Journal of Animal Science

Editor-in-Chief: James L. Sartin
Associate Editor-in-Chief: Joel S. Caton

Section: Subsection	Section Editors:
Animal Genetics	Paul F. Arthur (2017)
	Donagh P. Berry (2016)
	Catherine W. Ernst (2017)
	Michael G. Gonda (2015)
	Changxi Li (2016)
	Robert L. Weaber (2015)
Animal Physiology:	Terry D. Brandebourg (2015)
Cell Biology	Alan D. Ealy (2017)
Growth and Developmental Biology	Kristen E. Govoni (2016)
Physiology, Endocrinology, and Reproduction	Leon J. Spicer (2017)
Nonruminant Animal Nutrition:	Thomas D. Crenshaw (2015)
	Sung Woo Kim (2016)
	John F. Patience (2016)
	Chad H. Stahl (2016)
	Phil A. Thacker (2015)
Ruminant Animal Nutrition:	Paul A. Beck (2016)
	Brian J. Rude (2016)
	Eric J. Scholljegerdes (2017)
	Evan C. Titgemeyer (2016)
	Yuxi Wang (2016)
Animal Production:	Reinaldo F. Cooke (2017)
Behavior	Trevor Devries (2016)
Environmental Impact	James L. Klotz (2015)
Feedstuff Evaluation	Xavier E. Manteca (2017)
Health and Well-Being	James A. Pfister (2017)
Management	Kathy J. Soder (2016)
Pharmacology and Toxicology	Juan J. Villalba (2016)
Rangeland, Pasture, and Forage Utilization	
Animal Products:	Steven M. Lonergan (2016)
Meat Science and Muscle Biology	Richard A. Mancini (2015)
Meat Safety	Surendranath P. Suman (2016)
	Deborah L. VanOverbeke (2016)
Special Topics:	Robert A. Dailey (2015)
Biographical/Historical Sketches	
Contemporary Issues	
Symposia	Mark A. Mirando (2015)

Terms expire during the annual meeting of the American Society of Animal Science in July of the year indicated in parentheses

Officers and Directors of the American Society of Animal Science

Application for membership in the American Society of Animal Science (ASAS) is invited from persons with interest in animal science and livestock production. In 2014, annual dues including access to the electronic version of the Journal of Animal Science are $135 in the United States, Canada, and Mexico and in other countries. For those in the United States, Canada, or Mexico who wish to receive a paper copy of the journal, the additional fee is $200; for those in other countries, the additional fee is $300. Student affiliate membership is granted to those who are certified by a professional member as a regularly enrolled college student who does not hold a full-time position at the time of application for, or annual renewal of, membership. Graduate student memberships ($20 annually) and undergraduate student memberships (free) include access to the electronic version of the Journal of Animal Science. Postdoctoral fellows' membership dues are $65. An institutional subscription ($599 annually) entitles an institution Internet access to e-JAS within appropriate IP addresses. For an additional $125 fee, institutions within the United States, Canada, and Mexico will receive a paper copy of the journal (an additional $150 fee for all other countries). For corporate subscriptions, please contact the ASAS office for pricing. Individual sustaining membership, $375 per year. Applications for membership with remittance should be mailed to the ASAS Business Office.

ASAS Business Office, PO Box 7410, Champaign, IL 61826
Telephone: 217-356-9050; Fax: 217-689-2436; E-mail: asas@asas.org Office hours: 8:00 a.m.–5:00 p.m.

American Society of Animal Science World Wide Web address: http://www.asas.org

Calendar of American Society of Animal Science Upcoming Meetings

Innovate 2015	May 31–June 2, 2015	Braselton, GA
2015 ASAS Western Section	June 23–25, 2015	Ruidoso, NM
2015 ASAS Northeastern Section/ADSA Northeastern Branch	July 12–16, 2015	Orlando, FL

Manuscript Submission. Information about manuscript submission is given in *Style and Form* published on the journal website (http://jas.fass.org). All manuscripts submitted to the *Journal of Animal Science* must be accompanied by the JAS manuscript submission form certifying that any research that involves animals has followed established standards for the humane care and use of animals. Manuscripts should be submitted online via http://mc.manuscriptcentral.com/jas.

Address Change and Missing Copies. Notice of change in address should be received by the ASAS Business Office 60 days in advance of change.

Claims for missing copies should be received within three months (USA) or six months (international) of printing to be replaced without charge. ASAS will attempt to send one replacement for the issue requested if in the time period indicated. After free replacement period, missing back issues are available for $60.00 per issue for USA, Canada, and Mexico; $65 per issue for all other countries.

Additional requests for missing issues will also be charged at the above rate.

Journal of Animal Science (ISSN 0021-8812) is published 12 times per year (monthly) by the American Society of Animal Science. Periodicals postage paid at 201 W. Springfield, Ste 1202, Champaign, IL 61820 and at additional mailing offices. Form 3579 to be returned to the ASAS Business Office. Postmaster: Send change of address to American Society of Animal Science, PO Box 7410, Champaign, IL 61826.

Journal of Dairy Science (ISSN 0022-0302) is published monthly on behalf of the American Dairy Science Association® by the Federation of Animal Science Societies, Champaign, IL, and Elsevier Inc., 360 Park Avenue South, New York, NY 10010-1710. Business and Editorial Office: 1600 John F. Kennedy Blvd., Ste. 1800, Philadelphia, PA 19103-2899. Customer Services Office: 3251 Riverport Lane, Maryland Heights, MO 63043. Periodicals postage paid at New York, NY, and additional mailing offices. The electronic edition of the journal (ISSN 1525-3198) is published online at http://www.journalofdairyscience.org.

JOURNAL OF DAIRY SCIENCE® *SINCE 1917*
1800 S. Oak St., Ste 100, Champaign, IL 61820
Phone 217/356-5146 | Fax 217/378-4083 | adsa@assochq.org | http://www.journalofdairyscience.org

Postmaster: Send address changes to *Journal of Dairy Science*, Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043.

Customer Service (orders, claims, back volumes, online access, change of address): Elsevier Health Sciences Division, Subscription Customer Service, 3251 Riverport Lane, Maryland Heights, MO 63043. Telephone: 800.654.2452 (US and Canada), 314.447.8871 (outside US and Canada); fax: 314.447.8029; e-mail: journalscustomerservice-usa@elsevier.com (for print support) or journalsonlinesupport-usa@elsevier.com (for online support). Allow 4 to 6 weeks for the change of address to be implemented.

Institutional Subscription Rates: For institutions in the United States and possessions: $1020 for print. For institutions in all other countries (prices include airspeed delivery): $1150 for print. Current prices are in effect for back volumes and back issues. Electronic access is additional. Please contact customer service for pricing.

ADSA Membership Rates: For individual membership, contact the ADSA office (adsa@assochq.org) to pay dues and obtain access to the journal. For professional members: $110 per year, graduate student membership: $10, undergraduate student affiliate membership: $5. Membership includes electronic version of the journal; additional $61.50 for paper copy in US, and additional $91.50 for paper copy in all other countries). Membership in the ADSA is on a calendar year basis from January through December.

Advertising Information: To advertise a position announcement in the News and Announcements section of the journal, please use the FASS Job Resource Center (http://www.fass.org/job.asp); e-mail jrc@assochq.org if you have questions.

For display advertising orders and inquiries please contact Ken Senerth at 609.577.0916; by fax at 212.633.3980; or by e-mail at kensenerth@gmail.com. For non-recruitment classified advertising orders and inquiries please contact Rob Issler at 321.400.8279; by fax at 407.814.7516; or by e-mail at robisslerjr@gmail.com.

Author Inquiries: For inquiries relating to the submission of articles, complete Instructions for Authors can be found online at http://www.journalofdairyscience.org. Manuscripts submitted for consideration should be submitted electronically at http://mc.manuscriptcentral.com/jds in accordance with the Instructions for Authors. Need help? Contact shaunam@assochq.org.

Offprints. Authors may place orders for offprints when proof corrections are sent to the editorial office (before the journal is sent for printing). For queries about offprints or order status, e-mail vickip@assochq.org; fax 217.378.4083.

Reprints. To order author reprints after the issue has been printed, e-mail authorsupport@elsevier.com. To order 100 or more reprints for educational, commercial, or promotional use, contact the Commercial Reprints Department, Elsevier Inc., 360 Park Avenue South, New York, NY 10010-1710; fax: 212.633.3820; e-mail: reprints@elsevier.com. Access to single articles available online may be obtained by purchasing Pay-Per-View access on the journal website (http://www.journalofdairyscience.org).

Triennial Reproduction Symposium: Developmental programming of fertility

1 The importance of understanding the impacts of developmental programming on fertility: An overview. Lawrence Reynolds*, *North Dakota State University, Fargo, ND.*

Increasing evidence supports the idea that reproductive efficiency may be "programmed" during prenatal or early postnatal life. Developmental programming is the concept that an "insult" during any developmental stage can result in programming of organ/organismal function in the short or long term. Insults that result in developmental programming include external factors such as (1) malnutrition pre-mating, during pregnancy, or during infancy; and (2) exposure to environmental factors such as social stress, high temperature-humidity, smoke, herbicides, pesticides, or phytosteroids. Intrinsic factors that result in developmental programming include (1) maternal age, (2) multiple fetuses, and (3) maternal and embryonic genetic background. Based on large epidemiological studies primarily in humans, as well as controlled studies in animal models including livestock, developmental programming affects the function of various organ systems in the offspring, resulting in altered growth, body composition, metabolism, and behavior. The organ systems that have been shown to be affected include, among others, adipose tissue, brain, cardiovascular system, endocrine system, gastrointestinal tract, kidney, muscle, and reproductive system, including the ovary, utero-placenta, testis, and hypothalamic-pituitary-gonadal axis. In addition, the effects of developmental programming have been shown to be transmissible across generations. The 2015 Triennial Reproduction Symposium will focus on how developmental processes and systems can affect reproductive success in males and females in livestock and other species.

Key Words: Triennial Reproduction Symposium, developmental programming of fertility, overview

2 Beef heifer development systems and lifetime productivity. Andrew J. Roberts*[1], Rick N. Funston[2], Elaine E. Grings[3], and Mark K. Petersen[1], [1]*USDA-ARS, Fort Keogh LARRL, Miles City, MT,* [2]*University of Nebraska West Central Research and Extension Center, North Platte, NE,* [3]*Department of Animal Science, South Dakota State University, Brookings, SD.*

Research continues to amass proving nutrition and other environmental factors experienced during pregnancy affect the fetus, resulting in changes in traits exhibited through life. In livestock, small differences in nutritional profiles during gestation may result in fetal programing that alters lifetime production efficiency. Thus, the potential of fetal programing should be considered when determining supplemental feeding strategies during gestation. For example, evaluation of offspring born to cows grazing dormant pasture supplemented with either 1.1 or 1.8 kg/d of alfalfa hay during the last 3rd of gestation demonstrated females born to cows provided the lower supplementation level were 10 kg heavier and had greater BCS at 5 yr of age. These differences appeared beneficial for maintaining reproductive performance in offspring managed with less harvested feed inputs. Comparison of offspring from cows wintered on native range (low quality) or improved pasture (greater quality) for 30 to 45 d during the 5th to 6th mo of gestation resulted in a trend for longer productivity in daughters from cows wintered on improved pasture. In recent studies comparing offspring from cows with or without protein supplementation while grazing dormant winter range during late gestation, heifers from protein-supplemented dams had greater BW at weaning. This increase in BW persisted through pregnancy diagnosis and subsequent calving, and pregnancy rates were greater in heifers from protein-supplemented dams. Heifers from protein-supplemented dams appeared less feed efficient compared with heifers from un-supplemented dams. Thus, in utero exposure to nutritionally restricted environments (non-supplemented dams) may promote greater feed efficiency later in life. Nutrition during post-weaning development may also affect lifetime productivity. Heifers developed on low quality native range with RUP supplementation had greater retention beyond 3 yr of age than cohorts developed in a feed lot with higher quality feed and greater ADG. Collectively, these examples show long-term effects of nutritional management strategies used during gestation and development in given production environments need to be evaluated.

Key Words: fetal programing, lifetime productivity, nutritional supplementation

3 Effects of nutrition on reproductive development in bulls. Leonardo F. C. Brito*, *ABS Global Inc., DeForest, WI.*

A series of experiments were conducted to evaluate the effects of nutrition during calfhood (defined as the period from 10 to 26–30 wk of age) and peripubertal period (27–31 to 70–74 wk of age) on reproductive development in bulls. The overall objective of these experiments was to evaluate the effects of nutrition on endogenous metabolic hormones (leptin, insulin, GH, and IGF-I), gonadotropins and testosterone concentrations, sexual development, sperm production, and semen quality in bulls. Results of these experiments demonstrated that nutrition affected GnRH secretion and sexual development in bulls. Increased nutrition during calfhood resulted in a more sustained increase in LH pulse frequency during the early gonadotropin rise and greater testicular development at maturity. On the other hand, low nutrition during calfhood suppressed LH secretion during the early gonadotropin rise and resulted in delayed puberty and reduced testicular development at maturity. When low nutrition was accomplished by restricted feed intake, hypothalamic and pituitary function were compromised and LH secretion was more severely affected. Temporal associations between LH secretion patterns and circulating IGF-I concentrations implied that IGF-I is a possible signal to the central "metabolic sensor" involved in translating body nutritional status to the GnRH pulse generator. Nutrition also affected testicular steroidogenesis (testosterone concentrations), indicating effects on the number or function of Leydig cells, or both. Age-related increases in physiological and GnRH-stimulated circulating testosterone concentrations were hastened in bulls receiving high nutrition and delayed in bulls receiving low nutrition; these effects were probably mediated by both LH secretion and IGF-I concentrations. Circulating leptin and insulin may have only permissive roles on GnRH secretion, but may enhance testicular development. Growth hormone concentrations decreased concomitantly with increasing IGF-I concentrations during sexual development in bulls, suggesting that the testes could contribute considerable amounts of circulating IGF-I. In conclusion, management strategies to optimize reproductive function in bulls should focus on increasing nutrition during calfhood.

Key Words: bull, nutrition, sexual development

4 **Nutritional programming of puberty in heifers.** Gary L. Williams*[1,2], Rodolfo C. Cardoso[1,2], Bruna R. C. Alves[2], and Marcel Amstalden[2], [1]*Texas A&M AgriLife Research, Beeville, TX,* [2]*Texas A&M University, College Station, TX.*

Because multiple estrous cycles are required for heifers to express full fertility before first breeding, ensuring that puberty is achieved in advance of 14 mo of age is critical. This allows heifers to calve as 2 year olds and optimizes lifetime efficiency. Feeding diets that promote elevated BW gain during the prepubertal period has been the primary strategy for achieving these end-points. Based on research conducted in our laboratories and others, it appears that the interval between approximately 4 and 7 mo of age (juvenile period) is a critical window for metabolically programming the neuroendocrine axis to achieve targeted reproductive maturation in heifers. By focusing on nutritionally mediated changes in the hypothalamus, we have been able to characterize several structural and functional modifications in hypothalamic pathways that respond to high-energy diets during this period. These include the differential expression of several genes (NPY, AGRP, POMC, and GHR) within the arcuate nucleus, a reduction in NPY innervation of GnRH neurons, decreased concentrations of central NPY, and increased innervation of kisspeptin neurons by αMSH. These alterations are consistent with the hypothesis that accelerated growth during the juvenile period, resulting in increased circulating leptin, leads to decreased inhibition and accelerated excitation of GnRH neurons. Novel nutritional and managerial approaches for optimizing growth during sensitive periods of infantile and juvenile development are required in order for fundamental biology to reach practical translation. These approaches must facilitate nutritional imprinting of the brain during early calfhood, while minimizing feeding costs, optimizing the consistent establishment of estrous cycles by 11 to 12 mo of age, and avoiding precocious puberty or disrupted mammary gland development. Our recent studies indicate that this may be achieved by exposing heifers to a stair-step nutritional regimen. However, a role for the maternal metabolic environment in heifer offspring responses to postnatal diets may also be operative. If confirmed, successful managerial strategies will also include the pregnant dam (USDA-NIFA grants 2009-65203-05678 and 2013-67015-20960).

Key Words: heifer, programming, puberty

5 **Future reproduction in gilts and boars is affected prenatally by sow management and early in life by management conditions to which the developing swine are exposed.** Mark J. Estienne*, *Virginia Tech, Blacksburg, VA.*

Applied research at Virginia Tech has focused on effects of pre- or post-natal conditions on reproduction in adults. In utero, swine fetuses can be programmed as a consequence of intrauterine growth retardation (IUGR) caused by insufficient uterine capacity. Although negative effects of IUGR on postnatal growth are well documented, possible reproductive effects have been less studied. Preliminary work from our laboratory, however, showed that low BW boars had poorer libido and semen quality than high BW boars; in gilts, age at puberty was negatively correlated with pig BW. It is becoming apparent that fetuses can also be programmed by management of the gestating sow. For example, we compared growth and reproductive characteristics of gilts farrowed by sows that were kept in individual crates throughout gestation, group pens throughout gestation, or individual crates for the first 30 d post-mating and then group pens for the remainder of pregnancy. During the last 4 wk of the grow-finish period, BW of gilts farrowed by females housed in crates throughout gestation was greater than BW of gilts in the other 2 groups. Also, the efficiency of feed conversion was greatest and last-rib backfat thickness the least, in gilts farrowed by females housed in crates throughout gestation. Interestingly, fewer gilts farrowed by females kept in crates throughout gestation reached puberty by 165 d of age compared with the other 2 groups. In intensively managed swine operations, there are many potential environmental stressors to which postnatal pigs are exposed early in life and this may affect future reproduction as well. For example, we determined the effects of crowding in the nursery on future reproduction and longevity in gilts. Reproductive performance during the second parity, including the number of pigs born alive was significantly greater for gilts each allowed 0.25 m^2 of floor space in the nursery compared with gilts restricted to 0.17 m^2. Research will continue to identify prenatal or early-in-life stressors and to develop management strategies for mitigating adverse effects on swine reproduction.

Key Words: gilts, boars, development

6 **Our stolen figures: Using the process of sexual differentiation to think about endocrine-disrupting compounds and their effects on energy balance.** Jill E. Schneider*, *Lehigh University, Bethlehem, PA.*

Reproductive processes (gametogenesis, hypothalamic-pituitary-gonadal function, and behavior) are masculinized or feminized during fetal development. At least some of these effects are determined during fetal development by androgens, estrogens, and glucocorticoids acting on cognate steroid receptors. These receptors, however, render reproductive development sensitive to endocrine-disrupting compounds that also act on the same receptors. Less well known is the fact that endocrine disruptors can alter energy balance (energy intake, storage, and expenditure). Recent evidence indicates that endocrine disruptors affect many individual processes known to contribute to obesity, including the gut microbiome, adipocyte differentiation, energy metabolism, ingestive behavior, and the tendency to accumulate adipose tissue in response to certain diets. Understanding effects of endocrine disruptors on energy balance will be aided by attention to the processes involved in sexual differentiation. This is because many energy-balancing traits are sexually dimorphic with the masculine phenotype most closely linked to metabolic diseases such as type II diabetes and heart disease. So far, it is clear that at least some endocrine disruptors have masculinizing effects via classical organizational effects on sexually dimorphic energy balancing traits during fetal development. In addition, we should expect endocrine disruptors to affect other defined mechanisms of sexual differentiation (e.g., sex chromosome action, aromatization, active feminization, and organizing actions at later periods of development, such as puberty). Investigators interested in effects of endocrine disruptors on peripheral metabolism often work in isolation from those interested in the effects of endocrine disruptors on ingestive behavior. In fact, changes in peripheral metabolism have organizational and activational effects on the neural circuitry that controls ingestive behavior. Together, these considerations demand a concerted multidisciplinary and integrative approach to the study of endocrine disruptors.

7 **Environmentally induced epigenetic transgenerational inheritance of disease: Ancestral ghosts in your genome.** Michael K. Skinner*, *Center for Reproductive Biology, School of Biological Sciences, Washington State University, Pullman, WA.*

Transgenerational effects of environmental toxicants significantly amplify the effect and health hazards of these compounds. One of the most sensitive periods to exposure is during embryonic gonadal sex determination when the germ line is undergoing epigenetic programming and DNA re-methylation. Previous studies have shown that endocrine disruptors can cause an increase in adult onset disease such as infertility, prostate, ovary and kidney disease, cancers and obesity. Interestingly, this effect is transgenerational (F_1, F_2, F_3, and F_4 generations) and hypothesized to be due to a permanent (imprinted) altered DNA methylation of the germ-line. The transgenerational epigenetic mechanism appears to involve the actions of an environmental compound at the time of sex determination to permanently alter the epigenetic (i.e., DNA methylation) programming of the germ line that then alters the transcriptomes of developing organs to induce disease susceptibility and development transgenerationally. A variety of different environmental compounds have been shown to induce this epigenetic transgenerational inheritance of disease including: fungicide vinclozolin, plastics BPA and phthalates, pesticides, DDT, dioxin and hydrocarbons. The suggestion that environmental factors can reprogram the germ line to induce epigenetic transgenerational inheritance of disease and phenotypic variation is a new paradigm in disease etiology that is also relevant to other areas of biology such as evolution.

8 Environmental effects on programming of reproductive behavior.

Frederick vom Saal*, *University of Missouri-Columbia, Columbia, MO.*

Fetal development is a period of heightened sensitivity to hormones that regulate the differentiation of tissues. An example showing that very small differences in testosterone (T) and estradiol (E_2) during fetal life can lead to changes in the life history of males and females is the intrauterine position phenomenon or IUP. Developing between fetuses of the same or opposite sex in species in which there are multiple fetuses (polytocous species) results in very small differences in fetal serum T and E_2 and differences in the development of tissues, including the brain, responsive to these sex steroids. For example, in mice, 2F males (located in utero between 2 females) have elevated serum E_2 during fetal life and in adulthood show an increase in sexual behaviors relative to 2M males (located between 2 males); 2M males have elevated serum T during fetal life and in adulthood are more aggressive than 2F males. Similarly, 2F female mice are more sexually attractive to males and more sexually receptive, but less aggressive, than their 2M female siblings. There are now numerous environmental chemicals that have been found to bind to estrogen receptors and disrupt normal estrogen signaling. The best studied of these estrogenic endocrine-disrupting chemicals is bisphenol A or BPA. Developmental exposure to BPA has been related to numerous changes in brain structure, function, and behavior in both males and females. Of great interest is the finding that the magnitude of the sex differences in some behaviors observed in untreated rats and mice is reduced or eliminated as a result of exposure to doses of BPA that are relevant to exposures experienced by humans based on biomonitoring studies. While there is less information regarding the effects of endocrine disrupting chemicals such as BPA in farm animals relative to rodents or humans, there is evidence for effects of fetal exposure to BPA on neuroendocrine function in sheep. There is also evidence for transgenerational transmission of altered phenotype, including behavior, caused by exposure to endocrine disrupting chemicals during the period of germ cell epigenetic programming.

Key Words: endocrine disruptor, bisphenol A, fetal programming

9 Potential effects of real life exposure to environmental contaminants on reproductive health.

Neil P. Evans*[1], Michelle Bellingham[1], Corinne Cotinot[2], Stewart M. Rhind[3], Richard Sharpe[4], and Paul A. Fowler[5], [1]*College Medical Veterinary and Life Sciences, Institute of Biodiversity Animal Health & Comparative Medicine, University of Glasgow, Glasgow, UK,* [2]*INRA, 1198 Biologie du Developpement et Reproduction, Jouy en Josas, France,* [3]*James Hutton Institute, Aberdeen, UK,* [4]*Queens Medical Research Institute, MRC Centre for Reproductive Health, University of Edinburgh, Edinburgh, UK,* [5]*Institute of Medical Sciences, Division of Applied Medicine, University of Aberdeen, Aberdeen, UK.*

While much research has focused on the effects of individual chemical exposures on animal health, far less is known about the effects of exposure to the mixtures of chemicals often found within our environment, even though this is a more typical exposure pattern. Biosolids (processed human sewage sludge) contain low individual concentrations of an array of contaminants including heavy metals and organic pollutants [e.g., polycyclic aromatic hydrocarbons, polychlorinated biphenyls and polychlorinated dibenzo(p)dioxin and furan] and form the basis of our model with which to study the effects of exposure to mixtures of environmentally relevant concentrations of pollutants in a domestic animal, the sheep. Studies using this model have investigated the effects of developmental exposure to biosolids on a variety of reproductive endpoints, including GnRH, kisspeptin, and estradiol receptor expression within the hypothalamus, LH and estradiol receptor expression within the pituitary gland, and protein, mRNA, and gamete production within the gonads of male and female sheep. The studies suggest that exposure to biosolids in utero, via maternal exposure, has detrimental effects on the fetal hypothalamo-pituitary-gonadal axis that could affect subsequent fertility. Studies with adult animals, also exposed during fetal life, suggest long-term effects of environmental chemical exposure on the reproductive axis. Investigation of lambs born to ewes grazed on biosolid-treated pastures (1) throughout life, (2) up until gestation, or (3) only during gestation have shown that some effects of environmental chemicals (relative to unexposed controls) may be more pronounced when exposure is acute, or that physiological compensation may occur when exposure is prolonged. Overall, the results of this study question the reliance on no observed adverse effects levels, with regard to chemical safety, when chemical exposure normally occurs as complex mixtures. The results suggest that developmental chemical exposure may affect the hypothalamo-pituitary-gonadal axis at a variety of levels, although whether the effects are driven by central effects or occur at each organ studied remains to be determined. [Wellcome Trust grant 080338].

Key Words: endocrine-disrupting chemicals, environmental contamination, ruminant

Breeding and Genetics Symposium: Joint Interbull/JAM Session: Milk spectral data—Cost-effective information to improve expensive and limited traits in dairy cattle breeding

10 Capitalizing on fine milk composition for breeding and management of dairy cows. Nicolas Gengler*[1], Hélène Soyeurt[1], Frédéric Dehareng[2], Catherine Bastin[1], Frédéric Colinet[1], Hedi Hammami[1], and Pierre Dardenne[2], *[1]University of Liège-GxABT, Gembloux, Belgium, [2]Walloon Agricultural Research Center, Gembloux, Belgium.*

Management and breeding of dairy cows face the challenge of permanently adapting to changing production circumstances under socio-economic constraints. If management and breeding addresses different timeframes of action, both need relevant phenotypes that allow for precise monitoring of the status of the cows, their products (i.e., milk and subsequently dairy products), their behavior and their environmental impact. Milk composition has been identified as an important source of information since it could reflect, at least partially, all these elements. Major milk components such as fat, protein, urea, and lactose contents are routinely predicted by mid-infrared (MIR) spectrometry and have been widely used for these purposes. But, milk composition is much more complex and other components might be informative. Such new milk-based phenotypes should be considered given that they are cheap, rapidly obtained, usable on a large scale, robust and reliable. In a first approach, new phenotypes can be predicted from MIR spectra using classical prediction equation based techniques. This method was used successfully for many novel traits (e.g., fatty acids, lactoferrin, minerals, milk technological properties, citrate), that can then be useful for management and breeding purposes. An innovation was to consider the longitudinal nature of the relationship between the trait of interest and the MIR spectra (e.g., to predict methane from MIR). By avoiding intermediate steps, prediction errors can be minimized when traits of interest (e.g., ketosis) are predicted directly from MIR spectra. In a second approach, in an innovative manner, patterns detected by comparing observed from expected MIR spectra can be used directly. All these traits can then be used to define best practices, adjust feeding and health management, improve animal welfare, improve milk quality and limit environmental impact. Under the condition that MIR data are available on a large scale, phenotypes for these traits will allow genetic and genomic evaluations. Introduction of novel traits into the breeding objectives will need additional research to clarify socio-economic weights and genetic correlation with other traits of interest.

Key Words: milk, spectra, novel traits

11 Applications of milk spectroscopy data to select for feed efficiency and reduced methane emissions in dairy breeding programs. Sinead McParland*[1] and Frederic Dehareng[2], *[1]Animal and Grassland Research & Innovation Centre, Teagasc Moorepark, Fermoy, Co. Cork, Ireland, [2]Walloon Agricultural Research Centre, Gembloux, Belgium.*

Feed efficiency (FE), the difference between energy intake and the energy demanded and supplied by various reservoirs and sinks, is of increasing importance. One such energy sink is methane emissions (ME); ME also have repercussions on climate change. Collection of the necessary data for the computation of genetic evaluations for both FE and ME are, however, laborious and expensive. Mid-infrared spectrometry (MIRS) offers a solution to routinely collect data on milk recorded animals at no additional cost to milk recording. The use of MIRS to accurately predict animal and milk traits, including energy balance (EB) and milk fatty acids (FA) has recently been shown and validated. When changes in body mass are zero, EB is mathematically identical to residual feed intake (RFI), a measure commonly used to depict FE. The relationship between ME and milk FA has also been reported. Therefore, it was recently hypothesized that both RFI and ME could also be predicted from milk. Two separate studies were conducted using 1,270 records of RFI from Irish Holstein-Friesians, and 77 records of ME from Belgian Holstein cows. Accuracy (i.e., correlation) of predicting RFI and ME using partial least squares regression on the MIR spectral data was 0.62 and 0.87, respectively, in cross validation. Both studies were limited by small numbers, and have yet to be independently validated. The heritability of MIR-predicted RFI was 0.06, and was lower than the heritability of measured RFI using the same data set (0.10), however the genetic correlation between MIR-predicted and measured RFI was 0.78 using the limited data set. Furthermore, when prediction equations were applied to larger data sets of MIR spectral data, the lactation profile for RFI was in line with expectations based on profiles estimated from measured RFI. The shape of the lactation profile of predicted ME was, however, dependent on stage of lactation. The major limitation precluding FE and ME from breeding programs in the past can be resolved through the use of MIRS on milk recorded animals.

Key Words: feed efficiency, methane, mid infrared spectrum

12 Using milk spectroscopy phenotypes in genetic selection programs to improve the nutraceutical value of milk in dairy cows. Henk Bovenhuis*, *Animal Breeding and Genomics Centre, Wageningen University, Wageningen, the Netherlands.*

Milk is a unique product that is specifically suited to nourish the offspring and because initially milk is the young's only food it has to contain all essential ingredients. However, several studies have indicated that in modern human diets, a high intake of saturated fatty acids is a risk factor for cardiovascular diseases. Milk and dairy products are major sources of these fatty acids. Milk fat composition is strongly affected by genetic factors, which suggests that there are opportunities to change milk fat composition by means of selective breeding. A crucial factor in successful selection strategies is the availability of phenotypes. Milk fat composition can be accurately determined based on gas chromatography (GC); however, this analytical method is expensive and relatively time consuming. Alternatively, fatty acids can be predicted based on infrared spectra. Infrared prediction of unsaturated fatty acids might be based on indirect relations or on a direct relationship between infrared frequencies and the double bond within the fatty acid chain. Distinguishing direct and indirect relations is relevant as it might have consequences for the range of conditions under which prediction equations are valid. Bouwman (2014) compared genome-wide associations for GC-based fatty acids with infrared-predicted fatty acids and found considerable differences. A typical example was the region on BTA26 containing the SCD1 polymorphism. More recently, we studied the effect of the SCD1 polymorphism on all 1,060 individual infrared wavelengths (Wang et al., 2015). No wavelengths were significantly affected by the SCD1 polymorphism whereas the SCD1 polymorphism has been shown to have significant effects on the content of C10:0, C14:0, C18:0, C10:1, C12:1, C14:1, and C16:1 (Duchemin et al., 2012). This suggests that infrared spectra contain little direct information on the content of these fatty acids. This confirms results by Eskildsen et al. (2014), who concluded that prediction of individual fatty acids relies on correlations with fat content rather than on direct relations with specific Infrared frequencies.

Key Words: infrared, prediction, milk fatty acids

13 Do milk spectroscopy phenotypes have a role to play in dairy fertility and health breeding programs?

Catherine Bastin*[1], Léonard Théron[2], Aurélie Lainé[1], and Nicolas Gengler[1], [1]*University of Liège, Gembloux Agro-Bio Tech, Animal Science Unit, Gembloux, Belgium,* [2]*Faculty of Veterinary Medicine, Clinical Department of Production Animals, University of Liège, Liège, Belgium.*

Genetic selection allows for permanent improvement of dairy cow fertility and health. However, these traits are generally complex, difficult to record, and lowly heritable (<0.10). Hence, indicators have been proven as useful in the prediction of genetic merit for direct fertility and health traits as long as they are easier to measure, heritable, and genetically correlated. Considering that changes in (fine) milk composition over the lactation reflects the physiological status of the cow, the mid-infrared (MIR) analysis of milk opens the door to a whole new range of potential indicator traits of fertility and health. Previous studies investigated the phenotypic and genetic relationships between fertility and MIR-predicted phenotypes, most of them being related to negative postpartum energy balance and body fat mobilization (e.g., fat to protein ratio, urea, fatty acids profile). Results showed that a combination of various fatty acids traits (e.g., C18:1 *cis*-9 and C10:0) could be used to improve fertility. Furthermore, occurrence of (sub-)clinical ketosis has been related to milk-based phenotypes such as fatty acids and ketone bodies. Hence, MIR-predicted acetone and β-hydroxybutyrate contents in milk were demonstrated as useful for breeding cows less susceptible to ketosis. Although studies investigating the genetic association among mastitis and MIR-predicted phenotypes are scarce, a wide range of traits, potentially predicted by MIR spectrometry, are worth considering. It includes traits related to the disease response of the cow (e.g., lactoferrin), to the reduced secretory activity (e.g., lactose) and to the alteration of blood-milk barrier (e.g., minerals, citrate). Moreover, direct MIR-prediction of fertility and health traits should be further considered. To conclude, MIR-predicted phenotypes have a role to play in the improvement of dairy cow fertility and health. However, further studies are warranted to (1) grasp underlying associations among MIR-predicted indicator and fitness traits, (2) estimate the genetic parameters, and (3) include these traits in broader breeding strategies.

Key Words: health, fertility, mid-infrared spectrometry

14 Implementation of mid-infrared calculated tools to select for novel traits in dairy cattle breeding.

Eileen Wall*[1], Stephanie Smith[1], Sinead McParland[2], Vicky Hicks[3], and Mike Coffey[1], [1]*Scotland's Rural College, Edinburgh, UK,* [2]*Teagasc, Cork, Ireland,* [3]*National Milk Records, Chippenham, UK.*

Currently, mid infrared (MIR) spectroscopy of milk samples is used to predicted milk fat, protein, and lactose. While the technology has been utilized for milk recording for numerous years, the application of mid-infrared to measure other parameters in milk is a recent development. More recent studies have shown that MIR can predict different milk quality attributes (e.g., Soyeurt et al., 2011, 2012) as well as other performance traits such as energy balance (McParland et al., 2011, 2014), methane emissions (Dehareng et al., 2012) and health and fertility traits. Here we extend the predictions of novel traits from milk MIR to implementation in the industry as part of routine milk recording. We will discuss the system established to routinely capture and used milk spectra in an operational milk recording business. The system established has allowed us to apply prediction equations for a range of traits to national spectra on almost 117,000 animals (over 1 million test-dates) from 355 farms across the UK (from Feb 2013 to Jan 2015). Systems for routinely predicting novel traits have been established and routine extraction of data for the estimation of genetic parameters and breeding values developed. For example, heritability estimates for cow energy balance, body energy content and energy intake were 0.12, 0.23, and 0.15 respectively. Mid-infrared-based traits predictions from routinely collected data at a national level have potential use in genetic improvement of livestock for previously difficult and expensive to record traits.

Key Words: milk mid-infrared, genetic improvement, dairy cows

Breeding and Genetics Symposium: Joint Interbull/JAM Session: Use of genomics to improve limited and novel phenotypes in animal breeding

15 The effect of genomic technologies in the selection of novel phenotypes in dairy crossbreeding programs. Richard J. Spelman*, Mathew D. Littlejohn, Ric G. Sherlock, and Steve Davis, *Livestock Improvement Corporation, Hamilton, New Zealand.*

Genomic selection in dairy cattle has been successfully applied for milk production traits in many countries around the world. This has been enabled through the routine collection of phenotypes over several years and the large body of animals that have been genotyped. The application of genomics for non-routinely collected phenotypes has been less successful due to the cost of phenotyping and the smaller number of animals available for genotyping. Genomic estimates for Johne's susceptibility and residual feed intake have been recently commercialized in the New Zealand dairy population. Johne's susceptibility has been estimated in a case control experimental setting. Over 1,500 animals that have been identified to be affected by Johne's have been genotyped and compared with a control derived from the general population of animals that have been genotyped in the LIC genomic selection data set. The accuracy of evaluation for Johne's susceptibility is approximately 30% with a heritability of 18%. Residual feed intake was measured over 2000 growing Holstein-Friesian heifers in New Zealand and Australia, which were phenotyped over 42 d for feed intake and live weight gain. Genomic estimates for residual feed intake have a reliability of 10%.

Key Words: dairy, genomics, crossbreeding

16 Using genomic technologies to improve broiler health and production. Rachel J. Hawken*, *Cobb-Vantress, Siloam Springs, AR.*

Health and welfare traits have always been a critical factor toward the genetic improvement of broiler breeding stock. Current trends toward antibiotic free broiler production have emphasized the need to engage new technologies toward the improvement of these traits. Genomic technologies such as genome selection, genome sequencing, and mutation detection all offer great opportunities to advance these traits. For example, with the aid of genomics, genetic information from birds in disease challenged environments (on pure line breeders or crossbred product birds) can be utilized for the selection of superior breeding stock at the pedigree level, in non-diseased environments. Furthermore, the genetic basis of genetic diseases can be identified and deleterious alleles eliminated from breeding programs. This presentation will illustrate various opportunities for improving health and production traits using genomics at Cobb.

Key Words: poultry, genomics

17 Application of genomic technologies to improve feed efficiency traits in swine. Kent A. Gray*, *Smithfield Premium Genetics, Rose Hill, NC.*

One challenge that faces the US pork industry is the efficient use of feed resources as feed costs continue to be the largest variable expenditure. Typically, feed efficiency is measured as feed conversion ratio (FCR) or calculated through residual feed intake (RFI). Regardless of the measure defined as feed efficiency, average daily gain (ADG) and average daily feed intake (ADFI) remain the 2 main components for estimating nutrient utilization traits. Several studies demonstrate improvement of feed efficiency through selection programs focused on improving either FCR or RFI. However, these programs require recording individual feed intake, which is labor intensive, time consuming, and requires specialized equipment. Additionally, data from feed intake recording equipment (FIRE) systems contain several data errors that require careful editing before the data can be used. With the introduction of advanced genomic technologies in livestock species there is an opportunity to improve selection of feed efficiency. Genomic tools have helped us identify genomic regions associated with feed efficiency and other production traits through whole-genome association studies. One region in particular located on SSC1 ranging from 166 to 170 Mb was significantly associated with ADFI, ADG, and backfat (BF), where *SOCS6* and *DOK6* are proposed as the most likely candidate genes. The use of whole-genome selection methodologies can also be used to improve response to selection by increasing accuracy. Variance components were estimated with AIREML and (G)EBV were computed with either BLUP or single-step genomic BLUP (SSGBLUP). Comparisons of reliabilities between traditional BLUP estimates and SSGBLUP estimates indicate that GEBV estimates for FCR and component traits BF, ADFI, ADG, and off-test weight (WT) have increased reliabilities by 9% to 60% when compared with traditional EBV estimates. Because of this increased accuracy, we can conclude that application of genomic technologies will help us improve feed efficiency traits in swine.

Key Words: feed efficiency, swine, genomic selection

18 The role of genomics in the development of novel phenotype-based products in the beef industry. Matthew A. Cleveland*, *Genus plc, DeForest, WI.*

The use of genomics in beef cattle evaluation has experienced relatively widespread adoption. Breed associations and improvement programs have used genomic information to varying degrees, particularly for well-characterized traits. The opportunity for transformational change from genomics, however, lies with novel traits that are typically more difficult to capture or describe during normal production processes. Genomic associations have been reported for novel traits such as those related to feed efficiency, animal health, meat quality and consumer preference, reproduction, healthfulness of beef and effects on human health, the environment and animal welfare. While several interesting genomic regions have been identified across traits, there is scant evidence of application in structured breeding programs for beef cattle. The collection of phenotypes for some novel traits can have near-term direct genetic and economic impact. For example, improvements in individual feed intake or even disease resistance can generate measurable increases in beef system profitability. Other novel traits of interest, such as fatty acid composition or methane production, have large perceived consumer impact, but remain aspirational in terms of providing a direct economic benefit or even a logical selection objective. Regardless of the trait, the optimal use of genomics in a beef improvement program requires a structured data collection system, or large project-based phenotyping efforts, to realize the benefits and deliver a truly differentiated product. Ultimately, the value derived from genomics-enabled differentiation must at a minimum cover the cost of the investment. The value of genomics in the beef industry is difficult to elucidate without some measure of actual or "virtual" integration of the value chain, which is often lacking. Commercial breeding programs, such as Genus ABS, have developed the structure to deliver well-defined genetically improved products to the beef supply chain. At the core of this improvement is the ability to make rapid progress for economically relevant traits, which is often optimally achieved with the aid of genomic information.

Key Words: beef cattle, genomics, novel phenotype

19 Using genomics to enhance selection of novel traits in North American dairy cattle.

Jacques P. Chesnais*[1], Mehdi Sargolzaei[1,3], Filippo Miglior[2,3], and Jennie E. Pryce[4], [1]*The Semex Alliance, Guelph, Ontario, Canada,* [2]*Canadian Dairy Network, Guelph, Ontario, Canada,* [3]*CGIL, University of Guelph, Guelph, Ontario, Canada,* [4]*Department of Economic Development, Jobs, Transport and Resources, Bundoora, Victoria, Australia.*

Genomics offers new opportunities for the effective selection of novel traits. For traits such as mastitis resistance, hoof health, or milk composition records based on medium infrared (MIR) data, for example, enough records are usually available to carry out genomic evaluations based on sire genotypes and the phenotypes of their daughters. For traits that are more novel or expensive to collect, such as individual feed intake or immune response, the development of a cow reference population is the most effective approach. The reliability of the resulting genomic predictions depends primarily on the size of the reference population and on trait heritability, as shown by Daetwyler et al. (2008). To provide an empirical check of these theoretical estimates of reliability, the reliability of genomic selection was estimated for various traits using a reference population of 1,000 to 10,000 Canadian-born Holstein cows that had been genotyped with a panel of 6,000 SNP or more. All genotypes were imputed to 50K. The effects of SNP were estimated from cow records only, after excluding the dams of validation bulls. Bulls first proven in 2013 and 2014 were then used to carry out a validation and estimate the accuracy of genomic selection based on these SNP effects. Differences between accuracies obtained this way and using the Daetwyler formula are reported for traits of varying heritability and degree of indirect selection. Results confirm that large reference populations are usually required to achieve adequate accuracy. In many instances, the accuracy of genomic selection for novel traits can be increased through the use of indicator traits. Cow size and MIR data are used as examples to show how they can increase the accuracy of genomic selection for feed efficiency. Expected rates of genetic progress are calculated for each scenario, using the selection intensities and generation intervals currently realized in North American dairy cattle.

Key Words: novel trait, genomic evaluation, dairy cattle

ADSA-SAD (Student Affiliate Division) Undergraduate Competition: ADSA-SAD Undergraduate Student Poster Competition

M1 An analysis of cow cooling methods in lactating Jersey cows, while simultaneously assessing the accuracy of infrared thermography in characterizing heat stress. Amy P. McBirney*[1], Stan L. Henderson[1], and Luis A. Rodriguez[2], [1]*California Polytechnic State University, San Luis Obispo, CA,* [2]*Innovative Liquids LLC, El Dorado Hills, CA.*

Cow comfort is a crucial component to maximizing dairy cattle health and productivity. Combating high temperatures is of particular importance to dairy producers located in California's Central Valley who must ensure their herd remains cool and comfortable to maintain animal wellbeing and productivity. The purpose of this project was to determine differences in heat stress based on cow cooling methods on a California Jersey dairy while also using infrared technology to measure and predict heat stress. Infrared rear udder surface temperatures, digital rectal temperatures and respiration rates were collected on 30 Jersey cows. Fifteen cows from each of 2 different high-producing mature cow pens were selected to obtain measurements during 3 different times: morning in freestalls (8–9:15 AM), mid-morning in the milk barn (9:30–11 AM), and afternoon in freestalls (1:30–2:45 PM). Management and freestall barn design were similar between pens, with the exception of differing cow cooling methods. One pen was provided with soakers only, while the other pen was provided with soakers and fans. Low to high heat stress was observed in the sample of 30 cows throughout the day. The lowest respiration rates, rectal temperatures, and udder temperatures were observed in the milking parlor during the mid-morning, particularly as cows stood in the holding pen for greater lengths of time. Rectal temperatures for cows in Pen 6 (no fans) differed significantly ($P = 0.003$) from rectal temperatures measured on the same group of cows when in the milk barn. The positive response to the more frequent soaking times of the milk barn cooling system suggests this method may be more effective in reducing the effect of heat stress than either of the freestall cooling systems. Infrared body surface temperature is currently being explored as a potentially dependable and accurate means of quantifying heat stress in cattle (Jones, 1999; Berg et al., 2013). Data indicated a significant correlation ($P = 3 \times 10^{-4}$) between infrared udder temperatures and digital rectal temperatures, suggesting that infrared thermography is valuable in identifying heat stress.

Key Words: heat stress, infrared thermography, cow comfort

M2 Comparison of dry matter measurements between a hand-held near infrared unit and 48 hour-60°C oven drying with corn silage and alfalfa silage. Derek M. Donnelly*, Robb W. Bender, and David K. Combs, *University of Wisconsin-Madison, Madison, WI.*

Calculating accurate dry matter of forages is important for adjusting rations on a day-to-day basis. This study evaluated the accuracy of a hand-held near infrared (NIR) unit (Moisture Tracker, Digistar Inc., Fort Atkinson, WI) compared with conventional oven drying for 48 h at 60°C using 2 different forages: alfalfa silage and corn silage. Twenty frozen samples each of alfalfa silage and corn silage were obtained from a commercial feed testing laboratory (Rock River Labs Inc., Watertown, WI). The NIR unit was calibrated for each different forage type. Approximately 105 g of each sample was spread over an 8 cm × 8 cm area on brown paper and scanned with the NIR unit 30 times, each scan was in a different location on the sample. Upon the thirtieth measurement, the NIR unit would show the average dry matter content on its display. The average of the 30 scans was recorded as the dry matter content of the sample. Two 100-g subsamples of each forage sample were weighed into aluminum pans. The samples were then oven-dried for 48 h at 60°C and weighed back to calculate oven dry matter. Dry matter determined by NIR and oven were compared by *t*-test within each forage type. Dry matter determined for corn silage via the NIR (39.59%) were similar ($P = 0.557$) to those obtained from conventional oven drying (39.92%). Dry matter estimated from the NIR for alfalfa (48.6%) were greater ($P < 0.0001$) than obtained from oven drying (44.17%). The results of this experiment showed that dry matter values were similar with oven dry matter when analyzing corn silage, but were not similar when analyzing alfalfa silage.

Key Words: dry matter, near infrared, dairy cattle

M3 Evaluation of pH test strips for accuracy in determining pH of cow urine. Colleen N. Curtiss*[1], Kayleigh G. Gratz[1], David P. Chamberlin[1], Timothy F. Brown[2], and Elizabeth L. Karcher[1], [1]*Michigan State University, East Lansing, MI,* [2]*West Central, Ralston, IA.*

Hypocalcemia is a periparturient metabolic disorder that is costly to the US dairy industry. One strategy to reduce incidences is to feed anionic supplements during the close-up period. The effectiveness of this strategy may be monitored by evaluating urine pH of cows, with an effective preventative pH in the range of 6.0 to 7.0. There are multiple commercial urine pH strips available to test the acidity of urine. The objective of this study was to evaluate several pH test strips for accuracy in determining pH of cow urine. Urine was collected from 4 mid-lactation Holstein dairy cows, composited, and distributed into ten 250-mL samples. The pH of each sample was then adjusted, using 12 *N* HCl and a laboratory pH meter, to 1 of 10 pH values: 5.5, 6.0, 6.25, 6.5, 6.75, 7.0, 7.25, 7.50, 7.75, and 8.0. The pH of each standard was recorded at the end of sampling and the average of the 2 values (5.68, 6.10, 6.33, 6.63, 6.81, 7.06, 7.33. 7.57, 7.76, and 8) was used to compare the accuracy of the strips. Seven evaluators assessed each pH sample with 9 commercially available pH strips to determine equivalence between the pH strip reading and the pH of the prepared standard. Confidence intervals (90%) were calculated for each pH strip and sample combination and compared with the standard. Seven of the 9 strips fell within the 90% confidence interval ranges for 1 to 3 urine samples and 1 strip was within the range for 5 samples. Of the pH strips tested, only 1 was able to identify a correct pH for 7 of the 10 urine samples. Based on our results, this strip could be used to identify urine pH in a range from 5.7 to 7.75. These results depict the variation in the accuracy of the test strips to detect urine pH. Producers must be aware of these variations as they utilize urine pH to measure the effect of feeding anionic supplements in a transition cow program.

Key Words: hypocalcemia, pH, urine

M4 Rumen epithelial gene expression in response to oral $NaHCO_3$ treatment in Holstein bull calves. Emily R. Meese*[1], Taylor T. Yohe[1,2], Hannah L. M. Tucker[1,2], and Kristy M. Daniels[1,2], [1]*The Ohio State University, OARDC, Wooster, OH,* [2]*Virginia Tech, Blacksburg, VA.*

While common, concern exists that low rumen pH in periruminant calves should be avoided. Oral $NaHCO_3$ can increase rumen pH. The objective was to study effects of oral administration of $NaHCO_3$ on expression of select genes in the rumen epithelium at 49 d of age. Genes included in the investigation encode for proteins that are used for volatile fatty acid (VFA) absorption, pH regulation, and $NaHCO_3$ transport. Neonatal Holstein bulls (n = 12) were randomly assigned to one of 4 treatments, arranged in a 2 × 2 factorial design. Factors were treatment [control (con) or $NaHCO_3$ (bicarb)] and oral route of delivery (water-based drench or gelatin-filled capsule). Administration of $NaHCO_3$ dose was adjusted weekly and reached a maximum of 48 g/d. Treatments were administered before each of 2 daily feedings. Calves were fed 543 g DM/d of a 22% CP, 20% milk fat replacer, had access to a 20% CP starter and water. At wk 8, rumen tissue was obtained from the cranial ventral region of each calf. Total RNA was extracted from the epithelial portion of rumen tissue, reverse transcribed into cDNA, and used in quantitative reverse transcription PCR assays. Relative abundance of 10 VFA transporters, pH regulators, anion exchangers and cotransporters were quantified. Rumen pH was not increased by $NaHCO_3$, (measured 2, 4, and 6 h post-dosing) but urine pH was. This observation went against past findings regarding ruminal pH with oral $NaHCO_3$ administration but generally supports the notion that post-ruminal, rather than ruminal, $NaHCO_3$ absorption and metabolism occurs in young calves. In support of this, $NaHCO_3$ had no effect on expression of any ruminal gene measured here. Findings suggest that in young calves, low rumen pH is part of the developmental process and regulatory mechanisms associated with non-diffusional VFA transport, rumen pH, and $NaHCO_3$ transport are not affected by supplemental $NaHCO_{3.}$

Key Words: dairy calf, rumen, gene expression

M5 Effect of overstocking at the feed bunk on indicators of cow temperament.

Danielle N. Coleman*, Maurice L. Eastridge, Jessica A. Pempek, and Kathryn L. Proudfoot, *The Ohio State University, Columbus, OH.*

Our objective was to investigate the effect of overstocking the feed bunk on dairy cow behavioral responses to human approach and reactivity to blood sampling. One hundred and 20 dry Holstein cows were allocated to 1 of 2 treatment groups with different stocking densities [overstocked (OS): 0.88 headlocks/cow; understocked (US): 1.17 headlocks/cow]. Over 2 testing periods (7 d apart), flight response was assessed using a human-approach test with a 5-point ordinal scale defining the distance at which the cow stepped away from the approaching experimenter (0 = not approachable from 3 m to 4 = cow moves away when experimenter is 0 m from the cow). A qualitative assessment was also made of the cow's response to the experimenter using a visual analog scale (VAS) that included the terms: relaxed, nervous, alert, shy, aggressive, social, and curious. Reactivity to blood sampling via the coccygeal vein was assessed in the pen using a 4-point scale (0 = least reactive to 3 = most reactive). Data were analyzed through a mixed model analysis, using treatment, time, and their interaction. The relationship between qualitative measures was assessed using a Pearson correlation. Treatment did not affect the cow's flight response; however, there was a significant treatment by time interaction whereby flight response scores decreased with time in OS cows and increased with time in US cows (OS: 1.65 to 1.47, US: 1.33 to 1.68; $P = 0.02$). Reactivity to blood sampling did not differ by treatment (OS: 1.11, US: 0.98; $P = 0.47$), and there was also no treatment by time interaction (OS: 1.17 to 1.11, US: 1.01 to 0.98; $P = 0.88$). The overall correlation between qualitative terms was low. However, the terms 'relaxed' and 'nervous' showed a significant negative correlation (OS: r = −0.71; $P < 0.0001$; US: r = −0.61; $P < 0.0001$). In conclusion, overstocking the feed bunk affected the animal's response to an approaching human. Cows in the OS treatment became less approachable over time, which may indicate fear, stress, or an increase in arousal. Future research should investigate the effect overstocking may have on cow temperament for a longer duration, as this may further decrease approachability.

Key Words: stocking density, feed bunk, temperament

M6 Relationship between cow lying behavior and freestall barn design.

Jennifer Callanan* and Amber L. Adams-Progar, *Washington State University, Pullman, WA.*

There is concern that barn design may cause underutilization of isolated freestalls and, in turn, lead to overcrowding and decreased cow comfort. The objective of this study was to observe and describe cow utilization of isolated stalls in one pen of lactating dairy cattle. One pen of 67 Holstein cows, with lactations ranging from one to 7, was selected for observations because the pen was designed to include one row of 8 stalls (isolated stalls = IS) out of a total of 72 stalls that faced the northwest concrete wall of the barn. This design allowed cows within the IS to face a wall rather than other cows. All 67 cows were randomly assigned a study number and identified with fluorescent animal marking paint. Cow attendance in the IS was observed via 2 time-lapse cameras mounted on the northeast and southwest ceilings of the barn. Time-lapse images were captured at 20-s intervals over the course of 5 d. The scan sampling method was implemented to record the number of cows within the IS, cow study numbers, and cow behavior (standing or lying). Descriptive statistics and correlations were applied to analyze the data. A correlation was detected between time of day and the percentage of cows utilizing the IS ($r = -0.53$, $P = 0.007$), where maximum attendance (4.78 ± 0.19% of cows) occurred at 0300 h and 0500 h, and minimum attendance (0.30 ± 0.08% of cows) occurred at 1000 h. Throughout the study, most the cows within the IS preferred to lie down (95.25 ± 2.27% of cows) rather than stand (4.75 ± 2.27% of cows). Thirty-seven percent of the cows in the pen attended the IS at least once during the study, with 7.5% of the cows accounting for 64% of the visits to the IS. No correlation was detected between cow lactation and IS utilization ($r = 0.007$, $P = 0.95$). These results indicate that the IS in this study were utilized primarily for lying purposes by a small percentage of cows; however, additional research is needed to determine whether cow health or social status may explain the small number of cows that visited the isolated stalls throughout this study.

Key Words: cow comfort, lying behavior, barn design

M7 Effect of carbon dioxide on oxidative stability of raw milk.

Jayendra Kumar Amamcharla and Jia Xin Tang*, *Kansas State University, Manhattan, KS.*

Sensory attributes play a critical role in the consumer acceptability of pasteurized milk. Any off-flavor present in raw milk is carried onto the pasteurized milk. One such off-flavor is oxidized flavor (OF). This can have a huge economic impact on dairy farmers as well as on milk processors. Raw milk invariably undergoes oxidative changes as soon as the milk leaves the udder. Still, the rate of OF development mainly depends on nature, concentration, and distribution of pro- and anti-oxidants in the milk system. Antioxidants in raw milk play an important role by donating a hydrogen ion to terminate auto-oxidation. In this process, the antioxidant capacity raw milk diminishes during storage. Recent studies showed that the total antioxidant capacity (TAC) of raw milk decreases by 10% after 24 h and 27% after 48 h of storage. The objective of the present work was to mitigate the reduction in TAC of raw milk by using carbon dioxide (CO_2). It has been established that

CO_2 inhibits growth of psychrotrophic bacteria and extends the shelf-life of raw milk but the effect of CO_2 treatment on TAC of raw milk has not been established. Approximately one gallon of raw milk was divided into 4 sub-samples and 3 of the sub-samples were injected with CO_2 to 3 pH levels (pH 6.65, 6.55, and 6.45) and the remaining fourth subsample was used as a control. Subsequently, each of these 4 sub-samples were divided into 25 equal samples and stored at 4°C. On each experimental day, 5 equal samples were withdrawn and analyzed using a modified ferric reducing ability of plasma (FRAP) assay. Modified FRAP assay was used to determine the TAC of samples on Day 0, 1, 2, 3, and 4. The data were analyzed as repeated measures design using the MIXED procedure in SAS. The presence of CO_2, storage time, and their interaction significantly ($P < 0.05$) influenced the FRAP value of raw milk. It was observed that the TAC of all raw milk samples was gradually reduced during refrigerated storage. However, the drop in TAC was found to be significantly ($P < 0.05$) lower in CO_2 treated milk. Overall, CO_2 treatment of raw milk shows potential in reducing TAC loss during storage of raw milk.

Key Words: modified FRAP assay, total antioxidant capacity, raw milk

M8 Hepatic patatin-like phospholipase domain-containing protein 3 protein is regulated during the transition to lactation period in dairy cows.

Ryan S. Pralle*, Rafael C. Oliveira, Tawny L. Chandler, Sandra J. Bertics, and Heather M. White, *University of Wisconsin-Madison, Madison, WI.*

Patatin-like phospholipase domain-containing protein 3 (PNPLA3) is a membrane bound triglyceride lipase that contributes to lipid metabolism in the liver and is responsive to feed restriction. PNPLA3 mRNA expression is dynamic in dairy cows with lower expression during negative energy balance. The objective of this study was to characterize PNPLA3 protein abundance in transition cows subjected to fatty liver induction. Multiparous cows were blocked by expected calving date and randomly assigned to a control (n = 3) ad libitum intake group, or a fatty liver induction (n = 6) group that was overfed during the dry period, and feed restricted (80% of dry matter intake) at +14 d relative to calving (DRTC) until onset of clinical ketosis. Liver biopsies were taken in the prepartum (−28, −14 DRTC), lipid accumulation (+1, +14, +28 DRTC), and recovery (+42, +56 DRTC) periods and at the time of clinical ketosis. Liver PNPLA3 protein abundance was determined through Western blot analysis and normalized to total protein. Data were analyzed using PROC MIXED of SAS 9.3. Abundance of PNPLA3 was analyzed with main effects of treatment, period, and treatment x period, and random effect of cow. Protein abundance was also analyzed by PROC MIXED and PROC CORR based on total lipid accumulation diagnosed as high (>15%, dry matter) or low (<15%, dry matter). All fatty liver induction cows became clinically ketotic and developed fatty liver. Abundance of PNPLA3 was greater ($P = 0.02$) during the recovery period compared with the accumulation period (1.12 vs. 0.79 ± 0.09, arbitrary units). Cows with high liver lipids had decreased ($P < 0.01$) PNPLA3 abundance compared with cows with low liver lipids (0.69 vs. 1.0 ± 0.08, arbitrary units). There was a negative correlation ($P < 0.01$; $r = -0.427$) between liver lipid concentration and PNPLA3 abundance. These data indicate that regulation of PNPLA3 may influence liver lipid accumulation and potential recovery from fatty liver disease.

Key Words: patatin-like phospholipase domain-containing protein 3, adiponutrin, fatty liver

M9 Effect of management practices and housing type on somatic cell counts in Kentucky dairy farms.

Mickayla A. Myers*, Amanda E. Stone, and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

The objective of this research was to compare the effects of management practices and housing types on SCC. Data were acquired for 34 Kentucky dairy herds, participating in the Southeast Quality Milk Initiative project. Herds were grouped into SCC categories where low = 2013 mean bulk tank SCC ≤250,000 cells/mL (n = 16), and high = >250,000 cells/mL (n = 18). Herd size ranged from 42 to 660 lactating cows. Thirty-eight percent (n = 6) and 50% (n = 9) of low and high herds, respectively, were housed in freestalls. Lactating cow bedding of sawdust or wood shavings was most commonly used for low (47%, n = 7) and high (53%, n = 9) herds. Fans were provided in the parlor and housing for low (75%, n = 12) and high (67%, n = 12) herds. Mastitis-treated cows were not commonly housed separately from lactating cows for low (75%, n = 12) and high (67%, n = 12) herds. Lactating cow housing was split into 3 respective groups: total confinement, pasture access for <4 h a day, and pasture access for ≥4 h a day. Total confinement was used in 50% (n = 8) and 33% (n = 6) of low and high herds, respectively. Pasture access for <4 h a day was 6% (n = 1) and 17% (n = 3) for low and high, respectively. Finally, pasture access for ≥4 h a day was 38% (n = 6) and 50% (n = 9) for low and high, respectively. Of the herds using freestalls, manure was removed from stalls twice daily in 67% (n = 8) and 77% (n = 10) for low and high herds, respectively. Soakers were used in 31% (n = 5) and 41% (n = 7) of low and high herds, respectively. Udder hair was singed or clipped in 25% (n = 4) and 39% (n = 7) of low and high herds, respectively. Overall system checks of the parlor were performed annually in 31% (n = 5) and 53% (n = 9) of low and high herds, respectively. Results of this research may be used to help producers improve their dairy operations by understanding the management practices low and high SCC herds implement. This work was supported by a grant award from USDA-NIFA-AFRI (2013-68004-20424).

Key Words: low SCC, mastitis management practices, milk quality

M10 Effect of milking procedures and mastitis detection methods on somatic cell counts for Kentucky dairy herds.

Kerri A. Bochantin*, Amanda E. Stone, and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

The objective of this research was to compare the effects of milking procedures and mastitis detection methods on SCC. Data were acquired for 34 Kentucky dairy herds participating in the Southeast Quality Milk Initiative project. Herds were grouped into SCC categories where low = 2013 mean bulk tank SCC ≤250,000 cells/mL (n = 16; L), and high ≥250,000 cells/mL (n = 18; H). Herd size ranged from 42 to 660 cows. Fifty 6 percent (n = 10) of H and 38% (n = 6) of L herds used the California Mastitis Test (CMT) to detect clinical mastitis. Similarly, 33% of H (n = 6) and 31% (n = 5) of L herds used CMT to detect subclinical mastitis. All herds pre- and post-dipped (n = 34). Pre-dip application methods included pre-dip with a non-return dip cup with commercial disinfectant (H = 94%, n = 17; L = 80%, n = 12), non-return dip cup with homemade disinfectant (H = 6%, n = 1), and applied by sprayer with commercial disinfectant (L = 20%, n = 3). Teat drying methods included multiple-use paper towels (H = 6%, n = 1; L = 13%, n = 2), single-use paper towels (H = 47%, n = 8; L = 27%, n = 4), multiple-use cloth towels (L = 20%, n = 3), and single-use cloth towels (H = 47%, n = 8; L = 40%, n = 6). Pre-stripping was used in 72% of H (n = 13) and 75% of L (n = 12) herds. Post-dip application methods included dip cups with commercial disinfectant (H = 94%, n = 17; L = 94%, n = 15) or homemade disinfectant (H = 6%, n = 1). Wearing latex or nitrile gloves "always" during milking was practiced in 33% of H (n = 6) and 81% of L (n = 13) herds. Producers were asked to estimate the cost of clinical mastitis and answers ranged from \$0 to \$250 (26%, n = 9), \$251 to \$500 (35%, n = 12), \$501 to \$750 (3%, n = 1), \$751 or more (6%, n = 2), or unknown (24%, n = 8). When asked to rate the pain experienced in a mild case of clinical mastitis, responses ranged from 0 to 2 (24%, n = 8), 3 to 5 (62%, n = 21), and 6 to 8 (15%, n = 5), where 1 is no pain and 10 is severe pain. Responses for rating severe clinical mastitis pain included 5 to 8 (32%, n = 11) and 9 to 10 (68%, n = 23). Results of this survey may be used to improve mastitis management in dairy cattle herds in Kentucky.

Key Words: mastitis, milking procedure, Kentucky

M11 Effect of a probiotic on dairy calf diarrhea and growth rate.

Alexis C. Thompson*, Donna M. Amaral-Phillips, and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

Probiotics may prevent or reduce illness occurrence. The objective of this study was to observe the effects of a probiotic (Protect, Provita Animal Health, Omagh, Northern Ireland) on calf diarrhea incidence and average daily gain. This study was conducted at the University of Kentucky Coldstream Dairy during the winter of 2014 and 2015. All female and male Holstein calves were enrolled at birth, fed a colostrum replacer (Bovine IgG Colostrum Replacer, Land O'Lakes, Shoreview, MN), and did not receive any vaccinations. Calves were housed in individual sawdust-bedded hutches with ad libitum access to water and 18% CP starter until weaning at 8 weeks of age. Calves were fed a 20:20 non-medicated milk replacer (total 0.71 kg powder daily) twice daily. Calves were randomly assigned to one of 3 treatments: 10 g liquid oral probiotics at birth (O, n = 10), 10 g liquid oral probiotics at birth plus 1 g powder probiotic once daily incorporated in morning milk from d 2 to 14 (O+P, n = 9), and a negative control (CON, n = 9). Calves were weighed once weekly using a scale (Cardinal Digital HSDC Series, Cardinal Scale Mfg. Co, Webb City, MO). Feces were scored once weekly, where 1 represented firm feces which settled once hitting the ground, 2 feces that did not hold form well, 3 feces that readily spread, and 4 feces that was liquid and splattered (Larson et al., 1977). A fecal score of 4 indicated diarrhea. The GLM and FREQ procedures of SAS Version 9.3 (SAS Institute Inc., Cary, NC) were used to analyze data. The incidence of an episode of diarrhea was 80% for O, 75% for O+P, and 88% for CON ($P = 0.79$). Mean fecal scores from birth to weaning were 2.18 ± 0.55 for O, 2.18 ± 0.35 for O+P, and 2.28 ± 0.52 for CON ($P = 0.73$). Calves were confirmed with *Rotavirus* and *Coronavirus* through PCR in all treatment groups. Average daily gain during the study was 0.47 ± 0.10 kg/d for O, 0.52 ± 0.10 kg/d for O+P, and 0.56 ± 0.10 kg/d for CON ($P = 0.42$). No significant differences were observed among treatments for average daily gain, fecal score, or incidence of calf diarrhea.

Key Words: calf diarrhea, probiotic, growth rate

M12 Genomic testing of female Holsteins: A resource for selection and improvement.

Kimberly M. Davenport*, Joshua J. Peak, and Brenda M. Murdoch, *University of Idaho, Moscow, ID.*

Genomic testing is providing a powerful tool for use in dairy management decisions across the United States. While genetic testing has been more broadly implemented for sire selection, its use in selection of females is only now being applied. The identification of females with the most promising genetic potential can influence selection decisions including replacement heifers and cull cows, as well as identify female candidates for embryo donations. Identifying the genetic potential in both male and female contributors to the herd will accelerate genetic improvement and identify potential problems of disease carrier matings before they occur. The purpose of this study was to (1) confirm pedigree information with genetic parentage, (2) identify females that may carry a disease-associated allele, and (3) compare recorded herd data of cows that have been phenotypically selected for reproduction performance to genomic predictions of the Clarifide test. Purebred Holstein cows (n = 162) were sampled by ear punch. Tissue samples were sent to Zoetis and a low density Clarifide genomic test was used to correct pedigree parentage and evaluate the genomes for several markers associated with common selection parameters. Several traits economically important to dairy herds such as milk yield, milk fat component percentage, and traits related to reproductive efficiency and productive life, were compared with results from the Clarifide genomic tests for each animal. The accuracy of parentage records utilizing the parentage correction tool was used to eliminate animal misidentification. The relative similarity of the genomic prediction to phenotypic data and parentage corrections for these traits suggest all be incorporated into future management decisions to accelerate genetic progress of the herd. The sustainability of the US dairy industry will become more dependent upon the effective implementation and strategic use of genomic selection of desirable complex phenotypic traits.

Key Words: genetics, dairy, selection

M13 Effects of rubber coverings for slatted floor facilities on cattle performance and cleanliness.

Derrick S. Smith*, Bryant R. Chapman, Colleen N. Curtiss, Monica J. Atkin, Steven R. Rust, and Dan L. Grooms, *Michigan State University, East Lansing, MI.*

Approximately 1 to 3% of steers housed on slatted floors must be removed for lack of mobility and foot problems. The objective of this study was to compare animal performance and hide soiling of cattle housed on slatted floors with (RC) and without (NC) rubber coverings. Angus-based steers (250–300 kg) were randomly assigned to pens with NC (n = 4) or RC (n = 4). Each pen contained 7 steers at a stocking density of 6.9 m^2/steer. Locomotion scores, tail lesions, left carpal joint circumference, and hoof dimensions were recorded and reported in a companion abstract. Average daily gain, feed conversion efficiency, cleanliness, and carcass traits were collected and reported. Hide cleanliness was graded on a scale of 0 to 9, with 0 being less than 5% soiled and 9 being completely soiled. Cattle housed on the rubber-covered slats had more soiling of the hide ($P < 0.05$) and slightly lower dressing percentages ($P < 0.13$) than steers on concrete slats. Average daily gain, dry matter intake and feed conversion efficiency were similar among treatments. Cattle on NC tended to have more backfat thickness ($P < 0.06$) and high yield grade scores ($P < 0.05$) compared with RC. There were negative correlations between toe angles of the front ($r = -0.86$; $P = 0.006$) and rear ($r = -0.72$; $P = 0.04$) hooves to carcass adjusted feed conversion efficiency. In summary, provision of rubber covers for concrete slats had minor effects on overall cattle performance. Cattle fed on rubber-covered slats may have more soiling of the hide and lower dressing percentages.

Key Words: feed conversion efficiency, slatted floor, dressing percent

M14 Expression of aryl hydrocarbon receptor in the endometrium of dairy heifers during early pregnancy and the estrous cycle. Michelle C. Hartzell*, Troy L. Ott, Manasi M. Kamat, and Sreelakshmi Vasudevan, *Pennsylvania State University, State College, PA.*

Early embryo loss in dairy cattle is a major economic cost to dairy producers. A dairy operation with a low herd conception rate must use more feed and resources to be as productive as a herd with a higher conception rate and shorter calving interval. Our overall hypothesis is that a portion of these early embryo losses are mediated by aberrant response of the uterine immune system to the embryo. This research seeks to improve our knowledge of a potential cellular mechanism that may be involved in maintaining pregnancy, the aryl hydrocarbon receptor (AhR). The AhR is a ligand activated transcription factor involved in differentiation of T regulatory cells (T reg). We hypothesize that activation of T reg by AhR causes suppression of the maternal immune response to the allogeneic embryo. Holstein dairy heifers (n = 22) were estrous synchronized and bred by artificial insemination (Day = 0) or remained cyclic. Uterine endometrium was collected from heifers on Day 17 of the estrous cycle (n = 9), and Days 17 (n = 9) and 20 (n = 4) of pregnancy. Total cellular RNA was isolated from endometrial tissue using Trizol. The RNA was converted to cDNA and subjected to PCR using primers designed to recognize the bovine AhR. A single amplicon was visualized by gel electrophoresis and the DNA was excised, purified, and sequenced to confirm its identity. Purified cDNA from the amplicon was used to create a standard curve and a qPCR assay was developed and validated with a slope of −3.5 and efficiency of 93%. Analysis of steady-state mRNA abundance for AhR was conducted using RPL19 as the reference gene. Critical threshold (Ct) data were adjusted for RPL19 and $2^{-\Delta Ct}$ values were analyzed using PROC Mixed and orthogonal contrasts. Although AhR was abundantly expressed in the endometrium, there was no difference in AhR mRNA abundance between pregnant and nonpregnant heifers nor between d 17 and d 20 pregnant heifers ($P > 0.1$). Studies are ongoing to localize the AhR in endometrial tissue using immunofluorescence analysis. This study confirms the presence of the AhR gene in the bovine endometrium during the estrous cycle and early pregnancy.

Key Words: aryl hydrocarbon receptor (AhR), embryo

M15 Absence of milk residues after using a hydrogen peroxide pre-dip. Jamie E. Leistner*, Joey D. Clark, and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

Some pre-dips leave residues in bulk tank after milking. Hydrogen peroxide is digested by lactoperoxidase, an enzyme released from the mammary gland during milking, which would mean this teat dip would not leave residues in the milk. The objective of this study was to determine if hydrogen peroxide-based teat dip a (OxyCide, GEA, Naperville, IL) leaves a residue in the bulk tank milk after use as a pre-dip. The study was conducted using 97 Holstein cattle at the University of Kentucky Coldstream Dairy. Three samples were collected from the bulk tank 20 different times, 10 from the 3:30 a.m. and 10 from the 4:00 p.m. milking sessions; once at the beginning of milking, once during the middle, and once at the end of milking. The bulk tank is collected every other day so the dates of sampling were determined to have 10 a.m. and 10 p.m. samples before and after the bulk tank was emptied. The pre-dip was applied to the teats using teat dip cups. Then, 236.8 mL of milk from the bulk tank were collected into the same liquid measuring cup each sample. Peroxide test strips (Em Quant, Santa Ana, CA) were used to determine if hydrogen peroxide residues were present in the sample. In all samples collected throughout the study, the test strips tested negative for hydrogen peroxide residue. This study demonstrated that the enzymes in the milk successfully digested all detectable hydrogen peroxide from the pre-dip. This study suggests hydrogen peroxide can be used as a pre-dip to prevent any risk of residue left in the milk after milking.

Key Words: milk residue, hydrogen peroxide, pre-dip

M16 Effects of adding a pasteurized milk balancer on dairy calf growth and performance. Lydia H. Hoene*[1], B. Houin[2], and Tamilee Nennich[1,3], [1]*Purdue University, West Lafayette, IN,* [2]*Homestead Dairy, Plymouth, IN,* [3]*Famo Feeds, Freeport, MN.*

Milk is one of the largest costs of raising dairy calves. Therefore, increasing growth performance and efficiency of dairy calves is very important. The objective of this study was to determine the effect of adding a protein based pasteurized milk balancer (PMB) on the growth performance of dairy calves over the summer months. A total of 90 Holstein heifers were randomly assigned at 1 d of age to 1 of 3 treatments. The treatments were (1) 7.6 L/d of pasteurized milk (CONT), (2) 7.6 L/d of pasteurized milk supplemented with a PMB (PMB), and (3) pasteurized milk supplemented with a PMB and fed at a reduced volume amount of 5.4 L/d (LESS). The calves were fed milk 3 times a day and allowed ad libitum access to 20% CP starter. Calves were weighed at birth and measured every 2 wk until 8 wk of age for body weight (BW), hip height, heart girth circumference (HGC), and hip width. Starter intakes were measured weekly. Milk intake of calves was reduced to one-third of their milk allowance at 7 wk and they were weaned at 8 wks. Data were analyzed using Proc Mean of SAS with calf as the experimental unit. At 8 wk, BW were similar ($P = 0.18$) for all calves on the CONT, PMB, and LESS treatments (81.2, 84.9, 84.1 kg of BW, respectively). Average daily gain (ADG) was similar regardless of treatment and averaged 0.78 kg/d over the 8 wk. Total starter DM intake was similar for all treatments ($P = 0.71$) over the 8 wk, resulting in similar overall feed efficiency among treatments ($P = 0.53$) at 0.44, 0.44, and 0.41 kg of starter per kg of gain for CONT, PMB, and LESS, respectively. Hip heights at 8 wk tended ($P = 0.10$) to be greater for LESS compared with CONT (97.6 and 96.0 cm, respectively). There also tended ($P = 0.09$) to be a difference in HGC with PMB calves having a HGC of 104.4 cm compared with 102.3 cm for CONT, with LESS calves being intermediate at 103.4 cm. Hip widths were similar between treatments ($P = 0.26$). At 8 wk of age, supplementing calves with PMB tended to increase the HGC of calves, and feeding calves a reduced amount of milk with PMB added tended to result in taller calves compared with when calves were fed only pasteurized waste milk.

Key Words: dairy calves, pasteurized milk balancer, waste milk

Animal Behavior and Well-Being I

M17 Associations between feed push-up frequency, lying and feeding behavior, and milk composition of dairy cows. Emily K. Miller-Cushon*[1] and Trevor J. DeVries[2], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

The objectives of this study were to assess the effects of feed push-up frequency on lying behavior and feed sorting of dairy cows, and to determine associations between behavior and milk composition. Lactating Holstein dairy cows (n = 30; parity = 1.9 ± 1.1; mean ± SD) were individually housed in tie stalls, milked 2×/d, and offered ad libitum access to water and TMR (containing on DM basis: 25% corn silage, 25% grass/alfalfa haylage, 30% high-moisture corn, and 20% protein/mineral supplement), provided 1×/d. Cows were divided into 2 groups of 15 (balanced by DIM, milk production, and parity) and individually exposed to 2 treatments in a crossover design with 21-d periods: (1) infrequent feed push up (3×/d), and (2) frequent feed push up (5×/d). During the last 7 d of each period, DMI and milk production were recorded and lying behavior was monitored using electronic data loggers. During the last 2 d of each period, milk samples were collected for analysis of protein and fat content and feed samples were collected for particle size analysis. The particle size separator had 3 screens (19, 8, and 1.18 mm) and a bottom pan, resulting in 4 fractions (long, medium, short, fine). Sorting was calculated as the actual intake of each particle size fraction expressed as a percentage of the predicted intake of that fraction. Data were analyzed in multivariable mixed-effect regression models. Feed push up frequency had no effect ($P > 0.3$) on lying time (11.4 h/d; SE = 0.37) or feed sorting; cows sorted ($P < 0.001$) against long particles (78.0 ± 2.2%; mean ± SE) and for short (102.6 ± 0.6%) and fine (108.4 ± 0.9%) particles. Milk fat content increased ($P < 0.001$) by 0.1% for every 10% increase in sorting for long particles and was not associated with lying behavior or other cow-level factors. Milk protein content increased ($P < 0.003$) by 0.07% for every 1 h/d increase in lying time and by 0.05% for every 10% increase in sorting in favor of long particles. These results suggest that reduced lying time and sorting against long ration particles negatively affected milk composition. Further, this study did not find that altering feed push-up frequency affected feed sorting.

Key Words: feed sorting, lying behavior, milk

M18 Effect of timing of feed delivery on feeding behavior and productivity of dairy cows. Meagan T. M. King*, Robin E. Crossley, and Trevor J. DeVries, *Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

The objective of this work was to assess the effect of timing of feed delivery on behavior and productivity of cows milked 3×/d. Twenty-four lactating Holstein dairy cows (7 primiparous and 17 multiparous), milked 3×/d (at 1400, 2100, and 0700 h), were individually exposed to each of 2 treatments (over 21-d periods) in a replicated crossover design. Treatments were the manipulation of timing of TMR delivery, 2×/d, in relation to milking time: (1) feeding at milking time (at 1400 and 0700 h) and (2) feeding halfway between milking times (at 1730 and 1030 h). Milk production, feeding, and rumination behavior were electronically monitored for each animal for the last 7 d of each treatment period. Milk samples were collected for 2 of the last 4 d of each period for milk component analysis. Data were then summarized across treatment period by cow and analyzed in a general linear mixed model. With a feed delay, DMI was lower (26.3 vs. 27.6 kg/d; SE = 0.6; $P = 0.04$). Although there was no difference in feeding time (230.2 min/d), cows fed with a delay consumed their feed slower (0.12 vs. 0.13 kg DM/min; SE = 0.003; $P < 0.001$) and had more meals (10.1 vs. 9.2 meals/d; SE = 0.3; $P = 0.02$), which were smaller in size (2.8 vs. 3.1 kg/meal; SE = 0.1; $P = 0.008$) and shorter (27.9 vs. 30.8 min/meal; SE = 1.3; $P = 0.03$). Rumination time (8.7 h/d) and lying time (9.9 h/d) were similar between treatments. Cows without fresh feed at their 1400 h milking stood for less time following that milking (72.2 vs. 86.4 min; SE = 6.9; $P = 0.045$), however, no differences in this latency to lie down were seen for either of the other 2 milking times. Milk yield (46.3 kg/d), milk fat content (3.65%), milk protein content (2.90%) were similar between treatments. Given the difference in DMI and no change in yield, with a feed delay, efficiency of production was improved (1.80 vs. 1.69 kg milk/kg DMI; SE = 0.04; $P = 0.01$). These data suggest that moving the timing of feed delivery away from milking resulted in cows consuming their feed more slowly in smaller, more frequent meals, contributing to an improvement in efficiency of production.

Key Words: feed delivery, meal pattern, behavior

M19 Relationships between dry matter intake, rumination time, lying behavior, and milk yield in lactating cows. Dafu Shao*, Fengxia Wang, YaJing Wang, Shengli Li, and Zhijun Cao, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

The objective of this study was to investigate the relationship between dry matter intake (DMI) and rumination time (RT), lying behavior (lying time and frequency), and milk yield in dairy cows. Data were collected from 32 mature Holstein dairy cows (16 primiparous, PR; 16 multiparous, MP, parity = 1.7 ± 0.8; milk production = 10,019 ± 166 kg/year; mean ± SD). DMI was monitored using Insentec feed bins (Insentec BV, Marknesse, the Netherlands). RT was monitored electronically using HR-Tags (SCR Engineers Ltd., Netanya, Israel). Lying behavior was monitored using an activity logger (HOBO Pendant G; Onset Computer Corp., Cape Cod, MA). Data were analyzed by the R programming language (Mathsoft). According to the level of RT, cows were assigned to the low-RT group (L: RT = 277.65 ± 39.61 min/d; 8 PR and 8 MP) and the high-RT group (H: RT = 413.21 ± 46.89 min/d; 8 PR and 8 MP). One-way ANOVA was used to analyze the difference between H and L groups. There was no significant difference between H and L group in DMI (H: 20.59 ± 2.63 kg/d; L: 20.31 ± 3.34 kg/d; $P = 0.79$), lying behavior (lying time, H:690.44 ± 155.46; L:773.00 ± 163.41, $P = 0.20$; Lying frequency, H:11.25 ± 3.14, L:10.79 ± 3.39, $P = 0.43$), and milk yield (H: 32.04 ± 6.00 kg/d; L: 32.15 ± 4.31 kg/d; $P = 0.95$). Pearson correlation was used to describe associations among DMI, RT, lying behavior (lying time and frequency) and milk yield. Multiple Linear Regression analysis was performed with lm package of the R programming language. A significant positive relationship existed between DMI and milk yield ($P = 0.01$, $r^2 = 0.93$). Rumination time ($P = 0.34$) and lying behavior (Lying time, $P = 0.36$; and Lying frequency, $P = 0.14$) were not affected by DMI. Only the milk yield ($P < 0.01$) was significantly affected by DMI, and the equation was $\mathrm{DMI} = 8.97934 + 0.35762 \times \mathrm{MY}$, $R^2 = 0.3865$, and which MY represents milk yield. These results indicate that milk yield can be used to estimate DMI; however, RT and lying behavior are independent variables and not the suitable indicators for DMI.

Key Words: rumination time, lying behavior, DMI

M20 Association between lying behavior and subclinical ketosis in transition dairy cows. Emily I. Kaufman*[1], Stephen J. LeBlanc[2], Brian W. McBride[1], Todd F. Duffield[2], and Trevor J. DeVries[1], *[1]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [2]Department of Population Medicine, University of Guelph, Guelph, ON, Canada.*

The objective of this study was to characterize the relationship between lying behavior and subclinical ketosis (SCK) in transition dairy cows. A total of 339 dairy cows (107 primiparous and 232 multiparous) on 4 commercial dairy farms, in Eastern Ontario, Canada, were monitored for lying behavior and SCK from 14 d before calving until 28 d after calving. Daily lying time was measured using automated data-loggers 24 h/d. A blood sample was taken from the coccygeal vein of each cow for measurement of β-hydroxybutarate (BHBA) 1x/wk. Cows with BHBA ≥1.2mmol/L postpartum were considered SCK. Cases of retained placenta, metritis, milk fever, or mastitis during the study period were also recorded. Cows were categorized into 1 of 3 groups: healthy (H) cows had no SCK or any other health issue (n = 139); SCK (K) cows with no other health problems during transition (n = 97); or ketotic plus (K+) cows that had SCK and one or more other health problems (n = 53). Data were summarized by wk and analyzed in a repeated measures general linear mixed model. A 3-way interaction was found between parity, disease status, and wk ($P < 0.001$); thus, first lactation and multiparous (MP) cows were analyzed separately. There was no difference among H, K and K+ ($P = 0.5$) in daily lying time from 2 wk before (−2) to 4 wk after calving (+4) for first-lactation cows. In MP cows, an interaction of disease status and week was detected ($P < 0.001$). Prior to calving, lying time was similar for MP cows (746 ± 32.8 min/d), decreasing ($P < 0.001$) after calving to an average of 598 ± 10.8 min/d. Differences in lying time for MP cows were seen in wk +1 when K+ cows spent 92 ± 24.0 min/d more time ($P < 0.001$) lying down than H cows, and during wk +2 where K+ cows tended ($P = 0.07$) to spend 38 ± 21.3 min/d more time lying down than H cows. Differences in lying time were also seen in MP cows in wk +3 and +4 where K cows spent 44 ± 16.7 min/d and 41 ± 18.9 min/d, respectively, more time ($P \leq 0.03$) lying down than H cows. Overall, these results suggest that monitoring lying time might contribute to identifying MP cows experiencing multiple health issues, including SCK, after calving.

