ for interaction). The proportion of particles below the 8 mm screen was 22 and 28% of fresh forage for TLOC 6 and 8.5 mm with KP, respectively, and 35% for 3 mm without KP. The TLOC 3 mm without KP had smaller proportion of starch below the 8 mm screen (21% of starch) than all TLOC with KP (29 to 35% of starch). The TLOC 3 mm without KP had 72% of NDF greater than 8 mm and 6 and 8.5 mm with KP had 79% and 82%, respectively. Although KP reduced NDF particle size, the reduction was not as large as the reduction induced by small TLOC. Reducing TLOC was more effective in reducing NDF particle size when KP was not used ($P < 0.01$ for interaction). Large TLOC with KP resulted in forage with longer NDF and increased kernel damage than small TLOC without KP, which is nutritionally desirable.

Key Words: forage harvester, particle size, corn silage

W183 The relative effects of external factors on variability of in situ fiber digestion. Abebe T. Hassen, Fredric Owens*, Lesa Nuzback, Chris Iiams, and Mark Hinds, *DuPont Pioneer, Johnston, IA.*

Differences in fiber digestibility among high-yielding corn silage hybrids usually are small. Therefore, screening tools should be precise. This study was designed to evaluate the relative influence of several external factors on variability among in situ NDF digestibility values, and estimate the potential precision improvements from increasing the number of steers and of replicate samples per steer. Samples from 3 corn hybrids were used as check hybrids during 85 routine in situ trials conducted over several years. Dry ground whole plant from the check hybrids were weighed into sealed Dacron in situ bags; duplicate bags containing each check hybrid were placed into each of 4 larger mesh bags with other samples being assayed. Within each 48 h run, 4 steers were used. Initially data were averaged by hybrid, run, steer, and mesh bag. These then were analyzed by hybrid using a model that included random effects of run, steer, run × steer interaction, and an error term. Data pooled across hybrids were analyzed using models that included the above effects as well as hybrid. In separate models, the hybrid effect was considered fixed and random. Mean in situ fiber digestibility for check hybrids ranged from 56% to 69%; ranking of these hybrids was consistent across runs. Results from the pooled analysis showed that of the total variability, 56% could be attributed to the error term. Contributions of run, steer, and their interaction were 15%, 20%, and 9%, respectively with contributions being similar when analyzed by hybrid. Repeatability SD of hybrid measurements based on 4 data points per steer was 2.2%. Reproducibility SD of measurements based on different steers and runs was 4.4%. Intra-class correlation of measurements from a hybrid evaluated within the same run using different steers was 0.64. Current results showed that SEM would be reduced by 30 to 40% by increasing the number of steers per run from 1 to 4. Based on 4 steers per run, SEM could be reduced an additional 16% by increasing the number of mesh bag per steer from 1 to 4. Additional improvements in precision from resource re-allocation were minimal.

Key Words: digestibility, fiber, in situ

W184 Characterizing corn silage in Brazil. M. Pinho[1], M. Martins[1], D. Combs[2], J. Goeser[3], D. Meyer[3], L. Meyer[3], Z. Meyer[3], F. Lopes[4], and M. H. Ramos*[1], *[1]3rlab, Belo Horizonte, Minas Gerais, Brazil, [2]University of Wisconsin, Madison, WI, [3]Rock River Laboratory, Watertown, WI, [4]Kemin Industries, Indaiatuba, São Paulo, Brazil.*

A data set of 1796 commercial samples of corn silage assessed for nutritive value by NIR was utilized to generate population descriptive information for the dairy industry in Brazil. Representing silage samples were harvested in the year of 2014 and came from 13 states. Corn silage data were queried from a commercial database and population descriptive statistics were generated with MS excel. Average NDF and starch content were 50% and 24% of DM with a SD of 6.67 and 8.05, respectively, suggesting Brazil corn silage is of lesser energetic value. Typical US corn silages average 44 and 29% NDF and starch for comparison. Rumen in vitro NDF digestibility and predicted in vivo TTNDFD (total-tract neutral detergent fiber digestibility) values exhibited substantial variation, with CV ranging from 15.8 to 38.1, suggesting that opportunity exists to improve forage quality. The database presented here showed a great variation in carbohydrate content (NDF and starch) and NDF availability (TTNDFD). To our knowledge, this is one of the first studies documenting corn silage produced in Brazil variability. With the variation in important nutrients and measurements presented here, there may be potential for genetic selection and improvement for

Brazilian growing conditions. Selecting for lower NDF, greater starch and greater fiber digestibility, including greater TTNDFD, will result in hybrids that allow for greater milk production.

Table 1 (Abstr. W184).

Item	CP	NDF	Starch	Sugar	Fat	Ash	NDFD at 24 h	NDFD at 30 h	NDFD at 48 h	TTNDFD
Median	6.9	50.5	25.1	0.9	3.4	3.3	16.4	24.8	40.2	36.9
Average	6.9	50.8	24.5	1.1	3.3	3.3	16.0	24.5	39.9	36.8
SD	1.0	6.6	8.0	1.0	0.7	0.9	6.1	5.7	7.0	5.8
CV	14.5	12.9	32.6	90.1	21.2	27.3	38.1	23.3	17.5	15.8

W185 Effect of light intensity and wavelength on concentration of antiherbivory compounds in *Flourensia cernua* leaves. Rick E. Estell*[1], Ed L. Fredrickson[2], and Darren K. James[1], [1]*USDA-ARS Jornada Experimental Range, Las Cruces, NM,* [2]*Eastern Kentucky University, Richmond, KY.*

Shrub encroachment negatively affects forage production and rangeland health in many semi-arid regions. *Flourensia cernua* (tarbush) has increased in the northern Chihuahuan Desert at the expense of grasslands. Our previous studies have shown a negative relationship between tarbush terpene concentrations and livestock herbivory. Concentrations of secondary compounds are affected by many biotic and abiotic factors, including amount and wavelength of solar radiation. A 3-year study was conducted to examine the impact of shade and UV light restriction on phenolic and terpene concentrations in tarbush. Our hypothesis was that UV restriction and partial shade would reduce carbon based secondary compounds. Sixty plants were randomly selected and assigned to 3 treatments (control, UV light restriction, or 50% incident light restriction) in a randomized complete block. Frames covered with clear plastic film (UV blocking treatment), black shade cloth (50% shade treatment) or frame only were placed over 20 plants each. Leaves were collected from each plant in late September each year and freeze-dried for total phenolic analysis (Folin-Denis method) or frozen for leaf surface terpene analysis (extracted with ethanol and identified and quantified with GCMS). Data were analyzed using repeated measures linear mixed effects models with treatment as the fixed effect and year as a repeated effect. Means were separated by LSD. Mean concentrations of total phenolics and total volatiles in tarbush were 82.4 and 12.5 mg/g DM, respectively. Tarbush leaves contained 102 individual terpenes (including 19 unknowns). No year x treatment interactions were detected for any variable ($P > 0.05$). Total phenolics did not differ between controls and UV restricted plants, but were lower for shaded plants than the other 2 treatments ($P < 0.05$). Total volatiles were higher for the UV restriction treatment than controls ($P < 0.05$), with shaded plants not differing from either treatment. Treatment effects were detected for 18 compounds ($P < 0.05$). Shade reduced total phenolics as predicted, but did not affect total volatiles. In contrast to our expectations, UV restriction had no effect on total phenolics, and increased total volatile concentrations.

Key Words: light, phenolic, terpene

W186 In situ ruminal degradability of diets based on passion fruit (*Passiflora edulis*) flour substituting maize. Adolfo Sánchez*[1], Emma Torres[1], Leon Montenegro[1], Italo Espinoza[1], and Daniela Sanchez[2], [1]*Universidad Técnica Estatal de Quevedo, Quevedo Los Rios, Ecuador,* [2]*Universidad Estatal Amazonica, Puyo Pastaza, Ecuador.*

This investigation was carried out in the Nutritional Metabolism and Ruminal Laboratory, located at the Experimental Campus "La Maria," of Quevedo State Technical University (UTEQ – Ecuador) with the objectives of determining in situ ruminal degradability of dry matter (DM), organic matter (OM), neutral detergent fiber (NDF), and acid detergent fiber (ADF), as well as of identifying ruminal pH variation in cattle fed with diets based on passion fruit flour. A complete randomized block design (CRBD) was applied with 4 treatments ((T1: 0%; T2: 10%; T3: 20% and T4: 30% inclusion of passion fruit flour substituting maize in diet), (diet components: corn, rice powder, bagasse soy, $CaCO_3$, Ca $(H_2PO_4)_2$ x H_2O and NaCl) and 3 blocks (cattle rumen fistulated) and 7 incubation times (0; 3; 6; 12; 24; 48 and 72 h). To establish the differences between treatment averages, Tukey ($P \leq 0.05$) test was applied. The highest ($P < 0.05$) degradability within 48 and 72 DM - OM and NDF - ADF incubation hours was registered by treatments T1 and T2 (67.68; 69.10% MS - 65.40; 66.71% DM); (71.79; 74.14% OM - 69.28; 70.07% OM); T4 and T3 (86.46; 88.33% NDF - 80.44; 81.02% NDF); (53.94; 56.21% ADF - 47.86; 49.36% ADF respectively. The levels of passion fruit flour inclusion made it possible to keep a (6.3 – 6.8) pH after 12 h of incubation, what is considered adequate for aminolytics and fibrolytics microorganism growing.

Key Words: digestibility, degradability, feeding

W187 Dry matter production of four *Brachiaria* grasses. Virginia L. N. Brandão, Gabriel C. B. Oliveira, Bruno P. Ignacchiti, Kaik Faria, Marcos Rosa, Guilherme D. Castro, Marcos I. Marcondes*, and Fernanda H. M. Chizzotti, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Studies to determine and compare the productive potential of forages from genus *Brachiaria* under same management conditions are scarce. Therefore, we believe that cultivars with similar morphological characteristics have similar nutritional value, and that management can affect this response. Thus, we aimed to determine and compare the productivity of forage produced during dry and rainy season of *Brachiaria* pastures when managed with 28 d or 95% light interception as criteria for interrupting regrowth. The treatments consisted of 4 cultivars of *Brachiaria*: *B. decumbens* 'Basilisk', *B. brizantha* 'Marandu', *B. brizantha* 'Piatã' and *B. brizantha* 'Xaraés', managed under 2 pasture strategies: every 28 d (28D), or when the canopy reaches 95% of light interception (IL95). The experiment was designed in completely randomized blocks, in a factorial arrangement of 4 × 2, with 3 replications (blocks). The evaluated variable was dry matter production (DM) in the pre- and post-grazing. The management did not affect DM production per year ($P = 0.696$), but during the rainy season the IL95 had higher DM than 28D. During dry season the 28D management provided higher DM than IL95, because the dry season had 6 grazing cycles, while IL95 had only one cycle. Xaraés was the most productive forage, with 14,961 kg DM/ha/yr; Marandu and Piatã were not different (12,766 and 13,076 kg DM/ha/yr respectively), and *B. decumbens* had the lowest productivity (10,986 kg DM/ha/yr). We conclude that management of IL95 provided higher DM during rainy season; however, they had the same productivity per year. Xaraés had the greatest total dry matter production, and *B. decumbens* had the lowest productivity.

Key Words: season, light interception, fixed-days management

W188 Forage yield of four maize cultivars sown in single and double rows.

Marco A. Ramírez*[1], Pedro A. Martínez[2], Jesús Jarillo[3], Francisco A. Castrejón[1], and Luis Corona[1], [1]*Departamento de Nutrición Animal, Universidad Nacional Autónoma de México, FMVZ, México City, México,* [2]*Departamento de Zootecnia, Universidad Autónoma Chapingo, Texcoco, México,* [3]*CEIEGT, Universidad Nacional Autónoma de México, Veracruz, México.*

In Mexico corn silage is widely fed to dairy and beef cattle, and in the market, farmers have many maize hybrids and native cultivars with some sowing strategies to choose from. The objective of the study was to determine total forage yield and by component (leaf, stem, ear and husk, kg DM ha^{-1}) in 4 maize cultivars under 2 sowing strategies. Maize cultivars were 2 hybrids: Gladiator and Fog, and 2 native: Red and White; sowing strategies were single and double row, the former was seeding in rows every 80 cm, the latter in pairs of rows separated 40 cm with 80 cm between consecutive pairs of rows. Seeding rate was 80 000 plants ha^{-1}. Experimental design was a completely randomized design in a factorial arrangement 4 (maize cultivars) × 2 (sowing strategies) with 4 replicates and the experimental unit was a 4.8 × 3 m plot. Harvest was 135 d after sowing. The cultivar × sowing strategy interaction did not influence ($P > 0.05$) any of the variables measured. There was a trend ($P = 0.10$) for native cultivars to show higher total forage yield than the hybrids (25408 vs. 21481.5 respectively); while double-row sowing tended ($P = 0.19$) to promote on the average 12% higher total forage yield than single-row (24,763 vs 22,203). Native cultivars gave 63% higher ($P < 0.05$) stem yield (14635.5) than the average of the 2 hybrids (8958) which showed similar ($P > 0.05$) stem yield. Gladiator showed the lowest ($P < 0.05$) leaf yield (2,677), 34% lower than the average yield observed in the other 3 cultivars (3589.7) which showed no difference ($P > 0.05$) among them. Both hybrids gave 48% higher ($P < 0.05$) ear yield than the average of the 2 native cultivars (6939.5 vs. 4672) which gave similar ($P > 0.05$) ear yield. Only in leaf yield did sowing strategy show an influence, double-row gave 18% more ($P < 0.05$) leaf than single-row (3646 vs. 3078 respectively). Native cultivars might show higher total forage yield than hybrids but of lower quality as the formers have higher amount of stems and lower of ears. It was concluded that total forage yield and by component are influenced by maize cultivar and sowing strategy and that total forage yield should not be the only one attribute to decide on which maize cultivar and sowing strategy to use on the farm.

Key Words: maize, cultivar, sown

W190 Effects of maturity at harvest on the nutritional value, yield and milk production potential of corn hybrids planted under tropical/subtropical conditions.

Kathy G. Arriola*[1], Rafael M. Martins[1], Thiago F. Bernardes[1], Fabiola M. da Silva[1], Felipe X. Amaro[1], Bibiana Coy[1], Enrique Alias[2], Ernesto Marin[2], Ludwing Leyton[2], Zhengxin X. Ma[1], Ibukun M. Ogunade[1], Yun Jiang[1], Musibau A. Bamikole[1], and Adegbola T. Adesogan[1], [1]*University of Florida, Gainesville, FL,* [2]*University of El Salvador, San Salvador, El Salvador.*

This study examined the effect of maturity at harvest on key agronomic and nutritional traits of corn hybrids planted in the Florida Summer. Eighteen corn hybrids from 5 seed companies (Agra Tech, Croplan Genetics, Mycogen, Pioneer, and Syngenta) were grown on 4 replicate plots (1.8 × 6.1 m) in each of 4 blocks in August 2013. Hybrids were harvested at target maturity stages of 30, 35, 40, and 45% DM by removing 1.8-m sections from 2 rows in each plot. Temperatures ranged from 14.1 to 29.3oC and rainfall was 432 mm during the growing season. Disease ranking (1, low to 5, high scale), DM yield, kernel milk line position, and chemical composition at harvest were measured. Milk-per-ton (MPT) and milk-per-hectare (MPH) values were calculated with the Milk 2006 model. Data were analyzed with a model including hybrid, maturity and the interaction using the Glimmix procedure of SAS. Mean DM concentrations at harvest were 32.3, 34.6, 40.7, and 42.5% at the respective target maturity stages above. Milk-per-hectare was unaffected by maturity (1,529–1,679 kg/t) but MPT was greater when hybrids were harvested at 30 or 35% DM than at 40 or 45% DM (1668 vs. 1531 kg/t). The NDF digestibility decreased at each maturity stage ($P < 0.05$; 59.2, 58.0 and 57.2 and 55.7%, respectively), whereas DM yield did not change (22.2 t/ha) until the 45% DM stage when it increased (25.5 t/ha). For most hybrids, disease ranking and NDF concentration decreased to a nadir and starch concentration peaked when they were harvested at 40% DM (hybrid x maturity, $P < 0.05$). Kernel milk line position increased quadratically with maturity for most hybrids (hybrid × maturity, $P < 0.05$). Six hybrids had among the highest MPT (>1641 kg/t) and MPH (>39164 kg/ha) values and their NDF digestibility (57.3 to 60.3%) and starch concentration (27.7 to 32.0%) ranges were moderately high. Differences in MPT and MPH among hybrids of 150 kg/t and 14,132 kg /ha, respectively were evident. Yield and quality measures were simultaneously optimized when hybrids were harvested at 35 to 40% DM.

Key Words: corn hybrid, maturity, dry matter yield

W191 Application of *Pediococcus pentosaceus*, *Pichia anomala*, and chitinase to high moisture alfalfa hay at baling: effects on ruminal digestibility.

Long Jin[1], Lysiane Dunière[1], Joseph.P. Lynch[1], Eric Chevaux[2], Tim.A. McAllister[1], John Baah[3], and Yuxi Wang*[1], [1]*Agriculture and Agri-Food Canada, Lethbridge, AB, Canada,* [2]*Lallemand animal nutrition, Blagnac, France,* [3]*Best Environmental Technologies Inc., Edmonton, AB, Canada.*

Baling of alfalfa hay at higher than optimum moisture level can lead to spoilage and a reduction in the nutritive quality of the forage. Organic acids such as propionic acid (PA) have been added to high moisture hay (HMH) to prevent the growth of spoilage microorganisms, but the high rates of application, costs and environmental concerns associated with these preservatives has discouraged hay producers from using them. The objective of this study was to assess the effects of applying *Pediococcus pentosaceus* (PED) and *Pichia anomala* (PIC) alone or in combinations with chitinase (CH) at baling on the nutritional quality of high-moisture alfalfa hay using in vitro and in situ procedures. Alfalfa hay was harvested at the mid-bloom stage, wilted to 73–77% DM and baled without (HMH) or with PED, PIC, PED+PIC, PED+CH, PIC+CH, and PA. The control (HMH), PED+CH, PIC+CH and PA and alfalfa hay baled at >85% DM (NMH) were repeated in 3 consecutive yrs. Other treatments were assessed only in single yr. Samples collected 90 d after baling over the 3 yr were assessed in vitro and only 1 yr samples were assessed for rumen degradability. For all 3 yr, in vitro DM disappearance (IVDMD), asymptotic gas production and rate of gas production of HMH, irrespective of treatment, was lower ($P < 0.05$) than NMH. Among treatments, PED+CH and PIC+CH had higher ($P = 0.01$) IVDMD than HMH and PA, but only PED+CH had higher ($P < 0.01$) asymptotic and rate of gas production as compared with HMH and PA in yr 1. The potential degradable fraction of DM did not differ among treatments. However, PED+CH and PIC+CH had a higher ($P < 0.01$) rapidly degradable fraction than PA. The 24-h in situ NDF digestibility of PED+CH and PIC+CH was higher ($P < 0.001$) than that of all other treatments including NHM. These results suggest that application of *P. pentosaceus* or *P. anomala* combined with chitinase at baling of high moisture alfalfa hay has potential to reduce nutrient losses and to increase fiber digestibility.

Key Words: high moisture alfalfa hay, additives, in situ digestibility.

W192 ***Malva sylvestris*** **extract affected kinetics of fermentation, methane production, and protozoa population of barley grain incubated with rumen fluid.** Saba Khamooshi[1], Farokh Kafilzadeh[1], Hossein Jahani Aziz Abadi[2], and Golnaz Taasoli*[1], *[1]Razi University, Kermanshah, Iran, [2]Kurdestan University, Kurdestan, Iran.*

This study was conducted to evaluate the effect of *Malva sylvestris* leaf or stem extracts on in vitro fermentation kinetic, methane production and protozoa population of barley grain. Juice from leaves and stems were prepared by extraction from crushed materials. The extracts were then centrifuged at 454 × *g* for 15 min before use. The extracts were added at levels of 0, 25, 50 and 100 μL/250 mg barley incubated in 30 mL mixture of buffer and rumen fluid. Addition of both extracts increased the potential gas production (mL/200 mg DM), and constant rate (mL/h) but decreased the lag time (h) of barley grain ($P < 0.01$). Methane production from fermentation of barley grain decreased due to the addition of the extracts ($P < 0.01$). Methane reduction potential from fermentation of barley grain were 13.15, 7.30 and 13.28% when leaf extract was added at 25, 50 and 100 μL/250 mg barley, respectively. Corresponding values for similar levels of the stem extract were −1.94, 1.80 and 9.12%, respectively. Protozoa population in incubated barley grain medium with no extract was 9.94×10^4/mL. The extracts particularly the extract from leaf resulted in much more protozoa reduction from barley grain fermentation (average values of protozoa population when leaf and stem extracts were added to barley grain incubation medium were 7.67×10^4 vs. 7.85×10^4/mL). The result of this study show *M. sylvestris* extract has some potential in improving the fermentation of barley grain

Key Words: *Malva sylvestris*, methane production, protozoa population.

W193 Effect of a protease enzyme (papain) on in vitro NDF digestibility of alfalfa hay stem. Shahab Payandeh, Farokh Kafilzadeh, and Golnaz Taasoli*, *Razi University, Kermanshah, Iran.*

An in vitro experiment was conducted to examine the effect of a protease (papain, EC 3.4.22.2) on ruminal fiber digestibility of alfalfa hay stem. Exactly 100 mg of enzyme powder was solubilized using 5 ml of water. Serum bottles containing 500 mg of alfalfa hay stem, modified McDougall's buffer and rumen fluid with addition of 0, 50, 100 or 200 μL of the papain solution/g alfalfa hay stem DM were incubated under anaerobic conditions at 39°C for 24 and 48 h. Total gas production and NDF disappearance were determined. Partitioning factor (PF) was calculated as the ratio of NDF degraded (mg) to the volume of gas (mL) produced. Data were analyzed as a completely randomized design by ANOVA using SAS 9.2. The enzyme with a level of 200 μL/g alfalfa hay stem DM significantly ($P < 0.05$) increased in vitro NDF degradability after 24h incubation (40.2, 41.6, 40.6 and 45.9% in alfalfa hay stem, alfalfa hay stem+50, alfalfa hay stem+100 and alfalfa hay stem+200 μL of enzyme/g alfalfa hay stem DM, respectively). No significant difference was observed after 48h incubation. The PF was also increased significantly ($P < 0.01$) with addition of all levels of papain (1.57, 1.76, 1.70 and 1.77 in alfalfa hay stem, alfalfa hay stem+50 alfalfa hay stem+100 and alfalfa hay stem+200 μL of enzyme/g alfalfa hay stem DM, respectively). From the result of this experiment, it appears that addition of papain at the highest level has a pronounced effect on the digestion of NDF after 24h incubation. It is concluded that this enzyme has some potential on removing structural proteins in the cell wall, allowing ruminal microbes to gain faster access to digestible substrates.

Key Words: papain, NDF digestibility, partitioning factor

W194 Effect of bacterial additives on fermentation quality and aerobic stability of rye silage harvested at dough stage. Young Ho Joo*[1], Seong Shin Lee[1], Dong Hyeon Kim[1], Hyuk Jun Lee[1], Sardar M. Amanullah[1,3], Ouk Kyu Han[2], and Sam Churl Kim[1], *[1]Division of Applied Life Science (BK21Plus, Inst. Agric. & Life Sci.), Gyeongsang National University, Jinju, Gyeongsangnam-do, South Korea, [2]National Institute of Crop Science, RDA, Suwon, South Korea, [3]Bangladesh Livestock Research Institute, Dhaka, Bangladesh.*

This study was carried out to determine the effect of different additives on chemical composition, fermentation characteristics and aerobic stability of rye silage harvested at dough stage. Rye forage was grown at National Institute of Crop Science, Suwon, South Korea, and harvested at 37% of dry matter. The harvested forages were divided into the following 4 treatments: CON (distilled water at 2 mL/kg of fresh forage); LP (*L. plantaruma* t 1.5×10^4cfu/g of fresh forage); LB (*L. buchneri* at 1.2×10^4cfu/g of fresh forage) and MIX (mixture of LP and LB at 1:1 ratio). The forage was chopped to 3–6 cm length and ensiled into 10 L bucket silo with 4 replications for 0, 1, 4, 7, 48 and 100 d. On 100 d of ensiling, crude protein concentration (7.61 vs. 6.63%) in LP was higher ($P < 0.05$) than that in CON. The concentrations of neutral detergent fiber and hemicellulos were higher ($P < 0.05$) in LB (73.7 and 24.6%) and MIX (72.9 and 24.0%) than those in CON (70.4 and 21.7%) and LP (69.5 and 22.6%), while acid detergent fiber concentration was lowest ($P < 0.05$) in LP (46.9 vs. 48.7, 49.1 and 48.9%). The CON had higher ($P < 0.05$) pH (4.56 vs. 4.15, 4.11 and 4.12) than all treatments applied bacterial additives. The pH in LB and MIX silage decreased more drastically than those in CON and LP on early ensiling periods (d 0–7). The concentrations of lactate and propionate were highest ($P < 0.05$) in LP (13.4 and 5.72%), but acetate concentration was highest ($P < 0.05$) in LB (27.5%) and MIX (22.1%). Lactate to acetate ratio (1.23 and 1.43 vs. 0.29 and 0.35) was higher ($P < 0.05$) in CON and LP than that in LB and MIX. Lactic acid bacteria (6.71, 6.59 and 6.48 vs. 5.25 log10 cfu/g) in CON, LP and LB were higher ($P < 0.05$) than that in MIX, whereas aerobic stability (760.5 vs. 616.3, 606.5 and 634.3 h) was higher ($P < 0.05$) in MIX than all other treatments. Yeast was highest ($P < 0.05$) in LB (7.64 log10 cfu/g), while mold was not detected in all treatments. In conclusion, LP or MIX supplementation can improve the aerobic stability by increase of acetate concentration which has strong anti-fungal effect.

Key Words: aerobic stability, barley silage, inoculant

W195 Fermentation quality and chemical composition of mixed silage with shrub and corn. Bing-wen Si*[1], Zong-li Wang[2], Qi-zhong Sun[2], Hong-mei Wang[1], and Qi-yu Diao[1], *[1]Feed Research Institute, Chinese Academy of Agricultural Sciences, Key Laboratory of Feed Biotechnology of the Ministry of Agriculture, Beijing, China, [2]Grassland Research Institute, Chinese Academy of Agricultural Sciences,, Hohhot, Inner Mongolia, China.*

With development of Chinese animal husbandry, shortage of feedstuffs is a main limit factor for livestock development. Rush bushclover (RB) and shrubby sweetvetch (SS) have the characteristics of high biomass, drought resistance, leanness tolerance. Moreover, they are of high nutritive value, rich in crude protein (CP), and potential new resources for livestock feed. Shurb is seldom used as material to make silage as legumes are often considered hard to ensile well due to low fermentable carbohydrate content in combination with a high buffering capacity (BC). Whole-crop corn is ascribed to easy ensiling procedure and has high fermentative quality and palatability for cows, because of the chemical composition of corn, mainly in high fermentable carbohydrates. Silage produced from a mixture of whole-crop corn and 2 kinds of shrub is likely to have a better fermentation quality and nutritive value compared with silage consisting solely of herbage from RB and SS. RB and SS (315 and 274 g dry matter per kg) were cut into 2 to 5 cm by a rubbing filament machine and ensiled in 1.5 L laboratory silos with whole-crop corn as mixtures of 1, 0.7, 0.5, and 0.3 of fresh weight (FW). After 60 d, the nutrition and fermentation quality of all treatments were analyzed. Results showed that the pH of silage consisting solely of herbage from RB and SS were significantly ($P < 0.05$) higher and the lactic acid content were significantly ($P < 0.05$) lower than silages mixed with whole-crop corn. With the increase of the proportion of corn, lactic acid and acetic acid content also increased ($P < 0.05$). Dry matter and WSC content decreased with the increase of the proportion of corn ($P < 0.05$). In conclusion, RB and SS with a high BC and a low WSC concentration is best ensiled using whole-crop corn. Inclusion of 0.5 to 0.7 of whole-crop corn is recommended to ensure a good fermentation.

Key Words: mixed silage, fermentation quality, shrub

W196 Late season forage yield, quality, and digestibility from mixed cropping of organic certified corn and soybean hybrids at different seeding rates.

Ishwary Acharya* and David Casper, *Dairy Science Department, South Dakota State University, Brookings, SD.*

The production of forage resulting from the mixed cropping of corn and soybeans at planting has the potential to yield greater quantities of digestible nutrients to meet the nutrient requirements of lactating dairy cows. A field plot study was laid out using a completely randomized design to evaluate 2 organic corn hybrids [Normal (N) and MasterGraze (MG)] with 2 soybean hybrids [Regular (R) and Vining (V)] at 4 seeding rates (R1 = 65:35; R2 = 55:45; R3 = 45:55, and R4 = 35:65 of corn and soybean) having a 2 × 2 x 4 factorial treatment design replicated 3 times. Forage was hand harvested 93 d after planting during the 2014 growing season, inoculated, packed into buckets, weighed, and ensiled for 60 or 90 d. Buckets were then re-weighed, opened, and forage samples collected and submitted for nutrient analysis (Analab, Inc., Fulton, IL). Yield of DM (6.74 and 7.65 T/ha for N and MG, respectively) for main effect of corn was similar ($P > 0.05$), while V yielded greater ($P < 0.05$) than R (6.13 and 8.27 T/ha for R and V, respectively) for main effect of soybean, while seeding ratio main effect was similar [($P > 0.05$); 7.91, 6.29, 7.81, and 6.77 T/ha for R1, R2, R3, and R4, respectively]. Yield of fresh digestible DM (DDM; 4.40 and 5.06 T/ha) and CP (1.04 and 1.22 T/ha) were similar ($P > 0.05$) for corn, while V yielded greater ($P < 0.05$) DDM (4.03 and 5.43 T/ha) and CP (0.97 and 1.29T/ha) than R and seeding ratios were similar ($P > 0.05$) in yield of DDM (5.20, 4.15, 5.08, and 4.50 T/ha) and CP (1.14, 1.05, 1.25, and 1.07 T/ha). A significant interaction ($P < 0.05$) was detected for corn × soybean × seeding ratio for ensiled DDM yield at 60 and 90 d, while no other significant ($P > 0.05$) interactions of main effects were detected. The combination of MG seed corn with V soybean hybrids at the ratio of 67:33 resulted in the greatest yield of DDM after 60 and 90 d of ensiling the forage. The mixed cropping of corn and soybeans holds great potential for increasing the production of forages to meet the nutrient requirements of lactating dairy cows.

Key Words: corn, soybean, yield

W197 Climatic and management factors affecting the forage yield and quality of a high density mulberry forage bank established under low input tropical farming conditions.

Eliel González-García*[2] and Giraldo Martín-Martín[1], [1]*Estación Experimental de Pastos y Forrajes "Indio Hatuey," Matanzas, Cuba,* [2]*INRA UMR868, Systèmes d'Elevage Méditerranéens et Tropicaux (SELMET), Montpellier Cedex 2, France.*

Effects of year season (SEAS), organic fertilization (N) and harvest frequency (FREQ) on forage yield and composition were evaluated in a high density mulberry forage bank, established under low input tropical farming conditions. The experiment, replicated 2 consecutive years, was arranged in 18 treatments resulting from a 3 × 3 × 2 factorial design combining 3 FREQ (60, 90 and 120 d), 3 N rates (100, 300 and 500 kg N/ha/year) and the 2 seasons (RAIN and DRY). Forage yield, leaf to stem ratio, the edible fraction (EDIB, %), nutrient content by plant fraction (PFR; i.e., leaves, tender and ligneous stems) and the maturity indexes were monitored. Either forage yield or nutrient content was strongly affected by SEAS, FREQ, PFR, N rate and, in some cases, by their interactions. Total forage yield increased ($P < 0.0001$) with FREQ (26.5, 31.2 and 40.6 t for 60, 90 and 120 d, respectively), irrespective of the SEAS (44.7 and 21.1 t for RAIN and DRY, respectively), PFR (19.2, 3.0 and 10.7 t for LEAF, TST and LST, respectively) or N (28.1, 32.0 and 38.5 t for 100, 300 and 500 kg N/ha/year, respectively). The EDIB yield was higher in RAIN (25.3 vs. 13.2 t; RAIN vs. DRY) and diminished while increasing FREQ, irrespective of SEAS or N. This decrease in EDIB yield was directly related to the decrease in the LEAF proportion and the concomitant increase of the LST fraction with FREQ. Harvesting at 60 and 90 d in RAIN and DRY, respectively, with a N rate of 300 kg N/ha/year seems the best agronomic choice as a most optimal condition between forage yield and nutritive value.

Key Words: forage yield and composition, harvest frequency, organic fertilization

W198 Response to using rumen inoculum from high and low feed efficient cows on in vitro fermentation of alfalfa ensiled with different additives.

Francisco E. Contreras-Govea*[1], Richard E. Muck[2], Paul J. Weimer[2], and Ursula C. Hymes-Fecht[2], [1]*Department of Dairy Science, University of Wisconsin-Madison, Madison, WI,* [2]*USDA-Dairy Forage Research Center, Madison, WI.*

Alfalfa from 2 consecutive harvests (H1, H2) was treated with *Lactobacillus plantarum* (LP, 10^6 cfu/g alfalfa), formic acid (FA, 5.4 kg/Mg), and no additive (control), ensiled in mini-silos, fermented for 60-d at room temperature (22°C), and analyzed for nutritive value and fermentation profile. Silages were wet ground to a particle size of 2–3 mm using a food processor for in vitro true DM digestibility (IVTDMD). High (HE) and low efficient (LE) groups of 3 cannulated cows each were identified based on 2 lactations and had an average energy corrected milk/dry matter intake (ECM/DMI) ratio of 1.88 and 1.61, respectively. In each in vitro run, 12 silos from a harvest were analyzed simultaneously with 6 rumen inocula, one from each cow, for 24 h. Data analysis was conducted using the MIXED procedure of SAS, as a split plot design. For silage fermentation, harvest was the whole plot and alfalfa treatment as subplot. For the in vitro, HE and LE groups were main plot and treated alfalfa as sub-plot. In both cases mean differences were declared significant at $P < 0.05$. Across harvests, LP had lower pH (4.47) and greater lactic acid concentration (64.3 g/kg DM) than control (4.77, 52.1) and FA (4.70, 33.9). Moreover, ammonia-N was lower in LP (3.8% total N) and FA (4.2) than control (5.4) in both harvests. IVTDMD of the H1 silages was greater with the HE cows (79.6%) than LE cows (75.13%), but there was no difference at H2 ($P = 0.310$). The IVTDMD was not different among silage treatments at H1 ($P = 0.078$), but at H2 control had greater IVTDMD (79.8%) than did LP (78.1) and FA (77.6). Rumen fluid from HE cows produced greater acetate and butyrate than did LE on H1 silages, with no differences on H2. In vitro acetate and propionate were contrasting between H1 and H2 by silage treatment. At H1, LP and FA had greater acetate and propionate than control, but it was opposite at H2. It is concluded that LP and FA decrease ammonia-N during fermentation of alfalfa silage, and rumen inocula from HE cows displayed numerically higher IVTDMD, but the effect was only significant with the earlier harvested silage.

Key Words: alfalfa silage, additive, feed efficiency

W199 Ruminal degradability of a *Musa* sp. fodder bank located in the central part of Costa Rica.

Pablo Chacón Hernández*, Carlos Boschini Figueroa, and Ricardo Russo Andrade, *Universidad de Costa Rica, San Pedro, San José, Costa Rica.*

When bananas are grown for fruit, the bigger part of the plant gets wasted. In tropical areas, producers use the pseudo-stems and leaves as feed for cattle. An experiment was performed to determine the potential value of the banana plant nutrient availability for ruminants. Fifteen adult plants were randomly harvested from a fodder bank located at the University of Costa Rica's Alfredo Volio Mata Experimental Station during the rainy season of 2012. Each plant was harvested at 20–25 cm above ground and divided into 5 sections for sampling (base, center and tip of the pseudo-stem and lamina and petioles of the leaves), all 15 samples from each portion were dried, ground and incubated by duplicate within 2 Jersey-Reyna ruminally fistulated cows with results analyzed using the Marquadt algorithm. Values ranging from 18.38% to 47.43% were found for the percentage of soluble fraction, from 33.45% to 45.76% for the degradable fraction, from 1.65%/h to 7.51%/h for the degradation speed and from 64.14% to 82.86% for the potentially degradable percentage, depending on the plant part. According to the obtained results, pseudo-stems have better degradability values than leaves and may be used as a feed source on cattle diets where the material is available.

Table 1 (Abstr. W199). Ruminal degradability constants on a *Musa* sp. fodder bank

Plant section	Soluble fraction, %	Degradable fraction, %	Degradation speed, %/h	Potentially degradable fraction, %
Pseudo-stem base	47.43^{a}	35.43^{b}	0.07518^{a}	82.86^{a}
Pseudo-stem center	42.51^{a}	34.13^{b}	0.06512^{ab}	76.64^{a}
Pseudo-stem tip	44.77^{a}	33.45^{b}	0.05824^{abc}	78.22^{a}
Petiole	33.34^{b}	38.85^{ab}	0.06689^{ab}	72.19^{b}
Lamina	18.38^{c}	45.76^{ab}	0.01653^{d}	64.14^{c}

$^{a–c}$Indicate statistical differences ($P < 0.05$) within a column.

Key Words: degradability, *Musa*, fodder bank

W200 Purple prairie clover (*Dalea purpurea* Vent) reduces fecal shedding of *Escherichia coli* in pastured cattle.

Yuxi Wang*[1], Long Jin[1,2], Alan Iwaasa[3], Yuanheng Li[3,5], Zhong Xu[1], Mike Schellenberg[3], Xiuli Liu[1,6], Tim McAllister[1], and Kim Stanford[4], *[1]Lethbridge Research Centre, Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Department of Animal Science, Northeast Agricultural University, Harbin, China, [3]Semiarid Prairie Agricultural Research Centre, Agriculture & Agri-Food Canada, Swift Current, SK, Canada, [4]Alberta Agriculture and Rural Development, Lethbridge Agriculture Centre, Lethbridge, AB, Canada, [5]Institute of Grassland Research, Chinese Academy of Agricultural Sciences, Hohhot, China, [6]Inner Mongolia Academy of Agricultural and Animal Husbandry Sciences, Hohhot, China.*

A 3-year (2009–2011) grazing study was conducted to assess the effects of purple prairie clover (PPC, *Dalea purpurea* Vent) on fecal shedding of total *Escherichia coli* in cattle. Three pasture types were used in the experiment; bromegrass (Check), mixed cool season grasses with PPC (Simple) and mixed cool and warm grasses with PPC (Complex). Pastures were rotationally grazed (5, 10 and 10 cattle for Check, Simple and Complex) during a summer and fall grazing period. Purple prairie clover was grazed in summer at the vegetative/early flower stage and at the flower/early seed stage during the fall. Weekly and biweekly fecal samples were collected from each animal for enumeration of *E. coli* and chemical analyses. Forage samples were collected throughout the season for analysis. Condensed tannins (CT) were only detected in Simple and Complex pastures that contained PPC, with concentrations being higher in the fall than in the summer. Fecal counts of *E. coli* in cattle grazing Simple and Complex pastures linearly decreased ($P < 0.05$) over summer to fall in all 3 years, an outcome not observed in cattle grazing the Check pasture. Across the 3 grazing seasons, fecal *E. coli* was lower ($P < 0.05$) in cattle grazing Simple and Complex pastures than Check during the fall. During the fall, feces collected from cattle grazing the Check pasture had higher ($P < 0.05$) pH, N, NH_3-N, total volatile fatty acids (VFA) and branched-chain VFA, but a lower ($P < 0.05$) acetate: propionate ratio than that collected from cattle grazing Simple or Complex pastures. In a second experiment, 2 strains of *E. coli* were cultured in M9 medium containing 25 to 200 µg/mL of PPC CT. Growth of *E. coli* was linearly ($P < 0.01$) reduced by increasing levels of PPC CT. The scanning electron micrographs showed electron dense filamentous material associated with the outer membrane of *E. coli* cells exposed to CT. Incorporation of PPC into forage reduced the fecal shedding of *E. coli* from grazing cattle, likely due to the anti-*E. coli* properties of PPC CT.

Key Words: grazing pasture, purple prairie clover, *Escherichia coli*

W201 Yield, chemical composition, and efficiency of use of nitrogen by Marandu grass.

Tadeu Silva de Oliveira*[1], Ricardo Augusto Mendonça Vieira[1], Alberto Magno Fernandes[1], Danielle Ferreira Baffa[2], and José Carlos Pereira[2], *[1]Universidade Estadual do Norte Fluminense-Darcy Ribeiro, Campos dos Goytacazes, Rio de Janeiro, Brazil, [2]Universidade Federal de Viçosa, Campus Universitário, Viçosa, Minas Gerais, Brazil.*

The objective of this study was to evaluate the effect of 5 nitrogen levels on the yield and quality characteristics and the use efficiency of *Brachiaria brizantha* 'Marandu' grass. The soil, classified as a Red-Yellow Acrisol, was sampled at a depth of 0 to 0.20 m, for analyses. Soil analyses results were follows: pH in water = 5.6; CEC (T) = 8.17; H +Al = 4.21; sum of bases = 3.96; Ca = 2.8; Mg = 1.1 cmolc dm^{-3}; P = 66.6 mg dm^{-3}; K = 123 mg dm^{-3}; and 1.49 dag kg^{-1} organic matter. The area was prepared by plowing followed by disking two times and then fertilized with 300 kg/ha of N-P-K formulation (8-28-16). The *Brachiaria brizantha* 'Marandu' was sown at a rate of 3 kg/ha of pure viable seeds in a row spacing of 0.45m. Because of the uniformity of the area, we adopted a completely randomized design with four replicates. The treatments consisted of four levels of nitrogen (0, 60, 120, 180 and 240 kg/ha). Samples of the material were collected to analyze productivity variables, concentrations of neutral detergent fiber, crude protein and neutral detergent insoluble nitrogen, and in vitro dry matter digestibility. The nitrogen use efficiency, recovery of the applied nitrogen (RAN) and agronomic efficiency of the applied nitrogen (AE) were calculated. The statistical analyses involved the application of procedure PROC MIXED. To select the regression models the criteria utilized was Akaike's information criterion. Dry mass production increased ($P < 0.001$) by 1,624.67 (kg/ha) as the nitrogen doses were increased. The doses of nitrogen affected ($P < 0.05$) the concentrations of neutral detergent fiber (from 294.6 to 381.4 g/kg, in the leaf), crude protein (from 86.1 to 99.6 g/kg, in the leaf) and neutral detergent insoluble protein (from 402.9 to 396.2 g/kg CP, in the leaf). Nitrogen use efficiency increased, whereas RAN and AE were not affected ($P > 0.05$) by the nitrogen doses. In conclusion, nitrogen fertilization promotes improvement in productivity and chemical composition of Marandu grass, also improving the efficiency with which the grass utilizes the nitrogen.

Key Words: nitrogen use efficiency, nutritional characteristics, urea

W202 Effect of ensiling on kernel processing score in whole-plant corn silage harvested with varied processors and settings.

Luiz F. Ferraretto*[1], Gilson S. Dias Junior[1,2], Lucas C. de Resende[1,2], and Randy D. Shaver[1], [1]*University of Wisconsin, Madison, WI,* [2]*Universidade Federal de Lavras, Lavras, MG, Brazil.*

Two experiments were conducted to evaluate the impact of (1) ensiling on kernel processing score (KPS; % of starch passing through 4.75 mm sieve) of whole-plant corn silage (WPCS) of varied processors and settings; and (2) extended ensiling times on KPS of corn shredlage. In Experiment 1, samples from 2 self-propelled forage harvesters (SPFH) were collected at harvest. One SPFH was fitted with a conventional-type processor with greater (32% vs. 21%) roll-speed differential than normal. Samples collected were from 3 theoretical lengths of cut (TLOC; 19, 22 and 26 mm; 3-mm roll-gap setting) in 2 hybrid types (leafy and dual-purpose). The other SPFH was fitted with an intermeshing-disc processor and samples were from 3 TLOC (17, 19 and 26 mm) at 2 roll-gap settings (1.5 and 2.5 mm) in one hybrid. Samples for each processor and settings collected at harvest (12 samples total) were divided into 2 piles. The first pile was unfermented and analyzed for KPS in duplicate. The second pile was vacuum-sealed in 3 plastic bags and ensiled for 30 d. After fermentation, the 3 bags were composited and analyzed for KPS in duplicate. Data were analyzed using Proc Mixed of SAS with the fixed effect of fermentation and the random effect of sample. In Experiment 2, WPCS was harvested using a SPFH fitted with a shredlage processor with cross-grooved rolls set at 2.5 mm roll-gap and 32% roll speed differential and the SPFH set at 26 mm of TLOC. Samples were collected at harvest and vacuum-sealed in plastic bags and ensiled for 0, 30, and 120 d in triplicate. Samples from each bag were analyzed for KPS in duplicate. Data were analyzed using Proc Mixed of SAS with the fixed effect of ensiling time and the random effect of bag. In Experiment 1, ensiled samples had 10%-units greater ($P = 0.01$) KPS than the unfermented samples (60.1% vs. 50.2%, respectively). In experiment 2, WPCS ensiled for 120 d tended ($P = 0.07$) to have 7%-units greater KPS than 0 d (67.2% vs. 60.3%, respectively), but not 30 d (63.6%). These findings suggest that fermentation increases KPS.

Key Words: corn silage, ensiling time, corn silage processing score

W203 Morphological responses and chemical composition of Tanzania grass subjected to two pasture-management strategies.

Alberto Magno Fernandes*[1], Ricardo Augusto Mendonça Vieira[1], Tadeu Silva de Oliveira[1], and Fermino Deresz[2], [1]*Universidade Estadual do Norte Fluminense, Campos dos Goytacazes, Rio de Janeiro, Brazil,* [2]*EMBRAPA-Gado de Leite, Juiz de Fora, Minas Gerais, Brazil.*

The objective of this study was to evaluate the morphogenetic traits and chemical composition of Tanzania grass using a fixed resting period (FR) or according to 95% light interception (LI, by accuparLP-80) for managing Tanzania-grass pastures. As the LI of the herbage mass reached 95%, the animals were allowed to graze each paddock for 3 d; and (2) 30 d defoliation interval with a 3 d grazing period (FR). Experimental unit consisted of 11 paddocks grazed by 5 Holstein-Gir cows allowing for 2 replicates per defoliation treament in the first year with the same areas assigned to the same treatment the following year grazed by 4 Holstein-Gir cows per experimental unit. Six samples per paddock were taken on 2 crossed transect lines. Sward height, forage mass, and morphological components and their chemical composition were evaluated. The fixed effects were treatments (LI or FR), year (one or 2), and the interaction, whereas the random effect was area within treatment and the model was fitted as a mixed model with yearly repeated measures (using SAS). The interaction was significant only for senescent material ($P = 0.026$). The treatments did not affect pasture mass, height, and the proportion of stems in the pre- ($P = 0.455$, 0.715, 0.457, respectively) and post-grazing ($P = 0.199$, 0.160, 0.457, respectively) conditions. However, the proportion of leaves and crude protein content of the herbage mass were greater in LI than FR paddocks ($P = 0.031$, and 0.018, respectively). The concentration of other nutrients were not affected by treatments ($P > 0.05$). Therefore, LI might affect at least some quality traits of the paddock.

Key Words: grass, grazing system, sward height

W204 How does the chemical additive calcium oxide affect the in vitro growth of lactic acid bacteria and yeast?

R. A. de Paula, O. G. Pereira*, T. C. da Silva, K. G. Ribeiro, and H. C. Mantovani, *Universidade Federal de Vicosa, Vicosa, Minas Gerais, Brazil.*

Sugarcane has a high concentration of sucrose, which is metabolized by yeasts during ensiling producing high concentrations of ethanol. Calcium oxide (CaO) has been used as a silage additive resulting in a reduction of yeasts, less ethanol and improved DM recovery. The objective of this study was to evaluate the effect of CaO on the in vitro growth of lactic acid bacteria (LAB) and yeast in an aqueous-extract of sugarcane. The aqueous-extract of sugarcane was made by blending fresh sugarcane and distilled water in the proportion 5:1 for 5 min. The extract was filtered through layers of cheesecloth and sterilized at 121°C for 15 min. The microorganisms evaluated were one yeast (*Saccharomyces cerevisiae)*, and 3 LAB (*Lactobacillus brevis*, *L. plantarum*, and *Pediococcus pentosaceus*, isolated from alfalfa silage). The LAB and the yeast (initial population of 6 log cfu/mL) were grown in the sugarcane extract with levels of CaO: 0 (control), 0.5, 1, 1.5, and 2% (fresh basis) and incubated at 37 and 30°C for 48 h, respectively. Two tests were conducted, one with no pH adjustment and another adjusting the initial pH to 6 ± 0.13. The pH was evaluated before and after the incubation. In the first trial, the final pH of the control was 5.62 whereas the pH of the extracts containing CaO were higher than 11.6 for all microorganisms. In addition, there was inhibition of growth of all microorganisms at the concentration of 0.5% CaO. In the second test, the numbers of *L. brevis* and *P. pentosaceous* decreased from 7.94 and 7.82 log cfu/mL to 4.97 and 5.98 log cfu/mL with adding 1% CaO and no growth was observed for all LAB at 1.5% CaO, except for *L. brevis* (3.75 log cfu/mL at 1.5% CaO). Numbers of *S. cerevisiae* remained constant in all concentrations of CaO (average 7.82 log cfu/mL). The results indicate that the initial rise in the pH caused by the addition of CaO delays the fermentation process and thus controls the growth of yeasts and ethanol production.

In addition, other microorganisms other than those in the present study are responsible for lowering the pH in the early stages of fermentation.

Key Words: lactic acid bacteria, sugarcane silage, *Saccharomyces cerevisiae*

W205 Application of *Pediococcus pentosaceus*, *Pichia anomala*, and chitinase to high moisture alfalfa hay at baling: Effects on chemical composition and conservation characteristics.

Long Jin[1], Lysiane Dunière[1], Joseph P. Lynch[1], Eric Chevaux[2], Tim A. McAllister[1], John Baah[3], and Yuxi Wang*[1], *[1]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]Lallemand animal nutrition, Blagnac, France, [3]Best Environmental Technologies Inc., Edmonton, AB, Canada.*

The need to attempt to bale alfalfa hay at higher than optimum moisture level has increased in recent years due to unpredictable weather conditions driven by climate change. This often results in heating of the forage and a reduction in its nutritive quality. Although organic acids such as propionic acid (PA) are generally effective in preventing fungal growth in moist forage, the high rate of application and field handling costs coupled with environmental concerns makes hay producers reluctant to use them. The objective of this study was to assess the effects of applying *Pediococcus pentosaceus* (PED) and *Pichia anomala* (PIC) alone or in combinations with chitinase (CH) at baling on conservation characteristics of high moisture alfalfa hay. Alfalfa was harvested at the mid-bloom stage, wilted in the field to 73–77% DM (HMH) and baled without or with PED, PIC, PED+PIC, PED+CH, PIC+CH, and PA. Control (HMH), PED+CH, PIC+CH and PA and alfalfa hay baled at >85% DM (NMH) treatments were repeated over 3 yrs while other treatments were examined only within a single year. Interior temperature was recorded and samples were taken 90 d after baling for chemical and microbial assessment. Averaged over 3 yr, HMH had higher ($P < 0.001$) temperature degree days (>30°C, HDD) than NMH. The HDD of PED+CH was lower ($P < 0.001$) than that of other treatments in yr 1 and 3, but the max temperature achieved was lower ($P < 0.05$) for PED+CH as compared with other treatments only in yr 3. The NDF and NH_3-N contents were lower ($P < 0.001$) for PED+CH and PIC+CH, but WSC was higher ($P < 0.001$) for PED+CH than that of HMH and PA in yr 1. Mold and yeast counts did not differ among treatments, but CH^+PED and CH^+PIC had lower ($P < 0.05$) total culturable bacteria than other treatments in yr 1. The results indicated that *P. pentosaceus* and *P. anomala* combined with chitinase applied at baling have the potential to improve the conservation of HMH alfalfa by preventing spontaneously heating.

Key Words: high moisture alfalfa hay, additives, spontaneous heating

W206 Nitrogenous compounds and fermentation characteristics of king grass-cassava tops silages.

Tyrone Clavero*, *Universidad del Zulia, Maracaibo, Estado Zulia, Venezuela.*

To increase nitrogenous compounds and improve fermentation quality of King grass (*Pennisetum purpureum* × *Pennisetum typhoides*) silage, ensiling with *Manihot esculenta* was tested. The treatments for silage making were: 100% king grass (KG), 25% cassava (C):75% KG, 50% C:50% KG, 75% C:25% KG and 100% C. Fresh plant materials were chopped to 1 cm length, mixed according to treatments, ensiled in laboratory silos and stored a 25°C for 60 d. After opening silos, dry matter (DM), pH, total nitrogen content (TN), protein nitrogen (PN), soluble nitrogen (SN), PN/TN, ammonia nitrogen (AN), neutral detergent fiber nitrogen of total nitrogen (NNDF/TN), and acid detergent fiber nitrogen of total nitrogen (NADF/TN) were determined. The data were analyzed according to a completely randomized design with 3 replications, significance among mixing levels was determined by Tukey test. Silage DM increased ($P < 0.01$) with the inclusion of cassava in the mixtures, reaching the highest values (25.95%) with 75%. The introduction of cassava significantly ($P < 0.05$) decreased pH levels of the silages, showing the lowest value (3.88) with 100% cassava. The TN, PN, SN, and PN/TN contents increased linearly ($P < 0.05$) as the percentage of cassava increased in the mixtures. Proportion of neutral and acid detergent nitrogen (NNDF and NADF) to total nitrogen were not affected by treatments ($P > 0.05$). A small amount of AN was detected in silage, however, there were not significant differences ($P > 0.05$) between 50 and 100% mixing levels of cassava. In this study, the inclusion of cassava at the rate of 25% or more, increased nitrogenous compounds and improved silage fermentation.

Key Words: silage mixture, cassava, nitrogenous compound

W207 Relationship between grinding energy and chemical composition and NDF digestibility in forages.

E. Prinsloo[1], C. Anelich[1], E. Raffrenato*[2], W. A. van Niekerk[1], and L. J. Erasmus[1], *[1]Department of Animal & Wildlife Sciences, University of Pretoria, Pretoria, South Africa, [2]Department of Animal Sciences, Stellenbosch University, Stellenbosch, South Africa.*

Objectives of our work were to assess the relationship between chemical components and forage fragility, when measured as grinding energy (GrE), and between fragility and digestibility of forages. In Experiment 1 28 forages were analyzed for DM, total N, starch, NDF, ADF, ADL, 24 h ivNDFd, total phenols (TP) and non-tannic phenols (NTP). Initial particle size (IPS) was determined after pre-grinding the samples with a 2 cm fitted screen knife mill. The GrE was measured using an ultra-centrifugal and a hammer mill, fitted with a 1 mm screen and final particle size (FPS) was determined. Difference between the 2 mills was determined using a *t*-test for 2 dependent samples. Multiple regressions were used to best predict observed GrE measurements from the set of parameters obtained. Energy measurements ranged from 34.9 to 356 J/g with the ultra-centrifugal mill consistently using less energy than the hammer mill ($P < 0.001$). The independent variables selected were able to explain 77 to 89% of the GrE and IPS consistently accounted for most of the variation, showing the difficulty of having a homogenous IPS. Forage resistance to grinding did not depend on the fiber quantity alone, but on the different quality and interaction of its components. In Experiment 2 GrE was measured on 34 forages, including corn silages, alfalfa and eragrostis hays. In vitro NDF digestibility was obtained from 0 to 240 h. Correlations between GrE and NDFd at various time points and NDF rates of digestion (kd) were calculated and the best predictors among fiber, its components and digestibility values were selected. The results showed high negative correlations of NDFd and kd with GrE ($P < 0.001$). In particular 18 and 24 h NDFd had the highest correlation values (−0.65 and −0.77) across samples and species, showing the important relationship between fragility and fiber digestibility. The IPS, FPS, cellulose (ADF-ADL) and kd explained up to 60% of the variation. Grinding energy can be used to rank forages to account for different fragility, but IPS represents a limitation. Forages with similar peNDF may then be adjusted to account for different GrE and fragility.

Key Words: forage fragility, grinding energy, particle size

W208 The effect of a bacteria inoculant on fermentation and aerobic stability of a brown-midrib and conventional corn silage.

Zhenzhen Li*[2,1], Daniel Undersander[1], and David Combs[1], [1]*University of Wisconsin, Madison, WI,* [2]*China Agricultural University, Beijing, China.*

Objective of this study was to test the effect of a forage inoculant (Bonsilage corn, Schaumann Inc., Mendota Heights, MN) containing *Lactobacillus buchneri,* (DSM16774) and *Lactobacillus plantarum,* (DSM12837) on fermentation and aerobic stability of corn silage. Brown-midrib and conventional corn (33.8% and 37.0% DM, respectively) were ensiled untreated or treated with inoculant at 5×10^5 cfu/g of fresh forage in bags. Data were analyzed by proc GLM (SAS v.9.4) as a 2 × 2 factorial with inoculant and corn silage as main effects. Ninety days after ensiling, the silages showed a similar response to the inoculant, except that BMR silage had a higher content of acetic acid and ethanol than conventional corn silage. The treated corn silages had less lactic acid compared with untreated silages and a greater concentration of acetic acid. The pH of treated silages was higher than untreated silages because of the decreased lactic acid and higher content of acetic acid. Untreated corn silages increased significantly in temperature after 95h of exposure to air, while treated silages did not increase in temperature during 168h of monitoring. Inoculating corn silage with 5×10^5 cfu/g of the bacteria inoculant resulted in a more hetero fermentation and markedly improved the aerobic stability of corn silage.

Table 1 (Abstr. W208). The chemical composition and aerobic stability of corn silage[1] after 90 d of ensiling

	BMR		CS		*P*-value	
Item	Control	Treated	Control	Treated	Inoculant	Silage
DM, % as fed	32.8	31.2	37.5	36.2	0.92	<0.001
pH	3.80	4.23	3.80	4.20	<0.001	0.37
Lactic acid, % of DM	4.75	1.04	4.76	1.18	<0.001	0.57
Acetic acid, % of DM	1.69	3.81	1.58	3.17	<0.001	0.01
Total acids, % of DM	6.44	4.88	6.34	4.35	<0.001	0.12
Ethanol, % of DM	0.88	0.81	0.39	0.56	0.37	<0.001
L/A Ratio	2.82	0.27	3.02	0.37	<0.001	0.11
Aerobic stability[2]	98 h	ND	95 h	ND		

[1]BMR = brown-midrib; CS = conventional corn silage; treated with 5×10^5 cfu/g of inoculant.

[2]Hours before temperature of silage increased 2? above ambient temperature.

Key Words: inoculant, buchneri, silage

W209 Nutritional evaluation of leaves, twigs, and fruits of *Gmelina arborea* as feed resource for ruminants.

Ronke Y. Aderinboye*, Olukayode O. Showunmi, Chryss F. I. Onwuka, and Victoria O. A. Ojo, *Federal University of Agriculture, Abeokuta, Ogun, Nigeria.*

Browse species have played major roles as feed alternatives particularly when grasses are of low nutritive quality serving as sources of crude protein in the tropics. Although, the leaves of some browses have been harvested for small ruminant feeding, the pods or fruits have not been extensively utilized. In this study, the nutritional value of the leaves, twigs and fruits of *Gmelina arborea* was evaluated through determination of their chemical composition, in vitro gas production and digestibility in a completely randomized design. Five hundred grams (n = 6) each of fresh *Gmelina* leaves, twigs and fruits was harvested from the different tree stands and oven-dried to constant weight for dry matter determination. Dried samples were used for chemical analysis and in vitro studies. In vitro digestibility of leaves, twigs and fruits and their combinations were evaluated. Statistical analyses was done using one-way ANOVA procedure and means separated using Duncan's multiple range test. Results revealed that *Gmelina* leaves had higher dry matter (DM) and crude protein (CP) contents (39.07%DM; 15.54%CP) than the twigs (35.26%DM; 10.63%CP) and fruits (34.36%DM; 10.42%CP). Leaves and twigs were higher in calcium and phosphorus content than the fruits. Cell wall fractions were higher in the twigs than the leaves and fruits. The fruits had the highest nitrogen free extract content, higher ($P < 0.05$) in vitro net gas production, dry matter degradability (63.4%) and short chin fatty acid content. The gas produced from degradable fraction; b was lower in twigs relative to the leaves and fruits while rate of degradation; c was similar for the leaves, twigs and fruits. The combination of leaves, twigs and fruits showed better nutritive value than sole twigs. Chemical composition of *Gmelina* leaves, twigs and fruits suggests them as a nutritive feed resources for ruminants. The leaves and fruits can serve as potential sources of crude protein and fermentable carbohydrate while the twigs can be a good source of fiber.

Key Words: *Gmelina*, aerial part, ruminant

W210 Comparison of Ankom filter bag types for the determination of acid and neutral detergent fibers.

Chris D. Teutsch, Brian T. Campbell*, and W. Mac Tilson, *Virginia Tech, Blackstone, VA.*

In the mid-1990s Ankom Technology developed a filter bag system for fiber determination. This system reduced labor and costs and simplified the operation. More recently, a new filter bag (F-58) was developed. This bag possesses reduced pore size and has been directed toward end users who utilize a finer grind size to support near infrared spectroscopy (NIRS). Little work has compared the older (F-57) and newer (F-58) bags. The primary objective of this study was to compare F-57 and F-58 filter bags for determination of ADF and NDF. Four forage species were collected, dried, and sequentially ground to pass through a 2 and 1 mm screen. These species included orchardgrass (*Dactylis glomerata* L.), bermudagrass (*Cynodon dactylon* L.), white clover (*Trifolium repens* L.), and sericea lespedeza (*Lespedeza cuneata* L.). Acid and NDF were determined using the Ankom 200 Fiber Analyzer. Trial x treatment interactions occurred for ADF ($P < 0.01$). Therefore data are presented by trial. Within trials, significant forage x filter bag interactions occurred ($P < 0.01$). In general, the use of the F-58 bag decreased ADF concentrations in all forages except bermudagrass ($P < 0.01$) and had no effect on NDF concentrations ($P > 0.05$). However, the impact on ADF concentrations was not consistent across forage species. Bermudagrass ADF concentrations did not differ between bags for either trial and orchardgrass differed in Trial I only where the % ADF was decreased from 38 to 35% for F-57 and F-58 bags respectively ($P < 0.01$). At the current time our data indicate that the inconsistent performance across forage species and the increased cost does not justify the use of the F-58 bags.

Key Words: fiber, forage, detergent

W211 Effect of corn planting density on yield and nutritional quality of corn silage when planted after ryegrass harvested for silage.

Gonzalo Ferreira*[1], Paul Hammock[2], Mary Hammock[2], Issac Hammock[2], and Nathan Hammock[2], [1]*Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, VA,* [2]*Hammock Dairy Inc., Museville, VA.*

The objective of this study was to determine the effect of planting density on yield and nutritional composition of corn silage in a 2×-crop

Table 1 (Abstr. W211). Effect of corn planting density (plants/ha × 1000) on yield and nutritional quality of corn silage

	Nonirrigated				Irrigated					$P <$		
	55	70	85	100	55	70	85	100	SEM	I	D	I×D

rotation system. The study was performed at an 800-cow dairy farm located in south Virginia. Corn was planted in experimental plots within 2 cornfields, one of which was irrigated with a central-pivot irrigating system. Planting densities were 55, 70, 85, and 100 seeds/ha (×1000) in 4 replicates per cornfield (2 fields x 4 densities x 4 replicates = 32 plots). Plots were 12 25-m long rows separated by 76 cm. The irrigated cornfield was watered with 100 mm of water before tasseling. At the early-dent stage of maturity, 10 plants from each plot were cut (15 cm above ground), weighed, chopped, mixed thoroughly, and ensiled in bags for 60 d. Nutritional composition was performed by wet chemistry. The statistical model included the effects of irrigation (I), density (D), the 2-way interaction (I×D), block, and field-by-block interaction. No interactions between irrigation and planting density were observed for any of the variables of interest. Dry matter yield was not affected by planting density. Increasing planting density reduced plant biomass. Planting density did not affect the concentrations of CP, NDF, ADF, ADL, and starch, but tended to affect IVNDFD quadratically. In conclusion, under a double-crop rotation system increasing planting density of corn does not increase DM yield and also does not affect the nutritional composition of corn silage when harvested at an early stage of maturity.

Key Words: plant density, corn silage, nutritional quality

Growth and Development II

W212 Sodium butyrate induces adipocytic differentiation of porcine mesenchymal stem cells. Benedetta Tugnoli[1], Chiara Bernardini[1], Monica Forni[1], Andrea Piva[1], Chad H. Stahl[2], and Ester Grilli*[1], *[1]DIMEVET, University of Bologna, Ozzano Emilia, Bologna, Italy, [2]Laboratory of Developmental Nutrition, College of Agriculture and Life Sciences, North Carolina State University, Raleigh, NC.*

Sodium butyrate (SB) has been shown to affect the differentiation of mesenchymal stem cells (MSC) through the activation of different transcriptional pathways. The aim of this study was to investigate the effects of SB on the proliferation and differentiation potential of porcine bone marrow-derived MSC. Third passage MSC were verified by flow cytometry to be > 95% CD105$^+$, CD90$^+$, CD44$^+$, CD45$^-$, and CD34$^-$. Cells were cultured in either a low glucose DMEM+10% FBS (BM), BM + 2.5 m*M* SB (SB2.5) or BM + 5 m*M* SB (SB5) in a randomized complete block design. Data were analyzed with 1-way ANOVA followed by linear and quadratic contrasts and the treatments had 6 independent replicates (n = 6). Cell proliferation was significantly decreased by both SB2.5 and SB5 after 48h (−55% on average, $P = 0.001$) and 72h (−63% on average, $P = 0.001$). To assess the impact of SB on spontaneous differentiation, MSC were cultured for 27 d, with complete media change every 3 d. At 3 d, SB treated cells showed changes in morphology compared with controls, from spindle-shaped fibroblast-like to larger sail-shaped cells with intracellular shiny droplets. At 27d, cells were stained for osteocytic (Alizarin Red), chondrocytic (Alcian Blue) and adipocytic (Oil-Red-O) differentiation. No terminal differentiation was detected in MSC cultured in the BM alone, while accumulated lipids were clearly stained by Oil-Red-O in MSC cultured in the presence of SB. The phenotypic changes observed from 3 to 27 d were supported by a change in the pattern of gene expression, analyzed by semiquantitative real-time PCR. At 3 d, both SB2.5 and SB5 increased mRNA expression of peroxisome proliferator-activated receptor gamma (PPARg; $P = 0.05$, linear effect) and decreased osteocalcin (OC; $P = 0.02$, quadratic) and aggrecan ($P = 0.04$, quadratic) mRNA levels compared with untreated cells. At 27d, there was an increase in PPARg mRNA level ($P = 0.02$, linear) and decreased OC and aggrecan ($P = 0.02$ and $P = 0.002$, respectively, both linear and quadratic) with SB treatment. To conclude, our data suggest that SB promotes the differentiation of porcine bone marrow-derived MSC toward an adipocytic lineage.

Key Words: sodium butyrate, mesenchymal stem cells, pig

W214 Effect of butyrate on inflammatory and oxidative gene markers in porcine IPEC-J2 intestinal epithelial cells. Hui Yan* and Kolapo Ajuwon, *Purdue University, West Lafayette, IN.*

The small intestine is important for nutrient digestion and absorption as well as immune function. Newborns are sensitive to pathogen and diet-induced inflammation, which influences development of intestinal function. Butyrate has been shown to possess immune modulatory effect in various cells and tissues. But its effect on LPS-induced inflammation in the porcine IPEC-J2 intestinal cell model are unclear. Therefore, we investigated the effects of butyrate on expression of cytokines and metabolic gene markers in this cell line. A randomized complete block design was used. Main effect was the different concentrations of butyrate and replicate was used as the blocking factor. There were at least 6 replicates per treatment. Data were analyzed using PROC GLM. Gene expression was determined by RT-PCR. High concentration of butyrate (1mM) significantly increased ($P < 0.05$) LPS-induced TNFα, IL-6, IL-8 and MCP1 expression, and this indicated that this concentration was harmful to the cells. However, lower concentrations of butyrate (10 μ*M* to 100 μ*M*) significantly decreased ($P < 0.05$) LPS-induced MCP-1 and TLR4 expression (100 μ*M* concentration) and IL-1β (50 μ*M*) compared with control. Butyrate treatment also significantly increased expression of metabolic genes such as ACO (100 μ*M*) and PPARα (10 to 100 μ*M*), indicating that butyrate increases energy expenditure. LPS treatment significantly reduced ACO expression and eliminated the effect of butyrate on ACO and PPARα expression. Taken together, butyrate exhibited limited anti-inflammatory effect in IPEC-J2 cells, but strongly enhanced oxidative capacity through induction of oxidative genes.

Key Words: IPEC-J2, butyrate, inflammation.

W215 MicroRNA exert a role in the process of arginine promoting rat mammary gland development. Lianmin Chen*[1], Liangyu Hu[1], Mengzhi Wang[1], J. J. Loor[2], Hongrong Wang[1], and Lihuai Yu[1], *[1]College of animal science and technology, Yangzhou University, Yangzhou, Jiangsu Province, China, [2]University of Illinois, Urbana, IL.*

Except for its use during milk protein synthesis, extra arginine (Arg) might exert other unknown biological or metabolic functions in the mammary gland. Previous work focused on the effect of Arg on bovine mammary epithelial cell casein production showed that 556.00 mg/L Arg (2 × the basal level) in the medium elicited the greatest stimulation of casein and mTOR-related genes. Whether Arg regulates cell development via effects on microRNA (miR) is unclear. The specific objective was to determine if miR expression in rat mammary tissue are altered by feeding 2 × Arg. Twelve pregnant littermate Wistar rats were randomly divided into 2 groups and experimental diets designed according to the AIN-93G purified diets. The Arg concentration was 12.8 g/kg in the Arg group while in the Control was 6.4 g/kg. A total of 21.62 g/kg glutamic acid was added to the Control group to keep diets iso-nitrogenous. At 17 d postpartum rats were killed and the mammary tissue harvested. Histological changes were measured by paraffin section, and mammary acinar area measured using digital imaging system software (MC30). Statistical analysis was carried out via *t*-test using SPSS16.0. Differentially expressed miR were measured using Solexa miR-Seq and verified by RT-qPCR. The miR target genes were analyzed using SBC prediction wizard (TargetScan, miRanda, PicTar, MirTarget2, PITA supported). Gene functions were analyzed via DAVID 6.7 and GO analysis. The mammary acinar area was significantly greater ($P < 0.001$) due to Arg (452.71 um^2) compared with the Control (388.68 μm^2). A total of 8 miR had greater ($P < 0.05$, fold-change > 2) expression in Arg compared with the Control. Among those upregulated, miR-1-3p plays a role in the control of cellular component synthesis; miR-133a-3p and miR-133a-5p play a role in the regulation of cell developmental process; miR-133b-3p exerts control of transporter activity and enzyme activity; and miR-206-3p has an important role in the regulation of cellular processes. There was no clear cellular function prediction for the upregulated miR such as miR-149-5p, miR-1b and miR-486. Results suggest dietary Arg might promote mammary tissue development through altering miR expression. The exact regulatory mechanisms need further investigation.

Key Words: micro RNA, arginine, development of mammary

W216 Poor maternal nutrition decreases longissimus dorsi cross sectional area of fetal offspring at d 45 of gestation. Joseline S. Raja*, Sambhu M. Pillai, Amanda K. Jones, Maria L. Hoffman, Katelyn K. McFadden, Kristen E. Govoni, Steven A. Zinn, and Sarah A. Reed, *Department of Animal Science, University of Connecticut, Storrs, CT.*

Poor maternal nutrition during gestation results in long-term postnatal changes in muscle morphometrics, muscle mass and fiber number, and intramuscular adipose deposition of the offspring. Thus, we hypothesized that under- and over-feeding ewes during gestation would inhibit fetal muscle development. To test this hypothesis, 82 pregnant Western Whiteface ewes were individually housed and fed 100%, 60%, or 140% of NRC requirements for TDN beginning at d 30.2 ± 0.2 of gestation. Offspring (CON, RES, and OVER, respectively), were necropsied at d 45, 90, and 135 of gestation and within 24 h of birth. At d 45 of gestation ($n = 7$ ewes per diet), the triceps brachii (TB), semitendinosus (STN), and longissimus (LM) muscles were weighed. The LM were frozen and cryosectioned to determine muscle fiber cross sectional area (CSA) and the number of muscle fibers per μm^2. Muscle weight was expressed as percent of fetal weight and data were analyzed using the MIXED procedure of SAS, with maternal diet as the main effect. Fetal weight tended to be less in OVER compared with CON ($P = 0.07$; CON: 11.0 ± 0.6 g, RES: 10.1 ± 0.5 g, OVER: 9.2 ± 0.5 g). No differences in the weight of TB, STN, or LM due to maternal diet were detected ($P \geq 0.53$). The CSA of LM ($n = 6$ fetuses per treatment [2 fetuses per ewe]) from OVER and RES were smaller compared with CON ($P \leq 0.008$; CON: 287.1 ± 3.2 μm^2; RES: 223.4 ± 2.9 μm^2; OVER: 254.9 ± 3.2 μm^2). However, the number of fibers per μm^2 of LM was not different due to maternal diet ($P = 0.47$). Smaller muscle fiber CSA could result from inadequate protein accretion, decreased fusion of myogenic precursor cells, or both. Similar fiber numbers suggest increased interfibrillar space, which may lead to increased connective tissue formation. In conclusion, poor maternal nutrition during early gestation alters the formation of muscle fibers as early as d45, potentially resulting in decreased muscle mass at birth.

Key Words: muscle, maternal nutrition

W217 The effects of maternal under- and over-feeding on muscle development of lambs as determined by RNA-Seq analysis. Maria L. Hoffman*, Kristen N. Peck, Jill L. Wegrzyn, Sarah A. Reed, Steven A. Zinn, and Kristen E. Govoni, *University of Connecticut, Storrs, CT.*

We previously reported that both maternal under- and over-feeding altered muscle cross sectional area and lipid content in offspring. Therefore, we hypothesized that poor maternal nutrition would alter key pathways and novel genes involved in muscle development of lambs. Ewes ($n = 3$/treatment) were fed 100% (CON), 60% (RES), or 140% (OVER) of NRC requirements for TDN and one twin lamb per ewe was euthanized within 24 h of birth and muscle tissue was collected for RNA-Seq analysis. RNA was prepared into cDNA libraries and sequenced using the Ion Torrent Proton. Data were aligned to the *Bos taurus* (Btau_4.61) and *Ovis aries* (Oar_V.3.1) reference genomes using Tophat and expression evaluated with Cufflinks. Differential gene expression was determined using the Benjamini-Hochberg multiple testing correction ($q \leq 0.05$). Using the ovine and bovine references, 10 and 35 differentially expressed genes were identified, respectively. The differentially expressed genes are involved in metabolic regulation, hypertrophy, nutrient uptake, and protein turnover. Using the ovine reference, compared with CON, expression of *myogenic factor 6,* and *myostatin* increased 1.7 and 2.0-fold in OVER ($q \leq 0.05$). *BTG family member 2*, *ankyrin repeat domain 1,* and *phosphoserine phosphatase* expression decreased 1.5, 2.5, and 3.1-fold, respectively in OVER ($q \leq 0.05$). Expression of *FHJ murine osteosarcoma viral oncogene homolog* (*FOS*) was reduced 1.6-fold in RES compared with CON ($q = 0.05$). Using the bovine annotation, compared with CON, *arrestin domain containing 2* and *AT rich interactive domain 5B* expression were 3.5 and 2.9-fold greater, respectively in OVER ($q = 0.05$). Expression of *PPARγ coactivator 1 α*, *regulator of G-protein signaling 16*, *thrombomodulin*, and *jun B proto-oncogene* were reduced ≥2-fold ($q \leq 0.05$) in OVER. *Tripartit motif containing 63*, *FOS* and *suppressor of cytokine signal 3* expression were reduced 1.4, 1.6, and 2.8-fold, respectively in RES ($q \leq 0.05$). In conclusion, although both under- and over-feeding had similar effects on offspring muscle development, based on gene expression, the mechanisms through which this occurs appear to be different.

Key Words: transcriptome, muscle, sheep

W218 Muscle fiber hypertrophy is associated with increased expression of key transcriptional and epigenome regulatory genes. Yue Lu, Jennifer S. Bradley, Sarah R. McCoski, Adam J. Geiger, R. Michael Akers, Alan D. Ealy, and Sally E. Johnson*, *Virginia Polytechnic Institute and State University, Blacksburg, VA.*

Early neonatal nutrition affects the rate and extent of muscle growth and fiber hypertrophy in calves. The objective of the experiment was to examine the effect of caloric intake on LM, infraspinatus (INF) and semitendinosus (ST) fiber cross-sectional area (CSA), fiber type and muscle gene expression in neonatal heifers. Newborn Holstein heifers were assigned to a high nutritional plane (HNP; 28% CP, 25% fat, $n = 5$) or low nutritional plane (LNP; 20% CP, 20% fat, $n = 5$) milk replacer diet for 8 wks. Calves were pair-fed equivalent amounts of grain (25% CP, 4% fat) beginning at wk 5. Caloric intake supported ADG of 220 g/d and 771 g/d for the LNP and HNP heifers, respectively. Heifers were euthanized at 8 wks of age and samples of LM, INF and ST were collected. Gene expression was measured by RT-qPCR. Data were analyzed by ANOVA for the main effect of diet, muscle and their interaction with post-hoc Tukey separation of means. Plane of nutrition differentially affected muscle fiber hypertrophy with HNP LM and ST fiber cross-sectional area (CSA) larger ($P < 0.05$) than LNP. No differences in CSA were noted between HNP and LNP INF. The smaller LNP LM and LNP ST sizes were reflected by greater ($P < 0.05$) numbers of fibers/mm^2. *Pax7* expression is 38% greater ($P < 0.05$) in HNP LM than LNP LM and *BTG2*, *E2F6* and *myogenin* mRNA amounts are 60% greater ($P < 0.05$) suggesting that muscle stem and progenitor cells are active and supplying the growing fiber with myonuclei. Messager levels of *IGF-I* are greater ($P < 0.05$) in HNP LM than LNP LM further supporting increased fiber hypertrophy. No differences ($P > 0.05$) were observed in the protein degradation enzyme genes, *FOX03*, *atrogin* or *MuRF*, indicating that protein accretion is due to elevated protein synthesis. Diet can serve as an epigenetic modifier of phenotype. Calves maintained on the LNP diet expressed lower ($P < 0.05$) amounts of the histone deacetylase genes, *HDAC1* and *HDAC3*, and the lysine-specific demethylase, *KDM2A,* in the LM than their HNP counterparts. Altered expression of epigenome modifiers provides evidence for diet-induced changes in the muscle fiber chromatin architecture that may contribute to long-term metabolic responses.

Key Words: skeletal muscle, hypertrophy, epigenome

W219 Myogenic regulatory factors are increased in bovine satellite cells by polyamines and their precursor amino acid ornithine.

Kara J. Thornton[2], Stephen C. Tamm*[1], Samantha L. Faulkner[1], and Gordon M. Murdoch[1], [1]*University of Idaho, Moscow, ID,* [2]*University of Minnesota, Minneapolis, MN.*

Skeletal muscle is unique in its growth and developmental characteristics in that normal hypertrophy is carried out through activation and fusion of satellite cells (SC) surrounding individual muscle fibers. These SC are responsive to signals from their extracellular environment especially growth factors and nutrients. Polyamines (PA) are a class of small, positively charged molecules that favorably affect growing cells through somewhat undefined physiological mechanisms. Polyamines exist in mammalian species primarily as ornithine derivatives. Abnormalities in polyamine metabolism are associated with irregular development in mammals emphasizing their critical role as regulators of growth. To test the direct effect of PA on skeletal muscle development, primary bovine SC cultures were differentiated in media containing either methionine (10 m*M* control 1), ornithine (10 m*M*), putrescine (5 m*M*), spermine (0.5 m*M*), or no supplement (control 2). SC were differentiated as a monoculture (MC) as well as in coculture (CC) alongside preadipocytes isolated from bovine intramuscular fat depots. This coculture provided a more realistic environment of that which would surround skeletal muscle and impact SC activity. Following treatment, SC were isolated from CC using laser micro-dissection technique. SC populations were analyzed for temporal expression of the myogenic regulatory factors (MRF) *MyoD*, *Myf5*, and *Myf4* (myogenin) to identify differentiating cells along with the genes *Pax7* and *Spry1* representative of quiescent cells. Protein isolation and Western Blot analyses were also performed to measure protein expression in a temporal manner. Exposure of SC's to PA in CC resulted in upregulation of *MyoD* ($P = 0.05$), *Myf5* ($P = 0.02$), and *Myf4* ($P = 0.09$) and attenuation of *Pax7* ($P = 0.10$) and *Spry1* ($P = 0.07$). Statistics generated in SAS (Cary, NC) using PROC MIXED procedure. Treatment was included as a fixed effect. These results suggest that ornithine metabolism and polyamine metabolites can affect bovine skeletal muscle myogenesis, and may therefore be promising as candidates for natural means of promoting growth of lean tissue in cattle.

Key Words: polyamine, satellite cell, myogenic regulatory factor

W220 Muscle gene expression patterns in finishing steers supplemented with dietary Amaize *(Aspergillus oryzae* extract).

Daniel E. Graugnard*[1], Kristen M. Brennan[1], Allison C. Smith[1], Sonia J. Moisá[2], and Juan J. Loor[2], [1]*Alltech Center for Animal Nutrigenomics and Applied Animal Nutrition, Nicholasville, KY,* [2]*Department of Animal Sciences, University of Illinois, Urbana, IL.*

We evaluated the effect of dietary *Aspergillus oryzae* extract on gene expression profiles in the *Longissimus lumborum* from finishing steers. Cross-bred (Simmental × Angus) yearling steers were randomly assigned to one of 2 groups (n = 10/treatment). From receiving until d21, starter and step-up diets were fed to acclimate steers to a traditional mid-west finishing diet. Steers were then fed *ad libitum* to meet or exceed NRC requirements until slaughter (d140): basal diet with or without 5 g/hd/d of *A. oryzae* extract (Amaize, Alltech Inc., Nicholasville, KY) containing α-amylase (AMZ). On d90, *Longissimus lumborum* tissue was collected for gene expression analysis. Serum was collected at d 40, 90 and 140 for analysis of metabolites (BHBA, glucose, insulin, urea). Data from blood metabolites was analyzed using a mixed model. Gene expression was profiled using the Affymetrix Bovine Gene 1.0 ST Array. Performance did not differ between treatments. Hierarchical clustering indicated a treatment effect ($P < 0.05$) of the AMZ-supplemented group compared with the control. A total of 1148 genes were differentially affected ($P < 0.05$; 430 upregulated; 718 downregulated) between treatments. The genes affected, enriched ($P < 0.05$) and activated several pathways, including IGF-1 signaling, insulin receptor signaling, valine degradation, and VDR/RXR activation. The pathways activated are involved in the regulation of muscle development and growth. Blood metabolites indicated greater levels of BHBA, urea and insulin ($P < 0.05$) at d40 in AMZ-supplemented steers. Only insulin remained at a greater concentration in the AMZ group than the control throughout the experiment. In conclusion, AMZ supplementation in the finishing diet affects muscle gene expression and insulin metabolisms, potentially causing a positive effect for the development of skeletal muscle in finishing steers.

Key Words: amylase, muscle, cattle

W221 Investigation of effects of maternal nutrition intensification and fetal sex on development of skeletal muscle of bovine fetuses.

Tathyane RS Gionbelli*[1,2], Polyana P. Rotta[2], Cristina M. Veloso[2], Marcos I. Marcondes[2], Sebastiao C. Valadares Filho[2], Bruno C. Carvalho[3], Joao V. R. Lovatti[2], Camila S. Cunha[2], Marco A. S. Novais[2], Marcio S. Duarte[2], and Mateus P. Gionbelli[1], [1]*University of Lavras, Lavras, Minas Gerais, Brazil,* [2]*University of Viçosa, Viçosa, Minas Gerais, Brazil,* [3]*Embrapa Dairy Cattle, Brazilian Corporation of Agricultural Research, Coronel Pacheco, Minas Gerais, Brazil.*

This study aimed to evaluate the effects of maternal feeding level (MN) and fetal sex (FS) on skeletal muscle development of bovine fetuses at different stages of gestation (SG). Fourty-4 multiparous, dry Holstein × Gyr cows with average initial body weight of 480 ± 10 kg were fed either restricted feeding at 1.15% of body weight (CO, n = 24) or ad libitum (ON, n = 20) with the same diet (93% corn silage and 7% concentrate; 111 g/kg of CP and 674 g/kg of TDN). Eleven cows of each dietary treatment were slaughtered at 139, 199, 241 and 268 d of gestation. Fetuses were necropsied to evaluate the development of skeletal muscle. Data were analyzed by MIXED procedure of SAS considering the fixed effects of MN, FS and SG (2 × 2 × 4 factorial). Modifications in gene expression of skeletal muscle of fetuses were observed in function of MN and FS despite the lack of effect of MN ($P = 0.330$) and FS ($P = 0.518$) on fetal weight. The muscle mRNA expression of myogenic markers β-catenin and MyoD was greater in male than in female fetuses, as well the expression of all adipogenic markers evaluated (Zfp423, C/EBPα and PPARγ), 3 of the 4 fibrogenic markers evaluated (Collagen I, Collagen III and Fibronectin) and the number of myocytes in muscle. Marginal effects of MN were observed on mRNA expression as well on the phenotypic indicators of myogenesis, adipogenesis and fibrogenesis. At the mid-gestation (139 DG) β-Catenin, Zfp423 and PPARγ expression and myocytes number were greater in ON than in CO fetuses and in males than in females, but these differences were not observed at subsequent SG. Fat content of fetal muscle was not affected by MN and FS. Almost all myogenic, adipogenic and fibrogenic markers were less expressed in late gestation than in mid-gestation, however collagen deposition, fat and crude protein content of fetal muscle were greater at late gestation than in mid-gestation. The MN changed gene expression of myogenic, adipogenic and fibrogenic markers at mid-gestation (greater in ON than in CO) but some compensatory gene expression made the effect of MN not significant in late gestation.

Key Words: adipogenesis, fetal programming, fibrogenesis

W222 High-energy diet reduced myogenic gene expression of Hanwoo steers fed to three different endpoints.

K. Y. Chung*, S. S. Chang, H. S. Kim, E. M. Lee, H. J. Kim, and H. S. Kang, *Hanwoo Research Institute, NIAS, Pyeongchang, Korea.*

High energy diets have been used for enhancing marbling fat in high quality beef cattle. However, this has been associated with reduced yield grade when the steers were fed for long-term. The aim of this experiment was to determine the effect of additional 3% TDN (77%) diet compared with control diet (74%) on the level of adipogenic and myogenic gene expressions at 3 different endpoints. A 2 × 3 factorial arrangement (High, Control, and 26, 28, 30 mo endpoints) was used to feed 48 Hanwoo steers. Four steers were fed in same pen and 12 pens were used for treatment. Longissimus dorsi (L.D.) muscle was collected within 10 min of harvest for analysis of PPAR?, SCD, GLUT4, MHC1, MHC2X, and myogenin mRNA abundance. Real-Time RT-PCR was used to measure the quantity of respective mRNA relative to a ribosomal protein subunit 9 (RPS9) mRNA. Data were analyzed as a completely randomized design using the MIXED model, each treatment performed in triplicate. Difference between control and treatments were determined using the LSD procedure. Overall ADG did not differ between high-energy diet or control diet ($P > 0.05$). ADG tend to increase in high-energy diet at 30 mo endpoint compared with control diet ($P = 0.09$). Marbling score and carcass weight were greater at 30-mo endpoint than at other endpoints ($P < 0.05$). Yield grade was not different among endpoints ($P > 0.05$). Percentage of protein in L.D. muscle tend to decrease at 30 mo endpoints ($P = 0.09$). Real-time quantitative PCR revealed that the mRNA content of MHC2X in muscle from high-energy diet cattle decreased (diet x endpoint, $P < 0.05$) as compared with the control group. There was no interaction for MHC1 gene expression among 3 endpoints ($P > 0.05$). These data indicated that high-energy diet decreased relative mRNA level of MHC2X on long-fattening periods. These fast-glycolytic genes may affect muscle protein composition in Hanwoo L.D. muscle.

Key Words: Hanwoo, myogenic, gene expression

W223 α-Solanine induces myogenesis of bovine satellite cells isolated from semimembranosus and longissimus muscle tissue.

K. Y. Chung[1], J. K. Kim*[2], H. S. Kim[1], E. M. Lee[1], H. J. Kim[1], S. S. Chang[1], and H. S. Kang[1], [1]*Hanwoo Research Institute, NIAS, Pyeongchang, Korea,* [2]*Animal and Food Science, Texas Tech University, Lubbock, TX.*

Solanine is a glycoalkaloid compound found in leaves, fruit and tubers of potato, tomato, and eggplant. Solanine poisoning was reported in various animal models such as mice, rabbit, and chicken. However, it is used as a treatment for human asthma. Some medicine used for treating human asthma has been used to induce myogenesis of bovine skeletal muscle. We hypothesized that α-solanine may affect myogenesis of bovine satellite cells isolated from different muscle depots. Bovine satellite cells were pronase-liberated from semimembranosus (SM) and longissimus dorsi (LD) muscle tissues of 3 newborn Hanwoo calves. Bovine SM and LD satellite cells were incubated with dulbecco modified eagle medium (DMEM) with 10% fetal bovine serum for proliferation and induced differentiation with DMEM with 3% horse serum. Bovine satellite cells were treated with various levels of α-solanine (control, 0.001, 0.01, 0.1, 1, and 10 μM). mRNA abundance for myosin heavy chain 1 (MHC1), MHC2X, glucose transporter 4 (GLUT4), myogenin, G-coupled protein receptor 43 (GPR43), and β2-adrenergic receptor (β2-AR) were measured by real-time quantitative PCR. Data were analyzed as a completely randomized design using the MIXED model, each treatment performed in triplicated. Means were considered different at $P < 0.05$. Relative MHC2X mRNA abundance was greater in both, SM and LD satellite cells with 1 μM solanine treatments compared with the control ($P < 0.05$). Relative level of MHC2X and GLUT4 were decreased in 10 μM solanine treatments ($P < 0.05$). Relative level of MHC2X and β2-AR were greater in SM satellite cell compared with LD satellite cells ($P < 0.05$). There was no tissue x dose interaction among MHC1 mRNA concentration ($P > 0.05$). These result indicated that α-solanine have a dose-dependent effect on MHC2X mRNA but did not affect to MHC1 mRNA in bovine satellite cell.

Key Words: α-solanine, Hanwoo, semimembranosus

W224 Role of epidermal growth factor receptor and erbB2 in trenbolone acetate mediated increases in bovine satellite cell proliferation and protein synthesis and deceases in protein degradation.

Kara J. Thornton*, Ernest Kamanga-Sollo, Michael E. White, and William R. Dayton, *University of Minnesota, St. Paul, MN.*

Trenbolone acetate, TBA, has been shown to increase proliferation and protein synthesis rates and decrease protein degradation rate in bovine satellite cell (BSC) cultures. Although we have previously shown that the androgen receptor is involved in these TBA effects, our current data show that 2 receptors from the erbB family, epidermal growth factor receptor (EGFR) and erbB2, also play a role in the effects of TBA on BSC proliferation, protein synthesis and protein degradation in BSC cultures. We have assessed the effects of treating BSC with AG1478, a specific EGFR tyrosine kinase inhibitor, and/or AG879, a specific erbB2 tyrosine kinase inhibitor, on the ability of TBA to affect proliferation rate (^{3}H-Thymidine incorporation) in proliferating BSC cultures and to affect protein synthesis rate (^{3}H-phenylalanine incorporation/mg protein) and percent protein degradation in fused BSC cultures. Statistics were done using Proc MIXED in SAS; the model included treatment as a fixed effect and experiment, BSC number and experiment replicate as random effects. Treatment with AG1478, AG879 or a combination of AG1478/AG879 significantly ($P < 0.05$) suppressed TBA-induced increases in proliferation. Treatment with AG1478 significantly ($P < 0.05$) suppressed specific TBA-induced increases in protein synthesis. Treatment with AG879 or a combination of AG879/1478 also decreased TBA-induced increases in protein synthesis ($P < 0.05$) although the effects of AG879 or AG879/1478 may be non-specific as there was also a significant ($P < 0.05$) decrease in protein synthesis rate in control cells (not treated with TBA) receiving these treatments. While treatment with either AG1478 or AG879 alone had no effect on the ability of TBA to reduce protein degradation rate in fused BSC cultures, treatment with a combination of AG879/1478 significantly ($P < 0.05$) suppressed TBA-induced decreases in protein degradation rates. In summary our results show that receptors from the Erb family are necessary to support TBA-induced effects on proliferation, protein synthesis and protein degradation in BSC cultures.

Key Words: bovine, satellite cell, EGFR

Nonruminant Nutrition: Energy and fiber

W225 Fitting and validating prediction equations of metabolizable energy of meat and bone meal for pigs.

R. A. Castilho[1], P. C. Pozza*[2], N. T. E. Oliveira[3], C. P. Sangali[2], C. N. Langer[4], and R. V. Nunes[3], *[1]Safeeds Nutrição Animal, Cascavel, Paraná, Brazil, [2]Universidade Estadual de Maringá, Maringá, Paraná, Brazil, [3]Universidade Estadual do Oeste do Paraná, Mchal Candido Rondon, Paraná, Brazil, [4]Swine Production System, Quatro Pontes, Paraná, Brazil.*

The aim of this study was to fit and validate models to predict the metabolizable energy (ME) of meat and bone meal (MBM) for pigs. Thirty-two barrows (26.75 ± 1.45 kg) were allotted in a randomized blocks design with 8 treatments (7 MBM that replaced 20% the basal diet) and 4 replicates, to determine the ME. All MBM samples were analyzed for dry matter (DM), crude protein (CP), ether extract (EE), gross energy (GE), crude fiber (CF), mineral matter (MM), calcium (Ca) and phosphorus (P). The multiple linear regression models were adjusted using GE, CP, EE, MM, Ca and P as regressors (DM basis) using the ordinary least square method. To validate prediction equations, a database was compiled containing 48 pairs of observed and predicted ME. The 48 observed ME values were compiled from the literature and classified according to the scientific origin, resulting in 15 Brazilian data and 33 from international literature. The validity was initially assessed by adjusting the linear regression of 1st degree of the observed ME in function of the estimated ME, using the ordinary least squares. This procedure was adopted for the databases from the Brazilian, international and mixed literature. The validation of the estimated equations, as predictors of the linear ratio of ME, was checked by fitting a linear model of 1st degree of the predicted values ($y = b_0 + b_1x_i$) of ME by the equations initially estimated in function of the observed values. The ME values of MBM ranged from 1645 to 2645 kcal/kg. The prediction equations $ME_1 = -4233.58 + 0.4134GE + 72P + 89.62MM - 159.06Ca$ ($R^2 = 0.90$); $ME_2 = 2087.49 + 0.3446GE + 31.82MM - 189.18Ca$ ($R^2 = 0.87$); $ME_3 = 2140.13 + 0.3845GE - 112.33Ca$ ($R^2 = 0.86$); $ME_4 = -346.58 + 0.656GE$ ($R^2 = 0.80$); and $ME_5 = 3221.27 + 178.96EE - 76.55MM$ ($R^2 = 0.82$) were effective in predicting the ME of Brazilian MBM. However, there was no validation when using data obtained from international researches. In conclusion, the equations that efficiently estimates the ME of MBM for pigs in Brazilian conditions are $ME_1 = -4233.58 + 0.4134GE + 72CP + 89.62MM - 159.06Ca$ and $ME_2 = 2087.49 + 0.3446GE + 31.82EE - 189.18Ca$.

Key Words: chemical composition, feedstuff, model

W226 Effects of different net energy concentrations of diets on the growth performance of growing or finishing pigs housed individually.

Gang Il Lee[1], Kwang-sik Kim[2], Jun Cheol Park[2], and Dong Yong Kil*[1], *[1]Chung-Ang University, Anseong-si, Gyeonggi-do, Republic of Korea, [2]Rural Development Administration, Cheonan-si, Chungnam, Republic of Korea.*

This experiment was conducted to investigate the effects of different net energy (NE) concentrations of diets on the growth performance of growing or finishing pigs housed individually. In experiment 1 (growing pigs), a total of 60 growing pigs (Landrace × Yorkshire × Duroc; initial BW = 34.3 ± 3.7 kg) were allotted to 5 dietary treatments with 12 replicate pens and 1 pig per pen in a 35-d feeding trial. In experiment 2 (finishing pigs), a total of 60 finishing pigs (Landrace × Yorkshire × Duroc; initial BW = 73.7 ± 5.6 kg) were allotted to 5 dietary treatments with 12 replicate pens and 1 pig per pen in a 28-d feeding trial. Within each experiment, a corn-soybean meal-based basal diet (91.75%) was prepared to meet all nutrient requirements for growing or finishing pigs (NRC, 2012). The remaining portion (8.25%) was added to the basal diet by different inclusion ratio of soybean oil and starch to create 5 NE concentrations (2,318, 2,390, 2,462, 2,533, or 2,605 kcal NE/kg) of diets for growing or finishing pigs. The NE and amino acids concentrations in diets were calculated based on the values from NRC (2012). Pigs were allowed ad libitum access to feed and water in both experiments. Statistical model included dietary treatment as a fixed effect. Orthogonal polynomial contrast test was performed to determine linear and quadratic effects of NE concentrations of diets. Results indicated that the final BW, ADG, ADFI, and feed efficiency (G:F) of growing pigs were not affected by dietary treatments. Similarly, final BW, ADG, and ADFI of finishing pigs were not affected by dietary treatments. However, the G:F of finishing pigs was improved (linear, $P < 0.01$) with increasing NE concentrations in diets (0.326, 0.331, 0.323, 0.352, and 0.349 for 2,318, 2,390, 2,462, 2,533, or 2,605 kcal NE/kg, respectively). In conclusion, increasing NE concentrations in diets from 2,318 to 2,605 kcal/kg have no beneficial effects on the growth performance of growing pigs, but improve feed efficiency of finishing pigs.

Key Words: growth performance, net energy, pig

W227 Effects of dietary metabolizable energy levels on performance and energetic metabolism of broiler chickens.

M. P. F. Teixeira, N. C. Baiao, L. J. C. Lara, M. A. Pompeu*, L. F. P. Pereira, C. W. R. Gondim, K. R. Soares, and W. L. S. Climaco, *Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brazil.*

Recent research has demonstrated a reduction in dietary heat increment and improvements in production performance from supplementing lipids as an energy source. This performance improvement can be attributed to increased availability of nutrients from feed ingredients, in addition to improved energy efficiency by increasing net energy (NE) of diet. The present study was conducted to evaluate the effects of increasing metabolizable energy (ME) levels in the diet on performance parameters, nutrient digestibility and energy balance of 19 to 41 d of age broilers kept in thermoneutral conditions. A total of 336 male broiler chickens were evaluated in this study, distributed in a completely randomized design with 4 treatments and 6 replicates with 14 broilers each. The treatments consisted of 4 diets containing 19% CP and increasing ME levels (2,980, 3,080, 3,180 and 3,280 kcal/kg), which were obtained by addition of soybean oil. The data were submitted to ANOVA and the means were compared by the Tukey test ($\alpha = 0.05$). Feed intake was not affected by ME levels; although the best results for weight gain (2.3 kg) and feed conversion ratio (1.53 kg/kg) were obtained in broilers fed with diets containing 3,280 kcal/kg ($P < 0.01$). The viability rate and feed cost per kg of live weight did not differ between treatments, but production efficiency ratio increased linearly as ME was increased ($P < 0.01$). The ME levels affected the EE digestibility, broilers fed with more energetic diets (3,180 and 3,280 kcal/kg) achieved better EE digestibility (79.8% and 81.4%, respectively; $P < 0.01$). Heat production and increment was not affected by ME levels. The dietary ME levels had a linear effect over NE ($P < 0.03$), but ME conversion into NE remained constant between diets. In conclusion, ME levels has influence on performance and energetic metabolism of broiler chickens under thermoneutral condition.

Key Words: heat increment, net energy, thermal comfort

W228 Effects of dietary metabolizable energy levels on performance and energetic metabolism of broiler chickens under cyclic heat stress condition. M. P. F. Teixeira, N. C. Baiao, L. J. C. Lara, M. A. Pompeu*, L. F. P. Pereira, K. R. Soares, A. F. Silva, J. F. V. Braga, and A. R. C. Abreu, *Universidade Federal de Minas Gerais, Belo Horizonte, MG, Brazil.*

Improving broiler performance during heat stress has been the aim of many researches, and one of most common approach is to increase dietary metabolizable energy (ME), which may increase nutrients availability and improve energy efficiency by both reducing heat increment (HI) and increasing ME conversion into net energy (k). This study aimed to evaluate the effects of increasing ME levels on performance, nutrient digestibility and energy balance of 19 to 41 d old broilers kept under cyclic heat stress (16 h of 23 ± 2°C and 8 h of 32 ± 2°C; 60 ± 2% RH). A total of 336 male broilers were used, distributed in a completely randomized design with 4 treatments and 6 replicates of 14 birds each. Treatments consisted of 4 diets containing 19% CP and 4 ME levels (2,980, 3,080, 3,180 and 3,280 kcal/kg), which were obtained by the addition of soybean oil. Data were submitted to ANOVA and the means were compared by Tukey and SNK test for performance and energetic metabolism, respectively ($\alpha = 0.05$). Weight gain, feed intake, viability and productive efficiency ratio were not influenced by ME levels ($P > 0.05$). However, broilers presented a better feed conversion ratio when fed with 3,280 kcal/kg, followed by 3,180 kcal/kg ($P = 0.003$). Moreover, the lowest feed cost per kg of live weight was observed with 2,980 kcal/kg, followed by broilers that consumed 3,080 kcal/kg of feed ($P = 0.028$). The digestibility of CP and EE increased linearly with ME increase in diet ($P < 0.001$). The consumption of ME adjusted to zero nitrogen balance was not affected by diet treatment ($P > 0.05$), but a higher heat production was observed in broilers that received diets with the lowest ME level ($P = 0.012$). HI was higher in broilers fed with 2,980 kcal/kg diet (93.9 kcal/kg$^{0.75}$/day) ($P = 0.016$). The dietary ME levels had a linear effect over net energy ($P < 0.021$), but k remained constant between diets ($P > 0.05$). We conclude that ME level influences on performance and energetic metabolism.

Key Words: cyclic heat stress, heat production, net energy

W229 Determination of apparent digestibility of fibrous sources for finishing pigs. Bernardo Berenchtein*[1], Evelyn Brito[1], Adibe Abdalla[2], Helder Louvandini[2], Dineshkumar Danashekaran[2], Adibe Abdalla Filho[2], Paulo Lima[2], and Patrícia Righetto[2], *[1]Laboratory of Studies and Researches of Production and Nutrition of Poultry and Swine; Federal University of Amazonas, Parintins, AM, Brazil, [2]2Center of Nuclear Energy in Agriculture, Piracicaba, SP, Brazil.*

Many studies evidenced that the possibility of using forages and other grasses as feedstuffs in swine production. However, there is a need to study the potential fibrous feedstuffs in swine production in terms of identification, quantification and evaluation of interactions between physiological and associative effects on digestibility and animal performance. Hence, the objective of the present study was to evaluate the apparent digestibility of Tifton-hay, Citric Pulp and Soybean hulls in finishing pig diets. Twenty crossbred barrows (70 ± 1.95 kg) were distributed in a randomized block design with 4 treatments (n = 5) fed 20% replacement of fibrous diets on basal diet, Group I- 100% basal diet; Group II- 80% basal diet +20% Tifton hay; Group III- 80% basal diet +20% Citric pulp and Group IV- 80% basal diet +20% Soybean hulls, in individual metabolism cages. Apparent digestibility of Dry Matter and nutrients was performed by total feces and urine collection method for pigs, which animals were housed in metabolism cages for 12 d (7 d for acclimation and 5 d for collection). Feeds and feces were analyzed for dry matter (DM), crude energy (CE), crude protein (CP), neutral detergent fiber (NDF) and acid detergent fiber (ADF). Our result shows that Tifton hay had 2.425 kcal/kg of apparent digestible energy and 3.36% of apparent digestible protein. In addition, apparent digestibility of NDF and ADF of Tifton hay were 28.47 and 22.63% respectively. However, the results for Citric pulp were 2.850 kcal/kg of apparent digestible energy, 1.47% of apparent digestible protein and also apparent digestibility of NDF and ADF, were 8.14 and 7.85%. Soybeans hulls showed 2.250 kcal/kg of apparent digestible energy, 7.85% of apparent digestible protein and apparent digestibility of NDF and ADF were 21.7 and 26.39%, respectively. Therefore, our present study concluded that fibrous sources were used like feedstuffs in finishing pig diets. Moreover, it confirms that fibrous feeds will be both nutritionally and economically beneficial to swine production. The authors thank for the support of CNPq and FAPEAM.

Key Words: citric pulp, soybean hulls, Tifton hay

W230 Feeding diets containing low-protein or rapidly fermentable carbohydrate to weanling pigs does not affect growth performance. Vivian V. Almeida*[1], Amoracyr J. C. Nuñez[1], Patrícia V. A. Alvarenga[2], Fabrício R. Castelini[2], Ysenia V. Silva-Guillen[2], and Maria Cristina Thomaz[2], *[1]Department of Animal Sciences, Purdue University, West Lafayette, Indiana, [2]Department of Animal Science, São Paulo State University, Jaboticabal, São Paulo, Brazil.*

The objective in this study was to evaluate the effects of dietary CP and dried citrus pulp (DCP, rapidly fermentable carbohydrate source) contents on growth performance of weanling pigs. A total of 108 barrows weaned at 21 d of age were blocked by initial BW (5.82 ± 0.96 kg) and randomly assigned to 4 treatments with 9 replicate pens per treatment and 3 pigs per pen. Treatments were arranged in a 2 × 2 factorial, with 2 CP contents (HCP and LCP; high- and low-CP diets, respectively) and 2 DCP contents (0 and 7.5%, as-fed basis). The HCP treatments consisted of feeding 20 and 21% CP diets (as-fed basis) throughout the pre-starter I (1 to 14 d) and pre-starter II (15 to 28 d) phases, respectively. For the LCP treatments, CP contents were 16 and 17% for the pre-starter I and II diets, respectively. The AA contents in the diets were balanced by supplementation with crystalline AA, such as L-Lys, DL-Met, L-Thr, L-Trp, L-Val, and L-Ile to maintain an ideal AA pattern. Ideal AA ratios (standardized ileal digestible basis) were: 100% Lys; 28% Met; 63% Thr; 18% Trp; 69% Val; and 55% Ile. Individual pig BW and pen feed disappearance were recorded weekly to determine ADG, ADFI, and G:F. Data were analyzed as repeated measures using the MIXED procedure of SAS, with pen and block as the random effects and CP, DCP, day, and 2-way and 3-way interactions as the fixed effects. There were no CP x DCP interactions for BW, ADG, ADFI, and G:F; thus, the main effects are discussed. Growth performance was not affected by the dietary DCP contents. Even though BW and ADFI did not differ between dietary CP contents during the 28-d feeding period, pigs fed the LCP-diet showed decreased ADG ($P = 0.03$) and G:F ($P = 0.02$) from d 21 to 28 post-weaning compared with those fed the HCP-diet. However, overall ADG and G:F were not affected by reducing the dietary CP content. In conclusion, feeding diets containing 7.5% DCP to weanling pigs does not affect growth performance. Moreover, dietary CP content in pig pre-starter diets may be reduced by 4 percentage units when combined with AA supplementation without depressing overall growth performance.

Key Words: amino acid, fiber, pig

W231 Effects of dietary protein and rapidly fermentable carbohydrate contents on cecal microbial fermentation profile of weanling pigs.

Vivian V. Almeida*[1], Amoracyr J. C. Nuñez[1], Patrícia V. A. Alvarenga[2], Fabrício R. Castelini[2], Ysenia V. Silva-Guillen[2], and Maria Cristina Thomaz[2], [1]*Department of Animal Sciences, Purdue University, West Lafayette, Indiana,* [2]*Department of Animal Science, São Paulo State University, Jaboticabal, São Paulo, Brazil.*

A total of 108 barrows weaned at 21 d (5.82 ± 0.96 kg initial BW) were used to determine the effects of dietary CP and dried citrus pulp (DCP; rapidly fermentable carbohydrate source) contents on VFA and ammonia concentrations in the cecal digesta of weanling pigs. Pigs were blocked by initial BW and randomly assigned to 1 of 4 treatments with 9 replicate pens per treatment and 3 pigs per pen in a randomized complete block design. Treatments were arranged in a 2 × 2 factorial, with 2 CP contents (HCP and LCP; high- and low-CP diets, respectively) and 2 DCP contents (0 and 7.5%, as-fed basis). The HCP treatments consisted of feeding 20 and 21% CP diets (as-fed basis) throughout the pre-starter I (1 to 14 d) and pre-starter II (15 to 28 d) phases, respectively. For the LCP treatments, CP contents were 16 and 17% for the pre-starter I and II diets, respectively. Crystalline AA were added to the HCP and LCP diets to maintain an ideal AA pattern. Cecal digesta samples were collected from 1 pig per pen on d 7 and 28 postweaning for determinations of VFA profile by gas chromatography and ammonia concentration by colorimetry. Data were analyzed as repeated measures using the MIXED procedure of SAS, with pen and block as the random effects and CP, DCP, day, and 2-way and 3-way interactions as the fixed effects. Pigs fed diets containing 7.5% DCP tended ($P = 0.06$) to have increased acetate concentration and decreased ($P < 0.01$) propionate, isovalerate, and valerate concentrations in the cecum. Cecal butyrate, isobutyrate, and total VFA concentrations were not affected by the treatments. There was a DCP × day interaction ($P < 0.05$) for isovalerate concentration, in which dietary inclusion of 7.5% DCP decreased ($P < 0.01$) isovalerate concentration only at 28 d postweaning. There was a CP × DCP interaction for ammonia concentration ($P < 0.01$), in which adding 7.5% DCP to the diet tended ($P = 0.06$) to decrease cecal ammonia concentration only for pigs fed the LCP diet. In conclusion, low-protein AA-supplemented diets with 7.5% DCP inclusion may reduce proteolytic fermentation in the cecum of weanling pigs.

Key Words: microbial metabolite, protein, piglet

W232 Effect of feeding wheat- or barley-based diets with high- or low- nutrient density on diet nutrient digestibility and growth performance in weaned pigs.

X. Zhou*[1], M. G. Young[2], M. L. Swift[1,3], E. Beltranena[1,4], and R. T. Zijlstra[1], [1]*University of Alberta, Edmonton, AB, Canada,* [2]*Gowans Feed Consulting, Wainwright, AB, Canada,* [3]*Alberta Agriculture and Rural Development, Lethbridge, AB, Canada,* [4]*Alberta Agriculture and Rural Development, Edmonton, AB, Canada.*

Barley grain is a commonly fed energy feedstuff for grower-finisher pigs in western Canada. However, its feeding value for weaned pigs is poorly characterized, especially by modern feed formulation method using NE values and standardized ileal digestible (SID) AA coefficients for feedstuffs. Formulating lower nutrient dense diets may reduce feed cost, provided weaned pigs can maintain growth performance by increasing ADFI to meet requirements. To compare the feeding value of wheat- and barley-based diets with high- or low- nutrient density, 4 diets based on 64% wheat or 68% barley grain providing either 2.4 or 2.3 Mcal NE/kg were fed in a 2 × 2 factorial arrangement to 208 weaned pigs (9.0 kg) housed in 13 pens per diet. Diets were formulated to 4.5 g SID Lys/Mcal NE and were fed for 21 d. Feed added, remaining, and pig BW were measured weekly to calculate pen ADFI, ADG, and G:F. Freshly-voided feces were collected on d 19 and 20 to measure diet apparent total-tract digestibility (ATTD) of DM, GE, and CP and diet DE values. No interactions between cereal source and nutrient density were observed. Compared with wheat-based diets, feeding barley-based diets reduced ($P < 0.01$) the ATTD of DM, GE, and CP by 2.7, 3.0, and 4.4%, respectively, and reduced ($P < 0.01$) measured diet DE value by 0.05 Mcal/kg. Compared with high-nutrient density diets, feeding low-nutrient density diets reduced ($P < 0.01$) ATTD of DM, GE, and CP by 2.6, 1.8, and 2.3%, respectively, while measured diet DE value was not affected. Overall, feeding barley-based diets increased ($P < 0.01$) ADG by 41 g and G:F by 0.04 g:g compared with feeding wheat-based diets, but ADFI was not affected. Diet nutrient density did not affect ADFI, ADG, or G:F. In conclusion, feeding barley grain instead of wheat as cereal energy source for weaned pigs may increase growth performance. Growth performance of weaned pigs was not affected by reducing dietary NE by 0.1 Mcal/kg when SID Lys/NE was maintained. Feeding barley- instead of wheat-based diets provided advantages for the feeding of weaned pigs.

Key Words: barley, energy, weaned pig

W233 Graded concentrations of dietary wheat bran reduce ileal and total tract digestibility of nutrients but increase hindgut digestibility of dry matter and organic matter in pigs.

A. R. Son*, W. B. Kwon, and B. G. Kim, *Konkuk University, Seoul, Republic of Korea.*

The objective was to determine the effects of graded concentrations of wheat bran (WB) on apparent ileal (AID), apparent total-tract (ATTD), and hind gut digestibility of nutrients and to test the effects of time for collecting fecal grab samples on nutrient digestibility in pigs. Six barrows (initial mean BW of 70.7 ± 5.7 kg) surgically fitted with a T-cannula in the distal ileum were used. A replicated 3 × 3 Latin square design was used with 3 diets, 3 periods, and 6 pigs. A basal diet was prepared to mainly contain wheat, soybean meal, and cornstarch. Two additional diets were formulated to contain 20 or 40% of WB at the expense of cornstarch. Each experimental period consisted of a 7-d adaptation period and a 4-d collection period. After the adaptation period, fecal samples were collected on d 8 and 11 using a grab sampling method, and ileal digesta samples were collected on d 9 and 10. To compare differences between nutrient digestibility calculated based on time points for fecal grab sampling, before or after the collection period for ileal digesta, a paired *t*-test was used. The AID of DM (81.8, 71.4, and 58.4%), OM (84.9, 75.0, and 62.4%), CP (78.2, 77.5, and 68.9%), and ADF (49.7, 45.4, and 36.1%) linearly decreased ($P < 0.05$) with increasing inclusion rate of WB from 0 to 40%. The ATTD of DM (91.8, 84.7, and 76.0%), OM (93.9, 87.2, and 78.8%), CP (89.7, 88.5, and 84.1%), and ADF (68.6, 53.4, and 39.1%) linearly decreased ($P < 0.01$) as the inclusion rate of WB increased. Hindgut digestibility of DM (9.6, 13.4, and 17.6%) and OM (8.7, 12.2, and 16.4%) linearly increased ($P < 0.05$), and that of NDF (30.5, 15.2, and 10.3%) and Ca (19.9, 18.2, and 10.1%) linearly decreased ($P < 0.05$) with increasing inclusion rate of WB. However, there were no differences in ATTD of nutrients between time points for feces grab sampling. In conclusion, the inclusion of WB reduced AID and ATTD of nutrients but increased hindgut digestibility of DM and OM, and there were no difference in the ATTD between the fecal collection time points of before and after ileal digesta collection in pigs.

Key Words: digestibility, swine, wheat bran

W234 Up to 30% insoluble dietary fiber reduces carcass fat content of heavy pigs.

Daniela Junqueira Rodrigues[1], Maria Cristina Thomaz[1], Urbano dos Santos Ruiz[2], Maryane Sespere Oliveira*[1], Everton Daniel[1], Fabrício Rogério Castelini[1], Ysenia Victoria da Silva Guillen[1], Vivian Vezzoni Almeida[1], and Sarah Sgavioli[1], *[1]Universidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil, [2]Universidade de São Paulo, Piracicaba, Sao Paulo Brazil.*

The slaughter of heavy pigs (120 to 130kg BW) provides relatively bigger carcasses and a higher amount of meat, but has the disadvantage of a higher fat deposition, given that animals have higher food intake while protein deposition remains the same. Qualitative feed restriction is a technique that provides caloric intake control, diluting the diet energy with a fibrous ingredient. Our aim was to test the effects of diets containing increasing concentrations of insoluble fiber as part of a qualitative feed restriction program on carcass traits. Thirty 2 barrows (commercial crossbred; initial BW 78.53 ± 11.02kg), were assigned to 4 dietary treatments (ad libitum) with 8 replicate pens per treatments and one animal per pen in a randomized block design: control (corn and soybean meal based; 3230 kcal/kg calculated ME, 13.9% CP, 15.5% insoluble fiber) and 3 diets with increasing concentrations of insoluble fibers (20, 25 and 30%; from purified cellulose), and consequently decreased concentrations of calculated ME. The slaughtered happened when BW means were 133.30 ± 11.59kg. The yields were calculated based on the final BW, the backfat thickness, loin eye and fat area were measured at last ribs, in the insertion of the last thoracic vertebra to the first lumbar. Data were analyzed by ANOVA using GLM procesure of SAS, polynomial regression were used to determine the effect of insoluble fiber. We observed linear reduction ($P < 0.05$) to backfat thickness and fat area, moreover, linear increase to meat:fat ratio. There were no differences in final BW, yield, lean meat, loin eye area and ham yield. In conclusion, using up to 30% of insoluble fiber in diets of heavy pigs as part of a qualitative feed restriction program reduces carcass fat without altering other carcass traits.

Table 1 (Abstr. W234). Carcass traits from swine fed different levels of insoluble fiber

Item	Experimental diets (% IF)				SEM	Effect of IF
	15.5	20	25	30		
Final BW, kg	136.18	132.38	131.83	130.97	2.23	—
Yield, %	80.83	80.54	79.72	79.14	0.76	—
Lean meat, %	55.53	54.53	56.11	57.39	0.75	—
Backfat thickness, mm	33.97	31.62	32.16	26.78	0.90	Linear
Loin eye area, cm^2	44.14	39.14	43.14	45.43	1.36	—

W235 Effect of dietary inclusion of insoluble fiber from sugar cane on meat quality of finishing swine.

Maryane Sespere Oliveira*, Maria Cristina Thomaz, Marco Monteiro Lima, Fabricio Faleiros Castro, Patricia Versuti Arantes Alvarenga, Manuela Vantini Marujo, and Daniela Junqueira Rodrigues, *Universidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil.*

The objective of this study was to evaluate the effects of insoluble fiber, extracted from sugar cane, in finishing swine diets on meat quality. Fifty barrows were blocked by initial BW (79.33 ± 2.20 kg) and randomly assigned to one of 5 treatments with 10 replicate pens per treatment and one animal per pen. Treatments consisted of corn/soybean meal-based diets formulated to contain 0, 5, 10, 15 to 20% insoluble fiber and the levels of calculated ME (3230, 3069, 2905, 2745 and 2586 kcal/kg) were decreased according to increased dietary fiber. Pigs were slaughtered when BW means were around 130 kg. Initial pH (pH45) in *longissimus dorsi (LD)* was measured at the last rib position 45 min after slaughter and final pH (pHu) was measured 24 h after slaughter. The left *LD* muscle was removed, and sections of about 10 cm thickness were cut from the anterior end for meat quality analysis, such as, color, drip loss, oxidative stability, shear force, the concentration of cholesterol and lipids. The color of *LD* was measured with a Minolta Chromameter. The oxidative stability was assessed by TBARS. The shear force required to shear each block of muscle was determined by means of a Stable Micro systems texture analyzer fitted with Volodkevitch jaws. Data were analyzed by ANOVA using the MIXED procedure of SAS, diet was the fixed effect and replicate was the random effect. Polynomial contrasts were used to determine the effect of insoluble fiber inclusion. The drip loss, color parameters *L* (lightness), *a* (redness), *b* (yellowness) of *LD* and muscle pH were unaffected by dietary fiber treatments. But linear responses in Shear force (2.00, 1.74, 1.75, 2.00 and 1.87 ± 0.12, $P < 0.05$) and quadratic responses in Cholesterol (27.35, 25.24, 28.59, 27.00 and 24.51 ± 2.12, $P = 0.02$) were observed as amount of insoluble fiber increased in the diet. Insoluble fiber level had no effect on oxidative stability and lipids of *LD*. In conclusion, increasing insoluble fiber in the diet may soften meat and reduce cholesterol in the swine meat, without altering other meat qualities.

Key Words: insoluble fiber, meat quality, pig

W236 Mannans and glucans in diets for weanling pigs and their effects on the diarrhea incidence and pH of the digestive tract.

Patricia V. A. Alvarenga, Maria C. Thomaz, Marco M. Lima*, Daniela J. Rodrigues, Manuela V. Marujo, Fabricio F. Castro, and Maryane S. F. Oliveira, *Univesidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil.*

An experiment was conducted to evaluate the effects of diets containing mannans and glucans on diarrhea incidence and pH of the digestive tract organs of weanling pigs. Ninety-six piglets weaned at 24 d (7.7 ± 1.76 kg initial BW) were blocked by initial BW and randomly assigned to 4 treatments with 8 replicate pens per treatment and 3 pigs per pen in a randomized complete block design. Pigs had ad libitum access to feed and water over a 42 d study. The treatments were: PC (positive control diet: 40ppm of colistine sulfate); NC (negative control diet: free of antimicrobial); NC+CA (NC + Compound A: 10% MOS and 18% β-glucan); NC+CB (NC + Compound B: 18% MOS and 20% β-glucan). The inclusion of Compound A was 10 kg/ton and of Compound B was 2 kg/ton. The diarrhea incidence was measured 2 times a day, every day until the 21 d of experiment, using subjective scores according to the consistency and appearance of feces (1 = well-formed, 2 = soft, and 3 = diarrhea). One animal per pen was slaughtered on d 14 of experiment. The pH of the organs contents were measured using a pH meter. Data were analyzed by ANOVA and Tukey's test (5%), using the GLM procedure of SAS. Higher incidence of diarrhea and also less incidence of well-formed and soft feces were observed for NC ($P < 0.01$). The pH of the stomach content was lower for NC+CB and PC ($P < 0.05$), and the pH of the small intestine was lower for NC+CA compared with PC ($P < 0.05$), but did not differed from NC and NC+CB. In conclusion, feeding diet with no additives results in higher incidence of diarrhea, also treatments NC+CB and PC are able to reduce the pH of the stomach.

Table 1 (Abstr. W236). Diarrhea incidence and pH of the digestive tract organs

	Treatments					
Item	NC	NC+CA	NC+CB	PC	SEM	*P*-value
pH						
Stomach	3.309^{b}	3.278^{b}	2.615^{a}	2.591^{a}	0.1994	<0.05
Small intestine	5.366^{ab}	4.900^{a}	5.310^{ab}	5.763^{b}	0.1988	<0.05
Cecum	5.504	5.230	4.931	5.023	0.1867	>0.05
Diarrhea incidence						
Well-formed	6.870^{b}	17.375^{a}	15.000^{a}	15.250^{a}	1.9483	<0.01
Soft	6.000^{b}	10.750^{a}	11.500^{a}	15.000^{a}	1.5889	<0.01
Diarrhea	25.000^{b}	9.250^{a}	11.375^{a}	7.625^{a}	1.6219	<0.01

Key Words: glucan, mannan, diarrhea

W237 Influence of hydrolysable tannin extract supplementation on performance of growing-finishing pig.

Rubén Aguirre[1], Javier A. Romo[1], Rubén Barajas*[1], Juan M. Romo[1], and Héctor R. Güémez[1,2], [1]*FMVZ-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México,* [2]*Granja Porcina La Huerta, Culiacán, Sinaloa, México.*

Seventy-two pigs (36 males and 36 females) with 26.98 ± 4.26 kg of initial weight and 70 d old were used in a 90 d experiment to evaluate the influence of hydrolysable tannin extract supplementation on performance of growing-finishing pig. Animals were weighed, allotted by initial weight, and in groups of 6 (3 males and 3 females) they were placed in 12 paved floor pens (7 × 1.5 m). Pen constituted the experimental unit. In a randomized complete block design, pens were assigned to treatments as follows: 1) Growing and finishing diets formulated with corn and soybean meal (Control); or 2) Control plus addition of 0.2% of hydrolysable tannin extract (HT). The hydrolysable tannin extract was provided as SilvaFeed NutriP (Pronutrient Developer, Mexico). Results were analyzed by ANOVA for a randomized complete block design. During the first 49 d that constituted the growing phase (d 1–49), HT supplementation augmented ($P = 0.04$) body weight (66.11 vs. 60.18 kg) and improved average daily gain ($P = 0.04$) by 18% (0.802 vs. 0.680 kg). Addition of HT increased ($P < 0.01$) average daily feed intake (0.805 vs. 1.675 kg), but the feed intake as proportion of mean body weight was similar between treatments (3.84 vs. 3.89%).The feed efficiency (Gain/feed ratio) was no affected by treatments (0.410 vs. 0.447). During the finishing phase (d 50 to d 90), HT supplementation increased ($P = 0.02$) feed intake (2.44 vs. 2.08 kg) without effect on ADG and feed efficiency. In complete 90 d experiment (joint growing and finishing phases), HT supplementation tended ($P = 0.06$) to improve final weight (97.17 vs. 88.17 kg) and average daily gain (0.782 vs. 0.681 kg); increased ($P < 0.01$) feed intake (2.093 vs. 1.858 kg), without effect on feed efficiency. It is concluded that 0.2% hydrolysable tannin supplementation during the growing phase improves performance of pig, but its addition during the finishing phase does not represent any advantage.

Key Words: growth performance, hydrolyzable tannin, pig

Physiology and Endocrinology: Male reproduction, deers, and poultry

W238 The effect of moringa oleifera leaf meal on follicle stimulating hormone, luteinizing hormone and testosterone of wad goat bucks serum. Abimbola O. Ladokun*, Khadeejah Kareem-Ibrahim, Bukola D. Adenaike, Oladimeji M. Abioja, and John A. Abiona, *Federal University of Agriculture, Abeokuta, Ogun, Nigeria.*

Moringa as a plant has been attributed with possessing anti-oxidative properties and lowering of blood cholesterol. It has also been reported to be involved as an endocrine system blocker (ESB). This study investigated the effect of moringa leaf meal supplemented in the feed of West African dwarf (WAD) goat bucks on their serum FSH, LH and testosterone. Sixteen matured WAD bucks were used; they were assigned into 4 groups with 2 replicates and 2 bucks per replicate. They were semi-intensively managed, allowed to graze and their concentrate supplemented with blended moringa leaf at 0g/kg concentrate, 100, 200, and 300 g/kg respectively for 8 weeks. Blood was sampled 3 times (Start, 4th week and end of 8th week) and serum harvested for analyses using EIA for testosterone and ELISA kits and reader for FSH and LH. Data were analyzed using one-way ANOVA of SAS, and significant (P = 0.05) means were separated using the Duncan test in SAS. Concentrations of testosterone were similar across the groups (5.65–5.95ng/L). At the 4th and 8th week, the concentrations though greater than start, they were also similar across the groups indicating that moringa did not influence testosterone concentration in WAD bucks. Concentrations of FSH were also similar at the start (4.85–5.0), but there were decreases in concentrations at the 4th and 8th week as compared with start. It is noteworthy that for bucks supplemented with 200g/kg moringa, there was a significant (P = 0.05) decrease in concentration at 4th and 8th week (5.0–4.40–4.30ng/L). The average serum LH at start was similar among groups (3.75–4.10ng/L). At the 4th and 8th week, treatment did not affect concentrations of LH. Results indicate that moringa leaf at the level used in this study did not elicit any response indicative of disrupting the concentration of testosterone, FSH and LH in WAD bucks.

Key Words: moringa, goat buck, hormone

W239 Proteomic analysis of testicular proteins between yak and its sterile hybrid by iTRAQ labeling mass spectrometry. Wei Fu[1], Wenlin Bai[2], Lin Huang[1], Wenjing Liu[3], Caixia Li[1], Suyu Jin[1], Xiang Qiu[1], Liang Ren[1], and Yucai Zheng*[1], [1]*Southwest University for Nationalities, Chengdu, Sichuan Province, China,* [2]*Shenyang Agricultural University, Shenyang, Liaoning Province, China,* [3]*Southwest University of Science and Technology, Mianyang, Sichuan Province, China.*

The objective of the present study aimed at identifying differential expression proteins in testes of adult yak (*Bos grunniens*) and its sterile hybrid (cattle-yak), to provide basic data for elucidating the molecular mechanisms of the male sterility of cattle-yak. Cattle-yak is a hybrid of male cattle (*Bos taurus*) with female yak, exhibiting higher body size, milk and meat yields than those of yak, but F_1 to F_3 male sterility, the mechanism is still unknown. In the present study, total proteins were extracted from the testes of adult yaks (n = 6) and cattle-yaks (n = 4), respectively, followed by analysis of the testicular protein profiles (pooled samples for each group) by isobaric tags for relative and absolute quantitation (iTRAQ) technique. Proteins with a fold change of >1.2 and $P < 0.05$ (t-test) were considered to be significantly differentially expressed. Hypergeometric test was used in Gene Ontology analysis. A total of 4464 proteins were identified, of which 714 proteins were differentially expressed, including 432 downregulated and 282 upregulated proteins in the testis of cattle-yak compared with that of yak. Interestingly, approximately 30% of the top 50 downregulated proteins in cattle-yak testis are testis-specific or highly expressed in testis, and most likely exert crucial effects on spermatogenesis. Gene Ontology analysis of the differentially expressed proteins demonstrated that 19 major protein categories belong to carbohydrate metabolism and protein folding were highly enriched in the Biological process category, implying the important roles of the 2 processes in spermatogenesis. Further analysis of Biological process category revealed 43 proteins associated with reproductive process, and most of which were downregulated in the testis of cattle-yak. In addition, fatty acid oxidation metabolism was found to be more active in cattle-yak testis than in yak testis. Based on the testicular protein profiles, protein functions and protein-protein interaction analysis, we propose that the abnormal expression of several downregulated proteins of testis-specificity or with high abundance in testis, such as YBX2, PIWIL1, TDRD1, and BAG6, might be closely associated with the sterility of male cattle-yak.

Key Words: yak, hybrid sterility, proteomics

W240 Effect of androstenone level on the boar testis transcriptome. Dianelys Gonzalez-Pena*, Robmay Garcia, and Robert V. Knox, and Sandra L. Rodriguez-Zas, *University of Illinois at Urbana-Champaign, Urbana, IL.*

Androstenone is the most abundant steroid produced in boar testis and share a precursor (pregnenolone) with testosterone, the principal male sex hormone needed for sperm production in the testis and its maturation on the epididymis. Androstenone is a pheromone of non-castrate males present in urine, sweat, saliva, and fatty tissues responsible for boar taint, which includes unpleasant odor and meat flavor. The objective of this study was to understand the differences in the transcriptome between high (greater than 1.0 µg/g) and low (less than 0.5 µg/g) androstenone boars. Testis mRNA from 10 Duroc crossbred boars was profiled. Single-end reads were mapped to the *Sus scrofa* reference genome (UCSC susScr3) using Tophat v2.012. In total, 4,969 transcripts from 4,744 genes were tested and 69 transcripts from 72 genes were differentially expressed between the high and low androstenone groups using Cufflink v2.2.1 (False Discovery Rate adjusted P-value <0.05). Among these, steroidogenic acute regulatory protein (STAR), cytochrome P450 family 19 subfamily A polypeptide 1 (CYP19A1), and sulfotransferase family cytosolic 2A dehydroepiandrosterone-preferring member 1 (SULT2A1) were overexpressed, while macrophage receptor with collagenous structure (MARCO) and anti-Mullerian hormone receptor type II (AMHR2) were underexpressed in the high relative to low androstenone groups. CYP19A1 encodes enzymes that participate in the synthesis of cholesterol, steroids, and other lipids and STAR encodes a protein critical in steroid hormone synthesis by enhancing the metabolism of cholesterol into pregnenolone the precursor of testosterone and androstenone. The overexpression of SULT2A1 in high relative to low androstenone groups is consistent with the role of this enzyme in the sulfo-conjugating of androstenone. Functional analysis of the differentially expressed genes using DAVID identified 2 category clusters (enrichment score >2) that include hormone metabolism biological processes and regulation, steroid and lipid biosynthetic and metabolism. These functional categories suggest that practices to reduce androstenone should aim to minimize transcriptome changes that can negatively impact testosterone and boar fertility.

Key Words: transcriptome, androstenone, testis

W241 Gonadal sperm characteristics of growing boars fed varying levels of raw or fermented cottonseed cake.

Mayowa Mojeed Oguntunde* and Olajide Abraham Amao, *Ladoke Akintola University of Technology, Ogbomoso, Oyo, Nigeria.*

Cottonseed cake (CSC) is a veritable source of protein, energy and fiber for a variety of livestock species. However, it contains a deleterious polyphenolic compound, gossypol that restricts it use to ruminant feeding. Fermentation is one of the biotechnological options for reducing toxicity of many feed ingredients. This study was conducted to determine the effect of different levels of raw or fermented CSC on sperm characteristics of growing boars. Thirty (30) cross-bred (Landrace × Large White) with average weight of 7 kg, weanling boars (n = 6 per treatment) were randomly assigned to 5 dietary treatments arranged in a 2 × 2 factorial with a control within a completely randomized design (CRD). The CSC was included in diets at 0 (control), 10 and 20% (raw or fermented). Animals were fed for 12 weeks after which they were killed at average weight of 17.1 kg and the reproductive organs removed and processed for sperm characteristics. Sperm concentration was significantly ($P < 0.05$) higher for the control (48.50×10^6/mL) than other treatments. Sperm motility for the raw CSC (68.55%) was similar to that of the control (68.01%). Boars that were fed 10% fermented CSC recorded lowest sperm motility (56.05%). Normal sperm was highest (71.34%) ($P < 0.05$) for the control while the lowest value was obtained at 10% fermented CSC (52.76%). Gonadal sperm reserve (GSR) was the highest ($P < 0.05$) for the control group (1.928×10^9), while the lowest value was observed at 20% fermented CSC (0.610×10^9). Boars fed raw CSC, irrespective of level, had higher GSR than those fed fermented CSC. Daily sperm production (DSP) was significantly ($P < 0.05$) higher for the control than 10% and 20% fermented CSC groups. Daily sperm production/gram (DSP/g) was significantly ($P < 0.05$) higher for 10% raw CSC (40.44×10^6) compared with other treatments. This study shows that growing boars could tolerate raw CSC up to 10% in diets on a short-term basis without adverse effects on the gonadal sperm characteristics.

Key Words: boar, cottonseed cake, fermentation and sperm characteristics

W242 GameteGuard treatment improves post-thaw sperm quality and pregnancy per insemination in dairy cows.

Lisa Herickhoff*[1], Allison Lindsey[1], Amanda Fritts[1], and Patrick Burns[2], *[1]Membrane Protective Technologies Inc., Fort Collins, CO, [2]School of Biological Sciences, University of Northern Colorado, Greeley, CO.*

GameteGuard is a blend of plant extracts containing antioxidants and membrane stabilizers. Previous studies have shown improvements in post-thaw sperm health with GameteGuard addition to the extender, and therefore it was hypothesized that the addition of GameteGuard to sperm extender would result in increased pregnancy rates per AI in lactating cows. Sperm from 2 ABS Global Inc. production Holstein bulls was extended in egg yolk citrate or egg yolk citrate plus GameteGuard to 30 × 106 sperm/mK (15×10^6 sperm/dose) in a split ejaculate study. Sperm was packaged and frozen according to industry standards. The effectiveness of GameteGuard on pregnancy was assessed by first postpartum insemination of 208 Holstein cows. Over 6 mo, cows were cleared for insemination by the farm veterinarian then 2 farm personnel determined estrus status using visual cues such as disturbed tail chalk. The cows were inseminated within 12 h by one trained farm employee. Cows were inseminated with either Bull 1 or 2, treated or control sperm, where treatment was blind to farm personnel. Bull and treatment combinations were dictated by a calendar day. For example, all cows to be bred on May 15 would use bull 1, red straw (control) while May 16 would use bull 1, blue straw (treated). Cows having postpartum problems and those with reproductive issues, such as ovarian cysts, were excluded from the study. Thirty-five to 45 d post-insemination pregnancy was assessed using transrectal ultrasonography and data were analyzed using Chi-squared. GameteGuard improved pregnancy per AI by 31% (from 38 to 50%; $P < 0.05$; ~100 cows/treatment) across both bulls. Importantly, of the 124 animals bred within 83 d of calving, GameteGuard improved pregnancy per AI 36.1%.

Key Words: artificial insemination, sperm quality, pregnancy per insemination

W243 Evaluation of factors affecting pregnancy rate to AI in pen-raised white-tailed deer.

Kyle J. Stutts*, Jessica L. Leatherwood, Christopher R. Stewart, Mark J. Anderson, Marcy M. Beverly, and Stanley F. Kelley, *Sam Houston State University, Huntsville, TX.*

Factors known to influence pregnancy rate in livestock species were evaluated in white-tailed deer. Pen-raised white-tailed does (n = 53) ranging in age from 1.5 yr to 6.5 yr were utilized to evaluate the effects of BCS, BW, disposition, and serum cortisol concentration on fawning rate to AI. All does received a CIDR for 14 d and an injection (i.m.) of 300 IU PMSG at CIDR removal. Laparoscopic insemination was conducted at approximately 60 h following CIDR removal. Prior to insemination, does were restrained in a drop-floor chute and were administered sedative. At this time, BW was collected and disposition scores ranging from 1 to 5 (1 = docile and 5 = aggressive) were assigned by independent observers to evaluate deer behavior as an indicator of stress while restrained in the chute. Immediately following insemination, BCS was evaluated and blood samples were obtained via jugular venipuncture to determine cortisol concentration by RIA analysis. Previous research indicated a moderately positive relationship (r = 0.30) between disposition score and serum cortisol concentration. Does were placed with cover bucks one week post AI. During fawning season, DNA samples were collected from all fawns to identify the sire of each fawn and determine fawning rate to AI. Data were analyzed using the LOGISTIC procedure of SAS. Pregnancy rate to AI was 67.9% and final pregnancy rate was 94.0% following natural service. Mean BCS was 3.02 ± 0.52 (range of 2 to 4), and mean disposition score was 2.16 ± 1.21 (range of 1 to 4). There was no significant effect of BCS ($P = 0.59$), BW ($P = 0.19$), cortisol concentration ($P = 0.30$), or disposition score ($P = 0.64$) on pregnancy rate to AI. Results of this study indicate that body condition and BW may not have as great of an influence on pregnancy rate in white-tailed deer as observed in livestock species. These data also indicate that the stress response to being restrained may not influence pregnancy rate to AI in white-tailed deer. Given the small sample size of this study, further research is needed to fully elucidate the influence of these factors on pregnancy rate to AI in white-tailed does.

Key Words: white-tailed deer, artificial insemination, disposition

W244 Blood profiles of Ross 308 broiler and indigenous Venda chickens aged 42 and 90 days fed a similar diet.

Monnye Mabelebele*, David Norris, Jones Ng'ambi, and John Alabi, *University of Limpopo, Polokwane, Limpopo, South Africa.*

A study was conducted to assess blood profiles of Ross 308 broiler and indigenous Venda chickens. A total of 120 Ross 308 broiler and Venda chickens were raised for a period of 90 d on a commercial grower diet containing 20% crude protein and 13 MJ ME/kg DM. Ten chickens per breed were randomly selected at 42 and 90 d of age and 3 mL of blood samples from both chicken breeds were collected from the jugular vein into 2 test tubes per bird to determine the blood profiles. A *t*-test was used to test the significance of differences between breeds ($P < 0.05$). Differences among hematological parameters of Ross-308 and Venda chickens at 42 d of age were not significant ($P > 0.05$) except for platelets ($\times 10^3$μ/L) for Ross 308 broiler (59.2 ± 10.13) and Venda chickens (24.0 ± 10.00); serum creatinine (μmol/L) for Ross 308 broiler (17.5 ± 50.05) and Venda chickens (9.0 ± 5.02) and total protein (g/L) of Venda (25.5 ± 3.20) and Ross 308 broiler chickens (20.0 ± 3.12). At 90 d of age, white blood cells (734.4 ± 18.97 $\times 10^3$ cell/μL), red blood cells (2.3 ± 0.15; $\times 10^6$ cell/μL), mean corpuscular volume (121.1 ± 4.10 f/L), serum calcium (2.6 ± 0.01 mmol/L), creatinine (10.7 ± 0.76 μmol/L), cholesterol (3.9 ± 0.12 mmol/L) and albumin (9.5 ± 0.23 g/L) were higher for Ross 308 broiler chickens. However, platelets ($\times 10^3$μ/L) were higher in Venda (14.4 ± 3.29) than in Ross 308 broiler (12.2 ± 3.00) chickens. In the adult stage, broiler chickens have better hematological properties than indigenous chickens. Further investigation on immunological parameters of these breeds needs to be conducted.

Key Words: hematology, chicken, disease

W245 Transition period concentrations of nonesterified fatty acids and β-hydroxybutyrate in dairy cows are not well correlated. Maris M. McCarthy*[1], Sabine Mann[2], Daryl V. Nydam[2], Thomas R. Overton[1], and Jessica A. A. McArt[2], *[1]Department of Animal Science, Cornell University, Ithaca, NY, [2]Department of Population Medicine and Diagnostic Sciences, Cornell University, Ithaca, NY.*

The objective was to use longitudinal data of blood nonesterified fatty acids (NEFA) and β-hydroxybutyrate (BHBA) concentrations to describe the relationship between NEFA and BHBA in dairy cows during the periparturient period. Blood NEFA and BHBA concentration data collected from d −21 prepartum to 21 postpartum for 269 multiparous Holstein cows were recruited from 4 different studies carried out within our research groups. Of the 269 cows enrolled in the data set, 117 cows (43.5%) had at least 1 postpartum hyperketonemic event (BHBA ≥ 1.2 mmol/L), and 202 cows (75.1%) had at least 1 event of elevated postpartum NEFA (≥700 µEq/L) between 3 and 21 d in milk. Area under the curve (AUC) was used to investigate relationships between metabolites over time. Overall, Pearson correlation relationships between transition period NEFA and BHBA AUC were poor. There was a negative correlation between postpartum NEFA AUC and prepartum BHBA AUC, although the correlation coefficient was low (r = −0.26). A positive correlation existed between postpartum NEFA AUC and postpartum BHBA AUC; however, the correlation coefficient was low (r = 0.26), reinforcing a poor relationship between these metabolites during the periparturient period. Large variation was found between the day of maximum NEFA concentration within the first 21 d in milk and day of maximum BHBA concentration for the same time period. The mean and median days of maximum NEFA concentration were 6.8 and 6 d, respectively, whereas the mean and median days of maximum BHBA concentration were 9.6 and 8 d, respectively; however the range in days for both the mean and median day of maximum concentrations was very large. Overall, our data set indicates a poor relationship between blood concentrations of NEFA and BHBA during the periparturient period of dairy cows, suggesting that elevated concentrations of one should not be extrapolated to suggest elevated concentrations of the other metabolite.

Key Words: transition period, nonesterified fatty acids, β-hydroxybutyrate

W246 Associations of circulating haptoglobin with performance and metabolism in dairy cows during early lactation. Maris M. McCarthy*, Takashi Yasui, and Thomas R. Overton, *Department of Animal Science, Cornell University, Ithaca, NY.*

The objective of the current study was to clarify associations between the severity of systemic inflammation during the early postpartum period with performance and energy metabolism. Cows were assigned to categorical quartiles (Q; Q1 = 0.18–0.59, Q2 = 0.60–1.14, Q3 = 1.15–2.05, and Q4 = 2.06–2.50 g haptoglobin/L) based on the highest plasma haptoglobin concentration measured during wk 1 postpartum. Linear and quadratic contrasts were tested for all measurements, and data analyzed over time were subjected to repeated-measures ANOVA using PROC MIXED of SAS (v 9.3) and the REPEATED statement. There was a quadratic relationship ($P = 0.01$) on prepartum net energy for lactation (NE_L) intake such that cows in Q3 had lower prepartum NE_L intake compared with cows in the other Q (Q1 = 21.1, Q2 = 19.2, Q3 = 16.6, Q4 = 19.6 Mcal/d). There was a quadratic relationship ($P = 0.02$) on postpartum NE_L intake such that cows in Q3 also had lower postpartum NE_L intakes compared with cows in the other Q (Q1 = 36.3, Q2 = 34.6, Q3 = 29.8, Q4 = 33.7 Mcal/d). There was also a quadratic relationship ($P = 0.05$) with postpartum milk yield (Q1 = 42.6, Q2 = 40.1, Q3 = 34.2, Q4 = 37.4 kg/d), with similar relationships with 3.5% fat-corrected milk ($P = 0.02$) and energy-corrected milk ($P = 0.03$). There was a linear tendency ($P = 0.06$) for cows with increasing inflammation to have higher plasma glucose concentrations compared with cows with low inflammation. There was a similar linear relationship ($P = 0.04$) for plasma insulin and cows in Q3 and Q4 had higher postpartum insulin compared with cows in Q1 and Q2. There was a linear relationship ($P = 0.04$) for plasma NEFA and cows with increasing inflammation had lower NEFA (Q1 = 498, Q2 = 456, Q3 = 430, Q4 = 407 µEq/L). There was a quadratic relationship of inflammation ($P = 0.02$) with liver triglyceride content at d 7 postpartum and cows in Q3 had the lowest triglyceride content. There was also a quadratic relationship ($P = 0.02$) for liver glycogen and cows in Q3 had elevated liver glycogen content on d 7 postpartum compared with cows in other Q. Overall, cows with elevated haptoglobin in the first week after calving had reduced milk yields and alterations in metabolism; however, cows that have high early lactation haptoglobin (>1.14 g/L) had a diverse range of production responses and further investigation is warranted.

Key Words: transition period, haptoglobin, metabolism

W247 Intestinal permeability and incidence of diarrhea in Holstein calves. Gemma Araujo[1], Cristina Yunta[1], Marta Terré[1], Alessandro Mereu[2], Ignacio Ipharraguerre[2], and Alex Bach*[3,1], *[1]Department of Ruminant Production, IRTA (Institut de Recerca i Tecnologia Agroalimentàries), Caldes de Montbui, Spain, [2]Lucta S.A., Montornès del Vallès, Spain, [3]ICREA (Institució Catalana de Recerca i Estudis Avançats), Barcelona, Spain.*

Seventy-six newborn Holstein calves (44.4 ± 6.15 kg BW) were involved in this study from birth until 21 d of age. Within 2 h after birth, calves received 4 L of maternal colostrum via an esophageal tube. The following 3 meals consisted of 2 L of late colostrum (or transition milk). After that, calves were fed 1.5 L of milk replacer (22.9% CP, 20.1% fat) twice daily. Calves were considered diarrheic when showed fecal scores ≥3 for 3 consecutive days. Then, data from a random subset of 30 calves (45.9 ± 5.47 kg BW), 15 that never had diarrhea and 15 that had diarrhea were used to assess potential associations between intestinal permeability and incidence of diarrhea. On 0, 7, 14 and 21 d of life, intestinal permeability of calves was measured by dosing 2 markers (lactulose and D-mannitol) and assessing their concentration in serum by ultra-high performance liquid chromatography-mass spectrometry. Plasma IgG was measured at birth and at 6 and 24 h after first colostrum intake and efficiency of IgG absorption calculated. Plasma and colostrum IgG contents were determined by radioimmunoassay and bacterial load in colostrum samples by colony counting. Data were analyzed with a mixed-effects model for repeated measures. All diarrhea incidences occurred between 7 to 14 d of study. Overall colostrum quality was good, with an IgG content >50 mg/mL but total bacterial load was high (>100,000 cfu/mL). However, there were no differences in these 2 parameters between colostrums consumed by calves that did and those that did not incur diarrhea. Also, efficiency of IgG absorption was similar for all calves (~16%).

However, intestinal permeability was increased in diarrheic compared with healthy calves. Diarrheic calves had greater ($P < 0.01$) lactulose serum concentrations (15.3 ± 0.37 µg/mL) than healthy calves (8.4 ± 0.37 µg/mL). Furthermore, diarrheic calves tended ($P = 0.06$) to have a greater lactulose to D-mannitol ratio (1.26 ± 0.16) since birth until 21 d of life than healthy calves (0.81 ± 0.16). In conclusion, calves correctly immunized that develop diarrhea may be predisposed to suffer scours due to altered intestinal permeability right from birth.

Key Words: colostrum, intestinal integrity, scours

W248 Effects of realimentation on umbilical blood flow, fetal and placental measurements, and birth weight in nutrient-restricted pregnant ewes.

Manuel Vasquez*, Kendall Swanson, and Kimberley Vonnahme, *North Dakota State University, Fargo, ND.*

Nutritional restriction (60% of total nutritional requirement) from d 50 to 130 applied in nulliparous ewes has shown to reduce umbilical blood flow (UBF; Lemley et al., 2012; AJP 302:R454-R467). We hypothesized that during restriction, UBF and fetal and placentome measurements would be less than in adequately fed ewes, but upon realimentation, ewes would have similar UBF as ewes that were never restricted. Second parity Dorset ewes were assigned either to an adequate nutrition group (CON, n = 7) or a restricted (60% of CON) group (RES, n = 8), from d 50 to 90 of gestation. On d 90, all ewes were fed 100% of nutritional requirements according to body weight. Ewe body weight and conceptus measurements via ultrasonography were recorded every 10 d from d 50 to 130 of gestation. Every 10 d, length and width from 10 random placentomes were averaged and then multiplied to obtain placentome area. Fetal biparietal and abdominal lengths were recorded. Doppler mode was used to obtain UBF, pulsatility index (PI), and resistance index (RI). At birth, lambs and placental measurements were obtained. The data were analyzed using the Proc Mixed procedure of SAS. Treatment and day were treated as fixed effects, ewe as random. By d 70, RES ewes were lighter ($P < 0.01$), and remained lighter than CON ewes throughout the experiment. While there were no treatment by day interactions or main effects of treatment ($P > 0.13$) for any measurements obtained by ultrasonography, there were some interesting observations. On d 80, UBF and placentome area were decreased, and PI, RI, and biparietal distance increased in RES vs CON ewes ($P \leq 0.05$; means separation of unprotected F test). On d 90, before the realimentation, all ultrasound measurements were similar. After realimentation, there was no effect of treatment on any of the ultrasound measurements. At birth, lambs and placental measurements were similar ($P > 0.43$). Perhaps the increased resistance indices and smaller placentome size on d 80 were a trigger to the dam to enhance UBF to the growing fetus. Further studies are needed to determine the impact of maternal age and parity in the face of nutrient restriction on UBF.

Key Words: ewe, pregnancy, blood flow

W249 Changes in insulin-like growth factor I and II profiles following anti-bPL antibodies infusions in six long-term-cannulated bovine fetuses at late gestation.

Andrea Alvarez-Oxiley*[1], Noelita Melo de Sousa[2], Jean L. Hornick[2], Kamal Touati[2], and Jean F. Beckers[2], [1]*Facultad de Agronomia, Universidad de la Republica, Montevideo, Montevideo, Uruguay,* [2]*Faculty of Veterinary Medicine, University of Liege, Liege, Liege, Belgium.*

Studies were conducted to evaluate the changes in plasma concentrations of bovine fetal placental lactogen (bPL), insulin-like growth factor (IGF-I) and IGF-II following anti-bPL antibody infusion in fetal circulation. Abdominal aorta of bovine fetuses (n = 6) were chronically cannulated on the medial tarsal artery and infusion of rabbit anti-bPL IgG was performed during late gestation. From the first infusion, blood samples were collected from the fetus on a daily basis. Fetuses remained cannulated during the last 10 to 95 d of gestation. The time-series of hormonal data (bPL, IGF-I and IGF-II) were statistically analyzed for repeated measures as a split plot in time with number of anti-bPL infusions (one vs. more than one), dose of anti-bPL infused L (low, 4, 6, 8 mL) vs. H (high, 20 mL) and days after infusions (d 1 to d 7) as the fixed effects using the Mixed procedure of SAS (1998). IGF-I concentrations tended to reach a minimal concentration on d 3 after infusions (15.5 ± 3.4 ng/mL; $P = 0.056$). No changes were observed on IGF-II concentrations. The mean values of bPL on d 3 after infusion showed a significant increase. When low doses of anti bPL IgG were administered, no peak of binding in fetal serum was observed. When higher or repeated doses of anti bPL IgG were injected, a significant binding rate of the tracer (B/T) was recorded in the fetal serum during 1, 2 or several days. This high B/T can be due to circulating free anti bPL IgG; these rabbit IgG can remain in solution during the step of separation of free and bound fraction of the RIA and thus can bind part of the tracer and create an artifactual overestimation of the circulating bPL. However generally, concentrations of circulating bPL after anti bPL IgG injection were decreased justifying a transitory decrease in IGF-I concentrations. These data showed that following anti-bPL infusion, a transient decrease in IGF-I but not in IGF-II is observed. Our work suggests that PL somatogenic activities at the maternal-fetal interface are mediated through the IGF-I rather than IGF-II.

Key Words: IGF, bovine placental lactogen, fetus cannulation

W250 Effects of different feeding intensities during the first weeks of rearing on the metabolic status and on the circulating concentrations of adiponectin in dairy calves until 110 days of age.

Julia Kesser[1], Miriam Hill[1,2], Christian Koch[2], Marion Piechotta[3], Jürgen Rehage[3], Klaus Eder[4], Hassan Sadri[1], Ute Müller[1], and Helga Sauerwein*[1], [1]*Physiology and Hygiene Group, Institute for Animal Science, University of Bonn, Bonn, Germany,* [2]*Lehr- und Versuchsanstalt Neumühle, Münchweiler an der Alsenz, Germany,* [3]*Clinic for Cattle, University of Veterinary Medicine Hannover, Hannover, Germany,* [4]*Animal Nutrition, University of Giessen, Gießen, Germany.*

Dairy calves are commonly reared at restrictive levels of feeding, but greater allowances of feed intake may yield beneficial effects for both animal welfare and later milk production. We aimed to test the hypothesis that different feeding levels in early life will continue to affect the circulating concentrations of metabolically relevant hormones beyond the time of differential feeding. After receiving colostrum for the first 3 d of life, 57 German Holstein calves were randomly allocated to 3 groups fed either restrictively (r) with milk replacer (MR) (group MRr: 130 g MR/L, 6 L/d, n = 20), or MR ad libitum (al) (MRal: 160 g MR/L, n = 17) or whole milk (MI) al (MIal, n = 20). All calves received colostrum from their dams for the first 3 d of life, and were then fed according to their group regimen from d 1 – 27 (phase (P) 1). Thereafter all calves were fed according to the MRr plan and were gradually weaned from d 56 - 70 (P2). Calves were further observed for the subsequent P3, i.e., d 71 – 109. All calves had free access to hay, water and concentrate and received a TMR in P3. Blood samples were collected on d 0 (before colostrum feeding), and on 10 other d covering P1-P3 to assess the concentrations of glucose, NEFA, leptin and adiponectin (bovine specific ELISA). Data were analyzed using the linear mixed model (SPSS). Differences ($P < 0.05$) between the groups were largely limited to the time of differential feeding (P1): glucose was greater in MIal than in MR fed groups (glucose: 1.1-fold), insulin was greater in MRal and MIal than in MRr (2.3-fold), whereas NEFA were lower in MRal than in MRr (0.65-fold). Leptin was not different between the groups at any time. Adiponectin concentrations did not differ between groups in P1, but tended ($P < 0.1$) to lower values in MRr as compared with MRal and MIal in P2. In P3 the MRal group had higher values ($P < 0.05$) than MRr and MIal, thus supporting continued effects of the differential feeding. In view of the insulin-sensitizing effects of adiponectin, feeding intensity in early life might thus affect insulin sensitivity at older ages.

Key Words: adiponectin, dairy calves, insulin sensitivity

W251 Mitochondrial DNA copy numbers in blood cells during early and late lactation in dairy cows.

Lilian Laubenthal, Michael Hölker, Karl-Heinz Südekum, Helga Sauerwein, and Susanne Häussler*, *University of Bonn, Institute of Animal Science, Bonn, Germany.*

During the transition period most high-yielding dairy cows suffer from negative energy balance due to decreased energy intake and increased energy demands required for milk synthesis. Mitochondria are the main sites of energy metabolism in mammalian cells and their number varies depending on age, sex, organ, and physiological or pathological conditions. Mitochondria exhibit their own genome, the mitochondrial DNA (mtDNA), and its copy numbers reflect the abundance of mitochondria within a cell. In the course of lactation, environmental, physiological, and energetic conditions alter. We hypothesized that these changes may influence the number of mtDNA/cell in dairy cows and thus investigated the number of mtDNA copies in blood during early and late lactation. German Holstein cows (n = 21; BCS: 3.0 ± 0.1) were fed according to their requirements. Estimated total energy requirements were calculated by adding the requirements for maintenance and milk production. Blood samples from the jugular vein were collected 3 and 35 wk postpartum. Genomic DNA was extracted from whole blood using a commercially available kit. Based on the amplification of the 12S rRNA (mtDNA target gene) and the β-globin (reference gene) to normalize the DNA content in each sample, mtDNA copy number was assessed by a multiplex qPCR. Data (mean ± SEM) were analyzed by the pairwise Student's *t*-test (SPSS 22). In early lactation the number of mtDNA (87.4 ± 15.5 copies/cell) was about twice as much as in late lactation (46.0 ± 3.7; $P = 0.008$). In early lactation energy demands are increased compared with late lactation, as indicated by the estimated total energy requirements for wk 3 (132 ± 8.26 MJ NE_L) and wk 35 (103 ± 5.77 MJ NE_L). The greater energy demands in early lactation were accompanied by elevated mtDNA copy numbers in peripheral blood when compared with late lactation. The observed changes meet the expectation that the metabolic load during early lactation requires more mitochondria. Peripheral blood thus forms a suitable matrix to assess the cellular content of mitochondria and the cellular energetic status of dairy cows when tissues are not accessible.

Key Words: mtDNA copy number, dairy cow, lactation

W252 Mitochondrial DNA copy number in liver, mammary gland, and adipose tissue of early lactating dairy cows.

Lilian Laubenthal, Michael Hölker, Karl-Heinz Südekum, Helga Sauerwein, and Susanne Häussler*, *University of Bonn, Institute of Animal Science, Bonn, Germany.*

With the onset of lactation, energy requirements rapidly increase in high-yielding dairy cows. To adapt to lactation, energy metabolism needs to be regulated and coordinated among the key organs, namely adipose tissue (AT), liver, and mammary gland. Mitochondria are the main site for energy production in mammalian cells and their number depends on the energy demand and physiological state of each individual. Mitochondria have their own DNA and therefore the abundance of mitochondria in a cell is reflected by the copy number of mitochondrial DNA (mtDNA). Age-related differences of mtDNA are known for mice and humans, in which mtDNA varies between different tissues. However, little is known about mtDNA copy numbers in dairy cows; we thus aimed to provide an overview of mtDNA copy numbers in liver, subcutaneous (sc) AT and mammary gland of lactating dairy cows. Lactating German Holstein cows (n = 21; BCS: 3.0 ± 0.1) were fed according to their requirements. Liver, mammary gland and subcutaneous (sc) AT from the tailhead region were sampled during early lactation (3 wks postpartum), in which the estimated total energy requirement was 132 ± 8.26 MJ NE_L. Biopsies were immediately snap frozen after sampling. Genomic DNA was extracted using commercially available kits and the number of mtDNA copies/cell was quantified by a multiplex qPCR, targeting the 12S rRNA gene and using b-globin as reference gene. Tissue-specific differences were examined by Student's *t*-test (SPSS 22). Data are presented as means ± SEM. The number of mtDNA copies/cell in liver (360 ± 22.3 copies/cell) was 7.7-fold and 5.3-fold higher ($P < 0.001$) than in scAT (46.7 ± 2.32 copies/cell) and mammary gland (68.3 ± 4.66), respectively. Moreover, mammary gland contained 1.5-fold more mtDNA copies/cell than scAT ($P = 0.001$). The differences in mtDNA content observed between the organs investigated herein are presumably reflecting their metabolic activity during the first weeks of lactation with liver playing a key role.

Key Words: mtDNA copy number, dairy cow, liver

W253 Lipolysis induces adipose tissue macrophage infiltration in lactating dairy cows.

G. Andres Contreras*[1], Kyan Thelen[2], Courtney L. Preseault[2], Sarah E. Schmidt[2], and Adam L. Lock[2], [1]*Department of Large Animal Clinical Sciences, Michigan State University, East Lansing, MI,* [2]*Department of Animal Science, Michigan State University, East Lansing, MI.*

Excessive rates of lipolysis during periods of negative energy balance (NEB) are associated with increased susceptibility to disease. Lipolysis increases adipose tissue macrophage (ATM) populations. Depending on their phenotype, ATMs modify inflammatory processes and alter adipose metabolic functions. Classically activated ATMs (M1) are pro-inflammatory while alternatively activated ATMs (M2) promote inflammation resolution. The objective of this study was to evaluate changes in ATM trafficking and phenotype in healthy cows during feed restriction-induced NEB. Lactating multiparous dairy cows (DIM 119–210) were fed a common diet to meet nutrient requirements during a 14d preliminary period (d1 to 14) and then randomly assigned to one of 2 feeding protocols: ad libitum (AL; n = 6) or feed-restricted (FR; n = 7). Caloric intake was reduced in FR cows for 4 d (d15 to 18) to achieve a targeted NEB of −15 Mcal/d. Omental and subcutaneous adipose tissue samples were collected to harvest stromal vascular cells (SVC) on d11 and d18. Data were analyzed in a mixed model with treatment and day as fixed effects and cow as a random effect. FR cows reached a NEB of −13.5 ± 1.9 Mcal/d inducing a lipolytic response (NEFA on d18: FR = 0.52 mEq/L; AL = 0.17 mEq/L; $P < 0.01$), while AL animals remained in positive energy balance (3.2 ± 2.2 Mcal/d). Flow cytometry analysis revealed that at d18, FR increased the infiltration ratio of $CD68^+$, a specific ATM surface marker, in omental SVC (FR = 2.85 ± 0.39; AL = 1.25 ± 0.35; $P = 0.01$), while the expression ratio of CD14, an M1 marker, remained unaltered ($P = 0.86$). Adipose tissue from FR cows

exhibited an increased expression of the macrophage-related gene SIRPA ($P = 0.01$), but no change in M1 genes CCL2 and TNFα (both $P > 0.49$). Additionally, compared with AL, FR upregulated the expression of M2 specific genes IL10 and ARG1 (both $P < 0.01$). This finding contrasts with the predominately M1 phenotype observed previously in ATMs from clinically diseased cows. These results provide evidence for an active role of ATMs during NEB in ruminants and emphasize changes in their inflammatory phenotype during lipolytic periods.

Key Words: lipolysis, adipose tissue macrophages, negative energy balance

W254 Longitudinal characterization of the gene expression of key components of the mTOR signaling and ubiquitin proteasome system in skeletal muscle of dairy cows during the periparturient period and subsequent lactation. Yi Yang[1], Helga Sauerwein*[1], Sven Dänicke[2], Jürgen Rehage[3], and Hassan Sadri[1], *[1]Institute of Animal Science, Physiology and Hygiene Group, University of Bonn, Bonn, North Rhine-Westphalia, Germany, [2]Institute of Animal Nutrition, Friedrich-Loeffler-Institute (FLI), Braunschweig, Lower Saxony, Germany, [3]Clinic for Cattle, University for Veterinary Medicine, Foundation, Hannover, Lower Saxony, Germany.*

At the onset of lactation when voluntary feed intake is insufficient to cover the total needs for maintenance and lactation, dairy cows need to mobilize body reserves. Besides fat, skeletal muscle protein is also degraded. Muscle is the main labile source of amino acids (AA) and may thus partition AA to protein syntheses in other organs, mainly the mammary gland, for gluconeogenesis and for generating ATP. The mammalian target of rapamycin (mTOR) and ubiquitin-proteasome system (UPS) are considered as the major regulators of protein synthesis and protein degradation, respectively. We hypothesized that the transcript abundance of key components of mTOR signaling and of 2 major muscle-specific E3 ubiquitin ligases, MuRF1 (muscle RING-finger protein-1) and atrogin-1 in skeletal muscle will change throughout late pregnancy and the subsequent lactation period. From 14 German Holstein cows, muscle tissue (*M. semitendinosus*) were obtained for biopsy on d −21, 1, 21, 70, 105, 182, 196, 224, and 252 relative to calving. The target mRNAs were quantified by qPCR. Data were analyzed by the MIXED procedure of SAS and results are reported as LSM with P-values adjusted by the method of Tukey-Kramer. The mRNA abundance of mTOR increased ($P < 0.05$) from d −21 to d 1, followed by a decline toward pre-partum values by d 180 and then increased thereafter. A 6-fold increase in eukaryotic initiation factor 4E-binding protein mRNA was observed from d −21 to d 1, and then a gradual decrease until d 105 with relatively stable values thereafter. The encoding ribosomal protein S6 kinase mRNA decreased ($P < 0.0001$) during lactation. The abundance of MuRF1 mRNA increased (3.6-fold) from d −21 to d 1, declined to nearly pre-partum values by d 105 and then remained unchanged. The mRNA abundance of atrogin-1 followed almost a similar trend as that of MuRF1; a 2.2 fold increase was noted from d −21 to d 1, and then a decrease until d 21 and unchanged values thereafter. In conclusion, our data show that key components of mTOR and UPS are upregulated at the level of the mRNA on d 1, suggesting a greater rate of protein turnover in muscle around calving.

Key Words: skeletal muscle, mTOR, ubiquitin-proteasome system

W255 Comparison of fractional gluconeogenesis estimates in sheep determined with D_2O administered via vein or rumen and by intravenous infusion of $^{13}C_6$-glucose. Cornelia C. Metges*[1], Solvig Görs[1], Gürbüz Das[1], Umang Agarwal[2], and Brian J. Bequette[2], *[1]Institute of Nutritional Physiology, Leibniz Institute for Farm Animal Biology, Dummerstorf, Germany, [2]Dpt. Animal and Avian Sciences, University of Maryland, College Park, MD.*

In ruminants, the main precursor for GNG is ruminal propionate which fundamentally differs from gluconeogenic precursors of monogastrics. The D_2O method has been used to measure fractional gluconeogenesis (GNG) in humans. We aimed to determine whether the route of D_2O administration (rumen (IR) or jugular vein (IV)) affects D enrichment of rumen fluid, ruminal propionate and estimates of fractional GNG. In addition, we compared these GNG estimates with estimates derived from $^{13}C_6$-glucose infusion. Four sheep (23.5 ± 1 kg BW), equipped with a rumen fistula and a jugular vein catheter, were fed a pelleted ration (35 g/kg BW and d; 9 MJ ME/d) at 2-h intervals. Water was offered ad lib. Sheep were given 2 boli of 7 g D_2O (99.2 atom% (AP) D/kg BW) at 0800 and 1200 h either IR (method 1) or IV (method 2), or received continuous IV infusion of $^{13}C_6$-glucose (0.15 g/h) for 10 h (method 3) in a crossover design with 1 wk separating tracer administrations. Ruminal D enrichments were measured by isotope ratio mass spectrometry whereas ruminal propionate and plasma glucose D enrichment was measured by GC-MS. Fractional GNG was calculated from the ratio of D enrichment at C-5 of glucose (labeling via GNG only) to that at C-2 (labeling during GNG and glycogenolysis). The ^{13}C-mass isotopomer enrichment of plasma glucose was determined by GC-MS and GNG was calculated. Statistical comparison of GNG estimates was made with repeated measures ANOVA using PROC MIXED of SAS. Rumen fluid D enrichment attained a plateau 6 h after the first bolus (IR: 1.51; IV: 1.43 APE; $P > 0.1$). The D enrichment of ruminal propionate as a precursor for GNG showed faster labeling with the IR route (3 h: $P < 0.10$; 6 h: $P < 0.05$). However, the plateau enrichments of rumen fluid D and propionate D did not differ ($P > 0.10$). GNG estimates derived from IR and IV routes of D_2O administration did not differ ($P = 0.83$) which resulted in an overall GNG estimate of 58.8%. In contrast, GNG estimate derived from $^{13}C_6$ glucose dilution was at 72.8%, which did not differ from the other 2 methods ($P > 0.13$). Thus all 3 methods yield similar estimates of GNG in ruminants.

Key Words: ruminants, gluconeogenesis, stable isotope-labeled tracer

W256 Propionate and cyclic AMP induced bovine PCK1 gene transcription is concurrently mediated by CRE and HNF4α binding elements. Qian Zhang, Stephanie L. Koser, and Shawn S. Donkin*, *Purdue University, West Lafayette, IN.*

Cytosolic phosphoenolpyruvate carboxykinase (PCK1), a key glucogenic enzyme, is controlled at the transcriptional level. Our objective was to determine regulatory elements within the bovine PCK1 promoter that control transcription in response to cyclic AMP (cAMP), glucocorticoids, and propionate (PROP). Putative DNA promoter transcription factor protein binding sequences were identified for cAMP response element (CRE) at −94 to −87 and for Hepatic Nuclear Factor 4α (HNF4α) at +68 to +72 (HNF4α1) and −1078 to −1074(HNF4α2). To test control of transcription, the wild-type (WT) bovine PCK1 promoter (−1238 to +221) was ligated to a luciferase reporter gene and transfected into H4IIE cells followed by incubation with 2.5 m*M* PROP, 1 m*M* cAMP (cAMP), 5 μ*M* dexamethasone (DEX) or their combinations. The functionality of CRE, HNF4α1, and HNF4α2 cis-regulatory elements was determined using deletion mutations of the core transcription factor binding regions within the PCK1 promoter DNA. The deletion mutations tested were $HNF4\alpha1^-$; $HNF4\alpha2^-$; CRE^-; $HNF4\alpha1^-/HNF4\alpha2^-$; $CRE^-/HNF4\alpha1^-$; $CRE^-/HNF4\alpha2^-$; and $CRE^-/HNF4\alpha1^-/HNF4\alpha2^-$. H4IIE cells were transfected with the promoter-reporter constructs and exposed to treatments for 23 h. Luciferase activity was measured in the cell lysates as a direct proxy for bovine PCK1 promoter activity. Within each construct, treatment effect was expressed as the fold change of luciferase activity relative to base media control (n = 3 cell preparations). Analyses of variance of the data were performed using the Proc Mixed procedure of SAS 9.3. Exposure to cAMP, DEX, cAMP+DEX, PROP, cAMP+PROP, cAMP+DEX+PROP induced ($P < 0.05$) expression of the WT promoter relative to no addition controls by 2.0, 2.3, 3.9, 6.0, 7.3, 14.4 ± 1.4 x respectively. A similar pattern was observed for each single mutant bovine PCK1 promoter. Responses to cAMP, DEX, PROP and their combinations were abolished for mutations lacking both HNF4α1 and CRE binding sites indicating that these elements act synergistically to control bovine PCK1 transcription.

Key Words: promoter, transcription factor binding site

W257 Hepatic mRNA expression of genes related to somatotropic axis and metabolism of dairy cows treated with recombinant bovine somatotropin during the periparturient period.

Paula R. B. Silva*[1], Wanda Weber[1], Brian Crooker[1], and Ricardo C. Chebel[1,2], [1]*University of Minnesota, St Paul, MN,* [2]*University of Florida, Gainesville, FL.*

Objectives were to determine the effects recombinant bovine somatotropin (rbST) treatment during the peripartum period on hepatic mRNA expression of genes related to inflammation and immune response. Holstein cows were assigned randomly to receive no treatment (control; n = 10), 87.5 mg (rbST87.5; n = 12), or 125 mg (rbST125; n = 10) of rbST every 7 d from −21 to 21 d relative to calving. Liver biopsies were collected −21, −7, and 7 d relative to calving. Twenty 4 genes were assessed by direct molecular counts using NanoString technology. Continuous data were analyzed by ANOVA. Gene expression on d −21 was used as a covariate for analyses of mRNA expression on d −7. No differences in mRNA expression were observed among treatments on d −21 for all the genes except SOCS3, which had lower ($P \leq 0.05$) mRNA expression in control cows compared with rbST87.5 cows. On d −7, expression of mRNA for ANGPTL4 and SCARB1 was higher ($P \leq 0.05$) in rbST87.5 and rbST125 cows than control. Cows in the rbST87.5 treatment had ($P \leq 0.05$) higher mRNA expression for HP, ICAM1, SOCS2 and XBP1 on d −7 than control cows. Control cows had ($P \leq 0.05$) higher mRNA expression for HIF1A than rbST125 cows on d −7. On d 7, control cows had ($P \leq 0.05$) higher mRNA expression for CXCL1, IL1RN, MYD88, NFKBIA, and SOCS3 compared with rbST87.5 and rbST125 cows. Control cows had ($P \leq 0.05$) higher mRNA expression for ICAM1 and XBP1 than rbST125 cows and had higher mRNA expression for HIF1A than rbST87.5 cows. On the other hand, expression of mRNA for NR3C1 and SOCS2 was ($P \leq 0.05$) lower in control cows than rbST125 and rbST87.5 cows, respectively. Treatment did not affect hepatic expression of the genes CEBPD, JUN, M-CSF1, NFKB1, PPARGC1A, STAT5B, TLR2, TNF, TNFRSF1 and TNFRSF5. The gene G-CSF was not detected. Weekly treatment of periparturient cows with rbST regulates liver mRNA expression of genes related to inflammation and immune response during the prepartum and postpartum periods. Increased postpartum mRNA expression of inflammatory and immune responses genes in control cows might be a consequence of increased incidence of postpartum diseases.

Key Words: periparturient cow, recombinant bovine somatotropin, hepatic gene expression

W258 A direct method is not as effective as an indirect method for determination of fatty acids from bovine placental tissue.

Patricia A. Dutra[1,2], Mohanathas Gobikrushanth*[2], Reza Salehi[2], Ana Ruiz-Sanchez[2], Marcos G. Colazo[3], and Divakar J. Ambrose[3,2], [1]*Departamento de Zootecnia, Universidade Federal da Bahia, Salvador, Bahia, Brazil,* [2]*Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada,* [3]*Livestock Research Branch, Alberta Agriculture and Rural Development, Edmonton, Alberta, Canada.*

Quantification of fatty acids (FA) in reproductive tissues including the placenta is important to understand the influence of FA on reproductive function. Two methods of FA determination (direct and indirect) are commonly used, but their comparative efficacy to quantify FA in bovine tissue is not known. Therefore, we compared the efficacy of the 2 methods of FA determination in bovine placental tissue. Placenta (fetal cotyledon) samples from 13 dairy cows were collected within 5 h of calving, before placental release, snap frozen and stored. Tissues (0.05 g) were assigned in duplicate to either direct methylation (samples directly subjected to methylation process with no extraction step [direct method]) or indirect methylation (samples first subjected to FA extraction and then methylated [indirect method]). The indirect method was approximately 6 h long that involved an 18-step procedure, whereas the direct method took 3 h and had only 10 steps. Briefly, frozen tissue samples were pulverized under liquid nitrogen and methylated either directly, without extraction, or indirectly, after extraction. The FA methyl esters were then injected for gas chromatographic analysis. Fatty acid data were analyzed using the Mixed procedure of SAS. Forty-five different FA were identified from the placental tissue, of which 32 FA were significantly higher in the indirect method. Moreover, the unsaturated-long chain FA of our interest, i.e., oleic, linoleic, α-linolenic, eicosapentaenoic and docosahexaenoic acid were significantly higher ($P < 0.0001$) in the indirect method than in the direct method (0.42, 0.08, 0.008, 0.02 and 0.05 vs. 0.30, 0.06, 0.005, 0.01 and 0.04 mg per 50 mg sample, respectively). In addition, the total amount of FA, saturated FA, polyunsaturated FA, omega-3 and −6 FA were also higher ($P < 0.0001$) with the indirect method than the direct method. Even though, the direct method is shorter and faster, it reduced the amount of FA extracted. We conclude that the indirect method has higher efficacy and should be preferred over the direct method for extraction of FA from placental tissue.

Key Words: extraction, methylation, bovine placenta

W259 The effect of prepartum diets supplemented with oilseeds on maternal and newborn calf plasma fatty acid profile.

R. Salehi*[1], M. G. Colazo[2], M. Oba[1], and D. J. Ambrose[1,2], [1]*University of Alberta, Edmonton, Alberta, Canada,* [2]*Alberta Agriculture and Rural Development, Edmonton, Alberta, Canada.*

Long-chain polyunsaturated fatty acids (PUFA) have important roles during pregnancy, both in the dam and the fetus. However, limited information is available regarding the transfer of specific PUFA from dam to fetus in cattle. Our objective was to examine the effects of oilseed (oilseed vs. no oilseed) and type of oilseed (canola vs. sunflower) supplementation during late gestation on the fatty acid (FA) profile of maternal and newborn calf plasma. Pregnant Holsteins were assigned to 1 of 3 diets containing 8% rolled sunflower (SUN, high in linoleic acid; 8 cows) or canola seed (CAN, high in oleic acid; 7 cows) on dry matter (DM) basis, or no oilseed (CON; 7 cows), for the last 35 ± 2 d of gestation. Blood samples were collected within 3 h after calving from dam and newborn calf to determine FA profile. Data were analyzed using the Mixed procedure of SAS. The proportion of total saturated FA (TSFA) was higher in CON (46.8 ± 3.7) fed cows than in those fed

oilseeds (37.5 ± 2.7). Feeding SUN increased the proportion of total PUFA and linoleic acid (47.8 ± 2.5 and 45.5 ± 2.9) relative to those fed CAN (39.5 ± 2.7 and 36.0 ± 2.9, respectively). Moreover, SUN fed cows had higher TPUFA:TSFA ratio (1.29 ± 0.06) than those fed CAN (0.99 ± 0.06) or CON (0.88 ± 0.06). However, oilseed or type of oilseed supplementation during prepartum period did not affect FA profile of calves. Correlation analysis in CON treatment indicated that calf and dam TSFA were positively associated ($R = 0.79$, $P = 0.03$). Total monounsaturated FA (TMUFA, $R = -0.66$, $P = 0.10$) and oleic acid (OLA, $R = -0.68$, $P = 0.08$) in calf were negatively correlated with dam TSFA in CON treatment. Calf OLA ($R = 0.68$, $P = 0.05$) and TMUFA ($R = 0.67$, $P = 0.06$) in SUN treatment had positive association with dam total n-6. There was no relationship between dam and calf FA profile in CAN treatment. In summary, oilseed and type of oilseed supplemented during late gestation affected maternal FA profile but not that of newborn calf. Moreover, oilseed supplementation and the type of oilseed supplemented during prepartum period affected the association between maternal and newborn calf FA.

Key Words: sunflower seed, canola seed, fatty acid profile

W260 Examining peripheral activity of catechol-O-methyltransferase (COMT) in Holstein cows following artificial insemination. Rachel M. Wilson*, Christa L. Gilfeather, Caitlin G. Hart, and Caleb O. Lemley, *Mississippi State University, Mississippi State, MS.*

The objective was to determine peripheral activity of COMT in pregnant versus non-pregnant lactating Holstein cows. Cows (n = 22) were synchronized using the Ovsynch plus CIDR protocol and bred via artificial insemination on d 0. Cows were retrospectively classified as pregnant (n = 4) or open (n = 14) based on rectal palpation at d 35 post-insemination. Moreover, cows were classified as rebred (n = 4) if they showed signs of estrus and were re-inseminated before rectal palpation. Blood samples were collected on d 0, 4, 8, 12, 16, 20, and 24 post-insemination. Plasma was separated by layering 3 mL of blood onto 3 mL of Ficoll and centrifuged at 400 × *g* at room temperature for 30 min. One mL of erythrocytes were collected and stored at −80°C. Peripheral activity of COMT was determined by incubating erythrocyte cell homogenates with 2 m*M* s-adenosyl methionine, 3 m*M* cysteine, 10 m*M* $MgCl_2$, and 1 m*M* of the COMT specific substrate 6–7-dihydroxycoumarin. Samples and substrates were incubated at 37°C for 30 min and enzyme reactions were stopped by adding 0.5 *M* HCl, 10% $NaNO_2$, 10% $NaMoO_4$, and 1 *M* NaOH to each sample. Lastly, the disappearance of 6–7-dihydroxycoumarin was determined by measuring the amount of light absorbed at 510 nm using a Spectra Max Plus plate reader. Activity of COMT was analyzed using repeated measures ANOVA of the MIXED procedure of SAS and the model statement included day, pregnancy status, and their respective interaction. Activity of COMT was increased ($P < 0.01$) on d 16 post-insemination compared with all other days in cows classified as open or pregnant. Activity of COMT was not different ($P = 0.87$) throughout the sampling period in cows classified as rebred. Moreover, activity of COMT was increased ($P < 0.01$) on d 16 in pregnant cows versus rebred cows. Therefore, peripheral activity of COMT in lactating Holstein cows, which is involved in catechol-estrogen metabolism, may be altered by pregnancy status as well as days post-insemination.

Key Words: catechol-O-methyltransferase, erythrocytes, pregnancy

W261 IGF-1 concentrations during early pregnancy in suckled Nellore beef cows. Rogerio F. G. Peres*[1], Ky G. Pohler[3], Hugo B. Graff[2], Adnan D. P. Rodrigues[1], Michael F. Smith[3], Duane H. Keisler[3], and Jose L. M. Vasconcelos[1], [1]*Departamento de Produção Animal, Faculdade de Medicina Veterinária e Zootecnia-UNESP, Botucatu, São Paulo, Brazil,* [2]*Agropecuária Fazenda Brasil, Barra do Garças, Mato Grosso, Brazil,* [3]*Department of Animal Sciences, University of Missouri, Columbia, MO.*

The objective of this experiment was to evaluate temporal changes in serum IGF-1 concentrations in Nellore postpartum cows and its effect on the pregnancy rates to TAI. Cows (n = 1208) from 2 farms with different grass quality (Farm1 = high quality forage; n = 931, BCS 2.81 ± 0.01; Farm2 = low quality forage; n = 277, BCS 2.97 ± 0.03) with 53 ± 6.2 d postpartum were supplemented with mineral premix (110 g/cow/day) throughout the study. Cows underwent an estrous synchronization protocol with TAI. Blood was sampled on D-11 (first day of protocol), D0 (TAI), and D30 (pregnancy diagnosis) and analyzed for IGF-1 concentrations (all cows). Concentrations of IGF-1 on Days −11, 0 and 30 were analyzed using PROC MIXED including farm, BCS, pregnancy status on D30 and cow within pasture as a random effect. PROC GLM was used to evaluate IGF-1 concentrations effect on pregnancy rates. The pregnancies to TAI were 48.2% (449/931) and 45.5% (126/277) for Farm1 and 2, respectively. IGF-1 concentrations were greater ($P < 0.05$) in all days in Farm1 compared with Farm2 ($P < 0.05$). IGF-1 concentrations decreased during the study on Farm1 (D-11: 145.0 ± 2.4a, D0: 125.2 ± 2.9b and D30: 98.6 ± 1,8c ng/mL, $P < 0.05$). On farm 2 the IGF-1 concentrations were greater on D-11 compared with D0 and D30 (D-11: 73.0 ± 1.5a, D0: 65.1 ± 1.5b, D30: 63.0 ± 1.4b ng/mL, $P < 0.05$). There was a linear negative association of IGF-1 concentrations on pregnancy rates ($P < 0.05$). There was no difference in IGF-1 concentrations on D-11 and D0 between pregnant and open cows. Cows in Farm1 that became pregnant (96.0 ± 1.9a ng/mL) had less IGF-1 concentrations on D30 compared with nonpregnant cows (102.4 ± 1.9b ng/mL). In Farm 2 pregnant (60.0 ± 1.7b ng/mL) cows tended ($P < 0.06$) to have less IGF-1 concentration than nonpregnant cows (63.7 ± 1.5b ng/mL). These data show that Nellore cows have a decrease in IGF-1 concentrations within 30 d of the first insemination and pregnant cows had less IGF-1 concentration on D30 compared with nonpregnant cows. Although the farm with better quality forage had cows with increased IGF-1 concentrations compared with cows in the farm with low quality forage, in both farms pregnant cows had a decrease in IGF-1 after TAI. Further research is needed to understand mechanisms by which less IGF-1 is associated with pregnancy in beef cows. FAPESP Project #2014/03209–0.

W262 Circulating anti-Müllerian hormone (AMH) in Holstein and Jersey breeds, at different physiological states and in dam-daughter pairs. E. O. S. Batista*[1,2], C. Collar[1], N. Silva-Del-Rio[1], P. D. Carvalho[4], J. P. Verstegen[3], P. S. Baruselli[2], M. C. Wiltbank[4], and A. H. Souza[1], [1]*University of California, Tulare, CA,* [2]*University of Sao Paulo, Sao Paulo, SP, Brazil,* [3]*Mofa Global, International Center for Biotechnology, Wisconsin, WI,* [4]*University of Wisconsin, Wisconsin, WI.*

Our aim was to investigate circulating levels of the anti-Müllerian hormone (AMH) in Holstein and Jersey breeds at different physiological states. A second objective was to study possible associations between circulating AMH in dam-daughter pairs. Mature cows and heifers were located in 2 commercial facilities in Central-California. Blood sample for AMH analysis was taken from Holstein (Mature cows = 141; pregnant Heifers = 408) and Jersey (Mature cows = 148; pregnant Heifers =

123) breeds and measured with the MofA-Global bovine fertility assay. Data were analyzed by the GLIMMIX and CORR procedures of SAS. Circulating AMH differed ($P < 0.01$) across cattle breeds (Holstein cows = 243.9 pg/mL; Holstein heifers = 237.8 pg/mL vs Jersey cows = 312.2 pg/mL; Jersey heifers = 334.4 pg/mL). Despite of cattle breed, circulating AMH seem to be increased in cows with greater days in milk ($P = 0.01$); but was not influenced by level of milk production in lactating cows ($P = 0.92$) or even parity number ($P = 0.68$). In virgin heifers, stage of pregnancy did not influence circulating AMH ($P > 0.10$) in both Holstein and Jersey breeds. Interestingly, there was a significant although somewhat low correlation of circulating AMH in dam-daughter pairs (Holsteins: n-pairs = 116, r = 0.18, $P < 0.01$; Jerseys: n-pairs = 106, r = 0.22, $P < 0.01$). In conclusion, AMH results are specific within major dairy breeds and some important nuisance variables may need to be taken into account when interpreting AMH results. The significant correlation between circulating AMH in dams and their respective daughters might allow for selection of this important heritable trait.

Key Words: anti-Müllerian hormone (AMH), dairy breed, heritability

Production, Management and the Environment III

W263 Technical and economic performance on beef cattle in the Livestock Low Carbon Integrated Project-ICV. Fabiano Alvim Barbosa*[1], Vando Telles Oliveira[2], Filipe Lage Bicalho[3], Luciano Bastos Lopes[4], Juliana Mergh Leão[1], and Lucas Luz Emerick[1], *[1]Universidade Federal de Minas Gerais, UFMG, Belo Horizonte, Minas Gerais, Brazil, [2]Instituto Centro de Vida, ICV, Alta Floresta, Mato Grosso, Brazil, [3]Soluções Integradas ao Agronegócio, SIGA, Alta Floresta, Mato Grosso, Brazil, [4]Empresa Brasileira de Pesquisa Agropecuária, Embrapa, Sinop, Mato Grosso, Brazil.*

Economic efficiency and productivity of 6 farms on cattle production systems were evaluated in Mato Grosso State, Amazon biome, during January 2013 and December 2014, part of the Livestock Low Carbon Integrated Project-ICV. Production and economic data were collected using control software (*Prodap Profissional GP*) and analyzed by electronic spreadsheets (Microsoft Excel). The systems was developed exclusively on a grazing system with a base herd comprised of Zebu (Nelore) and crossbred *Bos taurus* × *Bos indicus* cattle in 4 farms. The total of pasture was 6,560 ha (ha) and 14,260 cattle. The average of pasture was 547 ha/farm and 1,188 cattle/farm. Introduction of technologies related to good practices agricultural of fertilization of pasture, feeding supplementation, breeding program, animal health practices, associated with technical-administrative management were evaluated. The zootechnical and economic indexes were compared by Duncan and Tukey test with significance level of $P < 0.05$. There was no statistical difference ($P > 0.05$) between zootechnical indexes, stocking rates was 2.17 animals/ha, 755 kg live weight/ha, 256.73 kg body weight produced/ha and 0.87% of mortality rate. There was no statistical difference ($P > 0.05$) between economic indexes, total operating costs was US$0.68/kg, net margin of US$165.09/ha. The net present values (NPV) and internal rate of return (IRR) were higher in 2014 than 2013 ($P < 0.05$), due to increased financial resources for the technologies in 2013. NPV was US$74.92 and US$208.68/ha in 2013 and 2014, respectively ($P < 0.05$), IRR was 1.43 and 3.49% per month in 2013 and 2014, respectively ($P < 0.05$). The economic results indicated that the activity of beef cattle in Amazon biome can be sustainable use good agricultural practices.

Key Words: costs, profitability, sustainability

W264 Lactation and immune responses of lactating dairy cows vary with different environmental stressors. Ricardo O. Rodrigues*[1], Ann L. Kenny[1], Matthew R. Waldron[1,2], and Thomas B. McFadden[1], *[1]Division of Animal Sciences, University of Missouri, Columbia, MO, [2]Nutrition Professionals Inc., Chilton, WI.*

Meta-analysis was used to evaluate the response of dairy cows to different stressors. Holstein cows ($n = 24$; 2.8 ± 0.7 parity; 153 ± 25 DIM) were housed in free-stalls for 14d (P1), then moved to environmentally controlled tie-stall rooms at thermoneutral temperature for 7d (P2; constant 20°C), then exposed to 14d of programmed 12h cyclical heat stress (HS; mean THI range 72.5 ± 0.1 to 81.3 ± 0.5; P3), and finally, moved back to free-stalls for 7d (P4). Response of animals to housing (P1 vs. P2), HS (P2 vs. P3), and recovery from HS (P3 vs. P4; effect confounded with housing) were evaluated. For analyses, each variable within each period was averaged over the 3 median days. Data were analyzed using Proc MIXED of SAS; the original treatments were random effects and period was a repeated effect. For each comparison, data from the previous period were used to covariate-adjust for carryover effects. Moving cows from free- to tie-stalls did not affect BW, but reduced ($P < 0.01$) milk yield and DMI by 5 and 10%, respectively. Feed efficiency (FE) and ECM FE improved 6% ($P < 0.03$) but milk components declined ($P < 0.05$) from free- to tie-stalls, except for fat and SCS, which increased ($P < 0.05$). Plasma NEFA decreased ($P < 0.01$) and BHBA increased ($P < 0.03$) in tie-stalls. Immune measurements were minimally affected. Respiration rate (RR) increased ($P < 0.06$) 10% in cows housed in tie-stalls, but rectal temperature (RT) was only 0.2°C higher ($P < 0.01$). Heat stress negatively affected ($P < 0.01$) BW, milk yield and DMI (10, 28 and 28% decline, respectively) but did not affect FE, ECM FE or 3.5% FCM FE. Immune response was negatively affected ($P < 0.05$) during HS. Rectal temperature and RR increased ($P < 0.01$) 1.5°C and 65%, respectively, in P3 compared with P2. During recovery from HS (P4), milk yield and DMI were higher ($P < 0.03$), FE and ECM FE were lower ($P < 0.01$), and BW did not change from P3. Although recovery from HS markedly reduced RT and RR (1.7°C and 42%, respectively; $P < 0.01$), milk composition and most immune responses did not change from P3 to P4. We conclude that different stressors elicit different responses in performance variables and immune function.

Key Words: adaptation, heat stress, housing

W265 A descriptive analysis of how dairy cows convert feed into food in the United States. Juan M. Tricarico*, *Innovation Center for U.S. Dairy, Rosemont, IL.*

The net contributions dairy cows make to the food system in the United States are not necessarily well understood by consumers. Estimates of nutrient conversion efficiency are sometimes used to describe these contributions but are often poorly documented or based on dubious assumptions. The main objectives of this study were to 1) define coefficients to calculate human-edible fractions of major dairy feed ingredients used in the United States, and 2) estimate the share of the dairy ration that is human-edible on a national level using these coefficients. The analysis was performed on a national average dairy ration computed from 350 farm surveys used in the carbon footprint life cycle assessment for fluid milk (available at http://www.lcacommons.gov/). The national average ration includes weighed rations for calves, open heifers, bred heifers, first calf heifers, springers, lactating cows, and dry cows, and accounts for forage grazed during the year. The national average ration includes 33 ingredients and contains 53% forage and 47% concentrate (DM basis). Food, fuel, and fiber industry by-products (14 ingredients) account for 19% of dairy feed DM. Eight major crops account for 80% of dairy feed DM (corn 42%, alfalfa 22%, wheat 3.1%, soybean 3.0%, canola 1.8%, sorghum 1.7%, barley 1.4%, and cottonseed 1.4%). Two coefficients were calculated to estimate human-edible fractions of each ingredient. The first coefficient was calculated as 1 minus NDF content. The non-NDF fraction was considered human-edible if it does not contain toxic compounds, and ingredients containing more than 30% NDF were excluded. The second coefficient was calculated by multiplying the first coefficient by the proportion of total ingredient production currently demanded by the US food industry. This coefficient incorporates current consumer demand, preferences and eating habits. The amount of human-edible dairy feed is either 20 or 0.9% of ration DM when using coefficients 1 or 2, respectively. Dairy cows make a net positive contribution to food supply in the United States by converting significant amounts of otherwise unusable plant matter in feed into food.

Key Words: dairy, human-edible, food security

W266 Study of ethyl-2-nitropropionate, ethyl nitroacetate, nitroethane, and 2-nitroethanol as alternatives to reduce ruminal methane production. Pedro A. Ochoa*[1], Agustín Corral[1], Michael Hume[2], Oscar Ruiz[1], Claudio Arzola[1], and Robin C. Anderson[2], [1]*Facultad de Zootecnia y Ecología. Universidad Autónoma de Chihuahua, Chihuahua, Chihuahua, México,* [2]*U.S. Department of Agriculture, College Station, TX.*

Methane (CH4) is a greenhouse gas, as well as an energy loss in ruminant animals. Much research has been done aimed to reduce CH4 emission from cattle industry. Nitrocompounds such as nitroethane (NE), 2-nitroethanol (2NEOH), and 3-nitropropionic acid (3NPA), have been shown to possess the ability to inhibit methane production on in vitro conditions. However, the potential of ethyl-2-nitropropionate (E2NPA) and ethyl nitroacetate (ENA) to reduce methane production have never been evaluated. We evaluated the ability of ENA, E2NPA, 2NEOH, and NE to reduce total gas, CH4 production and microbial diversity changes in a consecutive batch culture. Mixed populations of ruminal bacteria were incubated in tubes 18 × 150 mm containing a basal medium with 0.2 g of ground alfalfa and a H_2/CO_2 (1:1) gas phase. Tubes were supplemented with water (control) or the corresponding nitrocompound to reach a 12 m*M* concentration and incubated at 39°C. Total gas production was determined after 24 h. Microbial diversity was determined by DGGE. Gas composition was determined by gas chromatography. Data were analyzed using PROC GLM of SAS by a complete randomized design considering each nitrocompound as sole effect. According to our results, the use of nitrocompounds as supplement had no significant effect on total gas production, except for nitroethane ($P \leq 0.000$; Table 1). In the other way, methane production was decreased ($P \leq 0.0001$) by all nitrocompounds compared with the controls. In addition, each nitrocompound does not showed difference on its capacity of reducing methane emissions ($P \leq 0.05$). The DGGE indicates that all nitrocompounds change the microbial diversity. Results of the study also reveal that the capacity of ENA and E2NPA to decrease methane production is very similar to the 2NPOH and NE. There is some evidence that these nitrocompounds could be supplemented to reduce methanogenesis.

Table 1 (Abstr. W266).

Treatment (nitrocompound)	Total gas volume production (mL)	Reduction (%)	Methane (µ*M*/mL)	Reduction (%)
Control	19.00	—	43.77	—
Ethyl nitroacetate	18.10	4.73	1.41	96.80
2-Nitropropionate	18.79	1.10	1.06	97.70
2- Nitroethanol	18.36	3.36	1.17	97.33
Nitroethane	15.40	18.94	1.83	95.86

Key Words: nitrocompounds, methane, ruminant

W267 Use of udder skin temperature as a heat stress indicator in lactating dairy cattle. Kristen M. Perano* and Kifle G. Gebremedhin, *Cornell University, Ithaca, NY.*

The objective of this research was to test whether the udder skin temperature of a cow is useful as a heat stress indicator. Heat stress leads to an increase in respiration rate, skin temperature, and rectal temperature, followed by a decrease in milk production and feed consumption. Rectal temperature is a reliable indicator of heat stress, but measuring rectal temperature may require restraint of the animal. Skin temperature is considered a less reliable indicator of heat stress, but skin temperature measurements are fast and non-invasive. For this research, 8 primiparous, mid-lactation Holstein cows producing 34.4 ± 3.7 kg/d of milk were housed in 2 identical climate-controlled rooms with tie stalls and exposed to moderate heat stress (THI 79.5 ± 1.2) for 8 h per day. Cows were given 1 week to adjust to the facility, then data was collected for 5 weeks on milk production, feed consumption, rectal temperature, respiration rate, udder skin temperature, and body surface temperature in 3 unshaved locations (neck, back and side). Cows were milked twice daily and fed ad libitum. Rectal temperature was measured twice each day before heat stress conditions and after 8 h of heat stress. Respiration rate, udder skin temperature, and body surface temperatures were measured before heat stress and every 2 h during heat stress. Four experimental cows were randomly assigned to be cooled with conductive cooling by circulating chilled water through modified DCC waterbeds, and these cows experienced less heat stress than control cows. For the final week of the experiment, experimental and control cows were switched. Correlations among daily milk production and feed consumption, rectal temperature at the end of heat stress, and the daily average under heat stress of respiration rate, udder skin temperature, and body surface temperature were analyzed in JMP. Correlation with milk production was strongest for rectal temperature (0.67), followed by feed consumption (0.58), udder skin temperature (0.53), respiration rate (0.38), and body surface temperature (0.23). Thus, udder skin temperature may be useful as a fast, non-invasive measurement of heat stress.

Key Words: heat stress, skin temperature, milk production

W268 Maternal heat stress affects calf passive immunity: Effects on intestinal cell apoptosis. Bahroz M. S. Ahmed*[1], Ana Paula A. Monteiro[1], Umair Younas[1], Turky O. Asar[1], J-D. Liu[2], Joyce Hayen[1], Sha Tao[2], and Geoffrey E. Dahl[1], [1]*University of Florida, Gainesville, FL,* [2]*University of Georgia, Tifton, GA.*

Heat stress (HT) in utero not only induces fetal growth retardation but also influences postnatal performance of the offspring, such as immune function and metabolic adaptation. The objective was to examine the cellular mechanism of altered passive immunity in neonatal bull calves after in utero heat stress during late gestation. Specifically, by examination of the rate of apoptosis of intestinal cells early in life, as that has been shown to influence gut closure. Cows were dried off 60 d before expected calving and randomly assigned to one of 2 treatments: HT or cooling (CL). During the dry period, all cows were housed in a freestall barn, the pen for CL cows was equipped with active cooling including water soakers and fans whereas the pen for HT cows had no soakers. Heat stress was moderate compared with other studies, as HT cows had only 0.1°C increase in rectal temperature and 8 breath/min increase in respiration rate compared with CL cows. After birth all bull calves were immediately separated from their dams and weighed. Bull calves (n = 30) were killed at birth without colostrum feeding (5/trt) and 1 and 2 d of age (DOA, following colostrum feeding, 5/trt). Colostrum (3.8 L) was fed within 2 h after birth to bulls slaughtered on 1 and 2 DOA. After slaughter, the intestine was removed, weighed, and dissected into duodenal, jejunal and ileal segments, and tissue samples from each section were fixed in 4% neutral formalin and then transferred to 70% ethanol for immunohistochemistry. Apoptosis was measured in the jejunum using TUNEL labeling, counting 6 different sections per slide per calf. Small intestine weights did not differ (HT: 1376 ± 45; CL: 1309 ± 45 g; $P = 0.30$). In both groups, apoptosis reactive cell counts decreased with time after birth (HT: 0DOA: 58.8; 1DOA: 21.6; 2DOA: 41.4; CL: 0DOA: 88.6; 1DOA: 58.0; 2DOA: 53.8; SEM = 16.7; $P = 0.05$). However, apoptotic counts in CL bulls were higher than HT bulls (66.8 ± 9.6 vs. 40.6 ± 9.6, respectively; $P = 0.10$). The results indicate that jejunal cell apoptosis progresses with time after birth, but in utero HT reduces the apoptotic rate.

Key Words: heat stress, bull, apoptosis

W269 Methane emissions from Holstein cows in tropical environment.

Camila S. Cunha*[1], Marcos I. Marcondes[1], Cristina M. Veloso[1], Maria I. B. Brandão[1], Elves C. Godinho Jr[1], Marcelo M. D. Castro[1], Aline S. Trece[1], Luisa F. L. Salazar[2], Erick Iglesias[1], Otávio H. G. B. D. Siqueira[1], Diego Zanetti[1], and Tadeu E. Silva[1], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Universidad de Antioquia, Medellin, Colômbia.*

The objective was to quantify enteric methane (CH_4) emissions from Holstein cows of 2 levels of milk production in tropical environment and compare data observed in this study to data obtained from the equations proposed by the Intergovernmental Panel in Climate Change (IPCC). The study was carried out at the Universidade Federal de Viçosa, Brazil. High milk production cows (29 ± 0.89 L/d, n = 6) and low milk production cows (10 ± 0.34 L/d, n = 5) were used in the assays. Each assay had the first 5 d for cows' adaptation plus the number of days required to have 5 d of gases samples of each animal. Cows were held in free stall barns. High production cows diet were constituted, in dry matter (DM) basis, by 48.5% of corn silage, 1.5% of Coast-cross (*Cynodon* sp.) hay and 50% of concentrate based on corn and soybean meal. The diet of low production cows were in DM basis, 80% of corn silage and 20% of concentrate based on corn, soybean meal and wheat meal. Food and refusals were sampled to dry matter ingestion (DMi) analyses. Average feed intake observed to each group of cows were, respectively, 20.14 e 13.13 kg of DM/day. The sulfur hexafluoride (SF_6) tracer methodology was used to obtain the observed methane emissions. IPCC Tier 2 equations were used to obtain the calculated methane emissions. A *t*-test were used for test the differences between the observed and the calculated data. Methane emissions observed from high production cows were 115.67 g CH_4/day, 5.74 g CH_4/kg of DMi and 3.94 g CH_4/L of milk and from low production cows were 174.68 g CH_4/day, 13.30 g CH_4/kg of DMi and 17.22 g CH_4/L of milk. When using the IPCC equations, methane emissions for the 2 groups of cows in g of CH_4/day were 403.08 and 261.15, respectively. There are significant differences ($P < 0.01$) between the observed and the calculated methane emissions data for the 2 groups of cows. It was concluded that the equations for estimating methane emissions from IPCC are not representative for high and low production cows in tropical environment.

Key Words: greenhouse gas, lactation, sulfur hexafluoride

W270 Effects of condensed tannin extract supplementation on beef cattle performance and nitrogen balance: I. Growing phase.

Landon G. Canterbury*, Lee-Anne J. Walter, Brandon M. Koch, David G. Lust, and Eric A. Bailey, *West Texas A&M University, Canyon, TX.*

Condensed tannins (CT), a polyphenolic of various forages, reportedly binds with dietary protein in the rumen and may affect site of nitrogen excretion in beef cattle. To evaluate the effect of CT on N excretion, a commercially available condensed tannin extract was top-dressed on a cereal grain-based diet at 3 levels (0, 1, or 2% of diet, DM basis). Nutrient digestibility and nitrogen balance were measured in British-cross steers (n = 18; BW = 374 ± 34 kg) offered ad libitum access to the basal diet (15.6% CP). Due to a limited number of metabolism crates, steers were randomly assigned to 3 groups first and then assigned to treatments within group. Steers were offered treatments for 10 d (7 d in individual stalls and 3 d in metabolism crates), followed by 4 d for total fecal and urine collections in metabolism crates. No group by treatment interactions was detected ($P \geq 0.18$) among the response variables. Provision of CT did not affect ($P \geq 0.56$) OM intake or apparent total-tract OM digestion. Similarly, NDF intake and apparent total-tract NDF digestion were not different ($P \geq 0.52$) among treatments. Nitrogen intake was not affected ($P = 0.58$) by inclusion of CT in the diet, but fecal N output increased ($P = 0.02$) at 2% CT inclusion compared with control. However, there was no difference ($P = 0.36$) in urine N output among treatments. Nitrogen retention was lesser ($P = 0.03$) with 2% CT than 0 or 1% CT. Proportion of total N excreted in urine decreased ($P = 0.03$) with CT supplementation at 1 or 2% in the diet. Similarly the proportion of total N excreted in feces increased ($P = 0.03$) with 1 or 2% CT inclusion. Under the conditions of this experiment, site of N excretion was shifted away from urine and toward feces when CT was included in a complete diet fed to beef cattle. Further work is needed to investigate possible effects of CT on N emissions from concentrated animal feeding operations.

Key Words: condensed tannin, digestibility, nitrogen balance

W271 Tannin extract supplementation on gas production in feces of receiving bull-calves.

Eva X. Murillo[1], Ernesto A. Velázquez[1], Melissa B. Corona[1], Idalia Enríquez[1], Billy J. Cervantes[2], Javier A. Romo[1], and Rubén Barajas*[1], *[1]FMVZ-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México, [2]Ganadera Los Migueles, S.A. de C.V., Culiacán, Sinaloa, México.*

The addition of condensed tannins to feces of beef cattle decreases the amount of in vitro gas production; but it is not clear if the same effect occurs when tannin extracts are fed to cattle. In this research, 30 Brahman bull-calves (230 ± 12.7 kg) were used to evaluate the influence of tannin extract supplementation on gas production in feces of receiving bull-calves. Fecal samples were taken from each bull-calf during 3 consecutive days, 40 g aliquots were placed in 600 mL plastic flasks, and 40 g of distillated water were added, flask were closed, and connected with a plastic pipe toward a 250 mL graduate glass flask inverted in a water bath. Flasks were incubated at 37°C during 24 h, and displaced water was recorded as the in vitro gas production. Other feces aliquots of 20 g were used to DM determination. Before receiving the treatments, the values of in vitro gas production (BGP) were computed as mL gas/g of feces DM basis. Bull-calves were placed in 6 dirt-floor pens, using a completely randomized design experiment, 3 treatments were randomly assigned: 1) corn silage based-diet (15.2% CP; 1.36 Mcal NEm/kg DM) without extra additives (Control): 2) Control plus 0.6% of condensed tannin extract (CT); and 3) Control plus 0.6% of hydrolysable tannin extract (HT). After 28 d on treatment diets, fecal samples were taken during 3 continuous days again, and after treatment fecal gas production (AGP) was measured as previously described. Each bull-calf was considered as the experimental unit. Results were analyzed by ANOVA for a completely randomized design. The BGP values were similar between treatments ($P = 0.53$) with a mean of 4.7 ± 0.45 mL/g of feces DM. The AGP values were not affected by treatments ($P = 0.54$) with a mean of 5.9 ± 0.49 mL/g of feces DM. Results indicate that when both, hydrolysable or condensed tannin are supplemented in the diet; they have no influence on the amount of gas produced in the feces of receiving bull-calves.

Key Words: feces, gas production, tannin

W272 Composting of dairy manure and grape vine prunings as a tool to reduce both industries' environmental impact. Mario E. de Haro-Marti*[1], Mireille Chahine[2], Ariel Agenbroad[3], and Tony McCammon[2], [1]*University of Idaho, Gooding, ID,* [2]*University of Idaho, Twin Falls, ID,* [3]*University of Idaho, Caldwell, ID.*

Composting of dairy manures is an acceptable and greatly used technique, but in most cases dairy manures don't have the proper carbon to nitrogen ratio (C:N) for composting without the loss of nitrogen as ammonia during the composting process. At the same time, the grape industry uses burning as the most widespread technique to dispose of carbon rich annual prunings. The objectives of this project were to demonstrate the effects of increasing the C:N content of dairy manures using grape vine prunings and to showcase 3 different composting techniques. Manure from an open lot dairy was mixed with ground grape vine prunings from an organic vineyard. The C:N ratios of the initial composting mix were adjusted to >40:1 to meet organic standards. Because grape prunings had a low C:N (79:1), sawdust from a horse stable was added to reach the desired C:N level. Three composting systems were showcased, mechanically turned windrows, passively aerated, and forced aerated. Three replications were built for each system. Control windrows consisted of 3 replications of mechanically turned windrows using only dairy manure and some straw to simulate regular dairy operations (C:N 23:1). A significant nitrogen loss reduction (4.33 kg/t, equivalent to an 85% reduction on total nitrogen loss) was observed in compost windrows with carbon-enhanced mixes (0.72 kg/t, $P < 0.05$) as compared with just dairy manure mix (5.03 kg/t, $P < 0.05$). Compounds' concentrations (nutrients) that usually limit compost application rates (e.g., P, K, salts) were also reduced in the final product when grape prunings were added to the initial mix. The reduction in these components can allow an increase in field application rates of compost before reaching maximum concentrations of limiting nutrients. The project demonstrated the feasibility of using composting as a Best Management Practice to reduce or eliminate the annual burning of grape prunings, reducing carbon emissions from the grape industry. It also demonstrated the reduction in ammonia emissions that can be achieved by the dairy industry when mixing wastes rich in C:N.

Key Words: composting, manure, grapes

W273 Effect of floating islands on parlor wastewater multi-stage treatment system effectiveness. Vinicius R. Moreira*[1], Brian D. LeBlanc[2], Eric Achberger[3], and Laura Zeringue[1], [1]*LSU AgCenter Southeast Research Station, Franklinton, LA,* [2]*LSU AgCenter School of Plant, Environmental and Soil Sciences, Baton Rouge, LA,* [3]*LSU AgCenter, Baton Rouge, LA.*

Most manure stored in grazing dairy farms is wastewater collected from the milking parlor and adjacencies. Anaerobic lagoons are designed to treat this liquid waste by reducing solids and oxygen demand, but may release methane, ammonia, odors, and pathogens in the process. Treatment intensification may be a more efficient and economical long-term solution for small grazing dairies. LSU AgCenter Dairy Waste and Nutrient Management Team have been evaluating technologies and practices to improve wastewater treatment using the Southeast Research Station Dairy Wastewater Treatment Evaluation System (DWTES). The system is a replicated set of anaerobic lagoon, aerobic lagoon and constructed wetlands. The objective of this study was to evaluate the effect of artificial floating islands on DWTES effluent quality. Biohaven Floating Islands (Martin Ecosystems, Baton Rouge, LA) were deployed in an anaerobic lagoon (186-m^2 floating islands) and an aerobic lagoon (93 m^2 floating islands). Wastewater was sampled from every stage, approximately every 3 mo for 17 mo. Samples were analyzed for temperature, pH, chlorophyll-A, chemical oxygen demand (COD), total solids, total dissolved solids, total suspended solids (TSS), ammonia-N, nitrate-N, nitrite-N, total Kjeldahl nitrogen (TKN), total phosphorus, anions, dissolved oxygen concentrations, total coliforms and *E. coli*. Total solids (931 mg/L), COD (711 mg/L), TKN (72 mg/L) and sulfate (14 mg/L) concentrations in raw wastewater decreased by 50% or more in the system's effluent. *Escherichia coli* counts were reduced from 6.5 log MPN/100 mL in raw wastewater to 3 ± 0.41 log MPN/100 mL in wetland effluents. Floating islands improved treatment effluent for TSS (66 vs. 49 ± 18 mg/L), COD (212 vs. 168 ± 16 mg/L), and TKN (27 vs. 21 ± 2 mg/L). Ammonia-N as a proportion of TKN and nitrate-N (3.79 vs. 4.73 ± 1.1 mg/L) increased in the replicate containing floating islands. Floating islands appeared to effectively improve dairy parlor wastewater treatment in a multi-stage treatment system.

Key Words: dairy wastewater, floating island, lagoon

W274 Cross-species intake responses to temperature stress. Robin R. White*[1,2] and Mark D. Hanigan[1], [1]*Department of Dairy Science, Virginia Tech, Blacksburg, VA,* [2]*National Animal Nutrition Program, University of Kentucky, Lexington, KY.*

The objectives of this study were to compare and model feed intake responses to temperature across species and to assess opportunities to use cross-species (CS) data to parameterize models when species-specific (SS) data were limited. Literature searches were conducted to identify studies reporting intake during climate-stress treatments compared with 1 or more thermoneutral treatments. The resulting data set comprised 614 treatment means for 108 studies on livestock responses to heat or cold stress. An ANOVA was conducted on the CS data set to identify the effects of species, temperature and species by temperature interactions on intake as a fraction of thermoneutral intake (FFI). Four models were derived from the CS data set and SS root mean squared prediction error (RMSPE) and concordance correlation coefficients (CCC) of these models were compared with models of the same form derived from SS data sets. Models used explanatory variables for (1) duration of exposure; (2) mean temperature; (3) low and high temperatures; and (4) difference between low and high temperatures and duration of exposure. An additional model accounting for temperature and stage of production was derived from the SS data. ANOVA demonstrated that the species by temperature interaction did not have a significant effect on FFI ($P = 0.162$). Across species, intake decreased with temperature. Notably, all species demonstrated a constant decrease in intake across the thermoneutral zone indicating the previous assumption of constant intake during thermoneutrality may be incorrect. The CS-derived models had marginally lower RMSPE and higher CCC when compared with those derived from the SS data sets. The model fit with production data had the lowest RMSPE and highest CCC within the study. When compared over areas with notable knowledge gaps, using CS models often had reduced RMSPE and improved CCC when compared with SS models. Although fitting models based on SS data allows for incorporating unique covariates, like level of production, fitting responses based on CS data can help to improve model estimates when knowledge gaps exist.

Key Words: modeling, multi-species, heat stress

W275 Comparative feedlot response of Angus-cross and Brahman bull-calves to pen-shade under hot weather conditions. Ruben Barajas*[1], Billy J. Cervantes[2], Alejandro Camacho[1], Leopoldo R. Flores[1], Juan J. Lomeli[1], and Javier A. Romo[1], [1]*FMVZ-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México,* [2]*Ganadera Los Migueles, S.A. de C.V., Culiacán, Sinaloa, México.*

Pen-shade improves performance of beef cattle under hot weather. Brahman cattle pose better capability than Angus-cross cattle to confront hot environmental conditions. There are few comparative studies evaluating pen-shade benefices across breed's types. This research was performed to determine the comparative feedlot response of Angus-cross (AC) and Brahman (BR) bull-calves to pen shade under hot weather conditions. In a completely randomized design experiment with a 2 × 2 factorial arrangement, 30 AC and 30 BR bulls-calves (233 ± 24.9 kg) were grouped by breed type and placed in 2 types of pens: (1) Without shade (NO SHADE); or (2) Shaded (SHADE). Shade was provided by a ceiling of 6 × 4 m of metal sheeting positioned 3.7 m over soil level. Bull-calves were fed with a corn silage-based diet (15% CP 1.35 Mcal NEm/kg DM), served at 1700 h to minimize digestion heat load impact. Length experiment was 98 d, and pen was the experimental unit. Results were analyzed by covariance, and initial body weight was used as the associated co-variable. Across experiment, climatic conditions were air temperature 36.4 ± 4.04°C (range 27.6 to 49.5°C), relative humidity 47.9 ± 11.87% (range 24.7 to 82.5%), and THI 85.7 ± 3.16 (range 79.1 to 96.4). Interactions breed × pen shade ($P < 0.05$) were observed on final body weight, average daily gain, and feed efficiency. Angus-cross SHADE bull-calves were heavier ($P < 0.01$) as compared with AC NO SHADE (369.9 vs. 350.3 kg), while SHADE had no influence ($P > 0.10$) on final weight of BR. The Angus cross in SHADE gain 16% more wt ($P < 0.01$) than Angus cross allotted in NO SHADE (1.40 vs. 1.20 kg/d), but ADG was similar ($P > 0.10$) for BR both in SHADE and NO SHADE. AC SHADE bull-calves had a 12% better feed/gain ratio ($P = 0.03$) than AC NO SHADE (0.18 *vs*. 0.16 kg gain/kg DMI). Results suggest that feedlot response to pen shade vary with breed type, and become important as the proportion of Brahman breed decreases in genetic composition of beef cattle under hot climate conditions.

Key Words: bull-calves, feedlot performance, pen shade

W276 A multi-objective diet optimization to reduce land, water, and greenhouse gas emissions from US dairy production.

Robin R. White* and Mark D. Hanigan, *Department of Dairy Science, Virginia Tech, Blacksburg, VA.*

The objectives of this study were to construct an optimization model to identify opportunities to reduce land use, water use and greenhouse gas (GHG) emissions within dairy production systems and to assess how improved energy and protein use efficiency could affect opportunities to reduce environmental impact (EI) of dairy production systems. Nonlinear programming was used to adjust monthly diets fed to 10 cattle groups to minimize EI associated with an average United States (US) dairy production system. System boundaries extended from the inputs to the cropping system to the dairy farm gate. The effects of improved biological efficiencies were modeled as a 15% decrease in the allometric energy constant used to calculate maintenance energy requirements or as a 15% decrease in maintenance metabolizable protein requirements. Least-cost optimization was used as a baseline. A total of 28 scenarios were simulated which varied in objective, biological efficiency and allowable cost increase. Objectives included minimizing land, water, greenhouse gases, or all EI metrics. Allowable cost increases ranged from 1% to 20%. Baseline land use (1.22 m^2/kg milk), water use (14.6 m^3/kg) and GHG emissions (1.45 kg CO_2/kg) agreed well with established values for US dairy production. At cost increases between 1% and 20% above baseline, EI metrics could be simultaneously reduced by 5.9 to 16.6%. Improving energy or protein efficiency greatly improved opportunity to reduce EI. When both energy and protein efficiency were improved by 15%, EI reductions ranged from 14.6 to 21.1%. Opportunity to reduce EI varied greatly with allowable cost increase and diminishing environmental returns to cost were apparent. The cost of reducing environmental impact by 15% was decreased by 87.7% when energy and protein efficiency improved compared with the national average production efficiency scenario. Improving energy and protein use efficiency of dairy cattle represents a promising way to reduce EI without sacrificing profitability.

Key Words: feed efficiency, dairy, environmental impact

W277 Effect of temperature humidity index patterns on fertility, postpartum disease and culling risk in New York dairy farms.

Benjamin D. Scott* and Julio O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Objectives were to use within-barn measurements of temperature-humidity index (THI) to evaluate its effect on (1) Pregnancies per AI (P/AI) relative to THI at or near AI; (2) postpartum disease incidence rates (DZ30); and (3) exit from the herd (E30) relative to THI near parturition. Temperature and humidity measurements were collected hourly on 5 farms using HOBOware data loggers. Hourly measurements were averaged daily. The effect of THI on P/AI was evaluated using a THI threshold of 72 on the day of AI (THI1) or by 3-d (THI3) and 7-d (THI7) rolling averages (day of AI and prior). The DZ30 and E30 were analyzed by THI on the day of parturition (THIC), THI 7 d before and after parturition (THI14), 7 d before parturition (PreTHI), and the day of parturition plus 6 d after (PostTHI). The DZ30 and E30 were analyzed by a 68 THI threshold and represent a 30-d risk period. DZ30 represented a minimum of 1 reported event of: displaced abomasum, milk fever, metritis, retained placenta, ketosis, or mastitis. Pregnancies per AI were lower ($P < 0.01$) for AI occurring at ≥72 THI threshold using all 3 THI approximations. Mean P/AI were 38.7% (n = 9,334) vs 32.5% (n = 1,140) for THI1 <72 or ≥72, 34.8% (n = 9,291) vs 30.3% (n = 1,074) for THI3 <72 or ≥72, and 38.8% (n = 9,392) vs 28.9% (n = 748) for THI7 <72 or ≥72. The DZ30 for THI ≥68 vs THI <68 tended to be different for THIC ($P = 0.08$), was similar for PostTHI ($P = 0.15$) but it was greater for THI14 ($P = 0.01$) and PreTHI ($P = 0.02$). Mean (95% CI) DZ30 was 26.3% (24.3–28.4%) vs 30.3% (27.9–32.9%) for THI14 <68 (n = 2,381) or ≥68 (n = 1,922) and was 26.3% (24.3–28.5%) vs 30.2% (27.8–32.7%) for PreTHI <68 (n = 2,388) or ≥68 (n = 1,905). Relative risk (RR) of DZ30 (95% CI) was greater than 1 for THI14 ≥68:THI14 <68 (1.15, 1.03–1.29) and PreTHI ≥68:PreTHI <68 (1.15, 1.02–1.29). Thus, attributable risk (AR) of THI14 ≥68 to DZ30 is 13.2% and of PreTHI ≥68 is 12.9%. Rates of E30 were similar ($P > 0.10$) for all THI measurements using a 68-unit threshold. We conclude that THI before insemination reduces P/AI, that THI around parturition affects 30-d postpartum disease risk with prepartum THI having the greatest effect. Also, THI around parturition does not strongly affect postpartum 30-d exit probabilities.

Key Words: heat stress, disease risk, transition

W278 Methane and carbon dioxide emissions from manure of dairy cows fed regular or brown midrib corn silage-based diets.

Fadi Hassanat* and Chaouki Benchaar, *Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada.*

The objective of this study was to examine the effects of feeding dairy cows with regular corn (RCS) or brown midrib (BMCS) corn silage on CH_4 and CO_2 emissions from manure storage. For this purpose, 8 lactating cows fed diets containing 59% of RCS or BMCS were used in a block design. Total manure (feces and urine) collection from each cow was performed on 2 consecutive days. Manure was mixed (1:1) with an inoculum from a bioreactor and stored (20°C) under anaerobic conditions in glass bottles (6 replicates/cow) for 17 weeks. Quantity of gas produced was measured daily and sampled to determine gas composition, while manure was sampled weekly to measure volatile fatty acid (VFA) and NH_3 concentrations. The MIXED procedure of SAS was used to determine the effects of corn silage cultivar on measured parameters and significance was declared at $P \leq 0.05$. Cows fed BMCS-based diets excreted more ($P < 0.01$) manure (86 vs 64 kg/d, respectively) and organic matter (8.6 vs 6.5 kg/d, respectively) than cows fed RCS-based diets. Excretion of N averaged 370 g/d and was not affected ($P = 0.16$) by the dietary treatment. Compared with manure from cows fed RCS-based diets, manure from cows fed BMCS-based diets emitted more ($P \leq 0.01$) CH_4 (173 vs 146 L/kg organic matter [OM]) and CO_2 (148 vs 118 L/ kg OM) during storage period. Total VFA concentration tended to higher ($P = 0.08$) in manure from cows fed BMCS compared with cows fed RCS, indicating more extensive degradation of OM during storage of manure when cows were fed BMCS vs. RCS. Losses of OM from manure of cows fed BMCS based-diets was higher ($P < 0.01$) than losses from cows fed RCS-based diets (38 vs. 31%). In conclusion, feeding BMCS-based diets to dairy cows can increase daily volatile solid excretion and CH_4 and CO_2 emissions (per kg volatile solids) compared with feeding RCS-based diets.

Key Words: manure, CH_4 emission, brown midrib corn silage

W279 Determination of climatologically suitable places in Turkey for feedlot cattle production by using comprehensive climate index model.

Hayati Koknaroglu*[1], John A. Harrington Jr[2], and Terry L. Mader[3], [1]*Suleyman Demirel University, Isparta, Turkey,* [2]*Kansas State University, Manhattan, KS,* [3]*University Nebraska, Lincoln, NE.*

The objective of this study was to determine climatologically suitable places to raise feedlot cattle in Turkey. Daily average temperature, relative humidity and wind speed values for 15 locations (Antalya, Balikesir, Corum, Diyarbakir, Edirne, Elazig, Erzincan, Erzurum, Eskisehir, Isparta, Izmir, Kayseri, Konya, Sivas and Van), spanning last 30 years, were obtained. Daily solar radiation values could not be obtained from the weather stations and were calculated based on a formula that takes hemisphere, latitude and day of the year into account. The comprehensive climate index (CCI) model that enables one to quantify beef cattle performance based on environmental conditions (temperature, relative humidity, wind speed, solar radiation) at any time in the year was used to predict dry matter intake (DMI), average daily gain and feed efficiency of feedlot cattle. Because mostly dairy breed calves are placed into the feedlot in Turkey, Holstein option in CCI was chosen to calculate maintenance energy requirement of cattle. Based on the previous feedlot feeding studies conducted in Turkey, it was assumed that calves would be placed on feed at 250 kg and be marketed at 520 kg, diet would have 2600 kcal/kg metabolic energy and would have dry matter intake of 2.31% of the body weight. Results comparing the 15 locations indicate that cattle raised in Antalya, known to be hottest place and Erzurum, known to be coldest place, had the lowest and highest DMI, respectively ($P < 0.05$). Environmental conditions in summer lowered cattle DMI in hotter locations and winter conditions increased DMI in colder locations ($P < 0.05$). Feedlot cattle raised in hotter and colder portion of Turkey had lower average daily gain than other places having a milder climate ($P < 0.05$). In general, cattle raised in hotter climate had better feed efficiency than those raised in cold climate ($P < 0.05$).

Key Words: comprehensive climate index, feedlot, performance

W280 Methane prediction equations for beef cattle fed high forage diet.

Paul Escobar-Bahamondes*[1,2], Masahito Oba[1], and Karen A. Beauchemin[2], [1]*University of Alberta, Edmonton, AB, Canada,* [2]*Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

The study aim was to improve the prediction of CH_4 emissions from beef cattle by developing equations specific for high forage diets (≥40% DM basis). Treatment means from 38 beef studies published between 2000 and 2014 with dietary forage ≥40% DM were compiled into a database. Criteria for inclusion in the database were intake, diet composition and enteric CH_4 production. Principal component analysis detected relevant variables associated with CH_4. Because of the limited size of the original database (n = 123), a Monte Carlo technique was used to resample 1,000 times the data from each study to create a new virtual data set. Outliers were excluded by Mahalanobis distance in both the original database and virtual data set. Using the original database, forward stepwise multiple regression was used to obtain prediction equations. The random effect of study was included in the analysis using the Mixed procedure and 'leave-one-out' cross validation was used to internally validate the equations. Using the virtual data set (n = 100,305), equations were developed using forward stepwise multiple regression and K-fold cross validation (n = 10). Model performance was evaluated as observed-predicted values using concordance correlation (r_c) and root mean square prediction error (RMSPE, g/d). Statistical analysis was performed using JMP v11. Using the original database, the best-fit equation was: CH_4 (g/d) = 71.5(±11.45) + 0.12(±0.03) × BW (kg) + 0.10(±0.01) × DMI^3 (kg/d) − 244.8(±56.44) × fat^3 (kg/d) with $P < 0.0001$, r_c: 0.72 and RMSPE: 39.1; where BW = body weight; DMI = dry matter intake. Using the Monte Carlo data set, the best-fit equation was: CH_4 (g/d) = 25.9(±0.54) + 0.13(±0.001) × BW (kg) + 145.4 (±1.31) × fat (kg/d) + 10.3(±0.16) × $(NDF - ADF)^2$ (kg/d) + 0.1(±0.00) × DMI^3 (kg/d) − 27.4 (±0.20) × (starch/NDF) with $P < 0.0001$, r_c: 0.81 and RMSPE: 36.4 where NDF = neutral detergent fiber and ADF = acid detergent fiber. Monte Carlo data set equation improved prediction accuracy compared with the original database equation, but extensive feed analysis is required to use the equation. Both equations specifically developed for beef cattle fed forage diets may increase the accuracy of predicting CH_4 production.

Key Words: methane, beef cattle, equation

W281 Mathematical models to predict phosphorus output in manure and milk from lactating dairy cows.

G. Alvarez[1,2], J. A. D. R.N. Appuhamy*[2], and E. Kebreab[2], [1]*Universidad Autonoma de San Luis Potosi, San Luis Potosi, Mexico,* [2]*Department of Animal Science, University of California, Davis, CA.*

Accurate manure and milk phosphorus (P) output estimates are important for monitoring P released to the environment and assist in quantifying P balance in lactating dairy cows. The objectives of the study were (1) to develop empirical models, and (2) evaluate extant models for estimating P output from lactating dairy cows. A meta-regression analysis was conducted using 191 fecal (Pf), 83 urine (Pu), and 110 milk (Pm) P output measurements from 39 studies. Dry matter intake (kg/cow/d), diet composition, milk yield and composition and DIM were used as predictor variables. The Pu was highly variable with a mean of 0.34 ± 0.027 g/cow/d. Two models; with and without DMI data were developed for each Pf and Pm (g/cow/d, Table 1). The DMI-based extant model by Weiss and Wyatt (2004) was the most successful in predicting manure P output [root mean square prediction error (RMSPE) as a percentage of average observed value = 19.6%]. Models developed in this study with and without DMI predicted Pf with RMSPE of 18.6 and 24.0%, respectively. The Pm predictions with and without DMI were related to

RMSPE <17.0% of the average measured Pm. Our models also predicted total P output [Pf + Pm + Pu] from lactating dairy cows with good accuracy (RMSPE = 11.8 – 17.3%). The models can be used to improve our understanding of P utilization and excretion in dairy production systems.

Table 1 (Abstr. W281). Models developed in this study

Equation[1]	RMSPE (%)
With DMI data	
$Pf = -10.7(4.06) + 0.69(0.03) \times Pintake + 0.56(0.24) \times CP + 0.68(0.17) \times GE - 0.50(0.10) \times Milk$	18.6
$Pm = 19.1(7.28) + 1.25(0.17) \times DMI + 0.20(0.06) \times Milk - 6.20(2.21) \times MProt - 0.02(0.01) \times DIM$	13.9
Without DMI data	
$Pf = -10.2(7.43) + 151.0(10.6) \times P + 0.96(0.22) \times GE - 0.52(0.22) \times ADF$	24.0
$Pm = 36.6(8.46) + 0.45(0.06) \times Milk - 0.03(0.01) \times DIM - 5.20(2.7) \times MProt$	16.9

[1] PIntake = P intake (g/cow/d), GE = dietary gross energy (MJ/kg DM), Milk = milk yield (kg/cow/d), MProt = milk protein (%), CP, P and ADF (% of dietary DM).

Key Words: mathematical model, phosphorus excretion, dairy cow

W282 Enteric methane mitigation and evaluation ruminal parameters of cattle fed cottonseed and vitamin E.

Ricardo Galbiatti Sandoval Nogueira*, Flavio Perna Jr., Eduardo Cuellar Orlandi Cassiano, Lizbeth Collazo Paucar, Mariane Cheschin Ernandes, Diana Carolina Zapata Vasquez, Adrielle Matias Ferrinho, Romulo Germano de Resende, Felipe Bispo Mendonça, Renata Gardenalli, Angélica Simone Cravo Pereira, and Paulo Henrique Mazza Rodrigues, *University of São Paulo, Pirassununga, São Paulo, Brazil.*

Objective this study was verify the enteric methane emissions and evaluate ruminal parameters caused by the inclusion of 30% of cottonseed (diet with 8,32% ether extract) and 0,4% vitamin E (500 IU) in the diet of cattle. Six cannulated cows were distributed in a replicate 3x3 Latin square. Treatments were (1) control: basal diet; 2) CS: basal diet plus 30% cottonseed and 3) VitE: basal diet plus 30% cottonseed plus 0,4% vitamin E. Ruminal fermentation ex situ (micro-rumen) technique, in which, a sample (10 mL solid and 20 mL liquid) of rumen content was collected via cannula and put inside a sealed glass flask and incubated for 30 min at 39°C, starting samples removed the vials analyzed for the enteric methane emissions, total short chain fatty acids production (SCFA) and energy loss on methane compared with other products of rumen fermentation (REL). Results were compared through orthogonal contrast, where contrast 1: CS and VitE vs control; contrast 2: CS vs VitE. Data analyzed for SAS 9.3 and was considered 5% significance level. Results are shown in Table 1. Cottonseed inclusion reduced methane emissions. Production of propionate was similar between treatments, in average 82.76 g kg d⁻1. Cottonseed inclusion reduced the acetate, butyrate, SCFA and acetate propionate ratio (C2:C3). REL was similar between treatments, in average 29.45%. Include 30% of cottonseed in cattle diet reduces rumen fermentation, resulting in lower enteric methane emissions and total short chain fatty acids production. Vitamin E does not affect ruminal fermentation products.

Contd.

Table 1 (Abstr. W282). Effect of including cottonseed and vitamin E on the production of SCFA, methane, and REL

Variable	Control	CS	VitE	SEM	C1	C2
Acetic, g kg d^{-1}	210.1	143.9	133.9	11.8	0.0028	0.7091
Propionic, g kg d^{-1}	80.94	85.35	82.02	5.51	0.8017	0.7910

W283 The effect of temperature, pH, total solids and type of shape of goat manure for biogas production.

Bruno Biagioli*[1], Kleber T. Resende[1], Izabelle A. M. A. Teixeira[1], Normand St-Pierre[2], Carla J. Härter[1], and Márcia H. M. R. Fernandes[1], [1]*Univ. Estadual Paulista, Department of Animal Sciences, Jaboticabal, SP, Brazil,* [2]*The Ohio State University, Department of Animal Sciences, Columbus, OH.*

The aim of this study was to obtain the best combination of factors that could be easily manipulated by men to optimize the production of biogas. To evaluate the anaerobic digestion of goat manure, we used 24 digesters distributed in factorial design 3 × 3 × 3 × 2, and considered the following factors: temperature (20.1°C, 21.5°C, 30.2°C, 33.7°C and 34.7°C), pH (6.8, 6.84, 7.01, 7.15, 7.22), total solids (2.6%, 3.5%, 4.5%, 6.8%, 6.9%), and type of shape (whole goat manure and broken goat manure) in a central composite design. Data were analyzed as a mixed model with fixed effect of temperature, pH, TS, shape of manure, and their interactions and the random effect of day and digester, using the PROC MIXED procedure of SAS (version 9.0). The shape of manure did not affect biogas production. The isolated effect of temperature and pH in the biogas production was not significant whereas only the highest level of total solids resulted in greater biogas production by day (0.11 m^3 ± 0.02; $P = 0.0008$). We also observed interaction among temperature, pH, and total solids (5.36 m^3 ± 0.12 $P = 0.0020$) on the biogas production. Additionally, the percentage of methane in the biogas was not affected by the amount of total solids, pH, and temperature in the biodigester. The best volume of biogas production was obtained when the following values were applied: 34.7 (temperature), 6.8 (pH) and 7.0 (total solids). Our results reveal that even under low pH and low temperature, biogas production increases as a function of increasing total solids of goat manure, however none of the factors affected the proportion of methane in the biogas. The fact that we detected the best biogas yield using 6.8% total solids is extremely important, because a greater supply of substrate requires fewer amounts of water and time, it is less labor-intensive, while methane production is greater than that found using 5% total solids. Even though water returns in the biofertilizer form, if less water is required through biodigestion it would represent a significant water saving.

Key Words: biodigester, methane, caprine

W284 Idle cattle, water buffalo, and swine consume 44% of global feed resources.

J. R. Knapp*[1] and R. A. Cady[2], [1]*Fox Hollow Consulting LLC, Columbus, OH,* [2]*Elanco Animal Health, Greenfield, IN.*

The objectives of this study were to estimate the number of idle cattle, water buffalo, and swine globally and evaluate their impact on feed and water resource utilization as part of the larger Food Forward Sustainability Project. The term “idle” is defined as an animal that is not growing, pregnant, lactating, held for breeding, or used for draft. Two data sources were used: 1) USDA Foreign Ag Service data that includes cattle and swine inventories for 19 countries, and 2) FAO data that includes inventories of cattle, water buffalo, and swine for 16 sub-continental regions. A gamma distribution was used to estimate survival and the number of non-breeding animals alive after 4, 5, and 1 years for cattle, water buffalo, and swine, respectively. Non-breeding stocks were adjusted for imports and exports. Turnover age was calculated as stock numbers divided by slaughter numbers and represents the average lifespan of an animal in the non-breeding population in steady state conditions. Feed consumption estimates were cross-validated using maintenance energy requirements and found to be in reasonable agreement. Turnover ages ranged from 2.6 to 14.7 years for cattle, 3.0 to 8.5 years for water buffalo, and 4.8 to 21.1 mo for swine across regions. It was estimated that 46.6 ± 0.6% of 1.45 billion cattle, 61.1 ± 0.5% of 190 million buffalo, and 9.8 ± 0.3% of 946 million swine in the world in 2010 were mature, non-breeding animals. With cattle and water buffalo, a portion of these animals may be maintained for draft purposes and would not be completely idle. At this time, no data are available to reliably estimate the draft use of cattle and water buffalo. Also, in some societies, mature animals may be maintained as a form of personal wealth, defense against times of food scarcity, or both. Idle and draft cattle, water buffalo, and swine consumed an estimated 1068, 132, and 62 million metric tons of feed (DM basis) or 44% of total feed required, and 2840, 364, and 154 billion liters of water, respectively, in 2010. Reducing the number of idle cattle, water buffalo, and swine is one of several viable options to increase system-wide production efficiency and decrease the total amount of resources required to produce animal-based foods.

Key Words: sustainability, food supply, resource utilization

W285 Crop and grazing land requirements to meet consumer demand for animal products in 2050.

J. R. Knapp*[1] and R. A. Cady[2], *[1]Fox Hollow Consulting LLC, Columbus, OH, [2]Elanco Animal Health, Greenfield, IN.*

As part of the larger Food Forward Sustainability Project, we have estimated the quantity of feed required to produce animal products and meet global consumer demands in 2050 under different production scenarios using population-based models (Table). The objectives of this study were 1) to determine how much crops and crop residues were available globally in 2010 in support of animal feed production and might be available in 2050 under reasonable estimates of increasing crop yields, 2) compare them to feed requirements, and 3) to evaluate the impact on land requirements for feed production. Data from USDA National Agricultural Statistics Service and FAO were utilized to estimate yields and utilization of major grain and oilseed crops. Proportions of crops used in feed, food, seed, and other uses were assumed to be the same in 2050 as in 2010. Crop residues were estimated from crop yields and represent the maximum potentially available feed, but do not account for use in bedding, soil amendment, etc. While production and utilization of grain, oilseed, and byproducts for feed in 2010 appears to be lower than feed requirements (Table), it is likely underestimated due to under-reporting of grain byproducts by FAO and neither data source fully accounting for secondary byproducts or animal protein byproducts. These results indicate that continued innovation supporting sustainable intensification in livestock and poultry agriculture and increasing crop yields can produce adequate amounts of food and feed in 2050 without increasing crop lands (Table). Also, increasing crop yields have the potential to provide more crop residues for feeding ruminant livestock that could increase the efficiency of feed use and reduce pressure on grazing lands (Table). Without innovation in animal and plant agriculture, 36 to 58% more land would be required in 2050 to produce food and feed.

Table 1 (Asbtr. W285). Feed requirements and annual production (million metric tonnes as is, 85-90% dry matter)

	2010	2050 Continued innovation	2050 Frozen productivity
Feed requirements			
Grain & byproducts	1,111	1,331	1,872
Oilseed & byproducts	320	396	557
Crop residues & forage	3,146	3,245	4,545
Feed production & utilization			
Grains & by-products	878	1,403	
Oilseeds & byproducts	261	367	
Crop residues	2,075	2,905

W286 Climatic factors associated with abortion occurrences in Japanese commercial pig herds.

Ryosuke Iida, Satomi Tani*, and Yuzo Koketsu, *Meiji University, Kawasaki, Kanagawa, Japan.*

Our objectives were to determine climatic and production factors associated with abortions in female pigs in commercial herds and to compare the reproductive performances and culling patterns between aborting and nonaborting reserviced female pigs. We analyzed 309,427 service records of female pigs entered into 100 herds located in humid subtropical or continental climate zones. Climate data were obtained from 21 weather stations located close to the studied herds. Mean daily average temperatures (Tavg) for the 21-d pre-mating period for each female pig were coordinated with that female’s reproductive data. Generalized linear models were conducted for whether or not a female pig aborting. Abortion risk per service (±SEM) was 0.7 ± 0.06%, and mean daily average temperature (range) was 15.0°C (−11.0 to 32.7°C). Risk factors associated with an increased abortion risk per service were higher parity, having more stillborn piglets, higher Tavg and reservicing ($P < 0.05$). Also, abortion risks in parity 1 and parity 2–5 sows linearly increased by 0.3 and 0.1%, respectively, as Tavg increased from 20 to 30°C ($P < 0.05$), but there were no such associations in parity 0 and or parity 6 or higher female pigs ($P \geq 0.37$). Aborting reserviced female pigs had 0.4 fewer pigs born alive than nonaborting reserviced female pigs ($P < 0.05$). Also, 64.6% of all aborting female pigs were culled for reproductive failure, compared with only 23.4% of nonaborting females. In conclusion, producers should closely monitor female pigs at high risk of aborting and apply more advanced cooling systems.

Key Words: abortion, heat stress, incidence rate

W287 Estimated feed and water requirements to meet global 2050 demand for animal proteins.

J. R. Knapp*[1] and R. A. Cady[2], *[1]Fox Hollow Consulting LLC, Columbus, OH, [2]Elanco Animal Health, Greenfield, IN.*

FAO has published predictions for 2050 global milk and meat consumption. As part of the larger Food Forward Sustainability Project, the objective of this study was to estimate the quantities of feed and water required to produce the FAO forecasted quantities of animal products under 2 scenarios and independent of advances in crop production. In the first scenario, innovation continues, and in the second, development and application of technologies are limited, freezing productivity at 2010 levels. Models capturing animal population dynamics were formulated with biological constraints and used to predict the resources needed for egg, dairy, and meat production from chickens, swine, cattle, and water buffalo. Global consumption of chicken meat, pork, and beef is expected to increase 134, 51, 43%, respectively, based on increases in population and per capita consumption. For swine and beef, options exist with current technology and management that if applied more broadly could increase production efficiency and maintain or reduce resource utilization by these species' production systems relative to 2010 levels. The impact of increased dairy consumption would increase feed and water utilization by 10% with continued innovation. In swine, beef, and dairy, it is biologically possible to increase total production while decreasing animal numbers. In contrast, production of chicken meat cannot be increased to meet the very large projected demand without significant increases in both animal numbers and carcass size. Likewise, increasing egg production to meet future demands will require modest increases in eggs per hen and number of hens. Innovation and broader adoption of existing technology have strong potential to mitigate the impacts of increased animal production on feed and water utilization while meeting future demands for animal products, thus minimizing the expansion of animal numbers as has happened historically.

Table 1 (Abstr. W287).

	2010	2050 Cont. Innovation	2050 Frozen Productivity
Human population (billion)	6.9	9.4	9.4
Animal product consumption (kg×yr^{-1}×person^{-1})	148.4	170.7	170.7
Total animal product consumption (billion MT)	1.02	1.60	1.60
Feed (as is, billion MT)	4.6	5.0	7.0
Water (trillion L)	15.8	17.3	24.9

Key Words: sustainability, food supply, animal protein

W288 Climatic factors associated with reproductive performance in English Berkshire pigs raised in a subtropical climate region of Japan.

Shiho Usui, Satomi Tani*, and Yuzo Koketsu, *Meiji University, Kawasaki, Kanagawa, Japan.*

Our objective was to clarify the reproductive characteristics of English Berkshire female pigs in a humid subtropical zone. We examined interactions between 2 breeds (English Berkshire and crossbred females) and climatic factors for reproductive performance. We analyzed 63,227 first-service records of 11,992 females in 12 herds. Climate data were obtained from 4 weather stations located close to the studied herds. Mean daily maximum temperatures (Tmax) and daily average relative humidity (ARH) for different periods around servicing and farrowing of each female were coordinated with that female's reproductive performance data. Multilevel mixed-effects models were applied to the data. There were 2-way interactions between the breed and either Tmax or ARH for weaning-to-first-mating interval (WMI), total born and farrowing rate ($P < 0.05$). The WMI in Berkshire sows increased by 0.10 (SE: 0.008) days as Tmax increased by each degree Celsius ($P < 0.05$), whereas in crossbred sows it only increased by 0.01 (0.005) days ($P < 0.05$). The WMI in crossbred sows also increased by 0.03 (0.007) days as ARH increased by one percent ($P < 0.05$). However, there was no such association in Berkshire sows ($P = 0.37$). In Berkshire females total born decreased by 0.02 (0.003) pigs for each degree Celsius increase in Tmax ($P < 0.05$), whereas that in crossbred females decreased by 0.03 (0.002) pigs ($P < 0.05$). With regard to farrowing rates, the odds ratios in Berkshire and crossbred females were 0.973 (95% confidence intervals: 0.967–0.979) and 0.986 (0.981–0.991) for Tmax, respectively. Therefore, we recommend producers applying advanced cooling systems for Berkshire females as well as crossbred females.

Key Words: Berkshire, climatic factor, reproductive performance

Ruminant Nutrition: Beef III

W289 Effect of increasing levels of alfalfa hay on ruminal fermentation in growing Simmental heifers fed high-concentrate diets.

Ana Madruga*[1], Alfred Ferret[1], María Rodríguez[1], Eva Mainau[1], Jose Luis Ruiz de la Torre[1], Xavier Manteca[1], and Luciano Adrian Gonzalez[2], [1]*Animal Nutrition and Welfare Service (SNIBA), Universitat Autonòma de Barcelona, 08193 Bellaterra, Spain,* [2]*Centre for Carbon, Water and Food, The University of Sydney, Camden, Australia.*

Eight rumen cannulated Simmental heifers (BW = 281.4 ± 18.5 kg) were randomly assigned to 1 of 4 experimental treatments to determine the effects of increasing levels of alfalfa hay on ruminal fermentation. Treatments tested were: a) total mixed ration with 10% barley straw as forage source (10BS), b) total mixed ration with 13% alfalfa hay as forage source (13AH), c) total mixed ration with 16% alfalfa hay as forage source (16AH) and d) total mixed ration with 19% alfalfa hay as forage source (19AH). Forages were coarsely chopped before their incorporation in total mixed ration. Diets were offered on an ad libitum basis, and formulated to be isocaloric (2.83 Mcal ME/kg DM) and isonitrogenous (14% CP on DM basis). After 2 weeks of diet adaptation, ruminal samples were taken immediately before feeding and at 4, 8, 12, 16, and 24 h after feeding on d1, d4 and d7 of the sampling week. Differences were analyzed by using the MIXED procedure of SAS. The model contained the fixed effects of treatment and the random effect of heifer. Day and hour were used as repeated measure. Intake of DM recorded during the sampling week was affected by treatment, being higher in heifers fed 16AH and 19AH than in heifers fed 10BS and 13AH (8.9 and 8 kg/d on average, respectively; $P < 0.001$). Heifers fed 19AH had a higher mean ruminal pH compared with the other treatments (6.74 vs. 6.55 on average; $P = 0.02$) and a higher total area under the pH curve ($P = 0.01$). Concentration of NH_3-N (1.8 mg N/100mL) and total VFA (84 mM) were not affected by treatment ($P > 0.10$). Heifers fed 10BS presented the lowest proportion of acetate ($P = 0.05$) and the highest proportion of propionate ($P = 0.04$). Molar proportions of butyrate, valerate, isobutyrate and isovalerate were not affected by treatment ($P > 0.10$). Results indicate that the inclusion of alfalfa hay at 19% of total DM in a high-concentrate diet fed to growing heifers did not affect total VFA and NH_3-N concentration, increased acetate and decreased propionate proportion, and increased mean ruminal pH, which can reduce the risk of ruminal acidosis.

Key Words: alfalfa hay, beef cattle, high-concentrate diet

W290 Protein requirements of Nellore and Angus young bulls.

Rafael A. Gomes*[1,3], Mario L. Chizzotti[2], Karina C. Busato[1], Marcio M. Ladeira[1], Aline C. Rodrigues[1], Matheus C. Galvão[1], José Rodolfo R. Carvalho[1], and Maria Helena Oliveira[1], [1]*Universidade Federal de Lavras, Lavras, Minas Gerais, Brazil,* [2]*Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil,* [3]*Washington State University, Pullman, WA.*

We used 48 animals with initial body weight (BW) of 380.2 ± 4.73 kg to determine protein requirements of Nellore and Angus young bulls by comparative slaughter technique. Four animals of each breed were slaughtered at beginning of the experiment (baseline animals). The remainder were housed in individual stalls, where 8 animals of each breed were fed ad libitum with a whole corn shell (WCS) diet (85% WCS and 15% of a pellet based on soybean meal) or a silage/concentrate (SC) diet (30% silage and 70% concentrate based on corn and soybean meal). Other 4 animals of each breed were fed with the SC diet at 50% of the dry matter intake adjusted for metabolic BW of animals that received the SC diet ad libitum. Intake was measured daily and a metabolism trial was conducted with total collection of feces and urine. These data were used to estimate the crude and metabolizable protein intake (CPI and MPI, respectively). At 90 d of growth the cattle were slaughtered. The net requirement of protein for maintenance (NP_m, g/kg $EBW^{0.75}$/d) was assumed to be the intercept of the linear regression of the retained protein (RP) on CPI and the slope of the linear regression of RP on MPI was assumed to be the efficiency of protein utilization for maintenance (k). The NP_m was divided by the k to obtain the metabolizable requirement of protein for maintenance (MP_m, g/kg $EBW^{0.75}$/d). The net requirement of protein for growth (NP_g) was calculated by NP_g (g/kg EBG/day) = a + b × RE, where EBG is the empty body gain and RE is the retained energy. The data were analyzed using the GLM procedures of SAS adopting significance level of 0.05. We did not observe an effect ($P > 0.05$) of breeds on NP_m (1.01 g/kg $EBW^{0.75}$/d) and k (38%). MP_m was 2.68 g/kg $EBW^{0.75}$/d. In addition, breed did not significantly affect ($P > 0.05$) on NP_g (NP_g g/day = EBG × [286 – 8.23 × (ER/EBG)]). Funded by FAPEMIG, INCT-CA and CNPq.

Key Words: maintenance, growth

W291 Intake and digestibility of Nellore steers fed different sources of forage in diets with crude glycerin in feedlot.

Andressa F. Ribeiro, Antonio Jose Neto*, Luis G. Rossi, Erick E. Dallantonia, Monaliza O. Santana, Ana Laura E. G. F. Carvalho, Gabriela Dellamagna, Juliana D. Messana, and Telma T. Berchielli, *Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil.*

Nine ruminally cannulated Nellore steers (300.0 ± 30kg of BW and 18 ± 2 mo of age) were used in a 3x3 Latin Square experimental design to evaluate the effect of different sources of forage in diets with crude glycerin (80.64% of glycerol) on DM, CP, NDF and NFC intake and digestibility. The treatments were different sources of forage (fixed 15% of NDF from forage; fNDF): corn silage, sugar cane and sugar cane bagasse, in diets with 10% (DM) of crude glycerin. For this study intake, refusals and total feces collection were recorded for 3 d, experimental periods were 17 d (14 d for adaptation, 3 d for intake and total digestibility. Data were analyzed as a triple Latin square design with 3 treatments and 3 animals in 3 simultaneous triplicates using the PROC MIXED procedure of SAS. The least squares means were generated and compared ($P < 0.05$) using Tukey's test. There was no difference on DM and CP intake among diets. On the other hand, the intake of NDF increased ($P < 0.05$) in animals fed corn silage which did not differ from animal fed with sugar cane bagasse. Furthermore, animals fed with sugar cane bagasse decreased NFC intake ($P < 0.05$). Animals fed with corn silage increased DM and NDF digestibility compared with the other diets ($P < 0.05$). Additionally, an increase on CP digestibility was observed in animals feed with sugar cane bagasse, which not differed from animals fed with corn silage ($P < 0.05$). NFC digestibility increased in animals fed with sugar cane ($P < 0.05$). Different sources of forage included in 15% of fNDF in diets with crude glycerin (10% DM) altered intake and digestibility.

Key Words: biofuel, corn silage, sugar cane

W292 Effect of glycerol supplementation and ambient temperature on growth and metabolic and immunological responses in Korean cattle steers. Hyeok Joong Kang, Min yu Piao, Hyun Jin Kim, In Kyu Lee, Min Jeong Gu, Cheol Hee Yun, and Myunggi Baik*, *Seoul National University, Seoul, Republic of Korea.*

This study was performed to evaluate whether glycerol supplementation and ambient temperature affects growth and blood metabolic and immunological parameters in beef cattle. Twenty Korean cattle steers with average 14.4 mo of age and 405 kg of body weight (BW) were used. Animals were divided into conventional control diet group and 2% glycerol supplementation group. Steers were allowed a concentrate diet with the amount of 1.5% of BW and a tall fescue with the amount of 0.75% of BW for 8 weeks. Experimental period 1 (P1) was 4 weeks from July 28 to August 26, and period 2 (P2) 4 weeks from August 27 to September 26. Blood was collected 4 times at July 28, August 11, August 27, and September 26. Maximum temperature-humidity index (THI: 75.8) of August (P1) was higher ($P < 0.001$) than that (69.7) of September (P2), although maximum ambient temperature (27.8°C) of P1 was numerically higher than that (26.3°C) of P2 without statistical significance. Glycerol supplementation did not affect both concentrate and forage intake, average daily gain (ADG), and feed/gain ratio at P1 and P2. ADG was lower ($P = 0.03$) at P2 (0.74 kg/d) compared with P1 (0.89 kg/d). Feed/gain ratio was improved ($P < 0.001$) at P2 compared with P1. Glycerol supplementation did not affect blood concentrations of glucose, triglyceride (TG), cholesterol, high-density lipoprotein (HDL), low density lipoprotein (LDL), nonesterified fatty acid, and albumin. Blood concentrations of TG, cholesterol, HDL, LDL, glucose, and albumin were lowest ($P < 0.05$) at late July compared with other times (August and late September). Glycerol supplementation decreased blood CD8+ T cell population at late July and mid-August. However, it did not affect other blood immune cell populations. Blood granulocyte to lymphocyte ratio was highest at August 27. Monocyte and B cell populations were lowest ($P < 0.05$) at August 11. In conclusion, glycerol supplementation did not affect growth and blood metabolic parameters. Feed efficiency was lower at higher THI August compared with September. Some blood metabolic and immunological parameters were influenced by ambient temperature.

Key Words: beef cattle, ambient temperature, glycerol supplementation

W293 Comparison of fatty acid profiles and volatile compounds among quality grades and their association with carcass and sensory traits in loin and rump of Korean cattle steer. MinYu Piao, Hyun Jin Kim, Cheorun Jo, Hyun Joo Kim, and Myunggi Baik*, *Department of Agricultural Biotechnology, College of Agriculture and Life Science, Seoul National University, Seoul, Republic of Korea.*

This study was performed to compare fatty acid contents and volatile compounds among quality grades (QG) and to understand association between QG and above parameters in loin and rump of Korean cattle steers. Loin and rump samples were obtained from 48 Korean cattle steers with each of 4 quality grades (QG 1++, 1+, 1, and 2; average 32 mo of age). In loin, oleic acid (C18:1n9) contents were highest ($P < 0.05$) in QG 1++ and lowest in QG 2. Linoleic acid (C18:2n6), eicosapentaenoic acid (C20:5: EPA), and polyunsaturated acid (PUFA) contents were lowest ($P < 0.05$) in QG 1++ and highest in QG 2. Palmitic acid, stearic acid, oleic acid, SFA, and MUFA contents were higher ($P < 0.05$) in loin than in rump. In loin, major fatty acid contents per meat, including palmitic acid (C16:0), oleic acid and saturated fatty acid (SFA) and USFA, were highest ($P < 0.05$) in QG 1++ and lowest in QG 2. Marbling score (MS), QG, and overall acceptability of sensory evaluation were positively correlated ($r > 0.47$, $P < 0.05$) with oleic acid contents of fat. In contrast, MS, QG, tenderness, juiciness, flavor and overall acceptability were inversely correlated ($r < -0.62$, $P < 0.05$) with linoleic acid, EPA, and PUFA contents. MS and QG were positively correlated ($r > 0.59$, $P < 0.001$) with most of fatty acid contents per meat, including palmitic acid, stearic acid, oleic acid, SFA and USFA contents. Total 20 volatile compounds, including aldehydes and hydrocarbons, were detected in loin and rump by GC/MS analysis. Few hydrocarbon contents, including n-pentane, n-hexane, and 2-butene, were higher in QGs 1++ and 1+ than in QGs 1 and 2. Other volatile compounds did not show significant patterns among QGs. MS and QG were positively correlated ($r > 0.67$, $P < 0.05$) with 2-butene, n-pentane, chloroform, and n-hexane contents. Our results revealed that MS and QG are linked with fatty acid contents such as oleic acid in loin. Among 20 volatile compounds detected, only few compounds were associated with MS and QG.

Key Words: Korean cattle steers, quality grade, fatty acid

W294 Effects of essential oils and exogenous enzymes on in vitro ruminal fermentation. Fabiola A. Lino[1], Lidiamar L. R. Vieira[1], Andrea M. Mobiglia[1], Débora G. Sousa[1], Fernando R. Camilo[1], José Tiago Neves Neto[1], Tiago S. Acedo[2], Cristina S. Cortinhas[2], João Ricardo R. Dórea[2], Luis Fernando M. Tamassia[2], and Juliano J. R. Fernandes*[1], *[1]Universidade Federal de Goiás, Goiânia, Goiás, Brazil, [2]DSM Nutritional Products, São Paulo, São Paulo, Brazil.*

The objective of this study was to evaluate the inclusion of a blend of essential oils and exogenous enzymes on in vitro ruminal fermentation (dual flow continuous culture fermenters). Ten fermenters with dual continuous flow and they each have 1.4 L capacity. The dilution rate of the liquid and solid content has maintained 10% and $5\%.h^{-1}$, respectively. The design was randomized complete block with 4 replicates. Two experimental periods, each one has 8 d, were considered a block. The ruminal fluid was collected from 5 Nellore steers with ruminal cannula. The experimental period has 8 d with a 5-d adaptation period and 3-d collection period. The diet composition on dry matter (DM) was 8.5% sugarcane bagasse, 82.5% corn, 5% soybean meal and 4% mineral mixture. Each fermenter received daily 100g of the diet (on DM) with additives includes, as follows: T1–300mg of monensin (0.012%, monensin from Tortuga); T2–essential oil (0.008%, Crina Ruminants); T3–blend of essential oil (0.008%, Crina Ruminants) and 300 mg of monensin (0.0024%, monensin from Tortuga); T4-blend of essential oil (0.008%, Crina Ruminants) and exogenous amylase (0.05%, Ronozyme Rumistar); T5- blend of essential oil (0.008%, Crina Ruminants), exogenous amylase (0.05%, Ronozyme Rumistar) and exogenous protease (0.08%, Ronozyme Proact). In this study were evaluated short-chain fatty acids (SCFAs) and the apparent digestibility of DM and crude protein (CP). The data were analyzed by R software and the probability of 5% was considered as statistical difference. There were no statistical differences for all variable studied. The data demonstrate that the use of essential oils and exogenous enzymes and their associations must be studied further because they showed the same fermentation parameters than the monensin treatment. Thus, these additives represent a good alternative to monensin.

Contd.

W295 Effect of steam-flaking on in situ degradability and PDI values of maize, wheat and rice.

Fei Wang*, Yunlong Huo, and Qingxiang Meng, *China Agricultural University, Beijing, China.*

The objective of this study was to investigate effects of cereal type and steam-flaking processing on nutritive values of maize, wheat and rice (with whole hulls). Intact and steam-flaked grains of maize, wheat and rice were measured for in situ degradability using nylon bag method and predicted for protein digested in the small intestine (PDI) using the method of French Protein System. Data obtained were subjected to ANOVA as a 2 × 3 factorial design with 3 replicates by the GLM procedure of SAS (Version 9.0; SAS Institute, Carry), and a Duncan significant difference test was used to determine the differences among means. Significance was declared at $P \leq 0.05$. Three ruminally cannulated Limousin steers averaging 400kg of body weight were used. Steers were fed a TMR diet twice daily. The results showed that the rumen effective degradation rate of dry matter (DM), organic matter (OM), starch and crude protein (CP) of the grains were: wheat (80.91%, 81.34%, 87.68% and 81.34%) > rice (71.10%, 72.84%, 84.79% and 72.84%) > maize (65.80%, 63.99%, 74.60% and 63.99%). The rumen degradation rate from fast to slow were: rice > wheat > maize. DM, OM, Starch and CP effective degradability of rice were increased by steam-flaking (SF) processing. SF processing also increased DM, OM, Starch and CP degradation rates of maize and wheat. However, DM, OM, Starch and CP degradation rates of rice were decreased by SF processing. Rumen nondegradable nitrogen from feed (PDIA) and PDI of wheat (50.07 and 99.97g/kg DM) were significantly higher ($P < 0.01$) than maize (34.83 and 55.03 g/kg DM) and rice (23.16 and 46.27 g/kg DM). PDI of maize was reduced ($P < 0.01$) by SF processing, while no significant differences were observed between PDI values of intact and steam-flaked wheat or rice. In summary, rumen effective degradation rate and PDI of wheat are higher than maize and rice. Steam-flaking can significantly improve the rumen effective degradability of rice and decrease the PDI value of maize, but have no significant effect on PDI values of wheat or rice.

Key Words: steam-flaking, in situ, protein digested in the small intestine (PDI) DI

W296 Effects of conventional dietary adaptation over periods of 6, 9, 14, and 21 days on feedlot performance and carcass traits of Nellore cattle.

Daniela Dutra Estevam[1], Danilo Domingues Millen*[2], Ismael de Castro Pereira[1], Ramon Argentini Rizzieri[1], Gabriel Fernandes Melo[1], Alexandre Perdigão[1], Cyntia Ludovico Martins[1], and Mario De Beni Arrigoni[1], *[1]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [2]São Paulo State University (UNESP), Dracena, São Paulo, Brazil.*

This study, conducted at the São Paulo State University feedlot, Botucatu Campus, Brazil, was designed to determine the effects of adaptation periods of 6, 9, 14 and 21 d on feedlot performance and carcass traits of Nellore cattle. Cattle were fed for 88-d regardless of adaptation period adopted. The experiment was designed as a completely randomized block, replicated 6 times, in which ninety-six 20-mo-old yearling Nellore bulls (391.1 ± 30.9 kg) were fed in 24 pens (4 animals/pen) according to the different adaptation periods adopted: 6, 9, 14, and 21 d. The adaptation program consisted of ad libitum feeding of 3 diets over adaptation periods with concentrate level increasing from 70% to 86% of diet DM. Each of the adaptation diets containing 70.0%, 75.0%, and 80.5% concentrate were fed for 2-d, 3-d and 7-d to cattle adapted for 6-d, 9-d and 21-d; respectively. Also, the adaptation diets containing 70.0%, 75.0%, and 80.5% concentrate were fed for 4-d, 5-d and 5-d, respectively, to cattle adapted for 14-d. The finishing diet contained: 71.5% cracked corn grain, 14.0% sugarcane bagasse, 10.5% peanut meal, 2.5% supplement, 1.0% urea, and 0.5% limestone (DM basis). Cattle were fed ad libitum twice daily throughout the study, and feed offerings and refusals were weighed daily. Orthogonal contrasts were used to evaluate linear, quadratic, and cubic relationship between adaptation periods and the dependent variable. The use of different adaptation periods did not affect ($P > 0.10$) DMI, either expressed in kg or as % of BW. However, as the adaptation period lasted longer, final BW (6-d = 512.0 kg; 9-d = 521.9 kg; 14-d = 527.6 kg; 21-d = 514.8 kg), ADG (6-d = 1.37 kg; 9-d = 1.48 kg; 14-d = 1.56 kg; 21-d = 1.41 kg), G:F ratio (6-d = 0.142; 9-d = 0.153; 14-d = 0.153; 21-d = 0.146), and HCW (6-d = 277.3 kg; 9-d = 283.3 kg; 14-d = 287.8 kg; 21-d = 283.3 kg) were affected ($P < 0.05$) quadratically. Moreover, dressing percentage increased linearly ($P = 0.05$), as the adaptation period lasted longer (6-d = 54.13%; 9-d = 54.27%; 14-d = 54.55%; 21-d = 55.04%). Thus, yearling Nellore bulls should be adapted for 14 d. Grant provided by São Paulo State Foundation (FAPESP), São Paulo, São Paulo, Brazil.

Key Words: adaptation, Nellore

W297 The effect of crude glycerin concentration on fiber digestion in beef calves.

Robert G. Bondurant*, Jana Harding, Melissa Jolly-Breithaupt, James C. MacDonald, Andrea R. McCain, and Samodha C. Fernando, *University of Nebraska-Lincoln, Lincoln, NE.*

Ruminally and duodenally cannulated steers (n = 7; 363 kg) were utilized in a 7 × 4 Latin rectangle to determine the effects of crude glycerin (GLY) on total-tract digestibility, rate and extent of fiber digestibility an rumen fermentation parameters. Crude glycerin replaced soybean hulls (SH) at 0, 4, 8, or 12% of diet DM. Basal diets consisted of 50% wheat straw (WS), SH, 4% supplement, and soybean meal, to maintain a consistent CP level. Fecal samples, rumen and duodenal fluid were collected 1 h before feeding and at 2, 5, and 8 h post feeding. In situ bags containing ground WS or SH were incubated in the rumen for 0, 6, 12, 16, 24, 48, and 96 h to determine NDF digestion rates. Both DM intake and OM intake, decreased quadratically ($P = 0.04$) as GLY increased in the diet, with lowest DM intake and OM intake at 4% GLY inclusion. As GLY inclusion increased from 0 to 12% diet DM, NDF intake linearly decreased ($P < 0.01$) (5.86 and 5.27kg, respectively). Glycerin inclusion level had no effect on total-tract DM or OM digestibility ($P \geq 0.66$). As

GLY inclusion increased from 0 to 12%, total-tract NDF digestibility decreased linearly ($P = 0.02$) from 64.78% to 53.76%, respectively. The inclusion of GLY had no effect on in situ rate of NDF digestibility ($P \geq 0.27$) for WS or SH. Molar acetate proportion decreased linearly ($P < 0.01$) as time post-feeding progressed as well as GLY increased. Molar propionate concentrations increased ($P < 0.01$) as GLY inclusion increased and time to feeding increased from −1 to 8 h. Butyrate concentration increased ($P < 0.01$) at 2, 5, and 8 h post feeding for 8 and 12% GLY, while concentrations were unchanged for 0 and 4% GLY. Subsequently, acetate to propionate ratio decreased ($P < 0.01$) as GLY level increased from 0 to 12% and time from feeding increased from −1 to 8 h. Although the inclusion of GLY in forage-based diets has a negative impact on NDF digestibility, a decrease in acetate to propionate ratio could result in improved G:F.

Key Words: glycerin, fiber, volatile fatty acid

W298 Effect of supplementing feedlot cattle with live *Saccharomyces cerevisiae* on feed intake and rumen parameters.

D. O. Sousa*[1], C. A. Oliveira[1], J. M. Souza[1], J. A. Marques[1], A. V. Velasquez[1], E. Chevaux[2], L. J. Mari[2], and L. F. P. Silva[1], [1]*University of São Paulo, Pirassununga, São Paulo, Brazil,* [2]*Lallemand Animal Nutrition, Aparecidada de Goiânia, Goiás, Brazil.*

Our objective was to evaluate the effect of supplementation with live yeast (*Saccharomyces cerevisiae* CNCM I-1077) on feed intake and rumen parameters of beef cattle. Eight rumen cannulated steers with 24 mo and weighting 450 kg were used in a duplicated 4x4 Latin square design. Two levels of concentrate (60 or 80% of DM) and 2 treatments (with or without yeast supplementation) were applied, having sugarcane silage as the roughage source. The product was given in capsules, via rumen cannula, to achieve 8×10^9 cfu of yeast per animal. Animals were housed individually in tie-stalls with free access to water, and fed ad libitum allowing for 5 to 10% of orts. Feed was offered twice daily and orts weighed daily to measure DMI. Each period lasted for 28d to allow for complete washout of the previous treatment. The last 2 d of each treatment period were used for rumen fluid sample collection for pH and short chain fatty acids (SCFA) measurements. Feeding diets with 80% concentrate increased feed intake (9.4 vs. 8.6 kg ± 0.4, $P = 0.05$); however, yeast supplementation had no effect on feed intake. Feeding a greater concentrate diet decreased mean rumen pH (6.52 vs. 6.69 ± 0.07, $P < 0.01$), and live yeast supplementation prevented the drop in rumen pH. Feeding the greater concentrate diet increased rumen total concentration of SCFA (43 vs. 36 mM ± 3, $P = 0.03$), but only without yeast supplementation. Supplementation with live yeast increased the molar proportion of acetate (63.2 vs. 62.4% ± 0.8, $P = 0.03$), and of valerate (1.23 vs. 1.18% ± 0.06, $P = 0.06$) in the rumen, and decreased the concentration of butyrate (10.6 vs. 11.4% ± 0.5, $P = 0.03$). Yeast supplementation promoted changes in rumen fermentation that are associated with better maintenance of a higher pH, and a higher proportion of acetate in the rumen. However, these changes did not translate into a detectable increase of feed intake.

Key Words: short chain fatty acids, sugarcane silage, yeast

W299 Effect of adding virginiamycin in combination with different doses of monensin on feedlot performance.

Raul Lizarraga[1], Juan Pablo Russi[1], Luis Casares[2], Milton Gorocica[2], and Alejandro Relling*[1,3], [1]*Fac Cs Veterinarias, UNLP, Argentina,* [2]*Phibro Animal Health, Argentina,* [3]*IGEVET, CCT La Plata, CONICET, Argentina.*

The objective of this experiment was to evaluate the effect of the addition of virginiamycin (Vm) in combination with different doses of monensin (Mn) on feedlot performance. Two-hundred 40 crossbred steers (189 ± 3 kg) were used in an 80 d experiment. Steers were blocked by BW and randomly distributed in 24 pens, 9 animals each. Steers were fed a finishing diet (90% concentrate) based on whole-shelled corn and milo silage as roughage source. Three dietary treatments were evaluated: T1, basal diet supplemented with 180 mg Mn/hd/d; T2, basal diet supplemented with 200 mg Vm and 180 mg Mn hd/d; and T3, 200 mg Vm and 120 mg Mn hd/d. Body weight was measured on d 0, 40 and 80. Dry matter intake was measured weekly and G:F was estimated for the entire feeding period. Prior to harvest, on d 80, an ultrasound was performed to measure back fat (BF) and ribeye area (REA). Hot carcass weight was measured at harvest. Data were analyzed using a complete randomized block design with block as random effect and treatment as fixed effect. Fisher's protected test was used for mean separation. Pen was used as the experimental unit. Hot carcass weight and G:F were greater and DMI lower in the T2 group (all $P < 0.05$, Table 1). Back-fat tended to be greater in T2 ($P = 0.09$), BW on d 40 and 80, and REA were numerically greater in T2 but not statistically different among treatments. Feedlot performance (ADG, G:F) of T3 was numerically greater than that of T1, but differences were not significant (all $P > 0.10$). In conclusion the addition of 200 mg Vm to a higher dose of Mn improved feedlot performance (HCW and G:F).

Table 1 (Absr. W299). Feedlot performance and carcass characteristics in cattle supplemented with Vm in diets with two levels of Mn

	T1	T2	T3	*P*-value
BW d 0, kg	189.4	188.9	188.9	0.80
BW d 40, kg	278.3	282.8	279.6	0.44
BW d 80, kg	302.6	305.8	303.1	0.64
ADG, kg/d	1.42	1.46	1.42	0.73
DMI, kg/d	9.32^{a}	8.59^{b}	9.19^{a}	<0.01
G:F	0.137^{a}	0.150^{b}	0.137^{a}	0.05
Carcass weight, kg	173.5^{c}	178.0^{d}	171.2^{c}	0.05
Ribeye area, cm^2	52.1	52.4	52.1	0.95
Back fat, cm	0.49	0.53	0.50	0.09

^{ab}Values with different superscripts are statistically different at $P < 0.05$.
^{cd}Values with different superscripts are statistically different at $P < 0.10$.

W300 Evaluation of rumen microbiota in sugarcane silage based diet with different sources of nonfibrous carbohydrates.

J. M. Souza, D. O. Sousa*, L. G. Mesquita, N. R. B. Cônsolo, M. O. Frasseto, C. A. Oliveira, and L. F. P. Silva, *University of São Paulo, Pirassununga, São Paulo, Brazil.*

With the increasing adoption of sugarcane silage in ruminant feed, it becomes essential to understand the effects of supplementation with different levels and sources of non-fiber carbohydrates (NFC) on ruminal microorganisms. The aim of this study was to characterize the population change of cellulolytic and amylolytic rumen bacteria, caused by the increase of concentrate, and by the use of different sources of NFC in diets with sugarcane silage. Six Nellore beef cattle, castrated, and cannulated in the rumen, were used in a 3 0215 3 Latin square design. The experimental diets were formulated with 2 levels of concentrate: 60% or 80%, and the roughage used was sugarcane silage. Within each level of concentrate inclusion, 3 different sources of NFC were used: steam flaked corn (SFC), pelleted citrus pulp (PCP), or ground corn (GC). SFC and PCP were included in the diet in partial replacement of 70% of GC.

At d 14 of each period, samples of rumen contents were collected for DNA extraction and subsequent analysis of the relative quantification of rumen microorganisms by real time PCR. The increase of concentrate in the diet resulted in a decrease in population of *Fibrobacter succinogenes* ($P < 0.01$) and *Streptoccocus bovis* ($P < 0.01$), and in an increased of *Ruminoccocus flavefacien*s ($P = 0.05$) and *Megasphaera elsdenii* population ($P = 0.04$), without changing the *Ruminoccocus albus* population ($P = 0.63$). The partial replacement of GC by PCP resulted in an increase of *S. bovis* population ($P = 0.01$) and in a reduction of *R. flavefaciens* ($P < 0.01$), without changing *F. succinogenes* ($P = 0.64$). Moreover, the replacement of GC by SFC increased the population of *M. elsdenii* ($P = 0.03$) and reduced *R. albus* ($P < 0.01$). There was a significant Diet*NFC interaction only for *M. elsdenii* ($P = 0.02$), where SFC increase *M. elsdenii* population only at the 80% concentrate diet. In conclusion, substituting GC for PCP resulted in an increase only in population of *S. bovis*, while substituting GC for SFC resulted in a decrease in population of *R. albus*, and in an increase of *M. elsdenii*, in diets with sugarcane silage as the roughage source.

Key Words: beef cattle, rumen microorganism, qPCR

W301 Effects of rotating antibiotic and ionophore feed additives on enteric methane and volatile fatty acid production of steers consuming a high forage diet.

Whitney Crossland*[1], Luis Tedeschi[1], Todd Callaway[2], Mike Miller[1], Brandon Smith[1], and Matt Cravey[3], [1]*Texas A&M University, College Station, TX,* [2]*USDA-ARS Southern Plain Region, College Station, TX,* [3]*Huvepharma Inc., Amarillo, TX.*

Feed additives such as ionophores and antibiotics have been shown to decrease ruminal methanogenesis, but evidence as a long-term means of mitigation is lacking. In the present study, we proposed a rotation of feed additives as an alternative to reduce methane (CH4) production and to increase animal responses. Rumen-cannulated steers (n = 12) were fed a basal high forage diet at 2% of BW (DM) for 13 wk in a Calan gate facility for individual DMI measurement. Steers were randomly assigned to 1 of 6 treatments: (1) control (C) containing the basal forage diet and no additive, (2) bambermycin (B) = C + 20 mg B/hd/d, (3) monensin (M) = C + 200 mg M/hd/d, (4) B7M = rotating B and M treatments weekly, (5) B14M = rotating B and M treatments every 14 d, and (6) B21M = rotating B and M treatments every 21 d. Steers were blocked by weight in a RCB design with repeated measures each wk. Performance data and rumen fluid were collected weekly for in vitro analysis (n = 13) and results were interpreted on organic matter intake (OMI) basis. Treatments did not affect ADG. Potential activity of CH4 (PAM) was greatest for M-fed steers and least for B21M-fed steers (0.219 vs 0.172 mM/kg OMI, respectively; $P < 0.05$). Additionally, PAM of the B21M-fed steers was most consistent of all treatments. Total VFA concentration differed ($P < 0.05$), being greatest for M- and B14M-fed steers (3.46 and 3.47 mM/Kg OMI) and lowest for the B7M treatment (2.87 mM/Kg OMI), but were not different from other treatments. The PAM differed over time for all treatments decreasing toward wk 6 then increasing toward wk 12. Wk also affected total VFA peaking at wk 3 followed by a significant depression in wk 4 (4.02 vs 2.86 mM/Kg OMI; $P < 0.05$). There is an evidence to suggest that weekly rotation of B and M feed additives may not provide additional benefit at either the ruminal or environmental level when compared with continuous feeding of single feed additives. However, a 21-d rotation may combine desirable animal performance, decreased CH4 emissions, and provide a novel practical approach for industry feeding protocol.

Key Words: feed additive, CH_4, VFA

W302 Flint corn processing methods and dietary concentrations of roughage NDF for finishing cattle: 1. Intake and digestibility of nutrients.

Antonio Humberto Fleury de Melo[1], Murillo Alves Porto Meschiatti[1], João Meneghel de Moraes[1], Camila Delveaux Araujo Batalha[1], Lucas Jado Chagas[1], Débora de Carvalho Basto[1], Jonas de Souza[1], Nayana Carla Gonçalves Barbosa[2], and Flávio Augusto Portela Santos*[1], [1]*University of São Paulo, Piracicaba, São Paulo, Brazil,* [2]*Federal University of Goiás, Jataí, Goiás, Brazil.*

The objective of this trial was to evaluate intake and total-tract apparent digestibility (AD) of nutrients in finishing diets containing flint corn (70 – 75% vitreous endosperm) either ground (particle size: 2.70 mm) or steam-flaked (bulk density: 360 g/L), combined with dietary contents of 4, 7, 10 or 13% (DM basis) NDF from sugarcane bagasse. Sixteen Nellore bulls (BW = 484.46 ± 7.47 kg) fitted with rumen cannula, were fed diets containing 76–86% corn and randomly allocated to 16 pens for 2 periods (14 d for adaptation and 6 d for collection) in a 2 × 4 factorial arrangement. Total feces collection was carried out for 4 d. During the collection period the amount of diet offered was restricted to 85% of previous ad libitum intake. The data were analyzed using a PROC MIXED model with period and animal as random effect. Linear and quadratic effects were tested for dietary concentrations of roughage NDF. There were no interactions between corn processing and dietary concentrations of sugarcane bagasse NDF. Steam flaking of flint corn tended ($P = 0.07$) to decrease DMI (7.76 vs. 7.28 $kg.d^{-1}$), it decreased ($P < 0.01$) AD of NDF (50.73 vs. 33.12%) and of crude protein (75.05 vs. 71.93%), but it increased ($P < 0.01$) AD of DM (73.45 vs. 77.38%) of TCHO (75.19 vs. 81.93%), of NFC (84.1 vs. 95.16%) and of starch (95.95 vs. 99.36%). Steam flaking increased ($P < 0.01$) dietary TDN concentration (80.26% vs. 84.22%) but had no effect ($P = 0.73$) on TDN intake (6.22 vs. 6.15 $kg.d^{-1}$). Increasing roughage NDF content of the diets caused a quadratic response for DMI (6.95, 7.90, 7.80 and 7.41 $kg.d^{-1}$, respectively) and nutrient intakes and a linear decrease for AD of DM (78.80; 75.95; 75.90 and 72.80% respectively), of TCHO (81.55, 78.76, 78.86 and 75.07% respectively) and had no effect ($P =$ 0.40, 0.11, 0.94 and 0.29, respectively) on AD of NDF, NFC, CP, EE and starch. In conclusion, steam flaking increases energy value of flint corn and feeding around 7% of sugarcane bagasse NDF in finishing diets optimizes energy intake of Nellore bulls.

Key Words: feedlot, steam-flaked corn, roughage NDF

W303 Effect of excess MP supplementation from corn gluten meal or soybean meal on plasma amino acid concentrations of beef cows consuming low quality forage.

Taylor C. Geppert*[1], Allison M. Meyer[2], and Patrick J. Gunn[1], [1]*Department of Animal Science, Iowa State University, Ames, IA,* [2]*Division of Animal Sciences, University of Missouri, Columbia, MO.*

The objective was to determine the effects of excess MP supplementation from feedstuffs differing in rumen degradability of protein on plasma AA concentrations. As part of a larger study, we hypothesized excess MP supplementation from feedstuffs differing in rumen degradability would alter reproductive performance of beef cows around the time of ovulation, potentially due to changing circulating AA concentrations. Non-pregnant, nonlactating mature beef cows (n = 18) were allotted by age, BW and BCS to ad libitum corn stalks and 1 of 2 isocaloric, isonitrogenous dietary supplements consisting primarily of either (1) corn gluten meal (GLM) or (2) soybean meal (SBM), supplemented at 150% of NRC MP requirements. Cows were individually supplemented once daily for 58 d and coccygeal blood samples were taken on d 47 for AA analysis. Data were analyzed using the MIXED procedures of SAS.

On d 47, total AA, essential AA, nonessential AA, glycogenic AA and branched-chain AA were not different ($P \geq 0.21$) between treatments. However, total ketogenic AA tended to be greater ($P = 0.07$) in excess GLM than excess SBM supplemented cows. When expressed as a percent of total AA, arginine, lysine, threonine, tryptophan and valine were lesser ($P \leq 0.05$) in GLM than SBM supplemented cows. However as a percent of total AA, leucine, methionine and phenylalanine were greater ($P \leq 0.03$) in GLM than SBM cows. In addition, as a percent of total AA asparagine and proline were greater ($P < 0.05$) in cows supplemented with GLM than SBM. As a percent of essential AA, arginine, lysine, valine, tryptophan and threonine were lesser ($P \leq 0.04$), and methionine, phenylalanine and leucine were greater ($P \leq 0.03$) in GLM than SBM. These data illustrate that supplementing MP at 150% of NRC requirements from feedstuffs differing in rumen degradability may change the profile of circulating plasma AA around the time of ovulation in beef cows consuming low quality forage. However, the effects of this change in AA profile on reproductive function of beef cows are still largely undetermined and warrant further investigation.

Key Words: amino acid, corn stalk, protein

W304 Flint corn processing methods and dietary concentrations of roughage NDF for finishing cattle: 2. Rumen fermentation, N metabolism, and ingestive behavior.

Antonio Humberto Fleury de Melo[1], Murillo Alves Porto Meschiatti[1], Camila Delveaux Araujo Batalha[1], Jonas de Souza[1], João Meneghel de Moraes[1], Débora de Carvalho Basto[1], Lucas Jado Chagas[1], Nayana Carla Gonçalves Barbosa[2], and Flávio Augusto Portela Santos*[1], *[1]University of São Paulo, Piracicaba, São Paulo, Brazil, [2]Federal University of Goiás, Jataí, Goiás, Brazil.*

The objective of this trial was to evaluate rumen fermentation, N metabolism and ingestive behavior of cattle fed diets containing flint corn (70 – 75% vitreous endosperm) either ground at 2.70 mm or steam-flaked at 360 g/L, combined with dietary contents of 4, 7, 10 or 13% (DM basis) NDF from sugarcane bagasse. Sixteen Nellore bulls (484.46 ± 7.47 kg) fitted with rumen cannula, were fed diets containing 76–86% corn and randomly allocated to 16 pens for 2 periods (14d adaptation; 6d collection) in a 2 × 4 factorial arrangement. During the collection period the amount of diet offered once a day was restricted to 85% of previous ad libitum intake. Rumen samples were collected on d 16 at 0, 2, 4, 6, 8, 10, 12, 16 and 24 h post feeding. Blood samples and urine spot samples were collected on d 15, 4 h post feeding. Microbial synthesis was estimated based on the purine derivative method. The data were analyzed using a PROC MIXED model with period and animal as random effect. Linear and quadratic effects were tested for dietary concentrations of roughage NDF. No interactions were observed between corn processing and NDF level. Steam-flaking increased ($P < 0.01$) rumen propionate and decreased ($P < 0.01$) butyrate and N-NH_3 concentrations. Steam-flaking decreased ($P < 0.01$) N ingestion, blood urea nitrogen (BUN), N urine and total N excretion and increased ($P = 0.03$) microbial efficiency. Increasing dietary sugarcane bagasse NDF tended to increase linearly ($P = 0.10$) rumen pH and decreased linearly ($P = 0.05$) rumen propionate and ($P = 0.05$) total VFA. Increasing bagasse NDF caused a quadratic effect ($P < 0.01$) on N ingestion and absorption. Rumination and mastication time were increased linearly ($P < 0.01$) as roughage NDF was increased. Blood glucose and BUN were not affected ($P = 0.53$ and 0.54, respectively) by bagasse NDF level. In conclusion, steam-flaking of flint corn improves energetics and N metabolism of beef cattle. Feeding increasing levels of bagasse NDF stimulates rumination but it decreases the efficiency of energy production in the rumen.

Key Words: feedlot, steam-flaked corn, roughage NDF

W305 Carcass traits of Nellore cows finished in different times of high intake supplementation in pasture.

Flavio Dutra de Resende*[1,2], Ana Paula Reiff Janini[2], Ivanna Moraes de Oliveira[1], Aline Domingues Moreira[2], Fernanda Diamantino dos Santos[3], Paloma Helena Gonçalves[3], Michele Aparecida Prado Alves[3], and Gustavo Rezende Siqueira[1,2], *[1]Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brazil, [2]UNESP, Jaboticabal, São Paulo, Brazil, [3]UNIFEB, Barretos, São Paulo, Brazil.*

This project aimed to evaluate the carcass traits of Nellore cull cows finished in different times of high intake supplementation in *Brachiaria brizantha* 'Marandu' pasture, in dry season. It is assumed that the high intake supplementation in pasture could improve the carcass traits of these animals. The experiment was performed from 09/2014 to 11/2014, assessing 4 times of finishing with high intake supplementation – 2% of BW – in pasture (0, 21, 42 and 63 d). Several 60 Nellore cull cows were used and kept, before the beginning of the study, in system extensive production, pasture plus mineral salt ad libitum. The cull cows were distributed randomly (experimental design in randomized blocks) on 20 experimental units (paddock), composed by 3 animals/paddock and 5 paddocks/supplementation time. At zero time, the cows were conducted directly to slaughter and, at the end of feeding times 21, 42 and 63 d, the remaining cull cows were slaughtered for evaluation of carcass traits. The supplementation time did not alter the carcass length (136.43 cm; $P = 0.90$), carcass depth (45.59 cm; $P = 0.53$) and size of round (87.03 cm; $P = 0.79$) from cull cows. It was a linear increase ($P < 0.01$) on weight and carcass yield, *longissimus* muscle area (LM area) and subcutaneous fat thickness (12th-rib fat). Cull cows finished with 63 d of supplementation at pasture presented increased weight from 203.7 kg to 257.8 kg and the LM area became from 56.9 cm^2 to 70.8 cm^2, regarding the slaughtered cull cows at d 0. At the same period, it was registered an increase of 3.59 percentage points in carcass yield, initially of 51.5%; as well in 12th-rib fat, passing from 2.02 mm to 6.15 mm. Therefore, the increase in supplementation time applied in finishing of Nellore cull cows allows an improvement the carcass traits.

Key Words: carcass, loin eye area, subcutaneous fat thickness

W306 Sugar cane straw replacing whole corn on growth and intake of feedlot finishing bulls.

Barbara J. M. Lemos*[1], Flavio G. F. Castro[2], Bruno P. C. Mendonça[2], Dheividy B. Fernandes[2], and Juliano J. R. Fernandes[1], *[1]Universidade Federal de Goias, Goiania, Goias, Brazil, [2]AgroCria, Goiania, Goias, Brazil.*

The effects of increasing amounts of pelleted sugar cane straw (SCS) replacing corn in finishing diets (85% whole corn + 15% pelleted concentrate) of feedlot young bulls were evaluated during a 103 d period. Nellore bulls (n = 80; 337 ± 31 kg of BW) were allotted to 20 outdoor pens (4 bulls per pen) and assigned to a complete randomized block design with 5 blocks (initial BW) and 4 dietary treatments (Table 1): Control (whole corn), SCS3%, SCS6%, SCS9%. Bulls were adapted over 21 d by decreasing inclusion of SCS on dietary DM (d 1 to 7, 30% of SCS; d 8 to 14, 20% of SCS; d 15 to 21, 10% of SCS). The DMI increased linearly up to 23%, as kg/d and 22% as % of BW ($P = 0.01$), 19% on DIP intake ($P = 0.03$) and 39% on peNDF intake ($P < 0.01$) with increased addition of SCS. No effects were observed in NE intake ($P > 0.05$). The Final BW and ADG tended to increase linearly ($P = 0.10$, BW; $P = 0.07$, ADG) with increasing amounts of SCS. In conclusion, SCS is a possible peNDF source replacing whole corn. There were evidences of growth and nutrients intake improvement.

Table 1 (Abstr. W306). Composition of finishing diets with increasing amounts of pelleted sugar cane straw (SCS; composition of 92% DM, 6.9% ash, 1.8% CP, 0.5% EE, 69% NDF, 13% peNDF, 37% ADF) replacing corn (3, 6, and 9% of dietary DM) and effects on growth and intake of Nellore bulls fed 85% whole corn + 15% pelleted concentrate

W307 Impact of a molasses-based liquid feed supplement on the diet selection behavior and growth of fattening calves.

Lisa J. Gordon and Trevor J. DeVries*, *Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

The objective of this study was to assess the impact of a molasses-based liquid feed (LF) supplement on the feed sorting behavior and growth of young, fattening cattle fed a high-grain diet. Twenty-four male Holstein calves, 90.2 ± 2.6 d old and weighing 137.5 ± 16.9 kg, split into groups of 4, were exposed to each of 2 treatments in a crossover design with 35-d treatment periods. Treatments were (1) control diet (76.0% high-moisture corn, 19.0% protein supplement, 5.0% alfalfa/grass haylage), and (2) LF diet (68.4% corn, 17.1% protein supplement; 9.0% molasses-based LF, and 4.5% alfalfa/grass haylage). Diets were designed to support 1.5 kg/d ADG. Data were collected for the final 3 wk of each treatment period. Feed intakes were recorded daily and calves were weighed 2×/wk. Feed samples of fresh feed and refusals were collected 3×/wk for particle size analysis. The particle size separator had 3 screens (19, 8, and 1.18 mm) and a bottom pan, resulting in 4 fractions (long, medium, short, fine). Sorting was calculated as the actual intake of each fraction expressed as a % of its predicted intake. Data were summarized by pen and week and analyzed in a repeated measures general linear mixed model. Calves tended (SE = 4.8; $P = 0.08$) to sort for long particles on the control diet (110.5%) and did not sort these particles on the LF diet (96.8%). Sorting for medium particles (102.6 ± 0.6%) was similar ($P = 0.9$) across diets. Calves sorted against short particles on the LF diet (97.5%; SE = 0.5; $P = 0.04$), but did not sort this fraction on the control diet (99.4%). Calves sorted against fine particles (79.3 ± 4.0%), to a similar extent ($P = 0.2$), on both diets. DMI was similar across diets (6.1 kg/d; SE = 0.1; $P = 0.9$), but day-to-day variability in DMI was higher (0.5 vs 0.4 kg/d; SE = 0.02; $P = 0.04$) when calves were fed the control compared with the LF diet. Calves on both diets had similar ADG (1.6 kg/d; SE = 0.04; $P = 0.8$) as well as within-pen variability in ADG (0.4 kg/d; SE = 0.05; $P = 0.7$). Feed conversion was also similar between control and LF diets (4.3 vs 3.9 kg DM/kg gain; SE = 0.3; $P = 0.4$). The results suggest that despite promoting more consistency in DMI, addition of a molasses-based LF to a high-grain, finishing calf diet did not affect calf growth.

Key Words: molasses, fattening calf, sorting

W308 Feedlot performance and carcass traits of Nellore and ½ Angus x Nellore cattle adapted either for 9 or 14 days.

Daniel Hideki Mariano Watanabe*[1], Murillo Ceola Stefano Pereira[2], Ana Carolina Janssen Pinto[1], Wilson Inácio Silva Filho[1], Gustavo Perina Bertoldi[1], André Luiz Nagatani Rigueiro[1], Anderson Augusto Santos[1], Paulo César da Silva Santos[1], Luis Felipe Rebeschini Oliveira[1], Pedro Fernando Santi[1], João Victor Tino Dellaqua[1], Mário De Beni Arrigoni[2], and Danilo Domingues Millen[1], *[1]São Paulo State University (UNESP), Dracena, São Paulo, Brazil, [2]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil.*

This study, conducted at the São Paulo State University feedlot, Dracena Campus, Brazil, was designed to evaluate the length of adaptation period to high concentrate diets on overall feedlot performance and carcass traits of Nellore (NE) and 1/2 Angus × Nellore (AN) cattle. The experiment was designed as a completely randomized block with 2 × 2 factorial arrangement, replicated 6 times (3 animals/pen), in which seventy-two 22-mo-old yearling bulls [36 NE, and 36 AN] were fed in 24 pens for 89 d according to the treatments: NE adapted for 9-d; NE adapted for 14-d, AN adapted for 9-d, and AN adapted for 14-d. Average initial BW was 319.2 ± 18.5 kg, and 307.9 ± 29.5 kg for NE and AN, respectively. The adaptation program consisted of ad libitum feeding of 3 diets over adaptation periods with concentrate level increasing from 62% to 86% of diet DM. Each of the adaptation diets containing 62%, 70%, and 78% concentrate was fed for 3-d to cattle adapted for 9-d. For cattle adapted for 14-d, the adaptation diets containing 62%, 70%, and 78% concentrate were fed for 5-d, 4-d and 5-d, respectively. The finishing diet contained: 66.5% cracked corn grain, 14.0% sugarcane bagasse, 16.0% cottonseed meal, 1.5% supplement, 1.2% urea, and 0.8% limestone (DM basis). Cattle were fed ad libitum twice daily throughout the study, and feed offerings and refusals were weighed daily. No significant ($P > 0.10$) adaptation length main effects were observed for any of the feedlot performance and carcass traits variables evaluated. However, significant ($P < 0.01$) biotype main effects were observed, in which AN yearling bulls had greater final BW (466.6 kg vs. 425.8 kg), ADG (1.71 kg vs. 1.27 kg), DMI expressed in kg (11.8 kg vs. 9.5 kg), and DMI expressed as % of BW (3.07% vs. 2.53%), improved G:F ratio (0.146 vs. 0.134), and heavier HCW (243.6 kg vs. 229.0 kg). No significant ($P = 0.74$) biotype main effect was observed for dressing percentage (AN = 53.5%; NE = 53.2%). Thus, AN yearling bulls performed better than NE yearling bulls regardless of length of the adaptation period adopted. Cattle should be adapted for 14-d, because longer adaptation periods are safer. Grant provided by São Paulo State Foundation (FAPESP), São Paulo, São Paulo, Brazil.

Key Words: adaptation, biotype

W309 Rumen morphometrics of Nellore and ½ Nellore x Angus cattle adapted either for 9 or 14 days to high-concentrate diets.

André Luiz Nagatani Rigueiro*[1], Daniel Hideki Mariano Watanabe[1], Murillo Ceola Stefano Pereira[2], Wilson Inácio Silva Filho[1], Gustavo Perina Bertoldi[1], Ana Carolina Janssen Pinto[1], Anderson Augusto Santos[1], Mariana Squizatti[1], Daniela Dutra Estevam[2], Lais Aquino Tomaz[1], Osvaldo Alex Souza[1], and Danilo Domingues Millen[1], *[1]São Paulo State University (UNESP), Dracena, São Paulo, Brazil, [2]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil.*

This study, conducted at the São Paulo State University feedlot, Dracena Campus, Brazil, was designed to evaluate the length of the adaptation period to high concentrate diets on rumen morphometrics and rumenitis of Nellore (NE) and 1/2 Angus × Nellore (AN) cattle. The experiment was designed as a completely randomized block with 2 × 2 factorial arrangement, replicated 6 times (3 animals/pen), in which seventy-two 22-mo-old yearling bulls [36 NE (319.2 ± 18.5 kg), and 36 AN (307.9 ± 29.5 kg)] were fed in 24 pens for 89 d according to the treatments: NE adapted for 9-d; NE adapted for 14-d, AN adapted for 9-d, and AN adapted for 14-d. The adaptation program consisted of ad libitum feeding of 3 diets over adaptation periods with concentrate level increasing from 62% to 86% of diet DM. Each of the adaptation diets containing 62%, 70%, and 78% concentrate was fed for 3-d to cattle adapted for 9-d. For cattle adapted for 14-d, the adaptation diets containing 62%, 70%, and 78% concentrate were fed for 5-d, 4-d and 5-d, respectively. The finishing diet contained: 66.5% cracked corn grain, 14.0% sugarcane bagasse, 16.0% cottonseed meal, 1.5% supplement, 1.2% urea, and 0.8% limestone (DM basis). At harvest, rumenitis incidence (RUM) was determined, on the entire washed rumen, using a scale of 0 (no lesions noted) to 10 (severe ulcerative RUM). Likewise, a 1-cm^2 fragment of each rumen was collect from cranial sac. The number of papillae per cm^2 of rumen wall (NOP) was determined, as well as the mean papillae area (MPA). The rumen wall absorptive surface area in cm^2 was calculated as follows: 1 + (NOP × MPA) – (NOP × 0.002). No significant ($P > 0.10$) biotypes and adaptation length main effects were observed for any of the rumen morphometrics variables evaluated. However, a significant ($P < 0.01$) biotype main effect was observed for RUM, where NE yearling bulls had greater RUM scores than AN yearling bulls (2.05 vs. 1.35). No significant ($P = 0.15$) adaptation length main effect was observed for RUM. Thus, NE yearling bulls are more sensitive to rumen epithelium damage, regardless of length of the adaptation period adopted. Grant provided by São Paulo State Foundation (FAPESP), São Paulo, São Paulo, Brazil.

Key Words: adaptation, rumenitis

W310 Relationships of feedlot performance and rumen morphometrics of Nellore cattle differing in phenotypic residual feed intake.

Murillo Ceola Stefano Pereira[2], Gustavo Durante Cruz[3], Mario De Beni Arrigoni[2], Juliana Silva[1], Tássia Veluma Barbosa Carrara[2], and Danilo Domingues Millen*[1], *[1]São Paulo State University (UNESP), Dracena, São Paulo, Brazil, [2]São Paulo State University (UNESP), Botucatu, São Paulo, Brazil, [3]Cargill Animal Nutrition, Elk River, MN.*

The objective of this study was to examine the relationship of feedlot performance, DMI variation and rumen morphometrics of Nellore cattle classified by residual feed intake (RFI). A study was conducted, in 2 consecutive years, using individual pens at São Paulo State University feedlot, Dracena campus, Brazil. At year 1, forty-eight 20-mo-old Nellore bulls (358.2 ± 19.4 kg) were fed for 94 d. At year 2, sixty 20-mo-old Nellore bulls (402.5 ± 33.0 kg) were fed for 84-d. All Nellore bulls were categorized as high RFI (RFI >0.5 SD above the mean, n = 25), medium RFI (RFI ± 0.5 SD from the mean, n = 56) and low RFI (RFI <0.5 SD below the mean, n = 27). The finishing diet, in both years, contained: 71.5% cracked corn grain, 16.0% sugarcane bagasse, 7.7% soybean meal, 3.5% supplement, and 1.3% urea (DM basis). Variables were analyzed by a linear model with year and RFI groups as the main effects, with interactions. Animals classified as low RFI had lower ($P = 0.01$) initial BW (high = 382.5 kg; medium = 378.1 kg; low = 371.8 kg), daily DMI in kg (high = 10.1 kg; medium = 9.5 kg; low = 8.2 kg), daily DMI expressed as % of BW (high = 2.32%; medium = 2.18%; low = 1.92%), and improved ($P = 0.01$) G:F ratio (high = 0.112; medium = 0.131; low = 0.143). However, no significant ($P > 0.10$) RFI effect was observed for ADG (high = 1.14 kg; medium = 1.25 kg; low = 1.16 kg), final BW (high = 484.0 kg; medium = 489.5 kg; low = 474.7 kg) and HCW (high = 266.7 kg; medium = 262.7 kg; low = 256.1 kg). Moreover, animals categorized as high RFI had lower ($P = 0.02$) DMI variation (high = 12.28%; medium = 15.14%; low = 16.24%). No significant ($P > 0.10$) RFI effect was observed for rumenitis (high = 1.4; medium 1.4; low = 1.1), number of papillae (high = 45.6; medium = 43.6; low = 43.1), and absorptive surface area (high = 25.4 cm^2; medium = 26.3 cm^2; low = 22.7 cm^2). Nonetheless, Nellore bulls ranked as low RFI presented smaller ($P = 0.07$) mean papillae area (high = 0.55 cm^2; medium = 0.60 cm^2; low = 0.50 cm^2). Selection of low RFI Nellore bulls is feasible because it does not negatively affect feedlot performance, HCW, and rumen characteristics.

Key Words: papillae, Nellore

W311 Effects of crude glycerin on feed intake and apparent total-tract digestibility of finishing diets in crossbred heifers.

E. H. C. B. van Cleef*[1,3], S. Uwituze[2], C. A. Gilis[2], C. L. Van Bibber-Krueger[2], K. A. Miller[2], C. C. Aperce[2], and J. S. Drouillard[2], *[1]São Paulo State University, Jaboticabal, São Paulo, Brazil, [2]Kansas State University, Manhattan, KS, [3]FAPESP, São Paulo, Brazil.*

Expansion of the biodiesel industry worldwide has increased availability of crude glycerin, a major by-product of biodiesel production from animal and vegetable oils. Our objective was to evaluate DMI and apparent total-tract digestibilities of DM, OM, and NDF in crossbred heifers fed finishing diets in which 15% crude glycerin was used to replace a portion of dry-rolled corn. Twenty-four crossbred heifers (334.4 ± 0.9 kg initial BW) were randomly assigned to 12 pens and allowed ad libitum access to isonitrogenous finishing diets containing 10% corn silage and 90% concentrate composed of dry-rolled corn, soybean hulls, corn gluten feed, soybean meal, mineral premix, and 0 (CON) or 15% crude glycerin (GLY). Glycerin contained 81.5% glycerol, 13.3% water, 6.3% ash, and <0.02% methanol. Animals were fed chromic oxide (0.1% of diet DM), and fecal grab samples were collected 3 times daily (8, 16, and 24 h after feeding) on d 7, 21, and 35; composited by animal; dried; and ground through a 1-mm screen. Chromic oxide contents of feces and diets were determined by atomic absorption and used to calculate apparent total-tract digestibilities of DM, OM, and NDF. Weights of feed DM delivered and refused were recorded daily to calculate DMI. Data were analyzed as a completely randomized design with repeated measures using a mixed model with diet, time, and diet × time as fixed effects, and animal within diet × time as a random effect. There were no interactions between treatment and time of sampling ($P > 0.10$), suggesting no adaptive response to dietary glycerin. Feed DMI was similar among treatments (10.93 and 10.92 kg/d for CON and GLY, respectively; $P > 0.1$). Organic matter digestibility of GLY diet was greater than that of the CON diet ($P = 0.04$), and DM digestibility followed a similar trend ($P = 0.06$). Digestibility of NDF was unaffected

by glycerin addition ($P > 0.10$). Crude glycerin can effectively replace dry-rolled corn in diets for beef heifers when fed at 15% of diet DM, improving OM digestion without adversely affecting NDF digestibility.

Key Words: apparent total-tract digestibility, by-product, glycerin

W312 Impact of the nutritional plan in the growing phase on performance of Nellore cattle during the finishing phase.

Ivanna Moraes de Oliveira*[1], Matheus Henrique Moretti[2], João Alexandrino Alves Neto[3], Aline Domingues Moreira[4], Rodolfo Maciel Fernandes[4], João Marcos Beltrame Benatti[5], Gustavo Rezende Siqueira[1,4], and Flávio Dutra de Resende[1,4], *[1]Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brazil, [2]Agroceres Multimix, Rio Claro, São Paulo, Brazil, [3]Campos Rações e Minerais, Acreúna, Goias, Brazil, [4]UNESP, Jaboticabal, São Paulo, Brazil, [5]Trouw Nutrition/Bellman, Mirassol, São Paulo, Brazil.*

The effects of nutritional plans (NP) in the growing phase on the performance of Nellore cattle during the finishing phase were evaluated. Our hypothesis was that the NP in the growing phase affect the body weight gain rate (BWGR) in the finishing phase, and that there is an interaction between the NP. The evaluated NP were characterized by the combination of different types of supplementation in the dry season (post-weaning - phase I) e wet season (phase II) (both growing phase) and finishing stage (dry season - phase III). In phase I, the animals received protein supplementation (PS; 0.1% BW) or protein-energy supplementation (PES; 0.5% BW); in phase II, mineral salt (MS; ad libitum), or PES (0.5% BW); and in phase III, the animals under the different NP in the growing phase (PS/MS; PS/PES; PES/MS and PES/PES) received 1.5 or 2.0% BW of supplement. Animals were maintained on a Marandu-grass pasture at all phases. Animals were weighed after 16 h of solid-feed deprivation. The BWGR was calculated as (ADG ÷ average BW of the animal - in each phase) × 100. The experimental design was completely randomized, with a 2 (supplements in phase I) × 2 (supplements in phase II) × 2 (supplements in phase III) factorial arrangement; n = 5 (animals as replicate). The *t*-test was applied at 10% probability. No interaction was detected ($P > 0.10$) between phases I, II, and III. In addition, the NP supplied in phase I did not influence ($P > 0.10$) ADG, BWGR, or the final BW in phase III. The ADG during phase III was influenced only by the nutritional history of phase II. In phase III, the animals fed MS (1.02 kg) during phase II had a greater ($P = 0.02$) ADG than those fed PES (0.92 kg). Likewise, the animals fed MS had a higher BWGR in phase III than those fed PES (0.27 *vs*. 0.21 kg/100 kg BW, respectively). In phase II, the animals fed PES gained 60.3 kg more than those which received MS. At the end of phase III, this difference became 47.2 kg, i.e., 78% of the gain obtained in phase II was maintained. The nutritional plan utilized during the growing phase, before finishing (wet season), alters the gain rate in the finishing. Trouw Nutrition/Bellman provided financial support, and FAPESP provided the fellowship grant.

Key Words: growth, historic nutritional, supplementation

W313 Performance of grazing Nellore cattle finished with high-intake supplementation.

Flavio Dutra de Resende*[1,3], Beatriz Lima Vellini[1], Ivanna Moraes de Oliveira[1], João Marcos Beltrame Benatti[2], Matheus Henrique Moretti[2], Rodolfo Maciel Fernandes[3], Aline Domingues Moreira[3], and Gustavo Rezende Siqueira[1,3], *[1]Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brazil, [2]Trouw Nutrition/Bellman, Mirassol, São Paulo, Brazil, [3]UNESP, Jaboticabal, São Paulo, Brazil.*

The effects of high intake supplementation on the performance of Nellore cattle finished on *Brachiaria brizantha* 'Marandu' pastures was evaluated. It was hypothesized that the performance Nellore cattle finished under high intake supplementation and with a high forage allowance is improved when corn is used as the source of energy, and that under conditions of low forage allowance, citrus pulp is the most suitable source of energy. Two forage allowances (FA; 2.5 and 4.5 kg DM kg^{-1} BW) and 2 sources of energy (SE; corn and pulp included in the diet at 2% of the BW) were evaluated. In the experiment, were used 48 (48) uncastrated Nellore cattle at 30 mo of age, with an initial BW of 430.0 ± 2.7 kg. The animals were blocked according to body weight and the data evaluated in randomized blocks in a 2 × 2 factorial arrangement (FA and SE). The paddock was considered the experimental unit, with 3 replicates per treatment (4 animals/paddock). There was no interaction between SE and FA ($P > 0.10$). None of the factors led to any differences ($P > 0.10$) in carcass yield (58.8%), average daily gain (1.22 kg day^{-1}) or gain yield (carcass gain/weight gain: 805.6 g kg^{-1}). The higher FA resulted in an increase in BW (559.0 kg; $P = 0.06$) as compared with the animals on lower FA (534.0 kg). However, no difference was detected for carcass gain (0.98 kg day^{-1}; $P = 0.28$), carcass weight (322.2 kg; $P = 0.11$), subcutaneous fat thickness (SFT; 4.31 mm; $P = 0.24$), or loin eye area (LEA; 78.4 cm^2; $P = 0.49$) for the animals under different FA. Corn and pulp did not alter the final BW (546.5 kg; $P = 0.19$). Contrastingly, the carcass gain (1.02 kg day^{-1} *vs* 0.93 kg day^{-1}; $P = 0.09$), the carcass weight (327.6 kg *vs* 316.8 kg; $P = 0.09$), and the SFT (4.72 mm *vs* 3.89 mm; $P = 0.18$) were greater in the animals fed corn as compared with pulp. Citrus pulp provided animals with a larger LEA ($P < 0.01$) as compared with corn (81.0 cm^2 *vs* 75.8 cm^2). It is recommended to use a forage allowance of 4.5 kg DM kg^{-1} BW and corn as the source of energy. Nutreco/Bellman provided support.

Key Words: carcass, energy source, forage allowance

W314 Different supplementation strategies to grazing beef cattle in tropical conditions.

Bruna B. Menezes[2], Henrique J. Fernandes*[1], Maria G. Morais[2], Marina N. Bonin[3], Gelson L. D. Feijó[3], Ednéia P. Rosa[1], Lucy M. Surita1,3, Yasmin S. Falcão[1], and Amanda A. Perestrelo[1], *[1]State University of Mato Grosso do Sul, Aquidauana, MS, Brazil, [2]Federal University of Mato Grosso do Sul, Campo Grande, MS, Brazil, [3]EMBRAPA Beef Cattle, Campo Grande, MS, Brazil.*

The objective of this study was to evaluate the effect of different supplementation strategies on the average daily gain (ADG) and carcass characteristics of Nellore bulls grazing Piatã grass (*B. brizantha* cv. BRS Piatã) pastures from the weaning until a Brazilian commercial slaughter weight of 450 kg. Thirty 2 bulls (initial BW of 189 ± 15.7 kg) from the State University of Mato Grosso do Sul, Aquidauana, Brazil, were randomly distributed in 4 treatments (8 animals/experimental units per treatment): mineral supplementation (Control), continuous concentrate supplementation (Continuous), concentrate supplementation from weaning until a BW of 320 kg (Growing), and concentrate supplementation from 320 kg until 450 kg BW (Finishing). Concentrate supplement used was Recrimax AC (until BW of 320 kg) and Lipomax (BW from 320 to 450 kg) (Real H, Campo Grande, MS, Brazil) and was supplied at 0.5% of body weight. Recrimax AC and Lipomax were formulated with corn, soybean meal, urea, molasses, rumen-protected fat (Lactoplus), salt (sodium chloride), dicalcium phosphate, virginiamycin, and a premix with methionine, lysine, minerals and vitamins A, D and E. These supplements had 75.6 and 85.1% OM, 24.3 and 18.6% CP, 1.34 and 2.3% EE, 7.1 and 12.3% NDF, 44.2 and 54.2% NFC, 68.3 and 77.6% TDN, respectively. Mineral supplement was supplied ad libitum.

To calculate ADG, animals were weighted (after 16 h of solid fasting) at the beginning of the trial and at the slaughter day. After slaughter, measurements of loin eye areas (LEA) and fat thickness at the 12th rib (FT) were taken. The effect of the concentrate supplementation, of the continuous or tactical (just in part of the animal's life) concentrate supplementation, and of the phase of the tactical supplementation were evaluated by the partition of the sum of squares of treatment in orthogonal contrasts. ADG was greater to supplemented animals and to continuous compared with tactical concentrate supplementation ($P < 0.05$), and did not differ between phases of tactical concentrate supplementation (0.449, 0.611, 0.519 and 0.557 kg/d for Control, Continuous, Growing and Finishing treatments, respectively). Concentrate supplementation and continuous supplementation (when compared with tactical supplementation) also increased ($P < 0.05$) LEA (64.6, 88.8, 72.0 and 77.6 cm^2 for Control, Continuous, Growing and Finishing, respectively). FT (1.59, 1.72, 2.05 and 1.85 mm for Control, Continuous, Growing and Finishing, respectively) was not affected ($P > 0.05$) by the treatments. Acknowledgments to FUNDECT – Foundation to Support development of education, science and technology of the state of Mato Grosso do Sul, for financial support of the project.

Key Words: carcass, concentrate, Nellore

W315 Effect of high-fiber concentrate diets on intake, performance, carcass traits and meat quality of feedlot Nellore heifers.

J. M. B. Ezequiel*[1], P. S. N. Oliveira[1], R. L. Galati[2], D. S. Ferreira[1], V. C. Santos[1], A. C. Homem Junior[1], and E. H. C. B. van Cleef[1], [1]*São Paulo State University, Jaboticabal, São Paulo, Brazil,* [2]*Federal University of Mato Grosso, Cuiabá, Mato Grosso, Brazil.*

The use of fiber-rich by-products, as corn germ meal, could prevent metabolic disorders in feedlot cattle fed high-concentrate diets, avoiding losses in performance. Therefore, the objective of this study was to evaluate high-concentrate diets with corn germ meal totally replacing corn grain on performance, carcass traits, and meat sensory characteristics of feedlot Nellore heifers. Twenty-eight heifers (200 ± 22.5 kg BW) were randomly assigned to 4 treatments in a 2 × 2 factorial arrangement: 2 concentrate levels (70 and 80%), and 2 energy sources (corn grain and corn germ meal). Corn silage was used as roughage, and concentrate was composed of soybean hulls, sunflower meal, mineral premix and corn or corn germ meal. Animals were gradually adapted to the finishing isoenergetic and isonitrogenous diets over a 6-wk period. Weights of feed delivered and refused were recorded daily and composited samples were analyzed for DM, CP and aNDF contents. At the end of 112-d feedlot period, heifers were transported for 100 km to a commercial abbatoir. There was no interaction ($P > 0.05$) of concentrate levels and energy sources for DM intake, which was not affected by treatments. The concentrate level of 80% and corn, allowed the greatest CP (1.17 kg/day) and aNDF (4.05 kg/day) intakes. Final BW ($P < 0.05$) and ADG ($P < 0.01$) were decreased when corn germ meal was used. Dressing percentage, HCW, LMA, as well as BF were unaffected by treatments. Carcass muscle and fat were greater for animals fed 80% concentrate diets ($P < 0.05$). Preference and texture of *Longissimus* muscle were greater when animals were fed 80% concentrate diets with corn germ ($P < 0.05$). In conclusion, high proportions of concentrate containing corn as energy source seems to provide best performance, but the total replacement of corn with corn germ meal in high-concentrate diets promote better sensory characteristics of meat from finishing Nellore heifers.

Key Words: by-product, cattle, corn germ meal

W316 Use of virginiamycin in Nellore cattle fed mineral supplement or protein supplement.

Gustavo Rezende Siqueira*[1,3], Michele Aparecida Prado Alves[2], Paloma Helena Gonçalves[2], Ivanna Moraes de Oliveira[1], Rodolfo Maciel Fernandes[3], Guilherme Felipe Berti[2], Fernanda Diamantino dos Santos[2], and Flávio Dutra de Resende[1,3], [1]*Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brazil,* [2]*UNIFEB, Barretos, São Paulo, Brazil,* [3]*UNESP, Jaboticabal, São Paulo, Brazil.*

The objective of this study was to evaluate the use of virginiamycin (VM) and the supplementation level on the performance of Nellore cattle in their post-weaning phase grazing on *Brachiaria brizantha* 'Marandu' during the wet season. We hypothesized that VM works on the gram-positive bacteria by inhibiting processes that result in loss of energy, modulating the ruminal fermentation and promoting an improvement in animal performance. The following supplements were utilized in this experiment: mineral (ad libitum) and protein (0.1% of BW), with or without inclusion of VM. The experiment was conducted from January to March 2014, divided into 3 25-d periods. Eighty (80) post-weaning uncastrated Nellore, with an average initial BW of 205.4 ± 21.9 were used in the experiment. Animals were weighed at the end of each period, after a solid food-deprivation period of 16 h. Data were analyzed in randomized blocks with repeated measures over time, in 2 × 2 factorial arrangement in which the factors were the supplements and lack or inclusion of VM. The paddock was considered the experimental unit, with 4 paddocks per treatment (5 animals/paddock). Means were compared by the *t*-test at 10% probability, and a trend at 15%. There was no interaction between VM and the supplementation level ($P = 0.78$). It was considered that there was an upward trend of 0.06 kg in ADG for animals fed VM ($P = 0.16$), which resulted in the increased final BW of the animals fed VM (269.5 *vs* 264.8; $P = 0.09$). The protein supplement provided an additional gain of 0.09 kg/day as compared with the mineral supplement, which represented a 11% higher ADG ($P = 0.03$) and an increase in BW (271.7 *vs* 262.6; $P = 0.01$). The highest ADG ($P < 0.01$) was observed in the first period (1.01 kg), decreasing by 48% in the second period, and increasing by 0.30 kg/day in the third period as compared with the second; this variation was due to the climatic conditions. The use of VM and protein supplement improves animal performance during the wet season. Acknowledgments: Paraíso Nutrição Animal.

Key Words: additive, supplements, wet season

W317 Finishing strategies for grazing Nellore cattle in the wet season.

Gustavo Rezende Siqueira*[1,3], Paloma Helena Gonçalves[2], Michele Aparecida Prado Alves[2], Ivanna Moraes de Oliveira[1], Rodolfo Maciel Fernandes[3], Carlos Carvalho Marcolino[2], Fernanda Diamantino dos Santos[2], and Flavio Dutra de Resende[1,3], [1]*Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brazil,* [2]*UNIFEB, Barretos, São Paulo, Brazil,* [3]*UNESP, Jaboticabal, São Paulo, Brazil.*

The effects of supplementation strategies on the performance of Nellore cattle finished on Marandu-grass pastures (wet season) were evaluated. It was expected that with the increased energy density at the final stage of finishing there would be improvement in animal performance. The experimental period (EP) was from 12/2013 to 05/2014 (five 28-d periods). Seventy-two uncastrated cattle with an average initial BW of 409.3 ± 17.8 kg were used in the experiment. The following nutritional plans were adopted: mineral supplement (MS; ad libitum), 140 d of the EP; energy supplement (ES; 0.7% of the BW), 140 d of the EP; MS/high supplementation on pasture (MHS; MS on the first 70 d of the EP and supplementation at 2% BW in the last 70 d of the EP). At the end of each period, the animals were weighed (after 16 h of feed deprivation) to determine the average daily gain (ADG). To calculate the carcass gain and carcass gain percent (carcass gain/weight gain), 6 animals were slaughtered at the beginning of the EP (control slaughter). The experimental design was of randomized blocks, analyzed as a repeated measure over time, in which the experimental unit was the paddock (6 animals/paddock). There was interaction between periods and nutritional plans on ADG ($P < 0.01$). In the first 2 periods, animals fed ES showed a 27% higher ADG ($P < 0.01$) than the others. In the last 2 periods, however, MHS (1.83 kg/day) provided a greater ($P < 0.01$) ADG as compared with ES (1.27 kg/day) and MS (0.92 kg/day). Carcass gain in the animals fed MHS was 56% and 16% higher ($P < 0.01$) than in those receiving MS and ES, respectively. Nutritional plan MHS increased ($P < 0.01$) the carcass gain percent by 5% and 20% as compared with the animals fed MS and ES, respectively. Dressing percent and final carcass weight were higher ($P < 0.01$) in the cattle that received MHS (58.7%; 355.2 kg), followed by those that received ES (56.8%; 333.0 kg) and then MS (52.8%; 281.9 kg). A greater uptake of nutrients, through increased supplementation during the final stage of finishing, improves the animal performance by increasing carcass gain percent, weight, and dressing percent. Acknowledgments: Trouw Nutrition/Bellman.

Key Words: high supplementation on pasture, nutritional plans, wet season

Ruminant Nutrition: Dairy III

W318 Milk yield and composition of Holstein cows fed increasing levels of amylolytic enzyme. Caio Seiti Takiya*[1], Gustavo Delfino Calomeni[1], Thiago Henrique Annibale Vendramini[1], Thiago Henrique Silva[1], Guilherme Gomes Silva[1], Jessica Cristiane Bertoni[1], Carlos Eduardo Cardoso Consentini[1], Rodrigo Gardinal[1], Jefferson Rodrigues Gandra[2], José Esler Freitas Jr.[3], and Francisco Palma Rennó[1], *[1]Departamento de Nutrição e Produção Animal da Universidade de São Paulo, Pirassununga, São Paulo, Brazil, [2]Faculdade de Ciências Agrárias da Universidade de Grande Dourados, Itahum, Mato Grosso do Sul, Brazil, [3]Departamento de Zootecnia da Universidade Federal da Bahia, Ondina, Bahia, Brazil.*

The objective of this study was to evaluate the effects of increasing doses of amylolytic enzyme in diet of dairy cows on milk yield and composition. The enzyme used comes from *Aspergillus oryzae* extract enriched with α amylase activity (Amaize, Alltech Inc., Nicholasville, KY). The extract is in powdered form and was offered hand mixed into concentrate. Twent-four multiparous Holstein cows (average 120 DIM, 32 kg/d of milk yield and 580kg of live weight) were distributed in 4 × 4 Latin square design with 21-d periods and received the following treatments: (1) Control, without Amaize; (2) A150, diet containing 150 FAU/kg of Amaize (diet DM basis); (3) A300, diet containing 300 FAU/kg DM of Amaize (diet DM basis) diet; (4) A450, diet containing 450 FAU/kg of Amaize (diet DM basis). One FAU (fungal α-amylase unit) is the amount of enzyme which breaks down 1g starch in 1 h based on 11–25 min at pH 4.7 and 30°C. Experimental diet was formulated to achieve 30% of starch content. Corn silage was used as forage source and diet contained 48:52 ratio of forage and grain mixture. Cows were mechanically milked twice daily, and samples were collected proportionally from each milking on d 15, 16 and 17 of each experimental period. Milk samples were analyzed for fat protein and lactose (Milkoscan; Foss Electric, Hillerod, Denmark). Data were subjected to ANOVA and regression using PROC MIXED of SAS (2001). No differences were observed in milk yield and composition (Table 1). Inclusion of exogenous amylolytic enzyme did not improve milk yield and composition of mid lactating cows.

Table 1 (Abstr. W318)

	Treatment[1]					*P*-value[2]	
Item	0	A150	A300	A450	SEM	L	Q
Milk yield, kg/d	32.81	32.72	32.34	32.40	1.37	0.275	0.829
3.5% FCM, kg/d	34.78	34.87	34.19	34.60	1.28	0.543	0.714
Fat, kg/d	1.26	1.28	1.24	1.26	0.05	0.594	0.917

W319 Biofortificated milk: Selenium and vitamin E in cow's diet to improve nutritional components in milk. Marcia S. V. Salles*[1], Arlindo Saran Netto[2], Luiz C. Roma Junior[1], Marcus A. Zanetti[2], Karina Pfrimer[3], and Fernando A. Salles[1], *[1]APTA, Ribeirão Preto, SP, Brazil, [2]FZEA/USP, Pirassununga, SP, Brazil, [3]FMRP/USP, Ribeirão Preto, SP, Brazil.*

Healthy nutrition is a preoccupation of most of the world's population, thus the importance of animal science studies to improve milk nutrient composition. The aim was to study the vitamin E and selenium with sunflower oil (SFO) added to the diet of lactating cows to improve the nutrient profile of milk. Twenty-eight cows were allocated in 4 treatments, as follows: C (control diet); O (4% of SFO in dry matter (DM) diet); A (3,5 mg/ kg DM of organic selenium + 2000 IU of vitamin E/cow per day);OA (4% of SFO in DM diet + 3,5 mg/ kg DM of organic selenium + 2000 IU of vitamin E/cow per day). Cows were fed with 0.50 of concentrate, 0.42 of corn silage and 0.08 of coast-cross hay (DM). Blood and milk were taken in the last week of trial and analyzed for selenium and α-tocopherol. Data were analyzed as a RCBD with a factorial treatment structure (GLM/SAS). The addition of selenium and vitamin E in the cow's diet increased selenium and α-tocopherol serum (0.083, 0.085, 0.337 and 0.389 µg/L, $P < 0.0001$, 0.022 SEM of selenium and 4.51, 6.26; 6.92 and 8.97 mg/dl, $P = 0.0009$, 0.66 SEM of α-tocopherol for C, O, A and OA, respectively) and milk (0.011, 0.027, 0.235 and 0.358 µg/L, $P < 0.0001$, 0.033 SEM of selenium and 2.27, 1.56; 3.08 and 2.89 mg/L, $P = 0.0088$, 0.36 SEM of α-tocopherol for C, O, A and OA, respectively). SFO supplementation increased α-tocopherol in cow's blood ($P = 0.0097$). The antioxidants added to the diet of lactating cows improved the nutrient profile of milk. Financial support: FAPESP.

Key Words: nutrient, mineral, vitamin

W320 Effect of fermented corn silage density and gas filled porosity on corn silage pH and fermentation end-products. William L. Braman*, John E. Kurtz, and Keith A. Bryan, *Chr. Hansen Inc., Milwaukee, WI.*

Increasing density (D) of ensiled corn forage by proper harvest dry matter, chop length and silo packing results in decreased presence of oxygen which enhances bacterial fermentation of corn silage (CS). This research measured the effect of CS D and calculated gas filled porosity (P) (Holmes and Muck, 2006) on selected fermentation characteristics. From December, 2012 to July, 2013, 46 dairy operations in the Midwest United States ranging in size from approximately 300 to 4,500 cows (62,500 total) participated in a study to evaluate the effect of silo density (kg/meter^3) of ensiled CS on the pH, lactic acid (LA), total volatile fatty acids (VFA), ammonia (NH_3), and ethanol (ETOH), all % of CS DM, of the corresponding corn silage. A minimum of at least 6 core samples from the face of CS bunkers or drive-over piles was consolidated and a composite sample sent to a commercial lab (Rock River Laboratories, Watertown, Wisconsin) for analysis using wet chemistry methods. Some dairies were sampled more than once as they changed sources of CS. The average D was 292.6 kg/meter^3 (range 174.6–350.8). The REG procedure of SAS was used to analyze the relationship between D/P and the dependent variables. There were negative relationships between D and pH ($R^2 = 0.31$, $P < 0.001$), NH_3 ($R^2 = 0.25$, $P < 0.001$), and ETOH ($R^2 = 0.14$, $P = 0.003$). There were positive relationships between D and LA ($R^2 = 0.26$, $P < 0.001$), VFA ($R^2 = 0.17$, $P < 0.05$). Gas filled P was calculated as an alternative measurement of CS D with 0.4 or lower P recommended for proper fermentation. The CS calculated P average was 0.32 (range 0.06–0.69). Regression analysis indicated a negative relationship between P and LA ($R^2 = 0.23$, $P < 0.001$) and VFA ($R^2 =$

0.18, $P = 0.001$). A positive relationship between P and pH ($R^2 = 0.30$, $P < 0.001$) was observed. These results suggest that increased CS bunker/pile D measured by silage face core sampling is strongly correlated with improved fermentation characteristics of low pH, $NH_{3,}$ ETOH and high VFA and LA concentrations. Gas filled P is an alternative measurement that was correlated with the increased fermentation acids measured and a decreased pH. This work demonstrates the importance of high D on improving the fermentation quality of CS.