Key Words: transition cow, lying behavior, subclinical ketosis

M21 Metritic heifers search for a safe place. Julia C. Lomb[1], Julie M. Huzzey[2], Heather W. Neave*[1], Daniel M. Weary[1], Bianca Costa[1], and Marina A. G. von Keyserlingk[1], *[1]University of British Columbia, Vancouver, BC, Canada, [2]California Polytechnic State University, San Luis Obispo, CA.*

Isolation from the group is a common behavioral response to illness in social animals. Modern freestall barns do not provide a refuge area for sick cows, but animals feeling ill may be able to use the lying stall itself to get away from herd mates. First-lactation cows are smaller, and thus better able to stand with all 4 feet in a stall and benefit from its protection. The objective of this study was to determine if these cows increase standing in the stall when they develop metritis, a common uterine infection. Metritis diagnosis was based on vaginal discharge, scored on every third day between calving and 21 d in milk (DIM). First-lactation cows identified as metritic (M, n = 8) were paired with healthy individuals (H, n = 8), based on body weight and days in milk. Cows were housed in a dynamic, mixed-parity group of 20 and had access to 24 lying stalls. Cameras installed above the experimental pen allowed for 24 h of continuous observation. Time spent standing with either the 2 front feet or all 4 feet in the stall was measured using 5-min scan sampling of the video recordings. The observation period included the 3 d before diagnosis in the metritic animals and the corresponding DIM for healthy pairs. A Mixed procedure in SAS (SAS Institute Inc., Cary, NC) was used for statistical analysis. Time standing with 4 feet in the stall was normalized using a log-transformation; values reported are back-transformed geometric means and 95% CI. Metritic heifers spent more time standing with all 4 feet in the stall (102.5, 49–214 min/d; mean, 95% CI) than the paired healthy heifers (10.5, 5–22 min/d; mean, 95% CI; $P < 0.001$). Differences in time spent perching with the 2 front feet in the stall were not significant (M: 209.6 ± 31; H: 284 ± 31; LS means ± SE; $P > 0.1$). There was no significant difference in overall time spent standing in the stall. We suggest that cows experiencing malaise with the onset of metritis spend more time standing with 4 feet in the stall because they perceive this to be a protective environment.

Key Words: sickness behavior, disease, standing behavior

M22 Feeding and social behaviors change prior to metritis diagnosis in transition dairy cows. Heather W. Neave*, Julia C. Lomb, Julie M. Huzzey, Daniel M. Weary, and Marina A. G. von Keyserlingk, *University of British Columbia, Vancouver, BC, Canada.*

Metritis is common in the days after calving and can reduce milk production and reproductive performance. Early identification of metritic animals may improve the welfare of affected dairy cows and the economic viability of the farm. The aim of this study was to identify feeding and social behaviors that could be used for the early detection of metritis. Healthy Holstein cows were enrolled in the study 3 wk before calving and all behaviors were recorded using an electronic feeding system. Metritis was diagnosed based on condition of vaginal discharge assessed on d 6 after calving. Twenty-one primiparous and 12 multiparous cows were diagnosed with metritis (more than 50% pus, or watery and red-brown in color with putrid smell) with no other health conditions; these were compared with 49 healthy primiparous and 96 healthy multiparous cows. In the 5 d leading up to clinical diagnosis, metritic primiparous cows ate less (metritic: 13.0 ± 0.42 kg DM/d; healthy: 14.6 ± 0.27 kg DM/d), spent less time eating (metritic: 137.7 ± 5.9 min/d; healthy: 152.1 ± 3.8 min/d) and had fewer visits to the feed bins per day (metritic: 53.8 ± 3.1; healthy: 65.5 ± 2.0) compared with healthy primiparous cows; healthy and metritic multiparous cows did not differ in these measures. No differences were found between healthy and metritic primiparous or multiparous cows in feeding rate and number of meals per day. Metritic multiparous cows were more likely than healthy multiparous cows to be competitively replaced at a feed bin by another cow (proportion of total feed bin visits where cow was replaced; metritic: 0.25 ± 0.02 vs. healthy: 0.20 ± 0.01). We conclude that cows at risk for metritis can be identified by changes in feeding and social behavior in the days before diagnosis.

Key Words: sickness behavior, disease, intake

M23 LPS injection in pregnant ewes and the number of lambs born affect maternal behavior and the time to first suckling. Cristiane G. Titto*[1], Fábio L. Henrique[1], Evaldo A. L. Titto[1], Adroaldo J. Zanella[2], Henrique B. Hooper[1], Lina F. P. Rodriguez[1], Ana Luisa S. Longo[1], Thays M. C. Leme-dos Santos[1], Raquel F. Calviello[1], Jessica C. Veronezi[1], and Alfredo M. F. Pereira[3], *[1]Faculdade de Zootecnia e Engenharia de Alimentos, Universidade de São Paulo, Pirassununga, São Paulo, Brazil, [2]Faculdade de Medicina Veterinária e Zootecnia, Universidade de São Paulo, Pirassununga, São Paulo,*

Brazil, [3]Instituto de Ciências Agrárias e Ambientais Mediterrânicas, Universidade de Évora, Évora, Alentejo, Portugal.

Stress during gestation and multiple births can alter postpartum maternal care in sheep. The objective of this study was to determine the effect of LPS injection during the second and last third of gestation and the number of lambs born per ewe on maternal behavior and time to first suckling. Pregnant multiparous crossbred Santa Ines ewes were challenged with an intravenous administration of 0.8 $\mu g \cdot kg^{-1}$ of lipopolysaccharide *E. coli*, or saline. Forty-two ewes were placed in individual pens with full open view of other animals, inside of a barn, during an adaptation period of 5 d. Ewes had free access to water, shade and food. Ewes were divided into 3 groups: CG - control group, (n = 14) that were not subjected to LPS injection; SG – stress at second third of gestation (70 d; n = 14); LG – LPS injection during the last third of their gestation period (120 d; n = 14). Behavior was recorded as positive (facilitated and encouraged suckling) and negative maternal behavior (aggressive, lack of co-operation with the lamb's sucking attempts) using 1-min scan sampling interval. Data were recorded from the time of birth until the first effective suckling event. If there were multiple births (2 lambs), each lamb was assessed separately. Data were analyzed as a completely randomized design using MIXED/SAS, and the ANOVA model had gestation LPS injection and the number of lambs born as the fixed effects as their interaction. Differences between LPS injection periods x birth were significant at a $P < 0.05$. Mother-offspring positive interactions were observed more than negative interactions ($P < 0.05$), except for the LG with multiple births, where the opposite occurred. Negative interactions were only observed in ewes with multiple births ($P < 0.05$). Lambs born from ewes in SG and LG groups, in twin births, spent more time until the first suckling ($P < 0.05$). It is likely that the delay in colostrum intake decreases the immunological capacity of the lamb, and the success of the ewe and lamb bond. LPS injection, which mimics a disease process, in late pregnancy is more harmful to the newborn lamb increasing negative maternal behavior and the time to first suckling.

Key Words: LPS, sheep, welfare

M24 Effect of increasing levels of babassu flour starch on feeding behavior of feedlot lambs.

Michelle de Oliveira Maia Parente[1], Osman José de Aguiar Gerude Neto[1], Paull Andrews Carvalho Santos[1], Henrique Nunes Parente[1], Miguel Arcanjo Moreira Filho[1], Ruan Mourão da Silva Gomes*[1], Itamara Gomes França[1], Arnaud Azevedo Alves[2], and Valdi Lima Júnior[3], *[1]Universidade Federal do Maranhão, Chapadinha, Maranhão, Brazil, [2]Universidade Federal do Piauí, Teresina, Piauí, Brazil, [3]Universidade Feredral do Rio Grande do Norte, Natal, Rio Grande do Norte, Brazil.*

Babassu (*Orbignya phalerata* Mart.) is a palm tree native to Brazil's northeast and north states that appears between Cerrado and the Amazon rain forest. Usually, each tree produces 15 to 25 bunches of fruit, each fruit weighting 98 to 280 g. The average weights of each component of the babassu coconut are 11% exocarp, 23% mesocarp, 59% endocarp and 7% kernels. From mesocarp can be extracted a flour, whose composition is 60% starch. The use of babassu flour starch can be used as an energy source for ruminants, however because of composition, it is important to study the feeding behavior. Twenty crossbred lambs (initial BW of 21.6 ± 3.5 kg and 120 d old) were used in a randomized complete block design according to initial BW and age. Lambs were penned individually during 50 d and fed an isonitrogenous diet (16.5 ± 0.2 CP, DM basis) containing 70% concentrate and 30% coastcross hay. Increasing levels of BSF were 0, 10, 20 and 30%, DM basis, corresponding to the experimental diets BFS0, BFS10, BFS20 and BFS30, respectively. Animals were monitored every 5 min during 24 h, on the 25th day of the experiment, according to the activities: eating, rumination, idle and other activities. The feed and rumination efficiencies, expressed as g DM/hour were obtained by dividing the average daily intake of DM by the total time spent eating and ruminating in 24 h, respectively. Orthogonal polynomials for diet responses were determined by linear and quadratic effects. Effects were declared significant at $P \leq 0.05$. There was a quadratic response ($P \leq 0.05$) for time spent in eating (164.0, 231.0, 270.0 and 250.0 min/d for BFS0, BFS10, BFS20 and BFS30), time spent in other activities (289.0, 206.0, 179.0 and 168.0 min/d for BFS0, BFS10, BFS20 and BFS30) and eating efficiency on DM (402.9, 331.6, 234.5 and 180.7 g DM/hour for BFS0, BFS10, BFS20 and BFS30). The increasing levels of BFS did not affect ($P \geq 0.05$) the time spent in rumination, rumination efficiency and time spent in idle. It is concluded that increasing BFS levels changed the feeding behavior of lambs, especially for time spent for eating and feed efficiency.

Key Words: feed efficiency, mesocarp, rumination

M25 Residual feed intake selection: Effect on gilt behavior in response to a lipopolysaccharide challenge.

Samaneh Azarpajouh*[1], Jessica Colpoys[1], Anoosh Rakhshandeh[1,2], Jack Dekkers[1], Caitlyn Abell[3], Nicholas Gabler[1], and Anna Johnson[1], *[1]Department of Animal Science, Iowa State University, Ames, IA, [2]Department of Animal and Food Sciences, Texas Tech University, Lubbock, TX, [3]DNA Genetics, Columbus, NE.*

Increasing feed efficiency in swine is important for increasing sustainable food production and profitability for producers. However, it is unknown if selection for improved feed efficiency impacts the expression of sickness behavior. The objective of this study was to characterize gilt behaviors and postures when challenged with lipopolysaccharide (LPS). This work was conducted with 7 low residual feed intake (LRFI; more feed efficient) and 8 high RFI (HRFI; less feed efficient) gilts (63 ± 4 kg BW) from the 8th generation of the ISU Yorkshire RFI selection lines. All gilts were individually housed in metabolism crates. Gilts were challenged I.M. with 30 μg/kg BW *Escherichia coli* O5:B55 LPS at 10:00 ± 1 h. Gilts were video recorded one day before LPS challenge (baseline) and on the treatment day (LPS challenge). Video was analyzed using a 1-min scan sample interval at 2 time points; 1) for 2 h starting at the time of treatment injection and 2) for one hour starting at the evening feeding time (~17:00h). Standing, sitting, lying, eating, and drinking were recorded. Data were analyzed using the GLIMMIX procedure of SAS. The model included line, treatment, time, and the interaction, with a random effect of pig nested within replicate. There was no line by treatment interaction for behaviors and postures ($P \geq 0.32$). There were no selection line behavioral and postural differences in response to the LPS challenge ($P \geq 0.45$). Regardless of selection line, after the LPS challenge gilts laid more ($P < 0.0001$) and stood less ($P < 0.0001$). For the other behaviors and postures there were no treatment differences ($P \geq 0.16$). In conclusion regardless of divergent selection for RFI, the LPS challenge affected lying and standing behavior in gilts in the same way. This project was supported by USDA-AFRI Grant no. 2011-68004-30336.

Key Words: gilt, lipopolysaccharide challenge, residual feed intake

M26 Effects of light programs and tryptophan supplementation on stress indicator parameters and growth of weaned piglets.

Lívea Maria Gomes*[1], Gabriela de Mello Miassi[1], Luan Sousa Santos[2], Marcos Livio Panhoza Tse[1], and Dirlei Antonio Berto[1], *[1]Faculdade de Medicina Veterinaria e Zootecnia – FMVZ/UNESP, Botucatu, SP, Brazil, [2]Faculdade de Ciencias Agrarias e Veterinarias – FCAV/UNESP, Jaboticabal, SP, Brazil.*

Stressors such as weaning, social structure and environmental changes reduce piglet performance. Tryptophan (Trp) as a precursor of cerebral 5-hydroxytryptamine (5HT, serotonin) and melatonin may mitigate stress of animals. The photoperiod controls the transformation of Trp in its metabolites which in turn influence the consumption and welfare of piglets. This study aimed to evaluate the effects of light program and Trp levels on growth performance, blood glucose and plasma cortisol profile of piglets. Seventy-two 21-d-old piglets (initial BW = 6.6 ± 2.33 kg) were allotted to 4 treatments stratified by sex and initial BW with 6 pens/treatment and 3 piglets/pen. Data were analyzed as randomized complete block design in a 2 × 2 factorial arrangement (light programs: 12 or 23 h of light/d, and 2 digestible Trp levels: 2.6 or 5.2 g of L-Trp/kg of diet in pre-starter 1 from d 1 to d 14, and 2.4 or 4.8 g of L-Trp/kg of diet in pre-starter 2 from d 15 to d 24). The trial was carried out in a room with controlled temperature (26 and 23°C during the first 14 and during the last 10 d, respectively). Blood glucose was determined on d 0 and 24, and plasma cortisol on d 0 and 8. The baseline glucose and cortisol concentrations were used as a covariate adjustment in all analyses. No effects of light program and Trp levels interaction were observed on performance and blood glucose. From d 0 to 14 and 0 to 24, treatments did not influence ADG, ADFI and glucose, while G:F decreased ($P < 0.05$) from d 0 to 14 for pigs receiving 12 h of light/d compared with the ones receiving 23 h of light/d, but improvement was offset in the total period. Light program and Trp levels interaction was observed for plasma cortisol. Pigs receiving 23 h of light/d presented higher plasma cortisol ($P < 0.05$) than piglets receiving 12 h of light/d when fed diet with 2.6 g L-Trp/kg, however there was no difference on plasma cortisol ($P > 0.05$) in both light programs for pigs fed 5.2 g L-Trp/kg. In conclusion, higher levels of dietary Trp are recommended for piglets receiving light program of 23 h.

Key Words: cortisol, nursery pigs, photoperiod

M27 The effects of ethyl alcohol as a tool for pain management in neonatal pigs during castration.

Justin L. Lyles*[1], Scott D. Carter[1], John N. Gilliam[2], Keith L. Bailey[2], Johann F. Coetzee[3], and Michelle S. Calvo-Lorenzo[1], *[1]Oklahoma State University, Stillwater, OK, [2]Oklahoma State University College of Veterinary Medicine, Stillwater, OK, [3]Iowa State University College of Veterinary Medicine, Ames, IA.*

Castration without anesthesia is known to be a stressful procedure in neonatal pigs. The objective of this study was to examine the analgesic effects of ethyl alcohol (ETOH) during castration. Fifty boars across 14 litters (n = 14) were randomly assigned in a completely randomized design to 1 of 4 injection treatments: ETOH, Lidocaine, saline, or sham. One gilt from each litter was also selected as a handling control. At 3 days of age (doa), 1 ml of the respective treatment was injected into each testicle, and boars were castrated at 14 doa. Behaviors related to social cohesion, pain, and non-specific actions were continuously recorded in pens and during treatment injection and castration. Social cohesion behaviors identified how individuals acted in relation to the litter, pain-related behaviors quantified behaviors associated with pain, and non-specific behaviors signified general behaviors not associated with pain. Body weight (BW) and testicular wound scores were recorded daily post-injection and post-castration. All data were analyzed with the use of a mixed effects model with treatment as a fixed effect and pen as a random effect. The frequency of pain-related behaviors post-injection was significantly increased in the ETOH and Lidocaine groups ($P < 0.05$), but these groups had lower behavioral frequencies than the saline and sham treatments post-castration ($P < 0.05$). There were no significant differences in the frequency of non-specific behaviors after injection ($P = 0.252$) or castration ($P = 0.456$). The frequency of social cohesion behaviors did not differ across groups post-injection, but all groups had significantly greater frequencies than gilts post-castration ($P < 0.05$). Pigs treated with ETOH had increased wound scores post-injection versus all groups ($P < 0.05$). Wound healing scores did not differ across treatments post-castration ($P = 0.37$) and BW did not differ across treatments overall ($P = 0.40$). Pigs treated with ETOH behaved similarly to Lidocaine-treated pigs, but further analyses are needed to determine the effectiveness of ETOH as a practical solution to address the pain and welfare concerns of castration in pigs.

Key Words: pig, castration, pain

M28 Effect of surgical and band castration on indicators of chronic pain in 0-, 2-, and 4-month-old beef calves.

Sonia Marti[1], Daniela Melendez*[2,1], Eugene D. Janzen[2], Ed Pajor[2], Diego Moya[1,2], and Karen S. Schwartzkopf-Genswein[1], *[1]Agriculture and Agri-Food Canada, Lethbridge, AB, Canada, [2]University of Calgary, Faculty of Veterinary Medicine, Calgary, AB, Canada.*

Three experiments were conducted to evaluate the effects of band and surgical castration on behavioral and physiological indicators of pain in beef calves at 3 different ages (36 calves/age group): newborn (Exp. 1, 4 ± 1.15 d of age, 43 ± 1.13 kg BW); 2 mo of age (Exp. 2, 63 ± 2.35 d of age, 92 ± 1.75 kg BW); or 4 mo of age (Exp. 3, 125 ± 4.65 d of age, 160 ± 3.36 kg BW). In each experiment calves were randomly assigned to sham (CT), band (BA) or surgical (SU) castration. Exp. 1, 2 and 3 ended when the testicles of banded calves had sloughed off (68, 49, and 42 d, respectively). Animal BW and rectal temperature were recorded weekly over the experimental period. Salivary cortisol, scrotal area temperature using infrared thermography, visual evaluation of swelling (5-point scale), and gait stride length was collected on d 1 and immediately before castration, and weekly thereafter until the end of the study. Hair samples were collected 1 d before and 28 d after castration, and at the end of the study for cortisol concentration. Standing and lying behavior was recorded over a 28-d period immediately after castration. At 4 mo of age, salivary cortisol concentration, scrotal area temperature, and stride length were greater ($P \leq 0.05$) in BA compared with CT calves, and lying time was lower ($P \leq 0.001$) in SU than CT calves. At 2 and 4 mo, hair cortisol tended to be greater ($P \leq 0.07$) in BA and SU compared with CT calves. The maximum degree of swelling ($P < 0.05$) caused by BA and SU was 1.5 at age 0; 3 and 3.5, respectively, at 2 mo; and 4.5 and 4, respectively, at 4 mo. At 2 and 4 mo of age swelling was observed between d 7 and 14 in SU, and between d 21and 28 in BA. Newborn calves had maximum swelling between d 35 and d 42 in BA and between d 14 and d 21 for SU. Overall, band castration resulted in more chronic indicators of pain than surgical and sham methods. However, as calves got older, indicators of pain increased sequentially in band castrated calves.

Key Words: chronic pain, castration, beef calves

M29 Characteristics of agonistic behavior of commercially housed pigs after mixing.

Shin-Jae Rhim*[1], Hyun-Su Hwang[1], Seung-Hun Son[1], Hojeong Kang[1], and Joon-Ki Hong[2], [1]*Chung-Ang University, Ansung, Gyeonggi, South Korea,* [2]*National Institute of Animal Science, Cheonan, Chungnam, South Korea.*

This study was conducted to compare the aggressive behaviors of commercially housed pigs when mixed at different times after weaning. The behavioral patterns of 36 groups of pigs (a total of 360 animals) were observed by continuous monitoring over 3 consecutive days directly after weaning (25 ± 1.2 d of age), and 50 and 75 d with the aid of video technology. The pigs were not mixed previously and were same ages. The data were analyzed by ANOVA, Tukey's post hoc tests, and Wilcoxon rank-sum test using the SAS software. Fight latency and total duration and frequency of fighting were significantly different among the age groups. The agonistic behaviors decreased in 75-d old pigs if compared with 25- and 50-d-old animals. Moreover, dominance index (DI, DI was defined as the sum of wins minus defeats divided by the sum of wins, defeats, and stand-off outcomes) was higher in 25-d-old and lower in 75-d-old pigs. A comparison of dominant (DI >0) and submissive (DI <0) pigs showed significant differences ($P < 0.05$) for major aggressive behaviors in all age groups. Higher frequency and longer duration of aggressive interactions mean that dominant animals were more active than the submissive ones. Moreover, pigs with a positive dominance index initiated more fights ($P < 0.05$). Dominant pigs were involved in more aggressive interactions, had longer fights, and initiated more fights than submissive pigs. Moreover, older pigs have shorter fights after mixing and that they also sustain fewer injuries from these fights. Post-mixing aggressive behavior changed over time. Early experience of mixing in the rearing conditions might contribute to reduced aggressive behavior of growing pigs. It may have been occurred by more energetically efficiency strategy for stable social structure. This finding has potentially important consequences for animal welfare and economic production of commercial swine production.

Key Words: agonistic behavior, dominance index, interaction

M30 Determining feeder space requirement for growing-finishing pigs.

Yuzhi Li*[1], Kimberly McDonalds[2], and Harold Gonyou[2], [1]*West Central Research and Outreach Center, University of Minnesota, Morris, MN,* [2]*Prairie Swine Center Inc., Saskatoon, SK. Canada.*

A study was conducted to determine feeder space requirement for growing and finishing pigs based on the amount of time needed to maintain their feed intake and growth performance. The first trial used 16 pens of 12 pigs. Four pens were randomly assigned to each of 4 treatment combinations: mash diets fed from a dry feeder (DM), mash diets fed from a wet/dry feeder (WM), pelleted diets fed from a dry feeder (DP) and pelleted diets fed from a wet/dry feeder (WP). Both the dry and wet/dry feeder provided single feeding space and were similar in design. Eating behavior was video-recorded for 24 h in all pens when pigs were 35 to 45 kg and 90 to 100 kg, respectively. The videos were analyzed using scan-sampling at 5-min intervals to determine time spent eating for each size of pigs. In the second trial, 564 pigs in 32 pens were used to evaluate 4 levels (80%, 95%, 110%, and 125%) of feeder capacity for growing and finishing pigs, with 2 pens assigned to each level of feeder capacity under the same treatments. Feeder capacity was defined 100% when the feeder was expected to be used 100% of the time by pigs according to the eating behavioral data from trial one. The different levels of feeder capacity were generated by varying the number of pigs in a pen and modifying the pen size accordingly to maintain floor space allowance consistent cross treatments. Pigs fed WM spent less time eating (72 vs. 107 min/pig/d for growers, SE = 2.68; $P < 0.001$) and 67 vs. 106 min/pig/d for finishers, SE = 3.39; $P < 0.001$) compared with pigs fed DM. Likewise, pigs fed DP spent less time eating than pigs fed DM ($P < 0.001$) during both growing and finishing phases. There was no difference in total duration of eating between pigs fed DP and WP. Cross treatments, ADG decreased from 793 to 693 g during the grower phase (SE = 9; $P < 0.001$) and from 941 to 667 g (SE = 27; $P < 0.001$) during the finishing phase when feeder capacity increased from 80 to 125%, respectively. To maintain 80% feeder capacity, the estimated feeder requirement is 11 pigs per feeder space for pigs fed DM during both growing and finishing phases. For pigs fed WM, DP or WP diets, the estimated feeder requirement is between 14 and 16 pigs for the growing phase, and between 17 and 18 pigs for the finishing phase.

Key Words: eating behavior, feeder space, pig

M31 Effects of different number of animals relative to a single feeding space on performance and behavior in Holstein bulls fed high-concentrate diets.

Maria Devant*[1], Alex Bach[2,1], and Marçal Verdú[1], [1]*IRTA-Ruminant Production, Animal Nutrition, Management, and Welfare Research Group, Caldes Montbui, Spain,* [2]*ICREA, Barcelona, Spain.*

One hundred and eight Holstein bulls (155 ± 2.0 kg BW and 121 ± 0.8 d age) were randomly allocated to one of 6 pens and assigned either in groups of 16 (Ratio16) or in groups of 20 (Ratio20) to a single space feeder with lateral protections. Each pen (6 m × 12 m) had also 1 straw feeder, and 1 drinker. Concentrate intake was recorded daily, straw consumption weekly, and BW fortnightly (total 15 periods). Animal behavior was registered every 28 d by scan sampling. Animals were slaughtered after 219 d and HCW and carcass quality recorded. Data were analyzed using a mixed-effects model with repeated measures. Mean concentrate intake (6.77 ± 0.168 kg/d), concentrate efficiency (0.22 ± 0.016 kg/kg), and carcass weight (271 ± 2.2 kg) were not affected by treatments. An interaction between treatment and time was observed in most of eating behavior parameters. During the growing (period 1 to 11) in Ratio16 bulls the number of visits to the feeder tended ($P = 0.08$) to increase, total daily time devoted to eat was greater ($P = 0.01$), whereas meal size ($P = 0.05$), meal duration ($P = 0.001$), and eating rate (period 5 to 11; $P = 0.001$) were lesser compared with Ratio20 bulls. However, at the end of the fattening period (periods 12 to 15) no differences between treatments were observed. In Ratio16, the percentage of animals drinking was greater ($P = 0.05$) compared with Ratio20. Moreover, an interaction between treatment and time was observed in the percentage of animals performing self-grooming ($P < 0.05$) and attempting to mount ($P = 0.10$). In conclusion, when the ratio of number of animals to a single feeder was reduced by 20%, the number of visits tended to increase, animals had shorter meals and meal sizes, and eating rate decreased; however, these differences were only observed during the growing period. These data may suggest that feeding space to animal ratio has an effect on eating behavior during the growing period, where social facilitation may be important. However, at the finishing as eating behavior becomes more individualized and/or animals learn to take turns, the feeding space to animal ratio is less critical.

Key Words: bulls, feeding space to animal ratio, eating behavior

M32 Effects of stocking density and source of forage fiber on short-term behavioral and lactational responses of Holstein dairy cows.

Mackenzie A. Campbell*[1,2], Kurt W. Cotanch[1], Catherine S. Ballard[1], Heather M. Dann[1], Dave M. Barbano[3], Alyssa M. Couse[1], and Richard J. Grant[1], [1]*William H. Miner Agricultural Research Institute, Chazy, NY,* [2]*The University of Vermont, Department of Animal Science, Burlington, VT,* [3]*Cornell University, Ithaca, NY.*

Understanding the interaction of stocking density and diet is vital for the improvement of dairy cow well-being and productivity. Multiparous (n = 48) and primiparous (n = 20) Holstein cows were assigned to 1 of 4 pens (n = 17 cows/pen, based on previous response variability) to determine the short-term effects of stocking density and source of forage fiber on behavior and lactational performance. Pens were assigned to treatments in a 4 × 4 Latin square with 14-d periods using a 2 × 2 factorial arrangement. Two stocking densities (STKD; 100 or 142% of stalls and headlocks) and 2 diets (straw; S and no straw; NS) resulted in 4 treatments: 1) 100NS, 2) 100S, 3) 142NS, and 4) 142S. Dietary forage content consisted of 39.7% corn silage and 6.9% haycrop silage versus 39.7% corn silage, 2.3% haycrop silage, and 3.5% chopped straw (dry matter; DM basis) for NS and S, respectively. Both diets were formulated for 16% crude protein, 28% neutral detergent fiber (NDF), and 28% starch (DM basis). Alterations in forage fiber source resulted in physically effective NDF values of 18.8% and 20.1% for NS and S, respectively. Pen intake and milk yield were measured on d 8–14 of each period. Time spent feeding, ruminating, and lying were measured using 72-h direct observation on d 8–10 of each period. Milk component yields were quantified for 6 milkings on d 13 and 14 of each period. Data were analyzed using the MIXED procedure in SAS with pen as the experiment unit. Eating time (238 min/d, SEM = 4), rumination time (493 min/d, SEM = 9), and pen intake (25.3 kg/cow/d, SEM = 0.4) did not differ ($P > 0.10$) among treatments. Milk, true protein and lactose yields tended to decrease with S. Although higher STKD decreased lying time, diet had no effect. The dietary addition of straw had minimal effects on short-term production and behavioral responses at varying STKD.

Table 1 (Abstr. M32). Production of Holstein cows assigned to 2 stocking densities (STKD; 100 or 142% of stalls and headlocks) and 2 diets (straw; S and no straw; NS)

	100% STKD		142% STKD			*P*-value

M33 Effect of temperament on feedlot performance and carcass traits in purebred and crossbred Nellore cattle.

Aline C. Sant'Anna*[1], Fernanda M. Benez[2], Janaina S. Braga[2], Arquimedes J. R. Pellechia[2], and Mateus J. R. Paranhos da Costa[1], [1]*São Paulo State University, Department of Animal Science, Faculty of Agricultural and Veterinarian Sciences, Jaboticabal, São Paulo, Brazil,* [2]*São Paulo State University, Post Graduate Program in Animal Science, Faculty of Agricultural and Veterinarian Sciences, Jaboticabal, São Paulo, Brazil.*

The aim of this study was to assess the effect of temperament on feedlot performance and carcass traits in Nellore and crossbred cattle (F$_1$ Angus × Nellore and Caracu × Nellore). A total of 450 bulls raised on pasture and finished in feedlot were kept in outdoor feedlot pens with 12 m^2, during 87 d of confinement. Cattle temperament was assessed using the crush test (REA, recording the movements and tension inside the crush in a 7-point scale); and the flight speed test (FS, m/s), measuring the speed at which the animals exited the crush, measured in the beginning (d 0, initial) and in the end of the feedlot period (final). Performance and carcass traits used were: final BW, ADG, hot carcass weight (HCW), carcass yielding (CY), subcutaneous fat score (SFS), number of bruises in the carcass (BRU) and ultimate meat pH (pH$_{24h}$). Linear mixed models were fitted to assess the effects FS and REA on dependent traits. Final FS affected ($P < 0.05$) BW and ADG, with an estimated reduction of 7.92 kg in BW and 0.13 kg/d in ADG for an additional unity in FS (Table 1). Final FS had significant effects on most of the carcass traits assessed, resulting in reduction of CW ($P < 0.05$), SFS ($P < 0.01$), and increased BRU ($P < 0.05$) and meat pH$_{24h}$ ($P > 0.05$). Final REA affected only CY ($P < 0.05$). Initial FS and REA had less pronounced effects on performance traits, with initial FS effecting only BRU ($P < 0.01$), and initial REA affecting ADG ($P < 0.05$). We conclude that more excitable temperament (faster FS) may have negative effects on cattle feedlot performance, carcass traits and meat pH$_{24h}$. The FS assessed at the end of feedlot period was the best predictor of the detrimental effects of temperament on performance of Nellore and crossed cattle. Financial support: FAPESP (2013/20036–0).

Table 1 (Abstr. M33). Effects of initial and final flight speed (FS) and reactivity score (REA) on feedlot performance and carcass traits, expressed as regression slopes (β)

Trait	β FS initial	β REA initial	β FS final	β REA final
Final BW, kg	−4.58	−1.12	−7.92*	−0.91
ADG, kg/d	0.00	−0.05*	−0.13*	0.00
Carcass weight, kg	−1.70	−0.31	−6.23*	−1.52
Carcass yielding, %	0.23	−0.12	−0.10	−0.28*
Subcutaneous fat score	−0.29	−0.02	−0.66†	0.07
Bruises	0.25†	−0.01	0.22*	0.02
pH$_{24h}$	0.00	0.00	0.02*	0.00

M34 Agitated temperament related to worse carcass quality in feedlot cattle.

Désirée Ribeiro Soares*[1], Karen S. Schwartzkopf-Genswein[2], Joslaine N. Dos Santos Gonçalves Cyrillo[3], and Mateus J. Rodrigues Paranhos da Costa[1], [1]*Faculdade de Ciências Agrárias e Veterinárias, UNESP, Jaboticabal, São Paulo, Brasil,* [2]*Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, Alberta, Canada,* [3]*Centro APTA Bovinos de Corte, Instituto de Zootecnia, IZ, Sertãozinho, São Paulo, Brasil.*

The aim of this study was to determine the influence of flight speed (a proxy for cattle temperament) on dry matter intake (DMI), residual feed intake (RFI), performance and carcass composition. A total of 284 bull Nellore calves (256.9 ± 26.5 d of age) were evaluated during 2 feed efficiency tests in 2012 and 2013. Calves were housed over a period of 93 and 87 d, respectively, in 2 feedlot pens (41 $m^2 \cdot animal^{-1} \cdot pen^{-1}$), containing 8 feed troughs per pen equipped with a radio frequency system (GrowSafe System Ltd., Airdrie, AB, Canada) used to measure DMI ($kg \cdot d^{-1}$), RFI ($kg \cdot d^{-1}$) and feed conversion ratio (kg gain·kg DMI^{-1}). The diet was offered ad libitum, 3 times daily and consisted of corn silage, ground corn, soybean meal and mineral supplement. Calves were weighed every 14 d to calculate average daily gain (ADG; $kg \cdot d^{-1}$) for each individual. Carcass composition was recorded using ultrasound between the 12th and 13th ribs, on the last day of the feeding period to obtain ribeye area (REA; cm^2). Flight speed (FS; $m \cdot s^{-1}$) was assessed every 28 d at the time of weighing. Calves were classified for temperament type according to their flight speed as follows: Calm = calves within the slowest tertile; Agitated = calves within the fastest tertile; and Intermediary = calves between the slowest and fastest tertile. Comparison of temperament type was analyzed with the PROC MIXED procedure (SAS Inst. Inc., Cary, NC). The model statement contained the effects of temperament class, feed efficiency test, and age on d 1 of the feeding period, as a covariate. No FS effect ($P > 0.05$) was observed on RFI and ADG; however, calves categorized as Agitated temperament had lower ($P < 0.05$) DMI (7.20 ± 0.09, 7.40 ± 0.09, and 7.16 ± 0.09 $kg \cdot d^{-1}$) and REA (62.90 ± 0.71, 62.05 ± 0.72, and 60.69 ± 0.72 cm^2) than Calm and Intermediary groups, respectively. Based on these results we conclude that Nellore cattle characterized as having agitated temperaments during handling, consumed less feed, and had worse carcass composition.

Key Words: behavior, confinement, reactivity

M35 Effects of handling before and during processing on behavior and ADG of feedlot steers.

Ruth H. Woiwode*[1], Temple Grandin[1], Brett Kirch[1], and John Paterson[2], [1]*Colorado State University, Fort Collins, CO,* [2]*National Cattlemen's Beef Association, Centennial, CO.*

The objective of this study was to investigate if a relationship exists between handling, and behavior and ADG of feedlot cattle. Upon arrival at a commercial feedlot in Kansas, Hereford steers (n = 496; initial BW = 304 ± 35.6 kg) of similar genetic background were sorted into 4 pens to determine the effects of handling on behavior and ADG. Two handling conditions before processing and 2 conditions of release from the squeeze chute were imposed. Prior to processing, handlers were required to quietly walk all steers from their home pen to the processing area (SLOW); or handlers were permitted to bring steers to the processing area in the normal fashion (FAST). Individual steers were randomly assigned to one of 2 conditions of release from the squeeze chute. The first was a delay no longer than 30 s following the completion of procedures to allow cattle to stop struggling (DELAY); the second was release immediately following the completion of procedures (NORM). Vocalization, chute temperament, exit speed and exit behavior scores were assigned to all steers during intake processing. Vocalization was scored on a yes/no basis, and was recorded before procedures. Temperament scores were assigned after head gate capture, on a 5-point scale (1 = calm, 2 = shifting; restless, 3 = squirming; shaking squeeze chute, 4 = continuous, vigorous movement, 5 = rearing, struggling violently). Exit speed was scored on a 3-point scale (walk; trot; run), and exit behavior was scored on a 2 point scale with cattle classified as high or low on a reactivity scale (L = No behaviors other than exit speed, H = Stumble, rear, jump). Paired *t*-tests determined that cattle exiting the chute at a walk or trot vs. a run tended ($P = 0.08$) to have higher ADG. Cattle vocalizing during restraint had lower ($P = 0.04$) ADG than those that did not vocalize. The FAST group showed a tendency to vocalize more frequently than the SLOW group. Pearson correlation analysis showed a significant, positive correlation between exit speed and vocalization ($P = 0.0021$, r = 0.14256), and a significant, negative correlation between exit speed and ADG ($P = 0.0036$, r = −0.13542). Using this approach, handling was correlated with behavior and ADG.

Key Words: behavior, vocalization, ADG

M36 Temperament of beef cattle receiving supplementation on grazing system: daily gain, ultrasound measures, and intake behavior.

C. L. Francisco*, A. M. Castilhos, D. C. M. Silva, F. M. Silva, and A. M. Jorge, *Universidade Estadual Paulista-FMVZ, Botucatu, SP, Brazil.*

A study was conducted to evaluate the temperament of beef cattle on grazing system regarding daily gain, ultrasound measures, and intake behavior. Twenty growing animals [Nellore; non-castrated males; 220 ± 3.73 kg initial body weight (BW); 10 ± 1 mo of age] on rotational stocking system (*Brachiaria brizantha* 'Xaraés') were used. Animals were evaluated for BW and temperament at the beginning of the trial period. Individual temperament scores were calculated by averaging animal chute score and exit score [adequate (ADQ) ≤ 3; or excitable (EXC) > 3]. Animals were ranked by BW and assigned to receive (n = 10) or not (control = CON; n = 10) a supplementation treatment (SUP; 0.6% of BW; corn, urea and mineral salt). BW were measured on d 0 and d 84 to determine the total gain (TG) and average daily gain (ADG). Hip height (HH) and ultrasound evaluations (ribeye area; backfat thickness) were carried out on d 0 and 84. Intake behavior evaluations were obtained via direct observation (8 d; 24-h per day) with an interval of 15 min between observations (time of grazing, rumination, resting, and drinking water). Data were analyzed with PROC MIXED in SAS with fixed effects of temperament, treatment and the resultant interaction. No interaction was significant. ADQ animals had greater final BW ($P = 0.01$) and HH ($P = 0.01$) than EXC animals (310.78 vs. 273.06 kg for BW; 1.36 vs. 1.32 m for HH, for ADQ and EXC animals, respectively). SUP treatment had greater final BW ($P = 0.04$), TG ($P < 0.01$), ADG ($P < 0.01$), final ribeye area ($P < 0.01$), and HH ($P = 0.03$) than CON treatment (305.80 vs. 278.04 kg for BW; 79.60 vs. 57.43 kg for TG; 0.95 vs. 0.69 kg for ADG; 37.25 vs. 30.84 cm^2 for ribeye area; 1.35 vs. 1.32 m for HH, for SUP and CON treatments, respectively). For intake behavior outcomes, ADQ animals had greater time of rumination ($P = 0.01$) than EXC animals (456.30 vs. 440.31 min, for ADQ and EXC animals, respectively). In conclusion, some characteristics of performance and intake behavior are associated with temperament and it is independent of differences in supplementation treatment in Nellore cattle. Supported by FAPESP#2014/07406–5.

Animal Health: Beef cattle

M37 Functional capacities of blood neutrophils are influenced by both acute and chronic dexamethasone stress models in beef steers. Michael A. Ballou*[1], Jeff A. Carroll[2], Nicole C. Burdick Sanchez[2], Nathan D. May[3], Shelby L. Roberts[3], Heather D. Hughes[3], Paul R. Broadway[2], Kate P. Sharon[1,2], and John T. Richeson[3], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, TX, [2]USDA-ARS, Lubbock, TX, [3]Department of Agricultural Sciences, West Texas A&M University, Canyon, TX.*

This study investigated the effects of acute and chronic stress models on the functional capacity of blood neutrophils in beef steers. Steers (n = 32; 209 ± 8 kg) were blocked by BW and assigned to 1 of 3 treatments: (1) Control (CON), no dexamethasone (DEX); (2) Chronic stress (CHR), 0.5 mg/kg BW DEX administered i.v. at 1000 h on d 3 to 6; or (3) Acute stress (ACU), 0.5 mg/kg BW DEX administered i.v. at 1000 h on d 6 only. Multiple blood samples were collected from jugular catheters to profile hematology. A blood sample collected at 2 h after the 4th DEX injection in the CHR treatment and 2 h after the only DEX injection in the ACU treatment was analyzed for functional capacities of neutrophils, which included surface expression of L-selectin (CD62-L) and the phagocytic and oxidative burst capabilities to an environmental *Escherichia coli*. There was a treatment × time interaction ($P \leq 0.001$) for neutrophil concentrations in peripheral circulation. The concentration of neutrophils increased 24 h after the 1st DEX injection among the CHR steers when compared with CON (10.6 vs. $2.8 \pm 0.62 \times 10^{6}$/mL; $P \leq 0.001$) and remained greater until 72 h after the 4th DEX injection. Neutrophil concentrations also increased rapidly, within 2 h of the DEX, in the ACU steers. Treatment influenced ($P \leq 0.001$) the expression of L-selectin on the surface of neutrophils (119^{a}, 138^{b}, and $61^{c} \pm 5.2$ MFI) for CON, ACU, and CHR steers, respectively. The percentages of neutrophils phagocytizing and producing an oxidative burst were suppressed ($P \leq 0.001$) among the CHR steers only (72^{a}, 71^{a}, and $55^{b} \pm 4.2$%), whereas the intensity of the oxidative burst was suppressed ($P \leq 0.001$) for both ACU and CHR steers (170^{a}, 131^{b}, $63^{c} \pm 11.7$ MFI) for CON, ACU, and CHR steers, respectively. In contrast, the intensity of neutrophil phagocytosis was not influenced by treatment ($P = 0.439$). These data indicate that chronic DEX suppresses neutrophil L-selectin as well as neutrophil phagocytosis and oxidative burst, whereas the acute DEX may initially prime neutrophil L-selectin expression although the oxidative burst intensity was already partially suppressed.

Key Words: immunity, neutrophil, stress

M38 Transcriptome profiling of the endometrium of healthy beef cows postpartum. Robmay Garcia*, Dianelys Gonzalez-Pena, and Sandra L. Rodriguez-Zas, *University of Illinois at Urbana-Champaign, Urbana, IL.*

The uterine cervix remains open for 7 to 10 d postpartum, which facilitates bacterial infection resulting in $650M in losses to the US dairy industry. Understanding the molecular profiles of healthy endometrial involution and regeneration can help understand bacterial clearance and inflammation resolution mechanisms. The objective of this study is to characterize the endometrium transcriptome of beef cows at 15d and 30d postpartum. Individual paired-end reads libraries were mapped to the *Bos taurus* reference genome (Btau_4.6.1) using Tophat v2.0.12. In total 8,282 isoform transcripts pertaining to 8,124 genes were identified and 1002 isoform transcripts pertaining to 995 genes were found to be differentially expressed (false discovery rate-adjusted P-value <0.05) between 15d and 30d using Cufflinks v2.2.1. Among the top 50 differentially abundant transcripts T-Box 21 (TBX21), T cell receptor associated transmembrane adaptor 1 (TRAT1) and indoleamine 2,3-dioxygenase (IDO) were overexpressed at 15d relative to 30d. TBX21 controls the expression of the hallmark Th1 cytokine interferon-gamma IFNG. TRAT1 Stabilizes the TCR T-cell antigen receptor / CD3 complex at the surface of T-cells and IDO play a role in processes such as antimicrobial defense and immunoregulation. Functional analysis of the differentially expressed genes using DAVID identified 10 enriched (enrichment score >2) functional category clusters including the Gene Ontology molecular functions for regulation of cell death and apoptosis, cytokine and chemokine activity, inflammatory response; Gene Ontology biological processes of immune system development, leukocyte activation, proliferation and differentiation, among associated immunological. These categories confirm that endometrial involution elicits changes associated with the inflammatory response and immunological activation. Our results offer insights on the transcriptome changes during normal endometrium involution.

Key Words: endometrium, involution, transcriptome

M39 Cardiac damage assessment in beef cattle receiving different dosages of monensin in finishing diets as measured by Creatine-Kinase Myocardic kit. Ariel O. Miranda*[1], Oscar Frances[2], Hernan Romero Harry[1], and Anibal J. Pordomingo[1], *[1]INTA, Anguil, La Pampa, Argentina, [2]Fac. Cs. Vet. Gral Pico, Gral Pico, La Pampa, Argentina.*

Monensin (MN) has affinity for monovalent cations such as Na and disruption of Na dynamics in tissues could affect the permeability of cardiac muscle cells. High or continued doses of MN have been suggested to result in cardiac myopathy, blood stasis and interstitial pulmonary edema. The objective of this study was to evaluate cardiac damage, not clinically detected, using a Creatine-Kinase Myocardic (CK-MB) commercial kit. Thirty Angus × Hereford steers, (BW = 205 ± 12 kg) were used to evaluate the effect of 2 doses of dietary MN during finishing in feedlot. Steers were randomly allotted into 3 groups of 10 each for a feedlot period of 168 d. Group 1: un-supplemented MN (G1: Control, CO), group 2: supplemented with 1 mg of MN/kg of body weight (BW) (G2: 1 mg/kg) and group 3, supplemented with MN 1.5 mg of MN/kg of BW (G3: 1.5 mg/kg). Steers were weighed on d 0, 63, 98, 126 and 168, with blood sampling at each time. Steers that received MN were 25 and 30 kg heavier ($P < 0.05$) than the controls (G2 and G3, respectively). Concentration of CK-MB increased linearly ($P < 0.05$) for the 3 groups (Table 1). Treatment effects were not that evident. Concentration of CK-MB was greater for G3 than G1 and G2 on sampling at d 63 and 168 ($P < 0.05$). No macroscopic lesions either on lungs or cardiac muscle were observed at harvest.

Contd.

Table 1 (Abstr. M39). Concentration means and standard deviations for CK-MB throughout the trial

Group	Day 1	Day 63	Day 98	Day 126	Day 168
G1: Control	25.1 $\pm 10.0^{A}$	40.4 $\pm 22.4^{A}$	68.2 $\pm 9.0^{B}$	89.6 $\pm 18.3^{B}$	72.9 $\pm 20.3^{A}$
G2: 1 mg/kg BW	32.1 $\pm 6.3^{A}$	40.4 $\pm 14.7^{A}$	49.0 $\pm 13.7^{A}$	62.1 $\pm 22.5^{A}$	61.2 $\pm 23.9^{A}$
G3: 1.5 mg/kg BW	26.8 $\pm 13.1^{A}$	61.7 $\pm 21.4^{B}$	57.0 $\pm 11.3^{A}$	76.4 $\pm 25.0^{A}$	92.6 $\pm 18.4^{B}$

^{A,B} Treatment means followed by different letters denote statistical differences at $P \leq 0.05$.

Key Words: beef, monensin toxicity, respiratory symptomatology.

M40 Estimating glucose requirements of an activated immune system in Holstein steers.

Sara K. Stoakes*, Erin A. Nolan, David J. Valko, Mohannad Abuajamieh, Maria V. Sanz Fernandez, and Lance H. Baumgard, *Iowa State University, Ames, IA.*

Activated immune cells are obligate glucose utilizers and a large lipopolysaccharide (LPS) IV dose causes severe hypoglycemia. Therefore, study objectives were to use the quantity of glucose needed to maintain euglycemia during an IV bolus endotoxin challenge as a proxy for the immune system's glucose requirement. Fasting growing Holstein steers (148 ± 9 kg) were jugular catheterized bilaterally and assigned to 1 of 3 treatments: control (CON; 3 mL sterile saline; n = 5), LPS-infused (LPS; *E. coli* 055:B5; 1.5 µg/kg BW; n = 5), and LPS + euglycemic clamp (LPS-Eu; 1.5 µg/kg BW; 50% dextrose infusion to maintain euglycemia; n = 5). Following infusion, blood glucose was determined every 10 min and dextrose infusion rates were adjusted in LPS-Eu calves to maintain euglycemia for 12 h. Plasma samples were obtained 3, 6, 9, and 12 h relative to bolus infusion for further analysis. All calves survived the LPS challenge. Rectal temperature was increased in LPS (0.6°C, $P = 0.03$) and tended to be increased in LPS-Eu (0.5°C, $P = 0.06$) relative to CON calves. LPS and LPS-Eu calves were hyperglycemic for 3 h post-bolus, likely due to hepatic glycogenolysis. Thereafter, blood glucose was markedly decreased in LPS relative to both CON and LPS-Eu calves (30%, $P < 0.01$). Blood lymphocytes, and platelets were increased in LPS and LPS-Eu calves relative to CON (53 and 56%, respectively; $P < 0.01$). Ionized calcium was decreased in both LPS and LPS-Eu calves relative to CON (18%, $P < 0.01$). White blood cells decreased or tended to decrease in LPS-Eu and LPS (59%, $P = 0.03$; 44%, $P = 0.06$; respectively) relative to CON. During the 12 h, 516 ± 65 g of infused glucose was required to maintain euglycemia. If the amount of glucose required to maintain euglycemia can be used as a proxy, then the glucose requirements of an activated immune system are approximately 43 g/h in growing ruminants.

Key Words: lipopolysaccharide, immune challenge, glucose homeostasis

M41 A comparison of rumen bacterial communities in bloated and non-bloated cattle grazing alfalfa.

Elnaz Azad*[1], Robert Forster[2], Surya Acharya[2], Tim McAllister[2], and Ehsan Khafipour[1], [1]*Department of Animal Science, University of Manitoba, Winnipeg, Manitoba,* [2]*Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, Alberta, Canada.*

To study bacterial shifts during the bloat process, 2 dietary interventions for alleviating the severity of bloat on rumen bacterial composition were studied in 12 rumen-cannulated cattle in a 3-phase crossover study. Cattle were subjected to 1 of 3 treatments: (1) pure alfalfa pasture (PA), (2) pure alfalfa pasture supplemented with Alfasure (AA), and (3) alfalfa/sainfoin mixed pasture (AS). A 7-d washout interval was provided between phases during which cattle received a baseline diet. Rumen liquid and solid fractions were collected from non-bloated (NB; bloat score = 0) and bloated (B; bloat scores = 1–3) cattle within each treatment group and subjected to genomic DNA extraction and Illumina sequencing of the V3-V4 regions of bacterial 16S rRNA gene. On average, 47,211 high-quality sequences were generated per sample. Taxonomic classification revealed the presence of 20 different bacterial phyla among which Bacteroidetes followed by Firmicutes, Fibrobacteres, Cyanobacteria, and Spirochaetes were identified as predominant (>1% of population) members of rumen microbiota. The PERMANOVA analysis of UniFrac distances revealed distinct ($P < 0.05$) clustering patterns when comparing PA(B), AA(NB) and AS(NB)-associated microbiota. Statistical analysis (LEfSe) of phylogenetic data for rumen liquid and solid fractions also revealed significant associations between several members of microbiota and treatment groups ($P < 0.05$; Table 1). Further investigation can focus on manipulation of rumen microbiota in favor of increased bloat-resistant functional properties.

Table 1 (Abstr. M41). Association of bacterial genera with treatment groups[1]

Genus	Phylum	Treatment group[2]
Rumen liquid fraction		
Succinivibrio	Proteobacteria	PA(B)
Succiniclasticum	Firmicutes	PA(B)
Butyrivibrio	Firmicutes	AS(NB)
Coprococcus	Firmicutes	AS(NB)
Fibrobacter	Fibrobacteres	AA(NB)
Ruminococcus	Firmicutes	AA(NB)
Rumen solid fraction		
Butyrivibrio	Firmicutes	PA(B)
Streptococcus	Firmicutes	PA(B)
Prevotella	Bacteroidetes	AS(NB)
Fibrobacter	Fibrobacteres	AA(NB)

[1] Linear discriminant analysis effect size (LEfSe) was used to test for significant associations ($P < 0.05$, and >3 log fold increase in the relative abundance).

[2] PA(B) = pure alfalfa (bloated); AS(NB) = alfalfa-sainfoin (non-bloated); AA(NB) = alfalfa-Alfasure (non-bloated).

Key Words: frothy bloat, alfalfa, rumen microbiota

M42 Efficacy of dosing toltrazuril 5% as a coccidiostatic for cattle.

Rafahel C. Souza[1], Rogério C. Souza[1], Renato O. Santos[1], Sérvio V. G. Ribeiro[1], Andre B. D. Pereira*[3], Thiago M. Soares[2], and Maria I. V. Melo[1], [1]*Pontifícia Universidade Católica de Minas Gerais, Betim, MG, Brazil,* [2]*Ourofino Agronegocios, Cravinhos, SP, Brazil,* [3]*University of New Hampshire, Durham, NH.*

Coccidiosis is a protozoan disease that negatively affects animal production and can result in economic losses. *Eimeria* spp. is the most common parasite. Infection occurs mainly in young cattle and can lead to gastrointestinal problems and clinical signs as bloody diarrhea and hemorrhagic enteritis. The objective of this study was to evaluate fecal infestation and average daily gain of 100 Nelore heifers (Average weight of 191.22 kg) randomly distributed, as a completely randomized design, in 1 of 2 treatments: (1) Control (C, no coccidiostat), and (2) Treatment (T, dosage of 15 mg/kg of toltrazuril 5%, dosed once at weaning, 210 d after birth). The experiment was conducted in the Arrojo Farm (Teófilo Otoni, MG, Brazil). Animals were weighed in the first day of the experiment and then 30 and 60 d after. Fecal samples were collected for laboratory analysis in the first and last days of the experiment, for counting oocysts per gram of feces (OOPG). Data were analyzed using the MIXED procedure of SAS and Tukey as post hoc tests for separation of means. Friedman nonparametric test was done for repeated analysis and count of OOPG. There was no difference between treatments for average daily gain (596 g/d for C and 656 g/d for T, $P > 0.05$). However, presence of OOPG was lower for cattle in the treatment group after 60 d when compared with samples from the beginning of the experiment ($P = 0.01$), which did not happen with the control group ($P = 0.86$). Results of this experiment suggest that toltrazuril 5% in the dose of 15 mg/kg can reduce parasite infestation in the gastrointestinal tract. Infestation in the beginning of the experiment was not deleterious enough to cause changes in average daily gain.

Table 1 (Abstr. 42). Effects of dosing 15 mg/kg of toltrazuril 5% to cattle

	Group			
Item	Control	Treatment	SEM	*P*-value
ADG, g/d[1]	596^{a}	656^{a}	247.67	NS
Oocysts per gram of feces, d 1	$982.76^{a,A}$	$988.89^{a,B}$	108.94	0.91
Oocysts per gram of feces, d 60	$786.21^{a,A}$	$730.56^{a,A}$	113.34	0.30

[a,b, A,B] Values with lowercase letters indicate differences between treatments; those with uppercase letters indicate difference between d 1 and 60 (Friedman nonparametric test).

[1] Tukey post hoc test.

Key Words: toltrazuril, coccidiosis, oocysts per gram of feces

M43 In vitro evaluation of the antimicrobial activity of plant extracts from *Ruta graveolens* and *Annona muricata*.

Yadileiny Portilla[1], María Dolores Carro[2], Grethel Milián[1], Conrado Camacho[1], Aymara Valdivia[1], Alexey Díaz[3,4], Cristina Saro[3], Iván Mateos[3], and María José Ranilla*[3,4], *[1]Center for Biotechnological Studies, University of Matanzas, Matanzas, Cuba, [2]Agriculture Production Department. Technical University of Madrid, Madrid, Spain, [3]Animal Production Department. University of León, León, Spain, [4]4IGM (CSIC-ULE). Finca Marzanas s/n, Grulleros, León, Spa.*

Resistance of microorganisms to commercial drugs is increasing worldwide, and therefore the search for new antimicrobial agents is a key issue. The aim of this study was to identify the potential of plant extracts from *Ruta graveolens* and *Annona muricata* as candidates for the development of new antimicrobials. Plant extracts were obtained by the Soxhlet method and their biological evaluation was carried out by the agar diffusion method, with 4 doses assayed (6.25, 25, 50 and 100 mg/mL) and 4 replicates per dose. Eight bacterial strains from American Type Culture Collection (ATCC) were tested: *Escherichia coli* O157 (ATCC 43894), *Streptoccocus agalactiae* (ATCC 13813), *Salmonella enteritidis* (ATCC BBA664), *Enterobacter aerogenes (*ATCC 13048), *Staphylococcus aureus* (ATTC 13565), *Klebsiella pneumoniae* (ATCC 4352), *Proteus mirabilis* (ATCC 14153) and *Proteus vulgaris* (ATCC 9484). Extracts from both plants showed antibacterial activity against all bacteria tested, with the exception of *A. muricata* extract against *S. enteritidis*. Minimum inhibitory concentration for both extracts was 6.25 mg/mL for *E. aerogenes*, *S. agalactiae*, *S. aureus*, and *K. pneumoniae*, 25 mg/mL for *E. coli*, *P. mirabilis*, and *P. vulgaris*, and 50 mg/mL of *R. graveolens* for *Salmonella enteritidis*. There were no differences between extracts in their antibacterial activity against *P. vulgaris* ($P = 0.91$) and *K. pneumoniae* ($P = 0.37$), but *R. graveolens* extract showed greater ($P < 0.001$) antibacterial activity against *E. coli* and *S. agalactiae* than *A. muricata* extract, and a trend was also observed for *E. aerogenes* ($P = 0.064$). In contrast, *A. muricata* extract tended to have greater ($P = 0.094$) antibacterial activity against *P. mirabilis* compared with *R. graveolens* extract. The results suggest that these extracts have active ingredients that could help to develop new antimicrobial products for the improvement of animal production and health.

Key Words: *Ruta graveolens*, *Annona muricata*, gram-positive

M44 OmniGen-AF affects expression of immune-related genes in whole blood of healthy Angus heifers.

S. A. Armstrong*[1,2], D. J. McLean[1], T. H. Schell[1,2], G. Bobe[2], and M. Bionaz[2], *[1]Phibro Animal Health, Corvallis, OR, [2]Department of Animal and Rangeland Sciences, Oregon State University, Corvallis, OR.*

Purebred Angus heifers were used to determine the effect of OmnniGen-AF (OG) supplementation on expression of cytokines, chemokines, and associated receptors involved in the inflammatory response in whole blood cells of healthy Angus heifers within the first 28 d of supplementation. Heifers were randomly assigned to control or supplemented daily with 56 g OG group (n = 4/group), and fed a diet including grass hay, alfalfa and ground corn. Heifers were housed in a freestall barn and fed via Calan Broadbent system. Blood was collected via jugular before the study started (0) and on d 3, 5, 10, 14, 21, and 28 of supplementation. The qRT-PCR was performed using the Cow Inflammatory Cytokines and Receptor qPCR array (Qiagen). Data were analyzed using LinReg software to account for efficiency of amplification and normalized by 3 internal control genes (*HPRT1*, *TBP*, and *YWHAZ*). qRT-PR data were log-transformed and the samples with Studentized residuals $t > 2$ removed. The final data set (82 genes) was subjected to ANOVA analysis with treatment, time, and treatment × time as main effect and animal as random using JMP Genomics of SAS. Significance was deemed with a false discovery rate-adjusted P-values < 0.10. Genes coding for chemokine receptors (*CX3CR1, CXCR1*), stress response (*NAMPT*), osteoclastogenesis (*TNFRSF11B*), and angiogenesis (*VEGFA*) were affected by treatment x time. Thirteen genes coding for interleukins and interleukin receptors (*IL1B*, *IL9, IL1RN*, *IL1R1, IL10RB*, *IL10RA*), chemokine ligand and receptors (*CCR2*, *CXCL2, CXCR1, CCL26, CCR1*), macrophage function (*CSF1*), and secondary immune response (*BMP2*) were downregulated and *CCL1* was upregulated by OG supplementation. Of the 23 receptors evaluated, 9 (39%) were influenced by OmniGen supplementation. Overall, the data suggest a transcriptional inhibition of genes related to inflammatory response by OG during the first 28 d of supplementation of healthy Angus heifers.

Key Words: OmniGen-AF, immune, cytokine

M45 Influence of hydrolysable tannin extract on nematode egg count in feces of receiving beef cattle.

Melissa B. Corona[1], Eva X. Murillo[1], Billy J. Cervantes[2], Nohemi Castro[1], Javier A. Romo[1], Soila M. Gaxiola[1], and Rubén Barajas*[1], *[1]FMVZ-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México, [2]Ganadera Los Migueles, S.A. de C.V., Culiacán, Sinaloa, México.*

The nematode parasites decline productivity of beef cattle. The nematode egg count is decreased in feces of cattle grazing plants with high hydrolysable tannin content. There is little information of effect of added tannins to the diet on nematodes presence in beef cattle. In this experiment 40 receiving bull-calves were involved to determine the influence of hydrolysable tannin extract on nematode egg count in feces of receiving beef cattle. Bull-calves were placed in 8 dirt-floor pens, and during 3 continuous days, fecal samples were taken from each. They were randomly assigned to treatments: (1) 70% roughage (16.1% CP; 1.27 Mcal NE_m/kg DM) corn silage-based diet (Control); (2) Control plus 1.5% of hydrolysable tannin extract DM basis (HT). After 28 d on treatment diets, fecal samples were taken during 3 continuous days again, and nematode eggs per gram of feces (EGF) were counted. Before statistical analyses, data were normalized by transforming to $\log_{10}$ x + 17 EGF. Results were analyzed by ANOVA for a completely randomized design. Additionally, both in Control and HT, EGF before and after treatments were compared using paired *t*-test. *Haemonchus* spp. and *Cooperia* spp. were most frequently genus found (82.5 and 75%, respectively). At start of experiment *Haemonchus* spp. EGF was similar (223 ± 77 EGF) between treatments ($P > 0.87$). After 28 d of receiving treatments, HT decreased 67.9% ($P = 0.02$) *Haemonchus* spp. EGF comparatively with Control (62 vs. 196 EGF). The paired *t*-test results indicated that *Haemonchus* spp. EGF were similar ($P = 0.47$) before and after in Control, but in HT were 70% lower ($P < 0.01$) after treatments (210 vs. 62 EGF). At arriving *Cooperia* spp. EGF was similar between treatments ($P = 0.94$), but after 28 d, EGF count was reduced 67.8% ($P = 0.04$) by HT relative to Control (39 *vs.* 122 EGF). The paired *t*-test indicated that in Control, EGF count was similar before and after 28 d ($P = 0.29$), but in HT EGF decreased ($P < 0.01$) 53% (64 vs. 136 EGF). Results suggest that HT addition in to the diet contributes to decrease fecal shedding of nematode eggs in receiving feedlot cattle.

Key Words: bovine, nematode, tannin

M46 Effects of bambermycin or monensin on health and performance of receiving cattle.

William Galyen*[1], Tom Hess[2], Don Hubbell[2], Shane Gadberry[3], Elizabeth Kegley[1], Matt Cravey[4], Jeremy Powell[1], Elizabeth Backes[1], Laura Meyers[1], and Paul Beck[5], [1]*University of Arkansas Department of Animal Science, Fayetteville, AR,* [2]*University of Arkansas LFRS, Batesville, AR,* [3]*University of Arkansas Cooperative Extension Service, Little Rock, AR,* [4]*Huvepharma, Inc, Amarillo, TX,* [5]*University of Arkansas SWREC, Hope, AR.*

Growing steers and bulls, were received in 3 blocks (Block 1, n = 150, BW = 208 ± 12.4 kg; Block 2, n = 99, BW = 213 ± 16.7 kg; Block 3, n = 149, BW = 219 ± 14.9 kg) to evaluate the effects of supplying 20 mg of bambermycin (Gainpro; Huvepharma, Inc., Sofia Bulgaria) or 0.77 mg/kg BW monensin (Rumensin; Elanco Animal Health, Indianapolis IN) in receiving supplements (20% CP and 78% TDN) compared with non-medicated supplements (Control) on cattle morbidity, performance, and coccidia infection. Upon receiving, bulls were castrated, and calves were weighed on 2 consecutive days. Calves were then stratified by BW and arrival castrate status and randomly allocated to receiving pens (n = 12–0.4 ha pens in Block 1 and n = 6 pens in Blocks 2 and 3). Calves received 0.9 kg of supplement daily and ad libitum access to moderate quality hay. Fecal samples were collected from 6 steers/pen on d 0, 14, and 28 to evaluate coccidia infection. Water in the Gainpro pens was treated from d 14 to d 19 with 10 mg/kg BW amprolium (Corid; Merial, Duluth GA). Steers remained on treatment for 56 to 84-d for Block 1, 49-d for Block 2 and 42-d for Block 3. Data were analyzed as a randomized complete block design using the mixed procedure of SAS (SAS Inst. Inc., Cary, NC). Cocci counts were log-transformed before analysis as a repeated measure in time. There were no differences ($P \leq 0.36$) in morbidity, mortality, or animals identified as chronically morbid. There was no treatment by day interaction ($P = 0.12$) for cocci oocysts counts, and monensin decreased coccidia ($P \leq 0.03$) compared with Control and bambermycin, which did not differ ($P = 0.85$). No cattle were observed with or treated for symptoms of coccidiosis (bloody scours and diarrhea). At the end of receiving, BW and ADG for Control (237 ± 5.1 kg/steer and 0.49 ± 0.272 kg/d, respectively) was less than ($P \leq 0.04$) bambermycin (243 ± 5.1 kg/steer and 0.60 ± 0.272 kg/d) and monensin (247 ± 5.1 kg/steer and 0.68 ± 0.272 kg/d), and monensin tended ($P \leq 0.10$) tended to be greater than bambermycin. The results of this experiment indicate both bambermycin and monensin increased receiving cattle gain performance compared with Control, and monensin also provided greater benefits in reduction of coccidia counts.

Key Words: bambermycin, monensin, receiving steers

M47 Influence of *Papaveraceae* plant preparation on nematode egg count in feces of receiving bull-calves.

Rubén Barajas*[1], Melissa B. Corona[1], Eva X. Murillo[1], Billy J. Cervantes[2], Ingo Rogge[3], Nohemi Castro[1], and Luis E. Soto[4], [1]*FMVZ-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México,* [2]*Ganadera Los Migueles, S.A. de C.V., Culiacán, Sinaloa, México,* [3]*Phytobiotics Futterzusatzstoffe GmbH, Eltville, Germany,* [4]*FA-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México.*

Quaternary benzophenanthridine alkaloids and protopine alkaloids (QBA + PA) have systemic anti-inflammatory effects. However, its activity against nematode parasites of the gastro intestinal tract is not well documented. In the actual experiment, 20 receiving bull-calves 236 ± 4.12 kg were utilized to evaluate the influence of a standardized QBA + PA *Papaveraceae* family plant preparation named Sangrovit RS (SANG; Phytobiotics, Eltville, Germany) on fecal shedding of parasitic nematode eggs. In groups of 5, bull-calves were allotted in dirt-floor pens, fed with 70% roughage corn silage-diet. During 3 consecutive days fecal samples were taken from each animal and nematode eggs per gram of feces (EGF) were counted by McMaster method. Pens were randomly sorted to receive 10 g/d of Sangrovit RS (SANG) or not (Control) supplied on the feed bunk as top dressing. Once completed the 28 d period treatments, fecal samples were taken again during 3 consecutive days, and EGF count was performed. Results were analyzed by ANOVA for a completely randomized design. In fecal samples taken before applied treatments, the nematode EGF count was similar ($P > 0.30$) between treatments. After 28 d total nematode EGF was lower ($P = 0.04$) in the SANG group compared with the Control group (33 vs. 113 EGF). The amount of *Haemonchus* sp. EGF (an abomasum parasite) was lower ($P = 0.05$) in bull-calves fed SANG compared with Control group (12 vs. 48 EGF). The EGF count of *Cooperia* spp., a parasite of the small intestine, was inferior ($P = 0.03$) in SANG supplemented bull-calves in relationship to unsupplemented bull-calves (13 vs. 52 EGF). Results suggest that fed QBA + PA plant preparation contributes to decrease parasites nematode eggs shedding in receiving bull-calves.

Key Words: bovine, nematode, alkaloid

M48 Effect of Safeguard on fecal egg count and performance in received beef calves.

Antonio Jose Neto*[1], Curt J. Bittner[1], Galen E. Erickson[1], and Brandon L. Nuttelman[2], [1]*Department of Animal Science; University of Nebraska, Lincoln, NE,* [2]*Merck Animal Health, De Soto, KS.*

Parasite infestations can reduce or limit feed intake and subsequently depress the performance due to decreased absorption of nutrients. Fenbendazole (Safeguard, Merck Animal Health) is indicated for use in cattle for removal and control of lungworms, stomach worms and intestinal worms. The objective of this study was to measure the effects of Safeguard on fecal egg count (FEC) and performance of newly received calves in the feedlot over the first 25 d. Treatments were applied to steers at arrival and were: Safeguard and Doramectin (Dectomax, Zoetis Animal Health) injectable (SG+DTX) or only Dectomax injectable (DTX). Three hundred sixty-eight (265 ± 20 kg) steers were used in a completely randomized design with 16 pens (8 replications per

treatment and 23 steers per pen). The basal diet consisted 30% dry-rolled corn, 36% sweet bran), 30% alfalfa hay, and 4% supplement. Steers were assigned to pen based on processing order, with every other steer assigned to either SG+DTX or DTX. Once a pen replicate was filled, new pen replicates were started until all steers were assigned. On d 1, steers were weighed, and individual fecal sample collected. On d 19, fecal samples were collected per pen (10 samples/pen). Fecal samples were analyzed for FEC at a commercial laboratory. At the end of the receiving period, steers were limit-fed a diet consisting of 50% sweet bran and 50% alfalfa hay at 2% of BW for 5 d before being weighed. Data were analyzed using the Proc MIXED of SAS, with pen as the experimental unit. There were no differences in initial BW ($P = 0.13$), ending BW ($P = 0.33$), DMI ($P = 0.41$), ADG ($P = 0.94$), and G:F ($P = 0.43$) between SG+DTX or DTX. No difference for initial FEC ($P = 0.45$) was observed between treatments and averaged 16.9 eggs per 3 g of feces. However, FEC on d 19 was lower ($P = 0.03$) for animals receiving SG+DTX (FEC = 0.06 eggs per 3 g feces) compared with DTX (FEC = 0.50 eggs per 3 g feces). A combination of Safeguard and Dectomax reduced FEC of newly received calves in feedlot.

Key Words: dewormer, fecal egg count, performance

Animal Health: Immunology

M49 Comparison of antibody response, bacteriological culture and PCR based diagnostic methods in *Brucella ovis* inoculated rams.

Ariel O. Miranda*[1], Hernán Romero Harry[1], Valeria N. Baldone[1], Marcy Owens[2], and Scott Pratt[2], [1]*INTA, Anguil, La Pampa, Argentina,* [2]*Clemson University, Clemson, SC.*

Twenty-seven *Brucella ovis* (*B. ovis*)-negative adult Pampinta rams were used to evaluate 3 diagnostic methods for *B. ovis* detection post-inoculation. Twenty-four rams were inoculated by the conjunctival route and intraprepucially with a total of 3×10^9 cfu/ram of *B. ovis* (strain, INTA Bariloche, Argentina). Three rams were inoculated with a saline placebo. Blood and semen samples were taken for serological antibody detection, bacteriology culture and PCR at 0, 12, 24, 62 and 97 d post inoculation. Modified Thayer Martin medium was used to detect presence of *B. ovis* in semen. Serum samples were tested for antibodies to *B. ovis* using a commercial ELISA kit. *B. ovis* DNA from semen samples was extracted using a commercial kit (Qiagen) and PCR performed using primers pairs specific to *B. ovis*. The proportion of agreement (Kappa value, k) was calculated. *B. ovis* was not detected 12 d post-inoculation by any detection method. Nine rams were positive for *B. ovis* 24 d post-inoculation detected by ELISA; however, the rams were negative for *B. ovis* using the other 2 detection methods. Further, we observed a continued increase toward the end of the study. The intermittent elimination of *B. ovis* by semen agrees with the lower result response in culture and PCR. The low percentage of positive animals in culture on the 97 d could have been given to false negatives or methodology. Control group was negative to the 3 methods over the study. Seroconversion confirmed by ELISA is the most sensitive diagnostic measure of *B. ovis* exposure.

Table 1 (Abstr. M49). Number and percentage of positive rams by different methods and k value between them throughout the study

	Sampling day				
Test diagnostic	0	12	24	62	97
ELISA positive	0	0	9 (38%)	21 (88%)	23 (96%)
Culture positive	0	0	0	14 (58%)	2 (8%)
PCR positive	0	0	0	18 (75%)	17 (71%)
	Agreement (%), k-value (SE)				
ELISA vs. culture	100, 1.0 (–)	100, 1.0 (–)	62, 0.11 (0.10)	70, 0.33 (0.16)	12, 0.00 (0.01)

M50 Prevalence of brucellosis in Iraq and control through a vaccination campaign.

Alaa Khalil Ismaiel*, *Ministry of Agriculture, Veterinary Directorate, Central Veterinary Laboratory, Baghdad, Iraq.*

Brucella melitensis is primarily a cause of abortions in sheep and goats. It can be isolated from cattle, water buffalo, and camels, and transmits to humans through unpasteurized milk and cheeses. Little was known about the distribution of this organism around Iraq, which was needed for developing an effective control campaign. The goals of this study, initiated in 2005 in collaboration with the Food and Agriculture Organization (FAO), were to determine the prevalence of *Brucella* in sheep, goats, cattle, water buffalo, and camels across Iraq, and to test the effectiveness of a whole cell vaccine. Villages for sampling were selected from 15 governorates that had more than 2000 animals. In each governorate, goats and sheep were sampled in 17 villages, cattle and water buffalo in 11 villages, and camels in 9 villages; 60 animals were sampled in each category per village. Serum samples initially screened by the Rose Bengal test were further confirmed by ELISA. These results indicated that 6.5% (6.1–6.9, 95% CI), 1.0% (0.78–1.2, 95% CI) and 1.5% (1.2–1.8, 95% CI) of sheep and goats, cattle, and water buffalo were positive for *B. melitensis*, respectively. Prevalence for sheep and goats ranged from 0.2% in Murhana to 16.4% in Kirkuk, for cattle from 0.02% in Thyqar to 11.1% in Muthana, and for water buffalo from 0% in Babylon to 5.4% in Basrah. Approximately 1 to 2×10^9 cfu of the live attenuated *B. melitensis* vaccine, Rev1, was used to vaccinate 1.8 to 2.5 million lambs and kids each year, across all 15 governorates, from 2009 to 2014. During this time, cases of abortion in sheep and goats fell from 5090 in 2011, to 322 in 2013. This study concluded that the incidence of *Brucella* varies across different regions of Iraq, which can be related to animal handling practices. An aggressive strategy of vaccination was effective in reducing abortions in sheep and goats by over 90%. During the course of the vaccine intervention in this study, the Iraqi Ministry of Health reported that the incidence of brucellosis in humans decreased from 24 to 7 incidences per 100,000 people, further indicating an effective vaccination program.

Key Words: *Brucella*, vaccination, pathogen control

M51 Maternal undernutrition increases acylated ghrelin concentrations in the umbilical artery and vein of the twin ovine fetus.

Sahng-Wook Hahm*[1], Meghan Field[1], Russell V. Anthony[2], and Hyungchul Han[1], [1]*Department of Animal Sciences, Colorado State University, Fort Collins, CO,* [2]*Department of Biomedical Sciences, Colorado State University, Fort Collins, CO.*

Maternal undernutrition can induce intrauterine growth restriction and contribute to the development of adult metabolic diseases. Ghrelin, a peptide hormone purified from the gastric mucosa, activates food intake and energy homeostasis. Ghrelin exists in 2 forms, the non-acylated ghrelin and acylated ghrelin (active form). The acylation of ghrelin is mediated by membrane bound O-acyltransferase 4 (Mboat4). We hypothesized that maternal undernutrition would increase the acylated ghrelin in the blood of the fetus during gestation. Twin bearing western whiteface ewes were either fed 100% (C, n = 12), or 50% of their global nutrient requirements from 28 to 78 d of gestational age (dGA) and readjusted to 100% beginning at 79 dGA (LC, n = 12), or continuously restricted until 135 dGA (LL, n = 12). At 135 dGA, umbilical artery and vein plasma, and fetal abomasum samples were collected. Umbilical arterial and venous ghrelin concentrations were measured by radioimmunoassay. Mboat4 gene expression in fetal abomasum was measured using quantitative real-time PCR. Mboat4 protein concentration in the fetal abomasum was analyzed by Western blot analysis. Each ewe was treated as one experimental unit and twin fetuses were nested within the ewe. All data are presented as least squares means ± SEM using the PROC MIXED model of SAS. The umbilical arterial active ghrelin concentration tended to be greater in LL fetuses (41.63 ± 5.49 pg/mL) compared with control (27.17 ± 5.76 pg/mL; $P = 0.0523$) and LC fetuses (22.81 ± 5.28 pg/mL; $P = 0.0197$). The active to total ghrelin ratio was higher in LL than LC fetuses ($P < 0.05$). Umbilical vein active ghrelin concentration tended to be greater in LL, when compared with LC fetuses ($P = 0.0812$). No significant difference was observed in Mboat4 mRNA expression in fetal abomasum. Mboat4 protein concentration tended to be greater in fetal abomasum of LC and LL fetuses compared with control fetuses ($P = 0.0584$). These results are interpreted to mean that elevated active ghrelin but not total ghrelin in fetal circulation may be an adaptation of the fetus to prolonged undernutrition during gestation. USDA-AFRI Grant no. 2009–65203–05670.

Key Words: fetus, ghrelin, membrane bound O-acyltransferase 4 (Mboat4)

M52 Evaluating udder health in dairy goats: An old but still unsolved issue.

Andrea Bezerra[1], Candice De Leon[1], Magda Fernandes[1], Bryan White[2], Juan Loor[2], and Celso Oliveira*[1,2], [1]*Federal University of Paraiba (UFPB), Brazil, Areia, PB, Brazil,* [2]*The University of Illinois at Urbana-Champaign, Urbana, IL.*

Despite the high economical importance of goat milk production in certain regions, the real burden of subclinical mastitis caused by intramammary infections (IMI) is still unknown. This is mainly caused by the lack of reliable diagnostic tests, since the accuracy of somatic cell count (SCC) as an indirect indicator of udder health is questionable in this species. This study aimed to investigate the correlation among and somatic cell count (SCC), total bacterial count (TBC), California Mastitis test (CMT) and microbiological culture (MC) as indicators of udder health in dairy goats in Northeastern Brazil, the leading goat milk producing region in South America. From 6 farms, a total of 396 milk samples were individually collected from each teat of 66 goats at different lactation periods (begining, mid, end). Out of 146 (37%) positive samples, coagulase negative (CoNS, 73%) and positive *Staphylococcus* (21%), gram-positive bacilli (6%), streptococci (3.4%) and Enterobacteriaceae (1.4%) were identified. SCC and TBC were correlated ($r = 0.47$; $P < 0.01$) but a weak correlation (0.20; $P < 0.01$) was observed between SCC and infection by CoNS infection. Although a positive association ($P < 0.05$) was seen between SCC and MC using percentile 75 (6.05 log SCC/mL) as threshold, SCC was weakly (0.29) correlated with MC. Interestingly, the correlation was strong at the beginning of lactation (0.49, $P < 0.001$) but negligible at mid (0.3; $P = 0.79$) and end lactation (0.12; $P = 0.14$). Using MC as the gold standard, sensitivity values for CMT and SCC were 39.2 and 40.2%, whereas specificity reached 80 and 89.5%. SCC in non-infected goats increased ($P < 0.01$) at the end lactation. The low agreement among the diagnostic methods and the large physiological variations in SCC during lactation reinforce the limitations of the current methods to accurately predict udder health in goats, especially at the animal level. A better knowledge about the glandular tissue responses against IM agents is strongly needed. We have currently been using metagenomic approaches to investigate in-depth changes in the microbiome of naturally infected animals to bring new insights about mastitis in goats.

Key Words: goat mastitis, somatic cell, goat milk

M53 Effect of FMD vaccine on seminal traits of HF bulls.

Mohua Das Gupta*[1], Shivaji Hanmantrao Sontakke[1], Gunjan Rathi[1], Vinod Haribhau Shende[1], Mohammed Mushtaque[1], Samir Kumar Dash[1], Suresh B. Gokhale[1], Arun P. Phatak[2], Hemant Dasharath Kadam[1], Narayan Laxman Phadke[1], and Jayant Ramachandra Khadse[1], [1]*BAIF Development Research Foundation, Central Research Station, Uruli Kanchan, Pune, Maharastra, India,* [2]*601 Curran Drive, Waterford, CA.*

An attempt was made to study the effect of Foot and Mouth Disease vaccination on seminal traits of 30 Holstein Friesian bulls ranging between 3 and 5 years age maintained at BAIF Central Research Station Uruli Kanchan, Pune, India. Study period was from August to September 2013 and observations on semen were of bulls maintained under identical feeding and management regimens. Semen collections 15 d before vaccination, 15, 30 and 45 d after vaccination were evaluated for seminal traits such as fresh and post-thaw sperm motility, sperm concentration, semen volume, live and dead count, plasma integrity. Data generated were analyzed using ANOVA. It revealed that vaccination had significant ($P < 0.05$) effect on post-thaw motility and highly significant ($P < 0.01$) deleterious effect on host test, head and mid piece abnormalities as it causes derangement in spermatogenesis and epididymal function due to rise in testicular and body temperature; however, no effect was noted on seminal traits such as volume, concentration, initial motility viability and tail abnormalities. There was general decline observed in performance of seminal traits of bulls, confirming the reports of previous studies, which state that the secondary activities following vaccination remain unaltered. Therefore it can be concluded that FMD vaccination causes alteration in spermiogram but functions of accessory sex glands remain unaltered. Hence for better semen picture and to counter the effect, preventive immune enhancement before vaccination and sexual rest for highly affected bulls can be adopted.

Table 1 (Abstr. M53). Sperm characteristics before and after vaccination with FMD vaccine

Parameter	Pre-vaccination	Post-vaccination	*P*-value
Volume (mL)	6.63 ± 0.31	6.42 ± 0.17	0.59
Concentration (millions/mL)	1705.69 ± 86.09	1688.40 ± 43.29	0.88
Initial motility (%)	76.53 ± 0.38	76.3 ± 0.21	0.41
Live and dead (%)	82.89 ± 1.63	80.64 ± 1.03	0.93
Post-thaw motility (%)	58.19 ± 0.41	57.5 ± 0.24	0.03*

M54 Development of an effective oral animal vaccine using M cell targeting strategy.

Sangkee Kang*[1,2], Yoonseok Lee[2], Jinduck Bok[2], Chongsu Cho[3], and Yunjaie Choi[2,3], [1]*Graduate School of International Agricultural Technology, Seoul National University, Pyeongchang, Republic of Korea,* [2]*Institute of Green-Bio Science & Technology, Seoul National University, Pyeongchan, Republic of Korea,* [3]*Department of Agricultural Biotechnology, Seoul National University, Seoul, Republic of Korea.*

Development of oral vaccine is necessary in animal husbandry field because of not only its convenience in treatment but also its capability inducing mucosal immune response. M cells are well-known as antigen collecting portals for GALT (gut associated lymphoid tissue) in intestinal tract, thus targeted delivery of vaccine molecules to the M cells could be a promising strategy to improve efficiency of oral vaccine. Previously, our research group have identified an M cell targeting peptide moiety, CKS9, by phage display technique using in vitro M cell model consisting of coculture system with Caco-2 (human colon carcinoma cells) and human Raji B cells. In this study, we constructed a recombinant lactic acid bacteria, *Lactobacillus plantarum* producing a model antigen, M-BmpB, the BmpB (surface membrane protein originated from *Brachyspira hyodysenteriae*) conjugated with CKS9, to validate its potency as an efficient animal oral vaccine. We ascertained that the fusion protein, M-BmpB, was expressed as soluble form in the cytoplasm of *L. plantarum* by SDS PAGE and Western blot and confirmed its M cell targeting property in contrast to original BmpB (without CKS9) and P-BmpB (with unrelated peptide ligand) by in vivo closed ileal loop assay. In in vivo immunization assay (Balb/C, n = 5 in each group), Oral administration of *L. plantarum* producing M-BmpB (LP25-M-BmpB) to mice revealed significant improvement in induction of both serum IgG ($P < 0.05$) and fecal IgA ($P < 0.01$) against BmpB compared with control groups. Our results suggest that the recombinant lactic acid bacteria, such as *L. plantarum*, producing certain pathogenic antigen with M cell targeting strategy could have a great potential to develop an effective and convenient oral animal vaccine system.