Key Words: silage, ensiling, density

W321 Productive performance of dairy cows fed saturated and unsaturated fatty acids sources in the transition period and early lactation. Gustavo D. Calomeni*[1], Rodrigo Gardina[1], Jose Esler Freitas Junior[2], Cybele E. Araújo[1], Filipe Zanferari[1], Caio S. Takiya[1], Thiago H. A. Vendramini[1], Victor C. Galvão[1], and Francisco P. Renno[1], [1]*Department of Nutrition and Animal Production, School of Veterinary Medicine and Animal Science, University of São Paulo, Pirassunununga, São Paulo, Brazil,* [2]*School of Veterinary Medicine, Federal University of Bahia;, Ondina, Bahia, Brazil.*

The objective of the present study was to evaluate milk yield and composition of dairy cows receiving saturated or unsaturated fatty acids (FA) sources during transition period and early lactation. Thirty Holstein cows were divided into 3 experimental groups in randomized complete design. The animals were randomly assigned to receive one of the following treatments: 1) control (C; without fat addition, n = 10), basal diet containing (DM basis) 2.5 g/100g of ether extract (EE) in pre and postpartum period; 2) calcium salts of saturated FA (SAT; Magnapac - Tectron Ltd., n = 10), basal diet containing (DM basis) 4.5 g/100g of EE in pre-partum and 5.5 g/100g in postpartum; 3) whole raw soybeans (UNSAT; n = 10), basal diet containing (DM basis) 4.5g/100g of EE in pre-partum and 5.5g/100g of EE in postpartum period. The animals were fed individually, and the experimental diets were fed since 35 d before the expected calving date, and provided until 90 d of lactation and were formulated to meet the nutritional requirements of each period (pre and postpartum). Milk yield was measured daily and samples for milk composition were collected weekly from the first to the 13th week of lactation. Data were analyzed using PROC MIXED of SAS 9.1, with the effect of diet, time and interaction as fixed effects, and animal as random effect. The data were analyzed by orthogonal contrasts (C vs. UNS + SAT and UNS vs. SAT). Fatty acids sources did not influence ($P > 0.05$) milk yield, protein and lactose (kg/d and %). The average milk yields were 30.07, 28.86, and 30.85 kg for C, UNS and SAT, respectively. Unsaturated fatty acids source reduced the FCM (28.12 Kg/d vs 33.63 kg/d) ($P = 0.029$), and milk fat (4.16% vs. 3.37%; 1.23 kg/d vs 0.95 kg/d) ($P = 0.006$) ($P = 0.004$) for UNS vs SAT contrast. The supplementation of dairy cows with fatty acids sources in the transition period and early lactation affected the FCM and milk fat yield and percent.

Key Words: milk yield, milk composition, fat source

W322 Embryo production and oocyte quality of dairy cows fed saturated and unsaturated fatty acids in transition period and early lactation. Gustavo D. Calomeni*[1], Rodrigo Gardinal[1], Filipe Zanferari[1], Caio S. Takiya[1], Thiago H. A. Vendramini[1], Jose Esler Freitas Junior[2], Cybele E. Araújo[1], Victor C. Galvão[1], and Francisco P. Renno[1], [1]*Department of Nutrition and Animal Production, School of Veterinary Medicine and Animal Science, University of São Paulo, Pirassunununga, São Paulo, Brazil,* [2]*School of Veterinary Medicine, Federal University of Bahia, Ondina, Bahia, Brazil.*

The objective of the present study was to evaluate embryo production and oocyte quality of dairy cows receiving saturated or unsaturated fatty acids (FA) sources during transition period and early lactation. Thirty Holstein cows were divided into 3 experimental groups in randomized complete design. The animals were randomly assigned to receive one of the following treatments: 1) control (C; without fat addition, n = 10), basal diet containing (DM basis) 2.5 g/100g of ether extract (EE) in pre and postpartum period; 2) whole raw soybeans (UNSAT; n = 10), basal diet containing (DM basis) 4.5g/100g of EE in pre-partum and 5.5g/100g of EE in postpartum period; 3) calcium salts of saturated FA (SAT; MAGNAPAC - Tectron Ltd., n = 10), basal diet containing (DM basis) 4.5 g/100g of EE in pre-partum and 5.5 g/100g in postpartum. The experimental diets were fed from 35 d before the expected calving date, and provided until 90 DIM, formulated to meet the nutritional requirements of each period (pre- and postpartum). The procedure for ovum pick-up (OPU) was performed in 3 periods: 30 ± 7 DIM (OPU1), 60 ± 7 DIM (OPU2) and 90 ± 7 DIM (OPU3). After OPU, the viable oocytes were classified in grade I, II and III. Only oocytes with grade I, II and III were submitted to in vitro fertilization (IVF). Data were analyzed using PROC MIXED of SAS 9.1, with the effect of diet, OPU and interaction as fixed effects, and animal as random effect. The data were analyzed by orthogonal contrasts (C vs. UNS + SAT and UNS vs. SAT). No effects ($P > 0.05$) were observed for OPU, treatment and interaction (treatment*OPU). No differences were observed among contrasts for total oocytes, viable oocytes, oocytes grade and total embryo produced. The saturated and unsaturated FA supplementation did not influence embryo production and oocyte quality in postpartum period.

Key Words: fat source, ovum pick-up, transition period

W323 Effect of supplemental OmniGen AF and either a negative or positive DCAD prepartum on intake and blood and urine metabolites from dry off though 10 week postpartum. J. K. Bernard*[1], Z. Wu[4], D. J. Hurley[2], A. L. Jones[3], K. P. Zanzalari[4], J. D. Chapman[4], and D. J. McLean[4], [1]*Animal and Dairy Science, University of Georgia, Tifton, GA,* [2]*College of Veterinary Medicine,University of Georgia, Athens, GA,* [3] *College of Veterinary Medicine, University of Georgia,Tifton, GA,* [4]*Philbro Animal Health Corp., Quincy, IL.*

Multiparous Holsteins (80) were enrolled 60 d before expected parturition through 70 DIM to evaluate the effects of feeding OmniGen AF (OG) and Animate (AN, Phibro Animal Health Corp., Quincy, IL) on DMI, blood and urine metabolites, and milk yield and composition. Cows were blocked by expected calving date and assigned randomly within block to one of 8 treatment combinations arranged as a 2 × 2 x 2 factorial to provide: 0 (OG-) or 57 g OM (OG+) beginning at dry off through parturition; 0 (POS) or 0.59 kg/d AN (NEG) beginning 28 d before predicted calving; and OG- or OG+ postpartum. Three cows were dropped from the trial due to reasons unrelated to treatments. During the far-off period, no differences were observed in DMI: 13.7 and 14.8 kg/d for OG- and OG+, respectively. Cows fed OG+ had higher ($P < 0.05$) BUN and urinary pH and K concentrations compared with OG-. During the close up period, cows fed NEG had lower ($P < 0.05$) DMI compared with POS; 13.9 and 15.7 kg/d for NEG and POS, respectively. Concentrations of K, Cl, ionized Ca, and ionized Mg were higher ($P < 0.05$) for NEG (4.59, 104.05, 1.28, and 0.68) compared with POS (4.46 mEq/mL, 102.06 mEq/mL, 1.26 mmol/mL, and 0.66 mmol/mL, respectively). Immediately postcalving (0 - 2 DIM), cows fed NEG had lower concentrations of globulin, and urinary pH and Na concentrations but higher Cl ($P < 0.05$): 2.93, 7.59, 31.51, and 55.99 compared with 3.17 g/dl, 7.95, 53.69 mEq/L, and 37.7 mEq/L for NEG and POS, respectively.

Aspartate aminotransferase was greater ($P < 0.05$) for OG- compared with OG+: 127.16 and 106.21 U/L, respectively. No differences were observed in DMI or milk yield postpartum but cows fed OG+ had lower ($P < 0.05$) SCC compared with OG-. Milk fat percentage was higher for cows fed OG+ postpartum compared with those fed OG+ prepartum only. No interactions were observed among OG and AN. Carryover effects of NEG fed prepartum on blood mineral concentrations were observed 0–2 DIM. Supplemental OG did not affect postpartum milk yield but decreased SCC consistent with previous research.

Key Words: Animate, blood metabolite, DCAD

W324 Characterization of ingredient loading accuracy on commercial dairy farms in North America and Europe feeding total mixed rations. Michael C. Barry*, *AgModels LLC, Tully, NY.*

Successful implementation of precision feeding is predicated on the assumption that farms can accurately deliver the correct amounts and proportions of ingredients during the feed mixing process. Thirty-three commercial dairy herds of varying management styles across North America and Europe feeding total mixed rations (TMR) were surveyed with respect to ingredient loading accuracy. Across farms, 386,011 individual feed loading records were electronically recorded and compiled during the calendar year of 2014. Deviations from target load amounts were calculated as the difference between actual and the targeted amount of ingredient, both in absolute (kg) and relative (percent of target) terms. Absolute bullseyes were defined as those records with a deviation less than 5 kg from the target and averaged 24.1% across all observations, ranging from 4.3% to 73.9% between farms (median 19.8%). Relative bullseyes were defined as those records with a deviation less than 2% from the target and averaged 46.7% across all observations, ranging from 10.8% to 80.6% between farms (median 42.7%). Absolute deviation values that exceeded an absolute value greater than 62.5 kg from the target were designated as absolute outliers, and represented 11.85% of all values, ranging from 1.3 to 35.3% between farms (median 13.1%). Relative deviation values that differed more than 20% of target values were designated as relative outliers and represented 14.3% of all values and ranged from 2.7 to 40.3% between farms (median value of 15.1%). Several nonsensical values (those with actual values <0 kg) were identified and stratified by farm. 3.8% of all values were deemed as nonsensical and ranged from 0.7% to 10.2% between farms. Deviations were skewed toward positive values, indicating a tendency to overload ingredients. These results indicate a wide range of proficiency of feed loading across farms studied, and would suggest that there exists opportunities to assess and improve quality control procedures and the feed loading protocols on dairy farms feeding total mixed rations.

Key Words: total mixed ration, loading accuracy

W325 Effects of hydroxy versus sulfate forms of trace minerals in milk replacer or starter on dairy calves through weaning. Paul A. LaPierre*[1], Sarah Y. Morrison[1], Kevin Perryman[2], Terri Parr[2], and James K. Drackley[1], [1]*University of Illinois at Urbana-Champaign, Urbana, IL,* [2]*Micronutrients, Indianapolis, IN.*

Young dairy calves fed at a higher plane of nutrition may benefit from trace mineral (TM) sources with greater bioavailability, but few data are available for hydroxy forms of Zn, Cu, and Mn. The goal of this study was to evaluate differences in intake, growth, and health status of calves fed milk replacer and starter grain with different sources of TM. Male Holstein calves (n = 64) < 1 wk old were transported from a commercial farm to the research facility. Calves were assigned to treatments in a 2 × 2 factorial arrangement of TM source in milk replacer and TM source in starter grain in a randomized complete block design. All calves were fed milk replacer (28% crude protein, 20% fat) at a fixed feeding rate [700 g/d of powder for wk 1, 950 g/d of powder for wk 2–6, and 450 g/d of powder for wk 7] and had ad libitum access to starter [22% CP)] and water. Milk replacers were formulated to contain either sulfate (S) or hydroxy (H) TM (70, 10, and 50 mg/kg of Zn, Cu, and Mn, respectively). Starters formulated either with STM or HTM contained 150, 30, and 100 mg/kg of Zn, Cu, and Mn, respectively. All calves were weaned on d 49 and continued to have ad libitum access to water and starter until the end of the experiment at d 63. Body weights and measurements were taken on all calves on a weekly basis. Fecal and respiratory scores were monitored daily and any use of medications was recorded. Final body weight and average daily gain (overall mean of ADG = 0.91 kg/d) did not differ among treatments. Calves fed the HTM milk replacer plus STM starter had greater hip height ($P = 0.03$) and hip height average daily gain ($P = 0.007$). Starter intake was greater in calves fed HTM milk replacer than those fed STM milk replacer ($P < 0.0001$). Calves fed the STM milk replacer had a greater frequency of elevated fecal scores in the first 3 wk of life (odds ratio STM to HTM = 1.80), although use of medication was not different among treatments. Results indicated that calves fed HTM milk replacer and starter had similar overall growth as calves fed STM but maintained a better health status throughout the pre-weaning phase.

Key Words: dairy calf, mineral, hydroxy

W326 Effects of different forage supplement patterns on the growth of Holstein calves. Zhaohai Wu, Shengli Li, and Zhijun Cao*, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, Beijing, China.*

This study was conducted to investigate the effects of 2 forage sources supplemented from different time points on the growth performance of Holstein bull calves. Forty Holstein bull calves with similar body weights and birthdate were selected and randomly assigned to 5 treatments with 8 replicates each: control (CON) calves were fed starter feed only, and the other 4 treatments consisted of the same starter feed plus 2 forage sources started from different time points: chopped alfalfa hay started at the 15th day (AW) and the 3rd day (AD), chopped oat hay started at the 15th day (OW) and the 3rd day (OD). All calves were weaned at 56 d, and the study finished one week later. In the pre-weaning period, the starter feed intake was not significantly affected by forage supplement. Moreover, starter feed and total dry matter intake were increased in the first week of post-weaning by feeding forage from the 15th day and providing oat hay. In the pre-weaning period, the average daily gain of calves supplemented forage from the 15th day tended to be higher compared with that from the 3rd day ($P = 0.079$). In the first week of post-weaning, the average daily gain of calves fed forage from the 15th day was significantly higher compared with that from the 3rd day ($P = 0.045$) and CON calves ($P = 0.032$). Meanwhile, the body length of calves pre-weaning improved by feeding oat hay ($P = 0.071$), and the heart girth of calves fed forage from the 15th day tended to be greater than CON calves ($P = 0.089$) in the first week post-weaning. The contents of LDH, AKP, GOT and GPT in the serum of calves were improved by supplementing oat hay and providing forage from the 15th day ($P < 0.05$). The incidence of diarrhea in CON calves were numerically higher than the calves provided forage. In conclusion, forage supplementing did not adversely affect the growth and intake of calves in the pre-weaning period, and the growth performance of calves was improved in the first week of post-weaning by providing forage from the milk-feeding period, especially offering oat hay from the 15th day.

Key Words: calves, oat hay, alfalfa hay

W327 Effects of acidified and pasteurized waste milk on calf diarrhea occurrence.

J. Y. Ma*[1], X. X. Ren[1], H. T. Shi[1], G. Guo[2], X. Z. Li[2], and Z. J. Cao[1], *[1]State Key Laboratory of Animal Nutrition, China Agricultural University, Beijing, China, [2]Beijing Capital Agribusiness Group Co., Ltd., Beijing, China.*

Abstract: Waste milk is unfit for human consumption because it might be harmful for human health. However, it may be acceptable for calf feeding if properly processed. This study was designed to investigate the effect of 2 different sterilization methods of waste milk on diarrhea occurrence of calves. Forty female Holstein calves were randomly assigned into one of 2 groups and fed either acidified (by formic acid) or pasteurized waste milk and defined as treatment group (TT) and control group (CT). The total number of bacteria in milk was detected and found higher in pasteurized milk than in acidified milk (3.6×10^4 vs. 3.8×10^3 cfu/mL) on average. The birth weights of calves in 2 groups were similar (TT: 43.38 ± 4.100; CT: 43.83 ± 4.854; $P > 0.05$). All calves were fed 4 L of colostrum within 1 h after birth and were subsequently fed milk 3 times per day at 0730, 1430, and 1930. Fecal samples were collected from all calves daily for 8 weeks from the third day after birth. Feces were scored by UW-Madison calf health scoring. Calf diarrhea occurrence was described by 3 indexes including diarrhea rate (DA), diarrhea frequency (DF) and fecal indexes (FI). The calculation equations are as bellow. Data were statistically analyzed using the Two-Sample *t*-test for means procedure of SAS (version 9.2, SAS Institute Inc., Cary, NC). Diarrhea rate = number of diarrhea calves/total number of calves × 100%; diarrhea frequency= (∑ number of diarrhea calves × days in diarrhea)/total number of calves × number of days on trial × 100%; fecal index = the sum of fecal score/(total number of calves). Results indicate that the overall calf diarrhea in TT group was lower compared with CT group. DF and FI of TT group were lower than those of CT group (DF: 10.00 ± 0.02 vs. 15.9 ± 0.02%; FI: 1.41 ± 0.28 vs. 1.59 ± 0.25; $P < 0.05$). DR values were not significantly different between two groups during the whole trial period of 8 weeks ($P > 0.05$); however, DA, DF and FI within the first 6 weeks (d3 to d42) was lower in TT group than those in CT group (DR: 60 vs. 90%; DF: 3.75 ± 1.07 vs. 7.50 ± 1.10%; FI: 1.34 ± 0.029 vs. 1.50 ± 0.03; $P < 0.05$). We conclude that feeding waste milk acidified with formic acid can effectively reduce calf diarrhea occurrence compared with feeding pasteurized waste milk.

Key Words: acidification, pasteurization, calf diarrhea

W328 Investigating the impact of dietary changes on rumen microbial community during the transition period in Holstein dairy cows using high-throughput sequencing.

Ousama AlZahal*[1], Suzanne L. Ishaq[2], Benoit St-Pierre[3], Andre-Denis G. Wright[4], and Brian W. McBride[1], *[1]University of Guelph, Guelph, Ontario, Canada, [2]University of Vermont, Burlington, VT, [3]South Dakota State University, Brookings, SD, [4]The University of Arizona, Tucson, AZ.*

The transition period is a critical time in the life of a dairy cow and is associated with a dietary shift from a high-forage-based diet (HF) to a high-grain based (HG) diet. This study investigated the impact of such a dietary shift on the structure of the rumen bacterial population. Fourteen Holstein dairy cows were used in this experiment. Rumen digesta samples were obtained using an oral stomach tube 3 weeks before calving (HF) and 9 weeks postcalving (HG). Twenty-eight samples were collected, and bacterial 16S rRNA genes were sequenced using Roche 454 pyrosequencing with titanium chemistry. Processing of sequences, performing α and β diversities, and classifying sequences were conducted using MOTHUR. A total of 198,276 non-chimeric sequences were generated. Those sequences were assigned to 16,833 operational taxonomic units based on a 95% genetic similarity for each sample. Shannon and Inverse Simpson indices were calculated for each sample, and revealed an overall reduction ($P < 0.05$) in the diversity of the rumen bacterial population when cows were shifted from the HF to the HG (from 5.4 ± 0.2 to 4.3 ± 0.2 and from 153 ± 26 to 47 ± 26, respectively). UniFrac was used to test whether HF samples were different from HG samples. The normalized-weighted *P* test was <0.001, indicating a significant difference between the 2 bacterial communities; and the calculated UniFrac metric value was 0.968, indicating that most of the branch length belonged to one community or the other. Sequences from HF were allocated mainly into the following phyla: Bacteroidetes (38 ± 4%), an unclassified group (33 ± 2%), Firmicutes (23 ± 3%), and Proteobacteria (5 ± 4%), whereas samples from HG were allocated mainly into the Proteobacteria (36 ± 4%), Bacteroidetes (34 ± 4%), Firmicutes (15 ± 3%), and an unclassified group (14 ± 2%). ANOVA with time as the fixed effect showed that Proteobacteria and the unclassified group were significantly different ($P < 0.001$) between HF and HG, and Firmicutes had a tendency ($P = 0.07$) to be different.

Key Words: dairy cow, transition period, 16S rRNA

W329 Metabolic profile and onset of puberty in dairy heifers fed reduced-fat distillers grains in replacement of forage.

Angela K. Manthey*[1], Jill L. Anderson[1], George A. Perry[2], and Duane H. Keisler[3], *[1]Dairy Science Department, South Dakota State University, Brookings, SD, [2]Department of Animal Science, South Dakota State University, Brookings, SD, [3]Division of Animal Science, University of Missouri, Columbia, MO.*

Our objective was to determine the effect of increasing the inclusion rate of reduced-fat distillers dried grains (RFDDGS) in replacement of forage in limit-fed diets on the metabolic profile and onset of puberty in dairy heifers. A 16-wk randomized complete block design feeding study was conducted using 48 Holstein heifers (199 ± 2 d of age) with 3 treatments. Treatments were 30% RFDDGS with 68.5% grass hay (30DG), 40% RFDDGS with 58.5% grass hay (40DG), and 50% RFDDGS with 48.5% grass hay (50DG) on a DM basis. All diets also contained 1.5% mineral mix. Rations were limit-fed at 2.65, 2.50, and 2.35% of BW on a DM basis for 30DG, 40DG, and 50DG, respectively to have similar intakes of CP and energy among treatments. Jugular blood samples were collected on 2 d during wk 0, 4, 8, 12, and 16 for metabolite and metabolic hormone analysis. When heifers weighed 200 kg, coccygeal vein blood samples were taken twice per wk for progesterone analysis to estimate onset of puberty. Blood samples continued until cycling was confirmed via ultrasound for the presence of a corpus luteum. There were no interactions of treatment by wk for any of the metabolites and metabolic hormones measured. Glucose (76.3, 77.7, and 77.3 mg/dL; SEM = 1.60 for 30DG, 40DG, and 50DG, respectively) and leptin (4.42, 4.35, 4.59 ng/mL; SEM = 0.088) were similar ($P > 0.05$) among treatments. There was a quadratic effect ($P < 0.05$) for cholesterol (93.5, 89.2, and 97.1 mg/dL; SEM = 2.16), plasma urea nitrogen (17.8, 17.8, and 19.9 mg/dL; SEM = 0.35), and a quadratic tendency ($P = 0.05$) for IGF-1 (102.7, 100.0, and 109.4 ng/mL; SEM = 3.59). Age at puberty (234.6, 244.3, and 235.5 d; SEM = 13.7) and BW at puberty (246.4, 261.3, and 254.0 kg; SEM = 24.9) were similar ($P > 0.05$) among treatments. These results demonstrate that heifers can be limit-fed diets with greater inclusion rates of RFDDGS and maintain energy status without accumulating excess adipose tissue as indicated by leptin. Treatments had no detrimental effects on age or BW at puberty; however, at this time no measures were made on reproductive performance post-trial.

Key Words: distillers grains, metabolic profile, dairy heifer

W330 Gastrointestinal tract of healthy 1-week-old Jersey calves is well suited to digest, absorb, and incorporate nutrients into lean tissue even when fed a high plane of milk replacer.

Yu Liang*[1], Tyler L. Harris[1], Jeff A. Carroll[2], and Michael A. Ballou[1], *[1]Texas Tech University, Department of Animal and Food Sciences, Lubbock, TX, [2]USDA-ARS, Lubbock, TX.*

This study investigated the digestibilities of nutrients as well as nitrogen (N) retention of Jersey calves fed different planes of milk replacer nutrition. Twelve calves were blocked by BW at birth and randomly assigned to either a low (LPN) or high (HPN) plane of milk replacer nutrition. The LPN calves were fed 14.5 g DM/kg BW of a 20% protein and 20% fat milk replacer/d, and HPN calves 20 g DM/kg BW of a 28% protein and 20% fat milk replacer/d. Calves were fed twice daily at 0700 and 1900. All calves were fed 3 L of pooled colostrum within 6 h of birth and then were assigned treatments. Calves were given 1 d to adapt to treatments. The study was divided into two for the last 24 h of each period. Blood samples were collected at the beginning and end of each period and analyzed for plasma glucose and urea N concentrations. All data reported as HPN vs LPN, respectively. Fecal scores were greater (2.01 vs 1.52 ± 0.13; $P = 0.004$) for HPN calves during both periods; however, there was no difference (30.9 vs 31.9 ± 0.6%; $P \geq 0.253$) in the DM percentage of feces. The HPN calves had greater ADG over the entire study (0.211 vs −0.106 ± 0.6 kg/d; $P < 0.001$). There were no differences ($P \geq 0.239$) between treatments in either digestible or metabolizable energy efficiencies, which averaged 92.8 and 83.1%, respectively. There was a treatment × period interaction ($P = 0.038$) on the percentage of intake N retained, whereas calves fed the HPN had a greater N retention during period 1 (88.0 vs. 78.7 ± 1.79%; $P = 0.004$), but was not different from calves fed the LPN during period 2 (85.3 vs. 85.0 ± 1.79%; $P = 0.904$). Therefore, these data indicate that healthy Jersey calves have the capability to digest and absorb the additional nutrients when fed a higher plane of nutrition during the first week of postnatal life. Further, the additional energy and amino N absorbed by calves fed the HPN were incorporated into lean tissue growth at a high efficiency.

Key Words: calf, digestibility, nutrition

W331 Effects of glucose and propionate infusions on milk fat yield: A meta-analysis.

Sarah E. Schmidt* and Adam L. Lock, *Michigan State University, East Lansing, MI.*

Milk fat depression (MFD) research has primarily focused on inhibitory effects of rumen biohydrogenation intermediates, particularly *trans*-10,*cis*-12 18:2 (CLA), on fat synthesis in the mammary gland. However, several studies have shown that directly increasing insulin-secretagogues through infusion also results in MFD. The objective of this meta-analysis was to evaluate the effects of glucose and propionate infusions on milk fat yield and energy balance. The analysis included 22 publications representing 27 glucose infusion treatments and 15 propionate infusion treatments. Trial-adjusted values were calculated in a linear mixed model with study included as a random variable and weighted by the inverse of the variance of daily milk yield. Trial-adjusted values for percent change in milk fat yield were regressed across levels of glucose (0.33 to 2.40 kg/d) and propionate (0.25 to 1.52 kg/d) infusion and lines of best fit were applied ($r^2 = 0.76$; $r^2 = 0.65$). Change in milk fat yield ranged from 1.69% to −20.3% for glucose infusions and from 6.78% to −23.8% for propionate infusions. Increasing glucose and propionate infusion amount increased the magnitude of MFD ($P < 0.01$; $P < 0.01$). Cows in each glucose infusion study were categorized as having high (HF; milk fat >4.09%), moderate (MF; milk fat ≥3.58% and ≤4.09%), or low (LF; milk fat <3.58%) milk fat concentrations. Increasing glucose infusion amount decreased milk fat yield of HF cows at a greater rate compared with LF cows ($P = 0.03$). MF cows also exhibited a greater response to glucose infusion compared with LF cows ($P < 0.01$). Trial-adjusted values for change in energy balance were regressed on percent change in milk fat yield following glucose infusion and a line of best fit was applied ($r^2 = 0.74$). Reducing milk fat yield from 1.69 to −20.3% through glucose infusion increased energy balance (−1.3 to 4.8 Mcal/d; $P < 0.01$). While CLA has been shown to cause MFD, the effects of insulin-secretagogues on energy partitioning should also be considered in the development of a comprehensive model.

Key Words: energy balance, meta-analysis, milk fat depression

W332 Effect of the starch level in diets with soybean or canola meal on the performance of lactating dairy cows.

Juan I. Sanchez-Durte*[1], Kenneth F. Kalscheur[2], and David P. Casper[1], *[1]Dairy Science Department, South Dakota State University, Brookings, SD, [2]US Dairy Forage Research Center, USDA, ARS, Madison, WI.*

This study was designed to test the impact of reducing corn grain starch with nonforage fiber sources in diets using either soybean meal or canola meal as the primary protein source. Sixteen Holstein cows were assigned to a 4 × 4 Latin square design with 4 periods of 28 d. Treatments were arranged as a 2 × 2 factorial with 2 protein sources [soybean meal (SBM) and canola meal (CM)] and 2 starch levels (21 and 27% of DM). Diets were formulated to contain 16.5% CP and the starch levels were achieved by replacing corn grain with soybean hulls and beet pulp. Protein source × starch interactions ($P < 0.05$) were observed for DMI, feed efficiency (ECM/DMI), fat %, protein %, protein yield, and MUN. Cows fed the 27% starch diet consumed more DMI than cows fed the CM-21% diet. However, there was no interaction for milk yield, as cows fed 27% starch produced 2.5 kg/d more than cows fed 21% starch. Milk fat percentage was the least for cows fed CM-27% and greatest for cows fed SBM-27% and CM-21%. Milk protein percentage and yield was least for CM-21% compared with the other 3 diets. Milk urea nitrogen was least for cows fed CM-27% compared with the other 3 diets. Cows fed 27% starch produced 1.9 kg/d more energy-corrected milk (ECM) than cows fed 21% starch. Feed efficiency was the greatest for cows fed CM-21% and least for cows fed CM-27%. Overall, lower starch % in SBM or CM diets negatively affected DMI, milk yield, ECM, and milk protein percentage and yield, but not feed efficiency and milk fat percentage and yield. Increasing starch level in canola meal diets decreased milk fat percentage, but potentially improved protein balance because less MUN was observed.

W333 The effect of the supplementation of virginiamycin plus monensin on milk performance under grazing conditions in dairy cattle. Ramiro Desantadina[1], Luis Casares[2], Matias Bailleres[3], Milton Gorocica[2], and Alejandro Relling*[1,4], *[1]Fac Cs Veterinarias, UNLP, Argentina, [2]Phibro Animal Health, Argentina, [3]Ministerio de asuntos Agrarios, Buenos Aires, Argentina, [4]IGEVET, CCT La Plata, CONICET, Argentina.*

The aim of the present study was to evaluate the effect of virginiamycin (Vm) plus monensin (Mn) on milk production and composition of grazing dairy cows. Eighty dairy cows, with an average of 2.5 lactations, 129 d in milk and a milk yield (MY) of 27.7 kg per day were randomly distributed into 2 groups; Group 1 (n = 40): 300 mg/cow/d Mn (M), and Group 2 (n = 40): 300 mg/cow/d Vm and 300 mg/cow/d Mn (V). Cows were grazed in a rotational grazing system of 2 grass paddocks per day. The cows were milked twice a day and received 4 kg of a pelleted concentrate and mineral supplement in the parlor at each milking. Both groups were also fed once a d 7 kg corn silage, 6 kg grass haylage, 2 kg corn grain, and 2 kg wheat middlings (all quantities as fed). Milk yield and composition were measured on d 0, 17, 34, 52, 66, 78, 90, 101, 111, 120 and 129, and body condition score (BCS) was measured on d 0, 52 and 129. Four-percent fat corrected milk (FCM) was estimated using the following formula MY × (0.383 × % fat + 0.242 × % protein + 0.7832)/3.1138. Data were analyzed using a mixed model with repeated measures, using the cow as random effect, and treatment, time and their interaction as fixed effects. The treatment × time interaction was not significant in all evaluated variables (Table 1). However, on FCM a trend for time and treatment interaction ($P = 0.14$) was approached: V cows had greater FCM on d 52, 78 ($P < 0.1$) and 101 ($P < 0.05$) than M cows. The V treatment group had numerically greater MY, milk fat and protein content, and BCS at the end of the trial, but differences were not statistically significant (Table 1; all $P > 0.15$). In conclusion, the addition of Vm in diets containing Mn increases FCM during peak- to mid-lactation.

W334 Undegradable aNDFom in non-forage feeds. Alessandro Maria Zontini*, Andreas Foskolos, Deborah Ross, and Michael Van Amburgh, *Cornell University, Ithaca, NY.*

Non-forage fiber feeds are generally highly digestible, however, most calculations of undegradability are made from static calculations based on Chandler et al. (1980) or Weiss et al. (1992). The objective of this study was to analyze the extent of aNDFom degradation in non-forage fiber feeds, to obtain the undegradable aNDFom (uNDF). Samples of 12 feeds (citrus pulp, beet pulp, wheat middlings, soy hulls, corn gluten meal, corn gluten feed, wheat distillers, corn ethanol distillers, flaked corn, rice hulls, soybean meal, and canola meal) were collected, each from 2 providers, and analyzed in duplicate in 3 separate batches for the extent of NDF digestion using the in vitro technique. Samples, 0.5 g, were weighed into Erlenmeyer flasks and 40 ml of Goering and Van Soest (1970) buffer was added to each flask under continuous CO_2, and incubated in a water bath at 39°C. After 2 h of incubation, 10 mL of mixed rumen fluid from 2 lactating cattle were added to each flask and continuous CO2 was maintained throughout the fermentation. Fermentations were conducted for 96, 120, and 240 h consistent with previous data from Raffrenato (2011). Residues were filtered on a glass microfiber filter (934-AH, Whataman) with a 1.5 µm pore size to enhance residue recovery. To analyze changes in uNDF the residues were compared with a t-test in JMP. For non-forage aNDFom the uNDF was obtained at 120h with the exception of citrus pulp where residues continued to digest out to 240 h compared with 120 h residues (P-value = 0.002).

W335 Effect of two fat supplements differing in saturation on milk production and energy partitioning.

Enhong Liu*, Courtney L. Preseault, Michael J. VandeHaar, and Adam L. Lock, *Michigan State University, East Lansing, MI.*

Effects of feeding diets containing fat supplements differing in saturation on milk production and energy partitioning were evaluated. Holstein cows (n = 32; 93 ± 35 DIM) were randomly assigned to treatment sequence in a crossover design experiment. Treatments were diets containing a saturated fat supplement (2.5% DM palmitic acid-enriched triglyceride [BergaFat T-300], SF) or an unsaturated fat supplement (2.5% DM soybean oil, UF). Diets utilized corn silage and alfalfa silage as forage sources and contained 25% NDF, 18% forage NDF, 32% starch, 18% CP, and 4.6% FA. Treatment periods were 28 d in length with the final 5 d used for sample and data collection. The statistical model included the random effect of cow and fixed effects of treatment and period. Compared with UF, SF increased milk fat concentration (3.07% vs. 2.42%; $P < 0.01$) and yield (1.35 vs. 1.11 kg/d; $P < 0.01$), but reduced milk protein concentration (3.05% vs. 3.12%; $P < 0.01$) and yield (1.40 vs. 1.44 kg/d; $P < 0.05$). Treatment did not alter milk yield (46 kg/d; $P = 0.6$), but SF did increase FCM (41.9 vs. 38.1 kg/d; $P < 0.01$) and ECM (42.6 vs. 39.8 kg/d; $P < 0.01$) compared with UF. DMI and energy intake did not differ between treatments and averaged 25 kg/d and 41.2 Mcal/d, respectively (both $P > 0.6$). However, SF increased the milk to feed ratio (ECM/DMI) compared with UF (1.67 vs. 1.53; $P < 0.01$). Compared with UF, SF reduced BW gain (5.2 vs. 12.8 kg/28 d; $P < 0.05$) but did not alter BCS ($P = 0.8$) or fat thickness over the rump ($P = 0.7$) and rib ($P = 0.5$). SF decreased plasma concentration of insulin (1.18 vs. 1.34 µg/L, $P < 0.05$), NEFA (122 vs. 137 µEq/L, $P < 0.01$), and triglycerides (7.9 vs. 8.5 mg/dL, $P = 0.05$) compared with UF. There was no effect of treatment on plasma concentration of glucose ($P = 0.3$). Compared with UF, SF increased milk energy as a fraction of NE_L use (71 vs. 66%, $P < 0.01$) and reduced calculated body energy gain as a fraction of NE_L use (3 vs. 8%, $P < 0.01$). In conclusion, the 2 diets resulted in similar NE_L intake but the SF diet containing the palmitic acid-enriched triglyceride increased milk fat yield and partitioned more energy toward milk, while the UF diet containing soybean oil reduced milk fat yield and partitioned more energy toward body gain.

Key Words: fat supplementation, milk fat, palmitic acid

W336 Nutrient intake and blood parameters of dairy cows fed sugarcane in different ways of storage.

Viviane B. Ferrari*[1], Mauro D. S. Oliveira[2], and Francisco P. Rennó[1], [1]*University of São Paulo, Pirassununga, São Paulo, Brazil,* [2]*São Paulo State University, Jaboticabal, São Paulo, Brazil.*

This study aimed to evaluate nutrient intake and blood parameters of Holstein cows fed sugarcane based diets. Treatments consisted of fresh chopped sugarcane (FS), hydrolyzed sugarcane (HS) and HS + 6 g live yeast (*Saccharomyces cerevisiae*) (HSY). All treatments contained concentrate with ground corn, soybean meal, cottonseed meal, urea, mineral salt. Roughage:concentrate ratio offered was 60:40. Twelve Holstein cows with body weight of 590 kg were assigned into 4 contemporary 3 × 3 Latin Squares, with 3 periods of 21 d each and 3 treatments. The sugarcane used was IAC 862480 fifth cut and 12 mo of growth, chopped in particle size of 8 mm. The sugarcane was hydrolyzed with 0.5% of hydrated lime (95% of calcium hydroxide) using 0.5 kg of hydrated lime with 2 L of water to each 100 kg of sugarcane. Intake was regulated for animal by daily weighting of diet and orts, allowing for 5 to 10% of orts. Samples of feedstuffs and orts were weekly collected for chemical analyses and determination of dry matter (DMI), neutral detergent fiber (NDFI), crude protein (CPI) and ether extract (EEI) intakes. Blood samples were collected by jugular vein before the first meal for blood parameters determination: glucose (GLU), total protein (TP), total cholesterol (TC), albumin (AL), gamma-glutamyl transferase (GGT), aspartate aminotransferase (AST). Two contrasts were used to test the effect of FS vs. HS and HSY (C1); and HS vs. HSY (C2). Differences between treatments were considered significant at $P < 0.05$. FS promoted differences in all nutrient intakes. FS decreased DMI (11.43, 14.78 and 14.38 kg/d; $P = 0.03$); NDFI (5.78, 7.95 and 7.09 kg/d, $P = 0.02$); CPI (1.06, 1.32 and 1.39 kg/d; $P = 0.03$), EEI (0.48, 0.60 and 0.62 kg/d; $P = 0.03$), compared with HS and HSY, respectively. There were no differences for HS vs. HSY on nutrient intakes. There were no differences for none of the studied blood parameters ($P > 0.05$). Fresh chopped sugarcane decreased nutrient intake of Holstein cows compared with hydrolyzed sugarcane.

Key Words: crude protein, hydrolysis, neutral detergent fiber

W337 The effect of increasing concentrations of DL-methionine and HMB on hepatic genes controlling methionine and glucose metabolism.

Dean A. Bowen*[1], Nestor D. Luchini[2], and Heather M. White[1], [1]*University of Wisconsin-Madison, Madison, WI,* [2]*Adisseo, Alpharetta, GA.*

Metabolizable methionine (met) concentrations can be increased by feeding rumen-protected DL-Met (DL) or the isopropyl ester of 2-hydroxy-4-(methylthio)butanoic acid (HMB); however, hepatic response to these compounds have not been comparatively examined. The objective of this experiment was to examine the regulation of key genes in the Met and gluconeogenic pathways in response to doses of DL or HMB that mimic Met deficiency, adequacy, or supplementation in lactating dairy cows. Hepatocytes were isolated from 4 Holstein calves and were maintained as monolayer cultures in FBS for 24h before treatment. Treatments of DL or HMB (0, 10, 20, 40, 60 m*M*) were added to Met-free media in triplicate and after 24h, cells were collected for RNA isolation and quantification of gene expression by quantitative PCR. Data were analyzed in Proc Mixed of SAS 9.3. Analysis of covariance confirmed equivalent slopes of Met source and final model included source and dose, and random effect of calf within source. There was no main effect of Met source ($P > 0.1$) for any genes examined. Expression of BHMT and MTR, genes that catalyze generation of Met from betaine and homocysteine, decreased ($P \leq 0.05$) with

increasing Met concentration (BHMT: 0.7551, 0.7205, 0.6512, 0.582 ± 0.2563; MTR: 0.8897, 0.8481, 0.7648, 0.6815 ± 0.1763 arbitrary units). When concentrations of Met are high, Met can generate SAM, a methyl donor; however, expression of the gene that catalyzes this reaction, MAT1, was decreased ($P \leq 0.05$) as Met concentration increased (0.7828, 0.7108, 0.5667, 0.4226 ± 0.1554 arbitrary units). Expression of CPT1a, G6Pase, and PEPCKm was not altered ($P > 0.1$) suggesting that increased Met was not used as a gluconeogenic precursor at these concentrations. The decrease in hepatocyte production of Met at higher treatment doses suggest that cellular Met requirements were being met. The lack of influence on gluconeogenic enzymes and the decrease in the enzyme responsible for SAM generation may reflect metabolic priority for Met use at these concentrations, an adequate glucose concentration, or the lack of a Met deficiency before treatment.

Key Words: methionine, 2-hydroxy-4-(methylthio)butanoic acid (HMB), hepatocyte

W338 aNDFom degradation behavior in nonforage feeds.

Alessandro Maria Zontini*, Andreas Foskolos, Deborah A. Ross, and Michael E. Van Amburgh, *Cornell University, Ithaca, NY.*

Previous work conducted in our lab demonstrated that the extent of NDF degradation in nonforage fiber feeds is achieved by 120 h and results in undigested NDF (uNFD). Further, Raffrenato (2011) demonstrated that aNDFom degradation kinetic can be characterized with a dynamic model utilizing 4 data points (0, 30, 120 and 240 h). The objectives of this study were to characterize the degradation behavior of aNDFom, and to determine the time points required to model and calculate the degradation parameters, in nonforage fiber feeds. Samples of 12 feeds (citrus pulp, beet pulp, wheat middlings, soy hulls, corn germ, corn gluten feed, wheat distillers, corn ethanol distillers, flaked corn, rice hulls, soybean meal, and canola meal) were collected, each from 2 providers, and analyzed in duplicates and in 3 separate batches for NDF digestion kinetics using the in vitro technique. Fermentations were conducted for up to 3, 6, 9, 12, 15, 18, 21, 24, 30, 48, 72, 96, 120 h following the methods of Goering and Van Soest (1970). Residues were filtered on a glass microfiber filter (934-AH, Whatman). To study the digestion behavior of non-forage fiber NDF, the degradation curves were plotted on semi-log scale, and analyzed to determine the inflection point of the aNDFom residues. Overall, the natural log-transformation, demonstrated that NDF digestion in nonforage fiber feeds can be described by one degradable pool (no inflection points). To determine the time points, 7 combinations of 4 data points corresponding to: 0 h, 2 intermediate time points, and uNDF were used as inputs. The corresponding slope and intercept of each regression (observed on predicted) were then compared. The accuracy of the model did not allow for detecting statistically significant differences in slope and intercept among time point combinations, however 0, 12, 72, and 120 h were the time points that provided model predictions with an average slope and intercept closest to unity and zero respectively (intercept = 0.04, slope = 0.95). Thus, for routine determination of non-forage fiber digestibility and the estimation of rates of degradation for use in nutrition models, these time points provided adequate information among the feeds analyzed.

Key Words: aNDFom

W339 Can potential digestible fiber affect dietary crude protein level in lactating dairy cows? Milk production and feeding behavior.

H. R. Mirzaei Alamouti* and B. Mohtashami, *Department of Animal Science, University of Zanjan, Zanjan, Iran.*

Nitrogen (N) excretion from dairy farming systems is a major environmental challenge. An experiment was conducted to determine the effects of dietary potential digestible fiber (pdF) and crude protein (CP) levels in mid lactating Holstein cows on milk production and content, feeding behavior and nitrogen efficiency. Sixteen primiparous (n = 8) and multiparous (n = 8) cows (BW = kg and DIM = 118 ± 50 d) were allocated to 1 of 4 diets in balanced randomized complete block design in 2 periods (28 d). The diet containing: 1) 19% CP and low pdF, (HPLDF), 2) 17% CP and low pdF, (MPLDF), 3) 15% CP and high pdF, (LPHDF), and 4) 17% CP and high pdF, (MPHDF). The diets were balance for pdF by using different levels of dried alfalfa hay and corn silage in forage proportion of diets. Cows were fed individually and daily dry matter intake was recorded. Daily milk production and bi-weekly milk content were determined. Feeding behavior was recorded in 24 h with exception in milking times. Data were analyzed as repeated measurement with proc MIXED by using SAS software. The diets, periods, times and 2 or 3 ways interactions were constant effects and cows nested in diet and residual errors were random effects. Cows fed the diets with high pdF had greater DMI (17.87, 17.46, 18.44, and 18.60 kg/d, for HPLDF, MPLDF, LPHDF, and MPHDF respectively) and lower (21.8, 17.56, 12.86, and 15.78 for HPLDF, MPLDF, LPHDF, and MPHDF respectively) milk urea nitrogen ($P < 0.01$) than cows fed low pdF diets. Milk Production and content and blood metabolites were not significantly different among the experimental diets. There was no significant difference among diets in parities and periods. There was significant difference ($P < 0.05$) among diets in eating activity and cows fed to high pdF diets had greater eating activity (246.85 vs 261.2 min/d for high pdF vs low pdF). Results from this study indicate that increasing cp content in diets with low pdF and also increasing pdF content of diets with mid or low CP content can improve mid lactating Holstein cows' milk production and efficiency.

Key Words: potential digestible fiber, nitrogen efficiency, milk production

W340 Effects of prill size of a palmitic acid-enriched fat supplement on yield of milk and milk components and nutrient digestibility of dairy cows.

Jonas De Souza*, Joshua L. Garver, Courtney L. Preseault, and Adam L. Lock, *Michigan State University, East Lansing, MI.*

Effects of prill size of a palmitic acid-enriched fat supplement (PA; 85% C16:0) on feed intake, nutrient digestibility, and production responses of dairy cows were evaluated. Twenty-four Holstein cows (120 ± 44 DIM) were randomly assigned to treatment sequence in a 4 × 4 Latin square design. Treatments were a control diet (CON; no added PA), or 2.0% PA added either as a small prill size (SM; 284 ± 12.4 μm), medium prill size (MD; 325 ± 14.7 μm), or large prill size (LG; 600 ± 17.8 μm) supplement. PA replaced soyhulls in the ration and diets contained 21% forage NDF, 16% CP and 26% starch. Periods were 21 d in length with the final 5 d used for sample and data collection. Indigestible NDF was used as an internal marker to estimate fecal output and nutrient digestibility. The statistical model included the random effect of cow and period and the fixed effect of treatment. Overall, PA increased milk fat content (4.25 vs. 3.99%; $P < 0.01$), milk fat yield (1.48 vs. 1.39 kg/d; $P < 0.01$), tended to increase 3.5% FCM (39.2 vs. 37.7 kg/d; $P = 0.10$), and improved feed efficiency (FCM/DMI; 1.51 vs. 1.42; $P < 0.01$). However, compared with CON, PA treatments did not affect DMI, body condition score, or yields of milk, protein, and lactose. Overall, PA increased NDF digestibility (45 vs. 42%; $P < 0.01$) and reduced the digestibility of 16-carbon FA (72 vs. 79%; $P < 0.01$) and total FA (77 vs. 80%; $P < 0.01$). Compared with CON, PA reduced the yields of de novo-synthesized (<16-carbon) milk FA (251 vs. 297 g/d; $P < 0.01$)

and preformed (>16-carbon) milk FA (383 vs. 430 g/d; $P < 0.01$), and increased the yield of 16-carbon milk FA (457 vs. 378 g/d; $P < 0.01$). There was no effect of prill size of PA on DMI, yield of milk and milk components, or feed efficiency. However, LG increased 16-carbon FA digestibility compared with MD (74 vs. 71%; $P < 0.05$) and SM (74 vs. 72%; $P < 0.05$). Additionally, LG increased total FA digestibility compared with MD and SM (78, 76 and 76%, respectively; $P < 0.05$). These results demonstrate that PA increased milk fat concentration and yield and feed efficiency. Although prill size affected FA digestibility, this had no effect on animal performance.

Key Words: fatty acid digestibility, feed efficiency, milk fat

W341 Changes in dairy cattle performance due to addition of a live yeast product.

Heidi A. Rossow*[1], Tim Riordan[2], Andy Riordan[2], Dennis Ervin[3], and Dari Brown[3], [1]*University of California, Davis, Davis, CA,* [2]*Nutri-Systems Inc., Clovis,CA,* [3]*Phileo Lesaffre Animal Care, Milwaukee, WI.*

Live yeast products have been proposed to increase nutrient utilization and milk production. Therefore the purpose of this trial was to determine if a live yeast product (LYP; BioCell 20, Phileo Lesaffre Animal Care, Milwaukee, WI) administered at 3g/cow/d to cows at a commercial dairy could increase milk yield and milk component production. All milking cows were milked 2 times a day and given LYP in the TMR in an OFF, ON, OFF, ON, OFF design where each ON or OFF period lasted 45 d and LYP was added to TMR during the ON periods only. Only data from cows that had at least one Dairy Herd Improvement Association milk test during each period remained in the data analyses (1903). Pens were fed the same respective diet (Fresh cow, milk cow, milk heifer or pregnant cow TMR) twice per day. Statistics were performed using Proc GLM (SAS Institute, 2013). To compensate for differences in days in milk (DIM) and milk production due to a period effect, treatment was nested within period, repeated measures for cow and covariates pen, DIM, diet, relative value, milk yield during period 1 (control period) and fresh date were included in the statistical model. There were no differences in least squares means of parity and small differences in least squares means DIM among periods. Average DIM in periods 2–5 were not different ($P < 0.05$; range 143- 298 d). Overall, daily milk yield (31.8 and 32.9.0 kg, $P < 0.0001$) and milk protein (1.02 and 1.08 kg, $P < 0.0001$; 3.25 and 3.31%, $P < 0.0001$) for control and LYP supplemented treatments, respectively, were higher for cows fed LYP. Therefore LYP did increase milk yield and milk protein kg and % but decreased milk fat % (3.71 and 3.60%, $P < 0.0001$), respectively.

Key Words: live yeast, dairy cow performance

W342 Effects of feeding frequency and adding plant oil to diet on performance and feeding behavior of lactating Holstein dairy cows.

H. R. Mirzaei Alamouti* and K. Akbari, *Department of Animal Science, University of Zanjan, Zanjan, Iran.*

The objectives of this experiment were to investigate the effect of feeding frequency and oil supplementation to the diet on performance and feeding behavior of lactating dairy cows. Twenty 4 lactating Holstein cows, 12 primiparous, (BW = 626 ± 58 kg and DIM = 195 ± 44 d) and 12 multiparous, (BW = 617 ± 25 kg and DIM = 207 ± 39 d) were randomly assigned to the 4 diets contained 2.5 percent supplemental oil or no oil and feeding frequency of 3 or 1 time per day in a randomized complete block design with a 2 × 2 factorial arrangement. Frequency of feed delivery and oil supplementation had no effect on dry matter intake. Oil supplementation reduced slug feeding especially with feeding once per day ($P < 0.05$). Feeding frequency and oil supplementation interaction tended to significant for milk yield ($P = 0.09$), as there was a numerical increase in milk yield in 3 time feeding with oil diet. The cows fed oil diet in 3 time feed delivery had lower milk protein ($P < 0.05$), but milk fat increased with 1 time feeding and oil supplementation ($P < 0.05$). The results showed that oil supplementation to mid lactating cows diet can decrease compromised effects of decreasing feeding frequency.

Key Words: feeding frequency, oil supplementation, chewing behavior

W343 Effect of feeding hay during the nursery phase of calf rearing.

F. Xavier Suarez-Mena*, James D. Quigley, T. Mark Hill, and Rick L. Schlotterbeck, *Nurture Research Center, Provimi North America, Brookville, OH.*

Recommendations on the value of feeding forage to calves before weaning are inconsistent. This study aimed to evaluate the effects of feeding long hay during the nursery phase on calf performance. Treatments were to not feed hay or feed hay to calves throughout the 56-d trial. Forty-eight calves (45.4 ± 1.18 kg BW, 2 to 3 d of age) were fed a milk replacer (MR; 22% CP, 20% fat as-fed basis) powder at 568 g as-fed daily diluted at 12.5% solids. Calves were fed MR daily in 2 equal meals from 0 to 39 d, then at 313 g of MR powder daily (AM meal only) for d 40 to 42. All MR offered was consumed. Starter, hay, and water were fed ad libitum. Hay and starter were fed in separate pails. Calves were housed in individual pens bedded with straw in a nursery with natural ventilation and no added heat through d 56. Feces were scored daily using a 1 to 5 scale with 1 being normal and 5 being watery. Medical treatments were recorded daily. Calves were weighed initially and weekly thereafter. Body condition score (1 being thin and 5 being obese) and hip widths were measured initially and every 2 weeks thereafter. The average temperature in the nursery was 23°C with a range from 12 to 36°C. The average relative humidity was 78% with a range from 40 to 97%. Data were analyzed as a completely randomized design. Repeated measures analysis was performed on pre-weaning (0 to 42 d), post-weaning (42 to 56 d), and overall (0 to 56 d) data. Initial measurements differed for hip widths ($P < 0.05$) among treatments. Pre-weaning hip width change tended ($P < 0.09$) to be less for calves fed hay. Other measurements did not differ ($P > 0.05$). Hay intake was highly variable and averaged 6.1% of total intake overall. Hay intake as a percentage of overall intake ranged from less than 1 to 20% among the 24 calves fed hay. Hay intake was not related to starter intake. Feeing hay did not improve calf performance as measured in this study.

Key Words: starter intake, hay, performance

W344 Effects of non-fiber carbohydrate level in low energy diets on production and health responses in peripartum Holstein cows.

H. R. Mirzaei Alamouti* and P. Panahiha, *Department of Animal Science, University of Zanjan, Zanjan, Iran.*

Effects of rumen fermentability of carbohydrate and nonfiber carbohydrate during late gestation and early lactation on production and metabolic status of periparturient cows were studied. Sixteen multiparous and 40 primiparous cows were used in a randomized complete block design and assigned at random to 1 of 2 treatments in pre- and postpartum. The cows were fed diets as total mixed ration (TMR) with similar crude protein and energy (low energy diets) content, but different source of starch (ground barley vs. corn grain) from 20 ± 2 d relative to expected calving until calving. At parturition, half of the animals from each prepartum treatment were assigned to a lactation diet with 2 level of nonfiber carbohydrate until d 28 and, all cows received the same high energy lactation diet until d 90. The cows fed prepartum diet had a positive energy balance during the prepartum period. Blood samples were taken at −20, +1 and +21 d relative to calving. Data were separately analyzed for multi- and primiparous cows by proc Mixed of SAS with diet and time as fixed effect and animal nested in diet as random effect. There was no significant difference in milk content except milk lactose in primiparous cows fed prepartum diets. Milk production was higher for primiparous cows fed barley diet in prepartum and high NFC diet in postpartum, and also corn diet in prepartum and low NFC in postpartum. Milk fat content for multiparous cows was different. There was significant difference between β-hydroxybutyrate, albumin and nonesterified fatty acid for primiparous cows and total protein, alanine amino acid transferase and BHBA for multiparous cows in postpartum. There were differences in some reproductive parameters. Generally, the responses of fresh cow to nonfiber carbohydrate content in lactating diet is depends on fermentability of starch in low energy close-up diet.

Key Words: transition period, nonfiber carbohydrate

W345 Increase in total solids of whole milk and its effects on development of dairy calves.

Rafael Alves de Azevedo*[1], Sâmara Raiany de Almeida Rufino[1], Pâmela Michéli Furini[1], Fernanda Samarini Machado[2], Mariana Magalhães Campos[2], Paulo Campos Martins[1], Aloma Eitere Leão[1], Ângela Maria Quintão Lana[1], and Sandra Gesteira Coelho[1], [1]*Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil,* [2]*EMBRAPA Dairy Cattle, Coronel Pacheco, Minas Gerais, Brazil.*

Objectives were determine the best total solids (TS) concentration in liquid diet consisting of whole milk (WM) and milk replacer (MR) and its effects on preweaning calves feed intake and performance. Sixty crossbred Holstein-Gyr calves were distributed in 4 treatments, maintaining the balance for initial body weight and total protein concentration in blood serum and genetic composition. The treatments consisted of WM with the increasing addition of MR (Sprayfo Violet SSP), to adjust the TS to 12.50; 15.00; 17.50 and 20.00%, after the measurement the TS in WM using Brix refractometer (DD-3 MISCO Palm Abbe Digital), which had the degree brix value converted to TS (Moore et al., 2009). TS contents verified in the treatments after the addition of MR were 13.50; 16.10; 18.20 and 20.40%. The calves were fed 6 L/d, divided in 2 equal meals (8 and 16h) provided in buckets, from 5 to 55 d of age. From 56 to 59 d, the volume was reduced to 3 L/d (8h). At 60 d the animals were weaned. Starter (Soylac Rumen 20% CP) and water were provided ad libitum throughout the experiment. Feed intake, feed efficiency, average daily gain (ADG), structural body measures and days of diarrhea were measured. Data were analyzed by ANOVA using the PROC GLM procedure of SAS. Increasing TS resulted in a linear increase in water intake, total DMI, ADG, withers height and hearth girth. Starter intake, days of diarrhea, hip width and feed efficiency did not change as the TS increased up to 20.4%.

Key Words: milk system, milk replacer

W346 Increase in total solids of whole milk and its effects on development in postweaning calves.

Rafael Alves de Azevedo*[1], Pâmela Michéli Furini[1], Sâmara Raiany de Almeida Rufino[1], Fernanda Samarini Machado[2], Mariana Magalhães Campos[2], Aloma Eitere Leão[1], Paulo Campos Martins[1], Ângela Maria Quintão Lana[1], and Sandra Gesteira Coelho[1], [1]*Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil,* [2]*EMBRAPA Dairy Cattle, Coronel Pacheco, Minas Gerais, Brazil.*

This study aimed to evaluate the effects of intensive whole milk feeding in calves on postweaning feed intake and performance. Sixty crossbred Holstein-Gyr calves were distributed in 4 treatments until the weaning. The treatments consisted of WM with the increasing addition of MR (Sprayfo Violet SSP), to adjust the TS to 12.5; 15.0; 17.5 and 20.0%, after the measurement the TS in WM using Brix refractometer (DD-3 MISCO Palm Abbe Digital), which had the degree brix value converted to TS (Moore et al., 2009). The calves were fed 6 L/d, divided in 2 equal meals (8 and 16h) provided in buckets, from 5 to 55 d of age. From 56 to 59 d, the volume was reduced to 3 L/d (8h). At 60 d the animals were weaned. Starter (Soylac Rumen 20% CP) and water were provided ad libitum throughout the experiment. Corn silage was provided ad libitum to calves from 70 d of age. Feed intake, average daily gain (ADG) and structural body measures were measured in postweaning calves. Data were analyzed by ANOVA using the PROC GLM procedure in SAS. Results are presented in Table 1. Starter, corn silage and water intakes and ADG in postweaning calves did not change as the TS increased up to 20.4%. Increasing TS resulted in a tendency of linear increase in withers height and final body weight.

Table 1 (Abstr. W346). Feed intake and performance of postweaning calves fed liquid diet with increasing total solid content during preweaning period

	Treatment, % TS					
Item	13.5	16.1	18.2	20.4	SEM	*P*-value

W347 Effect of dietary starch content on the occurrence of subacute ruminal acidosis (SARA) and inflammation in fresh dairy cows.

Sarah E. Williams*[1], Heather A. Tucker[1], Yoritaka Koba[2], Ryo Suzuki[2], and Heather M. Dann[1], [1]*William H. Miner Agricultural Research Institute, Chazy, NY,* [2]*ZEN-NOH National Federation of Agricultural Cooperative Associations, Tokyo, Japan.*

Multiparous ruminally cannulated Holstein cows (n = 16) were fed either a lower starch [21% starch, 37% neutral detergent fiber (NDF)] or higher starch (27% starch, 32% NDF) diet from 1 to 21 d in milk (DIM) to assess the effect of dietary starch on rumen fermentation, rumination, energy metabolites, and inflammatory markers. Diets contained 28% corn silage, 22% haycrop silage, 2% straw, and 48% concentrate. Corn meal was replaced partially with soyhulls and wheat middlings in the lower starch diet. Cows were fed a close-up diet (16% starch, 44% NDF) for 21 d. Cows were housed in a bedded pack, fed individually, and milked 3x/d. Rumen pH was measured at 1-min intervals and rumination was measured continuously from −14 to 21 DIM. Rumen and blood samples were collected on −14, 1, 2, 3, 4, 5, 6, 7, 9, 13, 17, and 21 DIM at 0 and 6 h post feeding. Data were analyzed as a completely randomized design by ANOVA with the MIXED procedure of SAS with model effects of treatment, time, treatment x time, and covariate (data from −14 to −8 DIM). Cows averaged 20.4 ± 0.7 kg dry matter intake/d and 42.1 ± 1.9 kg milk/d with 4.6 ± 0.2% fat and 3.5 ± 0.1% true protein. Daily mean rumen pH was higher (6.19 vs. 6.04, SE = 0.05, $P = 0.03$), time with pH <5.8 was lower (1.6 vs. 4.5 h/d, SE = 0.7, $P < 0.01$), and rumen ammonia was higher (10.1 vs. 7.1 mg/dL, SE = 0.6, $P < 0.01$) for cows fed the lower starch diet. Diet did not affect ($P >$

0.10) rumination (481 ± 18 min/d), rumen volatile fatty acids (115 ± 3 m*M*), or acetate to propionate ratio (3.23 ± 0.13). Cows fed the lower starch diet had lower ($P < 0.10$) 6-h serum haptoglobin [0.10 (95% CI 0.06–0.14) vs. 0.17 (95% CI 0.11–0.27) mg/mL] and serum amyloid A [22 (95% CI 12–38) vs. 53 (95% CI 28–101) ug/mL]. Diet did not affect ($P > 0.10$) 0-h nonesterified fatty acids (680 ± 58 uEq/L), 0 and 6-h β-hydroxybutyrate (1.0 ± 0.2 m*M*), 6-h interleukin (IL) −1β (57.3 ± 5.1 pg/mL), 6-h IL-6 (457 ± 42 pg/mL), or 6-h tumor necrosis factor-α (40.7 ± 2.7 pg/mL). The nutritional strategy that is used during the transition period is critical for minimizing the risk of SARA and controlling inflammation.

Key Words: transition cow, starch, acidosis

W348 Physical and enzymatic hydrolysis characteristics of ruminal protozoal glycogen.

Mary Beth Hall*, *US Dairy Forage Research Center, USDA-ARS, Madison, WI.*

The characteristics of microbial glycogen have not been well described, but have implications for its analysis and digestion characteristics. A series of analyses, and comparisons carried out as randomized complete block designs were performed on glycogen isolated from protozoa from ruminal inoculum incubated in vitro with glucose. The isolated protozoal glycogen (IPG) was in the form of water and 0.9% NaCl insoluble granules 1.3 to 1.9 mm in length. IPG was not obviously birefringent under polarized light. a-Glucan was measured by AOAC Official Method 2014.10 as detected glucose × 0.9. a-Glucan contents of beef glycogen, wheat starch (WS), corn starch (CS), and IPG on a dry matter (DM) basis were 98.1, 99.5, 100.0, and 98.3%, respectively. Duplicate samples (each 50 mg in 5 mL water) were incubated at successively increasing temperatures (22, 37, 50, 57, 65, 70, 75, 80, and 85°C) for 30 min with vortexing every 5 min for 5 s. Gelatinization temperature was determined as the point at which transmittance % at 650 nm departed from baseline measurements of unheated samples. WS, CS, and IPG had gelatinization temperatures of 57, 65, and 65°C, respectively. Subsequent enzymatic hydrolysis of 0.2 mL of the sample suspensions was performed with addition of 1 mL 0.1 *M* Na acetate buffer (pH 5.0), and 4 U amyloglucosidase incubated for 2 h at 39°C. Digested a-glucan as a percentage of initial CS, WS, and IPG were 8.3, 9.0, and 24.7% for ungelatinized vs. 100.0, 88.9, and 95.6% for gelatinized (85°C) samples, respectively. Effects of sample, gelatinization, and sample × gelatinization all were $P < 0.01$ (standard error of the difference; SED = 0.4). Incubation of ungelatinized suspensions of IPG for 24 h at 57°C with 0, 1.8, or 4 U amyloglucosidase with Na acetate buffer gave a-glucan values of 0.03, 14.3, and 15.0% of DM, respectively ($P < 0.01$, SED = 0.06). Similar to native starch, gelatinization was required to achieve more extensive enzymatic hydrolysis of IPG. This suggests that protozoal glycogen digestion characteristics may be similar to those of native starch, and that IPG requires gelatinization for analysis involving enzymatic hydrolysis.

Key Words: rumen microbe, protozoa, glycogen

W349 The determination of the concentrations of isoforms of vitamin E in tissues, milk and blood via HPLC after short-term feeding in dairy cows.

Y. Qu*[1], T. H. Elsasser[2], J. R. Newbold[3], E. E. Conner[2], and k. M. Moyes[1], [1]*University of Maryland, College Park, MD,* [2]*Agricultural Research Service, US Department of Agriculture, Beltsville, MD,* [3]*Cargill Innovation Center, Velddriel, the Netherlands.*

The objective of this study was to determine the pattern of change in the concentrations of the 4 isoforms of vitamin E (α-, β-, γ- and δ-tocopherol) in bovine tissues (liver, mammary and muscle), blood and milk after short-term feeding of a vegetable-derived oil (Tmix) particularly enriched with γ- and δ-isoforms (9% α-, 1% β-, 24% δ- and 62% γ-tocopherol). Healthy multiparous Holstein cows (>90 DIM) were assigned to dietary control (Notoc, n = 4) or tocopherol-fed treatment groups (n = 5: TOC;~260g Tmix/cow/d, top-dressed) for 9 consecutive days. Milk and blood samples were collected in the mornings on d 0 and d 10 from the 5 TOC cows; tissues were harvested from those same cows on d 10 of treatment and the cohort of physiologically similar Notoc cows. Isoform concentrations were determined in samples by HPLC. Data were analyzed by Student's *t*-test and ANOVA. Delta-TOC was not detected in tissues, blood or milk. Concentrations of γ-TOC were increased ($P < 0.001$) in tissues, blood and milk with feeding ($P < 0.001$). In all tissues, α-TOC concentrations were higher ($P < 0.001$) than γ-TOC before and after feeding. Concentrations of both α- and γ-TOC were higher in blood and milk after feeding Tmix ($P < 0.05$). The content of α-TOC was higher than γ-TOC ($P < 0.001$) in milk and blood before and after feeding. In conclusion, short-term feeding of Tmix oil resulted in increases in the γ-isoform, largely no measurable content or significant change in the β- or δ-isoforms, and a variable change in the α-isoform of TOC across various tissues and biological fluids of the cow.

Key Words: concentration, cow, vitamin E

W350 Total replacement with organic minerals regulates endometrial gene expression patterns that improve reproductive performance status in dairy heifers.

Daniel E. Graugnard*, Allison C. Smith, Sylvie Andrieu, and Kristen M. Brennan, *Alltech Center for Animal Nutrigenomics and Applied Animal Nutrition, Nicholasville, KY.*

Reproductive performance in dairy cows is a major factor determining herd efficiency and profitability. The objective of this study was to evaluate the effect of dietary organic minerals on gene expression profiles of endometrial tissue. A total of 18 Holstein heifers (10–15 mo) were randomly assigned to 2 groups (n = 9/treatment) and supplemented for 90d with an organic premix (consisting of Bioplex Zn, Bioplex Cu, Bioplex Mn and EconomasE) or a standard inorganic premix (control). Endometrium was biopsied at d90 of supplementation and RNA was hybridized to the Affymetrix Bovine Genome Array. Hierarchical clustering analysis resulted in 2 different groups as a function of the pairwise distances corresponding to the treatments. Relative expression analysis between treatments resulted in a total of 580 differentially expressed genes ($P < 0.05$; 398 upregulated; 182 downregulated), which enriched ($P < 0.05$) different pathways related to reproductive performance: (1) Dendritic cell maturation, which regulates endometrium cell differentiation and the vascular responses associated with implantation; (2) Relaxin hormone signaling, which confers beneficial effects on the endometrium for implantation; (3) Gaq signaling function of smooth muscle tissue like endometrium; and (4) Thrombin signaling, which promotes coagulation and the binding and aggregation of platelets and facilitating the rapid adherence of neutrophils, monocytes and lymphocytes to the endothelial cell layer to overcome exogenous challenge or play an essential role in early pregnancy. In conclusion, supplementation with organic minerals potentially benefits reproductive performance, including improved regulation of the estrous cycle, shorter calving intervals, and improved implantation rates.

Key Words: organic mineral, endometrium, cattle

W351 Comparative bioavailability of lysine in three commercial rumen-protected lysine products using the in vivo plasma lysine response method.

Heather A. Tucker[1], Makoto Miura[2], Izuru Shinzato[3], and Catherine S. Ballard*[1], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Ajinomoto Co., Inc., Kawasaki-ku, Kawasaki-shi, Japan, [3]Ajinomoto Heartland Inc., Chicago, IL.*

Lysine bioavailability of second generation AjiPro-L (A2G; Ajinomoto Heartland, Inc.) has been determined using the plasma free amino acid dose response technique. The objective of this study was to compare bioavailability of MetaboLys (MBL; H. J. Baker & Bro., Inc.) and USA Lysine (USA; Kemin Industries Inc.) relative to A2G following the same technique. Fourteen multiparous lactating Holstein cows (113 ± 28 d in milk) were housed in a tie stall facility and used in a replicated 7 × 7 Latin square design with 7-d periods. Cows were blocked by days in milk and milk production, and assigned randomly to treatment sequence. A common basal diet adequate in Lys was fed proportionately at 3 intervals (33.4% at 0500 h, 33.3% at 1300 h, and 33.3% at 2100 h). Treatments included Lys supplemented at 0, 30, or 60 g/d from A2G, MBL, or USA and were administered 1 h before each feeding on d 2 through 7 of each period in amounts proportional to feed offered to simulate diet inclusion. Blood samples were obtained from each cow on d 6 and 7 of each period from the tail vein at 2-h intervals starting at 0600 h. Plasma, pooled by day, was analyzed for amino acid (AA) concentrations. Data were reduced to a period mean for each cow and analyzed using the MIXED procedure of SAS. REG procedure was used to generate linear regression models for each rumen-protected Lys product using the values of Lys (μmol) and Lys as a percentage of total AA (μmol-basis) to determine the degree of elevation of plasma Lys. Relative to A2G, estimated bioavailability of MBL and USA were determined using the slope ratio assay technique. Dry matter intake and milk yield ($P > 0.10$) did not differ among treatments. The slope for A2G was numerically greater (0.183; $r^2 = 0.72$) when compared with the slope for MBL (0.03; $r^2 = 0.58$) or USA (0.07; $r^2 = 0.99$) when expressing the concentration of plasma Lys as absolute value (μmol). Calculated bioavailability of MBL and USA was 18.3 and 38.2% of the bioavailability of A2G, respectively. Characterizing relative bioavailability of rumen-protected Lys in dairy cattle provides a means for comparing economic value of commercially available products.

Key Words: lysine, bioavailability, rumen-protected

W352 Plane of milk replacer nutrition influences the resistance to an oral *Citrobacter freundii* opportunistic infection in Jersey calves at 10 days of age.

Yu Liang*[1], Jeff A. Carroll[2], and Michael A. Ballou[1], *[1]Texas Tech University, Department of Animal and Food Sciences, Lubbock, TX, [2]USDA-ARS, Lubbock, TX.*

This study investigated how early life plane of milk replacer nutrition influences the resistance to an opportunistic enteric challenge with *Citrobacter freundii*. Twenty colostrum-fed Jersey calves were blocked by BW at birth and randomly assigned to either a low (LPN) or high plane of nutrition (HPN) treatment. The LPN calves were fed 400 and 450 g DM/d of a 20% CP and 20% fat milk replacer during the 1st wk and thereafter, respectively. The HPN calves were fed 600 and 700 g DM/d of a 28% CP and 20% fat milk replacer during the 1st wk and thereafter, respectively. All calves were challenged orally with 1×10^8 cfu of a stationary phase culture of *Citrobacter freundii* at d 10. Fecal scores were recorded throughout the study and rectal temperatures were recorded daily beginning on d 10. Fecal and plasma samples were collected at d 10, 12, 14, 16, 18, 20, 22, and 24. Fecal samples were analyzed for DM percentage and plasma for urea nitrogen, glucose, and haptoglobin concentrations. All calves were harvested at d 24 and ileal tissues were analyzed for morphology. All data reported as LPN vs HPN, respectively. Water intakes increased to a greater extent among HPN calves after the challenge ($P \leq 0.021$). There was no difference in DM percentage of feces between treatments (21.9 vs 19.9 ± 1.34%; $P = 0.291$) despite HPN having greater fecal scores (2.0 vs 2.5 ± 0.07; $P = 0.001$). Rectal temperatures were greater among the HPN calves (38.4 vs 38.6 ± 0.05°C; $P = 0.024$). Additionally, the HPN calves had numerically greater peak plasma haptoglobin concentrations after the challenge (266 vs 511 ± 108.0 μg/mL; $P = 0.118$) and a tendency to have a greater total mucosal height of the distal ileum (752 vs 921 ± 59.1 μm; $P = 0.059$). Therefore, these data indicate that calves fed a HPN during the neonatal period have a slightly greater acute phase response to an opportunistic bacterial enteric infection. Furthermore, these data reiterate that fecal scores should not be the only measure of enteric health, especially when evaluating the health effects associated with plane of nutrition.

Key Words: calf, disease, nutrition

W353 Pre-weaning calf responses to lysine: I. Development and evaluation of functions explaining nitrogen retention responses to dietary lysine and body weight.

Juan J. Castro Marquez*, Robin R. White, and Mark D. Hanigan, *Department of Dairy Science, Virginia Tech, Blacksburg, VA.*

The objective of this study was to define the nitrogen retention (NR) response of growing dairy calves as a function of dietary lysine intake (DLI) and body weight (BW). Raw, individual calf data from 3 published papers were collected. Lysine intake and NR were expressed as g per kg BW. Twelve models were derived relating NR, DLI and BW. Three equation forms (logistic, Michaelis-Menten or exponential), 2 effect types (fixed effects or mixed-effects with random study effect) and 2 error assumptions (equal error variance or heterogeneous error variance) were considered. The models were evaluated and compared based on their root mean squared prediction error (RMSPE), concordance correlation coefficient (CCC) and any mean and slope bias revealed by residual analysis. The asymptotic and rate-determining parameters of each function were assumed to vary as a function of BW and the primary explanatory variable within each equation form was DLI. Models varied notably in their predictive capacity and RMSPE ranged from 14.4 to 58.9%. A fixed-effects, logistic model with equal error variance returned the lowest RMSPE (14.4%), highest CCC (0.94) and had no appreciable mean or slope bias. All parameters were statistically significant ($P < 0.01$). This equation, $NR = (0.89–0.0067 \times BW+0.000015 \times BW2) \div (1+e(-((Lys-(0.0024 \times BW*e(−0.013 \times BW)))/0.032)))$, estimated that a young calf (50 kg BW) could potentially achieve a maximal NR efficiency of 2.72 g/g DLI/kg BW and at 250 kg BW a maximal NR efficiency of 1.25 g/g DLI/kg BW could be reached. Nitrogen retention efficiency reduced substantially as BW increased. Increasing DLI promoted NR at low BW more effectively than at high BW. Although DLI affects short-term protein accretion responses, NR rate was primarily dependent on calf maturity.

Key Words: calf, nitrogen retention, amino acid

W354 Saliva sodium, potassium, and phosphorus concentrations of post-peak lactating Holstein cows are not affected by dietary fiber or protein content.

J. A. D. R. N. Appuhamy*[1], M. Niu[1], T. Tewoldebrhan[1], A. Leytem[2], R. Dungan[2], and E. Kebreab[1], *[1]Department of Animal Science, University of California, Davis, CA, [2]USDA-ARS, Northwest Irrigation Research Lab, Kimberly, ID.*

Knowledge on saliva sodium (Na), potassium (K), and phosphorus (P) concentrations are important in modeling electrolyte, water, and P partitioning in dairy cows. Saliva mineral concentrations in ruminants are strongly associated with saliva secretion rates, which can be affected by diet composition. The objective of this study was to examine saliva Na, K, and P concentrations in lactating cows fed 2 levels of forage and CP contents. Saliva samples were collected from 12 lactating Holstein cows randomly assigned to a 2 × 2 factorial arrangement of 2 forage (alfalfa hay) levels [38 (LF) vs. 53% (HF)] and 2 CP levels [15.2 (LP) vs. 18.5% (HP)] over 3 periods. Saliva samples were acidified (pH = 5–6) and diluted by a factor of 50 using deionized water (pH = 4.0). The filtered samples were then analyzed for Na, K, P, and calcium (Ca) concentrations by inductively coupled plasma atomic emission spectroscopy. Treatment effects on saliva mineral concentrations were analyzed with mixed-effect models including random cow effect. Mean dietary concentrations and total intake (via feed and water) of Na, K, and P were 0.36 ± 0.01, 1.04 ± 0.10, and 0.40 ± 0.01% of DM and 81 ± 10, 236 ± 40, and 93 ± 9 g/cow/d, respectively. Only total K intake was negatively affected by dietary fiber content ($P < 0.01$). Saliva concentrations of Na and K were on average 70.3 ± 6.7 and 21.9 ± 1.3 mmol/L and were negatively correlated ($r = -0.40$, $P < 0.01$). A unit increase in average daily temperature (T, °C) increased and decreased saliva K ($P = 0.08$) and Na ($P = 0.05$) concentrations by 0.9 ± 0.5 and 4.9 ± 2.4 mmol/L, respectively. Saliva K concentration decreased by 0.010 ± 0.005 mmol/L ($P = 0.07$) for unit increase in BW. Saliva P concentration was on average 1.9 ± 0.4 mmol/L, and increased and decreased by 0.004 ± 0.002 ($P = 0.10$) and 0.61 ± 0.18 mmol/L ($P < 0.01$) for unit increase in BW and T. Saliva P concentration was negatively related to saliva Ca concentration ($r = -0.37$, $P < 0.01$). Dietary fiber or CP contents did not have significant effect on any of the saliva mineral concentrations. Information on BW, T, and relationship with other minerals are important in determining Na, K, and P partitioning in lactating dairy cows.

W355 Do the viability and dose of *Saccharomyces cerevisiae* affect the digestibility, ruminal fermentation, and performance of lactating dairy cattle?

Y. Jiang*[1], R. M. Martins[2], I. M. Ogunade[1], M. A. Bamikole[3], F. Amaro[2], W. Rutherford[4], S. Qi[4], F. Owens[4], B. Smiley[4], K. G. Arriola[1], C. Staples[1], and A. T. Adesogan[1], *[1]Department of Animal Science, University of Florida, Gainesville, [2]Animal Science Department, Federal University of Vicosa, Vicosa, Minas Gerais, Brazil, [3]Department of Animal Science, University of Benin, Benin City, Nigeria, [4]DuPont Pioneer, Johnston, IA.*

This study was conducted to examine the effect of the dose and viability of supplemental *Saccharomyces cerevisiae* on ruminal fermentation and performance of lactating dairy cows. Four ruminally cannulated lactating cows (284 ± 18 DIM) were assigned to 4 treatments arranged in a 4 × 4 Latin square design with four 21-d periods. Cows were fed a non-acidotic total mixed ration (46.8% corn silage, 8.5% wet brewers grain and 44.7% concentrate, dry matter basis). The diet was supplemented with no yeast (Control, CON) or with a low dose of live yeast (5.7×10^7 cfu/day; LLY), a high dose of live yeast (6.0×10^8 cfu/day; HLY), or a high dose of killed yeast (6.0×10^8 cfu/day before heating at 80°C; HDY). Ruminal pH and temperature were measured with indwelling probes. Ruminal fluid was collected 0, 2, 4, 6, 8 and 10 h after the morning feeding on d 21 for analysis of volatile fatty acids (VFA) and ammonia-N. All data were analyzed using the GLIMMIX procedure of SAS (SAS Institute, Cary, NC). In vivo digestibility was measured using chromic oxide as a marker. Supplemental LLY increased yields of milk (29.9 vs 31.8 kg/d; $P = 0.04$), milk fat (1.09 vs 1.17 kg/d; $P = 0.08$) and milk protein (0.95 vs 1.02 kg/d; $P = 0.05$), feed efficiency (0.85 vs 0.90; $P = 0.03$), acetate to propionate ratio ($P = 0.07$), and in vivo apparent digestibility of dry matter and neutral and acid-detergent fiber ($P = 0.02$, 0.02 and 0.02, respectively). Feeding HLY instead of LLY decreased milk yield (31.8 vs 30.1 kg/d; $P = 0.07$) and feed efficiency (0.90 vs 0.86 kg/d; $P = 0.05$). Supplementing with killed instead of live yeast decreased concentrations of acetate ($P = 0.06$), propionate ($P = 0.05$) and total VFA ($P = 0.05$). Supplementing with HDY instead of CON increased lactate ($P = 0.14$) concentration and acetate to propionate ratio ($P = 0.08$) and decreased the minimum ruminal pH ($P = 0.10$). The low dose of live yeast increased dry matter and neutral-detergent fiber digestibility, milk production and feed efficiency but the high dose of killed or live yeast did not.

Key Words: yeast, dairy cow, milk yield

W356 Pre-weaning calf responses to lysine: II. Sensitivity and optimization of nitrogen retention responses to dietary lysine and body weight.

Robin R. White*, Juan J. Castro Marquez, and Mark D. Hanigan, *Department of Dairy Science, Virginia Tech, Blacksburg, VA.*

The objective of this study was to use a model relating lysine (Lys) intake and weight gain in calves to identify optimal alternative protein sources for use in calf diets to minimize cost of gain (COG). A nonlinear optimization was used to minimize COG by adjusting milk replacer formulation subject to biological and practical constraints. The optimizer balanced milk replacer formulas for calves on a weekly basis from wk 1 through 8 of age. Body weight was diet dependent and updated weekly. Energy and mineral requirements of calves were calculated weekly following NRC (2001). Biological, practical and economic constraints were used to define the feasible set of ingredient combinations. Daily Lys intake was used to estimate nitrogen retention for each age group and change in body protein content was tracked. A literature search of calf slaughter balance studies was used to derive allometric equations relating body protein content to body fat, water and ash content. These functions were differentiated and change in body weight was calculated as the sum of the changes in body protein, fat, water and ash. Diet cost was estimated from current ingredient prices and dietary inclusion rates. Sensitivity of the model outputs to feedstuff Lys, protein content and digestibility was performed by taking 10,000 random draws of these parameters from normal distributions, running the growth model and calculating final weight and COG. Standard deviations in feedstuff Lys, protein content and digestibility were sourced from the National Animal Nutrition Program website. The optimal diet relied on a milk protein base with steadily increased inclusion of wheat gluten as animals aged. Blood meal and meat meal were also identified as key alternative protein sources. Model solutions were very robust. After 8 weeks calves weighed 87.8 ± 0.1 kg and COG was \$0.358/kg ± \$0.001/kg. Protein content and digestibility and Lys significantly ($P < 0.001$) affected COG and BW and protein digestibility was quantitatively the most important parameter to estimate.

Key Words: calf, nitrogen retention, optimization

W357 Effects of corn treated with foliar fungicide at various times of application on in situ ruminal digestibility of corn silage in Holstein cows.

Katie J. Haerr*[1], Naina M. Lopes[2], Japheth D. Weems[1], Carl A. Bradley[1], Marcos N. Pereira[2], Michael R. Murphy[1], Gary M. Fellows[3], and Felipe C. Cardoso[1], *[1]University of Illinois, Urbana, IL, [2]Universidade Federal De Lavras, Lavras, MG, Brazil, [3]B.A.S.F. Corporation, Research Triangle Park, NC.*

The main objective was to explore the associations of corn plant foliar fungicide application on harvested whole-plant corn silage digestibility. Treatments were control (CON), corn received no foliar fungicide application; treatment 1 (1×), corn received one application of pyraclostrobin foliar fungicide (PYR; Headline; BASF Corp. Florham Park, New Jersey) at corn stage V5; treatment 2 (2×), corn received 2 applications of foliar fungicides, PYR at corn stage V5, and a mixture of pyraclostrobin and metconazole (PYR+MET; Headline AMP; BASF Corp. Florham Park, New Jersey) at corn stage R1; and treatment 3 (3×), corn received 3 applications of foliar fungicides, PYR at corn stage V5, PYR+MET at corn stage R1, and PYR+MET at corn stage R3. Corn was harvested at the same time and ensiled for 7 mo. Three cannulated lactating multiparous Holstein cows (376 ± 28 DIM) were used to measure corn silage in situ digestibility. Dried unground corn silage was put into 288 (3 time points/treatment/cow) 10 × 20 cm bags and incubated for 0, 2, 4, 8, 12, 48, 72 or 96 h. A sample of unground undried corn silage was also placed into a 20 × 40 cm bag and incubated for 48 h. The degradable portion of DM was greater ($P = 0.01$) for corn silages treated with fungicide when compared with CON (0.36, 0.42, 0.40 and 0.47 for CON, 1×, 2×, and 3×, respectively). There was a linear ($P < 0.001$) effect of treatment frequency on the proportion of DM digestibility. The 2 different sizes of bags used (10 × 20 vs. 20 × 40 cm) for the in situ digestibility technique were different ($P < 0.02$) for DM, NDF, ADF, CP, and starch for 48h digestibility. Larger bags had greater ($P < 0.03$) digestibility for DM (33, 35%), and lower digestibility for NDF (42, 35%), and ADF (47, 39%), than smaller bags. In conclusion, corn silage with fungicide application had higher DM digestibility and a trend for a lower rate of digestion as well as linear effects for decreasing DM solubility, increasing DM degradability, and decreasing rate of DM digestion.

Key Words: in situ digestibility, corn silage, fungicide

W358 A multivariate mixed effects model to estimate the energetic efficiencies of synthesizing milk components.

Luis E. Moraes*[1], James G. Fadel[1], David P. Casper[2], and Ermias Kebreab[1], *[1]University of California-Davis, Davis, CA, [2]South Dakota State University, Brookings, SD.*

The current Northern American feeding system for dairy cows suggests that new feeding systems calculate milk energy requirements as individual requirements for milk fat, protein and lactose. Extant models from the literature provide efficiencies that are unrealistically larger than the partial efficiency of utilizing dietary metabolizable energy (ME) for milk production (k_L) or require inputs that are often not available to nutritionists when formulating diets. The objective of this study was to develop a model to estimate partial efficiencies of simultaneously synthesizing milk fat, protein and lactose from dietary ME and body stores. The model was developed as a multivariate mixed effects model and it was structured such that the partial efficiencies of synthesizing individual milk components additively determined k_L and the partial efficiency of utilizing body stores for milk production (k_T). The new energy balance function described the trivariate response vector comprising milk fat, protein and lactose energy outputs as functions of the animal's ME intake and tissue energy balance. The model was fitted with 930 energy balance records from 244 Holstein lactating cows. Measurements were conducted through indirect calorimetry at the former USDA Energy Metabolism Unit at Beltsville, Maryland. The partial efficiencies of synthesizing milk fat, protein and lactose additively determined a k_L of 0.62 (0.009) and a k_T of 0.80 (0.020) which are in good agreement with the partial efficiencies adopted by the NRC (2001). The net energy requirement for maintenance (NE_M) estimated with this model was 0.34 (0.015) MJ/kg $BW^{0.75}$ which is virtually identical to the NE_M adopted by the NRC (2001). The determination of the ME required to synthesize each milk component may be further evaluated with the estimation of the fraction of the ME intake directed to each milk component and through the estimation of the partial efficiencies of individually synthesizing each milk component. Therefore, the estimated partial efficiencies can be directly implemented in the current Northern American net energy system.

Key Words: energy, efficiency, milk component

W359 Effects of feeding slow-release NPN and microbial fermentation extracts on ruminal pH, ammonia and volatile fatty acids.

Fernando Díaz-Royón*[1], Alvaro D. Garcia[1], Kenneth F. Kalscheur[2], and Kamal Mjoun[3], *[1]Dairy Science Department, South Dakota State University, Brookings, SD, [2]U.S. Dairy Forage Research Center, USDA-ARS, Madison, WI, [3]Alltech, Brookings, SD.*

The objective of this study was to examine the effect of partial substitution of soybean meal with a product containing slow-release NPN and microbial fermentation extracts [(OPT); Optimase Alltech Inc., Nicholasville, KY)] on rumen fermentation. This is a companion study to a performance experiment (Díaz-Royón et al., 2014, J. Dairy Sci. 97 (E-Suppl. 1):332). Four cannulated, lactating Holstein cows were randomly assigned to a 4 × 4 Latin square in a 2 × 2 factorial arrangement of treatments. High (HF) and low forage (LF) diets contained, respectively, 61% and 46% forage, with and without OPT. Forages consisted of 75% corn silage and 25% alfalfa hay (DM basis). Experimental diets containing OPT (125 g/cow/day) were designed to partially replace soybean meal 48% CP (0.625 kg) with forage fiber [corn silage (0.225 kg) and alfalfa hay (0.075 kg)] and non-forage fiber [soybean hulls (0.200 kg)]. Increasing forage produced the expected pH increase (6.15 vs. 6.05 for HF and LF, respectively; $P < 0.01$) whereas ruminal pH was not affected by OPT inclusion. Ruminal ammonia concentration tended to be greater in cows fed HF than LF diets (8.07 vs. 7.28 mg/dL; $P = 0.08$), whereas OPT had no effect. Cows fed HF diets had a lower total VFA concentration compared with those fed LF (86.5 vs. 91.6 mM; $P = 0.02$). For cows fed HF diets, molar proportions of acetate (66.0 vs. 64.4%; $P < 0.01$), isobutyrate (0.89 vs. 0.82%; $P < 0.01$), and isovalerate (1.80 vs. 1.58%; $P < 0.01$) were greater, whereas those for propionate were lesser (19.4 vs. 21.1%; $P < 0.01$). Total VFA proportions increased by 6.4% in HF diets supplemented with OPT; however, it decreased by 4.4% on LF diets (forage × OPT, P value = 0.03). Feeding OPT increased molar proportions of acetate ($P < 0.01$), decreased propionate ($P < 0.01$), isobutyrate ($P < 0.01$), and isovalerate ($P < 0.01$), but did not change molar proportions for butyrate and valerate. Partial replacement of soybean meal with OPT in dairy cow diets altered ruminal fermentation in a manner that suggests improved fiber digestion.

Key Words: slow-release NPN, microbial fermentation extract, dairy cows

W360 Relationship between total-tract starch digestibility and fecal starch content in dairy cows.

Marcos N. Pereira*[1,2], Eugenio F. Barbosa[1], and Renata A. N. Pereira[3,2], *[1]Universidade Federal de Lavras, Lavras, MG, Brazil, [2]Better Nature Research Center, Ijaci, MG, Brazil, [3]Empresa de Pesquisa Agropecuária de Minas Gerais, Lavras, MG, Brazil.*

Fecal starch content has utility to estimate starch digestibility in dairy herds. We evaluated the relationship of total-tract starch digestibility and fecal starch content in individually fed lactating Holsteins. The data set from 5 experiments conducted at the Better Nature Research Center had 190 cow/observations fed at ad libitum intake. Starch content of feces, orts, and feeds were analyzed enzymatically at the Federal University of Lavras laboratory (Hall, 2009). Fecal production was measured by total collection of feces in buckets by trained personal. Feces were collected concurrent to defecation during 3 8 h sampling periods and weighed. The second and third sampling periods begun 8 h later than the previous sampling, to avoid a major disturbance to the animals while still representing a 24-h collection period. Fecal aliquots (equal fresh weight basis) were immediately frozen during the collection period and a composite sample was formed. Diets contained 37 to 42% whole plant corn silage in DM and mature finely ground corn grain and/or high moisture corn at 17 to 26% of DM. Cows BW, DMI, and milk yield (MY) during the period of fecal sampling were obtained. Mean ± SD (Min-Max) were: BW 636 ± 73 kg (500–860), DMI 20.74 ± 2.93 kg/d (11.88–27.83), MY 31.16 ± 6.22 kg/d (13.70–47.20), DMI/BW 3.28 ± 0.45% (2.07–4.57), MY/DMI 1.51 ± 0.25 (0.70–2.41), fecal starch content 5.09 ± 2.42% of DM (1.05–13.08), starch intake 6.021 ± 0.985 kg/d (3.374–8.356), consumed diet starch content 29.06 ± 2.84 (22.74–37.72), starch digestibility 94.96 ± 2.60% of intake (86.24–99.18). The correlation coefficient (r) of starch digestibility and fecal starch content was −0.924, higher than with starch intake (−0.219), diet starch content (0.136), DMI (−0.362), DMI/BW (−0.376), MY (−0.363), and MY/DMI (−0.121). Based on stepwise procedure, Starch digestibility (% of intake) = 100.02 – 0.9945 x fecal starch content (% of DM) ($r^2 = 0.854$, $P < 0.01$). Model R^2 was 0.878 when diet starch content was included and 0.882 when MY was further added (0.15 significance required for entry into the model). Fecal starch content was a good predictor of starch digestibility for this data set of cows sampled on similar experimental condition and fed corn based diets.

Key Words: starch in feces, starch digestibility, corn digestion

W361 Relationship between milk urea nitrogen and milk protein ratio with dietary and non-dietary variables in commercial dairy herds. Liliana Fadul-Pacheco*[1], Doris Pellerin[1], P. Yvan Chouinard[1], Michel. A. Wattiaux[2], and Edith Charbonneau[1], *[1]Université Laval, Quebec, Quebec, Canada, [2]University of Wisconsin-Madison, Madison, WI.*

Milk urea nitrogen (MUN) can be used as a tool for the nutritional and environmental management of dairy cows as an estimate of the efficiency of protein metabolism. Using MUN to milk protein ratio (MUN/PROT) was suggested to improve the prediction. Thus, the aim of this study was to better understand the relationships between MUN and MUN/PROT with non-nutritional and nutritional variables in commercial dairy herds. Data recorded by Valacta (Dairy Production Center of Expertise Quebec-Atlantic) for the years 2009 to 2011 was used and originally comprised 3,481,705 test-day records (275,758 cows in 3,140 herds). The analysis was restricted to data from Holstein cows, between 1 and 305 DIM, reducing the number of admissible records for the analysis to 1,339,156 (189,913 cows in 2,522 herds). Average (±SD) milk production, fat content and protein content were 30.8 ± 8.5 kg/d, 3.89 ± 0.60% and 3.25 ± 0.33%, respectively. MUN was statistically different between milkings (10.1 and 10.7 mg/dL for AM and PM, respectively; $P < 0.001$). MUN/PROT was also statistically different between milkings (31.1 and 32.1 mg urea-N/kg milk CP for AM and PM, respectively; $P < 0.001$). Average MUN was statistically different between parities (10.2 and 10.5 mg/dL for first and second or more lactation, respectively; $P < 0.001$). MUN/PROT was also affected by parity (30.7 and 32.0 mg urea-N/kg milk CP for first and second or more lactation, respectively; $P < 0.001$). Pearson correlations between MUN or MUN/PROT and diet variables were low, the highest correlation for both parameters being r = 0.16 ($P < 0.001$) with crude protein content. Both parameters were negatively correlated with milk fat percentage (r = −0.19 and r = −0.29 for MUN and MUN/PROT, respectively; $P < 0.001$) and with the estimated breeding value for protein content (r = −0.10 and r = −0.22 for MUN and MUN/PROT, respectively; $P < 0.001$). MUN/PROT was also correlated with daily milk production (r = 0.20; $P < 0.001$). These results show that in commercial conditions MUN and MUN/PROT are affected by factors other than diet composition.

Key Words: lactating dairy cow, MUN, MUN/protein ratio.

W362 Effects of corn treated with foliar fungicide at various times of applications on milk production of Holstein cows. Katie J. Haerr*[1], Naina M. Lopes[2], Marcos N. Pereira[2], Gary M. Fellows[3], and Felipe C. Cardoso[1], *[1]University of Illinois, Urbana, IL, [2]Universidade Federal De Lavras, Lavras, MG, Brazil, [3]B.A.S.F Corporation, Research Triangle Park, NC.*

The objective of this study was to determine if corn treated with foliar fungicide and ensiled as corn silage would increase milk production and efficiency in dairy cattle. This study utilized 64 Holstein cows with parity 2.53 ± 1.5, BW 653 ± 80 kg, and 161 ± 51 d in milk (DIM). Cows were blocked and randomly assigned to 1 of 4 treatments to be included in the total diet (35% of the DM as corn silage). Treatments were as follows: Control (CON), corn silage with no applications of a foliar fungicide, Treatment 1 (1×), corn silage received application of pyraclostrobin (PYR) foliar fungicide (Headline; BASF Corp.) at corn stage V5; treatment 2 (2×), corn received the same application as 1× and another application of a mixture of PYR and metconazole (MET; Headline AMP; BASF Corp.) at corn stage R1; and treatment 3 (3×), corn the same applications as 2× as well as third application of PYR and MET at R3. Corn was harvested at the 3/4 milk line stage of growth and ensiled for 200 d. The trial was conducted in 2 consecutive periods each consisting of 1 wk for adaptation (covariate) followed by 5 wk of measurements where cows received assigned treatments. Body weight, BCS, and lame scores were assessed weekly. Milk production, and DMI were measured daily. Milk samples for milk composition analysis were collected during wk 5. Blood samples were taken on d1 (covariate) and d 29 to assess blood metabolites. Data were analyzed using a MIXED procedure in SAS (v9.4). Dry matter intake was 23.78, 22.95, 19.54, and 21.33 kg for CON, 1×, 2× and 3×, respectively. There was a linear ($P = 0.08$) tendency for DMI. Milk yield (34.5, 34.5, 34.2, 34.4 kg/d) and milk components did not differ ($P > 0.05$) among treatments. However, there were trends for increased FCM/DMI (1.65 vs. 1.47. $P = 0.08$) and ECM/DMI (1.60 vs. 1.43. $P = 0.09$) for cows fed corn silage with fungicide compared with CON ($P < 0.09$). Serum glucose was lower for cows receiving treated silage with fungicide when compared with CON (51.1 vs. 63.4 mg/dL, $P < 0.01$). In conclusion, cows receiving corn silage treated with foliar fungicide had increased feed conversion when compared with CON.

Key Words: milk yield, corn silage, fungicide

W363 Increased plasma NEFA lowers the ratio of sphingomyelin to ceramide in Holstein cows. J. Eduardo Rico[1], Luciano S. Caixeta[2], Yves R. Boisclair[2], and Joseph W. McFadden*[1], *[1]West Virginia University, Morgantown, WV, [2]Cornell University, Ithaca, NY.*

Saturated fatty acids can antagonize insulin sensitivity in rodents by increasing ceramide (Cer) levels in liver and plasma. Cer can be generated via de novo synthesis, sphingomyelin (SM) hydrolysis, or sphingolipid recycling. In turn, Cer can be glycosylated to form monohexosylceramide (GlcCer) and lactosylceramide (LacCer). Analyzing the ratio between sphingolipids, within identical acyl chain length and saturation, can be a means to understand Cer metabolism. Our objective was to evaluate whether an increase in plasma NEFA can modify the sphingolipid ratio in cows. Six nonpregnant, nonlactating Holstein dairy cows (682 kg ± 22), were used in a crossover design with treatments consisting of i.v. infusion (100 ml/h) of either saline (control) or triacylglycerol (TG) emulsion (Intralipid 20%; Frasenius Kabi) for 16 consecutive hours. The feeding level was set at 120% of estimated energy requirement. Blood was collected at routine intervals. LC/MS was used to profile sphingolipids in plasma. Log-transformed data were analyzed using a mixed model with repeated measures. Nonparametric correlations were analyzed. TG infusion increased plasma NEFA by 454% at 3 h relative to control ($P < 0.01$) with no further increase at 16 h. Ratio of C16:0-SM to C16:0-Cer (C16:0 SM:Cer) decreased 9% by 3 h of TG infusion, relative to control ($P < 0.05$). C22:0, C22:1, and C24:0 SM:Cer decreased 27, 52, and 17% by 16 h of TG infusion, relative to control ($P < 0.01$). TG infusion did not modify C16:0-dihydro SM:Cer; however, TG-infusion lowered the ratio of C18:0-SM to C18:0-dihydro-SM ($P < 0.01$). C16:0 and C18:0 Cer:GlcCer decreased 24 and 13% by 16 h of TG infusion, relative to control ($P < 0.01$). In contrast, C24:0 Cer:GlcCer and C26:0 Cer:GlcCer increased with TG infusion, relative to control ($P < 0.05$). C18:0, C22:0, and C24:1 GlcCer:LacCer increased in TG-infused cows, relative to control ($P < 0.01$). C16:0 Cer:GlcCer and C24:0 SM:Cer were negatively correlated with NEFA, and C24:0 Cer:GlcCer was positively correlated with NEFA ($P < 0.01$). Increasing plasma NEFA lowers the ratio of SM to Cer in dairy cows, consistent with a shift in metabolism toward Cer accumulation.

Key Words: ceramide, dairy cow, insulin resistance

W364 Effects of clay (EcoMix) after an aflatoxin challenge on milk production and blood metabolism of Holstein cows. Saige A. Sulzberger*[1], Sergey Melnichenko[2], and Felipe C. Cardoso[1], *[1]University of Illinois, Urbana, IL, [2]United Minerals Group, Kyviv, Ukraine.*

Oral supplementation of clay to dairy cattle has been reported to reduce toxicity of aflatoxin in contaminated feed. The objective of this study was to determine the effects of 3 levels of dietary clay (EcoMix) supplementation after an aflatoxin challenge. Ten multiparous rumen-cannulated Holstein cows (BW = 669 ± 20kg, 146 ± 69 DIM), were assigned to 1 of 5 treatments in a completely randomized replicated 5 × 5 Latin square design. Periods consisted of a 14-d (d 1–14) adaptation period followed by a 3-d aflatoxin challenge (d 14–16; 100 µg of AFB1/kg of diet DM administered intra-ruminally). Cows were sampled daily during the last week of the period (d 14–21). Treatments were: POS, no EcoMix plus aflatoxin challenge; 0.5%, 1%, 2%, percentage of dietary DMI as EcoMix; and CON, no EcoMix and no aflatoxin challenge. Statistical analysis was performed using the MIXED procedure of SAS. Two contrasts CONT1 (POS vs. CON), CONT2 (POS vs. average of 0.5%, 1%, and 2%) were compared along with the linear and quadratic treatment effects. Milk samples were collected daily and tested with AFM_1 snap test (SNP; IDEXX, Inc.). Cows in CON had no positive SNP tests, while cows in POS had 14.2 ± 0.44 ($P < 0.001$, CONT2) positive SNP tests. Cows supplemented with EcoMix had lower number of positive SNP tests (0.5% = 13.9, 1% = 13.1, 2% = 12.4, SEM = 0.4, $P = 0.04$) than cows in POS (14.2, CONT2). Cows supplemented with EcoMix through the challenge had lower 3.5% FCM (0.5% = 38.2 kg, 1% = 39.3 kg, 2% = 38.4kg, SEM = 1.8, $P = 0.06$), ECM (0.5% = 37.1 kg, 1% = 37.1 kg, 2% = 37.1 kg, SEM = 1.6, $P = 0.05$, and Fat kg/d (0.5% = 1.36 kg, 1% = 1.43 kg, 2% = 1.40 kg, SEM = 0.09, $P = 0.09$) than cows in POS (41.3 kg, 39.6 kg, 1.5 kg, respectively, CONT2). Serum cholesterol and creatine phosphokinase concentrations were higher for cows fed EcoMix (232.6 mg/dL ± 8.3, $P = 0.08$, 140.1 U/L ± 9.3, $P = 0.04$, respectively) than cows in POS (227.4 mg/dL ± 8.4, 126.3 U/L ± 9.3, respectively). In conclusion, oral supplementation of EcoMix decreased the total number of positive SNP tests after an aflatoxin challenge and seems to work as a flow agent for aflatoxin contamination in dairy cattle.

Key Words: clay, aflatoxin, milk yield

W365 Discrepancies in milk urea nitrogen analysis among milk processing laboratories in Pennsylvania. Holley L. Weeks* and Alexander N. Hristov, *Department of Animal Science, The Pennsylvania State University, University Park, PA.*

Milk urea-N is used by dairy nutritionists and producers to monitor dietary protein intake and is indicative of N utilization in lactating dairy cows. Two experiments were conducted to explore discrepancies in MUN results among 3 laboratories and one experiment to evaluate the effect of 2-bromo-2-nitropropane-1,3-diol (bronopol) on MUN. In Experiment 1, 10 replicates of bulk tank milk samples, collected from the Pennsylvania State University's Dairy Center over 5 consecutive days, were sent to 3 milk processing laboratories located in Pennsylvania. Average MUN differed ($P \leq 0.05$) between Laboratory A (Foss 4000; 14.9 ± 0.40 mg/dL), Laboratory B (Foss FT + 600; 6.5 ± 0.17 mg/dL), and Laboratory C (Foss 6000; 7.4 ± 0.36 mg/dL). In Experiment 2, milk samples were spiked with urea at 0, 17.2, 34.2, and 51.5 mg/dL of milk. Two 35-mL samples from each urea level were sent to the 3 laboratories used in Exp. 1. Average analyzed MUN was higher than expected (calculated for each laboratory based on the control; 0 mg added urea): for Laboratory A (23.2 vs. 21.0 mg/dL; $P = 0.001$), Laboratory B (18.0 vs. 13.3 mg/dL; $P < 0.001$), and Laboratory C (20.6 vs. 15.2 mg/dL; $P < 0.001$). In Experiment 3, replicated milk samples were preserved with 0 to 0.30 g bronopol/35 mL milk (at 0.02 g increments) and submitted to one milk processing laboratory that analyzed MUN using 2 methods. Samples with increasing amounts of bronopol ranged in MUN concentration from 7.7 to 11.9 ± 0.27 mg/dL (linear increase due to bronopol; $P < 0.001$) and from 9.0 to 9.3 ± 0.05 mg/dL ($P = 0.06$) when analyzed on Foss 4000 or CL10, respectively. In this experiment, bronopol was calculated to contribute 7.9% of the total N in milk for the average milk vial (0.21 ± 0.003 g bronopol/ 35 mL milk) when milk protein was 3.01% and MUN was 8.5 mg/dL. In summary, MUN concentrations vary due to analytical procedures used by the milk processing laboratories. Amount of bronopol used to preserve the milk sample may also have an effect on MUN. Thus, it is important to maintain consistency in milk sample preservation and analysis to ensure precision and accuracy of MUN results.

Key Words: milk analysis, milk urea-N, bronopol

W366 Plasma long-chain acylcarnitines are elevated in overweight dairy cows experiencing greater lipolysis and insulin resistance during late pregnancy. J. Eduardo Rico*, Rachel E. Cokeley, and Joseph W. McFadden, *West Virginia University, Morgantown, WV.*

Excess saturated fatty acids can impair mitochondrial β-oxidation in overweight monogastrics. In turn, long-chain acylcarnitines (LCAC) can accumulate in plasma, biomarkers for insulin resistance in humans. Our objective was to determine whether plasma LCAC are associated with changes in estimated insulin sensitivity in dairy cows. Our data included multiparous Holstein cows grouped according to BCS at d −30 prepartum: lean (BCS < 3.0; n = 10) or overweight (BCS > 4.0, n = 11; OVER), with blood collected at d −45, −30, −15, −7, and 4, relative to calving. Profiling of LCAC was achieved using LC/MS. Data were analyzed using a mixed model with repeated measures including the random effect of cow and the fixed effects of BCS and time. Nonparametric correlations were analyzed. We previously demonstrated that OVER had greater NEFA mobilization and lower insulin sensitivity at d −30, −15 and −7 prepartum ($P < 0.05$), relative to lean. LC/MS detected C14:0-, C16:0-, C18:0-, and C20:0-LCAC, representing 12, 31, 48, and 9% of total plasma LCAC, respectively. Concomitant with lipolysis, plasma C14:0-, C16:0-, C18:0, and C20:0-LCAC, and total LCAC increased ($P < 0.01$). Plasma C16:0- and C20:0-LCAC, and total LCAC levels were greater in OVER at d −7 ($P < 0.05$). Plasma C14:0- and C18:0-LCAC levels were higher in OVER ($P = 0.10$). A BCS × time interaction was observed, where OVER had greater plasma C18:0- and C20:0-LCAC levels at d −7 ($P = 0.06$ and $P < 0.05$, respectively). Plasma C14:0-, C16:0-, C18:0-, and C20:0-LCAC, and total LCAC were positively correlated with NEFA ($P < 0.01$). Utilizing previously acquired GC/MS data, circulating C16:0- and C18:0-LCAC were positively correlated with mobilized palmitic acid, stearic acid, and lipolysis marker glycerol ($P < 0.01$). Plasma C14:0-, C16:0-, C18:0, and C20:0-LCAC, and total LCAC were negatively correlated with insulin sensitivity ($P < 0.01$). Our data demonstrate greater plasma LCAC in insulin resistant, overweight periparturient dairy cows; however, the origin and involvement of LCAC in the progression of insulin resistance is unclear.

Key Words: acylcarnitine, insulin resistance, periparturient dairy cow

W367 Effects of the dose and viability of *Saccharomyces cerevisiae* yeast on the diversity of ruminal microbes as analyzed by Illumina MiSeq sequencing and qPCR.

Y. Jiang*[1], I. M. Ogunade[1], S. Qi[2], F. Owens[2], B. Smiley[2], W. Rutherford[2], C. Staples[1], and A. T. Adesogan[1], [1]*Department of Animal Science, University of Florida, Gainesville, FL,* [2]*DuPont Pioneer, Johnston, IA.*

The objective was to examine the effect of the dose and viability of *Saccharomyces cerevisiae* (SC) on the ruminal microbial population of lactating dairy cows. Four ruminally cannulated lactating cows (284 ± 18 DIM) were used in a study with a 4 × 4 Latin square design with four 21-d periods. Cows were fed a TMR supplemented with no SC (Control) or a low dose of live SC (5.7×10^7 cfu/day; LLY), a high dose of live SC (6.0×10^8 cfu/day), or a high dose of killed SC (6.0×10^8 cfu/day before heating at 80°C). Ruminal fluid collected 0, 2, 4, 6, 8 and 10 h after the morning feeding on d 21 was strained through cheesecloth to obtain liquid (LF) and solid (SF) fractions. Microbial diversity was examined by high throughput Illumina MiSeq sequencing of the V4 region of the 16S rRNA gene. Populations of select ruminal bacteria and protozoa were also quantified by qPCR. Data were analyzed using the GLIMMIX procedure of SAS. In the SF and LF, *Prevotella* was the most abundant genus (23.8 and 49.1%) followed by *Fibrobacter* (10.7 and 1.5%) and *Succinivibrionaceae* (7.1 and 4.6%), respectively. Supplemental LLY increased the prevalence of *Butyrivibrio* ($P = 0.11$) and *Ruminococcus* ($P = 0.04$) in the LF. Supplementing with live instead of dead SC increased the prevalence of *Ruminococcus* in the LF and SF ($P \leq 0.05$). Supplemental killed SC decreased the prevalence of *Lachnospiraceae* ($P = 0.06$) and *Coprococcus* ($P = 0.13$) in the SF and increased those of *Ruminobacter* and *Porphyromonadaeae* in the SF and LF ($P \leq 0.12$, respectively). The qPCR results showed that in the SF, supplementing with LLY or with live instead of killed SC increased the prevalence of *F. succinogenes* ($P = 0.14$ and 0.04, respectively). Supplemental killed SC decreased the prevalence of protozoa ($P = 0.05$) and *B. fibrosolvens* ($P = 0.14$). In the LF, supplemental LLY decreased the prevalence of *R. albus* ($P = 0.12$) and increased that of *S. ruminantium* ($P = 0.14$). Unlike the high dose of live or killed SC, feeding the low SC dose or live instead of killed SC increased the prevalence of fiber-degrading bacteria.

Key Words: yeast, rumen microbes, MiSeq

W368 Effects of direct-fed *Bacillus pumilus* 8G-134 during the transition period on health of Holstein cows.

Shaoyu Luan[1], Elizabeth Galbraith[2], Megan Duersteler[2], and Felipe C. Cardoso*[1], [1]*University of Illinois, Urbana, IL,* [2]*Dupont Nutrition and Health, Waukesha, WI.*

The objective of this study was to evaluate the effects of a direct-fed microbials (DFM; *Bacillus pumilus* 8G-134) fed during the transition period on health of Holstein cows. Forty-three multiparous cows were fed a total mixed ration and assigned to 2 treatments in a randomized completely block design. Cows in the direct-fed microbial treatment (DFMt, n = 21) received 5.0×10^9 cfu of *B. pumilus* direct-fed microbial in 28g of maltodextrin carrier, whereas cows in the control treatment (CON, n = 22) received 28g of maltodextrin carrier alone. Treatments were top-dressed daily. Treatments were applied from 21 d before calving to 154 d after calving. Blood samples were collected on d 5 and 14 after calving. Cows that had nonesterified fatty acids (NEFA) serum concentrations higher than 0.7 mEq/L were classified as high (HNEFA). Cows that had blood β-hydroxybutyrate (BHBA) concentrations higher than 1.2 mmol/L were classified as experiencing sub-clinical ketosis (SCK). Cows that had serum haptoglobin concentrations higher than 20 µg/mL were classified as positive (POS). The immunoglobulins, IgA, IgG, and IgM were quantified in milk collected during the first week after calving and serum. Statistical analysis was performed using the MIXED, GLIMMIX and FREQ procedures of SAS. Cows on CON tended to have greater odds (OR = 3.55; $P = 0.09$) of being classified as POS than CON cows on d 14. Treatment DFMt had higher (584 ± 34 µg/mL; $P = 0.03$) IgA concentrations in milk than CON (478 ± 35 µg/mL) cows on the first week after calving. Cows on CON tended to have greater odds of being classified as HNEFA than DFMt cows on d 14 (OR = 3.21; $P = 0.07$). Cows on CON tended to have greater odds of being classified SCK than DFMt cows on d 5 (OR = 3.85; $P = 0.06$). Cows on CON tended to have higher odds for lower (<2) FS than DFMt cows (OR = 1.03; $P = 0.08$). In conclusion, cows receiving DFMt tended to have lower incidence of SCK and to have higher immunity than cows receiving CON. Therefore, supplementation with DFMt seems to contribute for a sound transition period for dairy cows.

Key Words: transition period, direct-fed microbial, immunity

W369 Bacterial communities in rumen fluid from lactating Holstein cows from Washington dairies.

Elizabeth D. Benda*[1], Nicola F. Beatty[1], Janet E. Williams[1], Matthew L. Settles[1], John P. McNamara[2], and Mark A. McGuire[1], [1]*University of Idaho, Moscow, ID,* [2]*Washington State University, Pullman, WA.*

The rumen serves as a fermentation tank for bacteria to break down nutrients from feed for the benefit of the cow. Culture-dependent methods have identified the most prevalent genera as *Ruminococcus, Fibrobacter, Butyrivibrio,* and *Prevotella*. The objective of the study was to determine if the bacterial community in rumen fluid differed within a herd or across dairies within a given geographic region as assessed by a culture-independent method. In this study, rumen fluid samples from 82 cows across 4 different dairies in Washington were collected via stomach tube and filtered through cheesecloth. Cows within a herd were in the same pen and fed the same ration. DNA was extracted using the Qiagen QIAamp DNA Stool Mini Kit, amplified via PCR with primers targeting the V1-V3 hypervariable region of the 16S rRNA, and amplicons sequenced using an Illumina Miseq v3 paired-end 300-bp protocol for 600 cycles. Sequence reads were processed using the custom python application dbcAmplicons. Sequencing data at different taxonomic levels were categorized by percent relative abundance for each cow. The least squares means of the top 15 genera were computed and compared among dairies to look at bacterial population differences using Generalized Linearized Mixed Models (SAS v9.3). Significance was declared at $P \leq 0.05$. Across all cows, *Prevotella* was the bacterial genus with the greatest relative abundance (44.8 ± 1.06), followed by *Hallella* (3.29 ± 0.11), *Treponema* (2.94 ± 0.15) and *Paraprevotella* (1.98 ± 0.06). Within a herd, the bacterial community of rumen fluid was similar among cows. However, each of the top 15 genera differed in abundance across dairies. These results suggest that cattle within a specific dairy have similar bacterial communities, but bacterial populations can differ across different dairies even within the same geographical region. Further work is necessary to determine the cause of the different levels of abundance of the top genera among dairies.

Key Words: rumen, microbial communities, dairy

W370 Effects cobalt source on rate and extent of DM and NDF degradation *in vitro*.

Claudio F. Vargas-Rodriguez*[1], Abigail J. Carpenter[1], Jeffrey DeFrain[2], and Barry Bradford[1], [1]*Kansas State University, Manhattan, KS,* [2]*Zinpro Corp., Eden Prairie, MN.*

Positive effects on fiber degradation have been observed when supplemental cobalt (Co) was added to diets for ruminants, but dose-dependent effects of different Co sources on ruminal fermentation have not been tested. Our objective was to determine the effects of different sources and concentrations of Co on in vitro fermentation rate, fermentation end products, and DM and NDF disappearance. Ruminal fluid was collected from heifers fed a wheat straw based diet (49%) with no supplemental Co, and fermentation substrate (46% NFC, 25% NDF, 22% CP) contained no measurable Co. Different inclusion levels (0.0, 0.1, 0.5, 1.0, 2.0, 5.0, 10.0, and 15.0 ppm) of Co glucoheptonate (S1) and Co carbonate (S2) were tested in vitro during study 1. Gas production was recorded every 15 min, and after 24 h, pH was measured and contents of each flask were used to determine NDF and DM disappearance (NDFD and DMD). Experiment 2 evaluated the effects of Co (S1 and S2 at 0, 0.33, 1, 3, and 9 ppm) on gas production, ruminal VFA and NH_3 concentration. In both studies, each treatment combination had 4 replicates and samples were incubated for 24 h; asymptotic gas production curves were modeled with NLIN of SAS using the Gauss-Newton fit method. Gas production kinetic values and all other data were modeled to assess the effects of Co concentration, source, and their interaction. Differences were declared at $P < 0.05$ and tendencies at $P < 0.10$. NDFD was increased by S1 at concentrations between 0.1 and 1.0 ppm (55.0 ± 1.8%), but decreased at 15 ppm (30.9%). S2 had no effect on NDFD across the concentrations tested. Moderate levels of Co tended to increase DMD, and S1 significantly increased this parameter compared with S2 (63.5 vs. 61.1% ± 1.6%), but interactions were not detected. Effects of Co source on gas production kinetics and pH change were inconsistent between experiments, largely because of dramatic negative effects at 15 ppm. Propionate concentration increased by S1 at 1.0 ppm, but not by S2 (dose by source interaction). Doses of 9 ppm Co decreased branched-chain VFA and NH_3 concentrations after 24-h incubation. In summary, Co does affect ruminal fermentation; however, concentrations of 9 ppm and greater may be inhibitory, particularly with a highly soluble source of Co.

Key Words: mineral, fermentation, ruminant

W371 Effects of long-term omega 6 fatty acid supplementation on blood metabolites of Holstein cows during transition period and early lactation.

Rodrigo Gardinal*[1,3], Gustavo Delfino Calomeni[1], Filipe Zanferari[1], Caio Seiti Takiya[1], Thiago Henrique Aniballi Vendramini[1], Jose Esler Freitas Junior[2], Jose Eduardo Portela Santos[3], and Francisco Palma Renno[1], [1]*University of Sao Paulo, Sao Paulo, SP, Brazil,* [2]*Federal University of Bahia, Salvador, BA, Brazil,* [3]*University of Florida, Gainesville, FL.*

The objective of this study was determine the effects of feeding omega 6 (ω6) fatty acids (FA) during an extended period of dry period until early lactation on blood metabolites of dairy cows. Thirty Holstein cows were used in 4 experimental groups in randomized design. The animals were randomly distributed to the following diets: Groups −90, −60, −30 and 0, supplemented with ω6 FA source (12% of whole raw soybeans – WRS, on DM basis) 90,60 and 30 d before expected calving date and from the calving date (0) until 90 d in milk. Diets were formulated according to NRC (2001) recommendations. Ether extract (EE) averaged 4.8 and 2.8% for diets containing WRS and without WRS respectively. The blood samples were taken on days −49, −35, −21, −14 and −7 of expected calving date, at calving and on d 7, 14, 21, 35 and 70 of lactation. Blood concentrations of glucose (GLU), total cholesterol (CHOL), very low density lipoprotein (VLDL), low density lipoprotein (LDL), high density lipoprotein (HDL), triglycerides (TRI), total protein (TP), urea, gamma-glutamyl transferase (GGT) and aspartate aminotransferase (AST) were measured. Data were subject to PROC MIXED of SAS 9.3, diet were considered as fixed effect and time, interaction between diet and time, animal and residual error as random effect. The data were analyzed using polynomial regression using PROC REG of SAS 9.3. Linear decrease ($P < 0.05$) in GGT concentration and linear increase of TP and CHOL concentration were observed as the length of ω6 FA supplementation was longer. Quadratic effect ($P < 0.05$) was observed in AST blood concentration and the highest value was presented by cows of group −30 (86.4 U/L). Interaction effect ($P < 0.05$) was detected in GLU, TRI and VLDL blood concentration. The higher length of ω6 FA supplementation during pre-partum may improve hepatic metabolism of cows during transition period and early lactation.

Key Words: dry period, linoleic acid, whole raw soybean

W372 Organic trace minerals during the transition period: 1. Supplementing Zn, Mn and Cu from AvailaMins and Co from CoPro improves postpartal performance of dairy cows.

J. S. Osorio*[1], E. Trevisi[2], J. K. Drackley[1], M. T. Socha[3], and J. J. Loor[1], [1]*University of Illinois at Urbana-Champaign, Urbana, IL,* [2]*Università Cattolica del Sacro Cuore, Piacenza, Italy,* [3]*Zinpro Corporation, Eden Prairie, MN.*

Beneficial effects of supplementing organic trace minerals (AAC) to lactating dairy cows have been reported. However, there are few studies evaluating AAC supplementation during the transition period. Thirty-seven Holstein dairy cows were enrolled at 60 d prior dry-off (~110 d before calving) and remained on experiment until 30 d in milk (DIM). Cows were offered a common diet supplemented entirely with inorganic trace minerals (INO) from −110 to −30 d before calving. Cows received a common prepartal (1.5 Mcal/kg DM, 15% CP) and postpartal (1.76 Mcal/kg DM, 18% CP) diet. Both diets were partially supplemented with an INO mix of Zn, Mn, and Cu to supply 35, 45, and 6 ppm, respectively, of the total diet DM. Cows were assigned to treatments in a randomized complete block design, receiving an oral bolus with a mix of INO (n = 21) or AAC (n = 16) containing Zn, Mn, Cu, and Co to achieve 75, 65, 11, and 1 ppm, respectively, in total diet DM. Inorganic trace minerals were provided in sulfate form and AAC were supplied via AvailaZn, AvailaMn, AvailaCu, and CoPro (Zinpro Corp., Eden Prairie, MN). Blood glucose and NEFA were measured at −30, −14, 3, 15, and 30 DIM. Liver biopsies were harvested at −30, −15, 10, and 30 DIM. BHBA was measured via Precision Xtra every other day from 1 to 15 d postpartum. Data were analyzed using the MIXED procedure of SAS. Prepartal DMI was lower ($P = 0.06$) in AAC cows. In contrast, a tendency ($P = 0.11$) was detected for diet by time (D × T) interaction that resulted in ca. 2 kg/d greater postpartal DMI in AAC. Milk and milk protein yield had a D × T ($P < 0.05$), because AAC cows produced ca. 3.3 kg/d more milk and 0.14 kg/d more protein during the first 30 DIM. Although blood glucose, NEFA, and liver triacylglycerol were not affected ($P > 0.56$) by diet, the Precision Xtra BHBA was lower ($P = 0.02$) in AAC than INO (1.44 vs 2.18 mmol/L). The positive response in milk yield and milk protein observed in AAC cows might be partly explained by the beneficial effect of AAC on postpartal DMI. Greater BHBA in cows fed INO suggests a mild-to-severe state of ketosis.

Key Words: metabolite, trace mineral, transition cow

W373 Evolution of milk freezing point depression during the year in Holstein and Normande dairy cows. .

Catherine Hurtaud*[1], Elise Vanbergue[1,2], Sophie Lemosquet[1], Ségolène Colette[3], Yves Gallard[3], and Luc Delaby[1], *[1]INRA-Agrocampus Ouest UMR1348 Pegase, Saint-Gilles, France, [2]Institut de l'Elevage, F-35650 Le Rheu, France, [3]INRA, Domaine du Pin-au-Haras, Exmes, France.*

Milk freezing point depression (FPD) content is regarded as being relatively stable in cows' milk during lactation. Since the 30s, its measurement is a means to determine if water has been added to the milk. However, results from commercial herds have suggested that changes in milk FPD occurred during the year. The reason of those variations is unclear. However, dairy cow feeding might be an explanation. The objective of this experiment was to compare the characteristics of milk (especially milk FPD measured by MIR spectrometry) based on low input grass-based system compared with corn silage-based system, across 2 breeds of dairy cows (Holstein vs. Normande). Sixty-four dairy cows were observed from calving to drying off. Two feeding systems were compared. The Intensive system was designed to maximize individual performance, with a high energy diet (in winter, corn silage with 30% concentrate; in spring, summer and autumn periods, pasture with 4 kg/d of concentrate supplemented with corn silage from July). The Grass system was designed to decrease inputs (in winter, conserved grass with no concentrate; in spring, summer and autumn, pasture with no concentrate). The experimental design was a continuous design. Data were analyzed by using SAS mixed procedure. There was no significant effect of breed and feeding system on milk FPD. There was a significant effect of month of sampling and month of lactation. Milk FPD did not change from calving to 7th month of lactation. After that date, it largely decreased. These effects could be related to the high temperature in summer, specific feeding (grazing), or restricted access conditions for watering. There was also a significant effect of rank of lactation. FPD was higher for multiparous cows. This difference could be due to the opening of mammary tight junctions and a different repartition of ions and lactose on both sides of the epithelial barrier. Surprisingly FPD did not correlate with lactose content the most important osmotic agent in mammary epithelial cells. Some investigations have to be done to explain the mechanisms of FPD and its physiological variations.

Key Words: milk, dairy cow, freezing point depression

W374 Influence of calcified seaweed supplementation on rumen pH, digestive efficiency, and health in lactating dairy cows fed an acidosis inducing diet.

B. P. Molloy*[1], E. W. Neville[2], S. J. Taylor[1], A. W. Fahey[2], and F. J. Mulligan[2], *[1]Celtic Sea Minerals Ltd., Carrigaline, Cork, Ireland, [2]College of Food Science, Veterinary Medicine and Agriculture. University College Dublin, Dublin, Ireland.*

Subacute ruminal acidosis (SARA) is a significant problem on intensively managed dairy farms throughout the world. High producing dairy cows are unable to acquire sufficient nutrients from forage-based diets to meet their needs during early lactation. Therefore, forage based diets are often supplemented with high-energy starch-rich ingredients to meet their caloric demand. High consumption of rapidly fermentable ingredients can cause excessive acidification of the rumen decreasing fiber digestion and milk fat %, inducing rumenitis, laminitis, reduced reproductive performance and liver abscesses. The objective of this experiment was to evaluate the potential for 3 different treatments to prevent SARA and the associated decrease in digestive efficiency. A highly fermentable diet containing 380 g of starch and 300g of total dietary NDF was fed to 4 ruminally fistulated lactating dairy cows. The diet was composed from grass silage, corn silage and concentrates and fed at a 45:55 forage to concentrate ratio. The diets were either not supplemented (control) or supplemented with calcified seaweed (CS), calcified seaweed and marine magnesium oxide (CS + MMgO) or sodium bicarbonate (SB) 4 treatments. A range of parameters investigating the effect of supplementation on rumen physiology were analyzed including pH, volatile fatty acid production, fiber digestion, rate of passage, total-tract digestibility, milk yield and milk quality. Rumen pH was measured every 10 min over 3 d during each experimental period, 25.4% of control, 3.2% of CS, 2.8% of CS + MgO and 13.2% of SB readings were <5.5. All treatments maintained rumen pH above 5.5 for significantly longer ($P < 0.0001$, respectively) than the control. The CS and CS + MMgO were significantly more effective ($P < 0.0001$, $P < 0.000$, respectively) than the SB in maintaining rumen pH above 5.5 (min). Supplementing with CS or CS + MMgO has the potential to maintain rumen pH above 5.5 for a longer period of the day.

Key Words: acidosis, calcified seaweed, rumen

W375 Evaluation of an on-farm tool to estimate physically effective neutral detergent fiber of forages and total mixed rations.

Sarah E. Schuling*[1], Eric J. Staudinger[1], Jeff A. Rortvedt[1], Paul M. Windschitl[1], Greg L. Golombeski[1], and Kurt W. Cotanch[2], *[1]Hubbard Feeds Inc., Mankato, MN, [2]William H. Miner Agricultural Research Institute, Chazy, NY.*

The objective of this experiment was to evaluate the use of a 3 screen Penn State Particle Separator box (19.0-, 8.0-, and 4.0-mm screens; PSPS4mm) to estimate physically effective factor (pef) and physically effective neutral detergent fiber (peNDF) of forages and total mixed rations (TMR) using the Ro-Tap method as the gold standard. Samples of corn silage (CS; n = 21), alfalfa silage (AS; n = 21), and TMR (n = 20) were collected from 20 Midwest dairy farms in summer/fall 2014. Four gallons of each sample were collected and mixed thoroughly. Samples were split and analyzed for pef using PSPS4mm and Ro-Tap with standard shaking methods. Sample nutrient composition was determined at Dairyland labs (Arcadia, WI). The pef was calculated as percentage of sample retained above 4.0-mm and 1.18-mm screens for PSPS4mm and Ro-Tap, respectively. The peNDF (%DM) of each sample was calculated as pef x NDF. Dry matter intake, milk yield, and milk protein and fat content were recorded for each herd. The REG procedure of SAS was used to determine the relationship between pef and peNDF estimated using PSPS4mm and Ro-Tap. The Stepwise Selection procedure was used to determine variables that affect herd milk components. The PSPS4mm was a good predictor of pef and peNDF in TMR and forages ($R^2 = 0.93$ and 0.98; slope = 0.86 and 0.91, respectively). For the CS, AS, and TMR samples, average pef estimated with Ro-Tap was (mean ± SD) 87.4 ± 3.99, 83.5 ± 4.34, and 64.3 ± 6.24, respectively, and average pef estimated with PSPS4mm was (mean ± SD) 88.4 ± 4.58, 87.6 ± 2.92, and 64.2 ± 6.35, respectively. Significant variables for predicting herd milk fat content were pef, concentrate intake, and milk yield (model $R^2 = 0.55$). Significant variables for predicting milk protein content were pef and forage intake (model $R^2 = 0.42$). The PSPS4mm is a useful tool to estimate pef and peNDF of forages and TMR. The pef within and across sample type varied, so estimating pef of individual samples on-farm will allow for more precise formulation of ration peNDF, which affects herd milk components.

Key Words: physically effective NDF, Penn State Particle Separator, milk component

W376 The effects of choice feeding during preweaning period on preweaning and postweaning growth performance of dairy calves.

Mohammad Wakil Hassani and Murat Gorgulu*, *Cukurova University Agriculture Faculty Department of Animal Science, Adana, Turkey.*

The aim of the study was to investigate the effects of choice feeding in preweaning period on growing performance of calf performance pre and postweaning period. Twenty-eight male and 28 female Holstein calves were used to test 2 feeding systems (TMR, total mixed ration, containing 10% alfalfa hay and choice feeding) and 2 sex (male and female) in a factorial arrangement. Before weaning TMR calves were fed with TMR containing 90% calf starter and 10% alfalfa hay and after weaning all calves were fed with the same TMR containing 50% calf grower and 50% alfalfa hay. Choice fed calves were fed with feed ingredients in TMR ad libitum and simultaneously. The choice fed calves before weaning preferred the diet containing lower alfalfa (10% vs. 5.78%, $P < 0.05$) and barley (52.29% vs. 15.87%, $P < 0.05$), and higher wheat bran (17.28% vs. 30.07%, $P < 0.05$) and SBM (17.73 vs. 45.39%, $P < 0.05$). Sex had no significant effects on diet preferences ($P > 0.05$). Choice feeding increased feed and nutrient intake (protein and fiber) and daily gain significantly ($P < 0.05$). After weaning, sex and feeding system during preweaning period had no effects on any parameters investigated ($P > 0.05$). But sex and feeding system interaction had significant effects on daily gain, feed and nutrient intakes ($P < 0.05$). The male calves fed TMR before weaning consumed more feed and nutrients and had higher daily gain than females but, choice fed calves in both sex had similar daily gain, feed and nutrient intake after weaning. When overall performance were evaluated, male calves had higher daily gain than females ($P < 0.05$). Sex × feeding system interaction had significant effects on feed and nutrient intake ($P < 0.05$). The male calves fed with TMR consumed more feed and nutrients than the females ones but this differences disappeared in choice feeding group. In conclusion, the results revealed that choice feeding may improve growth performance of calves by increasing protein intake before weaning and this effect may disappear after weaning. The female calve gave better response to choice feeding in respect to feed intake. This work was supported by Research Fund of the Cukurova University.

Key Words: choice feeding, calf, feeding system

W377 Effects of day of gestation and feeding regimen in Holstein × Gyr cows on apparent total-tract digestibility, nitrogen balance, and fat deposition.

Polyana P. Rotta*[1,2], Sebastiao C. Valadares Filho[1], Terry E. Engle[2], Luiz Fernando Costa e Silva[1,2], Marcos I. Marcondes[1], Fernanda S. Machado[3], Tathyane R. S. Gionbelli[1], Breno C. Silva[1], and Marcos V. C. Pacheco[1], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil [2]Colorado State University, Fort Collins, CO, [3]Embrapa Gado de Leite, Juiz de Fora, Minas Gerais, Brazil.*

This study investigated how feeding regimen (FR) alters apparent total-tract digestibility, performance, N balance, excretion of purine derivatives, and fat deposition in Holstein × Gyr cows at different days of gestation (DG). Forty-four pregnant multiparous Holstein × Gyr cows with an average initial body weight of 480 ± 10.1 kg and an initial age of 5 ± 0.5 yr old were allocated to 1 of 2 FR: ad libitum (AL; n = 20) and maintenance level (ML; n = 24). Maintenance level was considered to be 1.15% of body weight on a dry matter (DM) basis and met 100% of the energy requirements, whereas AL provided 190% of total net energy requirements. Data for hot and cold carcass dressing, fat deposition, average daily gain, empty body gain, and average daily gain without the gravid uterus were analyzed as a 4 × 2 factorial design. Intake, apparent total-tract digestibility, N balance, urinary concentration of urea, and purine derivatives data were analyzed as repeated measurements taken over the 28-d period. Pregnant cows were slaughtered on 4 different DG: 139, 199, 241, and 268 d. Overall, DM intake decreased as DG increased. This decrease observed in DM intake may be associated with the reduction in ruminal volume caused by the rapid increase in fetal size during late gestation. We observed an interaction for DM and organic matter apparent total-tract digestibility between FR and DG; at 150, 178, and 206 d of gestation, ML-fed cows had greater DM and organic matter apparent total-tract digestibility values than AL-fed cows. Rib fat thickness, mesentery, and kidney, pelvic, and heart fat were greater in AL-fed than in ML-fed cows at all DG, with the exception of rib fat thickness on d 139. Ad libitum-fed cows excreted more N in their feces and urine compared with ML-fed cows. Pregnant cows that were fed at maintenance had greater digestibility during some DG, excreted less N in feces and less N and urea in urine, and deposited less fat in the body. We therefore recommend ML (1.15% of body weight with 93% of roughage) as a FR for pregnant dry cows; however, during the last month of gestation, AL seems to be the most appropriate FR to avoid loss of body weight.

Key Words: ad libitum, maintenance, performance

W378 Effects of day of gestation and feeding regimen in Holstein × Gyr cows on maternal and fetal visceral organ mass.

Polyana P. Rotta*[1,2], Sebastiao C. Valadares Filho[1], Terry E. Engle[2], Luiz Fernando Costa e Silva[1,2], Marcos I. Marcondes[1], Mariana M. Campos[3], Tathyane R. S. Gionbelli[1], Luis H. R. Silva[1], Edilane C. Martins[1], Flavia A. S. Silva[1], and Faider A. C. Villadiego[1], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Colorado State University, Fort Collins, Colorado, [3]Embrapa Gado de Leite, Juiz de Fora, Minas Gerais, Brazil.*

This study investigated the influence of day of gestation (DG) and feeding regimens (FR) on maternal and fetal visceral organ mass in Holstein

× Gyr cows. Forty-four pregnant multiparous Holstein × Gyr cows with an average initial body weight of 480 ± 10.1 kg and an average initial age of 5 ± 0.5 yr were allocated to 1 of 2 FR: ad libitum (AL; n = 20) or maintenance level (ML; n = 24). Maintenance level was considered to be 1.15% of body weight (dry matter basis) and met 100% of the energy requirements; AL provided 190% of the total net energy requirements. Cows were individually fed a corn silage and concentrate-based diet composed of 93% roughage and 7% concentrate (dry matter basis) as a total mixed ration twice daily. Pregnant cows were slaughtered at 4 DG: 139 (n = 11), 199 (n = 11), 241 (n = 11), and 268 (n = 11) d, which was followed by necropsy. Mass of heart, liver, and gastrointestinal tract was greater in AL- than in ML-fed cows. Mammary gland mass was greater in AL- than in ML-fed cows, and the greatest mass was observed at 268 d of gestation. Feeding regimen did not influence fetal body weight in this study. The majority of the visceral organ masses were similar in fetuses from cows fed AL or ML. These data indicate that maternal feed restriction does not affect the development of most fetal organs or fetal development; however, some maternal organs are affected by the FR provided. Moreover, the negative effect on mammary gland mass caused by ML feeding will probably not affect the subsequent lactation because the crude protein concentration in the mammary gland increased with ML feeding. However, we suggest that the AL diet in pregnant dry cows should be provided with caution because the amount of fat in the mammary gland increased at 268 d of gestation.

Key Words: fetal development, gastrointestinal tract, mammary gland

W379 Dietary supplementation of palm- versus high-linoleic safflower oil to mid-lactating Holstein cows: Intake and milk fat yield.

Shahryar Kargar[1], Clayton M. Stoffel[2], Lou E. Armentano[3], and Francisco E. Contreras-Govea*[3], *[1]Department of Animal Sciences, College of Agriculture, Shiraz University, Shiraz, Iran, [2]Papillon Agricultural Co., Easton, MD, [3]Department of Dairy Science, University of Wisconsin-Madison, Madison, WI.*

Cows were fed diets supplemented with either palm oil (PO, rich in C16:0 and C18:1) or high-linoleic safflower oil (SO, rich in C18:2) at 1.5% of dietary DM. Sixty-four primiparous and multiparous, cows with an average of 100 ± 21.7 DIM, 48.6 ± 10.3 kg milk yield per d, and 657 ± 70.3 kg body weight at trial initiation were fed the 2 diets for 56 d, after a 2-week covariance period. Thirty-two primiparous and multiparous cows were assigned to one diet, and the other 32 cows to the other diet. The experimental design was a randomized complete block, blocking by parity. Cows were housed in a free-stall barn equipped with roughage intake control system gates (Insentec BV, Marknesse, the Netherlands), which recorded individual cow feed intake continuously. Milk yield was measured daily, and milk composition and cow's body weight were measured weekly. Data were analyzed as a randomized complete block design with diet, parity, week, and interactions as fixed effects, cow as random effect, and week as repeated measurement (SAS Institute, 2003). There was not difference in DMI (26.6 kg/d) and milk yield (46.5 kg/d) between the 2 diets ($P > 0.05$) but feeding PO instead of SO raised milk fat concentration (3.88 vs. 3.55%) and yield (1.79 vs. 1.65 kg/d) ($P < 0.05$), but milk protein yield tended ($P = 0.10$) to increase for PO (1.39 kg/d) than SO (1.36 kg/d). Feeding SO increased *trans*-C18:1 including *trans*-6/8, *trans*-9, *trans*-10, and *trans*-12. For cows fed PO vs. SO, yields of de novo (<16 carbons; 447 vs. 412 g/d) and preformed (>16 carbons; 701 vs. 662 g/d) fatty acids were no difference between the 2 diets. Yield of mixed origin fatty acids (C16:0 + C16:1) increased for cows fed PO (515 vs. 379 g/d), possibly due to less inhibition of endogenous synthesis of C16 when feeding less dietary C18:2; as well as providing more exogenous dietary C16 from palm oil. These results confirm the greater milk fat depressing effects of oils containing higher concentration of C18:2, as safflower has, relative to a combination of C18:1 and C16:0 as palm oil.

Key Words: palm oil, high-linoleic safflower oil, milk fat

W380 Short- and medium-term changes in glucose metabolism and insulin sensitivity of dairy calves offered different amounts of milk replacer early in life.

Cristina Yunta[1], Marta Terré[1], and Alex Bach*[2,1], *[1]Department of Ruminant Production, IRTA (Institut de Recerca i Tecnologia Agroalimentàries), Caldes de Montbui, Spain, [2]ICREA (Institució Catalana de Recerca i Estudis Avançats), Barcelona, Spain.*

The objective of the present study was to evaluate the consequences of 3 allowances of milk replacer (MR) during the first 2 mo of life on short- and medium-term glucose metabolism and insulin sensitivity (IS) of dairy replacement heifers. Forty-five newborn female Holstein calves (40.7 ± 4.94 kg) after receiving colostrum were randomly allocated to 4, 6, or 8 L/d of MR until 63 d of life (n = 15). A glucose tolerance test (GTT) was performed at 42, 86 and 300 d of life. Area under the curve for plasma insulin (IAUC), clearance rates of glucose (CRG) and insulin (CRI), insulin to glucose rate (ItoG), and IS were calculated. Data were analyzed using a mixed-effects model with repeated measures. There were no differences ($P = 0.67$) in CRG among treatments, although they decreased from 10.1 ± 0.55%/min at 42 d of age to 6.7 ± 0.56%/min at 300 d of age. Interestingly, CRI was greatest ($P < 0.05$) at 42 d of age, and calves fed 8 L/d had the greatest ($P < 0.05$) ICR throughout the study. Insulin release (measured as IAUC) after a GTT increased ($P < 0.005$) with age, and the increase observed between 42 and 300 d of life was more ($P < 0.05$) marked in calves that received 4 (from 1,000 ± 234.0 to 3,319 ± 242.7 µU/mL × 60 min) or 6 L/d (from 1,538 ± 226.1 to 3,887 ± 242.6 µU/mL × 60 min) than in those receiving 8 L/d (from 1,735 ± 226.1 to 2,940 ± 242.6 µU/mL × 60 min). The amount of MR offered had short- and medium-term effects on ItoG, with calves fed 4 and 6 L/d having lower ($P < 0.05$) values (145.2 ± 16.60 µU/mg) than calves fed 8 L/d (215.3 ± 16.02 µU/mg) independently of age. Insulin sensitivity tended ($P = 0.07$) to be lesser in calves fed 8 than in calves fed 4 or 6L/d (1.39 ± 0.04 vs 1.82 ± 0.05 mL/min x µU/mL per kg of BW, respectively). This difference was mainly due to a low IS of calves fed 8 L/d at 42 d, but as age increased, IS tended ($P = 0.06$) to become progressively similar among treatment groups. It is concluded that offering 4 L of MR twice daily elicits a decrease in IS and an increase in ItoG while animals are consuming MR, and the IS returns to normal values over time, but the increase in ItoG is maintained with age.

Key Words: calves, enhanced feeding, metabolism

W381 Energy expenditure in crossbred (Holstein x Gyr) calves differing in phenotypic residual feed intake.

Juliana Mergh Leão*[1], Fernanda Samarini Machado[2], Alexandre Lima Ferreira[2], Mariana Magalhães Campos[2], Juliana Campos Carneiro[3], Paulo Campos Martins[1], Juliana Aparecida Mello Lima[2], Thierry Ribeiro Tomich[2], Luiz Gustavo Ribeiro Pereira[2], Rayanne Soalheiro de Souza[1], and Sandra Gesteira Coelho[1], *[1]Universidade Federal de Minas Gerais-UFMG, Belo Horizonte, Minas Gerais, Brazil, [2]Embrapa Dairy Cattle, Juiz de Fora, Minas Gerais, Brazil, [3]Instituto de Ciências Agrárias da UFMG, Montes Claros, Minas Gerais, Brazil.*

The aim of this study was to evaluate the energy expenditure in crossbred Holstein-Gyr (F_1) calves at 50 d of age with different phenotypes for residual feed intake (RFI) by measuring the respiratory gas exchanges with a face-mask. Eighteen calves were housed in individual sand bed stalls in the experimental farm of Embrapa Dairy Cattle (Coronel Pacheco, Brazil). All animals were fed 6 L/d of whole milk (TS; 11.75%), divided in 2 equal meals (7 and 15h). Solid diet consisting of 95% of pelleted calf starter (88% DM; 20% CP and 3% Fat) and 5% Tifton 85 hay (81% DM; 13.4% CP; 72.8% NDF; 32.3% ADF), and water were provided ad libitum from the first day of life. Phenotypic RFI was calculated for each animal as the difference between actual dry matter intake (DMI) and expected DMI. Expected DMI was computed for each animal by regressing average daily DMI on conceptus-adjusted mean $BW^{0.75}$ and conceptus-adjusted ADG over a 60 d period. Twelve animals were ranked by RFI into low (efficient) and high (inefficient) groups. Oxygen consumption, carbon dioxide and methane production data were recorded in calves with 50 d age using Sable System (Sable Systems, Henderson, NV) attached to a facemask over a 2 d period, 3 h after morning milk supply, during 20 min. Heart rate (HR) was recorded during 20 min with Polar equine transmitter and monitor (RS800CX G3, Polar Electro Inc., Finland). Daily energy expenditure was calculated as heat production estimated from Brouwer equation (Brouwer, 1965). Methane production was not detected and urinary nitrogen was neglected in calculations. Data were analyzed as a completely randomized design by ANOVA using the GLM procedure of SAS software (version 9.4; SAS Institute Inc., Cary, NC). High RFI calves had DMI 12.39% higher ($P < 0.05$) than the low RFI group (1.07 and 0.941 Kg/d, respectively), but body weight was higher by 0.6% ($P < 0.05$) for the low RFI group. Heart rate did not differ between the groups. High RFI animals presented higher energy expenditure (177.64 kcal/kg of metabolic weight – MBW) than low RFI animals (144.40 kcal / kg of MBW).

Key Words: facemask, heat production, performance

W382 The effect of different energy and nitrogen sources on in vitro fiber digestion of high and low quality roughages.

Christian W. Cruywagen* and Mari Strauss, *Stellenbosch University, Stellenbosch, South Africa.*

Three energy sources (starch, sucrose and pectin) were used alone (without any N addition), or in combination with either soybean meal or urea as N source to investigate their effect on the in vitro digestion of NDF from alfalfa hay and wheat straw. The ratio of energy source to forage substrate was 50:50 on a hexose equivalent:NDF basis. Forage control treatments, without any energy or N sources added, were also included. The Goering/Van Soest incubation medium was used with slight modification; ammonium bicarbonate and tryptose were omitted (for the treatments with energy sources alone), or replaced by a similar amount of N from either soybean meal or urea. In the forage control treatments, the medium was used without modification. The trial was repeated in 6 runs. Samples were incubated at 39°C for 6 or 30 h. The substrate control data were analyzed per time according to a main effects ANOVA. For the factorial experiment, the data were also analyzed per time, but according to a 3 way factorial ANOVA with substrate, energy source and nitrogen source as factors. The 3 way interactions were interpreted with LSD multiple comparisons and Bonferroni tests. Significance was declared at $P < 0.05$. After 6 h of fermentation, NDF digestion was higher ($P < 0.01$) in alfalfa hay (13.6%) than in wheat straw (8.1%), but energy and nitrogen source had no effect in either forage. After 30 h of fermentation, sucrose with soybean meal (35.8%) did not differ from starch and soybean meal (29.0%), but compared with no supplementation (26.4%) it was the only combination that increased NDF digestion of alfalfa hay significantly ($P < 0.01$). In wheat straw, pectin with soybean meal (16.5%) did not differ from sucrose with soybean meal (12.4%), sucrose with urea (12.6%), pectin alone (15.0%) or starch alone (13.5%), but compared with no supplementation (11.5%) it was the only combination that increased wheat straw NDF digestion significantly ($P < 0.02$). In the current study, it appeared that sucrose and soybean meal was the best energy-nitrogen combination for alfalfa hay NDF digestion, whereas pectin and soybean meal was the best combination for wheat straw NDF digestion.

Key Words: NDF digestion, energy source, nitrogen source

W383 Milk fatty acid profile of dairy cows fed omega 3 and 6 fatty acid sources during transition period and early lactation.

Caio Seiti Takiya*[1], Jefferson Rodrigues Gandra[2], Lenita Carmago Verdurico[1], Rodolfo Daniel Mingoti[1], Rafael Villela Barletta[1], Jose Esler de Freitas Jr.[3], Gustavo Delfino Calomeni[1], Elmeson Ferreira de Jesus[1], Thiago Henrique Annibale Vendramini[1], and Francisco Palma Rennó[1], *[1]Departamento de Nutrição e Produção Animal da Universidade de São Paulo, Pirassununga, São Paulo, Brazil, [2]Faculdade de Ciências Agrárias da Universidade de Grande Dourados, Itahum, Mato Grosso do Sul, Brazil, [3]Departamento de Zootecnia da Universidade Federal da Bahia, Ondina, Bahia, Brazil.*

The objective of this study was to evaluate the effects of omega 3(n-3) and 6 (n-6) fatty acids (FA) supplementation on milk FA profile of dairy cows in early lactation. Forty 8 Holstein cows were divided randomly distributed into 4 groups to receive one of the diets: 1) Control (C, n = 12), without FA supplementation; 2) Flaxseed (WF, n = 12), addition of 60 and 80 g/kg diet DM of whole flaxseed (n-3 FA source) during pre and postpartum, respectively; 3) Soybean (WRS, n = 12), addition of 120 and 160 g/kg diet DM of whole raw soybean (n-6 FA source) during pre and postpartum, respectively; 4) Calcium salts of FA (CSFA, n = 12), addition of 24 and 32 g/kg diet DM of Megalac E (n-6 FA source) during pre and postpartum. The diets were offered from 35 d of expected calving date until 84 DIM and were formulated according to NRC (2001). Milk samples were collected weekly, proportionally of each milking (6h00 and 15h00) and proportionally of each cow yield. The extraction of lipids was made according to Feng et al. (2004) and methylated according to Kramer et al. (1997). Fatty acids were quantified by gas chromatography. Data were subjected to PROC MIXED of SAS (2004) using as fixed effect diet and weeks, and using as random effect interaction between week and diet and residual error. Orthogonal contrasts were performed (C vs WRS+CSFA+CSFA; WRS vs CSFA and WF vs WRS+CSFA). Fat supplemented diets increased total saturated FA compared with control ($P < 0.01$) and tended to increase C18 unsaturated FA ($P = 0.08$). Fatty acids with less than 16C were decreased with and FA with higher than 16Cwere increased FA supplementation. Whole raw soybeans increased C18:3, C18:2 and decreased C18:1 trans-11 FA compared with CSFA. However, SCFA presented higher unsaturated / saturated ratio than cows fed WRS. Increased cis-9, trans-11 FA was observed in cows fed WRS and CSFA when compared with WF. Whole flaxseed did not increase unsaturated FA in milk and SCFA increased the total unsaturated FA acids in milk. Supplementation of n-3 and n-6 FA altered milk fatty acid profile of early lactating cows.

Key Words: calcium salts of fatty acid, flaxseed, soybean

W384 The effect of feeding nucleotides on milk production, reproductive performance and immunity in lactating Holstein dairy cows.

Maria Rodriguez-Prado[1], Elisabet Borda*[2], Miquel Nofrarias[3], Carlos Sanchez[4], and Sergio Calsamiglia[1], *[1]Animal Nutrition and Welfare Service, Universitat Autonoma de Barcelona, Bellaterra, Spain, [2]R&D Animal Nutrition, Bioiberica SA, Palafolls, Spain, [3]CReSA-IRTA, Bellaterra Spain, [4]Tauste Ganadera, Tauste, Spain.*

Preliminary evidence suggests that nucleotide feeding improves fertility in dairy cows, most likely mediated by an improvement in general and (or) local immunity of the reproductive tract. The objective of this research was to determine the effect of supplementing nucleotides on dairy cow milk production, reproductive performance and immunity. Two hundred and 60 adult (≥2 lactations) Holstein dairy cows (87 d in milk) were divided in 2 groups and fed a standard diet (40% forage, 60% concentrate) without (CONTROL) or with nucleotides supplement (NUCLEOFORCE COWS, Biobierica S.A.) included at 4 g/cow/day during a period of 7 mo (May through December, 2014). Milk production (daily) and composition (monthly) were measured throughout the experimental period, and days from calving to first insemination and calving to pregnancy recorded. All cows were re-vaccinated against clostridia after 6 weeks in treatment. Serum IgG (n = 160) were determine immediately before and 8 weeks after vaccination, and mucus from the vagina (n = 34) was collected on the day of insemination at least 6 weeks after vaccination to measure IgA concentrations. Data were analyzed with PROC GLM of SAS and differences declared at $P < 0.05$. There were no differences ($P > 0.10$) in milk production (42.8 kg/d), milk fat content (2.85%) and yield (1.23 kg/d), milk protein content (3.13%) and yield (1.34 kg/d) or somatic cell counts (387.000 counts/mL) between treatments. However, the ratio pre-vaccination vs. post-vaccination serum IgG tended to be higher ($P < 0.08$) in the nucleotides supplementation (1.04) compared with CONTROL (0.93) treatment. Concentrations of IgA in vaginal mucus were higher ($P < 0.05$) in nucleotides supplementation compared with CONTROL (2274 vs. 2078 ng/mL) treatment. Results indicate that the supplementation with nucleotides improved the indicators of general and reproductive tract immunity in dairy.

Key Words: immunity, nucleotide, dairy cow

W385 Evaluation of a proprietary blend of essential oil and cobalt on a commercial dairy.

Olivia Kuester* and David Casper, *South Dakota State University, Brookings, SD.*

An 18 week field trial was conducted on a commercial dairy in southwest Minnesota equipped with 2 Lely robotic milking units. This study was designed to evaluate the response of feeding a proprietary essential oil and cobalt product (EOC) on the lactational performance and nutrient digestibility of lactating Holstein dairy cows. Cows were divided between 2 pens (57 ± 2 cows and 59 ± 3 cows for treatment [EOC] and control [C] pens, respectively), based on cow parity (2.65 ± 1.52 and 2.33 ± 1.20), days in milk (DIM) (184 ± 103 and 154 ± 94.2), and milk production (35.4 ± 11.3 kg/d and 36.9 ± 11.3 kg/d) before study initiation. Cows were fed either an EOC or C total mixed ration (TMR) 2x/d. Cows fed the EOC averaged 2.72 ± 0.11 milkings/d and cows fed C averaged 2.80 ± 0.13 milkings/d. Production data were collected daily from Lely Time for Cows (T4C) robotic milking software and was reduced to weekly observations for each cow. Fecal samples were collected weekly from each pen based on a composite from 15 cows. Weekly TMR samples were collected from EOC and C pens and were composited monthly. Milk samples were collected once every 2 weeks from all cows and were analyzed for milk components and somatic cell counts (SCC) by the Dairy Herd Improvement Association (DHIA). Daily milk production was not different ($P = 0.26$) between EOC and C fed cows, but was numerically greater for cows fed EOC (41.9 ± 1.91 kg/d) than cows fed C (38.8 ± 2.05 kg/d). The deviation in milk yield was greater ($P = 0.01$) for cows fed EOC (0.42 kg/d) than cows fed C (−0.75 kg/d). Total-tract NDF digestibility was numerically greater ($P = 0.36$) for cows fed EOC (54.4% NDFD) than cows fed C (50.6% NDFD). Cows fed EOC had lower ($P = 0.0002$) milk urea nitrogen (MUN) (15.2 ± 0.14 mg/dL) than cows fed C (15.9 ± 0.14 mg/dL). Feeding the proprietary EOC product on a commercial dairy operation, which used robotic milking units numerically increased milk production and total-tract NDF digestibility.

Key Words: essential oil, cobalt, commercial dairy

W386 Evaluation of rumen undegradable protein sources on lactational performance of Holstein dairy cows.

Heather A. Tucker[1], Shane M. Fredin*[1], Heather M. Dann[1], Kurt W. Cotanch[1], Catherine S. Ballard[1], Les W. Berghorn[2], and Rick J. Grant[1], *[1]William H. Miner Agricultural Research Institute, Chazy, NY, [2]Afgritech LLC, Watertown, NY.*

This study compared the effects of feeding a proprietary blend of heat-treated canola and soybean meal (AminoMax; Afgritech LLC; Watertown, NY) or heat-treated soybean meal (AminoPlus; Ag Processing Inc.; Omaha, NE) on lactational performance of dairy cows. Forty-two lactating Holstein dairy cows (21 per treatment) averaging 866 ± 98 kg of BW and 146 ± 30 DIM at study initiation were used in a randomized complete block design with a 2-wk covariate period followed by an 8-wk treatment period. Treatments were diets containing (DM basis) 7.7% AminoMax or AminoPlus. Diets also contained 19.3% conventional corn silage, 19.3% brown midrib corn silage, 14.0% hay crop silage, and 39.7% concentrate mix (excluding AminoMax or AminoPlus). Both diets contained 15.7% CP, 30.9% NDF, and 25.4% starch. Dry matter intake and milk yield were collected daily and milk composition was determined over 3 milkings once per week. Cow served as the experimental unit. Data from the last 7 d of the covariate period were used as a covariate adjustment. Data were analyzed by ANOVA using the MIXED procedure of SAS containing model effects of covariate, treatment, time, and treatment × time. Dry matter intake (27.4 ± 0.2 kg/d), solids-corrected milk (SCM) yield (43.8 ± 0.8 kg/d), milk fat yield (1.76 ± 0.04 kg/d), and milk true protein yield (1.39 ± 0.02 kg/d) were unaffected by diet ($P > 0.10$). Milk lactose yield tended to increase (2.14 versus 2.06 ± 0.03 kg/d; $P = 0.09$) for cows fed AminoPlus. Milk urea N concentration was decreased for cows fed AminoMax (11.4 vs. 9.6 ± 0.2 mg/dL; $P < 0.01$). Efficiency of SCM production (SCM/DMI; 1.59 ± 0.02 kg/kg) and N efficiency (0.322 ± 0.005 kg/kg) were unaffected ($P > 0.10$) by diet. In conclusion, lactational performance did not differ between the products, but N utilization appeared to be improved for cows fed AminoMax.

Key Words: lactation, rumen undegradable protein

W387 Evaluation of industry growth chart equations from birth until first calving of Holstein heifers fed a high plane of nutrition.

Marie E. Iwaniuk*[1], Jill A. Davidson[2], Catherine M. Bradley[2], and Tom J. Earleywine[3], *[1]University of Maryland, College Park, MD, [2]Purina Animal Nutrition, Gray Summit, MO, [3]Land O'Lakes Animal Milk Products, Shoreview, MN.*

The 2013 Penn State Customized Heifer Growth Chart (PS) was created as a tool to enable dairy producers to create herd-based heifer performance goals and track the performance of individual heifers until first calving. The prediction equations used in the program were derived from body weight (BW) and hip height (HH) benchmarks established by the 2001 *Nutrient Requirements of Dairy Cattle* and as previously reported BW and HH prediction equations (Heinrichs et al., 1992; Kertz et al., 1998). These prediction equations were derived from data sets in which heifers were fed standard diets; however, these prediction equations have yet to be evaluated for heifers fed a higher plane of nutrition. The objective of this study was to evaluate the PS prediction equations for BW and HH growth using data of heifers fed a high plane of nutrition at the Purina Animal Nutrition Center. PS growth curves for BW and HH were predicted using mature cow herd data as target parameters. To evaluate the PS equations, residuals were regressed on centered predicted values to detect the presence of mean and/or linear biases using methods published by St-Pierre et al. (2006). For BW, the linear bias was not significant ($P = 0.2131$); however, a significant mean bias ($P < 0.05$) indicated that the PS equations overestimate BW by an average of 1.63kg for heifers fed a high plane of nutrition. In regards to HH growth, a significant linear bias (0.53cm; $P < 0.05$) demonstrated that the PS equations overestimate HH from wk 0 to wk 5 and underestimate HH from wk 20 to wk 100 for heifers fed a high plane of nutrition. In addition, a significant mean bias indicated that the PS equations underestimate HH by an average of 5.41cm ($P < 0.05$). Moreover, the presence of mean biases for both BW and HH further indicates that collectively the PS equations do not accurately describe overall growth patterns of heifers fed a high plane of nutrition. Therefore, new BW and HH equations should be developed that adjust for level of nutrition.

Key Words: Penn State Customized Heifer Growth Chart, growth curve

W388 Milk urea nitrogen as a predictor of urinary nitrogen excretion in late lactation dairy cows fed four levels of dietary crude protein.

Tiago Barros* and Michel A. Wattiaux, *Department of Dairy Science, University of Wisconsin-Madison, Madison, WI.*

Our objective was to assess the relationship between milk urea nitrogen (MUN, mg/dL) and blood urea nitrogen (BUN, mg/dL), and the excretion of urinary nitrogen (UN, g/d), and urinary urea nitrogen (UUN, g/d) in late lactation dairy cows. Holstein cows (means ± SD; 736 ± 18 kg BW; 224 ± 54 DIM at the start of the trial) were used in a 16-pen study with 8 cows per pen, and fed one of 4 TMR containing either 11.9, 13.4, 14.4, or 16.3% CP (DM basis) for 12 weeks. Cows (n = 4 per pen) were sampled for BUN on wk 4, 8 and 12. Daily MUN (infrared analysis) was derived from sampling 4 cows per pen in 2 consecutive milkings in wk 3, 7 and 11. In the same 3 weeks, urine volume was estimated using creatinine concentration in spot urine samples collected 6 h before and 6 h after feeding in groups of 4 randomly selected cows in each pen. Linear models were built using PROC REG and differences in slopes were tested using PROC GLM in SAS. Week of sampling did not affect the slope between BUN and MUN ($P = 0.11$, Table 1), but affected the slope of the relationship between UN and MUN ($P = 0.042$) and between UUN and MUN ($P = 0.029$). Increased dietary CP resulted in increases in UUN/UN ratio (0.54, 0.68, 0.74, and 0.81). However, there was no difference in slope when UN or UUN were regressed against MUN. Excretion of non-urea-N was constant (40.8 g/d). Four published models showed a slope bias and over-predicted UN when applied to our data set (227, 214, 176 and 125 g/d compared with 116 g/d observed UN). The week effect observed here, and the inadequacy of previous models suggested that best equations to predict UN from MUN should consider stage of lactation.

Contd.

Table 1 (Abstr. W388).

Y variable	X variable	Week	Intercept	SE	Slope	SE	R^2	RMSE
BUN	MUN	3	0.19^{1}	0.79	0.96	0.076	0.94	0.94
		7	1.70^{1}	1.23	0.75	0.116	0.75	1.72
		11	-1.99^{1}	2.20	1.18	0.214	0.68	1.81

W389 Phosphorous excretion and digestibility in Jersey and Holstein consuming corn milling co-products.