Key Words: oral vaccine, M cell targeting, mucosal immunity

M55 Amino acid supplementation and lipopolysaccharide challenge alters bovine blood polymorphonuclear leukocytes response in vitro. M. Garcia*[1], T. H. Elsasser[2], Y. Qu[1], L. Juengst[1], B. J. Bequette[1], and K. M. Moyes[1], *[1]Department of Animal and Avian Sciences, University of Maryland, College Park, MD, [2]Agricultural Research Service, Animal Biosciences and Biotechnology Laboratory, U.S. Department of Agriculture, Beltsville, MD.*

Glutamine is the preferred amino acid (AA) utilized by polymorphonuclear leukocytes (PMNL) during the inflammatory response. However, the effect of other AA on bovine PMNL response during inflammation and how this is altered by stage of lactation are currently unknown. The objective of this study was to determine the effect of additional AA supplementation (pool of AA excluding glutamine) on AA profile, transcriptomic, and inflammatory function of PMNL from dairy cows in early and mid-lactation in vitro. Twenty Holstein dairy cows in early (n = 10; DIM = 17 ± 3.1) and mid-lactation (n = 10; DIM = 168 ± 14.8) were used for this study. PMNL were isolated and diluted using RPMI, containing basal concentrations of glucose (7.2 m*M*) and amino acids (3.1 m*M*). Working solutions of AA (0 m*M* or 4 m*M* of AA) and LPS (0 or 50 µg/mL) were added and tubes were incubated for 2 h at 37°C and 5% CO_2. Data were analyzed as a randomized block design. Stage of lactation did not alter PMNL responses in vitro. AA in combination with LPS increased ($P \leq 0.02$) the concentration of alanine and methionine and tended ($P < 0.10$) to increase that of leucine, isoleucine, threonine, and phenylalanine. Regardless of LPS challenge, AA supplementation downregulated ($P < 0.05$) the expression of genes associated with inflammation such as *NFKB1*, *IL10*, *IL1B*, *IL6*, *TNFA*, *LYZ*, *SOD2*, and *SLC2A3* but tended ($P < 0.10$) to increase the expression of *TLR6*, *G6PD*, *LDHA*, and *PDHA1*. Supplementation of AA reduced the concentration of TNF-α (104.0 vs. 34.9 ng/mL, $P = 0.01$) in medium but did not affect chemotaxis and phagocytic functions of PMNL. Metabolic profiles for cows in early lactation did not parallel those for cows during the early postpartum period and may partly explain the lack of stage of lactation effects. This study identified AA other than glutamine that may alter PMNL response during inflammation in vitro that may lead to new avenues to improve immune response during inflammation in vivo.

Key Words: amino acid, cow, polymorphonuclear leukocyte

M56 In vitro activity of *Pithecellobium dulce* and *Lysiloma acapulcensis* on exogenous development stages of sheep gastrointestinal strongyles. A. Olmedo-Juárez[1], R. Rojo-Rubio*[1], J. Arece-García[2], C. Marie-Magdeleine[3], and J. F. Vázquez-Armijo[1], *[1]Centro Universitario UAEM Temascaltepec, Universidad Autónoma del Estado de México, Temascaltepec, Estado de México, México, [2]Estación Experimental de Pastos y Forrajes, España Republicana, Matanzas, Cuba, [3]Instituto de Investigaciones Agronómicas (INRA), Guadaloupe, France.*

Parasitic nematodes of the digestive tract remain one of the main constraints in small ruminants in subtropical countries. In these regions there are a lot of browsed plant species with antihelmintic activity; in this way an experiment was conducted to evaluate the effects of 2 lyophilised aqueous extracts of *Lysiloma acapulcensis* (LAE) and *Phitecellobium dulce* (PDE) tree leaves on in vitro assessment of hatching of eggs, larval development and migration of gastrointestinal nematodes of sheep using a general linear model. Treatments contained extracts from both species at concentrations of 0, 125, 250 and 500 µg/mL. Both albendazole and levamisole were used at a level of 1% as positive control. The extract of LAE, compared with PDE, showed better inhibition ($P < 0.05$) of egg hatching. Different doses of both the LAE and PDE extracts showed a larvicidal effect ($P < 0.05$) on all larvae exposed to different doses of the extracts. In the larval migration assay, a similar effect with levamisole occurred with the LAE extract at doses of 250 and 500 µg/mL. The extract of *P. dulce* had a lower larvicidal effect ($P < 0.05$) than levamisole and *L. acapulcensis* extracts. The use of aqueous extract of *L. acapulcensis* could be a promising alternative to synthetic anthelmintics as treatments of gastrointestinal nematodes of sheep in organic and conventional production systems under subtropical conditions.

Key Words: anthelmintic, extract, sheep

M57 Changes in transcriptome of bovine monocytes-derived macrophage challenged with *Mycobacterium bovis*. Dianelys Gonzalez-Pena*, Robmay Garcia, and Andrew J. Steelman, and Sandra L. Rodriguez-Zas, *University of Illinois at Urbana-Champaign, Urbana, IL.*

Macrophages pertain to the mononuclear phagocytes system as part of the innate and acquired immunity responses. The interaction of macrophages with *Mycobacterium bovis* concludes with the formation of granulomas. However, the host-immune response to *M. bovis* could be compromised by the suppression of immuno-regulatory pathways leading to active tuberculosis. Therefore, transcriptome analysis of the macrophage response to *M. bovis* can offer insight into the host-pathogen interaction. Bovine monocyte derived macrophage (MDM) of peripheral blood was obtained from 7 non-infected Holstein cows, cultivated and infected with *M. bovis*. The RNA was isolated 24 h after infection and single-end reads were mapped to the *Bos taurus* (UCSC_bosTau7) reference genome using Tophat v2.012. Using Cufflink v2.2.1, 7,664 transcripts from 7,505 genes were tested and 1,192 transcripts from 1,187 genes were differentially expressed between the infected and non-infected MDM (false discovery rate adjusted *P*-value <0.05). Among the transcripts, 61% were upregulated in the infected relative to non-infected MDM. Interferon gamma (IFNG), indoleamine 2,3-dioxygenase 1 (IDO1), chemokine (C-X-C motif) ligand 10 (CXCL10), and chemokine (C-X-C motif) ligand 9 (CXCL9) were overexpressed in infected relative to non-infected MDM. The IFNG is a potent activator of macrophages, while IDO1 encoded an important rate-limiting enzyme in the kynurenine pathway, activated during the inflammation process that favors immune suppression and tolerance. The CXCL9 and CXCL10 are critical during the early stages of the immune response to *M. bovis*. The top 5 ranking category clusters detected by the functional analysis of the differentially expressed genes using DAVID (enrichment score >5) included immune defense, and the activation and proliferation of leukocyte, lymphocyte, mononuclear cells, and T and B cells as well as cytokines production and apoptosis regulation. This study unveils details of the host response of MDM to *M. bovis*.

Key Words: transcriptome, macrophage, *Mycobacterium*

M58 Phytochemicals in corn distillers grains.

Adebola Daramola and Byungrok Min*, *University of Maryland Eastern Shore, Princess Anne, MD.*

Corn is a major feedstock for the production of fuel ethanol as well as corn distillers grains that are widely used for animal feed. Corn is one of the most abundant sources of health-beneficial phytochemicals among crops. Little information is, however, available for phytochemicals in corn distillers grains. The objective was to determine amounts, availability, and antioxidant capacities of phytochemicals in corn distillers grains: dried distillers grains with solubles (DDGS), wet or modified wet distillers grains (WDG/MWDG), and condensed distillers solubles (CDS), compared with corn. Freeze-dried samples were extracted with 80% ethanol to obtain soluble phenolics. Residues were alkali-treated and extracted with ethyl acetate for cell-wall-bound phenolics. Amounts (total phenolic and flavonoid contents) and antioxidant capacities (DPPH radical scavenging, oxygen radical absorbance, hydroxyl radical averting, and iron chelating capacities) in both phenolics were evaluated. Phenolic acids and carotenoids were also identified and quantified using HPLC. Data were analyzed by ANOVA and sample means were compared using SNK multiple range test. Amounts and antioxidant capacities of soluble phenolics were the highest in DDGS, followed by CDS, WDG/MWDG, and corn ($P < 0.05$). Those of cell-wall-bound ones were the highest in DDGS, followed by WDG/MWDG, corn, and CDS ($P < 0.05$). Ferulic acid was the predominant phenolic acid (~90%) and its amount was the highest in DDGS ($P < 0.05$). Carotenoid content was the highest in DDGS, followed by WDG/MWDG, CDS, and corn ($P < 0.05$). Total phenolic, phenolic acid, and carotenoid contents in DDGS were over 3 times higher than in corn. It is known that, due to conversion of starch to ethanol and CO_2, macronutrients in corn are generally concentrated into DDGS over 3 times. The results indicate that phytochemicals in corn are well concentrated during the processing, thus DDGS have great potential as a source of phytochemicals to improve farm animal health and performance. However, cell-wall-bound phenolic contents in DDGS were 2–5 times higher than those of soluble ones, indicating that the majority of phenolics in DDGS are not readily absorbable. Hence, technologies to liberate them are needed to maximize health-beneficial potentials of DDGS.

Key Words: phytochemical, DDGS, corn

M59 Characterization of the binding potential of pathogenic bacteria to yeast probiotics and paraprobiotics.

Janet R. Donaldson*[1], Gabe Posadas[1], Jeffery A. Carroll[2], Paul R. Broadway[2], Amanda Lawrence[1], and Jimmie Corley[3], *[1]Mississippi State University, Mississippi State, MS, [2]USDA-ARS, Lubbock, TX, [3]Phileo, Lesaffre Animal Care, Milwaukee, WI.*

Probiotics and their associated derivatives (paraprobiotics) are frequently utilized to improve animal health and productivity. However, their mechanisms of action are not fully characterized, especially in regards to the interactions with pathogenic bacteria in the gastrointestinal tract. This study tested the hypothesis that yeast probiotics and paraprobiotics directly interact with pathogenic bacteria differently. To test this hypothesis, the binding capability of 5 different yeast probiotics or paraprobiotics to gram-negative bacteria (*Salmonella* sp. and *Escherichia coli* O157:H7) and gram-positive bacteria (*Listeria monocytogenes* and *Clostridium* sp.) were analyzed. Yeast and bacteria were co-incubated on coverslips, washed extensively, and examined by scanning electron microscope to determine the extent of binding between products and pathogens. Membrane filtration was also used to quantitate the amount of bacteria capable of binding to the yeast product; yeast products and bacteria were co-incubated, filtered using 3μM membrane filters, and the resulting filtrates were assessed for viable bacteria by plate counts. All bacteria tested bound with nearly equivalent efficiencies ($P > 0.05$) against the live yeast probiotics tested (~26%). However, much variation was observed in the binding efficiencies with the paraprobiotics. The gram-positive bacteria had, as a group, a preference for binding to one paraprobiotic in comparison to the other 2 products analyzed (25% adhered vs. 47% adhered; $P < 0.05$), whereas the gram-negative bacteria had greater efficiency to bind to 2 paraprobiotics (40% adhered; $P < 0.001$). These data suggest that the use of probiotics and paraprobiotics as therapies needs to be specific to the pathogen of interest; thus indicating a need for “designer” probiotic/paraprobiotic feeding strategies. Further research is needed to analyze specific binding efficiencies of probiotics and paraprobiotics against infectious agents in vivo.

Key Words: probiotic, bacteria, paraprobiotic

M60 Effects of polybrene and puromycin on equine infectious anemia virus replication.

Dustin A. Therrien, Rebecca D. Parr, and Sarah C. Canterberry*, *Stephen F. Austin State University, Nacogdoches, TX.*

Equine infectious anemia virus (EIAV) is a lentivirus that infects members of the family Equidae. Despite extensive study, there is no method for prevention or treatment of this disease. Novel mechanisms, such as RNA interference (RNAi), have been used to decrease replication of many viruses. Results of previous in vitro studies have indicated that in the process of generating transgenic cells, EIAV replication was inhibited. Thus, these data were inconclusive as to the efficacy of RNAi against EIAV. To further investigate the effectiveness of RNAi, it is essential to discern which aspects of generating transgenic cell lines affects viral replication. Here, we have investigated 2 common reagents: polybrene (Pol), a polycationic polymer used to increase initial cell transduction, and puromycin (Pur), an antibiotic selecting agent. Non-transgenic feline adenocarcinoma cells, persistently infected with $EIAV_{19}$ (a laboratory adapted strain of the virus), were exposed to high and low concentrations of Pol (8 and 16 µg/mL), and Pur, (1 and 2 µg/mL). Control cell lines were exposed to neither reagent. Supernatants were collected for 17 d and viral replication was quantified using a reverse transcriptase (RT) Assay. The RT values were analyzed using R (R, v. 2.15.3, R Development Core Team, 2012) to generate 9999 permutations of the data. Mean RT values (Table 1) for experimental groups were not significantly different from the mean RT values for the control groups. These data indicate that Pol and Pur alone have no effect on viral replication in these cells. Additional studies are needed to determine which reagents used in establishing transgenic cells is responsible for the observed decreases in viral replication.

Contd.

Table 1 (Abstr. M60). Mean RT values per 100,000 cells per day of viral accumulation

Day	Control	Pol High	Pol Low	Pur High	Pur Low

Key Words: equine infectious anemia virus (EIAV), RNA interference (RNAi)

M61 Co-aggregation ability of cell wall components of *Saccharomyces cerevisiae* to pathogenic bacteria.

Marlén Rodríguez[1], Ana Julia Rondón[1], Yadileiny Portilla[1], Ramón Bocourt[2], María José Ranilla*[3,5], María Dolores Carro[4], Alexey Díaz[3,5], and Grethel Milián[1], [1]*Center for Biotechnological Studies, University of Matanzas, Matanzas, Cuba,* [2]*Institute of Animal Science, Mayabeque, San José de las Lajas, Cuba,* [3]*Animal Production Department, University of León, León, Spain,* [4]*Agriculture Production Department, Technical University of Madrid, Madrid, Spain,* [5]*5IGM (CSIC-ULE), Finca Marzanas s/n, Grulleros, León, Spain.*

Autoaggregation in bacteria is the phenomenon of aggregation between cells of the same strain, whereas coaggregation is due to aggregation occurring among different species. Aggregation ability of prebiotic bacteria is related to adhesion ability, which is a prerequisite for the colonization and protection of the gastrointestinal tract in all animal species; however, coaggregation ability of prebiotic bacteria offers a possibility of close interaction with pathogenic bacteria. Coaggregation ability of cell wall components of *Saccharomyces cerevisiae* is known, because of their mannan content, but literature offers little information on this topic. The aim of this experiment was to assess the ability of coaggregation of 2 preparations of *S. cerevisiae* cell walls to 3 pathogenic bacteria (*Staphylococcus aureus* hemolytic enterotoxin A, *Salmonella enteritidis* and *Escherichia coli* serotype O157:H/7). Cell wall preparations consisted on either the distillery cream (DT), a byproduct of sugar cane, or a hydrolyzate (HT) obtained by enzymatic methods. Pathogens were grown in nutritive broth medium for 18 h at 37°C. After that, cultures were diluted (1:1) with DT and HT, and absorbance (560λ) was measured at 0 and 5 h. Both DT and HT showed the ability of coaggregate to the 3 pathogenic strains, and no bacterial strain × cell wall preparation interaction ($P = 0.379$) was detected. Coaggregation was higher ($P < 0.001$; SEM = 0.36) with HT (mean values of 85.3, 78.6 and 77.8% for *S. aureus*, *S. enteritidis*, and *E. coli*, respectively) compared with DT (mean values of 16.5, 5.8 and 6.0% for *S. aureus*, *S. enteritidis*, and *E. coli*, respectively). If confirmed with other pathogen species, these results support further research on the use of the HT from *S. cerevisiae* as a possible prebiotic additive for animal feed.

Key Words: coaggregation, pathogenic bacteria, *Saccharomyces cerevisiae*

M62 In vitro efficacy of chitosan against *Cryptosporidium parvum* and validation on infected goat kids.

Karim Adjou[1], Jean-Philippe Marden*[2], Eric Auclair[2], Christian Mage[3], and Isabelle Vallée[1], [1]*UMR BIPAR Anses-ENVA, Maisons-Alfort, France,* [2]*Phileo Lesaffre Animal Care, Marcq en Baroeul, France,* [3]*Mage Consultant, Estivaux, France.*

The aims of this study were to investigate (1) the efficacy of chitosan in 2 forms, the monomer *N*-acetyl glucosamine (NAG) and a chloride salt of chitosan (MIX) in culture systems HCT-8 and Caco-2 cell lines in vitro for *Cryptosporidium parvum* compared with a positive control, paromomycin (PARO) a classical drug used in veterinary medicine; (2) the action of a chitosan-yeast-bacteria based product on neonatal diarrhea and mortality in goat kids. Cryptosporidiosis is considered as an economically important disease with clinical signs and death in young ruminants. The usual clinical symptom is acute diarrhea affecting animals from 1 to 3 weeks old. As no drugs are fully effective in the treatment of cryptosporidiosis in man and animals, the research for new therapeutic agents is crucial. Chitosan is a sugar that is obtained from the hard outer skeleton of shellfish, including crab and shrimp and it is used in medicine. It has been found to be active against a variety of diseases including antimicrobial and anti-tumoral effects. Immunofluorescence technique was used for the identification and enumeration of the parasites. The results showed a significant reduction of viability of Cryptosporidium oocysts (>95%) after pre-incubation of 24h at 37°C with PARO ($P < 0.001$), MIX and NAG ($P < 0.001$). Additionally, PARO, MIX and NAG inhibited significantly the development of *C. parvum* in HCT-8 and Caco-2 cell lines ($P < 0.005$). These effects were dose-dependent. Synergistic effects were obtained when NAG treatment was associated with Paromomycin. The efficacy of MIX in combination with yeast and bacteria (Optisaf FIRST, Phileo, France) was evaluated experimentally in goat neonates inoculated with *C. parvum* oocystes (10^6 oocytes/mL) per oral route. Preliminary results showed a significant reduction in oocyst shedding and diarrhea score in goat kids and mortality was significantly reduced (36%) in treated animals ($P < 0.05$) compared with the control group (90%). In conclusion, these findings provide evidence of in vitro inhibitory activities of chitosan against *C. parvum* and its combination with yeast-based products revealed promising in lessening the incidence of neonatal diarrhea in young ruminants.

Key Words: chitosan, yeast, goat

Bioethics

M63 US consumer perceptions of and willingness to pay for "local" pork chops and chicken breasts. Elizabeth Byrd*, Nicole Widmar, and Michael Wilcox, *Purdue University, W. Lafayette, IN.*

As the debate continues about what animal agriculture "should" look like, it is important to understand what consumers perceive attributes and buzzwords such as "local" to mean. In our study, when asked how they defined "local" food, 37% of US consumers described local food as having been produced within 10 miles of their home, 21% described local to mean within 20 miles of their home, and 17% described local food as having been produced within the state. Several demographics were found to be correlated with perceptions of "local"; being male is correlated with defining local food as having been produced within 20 miles of home, whereas living in the Northeast is positively correlated with defining local food as produced within 10 miles of home. Households earning less than $40,000 more often defined local food as having been produced within 10 miles of home. Having visited a beef or dairy farm in the last 5 years is negatively correlated with defining local food as having been produced within 10 miles of home. Expressing concern for the welfare of beef or dairy cattle is positively correlated with defining local food as having been produced within 100 miles of home. Are consumers willing to pay (WTP) for verified locally grown pork chops and chicken breasts? Preliminary results of a simulated purchasing scenario indicate that consumers are WTP up to $2.02/lb. for USDA-verified locally produced chicken breasts, but are not WTP for verified locally produced pork chops. Is it possible consumers feel differently about pigs and chickens? But, when asked, 37% and 38% of consumers express concern for the welfare of farmed pigs and chickens, respectively. Do consumers exhibit more trust in different verification agencies? While consumers were WTP $2.02/lb. for the USDA to verify local production in chicken breasts, those same consumers were only WTP $0.37 for the poultry industry to verify that chicken breasts were produced locally. Knowledge about consumer perceptions of local production can help the animal industries make decisions about marketing livestock products.

Key Words: consumer demand, local food, preferences

M64 US consumer awareness of animal diseases and animal health requirements: Are we meeting the demands of the US public? Elizabeth Byrd*, Nicole Widmar, and John Lee, *Purdue University, W. Lafayette, IN.*

Have various segments of a representative sample of US consumers heard of prominent animal diseases such as bovine spongiform encephalopathy (BSE), porcine epidemic virus diarrhea (PEDV), tuberculosis (TB), chronic wasting disease (CWD), leptospirosis, rabies, and food and mouth disease (FMD)? We have found that 30% of respondents reported having heard of BSE, 17% heard of PEDV, and 27% heard of CWD. Various demographic factors have been found, through cross-tabulations, to be associated with the awareness of animal diseases. Being a college graduate, someone who regularly hunts, a pet owner, or a member of HSUS or PETA were all positively correlated with having heard of BSE, PED-v, and Leptospirosis. Reporting concern for the welfare of beef cattle, dairy cattle, or pigs was positively correlated with being aware of all diseases analyzed. Do people who have recently visited farms raising cattle, deer, or pigs show an increased awareness for their associated diseases? Having visited a beef cattle farm in the last 5 years was positively correlated with animal disease awareness. Visiting a dairy or pig farm in the past 5 years was positively associated with awareness of BSE, PED-v, CWD, and Leptospirosis. Consumers who raise their own food, either through gardening, raising chickens for eggs or meat, or raising animals for meat, are more likely to be aware of BSE and PEDV. Related to disease awareness is inspection; respondents were asked about veterinary inspection for transport. Sixty-eight percent of respondents agreed that livestock should be required to undergo a veterinary inspection before being transported within or outside the state. Likewise, 75% of US consumers who were aware of BSE agree that beef carcasses should be tested for BSE before being used for human food consumption. Understanding the demographics the predispose consumers to be more aware and sensitive to animal disease/health issues is important for animal industry communication to consumers to ensure consumer confidence in the food they choose to purchase.

Key Words: consumer demand, preference

M65 Consumers know food, but they don't know ag (how does that work?). Ann Cummins*, Nicole Widmar, Candace Croney, and Joan Fulton, *Purdue University, W. Lafayette, IN.*

This research examined a gap in some consumers' minds between being educated food consumers and being educated about agriculture. This research uses data from a survey that is representative of national household consumers in terms of age, sex, income, and region of residence, with a sample size of 1004. This research identified that to some consumers, being educated about food consumption did not necessarily mean being educated about agriculture. Results include that 37% of people thought they were educated about agriculture but 76% thought they were educated about food. Food consumption and agriculture are connected to one another, but how are we as food providers communicating if in many consumer minds being educated about food and educated about agriculture is not the same. This research examines individuals self-reported level of education about food consumption and education level about agriculture. We examine the differences in these self reported values and demographics, knowledge and perception about as livestock production, and personal consumption behaviors. This research examines the demographic, educational, and perceptions of livestock operation differences that are associated with the different groups, including, those who self-identified as more educated about agriculture than food, those who self-identified as very educated about both food and agriculture, and those who self identified as being more educated about agriculture than food. The methods used for this analysis were both Spearman and Pearson correlations, cross tabs and z-scores (all completed in SPSS). The majority of respondents, 51%, self-reported being more educated about food consumption than agriculture, 2.7% of respondents indicated that they were more educated about agriculture than about food consumption, and 35% of respondents indicated that they consider themselves to be highly educated about both food consumption and about agriculture. Of those who reported to be more educated about food consumption than agriculture, we see that they tend to be female, older in age, not a pet owner, and not visiting tourist attractions.

Key Words: consumers, education, perceptions of agriculture

M66 Ergonomic assessment of the milking routine in large dairy operations of the US Southwest.

Jose A. Garcia Buitrago*[1], Gerrit R. Hagevoort[1], David Gimeno[2], and David I. Douphrate[2], *[1]New Mexico State University, Clovis, NM, [2]University of Texas, San Antonio, TX.*

The US dairy industry has experienced a rapid transformation from small dairy farms to large operations. In southwest regions the majority of commercial dairy herds are large operations. Current trends are larger herds where a great number of cows are attended for few employees. Reasons for these trends are beyond the scope of this abstract. This transformation has led to significant changes in work tasks and in ergonomic challenges due to the repetitive work nature of the milking process. Despite the improvement in modern equipment and design of milking parlors, it seems that the musculoskeletal workload of dairy workers remains high. Field-based direct measures of physical exposures have been limited in these challenging work environments. To assess quantitatively the posture, muscle activity and muscular fatigue a throughout milking shift, we have recruited 30 milking parlor workers representing large-herd (1000+ head) dairy operations in 3 southwest US states. All participants were Latino males between 21 and 45 years of age, who were free of pain or upper extremities pathologies. Shoulder elevation and the trunk inclination angles, were estimated using wireless triaxial accelerometers. Surface electromyography was continually recorded of the upper trapezius, finger flexors, finger extensors and anterior deltoid muscles, while workers performed milking tasks. These muscles were chosen for their relevance when performing milking tasks. Preliminary findings suggest milking workers may be exposed to awkward postures, high velocity and repetitive movements, high repetition, and high muscle forces. These physical exposures have been often associated with the development of upper limb pathology. These results warrant the need for continued research in these working environments, for development of ergonomic strategies that permit improving work conditions and to reduce the negative effect of postures during the milking routine on the musculoskeletal system, as well as to prevent fatigue that would impair dairy workers performance.

Key Words: milking routine, ergonomic, electromyography

Breeding and Genetics: Application and methods in animal breeding—Swine, poultry, and other species

M67 Accuracy of estimated breeding values for males and females with genomic information on males, females, or both: A broiler chicken example. Daniela A. L. Lourenco*[1], Breno O. Fragomeni[1], Shogo Tsuruta[1], Ignacio Aguilar[2], Birgit Zumbach[3], Rachel J. Hawken[3], Andres Legarra[4], and Ignacy Misztal[1], *[1]University of Georgia, Athens, GA, [2]INIA, Las Brujas, Uruguay, [3]Cobb-Vantress Inc., Siloam Springs, AR, [4]INRA, Castanet-Tolosan, France.*

Phenotypes were available on 4 production traits recorded for up to 196,613 broiler chickens. Heritabilities ranged from 0.22 to 0.49. Among all phenotyped birds, 15,723 were genotyped for 39,102 segregating SNP. Traditional and genomic evaluations were run in a multiple-trait model. Single-step genomic BLUP (ssGBLUP) was used for genomic evaluations with 3 different reference sets including only males (4648), only females (8100), and both sexes (12,748). Realized accuracy of genomic EBV (GEBV) was used to evaluate the inclusion of genotypes for different reference sets on predictive ability of young genotyped males (1501), females (1474), and both sexes (2975). Using male genotypes as reference, the average increase in accuracy of GEBV over EBV for males and females was 12 and 1 percentage point, respectively. When the reference population included only female genotypes, the increase for males and females was 1 and 18 percentage points, respectively. Using genotypes on both sexes as reference increased accuracies by 19 points for males and 20 points for females. Adding genotypes for females without phenotypes did not improve predictions. For one trait, EBV and GEBV accuracies for females were much lower than for males. For another trait with similar heritability, both accuracies were higher, and females had higher accuracy than males. For validation animals $\text{GEBV} \approx w_1\text{PA} + w_2\text{DGV}$, where PA is parent average, DGV is genomic prediction, and the w terms are the weights for each component. When the number of genotyped animals is high, the highest weight is for w_2. When an animal is genotyped, the increase in accuracy comes mainly from the DGV portion of GEBV and marginally from improved PA. For non-genotyped animals there is no improvement in accuracy due to DGV. Accuracies for animals of one sex increase with genotypes of the other sex when that sex has independent phenotypic information and when the evaluation methodology avoids double counting. Realized accuracies are biased down by selection, and analysis of realized accuracies can reveal different selection pressure for traits and sex.

Key Words: genomic prediction, genotyping strategy

M68 Genetic parameters for length of productive life and lifetime production traits of purebred Landrace and Yorkshire sows in northern Thailand. Udomsak Noppibool*[1,2], Skorn Koonawootrittriron[1], Mauricio A. Elzo[2], and Thanathip Suwanasopee[1], *[1]Kasetsart University, Chatuchak, Bangkok, Thailand, [2]University of Florida, Gainesville, FL.*

The objective of this research was to estimate genetic parameters and trends for length of productive life (LPL), lifetime piglets born alive (LBA), lifetime piglets weaned (LPW), lifetime piglets' birth weight (LBW), lifetime piglets' weaning weight (LWW) in a commercial swine farm in Northern Thailand. Phenotypic records came from 1,983 Landrace (L) and 745 Yorkshire sows (Y) collected from July 1989 to August 2013. Variance and covariance components, heritabilities and correlations were estimated using a multiple-trait AIREML procedure. The 5-trait mixed animal model contained the fixed effects of first farrowing year-season, breed group (L and Y), and age at first farrowing. Random effects were sow and residual. Medium heritabilities were estimated for all 5 traits (LPL = 0.16 ± 0.04; LBA = 0.18 ± 0.04; LPW = 0.22 ± 0.04, LBW 0.18 ± 0.04 and LWW = 0.22 ± 0.04). Genetic correlations among these traits were positive and favorable (greater than 0.91; $P < 0.05$). Genetic correlation estimates were 0.94 ± 0.02 for LPL-LBA, 0.98 ± 0.03 for LPL-LPW, 0.92 ± 0.03 for LPL-LBW, 0.93 ± 0.02 for LPL-LWW, 0.96 ± 0.01 for LBA-LPW, 0.96 ± 0.01 for LBA-LBW, 0.93 ± 0.02 for LBA-LWW, 0.93 ± 0.02 for LPW-LBW, 0.97 ± 0.01 for LPW-LWW and 0.94 ± 0.02 for LBW-LWW. Dam genetic trends were positive, small and significant only for LBA (0.18 ± 0.05 piglets/yr; $P = 0.0024$), LPW (0.12 ± 0.05 piglets/yr; $P = 0.0153$), LBW (0.35 ± 0.09 kg/yr; $P = 0.0009$), and LWW (1.36 ± 0.40 kg/yr; $P = 0.0024$). Genetic trends for sows and sires were mostly small, negative and not significant for any trait. Thus, the selection program in this commercial herd was ineffective to improve LPL in sows, sires, and dams, and lifetime production traits in sows and sires. This program was only effective to improve lifetime productive traits in dams.

Key Words: genetic parameter, lifetime production trait, swine

M69 A study on *PIT1* gene polymorphism and its association with growth traits in pigs. S. Mohana Devi*[1], V. Balachandar[2], and I. H. Kim[1], *[1]Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea, [2]Department of Human Genetics and Molecular Biology, Bharathiar University, Coimbatore, Tamil Nadu, India.*

The pituitary transcription factor (PIT1) (or POU1F1) protein belongs to pituitary-specific transcription factors localized on chromosome 13 in porcine. The PIT1 gene was used as a candidate gene for selecting animals for growth and carcass traits. Thus, the aim of this study was to identify and compare the Rsa I polymorphism of the PIT1 gene in finishing pigs to evaluate mutations in the meat quality of porcine by screening to novel gene markers PIT-1 and to investigate the genotypic alteration of the pigs, which may help to locate the chromosomal regions that may be linked with candidate genes that are associated with pig muscle growth and pork quality. The genomic DNA from 460 pigs was extracted and the genotypes for polymorphism analysis were determined using PCR-RFLP. The PIT1 genotype frequencies analyzed were 42.39% for AA, 39.13% for AB and 18.48% for BB. Several significant associations of PIT1 gene polymorphisms with some of the growth traits were observed. The pigs with BB genotype showed the highest average daily gain. Several significant differences were observed in meat color (A, B and L*; $P < 0.05$). Meat carcass traits LMP and LMC seem to be lower in pigs with BB genotype compared with AA genotype animals. The AA finishers presented a lower level of back fat thickness compared with AB genotypes. The PIT1 are potential candidate genes, influencing quality traits as they encode proteins, which causes essential effects in its functions and the present study tries to confirm the association of its polymorphism with its economically important traits in pigs. Therefore the assumption that genetic unpredictability of the PIT1gene could be associated with swine population in commercial traits.

Key Words: *PIT1* gene, growth trait, pig

M70 Recombination rates in layer chickens. Zi-Qing Weng*[1], Anna Wolc[1,2], Rohan L. Fernando[1], Jack C. M. Dekkers[1], Jesus Arango[2], Petek Settar[2], Janet E. Fulton[2], Neil P. O'Sullivan[2], and Dorian J. Garrcik[1], [1]*Department of Animal Science, Iowa State University, Ames, IA,* [2]*Hy-Line International, Dallas Center, IA.*

Recombination events, which occur during meiosis, vary in frequency across chromosomes, and among individuals. Recombinations are more common in certain genomic locations known as hotspots and these are controlled by genes. The objective of this study was to assess recombination events across the genome, and identify quantitative trait loci (QTL) that influence recombination frequency in white and brown layer chickens. This study included 1,200 white layers hatched between 2006 and 2012, genotyped with a 600K single nucleotide polymorphisms (SNP) panel, and 5,108 brown layers hatched between 2003 and 2011, genotyped with a 40K SNP panel. FImpute was used to impute missing genotypes. After quality control, 173,224 and 23,098 segregating SNPs remained. There were 492 half-sib families in white layers averaging 3.0 ± 3.0 birds, and 1717 half-sib families averaging 5.4 ± 4.9 brown layer birds. Recombinations were identified within half-sib families using LINKPHASE. Total recombination rates within each 1-Mb window was calculated across 28 chromosomes (Chr). Windows with recombination rates greater than 0.03 (≥1.5 SD from the mean) were considered to be recombination hotspots, while those with no recombinations were cold-spots. Genome-wide recombination numbers of parents were analyzed in a weighted BayesB model. Windows that explained >1% genetic variance were considered to harbor QTL. There were 14,746, and 230,701 recombination events detected in white layers and brown layers, respectively. There were 163 and 281 windows with hotspots detected in white and brown layers, respectively, of which 66 were in common. There were 48 common cold-spots in these 2 breeds. Genome-wide recombination number (GRN) differed by breed and sex. White layers (10.9 ± 4.1) had smaller GRN than brown layers (24.1 ± 3.9). In white layers, females (13.6 ± 3.7) had higher GRN than males (9.3 ± 3.5) but in brown layers GRN were similar in females (24.2 ± 4.2) and males (23.9 ± 3.4). A total of 14 and 6 significant windows, which harbor candidate genes influencing genome-wide recombination, were detected in the 2 breeds. No common QTL windows were found in the 2 breeds. Sample size, marker density, inbreeding level and population structure lead to differences in detection of recombination events and QTL in the 2 breeds.

Key Words: recombination, layer chicken

M71 Genetic selection tool for number born alive and stillbirth piglets in commercial Thai populations. Thanathip Suwanasopee*[1], Skorn Koonawootrittriron[1], and Mauricio A. Elzo[2], [1]*Department of Animal Science, Faculty of Agriculture, Kasetsart University, Bangkok, Thailand,* [2]*Department of Animal Sciences, University of Florida, Gainesville, FL.*

Genetic markers are widely used for selection and prediction in commercial pig populations. Number of piglets born alive (NBA) and stillborn piglets (STB) within litters have a major effect on overall economic returns. The aim of this study was to determine the association between estrogen receptor gene (*ESR*) and paternally expressed gene 1 (*PEG1*) and NBA and STB. The data set included information from 2 commercial pig populations, one in Northern Thailand (210 sows; 123 Landrace and 87 Yorkshire) and another one in Northeastern Thailand (130 sows; 70 Landrace and 60 Large White). Each population was analyzed separately using 2 models. Model 1 included farrowing year-season, parity, age at first farrowing and breed group as fixed effects, and animal and residual as random effects. Model 2 included all effects from model 1 plus genotypes for *ESR* (AA, AB, and BB) and *PEG1* (AA, GA, and GG) as fixed effects. Association between predicted EBV from models 1 and 2 were analyzed using Spearman rank correlations. Genotype frequencies were 0.67, 0.29 and 0.04 for ESR and 0.01, 0.40, and 0.59 for PEG1 in the Northern population, and 0.42, 0.34, and 0.24 for ESR and 0.05, 0.25, and 0.70 for PEG1 in the Northeastern population. The *ESR* genotype influenced the EBV of Yorkshire sows for NBA ($P < 0.05$) and STB ($P < 0.01$). Yorkshire *ESR* AA sows had the highest average EBV for NBA (0.16 ± 0.03 piglets), whereas Yorkshire *ESR* AB sows had the lowest average EBV for STB (−0.01 ± 0.01 piglets). The *PEG1* genotype affected the EBV of Landrace, Yorkshire and Large White sows for NBA and STB ($P < 0.05$). Large White *PEG1* GG sows had the highest average EBV for NBA (0.43 ± 0.06 piglets), and Landrace *PEG1* AA sows had the lowest average EBV for STB (−0.09 ± 0.09 piglets). Positive rank correlations between EBV from models 1 and 2 existed in the 2 populations for all breeds (0.41 to 0.63; $P < 0.01$), except for Landrace sows in the Northern population (−0.08; $P > 0.05$). These rank correlations indicated that selecting sows with higher NBA and lower STB by using EBV from models with and without *ESR* and *PEG1* marker effects would likely yield similar outcomes.

Key Words: pig, genetic marker, selection

M72 Genomic correlation between piglet preweaning mortality and individual birth weight using a bivariate threshold-linear maternal effect model. Shogo Tsuruta*[1], Ching-Yi Chen[2], William O. Herring[2], and Ignacy Misztal[1], [1]*University of Georgia, Athens, GA,* [2]*PIC North America, Hendersonville, TN.*

The objective of this study was to predict genomic breeding values for preweaning mortality and birth weight using a bivariate threshold-linear maternal effect model.

The data for preweaning mortality and birth weight, and genotypes were obtained from PIC North America and contained 123,163 phenotypic records and 135,530 animals in pedigree. The genotype file contained 42,787 single nucleotide polymorphism (SNP) markers for 13,566 pigs. Birth weight and preweaning mortality were recorded at piglet level. The model included fixed contemporary group, sex, parity, and number of total born per litter effects, random direct and maternal genetic effects, random maternal permanent environmental effects (MPE), and random residual effects (R). First, direct and maternal heritabilities for preweaning mortality and birth weight and genetic correlations were estimated with the Gibbs sampling THRGIBBS1F90 program. Second, genomic breeding values (GEBV) were predicted with the CBLUP90IOD program, which uses preconditioning conjugate gradients and iteration-on-data for a large number of categorical records, using a single-step genomic BLUP. Direct heritability estimates for preweaning mortality and birth weight were 5.4 and 14.0%, respectively. Maternal heritability estimates were 2.1 and 17.2%. Direct and maternal genetic correlations between the two traits were −0.18 and −0.63, respectively. Environmental correlations were also negative (−0.34 and −0.41 for MPE and R). Correlations of GEBV for 13,566 genotyped animals between the two traits were −0.17 and −0.84 for direct and maternal genomic effects, respectively. Preweaning mortality is negatively affected by birth weight especially through maternal genetic components.

Key Words: preweaning mortality, birth weight, genotype

M73 Genetic parameters of lifetime characteristics of pre-weaning production traits of landrace sows raised under tropical conditions. Teerapong Jaichansukkit[1], Thanathip Suwanasopee*[1], Skorn Koonawootrittriron[1], and Mauricio A. Elzo[2], [1]*Kasetsart University, Bangkok, Thailand,* [2]*University of Florida, Gainesville, FL.*

Lifetime preweaning production traits are important for increasing profitability in commercial swine operations. Sows with larger pre-weaning production from the first to the last parity in her lifetime are preferred. Thus, it is important to determine how heritable lifetime pre-weaning production traits are in swine populations under tropical conditions in Thailand. Consequently, the objective of this study was to estimate genetic parameters for characteristics of lifetime pre-weaning production traits of Landrace (L) sows raised in an open-house system in Thailand. The pre-weaning production traits were number of piglet born alive (NBA), number of piglets weaned (NPW), average weight of piglets at birth (ABW), and average weight of piglets at weaning (AWW). The characteristics considered for these traits were first-parity value (FPV), peak-parity value (PPV), number of parities from first-parity to peak-parity (P1P), and persistency from the third to the last parity (regression coefficient; P3L). The data set contained 6,075 performance records from 941 sows that farrowed from 2004 to 2012. Variance components for each characteristic were estimated separately for the 4 traits using an AI-REML procedure. The 4-trait animal model for each characteristic included first-farrowing year-season and age at first farrowing as fixed effects, and sow and residual as random effects. Heritability estimates ranged from 0.04 (NPW) to 0.10 (ABW) for FPV, 0.06 (NPW) to 0.20 (NBA) for PPV, 0.01 (NBA) to 0.04 (ABW) for P1P, and 0.03 (NPW) to 0.17 (ABW) for P3L. Genetic correlation estimates ranged from −0.47 (NPW-AWW) to 0.87 (ABW-AWW) for FPV, −0.10 (NPW-AWW) to 0.85 (ABW-AWW) for PPV, −0.73 (NBA-NPW) to 0.58 (NBA-AWW) for P1P, and −0.70 (NPW-AWW) to 0.13 (NPW-ABW). The low estimates of heritability for all characteristics in these 4 lifetime preweaning production traits indicated that genetic improvement for these characteristics in all these traits would either be slow or nonexistent in this Landrace population.

Key Words: pig, lifetime production, tropics

M74 General and specific combining abilities for reproductive and growth performance of three color variants of Nigerian indigenous turkeys. Matthew A. Adeleke*[1], Rasheed O. Ojo[1], Sunday O. Peters[2], and Michael O. Ozoje[1], [1]*Department of Animal Breeding and Genetics, Federal University of Agriculture, Abeokuta, Ogun State, Nigeria,* [2]*Department of Animal Science, Berry College, Mount Berry, GA.*

Assessment of combining abilities is important in evaluation of hybrid combinations for genetic improvement. Our objective in this study was to determine combining abilities of 3 color variants of Nigerian indigenous turkeys. Two hundred fifty poults consisting of 41 White × White (WW), 40 Black × Black (BB), 32 Lavender × Lavender (LL) purebreds; 26 White × Black (W×B), 24 Black × White (B×W), 22 White × Lavender (W×L), 20 Lavender × White (L×W), 23 Black × Lavender (B×L) and 22 Lavender x Black (L×B) crossbreds were generated from matings among White, Black and Lavender color types. The poults were raised from day-old to 20 weeks. A 3 × 3 diallel design was set up and data analyzed using SAS (2005) to estimate general combining ability (GCA) and specific combining ability (SCA) for fertility, hatchability, weak-in-shell, dead-in-shell, dead-in-germ, body weight, breast girth, body length and thigh length. The highest GCA was recorded for fertility (4.44), hatchability (5.39) and dead-in-shell (2.60) in BB, LL and WW respectively. SCA for fertility was the highest in W×B (0.07). W×L had highest SCA (3.28) for hatchability. Least SCA for weak-in-shell (−0.50), dead-in-germ (−2.87) and dead-in-shell (−47.17) were observed in W×L crossbred. The highest GCA for body weight at wk 20 was recorded for WW (90.83). The highest SCA for body weight at wk 20 was recorded in W×L (0.62). BB had highest GCA values for breast girth, body length and thigh length at wk 20 (1.46, 0.46 and 0.41 respectively). B×W recorded the highest SCA (0.94) for breast girth; W×L gave the highest SCA (2.34) for body length while the highest SCA (0.89) for thigh length was observed in B×L turkey genotype. Based on genetic parameter estimates, additive variance was more important for growth parameters, fertility and dead-in-germ while dominance variance was higher and more important in controlling hatchability, weak-in-shell and dead-in-shell than additive variance. Dams from B×W crossbred local turkey can be used to improve growth performance while W×L can be used to achieve best combiners for improvement of reproductive traits in Nigerian indigenous turkeys.

Key Words: combining ability, turkey, plumage color

M75 Association with disease resistance markers and economic traits in Korean native chickens. Boyeong Park*, Anh Duc Truong, Jihye Ban, and Yeong Ho Hong, *Chung-Ang University, Anseong, Gyeonggi, Korea.*

Avian coccidiosis is a mucosal infectious disease that significantly impairs the growth and feed efficiency of chickens. There are associations between oocyst and body weight, the parameters of resistance to coccidiosis and SNPs in 2 genes [Myeloid leukemia factor 2 (*MLF2*), T cell receptor-β (*TCR-β*)] located on chromosome 1. A total of 5 SNPs of *MLF2* and *TCR-β* genes were assessed for genetic effects on disease resistance. The MLF2-SNP_892 (GG) is most significantly related to decreased oocyst shedding. Besides, a combination of SNPs is mostly associated with disease resistance. A total of 340 female chickens from 7 pure-bred chicken lines [Rhode Island Red (RIR) D line, Korean Native Chicken (KNC) gray, KNC black, KNC, Leghorn F, Leghorn K, and Ogey line] were used to genotype with real-time PCR (LightCycler 960). The SNP genotyping was carried out for each line using the High Resolution Melting Master (LightCycler 480) that represent melting curves after PCR amplification. Interestingly, their haplotype is significantly matched with their economic traits. Taken together, this new information will be a parameter that disease resistance markers related with phenotypes consist of body weight, weight of first egg and further study required to prove those marker's availability in poultry breeding industry

Key Words: chicken, disease resistance marker, high-resolution melting

M76 Breeding implications of heteroskedastic whole-genome prediction of genetic merit. Zhining Ou*[1], Robert J. Tempelman[2], Juan P. Steibel[2], Catherine W. Ernst[2], Ronald O. Bates[2], and Nora M. Bello[1], [1]*Kansas State University, Manhattan, KS,* [2]*Michigan State University, East Lansing, MI.*

Current breeding programs in animal production systems involve selection of candidate animals with superior genetic merit to serve as progenitors of the next generation. In this study, we predicted genomic breeding values (GEBV) for 2 quantitative traits from the Michigan State University Swine Resource Population using standard whole-genome prediction (WGP) models that assume homogeneous residual variance (i.e., RR-BLUP, BayesA, BayesB and BayesCπ) and their heteroskedastic counterparts. We divided the data into 5 mutually exclusive folds, such that 4 folds were alternatively used to train homoskedastic and heteroskedastic versions of each WGP model and then predict GEBV on animals on the remaining validation fold. The pseudo-Bayes factors indicated that heteroskedastic error WGP models improved model fit at all 5 crossvalidation folds. Within each fold, we then computed the Spearman rank correlation between homoskedastic- and heteroskedastic-based GEBV for top and bottom 10% individuals to compare their relative rankings. We noticed a considerable degree of re-ranking of animals with 10% top and bottom homoskedastic GEBV, particularly as the amount of residual heterogeneity in the data increased. For loin muscle pH at 45 min post-mortem, the median rank correlation of GEBV for top (bottom) 10% animals between heteroskedastic and homoskedastic models ranged from 0.52 to 0.70 (0.64 to 0.70) across data folds and WGP models. Similarly, for carcass temperature at 45 min post-mortem, the median rank correlation ranged from 0.05 to 0.38 (top 10%) and from 0.43 to 0.54 (bottom 10%). These results indicated non-negligible re-ranking of individuals with extreme genetic merit when heterogeneity of residual variances across environments is accounted for, thereby supporting potential practical implications for selection purposes in breeding programs.

Key Words: whole-genome prediction model, residual heteroskedasticity, re-ranking

M77 Co-association gene networks for meat quality and carcass traits in pigs and validating by transcription factors. Darlene A. S. Duarte*, Fabyano F. Silva, Renata Veroneze, Lucas L. Verardo, Ivan Carvalho Filho, Simone E. F. Guimarães, and Paulo S. Lopes, *Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

The aim of this study was perform genome association studies for meat quality and carcass traits and thereafter build gene network to improve the knowledge of genes, pathways and the physiological mechanisms that affect meat quality and carcass traits. In addition, the identification of transcriptional factors related to those genes was used to validate this network. We performed genome association studies for 12 traits (one trait at time) in a F_2 population (produced by crossing naturalized Brazilian breed Piau with commercial line) and we found 144 significant SNPs (p-value < 0.05). These SNPs were selected to build the Association Weight Matrix (AWM), which was used to investigate the genetic basis of these traits and generate gene network based on the co-association of pair-wise SNPs across phenotypes. Through this methodology, we found 45 genes that were used to build a gene network based on pair-wise correlations between them. We identified 25 transcription factors (TF) strongly related (p-value < 0.001) with genes in the network. The top 3 TF (Sox5, Nkx2–5 and T) were chosen for construction of a network with their pathways and gene ontology. The genes present in the network generated from AWM and also present in TF network were involved mainly in metabolism of adipose tissue and skeletal muscle. These results suggest that genes and TF identified here are important in the control of meat quality and carcass traits. However, further efforts should be made to study in more detail the new gene-gene interactions here identified, as well as, the key transcription factors and pathways involved in these traits.

Key Words: genome association studies, gene network, pig

M78 An improved approach for swine SNP genotyping using Genotyping-by-Sequencing. Cheng Tan*[1], Jiangli Ren[1], Zhuolin Huang[1], Yiqiang Zhao[1], Yang Da[2], and Xiaoxiang Hu[1], *[1]State Key Laboratory for Agrobiotechnology, China Agricultural University, Beijing, China, [2]Department of Animal Science, University of Minnesota, Saint Paul, MN.*

Genotyping-by-sequencing (GBS) technology has a capacity for delivering large numbers of single nucleotide polymorphism (SNP) marker genotypes with potentially lower cost than SNP chips. To achieve stable genotyping results, we selected the *Eco*RI-*Msp*I enzyme from a large number of candidate enzymes, and used the magnet beads-based purification method to stably and simply recapture GBS tags. Genomic DNA samples from 192 Duroc pigs were digested with *Eco*RI-*Msp*I enzyme, ligated to adapters containing unique barcode, and sequenced on the Illumina NextSeq 500 system with 75bp single-end sequencing. The results showed that all 192 barcoded DNA samples were represented evenly, and that on average 4 million reads per animal were produced. From these samples, about 450,000 unique sequence tags per sample containing 55,843 SNPs were identified through TASSEL4.0 analysis package requiring a minimum of 10 times that a tag must be present, which covered about 1% of the whole genome. The average call rate per individual was more than 94.6%. By repeating GBS genotyping on 2 different samples with 96 pigs in each sample performed by different technicians, 88.5% of the 55,843 SNPs had the same genomic locations from both samples. The cost of the 55,843 SNPs per sample was under $50 per animal. These results showed that our improved GBS technique is sufficiently high-throughput, economical and provides an acceptable marker density for genomic selection or genome-wide association studies.

Key Words: genotyping-by-sequencing, swine, SNP

M80 Growth curve analyses of three turkey genotypes in the hot humid tropics using a Bayesian mixed model approach. Michael O. Ozoje*[1], Sunday O. Peters[2], Kyle C. Caires[2], and Kadir Kizilkaya[3], *[1]Federal University of Agriculture, Abeokuta, Ogun State, Nigeria, [2]Berry College, Mount Berry, GA, [3]Adnan Menderes University, Aydin, Turkey,.*

Growth curves are critical for the understanding and formulation of breeding plans because they shift in response to selection. Nonlinear functions have been used extensively to represent changes in sizes with age, so that the genetic potentials of animals for growth can be evaluated. This study was undertaken to apply the nonlinear Bayesian mixed effect model to examine the changes in the growth pattern of 3 Turkey genotypes in Nigeria. Growth data of 435 turkey poults over a 20-wk period were evaluated using Logistic, von Bertalanffy and Gompertz growth models with normally or Student's-t distributed error. The parameter estimates were significantly different in the models by sexes and genotypes. However, the estimates of parameters were similar except for the differences observed among the local turkey genotypes whose values decreased significantly under the Student's-t distribution. The estimate of the average mature weight (A) in the von Bertalanffy model was the closest to the observed average. The estimate of constant B ranged from 15.62 to 22.17 under the Logistic model but significantly dropped to a range of 0.78 to 4.19 with Gompertz and von Bertalanffy models. The estimate of the rate of maturing (k) varied from 0.06 in von Bertalanffy to 0.26 in the Logistic model. Large estimates of A were generally associated with smaller estimates of k in the von Bertalanffy model. Evaluation of the goodness of fit based on the Deviance Information Criteria showed that the von Bertalanffy model was superior. The differences between functions with respect to average life time absolute growth rate, absolute maturing rate and relative growth rate reflect differences in rate of growth and maturing throughout the growing and maturing phases. In general, these differences are indicative of the differences that exist among the functions with respect to their abilities to fit the actual growth curve of these turkey genotypes and their sexes.

Key Words: turkey, growth curve, nonlinear function

M81 Inferring the causal effect of number of lambs born on milk yield in dairy sheep using propensity score methods.

Vera C. Ferreira*, Bruno D. Valente, David L. Thomas, and Guilherme J. M. Rosa, *University of Wisconsin-Madison, Madison, WI.*

Assigning causal interpretation to associations obtained from observational data is challenging as they are prone to confounding. Number of lambs born (prolificacy) in sheep may be considered as a potential factor contributing to milk yield (MY). However, inferring this effect using traditional regression or ANOVA techniques can generate spurious results whenever there are confounder variables that influence both the outcome (i.e., MY) and treatment (i.e., prolificacy). Propensity score (PS) methods tackle this issue by balancing baseline covariate distributions between treatment levels, allowing unbiased inference of marginal effects. This method belongs to the framework of causal models dealing with potential outcomes. It intends to mimic aspects of randomized trials, for which comparison of treatment groups is causally meaningful. Our goal was to infer the causal effect of ewe prolificacy on her subsequent MY using PS based on Matched Samples. Data comprised 4,319 records from 1,534 crossbred dairy ewes. The set of potential confounder variables was composed by lactation number (1st, 2nd, and 3rd – 6th) and dairy breed composition (<0.5, 0.5-0.75 and >0.75 of East Friesian or Lacaune). For the treatment variable, single lamb birth was assigned to Group 0, while multiple birth (2, 3 or 4 lambs) was assigned to Group 1. MY represented the volume of milk produced for the whole lactation (mean = 268.5 L and SD = 116.4 L). The analysis was conducted using the R package "nonrandom." A total of 1,166 pairs of treated/nontreated individuals with similar PS values were formed. The criterion for similarity was defined by a caliper size equal to 20% of the sd in the PS logit (0.13) and a ratio of treated/untreated = 1. Standardized differences were chosen as the statistical test for the hypothesis of PS balance, and all covariates were deemed balanced after matching (cutoff for standardized bias = 0.2). The estimated causal effect of prolificacy on MY was 20.52 L, SE = 3.77 L, 95% CI = 13.13–27.91 L. Hence, results indicate that ewes that gave birth to a single lamb would be expected to have MY increased by 20.52 L if they had given birth to multiple lambs and all other variables were held constant.

Key Words: causal inference, milk yield, prolificacy

M82 Comparative whole-genome analysis of CpG islands in camelid and selected mammalian genomes.

Arsalan Barazandeh[1,2], Mohammadreza Mohammadabadi[2], Ikhide G. Imumorin[3], Sunday O. Peters*[4], Bolaji N. Thomas[5], Mostafa Ghaderi-Zefrehei[6], and Hossein Nezamabadi-Pour[1], *[1]Shahid Bahonar University of Kerman, Keerman, Iran, [2]Jiroft University, Jiroft, Iran, [3]Cornell University, Ithaca, NY, [4]Berry College, Rome, GA, [5]Rochester Institute of Technology, Rochester, NY, [6]University of Yasousj, Yasousj, Iran.*

Camels are dromedaries found in extreme desert environments of Africa and Asia with adaptations to arid conditions of temperatures exceeding 40°C, water losses greater than 25% of total body weight, and the ability to survive up to 14 d without water. Camels are important as beasts of burden for transport and as sources of meat, milk and wool in many desert countries. Therefore, camel could be very useful in the weather extremes precipitated by global climate change. Recent sequences of camelidae genomes [wild bactrian camel (*Camelus bactrianus ferus*), bactrian camel (*Camelus bactrianus*), dromedary (*Camelus dromedaries*) and alpaca (*Vicugna pacos*)] provides the opportunity to better understand the genomic architecture of this unique group of animals. CpG island (CGIs) sequence patterns in complex genomes typically consists of high-frequency of CpG dinucleoetides associated with promoter regions of about 70% of all genes, found in almost all housekeeping genes and in about half of tissue-specific genes. CGIs play important roles in the regulation of gene expression including X-chromosome inactivation, imprinting, silencing of intragenic parasites and are extensively linked to the epigenetic causes of cancer. We used newly available genomic sequence to perform comparative large-scale whole-genome analysis of CGIs for the first time in Camelidae using 5 different CGI detection algorithms. These algorithms detected different numbers of CGIs, CGI density and CGI length distribution in Camelidae. All algorithms agreed on the alpaca genome as having the largest number of CGIs, CGI density and average length of CGIs. When compared with other mammalian genomes of human, mouse, dog, horse and cow, CGIs features in cow genome was the most similar with camelid genomes. These results contribute to better understanding of the evolutionary genetics of camelid genomes in comparison with other livestock species. Further analysis of camelid genomes may shed more light on molecular origins and mechanisms of heat adaptation in these extreme heat-adapted animals.

Key Words: Camelidae, genome, CpG island

M83 Genome-wide association study of mandibular inferior in multiple breeds of sheep.

Michelle R. Mousel*[1], Stephen N. White[1,2], J. Bret Taylor[3], and Donald P. Knowles[1,2], *[1]USDA-ARS, Animal Disease Research Unit, Pullman, WA, [2]Department of Veterinary Microbiology and Pathology, Pullman, WA, [3]USDA-ARS, Range Sheep Production Efficiency Research Unit, Dubois, ID.*

Misalignment of the jaw in sheep, which has long been considered a genetic condition, occurs in most sheep breeds, and culling of affected animals is recommended. Severe mandibular inferior, where the mandible is shorter than the maxillary, can lead to premature death due to starvation. A German breeding trial of affected sheep produced greater than 60% affected lambs and they estimated jaw misalignments were due to dominant and recessive gene effects. A genome wide association study was conducted using the OvineSNP50 marker set to genotype ewes that either produced unaffected lambs (n = 712) or at least 1 affected (n = 252) lamb during their lifetime. Large numbers of animals from multiple breeds improves the odds for detecting true positively associated genomic regions in multiple genetic backgrounds. Jaw misalignment was categorized as severe, greater than 1.3 cm longer maxillary, moderate, between 0.3 and 1.3 cm longer maxillary, mild, between 0.05 and 0.29 cm longer maxillary, and normal, no misalignment within 24 h of birth. Ewes were Rambouillet, Polypay, and Columbia breeds which produced a total of 8321 purebred and crossbred lambs over 13 y with 3.9% of lambs presented with mandibular inferior. Year of lamb birth was significant ($P < 0.01$) with lambs born in 2009 having more misaligned jaws compared with all other years. Sex of lamb was significant ($P < 0.01$) with a greater frequency of misaligned jaws in male lambs. Breed of lamb sire ($P > 0.52$), ewe age ($P > 0.32$), and breed of ewe ($P > 0.08$) did not affect lamb jaw alignment. A recessive model accounting for breed, population cluster, and minor allele frequency identified 2 genomic regions that were significantly (Bonferroni-corrected $P < 0.03$) and 2 genomic regions that were suggestively (unadjusted $P < 2.3 \times 10^{-6}$) associated with mandibular inferior. The 2 significant markers were located on chromosome 2, near a gene which affects growth, and chromosome 22 near a gene that plays a role in membrane trafficking.

Further evaluation of these genomic regions is required to identify underlying causal mutations, which would be useful in marker-assisted selection for sheep producers.

Key Words: sheep, mandibular inferior, genome-wide association study

M84 Integration of haplotype analysis of functional genomic information with single SNP analysis improved accuracy of genomic prediction.

Cheng Tan*[1,2], Dzianis Prakapenka[1], Chunkao Wang[1], Li Ma[3], John R. Garbe[4], Xiaoxiang Hu[2], and Yang Da[1], *[1]Department of Animal Science, University of Minnesota, Saint Paul, Minnesota, [2]State Key Laboratory of Agrobiotechnology, China Agricultural University, Beijing, China, [3]Department of Animal and Avian Sciences, University of Maryland, College Park, MD, [4]Minnesota Supercomputer Institute, University of Minnesota, Minneapolis, MN.*

We compared 3 methods of genomic prediction using additive and dominance effects of single SNPs and haplotype blocks. Method I was single SNP analysis of 423,131 SNPs covering all human autosomes from the Framingham Heart Study with over 6000 individuals. The next 2 methods add haplotype analysis of functional information to the single SNP analysis, i.e., Method II adds haplotype analysis of 595 “cholesterol-related genes” with 8,674 SNPs (2% of autosomes); Method III adds haplotype analysis of 9821 genes with 184,686 SNPs (36% of autosomes) after removing tiny genes without at least 2 SNPs. The results from 4 to 8 validation samples showed that adding haplotype analysis to single SNP analysis improved the prediction accuracy in most cases. Method II with cholesterol-related genes had the best prediction accuracy for total cholesterol with 4.78% increase in accuracy over single SNP analysis, and had stable accuracy increases across validation samples for all cholesterol phenotypes. Method III using all autosomal genes had the best accuracy for triglyceride with 17.75% increase in accuracy over single SNP analysis and tended to have the best performance across different phenotypes, but had larger variations than Method II across validation samples for cholesterol phenotypes. Results were also obtained from one validation sample for adding 3 other haplotype analyses to single SNP analysis: ChIPseq sites with 375,924 SNPs and average block size of 115.8Kb; non-hotspot blocks with each block between 2 crossover hotspots with 422,695 SNPs and average block size of 65Kb, and evenly divided blocks with block size of 100Kb of 422,814 SNPs. All 3 methods improved the prediction accuracy for most phenotypes but ChIPseq blocks mostly had better prediction accuracy than the other 2 methods, indicating that ChIPseq sites likely contained useful functional information not present in anonymous blocks. The results in this tudy tend to conclude that the integration of haplotype analysis of functional genomic information with single SNP analysis may improve the accuracy of genomic prediction for some phenotypes.

Key Words: haplotype, genomic selection, SNP

M85 Preliminary study of *DMRT3* variation and association with performance gait for American Saddlebred horses.

Inaê C. Regatieri*[1], John E. Eberth[2], Fred Sarver[3], and Ernest Bailey[2], *[1]Faculdade de Ciências Agrárias e Veterinárias, UNESP – Univ Estadual Paulista, Jaboticabal, São Paulo, Brazil, [2]Department of Veterinary Science, University of Kentucky, Lexington, KY, [3]Cornerstone Farm, Carlisle, KY.*

The Doublesex and Mab-3 Related Transcription Factor 3 (*DMRT3*) gene encodes an important transcription factor in the setting of spinal cord circuits controlling movement in vertebrates. The SNP g.22999655C>A of the *DMRT3* gene was significantly associated with performance of 4-beat gaits in horses, such as the running walk and the amble American Saddlebreds ridden and shown under saddle seat in both 3-gaited (walk, trot, and canter) or 5-gaited classes (walk, trot, slow gate, rack, and canter). We investigated whether SNP g.22999655C>A of *DMRT3* was more prevalent among 5-gaited horses than among the random population of Saddlebred horses. The genotyping of the SNP of the DMRT3 gene was performed by PCR-RFLP using the restriction enzyme *Dde*I. The frequency of the *A* allele among 37 randomly selected Saddlebreds was 0.28. This is in agreement with results from a previous study in which the prevalence of the *A* allele in American Saddlebred horses was 27.5. Only 3 of the horses in our study had been shown as 5-gaited horses and all 3 had the genotype *A/C*. Although consistent with the hypothesis that the *A* allele is more prevalent among for 5-gaited horses, the numbers are too small for any conclusion. Additional Saddlebred horses, and especially 5-gaited horses, will be tested and results reported allowing determination of statistical significance.

Breeding and Genetics: Molecular genetics

M86 Heat storage and HSP expression of Holstein females – an *in vivo* study. Ana C. A. P. M. Geraldo[1,2], Thays M. C. Leme[1], Reíssa A. Vilela[1], Cristiane G. Titto[1], Evaldo A. L. Titto*[1], Paulo Infante[3], Fernando J. Moreira da Silva[4], and Alfredo M. F. Pereira[2], *[1]Animal Science and Food Engineering Faculty, University of São Paulo, Pirassununga, São Paulo, Brazil, [2]Institute of Mediterranean Agricultural and Environmental Sciences,University of Évora, Évora, Portugal, [3]Mathematics Department, University of Évora, Évora, Portugal, [4]Department of Agrarian Sciences, University of Azores, Angra do Heroísmo, Azores, Portugal.*

One of the main factors that affect animals' performance is high temperature, causing several changes, including at the cellular level. These changes lead to an increased expression of heat shock proteins. This experiment aimed to study the *HSPA1A* and *HSP90AA1* gene expressions of Holstein cows after exposure to direct solar radiation. The heat tolerance test was performed and rectal temperature and respiratory rate measured, and blood samples collected. After the erythrocytes lysis to obtain the buffy-coat, the RNA was isolated by the TRIzol method and RT-PCR performed with SuperScript III after digestion with DNase I. The qPCR apparatus took place in 7500 Real Fast Time, using TaqMan Gene Expression Assays for HSPA1A and HSP90AA1 target genes, ACTB and PPIA as endogenous genes. The ΔCt ($Ct_{target} - Ct_{endogenous}$) were calculated as well as gene expression through the $2^{-\Delta\Delta Ct}$ method. The treatments considered for statistical analysis were $t < 44°C$ and $T \geq 44°C$ (with T being the black globe temperature). We used linear mixed models in the program R Project Software (version 3.0.1). There weren't significant differences between treatments for any of the variables. This way we can say that animals were in a moderate stress condition, which did not allow the identification of differences in *HSPA1A* and *HSP90AA1* gene expression.

Key Words: dairy cattle, *HSPA1A*, *HSP90AA1*

M87 Gene and pathway analysis of metabolic traits in dairy cows. Ngoc-Thuy Ha[1,2], Josef J. Gross*[1], Jens Tetens[3], Martin Schlather[4], Rupert M. Bruckmaier[1], and Henner Simianer[2], *[1]Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland, [2]Animal Breeding and Genetics Group, Department of Animal Sciences, Georg-August-University Goettingen, Goettingen, Germany, [3] Institute of Animal Breeding and Husbandry, Christian-Albrechts-University Kiel, Kiel, Germany, [4]Chair of Mathematical Statistics, University of Mannheim, Mannheim, Germany.*

During excessive body fat mobilization in early lactation, dairy cows experience a severe metabolic load. Here, a failure in metabolic adaptation often results in an increased susceptibility to health problems. In this study, we analyzed the genetic basis of the metabolic adaptability during the transition period. To this end, blood samples were taken from 178 cows (Holstein, Red Holstein, Fleckvieh and Braunvieh) at 3 critical stages: T1 = wk 3 before expected calving (not lactating and no metabolic load); T2 = wk 4 postpartum (lactating and high metabolic load), and T3 = wk 13 after parturition (lactating and no noteworthy metabolic load). Plasma concentrations of nonesterified fatty acids (NEFA), β-hydroxybutyrate (BHBA) and glucose, 3 metabolites characterizing the metabolic status and adaptability, were measured at T1, T2, and T3. All cows were genotyped with the Illumina next-generation High-Density Bovine BeadChip resulting in a data set of 777,692 SNPs. After quality control and filtering, the SNPs were annotated to known genes (Ensembl Genes Database) and pathways (KEGG Database). For each gene G with g SNPs, we performed a score test based on the linear regression model $y = \gamma_1 C_1 + \ldots + \gamma_m C_m + \beta_1 S_1 + \ldots + \beta_g S_g + \varepsilon$, where C_i are environmental or breed effects and y are either one of the 3 metabolites measured at T1, T2 or T3 or the ratio of their concentrations measured at the different points of time, to assess the association of the gene G to the phenotype y. The results were then used to identify pathways enriched with significant genes using a weighted Kolmogorov-Smirnov test. As a result, we found 99 significant genes associated with at least one of the 3 metabolites. For each metabolite, we found genes that are significant at T2 but not at T1 and T3 or vice versa. This strongly suggests the genes to be potential candidates for the adaptive regulation. We further find 3 pathways (steroid hormone biosynthesis, ether lipid metabolism and glycerophospholipid metabolism) to jointly affect the 3 metabolites. In conclusion, this may be regarded as evidence for the genetic basis for the adaptation performance of dairy cows and, at the same time, reveals its complexity.

Key Words: genome-wide association study, gene-based score test, dairy cow

M88 A novel intronic SNP marker candidate which associated with fatty acids profile in Korean cattle (Hanwoo). Yoonseok Lee*[1], Dongyep Oh[3], Jaejung Ha[3], Jinduk Bok[1], Sangkee Kang[1,2], YunJaie Choi[1,2], and Myunggi Baik[1,2], *[1]Institute of Green Bio Science & Technology, Seoul National University, Pyeongchang-gun, Gangwon-do, South Korea, [2]Department of Agricultural Biotechnology, Seoul National University, Gwanak-gu, Seoul, South Korea, [3]Gyeongsangbuk-do Livestock Research Institute, Yeongju, Gyeonsangbuk-do, South Korea.*

Recently, consumers have become increasingly health-conscious and demand not only palatable but also health-beneficial meat in the market. In Korea, degree of the intramuscular fat deposit (marbling) is one of the crucial indicators to judge beef quality. Thus, the fatty acids profile in beef is important because it affects both flavor and health-benefit. Various trials have been conducted to change fatty acids profile into health-beneficial composition, such as poly-unsaturated fatty acids-abundant meat, in Korean beef. The fatty acid binding protein 4 (*FABP4*) gene is a cytosolic protein abundantly expressed in adipocyte and plays an important role on lipid synthesis and intracellular fatty acid trafficking. An SNP located on the splice site variation between the third exon and the third intron of bovine FABP4 showed a statistically significant effect on intramuscular fatty acid deposition. The aim of this study was to investigate the relationship between SNP within the third intron region of FABP4 and fatty acids profile of longissimus dorsi area in Korean cattle. We sequenced the third intron region of bovine FABP4. Among this SNPs, the g.3996 C>T SNP show statistically significant effect on oleic acid and polyunsaturated fatty acids ($P < 0.001$). Especially, the animals with CC genotype have a lower ratio of omega-6/-3 fatty acid (5.4:1) than the ratio of animals with TT genotypes (9.9:1). Therefore, our result suggest that g.3996 C>T intronic SNP will be used as a useful marker-assisted selection for breeding on fatty acids profile of Korean cattle.

Key Words: Korean cattle, intronic SNP, fatty acid binding protein 4 (*FABP4*)

M89 A QTL on BTA16 is associated with *Mycobacterium avium* ssp. *paratuberculosis* (*Map*) tissue infection. Jennifer N. Kiser* and Holly L. Neibergs, *Washington State University, Pullman, WA.*

Johne's disease is a contagious bacterial infection in cattle caused by *Mycobacterium avium* ssp. *paratuberculosis* (*Map*) infection. A previous genome wide association study (GWAS) in Holstein cattle identified QTL on bovine chromosome 3 (BTA3) and BTA9 that were highly associated ($P < 5 \times 10^{-7}$) and on BTA1, BTA16, and BTA21 that were moderately associated ($P < 5 \times 10^{-5}$) with *Map* tissue infection. The objective of this study was to validate these GWAS results in Holsteins from the Pacific Northwest (PNW, n = 191) and a combined population from the PNW and the Northeast (PNW+NE, n = 432). DNA was genotyped using the Illumina BovineSNP50 BeadChip. Cases were ileo-cecal node positive for *Map* by PCR, and controls were *Map* tissue negative. Individuals were removed if the SNP call rate was < 90%, and SNPs were removed if the genotype call rate was < 95% or they had a MAF of < 0.01. After filtering, 162 cases, and 247 controls and 44,445 SNPs remained for analysis. A GWAS for the PNW and PNW+NE was conducted using an efficient mixed-model association eXpedited (EMMAX) method using 3 gene effect models. No loci were associated with the recessive model in PNW or PNW+NE. For the PNW cows, 4 dominant QTL were identified; 3 on BTA21 ($P = 1.18 \times 10^{-6}$, 8.15×10^{-6}, 2.13×10^{-5}) and 1 on BTA3 (9.88×10^{-6}). In the additive model, a new QTL on BTA21 (5.14×10^{-7}) and on BTA1 ($P = 5.82 \times 10^{-5}$) were identified. In the PNW+NE population, 2 QTL were identified with the dominant model: one on BTA14 ($P < 3.17 \times 10^{-5}$) and one on BTA16 ($P < 3.17 \times 10^{-5}$). The BTA16 QTL was also identified by the additive model ($P < 4.59 \times 10^{-5}$) and identified previously by our group using the NE cows alone ($P < 2.57 \times 10^{-5}$). SNPs associated with *Map* tissue infection on BTA16 lie within introns of *CDC42BPA*, a Serine/Threonine-protein kinase that has downstream effects on *CDC42*. Through the regulation of *CDC42, CDC42BPA* has been linked to several immunological pathways in humans including B-cell receptor and chemokine signaling pathways. Although none of the previous QTL in the NE GWAS were validated in the PNW population, a QTL on BTA16 was associated with susceptibility to *Map* tissue in both the NE and PNW+NE populations.

Key Words: bovine paratuberculosis, genomics

M90 Effect of the STAT5A *Bst*EII polymorphism on reproductive parameters of Holstein dairy cows. Pedro A. S. Silveira[1], Walter R. Butler[2], Carlos C. Barros[1], Marcio N. Corrêa[1], and Augusto Schneider*[1], *[1]Federal University of Pelotas, Pelotas, RS, Brazil, [2]Cornell University, Ithaca, NY.*

The signal transducer and activator of transcription 5A (STAT5A) is a transcription factor that mediates the function of various hormones and cytokines, including growth hormone (GH). Mutations in the STAT5A gene, such as the substitution of a G by a C in exon 8, have been associated with differences in production and reproductive performance of dairy cows. The aim of this study was to evaluate the effect of STAT5A *Bst*EII polymorphism on the days from calving to first ovulation and calving-conception interval (CCI). For identification of the polymorphisms DNA was extracted from blood and a fragment of the STAT5A gene was amplified by PCR. The presence of the G and C alleles was determined after digestion of the PCR products with the *Bst*EII enzyme and gel electrophoresis. For this study 73 Holstein cows were followed from 21 d prepartum to 210 d in milk (DIM). At 55 DIM the cows were submitted to an OvSynch-TAI protocol, which was repeated in cows diagnosed as not pregnant. From calving, milk production was recorded, milk samples for progesterone measurement were collected twice a week to determine ovulation day until 60 DIM, and the CCI was evaluated until 210 DIM. Serum samples for insulin-like growth factor I (IGF-I) measurement were collected at −21, 0, 7, 21 and 60 DIM. Data were analyzed using the GLM procedure of SAS. In total, 19 cows (26%) were of the CC genotype, 32 cows (43.8%) of the GC genotype and 22 cows (30.2%) of the GG genotype. The calving to ovulation interval was not different between genotypes ($P > 0.05$): 28.4 ± 3.1, 29.5 ± 2.5 and 29.4 ± 2.9 DIM for the CC, CG and GG genotypes. The CCI was 101.3 ± 9.4, 102.7 ± 7.6 and 93.9 ± 9.4 DIM for the CC, CG and GG genotypes ($P > 0.05$). Milk production was similar between the 3 genotypes ($P > 0.05$). Serum IGF-I was also not different between genotypes, being 66.3 ± 7.2, 61.8 ± 5.8, 65.6 ± 6.7 ng/mL for CC, CG and GG genotypes ($P > 0.05$). Therefore, the STAT5A *Bst*EII polymorphism did not affect the calving to ovulation interval, CCI, milk production or IGF-I concentrations in Holstein dairy cows. It should be noticed that this study used a small number of cows and larger studies are necessary to confirm current results.

Key Words: SNP, growth hormone (GH), insulin-like growth factor I (IGF-I)

M91 Differentially expressed genes for beef fatty acid profile in Nellore cattle. Mariana P. Berton*[1], Marcos V. A. Lemos[1], Hermenegildo L. J. Chiaia[1], Fabieli L. B. Feitosa[1], Carolyn Aboujaoude[1], Larissa F. S. Fonseca[1], Bianca F. Olivieri[1], Daniela F. R. J. Gimenez[1], Bruno L. Utembergue[2], Lucia G. de Albuquerque[1], Aline S. M. Cesar[2], Angélica S. C. Pereira[2], and Fernando Baldi[1], *[1]State University of Sao Paulo, Jaboticabal, Sao Paulo, Brazil, [2]University of Sao Paulo, Pirassununga, Sao Paulo, Brazil.*

The aim of this study was to use the RNaseq technique to identify differentially expressed (DE) genes in the *Longissimus thoracis* muscle of Nellore cattle finished in feedlot with extreme phenotypes for beef fatty acid profile. After slaughter, a muscle tissue sample was collected of each animal for the extraction of RNA and in the deboning a sample was taken for determining the fatty acid profile. The fatty acids were quantified by gas chromatography (CG-2010 Plus; Shimadzu), using capillary column SP-2560. The following fatty acids were quantified: myristic (C14:0), palmitic (C16:0), stearic (C18:0), oleic (C18:1 *cis*-9), linoleic (C18:2 *cis*-*cis*-9–12), CLA (C18:2 *cis*-9 *trans*-11) and linolenic (C18:3), total saturated fatty acids (SFA), total monounsaturated fatty acids (MUFA), total polyunsaturated fatty acids (PUFA), the ratio of polyunsaturated fatty acids on saturated (PUFA/SFA), n-3 (omega-3) fatty acids and n-6 and ratio of n-6 fatty acids on n-3 (n-6/n-3). Two groups of animals with extreme phenotypes for the composition of meat fatty acid were formed, being considered 10 animals with the highest (H) and 10 animals with the lowest (L) concentrations for each fatty acid. The RNA sequencing data were generated on the Illumina HiSeq System platform. The differential expression of RNA was determined using the iPlant Collaborative platform, containing the FastQC package (version 0.10.1), TopHat2 (version 2.0.9) and Cuffdiff (2.1.1). The analysis of the metabolic pathways of differentially expressed genes was performed with the DAVID tool. The ACSS1 was upregulated ($q < 0.05$) for saturated fatty acids (palmitic, stearic, oleic, total saturated), and downregulated ($q < 0.05$) for unsaturated acids, (omega-3). This gene assists in the conversion of acetate, into acetyl-CoA to incorporate it into the fatty acids by the action of acetyl CoA synthetase. Other DE genes involved in metabolic pathways of fatty acids synthesis were found, such as: BDH1_BOVIN, ACSM3, CBPE_BOVIN, F1N650_BOVIN. Through the RNaseq technique was identified possible genes acting in the synthesis of beef fatty acids, which can be beneficial for human health.

Key Words: *Bos indicus*, transcriptomic, fatty composition

M92 Polymorphisms in the promoter of interleukin-12β2 and interleukin-23 receptor genes influence milk production traits in Chinese Holstein cows. Yongjiang Mao*, Xiaorui Zhu, Shiyu Xin, Huiming Zhang, and Zhangping Yang, *College of Animal Science and Technology, Yangzhou University, Yangzhou, Jiansu, China.*

Interleukin-12 (IL-12) and interleukin-23 (IL-23) are proinflammatory cytokines produced by macrophages and dendritic cells in response to infection with intracellular pathogens. Given the importance of IL-12 and IL-23 for modulating inflammation and the host immune response, the IL-12 and IL-23 receptor genes may be suitable candidate genes for studying disease resistance in dairy cattle. Twenty Chinese Holstein cows were selected randomly for PCR amplification and sequencing, and used for SNP discovery in the bovine IL-12Rβ2 and IL-23R promoter region. One SNP (c.-246G>T) in IL-12Rβ2 gene and 2 SNPs (c.-856A>G and c.-207T>C) in IL-23R gene were identified. Chinese Holstein cows (n = 866) were then genotyped using Sequenom MassARRAY (Sequenom Inc., San Diego, CA) based on the 3 identified SNPs, and the associations between SNPs or haplotype of the genes and milk production traits, SCS were analyzed by the least squares method in the GLM procedure of SAS. The IL-23R c.-856A>G and IL-23R c.-207T>C showed close linkage disequilibrium ($r^2 = 0.89$). No association was found with SCS, but associations were found between 3 of these SNP with milk protein content and lactose content. The software MatInspector revealed that these SNPs were located within several potential transcription factor binding sites, and may alter gene expression, but further investigation will be required to elucidate the biological and practical relevance of these SNP.

Key Words: interleukin-12 receptor β2 (IL-12Rβ2), interleukin-23 receptor (IL-23R), SNP

M93 Evolution of mutational variance associated with age and sex of the parent for weaning weight in C57BL/6J mice. Mayela Castillo[1], Juan F. Medrano[2], and Joaquim Casellas*[1], [1]*Universitat Autònoma de Barcelona, Bellaterra, Spain,* [2]*University of California, Davis, CA.*

New mutations are a very relevant component of polygenic variability and they must be viewed as the raw material for the maintenance of genetic diversity. Nevertheless, the biological phenomena that originate new mutational variants are poorly understood, particularly in regard to the effects that factors such as a parent's age may have. This research focuses on the analysis of weaning weight (10.48 ± 0.02 g) in 12,644 C57BL/6J mice from 46 non-overlapping generations. Data (y) were analyzed under the following model: $y = Xb + Z_1p + Z_2a + Z_2m_p + Z_2m_m + e$, where systematic (b), permanent environmental (p), and additive genetic effects (a, m_p and m_m) were linked by appropriate incidence matrices (X, Z_1 ande Z_2). Note that mutational effects where modeled depending on their origin (i.e., paternal, m_p; maternal, m_m), and an independent set of parent-specific mutational effects were estimated on the basis of new mutations arising to each individual in the pedigree file (i.e., $m_p = m_{p,1} + m_{p,2} + \ldots + m_{p,12644}$). Within this context, $m_{p,i}$ was assumed multivariate normal (MVN) distributed, $p(m_{p,i}|M_i,\sigma_{mp}^2,\lambda_p) = \mathrm{MVN}(0,0.5M_i\sigma_{mp}^2\ [1+\varepsilon_{p,i}\lambda_p])$ M_i being the matrix of mutational relationships specific to new mutations arising in the *i*th individual, σ_{mp}^2 (σ_{mm}^2) being the paternal (maternal) mutational variance, $\varepsilon_{p,i}$ being sire's age when conceiving *i*th individual, and λ_p being a linear regression coefficient linking mutational variance and sire's age. This model was solved under a standard Bayesian approach. Mode (and credibility interval) for σ_{mp}^2 and σ_{mm}^2 were 0.113 (0.069 to 0.163) and 0.052 (0.020 to 0.097), respectively. Whereas linear regression coefficient for dam's age collapsed to 0 and discarded additional changes in σ_{mm}^2, λ_p reached a modal estimate of 0.001 (10^{-5} to 0.051); e.g., this linearly increased σ_{mp}^2 from ~0.11 g^2 (puberal sires) to 0.154 g^2 (one-yr-old sires). This parameterization allowed us to clearly characterize different mutational patterns associated with the sex of the parent, as well as the effect of the accumulation of new mutations along breeding stock's lifetime.

Key Words: age-related mutation, C57WL/6J, weaning weight

M94 A molecular evaluation of bovine respiratory disease and carcass traits in feedlot steers. Samantha Miller[1], Ryon Walker[3], Timothy Page[1,2], and Matthew Garcia*[1,2], [1]*Louisiana State University, Baton Rouge, LA,* [2]*Louisiana State AgCenter, Baton Rouge, LA,* [3]*Louisiana State AgCenter Hill Farm, Homer, LA.*

Bovine respiratory disease (BRD) is the most common disease affecting feedlot cattle and economic losses incurred by affected animals is estimated to be $640 million annually. The objective of the current study was to evaluate single nucleotide polymorphisms (SNP) and their potential associations with bovine respiratory disease susceptibility and carcass traits in feedlot steers. A population of 314 crossbred steers born from 2010 to 2013 and raised at LSU AG Center Central Research Station (CRS) in Baton Rouge, LA and LSU Ag Center Hill Farm Research Station (HFRS) in Homer, Louisiana, were utilized in the current study. Prior to shipping to a commercial feedlot, the measurements of birth weight, weaning weight and hip height were collected from each steer. After weaning, and the completion of a 45-d preconditioning period, steers were shipped to a commercial feedlot. A total of 16 steers over the entire 4-year evaluation period were affected by BRD. A total of 309 steers were harvested at a commercial packing plant and the traits of marbling score, rib eye area, back fat thickness and yield grade were collected. A total of 74 SNP were selected from a previously described BRD QTL region spanning between 40 and 80 MB on BTA 6. This same region has also been identified to have QTL associated with kidney pelvic heart fat percentage. A total of 33 SNP were selected from a previously described BRD QTL region spanning 0–30 MB on BTA 20. This region has been identified to have QTL's associated with kidney pelvic heart fat percentage, marbling score, intramuscular fat, sheer force and carcass weight. A mixed model design was fit with individual carcass traits, BRD status, and individual SNP genotype as dependent variables and sire breed and year fit as independent variables in the model to identify SNP that were significantly associated with the traits of interest. Although multiple SNP were identified as being significantly associated with carcass traits and BRD susceptibility, these SNP must be validated in larger, and more diverse populations before implementation into selection strategies.