Gabriel Garcia Gomez*, Alison Foth, and Paulk Kononoff, *University of Nebraska-Lincoln, Lincoln, NE.*

Excess dietary phosphorous (P) in dairy cows diet may result in increased excretion of this mineral. Additionally, P accumulation in the soil may be a result of high concentrations of P when manure is applied to cropland. The objective of this study was to evaluate P intake, digestibility and excretion when dairy cows consumed rations containing reduced fat distillers grains (RFDDGS). Data from this study originated from an energy balance study in which RFDDGS was included at 28.8% of the ration DM. In this study, corn was reduced from 22.9 to 8.95% and soybean meal was reduced from 14.8 to 0% of the ration DM in the control and co-product (Co-P) diet, respectively. The study included 8 Holstein (BW = 693.8 ± 12.9 kg) and 8 Jersey (BW = 429.1 ± 13.0kg) multiparous, lactating cows (93 ± 20 d DIM) in a repeated switchback design. The concentration of P in the test treatments were 0.44% and 0.59% ± 0.01% DM for the control and Co-P diet, respectively. The intake and excretion of P was estimated through feed sampling and total collection of feces. All feed and fecal samples were analyzed for P. Concentration of P in feces was lower in control diet compared with Co-P (0.97 versus 1.27 ± 0.05%, respectively; $P < 0.01$). Excretion of P was less for cows fed the control diet compared with the Co-P diet (62.34 versus 89.70 ± 3.82 g/d, respectively; $P < 0.01$). The excretion of P per kg of milk yield was higher in cows fed Co-P diet compared with control diet (21.7 and 15.8 ± 1.29 g/kg, respectively; $P < 0.01$). There was no difference between Holstein and Jersey in concentration of P in the feces (1.16 vs 1.08 ± 0.07%, respectively; $P = 0.36$), digestibility (32.3 versus 29.0 ± 2.83%, respectively; $P = 0.40$) and P efficiency (19.4 vs 18.0 ± 1.63g/kg, respectively; $P = 0.55$) across treatments. Results of this study suggest that rations formulated containing RFDDGS should be adjusted for P to reduce P excretion by dairy cows.

Key Words: phosphorus, excretion, digestibility.

W390 Relationship between protein molecular structure and protein metabolic characteristics of co-products from bio-oil processing (rapeseed meal, canola meal and soybean meal) in dairy cattle.

Xinxin Li*[1,2], Yonggen Zhang[2], and Peiqiang Yu[1,2], [1]*Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Saskatchewan, Canada,* [2]*College of Animal Science and Technology, Northeast Agricultural University, Harbin, China.*

This study was aimed to detect the relationship between protein inherent molecular structure features and protein rumen degradation kinetics and intestinal digestibility of 3 types of co-products from bio-oil processing including rapeseed meal, canola meal and soybean meal for dairy cattle. Three sources of rapeseed meal, 3 sources of soybean meal and 3 sources of canola meal were collected in 2014. The protein molecular structure in terms of chemical functional groups in these feed samples was analyzed using attenuated total reflectance-Fourier transform infrared spectroscopy (ATR-FT/IR) instrument. Rumen protein degradation kinetics was determined using in situ nylon bag method. Intestinal digestibility of rumen undegraded feed protein were determined according to the 3-step in vitro procedure with 12h pre-rumen incubated feed samples. The PROC MIXED procedure of SAS 9.3 was used to analyze the univariate protein spectral data, protein degradation kinetics and intestinal digestibility data. After normality test of the data, PROC CORR of SAS with a SPEARMAN option was used to investigate the relationship between protein molecular structure and metabolic characteristics in dairy cattle. Significances were declared at $P < 0.05$. The results showed that the ratio of protein amide I to amide II spectral peak height had a highly negative correlation with rumen undegraded protein (RUP^{NRC}; $r = -0.67$, $P = 0.05$), intestinal absorbable rumen degraded protein (IADP; $r = -0.67$, $P = 0.05$), intestinal digestible protein (IDP; $r = -0.77$, $P < 0.05$) and total digestible protein (TDP; $r = -0.67$, $P = 0.05$). Additionally, the ratio of protein secondary structure α-helix to β-sheet height was negatively correlated with rumen undegradable protein (RUP^{NRC}; $r = -0.67$, $P < 0.05$), rumen degradable protein (EDCP; $r = -0.83$, $P < 0.05$), and total digestible protein (TDP; $r = -0.93$, $P < 0.05$). The results indicated that protein molecular structure was highly related with its nutrient supply to dairy cattle.

Key Words: protein molecular structure, protein metabolic characteristics, correlation study

W391 The effect of decreasing dietary cation-anion difference in the prepartum diet on dry matter intake, milk production and milk composition in multiparous Holstein cows.

B. M. Sweeney*[1], C. M. Ryan[1], K. Zanzalari[2], D. Kirk[2], and T. R. Overton[1], *[1]Department of Animal Science, Cornell University, Ithaca, NY, [2]Prince Agri Products Inc., Quincy, IL.*

The objective of this study was to determine the effect of decreasing dietary cation-anion difference (DCAD) in the prepartum period on dry matter intake (DMI), milk production and milk composition. Multiparous Holstein cows (n = 89) were allocated randomly to one of 3 prepartum diets formulated with decreasing DCAD: CON (+17.5 mEq/100 g DM), MED (+3.6 mEq/100 g DM), or LOW (−10.9 mEq/100 g DM), beginning 24 d before expected parturition. Analyzed DCAD were +18.3, +5.9, and −7.4 mEq/100 g DM. Cows were fed a common postpartum diet from parturition until 63 d in milk. Repeated measures analyses were conducted using the MIXED procedure of SAS with linear and quadratic effects of decreasing prepartum DCAD as contrasts. A quadratic effect of decreasing DCAD on prepartum DMI was observed (CON = 14.6 kg/d, MED = 15.1 kg/d, LOW = 14.1 kg/d; $P < 0.01$). Postpartum DMI as a percent of body weight through wk 3 increased linearly with decreasing DCAD (CON = 2.94%, MED = 3.04%, LOW = 3.15%; $P = 0.03$) and tended to be increased through wk 9 ($P = 0.07$). During wk 1 to 3, milk yield (CON = 40.5 kg/d, MED = 42.1 kg/d, LOW = 43.8 kg/d; $P = 0.03$) and fat yield were increased linearly ($P = 0.13$) by decreasing prepartum DCAD resulting in a trend for greater 3.5% fat-corrected milk ($P = 0.07$). Protein percent decreased linearly ($P < 0.01$) with no effect on yield. Lactose yield ($P = 0.02$), total solids content ($P = 0.01$) and total solids yield ($P = 0.06$) were increased linearly, with a trend for greater energy-corrected milk for cows fed a lower DCAD ($P = 0.08$). Milk urea nitrogen increased linearly ($P = 0.04$) and there tended to be a quadratic effect on somatic cell score ($P = 0.06$). Effects of prepartum DCAD on milk yield and composition were smaller when assessed from wk 1 to 9. Cows fed lower prepartum DCAD had linearly decreased protein percent ($P = 0.02$) through wk 9 with a trend for a quadratic effect on yield ($P = 0.11$). Ultimately, there was no difference in fat or energy-corrected milk through wk 9. Feeding decreasing prepartum DCAD linearly increased DMI and milk yield during early lactation.

Key Words: dietary cation-anion difference, transition cow

W392 Effect of *Bacillus pumilus* on performance of primiparous dairy cows fed low or high starch diets.

D. N. Lobão da Silva*[1], Z. Sawall[1], J. Guillen[1], E. Galbraith[2], T. Parrott[3], M. Endres[1], and N. B. Litherland[1], *[1]University of Minnesota, Saint Paul, MN, [2]DuPont Nutrition and Health, Waukesha, WI, [3]DuPont Industrial Biosciences, Waukesha, WI.*

Bacillus species offer advantages as direct-fed microbials (DFMs) because their spores tolerate the harsh environment of the gastrointestinal tract and some strains can produce enzymes such as xylanase which breaks down xylan and the bonds that link lignin to cellulose, potentially increasing dietary fiber digestibility. This study aimed to investigate the effects of *Bacillus pumilus* 8G-134 (BP) supplementation on performance of primiparous dairy cows fed low (20%, LS) or high (27%, HS) starch diets from calving to 112 DIM. We hypothesized that BP would improve total-tract nutrient digestibility and performance of cows fed LS or HS diets postpartum. Forty-eight (n = 12/treatment) primiparous cows were assigned to a common prepartum diet 42d before expected calving date. At calving, cows were fed a LS or HS lactation diet and BP carrier or BP was top dressed on the TMR once daily to provide 5×10^9 cfu/cow/day until 112 DIM. Factors combined produced 4 treatments: LS+carrier (LSCO); LS+BP (LSBP); HS+carrier (HSCO); HS+BP (HSBP). Fecal samples collected on d 7, 14 were analyzed for NDFd. Data were analyzed using the MIXED procedure of SAS. Apparent total-tract NDFd was greater ($P = 0.05$) for diets supplemented with BP, by 4.4% (LS) and 8.5% (HS) which tended to increase milk yield, 3.5% FCM and 3.5% ECM by 13.9%, 14.9% and 15.2% for HS diets, but increases in LS supplemented diets were less apparent. The 112 d of BP supplementation increased DMI and milk fat yield, and tended to improve yields of 3.5% FCM and milk protein. Results indicated that BP supplementation to primiparous cows can increase fiber digestibility and milk yield resulting in potential increases in profitability.

W393 Balancing dairy cattle diets for methionine or all essential amino acids relative to energy at negative and adequate levels of rumen nitrogen.

Ryan J. Higgs[1], Brian K. Sloan[2], Larry E. Chase[1], Charles G. Schwab[3], and Michael E. Van Amburgh*[1], [1]*Cornell University, Ithaca, NY,* [2]*Adisseo, Alpharetta, GA,* [3]*Schwab Consulting LLC, Boscobel, WI.*

Updates have been made to the Cornell Net Carbohydrate and Protein System which includes estimations of recycled urea nitrogen, rumen protozoa production and yield, endogenous N secretions and a new system for calculating post-ruminal N digestion. The objective was to evaluate the ability of the updated model to balance diets of high producing dairy cattle below or close to requirements for both rumen N and EAA. Sixty-four high producing dairy cows (100 ± 31 DIM) were randomly assigned to one of 4 treatments: 1) limited in Met, MP and rumen N (Base); 2) adequate in Met but limited MP and rumen N (Base+M); 3) adequate in Met and rumen N, but limited MP (Base+MU); 4) adequate in MP, rumen N and balanced for all EAA (Positive). Dietary CP was 13.5, 13.6, 14.6 and 15.6% DM and model predicted dietary MP balance was −231, −310, −142 and 33 g/d for the Base, Base+M, Base+MU and Positive treatments, respectively. No differences were observed in DMI or milk yield (24.1 to 24.8 and 40.0 to 41.8 kg/d, respectively). Energy corrected milk, fat and true protein yield were greater (3.3, 0.09 and 0.11 kg/d, respectively; $P < 0.001$) in cows fed the Positive compared with the Base treatment. True protein concentration in milk was higher ($P < 0.001$) and milk fat tended to be higher ($P < 0.10$) in cows fed the Positive and Base+MU treatments than cows fed the Base and Base+M treatments. Bacterial growth was predicted to be depressed by 16% and 17% for the Base and Base+M treatments, respectively, due to the predicted rumen N balance and this prediction corresponded with lower ($P < 0.05$) apparent total-tract NDF digestion. The study demonstrated high levels of milk yield can be achieved when diets are formulated on rumen N balance and EAA, even when CP is less than 14% DM provided adequate AA are supplied to the small intestine. The highest milk yield was achieved when considering all EAA in the ration formulation process.

Key Words: CNCPS, nitrogen, amino acid

Ruminant Nutrition: General III

W394 Effect of heat-treated field beans (*Vicia faba*) on lactation performance of dairy cows. Mohammad Ramin*, Annika Höjer, Mårten Hetta, and Pekka Huhtanen, *Department of Agricultural Research for Northern Sweden, Swedish University of Agricultural Sciences (SLU), Umeå, Västerbotten, Sweden.*

In Sweden, the availability of organic protein feeds is rather limited (e.g., lack of soybean) and it was therefore the objective of this study to evaluate if the feeding value of heat-treated field beans (FB) could be improved. Other objective was to compare different protein supplements that could be used in organic farming on the performance of lactating dairy cows fed grass silage based diet. Twenty-four lactating Swedish Red cows (95 DIM, milk yield 29.1 kg per day) were used in a cyclic change-over trial with 3 21-d experimental periods. The control diet consisted of grass silage and barley (60:40, DM basis). For experimental diets barley was replaced with rapeseed expeller (RSE; 104 g/kg diet DM), or isonitrogenous supplements of peas (232), untreated FB (UFB; 140), heat-treated FB (TFB; 140) or heat-treated FB that provided the same dietary MP concentrations of UFB (80; TFB-low). Methane (CH_4) and carbon dioxide emissions were measured with the GreenFeed system. On average, protein supplementation had no significant effect on DMI (18.8 vs. 18.2 kg/d), milk yield (23.8 vs. 23.5 kg/d) or ECM yield (25.6 vs. 24.8 kg/d). This was mainly because peas or FB supplemented diets did not increase milk or protein yield compared with the control diet. The RSE treatment increased milk (24.8 vs. 23.6 kg/d) and protein yield (913 vs. 863 g/d) compared with other protein supplements. Heat-treated FB had no effect on DMI, milk or protein yield compared with UFB. Milk nitrogen efficiency (Milk N / N intake) decreased and MUN increased with protein supplementation compared with the control diet (265 vs. 306 g/kg and 3.92 vs. 3.01 mmol/L, respectively). The RSE supplemented diet tended to decrease ($P = 0.09$) CH_4 production compared with other protein supplements (383 vs. 399 g/d). Overall, this study suggests that in organic farming no improvement on the lactation performance of dairy cows were achieved by the inclusion of heat-treated FB or peas as compared with the control diet without any protein supplement, provided that RDP requirements are met. Only RSE supplementation resulted in significant improvements in animal performance compared with the control diet.

Key Words: heat treatment, methane production, organic feed

W395 Pre- and post-weaning performance of dairy calves fed a milk-wheat-plasma protein milk replacer. Max Thornsberry[1], Steve Younker*[1], Dave Ziegler[2], Hugh Chester-Jones[2], and Jim Linn[1], [1]*Milk Specialties Global, Eden Prairie, MN,* [2]*University of Minnesota, Southern Research and Outreach Center, Waseca, MN.*

Traditionally, replacing a portion of milk protein in calf milk replacer (CMR) with plant and animal proteins has lowered CMR cost, but reduced calf growth performance. Newer processing methods for wheat protein have improved digestibility and when combined with bovine plasma as a partial replacement for milk protein in a CMR resulted in similar performance of calves fed an all milk protein CMR. The objective of this study was to compare performance of calves fed either a CMR containing a blend (B-CMR) of milk proteins (9% units protein), hydrolyzed wheat gluten protein (5% units protein) and bovine plasma (8% units protein) or all milk protein CMR (AM-CMR). Fifty-two 2- to 5-d-old Holstein heifer calves were randomly assigned to one of 2 CMR treatments. The B-CMR and AM-CMR were similar (DM basis) in CP (23%) and crude fat (21%) and fed at 0.54 kg DM/d (13% solids) from study d 1 to 35. Both B-CMR and AM-CMR contained Bio-Mos, ClariFly and 1600 g/ton each of Neomycin sulfate and Oxytetracycline the first 14 d of CMR feeding. BovaTec replaced oxy/neo from 15 d until weaning (d 42). From 35 to 42 d of study, CMR was fed at 0.27 kg DM/d. All calves were fed a common 22% CP (DM basis) texturized calf starter from study d 1 to 56. Data were analyzed as a randomized complete block design using PROC MIXED (SAS). Total intake of CMR DM from 1 to 42 d was similar at 20.8 kg DM with no differences in DM intake by weeks. Total calf starter DM intake from study d 1 to 42 was not different ($P > 0.05$) at 27.6 kg for AM-CMR fed calves and 25.4 kg for B-CMR fed calves. Total 56 d calf starter intake was not different between treatments at 64.6 vs. 61.1 kg DM for AM-CMR and B-CMR fed calves. Average daily gain from 1 to 42 d of study tended ($P = 0.08$) to be slightly lower for calves on B-CMR (0.69 kg/d) than calves on AM-CMR (0.75 kg/d). There was no difference ($P > 0.05$) in daily gain from 1 to 56 d between B-CMR treatment calves (0.83 kg/d) and AM-CMR treatment calves (0.87 kg/d). Fecal scores (1 normal, 4 watery) were numerically lower (1.4 vs. 1.6) from d 1 to 14 and scour days were numerically lower (1.27 vs 1.88) from d 1 to 42 for B-CMR calves than AM-CMR calves, respectively.

Key Words: calves, milk replacer, protein

W396 Effects of ruminal dosing of dairy cows with *Megasphaera elsdenii* on milk fat depression and strain persistence. Paul J. Weimer*[1], Luciano da Silva Cabral[2], and Felipe Cacite[2], [1]*USDA-ARS, Madison, WI,* [2]*Federal University of Mato Grosso, Cuiabá, MT, Brazil.*

Megasphaera elsdenii (*Me*) is a lactate-utilizing bacterium whose ruminal abundance has been shown to be greatly elevated during milk fat depression (MFD). To further examine this association, a total of 23 cannulated multiparous Holstein cows were examined in 3 studies in which strains of *Me* were directly dosed into the rumen ($\sim 2 \times 10^{12}$ cells/dose); control cows were dosed with sterile lactate-free culture medium. Cows were fed a TMR (30% starch, dry matter (DM) basis) that contained primarily corn silage, alfalfa silage, finely ground high-moisture corn, supplemental protein, and corn oil (3 g/kg DM). Studies differed in stage of lactation of the cows (middle or late), dosing events (single dose, or 4 doses over a 5 d period), timing of dose (pre-feed or 3 h postfeed), and *Me* strain (lab strain YI9 or 3 strains isolated from cows in the same herd). DM intake, milk yield and composition were measured from 5 d to 0 d before dosing and 1 to 7 d after first dosing, plus later time points that varied by experiment. None of these measures were affected by dosing ($P > 0.05$). *Me* was quantified in the liquid phase of ruminal contents by polymerase chain reaction (PCR) with relative quantification (*Me* 16S rRNA gene copy number as a percentage of total bacterial 16S rRNA gene copies). Neither the *Me*-dosed or control cows displayed MFD after dosing, and in almost all cases *Me* populations returned to low baseline levels (<0.02% of 16S rRNA gene copy number) within 24 h of dosing. This rapid decline in *Me* also occurred in several cows that were dosed with a strain that had been isolated from that particular cow during a previous bout of MFD. Ruminal pH, total mM volatile fatty acids (VFA) and mM lactate did not differ between dosed and control cows ($P > 0.05$), although acetate:propionate ratio declined ($P < 0.01$) in both groups, and butyrate increased after dosing with *Me* ($P < 0.05$). The results confirm that establishing exogenously added bacterial strains in the rumen is difficult, even for strains previously isolated from the recipient cow. The potential role of *Me* as an agent of MFD remains unclear in the absence of successful establishment of the dosed strains.

Key Words: dosing, *Megasphaera elsdenii*, milk fat depression

W397 Effects of Cerrado plant extracts on in vitro rumen microbial fermentation in high inclusion concentrate diets. Flavia Martins de Souza*, Barbara Juliana Martins Lemos, Fabiola Alves Lino, Kiria Karolline Gomes Moreira, José Realino de Paula, Victor Rezende Moreira Couto, and Juliano José de Resende Fernandes, *Universidade Federal de Goiás, Goiânia, Goiás, Brazil.*

The objective was to study the effect of the typical plant extracts of the Brazilian Cerrado on in vitro rumen microbial fermentation under a high concentrate diet. Two separate trials were conducted to evaluate 4 doses (0, 30, 300 and 3,000 mg/L) of stem bark extract from *Stryphnodendron adstringens* (Trial 1; 48.1% tannins) and *Lafoensia pacari* (Trial 2; 21.1% tannins). The trials were analyzed as a randomized block design with 5 repetitions, treating incubation as the blocking factor. Treatments were evaluated using a TE-150 incubator ((Tecnal) in a batch culture of rumen fluid with a 10:90 forage:concentrate diet (15% crude protein, 20% neutral detergent fiber) incubated using filter bags of non-woven textile for 2, 4, 8, 12, 24, and 48 h (triplicates each time) to fit the disappearance of dry matter (DM). Volatile fatty acids (VFA), pH, and ammonia nitrogen (NH_3-N) were evaluated after 48 h of incubation. *S. adstringens* extract at 3,000 mg/L reduced ($P < 0.05$) in 34.5% the potential degradability (a + b) of DM. There was significant reduction in total VFA concentration from 66.3 mM (0 mg/L) to 40.2 and 24.3 mM by adding 300 and 3,000 mg/L of *S. adstringens* extract, respectively. This was also observed for NH_3-N concentration, representing a decrease of 36.9% (300 mg/L) and 57.8% (3,000 mg/L).The pH significantly increased (5.9 vs 6.1) with the addition of 3,000 mg/L. Regarding *L. pacari* extract, the addition of 3,000 mg/L promoted ($P < 0.05$) reduction of 20.3% in the potential degradability of DM but detrimental effects on the fermentation profile were not observed. The 30 mg/L dose increased ($P < 0.05$) the total VFA concentration (63.4 vs. 85.2 mM), decreased the acetate:propionate ratio (4.3 vs 3.6) and the proportion of isovalerate (1.9 vs 1.5 mM). Changes in the concentration of NH_3-N were only observed at a dose 3,000 mg/L, with a reduction of 43.0%. The results indicated that Cerrado plant extracts are potential modifiers of rumen fermentation under a high concentrate diet.

Key Words: antimicrobial additive, *Lafoensia pacari*, *Stryphnodendron adstringens*

W398 Effect of fibrolytic and aminolytic enzymes in ruminal metabolism and methane production in cattle. Ricardo Galbiatti Sandoval Nogueira, Lizbeth Lourdes Collazos Paucar*, Flavio Perna Jr, Eduardo Cuellar Orlandi Cassiano, Diana Carolina Zapata Vasquez, Lerner Arevalo Pinedo, and Paulo Henrique Mazza Rodrigues, *University of São Paulo, Pirassununga, São Paulo, Brazil.*

Methane (CH_4), a greenhouse gas, can be held responsible for loss of 2–12% the gross energy of the diet. The objective of this study was to evaluate the effect of enzymes on ruminal metabolism and the production of enteric CH_4 in cattle. Five cows with average weight of 923.04 ± 86.76 kg were assigned to 5 treatments in 5 × 5 Latin square design: (1) diet without enzymes (control); (2) diet with 7.5 g/animal/day of amylase (Amaize, Alltech); (3) diet with 15 g/animal/day of xylanase (Fibrozyme, Alltech); (4) diet with 7.5 g/animal/day of cellulase + protease (Allzyme VegPro PO, Alltech); (5) Diet with 30g/ animal/day of enzymes mixture (amylase, xylanase, cellulase + protease). Animals were fed twice daily at 0800 and 1600 h. Each experimental period consisted of 21 d, and collections were made in the last 6 d. On d 21, ruminal pH was measured every 10 min using a continuous measurement device and rumen contents were collected at 0, 3, 6, 9 and 12 h after feeding to determine the production of short chain fatty acids (SCFA) and CH_4 by ex situ technique. Data were analyzed using SAS, through the MIXED procedure. The model included the effect of treatment as fixed factors, animal and period effects as random factors. The addition of different enzymes in the cattle diet showed no significant difference ($P > 0.05$) in relation to dry matter intake. There were significant differences ($P < 0.05$) for SCFA production in relation to the control diet. The enzyme mixture improved the production of acetic acid, propionic acid and total SCFA, while protease + cellulase improved the production of propionic acid. The CH_4 production was not significantly difference among treatments ($P > 0.05$). Also no significant differences ($P > 0.05$) were observed for the pH variables, as minimum, average and maximum pH, as well as time and area whiche pH was below to 5.8, 6.0, 6.2 and 6.5. It is concluded that these additives did not affect the variables DMI, CH_4 production and pH. The association of the enzymes showed improvement in the production of rumen SCFA without increasing the emission of CH_4.

Key Words: enzyme, methane, SCFA

W399 Effects of diets containing glycerin, derived from biodiesel production, on instrumental meat quality characteristics of lambs. Rebeca D. X. Ribeiro*[1], Ronaldo L. Oliveira[1], Gleidson G. P. Carvalho[1], Thadeu M. Silva[1], André G. Leão[2], Jonival B. Costa[1], Sara M. Ribeiro[1], Elisiane S. Santos[1], and Abraão S. Nunes[1], [1]*University of Bahia, Salvador City, Bahia State, Brazil,* [2]*Federal University of Mato Grosso, Rondonópolis City, Mato Grosso State, Brazil.*

Glycerin is a low-cost byproduct from biodiesel production, and is also a potential source of carbohydrates. This study was conducted to determine the optimal amount of glycerin in the diets of lambs. Forty-four crossbreed male lambs (23.9 ± 3.4 kg) were distributed in a completely randomized design, and fed with a TMR that contained 50% of *Cynodon sp.* chopped hay and 50% of concentrate composed of corn bran, soybean meal, mineral premix, and the amounts of glycerin: 0; 7; 14 and 21% of total DM. Those amounts were the treatments. The feed trial lasted 78 d. The last day the animals were submitted to feed fasting, and slaughtered. The carcasses were stored in a cold chamber for 24h, and then the *Longissimus lumborum* was collected, stored in a freezer, and all measurements were made on this muscle, after thawing. The pH was measured by a digital potentiometer (skewer type extremity) directly in the muscle. The color measurement was made using a colorimeter to determine the parameters: L* - luminosity, a* red content and b* yellow content. Cooking losses were calculated by the weight difference from the samples before and after cooked, and results expressed in percentages. Tenderness was measured through the shear strength, using a texturometer equipped with a Warner Bratzler blade. The data were subjected to ANOVA and regression testing. Significance was declared as $P < 0.05$.There are no effects of glycerin inclusion on instrumental characteristics (Table 1). The similar values of pH, which is correlated with the glycogen source in muscle, can be related to the similarity among the other parameters. Glycerin, derived from biodiesel production, can be added up to 21.0% (DM) in the diets of lambs without compromising meat quality.

Contd.

Table 1 (Abstr. W399). Cooking losses (CL), shear force (SF), pH, and color of L. lumborum of lambs fed diets containing glycerin from biodiesel production

W400 Effects of salinomycin and virginiamycin supplementation on ruminal microbial population in Nellore steers fed a high concentrate diet. Amoracyr J. C. Nuñez*[1,2], Vivian V. Almeida[1], Italo E. Borges[2], Fabio Pinese[2], Fernando T. Mercado[2], Ligia G. Mesquita[2], Juliane Diniz-Magalhães[2], Luis Felipe P. Silva[2], Paulo R. Leme[2], and José Carlos M. Nogueira Filho[2], [1]*Purdue University, West Lafayette, IN,* [2]*University of São Paulo, Pirassununga, SP, Brazil.*

This experiment was conducted to evaluate the effects of adding salinomycin (SL), virginiamycin (VM), or their combination to finishing diets of Nellore steers on the ruminal population of *Streptococcus bovis*, *Megasphaera elsdenii*, *Selenomonas ruminantium*, and methanogenic archaea. Eight ruminally cannulated Nellore steers (322 ± 26 kg initial BW) were allotted to a 4 × 4 replicated Latin square design with four 16-d periods. Experimental diets had 80% concentrate (DM basis), and treatments were arranged in a 2 × 2 factorial, with 2 SL levels (0 and 13 ppm) and 2 VM levels (0 and 15 ppm) in the diet DM. Animals were housed in individual pens and fed once daily at 0800 h. Ruminal fluid samples were collected at 0 and 4 h post-feeding on d 13 of each period, and DNA was extracted from samples using the Qiagen DNA stool mini kit. Ruminal bacteria and methanogenic archaea populations were assessed by real-time PCR. Statistical analyses were performed using the MIXED procedure of SAS. No interactions between SL or VM levels, nor between time of collection and SL or VM levels were observed. The relative population of *S. bovis* tended to decrease ($P = 0.09$) for animals fed diets containing 15 ppm VM in comparison with those not receiving the additive, but no effects of dietary treatment were observed for any other microbial species (Table 1). There was an effect of time of collection in the relative populations of *M. elsdenii*, *S. ruminantium*, and methanogenic archaea, which were greater ($P \leq 0.01$) in samples collected at 0 h post-feeding. In conclusion, adding SL, VM, or both to the diets of Nellore steers had little effect on the populations of ruminal bacteria and methanogenic archaea.

Table 1 (Abstr. W400). Relative populations of ruminal bacteria and methanogenic archaea in Nellore steers fed diets with 2 levels of salinomycin (SL) or virginiamycin (VM)

W401 Productive performance of lambs fed diets containing glycerin from biodiesel production. Ronaldo L. Oliveira*[1], Rebeca D. X. Ribeiro[1], Gleidson G. P. Carvalho[1], Thadeu M. Silva[1], André G. Leão[2], Jonival B. Costa[1], Sara M. Ribeiro[1], Elisiane S. Santos[1], and Abraão S. Nunes[1], [1]*University of Bahia, Salvador City, Bahia State, Brazil,* [2]*Federal University of Mato Grosso, Rondonópolis City, Mato Grosso State, Brazil.*

Glycerin is a by-product from biodiesel production, an important alternative fuel. It is also a low-cost source of carbohydrates. This study was conducted to determine the optimal amount of glycerin to include in the diets of lambs. Forty-four crossbreed male lambs (23.9 ± 3.4Kg) were distributed in a completely randomized design, and fed with a TMR that contained 50% *Cynodon* sp. chopped hay and 50% concentrate composed of corn bran, soybean meal, mineral premix, and the amounts of glycerin: 0; 7; 14 and 21% of total DM. Treatments varied in the amount of glycerin included. During the performance trial the animals were fed ad libitum (diet was offered to allow 10% of orts). The feed and orts were weighed daily. The feedlot trial lasted 78 d, and on the last day the animals were weighed, submitted to feed fasting, and slaughtered. A general linear model was used to perform linear and quadratic regression. Significance was declared as $P < 0.05$. The glycerin inclusion promoted increase in final BW, BW gain, and gain:feed ratio up to 5.8, 3.8, and 2.75% of inclusion respectively (Table 1). After that, glycerin inclusion reduced those parameters. The initial increase can be related to the increment on energy intake, because the glycerin used in this study contained 30% of lipids. However, the increase in lipid intake can also reduce fiber digestibility, and then cause decrease in the DM intake, which is related to reduction in productive performance parameters. Glycerin, from biodiesel production, can be added between amounts of 2.75% and 5.8% without compromising the productive performance of lambs.

W402 Ruminal hydrogen sulfide concentrations on low-quality grass hay by lambs drinking saline water. Agustín López*[1,3], José I. Arroquy[1,2], Ana V. Juárez Sequeira[2,3], Nicolás DiLorenzo[4], Héctor Fissolo[1], and María C. Barrionuevo[3], [1]*INTA EEA Santiago del Estero, Santiago del Estero, Argentina,* [2]*CONICET, Santiago del Estero, Argentina,* [3]*FAyA - Univ. Nac. Santiago del Estero, Santiago del Estero, Argentina,* [4]*4University of Florida, NFREC, Marianna, FL.*

The objective of this study was to determine the impact of protein supplementation on dry matter intake and ruminal hydrogen sulfide concentration ($[H_2S]$) in lambs consuming low-quality tropical grass hay and drinking low salt water (LS) or high salt water (HS). Twenty lambs in individual cages were used in a 10 treatments by 2 period (10 × 2) trial. First factor was water quality (WQ): LS (466 mg/kg TDS) vs. HS (8927 mg/kg TDS of which 6680 mg/kg as sulfates). Second factor was 5 levels of soybean meal (SBM; %BW/d). Water quality × SBM interactions were significant for forage (FOMI; $P < 0.05$) and total OM intake (TOMI; $P < 0.05$), but not for water (WI; $P = 0.60$) and sulfur water intake (SWI; $P = 0.14$). At the higher levels of SBM (>0.5%) there was no statistical difference for FOMI and TOMI. Water intake was not affected by WQ ($P = 0.39$) but increased linearly ($P < 0.01$) in response to SBM. Ruminal H$_2$S concentration was affected by WQ × SBM interaction ($P < 0.01$). Our results suggest further research is needed on the water quality × protein interaction to understand the mechanisms involved in H$_2$S production, to generate efficient supplementation strategies on low-quality forages.

Table 1 (Abstr. W402). Effects of SBM supplementation and WQ on sulfur water intake (SWI) and ruminal H$_2$S concentration in lambs fed low-quality grass hay

Water quality	SBM	SWI, mg/kgBW$^{0.75}$	H$_2$S (ppm)[1]

W403 Effects of Cerrado plant oils on in vitro rumen microbial fermentation in high inclusion concentrate diets.

Flavia Martins de Souza*, Barbara Juliana Martins Lemos, Fabiola Alves Lino, Kiria Karolline Gomes Moreira, Edemilson Cardoso da Conceição, Victor Rezende Moreira Couto, and Juliano José de Resende Fernandes, *Universidade Federal de Goiás, Goiânia, Goiás, Brazil.*

The objective was to study the effect of the typical plant extracts of the Brazilian Cerrado on in vitro rumen microbial fermentation under a high concentrate diet. Two separate trials were conducted to evaluate 4 doses (0, 30, 300 and 3,000 mg/L) of trunk oil from *Copaifera langsdorffii* (Trial 1; 21.3% β-caryophyllene – essential oil) and fruit oil from *Pterodon emarginatus* (Trial 2; 5.3% β-caryophyllene – essential oil). The trials were analyzed as a randomized block design with 5 repetitions, treating incubation as the blocking factor. Treatments were evaluated using a TE-150 incubator ((Tecnal) in a batch culture of rumen fluid with a 10:90 forage:concentrate diet (15% crude protein, 20% neutral detergent fiber) incubated using filter bags of non-woven textile for 2, 4, 8, 12, 24, and 48 h (triplicates each time) to fit the disappearance of dry matter (DM). volatile fatty acids (VFA), pH, and ammonia nitrogen (NH$_3$-N) were evaluated after 48 h of incubation. The inclusion of 3,000 mg/L of oil *C. langsdorffi* reduced (84.7 vs 63.8%) the potential degradability (a + b) of DM and tended to decrease ($P < 0.10$) the VFA (76.6 vs 60.6 mM), acetate (52.27 vs 42.11 mM) and NH$_3$-N (119.12 vs. 101.47 mg/dL) concentration. Acetate:propionate ratio (C$_2$:C$_3$) was significantly reduced (3.55 vs 2.81) at a dose 300 mg/L of *C. langsdorffi*. The proportion of isovalerate was affected ($P < 0.05$) at a dose 300 (1.93 vs 1.88 mM) and 3,000 mg/L (1.9 vs 1.6mM). No effect ($P > 0.10$) of *P. emarginatus* on the kinetics of disappearance of rumen DM was detected. However, the addition of 30 and 300 mg/L of *P. emarginatus* oil increased ($P < 0.05$) the total VFA concentration by an average of 28.3%. The 3,000 mg/L dose significantly decreased C2:C3 ratio (3.77 vs 2.76 m*M*) due to a 27.9% reduction in the proportion of acetate. The results indicated that Cerrado plant oil are potential modifiers of rumen fermentation under a high concentrate diet.

Key Words: *Copaifera langsdorffii*, essential oils, *Pterodon emarginatus*

W404 Effects of the combined use of virginiamycin and salinomycin on ruminal microbial population in Nellore steers fed diets with two concentrate levels.

Amoracyr J. C. Nuñez*[1,2], Vivian V. Almeida[1], Fabio Pinese[2], Italo E. Borges[2], Fernando T. Mercado[2], Ligia G. Mesquita[2], Juliane Diniz-Magalhães[2], Luis Felipe P. Silva[2], Paulo R. Leme[2], and José Carlos M. Nogueira Filho[2], *[1]Purdue University, West Lafayette, IN, [2]University of São Paulo, Pirassununga, SP, Brazil.*

Eight ruminally cannulated Nellore steers (434 ± 35 kg initial BW) were allotted to a 4x4 replicated Latin square design (21-d periods) to evaluate the effects of concentrate and virginiamycin (VM) levels in diets containing salinomycin (SL) on the ruminal population of *Streptococcus bovis*, *Megasphaera elsdenii*, *Selenomonas ruminantium*, and methanogenic archae. Treatments were arranged in a 2 × 2 factorial, with 2 concentrate levels (70 and 90%) and 2 VM levels (0 and 15 ppm) in the diet DM. Animals were fed once daily at 0800 h and SL was included in all diets at 13 ppm (DM basis). Ruminal fluid samples were collected at 0 and 4 h post-feeding on d 18 of each period, and DNA was extracted from samples using the Qiagen DNA stool mini kit. Ruminal bacteria and methanogenic archaea populations were assessed by real-time PCR. Statistical analyses were performed using the MIXED procedure of SAS. No effects of time of collection nor treatment x time of collection interactions were observed for any variable. The relative populations of *S. bovis*, *M. elsdenii*, and *S. ruminantium* were greater ($P < 0.01$) for steers fed the 90% concentrate diet than for animals fed less concentrate, but no effects of VM were observed for those bacteria populations (Table 1). There was a concentrate x VM interaction ($P = 0.04$) for the relative populations of methanogenic archaea, but within each concentrate level, no differences between VM inclusions were observed. In conclusion, the ruminal microbial populations evaluated in this study were more affected by variations in concentrate levels than by VM inclusion in the diets.

Table 1 (Abstr. W404). Relative populations of ruminal bacteria and methanogenic archaea in Nellore steers fed diets containing 2 concentrate (C) levels and 2 virginiamycin (VM) levels (0 and 15 ppm)

W405 Ruminal fermentation of dairy cows supplemented with crude glycerin.

Pablo G. Paiva*[1], Carlos E. C. Consentini[2], Fernanda C. R. Santos[2], Arthur G. B. V. B. Costa[2], Victor C. Galvao[2], Guilherme F. Cabral[3], Elmeson F. Jesus[1], Tiago A. Del Valle[2], Thiago H. Silva[2], Caio S. Takiya[2], and Francisoo P. Renno[2], [1]*Animal Science Department, Universidade Estadual Paulista, UNESP/Jaboticabal-SP.,* [2]*School of Veterinary Medicine and Animal Science, Universidade de São Paulo, USP.,* [3]*School of Animal Science and Food Engineering, Universidade São Paulo, USP/Pirassununga-SP.*

The objective of this study was to evaluate the effects of glycerin in replacing corn grain on ruminal fermentation of lactating dairy cows. Eight rumen cannulated Holstein cows (184 ± 50 DIM; 29.38 ± 0.89 kg/d milk yield; 594 ± 39 kg BW) were assigned in a replicated 4 × 4 Latin square design, with 21 d of experimental periods. Cows were assigned within each square to receive one following diets: Control or 0% glycerin; 7% of glycerin; 14% of glycerin; and 21% glycerin added to diets in replacing corn ground. On 20 d of experimental period, ruminal fluid samples were collected before (0), 2, 4, 6, 8, 10 e 12 h after morning feeding for analysis of the ruminal pH, NH_3 and volatile fatty acids (VFA). Data were analyzed as repeated measures in PROC MIXED (SAS for Windows 9.0), in the statistical model the effects of animal, period, square, treatment, beyond the effects of time with their interactions with treatment were considered. There was no effect of glycerin on total VFA ($P > 0.05$); but glycerin inclusion in the diet increased propionate and butyrate, and decreased acetate concentrations, resulting in lower acetate: propionate ratio ($P < 0.05$). Cows fed glycerin had lower ruminal pH in the first time of collect ($P < 0.05$). Ruminal NH_3 was linearly decreased as glycerin levels increased ($P < 0.05$). Glycerin inclusion in the diets of lactating dairy cows changed ruminal fermentation, with increase in propionate concentration, that indicate better efficiency the use of the energy diet.

Key Words: by-product, glycerol, performance.

W406 Dry matter intake and nutrient digestibility of dairy cows supplemented with crude glycerin.

Pablo G. Paiva*[1], Fernanda C. R. Santos[2], Arthur G. B. V. B. Costa[2], Victor C. Galvao[2], Guilherme F. Cabral[3], Carlos E. C. Consentini[2], Elmeson F. Jesus[1], Tiago A. Del Valle[2], Thiago H. Silva[2], Caio S. Takiya[2], and Francisco P. Renno[2], [1]*Animal Science Department, Universidade Estadual Paulista, UNESP/Jaboticabal-SP.,* [2]*School of Veterinary Medicine and Animal Science, Universidade de São Paulo, USP.,* [3]*School of Animal Science and Food Engineering, Universidade São Paulo, USP/Pirassununga-SP.*

The aim of this study was to evaluate the effects of glycerin in replacing corn grain on dry matter intake (DMI) and nutrient digestibility of lactating dairy cows. Twenty-four Holstein cows (184 ± 50 DIM; 29.38 ± 0.89 kg/d milk yield; 594 ± 39 kg BW) were assigned in 4 × 4 Latin square design, with 21 d of experimental periods. Cows were assigned within each square to receive one following diets: Control or 0% glycerin; 7% of glycerin; 14% of glycerin; and 21% glycerin added to diets on replacing corn ground. On d 16 to 18 of each period, fecal samples were taken from each cow, twice daily after milking, comprising a composite sample. The indigestible acid detergent fiber was used as internal marker to estimate fecal excretion and total-tract apparent digestibility of the nutrients. Data were analyzed with PROC MIXED (Statistical Analysis System for Windows 9.0), diet, period, and square were considered as fixed effect, animal within square and residual error as random effect. The inclusion of glycerin in the diets decreased DMI ($P < 0.05$). However, total-tract digestibility of dry matter, crude protein, and ether extract was linearly increased, and neutral detergent fiber (NDF) linearly decreased with glycerin inclusion in the diet ($P < 0.05$). High glycerin levels in corn silage based diets affected NDF digestibility and decreased DMI of lactating dairy cows.

W407 Nitrogen utilization of Nellore bulls supplemented with energy sources associated crude glycerin on finishing phase.

Antônio José Neto*[1], Joanis Tilemahos Zervoudakis[2], Pedro Veiga Rodrigues Paulino[2], Luciana Keiko Hatamoto-Zervoudakis[2], Luciano da Silva Cabral[2], Juliane Quenoizoré Soares[2], Rosemary Lais Galati[2], Renata Pereira da Silva-Marques[2], and Lilian Chambó Rondena Pesqueira Silva[2], [1]*Department of Animal Science; São Paulo State University-UNESP, Jaboticabal, SP, Brazil,* [2]*Department of Basic Sciences and Animal Production; Federal University of Mato Grosso-UFMT, Cuiabá, MT, Brazil.*

Glycerin has the potential to partially replace starch-based ingredients in the diet, such as corn, because glycerol is converted to propionate in the rumen and acts as a precursor for hepatic glucose synthesis. The objective of this study was to evaluate the effects of crude glycerin (Gly) combined with protein sources on balance of nitrogen compounds of

Nellore bulls fed tropical pasture during the rainy season. Five Nellore bulls (448.2 ± 14 kg; 25 ± 3 mo) were evaluated in a 5 × 5 Latin square design with 5 treatments and 5 periods. The animals were allocated into 5 paddocks of 0.25 ha, consisting of *Brachiaria brizantha* 'Marandu' in the rainy season. Crude glycerin (83.9% of glycerol) was used in all supplements to replace (15% of DM) corn. The supplements were: T1 - Gly with urea, T2 - Gly with soybean meal, T3 - Gly with cottonseed meal, and T4 - Gly with gluten, and the control supplement received mineral mixture *ad libitum*. Animals were individually supplemented at the rate of 300 $g \cdot 100\ kg^{-1}$ of BW, daily, at 1000 h. The experimental period was the 17 d, divided in adaptation (14 d) and 3 d for collections the feces in different times. Urine samples were collected 4 h after the supplementation to determine the concentration of nitrogen, on the last day of period. Data were analyzed using the PROC MIXED of the SAS with $\alpha = 0.05$ and F-*test*. Nitrogen intake ($g \cdot d^{-1}$) was greater ($P < 0.01$) for Gly-urea compared with control and protein sources. There were differences in total grams of N excreted across treatments ($P < 0.01$). The increase in urinary and fecal N output by animals fed gly-urea contributed to greater total N output compared with other supplements. Nitrogen retained ($g \cdot d^{-1}$ or % of N intake) was not affected by protein sources, but there were greater than control supplement ($P < 0.01$). Independently of protein source utilized, there was an increase of 59.5% ($P < 0.01$) in the N utilization (N retained, $g \cdot d^{-1}$) for animals supplemented when compared with control group. Crude glycerin associated with protein sources can be efficient for improve the N utilization.

Key Words: beef cattle, glycerol, nitrogen

W408 In vitro production of gas in diets containing different levels of ethanolic extract of propolis. Sandra M. Yamamoto*, Cintia M. Araujo, Fernanda G. da Silva, Marcela A. Formiga, Layse A. Gordiano, and Daniel R. Menezes, *Federal University of Vale do São Francisco, Petrolina, Pernambuco, Brazil.*

In this study, we evaluated propolis as a safe alternative for ruminants feeding free of antibiotic additives and growth promoters. Phenolic compounds with antibiotic activity mainly against gram-positive bacteria, in the same manner as ionophores, are present in propolis. We evaluated the effects of different levels of ethanolic extract of propolis (EEP) at 30% on the in vitro production of gases by bacteria. Feed was formulated to contain 50% ground elephant grass (*Pennisetum purpureum*) and 50% concentrate, consisting of corn, soybean meal and core minerals and vitamins. EEP was added to the concentrate at 0, 6, 12, 24, and 36 mL/kg. A sample of 1000mg was weighed in nylon bags, with a weight of 20 mg/cm^2, sealed and added to the fermentation vials (160mL) previously injected with CO2, with 4 replicates per treatment. To each vial was added 90mL of buffer solution and 10 mL of ruminal fluid spray kept under CO_2. The vials were sealed, placed in a room at 39°C and stirred every 2 h. Gas pressure readings were made at 2, 4, 6, 8, 9, 11, 12, 14, 17, 20, 24, 28, 34, 48, 72, 96, and 120 h after incubation. Statistical analyzes were performed using SAS 9.1 (SAS Institute Inc., Cary, NC). Data were previously checked for normality of residuals by Shapiro-Wilk test (PROC UNIVARIATE) and the variances compared by orthogonal contrasts (PROC GLM) with significance level of 5%. When significant, the regression equations were determined (PROC MIXED). As EEP levels were not equidistant, it was generated vectors of each contrast using PROC IML. There were no effects ($P > 0.05$) of EEP levels to the fibrous (0.0715 ± 0.02 mL/hour), non-fibrous (0.013 ± 0.01 mL/hour), and total (0.083 ± 0.02 mL/hour) carbohydrate fermentation rates. For the potential production of total carbohydrate gases (Vt) there was a quadratic effect ($P < 0.05$). The lowest value of gas output (77.69 mL/g of DM) was obtained for the inclusion of 23 mL of EEP /kg of concentrate. For the gas production from non-fibrous carbohydrates, the lowest value (63.12 mL/g of DM) was obtained for the inclusion of 24.78 mL of EEP /kg of concentrate. The results suggests that EEP was efficient at inhibiting total gas production by ruminal microorganism in vitro.

Key Words: fermentation, growth promoters, propolis

W409 Influences of SmartCare in milk replacer and XPC in calf starter on the performance and health of pre-weaning Holstein calves challenged orally with an opportunistic infection with *Citrobacter freundii*. Tyler L. Harris*[1], Yu Liang[1], Matt D. Sellers[1], Cameron R. Nightingale[1], Kate P. Sharon[1,2], Jeff A. Carroll[2], Ilkyu Yoon[3], Mark F. Scott[3], and Michael A. Ballou[1], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, TX, [2]USDA-ARS, Lubbock, TX, [3]Diamond V, Cedar Rapids, IA.*

This study investigated how supplementing milk replacer with SmartCare (SC) and calf starter with original XPC (XPC) would affect performance and health following an oral challenge with *Citrobacter freundii*. The study was performed over a 54 d period with 30 Holstein bull calves. Calves were randomly assigned to treatments that included: CON: milk replacer and calf starter with no added products, SC: milk replacer with 1 g SC/calf/d and base calf starter, and SC+XPC: milk replacer with 1 g SC/calf/d and calf starter with 0.5% of DM as XPC. Calves were fed 350 g of milk replacer at 0700 and 1700 from d 0 to 42. Calf starter and water were offered *ad libitum* and recorded daily. Calves were challenged with 10^8 cfu of *Citrobacter freundii* orally on d 16 of the study. Blood samples were collected on d 0, 7, 14, 16, 18, 21, 24, 28, and 35 and analyzed for hematology. All data were reported as CON, SC, and SC+XPC, respectively. LSMeans with various superscripts differ ($P \leq 0.05$). Calf starter intake and ADG did not differ overall ($P \geq 0.127$); however, the SC+XPC calves consumed more calf starter from d 36 to 54 (0.865^{a}, 0.840^{a}, $0.981^{b} \pm 0.053$ kg/d; $P = 0.054$) and had increased ADG from d 15 to 21 (0.677^{a}, 0.696^{a}, $0.840^{b} \pm 0.046$ kg/d; $P = 0.006$). There was treatment x time interaction in neutrophil to lymphocyte ratio (N:L; $P = 0.043$), whereas CON calves had greater ($P \leq 0.019$) N:L than SC and SC+XPC on d 7 (1.21^{a}, 0.83^{b}, $0.72^{b} \pm 0.15$) and d 16 (1.43^{a}, 0.93^{b}, $0.99^{b} \pm 0.15$). Additionally, the SC+XPC calves had lower hemoglobin throughout the study (10.9^{a}, 11.2^{a}, $10.3^{b} \pm 0.19$ mg/dL; $P = 0.006$). Average fecal scores by period were greatest among CON calves after the challenge on d 17 to 21 (2.7^{a}, 2.1^{b}, $1.9^{b} \pm 0.003$; $P \leq 0.010$) and CON was also greater than SC+XPC calves on d 22 to 28 (2.8^{a}, 2.4^{ab}, $2.1^{b} \pm 0.15$; $P \leq 0.002$). The *Citrobacter* challenge increased scours, but did not result in systemic disease. Feeding SC in milk replacer and XPC in calf starter improved calf performance, health, and reduced the risk of scours during neonatal life.

Key Words: calf, health, yeast culture

W410 Effect of adding *Enterococcus faecalis* on in vitro ruminal fermentation profiles. Lovelia L. Mamuad, Ashraf A. Biswas, and Sang Suk Lee*, *Sunchon National University, Suncheon, Jeonnam, South Korea.*

Enterococcus faecalis is one of the beneficial microorganisms which produces enterolysin and converts fumarate to succinate. Hence, this study was conducted to determine the effect of adding *E. faecalis* on in vitro ruminal fermentation, methane concentration, microbial diversity and population. Ruminal samples were collected from ruminally cannulated Holstein Friesian cattle, and a substrate consisting of rice straw and concentrate mixture at 40:60 DM was offered at 1g DM/100mL buffered ruminal fluid. Fresh culture of *E. faecalis* (7.5×10^8 cfu/mL) at different inclusion rates were investigated using in vitro ruminal fermentation. The treatments tested were: non addition (control), 0.1% (T1), 0.5% (T2), and 1.0% (T3) of *E. faecalis*. All treatments were conducted in triplicates and analyzed by ANOVA for randomized complete block design. Duncan's Multiple Range Test (DMRT) and Orthogonal Polynomial Contrast were used to identify differences among treatments and control. All analyses were carried out using SAS version 9.1 (SAS, 2002). Total gas production and ammonia nitrogen concentration of cultures were directly proportional to incubation times, while culture pH was inversely proportional to incubation times. Addition of *E. faecalis* lowered ($P < 0.05$) the total gas production after 24 h but the opposite was observed after 48 h of incubation having the highest ($P < 0.05$) in T3 followed by T4, T2 and control with 93.80, 91.00, 88.33 and 82.20 ml, respectively. Higher concentrations of acetate were detected in *E. faecalis* treatments than control at 12 and 48 h but the opposite was observed at 24 h, while propionate was highest ($P < 0.05$) in T3 after 48 h with 12.59 m*M*. Butyrate concentration was higher ($P < 0.05$) in *E. faecalis* treatments than control after 12 and 24 h of incubations and the highest ($P < 0.05$) concentrations were detected in T2 at 24 h and T3 at 48 h with 14.61 and 14.88 mM, respectively. Higher ($P < 0.05$) concentrations in *E. faecalis* treatments than control were also observed in total volatile fatty acid (VFA) concentration after 12 and 48 h. Addition of *E. faecalis* enhanced in vitro ruminal fermentation by increasing the butyrate and total VFA concentrations in dose dependent manner.

Key Words: *Enterococcus faecalis*, in vitro, pyrosequencing

W411 Acetohydroxamic acid did not influenced ruminal microbiota but altered urea metabolism.

P. P. Wang[1], J. Q. Wang[1], D. P. Bu*[1,2], D. Jin[1], J. Zhang[1], and X. M. Nan1,3, [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*World Agroforestry Centre, East and Central Asia, Beijing, China,* [3]*Synergetic Innovation Center Of Food Safety and Nutrition, Harbin, China.*

The objective of this experiment was to investigate the effects of urea and acetohydroxamic acid (AHA) on in vitro ruminal urea-nitrogen (urea-N) metabolism and microbial community using total mixed ration as a substrate. Treatments were arranged in a 2 × 2 factorial design with urea supplemented at 0 or 2% dry matter (DM), and AHA equivalent to 0 or 450 mg/kg DM. Ruminal fluids were collected from 3 Chinese Holstein dairy cows through permanent ruminal fistula, diluted with artificial saliva (1: 2, v/v), and incubated anaerobically at 39°C for 0, 1, 2, 4, 6, and 12 h. Each treatment was performed in 3 serum bottles and experiment was run 3 times. Supplementation of urea increased ($P < 0.01$) ruminal pH, ammonia-nitrogen (NH_3-N) concentration and urease activity, while addition of AHA inhibited ($P < 0.01$) their increments. Acetohydroxamic acid was still stable within 6 h of incubation. When AHA was added, urea-N concentration of fermentation fluid in the treatment with urea supplied was gradual decline ($P < 0.05$). The peak of NH_3-N concentration was not delayed by AHA addition, comparing with treatment with urea supplementation only. The bacterial PCR-DGGE profiles of 4 treatments were similar to each other before and after incubation. Urea stimulated ($P < 0.01$) the decrements of *Ruminococcus albus*, *R. flavefaciens*, *Fibrobacter succinogene*, and *Butyrivibrio fibrisolvens* populations, but had no effect on *Prevotella* population ($P = 0.18$). However, all those functional bacterial populations were not influenced by AHA addition. It was concluded that AHA could slow down the degradation of urea by the inhibition of urease activity, and the dose of 450 mg/kg DM could not alter ammonia formation pattern in this fermentation condition. In addition, AHA had no effect on ruminal microbiota, which could be altered by urea supplementation.

Key Words: acetohydroxamic acid, in vitro fermentation, urea metabolism

W412 Effect of interaction of cereal and forage on rumen fermentation characteristics in the diet of cattle.

S. Y. Cao[1], C. W. Yang[2], Z. B. Yang*[1], and Y. Wang[3], [1]*College of Animal Science, Shandong Agricultural University, Tai-an, Shandong, China,* [2]*College of Life Science, Shandong Agricultural University, Tai-an, Shandong, China,* [3]*Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada.*

Four ruminally cannulated Limousin × Luxi beef cattle were used in a 4 × 4 Latin square design to monitor the changes in rumen fermentation during the feeding cycle and compare the differences caused by the type of cereal(C) and forage(F) in the diet. The 4 experimental diets contained 60% of either *Leymus chinensis* (LC) or sweet potato vine (SP) as forage and 40% of concentrate with either wheat (W) or maize (M). Cattle were fed twice daily and samples from rumen fluid were taken before morning feeding on the first 10 d after changing the diet and then at 0, 3, 6, 9 and 12 h after the morning feeding for 3 d. Significant variability in ruminal pH with the WSP diet was more pronounced on which pH dropped from 6.81 on d 1 (before the dietary changes) to 6.57 by d 10 ($P = 0.03$). The NH_3-N and total VFA concentrations of the cattle fed the *Leymus chinensis* were decreased ($P < 0.05$) after diet changes and then increased to values similar to that before changing. Whereas the total VFA concentrations of the cattle fed the sweet potato vine have the opposite trend. Mean rumen pH, acetate and propionate proportion and the ratio of acetate to propionate were not affected by the treatments ($P > 0.05$). The cattle fed WSP diet had greater ($P < 0.05$) NH_3-N and total VFA concentrations and greater ($P < 0.05$) proportion of butyrate. The average pH values and the ratio of acetate to propionate were affected by cereal ($P = 0.004$, $P = 0.046$ respectively) and the concentrations of total VFA, the proportion of propionate and butyrate were affected by forage ($P = 0.006$, $P = 0.045$, $P < 0.001$, respectively). No cereal × forage interactions were detected among all rumen fermentation characteristics ($P > 0.05$). The rumen pH values and concentrations of NH_3-N and total VFA were fluctuated at certain sampling days after the abrupt change of diets, however, at the end of the adaptation period the rumen fermentation characteristics were similar to the values before diets changes. The result also indicated that the type of cereal and forge had apparent effects on rumen fermentation characteristics, but no interactions were observed.

Key Words: cereal, forage, rumen fermentation

W413 Effect of dietary energy source and level on nutrient digestibility, rumen microbial protein synthesis, and milk performance in lactating dairy cows.

X. Q. Zhou[1,2], J. Q. Wang[1], D. P. Bu*[1,3], Y. D. Zhang[1], M. Zhao[1], P. Sun[1,4], and T. Zhang[1], [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*College of Animal Science and Technology, Northeast Agricultural University, Harbin, China,* [3]*Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China,* [4]*CAAS-ICRAF Joint Lab on Agroforestry and Sustainable Animal Husbandry, Beijing, China.*

This study examined the effects of dietary energy source and level on feed intake, digestion, rumen microbial protein synthesis and milk performance of lactating dairy cows fed corn stover as the main forage source. Eight primiparous Chinese Holstein cows (138 ± 19.4 DIM, 29 ± 0.8 kg/d milk, and 589 ± 57.6 kg of BW), 4 of which were fitted with ruminal cannula, were used in a replicated 4 × 4 Latin square design with a 2 × 2 factorial treatment arrangement (energy level: NE_L 1.52–1.53 Mcal for LE and 1.71–1.72 Mcal for HE; energy source: SFC and GC). The NE_L was calculated based on Chinese recommendation (2004). Changes to dietary energy level were induced by feeding the cows diets of either 35.6% corn stover plus 1.24% EB100 or 13% corn stover, 22% corn silage plus 1.84% EB100 (a saturated free fatty supplement). Milk yield [27.8 vs. 24.6 kg/d (0.45 SEM), $P = 0.007$], milk protein content and yield [0.86 vs. 0.76 kg/d (0.01 SEM), $P = 0.006$], and milk lactose yield [1.34 vs. 1.20 kg/d, (0.02 SEM) $P = 0.008$] increased in response to increased levels of dietary energy, while contents of milk fat [4.22 vs. 4.24% (0.06 SEM), $P = 0.433$]and milk lactose [4.94 vs. 4.90% (0.08 SEM), $P = 0.323$] were not affected. Cows fed HE diets had a higher microbial protein yield [1.57 vs. 1.34 kg/d (0.54 SEM), $P = 0.003$] than those fed LE diets. Apparent digestibilities of nutrients were higher in HE than in LE diets. Milk yield [25.8 vs. 23.3 kg/d (0.434 SEM), $P = 0.047$], milk protein yield [0.79 vs. 0.72 kg/d (0.02 SEM), $P = 0.043$] and microbial protein yield [1.42 vs. 1.25 kg/d (0.33 SEM), $P = 0.038$] were also higher when SFC was used to replace GC as the main energy source for lactating cows fed with LE diets. This study suggest that increased dietary energy level and ruminal degradation rate are beneficial to milk protein production when cows are fed corn stover as a forage source, and this can be attributed to the resulting increased supply of microbial protein.

Key Words: energy, corn stover, microbial protein

W414 Physico-molecular structures and metabolic characteristics of protein in brown and yellow flaxseed with altered nutrient traits for dairy cattle.

Nazir A. Khan[1], Helen Booker[2], Yajing Ban[1], and Peiqiang Yu*[1], [1]*Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada,* [2]*Department of Plant Sciences, University of Saskatchewan, Saskatoon, SK, Canada.*

Flaxseed (*Linum usitatissimum* L.), also known as linseed, is one of the most important commercial oilseed crop of Western Canada, providing valuable inputs for food, feed, manufacturing and pharmaceutical industries. The objectives of this study were to investigate chemical profiles; protein subfractions; ruminal CP degradation and intestinal digestibility of RUP of flaxseed in dairy cattle; and protein molecular structures of newly developed yellow-seeded flax. Four flaxseed genotypes with 2 yellow breeding lines and 2 brown varieties obtained from Crop Development Center were evaluated. Each genotype were sampled from 2 replicate plots at 2 different locations. The flaxseed samples were analyzed for protein molecular profiles in terms of amide I and II, α-helix and β sheet structures using a JASCO FT/IR-ATR. The rumen and intestinal digestion of flaxseed were determined using in situ and 3-step in vitro methods with 4 lactating Holstein dairy cows (body weight, 680 ± 10 kg). The cows were fed TMR with forage to concentrate ratio 50 to 50. The data were analyzed as a RCBD with in situ cows as a random effect using the PROC MIXED procedure of SAS. The results showed that the yellow-seeded lines had higher ($P < 0.001$) contents of oil (44.5 vs. 41.4% DM, SEM = 0.35) and CP (24.9 vs. 20.9% DM, SEM = 0.96) compared with the brown-seeded varieties. The CP in yellow-seeds contained lower ($P < 0.01$) contents of true protein subfraction (81.3 vs. 92.7% CP, SEM = 1.46), and more ($P < 0.001$) extensively degraded (70.8 vs. 64.9% CP, SEM = 0.46) in rumen resulting in lower ($P < 0.001$) content of RUP (29.2 vs. 35.1% CP, SEM = 0.71) than the brown-seeded varieties. However, the total supply of digestible RUP was not significantly different between the 2 seed types. Regression equations based on protein molecular structural features gave relatively good estimation for the contents of CP ($R^2 = 0.87$), soluble CP ($R^2 = 0.92$), RUP ($R^2 = 0.97$) and intestinal digestibility of RUP in dairy cattle ($R^2 = 0.71$). In conclusion, molecular spectroscopy can be used to rapidly characterize flaxseed protein molecular structures and predict their nutritive value in dairy cattle.

Key Words: protein molecular structure, protein subfraction, flaxseed

W415 Effect of rubber seed oil and flaxseed oil on milk performance, fatty acid composition and oxidative stability of milk fat.

Y. Pi[1], J. Q. Wang[1], D. P. Bu*[1,3], L. Ma[1,2], Y. X. Zhu[4], and J. C. Xu[4], [1]*Institute of Animal Science, State Key Laboratory of Animal Nutrition, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*CAAS-ICRAF Joint Lab on Agroforestry and Sustainable Animal Husbandry, World Agroforestry Centre, East and Central Asia, Beijing, China,* [3]*Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China,* [4]*Kunming Institute of Botany, Chinese Academy of Sciences, Kunming, Kunming, China.*

The experiment was conducted to investigate the effect of rubber seed oil compared with flaxseed oil when fed alone or in combination on the milk yield, milk composition, fatty acid composition and oxidative stability of milk fat from dairy cows. Forty-eight mid-lactation Holstein dairy cows were randomly assigned to one of 4 treatments according to a completely randomized block design. Cows were fed a basal diet (Control) or the basal diet supplemented with 4% rubber seed oil (RO), 4% flaxseed oil (FO), or 2% rubber seed oil plus 2% flaxseed oil (RFO) on a dry matter (DM) basis for 9 weeks. Feed intake (DMI), milk protein percentage, and milk fat levels did not differ among the treatments. Cows fed the RO, FO or RFO treatments had a higher ($P < 0.001$) milk yield than the control group (up to 6.5% more), while milk fat percentages were decreased. Compared with the Control, milk concentration of α-linolenic acid (ALA) content was substantially higher in cows receiving RO or RFO, and was double in cows receiving FO ($P < 0.001$). Both $C_{18:1}$ *trans*-11 (VA) and $C_{18:2}$ *cis*-9,*trans*-11 (CLA) levels were higher ($P < 0.001$) in cows fed added flaxseed or rubber seed oil. The increasing in VA, ALA, and CLA was greater in cows fed RFO than in cows fed RO alone. Compared with the Control, the milk fat from cows fed any of the dietary supplements had a higher concentration of unsaturated fatty acids (UFA), monounsaturated fatty acids (MUFA) and polyunsaturated fatty acids (PUFA), while the average saturated fatty acids (SFA) levels in milk fat were 30% lower. Compared with the Control, the superoxide dismutase (SOD) and glutathione peroxidase (GSH-Px) activities were all decreased ($P > 0.05$) in RO, FO and RFO treatments, while the catalase (CAT) activity was decreased ($P < 0.05$) in FO and RFO groups. The concentration of malondialdehyde (MDA) tended to increase ($P < 0.10$) in RO, FO and RFO treatments. These results indicated that the supplement of rubber seed oil and flaxseed oil in dairy diet could increase milk yield and the functional fatty acids content (ALA, VA, and CLA) in milk fat, while decrease the content of saturated fatty acids and oxidative stability of milk fat.

Key Words: milk fat, oxidative stability, rubber seed oil

W416 Varying the degrees of synchrony of energy and nitrogen release in rumen affect the synthesis of microbial protein in continuous culture system.

J. Zhang[1], J. Q. Wang[1], D. P. Bu*[1,2], S. G. Zhao[1], P. P. Wang[1], and X. M. Nan[1,3], [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Sciences, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*World Agroforestry Centre,* *East and Central Asia, Beijing, China, [3]Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China.*

A continuous rumen simulation system apparatus with 16 1000 mL fermentation vessels was used to investigate the effects of different degrees of synchrony between ruminal available energy and nitrogen on rumen fermentation and microbial protein synthesis (MPS). The basal substrate was diet of (g DM/day) 18.50 corn straw, 10.00 corn, 0.26 premix, and 11.24 soybean meal containing 67.5 g N/kg DM, and diets were divided into 2 equal feedings at 09:00 and 21:00 h. The treatments were: the basal diet with (1) 10.0 g maltodextrin which was in the McDougall's buffer infused continuously into the fermenter (CONT), (2) 10.0 g maltodextrin as 2 6-h infusions starting at 09:00 and 21:00h (FAST) and (3) 10.0 g maltodextrin given as 2 6-h infusions starting at 15:00 and 03:00h (SLOW). Rumen inoculum was obtained from 4 ruminal fistulated cows in early lactation that were fed TMR with 45:55 forage to concentrate ratio. A 8-d incubation period was used, with the first 5 d serving as an adaptation period followed by 3 d of sampling with solid and liquid dilution rates in the fermenters set at approximately 10.0 and 8.0%/h, respectively. Data were analyzed using the MIXED procedure of SAS. All 3 infusion treatments had no significant effect on the apparent digestibility of OM (65.0% for CONT, 62.2% for FAST, and 61.2% for SLOW), DM (66.1%, 63.4% and 63.6%), and CP (71.5%, 68.2% and 68.6%). The pH values among 3 treatments were similar (6.70, 6.68 and 6.71). The concentrations of total volatile fatty acid for CONT and FAST treatments have higher tendency ($P = 0.05$) than SLOW (79.51 and 77.58 vs. 72.31, mmol/L). However, the CONT and FAST treatments increased ($P < 0.05$) MPS compared with SLOW (4.0 and 3.8 vs. 2.2, g/day). Compared with SLOW, the lower ($P < 0.01$) concentration of ammonia in CONT and FAST treatments (7.90 and 8.44 vs. 16.29, mg/dL) may indicate better utilization of ammonia for the growth of ruminal microbe. It is concluded that altering the degree of synchrony in the rates of ruminal release of energy and nitrogen had a marked effect on MPS.

Key Words: synchrony, energy, nitrogen

W417 Effects of wilting and additives on fermentation quality of alfalfa (*Medicago sativa* L.) silage.

H. Liu[1,2], J. Q. Wang[2], D. P. Bu*[2,4], Z. W. Lv[2], and P. Sun[2,3], *[1]College of Animal Science and Veterinary Medicine, Heilongjiang Bayi Agricultural University, Daqing, Heilongjiang, China, [2]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [3]Synergetic Innovation Center Of Food Safety and Nutrition, Harbin, China, [4]CAAS-ICRAF Joint Lab on Agroforestry and Sustainable Animal Husbandry, Beijing, China.*

The effect of wilting and different additives on alfalfa silage fermentation and nutritive value were studied under laboratory conditions. Lucerne (at the early bloom stage of maturity), wilted for 3 and 12 h respectively, was ensiled at 27.4% and 39.2% dry matter (DM) contents. Chopped grasses at each moisture content were either untreated (control) or treated with (1)inoculant (LAB) containing *Lactobacillus plantarum* LP70, *Lactobacillus casei* LC05, and *Enterococcus faecium* EF08 (a final application rate of 2×10^5 cfu/g of fresh forage); (2)sugar beet pulp (SB) at 50g kg^{-1} of fresh forage weight; (3)sodium formate (SF) at 6g kg^{-1} of fresh forage weight; (4)a combination of inoculant and sugar beet pulp (LAB+SB), and (5)sodium formate and sugar beet pulp combined (SF+SB). Forages were packed into triplicate 1-L laboratory silos per treatment at a density of 650 g/L. Silos were opened and analyzed after 65 d of ensiling. The results showed that all treatments had lower pH and lower concentrations of acetic and ammonia-N (of % TN), but higher concentrations of lactic acid than did untreated silages ($P < 0.001$). These effects were stronger in the LAB+M-treated silage. Addition of LAB+M resulted in silage with the highest concentrations of lactic acid (5.12 ± 0.36; $P = 0.011$) and the lowest ammonia-N (1.87 ± 0.07; $P < 0.001$) over treatments. Treated silages had similar concentrations of neutral detergent fiber (NDF), acid detergent fiber (ADF) and dry matter recovery compared with untreated silage. The addition of sugar beet pulp (SB) greatly reduced crude protein (CP) concentrations (20.53 ± 0.12 vs. 21.57 ± 0.12; $P < 0.001$) compared with control. Water-soluble carbohydrate concentrations were found increased in silage from alfalfa herbage treated with LAB+SB (2.09 ± 0.04 vs. 1.80 ± 0.04; $P < 0.001$) and SF-treated silage (2.04 ± 0.04 vs. 1.80 ± 0.04; $P < 0.001$) compared with untreated silage. Wilting reduced the rate of decline of silage pH ($P < 0.001$) and produced silages with lower acetic acid ($P < 0.001$) and ammonia-N contents ($P < 0.001$). As silage wilting was increased, silage quality was improved. Inoculant and sugar beet pulp combined (LAB+SB) was found to be the most effective additive.

Key Words: wilting, additive, alfalfa silage

W418 Effect of choline inclusion on lamb performance and meat characteristics.

Julio Godinez-Cruz[1], Oswaldo Cifuentes-Lopez[1], Jorge Cayetano[1], Hector Lee-Rangel*[1], German Mendoza[2], Anayeli Vazquez[1], and Alejandro Roque[1], *[1]Universidad Autónoma de San Luis Potosí, Facultad de Agronomía y Veterinaria, San Luis Potosi, San Luis Potosi, Mexico, [2]Universidad Autónoma Metropolitana, Departamento de Producción Animal, Distrito Federal, Mexico.*

The objective of this experiment was to determine the effect of rumen-protected choline (RPC Reashure; Excential RumenPass CH) and a vegetal Bio choline (Indian Herbs) on lamb performance in finishing rations. The experimental units were 24 Rambouillet lambs (23.4 ± 1.1 kg initial BW) housed in individual metabolic cages. The experiment lasted 42 d and treatments were: no choline (T1, control); 4 g/d biocholine (T2); 4 g/d RPC (T3). Lambs were assigned to one of the 3 experimental treatments according to a completely randomized design and data were analyzed using PROC MIXED with initial BW as a covariable. There were no differences ($P = 0.05$) on average daily gain and feed conversion; however, final BW (T1 = 32.7a, T2 = 33.9a, and T3 = 35.6b kg) and daily feed intake (T1 = 1.06a, T2 = 1.07a, and T3 = 1.22b kg) were different ($P < 0.05$). In carcass characteristics (cold carcass weight, hot carcass weight and rib area), only for meat color the L value were different (41.18a, 42.68b, and 42.58b to T1, T2, and T3, respectively). Therefore, addition of a choline did not change performance of finishing lambs, but could change some meat characteristics and final weight.

Key Words: lamb, choline, carcass

W419 Effects of *Yucca schidigera* extract on *Rumen Fermentation Parameters* in vitro.

J. L. Niu[1], L. Ma[1,2,] D. P. Bu*[1,3], J. N. Li[1], L. Pan[1], and J. C. Xu[4], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]CAAS-ICRAF Joint Laboratory of Agroforestry and Sustainable Animal Husbandry, World Agroforestry Centre, East and Central Asia, Beijing, China, [3]Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China, [4]Kunming Institute of Botany, Chinese Academy of Sciences, Kunming, Kuming, Yunnan, China.*

To investigate the effects of *Yucca schidigera* extract on fermentation characteristics in vitro, 5 treatments consisted of supplemental *Y. schidigera* extract at 0, 0.5, 2.5, 12.5 and 62.5 mg, which were assigned ran-

domly to 6 of 30 incubation bottles together with 0.5 g TMR (therefore, the adding levels of *Y. schidigera* were 0, 1, 5, 25, 125 g/kg TMR), 50 mL basal media and 25 mL rumen fluid obtained from rumen-cannulated lactation Holstein dairy cows. Cumulative gas production was continuously measured in an automated trace gas recording system (AGRS-III, Beijing) lasted for 30 h at a 39°C incubator. All fermentation vessels were cultured in shaking incubator at 39°C for 30 h. All the data were analyzed by SAS9.2. Results showed that pH and microbial crude protein (MCP) were not affected by the treatments, while the average pH in the treatments were 6.6 ± 0.05, 6.6 ± 0.05, 6.6 ± 0.06, 6.6 ± 0.03 and 6.6 ± 0.04, the average MCP were 1.58 ± 0.025, 1.61 ± 0.034, 1.58 ± 0.049, 1.61 ± 0.018 and 1.67 ± 0.055 mg/mL, while the total gas production, in vitro dry matter degradability (IVDMD), neutral detergent fiber degradation rate (DNDF) and acid detergent fiber degradation rate (DADF) were improved ($P = 0.028$, $P = 0.042$) at the level of 25 and 125 g/kg TMR. The averages of the total gas production were 121.85 ± 0.034, 119.68 ± 0.037, 120.22 ± 0.037, 135.29 ± 0.041 and 130.35 ± 0.042 mL/g, respectively. The average percent of IVDMD were 60.48 ± 0.888, 62.45 ± 1.045, 62.22 ± 0.686, 64.55 ± 0.796 and 64.55 ± 0.765, while the DNDF were 43.24 ± 0.004, 43.28 ± 0.003, 43.69 ± 0.001, 44.72 ± 0.004 and 44.32 ± 0.003, and the DADF were 31.66 ± 0.003, 31.87 ± 0.007, 32.10 ± 0.001, 32.95 ± 0.001 and 33.01 ± 0.003, respectively. With the increasing levels of *Y. schidigera* extract, the concentration of NH_3-N was decreased ($P = 0.042$), while the acetate, propionate and total volatile fatty acids (TVFA) were increased ($P = 0.030$, $P = 0.009$, $P = 0.048$) after 30 h incubation. The mean values of NH_3-N were 39.60 ± 0.839, 36.18 ± 1.063, 35.07 ± 1.576, 34.28 ± 1.698 and 34.12 ± 1.073 mg/mL, while the TVFA were 65.72 ± 1.388, 67.04 ± 1.473, 73.52 ± 1.58,4 67.82 ± 1.824 and 72.57 ± 1.080 mmol/L, respectively. The results indicated that *Y. schidigera* extract was beneficial to manipulate rumen fermentation in vitro.

Key Words: *Yucca schidigera* extract, in vitro fermentation, gas production

W420 Influence of Indian odd fruit oil and combination with yucca saponin or rubber seed oil on in vitro rumen fermentation parameters.

J. L. Niu[1], L. Ma[1,2], D. P. Bu*[1,3], L. Pan[1], and J. C. Xu[4], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]CAAS-ICRAF Joint Laboratory of Agroforestry and Sustainable Animal Husbandry, World Agroforestry Centre, East and Central Asia, Beijing, China, [3]Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China, [4]Kunming Institute of Botany, Chinese Academy of Sciences, Kuming, Yunnan, China.*

The objective of this experiment was to investigate the effects of Indian odd fruit oil (IO) and combination with *Yucca schidigera* (YS) or rubber seed oil (RO) on in vitro rumen fermentation parameters. The treatments were as follows: 5 doses (0, 1, 2, 3 and 4% DM) of IO, 5 doses (0, 0.5, 1, 1.5 and 2% DM of IO mixed with YS (12.5 mg) (IO+YS), respectively, and 5 doses (0, 0.5, 1, 1.5 and 2% DM) of both IO and RO (IO+RO) (4 replicates per treatment). All treatments were evaluated in vitro 24 h batch culture of 25 mL rumen fluid with 0.5 g TMR (48% forage and 52% concentrate) and 50 mL basal medium. The cumulative gas production (GP) was continuously measured in an automated trace gas recording system (AGRS-III, Beijing). After 24 h, pH was determined, and samples were collected to analyze ammonia N (NH_3-N), in vitro dry matter degradability (IVDMD), neutral detergent fiber degradation rate (DNDF), acid detergent fiber degradation rate (DADF) and volatile fatty acids (VFA). Results showed that 3% and 4% DM of IO reduced the DNDF and DADF ($P < 0.05$), without effecting pH, NH_3-N, IVDMD, GP, total and individual VFAs, 2% DM of IO increased the concentration of acetate and propionate ($P < 0.05$). 4% DM of IO+12.5 mg YS supplement reduced the DNDF and DADF ($P < 0.05$), and did not affect pH, IVDMD, GP, the concentration of NH_3-N or total and individual VFAs. Supplementation of IO+RO increased pH ($P < 0.05$), while did not affect IVDMD, GP, the concentration of NH_3-N or total and individual VFAs. However, 0.5% of IO+RO increased DNDF and DADF ($P < 0.05$), 1% of IO+RO decreased DADF ($P < 0.05$). It was concluded that supplements of IO, IO+YS and IO+RO nearly had no effect on rumen fermentation.

Key Words: Indian odd fruit oil, *Yucca schidigera*, rubber seed oil

W421 Influence of rubber seed oil on in vitro rumen fermentation parameters, fatty acid composition and methane production.

J. L. Niu[1], L. Ma[1,2], D. P. Bu*[1,3], L. Pan[1], and J. C. Xu[4], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]CAAS-ICRAF Joint Laboratory of Agroforestry and Sustainable Animal Husbandry, World Agroforestry Centre, East and Central Asia, Beijing, China, [3]Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China, [4]Kunming Institute of Botany, Chinese Academy of Sciences, Kuming, Yunnan, China.*

A completely randomized block experiment was designed to investigate the effect of rubber seed oil on in vitro rumen fermentation, concentration of unsaturated fatty acids and gas production. Rubber seed oil was added to total mixed ration (TMR) at the rate of 0, 1, 2, 3 and 4% dry matter of the diet (4 replicates per treatment). The culture medium consisted of 25 mL rumen fluid collected from 3 fistulated Holstein cows, 50 mL basal medium and 0.5 g TMR (48% forage and 52% concentrate), and each treatment was incubated for 24 h at 39°C. Gas production, fermentation kinetics, in vitro dry matter digestibility (IVDMD), neutral detergent fiber degradation (DNDF), acid detergent fiber degradation (DADF) and volatile fatty acids (VFA) were determined. The results showed as follows, gas production, pH, NH_3-N, IVDMD, DNDF, DADF, total and individual VFAs were not affected by rubber seed oil ($P > 0.05$). However, the DNDF tended to decrease linearly with increasing levels of rubber seed oil ($P < 0.1$). After 24 h incubation, 3% and 4% DM of rubber seed oil increased the concentrations of t11C18:1, c9c12C18:2, c9t11CLA, C22:2 and total fatty acids (TFA) ($P < 0.05$), 4% DM of rubber seed oil increased the concentrations of t9C18:1, C18:3, t10c12CLA ($P < 0.05$). Rubber seed oil seemed to enhance the accumulation of unsaturated fatty acids in rumen but did not affect rumen fermentation.

Key Words: rubber seed oil, rumen fermentation parameter, unsaturated fatty acid

W422 Changes of the rumen microbial profiles as affected by urea and acetohydroxamic acid addition in vitro.

D. Jin[1,4], J. Q. Wang[1], D. P. Bu*[1,2], P. P. Wang[1], S. G. Zhao[1], and X. M. Nan[1,3], *[1]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]CAAS-ICRAF Joint Laboratory of Agroforestry and Sustainable Animal Husbandry, World Agroforestry Centre, East and Central Asia, Beijing, China, [3]Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China, [4]Gembloux Agro-Bio Tech, University of Liège, Gembloux, Belgium.*

In ruminants, urea was broken down rapidly to ammonia by rumen bacteria and urease inhibitors were used for increasing the efficiency of urea utilization by inhibiting ruminal urease. However, the effect of urea and urease inhibitors on the rumen microbes was not clear. This study investigated the effect of urea and AHA (acetohydroxamic acid) addition in the diets on rumen microbial diversity using dual-flow continuous culture systems. Eight fermenters were used in a period of 10 d (7 d for adaptation and 3 d for sampling) experiment and TMR (containing alfalfa hay 17.72%, corn silage 17.5%, steam corn 7.39%, soybean meal 2.64%) were placed into each fermenter twice a day. Based on this diet, the fermenters were assigned to a 2 × 2 factorial arrangement of treatments with urea supplemented at 0 or 0.5% dry matter intake (DMI), and AHA equivalent to 0 or 450 mg/kg DMI. While the urea and AHA were dissolve in the artificial saliva and infused into the vessels twice daily. On each sampling day, fermentation fluids were collected at 0 h, 2 h, 6 h and 10 h from each fermenter. Total DNA of rumen microbe were extracted and subjected for DGGE and 16S rRNA gene sequencing. Distinct bacterial profiles were observed with urea addition and little differences were found with AHA addition. UPGMA analysis showed that samples with urea and AHA addition were clustered together. Group with urea addition showed a higher Shannon diversity compared with other groups ($P < 0.01$). 16S rRNA gene sequencing analysis revealed that the dominant ruminal bacteria shared by all 4 groups belonged to phyla *Firmicutes*, *Bacteroidetes* and *Proteobacteria*. However, in urea adding groups, the bacteria *Lachnospiraceae*, *Clostridiaceae*, and *Succinivibrionaceae* were found in highest abundance compared with the other 2 groups ($P < 0.01$). In contrast, the *Paraprevotellaceae* and *Veillonellaceae* bacteria were abundant in treatments without urea ($P < 0.01$). Little difference of the bacteria abundance was found with AHA addition. In conclusion, adding urea to the diet could change the ruminal bacteria diversity while AHA addition had little effect on the rumen microbiota.

Key Words: rumen bacteria diversity, urea, acetohydroxamic acid (AHA)

W423 Milk production and composition responds to dietary neutral detergent fiber and starch ratio in dairy cows.

M. Zhao[1], J. Q. Wang[1], D. P. Bu*[1,3], X. Q. Zhou[1], D. Zhu[1], and P. Sun[1,2], [1]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*CAAS-ICRAF Joint Laboratory of Agroforestry and Sustainable Animal Husbandry, World Agroforestry Centre, East and Central Asia, Beijing, China,* [3]*Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China.*

The objective of this study was to investigate effects of dietary carbohydrate composition with different dietary neutral detergent fiber (NDF):starch ratio by altering the forage to concentrate ratio on milk production and milk composition synthesis in dairy cows. Eight primiparous (146 ± 21.6 d in milk) including 4 rumen cannulated dairy cows were assigned to 4 total mixed rations (TMRs) in a replicated 4 × 4 Latin square design. Each experiment period was 21 d containing 14 d of adaptation and 7 d of measurement. Four dietary treatments were designed in which corn grain was gradually replaced with corn silage and oat hay. The NDF:starch ratios of TMRs were 0.86, 1.18, 1.63 and 2.34 from group T1 to T4, respectively. Dry matter intake (DMI) and milk production was averaged 20.8 kg/d and 31.4 kg/d, and decreased by 21.1% and 14.8% from group T1 to T4 ($P < 0.01$). Digestibility of dry matter (DM), organic matter (OM), NDF, crude protein (CP) were linearly decreased from group T1 to T4 ($P < 0.01$), and averaged 69.9%, 72.1%, 50.5% and 72.8%, respectively. However, digestibility of starch showed no difference among groups and averaged 93.7% ($P > 0.05$). As NDF:starch ratio increased, milk protein content and production, and milk lactose content and production were linearly reduced ($P < 0.01$), and averaged 3.1%, 0.97 kg/d, 4.95% and 1.56 kg/d, respectively. However, milk fat content was linearly increased from 3.72% to 4.25% from group T1 to T4 ($P < 0.01$). Quadratic effect was observed on milk fat production ($P < 0.01$), which increased from 1.23 kg/d to 1.31kg/d from group T1 to T3, and then decreased to 1.20 kg/d in group T4. Therefore, it implied that great attention should be directed at this dietary factor (NDF:starch ratio) in practical diet formulation.

Key Words: carbohydrate composition, NDF:starch ratio, milk production

W424 Evaluation of enhanced mineral block on in vitro rumen microbial fermentation.

Chang Dae Jeong, Lovelia L. Mamuad, Catherine G. Avedoza, Sang Suk Lee*, Bang Geul Kim, and Maro Lee, *Sunchon National University, Suncheon, Jeonnam, South Korea.*

Mineral block is a strategic feed supplement for ruminants that provides a constant source of minerals to promote growth of rumen microbes. Hence, this study was conducted to investigate the effect of enhanced mineral blocks on in vitro rumen fermentation. Ruminal samples were collected from 3 ruminally cannulated Holstein Friesian cattle, and a commercial concentrate substrate was offered at 2g DM/100mL buffered ruminal fluid. Five enhanced mineral blocks were investigated and the treatments were: non addition (control), commercial mineral block (T1), T1+0.6ppm selenium (T2), T1+100ppm ammonium chloride (T3), T1+300ppm sodium bicarbonate (T4) and T1+0.03% molasses (T5). Each serum bottle was filled anaerobically and sealed before incubation at 0, 3, 6, 12 and 24 h. All treatments were conducted in triplicates and analyzed by ANOVA for randomized complete block design. Duncan's multiple range test (DMRT) was used to identify differences among treatments and control. All analyses were carried out using SAS version 9.1 (SAS, 2002). All treatments resulted in decreased pH and increased gas production as incubation time increases. Total gas production was higher ($P < 0.05$) in T1 to T4 than that of T5 and control at 12 h of incubation. Ammonia-nitrogen (NH_3-N) concentration was lowest ($P < 0.05$) in T4 (11.54 m*M*) after 24 h incubation followed by T5 and then T3. Also, propionate concentrations were higher ($P < 0.05$) in T2 to T5 at 12 h and T1 to T5 at 24 h incubation with T4 and T3 being the highest after 12 and 24 h of incubation with 22.56 m*M* and 27.55 m*M*, respectively. Acetate to propionate ratio was inversely proportional as the time increases in all treatment groups wherein lowest concentration was observed in T3 (1.47 m*M*) after 24 h incubation. Total volatile fatty acid (TVFA) was relatively higher in all treatments than the control group wherein T4 have the highest result after 12 and 24 h incubation with 72.13 and 86.56 m*M*, respectively. In conclusion, enhanced mineral block such as sodium bicarbonate (T4) can improve gas production, propionate and total volatile fatty acid for better rumen microbial fermentation.

Key Words: enhanced mineral block, in vitro, total volatile fatty acid

W425 Effects of cassava peel as a replacement for corn on nutrient digestibility and lactating performance of dairy cows.

Viviany Lúcia Fernandes dos Santos[1], Marcelo de Andrade Ferreira[2], Geraldo Tadeu dos Santos[3], Raphael Eduardo Moretti[3], Tobias Tobit de Barros Melo[2], Leônia Régia Costa da Silva[1], Thaynah Vasconcelos Gracindo[1], Michelle de Oliveira Maia Parente[4], and Valdi de Lima Júnior*[1], [1]*Universidade Federal do Rio Grande do Norte, Natal, Rio Grande do Norte, Brazil,* [2]*Universidade Federal Rural de Pernambuco, Recife, Pernambuco, Brazil,* [3]*Universidade Estadual*

de Maringá, Maringá, Paraná, Brazil, [4]Universidade Federal do Maranhão, Chapadinha, Maranhão, Brazil.

Fresh cassava peel (*Manihot esculenta*) has a potential used as a ruminant feed due to advantages such as a high amount of soluble carbohydrates with high digestibility. This agroindustrial residue could provide the energy necessary for animal production in situations where the availability of feed is limited, because it is cheaper than commodities such as corn. Eight Holstein cows (480 ± 24 kg BW and 88 ± 17 d in milk) were allotted in a double Latin-Square design (4×4) to evaluate the effect of the replacement of corn by cassava peel in the diets on performance of dairy cows. Each experimental period lasted 21 d, 14 d for adaptation and 7 d for sampling. Diets were isonitrogenous (12.8% ± 1.0 CP, DM basis) and composed of 37.5% concentrate and 62.5% corn silage and Tifton hay. Treatments were defined by 4 replacement levels of corn by cassava peel: 0, 33, 66, and 100% (DM basis). The data were analyzed by using the MIXED procedure (SAS Inst. Inc.). Orthogonal polynomials for diet responses were determined by linear and quadratic effects. Effects were declared significant at $P \leq 0.05$. The replacement of corn by cassava peel linearly decreased ($P \leq 0.05$) dry matter (DM) intake (17.0, 17.0, 16.0, and 16.07 kg.d^{-1} for 0, 33, 66, and 100% of replacement) and organic matter (OM) intake. Crude protein (CP) intake and neutral detergent fiber (NDF) intake did not differ ($P \geq 0.05$) among treatments. DM digestibility (65.2, 54.4, 46.7 and 44.2% for 0, 33, 66, and 100% of replacement corn by cassava peel), CP digestibility, OM digestibility and NDF digestibility also linearly decreased ($P \leq 0.05$) with the replacement of corn by cassava peel. In addition, there was a linear decrease ($P \leq 0.05$) in milk production (20.0, 20.0, 19.0 and 18.0 kg.d^{-1} of replacement corn by cassava peel). Although cassava peel decreased parameters evaluated, the replacement of corn with cassava peel may be interesting in locations near to starch industry, as well as cows with low nutritional requirements.

Key Words: digestibility, industry residue, milk production

W426 Creatinine excretion in Nelore heifers grazing during dry season. Jarbas Miguel da Silva Junior*, Luciana Navajas Rennó, Sebastião de Campos Valadares Filho, Edenio Detmann, Mario Fonseca Paulino, Rilene Ferreira Diniz Valadares, Taiane da Silva Martins, Lyvian Cardoso Alves, and Ricardo Marostegan de Paula, *Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The creatinine excretion through the sampling spot of urine has been studied as an indicator of urinary volume. However, no studies in the literature have reported its use in animal grazing. The aim of this study was to evaluate the excretion of creatinine in beef cattle. Five heifers with 300 ± 15 kg average body weight were distributed in three 5×5 Latin squares and kept in individual paddocks equipped with feeding and drinking troughs. The experimental treatments were defined to represent those commonly used in the dry season, as follows: control (mineral salt), concentrated with 20.31% crude protein (CP) on dry matter (DM) being offered (OF) level of 0.5 to 1% of body weight fasted (BWF) OF5 and OF10, respectively; and 2 concentrated self-regulating (SR) consumption, containing 69.38% CP on a DM basis (20% urea and 20% salt) offered ad libitum (SR70) and other concentrate containing 39.73% CP based on MS being offered ad libitum (SR40). The experiment included four 17-d periods; the first 12 d were for adaptation, and the remaining 5 d were for data collection. The total collection of urine was carried out between d 13 and 17 of each experimental period, for which a Foley catheter number 26 2-way was used, with 50-mL flask placed on the d 13 of each experimental period. At the free end, the probe was coupled by conductive polyethylene hose to 2 L collection bag (polyethylene bag) with secured with ropes in a sturdy cotton fabric bag to the animal's neck in the ventral region. The animals were led to a weigh crate every 2 h from 0800 to 2000 h, and every 4 h from 2000 to 0800 h to facilitate the emptying of the bag. A urine sampling was performed every 4 h, obtaining a sample of 10 mL diluted in 0.036 N H_2SO_4. The creatinine content was assessed through an kinetic colorimetric test. Data were analyzed using the *PROC* MIXED procedure of SAS 9.1. The creatinine excretion was not affected by treatments or day and time of sampling ($P > 0.05$) with an average rate of 23.03 ± 0.30 (22.73 to 23.33) mg/kgBW. The spot sampling technique may be used to estimate the daily excretion of creatinine in animals kept in a pasture system.

Key Words: creatinine, bovine, urine

W427 Influence of varying level of fibrolytic enzyme on nutritive value of oat grass silage in cannulated buffalo bulls. Mahr un Nisa*[1], Osman Ahmad Khan[2], Sarwar Muhammad[3], and Muhammad Sharif[3], *[1]Institute of Home and Food Science, Govt. College University, Faisalabad, Punjab, Pakistan, [2]Livestock and Dairy Development, Lahore, Punjab, Pakistan, [3]Institute of Animal Nutrition and Feed Technology, University of Agriculture, Faisalabad, Punjab, Pakistan.*

This experiment was conducted to examine the influence of varying levels of fibrolytic enzyme on oat grass silage nutrient digestibility and ruminal characteristic in ruminally cannulated buffalo bulls using 4×4 Latin square design. The enzyme used was blend of xylanase (350000 BXU/g, where 1 BXU is the amount of enzyme that will release 0.06 micromole of reducing sugar (xylose equivalent) from birch xylan per minute at pH 5.3 and 50°C) and cellulase (10000 ECU/g, where 1 ECU is the amount of enzyme that will release 0.06 micromole of reducing sugars as glucose from hydroxethyl cellulose per minute at pH 4.8 and 50°C) and was derived from *Trichoderma reesei*. The control diet (C) was without enzyme, whereas diets containing 1, 2 and 3 g enzyme per Kg of silage's dietary neutral detergent fiber (NDF) were denoted as low (LE), medium (ME) and high enzyme (HE) diets, respectively. Animals were fed only silage twice daily at 1% of their body weight. The apparent silage DM digestibility by animals fed ME diet (63.4 ± 3.70) was significantly higher ($P < 0.05$) and was lowest in animals fed C diet (60.7 ± 3.11). Similar trend was noticed in CP, NDF and ADF digestibility. The ruminal pH was higher ($P < 0.05$) in animals fed LE (6.73 ± 0.05), ME (6.64 ± 0.04) and HE (6.65 ± 0.06) diets than those fed C diet (6.52 ± 0.04). Similarly, ruminal NH_3-N concentration (mg/dL) was higher ($P < 0.05$) in animals fed LE (20.4 ± 2.05), ME (20.6 ± 2.21), HE (21.1 ± 1.96) diets than those fed C diet (18.7 ± 1.91). The blood glucose was higher ($P < 0.05$) in animals fed LE, ME and HE diets than those fed C diet at 3 and 6 h postprandial. However, blood urea nitrogen remained unaltered across all diets. In conclusion, enzyme supplementation increased nutrient digestibility, ruminal NH_3 and blood glucose.

Key Words: fibrolytic enzyme, cannulated buffalo bull, silage

W428 Adaptation of dairy cows to grazing after TMR feeding during early lactation: I. Effects on endocrine profile and hepatic expression of IGF system genes. Ana L. Astessiano*[1], Pablo Chilibroste[2], Diego A. Mattiauda[2], Ana Meikle[3], and Mariana Carriquiry[1], *[1]School of Agronomy, UDELAR, Montevideo, Uruguay, [2]School of Veterinary Medicine, UDELAR, Paysandú (EEMAC), Uruguay, [3]School of Veterinary Medicine, UDELAR,, Montevideo, Uruguay.*

Multiparous cows (n = 18) were used in a randomized complete block design to study endocrine profile and hepatic gene expression related to

IGF system on the adaptation to grazing after TMR feeding during early lactation. During the first 60 d postpartum (DPP), cows were assigned to 1) TMR (30 kgDM/d offered; 45% forage, 55% concentrate) and 2) 50% pasture in one (am) grazing session (6 h; pasture allowance 4 cm above ground level = 15 kgDM/d) + 50% TMR (15 kgDM/d offered) (G1). At 61 DPP and during 21 d, all cows were managed as G1 group determining 2 treatments (TREAT): PostTMR and G1. Plasma and liver biopsies were collected pre (+55 DPP) and post (+75 DPP) dietary change. Gene expression was quantified by SYBR-Green real time RT-PCR. Means from a repeated analysis using a mixed model were considered to differ when $P < 0.05$. Average milk energy output and BCS from 61 to 82 DPP did not differ between TREAT (27.5 and 25.7 ± 1.4 Mcal/d and 2.8 and 2.7 ± 0.1 units for PostTMR and G1, respectively). Plasma IGF1 concentrations at +75 DPP were greater in PostTMR than G1 cows (161 vs. 127 ± 26 ng/mL) as decreased from +55 at +75 DPP only in the latter cows. Plasma insulin and leptin as well as hepatic IGF1, IGF2 IGFBP2, and IGFBP4 mRNA were not affected by TREAT, DPP or its interaction. Before the diet change (+55 DPP), PostTMR cows had greater hepatic IGFBP1 mRNA but lower IGFBP3 mRNA than G1 cows. However, IGFBP1 mRNA had a 2.1-fold decrease while IGFBP3, IGFBP5 and IGFBP6 mRNA had 0.4 to 0.9-fold increase in PostTMR cows with the dietary change (+55 to +75 DPP). In addition, hepatic IGFBP3 mRNA decreased by 65% during this period in G1 cows. These changes determined that at +75 DPP, hepatic IGFBP3, IGFBP5 and IGFBP6 mRNA were greater while IGFBP1 mRNA was less in PostTMR than G1 cows. Decreased plasma IGF1 and hepatic IGFBP3 mRNA in G1 cows were associated with the increased milk yield from +55 to +75 DPP in these cows. In addition, while milk yield, BCS, and plasma IGF1 were maintained after the diet change in PostTMR cows, expression of IGFBP mRNA in the liver was modified in these cows

Key Words: nutrition, gene expression, grazing

W429 Effects of feeding 3-nitrooxypropanol (NOP) on rumen microbial profiles in lactating dairy cows and beef cattle.

Mi Zhou*[1], Yanhong Chen[1], Jennifer Haisan[1], Atmir Romero-Perez[1,2], Karen A. Beauchemin[2], Masahito Oba[1], Maik Kindermann[3], Stephane Duval[4], and Le Luo Guan[1], [1]*Department of Agricultural, Food, and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada,* [2]*Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada,* [3]*DSM Nutritional Products, Animal Nutrition & Health, Basel, Switzerland,* [4]*DSM Nutritional Products France, Research Centre for Animal Nutrition and Health, Saint Louis Cedex, France.*

3-Nitrooxypropanol (NOP) can reduce CH_4 production from the rumen of dairy cows and beef cattle, but the effect of NOP on the rumen microbiome is unknown. The current project aimed to evaluate the microbial profile changes in 4 studies with NOP fed to beef and dairy cows. Rumen contents were collected from 2 dairy (Study 1: Haisan et al., 2014; Study 2: unpublished data) and 2 beef (Study 3: Romero-Perez et al., 2014; Study 4: Romero-Perez et al., 2015) studies, and subjected to genomic DNA extraction. Bacterial, archaeal and protozoal rRNA fragments were amplified and subjected to pyrosequencing analysis using 454 Titanium FLX (Roche). The main bacteria phyla in the rumen were found to be affected by NOP treatments: in dairy, Firmicutes was greater in control than in NOP dairy cows for Study 1 (58 vs 55%, $P = 0.03$); while in beef, Bacteroidetes proportions varied among different NOP levels for Study 3 (from 31% for Control to 36% for NOP, $P < 0.01$) and among NOP treatment periods for Study 4 ($P = 0.04$). NOP also influenced other minor bacterial phyla, with the magnitude of impact differing among studies. The major methanogen genera were similar for all studies, and similar trends were found for both beef and dairy studies: *Methanobrevibacter ruminanitum* was greater ($P < 0.05$) in all 4 studies (57 vs 46%; 66 vs 51%; 52 vs 37%; 30 vs 20%) while *Mbb. gottschalkii* was less ($P < 0.01$) in cattle receiving NOP (Studies 2 to 4: 36 vs 20%; 59 vs 42%; 68 vs 54%). *Mbb. smithii* and *Methanosphaera stadtmanae* responded to NOP feeding in different ways depending upon the study. Entodiniomorphida predominated the protozoal community (>90%). The protozoa composition was not affected by NOP, and no clusters formed according to NOP dosage. In conclusion, NOP may reduce enteric CH_4 though changing rumen microbial community, but its effect of each phylotype was different, requiring further experimentation to understand its mode of action in altering the rumen microbiome.

Key Words: 3-nitrooxypropanol, rumen microbiome

W430 Effect of protein supplementation to low-quality forage diets on enteric methane production and ruminal microbial community structure of beef steers.

Adam L. Shreck*[1], Nirosh D. Aluthge[3], Jenny S. Jennings[2], Samodha C. Fernando[3], and N. Andy Cole[1], [1]*USDA-ARS, Bushland, TX,* [2]*Texas Agrilife Research, Amarillo, TX,* [3]*University of Nebraska-Lincoln, Lincoln, NE.*

British-cross steers (n = 23; initial BW: 344 ± 33.9 kg) were used in a 3-period crossover design to evaluate the effect of protein supplementation to low-quality forage on ruminal methane (CH_4) and metabolic carbon dioxide (CO_2) emissions, forage intake, and microbial composition. Steers were individually given ad libitum access to low-quality bluestem hay (3.9% crude protein) and provided one of 3 supplements: (dry matter basis): no protein (CON), cottonseed meal (CSM; 0.29% of body weight (BW) daily) or dried distillers grains with solubles (DDGS; 0.41% of BW daily). Ruminal CH_4 and metabolic CO_2 fluxes were obtained 6.3 ± 1.6 times/steer daily using a GreenFeed unit (C-Lock Inc., Rapid City, SD). Microbial community structure of ruminal fluid collected using stomach tubes was determined using 16S rRNA based sequencing. Forage intake increased ($P < 0.01$) by 35.0% with protein supplementation; however, no difference ($P = 0.14$; SEM: 0.36) was observed between CSM (5.82 kg/d) and DDGS (5.50 kg/d). Flux of CO_2 (g/d) was greater ($P < 0.01$; SEM: 172.0) for steers fed CSM (5,520) and DDGS (5,453) than for steers fed CON (4,895). Steers supplemented with CSM (204.9) had greater ($P < 0.01$; SEM: 5.8) CH_4 emissions (g/d) than DDGS (189.2), both of which were greater ($P < 0.01$) than CON (174.1). Methane emissions, as a proportion of GE intake (Y_m), were lower ($P < 0.01$; SEM: 0.25) for DDGS (7.27%) and CSM steers (7.80%) than CON (10.10%). Principal coordinate analysis revealed shifts in microbial community structure with CON having greater abundance of specific operational taxonomic units (OTU) classified as *Firmicutes* and *Streptococcus* while CSM contained greater *Bacteroidetes* and *Prevotella* and DDGS steers had greater abundance of specific OTUs belonging to *Clostridiales* and *Anaerobiviro*. Results of this study suggests that the common practice of supplementing protein to cattle consuming low-quality forage increases overall gas emissions but yields beneficial decreases in greenhouse gas emissions per unit of intake and alters microbial community structure.

Key Words: enteric methane, protein, 16S rRNA

W431 Effect of a *Saccharomyces cerevisiae* preparation on in vitro ruminal fermentation of four fibrous substrates.

Karla Y. Valdés[1], Ivàn Mateos[1], Cristina Saro[1], Alexey Díaz[1,4], María Dolores Carro[2], Abdelfattah Z. M. Salem[3], and María José Ranilla*[1,4], [1]*Animal Production Department, University of León, León, Spain,* [2]*Agriculture Production Department, Technical University of Madrid, Madrid, Spain,* [3]*Faculty of Veterinary Medicine and Animal Science,*

Autonomous University of the State of Mexico, Mexico, [4]IGM (CSIC-ULE). Finca Marzanas s/n, Grulleros, León, Spain.

Yeast cultures, especially *Saccharomyces cerevisiae*, are beneficial in the rumen, and have been progressively introduced into the feed industry. They can affect microbial activities, thus improving fiber digestion, modifying VFA production and increasing animal performance. Most of studies have focused on yeast effects when good quality and high concentrate diets are used, but much less attention has been paid to the possible effects with fibrous feeds. In this study, the effects of a preparation of *S. cerevisiae* (strain SC-47) on in vitro ruminal fermentation of 4 fibrous feeds differing in quality and chemical composition were analyzed. Two low-quality forages (barley straw and *Pennisetum purpureum* clon Cuba CT-115) and 2 medium-quality forages (alfalfa hay and grass hay) were used. Samples of the forages (500 mg) were accurately weighed into 120-mL serum bottles, and incubated with buffered rumen fluid (50 mL) at 39°C for 24 h. Based on previous experiments with the same product, 4 doses of the *S. cerevisiae* preparation were tested as feed additive in batch cultures at 0, 25, 50 and 100 µL/bottle. VFA and gas production, pH, ammonia-N concentrations and true in vitro digestibility (TIVD) were measured. There were no additive x substrate interactions ($P > 0.05$) for any variable. TIVD, ammonia-N concentration and acetate:propionate ratio were not affected ($P > 0.05$) by SC-47 addition to the batch cultures. Gas production and total VFA production were linearly increased ($P < 0.001$) by increasing amounts of SC-47, whereas pH was linearly decreased ($P = 0.010$). Also, the production of all individual VFA linearly increased with the addition of the different doses of SC-47 (acetate, $P = 0.001$; propionate, $P < 0.001$; butyrate, $P < 0.001$; and the sum of isobutyrate, isovalerate and valerate, $P < 0.001$). The results show that *S. cerevisiae* stimulate ruminal fermentation in vitro of these fibrous forages of different quality, and so, studies analyzing their possible influence on fermentation of low-quality substrates are recommended.

Key Words: *Saccharomyces cerevisiae*, batch culture, forage

W432 Nutritional evaluation of corn wet feed in cannulated Nili-Ravi buffalo bulls. M. Nisa*[1], M. Osman[3], S. Najeeb[4], and M. Sarwar[2], *[1]Department of Food Science, Nutrition and Home Economics, Govt. College University, Faisalabad, Pakistan, [2]Institute of Animal Sciences, University of Agriculture, Faisalabad, Pakistan, [3]Livestock and Dairy Development Board, Lahore, Pakistan, [4]Star Farm Pvt Ltd., Sargodha, Pakistan.*

The study was aimed to examine the influence of replacing corn wet feed (CWF) with corn grains on feed intake, nutrient digestibility, nitrogen balance and ruminal characteristics in ruminal cannulated buffalo bulls. The animals were fed 1% of their body weight. All diets were isocaloric (2.30 Mcal/kg) and isonitrogenous (12.55%CP). The control diet CWF0 did not contain CWF, Whereas CWF10, CWF20 and CWF30 diets had 10, 20, and 30% CWF, respectively. Animals were housed on concrete floor in separate pens and water was made available round the clock. The experiment lasted for 80 d. The 4 × 4 Latin square design was used in this experiment and means were compared by Duncan's new multiple range test. Dry matter (DM) and crude protein (CP) intakes were not differ ($P > 0.05$) in animals fed diets containing with and without CWF. Neutral detergent fiber (NDF) intake was higher ($P < 0.05$) in buffalo bulls fed diets contained different levels of CWF. Dry matter, CP and NDF digestibilities were highest ($P < 0.05$) in animals fed CWF10 diet than those fed CWF0, CWF20 and CWF30 diets while DM, CP and NDF digestibilities remained same ($P > 0.05$) among animals groups fed CWF0, CWF20 and CWF30 diets. All animal were in positive nitrogen balance. However, there was high nitrogen retention observed in animal fed CWF10 and CWF20 diets. Ruminal pH in buffalo bulls at 0, 3, 6 and 9 h remained same across all diets. Ruminal NH_3-N at 0 h was also same while significant ($P < 0.05$) difference was observed in buffalo bulls at 3, 6 and 9 h across all diets. In this study 10% replacement of corn grain with CWF showed better nutrient digestibility, nitrogen balance and ruminal characteristics of Nili-Ravi buffalo bulls.

Key Words: corn wet feed, corn replacement, buffalo bulls

W433 Effect of direct-fed microbial supplementation and different diets on performance and carcass characteristics in beef feedlot heifers. Laura F. Prados*[2,1], Galen E. Erickson[1], Nirosh Aluthge[1], Samodha C. Fernando[1], Curtis J. Bittner[1], and Fred H. Hilscher[1], *[1]University of Nebraska-Lincoln, Lincoln, NE, [2]Universidade Federal de Viçosa-MG, Viçosa, Minas Gerais, Brazil.*

The objective of this study was to measure feedlot performance and carcass characteristics of heifers fed a newly developed direct-fed microbial (DFM) or not within 2 different basal diets. Three hundred thirty-six heifers (348 ± 33 kg) were used in a randomized block designed study with 24 pens (6 replications/treatment). The treatment design was a 2 × 2 factorial arrangement consisting of 2 basal diets based on corn (CON) or 40% modified distillers grains plus solubles replacing corn (MDGS) and presence (1×10^9 cfu/mL of each bacteria species/animal per day) or absence of DFM. The DFM was isolated from prior experiments, grown in the lab, and consisted of members of *Bacteroides* and *Lachnospiraceae* that were top-dressed on feed immediately after feeding to ensure accurate supply daily to pens. One block (4 pens) of heifers was harvested after 133 d on feed and 3 blocks (20 pens) were harvested after 147 d on feed. Hot carcass weight was obtained the day of harvest, and LM area and fat thickness collected after a 48-h chill. Carcass adjusted final BW was calculated using HCW divided by a common dressing percentage (63%), and used for ADG and G:F. All data were analyzed using the MIXED procedure of SAS with an $\alpha = 0.05$ and pen as the experimental unit. There were no interactions ($P > 0.25$) between diet and DFM supplementation for DMI, ADG, G:F, and HCW; thus, main effects of basal diet and DFM are presented. There were no differences in DMI, ADG, and carcass characteristics ($P > 0.23$) due to supplementation of DFM. Heifers fed DFM tended ($P = 0.10$) to be less efficient. Feeding MDGS increased ($P < 0.01$) DMI, ADG, and HCW of heifers. Feed efficiency was improved ($P < 0.01$) by 7% for heifers fed MDGS diets compared with CON. Heifers fed MDGS were fatter ($P < 0.01$) compared with CON likely due to greater ADG. The DFM developed for this study did not enhance performance, while feeding modified distillers grains compared with corn improved performance.

Key Words: carcass characteristics, direct-fed microbial, modified distillers grains plus solubles

W434 Effect of Econase on rumen fermentation patterns, diet digestibility and performance pre-and postpartum of primiparous dairy cows. D. N. Lobão da Silva*[1], R. Riewer[2], A. Gander[1], N. Walker[2], B. Ellison[2], M. Endres[1], and N. B. Litherland[1], *[1]University of Minnesota, Saint Paul, MN. USA, [2]AB Vista, Marlborough, UK.*

The objective of this study was to examine the effect of feeding a fibrolytic enzyme preparation (Econase) via a molasses-based liquid feed (MLF) on digestibility, ruminal patterns and milk production of primiparous dairy cows. Thirty-six (n = 18) dairy heifers were blocked by BW, BCS, mature 305 ME and assigned to 2 treatments from d 45 pre- to 56 postpartum: 1) untreated MLF diet (CON); 2) enzyme treated MLF diet (ECO). Treated MLF preparation conferred activity of 3,500

BXU/g of xylanase. An amount of 0.5mL of treated or untreated MLF was mixed to each kg of DM of pre- and postpartum TMR before feeding. Data were analyzed using the MIXED procedure of SAS. Prepartum DMI was similar (14.2 vs. 15.0 kg/d; $P = 0.17$) between CON and ECO treatments and no differences were observed on ruminal pH (7.1 vs. 7.0; $P = 0.64$), %NDFd (60.0 vs. 57.9; $P = 0.48$) or %DMd (64.9 vs. 61.3; $P = 0.15$) for CON compared with ECO treatment, respectively. However, enzyme supplementation tended ($P = 0.09$) to increase colostrum yield by 32% (3.9 vs. 5.2 kg) although no changes were observed on total colostrum solids concentration. Postpartum DMI (20.6 vs. 20.9 kg/d; $P = 0.78$), 3.5% FCM yield (28.5 vs. 29.9 kg/d; $P = 0.27$) and milk fat (3.6 vs. 3.5%; $P = 0.59$) were similar for CON and ECO treatments, respectively. Postpartum NEFA and BHBA were also similar (181.0 vs. 161.1μEq/L; $P = 0.41$) and (5.8 vs. 5.6 mg/dL; $P = 0.66$), respectively for CON and ECO. Postpartum ruminal fluid pH tended ($P = 0.08$) to be greater for ECO (6.53 vs. 6.71) compared with CON, but % NDFd was similar (53.7 vs. 52.1; $P = 0.58$). Although numerical increases in milk yield (28.3 vs. 30.1 kg/d; $P = 0.15$) for ECO treatment, the design did not have enough statistical power to report a significant effect. Future research is needed to investigate whether different doses and feeding period length of this fibrolytic enzyme may affect performance and growth of first lactation animals.

Key Words: fibrolytic enzyme, primiparous, xylanase

W435 Effect of supplementation of rumen-protected vitamins (choline, riboflavin, and folic acid) in heat-stressed dairy cows in northern Mexico (La Laguna Region).

Pedro A. Robles-Trillo*[1], Janet Garcia[1], Francisco G. Veliz-Deras[1], Carlos Arechiga-Flores[2], Rafael Rodriguez-Martinez[1], and Karla Fernandez[1], [1]*Universidad Autonoma Agraria Antonio Narro, Torreon, Coahuila, Mexico,* [2]*Universidad Autonoma de Zacatecas, Calera, Zacatecas, Mexico.*

Purpose of present work was to evaluate the effect of supplementation of rumen-protected vitamins (choline, riboflavin and folic acid) on incidence and appearance metabolic diseases. Dairy cows (n = 105), on the transition period (fresh and challenged cows). Cows were randomly allotted from May to August into 2 groups: 1) Control cows (cows receiving the regular total-mixed ration without vitamin supplementation; TMR), and 2) RPV-cows (cows receiving a supplement containing rumen-protected vitamins; i.e., 50 g/cow/day). Five blood samplings were performed to determine incidence of metabolic disorders and/or postpartum diseases (d 0, 19, 30, 50, and 80 after R-PV supplementation). Three periparturient diseases were monitored: retained fetal membranes, metritis, and ketosis, defined as follows: (1) retained-fetal membranes (RFM), was considered when fetal membranes were not expelled 12 h after parturition; 2) metritis (M) was diagnosed when cows presented a blood-purulent vaginal discharge at 7 d after parturition; (3) ketosis: mount of β-hydroxybutyrate was determined though evaluation of a blood sample using reactive bands for ketone bodies (Abbott, Precision Xtra), and using a Ketometer (Ketometer Precision Xtra). Data were analyzed using a 2-independent samples comparison analysis, using a 2 × 2 contingency table (considering year and treatment). Supplementation of rumen-protected vitamins (RPV: choline, riboflavin and folic acid), during the transition period of dairy cows, reduced incidence of retained fetal membranes from 52.24 to 12.30%; incidence of ketosis from 29.52 to 6.67% and incidence of metritis from 79.05 to 15.24% ($P < 0.05$). In conclusion, under present study conditions, supplementation 50 g/cow/d of rumen-protected vitamins (choline, riboflavin and folic acid), during the transition period, significantly reduced incidence of retained fetal membranes, metritis and ketosis, in heat-stressed dairy cows at northern Mexico (La Laguna dairy region).

Key Words: dairy cow, metabolic disorder, vitamins

W436 Effect of reducing dietary calcium, phosphorus and trace minerals on intake and performance of finishing Nellore bulls.

Laura F. Prados*[2,1], Breno Silva[2], Herlon M. Alhadas[2], Marcos P. Rodrigues[2], Ana C. O. Lopes[2], Danillo F. T. Sathler[2], Paloma M. Amaral[2], Lays D. S. Mariz[2], Sebastião C. Valadares Filho[2], and Galen E. Erickson[1], [1]*University of Nebraska-Lincoln, Lincoln, Nebraska,* [2]*Universidade Federal de Viçosa-MG, Viçosa, Minas Gerais, Brazil.*

Mineral nutritional studies are important to establish dietary needs and avoid excesses for improved excretion and economics. The aim of this experiment was to evaluate the effect of decreasing calcium, phosphorus and trace mineral concentration in finishing performance and carcass characteristics using weaned Nellore bulls (n = 36; 273 ± 37 kg) in a RCBD-designed study. Treatments A and B contained 96.3 and 97.9% of the Ca and P requirement by supplementation of limestone and dicalcium phosphate whereas treatments C and D contained 47.8 and 66.8% of the BR-CORTE published requirement for Ca and P, respectively. Treatments A and B contained 56.8 ppm of Zn, 49.2 ppm of Mn, and 15.4 ppm of Cu and C and D contained 31.2 ppm of Zn, 42.3 ppm of Mn, and 5.8 ppm of Cu. The diets were isonitrogenous (13.3% CP). Intake was monitored every day. The cattle were slaughtered (84 and 147 d) and LM area and 12th rib fat thickness measured. Feed samples were analyzed for DM, ash, CP, Ca, P, and trace minerals (Zn, Mn and Cu). Treatment differences were declared significant by Tukey's test at $P \leq 0.05$. Calcium, P and trace mineral concentration did not affect DM and OM, CP, NDF, EE, and NFC intake ($P > 0.42$). Calcium and P intake were different among the treatments ($P < 0.01$) with supplemented bulls consuming more Ca and P in treatments A and B compared with treatments C and D. Final BW, empty BW, and ADG were similar ($P > 0.16$) among treatments. Carcass characteristics were not influenced ($P > 0.70$) by dietary treatment. These data suggest that dietary mineral concentration did not influence cattle performance. These results indicate that councils overestimate the requirements of Ca, P, and trace minerals, so supplementation is not necessary in conventional feedlot diets. Dietary reductions in these minerals would represent a significant decrease in the costs of feedlot and reduction in mineral excretion.

Key Words: mineral requirement, phosphorus, trace mineral

W437 Overfeeding energy alters visceral fat miRNA profiles in Holstein cow.

Afshin Hosseini[1], Hua Bao[2], Khuram Shahzad*[1], James K. Drackley[1], Leluo Guan[2], and Juan J. Loor[1], [1]*University of Illinois, Urbana, IL,* [2]*University of Alberta, Edmonton, AB, Canada.*

MicroRNAs (miRNAs) are small regulatory molecules (~22 nt) which cause post-transcriptional gene silencing. Our objective was to examine the effect of overfeeding a moderate-energy diet on miRNA expression in mesenteric adipose tissues of dry non-pregnant cows. Fourteen Holstein cows were assigned to treatments in a randomized complete block design. All cows were fed individually a control diet (CON; NEL = 1.3 Mcal/kg) to meet 100% of NRC requirements for 3 wk, after which half of the cows were assigned to a moderate-energy diet (OVE; NE_L = 1.6 Mcal/kg) and half of the cows continued on CON for 6 wk. The OVE diet was fed ad libitum and resulted in cows consuming energy at ~180% of NRC. CON cows were fed to consume only to 100% of NRC. The BW was measured from wk −3 to 6 wk. Cows were slaughtered after 6 wk, and samples of mesenteric fat collected for total RNA plus miRNA extraction, and miRNA sequencing. The differential expression of miRNAs in OVE vs. CON was assessed using *EdgeR* with an FDR adjusted *P*-value ($P < 0.05$). The analysis of predicted miRNA target genes was performed by estimating a Total Context+ Value ($TC+V \leq -0.7$) using the TargetScan database. OVE cows had greater ($P < 0.001$) BW at slaughter (758 vs. 693 kg). Fourteen miRNAs were differentially expressed ($P < 0.05$); the OVE cows had a greater expression of miRNAs bta-miR-378, 22–3p, 107, 103, 149–5p, 378c, 30c, 1307 and 6529a, whereas, the bta-miR-199a-5p, 205, 339b, 339a and bta-miR-27a-3p were upregulated in CON cows. The TargetScan analysis predicted the transcriptional change of 47 genes related to cellular ion transport and binding (e.g., Na$^+$/K+ and calcium), fat metabolism (*PPARGC1B*) and feeding behavior (*GPR178*). Overfeeding energy did not alter insulin sensitivity but seemed to affect adipogenesis and fatty acid metabolism in mesenteric adipose tissue. In OVE cows, *PPARG* was the main target gene triggered by bta-miR-30c upregulation. The results suggest that miRNAs can respond to dietary energy level and likely play a role in regulating adipose tissue metabolism and energy expenditure.

W438 Microbial protein yield of Nellore bulls supplemented with protein sources associated with crude glycerin on finishing phase. Antonio Jose Neto*[1], Joanis Tilemahos Zervoudakis[2], Luciana Keiko Hatamoto-Zervoudakis[2], Luciano da Silva Cabral[2], Juliane Quenoizoré Soares[2], Rosemary Lais Galati[2], Renata Pereira da Silva-Marques[2], Everton Riva Donida[2], and Lilian Chambó Rondena Pesqueira Silva[2], *[1]Department of Animal Science; São Paulo State University-UNESP, Jaboticabal, SP, Brazil, [2]Department of Basic Sciences and Animal Production; Federal University of Mato Grosso-UFMT, Cuiabá, MT, Brazil.*

Crude glycerin (Gly) has the potential to partially replace starch-based ingredients in the diet, such as corn, because glycerol is converted to propionate in the rumen and acts as a precursor for hepatic glucose synthesis. The objective of this study was to evaluate the effects of Gly combined with protein sources on microbial protein yield of Nellore bulls fed tropical pasture during the rainy season. Five Nellore bulls (448.2 ± 14 kg; 25 ± 3 mo) were evaluated in a 5 × 5 Latin square design with 5 treatments and 5 periods. The animals were allocated into 5 paddocks of 0.25 ha, consisting of *Brachiaria brizantha* 'Marandu' in the rainy season. Crude glycerin (83.9% of glycerol) was used in all supplements to replace (15% of DM) corn. The supplements were: Gly with urea (GU), Gly with soybean meal (GS), Gly with cottonseed meal (GC), and Gly with corn gluten (GG), and the control received mineral mixture ad libitum. Animals were individually supplemented at the rate of $300\ g \cdot 100\ kg^{-1}$ of BW, daily, at 1000 h. Urine samples were collected 4 h after the supplementation to determine the concentration of urea, creatinine, nitrogen and purine derivatives, on the last day of period. Data were analyzed using the PROC MIXED of the SAS. Purines derivatives absorbed, microbial N, microbial protein and CP intake per digestible organic matter intake was lower ($P < 0.05$) for control compared with protein sources (Table 1). Crude glycerin associated with protein sources can be efficient to improve microbial protein yield.

Contd.

W439 Effects of supplemental protein sources associated with crude glycerin in Nellore bulls finished on pasture on apparent digestibility. Antonio Jose Neto*[1], Joanis Tilemahos Zervoudakis[2], Luciana Keiko Hatamoto-Zervoudakis[2], Luciano da Silva Cabral[2], Renata Pereira da Silva-Marques[2], Rosemary Lais Galati[2], Juliane Quenoizoré Soares[2], Everton Riva Donida[2], and Felipe Cacite[2], *[1]Department of Animal Science; São Paulo State University-UNESP, Jaboticabal, SP, Brazil, [2]Department of Basic Sciences and Animal Production; Federal University of Mato Grosso-UFMT, Cuiabá, MT, Brazil.*

Previous studies demonstrated that crude glycerin (Gly) was an excellent energy source and can partially replace corn grain in ruminant diets. The aim of this study was to evaluate the effect of supplemental protein sources associated with Gly on digestibility of OM, NDF and CP of Nellore bulls in tropical pasture during the rainy season. Five Nellore bulls (448.2 ± 14.8 kg) were used in a 5 × 5 Latin square design (5 periods and 5 treatments). The pastures were divided into 5 paddocks of 0.25 ha each, consisting of *Brachiaria brizantha* 'Marandu'. Crude glycerin was used in all supplements to replace (15% of DM) corn. The supplements were: T1 - Gly with urea, T2 - Gly with soybean meal, T3 - Gly with cottonseed meal, and T4 - Gly with gluten, and the control received mineral mixture ad libitum. Animals were individually supplemented at the rate of $300\ g \cdot 100\ kg^{-1}$ of BW, daily, at 1000 h. To estimate feed intake, chromium oxide was used as external marker, and indigestible neutral detergent fiber (iNDF) was used as internal marker (forage intake). Fecal grab samples were collected on d 15–17 in different times. Fecal samples were composited on a wet-basis by period for each bull. Fecal and ingredients samples were analyzed for OM, NDF and CP contents. Data were analyzed using the PROC MIXED of the SAS. There was no effect of Gly associated protein sources on digestibility of OM and NDF (Table 1). However, there was effect on digestibility of CP ($P = 0.04$). Crude glycerin showed be an good energy source and can partially replace corn grain (15% of DM) in ruminant diets. Independently of protein source utilized, there was an increase of 21.3% ($P = 0.04$) on digestibility of CP for animals supplemented when compared with control group. Urea associated with Gly can be effective for improving CP digestibility of Nellore bulls in tropical pasture.

W440 Nutrient intake of Nellore bulls in tropical pasture supplemented with crude glycerin and different sources of protein.

Antonio Jose Neto*[1], Joanis Tilemahos Zervoudakis[2], Pedro Veiga Rodrigues Paulino[2], Luciana Keiko Hatamoto-Zervoudakis[2], Renata Pereira da Silva-Marques[2], Luciano da Silva Cabral[2], Juliane Quenoizoré Soares[2], Everton Riva Donida[2], and Felipe Cacite[2], *[1]Department of Animal Science; São Paulo State University-UNESP, Jaboticabal, SP, Brazil, [2]Department of Basic Sciences and Animal Production; Federal University of Mato Grosso-UFMT, Cuiabá, MT, Brazil.*

This study was aimed to evaluate the effect of supplemental protein sources associated with glycerin on DM and nutrient intake of Nellore bulls in tropical pasture during the rainy season. Five Nellore bulls (448.2 ± 14.8 kg) were used in a 5 × 5 Latin square design (5 periods composed of 17 d and 5 treatments). The pastures were divided into 5 paddocks of 0.25 ha each, consisting of Brachiaria brizantha 'Marandu'. All diets consisted of 15% of crude glycerin (DM) associated with protein sources: urea (GU), soybean meal (GS), cottonseed meal (GC), gluten (GG), and the control. Animals had a free access to mineral supplement. Animals were individually supplemented at the rate of 300 g·100 kg^{-1} of BW, daily, at 1000 h. To estimate feed intake, chromium oxide was used as an external marker, and indigestible neutral detergent fiber (iNDF) was used as an internal marker to estimate forage intake. All data were analyzed using the MIXED procedure of SAS. Dry matter intake (% of BW) was higher ($P < 0.01$) when animals were supplemented with GU (Table 1). Forage intake was increased ($P = 0.02$) fed animals with GU supplements compared with other treatments. Supplement intake was similar ($P = 0.89$) among treatments. Feeding GU increased ($P < 0.01$) OM, CP, NDF and TDN intake of bulls. Crude protein intake were greater in bulls consuming supplements ($P < 0.01$) compared with control, which is logical due the lower content of CP in forage. Providing supplement with association of crude glycerin and urea for grazing cattle in the rainy season improved dry matter and nutrient intake. Crude glycerin can partially replace (15% of DM) energy source in ruminant diets.

W441 Protein molecular structure and nutritive value of yellow and black canola seed.

Katerina Theodoridou[1,2], Ban Yajing*[2], and Peiqiang Yu[2], *[1]University of Saskatchewan, Saskatoon, SK, Canada, [2]Queen's University, Belfast, UK.*

Oilseeds and their products are the most valuable agricultural crops in world trade. Canola includes the yellow and the black-seeded varieties. Apart from the chemical composition of oilseed crops, their protein secondary structure profiles may also influence protein quality, nutrient utilization and availability. Although data are rare, is vital to study protein secondary structure to understand crop's digestive behavior and nutritional value. A new approach is the use of Fourier-transformed infrared-vibration spectroscopy (FT/IR), a technique for studying the secondary structural composition, stability and conformational changes. The objective was to evaluate the nutritive value of canola seed, for ruminants, in terms of: 1) chemical and nutrient profiles 2) rumen degradation kinetics, 3) in vitro intestinal protein digestibility and 4) protein molecular structures. Yellow (CS-Y) and black (CS-B) canola seeds ($n = 4$) were collected from 2 harvest years (2010, 2011) and used as feed sources. Three dry Holstein cows fitted with rumen cannula were used in an in situ trial; then a 3-step in vitro procedure was conducted to determine protein intestinal digestibility. CS-Y was lower in nitrogen detergent fiber and acid detergent fiber ($P < 0.05$). Crude protein content was not different between the 2 varieties but the non-protein nitrogen was lower ($P < 0.05$) for CS-Y compared with CS-B. The net energy for lactation, the digestible and metabolisable energy were higher ($P < 0.05$) for CS-Y compared with CS-B. The C20:1 eicosaenoic acid content (n-9) was lower ($P < 0.05$) while the total polyphenols were tended to be lower ($P \leq 0.10$) for the CS-Y than for the CS-B. No significant differences were observed for the effective degradability of protein and the protein's inherent molecular structural make up, between the CS-Y and the CS-B. The in vitro protein intestinal digestibility of CS-Y was higher ($P < 0.05$) compared with that of CS-B. In conclusion, the breeding of CS-Y has the potential to be a promising route to reducing fiber and hull content, while at the same time increasing the level of oil.

Key Words: canola, protein molecular structure, ruminal digestion

W442 Effect of supplementation of two sources and two levels of copper on performance, copper status and ruminal fermentation in Nellore bulls.

Lisia Bertonha Correa, Marcus Antônio Zanetti, Janaína Silveira Silva, Brenda Barcelos*, and Arlindo Saran Netto, *University of Animal Science and Food Engineering, Pirassununga, São Paulo, Brazil.*

Thirty-five Nellore bulls were used to determine the effect of supplementation of 2 levels and 2 sources of copper (organic and inorganic) on performance, copper status in the body and ruminal parameters. The 5 treatments used were: 1) Control (C) - without copper supplementation; 2) 10 mg of Cu / kg of DM (as Cu sulfate; CuI10), 3) 40 mg of Cu/ kg of DM (as Cu sulfate; CuI40); 4) 10 mg of Cu/ kg of DM (as Cu proteinate; CuO10); 5) 40 mg of Cu / kg of DM (as Cu proteinate; CuO40), for a period of 84 d. Body weight and blood samples were collected every 28 d for copper and ceruloplasmin analysis. At slaughter samples collected consisted of rumen fluid for short chain volatile fatty acids (VFA) determinations and ammonia nitrogen, also liver and muscle samples were collected for copper analysis. The experimental design was a completely randomized design with 7 replicates. Data were analyzed using PROC GLM of SAS. Means were compared by contrasts at a 5% significance level. There were no significant effects of copper level in the muscle (4.45, 4.24, 4.82, 4.21 and 5.79 with 1.05 of SEM for C, I10, I40, O10 and O40, respectively) and copper concentrations in the serum (0.873, 0.885, 0.967, 0.896 and 0.901 with

0.03 of SEM for C, I10, I40, O10 and O40, respectively). However, there was a quadratic effect for supplementation with different sources and Cu levels, with respect to time. The Cu concentration in the liver was higher ($P < 0.05$) in animals supplemented with CuO40 with the values 237.3, 435.7, 607.5, 466.6 and 765.4 with 48.71 of SEM for C, I10, I40, O10 and O40, respectively. The CuI40 treatment showed the highest serum activity of ceruloplasmin ($P < 0.05$). There was no significant effect for feed efficiency between treatments. The ruminal pH, VFA and ammonia nitrogen were not affected by treatments. In general, copper supplementation altered the Cu "status" in the animal with a greater accumulation of Cu in the liver of animals receiving the CuO40. These results show that feeding higher amounts of organic Cu make the mineral more bioavailable.

Key Words: cattle, mineral, performance

W443 Effects of dietary tannin extracts levels during a thirteen-week period on lactating cow performance and N use efficiency.

Matias J. Aguerre*[1], Benjamin D. Duval[2], Mark Powell[1], Peter Vadas[1], and Michel A. Wattiaux[1], [1]*Department of Dairy Science, University of Wisconsin-Madison, Madison, WI,* [2]*Department of Biological Systems Engineering, University of Wisconsin-Madison, Madison, WI.*

Our objective was to determine the long-term effect of feeding tannin extracts to lactating cows on performance and nitrogen (N) utilization efficiency. Thirty-four multiparous lactating cows (711 ± 59 kg BW; 113 ± 19 DIM) were randomly assigned to 3 dietary treatments in a randomized complete block design. Following a 2-wk covariate adjustment period, cows were fed their assigned treatment diets for 13 weeks. Rice hull was removed from a 54:46 forage to concentrate ratio (%DM) TMR as a tannin extract mixture from Quebracho and Chestnut trees (2:1 ratio) was included at 0 (control), 0.45, and 1.8% of dietary DM. Urinary excretion (g/d) was calculated as 0.0283 × BW (kg) × MUN (mg/dL). There was no interaction between dietary treatments and experimental week. Overall, milk yield (48.7 kg/d), fat-and-protein corrected milk (46.7 kg/d), milk fat content (3.89%) and yield (1.86 kg/d) and true protein yield (1.45 kg/d) were not affected by dietary treatments. There was a linear increase in DMI (29.2 to 30.9 kg/d), a linear decrease in milk/DMI (1.67 to 1.57 kg/kg) and a linear decrease in MUN (12.2 to 10.8 mg/dL) with incremental levels of tannin extracts in the diet (all $P < 0.01$). There was a quadratic effect ($P < 0.01$) for milk true protein content, (2.96, 3.13, and 3.00% for control, 0.45 and 1.8% tannin extract, respectively) and a tendency for linear ($P = 0.07$) and quadratic ($P = 0.06$) response for BW gain (0.31, 0.16 and 0.44 kg/d for control, 0.45 and 1.8% tannin, respectively). Intake of N increased linearly (782, 795, and 820 g/d) and N utilization efficiency (milk N/intake N) decreased linearly (0.30, 0.30 and 0.28) for control, 0.45 and 1.8% tannin, respectively. An 11% reduction ($P < 0.01$) in estimated urinary N excretion was observed between control and 1.8% tannin extract. In this study, adding tannin to the diet reduced feed efficiency, but had a positive effect on milk protein content at 0.45% tannin extract level. Feeding tannins at 1.8% in the diet may reduce dietary protein degradation and urinary N excretion without affecting milk protein yield.

Key Words: tannin, nitrogen efficiency, dairy

W444 Evaluation of inoculation method on rumen in vitro gas production kinetics.

F. O. Scarpino-van Cleef*[1] and J. P. Keim[2], [1]*São Paulo State University, Jaboticabal, São Paulo, Brazil,* [2]*Universidad Austral de Chile, Valdivia, Región Los Rios, Chile.*

This study evaluated the effect of pooling rumen fluid (RF) or using fluid of one cow across incubations on in vitro gas production (GP) on parameters of feedstuffs. A complete randomized block design was used and arranged in a 4 × 2 factorial scheme. Concentrate (corn grain, barley, soybean meal, mineral and vitamin premix) grass silage, grass hay and grass pasture were dried, ground and placed into 160-mL glass bottles. Duplicates of each substrate (1g) plus 2 blanks were incubated for three 48-h runs (considered as technical replicates). Bottles with 85 mL of Goering-Van Soest buffer solution were purged with CO_2 and 10 mL of RF was added to them. One treatment was incubated with RF from one cow (different for each run; not-pooled), whereas the other, a pool of RF from the same 3 cows was used for all runs. The volume of gas was extracted with a syringe, until the pressure in the digital display of the transducer reached 0, at times 2, 3, 4, 5, 6, 8, 10, 12, 18, 24 and 48h after incubation. A generalized Michaelis-Menten (MM) model was used to estimate fermentation kinetics, considering A: asymptote of GP (mL/g OM); N: shape of the curve; C: half-life rate degradation (%/h); K: time to ferment 50% of the substrate (h); MDR: maximum degradation rate (%/h); t25, t75: time to ferment 25 and 75% of asymptotic GP, respectively (h); 48GP: GP at 48 h. MIXED procedure of SAS was used, with the incubation method and substrate as fixed, and the run as random effect. The variance components (substrate, incubation, and error) were determined for each method with the varcomp procedure of SAS. There was no interaction between substrates and inoculation method; therefore, the variables were analyzed independently. The use of pooled RF promoted greater values of A (218) and t75 (23.3) compared with not-pooled RF (A = 212, t75 = 21.4), with P values and SED of 0.02 and 2.3, and 0.03 and 0.8 for A and t75, respectively. All other parameters did not differ between inoculation methods. Substrate effect was significant ($P < 0.001$) for all MM parameters. For both inoculation methods, more than 94% of the variance was due to the substrates for all MM parameters. The variance accounted for incubation-runs was similar among inoculation method. Gas production parameters of different substrates follow a same trend regardless of the inoculation method.

Key Words: batch culture, gas production

W445 In vitro evaluation of a treatment to flaxseed for reducing bio-hydrogenation of the n-3 fatty acid a-linolenic.

Scott L. Kronberg*[1] and Eric J. Scholljegerdes[2], [1]*USDA-ARS, Northern Great Plains Research Laboratory, Mandan, North Dakota,* [2]*Department of Animal and Range Sciences, New Mexico State University, Las Cruces, New Mexico.*

Given the human health benefits of increasing n-3 fatty acid intake, inadequate intake of these fatty acids by many people, and problems associated with supplying these fatty acids from marine sources, there is a need to increase amounts of n-3 fatty acids in foods that are frequently eaten and affordable. Therefore, this study evaluated the amount of the α-linolenic acid (ALA) that was bio-hydrogenated by bovine ruminal microbes to evaluate the potential effectiveness of a consumer-acceptable protective treatment to flaxseed. The proprietary treatment to flaxseed was evaluated with an in vitro fermentation trial that was conducted for 12 or 24 h. A small amount of quebracho tannin was included in the in vitro medium of some fermentation tubes to determine if this material could help reduce bio-hydrogenation of ALA. Residue from each tube was lyophilized then analyzed for fatty acids using direct trans-esterification with methanolic-HCl. The trial had a completely randomized design with a factorial arrangement of treatments. The treatment applied to flaxseed reduced ($P < 0.01$) bio-hydrogenation of ALA with 65% of ALA remaining after 24 h of fermentation versus 23% remaining for the non-treated flaxseed. Inclusion of tannin in fermentations did not help reduce bio-hydrogenation ($P = 0.15$), and the interaction of flaxseed treatment and tannin was not significant ($P = 0.56$). These results indicate that the protective treatment applied to flaxseed may reduce bio-hydrogenation of ALA in cattle and this may lead to greater amounts of n-3 fatty acids in their muscles if they consume the treated flaxseed daily for several months before harvest.

Key Words: n-3 fatty acids, cattle, ruminants

W446 Evaluation of botanical extracts supplemented or not with live yeast compared with monensin supplementation on rumen fermentation in lactating Jersey cows. Bertrand Medina*[1], Phillip Meiring[2], Bruno Ghilardi[1], and Lourens Erasmus[2], *[1]Laboratoires Phodé, France, [2]Dept of Animal & Wildlife Sciences, University of Pretoria, South Africa.*

More and more countries have banned the use of antibiotic growth promoters in livestock nutrition stimulating the neo-investigation for natural alternative additives. The objectives of this study were (i) to compare the effects of monensin sodium (MO), botanical extracts (BE) and its combination with a yeast product (BE+LY) on dairy cow performance by determining their effect on rumen pH and general rumen fermentation and (ii) to determine whether natural alternatives have the potential to replace ionophores as the primary fermentation altering feed additive for lactating Jersey cows. Four rumen cannulated lactating Jersey cows were used in a 4 × 4 Latin square design experiment. The 4 experimental treatments were: 1) Control (C), a lucerne hay/maize based TMR (10.7 MJ ME/kg, 17% CP, 32.1% NDF), 2) MO (15 mg/kg of Rumensin, Elanco Animal Health), 3) BE (1g/d/cow, Oleobiotec, Laboratoire PHODE, France) and 4) BE + LY (group 3 combined with $1x10^{10}$ cfu yeast (*Saccharomyces cerevisiae* CNCM I-1077)/d/cow. The experimental periods were 25 d with the last 4 d for milk performance, rumen sampling and the *in sacco* nutrient disappearance. Results (Table 1) suggest that the tested BE has potential to be a natural alternative to ionophore antibiotics in dairy diets.

Table 1 (Abstr. W446). Effect of feed additives

Parameter	C	MO	BE	BE + LY	SEM
DMI (kg/d)	22.0^{cd}	21.3^{d}	22.7^{c}	22.3^{cd}	0.5

W447 Fertilization and dried distillers grains supplementation effects on performance and nitrogen recovery by stocker cattle grazing old world bluestem. Phillip A. Gunter*, Brody D. Wallis, Phillip A. Lancaster, and Gerald W. Horn, *Oklahoma Agricultural Experiment Station, Stillwater, OK.*

A 2-yr study evaluated the efficacy of using dried distillers grains plus solubles (DDGS) as a substitute for nitrogen (N) or N and phosphorus (P) fertilizer in stocker cattle grazing Plains Old World bluestem. Cattle were allotted to 1 of 4 treatments:1) Old World bluestem pastures with no N or P fertilizer and low stocking rate of 325 kg BW/ha (CONT), 2) Old World bluestem pastures fertilized with 90 kg/ha of N and no P with high stocking rate of 650 kg/ha (NFERT), 3) Old World bluestem pastures fertilized with 90 kg/ha of N and 40 kg/ha of P with high stocking rate of 650 kg BW/ha (NPFERT), and 4) unfertilized Old World bluestem pastures with the same stocking rate as NFERT and NPFERT with cattle receiving 0.75% BW of corn DDGS per day for a 5 d/week feeding schedule (SUPP). Average forage mass in yr 1 and 2 was 3,170 and 6,051 kg/ha, respectively. In yr 1 final BW ($P < 0.05$), total BW gain ($P < 0.05$), overall ADG ($P < 0.05$), and gain/ha ($P < 0.05$) were greater for SUPP compared with CONT, NFERT, and NPFERT. Nitrogen recovery as cattle weight gain was greatest ($P < 0.05$) for CONT (28.32%), and SUPP (14.22%) was greater than NFERT (4.42%) and NPFERT (4.77%). In yr 2 there were no differences ($P > 0.05$) between final BW, total BW gain, or overall ADG between treatments. This may have been due to greater forage mass in yr 2. Gain per ha was greater ($P < 0.05$) for SUPP, NFERT, and NPFERT compared with CONT and may be due to increased stocking rates for those treatments. Nitrogen recovery was greater ($P < 0.05$) for CONT (45.45%), intermediate for SUPP (18.20%), and lowest for NFERT (6.91%) and NPFERT (6.81%). Dried distillers grains can be used as a substitute for forage and N fertilizer by improving performance and N recovery by stocker cattle grazing Old World bluestem.

Key Words: stocker cattle, Old World bluestem, nitrogen recovery

W448 Effect of altered nitrogen excretion by condensed tannin supplementation on steer energy losses. Adam L. Shreck*[1], Pake J. Ebert[3], Eric A. Bailey[3], Jenny S. Jennings[2], and N. Andy Cole[1], *[1]USDA-ARS, Bushland, TX, [2]Texas Agrilife Research, Amarillo, TX, [3]West Texas A&M University, Canyon, TX.*

Uncertainty remains regarding the effect of excess dietary protein on the energetic cost of urea excretion in beef cattle. We individually fed British-cross steers (n = 27; initial BW = 350 ± 32 kg) a finishing diet based on steam-flaked corn (14.4% CP) top dressed with commercially-available condensed tannin extract (CT) at 3 levels (0, 0.5, and 1.0% of diet, DM basis). Ruminal methane (CH_4) and metabolic CO_2 fluxes were measured using a GreenFeed unit (C-Lock Inc., Rapid City, SD) for two 20-d sampling periods, that coincided with fecal and urine sampling. Diet digestibility and N balance were estimated approximately 30 d after the experiment began (EARLY) and 30 d before the animals were harvested (LATE), using TiO_2 as a marker of fecal output and urinary creatinine:BW ratio as a marker for urine output, respectively. From this, we previously determined that fecal N excretion as a percentage of total N excretion increased approximately 10% as CT supplementation increased to 1.0%. Urine energy loss was estimated from urine N excretion, assuming all excreted N was urea. Heat production was estimated from the Brouwer (1965) equation. Oxygen consumption was estimated from CO_2 production assuming a respiratory quotient of 1.05. Flux of CO_2 (10,279, 10,537, and 10,478, g/d; SEM: 542.5) and CH_4 (144, 154, and 158 g/d; SEM:13.2) were similar ($P \geq 0.23$) among treatments during both sampling periods for 0, 0.5, and 1.0% CT, respectively. Percentage of GE intake lost as CH_4 was not different for 0 (3.27%), 0.5 (3.32%) or 1.0% (3.71%) CT. Proportion of GE intake lost in urine averaged 1.03, 1.01, and 0.97% for CT levels of 0, 0.5, and

1.0%, respectively but was not different among treatments ($P \geq 0.41$; SEM: 0.08). Heat production was similar across treatments (27.3, 28.0, 27.8 Mcal/d; $P \geq 0.52$; SEM: 1.37) and no difference was observed for heat production lost as a percent of GE intake (47.0%, 45.7%, 50.1%) for 0, 0.5, and 1.0% CT, respectively. The results of this study suggest that while N excretion was altered by 10% from urine to feces by tannin supplementation, no difference in energy losses was observed.

Key Words: condensed tannin, net energy, nitrogen

W449 Organ mass in pure and crossbred mature beef cows grazing different herbage allowances of grasslands.

Alberto Casal*[1], Ana L. Astesiano[1], Ana I. Trujillo[1], Ana C. Espasandin[2], Pablo Soca[2], and Mariana Carriquiry[1], *[1]Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay, [2]Facultad de Agronomia EEMAC, Universidad de la Republica, Paysandu, Uruguay.*

The aim of this study was to evaluate the effect of controlling the intensity of grassland grazing (Campos biome), through control of herbage allowance (HA), on mass of internal organs of beef cows of different genotype. Mature beef cows (n = 32) were used in a randomized complete block design with a factorial arrangement of herbage allowance (2.5 vs. 4 kg DM/d; LO vs. HI) of native pastures (52% DM, 8.4% crude protein, 39.7% acid detergent fiber,) and cow genotype (CG; pure breed: Angus-Hereford vs. F1 reciprocal crosses; PU vs. CR). The experiment was conducted for 3 years and at the end of the third year at 192 ± 10 d postpartum cows were slaughtered and weight of all tissues and organs were collected. Means from a mixed model with repeated measure analysis were considered to differ when $P \leq 0.05$. The gastrointestinal tract (GIT) mass (kg) was greater ($P = 0.02$) and the diaphragm and lungs mass tended ($P \leq 0.09$) to be greater in HI that LO cows, while liver and heart mass were greater ($P \leq 0.01$) in CR than PU cows. Absolute kidney mass was not affected by HA or CG. However, when expressed as a proportion of the carcass, GIT and kidney weights tended to be lower ($P < 0.08$) and diaphragm weight was lower ($P = 0.04$) in CR than PU cows (151.6 vs. 161.1 ± 4.0; 8.2 vs. 8.9 ± 0.3 and 12.4 vs. 13.3 ± 0.3 g/kg carcass for GIT, kidney and diaphragm, respectively). In addition, relative weights of heart and kidney were lower ($P \leq 0.05$) in HI than LO cows (8.2 vs. 8.9 ± 0.2 and 8.1 vs. 9.0 ± 0.3 g/kg carcass for heart and kidney, respectively). Neither absolute nor relative head weights differed between cow groups. Absolute weight of the skin tended ($P = 0.08$) to be greater and relative weight was greater ($P = 0.01$) in LO than HI cows (30.3 vs. 32.3 ± 1.0 g/kg carcass). Although absolute weight of legs was not affected by HA or CG, its relative weight was 16.7% less in CR than PU and 14.8% less in HI than LO cows. Results suggest that LO and PU cows could have increased maintenance energy requirements through increased relative organ weights, which could affect cow-calf system productivity.

Key Words: cattle, organ mass, rangeland

W450 Effect of cow parameters on enteric methane production in dairy cows: an individual variation approach.

Edward H. Cabezas-Garcia*[1], Sophie J. Krizsan[1], Kevin J. Shingfield[2], and Pekka Huhtanen[1], *[1]Swedish University of Agricultural Sciences, Department of Agricultural Research for Northern Sweden, Umeå, Vasterbotten, Sweden, [2]Aberystwyth University, Institute of Biological, Environmental and Rural Sciences, Aberystwyth, Ceredigion, UK.*

The current knowledge about the biological basis of between-animal variation in methane (CH_4) production is still limited. The aim of this study was to evaluate between-animal variability and repeatability animal factors expected to affect CH_4 emissions using a meta-analytical approach. The data set were collected from 35 studies conducted in Nordic countries involving 126 individual cows and 566 cow/period observations. All studies were conducted either using Latin square or change over designs. Diets comprised principally grass silage and cereal grain concentrates with the mean forage: concentrate ratio of 60:40 on DM basis. CH_4 emissions per mol VFA were calculated based on VFA stoichiometry (Wolin, 1960). The variance components analysis was conducted with MIXED procedure of SAS. Repeatability (R) was calculated as $R = \delta^2_{cow} / (\delta^2_{cow} + \delta^2_{Resid})$. Of animal variables affecting CH_4 emissions DMI showed the greatest variation and repeatability (Table 1), whereas both OMD and CH_4VFA displayed small variability. Efficiency of microbial N synthesis (ENS) and passage rate of iNDF were more variable and repeatable than CH_4VFA. Increased feed intake was negatively ($P < 0.001$) associated with reduced OMD and CH_4VFA and positively ($P < 0.01$) with EMPS (H_2 sink). Reduced CH_4/kg DM with increased DMI can be attributed to these factors. Efficiency of MPS decreased ($P < 0.001$) with improved OMD that can result from increased digesta retention time in the rumen. It is concluded that between-animal CV in rumen fermentation pattern cannot account observed variation in CH_4. Between-animal differences in passage rate can contribute to variation in CH_4 as it influences digestibility and partitioning of fermented substrate between VFA and microbial cells.

Table 1 (Abstr. W450). Between cow variability of variables possibly related to CH_4 production

Item	DMI[1]	OMD	ENS	iNDF-kp	Acet	Prop	CH_4VFA

W451 Rumen fermentation responses to plant extracts rich in tannins.

Barbara J. M. Lemos*, Flavia M. Souza, Fabiola A. Lino, Victor R. M. Couto, and Juliano J. R. Fernandes, *Universidade Federal de Goias, Goiania, Goias, Brazil.*

Effects of extracts derived from the husk of *Lafoensia pacari* (27.5% tannins, mainly hydrolysable) and *Stryphnodendron adstringens* (52.2% tannins, mainly condensed) on rumen fermentation were evaluated in 2 independent in vitro experiments. The doses were CTL, LOW, MEDIUM and HIGH (0, 30, 300, and 3000 mg/L of buffered rumen fluid, respectively). The diet (50:50 concentrate:roughage, 91% DM, 20% CP, 1.6% EE, 39% NDF) was ground (1 mm) and incubated using filter bags for 3, 6, 12, 24, 48, 72 and 96 h. The rumen fluid donor was fed with a 50:50 diet. The incubation was repeated 4 times in each experiment. The effective degradability (ED, passage rates of 5 and 8%/h) and potential degradability (PD) of DM were calculated based on DM disappearance. Culture fluid was sampled after 96 h of incubation. The responses of CTL, LOW, MEDIUM and HIGH doses of *L. pacari* were, respectively: ED5%/h = 51, 50, 50 and 28% (SEM = 0.75, $P < 0.01$); ED8%/h = 44, 43, 42 and 26% (SEM = 0.69, $P < 0.01$); DP = 81, 82, 81 and 48% (SEM = 2.57, $P < 0.01$); N-NH_3 = 12.3, 11.7, 9.8 and 6.5 mg/L (SEM = 0.88, $P < 0.01$); Total VFA = 62.9, 57.6, 50.9 and 42.3 m*M* (SEM = 4.28, $P = 0.03$); Acetate = 40.6, 37.1, 33.5 and 27.3 m*M* (SEM = 2.02,

$P = 0.01$); Propionate = 11.9, 11.2, 9.7 and 8.4 m*M* (SEM = 0.81, $P = 0.05$). The HIGH dose reduced ED5%/h (46%), ED8%/h (41%) and PD (40%), compared with CTL. The N-NH$_3$, total VFA, acetate and propionate decreased with HIGH and also with MEDIUM and LOW doses, which were similar. In the *S. adstringens* study, responses of CTL, LOW, MEDIUM and HIGH doses, were, respectively: ED5%/h = 51, 52, 52 and 25% (SEM = 1.59, $P < 0.01$); ED8%/h = 44, 45, 44 and 23% (SEM = 1.58, $P < 0.01$); DP = 81, 82, 83 and 37% (SEM = 1.74, $P < 0.01$); N-NH$_3$ = 10.2, 10.6, 9.8 and 6.4 mg/L (SEM = 0.83, $P = 0.01$); Total VFA = 55.7, 58.6, 52.8 and 32.7 m*M* (SEM = 4.40, $P < 0.01$); Acetate = 36.8, 37.1, 33.5 and 20.9 m*M* (SEM = 2.63, $P < 0.01$). The HIGH dose reduced the ED5%/h (52%), ED8%/h (48%), PD (54%), total VFA (41%) and acetate (43%), compared with CTL. CTL and LOW doses showed similar concentration of N-NH$_3$, which decreased with MEDIUM and HIGH doses. There was no effect on propionate ($P = 0.13$). In conclusion, these plant extracts can be potentially useful to modify rumen fermentation patterns.

Key Words: degradability, in vitro

W452 Carcass characteristics of Nellore beef cattle fed with whole corn diet. Andrea M. Mobiglia*[1], Fernando R. Camilo[1], Victor R. M. Couto[1], Wallace V. S. Santos[1], Lucas D. Silva[1], Bruno P. C. Mendonça[2], Flávio G. F. Castro[2], and Juliano J. R. Fernandes[1], *[1]Escola de Veterinária e Zootecnia da Universidade Federal de Goiás, Goiânia, Goiás, Brazil, [2]Agrocria Nutrição Animal e Sementes, Goiânia, Goiás, Brazil.*

The objective was to evaluate effects of virginiamycin (VM) and monensin sodium (MON) in whole corn diet, with or without the use of roughage during adaptation on carcass characteristics of feedlot cattle. The animals were kept in the feedlot in group pens for 106-d with a 21-d adaptation period. One hundred Nellore bulls were used in a randomized complete block design with a 2 × 2 factorial arrangement of 4 treatments, being 2 kinds of additive (VM and MON) and 2 adaptation strategies. Each treatment consisted of 5 pens with 5 bulls per pen. Treatments were defined by VM (25 mg/kg of DM) and MON (30 mg/kg of DM), with or without 10% (DM basis) sugarcane bagasse (SB) during adaptation period as follows: VM 10% SB; VM 0% SB; MON 10% SB and MON 0% SB. After the adaptation period, animals were fed ad libitum once daily with a diet containing 85% whole corn, 15% pelleted feed (soybean, minerals and the additive). Probability of 10% was considered as statistical difference and 15% of probability was discussed as tendency. There were no differences ($P > 0.10$) between VM and MON treatments for any variables studied (Table 1). However, differences were observed ($P < 0.10$) for average daily gain (ADG) when the animals were fed with SB in the adaptation period. There was no interaction between the additives and SB for any variables studied; in contrast, animals fed with SB at adaptation period tended ($P < 0.15$) to have higher carcass gain (CG) and carcass daily gain (CDG) than treatments without SB, independent of the additive used. Therefore, VM and MON had a similar effect on carcass characteristics, but the treatments containing SB showed great carcass gain when the tendency was discussed. The use of roughage source (SB) may increase the performance and carcass gain due to a greater adaptation of the Nellore bulls to whole corn diet.

Table 1 (Abstr. W452). Carcass data of bulls feedlot fed with whole corn diet

Variable	MON		VM			*P*-value

W453 Effect of the use of virginiamycin and monensin sodium in high concentrate diet on carcass characteristics of beef cattle feedlot. Fernando R. Camilo*[1], Andrea M. Mobiglia[1], Gustavo R. Siqueira[2], Flávio D. Resende[2], Regina K. Grizotto[2], Victor R. M. Couto[1], and Juliano J. R. Fernandes[1], *[1]Escola de Veterinária e Zootecnia da UFG, Goiânia, Goiás, Brazil, [2]APTA - Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brazil.*

Beef cattle feedlot is a strategy to increase the productivity, and to offer a great feedstock for the consumers. Ionophore and non-ionophore antibiotics have been used as feed additives for enable to supply of the high concentrate diets. The objective of this study was to evaluate the isolated and combined effects of the virginiamycin (VM) and monensin sodium (MON) in diets of crossbreed bulls feedlot. The animals were kept in feedlot in group pens for 105-d with a 28-d adaptation period. Three hundred thirty-nine 1/2 Nellore × 1/2 Guzera beef steers (402.7 ± 1.3 kg of initial BW) were used in a randomized complete block design with 5 treatments and 7 replicates (pens). The blocks were defined by initial BW. The treatments are defined by levels of the VM and MON (mg/kg of dry matter) as follows: 30MON; 15VM+30MON; 25VM+30MON; 34VM+30MON and 34VM. Animals were fed ad libitum twice daily with isonitrogenous and isoenergetic diets, with 88:12 concentrate: roughage (sugarcane bagasse) ratio. Bulls were weighted at the beginning, after the adaptation period and at the end of the trial. Nine animals

were slaughtered at the beginning of the trial to determine initial hot carcass weight (HCW). At the end of the experiment, 330 bulls were slaughtered and determined the final HCW (Table 1). There was not statistical difference ($P > 0.05$) between the treatments for all variables studied. Therefore, the use of additives, MON and VM, isolated and combined, do not influenced the carcass characteristics.

Key Words: additive, feedlot, Nellore

W454 Effect of supplementation with different levels and rates of protein degradation on performance of Nellore calves.

Gustavo Rezende Siqueira*[1], Lais Atayde dos Santos[2], Rodolfo Maciel Fernades[3], Chafic Mustafé de Almeida[4], Fernanda Diamantino Santos[2], Guilherme Felipe Berti[2], Verônica Aparecida Costa Mota[3], and Flávio Dutra de Resende[1], *[1]Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brasil, [2]Centro Universitário da Fundação Educacional de Barretos, Barretos, São Paulo, Brasil, [3]Universidade Estadual Paulista "Júlio de Mesquita Filho" /UNESP-Jaboticabal, Jaboticabal, São Paulo, Brasil, [4]Universidade Federal do Mato Grosso/UFMT-Sinop, Sinop, Mato Grosso, Brasil.*

The objective of the present study was to evaluate the effect of different levels and rates of protein degradation on the performance of Nellore animals in their post-weaning phase on *Brachiaria brizantha* 'Marandu' pastures. The following treatments were used: protein-energy supplement containing 25% CP (C-25); protein-energy supplement containing 40% CP, with 1/3 of the CP from urea, and 2/3 plant-derived (40–1/3NPN); protein-energy supplement containing 40% CP, with 1/2 CP from urea, and 1/2 plant-derived (40–1/2NPN); and protein-energy supplement containing 40% CP, with 1/3 of the CP plant-derived, and 2/3 from urea (40–2/3NPN). The experimental period was from June to September 2013, divided into a period for acclimation, and three 28-d periods. The experimental areas consisted of 12 paddocks averaging 2.3 ha, totaling 28 ha. Eighty-four (84) uncastrated Nellore cattle at 15 mo of age, with an initial weight of 332 ± 6.19 kg, were used. Animals were weighed every 28 d to determine the daily weight gain (DWG). The experimental design was completely randomized, wherein the initial animals' BW was used as a co-variable, and paddocks were considered the experimental unit. Data were analyzed as repeated measures over time in mixed models, with means compared by the *t*-test at 10% significance. No effect of supplements was found on DWG (0.673 kg; $P = 0.96$). There was also no interaction between supplements and experimental periods ($P = 0.76$); however, the periods altered the animal performance ($P = 0.02$). The initial period provided a 30% higher DWG than the others (0.842, 0.573 and 0.603 kg/d in the first, second, and third periods, respectively). Treatment did not alter BW significantly (380 kg ± 5.24; $P = 0.90$). In conclusion, different levels and rates of protein degradation do not modify the animal performance.

Key Words: protein degradation rate, protein levels, supplement

W455 Ruminal parameters of Nellore steers fed with high grain diet containing virginiamycin or monensin sodium.

Andrea M. Mobiglia*[1], Fernando R. Camilo[1], Alexandre A. Miszura[1], Ricardo A. Souza[1], Victor R. M. Couto[1], Flávio G. F. Castro[2], Bruno P. C. Mendonça[2], and Juliano J. R. Fernandes[1], *[1]Escola de Veterinária e Zootecnia da Universidade Federal de Goiás, Goiânia, Goias, Brazil, [2]Agrocria Nutrição Animal e Sementes, Goiânia, Goias, Brazil.*

The objective of this study was to evaluate the effects on ruminal parameters of Nellore steers fed with high-grain diet using virginiamycin (VM) and monensin sodium (MON). Twelve Nellore steers (268 ± 38 kg BW) with ruminal cannula were used in completely randomized design with 2 treatments and 6 replicates. Treatments were defined by kind of additive used in diet, VM (25 ppm) and MON (30 ppm). The animals were kept in feedlot in individual pens for 21 d. Ruminal ammonia nitrogen (NH$_3$-N), short-chain fatty acids concentration (SCFA) and ruminal fluid pH were measured before feeding (T0), 6 and 12 h after feeding (T6 and T12, respectively). Animals were fed ad libitum twice daily with a diet containing 85% whole corn and 15% pelleted feed (soybean, minerals and the additive). Data are shown in Table 1. There were no effects ($P > 0.05$) on NH$_3$-N and SCFA concentration and pH values when MON or VM were added in diet. Acetate:propionate ratio (A:P) did not show differences ($P > 0.05$) between treatments. However, the pH value decreased after feeding for both treatments. In conclusion, VM and MON did not affect pH, NH$_3$-N, SCFA and A:P ratio, however, the pH values were next to 6 and there was not wide variation between the measurement times.

W456 Characterization of the variation in linoleic acid (18:2) in corn silage and grain hybrids in test plots.

Michel Baldin*, Yun Ying, Gregory Roth, and Kevin J. Harvatine, *Penn State University, University Park, PA.*

Dietary unsaturated fatty acids (FA) provide many challenges to ruminants as they are toxic to rumen microbes and result in formation of bioactive *trans* FA in the rumen that reduce milk fat yield. Corn silage and high moisture corn are commonly recognized as a risk factor for milk fat depression (MFD). The mechanism of increased risk of MFD is not clear, but may be due to the high concentration of linoleic acid (18:2) in corn. Corn silage and corn grain have a low concentration of FA, but due to their high inclusion rate in diets they contribute substantially to the polyunsaturated FA intake. Limited literature has reported the variation in FA profile of commercial hybrids as well as the contribution of individual plant parts to total FA in corn. To determine the location of FA in the corn plant, 4 stalks from 4 different commercial hybrids were separated into: stalk, husk + shank, leaves, cob, and kernels. On a DM basis, 80.3% of total FA were in kernels, 11.9% in leaves, 5.1% in the stalk, 1.7% in the cob, and 1.0% in husk + shank. More than 96% of the 18:1 and 92.4% of the 18:2 was in kernels, whereas 71.3% of the 18:3 was in the leaves. Second, we screened 67 corn silage and 36 corn grain hybrids from commercial test plots. Corn silage total FA (% of

DM) averaged 2.54 ± 0.41 (mean ± SD, percentiles: 10th = 2.0 and 90th = 3.1). Corn silage 18:2 (% of DM) averaged 1.24 ± 0.24 (percentiles: 10th = 0.94 and 90th = 1.60) and 18:2 (% of FA) averaged 48.66 ± 3.0 (percentiles: 10th = 45.2 and 90th = 52.2). In the corn grains, total FA (% of DM) averaged 3.56 ± 0.27 (percentiles: 10th = 3.0 and 90th = 4.2), 18:2 (% of DM) averaged 2.05 ± 0.15 (percentiles: 10th = 1.8 and 90th = 2.4), and 18:2 (% of FA) averaged 57.5 ± 1.6 (percentiles: 10th = 53.4 and 90th = 60.8). In conclusion, moderate variation in 18:2 concentration (both % of DM and % of FA) was observed in commercially available hybrids. Corn FA profile may provide an additional tool to improve nutritional value of corn silage and other corn products for ruminants.

Key Words: corn silage, fatty acid, milk fat

W457 Performance of beef cattle fed with different levels of roughage in high whole grain diet during the adaptation period.

Andrea M. Mobiglia[1], Fernando R. Camilo*[1], Flávio G. F. Castro[2], Bruno P. C. Mendonça[2], Mohana D. Neves[2], Victor R. M. Couto[1], and Juliano J. R. Fernandes[1], *[1]Escola de Veterinária e Zootecnia da UFG, Goiânia, Goiás, Brazil, [2]Agrocria Nutrição Animal e Sementes, Goiânia, Goiás, Brazil.*

The objective of this study was evaluated the performance of beef cattle fed with whole grain diet and different levels of roughage during the adaptation period. The animals were kept in the feedlot in group pens (6 pens/treatment) for 120-d, with 21-d adaptation period and 99-d finishing period. Seventy 2 Nellore bulls were used in a randomized complete block design with 3 treatments and 6 replicates. All animals were fed with 85% of whole grain and 15% of pelleted feed (soybean, minerals and the additive, virginiamycin)(WG), and the treatments were defined by level of roughage (R) includes in diet, as follow: 0%R (animals fed with 100%WG during adaptation and finishing period); 15%R (animals fed with 85%WG:15%R during adaptation and 100% WG during finishing period) and 5% R (animals fed with 85%WG:15% R during adaptation and 95% WG:5% R during finishing period).In this study was evaluated the dry matter intake (DMI), average daily gain (ADG) and gain:feed (G:F). There were no differences ($P > 0.05$) for those variables between treatments. All animals showed the same performance and G:F, independent of roughage level in the diet. The roughage may be a problem in finishing cattle diet due to its management and storage. Therefore, animals fed without a roughage source may show the same performance when the roughage is added in the high grain diet.

Table 1 (Abstr. W457). Performance of beef cattle fed with different levels of roughage in high whole grain diet

W458 Microalgae meal affects heifer performance and plasma fatty acids.

Justin E. Axman*[1], Cadra L. Van Bibber-Krueger[1], Caleb P. Weiss[1], Christian A. Alvarado-Gilis[1], Jake D. Thieszen[1], Kelsey J. Phelps[1], John M. Gonzalez[1], Kate A. Jacques[2], and James S. Drouillard[1], *[1]Kansas State University, Manhattan, KS, [2]Alltech, Inc., Nicholasville, KY.*

Microalgae meal (MA; *Schizochytrium limacinum* CCAP 4087/2) was fed to finishing heifers (n = 285; 453 ± 24 kg initial BW) to assess impact on growth performance, carcass traits, and fatty acid composition in plasma. Heifers were stratified by weight, randomly assigned to pens of 8 animals each, and fed diets based on steam-flaked corn and corn gluten feed for 89 d. Treatments consisted of 0, 50, 100, or 150 g/animal daily of MA (Alltech, Inc., Nicholasville, KY) that was included in the feed additive premix and subsequently mixed in the total ration. Approximately 6 h before feeding, blood was collected via jugular venipuncture from 3 animals/pen on d 21 and 82 for analysis of plasma concentrations of eicosapentanoic, docosapentaenoic, and docosahexaenoic acids (EPA, DPA, and DHA, respectively), which are long chain omega-3 fatty acids that are most active within the body. Feeding MA did not affect ADG ($P = 0.58$), but decreased DMI ($P = 0.16$) and increased G:F, HCW, yield grade, and percent of USDA Choice carcasses in a dose dependent manner (linear, $P < 0.08$). Plasma concentrations of EPA (3.5, 23.6, 86.3, 153.5 ± 4.64, respectively), DPA (13.4, 15.4, 22.4, 30.8 ± 1.04, respectively), and DHA increased in proportion to the amount of MA fed (linear, $P < 0.01$). Data were analyzed as a randomized complete block design using the PROC MIXED procedure of SAS 9.4 (SAS Inst. Inc., Cary, NC) with pen as the experimental unit and animal as the observational unit. Microalgae meal has potential for improving growth performance and assimilation of omega-3 fatty acids into beef tissues.

W459 Effect of concentrate supplementation on milk yield and fatty acid profile of crossbred dairy cows on tropical pasture.

Arni Xochitemol-Hernández[1], Epigmenio Castillo-Gallegos[2], Manuel González-Ronquillo[3], Miguel Blanco-Ochoa[1], and Luis Corona*[1], *[1]Universidad Nacional Autónoma de México, FMVZ. Departamento de Nutrición Animal. Cd. Universitaria, DF, México, [2]Universidad Nacional Autónoma de México, FMVZ. CEIEGT, Veracruz, México, [3]Universidad Autónoma del Estado de México, FMVZ, Estado de México, México.*

The aim of this study was to evaluate the supplementation rate on yield, composition and fatty acid (FA) profile of milk from 12 crossbred (1/2 *Bos taurus* – 1/2 *Bos indicus*) dairy cows at 60 d in milk and assigned to 4 treatments: 0, 150, 300 y 450 g concentrate (as-fed basis)/kg daily milk production, in a crossover design, with 3 periods of 15d. The cows were fed grazed tropical pasture (28% native grasses, mainly *Paspalum* spp. and *Axonopus* spp. and 72% *Brachiaria* spp. and *Cynodon neumfluensis*). The trial was conducted at the research station in Martínez de la Torre, Veracruz, Mexico. The daily milk yield was recorded through the experiment and weekly milk sampling was evaluated for composition, percentages of milk fat, protein, lactose, solid not fat (SNF), density (kg/m^3) and fatty acids profile (g/100 g of fat). The data were analyzed with the SAS MIXED procedure and tested by means of orthogonal polynomials. Increasing concentrate at 0, 150, 300 and 450g/kg milk, increase (linear effect, $P < 0.05$) milk yield (7.35, 8.62, 8.79, 8.75 ±

0.049 kg) and quadratically affected ($P < 0.05$) for SNF (6.54, 6.53, 6.64, 6.85 ± 0.047) and density (1022.5, 1022.4, 1022.8, 1023.46 ± 0.63). The C15:0 and C:17:0 decreased (linear effect, $P < 0.05$) with increasing concentrate. The fatty acid profile particularly beneficial for human health as oleic (18:1N9C), Trans-vaccenic (18:1N11T), linoleic (C18: 2N6C), linolenic (C18:3N3) and conjugated linoleic acid (C18: cis-9, trans-11 CLA and C18: *trans*-10, *cis*-12 CLA) were not modified ($P > 0.05$) by increasing concentrate. Overall, this study indicates that the concentrate supplementation of grazing crossbred dairy cows increase milk production without compromising the FA profile or milk composition.

Key Words: milk, fatty acid profile, crossbred cow

W460 Composition and nutritive value of palm kernel meal for ruminants.

Jennifer K. Cuenca[1], Diego A. Vela[1], Darren D. Henry[2], Nicolas DiLorenzo[2], and Christian H. Ponce*[1], *[1]Departamento de Ciencias de la Vida y Agricultura, Universidad de las fuerzas Armadas ESPE, Sangolqui, Ecuador, [2]North Florida Research and Education Center, Department of Animal Sciences, University of Florida, Marianna, FL.*

Palm kernel meal originated from oil processing is readily available in Ecuador. However, information related to the nutritive value for ruminants is limited. Therefore, 2 experiments were conducted to evaluate the nutritive value of palm kernel meal (PKM) from oil palm extract plants for ruminants. For Exp. 1, 3 regional plants were selected, and PKM were collected weekly during 12 wk. Proximate analysis was performed on individual samples (mean values ± standard errors across plants for DM, OM, CP, fat and crude fiber were 94.5 ± 0.33, 95.8 ± 0.23, 14.8 ± 0.36, 8.9 ± 0.47, and 68.68 ± 2.42%, respectively). Significant variations were detected for all nutrients analyzed between plants ($P \leq 0.016$). Additionally, particle size was different between plants (403 ± 2 µm; $P < 0.001$). For Exp. 2, 2 ruminally cannulated cows (BW = 445 ± 49.5) were used to determine ruminal in situ degradability of DM, OM, NDF, ADF and CP of PKM, and in vitro ruminal degradability parameters. Cows had ad libitum access to forage, composed of Pennisetum clandestinum. Composite samples of PKM within each plant, from the 12 -wk period of Exp. 1 were used as substrate for determination of in situ degradation kinetics. Substrates were incubated in the ventral sac of the rumen for 0, 3, 6, 9, 12, 18, 24, 48, and 72 h, and in situ degradability was replicated in 2 different weeks. In situ digestibility fractions (i.e., immediate soluble, potentially degradable, undegradable, and effective degradability) were not affected by plant for all nutrients analyzed ($P \geq 0.231$), with exception of rate of digestion for OM and ADF (0.036 ± 0.001; $P \leq 0.042$). Calculated effective degradability for DM and OM were 42.3 ± 4.7, and 16.6 ± 2.1%, respectively. Crude protein effective degradability was 16.1 ± 3.9%. For the fiber contents, NDF and ADF effective degradability were 39.8 ± 5.0%; and 23.1 ± 4.2%, respectively. Additionally, 24 h IVDMD (44.7 ± 2.8%) and total gas production (154.1 ± 59.1 mL/g of substrate) were not different among plants ($P = 0.897$). Results from these experiments provide relevant nutritive information of PKM as feedstuff for ruminants, and reveal that significant variation between processing plants can be expected in nutrient profile.

Key Words: nutritive value, palm kernel meal, ruminants

W461 Effects of β-acid extract of hops on heifer performance and ruminal fermentation.

Justin E. Axman*, Cadra L. Van Bibber-Krueger, Christian A. Alvarado-Gilis, Jake D. Thieszen, and James S. Drouillard, *Kansas State University, Manhattan, KS.*

Beta-acid extract of hops was fed to finishing heifers (n = 80; 389 ± 23.6 kg initial BW) to assess effect on growth performance and ruminal fermentation. Heifers were randomly assigned to individual pens and fed diets based on steam-flaked corn and corn gluten feed for 147 d. Treatments consisted of a control (no additive); monensin (Elanco Animal Health, Greenfield, IN) fed at 33 mg/kg diet DM; and β-acid extract of hops (DSM Nutritional Products, France) fed at 10, 25, or 50 mg/kg diet DM. Ruminal fluid was collected on d 44 and 86 by rumenocentesis for analysis of VFA and NH3 concentrations. Feeding β-acid or monensin did not alter ruminal fermentation, growth performance, DMI, or gain efficiency ($P > 0.05$). Performance data were analyzed using a mixed model with diet as a fixed effect and weight block as a random effect. Pair-wise comparisons were performed using the PDIFF option. Categorical data were analyzed using the Glimmix procedure with diet as a fixed effect, weight block as the random effect, and feedlot pen as the experimental unit. In conclusion, under conditions of this experiment β-acid extract did not alter performance or ruminal fermentation.

Table 1 (Abstr. W461).

W462 Effect of a ruminal acidosis challenge on methane emission rate in lactating cows.

Matias J. Aguerre*, Fei Sun, Shayna Welch, and Michel A. Wattiaux, *Department of Dairy Science, University of Wisconsin-Madison, Madison, WI.*

The objective of this study was to determine the effect of a subacute ruminal acidosis (SARA) challenge on CH_4 emission rate from lactating cows. We hypothesized that low ruminal pH resulting from SARA would reduce CH_4 emission substantially especially in cows fed a low forage diet. Eleven ruminally cannulated Holstein cows (711 ± 59 kg BW; 103 ± 59 DIM) were randomly assigned to either a 45 or 67% forage diet (DM basis) in a complete randomized design. After 2-wks of adaptation to a GreenFeed CH_4 measuring unit, 4 cows on each treatment were selected to undergo the SARA induction protocol, which included 4 periods: baseline (4 d), feed restriction (50%; 1 d), challenge (TMR + wheat-barley pellet at 20% of baseline DMI; 2 d), and recovery (normal dietary treatments feeding; 2 d). Rumen pH was recorded every 5 min for 7 of the 9 d of protocol using wireless pH meters. Methane (g/h) was measured at 12 p.m., 5 p.m., 9 p.m., and 6 a.m. during the induction protocol. Overall, milk yield (40.4 ± 3.6 kg/d, $P = 0.16$), DMI (23.1 ± 1.8 kg/d, $P = 0.26$), mean ruminal pH (6.08 ± 0.15, $P = 0.84$), nadir ruminal pH (5.49 ± 0.15, $P = 0.31$), hours below pH 5.6 (3.2 ± 1.78 h/d, $P = 0.31$) and CH_4 emission rate (12.2 ± 1.0 g/h, $P = 0.29$) were not affected by dietary treatments. There was no treatment by period interaction but a significant period effect for reported variables. Compared with baseline (27.3 kg/d) DMI was not different ($P = 0.82$) during the challenge (26.1 kg/d) but was lower ($P = 0.05$) during recovery (25.2 kg/d). Milk yield dropped ($P < 0.01$) from 45.5 kg/d during baseline to 32.5 kg/d during challenge and returned almost to baseline during recovery (41.2 kg/d, $P = 0.10$). Methane emission (g/h) rate were 14 and 26% lower during challenge (11.7, $P = 0.03$) and recovery (10.1, $P < 0.01$) compared with baseline (13.6). During recovery, CH_4/DMI (g/kg) was lower (9.7, $P = 0.05$) compared with baseline (12.2). Hours below pH 5.6 increased from 1.5 to 6.4/d from baseline to challenge

($P < 0.01$). In this study, SARA reduced CH_4 emission but there was a complex temporal relationship between rumen pH and CH_4 emission during and after an acidosis episode.

Key Words: ruminal acidosis, methane, dairy

W463 Co-products (Micelio and Raffinate) from the corn processing industry for finishing cattle. Murillo Alves Porto Meschiatti*[1], Maria Erika Picharillo[1], Camila Delveaux Batalha[1], Julia Silveira Pereira[2], and Flavio Augusto Portela Santos[1], [1]*University of São Paulo,* São Paulo, Brazul, [2]*Cargill.*

The objective of this experiment was to evaluate the inclusion (7 and 15%, DM basis) of 2 corn co-products derived from the citric acid industry: Micelio (77% NDF, 0.5% lignin, DM basis) and Raffinate (25.5% soluble sugars, 32% soluble fiber, DM basis) in diets with high levels of flint corn fed to 200 finishing Nellore bulls (initial BW = 396.4 ± 37.7 kg). Animals were blocked based on initial BW and randomly allocated to 25 pens. The control diet contained 11.73% sugarcane bagasse, 67.2% corn, 18% corn gluten feed, 2.07% mineral supplement and 1% urea. The other 4 treatments were Micelio 7, Micelio 15, Raffinate 7 and Raffinate 15. The co-products partially replaced corn in the diets. The parameters evaluated were dry matter intake (DMI), average daily gain (ADG), feed efficiency (ADG/DMI) and carcass traits. The data were analyzed using PROC MIXED of SAS and means were compared by Tukey test considering the block as random effect and treatment as fixed effect. There was no effect of treatments ($P > 0.05$) on cattle performance and carcass traits. Average values for dry matter intake, average daily gain and feed efficiency were 10.5 kg/d, 1.6 kg/d, and 0.156 respectively. Average values for dressing (%), back fat thickness (mm) and rib eye area (cm^2) were 53.79, 2.84, and 64.08, respectively. The inclusion of 7 or 15% of Micelio or Raffinate in partial replacement of ground flint corn in finishing diets does not affect cattle performance

Key Words: co-product, feedlot, performance

W464 The effect of heating temperature on ruminal protein digestion kinetics and estimated intestinal digestibility of canola meal. Katarzyna Burakowska*[1], Pawel Górka[2], and Gregory B. Penner[1], [1]*University of Saskatchewan, Saskatoon, Canada,* [2]*University of Agriculture, Kraków, Poland.*

The objective of this study was to determine the optimal heat treatment temperature of canola meal to increase the rumen undegradable protein concentration without negatively affecting intestinal digestibility. Twelve samples of canola meal (25 kg/sample) were subjected to 1 of 4 heat treatments: an unheated control (H0), or heat-treated in a tumble dryer (POS, Saskatoon) to 100°C (H100), 110°C (H110) or 120°C (H120) for 10 min after reaching the specified temperature. Canola meal was placed in nylon bags (50-µm pore size) and incubated in the rumen of 4 heifers for 0, 2, 4, 8, 12, 16, 24 and 48 h to evaluate rumen degradation kinetics. Estimated intestinal digestibility was determined using samples incubated in the rumen for 12 h, followed by an in vitro gastric and enzymatic digestion. Samples were analyzed for DM and CP content. Data were analyzed using SAS 9.3 as completely randomized design with polynomial contrasts to determine whether provision of heat affected the response linearly or quadratically. The rate of DM disappearance in the rumen decreased (quadratic, $P = 0.02$, SE = 0.214) from 4.5%/h for H0 to 3.06 for H120. The rate of CP degradation ($P < 0.01$, SE = 0.590) and the degradable fractions of DM ($P < 0.01$, SE = 1.906) and CP responded quadratically ($P < 0.01$, SE = 3.531) with values of 4.89, 60.0 and 79.0 for H0, 4.59, 57.1 and 70.0 for H100, 3.54, 52.7 and 59.0 for H110, and 7.77, 34.1 and 22.3 for H120, respectively. Assuming a constant passage rate (5%/h), heat treatment decreased the effectively degradable DM (quadratic, $P < 0.01$, SE = 0.776) from 54.2 to 31.7% for H0 to H120 and decreased the effectively degradable CP (quadratic, $P < 0.01$, SE = 2.652) from 55.5 to 25.4%. The estimated intestinal CP digestibility (quadratic, $P = 0.03$, SE = 2.550) increased from H0 (45.9%) to H110 (51.0%) and decreased for H120 (37.2%). The results suggest that the temperature of 110°C decreases DM and CP degradation in the rumen without negative effects on intestinal digestibility.

Key Words: canola meal, heat treatment, digestibility

W465 Effects of postruminal AA supply and roughage removal on growth performance during growing phase of beef calves. Mariana M. Masiero*, Ryan L. Barnett, and Monty S. Kerley, *University of Missouri, Columbia, MO.*

Previous research demonstrated benefit in beef calves growth performance fed no roughage diets balanced to meet AA requirement. The study objective was to separate the effects of balancing diets for AA:effective energy (AA:EE) and roughage removal on steers growth performance (initial BW 338 ± 23 kg) during growing phase (GP; 84 d). We hypothesized balancing diets for postruminal AA:EE supply as well as roughage removal would improve feed efficiency and growth performance. Crossbred steers (n = 117) were randomly assigned to 3 corn-based diets. Control, common feedlot diet (CON; 13.5% CP, 20% NDF, 10% roughage, 60% corn, 27% dried distillers grains with solubles); roughage and AA:EE balanced (RBAL; 16% CP, 16% NDF, 10% roughage, 62% corn, 12% Aminoplus, 10% dried distillers grains with solubles, 2% soybean meal); or no roughage and AA:EE balanced (NRBAL; 16% CP, 10% NDF, 72% corn, 14% Aminoplus, 9% dried distillers grains with solubles, 2% soybean meal). Steers had ad libitum access to feed and water. Individual feed intake was measured using GrowSafe feed intake system and BW was recorded every 28 d. Data were analyzed as repeated measure. Dry matter intake (kg/d) was greater ($P < 0.01$, SEM 0.28) for CON (10.5) and RBAL (10.4) compared with NRBAL (9.0). Average daily gain (kg/d; 28 d) was greater ($P < 0.03$, SEM 0.09) for NRBAL (2.02) and RBAL (2.06) compared with CON (1.77) however throughout GP ADG did not differ among treatments ($P = 0.3$). Gain:Feed (28 d) was greater ($P < 0.01$, SEM 0.009) for NRBAL (0.22) compared with CON (0.18) however RBAL (0.20) did not differ. During total period (84 d) NRBAL (0.19) had greater ($P < 0.03$, SEM 0.005) G:F compared with RBAL (0.17) and CON (0.16). Balancing diets for postruminal AA:EE supply improved G:F by 11% and roughage removal improved G:F an additional 11%. In conclusion balancing diets for postruminal AA:EE supply can improve growth performance and feed efficiency when lean tissue deposition potential results in postruminal AA demand. Balancing diets to allow roughage removal also benefits growth performance throughout the feeding period.

Key Words: postruminal AA, feed efficiency

Ruminant Nutrition: Other ruminants

W466 Dynamic changes of main rumen microflora and ruminal fermentation in sheep supplemented with molasses-urea. Alatengdalai, Shuyuan Xue, Ming Hu, and Changqing Li*, *Inner Mongolia Academy of Agricultural and Animal Husbandry Sciences, Huhhot, Inner Mongolia, China.*

The digestion of diet and utilization of nutrients by sheep depends on rumen microbial fermentative digestion. Reproduction and growth rate of microbes is mainly determined by the availability of nutrient and energy levels in rumen. Therefore, rumen environment affects the extent of microbial protein (MCP) synthesis. The aim of this study is to evaluate the effects of licking the molasses-urea feed block on the rumen of sheep, including microbial biomass and fermentative efficiency. Eight sheep were selected and divided into 2 groups (control group and treatment group). The treatment group animals were supplied with molasses-urea feed block for ad libitum consumption. Rumen fluid was collected every 2 h and rumen fermentation parameters were measured. In addition, the population of majority bacteria were investigated by real-time PCR. The results showed that the population of majority bacteria is increased in rumen of treatment group animals ($P < 0.05$). The trend of daily change of rumen bacteria was same in all animals. Each bacterium quantity decreased gradually after feeding, and reached the lowest level after 2 h intake. It then increased slowly and reached the highest level after intake for 8 h. Finally, each bacterium quantity was back to same level as before intake. In contrast, the protozoa number raised to the highest in 4 h feeding and declined gradually, the concentration of protozoa in treatment group sheep was significantly higher than that of control group ($P < 0.05$). The pH of rumen liquids were in normal range and were not different between both groups. However, pH decreased from the highest level before feeding to the lowest level within 4 h. It was increased after intake for 8 h. The concentration of NH_3-N and MCP synthesis in the rumen liquids were both significantly higher than that of control group ($P < 0.05$), the highest concentration of NH_3-N and MCP were reached after feeding by 2 h and 4 h respectively. Block containing urea and molasses can be well utilized by sheep, it is conducive for rumen fermentation by the microbes in ruminant.

Key Words: molasses-urea, sheep, rumen

W467 Effects of corn levels on TMR on growth performance and economic efficiency in growing Korean black goats. S. U. Kim*, M. J. Ku, Y. S. Choi, S. K. Lee, D. H. Park, and S. G. Park, *Jeollanam-do Livestock Research Institute, Gangjin-gun, Jeollanam-do, Republic of Korea.*

This study was conducted to investigate the growth performance and economic efficiency in dietary corn mixing level on total mixed ration(TMR) in growing goats. A total of 32 castration goats with similar age (average 4 mo) and body weight (average 16kg) were equally allocated to dietary 4 treatments in a randomized complete block design. Dietary treatments included a controls (conventional) group and 3 corn mixing treatments groups (fed diets containing 15, 25, 35% corn mixing level of TMR). Average daily gain (ADG) was significantly ($P < 0.05$) higher in control group (103.5g). Within treatments, ranked the highest in 25% (91.2g), 15% (84.8g) 35% (72.6g) corn mixing treatments ($P < 0.05$). Daily feed intakes was significantly ($P < 0.05$) higher in control group (1,076g). Within treatments, ranked the highest in 15% (1,050g), 25% (1,041g), 35% (1,015g) corn mixing treatments ($P < 0.05$). The amounts of feed required for body weight gain ranked the lowest in control group (10.4), followed by 15% (11.4), 25% (12.4) and 35% (14.0) corn mixing treatments ($P < 0.05$). However, comparing the feed cost contrast with market price for economic analysis by comparing the income results, the income ranked the highest 396Won (36cents) in 25% corn mixing treatments, followed by 15% corn mixing treatments 344Won (31.2cents), control group 322Won (29.2cents) and 35% corn mixing treatments 254Won (23cents)($P < 0.05$). In conclusion, it was estimated that the optimal level of corn mix on TMR might be 25% feed intake, when diets based TMR were fed to growing Korean black goats for their improvements of economic efficiency.

Key Words: Korean black goats, corn mixing levels, total mixed ration (TMR)

W468 Effects of water restriction following feeding on microbial N supply and excretion of urinary purine derivatives in Corriedale ewes under heat stress condition. J. Ghassemi Nejad, B. W. Kim*, B. H. Lee, J. L. Peng, D. H. Ji, and K. I. Sung, *College of Animal Life Sciences, Kangwon National University, Chuncheon, Kangwon, South Korea.*

Urinary excretion of purine derivatives (PDs) is used to estimate the microbial N supply to sheep. The objective of this study was to determine the effect of water restriction following feeding on microbial N supply, and urinary excretion of PDs in Corriedale ewes under heat stress condition. Nine Corriedale ewes (average BW = 45.0 ± 4.5 kg) were fed diets based on maintenance requirements individually in metabolic crates. Sheep were assigned to 3 treatment groups according to a 3 × 3 Latin square design for 3 periods of 21 d duration each (9 sheep per treatment). Treatments were free access to water (FAW), 2h water restriction (2hWR), and 3h water restriction (3hWR) following feeding. No differences were found in body weight gain among all treatment groups ($P > 0.05$). Daily water intake decreased linearly as water restriction time following feeding increased ($P < 0.05$). Urine weight and volume were higher ($P < 0.05$) in FAW than restricted groups ($P > 0.05$). Water restriction following feeding decreased the urinary N (g/d) and urinary N as a percentage of N intakes ($P < 0.05$); however, fecal N (g/d) and fecal N as a percentage of N intake were not affected by water restriction following feeding ($P > 0.05$). Allantoin concentration tended to be higher ($P = 0.07$) in FAW group than 2hWR and 3hWR groups while no differences ($P > 0.05$) were observed in uric acid, xanthine + hypoxanthine and creatinine concentrations. Sum of PDs tended to be higher in FAW ($P = 0.08$) but water restriction following feeding reduced total PDs excretion compared with the FAW group ($P < 0.01$). It is concluded that water restriction following feeding for less than 3 h improved microbial N supply in ewes under heat stress condition.

Key Words: ewe, heat stress, microbial nitrogen

W469 Comparative study between two traditional camel rearing systems effects on milk fat and its fatty acids profile. Amir Ahmadpour[1], Abdol Hamid Karimi[2], Rupert Bruckmaier[3], and Mousa Zarrin*[4], *[1]Department of Animal Science, Bu-Ali Sina University, Hamadan, Iran, [2]Department of Animal Science, Fars Agricultural and Natural Resources Research Center, Shiraz, Fars, Iran, [3]Vetsuisse Faculty, University of Bern, Bern, Switzerland, [4]Department of Animal Science, Yasouj University, Yasouj, Iran.*

Raising awareness about harmfulness of high saturated fatty acid content of milk fat caused to increase the study to improve milk fat quality. The dromedary (*Camelus dromedarius*) is an important domestic animal in eastern Iran. In spite of importance of this specie, few studies have been reported on camel milk. The objective of the present study is comparison of the effects of different rearing systems on fat content and fatty acids profile of milk fat in camel. Eighteen lactating camels were assigned in 2 treatment groups include very extensive (VE, n = 9) and extensive (E, n = 9) rearing system. In the EV group, camels depended merely on pasture, but in the E group camels received 750g/animal barley after daily grazing. Animals watered twice daily and received 250 g/animal salt weekly. Animals were milked twice a day. Milk samples (250 mL from each camel) collected in the morning and analyzed for milk constituents. Thin-layer chromatography used for separation of triacylglycerol and fatty acids profile measured by gas chromatography method. Data are presented as means ± SEM. The fat content was 33.2 ± 9.2 g/L and 32.5 ± 11.6 g/L for VE and E group respectively. The amounts of short-chain (C4 – C8) and medium-chain (C10 – C13) fatty acids were higher in E group compared with VE group ($P < 0.05$), whereas the C14 like C16:0 and C16:1n-7 were higher in VE group ($P < 0.01$). Although C18:0 had no significant difference between groups, C18:1n-9 and C18:2n-6 in E and C18:3n-3 in VE were higher ($P < 0.05$). Moreover 20:0, 20:5n-3, 22:3n-3, and 22:6n-3 of VE was higher ($P < 0.05$). Milk fat of VE was less saturated ($P < 0.05$). Except free cholesterol and phospholipids that were lower and higher respectively in VE ($P < 0.05$), no significant difference observed between groups for cholesteryl esters, free fatty acids, triacylglycerols, diacylglycerols, and monoacylglycerols. The results demonstrated that the VE rearing system increases total polyunsaturated fatty acids and decreases free cholesterol compared with E group rearing system. In conclusion, the VE rearing system could produce healthier milk fat in camels.

Key Words: camel, milk, fat

W470 Influence of zilpaterol hydrochloride and enriched-Cr yeast supplementation on feedlot performance lambs.

Miguel A. Rodríguez[1,2], Ignacio A. Domínguez-Vara[1], Ernesto Morales-Almaráz[1], and Rubén Barajas*[2], [1]*Universidad Autónoma del Estado de México, FMVZ, Toluca, Estado de México, México,* [2]*FMVZ-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México.*

Twenty-eight Rambouillet cross lambs (27.85 ± 2.91 kg) were used in a 74-d feedlot experiment to evaluate the influence of zilpaterol hydrochloride (Zilmax, Merck Animal Health) and enriched-Cr yeast (BioChrome, Alltech) supplementation on feedlot performance of lambs. Sheep were weighed and individually allotted in 1.2 × 2.5 m concrete floor pens. They were randomly assigned to 4 treatments as follows: 1) A 85% concentrate diet, contained 15.5% CP and 1.87 Mcal NEm/kg, and formulated from corn grain and soybean meal (Control); 2) Control added with 0.2 mg of zilpaterol hydrochloride/ kg BW during last 28 d in the feedlot (ZH); 3) Control plus 0.3 mg of Cr/kg DM (YCr); and 4) Control plus ZH and YCr (ZHCr). Results were analyzed as a completely randomized design with a 2 × 2 factorial arrangement. Pen was the experimental unit; data were analyzed with initial weight as a covariate in the model. Final body weight tended ($P = 0.10$) to be increased by ZH supplementation (45.4 *vs*. 44.1 kg). Average daily gain tended ($P = 0.07$) to be higher for lambs in ZH treatment (0.306 *vs*. 0.280 kg/d). Dry matter intake was not affected by treatment ($P > 0.20$). Gain/feed ratio was increased ($P = 0.02$) by 11% (0.236 vs. 0.213 kg/kg) with ZH supplementation. Yeast-Cr supplementation did not modify any variable analyzed ($P > 0.20$). No interaction of ZH x Yeast-Cr was observed ($P > 0.20$). It is concluded, that zilpaterol hydrochloride supplementation promoted feedlot performance of lambs, whereas chromium supplementation from enriched-Cr yeast did not shown benefits to feedlot lambs both alone or in combination with zilpaterol hydrochloride.

Key Words: chromium, lamb, zilpaterol

W471 Influence of zilpaterol hydrochloride and enriched-Cr yeast supplementation on carcass characteristics and meat composition of feedlot lambs.

Miguel A. Rodríguez[1,2], Ignacio A. Domínguez-Vara[1], María A. Mariezcurrena-Berasain[1], Juan E. Sánchez-Torres[1], and Rubén Barajas*[2], [1]*Universidad Autónoma del Estado de México, FMVZ, Toluca, Estado de México, México,* [2]*FMVZ-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México.*

Twenty-eight Rambouillet cross lambs (27.85 ± 2.91 kg) were used in a 74-d feedlot experiment to evaluate the influence of zilpaterol hydrochloride (Zilmax, Merck Animal Health) and enriched-Cr yeast (BioChrome, Alltech) supplementation on carcass characteristics and meat composition of feedlot lambs. Lambs were weighed and individually allotted. They were randomly assigned to 4 treatments as follows: 1) A 85% concentrate corn-SBM diet, contained 15.5% CP and 1.87 Mcal NEm/kg, (Control); 2) Control with 0.2 mg of zilpaterol hydrochloride/ kg BW during last 28 d in the feedlot (ZH); 3) Control with 0.3 mg of Cr/kg DM (YCr); and 4) Control with ZH and YCr (ZHCr). Lambs were harvested, hot carcass weight measured and carcass dressing obtained. After 24 h chilling, *longissmus dorsi* muscle was cross sectioned at the 12th rib, and then back fat thickness and rib eye area were recorded. *Longissimus dorsi* samples were taken and meat chemical composition determined. Results were analyzed as a completely randomized design in a 2 × 2 factorial arrangement. Hot carcass weight tended to be greater ($P = 0.10$) in ZH (20.9 *vs*. 20.3 kg). Hot carcass dressing (46 ± 0.35%) was not different across treatments ($P > 0.20$). Back fat thickness was not affected by ZH ($P > 0.20$), but Cr tended ($P = 0.10$) to increase back fat thickness (2.02 vs.1.67 mm). Rib eye area (25 ± 0.68) was similar across treatments ($P > 0.20$). Meat dry matter, ash, and CP content were not altered by treatments ($P > 0.10$). ZH decreased ($P = 0.03$) fat content (28.3 *vs*. 39.14 g/kg). Shear force of the meat from lambs fed ZH treatments was greater ($P < 0.01$) than in meat lambs not fed ZH (5.8 *vs*. 2.8 kg/cm^2). Cooking losses were similar across treatments ($P > 0.10$). In conclusion, zilpaterol hydrochloride supplementation contributed to greater carcass weight and reduced fat content of meat, but shear force was greater. Yeast-Cr tended to increase back fat thickness without benefit in other carcass or meat characteristics.

Key Words: chromium, lamb, zilpaterol

W472 The nutritional value of confectionary sunflower hulls as forage source for finishing lambs.

Rae-Leigh A. Pederzolli* and Gregory B. Penner, *University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

The objective of this study was to determine whether sunflower hulls (SFH) could be used as a partial replacement for barley silage in diets for finishing lambs. Eighteen Canadian Arcott wether lambs were randomly assigned to 1 of 3 treatments: 0SFH (60% barley grain, 30% barley silage and 10% lamb mineral pellet), 7.5SFH (60% barley grain, 22.5% barley silage and 10% lamb mineral pellet) and 15SFH (60% barley grain, 15% barley silage and 10% lamb mineral pellet). The lambs were weighed on 2 consecutive days at the start and end of the 25-d feeding period. Total fecal collection was performed from d 21 to 24, and behavior was monitored on d 25. Samples of feed and refusals were analyzed to evalu-

ate the sorting index. Data were analyzed as a completely randomized design using mixed model of SAS. Dry matter intake was not affected ($P = 0.32$) averaging 1.4 kg/d but ADG increased (quadratic, $P = 0.03$) from 160 g/d for 0SFH to 215 g/d for 7.5SFH followed by a decrease for 15SFH (143 g/d). Sheep fed 15SFH sorted against particles retained on the 8 mm sieve ($P < 0.01$), tended to sort for particles retained on the 1.18 mm sieve ($P = 0.09$) and sorted for particles retained on the pan ($P < 0.05$) showing there was preference for the 19mm, 1.8mm and < 1.8mm particles in the diet. There was no difference in time spent ruminating or eating between the treatments ($P > 0.1$) but 15SFH spent less time drinking than lambs fed 0SFH ($P = 0.03$). Apparent total-tract digestibility was not affected by treatments ($P > 0.1$) with DM, CP, NDF, and ADF digestibility averaging 72.7, 71.6, 45.8, and 39.7%, respectively. The data in this study indicate that sunflower hulls can be used as a partial replacement for barley silage without negatively affecting DMI, G:F, feeding behavior and digestibility.

Key Words: ADG, lamb, sunflower hulls

Small Ruminant III

W473 Effects of the level of fish oil in the diet on lamb performance, ruminal fermentation and leptin gene expression. Pedro Hernandez[1], German Mendoza*[2], Nallely Sanchez[2], Jose Martinez[2], and Fernando Plata[2], [1]*Universidad Autonoma del Estado de Mexico, Amecameca, Mexico, Mexico,* [2]*Universidad Autonoma Metropolitana Unidad Xochimilco, Mexico, D.F., Mexico.*

The objective of this study was to evaluate the effects of fish oil on lamb performance, carcass yield, ruminal fermentation, and leptin gene expression. Thirty-two lambs (24.10 kg initial BW, Katahdin × Pelibuey) were used in a completely randomized design. Dietary treatments were: 1) 0 fish oil and 30% corn (DM), 2) 1% fish oil and 25% corn, fish oil substituted for corn (DM), 3) 2% fish oil and 20.5% corn (DM), and 4) 3% fish oil and 17% corn (DM). The lambs were weighed on consecutive days at the beginning (d 0 and 1) and at the end (d 55 and 56) of the trial. Ruminal fluid samples were collected on d 56 to evaluate the ruminal fermentation pattern. The lambs were slaughtered on d 56; the perirenal adipose tissue samples were collected, and the carcass yields were recorded. The VFA, ammonia N and leptin mRNA expression were not affected ($P > 0.05$) by the dietary treatments. However, the DMI, ADG, final BW and the hot carcass yield (HCY) showed linear or quadratic responses ($P < 0.05$) as fish oil was increased in the ration; the estimated optimal responses were obtained with fish oil levels of 1.16% for the final BW, 1.03% for the HCY, 1.12% for the ADG, and 0.78% for the DMI. Additionally, the feed efficiency and the back fat showed a quadratic response ($P < 0.05$) as fish oil was increased in the diet; the estimated optimal responses were obtained with fish oil levels of 1.4% for feed efficiency and 1.6% for back fat. Increasing fish oil in the diet did not have a negative impact on ruminal fermentation or leptin mRNA expression; however, levels of 1% fish oil improved lamb performance and allowed for a reduction in the amount of grains in the rations.

Key Words: finishing lamb, fish oil, leptin mRNA

W474 Growth rates of females from a Romane sheep breed flock reared in rangelands and effects of an early or late first mating regime on their offspring. Eliel González-García*[1], Didier Foulquié[2], François Bocquier[1], Dominique François[3], and Dominique Hazard[3], [1]*INRA UMR Systèmes d'élevage Méditerranéens et Tropicaux (SELMET), Montpellier Cedex 1, France,* [2]*INRA UE0321, Domaine de La Fage, Roquefort-sur-Soulzon, France,* [3]*INRA UMR1388 Génétique, Physiologie et Systèmes d'Elevage (GenPhySE), Castanet-Tolosan Cedex, France.*

Benefits in lifetime production of the ewe is often determined by the particular characteristics of the growth during the first stages of their life, including the related decision of the age at first mating. The objective of this work was to characterize the growth rates of the young female (from birth to first mating) from the Romane sheep breed, in a flock reared under the Mediterranean rangelands conditions of France. The effects of 2 contrasted first mating regimens (Early; 7 mo vs. Late; 19 mo old) on the individual growth rate of the ewe lamb and their first offspring were also evaluated. A database was built based on historical data that were extracted from the INRA database (GEEDOC). Data from 1359 females born during the period 2002–2012 were collected, processed and interpreted using SAS (9.3). From the total, 762 and 597 females were submitted to the Early or Late regimen, respectively. The effects of the litter size at their birth (singletons; SING vs. multiple; TWIN) and the age of their dams at birth (primiparous, PRIM vs. multiparous, MULT) were considered. The growth curves were built for both population (Early; 39.7 ± 0.07 kg and Late; 50.6 ± 0.04 kg BW at first mating) of ewes lambs. Significant interactions of the litter size at birth and the dam's parity were found for BW at birth and BW at weaning. Overall, the ewes lambs born from MULT × SING and PRIM × TWIN dams showed the highest (4.7 ± 0.03 and 26.2 ± 0.15 kg) and lowest (3.3 ± 0.01 and 22.5 ± 0.09 kg) BW at birth and weaning, respectively. Even if submitting the ewes lambs from the actual flock to the Late regimen constituted a change on the reproductive management policy of the farm (from 2010), data showed that females submitted to Late corresponded to those having a weaker growth from birth to weaning. When analyzing the growth traits of their first offspring, the first litter size (1.8 ± 0.01 vs. 2.1 ± 0.01 lambs/lambing) and its total weight (6.2 ± 0.03 vs. 7.4 ± 0.02 kg) were different ($P < 0.0001$) for ewes submitted to the early or late regimen, respectively. Other related carry over effects during the whole productive life of this females' population and their offspring are currently being analyzed.

Key Words: growth rate, Romane female lamb, mating regimen

W475 Effects of maternal lines and mating systems on susceptibility to parasitism in a pasture-lambing, low-input production system. Shuna A. Jones*[1], Chadwick C. Chase[1], Michael Heaton[1], Karen K. Shuck[2], Kreg Leymaster[1], and John Keele[1], [1]*US Meat Animal Research Center, Clay Center, NE,* [2]*Great Plains Veterinary Educational Center, Clay Center, NE.*

Internal parasites are a concern for industry as they negatively affect growth, survival, and reproduction. The objective was to evaluate the susceptibility of maternal lines to parasite infection, with the goal of developing genetic tests for this trait in US sheep. Purebred and Texel-sired lambs were born to Polypay, Katahdin, and Easycare (1/2 Romanov, 1/4 Katahdin, 1/4 White Dorper) ewes. Lambs were born on one of four 10-acre pastures, in a low-input system, 391 lambs were weaned at 70 d of age. Variation was accounted for by having all combinations of maternal lines and mating systems in each pasture. At weaning, a fecal sample was collected from individual lambs and the McMaster fecal egg count test (FEC) was performed on each sample. Data from 282 lambs were analyzed. For genetic evaluation, parentage was determined by allelic exclusion with genotype data from an international panel of 109 parentage SNPs. Data, log (FEC + 1), were analyzed using a mixed animal model with maternal line, mating system, maternal line × mating system, sex, and pasture as fixed effects. Variance components for additive genetic and environmental effects were estimated by REML using the iterative MIVQUE algorithm. Variance component estimates converged at positive values ensuring that the estimates were REML. Heritability was calculated as the additive genetic variance divided by the phenotypic variance after adjustment for fixed effects. The pasture effect for log (FEC + 1) was highly significant ($P = 9.38 \times 10^{-16}$). Mean log (FEC + 1) of the 4 pastures were 2.66, 3.29, 3.90, and 2.93 ± 0.12, and the corresponding median FEC (back-transformed from log-normal distribution) were 454, 1944, 7927, and 845 eggs/g. However, breed cross and sex were not significant, with P values of 0.99 and 0.49, respectively. The heritability estimate was 0.28 ± 0.17 which is moderate and significantly different from 0 ($P = 0.0025$) based on the restricted likelihood ratio test. These results indicate that the fecal egg count phenotype for sheep raised in central Nebraska is affected by parasite exposure and host genetics.

Key Words: sheep, internal parasite, heritability

W476 GnRH at moment or 24 hours after hCG treatment upon reproductive outcomes in anestrous goats. VH Gonzalez-Alvarez[1], CA Meza-Herrera[2], AS Alvarado-Espino[1], JM Gillen-Muñoz[1], R. Rodriguez-Martinez[1], G. Arellano-Rodriguez[1], PA Robles-Trillo[1], and FG Veliz*[1], *[1]Antonio Narro Autonomous Agricultural University, Torreon, Coahuila, Mexico, [2]Chapingo Autonomous University, Regional Universitary Unit on Arid Lands, Bermejillo, Durango, Mexico.*

The aim of this study was to evaluate if GnRH incorporation to the hCG treatment improves the reproductive parameters of seasonal anestrous goats in northern Mexico (26°N). Adult anovulatory adult (n = 36) were divided into 4 groups (n = 9), according to live weight and body condition score. On May 2, all goats were treated with progesterone (20 mg) intramuscular (im). Twenty-four hours before (d 0), Gc was treated with physiological saline (0.5 mL), Gh with hCG im (100 IU), G3 with hCG (100 IU) + GnRH (8.4 μg), and G4 with hCG (100 UI) + GnRH (8.4 μg) 24 h before hCG administration. The same day, all goats received PGF2α (7.5 mg) intravenously. Estrous was determined twice a day, from d-0 to d-5, using multiracial bucks provided with an apron; females were considered to be in estrus when allowed to be mounted. To determine ovulation occurrence, a transrectal ultrasonographic scanning (US) (Aloka SSD 500, Richmond, BC, Canada) was performed on d-10 in all goat; ovulation considered the presence of well defined corpus luteum at either ovary. Chi-squared test was performed to determine the differences among all groups concerning the reproductive traits measured (SYSTAT, Version 10, 2006), with a 95% interval confidence. The Gc group had no response in estrus, ovulation and gestation (0%, 0/9). The Gh-group had the highest percentages ($P < 0.05$) of both estrus (88.8%, 8/9) and pregnancy (71.4%, 5/9) and, along with G4, the highest ovulating rate (55.5%, 5/9). Results suggest that GnRH inclusion at moment or 24-h before hCG treatment negatively affects the reproductive outcomes of seasonally anestrous goats.

Key Words: goat, hCG, GnRH

W477 Application of 40 mg progesterone prior to the ram effect induces estrus response and ovulatory activity in Dorper sheep. LM Tejada*[1], CA Meza[2], O. Angel[1], R. Rodríguez-Martínez[1], MV Perales[1], E. Carrillo[3], G. Arellano[1], and FG Véliz[1], *[1]Universidad Autónoma Agraria Antonio Narro, Torreon, Coahuila, México, [2]Universidad Autónoma Chapingo Unidad Regional Universitaria de Zonas Áridas, Bermejillo, Durango, México, [3]Instituto Tecnológico de Torreón, Torreón, Coahuila, México.*

The aim of this study was to determine whether the application of intramuscular progesterone induces estrus activity in anovulatory Dorper sheep exposed to the male effect. A total of 20 ewes diagnosed as anovulatory, were divided into 3 homogeneous groups in terms of weight and body condition. Ewes had no contact with males at least 3 weeks before exposure to the male. While a group of ewes (G1; n = 6) received a single dose of 20 mg i.m. progesterone (day −2 of breeding), a second group (G2; n = 7) received a single dose of 40 mg i.m. of progesterone (day −2 of breeding), and the third group (GE n = 7) were inserted with a intravaginal sponge with 20 mg of progesterone (day −6 breeding) which was removed one day before introduction of the male. This experimental breeding was performed with males previously treated daily with testosterone (25 mg i.m.) during 15-d before mating to induce an intense sexual activity. Three males (one per group) were rotated every 12 h among experimental groups. Estrus activity was evaluated twice daily 1 h during 15-d. On d-12 after male introduction, an ultrasonographic scanning was performed to determine the percentage of ovulated females. Percentage of ewes depicting estrus and ovarian activity were compared using chi2, using the program SYSTAT 12. While no females from the G1 group expressed estrus activity (0/6, $P < 0.05$), all ewes of both the G2 and GE showed estrus activity ($P > 0.05$). In addition, most of the females from all the experimental groups depicted ovulatory activity (G1 5/6; G2 5/7 and GE 7/7 $P > 0.05$). The application of 40 mg i.m. of progesterone before the male effect was demonstrated to be as effective as the traditional use of intravaginal sponges to induce estrus response and ovulation in previously anovulatory females exposed to the male effect. Yet, the use of i.m. progesterone is significantly cheaper and easier to apply.

Key Words: sheep, progesterone, ram effect

W478 Evaluation of the use of hCG to promote the induction of reproductive activity in anovulatory Alpine goats. Alan S. Alvarado-Espino[1], Cesar A. Meza-Herrera[2], Vicente H. Gonzalez-Alvarez[1], Juan M. Guillen-Muñoz[1], Martha V. Perales-Garcia[1], Raymundo Rivas-Muñoz[3], Evaristo Carrillo[3], and Francisco G. Veliz*[1], *[1]Universidad Autonoma Agraria Antonio Narro, Torreón, Coahuila, Mexico, [2]Universidad Autonoma Chapingo-Unidad Regional Universitaria en Zonas Aridas, Bermejillo, Durango, Mexico, [3]Instituto Tecnologico de Torreon, Torreon, Coahuila, Mexico.*

The aim of this study was to evaluate the efficacy of the use of human chorionic gonadotrophin hormone (hCG) to induce reproductive activity in Alpine goats during seasonal anestrous in northern Mexico (26°N). Adult anovulatory goat (n = 30) were randomly divided into 3 groups according to body condition score (1.96 ± 0.32) and weight (37.36 ± 8.48). On July 23 (day −1), all goats received intra-vulvo-submucosal (ivs) administration of 20 mg of progesterone. On day 0 (D0), goats in the groups G300, (n = 10) received an ivs administration of 300 UI of hCG, the group G100, (n = 10) received 100 UI of hCG while the control group GC, (n = 10) received 0.5 mL of saline solution plus intramuscular administration (im) of 7.5 mg of synthetic prostaglandin. After D0, the onset of estrous behavior was evaluated twice a day for 5 min during the first 5-d after hCG administration by a sexually active buck. Goats were scanned by transrectal ultrasound (7.5 MHz probe) on d-45 after breeding for detection of pregnancy. Goats depicting estrus behavior were similar between groups (G100: 100% and G300: 90%, $P > 0.05$), with not estrus behavior in the GC-goats. The onset of estrous occurred earlier in G100 than G300 (54 ± 6.32 h vs 76 ± 30 h, respectively; $P < 0.05$). No differences were found ($P > 0.05$) in pregnancy rate between G100 (100%) and G300 (70%) groups. The kidding rate and prolificacy were similar ($P > 0.05$) in the G100 and G300 (80 vs 70% and 1.5 ± 0.56 vs 1.57 ± 0.53, respectively). These results indicate that administration of 100 UI of hCG could be used without a reduction in both estrus behavior and reproductive outcomes in anestrous Alpine goats at 26° N.

Key Words: hCG, induction, estrous

W479 Effects of mixing two different tannin-containing diets to evaluate rumen fermentation and microbial population changes in goats. D. Perkins*[1], B. R. Min[1], C. Wright[1], N. Gurung[1], T. Terrill[2], J.-S. Eun[3], W. H. McElhenney[1], R. Shange[1], and Y. Uyeno[4], *[1]Tuskegee University, Tuskegee, AL, [2]Fort-Valley*

State University, Fort Valley, GA, [3]Utah State University, Logan, UT, [4]Shinshu University, Minamiminowa, Japan.

Study was performed to investigate the influence of different sources of condensed tannins (CT) supplementations on ruminal fermentation and rumen microbial diversity changes of goats. The objective of this study was to determine whether the tannin-containing sericea lespedeza leaf pellet (SL, Lespedeza cuneate; 13.6% CT), ground pine bark (PB; Pinus; 16.3% CT), or its combination (SL+PB) would have effects on rumen fermentation and microbial diversity in meat goats. Twenty-four Kiko-crossbreed intact male goats (Capra hircus; BW = 38.6 ± 2.7 kg) were randomly assigned to 4 treatments (n = 6): 1) 30% bermudagrass hay and 70% grain mix, 2) 30% PB and 70% grain mix, 3) 30% SLP and 70% grain mix, and 4) 15% PB, 15% SL pellet, and 70% grain mix. Each treatment diet (30% DM) was mixed with remainder of each diet (70% DM) contained 70% commercial sweet feed and 30% alfalfa pellets. Feed intake and BW were monitored every 2 wks for 42 d. Rumen fluid samples were taken using a stomach tube at the d 0, 20, and 42 for microbial DNA analysis. Overall, there were no differences in DMI and BW gain among treatments. However, goats supplemented with PB and SLP+PB diets decreased ($P < 0.05$) concentrations of acetate, isobutyrate, and isovalerate compared with those in the control and SLP diets. There were no differences in rumen microbial kingdom (fungi, bacteria, and archaea) and phylum diversity. However, green algae population in rumen fluid was greater ($P < 0.01$) for control diet than for other treatments. In this study, Bacteroides (30 to 55%) and Firmicutes (30 to 47%) were the major bacterial phylum, while Prevotella spp. was the most predominant rumen bacterial species in the percentage of 22.1, 42.2, 28.9, and 23.9 for control, PB, SLP, and mixed diets, respectively. The population of rumen bacterial species in PB-supplemented group was greater for Bacteroides spp. ($P < 0.02$), Marinifilum spp. ($P < 0.04$), and Oribacterium spp. ($P < 0.03$) compared with other treatment groups. However, population of Fibrobacter succinogenes was greater ($P < 0.05$) for SLP than for other treatments. Supplementing tannins in goat diets such as PB and SLP diets has a potential to modify rumen bacterial population.

Key Words: goat, rumen microbial diversity, tannins

W480 Reproductive efficiency of anovulatory goats through bucks treated with testosterone and (or) estrogenized females in northern México.

Juan M. Guillén-Muñoz[1], César A. Meza-Herrera[2], Rafael Rodríguez-Martínez[1], Pedro A. Robles-Trillo[1], Carlos Leyva-Orasma[1], Evaristo Carrillo[3], Francisco Gerardo Veliz[1], and Gerardo Arellano-Rodríguez*[1], *[1]Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México, [2]Universidad Autónoma de Chapingo, Bermejillo, Durango, México, [3]Instituto Tecnologico de Torreon, Torreón, Coahuila, México.*

The aim of this study was to evaluate the effect of treated males with testosterone and (or) estrogenized female upon reproductive efficiency in anovulatory goats in northern México (26°N). Multiparous mix-dairy breed anestrous goats (n = 80) were randomly assigned to one 4 treatment groups: (GT; n = 20) exposed to testosterone-treated bucks (25 mg, 3 d x 3 weeks); (GTH; n = 20) joined to testosterone-treated bucks and expose to estrogenized females x 3-d (pen of bucks were separated of females by a metal mesh); (GH; n = 20) exposed to estrogen-treated females (kept in a pen aside to another pen whit 2 estrogenized females x 2-wk) and (GC; n = 20) exposed to untreated bucks. All goats in this study received an I.M. injection of 25 mg progesterone, 24-h before exposure to males. Response variables considered estrus response during 14-d, ovulatory response and pregnancy rate of goats. Percentages were analyzed through a chi-squared test (SYSTAT 12). Results from the treatment groups (GC; GT; GTH; GH) give important evidence that both treatments: testosterone-treated bucks and (or) exposure of males to estrogenized females were equally effective to promote not only estrus induction (75–90%) but also both an increased ovulatory response (70–90%) as well as pregnacy rates (70–90%; $P < 0.05$) respectively, in dairy mix-breed anovulatory goats under subtropical conditions.

Key Words: buck, testosterone, reproductive efficiency

W481 Impact of adequate or reduced mineral supplementation on rumen function and growth in lambs.

Abrigail M. Temple*[1], Gbenga A. Ayangbile[1], Dustin R. Vandermyde[1], Calvin R. Vandermyde[2], and Dan J. Schauff[1], *[1]Agri-King Inc., Fulton, IL, [2]Morrison Veterinary Clinic, Morrison, IL.*

Mineral supplementation is vital for optimum production and efficiency in livestock, but it is an added feed cost. We hypothesized a reduction in supplemental minerals in a ration may have minimal effect on rumen function and performance of lambs fed Ru-Mend, a product designed to enhance nutrient absorption. Sixty Katahdin wethers (average BW 13 ± 3 kg) 55 d of age were fed an ad lib corn silage plus alfalfa haylage-based diet with Ru-Mend, and either adequate (FULL) or reduced (RED) mineral supplements for 52 d. The total mixed rations were analyzed and RED diet found to be 30% lower in Co, Cu, Mn and Zn, 15% in S, 10% in Ca and Mg, and 5% in P as compared with the FULL diet. Diets were balanced for K, Na and Cl, but Na was 10% lower in the RED diet. Lambs were penned in groups of 15 with 2 pens per treatment. ADG was calculated for each animal from their initial and 44 d weight. DMI was calculated from pen daily intake. Lambs were euthanized on d 52, and tissues collected for analysis. Data were analyzed by ANOVA completely randomized design. Pearson correlations were used for comparison. Final rumen content pH was between 5.2 and 6.0 for all lambs. Lambs fed the FULL diet had higher DMI (640.71 vs. 513.13 g/d; $P < 0.0001$) and ADG (102.15 vs. 72.17 g/d; $P = 0.003$) than RED lambs. FULL lambs' ADG correlated with lower rumen ammonia ($P = 0.02$). The rumen fluid contents of FULL-fed lambs had higher total amino acids ($P = 0.004$) and essential amino acids [arginine, isoleucine, lysine, phenylalanine, threonine and valine] ($P \leq 0.03$) than RED-fed lambs. The lower ammonia and higher amino acids may indicate positive effect of minerals due to increased DMI and reduced protein degradation. Rumen osmolality and acetate were higher ($P = 0.05$) for FULL lambs. RED lambs had lower rumen and ileum contents Co, Cu and Mn ($P \leq 0.02$) and rumen Fe, Mg, P and S ($P \leq 0.03$). Lower ADG of RED lambs correlated with reduced ileum K, P and S ($P \leq 0.05$) and numerically less rumen Mg, Ca and Co ($P \leq 0.10$). This may indicate lambs fed the RED diet did not benefit from Ru-Mend, thus minerals needed for energy metabolism, growth and weight gain were unavailable.

Key Words: mineral, amino acid, rumen

W482 Tissue mineral deposition in growing lambs fed adequate or reduced levels of mineral supplements.

Abrigail M. Temple[1], Gbenga A. Ayangbile*[1], Dustin R. Vandermyde[1], Calvin R. Vandermyde[2], Dan J. Schauff[1], and Jeff G. Horst[1], *[1]Agri-King Inc., Fulton, IL, [2]Morrison Veterinary Clinic, Morrison, IL.*

Ru-Mend is a supplemental product designed to enhance nutrient absorption in the ruminant. Previous research shows animals fed Ru-Mend had increased mineral uptake and blood glucose versus the control. The objective of this study was to determine whether Ru-Mend supplementation would be a cost-effective way to improve mineral uptake and prevent performance issues in ruminants fed inadequate minerals by examining

blood metabolites and tissue mineral deposition. Sixty Katahdin wethers (average BW 13 ± 3 kg) approximately 55 d of age were split into groups and fed an ad lib corn silage plus alfalfa haylage-based diet with Ru-Mend, and either adequate (FULL) or reduced (RED) minerals for 52 d. The total mixed rations (TMR) were analyzed and RED diet found to be 30% lower in Co, Cu, Mn and Zn, 15% in S, 10% in Ca and Mg, and 5% in P as compared with the FULL diet. Diets were balanced for K, Na and Cl, but there was a 10% reduction in Na for the RED TMR. Lambs were penned in groups of 15 with 2 pens per treatment. Jugular blood samples were analyzed for each animal during wk 0, 2, 5, and 7. Animals were euthanized on d 52, tissues collected and prepared for analysis. Data were analyzed by ANOVA completely randomized design. Lambs on FULL supplement had higher blood hemoglobin and hematocrit ($P = 0.02$) and a tendency for higher glucose ($P = 0.09$). However, lambs on RED supplement had higher blood Cu ($P = 0.0001$) and a tendency for higher Fe ($P = 0.06$). Lambs fed RED treatment had significantly lower liver Ca, Cu, Mn and S ($P \leq 0.03$) and a tendency for lower Zn ($P = 0.06$). In addition, RED lambs had lower duodenum tissue Cu and Mn ($P < 0.03$), but higher spleen Ca, Cu, K, Mg, P and Zn ($P < 0.04$). This may suggest the spleen acted as an organ of sequestration. FULL TMR-fed lambs had higher hoof covering minerals of Co, Mn and Na ($P \leq 0.01$), whereas hoof bones were higher in Ca, Mn and P ($P \leq 0.04$). These results may indicate lambs receiving RED supplementation did not benefit from Ru-Mend as observed by lower blood hemoglobin and hematocrit as well as lower liver, duodenum, and hoof mineral levels compared with FULL-fed lambs.

Key Words: mineral, tissue, glucose

W483 Nutrient digestibility in growing lambs fed adequate or reduced levels of mineral supplements.

Abrigail M. Temple, Gbenga A. Ayangbile, Dustin R. Vandermyde, Dan J. Schauff*, and David A. Spangler, *Agri-King Inc., Fulton, IL.*

Minerals can be a costly addition to a livestock ration, and farmers may choose to reduce mineral supplementation to reduce feed costs. Ru-Mend is a product designed to enhance nutrient absorption in the ruminant. Previous research demonstrated animals fed Ru-Mend had improved rumen osmolality, mineral digestibility and blood glucose versus the control. We hypothesized Ru-Mend supplementation could be a cost-effective way to improve mineral uptake and prevent performance issues in ruminants fed inadequate mineral levels. The objective of this study was to observe the effect of Ru-Mend on nutrient digestibility in ruminants fed reduced levels of supplemental minerals. Sixty Katahdin wethers (average BW 13 ± 3 kg) approximately 55 d of age were split into groups and fed an ad libitum corn silage plus alfalfa haylage-based diet with Ru-Mend, and either adequate (FULL) or reduced (RED) minerals for 52 d. The total mixed rations (TMR) were analyzed and RED diet observed to be lower by 30% in Co, Cu, Mn and Zn, 15% in S, 10% in Ca and Mg, and 5% in P compared with the FULL diet. Diets were balanced for K, Na and Cl, but there was a 10% reduction in Na for the RED TMR. Lambs were penned in groups of 15 with 2 pens per TMR treatment. For determination of DMI, digestibility, and nutrient utilization, 9 animals from each treatment were placed in digestibility crates for 5 d sample collection of orts, fecal and urine. ADG was calculated for each animal from their initial and 44 d body weight (BW). Data were analyzed by ANOVA completely randomized design. Lambs fed FULL treatment had significantly higher DMI (427.49 vs. 332.68 g/d; $P < 0.0001$) and ADG (102.15 vs. 72.17 g/d; $P = 0.003$) compared with RED. Also, FULL TMR-fed lambs had significantly higher digestibility of ADF, CP and NDF ($P \leq 0.03$) and numerically higher DMD ($P = 0.14$). In addition, FULL lambs had significantly improved digestibility of Ca, Cu, Fe, K and S ($P < 0.04$) compared with RED. The data suggests lambs did not adequately benefit from Ru-Mend in the analyzed nutrient digestibility parameters or BW gain when the diet's mineral level was insufficient, as in the RED diet.

Key Words: mineral, digestibility

W484 Adipocyte differentiation-related protein promotes lipid accumulation in goat mammary epithelial cells.

Hengbo Shi, Kang Yu, and Jun Luo*, *College of Animal Science and Technology, Northwest A&F University, Yangling, Shaanxi, China.*

Milk fat originates from the secretion of lipid droplets (LDs) synthesized within mammary epithelial cells. Adipocyte differentiation-related protein (ADRP; also known as PLIN2) is an LD binding protein that is crucial for synthesis of mature LD. The hypothesis was ADRP regulate LD production and metabolism in goat mammary epithelial cells (GMEC), thus, play a role in determining milk fat content. The objective of the present study was to investigate the function of ADRP in milk fat metabolism by ADRP overexpression and knockdown in GMEC using an adenovirus system. The expression of ADRP mRNA was determined by RT-PCR, and concentration of triacylglycerol (TG) extracted from GMEC was quantified on a micro-titer plate reader. Immunocytochemical staining revealed that ADRP localize to the surface of LDs. Supplementation with oleic acid (OA) enhanced its localization on the LDs surface and lipid accumulation. Overexpression of ADRP increased lipid accumulation and the concentration of triacylglycerol in GMEC. In contrast, morphological examination revealed that knockdown of ADRP decreased lipid accumulation even when OA was supplemented. This response was confirmed by the reduction in mass of cellular TG when ADRP was knockdown. The fact that knockdown of ADRP did not completely eliminate lipid accumulation at a morphological level in GMEC without OA suggested that some other compensatory factors may also aid in the process of LD formation. ADRP reversed the decrease of LD accumulation induced by Adipose triglyceride lipase (ATGL). This indicated that ADRP promote TG stability within LD by preventing access to ATGL. Collectively, these data provide direct in vitro evidence that ADRP play a key role in LD formation and stability in GMEC. Further experiments need to explore the mechanisms for enlargement of LD via ADRP activity in GMEC.

Key Words: milk lipid droplet, Adipocyte differentiation-related protein (ADRP), goat mammary epithelial cells

W485 Activation of liver X receptor α and SREBP-1 promotes fatty acid synthesis in goat mammary epithelial cells.

Huifeng Xu and Jun Luo*, *College of Animal Science and Technology, Northwest A&F University, Yangling, Shaanxi, China.*

Liver X receptor α (LXRα) and sterol regulatory element binding protein-1 (SREBP-1) are key transcription factors regulating lipid synthesis in mammals, but the joint function of *LXRα* activation and *SREBP-1* maturation in milk fatty acid synthesis of lactating goat remains unclear. The objective of the present study was to determine the regulating function of LXRα and SREBP-1 in fatty acid metabolism of goat mammary gland using RT-qPCR. Goat mammary epithelial cells (GMEC) were treated by T0901317, a synthetic agonist of *LXRα*, to explore the regulatory function of *LXRα-SREBP-1* pathway in goat mammary gland. The results showed that there was no significant change in the mRNA level of *LXRα* following treatment with different concentrations of T0901317, but a dose-dependent increase were observed for levels of mRNA, protein and relative luciferase activity of *SREBP-1*.

Immunofluorescence results showed a clear accumulation of mature *SREBP-1* in cell nucleus by the addition of T0901317. Activation of *LXRα-SREBP-1* pathway increased significantly the mRNA expression of genes related to de novo fatty acid synthesis, fatty acid desaturation, elongation, transportation, and TG synthesis including *FASN*, *ACCα*, *SCD1*, *IHD1*, *ACSS2*, *Elovl6*, *FABP3*, *DGAT1*, *DGAT2*, *AGPAT6*, *LPIN1* and *PLIN2* ($P < 0.01$). One micro Mole T0901317 treatment caused a 20% increase of total content of cellular TG compared with the control ($P < 0.01$). Furthermore, addition of T0901317 remarkably increased the proportion of C16:1 and C18:1, while decreased that of C16:0 and C18:0. In conclusion, the *LXRα* regulates the expression and proteolytic maturation of *SREBP-1* in GMEC, which implied that the crosstalk between *LXRα* and *SREBP-1* may play an important role in the transcriptional regulation of de novo fatty acid synthesis and TG synthesis in goat mammary gland.

Key Words: LXRα, fatty acid synthesis, goat mammary epithelial cell

W486 Evaluation of different doses of intramuscular progesterone to induce reproductive activity in anestrous goats.

Viridiana Contreras*[1], Cesar Meza[2], Gerardo Arellano[1], Rafael Rodriguez[1], Ma de los Angeles De Santiago[1], Miguel Mellado[1], Raymundo Rivaz[3], and Francisco G. Veliz[1], [1]*Universidad Autonoma Agraria Antonio Narro, Torreon, Coahuila, Mexico,* [2]*URUZA-UACh, Bermejillo, Durango, Mexico,* [3]*Instituto Tecnologico de Torreon, Torreon, Coahuila, Mexico.*

The use of different doses of intramuscular progesterone for sexual activity induction in anestrous goats (26°N) was evaluated. During late May, mix-breed anovulatory adult goats (n = 15) were divided in 2 homogeneous groups regarding body condition score and body weight; 4 mix-breed bucks treated with testosterone were also used. Does grazed from 1000h to 1600h. Group 1 (10 mg; n = 7) received 10 mg i.m. progesterone + 200 IU i.m. eCG, while group 2 (20 mg; n = 8) received 20 mg i.m. progesterone + 200 IU i.m. eCG. Does were penned and kept there during 5-d and were fed with alfalfa hay ad libitum, 200 g commercial mix (14% CP, per animal/d) and trace mineral salt blocks and water ad libitum. Estrus activity was evaluated by introducing a male in each experimental group 15 min (morning) 15 min (noon) and 15 min (afternoon). Females depicting signs of heat were moved to a different pen with 2 males. A transrectal ultrasonographic scanning (TUS) was performed to detect ovulation (10 d) and pregnancy (45 d) after estrus detection. The percentage of females depicting estrus, ovulation and pregnancy were compared with a chi2. Reproductive response from both experimental groups is presented on Table 1. Results obtained allow us to conclude that administration of intramuscular progesterone, at 10 or 20 mg, induces sexual activity of goats during the normal anestrous season.

Table 1 (Abstr. W486). Reproductive response of mixed-breed anestrous goats receiving either 10 or 20 mg i.m. progesterone

	Group	
Sexual response	10 mg	20 mg
Estrus (no.)	$6/7^a$	$7/8^a$
Ovulation (no.)	$7/7^a$	$8/8^a$
Gestation (no.)	$5/6^a$	$5/8^a$

^{a,b}Different superscript within variables denote differences $P < 0.05$.

Key Words: progesterone, anestrous, goat

W487 Induction of sexual behavior in Dorper rams treated with glutamate and/or testosterone during the natural sexual resting season at 26°N.

Ma. Guadalupe Calderón-Leyva*[1], Cesar A. Meza-Herrera[2], Oscar Ángel-García[1], Juan Ramón Luna-Orozco[3], Raymundo Rivas-Muñoz[4], Gerardo Arellano-Rodríguez[1], F. Gerardo Véliz-Deras[1], and Rafael Rodríguez-Martínez[1], [1]*Universidad Autónoma Agraria Antonio Narro, Torreón, Coahuila, México,* [2]*Universidad Autónoma Chapingo, Unidad Regional Universitaria de Zonas Áridas, Bermejillo, Durango, México,* [3]*Centro de Bachillerato Tecnológico Agropecuario No. 1, Torreón, Coahuila, México,* [4]*Instituto Tecnológico de Torreón, Torreón, Coahuila, México.*

The study was performed in northern Mexico (25°64′ N, 103°26′ LW) to evaluate the effectiveness of different treatments to stimulate sexual behavior of rams during spring. Dorper rams (n = 20; 81 ± 0.32 kg BW; 3.8 ± 0.16 BCS) were divided in 4 homogeneous groups in terms of body weight (BW), body condition score (BCS) and odor, and were randomly assigned to 4 experimental groups: Glutamate Group (GG, n = 5; treated 7 mg kg^{-1} BW of L-Glutamate i.m.), Testosterone Group (TG, n = 5; treated with 25 mg of testosterone i.m.), Glutamate + Testosterone Group, (GTG, n = 5; receiving 7 mg kg^{-1} BW of L-Glutamate + 25 mg of testosterone i.m.) and Control Group (CONT, n = 5; which received 0.5 mL of saline i.m.). Odor score of rams was evaluated every 2 weeks by smelling the base of the horns at a distance of 15 cm and using a 0–3 scale. After 30 d of treatments, 2 males were randomly selected from each treated group and placed in one of 4 groups of anovulatory ewes (n = 14 each; 42 ± 2.36 kg BW; 3.04 ± 0.22 BCS) to evaluate the male sexual behavior, considering the appetitive sexual behavior (ASB), the consummatory sexual behavior (CSB) and isolation behavior (ISL), during 2-h daily x 2 d. While odor data were evaluated by ANOVA, sexual behavior considered X^2 (SYSTAT 12.0). No differences ($P > 0.05$) regarding odor score was observed in the first sample among experimental groups. Yet, at the end of the experimental period, the GTG showed the highest values (1.5 ± 0.29, $P < 0.05$) compared with groups GG and TG (0.75 ± 0.34 and 0.65 ± 0.75, respectively; $P > 0.05$). In the ASB, the GTG depicted the highest percentage of performed behaviors regarding GG, TG and CONT (43 vs 29, 11 and 18% respectively); only statistical differences ($P < 0.05$) occurred with respect to TG and CONT. In the CSB-phase, GG and GTG (37%) and the CONT (23%) did not differ ($P > 0.05$), yet, the TG depicted the lowest CSB performance ($P < 0.05$). In the case of ISL, the CONT accumulated the highest percentage (62%; $P < 0.05$) regarding GTG, GG and TG (25, 13 and 0%, respectively).Results demostrate that Dorper rams treated with glutamate + testosterone promoted not only an increased sexual behavior but also an augmented odor score during spring.

Key Words: rams, glutamate, testosterone

W488 Reproductive outcomes in nulliparous ewes exposed to dorper rams treated with glutamate and/or testosterone during increased photoperiods.

Ma. Guadalupe Calderon-Leyva[1], Cesar A. Meza Herrera[2], Oscar Angel-Garcia[1], Juan Ramon Luna-Orozco[3], Raymundo Rivas-Muñoz[4], Gerardo Arellano-Rodriguez[1], F. Gerardo Veliz-Deras[1], and Rafael Rodriguez-Martinez*[1], [1]*Universidad Autonoma Agraria Antonio Narr, Unidad Laguna, Torreon, Coahuila, Mexico,* [2]*Universidad Autonoma Chapingo, Unidad Regional de Zonas Aridas, Bermejillo, Durango, Mexico,* [3]*Centro de Bachillerato Tecnologico Agropecuario No 1, Torreon, Coahuila, Mexico.,* [4]*Instituto Tecnologico de Torreon, Torreon, Coahuila, Mexico.*

The aim of this study was to evaluate the ability to induce sexual activity in nulliparous Droper ewes during the anestrus season throughout the male effect in northern Mexico (26° N). Dorper rams (n = 8; 83 ± 3.6

kg BW) and 55 nulliparous anovulatory ewes (42 ± 2.36 kg BW) were used. Before to be in contact with males, ewes received 60 mg i.m. of progesterone to avoid short cycles and expect ovulation once estrus activity occurred, then ewes were divided in 4 homogeneous groups in terms of BW and BCS. Prior exposure to females, males were randomly divided in 4 experimental groups and treated during 30-d with: Glutamate (GG, n = 14 ewes; 2 males treated with 7 mg kg^{-1} BW of Glutamate, i.m.), Testosterone (TG, n = 14 ewes; 2 males treated with 25 mg i.m. of testosterone), Glutamate + Testosterone (GTG, n = 14 ewes; 2 males received 7 mg kg^{-1} BW of L-Glutamate and 25 mg of testosterone) and Control (CONT, n = 13; 2 males received 0.5 mL of saline). Since the first day of contact with males, estrus response and interval to estrus onset (h) were registered. Thereafter, embryo implantation rate was determined on d-45 from male exposure throughout transrectal ultrasound scanning. Data regarding the onset of estrus were analyzed using *t*-test, while the estrus response and implantation rate considered X^2 (SYSTAT 12.0). Ewes exposed to rams treated with glutamate or glutamate + testosterone showed the best reproductive outcomes ($P <$ 0.5), depicting, in average, the shortest interval to estrus (37.7 h) while the largest implantation (100%) and estrous response (100%) rates. Therefore, glutamate administration in rams emerges as an interesting option to improve the male effect. Nonetheless, it is futher required to elucidate the role played by testosterone in the GTG group, because ewes exposed to rams treated with testosterone alone (TG group) had the lowest reproductive outcomes.

Key Words: nulliparous ewe, male effect, glutamate

W489 Quality parameters of goat meat as influenced by dietary condensed tannins from pine bark.

Jolethia O. Jones*[1], Jung Hoon Lee[1], Byeng R. Min[2], Govind Kannan[1], and Brou Kouakou[1], [1]*Fort Valley State University, Fort Valley, GA,* [2]*Tuskegee University, Tuskegee, AL.*

This study was conducted to evaluate the quality characteristics of goat meat (chevon) from meat goats fed ground pine bark (PB, *Pinus* spp.) containing up to 13% condensed tannins (CT) on a DM basis. Twenty-four intact male Kiko goats (8 mo of age; BW = 39.7 ± 2.55 kg) were randomly assigned to pastures for a grazing trial. Goats were grazed in a winter rye grass-dominant pasture, and supplemented with either bermudagrass hay (BG) or PB pellet (n = 12 goats/supplementation). Each supplement consisted of alfalfa pellet, molasses, and mineral mixtures with either BG or PB powder, provided at 1.5% of BW at individual feeding stations. The dietary supplements were isocaloric and isonitrogenous. After 50 d grazing, goats were slaughtered and kept at 2°C for 24 h. *Longissimus muscle* (LM) pH was measured from individual carcasses and each carcass was fabricated to obtained 2.5-cm thick loin chops for meat quality analysis. All data were analyzed as a completely randomized design. The LM pH of goats was not significantly different ($P > 0.05$) between BG-hay and PB-pellet supplementations (5.65 and 5.70 ± 0.048, respectively). No significant differences were found in the CIE L* (lightness) and b* (yellowness) values of loin chops from goats supplemented either BG-hay or PB-pellet. However, the CIE a* (redness) values of chops from goats fed BG-hay were higher ($P <$ 0.05) than those from goats fed PB-pellet. No differences ($P > 0.05$) were found in the proximate composition of LM from the loin chops of goats fed the 2 different supplements. Furthermore, the thiobarbituric acid reactive substances (TBARS) values of LM from the loin chops were not significantly different between the 2 different supplements. No significant differences were found in the Warner-Bratzler shear values (3.90 vs 3.86 ± 0.13 kg) and cooking losses (20.1 vs 22.4 ± 1.12%) of loin chops from goats supplemented either BG-hay or PB-pellet. The results indicate that supplementing with pine bark pellet did not change the quality of chevon but it might influence the fresh red meat color of chevon.

Key Words: quality, goat meat, pine bark

W490 Fatty acid composition of different fat depots from hair and wool x hair sheep supplemented with soy hull on pasture.

Beruk B. Lemma[1], Jung Hoon Lee*[1], Stephan A. Wildeus[2], Brou Kouakou[1], and Govind Kannan[1], [1]*Fort Valley State University, Fort Valley, GA,* [2]*Virgina State University, Petersburg, VA.*

Terminal sire mating and supplementation were used to improve growth rate and muscling in hair sheep breeds. However, their effect on the fatty acid profile of different fat depots in lambs has not been reported. Forty-seven lambs (5-mo old), 23 purebred hair sheep (Barbados Blackbelly or BB, BW = 16.2 ± 1.9 kg; St.Croix or SC, BW = 19.5 ± 2.0 kg) and 24 crossbred wool (Dorset, D) x hair (BB; BW = 21.7 ± 2.3 kg or SC; BW = 21.7 ± 2.9 kg) of both sexes were rotationally grazed on predominately tall fescue with or without soy hull supplementation during summer. Soy hull was provided at 2.0% of BW at individual feeding stations. After 90 d of grazing, lambs were harvested, and intramuscular, subcutaneous and kidney fats were obtained from each carcass. Total lipids from each fat depot sample were extracted by the chloroform-methanol method. Extracted lipids were prepared for the fatty acid methyl esters (FAME) and then analyzed by a gas chromatography. All data were analyzed as a completely randomized design with breed type (pure- or cross-bred), supplement (with or without soy hull), and sex (male or female) as main effects. The fatty acid profiles of different fat depots from experimental lambs were significantly influenced by supplementation and sex. Compared with lambs fed supplement, pasture-only fed lambs had higher ($P < 0.01$) concentrations of linoleic (C18:2n6, 6.83 vs 4.96%), arachidonic (C20:4n6, 4.08 vs 2.27%), docosapentaenoic (C22:5n3, 1.41 vs 0.73%) and docosahexaenoic (C22:6n3, 0.45 vs 0.25%) acids in intramuscular fat; a higher ($P < 0.01$) concentration of stearic (C18:0, 26.0 vs 22.4%) acid, but lower ($P < 0.01$) concentrations of C16:0 (19.4 vs 22.2%) and C18:1n9 (31.4 vs 37.2%) in subcutaneous fat; and a higher ($P <$ 0.01) concentration of C18:1n9 (38.7 vs 33.1%), but lower ($P < 0.01$) concentrations of C18:0 (23.7 vs 29.4%) and C18:2n6 (1.13 vs 1.76%) in kidney fat. The results indicate that fresh lamb from pasture only fed-lambs might have healthier fatty acid profiles compared with that from lambs supplemented with soy hull, regardless of breed types.

Key Words: wool and hair sheep, fat depot, soy hull

W491 Relationship among somatic measurements, body condition score, live weight and internal fat depots in Sarda ewes and Saanen goats in early lactation.

Leonardo S. Knupp[1], Sheila N. R. Knupp[1], Mauro Ledda[2], Davide Rondina[1], Marco Acciaro[3], Carla Manca[3], Gesumino Spanu[1], Mondina F. Lunesu[1], and Antonello Cannas*[1], [1]*Dipartimento di Agraria, University of Sassari, Sardinia, Italy,* [2]*Dipartimento di Medicina Veterinaria, University of Sassari, Sardinia, Italy,* [3]*Agris Sardegna, Dipartimento di Ricerca nelle Produzioni Animali, Sardinia, Italy.*

Very little information is available on the relationship between BCS and LW in many dairy sheep and goat breeds. For these reasons, this work aimed to study in Sarda dairy ewes and in Saanen dairy goats: i) the relationship between BCS and LW; ii) the relationship between BCS, LW and the amount of internal body fat and its distribution in the abdominal cavity. Eight Sarda ewes (from 38.0 to 53.5 kg of LW and from 2.5 to 3.0 of BCS) and 8 Saanen goats (from 44.0 to 67.5 kg of LW and from 2.25 to 3.0 of BCS) in the second month of lactation were used in this study. Nine different somatic measurements were taken on each animal. At slaughter, omental, mesenteric, kidney and other internal fat were separated and weighed. LW linearly increased as BCS increased ($R^2 = 0.85$; $P < 0.001$) in Sarda ewes. BCS was a better predictor of LW ($R^2 = 0.92$; $P < 0.001$) than somatic body measurements. For each unitary change of BCS, the LW increased 23.45 kg. In contrast, in Saanen goats the relationship between LW and BCS was low ($R^2 = 0.25$) and not significant. In this species, chest of girth was instead a very good predictor of LW ($R^2 = 0.91$). Kidney, omental, mesenteric and others fat weighted, respectively, 0.2 kg, 0.9 kg, 0.4 kg, and 0.1 kg and represented 12.4%, 53.5%, 24.3%, and 9.7% of the total visceral fat depots in Sarda ewes. In Saanen goat they weighted, respectively, 0.3 kg, 1.0 kg, 0.7 kg, and 0.2 kg and represented 13.7%, 41.9%, 36.2%, and 8.2% of the total visceral fat depots. The weight of the total internal fat in relation of the EBW was very similar in ewes and in goats (0.4% and 0.5%, respectively). The kidney fat was highly correlated with the total visceral fat in sheep and goats ($R^2 = 0.92$ and 0.87, respectively). BCS and LW predicted equally well total internal fat (in kg) ($R^2 = 0.65$) in Sarda ewes, while in Saanen goats the BCS was a slightly better predictor ($R^2 = 0.63$) than LW ($R^2 = 0.59$). In conclusion, BCS was the best predictor of total internal fat in both species.

Key Words: body condition score, somatic measurement, visceral fat

W492 Assessment of RNA stability within six ovine tissues postmortem.

Fiona M. McGovern*[1], Tommy M. Boland[1], Francis P. Campion[1], Marion T. Ryan[1], and Torres Sweeney[2], *[1]School of Agriculture and Food Science, University College Dublin, Dublin , Ireland, [2]School of Veterinary Medicine, University College Dublin, Dublin, Ireland.*

Trancriptome analysis is commonly employed to evaluate biological processes in both human and livestock species. One of the prerequisites for this type of analysis is the possession of high purity, intact RNA. Postmortem tissue collection has inherent time delays and hence it is important to understand the temporal variation, both in the stability of total RNA and individual gene transcripts, with respect to particular tissues. The objective of this experiment was to both qualitatively and quantitatively assess the integrity of both total and mRNA species derived from ovine liver, spleen, thyroid, skeletal muscle, ileum and perirenal adipose tissue, which has been stored at ambient temperature and sampled at time points 0, 3, 6 and 9 h post-mortem. One hour after parturition, 6 lambs (5.12 ± 0.27 kg) were euthanized. Samples were collected from the liver, spleen, thyroid, skeletal muscle, ileum and perirenal adipose tissue and stored on a sterile Petri dish at ambient temperature. Approximately 1–2 g of tissue was then harvested at each time point (0, 3, 6, 9h), held for 24h in RNAlater and then stored at −80°C. The quality and quantity of total RNA was assessed on the NanoDrop spectrophotometer and Agilent 2100 Bioanalyzer, respectively. While postmortem sampling time had no effect on RNA quantity ($P \geq 0.05$) in 5 of the 6 tissue types analyzed, the RNA integrity number decreased over time and was significantly lower at 6 and/or 9 h postmortem in the spleen, thyroid, skeletal muscle, ileum and perirenal adipose tissues relative to the 0-h time point ($P < 0.05$). A reduction in the normalization factor in the liver, spleen, ileum and perirenal adipose tissues was observed over the time period ($P < 0.05$). In summary, the stability of total RNA remained intact within the first 3 h postmortem, regardless of tissue type, however tissue specific variation was evident in the RNA integrity across the 4 postmortem sampling times.

Key Words: ovine, RNA stability, postmortem

W493 A meta-analysis of net protein and energy requirements for growth of dairy goats.

Anaiane Souza*[1], Normand St-Pierre[2], Marcia Fernandes[1], Amélia Almeida[1], Julián Vargas[1], and Izabelle Teixeira[1], *[1]Universidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil, [2]The Ohio State University, Columbus, OH.*

Several factors including age, genotype, and sex affect the rate of body protein and fat deposition and, thus, the nutritional requirements for growth. Thus, the objective of this meta-analysis was to develop equations for estimating net protein (NP_g) and net energy (NE_g) requirements for growth of different sexes in dairy goats. A database of 244 individual records of Saanen goats weighing between 4.61 and 51.0 kg of body weight, from 7 comparative slaughter studies was used. Allometric equations were developed for body protein and energy contents in the empty body weight (EBW) as dependent variables and EBW as the allometric predictor. Parameter estimates were obtained using a linearized (log-transformation) expression of the allometric equations using the MIXED procedure of SAS 9.4. The model used included the random effect of study, and the fixed effects of sex (intact male, castrated male, and female; n = 93, 79, and 72, respectively). Net requirements for growth were estimated as the first derivative of the allometric equations. The NP_g equations differed across sexes ($P = 0.083$). The allometric equation for intact and castrated males was $\log_{10}$ EBW protein (g) = 2.221 ± 0.0224 + 1.015 ± 0.0165 x $\log_{10}$ EBW (kg); and for females: $\log_{10}$ EBW protein (g) = 2.277 ± 0.0288 + 0.958 ± 0.0218 × $\log_{10}$ EBW (kg) ($\sigma_e = 0.0374$; $\sigma_s = 0.0196$). The NP_g requirements for males were nearly 10% greater than those of females. The NE_g equations also differed between sexes ($P < 0.001$). The allometric equation for intact males was: $\log_{10}$ EBW energy (kcal) = 2.988 ± 0.0323 + 1.240 ± 0.0238 x $\log_{10}$ EBW (kg); for castrated males: $\log_{10}$ EBW energy (kcal) = 2.873 ± 0.0377 + 1.359 ± 0.0283 x $\log_{10}$ EBW (kg); and for females: $\log_{10}$ EBW energy (kcal) = 2.820 ± 0.0377 + 1.442 ± 0.0281 x $\log_{10}$ EBW (kg) ($\sigma_e = 0.0472$; $\sigma_s = 0.0309$). The NE_g requirements of castrated males were nearly 14% greater than those of intact males, and nearly 15% less than those of females. These results indicate that NP_g and NE_g requirements differ among sexes in growing dairy goats. This distinction is not done in the prevalent nutritional requirement systems (FAPESP grant # 2014/14734–9).

Key Words: allometry, Saanen, sex

W494 Effect of selenium supplementation on reproductive activity of Saanen bucks.

Khoboso C. Lehloenya*, Mamokou M. Mojapelo, and Jannes B. van Ryssen, *University of Pretoria, Pretoria, Gauteng, South Africa.*

Some parts of South Africa have soils deficient in selenium leading to selenium deficiency in animals grazing pastures or fed forages produced from these areas. Selenium deficiency is not only associated with poor fertility but also occurrences of several ruminant diseases. This study evaluated the effect of selenium supplementation on reproductive activity of Saanen bucks. Forty Saanen kids aged ± 3 mo were allocated into 2 groups comprising of selenium supplemented and the control. The study was conducted over a period of 6 mo. The Kids were fed lucerne ad libitum and had free access to water throughout the experiment. The supplemented group received sodium selenite orally at 3-mo intervals. Body weight and testicular measurements were recorded every 2 weeks while sexual behaviors were evaluated at weekly intervals. Semen was collected bi-weekly using an electro ejaculator from 5 mo of age. The supplemented group were significantly ($P < 0.01$) heavier (21.09 ± 4.1 kg) than the control group (19.03 ± 1.5 kg) and also they had larger ($P < 0\ 05$) scrotum circumference (22.77 ± 3.2 cm vs 20.94 ± 3.7 cm) and testicular length ($P < 0.01$) (8.92 ± 1.61 cm vs 8.20 ± 1.71cm).

Body weight had a positive correlation with the scrotal circumference; testicular length and width while it had a negative correlation with the expression of the mounting sexual behavior. Semen volume, mass motility and pH were not affected by selenium supplementation. However, the supplemented group had higher sperm concentration (2063.07×10^{6} mL^{-1} vs 1748.91 × 106 mL^{-1}), live sperm (77.50 ± 13.0% vs 76.64 ± 10.5%) than the control group. The percentage of dead sperm (22.50 ± 13.0 vs 23.36 ± 10.5) and secondary abnormalities (8.07 ± 7.6 vs 8.48 ± 9.7) was lower in the supplemented group than the control group. The higher morphologically abnormal sperm cells observed from the supplemented group was mostly due to higher percentage of primary abnormalities, which cannot be contributed by selenium supplementation. It is therefore concluded that selenium supplementation increased body weight however heavier bucks expressed mounting behavior at later age than lighter bucks. Selenium supplementation also improves the sperm quality and viability.

Key Words: goat, testicular measurement, semen characteristic

W495 Fatty acid profile of the meat of goats fed diets with soybean meals substituted with peanut cake. Thadeu M. Silva*[1], Ariosvaldo N. Medeiros[2], Ronaldo L. Oliveira[1], Severino Gonzaga Neto[2], Rita C. R. E. Queiroga[3], and Rebeca D. X. Ribeiro[1], [1]*Federal University of Bahia, Salvador, Bahia, Brazil,* [2]*Federal University of Paraíba, Areia, Paraíba, Brazil,* [3]*Federal University of Paraíba, João Pessoa, Paraíba, Brazil.*

Peanut cake is a by-product of biodiesel and contains relatively elevated lipid content. The inclusion of vegetable lipid sources in the diets can cause changes to the animal's fatty acid profile. This study was conducted to determine the effect of substituting soybean meal with peanut cake in the feeding of goats on meat fatty acid profile. Forty goats were assigned at a completely random design, to 1 of 4 diets. The concentrate was composed of corn bran, soybean meal, and mineral premix; soybean meal was substituted with peanut cake at substitution rates of 0.0, 33.33, 66.67, and 100%. Tifton-85 (*Cynodon* sp.) hay, was used at 50% of TMR. After 62 d of feeding, the animals were slaughtered. The left loin of each animal was collected and subjected to lipid extraction, methylation, and the quantification of the fatty acid esters were obtained through gas chromatography analysis. A general linear model was used to perform linear and quadratic regression with 5% significance. The sum of fatty acid and atherogenicity index was not influenced by the substitution of soybean meal with peanut cake (Table 1). Peanuts possess an elevated content of oleic acid (C18:1) compared with soy, which is rich in linoleic acid (C18:2). However, it is important to consider that these ingredients compose, at most, 21% of the total diet, so their lipid characteristics were diluted by the other ingredients. Another important factor is the ruminal biohydrogenation, which tends to convert oleic, linoleic and linolenic acids into stearic acid (C18:0). The peanut cake can replace completely the soybean meal in goat diet with no effect on fatty acid profile of the meat.

Table 1 (Abstr. W495). Sum of fatty acids as the percentage of total fatty acids and atherogenicity index in the loin of goats fed diets with soybean meal substituted with peanut cake

	Amount of substitution (%DM)					*P*-value	
Item	0.0	33.3	66.6	100.0	SEM	Lin	Quad

W496 Digestibility of nutrients in rams diets feed with fruit residue. Elenice Conceição dos Santos[1], Darcilene Maria Figueiredo*[1], Dorismar David Alves[2], Aldrin Vieira Pires[1], Paulo Gustavo Macedo de Almeida Martins[1], Janaína Leite Barbosa[1], Mônica Lopes Paixão[3], Cassiane Gomes dos Santos[1], and Marianne Schorer[1], [1]*Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, MG, Brazil,* [2]*UNIMONTES, Montes Claros, MG, Brazil,* [3]*Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

The objective of this study was to evaluate the digestibility of nutrients after the inclusion of pineapple (*Ananas comosus* L.), banana (*Musa* sp.), mango (*Mangifera indica*) and passion fruit (*Passiflora* sp.) residue in diet for confined rams replacing 75% corn silage. Twenty 5 Santa Ines crossbred rams, rumen fistulated, castrated were used with approximate initial age of 24 mo, and initial body weight of 45.4 ± 6.1 kg. Experiment was conducted in Latin square design (5 × 5), with 5 treatments, 5 animals per treatment, and 5 experimental periods of 13 d each. The forage: concentrate diet was 40:60 (% dry matter), and the forage in control diet was composed of 100% corn silage. To estimate the fecal nitrogen, animal feces were collected during 96 h using bag collectors. Samples of feces, bulky concentrates, and scraps of food provided were recorded. In all the samples we analyzed the chemical composition to estimate the digestibility of dry matter (DM), organic matter (OM), crude protein (CP), ether extract (EE), neutral detergent fiber (NDF), neutral detergent fiber corrected for ash and protein (NDFap), total carbohydrates (TC), and non-fibrous carbohydrates (NFC). The results were analyzed by ANOVA and Dunnett test at 5% probability, using the Statistical Analysis System. The inclusion of pineapple residue promoted increase ($P < 0.05$) in digestibility of OM, and TC, respectively, 2.5 and 4.5%, compared with control diet, which may be related to fermentation processes caused by this food, as there was a greater ($P < 0.05$) digestion of NDF, and NDFap with their inclusion in the diet. The diet containing banana residue decreased ($P < 0.05$) the EE digestibility by 23.6%, however provided an increase ($P < 0.05$) of the digestibility of NDFap in 7.78%. With the addition of mango residue, there was a reduction ($P < 0.05$) in DM by 1.5%. We concluded that the use of fruit residue instead of 75% corn silage (DM) do not cause reduction in the total apparent digestibility of nutrients in rams.

Key Words: alternative foods, confinement, sheep

W497 Nitrogen balance in sheep fed with fruit residue. Elenice Conceição dos Santos[1], Darcilene Maria Figueiredo*[1], Paulo Gustavo Macedo de Almeida Martins[1], Aldrin Vieira Pires[1], Dorismar David Alves[2], Mônica Lopes Paixão[3], Janaína Leite Barbosa[1], and Marianne

Schorer[1], [1]*Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, MG, Brazil,* [2]*UNIMONTES, Montes Claros, MG, Brazil,* [3]*Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

The objective of this study was to evaluate the effect of inclusion of pineapple (*Ananas comosus* L.), banana (*Musa* sp.), mango (*Mangifera indica*), and passion fruit (*Passiflora* sp.) residue in replacement of 75% corn silage in diets for confined sheep on nitrogen balance. Twenty 5 Santa Ines crossbred sheep male, rumen fistulated, castrated were used with approximate initial age of 24 mo, and initial body weight of 45.4 ± 6.1 kg. Experiment was conducted in Latin square design (5 ×5), with 5 treatments, 5 animals, and 5 experimental periods of 13 d each. The diets were formulated to contain approximately 72% total digestive nitrogen, and 14.7% crude protein. The forage: concentrate diet was 40:60 (% dry matter), and the forage in the control diet was composed of 100% corn silage. We carried out daily records of food provided and the remains of these, to ensure 10% of leftovers. To estimate the fecal nitrogen, total feces were collected during 96 h, using bag collectors. The urinary nitrogen were estimated collecting urine during 72 h. Nitrogen balance was measured by subtracting the total nitrogen intake and total nitrogen excreted in feces, and urine. The results were analyzed by ANOVA, and Dunnett test at 5% probability, using the Statistical Analysis System. There was no difference ($P > 0.05$) among fruit residue, and corn silage for nitrogen values (intake, fecal, urinary, absorbed, and retained). N itrogen balance was positive, and presented a mean value of 15.73 g day of nitrogen retained in animal body, representing 51.27% ingested nitrogen, indicating better utilization of nitrogen by sheep. The amount of nitrogen intake averaged 30.69 g day^{-1}, and fecal and urinary losses represented, respectively, 28.87 and 19.87% ingested nitrogen. We conclude that the use fruit residue to replace 75% corn silage DM is viable and do not interfere the nitrogen balance and nitrogen retention.

Key Words: alternative foods, urinary nitrogen, fecal nitrogen

W498 Ruminal parameters of sheep fed with fruit residue.

Elenice Conceição dos Santos[1], Darcilene Maria Figueiredo*[1], Dorismar David Alves[2], Aldrin Vieira Pires[1], Paulo Gustavo Macedo de Almeida Martins[1], Janaína Leite Barbosa[1], Mônica Lopes Paixão3,1, Adriano Cardoso dos Reis[3], and Marianne Schorer[1], [1]*Universidade Federal dos Vales do Jequitinhonha e Mucuri, Diamantina, MG, Brazil,* [2]*UNIMONTES, Montes Claros, MG, Brazil,* [3]*Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

The objective of this study was to evaluate the digestibility of nutrients after the inclusion of pineapple (*Ananas comosus* L.), banana (*Musa* sp.), mango (*Mangifera indica*) and passion fruit (*Passiflora* sp.) residue, in diet for confined sheep, replacing 75% corn silage. Twenty-five Santa Ines crossbred sheep male, rumen fistulated, castrated were used with initial age of 24 mo and initial body weight of 45.4 ± 6.1 kg. Experiment was conducted in Latin square design (5 × 5), with 5 treatments, 5 animals, and 5 experimental periods with 13 d each. The forage: concentrate diet was 40:60 (% dry matter), and the forage in the control diet was composed of 100% corn silage. At 13th day of each experimental period, rumen fluid samples were collected via ruminal fistula, to determine pH, and ammonia nitrogen (NH_3-N) in the following collections times: 0h (immediately prior the morning feeding), 2, 4, 6 h and 8 h after the morning feeding. Data collection was analyzed by regression, and to compare control diet with treatments, was performed by Dunnett test at 5% probability, using the Statistical Analysis System. There was no effect ($P > 0.05$) on the ammonia concentration levels (N-NH_3) in rumen fluid of animals fed with fruit residue, and obtained as an average value of 21.52 mg dL^{-1}. In the different collections (0, 2, 4, 6 and 8 h) of ruminal fluid was observed a quadratic effect ($P < 0.05$) for N-NH_3 (N-NH_3 = 19.64 + 3,11t −0,44t2; R2 = 0.63), where the highest concentration at this time was at 3.53 h post-treatment, which may be related to the lower diets fibrousness. Diet containing pineapple residue presented lowest ($P < 0.05$) pH value, with an average between 6.13 collection times. Quadratic effect was observed ($P < 0.05$) for pH (pH = 6.40 - 0,10t + 0,011t2; R2 = 0.61) as rumen fluid collection time, with lowest value of pH occurred at 4.54 h post-treatment. We conclude that the use of all fruits residue do not decrease the amount of N-NH_3 available for rumen microorganisms, and not interfere with the pH of rumen fluid suitable for the microbiota.

Key Words: alternative foods, confinement, lamb

W499 Effects of increasing dried distillers grains with solubles on intake, digestibility, blood and rumen metabolites of sheep consuming bermudagrass or eastern gamagrass hay.

Lamin Touray[1,2], Brou Kouakou*[1], and Jung H. Lee[1], [1]*Fort Valley State University, Fort Valley, GA,* [2]*University of Alabam at Birmingam, Birmingam, AL.*

In the southern United States, bermudagrass (*Cynodon dactylon*) is the predominantly used warm season forage. Eastern gamagrass (*Tripsacum dactyloides* L.) is being evaluated as an alternative to bermudagrass. The objective of this study was to determine intake and digestibility of bermudagrass or eastern gamagrass hay supplemented with increasing levels of dried distillers grains with solubles (DDGS) by sheep. In Experiment 1 (Exp. 1), bermudagrass hay (BG) was supplemented with 0, 10, 20, and 30% DDGS, and in Experiment 2 (Exp. 2), eastern gamagrass hay (EG) was also supplemented with the same levels of DDGS. In each experiment, a total of 4 crossbred wether sheep (Katahdin × Dorper; one year old, 33.2 ± 1.7 kg, BW) were used. The sheep were individually housed in pens and randomly assigned to each of the 4 diets. Each treatment consisted of 4 periods of 14 d/period (10 d adjustment and 4 d sample collection). Animals received hay ad libitum after the supplement was completely consumed. At the end of each period, a 7-mL blood sample was collected from each animal and analyzed for PUN, glucose, and NEFA concentrations and rumen fluid samples were also collected and analyzed for ruminal ammonia nitrogen (NH_3-N) and volatile fatty acids (VFA) concentrations. Nutrient digestibility was estimated using the total fecal (bag) collection method. Data from each experiment were analyzed as a separate Latin square design using SAS. DDGS supplementation did not ($P > 0.05$) affect BG hay DMI but increased ($P < 0.05$) EG hay DMI. In both experiments, DM, OM, ash, NDF and ADF digestibilities were not affected ($P > 0.05$) but CP and EE digestibilities increased ($P < 0.05$) with DDGS supplementation. Although DDGS supplementation did not affect total VFA concentrations in Exp. 1, it tended ($P = 0.09$) to decrease in Exp. 2. Plasma urea nitrogen (PUN) concentrations increased with DDGS supplementation in both experiments. Plasma glucose, NEFA, or rumen NH3-N, pH concentrations were not affected ($P > 0.05$) by DDGS in both experiments.

Key Words: DDGS, digestibility, metabolites

W500 Performance and feed efficiency of feedlot lambs fed different sources of non-protein nitrogen and carbohydrate.

Larissa Goltz, Ricardo D. Kliemann, Jean C. S. Lourenço, Eduardo M. Nascimento, Dayanna Pastal, Tiago M. Santos, Sergio R. Fernandes, and Américo F. Garcez Neto*, *Federal University of Paraná, Palotina, Paraná, Brazil.*

Despite of the huge availability of agricultural lands and good weather conditions to forage growth in Brazil, feedlots have been an effective way to increase animal production. The aim of this trial was to evaluate the performance and feeding efficiency of feedlot lambs fed diets with different non-nitrogen protein (NPN) and carbohydrates (CHO) sources in the concentrate. We used 20 non-castrated lambs with 4 mo of age and 26 kg of body weight. Lambs were fed ad libitum for 45 d with diets composed by 57% of grass hay (*Brachiaria* hybrid) and 43% of concentrate. The hay was harvested at late mature stage with high (72.4%) neutral detergent fiber and low (4.9%) crude protein. Four concentrates were formulated from the combination of 2 CHO (ground corn: starch; whey permeate: lactose) and 2 NPN (fast and slow release urea) sources. The diets were isoenergetic (2.32 Mcal/kg ME) and isoproteic (11% CP). Lambs were slaughtered at the end of trial after 45 d with a mean body weight of 30.4 ± 1.0 kg. A completely randomized design was used with 4 diets and 5 replicates. Data were analyzed by ANOVA following a 2 × 2 factorial scheme. Body weight gain (BWG), average daily gain (ADG), dry matter intake (DMI), gross feed efficiency (GFE) were analyzed. There was no interaction between CHO and NPN source ($P > 0.05$) and NPN had no effect on any variables ($P > 0.05$). Animals that were fed corn had higher BWG (5.28 vs. 3.54 kg), DMI (1.010 vs. 0.937 kg day^{-1}), ADG (117.30 vs. 78.60 g day^{-1}) and GFE (116.80 vs. 84.3 g kg^{-1} DM) than those fed whey permeate. The best performance and high intake of diets with corn can be related to a possible microbial growth limitation and the depression of fiber degradation in diets containing whey permeate. Lactose provides less carbon than starch on a mass basis and has a higher potential for energy-spilling due to its faster fermentation. The source of NPN in the concentrate feed had no effect on performance of finishing lambs fed a low quality diet. Ground corn was a better ingredient for concentrate feed in diets containing low quality forage.

Key Words: energy, intake, urea

W501 The use of Chambourcin grape extract as a natural anthelmintic in goat kids. Kimberly A. Cash*[1], James D. Caldwell[1], Bruce C. Shanks[1], Amy L. Bax[1], Luke S. Wilbers[1], Heather L. Hilsenbeck[1], Andrea T. McKnelly[1], Taylor N. Drane[1], Kelsey L. Basinger[1], Jessica K. Clark[1], Haley L. Bartimus[1], and Harley D. Naumann[2], *[1]Lincoln University, Jefferson City, MO, [2]University of Missouri Columbia, Columbia, MO.*

Gastrointestinal nematode parasitism is one of the greatest economic threats to goat production in the United States. With elevated incidences of anthelmintic resistance there is an increased interest in alternative natural dewormers, such as plants containing condensed tannins. Therefore, the objective of this study, supported by the NCR-SARE graduate grant program, was to evaluate the effects of fermented Chambourcin grape extract on parasite level and performance of goat kids. On October 14, 2014, a total of 45 mixed-breed goat kids (17.17 kg ± 0.79) were stratified by fecal egg count, weight, breed, and sex, and were allocated randomly to one of 3 treatments: 1) an oral dose (10 mL per 4.54 kg of BW) of fermented Chambourcin grape extract at 7-d (D7) intervals, 2) the same dose at 14-d (D14) intervals, or 3) control (30 mL oral dose of water at 14-d intervals). Condensed tannins were extracted, purified, and standardized by the Protein-Precipitable Phenolics method and found to have a concentration of 0.33 mg/mL. Goats were naturally exposed to gastrointestinal parasites on pasture consisting primarily of endophyte-infected tall fescue [*Lolium arundinaceum* (Schreb.) Darbysh] and mixed browse with access to 16% crude protein corn-soybean meal based creep feed for the duration of the 63-d study. Fecal egg counts, packed cell volumes, FAMACHA scores, weights, and body condition scores were measured every 7 d. Data were analyzed by the PROC MIXED procedure of SAS and treatments were reported as least squares means. Two contrast statements were used to compare the mean of control versus D7 and D14 and the mean of D7 versus D14. Animal was the experimental unit. Start, final, and change from start to final fecal egg counts, packed cell volumes, FAMACHA scores, and body condition scores did not differ ($P \geq 0.12$) across treatments. Average daily gain and total weight gain also did not differ ($P \geq 0.42$) across treatments. Therefore, fermented Chambourcin grape extract may not be an effective natural anthelmintic for controlling nematodes in creep-fed goat kids.

Key Words: natural anthelmintic, condensed tannin, grape extract

W502 Urushiol is not detected in blood or milk of Saanen dairy goats fed poison oak. Massimo Bionaz*, Claudia Ingham, Jennifer Belveal, Kristine Gomez, and Mark Keller, *Oregon State University, Corvallis, OR.*

Urushiol, the allergen present in *Toxicodendron diversilobum* (western poison oak), is responsible for contact dermatitis. More than 70% of adults have a reaction to urushiol, making this an important problem in the Northwest of US. Many anecdotal stories exist about desensitization to poison oak contact dermatitis acquired by drinking milk from goats fed poison oak. This has not been experimentally tested. In a previous study (Kouakou et al., 1992), urushiol was not detected in milk of goats fed 100% poison oak. To produce preliminary data for a large clinical trial, we have performed a pilot study in which 2 lactating Saanen goats were fed poison oak for 2 weeks. The experiment was carried out in the first 2 weeks of October 2014. The goats were at 80 d of lactation, weighed 70 ± 2 kg, produced 3 ± 0.7 kg/milk per day, and both were nursing triplets. The goats were kept in individual pens and fed twice a day with approx. 10% dry matter of fresh poison oak. Samples were obtained from each collection of poison oak. Feces, milk, and blood samples were collected at −1, 7, and 14 d after starting the experiment. Samples were spiked in with 2-dodecylphenol as internal standard and urushiol was extracted using 100% methanol. The extracted samples were purified using C-18 Solid phase Extraction columns before being injected into a Flexar HPLC (Perkin Elmer) equipped with a 5μm C18 HPLC column (Phenomenex). We were able to detect all 4 major congeners composing urushiol in the poison oak. We measured > 6 mg urushiol/g of fresh poison oak leaves (>14.0 mg/g of dry matter). Feces also contained urushiol (>1 mg urushiol/g of dry matter). We did not observe any urushiol in whole blood, plasma, or milk. The heptadecatrienylcatechol, the congener with the highest unsaturation and also the most irritant, was > 70% of the total extracted urushiol both in poison oak and feces. Our data confirmed the absence of detectable urushiol in milk; thus, milk from goats fed poison oak is safe to be consumed and handled by urushiol-sensitive people. Lack or minimal intestinal absorption and/or an extreme high clearance by the liver are inferred based on the absence of urushiol in blood.

Key Words: dairy goat, poison oak, milk

W503 Performance and carcass parameters of lambs fed high grain diets with different fiber contents. T. Brochado*, S. B. Gallo, M. C. Freua, P. R. Leme, and R. A. Brandi, *Faculty of Animal Science and Food Engineering, University of Sao Paulo, Pirassununga, SP, Brazil.*

Although high concentrate diets are commonly used for finishing lambs, literature about the effect of minimum levels of NDF on performance is limited. The purpose of this study was to evaluate the effects of increasing dietary fiber levels on performance and carcass parameters of in finishing lambs fed high concentrate diet. Twenty-four male lambs (initial BW of 24 ± 3 kg, 90 d old) were randomly assigned to 24 individual pens, in a complete randomized design with 3 treatments and 8 replicates. Treatments were dietary NDF levels of 12, 15 and 18% on DM basis. Diets were isoproteic, composed of corn, soybean meal, minerals and corn silage, and were offered twice a day with refusals daily measured to determine dry matter intake (DMI). Animals were weighed weekly and slaughtered after 50 d of feedlot, with average BW of 40 ± 4 kg. Hot and cold carcass weight (HCW and CCW) as well as hot and cold carcass yield (HCY and CCY) were measured. Data were submitted to polynomial regression analysis, with initial BW as a covariate, using the statistical software R. There was a linear increase in DMI ($P < 0.01$) from 1.26 ± 0.13 to 1.47 ± 0.21 kg/animal/d and a linear decrease on residual feed intake ($P < 0.01$) from 0.09 ± 0.11 kg/d to −0.06 ± 0.19 kg/d as dietary NDF increased. There was no difference in ADG ($P > 0.05$, 0.320 ± 0.06 kg/d) and feed conversion ($P > 0.05$, 4.27 ± 0.64 kg/kg) among treatments. There was a linear decrease ($P < 0.05$) on HCW (21.08 ± 1.10 to 19.65 ± 2.20 kg), HCY (51.93 ± 1.99 to 49.71 ± 2.47%) and CCY (50.04 ± 2.02 to 47.98 ± 2.64%) as dietary NDF increased. There was a trend of linear decrease ($P = 0.06$) for CCW from 20.31 ± 1.08 to 18.97 ± 2.15 kg as dietary NDF increased. In conclusion, although ADG was not affected by treatments, carcass weight and carcass yield increased as dietary levels of NDF decreased.

Key Words: feedlot, lamb, neutral detergent fiber

W504 Sheep performance under grazing supplemented with lime-hydrolyzed feather meal as a source of protein in their diet during the dry season in Mexico's Central Highlands.

Francisca Avilés Nova*[1], José M. Castro Salas[3], Octavio A. Castelán Ortega[2], Luis M. Ríos García[1], and Anastacio García Martínez[1], [1]*Centro Universitario Temascaltepec. Universidad Autónoma del Estado de México., Temascaltepec, Estado de México, México,* [2]*Facultad de Medicina Veterinaria y Zootecnia de la Universidad Autónoma del Estado de México, Toluca, Estado de México, México,* [3]*Unidad académica de Ciencias Agropecuarias y Ambientales. Universidad Autónoma de Guerrero, Iguala de la Independencia, Estado de Guerrero, México.*

The sheep continuous grazing on tropical forages during dry season requires supplementation with protein-based feed to improve production efficiency.The objective of this study was to evaluate the productive performance of grazing lambs supplemented with diets using 2 levels of inclusion of lime-hydrolyzed [$Ca(OH)_2$] feather meal. Experimental work was conducted at Rancho of the Temascaltepec University Center of the Autonomous University of the State of Mexico, from February to May. The treatments were: T1: grazing+diet with 6% feather meal; T2: grazing+diet with 9% feather meal; and T3: grazing+diet with 14% soybean meal.The diets were isoprotein (15.7%) and isoenergetic (4.6 Mcal/kg) and prepared with ground grain sorghum, wheat bran, molasses and minerals. The variables evaluated were daily weight gain, forage intake and feed conversion.Thirty lambs (Katahdin × Pelibuey) (initial weight of 26.1 kg ± 3.076) were used in the study. All lambs were weighed at the beginning of trial and thereafter every week before grazing.The lambs were randomly distributed among the 3 treatments. They grazed for 6 h daily in 3 mixed paddock (1.0 ha) of *Panicum* (Tanzania and Mombasa) and *Brachiaria* (Insurgente and Mulato II). At the beginning of each week the forage supplied was measured, and at the end of the week, the remaining forage was measured. Grass was cut using grass shears utilizing the quadrat. After grazing each day, each lamb was fed 250 g of the corresponding supplement.The lambs were kept in individual pens. A totally random design was used, with 3 treatments and 10 repetitions (each lamb representing one repetition). The Tukey's test was used ($P < 0.05$).The highest daily weight gain ($P < 0.05$) was obtained with the T2 (59.9 g d^{-1}) and T3 (67.6 g d^{-1}) treatments. No statistical difference ($P > 0.05$) in feed conversion was found between the T2 and T3 treatments, obtaining relations of 11:1 and 10:1, respectively. We concluded that lime-hydrolyzed feather meal may be used as a protein supplement, when it represents 9% of the diet of grazing lambs during the dry season, and may thus replace soybean meal in their diet.

Key Words: lamb, supplemented, lime-hydrolyzed feather meal

W505 Replacing corn with different levels of passion fruit by-product and its effects on feed intake, performance and digestibility in crossbred feedlot lambs.

Josemir S. Gonçalves*[1], Raimundo Neilson L. Amorim[2], Raquel L. Salgado[2], and Eric H. C. B. Van Cleef[1], [1]*UNESP-Univ Estadual Paulista, Faculdade de Ciências Agrárias e Veterinárias, Jaboticabal, São Paulo, Brazil,* [2]*UFERSA-Federal University of Semi-arid, Mossoró, Rio Grande do Norte, Brazil.*

Two studies were conducted to evaluate effects of corn grain replacement with passion fruit by-product (PFB) in finishing lambs on feed intake, feedlot performance, carcass traits and digestibility. In study 1, 20 Morada Nova ram lambs (21.8 ± 0.4 kg BW) were used in a completely randomized design with 4 treatments: isonitrogenous (19% CP) experimental diets contained 30% Tifton-85 bermudagrass hay and 70% concentrate (soybean meal, wheat meal, corn and 0, 25, 50, or 75% PFB). Over a period of 21 d, lambs were housed in digestibility cages (14 d adaptation and 7 d data collection) and DM, CP and NDF digestibilities estimated by total fecal collection technique. In the study 2, 32 Morada Nova ram lambs (22.4 ± 3.2 kg BW) were housed in individual pens and assigned to a randomized block design (initial BW) and fed the same diets of study 1 for 78 d (14 d adaptation and 64 d data collection). DM and nutrient intakes, average daily gain (ADG) and gain to feed (G:F) were evaluated and after slaughter (32 kg), yields of hot carcass (HCY) and cold carcass (CCY) were calculated. Data from study 1 were analyzed using the GLM procedure of SAS and means were compared with Tukey test ($P < 0.05$). For the study 2, data were analyzed with MIXED procedure with each animal as the experimental unit, and model effects included block and treatment. DM and CP digestibilities were not affected by PFB when it was added up to 50% (74.98 ± 2.0 and 77.38 ± 2.8%, respectively; $P > 0.05$). However, DM and CP digestibilities decreased in 75% PFB diet (69.7 ± 0.7 and 72.5 ± 1.1%, respectively). NDF digestibility was unaffected by treatments ($P > 0.05$), averaging 49.4 ± 3.4%. There were no differences in DM and digestible nutrient intakes ($P > 0.05$). No differences were evidenced ($P > 0.05$) in ADG (152 ± 0.03 g), G:F (0.147 ± 0.01 kg), HCY (46.6 ± 1.0%) and CCY (45.0 ± 1.0%). The data indicate that although passion fruit by-product decreases diets DM and CP digestibility, it is a suitable replacement for corn grain in diets for feedlot lambs when used at up to 75%.

Key Words: by-product, intake, sheep

W506 Effects of the utilization of increasing doses of aromatic plants on ruminal metabolism in Sarda dairy lactating ewes.

Roberta Boe, Oscar Boaventura Neto, Roberto Rubattu, Antonio Fenu, Antonio Mazza, and Antonello Cannas*, *Dipartimento di Agraria, Sezione di Scienze Zootecniche, Università di Sassari, Sassari, Italy.*

The objective of this study was to investigate the effects of increasing doses of 3 aromatic plants *Carum* sp. (CAR), *Coriandrum* sp. (COR) and

Satureja sp. (SAT) as a natural dietary additive on ruminal metabolism in Sarda dairy sheep. Forty-four Sarda dairy ewes (BW = 45.11 ± 4.62 kg) were randomly divided into 4 groups (11 ewes per group) assigned to an aromatic plant or to the control (CON). The 3 plants were tested, for each group in chronological order, at 3 increasing doses (low = 25g, medium = 75g and high = 125g), each supplied individually for 21 d during the 2 daily machine milkings. The ewes also received during the day dehydrated alfalfa, beet pulp, corn and pea meals. Rumen samples were taken by using a stomach tube. Rumen pH (mean value 6.87) was influenced by type of aromatic plant and dose level ($P < 0.004$), but not by their interaction. The ammonia content was higher in CON and COR groups (18.20 and 19.45 mg/dL, respectively) compared with CAR and SAT (14.79 and 15.87 mg/dL, respectively), and it was influenced by plant ($P < 0.001$) but not by dose or their interaction. The molar proportions of acetate and propionate were affected by diet and dose level ($P < 0.05$), with the higher values in CON and SAT (41.8% and 11.0%; 38.1% and 10.3%, respectively), while their ratio was influenced only by the dose level (increased from 3.19 to 4.34 for the low and high dose respectively). The molar proportion of butyrate was affected only by the type of plant, with the lowest value in COR and CAR (7.86% and 7.80%, respectively). A strong interaction ($P < 0.001$) between type of aromatic plants and dose level was detected in the concentration of odd-branched-chain (OBCFA), saturated (SFA), monounsaturated (MUFA) and polyunsaturated (PUFA) fatty acids. In particular, CON and SAT groups had the higher concentration of OBCFA (7.93 and 7.86 g/100g FA, respectively) and PUFA (5.04 and 4.42 g/100g FA), while the concentration of SFA and MUFA were higher in CAR and COR groups. These results suggest that the aromatic plants used altered the FA profile of the rumen.

Key Words: aromatic plant, ruminal metabolism.

W507 Effect of crude glycerin on in situ dry matter and neutral detergent fiber degradability in sheep. E. H. C. B. van Cleef*[1,2], M. T. C. Almeida[1], H. L. Perez[1], H. B. Bussioli[1], I. Monsignati[1], J. R. Paschoaloto[1], E. S. Castro Filho[1], and J. M. B. Ezequiel[1], [1]*São Paulo State University, Jaboticabal, São Paulo, Brazil,* [2]*FAPESP, São Paulo, Brazil.*

Eight ruminally cannulated crossbred male sheep (64.5 ± 8.5 kg) were used to evaluate the effect of inclusion of up to 30% crude glycerin, totally replacing corn, on dry matter intake, and DM and NDF in situ rumen degradability of rations. Animals were assigned into a replicated 4 × 4 Latin square design and, in pairs, were fed 1 of the 4 experimental treatments. Diets were composed of corn silage, soybean hulls, soybean meal, mineral premix, and crude glycerin (83% glycerol) replacing 0 (G0), 10 (G10), 20 (G20), or 30% (G30) corn cracked grain (DM basis), in a roughage:concentrate ratio of 40:60. Each experimental period lasted 21 d, composed of 14 d of adaptation and 7 d of data collection. Feed delivered and refused were weighed every morning to assess DMI. The 4 rations incubated in the rumen for 3, 6, 12, 24, 48, 72, and 96 h. The fraction "a" was determined by washing the bags in water and the residue after 96 h incubation was considered the fraction "c." The potential degradability was calculated with the model: $P = a + b\ (1 - e^{kt})$, and the effective degradability with the model: $P = a + b * [k / (k + K_p)]$. Treatments tented to promote a quadratic effect in DMI, with increased values observed for G10 and G20 ($P = 0.09$). Increasing crude glycerin linearly increased fraction "a" of DM and NDF of diets ($P < 0.0001$), and linearly decreased its fraction "c" ($P = 0.004$), increasing considerably the effective DM degradability ($P < 0.0001$). However, degradation rate of DM was unaffected by treatments, while degradation rate of NDF decreased in glycerin treatments ($P = 0.01$). No effects of crude glycerin was observed in effective degradability of NDF, regardless the passage rate evaluated (2, 5, and 8%/h). The addition of up to 20% crude glycerin seems to improve DMI. This by-product (up to 30% in dry matter basis) is a suitable energetic ingredient to replace corn in diets for sheep since it improves effective degradability of DM without affecting effective degradation of NDF.

Key Words: degradation kinetics, glycerol, sheep

W508 Effect of increasing concentration of babassu meal in diets for feedlot crossbred lambs on apparent total-tract digestibility of dry matter and nutrients. J. M. B. Ezequiel*[1], O. R. Serra[1,2], J. R. S. T. Souza[2], A. L. Lima[2], and E. H. C. B. van Cleef[1], [1]*São Paulo State University, Jaboticabal, São Paulo, Brazil,* [2]*Maranhão State University, São Luiz, Maranhão, Brazil.*

The objective of this study was to evaluate increasing concentrations of babassu (*Orbignya phalerata*) meal partially replacing Tifton-85 bermudagrass hay on dry matter and nutrients digestibility. Twenty-seven crossbred male lambs (90 d of age, 19.57 ± 0.41 kg BW) were randomly assigned to 1 of 3 experimental treatments. Isoenergetic (2.4 Mcal/kg ME) and isonitrogenous (19.6% CP) diets were formulated with 0.63% Ca, 0.36% P, and 2350 IU/kg vitamin A, to meet nutrient requirements for weight gain of 200g/d and were composed of ground corn, soybean meal, mineral premix, Tifton-85 bermudagrass hay, and 0 (T0), 15 (T15), or 30% (T30) babassu meal. Total fecal collection technique was used in this trial. Animals were adapted for 14 d to experimental diets, and between d 37 and d 41, samples of diets, feces and orts were collected. Samples were dried, ground (1 mm), and analyzed for dry matter, crude protein, neutral detergent fiber, acid detergent fiber, ether extract, and mineral matter contents. Digestibility coefficients (DC) were calculated by using the formula: DC (%) = [(nutrient ingested – nutrient in feces)/nutrient ingested] × 100. Data were analyzed as a completely randomized design by using mixed models. The animal was the experimental unit. Contrasts were used to determine linear and quadratic effect of babassu meal addition. The inclusion of babassu meal in the diets linearly increased digestibility of dry matter (T0 = 68.16, T15 = 74.38 and T30 = 79.63%), organic matter (T0 = 72.65, T15 = 78.06 and T30 = 82.44%), crude protein (T0 = 78.21, T15 = 83.19 and T30 = 87.13), ether extract (T0 = 79.62, T15 = 88.17 and T30 = 91.89), and neutral detergent fiber (T0 = 56.96, T15 = 62.91 and T30 = 68.30). Acid detergent fiber digestibility was unaffected by treatments and averaged 62.91%. In conclusion, babassu meal is a suitable feed ingredient to partially replace Tifton-85 bermudagrass in diets for finishing crossbred lambs and feasible for sheep producers, because this by-product is inexpensive when compared with grass hay, and improves dry matter and nutrient digestibility of diets when added up to 30% in dry matter basis.

Key Words: by-product, digestibility, sheep

874 Understanding the signaling pathways that regulate muscle mass in horses throughout the lifespan. K. L. Urschel*[1], A. L. Wagner[1], L. M. Mastro[1], C. M. M. Loos[1], A. A. Adams[2], and K.M. Brennan[3], *[1]Department of Animal and Food Sciences, University of Kentucky, Lexington, KY, [2]Department of Veterinary Science, University of Kentucky, Lexington, KY, [3]Alltech Inc., Nicholasville, KY.*

Skeletal muscle makes up ~50% of body weight in horses, with protein being the largest nonwater component. Muscle mass is largely determined by the balance of rates of muscle protein synthesis and breakdown. In an athletic species such as the horse, where muscle mass has been associated with performance, there is a need to understand how the underlying signaling pathways are regulated. In horses, similar to other species, activation of the downstream factors (4E-BP1, rpS6, S6K1) in the mechanistic target of rapamycin (mTOR) signaling pathway regulating protein synthesis is increased following feeding and insulin administration. The activation in response to feeding decreases with age in growing horses, with the muscle of yearlings being more responsive to feeding than that of 2 year olds. When horses are in an unfed state, there is no effect of age on the activation of mTOR signaling factors, either during growth or when comparing mature to old (> 20 yr old) horses. When comparing 2 populations of old horses: those that are relatively healthy and those with pituitary pars intermedia dysfunction, a condition that has been associated with a loss of muscle mass and insulin resistance, there were no differences between groups in the muscle activation or abundance of any of the mTOR signaling factors, myostatin (a factor related to muscle loss), or factors associated with the protein degradation signaling pathways (FoxO, atrogin-1, MuRF1), in response to either feeding or insulin infusion. Changes that occur in the muscle signaling pathways of old horses is an area where additional research is needed. In a dexamethasone-induced model of insulin resistance, where glucose uptake in response to insulin infusion was decreased by ~75%, there were profound decreases in the activation of mTOR signaling factors. These findings indicate that, in addition to being a risk factor for the development of laminitis and equine metabolic syndrome, insulin resistance may also impair the ability of the horse to maintain muscle mass, although additional research in other equine models of insulin resistance is needed. Understanding the factors that regulate the signaling pathways of muscle protein synthesis and breakdown will allow the development of management and feeding strategies to promote muscle mass accretion and maintenance throughout the lifespan.

875 The unexplored part of the rumen microbiome: Exploring the adaptive roles of bacteriophage auxiliary metabolism genes during dietary intervention in the rumen. Christopher L. Anderson[1,2], Galen Erickson[1], and Samodha C. Fernando*[1], *[1]Department of Animal Science, University of Nebraska-Lincoln, Lincoln, NE, [2]School of Biological Science, University of Nebraska-Lincoln, Lincoln, NE.*

Viruses are the most abundant biological entity, yet the roles of viruses within ecosystems are poorly understood. Work from other environments demonstrates that bacteriophage populations contain auxiliary metabolism genes thought to increase host fitness by altering host metabolism. As an attempt to better understand the viral influence on host bacterial populations, we investigated viral and total microbial community structure and function using culture-independent metagenomic approaches under 4 different dietary conditions. Using a shared read approach based on median k-mer profiling, the structure of total microbial communities significantly differed based on diet and host, whereas enriched viral metagenomes differed only by diet. The majority of differences between viral populations from different diets were metabolic in nature. Using community level metabolic networks, we further explored why different diets enrich phage communities for specific metabolic pathways. Enzymes differentially abundant in the total metagenome and virome had significantly higher betweenness centrality and a lower average shortest path length compared with nondifferential genes in the network. In addition, differential viral genes had a significantly higher total degree and in-degree compared with nondifferential genes. This ongoing work begins to suggest that diet, rather than host factors, has a stronger influence on the structuring of rumen phage populations and that phages encode for an adaptive repository of central metabolic functions related to selection pressures driven by altering environmental conditions. Current efforts are focused on better understanding what governs why certain central metabolic genes are enriched and how this is related to the flow of information through metabolic networks.

ASAS Graduate Student Symposium: Networking to achieve interdisciplinary research

643 Networking beyond the animal sciences to facilitate interdisciplinary research. Russell B. Muntifering*, *Auburn University, Auburn, AL.*

Researchable problems in the animal sciences are often highly intricate, and progress toward their resolution is often best achieved through integration of several scientific disciplines. Interdisciplinary research involving animal scientists does not need to transcend departmental boundaries because our departments by definition comprise disciplinary specialization in nutrition, genetics, physiology, biochemistry, and so on. However, identifying and networking with disciplinarians in other departments and universities can be a daunting task, especially for new faculty members whose discipline-focused graduate training may not have exposed them to the scrutiny of persons who were not trained within the same scholarly limitations, culture and traditions. For example, a legitimate concern among social scientists is that they are often recruited to join a natural-sciences project too late to provide input toward experimental design and data collection that can often provide more productive and interesting opportunities for socioeconomic analyses. Involving external disciplinarians early in the planning stages of research, even if they do not ultimately collaborate, can be extremely useful in terms of exchanging ideas for collecting useful data and becoming familiar with each others' work. Another hurdle to interdisciplinary research is mutual ignorance or naiveté among disciplines that can feed unrealistic expectations of capabilities and deliverables. Such impediments can be overcome by dialog and working through graduate students; seating external disciplinarians on graduate student advisory committees is a good way for them to become familiar with new researchable topics through thesis/dissertation literature reviews. The unique governance system and academic culture of universities should ideally provide an environment where interdisciplinary research can flourish, but this is not always the case. Faculty need to be knowledgeable of and sensitive to norms of valuation and reward within disciplines other than their own, and new faculty especially need to be cognizant of evaluation and reward systems at their institutions pertaining to single-investigator vs. collaborative scholarship.

Key Words: networking, interdisciplinary research

644 Effect of interdisciplinary research to animal science. Janet R. Donaldson*, *Mississippi State University, Mississippi State, MS.*

Interdisciplinary research is becoming increasingly more important to the progression of studies related to animal health. Broad training in interdisciplinary research, coupled with high quality specialized research, enhances job opportunities for students in government, academic, and industrial settings. Interdisciplinary training in animal science can entail, but is not limited to, associations with microbiologists, immunologists, and engineers. This symposium will focus on the need for people classically trained in microbiology, immunology, and so on, to network with animal scientists for the development of novel, translational therapeutic approaches to improve animal health. This symposium will be based on my personal experiences in multidisciplinary research from the approach of a microbiologist with no training in animal science. Networking beyond my discipline began during my first year in a faculty position. Through networking beyond my discipline, my research program has expanded to include a multidisciplinary team, consisting of animal physiologists, immunologists, gastrointestinal physiologists, and veterinary microbiologists. Together with this team, we have made substantial advancements toward progressive therapies for circumventing both animal and human diseases.

Key Words: networking, interdisciplinary research

645 Breaking the boundaries of animal science research through internationalization programs. Luis O. Tedeschi*[1] and James. P. Muir[2], [1]*Texas A&M University, College Station, TX,* [2]*Texas A&M AgriLife Research, Stephenville, TX.*

Globalization has imposed many changes in economic and political arenas in many regions around the world, but scientific knowledge has no boundaries and multinational collaboration can increase scientific knowledge by fostering the discovery of techniques and resources that can assist current and foreseeable problems, including hunger and sustainability. Ruminant animals, for instance, convert human-inedible resources into animal products for human consumption, and humankind have benefited from this prehistoric symbiotic relationship because ruminants can adapt to diverse environment (clime, soil, and vegetation), making them apt to inhabit virtually anywhere in the world. Collectively, humans of all socio-economic and socio-cultural strata have relied on animals for energy and/or protein consumption, wool, and draft power. This relationship has sometimes led to extreme production systems (due to economy-of-scale factors in some countries) that may cause irreversible damage to the environment. Thus, appropriate management of animal production is essential to enable long-term, sustainable continuation of this human-livestock relationship within acceptable animal welfare criteria. Proper education is the first step. Study abroad courses expose students and faculty to new endeavors in animal science and provide effective communication skills for the advancement of science. Internationalization programs minimize technical and economic disparities among countries. The educational exchange among countries is imperative to prepare leaders and extend the frontiers of knowledge in sustainable livestock intensification. For university and agency researchers, international exchanges advance technical, socio-economic, and environmental differences and strategic possibilities among countries. International business partnerships are critical for major multinational companies based in the United States involved in animal products and genetics, seed, fertilizer, and agrochemicals. Therefore, the investment on international research collaboration increases our awareness of human resource needs and enhances the career opportunities of our students by preparing them not only with technical expertise but also with language capabilities and in-depth understanding of other cultures.

Breeding and Genetics: Beef and meat species

646 Large-scale single-step genomic BLUP evaluation for American Angus. Daniela A. L. Lourenco*[1], Shogo Tsuruta[1], Breno O. Fragomeni[1], Yutaka Masuda[1], Ignacio Aguilar[2], Andres Legarra[3], Joseph K. Bertrand[1], Tonya S. Amen[4], Lizhen Wang[4], Dan W. Moser[4], and Ignacy Misztal[1], *[1]University of Georgia, Athens, GA, [2]INIA, Las Brujas, Uruguay, [3]INRA, Castanet-Tolosan, France, [4]Angus Genetics Inc., St. Joseph, MO.*

This study aims to investigate the feasibility of single-step genomic BLUP (ssGBLUP) for American Angus evaluation. Over 6 million records were available on birth weight (BW) and weaning weight (WW), 3.4 million on post-weaning gain (PWG), and 1.3 million on calving ease (CE). Genomic information was available on 51,883 animals. Realized accuracies were based on a validation population of 18,721 young animals born in 2013. Traditional and genomic EBV were computed by BLUP and ssGBLUP, respectively, using a multiple-trait linear model for growth traits and a bivariate threshold-linear model for CE-BW. Additionally, 2 methods for handling a large number of genotyped animals were tested: indirect prediction (IND) based on SNP effects derived from ssGBLUP, and algorithm for proven and young (APY) that uses genomic recursions on a small subset of reference animals to invert the genomic relationship matrix (G). All ssGBLUP, IND_ssGBLUP, and APY_ssGBLUP were based on reference populations of about 2000 high accuracy sires and cows (2k), 2k + all genotyped ancestors of the validation population (8k), and 8k + all remaining genotyped individuals not in the validation (33k). With BLUP, realized accuracies were 0.48, 0.67, 0.52, and 0.29 for BW, WW, PWG, and CE, respectively. With ssGBLUP and the 2k (33k animals) reference population, the accuracies were 0.55, 0.71, 0.60, and 0.31 (0.62, 0.78, 0.65, and 0.31), respectively. Low accuracy for CE was due to many missing records and low incidence rate. With 8k reference population, index of indirect prediction with parent average was as accurate as prediction from regular ssGBLUP. With 33k reference population, indirect prediction alone was as accurate as prediction from regular ssGBLUP. APY with recursions on 4k (8k) animals reached 97% (99%) of regular ssGBLUP accuracy; the cost of APY inverse of G is 1% (4%) of the regular inverse. The genomic evaluation in beef cattle with ssGBLUP is feasible while keeping the same models already used in regular BLUP. Indirect predictions allow for low cost interim evaluations. Use of the APY allows for inclusion of large number of genotyped animals in the main evaluation.

Key Words: beef cattle, genomic selection

647 Assignment of polled status using single nucleotide polymorphism genotypes and predicted gene content. John B. Cole[1], Daniel J. Null*[1], Chuanyu Sun[2], and Paul M. VanRaden[1], *[1]Animal Genomics and Improvement Laboratory, ARS, USDA, Beltsville, MD, [2]Sexing Technologies, Navasota, TX.*

There is growing interest in cattle that are naturally polled, but the polled allele has a very low frequency. The best way to increase its frequency is by index selection, which requires known polled status for all animals. Laboratory tests for polled are used as data, and US and Canadian bulls with ≥500 daughters and not designated as polled are assumed homozygous normal. Polled status is imputed for all other genotyped animals using these data. There are 2 mutations in the region around 1.7–1.9 Mb (UMD3.1) on BTA1 known to cause polled. The Celtic mutation is a deletion and an insertion, and the Friesian mutation a duplication. Both are located in a 75-marker window spanning 0.1–3.5 Mb on BTA1. An animal is heterozygous if it has either mutation, and is homozygous if both haplotypes contain polled, regardless of the mutation. This is consistent with -P and -PP coding in all breeds. Brown Swiss, Holstein, and Jersey polled haplotypes have frequencies of 0.41%, 0.93%, and 2.22%, respectively. The National Dairy Database has genotypes for only 678,848 of 39 million cows with records. Gene content (GC) for non-genotyped animals, the number of polled haplotypes in an animal's genotype, was computed using records from genotyped relatives. The GC are real-valued and range between 0 and 2. Prediction accuracy was checked by comparing polled status from recessive codes and animal names to GC for 1,615 non-genotyped Jerseys with known status. 97% (n = 675) of horned animals were correctly assigned GC near 0, and 3% (n = 19) were assigned GC near 1. Heterozygous polled animals had GC near 0 (52%, n = 474) and near 1 (47%; n = 433), although 3 animals were assigned a GC near 2. The expectation for GC is near 1 for heterozygotes, but can be lower if many polled ancestors have unknown status or when pedigree is unknown. In those cases GC may be set to twice the allele frequency, which is low. Some with -P in the name may actually be PP. All homozygous polled animals (n = 11) were assigned GC near 2. Polled status for non-genotyped animals can be accurately determined, and this method can be extended to other genes of interest.

Key Words: gene content, imputation, polled

648 Genetic analysis of hair coat shedding in beef cattle with data collection using a practical strategy. Trent Smith*[1], Michael D. MacNeil[2], and Joseph P. Cassady[3], *[1]Mississippi State University, Mississippi State, MS, [2]Delta G, Miles City, MT, [3]South Dakota State University, Brookings, SD.*

Hair coat characteristics can affect adaptability of beef cattle and performance in various environments. Objectives of this study were to examine the usefulness of an annual hair coat shedding score (HCS) during the spring transition period and determine its relationship with maternal productivity as indicated by weaning weight (WW). Data were collected on 5,294 purebred Angus cows in May of 2011 and 2012 from various herds throughout the Southeastern US, Missouri, and Texas. Measurements included a HCS (1–5) and BCS (1–9) scored independently by 2 trained technicians and averaged. The WW of calves were obtained from the breed association database. The data included 2,225 cows that were observed in both years. Two bivariate analyses were conducted to examine the relationships of HCS with BCS and WW. The same model was used to analyze HCS and BCS. It included fixed effects of contemporary group and age, and random direct genetic and permanent environmental effects due to animals. The model for WW included fixed effects of contemporary group, age of dam and sex, and a linear covariate for age of calf at weaning. Random effects in the model for WW were direct and maternal genetic effects, and a permanent environmental effect due to dams. Phenotypic correlations of HCS with BCS and WW were 0.17 and approximately zero, respectively. Heritability estimates for HCS and BCS were 0.42 ± 0.03 and 0.12 ± 0.03, with a genetic correlation of −0.25 ± 0.10. For WW, heritability estimates were 0.28 ± 0.05 for direct and 0.05 ± 0.04 for maternal effects. The genetic correlation for WW direct and maternal was −0.34 ± 0.24. Estimated genetic correlations of HCS with direct and maternal genetic effects on WW were 0.17 ± 0.22 and −0.30 ± 0.25, respectively. Results of this study suggest that HCS assessed once a year during a transitional period could be used in selection decisions if profitable in certain environmental conditions. Associations of HCS with other traits of economic importance need to be explored further.

Key Words: genetic variances, hair shedding, beef cattle

649 An application of MeSH enrichment analysis in livestock.

Gota Morota*[1], Francisco Peñagaricano[2,3], Jessica L. Petersen[1], Daniel C. Ciobanu[1], Koki Tsuyuzaki[4,5], and Itoshi Nikaido[5], *[1]University of Nebraska-Lincoln, Lincoln, NE, [2]University of Florida, Gainesville, FL, [3]University of Florida Genetics Institute, Gainesville, FL, [4]Tokyo University of Science, Noda, Chiba, Japan, [5]RIKEN, 2-1 Hirosawa, Wako, Saitama, Japan.*

It is an integral part of functional genomics studies to assess the enrichment of specific biological terms in gene lists found to be playing an important role in biological phenomena. Contrasting the observed frequency of annotated terms with those of the background is at the core of over-representation analysis (ORA). Gene Ontology (GO) is a means to consistently classify and annotate gene products and has become a mainstay in ORA. Alternatively, Medical Subject Headings (MeSH) offers a comprehensive life science vocabulary including additional categories that are not covered by GO. Although MeSH is predominantly applied in human and model organism research, its full potential in livestock genetics is yet to be explored. MeSH ORA was evaluated to discern biological properties of the identified genes and contrasted with the results obtained from GO enrichment analysis. Three published data sets were employed for this purpose representing a gene expression study in dairy cattle, the use of SNPs for genome-wide prediction in swine, and the identification of genomic regions targeted by selection in horses. We found that several over-represented MeSH annotations linked to these gene sets share similar concepts with those of GO terms. Moreover, MeSH yielded unique annotations, which are not directly provided by GO terms, suggesting that MeSH has the potential to refine the representation of biological knowledge. We demonstrated that MeSH can be regarded as another choice of annotation to draw biological inferences from genes identified via experimental analyses. When used in combination with GO terms, our results indicate that MeSH can enhance our functional interpretations for specific biological conditions or the genetic basis of complex traits in livestock species.

Key Words: MeSH, enrichment analysis, annotation

650 Use of partial least squares regression to predict individual milk coagulation properties and cheese yield from Fourier transform infrared spectra in Sarda dairy sheep.

Maria Grazia Manca[1], Jessica Serdino[1], Massimo Cellesi[1], Paolo Urgeghe[1], Ignazio Ibba[2], Marino Contu[2], and Nicolo P. P. Macciotta*[1], *[1]Dipartimento di Agraria, Università di Sassari, Sassari, Italy, [2]Associazione Regionale Allevatori della Sardegna, Cagliari, Italy.*

Milk coagulation properties (MCP) are popular indicators of milk cheese making ability. They are measured as rennet coagulation time (RCT, min), curd firming time (k_{20}, min) and curd firmness (a_{30}, mm). The potential cheese yield of milk could be also be assessed by individual cheese micro-manufacturing experiments (ILCY). However, the routine measure of these traits appears to be rather problematic in terms of costs and logistics. In this work, partial least squares regression (PLSR) is used to predict individual MCP and cheese yield of 965 Sarda breed ewes located in 47 flocks. MCP were measured using the Formagraph, and cheese yield was assessed by ILCY. Mid infrared spectra was obtained by Milkoscan (Foss Electric). Animals were split into 2 data sets: (1) training (700 ewes) that was used to estimate the PLS model and (2) validation (265 ewes), that was used to validate PLS predictions. One hundred replicates were performed, randomly assigning animals to training and validation sets. Goodness of predictions was assessed by calculating the determination coefficient (R^2), the residual mean squared error of prediction (RMSEP), the regression slope ($b_{obs,pred}$) and intercept ($a_{obs,pred}$) (Table 1).The R^2 indicates an accurate prediction for RCT and, to a lesser extent, a30, and very poor for k20. Also for ILCY the prediction was quite accurate. These figures were confirmed also by values of RMSEP and of regression parameters. The PLSR yielded prediction results of moderate accuracy for RCT and ILCY using mid-infrared spectral data as predictors and it could represent a valuable tool for the recording of these phenotypes for management and breeding purposes. Research supported by the regione Autonoma della Sardegna, project “Il latte Ovino della Sardegna”.

Table 1 (Abstr. 650). Statistics of PLS prediction for MCP and ILCY in the validation data set

	Mean obs	Mean pred	R^2	RMSEP	$b_{obs,pred}$	$a_{obs,pred}$
RCT (min)	15.25 ± 6.62	15.20 ± 5.82	0.71 ± 0.05	3.57 ± 0.35	0.97 ± 0.08	0.57 ± 1.17
k_{20} (min)	1.53 ± 0.85	1.55 ± 0.38	0.07 ± 0.03	0.83 ± 0.05	0.60 ± 0.17	0.60 ± 0.27
a_{30} (mm)	49.8 ± 20.2	49.8 ± 15.9	0.55 ± 0.05	13.5 ± 0.8	0.95 ± 0.08	2.5 ± 4.4
ILCY (%)	36.3 ± 9.3	36.3 ± 7.7	0.63 ± 0.06	5.7 ± 0.5	0.95 ± 0.06	1.7 ± 1.93

Key Words: milk coagulation properties, sheep, partial least squares regression

651 *MUC1* gene polymorphism in Murrah water buffaloes and its association with milk production traits.

Fernanda da Rosa*[1], Carla Moreira[2], Marina Mortati[3], Gregorio M. Camargo[3], Henrique Oliveira[3], Rusbel Borquis[3], Arione Boligon[2], Humberto Tonhati[3], Heden Moreira[2], and Fabio Souza[2], *[1]Oregon State University, Corvallis, OR, [2]Universidade Federal de Pelotas, Pelotas, RS, Brazil, [3]Universidade Estadual Paulista “Júlio de Mesquita Filho,” UNESP, Jaboticabal, SP, Brazil.*

MUC1 is a glycoprotein mucin expressed in apical mammalian epithelial tissues, such as mammalian gland, which the main function is protect the cell surface from the environment microorganisms. Hence, *MUC1* gene is a candidate gene to mastitis resistance. The MUC1 molecule is well defined in bovines, which has been associated with a highly polymorphic variable number of tandem repeats region (VNTR), which are highly conserved. However, there is no information about MUC1 for water buffaloes (*Bubalis bubalis*). Thus, the aim of this study was to identify the VNTR polymorphism of MUC1 gene in water buffaloes of Murrah breed and evaluated the polymorphism associations with economical traits and mastitis resistance. 200 animals from the experimental farm of State University of Sao Paulo (Brazil) were used. Genotyping was performed by the polymerase chain reaction (PCR). The amplified fragments were separated by electrophoresis on 1.5% agarose gel. The length of the alleles was estimated using the GeneRuler plus molecular weight marker. The traits evaluated were: somatic cell count (SCC), fat percentage (%F), age at first calving (AFC), calving interval (CI), fat yield (FY), protein percentage (%P), protein yield (PY) and milk production (MP). The analyses were performed using the PROC MIXED procedure of the SAS program to evaluate the effect of the presence/absence of the *MUC1* alleles on each trait. Differences with $P < 0.05$ were considered significant. Three alleles of different lengths were amplified and named allele 1, 2 and 3. Allele 2 was the predominant with a frequency of 0.56. Genotype 2/3 was the most frequent in all animals with a frequency of 0.41.The statistical analysis considering the presence/absence of the MUC1 alleles revealed that the alleles 1 and 3 were associated with some economic traits. A significant effect for the allele 1 was observed for higher means for SCC (7.52) and %P (4.39). The absence of allele 3 was significantly associated with higher means for PY (82.45) and AFC (862.12). The allele 1 effect for SCC persisted significant after the Bonferroni adjustment. Our data indicate MUC1 gene association with traits related to mastitis resistance like SCC and with economic traits like %P.

Key Words: buffaloes, mastitis, mucin1

652 The effects of sire breed on reproductive and progeny performance in Kiko meat goats.

Henry J. Henderson* and Chukwuemeka Okere, *Tuskegee University, Tuskegee Institute, AL.*

The aim of genetic selection in meat goat is to improve performance by incorporating the beneficial traits from a breed type. The primary objective of this study was to examine the effects of different sire types (Boer vs. Kiko) on reproduction and progeny performance of purebred Kiko does as well as growth and health performance of their offspring. Doe performance was analyzed by evaluating prolificacy (litter size), fecundity (fertility x prolificacy), and birth types (single, twins, or triplets). Doe and progeny performance were analyzed by evaluating prolificacy and pre-weaning growth and survival. A total number of 19 Kiko does were used in this study, 11 of which were bred to a Kiko buck and 8 to a Boer buck. Results revealed individual breed combination prolificacy values (1.9 and 1.75 kids/doe) for the Kiko Sired Group and Boer Sired group respectively. There were non-significant sire differences for gestation length (150 ± 2.66 vs. 148 ± 3.11 d, $P = 0.06$) for Boer and Kiko respectively. Weights of Kiko dams assigned to Boer and Kiko sires at breeding were similar (45.63 ± 10.17 vs. 42.39 ± 6.91, kg, $P = 0.41$). At weaning, weights of dams bred to Boer and Kiko sire were not significantly different (52.77 ± 14.64 and 42.76 ± 7.13, kg, $P = 0.10$). Litter size at birth and at weaning did not differ among sire breed (1.75 ± 0.46, $P = 0.37$ vs. 1.90 ± 0.30 and 1.50 ± 0.53 vs. 1.75 ± 0.46, $P = 0.33$) respectively. Boers sired kids were significantly heavier at birth but not at weaning (3.41 ± 0.48 vs. 2.78 ± 0.53 kg, $P = 0.001$ and 13.82 ± 2.78 vs. 12.43 ± 3.47 kg, $P = 0.26$). This suggests a growth-improvement potential for progeny when utilizing Boer sires. Non- significant differences were observed for ADG (0.15 ± 0.03 vs. 0.13 ± 0.03 kg/d) for Boer and Kiko sired kids respectively. Overall, results showed no consistent differences in reproduction and progeny performance traits between the main sire types used in this project.

Key Words: sire, prolificacy, progeny

653 Comparison of zinc finger sequences of hybrid sterility gene *Prdm9* between yaks, cattle, and their sterile hybrids.

Xiaoqin Ma[1], Qin Zeng[1], Juming Zhong[2], Wenjing Liu[3], Lin Huang[1], Suyu Jin[1], and Yucai Zheng*[1], [1]*Southwest University for Nationalities, Chengdu, Sichuan Province, China,* [2]*Auburn University, Auburn, AL,* [3]*Southwest University of Science and Technology, Mianyang, Sichuan Province, China.*

Prdm9 (PR domain containing 9) is the first hybrid sterility gene reported in vertebrates, it is a meiosis-specific gene and possibly related to male infertility. The objective of this study was to compare the *Prdm9* zinc fingers of yaks (*Bos grunniens*, n = 33), Yellow cattle (*Bos taurus*, n = 6) and their sterile male hybrids (i.e., cattle-yaks, n = 7). Genomic DNA was extracted from muscle or testis tissues of the experimental animals, and PCR was performed to amplify zinc finger sequences of *Prdm9*. The PCR products were gel-purified and sequenced from both strands. The zinc finger sequence of yak *Prdm9* is highly conserved, the deduced Prdm9 protein consists of 5 C_2H_2 type zinc fingers, which share identical sequences among 3 yak breeds or individuals. However, Yellow cattle *Prdm9* showed variations in both sequence and numbers of zinc fingers among the 6 individuals, with zinc finger numbers of 5, 7 and 8 (5 in 4 cattle, 7 and 8 in 2 cattle). Amino acid sequence comparison of corresponding zinc fingers between yak and cattle revealed 6 polymorphisms and 9 mutations, and 7 of the mutations are located at the positive selection sites. These results indicate that the zinc fingers of *Prdm9* gene evolves much faster in cattle than in yak. Further analysis of the zinc finger sequences of *Prdm9* in sterile cattle-yaks showed that cattle-yaks carry heterozygous *Prdm9* alleles, 4 of which contain alleles with different numbers of zinc fingers. Cattle-yak exhibits higher body size, milk and meat yields than those of yak, but F1 to F3 male sterility. We propose that the differences of Prdm9 zinc fingers at the positive selection sites as well as the numbers of zinc fingers between yak and cattle might be closely associated with the sterility of male cattle-yak.

Key Words: yak, *Prdm9* gene, hybrid sterility

Dairy Foods: Processing and chemistry

654 Effect of hydrodynamic cavitation on particle size of casein micelles, protein interactions and heat stability of skim milk.

Harsh Dahiya*[1], Hasmukh A. Patel[1], and Thom Huppertz[1,2], [1]*South Dakota State University, Brookings, SD,* [2]*NIZO Food Research, Ede, the Netherlands.*

Hydrodynamic cavitation (HC) is a process of vaporization, bubble generation followed by bubble collapse in a flowing liquid brought about by a decrease in pressure followed by a subsequent increase in pressure. We are currently applying this technology in the processing of milk and milk products. Therefore, the objective of this preliminary study was to investigate the effect of hydrodynamic cavitation (HC) on some important properties of milk such as particle size of casein micelles, interactions of proteins and heat stability of skim milk (SM). Pasteurized skim milk (3.5% protein and 9% total solids) was preheated to 50°C and then subjected to 2 sets of HC treatments, namely, HC at 20, 40, and 60 Hz at sufficiently high flow rate (950 L/h) to avoid any temperature increase during HC (T1) and HC at 60 Hz at low flow rates (200 L/h) to allow scale-free heating of skim milk increasing its temperature up to 90°C (T2) using APV Cavitator (supplied by SPX, Denmark) fitted with 4-row rotor in 6mm housing.The samples obtained from T1, T2 and untreated (control) skim milk samples were analyzed for changes in the particle size of casein micelles using Malvern Zetasizer Nano ZS and heat stability using the heat coagulation time (HCT) test at 140°C. The protein interactions in the whole sample and serum phase obtained from these samples were also studied using SDS-PAGE. SM subjected to T1 and T2 did not cause significant changes ($P < 0.05$) to the casein micelle size and HCT (165–171 nm and >5 min) compared with that in control sample (168 nm and >5 min respectively). On the other hand, samples subjected to T2 exhibited significantly higher levels ($P < 0.05$) of whey protein denaturation ($P < 0.05$) compared with those subjected to T1, which was attributed to the heat generated due to cavitation during T2. The high molecular weight aggregates were also generated in samples subjected to T2 due to extensive denaturation of whey proteins and their interactions with casein micelles. The results of this study suggested that HC can be promising technique that can be potentially used as an alternative technology for scale-free heating of milk with minimal effect on important properties of milk.

Key Words: hydrodynamic cavitation, denaturation, scale-free

655 Optimization of milk atomization by viscosity measurement.

Luc K. Belliere, Corentin Thierry*, Valerie Lefevre, and Philippe Burg, *Sofraser, Villemandeur, France.*

Every year, very large quantities of powdered milk are produced worldwide (~5 billion tonnes). Optimization of the manufacturing is the key to ensure product yield and profitability. This can be achieved by optimizing product viscosity during the drying and atomization of the milk. During drying, water is removed to reduce the energy required in the atomization column. Good viscosity control leads to a better evaporation and therefore lower water content. During atomization, droplet size has a direct effect on the heat required for drying and therefore the energy required to produce powdered milk. One of the methods to optimize atomization is by controlling the viscosity of the fluid before spraying as viscosity has a direct effect on droplet size. The viscometer used during the trial (MIVI, Sofraser) is a viscometer at resonance frequency working at a high shear rate. The active part of the sensor is a vibrating rod held in oscillation at its resonance frequency where the amplitude of the movement varies according to the viscosity of the product. The viscometer was rated for 500 bar and 200°C, with a full-scale range of 200 cP. The trials were performed at a Dutch milk processing company where the sensor was installed on a flow through-cell before the atomizer. The equipment was tested on 3 different products at the following operating conditions: atomization pressure between 150 and 225 bars, temperature in the cell ~75°C and flow rate of 2,800 L/h. The viscometer was used to control the viscosity of the incoming milk from the dryers and ensure the milk was within the optimal viscosity range for atomization. The setpoint viscosity for the 3 different formulations was 20, 50, and 180 cP. The viscometer allowed maintaining viscosity within ±1 σ for 85 to 90% of points and a maximum difference of 3% between setpoint and mean measurement. Depending on product 1 σ is between 5 and 10% of setpoint. Higher casein to whey protein ratio gave more stable results, as well as higher carbohydrate to fat ratio. This will not be explained as it is not part of the study. Finally, during the trials, the use of a viscometer allowed 2% energy savings which represent about $15,000 to $20,000/year (based on $0.07/kWh).

Key Words: process optimization, powdered milk, atomization

656 Effect of membrane channel geometry on limiting flux and serum protein removal during skim milk microfiltration.

Michael C. Adams, Emily E. Hurt, and David M. Barbano*, *Cornell University, Ithaca, NY.*

Our objectives were to determine the limiting fluxes (LF) and serum protein (SP) removal factors (SPR) of 2 100-nm ceramic microfiltration (MF) membranes: one with 4-mm round retentate flow channels (RFC) and one with 4-mm equivalent-diameter diamond-shaped retentate flow channels (DFC). Retentate and permeate were continuously recycled to the feed tank and a uniform transmembrane pressure (TMP) (TMP at the inlet minus TMP at the outlet) was maintained at 25 ± 3 kPa using a permeate recirculation pump. The LF for each membrane was determined by increasing flux once per h from 45 $kg \cdot m^{-2} \cdot h^{-1}$ until flux did not increase with increasing TMP. Temperature, average cross-flow velocity, and protein concentration in the retentate recirculation loop were maintained at 50°C, 7 $m \cdot s^{-1}$, and 8.5 ± 0.03%, respectively. Experiments were replicated 3 times and the Proc GLM procedure of SAS was used for statistical analysis. The LF of the DFC membrane (71 $kg \cdot m^{-2} \cdot h^{-1}$) was lower ($P < 0.05$) than the LF of RFC membrane (88 $kg \cdot m^{-2} \cdot h^{-1}$). Reynolds numbers based on the hydrodynamic diameter of the retentate flow channels were calculated for each membrane. Differences in Reynolds numbers between the membranes were proportional to the differences in LF. Permeate produced using the DFC membrane contained more ($P < 0.05$) protein than the permeate produced using the RFC membrane due to additional casein passage through the DFC membrane. SPR was calculated by dividing true protein in the permeate by SP in the permeate portion of the feed to describe the ease of SP passage through each membrane. Higher SPR indicate higher rates of SP passage. After accounting for casein contamination in each of the permeates with SDS-PAGE, the DFC membrane SPR remained higher ($P < 0.05$) than the RFC membrane SPR. Though DFC membrane LF was lower, DFC permeate removal on a modular basis was higher due to the increased module membrane surface area of the DFC membrane relative to the RFC membrane (2.07 m^2 vs. 1.41 m^2). Depending on the size of the system, using DFC membranes could reduce the capital cost of a MF system due to a reduction in the number of stainless steel modules.

Key Words: microfiltration, channel geometry, limiting flux

657 Effect of soluble milk components on limiting flux and serum protein removal during skim milk microfiltration.

Michael C. Adams, Emily E. Hurt, and David M. Barbano*, *Cornell University, Ithaca, NY.*

The tendency of calcium to promote microfiltration (MF) membrane fouling is well documented, but the role of lactose has not been studied. Milk protein concentrate that is 85% protein on a dry basis (MPC85) contains less calcium and lactose than skim milk (SM). Our objectives were to determine the limiting fluxes (LF) and serum protein (SP) removal factors (SPR) of 0.1 μm ceramic graded permeability membranes that were fed with 3 different milks: SM, MPC85 that had been standardized to the protein content of SM with reverse osmosis (RO) water (MPC), and MPC85 that had been standardized to the protein and lactose contents of SM with RO water and lactose monohydrate (MPC+L). Retentate and permeate were continuously recycled to the feed tank. The LF for each feed was determined by increasing flux once per h from 55 $kg \cdot m^{-2} \cdot h^{-1}$ until flux did not increase with increasing transmembrane pressure. Temperature, pressure drop across the membrane length, and protein concentration in the retentate recirculation loop were maintained at 50°C, 220 kPa, and 8.77 ± 0.2%, respectively. Experiments were replicated 3 times and the Proc GLM procedure of SAS was used for statistical analysis. The LF of SM (91 $kg \cdot m^{-2} \cdot h^{-1}$) was lower ($P < 0.05$) than the LF of MPC+L (124 $kg \cdot m^{-2} \cdot h^{-1}$) due to the role of calcium in fouling. The LF of MPC+L was lower ($P < 0.05$) than the LF of MPC (137 $kg \cdot m^{-2} \cdot h^{-1}$) due to the higher viscosity contributed by lactose. Permeates produced from the MPC and MPC+L contained more ($P < 0.05$) protein than the SM permeate due to the transfer of micellar casein into the reduced-calcium sera of the MPC and MPC+L. SPR was calculated by dividing true protein in the permeate by SP in the permeate portion of the feed to describe the ease of SP passage through the membrane. After accounting for the nonmicellar casein with SDS-PAGE, no differences ($P > 0.05$) in SPR were detected among the 3 feeds below the LF. As the fluxes approached the LF, SPR decreased ($P < 0.05$) due to fouling. Feeding a MF system with MPC instead of SM will reduce the required membrane surface area, but the permeate protein composition will be different.

Key Words: microfiltration, calcium, lactose

658 Comparison of 3 different variable selection strategies to improve the predictions of fatty acid profile in bovine milk by mid-infrared spectrometry.

Hélène Soyeurt*[1], Yves Brostaux[1], Frédéric Dehareng[2], Nicolas Gengler[1], and Pierre Dardenne[2], [1]*University of Liège-Gembloux Agro-Bio Tech, Gembloux,Belgium,* [2]*Walloon Agricultural Research Centre, Gembloux,Belgium.*

Mid-infrared (MIR) spectrometry is used to provide phenotypes related to the milk composition. Foss spectrum contains 1,060 datapoints. The number of reference values required to build a calibration equation is often lower than the spectral variables mainly due to the cost of chemical analysis. Problems of collinearity and overfitting appear when this high dimensional data set is used. This research will study the interest of using variable selection (VS) approach before the use of partial least square regression (PLS). The data set included 1,236 milk spectra related to their fatty acid (FA) contents. Saturated (SFA), monounsaturated (MUFA), polyunsaturated (PUFA), short chain (SCFA), medium chain (MCFA), and long chain FA (LCFA) were studied. The data set was randomly divided in 3 groups which were used to create 3 calibration and validation data sets. Three different VS methods were compared. The first strategy was based on the part of trait variability explained by each considered variables (R2VS). The second method was based on the regression coefficient estimated after PLS procedure divided by the standard deviation of the considered spectral variable (BSVS). The third strategy permitted to underline the uninformative variables which were the ones having the lowest ratio of average regression coefficient to their corresponding standard deviation estimated after a leave-one out cross-validation (UVEVS). For UVEVS and BSVS, the cutoff was determined from the known uninformative region of MIR milk spectrum. The cutoff for R2VS was determined by testing different thresholds ranged between 5 and 40%. The most interesting cutoff for R2VS was 25%. The worst results in terms of validation root mean square error of prediction (RMSEPv) were obtained using a full PLS (i.e., without VS). The maximum difference (g/dl of milk) of RMSEPv obtained from the full PLS and from the PLS using selected variables were 0.156 for SFA, 0.139 for MUFA, 0.011 for PUFA, 0.025 for SCFA, 0.164 for MCFA, and 0.188 for LCFA. R2VS gave the best results for all studied traits followed by UVEVS and then BSVS. In conclusion, the use of VS improved significantly the performance of FA MIR equations.