Key Words: bovine respiratory disease, feedlot, single nucleotide polymorphism

M95 Association of a polymorphism in the paraoxonase 1 (*PON1*) gene with reproductive performance, health and production of Holstein cows. Pedro A. S. Silveira[1], Walter R. Butler[2], Carlos C. Barros[1], Marcio N. Corrêa[1], and Augusto Schneider*[1], *[1]Federal University of Pelotas, Pelotas, RS, Brazil, [2]Cornell University, Ithaca, NY.*

Paraoxonase 1 (PON1) is a negative acute phase protein associated with uterine health conditions in postpartum dairy cows and may affect reproductive performance. Recently, a single nucleotide polymorphism (SNP) was found in the promoter of the *PON1* gene in dairy cows associated with serum PON1 activity. The aim of this study was to evaluate the association of the *PON1*(A/G)-221 SNP with reproductive performance, disease incidence and milk production in Holstein cows. For the study, 85 Holstein cows were followed from 21 d prepartum to 210 d in milk (DIM). For SNP identification DNA was extracted from blood and the tetra primer ARMS-PCR technique was used. The primers produced a control 700 bp product, and smaller specific products of 500 bp (allele A) or 200 bp (allele G). After gel electrophoresis it was possible to genotype all cows and some were confirmed by sequencing of the products. At 55 DIM the cows were submitted to an OvSynch-TAI protocol, which was repeated in cows diagnosed as not pregnant. From calving, milk production was recorded, milk samples for progesterone measurement were collected twice a week to determine ovulation day until 60 DIM, and disease incidence, the number of inseminations/pregnancy (AI/P) and the calving- conception interval (CCI) was evaluated. Data were analyzed using the GLM procedure of SAS and by survival analysis and Chi-squared on GraphPad Prism. After genotyping, we detected 57 cows (67.0%) of the AA genotype, 20 cows (23.6%) of the AG genotype and 8 cows (9.4%) of the GG genotype. Cows of the GG and AG genotype ovulated earlier than AA cows (27.6 ± 2.9 and 32.1 ± 2.2 DIM, respectively; $P = 0.02$). There was no difference between genotypes for milk production, number of AI/P or CCI ($P > 0.05$). Also, there was no difference for the occurrence of disease (metritis and mastitis) between the 3 genetic groups ($P > 0.05$). Therefore, the presence of at least one G allele at the position −221 of the *PON1* gene is associated with an earlier postpartum ovulation, although more studies on the mechanism for this effect are needed.

Key Words: *PON1*, SNP, dairy cow

M96 Effect of *POU1F1* gene polymorphism and dairy traits in Holstein cattle from Antioquia, Colombia. Jose V. Isaza*, Albeiro Lopez-Herrera, and Jose J. Ecehverri, *Universidad Nacional de Colombia Sede Medellin, Medellin, Antioquia, Colombia.*

Genetic improvement has allowed great advances in selecting individuals with interest for determine characteristics. Knowledge about bovine genome and genetic markers along each chromosome allow the search for genetic variants that affect important productive and reproductive traits, making possible the genetic improvement. The goal of this study was to determinate the association between the *POU1F1* gene with productive and reproductive traits in a population of Holstein cows from Antioquia, Colombia. The *POU1F1* gene belongs to transcription factors POU, which regulates growth and development in animals. This gene participates on pituitary development and hormonal expression in mammals, regulating the production of growth hormone, thyroid stimulating hormone and prolactin. DNA was extracted from 523 samples, and 2 alleles were identified using the PCR-RFLP technique. The frequency for the alleles A and B was 21.26 and 78.74%, respectively, and the 3 genotypes AA, AB and BB showed frequencies of 2.87, 36.78, and 60.34%, respectively. The association between the genotypes and the studied traits was analyzed with a linear mixed model including the fixed effect of *POU1F1* genotype, parity, year and month of birth, and the random effect of the animal. The analyzed SNP had no significant effect on the evaluated traits milk yield, protein percentage, fat percentage, calving interval and services per conception. The absence of association between the SNP and evaluated traits could be due to 2 reasons; the interaction of this gene with other genes involved in the POU1F1 pathway which may hide the individual effect of this SNP on the evaluated traits, and the genotype-environment interaction, the latter has a large effect on gene expression. This way, the *POU1F1* gene is not a good candidate to be used in breeding programs assisted by molecular markers (MAS) for the evaluated population.

Key Words: dairy herd, molecular marker, polymorphism

M97 Identification of genes and networks for the response to thermal stress. Hoyoung Chung*, *National Institute of Animal Science, Suwon, KY, Korea.*

This study has been aimed to investigate genetic responses for the genes related to heat stress when exposing Holstein calves that were selected based on no significant relationship (inbreeding coefficient <0.01). A total of 10 animals aged from 4 to 6 mo were selected, and heat stress was imposed on animals directly in an environmentally controlled house that was managed for 33°C and 90% of humidity based on THI values. After exposing heat stress for 8 h a day, animals were placed in a normal condition at least 12 h to recover from the heat stress. The blood samples, which were collected at the starting point (09:00 a.m.) and at the end of heat stress (21:00 p.m.), were immediately placed in liquid nitrogen. The RNA was extracted from blood samples between control and treatment, and cDNA library was constructed for each individual. After sequencing analysis that produced a minimum 3 G byte, expression analysis confirmed that 53 genes were differentially expressed according to the severe heat stress. The analysis also verified 4 major pathways (MAPK signaling; T-cell receptor signaling; B-cell receptor signaling, and Chemokine signaling) that were related to heat stress. As expected that heat-shock protein (*HSP*) is related to thermal stress and response, the analysis verified that *HSP70* presented 656.4 fold changes between control and treatments. To verify fold changes, 100 primer pairs from 51 genes with accession numbers were tested using real-time PCR, and the results confirmed 17 genes in statistical significances. The identified genes should be served as reference genes for the selection of superior animals against thermal stress.

Key Words: thermal stress, differentially expressed gene

M98 Transcriptome analysis of muscular tissue in Nellore cattle divergently ranked for meat tenderness. Larissa Fernanda Simielli Fonseca*[1], Daniele Fernanda Jovino Gimenez[1], Fernando Baldi[1], Jesus Aparecido Ferro[2], Rafael Espigolan[1], and Lucia Galvão Albuquerque[1], *[1]Departamento de Zootecnia, Faculdade de Ciências Agrárias e Veterinárias, UNESP, Jaboticabal, SP, Brazil, [2]Departamento de Tecnologia, Faculdade de Ciências Agrárias e Veterinárias, UNESP, Jaboticabal, SP, Brazil.*

The objective of the present study was to identify differential gene expression related to meat tenderness in Nellore cattle. Meat samples from 132 animals belonging to the same contemporary group were used. Meat tenderness was measured by shear force through Warner Bratzler method and 20 divergently ranked animals for this trait (10 with tough meat and 10 with tender meat) were selected. Means and the respective standard deviations for tough and tender meat groups were 7.4 ± 0.78 kg and 4.41 ± 0.40 kg, respectively. Total RNA was extracted from the selected samples and sequenced (RNA-Seq) using the HiSeq 2500 System (Illumina). The results were analyzed in the iPlant Collaborative platform. The workflow included: FastQC; TopHat2 and Cuffdiff. A total of 17 differentially expressed genes (q- value <0.05) were identified, and among them, 4 are highlighted. The genes *Q3ZCJ1* (transmembrane protein 37), *C1QTNF7* (C1q and tumor necrosis factor related protein 7) and *BDH1* (3-hydroxybutyrate dehydrogenase, type 1), were more expressed in tough meat samples, whereas the gene *ATP1A1* (ATPase, Na^+/ K^+ transporting, α 1 polypeptide) was more expressed in tender meat samples. The Q3ZCJ1 protein is involved in the same metabolic pathway of actin and myosin proteins that constitute the myofibrils, organelle which acts on muscle contraction. C1QTNF7 protein acts in complement and coagulation cascade metabolic pathway. This pathway is activated after an injury and the coagulation system is activated by exposed collagen after an injury. There is a direct link between collagen content and meat tenderness. The BDH1 enzyme is involved in the synthesis and degradation of ketone bodies that, if present, causes a decrease in muscle pH. The ATP1A1 enzyme is related to protons synthesis, which causes a decrease in intracellular pH during ATP degradation to ADP. Muscle pH decrease is related to meat tenderness during the post-mortem process. These genes seem to be involved in the meat tenderness process. This study was supported by São Paulo Research Foundation FAPESP (grants 2009/16118-5 and 2013/09190-7)

Key Words: RNAseq, differentially expressed gene, quality meat

M99 Environmental risk assessment by genetically engineered mice as transgenic animal model.

Dailu Guan[1], Qian Yu[1], Erhu Zhao[1], Yong Wang[2], and Yongju Zhao*[1], [1]*College of Animal Science and Technology, Southwest University; Chongqing Key Laboratory of Forage & Herbivore; Chongqing Engineering Research Center for Herbivores Resource Protection and Utilization, Beibei, Chongqing, China,* [2]*Department of Laboratory Animal Science, College of Basic Medicine, Third Military Medical University, Sapingba, Chongqing, China.*

Environmental safety on transgenic animals is often a controversial issue within the researchers and the public. Here, a total of 12 full-sib transgenic mice expressing enhanced green fluorescent protein (eGFP) were used for assessing foreign gene expression by single-line passage method and evaluating effects on GE gene with the environment with a total of 12 full-sib mice (positive: control = 6:6, with the same size of male and female mice). PCR method and fluorescent protein observation system (FPOs) were used for detecting the inserted exogenous genes in these mice. The results showed that the expression level of eGFP and WRPE gene (vector sequence) were not significantly different, but it significantly reduced by F1 to F4 generation (F1, F2, F3 and F4) ($P < 0.05$) by Real-time quantitative PCR (RT-qPCR). The effect of GE mice on the environment with 4- or 8-week-old full-sib transgenic mice offspring was evaluated. The exogenous genes were not detected by PCR in the mice manure. Microbial flora of transgenic mice were not significantly different with those of the control group ($P > 0.05$), neither male or female, at 4 or at 8 week-old. In addition, there was no significant difference of the microbial communities in mice gut as assessed by PCR-DGGE or by 16S rDNA sequencing between positive and control transgenic mice offspring. Furthermore, the phylogenetic analyses showed that the manure bacteria sampled during each of the 2 stages belonged primarily to 3 groups, *Firmicutes*, *Bacteroidetes* and *Actinobacteria*. No unknown microbial flora were found in the mice manure. [Supported by the National Natural Science Foundation of China (No. 31172195), the Fundamental Research Funds for the Central Universities(No: XDJK2014A010) and the 2013 Innovation Team Building Program in Chongqing universities (KJTD201334).]

M100 Associations between HEL5, AFZ1, ILSTS002, BMS3004, IDVGA-51, LHR, and FSHR alleles on reproductive evaluation of bulls.

Gabriel R. Pereira*[1], Silvio R. O. Menegassi[1], Paulo R. Aguiar[2], Katiana S. Pereira[2], Celso Koetz[3], Flavio G. Lopes[3], Vanerlei M. Roso[4], Vanessa Peripolli[1], Fernanda G. Moojen[1], and Julio O. J. Barcellos[1], [1]*Federal University of Rio Grande do Sul - UFRGS, Porto Alegre, RS, Brazil,* [2]*Lutheran University of Brazil - ULBRA, Canoas, RS, Brazil,* [3]*University of Northern Paraná - UNOPAR, Arapongas, PR, Brazil,* [4]*GenSys Association, Porto Alegre, RS, Brazil.*

This study emphasized the importance to develop new molecular tools to accurately identify candidate genes in predicting semen quality in bulls that can be used in livestock production. We assessed the frequency distribution of molecular markers linked to insulin growth factor I, follicle stimulating hormone (FSH), luteinizing hormone (LH) and leptin genes in Braford and Hereford population. All bulls (Braford and Hereford; n = 188) showed good body condition scores throughout the experiment. Blood sampling and measurements of scrotal circumference were performed on weaned bulls at 7 and 24 mo of age during the bull breeding soundness evaluations. Semen collection was performed using an electroejaculator on bulls at 24, 28, 32 and 36 mo. Blood samples for DNA extraction were collected by puncture of the coccygeal vein. Five microsatellites or short tandem repeats (HEL5, AFZ1, ILSTS002, BMS3004, and IDVGA-51) and 2 SNP markers (LHR and FSHR) were evaluated by the amplification of DNA products, which then underwent electrophoresis in 10.5% polyacrylamide gel. Molecular markers were analyzed with PROC GLM ANOVA using SAS and significant were considered when < $P < 0.05$. Hereford bulls that expressed the variation in the IDVGA51 allele was associated ($P < 0.05$) with sperm motility and vigor traits in Hereford bulls. Hereford animals showed polymorphic information content (PIC) of 0.36 to 0.75% along with expected heterozygosity (H) of 0.49 to 0.78%. However, Braford bulls that expressed the ILSTS002 and AFZ1 alleles were associated ($P < 0.05$) with major and minor defects, respectively. Braford PIC ranged from 0.28 to 0.78% with an expected H of 0.35 to 0.81%. We found no relation between HEL5, BMS3004, LHR and FSHR to predict semen quality in bulls ($P > 0.05$). Therefore the present study revealed that 3 microsatellite alleles are important male reproductive biomarkers for improving semen parameters in bulls. We concluded that the ILSTS002 and AFZ1 alleles in the Braford and the IDVGA51 allele in the Hereford may be used for improving the reproductive traits in bulls.

Key Words: molecular marker, microsatellite, genetic variability

Dairy Foods: Chemistry

M101 Inhibition of lipid oxidation in fish oil-in-water emulsions by the combination of bovine and caprine caseins with phospholipids.

Adela Mora-Gutierrez*, Rahmat Attaie, Sela Woldesenbet, and Jeneanne Kirven, *Prairie View A&M University, Prairie View, TX.*

The nutritional benefits of polyunsaturated fatty acids from fish oil in terms of their role in growth and development and in health and disease are limited by their oxidative degradation. The objective of this study was to investigate the effect of bovine and caprine caseins in combination with phospholipids on the oxidative stability of 5% fish oil-in-water emulsions at pH 7.0. Menhaden oil was emulsified with phospholipids such as phosphatidylcholine, phosphatidylethanolamine, and phosphatidylserine in a high-pressure valve homogenizer. The effect of bovine and caprine caseins in combination with phospholipids on oxidation rate was monitored by measurement of thiobarbituric acid reactive substances (TBARS) and lipid peroxides. Oxidation of 0.5% phospholipid-stabilized fish oil-in-water emulsions were performed at 25°C for 48 h, in the dark, in the presence of 0–0.3% bovine and caprine caseins and 0.1 mM Fe^{2+}. It was found that the emulsion stabilized with phosphatidylserine showed the best oxidative stability in terms of TBARS concentration and peroxide value. Formation of TBARS was inhibited 32% by addition of 0.3% caprine casein ($P < 0.05$). Inhibition of lipid oxidation by addition of 0.3% bovine casein was less effective, decreasing the concentration of TBARS by 24% ($P < 0.05$). The combination of casein and phosphatidylserine resulted in favorable structure and thickness of the interfacial layer, thus preventing lipid oxidation in the emulsion. These results indicated that the combination of casein and phosphatidylserine can be utilized to enhance the oxidative stability of emulsified fish oil.

Key Words: casein, phospholipid, fish oil

M102 Obtaining of casein fractions by preparative ion-exchange chromatography on weak anion-exchangers.

Andrij Iukalo[1], Orysya Tsisaryk*[2], and Volodymyr Yukalo[1], [1]*Ternopil Ivan Puluj National Technical University, Ternopil, Ukraine,* [2]*Lviv National University of Veterinary Medicine and Biotechnology, Lviv, Ukraine.*

The aim of study was to obtain the main casein fractions (α_{S1}-CN, α_{S2}-CN, β-CN, and κ-CN) in preparative amounts using weak anion-exchangers. Total casein was obtained using isoelectric precipitation from fresh skim milk for fractionation. Fractional composition of total casein and the homogeneity of its fractions at different stages of the isolation were analyzed by electrophoresis on the vertical plates of polyacrylamide gel. At this stage, an alkaline buffer system containing 25 mM tris, 27 mM dietylbarbiturate, 3 mM ethylenediaminetetraacetate, and 4.5 M urea was used. Electrophoregrams were fixed and stained by conventional methods. The concentration of protein was determined by spectrophotometer (SF-46, λ-280 nm). Previously installed absorbtion coefficients for different fractions of casein (D 1% in 1 cm) were used: 10.0 – for α_{S1}-CN; 10,1 – for α_{S2}-CN; 4,6 – for β-CN; 9,6 – for κ-CN, and 8,2 – for total casein. DEAE-cellulose (DEAE-52 “Serva”) and toyopearl DEAE 650M (Toyo soda) were used as anion-exchangers. Batch separation of total casein was performed in 0.02 M acetate buffer (pH = 6.5) in the presence of 3.3 M urea and 0.01 M 2-mercaptoethanol. $CaCl_2$ was used as eluent. This salt is more effective than NaCl due to the interaction with phosphoserine groups of caseins. For fractionation we used the following concentrations of $CaCl_2$: 0.0 M (I fraction); 0.005 M (II); 0.01 M (III); 0.02 M (IV); 0.035 M (V); 0.05 M (VI).The experiment was replicated 3 times. As a result, electrophoretic analysis shows that κ-casein is found in fraction I; II contains β-casein; III and IV – α_{S2}-casein; V – α_{S1}-casein with minor impurities of α_{S2}-casein, and VI contains only α_{S1}-casein. Obtained fractions were dialyzed, lyophilized and weighed. The total yield of caseins was 71% using DEAE-cellulose and 77% in the case of anion-exchangers toyopearl DEAE 650M ($P < 0.05$). Weak anion-exchangers are more effective than strong ones in caseins preparative fractionation. It allowed us to obtain a separate group of α_{S2}-caseins, which includes α_{S2}-, α_{S3}-, α_{S4}-, and α_{S6}-caseins. These fractions are characterized by the same sequence of amino acid residues and are precursors of many original bioactive peptides.

Key Words: casein, fraction, ion-exchange chromatography

M103 Size distribution of casein micelles in raw skim milk from individual cows as studied using cryo-TEM.

Maneesha S. Mohan* and Federico M. Harte, *Food Science Department, Pennsylvania State University, University Park, PA.*

Casein micelles have a complex structure comprising of 4 caseins: α_{S1}, α_{S2}, β, and κ caseins, assembling as many as 20,000 casein proteins. Polydispersity is the degree of disparity or variation in size of particles. Traditionally, casein micelles have been considered highly polydisperse with relative polydispersity between 0.27 to 0.5 as reported by different studies using dynamic light scattering techniques. A recent study has defined casein micelles to be more monodisperse. Hence, we decided to get a visual confirmation of the polydispersity of casein micelles by studying the casein micelle size distribution in milk from 4 cows by cryo-transmission electron microscopy (cryo-TEM). The raw milk from 4 cows of first parity, mid lactation and low somatic cell count, was skimmed by centrifugation (6414 × g for 20 min). The diluted skim milk (10 µL in 500 µL of protein-free serum obtained by ultrafiltration of skim milk using a 3-kDa filter) was subjected to cryo-TEM at 200kV. The diameter of casein micelles was measured manually using ImageJ software. The relative polydispersity (relative standard deviation of size distribution) of casein micelles was a Gaussian distribution (x-axis = number of micelles as a fraction of the total micelles measured, y-axis = diameter of casein micelles) spanning between 10 to 341 nm (1545 micelles), 24 to 693 nm (1073 66 micelles), 11 to 514 nm (2621 micelles) and 11 to 532 nm (1891 micelles) for milk from 4 cows, respectively. The positively skewed distribution curve had a tapering tail of large casein micelles of diameter greater than 350 nm. The maximum number of casein micelles existed in the size range of 90 to 110 nm for milk from all the 4 cows. The relative polydispersity ranged between 0.39 and 0.47 for casein micelles with mean diameters (D_{10}) between 112 to 134 nm for the milk from the 4 cows. The results indicate high level of polydispersity in the casein micelles in milk of every cow. Hence it was possible to effectively utilize cryo-TEM to elucidate the size distribution of casein micelles and visually reconfirm the polydispersity of casein micelles in bovine milk from individual cows.

Key Words: polydispersity, electron microscopy, Gaussian

M104 Effect of casein micelle dissociation and casein modification on plasmin-induced hydrolysis.

Hemang Bhatt[1,2], Aurelie Cucheval[1], Christina Coker[1], Hasmukh Patel*[3], Alistair Carr[2], and Rod Bennett[2], [1]*Fonterra Research and Development Centre, Palmerston North, New Zealand,* [2]*Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand,* [3]*Dairy Science Department, South Dakota State University, Brookings, SD.*

Plasmin-induced hydrolysis of casein in milk can lead to many defects including proteolysis, age gelation, and bitterness. We hypothesized that the susceptibility of casein micelles to plasmin can be affected by its micellar structure and modification of the lysine residues on caseins. Different levels of dissociation of the casein micelle structure were achieved by calcium chelation using EDTA and by succinylation by attaching a succinate group at the ε-amino group of lysine residues, leading to the formation of succinyl-lysine. The target sites for succinylation were identified using liquid chromatography-tandem mass spectrometry. Changes in the particle size and levels of casein micelle dissociation in skim milk were determined using a Zetasizer and sodium dodecyl sulfate PAGE, respectively. The subsequent plasmin hydrolysis was monitored by quantifying the hydrolyzed product using reverse phase high performance liquid chromatography. The EDTA-induced calcium chelation and dissociation of the casein micelle increased plasmin-induced hydrolysis. In contrast, succinylation had an inhibitory effect on plasmin-induced hydrolysis. Calcium chelation and succinylation of the skim milk resulted in dissociation of caseins from the casein micelle, a decrease in turbidity, extensive unfolding, and expansion of the polypeptide chain; all of these changes collectively reduced steric hindrance and made the protein more readily hydrolyzed by plasmin. However, the formation of succinyl−lysine rendered β-casein unrecognizable to the substrate-binding pocket of plasmin, resulting in a nonlinear decrease in the hydrolysis because of the competitive effect of micelle dissociation. These results clearly indicate the importance of the casein micelle structure and its susceptibility to plasmin action. They will be useful in understanding and controlling the plasmin-induced hydrolysis of milk proteins in food systems.

Key Words: plasmin, succinylation, liquid chromatography-tandem mass spectrometry

M105 The role of lactose and whey proteins in plasmin resistance of heat-treated milk.

Hemang Bhatt[1,2], Aurelie Cucheval[1], Christina Coker[1], Hasmukh Patel*[3], Alistair Carr[2], and Rod Bennett[2], [1]*Fonterra Research and Development Centre, Palmerston North, New Zealand,* [2]*Institute of Food, Nutrition and Human Health, Massey University, Palmerston North, New Zealand,* [3]*Dairy Science Department, South Dakota State University, Brookings, SD.*

Sterilization and UHT treatment are commonly used to increase the shelf life of milk and dairy beverages. However, the high heat resistance of the plasmin system enables it to partially survive UHT treatment, which could lead to defects in the texture (gelation, sedimentation) and the taste (bitterness) of these products. The present study investigated the effect of high heat treatment on plasmin-induced hydrolysis using a sequential approach. A high-heat-treated (120°C/15 min) skim milk had been found to have higher resistance to plasmin-induced hydrolysis, compared with a control skim milk. The effect of heat treatment on the resistance of skim milk was studied with a sequential approach. Different milk systems were prepared by removing whey protein and then lactose from skim milk and reconstituting each milk separately, to observe the effect of whey protein and lactose both individually and in combination. The milk systems were heated at 120°C for different times to achieve different levels of heat treatment. All treated milk systems were then hydrolyzed by adding plasmin and the reaction was monitored using reverse-phase HPLC. The extents of whey protein denaturation, dissociation of casein from the micelles and association of whey protein with the micelles were monitored using sodium dodecyl sulfate-PAGE. Particle size and levels of lactosylation were also measured. Plasmin-induced hydrolysis was negatively affected by an increase in the heat treatment. Both whey protein association with the casein micelles and lactosylation decreased the availability of protein to plasmin. These effects were compared and mechanisms for them have been proposed. Whey-protein-free milk was the most resistant to plasmin, followed by skim milk and lactose-free milk, suggesting that lactosylation plays a more major role than whey protein association with the casein micelles in making protein resistant to plasmin-induced hydrolysis.

Key Words: plasmin, lactosylation, sterilization

M106 Oxidative stability of an Iranian ghee (butter fat) versus soybean oil during storage at different temperatures.

Mahshid Azizi*[1], Maryam Enteshari[2], and Mohammadreza Dolatkhahnejad[3], [1]*Islamic Azad University of Birjand, Chemical Engineering and Food Industries Department, Tehran, Iran,* [2]*Department of Food Science and Technology, Shahid Beheshti University of Medical Sciences, Tehran,Iran,* [3]*Islamic Azad University of Ayatollah Amoli, Food Industries and Scientific Engineering Department, Tehran, Iran.*

The oxidative stability of an Iranian ghee (butter fat) and soybean oil, which were stored at 4 different storage temperatures (4, 25, 45, and 60°C) and during one-month storage was investigated. Oxidation changes were monitored every 2 weeks by analytical parameters including acid value (AV), peroxide value (PV), *p*-anisidin value (*p*-AV), thiobarbituric acid value (TBA) and oxidative stability index (OSI). In addition, iodine value (IV) and fatty acids profile were determined to elucidate intrinsic differences between ghee and soybean oil. The PV, *p*-AV and TBA were gradually increased during storage time, while the OSI decreased. The ghee in contrast to soybean oil, showed significantly ($P < 0.05$) lower amounts of PV, *p*-AV and TBA and higher OSI. However higher amounts of AV were obtained for ghee samples at all of mentioned storage temperatures which indicated higher free fatty acids (FFA %) as a result of production procedure for this kind of fat. Moreover, obtained data revealed that the effects of applied different temperatures on the mentioned oxidation parameters were significant during studied storage time ($P < 0.05$); additionally, at higher temperatures (45 and 60°C) these effects were more intensive particularly for the soybean oil samples. Results confirmed that ghee displayed better oxidative stability behavior as evidenced by lower PV, *p*-AV and TBA with higher values of OSI at accelerated storage conditions.

Key Words: oxidative stability, Iranian ghee, soybean oil

M107 Effect of hydrodynamic cavitation on acid gelation properties of skim milk.

Harsh Dahiya*[1], Hasmukh A. Patel[1], and Thom Huppertz[1,2], [1]*South Dakota State University, Brookings, SD,* [2]*NIZO Food Research, Ede, the Netherlands.*

Acid gelation is an important property of milk with relevance to yogurt manufacturing. Hydrodynamic cavitation (HC) is an emerging technology involving a process of vaporization, bubble generation followed by bubble collapse in a flowing liquid brought about by a decrease in pressure followed by a subsequent increase in pressure. In this study, we compared the effects of HC with conventional heat treatments used in dairy industry on acid gelation property of skim milk. Pasteurized skim milk (3.5% protein and 9% total solids) was preheated to 50°C and then subjected to 2 sets of HC treatments, namely, HC at 20, 40, and 60 Hz at sufficiently high flow rate (950 L/h) to avoid any temperature increase during HC (T1) and HC at 60 Hz at low flow rates (200 L/h) to allow scale-free heating of skim milk increasing its temperature to desired temperature up to 90°C (T2) using APV Cavitator (supplied by SPX, Denmark) fitted with 4-row rotor in 6mm housing. A portion of skim milk was also heated at 90°C for 10 min. Acid milk gels were prepared from untreated (control), skim milk samples obtained from T1, T2 as well as the skim milk samples conventionally heated to 90°C for 10 min using glucono-δ-lactone to obtain final pH4.6 ± 0.05 after 4h incubation at 30°C. Rheological characteristics of acid gels were studied using small amplitude oscillatory rheology (SAOR) at 1% strain and 0.1 Hz frequency. The soluble (serum) phases obtained by centrifugation of control, cavitated and heated milk samples at 25000g/1h were characterized using sodium dodecyl sulfate PAGE (SDS-PAGE). It was observed that the storage modulus (G′) of acid gels prepared with skim milk samples subjected to T1 was significantly lower ($P < 0.05$) than those prepared with samples subjected to T2. Acid gels prepared from the samples subjected to T2 with temperatures reaching 90°C had highest final G′, which was attributed to significant denaturation of whey proteins in these samples. It was also observed that this value of G′ was similar to the one obtained from the conventional heating of milk, suggesting that the cavitation treatment of milk do not adversely affect the acid gelation property of the milk.

Key Words: acid gel, cavitation, rheology

M108 Molar mass of a crude extract of *Streptococcus thermophilus* St-143 exopolysaccharide during fermentation of milk.

Som N. Khanal*[1] and John A. Lucey[1,2], [1]*Food Science Department, University of Wisconsin-Madison, Madison, WI,* [2]*Wisconsin Center of Dairy Research-Madison, Madison, WI.*

Some lactic acid bacteria produce high molecular weight polysaccharides (EPS) during milk fermentation. It is unclear if there is any change in the properties of EPS during the fermentation. The molar mass of EPS was investigated during fermentation of milk with *Streptococcus thermophilus* (St-143). We used crude extracts, instead of highly purified samples, to observe more native EPS systems. Reconstituted nonfat milk samples were fermented by *S. thermophilus* at 40°C until pH 4.5. Crude extracts of EPS were obtained at 4 different fermentation times starting from 150 min (pH ~5.3) to 330 min (pH~4.5). Whey from fermented milk was ultrafiltered using 100 kDa membrane to remove soluble milk sugars and proteins. The UF retentate was centrifuged and supernatant was further concentrated using single pass pressure UF cell with 100 kDa membrane. The concentrated EPS solution was analyzed for protein and sugar contents. Molar mass of EPS was estimated using size exclusion chromatography-multi angle laser light scattering (SEC-MALLS). Polysaccharide content of the EPS concentrates varied from ~0.3 to 0.4 mg/mL. Protein impurities in the EPS concentrate were high when sampled at pH 5.3, and significantly decreased ($P < 0.05$) until pH 4.5. Extracts separated using SEC gave an initial peak that appeared to be mostly high M_w protein aggregates and a second peak that corresponded to EPS. The molar mass of EPS ranged from 1.57×10^6 to 2.86×10^6 g/mol. EPS sampled at pH 5.3 had significantly higher ($P < 0.05$) molar mass than samples obtained at pH 4.5. EPS samples also appeared to be monodisperse (i.e., $M_w/M_n = 1$). The radius of gyration of EPS was ~54 nm and was not significantly different between the different pH samples. It appears that the properties of EPS may vary during milk fermentation.

Key Words: exopolysaccharide, molar mass, ultrafiltration

M109 Formation of hydroxymethylfurfural and other caramelization products during extrusion of lactose blends.

Catrin E. Tyl, Elizabeth M. Reid, and Tonya C. Schoenfuss*, *University of Minnesota, St. Paul, MN.*

As part of our ongoing efforts to finding value-added uses for lactose, we carried out reactive extrusion on blends of lactose, glucose, and citric acid to polymerize lactose to indigestible carbohydrates. This treatment can also induce the formation of color and hydroxymethylfurfural (HMF). The objective of this study was to investigate the effect of formula and extrusion conditions on color and HMF formation. Data analysis was carried out with ANOVA followed by Tukey's HSD test. Three citric acid (CA) concentrations (2, 4, and 6% w/w) were tested. Glucose comprised 20% w/w and lactose made up the remainder. All blends were extruded in duplicate at 2 feed rates: 15 and 30 kg/h. Color was measured as Hunter *L*, *a*, and *b* values and absorption at 420 nm, indicative for yellow-brown pigments. Absorption was higher for samples of all CA levels extruded at 15 kg/h and these extrudates also had lower *L* and higher *b* values (i.e., samples were darker and more yellow). Thus, the extent of caramelization increased when mixtures spent more time in the extruder at the low feed rate. Higher CA levels lead to more pigment formation at 15 kg/h, but not at 30 kg/h. Along with other caramelization products, HMF is formed in sugars heated with acids. HMF has shown toxicity in in vitro and animal studies. Thus, reducing its formation through optimum processing conditions and/or sample treatments is needed. HMF content was measured by RP-HPLC/ UV. Increasing CA in the raw mix produced extrudates with lower amounts of HMF. The lower feed rate resulted in significantly higher levels of HMF. We evaluated sample treatments to remove HMF using Amberlite (an ion exchanger) and activated charcoal. Filtration over Amberlite lead to 27–57% less HMF. Preliminary results indicate that charcoal treatment may further reduce HMF (>95%). However, because it also lead to losses in oligo- and polysaccharide yields, further optimization of this method is necessary.

Table 1 (Abstr. 109). Effect of formula (citric acid at 2, 4, and 6% wt/wt) and feed rate (15 and 30 kg/h) on color and hydroxymethylfurfural (HMF) formation

	15 kg/h			30 kg/h		
Item	2	4	6	2	4	6
A_{420}	0.554	0.654	0.934	0.194	0.195	0.200
L	83.84	83.59	80.99	87.41	88.50	89.17
b	27.23	30.01	35.03	14.83	15.21	15.79
HMF (mg/g)	1.20	0.91	0.73	0.71	0.55	0.52
HMF after Amberlite (mg/g)	0.51	0.46	0.53	0.42	0.38	0.31

Key Words: hydroxymethylfurfural, lactose, extrusion

Forages and Pastures: Silages and forages in dairy production systems

M110 Cool season grass-legume mixtures in north-central Florida. Erick R. S. Santos*[1], José C. B. Dubeux Jr.[1], Lynn E. Sollenberger[2], Marta M. Kohmann[2], Stephanie Pope[2], Hiran M. S. Silva[1], and Ana C. C. Melo[1], *[1]University of Florida–North Florida Research and Education Center (NFREC), Marianna, FL, [2]University of Florida – Agronomy Department, Gainesville, FL.*

Grass-legume mixtures may increase dry matter (DM) yield and forage N concentration due to biological N_2 fixation. A study was conducted to evaluate yield and botanical composition in different cool season grass-legume mixtures in Gainesville, FL from 4 February to 14 May 2014 (4 harvests). Treatments were allocated in a split-plot arrangement in a completely randomized block design with 4 replicates. Main plots were formed by annual ryegrass (*Lolium multiflorum* Lam.) or a rye (*Secale cereal* L.)-annual ryegrass mixture. The subplot was the combination of cool-season legumes or presence/absence of N fertilizer in grass monocultures, as follows: (1) hairy vetch (*Vicia villosa* ssp.), (2) crimson clover (*Trifolium incarnatum* L.), (3) red clover (*Trifolium pratense* L.), (4) ball clover (*Trifolium nigrescens* Viv.), (5) hairy vetch-red clover-ball clover, (6) crimson clover-red clover-ball clover, (7) N-fertilized grass (50 kg N·ha^{-1}·cut^{-1}), and (8) unfertilized grass. Total DM yield was greater for N-fertilized grass in the 2nd and 3rd harvests (660 and 1360 kg DM·ha^{-1}). Mixtures containing subplot-Treatments 3 and 6 increased total DM yield in the 4th harvest (1250 and 1280 kg DM·ha^{-1}, respectively) and did not differ from N-fertilized grass in this harvest. Legume DM yields were minimal in Harvests 1 and 2. In the 3rd and 4th harvests, the crimson clover-red clover-ball clover mixture had the greatest legume DM yield (330 and 730 kg DM·ha^{-1}), followed by crimson clover (320 kg DM·ha^{-1}) in the 3rd harvest, and by red clover (660 kg DM·ha^{-1}) in the 4th harvest, whereas hairy vetch presented the lowest productivity in both harvests (33 and 31 kg DM·ha^{-1}). Dry matter yield of annual ryegrass and rye-annual ryegrass did not differ among harvests. Grass DM yield was greater for N-fertilized grass in the 2nd and subsequent harvests (660, 1360, and 1220 kg DM·ha^{-1}). Red clover and the crimson clover-red clover-ball clover mixture were not different in DM yield than N-fertilized grass in the last harvest, while the other mixtures did not differ from the unfertilized grass.

Key Words: annual ryegrass, rye, crimson clover

M111 Length of ensiling effects on fermentation characteristics, DM recovery and aerobic stability of corn Shredlage. Luis C. Solórzano*[1], Luis L. Solórzano[2], and Abner A. Rodríguez[1], *[1]Universidad de Puerto Rico, Mayagüez, PR, [2]Lankin, Fitchburg, WI.*

The effect of length of ensiling (LOE) on fresh whole-plant corn Shredlage was evaluated after it was fermented for 0, 45, 90, or 180 d at a temperature of 20 to 23°C using 3-L capacity PVC mini-silos fitted with mechanics to vent gas. Mini-silos were filled with about 1.9 kg of the crop at about 33% DM, >3.1% soluble carbohydrates (fresh matter). Four mini-silos were opened at each LOE to determine fermentation characteristics and DM recovery. Statistical analysis was performed according to a completely randomized design with a 4 LOE. Aerobic stability (AS) was determined by placing the ensiled material from each mini-silo in Styrofoam containers placed inside a Styrofoam chamber. Temperature was measured at 6-h intervals for 7 d. Statistical analysis used a split-plot design with a 3 LOE by 29-timepoint factorial arrangement using silo as the repetitive measurement. Significance ($P < 0.05$) is denoted by $^{a,\,b,\,c}$. Ensiling increased the % of lactic acid, from fresh (0.12^{a}), to 45 d (5.26^{b}), 90 d (6.32^{b}), and 180 d (5.31^{b}). A similar trend occurred for acetic (0.07^{a}) and propionic acid (<0.01^{a}) from 0d to 45d (0.51^{b}, 0.16^{b}), 90 d (0.72^{b}, 0.19^{b}) and 180 d (0.62^{b}, 0.16^{b}). Low TVFA at 0 d (0.19^{a}), increased at 45 d (5.93^{b}), 90 d (7.23^{b}) and 180 d (6.09^{b}). Butyric acid was < 0.01 and not different among LOE. Recovery of DM did not differ among LOE and averaged 91.33%. Starting pH at 0d was highest (5.75^{a}) compared with 45d (3.71^{c}) and 90 d (3.64^{c}), and both of these were lower than pH at 180 d (3.87^{b}). Ammonia-N (% of CP) has an increasing trend from 0 d (0.65^{c}) to 45 d (2.54^{b}) and 90 d (2.37^{b}), which were lower than at 180 d (4.5^{a}). Loss of AS occurred on 45 d by 36 h post-aerobic exposure (PAE), 90 d by 48 h PAE, and 180 d by 42 h. PAE. Ensiling resulted in increases of lactic, acetic, propionic acids and TVFA, resulting in a lower pH. There were no differences in these parameters after 45 d of ensiling. Ammonia-N increased due to ensiling and was not different between 45 and 90 d, and increased after 180 d. The shorter LOE resulted in lower AS. Shredlage continues to cure for at least 180 d of fermentation.

Key Words: corn silage, fermentation, aerobic stability

M112 Fermentation of frozen whole-plant corn silage after defrosting. Luiz F. Ferraretto*[1], Gilson S. Dias Junior[1,2], John P. Goeser[1,3], and Randy D. Shaver[1], *[1]University of Wisconsin, Madison, WI, [2]Universidade Federal de Lavras, Lavras, MG, Brazil, [3]Rock River Laboratory Inc., Watertown, WI.*

Late harvest of whole-plant corn silage (WPCS) into late fall and winter months during 2014/2015 raised concerns among central and northern Wisconsin dairy farmers and their nutritionists about fermentation of frozen WPCS. The objective of the present study was to evaluate fermentation profile of defrosted WPCS after several months stored frozen. An unfermented WPCS sample that had been obtained from the University of Wisconsin–Madison Agricultural Research Station (Arlington, WI) on September 23, 2014, was immediately frozen and stored at −20°C until January 26, 2015. Sample was defrosted, homogenized, and divided into 24 sub-samples of 250 g each. Sub-samples were vacuum-sealed in plastic bags and randomly assigned to 8 treatments so that each treatment had 3 replications. Treatments were 0, 0.5, 1, 2, 3, 7, 14, and 28 d fermentations. Bags were stored in the dark at room temperature (approximately 20°C) until reaching the targeted ensiling time. All samples were analyzed for DM, pH, organic acids and ammonia-N (%DM). Data were analyzed using Proc Mixed of SAS with the Fixed effect of ensiling time and the random effect of bag. Content of DM did not differ ($P = 0.31$; 36.1% on average). Measurements of pH were affected by ensiling time ($P = 0.001$) with a decline observed after only 1 d (5.23) of fermentation and a gradual decrease until 28 d (3.84). This is related to the gradual increase ($P = 0.001$) in lactate and acetate concentrations from 1 (0.88% and 0.39%, respectively) to 14 d of fermentation (5.48% and 1.22%, respectively). Total acid concentrations follow the same pattern ($P = 0.001$). Propionate concentration did not differ ($P = 0.77$) whereas butyrate was not detected. Concentration of succinate increased ($P = 0.001$) after 1 d of fermentation, peaked on 3 d and decreased on 14 d. Ethanol concentration was greater ($P = 0.001$) for 2, 3, 7, 14 and 28 d (0.32% on average) compared with 0, 0.5 and 1 d (0.03% on average). Ammonia-N increased ($P = 0.001$) 3-fold from 0 to 28 d of fermentation (0.02% vs. 0.06%, respectively). These findings suggest that WPCS maintains fermentation capacity upon defrosting even after frozen for a prolonged period in storage.

Key Words: corn silage, fermentation

M113 Length of ensiling effects on starch characteristics of corn Shredlage.

Luis C. Solórzano*[1], Luis L. Solórzano[2], Beatriz A. Quintana[1], and Abner A. Rodríguez[1], [1]*Universidad de Puerto Rico, Mayagüez, PR,* [2]*Lankin, Fitchburg, WI.*

The effect of length of ensiling (LOE) on fresh whole-plant corn Shredlage was evaluated after it was fermented for 0, 45 or 180 d at a temperature of 20–23°C using 3 L capacity PVC mini-silos fitted with mechanics to vent gas. Mini-silos were filled with about 1.9 kg of the crop at about 33% DM, > 3.1% soluble carbohydrates (fresh matter). Four mini-silos were opened at each LOE to determine starch characteristics and in vitro starch digestibility (IVSd) during 2 in vitro fermentation endpoints (FEP, 3 or 7 h.). Statistical analysis for nutritional characteristics was performed using a completely randomized design (CRD) for 3 LOE. Data for IVSd was analyzed using a CRD with a 3 LOE by 2 FEP factorial arrangement. Different superscripts denote statistical significance ($P < 0.05$). The structure of the starch granule was documented using a scanning electron microscope (SEM) at each LOE. Ammonia-N (% of CP) and IVSd increased as LOE increased, while sugar decreased (Table 1). There were no changes for starch content across LOE. Increasing the FEP from 3 to 7 h. increased IVSd from 72.4^{a} to 84.1^{b}%. The 2,000× micrograph at ensiling (0 d) shows starch granules with a smooth surface and a spherical shape surrounded by protein bodies. After 45 d of ensiling, the starch granules lost their sphericity and some of the protein bodies start to break down into small pieces (supported by increases in ammonia-N). After 180 d of ensiling, starch agglutination may be observed as well as some pitting of the starch granule due to hydrolytic enzyme activity. In summary, structural changes in the starch-protein matrix and in the starch granule during ensiling result in increased starch digestibility.

Table 1 (Abstr. 113). Effects of length of ensiling (0, 45, or 180 d) on nutrient characteristics and starch digestibility of corn Shredlage

	Length of ensiling, d					
	0		45		180	
Item	Mean	SD	Mean	SD	Mean	SD
N	4		8		8

M114 Relationship between corn silage processing score and kernel fraction geometric mean particle size in whole-plant corn silage.

Gilson S. Dias Junior[1,2], Luiz F. Ferraretto*[1], Gustavo G. S. Salvati[1], Lucas C. de Resende[1,2], Pat C. Hoffman[1], and Randy D. Shaver[1], [1]*University of Wisconsin, Madison, WI,* [2]*Universidade Federal de Lavras, Lavras, MG, Brazil.*

Greater kernel processing increases starch digestibility in whole-plant corn silage (WPCS). Corn silage processing score (CSPS), the percentage of starch passing through a 4.75 mm sieve, is widely used to assess degree of kernel breakage in WPCS. However, the geometric mean particle size (GMPS) of the kernel fraction that passes the 4.75 mm sieve has not been well described. Therefore, the objective of this study was to evaluate the relationship between CSPS and GMPS of the kernel fraction. Samples of WPCS (n = 80) from 3 field trials representing varied theoretical lenght of cut settings and processor types and settings were evaluated. Each sample was divided in 2 and then dried at 60°C for 48 h. The CSPS was determined in duplicate on one of the split samples, while on the other split sample the kernel and stover fractions were separated using a hydrodynamic separation procedure. After separation, the kernel fraction was re-dried at 60°C for 48 h in a forced-air oven and dry sieved to determine GMPS (µm) and surface area using 9 sieves with nominal square apertures of 9.5, 6.7, 4.75, 3.35, 2.36, 1.70, 1.18, 0.589 mm and pan. Regressions to determine linear and quadratic relationships were performed using Proc Reg of SAS (SAS Institute, 2004). Linear relationships between CSPS and kernel fraction GMPS ($R^2 = 0.11$; $P = 0.01$), surface area ($R^2 = 0.06$; $P = 0.03$) and proportion passing through the 4.75 mm screen ($R^2 = 0.34$; $P = 0.001$) were poor. Strong quadratic relationships between proportion of kernel fraction passing through the 4.75 mm screen and kernel fraction GMPS ($R^2 = 0.70$; $P = 0.001$) and surface area ($R^2 = 0.56$; $P = 0.001$) were observed. Corn silage processing score was poorly correlated with kernel fraction GMPS and surface area. These findings suggest that hydrodynamic separation and dry sieving of kernel fraction may provide better assessment of kernel breakage in WPCS.

Key Words: mean particle size, corn silage, processing score

M115 The effects of different silo plastics on the fermentation, aerobic stability, and dry matter recovery of corn silage.

Michelle Windle*, *Vita Plus, Madsion, WI.*

The objective of this experiment was to evaluate the efficacy of 4 different silo plastics to mitigate silage surface spoilage. Bag silos (60 cm × 30 cm) were created by heat-sealing single layers of 4 different types of silo plastics: black and white plastic (BW, KSI Supply Inc., Sheboygan Falls, WI), Silostop oxygen barrier plastic (SS, Bruno Rimini Ltd., London, United Kingdom), KSI oxygen barrier plastic (KSI), and Hitec oxygen barrier plastic (HT, Shanghai Hitec Plastics Co. Ltd., Shanghai, China). There were 5 silos per each types of plastic, yielding 20 experimental silos. Approximately 2.75 kg of chopped whole plant corn (40.9% DM) were placed in each silo, manually compressed and sealed. One sample per plastic type was analyzed for oxygen transfer rate (OTR). Silages were stored for 112 d at 15–21°C and data were analyzed using the Fit Model procedure of JMP. Means were compared using the Tukey's test. Relationships were evaluated between OTR and fermentation parameters. The OTR for BW, KSI, SS and HT were 4039, 154, 23.2 and 8769 cc/m^2/d, respectively. Dry matter, CP, soluble CP, NH_3-N, and water-soluble carbohydrates of corn silage were not affected by plastic type ($P > 0.05$). Silages ensiled with HT had a lower DM recovery, higher pH, less lactic and acetic acids, and less ethanol, as compared with silages stored in BW, SS or KSI ($P < 0.05$). Aerobic stability was lowest for silages ensiled within HT (8 h), intermediate for BW (37 h) and greatest for KSI (76 h) and SS (67 h) ($P < 0.05$). Colony forming units of yeasts for KSI, SS, BW and HT were 3.94, 4.56, 6.19, and 8.05, respectively. Relationships between OTR and fermentation parameters indicated that as OTR increased, corn silage was less stable, had a higher pH, more yeasts, ethanol, and a lower lactic-to-acetic ratio ($P < 0.05$).

Results indicate that ensiling corn silage with differing "oxygen barrier" plastics results in large differences in silage quality.

Key Words: spoilage, silo plastic, yeast

M116 Length of ensiling effects on nutritional characteristics and in vitro NDF digestibility of corn Shredlage.

Luis C. Solórzano*[1], Luis L. Solórzano[2], and Abner A. Rodríguez[1], *[1]Universidad de Puerto Rico, Mayagüez, PR, [2]Lankin, Fitchburg, WI.*

We evaluated the effect of length of ensiling (LOE) on fresh whole plant corn shredlage (CS) that was fermented for 0, 45, 90, or 180 d at a temperature of 20 to 23°C using 3-L capacity PVC mini-silos fitted with mechanics to vent gas. Mini-silos were filled with approximately 1.9 kg of the crop at about 33% DM, >3.1% soluble carbohydrates (fresh matter). Four mini-silos were opened at each LOE to determine nutritional characteristics and in vitro NDF digestibility (NDFd) during 3 in vitro fermentation endpoints (FEP, 0, 30 or 120 h.) at a commercial laboratory. Statistical analysis for nutritional characteristics was performed using a completely randomized design (CRD) for 4 LOE. Data for NDFd was analyzed using a CRD with a 4 LOE by 3 FEP factorial arrangement. Significance ($P < 0.05$) is denoted by $^{a, b, c}$. There were no LOE differences ($P > 0.5$) on the % content of ADF, NDF, lignin and ash, which averaged, 24.19, 36.71, 1.76, and 3.96, respectively. There were significant differences in the % content of DM, CP, ADF bound protein (ADFBP), fat and cell wall protein (CWP). Increasing LOE led to a decrease in the DM content from 0 d (36.68^{a}), to 90 d (32.25^{b}), and 180 d (32.51^{b}), but did not differ from 45 d (34.04^{ab}). The content of CP increased for LOE 90 d (8.78^{a}) and 180 d (8.16^{a}) compared with LOE at 0 d (7.19^{b}) or 45 d (7.32^{b}). The amount of ADFBP was 0.52^{b} at 0 d, similar to ADFBP at 90 d ($0.62^{b,c}$). The ADFBP content at 90 d did not differ from 45 d (0.74^{a}) and 180 d ($0.67^{a,c}$). Fat content increased at 90 d (3.40^{a}) and 180 d (3.45^{a}) compared with 0 d (1.95^{b}) or 45 d (2.36^{b}). At 0 d (0.18^{b}) CWP did not differ from 45 d (0.47^{b}), or 180 d (0.28^{b}), but all 3 did differ from 90 d (1.20^{a}). Increasing the LOE led to an increase in IVNDFd from 0 d (40.39^{a}) and 45 d (34.91^{a}) to 90 d (50.46^{b}) or 180 d (60.83^{c}). Ensiling leads to various nutritional changes over time, which can affect ration balancing and on-farm ration preparation. This calls for continuous silage nutritional monitoring over time to proper balance rations and feed cows.

Key Words: corn silage, fiber digestibility, nutritional characteristics

M117 Ensiling practices of corn on California dairies.

Jennifer M. Heguy*[1] and Noelia Silva-del-Rio[2], *[1]University of California, Ag & Natural Resources, Modesto, CA, [2]University of California, VMTRC, Tulare, CA.*

The aim of this study was to obtain information on current corn ensiling practices in California's San Joaquin Valley. In summer 2014, 20 dairies were visited to create a snapshot of ensiling practices. Producers answered a short survey, and observations at the silage structure were made. Herd size ranged from 350 to 5250 cows (median = 1800). Five consecutive truckloads of corn silage delivered to dairies were sampled and composited for wet chemistry nutrient analysis (Table 1). Descriptive statistics were conducted with PROC MEANS of SAS and correlations were evaluated with PROC CORR of SAS. Structures were primarily wedge piles (n = 16). Delivery rate varied; the 5 truckloads of corn were delivered in as little as 8 min and in as many as 64 min. Most dairies utilized one packing tractor (n = 12), with delivery rate of the 5 loads ranging from 8 to 40 min. Fewer dairies used 2 packing tractors (n = 7), with delivery rate ranging from 10 to 64 min, and one dairy utilized 3 packing tractors with a delivery rate of 22 min. Fourteen custom harvesting companies were utilized on the 18 dairies that did not harvest their own corn, with 4 of the companies harvesting on more than one dairy. Corn silage processing score (CSPS) was analyzed; 9 samples were optimally processed (CSPS > 70%) and 11 samples were adequately processed (CSPS between 50% and 70%). No samples were inadequately processed. No correlation was found between DM and starch content (r = 0.290, $P = 0.214$) or DM and CSPS (r = −0.001, $P = 0.995$). Harvesting parameters varied, but kernel processing was a practice utilized on each dairy; CSPS showed that all samples were either adequately or optimally processed.

Table 1 (Abstr. M117). Nutrient composition (% of DM unless otherwise noted) of chopped corn (n = 20) taken at harvest in California's San Joaquin Valley

	DM, %	CP	ADF	NDF	Starch	NFC	Ash	CSPS (%)
Average	35.9	7.7	24.4	41.0	30.2	43.6	5.4	70.7
Median	35.9	7.8	24.9	42.3	29.0	43.2	5.4	69.4
Minimum	31.2	6.2	20.2	35.2	23.3	36.6	4.2	50.7

Key Words: California, corn silage, corn silage processing score

M118 Investigation into the accuracy of a commercially available activity meter for measuring grazing duration.

Emer Kennedy*, James Moloney, Donagh P. Berry, Michelle Liddane, and Frank Buckley, *Teagasc, Animal & Grassland Research and Innovation Centre, Moorepark, Fermoy, Co. Cork, Ireland.*

Grass intake is influenced by grazing duration. Current methods of measuring grazing behavior are best suited to research environments. Activity meters, used primarily for oestrus detection, are now incorporating behavioral measures. The hypothesis was that an activity meter would provide similar information on grazing duration to that generated by a behavior recorder. One hundred 24-h records were obtained from grazing Holstein-Friesian cows between August 26 and September 30, 2014. Grazing time was recorded using IGER behavior recorders (IGER), which were processed using the 'Graze' analysis software. All cows were fitted with MooMonitor+ activity meters (MOO; Dairymaster, Causeway, Co. Kerry). Total grazing time data from the MOO was obtained from the Dairymaster database. Total 24-h grazing duration determined by the IGER was linearly regressed on the MOO grazing duration to determine the association between each method; no intercept was fitted in the model. A fixed effects linear model was used to quantify the association between parity, measurement day and IGER recorder number on the IGER recorded grazing duration. Two-way interactions between the MOO grazing duration and the main fixed effects were considered in the model to determine if the association between the MOO and IGER grazing duration differed by any of the main effects. Mean 24-h grazing duration was 543 (±6.39 SEM) min for IGER and 540 (±5.9 SEM) min for MOO. A correlation of r = 0.72 existed between the IGER and MOO grazing durations. The regression coefficient of IGER grazing duration on MOO grazing duration was 1.003 (±0.008 standard error) which was not different from the expectation of unity should the measured differences in grazing duration between the 2 devices be equivalent. Neither parity nor calendar day was associated with the difference in grazing duration estimated by the 2 devices. The regression coefficient of the IGER on the MOO grazing duration varied from 0.87 to 1.1. The results from this study, albeit from a limited data set, indicate good concordance between 24-h grazing duration estimated from the IGER and MOO recorders.

Key Words: grazing behavior, dairy cow, activity meter

M119 Forage quality of two different pasture systems incorporating warm and cool season forages for grazing organic dairy cattle.

Kathryn E. Ruh*[1,2], Bradley J. Heins[1,2], and Jim C. Paulson[3], *[1]West Central Research and Outreach Center, Morris, MN, [2]University of Minnesota, St. Paul, MN, [3]University of Minnesota Extension, Rochester, MN.*

Two pasture systems (cool and warm season grass species) with enhanced in-field and landscape level species diversity were analyzed for forage quality characteristics across the grazing season at the West Central Outreach and Research Center organic dairy in Morris, Minnesota, for 2 years. System 1 was a diverse-mixture of cool season grasses and legumes (perennial ryegrass, white clover, red clover, chicory, orchardgrass, meadow bromegrass, alfalfa, meadow fescue). System 2 was a combination of perennial polycultures and annual-warm season grasses (BMR sorghum-sudangrass and teff grass). Grazing of lactating cows was initiated when forages were 20–30 cm tall and strip size was adjusted to leave 7 to 13 cm of refusals. Random samples of pasture forage were sampled every other day when a group of cows moved to a new paddock. Pasture clippings were randomly collected in a 0.76-m^2 square of pasture. Forage samples were sent to Rock River Laboratory, Inc., Watertown, WI and were analyzed with NIR spectrophotometry for DM, CP, and total-tract NDF digestibility (TTNDFD). Data were analyzed using the MIXED procedure of SAS. Independent variables for analyses were the fixed effects of system [cool (1) or cool-warm (2)], month (May to October), forage (grass pasture, turnips, BMR sorghum-sudangrass or teff), year (2013 or 2014) and their interactions, and date of harvest was a random variable. The DM averaged 20.7% and 21.2% for systems 1 and 2, respectively ($P = 0.75$). The CP was 21.2% and 18.3% for systems 1 and 2, respectively ($P < 0.05$). The CP for system 1 averaged 19.9% in 2013 and 22.5% in 2014 ($P < 0.01$). The CP for system 2 averaged 16.1% in 2013 and 20.4% in 2014 ($P < 0.01$). The TTNDFD averaged 69.9% and 53.1% for system 1 and system 2, respectively ($P < 0.01$). The TTNDFD was 78.1% in 2013 and 61.7% in 2014 for cool-season grasses, and 59.8% in 2013 and 46.4% in 2014 for warm season grasses ($P < 0.0001$). In summary, CP and TTNDFD were greater in cool-season pasture systems; however, DM did not differ between pasture systems. Yearly effects and weather may affect forage quality in both pasture production systems.

Key Words: teff, organic, grazing

M120 Effect of starchy or fibrous carbohydrate supplementation of an herbage diet on ruminal fermentation and methane output in continuous culture.

Kathy J. Soder*[1], Aimee N. Hafla[1], Andre F. Brito[2], Melissa D. Rubano[1], and Curtis J. Dell[1], *[1]USDA-ARS, Pasture Systems and Watershed Management Research Unit, University Park, PA, [2]University of New Hampshire, Durham, NH.*

A dual-flow continuous culture fermentor system was used to assess the effect of supplementing 2 levels (5 or 10% of diet DM) of starchy (barley: BAR) or fibrous (beet pulp: BP) carbohydrate (CHO) to an orchardgrass diet on nutrient digestibility, VFA production, bacterial protein synthesis, and methane output. Treatments were randomly assigned to fermentors in a 4 × 4 Latin square design with a 2 × 2 factorial arrangement using 7 d for diet adaptation and 3 d for sample collection. Treatments included: 1) 57 g DM herbage + 3 g DM BAR; 2) 54 g DM herbage + 6 g DM BAR; 3) 57 g DM herbage + 3 g DM BP; 4) 54 g DM herbage + 6 g DM BP. Feeding and pH sampling occurred at 0730, 1030, 1400 and 1900 h. Gas samples for methane analysis were collected at 0725, 0900, 1000, 1355, 1530, and 1630 h. Effluent samples were analyzed for OM, CP, NDF, nutrient digestibilities, estimation of bacterial protein synthesis, ammonia-N and VFA. Data were analyzed using the MIXED procedure of SAS with period and treatment as fixed effects and fermentor as random. Orthogonal contrasts were tested for CHO type and level. No significant interactions were detected. Apparent and true OM digestibilities were not affected ($P > 0.10$) by CHO source (72.4 and 81.9%, respectively). True CP digestibility was greater ($P < 0.05$) for BP (75.3%) than BAR (52.5%) diets. Apparent NDF digestibility was lower ($P < 0.05$) for BP (79.5%) than BAR (85.1%) diets. Barley diets produced lower ($P < 0.05$) molar proportions of acetate (43.5 vs. 49.4 mol/100 mol, respectively), lower concentrations of total VFA (67.2 vs. 72.2 mmol/L, respectively) and tended ($P = 0.08$) to have greater mean pH (6.75 vs. 6.72) compared with BP diets. Methane production was not affected ($P > 0.10$) by CHO source. The 10% supplement produced greater ($P < 0.05$) concentrations of methane (35 vs. 27 mmol/d) and tended ($P = 0.07$) to increase apparent DM digestibility. Diet had no effect on bacterial efficiency or ammonia-N. Supplementation of an herbage-based diet with BP improved CP digestibility compared with barley but did not affect OM digestibility, methane production, or microbial efficiency.

Key Words: barley, beet pulp, ruminal fermentation

M121 Heifer growth performance from fall-oat pastures.

Wayne K. Coblentz*[1], Geoff E. Brink[2], Nancy M. Esser[3], Jason S. Cavadini[3], and Patrick C. Hoffman[4], *[1]US Dairy Forage Research Center, Marshfield, WI, [2]US Dairy Forage Research Center, Madison, WI, [3]University of Wisconsin, Marshfield, WI, [4]University of Wisconsin, Madison, WI.*

Fall-grown oat has shown promise as an emergency fall forage option, or to extend the grazing season in Wisconsin. Our objectives for this project were: (1) to assess the pasture productivity and forage characteristics of 2 fall-grown oat cultivars (Ogle and ForagePlus; OG and FP, respectively) using grazing initiation dates timed to late-September (EARLY) or mid-October (LATE); and (2) to evaluate growth performance by heifers grazing these oat forages compared with performance of heifers reared under controlled conditions with traditional confinement management (CONTROL). A total of 160 gravid Holstein heifers (80 heifers/yr) were stratified by weight, and assigned to 10 research groups (8 heifers/group). Initial BW was 509 ± 40.5 kg in 2013 and 517 ± 30.2 kg in 2014. Heifer-groups were maintained as units, and assigned to specific pastures arranged as a 2 × 2 factorial of oat cultivars and grazing initiation dates. Grazing heifer groups were allowed to strip-graze oat pastures for 6 h daily before returning to the barn, where they were offered a forage-based basal TMR. During both years, oat forage mass increased until early-November before declining in response to freezing weather conditions, exhibiting linear ($P < 0.01$) and quadratic ($P < 0.01$) effects of calendar date, regardless of oat cultivar. For 2013 and 2014, the respective maximum forage mass was 5329 and 4501 kg/ha for FP, and 5046 and 5111 kg/ha for OG. ForagePlus oat did not reach the boot stage of growth during either year; in contrast, OG matured more rapidly, and reached a late-heading stage during 2013, but only the early-boot stage in 2014. For 2013, ADG for CONTROL did not differ from grazing heifer groups (overall mean = 0.63 kg/d; $P = 0.619$); however, ADG from FP was greater than OG (0.68 vs. 0.57 kg/d; $P = 0.02$), and greater from EARLY than LATE (0.82 vs. 0.43 kg/d; $P < 0.01$). During 2014, ADG from CONTROL exceeded grazing heifer groups

(0.81 vs. 0.57 kg/d; $P = 0.01$), and ADG from EARLY again exceeded LATE (0.70 vs. 0.44 kg/d; $P < 0.01$). These results suggest that delaying grazing until mid-October to allow more oat forage to accumulate will consistently suppress heifer growth performance.

Key Words: heifer, grazing, oat

M122 Fertilization of fall-grown oat with dairy slurry or urea.

Wayne Coblentz*[1], William Jokela[1], and Jason Cavadini[2], [1]*US Dairy Forage Research Center, Marshfield, WI,* [2]*University of Wisconsin, Marshfield, WI.*

Oat has shown promise as a fall-forage option for dairy producers in Wisconsin. Our objectives were to assess the effects of summer applications of urea fertilizer or dairy slurry on the DM yield, N uptake, and apparent N recovery from fall-grown oat forages. 'ForagePlus' oat was established in early-August of 2013 and 2014, and fertilized with 0, 20, 40, 60, 80, or 100 kg N/ha as urea (46–0-0), or dairy slurry applied at rates of 43,250 (LM) or 86,500 L/ha (HM). All plots were harvested in early-November of each year. Yields of DM increased in response to fertilization with urea, exhibiting linear ($P < 0.01$) and quadratic ($P = 0.03$) effects of fertilization rate. The 2-yr mean DM yield at the 100 kg N/ha fertilization rate was 3968 kg DM/ha, which was nearly twice that of the unfertilized (0 kg N/ha) check plots (2105 kg DM/ha). Yields of DM from LM and HM plots differed from unfertilized check plots (3164 vs. 2105 kg DM/ha; $P < 0.01$), but did not differ from each other (3029 vs. 3298 kg DM/ha; $P = 0.15$). Collectively, total N uptake from plots fertilized with urea differed from unfertilized check plots (89 vs. 44 kg N/ha; $P < 0.01$), and also increased linearly ($P < 0.01$) with N fertilization rate from 44 kg N/ha for the unfertilized checks to 110 kg N/ha at the greatest urea fertilization rate. Uptake of N for plots receiving dairy slurry also differed from unfertilized check plots (77 vs. 44 kg N/ha; $P < 0.01$), but the HM and LM application rates only tended to differ (82 vs. 71 kg N/ha; $P = 0.06$). The apparent N recoveries from plots receiving urea differed from those receiving dairy slurry (83.0 vs. 23.1%; $P < 0.01$); however, apparent N recoveries for plots fertilized with urea only tended ($P = 0.10$) to decrease with N fertilization rate (range = 101.2 to 67.8%), and apparent N recoveries for LM and HM plots did not differ (27.2 vs. 19.0%; $P = 0.65$). When expressed as a percentage of the NH_4-N applied within dairy slurry, apparent N recoveries for LM and HM accounted for approximately half of the NH_4-N applied, but there was no statistical difference between slurry rates (66.7 vs. 46.9%; $P = 0.22$). Overall, fall-grown oat exhibited excellent ability to recover readily available fertilizer and manure N during a short fall growing season.

Key Words: apparent N recovery, fall-grown oat, N uptake

M123 Effect of different ruminal incubation orders on in situ degradability of maize silage and alfalfa haylage in lactating dairy cows.

Shuangzhao Dong*, Yang Zou, Yun Du, Yajing Wang, Shengli Li, and Zhijun Cao, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

A study using 4 ruminally cannulated Holstein cows was conducted to evaluate the degradability of maize silage and alfalfa haylage by different ruminal incubation orders. Maize silage and alfalfa haylage samples were dried and ground to pass through a 2.5-mm screen. All nylon bags containing feed samples for each cow were either placed in rumen simultaneously (OI) or removed from rumen simultaneously (OII). Samples were incubated in the rumen for 2, 6, 12, 24, 36, 48, and 72 h. For maize silage, OI had higher neutral detergent fiber (NDF) and acid detergent fiber (ADF) degradability at 6 h and 12 h ($P < 0.05$) compared with OII. Contrarily, slowly degraded fraction (b) of OI was significantly lower than that of OII ($P < 0.05$). For alfalfa haylage, different ruminal incubation orders had significant effect ($P < 0.05$) on the NDF degradability at 6 h and 12 h, constant rate of slowly NDF degraded fraction (K_d), and rapidly ADF degraded fraction (a) (Table 1). Overall, the effects of different ruminal incubation orders concentrated during first 12 h of incubation period, but did not affect ruminally degradable part.

Table 1 (Abstr. 123). Degradability and degradation variations of NDF and ADF of maize silage and alfalfa haylage incubated in situ in different ruminal incubation orders[1]

M124 Productive performance and morphological composition of two genotypes of *Brachiaria* grazed by dairy calves in Mexico's Central Highlands.

Francisca Avilés Nova*[1], Sandra A. Vencez González[1], Octavio A. Castelán Ortega[2], José M. Castro Salas[3], and Luis M. Ríos García[1], [1]*Centro Universitario UAEM-Temascaltepec, Temascaltepec, Estado de México, México,* [2]*Facultad de Medicina Veterinaria y Zootecnia de la UAEM, Toluca, Estado de México, México,* [3]*Unidad Académica de Ciencias Agropecuarias y Ambientales. Universidad Autónoma de Guerrero, Iguala de la Independencia, Estado de Guerrero, México.*

The objective of this study was to evaluate the production and morphological characteristics of Insurgente (*Brachiaria brizantha*), and Mulato II (hybrid *Brachiaria*) forages, when grazed by dairy calves during the rainy season in Mexico's Central Highlands. The variables net herbage accumulation (NHA), leaf proportion and appearance of stems was evaluated in 3 periods consisting of 21 d each, between July and September 2014. The pasture used was composed of 16 plots (15 m × 4 m), with 4 plots per species and were fertilized with vermicompost ($10\ t\cdot ha^{-1}$). The pasture was grazed continually by 4 dairy calves, aged

12 ± 4 mo, weight of 250 ± 35 kg. Sixteen exclusion cages (1m × 1m) and a metal quadrant measuring 0.16 m^2 (0.40 m × 0.40 m) were used. Leaf proportion was measured for each period, with a 100 g sample taken randomly from each plot. In the appearance of stems was identified the number of plants for each plot by m2, and selected a single plant randomly. At the beginning of each period the initial population of stems was measured for each plant, and marked with a plastic yellow ring. Then, new stems were counted every 15 d and marked with a ring of another color. The design was based on plots divided at random, with larger plots (species) and smaller plots (time periods). A variance analysis was conducted, using MINITAB, and measurements were compared using the Tukey's test ($P < 0.05$). Significant differences ($P < 0.015$) in the NHA were noted in the Insurgente and Mulato II species and in the interaction ($P < 0.001$). Higher NHA was found in Mulato II forage (10,584 kg DM·ha^{-1}). In both species the highest NHA was found in P2 and P3 2,662 and 3,858 kg DM·ha^{-1}, respectively ($P < 0.05$). Also, 11% more leaf appearance was found in Mulato II. The greatest appearance of stems was found in Mulato II forage (240 stems/m^2; $P < 0.001$). Insurgente and Mulato II demonstrated different growth behaviors under continuous grazing during the rainy season. Mulato II showed better performance, had higher net herbage accumulation, leaf proportion and appearance of stems.

Key Words: *Brachiaria*, pasture

M125 Effect of processing methods on in situ degradability of maize silage and alfalfa haylage in lactating dairy cows.

Yang Zou*, Shuangzhao Dong, Yun Du, Yajing Wang, Shengli Li, and Zhijun Cao, *State Key Laboratory of Animal Nutrition, College of Animal Science and Technology, China Agricultural University, Beijing, China.*

A study using 4 ruminally cannulated Holstein cows was conducted to evaluate the degradability of maize silage and alfalfa haylage prepared by different processing methods. Maize silage (20-mm length) and alfalfa haylage (40-mm length) were either wet (MSW; AHW) or air-dried (MSD; AHD). Air-dried silage and haylage were also ground to pass through a 2.5-mm screen (MSG; AHG). Samples were incubated in the rumen for 2, 6, 12, 24, 36, 48, and 72 h. Cows were fed ad libitum with free access to water. Treatment MSW had a lower acid detergent fiber (ADF) degradability at 2 h ($P < 0.05$) compared with air-dried samples (MSD and MSG). Processing methods had significant effects ($P < 0.05$) on NDF degradability at 72 h, ADF degradability at 36, 48, and 72 h, and ruminal degradable ADF. All of the highest values were observed in AHG treatment (Table 1). Based on this study, processing methods of drying and grinding should be taken into consideration when evaluating nutritive values of forages.

Contd.

Table 1 (Abstr. M125). Degradabilities of NDF and ADF in differently processed maize silage and alfalfa haylage incubated in situ[1]

	Maize silage				Alfalfa haylage			
Item	MSW	MSD	MSG	*P*-value	AHW	AHD	AHG	*P*-value
NDF								
2 h	13.72	16.68	14.48	0.31	24.62	27.76	27.81	0.30
36 h	40.96	41.91	39.91	0.94	50.79	46.23	51.89	0.27
48 h	43.40	42.69	40.80	0.80	51.08	52.75	55.96	0.18
72 h	48.58	55.20	47.31	0.28	53.68^{b}	56.54^{ab}	59.42^{a}	0.03
RDNDF	31.16	34.18	29.81	0.39	41.96	42.82	44.57	0.31
ADF								
2 h	12.16^{b}	14.58^{ab}	16.17^{a}	0.09	20.61	21.50	23.91	0.54
36 h	41.54	41.39	51.57	0.22	41.71^{ab}	39.26^{b}	46.68^{a}	0.04
48 h	44.54	45.21	43.30	0.97	46.19^{b}	47.66^{b}	53.10^{a}	0.03
72 h	50.06	54.43	50.95	0.68	49.20^{b}	51.75^{b}	57.05^{a}	<0.01
RDADF	31.41	33.14	33.04	0.85	35.75^{b}	36.62^{b}	40.04^{a}	0.04

[a,b] Means with different superscript letters with the same row represent a significant difference between treatments ($P < 0.05$).

[1] MSW = wet maize silage, MSD = air-dried maize silage, MSG = air-dried ground maize silage, AHW = wet alfalfa haylage, AHD = air-dried alfalfa haylage, AHG = air-dried ground alfalfa haylage, RDNDF = ruminally degradable NDF, RDADF = ruminally degradable ADF.

M126 Effectiveness of plastic underlays with or without oxygen barrier properties in maintaining corn silage quality.

Peter H. Robinson*[1], Nadia Swanepoel[1], and Jim Ralles[2], [1]*Department of Animal Science, University of California, Davis, CA,* [2]*ARI, Belmont, CA.*

Use of only a single layer of plastic to cover silage piles can lead to substantial surface spoilage of silage (i.e., increased pH and temperature, discoloration, molding). The extent of spoilage losses can be curtailed if a thin plastic underlay film is utilized under the outer white/black plastic cover. Our objective was to determine if a clear plastic polyethylene film (Poly) has an impact on the nutritional quality of the outer 50 cm layer of corn silage vs. an oxygen barrier (OB) film when used as an underlay. Two wedge type corn silage piles with east/west, and 2 with north/south, orientation were constructed in fall 2014. Each pile was alternately covered with a clear, pliable polyethylene film of 1.6 mil HiTec Underlay (ARI, Belmont, CA) or an OB plastic film of 1.8 mil from Industria Plastica, Mongralese, Italy (trade name 'Silostop') with a 1.8 m overlap between sections and then covered with a conventional plastic cover. After 90 d, all piles were sampled to a 50 cm depth with a silage probe, divided into 2 samples of 25 cm (i.e., 0–25, 25–50 cm depth) each at 4 sample points in each of the 4 sections. Temperatures and pH were determined at core extraction. Each core sample was preserved individually (n = 32) for mold and yeast counts and part was pooled by section location (upper vs. lower; n = 16) and analyzed for volatile fatty acids, lactic acid and ethanol. There were no differences between the silages under the Poly and OB films in temperature (24.7 vs. 24.2 for N/S and 23.1 vs. 22.4°C for E/W piles), pH (3.79 vs. 3.84 for N/S and 3.77 vs. 3.84 for E/W piles) or mold and yeast counts, which were all below 0.5 million cfu/g. Volatile fatty acids were similar between treatments, with lactic, acetic and propionic acid averaging 2.93 and 3.57, 1.73 and 1.93, 0.38 and 0.24% DM for N/S and E/W piles respectively, with none being statistically different. Butyric acid occurred at a very low level, 0.05% DM, and ethanol was 0.53% DM, with no differences. Overall, it was judged that there were no differences in the silage quality of the outer 50 cm layer of corn silage after ~90 d of ensiling when covered with a clear polyethylene film vs. an oxygen barrier film under the outer black/white plastic cover.

Key Words: volatile fatty acids, silage quality

M127 Defining and measuring losses (shrink) from well-managed corn silage silos, and identifying stages in silo life where losses occur.

Peter H. Robinson*[1], Nadia Swanepoel[1], Jennifer Heguy[2], and Deanne Meyer[1], *[1]Department of Animal Science, University of California, Davis, CA [2]UCCE Stanislaus, San Joaquin & Merced Counties, University of California, Davis, CA.*

Silage shrink (weight lost between ensiling and feedout) represent loss of nutrients to dairy producers, and the potential to degrade air quality if that loss is as volatile carbon compounds, or degrade water quality due to weepage to surface water and seepage to subsurface aquifers. No research has documented silage shrink in large commercial silage structures (silos) common in the SW US. 'Shrink' can be expressed as loss of wet weight (WW), oven dry weight (oDM) and oDM corrected for volatiles lost in the oven (vcoDM). Shrink losses, and the phase of the process where losses occurred, were measured using 7 corn silage silos (2 rollover, 1 bunker, 4 wedge) from the 2013 crop year on 4 dairy farms in 2 San Joaquin Valley areas, all covered within 48 h with an oxygen barrier inner film and black/white outer plastic weighted with tire chains. Total WW, oDM and vcoDM losses (not including wastage) calculated from weights of fresh chop delivered to the silo and silage placed in a feed mixer (n = 7) were 9.0 ± 1.69, 6.8 ± 1.82 and 2.8 ± 2.08%, suggesting that much of the WW shrink was water and much of the oDM shrink was volatiles driven off during oven drying. The largest part of shrink occurred in the silage mass (measured using in/out weights of 9–15 buried bags in each of 4 silos) before face exposure (WW, oDW and vcoDW losses from the mass were 3.9 ± 2.40, 7.2 ± 1.12 and 3.5 ± 1.27% respectively), with losses from the exposed face (measured as loss in core weight between freshly exposed faces and ~21 h exposed faces from 4 cores of 50 cm depth on 2 occasions in each silo), as well as between face removal and the mixer (measured between compositional changes between freshly exposed faces and silage placed in the mixer on 2 occasions in 4 silos), being negligible. Silo bulk density, face management, rate of face use and face orientation had no obvious effects on shrink. Real shrink losses (i.e., vcoDM) of well managed corn silages piles are much lower than has been generally assumed, the exposed face is a very small portion of those losses, and many of the proposed mitigations may not be effective in reducing shrink, possibly because it is quantitatively so small in large well managed silos.

Key Words: volatile compound, air quality

M128 Effects of sealing time post-filling and sealing material on fermentation, nutritional quality, and organic matter loss of whole-plant corn ensiled in a drive-over pile.

Katie Nutcher[1], Estela Uriarte[2], Keith K. Bolsen*[2], Ron Kuber[3], and Connie Kuber[3], *[1]California Polytechnic State University, San Luis Obispo, CA, [2]Kansas State University, Manhattan, KS, [3]Connor Agriscience, Clovis, CA.*

Sealing time, immediate and 24-h delay, and sealing material, standard plastic (std.) and oxygen barrier (OB) film, was compared using whole-plant corn. The crop was harvested on August 21 and 22, 2013 in the 2-thirds milk line stage, contained 32% DM, and was inoculated at the forage harvester. The forage was ensiled in a drive-over pile, which was 18 m wide x 60 m long × 1.8 m apex height with an east to west orientation. One-half of the forage was harvested the first day, packed with a payloader, and not sealed. On the second day, the remainder of the corn was harvested and packed with a payloader. One-half of each day's forage surface was sealed with a sheet of std. plastic, and the other half sealed with a sheet of OB film, which was protected from UV light with a sheet of std. plastic. The sealing materials were removed from the south half of the pile after 90 d. Samples were collected at 0 to 15, 15 to 30, and 30 to 45 cm depths from the surface at 3 north to south locations, which were equal distance from the east and west boundaries of each of the 4 sealing treatments. The results are presented for the mean of the 3 sampling depths. The immediate sealed silages had a lower ($P < 0.05$) pH value than the delay sealed silages. The silage that was delay sealed with std. plastic had higher ($P < 0.05$) ash and NDF contents and lower ($P < 0.05$) NDF digestibility than the silage that was delay sealed with OB film and the silages that were sealed immediately with std. plastic or OB film. The OB film was more effective than std. plastic in preventing the entry of oxygen into the surface of the corn silage during the 90-d storage period. Delay sealing increased OM loss in the original top 0 to 45 cm of corn silage by 27.2% compared with immediate sealing (15.64 vs. 12.30%). However, delay sealing with OB film decreased OM loss in the original top 0 to 45 cm of corn silage by 20.6% compared with immediate sealing with std. plastic (12.33 vs. 15.54%).

Key Words: silage, sealing, delay

M129 Transcriptome profiling of pituitary gland from pre- and post-pubertal beef heifers. Robmay Garcia*, Dianelys Gonzalez-Pena, Bruce R. Southey, and Sandra L. Rodriguez-Zas, *University of Illinois at Urbana Champaign, Urbana, IL.*

Onset of puberty is a key component of animal production and reproductive efficiency. The pituitary gland plays a major role in reproductive readiness. A comprehensive understanding of the associated transcriptome changes during peripuberty will aid in the development of treatments and management practices to improve reproductive performance. The objective of this study was to gain understanding of the transcriptome associated with changes pre- and post-puberty. The transcriptome of pituitary tissue from 4 pre-pubertal beef heifers was compared with that of 4 different post-pubertal beef heifers using individual RNA-seq libraries. Single-end reads were mapped to the *Bos taurus* reference genome (Btau_4.6.1) using Tophat v2.0.12. In total, 10,489 isoform transcripts pertaining to 10,234 genes were identified and 1,162 isoform transcripts pertaining to 1,149 genes were differentially expressed between post-puberty and pre-puberty pituitary tissue (False Discovery Rate-adjusted P-value <0.05) using Cufflinks v2.2.1. Among the most relevant and significant (false discovery rate adjusted P-value <0.03) genes associated with reproductive maturation were leptin receptor (*LEPR*) and vasoactive intestinal peptide (*VIP*), and endothelin 1 (*EDN1*). Increments in leptin receptors encoded by *LEPR* are associated with gonad maturation, the advent of reproductive maturity and fertility. *VIP* encodes the VIP neuropeptide that among other roles, participates in ovarian development and stimulation of prolactin release under the influence of estrogen. *EDN1* encodes the EDN1 neuropeptide that is involved in mechanisms controlling the gonadotropins and prolactin secretion, also inhibiting synthesis of progesterone and premature luteinization of granulosa cells. Functional analysis of the differentially expressed genes using DAVID identified 4 enriched functional category clusters (enrichment score >2): blood vessels and vasculature development, collagen fibrin and extracellular organization, carbohydrate and hyaluronic acid binding, and transforming growth factor β receptor signaling pathway. These categories confirm a wide range of changes associated with beef heifers transitioning from pre- to post-puberty and suggest potential pharmacological targets.

Key Words: transcriptome, puberty, pituitary

M130 Prepartum supplementation of niacin increases colostral immunoglobulin G content in dairy cows. Kayla M. Aragona*, Colleen E. Chapman, André B.D. Pereira, and Peter S. Erickson, *University of New Hampshire, Durham, NH.*

In the US, 60% of colostrum fails to meet the minimum standard of 50g/L of immunoglobulin G (IgG). High quality colostrum is essential for the survival and future production of dairy heifers. Previous studies have shown that niacin (N) may increase vasodilation and in dairy cows, prepartum N supplementation may increase blood flow and potentially Ig flow, to the mammary gland. The objective of this study was to determine if feeding 48g/d of supplemental N to prepartum dairy cows effects colostrum quality. The experiment used 26 multiparous Holstein cows housed in a tie-stall barn. Cows were blocked by expected calving date and randomly assigned to 1 of 2 treatments 4wk prepartum: (1) 48g/d N (Lonza) or (2) 0g/d N (C), both with 52g/d of corn meal as a carrier. Total mixed ration amounts fed and refused were measured daily at 0800h to determine dry matter intake (DMI). Within 90min of parturition, colostrum was collected and weighed. IgG concentration was analyzed using a radial immunodiffusion (RID) assay (Triple J Farms). Calves were removed from their dams immediately and weighed. Calves received 3 bags of a lacteal based colostrum replacer (180g IgG, Saskatoon Colostrum Co.), fed within 2 h of birth. Blood samples were collected from calves via jugular vein at 0 and 24 h of age and analyzed for IgG concentration and apparent efficiency of absorption (AEA). No differences were observed for DMI [15.7 kg/d (C), 14.3 kg/d (N); $P = 0.13$], IgG yield [748.87 g (C), 773.67 g (N); $P = 0.83$], colostrum yield [10.64 L (C), 9.45 L (N); $P = 0.19$], fat % [5.5% (C), 4.72% (N); $P = 0.45$] and solids nonfat % [23.9% (C), 22.9% (N); $P = 0.7$]. No differences were observed for 24-h calf serum IgG concentration [15.9 g/L (C), 15.5 g/L (N); $P = 0.8$] or AEA [32.46% (C), 30.92% (N); $P = 0.5$]. Niacin tended to increase colostrum protein percent (14.6% (C), 17.9% (N); $P = 0.09$). Niacin increased IgG concentration in colostrum from 73.8 g/L (C) to 86.8 g/L (N) ($P < 0.05$). These results indicate that supplementing N (48 g/d) during the prepartum period improves colostrum quality.

Key Words: niacin, IgG, colostrum

M131 Innate immune cells may be involved in bovine mammary development. Kirsten. L. Beaudry*[1], Cathy. L. Parsons[1], Adam. J. Geiger[1], Steven. E. Ellis[2], and Robert M. Akers[1], *[1]Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, VA, [2]Department of Animal and Veterinary Sciences, Clemson University, Clemson, SC.*

Bovine mammary development begins before puberty with the elongation and branching of ducts and stromal remodeling. This process is highly regulated, and in mice impacted by the presence of innate immune cells which cluster near developing ductal structures. For the first time, we studied the presence, location and changes in numbers of eosinophils, mast cells and macrophages in prepubertal bovine mammary tissue. Chemical stains and immunofluorescence were used to identify the 3 cell types in formalin fixed, paraffin embedded mammary tissue from prepubertal female calves in archived sets. The first set (ONT) included samples (n = 4 per week) from birth to 6 wk of age. A second set (OVX) allowed for examination of the potential influence of ovaries on innate immune cells. It included samples from 19 animals who were either intact or ovariectomized 30 d before sample collection. These animals were 90, 120 or 150 d old at examination. The third set (EST) allowed for examination of the potential influence of exogenous estrogen on innate immune cells in the mammary gland. This set included samples from 10 calves given estrogen implants (n = 6) or placebo (n = 4) at 56 d of age. Calves were sampled at 70 d of age. Eosinophils were identified via LUNA staining, mast cells by May–Grunewald Giemsa staining, and macrophages with immunoflourescence. Stroma was examined in 20 images from each animal of the NEAR (<100 μm) and FAR (>100 μm) locations relative to the epithelial ducts. Results were expressed as cells/mm^2. More eosinophils and mast cells were observed in NEAR compared with FAR stroma in the ONT ($P < 0.001$) and OVX ($P < 0.05$) but not EST. More macrophages were also observed in NEAR compared with FAR in ONT ($P < 0.001$). Treatment (age, ovariectomy or estrogen) had no impact on stromal eosinophils. Age tended to affect mast cell numbers in ONT, with the most mast cells observed at 14 d of age. In summary, we show for the first time that innate immune cells are present in prepubertal bovine mammary tissue and that abundance is related to the epithelial structure and physiological state of development. We suggest there may be a role for these cells in control of bovine mammary development.

Key Words: mammary, immune cell, development

M132 An evaluation of precision dairy farming technologies monitoring rumination, feeding, and lying behaviors. Matthew R. Borchers*, I-Ching Tsai, Barbara A. Wadsworth, and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

The objective of this study was to evaluate commercially available precision dairy farming technologies against direct visual observations for feeding, rumination, and lying behaviors. Primiparous (n = 24) and multiparous (n = 24) lactating Holstein dairy cattle (mean ± SD; 223.4 ± 117.8 d in milk, producing 29.2 ± 8.2 kg milk/d) were fitted with 6 triaxial accelerometer technologies to evaluate cow behavior. Technologies recording feeding behavior were the CowManager SensOor (Agis, Harmelen, Netherlands) and the Track a Cow (ENGS, Israel). Technologies recording rumination behavior were the CowManager SensOor and the Smartbow (MKW electronics GmbH, Jutogasse, Austria). Lying behavior was recorded by the AfiAct Pedometer Plus (Afimilk, Kibbutz Afikim, Israel), HOBO Data Logger (HOBO Pendant G Acceleration Data Logger, Onset Computer Corporation, Pocasset, MA), CowAlert IceQube (IceRobotics Ltd., Edinburgh, UK), and Track a Cow. Over 8 d in October 2014, 6 cows per day were visually observed for feeding, rumination, and lying behavior for 2 h after morning and evening milking. The CORR procedure of SAS Version 9.3 (SAS Institute Inc., Cary, NC) was used to evaluate agreement between visual observations and technology-recorded behaviors. Visually recorded feeding behavior was strongly correlated with CowManager SensOor ($r = 0.97$; $P = 0.03$) and Track a Cow ($r = 0.91$; $P = 0.09$). Between the CowManager SensOor and Track a Cow, a strong correlation ($r = 0.91$; $P = 0.09$) was found. Visually recorded rumination was strongly correlated with the Smartbow ($r = 0.99$; $P < 0.01$) and CowManager SensOor ($r = 0.96$; $P < 0.01$). Between the Smartbow and CowManager SensOor, a strong correlation ($r = 0.94$; $P = 0.06$) was found. Visually recorded lying behavior was highly correlated with the AfiAct Pedometer Plus ($r = 0.97$; $P < 0.01$), HOBO Data Loggers ($r = 0.98$; $P < 0.01$), CowAlert IceQube ($r = 0.99$; $P < 0.01$), and Track a Cow ($r = 0.99$, $P < 0.01$). Results indicate these precision dairy farming technologies to be accurate dairy cattle behavioral monitors.

Key Words: precision dairy farming technologies, dairy cow behavioral monitoring, accuracy evaluation

M133 The effect of estrus expression on target genes in the endometrium, conceptus and corpus luteum of cows. Saeideh Davoodi*[1], Reinaldo F. Cooke[2], Arthur C. C. Fernandes[1], Bruno I. Cappellozza[2], Jose L. M. Vasconcelos[3], and Ronaldo L. A. Cerri[1], *[1]Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada, [2]Eastern Oregon Agricultural Research Center, Oregon State University, Burns, OR, [3]Faculdade de Medicina Veterinária e Zootecnia, UNESP – Botucatu, SP, Brazil.*

The aim of this study was to test the effect of estrus expression at artificial insemination (AI) on the endometrium, conceptus and corpus luteum (CL) gene expression. Twenty-three multiparous nonlactating Nelore cows were enrolled on a estradiol and progesterone (P4) based timed-AI protocol (AI = d 0), then slaughtered for endometrium, CL and conceptus collection on d 19. Body condition score (BCS), blood samples for analysis of P4 and ultrasound examination was performed on d 0, 7 and 18 of the experiment. RNA extraction and qRT-PCR analysis of 58 target genes were analyzed on tissues. Data were checked for normality and analyzed by ANOVA for repeated measures using proc GLM, MIXED and UNIVARIATE. Estrous expression had no correlation with parameters such as BCS, pre-ovulatory follicle and CL diameter, P4 concentration in plasma on d 7 and 18 after AI and IFN-tau concentration in the uterine flushing ($P > 0.05$); however, a significant increase was observed in conceptus size ($P = 0.02$; 38.3 ± 2.8 vs. 28.2 ± 2.9). The majority of transcripts affected by estrous expression in the endometrium belong to the immune system and adhesion molecule family (MX1, MX2, MYL12A, MMP19, CXCL10, IGLL10 and SLPI; $P \leq 0.05$). Genes related to apoptosis, P4 synthesis and prostaglandin receptor were downregulated (CYP11A, BAX and PGR; $P < 0.05$) in the CL tissue of cows in estrus. In addition, 4 genes were identified as differentially expressed in the 19 old conceptus from cows observed in estrus (ISG15, PLAU, BMP15 and EEF1A1; $P < 0.05$). There was an interaction ($P < 0.05$) between estrus expression and P4 concentration on d 7 which mainly affected genes involved in immune system (MX1, MX2, TRD, SLPI and IGLL1). This study demonstrated that estrous expression at the time of AI, in spite of ovulation being induced by estradiol, can alter the gene expression profile in reproductive tissues during the preimplantation phase. These effects seem to be more pronounced in endometrium during the time of dynamic remodeling to prepare a receptive uterus for embryo implantation.

Key Words: conceptus, corpus luteum, endometrium

M134 Accuracy and intensity of heat detection with activity monitoring systems for lactating dairy cows. Craig LeRoy* and Stephen LeBlanc, *Department of Population Medicine, University of Guelph, Guelph, ON.*

Activity monitors are becoming a widely used tool for estrus detection in dairy cows. The objective of this study is to assess the intensity and accuracy of estrus detection with automated activity monitoring systems. Three commercial dairy farms with an activity monitoring system (Heatime SCR Inc., or Afi PedoPlus, Afikim) that was used for essentially all inseminations between 50 and 80 d in milk (DIM) were enrolled in this observational study. Herds were visited once weekly. Blood samples were collected at wk 5, 7, and 9 postpartum and from a subset of cows on the day of insemination, to measure serum progesterone concentration. Cows were examined at wk 5 for purulent vaginal discharge (PVD). Lameness and body condition were scored at wk 7. Cows were classified as anovular if all 3 blood samples from wk 5, 7, and 9 had progesterone <1 ng/mL. Overall, 6.7% of cows were anovular (range of 3.6% to 8.2% among farms). Of these cows, 39% had a lameness score of 3 or above (1 to 5 scale) and 29% had PVD. Among cows that reached 80 DIM (n = 419), 14% had not been inseminated by 80 DIM; of these, 12% were anovular, 23% were lame, 21% had PVD and 4% had a BCS of < 2.5%. Among 352 blood samples taken on the day of insemination (all services; 212 signaled by the activity system and 140 by Ovsynch), 8% and 3% had progesterone >1 ng/mL; that is, the cows were not in estrus. In this sample, the accuracy of detection of estrus by AAM was high, but a subset of cows would likely require intervention for timely first AI and only a fraction of these were truly not cyclic.

Key Words: activity monitor, anovular, progesterone

M135 Extruded flaxseed products improve the fatty acid profile of bovine milk.

Janna Moats*[1,2], Timothy Mutsvangwa[2], and David Christensen[2], [1]*O&T Farms Ltd., Regina, SK, Canada,* [2]*University of Saskatchewan, Saskatoon, SK, Canada.*

There is interest in increasing the content of omega-3 (n-3) fatty acids in bovine milk, primarily because of their beneficial effects on human health. This study investigated the effects of extrusion and the inclusion of condensed tannins (CT) in a flaxseed product on rumen fermentation characteristics, animal performance and milk fatty acid composition in dairy cows. Eight Holstein cows were used in a replicated 4 × 4 Latin Square with 28-d periods (20 d for dietary adaptation and 8 d for collection). Four cows in one Latin square were ruminaly-cannulated. Cows were fed either a control diet (CTL) or one of 3 treatment diets that consisted of the daily substitution of 3 kg of the CTL concentrate pellet with 3 kg of either a non-extruded flaxseed and pea product (55% flaxseed, 36% peas,8% alfalfa,1% antioxidant; designated RAW), a extruded flaxseed and pea product (55% flaxseed, 36% peas,8% alfalfa,1% antioxidant; designated LPR), or a extruded flaxseed and high-tannin fava bean product (55% flaxseed, 36% fava beans,8% alfalfa,1% antioxidant; designated LPF). Diets were fed twice daily as total mixed rations. Dry matter intake was lower for cows fed LPR compared with those fed CTL ($P < 0.05$). Milk yield was unaffected by dietary treatment ($P > 0.05$). Rumen pH was not affected by dietary treatment ($P > 0.05$). Rumen ammonia concentration was lower in animals fed CTL compared with those fed RAW, LPR or LPF ($P = 0.04$). Propionate concentrations were higher for animals fed LPR compared with those fed RAW ($P = 0.04$), while acetate concentrations did not differ between dietary treatments ($P > 0.05$). Total n-3 and CLA milk contents were higher in cows fed LPR and LPF compared with those fed RAW and CTL ($P < 0.01$). Milk fat content was lower for cows fed LPF compared with those fed CTL ($P = 0.03$); however, milk fat yield was unaffected by dietary treatment ($P > 0.05$). The use of extruded flaxseed products is an effective strategy for increasing the n-3 and CLA concentrations of bovine milk without negatively affecting rumen fermentation or animal production; however, the inclusion of CT in the extruded product had no additional benefit.

Key Words: omega-3, flaxseed, milk

M136 Prebiotic supplementation influences feed intake, body weight gain, and adaptive immunity in Holstein heifer calves during commingling.

Caleigh E. Payne*, Luis G. D. Mendonça, Sonia J. Moisá, Sophia C. Trombetta, Lucas D. S. Rocha, Suzy Q. Fowler, Juan C. Gordienko, and Lindsey E. Hulbert, *Kansas State University, Manhattan, KS.*

After weaning, the transition from individual housing to group housing (commingling) is stressful for calves and increases the risk of respiratory disease during this period. Prebiotics can include mannan-oligosaccharide (MOS) and b-glucan (BG) which may help improve calf health and performance. Therefore, the objectives of this study were to determine if a daily bolus dose of oral prebiotics (20% MOS; 10% BG) influence feed intake, body weight gain, or adaptive immunity in Holstein heifer calves (n = 60) during the transition from individual hutches to pens of 3. One week before commingling, calves (age 52 ± 4.0 SD d; body weight 83 ± 14.92 SD kg) were randomly assigned to daily treatments of either 4 g of prebiotic (Preb) dissolved in 15 mL of molasses or control (Con; 15 mL of molasses only) for 7 weeks. Calves were fed ad libitum TMR top-dressed with 9 pounds of 18% CP calf starter once per day with refusals collected and measured daily. Calves were weighed and measured weekly. All calves were administered an innocuous protein injection, ovalbumin (OVA; subQ; 0.5 mg/mL), at commingling and 4 weeks after commingling. Blood was collected 2 weeks after OVA to measure primary and secondary OVA-specific IgG and IgA responses. Prebiotic-fed calves ate more than control-fed calves 2 weeks after commingling (3.18 vs. 3.06 ± 0.034 kg/d; $P = 0.015$). Prebiotic calves also gained more weight 3 weeks (ADG 0.90 vs. 0.86 ± 0.060 kg/d; $P = 0.037$) and 6 weeks post-commingling (ADG 1.08 vs. 0.96 ± 0.060 kg/d; $P = 0.025$). In addition, the interaction between treatment and week affected F:G ($P = 0.044$) with preb-calves having lower F:G 1, 3, and 6 weeks post-commingling. The Preb-calves had a greater primary IgA response to OVA than Con-calves ($P = 0.0315$), but no differences were observed for IgG ($P = 0.8289$). Prebiotic supplementation may improve calf performance and adaptive immunity in the transition to group-housing situations post weaning.

Key Words: prebiotic, bovine, performance

M137 Supplementation of conjugated linoleic acid during the transition to lactation period increased milk production in a commercial dairy.

Tawny L. Chandler*[1], Robert T. Fugate[1], Arnulf H. A. Troescher[3], Joshua A. Jendza[2], and Heather M. White[1], [1]*University of Wisconsin-Madison, Madison, WI,* [2]*BASF Corporation, Florham Park, NJ,* [3]*BASF Corporation, Lampertheim, Germany.*

Trans-10, *cis*-12 conjugated linoleic acid (CLA), a bioactive fatty acid, has the potential to alter energy partitioning in lactating cows by marginally reducing milk fat synthesis in the mammary gland. The objective of this study was to determine the effects of pre- and postpartum CLA supplementation on lactation performance in a commercial dairy setting. Holstein cows in a robotic milking system were blocked by multiparous (mp) or primiparous (pp), and expected calving date, and randomly assigned to either a CLA group (mp n = 100; pp n = 39) or control group (mp n = 98; pp n = 38). Cows were supplemented with 100g of lipid encapsulated CLA methyl esters (Lutrell Pure, BASF, Germany) mixed 50:50 with soybean meal to provide 10g each of *trans*-10,*cis*-12 CLA and *cis*-9,*trans*-11 CLA via a robot mineral supplement unit. Supplementation was from −21d precalving through 30d in milk (DIM) for mp or 70 DIM for pp. Milk yield, fat, and protein concentration were recorded daily and averaged by wk for the first 100 DIM. Data were analyzed using the MIXED procedure of SAS 9.4 with repeated measures. Treatment, wk, and treatment × wk were fixed effects with random effects of (cow)group. Means were considered different when $P \leq 0.1$ and tended to differ when $P \leq 0.15$. Daily milk yield over 100d was increased with CLA supplementation (100d mean mp: 49.7 vs. 51.3 ± 0.6 kg/d, $P = 0.07$; pp: 30.3 vs. 32.0 ± 0.7 kg/d $P = 0.09$) with the greatest increase in milk production being 3.0 kg/d for mp (wk 5; $P = 0.007$) and 3.9 kg/d for pp (wk 14; $P = 0.001$) cows. Supplementation with CLA did not alter milk fat concentration ($P > 0.15$) or yield ($P > 0.15$) over the 100 d period. Milk protein concentration was reduced ($P = 0.05$) with CLA supplementation in mp (3.18 vs. 3.12 ± 0.02%, control vs. CLA) but not changed ($P > 0.15$) in pp (3.27 vs. 3.22 ± 0.04%, control vs. CLA) cows; however milk protein yield was unaffected ($P > 0.15$). These results suggest that CLA supplementation during the transition to lactation period altered energy partitioning to increase milk production during the first 100 DIM.

Key Words: conjugated linoleic acid, transition cow, energy partitioning

M138 Effects of plane of nutrition on glucose tolerance test kinetics pre- and postweaning in Holstein calves fed twice daily.

Jayden A. R. MacPherson*[1], Harma Berendss[2], Leonel Leal[2], Javier Martin-Tereso[2], and Michael A. Steele[1], [1]*University of Alberta, Edmonton, Alberta, Canada,* [2]*Nutreco, Boxmeer, the Netherlands.*

Feeding an elevated plane of nutrition to dairy calves preweaning is becoming more popular as it has been linked to higher growth rates, earlier onset of puberty, and increased milk production. Providing these feeding schemes in 2 meals is thought to impair glucose clearance and insulin responsiveness in young calves, but whether or not there is a carryover effect postweaning remains unclear. The objective of this study was to investigate this using a glucose tolerance test (GTT). A total of 12 female Holstein calves were selected and blocked by cow parity and colostrum intake, then assigned to an elevated plane (EP; 8 L/d) or a low plane (LP; 4 L/d) of nutrition. Calves received 4 L of colostrum provided in 2 meals (1h and 6h after birth), and were stepped-down from milk by 50% during wk 7 then weaned on wk 8. All calves had ad libitum access to pelleted calf starter, chopped wheat straw, and water. Milk replacer consisted of 24% CP and 18% CF and was fed at 150g/L. The GTT (glucose 30%) was conducted at 4, 7 and 10 weeks of age by infusing 540 mg of glucose per kg of metabolic bodyweight at the time of the morning feeding after a 12 h fast. Blood samples were collected at −15, 0, 5, 10, 20, 30, 45, 60, 120, 180, and 240 min via a jugular catheter. Changes in glucose concentration (mmol/L), clearance rate (%/min), and area under the curve (AUC_{240}) were calculated. Preliminary data from a Hemocue blood glucose analyzer indicates that the increase in glucose (Cmax; mmol/L) was similar ($P = 0.31$) between treatment groups and no differences between ages (pre- and postweaning) were detected. The time to reach the peak concentration (Tmax; minutes) was similar across treatments and age (P 0.29). Area under the curve was significantly affected by calf age ($P = 0.005$) with AUC_{240} increasing with age, and a trend for interaction with treatment was observed, where EP calves tended ($P = 0.07$) to have a greater AUC at 10 weeks of age. The results show that the rate of glucose clearance following a tolerance test was not affected ($P = 0.14$) by plane of nutrition or age when calves were fed milk replacer in 2 meals per day.

Key Words: glucose, glucose tolerance test, calf nutrition

M139 Metabolic characteristics of protein, nutrient supply and feed milk value of the newly developed AAFC yellow and brown carinata lines for dairy cattle in comparison with commercial canola seeds.

Yajing Ban*, David A. Christensen, John J. McKinnon, and Peiqiang Yu, *Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Canada.*

New lines of *Brassica carinata*, which were developed recently as oil crops for bio-fuel production in the dry western Canadian prairie, could also be regarded as a potential new feed source for animals. To our knowledge, there is little research on metabolic characteristics of protein in the new yellow and brown lines of carinata seeds. The objective of this study was to determine the differences in metabolic characteristics of protein from the new lines of carinata seeds in yellow and brown coats for dairy cows compared with commercial canola seeds. The new carinata lines were bred by Agriculture and Agri-Food Canada (AAFC). The experiment of rumen and intestinal digestion was carried out in U of S dairy research facility. Four cannulated lactating dairy cows were used for rumen degradation trial. The nutrient supply to dairy cattle and feed milk value (FMV) were determined based on the DVE/OEB system with data from rumen and intestinal digestion experiments. Statistical analyses were performed using PROC MIXED procedure of SAS 9.3 with significance declared at $P < 0.05$. The results showed that yellow carinata seed line had higher ($P < 0.05$) rumen undegraded feed crude protein (RUP) and effective degradability of crude protein (EDCP) compared with canola seeds. From in vitro intestinal digestion results, carinata seeds had higher total digestible protein (TDP) than canola seeds ($P < 0.05$). Based on the DVE/OEB system, carinata seeds had higher truly absorbed rumen-synthesized microbial protein, total truly digested protein (DVE) in small intestine and feed milk value (FMV) than canola seeds ($P < 0.05$). Yellow carinata seed line had higher protein supply than the brown seed line. In conclusion, the new lines of carinata seeds could be regarded as a potential feed protein supplement for dairy cows, and yellow carinata seed line had greater protein digestibility than brown carinata seeds.

Key Words: carinata seed, metabolic characteristics of protein, DVE/OEB system

M140 Responses of neonatal goats (kids) to different concentrations of carbon dioxide gas.

Isabelle C. Withrock*, Paul J. Plummer, Timothy A. Shepherd, Anna Johnson, Hongwei Xin, Johann F. Coetzee, and Suzanne T. Millman, *Iowa State University, Ames, IA.*

The dairy goat industry faces challenges for kid euthanasia. The methods approved by the AVMA are barbiturate overdose, gunshot, and captive bolt. The disadvantages of these methods range from cost to operator safety. Currently, there is no published research on inhalant euthanasia methods for neonatal ruminants. The objective of this study was to evaluate carbon dioxide (CO_2) for kid euthanasia. A preference testing device was custom made to hold 2 connected chambers at static atmospheric concentrations. One chamber maintained ambient conditions, and the other designated CO_2 levels (treatment). A total of 7 mixed-breed dairy kids were enrolled in the study. Six males and 1 female were enrolled, and body weights ranged from 3.18 to 4.17 kg. Kids were individually trained for 5 consecutive days to enter the treatment chamber from the ambient chamber to access a milk ration (32oz). During training both chambers were set at ambient air concentrations. Kids were held in the ambient chamber for 5 min, after which the sliding door was opened to provide access to the treatment chamber. Kids were provided 10 min access to the treatment chamber after which they were removed and returned to their home pen. After training, testing began with the treatment chamber set at one of 3 CO_2 levels: 10%, 20% or 25%, while the ambient chamber was maintained at 1% CO_2. Kids were randomly assigned 10% or 20% as the first treatment and received 25% CO_2 last. Kids experienced all 3 CO_2 treatments, with a 2-d wash-out (ambient CO_2) between tests. Outcomes were collected using continuous sampling, and included latency to enter and exit treatment chamber to measure aversion, loss of muscle control (ataxia), and loss of posture. Five kids (71%) tolerated 10% CO_2 for 10 min. One kid left at 8.5 min after consuming his full ration. One kid lost posture at 289 s. At 20 and 25% $CO_{2,}$ a total of 100% of the kids became ataxic, and posture loss ranged from 93 to 215 s. All kids continued to consume milk before and during ataxia and reentered the treatment chamber on wash out days. In conclusion, kids did not display aversion to CO_2 and therefore, CO_2 has merit for goat euthanasia.

Key Words: carbon dioxide, euthanasia, goat

M141 Analyzing udder efficiency of Brown Swiss cattle using data envelopment analysis.

Keith D. Gibson* and Chad D. Dechow, *The Pennsylvania State University, State College, PA.*

Udder conformation traits such as udder depth are favorably associated with somatic cell score (SCS) and mastitis resistance, but unfavorably associated with yield, resulting in unclear selection aims. Data envelopment analysis (DEA) is an approach to characterize the efficiency of different units based on inputs and outputs. The objective of this research was to use DEA to create an efficiency trait for udders of Brown Swiss cattle, which we termed udder efficiency, and to evaluate the genetic relationship of udder efficiency with yield, fitness, and udder conformation. The lone input was identified as milking speed and the outputs were milk, fat, and protein yield, and the inverse of SCS. A SAS DEA macro was used to determine udder efficiency relative to herdmates, with the most desirable cows milking quickly, producing large volumes of milk, fat, and protein with a low SCS. Values for the trait ranged from 0.03 (very inefficient cows) to 1.0 (efficient cows). There were 105,164 first through fifth lactation yield and SCS records from 45,464 cows born in 2000 or later. There were 41,704 milking speed records with a high score corresponding to faster milking speed. From these, 40,960 udder efficiency records were derived. These data were analyzed using a series of 3 trait models in ASREML that included fixed effects for lactation, age, and herd-calving cluster. Random effects were animal, permanent environment, and residual. The heritability of udder efficiency was 0.23 ± 0.0133. Genetic correlations with udder efficiency were moderate and positive for yield (0.40 to 0.42), favorable with SCS (−0.21), and strongly positive for milking speed (0.86). Udder efficiency was also strongly correlated with productive life (0.69). Of the udder traits, rear udder height (0.30), teat length (−0.28), fore udder attachment (0.25), and rear udder attachment (0.21) were most favorably correlated to udder efficiency. The correlation of udder depth with udder efficiency was 0.16. Based on these findings, DEA could be a useful and novel method for evaluating udder efficiency, helping to identify traits that enable selection for mastitis resistance without compromising yield.

Key Words: Brown Swiss, udder efficiency, data envelopment analysis

Lactation Biology I

M142 Distribution and analysis of milk fat globule and crescent in Murrah buffalo and crossbred cow. Ratan K. Choudhary*, Harmanjot Kaur, Shanti Choudhary, and Ramneek Verma, *School of Animal Biotechnology, Guru Angad Dev Veterinary and Animal Science University, Ludhiana, Punjab, India.*

India is the largest buffalo milk producer in the world. Buffalo milk is rich in minerals like calcium and magnesium, contains 100% more fat and less cholesterol than cow milk. Physiochemical properties of dairy products depend upon the size and distribution of milk fat globules (MFG). Individual MFG from Murrah buffalo were analyzed as a function of size and distribution and comparisons were made with MFG of crossbred (Holstein Friesian × Sahiwal) cows. Main objectives of this study was to measure areas of buffalo MFG and analyze percentage of crescents associated with MFG using a simple microscopic technique. Crescents of MFG can provide an alternative source of RNA of mammary epithelial cells origin. Acridine orange staining of fresh milk was visualized by light microscopy under red and green channel filters. MFG and MFG with crescents were analyzed using ImageJ image analysis software. The percentage of large sized MFG (area >20 μm^2) was greater and the percentage of small sized MFG (area <10 μm^2) was lower in buffalo than cow milk. The percentage of crescents was < 1% of total MFG in both the species. These results indicate that MFG in buffalo milk is larger than that MFG of cow milk. RNA isolation from buffalo milk fat and its suitability for microarray analysis remains to be determined.

Key Words: buffalo, milk fat globule, crescent

M143 Fatty acid synthase (FASN) gene polymorphism and early lactation milk fat composition in Xinong Saanen goats. Abiel b Haile*, Zhang Wei, Wang Wei, Yang Dikun, Yi Yongqing, and Luo Jun, *Northwest A&F University, Yangling, Shaanxi, China.*

The fatty acid synthase (*FASN*) gene codes for a multifunctional protein, catalyzing the de novo fatty acid synthesis. Its high mRNA expression in GMEC (goat mammary epithelial cells), coinciding with medium to high heritability of milk fat, substantiated its role as a candidate gene for association analysis with milk fat profile. The main objectives of the study were to develop markers of *Capra hircus* FASN gene to improve healthfulness of goat milk FAs (fatty acids) and to investigate early lactation milk fat profile. A Linear mixed model association analysis of 46 dependent variables, analyzed from 300 milk samples 30 d postpartum, with 3 intragenic SNPs and 2 haplotype groups was conducted. The results had revealed associations of FASN SNPs and haplotype groups with myristic acid (C14:0), palmitic acid (C16:0) and linoleic acid (C18:2 n-6, cis). Herd was the predominant factor affecting fatty acid levels followed by herd-test-day (HTD) and parity, indicating the niche of nutrition and management in modulating early lactation milk fat profile. De novo FAs (C6:0 to C14:0) showed suppressed levels with strong negative correlations with C18 FAs. Contradicting to the presumed source of origin, butyric acid (C4:0) was impervious to the observed de novo FA depression, it had shown unique correlation patterns. Oleic acid (C18:1 *cis*-9) scored the highest mean value followed by palmitic acid. Palmitic acid had shown normal levels with weak negative correlations with C6:0 and C8:0. Here, its dual source of origin supposedly had played a role, in replenishing the diminished levels of de novo contribution, by the high C16 FAs bioavailability of body fat mobilization, which masked the inhibitory effect of long chain FAs. The correlation patterns of odd chain FAs with CLA and rumen derived biohydrogenation intermediates reinforce the supposition that odd chain fatty acids could serve as a diagnostic tool of rumen condition and biohydrogenation patterns. The SNP markers developed in the present study will assist in marker assisted selection, and the comprehensive analysis of early lactation milk fat profile will help to decipher main factors of variation, thereby aiding fatty acid profile modulation.

Key Words: dairy goat, SNP marker, milk fat

M144 Pattern of immunoglobulin A in milk from gorillas throughout lactation. M. Garcia*[1], M. L. Power[2], and K. M. Moyes[1], [1]*Department of Animal and Avian Sciences, University of Maryland, College Park, MD,* [2]*Smithsonian Conservation Biology Institute, Washington, DC.*

In cases when mother's milk is not available to a great ape infant (e.g., rejection), zoo nutritionists/veterinarians are responsible for formulating a milk replacer to maximize the chances of survival of the neonate. To accomplish this, they generally use milk from commercially available species (e.g., cow and goat) as well as nutritional supplements and other additives. As is the case in humans, placental transfer of immunoglobulin (Ig)A occurs throughout pregnancy in the gorilla. After birth, neonates rely solely on nutrients and Igs via the mother's milk until approximately 5 mo of age and are weaned at 3 to 4 years of age. Unfortunately, there is currently no useful information regarding the IgA profile of milk and how stage of lactation alters IgA concentration in gorilla milk. The objective of this study was to identify the pattern of IgA concentrations in milk from gorillas throughout lactation. Milk samples from 4 gorillas were collected between January 2009 and October 2014 and stored at −80°C until further analysis. Concentrations of IgA in milk were measured using a Human IgA ELISA kit. Data were grouped according to month in milk (MIM; $0 < \text{MIM} = 5$, $5 < \text{MIM} = 10$, $10 < \text{MIM} = 15$, $15 < \text{MIM} = 36$, and MIM >36). The data were analyzed as a complete randomized design with gorilla nested within MIM as a random term and MIM as a fixed effect. Month in milk had a significant ($P < 0.01$) affect IgA concentrations. Concentrations of IgA were highest for MIM >36 (81.3 μg/mL) followed by $0 < \text{MIM} = 5$ (53.9 μg/mL). The increase in concentrations of IgA in later lactation may reflect reductions in milk production and this warrants further investigation. Results from this study provided a better understanding of the IgA profile of milk from gorillas. Additional knowledge regarding fluctuations of other immunoglobulins as well as nutritional profiles in gorilla milk will assist professionals charged with their care in captivity to develop improved hand-rearing protocols.

Key Words: gorilla, immunoglobulin A, milk

M145 Peroxisome proliferator-activated receptor gamma (PPARγ) agonist does not stimulate mammary lipogenic gene expression or overcome the effect of *trans*-10,*cis*-12 conjugated linoleic acid (CLA) in lactating ewes. Eveline C. Sandri[1], Elvis Ticiani[1], Monica Urio[1], Maurício Camera[1], Ana P. Povaluk[1], Kevin J. Harvatine[2], and Dimas E. Oliveira*[1], [1]*Santa Catarina State University/CAV, Lages, Santa Catarina, Brazil,* [2]*Penn State University, State College, PA.*

Milk fat synthesis involves biochemical processes, including fatty acid synthesis, uptake, transport and desaturation. *Trans*-10,*cis*-12 CLA inhibits milk fat synthesis by decreasing the expression of genes and transcription factors. Peroxisome proliferator-activated receptor gamma (PPARγ) is a key regulator of lipid synthesis in many tissues and is affected by *trans*-10,*cis*-12 CLA but, the mechanisms by which *trans*-10,*cis*-12 CLA suppresses the expression or activity of PPARγ and expression of its targeted genes are not clear. This study used a chemical PPARγ agonist to evaluate the effect of PPARγ on mammary lipid synthesis and its interaction with *trans*-10,*cis*-12 CLA in lactating ewes. Twenty-four crossbred lactating ewes [70 ± 3 DIM; 60 ± 0.45 kg body weight (BW)] were randomly assigned to one of the 4 treatments (n = 6/treatment) for 7 d. Treatments were (1) Control (intravenous infusion of 100 mL/d of saline); (2) TZD (intravenous infusion of 4 mg/kg of BW per d in 100 mL of saline); (3) CLA (27 g/d orally dosed methyl ester containing 29.9% *trans*-10,*cis*-12 CLA); and (4) TZD+CLA. Mammary and adipose tissue biopsies were taken, RNA was extracted, cDNA synthesized and qRT-PCR analysis conducted for PPARγ, SREBP1 and SCD1. Compared with control, fat content was 22.3% lower in CLA ($P = 0.05$), tended to be 20.7% lower in TZD+CLA ($P = 0.06$). In the mammary gland, CLA decreased expression of PPARγ, SREBP1 and SCD1 by 64.4, 60 and 19% compared with control ($P = 0.02$, $P = 0.01$ and $P = 0.005$, respectively), confirming its negative effects on the expression of lipogenic genes. However, TZD did not stimulate the expression of these genes or overcome the effect of CLA in mammary tissue. In adipose tissue, expression of PPARγ were not affected by treatment, whereas SREBP1 expression was increased by TZD, CLA and TZD+CLA compared with control and SCD1 expression was higher in TZD+CLA compared with the other treatments. Overall, CLA negatively affected mammary expression of genes involved in lipid synthesis and TZD was unable to overcome those effects demonstrating that the mechanism of CLA is not dependent on inhibition of PPARγ

Key Words: lipogenesis, milk fat depression, milk synthesis

M146 Effect of *trans*-10,cis-12 CLA on the expression of genes involved in milk fat synthesis in ovine mammary gland tissue cultured in vitro.

Monica Urio, Ana P. Povaluk, Humberto T. Borges, June A. Favaretto, Maurício Camera, and Dimas E. Oliveira*, *Santa Catarina State University/CAV, Lages, Santa Catarina, Brazil.*

Culturing lactating mammary explants allows evaluating the effect of bioactive molecules in a controlled environment while maintaining the same characteristics found in vivo (Keys et al., 1997; In Vitro Cell. Dev. Biol. Animal, 33:206–21). However, studies using ovine mammary tissue are still scarce. The objective of this study was to evaluate the effect of *trans*-10,*cis*-12 CLA on the expression of key genes involved in milk fat synthesis in mammary explants cultured in vitro. Mammary samples were obtained through biopsies in lactating ewes (120 DIM) and were grown on plates with growth area of 1.9 cm^2 in mammary epithelial cell growth media supplemented with fetal bovine serum, antibiotics, insulin and growth factors at 37°C with 5% CO_2 and humidity saturated. Tissues were cultured for 3 and 24h in triplicates using the following treatments: 75 µmol/L of *trans*-10,*cis*-12 CLA or Control (no CLA). After cultures were stopped RNA was extracted, cDNA synthesized and qRTPCR performed. The genes studied were SREBP1 (sterol regulatory element-binding protein), PPARγ (peroxisome proliferator-activated receptor gamma) and SCD1 (stearoyl-CoA desaturase). Statistical analysis was performed using the MIXED procedure of SAS (2002) and ribosomal protein S18 housekeeping gene was used as a covariate in the model. CLA treatment had no effect on gene expression of SREBP1, PPARγ, and SCD1 at 3 h ($P = 0.19$, $P = 0.52$ and $P = 0.20$, respectively). At 24 h, there was a trend for CLA-treated explants to have reduced gene expression of SREBP1 and PPARγ ($P = 0.07$ and $P = 0.08$, respectively), and a 12-fold decrease in SCD1 gene expression ($P = 0.009$). Overall, our results suggest that *trans*-10,*cis*-12 CLA downregulates expression lipogenic genes in ovine mammary tissue, however explants may need to be cultured for at least 24 h

Key Words: dairy ewe, gene expression, milk fat depression

M147 Gene expression of transcription factors and genes involved in milk fat depression in lactating ewes of different body weights fed the same dose of CLA *trans*-10,*cis*-12.

Monica Urio, Eveline C. Sandri, Ana P. Povaluk, Elvis Ticiani, Camila Renneberg, Maurício Camera, June A. Favaretto, and Dimas E. Oliveira*, *Santa Catarina State University/CAV, Lages, Santa Catarina, Brazil.*

During milk fat depression (MFD) induced by the feeding of *trans*-10,*cis*-12 CLA the magnitude in the reduction of milk fat content and/or yield varies considerably among animals. The objective this study was to evaluate the gene expression of transcription factors and genes downregulated during MFD in lactating ewes fed a uniform dose of *trans*-10,*cis*-12 CLA but differing in body weight. Fourteen lactating ewes were selected according to BW and separated in 2 groups that averaged 51.0 ± 1.0 and 69.0 ± 4.0 kg of BW. Ewes received for 10 d a daily oral dose of 27g/d of CLA (rumen-unprotected, 29.9% *trans*-10,*cis*-12 isomer). Mammary and adipose tissue biopsies were performed on d 10. RNA was extracted, cDNA synthesized and qt-RTPCR carried out. Data were analyzed using the MIXED procedure of SAS (2002) and ribosomal protein S18 housekeeping gene was used as a covariate. Gene expression of SREBP1 (sterol regulatory element binding protein), S14 (thyroid hormone responsive) and SCD1 (stearoyl-CoA desaturase) were evaluated in mammary tissue samples and leptin in adipose tissue. Gene expression of SREBP1, S14 and SCD1 did not differ between the BW groups ($P = 0.29$, $P = 0.17$ and $P = 0.57$, respectively). Leptin gene expression was higher in the heavier BW group ($P = 0.02$). Overall, our results suggest that animals of different body weights receiving a uniform dose of *trans*-10,*cis*-12 CLA showed change in gene expression of leptin.

Key Words: fat synthesis, mammary biopsy, ovine

M148 Expression of acetyl-CoA carboxylase alpha (ACCα) transcripts from different promoters in mammary and adipose tissue from lactating ewes at different stages of lactation.

Grégory J. Cardoso[1], Elvis Ticiani[1], Monica Urio[1], Ana P. Povaluk[1], Maurício Camera[1], Rogério Ferreira[2], Kevin J. Harvatine[3], and Dimas E. Oliveira*[1], [1]*Santa Catarina State University/CAV, Lages, Santa Catarina, Brazil,* [2]*Santa Catarina State University/CEO, Chapecó, Santa Catarina, Brazil,* [3]*Penn State University, State College, PA.*

Initiation and maintenance of lactation are complex phenomena involving cellular and enzymatic changes including those in mammary gland and adipose tissue. Fat is the main energy component of the milk, originating from the diet, mobilization from adipocytes, and from de novo synthesis in the mammary gland. Milk fat synthesis is controlled in various ways and one example is via regulation of acetyl-CoA carboxylase α (ACCα), a key enzyme in the de novo fatty acid synthesis pathway. ACCα is encoded by mRNAs transcribed from 3 promoters (PI, PII and PIII) characterized as tissue-specific in the ovine genome. PI transcripts are restricted to the adipose tissue and liver, whereas PII is found in all tissues and PIII has been isolated from mammary tissue from lactating ewes. This study evaluated the transcription of ACCα from PI, PII and PIII in mammary and adipose tissue from dairy ewes at different stages of lactation. Mammary gland and adipose tissue biopsies were taken from 6 lactating ewes at 3 periods (15, 70 and 120 d in milk) to represent early, mid and late lactation. Subsequently RNA was extracted, cDNA synthesized and qRT-PCR analysis conducted. Data were analyzed by SAS using ribosomal protein S18 housekeeping gene as a covariate. As expected, no expression of PI was detected in the mammary gland. Transcripts from PII in mammary gland were higher in early lactation and decreased as lactation advanced (early vs. mid $P = 0.02$; early vs. late $P = 0.002$; mid vs. late $P = 0.23$). Similarly, the PIII transcripts decreased throughout lactation in mammary gland (early vs. mid $P = 0.001$; early vs. late $P = 0.001$; mid vs. late $P = 0.005$). On the contrary, in adipose tissue the PI gene expression was higher in mid and late lactation ($P = 0.001$), and transcripts from PII and PIII did not differ among periods. Results suggest that PII transcripts in mammary glands are upregulated in early and mid lactation according to a higher requirement for fat synthesis and PI transcripts have a greater expression level in adipose tissue in late lactation likely due to a positive energy balance replenishing body fat reserves.

Key Words: adipose tissue, gene expression, mammary gland

M149 Effects of sodium salicylate on early lactation milk production parameters.

Caroline M. Ylioja*, Abigail J. Carpenter, Laman K. Mamedova, and Barry J. Bradford, *Department of Animal Sciences and Industry, Kansas State University, Manhattan, KS.*

Treatment with non-steroidal anti-inflammatory drugs (NSAID) after calving can have a positive effect on whole-lactation milk production in older dairy cows. Ongoing research aims to determine whether this response is due to increased mammary epithelial cell function and whether this is also tied to changes to inflammation in early lactation. For this study, cows in 3rd or greater lactation (n = 8/treatment) were enrolled at parturition to receive a daily drench of sodium salicylate (SS; 125g/d) or water (CON) for 3 d beginning approximately 24 h postpartum. Mammary biopsies were conducted on d 1, 4, and 45 after calving. Daily milk weights were recorded and milk composition was determined 2×/week. Blood samples were taken 2×/wk and analyzed for metabolites. Results up to 45 DIM show no difference between treatments for plasma glucose, insulin, β-hydroxybutyrate, or nonesterified fatty acid levels. Weekly means of milk production parameters revealed no detectable differences for fat content or yield, milk urea nitrogen, somatic cell score, energy-corrected milk yield, or fat-corrected milk yield. Treatment interacted with week for average protein yield ($P = 0.02$), with SS cows increasing more (1.07 to 1.49 ± 0.09 kg/d) over the 7 weeks of the study than CON (1.19 to 1.37 ± 0.09 kg/d). Lactose content tended to be greater for SS (4.89%) compared with CON (4.74 ± 0.05%; $P = 0.06$). Milk yield tended to increase more for SS (from 26.6 to 55.8 ± 2.6 kg/d) than CON (from 30.7 to 52.3 ± 2.3 kg/d) over time (interaction $P = 0.10$). Results agree with previous studies where milk production increased for salicylate-treated cows, although the small sample size in the present study limited power to observe production responses, and production data included only the first 45 d of lactation. Ongoing analysis of morphological and transcriptional changes in mammary tissue may reveal mechanisms that contribute to a sustained increase in milk production following early-lactation NSAID administration.

Key Words: NSAID, inflammation, mammary function

M150 Effect of Leu and His on casein protein synthesis via mTOR signaling pathway in bovine mammary epithelial cells.

Haina Gao[1,2], Han Hu[1,3], Nan Zheng[1,3], and Jiaqi Wang*[1,3], *[1]Ministry of Agriculture-Milk Risk Assessment Laboratory, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China, [2]College of Animal Science and Technology, Gansu Agricultural University, Lanzhou, Gansu, China, [3]State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

Assessing the regulatory effect of individual amino acids (AA) on milk protein synthesis is vital to AA requirement models for lactation. This study employed the immortalized bovine mammary epithelial cells (CMEC-H) as a model to investigate the effects of Leu or His on mTOR signaling and casein synthesis by Western blotting. Cells were cultured in the Earle's balanced salts (EBSS) with Leu (0.45, 1.35, 5.4, 10.8 mmol/L) or His (0.15, 1.2, 4.8, 9.6 mmol/L) addition for 6h, respectively, and the EBSS without AA was set as negative control, the EBSS supplemented with 10% FBS was used as positive control. The protein band values from the AA-supplemented cells were related to their AA-deprived controls. The experimental data were analyzed using the Duncan's test for post-hoc multiple comparisons of treatment means by SAS. Meaningful relationships among phosphorylation of the signaling proteins and casein expression were quantified with simple linear regression models using the REG procedure of SAS. Differences between experimental groups were considered significant at a $P < 0.05$. The results showed that, compared with the negative control, Leu or His significantly increased the phosphorylation of mammalian target of rapamycin (mTOR, Ser2481), a binding partner of target of rapamycin (raptor, Ser792), the ribosomal protein S6 kinase 1 (S6k1, Thr389), eukaryotic initiation factor 4E (eIF4E, Ser209), eukaryotic elongation factor 2 (eEF2, Thr56) and casein synthesis ($P < 0.05$). These results suggest that the supplement of Leu or His could activate the mTOR pathway and in turn catalyze the phosphorylation of signaling protein and increase milk protein synthesis. Our linear regression model assay declared that the expression of αs1-casein was positively correlated with P-mTOR ($R^2 = 0.7820$, $P < 0.01$), P-S6k1, ($R^2 = 0.7881$, $P < 0.01$) and eEF2 ($R^2 = 0.7835$, $P < 0.01$) with a dose-dependent effect of Leu. While the expression of β-casein ($R^2 = 0.9638$, $P < 0.01$) and κ-casein ($R^2 = 0.9048$, $P < 0.01$) were positively correlated with P-eEF2 with a dose-dependent effect of His. In conclusion, our results can provide certain basic information for the further study of the regulation mechanism of Leu or His on casein expression via mTOR pathway in CMEC-H.

Key Words: leucine, histidine, mammalian target of rapamycin (mTOR)

M151 MicroRNA miR-200b regulates lactation and cell proliferation by concurrently targeting *Dnmt3a* and *Dnmt3b* in bovine mammary epithelial cells.

Yanjie Bian, Chunmei Wang, Na Zhang*, Yingjun Cui, and Qingzhang Li, *Key Laboratory of Dairy Science, Ministry of Education, Northeast Agricultural University, Harbin, P.R. China.*

With the rapid development of dairy industry and improvement of human living standards, the consumption market of dairy products constantly expanding. How to increase the milk yield and optimize milk quality has become the focus of dairy industry. Although numerous microRNA (miRNA) have been verified to play critical roles in the regulation of milk protein synthesis and mammary gland development in cows, but the mechanisms underlying their effects remain unknown. Here, 6 healthy, multiparous Chinese Holstein cows with similar genetic backgrounds were divided into 2 groups according to milk quality (n = 3 per group), statistical analyses were conducted using Student's test, and $P < 0.05$ was considered statistically significant. We found that the expression of miR-200b was significantly different between high-milk-quality cows and low-milk-quality ones by using small RNA sequencing and qRT-PCR techniques. Increasing evidences suggested that epigenetic mechanism was involved in the regulation of mammary function in the dairy cow. In recent studies, DNA methylation, as the major epigenetic regulators, has been shown to regulate the expressions of milk proteins in mammary epithelial cells. In vitro, subcultured bovine mammary epithelial cells (BMEC) were cultured in an incubator at 37°C in the presence of 5% CO_2 and were maintained in DMEM/DF-12 with 10% FBS. Our results showed that miR-200b regulated the DNA methylation level of BMECs by inversely targeting both DNMT3A and DNMT3B. We also found that the overexpression of miR-200b promoted BMECs proliferation and significantly decreased the expression of α_{S1}-casein and β-casein. The treatment of BMECs with 5-aza-2′-deoxycytidine (5-Aza-dC) increased the expression of α_{S1}-casein and β-casein. This study provided new insight into the molecular mechanisms of miR-200b in regulating lactation performance through DNA methylation, and provided a potential to optimize milk quality not only of the cows but also of their next generations.

Key Words: miR-200b, DNA methylation, bovine mammary epithelial cells (BMEC)

M152 MicroRNAs miR-181a and miR-194 can regulate the biosynthesis of milk fat and protein by targeting ACSL1 and STAT5a.

S. Lian[1,2], X. M. Nan[2,3], D. P. Bu*[2,4], F. Wang[2], and J. R. Guo[1], [1]*College of Animal Science and Veterinary Medicine, Heilongjiang Bayi Agricultural University, Daqing, Heilongjiang, China,* [2]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [3]*Synergetic Innovation Center of Food Safety and Nutrition, Harbin, China,* [4]*CAAS-ICRAF Joint Lab on Agroforestry and Sustainable Animal Husbandry, Beijing, China.*

MicroRNAs (miRNA) are a class of small noncoding RNAs and act as important post-transcriptional regulators of gene expression. *ACSL1* is an important gene in milk lipid synthesis and *STAT5a* is one of the key genes in milk protein synthesis. In a previous study dealing with incubation of stearic acid in bovine mammary epithelial cells, an opposite expression pattern was observed between *ACSL1* and miR-181a, *STAT5a* and miR-194. *ACSL1* and *STAT5a* were also predicted as potential target genes of miR-181a and miR-194 respectively by TargetScan and PicTar, which are the most popular target gene prediction softwares. The objective of this work was to determine the potential function of miR-181a and miR-194 on milk fat and protein synthesis by defining the regulatory relationship between miR-181a and *ACSL1*, miR-194 and *STAT5A*. In the study, primary bovine mammary epithelial cells harvested from mid-lactation cows were cultured in DMEM/F12 medium added with 10% FBS and lactational hormones. Cells were transfected with miR-181a mimic, miR-181a inhibitor, miR-194 mimic and miR-194 inhibitor, and non-transfected cells were set as control. After an 48 h treatment, expression of miR-181a, miR-194, *ACSL1*, *STAT5a* were determined by real-time reverse-transcription PCR. The results showed that the overexpression of miR-181a and miR-194 inhibited the expression of *ACSL1* and *STAT5a* respectively ($P < 0.05$), while the downregulation of the 2 miRNAs increased *ACSL1* and *STAT5a* expression ($P < 0.05$). Therefore suggesting that miR-181a and miR-194 may play important roles in milk fat and protein synthesis.

Key Words: miR-181a, miR-194, bovine mammary epithelial cells

M153 Establishment of a mammary epithelial cell line from a Chinese Holstein dairy cow and effects of different concentrations of insulin-like growth factor-I on expression of genes related to milk synthesis.

T. Qin[1], H. Y. Wang[1], D. P. Bu[2], and H. B. Zhu*[1], [1]*Embryo Biotechnology and Reproduction Laboratory, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China,* [2]*State Key Laboratory of Animal Nutrition, Institute of Animal Science, Chinese Academy of Agricultural Sciences, Beijing, China.*

This experiment was conducted to establish an efficient culture method for bovine mammary epithelial cells (bMEC) in vitro,a nd to research the effect of different concentrations (0, 0.1, 10 and 100ng/mL) insulin-like growth factor-I (IGF-1) on the mRNA expression of genes related to milk protein and fat synthesis in bMEC. Bovine mammary epithelial cells were cultured by tissue mass culture method, and cells were purified according to different sensitivity to trypsin of fibroblasts and bovine mammary epithelial cells. The growth curve of purified cells was detected by cell counting assay method. The expression of keratin 18 was detected by immunofluorescent histochemistry staining method. mRNA expression of 8 genes were measured by real time quantified PCR(RT-qPCR).The results showed that mRNA abundance of insulin-like growth factor-I receptor (*IGFIR*), insulin-like binding protein 3 (*IGFBP3*), α_{S1}-casein (*CSN1S1*) and k-casein (*CSN3*) did not differ ($P > 0.05$) within different concentrations of IGF-1. However, within the increasing concentrations of IGF-1, the mRNA abundance of β-casein (*CSN2*), acetyl-CoA carboxylase (*ACACA*), fatty acid synthase (*FASN*) and fatty acid binding protein 3 (*FABP3*) increased significantly ($P < 0.05$). These results indicated that IGF-1, as an important cytokine, might involve in regulating the mRNA expression of genes related to milk protein and fat synthesis in bovine mammary epithelial cells in vitro.

Key Words: insulin-like growth factor-I, bovine mammary epithelial cells, gene expression.

M154 Influence of heat stress and amino acid supplementation on microRNA expression in bovine mammary epithelial cells.

M. Duque*[1], A. A. K. Salama[2], and J. J. Loor[3], [1]*Grupo de Investigación Biogénesis and GRICA, Facultad de Ciencias Agrarias, Universidad de Antioquia, Medellín, Colombia,* [2]*Grup de Recerca en Remugants (G2R), Departament de Ciència Animal i dels Aliments, Universitat Autónoma de Barcelona, Bellaterra, Spain,* [3]*Department of Animal Sciences, University of Illinois, Urbana, IL.*

Heat stress and essential amino acid profiles are important factors that can affect milk fat and protein synthesis in the mammary gland of dairy cows. MicroRNAs (miRNA) are non-coding RNAs that play a critical role in post-transcriptional regulation of bovine mammary gene expression. Regulatory microRNAs affect a wide variety of cellular processes such as cellular differentiation, proliferation, apoptosis, genome stability and milk protein and fat synthesis pathways. Although miRNA expression profiling in various bovine tissues or cells have been performed, studies to elucidate the potential role of miRNAs under stress conditions are limited or nonexistent. The objective of this study was to determine using MACT cells the effects of heat stress and amino acid (AA) supplementation on microRNA expression. A thermo neutral (TN, 37°C) and heat stress (HS, 42°C) environment with one of 3 AA supplementation groups were studied: control (Con), control + methionine (Met) and control + arginine (Arg). A total of 6 treatments were evaluated: TN-Con, TN-Met, TN-Arg, HS-Con, HS-Met and HS-Arg. After 6 h of incubation cells were harvested, and miRNAs were extracted for quantitative RT-PCR analysis. Targets included miR-141, miR-221, miR-34a, miR-200a, miR-27a/b, miR-92a, miR-99a, miR-23a, miR-26a, miR-103, and miR-184. Both HS and AA increased ($P < 0.05$) the expression of miR-141 and miR-221, which were reported to decrease STAT5 protein expression and induce angiogenesis. An upregulation ($P < 0.05$) of miR-34a, miR-200a, miR-27a/b, miR-92a, miR-99a, and miR-184 was observed in the HS group, but not with AA supplementation. These miRNAs are reported to be involved in the regulation of heat-shock proteins, milk fat synthesis, prolactin receptor expression, cell cycle regulation, and mTOR and insulin signaling. Both miR-23a (MAPK pathway) and miR-26a (cell proliferation) were not affected ($P > 0.05$) by temperature, but Met and/or Arg decreased ($P < 0.05$) their expression. The sole miRNA unaffected by temperature or AA was miR-103. The results suggest that AA supplementation and HS can alter miRNA expression and, as such, could serve as another regulatory factor of genes that play important functions in the mammary gland.

Key Words: bovine mammary cells, miRNA, amino acid

M155 Characterization of prolactin and adrenergic and serotonergic receptors in bovine apocrine sweat glands.

Courtney A. Burger, Jayne L. Collier, and Robert J. Collier*, *University of Arizona, Tucson, AZ.*

Apocrine sweat glands are involved in thermoregulation via evaporative heat loss in the bovine and are most active at temperatures above thermoneutral. We have previously shown that serotonin (5-HT) receptors 5-HT 1b, 2b, 4, and 7 are found in whole skin, apocrine sweat glands, and epithelial cells, while 5-HT 2a is present in whole skin and epithelial cells. It has been shown that prolactin (PRL) plays a role in lactational homeostasis, because mammary glands are modified apocrine sweat glands, we hypothesized that PRL receptors would be present in sweat glands. Additionally, we looked at adrenergic (ADR) receptors, as epinephrine is known to influence sweating response. The present study was conducted to determine if the 5-HT, PRL, and ADR systems are involved in thermoregulation by examining the cDNA expression of receptors through conventional PCR in bovine whole skin, apocrine sweat glands, and epithelial cells. For the 5-HT system, brain was used as control and additional isoforms classified were 5-HT 1a, 1d, 1f, 5a, and 6. We identified isoforms 5-HT 1d, 1f, and 5a in whole skin, apocrine sweat glands, and epithelial cells, whereas 5-HT 1a is present in whole skin and epithelial cells, and 5-HT6 is present in whole skin and apocrine sweat glands. For the PRL system, bovine mammary epithelial cells (BMEC) were the control and 2 isoforms were identified: PRL receptor long (PRLr-L) and PRL receptor short (PRLr-S) which differ in their intracellular domain length and sequence. We found PRLr-S in whole skin, apocrine sweat glands, and epithelial cells, while PRLr-L is in whole skin only. For ADR receptors, BMEC and liver were used as control, and we found α1 ADR 1a, α2 ADR, β1 ADR, and β2 ADR receptors in whole skin, apocrine sweat glands, and epithelial cells. α1 ADR 1b was only present in BMEC and liver, while α1 ADR 1d was only in BMECs. The presence of these receptors in the apocrine glands and epithelial cells indicates that the 5-HT, PRL, and ADR systems are involved in regulation of apocrine sweat gland function.

Key Words: apocrine, bovine, serotonin

M156 RNA-sequencing analysis of milk somatic cells in heat-stressed dairy goats.

A. A. K. Salama*[1], B. Badaoui[2], S. Hamzaoui[1], and G. Caja[1], *[1]Grup de Recerca en Remugants (G2R), Departament de Ciència Animal i dels Aliments, Universitat Autónoma de Barcelona, Bellaterra, Spain, [2]Integrative Biology Group, Parco Tecnologico Padano - CERSA, Lodi, Italy.*

Milk transcriptome characterization could help in understanding how milk synthesis and mammary cell turnover are affected by heat stress. Eight multiparous Murciano-Granadina dairy goats (44.1 ± 1.7 kg BW; 2 ± 0.04 L/d; 90 ± 3 DIM) were kept in metabolic cages and randomly assigned to 2 climatic treatments according to a crossover design (2 28-d periods). Treatments were:1) thermal neutral (TN; 15 to 20°C, 40 to 45% humidity, THI = 59 to 65), and 2) heat stress (HS, 12 h/d at 37°C and 40%, and 12 h/d at 30°C and 40%, THI = 86 and 77, respectively). Milk samples were collected at d 28 of each period, somatic cells were separated, and RNA was extracted. The RNA of 4 goats for each treatment at each period was mixed, resulting in final 4 RNA samples (2 TN and 2 HS) that were analyzed by Illumina RNA-sequencing (RNA-Seq). The RNA –Seq reads were mapped to the bovine genome by "tophat" and the expression level was quantified by "cufflinks." The RNA-Seq produced a total of ~170 million reads with an average of 85 million reads for each treatment (range of reads for the 4 samples was 38 to 46 million). We detected 140,39 transcripts expressed in milk cells, 700 of them were differentially ($P < 0.01$) expressed between HS and TN. The HS reduced ($P < 0.01$) the expression of genes related to de novo fat synthesis (*ACACA* and *FASN*), fatty acid desaturation (*SCD*), milk fat globule formation (*BTN1A1*, *XDH*, and *GLYCAM1*), and protein and lactose synthesis (*CSN1S1*, *CSN1S2*, *CSN3*, and *LALBA*). The HS upregulated ($P < 0.01$) cathepsin genes (*CTSB*, *CTSD*, *CTSZ*, *CTSS*, *CTSC*, and *CTSL1*) as well as genes related to plasminogen pathway (*PLAU*, *PLAUR*) and ubiquitin-proteasome pathway (*FBXW2*, *UBAP1*, *RPS27A*). Furthermore, HS increased ($P < 0.05$) the expression of the pro-apoptotic tumor necrosis factor receptors superfamily (TNFRSF1A and TNFRSF1B). Seven miRNA (miR-23a, miR-24–2, miR-27a, miR-29c, miR-29d, miR-142, and miR-221) had a greater ($P < 0.01$) expression with HS. In conclusion, heat stress reduces the synthetic capacity of mammary cells and increases the expression of proteases in milk. This increase in proteases expression could negatively affect milk coagulation properties and cheese making using milk produced from heat-stressed goats.

Key Words: RNA-sequencing, heat stress, dairy goat

M157 Molecular background of differential expression of *THRSP* in bovine longissimus muscle. Lisa Schering*, Elke Albrecht, Yinuo Liu, Christa Kühn, Klaus Wimmers, and Steffen Maak, *FBN Dummerstorf, Dummerstorf, Germany.*

Increased expression of thyroid hormone responsive protein (THRSP) has been related to higher intramuscular fat (IMF) content in previous studies in cattle. Higher expression of the *THRSP* gene (1.7-fold, $P < 0.05$) could be confirmed in M. longissimus of bulls of a Charolais × Holstein F_2-cross with high IMF (6.8 ± 2.4%, n = 10) compared with those with low IMF (1.9 ± 0.5%, n = 10). The presented study aimed at elucidation of the background of the observed expression differences. First, we screened the *THRSP* locus including 700 bp located 5′ of the transcription start and 1,000 bp containing the 3′-untranslated region (UTR) for single nucleotide polymorphisms (SNPs) with potential effects on gene expression. Only 3 out of 23 previously annotated SNPs were polymorphic in our sample. One new SNP (c.*695T>C) was found in the 3′UTR. None of the SNPs was related to expression of THRSP. To account for the possibility that an elevated amount of THRSP mRNA is an effect of more adipocytes in muscle samples with high IMF, we analyzed adipocytes and myocytes separately. Cells of the respective types were isolated by laser capture microdissection from unstained sections of M. longissimus. Total RNA was extracted from both cell types and cDNA was reversely transcribed from mRNA. Besides THRSP, fatty acid binding proteins (FABP) 3 and 4 were determined as specific markers for muscle and fat cells, respectively. In 2 independent experiments, we found exclusive expression of FABP3 in myocytes and of FABP4 in adipocytes indicating purity of the cell type preparations. THRSP expression was observed in adipocytes but not in myocytes. Moreover, expression of THRSP was not different in subcutaneous fat between both groups of bulls (1.0-fold, $P = 0.93$) despite a high level of expression. Our results suggest that differences of *THRSP* mRNA abundance in muscle of cattle with differing IMF result from variable numbers of THRSP-expressing adipocytes in the samples rather than from different activity of the gene.

Key Words: cattle, THRSP, intramuscular fat

M158 Effects of feeding different sources of vegetable oils on meat quality traits of Nellore steers. Fabiane de Souza Costa*[1], Anderson Roberto Cabral[1], Marília Aparecida Izepi da Silva[1], Beatriz de Conti Fiorese[1], Danielle Leal Matarim[1], Saulo da Luz e Silva[1], and Angélica Simone Cravo Pereira[2], [1]*University of Sao Paulo/Faculty of Animal Science and Food Engineering, Pirassununga, Sao Paulo, Brazil,* [2]*University of Sao Paulo/School of Veterinary Medicine and Animal Science, Pirassununga, Sao Paulo, Brazil.*

The objective of this study was to examine the effect of feeding soybean, sunflower or linseed oils on beef quality traits of feedlot finished Nellore steers. Ninety-six steers were individually fed one of the following diets: CON = a control diet with 79% of concentrate and 21% of corn silage, without oil; SOY = diet with soybean oil; SUN = diet with sunflower oil; LIN = diet with linseed oil. Different oil sources were included at 3.5% of DM in substitution of corn at the same percentage. After 84 d of feeding steers were harvested and after 48 h of chilling 2 samples of *Longissimus* muscle (2.5 cm thick) were collected between 12th and 13th ribs, vacuum packed and aged for 0 and 14 d. Samples were analyzed for pH, color (L*, a*, b*), cooking loss (CL) and Warner-Bratzler shear force (WBSF). Data were analyzed using the MIXED procedure of SAS software as a randomized complete block (initial body weight) design, considering treatment, aging period, treatment × aging interaction as fixed effects, and block as a random effect. There was no treatment × aging period interaction for any trait. Treatments did not affect any trait evaluated in this study ($P > 0.05$). The average pH values (5.6 ± 0.02) were within the normal range for all treatments. The WBSF also did not differ among treatments but the average values (8.2 ± 0.46 kg) were considered very high, indicating a tough meat. The average cooking loss was 23.9 ± 1.71% and also is within the range normally reported in the literature for Nellore cattle. Color attributes averaged 32.7, 14.7 and 12.6 for L*, a* and b*, respectively. The pH showed a small increase with aging period, from 5.5 to 5.6 ($P < 0.001$) but was within the normal range. The WBSF and CL decreased with increase of aging period ($P < 0.001$) from 10.5 to 6.0 kg for WBSF and from 25.6 to 22.2% for CL for 0 and 14 d of aging, respectively. The L* values increased with aging period ($P < 0.001$) from 29.4 to 35.9, however the a* (14.6 ± 0.70) and b* (12.6 ± 1.80) values were not affected by aging. Inclusion of different oil sources does not affect meat tenderness and color attributes of feedlot finished Nellore steers.

Key Words: tenderness, feedlot, linseed oil

M159 Effects of beta agonist and immunocastration on fatty acid profile of cattle. Madeline Rezende Mazon*, Saulo da Luz Silva, Daniel Silva Antonelo, Keni Nubiato, Juan Fernando Morales Gomez, Roberta Ferreira Carvalho, and Paulo Roberto Leme, *University of São Paulo, Pirassununga, São Paulo, Brazil.*

Beta agonists (BAA) are known for decreasing lipogenic activity and increasing lipolysis on beef and immunocastration (IM) could be an alternative tool to improve fat deposition. Therefore, this work was developed to evaluate the effect of BAA and IM on meat quality traits of feedlot finished Nellore cattle. Ninety-six bulls (409 ± 50 kg LW; 20 mo old) were divided into 2 groups and half of the bulls remaining bulls and the other half receiving 2 doses of IM vaccine (Bopriva) over a 30 d period before arrival at the feedlot. Cattle were fed for a period of 70 d on common diet (76% concentrate and 24% roughage). Each of these groups were then split in 3 groups and fed during 30 d one of the following treatments: control diet without BAA (CON); CON diet plus 80 mg/day zilpaterol hydrochloride (Zilmax; ZIL); CON diet plus 300 mg/day of ractopamine hydrochloride (Optaflexx; RAC). The cattle fed ZIL were 2 d withdrawal period before harvested. After 100 d on feed, cattle were harvested and one samples of LM was collected between 12/13th ribs for fatty acid profile determinations. Data was analyzed by ANOVA as randomized complete block (initial LW) design in 2 × 3 factorial arrangement and means were compared by Student *t*-test. There was no significant interaction of gender condition and BAA for any traits evaluated. Immunocastrated cattle had a greater percentage of MUFA (45.9 vs. 43.0; $P = 0.002$), palmitoleic (3.0 vs. 2.6; $P = 0.002$), Oleic (36.1 vs. 33.3; $P = 0.002$) and total Lipids (3.2 vs. 2.3 g; $P = 0.002$) compared with non-castrated, respectively, whereas non-castrated had greater stearic concentration (13.8 vs. 12.6; $P = 0.006$). Treatments CON and RAC showed greater values than ZIL for myristic (2.5 and 2.4 vs. 2.1; $P = 0.017$) and palmitic (23.7 and 23.0 vs. 21.9; $P = 0.009$), whereas ZIL treatment had greater values than CON and RAC for linoleic (8.5 vs. 6.7 and 6.5; $P = 0.030$), arachidic (2.6 vs. 1.8 and 1.8; $P = 0.046$), Omega 6 (12.1 vs. 9.2 and 9.4; $P = 0.039$). Beef from cattle fed ZIL presented greater CLA and PUFA concentrations, thus having more healthy beef. Immunocastrated cattle have more fat (lipids), MUFA and saturated fatty acids. Sex condition and BAA can be used to change the fatty acid profile of beef from Nellore cattle.

Key Words: zilpaterol, ractopamine

M160 Growth and serial real-time ultrasound measurements for backfat and loin muscle area in three breeds of swine.

L. L. Lo* and C. C. Tsai, *Chinese Culture University, Taipei, Taiwan.*

A serial real-time ultrasonic measured of backfat and loin muscle area was recorded to examine the rate of change per unit of live weight during the finishing stage of production. Sixty-nine sets of 3 littermates (boar, gilt, and barrow one each) involving the 3 major breeds Duroc, Landrace, and Yorkshire in Taiwan were used in this study. Real-time ultrasonic measurements of backfat and loin muscle area were collected at average body weight (BW) of 57.2, 78.8, 94.2, 113.5, and 128.1 kg. Backfat was measured off the midline at the 3/4 point (TRBF) over the tenth rib. Loin muscle area (LMA) images were collected from the left side of each pig at the 10th rib. Deposition rates were calculated for the dependent ultrasound traits TRBF and LMA in models that included the independent variables BW and BW2. Body weight was regressed on age and age2 for growth rate (GR). The serial measurements data were analyzed using a mixed model (PROC MIXED, SAS) that included the fixed effects of test group, breed, sex, and random effect of animal. Significant breed effects were detected for deposition rate of TRBF ($P = 0.0405$), LMA ($P = 0.0210$), and GR ($P = 0.0082$). Backfat thickness was deposited at a mean of 0.109 mm/kg, whereas LMA was averaged 0.299 cm2/kg deposited across 3 breeds. Average GR across breeds was 677.3 g. Barrows deposited fat at a greater rate ($P = 0.0220$) and grew at a greater rate ($P = 0.0462$), when compared with gilts. However, barrows grew at a lesser rate ($P = 0.0380$) than boars. The results of this study indicated that effects of breed and sex play important roles for rates of backfat and loin muscle deposition and weight per day of age in swine, and therefore, breed- and sex-specific adjustment factor are required.

Key Words: backfat, loin muscle area, pig

M161 Effects of gender status on beef quality from crossbred Angus x Nellore cattle.

Lenise F. Mueller*[1], Júlio C. C. Balieiro[1], Adrielle M. Ferrinho[1], Joyce J. M. Furlan[1], Laura R. R. Mantilla[3], Fernando S. Baldi[2], and Angélica S. C. Pereira[1], [1]*University of Sao Paulo, Pirassununga, Sao Paulo, Brazil,* [2]*Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil,* [3]*University Cooperative of Colombia, Medellin, Colombia.*

The goal of this study was to evaluate the influence of gender status on beef quality from feedlot crossbred Angus x Nellore cattle. Twenty months old cattle (n = 454) presenting initial mean weight of 265 kg ± 24.24 were grouped into lots, confined and assigned into the following treatments: bulls, steers, immunocastrated, and heifers. Cattle were fed ad libitum high-grain diet containing 80% concentrate. At the end of the experimental period (190 d), 40 cattle from each group were chosen based on body weight (bulls 555 kg ± 43.36, steers 478 kg ± 32.40, immunocastrated 509 kg ± 30.75, and heifers 468 kg ± 34.21) and harvested. Steaks (2.54 cm thick) were collected from the *Longissimus dorsi* and aged for 0, 7, and 14 d (d) at 2°C; after aging, all steaks were stored at −18°C until analyzed for tenderness and pH. Statistical analyzes were performed using the proc MIXED SAS program (version 9.2), including the fixed effect of gender status (bulls, steers, immunocastrated, and heifers), and the covariate d on feed, and the random effect of cattle within of gender groups. Significant effects for gender status were evaluated by *t*-test using PDIFF option. On d 0, immunocastrated cattle and steers beef presented decreased shear force values ($P > 0.05$), when compared with heifers and bulls; heifers presented decreased shear values when compared with bulls ($P < 0.05$). After 7 d of aging bulls presented increased shear values (4.74kg ± 0.20) when compared with the other treatments ($P < 0.01$). Also, no difference was detected between immunocastrated cattle (3.40kg ± 0.20), steers (3.32kg ± 0.20), and heifers (3.94kg ± 0.20), however heifers presented increased shear force values when compared with steers ($P < 0.05$). At 14 d of aging bulls presented increased shear values (3.84kg ± 0.15) when compared with the other groups ($P < 0.01$); there was no difference ($P < 0.05$) between the other categories. Gender status influenced pH values, bulls showed higher pH values when compared with the other groups ($P < 0.05$). Despite the effect of gender status on beef quality, it is important to highlight that the use of steers, immunocastrated cattle and heifers is necessary to attend demanding consumers seeking for tender beef.

Key Words: immunocastration, tenderness, beef

M162 Influence of aging on intramuscular color variations in beef semimembranosus.

Mahesh Narayanan Nair*, Shuting Li, Ryan Chaplin, Gregg Rentfrow, and Surendranath P. Suman, *University of Kentucky, Lexington, KY.*

Previous research documented intramuscular variations in the color and color stability of beef semimembranosus, which can be separated into color-labile inside (ISM) and color-stable outside (OSM) regions. Post-mortem aging is employed to improve beef quality attributes such as tenderness and palatability. Aging can also influence fresh beef color, whereas its effect on intramuscular color variations in beef semimembranosus is yet to be examined. Therefore, the objective of the present study was to evaluate the influence of aging on color and color stability of ISM and OSM and to examine if aging can mitigate intramuscular color variations. Semimembranosus muscles from 8 (n = 8) beef carcasses (USDA Choice, 24 h post-mortem) were vacuum packaged and aged at 2°C for 7, 14, and 21 d. On each aging period, muscles were fabricated into ISM and OSM steaks. Aerobically packaged steaks were stored in the dark at 2°C for 6 d. On d 6 of storage, lightness (L^*), redness (a^*), yellowness (b^*), and color stability (ratio of reflectance at 630 nm and at 580 nm) were evaluated on the steak surfaces using a HunterLab LabScan XE colorimeter. The data were analyzed using PROC MIXED procedure in SAS. OSM exhibited greater ($P < 0.05$) surface redness (a^* value) than ISM after 7 and 14 d of aging. However, after 21 d of aging, ISM and OSM demonstrated similar a^* values ($P > 0.05$). While OSM was darker ($P < 0.05$; lower L^* value) than ISM at all aging periods, there was no difference ($P > 0.05$) in yellowness throughout the aging. Color stability was greater ($P < 0.05$) in OSM than in ISM on d 7 and 21 of aging, whereas ISM and OSM exhibited similar ($P > 0.05$) color stability on d 14. These results suggested that 21 d aging could be employed to potentially minimize the intramuscular variation in redness of beef semimembranosus.

Key Words: semimembranosus, beef color, aging

M163 Effect of oil source and storage time on burger sensorial traits from Nellore cattle.

Anderson R. Cabral*[1], Fabiane de Souza Costa[1], Maria E. Groto[1], Saulo da Luz e Silva[1], and Angélica S. Cravo Pereira[2], [1]*University of Sao Paulo/FZEA, Pirassununga, SP, Brazil,* [2]*University of Sao Paulo/FMVZ, Sao Paulo, SP, Brazil.*

The aim of this study was to evaluate the effect of fed plant based oil source over 2 different storage period in sensorial burger traits. Ninety-six Nellore steers were confined for 82 d. The experimental design used was a split plot in a 4 × 2 factorial arrangement (3 oil sources plus control x 2 storage time). The oils sources were sunflower oil (SU); linseed oil (LO) and soybean oil (SO). Plant oils were added to the feedlot diet at a rate of 3.5% of concentration in each diet (based upon DM). Utilizing the *Longissimus dorsi* and subcutaneous fat from the carcass. 40 (100g/patties) hamburger patties were prepared per treatment utilizing a commercial formulation (85.4% of meat, 12% of fat, 2% of salt, 0.3% of garlic and 0.3% of emulsifier) with a weight around 100g and packed in plastic bags permeable to oxygen and then immediately frozen at −18°C and stored for 2 time periods, 0 and 90 d. The burgers were grilled in 170°C for 4 min on each side (internal temperature 75°C). Each panel member received 4 pieces (one for each treatment) randomly. Sensory analysis was performed utilizing an acceptance test with 9 point hedonic scale (9 = like extremely, 1 = dislike extremely) by a consumer panel (n = 100). They evaluated aroma (A), texture (T), juiciness (J), flavor (F) and overall acceptability (OA). The data was analyzed using a mixed model (MIXED procedure of SAS), including the fixed effects of oil source, storage time, the interaction between storage time with oil source and the random animal effect. There was no interaction between storage times with oil source ($P = 0.56$ to A, $P = 0.51$ to T, $P = 0.85$ to J, $P = 0.41$ to F, $P = 0.89$ to OA) for any sensorial trait evaluated, neither the oil source for A ($P = 0.08$) and J ($P = 0.26$) nor storage time for A ($P = 0.36$) and J ($P = 0.07$). There was an effect ($P = 0.01$) of storage time for T (0d = 6.29; 90d = 5.90). There was a reduction OA ($P = 0.02$) at time zero (6.87) compared with the time 90d (6.58). The hamburgers patties from SO, SU and control were tastier than those fed LO (7.12, 7.10, 7.04 vs. 6.65) ($P = 0.001$). In conclusion, the storage time and oil source have an effect on the burger sensorial traits, and the use of linseed oil or the burger storage for a period of 90d would reduce the acceptance by the consumers.

Key Words: lipid, texture, flavor

M164 Association of SNPs in the *THRSP* gene with morphological and biochemical traits of longissimus muscle in F_2 offspring of a Charolais x Holstein cross.

Elke Albrecht*, Lisa Schering, Dirk Dannenberger, Gerd Nuernberg, Christa Kuehn, and Steffen Maak, *Leibniz Institute for Farm Animal Biology, Dummerstorf, Germany.*

Expression and genetic variants of the thyroid hormone responsive protein (*THRSP*) gene has been reported to be associated with marbling and fatty acid composition in cattle. The study was undertaken to investigate the effect of 2 single-nucleotide polymorphisms (SNP) in the THRSP gene, namely c.88 G>A and c.194 C>T, on morphological and biochemical traits of the longissimus muscle. Genotyping of 247 F_2-generation bulls of a Charolais × Holstein cross revealed that both SNPs were in complete linkage disequilibrium in our data set with 37 bulls of the GG/CC, 110 of the AG/CT, and 100 of the AA/TT diplotype. Muscle fiber composition, intramuscular fat cell and marbling traits were analyzed using image analysis. Fatty acid concentrations/proportions were determined with gas chromatography using internal standard procedure as fatty acid methyl esters. The F_2 design yielded substantially increased variation within the population compared with both founder breeds regarding muscle structure, fat cell, and marbling data within F_2 bulls ranged from 4.5 standard deviations (cross sectional area of intermediate muscle fibers) to 7.4 standard deviations (area percentage of slow muscle fibers). Furthermore, absolute and relative fatty acid composition exceeded variation of muscle structural traits with differences between individuals up to 11.3 standard deviations (C21) indicating extreme divergence in fat deposition within the population. However, association analysis indicated no clear effect of THRSP-SNP diplotype on longissimus muscle structure and intramuscular fat deposition, but showed an indication on association of the THRSP-SNPs with muscle fatty acid composition ($P < 0.05$).

Key Words: cattle, fatty acid, muscle structure

M165 Meat quality of M. Longissimus dorsi of lambs fed with sunflower cake.

Anny Graycy Vasconcelos de Oliveira Lima, Ronaldo Lopes de Oliveira*, Thadeu Mariniello Silva, Patrícia Gonçalves Cirqueira, and Marcondes Dias de Freitas Neto, *Federal University of Bahia, Salvador, Bahia, Brazil.*

This trial was conducted to determine the effect of sunflower cake on the physicochemical properties of meat lamb. Forty crossbreed Santa Ines rams were fed 50% hay (Tifton-85 chopped) to 50% concentrate (corn, soybean meal, urea, ammonium sulfate and inclusion of sunflower cake) on diet. The 4 treatment diets were 0, 10, 20, and 30% sunflower cake. To account for the increasing concentration of sunflower cake, corn and soybean meal were removed from the diet. The rams were fed the treatment diets twice daily for a period of 71 d in feedlot, and were slaughtered after that. After a period 24 h postmortem, the Longissimus dorsi muscle were removed of carcass, separated into proximal and distal portions. The muscles from the distal portion's left side were used to determine the pH and color measurements with Minolta colorimeter and pH probe. The muscles from proximal portion the right side were used to measure the cooking loss and Warner-Bratzler shear force analysis was conducted according to the guidelines of AMSA. The experiment followed a completely randomized design with 4 treatments and 10 replicates per treatment. The data were analyzed using PROC GLM procedure of SAS (SAS Institute, Cary NC) with the treatments as the fixed effect. Regardless of inclusion rate, sunflower cake did not have an effect on pH ($P = 0.15$), L* ($P = 0.28$), cooking loss ($P = 0.23$), shear force ($P = 0.47$). There was an effect on color a* ($P = 0.03$) and b* ($P = 0.04$) with increasing concentration of sunflower cake, that characterizing bright cherry red color meats. Many factors (endogenous and exogenous) can contribute to meat color stability as pH, muscle source and mitochondrial activity, as well as live animal related factors, such as management, diet, and genetics. The competition between mitochondria and myoglobin (Mb) is a key component in the development of bright-red color. Probably occurred saturation Mb with oxygen forming oxymyoglobin or saturation Mb with carbon monoxide, forming carboxymyoglobin that offer bright cherry-red color meat. The sunflower cake inclusion has provided bright redder color meat without changing the cooking loss and tenderness of meat.

Key Words: color, cooking loss, tenderness

Nonruminant Nutrition: Amino acids

M166 Effects of arginine supplementation during early gestation (d 1 to 30) on litter size and plasma metabolites in gilts and sows.

Jie Li[1], Huan Xia[1], Wei Yao[1], Tingting Wang[1], Jiliang Li[2], Xiangshu Piao[1], Phil Thacker[3], Guoyao Wu[4], and Fenglai Wang*[1], *[1]State Key Laboratory of Animal Nutrition, Ministry of Agriculture Feed Industry Centre, China Agricultural University, Beijing, China, [2]Tianjin National Breeding Pig Farm, Tianjin, China, [3]Department of Animal Science, University of Saskatchewan, Saskatoon, SK, Canada, [4]Department of Animal Science, Texas A&M University, College Station, TX.*

Two experiments were conducted, using typical commercial swine production conditions, to determine effects of dietary arginine supplementation during early gestation on the performance of gilts and sows. In Experiment 1, 62 Landrace gilts and 113 sows were used to evaluate the effect of dietary arginine supplementation during early gestation (d 1 to 30) on gilt and sow performance. On d 1 of gestation, all gilts and sows were randomly assigned to a corn-soybean meal basal diet supplemented with either 1.3% L-arginine-HCl or 2.2% L-alanine (isonitrogenous control). The total number of piglets born per litter for arginine-supplemented was increased ($P < 0.01$), compared with the control group. In Experiment 2, 155 Landrace sows were used to evaluate the effect of dietary arginine supplementation between d 1 and 14, d 15 and 30 or d 1 and 30 on sow performance. Among these sows, 24 with an average parity of 2.54 were used to determine the effect of dietary arginine supplementation on plasma amino acid composition and the concentration of plasma metabolites. The total number of piglets born per litter for arginine-supplemented sows tended to increase ($P = 0.08$), compared with the control group, with the greatest improvement in sows treated from d 1 to 14. The concentrations of nitric-oxide metabolites, arginine, proline, ornithine and spermidine were increased ($P < 0.05$) in the plasma of arginine-supplemented sows on d 14 and 28 of gestation, as were agmatine and putrescine on d 14 of gestation. The concentrations of urea and glutamine were lower in the plasma of arginine-supplemented than in the control group. These results indicate that dietary arginine supplementation in early gestation improved the reproductive performance and plasma biochemical metabolites in sows.

Key Words: arginine, early gestation, sow performance

M167 Limiting dietary lysine increased plasma concentration of total cholesterol in finishing pigs.

Naresh Regmi*, Taiji Wang, Mark A. Crenshaw, Brian J. Rude, and Shengfa F. Liao, *Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State, MS.*

Lysine is the first limiting amino acid (AA) in typical swine diets, and plays important roles in nutrient metabolism and growth performance of pigs. This research was conducted to study the effects of dietary lysine on blood plasma concentrations of protein, carbohydrate and lipid metabolites of pigs. Eighteen crossbred (Yorkshire × Landrace) finishing barrows and gilts (9/sex; BW 92.3 ± 6.9 kg) were individually penned in an environment-controlled barn. Pigs were assigned to 3 dietary treatments according to a randomized complete block design with sex as block and pig as experimental unit (6 pigs/treatment). Three corn and soybean-meal based diets were formulated to contain total lysine at 0.43, 0.71, and 0.98% (as-fed basis) for diets 1 (D1; lysine-deficient), 2 (D2; lysine-adequate), and 3 (D3; lysine-excess), respectively. After 4 weeks on trial, jugular vein blood was collected and plasma separated. The plasma concentrations of glucose, total protein, albumin, triglyceride, urea nitrogen (PUN), and total cholesterol were determined using an ACE Clinical Chemistry System (Alfa Wassermann, Inc.). Data were analyzed using the GLM Proc with pdiff (adjust = T) option of SAS. No differences were found between barrows and gilts in any of the measured metabolites. The plasma concentration of PUN was greater for pigs fed D1 than D3 ($P < 0.05$), and greater for pigs fed D3 than D2 ($P < 0.05$). The plasma albumin concentration was lower for pigs fed D1 than D2 or D3 ($P < 0.05$), and no difference between D2 and D3. The plasma total cholesterol concentration was greater in pigs fed D1 than D2 or D3 ($P < 0.05$), and no difference between D2 and D3. The plasma concentration of total protein, glucose or triglyceride did not differ among the 3 treatments. These results confirm that a diet deficient in one essential AA can lead to catabolism of other AAs and impair body protein syntheses, and that the excess amount of one AA over the requirement will be catabolized. However, the metabolic mechanism for the increased plasma total cholesterol concentration of finishing pigs by a lysine-deficient diet warrants further investigation. This research was supported by USDA-NIFA Hatch/Multistate Project 233803.

Key Words: lysine, nutrient metabolite, pig

M168 The effect of dietary protein and amino acid concentration on certain production parameters of growing ostrich chicks (*Struthio camelus*).

Tertius S. Brand*[1,2], Pieter D. Carstens[2], and Louw C. Hoffman[2], *[1]Directorate for Animal Sciences, Department of Agriculture, Western Cape Government, Elsenburg, South Africa, [2]Dapartment of Agricultural Sciences, Stellenbosch University, Stellenbosch, South Africa.*

The effect of 3 different dietary protein (with a specific associated amino acid profile) concentrations on certain production parameters in growing ostriches were investigated. Measured parameters included feed intake, feed conversion ratio, and growth rate. Basic abattoir mass, postmortem measurements of the commercial cuts of meat were also done. The crude protein and amino acid requirements of ostrich chicks for the different production phases (pre-starter; 19.0% CP, starter; 15.5% CP, grower; 14.25% CP and finisher; 12.6% CP) were predicted by a newly developed mathematical growth and optimization model for ostriches (Gous and Brand, 2008; Aust. J. Exp. Agric. 48:1266-1269). Three basic diets per production phase were then formulated to be 20% lower and 20% above these predicted levels for lysine, sulfur-containing amino acids, threonine, tryptophan and arginine (named diets with a low, medium or high protein content). In the study 18 groups of birds, with 10 birds per group were used as experimental animals and were alotted to the different treatments according to live weight. The 3 dietary treatments were evaluated with 6 groups of birds per treatment. The 3 diets with the different levels of dietary protein (with a specific amino acid composition related to the dietary protein content) were fed to the ostriches during each of the 4 production phases from hatching up to slaughtering. Feed and water was available ad libitum. Results were analyzed by ANOVA with dietary protein level as main effect. Differences were determined to be statistically significant at $P < 0.05$. Significantly lower values with the low protein diet for the final live mass of birds at slaughter at 300 d of age (respectively 89.6, 98.8 and 102.2 kg), cold carcass mass (respectively 41.2, 45.1 and 45.1kg) and thigh weight as well as for most of the weighed muscles were found, while values for the medium and high protein diet did not differ. Both ADG (respectively 338, 361 and 377 g/bird/day) and feed intake (respectively 1.63, 1.67 and 1.76

kg/bird/day) for the low protein diet was significantly lower than that of the high protein diet with the medium diet intermediate. Results indicated that birds that consumed the diet with the medium protein performed optimal in most cases, except during the starter phase where the high protein diet outperformed the other 2 diets. This study showed that feeding diets with a higher protein and amino acid content than that predicted by the model was unable to increase performance levels of growing ostriches in most cases.