Key Words: milk, fatty acid, infrared

659 Factors influencing laboratory performance of oven drying total solids on whole milk.

David M. Barbano* and Chassidy Coon, *Cornell University, Ithaca, NY.*

Milk analysis proficiency testing has been carried out monthly by a group 10 laboratories for about 10 years. Patterns of differences in total solids (TS) results among labs have been observed, but the causes of some of these differences (i.e., systematic increase or decrease in difference from the all-laboratory mean value as function of milk total solids level) have not been identified. Our objective was to identify specific sources that cause these variations in results among laboratories. The atmospheric force air oven method number 990.20 of the Association of Official Analytical Chemists was used. A set of 14 milks with a range of TS content from about 8.4 to 15.2% were tested in duplicate by 10 different labs and replicated in 4 mo. In mo 1 and 3, the 14 milks were tested on each of 3 different days by the same analyst and in mo 2 and 4, the 14 milks were tested on each of 3 different days by the different analyst within each lab. The differences from the all-lab mean with statistical outliers removed were analyzed using Proc GLM of SAS to test for effects of lab, day, sample, and their interactions. The ANOVA terms for lab and lab by sample interaction were significant ($P < 0.05$) and explained most of the variation. The lab by sample interaction manifested itself as some labs having upward slopes, while other laboratories had downward slopes of the residual plot of 28 differences from the 14 sample all lab means as TS increased. The direction of the slope, when it occurred, was a function of laboratory or technician within laboratory. Follow-up work was conducted to identify causes of this behavior of TS results. Oven temperatures and oven temperature recovery rates were within method specifications for all labs. Attention was focused on the interaction of the analyst and balance. At the various weighing steps, the weights were recorded 3 times: immediately, after the balance indicated the weight was stable, and 7 s after the indication of stability. Based on these observations, a series of sensitivity analyses were done. The accuracy of TS results was most sensitive to variation (both random and systematic) in control of the balance zero during the steps of weighing the empty pan and the pan plus dry solids.

Key Words: milk, solids, oven drying

660 Greek-style yogurt manufacture: A case study for eco-efficiency assessment in dairy processing. Yves Pouliot*[1], Alain Doyen[1], Catherine Houssard[2], Adriana Paredes Valencia[1], Scott Benoit[1], Dominique Maxime[2], and Manuele Margni[2], *[1]STELA Dairy Research Center, Université Laval, Québec, QC, Canada, [2]CIRAIG, CIRODD, École Polytechnique de Montréal, Montréal, QC, Canada.*

Greek-style yogurt is characterized by a higher protein content (>10% w/v) compared with conventional products (4–5% w/v). The protein concentration is typically achieved by ultrafiltration (UF) or centrifugation processes after milk fermentation by yogurt starter cultures. However, this approach requires 3 times more milk than the traditional yogurt and it generates Greek yogurt co-product acid whey permeate for which the subsequent valorization represents a challenge. Although the concentration step increases the commercial value of yogurt, depending on the processing options selected, its manufacture affects the use of milk constituents and on the process environmental footprint. The concept of eco-efficiency (EE) provides an assessment of the environmental performance of a product system in relation to its value. EE is a practical tool for managing environmental data (e.g., Life cycle analysis or LCA) and value aspects (e.g., financial, functional, sensory) in parallel. In a first part of our study, we have compared the environmental impact of Greek-style yogurt production from 2 different processing options, i.e., performing the UF concentration step before or after fermentation step. Pilot-scale experiments were performed to characterize both processes in terms of water use, energy consumption and waste generation such as permeate (acid or not). The relative environmental impact of both processes will be characterized by means of a comparative LCA. The value aspects of Greek-style yogurt manufacture in the EE equation will address its direct commercial value, but also the value (or costs) of co-products valorization (or disposal). Our research aims at developing an EE-based approach and provide a decision-support tool to help manufacturers identifying and selecting most eco-efficient processing options for the production of Greek-style yogurt.

Key Words: eco-efficiency, dairy processing, yogurt

Dairy Foods Symposium: Advances in bacterial exopolysaccharides—From production to applications in dairy foods and health

661 Advances in production of exopolysaccharides and simplified methods for their recovery and quantification. Luc De Vuyst* and Frédéric Leroy, *Vrije Universiteit Brussel.*

The capacity of strains to produce exopolysaccharides (EPS) is widespread among species of lactic acid bacteria, although the physiological role of these molecules is not clearly understood yet. When EPS are produced during milk fermentation, they confer technological benefits to the fermented end products, such as an improved rheology, a reduced syneresis, and an enhanced body and mouthfeel. In addition, some of these EPS may have beneficial effects on consumer health. This requires optimal and sufficient production of these molecules both in situ and ex situ not only to improve their yields but also to obtain a particular functionality. Therefore, appropriate methods of production and recovery should be established. One particular difficulty relates to the production and processing of the biomass of starter cultures when they produce high concentrations of EPS. All this requires a better understanding of EPS production and regulation mechanisms.

Key Words: lactic acid bacteria, exopolysaccharides, fermentation

662 Chemical modification of EPS to improve its health functionalities. Siqian Li and Nagendra Shah*, *The University of Hong Kong, Pokfulam Road, Hong Kong.*

Exopolysaccharides (EPS) from S. thermophilus ASCC 1275 (ST1275) were isolated, purified and lyophilized and sulfated using SO_3-pyridine complex and FT-IR was used to identify the characteristic bands in EPS and sulfated EPS. Changes in antioxidant activities after sulfate modification were examined by measuring FRAP, DPPH, superoxide anion and hydroxyl radical scavenging activities. Antibacterial activities and MIC tests of EPS and sulfated EPS were investigated against *S. aureus*, *E. coli* and *L. monocytogenes* by cylinder-plate diffusion method. Changes in anti-proliferative activities after sulfate modification were also examined on HepG2 and Caco-2 cells by MTT method, while changes in anti-inflammatory activities were examined in RAW264.7 macrophages. LPS was used to induce inflammation in RAW264.7 macrophages. Sulfate modification of EPS was achieved and the degree of sulfate modification, which was identified as the average number of oxygen-sulfate groups per residue in EPS, was 0.31. Additionally, bands in FT-IR spectra indicated that sulfate group was at the C6 position of the galactose skeleton in sulfated EPS. The results also revealed that the antioxidant activities of sulfated EPS were significantly ($P < 0.05$) improved compared with those of unmodified EPS in all the 4 antioxidant activities assays. Sulfated EPS had larger inhibition zone on *S. aureus*, *E. coli* and *L. monocytogenes* compared with those of unmodified EPS which indicated that the antibacterial activities of EPS were significantly ($P < 0.05$) improved after sulfate modification. Furthermore, sulfated EPS had lower MIC for *S. aureus*, *E. coli* and *L. monocytogenes*, which also suggested that the antibacterial activities of EPS improved after sulfate modification. Sulfated EPS had higher anti-proliferative activities on both HepG2 and Caco-2 cells. Also, pro-/anti-inflammatory (IL-6/IL-10; TNF-α/IL-10) cytokine secretion ratios of LPS-stimulated RAW264.7 macrophage were significantly ($P < 0.05$) decreased after sulfated EPS treatments at non-cytotoxic doses. In conclusion, our results indicated that antioxidant, antibacterial, anti-proliferative and anti-inflammatory activities of ST1275 EPS were improved after sulfate modification

Key Words: EPS, sulfate modification, antimicrobial activity

663 Advances in application of EPS in dairy foods, particularly in low-fat or fat-free yogurt, and low-fat mozzarella cheese. Donald J. McMahon*, *Western Dairy Center, Utah State University, Logan, UT.*

Exopolysaccharides (EPS) produced by bacterial cultures has a long history of usage in cultured dairy products such as yogurt for improving their texture and providing some of the unique attributes of these traditional foods. Depending of the organism that produces the EPS, the EPS material can be retained around the cell as a capsule or released into the surrounding medium. In some cases, the released EPS can form into clumps and strands of EPS and are these are considered to be ropey cultures. Investigations into use of capsular EPS+ cultures in cheese making became of interest 25 years ago as a means of improving the texture of low-fat cheeses and this still continues to be an area of research related to many different types of cheeses. A prime effect of using EPS+ cultures is the greater retention of moisture in low-fat cheeses either from using EPS+ starter cultures or by direct addition of an EPS mass into the cheese milk before renneting. Understanding the effect of EPS on both rennet and acid coagulated foods has depended on studies of the product's microstructure using electron microscopy and confocal laser scanning microscopy. The functional effects of inclusion of EPS into cheese and yogurt depends on the intrinsic chemical nature of the EPS such as sugar composition, extent of branching and charge. This presentation reviews recent findings related to biostructural analysis of fermented dairy foods containing EPS from a variety of EPS+ bacterial species.

Key Words: exopolysaccharides, microstructure, dairy

664 Beneficial effects of EPS on human health and gut microbiota. Hua Wei*[1,2], Zhihong Zhang[1], Xueying Tao[1,2], Feng Xu[2], Hengyi Xu[1], Cuixiang Wan[2], Qinglong Wu[3], and Nagendra P. Shah[3], *[1]State Key Laboratory of Food Science and Techonology, Nanchang, Jiangxi, China, [2]Jiangxi-OAI Joint Research Institute, Nanchang, Jiangxi, China, [3]The University of Hong Kong, Hong Kong, China.*

Recently bacterial exopolysaccharide (EPS) extracted from *Lactobacillus* spp. and *Bifidobacterium* spp. has received considerable attention, mainly due to the novel and unique physical characteristics and physiological functions. EPS contributes to biofilm formation and host healthy maintenance, it can be used as an instrument for probiotics to survive in harsh condition. In this review, we provide a fresh perspective and focus on the advancement of bioactivity and immune modulating capability of exopolysaccharide. Indeed, EPS from *Lactobacillus* spp. and *Bifidobacterium* spp. exhibit many beneficial bioactivity including anti-tumor activity, antiviral activity, radical scavenging activity and abrogate the cytotoxic effect. Therefore, it has great potential for further development as therapeutic agents or adjuvants for cancer. Furthermore, EPS binds to common surface receptors to elicit the immune response in host, it was able to reduce the secretion of the proinflammatory e.g., IL-6. Thus, the EPS seem to be critical in studying the physiology of *Lactobacillus* spp. and *Bifidobacterium* spp. and their interaction with the host.

Growth and Development Symposium: The mitochondrion—A powerhouse for the cell or a key to animal productivity?

665 Mitochondrial bioenergetics—Bringing the cell to life. Darrell Neufer*, *East Carolina Diabetes and Obesity Institute, East Carolina University, Greenville, NC.*

This presentation will provide an overview of mitochondrial bioenergetics and redox systems biology—how life for cells is generated and maintained. Mitochondria are known as the engines of the cell, converting fuel derived from food into a chemical form of energy (ATP) used to support various cellular processes. A lesser-known but no less important role of the mitochondria is to generate and maintain an "electrical" charge throughout the cellular proteome. The respiratory system is composed of a series of proteins imbedded within the inner mitochondrial membrane that transport electrons by default, using oxygen as the final acceptor to produce water. The engine relies on a type of electrical circuit or redox system that is primed or "pressurized," with energy demand decreasing and energy supply increasing that pressure. Normally the mitochondrial respiratory system operates as a demand based system, meaning that the rate of fuel utilization and oxygen consumption is determined by the rate at which energy is being utilized by cells, even at rest (i.e., idling). In fact, because skeletal muscle represents a high percentage of body mass, this idling of mitochondria represents a significant source of heat generation by animals. However, when energy supply exceeds energy demand, the redox pressure within the system increases, causing electrons to leak from the circuit to oxygen prematurely, leading to the formation superoxide and other reactive oxygen species (ROS) that can react with and damage proteins, lipids and DNA. Fortunately, antioxidant scavenging systems are extremely efficient and convert the majority of superoxide to the non-radical hydrogen peroxide (H_2O_2). H_2O_2 can freely diffuse out of the mitochondria and influence various signaling pathways. Thus, the mitochondrial respiratory system functions as a redox pressure gauge that senses and reflects cellular metabolic balance. When in positive balance, electron leak serves as a release valve, accelerating mitochondrial H_2O_2 emission which has been implicated to play a significant role in numerous diseases related to disorders of metabolism.

Key Words: mitochondria, energy, redox

666 Mitochondrial bioenergetics and aging. Hazel H. Szeto*, *Research Program in Mitochondrial Therapeutics, Department of Pharmacology, Weill Cornell Medical College, New York, NY.*

Mitochondria play a central role in energy generation in the cell, providing ATP to carry out essential biological functions. As energy output declines, the most energetic tissues are preferentially affected, including the skeletal muscles, heart and eyes. Age-related decline in function has been observed in these systems and is associated with a decline in mitochondrial function in both animals and humans. Furthermore, age-related decline in skeletal muscle and cardiac function results in immobility that further promotes loss of skeletal muscle mass (sarcopenia). This talk will summarize the current literature on the effects of age and immobility on mitochondrial function and ATP production in skeletal muscles, heart, and the retina. A novel compound (SS-31) that promotes mitochondrial bioenergetics has been shown to reverse skeletal and cardiac muscle dysfunction, and loss of visual acuity, associated with aging. The mechanism of action of SS-31 and its effects on aging will be presented.

667 Mitochondria function in Rendement Napole pig growth. David E. Gerrard[1], Samer W. El-Kadi[1], and Tracy L. Scheffler*[2], *[1]Virginia Tech, Blacksburg, VA, [2]University of Florida, Gainesville, FL.*

The capacity for lean growth may be related to muscle fiber type characteristics. Previously, much emphasis has been placed on contractile phenotype and myosin heavy chain isoforms, yet metabolic properties (oxidative versus glycolytic) may play a more intimate role. Muscle oxidative capacity, largely determined by mitochondrial content and functional properties, has immense potential to fuel anabolic processes including protein synthesis. Yet, enhanced oxidative capacity is also associated with increased protein degradation and may restrict hypertrophy. Intriguingly, the relationships between metabolic phenotype, energy status, and protein accretion change during the lifetime of the animal. Thus, the influence of oxidative capacity on the potential for muscle growth likely depends on growth stage, along with input from various signaling pathways. These signaling pathways integrate cues related to energetic and nutritional status, hormones and other factors; this interplay coordinates adaptations in fiber metabolism, structure, and size to optimize function. In particular, AMP-activated protein kinase (AMPK) plays a key role in regulating energy producing and energy consuming pathways to maintain cellular energy homeostasis. Activated AMPK affects acute regulation of enzyme activity, as well as long-term adaptation through changes in gene and protein expression. Specifically, activated AMPK limits protein synthesis, while simultaneously promoting mitochondrial biogenesis and oxidative capacity. Pigs with the Rendement Napole (RN) mutation possesses a single nucleotide polymorphism in the $\gamma 3$ subunit of AMPK, which results in increased AMPK activity. Therefore, the RN pig is a valuable model for investigating the effect of AMPK, energy status, and muscle metabolic phenotype on efficiency of lean gain during different stages of growth. Ultimately, understanding the relationship between muscle oxidative capacity and protein accretion and defining how this relationship evolves from birth to adult, is important for maximizing quantity and efficiency of meat production.

Key Words: mitochondria, AMP-activated protein kinase, skeletal muscle

668 Mitochondrial and cellular metabolism in response to selection for residual feed intake in pigs. S. M. Lonergan*, S. M. Cruzen, J. K. Grubbs, E. Huff Lonergan, J. C. M. Dekkers, and N. K. Gabler, *Iowa State University.*

A primary goal of animal agriculture is to improve the efficiency of meat production by optimizing the growth performance of livestock. Divergent genetic selection of swine for improved residual feed intake (RFI) has resulted in a line of pigs selected for low RFI that reaches the same market weight while consuming 10 to 15% less feed than the high RFI line. Our long-term goal is to define the contribution of mitochondria function to this improved growth efficiency. Investigations using RFI selection have demonstrated that muscle mitochondria from pigs in the low RFI line exhibited less electron leakage from the electron transport chain. This is particularly evident in the mitochondria from the red portion of the semitendinosus (complex I and II) and the white portion of the semitendinosus (complex I, II, and III). Reactive oxygen species production from electron leakage in the mitochondria was positively correlated with RFI, demonstrating a link between poorer mitochondria function and poorer growth efficiency. A parallel observation was that muscle from more efficient pigs had a greater capacity to decrease protein degradation and conserve muscle mass. Mitochondria from muscle of the more efficient low RFI pigs had a greater abundance of heat shock protein 70, heat shock protein 60, malate dehydrogenase, ERO1 α, and subunit 1 of the cytochrome *bc*1 complex. Mitochondria from muscle of the less efficient high RFI pigs had a greater abundance of pyruvate kinase and glyceraldehyde 3-phosphate dehydrogenase. It is important to note that post-translational modification of proteins plays a central role in mitochondria function. Heat shock protein 70, heat shock protein 60, and ATP synthase are among the mitochondria proteins modified by phosphorylation. The combined evidence demonstrates that muscle growth and maintenance is directly influenced by mitochondria efficiency and cellular protein homeostasis. (Funded in part by the AFRI competitive grant number 2010–65206–20670 from USDA NIFA and by Iowa Pork Producers grant number 10–009).

Key Words: mitochondria, RFI, swine

669 Browning of adipose tissue. Shihuan Kuang*, Pengpeng Bi, and Tizhong Shan, *Department of Animal Sciences, Purdue University, West Lafayette, IN.*

Adipose (fat) tissues mediate systemic energy homeostasis, and play an important role in animal growth, health and reproduction. In addition, adipose tissues contribute to meat marbling and are thus a key determinant of meat quality. Fat cells within adipose tissues can be classified into white, beige and brown adipocytes mainly based on their mitochondria content. White adipocytes contain few mitochondria and are the predominant cell type in various subcutaneous and visceral fat depots. Brown adipocytes contain numerous mitochondria and are mainly found in interscapular brown adipose tissues of many mammals. Beige adipocytes are a newly defined type of adipocytes containing intermediate abundance of mitochondria and are found to coexist with white adipocytes in subcutaneous fat depots. While white adipocytes are primarily involved in energy storage (storing lipids), brown and beige adipocytes are highly specialized in energy expenditure due to their higher mitochondria content and abundant expression of uncoupling protein 1 (UCP1), which detours mitochondrial proton gradient from regular ATP production to instead generate heat to warm up the body. Recent studies indicate that white and beige adipocytes are interconvertible, and the conversion of white to beige adipocytes is called browning. In this talk, I will present our latest results on the molecular regulation of adipose browning and its implication in animal health, production and meat quality.

Key Words: white adipose tissue, brown adipose tissue, beige adipocyte

670 Mitochondrial adaptations to physiological states in bovine adipose tissue. Susanne Häussler*, *University of Bonn, Institute of Animal Science, Physiology & Hygiene Group, Bonn, Germany.*

Mitochondria are key cellular components in energy metabolism. Their number and function varies depending on environmental, physiological or pathological conditions. The amount of mitochondria within a cell can be determined by measuring the mitochondrial DNA (mtDNA) copy number. In white adipose tissue (AT), mitochondria are important because they deliver energy for the differentiation of adipocytes. In addition, mitochondria provide key substrates in support of lipogenesis during adipogenesis. Therefore, the number of mitochondria is lower in mature adipocytes than in differentiating preadipocytes. Besides its role as an energy depot, AT is established as a major endocrine organ. Taking a focus on dairy cows, the extensive changes that AT undergoes during the course of lactation indicate alterations in mitochondrial content in that tissue. Differing needs for energy during lactation may lead to changes of mtDNA content. Being crucial for the lipogenic capacity of adipocytes, the number of mitochondria within bovine AT is thus important for the storage capacity for energy in dairy cows. In our laboratory, we investigated the number of mtDNA copies within AT by multiplex qPCR. Comparing different AT depots in dairy cows, more mtDNA copies were observed in visceral (vc) as compared with subcutaneous (sc) AT, which is in accordance with the higher metabolic activity of vcAT. Furthermore, increased mtDNA copy numbers were detected in scAT after excessive fat accretion in nonlactating, non-pregnant dairy cows. In that study, the number of mtDNA was positively associated with indicators of oxidative stress, thus pointing to an adaptive response to mtDNA damage caused by oxidative stress which resulted from increasing metabolic load. When compared with other tissues being of major importance in energy metabolism and lactation, such as liver and mammary gland, the mtDNA content in AT of high-yielding dairy cows was distinctively lower. Nevertheless, mitochondria are important for the cellular energy supply in AT of dairy cows and thus for the adequate adaptation by AT to the changes of energy balance and oxidative stress throughout lactation, that is important for animal health and efficiency.

Key Words: mitochondria, adipose tissue, cow

Horse Species Symposium: Recent advances in the microbiome and physiology of the hindgut of the horse and dog

671 Canine intestinal microbiology and metagenomics. Jan S. Suchodolski*, *Gastrointestinal Laboratory, Texas A&M University, College Station, TX.*

Recent molecular studies have revealed a complex microbiota in the dog intestine, consisting of thousand bacterial, fungal, and viral phylotypes. Convincing evidence has been reported linking changes in microbial communities to acute and chronic gastrointestinal inflammation, especially in canine inflammatory bowel disease (IBD). Most common microbial changes observed in intestinal inflammation are decreases in the bacterial phyla *Firmicutes* (i.e., *Lachnospiraceae*, *Ruminococcaceae*, *Fecalibacterium*) and *Bacteroidetes*, with concurrent increases in *Proteobacteria* (i.e., *E. coli*). Due to the important role of microbial-derived metabolites for host health, it is important to elucidate the metabolic consequences of gastrointestinal dysbiosis and a better understanding of the physiological pathways is helpful to potentially pinpoint specific diseases. Novel approaches such as shotgun sequencing of DNA allow characterizing functional changes in the bacterial metagenome in gastrointestinal disease. Furthermore, wide scale and untargeted measurements of metabolic products derived by the host and the microbiota in intestinal samples allow a better understanding of the functional alterations that occur in gastrointestinal disease. For example, changes in bile acid metabolism, short-chain fatty acid concentrations, and tryptophan pathways have recently been reported in humans and dogs. Also, metabolites associated with the pentose phosphate pathway were significantly altered in chronic gastrointestinal inflammation and indicate the presence of oxidative stress in dogs with IBD. Better understanding of the interactions of microbial-derived metabolites and the host will yield insights into the pathophysiology of gastrointestinal diseases. Furthermore, some of these metabolic pathways can be targeted to develop better treatment approaches.

Key Words: microbiome, metabolome

672 The microbiome of the horse hindgut. Véronique Julliand*, *AgroSup Dijon, Dijon, France.*

The collective genomes of the different microbes (bacteria, fungi, protozoa, yeasts, archaea and bacteriophages) that live inside the horse hindgut compose its intestinal microbiome. This microbiome can be characterized by its microbial community structure (diversity and composition) and function (metabolic activities and resulting end products). It plays a vital role due to its capacity of hydrolysing and fermenting cell-walls into volatile fatty acid that represent an essential energy source for the host. Although not fully understood, it also completes important roles in health and several diseases pathophysiology. Traditionally, the microbes of the horse hindgut were studied using culture dependent techniques. More recently culture-independent methods have been used and have brought new insights. Regarding the ciliate protozoa community, 18S rRNA gene pyrosequencing allowed identifying 15 genera in the feces of pasture-fed horses. Most of these genera had been identified in previous microscopy studies. The 2 clades *Methanobrevibacter ruminantium* and *Methanocorpusculum* and their relatives were showed to dominate the fecal Archaea community using 16S rRNA gene pyrosequencing as it had been reported via cultural techniques. Regarding the bacteria community several studies have been done with molecular methods such as fingerprint techniques or more recently 16S rRNA gene pyrosequencing. In the cecum and colon, *Firmicutes* and *Bacteroidetes* are the 2 predominant phyla. *Firmicutes* comprise *Clostridium* spp., *Ruminococcus* spp., *Butyrivibrio* spp., and *Eubacteria* spp. that play a major role in fiber degradation. The cellulolytic species *Fibrobacter succinogenes* was identified recently as the second most abundant species in the horse feces. Although a phylogenetic core bacteria community appeared to exist in all regions of the large intestine of healthy horses, strong inter-horse variations on bacteria populations are often reported. The microbiome can also be affected by several factors. The effect of the diet has been the most extensively studied on the microbial community structure and function. Understanding the microbiome changes and the factors in cause can help manipulating the microbiome to improve nutrition and health.

Key Words: horse, microbiome, hindgut

673 Evaluation of the effectiveness of the establishment of an equine research herd with dual cannulation at the ileum and cecum. Toree L. Bova*, Cate Mochal-King, Brian J. Rude, Ben C. Weed, Lauren B. Hodge, and Molly Nicodemus, *Mississippi State University, Mississippi State University, MS.*

Cecal and ileal cannulations have been utilized to determine equine digestibility and gastrointestinal physiology, but these cannulations were limited to a single segment of the digestive tract. While these earlier cannulations were successful, the recovery process was difficult for the single cannulation; and thus, the objectives of this case study were to document the post-operative recovery of a dual cannulation surgery in equines and to determine the effectiveness of establishing a dual cannulated research herd. Eight Hackney/Shetland pony cross mares (BW: 200 to 250 kg) were selected for development of a cannulated herd. Initial incisions for placement of the ileal and cecal cannulas were done on the same day. A novel ileal cannula was constructed of a biologically compliant silicone, which included a flange to assist with surgical anchoring to improve stoma formation. For the cecal cannula, a rumen cannula (#7C; Bar Diamond, Parma, ID) was placed into the cecal fistula similar to previous studies. Ileal stomas adhered after 14 d and the cecal stoma at 10 to 14 d post-surgery. Full vital analysis occurred every 4 h for 4 wk post-surgery. Due to granulation at the cecal site, the most common complication for all ponies was increased rectal temperature of 38.9 to 40.9°C from 4 to 10 d post-surgery with a mean ranging from 37.8 to 38.5°C and a standard deviation ranging 0.59 to 1.4. Five ponies showed signs of colic approximately 1 to 2 times during recovery. After surgical recovery, 5 ponies remained healthy during 7 mo of observations, demonstrating vital signs within normal ranges and no colic signs. The 3 ponies that died had intestinal leakage into the abdominal cavity due to lack of adherence of ileum to the body wall resulting in peritonitis within 2 wk post-surgery. Compared with other tubing or polyvinyl chloride options, the current novel ileal cannula design was effective as the ileal cannula design formed a stoma and was easily maintained for the remaining 5 ponies. With a survival rate of 63% at 7 mo post-surgery, the dual cannulation of the ileum and cecum was considered successful.

Key Words: equine cannulation, ileum, cecum

674 Can the microbiome of the horse be altered to improve digestion? Josie A. Coverdale*, *Texas A&M University, College Station, TX.*

Common management practices such as high concentrate diets, low forage quality, meal feeding, and confinement housing have an effect on intestinal function, specifically large intestinal fermentation. The microbiome of the equine large intestine is a complex and diverse ecosystem, and disruption of microflora and their environment can lead to increased incidence of gastrointestinal disorder. Digestion in the horse can be improved through a variety of mechanisms such as feedstuff selection, forage quality, feeding management, and inclusion of digestive aids. These digestive aids such as prebiotics and probiotics have been used to improve digestibility of equine diets and stabilize the microbiome of the large intestine. Probiotics, or direct fed microbials, have been widely used in horses for treatment and prevention of gastrointestinal disease. The introduction of these live, beneficial microorganisms orally into the intestinal tract has yielded variable results. However, it is difficult to compare data due to variations in choice of organism, dosage, and basal diet. While there are still many unanswered questions about the mode of action of successful probiotics, evidence suggests competitive inhibition and enhanced immunity. Lactic acid bacteria such as *Lactobacillus*, *Bifidobacterium*, and enterococci and *Saccharomyces* yeast have all been successfully used in the horse. Use of these products has resulted in improved fiber digestibility in horses offered both high starch and high fiber diets. When high concentrate diets were fed, probiotic supplementation helped maintain cecal pH, decreased lactic acid concentrations, and enhanced populations of cellulolytic bacteria. Similarly, use of prebiotic preparations containing fructooligosaccharide (FOS) or mannanoligosaccharides (MOS) have improved DM, CP, and NDF digestibility when added to high fiber diets. Furthermore, use of FOS in horses reduced disruptions in colonic microbial populations after an abrupt change in diet and altered fecal VFA concentrations toward propionate and butyrate. Potential use of prebiotics and probiotics to create greater stability in the equine microbiome affects not only digestibility but also health of the horse.

Key Words: horse, microbiome, prebiotic

Physiology and Endocrinology: Estrous synchronization and metabolism

675 Hormonal manipulation of progesterone before initiation of an Ovsynch protocol to increase ovulatory response to the first GnRH treatment in Holstein cows. P. D. Carvalho*, M. C. Wiltbank, and P. M. Fricke, *Department of Dairy Science, University of Wisconsin-Madison, Madison, WI.*

Our objective was to evaluate the effect of decreasing progesterone (P4) before initiation of an Ovsynch protocol on ovulatory response to the first GnRH injection (G1) and pregnancies per AI (P/AI). Lactating Holstein cows (n = 800) were synchronized using a Double Ovsynch protocol [Pre-Ovsynch protocol (GnRH; 7 d, PGF$_{2\alpha}$; 3 d, GnRH) followed 7 d later by an Ovsynch-56 protocol (G1; 7 d PGF$_{2\alpha}$; 24 h, PGF$_{2\alpha}$; 32 h, GnRH)] to receive first timed artificial insemination (TAI; 80 ± 3 DIM) 16 h after the last GnRH treatment. Cows were randomly assigned to receive a half-dose of PGF$_{2\alpha}$ (12.5 mg dinoprost tromethamine) 2 d before G1 (TRT) or serve as untreated controls (CON). Data were analyzed by logistic regression using GLIMMIX and ANOVA with MIXED procedures of SAS. Overall, CON cows had greater ($P < 0.01$) P4 than TRT cows at G1 (4.2 vs. 2.1 ng/mL). Ovulatory response to G1 was greater ($P < 0.01$) for TRT vs. CON cows [81.9% (90/110) vs. 60.9% (70/115), respectively]. Luteal regression during the second Ovsynch protocol did not differ ($P = 0.33$) between treatments [15.2% (15/99) vs. 10.6% (11/104); TRT vs. CON]. At 32 d after TAI, P/AI did not differ ($P = 0.34$) between treatments [56.2% (223/397) vs. 52.8% (209/396); TRT vs. CON]. At 67 d after AI, P/AI also did not differ ($P = 0.56$) between treatments [50.8% (190/374) vs. 48.6% (179/368); TRT vs. CON]. Pregnancy loss from 32 to 67 d after TAI did not differ [10.0% (21/211) vs. 9.6% (19/198); TRT vs. CON; $P = 0.90$]. Overall, cows that ovulated to G1 had greater ($P = 0.02$) P/AI compared with cows that did not ovulate [58.2% (89/153) vs. 41.5% (27/65), respectively]. The increase in P/AI in ovulating cows (16.7%) and observed increase in ovulation (21%; TRT – CON) produced an expected increase of 3.5% in P/AI in TRT vs. CON; similar to the observed 3.4% difference. Thus, administration of a half-dose of PGF$_{2\alpha}$ 2 d before G1 during a Double Ovsynch protocol decreased P4 at G1 and increased ovulatory response. Larger studies are needed to determine if this modified protocol increases P/AI. Supported by USDA Hatch project 231440.

Key Words: fertility, timed AI, ovulation

676 Progesterone concentration at initiation of Ovsynch and a second prostaglandin F$_{2\alpha}$ treatment affect luteal regression and fertility to timed AI in lactating Holstein cows. P. D. Carvalho*, M. J. Fuenzalida, V. G. Santos, A. Ricci, M. C. Wiltbank, and P. M. Fricke, *Department of Dairy Science, University of Wisconsin-Madison, Madison, WI.*

Our objective was to compare luteal regression and pregnancies per AI (P/AI) after timed AI (TAI) for dairy cows receiving the first GnRH injection (G1) of an Ovsynch protocol in a low (<1.0 ng/mL) or a high (≥1.0 ng/mL) progesterone (P4) environment. Lactating Holstein cows (n = 851) at first or second and greater AI service were randomized to receive an Ovsynch protocol (G1; 7d, PGF$_{2\alpha}$; 56h, GnRH; 16h, TAI) with 1PGF$_{2\alpha}$ (PGF) treatment (1PG; n = 440) or a modified Ovsynch protocol (G1; 7 d, PGF$_{2\alpha}$; 24 h, PGF$_{2\alpha}$; 32 h, GnRH; 16 h, TAI) with 2PGF treatments (2PG; n = 411). Blood was collected at G1, the first PGF treatment, and the last GnRH treatment (G2) of the Ovsynch protocol for analysis of P4. To eliminate cows undergoing early luteal regression, cows (n = 153) with P4 < 1.0 ng/mL at the first PGF treatment were excluded from the analysis. Cows with P4 < 0.4 ng/mL at G2 were defined as undergoing complete luteal regression after PGF, whereas cows with P4 ≥ 0.4 ng/mL at G2 were defined as failing to undergo complete luteal regression after PGF. Data were analyzed by logistic regression using PROC GLIMMIX of SAS. Overall, more ($P < 0.01$) cows with high P4 at G1 underwent luteal regression after PGF compared with cows with low P4 at G1 (92.2% vs. 82.8%, respectively). As expected, luteal regression after PGF was greater ($P < 0.01$) for 2PG (96.3%) compared with 1PG (83.8%) cows. For cows with low P4 at G1, more ($P < 0.01$) 2PG cows underwent luteal regression after PGF (69.6% vs. 96.2%, 1PG vs. 2PG). As a result, 2PG cows with low P4 at G1 had more ($P < 0.01$) P/AI compared with 1PG cows with low P4 at G1 (35.3% vs. 57.3% for 1PG vs. 2PG cows). By contrast, for cows with high P4 at G1, although luteal regression was greater for 2 PG (91% vs. 97%; 1PG vs. 2PG; $P = 0.05$), P/AI did not differ (35.9% vs. 39.7%; 1PG vs. 2PG; $P = 0.39$). We conclude that a second PGF injection 24 h after the first during an Ovsynch protocol increased luteal regression for cows with low or high P4 at G1 and increased P/AI for cows with low P4 at G1. Supported by USDA NIFA Hatch project 231440.

Key Words: Ovsynch, progesterone, fertility

677 Effect of high or low P4 during ovulatory follicle development on fertility of dairy cows. Joao Paulo N. Martins*[1], Dongliang Wang[2], Nanheng Mu[2], Guilherme F. Rossi[3], Vinicius R. Martins[1], Ana Paula Martini[4], Gilson A. Pessoa[4], and J. Richard Pursley[1], *[1]Department of Animal Science, Michigan State University, East Lansing, MI, [2]Shuozhou Vocational and Technical College, Shuozhou City, Shanxi, China, [3]Department of Preventive Veterinary Medicine and Animal Reproduction, FCAV-UNESP, Jaboticabal, SP, Brazil, [4]Department of Large Animal Clinical Science, Universidad Federal de Santa Maria, Santa Maria, RS, Brazil.*

The objective was to determine the effect of high vs. low progesterone (P4) during early and late stages of the ovulatory follicle development in lactating dairy cows. Cows that ovulated a d 7 1st wave dominant follicle were assigned to treatments. Ovaries were manipulated to induce high (H) or low (L) circulating concentrations of P4 during 0 to 4 d (early stage) and/or 5 to 7 d (late stage) of the wave forming 4 treatments: H/H, L/L, L/H and H/L. Luteolysis was induced with PG on d 7 of the treatment period. Ovulation of the dominant follicle was induced with GnRH 56 h following PG. All cows received AI 16 h later (n = 559). Pregnancy was determined 35 and 56 d after AI by ultrasonography and 117 d (±3) and 194 d (±3) by detection of pregnancy-specific protein B (PSPB) in milk. Data were analyzed with chi-squared analysis.Pregnancy/AI 35 d post AI was 43.2, 51.1, 53.6, and 60.4 for HH, HL, LH, and LL, respectively, and was greater for LL than HH cows. However, there was no difference on P/AI 56 d (HH = 42.4%, HL = 46%, LH = 51%, and LL = 51.1%), 117 d (HH = 38.3%, HL = 45.6%, LH = 48.3%, and LL = 48.9%), and 194 d post AI (HH = 36.8%, HL = 43.9%, LH = 44.4%, and LL = 46.3%). Pregnancy losses between 35 and 56 d post AI was 1.8, 10, 4.9 and 14.5% for HH, HL, LH, and LL, respectively, and was greater for LL than HH. There was no difference in pregnancy losses between 56 and 117 d post AI (HH = 5.8%, HL = 0%, LH = 2.8%, and LL = 2.9%) and between 117 and 194 d post AI (HH = 0%, HL = 0%, LH = 5.9%, and LL = 3.1%). Percentage of cows with double ovulations to the last GnRH was greater in LL (49%) compared with HH, HL and LH (12, 33, and 34% respectively). Cows that had double ovulation after the last GnRH had greater P/AI 35 d (45 vs. 66%) and 56 d post AI (43 vs. 57%) compared with cows with single ovulation. Pregnant losses between 35 and 56 d after AI was greater in cows with double ovulation compared with cows with single ovulation (4 vs. 14%) and tended to be greater if the ovulations were on the same ovary. In summary, low P4 during development of the ovulatory follicle increased the percentage of cows with double ovulations and P/AI 35 d post AI, but decreased embryonic survival between 35 and 56 d post AI.

Key Words: follicle, fertility, progesterone

678 Effect of a second dose of prostaglandin F_{2a} during Double-Ovsynch on successful luteolysis and fertility.

Giovanni M. Baez*[1], Rafael V. Barletta[1], Alessandro Ricci[1], Eduardo Trevisol[1], Jerry N. Guenther[1], Alvaro Garcia-Guerra[1], Beatriz O. Cardoso[1], Mateus Z. Toledo[1], João P. Ferreira[2], and Milo C. Wiltbank[1], [1]*University of Wisconsin-Madison, Madison, WI,* [2]*São Paulo State University, Botucatu, SP, Brazil.*

Lack of complete regression of the corpus luteum (CL) after prostaglandin F_{2a} (PGF) treatment may reduce fertility during timed AI (TAI) protocols. A total of 373 lactating Holstein cows (172 primiparous; 201 multiparous) were synchronized with Double-Ovsynch starting at 53 ± 3 DIM (GnRH-7d-PGF-3d-GnRH-7d-GnRH-7d-PGF-56h-GnRH-16h-TAI). At the final PGF, cows were randomized to 1 of 2 treatments: 1PGF = No additional PGF treatment; 2PGF = Second PGF treatment 24h after first PGF. Blood samples were collected at the final PGF and GnRH treatments (72 and 16 h before timed AI). Only cows with P4 above 2.0 ng/ml before PGF (n = 344) were further analyzed. Fisher's exact test and *t*-test were used to analyze categorical and continuous variables respectively, and logistic regression analysis was used to calculate probabilities of CL regression and P/AI. Primiparous cows had greater P4 than multiparous cows (7.7 ± 0.22 vs. 6.5 ± 0.18; $P = 0.0001$) before treatment. At 56 h after PGF, P4 was greater ($P = 0.005$) for 1PGF (0.4 ± 0.04) than 2PGF (0.2 ± 0.05) cows. The percentage of cows with complete CL regression (<0.5 ng/mL at 56 h after PGF) was increased by second PGF for primparous (81.2% vs. 97.5%; 1PGF vs. 2 PGF; $P = 0.001$) or multiparous (84.4% vs, 96.7%; $P = 0.006$) cows. Cows with lower P4 at time of PGF had a reduced probability of complete CL regression with 1PGF by logistic regression ($P = 0.02$) or by comparing ($P = 0.0016$) quartile 1 (lowest P4; 2.0 to 4.8 ng/mL; 66.7%; 28/42) to the other 3 quartiles (88.1%; 118/134) which did not differ. In contrast, 2PGF cows had elevated CL regression (>95%) regardless of P4 at time of PGF ($P = 0.60$). Nonetheless, 2PGF increased CL regression for cows in both quartile 1 (66.7% vs. 95.1%; $P = 0.0016$) or quartiles 2–4 (88.1% vs. 97.6%; $P = 0.0034$). Interestingly, there was increasing P/AI with increasing P4 before PGF treatment for 2PGF ($P = 0.02$), but not 1PGF cows ($P = 0.13$). Cows with lower P4 at the time of PGF (Quartile 1) had similar P/AI for 1PGF (31.0%; 13/42) or 2PGF (31.7%; 13/41). In contrast, for quartiles 2–4 there was a tendency for decreased P/AI ($P = 0.10$) in 1PGF (44.0%; 59/134) vs. 2PGF (52.8%; 67/127) cows. Thus, treatment with a second PGF during Double-Ovsynch reduced inadequate CL regression and tended to increase P/AI, particularly in cows with greater P4 at the time of PGF treatment.

Key Words: prostaglandin F_{2a}, fertility, luteolysis

679 Differentially expressed genes in endometrium and corpus luteum of Holstein cows selected for high and low fertility are enriched for sequence variants associated with fertility.

Stephen G. Moore*[1,2], Jennie E. Pryce[3], Ben J. Hayes[3], Amanda J. Chamberlain[3], Kathryn E. Kemper[3], Donagh P. Berry[1], Matthew McCabe[4], Paul Cormican[4], Patrick Lonergan[2], Trudee Fair[2], and Stephen T. Butler[1], [1]*Teagasc, Animal and Grassland Research and Innovation Centre, Moorepark, Fermoy, Co. Cork, Ireland,* [2]*University College Dublin, School of Agriculture and Food Science, Dublin, Ireland,* [3]*Department of Economic Development, Jobs, Transport and Resources & Dairy Futures Cooperative Research Centre (CRC), Agribio, La Trobe University, Bundoora, Australia,* [4]*Teagasc, Animal and Grassland Research and Innovation Centre, Grange, Dunsany, Co. Meath, Ireland.*

In this study, we combined RNA-sequence data, genome-wide association studies (GWAS) and imputed sequence data (Daetwyler et al., 2014; Nat. Genet. 46: 858–865) to identify variants associated with dairy cow fertility. We tested the hypothesis that genes differentially expressed in the endometrium and corpus luteum (CL) on d 13 of the estrous cycle between cows with either good (Fert+) or poor (Fert-) genetic merit for fertility, would identify quantitative trait loci (QTL) regions and sequence variants associated with fertility in cattle. After an adjustment for multiple testing (Benjamini and Hochberg, $P \leq 0.05$), 9 and 560 genes were differentially expressed in the endometrium and CL, respectively, between Fert+ and Fert– cows. These differentially expressed genes (DEG) identified 93 QTL regions ($P < 10^{-3}$) that were validated by fertility GWAS using high-density genotypes from independent dairy cattle populations in both Australia (16,794 bull and cow genotypes) and Ireland (2,660 bull genotypes), with 54% of the signals detected primarily on BTA18 (23%), 5 (9%), 7 (8%), 8 (8%) and 29 (6%). The QTL regions were primarily associated with genes involved in prostaglandin $F_{2\alpha}$ (synthesis, secretion and action) and immune-related processes in the endometrium and CL. In addition, genes involved in steroidogenesis and mRNA processing were also identified in the CL. Seventeen sequence variants significantly associated with fertility ($P \leq 10^{-5}$) in the Australian population were identified within 2 kb upstream and downstream of DEG involved in mRNA processing or the immune system. One missense variant (SIFT value = 0.01; i.e., deleterious to protein function) significantly associated with fertility was identified in *EIF4EBP3*, a gene involved in translation initiation. The results of this study enhance our understanding of (1) the contribution of the endometrium and CL transcriptome to phenotypic reproductive performance; and (2) the genomic architecture influencing a complex trait such as dairy cow reproductive performance.

Key Words: fertility, corpus luteum, endometrium

680 Liver metabolism in dairy cows during repeated short-term feed-restrictions and LPS induced systemic inflammation.

Josef J. Gross*[1], Emmanouil Kalaitzakis[2], Olga Wellnitz[1], Heiner Bollwein[2], and Rupert M. Bruckmaier[1], [1]*Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland,* [2]*Clinic of Reproductive Medicine, Vetsuisse Faculty University of Zurich, Zurich, Switzerland.*

Body fat mobilization during a negative energy balance (NEB) requires metabolic adaptations on the part of the liver. We investigated if responses of hepatic mRNA abundancies of genes involved in metabolism and immune system to an energy deficiency differ between lactational stages. Holstein dairy cows (n = 14) (control (CON) and restricted (RES) group) were fed with grass and additional concentrate from wk 3 ap until wk 12 pp, except the RES group receiving only grass during 1-wk feed-restrictions in wk 2, 5, 8, and 11 pp. At the end of the first restriction period, LPS from *E. coli* was infused intravenously (0.5 µg/kg BW) to induce an inflammatory status. Energy balance (EB) was calculated on a weekly basis. Blood was obtained weekly and liver tissue was collected for biopsy before and after restriction periods and at 8h after the systemic LPS challenge. Blood samples were analyzed for glucose, NEFA, and BHBA concentrations. Hepatic gene expression of 3-hydroxybutyrate dehydrogenase (BDH) 2, carnitine palmitoyltransferase (CPT) 1A and 2, mitochondrial glycerol-3-phosphate-acyltransferase (GPAM), 3-hydroxy-3-methylglutaryl-coenzyme A synthase (HMGCS) 2, cytosolic phosphoenolpyruvate carboxykinase (PEPCKc), growth hormone receptor (GHR) 1A, insulin-like growth factor (IGF) 1, Hp (haptoglobin), serum amyloid A (SAA), and tumor necrosis factor (TNF) α were measured. Data were analyzed using a mixed model including group and wk as fixed effects. During restriction periods, RES had a more distinct negative EB (wk 2: Δ17 MJ NEL/d; wk 5: Δ19 MJ; wk 8: 6 MJ; wk 11 Δ13 MJ) and in wk 5 higher NEFA (0.64 mmol/L) and BHBA (0.65 mmol/L) concentrations compared with CON (0.39 and 0.37 mmol/L, resp.; $P < 0.05$). Hepatic mRNA abundances showed expression patterns depending on the lactational stage. During feed-restriction periods, expression of IGF-1 was upregulated in RES compared with CON (based on ratios between RES and CON: +11.1 in wk 2, +14.7 in wk 5, +2.9 in wk 8, +7.3 in wk 11; $P < 0.05$). At 8h after the initiation of the systemic LPS challenge, SAA, TNFα and Hp were downregulated in RES and CON, while GPAM, HMGCS2, GHR1A, CPT1A and 2, PEPCKc, and BDH2 were upregulated ($P < 0.05$). In conclusion the experiment showed that hepatic metabolism was clearly affected by feed-restrictions and systemic LPS-challenge.

Key Words: feed restriction, metabolism, dairy cow

681 Prediction of portal and hepatic blood flow in cattle.

Jennifer L. Ellis*[1,2], Christopher K. Reynolds[3], Les A. Crompton[3], Mark Hanigan[4], Andre Bannink[5], James France[2], and Jan Dijkstra[1], *[1]Animal Nutrition Group, Wageningen University, Wageningen, the Netherlands, [2]Centre for Nutrition Modelling, Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [3]School of Agriculture, Policy and Development, University of Reading, Reading, UK, [4]College of Agriculture and Life Science, Virginia Tech University, Blacksberg, VA, [5]Animal Nutrition, Wageningen UR Livestock Research, Wageningen, the Netherlands.*

An integral part of linking a multi-organ post-absorptive model is the prediction of nutrient fluxes between organs via blood flow. This paper reports a multivariate meta-analysis approach to model portal vein blood flow (PORBF) and hepatic venous blood flow (HEPBF) simultaneously. The developmental database consisted of 296 measurements (pAH dilution) for growing and lactating cattle with 55 treatments from 17 studies, and a separate evaluation database with 31 treatment means from 8 studies. Both databases had information on feed intake, bodyweight and diet composition. Blood flows predicted with DMI or metabolizable energy intake (MEI) was tested with both linear and quadratic equations using the NLINMIX macro of SAS. Cow(study) and study were treated as random effects and blood flow location (PORBF or HEPBF) as a repeated effect. Equations based on DMI rather than MEI typically resulted in higher concordance correlation coefficient (CCC) values, indicating better predictions. Quadratic equations did not out-perform their linear counterparts (CCC analysis), and quadratic equation terms were frequently non-significant. The best predictive equations were: PORBF (L/d) = 4855(±1097) + 2007(±74.8) × DMI (kg/d) and HEPBF (L/d) = 4463(±1094) + 2492(±74.5) × DMI (kg/d), with CCC values of 0.887 and 0.922, respectively. The residuals (predicted – observed) for PORBF expressed as a fraction of HEPBF (PORBF/HEPBF), and hepatic arterial blood flow (ARTBF (L/d); = HEPBF – PORBF) were affected by the proportion of forage in the diet, and thus equations for PORBF and HEPBF based on forage and concentrate DMI were developed: PORBF (L/d) = 5043(±1186) + 1989(±148.8) × Forage (kg DM/d) + 1989(±141.4) × Concentrate (kg DM/d), and HEPBF (L/d) = 4416(±1177) + 2223(±145.5) × Forage (kg DM/d) + 2741(±137.5) × Concentrate (kg DM/d), where CCC values were 0.886 and 0.912, respectively. The CCC for ARTBF improved from 0.877 to 0.904 and PORBF/HEPBF from 0.115 to 0.447 with forage and concentrate DMI separation. Developed equations predicted blood flow well, and also suggest different sensitivity of PORBF and HEPBF to the downstream effects of DMI composition.

Key Words: blood flow, liver, meta-analysis

682 Effects of reducing dietary cation-anion difference level on plasma Ca concentration and VDR expression level in gastrointestinal tract of transition mice.

Wen-xuan Wu*, Hai-liang Xin, Yi Yang, and Ruo-yu Liu, *College of Animal Science, Guizhou Province, Guiyang, Guizhou Province, China.*

The mechanism of reducing dietary cation-anion difference (DCAD; $\text{Na}^{+}\text{K}–\text{Cl}^{-}\text{S}$, mmol/kg DM) to prevent hypocalcemia is not completely known. Therefore, this study was conducted to clarify the mechanism why reducing DCAD was effective for increase in plasma Ca concentration and thus for hypocalcemia prevention by detecting plasma Ca concentration and vitamin D receptor (VDR) expression level in gastrointestinal tracts (GIT) of transition mice. One hundred twenty transition mice were randomly allocated to 3 blocks with each of 40 individuals and were fed 3 diets with varying DCAD level at +300 (treatment 1, HD), +150 (control, CON), and −150 (treatment 2, LD), respectively. Ten mice for each treatment were killed to collect blood sample for plasma Ca concentration analysis and harvest GIT tissues (stomach, duodenum, jejunum, ileum, cecum, and colon) samples for VDR expression level detection at 4 time points: day of 20 (−20) and 5 (−5) before kidding, day of kidding (0), and day of 3 after kidding (+3). Data on plasma Ca was analyzed using SAS 9.3 with Proc MIXED and VDR mRNA with Proc NPar1 Way. Plasma Ca concentration (mg/dL) in LD mice (6.37) was higher than that in HD (4.43) and CON (4.98) mice for the whole and individual blood sampling time ($P < 0.05$). On d −20 diet LD resulted in higher VDR mRNA expression level in jejunum, ileum, and colon over diet HD ($P < 0.05$). On d −5 mice fed LD diet had more VDR mRNA expression level in jejunum and colon relative to HD and CON ($P < 0.05$). On d 0 feeding of treatment 2 had the highest VDR mRNA expression level in duodenum and colon, which was statistically higher than HD and CON ($P < 0.05$). On d 3 duodenum, jejunum, and colon were observed to show increased VDR mRNA expression level for LD compared with HD and CON ($P < 0.05$). These results indicated that reducing the DCAD upregulates VDR mRNA expression in GIT of transition mice and increases plasma Ca concentration, which explains some of the benefits of low DCAD on prevention of hypocalcemia.

Key Words: dietary cation-anion difference, plasma Ca, gastrointestinal VDR expression

Production, Management, and the Environment III

683 Analyzing the rear shape of dairy cows in 3D to better assess body condition score. Amélie Fischer*[1,2], Thibault Luginbühl[3], Laurent Delattre[3], Jean-Michel Delouard[3], and Philippe Faverdin[1], *[1]INRA/Agrocampus-Ouest UMR 1348 Pegase, St-Gilles, France, [2]Institut de l'élevage, Le Rheu, France, [3]D'Ouest, Lannion, France.*

Body condition is an important trait in dairy cow management, mainly because it reflects the level and the use of body reserves and indirectly reproductive and health performance. Body condition score (BCS), which is done visually or by palpation, is the usual method on farm but is subjective and not very sensitive. The aim was here to develop and to validate 3DBCS which estimates BCS from 3D-shapes of dairy cows rear, the body area commonly used to assess BCS. For the calibration, a set of 57 3D-shapes from 56 Holstein cows with large BCS variability (0.5 to 4.75 on a 0–5 scale) were transformed with a principal component analysis (PCA). A multiple linear regression was fitted on the principal components to assess BCS. Four anatomical landmarks were extracted to normalize the 3D-shapes: the validation results of a manual labeling proved the concept. Then an automated labeling method was developed to extract them. Prior to the PCA, the 3D-shapes were either regularized to fill in the holes or not regularized. External validation was evaluated on 2 sets: one with cows used for calibration, but with a different lactation stage (valididem) and one with cows not used for calibration (validdiff). Repeatability was estimated with 6 cows scanned 8 times each the same day. The automated method performed slightly better than manual method for external validation (RMSE = 0.27 versus 0.34 for validdiff) and both were more repeatable than usual BCS ($\sigma = 0.20$ for 3DBCS and 0.28 for BCS). Surprisingly, regularizing the 3D-shapes performed slightly less than without regularization. Nevertheless regularization should be an interesting process before BCS assessing, especially to avoid discarding too many 3D-shapes. The first results of 3D-BCS monitoring in dairy cows with a fully automated method show promising results in terms of phenotyping. The next step will try to reduce scanning time to decrease the number of bad 3D-shapes due to cow's movement without losing too much resolution.

Key Words: body condition score, 3D imaging, principal component analysis

684 Modelling performance consequences on the probability of reproducing, and thereby on productive lifespan in dairy cows. Ho N. Phuong[1,3], Pierre Blavy[1,3], Olivier Martin[1,3], Luc Delaby[2,4], Philippe Schmidely[1,3], and Nic C. Friggens*[1,3], *[1]INRA UMR MoSAR, Paris, France, [2]INRA UMR PEGASE, Rennes, France, [3]AgroParisTech, Paris, France, [4]AgroCampusOuest, Rennes, France.*

Reproductive success is a key component of lifetime efficiency (ratio of total energy in milk to total energy intake over the lifespan) as failure to get in calf results in culling and thus has a negative effect on productive lifespan. At the animal level, breeding and feeding management can substantially affect milk yield, body condition, and energy balance of cows, which are all major contributors to reproductive failure in dairy cattle. This study developed a reproductive module that was incorporated into an existing lifetime performance model to enable prediction of the performance consequences of different breeding and feeding strategies on probability of reproducing, and thereby on productive lifespan. This then allows more realistic prediction of cow lifetime efficiency. The model is dynamic and stochastic with an individual cow being the unit of modeling and one day being the unit of time. To evaluate the reproductive module, data from a French study including Holstein and Normande cows fed with high concentrate diet and data from a Scottish study including Holstein cows selected for high and average genetic merit for fat plus protein, fed with high versus low concentrate diets were used. On average, the model consistently simulated reproductive performance of various genotypes of cow across feeding systems. Relative to the French data, the model significantly under-predicted first service conception rate for Normande cows (48% vs. 58% for predicted vs. observed). On the Scottish data, simulated conception to first service was not significantly different from observed but interval traits (days to first service, days open) were under predicted, which was mainly due to the discrepancy between simulated and observed voluntary waiting periods. Simulation showed that genetic selection for greater milk production impaired reproductive performance and thus reproductive lifespan, but not lifetime efficiency. However, the definition of lifetime efficiency used did not include associated costs or consider herd-level effects, which should be included to allow more accurate simulation of lifetime profitability in different scenarios.

Key Words: dairy cow, lifetime efficiency, productive lifespan

685 Modeling the effect of forage allowance, forage mass, and body condition on calf weaning weight and calving conception interval of primiparous cows grazing Campos grasslands. Martín Claramunt*[1], Mariana Carriquiry[2], and Pablo Soca[3], *[1]Facultad de Veterinaria, Universidad de la República, Paysandú, Paysandú, Uruguay, [2]Facultad de Agronomía, Universidad de la República, Montevideo, Montevideo, Uruguay, [3]Facultad de Agronomía, Universidad de la República, Paysandú, Paysandú, Uruguay.*

The relationships among forage allowance (FA), forage mass (FM), and BCS during early (E) and middle gestation (M), calving (C) and lactation (L), and calf weight at weaning and calving conception interval (CCI) were studied employing records from an experiment that evaluated the effect 2 levels of FA on productivity of primiparous beef cows grazing Campos grassland. The study took place in Facultad de Agronomía, Uruguay (31°S 57°W). Eighty primiparous cows were assigned to a completely randomized experiment of 2 FA in spatial replication on 2 blocks during 2 years. The experiment started in autumn −150 d postpartum (dpp; early gestation [e]) and finished 190 dpp. Annual FA averaged 2.5 and 4 kg DM/kg liveweight (LW) for low (L) and high (H) FA, respectively. Cow LW and FM were measured monthly to adjust FA using the "put and take" method. The BCS was recorded (1–8 points scale). Calf birth weight (CBW) and weaning weight were recorded and calf weight adjusted at 205 d (CW) of age was estimated. Date of subsequent calving was recorded and CCI was calculated subtracting 285 d of gestation. Models were obtained by multiple regressions selected by Stepwise procedure (JMP 6.0). The BCSe, FAm, FMl, BCSe×FMl and CBW explain CW ($CW = - 8.6 + (13 \times BCSe) + (4.9 \times FAm) + (0.036 \times FMl) + (1.8 \times CBW) - [0.024 \times (BCSe - 5.6) \times (FMl - 1400)]$ ($r^2 = 0.54$; $P < 0.01$; Mean = 187; RMSE = 15). An increase in one unit of BCSe, FAe, and FMl increase CW in 13, 4.9 and 0.036 kg respectively. The interaction BCSe*FMl showed an increase in CW when BCSe increases, in FMl levels below 2000 kg DM/ha without effect on greater values. The CCI was affect by BCSc, Julian calving day (CD) and their interaction ($CCI = 191 - (8.6 \times BCSc) - (0.6 \times CD) + \{0.4 \times [(BCSc - 4.5) * (CD - 56)]\}$) ($r^2 = 0.39$; $P < 0.01$; Mean = 121; RMSE = 14). The BCSc mainly explains the CCI confirming his value to predict the reproductive response. Those models contribute to the study of CW and CCI, and could be employed to predict the productive and reproductive response of primiparous beef cows grazing Campos grassland.

Key Words: rangeland, grazing management, cow production

686 Associations between milk quality, type of bedding, and milking management on large Wisconsin dairy farms.

Robert F. Rowbotham*[1,2] and Pamela L. Ruegg[1], [1]*University of Wisconsin-Madison, Madison, WI,* [2]*Grande Cheese Company, Brownsville, WI.*

The objective of this study was to determine bedding and milking management practices associated with bulk tank (BT) quality (SCC and TBC), on large Wisconsin dairy farms. Ninety percent (325 of 360) of Wisconsin dairy farms producing in excess of 11,340 kg of milk daily participated in a personally administered survey consisting of 60 scripted questions. Milk quality test results were obtained from milk marketers for a 2-year period for 255 farms. Results were analyzed for 230 farms using the same bedding type (IB = Inorganic, MB = Manure solids, OB = Other organic) in all pens during the entire study period. Farms milked between 270 and 8,100 cows (mean = 908), selling an average of 33,714 kg daily. Farms which herd tested (n = 204) had an average RHA of 12,831 kg (IB), 11,746 kg (MB), or 11,973 kg (OB). The relationships between bulk tank somatic cell score (BTSCS), bedding type, and management practices were analyzed in a repeated measures model using PROC MIXED (SAS 9.4). Bulk tank SCS was least in the winter and spring, intermediate in the fall, and greatest in the summer with seasonal differences decreasing with increasing farm size ($P < 0.001$). Farms using Iodine based postdip had greater BTSCS than those using other postdips ($P = 0.011$) and BTSCS was lower on farms drying teats and wiping off predip than on those not drying teats ($P < 0.001$). Farms with a WMP using MB had a greater BTSCS than those using IB or OB. The SCS for farms without a WMP was less for herds using IB as compared with herds using OB ($P < 0.05$). Bulk TBC did not vary seasonally (Tukey adjusted $P > 0.2$) or among bedding types (Tukey adjusted $P > 0.75$).

Table 1 (Abstr. 686). Bulk tank SCS and SCC among farms with differing bedding types and presence of written milking protocols (WMP)

WMP	Bedding	n	SCS	SE SCS	SCC ($\times 10^3$)
Yes	Inorganic	122	4.06^{b}	0.08	210^{b}
Yes	Manure	17	4.55^{c}	0.14	293^{c}
Yes	Other organic	31	4.09^{b}	0.11	213^{b}
No	Inorganic	34	3.76^{a}	0.10	169^{a}
No	Manure	8	3.87^{ab}	0.16	183^{ab}
No	Other organic	18	4.30^{bc}	0.13	245^{bc}

^{abc}Results with different superscripts within column differ (Tukey adjusted $P < 0.05$).

687 Using routinely recorded herd data to predict and benchmark herd and cow health status.

Kristen L. Parker Gaddis*[1], John B. Cole[2], John S. Clay[3], and Christian Maltecca[4], [1]*Department of Animal Sciences, University of Florida, Gainesville, FL,* [2]*Animal Genomics and Improvement Laboratory, ARS, USDA, Beltsville, MD,* [3]*Dairy Records Management Systems, Raleigh, NC,* [4]*Department of Animal Science, North Carolina State University, Raleigh, NC.*

Genetic improvement of dairy cattle health using producer-recorded data is feasible. Estimates of heritability are low, indicating that genetic progress will be slow. Improvement of health traits may also be possible with the incorporation of environmental and managerial aspects into herd health programs. The objective of this study was to use the more than 1,100 herd characteristics that are regularly recorded on farm test days to benchmark herd and cow health status. Herd characteristics were combined with producer-recorded health event data. Parametric and nonparametric models were used to predict and benchmark health status. Models implemented included stepwise logistic regression, support vector machines, and random forests. At both the herd- and individual-level, random forest models attained the highest accuracy for predicting health status in all health event categories when evaluated by 10-fold cross validation. Accuracy of prediction (SD) ranged from 0.59 (0.04) to 0.61 (0.04) in logistic regression models, 0.55 (0.02) to 0.61 (0.04) in support vector machine models, and 0.61 (0.04) to 0.63 (0.04) with random forest models at the herd level. Accuracy of prediction (SD) at the cow level ranged from 0.69 (0.002) to 0.77 (0.01) for support vector machine models and 0.87 (0.06) to 0.93 (0.001) with random forest models. Results of these analyses indicate that machine-learning algorithms, specifically random forest, can be used to accurately identify herds and cows likely to experience a health event of interest. It was concluded that accurate prediction and benchmarking of health status using routinely collected herd data is feasible. Nonparametric models were better able to handle the large, complex data compared with traditional models. Further development and incorporation of predictive models into herd management programs will help to continue improvement of dairy herd health.

Key Words: health, machine learning, prediction

688 Using parlor data to map liner performance.

John F. Penry*[1], Stefania Leonardi[2], John Upton[3,1], Paul D. Thompson[1], and Douglas J. Reinemann[1], [1]*University of Wisconsin-Madison, Madison, WI,* [2]*Universita delgi Studi di Milano, Milan, Lombardia, Italy,* [3]*Animal & Grassland Research & Innovation Centre, Teagasc, Moorepark, Co. Cork, Ireland.*

Liner performance can be described in terms of milking gentleness, speed and completeness of milk-out, with gentleness being the most important. It is widely accepted that peak milking speed will be increased as vacuum and the milking phase of pulsation are increased, but it is also known that raising the vacuum and b-phase duration increases teat end congestion. Increasing liner compression (LC) also results in higher milk flow rates while also elevating the risk of teat end hyperkeratosis. The aim of this experiment was to characterize the average milk flow rate of 8 liners, representing differing LC estimates, across a range of pulsation and vacuum settings. The 36-d trial involved an 80-cow herd milking 2× at the UW-Madison Dairy Cattle Centre. The parlor was fitted with 8 commercial liners (round, triangular, vented and non-vented models), which were rotated through all stalls during the trial. Treatments were a combination of selected system vacuum and pulsation settings with a fixed 295ms d-phase. Nine treatments were used representing commercially applied settings for vacuum and pulsation applied over 3 equal periods in a central composite experimental design. Treatment settings for system vacuum level ranged from 36 to 49 kPa and pulsator ratios from 50:50 to 70:30. During the course of each 9 treatment cycle, the central point (42.3 kPa and 60:40 pulsator ratio) was applied every third day allowing for an estimate of within treatment variability. Parlor average milk flow (AMF) data were analyzed using a MIXED model in SAS 9.3. This model assessed the effect of liner, treatment, milking stall, milking time and milker. The SAS RSREG procedure was used to produce individual liner response surfaces. Liners with lower LC did not produce as high an AMF under high vacuum and long b-phase compared with a high LC liner due to the effects of teat end congestion during each individual pulsation cycle. Knowledge of individual liner compression estimates and, where available a response surface, is highly useful for determining the optimum vacuum and pulsation settings without compromising gentleness of milking.

Key Words: liner, performance, compression

689 A survey of management practices adopted by goat breeders in Azad Jammu and Kashmir (AJK), Pakistan. Ghulam Bilal*[1], Muhammad Moaeen-ud-Din[1], Muhammad Waseem[1], Naveed Ullah[1], James Reecy[2], Muhammad Khan[3], and Muhammad Yaqoob[1], [1]*Laboratories of Animal Breeding and Genetics, Faculty of Veterinary and Animal Sciences, PMAS-Arid Agriculture University, Rawalpindi, Pakistan,* [2]*2Department of Animal Science, Iowa State University, Ames, IA,* [3]*Institute of Animal Sciences, Faculty of Animal Husbandry, University of Agriculture, Faisalabad, Pakistan.*

A survey was carried out to gather information on current goat farming practices in 4 districts of Azad Jammu and Kashmir (Muzafrabad, Nelum Valley, Kotly, Mirpur). Survey included farmers (n = 50) of 5 goat breeds of AJK (Jattal, Buchi, Bairli, and Lambri and Kooti). Vaccination was never practiced by 42% farmers against prevailing diseases whereas 30% did vaccination occasionally and 28% on regular basis. Diseases for which vaccination was practiced were CCP (100%), enterotoxaemia (95.55%), FMD (31.03%) and HS and goat pox (3.45%). None of the farmer vaccinated against rabies and anthrax. As far as parasitic control is concerned, 30% of farmers did not deworm their flock while 44% of farmers dewormed their herds occasionally and 26% farmers did so on a regular basis. About 42% farmers were using traditional ways of treatment while other farmers got treatment for their goats from veterinary doctors on regular basis. Prevailing goat production system in the region was agro forestry (88%) followed by rangeland base system and crop livestock. Forty-eight percent of farmers had sheds for their herds, whereas 22% of farmers had only night confinement system and 40% confined their animals during winter season. Mostly farmer were relying on natural pasture (60%). Only 20% farmers used mineral mixture for their goats. Mating season of goats was April to June (84%). All respondents adopted ram selection and mating was not planned in most cases (98%). Animals were mainly marketed either to middlemen or local market (68%). The results from the present study could be used to formulate policies related to feeding, breeding and health management for overall improvement of goat production in the region.

Key Words: goat, Pakistan, management practices

Production, Management, and the Environment IV

690 Comparison of four beef production systems on carcass characteristics. Jefferson McCutcheon*, Steven Moeller, Henry Zerby, and Francis Fluharty, *The Ohio State University, Columbus, OH.*

The objective for the study was to compare novel beef production systems to determine the effects of 3 grass finishing regimens on carcass characteristics. This experiment was conducted at 3 research stations in Ohio over 5 yrs. The systems were: STOCK = calves born in March, weaned at 7 mo. of age, grazed in the fall, fed hay in the winter, and then grazed to 16 mo of age and slaughtered; DELAY = calves born in March, not weaned and slaughtered at 10 mo of age; FALL = calves born in September, fed hay when grazing was not possible and not weaned until slaughter in July; and FEED (control) = spring-born counterpart calves from each of the 3 research station locations weaned in October, transported to a feedlot, fed a 90% grain-10% forage diet until reaching 1.0 cm of backfat. All grass systems were conducted in all 3 locations in a randomized block experimental design (blocked by location). Each location had 12 calves and respective cows for each system. Statistics were run using SAS Proc Mixed with PDIFF for mean separation. Slaughter weight was greatest for FEED (505.0 kg, SEM 6.6 kg), followed by STOCK (421.2 kg), FALL (334.2 kg) and DELAY (312.8 kg; $P < 0.05$). Hot carcass weight was greatest for FEED (299.9 kg, SEM 4.8 kg), followed by STOCK (218.4 kg), FALL (183.3 kg) and DELAY (163.7 kg; $P < 0.05$). Ribeye area was greatest for FEED (71, SEM 1.7 cm^2), followed by STOCK (57.5 cm^2), and FALL (52.3 cm^2; $P < 0.05$) with no difference between DELAY (51.5 cm^2) and FALL ribeye area ($P > 0.05$). Backfat was greatest for FEED (1.52 cm, SEM 0.05 cm; $P < 0.05$) while STOCK (0.58 cm) was not different from FALL (0.51 cm; $P > 0.05$) and greater than DELAY (0.40 cm; $P < 0.05$). Marbling scores were greatest for FEED (604 Modest, SEM 18; $P < 0.05$) with DELAY (495 Slight) being greater than STOCKER (427 Slight) and FALL (419 Slight; $P < 0.05$). Spring born calves weaned in the fall and placed on feed resulted in heavier carcasses, with greater muscling and back fat than grazing systems. Spring born calves, not weaned and slaughtered at 10 mo. produced a higher quality grade carcass than the other grazing programs. Leaner carcasses were produced from the grazing programs.

Key Words: beef, system, carcass

691 BeefTracker mobile app for tracking and analysis of beef herd pasture use and location. James W. Oltjen*, Larry C. Forero, and Jeffrey W. Stackhouse, *University of California, Davis, CA.*

We have developed a web-based mapping platform named "BeefTracker" to provide beef cattle ranchers a tool to demonstrate that cattle production fits within sustainable ecosystems and to provide regional data to update beef sustainability lifecycle analysis. After initial identification and mapping of pastures, herd data (class and number of animals) are input on a mobile device in the field with a graphical pasture interface, stored in the cloud, and linked via the web to a personal computer for inventory tracking and analysis. Pasture use calculated on an animal basis provides quantifiable data regarding carrying capacity and subsequent beef production to provide more accurate data inputs for beef sustainability lifecycle analysis. After initial testing by university range scientists and ranchers, we have enhanced the BeefTracker application to improve automation for increased ease of use. The following have been added: ability to access and edit the BeefTracker livestock inventory while disconnected from Wi-Fi and cell service; ability to represent portions of a pasture in BeefTracker as irrigated and non-irrigated; ability to report animal unit harvest (by pasture) calculated on an annual basis–this will provide quantifiable data regarding carrying capacity and subsequent beef production to provide more accurate data inputs for the beef sustainability lifecycle analysis; enhanced map synchronization; and improved security to allow a single individual to access multiple livestock operations without needing multiple user ids and passwords. We are now in the process of education to increase its use.

Key Words: cloud data storage, graphical interface, animal mapping

692 Effect of yearling beef steer frame score, grazing sequence, and delayed feedlot entry on steer performance, carcass measurements, and system economics. Songul Senturklu*[1,2], Douglas G. Landblom[1], Robert J. Maddock[3], and Steve I. Paisley[4], *[1]North Dakota State University, Dickinson Research Extension Center, Dickinson, ND, [2]Canakkale Onsekiz Mart Universitesi, Animal Science Department, Canakkale, Turkey, [3]North Dakota State University, Animal Science Department, Fargo, ND, [4]University of Wyoming, Animal Science Department, Laramie, WY.*

Ninety-six yearling beef steers divided into 2 frame score groups and identified as small frame score (SF: n = 48, Avg. 3.40; Range 1.58–4.13; 1/2RA × 1/4LO × 1/4AN) and large frame score (LF: n = 48; Avg. 5.31; Range 4.48–6.65; 1/2SM or 1/2SH × 1/4AN × 1/4RA) were randomly assigned to replicated pens or fields (3) on May 1 to evaluate an extended grazing and delayed feedlot entry system (GRAZ) compared with a feedlot direct (FLOT) system. Growing and finishing for the FLOT treatment and final delayed finishing of the GRAZ treatment steers was at the University of Wyoming (UW), SAREC feedlot, Lingle, WY. FLOT steers were on feed 216 d and GRAZ steers were on feed 74 d. GRAZ steers grazed a sequence of native range (113 d), pea-barley intercrop (30 d), and unharvested corn (77 d) before being moved to the UW-SAREC feedlot. Grazing and feedlot total days was 294 d. Data were analyzed using the MIXED procedure of SAS. For the GRAZ-LF and GRAZ-SF steers, grazing gain, ADG, pasture grazing cost, annual forage crop expenses, and grazing cost/kg gain was 243 kg, 1.10 kg/d, $285.05/steer, and $1.17/kg; 211 kg, 0.96 kg/d, $278.04, and $1.32/kg, respectively. Compared with the LF steers in the feedlot, SF steers grew slower, consumed less feed, were equally efficient, but feed cost/kg of gain was higher. HCW for SF steers was lighter, and marbling score was greater for SF steers (Table 1). LF steer carcass value was greater and system net return was greater for the LF frame steers (Table 1). Managing grazing cost and delaying feedlot entry reduced DOF and enhanced LF and SF GRAZ system profitability.

Contd.

693 Housing and management practices on farms using automated calf feeders in the Midwestern United States.

Matthew Jorgensen*[1], Amber Adams Progar[1], Kevin Janni[1], Hugh Chester-Jones[2], Jim Salfer[3], and Marcia Endres[1], [1]*University of Minnesota, Saint Paul, MN,* [2]*University of Minnesota Southern Research and Outreach Center, Waseca, MN,* [3]*University of Minnesota Extension, Saint Cloud, MN.*

Automated calf feeding systems are growing in popularity across the United States, yet information regarding feeder use and management is limited. This ongoing study is investigating housing and management practices on dairy farms with automated feeders. Thirty-eight Midwestern dairy farms were visited approximately every 60 d for 18 mo. Management practices data were collected using a questionnaire and calves (n = 10,185) and facilities were observed by research personnel. Of 38 calf feeding facilities, 39% were specifically constructed to house automated feeders and 61% were retrofitted; 53% were naturally ventilated barns, 39% were mechanically ventilated, and 8% were within a tunnel ventilated barn. A great majority of facilities (84%) supplemented ventilation systems with positive pressure tubes. Mean (±SD) pen size available to calves was 72.1 (±33.0) m^2. Farms housed 17.6 (±7.8; range 2–63) calves per pen, allowing for 4.6 (±2.9; range 1.2–32.3) m^2 of space/calf and 16.7 (±6.6; range 2–38) calves per nipple station. Calves were introduced into group pens at 5.2 (±4.0; range 0–14) days of age. A total of 68% of farms fed calves reconstituted milk replacer, 24% whole milk plus replacer or protein balancer, and 8% unsupplemented whole milk. A medicated milk product was used by 76% of farms. Milk (or replacer) allowance per day at feeder introduction was 5.4 (±2.1; range 3–15) L rising to 8.3 (±2.0; range 5–15) L at its peak. Time from feeder introduction to peak milk allowance was 18.0 (±11.4; range 0–44) days. Weaning for calves on automated feeders started at 44.5 (±6.9; range 32–60) days of age and calves were fully weaned by 56.8 (±9.0; range 40–86) days. Management of automated feeding systems was highly varied among farms in this study and an investigation of the relationship between management factors and calf morbidity and mortality will provide an understanding of factors associated with improved calf performance and welfare. This project is supported by Agriculture and Food Research Initiative competitive grant no. 2012–67021–19280 from the USDA National Institute of Food and Agriculture.

Key Words: automated feeder, calf management, calf housing

694 Effect of calving interval on the economic results of dairy farms based on their typology.

Anne-Catherine Dalcq*[1], Yves Beckers[1], Patrick Mayeres[2], Benoit Wyzen[2], and Hélène Soyeurt[1], [1]*Université de Liège-Gembloux Agro-Bio Tech, Gembloux, Belgium,* [2]*Walloon Breeders Association, Ciney, Belgium.*

The calving interval (CI) can influence the milk production (MP) and the economic results of a farm. This research aimed to highlight the most economically important CI, on the basis of the accounts of breeders. The data set contained 1,318 accounts spread between 2007 and 2012. Technical information such as mean CI of the herd, percent of cows with a CI of less than 380 d (m380), between 380 and 419 d (e380419), between 420 and 459 d (e420459) and more than 459 d (p459), mean MP of the herd; as well as typological information such as quantity of equivalent concentrate (CC), number of ares of grass (GR) and of corn silage (CS) per livestock unit (LU); and economic information such as mean gross margin per cow were available. The relation between CI and the gross margin showed that if a single economic optimum of CI cannot be determined, this optimum could depend on the typology of the farm. Therefore, 4 groups were created by using a multiple correspondence analysis, including quantity of equivalent CC, number of ares of GR and of CS per LU as variables. The first group was the most intensive one with a feeding based mostly on CC and CS; the second group was similar but less intensive. The third group was the most extensive with high GR consumption. The fourth group was characterized by a near absence of CS but more CC. Moreover, m380, e380420, e420459, p459 were transformed from quantitative to qualitative variables by using numerical classification. A qualitative variable CI profile was created as a summary of all these variables. In each group, MP was modeled using the different CI variables. The assumption behind this modeling was that for a typological profile, the breeder must have the highest MP to maximize the gross margin. These models showed that MP is maximized when p459 is lower than 26%, lower than 37%, above 27% for the group 1, 2, 3 respectively. For the group 4, the model with the variable CI profile suggested that the economic optimum of CI is intermediate. These results underlined that the economic optimum of CI is related to the typology of the considered farm. Studying individual data is a perspective to determine more precisely CI with the best economic results.

Key Words: calving interval, milk production, economic results

695 Evaluation of winter housing systems for effects on production, udder health, BCS, hygiene, frostbite, and rumination of organic dairy cows.

Lucas S. Sjostrom*[1], Bradley J. Heins[1], Marcia I. Endres[2], Roger D. Moon[2], and Ulrike S. Sorge[2], [1]*University of Minnesota, West Central Research and Outreach Center, Morris, MN,* [2]*University of Minnesota, Saint Paul, MN.*

Certified-organic cows (n = 165), according to the USDA-National Organic Program rules, were used to evaluate the effect of 2 winter housing systems (December to April) on production, SCS, body weight, BCS, incidence of frostbite, and rumination. Cows were assigned to 2 treatments (2 replicates per group): (1) outdoor (straw pack, n = 81) or (2) indoor (3-sided compost-bedded pack barn, n = 84). There were 21 cows per replicate per year for the outdoor housing and 21 and 20 cows per replicate per year for the indoor housing. Cows calved during 2 seasons (spring or fall) at the University of Minnesota West Central

Research and Outreach Center, Morris, Minnesota, organic dairy. Milk, fat and protein production and SCS were recorded from monthly DHIA testing. Hygiene scores and BCS were recorded bi-weekly as cows exited the milking parlor. Frostbite incidence was collected monthly in year 2. The PROC MIXED of SAS was used for statistical analysis, and independent variables were fixed effects of year of study, season of calving (fall or spring), parity (1, 2, 3+), breed group, housing system, with replicate and cow nested within the interaction of housing system and season of calving as a random effect. Energy-corrected milk and SCS were not different for the indoor (15.8 kg/d, 2.75) and outdoor (15.5 kg/d, 2.88) housing systems. The BCS (3.38 for indoor cow vs. 3.08 for outdoor cows) within housing systems were not different. Indoor cows had greater ($P < 0.05$) udder hygiene scores (1.73 vs. 1.45) and greater ($P < 0.05$) abdomen hygiene scores (1.86 vs. 1.56) compared with outdoor cows. Incidence of clinical mastitis was greater ($P < 0.05$) in indoor cows compared with outdoor cows (30% vs. 13%). Frostbite incidence was not different between indoor (34%) and outdoor (21%) cows ($P = 0.14$). Daily rumination was 495 min/d for indoor cows and 474 min/d for the outdoor cows ($P = 0.12$). In summary, cows housed outdoors on straw-bedded packs did not differ from cows housed in an indoor compost-bedded pack barn for production and SCS; however, the indoor cows were dirtier and had reduced udder health compared with outdoor cows.

Key Words: organic, outwintering, compost barn

696 Risk factors for abnormal calf health scores on farms using automated feeders in the Midwest USA.

Matthew Jorgensen*[1], Amber Adams Progar[1], Sandra Godden[1], Hugh Chester-Jones[2], Anne Marie de Passillé[3], Jeff Rushen[3], and Marcia Endres[1], *[1]University of Minnesota, Saint Paul, MN, [2]University of Minnesota Southern Research and Outreach Center, Waseca, MN, [3]University of British Columbia, Vancouver, BC, Canada.*

Automated calf feeding systems are growing in popularity across the United States, yet research identifying risk factors that influence calf health is limited. This ongoing study is investigating associations between farm management, environment and housing with calf health outcomes. Thirty-eight Midwestern dairy farms were visited approximately every 60 d for 18 mo. During each visit calves (n = 10,185) were scored by a single observer for health outcomes including attitude, secretions of the ears, eyes and nose, and cleanliness of the rear end as evidence of diarrhea (0 = normal, clean calf – 58.1% of the scores; 1 = moderate coverage of loose feces – 32.4%; 2 = significant coverage of watery fecal material – 9.4%). Risk factors for higher cleanliness score (diarrhea) were assessed using multilevel ordinal logistic regression. Variables in the analysis included pen size, group size and stocking density, farm's colostrum management, and milk diet type, amount, formulation, and bacterial count. Non-significant variables were removed using backward elimination. Variable retention was set at $P < 0.05$. The association between season and cleanliness score was found to be highly significant. Odds ratios indicated that winter 2012–13 (0.78), spring 2013 (0.43), summer 2013 (0.54), fall 2013 (0.72), and spring 2014 (0.47) were all associated with reduced likelihood of diarrhea compared with winter 2013–14. Each liter increase in peak milk allowance was associated with an 11.6% decrease in odds of higher score or diarrhea (OR 0.88, $P = 0.001$). The number of days taken to reach peak milk allowance was also associated with higher score (OR = 1.02, $P = 0.006$). Increasing number of calves per group was associated with a small decrease in score or less diarrhea (OR = 0.99, $P = 0.04$). The magnitude of association observed for greater peak milk allowance suggests that feeding calves on a higher plane of nutrition, and reaching that plane earlier, may be beneficial in reducing observed diarrhea. This project is supported by Agriculture and Food Research Initiative competitive grant no. 2012-67021-19280 from the USDA National Institute of Food and Agriculture.

Key Words: automated feeder, calf health, calf nutrition

697 Management characteristics of cow-calf, stocker, and finishing operations in the North and South Plains.

Senorpe Asem-Hiablie*[1], C. Alan Rotz[1], Robert C. Stout[1], Jasmine A. Dillon[2], and Kimberly R. Stackhouse-Lawson[3], *[1]USDA-ARS PSWMRU, University Park, PA, [2]The Pennsylvania State University, University Park, PA, [3]National Cattlemen's Beef Association, Centennial, CO.*

Regional surveys of cow-calf, stocker, and finishing operations are being conducted nationwide to gather information on cattle, crop, and range management practices needed for a comprehensive life cycle assessment (LCA) of beef production in the United States. The South Plains (Kansas, Oklahoma, and Texas) and the North Plains (Nebraska, South Dakota, and North Dakota) make up 2 of 7 regions demarcated for the LCA and are the focus of the present study. A total of 633 ranch responses represented 1.4% of the beef cows maintained across both regions, with 0.9 and 2.8% represented in the South and North Plains, respectively. Notable differences in management practices among cow-calf and stocker ranches in both regions were observed. Mean stocking rates decreased from the wetter east to the drier, semi-arid west. In the South Plains, mean stocking rates decreased from 2.4 ha/cow (1.3 ha/stocker) in the east to 15.7 ha/cow (4.6 ha/stocker) in the west and the North Plains reported 2.9 ha/cow (1.9 ha/stocker) in the east and 6.7 ha/cow (4.3 ha/stocker) in the west. Differences in forage management influenced by varying soil morphology and rainfall patterns, showed decreasing fertilizer and lime use from east to west in both regions. A higher percentage of ranches in the North Plains (57%) produced a variety of feed crops including corn and alfalfa to feed cattle compared with 17% in the South Plains. Although the proportion of ranches that harvested rangeland as hay were similar at 42% and 47% in the South and North Plains, respectively, the portion of land harvested was lower in the South (2.5%) than in the North Plains (13%). Responses from 60 feedyards represented 9% of cattle finished in the South Plains, 4% in the North Plains, and 7.5% overall. The primary difference in feedyard management identified across regions and among states was size. Feedyard capacities increased from north to south with the largest located in Texas. The data collected are being used to develop representative operations in each state to serve as basis for a comprehensive national LCA studying the environmental, economic, and social impacts of beef production and to identify opportunities for improvement.

Ruminant Nutrition: Lactation responses

698 Effect of a phytogenic feed additive on feed intake and milk production in dairy cows.

Carina Schieder*[1], Annamaria Boczonadi[1], and Bryan Miller[2], *[1]BIOMIN Holding GmbH, Herzogenburg, Austria, [2]BIOMIN USA Inc., San Antonio, TX.*

Fifty-five Holstein Friesian cows were assigned according to previous milk performance and days-in-milk into control (n = 27) or experimental group (n = 28) on a commercial farm in Czech Republic. Animals were housed in groups including one milking robot in each building. Experimental cows received a partly mixed ration (PMR) with a phytogenic feed additive (PFA) including herbs, spices, essential oils and plant extracts [Digestarom Dairy (3 g/head/day), Biomin Phytogenics GmbH, Germany]. Control cows received PMR without any supplementation during the trial period of 90 d. Both groups received additional concentrates based on wheat, barley, corn and soybean extraction meal according to their milk performance in the milking robots. Feed intake was recorded per group. Feed refusals were evaluated once daily. Milk performance was recorded each time visiting the milking robot, while milk solids were determined 3 times during the trial period. Health status and medical treatments were recorded throughout the trial. Data of daily milk performance were statistically analyzed using the independent *t*-test (IBM SPSS 21.0). PFA addition in the PMR of dairy cows resulted in a slightly higher dry matter intake (44.23 vs. 43.88 kg/d). The PFA supplemented group produced higher quantities of milk fat (1.27 vs. 1.19 kg/d; $P > 0.05$), milk protein (1.20 vs. 1.18 kg/d; $P > 0.05$) and lactose (1.75 vs. 1.67 kg/d; $P > 0.05$). Animals receiving the PFA showed a significantly higher milk production (35.37 vs. 33.67 kg/d; $P < 0.001$). Increased daily milk yield and enhanced quantity of milk solids resulted in a superior amount of energy-corrected milk (33.01 vs. 31.89 kg/d; $P > 0.05$). In conclusion, the tested PFA was able to improve feed intake and milk performance, hence resulting in an increased farm benefit.

Key Words: dairy cow, performance, phytogenic feed additive

699 Fractionated harvest and alkali treatment of whole-plant corn silage fed to lactating dairy cattle can increase intake and production.

David E. Cook, Robb W. Bender*, Kevin J. Shinners, and David K. Combs, *Department of Dairy Science, University of Wisconsin-Madison, Madison, WI.*

The objective of this study was to evaluate alkali treatment of whole plant corn and stalks fractionated from the whole plant at harvest as feeds for lactating dairy cows. A forage harvester with a 6-row modified ear-snapping head was setup to snap the corn ear from 2 rows and cut 4 rows at a height of 82 ± 5cm, resulting in a feed product called toplage. The toplage used in this study was 82% of the DM yield from the field and contained 44% starch. The remaining stalks were harvested with a forage harvester at a height of 12 ± 2 cm on a second pass. Stalks were treated with calcium hydroxide at a rate of 70 g·kg^{-1} DM and ensiled. A second treatment was comprised of whole plant corn harvested at 28 ± 3cm and treated with calcium hydroxide at a rate of 70 g·kg^{-1} DM, then ensiled. Conventional corn for the negative control diet (CON) was harvested at 26 ± 3cm from the same fields. BMR corn for the positive control diet was harvested from an adjacent field at a height of 26 ± 5cm. One hundred twenty-eight Holstein cows were stratified among 4 treatments in a randomized complete block design. Data were analyzed using the MIXED procedure of SAS, with treatment, week, and relevant interactions as fixed effects. Diets were TMR containing 40% corn silage, 20% alfalfa silage, and 40% concentrate. Treatments were complete substitution of corn silage with a negative control (CON), positive control (BMR), treated whole plant (TRTCS), and a combination of toplage (82% of corn silage) and stalklage (18% of corn silage) (TOP). The TOP and BMR diet resulted in a similarly increased ECM over the CON diet ($P < 0.01$), and the TRTCS resulted in the highest ECM.

Table 1 (Abstr. 699). Effects of treatment on DMI, production, and rumination

700 Effect of abomasal infusions of saturated fatty acids differing in chain length on milk production, composition, and fatty acid profile in Holstein dairy cows.

Daniel E. Rico*[1], Jair E. Parales[2], Ben A. Corl[3], Andrea Lengi[3], P. Yvan Chouinard[1], and Rachel Gervais[1], *[1]Université Laval, Quebec, QC, Canada, [2]Universidad Nacional de Colombia, Bogotà, DC, Colombia, [3]Virginia Polytechnic Institute and State University, Blacksburg, VA.*

Fat supplements are commonly fed to increase dietary energy density and improve animal performance. However, metabolic effects may vary depending on fatty acid (FA) chain length. Eleven multiparous Holstein dairy cows (150 ± 52 DIM; Mean ± SD) were randomly assigned to treatment sequence in a replicated 3 × 3 Latin Square design testing the effect of saturated fat supplements differing in chain length on milk production and composition, and on milk FA profile. Treatment periods were 7 d in length and were separated by 7 d of washout. Treatments were administered as abomasal infusions of emulsions providing 280 g/d of FA from: 1) free FA enriched in palmitic acid (>85% 16:0; PA), 2) free FA enriched in stearic acid (98% 18:0; SA), or 3) medium chain triglycerides (50% 8:0 and 50% 10:0; MCT),. Milk yield was recorded and samples taken on the last 3 d of each period. The statistical model included the random effects of period, cow and sequence, and the fixed effect of treatment. Preplanned contrasts tested were PA vs. SA, and PA vs. MCT. Fat- and energy-corrected milk were not affected by treatments, and averaged 36.0 ± 2.0 kg/d and 35.1 ± 2.0 kg/d, respectively ($P > 0.11$). Milk fat content was higher in PA (4.49%) than in SA (4.18%, $P < 0.001$), but was not different between PA and MCT (4.37, $P = 0.17$). Similarly, milk fat yield was increased by PA (1.56 kg/d) relative to SA (1.46 kg/d, $P = 0.01$) and tended to be higher in PA than in MCT (1.48 kg/d; $P = 0.06$). De novo synthesized FA were higher in both SA and MCT (27.3 and 30.5% of FA, respectively) compared with PA (24.5% of FA; $P < 0.001$). The sum of 16:0 and cis-9 16:1 was higher in PA (43.7% of FA) relative to MCT and SA (38.0 and 35.6, respectively; $P < 0.001$). Lastly, the concentration of 18:0 plus cis-9 18:1 was increased by SA (31.2% of FA) relative to PA (26.6% of FA; $P < 0.001$), but was not different between PA and MCT (25.8%, $P = 0.42$). The chain length of fat supplements infused into the abomasum affected milk fat and fatty acid profile.

Key Words: dairy cow, chain length, fat supplement

701 Effect of *Bacillus pumilus* on early lactation performance of dairy cows fed low or high starch diets postpartum.

D. N. Lobão da Silva*[1], Z. Sawall[1], K. Froehlich[1], E. Galbraith[2], T. Parrott[3], M. Endres[1], and N. B. Litherland[1], [1]*University of Minnesota, Saint Paul, MN,* [2]*DuPont Nutrition and Health, Waukesha, WI,* [3]*DuPont Industrial Biosciences, Waukesha, WI.*

Strains of *Bacillus pumilus,* a spore-forming gram-positive bacterial species can be highly resistant to environmental stresses and have the potential to produces xylanase. Xylanase increases fiber digestion and feed efficiency which might benefit cows during early lactation. This study aimed to investigate the effects of low (20%, LS) or high (27%, HS) dietary starch concentration and *Bacillus pumilus* 8G-134 (BP) supplementation during early lactation. We hypothesized that BP would increase DMI and milk yield of cows fed LS or HS diets postpartum. Forty-four (n = 11/treatment) multiparous cows dried-off 42d before expected calving date were assigned to a common prepartum diet. At calving, cows were fed a LS or HS lactation diet and BP carrier or BP was top dressed on the TMR once daily to provide 5×10^9 cfu/cow/day until 112 DIM. Factors combined produced 4 treatments: LS+carrier (LSCO); LS+BP (LSBP); HS+carrier (HSCO); HS+BP (HSBP). Blood samples collected on d 7, 14, 21 and 28 after calving were analyzed for NEFA and BHBA concentrations. Data were analyzed using the MIXED procedure of SAS. No changes were observed on postpartum DMI and 3.5%FCM yield; however, NEFA was lower and BHBA tended to be lower in serum of BP vs. Control. Results indicated that BP supplementation during early lactation decreased body lipid mobilization. We hypothesize that greater amounts of digestible energy available from fiber digestion might have caused lower lipid mobilization in cows fed BP. Future research should further investigate the use of BP as a feed additive because it appears to modify blood metabolite concentrations in early lactation.

Table 1 (Abstr. 701). Body condition, lactation performance, and blood metabolites in early lactation

	Treatment							
	LS		HS			*P*-value

702 Effects of direct-fed *Bacillus pumilus* 8G-134 fed pre- and postpartum on feed intake, milk yield, milk composition, and feed efficiency of Holstein cows.

Shaoyu Luan[1], Elizabeth Galbraith[2], Megan Duersteler[2], and Felipe C. Cardoso*[1], [1]*University of Illinois, Urbana, IL,* [2]*Dupont Nutrition and Health, Waukesha, WI.*

The usage of direct-fed microbials (DFM) has become common in the dairy industry, but questions regarding their value and mode of action on dairy cows performance remain prevalent. The objective of this study was to evaluate the effects of DFM (*Bacillus pumilus* 8G-134) on pre- and postpartum performance. Forty-three multiparous Holstein cows were fed a total mixed ration (TMR) according to NRC (2001) recommendations and assigned to 2 treatments in a randomized completely block design. Cows in the direct-fed microbial treatment (DFMt, n = 21) received 5.0×10^9 cfu of *B. pumilus* 8G-134 direct-fed microbial in 28g of maltodextrin carrier, whereas cows in the control treatment (CON, n = 22) received 28g of maltodextrin carrier alone. Treatments were top-dressed on the TMR daily. Treatments were applied from 21 d before expected calving date to 154 d after calving. Intake from each cow was measured and dry matter intake was recorded daily. Milk weights were recorded daily, and milk samples were obtained weekly. Composite milk samples were analyzed for fat, protein, lactose, urea N (MUN), total solid and somatic cell count (SCC). Statistical analysis was performed using the MIXED procedures of SAS. Cows on DFMt had higher milk yield (41.2 ± 1.34 vs. 37.8 ± 1.33 kg; $P = 0.02$), fat corrected milk (48.5 ± 1.48 vs. 42.0 ± 1.49 kg; $P = 0.01$), energy-corrected milk (46.6 ± 1.40 vs. 40.9 ± 1.38 kg; $P = 0.01$), fat production (1.85 ± 0.06 vs. 1.57 ± 0.06 kg; $P = 0.03$), and protein production (1.27 ± 0.04 vs. 1.18 ± 0.04 kg; $P = 0.02$) on the second week of lactation than CON. There were no differences ($P > 0.27$) between treatments for milk yield, fat, protein, lactose, total solids, MUN or SCC overall. Dry matter intake, BW, body condition score (BCS) were not affected ($P > 0.35$) by DFMt supplementation. Cows on DFMt tended ($P = 0.06$) to have higher feed conversion (ECM/DMI; 2.02 ± 0.04) than cows fed CON (1.92 ± 0.04). In conclusion, cows fed DFMt tended to have higher feed conversion than CON with no detrimental consequences (i.e., BCS).

Key Words: direct-fed microbial, feed efficiency, *Bacillus pumilus*

703 Effects of fecal contents of aluminum (Al), iron (Fe), and manganese (Mn) on the apparent digestibility of phosphorus in dairy cows.

Jan Plaizier*, Emma McGeough, and Kim Ominski, *University of Manitoba, Winnipeg, MB, Canada.*

To test if the apparent absorption of phosphorous (P) is reduced by aluminum (Al), iron (Fe), and manganese (Mn), relationships between the fecal contents of these minerals and the apparent digestibility (ADC) of P in dairy cows were determined. The study involved 10 commercial dairy farms in Manitoba, and 10 early and peak lactation, 10 mid lactation and 10 late lactation cows on each farm. Farms were visited once to collect diet, feed and fecal grab samples of individual cows. Feed, diet, and feces samples were analyzed by ICP for P and for the internal marker acid insoluble ash (AIA). Feces samples also were analyzed for Al, Fe, and Mn by ICP. Apparent digestibility coefficients (ADC) of P for individual cows were determined from the contents of P and AIA in the diet and the feces. Fecal Al contents of individual cows ranged from 2.7 to 36.8 ppm, with an average of 9.8 ppm (DM basis). Fecal Fe contents of individual cows ranged from 5.5 to 34.5 ppm, with an average of 11.6 ppm (DM basis). Fecal Mn contents of individual cows ranged from 0.6 to 5.6 ppm, with an average of 2.3 ppm (DM basis). These concentrations do fecal mineral contents do not indicate that the fecal Al, Fe, and Mn contents were excessive. The ADC of P ranged from 15.9 to 59.7% among individual cows with an average of 35.1%. The fecal Al and Fe contents were correlated ($r = 0.60$, $P < 0.0001$), but the fecal contents of Mn were not correlated with those of Al ($P = 0.91$) and Fe ($P = 0.65$). The regression equation between the ADC of P and the fecal contents of Al, Fe, and Mn (in ppm) determined by SAS Mixed Procedure was $\text{ADC P} = 27.51(\pm 2.79, \text{estimate + SE}) + 1.18 (\pm 0.15) \times \text{Al} - 1.11(\pm 0.19) \times \text{Fe} + 1.73(\pm 0.93) \times \text{Mn}$ ($R^2 = 0.31$). This shows that, as expected, the increases in fecal Fe contents were associated with decreases in the ADC of P, but that for the fecal Al and Mn contents the opposite occurred. These discrepancies may be the result of the confounding of these fecal contents with other factors that affect the ADC of P and variation in the form that the dietary Al, Fe, and Mn contents were in. Nevertheless, results suggest that at the levels observed in our study the fecal contents of Al, Fe, and Mn may affect the digestibility of P.

Key Words: aluminum, phosphorus, iron

704 Effects of feeding diets differing in dietary cation-anion difference (DCAD) and source of vitamin D on Ca status, health, and lactation performance in Holstein cows.

N. Martinez*[1], R. Rodney[2], R. M. Santos[1], L. F. Greco[1], R. S. Bisinotto[1], E. S. Ribeiro[1], L. L. Hernandez[3], C. D. Nelson[1], E. Block[4], I. J. Lean[2], and J. E. P. Santos[1], *[1]University of Florida, Gainesville, FL, [2]SBScibus, Camden, NSW, Australia, [3]University of Wisconsin, Madison, WI, [4]Arm and Hammer Animal Nutrition, Princeton, NJ.*

Objectives were to evaluate the effects of feeding diets differing in DCAD (PD = +130 vs. ND = −130 mEq/kg) and source of vitamin D3 prepartum (CH; cholecalciferol vs. CA; calcidiol; both fed at 0.27 mg/kg of diet DM) on Ca status, health, and lactation performance in dairy cows during the transition period. Seventy-nine Holstein cows, 51 parous and 28 nulliparous, at 255 d gestation were blocked by parity, and randomly assigned to 1 of 4 dietary treatments arranged as a 2 × 2 factorial that were fed for the last 21 d prepartum. Dry matter intake (DMI) was measured from 21 d pre- to 42 d in milk (DIM). Prevalence of subclinical hypocalcemia (SCH) was evaluated in the first 3 DIM and defined as blood ionized Ca <1.06 m*M*. Incidence of diseases was monitored daily for the first 30 DIM. Milk yield and composition were recorded for the first 49 DIM. Data were analyzed using PROC MIXED and PROC GENMOD of SAS. Feeding CA compared with CH increased ($P < 0.01$) prepartum plasma concentrations of 25OH-D_3 (237.0 vs. 59.5 ± 6.4 ng/mL), 24,25$(OH)_2$-D_3 (19.2 vs. 1.6 ± 1.0 ng/mL), and 1,25$(OH)_2$-D_3 (55.3 vs. 48.4 ± 1.7 pg/mL), but decreased that of cholecalciferol (1.7 vs. 15.3 ± 0.5 ng/mL). Feeding ND increased prepartum concentration 1,25$(OH)_2D_3$ (57.2 vs. 46.9 ± 1.7 pg/mL). The ND diet reduced ($P < 0.01$) prepartum DMI in multiparous (11.5 vs. 13.7 ± 0.4 kg/d) but not in primiparous cows (11.3 vs. 11.0 ± 0.5 kg/d). Feeding the ND diet reduced ($P < 0.05$) the prevalence of SCH at 0 and 1 DIM (20.0% and 34.3%) compared with PD (69.3% and 76.5%). Incidence of clinical hypocalcemia (milk fever) was 0% in ND compared with 23.1% in PD cows ($P < 0.05$). Feeding CA compared with CH reduced ($P < 0.05$) the incidences of retained placenta (2.5 vs. 30.8%) and metritis (23.1 vs. 46.2%). Cows fed prepartum ND and CA had reduced ($P = 0.04$) morbidity compared with all other 3 treatments. Cows fed CA produced 3.70 ± 1.2 kg/d more ($P < 0.04$) 3.5% fat- and energy-corrected milk than those fed CH. The use of prepartum ND in combination with CA improved Ca status, health, and lactation performance in dairy cows.

Key Words: dairy cow, vitamin D, DCAD

705 Effects of the interaction between photoperiod and nutritional management on milk yield for dairy cows.

Oswaldo S. Espinoza* and Masahito Oba, *University of Alberta, Edmonton, Alberta, Canada.*

The objective of this study was to evaluate the interaction effects of photoperiod management and nutritional management on milk production of lactating dairy cows. We hypothesized that feeding a high grain diet increases milk yield of cows exposed to long photoperiod to a greater extent compared with those exposed to short photoperiod. The study was conducted at a tie-stall barn with metal halide light fixtures. Thirty mid-lactating cows (109 ± 37 d in milk; mean ± SD) were exposed to long photoperiod (LP; 16 h/d light; n = 15) or short photoperiod (SP; 8 h/d light; n = 15). After 30 d of light adaptation, cows within each photoperiod treatment were fed 3 diets containing steam rolled barley grain at 15, 25 and 35% of dietary dry matter (LG, MG, and HG, respectively) in a 3 × 3 Latin square design. Dry matter intake was greater for cows fed the HG diet compared with those fed the LG diet (22.7 vs. 20.4 kg/d; $P < 0.001$) whereas it was not affected by photoperiod treatment. The interaction effects between photoperiod and dietary treatments were significant for yields of milk ($P = 0.03$), milk fat ($P < 0.01$), and milk protein ($P = 0.02$). Feeding the HG diet increased milk yield by 4.0 kg/d compared with the LG diet for cows exposed to SP treatment (30.5 vs. 26.5 kg/d, $P < 0.05$) whereas the increase was 2.2 kg/d for cows on the LP treatment (30.4 vs. 28.2 kg/d, $P < 0.05$). Likewise, the HG diet increased milk protein yield compared with the LG diet to a greater extent for cows on the SP treatment (1.03 vs. 0.84 kg/d, $P < 0.05$) than those on the LP treatment (0.99 vs. 0.90 kg/d, $P < 0.05$). However, dietary grain content did not affect milk fat yield for cows on the LP treatment while the HG diet increased milk fat yield compared with the LG diet for cows on the SP treatment (1.25 vs. 1.10 kg/d, $P < 0.05$). These results indicate that milk production responses to high grain diets may be greater for cows exposed to short photoperiod, and that dietary grain content can be reduced without negatively affecting milk fat yield if lactating dairy cows are exposed to long photoperiod.

Key Words: photoperiod, grain, interaction.

Ruminant Nutrition: Mineral nutrition

706 Organic trace minerals during the transition period: 2. Supplemental Zn, Mn, and Cu from Availa Mins and Co from CoPro have a positive effect on systemic and hepatic indicators of inflammation and oxidative stress in Holstein cows. Fernanda Batistel*[1], Johan S. Osorio[1], Jin Ji[1], Erminio Trevisi[2], James K. Drackley[1], Michael T. Socha[3], and Juan J. Loor[1], *[1]University of Illinois, Urbana, IL, [2]Università Cattolica del Sacro Cuore, Piacenza, Italy, [3]Zinpro Corporation, Eden Prairie, MN.*

The peripartal dairy cows undergoes a state of reduced liver function linked with increased inflammation and oxidative stress. Objectives were to evaluate hepatic mRNA expression and systemic biomarkers of inflammation and oxidative stress in cows receiving supplementation of inorganic (INO) or organic (AAC) trace minerals. Twenty multiparous cows were assigned in a randomized complete block design to a common prepartal (1.5 Mcal/kg DM, 15% CP) and postpartal (1.76 Mcal/kg DM, 18% CP) diet. Both diets were partially supplemented with an inorganic mineral mix of Zn, Mn, and Cu to supply 35, 45, and 6 ppm, respectively, of the total diet DM. Treatments included cows receiving an oral bolus containing a mix of INO (n = 11) or AAC (n = 9) Zn, Mn, Cu, and Co to achieve 75, 65, 11, and 1 ppm, respectively, in total diet DM. Organic trace minerals were supplied via Availa Zn, Availa Mn, Availa Cu, and CoPro (Zinpro Corp., Eden Prairie, MN). Liver biopsies were collected at d −30, −15, 10 and 30, and blood samples at d −30, −14, 3, 15, and 30 relative to parturition. Although AAC did not affect biomarkers of liver function, an interaction (diet × time; $P < 0.05$) for the concentration of albumin, glutamic-oxaloacetic transaminase (GOT), cholesterol (CHO) and γ-glutamyltransferase (GGT) was observed. The lower GGT at d 15 and 30, and GOT at d 15 in cows receiving AAC suggests a lower degree of liver cell damage. Furthermore, greater albumin concentration at d 15 and 30 ($P < 0.05$), and greater gene expression of albumin (*ALB*; $P < 0.01$) and interleukin 10 (*IL10;* $P = 0.03$) in cows given AAC suggest a less pronounced inflammatory status. An interaction (diet × time; $P < 0.05$) was observed for signal transducer and activator of transcription 3 (*STAT3*) and superoxide dismutase 2 (*SOD2*) because expression increased from d 10 to 30 in cows fed AAC compared with INO. Overall, these data provide some evidence that source of trace mineral during the peripartal period alters immunometabolism.

Key Words: immunometabolism, trace mineral

707 Organic trace minerals during the transition period: 3. Favorable alterations in blood neutrophil (PMN) and endometrial inflammatory and oxidative status in Holstein cows supplemented with Zn, Mn, and Cu from Availa Mins and Co from CoPro. Fernanda Batistel*[1], Johan S. Osorio[1], Cong Li[2], Ed F. Garrett[1], Mohamed M. Elhanafy[1], Jessica Caputo[3], James K. Drackley[1], Michael T. Socha[4], and Juan J. Loor[1], *[1]University of Illinois, Urbana, IL, [2]China Agricultural University, Beijing, China, [3]University of Milan, Milan, Italy, [4]Zinpro Corporation, Eden Prairie, MN.*

Objective was to evaluate mRNA expression of genes associated with inflammation, oxidative stress, eicosanoid synthesis and transcription regulation in PMN and endometrium in cows receiving inorganic (INO) or organic (AAC) trace minerals. Twenty multiparous cows were allocated in a randomized complete block design, and received the same prepartum (1.5 Mcal/kg DM, 15% CP) and postpartum (1.76 Mcal/kg DM, 18% CP) diet. The diets were partially supplemented with an inorganic mineral mix of Zn, Mn, and Cu to supply 35, 45, and 6 ppm, respectively, of the total diet DM. Cows were assigned to an oral bolus administration containing a mix of either INO (n = 11) or AAC (n = 9) Zn, Mn, Cu, and Co to achieve 75, 65, 11, and 1 ppm, respectively, in total diet DM. Treatments began on d −30 and continued through d 30 relative to parturition. Organic trace minerals were supplied via Availa Zn, Availa Mn, Availa Cu, and CoPro (Zinpro Corp., Eden Prairie, MN). Endometrial biopsies were collected at d 14 and 30 postpartum. In PMN, expression of DEAD box polypeptide 58 (*DDX58*) was greater and Z-DNA binding protein 1 (*ZBP1*) was lower in cows supplemented with AAC. In addition, feeding AAC increased expression of genes related to oxidative stress (*MPO*) and eicosanoid metabolism (*PLA2G4A*, *ALOX5AP*). In endometrium, feeding AAC increased expression of genes related to oxidative stress (*SOD1*, *NRF2*), eicosanoid metabolism (*PTGES*) and inflammation (*MYD88*, *STAT3*, *IL10*). An interaction was observed for *IL6* (inflammation) because expression increased from d 14 to 30 in cows fed INO compared with AAC. The decrease in *IL1B, IL10, IL8* (inflammation) and *PTGES* (eicosanoids) expression on d 30 was more pronounced for cows fed AAC, whereas *PPARG* (an anti-inflammatory transcription regulator) increased on d 30. Overall, data demonstrate favorable alterations in PMN and endometrium inflammatory and oxidative status in cows supplemented with organic trace minerals.

Key Words: inflammation, trace mineral

708 Parameterization of a ruminant model of phosphorus digestion and metabolism. Xin Feng*, Katharine F. Knowlton, and Mark D. Hanigan, *Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, VA.*

The objective of the current work was to parameterize the digestive elements of the model of Hill et al. (2008) using data collected from animals that were ruminally, duodenally, and ileally cannulated, thereby providing a better understanding of the digestion and metabolism of phosphorus (P) fractions in growing and lactating cattle. The model of Hill et al. (2008) was fitted and evaluated for adequacy using the data from 6 animal studies (Feng et al., 2011, Ray et al., 2012b, Feng et al., 2013, Ray et al., 2013, Jarrett et al., 2014, Feng et al., 2015). It was hypothesized that sufficient data would be available to estimate P digestion and metabolism parameters and that these parameters would be sufficient to derive P bioavailabilities of a range of feed ingredients. Inputs to the model were DM intake; total feed P concentration (P_{PtFd}); phytate (Pp), organic (Po) and inorganic (Pi) P as proportions of total P (P_{PpPt}, P_{PoPt}, P_{PiPt}); microbial growth; amount of Pi and Pp infused into omasum or ileum; milk yield; and BW. The available data were sufficient to derive all model parameters of interest. The final model predicted that given a 75 g/d total P input, the total-tract digestibility of P was 40.76%, Pp digestibility in the rumen was 92.4% and in the total-tract was 94.7%. A large proportion of Pi was absorbed from the small intestine (SI), however additional Pi was absorbed from the large intestine (3.15%). Absorption of Pi from the SI was regulated. Salivary recycling of blood P to the rumen was a major source of Pi flow into the SI, and the primary route of excretion. Milk synthesis used 16% of total absorbed P, and less than 1% was excreted in urine. The resulting model could be used to derive P bioavailabilities of commonly used feedstuffs in cattle production.

Key Words: model, phosphorus, digestion and absorption

709 Comparison of predicted ration phosphorus balance using bioavailabilities from the NRC (2001) and Virginia Tech models.

Xin Feng*, Katharine F. Knowlton, Mark D. Hanigan, Jamie Jarrett, and Robert James, *Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, VA.*

The objective of the current work was to use digestion coefficients from the Hill et al. (2008) model after parameterization by Feng et al. (2015; VT model) to calculate phosphorus (P) bioavailability (P_{VT}) of common feeds used in dairy production. Compared with the bioavailability calculated by the VT model, using the NRC (2001) P absorption coefficient of 0.64 for forages would underestimate the bioavailabilities of alfalfa hay, alfalfa silage, corn silage, grass hay, mixed mainly legume silage and western hay. For concentrates, using the NRC (2001) P absorption coefficient of 0.70 would overestimate the bioavailabilities of canola, corn grain, dry barley, soybean meal and whole cottonseed but underestimate bioavailability of high moisture corn. Two dairy rations were formulated using nutrient values from the NRC (2001): a standard diet which includes minimal byproducts and a byproduct diet which has reduced corn and soybean meal that was replaced with corn gluten feed, distillers grains, hominy feed and wet brewers grains. For each diet, total bioavailable P was calculated using availability values from the NRC (2001) and the VT models. Comparison of P balance (the difference between required and bioavailable P) for each diet was made using the 2 sets of bioavailabilities for a reference cow weighing 682 kg, producing 38.6 kg of milk/d (3.5% fat and 3.0% true protein, 100 DIM) and consuming 23 kg of DM/d yielding an absorbable P requirement of 59.4 g/d. The standard diet supplied 56.7 g and 53.5 g of bioavailable P per day using bioavailabilities from the NRC (2001) and VT models, respectively, resulting in a P balance of −2.72 and −5.9 g/d. The byproduct diet provided 75.75 and 78.47 g/d of bioavailable P yielding P balances of 16.4 and 19.1 g per day respectively using the 2 sets of bioavailabilities. Thus using P bioavailabilities for individual ingredients that were based on the VT model resulted in different calculated P balances by diet and would result in differing P feeding levels if used in a field setting.

Key Words: phosphorus, balance, bioavailability

710 Effects of Se-fertilization on forage Se concentration and Se status of growing calves consuming these forages.

Juliana Ranches*, Joao M. Vendramini, and John D. Arthington, *UF/IFAS Range Cattle Research and Education Center, Ona, FL.*

The objective of this study was to evaluate the effect of Se fertilization of ‘Jiggs’ bermudagrass (*Cynodon dactylon* L.) hayfields on the forage Se concentration and subequent Se status of calves consuming the forage. Sodium selenate was dissolved into water (8.8 g/L) and sprayed onto bermudagrass hayfields at a rate of 257 g Se/ha and harvested 8 wk after Na selenate application. Forage fertilized with Na selenate had greater ($P < 0.001$) Se concentration compared with the control forage without Se fertilization (7.7 ± 1.81 vs. 0.1 ± 0.04 mg/kg DM). Control and high-Se hay were fed for 42d to weaned calves (n = 32; initial BW = 176 ± 8.7 kg) stratified by initial BW and randomly assigned to partially covered drylot pens (16 pens; 2 calves/pen). Treatments were randomly assigned to pens, including control hay + high-Se hay, control hay + supplemental Na selenite, or control hay without supplemental Se (n = 7, 7, and 2 pens, respectively). A pair-feeding design was utilized, whereas each pen receiving high-Se hay was paired to a pen receiving Na selenite. Ground, high-Se hay was offered to assigned pens for a 4 h period each morning. Hay intake was measured and total Se intake was estimated. The Na selenite paired-pen was then provided the same daily amount of Se via Na selenite hand-mixed into a limit-fed grain supplement resulting in a range of daily Se intakes of 2.08 to 3.98 mg/d. Liver Se concentrations were greatest ($P \leq 0.004$) on d 42 for calves consuming high-Se hay compared with calves receiving Na selinite or no supplemental Se (2.97, 2.49, and 0.60 mg/kg DM, respectively; SEM = 0.142). Amount of daily Se intake affected Se status, whereas, calves consuming <3.0 mg/d from high-Se hay had 54% greater ($P = 0.02$) liver Se concentrations compared with calves consuming the same amount of Se from Na selenite. When consuming >3.0 mg/d, there were no differences ($P = 0.71$) in liver Se concentrations due to Se source. These results imply that Se fertilization of bermudagrass hayfields results in increased Se concentration of harvested forage. Additionally, calves consuming this forage in amounts providing <3.0 mg Se daily have greater Se status compared with calves consuming the same amount of Se from Na selenite.

Key Words: calves, hay, selenium

711 Effect of Cu, Zn, and Mn source on preferential free-choice intake of salt-based supplements by beef calves and precipitation-induced metal loss.

Aline T. Wiebusch[2], Maria L. Silveira[1], Luana S. Caramalac[2], Henrique J. Fernandes[2], and John D. Arthington*[1], *[1]UF/IFAS Range Cattle Research and Education Center, Ona, FL, [2]Graduate Program in Animal Sciences, State University of Mato Grosso do Sul, Aquidauana, Brazil.*

Two studies were completed to evaluate the effects of Cu, Zn, and Mn source on preferential intake and precipitation-induced metal loss of salt-based mineral supplements. Complete free-choice, salt-based mineral supplements were formulated to contain 2,500, 5,500, and 4,000 mg/kg of Cu, Zn, and Mn, respectively. The supplements differed only by the source of Cu, Zn, and Mn, which were hydroxy, organic, or sulfate sources. In Exp. 1, the 3 formulations were offered simultaneously to preweaned beef calves (4 pasture replications; 17 calves/pasture) within separate stainless steel bowls inside covered cow-exclusion areas. Preferential intake was evaluated weekly for 18 wk. Consumption of mineral averaged 21 ± 2.4 g/d (sum of all 3 sources), with a greater ($P < 0.001$) percentage of the total intake coming from the formulation containing the hydroxy vs. organic or sulfate sources of Cu, Zn, and Mn (42.8, 30.2, and 27.0% of total intake, respectively; SEM = 1.03). In Exp. 2, each of the mineral formulations from Exp. 1, were exposed to a 10.2 cm precipitation event delivered in equal 3.4 cm applications on Monday, Wednesday, and Friday (4 replications/formulation). To accomplish this, 750 g of mineral was placed into Buchner funnels (177 cm^2) on 20 to 25 µ pore filter paper. Deionized water (pH adjusted to 5.6) was poured over the mineral and the leachate collected into volumetric flasks and analyzed for Cu, Zn, and Mn concentration using inductively coupled plasma spectroscopy techniques. Total leaching losses of Cu, Zn, and Mn were less ($P < 0.001$) for formulations containing hydroxy- vs. organic- and sulfate-sources (Cu losses = 0.8, 5.8, and 3.8%, SEM = 0.22; Zn losses = 18.0, 54.6, and 52.3%, SEM = 1.83; and Mn losses = 6.2, 50.1, and 54.8%, SEM = 1.83 for formulations containing hydroxy, organic, and sulfate sources, respectively). These results imply that calves preferentially consume free-choice salt-based mineral supplements formulated with hydroxy vs. sulfate or organic sources of Cu, Zn, and Mn. In addition, hydroxy sources of Cu, Zn, and Mn are less susceptible to precipitation-induced leaching losses compared with sulfate and organic sources.

Key Words: calves, supplementation, trace mineral

712 Effects of trace mineral source on cow performance and mineral status during a production cycle.

Deborah M. Price*[1], Kaitlyn M. Havill[1], Alex F. Swain[1], Joseph M. Guevera[2], Carley R. Trcalek[2], Max Irsik[2], Owen Rae[2], Matthew J. Hersom[1], and Joel V. Yelich[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]College of Veterinary Medicine, University of Florida, Gainesville, FL.*

Effect of trace mineral (TM) supplement source on cow performance and TM status over the production cycle were examined. Cows (n = 200, BW = 523 ± 6 kg, BCS = 5.1 ± 0.03) were divided in a factorial treatment arrangement, Angus (AN, n = 99) and Brangus, (BN, n = 101) and TM treatments (TRT; Inorganic = ING, n = 100, and Organic = ORG yeast source, n = 100). Supplementation (3 d/wk, 0.4 kg$\cdot^{-1}$454 kg BW$\cdot^{-1}$d in a pellet) of TM began ≥90 d before expected parturition and continued to weaning. A subset of cows had liver biopsies and serum collected, frozen and analyzed for TM content (Co, Cu, Fe, Mn, Mo, Se and Zn), by ICP-MS at 4 and 6 periods, respectively: start of TM (TMst), pre-calving (PreC), calving (C, serum only), post-calving (PostC, serum only), prebreeding (Pbrd) and weaning. Cow BW and BCS were recorded each period. Data were analyzed in SAS using Proc Mixed and repeated measures, with TRT, breed and time as fixed effects. No 3-way interactions were detected except for serum Cu, Mn and Mo. At PostC, BN were 0.17 BCS greater ($P = 0.03$) than AN. Cow BW and BCS did not differ ($P > 0.21$) by TRT at each period. The AN had greater ($P \leq 0.03$) BW change from TMst to PreC (49 vs. 40 ± 2 kg) and from PostC to Pbrd (−44 ± 4 vs. −33 ± 3 kg) than BN. Change in BCS from PreC and Pbrd to weaning were greater ($P < 0.05$) in ING (−0.15 vs. −0.001 ± 0.05 and −0.36 vs. −0.10 ± 0.08, respectively) than ORG. Time ($P \leq 0.02$) affected all serum and liver TM concentrations except for serum Fe ($P = 0.13$). Serum Co and liver Cu concentrations were greater ($P < 0.05$) in ING (1.7 vs. 1.3 ± 0.1 ng/mL and 266.4 ± 15.0 vs. 201.2 ± 14.1 µg/g, respectively), while serum Mo was greater ($P = 0.006$), in ORG (2.8 vs. 1.7 ± 0.3 vs. ng/mL). Serum Fe and liver Cu and Mn concentrations in BN (149.1 ± 5.5 µg/dL, 280.9 ± 15.2 and 11.7 ± 0.5 µg/g) were greater ($P < 0.03$) than AN (132.4 ± 5.3 µg/dL, 186.7 ± 13.9 and 9.5 ± 0.5 µg/g). Serum Se was greater ($P = 0.003$) in AN than BN (73.5 ± 1.7 vs. 65.4 ± 1.8 ng/mL). Cow TM status varies over time and is affected by breed and TM source; indicating development of nutritional management strategies can be based on cattle breed.

Key Words: trace mineral, liver, cattle

713 Effect of prenatal trace mineral source on preweaning and weaning calf liver and serum mineral status.

Deborah M. Price*[1], Alex F. Swain[1], Meaghan M. O'Neil[1], Joseph M. Guevera[2], Carley R. Trcalek[2], Max Irsik[2], Owen Rae[1], Matthew J. Hersom[1], and Joel V. Yelich[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]College of Veterinary Medicine, University of Florida, Gainesville, FL.*

The effect cow prenatal trace mineral (TM) supplement source has on calf serum and liver TM status from 115 ± 21 d of age through weaning (206 ± 21 d) was investigated. Factorial arrangements [Angus = AN, n = 95 and Brangus = BN, n = 96 cows; Inorganic = ING, n = 98, and Organic = ORG yeast, n = 93] utilized calves born to cows supplemented (3 d/wk at a rate of 0.4 kg$\cdot^{-1}$454 kg BW$\cdot^{-1}$d in a pellet) with TM ≥90 d before expected parturition. All calf (n = 190) BW were collected at d 115 and weaning, while a subset of calves (ING, n = 12, 6/breed, ORG, n = 14, 7/breed) had liver biopsies performed and serum collected by jugular vein puncture. Processed serum and liver samples were frozen at −20°C until analyzed for TM (Co, Cu, Fe, Mn, Mo, Se and Zn), by ICP-MS. Data were analyzed in SAS using Proc Mixed and repeated measures, with TRT, breed and day as fixed effects. With the exception of serum Co, Mn and Mo, there were no ($P \geq 0.08$) 3-way interactions. Calf d 115 BW (149 ± 2 kg) were not affected ($P = 0.65$) by TRT. At weaning, ORG had greater ($P \leq 0.02$) BW (226 vs. 216 ± 3 kg), 205 d adjusted BW (227 vs. 216 ± 3 kg), BW gain (190 vs. 181 ± 3 kg) and ADG (0.93 vs. 0.89 ± 0.01 kg) than ING. Serum Co and Zn were affected ($P < 0.001$) by day, while all liver TM except for Co were affected ($P < 0.03$) by day. The ORG calves had greater ($P \leq 0.01$) serum Se (29.8 vs. 18.2 ± 1.1 ng/mL), liver Se (0.7 vs. 0.5 ± 0.1 µg/g) and Mn (9.3 vs. 7.8 ± 0.4 µg/g) than ING. The AN had greater ($P \leq 0.04$) serum Co (0.8 vs. 0.5 ± 1.2 ng/mL), Se (27.9 vs. 19.4 ± 1.1 ng/mL) and liver Co (0.2 vs. 0.1 ± 0.02 µg/g), Fe (573.5 vs. 435.9 ± 1.1 µg/g) and Zn (128.1 vs. 116.7 ± 1.0 µg/g), while BN had greater ($P < 0.05$) serum Mo (5.0 vs. 2.5 ± 0.6 ng/mL) and liver Mn (9.1 vs. 8.0 ± 0.4 µg/g). Calf BW and ADG at weaning were increased by prenatal ORG TM. These data indicate calf TM status varies by day relative weaning, prenatal TM source and breed. Additional research is needed to determine how TM source affects calf immune function, performance, carcass traits and reproductive potential.

Key Words: trace mineral, prenatal nutrition, weaning

Small Ruminant Symposium: Genetic improvement in small ruminants for the future

714 National Sheep Improvement Program. David Notter*, *Virginia Tech, Blacksburg, VA.*

The US National Sheep Improvement Program (NSIP) was established in 1987 and is supported exclusively by US sheep breeders and their organizations. In 2010, limited options for sustainable involvement with US institutions led NSIP to establish a partnership with Meat and Livestock Australia to merge genetic evaluation activities with LAMBPLAN, the Australian sheep genetic evaluation system. Outsourcing genetic evaluation services to LAMBPLAN expanded NSIP resources and increased the frequency of updating of EBV. The operating philosophy of NSIP correspondingly evolved to become a proactive force for genetic improvement of US sheep. LAMBPLAN offers EBV for 85 different traits. NSIP provides EBV for a subset of these traits including body weights from birth through adulthood, reproductive and ewe productivity traits, ultrasonic predictions of fat and loin muscle depths, fleece weight and quality measurements, and worm resistance. LAMBPLAN offers selection indexes for various breeds and production objectives, and NSIP offers indexes specific to US breeds and conditions. NSIP serves all US sheep breeds, and also offers genetic evaluation services for meat goats, but is dominated by 4 groups: (1) Western range breeds (mainly Targhee, Rambouillet and Columbia), (2) terminal sire and other meat breeds (mainly Suffolk, Hampshire, Dorset, and Shropshire), (3) maternal wool breeds (mainly Polypay), and (4) hair sheep breeds (mainly Katahdin). In 2013, 123 flocks submitted data to NSIP. The 4 breed groups each submitted records on 2,700 to 3,200 lambs, and the 9 breeds listed above accounted for over 85% of NSIP flocks. Genetic trends in US breeds document the effectiveness of selection. Use of genomic strategies to increase accuracies of EBV is a major focus of LAMBPLAN research and development, providing opportunity for corresponding activities in NSIP. Detailed phenotypic records of animal performance are increasingly recognized as essential for discovery and validation of genomic markers, and NSIP is increasingly recognized as the most comprehensive repository of sheep data in the US. Storage of DNA from all progeny-tested NSIP sires and a sample of lambs in each major NSIP breed is intended to allow NSIP to make a larger contribution to meeting the research needs of the sheep industry.

Key Words: sheep, estimated breeding value, genetic evaluation

715 Genomics and marker-assisted selection in small ruminants. Brian L. Sayre*, *Virginia State University, Petersburg, VA.*

As the world climate and population levels evolve, high demands are placed on livestock production systems. Small ruminants, especially goats, are critical to the small-scale producer as they are easy to acquire and maintain in sparse pasture and marginal crop regions that cannot easily sustain other livestock. Current small ruminant production systems around the world depend heavily on locally adapted breeds. While indigenous small ruminant genetics are relatively uncharacterized, most have undergone generations of adaptation and genetic isolation or bottlenecks, creating a large genetic reservoir of variation in genes and genetic markers. Identifying genes and genetic markers associated with disease susceptibility and resistance in locally adapted breeds is necessary to preserve local germplasm and to apply state-of-the-art genomic-based strategies to meet global food security challenges. Of particular interest are the genes or genetic markers involved in resistance to internal parasites and disease, and resilience to climate differences. The aim of the current small ruminant genetics and genomics research is the development and utilization of state-of-the-art genomic-based evaluation tools for characterization of sheep and goat populations, development of sustainable strategies for improved production, and increased education and research opportunities. International collaborations have led to the development of de novo genome assembly projects, Illumina SNP panels and, for goats, a collaborative database for submission and access to goat SNP and re-sequencing data for breeds and populations worldwide (ADAPTmap). These tools establish the baseline necessary for the development and application of marker-based selection to the sheep and goat industry.

Key Words: genomics, marker-assisted selection, small ruminant

716 Genetic improvement for internal parasite resistance. Daniel J. Brown*, *Animal Genetics and Breeding Unit, University of New England, Armidale, NSW Australia.*

Internal parasites impose a huge financial burden for small ruminants across the world with recent estimates in Australia suggesting the cost could be as high as $10AUD per breeding ewe per year. Genetic improvement has to be a key part of any integrated pest management plan for internal parasites. The number of worm eggs per gram of feces (WEC) is known to be a good indicator of internal parasite burden and is moderately heritable in both sheep and goats ($h^2 = 0.2$ to 0.3). Breeding for internal parasite resistance is complicated by the fact that several different worm species can be present depending on the location, time of year, management practices and prevailing environmental conditions. In Australia, the national genetic evaluation system (Sheep Genetics) only uses data from *Haemonchus contortus* and *Trichostrongylus* spp. to reduce some of the complications caused by these multiple worm species. It is also known that WEC is genetically not the same trait across ages and thus there is benefit in breeders recording multiple assessments throughout the animal's life. Furthermore, research in Australia suggests that the genetic correlations between different sites across Australia may also be significantly less than one, and thus making it important for breeding animals to be assessed in similar environments to those in which their progeny are expected to exhibit their resistance. These issues make the estimation of breeding values and genetic improvement of this trait more challenging. Despite these challenges ram breeders in Australia have managed to make significant genetic improvements in WEC. Some breeders have reduced WEC by up to 5% per year for the last 15 years, while simultaneously improving other production traits. On-farm, these breeders have reported reduced requirements for drenching, less scouring and greater production. Genomic information has also been incorporated into the routine Sheep Genetics evaluations. Breeders now have the ability to obtain moderately accurate ASBV predictions for WEC (plus a range of other traits) via a simple blood test.

Key Words: internal parasite, worms, sheep

717 Breeding strategies in sheep for low-input management systems. Ronald M. Lewis*[1], Napoleón Vargas Jurado[1], and Kreg A. Leymaster[2], [1]*Department of Animal Science, University of Nebraska, Lincoln, NE,* [2]*Roman L. Hruska US Meat Animal Research Center, USDA-ARS, Clay Center, NE.*

Profitability of sheep enterprises increasingly depends on using low-input, pasture-based management systems where costs can be curtailed without sacrificing productivity. Their success rests on using maternal genetics well adapted to such systems yet with attributes to produce a quality product. In historically medium-wool industries, fleece has become a cost rather than a source of revenue. Therefore, hair sheep germplasm has been incorporated into maternal lines to facilitate wool shedding (WS), and to enhance health (e.g., internal parasite resistance) and fitness (e.g., vigor, aseasonality, longevity). Yet, there are caveats. Hair sheep are smaller in mature size and typically lighter muscled. Within the US, carcass weights are traditionally at least 30 kg, a challenge to achieve with smaller breeds. The Katahdin breed reflects that concern, where Caribbean hair sheep were combined with wool breeds and Wiltshire Horn, a larger mature size breed that sheds. Markets for hair sheep lambs of lighter weight have evolved, allowing greater flexibility. Crossing with terminal sires offers another option, although its impact on overall productivity needs attention. The definition of a maternal breed-type ideal for low-input systems is equivocal. At the US Meat Animal Research Center, a 1/4 Katahdin, 1/4 White Dorper and 1/2 Romanov composite has been established to attain an intermediate optimum. The inclusion of Romanov increased prolificacy, allowing identification of ewes able to produce, nurture and rear twin and triplet lambs in a low-input system. The composite retains 62.5% of heterosis benefiting health and fitness. Data on WS, color, horns, major genes affecting disease, and rearing status have been collected, and used independently in selection. Genetic analyses of WS data have been conducted. Among 3345 autumn WS records on ewes, 64% had less than 25% wool coverage; WS was moderately heritable (0.26) and repeatable (0.40). This composite is early in development, and further generations of *inter se* mating would benefit its evaluation. A breeding program for low-input systems necessitates combining breeds. A strategy capturing key attributes of a maternal breed-type, as defined through a selection index, is needed to sustain its role in the sheep industry.

Key Words: sheep, low-input, maternal composite

ADSA-ASAS Northeast Section Symposium: Bridging the gap between animal protein production and consumers, current and future

718 University efforts to generate community support for a university farm. Joe Hogan*, *The Ohio State University, Wooster, OH.*

Maintaining the functional viability of university farms to assure availability of animals for teaching and research requires the cooperation of many entities both within and outside the university. The approach used by the Waterman Dairy on the Columbus campus of The Ohio State University to involve several groups outside the university will be presented as a successful example of community support. Key contributions from communities outside the university to be highlighted were provided by dairy producers, a breed association, local civic organization dedicated to water conservation, state governmental agencies and a dairy processor. The essential needs for cooperation from college and departmental administration will also be discussed. Specific outcomes from these private sector and university communal approaches for dairy farm support were the repopulation of the herd, renovation of facilities, employment of land and water conservation measures, and innovative marketing of products from the herd. Based on the experiences gained from revitalization of the Waterman Dairy, specific suggestions for involving community support for university farms will be presented.

Key Words: university farm, community support

719 The New York State Junior DAIRY LEADER Program. Deborah J. Grusenmeyer*, *Cornell University, Ithaca, NY.*

The Junior DAIRY LEADER program prepares 16 to 19 year olds for successful dairy industry careers. The mission is to give teens an opportunity to build enthusiasm for the dairy industry through personal, professional and leadership development in a networking environment, while discovering the diversity of career options in agriculture. Exposure to different herd, crop and farm business management techniques gives participants the opportunity to experience diverse dairy management styles and ideas. The program also focuses on developing leadership skills necessary to make positive changes and contributions to the dairy industry and challenges participants to focus on personal and career development. Junior DAIRY LEADER is a yearlong program combines a series of 8 hands-on workshops focusing on specific facets of the dairy industry in veterinary science, dairy nutrition, production management, and on-farm production analysis. In addition, participants interact with dairy producers, industry professionals, and other dairy interested young people from across the state and region. Youth will gain advanced industry training for employment and furthering their education and career planning for successful dairy careers. Since 1999, 319 participants and graduates of the program have or will continue their education in dairy or industry related careers. Based on survey results from participants from 1999 to 2013 (using a scale of 1 to 5 and considering rankings of 3 and up to be considered significant influence), 96% of participants felt the program influenced their decision to pursue or enter into an agricultural career. In the area of dairy knowledge and technical skills 98% had an increase in dairy knowledge and 77% learned technical skills directly applicable to production management. In addition participants responded to being better prepared in the following areas: communication skills (97%), working as a team (87%), choosing a career path (92%), problem solving (69%), and networking with other dairy industry people/leaders (85%). The Junior DAIRY LEADER survey results from the 1999 to 2013 show that 58% of participants who were undecided on a career path before the program, chose to a career path in agriculture after participating in the program

Key Words: dairy, education

720 Using social media to increase consumer acceptance of animal agriculture. Janeal W. Yancey*, *University of Arkansas Division of Agriculture, Fayetteville, AR.*

Social media has fundamentally changed the way people communicate. As animal scientists, we have a story to tell and information to share about agriculture, and we need to be part of this new digital conversation. In today's environment, we see that science is constantly being denied, whether it concerns technology used in food production or the science behind vaccinations for our children. Consumers receive lots of information about their food and try to use that information to make decisions about feeding their families. Decisions about food are highly personal, and in the food industry, we must understand that facts alone do not drive the decisions consumers are making. To really reach consumers, we should be ready and willing to engage in dialog with them. Animal scientists have to embrace a listen-first mentality. We must understand a consumer's questions before we can answer them. Be ready to embrace skepticism; to connect with someone, you must let them know that you understand their concerns. Do not dismiss them. Research from the Center for Food Integrity reveals that a Mom Scientist is the most believable messenger for consumers concerning controversial topics about food production, such as antibiotics or GMO foods. Theodore Roosevelt said, "People don't care about how much you know until they know how much you care." On social media, scientists should be more than the researcher; you need to also be a mom, a dog lover, an artist, or a runner. Shared values carry more weight with consumers over time than a PhD. Last, remember that many voices are needed to fully engage the consumer population. Embrace the diversity among animal scientists and share animal agriculture with people that you really connect with. The ultimate goal is not to win scientific or social arguments, but to connect with people in ways that you become a resource to them (and them to you) for years to come.

Key Words: advocacy, consumer education, social media

Animal Behavior and Well-Being II

721 Effects of dietary fiber on the welfare of submissive multiparous sows.

Eridia Pacheco*, Mayra Lopez, and Janeen Salak-Johnson, *University of Illinois at Urbana-Champaign, Urbana, IL.*

The effect of social rank, dietary fiber, and length of feeding stalls on the well-being of sows kept in groups was assessed on a sub population within the pens of the larger study. At gestational d 37, sows that were randomly assigned by BW and parity in a 2 × 2 factorial arrangement to a dietary treatment of either (a) soy hulls-wheat middlings diet (WM) or (b) DDGS-corn germ meal diet (DDGS); and feeding stall length of either (c) 2 ft. (short) or (d) 6 ft. (long) in groups of 9 sows/treatment (36/block), were put in a feed competition test to determine social rank (n = 48). Within each treatment pen, dominance value was calculated based on aggressive encounters among sows from the feeding test; with the 2 highest-ranking sows being dominant (DOM) and 2 lowest-ranking sows being submissive (SUB). Analysis of data was focused on this sub population of sows. Sow BW was recorded on gestational d 30, 70, 90, 104, and d 131 (end of lactation). Lesion scores and blood glucose levels were recorded every 3 d for 2-wks post mixing (Phase 1), and then bi-weekly until gestational d 104 (Phase 2). Live observations during feedings were performed at the first feeding, after mixing, and every 3-wk until gestational d 104, all aggressive encounters were recorded. Regardless of diet, SUB sows had greater ($P < 0.01$) blood glucose than DOM sows. Overall, lesion scores decreased in severity from phase 1 to phase 2, but in phase 2, DOM-sows had less severe scores compared with SUB-sows ($P < 0.01$). DOM-sows gained more ($P < 0.01$) BW from d 30 till d 70 of gestation, and then again from d 90 till d 104. Total number of aggressive encounters were lowest among DOM-sows fed DDGS-diet and in pens with long feeding stalls and these same sows made less aggressive encounters toward SUB-sows ($P < 0.01$). SUB-sows fed WM-diet had more ($P < 0.05$) total piglets born alive than DOM-sows fed the same diet. SUB-sows fed WM-diet and kept in pens with short feeding stalls had more ($P < 0.05$) total piglets born compared with SUB-sows on other treatments. These results indicate that dietary strategies and social status may serve as a management tool to improve sow well-being in small group pens.

Key Words: swine, social rank, welfare

722 Behavioral changes in steers supplemented with tryptophan and vitamin E.

Paula R. Huenchullán[2] and Rafael E. Larraín*[1], [1]*Facultad de Agronomía e Ingeniería Forestal, Pontificia Universidad Católica de Chile, Santiago, Chile,* [2]*Facultad de Ciencias Veterinarias y Pecuarias, Universidad de Chile, Santiago, Chile.*

Tryptophan (TRP) and vitamin E (VITE) modulate the stress response in animals, so they may also induce changes in behavior. The goal of the study was to determine the effect of high TRP and VITE diets on steers behavior. Angus steers were used in 2 experiments (E1 and E2), with a 21-d washout period in-between. Steers were distributed in pairs in 16 pens and fed the experimental diets for 5 d before a stressful event (45 min in a single file chute for E1 and slaughter for E2). Diets were designed in a factorial arrangement, with TRP at 0 and 100 mg·kg $BW^{-1}·d^{-1}$ and VITE at 0 and 2000 $IU·hd^{-1}·d^{-1}$ (n = 4 pens). Steers were randomly assigned to diets in E1, and E1 diet was used as blocking factor for randomization in E2. Video cameras were used to record 24 $h·d^{-1}$ during supplementation, and also one day after stress in E1. Behavior was evaluated at d 2, 4, 5 and 6 of starting supplementation in E1, and at d −1, 0, 2 and 4 in E2. Behavior was observed every 10 min and compared as proportion of observations where animals were in standing or lying posture; and doing one of the following activities: defecating, drinking, eating, interacting, no detectable activity, ruminating, self-grooming, and stereotypic movements (bar licking, tongue rolling, etc.). Statistical analysis was made using repeated measures, with TRP, VITE, time and their interaction in the model. In E2, diet in E1 was used as blocking factor and d −1 was used as covariate. When ANOVA $P < 0.1$ for TRP, VITE or TRP × VITE, comparisons with control were made using Dunnett adjustment. When ANOVA $P < 0.1$ for any interaction with time, comparisosns were made within day. In E1, none of the diets including TRP or VITE was different to the control in any variables. In E2, animals receiving TRP tended to spend a higher proportion of their time eating ($P = 0.091$), while animals receiving VITE tended to spend a smaller part ($P = 0.076$) than their controls. Animals receiving TRP and TRP+VITE presented less stereotypic movements ($P = 0.008$ and 0.017, respectively) than their controls, and animals receiving VITE spent a smaller proportion of their time interacting ($P = 0.032$). We concluded that TRP and VITE produced small changes in behavior in steers and no changes the day after a stressful event.

Key Words: tryptophan, vitamin E, behavior

723 Rumen and cecum expression of genes related to inflammation and behavior in Holstein bulls fed high-concentrate diets with different concentrate presentation forms and with or without straw supplementation.

Maria Devant*[1], Greg Penner[2], Bruna Quintana[1], Francesc Fábregas[1], Alex Bach[3,1], and Anna Arís[1], [1]*IRTA-Ruminant Production, Animal Nutrition, Management, and Welfare Research Group, Caldes Montbui, Spain,* [2]*University of Saskatchewan, Saskatoon, Saskatchewan, Canada,* [3]*ICREA, Barcelona, Spain.*

Twenty-four individually housed Holstein bulls (395 ± 7.3 kg BW and 252 ± 3.1 d age) were exposed to a 2 × 2 factorial design (meal vs. pellet and with vs. without straw) to evaluate the effect of concentrate form and provision of straw in finishing diets. Concentrate and straw consumption were recorded monthly, and behavior by scan sampling biweekly. Bulls were slaughtered after 64 d. Rumen and liver lesions were recorded and tissue samples were collected. Data were analyzed using an ANOVA. Straw supplementation increased ($P < 0.01$) percentage of rumination observations (9.4 vs. 3.1 ± 1.02%), and decreased ($P < 0.01$) oral non-nutritive behaviors (0.74 vs. 1.68 ± 0.12 times/15 min) relative to bulls not provided straw. Provision of straw increased rumen pH, but the magnitude was greater when meal was provided compared with pellet (interaction $P < 0.05$). When straw was not supplemented, all rumens had papillae fusion, whereas only 16.7% of bulls fed pellet and straw had papillae fusions ($P < 0.05$). In the rumen straw provision numerically increased expression of free fatty acid receptor 2 (stimulates PYY and serotonin secretion, $P = 0.06$), α-2C adrenergic receptor (modulates immune reactions and behavior, $P = 0.09$), and increased occludin and claudin-4 (tight junction proteins, $P < 0.05$), along with IL-1β, TNFα (pro-inflammatory cytokines, $P < 0.01$) and toll-like receptor-4 ($P < 0.01$); moreover, it also numerically increased β-defensin1 (antimicrobial peptide, $P = 0.10$), and intestinal alkaline phosphatase ($P = 0.10$), and increased CASP3 (pro-apoptotic gene, $P < 0.05$) and numerically increase SPC25 (proliferative marker, $P = 0.06$). Pellet decreased rumen gene expression of α-2C adrenergic receptor ($P < 0.05$) and increased occludin ($P = 0.06$) and monocarboxylate transporter 1 ($P < 0.05$). Bulls without straw had increased expression of IL-1β in the cecum. In conclusion, the lack of straw supplementation in bulls fed

high-concentrate diets modifies behavior, affects rumen macroscopic morphology, and expression of epithelial genes related to inflammation.

Key Words: bull, gut-brain axis, nutrition and behavior

724 Immunological castration of gilts changes behavior, weight gain, and reproductive development. Guilherme Picinin* and John J. McGlone, *Texas Tech University, Lubbock, TX.*

Physical castration is a current practice on commercial farms used to reduce boar taint and aggressive behavior. Immunological castration (IC) using a GnRF conjugate is an alternative to physical castration. IC males eat more, grow faster and are easier to handle than intact males. The objective of this study was to evaluate the effect of IC on gilt behavior, handling during loading and unloading, weight gain, reproductive function, and physiological responses. Gilts were given a first immunization at wk 3 of the finishing period (about 12 weeks of age) followed by a second immunization at wk 7 of the finishing period. Gilts were marketed when they were 143.6 kg on average. Behaviors of immunized gilts (IG) ($n = 48$) and control gilts (CG) ($n = 48$) were assessed 2 times through the finishing period, one before (second week of grower-finisher phase) and one after effective immunization (eleventh week of grower-finisher phase). Handling during loading and unloading a livestock trailer was also recorded during a simulated transport experience. Weight gain was assessed weekly. Physiological response was assessed via heart rate, plasma cortisol and ovarian weights. IG spent more time feeding (4.17%) ($P = 0.04$) than CG (3.43%). However, CG spent 1.41% more time standing ($P = 0.002$) and 0.17% more time drinking ($P = 0.01$) than IG. No difference was found in transport and handling measures between treatments. At the last week of grower-finisher phase IC were 5.15 kg heavier than CG ($P = 0.04$). Control gilts had 225% heavier ovaries than IG ($P < 0.001$). No differences were found in plasma cortisol and heart rate between CG and IG. Immunological castration does not induce a stress response or cause behavioral problems in the home pen or during handling and transport compared with intact gilts. IC is an effective tool to increased gilt feeding behavior, feed intake, and weight gain with no identified animal welfare concerns.

Key Words: GnRF immunization of gilts, heavy market weight, behavior-handling

725 Behavioral responses of livestock exposed to unmanned aerial systems. Phil Urso, Marcy Beverly*, Stanley Kelley, John Wilson, Jessica Leatherwood, Mark Anderson, and Kyle Stutts, *Sam Houston State University, Huntsville, TX.*

Unmanned aerial systems (UAS) have been gaining popularity in several fields. Their uses in agriculture provide major management benefits while assessing production conditions. This study utilized an UAS to determine the flight zone upon approach and while hovering over different livestock species: cattle, goats, and horses. Barometric pressure, temperature, wind speed, and noise levels were all recorded to eliminate environmental variables affecting behavior. Selected animals were held in pens several days before the UAS flight to allow for the animals to acclimate and become familiar to the test area. Test areas were spacious so animals could flee and not feel confined during UAS approach and hover. Groups were tested with the UAS 3 times on separate days. Horses were tested in 2 independent groups: outdoor round pens and indoor arena. Cattle were split into 3 groups: cows with calves (CWC), cows without calves (COC), and weaned heifers (WH). Goats were tested as a group in their home pasture. With each test group, the UAS began at a height of 75 feet above the group and descended at 5 feet increments when hovering. Environmental measurements were similar for each flight. All groups were acoustically signaled before seeing the UAS. The animal flight zone varied by test group at different hovering heights. The COC and WH allowed the system to hover at 15 feet above ground before they casually moved from the UAS. CWC, did not flee from under the drone, but huddled closer together around their offspring responding in a protective behavior. The goats allowed the UAS to hover at 10 feet before moving. Horses tested indoors expressed a startled, frightened behavior at 25 feet. The outdoor tested horses were calm and showed unstartled behaviors consistent with other test groups. The geldings were much more relaxed and calm with the approach of the UAS than the mares, which had a higher flight zone. Though foals were not present, this difference could be attributed to their protective instinct. Understanding these behavioral responses could help producers utilize UAS for herd observations without disturbing animals in their natural environments.

Key Words: unmanned aerial system (UAS), flight zone, behavior

726 ADSA®-EAAP Speaker Exchange Presentation: REM sleep time varies during the lactation cycle. Emma Ternman[1], Emma Nilsson[1], Per Peetz Nielsen[1,2], Laura Hänninen[3], and Sigrid Agenäs*[1], [1]*Department of Animal Nutrition and Management, Swedish University of Agricultural Sciences, Uppsala, Sweden,* [2]*Department of Large Animal Sciences, University of Copenhagen, Copenhagen, Denmark,* [3]*Department of Production Animal Medicine and Research Centre for Animal Welfare, University of Helsinki, Helsinki, Finland.*

Little is known about sleep in dairy cows. This study investigated the influence of stage of lactation on total lying time, rumination time and rapid eye movement (REM) sleep in dairy cows. Data on rumination and REM sleep was obtained by electrophysiological recordings in 19 high yielding dairy cows during 7 24-h recording sessions; late dry period, lactation week (wk) 2, 7, 13, 21, 37 and early in the next dry period. In addition, standing and lying was recorded using IceTag data loggers. During recordings cows were kept in individual pens with ad lib access to silage and water. Data analysis included total time and duration of bouts and was separated for daytime (05.00–21.00 h) and night (21.00–05.00 h). Effect of stage of lactation cycle and day/night distribution of activity was tested with a linear mixed model (SAS 9.4). In total, cows were lying down for 50 ± 4% of the time in the study, distributed as lying half of the night in early lactation (wk 2 and 13) and up to 2/3rds of the night in other stages of the lactation cycle. During daytime more time was spent standing than lying in all stages of lactation. Overall, lying bouts were longer at night than at daytime (51.7 ± 3 vs. 43.3 ± 3 min, $P < 0.005$) and standing bouts were shorter at night than at daytime (33.1 ± 3 vs. 58.8 ± 3 min, $P < 0.001$). Rumination time was longest in wk 7 (573 ± 23 min) and shortest in late dry period (458 ± 23 min) ($P < 0.01$) and bouts were longer at night than day (36.3 ± 1.2 vs. 29.7 ± 1.1 min, $P < 0.001$). REM sleep time was affected by stage of lactation ($P < 0.05$) with the longest time (52 ± 4 min) in late lactation (wk 37) and shortest in early lactation (34 ± 4 min). The main part of REM sleep was found at night and REM sleep bouts were longer at night than day (4.6 ± 0.1 vs. 4.1 ± 0.2 min, $P < 0.001$). Total lying time and rumination time found in this study was in accordance with previous findings. Cows rest lying down and even if total lying time during 24 h does not vary during the lactation cycle there is a variation in the distribution of the lying time between day and night and in the amount of REM sleep.

Key Words: lying, REM, sleep

727 Assessment of cognitive ability and memory retention in neonatal goats. Isabelle C. Withrock*, Paul J. Plummer, Timothy A. Shephard, John Stinn, Hongwei Xin, Johann F. Coetzee, and Suzanne T. Millman, *Iowa State University, Ames, IA.*

Our research team is exploring the suitability of inhalant methods for euthanasia of neonatal livestock. A key component of this project is examining the aversiveness of carbon dioxide and argon gases by preference tests and conditioned place avoidance. However, little is known about the cognitive ability of neonatal livestock. The objective of this study was to determine the problem-solving ability of goat kids by using a conditioned place preference paradigm. A secondary objective was to determine if the presence of a novel odor disrupts previous learning. A preference-testing box was custom built with 2 connected chambers divided by a sliding door. One chamber was vacant while the second chamber held a 32oz milk reward. Twelve mixed breed dairy kids were enrolled in the study. Kids were given a 5 min acclimatization period in the control chamber before the sliding door was opened. Kids were then given 5 min to travel through the doorway to access the milk, after which kids were physically assisted through the doorway. Kids were allotted 10 min in the treatment chamber to consume their milk meal. After 5 d of testing, kids were not tested for 3 to 6 d. Kids were then tested with a novel odor (<1 oz peppermint oil) present in the treatment chamber. The following behaviors were collected using live observation: frequency of vocalizations and defecation, latency to enter treatment chamber, latency to suckle and volume of milk consumed. A mixed effect Poisson regression model showed that vocalizations were reduced from d 1 to all other days ($P < 0.0001$). Mixed effect logistic regression models showed defecation behavior did not differ ($P = 0.3064$). Mixed effect Cox models showed that latency to enter the treatment chamber and latency to suckle also decreased from d 1 ($P < 0.0001$). Milk consumption increased from d 1 to d 6 based on a linear mixed model ($P < 0.0001$). These results suggest neonatal kids have the ability to problem solve, and a novel odor did not disrupt learning. Hence, approach-avoidance and conditioned place associations using a milk reward are relevant paradigms for asking kids about aversiveness of inhalants used for stunning and euthanasia.

Key Words: goat, learning, memory

728 Development of a novel automated method of measuring tail-flick behavior in beef cattle. Diego Moya*[1,3], Carollyne E. J. Kehler[2], Sonia Marti[3], Kim H. Ominski[2], Christy Goldhawk[1], and Karen S. Schwartzkopf-Genswein[3], [1]*University of Calgary, Calgary, AB, Canada,* [2]*University of Manitoba, Winnipeg, MB, Canada,* [3]*Agriculture and Agri-Food Canada, Lethbridge, AB, Canada.*

Tail-flicking behavior is a reliable indicator of pain in cattle, however visual observation is challenging and time-consuming. Two trials were conducted to validate the use of tri-axial accelerometers to assess tail-flicking behavior in beef cattle. In Exp. 1 (proof of concept), accelerometers (HOBO, Onset Computer Corp., Pocasset, MA) were affixed with vet wrap to the tail of 5 Angus heifers at 3 different positions: 8 cm below the base, 26 cm below the base, and above the tail switch. The HOBOs were set to measure acceleration at 20 readings × s^{-1} for a 10-min period, with a total of 49 periods of data collection. The heifers were videotaped concurrently, and viewed by the same observer to determine the number of tail movement events. Data obtained from the vector sum of the acceleration of the X, Y and Z axes was cleaned using either 2 standard deviations, the 80th percentile or the mean as the threshold below which tail movement was considered unintentional, and therefore removed from the data set. Data were then pooled into movement events using either a 1- or 2-s criteria as the time between 2 tail movements to be considered separate movement events. The resulting data sets were summarized for each 10-min period as total acceleration, maximum acceleration, average acceleration per movement event, and percentage of time in motion. Data from HOBOs located at the tail switch, and processed with the 80th percentile threshold and the 2-s criteria, resulted in the greatest ($P < 0.01$) correlation with the number of tail movement events observed via video ($r = 0.9217$; $P < 0.01$). In Exp. 2 (biological validation), accelerometers were affixed above the tail switch of 14 bulls to measure movement of the tail during 2 20-min periods that took place from 3 to 6 h before and immediately after castration. Total acceleration was greater ($P = 0.03$) after than before castration (805.0 vs. 409.7 ± 18.27 *g*-force, respectively), suggesting that HOBO captured the tail-flicking behavior caused by the discomfort of the procedure. Accelerometers provide an objective and efficient method of measuring tail-flick behavior in beef cattle.

Key Words: welfare, behavior, pain

729 Relationships between maternal defensiveness behavior and pre-calving flight speed in primiparous Nellore cows. Mateus J. R. Paranhos da Costa*[1,2], Tiago S. Valente[2], and Aline C. Sant'Anna[1], [1]*Departamento de Zootecnia, Faculdade de Ciências Agrárias e Veterinárias, UNESP, Jaboticabal-SP, Brazil,* [2]*Programa de Pós-Graduação em Genética e Melhoramento Animal, Faculdade de Ciências Agrárias e Veterinárias, UNESP, Jaboticabal-SP, Brazil.*

Defensiveness is an important aspect of maternal temperament, which can be defined as the set of cow's behavior in response to disturbance of their relationship with newborn calf. The aim of this study was to evaluate the relationship between 2 temperament traits, flight speed (FS) measured 6 mo before calving and maternal defensiveness in primiparous Nellore beef cows. The FS was performed for 196 heifers measuring the speed (in m/s) at which each animal exited the cattle crush after weighting. The females calved around 24 mo of age and had their maternal temperament assessed 24h after birth, during the handling for calf earmarking and weighing. We assessed the reactions of cows when their newborns were caught in a corral pen, using a maternal defensiveness score (MD), which ranged from 1 (cow exhibited no attention to the calf and remained indifferent to the procedure) to 6 (cow displayed aggressive behaviors toward the handler, trying to attack them). The latency to each cows touch the calf (LT, s) after finishing the handling procedure and the calf be released to the pen was also recorded. Pearson's coefficients of correlation were calculated among the MD, LT and FS. A significant correlation was found between MD and LT ($r = -0.62$, $P < 0.01$), indicating that the shortest latency was related to a more defensive behavior toward the calf. The FS had significant, but low correlation with LT ($r = 0.16$, $P = 0.04$), and it was not correlated with MD ($r = -0.10$, $P = 1.79$), suggesting that an indicator of fear/excitability is not associated with an indicator of MD. There is a belief among the Brazilian farmers that the calmer Nellore cows during handling are likely to be less defensive toward their calves. However, according to the present results the cows' temperament assessed during handling in the corral is not related with cows' MD, providing clear evidence that cows with more excitable yearling temperament (faster FS) would not present more defensive behavior toward their calves compared with the calmer ones.

Key Words: maternal behavior, temperament, beef cattle

730 Relationship between quantitative measures of temperament and observed behaviors in receiving cattle. Kelsey A. Bruno*, Eric S. Vanzant, Alex W. Altman, Monoj Kudupoje, and Kyle R. McLeod, *University of Kentucky, Lexington, KY.*

Temperament has been related to gain and intake in beef cattle; more temperamental animals often have decreased gain and intake. Intake effects may be partially mediated through social interactions in that some temperament measures may directly relate to social dominance behavior. To examine the relationships between temperament, growth, and social dominance behavior, 32 crossbred steers were used is a 56-d RCBD experiment with a 2 × 2 factorial treatment structure. Temperament treatments (assigned on d −7) were chute exit velocity (EV; slow vs. fast) and objective chute score (OCS; low vs. high), a novel temperament measure, the CV of weights collected at 5 Hz for 10 s while an animal's head was restrained in a chute. Electronic ear tags with accelerometers were used to continuously measure animal activity. Social dominance behaviors were quantified using video records of 2-h intervals directly following feeding for d 1–13. Dominance was calculated as average dominance index and David's score. Jugular blood samples were collected to analyze antibody response to leptospirosis vaccines. There were no EV by OCS interactions ($P \geq 0.23$) for average daily gain (ADG) or antibody titers. High OCS steers had higher ADG than low OCS steers ($P < 0.01$) and slow EV steers had higher ADG than fast EV steers ($P = 0.02$). Slow EV animals had an increased antibody response compared with fast EV animals ($P = 0.05$). Ranking in the dominance hierarchy was influenced by an EV x OCS interaction ($P \leq 0.02$), but there was not a linear relationship between dominance ranking and ADG. Low OCS steers tended to have higher daily activity counts than high OCS steers ($P = 0.11$), and fast EV steers had higher ($P = 0.08$) activity counts than slow EV steers. EV and OCS were independently related to differences in ADG. Although dominance ranking was significantly related to these 2 independent temperament measures, it was not linearly related to ADG. Alternatively, differences in accelerometer-based activity counts among temperament groups did correspond with trends in growth responses.

Key Words: temperament, dominance, beef cattle

Animal Health Symposium: Maintaining animal health in organic dairy herds

731 Understanding animal welfare on organic dairy farms.

Kathryn Proudfoot*, *The Ohio State University College of Veterinary Medicine, Columbus, OH.*

In response to an increasing demand for organic products, the number of certified organic dairy farms in the United States has increased dramatically over the last decade. The consumers and concerned citizens who are driving this demand report a desire to support agricultural systems that are perceived to be more sustainable, more natural, and have higher standards of animal welfare. Despite the perception that organic farms maintain high levels of animal welfare, the relationship between the 2 is not straightforward. The objective here is to review the current literature on the welfare of dairy animals in organic systems compared with conventional. The 2 systems clearly place different value on animal welfare concerns; conventional farms place greater emphasis on biological functioning and health, whereas organic farms place higher value on the animals' ability to perform natural behaviors and live in a natural environment. In the United States, organic farms are required to provide animals with year-round access to the outdoors, including at least 120 d of access to pasture during the grazing season. Moreover, synthetic chemicals are restricted, including antimicrobials commonly used to treat ill animals on conventional farms. A reliance on naturopathic remedies leads to challenges when it comes to improving welfare for the individual animal, as organic producers have fewer treatment options and must make difficult decisions when dealing with ill animals. There is also concern regarding the efficacy of these naturopathic treatments, and little research to support their usage. Despite efforts to create preventative disease control strategies, the limited research available indicates that there is little difference in disease prevalence between organic and conventional systems. There are clear gaps in the literature evaluating the welfare of animals on organic dairy farms. Continued efforts are still needed to identify effective ways of preventing disease, and to develop effective naturopathic therapies to help reduce the number of ill animals and the duration of time that each animal is ill. A better understanding of how some organic farms are currently able to maintain low disease incidence could also provide valuable insight into ways forward.

Key Words: well-being, organic, dairy

732 Nutrition and performance of lactating dairy cows in organic dairy herds.

Andre F. Brito*, *University of New Hampshire, Durham, NH.*

The number of US organic dairy cows increased from 2,265 in 1992 to 254,771 in 2011. Despite this rapid growth, organic herds are smaller than conventional herds, and produce approximately 30% less milk/cow (McBride and Greene, 2009). These discrepancies are explained by geographical location as well as management and nutrition. First, about 86% of organic dairies are located in the Northeast and Upper Midwest, which are characterized by herd sizes smaller than those from the West (McBride and Greene, 2009). Second, organic dairies must comply with the National Organic Program Pasture Rules, which mandate ruminants to consume at least 30% of their total DMI from pasture for a minimum of 120 d during the grazing season. Even though 95% of organic dairies use rotational grazing, they feed approximately 45% less grain than conventional dairies (Stiglbauer et al., 2013). Moreover, only 49% of WI organic dairies use corn silage (Hardie et al., 2014), and this figure is likely lower in other regions (e.g., Northeast). Thus, higher reliance on pasture and less grain and corn silage feeding limit metabolizable energy intake likely explaining the lower milk production in organic than conventional farms. Reduced milk production in organic dairies may be also associated with the low number of nonpasture feeds incorporated into lactation rations as well as the predominant use of component feeding in detriment of TMR. There is a growing interest among organic dairy farmers to feed lactating cows exclusively forage-based diets. In fact, organic milk processors (e.g., Organic Valley) are currently paying premiums for farmers shipping "grass-fed milk" in specific states (e.g., NY, PA, CA). In addition to reduced animal performance, the short- and long-term implications of no grain supplementation on animal health, BCS, and reproduction need to be addressed. Research should further address the effects on animal performance and health of feedstuffs commonly fed in organic dairies such as kelp meal, liquid molasses, and barley fodder, as well as the incorporation of alternative forage crops (e.g., small grains, millet, brassicas) as grazing options.

Key Words: organic dairy, nutrition, performance

733 Managing transition cows and reproduction in certified organic dairy herds.

G. M. Schuenemann*[1], M. G. Maquivar[2], A. Hunter[1], A. A. Barragan[1], J. M. Piñeiro[1], J. S. Velez[3], H. Bothe[3], and S. Bas[1], *[1]The Ohio State University, Columbus, OH, [2]Washington State University, Pullman, WA, [3]Aurora Organic Farms, Boulder, CO.*

It is common to observe large between-herd variation in transition management practices and reproductive performance of dairy cows under certified organic management. Metabolic and infectious diseases increase the risk of voluntary and involuntary culling within 60 d in milk (DIM) and are a major animal welfare issue for the dairy industry in both organic and conventional herds. Reproductive performance of lactating dairy cows directly influences the annual frequency of calving; thus, the number of replacement heifers and milk yield (due to extended low productivity and dry period). Recent studies involving 4,111 pre- and postpartum cows from organic herds showed that cows experiencing hypocalcemia (HYPO) at calving had greater proportion ($P < 0.05$) of metritis and culling rate within 60 DIM compared with non-HYPO cows. Furthermore, uterine diseases (primarily metritis and purulent vaginal discharge [PVD]) significantly increased ($P < 0.05$) the risk of cysts at 26 ± 3 DIM, reduced cyclicity (progesterone concentration ≥1 ng/mL) at 40 ± 3 DIM as well as the hazard of pregnancy up to 300 DIM, and increased the risk for pregnancy loss. Regardless of parity, uterine diseases (RP, metritis and PVD) had an additive effect on milk loss and quality for at least one of the first 4 DHIA test-days ($P < 0.05$), but was not different at later tests. Many factors such as feed management (i.e., diets, dry matter intake and water quality) and comfort (e.g., resting time) of transition cows determine the energy (e.g., BHBA, NEFA) and calcium balance. These factors also determine the status of the immune system of the animal; thus, the prevalence of infectious diseases in postpartum cows (e.g., metritis). Implementing a proactive transition cow program that focuses on preventing metabolic diseases by managing the leading risk factors (e.g., diets, resting time of cows per day, dry matter intake) will significantly reduce calving-related losses and improve uterine environment and ovarian structures (cyclicity); thus, improving the overall performance of lactating dairy cows and profitability of the herd, regardless of size.

Key Words: organic, dairy, reproduction

734 Mastitis and milk quality in organic dairy herds. Pamela Ruegg*, *University of Wisconsin, Madison, WI.*

The purpose of this paper is to review research about mastitis and milk quality on organic dairy herds. Mastitis is consistently the most commonly reported disease on both ORG and conventional (CON) dairy farms. In the US, concern about udder health of cows on ORG herds is often related to the blanket prohibition of antimicrobial usage. Cows on ORG herds that develop mastitis are usually treated with a variety of alternative compounds such as whey-based products, herbals, and essential oils. Although none of these products have any proven efficacy, ORG dairy farmers are able to successfully manage mastitis. Several studies have compared bulk tank SCC and rate of clinical mastitis between herds managed using ORG or CON systems. Although most studies have shown no difference in bulk tank SCC between management systems, some studies have reported higher bulk tank SCC for ORG as compared with CON herds. ORG herds are typically smaller than CON herds and studies that have accounted for herd-size have not reported significant differences in bulk tank SCC or other measures of milk quality. Management practices used to achieve low bulk tank SCC have slightly varied. In one study a greater proportion of lactating cows in ORG herds had milk withheld from sale as compared with cows in CON herds. In contrast to bulk tank SCC, fewer cases of clinical mastitis are generally reported in cows on ORG as compared with CON farms. A recent study reported 0.21 versus 0.31 cases of clinical mastitis per 305-cow-days for cows in ORG versus CON herds. Within the framework provided by NOP regulations, the size and intensity of management of ORG dairy herds varies considerably. Milking practices used on ORG farms are very similar to practices used on similarly sized CON farms. Several management practices such as use of milking gloves and a quarantine unit to isolate infected cows have been shown to result in improved udder health and milk quality for ORG herds. The use of external consultants has also been associated with improved milk quality. In summary, both ORG and CON herds that use well-known mastitis prevention practices and consult with qualified advisors can minimize mastitis and produce high quality milk.

Key Words: organic, milk quality, mastitis

735 Panel discussion: Best management practices to maintain animal health in organic dairy herds. J. S. Velez*[1], P. Clutts[2], G. Jodarski[3], and G. M. Schuenemann[4], [1]*Aurora Organic Farms, Boulder, CO,* [2]*Pleasantview Farm, Circleville, OH,* [3]*CROOP Cooperative/Organic Valley, La Farge, WI,* [4]*The Ohio State University, Columbus, OH.*

The organic dairy industry in the US has been growing steadily since 1990, and organic farmers have struggled to produce enough supply to meet the growing domestic demand. The whole certified organic process relies on several preventive management practices (e.g., transition cow program, vaccination, water quality, nutrition, reproduction) that ultimately will allow the animal to produce nutritious high quality milk. The basic physiological functions to prevent metabolic disorders in transition cows are dry matter intake and maintenance of calcium and energy balance (ketosis). These factors also determine the status of the immune system of the animal; thus, the prevalence of infectious diseases (e.g., metritis and mastitis), the risk of culling within 60 DIM, and performance of lactating dairy cows. Reproductive failure and mastitis are the top 2 reasons for early removal of lactating cows from dairy herds. This causes severe economic losses to organic dairy producers because of decreased milk yield and quality as well as increased replacement costs. Designing and implementing a proactive transition management program (i.e., protocols) that focuses on monitoring the leading risk factors (e.g., diets and feed management, water quality, comfort of pre- and postpartum cows [e.g., resting time], calving management, and personnel training) will significantly reduce calving-related diseases and the risk of culling while optimizing performance of lactating dairy cows. Therefore, best transition cow management practices during the weeks before and after calving are key determinants to avoid a drop in dry matter intake, hypocalcemia, and ketosis; and the subsequent negative effect on the immune system of animals in organic dairy herds.

Key Words: organic, dairy cattle, health

Beef Species I

736 Relationships between feed efficiency traits and indicators of energy expenditure in growing cattle. Phillip A. Lancaster*[1], Gordon E. Carstens[2], Luis O. Tedeschi[2], Timothy P. Vining[1], Nicolas DiLorenzo[3], and G. Cliff Lamb[3], *[1]Range Cattle Research and Education Center, University of Florida, Ona, FL, [2]Department of Animal Science, Texas A&M University, College Station, TX, [3]North Florida Research and Education Center, University of Florida, Marianna, FL.*

Recent research indicates that residual feed intake (RFI) may not be related to efficiency of energy use, but few results have been published for other feed efficiency traits. The current objective was to determine the relationships of different measures of feed efficiency with indicators of energy expenditure at constant feed intake. Five performance trials were conducted to measure feed intake, growth and heart rate (HR) or heat production in growing cattle. Feed efficiency traits included those where a lesser value is more efficient [feed conversion ratio (FCR), RFI, RFI adjusted for fat composition (RFIc), RFI from model predicted feed intake (RFIm)] and those where a greater value is more efficient [partial efficiency of growth, residual gain efficiency (RGE), and residual intake and gain (RIG), which is combination of RFI and RGE]. Heart rate alone or heat production (heart rate × oxygen pulse) was measured following the performance trial. Trials 1, 3, 4 and 5 included 39 Angus bulls and heifers, 119 Brangus heifers, 115 Brangus heifers, and 45 Angus heifers fed high-roughage diets with heart rate measured on 39 animals at fasting, 16 heifers at 1.1× expected maintenance requirement (MEm), 16 heifers restricted-fed at120 g DM/kg$^{.75}$, and 16 heifers at 1× expected MEm, respectively. Trial 2 included 56 Angus bulls and heifers fed a high-concentrate diet with heart rate measured on 12 bulls and 12 heifers at 1.1× expected MEm. Phenotypic correlations of feed efficiency traits with DMI and ADG were similar to published studies. Phenotypic correlations of feed efficiency traits with fasting HR in Trial 1, maintenance HR in Trial 2 and 3, and restricted-intake HR in Trial 4 were not significant. In Trial 5, FCR (−0.62), RFI (−0.56), RGE (0.60), RFIc (−0.60), RFIm (−0.60), and RIG (0.65) had strong phenotypic correlations with maintenance heat production such that more efficient heifers had greater maintenance heat production. These data indicate that proposed traits to select for improved feed efficiency have no or an inverse relationship with energy expenditure when growing cattle are fed at constant feed intake.

Key Words: cattle, energy expenditure, feed efficiency

737 Effect of post-weaning heifer development on pregnancy rates and subsequent feed efficiency as a pregnant first calf heifer. Hazy R. Nielson*, T. L. Meyer, and Rick N. Funston, *University of Nebraska, West Central Research and Extension Center, North Platte, NE.*

To determine the effect of heifer development system on pregnancy rates and feed efficiency as a pregnant first calf heifer a 3-yr study was conducted. In Yr 1, weaned heifers either grazed corn residue (CR) or were fed in a drylot (DLHI). In Yr 2 and 3 heifers either grazed CR, upland range (RANGE), or were fed diets differing in energy, high (DLHI) or low (DLLO), in a drylot setting. Percent of mature BW before the breeding season was similar among treatments except DLHI which was significantly greater ($P = 0.04$) at 66.6% compared with 60.0, 61.0, and 61.7% for RANGE, CR, and DLLO treatments, respectively. Pregnancy rates to AI were similar ($P = 0.62$) among treatments (58.6, 66.3, 59.9, 52.6 ± 9.7%; RANGE, CR, DLHI, DLLO). A subset of AI-pregnant heifers from each development treatment were placed in a Calan gate system; they were allowed a 20 d acclimation and training period before beginning the 90 d ad libitum hay treatment period on approximately gestational d 170. Offerings were recorded daily and orts collected weekly. Initial BW was not different ($P = 0.62$) among treatments (458, 468, 473, 464 ± 9 kg; RANGE, CR, DLHI, DLLO). Body weight at the end of the treatment period was also not different ([$P = 0.55$] 485, 497, 503, 491 ± 17 kg; RANGE, CR, DLHI, DLLO). Intake did not differ among treatments, either as DMI ([$P = 0.59$] 9.2, 9.4, 9.5, 9.4 ± 0.7 kg; RANGE, CR, DLHI, DLLO) or as a percentage of BW ([$P = 0.98$] 1.96, 1.95, 1.95, 1.96 ± 0.15%; RANGE, CR, DLHI, DLLO). There was no difference ($P = 0.61$) in ADG (0.28, 0.33, 0.32, 0.28 ± 0.17; RANGE, CR, DLHI, DLLO) or residual feed intake ($P = 0.41$) (−0.095, −0.096, 0.144, 0.113 ± 0.156; RANGE, CR, DLHI, DLLO) among treatments. Although there was no difference ($P = 0.41$) in the 3-mo-development cost among treatments ($166.06, 141.66, 160.63, 171.80 ± 12.52; RANGE, CR, DLHI, DLLO), there was a $30.14 numerical difference between the most expensive treatment, DLHI, and the least costly treatment, CR. Post-weaning heifer development system did not affect heifer pregnancy rate or feed conversion as pregnant first calf heifers.

Key Words: beef heifer, feed conversion, heifer development

738 Effects of prepartum supplement level on growth performance, feed efficiency, and reproductive performance of female progeny. Lindsay M. Shoup*, Thomas B. Wilson, Dianelys González-Peña, Frank A. Ireland, Sandra Rodriguez-Zas, Tara L. Felix, and Daniel W. Shike, *University of Illinois, Urbana, IL.*

Objectives were to determine the effect of prepartum dam supplement level on growth performance, feed efficiency, and reproductive performance of female progeny (127 heifers in yr 1, n = 9 dam pastures; 138 heifers in yr 2, n = 9 dam pastures). Mature, multiparous, Angus × Simmental cows (BW = 623 ± 70 kg; BCS = 5.7 ± 0.7) were offered 1 of 3 supplement levels (supplement contained 70% dried distiller's grains plus solubles and 30% soybean hulls; fed 103 ± 11 d prepartum to 2 ± 11 d postpartum): no supplement (NS), 2.16 kg/d·hd^{-1} (LS), or 8.61 kg/d·hd^{-1} (HS) while grazing tall fescue pastures. Heifer progeny were weaned at 187 ± 11 d of age and retained as replacements in a fall-calving system. Experimental unit was pasture (9 per year), and data were analyzed using PROC MIXED in SAS. Dam prepartum supplementation did not affect ($P = 0.99$) heifer progeny BW at weaning. During a 70-d intake and feed efficiency evaluation, starting at 305 ± 31 d of age, DMI, ADG, and RFI were similar ($P \geq 0.14$) among heifer progeny, regardless of dam supplement level. Heifer body weight and BCS, at start of 1st breeding season, also did not differ ($P \geq 0.60$). Body weight at pregnancy verification, percentage of heifers that conceived to AI in 1st breeding season, and overall pregnancy percentage in 1st breeding season were not different ($P \geq 0.51$) among heifer progeny, regardless of dam supplement level. At first calving, calf birth BW and percentage of unassisted births were similar ($P \geq 0.32$) among heifer progeny, regardless of dam supplement level. Milk production also did not differ ($P = 0.48$) among heifer progeny, regardless of dam supplement level. In conclusion, these data suggest that within a fall-calving fescue-based production system, supplementing dams with 2.16 or 8.61 kg/d·hd^{-1} of a DDGS-based supplement does not affect growth performance, feed efficiency, and reproductive performance of subsequent female progeny.

Key Words: beef heifer development, fetal programming, maternal nutrition

739 Stocking rate and feeder design affects hay waste . Dexter J. Tomczak*, Nick E. Mertz, Dylan L. Hamlin, and William J. Sexten, *University of Missouri-Columbia, Columbia, MO.*

Ninety-six mid-gestation spring-calving cows were stratified by BW (562.9 ± 72.6), BCS (4.9 ± 0.7), and age (4.5 ± 2.0) into 2 replicate groups of 8, 16, and 24 cows to evaluate stocking rate and feeder design effects on hay waste. Cone feeders were equipped with cradle-chains (cone), sheeting on upper (50 cm) and lower (60 cm) portion, and 16 feeding stations (45.2 cm wide) separated by vertical bars (230 cm diameter, 170 cm height). Open feeders (ring) had no sheeting and 17 feeding stations (44.4 cm wide) separated by angled bars (240 cm diameter, 120 cm height). Feeder type and stocking rate were arranged in a 2 × 3 factorial, and randomly assigned to a 6 × 6 Latin square. Tall fescue round hay bales (87.3% DM, 6.33% CP, 66% NDF, 152 cm width x 170 cm diameter) were offered on circular end and replaced every third d (8), every other d (16), or daily (24) to ensure ad libitum hay access. A single bale was offered to 8 and 16 each period, while 24 were offered 3 bales. Bale number was not significant, so bale measures were averaged within period. Waste was collected daily, and residual forage (ORTs) was collected before new bale offering. Estimated DMI was hypothesized to not differ, while waste was expected to decrease with increasing stocking rate in ring, but not differ in cone. Estimated DMI did not differ ($P > 0.10$) as percent of BW (2.0 ± 0.1%) or kg·hd^{-1}·d^{-1} (11.8 ± 0.3 kg·hd^{-1}·d^{-1}). A stocking rate by feeder interaction was observed due to changes in magnitude of difference when waste was expressed as kg·hd^{-1}·d^{-1} ($P = 0.05$), percent of disappearance (%disp) ($P = 0.07$), and percent of intake (%intake) ($P = 0.09$). Waste was greater in ring ($P < 0.05$) than cone for 8 (2.9 vs. 2.0 kg·hd^{-1}·d^{-1}, 18.8 vs. 14.0%disp, 23.4 vs. 16.4%intake) and 24 (3.3 vs. 1.7 kg·hd^{-1}·d^{-1}, 22.4 vs. 12.5%disp, 29.2 vs. 14.7%intake), for 16 waste was increased ($P = 0.09$) (2.7 vs. 2.1 kg·hd^{-1}·d^{-1}, 18.8 vs. 15.4%disp, 23.6 vs. 18.3%intake). Increasing stocking rate to greater than 1 cow per individual feeding space did not reduce estimated DMI. Stocking hay feeders greater than 1 cow per individual feeding space or having no defined feeding space within feeder increased hay waste.

Key Words: hay waste, stocking rate, feeder design

740 Effects of feeding stockpiled tall fescue versus tall fescue hay to late gestation beef cows on circulating blood urea nitrogen and glucose concentrations. Jill M. Larson*, Katlyn N. Niederecker, and Allison M. Meyer, *Division of Animal Sciences, University of Missouri, Columbia, MO.*

We hypothesized that cows grazing stockpiled tall fescue (STF) during late gestation would have increased nutrient intake compared with cows fed summer-baled hay, which would result in increased nutrient availability for fetal growth and development. Forty-eight multiparous, spring-calving crossbred beef cows were allocated by BW (683 ± 16 [SE] kg), BCS (5.8 ± 0.1), age (5.6 ± 0.4 yr), and expected calving date (average = February 18) to 1 of 2 forage systems beginning on d 188 ± 2 of gestation. Forage systems were: 1) strip-grazed endophyte-infected STF (59.7% NDF, 12.3% CP; DM basis; 80.4% utilization) in 4.05-ha pastures (n = 4), or 2) ad libitum endophyte-infected tall fescue hay (64.9% NDF, 6.2% CP; DM basis) fed in uncovered drylots (18 m × 61 m, n = 4). Cows remained on their respective treatments until calving. Jugular blood samples were obtained from cows on d 0 (baseline; d 188 of gestation), 35 (d 223 of gestation), and 77 (d 265 of gestation) for determination of serum blood urea nitrogen (BUN) and plasma glucose. Data were analyzed using a mixed model containing effects of treatment, sampling day, and their interaction, where sampling day was used as a repeated measure. Pasture or drylot was considered the experimental unit. During late gestation, there was a forage system × day interaction ($P < 0.001$) for serum BUN concentrations. Baseline serum BUN concentrations did not differ ($P = 0.95$) between forage systems. On d 35 and 77 of the study, cows grazing STF had greater ($P < 0.001$) serum BUN concentrations than cows fed hay only. There was no treatment × day interaction ($P = 0.57$) for plasma glucose, but cows grazing STF tended to have greater ($P = 0.11$) glucose concentrations than cows consuming hay. Additionally, as gestation progressed, plasma glucose increased ($P = 0.02$). We conclude that cows grazing stockpiled tall fescue had increased circulating BUN and glucose concentrations due to increased nutrient intake during late gestation, which may affect fetal development and subsequent calf performance.

Key Words: forage system, metabolite, pregnancy

741 Preweaning calf circulating blood urea nitrogen and glucose concentrations in a tall fescue forage system model of developmental programming. Katlyn N. Niederecker*[1], Jill M. Larson[1], Brian L. Vander Ley[2], and Allison M. Meyer[1], *[1]Division of Animal Sciences, University of Missouri, Columbia, MO, [2]Department of Veterinary Medicine and Surgery, University of Missouri, Columbia, MO.*

We hypothesized that cows grazing stockpiled tall fescue (STF) during late gestation have greater nutrient intake than cows fed summer-baled hay, which would result in increased prenatal nutrient supply and ultimately improved fetal development and subsequent postnatal performance. Forty-eight multiparous, spring-calving crossbred beef cows (683 + 16 [SE] kg BW) were allocated by BW, BCS, age, and expected calving date to either strip-graze endophyte-infected STF (59.7% NDF, 12.3% CP; DM basis; n = 4 pastures) or consume ad libitum endophyte-infected tall fescue hay (HAY; 64.9% NDF, 6.2% CP; DM basis) in uncovered drylots (n = 4) beginning on d 188 ± 2 of gestation. Cows remained on their respective forage systems until calving, but STF cows were moved to drylots at 7.0 ± 1.0 d pre-calving and fed ryelage (58.6% NDF, 12.3% CP; DM basis). Within 1 wk postpartum, cow-calf pairs were moved to a single pasture for common pre-weaning management. At 52 ± 0.6 h and 83 ± 1 d postnatally, calf jugular blood samples were obtained for determination of serum blood urea nitrogen (BUN) and plasma glucose. Data were analyzed using a mixed model containing effects of forage system, sampling day, and their interaction, where sampling day was used as a repeated measure. Pasture or drylot was included as the experimental unit; calf date of birth and sex were included in the model when $P < 0.25$. We have previously reported that calves born to cows consuming STF tended to weigh more at birth and d 80. There was a tendency ($P = 0.07$) for a forage system × day interaction for serum BUN concentrations. At 52 h postnatally, calves born to cows consuming hay had decreased ($P = 0.02$) serum BUN compared with STF, but BUN did not differ ($P = 0.95$) between forage systems at 83 d of age. Treatment did not affect ($P \geq 0.20$) plasma glucose concentrations. Despite this, calves had greater ($P < 0.001$) glucose concentrations at 52 h then at 83 d. In conclusion, neonatal calves born to cows grazing

STF had increased circulating BUN, which may indicate increased perinatal nutrient supply.

Key Words: calf metabolite, developmental programming, pregnancy

742 Effect of supplementing heifers on pasture with bambermycin or monensin on growth and development.

Paul Beck*[1], John Tucker[2], William Galyen[3], Shane Gadberry[4], Don Hubbell[2], Tom Hess[2], Doug Galloway[3], Michael Sims[1], Beth Kegley[3], and Matt Cravey[5], [1]*University of Arkansas SWREC, Hope, AR,* [2]*University of Arkansas LFRS, Batesville, AR,* [3]*University of Arkansas Department of Animal Science, Fayetteville, AR,* [4]*University of Arkansas Cooperative Extension Service, Little Rock, AR,* [5]*Huvepharma Inc., Amarillo, TX.*

Spring calving (Block 1; n = 70 heifers; BW 208 ± 21.7 kg; age 231 ± 17.0 d) and fall calving (Block 2; n = 72 heifers; BW 225 ± 31.7 kg; age 276 ± 12.8 d) heifers were used to test the effects of feeding 20 mg of bambermycin (Gainpro; Huvepharma; Sofia, Bulgaria) or 150 mg of monensin (Rumensin; Elanco Animal Health, Greenfield, IN) in 0.91 kg/d corn gluten feed based supplements compared with non-medicated (Control) supplements on growth performance and development of grazing heifers. Heifers were allocated by breed, BW, and age to pasture groups (n = 5/group for Block 1 and n = 6/group for Block 2). Pasture groups were then randomly assigned to treatment (Control n = 4 pastures in Blocks 1 and 2; bambermycin and monensin n = 5 pastures in Block 1 and n = 4 pastures in Block 2). Block 1 began on 29 October 2013 and lasted 189-d, and Block 2 began on 24 June 2014 and lasted for 161-d. Heifers were weighed full on 2 consecutive days at beginning and end of each block. Reproductive tract scores (1 to 5 score) were assessed before breeding using ultrasound in Block 1 and rectal palpation in Block 2. In Block 1, heifers grazed non-toxic endophyte infected tall fescue pastures, while in Block 2 heifers grazed bermudagrass pastures until 14 October and then grazed non-toxic endophyte infected tall fescue pastures. Heifers were AI bred over 10-d, and natural service bulls were placed with heifers 14-d following final AI date. Data were analyzed as a randomized complete block design using the mixed procedure of SAS (SAS Inst. Inc., Cary, NC) least squares means were separated using contrasts: Control vs. Medicated and bambermycin vs. monensin. Ending BW and ADG of Control (323 ± 4.8 kg and 0.68 ± 0.0167 kg/d) was less ($P \leq 0.04$) than medicated, yet monensin (346 ± 4.6 kg and 0.73 ± 0.0163 kg/d) and bambermycin (344 ± 4.6 kg and 0.74 ± 0.0163 kg/d) did not differ ($P \geq 0.69$). Reproductive tract scores (3.5 ± 0.60), AI pregnancy rates (30 ± 12.3%) and total pregnancy rates (82 ± 11.5%, respectively) did not differ ($P \geq 0.36$) among treatments. This experiment indicates that both bambermycin and monensin effectively increase performance of growing heifers, but did not affect reproduction.

Key Words: bambermycin, heifer development, monensin

743 Effect of pre and postpartum herbage allowances of grasslands on metabolic and endocrine parameters of primiparous beef cows.

Alberto Casal*[1], Martin Clatamunt[2], Ana L. Astessiano[1], Pablo Soca[3], and Mariana Carriquiry[1], [1]*Facultad de Agronomia, Universidad de la Republica, Montevideo, Uruguay,* [2]*Facultad de Veretinaria, Universidad de la Republica, Paysandu, Uruguay,* [3]*Facultad de Agronomia EEMAC, Universidad de la Republica, Paysandu, Uruguay.*

The aim of this study was to evaluate the effect of herbage allowance of grasslands during the prepartum and postpartum on metabolic and endocrine parameters of beef cows. Forty Hereford heifers were used in a randomized block design and a factorial arrangement of prepartum (fall-winter; high vs. low, PREH vs. PREL) and postpartum (spring-summer, high vs. low, POSTH vs. POSTL) herbage allowance (4 vs. 2.5 kg of DM/kg of BW of annual mean for high vs. low). At the −90, −35, +80 and +160 ± 17 DPP (fall, winter, spring and summer, respectively), BW and BCS was recorded and blood samples were collected. Means from a repeated analysis using a mixed model were considered to differ when $P \leq 0.05$. During the prepartum (−90 to −35 DPP; fall and winter) all cows lost BW and BCS, increasing plasma urea, nonesterified fatty acids (NEFA) and β-hydroybutyrate (BHB) while decreasing glucose, insulin and leptin concentrations. During this period, BCS and concentrations of urea were lower and NEFA tended ($P = 0.09$) to be greater in PREL than PREH cows (4.6vs. 5.0 ± 0.04 units, 7.3vs. 8.1 ± 0.1mmol/L and 1.1 vs. 0.9 ± 0.03 mmol/L for BCS, urea and NEFA, respectively). During the postpartum (spring and summer), BCS and metabolic-endocrine profiles were affected by POST but did not differ due to PRE or the PRE by POST interaction. Cow BCS and plasma glucose and leptin were greater whereas urea and NEFA were less in POSTH than POSTL cows (3.9 vs. 3.6 ± 0.04 units, 2.9 vs. 2.7 ± 0.05 mmol/L; 5.7 vs. 3.8 ± 0.1 ng/mL; 5.2 vs. 5.7 ± 0.1 mmol/L and 0.63 vs. 0.66 ± 0.03 mmol/L for BCS, glucose, leptin, urea and NEFA, respectively) during the lactation period. Plasma urea and NEFA decreased during spring to increase again toward mid-summer when insulin and BHB concentrations also decreased. Metabolic and endocrine profiles of grazing primiparous beef heifers reflected negative energy balance as herbage mass and/or quality decreased during winter gestation or during summer in the late lactation. Improve PRE and POST herbage allowance reduced negative energy balance during the pre and postpartum, respectively.

Key Words: beef cattle, endocrinology, rangeland

744 The influence of tick loads of Senepol cows on calf tick loads and production traits in the tropics.

Robert W. Godfrey*, Adam J. Weis, and Henry C. Nelthropp, *Agricultural Experiment Station, University of the Virgin Islands, St Croix, VI.*

This study was conducted to evaluate the relationship of tick load between multiparous Senepol cows (n = 127 observations) and their calves (n = 144 observations) born in fall 2010 and 2011 and spring 2011, 2012, 2013 and 2014. Cow tick load was evaluated using a visual score (clean, light, moderate or heavy) before monthly acaricide treatment at weaning. Calf BW and tick load were measured at weaning and yearling. Average daily gain (ADG) was calculated for birth to weaning and weaning to yearling. Data were analyzed using correlation and GLM procedures with calving season and cow tick load as the main effects and sire as a covariate due to unequal representation of sires across years. Calves born in the spring had greater 205-d adjusted weaning weights ($P < 0.002$) than calves born in the fall (319.4 ± 10.7 vs. 236.9 ± 23.2 kg, respectively) but there was no effect of cow tick loads ($P > 0.10$). There was no effect of calving season or cow tick load on 365-d adjusted weight of calves ($P > 0.10$). Spring-born calves had a higher ADG from birth to weaning ($P < 0.0001$) than fall-born calves (1.23 ± 0.04 vs. ± 0.93 ± 0.09 kg/d, respectively) but there was no effect of cow tick load ($P > 0.10$). Calves of cows with light tick loads had lower ADG from weaning to yearling ($P < 0.0001$) than calves of cows with clean, moderate or high tick loads (0.29 ± 0.02 vs. 0.49 ± 0.03 vs. 0.45 ± 0.03 vs. 0.44 ± 0.03 kg/d, respectively). Spring-born calves had greater tick loads at weaning ($P < 0.001$) than fall-born calves (2.3 ± 0.1 vs. 1.5 ± 0.2, respectively) but there was no difference ($P > 0.10$) as yearlings. Calves of cows with high tick loads at weaning had lower yearling tick loads ($P < 0.02$) than calves from cows with clean, light or moderate tick loads (1.4 ± 0.3 vs. 2.1 ± 0.3 vs. 2.5 ± 0.2 vs. 2.1 ± 0.3, respectively). Cow tick load at weaning had low correlations with calf tick load at weaning (r = 0.24, $P < 0.008$) and at yearling (r = −0.23, $P < 0.04$). Calf tick load at weaning was not correlated with tick load at yearling (r = −0.01, $P > 0.10$). Cow tick load does not affect calf tick load or pre-weaning growth, Because of the low correlation of tick load between cows and calves, and within calves, it may be difficult to select for this trait.

Key Words: cow, calves, tick load

745 Comparison of the growth of F_1 Senepol x Brahman and Brahman steers in an Indonesian feedlot.

Tim J. Schatz*, *Northern Territory Department of Primary Industry and Fisheries, Darwin, Northern Territory, Australia.*

Most cattle in northern Australia have a high *Bos indicus* (usually Brahman) content as they perform better in the harsh conditions than *Bos taurus* cattle. However, Brahmans from northern Australia often suffer price discrimination when they are sent to Australian domestic markets as they are regarded as having less tender meat than *Bos taurus*. Crossbreeding with Senepol bulls has been found to be a way of producing offspring from northern Australian herds that have higher growth rates and more tender meat than Brahmans. However there is some resistance to adoption of crossbreeding as there are concerns that crossbreds are discriminated against in the Indonesian live export market (which is a major destination for young northern Australian cattle) due to the perception that they do not perform as well as high grade Brahmans in the tropical environment. Therefore a study was conducted to compare the growth of Brahman (BRAH) and F_1 Senepol × Brahman (F_1 SEN) steers in an Indonesian feedlot. F_1 SEN (n = 54) and BRAH (n = 32) steers were exported from Darwin (Northern Territory, Australia) to Indonesia through the normal live export process and fed for 121 d in a commercial feedlot near Lampung (Sumatra, Indonesia). The average weights of the genotypes at feedlot induction were 312.3 kg (F_1 SEN) and 308.5 kg (BRAH). All the steers were fed in the same pen and received the normal feedlot management and rations. Their growth was studied and the average daily gain over the feeding period was 0.17 kg/d higher ($P < 0.001$) in the F_1 SEN compared with BRAH (1.71 vs. 1.54 kg/d). As a result the F_1 SEN put on 21.6 kg more weight ($P = 0.002$) over the feeding period. There was no significant difference between the genotypes in average fat depth at the P8 site at the end of the feeding period (F_1 SEN = 10.5 mm, BRAH = 10.6 mm) despite the F_1 SEN being 25.4 kg heavier on average. This study found that that F_1 SEN steers performed better than BRAH in an Indonesian feedlot, and so the results should allow live export cattle buyers to purchase these types of animals (Brahman × tropically adapted *Bos taurus*) with confidence that Indonesian feedlotters will be happy with their performance.

Key Words: Senepol, Brahman, feedlot

746 Alternative weaning and finishing strategies affect finishing residual feed intake of beef steers.

Jason K. Smith*[1], Deidre D. Harmon[1], Mark D. Hanigan[2], Samer W. El-Kadi[1], Sally E. Johnson[1], Scott P. Greiner[1], and Mark A. McCann[1], *[1]Department of Animal and Poultry Sciences, Virginia Tech, Blacksburg, VA, [2]Department of Dairy Science, Virginia Tech, Blacksburg, VA.*

Recent evidence suggests that alternative early nutritional management strategies may metabolically imprint beef steers for reductions in finishing residual feed intake (RFI). To further evaluate this effect, as well as that of an alternative finishing nutritional management strategy, a 2 × 2 × 2 factorial experiment was conducted that included Angus (ANG) and Simmental (SIM) sired steers randomly assigned to one of 2 weaning treatments (early weaned [EW; weaned at 111 ± 23 d or age; n = 14] or conventionally weaned [CW; weaned at 233 ± 21 d of age; n = 14]) and one of 2 finishing treatments (high corn [HC; 68.7% of DM from steam-flaked corn; n = 14] or low corn [LC; 50% of DM from steam-flaked corn isoenergetically replaced with dried corn gluten feed; n = 14]). EW steers were fed a concentrate-based ration ad libitum for 122 d following weaning. All steers were then commingled and backgrounded on pasture for 190 d, finished in a feedlot for 154 ± 64 d, and harvested in groups upon reaching a common 12th-rib fat thickness of 1 cm. Feed intake was measured daily following a 42 d finishing ration adaptation period using a Calan-Broadbent system. Observed ADFI expressed in Mcal of NE_g was regressed against average $BW^{0.75}$, ADG and duration of the measurement period ($R^2 = 0.73$; $P < 0.0001$) via the Fit Model procedure of JMP Pro, and RFI was calculated as the difference between observed and predicted ADFI. Analysis of variance was conducted to determine the fixed main and interaction effects of sire breed, weaning treatment and finishing treatment on ADFI, ADG and RFI. Although no effects were observed for ADFI ($P \geq 0.45$) or ADG ($P \geq 0.36$), RFI of ANG HC steers was lower than ANG LC (−0.91 vs. 0.49 Mcal NE_g; SEM = 0.22; $P < 0.001$), SIM LC (−0.91 vs. 0.20 Mcal NE_g; SEM = 0.22; $P < 0.01$) and SIM HC (−0.91 vs. 0.10 Mcal NE_g; SEM = 0.22; $P < 0.05$), and was lower for EW than CW steers (−0.27 vs. 0.21 Mcal NE_g; SEM = 0.15; $P < 0.05$). These results provide additional evidence of metabolic imprinting of EW steers for reductions in RFI, and independent effects of finishing energy source on RFI of ANG steers.

Key Words: early weaning, metabolic imprinting, residual feed intake

747 Alternative weaning and finishing strategies affect beef carcass marbling score.

Jason K. Smith*[1], Hailey S. Cassell[1], Deidre D. Harmon[1], Mark D. Hanigan[2], Samer W. El-Kadi[1], Sally E. Johnson[1], Scott P. Greiner[1], and Mark A. McCann[1], *[1]Department of Animal and Poultry Sciences, Virginia Tech, Blacksburg, VA, [2]Department of Dairy Science, Virginia Tech, Blacksburg, VA.*

Increased volatility in climate, grain prices and grid-based carcass premiums have led beef producers to search for alternative weaning and finishing management options. An experiment was conducted to evaluate the effects of an alternative weaning strategy and finishing diet on carcass marbling score (MS), quality grade (QG) and Certified Angus Beef LLC (CAB) retail brand acceptance. Angus (ANG) and Simmental (SIM) sired steers were randomly assigned to one of 2 weaning treatments (early weaned [EW; weaned at 111 ± 23 d of age; n = 14] or conventionally weaned [CW; weaned at 233 ± 21 d of age; n = 14]) and 1 of 2 finishing treatments (high corn [HC; 68.7% of DM from steam-flaked corn; n = 14] or low corn [LC; 50% of DM from steam-flaked corn isoenergetically replaced with dried corn gluten feed; n = 14]) in a 2 × 2 × 2 factorial design. Following weaning, EW steers were fed a concentrate-based ration ad libitum for 122 d before commingling and pasture backgrounding with CW steers for 190 d. Steers were then finished for 154 ± 64 d and harvested in groups upon reaching a common ultrasound-estimated 12th-rib fat thickness of 1 cm. Chilled carcasses were evaluated to determine MS, QG and CAB acceptance, and ANOVA was conducted to determine the fixed main and interaction effects of sire breed, weaning treatment and finishing treatment using the Fit Model procedure of JMP Pro. All interaction effects were removed from the final ANOVA model due to lack of significance ($P \geq 0.54$). MS was greater for carcasses of EW than CW steers (741 ± 14 vs. 680 ± 15; $P < 0.01$), and HC than LC steers (775 ± 17 vs. 646 ± 15; $P < 0.0001$), however no main effects were evident for QG or CAB acceptance ($\chi^2 \leq 2.32$; $P \geq 0.13$). Although weaning and finishing treatments affected MS, the effects were not detectable in QG and CAB acceptance within this experiment, and further research is warranted to increase sample size and statistical power. Nonetheless, the management practices utilized in this experiment affected MS independently, indicating that both early and late nutritional management strategies affect marbling development.

Key Words: early weaning, carcass, marbling

Breeding and Genetics: Application and methods—Dairy II

748 The "it factor" for long-lived, high-producing dairy cows. Roger D. Shanks*[1,2] and Robert Miller[3], *[1]Holstein Association USA, Brattleboro, VT, [2]University of Illinois, Urbana, IL, [3]Mil-R-Mor Dairy, Orangeville, IL.*

Holstein cows that dairyman love live a long time and produce lots of milk. What is unique about these high-producing, long-lived cows? Obviously, these cows have received good management and avoided major health issues. Are the 50K genetics of these elite cows different from other Holsteins? Elite cows were defined phenotypically as having produced over 68,039 kg (150,000 lb) of milk during their lifetime and were classified as very good (VG) or excellent (EX). Elite cows were born in the decade before 2008. For a control, females born in the decade before 2008 with a 50K Holstein genome evaluation were chosen. Control females either had not produced 68,039 kg of milk during their lifetime or were not classified VG or EX. Genomes (50K or 77K) were available on 823 elite cows and 1,589 control females. Defining elite or control as binomial allowed detection of almost 200 markers that were different in allele frequency between elite cows and control females. The most significant chi-squared for differences in allele frequency between elite cows and control females identified a marker on chromosome 5, which had the largest difference in minor allele frequency of 0.17 between elite and control groups. Basing significance on chi-squared $-\log_{10} P$ of 8.000 as a threshold, 199 markers were significant and were distributed across all bovine chromosomes. Minor allele frequencies of elite cows were greater for 140 of these markers and minor allele frequencies of control females were greater for 59 markers. As interpretation, minor allele frequencies define uniqueness. The uniqueness of elite cows was supported by more positive changes in minor allele frequencies for the elite cows. A single "it factor" is insufficient to identify uniqueness of elite cows, but many markers are candidates to contribute to the uniqueness. Because allele frequency differences were found across all chromosomes, balance continues to be important in striving to increase the number of elite cows in the breed.

Key Words: genome, milk production, longevity

749 Identification of gene networks underlying dystocia in dairy cattle. Maria Arceo*[1], Francesco Tiezzi[1], John Cole[2], and Christian Maltecca[1], *[1]North Carolina State University, Raleigh, NC, [2]Animal Genomics and Improvement Laboratory, ARS, USDA, Beltsville, MD.*

Dystocia is a trait with high impact in the dairy industry. Among its risk factors are calf weight, gestation length, breed and conformation. Biological networks have been proposed to capture the genetic architecture of complex traits, where GWAS show limitations. Our objective was to identify gene networks in Brown Swiss (BS), Holstein (HO) and Jersey (JE) cattle related to dystocia. De-regressed PTA (dPTA) for calving ease, gestation length, stature, strength and rump width of 8780 HO, 505 BS, and 1818 JE bulls were used in the analysis. A total of 45188 genotypes were available for all bulls. A single trait Bayes B GWAS was performed within breed with $\pi = 0.9$. The proportion of genetic variance (PV_g) explained by each SNP was $(2pq\tilde{a}^2)/\sum^{45188}(2pq\tilde{a}^2)$, with $\tilde{a}$ = posterior mean of the allelic effect. SNP with $VP_g \geq$ 75th percentile of the sample were ruled significant. Relevant SNP (rSNP) were defined as: significant in all traits, significant in all functional traits, or significant in all type traits. An association weight matrix (AWM) was constructed with rSNP in rows and traits in columns. Cells of the AWM corresponded to rSNP normalized effect size. These were mapped to genes with a 5′ or 3′ maximum distance of 2500 bp, rows in the AWM were indexed with genes. Genes were used to search for enriched functional annotation (FDR ≤ 0.15 HO, JE; FDR ≤ 0.3 BS). AWM row-wise partial correlations were computed. Significant correlations were interpreted as gene-gene interactions, resulting in a gene network. Networks included 1454 (BS), 1272 (HO) and 1455 (JE) genes. Their number of connections ranged between 1 and 15 (BS), 80 (HO), 13 (JE). A total of 13 (BS), 152 (HO), 108 (JE) genes in the networks were within reported dystocia QTL. Top enriched terms were cell adhesion (HO, JE), regulation of purine nucleotide metabolic process (BS). Most connected genes in the networks, enriching GO terms and within dystocia QTL were: FLOT1 (BS, 9 interactions), RASA1 (HO, 77) and ADRBK2 (JE, 12). Integrating knowledge from annotation tools to identify the functional biology of dystocia in dairy cattle can potentially improve genomic predictions that could result in increasing profitability of the dairy industry.

Key Words: dystocia, gene network, dairy cattle

750 Distribution of runs of homozygosity and its association with inbreeding depression in United States and Australia Jersey cattle. Jeremy T. Howard*[1], Christian Maltecca[1], Mekonnen Haile-Mariam[2,3], Ben J. Hayes[2,3], and Jennie E. Pryce[2,3], *[1]North Carolina State University, Raleigh, NC, [2]Dairy Futures Cooperative Research Centre, Bundoora, Victoria, Australia, [3]La Trobe University, Bundoora, Victoria, Australia, [4]Biosciences Research Division, Bundoora, Victoria, Australia.*

Differences in environment, management practices or selection objectives have led to a variety of choices being made in the use of dairy sires between countries. This may result in variation in selection intensity across the genome and could result in detectable differences in patterns of genome-level homozygosity between populations and consequently affect inbreeding depression differently across populations. The objective of the study was to characterize the frequency of homozygosity and its relationship with regions associated with inbreeding depression in Jersey dairy cattle from the United States (US) and Australia (AU). Genotyped cows with phenotypes on milk, fat and protein yield ($n = 6{,}751$ US; $n = 3{,}974$ AU) and calving interval ($n = 5{,}816$ US; $n = 3{,}905$ AU) were utilized in a 2-stage analysis. A run of homozygosity statistic (ROH4Mb), counting the frequency of a SNP being in a ROH of at least 4 Mb, was calculated across the genome. In the first stage residuals were obtained from a model that accounted for the additive genetic as wells as fixed effects. In the second stage these residuals were regressed on ROH4Mb using a single marker regression model or a machine-learning tree based regression algorithm (gradient boosted machine). The relationship between ROH4Mb and the SNP effect of a region for each trait was further characterized based on sliding window (500kb) direct genomic value (DGV) derived from a Bayesian LASSO analysis. The ROH4Mb effects were estimated by regressing residuals from the 2-stage approach on ROH4Mb and SNP effects estimated by regressing residual deviations from a model including only fixed effects on SNP markers. Genomic regions across multiple traits were found to be associated with ROH4Mb on BTA13, BTA23 and BTA25 for the US population and BTA3, BTA7, BTA17 for the AU population. Furthermore, multiple potential epistatic interactions were characterized. Lastly, the covariance between ROH4Mb and the SNP effect of a region depended on the genome region, with positive covariances in some regions

Key Words: run-of-homozygosity, genome-wide association study, inbreeding depression

751 The effect of *DGAT1* polymorphism on milk production and fat, protein, and mineral composition of dairy cattle.

Henk Bovenhuis*[1], Marleen Vikser[1], Nina Poulsen[2], Jakob Sehested[3], Hein van Valenberg[4], Johan van Arendonk[1], Lotte Bach Larsen[2], and Bart Buitenhuis[5], [1]*Animal Breeding and Genomics Centre, Wageningen University, Wageningen, the Netherlands,* [2]*Department of Food Science, Aarhus University, Tjele, Denmark,* [3]*Department of Animal Science, Aarhus University, Tjele, Denmark,* [4]*Dairy Science and Technology Group, Wageningen University, Wageningen, the Netherlands,* [5]*Center for Quantitative Genetics and Genomics, Department of Molecular Biology and Genetics, Aarhus University, Tjele, Denmark.*

Since the identification of the diacylglycerol O-acyltransferase 1 (*DGAT1*) K232A polymorphism, many studies reported associations between this polymorphism and milk production traits but only a few investigated effects on detailed milk composition. In the current study data collected as part of the Dutch and Danish-Swedish Milk Genomic Initiatives were used to estimate the effect of *DGAT1* polymorphism on milk fat, protein, and mineral composition in Holstein and Jersey cattle. The use of data from different breeds allows identifying associations of *DGAT1* that are consistent across populations. Results showed that effects of *DGAT1* K232A polymorphism on especially milk yield, fat% and protein% are not constant during lactation. Effects of *DGAT1* were small in early lactation and they gradually increased until d 50 to 150 in lactation. Analyses of the effects of *DGAT1* polymorphism on detailed milk fat, milk protein, and mineral composition showed that *DGAT1* has major effects on fat- and mineral composition of milk. There is also evidence for effects on milk protein composition but these effects seem to be more subtle. Part of the effects of the *DGAT1* polymorphism on milk composition can be explained by effects on de novo fatty acid synthesis and on excretion of water (dilution effect). For example, the total amount of Ca, P, and Zn excreted in milk of cows with different *DGAT1* K232A genotypes is identical; however, the milk volume differs and therefore contents of Ca, P, and Zn differed between *DGAT1* genotypes. A similar "dilution effect" can be observed when studying effects on fatty acids: there were no significant effects of *DGAT1* on the yields of C18:1 *cis*-9, CLA *cis*-9,*trans*-11, C18:2 *cis*-9,12 and C18:3 *cis*-9,12,15; however, there were highly significant effects of DGAT1 on these fatty acids when expressed as w/w%.

Key Words: *DGAT1*, mineral, fatty acid

752 Variation in milk fat globule size in Canadian dairy cattle and its prediction using mid-infrared spectroscopy.

Allison Fleming*[1], Astrid Koeck[1], Flavio Schenkel[1], Milena Corredig[2,3], Mehdi Sargolzaei[1,4], Bonnie Mallard[5], R. Ayesha Ali[6], Saranya Gunasegaram[1], and Filippo Miglior[1,7], [1]*CGIL, University of Guelph, Guelph, ON, Canada,* [2]*Gay Lea Foods, Mississauga ON, Canada,* [3]*Dept of Food Science, University of Guelph, Guelph, ON, Canada,* [4]*Semex, Guelph, ON, Canada,* [5]*Dept of Pathobiology, OVC, University of Guelph, Guelph, ON, Canada,* [6]*Dept of Mathematics and Statistics, University of Guelph, Guelph, ON, Canada,* [7]*Canadian Dairy Network, Guelph, ON, Canada.*

Milk fat globule (MFG) size in bovine milk is a trait of interest for selection due to its influence on the composition and nutritional quality of the milk as well as its technological properties. However, large-scale phenotyping is currently impractical. For a given fat content, milk with smaller MFG will have more membrane material, which has been proposed nutraceutical. The objective of this study was to examine the variation in MFG size and the potential of its prediction using mid-infrared spectral data. A total of 1,689 milk samples from 343 Canadian cows representing 4 dairy breeds from 44 herds across the provinces of Ontario, Alberta, and Quebec were collected during routine milk testing. Samples were divided and a certain portion was sent to a Canadian DHI laboratory and their spectral data were recorded using FOSS MIR machines. The MIR data for each sample contained 1,060 data points in the infrared range from 900 to 5,000 cm^{-1}. The additional portion was analyzed for mean MFG size using integrated light scattering and reported as both a volume moment mean and surface moment mean. Mean values (±SD) for volume and surface moment means were 4.16 ± 0.51 μm and 3.49 ± 0.34 μm, respectively. The average MFG size was positively correlated with the percent fat in the sample (volume moment mean, $r = 0.30$; surface moment mean, $r = 0.32$). MFG size records were combined with their spectral data, and outliers and non-informative regions of the spectrum were removed. Records were randomly assigned to either the training or validation sets. Partial least squares regression method was utilized to predict MFG size. For volume moment mean, an R^2cv of 0.52 and R^2v of 0.41 were found. Surface moment mean equations had an R^2cv of 0.55 and R^2v of 0.52. At this time MFG size cannot be accurately quantified through MIR prediction, but it may be possible to identify milk samples with either small or large MFG.

Key Words: milk fat globule, dairy cattle, mid-infrared spectroscopy

753 Including different groups of genotyped females for genomic prediction in the Nordic Jersey population.

Hongding Gao*[1], Per Madsen[1], Ulrik S. Nielsen[2], Gert P. Aamand[3], and Just Jensen[1], [1]*Center for Quantitative Genetics and Genomics, Department of Molecular Biology and Genetics, Aarhus University, Tjele, Denmark,* [2]*Knowledge Centre For Agriculture, Aarhus N, Denmark,* [3]*Nordic Cattle Genetic Evaluation, Aarhus N, Denmark.*

Including genotyped females in the reference population (RP) is an obvious way to increase RP but caution is needed because of potential preferential treatment of the genotyped cows and lower reliabilities of phenotypes compared with proven bulls. Denmark, Finland and Sweden have implemented a female genotyping project with voluntary genotyping of entire herds using low-density chip (LD project). The objective of the present study was to examine the effect of adding different sources of genotyped females to RP for Nordic Jersey. Five scenarios for building RP were considered: (1) bulls only; (2) bulls with females from LD project; (3) bulls with females from LD project plus non-LD project females genotyped before their first calving date; (4) bulls with females from LD project plus non-LD project females genotyped after their first calving date; (5) bulls with all genotyped females included. Genomically enhanced breeding values (GEBV) were predicted for 8 the traits in the Nordic Total Merit (NTM) index through a genomic BLUP (GBLUP) model using deregressed proofs (DRP). The validation population (VP) was formed by a cut-off using birth year of 2005 based on the genotyped bulls with DRPs. Average gain in reliability over the 8 traits ranged from 1.8% to 4.5% points compared with the scenario with only bulls in RP (scenario 1). Adding all the genotyped females in the RP achieved highest gain in reliability (scenario 5), followed by scenario 3, scenario 2 and scenario 4. The mean reliability of scenario 3 was 0.5% points higher than scenario 2 due to a slightly larger size

of RP, and a decrease of 1.1% points in mean reliability were observed when including the extra 143 genotypes cows in scenario 4 compared with scenario 2. The mean reliabilities of scenario 2 and 3 were 1.6 and 1.1% points lower than of scenario 5. All scenarios led to inflated GEBVs since the regression coefficients are below 1. However, scenario 2 and scenario 3 led to less bias of genomic predictions than scenario 5 with the mean regression coefficients closer to 1. The results suggest adding unselected females in the RP significantly improve the reliabilities and tend to reduce the prediction bias compared with adding selectively genotyped females.

Key Words: genotyped female, reliability, prediction bias

754 Estimation of genetic parameters for metabolic disease traits and their predictors in Canadian Holsteins.

Astrid Koeck*[1], Janusz Jamrozik[1,2], Gerrit J. Kistemaker[2], Flavio S. Schenkel[1], Robert K. Moore[4], Daniel M. Lefebvre[4], David F. Kelton[3], and Filippo Miglior[1,2], *[1]CGIL, Dept. of Animal and Poultry Science, Guelph, ON, Canada, [2]Canadian Dairy Network, Guelph, ON, Canada, [3]Department of Population Medicine, Ontario Veterinary College, Guelph, ON, Canada, [4]Valacta, Québec, QC, Canada.*

The objective of this study was to estimate genetic parameters for metabolic diseases and their main predictors in Canadian Holsteins. Records from first to fifth lactation were considered for ketosis (KET), displaced abomasum (DA), milk fever (MF), fat to protein ratio (F:P) and milk β-hydroxybutyrate (BHBA), whereas for body condition score (BCS) only records from first lactation cows were available. Binary disease traits (0 = no case, 1 = at least one case), F:P and milk BHBA were treated as different traits in first and later lactations. Records for MF in first lactation were not considered in the present study as the disease frequency was near zero and a preliminary analysis revealed a heritability of zero. Bivariate and multivariate linear sire models were fitted using AI-REML. Heritability for metabolic disease traits ranged from 0.011 to 0.047. Higher heritabilities were found for BCS, F:P and milk BHBA, with estimates ranging from 0.10 to 0.22. First-lactation KET was strongly correlated with DA (0.76) and milk BHBA (0.75), whereas lower genetic correlations were found with BCS and F:P (−0.54 and 0.37, respectively). Displaced abomasum in first lactation was moderately correlated with BCS (−0.40) and F:P (0.19). Similar genetic correlation estimates were estimated in higher lactation cows. Milk fever, which was only evaluated in higher lactation cows, was moderately correlated with KET (0.39) and milk BHBA (0.33). Genetic correlations of disease traits between first and later lactations were relatively high (0.79 for KET and 0.86 for DA).

Key Words: metabolic disease, predictor, genetic correlation

755 A genomic-wide association study on development of hyperketonemia in periparturient Holstein dairy cows.

Francisco A. Leal Yepes*[1], Heather J. Huson[1], Sabine Mann[2], Jessica A. A. McArt[2], Luciano Caixeta[1], Thomas R. Overton[1], Joseph J. Wakshlag[2], and Daryl V. Nydam[2], *[1]College of Agriculture and Life Sciences, Cornell University, Ithaca, NY, [2]College of Veterinary Medicine, Cornell University, Ithaca, NY.*

The objective was to detect cows with elevated postpartum nonesterified fatty acids (NEFA) and β-hydroxybutyrate (BHBA) concentrations, with or without concurrent hyperketonemia, and identify genomic regions associated with development of hyperketonemia in periparturient Holstein cows. The study population consisted of cows from 2 different trials: In the first study, 63 cows (parity ≥ 2) were enrolled and blood was collected from 3 to 16 d in milk. In the second study, 84 cows (parity ≥ 2) were enrolled and sampled from −21 d to +21 d relative to calving. Blood samples were tested for NEFA and BHBA concentration. Hyperketonemia was defined as a BHBA concentration ≥ 1.2 mmol/L. All BHBA and NEFA measurements were grouped using incremental area under the curve (AUC) to identify individuals with the most variation. Holstein cows were genotyped on the Illumina Bovine High-density (777K) Beadchip. Quality control filtering produced (n = 522,231) single-nucleotide polymorphism (SNP). A genomic wide association study was performed to establish correlation between low frequency SNP (<5%) and development of hyperketonemia using Golden Helix software. The linear regression $R^2 = 0.21$ suggested a low strength correlation between BHBA AUC and NEFA AUC concentration. Although a small sample size, given that these cows were managed under similar conditions, multiple SNP associated with high concentrations of BHBA were found (Table 1). These results might improve genetic selection criteria to identify high-risk animals and develop preventative measures to decrease hyperketonemia development.

Table 1 (Abstr. 755). Regions and candidate genes associated with development of hyperketonemia

Index	Chr.	Region start (bp)	Region end (bp)	$-\text{Log}_{10}$ (*P*-value)	Genes
1	2	12,122,028	12,128,393	5.086193951	*RRAGA*
2	2	104,958,840	104,958,840	5.410113588	*PECR; IGFBP2* and *IGFBP5*
3	3	93,634,769	93,634,769	5.031371132	*LRP8; CPT2* and *SCP2*
6	21	14,153,070	14,153,070	5.111968697	*CHD2*

756 Evaluation of survival in the first year after calving across years and seasons.

Mathijs L. van Pelt*[1,2] and Roel F. Veerkamp[1], *[1]Wageningen UR Livestock Research, Animal Breeding and Genomics Centre, Wageningen, the Netherlands, [2]CRV BV, Arnhem, the Netherlands.*

Longevity of dairy cattle is an important trait from an economic and welfare perspective. Dairy cows are culled for various reasons and therefore the trait definition of longevity might have changed over time. Also, culling is likely to be affected by the end of the quota year, and therefore a seasonal effect is expected. Therefore the objective was to evaluate if longevity is a different trait between years or seasons of first calving, utilizing genetic links through common bulls. Survival was defined as survival until 12 mo after first calving. The data set comprised 524,529 animals that could have lived until 12 mo after the first calving, with the first calving between 1988 and 2011. Multiple trait models were used with survival defined in 3 8-year blocks (1988–1995, 1996–2003, and 2004–2011) or 4 seasons of first calving (Jan-Mar, Apr-Jun, Jul-Sep, and Oct-Dec). The mean survival was 87.8% in the total data set, but increased with more recent calving years. The lowest survival rate was in 1991 with 82.9% surviving the first 12 mo and highest survival rate was in 2007 (92.2%). Survival rate also varied between calving months, with highest survival rate in September with 89.2% and lowest survival rate in March with 86.3%. Age of first calving showed an optimum for survival for heifers calved between 22 and 26 mo of age, with survival rates of 88.4% or higher. Survival rate decreases 0.75% for each extra month calving after 26 mo. Genetic correlations between 1988 and 1995 and 2004–200 was lowest (0.67 ± 0.15), and suggests survival has changed over years. Genetic correlations between all seasons were higher than 0.90, and although there appears a phenotypic effect of the end of the quota year on survival, genetically there is no effect of season of calving on survival until 12 mo after first calving.

Key Words: longevity, survival, genetic correlation

757 Genetic and genomic analysis of superovulatory response in Canadian Holsteins.

Cindy Jaton*[1,2], Astrid Koeck[1], Mehdi Sargolzaei[1,3], Christopher A. Price[4], Flavio S. Schenkel[1], and Filippo Miglior[1,5], *[1]Centre for Genetic Improvement of Livestock, University of Guelph, Guelph, ON, Canada, [2]Centre d'insémination artificielle du Québec, St-Hyacinthe, QC, Canada, [3]Semex Alliance, Guelph, ON, Canada, [4]Université de Montréal, Faculté de Médecine Vétérinaire, St-Hyacinthe, QC, Canada, [5]Canadian Dairy Network, Guelph, ON, Canada.*

Superovulation of dairy cattle is frequently used in Canada. The cost of this protocol is high, and so is the variability of the outcome. Knowing the superovulatory potential of a donor cow could influence the breeder's decision to superovulate it or not. The ultimate objective of this study was to identify chromosome regions associated with superovulatory response in Canadian Holsteins. Data were provided by Holstein Canada and contained the total number of embryos and the number of viable embryos from every successful flushing performed across Canada. After editing, 137,446 records of superovulation done between 1992 and 2014 were considered for the analysis. A univariate repeatability animal model analysis was performed for both total number of embryos and number of viable embryos, yielding heritability estimates (SE) of 0.18 (0.01) and 0.14 (0.01), respectively. Breeding values were estimated for 54,463 cows, and 3,513 sires. Only estimated breeding values of animals that were genotyped with a SNP panel denser than 3K and having a reliability higher than 40% were considered (n = 5,122) for further analyses. All lower density genotypes were imputed to 50K using FImpute software. A genome-wide association study was carried out using a single SNP regression method, which also fits a polygenic background effect. Results were similar for the 2 highly genetically correlated ($r_g = 0.94$) traits considered in this study. A major significant peak on chromosome 11 was detected, suggesting the presence of an important candidate gene in this region.

Key Words: superovulatory response, heritability, GWAS

759 Genetic parameters of individual hoof lesions in Canadian Holsteins.

Francesca Malchiodi*[1], Astrid Koeck[1], Núria Chapinal[2], Mehdi Sargolzaei[1,3], Allison Fleming[1], David F. Kelton[4], Flavio S. Schenkel[1], and Filippo Miglior[1,5], *[1]Centre for Genetic Improvement of Livestock, University of Guelph, Guelph, ON, Canada, [2]Animal Welfare Group, University of British Columbia, Vancouver, BC, Canada, [3]Semex Alliance, Guelph, ON, Canada, [4]Department of Population Medicine, Ontario Veterinary College, Guelph, ON, Canada, [5]Canadian Dairy Network, Guelph, ON, Canada.*

Hoof lesions in dairy herds represent a painful condition for the cow and pose a financial loss for farmers, due to the costs associated with treating lesions, as well as to decreased cow performance. The objective of this study was to estimate genetic parameters for individual hoof lesions in Canadian Holsteins. Data were recorded by 26 hoof trimmers serving 365 herds located in Alberta, British Columbia and Ontario, and trained to use a rugged touch-screen computerized lesion recording system. A total of 108,032 hoof-trimming records from 53,654 cows were collected between 2009 and 2012. Hoof lesions included in the analysis were digital dermatitis, interdigital dermatitis, interdigital hyperplasia, sole hemorrhage, sole ulcer, toe ulcer, and white line lesion. All variables were analyzed as binary traits, as the presence or the absence of the lesions, and as categorical variables, using a severity score from 1 to 3. Only the first hoof-trimming session of each lactation was included in the analyses. When considering the presence or absence of the lesions, heritabilities (SE) for digital dermatitis, interdigital dermatitis, interdigital hyperplasia, sole hemorrhage, sole ulcer, toe ulcer, and white line lesion were 0.053 (0.005), 0.011 (0.002), 0.025 (0.004), 0.012 (0.002), 0.031 (0.004), 0.004 (0.001), and 0.012 (0.002), respectively. Similar results were found when severity was considered. The estimated breeding values between these 2 set of variables showed correlations ranging from 0.88 to 0.97. The reliability of EBV was slightly higher when severity was analyzed. Infection lesions showed moderate genetic correlations with interdigital hyperplasia and low negative correlations with horn lesions. Among horn lesions, moderate to high genetic correlations were found.

Key Words: hoof lesion, dairy cattle

Breeding and Genetics: Poultry and swine

760 Comparison of traditional vs. genomic, and single vs. multiple trait analyses of broiler chicken mortality.

Xinyue Zhang*[1], Shogo Tsuruta[1], Daniela A. L. Lourenco[1], Robyn L. Sapp[2], and Rachel J. Hawken[2], [1]*University of Georgia, Athens, GA,* [2]*Cobb-Vantress Inc., Siloam Springs, GA.*

The purpose of this study was to determine whether broiler mortality is influenced by selection on correlated traits, determine the accuracy of genetic evaluation for mortality with traditional and genomic evaluations, and determine whether the use of the multi-trait model increases the accuracy of predictions. Phenotypes were available on 181,022 broilers for up to 8 traits, 4 linear and 4 categorical. Pedigree was available for 186,596 broilers and genotypes were available on 18,047 animals. For linear traits the model included the fixed effects of sex and contemporary group, random direct genetic, and maternal genetic effect for body weight. Contemporary group is the grouping of source, mini-generation and hatch. For categorical traits, the contemporary group was treated as random and a fixed effect of generation was added. (Co) variance components were estimated with a Gibbs sampling program THRGIBBS1F90 for threshold-linear models. A traditional BLUP using a pedigree relationship matrix and a genomic BLUP (ssGBLUP) using a combined pedigree-genomic relationship matrix were used to predict EBV and genomic EBV, respectively. Because few dead animals were genotyped, the traditional validation techniques did not apply. Subsequently models were compared using a data splitting technique based on the correlation of EBV from 2 non-overlapping samples, each one with one-half of the phenotypes selected across contemporary groups. The correlations were computed only for genotyped animals in the last generation and are measures of realized accuracy. The genetic correlation between mortality and the other traits were generally small (absolute value < 0.15), with notable differences for maternal body weight (−0.50) and Ascites (0.77); heritability for mortality was 13%. The correlations between independent samples in a univariate model for mortality were 0.59 for the non-genomic and 0.64 for the genomic model. In a multiple trait genomic model, the correlations increased by 0.09 over single trait genomic model. Results indicate mortality may be more affected by ascites and maternal growth compared with other traits under selection. Use of the genomic data increases the accuracy of genetic evaluation for mortality.

Key Words: mortality, broiler, threshold model

761 Polymorphisms in *CAST*, *TNNI1*, and *MYOG* genes and their relationship with pig carcass traits at different weight groups.

Andrea Nyisalovits*[1], János Posta[2], Levente Czeglédi[2], Márta Horváth[1], and László Babinszky[1], [1]*Department of Feed- and Food Biotechnology, University of Debrecen, Debrecen, Hungary,* [2]*Department of Animal Breeding, University of Debrecen, Debrecen, Hungary.*

The aim of this study is to determine the relationship between 3 previously described polymorphisms (SNPs) located at 3 candidate genes (*CAST*, *TNNI1*, *MYOG*) and slaughter traits in different weight groups of commercially housed hybrid pigs. A total of 402 pigs [Large White × (Landrace × Duroc) sows line × Pietrain boar line] were tested using PCR-RFLP method. After 111 and 118 d in fattening (DF) their carcasses were qualified in a slaughterhouse where the hot weight (HW), backfat thickness (BF) and loin diameter (LD) were measured, lean meat % (LM %), live weight (LW) and average daily gain (ADG) were calculated. Because of the wide range of LW (82–144 kg) heterogeneity of experimental population had to be reduced, therefor animals were divided into 3 groups based on mean (116.1 kg) and SD (10.2 kg) of LW as follows: low (L) (<mean-1 SD, n = 63), medium (M) (mean ± 1 SD, n = 276) and high (H) (>mean+1 SD, n = 63). The effects of SNPs on carcass quality traits were analyzed in the 3 classes separately using the least square analysis of the GLM method with Tukey-Kramer correction (SAS 9.1) including sex and DF as fixed effects and LW as covariance factor. According to our results the examined SNPs show different effects on carcass quality at different weight. Pigs with the GG genotype of CAST (Ser66Asn) gene show the worst BF and LM % ($P < 0.05$) values in the L group, but no significant results were found in the other 2 groups. The TNNI1 gene has no significant effect on traits. The SNP in 3′ UTR region of MYOG gene influenced BF and LM % ($P < 0.05$) values, but only in the H group. The marker-assisted selection plays crucial role in animal husbandry, despite economically important traits show multifactorial inheritance with a strong environmental influence. Our results prove that the effect of polymorphisms depends on LW, moreover, the LW strongly influences the carcass quality traits, therefore if the test population shows a high degree of variability the use of weight categories should be considered.

Key Words: carcass quality, pig, RFLP

762 Estimates of variance components for gilt retention traits.

Matthew D. A. Morrison*[1], Kent A. Gray[2], Miles T. See[1], and Mark T. Knauer[1], [1]*North Carolina State University, Raleigh, NC,* [2]*Smithfield Premium Genetics, Rose Hill, NC.*

Numerous studies have been conducted on sow retention and longevity; however, less research has been completed on gilt retention. Increasing the percentage of gilts that farrow a litter would reduce gilt development costs, improve sow longevity, and enhance farmer profitability. Hence the purpose of this study was to estimate variance components for gilt retention traits. Data consisted of 6,282 commercial gilts from Large White dams and Landrace sires (Smithfield Premium Genetics, Rose Hill, NC). During development, gilts were reared in environmentally controlled facilities with slatted concrete flooring, natural ventilation and ad libitum access to feed and water. At an average age of 211 d (SD ± 41.5) females were moved to one of 11 sow farms in eastern North Carolina. Traits included successful gilt farrow event (STAY; success = 1, failure = 2) gilt culled for reproductive (REPRO; Yes = 1, no = 2), or non-reproductive reasons (OTHER, yes = 1, no = 2), age at first service (AFS), and age at first farrowing (AFF). Variance components were estimated using an animal model with THRGIBBS1F90 for categorical traits and AIREMLF90 for linear traits. All models contained a fixed effect of contemporary group (farm × year × month) and a random effect of animal. Of the gilts entering sow farms, 15.4% did not farrow a litter, 7.3% were culled for REPRO, and 8.1% were culled for OTHER. Average AFS and AFF were 262 d (SD ± 24.7) and 377 d (SD ± 24.9), respectively. Heritability estimates for STAY, REPRO, OTHER, AFS, and AFF were 0.15, 0.19, 0.05, 0.27, and 0.21, respectively. Phenotypic variance estimates for STAY, REPRO, OTHER, AFS, and AFF were 1.18, 1.24, 1.06, 356.2, and 386.2, respectively. Results suggest selection for increased gilt retention is possible.

Key Words: gilt, heritability, retention

763 Estimates of genetic parameters for sow body weight loss during lactation.

Cassandra L. Ferring*[1], Dale Hentges[2], Clint Schwab[2], and Mark T. Knauer[1], [1]*North Carolina State University, Raleigh, NC,* [2]*The Maschhoffs, Carlyle, IL.*

The purpose of this study was to estimate genetic parameters for sow BW loss during lactation. Data and pedigree information were available for Landrace (n = 3,310), York (n = 827) and Landrace × York F_1 sows (n = 354) from The Maschhoffs (Carlyle, IL). Sows were housed in environmentally controlled facilities with slatted concrete flooring and had ad libitum access to water. Females were restricted fed during gestation based on a visual body condition score of 1 to 5 (1 = thin, 5 = fat). During lactation sows were fed ad libitum. Sow traits analyzed included body condition score at farrowing (FBCS), total number born (TNB), number born alive (NBA), litter birth weight (LBW), litter weaning weight (LWW), number weaned (NW), body condition score at weaning (WBCS), and sow BW loss during lactation (WTΔ). Variance components were estimated using ASReml. All models included fixed effects of genetic line, parity, and contemporary group and random effects of animal (sow) and permanent environment. Covariates were included for LBW (NBA), LWW (piglet age at weaning and number of piglets fostered), NW (number of piglets fostered), WBCS (lactation length) and WTΔ (lactation length). Heritability estimates for FBCS, TNB, NBA, LBW, LWW, NW, WBCS and WTΔ were 0.17, 0.15, 0.15, 0.25, 0.15, 0.11, 0.16, and 0.13 respectively. Permanent environment variance estimates for FBCS, TNB, NBA, LBW, LWW, NW, WBCS and WTΔ were 0.0007, 0.26, 0.20, 0.49, 2.65, 0.04, 0.0004 and 1.29 respectively. Phenotypic variance estimates for FBCS, TNB, NBA, LBW, LWW, NW, WBCS and WTΔ were 0.015, 11.50, 10.49, 5.66, 112.4, 4.35, 0.014 and 251.5 respectively. Genetic correlations between WTΔ with FBCS, TNB, NBA, LBW, LWW, NW and WBCS were −0.05, 0.01, −0.02, 0.50, 0.28, 0.05 and −0.19 respectively. Phenotypic correlations between WTΔ with FBCS, TNB, NBA, LBW, LWW, NW and WBCS were 0.10, 0.09, 0.08, 0.15, 0.20, 0.15 and −0.03 respectively. Selection for reduced BW loss during lactation appears possible and would have minimal effect on litter size.

Key Words: body weight, lactation, reproduction

764 Genetic selection for feed efficiency in crossbred animals.

Rob Bergsma* and Egbert F. Knol, *Topigs Norsvin Research Centre B.V., Beuningen, the Netherlands.*

Worldwide, the majority of the commercial slaughter pigs are a cross of 3 or even 4 purebred lines. Although genetic selection takes place in purebred lines, the breeding goal should be directed toward crossbred performance. Applying a crossbred breeding goal is important if purebred traits show a genetic correlation significantly lower than 1.0 with their crossbred counterparts and/or when the genetic variation of purebred traits is different from those of crossbred traits. Recent research showed that this especially applies to feed intake and feed efficiency, while carcass composition in purebreds and crossbreds appeared to be more similar traits. The percentage of the genetic trend in purebred lines, expressed in crossbreds can be calculated as the ratio of the crossbred genetic standard deviation multiplied by the genetic correlation and the genetic purebred standard deviation. Our results show that of the genetic progress in purebreds 62, 52, 111 and 85% is expressed in crossbreds for daily gain, feed intake, back fat and loin depth, respectively. For feed efficiency this ratio depends on the trait considered. For feed conversion ratio, 60% of the genetic trend in purebreds was expressed in crossbreds, whereas for residual feed intake this ratio was only 41%. Feed intake (and thus feed efficiency) are traits that are not widely available on individual crossbred animals. The limited availability may also indicate that the crossbred/purebred phenotypes are confounded with their environment, given rise to a possible genotype by environment interaction. Another possible explanation is that dominance plays a larger role in feed intake and feed efficiency compared with other traits. And finally, genomic selection has been implemented for purebreds but when using crossbred animals as reference population we have to take into account that a QTL in breed A can behave different than in breed B. Current research focuses on partitioning the possible causes in explaining the lower expression of the genetic trend of purebreds in crossbred. Results will facilitate decisions on the most appropriate genetic model to include crossbred information in a combined crossbred purebred breeding program.

Key Words: pig breeding, crossbred performance, feed efficiency

765 Genomic regions associated with response to PRRSV and PCV2b co-infection in nursery pigs.

Jenelle R. Dunkelberger*[1], Nick V. L. Serão[1], Maureen A. Kerrigan[2], Joan K. Lunney[3], Raymond R. R. Rowland[2], and Jack C. M. Dekkers[1], [1]*Department of Animal Science, Iowa State University, Ames, IA,* [2]*College of Veterinary Medicine, Kansas State University, Manhattan, KS,* [3]*USDA, ARS, BARC, APDL, Beltsville, MD.*

The objective of this study was to identify genomic regions associated with porcine reproductive and respiratory syndrome (PRRS) viral load (VL), porcine circovirus type-2b (PCV2b) VL, and weight gain (WG) in nursery pigs co-infected with PRRS virus (PRRSV) and PCV2b. Two PRRS Host Genetics Consortium trials were conducted using commercial crossbred pigs (n = 400) pre-selected (50% AA and 50% AB) for the WUR single nucleotide polymorphism (SNP) on chromosome (SSC) 4 that is associated with response to PRRS. Half of the pigs received a PRRS modified live vaccine and all pigs were co-infected with PRRSV and PCV2b 28 d later. For the genome-wide association studies (GWAS), 61,730 SNPs were fitted simultaneously using the BayesB method with $\pi = 0.994$. For analysis of PCV2b VL, trial, WUR, vaccination (Vx), WUR×Vx, weight at Vx, age at Vx, PRRS viremia at 0 dpi, PCV2b viremia at 0 dpi, and pen were fitted as fixed effects. For analysis of WG and PRRS VL, trial×Vx replaced WUR×Vx. Marker-based heritability estimates were 0.33, 0.34, and 0.14 for WG, PCV2b VL, and PRRS VL, respectively. Compared with AA pigs, AB pigs did not significantly differ ($P = 0.70$) in WG but had lower PRRS VL ($P < 0.0001$) and, in the vaccinated group, lower PCV2b VL ($P = 0.09$). Sizable genetic associations were identified for the GWAS of WG and PCV2b VL, but not for PRRS VL. A 2-Mb window on SSC9, at 27–28 Mb, explained 7.7% of genetic variance in WG, which has been associated with growth of nursery pigs across multiple breeds. For PCV2b VL, 1-Mb windows on SSC1 (162 Mb), SSC5 (102 Mb), and SSC7 (41 Mb) explained 1.4, 1.1, and 1.0% of genetic variance, respectively. Thus, the AB WUR genotype was associated with reduced PRRS VL and with reduced PCV2b VL in vaccinated pigs, following co-infection with PRRSV and PCV2b. Genomic regions associated with WG and PCV2b VL were identified, regions for the latter trait being novel. These results suggest the possibility of selectively breeding pigs, based on these regions, for improved host response to PRRSV/PCV2b co-infection. This work was supported by the USDA ARS NIFA awards 2012–38420–19286 and 2013–68004–20362.

Key Words: genetic susceptibility, GWAS, swine

766 Genetic and economic effects of incorporating genomic predictions on health in swine breeding schemes.

Chandraratne M. B. Dematawewa*[1], Anna Grosse Holthaus[2], Henner Simianer[2], and Jack C. M. Dekkers[1], [1]*Iowa State University, Ames, IA,* [2]*University of Göttingen, Göttingen, Germany.*

A study was conducted to determine the effect of inclusion of genomic evaluations for health (GE-health) on improvements in health, the overall breeding goal (ΔH) and discounted profit ($\Delta\Omega$) in commercial cross breeding schemes. A 3-way cross breeding scheme with 2 maternal lines [female: Yorkshire (YS); male: Landrace (LR)] and a terminal sire line (Duroc, DU) was deterministically simulated using the ZPLAN+ software. The YS nucleus consisted of 50 boars and 1000 sows, while LR and DU nuclei had 100 boars and 800 sows each. Productive life of nucleus and multiplier ($n = 2400$) animals was 1 year, while F_1 crossbred sows were kept for 2 years to produce 532,400 commercial piglets/year. Days to market (DY), backfat thickness (BF), and litter weight at 21 d (LW; for YS and LR only) were considered with heritabilities (h^2) of 0.4, 0.5, and 0.09. The traits were standardized to genetic SD = 1. A health trait (HL) was simulated with $h^2 = 0.05$ and genetic SD = 1, with positive genetic (0.2) and phenotypic (0.3) correlations with DY and BF, and zero correlations with LW. HL was recorded from 80 commercial halfsibs/animal. Economic weights ($) for DY, BF, LW and HL were −1.86, −1.82, 5.35, and 1.86 per genetic SD, respectively. Planning horizon was 10 years (discount rate = 0.05). Costs for high and low density genotyping and health recording were $100, $40 and $10 per animal, respectively. Accuracy of GE-health ($r_{\text{MG-HEALTH}}$) was varied from 0 to 1.0 and 0.7 for the other traits. Inclusion of GE-health for both sires and dams increased both ΔH and $\Delta\Omega$ as $r_{\text{MG-HEALTH}}$ increased, mainly due to greater genetic gain in HEALTH. At $r_{\text{MG-HEALTH}} = 0.8$, extra response in ΔH and $\Delta\Omega$ for were 6.25% and $0.55 per animal in the breeding program, compared with having no GE-health. The corresponding values were higher (7.06% and $1.34, respectively) when HEALTH phenotypes were not recorded, partly due to lower initial response. The benefit of health recording diminished when $r_{\text{MG-HEALTH}}$ increased. These results show economic feasibility for implementing GE-health in commercial swine breeding. Funded by Genome Canada.

Key Words: genomic selection, health, swine breeding

767 Exploring causal networks underlying fat deposition and muscularity in pigs through the integration of phenotypic, genotypic and transcriptomic data.

Francisco Peñagaricano*[1,2], Bruno D. Valente[1], Juan P. Steibel[3], Ronald O. Bates[3], Cathy W. Ernst[3], Hasan Khatib[1], and Guilherme J. M. Rosa[1], [1]*University of Wisconsin-Madison, Madison, WI,* [2]*University of Florida, Gainesville, FL,* [3]*Michigan State University, East Lansing, MI.*

Joint modeling and analysis of phenotypic, genotypic and transcriptomic data have the potential to uncover the genetic control of gene activity and phenotypic variation, as well as shed light on the manner and extent of connectedness among these variables. Current studies mainly report associations; that is, undirected connections among variables without causal interpretation. Knowledge regarding causal relationships among genes and phenotypes can be used to predict the behavior of complex systems, as well as to optimize management practices and selection strategies. Here, we performed a multistep procedure for inferring causal networks underlying carcass fat deposition and muscularity in pigs using multi-omics data obtained from an F_2 Duroc × Pietrain resource pig population. The data set included several carcass and meat quality phenotypes, genotypic information spanning the whole swine genome, and gene expression data from loin muscle for a total of 171 F_2 individuals. We initially explored marginal associations between genotypes and phenotypic and expression traits through whole-genome scans, and then, in genomic regions with multiple significant hits, we assessed gene-phenotype network reconstruction using causal structural learning algorithms. One genomic region in SSC6 showed significant associations with 3 relevant phenotypes, midline 10th-rib backfat thickness, loin muscle weight, and average intramuscular fat percentage, and also with the expression of 7 genes, including *ZNF24*, *SSX2IP*, and *AKR7A2*. The inferred network indicated that the genotype affects the 3 phenotypes mainly through the expression of several genes. Among the phenotypes, fat deposition traits negatively affected loin muscle weight. Overall, our findings shed light on the antagonist relationship between carcass fat deposition and meat lean content in pigs. In addition, the procedure described in this study has the potential to unravel gene-phenotype networks underlying complex phenotypes.

Key Words: causal inference, complex trait, systems genetics

768 Genomic prediction accuracy of porcine respiratory and reproductive syndrome (PRRS) antibody response in commercial gilts and sows.

Nick V. L. Serão*[1], Robert A. Kemp[2], Benny E. Mote[3], John C. S. Harding[4], Philip Willson[4], Stephen C. Bishop[5], Graham S. Plastow[6], and Jack C. M. Dekkers[1], [1]*Iowa State University, Ames, IA,* [2]*Genesus, Oakville, ON, Canada,* [3]*Fast Genetics, Saskatoon, SK, Canada,* [4]*University of Saskatchewan, Saskatoon, SK, Canada,* [5]*The Roslin Institute, Easter Bush, Midlothian, UK,* [6]*University of Alberta, Edmonton, AB, Canada.*

The objective of this study was to assess the genomic prediction accuracy (GPA) of antibody response to PRRS in purebred sows and crossbred gilts. Data on 2,180 commercial crossbred gilts (CrossData), from 7 breeding companies, and 512 purebred multiplier Landrace sows (PureData), from one breeding company, were used to assess the ability to predict PRRS antibody response, measured as sample-to-positive (S/P) ratio, using 38,191 single nucleotide polymorphisms (SNPs). S/P ratio was measured in the CrossData at 40.7 ± 16 d after gilts entered commercial herds with a history of health problems, whereas in the PureData, S/P ratio was measured 46 d after a natural PRRS outbreak. Two prediction strategies were used: 1) CrossData was used for training and PureData for validation; 2) 7-fold cross-validation using the CrossData. Previous results showed that S/P ratio is mainly controlled by 2 regions on chromosome 7 (SSC7), at 24–31 Mb and 128–131 Mb. Therefore, different sets of SNPs were used for prediction: all SNPs (All_SNP), SNPs on SSC7 24–31 Mb (QTL1_SNP), SNPs on SSC7 128–131 Mb (QTL2_SNP), SNPs on both regions (SSC7_SNP), all SNPs except those on the SSC7 regions (Not7_SNP). GPA was measured as the correlation between genomic estimated breeding values and pre-adjusted phenotypes, divided by square root of heritability. Heritability estimates were 0.46 (PureData) and 0.31(CrossData). When training using the CrossData and validating on PureData, GPAs were 0.49 (All_SNP), 0.55 (QTL1_SNP), 0.30 (QTL2_SNP), 0.63 (SSC7_SNP), and 0.15 (Not7_SNP). GPAs were slightly lower using from cross-validation in the CrossData: when averaging across folds: 0.32 (All_SNP), 0.30 (QTL1_SNP), 0.27 (QTL2_SNP), 0.39 (SSC7_SNP), and 0.1 (Not7_SNP). The highest and lowest GPA from individual folds were −0.14 (Not7_SNP) and 0.60 (SSC7_All). These results show that S/P ratio can be accurately predicted using SNPs in pure and crossbred female pigs. In addition, greater accuracy can be obtained using the 2 QTL on SSC7 than the whole genome. Financial support from Genome Canada, the Canadian Swine Health Board, and PigGen Canada.

Key Words: SNP, host genetics, cross-validation

769 Genetic analysis and whole-genome wide association for feeding behavior traits in Duroc pigs.

Shihui Jiao*[1], Christian Maltecca[1], Yijian Huang[2], and Kent A. Gray[2], [1]*North Carolina State University, Raleigh, NC,* [2]*Smithfield Premium Genetics, Rose Hill, NC.*

This study was aimed at estimating genetic parameters for feeding behavior and production traits and identifying genomic regions influencing those behavior traits in a Duroc population. Feed intake and related measures were collected from 2004 to 2013 for 14,869 boars with 4,940,348 visits. Several 7,319 pigs were genotyped with 35,700 SNP available for analysis. Traits included 4 production traits; average daily feed intake, average daily gain, off-test body weight and backfat thickness and 12 feeding behavior traits include; daily occupation time (OTD), number of visits (NVD), feeding rate (DFR), feed intake per visit (FIV), occupation time per visit (OTV), standard deviation (SD) of feed intake per visit (ASDFIV), SD of occupation time per visit (ASDOTV), SD of feeding rate per visit (ASDFRV), SD of daily feed intake (SDFI), SD of daily occupation time (SOTD), SD of number of visits (SDNVD) and SD of feeding rate (SDFR). Except for SDFI and SDFR, all behavior traits were moderately heritable with estimates ranging from 0.32 ± 0.03 (SOTD) to 0.68 ± 0.03 (FIV). Genomic heritability estimates using single-step methods incorporating genotypes were slightly lower than those obtained using pedigree by 0.10 ± 0.09 averaged across all behavior traits. Genetic correlation of behavior traits with production traits varied (ranging from −0.481 to 0.618). Single trait association analyses for behavior traits for 1,541 boars were performed using mixed linear models. Significance of marker was declared with a p-value less than 1.40×10^{-6} (Bonferroni correction). A total of 35 significant markers on SSC 2, 7, 8, 9 and 18 associated with NVD, OTV, ASDFRV and SOTD were identified and putative genes included *NCR3* (involving in natural killer cell mediated cytotoxicity and associated with obesity in human), *CLPS* (activating in digestion of dietary lipid and absorption) and *PPARD* (regulator of lipid metabolism). In conclusion, feeding behaviors were moderately heritable and we have identified several genomic regions associated with traits affecting feeding behaviors that may help us understand the genetic mechanism controlling the traits.

Key Words: genomics, feeding behavior

770 Genomic mitigation of seasonality effect on carcass weight in commercial pigs.

Breno D. Fragomeni*[1], Shogo Tsuruta[1], Daniela A.L. Lourenco[1], Kent Gray[2], Yijian Huang[2], and Ignacy Misztal[1], [1]*Department of Animal and Dairy Science, University of Georgia, Athens, GA,* [2]*Smithfield Premium Genetics, Rose Hill, NC.*

The purpose of this study was to determine the effect of heat stress on carcass weight in a commercial pig population. Phenotypes included hot carcass weight records on 227,043 commercial pigs collected from 2 packing plants located in the states of North Carolina and Missouri; the pigs were a cross between purebred Duroc sires and F1 Landrace x Large White dams. The pedigree file included 553,442 animals, and 60k SNP genotypes were available for 8,232 sires. Weather information was collected from airport weather stations within 100 miles distance from the finishing farms. Average temperature humidity index (THI) was calculated for a period of 70 d before each HCW was collected. The THI measurement was classified as heat stress (THI > 78, n = 32,783) or comfort conditions (THI = < 78, n = 194,260). Analyses were done with an animal model as either a single-trait or 2-trait model using records identified as heat stress and comfort conditions treated as separate traits. Variance components were estimated with AIREML, and traditional and genomic (G) EBV were computed either with BLUP or single-step genomic BLUP (ssGBLUP). Validations were computed for 94 animals from the last generation using the forward prediction method, and reliability of (G)EBV was calculated as R^2 of predictions based on the training population (all except the last generation) on progeny yield deviations of the last generation. The heritability estimate for hot carcass weight in the single-trait model was 0.20. In the multiple trait model, the heritability estimate was 0.20 under comfort conditions and 0.25 under heat stress, with a genetic correlation of 0.62. Under comfort conditions and heat stress, reliabilities in traditional EBV were 0.22 and 0.14 whereas reliabilities in GEBV were 0.38 and 0.19, respectively. The heritability of carcass weight is higher under heat stress. Use of ssGBLUP increases reliabilities of carcass weight under both heat stress and comfort conditions. Effects of seasonality on carcass weight can be mitigated by genetic selection, especially with the genomic information.

Key Words: heat stress, genotype × environment interaction, genomic selection

771 Effect of divergent selection for residual feed intake in finishing pigs on juvenile IGF-I.

Emily D. Mauch*[1], Nick V. L. Serão[1], Joel R. Steckelberg[1], Anna Wolc[1,2], and Jack C. M. Dekkers[1], [1]*Department of Animal Science, Iowa State University, Ames, IA,* [2]*Hy-Line International, Dallas Center, IA.*

Since 2001, purebred Yorkshire pigs at Iowa State University have been divergently selected for increased (Low RFI) and decreased (High RFI) feed efficiency based on single trait selection for residual feed intake (RFI). Using data from generations 2–5 (G2–5), Bunter et al. (2010) found that serum insulin-like growth factor-I (IGF-I) concentration in young pigs (33–42 d) was lower in the Low RFI line, and had a high genetic correlation (0.63) with RFI, suggesting that it could be used as an indicator trait for RFI. The objective here was to validate these findings in G10 of the RFI lines. IGF-I concentration was measured by Rivalea Ltd. (Australia) using the Primegro assay on blood samples collected from 35 to 42 d of age on 377 piglets from G10. IGF-I data were analyzed in ASREML with a univariate sire model and a bivariate animal model with RFI data on 2,370 pigs from G1–10. Both models for IGF-I included the fixed effects of line, sex and contemporary group, covariates of age at blood collection and interval from weaning to blood collection, and random effects of litter, and sire (no pedigree) or animal (with complete pedigree). The concentration of IGF-I (ng/mL) was estimated to be 55.7 (±19.1) and 53.4 (±44.2) lower in the Low RFI line compared with the High RFI line based on the sire ($P = 0.01$) and animal ($P = 0.3$) models, respectively. Bunter et al. (2010) reported a similar line difference of 47.0 ng/mL in G5. The estimated genetic correlation between RFI and IGF-I was 0.68 (±0.38), similar to Bunter et al. (2010). In conclusion, lower juvenile IGF-I concentration was validated to be associated with pigs selected for increased feed efficiency based on RFI and, therefore, may serve as an early blood indicator to select for feed efficiency. However, when considering the full pedigree, the line difference was not significant. Funding provided by AFRI-NIFA grant #2011–68004–30336 and by Rivalea Ltd. (Australia).

Key Words: swine, genetic parameter, residual feed intake

Companion Animal Symposium: Comparative nutrition—Protein and energy across species

772 Thinking comparatively allows flexibility: The legacy of Duane Ullrey. Mark S. Edwards*, *California Polytechnic State University, San Luis Obispo, CA.*

A Michigan native, Duane Ullrey completed a BS degree in animal husbandry (1950) and an MS degree in animal pathology (1951) from Michigan State College. Duane earned a PhD in animal nutrition with minors in physiology and biochemistry (University of Illinois, 1954). Upon graduation, he taught at Oklahoma A&M University. In 1956, Duane was hired as an assistant professor, becoming a full professor in 1968, of animal nutrition with a joint appointment in Departments of Animal Science and Fisheries and Wildlife at Michigan State University. He taught and conducted research in swine and white tailed deer nutrition, as well as taught Animal Nutrition in the College of Veterinary Medicine, ultimately developing a Comparative Animal Nutrition program. Duane influenced many (34 graduate students, 140 graduate committees) in formal and informal learning environments. Duane established new care standards in the field of zoo animal nutrition. His comparative approach facilitated service on prominent committees, including the National Academy of Sciences, Committee on Animal Nutrition (1981; Chair, 1985), Lab Animal Nutrition (1978), Mineral Toxicity (1980), Horse Nutrition (1989), and Primate Nutrition (Chair, 2003). Duane was recognized by his colleagues with honors, including the MSU Distinguished Faculty Award (1983), ASAS Morrison Award (1988), ASAS Fellow (1990), the first Comparative Nutrition Society honorary life member (1996), and the first award recipient of the Duane E. Ullrey Achievement Award by the American Association of Zoo Veterinarians (1999). Duane was a mentor, friend and colleague. He cultivated sound scientific principles in species husbandry, emphasized a strong foundation in nutrition, and guided our comparative discovery of relevant similarities and differences among novel species with known models. A consummate life-long learner, Duane embodied integrity, thoughtfulness, humor, honesty, and perseverance in his personal and professional life. Through his students, he continues to make remarkable contributions in academia, industry, and regulatory agencies in areas of animal agriculture, wildlife and natural resource management, veterinary medicine, and human nutrition and health.

Key Words: comparative animal nutrition

773 Protein and energy metabolism in the development and management of obesity and chronic diseases in humans. David J. Baer*, *USDA, ARS, Beltsville, MD.*

Obesity and several obesity-related diseases, such as cardiovascular disease and diabetes, are epidemic not only in the United States but around the globe. In addition to their impact on premature death and loss of quality of life, the combined economic burden of obesity and diabetes is nearing one-half trillion dollars in the United States. Furthermore, in many countries, including the United States, there is significant growth in the proportion of the older population, and optimal dietary protein is necessary for healthy aging to minimize age-associated loss of muscle (sarcopenia). Protein is an energy yielding macronutrient, and consumption of protein or any energy yielding macronutrient in excess of need will contribute to unhealthy weight gain. However, some studies have demonstrated that consumption of protein in excess of the Recommended Dietary Allowance for adults (0.8 g/kg body weight/day) is associated with improved health outcomes, including improved body composition and improved insulin sensitivity without detrimental effects on bone or renal function. The effect of higher protein diets on reducing food intake is one mechanism by which protein may influence body composition. In addition to the amount of dietary protein, the quality of that protein can affect health outcomes. Increased consumption of dairy protein, and whey protein in particular, has been associated with decreased body fat without a loss of lean mass. The relatively high branch-chain amino acid concentrations of whey protein may contribute to its physiological effects. Leucine, and perhaps other branched chain amino acids, might mediate changes in body composition through modulation of the mTOR or other key regulatory pathways. With the global public health challenges of obesity and its comorbidities, dietary recommendations to improve health continue to be evaluated. Higher protein diets and high quality proteins can play an important role in improving body composition and supporting healthy aging.

Key Words: obesity, protein, humans

774 Brain and cognitive development: Assessing the impact of nutrition in a neonatal piglet model. Rodney W. Johnson*, *University of Illinois, Urbana, IL.*

Prenatal and early postnatal insults increase the likelihood for neurobehavioral problems later in life. One hypothesis suggests that the pre- and postnatal periods represent sensitive periods during which exposure to adversity programs biological systems in a manner that persists and accentuates vulnerability to behavioral problems later in life. This hypothesis is predicated on pre- and/or postnatal stress influencing structural and functional plasticity of the brain and subsequent stress resilience. The piglet is an excellent model for perinatal developmental studies because it is a gyrencephalic species with brain growth and morphology similar to humans. Its gastrointestinal anatomy and physiology are comparable and in a recent study that examined the similarity of immune-related genes in humans, pigs, and rodents, the overall mean similarity to human immune-related proteins was significantly higher for pigs compared with mouse. In the piglet model we have reported profound effects of perinatal infection, postnatal nutrition, and being born small for gestational age on brain development and behavior. The later issue is particularly relevant to this symposium because protein-energy malnutrition during pregnancy is a leading cause of intrauterine growth restriction and small for gestational age births.

Key Words: low birth weight, learning and memory, stress resilience

775 Comparative gastrointestinal utilization of nitrogen, lysine, and glucose in equids and suids. Nathalie Trottier*, *Michigan State University, East Lansing, MI.*

Equids are obligate hindgut fermenters and thus are equipped with a large cecum and voluminous proximal colon for microbial fermentation of plant cell wall fiber components. Suids are also hindgut fermenters; however, because they have evolved consuming highly diverse diets, they are also classified as omnivores. Suids share similar gastrointestinal anatomical features with equids, and therefore may be a useful model of gastrointestinal nitrogen and carbohydrate metabolism. Important differences exist in the kinetics of glucose transport between equine and porcine small and large intestinal tissues, and these differences shed light on the divergent ability of these 2 species to absorb dietary carbohydrates. In contrast, the 2 species share distinct similarities in intestinal Lys transport kinetics. In both species, the large colon apical membrane is capable of Lys transport via a high capacity and lower affinity transport process that is higher than that of the small intestine. Lys transport across the pig and the pony jejunum is 1.14 and 1.16 pmol/mg tissue (V_{max}), respectively, and uptake by the pig and pony colon is 0.84 and 0.91 pmol/mg tissue (V_{max}), respectively. In both species, the large colon has a lower affinity for Lys compared with the small intestine (i.e., 0.89 and 1.05 K_M, pig and pony, respectively). The broader capacity of Lys transport in the large colon is indicative of the potential role it plays in the uptake of Lys. It is proposed that the porcine model may be useful to predict amino acid requirements for maintenance and digestibility in equids.

776 Carnivores, omnivores, and herbivores—Concepts of ideal protein formulation for ornamental and commercial aquaculture feeds.

Delbert M. Gatlin III* and Sergio Castillo, *Texas A&M University System, College Station, TX.*

Aquacultural production of various fish and crustacean species is continuing to grow throughout the world at over 6% per year, and projected to continue expanding as the demand for seafood increases and harvests from wild stocks remain at or beyond maximum sustainable levels. The efficiency of producing various aquatic species is generally considered to be greater than that of terrestrial livestock, primarily due to efficient feed utilization and protein accretion per unit of energy consumed. There is considerable variation in dietary protein requirements of various fish and crustacean species as well as their ability to use protein and lipid for energy. This variation appears to be primarily related to natural feeding habits in which aquatic species are generally categorized as being herbivorous, omnivorous of carnivorous. This presentation will provide an overview of the protein and amino acid requirements of prominent freshwater omnivorous and carnivorous fish species such as the channel catfish (*Ictalurus punctatus*) and rainbow trout (*Oncorhynchus mykiss*). Those requirements will be compared and contrasted with that of the red drum (*Sciaenops ocellatus*), a marine carnivore, and the omnivorous common carp (*Cyprinus carpio*) of which colored varieties are produced for ornamental purposes. Specific emphasis will be placed on application of the ideal protein concept in formulating diets for these various species.

Key Words: aquatic animals, amino acid requirement, comparative nutrition

Dairy Foods Symposium: Processing and ingredient innovations to grow fluid milk sales

777 Market implications and opportunities in the fluid milk and beverage sector. Alan Reed*[1], Madlyn Daley[1], Marla Buerk[1], and Chris Costagli[2], *[1]Dairy Management Inc., Rosemont, IL, [2]Information Resources Inc., Chicago, IL.*

Changing consumer demographics, habits, practices, and attitudes create both challenges and opportunities for fluid milk in the current beverage marketplace. This presentation will explore data from a variety of sources detailing these consumer trends, and suggest possible opportunities and strategies for growth in the fluid milk category. Data demonstrating the market and consumer impacts of competitive entrants, including non-dairy alternatives made of soy, almond, coconut and rice, will also be explored.

Key Words: milk, seminar, consumer

778 Implications of microbial quality of incoming milk and plant sanitation on shelf life and acceptance. Nicole H. Martin*, Rachel A. Miller, Stephanie N. Masiello, David J. Kent, Kathryn J. Boor, and Martin Wiedmann, *Cornell University, Ithaca, NY.*

Microbial growth in fluid milk is one of the primary drivers of consumer liking. In an age of declining fluid milk consumption, control of microbial growth is critical. The 2 primary mechanisms of microbial spoilage in fluid milk are (1) post-pasteurization contamination (PPC) in the processing facility with psychrotolerant gram-negative bacteria (i.e., *Pseudomonas*); and (2) entry of psychrotolerant sporeforming bacteria (i.e., *Paenibacillus*) via raw milk contamination. Historically, the majority of fluid milk was spoiled by psychrotolerant gram-negative bacteria introduced into the product post-pasteurization. This type of contamination leads to drastically reduced shelf-life and significant flavor, body and odor defects. Results of recent work indicate that over 50% of fluid milk samples show signs of PPC, and of those samples, only 40% are contaminated with coliform bacteria, a commonly used indicator of PPC. These results indicate that PPC is still an issue that needs to be addressed by the dairy industry to offer consumers the highest quality fluid milk. Additionally, traditionally used hygiene indicators (i.e., coliform) need to be reexamined to provide relevant, actionable information to dairy processors regarding PPC. In the absence of PPC, psychrotolerant sporeforming bacteria become the limiting biological factor in fluid milk shelf-life. Addressing fluid milk spoilage from psychrotolerant sporeforming bacteria includes understanding and reducing the transmission of these organisms through identification of key management practices associated with their presence in raw milk, as well as sources of these organisms in the farm environment. Recent work indicates that udder hygiene and farm size are associated with the presence of psychrotolerant spores in raw bulk tank milk. Further, these organisms have been identified in diverse environmental samples (e.g., bedding, feed, manure and soil), indicating their abundance in the dairy farm environment. Ultimately, providing consumers with high quality, long lasting fluid milk requires a systems approach to preventing contamination of fluid milk throughout the grass to glass continuum.

Key Words: quality, sporeformer, sanitation

779 Effect of milk composition and processing conditions on consumer liking. M. A. Drake*, *Southeast Dairy Foods Research Center, North Carolina State University, Raleigh, NC.*

Fluid milk consumption has decreased in the past 20 years while the beverage market continues to expand and diversify. Understanding consumer desires and perceptions for milk and milk flavor are crucial to identify opportunities. A combination of consumer and product research is required. Surveys and interviews demonstrate that flavor and nutrition are the key desires for consumers, and fluid milk holds unique associations with comfort and family. Variety and enhanced protein are 2 opportunities for milk/milk beverage expansion. Appearance plays a critical role in fluid milk preferences, especially for skim milk, and fat, protein and heat treatment also influence the sensory properties. A thorough knowledge of the role of processing conditions and composition on sensory properties and consumer perception of fluid milks will enable milk and milk beverage innovation.

Key Words: milk, consumer liking, processing

780 Shedding light on consumer acceptability of fluid milk: The partnership of retail dairy case lighting systems and packaging. Susan Duncan*, *Virginia Tech, Blacksburg, VA.*

Declining fluid milk purchasing and consumption trends suggest that fluid milk is not competing well in the beverage market. Contributors to this trend include a lack of established packaging selection criteria as well as storage conditions during the early stages of shelf-life before purchase. Fluid milk quality changes rapidly during light exposure, especially in retail lighted display cases. However, lighting in retail refrigerated cases enhances product marketing by showcasing product and package color. Traditionally, fluorescent light is used in retail systems; however, LED lighting systems are increasing because of new federal mandates for energy conservation as well as brighter, more efficient, more attractive display capabilities. It is well established that translucent or clear packaging with no light protective additives does not protect milk flavor and nutrient quality. However, only limited information is available on how fluorescent or LED light exposure influences milk acceptability. Changes in milk flavor are detectable within 2 to 3 h of lighted exposure and acceptability decreases significantly within 8 h of storage under fluorescent lighting when packaged in a translucent high-density polyethylene package. Acceptability does not tell the complete story though. In a recent study from our laboratory, consumers reported more negative emotion terms, specifically disgust, when light-exposed milk was evaluated. Lower hedonic scores were directly related to negative emotions. Milk that was packaged for light protection retained high acceptability scores and positive emotional terminology through 7 d of lighted retail storage conditions. Processors should select packaging that protects milk quality during retail dairy case display lighting to positively influence fluid milk purchasing and consumption behavior. Packaging criteria for protecting fresh fluid milk flavor and nutrients from processing to purchase will be described and justified.

Key Words: consumer, milk, packaging

781 Characterizing factors that influence milk flavor quality. Smaro Kokkinidou, David Potts, and Devin Peterson*, *University of Minnesota, St. Paul, MN.*

Flavor is known to be a key attribute that determines the acceptability of milk. This presentation will cover a range of off-flavor development sources, from farm to processing, focusing on spontaneous oxidized flavor (SOF) milk as well as aseptically processed milk. Spontaneous oxidized flavor (SOF) milk has been a problem for the dairy industry for many years, causing significant economic losses. After collecting raw milk labeled as SOF milk from the Midwest, causative off-flavor compounds were identified as microbial taints (i.e., 2-methylisoborneol) and disproved the hypothesis that the off-flavor was of oxidative origin. Identifying the source of the off-flavor marker provided a basis to improve farming practices to produce higher quality milk. Additionally it demonstrated the likelihood off-flavors in milk of the misclassification as SOF milk, which would inhibit developing solutions. In the second part of this presentation, a more in-depth understanding of the off-flavors generated during aseptic thermal treatment and subsequent storage will be discussed. Milk undergoes aseptic processing to enhance product stability and shelf life but the high temperature short time treatment can also be detrimental to flavor quality. Key off-flavor markers in aseptic milk were identified and pathways of generation were defined providing information for the development of successful flavor improvement strategies. The application of common food phenolic compounds (i.e., in cocoa, tea, and soybeans) to suppress off-flavor development and improve consumer acceptability in UHT products will also be discussed.

Key Words: milk flavor, quality, off-flavor

Milk Protein and Enzymes

782 Dietary whey and casein produce differential effects on energy balance, gut hormones, glucose metabolism, and taste preference in diet-induced obese rats. Adel Pezeshki*, Andrew Fahim, and Prasanth Chelikani, *University of Calgary, Calgary, AB, Canada.*

Milk proteins decrease food intake, body weight, and improve glycemic control; however, little is known about the underlying mechanisms of improvements in energy balance and glucose metabolism. The objectives of this study were to determine the effects of dietary whey, casein, and a combination of the 2, on food intake, energy expenditure, body composition, gut hormones, glucose tolerance, metabolic markers, and taste preference in diet-induced obese rats. In experiment 1, obese rats were randomly assigned to isocaloric high-fat diets (n = 12/group; 33% calories from fat) containing egg white (control; 14% protein calories), whey (WH; 40% protein calories), casein (CA; 40% protein calories) or whey + casein (WHCA; 40% protein calories). Measurements included various behavioral and metabolic parameters. In experiment 2, following an 8-d training period, preference for WH, CA, WHCA or control diets was assessed on consecutive days. Data were analyzed by MIXED procedure. WH, CA and WHCA decreased food intake, body weight and fat content with WH and CA producing pronounced effects. The hypophagic effects of WH were likely due to reduced dietary preference. WH and CA but not WHCA improved glucose tolerance, with WH being more effective. WH reduced energy expenditure at early stages, whereas CA and WHCA increased energy expenditure at later stages of the study. WH, CA and WHCA decreased plasma leptin, glucose-dependent insulinotropic polypeptide and interleukin-6, whereas WH increased glucagon-like peptide-1 concentrations. The CA and WHCA diets increased plasma membrane glucose transporter-4 (GLUT4) to total GLUT4 ratio in skeletal muscle; protein abundance of other markers of glucose and energy metabolism (total Akt, AMPKα, COX-IV, HADH, SIRT3) in the adipose and cardiac tissues did not differ. Overall, our data demonstrate that dietary whey, casein, and their combination, improve energy balance through divergent effects on food intake, energy expenditure, glucose tolerance and gut hormone secretion, with whey being more efficacious. These findings have potential significance for developing whey-based functional foods and nutraceuticals for weight and diabetic control.

Key Words: whey, casein, energy balance

783 Characterization of the bovine milk proteome produced by Holstein and Jersey breeds of dairy cows. Rink Tacoma*, Lam Ying Wai, Julia Ganister Fields, and Sabrina Greenwood, *University of Vermont, Burlington, VT.*

Low-abundance milk proteins are of interest because of their diverse bioactivity. The objective of this study was to characterize the low-abundance protein profile within the whey fraction of milk produced by 2 dairy cattle breeds. A 7-d trial was conducted with 6 Jersey (80 ± 49 DIM) and 6 Holstein (75 ± 21 DIM) cows paired by DIM and parity, housed in the same tie-stall barn. Cows were all maintained on the same TMR diet and were fed individually to determine daily DMI. Milk samples were collected at a.m. and p.m. milking during the experiment. Milk composition (protein, fat, milk urea nitrogen (MUN), SCC) was determined in all samples collected and subsamples were collected and stored at −80C for low-abundance protein analysis. Milk samples for low-abundance protein analysis were thawed, pooled within animal and a mammalian protease inhibitor was added to each sample before centrifugation to isolate the whey fraction. Samples were depleted of casein and separated by SDS-PAGE. Samples were excised and subjected to a tryptic digest followed by LC-MS/MS analysis on a linear ion trap (LTQ)-Orbitrap Mass Spectrometer (MS). Product ion spectra were searched using SEQUEST on Proteome Discoverer 1.4 against a curated Bovine database. A linear mixed model was used to perform a repeated measures analysis on milk parameters and DMI in SAS (9.4). DMI ($P = 0.0108$), milk protein % ($P = 0.0021$), protein yield (kg/d; $P = 0.0068$) and fat % ($P = < 0.001$) were different between breeds whereas MUN ($P = 0.86$) and SCC ($P = 0.59$) were not different between breeds. MS analysis identified 947 proteins including over 45 proteins present at significantly different peptide counts between breeds ($P < 0.05$) with fold differences in peptide counts ranging from 0.2 to 6.5. Some known bioactive proteins were present at significantly different levels, including lactotransferrin ($P = 0.0026$) and complement C2 ($P = 0.0001$), whereas other known bioactive proteins including osteopontin ($P = 0.17$) and lactoperoxidase ($P = 0.29$) were present at similar levels in both breeds. This work provides insight into the low-abundance protein composition of milk produced by 2 dairy breeds.

Key Words: bioactive, whey

784 Lactoferrin and lactalbumin are more effective than whey protein in improving energy balance and glucose tolerance in diet-induced obese rats. Rizaldy Zapata*[1], Adel Pezeshki[1], Arashdeep Singh[1], Mary Chou[2], and Prasanth Chelikani[1], *[1]University of Calgary, Calgary, AB, Canada, [2]Advanced Orthomolecular Research Inc., Calgary, AB, Canada.*

Whey protein is often reported to promote satiety, aid in weight loss and stimulate energy expenditure. However, there is limited information on the relative efficacies of the individual components of whey – lactalbumin and lactoferrin – on energy balance and diabetic control. Our objectives were to compare the effects of whey with lactalbumin and lactoferrin on weight, body composition, food intake, energy expenditure, glucose tolerance and meal-induced hormone responses in diet-induced obese (DIO) rats. The DIO rats were randomized to receive one of 3 isocaloric and isonitrogenous high-fat diets (n = 8/group; 40% calories from fat, 30% protein calories): (1) whey (WH), (2) lactalbumin (LA), or (3) lactoferrin (LF) and were followed for 65 d (d). Food intake, energy expenditure, body composition, glucose tolerance and plasma satiety hormone concentrations were measured. Data were analyzed by repeated measures ANOVA or ANCOVA. Compared with WH, LF decreased food intake, and decreased energy expenditure during the dark period for the first 14 d of treatment. LA did not alter food intake, but increased energy expenditure during the first 3 h of the dark period after ~34 d of treatment interventions. LF reduced body weight by reducing adipose mass after 7 d whereas LA did not alter body weight and composition. When food intake was used as a covariate, LF reduced blood glucose and plasma leptin, but neither LA nor LF altered plasma concentrations of satiety hormones (GLP-1, GIP, PYY, insulin, amylin). Though glucose tolerance did not differ between WH, LA and LF by 30 d, LA and LF improved glucose tolerance by 60 d. In summary, lactoferrin is more effective than whey in inducing hypophagia, promoting fat loss, improving glucose tolerance and in decreasing plasma leptin, whereas lactalbumin is effective in increasing energy expenditure and improving glucose tolerance. These components seem to be more beneficial than just whey itself in improving energy balance and glucose tolerance.

Key Words: whey, lactoferrin, lactalbumin

785 Partial hydrolysis of whey protein using immobilized enzymes and conjugation of these hydrolyzates with the aim of lowering whey protein allergenicity.

Yuansheng Gong*[1], Lei Xu[1], and John A. Lucey[1,2], [1]*Department of Food Science, University of Wisconsin-Madison, Madison, WI,* [2]*Center for Dairy Research, University of Wisconsin-Madison, Madison, WI.*

Our previous research indicated that conjugation of whey protein isolates (WPI) with dextran (DX) via the Maillard reaction could provide an alternative approach to decrease the immunogenicity of whey protein. It has been well established that partial enzymatic hydrolysis of proteins also reduces their antigenicity. We want to explore a combination of partial protein hydrolysis and conjugation to decrease whey protein immunogenicity. In this study, we partially hydrolyzed whey protein by immobilized trypsin and chymotrypsin. All the hydrolyzed proteins were then conjugated with dextran (molecular weight 40kDa). Trypsin and chymotrypsin from bovine were immobilized onto (aldehyde) agarose (6% gels). WPI was partially hydrolyzed by these enzymes at 40, 45 and 50°C. Samples of hydrolyzed whey protein at 30, 60, 120, 180 and 240 min of hydrolysis were analyzed by SDS-PAGE and HPLC. The molecular weight of hydrolyzates was measured by Size-exclusion chromatography coupled with multi-angle laser light scattering detector. The degree of hydrolysis (DH) was 5 and 12% after 30 and 180 min respectively of hydrolysis at 50°C. Molecular weights of most hydrolyzates were between 1 to 5 kDa after 180 min hydrolysis at 50°C. Two hydrolyzates with DH values of 5 and 12% were conjugated with 40 kDa molecular weight dextran via our novel aqueous Maillard reaction method. Conjugates were separated and purified by chromatography. The IgE binding capacity was determined by ImmunoCap method using blood serum from cow's milk protein patient. The IgE binding capacity of conjugated whey protein hydrolyzates is currently being investigated and will be reported. Partial hydrolysis of whey protein plus conjugation with dextran may provide another option to reduce whey protein allergenicity.

Key Words: hydrolysis, conjugation, allergenic

786 Effect of Maillard modification on reducing immunogenicity of whey protein isolate.

Lei Xu*[1], Yuansheng Gong[1], and John A. Lucey[1,2], [1]*University of Wisconsin-Madison, Department of Food Science, Madison, WI,* [2]*Wisconsin Center for Dairy Research, Madison, WI.*

A growing concern around the world is the number of people that are suffering from food protein allergies, especially among infants and young children. One potential approach is to block IgE binding epitopes of the protein allergen via the Maillard reaction with polysaccharides to decrease the allergy potential. Dairy infant formula is often formulated to a high proportion of whey proteins, and if infants are sensitive to whey proteins then hydrolysis of whey proteins is often used. The goal of this research was to reduce the immunogenicity of whey protein isolate (WPI) by conjugating WPI with dextran (DX). During this study, the effect of the molecular weight (M_W) of DX, ranging from 1 to 2000 kDa, on the immunogenicity of WPI-DX were explored. Our data indicated that the WPI to DX molar ratios in the conjugates made from DX with M_W values of 1 (G1), 3.5 (G3.5), 10 (G10), 150 (G150), 500 (G500), and 2000 kDa (G2000) were 1:4, 1:3, 1:2, 1:1.5, 1:1, and 1:1, respectively. With the increase in the M_W of DX, the M_W values of the corresponding conjugates were also increased, as determined by size exclusion chromatography with multiangle laser light scattering. The immunogenicity of conjugates were evaluated by IgE binding capacity of conjugates incubated with serum from blood samples obtained from patients with cow's milk protein allergy. Our results showed that WPI-DX conjugates have a lower WPI-specific IgE binding capacity than native WPI, with the lowest IgE binding capacity obtained in G10 conjugate, demonstrating that glycation via Maillard reaction did significantly reduce the immunogenicity of WPI. Furthermore, atomic force microscopy images suggested that conjugation of WPI with small M_W dextran resulted in greater surface coverage on the protein compared with large dextran conjugates, hence significantly reducing protein immunogenicity by creating steric hindrance that limited IgE binding.

Key Words: whey protein isolate, dextran, immunogenicity

Nonruminant Nutrition: Immune support

787 Evaluating the efficacy of chemicals to mitigate *Salmonella* cross contamination in rendered protein meals. Roger A. Cochrane*, Anne R. Huss, and Cassandra K. Jones, *Kansas State University, Manhattan, KS.*

Salmonella is a potential feed safety hazard that is destroyed during rendering, but this does not eliminate the potential for cross contamination. The objective of this experiment was to evaluate the effectiveness of chemicals to mitigate *Salmonella* cross-contamination in rendered proteins. Treatments were arranged in a 6 × 4 factorial with 6 chemical treatments: (1) chemically negative control, (2) 0.3% commercial formaldehyde, (3) 2% essential oils (1:1 garlic, turmeric, capsicum, oregano, and rosemary), (4) 2% medium chain fatty acids (1:1 caproic, caprylic, and capric acid 1:1), (5) 3% organic acids (1:1 lactic, propionic, formic, and benzoic), (6) 1% sodium bisulfate in 4 rendered proteins: (a) feather meal, (b) blood meal, (c) meat and bone meal, and (d) poultry by-product meal. Matrices were chemically treated, then inoculated with *Salmonella* Typhimurium, and enumerated on d 0, 1, 3, 7, 14, 21, and 42 post-inoculation. Analyzed values represent colony forming units per gram (cfu/g). All main effects and interactions were significant ($P < 0.05$). *Salmonella* concentration in ingredients treated with medium chain fatty acid and commercial formaldehyde were similar to one another ($P = 0.23$), but 2 logs lower than the control ($P < 0.05$; 3.20×10^0 and 4.45×10^0 vs. 3.65×10^2 cfu/g, respectively). Ingredients treated with organic acid and essential oils had less *Salmonella* than the control ($P < 0.05$; 1.58×10^1 and 1.26×10^2 cfu/g, respectively). However, treating ingredients with sodium bisulfate resulted in similar *Salmonella* concentrations as the control ($P < 0.05$; 2.42×10^2 cfu/g). Time played a role in *Salmonella* mitigation as all days ($P < 0.05$) except d 14 and 21 ($P = 0.92$) were different from one another (3.14×10^4, 4.48×10^2, 5.57×10^1, 8.98×10^0, $3.07 \times 0°$, 3.16×10^0, 1.35×10^0 cfu/g for d 0, 1, 3, 7, 14, 21, and 42, respectively). Matrix also affected *Salmonella* stability as concentrations in meat and bone meal and blood meal and were similar to one another ($P = 0.36$; 6.54×10^1 and 5.32×10^1 cfu/g, respectively), but greater than ($P < 0.05$) levels in feather meal and poultry by-product meal (2.29×10^1 and 2.31×10^1 cfu/g, respectively). In summary, chemical treatment and time both mitigated *Salmonella*, but their effectiveness was matrix dependent. Chemical treatment with medium chain fatty acids or a commercial formaldehyde product was most effective at mitigating *Salmonella* in rendered protein meals.

Key Words: *Salmonella*, chemical treatment, feed safety

788 Supplemental effects of herbal additive on growth performance, health status, and carcass quality in finishing pigs as alternatives to the use of antibiotics. W. Parnsen*, S. H. Zhang, and S. W. Kim, *Department of Animal Science, North Carolina State University, Raleigh, NC.*

This study was conducted to determine the effect of herbal additive (AV/AGP/10, Ayurvet Limited, Baddi, H.P., India, based on extracts of garlic, ginger, menthol, cinnamon, and thyme) on the growth performances, health status, and carcass quality of finishing pigs fed diets. Ninety-six pigs (48 barrows and 48 gilts) at 84 d of age (41.5 ± 2.7 kg BW) were allotted to 4 treatments (2 × 2 factorial arrangement with 0 and 0.05% Tylan40 (Elanco) and herbal additive (0 and 0.05% AV/AGP/10) based on a randomized complete block design with 8 pens (3 pigs per pen, 4 barrow and 4 gilt pens) per treatment. Body weight and feed intake were measured weekly. Blood samples were taken on d 37 to obtain plasma to measure tumor necrosis factor α (TNF-α), protein carbonyl, and immunoglobulins. On d 40, 32 pigs (1 pig from each pen and 8 pens per treatment) were euthanized to collect duodenal and jejunal mucosa layers for TNF-α, protein carbonyl, IgA, and IgG concentrations. Gut tissues from middle part of jejunum were obtained to measure villus height (VH), crypt depth (CD), villus width and VH/CD. Carcass traits were measured including backfat thickness (10th rib), loin pH, marbling score, loin color, and drip loss. Data were analyzed using the MIXED procedure in SAS with pen as the experimental unit (treatment and sex as fixed effects and BW as a random effect). Overall, antibiotic supplementation increased ($P < 0.05$) final BW (88.0 to 90.4 kg), ADG (1.176 to 1.225 kg/d), hot carcass weight (62.0 to 63.8 kg), and cold carcass weight (60.0 to 61.7 kg). Herbal supplementation tended to reduce ($P = 0.079$) ADFI (2.829 to 2.785 kg/d), tended to enhance ($P = 0.060$) G:F at wk 5 (0.430 to 0.460), and enhanced ($P < 0.05$) G:F at wk 6 (0.612 to 0.643). Backfat thickness, loin weight, loin color, marbling score, plasma TNF-α, and tissue TNF-α were not affected by factors. There were no interactions between 2 factors in all measurements. Collectively, antibiotic supplementation improves growth performance and carcass weight whereas herbal additive can potentially enhance feed efficiency if it is fed to finisher pigs longer than 4 wk regardless of the use of antibiotics.

Key Words: carcass quality, gut health, herbal additive

789 Effect of additives on survival of swine delta coronavirus (SDCoV) in complete feed. Katie M. Cottingim*[1], Harsha Verma[2], Fernando Sampedro[2], Pedro E. Urriola[1], Gerald C. Shurson[1], and Sagar M. Goyal[2], *[1]Department of Animal Science, University of Minnesota, St. Paul, MN, [2]Veterinary Population Medicine, University of Minnesota, St. Paul, MN.*

Swine delta coronavirus was first discovered in 2012 in China, and the first confirmed case in the US was in Ohio in 2014. Feed contaminated with feces from infected pigs is a potential route of transmission of SDCoV. Organic acids (OA) and feed additives are included in diets to improve nutritional value. The objectives of our study were to determine if OA or additives at recommended or twice the recommended concentrations are effective in reducing the survival of SDCoV in feed. Five g aliquots of complete feed were placed in scintillation vials followed by addition of 1 of 8 additives at recommended concentrations of 150mg Ultracid P (orthophosphoric, citric, fumaric, and malic acid; Nutriad), 20mg Activate DA (organic acids and 2-hydroxy-4-methylthio butanoic acid; Novus Intl.), 10mg KEM-GEST (phosphoric, fumaric, lactic, and citric acid; Kemin Agrifoods), 10mg Acid Booster (phosphoric, citric, and lactic acid; Agri-Nutrition), 56μL Luprosil (propionic acid; BASF), 46μL formic acid (formic acid; BASF), 20mg salt, or 20mg sugar. Virus was grown and titrated in swine testicular (ST) cells and was added to all vials at 1mL/vial (initial virus titer = 3.2×10^5 $TCID_{50}$/mL) followed by vortexing and storage of vials at room temperature (25°C) for 5 wk. Exp. 2, twice the recommended concentration of additives was added to aliquots and experimental conditions were identical to those used in Exp. 1 except that virus survival was evaluated on d 0, 1, 3, 7, and 10 of storage. Samples were eluted with 3% beef extract-0.05M glycine solution and inoculated in ST cells to calculate $TCID_{50}$/mL. Data were analyzed using Weibull inactivation kinetics model. In Exp. 1, we observed that it takes 0.86 d to reduce the concentration of virus by 1 log. None of the additives tested reduced the inactivation kinetics of the virus at recommended doses. However, adding twice the recommended concentration reduced the time for 1 log inactivation in feeds with Acid

Booster (0.28 d) ($r^2 = 0.93$), Activate DA (0.12 d) ($r^2 = 0.72$), and salt (0.09 d) ($r^2 = 0.91$). Thus, using these feed additives may reduce virus survival in complete feed faster.

Key Words: feed additive, organic acid, swine delta coronavirus

790 Infection with porcine reproductive and respiratory syndrome virus (PRRSV) affects body protein deposition and alters amino acid metabolism in growing pigs.

Whitney D. Stuart*[1], Thomas E. Burkey[2], Nicholas K. Gabler[3], Kent Schwartz[3], Thu Dinh[4], Cornelius F. M. de Lange[5], David Klein[1], John A. Dawson[1], and Anoosh Rakhshandeh[1], *[1]Texas Tech University, Lubbock, TX, [2]University of Nebraska-Lincoln, Lincoln, NE, [3]Iowa State University, Ames, IA, [4]Mississippi State University, Mississippi State, MS, [5]University of Guelph, Guelph, ON, Canada.*

Changes in plasma free amino acid (AA) kinetics reflect modification of AA metabolism in different metabolic states. Infectious diseases in growing pigs redistribute AA from body protein deposition (PD) toward processes involved in immune response. The aim of the current study was to quantify the effects of PRRSV infection on PD and AA metabolism. Twenty PRRSV-negative gilts (BW 9.4 ± 0.9 kg) were blocked by time, surgically catheterized, housed in metabolism crates, fed a corn-SBM based diet (ME 14 MJ/kg, SID Lys 11.5 g/kg), feed-restricted (550 g/d), and then inoculated intramuscularly with a live PRRSV. Blood samples were collected via the catheters at 0, 2, 4, 6, 8, and 10 d post inoculation, and assayed for blood chemistry, hematology, and serum viral load. Body temperature (BT) was monitored on a daily basis. N-balances were determined during a 3 d pre inoculation period and a 3 d post inoculation period. At the end of each N-balance period a single dose of [U-13C, U-15N] AA mixture (Lys, Met, Thr, Trp, Ile, Leu, Val, Phe, Gln) was infused intravenously to study plasma AA kinetics. For each pig and AA, an irreversible loss rate (ILR; disappearance of AA from plasma pool) was determined. Data were analyzed using a randomized complete block design (PROC MIXED in SAS). Blood chemistry, hematology, BT, and serum viral load results indicated that PRRSV injection induced effective immune system stimulation in pigs ($P < 0.05$). The PRRSV challenge reduced PD from 59.4 to 38.1 g/d, SE 4.56, but increased the ILR (μmol/kg BW/h) for Met (from 108 to 228, SE 26.7) and Thr (from 83 to 129, SE 11.5; $P < 0.05$). The ILR for other AA was not affected by PRRSV. These results suggest that PRRSV infection reduces PD and alters metabolism of Met and Thr in growing pigs. The increased ILR for Met and Thr in PRRSV challenged pigs could be associated with enhanced utilization of Met and Thr for synthesis of immune system metabolites and increased catabolism of these AA. This may increase dietary Met and Thr requirements of health challenged pigs, relative to requirements for other AA.

Key Words: amino acid, kinetic, PRRS

791 Effect of selenium and vitamin E supplementation on muscular damage enzymes in horses under moderate exercise.

Elias Velázquez-Cantón*, Aurora H. Ramírez-Pérez, Luis Alberto Zarco-Quintero, Delia Arlette Castillo-Mata, and Juan Carlos Ángeles-Hernández, *Facultad de Medicina Veterinaria y Zootecnia, Universidad Nacional Autónoma de México, Av. Universidad 3000 México, D.F., México.*

Twenty-four horses (450 kg, 5–15 yr) were involved in an 11-wk trial to study the effect of both selenium (Se, Se-yeast) and vitamin E (E, α-tocopheryl) supplements on serum concentration of muscle damage enzymes (creatinine phosphokinase, CK; aspartate aminotransferase, AST and lactate dehydrogenase, LDH) in horses under moderate exercise. Horses were not exercised for a month before this study; they were housed in individual stables and assigned into a factorial trial arrangement (2 × 2; Se, E levels; n = 6) with repeated measures. Basal ration was deficient in Se and vitamin E (<2 μg; 14.4, IU/kg DM). The supplementation levels met NRC 2007 requirements: low (L: Se, 0.1 mg/kg DM; E, 1.6 IU/kg BW) and high (H: Se, 0.3 mg/kg DM; E, 2 IU/kg BW) for horses under moderate or intense exercise, respectively. Hence, treatments were: LSeLE, HSeLE, LSeHE and HSeHE. Exercise was done from wk 4 to wk 7: 3 consecutive days for 30 min (5–20–5), including: warm up-moderate gallop-cool down. Serum samples were taken every week (wk 4-wk 7, at the end of last exercise day). Creatine phosphokinase, AST and LDH were quantified by spectrophotometry. Data were analyzed using the SAS PROC MIXED procedure (SAS Inst. Inc., Cary, NC) for the design described above. Fixed effects were Se, E, wk, and their interactions, while horse nested within treatment was the random effect. Tukey-Kramer test was used to compare LSM. Neither Se nor vitamin E levels affected enzymes concentrations ($P < 0.01$). An effect of wk was observed for CK and AST at wk 6, exercise explained this fact; CK, AST and LDH increased at wk 3 and wk 11 (unsupplemented horses)

Key Words: exercise, antioxidant, horse

792 Effect of Sal CURB on digestibility of energy and nutrients by growing pigs.

Yanhong Liu* and Hans H. Stein, *Department of Animal Sciences, University of Illinois, Urbana, IL.*

Sal CURB brand ASF liquid antimicrobial is a blend of aqueous formaldehyde 37% solution and propionic acid. An experiment was conducted to determine the effects of Sal CURB on apparent total-tract digestibility (ATTD) of energy, Ca, and P, and apparent ileal digestibility (AID) of CP and AA in a diet fed to growing pigs. Eight barrows (initial BW: 26.81 ± 1.77 kg) had a T-cannula installed in the distal ileum and were allotted to a 2-period switch back design with 2 diets and 8 replicates per diet. A saline treated base mix or a Sal CURB treated base mix was added to the diet that were based on corn, soybean meal, distillers dried grains with solubles, and oats (10.0%). Each period lasted 7 d and fecal samples were collected on d 5 and 6 and ileal digesta were collected on d 6 and 7 of each period. Three random samples from each of the 2 base mixes were analyzed for phytase and vitamins on d 0, 7, 28, and 49 after sampling to determine stability of vitamins and phytase in the base mixes. Data were analyzed by ANOVA using PROC MIXED of SAS in a randomized complete block design with diet as fixed effect and pig and period as random effects. Pigs fed Sal CURB diet had greater ($P < 0.05$) ATTD of Ca (69.33%) and P (61.72%) than pigs fed the control diet (63.80 and 57.53%, respectively). No differences were observed in the ATTD of DM and GE and the AID of CP and all AA between the control diet and the Sal CURB diet, with the exception that the AID of Met was greater ($P < 0.05$) in the Sal CURB diet (89.56%) than in the control diet (88.41%). The Sal CURB treated base mix contained less ($P < 0.05$) phytase than the saline treated base mix on d 0, 7, 28, and 49. The Sal CURB treated base mix contained more ($P < 0.05$) vitamin B3 and B9 on d 0, more ($P < 0.05$) vitamin B1 on d 28, and more ($P < 0.05$) vitamin B1, B2, and D3 on d 49, compared with the saline treated base mix. In conclusion, supplementation of Sal CURB to diets for growing pigs does not affect the digestibility of energy and AA, but increases the digestibility of Ca and P in phytase containing diets. However, Sal CURB treatment reduces the concentration in the base mix of phytase by approximately 20%, but concentrations of vitamins are not reduced.

Key Words: digestibility, pigs, Sal CURB

793 Effect of a 3-strain *Bacillus*-based direct-fed microbial on growth performance, volatile fatty acid production, carcass characteristics, and gastrointestinal tract weights in growing-finishing pigs fed low or high fiber diets.

Neil W. Jaworski*[1], Augustine Owusu-Asiedu[2], Ajay Awati[2], Alastair Thomas[2], and Hans H. Stein[1], *[1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]Danisco Animal Nutrition, DuPont Industrial Biosciences, Marlborough, UK.*

The effect of a 3-strain *Bacillus*-based direct-fed microbial (DFM) on growth performance, VFA production, carcass characteristics, and gastrointestinal tract weights in growing-finishing pigs was evaluated. A total of 160 pigs (initial BW: 26.61 ± 2.17 kg) were randomly allotted to a 2 × 2 factorial design with 2 diet types [low fiber (LF) or high fiber (HF)] and 2 levels of DFM [0 or 60 g DFM (2.4×10^{12} cfu/kg feed)/t of feed] and 4 pigs per pen. Grower and early finisher diets were fed for 5 weeks and late finisher diets were fed for 24 d. The LF diets contained corn and soybean meal as main ingredients and HF diets contained corn, soybean meal, corn distillers dried grains with solubles (30%) and wheat middlings (10%). One pig/pen was harvested at the conclusion of the experiment. Cecum and rectum contents were analyzed for VFA, and carcass characteristics and gastrointestinal tract weights were measured. Data were analyzed as a 2 × 2 factorial with DFM level, diet type, and the interaction of DFM and diet type as fixed effects and rep as a random effect using the Mixed procedure of SAS. Results indicated that for the overall growing-finishing period, there was no difference in ADG between pigs fed LF and HF diets, but pigs fed HF diets had greater ($P < 0.01$) ADFI (2.5 vs. 2.4 kg/d), reduced ($P < 0.01$) G:F (0.36 vs. 0.37 kg/kg), reduced ($P < 0.05$) dressing percentage (77.5 vs. 78.2%), and increased ($P < 0.05$) weight of empty intestinal tract ($P < 0.05$) compared with pigs fed LF diets. Pigs fed LF diets had a greater ($P < 0.05$) concentration of propionate in cecum contents and greater ($P < 0.05$) concentrations of all VFA in rectal contents compared with pigs fed HF diets. Pigs fed diets supplemented with DFM had greater ($P \leq 0.05$) HCW (88.5 vs. 84.3 kg) and backfat thickness than pigs fed diets with no DFM, but fat-free lean percentage was reduced ($P < 0.05$). In conclusion, pigs fed HF diets had greater overall ADFI, lower G:F, and a lower dressing percentage than pigs fed LF. The addition of this DFM to LF or HF diets had no effect on growth performance, but increased HCW.

Key Words: direct-fed microbial, fiber, pig

794 Effect of a 3-strain *Bacillus*-based direct-fed microbial on growth performance and volatile fatty acid production in nursery pigs fed low or high fiber diets.

Neil W. Jaworski*[1], Augustine Owusu-Asiedu[2], Ajay Awati[2], Alastair Thomas[2], and Hans H. Stein[1], *[1]University of Illinois at Urbana-Champaign, Urbana, IL, [2]Danisco Animal Nutrition, DuPont Industrial Biosciences, Marlborough, UK.*

The effect of a 3-strain *Bacillus*-based direct-fed microbial (DFM) on growth performance and VFA production in weanling pigs fed low or high fiber diets was evaluated. Two hundred pigs (initial BW: 6.31 ± 0.73 kg) were allotted to 1 of 4 dietary treatments with 5 pigs/pen. Treatments were arranged in a 2 × 2 factorial design with 2 diet types [low fiber (LF) or high fiber (HF)] and 2 levels of DFM [0 or 60 g DFM (2.4×10^{12} cfu/kg)/t of feed]. Phase 1 diets were fed for 2 weeks post-weaning and phase 2 diets for the following 29 d. The LF diets contained corn and soybean meal as main ingredients and HF diets contained corn, soybean meal, corn distillers dried grains with solubles (7.5 and 15.0% in phase 1 and 2, respectively) and wheat middlings (10.0%). The NE in phase 1 LF and HF diets was 2,525 and 2,463 kcal/kg, respectively. The NE in phase 2 LF and HF diets was 2,483 and 2,414 kcal/kg, respectively. No diets contained antibiotic growth promoters. Pigs and feed were weighed at the start and at the end of each phase, and ADG, ADFI, and G:F were calculated. At the conclusion of phase 2, 1 pig/pen was killed. Cecum and rectum contents were collected and analyzed for VFA. Data were analyzed as a 2 × 2 factorial with DFM, diet type, and the interaction of DFM and diet type as fixed effects and rep as a random effect using the Mixed procedure of SAS. During phase 1, a reduction ($P < 0.05$) in ADFI of pigs fed HF diets and a tendency for pigs fed diets supplemented with DFM to have an improved ($P = 0.10$) G:F were observed. Pigs fed LF diets had a greater ($P = 0.05$) BW (27.06 kg) at the end of phase 2 compared with pigs fed HF diets (26.31 kg). The concentration of acetate, propionate, and isovalerate in rectum contents were greater ($P < 0.05$) in pigs fed LF diets, and there was a tendency for addition of this DFM to increase ($P = 0.10$) isovalerate concentration in cecum content. For the entire experimental period, HF diets decreased ($P = 0.05$) ADFI and ADG of pigs by 32.5 and 17.5 g / d, respectively, and the addition of this DFM improved ($P < 0.05$) G:F. In conclusion, the 3 strain *Bacillus*–based DFM improved overall G:F by 0.8 and 7.3% in LF and HF diets, respectively.

Key Words: direct-fed microbial, fiber, pig

795 Effect of L-DOPA on performance and serum cholesterol of broiler.

Babatunde R. Omidiwura*, Adebisi F. Agboola, and Eustace A. Iyayi, *University of Ibadan, Ibadan, Oyo, Nigeria.*

The L-DOPA found in mucuna seed, when present with other antinutritional factors, has been implicated in nutritional disorders of monogastric animals. It is also reputed to influence muscular development. However, information on its effect on the hydrolysis of triglycerides is scanty. Therefore, the effect of L-DOPA on growth performance and serum cholesterol in broiler chickens was investigated. Two hundred forty 1-d-old chicks were allotted to 6 treatments containing positive control (PC) with normal energy, negative control (NC) with high energy, NC+0.1, NC+0.2, NC+0.3 and NC+0.4% L-DOPA. All treatments had 4 replicates in a completely randomized design. Feed intake (FI), final weight (FW), body weight gain (BWG), feed conversion ratio (FCR), dressed weight (DW), serum total cholesterol (TC), triglyceride (Tg), high density lipoprotein (HDL), low density lipoprotein (LDL) and very low density lipoprotein (VLDL), were determined following standard procedure. Data were analyzed using descriptive statistics and ANOVA at $\alpha_{0.05}$. The body weight gain and final weight of birds fed PC were 1791.0 and 1830.0 g, NC+0.1% L-DOPA were 1827.7 and 1866.7 g and NC+0.2% L-DOPA were 1871.9 and 1910.9 g, respectively, and the feed intake of PC (3231.5 g), were better than other treatments. The serum total cholesterol were 125.0, 129.4, and 131.5 mg/dL of PC, NC and NC+0.4% L-DOPA, respectively, and LDL were 75.1 and 75.7 mg/dL of PC and NC, respectively. The values observed were similar but higher than other treatments with lowest LDL observed in birds fed NC+0.2% (61.2 mg/dL) and NC+0.3% L-DOPA (62.4 mg/dL). The VLDL values observed, 19.8, 22.0, 22.3 and 22.7 mg/dL of birds fed NC+0.1%, NC+0.2%, NC+0.3% and NC+0.4% L-DOPA, respectively, were similar, lower than 26.8 mg/dL of NC but higher than 15.7 mg/dL of PC. The dressed weight at 1375.0 g and 1357.1 g of NC+0.1% and NC+0.2% L-DOPA, respectively, were similar but better than other treatments. Triglyceride and HDL were not affected across treatments. L-DOPA extract, at levels tested, had no detrimental effect on broilers; rather, the serum cholesterol profile was improved and better bird performance was observed especially at 0.1 and 0.2% L-DOPA inclusion rates. Therefore, 0.2% inclusion is recommended in diets of broiler chickens for improved performance, carcass characteristics and cholesterol profile.

Key Words: L-DOPA, serum cholesterol, broiler

796 Effect of high caloric diet enriched in medium-chain triglycerides and arginine supplementation on cholesterol and lipid metabolism in finishing pigs. Z. H. Zhou, D. W. Chen, P. Zheng, G. Tian, B. Yu*, and Y. Yao, *Animal Nutrition Institute, Sichuan Agricultural University, Chengdu, Sichuan, China.*

A total of 60 DLY pigs (88.16 ± 8.03 kg) were used in a 28-d study to determine the effects of high caloric diet enriched in medium-chain triglycerides (HCD-MCT) and L-arginine (Arg) supplementation on cholesterol and lipid metabolism in a 2 × 2 factorial design. Data were analyzed by ANOVA using the GLM procedures of SPSS with the main effects of diet (10% corn starch vs. 10% coconut oil, coconut oil is enriched in MCT, dietary DE were 3.40 Mcal/kg and 3.87 Mcal/kg), supplemented Arg (0 vs. 1%) and their interaction. HCD-MCT increased serum triacylglycerol (+35.48%), total cholesterol (+34.80%) and HDL-C (+66.05%) levels ($P < 0.05$), decreased the ratio of LDL-C to HDL-C (−35.24%, $P < 0.05$). Moreover, HCD-MCT upregulated mRNA expression of 3-hydroxy-3-methylglutaryl coenzyme A reductase (+30.69%) and lecithin cholesterol acyltransferase (+53.06%) in liver ($P < 0.05$), downregulated mRNA expression of fatty acid synthase (FAS) in backfat (−50.72%, $P < 0.05$) and peroxisome proliferator-activated receptor-γ (PPAR-γ, −23.93%) in liver ($P < 0.05$), accompanied by decreased backfat thickness and fat content in liver (−11.91% and −12.76%, $P < 0.05$). Arg supplementation suppressed gene expression of FAS in backfat (−47.41%, $P < 0.05$) and PPAR-γ in liver (−19.50%, $P < 0.05$), elevated gene expression of hormone-sensitive lipase (HSL) and carnitine palmitoyltransferase1 (CPT-1) in backfat (+78.20% and +30.53%, $P < 0.05$), while reduced backfat thickness (−11.48%, $P < 0.05$) and fat content in liver (−7.18%, $P < 0.05$). There was a diet × supplemented Arg interaction observed for FAS, CPT-1 and PPAR-γ mRNA abundance in backfat and liver ($P < 0.05$), in which pigs fed control diet had less mRNA expression of FAS (−62.00% in backfat, −59.00% in liver) and PPAR-γ (−37.00% in liver), and greater CPT-1 expression (+66.00% in liver) compared with pigs fed HCD-MCT diet. In conclusion, our results indicated that HCD-MCT was helpful to reduce fat deposition in backfat and liver, and improve serum HDL-C concentration. Arg supplementation also prevented fat deposition by regulating lipid metabolism without any effects on cholesterol profile.

Key Words: medium-chain triglyceride, arginine, metabolism

797 Effects of lactulose on growth, carcass characteristics, fecal microbiota, and blood constituents in broilers. M. Mohammadi*, S. Shanmugam, H. Y. Shin, S. Mohana Devi, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea.*

A total of 324 one-day-old Ross 308 mixed-sex broiler chicks with an average initial body weight of 38 g were used in a 35-d growth assay to determine the effect of supplementing diets with lactulose on growth performance, carcass characteristics, fecal microbiota, and blood constituents. There were 18 birds/pen and 6 pens/treatment with food and water consumed ad libitum. Treatments were a corn-soybean-meal-based diet with none, 0.25 and 0.5% of lactulose. Data were analyzed as a completely randomized design using the mixed procedures of SAS (SAS Institute, 1996), orthogonal polynomial contrasts were used to look for linear and quadratic effects of Lactulose dose in the diet. Results indicated that gain of body weight (BWG; 1,715 vs. 1,765 vs. 1,843 g/d) and feed conversion ratio (FCR; 1.63 vs. 1.58 vs. 1.54) were improved linearly ($P < 0.05$). As for results increasing concentration of lactulose in the diet from none to 0.5% increased ($P < 0.05$) BWG and decreased FCR for d 8 to 21, 21 to 35, and 0 to 35. Also chickens fed supplemented diet with 0.5% lactulose showed higher relative weight of breast meat compared with other groups (7.26 vs. 8.50 vs. 8.64%). Inclusion of lactulose decreased the count of *Salmonella* (2.73 vs. 2.50 vs. 2.47 log10cfu/g) and *E. coli* (6.57 vs. 6.39 vs. 6.40 log10cfu/g) of feces in chickens fed diets containing 0.25 and 0.5% lactulose ($P < 0.05$), but the count of *Lactobacillus* was not affected. Addition of 0.5% lactulose decreased drip loss percentage on d 1 ($P < 0.05$; 3.98 vs. 2.94 vs. 2.35%) but there wasn't any significant effect on meat color. Blood characteristics were not influenced. Thus it was concluded that inclusion of lactulose improved growth performance and altered fecal microbial populations with no negative effect meat quality and blood profile.

Key Words: broiler, carcass characteristic, lactulose

798 Effect of supplying a nucleotide product (Ascogen) to sow diets on growth performance of the offspring in the nursery. I-Fen Hung*[1], Klaus Hoffmann[2], Peter Koeppel[2], and Merlin D. Lindemann[1], *[1]University of Kentucky, Lexington, KY, [2]Chemoforma Ltd., Augst, Switzerland.*

Nucleotides are not classified as essential nutrients as animals can synthesize them to a limited extend. However, studies have demonstrated their ability to improve biological responses including growth, immunity, and stress resistance. This experiment was conducted with a subset of sows in a commercial farm in China to evaluate the effects of late gestation and lactation supplementation with nucleotides and the performances of pigs post weaning. Sows (n = 40) around d 87 of gestation were randomly assigned to 2 dietary treatments: 1) the farm standard gestation and lactation diets (corn and soybean meal based,) or 2) the standard diets blended with 0.05% Ascogen (NT; Chemoforma, Switzerland) during gestation and 0.1% during lactation. At weaning, piglets (n = 112) from sows on each diet were split into 2 groups and fed diets that contained either 0 or 0.1% NT in a 42-d study which resulted in a 2 × 2 factorial arrangement. The data were analyzed by ANOVA using GLM program of SAS. Supplying NT to sow diets tended to

reduce piglet mortality at birth (2.4 vs. 9.5%, $P = 0.10$) and the days to rebreeding (5.4 vs. 9.6d, $P = 0.10$). The individual piglet weight at birth and weaning as well as milk and serum immunoglobulin profile (IgA, IgG, IgM by ELISA) were not affected by NT. However, pigs from NT sows were heavier than those from control sows at Week 3 (13 vs. 12kg, $P = 0.02$) and Week 6 post weaning (22 vs. 20 kg, $P = 0.01$). They also had increased ADG (353 vs. 320 g, $P = 0.01$) and ADFI (592 vs. 539 g, $P = 0.04$) throughout the nursery period. Nursery treatments had no effect on growth performance. Piglets from NT sows had higher serum IgA levels at weaning (0.17 vs. 0.13 mg/mL, $P = 0.01$) and 1 week post weaning (0.20 vs. 0.17 mg/mL, $P = 0.05$), but no effect on serum IgG and IgM levels was observed. In conclusion, adding NT to the sow diets had beneficial effects on mortality of birth, days to rebreeding, and the growth of piglets during nursery in the commercial environment of this study. However, dietary NT supplementation in nursery may have no effect on growth.

Key Words: nucleotide, sow, nursery

Physiology and Endocrinology Symposium: Insulin revisited

799 Insulin receptor signaling in normal and insulin-resistant states. Brian O'Neill*[1,2], [1]*Joslin Diabetes Center, Boston, MA,* [2]*Harvard Medical School, Boston, MA.*

As type 2 diabetes has reached pandemic levels affecting nearly 370 million people worldwide, it is critical to understand the cellular processes that influence this disease. Insulin resistance, or the inability of normal levels of insulin to achieve the normal effect, is a hallmark of type 2 diabetes and metabolic syndrome. When going from the fasted to the fed state, insulin binds to the ubiquitously expressed insulin receptor to activate downstream signaling, which regulates many cellular actions such as glucose, lipid, and protein metabolism. At the level of the organism, insulin's effect on glucose and lipid metabolism occurs primarily through actions on liver, skeletal muscle, and adipose tissue. The various proteins and isoforms that positively and negatively modulate the insulin-signaling cascade ensure a proper response to feeding. However, these regulators of insulin signaling can be disrupted in a variety of ways in response to disease states such as obesity, inflammation, or even during the aging process and contribute to insulin resistance. Understanding the processes by which insulin signaling is affected in response to these disease states is critical to the discovery of new treatments to prevent diabetes, metabolic syndrome, and their complications.

Key Words: diabetes, insulin resistance

800 Roles for insulin-supported skeletal muscle growth. Robert P. Rhoads*[1] and Lance H. Baumgard[2], [1]*Virginia Tech, Blacksburg, VA,* [2]*Iowa State University, Ames, IA.*

Basic principles governing skeletal muscle growth and development, from a cellular point of view, have been realized for several decades. Skeletal muscle is marked by the capacity for rapid hypertrophy and increases in protein content. Ultimately, skeletal muscle growth is controlled by 2 basic means; myonuclear accumulation stemming from myoblast proliferation and the protein synthesis and degradation balance. Each process underlies the rapid changes in lean tissue accretion evident during fetal and neonatal growth and are particularly sensitive to nutritional manipulation. Although multiple signals converge to alter skeletal muscle mass, postprandial changes in the anabolic hormone, insulin, link feed intake with enhanced rates of protein synthesis in the neonate. Indeed, a consequence of insulin-deficient states such as diabetes or malnutrition is reduced myoblast activity and a net loss of body protein. A well-characterized mechanism mediating the anabolic effect of insulin involves the phosphatidylinositol 3-kinase (PI3K) mammalian target of rapamycin (mTOR) signaling pathway. Activation of mTOR leads to translation initiation control via the phosphorylation of downstream targets. Modulation of this pathway by insulin, as well as other hormones and nutrients, accounts for enhanced protein synthesis leading to efficient lean tissue accretion and rapid skeletal muscle gain in the growing animal. Dysfunctional insulin activity during fetal and neonatal life stages likely alters growth through cellular and protein synthetic capacities.

Key Words: insulin, skeletal muscle, myoblast

801 The biology of hyperinsulenemia induction of polycystic ovarian syndrome and its complications. Jean-Patrice Baillargeon*[1,2], [1]*Université de Sherbrooke, Sherbrooke, QC, Canada,* [2]*Research Center of Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, Canada.*

Polycystic ovarian syndrome (PCOS) is a common condition affecting 6 to 10% of women of childbearing age. It is the most frequent endocrine disorder among young women in North America. In addition of being the most frequent cause of female infertility, PCOS is the commonest cause of hyperandrogenism in women, thus leading to esthetical concerns such as excessive hair growth, acne and alopecia. Accordingly, PCOS women are more likely to have impaired quality of life, including depression, anxiety and increased risk of social phobia and suicide attempts. In addition, PCOS is currently considered as a paradigm of cardiometabolic disease, because the prevalence of metabolic syndrome, dyslipidemia and type 2 diabetes (T2D) are much higher in PCOS than in normal age- and BMI-matched women. Indeed, PCOS women demonstrate metabolic insulin resistance (IR) and compensatory hyperinsulinemia, which play a critical role in the syndrome's development. Yet, many questions remain unanswered regarding the mechanisms by which metabolic IR and hyperinsulinemia leads to hyperandrogenemia and PCOS infertility. The existence of women developing PCOS without IR suggests that it is not a requisite for the development of this syndrome. Nevertheless, several evidences suggest that impairment in insulin signaling may be implicated in androgen overproduction at the level of androgen producing tissues. This talk will therefore review potential metabolic mechanisms in the development of PCOS in predisposed women. This talk's objectives are to (1) review briefly the PCOS and some characteristics of insulin resistance in PCOS; (2) describe the mechanisms of insulin action on androgen biosynthesis in PCOS; and (3) discuss the implication of nonesterified fatty acids (NEFAs) in PCOS hyperandrogenemia and its metabolic complications. This talk will discuss the hypothesis that lipotoxicity (the cellular adverse consequences of NEFAs) may cause both the hyperandrogenemia and insulin resistance that characterize PCOS women. Lipotoxicity could therefore explain PCOS symptoms, mainly due to hyperandrogenism, and long-term metabolic consequences.

Key Words: polycystic ovary syndrome, insulin, lipotoxicity

802 Insulin effects on mammary gland extraction and milk synthesis. Wendie S. Cohick*, *Rutgers University, New Brunswick NJ.*

During lactation there is an increased demand for nutrients required for milk protein and lipid synthesis as the mammary gland undergoes functional differentiation from late pregnancy to early lactation. Insulin resistance in insulin-sensitive peripheral tissues channels nutrients to the mammary gland for milk synthesis in early lactation. Glucose uptake by the mammary gland is insulin-independent, with insulin showing little effect on mRNA expression of glucose transporters. In contrast, it has long been known that the lactogenic hormones hydrocortisone, insulin and prolactin are required for maximum expression of milk protein genes in the mammary gland. Recently it has been recognized that the regulation of protein translation may play a central role in determining milk protein production. The mammalian target of rapamycin (mTOR) signal transduction pathway has been identified as a master regulator of protein translation. Data indicating that hormones (i.e., insulin and IGF-I), nutrients (i.e., amino acids) and intracellular energy status interact to regulate the mTOR signaling pathway and thus protein synthesis in the mammary gland will be presented.

Key Words: insulin, milk synthesis, differentiation

803 Effects of insulin and heat stress on mTOR signaling cascade in bovine mammary epithelial cells.

Kimberly R. Kassube*, Jeffrey D. Kaufman, and Agustin G. Ríus, *The University of Tennessee, Knoxville, TN.*

Insulin increases protein synthesis by activating the signaling pathway that regulates protein translation in mammary tissue. Lactating cows exposed to heat stress (HS) have increased basal levels of insulin but exhibit reduction in milk protein synthesis. The activity of mammalian target of rapamycin (mTOR) signaling cascade is mediated upon phosphorylation and dephosphorylation of protein kinase B (Akt), P70 S6 kinase (S6K1), ribosomal protein S6 (rpS6), and eukaryotic elongation factor 2 (eEF2). The objective of this study was to determine the effects of insulin and HS on phosphorylating activity in Akt, S6K1, rpS6, and eEF2 factors in immortalized bovine mammary cell line (MAC-T). Cells were cultured in 15 mL of Dulbecco's Modified Eagle Medium with 10% fetal bovine serum and 1 µg/mL of insulin at 37°C and 5% CO_2 before the treatments were imposed. The experimental design consisted of a 2 × 2 factorial arrangement of treatments with 2 temperature environments, 37°C thermoneutral or 41°C HS, and 2 insulin concentrations, 0 µg/mL and 1 µg/mL for 12 h. Cell lysates were separated by gel electrophoresis and transferred onto a polyvinylidene fluoride membrane. Western blotting was conducted to identify total and site-specific phosphorylated forms of Akt (Thr308/Ser473), S6K1 (Thr389), rpS6 (Ser235/236) and eEF2 (Thr56). The relative densities for phosphorylated and total forms of Akt, S6K1, rpS6 and eEF2 were quantified and expressed as phosphorylated to total ratio. ANOVA was conducted with SAS 9.4 using mixed models. Preliminary results indicate a significant HS by insulin interaction for rpS6 ($P < 0.05$). There was an increase in phosphorylated to total ratio from 0.26 ± 0.09 to 0.6 ± 0.09 in response to insulin when cells were exposed to HS. However, there was a reduction of this ratio from 0.38 ± 0.09 to 0.2 ± 0.09 in response to insulin when cells were exposed to thermoneutral conditions. The remaining protein factors were not affected by treatments. These results would indicate that the response of mTOR signaling cascade to insulin was altered in MAC-T cells exposed to HS.

Key Words: heat stress, insulin, protein synthesis

804 Heat stress reduces the phosphorylation activity of mTOR signaling cascade in bovine mammary cells.

Jeffrey D. Kaufman*[1], Kimberly R. Kassube[1], Celina Baravalle[2], and Agustin G. Ríus[1], *[1]The University of Tennessee, Knoxville, TN, [2]Universidad Nacional del Litoral, Esperanza, Santa Fe, Argentina.*

Heat stress (HS) alters metabolism of amino acids and reduces synthesis of caseins in bovine mammary glands. The mammalian target of rapamycin (mTOR) cascade regulates the initiation of the translation of protein synthesis and is mediated by protein factors that are activated or inhibited upon phosphorylation. It has been reported that essential amino acids increased protein synthesis by activating the mTOR cascade. Our objective was to determine the effect of HS in phosphorylating mTOR protein factors in immortalized bovine mammary cells line (MAC-T). It was hypothesized that the phosphorylation activity of mTOR signaling factors would be altered in MAC-T cells exposed to HS. Cells were cultured in 15 mL of Dulbecco's Modified Eagle Medium with 10% fetal bovine serum at 37°C and 5% CO_2. Cells were subjected to one of 2 treatments: 1) 37°C (control) and 2) 41.5°C (HS) for 12 h. The treatments were repeated 5 times in 5 different days. Cell proteins were harvested and separated by gel electrophoresis and transferred to a polyvinylidene fluoride membrane. Western blotting was conducted to identify total and site-specific phosphorylated forms of protein kinase B (Akt; Thr308/Ser473), P70 S6 kinase (S6K1; Thr389), ribosomal protein S6 (rpS6; Ser235/236), and eukaryotic elongation factor 2 (eEF2; Thr56). Relative densities for phosphorylated and total forms of Akt, S6K1, rpS6 and eEF2 were quantified and expressed as phosphorylated to total ratio. ANOVA was conducted using a mixed model. Compared with control, cells exposed to HS decreased phosphorylation to total ratio of Akt (0.41 vs. 0.29; $P < 0.001$), S6K1 (1.65 vs. 0.97; $P = 0.042$), and rpS6 (1.45 vs. 1.07; $P < 0.001$). However, preliminary results indicated that HS did not affect the ratio of eEF2. These results indicate that HS impaired the translation of proteins by altering the phosphorylation activity of mTOR signaling factors in MAC-T cells.

Key Words: heat stress, mammary cell, translation of protein

805 Proteome of adipose tissue in periparturient dairy cows related to insulin resistance.

Maya Zachut*, *Department of Ruminant Science, ARO, Volcani, Bet Dagan, Israel.*

Adipose tissue serves as a major endocrine organ with a profound influence on metabolism by secreting and regulating numerous molecules, hormones and adipokines. Many proteins activate intracellular pathways that promote the development of insulin resistance (IR); however, the role of specific proteins in adipose tissue dysfunction is not well defined. The objective was to identify proteins in adipose that are linked to IR and to cows' metabolic status. Adipose tissue biopsies were obtained from 8 multiparous cows at −17 and +4 d relative to parturition. Proteins were analyzed by intensity based, label-free quantitative shotgun proteomics at Weizmann Institute of Science (Rehovot, Israel). Proteins were extracted and subjected to in-solution tryptic digestion. This was followed by nanoflow liquid chromatography coupled to high-resolution tandem mass spectrometry (nanoLC-MS/MS). Quantitative data were extracted using the Genedata Expressionist data analysis package and proteins identified using the Mascot search engine. Cows were previously divided to those with IR or insulin-sensitive (IS) adipose based on phosphorylation of protein kinase B (Akt) in response to insulin stimulation. Proteomics data, after logarithmic transformation, were analyzed by 2-way ANOVA to measure the effects of time (prepartum vs. postpartum), subgroup (IR vs. IS) and their interaction. Body weight (BW) differences were analyzed with GLM of SAS. It was found that cows with IR adipose lost more BW postpartum compared with IS cows. Proteomic analysis revealed 586 proteins in adipose tissues. Comparing IR to IS adipose showed that 18.9% of proteins were differentially expressed (fold change (FC) > 1.5 and $P < 0.05$). The expression of 106 proteins were increased, whereas only 5 were decreased, in IR adipose compared with IS. The abundance of several proteins related to lipolysis was increased in IR adipose compared with IS: hormone-sensitive lipase (FC = 6.8, $P < 0.03$), perilipin (FC = 1.5, $P < 0.05$), and monoglycerol-lipase (FC = 8.2, $P < 0.0003$). This is in accordance with the elevated lipolysis in IR adipose. These proteins could be used as novel biomarkers to identify IR cows, which may indicate of the metabolic status of the peripartum dairy cow.

Key Words: proteomics, adipose, insulin

Production, Management, and the Environment V

806 Metabolizable energy intake effects on carcass quality of steers finished in southern Chile during summer time. Rodrigo A. Arias*[1], Christian Alvarado-Gilis[1], Tami Brown-Brandl[2], and Terry L. Mader[3], [1]*Instituto de Producción Animal, Universidad Austral de Chile, Valdivia Chile,* [2]*MARC-ARS-USDA, Clay Center, NE,* [3]*Mader Consulting LLC, Gretna, NE.*

A total of 24 red Angus steers (BW = 431.2 ± 10.4) were sorted by BW and allocated in 4 pens (6/pen) equipped with a Calan Broadbent Feeding System to assess the effect of metabolizable energy intake (MEI) on carcass quality during the summer in southern Chile, and then allocated into one of 2 treatments 1.85 × or 2.72 × MEI for maintenance. Animals were fed once per day with the same diet, and treatments were applied by controlling DMI. Climatic data were obtained from a weather station located at 5 km southeast to assess animal thermal comfort by mean of 2 thermal indices (THI and the Comprehensive Climate Index). The study considered a period of 84 d on feed plus 19 d of pre-experimental period to allow the animals get used to the facilities and feeders. Finally, steers were slaughtered on 04/28/2014 in Temuco, where carcass data including hot and cold carcass weight, KPH, muscle pH, rib eye area, marbling score, and back fat were collected between 9th and 10th rib, after 48 h post slaughtering. All data were analyzed under a randomized complete block design arrangement ($\alpha = 0.05$), with each steer an experimental and observational unit. The pH values in both treatments were considered suitable, 5.57 and 5.52 ± 0.05 for T1 and T2, respectively ($P = 0.42$). Values of back fat observed did not show differences (3.92 and 3.87 ± 0.77 for T1 and T2, respectively; $P = 0.96$). In the case of average values for rib eye area and KPH were also similar between treatments ($P > 0.05$). Finally, hot carcass weight was also similar between treatments ($P = 0.15$). Therefore, no differences between T1 and T2 were observed for carcass quality of steers finished during summer time in any of the variables measured. In addition, based on the thermal comfort indices assessed, animals did not suffer heat stress, being able to deal in good shape the summer season. The latter mainly due to the large temperature drop as resulting of cold nights and the availability of water. On the other hand, there were no differences in ADG (0.95 vs. 1.25 ± 0.15 kg/day for T1 and T2, respectively; $P = 0.18$). Based on the data herein collected we can conclude that for southern Chile conditions during summer time, MEI had no effect on beef carcass quality

Key Words: beef, summer, heat stress

807 Metabolizable energy intake effects on tympanic temperature and ADG of steers finished in southern Chile during summer. Rodrigo A. Arias*[1], Christian Alvarado-Gilis[1], Tami Brown-Brandl[2], and Terry L. Mader[3], [1]*Instituto de Producción Animal, Universidad Austral de Chile, Valdivia, Chile,* [2]*MARC-ARS-USDA, Clay Center, NE,* [3]*Mader Consulting LLC, Gretna, NE.*

A total of 24 red Angus steers (BW = 431.2 ± 10.4) were used to assess the effect of metabolizable energy intake (MEI) on ADG and tympanic temperature (TT) during summer time in southern Chile. Steers were sorted by BW and allocated in 4 pens (6/pen) equipped with a Calan Broadbent Feeding System, and then allocated into one of 2 treatments 1.85 × or 2.72 × MEI for maintenance. Animals were fed once per day with the same diet, and treatments were applied by controlling DMI. The TT of each steer was collected during 10 d in the summer with an ibutton device. Ambient temperature (AT), relative humidity, wind speed, and solar radiation data were obtained from a weather station near to the farm and used to estimate 2 thermal indices (THI and the Comprehensive Climate Index; CCI). All data were analyzed under a randomized complete block design arrangement ($\alpha = 0.05$). The mean AT for all the period was 17.2°C. However, there was a great fall of AT (24°C) between day and night. The low temperatures at night allowed for the dissipation of heat accumulated during the day. The steers fed with 1.85 × MEI showed higher TT than those fed with 2.72 × MEI (38.07 vs. 38.02 ± 0.001°C; $P < 0.01$). However, this difference does not represent a significant change from the biological standpoint. None of the observed thermal comfort indices outperformed the thresholds established in the literature (THI = 68 and CCI = 25). However, maximum values of thermal indices THI, THI_{adj} and CCI were 75.5, 79.97, and 34.66, respectively. Animals showed signs of thermal discomfort, due to the increase in respiration rate, which was higher by 20 points during the afternoon ($P < 0.01$). This could be associated with the largest solar radiation received during the afternoon. On the other hand, there were no differences in ADG (1.25 vs. 0.95 ± 0.15 kg/day for 2.72 × and 1.85 × MEI, respectively; $P = 0.18$). In addition, both values are in line with those projected by the NRC Beef model, with superior value predicted in the case of 1.85 × MEI. Based on the data herein collected we can conclude that for southern Chile, the summer weather conditions and MEI had no effect on productive and physiological responses of animals

Key Words: thermal index, environment, climate

808 Effect of maternal heat stress on calf growth performance and metabolism. J-D. Liu*[1], A. P. A. Monteiro[1], B. M. Ahmed[2], T. O. Asar[2], Z. Wu[1], M. J. Hayen[2], G. E. Dahl[2], J. K. Bernard[1], and S. Tao[1], [1]*University of Georgia, Tifton, GA,* [2]*University of Florida, Gainesville, FL.*

Preliminary study suggests that maternal heat stress (HS) during late gestation exerts carryover effects on calf's insulin response after weaning, but comprehensive evaluation of how maternal HS affects calf feed intake and metabolic response from birth to weaning is still lacking. Our objective was to evaluate the effects of maternal HS during the dry period on calf feed intake, growth and metabolism from birth to weaning. After birth, 20 heifers born to either HS (n = 10) or cooled (CL, n = 10) dry cows were immediately separated from their dams and fed 3.8 L of pooled colostrum within 4 h. Then, all heifers were managed identically and weaned at 49 d of age (DOA). Calf starter intake was recorded daily, and body weight and withers height were assessed twice a week from birth to 56 DOA. Blood samples were collected at birth (before colostrum feeding), 24 h after birth, and then twice weekly until 56 DOA to assess hematocrit, plasma total protein, and concentrations of insulin and metabolites. To evaluate metabolic responses to maternal HS, a glucose tolerance test, insulin and epinephrine challenges were performed on 3 consecutive days for all heifers at 8, 29, and 57 DOA. Maternal HS during the dry period did not affect heifer birth weight. Compared with HS, CL calves consumed more starter (0.34 vs. 0.53 kg/d, $P < 0.06$) from birth to 56 DOA, were heavier (61.4 vs. 71.7 kg, $P < 0.01$) and tended to be taller (82.2 vs. 84.5 cm, $P = 0.15$) at 56 DOA. Although there was no treatment effect on hematocrit, a treatment by time ($P < 0.05$) interaction was observed, such that CL calves had higher hematocrit at birth (35.7 vs. 32.3%, $P = 0.03$) and 24 h after birth (31.9 vs. 28.4%, $P < 0.05$) compared with HS. Further, there were no differences between treatments on plasma total protein and concentrations of insulin and glucose. In conclusion, maternal HS during late gestation reduces calf starter intake and negatively affects calf growth. The lower hematocrit of HS calves relative to CL at birth may indicate fetal hypoxia due to maternal HS.