Key Words: ostrich, amino acid requirement, dietary protein level

M169 Oral supplementation of tryptophan and pyridoxine to nursing piglets on performance and behavior after weaning. L. Bonagurio[1], P. C. Pozza*[1], T. J. Pasquetti[2], L. M. Diaz-Huepa[1], L. D. Castilha[1], L. A. C. Esteves[1], A. N. T. R. Monteiro[1], V. P. Ricardo[1], and N. Galoro[1], *[1]Universidade Estadual de Maringá, Maringá, Paraná, Brazil, [2]Universidade Estadual do Oeste do Paraná, Mchal Candido Rondon, Paraná, Brazil.*

The objective of this study was to evaluate the oral supplementation of Trp and pyridoxine to nursing piglets on performance and behavior after weaning. Forty 8 piglets (24 males and 24 females) from 8 sows were used. At d 14, 6 piglets per sow were divided into 3 treatments (2 animals/treatment) and were allotted in a randomized block design with 8 replicates. Treatments consisted of a Control (alanine + glucose + distilled water); Trp (3.5 g Trp/day + distilled water); Trp + pyridoxine (3.5 g Trp/day + 0.0095 g pyridoxine/day + distilled water). Each treatment was orally supplied 5 times/d and each dose contained 2.5 mL, totalling 12.5 mL/d. The supplementation was carried out during a 7 d period (d 14 to d 21 of age), and at d 21 piglets were weaned. After weaning, piglets from the same treatment were housed together in nursery pens and all animals, from each treatment, received the same pre-starter diet. During nursery period (d 21 to d 34) piglets were monitored in 3 different periods (at d 22, from d 28 to d 29 and from d 33 to d 34 of age) by a set of cameras. Behavior (standing, lying, eating, socializing, sitting and drinking) was assessed by an instantaneous sampling that was performed with intervals of 5 min to obtain the frequencies (%) of each behavior. Eating behavior was considered when pigs were eating at the feeders. Piglets' performance was evaluated in the nursing and nursery period. Piglets receiving oral Trp + pyridoxine showed higher body weight ($P = 0.06$) on the first day after weaning (d 21 to d 22) compared with the Control which probably affected the weight loss ($P = 0.06$) of piglets on the first day after weaning, which was lower for piglets that received oral Trp + pyridoxine. No changes in performance were observed in the remaining periods. From d 28 to d 29 piglets that received Trp supplementation in nursing period, with or without pyridoxine, showed a higher eating behavior ($P = 0.01$) than the Control, which probably affected eating behavior ($P < 0.01$) in the total period (from d 21 to d 34). It can be concluded that oral supplementation of Trp and its association with pyridoxine, one week before weaning, reduces the weight loss in the first day after weaning and increases eating behavior until 1 wk after weaning.

Key Words: postweaning stress, B6 vitamin, tryptophan

M170 Methionine + cysteine and its ratios for barrows from 15 to 30 kg. C. F. Muniz, P. C. Pozza*, A. C. Furlan, C. A. L. Oliveira, F. Sato, L. D. Castilha, L. A. C. Esteves, C. P. Sangali, and M. R. Fachinello, *Universidade Estadual de Maringá, Maringá, Paraná, Brazil.*

Aiming to determine the requirements of SID methionine + cysteine (SID Met + Cys) for barrows (15–30kg) 70 pigs (15.216 ± 0.540kg) were used, being distributed in 7 treatments with 5 replicates. A basal diet was formulated to contain 0.52% SID Met + Cys (0.26% SID Met + 0.26% SID Cys). Three treatments consisted in levels of SID Met + Cys (0.58, 0.64, 0.70%) that was maintained the 1:1 ratio between sulfur amino acids (using DL-methionine and L-cysteine) and other 3 treatments consisted in the same levels (0.58, 0.64, 0.70%), but not maintaining the 1:1 ratio (using only DL-methionine), assuring 0.55:0.45, 0.59:0.41 and 0.63:0.37 ratios. Performance, blood parameters, longissimus dorsi muscle depth (LD) and backfat thickness (BF) were evaluated. The sulfur linkages (S-S) in animals' bristles were determined by using a confocal microscope Senterra Raman. First- and second-degree models were fitted for the levels of SID Met + Cys (0.52, 0.58, 0.64, 0.70%) maintaining or not the 1:1 ratio and the low SID Met + Cys level (basal diet, 0.52%0) was used to fit models maintaining or not the 1:1 ratio. Initial body weight was also included as a covariate. A likelihood ratio test was used to determine the best fitting model (specific models for maintaining or not the 1:1 ratio or a common model for both situations). Linear Response Plateau was used to determine the better SID Met + Cys level when the model of second degree was fitted. The significance level adopted was $P < 0.05$. The average daily gain (ADG) was affected ($P < 0.01$) only when the 1:1 ratio was not maintained (using only DL-methionine), reaching a plateau at 0.661% of SID Met + Cys. The LD and BF were not affected. Plasma glucose increased ($P < 0.01$) and cholesterol decreased ($P < 0.01$) as SID Met + Cys increased in the diets when supplementing only DL-methionine in the diet. Homocysteine in the blood serum was not affected. In conclusion, barrows from 15 to 30 kg needs 0.661% of SID Met + Cys in the diet (7.88g/day) for a maximum ADG, being not necessary to maintain the 1:1 ratio between SID Met and SID Cys.

Key Words: carcass trait, homocysteine, sulfur amino acid

M171 Bioavailability of L-methionine relative to DL-methionine in weaned pigs. John K. Htoo*[1] and Georg Dusel[2], *[1]Evonik Industries AG, Hanau-Wolfgang, Germany, [2]University of Applied Sciences Bingen, Bingen am Rhein, Germany.*

Information about the relative bioavailability (RBV) of L-methionine (LM; 100% L-isomers, 99% purity) compared with DL-methionine (DLM; a 50:50 mixture of D- and L-isomers; 99% purity) for pigs is limited. A 21-d experiment was conducted to determine the RVB of LM compared with DLM to maximize the performance of 7 to 13 kg weaned pigs. A total of 168 weaned pigs (Topigs; initial BW of 7.01 ± 0.04 kg) were assigned to 7 dietary treatments with 6 pen replicates (2 barrows and 2 gilts/pen). A corn-wheat-soybean meal-whey powder and fish meal-based basal diet (BD) was formulated using analyzed ingredient AA contents and published SID coefficients to contain 0.27% standardized ileal digestible (SID) Met and 0.54% SID Met + Cys but adequate in all other AA (1.35% SID Lys) and contained 2,498 kcal/kg NE. Dietary treatments included (1) BD, (2) BD + 0.05% DLM, (3) BD + 0.10% DLM, (4) BD + 0.15% DLM, (5) BD + 0.05% LM, (6) BD + 0.10% LM, and (7) BD + 0.15% LM. Data were analyzed by ANOVA using the GLM procedure of SAS. Orthogonal-polynomial contrasts were used to determine linear and quadratic effects of increasing levels of DLM and LM on response criteria, and the effect of Met sources. The final BW at d 21 (11.73, 12.49, 12.74, 12.68, 12.42, 12.65, and 12.82 kg for diets 1 to 7) and overall ADG (224, 258, 271, 269, 255, 268, and 272 g/d for diets 1 to 7) increased linearly ($P < 0.05$) by graded additions with both Met sources. The ADFI increased linearly ($P = 0.03$) by graded additions with DLM but was not affected by LM additions.

The overall FCR (1.42, 1.32, 1.29, 1.31, 1.35, 1.32, and 1.29 for diets 1 to 7) improved ($P < 0.01$) linearly and quadratically by DLM additions and linearly by additions with LM. Performance responses (ADG, ADFI and FCR) of pigs fed diets supplemented with the same inclusion levels of DLM and LM were not different ($P \geq 0.487$). Based on ADG as a response of Met intake, the nonlinear asymptotic model estimated the RBV of 89% (95% confidence interval: 49–128%) for LM relative to DLM. In conclusion, the bioavailability of LM relative to DLM is not different to optimize the performance of 7 to 13 kg weaned pigs.

Key Words: bioavailability, DL-methionine, L-methionine

M172 Bioavailability of L-lysine sulfate compared with L-lysine·HCl to optimize performance of 12 to 25 kg pigs.

J.P. Oliveira*[1], J.K. Htoo[2], L. F. T. Albino[1], M. I. Hannas[1], R. J.B. Rodrigueiro[3], N. A.A. Barbosa[3], and H. S. Rostagno[1], *[1]Federal University of Viçosa, Federal University of Viçosa, Viçosa, Minas Gerais, Brazil, [2]Evonik Industries AG, Evonik Industries AG, Hanau-Wolfgang, Germany, [3]Evonik Industries do Brasil, Evonik Industries do Brasil, São Paulo, Brazil.*

L-Lysine sulfate (Biolys), containing 54.6% L-Lys as well as other amino acids (AA) and phosphorus as fermentation co-products, is available as an alternative to L-lysine.HCl. A 21-d experiment was conducted to evaluate the relative bioavailability (RBV) on equimolar basis of Biolys relative to L-Lys.HCl (set at 100% availability). A total of 135 barrows (PIC; initial BW of 12.46 ± 0.55kg) were assigned to 5 treatments with 9 pen replicates (3pigs/pen) for 21 d. A Lys-deficient basal diet (BD) was formulated to contain 0.57% standardized ileal digestible (SID) Lys but adequate in all other AA. The diets included (1) BD, (2) BD + 0.128% L-Lys.HCl, (3) BD + 0.256% L-Lys.HCl, (4) BD + 0.183% Biolys, and (5) BD + 0.366% Biolys. The final BW on d 21 and the overall ADG increased linearly ($P < 0.01$) by adding both Lys sources. Feed intake was not different but F:G improved ($P < 0.01$) linearly by supplementing both Lys sources. Performance responses (ADG, ADFI, F:G) of pigs fed diets supplemented with the same inclusion levels of L-Lys·HCl and Biolys were not different ($P > 0.05$). Using multiple linear regression and the slope ratio the RBV estimates were 104.1 and 113.3% for Biolys relative to L-Lys·HCl to optimize ADG and F:G, respectively. In conclusion, Biolys and L-Lys·HCl are equally bioavailable on equimolar basis as Lys sources for 12 to 25 kg pigs.

M173 Pig's biochemical plasmatic variables response to methionine ingestion in a phase-feeding program or an individual daily feeding program.

Aline Remus*[1,4], Dani Perondi[1], Jaqueline P. Gobi[1], Ines Andretta[2], Luciano Hauschild[1], Marie-Pierre L. Montminy[3], and Candido Pomar[4], *[1]FCAV-UNESP, Jaboticabal, SP, Brazil, [2]UFRGS, Porto Alegre,RS, Brazil, [3]Université Laval, Quebec, QC, Canada, [4]AAFC, Sherbrooke, QC, Canada.*

The effect of different methionine intakes and pig's individual response to this amino acid in precision feeding program is not completely known. The aim of this study was especially to evaluate the existence of methionine (met) toxicity in traditional group-phase-feeding program and in precision feeding program in which pigs are fed individually with daily tailored diets. Sixty pigs with initial BW of 25 kg (MSE = ± 2.23) were used in a 28-d trial, and were arranged in a 2 × 3 factorial randomized design testing: (1) 2 feeding programs (individual daily program (IDP) or a conventional 1 phase program by group (1PP) and (2) 3 methionine levels (70, 100, or 130% of recommended level). In the IDP pigs had the daily and individually SID lysine requirements (SIDLys) estimated using the Precision Feed model (Hauschild et al., 2012) and in the 1PP the phase SIDLys was established using the average pig of the population at day one (Rostagno et al., 2011). In both programs the amino acids profile was kept constant with exception of met. Blood samples were collected weekly at jugular vena after an 8-h fasting period and analyzed for alanine aminotransferase (ALT), aspartate aminotransferase (AST), creatinine (CK), plasmatic total protein (PTP), and protein C-reactive (CRP) levels. The variables were analyzed as a 2 × 3 factorial arrangement (confidence interval = 95%) using GLM procedure of SAS. The main effects included feeding program, methionine level, and their interaction (P × L). The met intake inside the IDP was 2.7, 3.7 and 6.0 g/day for the 70, 100 and 130% treatments, in the same order for the 1PP, the met intake was 4.6, 6.1 and 8.5 g/day. The PTP showed no differences among the treatments. The ALT and AST presented quadratic tendency for P × L interaction ($P < 0.10$). The CK showed a P × L interaction with quadratic effect ($P = 0.02$) and linear effect inside IDP program ($P = 0.02$). As the met requirement could increase in sanitary challenge the protein C-reactive was analyzed, and concentration was not influenced ($P > 0.05$) by programs or by methionine levels. Current results showed no evidence that supports toxicity of increasing the methionine until a lysine ratio up to 30% in both feeding-programs.

Key Words: amino acid requirement

M174 Effects of dietary supplementation of branched-chain amino acids on growth performance, nitrogen balance, and whole-body protein turnover in piglets.

Liufeng Zheng, Hongkui Wei*, Chuanshang Chen, Quanhang Xiang, and Jian Peng, *Department of Animal Nutrition and Feed Science, College of Animal Science and Technology, Huazhong Agricultural University, Wuhan, Hubei, China.*

The aim of the study was to investigate the effects of dietary BCAA supplementation on growth performance, N balance, and whole-body protein turnover in piglets from 8 to 21 kg. Twenty-eight individually caged Large White × Landrace barrows were randomly assigned to 1 of 4 dietary groups (n = 7). All 4 diets were fortified with Lys, Met, Thr and Trp to satisfy the SID AA requirements recommended by NRC (2012). Diet PC was a positive control diet (19.5% CP); diet NC was a reduced-CP negative control diet (16.7% CP); diets T1 and T2 were reduced-CP diets to which 0.17% Ile, 0.16% Val, and 0.24% Leu or 2-fold dose of each BCAA were added, respectively. Nitrogen balance was determined over 5 subsequent days at the beginning of the 3rd week of the experiment. Whole-body protein turnover was determined by using the end product method after a single oral dose of ^{15}N-glycine. All data were analyzed using the One-way ANOVA and Duncan's procedures. The results showed that NC group had decreased ADG, ADFI and absolute N retention compared with the PC group, which were restored in T1 and T2 groups ($P < 0.05$). Total N excretions (g/d) were reduced ($P < 0.05$) in NC, T1 and T2 groups compared with PC group. There was no difference between PC and NC groups for protein synthesis, whereas T1 and T2 groups had higher ($P < 0.05$) protein synthesis than NC group. No difference in protein degradation were detected among 4 groups. There was no difference between T1 and T2 groups except for a higher N excretions in T2 group. These results indicate dietary BCAA supplementation improves growth performance and dietary N utilization for protein accretion in piglets.

M175 Standardized ileal digestibility of amino acids in single cell protein and tuna fish meal fed to growing pigs.

A. R. Son* and B. G. Kim, *Konkuk University, Seoul, Republic of Korea.*

The objective was to determine the apparent ileal digestibility (AID) and standardized ileal digestibility (SID) of CP and AA in 2 sources of single cell protein (SCP) and fish meal (FM) fed to growing pigs. The SCP1 (produced in Korea) contained 88.0% DM, 65.1% CP, 2.8% ether extract, and 4.2% ash; the SCP2 (produced in China) contained 90.4% DM, 75.6% CP, 1.3% ether extract, and 4.3% ash; and the FM (tuna fish meal produced in Korea) contained 85.2% DM, 54.9% CP, 8.8% ether extract, and 19.8% ash. Eight barrows (initial BW = 41.3 ± 1.2 kg) surgically fitted with a T-cannula in the distal ileum were allotted to a replicated 4 × 4 Latin square design. Three experimental diets were formulated to contain 25% SCP1, SCP2, and FM, respectively, which were the sole source of nitrogen in each experimental diet. A nitrogen-free diet was also prepared. All experimental diets contained 0.5% chromic oxide as an indigestible index. Values for the AID and SID of most indispensable AA in the SCP1 and FM were greater ($P < 0.05$) than those in the SCP2. There were no differences in the AID and SID of most indispensable AA between the SCP1 and FM. In conclusion, the digestibility of most indispensable AA in the SCP1 and FM were greater than those in the SCP2.

M176 Apparent and standardized ileal digestibility of amino acids in soybean meal and canola meal in finished pigs.

Juan Edrei Sanchez*[1], Ignacio Arturo Dominguez[1], Ernesto Morales[1], Jose Luis Yañez[2], and Miguel Cervantes[3], [1]*Universidad Autonoma del Estado de Mexico, Toluca, Estado de Mexico, Mexico,* [2]*Universidad Autonoma de Tlaxcala, Tlaxcala, Tlaxcala, Mexico,* [3]*Universidad Autonoma de Baja California, Mexicali, Baja California, Mexico.*

In México the production of soybeans and canola seeds are limited; the countries exporters of these ingredients to Mexico are United States and Canada for oil extraction and animal feed. The remainder after oil extraction in these ingredients is used in swine nutrition. Digestibility studies in soybean meal and canola meal have been conducted in other countries, however, the digestibility of these ingredients in Mexico is unknown. A study was conducted to determinate apparent ileal digestibility (AID) and standardized ileal digestibility (SID) of amino acids (AA) for soybean meal and canola meal. Six Ileal-cannulated barrows (75.1 kg BW) were fed 3 diets in a replicated 3 × 3 Latin square design in finished pigs in 3 periods, which consisted at 2.8 maintenance over 3 periods consisting of a 5-d diet adaptation, 2-d collection of feces, and a 2-d collection of ileal digesta. In the total AID of AA was similar ($P > 0.05$) between soybean meal and canola meal, and had 79.62 and 78.60%, respectively. With respect to lysine and threonine the soybean meal had higher ($P < 0.05$) AID values in 84.7 *vs* 78.4 and 74.4 *vs*. 70.8%, respectively, than canola meal. The AID in methionine was higher ($P < 0.05$) 3.88% in canola meal than soybean meal. for SID, all indispensable AA was higher ($P < 0.05$) in the soybean meal that canola meal except for methionine that was higher ($P < 0.05$) in canola meal (3.61%-units) that soybean meal. The digestibility of AA in the present study was lower compared with other studies. The difference may be due to the varieties of soybean meal and canola meal used for feed pigs, furthermore, The temperature used in the process of oil extraction in soybean and canola seeds is the main factor that could affect the quality of AA, decreasing the digestibility of CP and AA.

Key Words: soybean meal, canola meal, digestibility

M177 Nutritional value of soybean products for growing pigs.

Tofuko A. Woyengo*[1,2], Jorge Yañez[1,3], and Ruurd T. Zijlstra[1], *[1]University of Alberta, Edmonton, AB, Canada, [2]South Dakota State University, Brookings, SD, [3]Universidad Autónoma de Tlaxcala, Tlaxcala, México.*

A study was conducted to determine the standardized ileal digestibility (SID) of AA and calculate NE value for 9 soybean products. Ten ileal-cannulated barrows (30 kg BW) were fed 10 diets in a 10 × 6 Youden square at 2.8 × maintenance requirement for energy. The 10 diets were 9 cornstarch-based with 1 soybean co-product as the sole source of protein, and cornstarch, sucrose, canola oil and soybean product as energy source; and an N-free diet with cornstarch, sucrose, and canola oil as energy source. The ratio of cornstarch to sucrose and canola oil in soybean product diets was identical to the N-free diet to allow calculation of energy digestibility of soybean products by difference. The SID of AA for the soybean products was calculated using the N-free diet. The macronutrient profile of the 9 soybean products ranged from 35.4 to 65.8% CP, 1 to 21% ether extract, and 10.1 to 28.1% NDF. The SID of Lys ranged from 86 to 97% (Table 1). Apparent total-tract digestibility of GE digestibility was lower ($P < 0.05$) for high-ether extract than low-ether extract soybean products. The NE value ranged from 2.3 to 4.5 Mcal/kg of DM, and did not differ among the soybean products. In conclusion, the soybean products had high SID of AA, and hence they can serve as a good source of AA in swine diets. However, ether extract may hinder energy digestibility in the soybean products.

Table 1 (Abstr. M177). Lysine, ether extract (EE), and NDF content; Lys and GE digestibility; and NE value for soybean products fed to growing pigs[1]

Nonruminant Nutrition: Enzymes and minerals

M178 Porcine in vitro degradation and fermentation characteristics of regular and low-fat corn distillers dried grains with soluble without or with carbohydrase. Tofuko A. Woyengo*[1,2], Natasha Miceli[1], and Ruurd T. Zijlstra[1], [1]*University of Alberta, Edmonton, AB, Canada,* [2]*South Dakota State University, Brookings, SD.*

Low-fat corn DDGS (L-DDGS) is available for pig feeding. However, information is lacking on fermentation characteristics of L-DDGS in the pig intestine and on the effect of fiber-grading enzymes (carbohydrases) on fermentation characteristics of L-DDGS. Thus, we determined porcine in vitro digestion and fermentation characteristics of regular (R-DDGS) and L-DDGS without or with a carbohydrase that supplied 4,880 units of xylanase and 608 units of β-glucanase per treated feedstuff in a completely randomized design. Samples were hydrolyzed in 2 steps using pepsin and pancreatin. Subsequently, residues were incubated in a buffer solution with minerals and fresh pig feces as inoculum. Gas production was measured for 72 h, and modeled to estimate kinetics of gas production. Concentration of VFA per unit weight of residue incubated or feedstuff was measured in fermented solutions. Carbohydrase did not affect in vitro digestibility of DM (IVDDM) and total gas production. However, IVDDM for L-DDGS (61.1%) was greater ($P < 0.05$) than that for R-DDGS (54.7%). Also, total gas production for L-DDGS (129.9 mL/g DM) was greater ($P < 0.05$) than that for R-DDGS (119.0 mL/g DM). Total VFA production per unit weight of residue incubated for L-DDGS (2.66 mmol/g DM) was lower ($P < 0.05$) than for R-DDGS (2.93 mmol/g DM). Also, total VFA production per unit weight of feedstuff for L-DDGS (1.19 mmol/g DM) was lower ($P < 0.05$) than for R-DDGS (1.51 mmol/g DM). Carbohydrase and feedstuff interacted ($P < 0.05$) on total VFA production per unit weight of feedstuff such that the carbohydrase tended to increase ($P = 0.09$) total VFA production per unit weight of feedstuff for R-DDGS, but did not affect total VFA production per unit weight of feedstuff for R-DDGS. In conclusion, L-DDGS may be more digestible in the small intestine of pigs than the R-DDGS, whereas R-DDGS may be more fermentable in hindgut of pigs than the L-DDGS. The carbohydrase used in the present study may have limited effect on porcine small intestine digestibility and hindgut fermentation of R-DDGS and L-DDGS.

Key Words: corn DDGS, in vitro fermentation, pig

M179 Nutrient digestibility of sorghum, with or without exogenous enzymes, for young broiler chickens. C. Gallardo, J. C. Dadalt*, J. C. C. Balieiro, and M. A. Trindade Neto, *University of São Paulo, Pirassununga, SP, Brazil.*

A total of 245 male Cobb broilers (10 to 18 d old) were used to determine the total-tract nutrient digestibility (TTND) of dry matter (DM), mineral matter (MM), metabolizable energy (ME), nitrogen retention (NR), calcium (Ca), phosphorus (P) and neutral detergent fiber (NDF) of sorghum, with or without multi-carbohydrase (Carb) and phytase (Phy) enzyme supplementation. The birds were allotted in a completely randomized design with 5 treatments and 7 replications (7 birds per replication). The experimental period was 8 d, 5 d of adaptation and 3 d of total feces collection. The treatments were: Control diet (CD); CD + 30% sorghum (Sorghum); CD + 30% of sorghum + 200 mg/kg of Carb (Sorghum + Carb); CD + 30% of sorghum + 50 mg/kg of Phy (Sorghum + Phy); CD + 30% of sorghum + Phy + Carb (Sorghum + Phy + Carb). The diets were formulated to meet or exceed the nutrient requirements (Rostagno et al., 2011) for broiler chickens. The TTND coefficients of sorghum nutrients are presented in the table below. The Carb and Phy, isolated or in combination, improved ($P < 0.05$) the TTND of sorghum. Positive effects of Carb and Phy supplementation in sorghum-based diets for broiler chicks are associated with reduction in the antinutritional factors from ingredient. In general, the enzymes improved the TTND of sorghum for young broiler chickens, however, when isolated, Carb and Phy were effective to improve only NR and ME.

M180 Performance of commercial market hogs supplemented with a new generation *Buttiauxella* phytase. Janet C. Remus*[1], Yueming Dersjant-Li[2], Peter Plumstead[3], and Ajay Awati[2], [1]*Danisco Animal Nutrition/DuPont Industrial Bioscience, St. Louis, MO,* [2]*Danisco Animal Nutrition/DuPont Industrial Bioscience, Marlborough, Wiltshire, UK,* [3]*University of Pretoria, Pretoria, South Africa.*

This experiment was conducted to determine if a new generation phytase from *Buttiauxella* sp. can replace all inorganic phosphate (PO_4) in diets also reduced in Ca and ME and fed to commercial pigs from 12 kg to slaughter while maintaining performance and carcass quality. Four treatments were tested in a randomized block design with 9 replicate pens, each with 31 mixed sex pigs of Newsholm Choice genetics. The corn-soybean meal-wheat middlings-based treatment diets are (1) positive control (PC) that met nutrient requirements; (2) negative control (NC) without inorganic PO_4 and with incremental phase nutrient reductions of 0.131% Ca and 35 kcal ME/kg; (3) NC+500 FTU/kg phytase (NC+500) and (4) NC+1000 FTU/kg phytase (NC+1000). The mash diets were fed ad lib in 5 feed phases. Data were tested using the Fit Model procedure in JMP, mean separation utilized Tukey's test. Significance was $P \leq 0.05$ unless noted. Due to poor growth at the end of Finisher 1, the NC was placed on PC feed in Finisher 2 (F2) to see if they could get to target weight. Performance from Nursery 2 (N2) thru F2 shows the PC and NC+1000 have similar ADG and improved results versus NC. The

NC+500 had better ADG and FCR than the NC and had similar FCR with PC and NC+1000 in N2 thru F2. From N2 to processing, the PC and both phytase treatments were similar on performance (no NC due to insufficient pens at target weight by F2 end). No differences noted for carcass weight, lean carcass or yield. Carcass data for PC, NC+500, and NC+1000 shows that the NC+500 had higher 10th rib fat but had a tendency ($P = 0.07$) toward lower yield while NC+1000 had lower muscle depth. Overall, the data indicate that 500 and 1000 FTU phytase/kg can replace all inorganic PO_4 and maintain performance compared with PC in pigs fed a corn-soybean meal-wheat middlings based diet.

Table 1 (Abstr. M180). Performance and carcass data

	N2 to F2 (12-120 kg)			Carcass

M181 Ileal amino acid digestibility in high protein sunflower meal and pea protein isolate fed to growing pigs with or without multi-carbohydrase supplementation. J. C. Dadalt*[1], D. E. Velayudhan[1], M. A. Trindade Neto[2], and C. M. Nyachoti[1], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]University of São Paulo, São Paulo, SP, Brazil.*

Eight ileal-cannulated barrows (initial BW = 23.5 ± 0.85 kg) were used to determine the apparent (AID) and standardized (SID) ileal AA digestibilities in high protein sunflower meal (HiPSF) and pea protein isolate (PPI) with or without multi-carbohydrase enzyme (MC) supplementation. Pigs were randomly assigned to 1 of 5 treatments in a replicated 4 × 5 incomplete Latin square design to give 8 observations per treatment. The experimental diets consisted of HiPSF or PPI as the sole source of protein with or without MC and a low-protein diet (5% casein) used to quantify endogenous AA losses. All diets contained titanium dioxide (0.3%) as indigestible marker. Pigs were given their daily feed allowance at a rate of 4.5% of BW determined at the beginning of each experimental period. Each experimental period lasted 7 d and the ileal digesta were collected on d 6 and 7. All data were analyzed using the MIXED procedure of SAS (SAS Inst. Inc., Cary, NC). The model included diet as the fixed variable and animal and period as the random variables. In general, AA digestibilities were higher in PPI than in HiPSF, with the exception of Met and Cys ($P > 0.05$). There was no effect of MC ($P > 0.05$) on AA digestibility. The AID and SID of essential AA in HiPSF and PPI (without MC) were, respectively: Arg, 83.2, 87.8 and 90.0, 94.2; His, 29.6, 40.3 and 50.0, 60.5; Ile, 73.9, 79.8 and 83.1, 88.6; Leu, 72.9, 78.0 and 83.4, 87.7; Lys, 66.1, 72.6 and 88.3, 91.4; Met, 82.1, 86.0 and 80.8, 87.3; Phe, 75.5, 79.0 and 83.0, 86.1; Thr, 62.3, 72.9 and 72.6, 82.6; Val, 70.1, 76.1 and 79.2, 85.0. The MC increased ($P < 0.01$) the AID and SID of Proline (75.37 vs 82.14% and 86.82 vs 93.66%, respectively) in PPI. Compared with HiPSF, PPI had better digestible AA profile for growing pigs. However, no differences were detected for the digestibility of most AA when diets were supplemented with MC.

Key Words: enzyme, high-protein sunflower meal digestibility, pea protein isolate

M182 Ileal amino acid digestibility in rice polished and broken fed to weaned pigs with or without multi-carbohydrase and phytase supplementation. J. C. Dadalt*[1], G. V. Polycarpo[1], C. Gallardo[1], T. W. Almeida[1], J. C. S. M. Souza[1], F. E. L. Budiño[2], and M. A. Trindade Neto[1], *[1]University of São Paulo, São Paulo, SP, Brazil, [2]Institute of Animal Science, Nova Odessa, SP, Brazil.*

Twenty-five barrows (initial BW = 8.81 kg ± 1.52 kg) were used to determine the apparent (AID) and standardized (SID) ileal AA digestibilities in rice polished and broken (RB) with or without multi-carbohydrase (Carb) and phytase (Phy) enzyme supplementation. Pigs were allotted in a completely randomized design to 5 treatments with 5 replicates. The experimental diets consisted of RB as the sole source of protein without enzymes, with Carb, Phy or Carb+Phy and a low-protein diet (5% casein) used to quantify endogenous AA losses. All diets contained chromic oxide (0.3%) as indigestible marker. Pigs were given their daily feed allowance at a rate of 4.5% of BW determined at the beginning of each experimental period. Animals were slaughtered at d 43 and ileal contents collected. The data were analyzed using the GLM (SAS Inst. Inc., Cary, NC), and means were compared by Tukey's test. The phytase, singly or in combination with multi-carbohydrase, improved AID and SID ($P < 0.05$) of histidine, leucine and lysine of polished and broken rice, while singly carbohydrase improved only AID and SID ($P < 0.05$) of histidine. Coefficients of AID and SID of AA in RB (without enzymes) were, respectively: Arg, 0.662 and 0.841; His, 0.626 and 0.769; Ile, 0.596 and 0.792; Leu, 0.700 and 0.790; Lys, 0.663 and 0.775; Met, 0.710 and 0.808; Phe, 0.721 and 0.843; Thr, 0.492 and 0.650; Val, 0.630 and 0.811; Ala, 0.509 and 0.613; Asp, 0.618 and 0.735; Glu, 0.667 and 0.778; Pro, 0.623 and 0.853; Ser, 0.404 and 0.716; Tyr, 0.744 and 0.865. In general, these results were lower than those in NRC (2012). Underestimated digestibility coefficients may be related to animal ages in the present study, since most of the studies in literature were obtained from pigs with higher weights. The phytase, singly or combined with carbohydrase, improves the digestibility of His, Leu and Lys in rice polished and broken.

Key Words: alternative ingredient, enzyme, piglet

M183 Ileal amino acid digestibility in micronized full fat soybean fed to weaned pigs with or without multi-carbohydrase and phytase supplementation. J. C. Dadalt*[1], C. Gallardo[1], T. W. Almeida[1], P. A. P. Ribeiro[1], G. V. Polycarpo[1], G. Galvão[1], B. A. Malheiros[1], F. E. L. Budiño[2], and M. A. Trindade Neto[1], *[1]University of São Paulo, São Paulo, SP, Brazil, [2]Institute of Animal Science, Nova Odessa, SP, Brazil.*

Twenty-five barrows (initial BW = 8.53 kg ± 1.48 kg) were used to determine the apparent (AID) and standardized (SID) ileal AA digestibilities in micronized full fat soybean (MFFS) with or without multi-carbohydrase (Carb) and phytase (Phy) enzyme supplementation. Pigs were allotted in a completely randomized design under 5 treatments and 5 replicates. The experimental diets consisted of MFFS as the sole source of protein without enzymes, with Carb, Phy or Carb+Phy. A low-protein diet (5% casein) was used only to calculate the digestibility of the MFFS. All diets contained Chromium (0.3%) as indigestible marker. Pigs were given their daily feed allowance at a rate of 4.5% of BW determined at the beginning of each experimental period. Animals were slaughtered at d 43 and ileal contents collected. The data were analyzed using the GLM (SAS Inst. Inc., Cary, NC), and means were compared by Tukey's test. The AID and SID of AA in MFFS (without enzymes) were lower (average 16.9 and 14.7%, respectively) compared with NRC (2012). Underestimated digestibility coefficients may be related with animal ages in the present study, since most of the studies related in literature were obtained from pigs with higher weights. There was no effect of Carb, Phy or Carb+Phy ($P > 0.05$) on AA digestibility. According with literature, sometimes the use of exogenous enzymes to degrade indigestible dietary components has inconsistent results mainly because of the presence of complex substrates in feedstuffs and the use of enzyme activities often not suitable for effective hydrolysis of such components. The AID and SID of AA in MFFS (without enzymes) were, respectively: Arg, 71.6 and 76.5; His, 69.8 and 77.0; Ile, 59.9 and 66.0; Leu, 68.1 and 74.2; Lys, 75.8 and 79.6; Met, 72.3 and 81.1; Phe, 68.8 and 74.2; Thr, 61.4 and 74.6; Val, 65.2 and 72.1; Ala, 66.7 and 78.0; Asp, 66.9 and 69.8; Glu, 71.1 and 75.0; Pro, 70.1 and 80.7; Ser, 70.0 and 81.5; Tyr, 68.9 and 74.0. Carbohydrase and phytase, alone or in combination, don’t affect AA digestibilities of MFFS for weaned pigs.

Key Words: antinutritional factor, enzyme, piglet

M184 Nutrient digestibility of rice bran, with or without exogenous enzymes, for young broiler chickens.

C. Gallardo, J. C. Dadalt*, J. C. C. Balieiro, and M. A. Trindade Neto, *University of São Paulo, Pirassununga, SP, Brazil.*

A total of 245 male Cobb broilers (10 to 18 d old) were used to determine the total-tract nutrient digestibility (TTND) of dry matter (DM), mineral matter (MM), metabolizable energy (ME), nitrogen retention (NR), calcium (Ca), phosphorus (P) and neutral detergent fiber (NDF) of rice bran (RB), with or without multi-carbohydrase (Carb) and phytase (Phy) enzyme supplementation. The birds were allotted in a completely randomized design with 5 treatments and 7 replications (7 birds per replication). The experimental period was 8 d, 5 d of adaptation and 3 d of total feces collection. The treatments were: Control diet (CD); CD + 30% of RB; CD + 30% of RB + 200 mg/kg of Carb (RB+Carb); CD + 30% of RB + 50 mg/kg of Phy (RB+Phy); CD + 30% of RB + Carb + Phy (RB+Carb+Phy). CD was used only to calculate the digestibility of the RB. The diets were formulated to meet or exceed the nutrient requirements (Rostagno et al., 2011) for broiler chickens. The TTND coefficients of RB are presented in Table 1. Alone or combined, Carb and Phy improved ($P < 0.05$) the TTND of RB. These results are associated with enzymatic activity to enhance nutrient digestibility, focusing primarily on removing the antinutritive effects of nonstarch polysaccharides (NSP), such as arabinoxylans and β-glucans from broiler diets based on viscous grains. In general, enzymes improved the TTND of RB for young broiler chickens.

Table 1 (Abstr. M184). Apparent digestibility coefficients and metabolizable energy of rice bran for broiler chickens

Item	DM (%)	MM (%)	ME (kcal·kg^{-1})	NR (%)	Ca (%)	P (%)	NDF (%)

M185 Effects of phosphorus source and content on bone mineralization and performance of broiler chickens.

Roseline Kahindi*[1], Phil Thacker[2], and Martin Nyachoti[1], [1]*University of Manitoba,* [2]*University of Saskatchewan.*

Two hundred and ten 1-d-old, (Ross 308 strain) broiler chicks were housed in a temperature controlled room with 5 birds per cage and randomly allocated to 1 of 7 dietary treatments for a 21 d study. The objective of the study was to determine the effect of feeding diets containing low phytate barley and pea vs. the normal phytate cultivars and the effects of inorganic P reduction on performance and bone characteristics of broiler chicks. The main feed ingredients used were: low phytate barley (LPB), low phytate pea (LPP), normal hull barley (NHB), normal phytate pea (NPP), and soybean meal (SBM). The dietary treatments included (1) Control that was SBM-NHB based with 100% inorganic P; (2) control with 50% inorganic P; (3) low phytate cultivars based on SBM-LPB-LPP with 100% inorganic P; (4) treatment 3 with 50% inorganic P; (5) treatment 3 with no addition of inorganic P; (6) normal phytate cultivars based on SBM-NHB-NPP with 100% inorganic P; (7) normal phytate cultivars with 50% inorganic P. Feed and water were offered ad-libitum throughout the study and average daily gain (ADG) and feed intake (ADFI) were determined weekly and used for calculating feed conversion ratio (FCR). On d 21, 2 birds per cage were killed to collect left tibias for bone length and ash determination. Data were subjected to ANOVA as a completely randomized design using Proc Mixed of SAS 9.2. In addition, orthogonal contrasts were used to compare diets 1 and 2 vs. the rest of the diets, to compare 100 vs. 50% inorganic P diets, and to compare diets with low phytate vs. the normal phytate grain cultivars. The reduction in dietary inorganic P content significantly decreased ADG and ADFI but had no effect on FCR. The ADG was 18 g/chick and lowest ($P < 0.05$) for treatment 7, whereas ADG was similar for treatments 1 3, and 6 that is, 38, 42, and 41 g/chick, respectively. The overall ADG tended ($P < 0.10$) to be higher for the low phytate compared with normal phytate diets. The tibia ash and length were significantly decreased with inorganic P reduction. The results indicate that feeding low phytate barley and pea based diets can replace 29% of supplemental inorganic P required in normal phytate cultivars.

Key Words: broiler chicken, low phytate cultivar, performance

M186 A comparison of total, apparent total-tract digestible, and standardized total-tract digestible phosphorus on excretion and digestibility of phosphorus in pigs.

W. B. Kwon*[1], S. K. Park[2], and B. G. Kim[1], [1]*Konkuk University, Seoul, Republic of Korea,* [2]*Sejong University, Seoul, Republic of Korea.*

An experiment was conducted to test a hypothesis that 3 diet formulation methods of using total, apparent total-tract digestible (ATTD), and standardized total-tract digestible (STTD) phosphorus (P) differ in excretion and digestibility of P in pigs. Twenty-four barrows with an initial BW of 18.1 ± 0.7 kg were randomly allotted to 3 dietary treatments with 8 replicate pigs per diet in a completely randomized design. Experimental diets were formulated to contain constant amounts of corn, soybean meal, whey powder, and dicalcium phosphate. The 3 diets were formulated based on a total, ATTD, or STTD basis to meet the dietary P requirement by changing the inclusion rate of rice bran at the expense of cornstarch and cellulose. Each experimental period consisted of a 4-d adaptation period and a 5-d fecal collection period. During the collection period, total feed intake did not differ among the treatments. The daily P intake and daily P output of pigs fed the diet based on ATTD P was greater (10.87 vs. 7.65 or 8.96 g/d and 4.27 vs. 2.60 or 3.30 g/d, respectively; $P < 0.05$) compared with the total P- or STTD P-based group. The ATTD of P was not different among the treatment groups.

Taken together, formulating a diet based on total P or STTD P resulted in less P excretion mainly due to the less concentration of dietary P compared with a diet based on ATTD P. Further research is warranted to investigate performance and P retention in pigs fed diets formulated based on total P, ATTD P, and STTD P.

Key Words: diet formulation, phosphorus, swine

M187 Standardized total tract digestibility of phosphorus in various inorganic phosphates fed to growing pigs.

W. B. Kwon* and B. G. Kim, *Konkuk University, Seoul, Republic of Korea.*

An experiment was conducted to determine the standardized total-tract digestibility (STTD) of phosphorus (P) in 5 sources of inorganic phosphate fed to pigs. The 5 sources of inorganic phosphate were dicalcium phosphate (DCP, 19.3% P), monocalcium phosphate (MCP, 22.7% P), monodicalcium phosphate (MDCP, 22.0% P) which is the mixture of MCP and DCP at a ratio of 3:1, monosodium phosphate (MSP, 24.5% P), and tricalcium phosphate (TCP, 19.4% P). Six barrows with an initial body weight of 42.4 ± 1.1 kg were individually housed in metabolism cages equipped with a feeder. Pigs were randomly allotted to a 6 × 6 Latin square design with 6 dietary treatments and 6 periods. Each experimental period consisted of a 4-d adaptation and a 5-d collection period. Five experimental diets contained 0.25% P from each inorganic phosphate as a sole source of P, and were formulated to contain calcium in amounts that were 1.3 times greater than the concentration of P except the TCP diet. A P-free diet mainly based on cornstarch, gelatin, and sucrose was also prepared to estimate the basal endogenous loss of P. Feces were collected using the marker-to-marker procedure. Data were analyzed using the MIXED procedure of SAS with a model including dietary treatment as a fixed variable and animal and period as random variables. Values for the apparent total-tract digestibility of P in DCP, MCP, MDCP, and MSP (83.0, 86.5, 81.4, and 88.7% respectively) were greater ($P < 0.05$) than in TCP (67.0%). Values for the STTD of P in DCP, MCP, MDCP, and MSP (89.8, 93.3, 88.2, and 95.5%) were also greater ($P < 0.05$) than in TCP (72.8%). In conclusion, digestibility of P in TCP was less than other inorganic P sources.

Key Words: inorganic phosphate, phosphorus digestibility, swine

M188 Effect of phosphorus and calcium depletion-repletion sequences on femoral mechanical properties in growing pigs.

Enrique Gonzalo*[1,2], Thomas D. Crenshaw[1], Marie-Pierre Letourneau-Montminy[2], and Candido Pomar[3], *[1]University of Wisconsin, Animal Sciences Department, Madison, WI, [2]Laval University, Animal Sciences Department, Quebec, QC, Canada, [3]Agriculture and Agri-food Canada, Sherbrooke, QC, Canada.*

Consequences of a P-Ca deficient diet (depletion) or a control diet (repletion) on the mechanical properties of growing pig femurs were studied. Two different groups of pigs were fed with different P-Ca depletion-repletion sequences, that involved a control diet (C) or a deficient diet (L), supplying 100% or 60% of P-Ca requirements, respectively, in an incomplete factorial design. The first group (n = 30; initial BW 24 ± 3.3 kg) received during 2 28-d phases CC, CL or LC dietary treatments. The second group (n = 50; initial BW 24 ± 2.8 kg) received during three 28-d phases CCC, CLC, LCC, LLC or LLL diets. At the end of the 2nd and 3rd phases, respectively, pigs were killed and right femurs collected for computer tomography (CT) scans and mechanical tests. Data were analyzed using Proc Mixed procedures and orthogonal contrasts for treatments interferences. A 28-d repletion period in the 2nd phase (CC, LC) increased (43%, $P = 0.03$) bone-bending moment (BM, kg-mm) compared with depleted pigs (CL). Repletion P-Ca diets in the 3rd phase (CCC, CLC, LCC and LLC) increased BM ($P < 0.01$) and strain ($P = 0.03$) compared with LLL pigs. Moment of inertia (MI, mm^4) tended to be lower ($P = 0.08$) in depleted animals (LLL) compared with repleted animals, resulting in a reduced ($P = 0.02$) bone stress (kg/mm^2) in LLL pigs. However, neither bone MI nor stress differed among treatments. P-Ca depletion at the end of the 2nd or 3rd phase (CL, LLL) reduced bone mechanical properties. No differences were found between CC and LC treatments regarding mechanical properties, which implies bone recovery from P-Ca deficiencies of the 1st phase. Mechanical properties after three 28-d growing phases (final BW 107 ± 11.3 kg) are shown in the table. Superscripts indicate treatment differences ($P < 0.05$). A 28-d repletion in the 3rd phase (CCC, CLC, LCC or LLC) is sufficient for recovery from previous deficiencies as similar mechanical properties were detected among treatments.

Table 1 (Abstr. M188).

	Trait					
Item	CCC	CLC	LCC	LLC	LLL	SEM
BM (kg·mm)	3049^{A}	2501^{A}	2527^{A}	2354^{AB}	1726^{B}	259
Strain	0.026^{AB}	0.027^{AB}	0.030^{A}	0.025^{AB}	0.023^{B}	0.002
Stress (kg/mm^2)	1.346	1.129	1.170	1.105	0.886	0.123

Key Words: phosphorus-calcium, depletion-repletion, mechanical properties

M189 Effects of dietary calcium concentrations on growth performance, litter quality, and tibia characteristics in starter broiler chickens.

Jong Hyuk Kim*[1], Byung Bo Lee[1], Moon Chan Kim[1], Jae Sang Um[2], and Dong Yong Kil[1], *[1]Chung-Ang University, Anseong-si, Gyeonggi-do, Republic of Korea, [2]Nonghyup Feed, Gangdong-gu, Seoul, Republic of Korea.*

The objective of this experiment was to investigate the effects of dietary calcium (Ca) concentrations on growth performance, litter quality, and tibia characteristics in starter broiler chickens. A total of 2,520 one-day-old broiler chicks were used and housed in floor pens for 3 weeks. Birds were randomly allotted to 1 of 6 dietary treatments with 6 replicates. Each replicate consisted of 70 chicks. Dietary Ca concentrations were set to 1.0, 0.9, 0.8, 0.7, 0.6, and 0.5%. Non-phytate P (NPP) was maintained at 0.35% and 0.02% of a 5,000 FTU/g phytase (Phyzyme XP, Danisco Animal Nutrition, Marlborough, UK) was included in all diets. At the end of experiment, 2 birds from each replicate were euthanized and tibia samples were collected. Litter samples were also collected from each pen floor. Pre-planned orthogonal polynomial contrast test was performed to determine linear and quadratic effects of Ca concentrations. Results indicated that decreasing concentrations of Ca in diets from 1.0 to 0.5% increased (linear, $P < 0.05$) BW, BWG, FI, and feed efficiency. Litter quality including litter pH, litter moisture, and litter nitrogen and tibia characteristics including breaking strength were not affected by dietary Ca concentrations. In conclusion, decreasing concentrations of Ca from 1.0 to 0.5% in diets containing 0.35% NPP and phytase (1,000 FTU/kg) have positive effects on growth performance of starter broiler chickens, but little effects on litter quality and tibia characteristics.

Key Words: starter broiler chicken, dietary calcium, performance

M190 Effects of dietary calcium concentrations on growth performance, litter quality, and tibia characteristics in growing broiler chickens.

Jong Hyuk Kim[1], Byung Bo Lee*[1], Moon Chan Kim[1], Jae Sang Um[2], and Dong Yong Kil[1], [1]*Chung-Ang University, Anseong-si, Gyeonggi-do, Republic of Korea,* [2]*Nonghyup Feed, Gangdong-gu, Seoul, Republic of Korea.*

This study was conducted to investigate the effects of dietary calcium (Ca) concentrations on growth performance, litter quality, and tibia characteristics in growing broiler chickens. A total of 1,800 21-d-old broiler chickens were used and housed in floor pens for 2 weeks. Birds were randomly allotted to 1 of 6 dietary treatments with 6 replicates. Each replicate consisted of 50 chickens. Dietary Ca concentrations were set to 0.9, 0.8, 0.7, 0.6, 0.5, and 0.4%. Non-phytate P (NPP) was maintained at 0.3% and 0.02% of a 5,000 FTU/g phytase (Phyzyme XP, Danisco Animal Nutrition, Marlborough, UK) in all diets. After 2 weeks, 2 birds from each replicate were euthanized and tibia samples were collected. Litter samples were also collected from each pen floor. Pre-planned orthogonal polynomial contrast test was performed to determine linear and quadratic effects of dietary Ca concentrations. Results indicated that growth performance including BWG, feed intake (FI), and feed efficiency (FE) was not affected by dietary Ca concentrations. Litter quality including litter pH, litter moisture, and litter nitrogen was not influenced by dietary Ca concentrations. However, decreasing concentrations of Ca in diets from 0.9 to 0.4% decreased (linear and quadratic, $P < 0.01$) the concentrations of Ca and P in tibia. In conclusion, decreasing concentrations of Ca from 0.9 to 0.4% in diets containing 0.3% NPP and phytase (1,000 FTU/kg) decrease the concentrations of Ca and P in tibia, but no adverse effects on growth performance and litter quality in growing broiler chickens.

Key Words: growing broiler chicken, dietary calcium, performance

M191 Determination of additivity of apparent and standardized total tract digestibility of phosphorus in mixed diet fed to growing pigs.

W. B. Kwon*[1], S. K. Park[2], and B. G. Kim[1], [1]*Konkuk University, Seoul, Republic of Korea,* [2]*Sejong University, Seoul, Republic of Korea.*

This study was conducted to test the hypothesis that the values of standardized total-tract digestibility (STTD) of phosphorus (P) measured in individual feed ingredients are additive when used in diet formulation for swine. Eight crossbred barrows with an initial BW of 30.5 ± 1.5 kg were individually housed in metabolism cages equipped with a feeder. The pigs were randomly allotted to a replicated 4 × 4 Latin square design with 4 dietary treatments and 4 periods. Three diets were formulated by mixing cornstarch, sucrose, and soybean oil with SBM (50%), wheat (70%), or both (30.6% of SBM and 55.7% of wheat), as the source of P in each diet. A P-free diet was also formulated to estimate the basal endogenous loss of P. All experimental diets were formulated to maintain constant total calcium to total P ratio of 1.2:1 except the P-free diet. Each experimental period consisted of a 4-d adaptation period and a 5-d collection period. Feces were collected using the marker-to-marker procedure. In the mixed diet, a relative contribution of P from SBM and wheat was 51.9 and 48.1%, respectively. The ATTD of P for SBM and wheat was measured to be 40.9 and 41.8%, respectively, and the measured ATTD of P in the mixed diet was greater (45.1 vs. 41.3%; $P < 0.05$) than the predicted ATTD of P. The determined STTD of P for SBM and wheat was 46.4 and 49.3%, respectively, and the measured STTD of P in the mixed diet was not different (49.7 vs. 47.8%; $P = 0.26$) from the predicted STTD of P. In conclusion, the ATTD values of P are not additive whereas STTD values of P may be additive when formulating swine diets.

Key Words: additivity, phosphorus digestibility, swine

M192 Effect of dietary calcium and phosphorus concentration on apparent ileal and total-tract digestibility of calcium and phosphorus of pigs.

Fengrui Zhang*[1], Darryl Ragland[2], and Layi Adeola[1], [1]*Department of Animal Science, Purdue University, West Lafayette, IN,* [2]*Department of Veterinary Clinical Sciences, Purdue University, West Lafayette, IN.*

The objective of this study was to test the hypothesis that the apparent total-tract digestibility (ATTD) of calcium (Ca) is not different from the apparent ileal digestibility (AID) in growing-finishing pigs fed different Ca and Phosphorus (P) concentration diets with a fixed Ca:total P (tP) ratio. Diets with 4 Ca concentrations (0.39%, 0.59%, 0.79% and 0.99%) were formulated by adjusting the dietary level of calcium carbonate. Potassium phosphate was supplemented to adjust the dietary P level and maintain a 1.5:1 Ca:tP ratio. Sixteen pigs (initial BW = 73 ± 4 kg), fitted with a T-cannula at the distal ileum, were sorted by BW and assigned in a randomized complete block design to 4 treatments and 2 experimental periods. Each period consisted of a 3-d acclimation period, a 2-d fecal collection, and a 2-d ileal collection period. Data from the study was analyzed as a split-plot in a randomized complete block design using the GLM procedure of SAS (SAS Inst. Inc., Cary, NC). Diets with different Ca and P levels were the main-plot factor, and digestibility sites (AID and ATTD) were the split-plot factor. Results indicated that the ATTD of Ca or P is not different from AID in all treatments. Furthermore, the results also showed the digestibility of Ca was not affected by the dietary treatments, but the apparent digestibility of Ca had a tendency to increase as the dietary Ca concentration increased (linear, $P = 0.095$). The AID and ATTD of P linearly increased ($P < 0.05$) from 34.45 to 63.07% and 35.96 to 62.35% respectively, as the Ca and P concentration increased. Therefore, current study showed that with the same dietary Ca:tP ratio, there is no difference between the AID and ATTD of Ca and P. Thus, the net absorption of Ca and P in large intestine of growing-finishing pigs is negligible and both AID and ATTD can be used to describe the digestibility of Ca for growing-finishing pigs. It is also concluded that the effects of adding different levels of calcium carbonate and potassium phosphate on digestibility of Ca is not statistically significant, but it increased the apparent ileal and total-tract digestibility of P in the diets based on Corn-SBM.

Key Words: calcium, digestibility, phosphorus

M193 Influence of calcium source and fat level on broiler performance and nutrient utilization.

O. El-Husseiny[1] and M. A. Michael*[1,2], [1]*Department of Animal Sciences, Cairo University, Egypt,* [2]*Affor. and Environment, Ministry of Agriculture, Egypt.*

The objective of this experiment was to evaluate the effect of the dietary inclusion of calcium lactate (CL), calcium bio lactate (CBL) or calcium carbonate (CC) at NRC calcium level, in the presence of 0, 3%, 6% or 9% beef tallow on improving the performance, intestinal digestion and absorption of broiler chicks. Where, CBL derived from reacted between calcium hydroxide and biologically lactic acid secreted from lactic acid bacteria based on probiotic. Three hundred and six 1-d-old Cobb 500 broiler chicks were fed 12 treatments containing 3 calcium sources and 4 fat levels in a 3 × 4 factorial design with 3 replicates, 10 chicks each. Weight gain (WG), feed intake (FI), feed conversion rate (FCR), blood composition, nutrient digestibility and soap formation

were recorded up to 7 weeks of age. The weight gain of broilers fed diets containing CBL with 6% tallow fortified diet was higher than those fed CL plus 6% tallow. Improvement ($P < 0.05$) in FCR was observed when broilers fed diets contained CL or CBL compared with those fed diets contained CC with different fat levels. Abdominal fat was increased ($P < 0.05$) when broilers fed diets containing CBL with 9% fat than those fed the other calcium sources and fat levels. The digestibilities of all nutrients were higher ($P < 0.05$) with broilers fed diets contained CBL or CL plus 6% tallow than those fed diets contained CC with different fat levels. The highest amount of excreted fat as soap formation were noticed for broilers fed diets contained CC with 9% tallow, while the lowest values observed with those fed diets contained CBL with 6% or 9% tallow. Total blood lipid of broilers fed diets contained CL or CBL with 6 or 9% tallow were greater ($P < 0.05$) compared with those fed the other treatments. Broilers fed diets contained CBL recorded the highest nitrogen and calcium retained compared with those fed diets contained CL or CC. It is concluded that the calcium lactate or calcium bio lactate based on probiotic were effective improving fat absorption and calcium retention with positive effect on broiler performance.

Key Words: calcium bio lactate, beef tallow, soap formation

M194 Dietary nitrogen level affects ileal phosphorus digestion in growing pigs. Pengcheng Xue*[1], Darryl Ragland[2], Kolapo Ajuwon[1], and Olayiwola Adeola[1], [1]*Departments of Animal Sciences, Purdue University, West Lafayette, IN,* [2]*Departments of Veterinary Clinical Sciences, West Lafayette, IN.*

A study was conducted to investigate the effect of dietary CP levels on ileal phosphorus (P) digestion in growing pigs. A total of 18 ileal-cannulated pigs (initial BW 44.2 ± 3.2 kg) were used in a duplicated 9 × 3 incomplete Latin Square design, with 9 treatments and 3 7-d experimental periods giving 6 replicates per treatment. The 9 treatments consisted of 1 nitrogen free diet to estimate basal endogenous loss of AA, and 8 corn-soybean meal based diets in a 2 × 4 factorial arrangement, which included 2 CP levels (6.9 or 13.4%) and 4 apparent total-tract digestible P (ATTDP) levels (0.09, 0.16, 0.24, or 0.32%). Soybean meal and mono-calcium phosphate were used to adjust the CP level and ATTDP level, respectively. Limestone was included in diets to maintain the Ca: ATTDP ratio across treatments. Ileal digesta was collected continuously for 10 h on the last 2 d of each 7-d experimental period. The ileal digesta samples were lyophilized and analyzed to calculate ileal digested N and P. Data were analyzed using PROC MIXED procedure of SAS (9.3) and contrasts were used to test the linear and quadratic effects of increasing levels of P within each CP level. In the model, CP and P levels were considered as fixed effects and block (BW) was the random effect. In the low CP groups (6.9%), the ileal digested P were 0.71, 1.16, 1.64, and 2.03 g/kg of DMI for diets that contained 0.09, 0.16, 0.24, and 0.32% ATTDP, and their counterparts in high CP groups (13.4%) were 0.70, 1.54, 2.03, and 1.99 g/kg of DMI. There was a main effect of CP level ($P < 0.05$) on ileal digested P (g/kg of DMI). The ileal digested P (g/kg of DMI) increased linearly ($P < 0.01$) with increasing ATTDP levels in low CP groups, but the pattern was linear ($P < 0.01$) and quadratic ($P < 0.01$) in high CP groups. In conclusion, this research indicated that the amount of ileal digested P (g/kg of DMI) could be limited by protein deficiency and thus, dietary CP level could affect ileal P digestion.

Key Words: amino acid, ileal digestibility, phosphorus

M195 Could a reduction of crude protein content avoid the use of ZnO and antibiotics in pig diets without affecting their subsequent performance? Sergi López-Vergé, Laia Blavi*, David Solà-Oriol, José Francisco Pérez, and Josep Gasa, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

It's well known that ZnO and antibiotics (Ab) are usually included in nursery diets as a therapeutic use to reduce the impact of weaning in young piglets. The objective of this study was to analyze the effect of removing ZnO and Ab associated with CP reduction in piglet's diets in terms of mortality and days required to reach marketing BW (MBW, fixed at 105 kg). A total of 400 crossbreed piglets [Pietrain × (Landrace × Large White)] from 40 litters were used. During the nursery period, pigs were reared in 40 pens (10 piglets/pen) and assigned to 2 treatments taking into account the BW at weaning following a RCBD: medicated, M (2,480ppm Zn as ZnO, 120 ppm colistin sulfate, 300 ppm amoxicillin, 11.0 MJ/kg NE, 20.2% CP, 1.37% Lys) and unmedicated, Ø (10.6 MJ/kg NE, 16.5% CP, 1.20% Lys) diets until 35 d post-weaning. Thereafter, pigs were moved to a growing-finishing facility (maintaining the same littermates). Pigs were fed ad libitum the same commercial growing and finishing diets (10.0 MJ/kg NE, 16.0% CP, 0.95% Lys). Mortality rate (MR) was monitored from 0 to 14 d post-weaning. All animals were individually weighed at d 2 (CF; cross fostering), d 28 (weaning), d 42 (14 d post-weaning), d 63 (35 d post-weaning) and every 3 weeks until pigs were slaughtered. Data were adjusted using the Gompertz model: $BW = A \times \exp\{-\exp[b - (c \times t)]\}$; the predicted time to reach 7, 10, 20, 40, and 105 kg of BW were statistically analyzed by ANOVA by using the GLM procedure of SAS. No differences in time to reach BW of 7 (M = 34.2 d vs. Ø = 35.0 d; $P = 0.22$), 10 (M = 43.5 d vs. Ø = 44.3 d; $P = 0.24$), 20 (M = 65.4 d vs. Ø = 66.3 d; $P = 0.31$) and 40 kg (M = 95.4 d vs. Ø = 96.5 d; $P = 0.28$) were observed. In contrast, time to reach MBW was slightly higher in Ø pigs (179.3 d vs. 175.1 d; $P = 0.01$) and also had higher MR than the M (control) diet (11.7% vs. 4.5%; $P = 0.02$) during the 14 d post-weaning. Results suggest that removing ZnO and Ab (also reducing CP and Lys) in early diets, seems not to have a huge impact in the time to reach MBW but causes higher MR in the first 14 d post-weaning.

Key Words: performance, piglet, zinc oxide

M196 Comparing zinc status, growth, and mortality in piglets fed with or without therapeutic doses of Zn oxide. Laia Blavi*, Sergi López-Vergé, David Solà-Oriol, and José Francisco Pérez, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Zinc (Zn) is an essential micronutrient required for multiple biological functions and used at therapeutic doses to reduce diarrhea and increase feed intake and performance in piglets. However, high doses of Zn in the diet are associated with heavy metal soil contamination and antimicrobial resistance which it may indicate the need to restrict or modify the therapeutic use of ZnO in piglets. A study was performed to assess how growth, mortality and Zn serum concentration change when Zn therapeutic is removed. A total of 400 weaned piglets [Pietrain × (Landrace × Large White)] were assigned to 2 different dietary strategies: Therapeutic (T diet, 122ppm of Zn as nutrient and 2,480ppm Zn as ZnO, 11.0 MJ/kg NE, 20.2% CP, 1.37 Lys) and Nutritional, in which the diet was formulated with a lower CP content, (N diet with 125ppm Zn as nutrient, 10.6 MJ/kg NE, 16.5% CP, 1.20 Lys) during the nursery period

(0 to 35d). On d 35, piglets were moved to the growing barns and fed the same diet (110 ppm Zn, 10.0 MJ/kg NE, 16.0% CP, 0.95 Lys). Piglets were weighted on d 0, 14, 35 and 57 and mortality was registered. Blood samples were obtained from 15 piglets per group to analyze Zn status on d 0, 7, 35 and 49 post-weaning. All studied parameters were analyzed with one-way ANOVA taking into account the experimental treatment as main factor with α level of 0.05. No differences were observed on growth during the whole period, but higher mortality was observed in the N group compared with the T group. A temporary decrease of Zn serum concentration was observed after weaning in pigs fed the N diet (0.95, 0.67 and 1.07 mg/L on d 0, 7 and 35, respectively), whereas T piglets increased Zn concentration (0.95, 1.20, 1.31 mg/L, on d 0, 7 and 35, respectively; $P < 0.001$). When T piglets were moved to the growing barns showed a decrease of Zn concentration (1.05 mg/L on d 49) while the N piglets showed a recuperation of Zn status to physiological levels (1.20 mg/L on d 49). These results might indicate a drop of blood Zn levels and an increase on mortality when therapeutic doses of Zn are removed and low CP diet is used, suggesting the need of using new, more efficient Zn compounds.

Key Words: ZnO, Zn status, piglet

M197 Prediction equation to estimate digestible energy content of crude glycerin for swine based on chemical composition.

Ciro A. Ordoñez-Gomez*[1], German Afanador-Tellez[2], and Claudia Ariza-Nieto[3], [1]*Universidad Francisco de Paula Santander-Ocaña, Ocaña, Colombia,* [2]*Universidad Nacional de Colombia, Bogota, Colombia,* [3]*Corpoica, Mosquera, Colombia.*

The energy value of crude glycerin (CG) from a palm oil biodiesel facility was determined in growing pigs to estimate its digestible energy (DE) based on chemical composition. The study was conducted using the mobile nylon bag technique (MNBT). Nylon bags were inserted into the duodenum of 8 barrows (average body weight of 57.7 kg) through simple duodenal T-cannulas. Carboxymethylcellulose was used as a carrier of CG. Treatments consisted of a control (carboximethylcellulose) and 15 mixtures containing 10%, 20% and 30% of CG from 5 different batches of biodiesel production. Each batch showed variation in the content of glycerol and it was analyzed for dry matter (DM), gross energy (GE), ether extract (EE), ash, glycerol (GLY), pH and acid index (AI). Eight bags were administered to each pig daily (2 bags being inserted at 8, 10:30, 13:00 and 15:30 h into each of the 8 barrows). Sixteen nylon bags were prepared for each mixture (one gram per bag) therefore 256 bags were inserted over a 4-d period. The GE of each mixture was determined in a bomb calorimetry. The DE values of each mixture were estimated by difference, where by the DE content of the control was subtracted from each mixture containing CG. A multiple linear regression model was used to determine the value of the DE of CG as the slope relative to the DM of the CG included. The DE values of CG were correlated with its chemical composition and the value ranged from 3264 ± 202 to 3731 ± 202 kcal/kg DM ($P < 0.01$). The prediction model with the lowest AIC (Akaike's information criterion) was selected. DE (kcal/kg as fed) = [1.29 × GE (kcal/kg as fed)] + [109.7 x ash (%)] – (19.4 × GLY), (R^2-adj = 0.999, $P < 0.02$). According to these results, the CG from palm oil biodiesel is a valuable energy source, with DE concentration depending on the concentration of GLY, GE and ash. The DE of crude glycerin was 77.5% of the GE.

Key Words: crude glycerin, digestible energy, prediction

Nonruminant Nutrition: General I

M198 Effect of dietary gamma-aminobutyric acid on egg production, egg quality, blood profiles, cecal microbial populations and excreta gas emission in layers. J. H. Park*[1], B. Balasubramanian[1], S. Kathannan[1], J. H. Cho[2], and I. H. Kim[1], *[1]Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea, [2]Department of Animal Science, Chungbuk National University, Cheongju, Chungbuk, South Korea.*

Thirty-two-week-old Hy-line brown commercial layers were used to investigate the additive effect of gamma-aminobutyric acid (GABA) derived from *E. coli* strains, on the productivity, egg quality, blood profile, cecal population and excreta noxious gas emission. Two hundred eighty-eight birds (46 ± 0.5 g) were fed 4 different levels of GABA (0, 25, 50 and 100 ppm), in a basal diet based on corn-soybean meal, for 5 wks. Daily egg production was expressed on a hen-day basis, and egg quality and blood profiles were determined using an egg multi tester and an automatic blood analyzer, respectively. The *Lactobacillus* and *E. coli* medium agar plates were incubated for 24 h at 37°C, under anaerobic and aerobic conditions, respectively. A Gastec gas sampling pump was used for noxious gas detection. Polynomial contrasts were conducted to measure the linear and quadratic effects for increasing GABA levels on all measurements. As a result of the current study, egg production (93.5 vs. 95.2, 95.4, 97.1), egg weight (62.2 vs. 64.3, 65.9, 66.8), and egg mass (58.2 vs. 61.2, 62.9, 64.9) during 32–36 wks showed significant improvement, as dietary GABA increased from 0 to 100 ppm (linear, $P < 0.05$). In addition, GABA supplementation was associated with increased eggshell breaking strength (4.28 vs. 4.48, 4.46, 4.44; quadratic, $P < 0.05$) and albumen height (8.16 vs. 8.58, 8.62, 8.78; linear, $P < 0.05$). Blood parameters, such as white blood cells, red blood cells, lymphocyte, cortisol, epinephrine and norepinephrine concentrations, were not influenced by GABA added into the diet; however, the haptoglobin concentration (15.0 vs. 12.3, 11.0, 10.8) was significantly decreased linearly, and IgG concentration (48.8 vs. 54.0, 54.3, 68.3) was increased quadratically in GABA-fed groups ($P < 0.05$). *Lactobacillus* populations (7.46 vs. 7.48, 7.58, 7.90) in the cecum were significantly increased, as dietary GABA supplementation increased (linear, $P < 0.05$). The ammonia (70 vs. 62, 59, 54) and hydrogen sulfide (12.0 vs. 9.7, 9.3, 7.7) gas emissions in the excreta were significantly decreased (linear, $P < 0.05$). These results suggest that diets containing GABA may beneficially affect productivity, egg quality, serum haptoglobin and IgG concentration, and excreta noxious gas emission. Besides, GABA may also improve the intestinal environment, by increasing the *Lactobacillus* population of layers.

Key Words: blood profile, egg production, gamma-aminobutyric acid

M199 Egg production, egg quality, blood profiles, cecal microflora, and excreta noxious gas emission in layer hens fed with fenugreek (*Trigonella foenum-graecum* L.) seed powder. J. H. Park*[1], P. Y. Zhao[1], H. L. Li[1], J. H. Cho[2], and I. H. Kim[1], *[1]Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea, [2]Department of Animal Science, Chungbuk National University, Cheongju, Chungbuk, South Korea.*

The objective of this study was to investigate the effects of dietary fenugreek seed powder (FSP) supplementation in layers. A total of 288 layers (26 weeks old, Hyline-brown) were divided into 3 groups fed a corn-soybean meal diet (corn 50.4%, soybean meal 18.7%) containing 0 [control (CON)], 0.05 or 0.1% FSP for 5 weeks. Data were statistically analyzed via ANOVA using the GLM procedure of SAS for a completely randomized design, replicated 8 times with 12 layers per replication. Egg production was recorded daily on a hen-day basis, and egg quality and blood profiles were analyzed using an egg multi tester and an automatic biochemistry blood analyzer, respectively. For the measurement of cecal *Lactobacillus* and *E. coli*, cecal digesta was serially diluted in 0.1% peptone water, and incubated onto agar plates at 37°C for 24 h, under anaerobic and aerobic conditions, respectively. A Gastec gas sampling pump was used to detect gases in layer excreta. The inclusion of FSP in the layer diet did not affect egg production, feed intake and feed conversion among treatments. However, egg weight (CON = 63.1 vs. 0.1% FSP = 66.4 g), eggshell breaking strength (CON = 4.39 vs. 0.1% FSP = 4.66 kg/cm^2), eggshell thickness (CON = 35.4 vs. 0.1% FSP = 36.7 mm^{-2}) and yolk color (CON = 7.0 vs. 0.1% FSP = 7.8) was increased in FSP-fed groups ($P < 0.05$). Supplemental FSP decreased serum total cholesterol concentration (CON = 222 vs. 0.05% FSP = 172, 0.1% FSP = 184 mg/dL), whereas the HDL-cholesterol (CON = 33 vs. 0.1% = FSP 44 mg/dL) and IgG concentration (CON = 446 vs. 0.1% FSP = 469 mg/dL) was increased in the FSP fed-groups ($P < 0.05$). The inclusion of FSP led to an increase in cecal *Lactobacillus* number (CON = 6.98 vs. 0.1% FSP = 7.42 cfu/g; $P < 0.05$) and a decrease in *E. coli* number (CON = 6.57 vs. 0.05% FSP = 6.14 cfu/g; $P < 0.05$) and excreta ammonia gas emission (CON = 48 vs. 0.1% FSP = 30 ppm; $P < 0.05$). These results suggest that the addition of FSP does not increase egg production, but may affect egg quality, serum total- and HDL-cholesterol, IgG concentration and cecal microflora. The inclusion of FSP also decreased ammonia gas emission in layer excreta.

Key Words: blood profile, egg quality, fenugreek

M200 Effect of astaxanthin produced by *Phaffia rhodozyma* on growth performance, meat quality, and fecal noxious gas emission in broilers. M. M. Hossain*, M. Begum, H. Y. Shin, J. S. Jeong, M. Mohammadi, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea.*

Phaffia rhodozyma is a species of yeast that produces the carotenoid pigment astaxanthin (AST), which exhibits a wide variety of biological activities in animals. A total of 432 1-d-old male broilers (Arbor Acres) was used in a 4-wk trial. Birds were allotted to 1 of 3 corn-soybean meal-based diets supplemented with 0 mg (CON, basal diet), 1,000 mg (CON + AST production 0.1%) or 2,000 mg (CON + AST production 0.2%) *P. rhodozyma* yeast per kg feed. There were 9 replicate cages per treatment, with 16 broilers per pen. Nine broilers were randomly selected from each treatment (1 bird per cage) for sampling on d 28. Statistical analysis was performed using the mixed models analysis procedures in SAS, with AST treatment and pen serving as the fixed and random effect model terms, respectively. In addition, orthogonal comparison was conducted using polynomial regression to measure the linear and quadratic effect of increasing dietary concentrations of supplemental AST production. Alpha level of significance was set at $P < 0.05$. The inclusion of yeast-AST in feed improved body weight gain in a linear fashion with increasing AST concentration (969, 989, 1024 g) in the finisher period and the overall experimental period (1377, 1401, 1439 g). Furthermore, yeast supplementation reduced feed conversion ratio (1.650, 1.603, 1.562) in the finisher period, and tended ($P < 0.10$) to reduce feed conversion ratio for the overall experimental period (1.588, 1.554, 1.525). The yeast-AST supplemental diet had no effect on breast muscle color or pH, and water holding capacity values. Treatments with yeast-AST reduced ammonia emission in a linear fashion (17.98, 14.42, 14.32 ppm). This study demonstrated that yeast producing AST supplementation has a positive effect on BWG and FCR in the finisher period and the overall experimental period. It is possible that yeast-AST might maintain and promote the growth of a beneficial microbial population in fast-growing broilers. Moreover, there was an effective reduction in the fecal ammonia in response to treatment with yeast-AST. Ammonia is considered the most harmful gas to livestock, and can reduce daily weight gains and feed utilization.

Key Words: astaxanthin, growth performance, noxious gas emission

M201 Effect of protected organic acid blends on growth performance, nutrient digestibility and fecal micro flora in growing pigs. Y. H. Liu*[1], J. K. Kim[1], P. Y. Zhao[1], K. Y. Lee[2], and I. H. Kim[1], *[1]Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea, [2]Morningbio Co., LTD, Cheonan, Chungnam, South Korea.*

Protected organic acids are suggested to more effectively deliver acids to the distal ileum, cecum, and colon of piglets. The objective of this study was to evaluate the effects of dietary supplementation of protected organic acid blends (17% fumaric acid, 13% citric acid, 10% malic acid, 1.2% medium chain fatty acid) and carrier on growth performance, nutrient digestibility and fecal micro flora in growing pigs. A total of 100 crossed [(Landrace × Yorkshire) × Duroc] with an average initial BW of 23.4 kg was used in a 6-wk trial. Pigs were randomly allocated into 1 of 4 treatments (5 replications with 5 pigs per pen) in a randomized complete block design based on their BW. Treatments consisted of a control diet (CON) and the control plus 0.1, 0.2, and 0.4% of organic acid blends. Body weight and feed intake were measured initially and at the end of 6 wk to determine average daily gain (ADG), average daily feed intake (ADFI) and gain/feed. The digestibility of nutrients and fecal micro flora was also assessed at the end of the experiment. Data were analyzed using contrast statements to test the linear and quadratic effect of organic acid concentration in the diet. Linear effects ($P < 0.05$) were observed for ADG (713 g, 724 g, 745 g, and 737g) as well as G:F (0.450, 0.456, 0.471, and 0.464) with the increase in the level of organic acid blends. Dietary supplementation with 0.1%, 0.2% and 0.4% protected organic acid did not affect DM, N and energy digestibility. Supplementation of organic acid blends in the diet linearly increased ($P < 0.01$) fecal *Lactobacillus* population counts (7.26, 7.31, 7.47, and 7.38 $\log_{10}$ cfu/g) with the increase in the dose of organic acid blends. Our result suggests that protected organic acid has the potential to enhance growth performance and improve microbial population in growing pigs.

Key Words: growth performance, microflora, protected organic acids

M202 Effect of phytogenics on egg production, egg quality, excreta microbiota, noxious gas emission and nutrient digestibility in laying hens fed with different density diets. A. Hosseindoust*, H. L. Li, P. Y. Zhao, J. S. Jeong, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea.*

This study was conducted to evaluate effects of dietary supplementation with phytogenics on production performance, feed intake, egg quality, excreta microbiota, noxious gas emission, and nutrient digestibility in laying hens. Total of 240 Hy-line Brown 50-week-old laying hens were randomly assigned to 1 of 4 treatments. The dietary treatments included (1) T1, basal diet (ingredients included Ca: 4.92%; protein: 16.9%, phosphorus: 0.64% and energy: 3920 kcal/kg); (2) T2 = T1 + 150 ppm phytogenics (quillaja 30%, anise 20% and thyme 17%); (3) T3 = T1 + 150 ppm phytogenics w/matrix (reduction in Ca −0.072% and P −0.068% only; (4) T4 = T1 + 150 ppm phytogenics w/matrix (reduction in Ca −0.072%, P −0.068%, protein −0.5%, energy −32 kcal/kg and amino acids). Variability in the data was expressed as the pooled standard error (SE) and probability level of $P < 0.05$ was considered to be significant. Egg weight was improved ($P < 0.05$) by the T2 (62.95), T3(63.54) and T4 (61.02) treatments compared with the T1 treatment during wk 15–20. The feed intake was higher ($P < 0.05$) in the T3 (112) and T4 (115) treatments than the T1 and T2 treatments. The yolk height in the T4 treatment (8.38) was higher ($P < 0.05$) than that in the T1 treatment at wk 20. T2 (8.95) and the T4 (9.00) treatments had higher ($P < 0.05$) yolk color compared with that in the T3 treatment at wk 15. *E. coli* and *lactobacillus* counts were not affected by dietary treatments. Laying hens in T3 (14.2) and T4 (16.4) treatments excreted significantly less ($P < 0.05$) ammonia than that in the T1 and T2 treatments at wk 20. At wk 15, the T1 (59.25) treatment had the greater ($P < 0.05$) ATTD (apparent total-tract digestibility) of Ca compared with the T3 treatment. Meanwhile, the T2 (47.59) and T4 (48.53) treatments had greater ($P < 0.05$) ATTD of P compared with the T1 and T3 treatments. At wk 20, the T3 (48.90) group had the highest ($P < 0.05$) ATTD of P when compared with the T2 and T4 groups. Thus the dietary supplementation with phytogenics has some influence on performance, feed intake, egg quality, excreta microbiota, noxious gas emission, and nutrient digestibility in laying hens.

Key Words: phytogenics, performance, egg quality

M203 Effects of gel based phytogenic feed supplement on growth performance, nutrient digestibility, blood characteristics, and intestinal morphology in weanling pigs. P. Y. Zhao*[1], H. M. Yun[1], H. L. Li[1], J. D. Hancock[2], and I. H. Kim[1], *[1]Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea, [2]Department of Animal Science & Industry, Kansas State University, Manhattan, Kansas.*

Gel based phytogenic feed supplement (GBP) is designed to facilitate the transition from a liquid diet (sow milk) to dry ration. It contains both feed component and water component thereby influencing feed consumption and intestinal health. In the current study, 120 weanling pigs [(Landrace × Yorkshire) × Duroc] with an average body weight of 6.71 kg were used in a 42-d feeding trial divided into 3 phases; d 1 to d 7 (Phase 1), d 8 to 21 (Phase 2) and d 22 to d 42 (Phase 3) to evaluate effects of GBP containing essential oil from caraway seed on growth performance, nutrient digestibility, blood chemistry and intestinal morphology. Pigs were randomly distributed on the basis of body weight and sex with 5 pigs per pen and 8 pens per treatment. Dietary treatments were: CON (basal diet), CON + 50 g GBP per pig a day, (F50) and CON + 100 g GBP per pig a day, (F100). The GBP was mixed with powdered feed just before feeding and fed during phase 1 post weaning and thereafter all pigs were fed only basal diet without GBP. All experimental data were analyzed as a randomized complete block design using the GLM procedures (SAS) with pen as the experimental unit and blocks based on initial BW. The digestibility of nutrients and measurement of villi of small intestine was done on d 10. Orthogonal contrasts were used to test the effect of treatments. During phase 3, feeding GBP linearly increased ($P < 0.05$) ADG (544 g, 553 g, 562 g) and G:F (0.644, 0.657, 0.674). Overall, linear increase were shown ($P < 0.05$) in ADG (462 g, 470 g, 477 g) and G:F (0.679, 0.694, 0.707). However, ADFI was neither improved nor reduced in piglets fed GBP. The digestibility of DM (78.2%, 81.8%, 82.5%) and GE (78.2%, 82.2%, 81.9%) increased linearly ($P < 0.05$). The villi length of jejunum (540, 695, 755μm) and ileum (556, 713, 774μm) was improved linearly ($P < 0.05$) with the increase in the level of GBP. In conclusion, phytogenic feed supplement did not influence feed intake but increased ADG, improved G:F through enhancement of dry matter and energy digestibility as well as improved jejunum and ileum villi length.

Key Words: gel-based phytogenic feed supplement, growth performance, phytogenic

M204 Effect of medium chain fatty acids and probiotic (*Enterococcus faecium*) supplementation on the growth performance, nutrient digestibility, fecal score, fecal microflora, and fecal noxious gas emission in weanling pigs. P. Y. Zhao*, B. Balasubramanian, M. Begum, M. Mohammadi, and I. H. Kim, *Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea.*

The objective of the present study was to evaluate the effects of medium-chain fatty acids (MCFA) and probiotic (*Enterococcus faecium* DSM 7134) supplementation in weanling pigs. A total of 140 weanling pigs [(Yorkshire × Landrace) × Duroc] were allotted to 4 treatments, 7 replicates/treatment and 5 pigs/replicate. Diets include: CON, basal diet; TRT 1, CON + MCFA 0.2%; TRT 2, CON + probiotic 0.01%; TRT 3, CON + MCFA 0.2% + probiotic 0.01%. Titanium oxide was added to the feed at 0.2% dosage (2 kg/t of feed) and for a duration of 5 d as an indigestible marker for digestibility determination. Fresh fecal grab samples collected from 2 pigs per pen were mixed and pooled, and a representative sample was stored in a freezer at –20°C until analysis. Data were analyzed as 2 × 2 factorial arrangement by using the GLM Procedure of SAS. During wk 0–2, probiotics supplementation increased ($P < 0.05$) ADG (393 vs. 352) and G:F (0.831 vs. 0.741). During the overall period (wk 0–6), increased ($P < 0.05$) ADG (454 vs. 424) and G:F (0.709 vs. 0.660) were detected in probiotic treatments. The ATTD of DM, N, and energy were increased ($P < 0.05$) by probiotic (80.07% vs. 77.67%; 80.06% vs. 77.09%; 80.28% vs. 78.10%), MCFA (80.22% vs. 77.52%; 79.86% vs. 77.29%; 80.46% vs. 77.92%) and their combination (80.96% vs. 75.86%; 81.17% vs. 75.63%; 81.12% vs. 76.40%). There was no significant difference in fecal score, microflora (*Lactobacillus* and *E. coli*) and noxious gas emission (ammonia, hydrogen sulfide, total mercaptans, and acetic acid) in all the treatments. In conclusion, dietary probiotic supplementation have beneficial effect on growth performance, additionally, MCFA, probiotic and their combination can improve nutrient digestibility in weanling pigs.

Key Words: medium-chain fatty acids, weanling pig, growth performance

M205 Effect of dietary protected organic acids on growth performance, nutrient digestibility, blood profiles, microflora, and gas emission in weanling pigs. P. Y. Zhao*[1], M. Mohammadi[1], K. Y. Lee[2], M. Begum[1], and I. H. Kim[1], *[1]Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea, [2]Morningbio Co. Ltd., Cheonan, Chungnam, South Korea.*

The protected organic acids consist of medium chain fatty acid (MCFA) for animal nutrition and metabolism made by technology of Joint Matrix coating (JMT). The objective of the present study was to evaluate the effect of protected organic acid supplementation in piglets particularly at the weaning. A total of 112 weanling pigs with an average BW of 6.70 ± 1.31 kg were allotted to 4 experimental diets as: CON (basal diet); OA1 (CON + unprotected organic acid 0.2%); OA2, (CON + protected organic acid 0.1%) and OA3 (CON + protected organic acid 0.2%). There are 7 replications/treatment and 4 pigs/replication. The organic acid such as 17% fumaric acid, 13% citric acid, and 1.2% medium chain fatty acid (capric and caprilic acid) were used in the present experiment. Effects of treatments (Control, OA1, OA2, OA3) were analyzed by ANOVA as a randomized complete block design. Results are presented as least squares means and the variability in data was expressed as standard error (SE). The probability values less than 0.05 were considered as significant. Average daily gain (ADG), average daily feed intake (ADFI), gain to feed ratio (G:F), apparent total-tract digestibility (ATTD) were determined along with WBC, RBC, lymphocytes, IgG, *Lactobacillus* and *Escherichia coli* (*E. coli*). Average daily gain (ADG) at 0–2 wks were increased linearly (CON:307 g, OA1: 311 g, OA2: 319 g, OA3: 324 g) ADFI at 2–6 weeks (CON:762 g, OA1:757 g, OA2:755 g, OA3:750 g) and the overall ADFI was increased. A linear increasing effect was shown in the ATTD of dry matter (DM) (CON: 80.40%; OA1: 80.24%; OA2: 82.87%; OA3: 83.11%) with OA2 and OA3 treatments, the serum IgG in OA2 (235 mg/dL) and OA3 (245 mg/dL) treatments and the lymphocyte in OA3 treatments (50.9%) and in supplementation coated protected organic acid of *Lactobacillus*. However, a linearly reduced effect was observed in the population of *E. coli* (CON: 5.70, OA1: 5.65, OA2: 5.60, OA3: 5.49). In conclusion, dietary protected organic acids improve health status and performance in weanling pigs.