Key Words: calf, heat stress, growth performance

809 Cows exposed to heat stress in utero exhibit improved thermal tolerance.

Bahroz M. S. Ahmed*[1], Umair Younas[1], Turky O. Asar[1], Serdal Dikmen[2], Peter J. Hansen[1], and Geoffrey E. Dahl[1], *[1]University of Florida, Gainesville, FL, [2]University of Uludag, Bursa, Turkey.*

Maternal heat stress during the dry period affects calf performance during postnatal life. The objective was to evaluate whether calves that experienced heat stress in utero have altered thermoregulatory responses to acute heat stress later in life. Cows used in the study were born to dams exposed to heat stress (HT) or cooled (CL) during the dry period preceding their birth. All animals were raised postnatally under identical management. Eight HT (173 ± 132 DIM; 28.9 ± 5.2 kg/d milk) and 8 CL (167 ± 124 DIM; 30.1 ± 8.0 kg/d milk) lactating Holstein cows were used for the study. A heat stress challenge was conducted in 2 blocks using 4 HT and 4 CL cows matched according to milk yield, stage of lactation, and parity. Each challenge, which consisted of transfer from a barn with shade and evaporative cooling to one with shade but no additional cooling for a period of 48 h, was replicated twice for each block. Sweating rate, respiration rate, rectal temperature (RT), and skin surface temperature were measured on each cow at 0900, 1100, 1300, 1500 and 1700 h for 2 consecutive days. Mean ambient temperature across 4 challenge days was 23.8 ± 3.8°C. Sweating rate and skin temperature were measured on the right side of the cow on both shaved (5 × 5 cm) and un-shaved areas on the rump of the cow. During the challenge, differences were observed between treatments for RT (CL: 39.2 ± 0.06; HT: 39.0 ± 0.06°C; $P = 0.02$) and respiration rate (CL: 68.1 ± 1.6; HT: 62.2 ± 1.6 breath/min; $P = 0.01$). There were also tendencies for differences in sweating rate for shaved skin (CL: 30.7 ± 1.6; HT: 27.1 ± 1.6 g/m^{2}h; $P = 0.12$) and for unshaved skin (CL: 23.95 ± 1.18; HT: 21.44 ± 1.18 g/m^{2}h; $P = 0.13$). There was no effect on skin temperature at the shaved area (CL: 35.28 ± 0.12; HT: 35.32 ± 0.12°C; $P = 0.81$) or the un-shaved area (CL: 34.1 ± 0.14; HT: 34.0 ± 0.14°C; $P = 0.55$). The results support the hypothesis that heat stress in utero in late gestation increases heat tolerance at maturity by increasing capacity to dissipate heat to maintain core body temperature.

Key Words: heat stress, heat tolerance, cow

810 Feeding slow fermentable grains has the potential to ameliorate heat stress in sheep.

Paula A. Gonzalez-Rivas*, Kristy DiGiacomo, Brian J. Leury, Jeremy J. Cottrell, and Frank R. Dunshea, *Faculty of Veterinary and Agricultural Sciences, The University of Melbourne, Parkville, Victoria, Australia.*

Rapid rumen starch fermentation of wheat increases the heat of fermentation and may increase the risk of heat stress (HS). Therefore, feeding slowly fermentable grains such as maize and reducing metabolic heat load may reduce HS in grain-fed sheep. Twenty-two Merino x Poll Dorset wethers were housed in 2 climate-controlled rooms and were fed either maize grain plus forage (39% starch) (MF, n = 11) or wheat grain plus forage (37% starch) (WF, n = 11) during 3 experimental periods: P1) 7 d of thermoneutral conditions (18–21°C and 26–30% relative humidity (RH)) and restricted feed intake (85% of unrestricted feed intake) ; P2) 7 d of HS (28–38°C and 40–50% RH) and restricted feed intake ; and P3) 7 d of HS as P2 with unrestricted feed intake (1.5 times maintenance) in a complete randomized block design. Water was offered ad libitum. Physiological parameters—rectal temperature (RT), heart rate (HR), respiration rate (RR) and left and right flank skin temperature (LST, RST)—were measured at 0900, 1300, 1700, and 2100 h. Blood samples were collected on d 2 and 7 of each period for pH, blood gas and hematocrit (HcT). Data were analyzed using restricted maximum likelihood (REML) in GenStat v14. All physiological parameters were elevated ($P < 0.001$) during HS especially during P3. RR, RT, LST, RST and HR were lower ($P < 0.05$) in sheep fed MF, particularly during HS. LST was higher ($P < 0.001$) than RST and sheep feed WF had a larger ($P < 0.001$) difference between LST and RST. During HS total CO$_2$ (cTCO$_2$), hemoglobin (cHgb), bicarbonate (cHCO^{-3}), HcT, lactate, glucose and base excess were lower than P1 ($P < 0.05$). In sheep fed MF, the partial pressure of CO$_2$, cTCO$_2$ and cHCO^{-3} were higher ($P < 0.05$), while cHgb, pH and HcT were lower ($P < 0.05$) than WF. In conclusion, dietary maize, a slowly fermentable grain, reduced the metabolic heat load from feeding, expressed as reduced physiological parameters at thermoneutral conditions and ameliorated some of the physiological responses negatively affected by HS compared with dietary wheat.

Key Words: heat stress, sheep, grain

811 Heat stress at conception affects lifetime fertility, milk yield, and survival of Holstein cows.

Pablo Pinedo*[1,2] and Albert De Vries[3], *[1]Texas A&M AgriLife Research, Amarillo, TX, [2]Department of Veterinary Pathobiology, College of Veterinary Medicine & Biomedical Sciences, Texas A&M University System, College Station, TX, [3]Department of Animal Sciences, University of Florida, Gainesville, FL.*

The objective of this study was to analyze the association between month of conception (associated with heat stress) and subsequent milk yield, fertility, and survival in cows maintained in FL dairy farms. The hypothesis was that stress conditions at conception and during the initial stages of embryonic development would have a lifetime impact on performance and survival after birth. Initial data consisted of 667,104 DHI lactation records from cows calving between 2000 and 2012 in 152 FL herds. The magnitude of heat stress in each herd was evaluated after fitting Wood's lactation curves and comparing residuals from predicted and actual test-day milk yields by month as the direct effect of season. A sine function was fitted on the 12 residuals per farm using PROC NLIN (SAS). The difference between the highest and lowest points on the sine function was used as a seasonality index (SI). Only herds within the highest quartile for SI were included in the analyses. Cows were grouped according to the date when they were conceived: Summer (SU: Jul-Sept) and winter (WI: Dec-Feb) and comparisons were performed by parity using logistic regression and ANOVA. Control variables included calving month and year, age at first calving, and herd. Age at first calving (d) were 781 vs. 796 ($P < 0.001$) for WI and SU. The odds (95%CI) of survival to a second calving for WI cows were 1.19 (1.09–1.28) times the odds of survival for SU cows. Days from calving to first breeding were 138 vs. 143 ($P = 0.070$); 126 vs. 132 ($P = 0.030$); and 124 vs. 131 ($P = 0.004$) for WI and SU in parities 1, 2, and ≥ 3. Days to conception were 172 vs. 180 ($P = 0.003$); 182 vs. 187 ($P = 0.070$); and 179 vs. 184 ($P = 0.010$) for WI and SU in parities 1, 2, and ≥ 3. Milk yields (305d; kg) were 7,612 vs. 7,099 ($P < 0.001$); 8,011 vs. 7,665 ($P < 0.001$); and 7,814.6 vs. 7,532 ($P < 0.001$) for WI and SU in parities 1, 2, and ≥ 3. Milk yield by 70 DIM (kg) were 30.0 vs. 27.3 ($P < 0.001$); 35.5 vs. 33.1 ($P < 0.001$); and 36.8 vs. 35.2 ($P < 0.001$) for WI and SU in 1, 2, and ≥ 3 parity. In conclusion, cows that were conceived in the winter had better subsequent performance and survival than cows that were conceived in the summer.

Key Words: heat stress, conception, performance

812 Effect of mild and moderate heat stress on milk yield and bovine milk composition in the tropical region.

Vivian Fischer*[1], Alexandre Sausenbach Abreu[3], Marcelo Tempel Stumpf[4], André Thaler Neto[2], Daise Werncke[1], and Fernando André Schmidt[2], [1]*Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil,* [2]*Universidade Estadual de Santa Catarina, Lages, SC, Brazil,* [3]*Universidade do Sul de Santa Catarina, Tubarão, SC, Brazil,* [4]*Universidade de Rio Grande, São Lourenço, RS, Brazil.*

In hot climates, the combination of high temperature, humidity and intense solar radiation impose stress to the animals, especially if temperature is not sufficiently reduced during the night or if animals do not have protection against high temperatures or radiation, which is very frequent in the tropics. Variation in environmental variables between and within days affects the negative impact on dairy production. The present trials aimed to evaluate the effect of mild and moderate heat stress on dairy production, stability and physicochemical characteristics of milk. The temperature and humidity index (THI) was used to classify the heat stress as mild (72 to 78) or moderate (79–88). Two experiments were conducted in the tropical region, from January to March, on Tifton pasture. The first was conducted with 16 lactating Holstein cows, 520 ± 74 kg BW, BCS of 3.0 ± 0.3, MY of 21.5 ± 4.2 kg/day, 120 ± 61.2 DIM. The second trial was carried out with 14 lactating Holstein cows, 537.6 ± 93.5 kg of BW, BCS of 2.8 ± 0.3, MY of 20.6 ± 6.5 kg/day, 149.3 ± 48.9 DIM. In both trials the cows were allocated into 2 groups: paddocks without shade (NSH) and paddocks with natural shade (SH) - more than 10m^2/head of shade. At 15:00 h, under mild stress, paddocks with shade and without shade presented THI values of 75.2 and 77.7, respectively. Under moderate stress, THI values in paddocks with and without shade were 77.7 and 83.8, respectively. Under mild stress, cows in NSH and SH did not present any differences in MY and composition. Under moderate stress, cows in NSH decreased MY by 50%, ethanol stability from 75% to 68%v/v, coagulation time from 190 s to 49 s, crude protein by 15%, lactose by 4% while they increased titratable acidity by 43%, fat by 13% and MUN by 12% when compared with cows in SH. After 1 week of regaining access to shade, all differences disappeared. Shade kept MY and milk composition within normal range under moderate stress. Under mild stress shade did not provide beneficial effects on milk yield and composition.

Key Words: heat stress, milk composition, severity of stress

813 A cow cooling investment decision support tool for dairy farms in low and high humidity regions.

Bettie S. Kawonga* and Jeffrey M. Bewley, *Department of Animal and Food Sciences, University of Kentucky, Lexington, KY.*

The objective of this study was to develop an interactive cow cooling investment decision support tool for dairy farms in low and high humidity regions, and to demonstrate the economic benefits of investing in cow cooling. The low humidity region in the study was specific to semi-arid areas of sub-Saharan Africa (e.g., Malawi and Zambia) with THI range of 68 to 72. The high humidity region represented countries in the temperate regions with a climate distinctly different from that of sub-Saharan Africa in terms of humidity and temperature. The user inputs included total herd size, lactating herd size, milk yield, feed required per kg of added milk, feed price per ton, and milk price. Cow cooling inputs included fan and soaker costs, water and electricity cost, annual number of days cooling system was used, annual interest rate, discount rate, tax rate, predicted daily increase in milk production due to cooling and predicted yearly increase in pregnancy rate for the herd. The investment analysis outputs included net present value (NPV) and benefit: cost ratio (BCR). Assumptions used in calculating NPV and BCR included economic benefits of reduced heat stress extend to periods of low heat stress, no cooling existed, fans installed in stalls and holding area, and soakers installed in feed line and exit area from parlor. The assumptions were sourced from published literature and actual market prices of farm inputs and utilities. Using a herd size of 100 cows and a 10-year investment horizon, cow cooling in a high humidity region had a greater NPV ($54,653) compared with a low humidity region ($26,520). This could be attributed to high operating and initial investment cost for low humidity region. The BCR was greater than 1 for all the regions, indicating a good investment scenario. Further studies should be conducted to compare the current cow cooling investment analysis and other heat abatement strategies such as feed adjustment for small herd sizes in low humidity regions and semi-arid environments.

Key Words: cow cooling, net present value, cost:benefit ratio

814 Effect of feeding phytogenic compounds on preweaned dairy calves in a commercial setting.

Bryan G. Miller*[1] and Nicolas D. Bettencourt[2], [1]*Biomin USA, San Antonio, TX,* [2]*A.L. Gilbert, Oakdale, CA.*

Feeding programs and feed ingredients that maximize calf growth rate add to a dairy's profitability through both reduced feed costs and lifetime days open. Phytogenic feed additives, derived from plant extracts, offer a potential means of supporting feed intake and calf growth. A field trial was conducted at a commercial "calf ranch" near Atwater California in the summer and fall of 2014. Calf growth was compared between those that consumed a standard calf starter with those that received the same diet with a phytogenic product, Digestrom Calf (Biomin Inc.) Holstein heifer calves were individually housed. To accommodate farm labor, calves were fed calf starter with or without Digestarom Calf as a group based upon calving date. Calves were fed a calf milk replacer (26% CP, 11% CF) and a calf starter (18% CP, 4.4% CF) either containing or not containing Digestarom Calf. Calves were fed between 72 and 78 d. Weight and height were measured at weaning. During the trial, morbidity, both in the form of scours and respiratory issues, was recorded for each set of calves. There were no apparent starting date effects and data from all groups were combined and a simple *t*-test for differences was conducted. Treatments for scours or respiratory diseases were analyzed using Chi-squared differences; results are in Table 1. Those calves supplemented with the phytogenic product, Digestarom, had greater average daily gain and hip height.

Table 1 (Abstr. 814). Growth and recorded health incidences among preweaned calves in a commercial setting

Treatment	Calves (no.)	Average days fed (no.)	Initial wt (kg)	Final wt (kg)	ADG (kg)	Hip height (cm)	Scours (%)	Pneumonia (%)
Control	50	73.7	38.5	80.3^{a}	0.57^{a}	92.5^{a}	60.0^{c}	28.6^{e}
Digestarom	115	72.0	38.2	84.0^{b}	0.64^{b}	95.0^{b}	42.5d	18.4^{f}

^{ab}Means in the same column differ ($P = 0.0002$).
^{cd}Means in the same column did not differ ($P = 0.1352$).
^{ef}Means in the same column differ ($P = 0.0732$).

Key Words: calves, phytogenic, growth

815 Effect of condensed tannin extract supplementation on beef cattle performance and nitrogen balance: II. Finishing phase.

Pake J. Ebert*[1], Adam L. Shreck[2], Jenny S. Jennings[3], Noel A. Cole[2], and Eric A. Bailey[1], [1]*West Texas A&M University, Canyon,* *TX, [2]USDA-Agricultural Research Service, Bushland, TX, [3]Texas A&M AgriLife Research, Amarillo, TX.*

Nitrogen emissions from concentrated animal feeding operations are of increasing concern to regulatory agencies. As such, we evaluated the effect of top-dressing a finishing diet (14.4% CP) for beef cattle with a commercially available condensed tannin extract (CT) at 3 levels (0, 0.5, and 1.0% of diet, DM basis). British-cross steers (n = 27; initial BW = 350 ± 32 kg) were fed individually via a Calan gate system for 126 d. Diet digestibility and N balance were estimated approximately 30 d after the experiment began (EARLY) and 30 d before the animals were harvested (LATE), using TiO_2 as a marker of fecal output and creatinine:BW ratio as a marker for urine output, respectively. Inclusion of CT in the diet did not affect ($P \geq 0.21$) ADG or DMI over the entire finishing period. Hot carcass weight was not different ($P = 0.83$) among treatments, but fat thickness and LM area tended to decrease ($P \leq 0.08$) when CT was included in the diet. Organic matter intake tended ($P = 0.10$) to increase when CT was fed during EARLY. Apparent total-tract starch digestibility during EARLY was lesser ($P = 0.03$) for 1% CT than either 0 or 0.5% CT. Intakes of OM and starch were similar ($P \geq 0.31$) among treatments during LATE; similarly, apparent total-tract digestibility of OM and starch were similar ($P \geq 0.31$) during LATE. Nitrogen intake did not differ ($P \geq 0.11$) among treatments during EARLY and LATE, but fecal N excretion was greater ($P = 0.05$) for 1.0% CT than 0% CT during EARLY. Urinary N excretion was not different ($P \geq 0.43$) among treatments during EARLY and LATE, but urine N:total N excretion decreased when CT was included in the diet during EARLY. Retention of N was not different ($P = 0.40$) among treatments during EARLY, but tended to decrease ($P = 0.07$) when CT was included in the diet during LATE. Under the conditions of this experiment, supplementation of a finishing diet with condensed tannins had minor effects on performance and nutrient digestibility of beef steers fed a finishing diet, but did alter the site of N excretion.

Key Words: condensed tannin, feedlot, nitrogen balance

816 Evaluation of an extended release anthelmintic on performance and fecal parasite load of beef cattle grazing cool season pastures.

J. D. Rivera*, M. L. Gipson, R. G. Gipson, and P. J. Slusher, *Mississippi Agriculture and Forestry Exp. Station White Sand Branch Unit, Poplarville, MS.*

Seventy-four crossbred beef steers (average BW = 239.2 + 10.7 kg) were used in a randomized complete block to evaluate the use of an extended-release eprinomectin (ER) on performance and fecal worm count during grazing. Steers were stratified and blocked by BW into sixteen 1.2-ha pastures of annual ryegrass, and pasture was randomly assigned to one of 2 treatments: a single injection of an extended release eprinomectin (ER) or 2 injections (d 0 and d 64) of a typical anthelmintic used in stocker operations (doramectin; DOR). Steers were individually weighed and fecal samples collected on d 0 and 114. Steers in the DOR group were re-worked on d 64 for a second dose of DOR. Data were analyzed as a mixed model with block considered random and treatment considered fixed, LSMEANS were separated using PDIFF. Pasture was the experimental unit. No differences ($P = 0.36$) were noted in initial BW (238.9 vs. 239.6 kg for DOR and ER, respectively), however at final BW, steers treated with ER (366.4 kg) were heavier ($P = 0.04$) than steers treated with DOR (357.8 kg). Moreover, steers treated with ER had greater ADG than DOR ($P = 0.05$; 1.11 vs. 1.04 kg/d for ER and DOR, respectively). As a result, steers treated with ER had greater gain per ha compared with steers administered DOR ($P = 0.05$). Due to the greater cost of ER and despite reworking costs of DOR, overall working cattle cost was greater for ER compared with DOR ($P = 0.009$; $41.44/hd vs. $39.83/hd for ER and DOR respectively. Total pasture cost per ha was greater ($P = 0.009$) for ER ($99.82/ha) compared with DOR ($99.37/ha), however increased weight gain resulted in decreased cost of gain ($P = 0.04$) for ER ($1.13/kg) compared with DOR ($1.19/kg). No differences among treatments ($P = 0.66$) were noted for fecal egg count at d 0, nor were any differences detected for fecal egg count at d 114 ($P = 0.32$), with a tendency ($P = 0.13$) for decreased percentage of fecal egg count associated with ER (88.9%) when compared with DOR (76.1%). Despite the greater costs associated with ER and similar fecal egg control compared with DOR, ER resulted in greater performance and decreased cost of gain.

Key Words: beef cattle, anthelmintic, grazing performance

817 Effect of yeast culture plus enzymatically hydrolyzed yeast supplementation during transition period on milk production and metabolic profile of dairy cows.

Claudia Faccio Demarco[1], Vanessa Oliveira Freitas[1], Tatiele Mumbach[1], Eduardo Xavier[2], Raquel Fraga e Silva Raimondo[3], Fernanda Medeiros Gonçalves[1], Francisco Augusto Del Pino[1], Viviane Rohrig Rabassa*[1], Sangita Jalukar[4], Marcio Nunes Corrêa[1], and Cássio Cassal Brauner[1], *[1]Universidade Federal de Pelotas, NUPEEC, Pelotas, RS, Brazil, [2]Granjas 4 Irmãos S/A, Rio Grande, RS, Brazil, [3]Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brasil, [4]Arm & Hammer Animal Nutrition, Princeton, NJ.*

The aim of this study was to evaluate the effect of yeast culture plus enzymatically hydrolyzed yeast on milk production and metabolic profile during transition period of dairy cows. Twenty-nine multiparous Holstein cows were blocked by milk production on the previous lactation and randomly assigned into 2 groups: one received 28 g/d top-dressed yeast culture plus enzymatically hydrolyzed yeast (YC-EHY; Celmanax, Arm & Hammer Animal Nutrition, Princeton, NJ), while the control group did not receive the supplement. The experiment was conducted from d −35 relative to calving until 150 of lactation. During this period cows were weighed weekly and their body condition score (BCS) evaluated. Cows were milked twice daily and were kept in a semi-extensive production system. Milk yield and milk composition were evaluated weekly from calving to 150 DIM. Plasma samples collected on −21, −14, −7, 0, 3, 7, 14, 21, 28, 35, and 42 d relative to calving were analyzed for β-hydroxybutyrate (BHBA), Nonesterified fatty acids (NEFA), cholesterol and plasma urea nitrogen (PUN). Data were analyzed using mixed models with repeated measures over time. The YC-EHY group had higher milk yield (27.75 vs. 24.98 ± 0.5 kg/d, $P = 0.05$) versus the control group. However, the control group had more milk protein concentration (2.97 vs. 2.87 ± 0.03%/d, $P = 0.03$) in comparison with YC-EHY group. Other milk compounds were not affected ($P > 0.05$) by supplementation. No differences ($P > 0.05$) were observed for BHBA, NEFA, cholesterol, and PUN concentrations during the transition period. Also body weight and BCS were not affected ($P > 0.05$) by supplementation. In conclusion, yeast culture plus enzymatically hydrolyzed yeast supplementation increased milk production during the first half of lactation, however, metabolic profile are not affected by supplementation during the transition period in dairy cows.

Key Words: yeast, bovine, metabolism

Production, Management and the Environment Symposium: Environmental footprint of livestock production—Greenhouse gas emissions and climate change

818 Environmental footprint of livestock production: A global perspective. Frank M. Mitloehner*, *University of California, Davis, Davis, CA.*

Global livestock production is projected to double by 2050 and the majority of this growth will be occurring in the developing world. Much of the growth in the global livestock sector will occur in areas that are currently forested (i.e., parts of South America and South East Asia). It has been well established that significant reductions of carbon sequestering forests will have large effects on global climate change. Livestock production in most countries of the developed world (e.g., United States and Europe) has a relatively small greenhouse gas (GHG) contribution within the countries' overall carbon portfolios, dwarfed by large transportation, energy, and other industry sectors. In contrast, livestock production in the developing world can be a dominant contributor to a country's GHG portfolio, due to the developing world's significantly smaller transportation and energy sectors. The fact that land-use changes associated with livestock (i.e., forested land converted to pasture or cropland used for feed production) are a significant source of anthropogenic GHGs in Latin America and other parts of the developing world is apparent. The Food and Agriculture Organization attributes almost half of the climate-change impact associated with livestock to the change of land-use patterns. The United States and most other developed countries have not experienced significant land-use change practices around livestock production within the last few decades, sometimes centuries. Intensification of livestock production provides large opportunities for climate change mitigation and can reduce greenhouse gas emissions from deforestation, thus becoming a long-term solution to a more sustainable livestock production. Overall, growing demands for animal protein could strongly increase GHG emissions from agriculture. However, knowledge exists to improve efficiencies in livestock production, which dramatically reduces GHG per unit of production. What is called for is a sustainable intensification in animal agriculture, coupled with technology transfers from developed to developing countries, to supply a growing demand for animal protein using sustainable and modern production practices.

Key Words: environmental footprint, livestock

819 Environmental impact reduction strategies for pig farms. Richard Ulrich*[1], Greg Thoma[1], Jennie Popp[1], and Mark Hanigan[2], *[1]University of Arkansas, Fayetteville, AR, [2]Virginia Tech, Blacksburg, VA.*

The purpose of this project was to determine what design and operational factors have a significant influence with minimal cost on the GHG, water and land usage impacts of a pork production facility. The Pig Production Environmental Footprint Calculator provides a detailed comparison of impacts as a function of animal feed practices, manure treatment strategies, barn heating/cooling settings and additives. The model utilizes the NRC nutrition equations to estimate feed intake and manure production as a function of barn temperature, animal gender, immunocastration, ractopamine use, and crowding. The model's economic code calculates the dollars per kg of avoided equivalent carbon dioxide emissions. The results confirm that feed production and manure management are the leading causes of environmental impacts from pig farms but differential improvements can come from other areas. Decreasing treatment temperatures can lessen GHG emissions from manure systems through managing barn and tank conditions. Digesters can recover energy from produced methane while converting the methane to lower-impact carbon dioxide. Barn temperatures have an impact on animal feed intake and subsequent growth rates. Common feeds are evaluated for their environmental impacts per calorie or gram protein provided.

Key Words: environmental impact, modeling, pig farms

820 Quantifying greenhouse gas fluxes in animal production. Wendy Powers* and Matheus Capelari, *Michigan State University, East Lansing, MI.*

Direct and indirect sources of CO_2, CH_4, and N_2O emissions in animal production systems includes the animals, feed storage areas, manure deposition and storage areas, and feed and forage production fields. These 3 gases comprise the primary greenhouse gas (GHG) emissions from animal feeding operations. Each GHG may be more or less prominent from each emitting source. Similarly, species dictates importance of enteric CH_4 emissions. Measures of GHG flux from animals are often made using respiration chambers for measurement of concentration and flux, head boxes or halters allowing for measures of concentration directly and flux indirectly (tracer gas techniques), or in vitro gas production techniques. Concentration measures are made using gas chromatography, photoacoustic, open path Fourier transform infrared (FTIR) or non-dispersive infrared (NDIR) spectroscopy. The prominent methods for measuring GHG emissions from housing include tracer gas techniques (indirect ventilation measures) or direct ventilation measures, each coupled with concentration measures of gases of interest. Methods for collecting and measuring GHG emissions from manure storage and/or production lots include use of downwind concentration measures combined with modeling techniques, static chambers or flux hood methods. Similar methods can be deployed for determining GHG emissions from fields. Each method identified has its own benefits and challenges to use for the stated application. Considerations for use include intended goal, compatibility with production system, equipment investment and maintenance, frequency and duration of sampling needed to achieve desired representativeness of emissions over time, accuracy and precision of the method, and environmental influences on the method. In the absence of a perfect method for all situations, full knowledge of the advantages and disadvantages of each method is extremely important during the development of the experimental design and interpretation of results. Attributes of the various options for measuring GHG flux from different sources within a farming system will be discussed including methods to measure both concentration of gas and flux from the various emission sources.

Key Words: emissions, flux, greenhouse gas

821 Greenhouse gas emissions and nitrogen cycling from beef production systems: Effects of climate, season, production system, and diet. Galen E. Erickson*, Samodha C. Fernando, Terry J. Klopfenstein, Andrea K. Watson, James C. MacDonald, Anna C.

Pesta, Allison L. Knoell, and Henry Paz, *University of Nebraska-Lincoln, Lincoln, NE.*

Greenhouse gas (GHG) and nitrogen emissions from beef cattle production systems are receiving greater attention. Emissions of methane and nitrous oxide in grazing and confined feedlot systems are microbial-mediated, whether from the rumen (methane) or soil surfaces (methane and nitrous oxide). Additionally, emissions of ammonia are microbial-mediated as well as dependent on ammonium concentration. Factors that increase microbial activity, such as temperature and season, are positively correlated with emissions from soil surfaces, whereas enteric methane emissions are not affected by ambient temperature and therefore not affected by climate or season. Previous research illustrates that diet, season, and type of production system dramatically affect N emissions as ammonia. However, the effect of season, diet, and type of production system on nitrous oxide emissions from cattle production systems and soils are poorly understood. Additionally, methane emissions data from production systems are lacking and needed. Enteric methane emissions have received the greatest attention across a wide array of climates, season, and diets. Forage quality has been shown to have a large impact on methane emissions, with lower quality forage increasing methane per unit of energy intake. Likewise, feeding finishing diets results in less enteric methane per unit of energy intake compared with forages. However, both high quality forages, and finishing diets increase energy intake and thus absolute amount of methane produced per day. Expressing enteric emissions as amount per day will lead to different mitigation strategies compared with decreasing methane emissions per unit of energy intake or per unit of productive function (i.e., gain). Many benefits exist to utilize forages in beef production systems, thus converting existing forage-based systems to intensive (i.e., grain-based) beef production as a mitigation strategy for methane emissions is not logical. However, greater opportunity likely exists to mitigate methane emissions within forage-based production systems as compared with grain-based systems, which will require understanding microbial mediated processes to dramatically decrease enteric methane.

Key Words: emissions, methane, nitrogen

822 Forage utilization to mitigate greenhouse gas emissions by ruminants.

Karen A. Beauchemin*, *Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada.*

Meat and dairy products account for almost half of food-generated greenhouse gases (GHG), and as global consumption of livestock products continues to grow there is pressure on the livestock industry to lower its emissions. Poultry, pig, dairy, and feedlot production rely on the use of grains and oilseeds, increasing the demand for limited resources. With continued expansion of livestock production to meet global demand for protein, ruminant production will need to increase its use of forages. Unlike pigs and poultry, ruminants can utilize cellulosic materials to produce high quality protein for human consumption. Furthermore, perennial forages, forage-cropping rotations, and well-managed grazing lands provide numerous environmental benefits. However, high-fiber diets increase enteric CH_4 emissions from ruminants, so increasing forage use by ruminants may at first seem counterproductive in terms of reducing GHG emissions. However, there is increasing knowledge of mitigation practices that lower CH_4 emissions from cattle. Some strategies are (1) technologies to reduce methanogenesis in the rumen (nitrate, inhibitors), (2) improving fiber digestibility (pre-treatment, genetic selection of forages, harvest management), and (3) targeted supplementation and management of animals to improve productivity. When examining the total GHG emissions from a system, all emissions and removals of CH_4, N_2O, and CO_2 on the farm and from purchased inputs must be considered using a life cycle approach. Forage-based ruminant systems tend to be relatively low input with less fossil fuel CO_2 emissions and fertilizer-based N_2O emissions than grain-based systems. Use of N-fixing legume forages further displaces the use of fertilizers. With grazing systems, the nutrient cycle is relatively closed with excreted nutrients returned directly to the land. Well managed grasslands subject to moderate grazing can augment soil carbon reserves. Such lands also provide many other ecosystem services including conservation of biodiversity, water quality, and wildlife habitat. Thus, continued development and adoption of mitigation strategies will allow ruminant production systems to rely more extensively on forages while lowering GHG emissions and providing enhanced ecosystem services.

Key Words: forage, methane, environmental sustainability

Ruminant Nutrition: Modifying rumen microbial populations

823 Protozoa reduction in the rumen of grazing cattle fed mixtures of coconut and palm kernel oils. Oludotun O. Adelusi, Adebayo O. Oni*, Oluwaseun J. Idowu, Victoria O. Ojo, and Christopher F. Onwuka, *Federal University of Agriculture, Abeokuta, Ogun State, Nigeria.*

A 12-wk study was conducted to investigate the effect of feeding ratios of coconut and palm kernel oils (CNO-PKO) on the rumen microbial population of grazing cattle. The experiment was carried out at Cattle Production Venture Farm, Federal University of Agriculture Abeokuta, Ogun State, Nigeria. Twelve (12) White Fulani cattle with average weight of 164 ± 2.81 kg were allotted into 4 treatments of CNO-PKO administration (0 g/day (control), 100:50 g/day (HCLP), 50:100 g/day (LCHP) and 75:75 g/day (ECP) in a completely randomized design. Rumen fluid samples were obtained from each cattle after oil administration period and microbial population was determined by total direct count of protozoa and fungal zoospores while bacteria analysis was carried out using anaerogen packs. Data were analyzed using one-way ANOVA (SPSS Statistics 20). The results showed that rumen bacteria in the genus *Bacteroides* spp. was not significantly ($P > 0.05$) affected by the treatments. *Clostridium* spp. count of those maintained in the control group recorded the greatest ($P < 0.05$) number with 6.08×10^6 cfu/mL while the least ($P < 0.05$) was recorded from cattle maintained on HCLP administration with 2.35×10^6 cfu/mL. *Lactobacillus* spp. count of cattle maintained in the control group and those on ECP administration recorded greater ($P < 0.05$) counts of 0.20×10^6 cfu/mL and 0.15×10^6 cfu/mL respectively while lesser ($P < 0.05$) counts were obtained from cattle maintained on HCLP and LCHP with both recording 0.05×10^6 cfu/mL. Rumen fungi count increased ($P < 0.05$) with LCHP administration recording 0.60×10^6 cfu/mL while the least ($P < 0.05$) was recorded with HCLP administration (0.10×10^6 cfu/mL). Rumen protozoa population of cattle was significantly ($P < 0.05$) reduced with the greatest ($P < 0.05$) count obtained from cattle maintained in the control group recording 755.99 FEC/g while the least ($P < 0.05$) was obtained from cattle maintained on ECP administration recording 0.00 FEC/g. Feeding 75 g/d each of coconut and palm kernel oils to grazing cattle reduced the protozoa population of the rumen and might therefore be employed as rumen modifier for methane mitigation.

Key Words: cattle, rumen, protozoa

824 Total-tract fatty acid digestibility responses to increasing levels of palmitic acid supplementation of dairy cows receiving low- and high-fat diets. Jonas De Souza*, J. Eduardo Rico, Courtney L. Preseault, Michael S. Allen, and Adam L. Lock, *Michigan State University, East Lansing, MI.*

Dose-dependent effects of a palmitic acid-enriched fat supplement (PA; 87% C16:0; Bergafat F-100) on total-tract digestibility responses of dairy cows were evaluated. Low and high basal dietary fatty acid (FA) diets (LF: 2.2% DM and HF: 3.5% DM) were used as a split-plot to determine relationships between basal dietary FA content and PA dose. Sixteen Holstein cows (149 ± 56 DIM) were assigned randomly to treatment sequence within basal FA groups. PA was supplemented at 0, 0.75, 1.50, or 2.25% of ration DM in a 4 × 4 Latin Square design within each basal FA group. Periods were 14 d with the final 4 d used for data collection. FA content of LF and HF diets was achieved by altering the proportion of soyhulls and cottonseed in diets. The statistical model included the random effect of cow and the fixed effects of basal FA group, PA dose, period, and their interactions. Linear, quadratic, and cubic contrasts were used to determine effects of PA dose. Compared with HF (with cottonseed), LF diets (with soyhulls) increased NDF digestibility (50 vs. 48%; $P < 0.01$). PA dose also increased NDF digestibility (46, 50, 51, and 52%; linear $P < 0.01$). There was a tendency for an interaction of treatments ($P = 0.12$) as NDF digestibility increased more for HF with increasing PA than for LF. Compared with HF, LF diets decreased 16-carbon FA digestibility (65 vs. 71% $P < 0.01$) and tended to increase 18-carbon FA digestibility (85 vs. 82%; $P = 0.07$). PA dose decreased 16-carbon FA digestibility (76, 67, 64 and 64%; quadratic $P < 0.01$) and increased 18-carbon FA digestibility (82, 83, 85 and 85%; linear $P < 0.05$) for 0, 0.75, 1.50, and 2.25% PA, respectively. PA dose linearly decreased the digestibility of total FA in LF diets (81, 76, 73, and 71%) but did not in HF diets (77, 76, 76, and 76%; interaction $P < 0.05$) for 0, 0.75, 1.50, and 2.25% PA, respectively. HF diets increased total FA absorbed compared with LF diets (0.94 vs. 0.71 kg/d; $P < 0.05$). Additionally, PA dose increased total FA absorbed (0.64, 0.77, 0.90 and 0.97 kg/d; linear $P < 0.01$) for 0, 0.75, 1.50, and 2.25% PA, respectively. In conclusion, the total-tract FA digestibility responses to PA dose were affected by the FA content of the basal diet.

Key Words: dietary fat, digestibility, palmitic acid

825 Daily patterns of hydrogen and volatile fatty acid concentrations in relation to thermodynamic control on fermentation in the bovine rumen. Hendrikus J. van Lingen*[1,2], Jueeli D. Vaidya[1,3], Sanne van Gastelen[1,2], Bartholomeus van den Bogert[1,3], André Bannink[4], Caroline M. Plugge[3], Hauke Smidt[3], and Jan Dijkstra[2], [1]*Top Institute Food and Nutrition, Wageningen, Gelderland, the Netherlands,* [2]*Animal Nutrition Group, Wageningen University, Wageningen, Gelderland, the Netherlands,* [3]*Laboratory of Microbiology, Wageningen University, Wageningen, Gelderland, the Netherlands,* [4]*Animal Nutrition, Wageningen UR Livestock Research, Wageningen, Gelderland, the Netherlands.*

Elevated levels of both hydrogen and molar proportions of propionate to acetate and butyrate are found in the bovine rumen right after meals. Hydrogen is believed to thermodynamically control fermentation pathways in the rumen in favor of propionate production. Elevated levels of hydrogen inhibit reoxidation of NADH to NAD^+. Propionate production, however, enables this reoxidation and explains why elevated levels of hydrogen and propionate are hypothesized to occur simultaneously. Nonetheless, hydrogen partial pressure in the rumen headspace may not be high enough to inhibit NADH reoxidation. Furthermore, studies reporting diurnal patterns of volatile fatty acids (VFA) concentration and hydrogen pressure simultaneously, if any, are limited. The aim of this study is to monitor daily patterns of hydrogen pressure, pH, and VFA concentration in the bovine rumen and to calculate thermodynamic inhibition of specific fermentation pathways. Four rumen fistulated multiparous lactating cows were used in a crossover design with 2 17-d experimental periods and a control and treatment diet. Both diets consisted of 40% corn silage, 30% grass silage and 30% concentrates on DM basis. The treatment diet had a 2.5% higher fat content by supplementing the concentrate with linseed oil. On d 11, rumen headspace gas and fluid samples were taken at 0, 0.5, 1, 1.5, 2, 3, 4, 5, 6, 8, 10 h after morning feeding using a custom fistula lid enabling rumen gas and fluid sampling. Gas samples were analyzed for hydrogen pressure, and fluid samples for pH and concentrations of dissolved hydrogen as well as VFA. Fluid samples were also taken for transcriptome analysis to monitor microbiome gene expression. From d 13 to 17 cows were housed in respiration chambers to relate rumen headspace pressure to emissions of hydrogen. An increase of hydrogen partial pressure by 2 orders of magnitude up to 30 mbar was observed following feeding. This finding might indicate hydrogen partial pressure to be high enough to inhibit NADH reoxidation.

Key Words: rumen fermentation, thermodynamics, hydrogen

826 Effects of chitosan on ruminal metabolism and in situ degradability of beef cattle.

Darren D. Henry*, Francine M. Ciriaco, Vitor R. G. Mercadante, Tessa M. Schulmeister, Martin Ruiz-Moreno, G. Cliff Lamb, and Nicolas DiLorenzo, *North Florida Research and Education Center, University of Florida, Marianna, FL.*

We determined the effects of supplementing chitosan, a natural biopolymer, on ruminal metabolism and in situ degradability in beef steers consuming hay. Eight ruminally cannulated crossbred steers (345 ± 81 kg BW) were used in a crossover design. Steers were stratified by weight and randomly assigned to 1 of 2 treatments: control (CTRL; no chitosan supplementation) or treatment (TRT; 80 g/d of chitosan). Chitosan was dosed daily via ruminal cannula and steers had ad libitum access to Tifton 85 bermudagrass hay and water throughout the study. Ruminal fluid was collected before dosing of chitosan (0 h) and every 3 h post-dosing for 24 h. Immediately after each collection, ruminal pH was measured. Ruminal fluid was analyzed for VFA and NH_3-N concentrations. Data were analyzed as repeated measures and the model included the fixed effects of treatment, time, and treatment × time interactions. In situ degradability of DM, NDF, and ADF was determined by incubating Tifton 85 bermudagrass hay in nylon bags within the rumen for 24, 48 or 72 h. Supplementing with 80 g/d chitosan had no effect ($P > 0.05$) on ruminal in situ degradability of DM, NDF or ADF. Chitosan did not affect ($P = 0.97$) NH_3-N concentrations (7.4 ± 0.58 m*M*) within the rumen. A treatment × time interaction was observed ($P < 0.001$) on ruminal pH. A treatment × time interaction ($P = 0.016$) was observed for acetate-to-propionate ratio (A:P), being decreased ($P < 0.05$) at h 21 and 24 for TRT vs. CTRL. Molar proportions of acetate and propionate had a treatment × time interaction ($P < 0.05$). Molar proportions of propionate were increased at h 18, 21 and 24 for TRT when compared with CTRL. Supplementing 80 g/d of chitosan to steers consuming ad libitum hay had no effect on in situ ruminal degradability; however, VFA molar proportions were shifted to an energetically more efficient composition by increasing propionate and decreasing A:P.

Key Words: chitosan, ruminal metabolism, in situ degradability

827 Ellipsoid equation improves accuracy and efficiency of estimating protozoal volume.

Benjamin A. Wenner*, Brooklyn K. Wagner, and Jeffrey L. Firkins, *Department of Animal Sciences, The Ohio State University, Columbus, OH.*

Previous observations of protozoa in cultures treated with essential oils or ionophores indicated possible cell shrinkage due to deleterious effects on cell function. Cell volume reduction by formaldehyde preservation, combined with visually flattened or tapered morphology of rumen protozoa limited our ability to detect volume differences using common cylindrical derivations for protozoa. The advent of affordable, high definition imaging equipment enables recording of live protozoa from cultures treated with various additives that potentially shrink cells. We hypothesized that using still frames from video of protozoa swimming would improve accuracy of volume predictions by optimizing an approach to measure one maximal longitudinal measurement and both minimum and maximum diameter measurements perpendicular to the longitudinal axis, thus yielding a 3-dimensional estimation of protozoal volume. An ellipsoid formula (E, $^4/_3\pi abc$) was compared with previously published estimations using cylindrical [C, $L\pi(^W/_2)^2$] or species coefficient (SP, $X LW^2$) calculations. Testing this method on objects shaped similarly to protozoa demonstrated the ellipsoid is more accurate in predicting volume as measured by displacement. True displacement was 11.8 mL for 10 large particles, and estimated volumes were 12.7 to 27.1, 7.7 to 16.6, and 12.3 mL for C, SP, and E, respectively. For smaller particles with more surface area, true displacement was 4.5 mL, and estimated volumes were 5.6 to 13.1, 3.2 to 7.5, and 5.6 for C, SP, and E, respectively. Rumen fluid sampled from 2 lactating Jersey cows was flocculated and wet-mounted on a microscope fitted with an HD (1080p) camera. Residuals (SP − E) were plotted against predicted (E) centered to the mean (X – mean) to evaluate for both mean and slope bias. For entodinia (ENTO), $Y = 1.97 \times 10^4 (\pm 1.48 \times 10^3) + 0.248(\pm 0.0371)(X - 7.98 \times 10^4)$ µm³, with significant slope ($P < 0.01$) and mean ($P < 0.01$) bias. For isotrichids (ISO), $Y = -1.21 \times 10^4 (\pm 4.86 \times 10^4) - 0.124(\pm 0.0685)(X - 2.54 \times 10^6)$ µm³, where slope trended toward significance ($P = 0.08$) with no mean ($P > 0.10$) bias. For epidinia (EPI), $Y = 1.02 \times 10^5 (\pm 1.46 \times 10^4) + 0.372(\pm 0.219)(X - 1.45 \times 10^5)$ µm³, with no slope ($P > 0.10$) and significant mean ($P < 0.01$) bias. This demonstrates that SP more likely overestimates volume for ENTO or EPI than for teardrop-shaped ISO. This ellipsoid method offers potential to advance prediction of treatment effects on protozoal viability and volume.

Key Words: protozoa, imaging, rumen

828 Effect of monensin inclusion on ruminal fermentation parameters in *Bos indicus* and *Bos taurus* steers consuming bermudagrass hay.

Natasha L. Bell*[1,2], Robin C. Anderson[3], Todd R. Callaway[3], Marcia O. Franco[4], and Tryon A. Wickersham[1], [1]*Texas A&M University, College Station, TX,* [2]*Texas A&M University-Kingsville, Kingsville, TX,* [3]*Southern Plains Agricultural Research Center, Agricultural Research Service, USDA, College Station, TX,* [4]*Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Effects of monensin inclusion and the subspecies of cattle on utilization of bermudagrass hay (13.7% CP) were evaluated using ruminally cannulated steers (5 *Bos indicus*, BI and 5 *Bos taurus*, BT; 398 kg BW). Subspecies were concurrently subjected to a 2 period, 2 treatment crossover design. Treatments consisted of 0 (CON) or 200 (MON) $mg \cdot hd^{-1}$ monensin (Rumensin 90; Elanco Animal Health, Greenfield, IN) fed daily in 0.91 kg DDGS. Steers were group housed during adaptation periods and moved to individual covered pens to facilitate sampling. Periods were 70 d in length allowing 42 d adaptation, and 28 d withdrawal between periods. Ruminal fluid was collected with a suction-strainer 0, 2, 4, 8, and 12 h after feeding on d 42 for analysis of pH, VFA, and ruminal ammonia-N. Ruminal contents were squeezed through 4 layers of cheesecloth into insulated containers 2 h after feeding on d 42 for determination of rate of ammonia production and CH_4-producing activity. No subspecies × treatment interactions were observed ($P \geq 0.14$). There was an effect of time after feeding ($P \leq 0.01$) on pH, ruminal ammonia-N, total VFA, acetate:propionate, and molar percentages of acetate and propionate. Total VFA concentration was greater ($P = 0.01$) in CON vs. MON steers (66.5 vs. 62.0 m*M*). Total VFA concentration was similar ($P = 0.28$) for BI and BT subspecies (62.7 and 65.8 m*M*, respectively). Monensin decreased the molar percentage of acetate ($P = 0.02$) from 72.5% to 71.2% and increased the molar percentage of propionate ($P < 0.01$) from 16.9% to 18.7%, reducing ($P < 0.01$) the acetate:propionate ratio from 4.34 to 3.85. Although CH_4- producing activity was not significantly different ($P = 0.19$) between CON and MON, monensin feeding resulted in a 15.8% reduction in CH_4-producing activity. *Bos indicus* steers had greater ($P = 0.07$) CH_4-producing activity than BT steers (21.37 vs. 16.62 μmol $CH_4 \cdot mL^{-1} \cdot h^{-1}$). Monensin had no effect ($P \geq 0.19$) on pH, ruminal ammonia-N, or rate of ammonia production. Overall, monensin decreased the acetate:propionate ratio by decreasing acetate and increasing propionate and numerically reduced CH_4-producing activity. *Bos indicus* had greater CH_4-producing activity compared with BT steers.

Key Words: cattle subspecies, ionophore, VFA

829 Effect of monensin withdrawal on ruminal fermentation parameters in *Bos indicus* and *Bos taurus* steers consuming bermudagrass hay.

Natasha L. Bell*[1,2], Robin C. Anderson[3], Todd R. Callaway[3], Marcia O. Franco[4], and Tryon A. Wickersham[1], [1]*Texas A&M University, College Station, TX,* [2]*Texas A&M University-Kingsville, Kingsville, TX,* [3]*Southern Plains Agricultural Research Center, Agricultural Research Service, USDA, College Station, TX,* [4]*Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Effects of monensin withdrawal and subspecies of cattle on the utilization of bermudagrass hay (13.7% CP) were evaluated using ruminally cannulated steers (5 *Bos indicus*, BI and 5 *Bos taurus*, BT; 398 kg BW). Subspecies were concurrently subjected to a 2 period, 2 treatment crossover design. Treatments were withdrawal from either 0 (CON) or 200 $mg \cdot hd^{-1} \cdot d^{-1}$ (MON) monensin (Rumensin 90; Elanco Animal Health, Greenfield, IN) in 0.91 kg DDGS, fed for 42 d. Withdrawal was evaluated for a 28 d period. Rumen fluid was collected 2 h after feeding on d 1, 4, 7, 14, and 21 after the cessation of MON feeding for determination of pH, VFA, ruminal ammonia-N, rate of ammonia production and methane-producing activity. No subspecies × treatment or subspecies × treatment × day interactions were observed ($P \geq 0.16$). Treatment × day interactions ($P \leq 0.01$) were observed for acetate:propionate ratio and molar percentages of acetate and propionate. There was a marked decrease in molar % propionate between d 1 and 4 from 19.1 to 18.0%; however, molar % propionate remained greater ($P \leq 0.09$) for MON than CON through d 7. Molar percentage of acetate increased with MON withdrawal from 68.8 to 69.8 between d 0 and 4. Acetate:propionate ratio was lower ($P \leq 0.01$) on d 0 for MON than CON (3.4 vs. 4.0). By d 4, MON had increased to 3.8, and was not different ($P = 0.14$) from CON. By d 14, no differences ($P \geq 0.88$) between MON and CON remained for acetate, propionate, and acetate:propionate ratio. Steers previously fed monensin had similar ($P \geq 0.12$) total VFA concentrations by d 4. Greater ($P < 0.01$) ruminal ammonia-N concentrations (1.88 vs. 1.73 m*M*) were observed in CON than MON steers. Monensin had no effect ($P \geq 0.69$) on rate of ammonia production or methane-producing activity. A treatment × day interaction occurred ($P \leq 0.05$) for pH with MON steers having higher pH than CON on d 1, 7, and 14. *Bos indicus* steers tended to have higher ($P = 0.08$) pH than BT (6.53 vs 6.46); no other subspecies effects were observed. Results indicate that the monensin induced reduction in acetate:propionate ratio persists for at least 7 d post-withdrawal.

Key Words: cattle subspecies, ionophore, VFA

830 Effects of solid feed level and roughage-to-concentrate ratio on ruminal drinking and passage kinetics of milk, concentrates, and roughage in veal calves.

Harma Berends*[1], Joost van den Borne[1], Norbert Stockhofe[2], Myrthe Gilbert[1], Tamme Zandstra[1], Wilbert Pellikaan[1], Kees van Reenen[3], Eddie Bokkers[4], and Walter Gerrits[1], [1]*Animal Nutrition Group, Wageningen University, Wageningen, Gelderland, the Netherlands,* [2]*Central Veterinary Institute, Lelystad, Flevoland, the Netherlands,* [3]*Livestock Research, Wageningen, Gelderland, the Netherlands,* [4]*Animal Production Systems Group, Wageningen University, Wageningen, Gelderland, the Netherlands.*

Effects of solid feed (SF) level and roughage-to-concentrate (R:C) ratio on ruminal drinking and passage kinetics of milk, concentrate, and roughage in veal calves were studied. Eighty calves (2 wk of age, 45 kg bodyweight) were divided over 16 pens. Pens were randomly assigned to a low (LSF) or a high (HSF) SF level, and to one of 2 R:C ratios; 20:80 or 50:50 on a DM basis. Roughage was composed of 50% corn silage and 50% chopped straw on a DM basis. During the measurement period at 27 wk of age, SF intake was 1.2 kg DM/d for LSF and 3.0 kg DM/d for HSF, and milk (replacer) intake averaged 2.3 kg DM/d for LSF and 1.3 kg DM/d for HSF. To estimate passage kinetics of milk, concentrate, and straw, indigestible markers (respectively CoEDTA, hexatriacontane C_{36}, Cr-NDF) were supplied with the feed as a single dose at respectively 4, 24, and 48 h before slaughter. At slaughter, marker recovery was quantified in the rumen, abomasum, small intestine, and large intestine. Rumen Co recovery averaged 20% of the last milk meal. Recoveries of milk remained largely unaffected by SF level and R:C ratio. Ruminal recovery of C_{36} and Cr was unaffected by R:C ratio. Rumen fractional passage rate of concentrate was estimated from recovery of C_{36} in the rumen and increased ($P < 0.001$) from 3.3%/h for LSF to 4.9%/h for HSF. Rumen fractional passage rate of straw was estimated from Cr recovery in the rumen and increased ($P < 0.01$) from 1.3%/h for LSF to 1.7%/h for HSF. A greater SF level increased ($P < 0.001$) fresh and dry rumen contents. In HSF calves, pH decreased (from 6.9 to 6.0; $P < 0.01$) and VFA concentrations increased ($P < 0.05$) with a lower R:C ratio, indicating increased fermentation. The Cr:C_{36} ratio was similar in the small and large intestine, indicating that passage of concentrate and straw was mainly determined by rumen and abomasum emptying. In conclusion, SF level rather than R:C ratio influences rumen passage of concentrate and roughage. Our data provide insight in passage kinetics of milk and SF and may contribute to the development of feed evaluation models for veal calves.

Key Words: fractional passage rate, rumen retention time, marker recovery

831 Effect of dietary supplementation with resveratrol on nutrient digestibility, methanogenesis and ruminal microbial flora in sheep.

Tao Ma[1], Dan-dan Chen[1], Yan Tu[1], Nai-feng Zhang[1], Bing-wen Si[1], Kai-dong Deng[2], and Qi-yu Diao*[1], [1]*Feed Research Institute, Chinese Academy of Agricultural Sciences, Key Laboratory of Feed Biotechnology of the Ministry of Agriculture, Beijing, China,* [2]*College of Animal Science, Jinling Institute of Technology, Nanjing, Jiangsu, China.*

Two experiments were conducted to evaluate the effect of resveratrol on methanogenesis and microbial flora in Dorper × thin-tailed Han crossbred ewes. In experiment 1, Eighteen ewes (60.0 ± 1.73 kg BW) were assigned to 2 dietary treatments, a basal diet and a basal diet supplemented with resveratrol (0.25 g/head·d), to investigate the effect of resveratrol on nutrient digestibility and nitrogen balance. In experiment 2, 6 ewes (64.0 ± 1.85 kg BW) with ruminal cannulas were assigned to the identical dietary treatments used in experiment 1 according to change over design, to investigate supplementary resveratrol on ruminal fermentation and microbial flora using q-PCR. The digestibility and nitrogen balance data were analyzed using *t*-test procedures in SAS. Data referring to ruminal fermentation parameters (ruminal pH, ammonia, and volatile fatty acid) and microbial flora measured at each sampling time were analyzed using a repeated measures one-way ANOVA. Significant differences were accepted when $P < 0.05$. The results showed that supplementary resveratrol improved the digestibility of organic matter ($P < 0.001$), nitrogen ($P = 0.007$), neutral detergent fiber ($P < 0.001$), and acid detergent fiber ($P < 0.001$). The excretion of fecal N was reduced ($P = 0.007$), whereas that of urinary N increased ($P = 0.002$), which led to an unchanged N retention ($P = 0.157$). Both CO_2 and CH_4 output scaled to digestible dry matter intake decreased from 602.5 to 518.7 ($P = 0.039$) and 68.2 to 56.6 ($P < 0.001$), respectively. Ruminal pH ($P = 0.341$), ammonia ($P = 0.512$), and total volatile fatty acid ($P = 0.249$) were unaffected by resveratrol. The molar proportion of propionate increased from 13.1 to 17.5% ($P < 0.001$) while that of butyrate decreased from 11.0 to 9.55% ($P < 0.001$). The ratio of acetate to propionate decreased from 5.44 to 3.96 ($P < 0.001$). Supplementary resveratrol increased ruminal population of *F. succinogenes*, *R. albus*, and *B. fibrisolvens* ($P < 0.001$) while decreased protozoa and methanogens ($P < 0.001$). In conclusion, dietary resveratrol inhibited methanogenesis without adversely affecting ruminal fermentation.

Key Words: CH_4, resveratrol, sheep

832 Essential oils from goat weed (*Ageratum conyzoides*) and African basil (*Ocimum gratissimum*) can reduce in vitro enteric methane production.

Musibau A. Bamikole[1,2], Ibukun M. Ogunade*[1], Felipe Amaro[1], Yun Jiang[1], Thiago F. Bernardes[1], Vania R. Vasconcelos[1], Darren D. Henry[3], F. O. Ugiagbe[2], U. J. Ikhatua[2], Nicolas DiLorenzo[3], and Adegbola T. Adesogan[1], [1]*University of Florida, Gainesville, FL,* [2]*University of Benin, Benin City, Nigeria,* [3]*North Florida Research and Education Center, University of Florida, Marianna, FL.*

The potential of essential oils (EO) from leaves of goat weed (EOG) and African basil (EOB) to reduce in vitro enteric methane production and improve rumen fermentation was examined. A corn silage-based TMR (0.5 g; CP 16.6%; NDF 35.9%) was treated with EOG or EOB at rates of 0 (Control), 10 (Low), 20 (Med) and 30 (High) μL/50 mL of rumen fluid - buffer inoculum (ratio 1:2) and with monensin (0.6 mg/50 mL). Each suspension was incubated in a 120-mL gas-tight culture bottle in triplicate at 39°C for 24 h in each of 2 runs. Fermentation parameters, gas and methane production, in vitro DM digestibility (DMD), and fermentation efficiency (DMD g kg^{-1}/gas volume) were measured. Data for each EO were separately analyzed with the Glimmix procedure of SAS. Compared with respective Controls, monensin and High EOG or EOB reduced ($P < 0.05$) gas volume (66.8, 71.7 and 49.3 vs. 85.0), DMD (526, 520, and 514 vs. 555 g/kg) and methane percentage in total gas (7.95, 9.02 and 7.19 vs. 10.4%) and increased ($P < 0.05$) fermentation efficiency (7.92, 7.39, and 11.58 vs. 6.58). The respective reductions in methane production (mg/g DM digested) were 36.9, 24.1, 57.2%. Ammonia nitrogen concentration, pH of EOB and VFA concentrations of EOG were unaffected ($P > 0.05$) by treatment. However, monensin and High EOG increased ($P < 0.05$) the pH (5.75, 5.75 vs. 5.66, respectively) and monensin and High EOB increased ($P < 0.05$) molar proportions of butyrate and High EOB decreased ($P < 0.05$) that of propionate. Low rates of EOB and EOG increased ($P < 0.05$) CH4 production (mg/g DM digested) and Med rates decreased ($P < 0.05$) DMD. Low EOG increased ($P < 0.05$) gas volume and methane production (mg/g DM digested), and decreased ($P < 0.05$) fermentation efficiency. A high dose of essential oils from goat weed and African basil leaves improved fermentation efficiency and reduced DMD and methane production in a manner that is comparable with monensin.

Key Words: essential oil, medicinal plant, in vitro fermentation

833 Effects of supplemental energy and protein source on performance of steers grazing irrigated corn residue.

Benjamin T. Tibbitts*[1], Cody A. Welchons[1], Robert G. Bondurant[1], Fred H. Hilscher[1], James C. MacDonald[1], and Rick N. Funston[2], [1]*University of Nebraska-Lincoln, Lincoln, NE,* [2]*University of Nebraska West Central Research and Extension Center, North Platte, NE.*

Seventy-five crossbred steer calves (235 ± 1.1kg) grazing irrigated corn residue were blocked by BW and randomly assigned to 5 treatment groups (n = 15) to evaluate the effects of protein and energy supplementation on steer performance. Steers were supplemented daily at 1100–1200 via a Calan gate system for 86 d. Treatment supplements consisted of 60% soy-pass + 40% soybean meal (SP), dried distillers grains (DDG), 89% Corn/6% Molasses/5% Urea (C + RDP), corn only (CRN), and control (NS) fed at 1.59, 1.36, 1.82, 1.7, and 0.0 kg DM/d respectively. Supplements were fed at different DM amounts to provide equal TDN intake. Estimated TDN values by supplement were 87% (SP), 104% (DDG), 87% (C + RDP), and 83% (CRN). Ending BW ($P < 0.05$) differed among treatments and was 291, 286, 254, 245, and 229 (SEM 4.9) kg for SP, DDG, C + RDP, CRN, and NS respectively. Average daily gain among treatments was 0.67, 0.6, 0.24, 0.14, and - 0.09 kg (SEM 0.06) for SP, DDG, C + RDP, CRN, and NS respectively and was significantly different ($P < 0.05$) among all treatments. Treatment groups supplemented with SP and DDG achieved average daily acceptable gains above 0.5 kg, while C + RDP, CRN, and NS treatment groups achieved average daily gains lower than 0.5 kg. The SP treatment provided a combination of RDP and RUP which resulted in greatest ADG among treatments when supplement TDN was similar.

Key Words: beef steers, corn residue grazing, supplementation

834 Variability in predicted weaning weight of nursing calves using four models.

Phillip A. Lancaster*[1] and Luis O. Tedeschi[2], [1]*Range Cattle Research and Education Center, University of Florida, Ona, FL,* [2]*Department of Animal Science, Texas A&M University, College Station, TX.*

The objective of this study was to assess the variability surrounding predicted weaning weight (WW) of nursing beef calves at 210 d of age using 2 models developed to predict milk yield (MY) and calf forage DMI. These models were developed to predict calf WW based on peak milk (PKMK), calf BW, and forage DE. Equations to predict calf forage DMI were published by Tedeschi et al. (2006; Nutrient Digestion and Utilization in Farm Animals; TED06) and Tedeschi et al. (2009; J. Anim. Sci. 87:3380; TED09). Additionally, we evaluated 2 equations to predict MY: Wood (1967; WOD) and the NRC (2000; NRC). Calf ADG was computed using NRC (2000) equations for energy requirements assuming ME content of 5.29 Mcal/kg for milk. A Monte Carlo simulation with 5,000 iterations assumed normal distribution with mean and SD of 3 ± 0.5 Mcal/kg for forage DE, 35 ± 2 kg for calf birth weight (CBW), and 550 ± 50 kg for final shrunk BW (FSBW), and uniform distribution with minimum and maximum at 3 and 12 kg/d for PKMK. Although predicted WW overlapped for all model combinations, their mean and SD varied considerably: 147 ± 72.9, 219 ± 95.1, 262 ± 91.6, and 278 ± 82.2 kg for NRC&TED09, WOD&TED09, NRC&TED06, and WOD&TED06, respectively. Their predicted WW tended to follow

normal distributions, except for NRC&TED09 that was skewed to the right. The percentage of predicted WW within 100 and 300 kg were 75.3, 76, 67, and 62.8%, respectively, and within 200 and 300 kg were 10.1, 36.1, 42.4, and 46.4%, respectively. Forage DE had the greatest Spearman correlation (0.74 < r <0.86) with WW, followed by PKMK (38 < r <44), FSBW (0.16 < r <0.18), and CBW (r = 0.01). Forage DE also had the greatest standardized regression coefficient (SRC) for WW: 073, 0.84, 0.81, and 0.80 for NRC&TED09, WOD&TED09, NRC&TED06, and WOD&TED06, respectively, and PKMK had the second greatest SRC: 0.28, 0.39, and 0.43 for WOD&TED09, NRC&TED06, and WOD&TED06, respectively. For NRC&TED09, FSBW had the second greatest SRC (0.18). We concluded that forage DE is the most influential factor that affects calf WW and these predictive models have distinct prediction patterns for calf WW. Future analysis should focus on consolidating predicted MY between these models.

Nonruminant Nutrition: Fiber

835 Effects of dietary mannan oligosaccharide supplementation on performance and immune response of sows and their offspring. X. D. Duan[1], D. W. Chen[1], P. Zheng[1], G. Tian[1], J. P. Wang[1], X. B. Mao[1], J. Yu[1], J. He[1], B. Li[1], Z. Q. Huang[1], Z. G. Ao[2], and B. Yu*[1], *[1]Institute of Animal Nutrition, Sichuan Agricultural University, Chengdu, Sichuan, China, [2]Alltech Biological Product (China) Co. Ltd., Beijing, China.*

A study was conducted to determine effects of mannan oligosaccharide (MOS) supplementation of the diets of sows and their offspring on maternal and offspring performance and immune status. Sixty multiparous sows were fed either a control diet (sCON, $n = 30$) or a diet containing 400 mg/kg MOS (sMOS, $n = 30$) from d 86 of gestation until the end of lactation. On d 7 of age, offspring were assigned within sow treatments to the piglet basal diet (pCON) or the piglet basal diet + 800 mg/kg MOS (pMOS) for 28 d. Thus, the offspring treatments were sCON-pCON, sCON-pMOS, sMOS-pCON, and sMOS-pMOS, 15 litters per treatment. No dietary effect was observed on the number of total piglets born and born alive and the piglet weight at birth. Serum-specific antibody concentrations of porcine reproductive and respiratory syndrome, classical swine fever, and porcine pseudorabies of sows and immunoglobulins concentrations in colostrum and milk were not affected by sow dietary MOS ($P > 0.05$). However, the weaning to estrus interval of sows was shortened significantly in the sMOS treatment compared with the sCON treatment ($P = 0.05$). The weaning weight ($P = 0.03$) and pre-weaning weight gains ($P = 0.01$) of piglets from the sMOS were greater than those from the sCON. Piglets from sMOS had higher serum concentrations of IgA ($P < 0.01$), IgG ($P < 0.01$), complement 3 (C3) ($P < 0.01$), lysozyme(LYZ) ($P < 0.01$) and complement 4 (C4) ($P = 0.05$) at weaning, as well as C3 ($P < 0.01$) and LYZ ($P < 0.01$) on d 35 of age. MOS supplementation of piglet diet improved both pre- and post-weaning weight gain ($P < 0.01$) and increased serum concentrations of IgA ($P = 0.01$) and IgG ($P = 0.01$) at weaning, as well as C3 ($P < 0.01$), LYZ ($P < 0.01$) and C4 ($P = 0.01$) on d 35 of age. Piglets of the sMOS-pMOS group had higher body weight and better immune statue at weaning and on d 35 of age compared with other groups. These results indicate that supplementing sow diets with MOS during late gestation and lactation improved the growth potential and immune responses of nursing piglets. Furthermore, dietary addition of MOS to pre- and post- weaning piglets also has potential growth and immune-promoting effects.

Key Words: immune response, mannan oligosaccharide, performance

836 Dietary chitooligosaccharide supplementation alleviates immune challenge induced by lipopolysaccharide in weaned piglets. L. Zhang, G. Tian, D. W. Chen, B. Yu*, Y. Yao, J. Yu, P. Zheng, X. B. Mao, J. He, and Z. Q. Huang, *Animal Nutrition Institute, Sichuan Agricultural University, Chengdu, Sichuan, China.*

A total of 24 weaned piglets (8.53 ± 1.00 kg) were used to investigate the effects of chitooligosaccharide (COS) supplementation on immunological responses challenged with *E. coli* lipopolysaccharide (LPS). Experimental treatments were arranged in a 2×2 factorial design ($n = 6$/group), with the main effects of COS (0 vs. 300 mg/kg) and LPS challenge (LPS vs. saline). Piglets were raised individually in metabolic cages and fed 0 or 300 mg/kg COS for 18 d. On d 15~17, piglets were challenged with LPS (80 μg/kg BW) or saline daily. Blood was obtained at 3 h and 48 h post-injection on d 17. At 48 h post-injection, weight of spleen was recorded, thymus and spleen were sampled. All data were analyzed by 2-way ANOVA using GLM procedures of SAS, including COS, LPS, and their interaction as the fixed effects. Spleen index was elevated by LPS challenge (+37.88%, $P < 0.01$), without an effect of COS supplementation. Serum TNF-α (+16.99%, $P < 0.05$) concentrations increased and IL-10 (−11.61%, $P < 0.01$) decreased in pigs injected with LPS at 3 h after injection. Serum IL-1 β, IL-2 and IL-4 content were increased (+5.58%, +12.69% and +11.77%, $P < 0.05$) at 48 h after injection. Piglets supplemented with COS had lower serum IL-1 β and IL-2 at 3 h (−48.36% and −12.14%, $P < 0.05$) post-injection, and lower serum IL-6 at 3 and 48 h post-injection (−10.43% and −13.13%, $P < 0.05$). However, COS supplementation increased serum IL-10 at 3h post-challenge compared with non-supplemented pigs (+8.44%, $P < 0.01$). These alterations in serum inflammatory factor traits in piglets challenged by LPS were accompanied by increased gene expressions of CD14, MyD88 in spleen (+12.63% and +26.77%) and TLR4, NF-kB, TRIF, IRF3 in thymus (+245.81%, +44.44%, +17.13% and +86.55%) that are related to MyD88 dependent and independent signaling pathway ($P < 0.05$), while COS supplementation alleviated most of these changes (−37.23% for CD14, −34.87% for MyD88, −30.43% for NF-kB, −24.30% for TRIF and −31.82% for IRF3, $P < 0.05$). In conclusion, results indicated that COS supplementation attenuated the immune challenge of LPS possibly by inhibiting over-activation of TLR4-MyD88 dependent and independent signaling pathway.

Key Words: chitooligosaccharide, lipopolysaccharide, piglet

837 Effects of feeding fermented wheat with *Lactobacillus reuteri* on nutrient digestibility, growth performance, and intestinal fermentation in weaned pigs. M. H. A. Le*[1], Y. Yang[1], S. Galle[1], J. L. Landero[1], E. Beltranena[1,2], M. G. Gänzle[1], and R. T. Zijlstra[1], *[1]University of Alberta, Edmonton, AB, Canada, [2]Alberta Agriculture and Rural Development, Edmonton, AB, Canada.*

Feeding fermented feed to weaned pigs may improve gut health and thereby reduce diarrhea incidence. Effects of feeding wheat grain fermented for 24 h with *Lactobacillus reuteri* were evaluated in 36 weaned pigs (7.3 kg BW). The fermented wheat contained (DM basis) 14.3% CP, 0.45% chemically available Lys, and 7.8% NDF, whereas the nonfermented wheat contained 17.0% CP, 0.47% chemically available Lys, and 11.7% NDF. Pigs were fed 6 mash wheat-based diets balanced for water content during 2 phases: phase 1 diets for 1 wk (d 0–7) with 20% unfermented or fermented wheat and subsequently phase 2 diets for 2 wk (d 8–21) with 50% unfermented or fermented wheat. The 6 diets were negative control (NC; non-fermented), positive control (PC; nonfermented + organic acid including lactic and glacial acidic acid in the ratio of 4:1), and 4 fermented wheat diets (*L. reuteri* TMW1.656 and *L. reuteri* LTH5794 with or without added sucrose). Diets were formulated to provide 2.5 and 2.4 Mcal NE/kg and 5.3 and 5.0 g SID Lys/Mcal NE for phase 1 and 2 diets, respectively. Data were analyzed using the MIXED procedure with contrast statements to test effects of fermentation with or without sucrose. Feeding fermented wheat reduced ($P < 0.05$) the apparent total-tract digestibility (ATTD) of diet GE (84.4 vs. 85.2%) and CP (81.8 vs. 83.6%) for wk 3 compared with the controls. Weaned pigs fed fermented wheat diets had lower ADFI ($P < 0.05$) than pigs fed NC and PC for wk 1 and for the entire study (271 vs. 300 g of DM/d). Pigs fed fermented wheat diets had lower ADG ($P < 0.05$; 232.8 vs. 260 g/d) and G:F ($P < 0.10$; 0.81 vs. 0.80) vs. pigs fed NC and PC in wk 3, but ADG and G:F did not differ for the entire study. Concentrations of acetic, propionic, branched-chain, and total VFA in feces increased

($P < 0.05$) in pigs fed fermented wheat with added sucrose; however, VFA did not differ in ileal digesta. In conclusion, feeding fermented wheat diets to weaned pigs stimulated hindgut fermentation but did not increase growth performance and ATTD of diet nutrients.

Key Words: fermented wheat, performance, weaned pig

838 Extracted rice bran improves performance and fecal parameters in weaning pigs via prebiotic action.

M. Begum*, B. Balasubramanian, M. M. Hossain, S. D. Upadhaya, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea.*

One hundred forty weaning pigs [(Yorkshire × Landrace) × Duroc] with an average BW of 5.70 ± 1.41 kg (21 d) were used in a 6-wk experiment to evaluate the effect of extracted rice bran (ERB) on growth performance, ATTD of nutrients, diarrhea score, blood profiles, fecal microbial shedding and fecal noxious gas emissions. Weaning pigs were allotted to diets containing 0 or 0.1 g ERB/kg of diet and 2 levels of antibiotic (tiamulin; ANT, 0 and 33 ppm) according to a 2 × 2 factorial arrangement of treatments. There were 7 replicated pens per treatment with 5 pigs per pen. The experiment included 2 phases: 0 to 2 weeks and 2 to 6 weeks. At 2 and 6 wk, 2 pigs from each pen were subjected for the fecal microbiota and blood profiles. All data were statistically analyzed using the repeated-measure statement of the MIXED procedure of SAS. The model included diet as a fixed effect whereas pig and period were included as random effects. During phase 1 and overall, ERB supplementation increased growth efficiency (G:F) compared with the ERB-free diet in weaning pigs (0.84 vs. 0.80 and 0.69 vs. 0.67; $P = 0.01$ and $P = 0.04$, respectively). Pigs receiving diets supplemented with ANT increased DM and N digestibility than their counterparts during phase 1 (82.89 vs. 81.19% and 82.85 vs. 80.71%; $P = 0.04$ and 0.01, respectively). Pigs fed ERB had higher N digestibility than pigs fed the non-ERB diet during phase 1 and phase 2 (83.60 vs. 79.96% and 82.48 vs. 79.22%, $P = 0.01$ and 0.02, respectively). Supplementation of ANT × ERB diets had positive effects for DM digestibility ($P = 0.04$). During phase 2, the supplementation of ERB decreased total cholesterol (TC) than pigs fed the diet lacking ERB (97.30 vs. 103.60 mg/dL; $P = 0.01$). During phase 2, the supplementation of ERB increased the *Lactobacillus* and reduced *Salmonella* counts than pigs fed the ERB-free diet (7.72 vs. 7.58 $\log_{10}$ cfu/g and 2.37 vs. 2.49 $\log_{10}$ cfu/g; $P = 0.04$ and $P = 0.02$, respectively). Pigs fed ERB diets reduced ammonia (NH_3) gas emission compared with non-ERB diets (22.70 vs. 26.46 ppm; $P = 0.01$). In conclusion, results indicated that dietary supplementation of ERB improved performance in weaning pigs.

Key Words: extracted rice bran, microbial shedding, noxious gas emissions

Production, Management, and the Environment VI

839 Associations between management practices and reproductive performance in Canadian dairy herds.

José Denis-Robichaud*[1], Ronaldo L. A. Cerri[2], Andria Jones-Bitton[1], and Stephen J. LeBlanc[1], *[1]Department of Population Medicine, University of Guelph, Guelph, Ontario, Canada, [2]Faculty of Land and Food Systems, University of British Columbia, Vancouver, British Columbia, Canada.*

The objective of this study was to identify management practices associated with reproductive performance on Canadian dairy farms. A questionnaire was distributed online and by mail to Canadian dairy farmers from March to May 2014 to assess reproduction management. From 833 responses, reproduction management was categorized as mainly visual heat detection (n = 415 herds), timed artificial insemination (TAI; n = 175), automated activity monitoring (AAM; n = 85) where each represented >50% of AI, or "combined" practices (n = 131). Pregnancy rate (PR), insemination rate (IR), and conception risk (CR) per 21 d for 2013 were extracted from dairy herd information (DHI) files of 346 farms. Univariable linear regression models adjusted for region were used to identify associations of these reproduction performance measures with farms' characteristics and management practices. The average (±SD) PR, IR, and CR were 17 ± 4.7%, 43 ± 11.3%, and 40 ± 8.5%, respectively. Pregnancy rate was lower in tiestall barns (15.2% CI = 14.4–16.0) than in freestall barns (17.9% CI = 17.2–18.6), in herds inseminating once per day (15.7% CI = 14.9–16.6) than in herds inseminating twice per day (17.8% CI = 16.8–18.7), and in herds with <100 lactating cows (16.2% CI = 15.5–16.8) than in herds with more than 250 lactating cows (20.1% CI = 17.2–22.9). Pregnancy rates were not significantly different by main reproduction management practice: visual heat detection (15.9% CI = 15.0–16.8), TAI (16.7% CI = 15.4–18.0), AAM (17.4% CI = 16.0–18.9), or combined practices (18.2% CI = 16.6–19.9). Insemination rates were lower in herds using visual heat detection (40.0% CI = 37.3–42.6) than in herds using TAI (47.4% CI = 43.8–50.9), or combined practices (46.7% CI = 42.6–50.7), but not significantly different from herds using AAM (44.0% CI = 40.3–47.7). Conception risks were higher in herds using visual heat detection (40.7% CI = 37.2–44.1) than in herds using TAI (36.8% CI = 33.0–40.3), but not significantly different from herds using AAM (40.0% CI = 36.1–43.9), or combined practices (39.8% CI = 35.8–43.9). Performance was influenced by factors other than the reproductive management program.

Key Words: dairy cow, management, reproduction

840 Evaluation of Ovsynch and CIDR inserted concurrently with or two days after initiation of Ovsynch protocol to improve reproductive performance in lactating dairy cows with low estrus detection efficiency.

Abid Hussain Shahzad*[1], Abdul Sattar[1], Nasim Ahmad[1], Ijaz Ahmad[1], Deniz Nak[2], and Yavuz Nak[2], *[1]University of Veterinary and Animal Sciences, Lahore, Lahore, Punjab, Pakistan, [2]Uludag University, Bursa, Bursa, Turkey.*

To assess the efficiency of 3 synchronization methods as postpartum reproductive management tools in dairy cattle on a commercial dairy farm. Cyclic Holstein lactating cows (n = 167),55–90 DIM, were randomly allotted to 1 of 3 treatments. First group was (Ovsynch: n = 58) given a 2-mL i.m. injection of synthetic GnRH on d 0. After 7 d, PGF_{2a} (2 mL i.m.) was injected. A second injection of GnRH was administered 48 h after the PGF_{2a} injection and all cows were bred by timed AI 16 h after the second GnRH injection. Cows in second group (Ovsynch+P7: n = 55) were introduced a modified Ovsynch TAI treatment similar to Ovsynch but CIDR was inserted for a 7-d period (CIDR was inserted with GnRH and removed on PG Shot). In third group (Ovsynch+P5; n = 54), cows were subjected to Ovsynch protocol in addition to CIDR insertion for 5 d (CIDR was inserted after 2 d of GnRH and removed with PG shot). P4 conc. was measured on d 30 and 60. Pregnancy diagnosis was carried out at d 30, 60, 90 post insemination in all 3 groups. Progesterone profile was significantly higher ($P < 0.05$) for Ovsynch + P5 (7.75 ± 0.38 ng/mL) and Ovsynch + P7 (7.58 ± 0.26 ng/mL) compared with Ovsynch (6.52 ± 0.32 ng/ mL) on d 30 PTAI but nonsignificant among all 3 synchronization treatments (i.e., 6.37 ± 0.49 in Ovsynch, 6.75 ± 0.36 in Ovsynch+P5 and 6.80 ± 0.41 in Ovsynch+P7 group). Pregnancy rate in Control group was 39.7, 36.2, and 32.80 on d 30, 60 and 90 post insemination. In second modified Ovsynch group with 7d CIDR (Ovsynch+P7) insertion pregnancy rate was 42.6% on d 30, 37% on d 60 and 90 PAI. In third group pregnancy rate was 45.5, 43.6 and 41.8 on corresponding 30, 60, 90 d PAI. Although pregnancy rate were statistically not significant but, by percentage points, improved pregnancy rate was observed on all 3 time points in Ovsynch+p5 group.

Key Words: modified Ovsynch, postpartum lactating cow, progesterone

841 Reproductive outcomes following presynchronization of dairy heifers with a 14-d CIDR and prostaglandin $F_{2\alpha}$.

Courtney K. Claypool*[1], Jennifer A. Spencer[1], Saulo Menegatti Zoca[3], Bahman Shafii[1], William J. Price[1], Amin Ahmadzadeh[1], Neil R. Rimbey[2], and Joseph C. Dalton[2], *[1]University of Idaho, Moscow, ID, [2]University of Idaho, Caldwell, ID, [3]UNESP, Botucatu, Sao Paulo, Brazil.*

Efficient pregnancy production in heifers provides an earlier return on investment for dairy producers. The research hypotheses were that presynchronization would result in a faster insemination rate following entry to the breeding program, and an increased proportion of pregnant heifers within the first week of entry into the breeding program compared with no presynchronization. Heifers were assigned to 1 of 3 groups: (1) 14-d CIDR, (2) prostaglandin $F_{2\alpha}$ (2× PG), or control (1× PG). The 14-d CIDR group (n = 119) received a CIDR on d −30, which was removed on d −16. The 14-d CIDR group received an injection of PG (25 mg i.m.) upon entry to the breeding program (d 0). The 2× PG group (n = 118) received an initial injection of PG on d −11, and a second injection of PG on d 0. The 1× PG group (n = 121) received an injection of PG on d 0. Data were analyzed using ANOVA procedures within the generalized linear mixed models in SAS (9.4). All animals received tail paint and were observed for behavioral estrus daily. Pre-synchronization affected ($P < 0.05$) the proportion of heifers observed in estrus and inseminated in the first week: 95.8% (14-d CIDR), 74.5% (2× PG), 66.9% (1X PG). Days to AI (LSM ± SEM) following entry to the breeding program were also affected ($P < 0.05$) by treatment: 3.6 ± 0.4 d (14-d CIDR), 4.9 ± 0.4 d (2× PG), 6.8 ± 0.5 d (1× PG). Proportion of heifers pregnant in the first week of the breeding program also differed ($P < 0.05$): 68% (14-d CIDR), 43% (2× PG), 41% (1× PG). Conception rates to AI in the first week were 71.9% (14-d CIDR), 57.9% (2× PG), and 61.7% (1× PG), and were different ($P < 0.05$) between 14-d CIDR and 2× PG heifers. Days on feed from entrance to the breeding program to projected calving date were calculated for all heifers: 295 ± 2.6 d (14-d CIDR), 302 ± 2.6 d (2× PG), and 305 ± 2.5 d (1× PG), and were different ($P < 0.05$) between 14-d CIDR and 1× PG heifers. Pre-synchronization with a 14-d CIDR and PG appears to be an effective strategy to increase the proportion of heifers identified in estrus, inseminated, and pregnant within the first week upon entry to the breeding pen.

Key Words: dairy heifer, presynchronization, CIDR

842 Effects of expression of estrus measured by activity monitors on ovarian dynamics and conception risk in Holstein cows.

Augusto M. L. Madureira*[1,2], Bruna F. Silper[2], Tracy A. Burnett[2], Liam B. Polsky[2], Eraldo L. Drago Filho[1], Sergio Soriano[3], Alex F. Sica[3], José L. M. Vasconcelos[1], and Ronaldo L. A. Cerri[2], *[1]Sao Paulo State University, Botucatu, SP, Brazil, [2]University of British Columbia, Vancouver, BC, Canada, [3]Colorado Dairies, Araras, SP, Brazil.*

The objective of this study was to determine intensity of physical activity as a result of estrus expression and its relationship with ovarian dynamics and fertility. Estrus events were recorded at 2 commercial dairies. A collar-mounted accelerometer (Collar; SCR Heatime) and a leg-mounted pedometer (Leg1; Boumatic Heat-seeker-TX) were used in farm 1. A second leg-mounted pedometer (Leg2; AfiMilk Pedometer Plus) was used in farm 2. Only spontaneous estrus (SE) events were registered at farm 1 (collar and Leg1; 1,099 events; 318 cows). Cows with Leg2-tags were induced to ovulate (IO; 1,411 events; 1,040 cows) with an E2/P4-based TAI protocol. Blood samples and ovarian ultrasonography were done at detection of activity increase (SE), or at the moment of AI and 10 d after AI (IO). IO cows' were scanned on d 7 after AI to assess CL presence. Pregnancy diagnosis was performed at 42 ± 7 d. Data were analyzed with ANOVA, logistic regression, proc MIXED. Peak estrus activity (PA) for Collar was 71.6 ± 20.7 index value, and for Leg1 and Leg2, 334.3 ± 155.7% and 286.18 ± 163.3% relative increase. Preovulatory follicle diameter was 18.8 ± 0.3 mm (SE) and 13.3 ± 3.5mm (IO). Follicle diameter was not correlated with AAM measurements (r = 0.007). Cows with high PA had greater E2 concentration (9.5 ± 0.3 vs. 8.2 ± 0.2 ng/mL [Collar]; 8.9 ± 0.2 vs. 8.1 ± 0.2ng/mL [Leg1]). P4 concentration at d of AI was not correlated with relative increase (Leg2), but it was higher on d 10 for cows that had more intense estrus (3.17 ± 0.11 ng/mL vs. 3.73 ± 0.21 ng/mL). Cows with greater PA had greater P/AI than those with lower PA (36.5% vs. 24.6% [Collar], 33.5% vs. 21.4% [Leg1] and 42.9% vs. 28.9% [Leg2]). Likelihood of ovulation was greater for high vs. low relative increase (94.6% vs. 86.2%). Greater estrus intensity improved ovulation and P/AI. Data from AAM might be used to survey and predict fertility measures in dairy cows. More studies are needed to determine management and selection tools to improve estrus expression, detection, and fertility.

Key Words: pedometer, follicle, pregnancy

843 Vitality and morphology of Boer buck spermatozoa stored fresh for 72 hours.

Olumide A. Ajao*, Daniel M. Barry, and Kow K. Benyi, *University of Venda, Thohoyandou, Limpopo Province, South Africa.*

The study was aimed at evaluating the effects Biladyl and Triladyl extenders on the percentage live proportion and morphological status of the Boer buck spermatozoa when stored at 5°C, 12°C and 17°C in programmable refrigerators for 72 h. Four (n = 4) healthy Boer bucks aged 3.12 ± 0.55 years were ejaculated using an artificial vagina (AV) once every 4 d for 6 replicates. Semen was extended at ratio 1: 5 v/v (semen to extender). All smears were duplicated. Semen samples were evaluated for percentage live spermatozoa and morphological status after every 12 h in 72 h of storage. Data were analyzed by ANOVA using the GLM procedure of Minitab. Spermatozoa viability and morphological correlations between extender type and temperature were assessed using the principal component analysis (PCA). The interaction between extender type and storage temperature indicated no significant difference ($P > 0.05$) on the proportion of live spermatozoa. The percentage live spermatozoa in Biladyl stored at 12°C was 76.6% compared with the higher percentage of live spermatozoa in Triladyl (80.0%) which were kept at 12°C. Among the conditions storage tested, temperature 12°C kept the least number of spermatozoa alive after the 72 h of storage with 69% of live spermatozoa. The percentage of live spermatozoa found in Triladyl after 72 h at 17°C was highest (86.3%). Spermatozoa kept in Biladyl at 12°C and in Triladyl at 12°C statistically produced higher morphological abnormality with ($P < 0.05$) effect than the morphological abnormality discovered in Biladyl 17°C and Triladyl 17°C. Temperature 12°C had the highest percentage of morphologically abnormal spermatozoa (23.33%) in Biladyl, followed by the Triladyl extender (22.46%) stored at 12°C, followed by the percentage found in Biladyl stored at 12°C (18.68%) and lastly by the 17.46% of sperm found in semen extended with Triladyl stored at 17°C. With appropriate protocol, Biladyl and Triladyl extenders can keep acceptable percentage of goat spermatozoa alive when stored at 5°C, 12°C and 17°C up to 72 h.

Key Words: extender, vitality, morphology

844 Milk composition and fatty acids in mare's milk fat produced in the mountains and highlands of Kyrgyz Republic during milking season.

Aichurok T. Mazhitova*, Asylbek A. Kulmyrzaev, and Zhyldyzai E. Ozbekova, *Kyrgyz-Turkish Manas University, Bishkek, Kyrgyzstan.*

In Kyrgyzstan, mare's milk is used for preparation of the fermented dairy beverage koumiss and fresh mare's milk has also been used to treat lung diseases as a traditional method of treatment, but mare milk production is seasonal. Accordingly the effect of the milking season on the chemical composition (with $P < 0.01$) and fatty acid profile ($P < 0.05$) of mares' milk of the Kyrgyz Novokirgizskaya horse breed grazing on the pastures at 1700 and 2200 m above the sea level was investigated. The animals were kept under extensive pasture conditions and received no additional feed supplements. Milk samples were collected monthly after machine milking from May to July 2014 and from May to August 2014 from 25 mares grazing at 1700 m and 2200 m, respectively. Total solids (11.84–11.05%), milk fat (2.23–1.23%) and ash (0.53–0.40%) content of milk produced at 1700 m were decreased to the end of milking season, while these constituents in the milk produced at 2200 m (10.93–11.11% total solids; 1.29–1.60% milk fat) and also protein (2.20–2.29%) and lactose (6.98–6.93%) did not change significantly during the milking season, except for ash content (0.46–0.295). Fatty acid composition of the milk obtained at 2200 m (vegetation is dominated by grasses, forbs, sub-shrubs) was richer in unsaturated fatty acids than that of produced at the pastures at 1700 m above the sea level (vegetation is dominated by shrubs and sub-shrubs). The results of the study have show that the chemical composition and fatty acid profile of the mare milk is influenced by milking season and geographical location of pastures.

Key Words: mare milk, milking season, geographical location

845 Environmental and economic consequences of subclinical ketosis and related diseases in dairy farming.

P. F. Mostert*, E. A. M. Bokkers, C. E. Van Middelaar, and I. J. M. De Boer, *Wageningen University, Animal Production Systems group, Wageningen, the Netherlands.*

Subclinical ketosis (SCK) in dairy cattle is a metabolic disease that occurs around the calving period and increases the risk on other diseases. SCK and other diseases result in, e.g., milk losses, reduced pregnancy rate, culling, and therefore have environmental and economic

consequences. This study aimed to estimate the environmental and economic consequences of SCK and related diseases in dairy farming. A dynamic stochastic simulation model at cow level was developed and combined with a life cycle assessment and partial budget analysis. The model was divided into 4 parts. In part one, cows receive a parity (1–5+) and a potential milk production. Cows subsequently have a risk on getting retained placenta or milk fever (part 2), SCK (part 3), and metritis, displaced abomasum, clinical ketosis, lameness or mastitis (part 4). The risk on diseases depends on parity and previous diseases. The model was parameterized using literature. Inputs are the number of dairy cows, prevalence of diseases and culling rate, outputs are the change in global warming potential (GWP) and profit per case of SCK. Outputs were divided in direct (SCK) and indirect (other diseases due to SCK) consequences, that were estimated with the attributional risk of SCK. Cows with (a combination of) diseases had: a reduced daily milk yield, discarded milk if treated, an increased calving interval, and risk of culling. Monte Carlo simulation was performed to find the variation in the output. Preliminary results showed that the costs increased from €33.0 (±31.3) to €55.2 (±58.3) and GWP increased from 1.3 (±1.3) to 1.8 (±2.0) % CO_2-e/unit milk per parity based on milk losses per case of SCK. Results differ per parity ($P < 0.001$) due to differences in milk yield and risk on diseases. The highest contribution came from SCK (68%). Other diseases particularly had an effect on the variation of the output. Future calculations will be extended by including reproduction and culling, and by performing sensitivity analyses. In conclusion, SCK has an effect on the environmental and economic performance of dairy farming.

Key Words: greenhouse gas emissions, costs, health

846 Characterizing the temporal pattern of leaky gut biomarkers in healthy and ketotic cows during the transition period. M. Abuajamieh*[1], S. K. Stoakes[1], M. V. Sanz Fernandez[1], J. S. Johnson[1], J. T. Seibert[1], E. A. Nolan[1], S. M. Lei[1], H. B. Green[2], K. M. Schoenberg[2], W. E. Trout[2], and L. H. Baumgard[1], [1]*Iowa State University, Ames, IA,* [2]*Elanco Animal Health, Indianapolis, IN.*

The dairy cow transition period is associated with increased incidence of metabolic disorders. Ketosis is the most prevalent metabolic disease and approximately 10–25% of cows experience clinical ketosis following calving. We hypothesize that a compromised gastrointestinal barrier (a.k.a. leaky gut) and subsequent lipopolysaccharide (LPS) infiltration may play a key-role in ketosis etiology. Study objectives were to retrospectively characterize biomarkers of leaky gut during the transition period in healthy and clinically diagnosed ketotic (urine acetoacetic acid >15 mg/dL) cows. Blood samples from lactating Holstein cows (n = 164, parity 2–7; from a commercial herd) were obtained at 21, 14, and 7 d antepartum (±3 d) and 3, 7, 10, and 14 d postpartum (±1 d). Cows were retrospectively categorized into one of 2 treatments: healthy (H; n = 24; no diagnosed health disorder) and ketotic (KET; n = 22; cows diagnosed only with ketosis). KET cows had reduced milk production compared with H (10%, $P < 0.01$). Antepartum circulating LPS in KET cows was increased (129%, $P = 0.02$) compared with H, and they tended to have increased NEFA (70%; $P = 0.08$) when compared with H. Postpartum KET cows had increased NEFA (49%; $P < 0.01$), BHBA (16%; $P = 0.01$), SAA (75%; $P = 0.04$), haptoglobin (273%; $P = 0.03$), and L-lactate on d 3 (74%: $P = 0.02$) and tended to have higher LPS binding protein (LBP; 4854 vs. 3569 ng/mL; $P = 0.07$), when compared with H. Postpartum circulating insulin was decreased (11%; $P = 0.02$) in KET cows compared with the H. The postpartum LPS area under the curve (a measure of total LPS exposure over time) tended to be decreased in KET cows ($P = 0.06$), which may be explained by treatment differences in LBP and its role in LPS removal. In summary, blood bioenergetics and gut integrity biomarkers indicate that ketosis may be closely associated with biomarkers of leaky gut during the transition period.

Key Words: ketosis, intestine, lipopolysaccharide

847 A randomized clinical trial assessing the use of a single injection of dexamethasone combined with oral propylene glycol therapy for the treatment of hyperketonemia. Elise H. Tatone*[1], Michael B. Capel[2], Jessica L. Gordon[1], Stephen J. LeBlanc[1], and Todd F. Duffield[1], [1]*Department of Population Medicine, University of Guelph, Guelph, ON, Canada,* [2]*Perry Veterinary Clinic, Perry, NY.*

The treatment of hyperketonemia [HK, blood β-hydroxybutyrate (BHBA) ≥ 1.2 mmol/L] with oral propylene glycol has proven benefits. Parenteral administration of glucocorticoids has been suggested as an adjunctive therapy, however it has not been assessed in a randomized field trial setting. The objective of this research was to evaluate the effect on cure rate of a one-time intramuscular injection of dexamethasone as an adjunctive therapy for hyperketonemia. A randomized control trial was conducted from May to August 2014 on 4 dairy farms in New York State. Cows were tested from 3 to 16 d in milk, once weekly, for blood BHBA using the Precision Xtra device. All cows testing positive for HK were randomly assigned to receive a single intramuscular injection of 20 mg dexamethasone (DX) or an equivalent volume of sterile saline placebo (PB). Both groups received 4 d of oral propylene glycol therapy. Cure risk was determined by blood BHBA obtained the week following enrollment. A multivariable multi-level logistic regression model was constructed for the outcome of being ketotic at first follow-up. Herd was controlled as a random effect. A total of 498 cows were enrolled, 248 treated with DX and 250 receiving PB. At first follow-up, 250 individuals (50.2%) remained HK. Of those, 131 (52.4%) were from the DX group and 115 (46.0%) from the PB group ($P = 0.26$). Lactation number and BHBA at enrollment modified the effect of treatment. The odds of recovering were higher in first lactation animals treated with DX compared with PB treated first-lactation animals (OR: 3.59 CI: 1.29–10.03). Cows enrolled with BHBA at 1.2 and 1.4 mmol/L and treated with DX had odds of recovering 2–3 times higher (OR: 3.09, CI: 1.65–5.75, OR: 2.31, CI: 1.39–3.83, respectively) than those treated with the PB. There is no significant association between treatment and cure risk at higher BHBA at enrollment. Adding DX to HK treatment protocols was beneficial for cows in first lactation or had a blood BHBA at enrollment of 1.2 or 1.4 mmol/L.

Key Words: ketosis, treatment, dexamethasone

848 Effects of prepartum digital dermatitis on first-lactation performance. Arturo Gomez*[1,2], Nigel Cook[1], Mike Socha[2], and Dörte Döpfer[1], [1]*University of Wisconsin-Madison, Madison, WI,* [2]*Zinpro Corporation, Eden Prairie, MN.*

The objective of this study was to describe and quantify the effect of prepartum digital dermatitis (DD) on first-lactation performance. A cohort of 719 pregnant heifers was monitored for DD for a period of 6 mo before calving. The heifers were classified by the number of DD events diagnosed as Type I, Type II and Type III (no DD, one DD event, and multiple DD events, respectively) during this period. After calving, health during initial 60 d in milk (DIM), reproductive and hoof health outcomes, and milk production were compared among the 3 group types. Multivariable logistic and linear models were adjusted for age, height, and girth circumference at enrollment, as well as type of trace mineral supplementation during the pre-partum period. Overall, cows experiencing DD during the rearing period showed inferior production and health outcomes compared with healthy heifers during the first lactation. A numerical difference was found on the percentages of assisted calvings, stillbirths, culls before 60 DIM, and diseased cows during the fresh period between Type III and Type I cows. Significantly lower conception risk at first service (OR [95% CI] = 0.55 [0.33, 0.89]) and increased number of days open (mean [95% CI] = 24 d [5.2, 43]) were observed in Type III compared with Type I cows. In relation to hoof health, a significantly increased risk of DD during first lactation was found in Type II and III cows (OR = 5.16 [3.23, 8.29] and 12.5 [7.52, 21.1], respectively), as well as the earlier occurrence of DD post-calving (mean [95% CI] = 59 d [20, 96], and 74 d [37, 109]). Compared with Type I cows, decreased milk production during initial 305 DIM was estimated at 199 and 335 kg for Type II and III cows, respectively. This difference was due to a greater decline in rate of production (less persistence) after peak yield ($P < 0.01$). Given the long-term effects of DD on health, reproduction, and production, priority should be given to efficient DD prevention and control programs during the rearing period of dairy heifers. Intensive intervention programs are expected to increase overall well-being and farm profitability, based on active long-term DD surveillance, mitigation of risk factors, and prompt treatment.

Key Words: digital dermatitis, heifer, milk production

849 Identification of the most likely classical swine fever outbreak scenarios in the swine industry of Indiana.

Shankar Yadav*[1], Nicole Olynk Widmar[2], and Hsin-Yi Weng[1], [1]*Department of Comparative Pathobiology, Purdue University, West Lafayette, IN,* [2]*Department of Agricultural Economics, Purdue University, West Lafayette, IN.*

The objectives of this study were to develop metrics using empirical data for the identification of the most likely outbreak scenarios of classical swine fever (CSF) in Indiana and to describe the characteristics of the outbreaks. Three types of CSF outbreak scenarios were considered: single, multiple, and outbreak due to delay in detection. The data sources included Indiana premise identification database, feral hog population, and US census data. The attributes included in the metrics were distribution of swine premises and operation types, import frequencies (domestic and international), import origins, number of imported pigs, proximity to feral hogs, and immigrant population. Different weights were assigned to each of the attributes based on their importance. The metrics were used to identify the top 10 Indiana's counties that were most likely to initiate a CSF outbreak; premises with high risk of outbreak were identified within the top 10 counties. Each of the identified swine premises represented a single outbreak scenario. The swine import data of the identified premises were used for identifying the multiple outbreak scenarios while the export data for identifying the outbreak due to delay in detection scenarios. These identified outbreak scenarios were simulated to derive the outbreak-related measures. In 2012, there were 8589 swine premises in Indiana. A total of 3,145 import shipments from 27 US states and 3 Canadian provinces were received. Similarly, 3,154 export shipments of live pigs were sent to 41 US states. Nineteen single and 15 multiple outbreak scenarios were identified, while no outbreak due to delay in detection was identified. The median number of premises in the multiple outbreak scenarios was 17 (range: 4–32). The estimated median epidemic durations (days) for single and multiple CSF outbreak scenarios in Indiana were 57 and 121, respectively. The identified most likely CSF outbreak scenarios can be used to estimate epidemic duration and magnitude of an outbreak and provide guidance for developing a risk-based surveillance for the CSF in Indiana.

Key Words: classical swine fever, epidemic, risk assessment

Ruminant Nutrition: Dairy rumen metabolism

850 A novel inhibitor persistently decreased enteric methane emission and increased weight gain of high-producing Holstein cows without negatively affecting milk production. Alexander N. Hristov*[1], Joonpyo Oh[1], Fabio Giallongo[1], Michael T. Harper[1], Holley Weeks[1], Antonio F. Branco[2], Peter J. Moate[3], Matthew H. Deighton[3], S. Richard O. Williams[3], Maik Kindermann[4], and Stephane Duval[5], *[1]Department of Animal Science, The Pennsylvania State University, University Park, PA, [2]Departamento de Zootecnia, Universidade Estadual de Maringá, Maringá, Parana, Brazil, [3]Agriculture Research Division, Department of Economic Development Jobs Transport and Resources, Ellinbank, Victoria, Australia, [4]DSM Nutritional Products, Animal Nutrition and Health, Basel, Switzerland, [5]DSM Nutritional Products France, Research Centre for Animal Nutrition and Health, Saint Louis Cedex, France.*

This study investigated the effect of a CH_4 inhibitor, 3-nitrooxypropanol (3NOP), on enteric CH_4 emissions in lactating Holstein cows. The experiment was a randomized block design with 48 cows (DIM, 77 ± 3.9; lactations, 2.2 ± 0.15), with a 2-wk covariate and a 12-wk data collection periods. Treatments were: control (no additive) and 3NOP applied at 40, 60, and 80 mg/kg feed DM. 3NOP was mixed with the TMR and cows were fed once daily. Methane and H_2 emissions were measured using 2 methods, the GreenFeed system and the modified SF_6 tracer technique, during the covariate period and experimental wk 2, 6, 9, and 12. Compared with the control, 3NOP decreased the average CH_4 emission by 25, 31, and 32%, respectively, when measured using the GreenFeed system (481, 363, 333, and 329 g/cow/d; SEM = 15.9; $P < 0.001$). Similar inhibition of CH_4 emission by 3NOP was observed when determined using the SF_6 technique. Hydrogen emissions from the control cows were negligible throughout the experiment (on average 0.02 g/cow per day), but increased considerably for the 3NOP treatments (0.48, 0.96, and 1.27 g/cow per day, respectively; SEM = 0.116, $P < 0.001$). Methane emissions per kg of DMI or ECM were on average 29 and 31%, respectively, lower for the 3NOP treatments compared with the control. Treatment had no effect on DMI (27.8 ± 0.45 kg/d), milk production (45.5 ± 1.21 kg/d), and feed efficiency (1.65 kg/kg). Milk composition was not affected by 3NOP. Milk protein and lactose yields were increased ($P \leq 0.05$) by 3NOP. Body weight gain during the experiment was about 168 g/d greater ($P = 0.05$) for the 3NOP-treated cows. Apparent total-tract digestibility of DM, OM, CP, and ADF were quadratically increased ($P \leq 0.06$) by 3NOP compared with the control. This experiment demonstrated that enteric CH_4 emissions from ruminant animals can be successfully decreased by the use of a CH_4 inhibitor, without negatively affecting animal productivity. If adopted, this mitigation practice could substantially reduce greenhouse gas emissions from the ruminant livestock sector.

Key Words: methane, hydrogen, 3-nitrooxypropanol

851 Effect of frequency of total mixed ration delivery on digestibility and milk production in lactating dairy cows: A meta-analysis and meta-regression. Hamidreza Mirzaei-Alamouti*[1], Mehdi Kazemi-Joujili[1], Hamid Amanlou[1], and Mina Vazirigohar[2], *[1]Department of Animal Science, Faculty of Agriculture, University of Zanjan, Zanjan, Iran, [2]Department of Animal Science, Campus of Agriculture and Natural Resources, University of Tehran, Karaj, Alborz, Iran.*

The objectives of this study were to evaluate the effect of frequency of feeding dairy cows with total mixed ration (TMR) on digestibility, feeding behavior, and milk production and composition in lactating cows, using meta-analysis and meta-regression methods. A total of 14 studies with 25 comparisons between treatment (higher feeding frequency) and control (lower feeding frequency) groups, met the selection criteria and included in the analysis. Type and amount of feed ingredients did not differ between treatment and control diets. The mean (±SD) forage and grain amount in the experimental diets were 539 ± 89.9 and 274 ± 104.2 g/kg DM, respectively. Increasing frequency of feeding (in average; 1.0× vs. 3.3×) decreased dry matter intake [DMI; weighted mean differences (WMD) = −0.134 kg/d; 95% confidence interval (CI) = −0.505 to 0.236) but had no effect on milk production. The amount of forage in the basal diet and DIM were the sources of heterogeneity for DMI. Thrice-daily feeding compared with once a day increased milk fat yield (WMD = 15.02 g/d; 95% CI = 10.93 to 40.96), but milk fat content, and milk protein content, and yield remained unchanged. Increasing feeding frequency increased NDF digestion (WMD = 5.663%; 95% CI = 0.631 to 10.69). Results of meta-regression showed that more frequent feeding of diets containing high level of grains improved NDF digestibility in lactating cows, but lowered NDF digestion for high forage diets. Increasing the frequency of feeding did not change total feeding and ruminating times. In conclusion, feeding a TMR containing equal amounts of forage and concentrate 3 times a day vs. once a day decreased DMI without any changes on milk production.

Key Words: feeding frequency, lactating cow, meta-analysis

852 Relationship between rumen molar volatile fatty acid proportions and milk odd- and branched-chain fatty acid concentrations in cows fed diets containing sunflower oil. Mina Vazirigohar*, Mehdi Dehghan-Banadaky, Kamran Rezayazdi, and Ardeshir Nejati-Javaremi, *Department of Animal Science, Campus of Agriculture and Natural Resources, University of Tehran, Karaj, Alborz, Iran.*

Principal component analysis (PCA) was used to explore the relationship among molar proportions of individual rumen volatile fatty acid (VFA) and milk odd- and branched-chain fatty acid (OBCFA) concentrations. Data were obtained from an experiment with 24 lactating Holstein cows examining the effects of diets containing variable proportions of forage (39, 43.5 or 48% of forage in total diet DM) and concentrate containing sunflower oil (3% in diet DM) on milk fat content and composition. The data were analyzed using the loading plot of PCA which was performed using PASW (version 18.0). Molar proportions of butyrate were included in the initial evaluation, but these data were subsequently excluded because these did not meet the necessary PCA model fit criteria. Loading plot of PCA revealed that rumen molar acetate proportions clustered with milk *iso* fatty acids of <15 carbon atoms, whereas rumen molar propionate proportions clustered with milk straight odd-chain fatty acids (15:0 and 17:0) and their desaturation products in the opposite side of both PCs. Concentrations of 15:0, *cis*-9 15:1 and *cis*-9 17:1 had high loadings on PC1, whereas 17:0 had high loading on PC2 which was located close to molar propionate proportions. In conclusion, rumen molar acetate and propionate proportions were closely associated with milk fat *iso* and straight odd-chain fatty acids concentrations, respectively, in cows fed diets containing sunflower oil.

Key Words: milk odd- and branched-chain fatty acid, principal component analysis, rumen volatile fatty acid

853 The effect of increasing level of by-product inclusion on milk production, milk composition, nutrient digestibility and nitrogen excretion in early lactation grazing dairy cows.

Billy Carey[1], Tommy M. Boland*[1], Stephen J. Whelan[2], Gaurav Rajauria[1], and Karina M. Pierce[1], [1]*School of Agriculture and Food Science, University College Dublin, Dublin, Ireland,* [2]*DairyCo, Agriculture & Horticulture Development Board, Stoneleigh Park, Kenilworth, United Kingdom.*

Irish dairy farming is characterized by a predominantly spring calving, pasture based production system with strategic use of concentrate supplementation when pasture availability is less than herd demand. Cereal grains are used extensively in concentrates as an energy source, but the use of these human edible energy sources is becoming somewhat controversial. By contrast, by-products, which cannot be consumed by humans, such as maize dried distillers' grains (DDG), palm kernel expeller meal (PKE) and soybean hulls (SH) can provide an economical source of nutrients to complement grazed grass. While these products have been extensively studied in US and New Zealand production systems, there is a paucity of information on their use in moderately yielding (30 kg/d) pasture fed cows. The objective of this research was to evaluate the effect of replacing barley with increasing dietary levels of by-products (DDG, PKE and SH) on milk production and composition, pasture and total dry matter intake (DMI), body condition score (BCS) and body weight (BW) and nitrogen (N) excretion in early lactation dairy cows grazing perennial ryegrass-based pasture. Forty-eight Holstein Friesian dairy cows (64 DIM ± 24) were blocked by pre-experimental milk yield and offered 1 of 4 supplementary concentrates (5.17 kg of DM/d) containing 35, 55, 75 and 95% by-products for T1, T2, T3 and T4 respectively. The concentrates offered contained DDG, PKE and SH in equal portions and the experiment continued for 70 d. Data were tested using Proc Mixed of SAS with trt, week, parity and their interactions included as fixed effects in the model. Treatment had no effect on milk yield (30.8 kg/d; $P = 0.78$) or fat and protein yield (2.1 kg/d; $P = 0.57$). Similarly, BCS (2.75; $P = 0.76$) and BCS change (−0.05; $P = 0.74$) were not affected by treatment. There was also no effect of treatment on pasture DMI (15.73 kg of DM/cow/d; $P = 0.99$), total DMI (21.05 kg of DM/cow/d; $P = 0.99$), digestibility of NDF (0.69; $P = 0.34$), ADF (0.59; $P = 0.36$) or N (0.33; $P = 0.70$) or the excretion of N in urine (0.26 kg/d; $P = 0.99$). The results from this research show that cereals can be replaced with by-products (DDG, PKE and SH) in the diet of grazing dairy cows without any adverse effects on production, feed intake, digestibility, BW, BCS or N excretion.

Key Words: dairy, byproduct, cereal

854 Effects of feeding Fermenten or urea on milk production, rumen nitrogen metabolism, and microbial nitrogen content in lactating dairy cattle.

Samuel W. Fessenden*[1], Andreas Foskolos[1], Elliot Block[2], and Michael E. Van Amburgh[1], [1]*Department of Animal Science, Cornell University, Ithaca, NY,* [2]*Arm & Hammer Animal Nutrition, Princeton, NJ.*

The objective of this study was to evaluate effects of 2 different sources of rumen available nitrogen on cattle performance, rumen nitrogen dynamics, and rumen microbial metabolism in lactating dairy cattle. Eight ruminally cannulated multiparous Holstein cows averaging 60 ± 10 DIM and 637 ± 38 kg of BW were assigned to one of 2 treatment sequences in a switchback design. Diets contained (DM basis) 44% corn silage, 13% alfalfa haylage, 12% ground corn, and 31% protein premix containing either a control mix of urea and wheat middlings (CON) or Fermenten at 3% diet inclusion rate (EXP). Both diets provided similar level (DM basis) of aNDFom (31%), CP (16.5%), RDP (8.2%) and metabolizable energy (64 Mcal ME/d). Diets were formulated to provide approximately 115% of rumen NH_3-N requirement as predicted by the CNCPS. The trial consisted of 3 28 d experimental periods, where each period consisted of 21 d of diet adaptation and 7 d of data and sample collection. Digestion markers were infused continuously during the sampling period and composited omasal samples were used to calculate nutrient flows. All data were analyzed using the Proc Mixed procedure in SAS. Dry matter intake was 25.5 and 25.2 kg/d for CON and EXP, respectively ($P = 0.73$). Energy corrected milk yield was 42.2 and 43.2 kg/d for CON and EXP, respectively ($P = 0.43$), with no treatment differences ($P > 0.05$) in milk fat and protein yield or content. Compared with CON, EXP increased milk urea nitrogen (10.7 vs. 13.5 mg/dL; $P = 0.01$) and rumen NH_3-N (4.4 vs. 5.3 mg/dL; $P = 0.03$). Rumen bacteria and omasal protozoa N content tended to increase with EXP inclusion ($P < 0.1$), while rumen protozoa and omasal bacteria N content increased ($P < 0.05$) with EXP inclusion. Effects of Fermenten inclusion on rumen microbial metabolism, especially microbial N content, were consistent with previous observations of increased microbial growth and turnover associated with supplementation of rumen available non-NH_3-N in N efficient diets.

Key Words: microbial protein, omasum, Fermenten

855 Effect of passage rate and pH on microbial diversity and total methanogens in continuous culture.

Benjamin A. Wenner*, Jill A. Stiverson, Zhongtang Yu, and Jeffrey L. Firkins, *Department of Animal Sciences, The Ohio State University, Columbus, OH.*

The present study was conducted as a 2 × 2 factorial treatment arrangement in a Latin square design using 4 continuous culture fermenters. Treatments were control pH (CpH; ranging 6.3 to 6.9) or low pH (LpH; 5.8 to 6.4) factorialized with solids passage rates (k_p) set to be either low (Lk_p; 2.5%/h) or high (Hk_p; 5.0%/h); total buffer k_p was constant at 7.0%/h. Fermenters were fed once daily (40 g DM; a 50:50 concentrate:forage diet). Periods lasted 10 d, with 3 d of sample collection. Effluent samples were collected once every 24 h for 3 d and pooled. Fermenter contents were sampled at 0, 4, 8 and 12 h post-feeding on d 6. We hypothesized that lowering pH would limit methanogen ability to grow in culture, and increasing k_p would challenge methanogens to increase growth rate for survival. Further, the combination of these treatments would decrease daily methane production per total archaeal 16s copy outflow and decrease methanogen concentration in culture. DNA was extracted using repeated bead beating protocols and amplified for total bacteria and total archaeal PCR-DGGE using respective universal 16S rRNA gene primers with GC clamps. Banding analysis clearly demonstrated clustering of effluent versus fermenter samples for bacteria and archaea. However, there were no clear banding patterns for treatment combinations or for times post-feeding. Total archaeal 16S rRNA gene copies were quantified using 787f and 1059r primers using qPCR. There was no significant ($P > 0.10$) interaction for treatment by time, and no difference in total archaeal 16S rRNA (copies/mL) between treatments: CpH, Lk_p: 1.13×10^5, CpH, Hk_p: 5.85×10^4, LpH, Lk_p: 6.84×10^4 and LpH, Hk_p: 4.67×10^4. Daily methane production per 16s copy was not significantly different ($P > 0.10$) between treatments: CpH, Lk_p: 1.12, CpH, Hk_p: 0.11 LpH, Lk_p: 0.67 and LpH, Hk_p: 0.43 nmol CH_4/archaeal 16s copy. Rumen microbes are resilient to small daily disturbances in pH or slight increases in k_p, but there is a lack of clear relationship between methanogen concentration and methane production. The poor methane/copy relationship of these treatments indicates a need to move methane mitigation research beyond inhibition toward potential influencers on methanogen metabolism and growth.

Key Words: fermenter, methanogen, methane

856 Lactational performance and ruminal morphometrics when mid-lactation dairy cows are fed *Saccharаromyces cerevisae* fermentation products. Jon P. Pretz*[1], Subash Acharya[1], Ilky Yoon[2], Mark Scott[2], and David P. Casper[1], [1]*South Dakota State University, Brookings, SD,* [2]*Diamond V Mills Inc., Cedar Rapids, IA.*

This study evaluated *Saccharomyces cerevisiae* fermentation products (Diamond V original XPC and 2 prototypes) on lactational performance and ruminal fermentation. Eight ruminally cannulated (132 DIM and 34.4 kg milk) Holstein dairy cows (2 primiparous and 6 multiparous) were blocked by milk yield, DIM and parity and randomly assigned in a replicated 4 × 4 Latin square design. Treatments were (1) Control (C): corn silage and haylage based ration; (2) XPC: C ration with 14 g/hd/d Original XPC; (3) Prototype 1 (P1): C ration with 5 g/hd/d P1; and (4) Prototype 2 (P2): C ration with 19 g/hd/d P2. Treatments were mixed with dried distillers grains and then mixed in the TMR at 454 g/hd/d. Periods were 28 d with the first 21 d for adjustment followed by 7 d of data collection. Milk yield (3×/d) was recorded d and milk samples (2 d) during wk 4. On d 25 or 27, rumens were evacuated, weighed, markers added (Co and valeric acid), mixed, block the rumen-omasal orifice using a sponge, and rumen contents returned to the rumen. Ruminal samples were collected for 4 h at 20 min intervals to determine ruminal pH, ammonia, and volatile fatty acid concentrations. After 4 h of sample collection, rumen contents were re-evacuated, re-weighed, rumen-omasal sponge removed, and rumen contents returned. One cow died unrelated to study objectives and data were removed. Milk yield (30.7, 32.3, 32.0, 31.3 kg/d for C, XPC, P1, and P2, respectively) and intake of DM [(DMI); 24.5, 23.6, 23.6, and 25.3 kg/d] were similar ($P > 0.10$) between all cows, but feed efficiency (1.26, 1.36, 1.36, and 1.24 kg/kg milk/DMI) and energy-corrected milk/DMI (1.42, 1.54, 1.52, and 1.38 kg/kg was greater ($P < 0.01$) for cows fed XPC and P1 compared with cows fed C and P2. Milk composition was similar ($P > 0.10$) between cows fed all rations. Ruminal pH (6.06, 6.07, 6.02 and 6.13) was greater ($P < 0.05$) for cows fed P2 compared with cows fed other rations. The feeding of a dairy ration with a *Saccharomyces cerevisiae* fermentation product can improve ruminal pH and feed efficiency of mid-lactation cows.

Key Words: dairy cattle, volatile fatty acid, *Saccharomyces cerevisiae* fermentation product

857 Effects of nitrate and docosahexaenoic acid on methane production in lactating dairy cows. G. Klop*[1], B. Hatew[1], A. Bannink[2], and J. Dijkstra[1], [1]*Wageningen University, Animal Nutrition Group, Wageningen, the Netherlands,* [2]*Wageningen UR Livestock Research, Wageningen, the Netherlands.*

The objective of this experiment was to study the effects of dietary nitrate (NO_3) and docosahexaenoic acid (DHA; C22:6 n-3) on enteric methane (CH_4) production in lactating dairy cows. Twenty-eight lactating Holstein dairy cows were grouped into 7 blocks of 4 cows each. Within blocks, cows were randomly assigned to one of 4 treatments: CON (urea as alternative NPN source); NO_3 (21 g/kg DM); DHA (3 g/kg DM and urea as alternative NPN source); or NO_3 + DHA (21 g/kg DM and 3 g/kg DM, respectively). Cows were fed a total mixed ration consisting of 20% grass silage, 50% corn silage and 30% concentrate on a DM basis. Treatments were included in the concentrates. Methane production was measured during a 5-d period in climate respiration chambers after adaptation to the diet for 12 d. Previous to this 17-d period, cows assigned to a treatment including NO_3 were gradually pre-adapted to the treatment dose of NO_3 over a period of 21 d. Preliminary results show a significant ($P < 0.05$) NO_3 × DHA interaction for CH_4 expressed in g/d, and cows produced on average 368, 264, 369 and 298 g CH_4/d on treatments CON, NO_3, DHA and NO_3 + DHA, respectively. This interaction effect is explained by a lower DMI for the NO_3 treatment despite the restricted feeding regimen during the CH_4 measurement period. Per kg DMI, cows receiving NO_3 produced less CH_4 than cows receiving no NO_3 in their diets (17.5 vs. 22.4 g/kg DMI; $P < 0.01$). Feeding DHA did not affect CH_4 production per kg DMI, but did result in a higher ($P < 0.01$) CH_4 production per kg FPCM. Milk production was not affected by treatment, but FPCM was reduced ($P < 0.05$) by DHA because of a reduced milk fat concentration ($P < 0.01$), which averaged 29.6 and 41.1 g/kg for treatments with or without DHA, respectively. Milk protein concentration was reduced ($P < 0.05$) by NO_3 and averaged 30.0 and 31.0 g/kg for treatments with or without NO_3, respectively. In conclusion, NO_3 but not DHA reduced enteric CH_4 production and there were no interaction effects on CH_4 production expressed in g/kg DMI and g/kg FPCM.

Key Words: methane, nitrate, docosahexaenoic acid

858 Effects of clay (EcoMix) after a grain challenge on rumen health and metabolism of Holstein cows. Saige A. Sulzberger*[1], Carlie C. Kalebich[1], Sergey Melnichenko[2], and Felipe C. Cardoso[1], [1]*University of Illinois, Urbana, IL,* [2]*United Minerals Group, Kyviv, Ukraine.*

Oral supplementation of clay has been reported to function as buffer in dairy cows. However, its effects on rumen, blood, and fecal pH have been variable among studies. Our objective was to determine the effects of 3 levels of dietary clay (EcoMix) supplementation after a grain challenge. Ten multiparous rumen-cannulated Holstein cows (BW = 648 kg ± 12kg), 142 (60–502) DIM, were assigned to 1 of 5 treatments in a completely randomized replicated 5 X 5 Latin Square. Periods consisted of an 18-d adaptation period followed by a 3-d (d 19–21) measurement period. Cow average DMI from d 15–17 was used to restrict feed to 75% on d 18 and to give 20% wheat flour (grain challenge) on d 19, via cannula. Treatments were: CON, no EcoMix and no grain challenge; POS, no EcoMix with a grain challenge; 0.5%, 1%, and 2%, EcoMix as percentages of dietary DMI all with a grain challenge. Statistical analysis was performed using the MIXED procedure of SAS. Two contrasts CONT1 (POS vs. CON), CONT2 (POS vs. average of 0.5%, 1%, and 2%) were compared along with the linear and quadratic treatment effects. Rumen, fecal, and blood pH along with blood metabolites were measured at 0, 4, 8, 12, 16, 20, 24, 36, and 48 h relative to grain challenge. Rumen pH ($P = 0.003$) and fecal pH were lower (CONT1, $P < 0.001$) for POS (6.03 ± 0.06; 6.14 ± 0.04) than CON (6.20 ± 0.06; 6.38 ± 0.04), respectively. There was a linear treatment effect for rumen pH ($P = 0.001$) and fecal pH ($P = 0.05$). Fecal pH (6.22 ± 0.04, $P < 0.0001$) was higher for cows that received EcoMix then POS (6.14 ± 0.04, CONT2). There was a difference for negative incremental area under the curve (Rumen pH below 5.6/24h; 0.5% = 7.93 1% = 8.56, 2% = 7.79, SEM = 0.8, $P = 0.005$) when compared with POS (11.0, CONT2). Cows fed EcoMix had higher milk yield, (0.5% = 28.8 kg, 1% = 30.2 kg, 2% = 29.1 kg, SEM = 3.4), 3.5% FCM (0.5% = 29.9 kg, 1% = 34.1 kg, 2% = 33.1 kg, SEM = 3.4, $P = 0.02$) and ECM (0.5% = 29.1 kg, 1% = 32.8 kg, 2% = 31.6 kg, SEM = 3.3 $P = 0.01$) than cows in POS (CONT2, 27.72 kg, 28.0 kg, 27.71kg, respectively). In conclusion, cows that received EcoMix had higher rumen pH, milk yield, ECM and FCM than cows in POS.

Key Words: buffer, clay, rumen pH

859 Magnitude of difference in chemical and nutrient profiles, ruminal degradation kinetics, and intestinal digestion of three different types of co-products from bio-oil processing for dairy cattle.

Xinxin Li*[1,2], Yonggen Zhang[1], and Peiqiang Yu[1,2], [1]*College of Animal Science and Technology, Northeast Agricultural University, Harbin, China,* [2]*Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

Co-products from bio-oil industry, rapeseed meal, canola meal and soybean meal, are good sources of feed protein for livestock. The objectives of this study were to determine the magnitude of differences among 3 types of co-products in terms of (1) protein nutrient profile, (2) protein subfractions associated rumen utilization, (3) protein rumen degradation kinetics and (4) intestinal absorbed true protein supply to dairy cattle. Rapeseed meal, canola meal and soybean meal were collected from 3 different sources in 2014. Crude protein was partitioned into 5 subfractions according to the Cornell net carbohydrate and protein system (CNCPS 6.5). Three lactating Holstein cows fitted with permanent rumen cannula were used for determining the protein rumen kinetics in the in situ trial. The estimation of intestinal rumen undegraded feed protein digestibility was determined using a modified 3-step in vitro procedure with 12 h pre-rumen incubation in lactating Holstein cows. In this study, statistical analyses were carried out using the PROC MIXED procedure of SAS 9.3. Significances were declared at $P < 0.05$. The results showed that CP content in soybean meal was higher than rapeseed meal and canola meal ($P < 0.05$). Rapeseed meal had the highest NPN content, followed by canola meal with NPN content lowest in soybean meal ($P < 0.05$). The contents of SCP, ADICP and NDICP in rapeseed meal and canola meal were higher than soybean meal ($P < 0.05$). Protein fractions of $PA_{2,}$ PB_2 and PC were greater in rapeseed meal and canola meal than soybean meal ($P < 0.05$), but no significant difference was found between rapeseed meal and soybean meal. Both soybean meal and rapeseed meal had higher rumen degradable protein (RDP) than canola meal ($P < 0.05$). Soybean meal was greater than rapeseed meal and canola meal in intestinal digestible protein (IDP, $P < 0.05$). Total digestible protein (TDP) was highest in soybean meal, and lowest in canola meal ($P < 0.05$). Overall, the results indicated that soybean is a greater source of protein feed than canola meal and rapeseed meal.

Key Words: soybean meal, rapeseed meal, degradation profile

860 Amino acid profiles of ruminal microbes, ruminal undegradable protein, and gastrointestinal contents in lactating dairy cows when corn stover or rice straw replaces alfalfa hay.

Bing Wang*[1,2] and J. X. Liu[1,2], [1]*Institute of Dairy Science, College of Animal Sciences, Hangzhou, P. R. China,* [2]*MoE Key Laboratory of Molecular Animal Nutrition, Zhejiang University, Hangzhou, P.R. China.*

The objective of this study was conducted to evaluate the effects of replacing alfalfa hay with rice straw or corn stover on amino acid (AA) profiles of ruminal microbes, rumen undegradable protein (RUP), and gastrointestinal contents in lactating cows. Eighteen Holstein dairy cows were individually fed, and randomly assigned into one of 3 treatments. Isonitrogenous diets contained similar concentrate and 15% corn silage, with 3 forage sources (DM basis): 23% alfalfa hay and 7% Chinese wild rye hay (AH); 30% corn stover (CS); and 30% rice straw (RS). After 14-wk feeding, all the cows were slaughtered to collect the samples of rumen fluid and gastrointestinal contents. The AA were analyzed with an AA analyzer (Model L-8800, Hitachi, Tokyo, Japan). The variance of the data was analyzed as a completely randomized design using PROC MIXED of SAS. The AA profiles of ruminal microbes were similar among 3 treatments except for the lower value of Asp in diet RS than in CS ($P < 0.01$) or AH ($P < 0.02$) and the greater value of Gly in AH than in RS ($P = 0.02$). Significant differences were found in the AA profiles among ruminal microbes, fluid, and digesta, with greater percentage of essential AA in digesta than in microbes or fluid ($P < 0.01$), and in microbes than in rumen fluid ($P < 0.01$). The free AA concentration in jejunum was the greatest, but the peptide-binding AA concentration was the greatest in duodenum, resulting in lower ratio of peptide-binding AA to free AA. In addition, the free essential AA profiles in jejunum fluids for all the 3 diets were similar with the recommended digestible AA and milk AA, with the ratio of Lys to Met at 3:1. Most of AA of RUP was independent on forage sources except for Phe ($P = 0.035$) and Gly ($P = 0.05$). There was linear correlation between dietary AA profile and AA composition in ruminal fluids ($P < 0.01$). The AA profiles of ruminal microbes and RUP were constant and independent on forage sources. It is indicated that the AA profile of metabolizable protein may be constant independent on dietary effects.

Key Words: amino acid profile, dairy cattle, gastrointestinal content

861 Effect of increasing concentration of dietary fiber in diets rich in plant oil on milk fat concentration, rumen parameters and feeding behavior of mid-lactating cows.

H. R. Mirzaei Alamouti* and A. Aghaei, *Department of Animal Science, University of Zanjan, Zanjan, Iran.*

This experiment was conducted to investigate the effects of different levels of dietary NDF in diets rich in plant oil (sunflower and soybean) on feeding behavior, rumen parameters, milk yield and components of mid-lactating Holstein dairy cows. Four primiparous (BW: 525 ± 30 kg; days-in-milk: 103 ± 6) and 4 multiparous (BW: 587 ± 88 kg; DIM: 99 ± 12) cows were used in a 4 × 4 replicated Latin square design with 21-d experimental periods. Cows were received 1 of 4 dietary treatments: (1) 31% fiber and no supplement plant oil, LFNO; (2) 31% fiber with 3% supplement plant oil, LFHO; (3) 35% fiber with 3% plant oil, MFHO; (4) 39% fiber with 3% plant oil, HFHO. Daily dry matter intake (DMI), milk yield and composition, blood metabolites, dry matter digestibility, rumen fluid characteristics and BW variations were determined. There was no significant different in milk production among diets. Milk fat ($P < 0.01$) and protein ($P < 0.05$) concentrations were significantly affected by treatments. Dry matter intake and DM digestibility were higher ($P < 0.01$) in LFHO diet. The cows fed HFHO had higher NDF digestibility ($P < 0.01$). Total VFA and acetate concentration were greater for HFHO diet and propionate concentration was greater for LFHO diet ($P < 0.01$) than the others. Rumen fluid pH was increased by increasing dietary NDF concentration ($P < 0.01$). Plasma insulin ($P < 0.01$) and cholesterol ($P < 0.05$) concentration were affected by diets. Chewing activity was positively affected by increasing concentration of dietary NDF ($P < 0.01$). This study showed that diets rich in plant oil and low concentration of NDF induce the milk fat depression in mid-lactating cows, and with increasing dietary NDF concentration severity of milk fat depression can be alleviated.

Key Words: feeding behavior, oil supplementation, dietary fiber

Ruminant Nutrition: Feedlot nutrition

862 Comparison of methods to calculate metabolizable protein requirements of growing beef cattle. Andrea K. Watson*[1], Terry J. Klopfenstein[1], Vic A. Wilkerson[2], Galen E. Erickson[1], and Jim C. MacDonald[1], *[1]University of Nebraska, Lincoln, NE, [2]Purina Animal Nutrition, Forest Grove, OR.*

Data from 3 trials were compiled to calculate microbial CP (MCP) production and MP requirements of growing calves on high forage diets. Individually fed steers (n = 335; 256 ± 15.6 kg midpoint BW) were utilized, each trial lasted 84. Diets consisted of 44% sorghum silage, 44% corn cobs, and 12% protein supplement. Source of protein within the supplement varied and included urea, meat and bone meal, soybean meal, feather meal, poultry by-product meal, or corn gluten meal. All trials included a urea only treatment. Dry matter intake of all calves within a trial was held constant, as a percent of BW, established by the urea supplemented group. The base diet was MP deficient, composition of the protein supplement varied with increasing amounts of test protein replacing urea. As protein in the diet increased, ADG plateaued. This methodology was used by Wilkerson et al. (1993) and is the basis of performance models used by the NRC (1996). Gain ranged from 0.19 to 0.56 kg/d, averaging 0.37 kg/d. Three microbial efficiencies were used to calculate MP. Maximum gain was then regressed against calculated MP to determine MP requirement for maintenance and gain. Method 1 (based on a constant 13% microbial efficiency suggested by the NRC, 1996) predicted an MP requirement of 3.4 g/kg $BW^{0.75}$ for maintenance and 461 g/kg gain ($r^2 = 0.55$). Method 2 (based on an equation developed by Patterson et al., 2006) predicted MP requirements of 2.9 g/kg $BW^{0.75}$ and 483 g/kg gain ($r^2 = 0.56$). Method 3 (based on an equation developed by Galyean et al., 2014) predicted MP requirements of 2.6 g/kg $BW^{0.75}$ and 449 g/kg gain ($r^2 = 0.59$). The factorial method of calculating MP maintenance requirements accounts for scurf, endogenous urinary, and metabolic fecal protein losses and averaged 4.2 ± 0.10 g/ kg $BW^{0.75}$, for the 3 trials summarized here. Factors affecting MCP production include TDN, RDP, and microbial efficiency. Dietary TDN and RDP have been measured on a variety of feedstuffs; microbial efficiency is not well defined and is a crucial component in calculating MCP production and MP requirements of growing cattle.

Key Words: beef cattle, metabolizable protein, microbial crude protein

863 The effect of zilpaterol hydrochloride supplementation on gain efficiency, harvest yields and carcass grading of steers fed a maintenance intake. Lee-Anne J. Walter*[1], N. Andy Cole[2], Jenny S. Jennings[3], John P. Hutcheson[4], Beverly E. Meyer[2], Angela N. Schmitz[1], DeMetris D. Reed[1], and Ty E. Lawrence[1], *[1]West Texas A&M University, Canyon, TX, [2]USDA ARS, Bushland, TX, [3]Texas A&M AgriLife Research and Extension Center, Amarillo, TX, [4]Merck Animal Health, Summit, NJ.*

A trial was conducted to examine gain efficiency, harvest yields and grading characteristics of steers fed only to maintenance intake (MI) and supplemented with zilpaterol hydrochloride (ZH). Beef steers (n = 20; 463 ± 14 kg) blocked (n = 5) by weight and source were individually fed and adapted to MI {[$(BW \times 0.891)^{0.75} \times 0.077$]/diet NE_m, BW d −1 and 1} for 21 d before ZH (90 mg/hd/d) or non-ZH treatment for 20 d (455 ± 14 kg, SOT). During the 21d maintenance period, MI was adjusted based on BW (d −1, 1 vs. 4, 5, 9, 10, 14, 15, 19 and 20) after 10h water and feed withdrawal (no feed remained for any animals at start of withdrawal periods). Intakes were not adjusted during 20 d treatment period but steers were weighed on d1, 2, 11, 12, 17, and 18 of ZH treatment and on d 1, 2, 5, and 6 of withdrawal. Cattle were harvested after a 6 d withdrawal and carcasses graded 24 h post-harvest. Data were analyzed as a mixed model with fixed effect of ZH and random effect of block. Gain efficiency, ADG and end of ZH BW was not different between treatments ($P > 0.10$). Control cattle lost more BW ($P < 0.01$; 9 vs. 2 kg, respectively) than ZH fed cattle during the maintenance collection period (d12–16 of ZH) while BW loss of ZH fed cattle was greater ($P < 0.01$; 9 vs. 4 kg, respectively) during fasting heat production period (FHP; d18–19 of ZH, 4-d total fast). Harvest BW, exsanguinated BW, empty body weight (EBW) and harvest yields (g/kg EBW) were not different between treatments ($P > 0.10$). Supplementation of ZH did not improve HCW ($P = 0.12$) but did increase dressed carcass yield ($P = 0.02$; 62.12 vs. 60.65%, respectively). Feeding ZH improved LM area ($P = 0.02$; 77.81 vs. 70.90 cm^2) and tended to lower USDA calculated yield grade ($P = 0.06$; 1.8 vs. 2.2). Marbling, 12th rib fat depth and calculated empty body fat did not differ ($P > 0.10$) between treatments. Results from this trial indicate that ZH supplementation alters carcass traits in steers fed reduced energy intakes by improving dressed carcass yield and LM area ($P = 0.02$) and exhibiting a tendency to improve yield grade ($P = 0.06$).

Key Words: feed efficiency, carcass grading, zilpaterol

864 The effect of zilpaterol hydrochloride supplementation on apparent nutrient digestibility and carbon-nitrogen retention of steers fed at maintenance intake. Lee-Anne J. Walter*[1], N. Andy Cole[2], Jenny S. Jennings[3], John P. Hutcheson[4], Beverly E. Meyer[2], Angela N. Schmitz[1], DeMetris D. Reed[1], and Ty E. Lawrence[1], *[1]West Texas A&M University, Canyon, TX, [2]USDA ARS, Bushland, TX, [3]Texas A&M AgriLife Research and Extension Center, Amarillo, TX, [4]Merck Animal Health, Summit, NJ.*

A trial was conducted to examine apparent nutrient digestibility and carbon (C) -nitrogen (N) retention of cattle supplemented zilpaterol hydrochloride (ZH). Beef steers (n = 20; 463 ± 14 kg) blocked (n = 5) by weight and source were individually fed and adapted to maintenance intake (MI; {[$(BW \times 0.891)^{0.75} \times 0.077$]/diet NE_m, BW d −1 and 1}) for 21 d before ZH (90 mg/hd/d) or non-ZH treatment for 20 d (455 ± 14 kg, SOT). During the 21d maintenance period, MI was adjusted based on BW (d −1, 1 vs. 4, 5, 9, 10, 14, 15, 19 and 20) after 10h water and feed withdrawal (no feed remained for any animals at start of withdrawal periods). Intakes were not adjusted during 20 d treatment period. Feces and urine was collected at MI (d12–16 of ZH period) with daily feed and fecal samples analyzed for proximate analysis, ADF, NDF, starch and C; urine was analyzed for C and N. Data were analyzed as a mixed model with fixed effect of ZH and random effects of block and chamber. Dry matter (DM) intake, DM digestibility, fecal or urine output did not differ ($P > 0.10$) between treatments. Intake, fecal excretion and apparent digestibility of NDF, starch or ether extract did not differ ($P > 0.10$) between treatments. Control cattle excreted more ($P < 0.05$) N in urine (39.8 vs. 32.4 g/d, respectively) and tended ($P < 0.07$) to excrete more N daily than ZH treated cattle. Cattle fed ZH tended to have increased absolute N retention ($P = 0.07$; 22.14 vs.14.12 g/d) and increased N retention as a percentage of digested N ($P = 0.06$; 39.73 vs. 25.49%) while apparent N digested did not differ ($P > 0.10$) between treatments. Total C loss via, urine, fecal, or CH_4 did not differ ($P > 0.10$) between treatments but ZH treated cattle lost more C via CO_2 than control cattle ($P = 0.04$; 1036.9 vs. 974.3 g, respectively). Total C digested and retained did not differ between treatments ($P > 0.10$). Results from this trial indicate that ZH treatment does not alter apparent digestibility of nutrients or C retention but does tend to increase N retention ($P = 0.07$) while increasing C loss through CO_2 production ($P = 0.04$)

Key Words: beef, carbon nitrogen retention, zilpaterol

865 The effect of zilpaterol hydrochloride supplementation on energy metabolism of steers at maintenance and fasting intake levels.

Lee-Anne J. Walter*[1], N. Andy Cole[2], Jenny S. Jennings[3], John P. Hutcheson[4], Beverly E. Meyer[2], Angela N. Schmitz[1], DeMetris D. Reed[1], and Ty E. Lawrence[1], *[1]West Texas A&M University, Canyon, TX, [2]USDA ARS, Bushland, TX, [3]Texas A&M AgriLife Research and Extension Center, Amarillo, TX, [4]Merck Animal Health, Summit, NJ.*

An indirect calorimetry trial examined the energetic efficiency of cattle supplemented zilpaterol hydrochloride (ZH). Beef steers (n = 20; 463 ± 14 kg) blocked (n = 5) by weight and source were individually fed and adapted to maintenance intake (MI; $\{[(BW\times0.891)^{0.75}\times 0.077]/\text{diet } NE_m, \text{BW d } -1 \text{ and } 1\}$) for 21 d before ZH (90 mg/hd/d) or non-ZH treatment for 20 d (455 ± 14 kg, SOT). During the 21d maintenance period, MI was adjusted based on BW (d −1, 1 vs. d 4, 5, 9, 10, 14, 15, 19 and 20) after 10h water and feed withdrawal (no feed remained for any animals at start of withdrawal periods). Intakes were not adjusted during 20 d treatment period. Respiration chambers were used to quantify energetics for maintenance (d12–16 of ZH period) and fasting heat production (FHP; d19–20 of ZH period, total 4d fast). Daily feed and fecal samples were analyzed for gross energy (GE); urine was analyzed for nitrogen and GE was calculated from the energetic value of urea. Data were analyzed as a mixed model with fixed effect of ZH treatment and random effects of block and chamber. No difference in DMI, O_2 consumption or CH_4 production ($P > 0.10$) was detected between treatments but ZH cattle had higher CO_2 production ($P = 0.04$; 2325 vs. 2185 L/steer; 23.6 vs. 22.4 L/kg $BW^{0.75}$). During FHP, O_2 consumption was not affected ($P > 0.10$) by treatment whereas CO_2 production (L/steer) increased with ZH treatment ($P = 0.04$; 1423 vs. 1338 L/steer). Gross energy, fecal energy, digestible energy and methane energy did not differ between treatments ($P > 0.10$), however urinary energy was higher ($P = 0.05$; 0.091 vs. 0.074 Mcal) in control cattle. There was no difference in metabolizable energy between treatments ($P > 0.10$). Heat production tended ($P = 0.09$) to increase for ZH treated cattle (12.44 vs. 11.69 Mcal, respectively) on an absolute basis, but not on a $BW^{0.75}$ basis ($P = 0.12$; 0.126 vs. 0.120, respectively). No difference in FHP was detected between treatments ($P = 0.32$). Results from this trial indicate that ZH treatment tends ($P = 0.09$) to modify heat production during maintenance by increasing CO_2 production ($P = 0.04$).

Key Words: beef, energy metabolism, zilpaterol

866 Effects of chromium propionate in combination with yeast on growth performance and carcass quality of finishing steers.

Cadra L. Van Bibber-Krueger*, Justin E. Axman, John M. Gonzalez, and Jim S. Drouillard, *Kansas State University, Manhattan, KS.*

A combination of chromium propionate and yeast supplement (CrY; TruMax, Varied Industries Corp., Mason City, IA) was added to diets of crossbred steers (n = 504; 402 ± 5.8 kg initial BW) to evaluate the effect on feedlot performance and carcass quality. Steers were selected on the basis of initial plasma glucose concentrations ≤6.0 m*M*, stratified by initial BW, blocked into heavy (H; 420 kg BW) and light (L; 384 kg BW) groups, and assigned to treatments of 0 (CON) or 3.3 g/d CrY (provided 0.5 mg Cr/kg diet DM) with 6 pens/diet within each block. Body weights were measured at 21-d intervals. Finished cattle were weighed and transported to a commercial abattoir where severity of liver abscesses and HCW were collected at harvest, and yield and quality grades, LM area, and 12th rib subcutaneous fat thickness were determined after 36 h of refrigeration. There were no CrY × time × weight block interactions for ADG, DMI, and G:F ($P = 0.36$; $P = 0.49$; $P = 0.41$, respectively), and no CrY × block interactions for ADG and DMI ($P = 0.06$; $P = 0.75$, respectively), but a CrY × block interaction ($P = 0.03$) was observed for G:F; CON-L had poorer efficiency compared with other groups. Yield grade and marbling score tended to be less ($P > 0.07$) for CrY compared with CON, but other carcass measurements were unaffected by treatment ($P > 0.30$). Chromium propionate in combination with yeast may improve feed efficiency of lighter cattle, but other effects were minimal.

Table 1 (Abstr. 866). Feedlot performance and carcass traits of steers

Item	CON-L	CrY-L	CON-H	CrY-L	SEM
DMI, kg/d	12.57	12.29	13.00	12.83	0.17
ADG, kg/d	1.70	1.76	1.88	1.84	0.03
G:F[1,3]	0.1349	0.1430	0.1445	0.1434	0.0023
HCW, kg	398	400	408	407	3.65
LM area, cm^2	88.13	90.06	93.10	92.97	0.96

867 The influence of supplemental Zn-amino acid complex and Optaflexx feeding duration on growth performance and carcass characteristics of finishing beef cattle.

Olivia N. Genther-Schroeder*[1], Mark E. Branine[2], and Stephanie L. Hansen[1], *[1]Iowa State University, Ames, IA, [2]Zinpro Corporation, Eden Prairie, MN.*

Previous research indicates that finishing steer ADG and G:F increases linearly with increasing dietary Zn-amino acid complex supplementation. The objective of this study was to determine the influence of supplemental Zn-amino acid complex on growth performance and carcass characteristics of finishing steers fed Optaflexx (OPT; ractopamine hydrochloride) for 0, 28, or 42 d before harvest. This study was organized as 2 groups (Grp) of steers fed concurrently, for 91 (Grp 1) or 84 d (Grp 2). A total of 324 steers (463 ± 23.4 kg) were fed a corn-based finishing diet supplemented with 60 mg Zn/kg diet DM (as $ZnSO_4$). Steers were blocked by weight (6 steers per pen) and assigned to receive either 0 (CON) or 60 mg supplemental Zn/kg DM from a Zn amino-acid complex (ZnAA; n = 27 pens per treatment). Receiving ZnAA for 49 (Exp 1) or 42 d (Exp 2) before start of OPT feeding had no effect on growth of steers *($P \leq 0.30$)*. Forty-two days before harvest, pens were equally assigned within CON or ZnAA treatments to receive OPT at 300 mg·steer^{-1}·d^{-1} for 0, 28 (28-OPT) or 42 d (42-OPT) before harvest, creating 6 final treatments (n = 9 pens per treatment). All steers within an experiment were harvested on the same day. Pen was the experimental unit, and the SAS model included the fixed effects of

ZnAA, OPT, and block nested within group, and the random effect of pen. Optaflexx supplementation increased carcass-adjusted ADG ($P = 0.004$), final BW ($P = 0.004$), HCW ($P = 0.004$), and ribeye area ($P = 0.007$). There was an effect of ZnAA within 28-OPT and 42-OPT where carcass-adjusted ADG ($P \leq 0.10$), final BW ($P \leq 0.05$), and HCW ($P \leq 0.05$) were greater in ZnAA supplemented vs. CON steers. However, when steers did not receive OPT there was no effect of ZnAA on final BW ($P = 0.78$), ADG ($P = 0.98$), or HCW ($P = 0.78$). In conclusion, there appears to be a synergistic effect of ZnAA on OPT-induced cattle growth, as supplementing 60 mg Zn/kg DM from ZnAA to cattle fed OPT improved overall growth and HCW.

868 Residual feed intake in ad libitum and limit-fed steers.

Roberto D. Sainz*, *University of California, Davis, CA.*

To determine if nutritional restriction alters the fundamental relationships between intake, growth and efficiency, 60 Angus-Hereford steers (310 ± 33 d of age, 263 ± 33 kg BW) were randomly assigned to 2 intake groups (IG): ad libitum (AL) or limit-fed (LF, 80% of ad libitum) and fed in individual pens. Intakes were monitored weekly, and steers were weighed monthly. Steers were harvested when they reached a minimum of 12.5 mm backfat, determined by ultrasound at each weighing. Carcass composition was determined from specific gravity. Residual feed intake (RFI) was calculated as the residual of the regression of DMI on average metabolic BW and ADG, with intake group included as a fixed effect; slopes were not found to be heterogeneous ($P > 0.05$). The model was: DMI (kg/d) = IG + 0.0737 $BW^{0.75}$ + 3.296 ADG, where IG = −0.12 (AL) or −1.11 (LF). RFI groups were defined as Low (RFI < −0.5 SD from mean), Medium (−0.5 SD < RFI <0.5 SD) or High (RFI >0.5 SD). Data were analyzed by regression and ANOVA, including IG and RFI groups as main effects; no interactions were significant. (Minitab Inc., State College, PA). Days on feed were greater ($P < 0.0001$) in LF (198 d) than in AL (175 d) steers, however final BW were not different (455 kg; $P > 0.10$) between AL and LF groups. DM intakes were lower ($P < 0.0001$) in LF than in AL steers, both in absolute and relative terms (8.71 and 6.60 kg/d and 2.37 and 1.93% of BW, respectively). RFI groups also differed ($P < 0.001$) in DMI, both in absolute and relative terms (8.08, 7.91 and 6.97 kg/d and 2.29, 2.16 and 1.99% of BW, for High, Medium and Low RFI groups, respectively). Gain:feed was different among IG (0.0952 and 0.0868 for AL and LF, respectively, $P = 0.003$) and RFI groups (0.0806, 0.0888 and 0.1036 for High, Medium and Low RFI, respectively; $P < 0.001$). Carcass fat contents were not different ($P > 0.10$) among RFI groups, but tended to be lower ($P = 0.064$) in LF than in AL (28.3 and 30.3%, respectively). These results confirm that nutritional restriction limits rate and efficiency of gain and prolongs the finishing period in beef cattle, and tends to produce leaner carcasses. The lack of any difference in the slopes of the equation used to predict intake between ad libitum- vs. limit-fed steers indicate that feed restriction did not alter the fundamental relationships between intake, metabolic weight and rate of gain.

Key Words: efficiency, limit-fed, steer

869 Behavioral evaluation when using wet corn gluten feed or wet distillers grains plus solubles to adapt cattle to finishing diets.

Lauren A. Ovinge*[1], Jhones O. Sarturi[1], Rick A. Stock[2], Galen E. Erickson[3], and Terry J. Klopfenstein[3], *[1]Texas Tech University, Lubbock, TX, [2]Cargill Wet Milling, Blair, NE, [3]University of Nebraska-Lincoln, Lincoln, NE.*

Behavioral responses to adaptation diets using wet corn gluten feed branded Sweet Bran (SB-WCGF) or wet distillers grains plus solubles (WDGS) were evaluated. Six ruminally cannulated steers (300 ± 22 kg) at 11 mo of age were assigned randomly using a CRD experiment to one of 2 adaptation strategies including either SB-WCGF or WDGS. Steers were fed a series of 6 diets: 4 adaptation steps, a finishing, and a finishing blend diet. The first step included 87.5% DM of either SB-WCGF or WDGS, with 0% dry rolled corn (DRC), and was reduced to 35% of the finishing diet over a period of 4 steps (7 d each), and increasing the level of DRC to 52.5%. Diets also included 7.5% alfalfa hay and 5% supplement. Blend diet (50:50) contained WDGS and SB-WCGF (17.5% of each, DM basis). Behavioral status (24 h) was recorded by video cameras strategically located on top of individual pens. Behavior was evaluated every 5 min during d-4 of each period, and it was noted whether the steers were resting or ruminating, as well as standing up or lying down, eating, or drinking. Data were analyzed using the GLIMMIX procedures of SAS, and blend diet was used as a covariate. Steers fed SB-WCGF strategy spent more time ($P < 0.10$) ruminating while lying down than WDGS in steps 1 and 4 (223 vs. 93; 289 vs. 77 min/d, respectively); and tended ($P \leq 0.15$) for similar pattern for total rumination in steps 1, 2, and 4 (259 vs. 105; 323 vs. 129; and 321 vs. 65 min/d, for SB-WCGF and WDGS strategies, respectively). Steers fed SB-WCGF strategy also spent more time ($P < 0.10$) ruminating per percentage unit of NDF in step 4 (11.38 vs. 2.29 min-d/%NDF, respectively), as well as tended ($P \leq 0.15$) to spend more time chewing (ruminating plus eating activities) than WDGS strategy in step 4 (418 vs. 227 min/d). Steers fed WDGS strategy had greater ($P < 0.10$) time resting while standing up in steps 2 and 3 (267 vs. 174; 283 vs. 211 min/d; respectively). Overall, the SB-WCGF adaptation strategy shows a more desirable rumination pattern during adaptation to DRC-based finishing diets in feedlot steers than strategy using WDGS.

870 Effects of *Megasphaera elsdenii* on ruminal pH, VFA, and lactate during transition from 60 to 80% concentrate diet.

Jake D. Thieszen*[1], Cadra L. Van Bibber-Krueger[1], Justin E. Axman[1], Celine C. Aperce[2], James S. Drouillard[1], and Kevin A. Miller[2], *[1]Kansas State University, Manhattan, KS, [2]MS Biotec, Wamego, KS.*

Our objective of this study was to evaluate changes in ruminal pH, concentrations of VFA and lactate in cattle during a transition from 60% to 80% concentrate diet. *Megasphaera elsdenii* culture (ME; Lactipro, MS-Biotec, Wamego, KS) was administered by oral drench to crossbred heifers (n = 240; 498 ± 18 kg initial BW) at rates of 0, 25, 50, 75, or 100 mL immediately before transition from 60 to 80% concentrate diet. Cattle were fed in pens of 8 head each, and ruminal contents of animals in one pen/treatment were obtained via rumenocentesis for estimation of ruminal pH and concentrations of VFA and lactate at 5, 10, 15, 20, 25, and 30 h after dosing and introduction of the 80% concentrate diet. Lactate concentrations were unaffected by treatment and were <1 m*M* ($P > 0.10$). Differences in pH and VFA concentrations were not apparent until 20 to 25 h after dosing, and were characterized by lower propionate production and increased A:P ratios for the 75- and 100-mL dosages compared with other treatments. *Megasphaera elsdenii* may help to avoid pH decline frequently associated with transition to high-concentrate diets.

Contd.

Table 1 (Abstr. 870). Ruminal pH in heifers receiving an oral drench of *Megasphaera elsdenii* (ME) culture (0, 25, 50, 75, or 100 mL)

	ME, mL						
Hour	0	25	50	75	100	SEM	*P*-value
5	6.03	5.80	6.08	5.73	5.89	0.101	0.06
10	5.83	5.78	5.83	5.82	5.78	0.101	0.80
15	6.02	6.10	5.95	6.16	5.93	0.095	0.36
20	5.91^{ac}	6.13^{bc}	5.76^{a}	5.93^{abc}	6.20^{b}	0.101	0.01

871 Dry matter intake patterns of feedlot cattle.

R. B. Hicks[1], R. P. Lake[2], and F. N. Owens*[3], [1]*Oklahoma State University, Goodwell, OK,* [2]*Hitch Consulting Services, Guymon, OK,* [3]*DuPont Pioneer, Johnston, IA.*

Most intake equations for feedlot cattle strive to predict mean intake for the total feeding period. Yet, DMI of feedlot cattle typically plateaus after 2 to 4 wk on feed and declines steadily thereafter. Consequently, dietary requirements change over time. To quantify intake patterns, weekly DMI data were compiled from 2,329 pens (minimum of 50 steers per pen) fed high concentrate diets an average of 158 d in one southern Great Plains feedlot. Intake of DM differed with initial weight ($P < 0.01$), so pens were grouped by initial weight (216 to 443 kg) into 10 sets. Adjusted for death loss and sick pen days, DMI averaged 9.56 kg/d. Within weight groups, DMI later (wk 8 to 17) was correlated ($R^2 = 0.77$) with DMI earlier (wk 4 through 7). Based on DMI and steer weights, ME realized by each pen of steers was calculated (mean ME = 3.45 ± 0.18 Mcal/kg). Based on initial weight and ME intake, mean weight of steers within each pen each week was calculated. Following 3 wk for diet adaptation, Intake of DM as a percentage of mean weight (DMIpc) was lower for pens of steers with greater initial weight and decreased linearly over time (DMIpc = 2.954 – 0.04776 × week on feed – 0.000859 × initial weight, kg); calculated DMI was related to observed DMI ($R^2 = 0.79$; RMSE = 0.61 kg). Pens of cattle with greater initial weights had greater DMI and ADG but lower DMIpc and feed-to-gain ratios. Adjusted for initial weight, and DMIpc, expressed as a fraction of current body weight, was greater ($P < 0.05$) during October and November than in January through May or during a summer intake slump (July and August). The dietary CP percentage required, assuming a 64% efficiency of retention of CP intake, added to inevitable N losses was greater for lighter cattle, peaked early, and declined steadily (CP = 17.1 – 0.1407 × week – 0.0142 × initial weight; $R^2 = 0.80$). In conclusion, later DMI can be predicted from DMI early in a feeding period. Because DMI and performance vary with initial weight and time on feed, data on interim pen weights, DMI, and ADG should permit nutrient requirements to be predicted more precisely than DMI means for the total feeding period.

872 Effect of backgrounding system on beef calf performance.

Jordan L. Cox*[1], Kristin E. Hales[2], Kristen M. Ulmer[1], Rick J. Rasby[1], Steven D. Shackelford[2], Harvey C. Freetly[2], and Mary E. Drewnoski[1], [1]*University of Nebraska-Lincoln, Lincoln, NE,* [2]*USDA-ARS, US Meat Animal Research Center, Clay Center, NE.*

In the Midwest opportunity to integrate cattle production into cropping systems abounds. Two winter forage sources are corn residues and double cropped cool season annuals planted after corn silage harvest. The objective of this study was to evaluate backgrounding spring born calves using these feed resources. Composite MARC II steers (n = 355) were stratified by BW (277.6 ± 0.52 kg) and genetic line and assigned to 1 of 3 treatments: (1) corn residue grazing with distillers supplementation (CRD), (2) oat-brassica forage grazing (OBF) or (3) drylotting on a grower ration (DGR). Each treatment had 4 replicates. Calves on CRD were supplemented 6 d a week with 2.77 kg DM/hd of a dried distillers grains mix containing 2% limestone (DM basis). The OBF was planted in early September and the forage produced was 28% purple top turnip, 14% daikon radish and 59% oats (DM basis). The initial forage mass of OBF was 3516 ± 121 kg DM/ha and calves were stocked at 1538 ± 37 kg DM/hd. Both CRD and OBF calves were given access to a free choice mineral containing 1.32 mg monensin per g. The grower ration consisted of 25% alfalfa hay, 51% corn silage, 20% wet distillers grains and 4% supplement containing 732 mg monensin/kg (DM basis). All calves consumed the grower ration before initial weights. The CRD and OBF calves were removed from grazing after 64 d when the OBF biomass was 1445 ± 104 kg DM/ha and calves were fed the grower ration for 6 d and then weighed. The free-choice mineral intake of the CRD calves (173 g/hd/d) was greater ($P < 0.01$; SEM ± 9.6) than OBF calves (121 g/hd/d). The backgrounding phase of DGR calves ended after 54 d when they reached 365 kg BW. Intake of DGR calves during backgrounding was 8.27 ± 0.031 kg/hd. During the backgrounding phase the ADG of the DGR calves (1.57 kg/d) was greater ($P < 0.01$; SEM ± 0.034) than both OBF (1.00 kg/d) and CRD (0.75 kg/d) and ADG of OBF was greater ($P < 0.01$) than CRD. Although the calves drylotted and fed a grower ration had a greater rate of gain, the lower cost of gain associated with the grazing systems make these backgrounding methods economically competitive.

Key Words: backgrounding calves, brassicas, corn residue

873 Gene expression of the hypothalamus in steers fed high-concentrate diet upon entering feedlot phase.

Jason E. Griffin*[1], Zhongde Wang[2], Jeffrey A. Clapper[1], Robbi H. Pritchard[1], Keith R. Underwood[1], and Michael G. Gonda[1], [1]*South Dakota State University, Brookings, SD,* [2]*Utah State University, Logan, UT.*

Finishing diets used in beef feedlots are high in energy to allow for rapid growth and fat deposition. Previous studies have shown that the use of high concentrate post-weaning diets changes expression of genes in the hypothalamus involved with regulating feed intake, metabolism, signaling, and neuronal communication. The objective of this study was to investigate whether expression of key growth and developmental genes in the hypothalamus can be altered by feeding a high concentrate diet when calves enter the feedlot. Predominantly Angus steers (n = 12) were randomly allocated to 1 of 2 treatment groups: (1) high energy/high concentrate (HE/HC), a diet fed to provide 1.33 mcal/kg NE gain; or (2) traditional backgrounding/finishing (B/F), fed to provide 1.10 mcal/kg NE gain for the first 84 d on feed (DOF) and 1.43 mcal/kg NE gain for the remaining 118 DOF. Growth at d28 ($P < 0.01$) was greater for the HE/HC treatment group; however, no difference between treatments was observed at the beginning ($P > 0.14$) and end ($P > 0.13$) of the feeding trial. At slaughter, hypothalami were dissected and frozen for RNA extraction. RNA was extracted and expression differences between treatments were measured by RNA-seq. Carcass characteristics and composition, and Warner-Bratzler shear force (WBSF) analysis were conducted. Kidney, pelvic, heart fat percentage was higher ($P <$

0.04) in HE/HC steers; however, no difference in other carcass traits ($P > 0.10$) and WBSF ($P > 0.22$) were detected. One hundred and 30 one genes were expressed only in the B/F steers, while 195 were only expressed in the HE/HC steers. Nine genes were expressed in both treatments; 3 genes had higher expression in the HE/HC steers and 6 genes had higher expression in B/F steers. Gene Ontology terms involved with differentially expressed genes included virus immune response, cell cycle regulation, signaling pathway regulation, and hydrogen and oxygen transport pathways. Feedlot calves fed a high concentrate diet upon entering the feedlot have altered gene expression in the hypothalamus, with many differentiated genes involved with signaling and metabolic pathways.

Key Words: bovine, hypothalamus, expression