Key Words: protected organic acid, weaning pig, growth performance

M206 Effects of dietary fiber and benzoic acid on growth performance, nutrient digestibility, reduction of harmful gases, and lipid profiles in growing pigs. H. Y. Shin*[1], T. S. Li[1], J. Y. Cheong[2], C. M. Nyachoti[3], and I. H. Kim[1], *[1]Department of Animal Resource & Science, Dankook University, Cheonan, Choongnam, South Korea, [2]Daehan Feed Co. Ltd., Incheon, South Korea, [3]Department of Animal Science, University of Manitoba, Winnipeg, Manitoba, Canada.*

We assessed the possible synergistic effects of fiber from sugar beet pulp and benzoic acid in growing-finishing pigs. In total, 96 growing pigs ([Landrace × Yorkshire] × Duroc) with an average initial BW of 22.8 kg were selected and provided the dietary supplements based on their BW in a 2 × 2 factorial experiment, with the respective factors being fiber (low vs. high; 140 g/kg, 160 g/kg NSP, respectively) and BA (0, 5 g/kg benzoic acid) in 6 replicate pens consisting of 4 pigs per pen. Sugar beet pulp was used as a DF sources, at 50 g/kg of the diet. All diets were formulated to contain 14.44 ME MJ/kg and 190 g/kg CP. This experiment was conducted to evaluate the growth performance, nutrient digestibility, and reduction of harmful gases and serum metabolites. The pen was considered as the experimental unit for growth performance and each pig was considered the experimental unit for gas emission and serum metabolites. The final model included the main effects of DF level and BA as well as the interaction between DF and BA. Data are reported as means ± standard error (SE). Differences were considered statistically significant when $P < 0.05$. There was no significant difference in feed intake (1.428). No difference was found in weight during treatments. Fiber levels affect the dry matter digestibility: it was higher in the high fiber group (79.91) than the low fiber group (78.80) ($P < 0.05$). Addition of BA also improved the energy digestibility ($P < 0.05$). No interaction was found between fiber level and benzoic acid treatment. There was no difference in NH_3, but RSH (25.0, 26.1) and H_2S (20.2, 25.5) gases emissions shows significant reduction with fiber and benzoic acid treatment. Additionally, serum metabolites, including lipoprotein (LDL: 56.25, HDL: 36.25) and cholesterol (93.25), were also apparently unaffected by these treatments. Thus, the addition of 50 g sugar beet pulp per kg of growing feed as a DF source and the addition of BA had no significant effect on the growth performance of pigs during the growth period. We now consider that 50 g of sugar beet pulp per kg of diet may have been insufficient to reduce serum cholesterol in grower pigs. The findings of this study also

suggests that the metabolism of benzoic acid may differ from that of niacin.

Key Words: fiber, benzoic acid, growing pig

M207 Ileal digestibility of nutrients and amino acids in conventional hulled (44% CP) and dehulled (48% CP) soybean meal treated with β-mannanase for growing pigs.

S. Shanmugam*[1], J. K. Kim[1], H. M. Yun[1], J. H. Cho[2], and I. H. Kim[1], [1]*Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea,* [2]*Department of Animal Science, Chungbuk National University, Cheongju, Chungbuk, South Korea.*

This experiment was conducted to determine the efficacy of β-mannanase supplementation to corn SBM based diet on ileal digestibility of nutrients and amino acids in growing pigs. Twenty barrows [(Landrace × Yorkshire) × Duroc] with an average body weight of 25 kg were fasted for 16 h and T-cannulas were surgically attached 15 cm proximal to ileo-cecal junction upon induction of anesthesia. The experimental diet consisted of corn based hulled or de-hulled SBM supplemented with or without 400U β-mannanase/kg. Cannulated pigs were allotted to one of 4 dietary treatments plus a nitrogen-free diet in a completely randomized design with 4 pigs per treatment. A nitrogen-free diet was used to determine basal endogenous losses of CP and amino acids. Data were analyzed as a completely randomized design with 2 × 2 factorial arrangement using GLM procedures of SAS. The main effect included dietary SBM (hulled vs dehulled) and with or without β-mannanase supplementation as well as the interaction between β-mannanase and types of SBM. Each experimental period consisted of 7 d of diet adaptation followed by total feces and ileal digesta collection. The supplementation of β-mannanase improved ($P < 0.05$) apparent ileal digestibility (AID) of DM compared with non-supplemented in hulled SBM (80.9% vs. 77.2%) and in de-hulled SBM (83% vs. 79.5%) but it did not influence N and GE digestibility. The AID of Thr and Pro was higher ($P < 0.05$) in dehulled SBM (81.3%, 82.6%) than hulled SBM (77.3%, 78.0%). Likewise, the SID (standardized ileal digestibility) of Thr and Pro was higher ($P < 0.05$) in dehulled (87.3%, 83.9%) than hulled SBM (83.9%, 80.3%). The supplementation of mannanase led to higher ($P < 0.05$) AID of amino acids such as Arg (78.2, 79.6% vs. 74.0, 75.5%), His (82.2, 83.2% vs. 79.0, 81.5%), Lys (84.6, 86.9% vs. 79.4, 80.1%), Val (78.2, 80.2% vs. 74.3, 76.7%) and Gly (81.2, 82.9% vs. 77.1, 80.3%) in hulled and dehulled SBM than non-supplemented diet and higher ($P < 0.05$) SID of Lys (89.0, 89.8% vs. 84.2, 87.0%) in hulled and dehulled SBM than non-supplemented diet. In conclusion the supplementation of enzyme increased the AID of Arg, His, Lys, Val and Gly and SID of Lys.

Key Words: mannanase, soybean meal, growing pig

M208 Effect of flavor and sweetener on growth performance, nutrient digestibility, blood profile, and diarrhea score in weaning pigs.

Y. Lei*[1], P. Y. Zhao[1], H. L. Li[1], C. M. Nyachoti[2], and I. H. Kim[1], [1]*Department of Animal Resource & Science, Dankook University, Cheonan, Chungnam, South Korea,* [2]*Department of Animal Science, University of Manitoba, Winnipeg, Manitoba, Canada.*

A total of 120 weaning pigs [(Landrace × Yorkshire) × Duroc; BW = 8.95 ± 0.88 kg] were allotted to 4 treatments (6 pens/treatment, 5 pigs/pen) to evaluate the effect of anise flavor (F), sweetener (ST), and compound of them in weaning pigs. Treatments were as follows: 1) control, 2) control + 500 ppm F, 3) control + 150 ppm ST, 4) control + 500 ppm F + 150 ppm ST. Individual pig BW and pen feed intake were recorded on d 1, 14 and 42 (phase 1: d 1–14, phase 2: d 15–42) to calculate ADG, ADFI, and G:F. Cr_2O_3 (0.2%) was added to the diets from d 7 to 14 and d 35 to 42 as indigestible marker to determine apparent total-tract digestibility (ATTD) of DM, N, and GE. Blood samples were collected from the cervical vein of 2 pigs in each pen at 24, 48, and 72 h after weaning. Subjective diarrhea scores were recorded daily from d 1 to 7 and d 8 to 14. Data were analyzed as 2 × 2 factorial arrangement by using the GLM Procedure of SAS. During d 1 to 14, ADFI (-F vs. +F = 412 vs. 447.5 g; -ST vs. +ST = 407.5 vs. 452 g) and ADG (-F vs. +F = 323 vs. 355 g; -ST vs. +ST = 317.5 vs. 360.5 g) respectively improved by F ($P < 0.01$) and ST ($P < 0.01$) supplementation. During d 1 to 42, ST increased ADFI (-ST vs. +ST = 689.5 vs. 732 g; $P < 0.01$) and ADG (-ST vs. +ST = 461 vs. 508 g; $P < 0.05$). Digestibility of N was improved (-ST vs. +ST = 83.5 vs. 86.1%; $P < 0.05$) in ST treatments on d 14. The epinephrine level at 48 h after weaning was decreased (-ST vs. +ST = 154 vs. 148.5 pg/mL; $P < 0.05$) by supplementation of ST. Diarrhea score (scoring system from 1 to 5) was decreased ($P < 0.05$) by F (-F vs. +F = 4.04 vs. 3.93) and ST (-ST vs. +ST = 4.05 vs. 3.92) during d 1 to 7. No interaction effect was observed in our experiment. In conclusion, sweetener improved growth performance and nutrient digestibility, decreased serum norepinephrine concentration, epinephrine concentration and diarrhea score. Anise flavor could improve growth performance, decreased norepinephrine concentration and diarrhea score after weaning. It implies the benefit of anise flavor and sweetener might be more effective in the first week after weaning, and the effect sweetener seems better than anise flavor.

Key Words: flavor, sweetener, weaning pig

Physiology and Endocrinology: Effects of nutrition and metabolism on ruminant reproduction

M209 Consistency of metabolic responses to nutrient deficiencies in early and mid-lactation of dairy cows. Josef J. Gross* and Rupert M. Bruckmaier, *Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland.*

The adaptive response to a given metabolic load during energy deficiencies varies considerably among animals. The aim of this study was to investigate if individual cows respond in a repeated manner to a negative energy balance (NEB) in early and mid-lactation. Twenty-five multiparous Holstein dairy cows (3.0 ± 1.1 parities; mean ± SD) experienced a NEB during the first weeks of lactation, and after getting into a positive EB, cows were exposed to a 3-wk feed-restriction period providing 50% of estimated requirements starting at around 100 DIM. Dry matter intake and milk yield were recorded daily. Blood samples for analysis of plasma concentrations of glucose, NEFA, BHBA, cholesterol, and IGF-1 were obtained once weekly. Retrospectively, cows were ranked according to plasma NEFA concentration in early lactation. The cows with the 33% highest and 33% lowest NEFA concentrations (8 animals each) were selected and classified either a high response (HR) or a low response (LR) group, respectively. Data were analyzed using MIXED models in SAS including wk, group (HR or LR), parity, and the wk × group interaction as fixed effects and the individual cow as repeated subject. Differences between HR and LR over time were detected by the Bonferroni *t*-test. Significant effects were assumed at a level of $P < 0.05$. Before parturition, no differences were detected between LR and HR. After parturition, milk yield and ECM were higher for HR (milk yield: +7.4 kg/d, ECM: +4.9 kg/d from wk 2 to 14 pp) compared with LR ($P < 0.05$). Although plasma concentrations of glucose and cholesterol showed group differences in early lactation, but not during feed-restriction, concentrations of NEFA, BHBA, and IGF-1 showed a consistent similarly directed, but different response to a NEB at the 2 stages of lactation despite a similar EB. HR had higher NEFA (+0.8 mmol/L in wk 2 pp, +0.2 mmol/L in wk 2 of feed-restriction), BHBA (+1.3 mmol/L in wk 3 pp, +0.3 mmol/L in wk 1 of feed-restriction) and lower IGF-1 concentrations (−48.7 ng/mL in wk 2 pp, −54.9 ng/mL in wk 2 of feed-restriction) compared with LR at the 2 stages of lactation ($P < 0.05$). Cows responding to high milk production and negative energy balance with higher plasma NEFA and BHBA did again respond with higher NEFA and BHBA to a negative energy balance in later lactation as compared with cows with lower NEFA and BHBA concentrations with similar production levels.

Key Words: adaptation, metabolic plasticity, negative energy balance

M210 Relationship of dietary and serum phosphorus during the transition period to fertility measures. Ellen R. Jordan[1], Kevin J. Lager[1,2], J. Armando Garcia Buitrago*[3], Don R. Topliff[4], and Pablo J. Pinedo[5], *[1]1. Texas A&M AgriLife Extension, Dallas, TX, [2]2.West Texas A&M University, Canyon, TX, [3]3. New Mexico State University, Clovis, NM, [4]4. Angelo State University, San Angelo, TX, [5]Texas A&M AgriLife Research, Amarillo, TX.*

The objective was to evaluate the relationship between dietary and serum phosphorus (P) during the transition period and its relationship to fertility measures. Blood samples were collected into vacuum tubes at the morning feeding from cows (n = 4129) in 8 Holstein (H) herds in the summer (S) and winter (W), as well as 8 Jersey (J) herds in the S. Samples were placed on ice immediately. After processing, samples were stored at −20°C until analysis. On the day of sampling, total mixed ration samples were collected for subsequent analysis. Associations were tested by logistic regression, correlation analysis, and ANOVA. During S, P in the ration (% DM) averaged 0.35 ± 0.05, prepartum H; 0.45 ± 0.12, prepartum J; 0.42 ± 0.03, postpartum H; and 0.47 ± 0.07, postpartum J; and during W averaged 0.35 ± 0.05, prepartum H and 0.42 ± 0.03, postpartum H. Serum P values (mg/dl) for wk −3, −2, −1, 1, 2, and 3 relative to calving were 5.23 ± 0.09, 5.26 ± 0.19, 5.34 ± 0.10, 4.79 ± 0.12, 4.97 ± 0.12, and 5.40 ± 0.10 for S-H; 6.38 ± 0.09, 6.30 ± 0.07, 6.21 ± 0.07, 5.88 ± 0.09, 5.78 ± 0.08, 5.65 ± 0.10 for S-J; and 5.23 ± 0.12, 5.29 ± 0.20, 5.71 ± 0.1, 5.08 ± 0.13, 5.44 ± 0.11, and 5.53 ± 0.10 for W-H. The ration and serum P correlation coefficients ($P < 0.0001$) ranged from 0.14 over all weeks to a high of 0.34 for wk 3. During S, serum P concentrations were significantly associated with breed for wk −3, −2, −1, 1 and 2 ($P < 0.0001$), while lactation was significant for wk −1, wk 2, and wk 3 ($P = 0.0157$) and tended to be significant during wk −2 ($P < 0.0575$). In univariable analysis, P serum concentration appeared to be associated with days to first service (DFS) and days open (DO); however when season and dairy were added in multivariate analysis, P serum concentration was no longer significant ($P > 0.10$). When estimating the odds of pregnancy in either the first 90 (P90) or 150 (P150) d postpartum, serum P concentration was not significant in the multivariate analysis; when season and lactation were included. Serum P concentrations in the peripartum period were correlated with P intake; however, the main factors influencing the reproductive factors of DFS, DO, P90, and P150 were breed, season and lactation rather than serum P concentration.

Key Words: phosphorus, transition cow

M211 Reproductive performance of lactating dairy cows with an extended duration of the postpartum voluntary waiting period and injectable trace mineral supplementation. Matias L. Stangaferro*[1], Robert Wijma[1], Magdalena Masello[1], Rodrigo C. Bicalho[2], Mark J. Thomas[3], and Julio O. Giordano[1], *[1]Department of Animal Science, Cornell University, Ithaca, NY, [2]Department of Population Medicine and Diagnostic Sciences, Cornell University, Ithaca, NY, [3]Dairy Health and Management Services, Lowville, NY.*

Objectives were to evaluate (1) the effect of extending the duration of the voluntary waiting period (VWP) from 60 to 88 DIM; and (2) the effect of injectable trace mineral (Zn, Mn, Se, Cu) supplementation (TMS) on reproductive performance of dairy cows. Holstein cows [n = 1,105; 441 primiparous (PP) and 664 multiparous (MP)] were blocked by parity and total milk production in their previous lactation (MP only) and assigned to a 2x2 treatment arrangment to receive: TMS or NoTMS and first timed-AI (TAI) at 60 ± 3 (SVWP) or 88 ± 3 DIM (LVWP) after synchronization of ovulation with the Double-Ovsynch protocol (GnRH-7d-PGF-3d-GnRH-7d- GnRH-7d-PGF-56h-GnRH-16h-TAI) resulting in the following groups: TMS-SVWP (n = 315), NoTMS-SVWP (n = 325), TMS-LVWP (n = 228) and NoTMS-LVWP (n = 237). Cows in TMS received 3 SQ injections of 5 mL of TMS (Multimin 90®) as follows: 2 injections prepartum at 229 ± 3 and 259 ± 3 d of gestation for MP and 243 ± 3 and 263 ± 3 d of gestation for PP. A third injection was given at 20 ± 3 d before first TAI. The effect of VWP duration, TMS, parity, and their interaction on pregnancy per AI (P/AI) at 39 d after AI, pregnancy loss (PL), and cows pregnant by 90 DIM (PG90) were evaluated by logistical regression. At 39 d after AI, P/AI was greater for cows in the LVWP (47.5%) than SVWP (39.1%) group. At 39 d after AI, TMS did not affect ($P = 0.96$) P/AI (42.7% and 42.5% for TMS and NoTMS). Primiparous cows had greater ($P < 0.01$) P/AI than multiparous cows (49.0% and 38.4%). Pregnancy losses were similar ($P = 0.68$) for cows in LVWP (5.8%) and SVWP (4.7%) and for cows in TMS (5.7%) and NoTMS (4.9%). Also, PL were similar ($P = 0.13$) for PP (3.1%) and MP (7.1%) cows. No differences ($P = 0.59$) in PG90 were observed for cows in LWVP (46.2%) and SVWP (48.0%) and for cows in the TMS (48.3%) and NoTMS (46.0%) group ($P = 0.49$). Conversely PG90 was greater ($P < 0.01$) for PP (52.5%) than MP (43.7%) cows. We conclude that extending the duration of the VWP from 60 to 88 DIM improved P/AI of lactating dairy cows. Conversely, TMS supplementation during the prepartum period and 20 d before TAI did not improve fertility of lactating dairy cows.

Key Words: voluntary waiting period, trace mineral, dairy cow

M212 Resumption of ovarian cycle postpartum in dairy cows is affected by metabolic load in herbage-based feeding systems. Josef J. Gross*[1], Chiho Kawashima[2], Frigga Dohme-Meier[3], Akio Miyamoto[2], and Rupert M. Bruckmaier[1], [1]*Veterinary Physiology, Vetsuisse Faculty, Bern, Switzerland,* [2]*Obihiro University of Agriculture & Veterinary Medicine, Obihiro, Japan,* [3]*Agroscope Institute for Livestock Sciences ILS, Posieux, Switzerland.*

Due to topographic and climatic conditions, milk production in Switzerland is mainly based on herbage feeding with only little input of concentrates. This study investigated the effects of a solely herbage-based diet on production, metabolic, and endocrine parameters of dairy cows, and determined the factors affecting the resumption of ovarian cycle postpartum (pp). Twenty-three multiparous Holstein dairy cows (were divided into 2 groups according to their previous lactation yield (4679–10808 kg): a control (C, n = 13) and a treatment group (nC, n = 10) from wk 3 antepartum until wk 8 pp. While C received fresh cut herbage plus additional concentrate according to their estimated energy and nutrient requirements, no concentrate was fed to nC throughout the experiment. Milk yield and DMI were recorded daily. Blood samples were taken weekly and analyzed for IGF-1, glucose, NEFA, and BHBA. Milk progesterone (P4) concentrations were measured every 3 d in morning milk samples (skim milk) by RIA, and considered as resumption of ovarian cycle if the P4 level reached >1 ng/mL. Data were analyzed using mixed models. Plasma NEFA and BHBA concentrations pp were higher in nC (0.82, 1.18 mmol/L) compared with C (0.55, 0.63 mmol/L, $P < 0.05$). Days to resumption of ovarian cycle was similar between 2 groups (C = 29.8 d, nC = 33.3 d), thus the cows were divided into further 2 sub-groups with earlier/later than the above mean value, and categorized as earlier ovulation (E-OV; C = 22.6 d, n = 7; nC = 21.4 d, n = 6) and delayed ovulation (D-OV; C = 38.3 d, n = 6; nC = 45.2 d, n = 4). In C group, only BCS pp revealed lower in D-OV (2.81) compared with E-OV (3.21, $P < 0.05$). In nC group, however, D-OV showed lower BW (571 vs. 697 kg in E-OV) and glucose (3.5 vs. 3.6 mmol/L in E-OV + nC), higher BHBA (1.39 vs. 1.04 mmol/L in E-OV + nC) and NEFA pp (0.89 vs. 0.76 mmol/L in E-OV + nC, $P < 0.05$), suggesting an energy deficiency/stress on lipid metabolism. Other metabolic and welfare-related parameters were similar between E-OV vs. D-OV. In conclusion, in herbage-based feeding system without supplementary concentrate, dairy cows experience a higher metabolic load, which is very likely to affect resumption of ovarian cycle.

Key Words: metabolic load, ovulation, herbage feeding

M213 Blood β-hydroxybutyrate (BHBA) concentrations during the first two weeks after calving affect pregnancy establishment in postpartum dairy cows. Monica O. Caldeira*[1], Matthew C. Lucy[1], Ricardo O. Rodrigues[1], and Scott E. Poock[2], [1]*Division of Animal Sciences, University of Missouri, Columbia, MO,* [2]*College of Veterinary Medicine, University of Missouri, Columbia, MO.*

Negative energy balance (NEB) occurs in early postpartum dairy cows as a normal process when the energy demand at the onset of lactation exceeds feed energy intake. A poor response to NEB leads to greater blood concentrations of nonesterified fatty acids (NEFA) and BHBA, and also lesser blood glucose concentration. The objective was to determine whether blood BHBA and glucose concentration early postpartum affected pregnancy establishment after 3 inseminations in dairy cows. Blood samples were collected from lactating Holstein dairy cows (n = 204) twice weekly for the first 4 wk postpartum (n = 8 samples per cow). Blood BHBA and glucose were measured cowside by using a hand-held meter (Precision Xtra; Abbott Diabettes Care, Alameda, CA). Body weight (BW) and body condition score (BCS) were measured at calving, 2 wk, and 4 wk. Data were analyzed using the GLIMMIX, GLM, and MIXED procedures of SAS. The mean (SD) d postpartum of sample collection was 2.1 (1.3), 5.6 (1.5), 9.2 (1.4), 12.7 (1.6), 16.3 (1.6), 19.7 (1.6), 23.4 (1.6), and 26.8 (1.7) for samples 1 to 8. There were 171 cows with pregnancy data and 127/171 (74%) were pregnant after 3 inseminations. The blood BHBA concentration for sample 1 to 3 affected whether the cow became pregnant postpartum (lesser BHBA favorable toward pregnancy). The BHBA for non-pregnant and pregnant (respectively) was 0.91 ± 0.07 and 0.73 ± 0.04 (sample 1; $P < 0.029$), 0.92 ± 0.07 and 0.76 ± 0.04 (sample 2; $P < 0.043$) and 0.76 ± 0.04 and 0.68 ± 0.02 (sample 3; $P < 0.08$). The BHBA concentration for samples 4 to 8 did not affect pregnancy. Greater blood glucose concentration for sample 2 tended to be associated with pregnancy (51.3 ± 2.2 and 55.3 ± 1.3 for nonpregnant and pregnant; $P < 0.11$). Glucose in sample 1 and 3 to 8 were not associated with pregnancy later postpartum. BW loss and BCS loss postpartum did not affect pregnancy. In conclusion, BHBA concentrations within the first 10 d postpartum affected pregnancy outcome later postpartum.

Key Words: β-hydroxybutyrate, glucose, reproduction

M214 Effects of prepartum diets supplemented with oilseeds on reproductive performance in dairy cows. R. Salehi*[1], M. G. Colazo[2], M. Oba[1], and D. J. Ambrose[1,2], [1]*University of Alberta, Edmonton, Alberta, Canada,* [2]*Alberta Agriculture and Rural Development, Edmonton, Alberta, Canada.*

We investigated the effects of dietary fat supplementation (oilseed vs. no-oilseed) and type of oilseed (sunflower vs. canola) during late gestation on postpartum (pp) reproductive performance. Pregnant Holsteins were, blocked by BCS and parity, assigned to 1 of 3 diets containing 8% DM rolled sunflower (SUN; n = 45) or canola seed (CAN; n = 43), or no oilseed (CON; n = 43), for the last 35 d of gestation and then a common lactation diet pp. Ovaries were scanned 2x/wk until 35 DIM in 95 cows to record first appearance of 10 (DF) and 16 mm (PreOVF) follicles, and ovulation. Blood samples were collected strategically to evaluate NEFA, BHBA and glucose, and endometrial cytology performed at 25 ± 1 d pp (n = 12/diet). Data were analyzed using the Mixed procedure of SAS. Multiparous CON cows consumed more DM (19.5 ± 0.2) than those fed oilseed (18.0 ± 0.2 kg) during pre- and pp, until wk+3 pp. Cows fed SUN consumed more than those fed CAN (23.5 ± 0.2 vs 22.5 ± 0.3 kg) pp from wk+2 to wk+5. Cows fed oilseed had higher NEFA (mEq/mL) than CON at wk-3 (108.0 ± 10.3 vs. 70.8 ± 10.3), wk+1 (388.7 ± 56.2

vs. 271.0 ± 56.2), and wk+4 (242.0 ± 36.6 vs. 163.5 ± 36.6), but pre and pp energy balance (EB) did not differ (8.1 ± 1.6 Mcal). Prepartum diets did not affect BHBA (12.1 ± 1.6 mg/dL) and glucose (54.5 ± 2.9 mg/dL) pre or pp. Prepartum oilseed and type of oilseed supplemented neither altered the intervals (d) from calving to DF (9.4 ± 0.5), PreOVF (14.7 ± 0.8), or ovulation (21.4 ± 1.5), nor conception rate to first AI (27.2%) and cumulative pregnancy rate (67.3%) up to 5 AI. The interval to DF was correlated with % of polymorphonuclear cells (PMN; R: 0.38), DMI (R: −0.28) and glucose (R: −0.32) on wk+2. Interval to PreOVF was determined by % of PMN (R: 0.38) and DMI on wk −4 (R:-0.27), −3 (R:-0.27), −2 (R:-0.33),-1 (R:-0.38), +1 (R:-0.38), +2 (R:-0.45) and +3 (R:-0.39). None of the metabolites, glucose, EB, DMI or PMN affected interval to ovulation, although the latter was associated with interval to PreOVF (R: 0.41). In summary, feeding oilseeds prepartum, particularly canola, reduced DMI and increased NEFA without affecting reproductive performance.

Key Words: endometrial cytology, oilseed, ovarian function

M215 Distribution of fatty acids in reproductive tissues of cows fed flax-, canola-, or sunflower seed-based rations. Patricia A. Dutra[1,2], Mohanathas Gobikrushanth*[2], Reza Salehi[2], Marcos G. Colazo[3], and Divakar J. Ambrose[2,3], *[1]Departamento de Zootecnia, Universidade Federal da Bahia, Salvador, Bahia, Brazil, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada, [3]Livestock Research Branch, Alberta Agriculture and Rural Development, Edmonton, Alberta, Canada.*

Essential fatty acids (FA) like linoleic (C18:2) and α-linolenic (C18:3) acids play key roles in reproductive function. The objective of this study was to determine the distribution of fatty acids in the reproductive tissues of cows fed 3 different lipid diets. Nonlactating Holstein cows were randomly assigned to receive one of the 3 diets supplemented with rolled oilseeds: canola (CAN = 5), sunflower (SUN = 5), or flax (FLX = 5) at 8%DM. After cows had been on the experimental diets for at least 60 d, they were superovulated, inseminated and slaughtered 14 d after insemination. While embryos were used in another study, tissue samples of the uterus, oviduct and corpus luteum (CL) were collected and kept frozen until analyzed for FA. Fats from the reproductive tissues were extracted and methylated using indirect methylation method, and FA profiles in each tissue type were determined by gas chromatography. Primarily, the effects of diet, type of tissue, and their interactions on FA of our interest [oleic (C18:1), C18:2, C18:3, eicosapentaenoic (C20:5) and docosahexaenoic (C22:6)] were evaluated using Mixed procedure of SAS. As the interactions between diet and type of tissue were not significant, FA concentration was finally modeled against effects of diet and type of tissue. Diet did not affect FA concentrations. Except for oleic acid ($P = 0.07$), all of the other aforementioned FA differed ($P < 0.05$) among tissue types. The concentrations (mg/50mg tissue) of C18:2, C18:3 and C20:5, respectively, were higher in CL (0.282, 0.020 and 0.019) than in uterus (0.075, 0.004 and 0.008) and oviduct (0.037, 0.003 and 0.001). However, the concentration of C22:6 was higher in uterus than oviduct or CL (0.008 vs. 0.005 or 0.004). In addition, the amount of total FA, saturated FA, polyunsaturated FA, n-3 and n-6 FA were significantly higher in CL than uterus or oviduct. Results indicate that CL accumulates most of the FA of our interest than the uterus or oviduct, whereas C22:6 was more concentrated in the uterus. The biological reasons for this differential accumulation of FA among reproductive tissues need further investigation.

Key Words: fatty acid, reproductive tissue, diet

M216 Fatty acid profile in follicular fluid and serum of dairy cows fed diets supplemented with rolled canola, sunflower or flax seed. Patricia A. Dutra[1,2], Mohanathas Gobikrushanth*[2], Reza Salehi[2], Marcos G. Colazo[3], and Divakar J. Ambrose[3,2], *[1]Departamento de Zootecnia, Universidade Federal da Bahia, Salvador, Bahia, Brazil, [2]Department of Agricultural, Food and Nutritional Science, University of Alberta, Edmonton, Alberta, Canada, [3]Livestock Research Branch, Alberta Agriculture and Rural Development, Edmonton, Alberta, Canada.*

Polyunsaturated fatty acids such as n-3 and n-6 are known to influence reproductive performance of dairy cows. The objective of this study was to determine fatty acid (FA) profile in serum and follicular fluid of cows fed 3 different lipid diets as well as to determine the association between serum and follicular fluid in terms of FA concentrations. Nine nonlactating Holstein cows were randomly assigned to receive 1 of 3 diets supplemented with rolled oil seeds: canola (CAN = 3), sunflower (SUN = 3) or flax (FLX = 3) at 8%DM. After cows received their respective diets for at least 60 d, they were superovulated, inseminated and slaughtered 14 d after insemination. The experimental diets continued until 12 h before slaughter. Embryos and reproductive tissues collected were used in another study. Blood samples were collected on the day of insemination, and follicular fluid was collected from large ovarian follicles within 4 h of slaughter. Serum and follicular fluid were kept frozen until analyzed for FA concentrations. Fats from the follicular fluid and serum were extracted, methylated and FA profiles were determined by gas chromatography. Data were analyzed using the MIXED and CORR procedures of SAS. In follicular fluid, cows fed SUN had higher concentrations (mg/mL) of linoleic acid (0.60 vs. 0.30, 0.32) and total n-6 FAs (0.62 vs. 0.31, 0.33) and higher n-6/n-3 ratio (9.25 vs. 2.09, 3.84) than those fed either FLX or CAN. Similarly, cows fed FLX had higher concentrations of α-linolenic acid (C18:3; 0.14 vs. 0.08, 0.06), total n-3 FAs (0.16 vs. 0.09, 0.07) and higher n-3/n-6 ratio (0.49 vs. 0.10, 0.11) in follicular fluid than those fed either CAN or SUN. None of the FA other than γ-linolenic acid, in FLX cows, was altered by diet in serum. No significant correlations were observed between follicular fluid and serum FA profiles. Although diets supplemented with oilseeds selectively altered FA concentrations in follicular fluid, none of the major FA of relevance to reproductive function was altered in serum.

Key Words: fatty acid, follicular fluid, serum

M217 Effects of rumen-protected methionine and choline supplementation on gene expression of follicular cells of the first postpartum dominant follicle. Diego A. Velasco Acosta*[1,2], Ines M. Rivelli[2], Cassandra Skenandore[2], Daniel Luchini[3], Marcio Corrêa[1], and Felipe Cardoso[2], *[1]Universidade Federal de Pelotas, Pelotas, Rio Grande do Sul, Brazil, [2]University of Illinois, Urbana, IL, [3]Adisseo NA, Alpharetta, GA.*

This study aimed to determine the effects of rumen-protected methionine and choline supplementation during the transition period on mRNA expression of follicular cells of the 1st postpartum dominant follicle in Holstein cows. Multiparous cows were assigned in a randomized complete block design into 4 treatments from 21 d before calving to 30 DIM. Treatments were: CON (n = 10, fed the close-up and fresh cow diets with a Lys:Met = 3.5:1), MET (n = 9, fed the basal diet + methionine, Smartamine M to a Lys:Met = 2.9:1), CHO (n = 9, fed the basal diets + choline 60 g/d, Reashure), and MIX (n = 12, fed the basal diets plus Smartamine M to a Lys:Met = 2.9:1 and 60 g/d Reashure). Follicular development was monitored via ultrasound every 2 d starting at 7 DIM until the first dominant follicle reached a diameter of 16 mm. Follicular fluid from each cow was aspirated and cells were retrieved immediately by centrifugation and stored at −80°C until RNA extraction. Statistical analysis was performed using the MIXED procedure of SAS. Gene expression of *LHCGR, STAR, 3β-HSD, P450scc, P450c17, CYP19A1, IRS1, IGF, MAT1A, SAHH, TLR4, TNF, IL1-β, IL8* and *IL6* was measured by real-time PCR. Treatments did not affect mRNA expression of *LHCGR*, *STAR*, *P450scc*, *CYP19A*, *SAHH*, *MAT1A* and *IL6* ($P > 0.05$) however, *3β-HSD* expression was higher ($P < 0.05$) for MET (1.46 ± 0.3) and MIX (1.25 ± 0.3) than CON (0.17 ± 0.04) and CHO (0.26 ± 0.1). For *TNF, TLR4* and *IL1-B* mRNA expression was higher ($P < 0.05$) for CON (11.70 ± 4.6, 21.29 ± 10.4, 6.28 ± 1.4) than CHO (2.77 ± 0.9, 2.16 ± 0.9, 2.29 ± 0.7) and MIX (2.23 ± 0.7, 1.46 ± 0.6, 2.92 ± 0.8). There was higher ($P < 0.05$) *IL1*-β expression and a tendency ($P = 0.07$) for higher TNF expression in CON (6.27 ± 1.4, 11.70 ± 4.6) than MET (3.28 ± 0.6, 3.06 ± 0.8). There was no difference ($P = 0.43$) between CON and MET for *TLR4*. Expression of IL8 mRNA was lower ($P < 0.05$) for CHO (0.98 ± 0.3) than CON (4.90 ± 0.7), MET (6.10 ± 1.7) and MIX (5.05 ± 1.8). In conclusion, supplementing Smartamine M and Reashure during the transition period changed mRNA expression in follicular cells of the 1st postpartum dominant follicle in Holstein cows.

Key Words: methionine, choline, gene expression

M218 Effect of yeast culture plus enzymatically hydrolyzed yeast supplementation starting prepartum on acute phase protein profiles and reproductive performance in dairy cows. Vanessa Oliveira Freitas[1], Claudia Faccio Demarco[1], Tatiele Mumbach[1], Eduardo Gularte Xavier[2], Raquel Fraga Silva Raimondo[3], Fernanda Medeiros Gonçalves[1], Francisco Augusto Burkert Del Pino[1], Viviane Rohrig Rabassa[1], Sangita Jalukar[4], Marcio Nunes Corrêa[1], and Cassio Cassal Brauner*[1], [1]*Universidade Federal de Pelotas, NUPEEC, Pelotas, RS, Brazil,* [2]*Granjas 4 Irmãos S/A, Rio Grande, RS, Brazil,* [3]*Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil,* [4]*Arm & Hammer Animal Nutrition, Princeton, NJ.*

The aim of this study was to evaluate the effect of yeast culture plus enzymatically hydrolyzed yeast supplementation starting prepartum on acute phase protein profile and reproductive performance in dairy cows. Twenty 9 multiparous Holstein cows were blocked by milk production on the previous lactation and randomly assigned into 2 groups which consisted in one (n = 15) receiving 28 g/d top-dressed yeast culture plus enzymatically hydrolyzed yeast (YC-EHY; Celmanax, Arm & Hammer Animal Nutrition, Princeton, NJ), while the control group (n = 14) did not receive the supplement. The experimental period lasted from d −35 relative to calving to 150 d postpartum. Plasma samples collected on −21, −14, −7, 0, 3, 7, 14, 21, 28, 35, and 42 d relative to calving were analyzed for acute phase proteins (haptoglobin, paraoxonase and albumin). To assess estrous cyclicity resumption, blood samples were collected weekly from 14 to 35 d after calving to evaluate the concentration of progesterone. Reproductive performance was also monitored until 150 d after calving. Data were analyzed using mixed models with repeated measures over time. Interval from calving to conception was analyzed using Kaplan-Meier survival curves. The YC-EHY group had lower ($P = 0.04$) interval from calving to conception than control group respectively, 95.35 ± 10.78 vs.130.73 ± 10.35 d. The interval from calving to the first ovulation were similar ($P = 0.18$) between groups, 23,33 ± 2,8 d vs. 29,16 ± 2,8 d, respectively for YC-EHY and control groups. The YC-EHY tended ($P = 0.07$) to have lower activity of paraoxonase during the postpartum period (112.54 ± 3.49 U/L vs. 106.39 ± 3.60 U/L) than the control group. No differences ($P > 0.05$) were observed in albumin and haptoglobin concentrations during the transition period. In conclusion, dairy cows supplemented since prepartum with yeast culture plus enzymatically hydrolyzed yeast, had lower interval from calving to conception, without affect calving to first ovulation interval and tend to have lower activity of paraoxonase during the postpartum period.

Key Words: nutrition, reproduction, supplement

M219 Nutritional level of the recipient ewe, but not of the donor, determines the embryo fate when good quality embryos are transferred. Victoria de Brun*[1], Ana Meikle[1], Fernando Forcada[2], Inmaculada Palacín[2], Cecilia Sosa[3], and José Alfonso Abecia[2], [1]*Laboratorio de Técnicas Nucleares, Montevideo, Uruguay,* [2]*Departamento de Producción Animal y Ciencia de los Alimentos, Zaragoza, Spain,* [3]*Departamento de Anatomía Patológica, Medicina Legal y Forense y Toxicología, Zaragoza, Spain.*

We aimed to isolate effects of undernutrition on the embryo or the mother and whether or not the endocrine signals differ from ewes that presented late embryo mortality. Forty-five donors and 52 recipient Rasa Aragonesa ewes were fed 1.5 (control group; donor n = 20; recipient n = 25) or 0.5 (low group; donor n = 25; recipient n = 27) times the daily requirements for maintenance. These regimens were maintained up to day of embryo collection and transfer. Embryos were collected 7 d after the onset of estrus, and 2 good quality embryos per ewe were transferred into recipient ewes. Blood samples were collected at days −14, −1, 7 and 18. Pregnancy and late embryonic mortality were analyzed using the GENMOD procedure, and hormone and metabolite concentrations using a MIXED model in SAS. Nutritional treatment of donor did not affect fertility. Pregnancy evaluated by ultrasound on d 40 did not differ between control and undernourished ewes (72% vs. 55%, $P = 0.17$). Embryonic mortality between d 18 and 40 tended to be greater in undernourished than in control recipient ewes (35% vs. 14%, $P = 0.11$). Undernourished ewes had reduced live weight and body condition score ($P < 0.01$), and increased concentration of nonesterified fatty acid ($P < 0.05$). Pregnancy rates at d 18 and 40 were similar between groups, but recipient undernourished ewes presented a greater late embryonic mortality (d 18 to 40) than control ewes ($P = 0.11$). Pregnant ewes had greater ovulation rate than nonpregnant ewes ($P = 0.02$). In recipient ewes, pregnant undernourished presented greater P4 concentrations than pregnant control ($P < 0.05$) and nonpregnant underfed ewes ($P < 0.05$). Recipient undernourished ewes that suffered late embryo mortality (d 18 to 40) presented or tended to present lower insulin and progesterone concentrations than low pregnant ewes ($P = 0.05$ and $P = 0.07$, respectively). In conclusion, the failure in reproductive performances in underfed ewes transferred good quality embryos is caused principally by maternal factors, so a suitable maternal environment is crucial to ensure a normal embryo growth. In addition, the endocrine profiles such as progesterone during early luteal phase and insulin are associated with pregnancy outcome.

Key Words: sheep, undernutrition, embryo

M220 Evaluation of the hypothalamic kisspeptin system during the attainment of puberty in gilts. Eric S. Jolitz*[1], Waljit S. Dhillo[2], and Jeffrey A. Clapper[1], [1]*South Dakota State University, Brookings, SD,* [2]*Imperial College, London, UK.*

It has been demonstrated that circulating kisspeptin is increased during the attainment of puberty in humans. To determine if hypothalamic (MBH) expression of kisspeptin (Kiss1), anterior pituitary (AP) expression of GnRH receptor (GnRHr) and LH-β, and MBH and AP kisspeptin content increase at pubertal onset in the gilt, the following experiment was performed. Twenty-four crossbred gilts of similar age (150 d) and weight (102.7 ± 0.3 kg) were relocated and exposed to a mature boar for estrus detection on d 1 and continuing for 6 d. Gilts that stood immobile within 24 h of slaughter (d 6) were considered to have attained puberty. Plasma samples were collected on d 1, 3, and 6. All gilts were slaughtered on d 6 when MBH, AP, and blood were collected. Relative expression of MBH Kiss1 and β-actin and AP GnRHr, LH-β, and β-actin was determined using real-time reverse transcriptase PCR. Fold changes in relative expression were determined using the Relative Expression software tool. Relative expression is based on the expression ratio of a target gene versus a reference gene. The expression ratio results of the transcripts were tested for significance by a pair-wise fixed reallocation randomized test with day compared as independent time effects. Hypothalamic and AP content of kisspeptin were determined by RIA and differences were determined using the MIXED procedure of SAS. Relative expression of Kiss1 was increased ($P = 0.005$) 2.2 fold in the gilts that had attained puberty. Relative expression of GnRHr did not differ ($P > 0.05$) in gilts that had attained puberty versus those that did not. Relative expression of LH-β tended to be decreased ($P = 0.09$) 0.80 fold in gilts that had attained puberty. AP concentrations of kisspeptin were not different ($P > 0.05$) between treatments. Kisspeptin content in the MBH was increased ($P = 0.03$) in gilts that attained puberty (0.72 ± 0.14 ng/μg protein) compared with gilts that did not (0.44 ± 0.05 ng/μg protein). These data provide preliminary evidence that hypothalamic expression of Kiss1 and content of kisspeptin are increased during the attainment of puberty in the pig, which may modulate the release of GnRH.

Key Words: kisspeptin, hypothalamus, pig

M221 Ovine maternal nutrient restriction from mid to late gestation induces steroid metabolizing enzyme activity in maternal and fetal reproductive and liver tissues.

Megan P. T. Coleson*[1], Christa L. Gilfeather[1], Kimberly A. Vonnahme[2], and Caleb O. Lemley[1], [1]*Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State, MS,* [2]*Department of Animal Sciences, North Dakota State University, Fargo, ND.*

The objective was to determine the effects of nutrient restriction on steroid metabolizing enzymes within maternal, placental, and fetal tissues. Singleton pregnant ewe lambs (n = 30) were allocated to receive either 100% [adequate (ADQ; n = 14)] or 60% [restricted (RES; n = 16)] of nutrient requirements from d 50 until d 130 of gestation. At slaughter both maternal and fetal livers and maternal (caruncle; CAR) and fetal (cotyledon; COT) placentas were collected for analysis. Activity of cytochrome P450 2C (CYP2C), cytochrome P450 1A (CYP1A), and cytochrome P450 3A (CYP3A), were determined using specific luminogenic substrates. Activities were expressed relative to mg of protein, total tissue weight, or BW. Data were analyzed using MIXED procedure of SAS and the model statement included nutritional plane. Activity of CYP2C was not detected in CAR or COT tissues. Activity of CYP1A and CYP3A were not different in CAR tissue between the 2 treatments. Activity of CYP1A relative to BW was increased ($P = 0.03$) in COT tissue of RES ewes compared with ADQ fed; however, CYP3A activity in COT was not different between treatments. Maternal liver activity of CYP2C was decreased ($P < 0.01$) in RES ewes compared with ADQ; however, activity of CYP1A (relative to mg of protein), and CYP3A (relative to mg of protein or maternal BW) were increased ($P \leq 0.05$) in RES ewes compared with ADQ. Fetal liver activity of CYP1A (relative to liver weight or fetal BW), CYP2C (relative to liver weight), and CYP3A (relative to mg of protein, liver weight, or fetal BW) were decreased ($P < 0.05$) in RES ewes compared with ADQ. In conclusion, maternal nutrient restriction increased activity of CYP1A and CYP3A in maternal liver, but decreased the activity of CYP1A and CYP3A in fetal liver. A similar downregulation of CYP2C activity was observed in both maternal and fetal liver. The differential regulation of hepatic cytochrome P450 in maternal and fetal tissues may influence peripheral steroid concentrations during late pregnancy and deserves future investigation.

Key Words: cytochrome P450, nutrient restriction, steroid

M222 Effects of maternal nutrient restriction on bovine placentome and miRNA expression during mid-gestation.

Regina K. Taylor*, Kayla S. Mangrum, Christopher T. LeMaster, Scott L. Pratt, and Nathan M. Long, *Clemson University, Clemson, South Carolina.*

Primiparous Angus-cross cows (n = 22) were synchronized and AIed with sexed semen from a single Angus sire. Animals were fed at 1.3× (Control [CON]) or 0.55× (Nutrient Restricted [NR]) of maintenance energy and protein requirements based on BW (NRC 1996). Animals were blocked by BCS and BW and assigned to 1 of 3 treatments: CON; (n = 8) d 30–190; NR/CON; (n = 7) NR d 30–110 then CON d 110–190; or CON/NR; (n = 7) CON d 30–110 then NR d 110–190. Cows were killed on d 190 of gestation, and the fetus and placenta collected. Isolation of RNA was performed from flash frozen cotyledon samples (3 subsamples/treatment) using the *mir*Vana microRNA Isolation kit and analyzed using a previously validated microarray. Placentome measures and microRNA expression was analyzed as an ANOVA analysis using appropriate procedures correcting for false discovery rate of microarray data. Total placentome weight and total caruncular weight tended to be decreased ($P = 0.056$, $P = 0.07$, respectively) in NR/CON animals vs. CON/NR and CON/CON. Total cotyledonary weight was increased ($P = 0.017$) in CON/NR animals vs. NR/CON and CON/CON. Ratio of cotyledon weight:caruncle weight was increased ($P = 0.02$) in NR/CON and CON/NR vs. CON/CON animals. Total placentome surface area tended to be increased ($P = 0.09$) in CON/NR animals vs. NR/CON and CON/NR. Cotyledons from CON had mdo-miR-195 upregulated ($P < 0.01$) and 8 downregulated ($P < 0.01$) miRNAs, including mmu-mir-5105-p3 and bta-miR-2484 vs. NR/CON and CON/NR cotyledons. Cotyledons from NR/CON had mmu-mir-5117-p3_1ss19TA and bta-miR-99b upregulated ($P < 0.01$) and mmu-mir-5105-p3_1ss24TC and bta-miR29a downregulated ($P < 0.01$) vs. CON/NR and CON cotyledons. Cotyledons from CON/NR had 11 upregulated ($P < 0.01$) miRNAs including bta-miR29a and bta-miR2484, and mdo-miR-195 and bta-miR-99b downregulated ($P < 0.01$) vs. CON and NR/CON cotyledons. The data show that maternal nutrient restriction during early or mid gestation causes asymmetrical fetal growth restriction and affects miRNA regulation differently depending on if the restriction is preceded or followed by a non-restriction period.

Key Words: fetal growth, undernutrition, fetal programming

M223 Maternal overnutrition/obesity (MO) in the ewe has multigenerational metabolic programming effects on adult granddaughters (F_2).

Megan A. Walton*, John F. Odhiambo, Peter W. Nathanielsz, and Stephen P. Ford, *Department of Animal Science, University of Wyoming, Laramie, WY.*

We have reported on a model in which MO ewes are fed 150% of NRC recommendations from 60 d before conception to term or fed only to requirements (CON). Offspring (F1) of MO ewes exhibit hyperphagia, increased weight gain and adiposity, and insulin resistance in response to an ad libitum feeding challenge when compared with CONF1 (J. Anim. Sci. 2010. 88:3546). We recently reported that male grandsons (MOF2) also experience a significant increase in body mass and insulin resistance in response to a similar bout of ad libitum feeding as 2-year-old adults, demonstrating a multigenerational effect of MO grandmothers on their grandsons. To evaluate potential offspring sex differences, we studied the multigenerational impact of MO on the response of 2-year-old adult female F2 to a 12-week ad libitum feeding challenge, MOF2 (n = 6) or CONF2 (n = 6). A dual x-ray absorptiometry (DEXA) scan was performed before and after the feeding challenge to determine changes in % body fat and % lean. Body weights and plasma samples were obtained bi-weekly. Glucose was evaluated via a colorimetric assay and insulin was analyzed via a validated RIA. Data (M ± SEM) were analyzed using the mixed procedure in SAS. No differences in body weight, % body fat or % lean were observed for CONF2 and MOF2 females either before or after the feeding trial. By the end of the feeding trial, body weight and % body fat were markedly increased ($P < 0.05$) in both groups. Plasma glucose was greater ($P < 0.05$) in MOF2 than CONF2 females, while plasma insulin tended to be greater ($P < 0.06$) in MOF2 than CONF2 females throughout the trial, resulting in a markedly elevated ($P < 0.01$) HOMA-IR in MOF2 vs. CONF2 females (7.8 ± 0.7 vs. 5.0 ± 0.7, respectively) demonstrating severe IR in MOF2. These data demonstrate that as previously reported for male OBF2, an ad libitum feeding challenge during adulthood induced marked insulin resistance in female OBF2. In contrast to the male OBF2, however, this elevated insulin resistance developed in the total absence of any increase in weight gain over that of female CONF2 in response to ad libitum feeding.

Key Words: programming

M224 Effect of prepartum dam supplementation, creep-feeding and post-weaning diet on age at puberty in Nellore heifers.

Marcos V. C. Ferraz Junior*[1], Delci D. Nepomuceno[2,1], Marcos V. Biehl[2], Alexandre V. Pires[2,1], Marcelo H. Santos[1], Renan G. Silva[1], Vinicius N. Gouvea[1], Jose R. S. Gonçalves[3], Thiago S. Andrade[1], and Michael L. Day[4], [1]*University of São Paulo, Pirassununga, São Paulo, Brazil,* [2]*University of São Paulo, Piracicaba, São Paulo, Brazil,* [3]*Experimental Station Hildegard Georgina Von Pritzelwitz, Londrina, Paraná, Brazil,* [4]*The Ohio State University, Columbus, OH.*

The objective of this study was to evaluate the effect of various nutritional strategies on age at puberty in Nellore heifers. Nellore cows (n = 237 / BW 432 ± 50 kg / BCS 2.85 ± 0.4; 1 to 5 scale) were used in randomized design with a 2 × 2 x 2 factorial arrangement of treatments. Factors were as follows: factor 1 = prepartum supplementation with protein (PPS; n = 122; 0.5 kg soybean meal/cow daily) during the last trimester of gestation or no supplementation (NPPS; n = 115); factor 2 = provision of creep-feed to calves for 95 d before weaning (CF; n = 117) or no creep-feeding (NCF; n = 120; 22% CP and 72% TDN); and factor 3 = fed post-weaning from 7 to 14 mo of age in a feedlot (PWF; n = 117; 15% CP and 56% TDN) or no feedlot (NPWF; n = 120; *Brachiaria* pasture). After 14 mo of age, heifers were maintained in *Brachiaria* ssp. pastures. Heifers were weighed and reproductive status assessed by ovarian US (detection of presence of CL) monthly from 12 to 30 mo old. The proportion of heifers that had attained puberty by 14, 18, 26 and 30 mo of age, and BW at puberty were assessed using PROC MIXED and GLIMMIX. At weaning (220.1 ± 2.0), cow supplementation did not affect BW of heifer calves (168.2 ± 0.4 vs. 170.5 ± 0.5 kg for PPS and NPPS cows, respectively), but BW at weaning were greater ($P = 0.01$) in the CF (172.7 ± 1.4) than NCF (165.8 ± 1.4 kg) treatment. At the end of the post weaning period (Factor 3) BW were greater ($P < 0.01$) in the PWF (234.1 ± 2.2) than NPWF (187.2 ± 2.1) treatment and this difference was maintained through 18 mo of age. Proportions of heifers that attained puberty at 14 (7.1%), 18 (22.3%), 26 (70.0%) and 30 (93.2%) mo of age were not influenced by cow supplementation or creep feed. However, the post-weaning feedlot treatment (PWF) increased the proportion of heifers that reached puberty at 14 (13.7 vs. 0.9%; $P < 0.01$) and 18 (31.7 vs. 13.3%; $P < 0.01$) mo of age and tended ($P = 0.10$) to anticipate puberty at 26 mo of age (73.8 vs. 66.1%; PWS and NPWS, respectively). In conclusion, enhanced nutrition during the post weaning period increased the proportion of heifers that reached puberty between 14 and 26 mo of age and is an effective method to anticipate puberty.

Key Words: puberty, Nellore, supplemental management

M225 Effect of prepartum dam supplementation and creep-feeding on age at puberty in Nellore heifers.

Elizangela M. Moreira[1], Alexandre V. Pires[2,1], Delci D. Nepomuceno[2], Marcos V. C. Ferraz Junior*[1], Jose A. Faleiro Neto[1], Marcos V. Biehl[2], Jose R. S. Goncalves[3], Renan G. Silva[1], Marcelo H. Santos[1], Vinicius N. Gouvea[1], and Michael L. Day[4], [1]*University of São Paulo, Pirassununga, São Paulo, Brazil,* [2]*University of São Paulo, Piracicaba, São Paulo, Brazil,* [3]*Experimental Station Hildegard Georgina Von Pritzelwitz, Londrina, Paraná, Brazil,* [4]*The Ohio State University, Columbus, OH.*

The objective of this study was to evaluate the effect of 2 nutritional strategies on age at puberty in Nellore heifers. Nellore cows were allocated to treatments by BW (438 ± 48 kg) and BCS (3.0 ± 0.5; 1 to 5 scale). The factorial experimental design (2 × 2) included 2 phases of supplementation: phase 1 – prepartum supplementation with protein (PPS; n = 73; 0.5 kg soybean meal/cow daily) during the last trimester of gestation or no supplementation (NPPS; n = 81); phase 2 – provision of creep-feed (creep diet was 22% CP, and 62% TDN) to calves for 118 d before weaning (CF; n = 78) or no creep-feeding (NCF; n = 75). After 7 mo of age (weaning), heifers were maintained in *Brachiaria* ssp. pastures. Heifers were weighed and reproductive status assessed by ovarian ultrasonography (detection of presence of CL) monthly from 14 to 30 mo old. The proportion of heifers that had attained puberty by 18, 26 and 30 mo of age, and BW were assessed using PROC MIXED and PROC GLIMMIX (differences with $P < 0.05$ considered significant). At weaning (6.4 mo), cow supplementation in last trimester of gestation did not affect BW of heifer calves (183 ± 1.9 vs. 184 ± 1.9 kg, $P = 0.98$ for PPS and NPPS cows, respectively). Creep feeding supplementation also did not influence BW at weaning (184 ± 1.9 vs. 183 ± 1.9 kg, $P = 0.78$ for CF and NCF, respectively). Prepartum supplementation did not change the proportion of heifers pubertal at 18 mo (4.1 vs. 6.2%, $P = 0.53$), 26 mo (18.5 vs. 16.4%, $P = 0.57$) and 30 mo (82.2 vs. 76.2%, $P = 0.36$ for PPS and NPPS, respectively) of age. Supplementation of suckled calves by Creep Feeding also did not change the proportion of heifers pubertal at 18 mo (3.8 vs. 6.7%, $P = 0.43$), 26 mo (15.8 vs. 19.1%, $P = 0.77$) and 30 mo (80.7 vs. 77.3%, $P = 0.59$ to CF and NCF, respectively) of age. In conclusion, neither the cow supplementation nor creep feeding used in the present study anticipated puberty in Nellore heifers.

Key Words: puberty, Nellore, supplemental management

M226 Effect of energy supplementation on plasmatic concentration of leptin in pre-pubertal beef heifers.

Maria Carolina V. Miguel*[1], Siobhan W. Walsh[2], Heni F. Costa[1], Juliana S. Souza[1], Rafael S. Cipriano[1], David Giraldo-Arana[1], Marcos Antônio Maioli[1], Devani M. Pinheiro[1], Alexander C. Evans[2], and Guilherme P. Nogueira[1], [1]*São Paulo State University, Araçatuba, SP, Brazil,* [2]*University College Dublin, Dublin, Ireland.*

The objective was to evaluate nutritional influence on plasma leptin concentration in prepubertal Nellore heifers. Sixteen calves at birth were assigned to 2 groups:1) calves received a concentrate of ground corn (2% of BW; Treated; n = 8); and, 2) calves received mineral salt without supplementation (Control; n = 8), calves from both groups had access to the cow's diet. After weaning (5 mo of age), both groups received sugar cane bagasse, citrus pulp and concentrate, but the Treated group also received a 2% of BW ground corn supplement until first ovulation or 22 mo of age. Heifers were weighed weekly to calculate monthly weight gain and blood samples were collected twice a week. Leptin was quantified with a RIA kit; the intra-assay CV were 7.64% for high (6.84 ng/mL) and 2.09% for low controls (0.58 ng/mL); the inter-assay CV were 21% for high and 12% for low controls, and assay sensitivity was 0,229 ng/mL. Data were analyzed by ANOVA with the Mixed procedure of SAS for repeated measures. The weight gain from weaning to puberty was 19.5 ± 0.03 kg/month for Treated and 13.2 ± 0.03 kg/month for Control heifers. The first ovulation occurred when the Treated heifers (n = 5) weighed 398.2 ± 10.6 kg (17.8 ± 1.1 mo) and the Control heifers (n = 1) 361kg (20.1 mo). After the 7th month of age there was a difference ($P < 0.0001$) in monthly weight between treatments. In both treatments, plasma leptin increased according to age ($P < 0.0001$). Plasma leptin concentration was greater ($P = 0.023$) in Treated compared with Control heifers at 13, 14, 16 and 17 mo of age, averaging, respectively, 5.67 ± 0.53 vs. 4.04 ± 0.53 ng/mL, 5.79 ± 0.53 vs. 4.34 ± 0.53 ng/mL, 7.12 ± 0.53 vs 5.21 ± 0.53 ng/mL and 6.74 ± 0.67 vs. 5.11 ± 0.53 ng/mL. The greatest weight gain in Treated heifers was observed close to first ovulation. The greatest plasma leptin concentration in Treated heifers was at the 16th month of age. Thus, supplementing heifers with corn hastened age at first ovulation, which is likely mediated by increased weight gain and leptin concentrations ($r = 0.96$; $P < 0.0001$), permissive factors that influence GnRH/LH secretion.

Key Words: *Bos indicus*, heifer, feed supplementation

M227 Form of selenium in free-choice mineral mixes affects ovarian production of progesterone but not estradiol in cycling beef cows.

Phillip J. Bridges*[1], Katheryn L. Cerny[1], Michelle Rhoads[2], Leslie H. Anderson[1], Walter R. Burris[1], and James C. Matthews[1], *[1]University of Kentucky, Lexington, KY, [2]Virginia Polytechnic Institute and State University, Blacksburg, VA.*

Selenium (Se) affects gonadal function, and the form of Se provided to cows affects tissue-specific gene expression. The objective of this study was therefore to determine whether the form of Se consumed by cows would affect follicular growth and the production of ovarian steroids. Pasture-fed Angus crossbred cows were randomly assigned to have ad libitum access to free-choice vitamin-mineral mixes containing Se (35 ppm) in either (TRT) inorganic (ISe, n = 41), organic (OSe, n = 42), or a 50/50 mix of ISe and OSe (MIX, n = 44) forms for 175 d. A subset of these cows (n = 9–11 per TRT) with a detectable corpus luteum were maintained on TRT and administered 25 mg PGF$_{2\alpha}$ to induce luteal regression, then assigned for further sampling on estrus (Day 0). Between Day 4 and 8, follicular diameter was determined by ultrasonography. On Day 6, cows were treated with 20 mg then 15 mg PGF$_{2\alpha}$, 8 to 12 h apart, to induce luteal regression and differentiation of the first-wave dominant follicle into a preovulatory follicle. On Day 8, 36 h after PGF$_{2\alpha}$, the contents of the preovulatory follicle were aspirated by ultrasound-guided follicular puncture. Progesterone and estradiol were determined in plasma collected on Day 6 and 8, and in follicular fluid collected on Day 8. TRT effects were assessed by ANOVA and Fisher's LSD. TRT affected ($P < 0.02$, OSe > MIX) total blood Se (OSe: 156 ± 5, ISe: 146 ± 4, MIX: 140 ± 6 µg/mL). TRT affected ($P < 0.04$, MIX > ISe) systemic progesterone on Day 6 (MIX: 5.1 ± 0.6, OSe: 4.6 ± 0.5, ISe: 3.4 ± 0.2 ng/mL) but not Day 8. TRT did not affect systemic estradiol on Day 6 or 8. TRT tended ($P = 0.07$, OSe > MIX, ISe) to affect follicular fluid progesterone (OSe: 58.9 ± 11.5, MIX: 44.4 ± 3.8, ISe: 30.5 ± 8.1 ng/mL) but not estradiol. TRT did not affect diameter of the dominant follicle on Days 4 to 6, and tended ($P = 0.08$, ISe > OSe, MIX) to affect the diameter of the preovulatory follicle on Day 8 (ISe: 12.6 ± 0.6, OSe: 11.4 ± 0.3, MIX: 11.3 ± 0.4 mm). Our results indicate that form of Se fed to cows affects progesterone but not estradiol synthesis, and tends to affect follicular diameter, in a manner independent of total blood Se concentrations.

Key Words: selenium, follicle, corpus luteum

M228 Relationship between plasma amino acid profile and ovarian function around the time of ovulation in beef cows.

Taylor C. Geppert*[1], Allison M. Meyer[2], George A. Perry[3], and Patrick J. Gunn[1], *[1]Department of Animal Science, Iowa State University, Ames, IA, [2]Division of Animal Sciences, University of Missouri, Columbia, MO, [3]Department of Animal Sciences, South Dakota State University, Brookings, SD*

The objective of this experiment was to determine the relationship between plasma AA concentrations and reproductive parameters of beef cows (n = 26). Two studies evaluating the effects of excess MP on reproductive function were compiled for this analysis. Non-pregnant, nonlactating mature beef cows consuming ad libitum corn stalks were offered a once-daily supplement designed to meet NRC NE$_m$ and exceed MP requirements by 25–50%. After a 20 d adaptation period, cows were synchronized for ovulation using the 5-d CO-Synch + CIDR protocol. Ten days after synchronization, 100 µL of GnRH was administered to reset ovarian follicular growth. Daily transrectal ultrasonography was performed to diagram ovarian activity, and blood samples were taken for hormone and AA analyses. Corpus luteum (CL) volume was determined via ultrasound, and supplementation ended 7 d after estrus. Blood samples collected between d 47 and d 49 underwent AA analysis. Data were analyzed using the CORR procedure of SAS. No significant correlations were observed between AA profile and ovulatory follicle size or antral follicle count ($P > 0.13$). However, a positive relationship between length of proestrus and total AA ($r = 0.49$, $P < 0.01$) and total essential AA ($r = 0.48$, $P < 0.01$) was observed. In addition, a positive relationship between length of proestrus and total glycogenic AA, branched-chain AA, urea cycle AA, arginine, threonine, valine and isoleucine ($r \geq 0.44$, $P \leq 0.04$) were observed. As a percent of essential AA, leucine and phenylalanine were negatively correlated ($r \leq -0.39$, $P < 0.05$) with length of proestrus. However, AA profile was not correlated with estradiol at estrus ($P > 0.05$). As a percent of total AA and essential AA, arginine was positively correlated with circulating progesterone 7 d post-estrus and ratio of progesterone to CL vol ($r \geq 0.41$, $P \leq 0.04$). Based on these data, total and essential AA concentrations may be related to several reproductive parameters around the time of ovulation; however, further research is needed to establish a causal relationship between individual AA and reproductive functions at ovulation.

Key Words: amino acid, correlation, ovulation

M229 Association between circulating blood or plasma urea nitrogen concentrations and reproductive efficiency in beef heifers and cows.

Patrick J. Gunn*[1], Allie L. Lundberg[1], Robert A. Cushman[2], Harvey C. Freetly[2], Olivia L. Amundson[3], Julie A. Walker[3], and George A. Perry[3], *[1]Department of Animal Science, Iowa State University, Ames, IA, [2]USDA, ARS, US Meat Animal Research Center, Clay Center, NE, [3]Department of Animal Sciences, South Dakota State University, Brookings, SD.*

The objective was to examine the effect of circulating blood or plasma urea nitrogen concentrations (BPUNC) on reproductive efficiency in beef heifers and suckled beef cows. Data from nulliparous heifers ($n = 284$) as well as primiparous ($n = 241$) and multiparous ($n = 806$) beef cows were compiled across 15 experiments. A single blood sample collected from each female during estrous or ovulation synchronization was analyzed for BPUNC. Only females that were maintained on the same nutritional management scheme (pasture or coproduct-based drylot ration) for at least 1 wk before synchronization though the first 21 d of the breeding season were included in the analysis. To determine if BPUNC affected first service pregnancy rate, cattle were categorized as having BPUNC above or below each integer from 10 to 25 mg/dL. The GLIMMIX procedure of SAS was used for data analysis. The model for each BPUNC classification analysis also included the fixed effects of age classification and nutritional management scheme. Interactions among fixed effects were not significant and removed ($P \geq 0.10$). Days postpartum at synchronization was included in the model as a covariate when applicable and experiment was included as a random effect. Average first-service pregnancy rate across the data set was 55.6%. Irrespective of age and nutritional management scheme, a BPUNC that was associated with decreased pregnancy rates could not be established. In fact, there was a tendency for improved pregnancy rate as BPUNC increased ($P = 0.08$, $r = 0.05$) and cattle with BPUNC above 16 mg/dL tended to have greater pregnancy rates (57.0%) than those below 16 mg/dL (54.6%; $P = 0.07$). There were no differences ($P \geq 0.16$) in pregnancy rates between cattle that had BPUNC above or below any other integer from 10 to 25 mg/dL. Based on these data, when cattle are allowed to adapt to a nutritional management scheme before breeding and maintained on that diet through the first 21 d of the breeding season, BPUNC is not negatively associated with first-service pregnancy rates. USDA is an equal opportunity provider and employer.

Key Words: crude protein, cyclicity, pregnancy

Physiology and Endocrinology: Estrous synchronization and detection of estrus in cattle

M230 Efficacy of PGF$_{2\alpha}$ doses to induce luteolysis on day 5, 7, or 9 of estrus cycle in nonlactating Nellore cows. Marcos V. Biehl*[1], Alexandre V. Pires[1,2], Marcos V. C. Ferraz Junior[2], Jose R. S. Gonçalves[3], Anibal B. Nascimento[1], Marcelo H. Santos[2], Vinicius N. Gouvea[2], Alexandre A. Miszura[2], Leandro H. Cruppe[4], and Michael L. Day[4], *[1]University of São Paulo, Piracicaba, São Paulo, Brazil, [2]University of São Paulo, Pirassununga, São Paulo, Brazil, [3]Experimental Station Hildegard Georgina Von Pritzelwitz, Londrina, Paraná, Brazil, [4]The Ohio State University, Columbus, OH.*

The aim of this preliminary study was to evaluate the luteolytic competence of different PGF2α (PGF, Lutalyse) doses on d5, d7 and d9 of the estrous cycle. Nonlactating Nellore cows (n = *97*) were synchronized with the 7-d estradiol benzoate + CIDR program. Cows received Estrotect patches at CIDR removal to determine estrus response. Presence of ovulatory follicle and its disappearance were confirmed 48 and 72 h after CIDR removal, respectively. Cows detected in estrus within 48 h and with confirmed ovulation 72 h after CIDR removal remained in the study (n = *68*). Cows were assigned to treatments according to BW (407.9 ± 5.1) and BCS (3.01 ± 0.02, scale 1 to 5). One of 4 PGF doses were administered either 5, 7 or 9 d after estrus and confirmed ovulation (a single 12.5, 25 or 50 mg dose or 2 25 mg doses 8 h apart of dinoprost trometamine), in a 3 × 4 factorial arrangement of treatments. Presence of a corpus luteum was determined by ovarian ultrasound scan and progesterone (P4) analyses (P4 ≥ 1ng/mL) on either d 5, 7, or 9 (0h) of the estrous cycle. Blood samples were collected at 0, 24, 48 and 72 h after PGF administration to assess the incidence of luteal regression (defined as concentration of P4 < 1ng/mL at 72 h after PGF). Serum P4 concentrations were quantified using a chemiluminescent immunoassay. Data were analyzed using GLIMMIX procedure of SAS. Differences in proportion of cows that experienced luteal regression were not detected for day of cycle ($P = 0.19$); PGF dose ($P = 0.13$) or their interaction ($P = 0.99$). The incidence of luteal regression by day of cycle was 45.0% (9/20; 5 d), 66.6% (16/24; 7 d) and 70.8% (17/24; 9 d) and for PGF dose was 42.1% (8/19; 12.5 mg), 56.2% (9/16; 25 mg) 76.4% (13/17; 50 mg) and 75.0% (12/16; 25 + 25 mg given 8 h apart). Animal numbers used in the present study limited the capacity to determine significance of numerical differences that were observed. It is interesting that luteal regression was induced in less than 50% of cows on d 5 of the estrous cycle and in cows that received 12.5 mg of PGF. Additional research is necessary to determine the optimal dose of PGF and timing during the estrous cycle to ensure luteal regression in cyclic Nellore cows.

Key Words: corpus luteum, regression, Nellore cow

M231 Addition of gonadotropin-releasing-hormone treatment at the beginning and/or at the end of an estradiol-based protocol for timed artificial insemination in Nelore (*Bos indicus*) cows. Carla Cristian Campos*, Estevão Vieira de Rezende, Mayara Oliveira, Renata de Freitas Ferreira Mohallem, and Ricarda Maria dos Santos, *Federal University of Uberlândia, Uberlândia, Minas Gerais, Brazil.*

Objective was to determine the effects of adding a gonadotropin-releasing-hormone (GnRH) treatment at the beginning and/or at the end of an estradiol-based protocol for timed artificial insemination (TAI) on pregnancy per AI (P/AI) in Nelore (*Bos indicus*) cows. The experiment was conducted in 2 beef cattle farms (A and B) located in a central-western state in Brazil. The body condition score (BCS) evaluation and the ultrasound examination to determine ovarian status (follicle diameter <10 mm; ≥10 mm; or presence of corpus luteum - CL) were performed at the beginning of TAI protocol. Cows (n = 494) were randomly assigned to 4 groups: Control (n = 126), GnRH at day zero (D0) of the protocol (n = 123), GnRH at d 10 (D10) (n = 123), and GnRH in both times (D0+D10) (n = 122). The GnRH treatment consisted of one 50 µg i.m. injection of gonadorelin. All the cows were submitted to the following TAI protocol: Day 0 = insertion of intravaginal progesterone device previously used for 8 or 16 d and 2.0 mg of estradiol benzoate (EB) i.m.; Day 8 = progesterone device withdrawal, 750 IU i.m.injection of equine chorionic gonadotropin (eCG), 1.0 mg of estradiol cypionate (ECP) i.m. and 0.265 mg of sodium cloprostenol (PGF$_{2\alpha}$) i.m.; Day 10 = TAI, performed by a single inseminator. Pregnancy was diagnosed by ultrasound 39 ± 10 d after TAI. Data were analyzed by GLIMMIX procedure of SAS. Overall P/AI was 42.7%. No effect of treatment was detected ($P = 0.25$) on P/AI, and it was 37.3% for Control, 45.5% to GnRH D0, 49.6% to GnRH D10 and 38.5% to GnRH D0+D10. An effect of farm was detected on P/AI, where Farm A had 47.3% and Farm B 38.2% ($P = 0.02$). Cows with follicles <10 mm had lower P/AI (16.4%; $P < 0.01$) than cows with follicles ≥10 mm (46.2%) and the ones that had a CL (48.4%). The interactions between farm and treatments ($P = 0.77$) or between ovarian status and treatments ($P = 0.12$) did not affect P/AI. In conclusion, gonadotropin-releasing-hormone treatment used at the beginning and/or at the end of an estradiol-based TAI protocol did not affect pregnancy per AI in Nelore (*Bos indicus*) cows.

Key Words: GnRH, Nellore, timed AI

M232 Using estrus-detection patches to optimally time artificial insemination improved pregnancy rates in suckled beef cows in a timed AI program. Scott L. Hill*[1], David M. Grieger[1], K. C. Olson[1], John R. Jaeger[1], Jason K. Ahola[2], Mariah C. Fischer[2], Teresa L. Steckler[3], G. Allen Bridges[4], Jamie A. Larson[5], Carl R. Dahlen[6], Sarah R. Underdahl[6], George A. Perry[7], William D. Whittier[8], John F. Currin[8], Jeffrey S. Stevenson[1], *[1]Kansas State University, Manhattan, KS, [2]Colorado State University, Fort Collins, CO, [3]University of Illinois, Dixon Springs, IL, [4]University of Minnesota, Grand Rapids, MN, [5]Mississippi State University, Mississippi State, MS, [6]North Dakota State University, Fargo, ND, [7]South Dakota State University, Brookings, SD, [8]Virginia Tech, Blacksburg, VA.*

A multiple-location study examined pregnancy rates after delaying AI in suckled beef cows from 60 to 75 h when estrus had not been detected by 60 h after a 7-d CO-Synch + progesterone insert (CIDR) timed AI (TAI) program (d 0: progesterone insert [CIDR] concurrent with injection of GnRH; d 7: prostaglandin F$_{2\alpha}$ injection and removal of CIDR; and GnRH injection at TAI [60 or 75 h after CIDR removal]). A total of 1,519 suckled beef cows at 14 locations in 8 states (CO, IL, KS, MN, MS, ND, SD, and VA) were included. Before applying the TAI program, BCS were assessed. Estrus was defined to occur when an estrus-detection patch was > 50% colored (activated). Pregnancy was determined 35 d after AI via transrectal ultrasound. Cows in estrus 60 h (n = 689; 45.6%) after CIDR removal were inseminated and injected with GnRH (control). Remaining nonestrus cows were allocated to 3 treatments: (1) GnRH injection and AI at 60 h (Early-Early = EE; n = 281), (2) GnRH injection at 60 h and AI at 75 h (Early-Delayed = ED; n

= 270), or (3) GnRH injection and AI at 75 h (Delayed-Delayed = DD; n = 279). Binomial data were analyzed using procedure GLIMMIX. More cows ($P < 0.05$) that showed estrus by 60 h conceived to AI at 60 h than those not showing estrus (65.9 vs. 44%). Further, more ($P < 0.001$) cows showing estrus by 75 h conceived to AI (64.9 vs. 38.5%) than cows not showing estrus. Control cows had a greater ($^{abc}P < 0.05$) pregnancy rates (65.9%^{a}) than other treatments (ED = 54.6%^{b}, DD = 53.0%^{b}, and EE = 44.0%^{c}). Cows not in estrus by 60 h but with activated patches by 75 h (49.8%) were more ($P < 0.05$) likely to become pregnant than nonestrus herd mates when they were in the DD (71.6 vs. 39.1%), ED (70.2 vs. 46.0%), and EE (53.7 vs. 41.4%) treatments, respectively. Pregnancy rates also were greater ($P < 0.05$) in early-calving (>76 d postpartum) than later-calving (≤76 d postpartum) cows (57.5 vs. 51.4%) but were not affected by parity or BCS. Use of estrus-detection patches to delay AI in cows not in estrus by 60 h after CIDR removal optimized time of AI and improved pregnancy rates to TAI.

M233 Treatment of primiparous lactating dairy cows with GnRH before first insemination during summer heat stress.

Benjamin E. Voelz*, Lucas Rocha, Filippe Scortegagna, Jeffrey S. Stevenson, and Luís G. D. Mendonça, *Department of Animal Sciences and Industry, Kansas State University, Manhattan, KS.*

Objectives were to evaluate concentrations of progesterone (P4), ovulation incidence, fertility, and insemination pattern of primiparous dairy cows treated with GnRH before a presynchronization protocol during summer heat stress. At 60 ± 3 d postpartum, primiparous cows (n = 1,352) from 3 dairies were assigned randomly to 2 treatments (d 0): receiving GnRH (Gpresynch) or no GnRH (Control). Cows were presynchronized with 2 injections of prostaglandin $F_{2\alpha}$ (PGF) given 14 d apart beginning on d 7. Cows detected in estrus based on tail paint removal were inseminated. Cows not detected in estrus were enrolled in a Cosynch-72 protocol on d 35 (GnRH on d 35 and 45; PGF on d 42; timed AI on d 45). Incidence of uterine health disorders and mastitis recorded by farm personnel were collected. Cows were considered diseased if 1 disease event occurred before AI. Pregnancy diagnosis was conducted 36 ± 3 d after AI by transrectal ultrasonography. In a subgroup of cows, examinations of ovarian structures were performed on d −14, 0, and 7 (n = 161) and blood samples were collected on d 0 and 7 to determine concentration of P4 (n = 167). Logistic regression analysis was used for dichotomous outcomes and continuous variables were analyzed by ANOVA. The rate at which cows were inseminated was analyzed using the Cox's proportional hazard model. Ovulation risk to GnRH treatment was greater ($P < 0.01$) for Gpresynch than control cows. Percentage of cows that had a corpus luteum (CL) and concentration of P4 ≥ 1 ng/mL on d 7 was ($P < 0.01$) greater for Gpresynch cows. Concentration of P4 on d 0 ($P = 0.91$) and d 7 ($P = 0.31$) did not differ between treatments. An interaction between treatment and disease tended ($P = 0.08$) to affect P4 on d 7 because diseased cows treated with GnRH had greater P4 than diseased control cows. Controls tended ($P = 0.06$) to have a faster insemination rate than Gpresynch cows [adjusted hazard ratio = 1.12 (95% CI = 1.00, 1.26)]. In addition, pregnancy per AI did not differ ($P = 0.25$) between treatments. Although GnRH treatment increased the percentage of cows with a CL, no difference in subsequent fertility was detected.

Key Words: dairy cow, gonadotropin-releasing hormone

M234 Treatment of multiparous lactating dairy cows with GnRH before first insemination during summer heat stress.

Benjamin E. Voelz*, Lucas Rocha, Filippe Scortegagna, Jeffrey S. Stevenson, and Luís G. D. Mendonça, *Department of Animal Sciences and Industry, Kansas State University, Manhattan, KS.*

Objectives of the experiment were to evaluate concentrations of progesterone (P4), ovulation incidence, fertility, and insemination pattern of multiparous dairy cows treated with GnRH before a presynchronization protocol during summer heat stress. At 49 ± 3 d postpartum, multiparous cows (n = 1,941) from 3 dairies were assigned randomly to 2 treatments (d 0): receiving GnRH (n = 965; Gpresynch) or no GnRH (n = 976; Control). Cows were presynchronized with 2 injections of prostaglandin $F_{2\alpha}$ (PGF) given 14 d apart beginning on d 7. Cows detected in estrus based on tail paint removal were inseminated. Cows not detected in estrus were enrolled in the Cosynch-72 protocol on d 35 (GnRH on d 35 and 45; PGF on d 42; timed AI on d 45). Incidence of uterine health disorders and mastitis recorded by farm personnel were collected. Cows were considered diseased if one disease event occurred before AI. Pregnancy diagnosis was conducted 36 ± 3 d after AI by transrectal ultrasonography. In a subgroup of cows, ultrasonography examinations of ovarian structures were performed on d −14, 0, and 7 (n = 351), and blood samples were collected on d 0 and 7 to determine P4 concentrations (n = 361). Logistic regression analysis was used for dichotomous outcomes and continuous variables were analyzed by ANOVA. The rate at which cows were inseminated or became pregnant was analyzed using the Cox's proportional hazard model. Ovulation risk to GnRH treatment was ($P < 0.01$) greater for Gpresynch than control cows. Percentage of cows that had a corpus luteum ($P = 0.01$) and P4 concentration ≥1 ng/mL at first PGF ($P = 0.03$) was greater for Gpresynch than control cows. Concentrations of P4 on d 0 ($P = 0.30$) and d 7 ($P = 0.54$) did not differ between treatments. Furthermore, insemination rate did not ($P = 0.52$) differ between treatments. In contrast, control cows tended ($P = 0.07$) to become pregnant at a slower rate than Gpresynch cows [AHR = 0.81 (95% CI = 0.64, 1.02)]. Treatment with GnRH before a presynchronization protocol using PGF injections increased the percentage of cows bearing a CL at first PGF, but did not improve pregnancy per AI.

Key Words: dairy cow, gonadotropin-releasing hormone

M235 Presynchronization strategy using prostaglandin $F_{2\alpha}$ and GnRH to improve fertility in a resynchronization program based on detection of estrus.

Lucas S. Rocha, Jeffrey S. Stevenson, and Luís G. D. Mendonça*, *Department of Animal Sciences and Industry, Kansas State University, Manhattan, KS.*

Objectives were to evaluate pregnancy per AI (P/AI) and pattern of insemination of 2 resynchronization protocols to maximize insemination rate based on estrus detection in lactating dairy cows. Holstein cows (n = 1,929) from 3 herds were assigned randomly to 2 presynchronization (Presynch) protocols based on their ear tag number. At non-pregnancy diagnosis (day of enrollment [d 0]), odd-numbered cows (P7GPG; n = 967) received a Presynch treatment of $PGF_{2\alpha}$ (PGF) and were enrolled in a resynchronization protocol on d 7 (GnRH on d 7 and 17; PGF on d 14; timed AI [TAI] on d 17). Even-numbered cows (P7GGPG; n = 962) received a Presynch treatment of PGF on d 0 and GnRH on d 7, and were enrolled in a resynchronization protocol on d 14 (GnRH on d 14 and 24; PGF on d 21; TAI on d 24). Detected estrus based on tail paint removal was conducted once daily during the study period and cows detected in estrus were inseminated within 1 h of detected estrus. Cows not detected in estrus by d 7 (P7GPG) or d 14 (P7GGPG) received their assigned TAI treatment. Cows were examined by transrectal ultrasonography to determine pregnancy status 36 d after AI. Binary outcomes were analyzed by logistic regression. The rate at which cows were inseminated was analyzed using the Cox's proportional hazard model. No treatment difference was detected for the percentage of cows inseminated based on detected estrus (72.2%). Presynch treatment ($P < 0.01$), TAI ($P < 0.01$), and the interaction between TAI and Presynch treatment ($P = 0.02$) affected P/AI. Cows inseminated in estrus were more likely to become pregnant than TAI cows (30.5 vs. 23.1%). No difference was detected in P/AI for cows inseminated at estrus (30.5%). In contrast, for cows receiving a TAI, P/AI was ($P < 0.01$) greater for P7GGPG than P7GPG cows (28.9 vs. 17.6%). Hazard of insemination was affected ($P < 0.01$) by treatment because P7GPG cows were inseminated sooner than P7GGPG cows (AHR = 1.70 [95% CI = 1.53 to 1.89]). Presynchronizing cows with GnRH delays AI but improves P/AI of cows submitted to a TAI protocol.

Key Words: estrus, presynchronization, resynchronization

M236 Progesterone concentration at each treatment during an Ovsynch protocol affects fertility to timed AI in lactating Holstein cows.

P. D. Carvalho*, A. H. Souza, M. C. Wiltbank, and P. M. Fricke, *Department of Dairy Science, University of Wisconsin-Madison, Madison, WI.*

Our objective was to assess the association between progesterone (P4) concentration at each treatment of an Ovsynch protocol and pregnancies per AI (P/AI) to timed AI (TAI) in lactating Holstein cows. Data from 7,792 cows from 14 experiments in which P4 was measured during an Ovsynch protocol [GnRH (G1); 7 d $PGF_{2α}$ (PGF); 56 h, GnRH (G2); 16 h, TAI] were analyzed. Cows receiving exogenous P4 or that received 2 injections of PGF or an increased dose of PGF were excluded from the analysis. The association between P4 during the Ovsynch protocol and P/AI to TAI was analyzed independently because P4 was not measured for all cows at every time point in all experiments. Data were analyzed by logistic regression using the GLIMMIX procedure of SAS. At G1, cows (n = 6,144) were stratified into 9 P4 categories from 0 to ≥7 ng/mL using 0.5 ng/mL increments. Overall, P/AI differed ($P < 0.01$) among P4 categories at G1 with fewer P/AI for cows with P4 < 0.5 ng/mL (30%; 375/1,259) or P4 > 7.0 ng/mL (30%; 115/381) compared with cows with intermediate P4 (41%; 1,839/4,504; calculated relative decrease in P/AI of 27%; 41–30 = 11/41 = 27%). At PGF, cows (n = 3,383) were stratified into 9 P4 categories from 0 to ≥8 ng/mL using 1.0 ng/mL increments. Overall, P/AI differed ($P < 0.01$) among P4 categories at PGF with a 51% relative decrease in P/AI for cows with P4 < 1.0 ng/mL (21%; 140/681) compared with cows with P4 > 1.0 ng/mL (43%; 1,151/2,702). At G2, cows (n = 3,148) were stratified into 8 P4 categories from 0 to ≥0.7 ng/mL using 0.1 ng/mL increments. Overall, P/AI differed ($P < 0.01$) among P4 categories at G2 with a 66% relative decrease in P/AI for cows with P4 > 0.4 ng/mL (14%; 61/435) compared with cows with P4 < 0.4 ng/mL (41%; 1,125/2,713). Based on this large data set, suboptimal P4 concentrations could be identified at G1 in 26% of cows (26% lower P/AI), at PGF in 21% of cows (51% lower P/AI), and at G2 in 14% of cows (66% lower P/AI). We conclude that achieving optimal P4 during an Ovsynch protocol may allow for a dramatic increase in fertility in lactating dairy cows. Supported by USDA NIFA Hatch project 23144.

Key Words: progesterone, fertility, Ovsynch

M237 Timed AI improves reproductive performance and reduces cost per pregnancy in dairy heifers.

Thiago V. Silva[1], Fabio S. Lima[2], William W. Thatcher[1], and Jose E. P. Santos*[1], [1]*University of Florida, Gainesville, FL,* [2]*University of Illinois, Urbana, IL.*

Objectives were to evaluate the effects of implementing timed AI for first insemination on reproduction and cost per pregnancy in dairy heifers. Non-pregnant Holstein heifers (n = 611) at 400 d of age from 3 farms were allocated randomly to AI after detected estrus (Control, n = 306) or to timed AI for first AI (TAI, n = 305) followed by detection of estrus. Heifers in TAI were enrolled in the 5-d timed AI protocol on study d −6 [d −6, GnRH and an intravaginal progesterone insert; d −1, $PGF_{2α}$ and insert removal; d 0, $PGF_{2α}$; d 2, GnRH + AI). Starting on study d 0, heifers had tailheads painted daily with chalk for detection of estrus. Control heifers received $PGF_{2α}$ if not inseminated within 7 d of moving to the breeding pen. The study lasted 84 d to allow 4 21-d estrous cycle periods of breeding. A herd budget was created to determine cost per pregnancy. Data were analyzed by ANOVA, logistic regression, and the Cox's proportional hazard model using the MIXED, GLIMMIX, and PHREG procedures of SAS and models included the effects of treatment, farm, and treatment by farm interaction. The interval to first AI was 8 d shorter ($P < 0.01$; 10 vs. 2 d) and the 21-d cycle insemination rate was greater ($P < 0.01$) for TAI than Control heifers (82.4 vs. 91.4%). Pregnancy at first AI (PAI; Control = 58.3% vs. TAI = 62.8%) and all AI (Control = 56.0 vs. TAI = 57.4%) did not differ ($P > 0.15$) between treatments. Implementing timed AI increased ($P < 0.01$) the 21-d cycle pregnancy rate from 47.9% in Controls to 57.2% in TAI heifers and reduced ($P < 0.01$) median d to pregnancy (Control = 14.0 vs. TAI = 2.0). In fact, the hazard of pregnancy improved ($P < 0.01$) 60% for TAI than Control heifers (adjusted HR = 1.60; 95% CI = 1.35–1.89), resulting in increased ($P < 0.01$) proportion of pregnant heifers by 84 d of breeding (Control = 85.2 vs. TAI = 91.5%). The cost per pregnancy for was $17.16 less expensive ($P < 0.01$) for TAI than Control heifers. Implementing timed AI for first service followed by detection of estrus improved reproductive performance and reduced the cost per pregnancy when compared with heifers managed under detected estrus only.

Key Words: dairy heifer, timed AI, reproduction

M238 Addition of a second dose of prostaglandin $F_{2α}$ to a fixed-time AI protocol improves fertility of anestrous dairy cows.

Francisco R. Lopes Jr.*, Marcos H. C. Pereira, Anderson K. Munhoz, and José L. M. Vasconcelos, *Sao Paulo State University, Botucatu, SP, Brazil.*

This study was conducted to evaluate if addition of a second prostaglandin (PG) $F_{2α}$ dose improves fertility of anestrous lactating Holstein cows submitted to an estradiol/progesterone (P4) based timed AI (TAI) protocol. Ovaries were scanned by ultrasound to determine if a corpus luteum (CL) was present at the protocol initiation (d-11) and on the day of $PGF_{2α}$ (d −4). Cows without CL on d −11 and d −4 were classified as anestrous (n = 436). Anestrous cows were submitted to the TAI protocol: d −11: 2 intravaginal P4 devices (1.9g P4, CIDR, Zoetis) and 2.0 mg of estradiol benzoate (EB) i.m. (Estrogin, Farmavet); d −4, 25mg of PGF2a i.m. (Lutalyse, Zoetis) and withdrawal of one CIDR; d −2 withdrawal of the second CIDR and 1.0 mg i.m. of estradiol cypionate (ECP, Zoetis); on d 0 TAI. On d-4, cows were randomly assigned to 1 of 2 treatments: one dose of $PGF_{2α}$ on d −4 (1PGF) or 2 doses of $PGF_{2α}$ (2PGF), the first on d −4 and the second on d −2. Rectal temperature was measured on the day of TAI and 7 d later. The average rectal temperature was calculated and the cows were divided into 2 groups: without hyperthermia (<39.1°C) or with hyperthermia (≥39.1°C). Pregnancy was diagnosed 60 d after AI. Binomial variables were analyzed using the GLIMMIX and continuous using the MIXED procedures of SAS. The 2PGF treatment tended to improve the synchronization rate (80.2% [n = 218] vs. 72.4% [n = 218] $P = 0.07$). An interaction ($P = 0.05$) between treatment and hyperthermia was observed for pregnancy per AI (P/AI) on d 60. For hyperthermic cows, P/AI were 9.1% (n = 123) and 9.4% for 1PGF and 2PGF, respectively. For cows without hyperthermia, P/AI were 16.3%

(n = 95) and 30% (n = 88) in 1PGF and 2PGF, respectively. When only ovulated cows were included in the analysis, then an interaction ($P = 0.05$) existed between treatment and hyperthermia on P/AI at 60 d. For cows with hyperthermia, P/AI were 13.8% (n = 80) and 12.1% (n = 100) in 1PGF and 2PGF, respectively. For cows not suffering of hyperthermia, P/AI were 19.4% (n = 78) and 34.8% (n = 75) in 1PGF and 2PGF, respectively. The addition of a second PGF dose during the TAI protocol increased fertility in anestrous dairy cows without hyperthermia on the first 7 d after AI.

Key Words: anestrous, PGF$_{2\alpha}$, TAI

M239 Effect of a second treatment with prostaglandin F$_{2\alpha}$ during the Ovsynch protocol on pregnancy to the timed AI.

Fenella Cochrane*[1], Giovanni M. Baez[2], Cheryl R. Trayford[1], Robert T. Joseph[1], and Milo C. Wiltbank[2], *[1]Parnell Corporate Services US Inc, Overland Park, KS, [2]University of Wisconsin-Madison, Madison, WI.*

Lack of complete regression of the corpus luteum (CL) after prostaglandin F$_{2\alpha}$ (PGF) treatment can reduce fertility during timed AI (TAI) protocols. The main objective of this study was to evaluate the effect of a second treatment with PGF during the Ovsynch protocol on fertility to the timed AI (TAI). A total of 2,148 lactating dairy cows were used on 11 dairy farms in 4 different regions of the USA, 3 in WI, 3 in CA, 2 in NY, one in PA, one in NM, and one in TX. Cows were synchronized with Ovsynch (GnRH [Gonadorelin acetate; 100 µg/mL; GONAbreed, Parnell]-7d-PGF[Cloprostenol sodium; 250 µg/mL; estroPLAN; Parnell]-56h-GnRH-16h-TAI) for TAI at 50 ± 3 DIM. The cows were randomized to receive: (1) No additional treatments with PGF = Ovsynch, or (2) A second PGF treatment at 24 h after the first PGF treatment = PROCEPT. Statistical analyses were performed using PROC Logistic in SAS, with treatment and parity as factors. In the overall logistic regression model there was no significant effect of Farm ($P = 0.712$); although, treatment effects on individual farms ranged from positive ($P = 0.01$) to a tendency for a negative effect ($P = 0.12$). There was also no interaction of parity and treatment in the overall model ($P = 0.741$). Overall, there was a tendency ($P = 0.068$) for an effect of treatment on P/AI with an increase from 33.3% in Ovsynch compared with 36.1% in PROCEPT (2.8% absolute increase; 8.5% relative increase [2.8/33.3]). There was no effect of treatment in primiparous cows (37.1% [99/267] vs. 38.2% [99/259]; Ovsynch vs. PROCEPT; $P = 0.393$). However, there was a tendency for an effect of treatment in multiparous cows (32.0% [259/809] vs. 35.4% [288/813]; 10.7% relative increase; $P = 0.073$). When multiparous cows were evaluated by parity, it was found that there was an effect of treatment in cows of second and third lactation ($P = 0.047$) but no effect of treatment in older cows ($P = 0.517$). Thus, treatment with a second PGF during the Ovsynch protocol tends to increase pregnancies per TAI producing about 10% more pregnancies per TAI in multiparous cows, with a significant increase in second and third lactation cows.

Key Words: Ovsynch, prostaglandin F$_{2\alpha}$, fertility

M240 Efficacy of different fixed-time AI protocols using GnRH, estradiol, and progesterone in lactating dairy cows.

Leonardo F. Melo*[1,2], Pedro Leopoldo Monteiro Jr[1], Jessica N. Drum[1], Ricardo S. Surjus[1], Milo C. Wiltbank[2], and Roberto Sartori[1], *[1]University of São Paulo, Piracicaba, São Paulo, Brazil, [2]University of Wisconsin-Madison, Madison, WI.*

This study compared the reproductive efficiency of dairy cows submitted to fixed-time AI (FTAI) protocols using GnRH and/or different esters of estradiol. A total of 1,029 lactating Holstein cows (358 primiparous and 671 multiparous; BCS 2.99 ± 0.01, 159.8 ± 3.4 DIM; 36.4 ± 0.29 kg/d of milk; LS means ± SEM) were housed in freestall barns and randomly assigned to 1 of 4 treatment groups using a completely randomized design with a 2 × 2 factorial arrangements of treatments. Cows were assigned to 1 of 2 treatments at the beginning of the FTAI protocol (GnRH [G] or estradiol benzoate (EB]) and 1 of 2 treatments at the end of the protocol (EB or estradiol cypionate [ECP]), resulting in: G-EB (n = 263), G-ECP (n = 277), EB-EB (n = 259) and EB-ECP (n = 230). All cows received an intravaginal progesterone (P4) implant at the start of the protocol (d 0) and it was removed on d 8. All cows also received PGF$_{2\alpha}$ (500 µg) on d 7 and d 8. At the end of the protocol, treatment with ECP was on d 8 or treatment with EB was on d 9 with FTAI on d 10. Statistical analyses were performed using Proc GLIMMIX of SAS 9.3. There were no interactions between treatments on pregnancies per AI (P/AI) at 30 and 60 d pregnancy diagnoses ($P > 0.05$). At 30 d, there was no effect of EB or GnRH at start of protocol (33.9 vs. 37.0%; $P = 0.30$) and no effect of treatment at end of protocol (33.1 vs. 37.9%; EB vs. ECP; P = 0.11). At 60 d, there were no treatment effects at start (29.8 vs. 32.2%; EB vs. GnRH; $P = 0.43$) or end (30.3 vs. 31.7%; EB vs. ECP; $P = 0.63$) of the protocol. For pregnancy loss (d 30 to 60 of pregnancy), there were no interactions ($P > 0.05$) and no effect of treatments at start ($P = 0.72$), however, there was an effect of treatment at end (8.6 vs. 15.7%; EB vs. ECP; $P = 0.04$) of the protocol. Independent of treatments, DIM tended to affect P/AI at 30 d ($P = 0.08$) and at 60 d (34.8 vs. 27.4%, low vs. high DIM; $P = 0.01$), but did not affect pregnancy loss ($P = 0.05$). We concluded that in lactating Holstein cows, the use of EB or GnRH at the beginning or EB or ECP at the end of the protocol provided same P/AI at 30 and 60 d after FTAI, despite that ECP, at the end of protocol, provided greater embryonic/fetal loss. Also, cows with less DIM had greater P/AI at 60 d. Thanks to CNPq, FAPESP, CAPES and VALLÉE.

Key Words: fertility, synchronization.

M241 The use of a modified 5-day CIDR-Cosynch protocol for resynchronization in lactating dairy cows.

J. A. Spencer*[1], K. G. Carnahan[1], B. Shafii[1], C. Claypool[1], J. C. Dalton[2], and A. Ahmadzadeh[1], *[1]University of Idaho, Moscow, ID, [2]University of Idaho, Caldwell, ID.*

Approximately 60% of lactating Holstein dairy cows fail to conceive to the first artificial insemination (AI) and are required reinsemination. Resynchronization facilitates timely reinsemination; however, pregnancy rates to the second AI (PR/AI) from resynchronization protocols have been inconsistent. The development of an effective resynchronization protocol is needed to improve PR/AI to second AI. The objective of this study was to determine the effect of the initial GnRH on PR/AI using a 5-d CIDR-Cosynch resynchronization protocol for second AI in lactating Holstein dairy cows. Approximately 37 d after first AI and upon non-pregnancy diagnosis, cows eligible for second AI (n = 429) were subjected into a modified 5-d CIDR-Cosynch protocol. On d 0, all cows received CIDR inserts and were assigned randomly to oe one of 2 treatments, initial GnRH (100µg; n = 226) or no GnRH (n = 203). On d 5, CIDR inserts were removed and all cows received one injection of PGF$_{2\alpha}$ (500 µg). From d 5 to 7, cows were monitored daily for estrus. Animals detected in estrus on d 6 or 7 received AI and were not given GnRH. On d 8, all cows not identified in estrus on d 6 or 7 were timed AI (TAI) and receieved GnRH. Blood samples were collected from cows (n = 184) on d 0 and analyzed for progesterone (P$_4$) concentration. Logistic regression was used to examine the main effects of treatment, day of AI, sire, parity and all 2-way interactions with treatment on PR/AI. There were no effects of treatment (no GnRH, 27.1% vs. initial GnRH, 21.2%) on PR/AI ($P > 0.10$). There were also no effects of method of AI (based on estrus vs. TAI), sire (n = 10), or any 2-way interactions with treatment on overall PR/AI. There was a significant difference ($P < 0.05$) between primiparous (n = 119) and multiparous cows (n = 310) in PR/AI (31% vs. 21%). Progesterone concentrations (n = 184) were categorized into high (≥1 ng/mL) and low (<1 ng/mL) groups. Overall, PR/AI tended ($P = 0.09$) to be greater for high P_4 (n = 136) compared with low P_4 (n = 48) (26% vs. 16%). These results provide evidence that the initial GnRH injection in a 5-d CIDR-Cosynch resynchronization program may not be necessary to achieve a similar PR/AI following second AI.

Key Words: dairy cows, resynchronization, 5-d CIDR-Cosynch

M242 Assessment of an application for mobile devices developed to evaluate the AI procedure. Santiago Bas* and Gustavo M. Schuenemann, *Department of Veterinary Preventive Medicine, College of Veterinary Medicine, The Ohio State University, Columbus, OH.*

Improving reproductive performance in dairy cattle is paramount to maximize dairy productivity and sustainability. Artificial insemination (AI) is the most common breeding practice for dairy cattle in the US and worldwide. It is common to observe large within- and among-herd variation in conception rate and performance of AI technicians. The objective was to assess a user-friendly application (APP) for mobile devices developed to allow the evaluation of the AI procedure under field conditions. The APP was designed to collect information during the AI procedure to allow the identification of breeding practices (e.g., semen handling, breeding procedures) that may affect reproductive outcomes. In addition, the APP generates a database for benchmarking metrics associated with performance of AI technicians. Novel components of the APP include: (1) login screen for individual users, (2) capture of farm information (e.g., type of facility, herd size), (3) sire identification, (4) semen used (sexed or conventional), (5) breeding strategies (e.g., estrous detection, synchronization programs), (6) animals inseminated (e.g., cows, replacement heifers), and (7) recording of the following metrics: number of semen straws simultaneously thawed, thawing time, AI catheter loading time, time from loading of AI catheter to the cow, time to AI, and time elapsed for each round of insemination. In addition, information is summarized to generate an electronic report, and all captured data are uploaded into a cloud database. The APP features a user-friendly interface for entering and managing data, and accurately (100%) captured, summarized and integrated multiple events associated with the AI procedure under field conditions.

Key Words: dairy, app, artificial insemination

M243 Estradiol and GnRH on ovulation induction in crossbred cows estrus synchronized. Fabrício Albani Oliveira, Jurandy Mauro Penitente Filho, Erly Luisana Triana Carrascal, Carlos Thiago Oliveira, Adriana Moreira Zolini, Italo Augusto da Costa Soares, and Ciro Alexandre Alves Torres*, *Federal University of Viçosa, Viçosa, MG, Brazil.*

Three different ovulation inductors, estradiol benzoate (EB), estradiol cypionate (EC) and gonadotropin releasing hormone (GnRH) were evaluated in timed artificial insemination (TAI) of lactating crossbred cows. Two hundred and 16 (216) cows were used in 2 experiments. In experiment I (n = 45), follicular dynamics and in the experiment II (n = 171) pregnancy per AI were evaluated. All cows were submitted to a synchronization protocol: d 0 (D0) insertion of a progesterone-release intravaginal device (PRID) plus IM injection of EB 2 mg; D8, PRID removal plus IM injection of PGF_{2a} (0.150 mg) and eCG (400 IU). The cows were then randomly assigned into 1 of 3 groups: (1) EB9 (n = 61): IM injection of EB (1 mg) on D9, and AI 52 h after PRID removal; (2) EC (n = 58): IM injection of EC (1.0 mg) on D8 and AI 48 h after PRID removal and (3) GnRH (n = 52): IM injection of GnRH (100 µg) on D10 and AI 52 h after PRID removal. Ultrasonographic examinations of the ovaries were performed on d 0, 8, and on the day of TAI to determine follicular diameter and ovulation. Follicular data were analyzed using ANOVA and pregnancy per AI with Chi-squared test at 5% probability. No interaction was found between treatment and observation day on number of follicles or on the follicular classification ($P > 0.05$). The intervals from TAI to ovulation were 12.4, 12.8 and 14.8 for EB, EC and GnRH, respectively ($P > 0.05$). No interaction between treatment and day of observation was detected for diameter of the largest follicle (11.4, 11.0 and 10.7 mm for EB, EC and GnRH, respectively; $P > 0.05$). The rate of follicle growth was slower in the EC cows than the other treatments (EB = 1.5, EC = 0.7 and GnRH = 1.9 mm; $P < 0.05$). There were no effects ($P > 0.05$) of treatment on ovulation rate (EB = 100, EC = 93.3, GnRH = 93.3%) and pregnancy per AI (EB = 62.3, EC = 37.9, GnRH = 51.9%). Sample size might have limited the ability to detect statistical differences among treatments. The use of EB, EC, and GnRH as ovulation inductors in TAI protocols in crossbred cows resulted in no differences in ovulatory responses or pregnancy per AI.

Key Words: ovulation, crossbred cows, timed AI

M244 Effect of estrous synchronization program, season, body condition score and ovarian status on pregnancy rate to fixed-time AI in beef cows. Federico Randi*[1,2], Mervyn Parr[2], Peter Doolan[2], Michael G. Diskin[2], Alessio Valenza[3], Pedro Rodriguez[3], Pat Lonergan[1], and David A. Kenny[2], *[1]University College Dublin, Dublin, Ireland, [2]AGRIC Teagasc Grange, Dunsany, Meath, Ireland, [3]CEVA Sante Animale, Libourne, France.*

Reproductive efficiency in the Irish beef cow population is challenged by age at first calving, long calving intervals and limited AI usage. Low average herd size and often part-time nature of beef production increases the challenge of detecting cows in estrus. The objective was to establish an estrous synchronization regimen to facilitate fixed-time AI (TAI) in beef cows under Irish conditions. A total of 1410 suckled cows located on 61 farms were enrolled across 2 replicates (Spring, n = 703 and Autumn, n = 707). Presence of a corpus luteum (CL) and body condition score (BCS) were recorded at treatment initiation. Following a voluntary waiting period of 35 d postpartum, cows were assigned to (1) receive progesterone-releasing intravaginal device (PRID Delta) on d 0 and PRID removal on d 7 with an 25 mg injection of PF2α (Enzaprost) (Group 1); (2) same as Group 1, but cows received a 100 ug of GnRH analog (Ovarelin) on d 0 (Group 2); (3) same as Group 2, but cows received 400 IU equine chorionic gonadotropin (eCG) (Syncrostim) on d7; (Group 3). All cows received GnRH at TAI 72 h after PRID removal with pregnancy diagnosis by transrectal ultrasonography 35–40 d later. Data were analyzed using the GENMOD procedure of SAS. Presence of a CL (Spring 50.6%; Autumn 70.0%) increased pregnancy rate independent of treatment and season ($P = 0.03$). Mean BCS in Spring and Autumn was not different but BCS positively affected pregnancy rate independent of treatment or season ($P = 0.003$). There was a significant treatment × season interaction for pregnancy rate ($P = 0.0002$). In spring, overall pregnancy rate was 59.1% (416/703) and was affected by treatment (49.6 vs. 59.3 vs. 68.5%, for Groups 1, 2 and 3, respectively $P <$

0.05). In contrast, in autumn, overall pregnancy rate (52.6%, 364/707) was unaffected by treatment (53.7 v 52.0 v 48.7%, respectively). In conclusion, GnRH at the initiation of a TAI synchronization protocol and eCG both increased pregnancy rate in spring-calving suckled beef cows. This effect was not evident in autumn-calving cows. Seasonal differences in outcome may reflect differences in management (grazing vs. confinement), days postpartum or breed type and remain to be elucidated.

Key Words: bovine, fertility, synchronization

M245 Body weight loss of cows early postpartum is associated with negative effects on estrous expression.

Tracy A. Burnett*, Muhammad A. Khan, Marina A. G. von Keyserlingk, and Ronaldo L. A. Cerri, *University of British Columbia, Vancouver, BC, Canada.*

The aim of this study was to determine the association of weight loss during the transition period with the expression of estrus. Sixty-seven Holstein cows were enrolled onto the study 2 wk before parturition. Body weight (BW) was determined 1 and 2 wk before expected calving date and again 5 wk postpartum. Beta-hydroxybutyrate (BHBA) and glucose concentrations were analyzed 2 wk postpartum. Cows were equipped with collar-mounted activity monitors (Heatime, SCR Engineering, Israel). Estrous expression was measured by an automated activity monitor (AAM) and quantified using 2 parameters: 1) peak activity and 2) duration of the estrus episode. Peak activity was defined as the maximum activity index during an estrus episode; the threshold activity was set at an index of 35 (an 80% increase relative to baseline). The duration of an estrus episode was calculated as the amount of consecutive time whereby the index level was greater than 35. Loss of BW from 2 wk prepartum until 5 wk postpartum was determined for all cows and used to retrospectively group them: (1) those that lost less than or equal to 100 kg of BW (Low; n = 46), and (2) BW loss more than 100 kg (High; n = 21). Data were analyzed by ANOVA using the MIXED procedure of SAS. Increased BW loss was associated with decreased estrous expression as measured with an AAM. Animals within the High group had decreased peak activity (63.6 ± 3.0 vs. 74.0 ± 3.9 peak activity index; $P = 0.04$) and decreased duration of estrus (8.4 ± 0.7 vs. 11.5 ± 0.9 h; $P < 0.01$). Ovulatory follicle diameter and estradiol concentration in plasma were unaffected. Additionally, cow within the High group had increased BHBA concentrations (0.57 ± 0.12 and 0.90 ± 0.10 mmol/L; $P = 0.03$) and reduced glucose concentrations (48.3 ± 1.5 vs. 53.8 ± 1.6 mmol/L; $P = 0.02$) at 2 wk postpartum. Also, the High group had increased days open in comparison to the Low group (163 ± 13 vs. 113 ± 17 d open; $P = 0.03$). In conclusion, excessive BW loss early postpartum has negative effects on estrous expression as measured by an AAM and is associated with increased days open.

Key Words: activity monitor, body weight loss, estrus

M246 Automated detection of estrus using multiple commercial precision dairy farming technologies in synchronized dairy cows.

L. M. Mayo*, W. J. Silvia, G. Heersche, I. C. Tsai, B. A. Wadsworth, A. E. Stone, and J. M. Bewley, *Department of Animal and Food Sciences, University of Kentucky, Lexington, KY.*

The objective of this study was to evaluate precision dairy farming technologies (PDFT) for estrous detection. Estrus was synchronized in 24 lactating Holstein dairy cows using a modified G7G-Ovsynch protocol (last GnRH injection withheld to permit expression of estrus) beginning 45–85 DIM. Resumption of ovarian cyclicity at enrollment, presence of a corpus luteum (CL) on the day of the final injection (designated experimental d 0), regression of the CL by d 5, and presence of a new CL on d 11 were verified by transrectal ultrasonography. Cows were observed for estrous behaviors for 30 min, 4× per day, on d 2 to 5. Blood samples were collected on d −2, −1, 0, 1, 2, 5, 7, 9, and 11 to quantify progesterone to verify luteal regression and ovulation. Potential periods of estrus (gold standard) were defined by the temporal pattern of progesterone (>1.0 ng/mL on days −2, −1 and 0, <1.0 ng/mL on d 2 and > 1.0 ng/ml on d 9 and 11). Eighteen cows followed this pattern. Cows that failed to follow the pattern served as negative controls (n = 6). Detection of estrus by PDFTs, an estrous behavioral scoring system, and by visual observation of standing estrus were compared with the gold standard (Table 1). Sensitivity and specificity for detection of estrus was similar among all PDFT. Only 56% of cows that ovulated were observed standing by visual estrous detection. All systems tested are capable of detecting estrus at least as effectively as visual observation.

Table 1 (Abstr. M246). Detection of estrus using alerts generated by PDFT[1] and visual observation (n = 24)

Detection method	TP	FP	TN	FN	Sensitivity (%)	Specificity (%)
Afimilk AfiAct Pedometer Plus	16	0	6	2	89	100
GEA CowScout (leg version)	15	0	6	3	83	100
ENGS Track A Cow	14	0	6	4	78	100
Agis SensoOr	14	0	6	4	78	100
Estrus behavioral score[2]	12	1	5	6	67	83
Standing behavior	10	0	6	8	56	100

[1] Sensitivity = TP/(TP + FN) and specificity = TN/(TN + FP); where TP = true positive, TN = true negative, FP = false positive, and FN = false negative.

[2] Scoring system as defined by Van Eerdenburg et al. (1996).

Key Words: automated estrus detection, precision dairy technology, estrous behavior

M247 Using the Draminski Estrous Detector in the dry cow to measure electrical resistance of vaginal mucus as it relates to animal factors pre- and postcalving.

Caitlin L. Widener*, William M. Graves, and Jillian F. Bohlen, *University of Georgia, Athens, GA.*

Poor uterine health can be detrimental to a fresh cow's ability to efficiently re-breed. This 2-phase study aimed to establish changes in vaginal mucus resistance as it relates to calving date and uterine health post-calving. In phase one, nulliparous heifers (n = 11) and multiparous cows (n = 21) were examined approximately 2 weeks before and the week of calving with a device designed to measure changes in electrical resistance in ohms (Ω) of cervical/cranial vaginal mucus (Draminski Estrous Detector, Poland). Three consecutive readings were taken at each time point with the average being utilized for analysis. At time of Draminski readings, urine pH, rectal temperatures, body condition scores and udder edema levels were recorded. Increasing blood-flow and uterine contractions associated before calving as the result of estrogen may change the deposition of circulating minerals in mucus, as indicated by electrical resistance, which may have an impact on the uterine environment post-calving. In phase 2, 10 heifers and 14 cows from the original groups were assessed for incidence of metritis on d 7 and 14 (±3 d) post-calving. Vaginal mucus was visually examined using the Metricheck (Simcro, New Zealand) and subjectively scored by one individual (0-clear, 1-up to 25% white or off white pus, 2–25–75% pus, 3- > 75% pus). Draminski readings averaged 183 ± 28.8Ω and 184 ± 42.8Ω for the first and second readings, respectively. The Draminski readings did not consistently increase (n = 12) or decrease (n = 15) relative to calving date. Precalving data were analyzed using the PROC GLM procedure of SAS for their relationship to postcalving mucous scores. The first model included overall increase or decrease in Draminski readings relative to calving, rectal temperature and body condition score with group (heifer or cow) held constant. The second model included the first or second Draminski reading with group held constant. There was no association between actual Draminski readings ($P > 0.05$) or changes in Draminski readings over time ($P > 0.05$) and the Metricheck scores postcalving. The lack of statistical associations was likely the result of high variability in Draminski readings.

Key Words: electrical resistance, metritis, periparturient

M248 Estrus lying behavior of Holstein cows: Risk factors for estrus expression, ovulation risk and pregnancy per AI.

Bruna F. Silper*[1], Augusto M. L. Madureira[2], Liam B. Polsky[1], Eraldo L. Drago Filho[2], José L. M. Vasconcelos[2], and Ronaldo L. A. Cerri[1], *[1]Faculty of Land and Food Systems, University of British Columbia, Vancouver, BC, Canada, [2]Faculdade de Medicina Veterinária e Zootecnia, UNESP, Botucatu, SP, Brazil.*

Objectives were (1) to quantify lying behavior (LB) changes around estrus, and (2) to assess risk factors for reduced changes in LB during estrus, ovulation risk and pregnancy per AI (P/AI). Holstein cows (n = 1,039; 45.6 ± 10.7 kg milk/d) were fitted with pedometers; 1,179 estrus episodes were evaluated. LB measurements were bout frequency (BOUT), total lying time/d (TOTAL), average lying bout duration (AVG), and ratio of lying/standing time (RATIO). Relative changes from d −7 to d −1 (d of estrus) and from d −7 to d +1 were calculated. Thresholds for high intensity estrus were set as a decrease in BOUT >25% and in TOTAL and RATIO >22%. AVG did not change with estrus. Descriptive statistics and logistic regressions were used to analyze the data. At d −1 BOUT, TOTAL, and RATIO were, respectively, 19 ± 34% (−3 ± 5 bouts/d), 20 ± 30% (−145 ± 190 min/d), and 21 ± 26% (−11 ± 21%) lower than at d −7. Major risk factors associated with reduced estrus expression were d 0 progesterone (P4) concentration, season and parity. Cows with P4 < 0.2 ng/mL were twice as likely to have high intensity estrus (large decrease in LB from d −7 to d −1). High intensity estrus increased ovulation rate (OR = 2.7 [BOUT], 4.6 [TOTAL], 4.8 [RATIO]). Cold season also increased ovulation rate (OR = 1.8 [BOUT] and 1.9 [TOTAL and RATIO]). BOUT, TOTAL, and RATIO tended to affect P/AI at 32 and 60 d, but parity, BCS, and season were more important predictors. Interestingly, TOTAL, RATIO, and AVG were greater at d +1 than at d −7 by 8 ± 30% (TOTAL), 10 ± 21% (RATIO), and 13 ± 36% (AVG). When d +1 TOTAL and RATIO were ≥10% d −7 values, there was greater likelihood of ovulation (OR = 2.6 [TOTAL] and 2.4 [RATIO]; 92% vs. 81%). P/AI at 32 d was 1.5 and 1.6 times greater for episodes followed by high d +1 TOTAL and RATIO (38% vs. 27%). BOUT, TOTAL and RATIO could improve the use of information from activity monitors (e.g.: increased estrus detection, fertility prediction). Relationships between P4 at AI, estrus behavior, ovulation and conception should be further investigated.

Key Words: estrus, lying behavior, progesterone

M249 Characterization of ovarian function in nonpregnant previously inseminated lactating dairy cows.

Robert Wijma*, Matias L. Stangaferro, and Julio O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Our objective was to characterize ovarian dynamics in lactating dairy cows diagnosed nonpregnant after AI focusing on time points when resynchronization programs are initiated or PGF2α can be used to induce estrus expression. After synchronization with the Presynch-Ovsynch (PGF-14d-PGF-12d-GnRH-7d-PGF56h-GnRH-16h-TAI) protocol cows (n = 64) received timed-AI. Blood was collected every 48 h from 14 to 42 d after AI to determine concentrations of progesterone (P4) and estradiol (E2). Daily, ovarian ultrasound (US) was used to determine size and location of all ovarian structures. Retrospectively, cows were classified as pregnant (n = 25; PG) when a viable embryo was observed (excluded from analysis) or nonpregnant (n = 39; NP) when no viable embryo was observed. A cow was considered to have an active CL (ACL) when P4 > 1 ng/mL and ≥ 1 CL was observed. Also, a CL was considered mature (MCL) starting 7 d after ovulation based on the timing when the CL becomes sensitive to PGF2α. Follicles were considered active (AFOL) when reached 10 mm until 2 consecutive days of reduction in diameter. Periods evaluated were: 24(D24), 32(D32), and 38(D38) d after AI. Parameters evaluated were cows with ACL, MCL, and an AFOL by day, E2 concentrations and E2 to P4 ratio. Quantitative data were analyzed by ANOVA using PROC MIXED whereas binary data were analyzed by logistical regression using PROC GLIMMIX of SAS. More ($P < 0.01$) cows had an ACL on D32 (82.1%) and D38 (84.2%) than on D24 (35.9%). The greatest ($P < 0.01$) proportion of cows with a MCL was for D38 (84.6%) followed by D32 (56.4%) and least for D24 (28.2%). The proportion of cows with an AFOL tended ($P = 0.06$) to be affected by day with 79.5, 92.3, and 97.4% of cows with an AFOL for D24, D32, and D38, respectively. Concentrations of E2 were greater ($P = 0.05$) for cows with an AFOL (1.1 ± 0.3 pg/mL) vs cows without AFOL (0.5 ± 0.1 pg/mL) across all days. Concentrations of E2 were affected by day because on D24 (1.3 ± 0.2 pg/mL) E2 was greater ($P < 0.05$) than for D32 (0.7 ± 0.2 pg/mL) whereas on D38 (1.0 ± 0.2 pg/mL) E2 was intermediate. We conclude that there is more variation in ovarian function than expected based on the number of days after AI in nonpregnant previously inseminated cows. Supported by Hatch project NYC-127813.

Key Words: corpus luteum, follicle, dairy cow

M250 The effects of ovulatory status of the dominant follicle and spatial relationship of the corpus luteum on diameter and average growth rate of that dominant follicle.

Ashleigh M. Muth-Spurlock*, Garrett F. Cline, Caleb O. Lemley, and Jamie E. Larson, *Mississippi State University, Mississippi State, MS.*

The aim of this study was to investigate the effects of ovulatory status of the dominant follicle (whether the follicle eventually ovulated or not) and spatial relationship of the corpus luteum (CL; contralateral or ipsilateral to the dominant follicle) on the diameter and average growth rate of that dominant follicle. Sixteen non-pregnant, multiparous beef cows were observed daily for estrus. Cows were randomly assigned to 1 of 2 treatments, daily ultrasound of: (1) the dominant anovulatory (AN) follicle (1st follicular wave), or (2) the ovulatory (OV) follicle (2nd or 3rd follicular wave). Ultrasonography exams were initiated on d 1 (AN treatment group) or on d 7 (OV treatment group) of the estrous cycle. Exams ended after 5 d of follicular dominance. Follicle diameter and whether the CL was ipsilateral or contralateral to the dominant follicle were recorded. The MIXED procedure of SAS was used for data analysis, with d of dominance (0 to 4) as a repeated measure; LSMeans and pooled SEM are reported. There was a treatment × spatial relationship interaction ($P = 0.056$) when evaluating average growth rate of the dominant follicle. Anovulatory follicles contralateral to the CL grew faster (1.137 ± 0.045 mm/d) than both ovulatory follicles contralateral to the CL (0.954 ± 0.036 mm/d) or ovulatory follicles ipsilateral to the CL (0.996 ± 0.029 mm/d). However, average growth rate of the dominant follicle was less ($P = 0.041$) in cows in the OV group compared with cows in the AN group (0.975 ± 0.023 and 1.07 ± 0.040 mm/d, respec-

tively). When evaluating diameter of the dominant follicle over the 5 d of dominance, treatment, spatial relationship of the CL, d of dominance, and treatment × spatial relationship all affected diameter of the dominant follicle. However, when only evaluating the last d of dominance, these parameters did not significantly affect diameter of the dominant follicle. In conclusion, additional research is necessary to understand the interactions between future ovulatory status of a dominant follicle and spatial relationship of the CL.

Key Words: corpus luteum, follicle diameter, follicle growth rate

Production, Management and the Environment I

M251 Canadian dairy producers' transition to automatic milking systems: preliminary results of a national survey. Christina Tse*[1], Trevor DeVries[2], Elsa Vasseur[3], Herman Barkema[1], and Ed Pajor[1], [1]*Department of Production Animal Health, University of Calgary, Calgary, AB, Canada,* [2]*Department of Animal and Poultry Science, University of Guelph, Kemptville, ON, Canada,* [3]*Organic Dairy Research Centre, University of Guelph, Alfred, ON, Canada.*

Usage of automatic milking systems (AMS) is becoming increasingly common in Canada. The purpose of this study was to describe producers' transition to AMS and document their satisfaction. A total of 149 AMS producers were surveyed in 9 provinces by telephone and email. The average number (±SD) of robotic units/farm was 2 ± 1. The median AMS age was 32 mo, with a range of 4 to 170 mo. Of the respondents, 88% of farms used a free-flow traffic system, while 12% used a directed traffic system. Results show that 56% of producers built a new barn and 50% changed housing systems for the transition. Concerning animal training programs, 21% of producers trained cows before first milking with the robot and 38% used a training program for heifers. It took, on average, one week to train cows (7.4 ± 6.0 d) and heifers (7.7 ± 5.9 d), but 2.7 ± 0.4 mo for the entire herd to adapt to the robot. Sixty percent of farms had cows that were not able to adapt to the robot. The median proportion of the herd culled for not adapting was 1% (with a range of 0 to 40%). The average number of lactating cows increased from 92 ± 56 to 102 ± 68. The total hours devoted to milking/day, which included moving/fetching cows, milking time, preparation and cleaning of milking system, decreased by 40%. Milking frequency averaged 3.1 ± 0.4 milkings/day. The majority (84%) of surveyed farms experienced an increase in milk yield from their previous milking system. The median bulk tank somatic cell count (SCC) was 180,000 cells/mL, with a range of 43,000 to 375,000 cells/mL. Changes in bulk tank SCC were variable with producers reporting increases, decreases or no change. Producers also reported an increase in time flexibility, life quality and a willingness to recommend AMS to other dairy producers. Transitioning to an AMS requires effort in training cows and learning a new management system. Producers reported that AMS have met their economic and lifestyle expectations, while improving animal welfare.

Key Words: automatic milking, dairy producer, transition

M252 A stochastic dairy farm model to evaluate the effect of changes in technical or economic factors on performance and benefits. Sergio Calsamiglia*[1], Susana Astiz[2], Lorena Castillejos[1], Carlos Lopez de Toro[1], and Joaquim Baucells[3], [1]*Universitat Autonoma de Barcelona, Bellaterra, Spain,* [2]*INIA, Madrid, Spain,* [3]*Centre Veterinari Tona, Tona, Spain.*

Dairy farms are constantly challenged with decisions. The evaluation of the outcome of such decisions requires the integration of technical and economic effects over time. The complexity of the multiple interactions can be resolved with the use of mathematical models that integrate biological and economical processes. The objective of the study was to develop a stochastic model to simulate technical and economic consequences of changes implemented in dairy farms. Individual cows of a dairy farm are uploaded. Data on reproduction, diseases, economics, labor, finances, management decisions, facilities and environment are introduced (default values are provided). Farm performance is modeled over a period and technical and economic performance is provided in the output. An 810 dairy cow farm (10,800 L/cow/year), 205 DIM, 15% pregnancy rate with average incidences of diseases and prices was used as a model. Three scenarios were tested: (1) CON = No change in the current conditions; (2) CULL = Increase in voluntary culling rate by 5 percentage units (31 vs. 36%); and (3) SEMEN = Change from the use of low cost semen vs. high cost semen (€10 vs. €20) assuming that the use of the more expensive semen results in an increased genetic potential of 2% in the daughters. A simulation of 10 years was repeated 40 times with stable technical and economic conditions. At the end of the 10-year simulation, CULL increased benefits by 14%. Treatment SEMEN resulted in reduced income for the first 5 years, probably due to the increased cost of semen and the time required for the expression of the genetic improvement. After the 10-year simulation, SEMEN accumulated a 20% loss, although in the year 10 of simulation SEMEN had a 16% higher benefit. It took 13 years to reach the breakeven point for SEMEN. Although genetic improvement cannot be ignored in dairy farms, the benefits are long-term. In contrast, CULL resulted in short and medium term benefits.

Key Words: model, dairy farm, economic performance

M253 Changes in temperature-humidity index and number of hot days related to heat stress of dairy cattle in Thailand. Thirarat Sae-tiao[1], Skorn Koonawootrittriron*[1], Thanathip Suwanasopee[1], and Mauricio A. Elzo[2], [1]*Kasetsart University, Bangkok, Thailand,* [2]*University of Florida, Gainesville, FL.*

Global climate is changing and becoming warmer. Higher ambient temperatures and humidity increase stress and lower dairy cattle production, particularly in tropical countries. Temperature-humidity index (THI) has been used to assess the risk of heat stress in dairy cattle. When THI exceeds 72, cows are likely to begin experiencing heat stress. The objective of this research was to characterize yearly changes in THI and number of days that THI exceeded 72 (NHD) in Thailand from 2002 to 2014. Average daily temperatures and relative humidity were measured in 17 meteorological stations located in 5 regions across Thailand (n = 78,713). Regions were Northern, Northeastern, Central, Eastern, and Southern. The overall yearly means and SD were 81.9 and 4.2 for THI and 361.5 d and 13.8 d for NHD, and the corresponding ranges were 58.7 to 93.2 for THI and 166 to 366 d for NHD. The THI and NHD were analyzed using a model that included year, region and interaction between year and region as fixed effects, and residual as a random effect. All fixed effects influenced THI and NHD ($P < 0.01$). Yearly LSM ranged from 79.3 (Northeastern-2011) to 84.1 (Central-2010) for THI, and from 315 (Central-2002) to 366 d (Southern-2012) for NHD. Trends across years were non-significant for THI ($b = -0.003$ units/yr; $P = 0.93$) and for NHD ($b = 0.39$ d/yr; $P = 0.34$). However, larger fluctuations in THI existed from 2009 to 2014 than from 2002 to 2008 (81.3 to 83.3 vs. 81.5 to 82.4). Conversely, NDH showed similar ranges in both periods (349 to 364 d vs. 341 to 357 d). The LSM for THI and NHD were higher in the Central (83.0 and 354 d), Eastern (83.0 and 363 d), and Southern (82.8 and 361 d) regions than in the Northeastern (80.6 and 344 d) and Northern (80.6 and 346 d) regions. Although increasing trends in THI and NHD did not occur during the years of the study, variability in THI increased since 2009. Regional effects indicated that more comprehensive strategies for reduction of heat stress in dairy cattle might be needed in the Central, Eastern, and Southern Thailand than in the Northern and Northeastern parts of the country.

Key Words: environment, dairy, tropic

M254 Checks and balances: Evaluating reliability of dairy nutrient management data to better protect groundwater resources. Christine Miller* and Deanne Meyer, *University of California, Davis, Davis, CA.*

To protect groundwater from further nitrate contamination, California regulations prohibit dairy producers from applying more than 140% of the nitrogen (N) that their crops remove. The regulations require copious annual reporting of crop field management, farm infrastructure, and animal population. The data collected in these annual reports could be integral to evaluating and improving both farm practices and the regulations themselves. Data reliability and accuracy must be assessed to use the information responsibly. Annual Reports from 18 dairies were obtained to assess reliability. Mass balance calculations were preformed to check the self-consistency of data within a facility. The results of mass balance calculations show that the data do not account for a remarkably large percentage of the nutrients being produced on the farms. Literature suggests that over 60% of N and 90% of P should be recovered; however, a median of only 25% of both N and P in cattle manure was recovered based on annual report data. This could be due to many different causes including inaccurate nitrogen sampling and analysis techniques, systematic reporting errors, or fraudulent reporting. Given that the accuracy of the majority of the recommended sampling and analysis protocols has not been assessed, it is likely that these methods are a significant source of error. Projects that should improve data collection protocols in both the short and long term are in progress. Online decision trees are being developed to help farmers self-assess their current data collection practices, and provide personalized suggestions for improvement. Additionally, I will use a statistical modeling approach paired with field experiments to examine the uncertainty in these recommended protocols (and thereby the overall uncertainty in regulations). By separating the various sources of measurement error, the model will identify the best ways to improve data collection and regulation efficacy. Results of this and future studies will influence future nutrient management regulations in California and other states with active livestock industries.

Key Words: dairy waste management, nitrate leaching

M255 Reproductive performance of North American dairies by geographic region. Cristian F. Vergara*[1,2], Flavio Bitencourt[1], Lydia M. Johnson[1], Diego Vallejo[1], and Hernando Lopez[1], *[1]ABS Global Inc., DeForest, WI, [2]ABS Chile Ltda., Santiago, Chile.*

Our objectives were to compare reproductive indicators from Holstein, Jersey and Crossbred dairies in 4 regions of United States of America and establish benchmarks for the 20% most efficient herds. Data from 290,351 cows and their records in DC305 were collected from February to November 2014 from a sample of 162 ABS customers. Regions (herds) represented were: Eastern (E; n = 28), Midwestern (MW; n = 58), Northwestern (NW; n = 10), and Southwestern (SW; n = 66). Univariated analyses were conducted with the MIXED and FREQ procedures of SAS using herd as the experimental unit. The Regions differed ($P < 0.05$) by mean (SE) herd size (E = 1,022 ± 580; MW = 690 ± 537; NW = 4,919 ± 496; SW = 2,760 ± 533) and kg of daily milk production (E = 37.4 ± 1.7; MW = 36.1 ± 1.6; NW = 32.3 ± 1.5; SW = 36.5 ± 1.6). Crossbred were not represented in the South Regions and Jerseys not represented in MW, making this effect significant ($P < 0.05$). The West Regions had a lower use of timed AI ($P < 0.05$) than E and MW (E = 46.1%; MW = 49.1%; NW = 17.6%; SW = 15.4%); but a lower conception rate (CR) ($P < 0.05$) than E and MW Regions (E = 36.6%; MW = 36.9%; NW = 31.5%; SW = 32.7%). Regarding insemination risk, only MW did lower ($P < 0.05$) than the other 3 Regions (E = 63.8%; MW = 52.8%; NW = 62.3%; SW = 61.8%). As a result, the E Region had the best pregnancy risk (PR) and MW the lowest (E = 22.9%; MW = 18.2%; NW = 20.0%; SW = 20.3%). The West Regions reported a higher ($P < 0.05$) pregnancy loss (E = 11.4%; MW = 10.3%; NW = 16.0%; SW = 13.3%). The 20% most efficient herds based on PR ranking (n=71) had a mean PR of 24%. Breeds were represented in both strata and was not a significant effect ($P > 0.05$). The top 20% had a 10 points higher insemination risk (mean 64%) and a 6 points higher CR (mean 38%) than bottom 80% ($P < 0.05$). Additionally, they breed open cows at pregnancy diagnosis 3 days earlier (mean 10 ds), but did not differ in timed AI usage ($P > 0.05$). The top 20% herds were not different in their daily milk production, voluntary waiting period, and pregnancy loss in comparison with the bottom 80% ($P > 0.05$). Despite regional differences, the best combination of factors led the East Region to achieve the highest PR. The top 20% herds in PR had higher overall reproduction but did not differ in herd management performance with the bottom 80%. Further analysis is needed.

Key Words: dairy, reproduction

M256 Lactation stage alters the rumen protozoal communities in three breeds of primiparous dairy cattle. L. M. Cersosimo*[1], M. Bainbridge[1], A.-D. G. Wright[2], and J. Kraft[1], *[1]University of Vermont, Burlington, VT, [2]University of Arizona, Tucson, AZ.*

Rumen protozoa are anaerobic ciliates that degrade fiber, starch, and proteins consumed by the host. The objective of our study was to determine if breed (B) or lactation stage (LS) affect the rumen protozoal community. Whole rumen digesta samples were collected at 3 and 93 d in milk (DIM) from 7 Holstein (H), 8 Jersey (J), and 7 Holstein-Jersey crossbreds (X) co-housed in free stalls. To characterize the rumen protozoa, the V3-V4 region of the 18S rRNA gene was amplified with the primers 316F and 758R. Sequence reads were produced by Illumina MiSeq (v.3) and the program Mothur was used for all bioinformatics analyses. The protozoal densities (cells/mL digesta) were determined by real-time PCR amplification of the 18S rRNA gene. The effects of B, LS, or B x LS on rumen protozoa were evaluated with the PROC MIXED model in SAS. At 3 DIM, 307,739 sequence reads clustered at a 4% cutoff into 3–21 operational taxonomic units (OTU) per animal with means of 5, 6, and 7 for H, J, and X, respectively. At 93 DIM, 536,846 sequence reads clustered into 1–15 OTU per animal with an average of 3 OTU for each breed. For both stages, greater than 98% of the sequences clustered with OTU 1, belonging to the family, *Ophryoscolecidae*. The OTU-based diversity measures, Shannon index ($P < 0.01$), Inverse Simpson index ($P < 0.05$), and Chao I estimator ($P < 0.001$) showed greater diversities at 3 DIM. The abundances of protozoal genera *Epidinium* (0.4–9.3% abundance), *Ostracodinium* (3.5–21.6%), *Ophryoscolex* (0.2–3.0%), and *Polyplastron* (2.4–7.1%) were affected by LS ($P < 0.05$). However, no differences in abundance were observed in the genera, *Entodinium* (19.8–36.3%), *Metadinium* (0.8–21.2%), *Isotricha* (0.3–1.7%), or *Diploplastron* (0.7–2.7%). *Eudiplodinium* spp were less abundant in H than in X ($P < 0.05$), respectively, at 3 DIM (H: 2.0, X: 12.2%) and at 93 DIM (H: 2.6, X: 20.3%). Protozoal densities at 3 DIM (10^4-10^6 cells/mL) and 93 (10^3-10^6 cells/mL) DIM did not differ. The present study suggests that early and peak LS, but not B, affects the rumen protozoal community in primiparous dairy cattle.

Key Words: ciliates, 18S, diversity

M257 Quality of hatching eggs from different broiler breeder ages. Vanessa Michalsky Barbosa*[1], Bruno Delphino Medrado[1,2], Isabela Cláudia Barbosa Santos[1], Larissa Kiana Santos Azevedo Martins[1], Taís Pinheiro Borges Silva[1], Tayana Nery Franca[1], Silvania Belo Dourado[1], Juliana Cantos Faveri[1], and Lia Muniz Barretto Fernandes[3], *[1]Department of Animal Science, Faculty of Veterinary Medicine and Animal Science, Federal University of Bahia, Salvador, Bahia, Brazil, [2]Federal Institute of Education, Science and Technology–Santa Inês Campus, Santa Inês, Bahia, Brazil, [3]Department of Animal Production, Faculty of Veterinary Medicine and Animal Science, Federal University of Bahia, Salvador, Bahia, Brazil.*

Several requirements before and during the artificial incubation process interfere with the success of the day-old chicks production, and the quality of the eggs to be incubated is an important factor to be considered. The aim of this study was to investigate the characteristics of young and old broiler breeder eggs. We studied 200 incubating eggs produced by Cobb broiler breeders aged 29 wk (n = 100) and 62 wk (n = 100). It was used a completely randomized design. The treatments were the age and each egg was considered replication. The eggs were weighed (EW), and also its components: eggshell (ES%), yolk (Y%) and albumen (A%). Specific weight analysis (SW) was determined by the solutions of different densities method. The eggshell resistence (ER) was analyzed by compression strength test. The means of eggshell thickness (ET) and number of pores (PO) were obtained in 3 different regions. Additionally we evaluated albumen pH (pHA), yolk pH (pHY), albumen height (AH), yolk height (YH) and Haugh Units (HU). Data were analyzed using PROC GLM of SAS 9.2 and the means were compared by F test. EW, Y%, pHA were higher ($P < 0.05$) from the old flock as compared with the young flock (72.48 vs 57.91 g; 31.19 vs 26.30%; 8.84 vs 8.64; respectively). ES%, A%, SW, ER, ET, PO, AH, HU were higher ($P < 0.05$) from the young flock as compared with the old flock (8.99 vs 8.71%; 64.70 vs 60.10%; 1.082 vs 1.076 g/mL H_2O; 2320 vs 2158 g; 0,438 vs 0,428 mm; 122 vs 105 pores/cm^2; 8,12 vs 7,19 mm; 82,22 vs 71,61 HU; respectively). There was no effect between the treatments for pHY and YH. The hatching eggs quality from 62-wk-old broiler breeder is less than that of 29-wk-old broiler breeder. Due to the influence of the structural characteristics of eggs in embryo development, it is necessary to monitor the quality parameters and performing further studies that aim adapt the conditions of the incubation process according to the egg to be incubated.

Key Words: artificial incubation, eggshell, poultry production

M258 Effects of turning duration during incubation and broiler breeder age on hatchability, chick organs, and poultry performance. Vanessa Michalsky Barbosa*[1], Bruno Delphino Medrado[1,2], Mariana André Pompeu[3], Júlia Sampaio Rodrigues Rocha[3], Edgard Onoda Luiz Caldas[3], Genilson Bezerra Carvalho[4], Leonardo José Camargos Lara[3], and Nelson Carneiro Baião[3], *[1]Department of Animal Science, Faculty of Veterinary Medicine and Animal Science, Federal University of Bahia, Salvador, Bahia, Brazil, [2]Federal Institute of Education, Science and Technology–Santa Inês Campus, Santa Inês, Bahia, Brazil, [3]Department of Animal Science, Veterinary School, Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil, [4]Department of Animal Science, Veterinary Medicine and Animal Science School, Federal University of Goiás, Goiânia, Goiás, Brazil.*

We evaluated in an industrial scale, the effects of turning duration (15, 17 and 19 d) in the incubation phase and Cobb broiler breeder age (33 and 63 weeks) on the hatchability of fertile eggs (HF), the weights of the heart (HW) and yolk sac (YSW) and their relation to the weight of chicks: (HW/CW and YSW/CW, respectively). The poultry performance was analyzed by chick weights during the housing (BW1), broiler weights at 42 d old (BW42), weight gain from 1 to 42d (WG), feed intake from 1 to 42d (FI), feed conversion from 1 to 42d (FC) and viability from 1 to 42d (VIAB). It was used a completely randomized design. Eighteen trays (replication) with 96 eggs each were used for the evaluation of hatchability. For the organs it were used 36 chicks per treatment, and the chick was considered the replication. To evaluate the poultry performance, we used 6 pens with 25 birds per treatment, with pen considered the repetition. Eggs were set in an incubator Casp CMg 125E multistage. On the 15th, 17th or 19th days of incubation, the cessation of egg turning was performed and the eggs were transferred to the hatchers. The unhatched eggs were analyzed to determine infertility. The male chicks were housed in an experimental stable and the performance parameters were measured weekly. Data were analyzed using PROC GLM of SAS 9.2 and the means were compared by F test. In the incubation phase, we used a split plot design and in the performance phase it was used a factorial design. Compared with old flocks, chicks and broilers from young breeder flocks had lower HW (0.36 vs 0.40 g), YSW (5.28 vs 6.47 g), YSW/CW (12.5 vs 13.5%), BW1 (40.0 vs 44.7 g), BW42 (3047.6 vs 3131.4 g), WG (3007.6 vs 3086.8 g) and FI (4860.8 vs 4989.3), independent of the turning duration, but there were no effects of breeder age on HF, HW/CW, FC, VIAB. There were no effects of turning duration, regardless the breeder age. The turning can be discontinued after 15 d of incubation without negative effects on hatchability, heart weight, yolk sac weight, and poultry performance.

Key Words: animal production, day-old chick, embryo development

M259 Health, milk yield and quality for Parmigiano Reggiano cheese evaluated in cows fed OmniGen-AF from dry-off to 150 days in milk. Ludovica M. E. Mammi*, Mattia Fustini, Elena Bonfante, Alberto Palmonari, Giorgia Canestrari, and Andrea Formigoni, *Department of Veterinary Medical Sciences, University of Bologna, Ozzano Emilia, Italy.*

One hundred ninety-one Holstein and x-bred cows were used to study the effect of feeding OmniGen-AF (OG, Phibro Animal Health, Quincy, IL) from dry-off to 150 d in milk (DIM) on health, milk yield (MY) and milk components for making Parmigiano Reggiano cheese. Cows were assigned randomly to either a control (C, n = 95) or a group fed 55g/h/d of OG (n = 96). Groups were balanced on parity, breed, expected calving date, BCS and previous MY. Cows were housed in comparable pens during the dry and lactation phases with diets fed as TM rations. Cows were milked 2× and MY recorded daily using Afimilk. Individual cow milk was sampled at dry-off, once between DIM 4 and 10 and then every 4 wk to 150 DIM and analyzed for fat, casein, protein, lactose, somatic cell count (SCC), acidity and lactodynamographic analysis (LDG). Health events were recorded. Treated or culled cows (n = 43) were excluded from the statistical analysis for milk production and quality. Milk was analyzed by ANOVA-Repeated Measures, SCC by Kruskal-Wallis test and all data processed using Statsoft Statistica v.10. Significance declared at $P \leq 0.05$. MYs were not different, although OG cows tended ($P = 0.25$) to produce more milk (+1.39kg/d) with a lower SCC linear score (−0.06, $P < 0.10$) than C cows. A higher % of milk samples (23%) in C group had SCC > 300,000 cells/mL ($P < 0.10$) compared with OG cows (18.2%). The same trend was observed in cows with 2 or more samples > 300,000 cells/mL (C = 32.4%, OG = 22.9%, $P = 0.27$). Milk composition did not differ between C and OG cows, except milk from OG cows had a tendency ($P = 0.12$) for a better LDG score (OG = 18.24, C = 19.24). Culling rates were higher in the C cows group (12.6%) compared with OG (7.4%) and culling tended to occur sooner (DIM) for C cows than OG cows (57.3 vs. 102.6, $P < 0.10$). Incidence rates (%) of mastitis and metritis were higher in the C (18.9, 17.9) versus the OG cows (10.4, 15.6). In this study, cows fed OG from dry-off to 150 DIM tended to have fewer diseases and culls, plus a tendency for improved MY and properties associated with quality Parmigiano Reggiano cheese.

Key Words: OmniGen-AF, Parmigiano Reggiano, health

M260 Body weight gain of dairy heifers fed diets with *Origanum vulgare* or *Camellia sinensis* extracts.

Vivian Fischer*[1], Giovani Jacob Kolling[1], Débora Strider[1], Dejani Maira Panazzolo[1], Carolina da Silva dos Santos[1], Alexandre Mossate Gabbi[1], Mateus Wanderer[1], Andress Sopelsa[1], and Renata Wolf Sune Martins da Silva[2], *[1]Universidade Federal do Rio Grande do Sul, Porto Alegre, RS, Brazil, [2]Empresa Brasileira de Pesquisa Agropecuária, Bagé, RS, Brazil.*

Biological effects of plant extracts containing essential oils and polyphenols have been extensively studied for humans and nonruminant production animals, but in vivo studies with ruminants in field conditions are relatively scarce. This work aimed to investigate the effect of addition of *Origanum vulgare* or *Camellia sinensis* extracts upon average daily weight gain (ADG) of dairy heifers. Two trials were conducted for 70 d to test the levels of *Origanum vulgare* (0, 2.5, 5, 7.5 g/heifer/day) and *Camellia sinensis* (0, 1, 2, 3 g/heifer/day) extracts. Trial 1 used 32 Holstein heifers with initial overall BW 442.1 ± 96 kg and trial 2 used 34 heifers: 11 Jersey and 23 Holstein, with initial overall BW 305 ± 42 kg. Heifers grazed range pasture (trial 1) and Tifton (*Cynodon dactylon*; trial 2) and were individually supplemented with 2.5 and 1.5 kg of concentrate once a day in the morning, in trials 1 and 2, respectively. Heifers were weighed on day −14 (used as covariate), and afterward, on d 1, 28 and 56 after the inclusion of the extracts into the concentrate. Data of each trial was submitted to variance analysis, using the Mixed procedure of SAS according to a completely randomized design, considering the effect of diet (n = 4), period, interaction diet x period, breed and interaction diet × breed (just for trial 2) and the initial body weight as a covariate. Heifers supplemented with *Origanum vulgare* extract did not change daily weight gain and overall ADG was 0.56 kg. Heifers supplemented with 1 g of *Camellia sinensis* extract had greater ADG ($P < 0.05$) than those fed with zero and 3 g of *Camellia sinensis* extract. Inclusion of 1 g of *Camellia sinensis* extract increased ADG 11%. In this study feeding *Carmllia sinensis* at 1g/heifer daily improved ADG of dairy heifers.

Table 1 (Abstr. M260).

	Trial 1 – *Origanum vulgare* (g/heifer/day)					Trial 2 – *Camellia sinensis* (g/heifer/day)				
Item	0	2.5	5.0	7.5	$P > F$	0	1	2	3	$P > F$
ADG (kg/d)	0.62^a	0.68^a	0.66^a	0.73^a	NS	0.55^a	0.61^b	0.57^{ab}	0.52^a	*

*$P < 0.05$.

M261 Effect of cow BCS during gestation on performance variables of the offspring.

Rodrigo Marques*, Reinaldo Cooke, Murilo Rodrigues, Bruno Cappellozza, and David Bohnert, *Oregon State University-EOARC, Burns, OR.*

The objective of this experiment was to evaluate the effects of cow BCS during gestation on productive parameters of the offspring. Ninety-seven Angus × Hereford cows pregnant to AI and to the same sire were assigned to the study based on their BCS during gestation: (1) ADQ = cows with adequate BCS throughout gestation (n = 20), (2) INDQ = cows with inadequate BCS throughout gestation (n = 20), (3) EARLY = cows that gained BCS during the first trimester of gestation and maintained BCS until calving (n = 19), (4) MID = cows that gained BCS during the second trimester of gestation and maintained BCS until calving (n = 19), and (5) LATE = cows that gained BCS during the third trimester of gestation and maintained BCS until calving (n = 19). Upon calving, calf BW was recorded. Approximately 60 d after calving, cow milk production was assessed using the weigh-suckle-weigh technique (12 h calf removal following by 30 min of nursing). Calves were weaned at 7 mo of age. All data were analyzed with the MIXED procedure of SAS. Cow BCS did not change ($P \geq 0.30$) for ADQ and INDQ cows during gestation (average 4.6 and 6.0, respectively) and increased ($P \leq 0.01$; based on BCS collected at AI, beginning of the second and third trimesters of gestation, and calving) for EARLY (4.4, 5.4, 6.0, and 6.1; SEM = 0.2), MID (4.4, 4.5, 6.1, and 6.1; SEM = 0.2), and LATE (4.5, 4.6, 4.7, and 5.9; SEM = 0.2). No treatment effects were detected ($P \geq 0.42$) for calving rate (93, 100, 93, 100, and 100%, respectively; SEM = 5), calf BW at birth (45.2, 42.8, 43.2, 44.3, and 42.2 kg, respectively; SEM = 2.1), and estimated cow milk production (14.8, 13.7, 13.4, 14.2, and 15.7 kg/d, respectively; SEM = 1.6). However, calves from cows that gained BCS during gestation (EARLY, MID, and LATE) were heavier at weaning compared with calves from cows that maintained BCS during gestation (ADQ and INDQ; 253, 251, 260, 268, and 264 kg, respectively; SEM = 3.5). Therefore, these results indicate that increasing BCS during gestation in beef cows benefits weaning BW of the offspring,

Key Words: cow BCS, gestation, offspring performance

M262 A comparison of two evaporative cooling systems on a commercial dairy farm in Saudi Arabia.

Xavier A. Ortiz*[1], John F. Smith[1], Fernando Villar[1], Laun W. Hall[1], Jamison D. Allen[2], Andrew Odde[3], Adnan al-Haddad[3], Peter Lyle[4], and Robert Collier[1], *[1]The University of Arizona, Tucson, AZ, [2]Northwest Missouri State University, Maryville, MO, [3]Al Safi Dairy Company, Al-Kharj, Kingdom of Saudi Arabia, [4]Schaefer Ventilation Equipment, Sauk Rapids, MN.*

Efficacy of 2 cooling systems, (Korral Kool, KK; Korral Kool Inc., Mesa, AZ, FlipFan dairy system, FF; Schaefer Ventilation Equipment LLC, Sauk Rapids, MN) was estimated utilizing 4 hundred multiparous Holstein dairy cows randomly assigned to one of 4 cooled California style shade pens (2 shade pens per cooling system). Each shaded pen contained 100 cows (DIM = 58 ± 39 d, milk production = 56 ± 18 kg/day and lactation = 3 ± 1). Production data (milk yield and reproductive performance) were collected during 4 mo (May–August, 2013) and physiological responses (core body temperature, respiration rates, skin temperatures and resting time) were measured, in June and July to estimate responses of cows to the 2 different cooling systems. Water and electricity consumption were recorded for each system. Cows in the KK system displayed slightly lower respiration rates in the month of June ($P < 0.05$) and lower skin temperatures in June and July ($P < 0.05$). However, no differences were observed in the core body temperature of cows, resting time, DMI, milk yield, services/cow and conception rate between systems. The FF system utilized less water and electricity during this study ($P < 0.05$). In conclusion, both cooling systems (KK and FF) were effective in mitigating the negative effects of heat stress on cows housed in arid environments while the FF system consumed less water and electricity and did not require use of curtains on the shade structure.

Key Words: heat stress, dairy cow, evaporative cooling

M263 Association between changes in body condition score and back fat thickness during the transition period with fertility and health events in Holstein cows.

P. D. Carvalho* and P. M. Fricke, *Department of Dairy Science, University of Wisconsin-Madison, Madison, WI.*

Our objective was to assess the association between body condition score (BCS) change and back fat thickness (BFT) during the transition period with pregnancies per AI (P/AI) and health events in Holstein cows in a prospective cohort study. Measurement of BCS and BFT in Holstein cows (n = 645) began ~3 wk before calving, and at 4 ± 3, 25 ± 3, 52 ± 3, 80 ± 3, and 113 ± 3 d after calving. All cows received a timed artificial insemination (TAI) at 80 ± 3 DIM after a Double Ovsynch protocol. Health events included milk fever, ketosis, retained placenta, DA, mastitis, and respiratory disorders. Data were analyzed using logistic regression with GLIMMIX and ANOVA with MIXED procedures of SAS. Changes in BCS before but not after calving were associated with P/AI at first TAI. Cows were grouped based on BCS change (5 point scale; 0.25 point increments) before calving as follows: 1) cows that lost ≥0.5; 2) cows that lost 0.25; and 3) cows that maintained or gained BCS. Change in BCS before calving differed ($P < 0.01$) among groups and was −0.57; −0.25; and 0.03 for cows in groups 1, 2, and 3, respectively. Change in BFT before calving differed ($P < 0.01$) among groups and was −2.49, −1.32, and −0.66 mm for cows in groups 1, 2, and 3, respectively. The proportion of cows with ≥1 health event during the first 120 DIM differed ($P = 0.01$) among groups and was 77% (54/70), 60% (105/174), and 62% (116/186) for cows in groups 1, 2, and 3, respectively. At 32 d after TAI, P/AI differed ($P = 0.04$) among groups and was 37% (23/62), 48% (73/153), and 55% (92/168) for cows in groups 1, 2 and 3, respectively. Cows with ≥1 health event had fewer P/AI compared with healthy cows [47% (180/379) vs. 64% (127/199), respectively]. The proportion of cows culled by 300 DIM did not differ ($P = 0.74$) among groups and was 25% (14/56), 27% (36/135) and 23% (33/145) for cows in groups 1, 2, and 3, respectively. We conclude that cows that lost BCS before calving lost more back fat, had fewer P/AI, and had more health events during the first 120 d of lactation. Supported by USDA NIFA Hatch project 231440.

Key Words: fertility, body condition score, back fat thickness

M264 Effect of an automated teat preparation system on teat skin bacterial counts.

Cecilia Baumberger* and Pamela L. Ruegg, *University of Wisconsin, Madison, WI.*

The aim of this study was to compare reduction in bacterial counts of teats cleaned using a commercial teat scrubber system (TS; FutureCOW, Longwood, FL) or using conventional premilking preparation (CONV). Cows (n = 394) from 10 WI dairy farms that were currently using TS were assigned to either CONV (n = 198; 20/farm) or TS (n = 196; 20/farm) premilking routines. CONV preparation consisted of forestripping, predipping using 0.5% iodine and drying with a cloth towel. Preparation with TS was performed using chlorine dioxide and varied according to each farm routine; most included forestripping and some included a dry prewipe. Teat skin swabs were collected before and after sanitation and analyzed for total bacteria count (TBC), *Strep.* spp., *Staph.* spp. and gram-negative bacteria (GNB). Reduction (RED) in each bacterial count was the difference between the $\log_{10}$ values before and after sanitation. RED was assessed using models that included treatment (CONV and TS), farm and treatment by farm interactions. For preparation using TS, the influence of the concentration of chlorine dioxide on RED was assessed using PROC GLM (SAS Institute, 2008). For teats prepared by CONV, RED was 2.26, 2.34, 2.23 and 2.04 $\log_{10}$ cfu/mL for TBC, *Strep.* spp., *Staph.* spp. and GNB, respectively. For TS, RED was 1.97, 2.14, 1.97 and 2.79 $\log_{10}$ cfu/mL for TBC, *Strep.* spp., *Staph.* spp. and GNB, respectively. However, significant interactions of treatment by farm were identified for RED in all bacterial counts. Differences in RED based on preparation were not different for TBC (7 farms), *Strep.* spp. (8 farms), *Staph.* spp. (8 farms) or GNB (7 farms). Teats receiving CONV prep had greater RED of TBC on 3 farms, of *Strep.* spp. on 2 farms and of *Staph.* spp. on 2 farms. In contrast, RED in GNB was greater for teats prepped using TS for cows on 3 farms. For all bacterial counts, the concentration of chlorine dioxide was positively associated with increased RED. Results of this study suggest that TS can achieve similar RED in bacterial counts on teat skin but effectiveness of premilking teat preparation is influenced by management practices that differ among farms.

Key Words: teat sanitation, teat skin bacterial count

M265 Effect of timing of insemination of lactating Jersey cows with sex-sorted semen on probability of pregnancy.

Gabriel D. Bombardelli[1], Henrique F. Soares[1], and Ricardo C. Chebel*[1,2], [1]*University of Minnesota, St Paul, MN,* [2]*University of Florida, Gainesville, FL.*

The objectives of the current experiment were to determine the effect of interval from reaching activity threshold to artificial insemination with sex-sorted semen on probability of pregnancy. Jersey cows (n = 500) from a commercial dairy herd were fitted with a rumination/activity SCR collar at approximately at 42 ± 7 d postpartum. Cows were presynchronized with 3 injections of prostaglandin-F2α given 14 d apart starting on d 39 ± 3 postpartum. Cows in estrus, based on tail paint removal, after 50 ± 3 d postpartum were inseminated by 1 of 3 technicians. Only cows inseminated in estrus were used in the experiment. Cows were examined for pregnancy at 31 ± 3 and 66 ± 3 d after insemination. A sub-sample of cows (n = 35) were examined by ultrasound every 8 h after onset of estrus to determine time of ovulation, which was determined by the disappearance of a growing follicle ≥10 mm in diameter. Ovulation was estimated to have occurred between the exam in which it was last recorded and the exam in which it had disappeared. Dichotomous data were analyzed by logistic regression with a model that included interval from onset of estrus to insemination (linear, quadratic, and cubic), parity, yield of energy corrected milk, and insemination technician. Interval from onset of estrus to ovulation was analyzed by ANOVA with a model that included size of the follicle at the first ultrasound exam, number of follicles >10 mm in diameter in the first exam, and yield of energy corrected milk. The mean (±SEM) and median intervals from reaching activity threshold to ovulation were 25.7 ± 1.2 h and 27 h (95% CI = 25, 28.2 h), respectively. Interval from onset of estrus to insemination tended to affect probability of pregnancy at 31 ± 3 and 66 ± 3 d after AI in a quadratic manner. Probability of pregnancy 66 ± 3 d after AI increased from 23% to 44%, when AI occurred between 4 and 29 h, respectively, after cows reached activity threshold. Insemination of lactating dairy cows with sex-sorted semen closer to expected ovulation yields the highest probability of pregnancy.

Key Words: timing of insemination, lactating Jersey cow, sex-sorted semen

M266 Determining the effect of transporting dairy cattle after calving on production and reproduction performance.

Danilo Domingues Millen*[1], Joaquim Baucells[2], and Sergio Calsamiglia[3], [1]*Sao Paulo State University, Dracena, Sao Paulo, Brazil,* [2]*Centre Veterinari Tona, Tona, Spain,* [3]*Animal Nutrition and Welfare Service, Universidad Autonoma de Barcelona, Bellaterra, Spain.*

Recently, it has been suggested that concentration of calvings in a centralized facility (FAC) may allow specialization of the drying, transition and freshening period. However, that requires the transportation of fresh cows to the host farm after calving. The objective of this study was to evaluate if transportation after calving affects milk production and reproductive performance of lactating dairy cows. A data set of 762 dairy cows from a commercial farm in Spain was used. After drying, 519 cows were transported from host farm to FAC (~80 km). The other 243 cows were at FAC, and they were not transported. Dry and production diets were identical in both farms. Milk production of previous (L-1; with no transportation) and current (L0; after transportation) lactation was recorded. Days open and current milk production were the dependent variables in the analysis, and previous milk production was used as co-variable. Transportation of cows after calving, from FAC back to the host farm, had greater 305-mature milk production when compared with cows that remained at FAC all the time (11,925 kg vs. 10,708 kg; $P < 0.001$). Transportation had no effect ($P > 0.20$) on days open (121 vs. 132). In a second analysis, the effect of DIM at time of transportation from FAC to the host farm on productive and reproductive performance was evaluated. The 519 transported cows were divided into 2 groups: 1) cows transported from FAC back to host farm at less than 8 DIM (n = 149); and 2) cows transported from FAC back to host farm at more than 7 DIM (n = 370). Cows transported earlier had greater 305-mature milk production (12,400 vs. 11,442 kg; $P < 0.01$) but had more days open (163 vs. 112 d; $P < 0.01$). Transporting dairy cows after calving does not negatively affect productive and reproductive performance. Transporting dairy cows at less than 8 DIM had positive effects on production but increased days open.

Key Words: centralized calving facility, postpartum transport, performance

M267 Antibiotic resistance of *Escherichia coli* isolated from gastrointestinal tracts of dairy calves fed waste milk or milk replacer.

Georgina Maynou[1], Anna Arís[1], Alex Bach*[1,2], Francesc Fàbregas[1], Alba Ferré[1], and Marta Terré[1], [1]*Institut de Recerca i Tecnologia Agroalimentàries, Caldes de Montbui, Spain,* [2]*Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain.*

The use of waste milk (WM) to feed calves is a common practice in dairy farms to avoid economical losses of milk disposal. The aim of this study was to determine whether there is an increase of antibiotic resistance patterns in *E. coli* isolated from feces of calves fed either WM or milk replacer (MR). Fecal swabs were collected from 20 ± 5 calves at 6 wk of age from 8 dairy farms. In 4 farms, calves were fed MR and in the other 4 they received WM. Fecal swabs were cultured to obtain 5 *E. coli* isolates per sample. Each colony was tested for its susceptibility to 9 antibiotics by disk diffusion. Binomial logistic regressions were used to analyze the resistance of *E. coli* isolates for each calf and for each antimicrobial agent tested. Feeding practice (MR or WM) and the use in the farm of the antibiotic tested (as a disease treatment) were the fixed effects of the model, and farm the random effect. Multidrug resistance profiles among *E. coli* isolates were described by cluster analyses using the Ward's minimum variance method. Then, a Chi-squared analysis was performed to assess the distribution of *E. coli* isolates in each of the 6 clusters defined within the 2 milk-feeding practices. The probability of streptomycin (STR) resistant *E. coli* isolates was greater ($P < 0.05$) in calves fed WM than in those fed MR, but the use of STR in the farm did not affect the incidence of *E. coli* resistance. The number of *E. coli* resistant to enrofloxacin (ENR) isolated from calves fed WM tended ($P = 0.08$) to be greater than that from calves fed MR, and the use of ENR in the farm did not affect the incidence of *E. coli* resistance either. Most colonies isolated (93.9%) were included in 2 of the 6 clusters defined: 1 cluster included resistant *E. coli* isolates to 1 antibiotic and the other, resistant *E. coli* isolates to 3 antibiotics. The percentage of *E. coli* isolates within the most resistance cluster was greater ($P < 0.001$) for WM treatment than for MR. It is concluded that feeding calves WM increases the presence of antimicrobial resistance in fecal *E. coli.*

Key Words: antibiotic resistance, dairy calf, waste milk

M268 Effect of feeding calves waste milk on antibiotic resistance patterns of fecal *Escherichia coli.*

Georgina Maynou[1], David Ziegler*[3], Hugh Chester-Jones[3], Alex Bach[2,1], and Marta Terré[1], [1]*Institut de Recerca i Tecnologia Agroalimentàries, Caldes de Montbui, Spain,* [2]*Southern Research and Outreach Center, Waseca, MN, United States,* [3]*Institució Catalana de Recerca i Estudis Avançats, Barcelona, Spain.*

The use of waste milk in a calf feeding program is suspected to contribute to the development of bacterial antimicrobial resistance. Fifty-two calves allocated in individual pens were randomly assigned to milk replacer (MR) or pasteurized waste milk (pWM) fed twice daily for 42 d and once daily from d 43 to weaning (49 d). Waste milk was picked up from a local dairy farm twice weekly during the study and tested for detection of β-lactam antibiotic class from each load of milk. Fecal swabs were taken from each calf at 5 and 8 wk of age and cultured to obtain 3 *E. coli* isolates per sample. Each colony was tested for its susceptibility to 12 antibiotics by disk diffusion. Feeding practice (MR or pWM) and age (5 or 8 wk) effect on *E. coli* antimicrobial resistance were analyzed using binary logistic regressions for each antibiotic tested. Feeding practice, calf age and interaction between treatment and age were the fixed effects of the model, calf the random effect and calf age the repeated. β-lactam antibiotic residues were detected from each pWM load. Calves fed pWM had greater probability ($P < 0.05$) to have ampicillin (AMP) and cephalothin (KF) (β-lactam antibiotics) resistant *E. coli* than calves fed MR, whereas the number of *E. coli* resistant to florfenicol tended ($P = 0.07$) to be greater in calves fed pWM than in those fed MR. However, the probability of isolating *E. coli* resistant to AMP and KF tended ($P = 0.11$; $P = 0.06$) to decrease in pWM from 5 to 8 wk of age, in contrast to MR calves that had similar probability of isolating *E. coli* resistant to AMP and KF from 5 to 8 wk of age. It is concluded that treating cows with antibiotics generates antimicrobial residues in milk and feeding calves pWM triggers the presence of resistant *E. coli* in the gut of dairy calves.

Key Words: antibiotic resistance, *E. coli*, pasteurized waste milk

M269 Fatty acid profile of bulk milk samples in commercial dairy herds in Quebec, Canada.

Melissa Duplessis*, Debora E. Santschi, Rene Lacroix, and Daniel M. Lefebvre, *Valacta, Ste-Anne-de-Bellevue, QC, Canada.*

Consumer awareness of the potential health issues related to the consumption of saturated fats has increased over the past years. As milk fat contains more saturated fats than most plant oils, the effect of milk and dairy product consumption on human health has been questioned. The objective of this trial was to provide an assessment of the current fatty acid (FA) profile, especially saturated FA, of bulk milk from 3 breeds [Holstein (HO), Jersey (JE), and Brown Swiss (BS)] in Quebec, Canada. Every wk from August 2014 to February 2015, milk samples (n = 97,999) from the bulk tank of 4,026 dairy herds were collected and sent to the Valacta laboratory (Ste-Anne-de-Bellevue, QC, Canada) for analysis. Milk fat and FA contents were determined using Fourier transform infrared spectroscopy. Data were analyzed using the MIXED and SQL procedures of SAS. As expected, bulk milk from JE had the highest milk fat content (5.24%) followed by bulk milk from BS (4.42%) and HO (4.15%; $P < 0.0001$). Table 1 shows that bulk milk FA profile differs between the 3 studied breeds; milk from JE herds had the highest content of saturated FA and the lowest content of polyunsaturated FA. Saturated FA content in bulk milk increased from August to February, varying from 64.66 in August to 67.11 g/100 g of total FA in February ($P < 0.0001$). Significant variation among herds was also observed ($P < 0.0001$), with saturated FA ranging from 51.18 to 76.28 g/100 of total FA. These results suggest that bulk milk FA profile varies according to breed, sampling month, and herd.

Table 1 (Abstr. M269). Milk fatty acid (FA) profile in bulk milk of 3 breeds (g/100 g of total FA; least squares means ± SEM)

Item	HO	JE	BS	*P*-value
C16:0	34.50 ± 0.01	35.12 ± 0.06	32.93 ± 0.10	<0.0001
C18:0	13.01 ± 0.00	13.11 ± 0.02	13.88 ± 0.04	<0.0001
C18:1	31.07 ± 0.01	28.00 ± 0.06	30.00 ± 0.10	<0.0001
Short-chain FA	9.62 ± 0.00	11.12 ± 0.02	10.74 ± 0.03	<0.0001
Medium-chain FA	43.75 ± 0.01	48.91 ± 0.11	46.00 ± 0.18	<0.0001
Long-chain FA	39.97 ± 0.01	36.90 ± 0.07	40.26 ± 0.12	<0.0001
Saturated FA	66.05 ± 0.01	69.36 ± 0.07	65.64 ± 0.12	<0.0001
Unsaturated FA	29.76 ± 0.01	27.77 ± 0.06	30.73 ± 0.11	<0.0001
Polyunsaturated FA	8.38 ± 0.00	7.43 ± 0.02	8.40 ± 0.03	<0.0001

Key Words: fatty acid profile, milk, cow

M270 Determination of β-hydroxybutyrate concentration in hand-stripped milk samples taken at different times relative to milking.

Melissa Duplessis*, Debora E. Santschi, Jean Durocher, and Daniel M. Lefebvre, *Valacta, Ste-Anne-de-Bellevue, QC, Canada.*

Analyzing β-hydroxybutyrate (BHBA) concentration in Dairy Herd Improvement (DHI) milk samples is a practical tool to determine incidence of hyperketonemia (HKET) in dairy herds. The objective of this trial was to determine BHBA concentration from hand-stripped milk samples outside DHI milking tests to assess HKET. A total of 31 cows with 90 d in milk or less in 3 herds was involved. Milk samples were taken just before, during and right after the morning milking and at 2, 4, 6, and 9 h after milking. Samples during milking were collected using approved metering devices used for DHI tests. Other milk samples were obtained by hand from one or several quarters. All samples were sent to the Valacta laboratory (Ste-Anne-de-Bellevue, QC, Canada). Two analytical methods were used to analyze BHBA concentration in milk, i.e., the Fourier transform infrared (FTIR) spectroscopy and the continuous flow analyzer (Skalar; which is the reference method used to calibrate FTIR). Threshold used to determine HKET was ≥0.20 mmol BHBA/L. Data were analyzed with the Glimmix and Corr procedures of SAS. A significant analytical method × time relative to milking interaction was noted on the incidence of HKET ($P = 0.0004$). Incidence of HKET differed in the samples taken right after milking ($P = 0.006$) and 2 h after milking ($P = 0.10$) between the analytical methods whereas no difference was noted for other times relative to milking ($P \geq 0.13$). Indeed, incidence of HKET was 25.8 ± 7.8% and 29.0 ± 8.0% for Skalar and 61.3 ± 8.7% and 70.0 ± 5.0% for FTIR right after and 2 h after the milking, respectively. Pearson correlation coefficient between Skalar and FTIR BHBA results was 0.95 for the samples collected during milking and was lower for other times relative to milking (ranging from 0.6 to 0.9). In conclusion, BHBA concentration in milk is a practical tool to assess HKET, especially for milk samples taken during DHI tests. Hand-stripped milk samples collected right after or 2 h after milking require further calibration of FTIR before recommending BHBA concentration analysis.

Key Words: hyperketonemia, β-hydroxybutyrate, dairy cow

M271 Prevalence of *Salmonella* and *Campylobacter* from composite fecal samples on US dairy operations.

Charles P. Fossler[1], Jason E. Lombard*[1], Paula J. Fedorka-Cray[2,3], Jodie R. Plumblee[2], Christine A. Kopral[1], and R. Camilla Kristensen[1], [1]*USDA:APHIS:VS: Center for Epidemiology and Animal Health, Fort Collins, CO,* [2]*USDA:ARS:Bacterial Epidemiology and Antimicrobial Resistance Research Unit, Athens, GA,* [3]*North Carolina State University, Raleigh, NC.*

During the National Animal Health Monitoring System's Dairy 2014 study, 6 composite environmental fecal samples were collected from 234 operations for culture of *Salmonella*. On 232 of the 234 operations, these samples were also tested for *Campylobacter*. One objective of the study was to estimate the herd-level prevalence of *Salmonella* and *Campylobacter* on US dairy operations. Samples were collected from March through July 2014. Estimates incorporated weighting procedures and were adjusted for study design. *Salmonella* was identified via culture from at least one sample on 39.2% of operations. Operations with 500 or more cows were more likely to be *Salmonella*-positive compared with operations with 30–99 cows (62.0% vs. 26.0%). No regional differences were observed in the percentage of *Salmonella*-positive operations. The largest percentages of *Salmonella*-positive samples were from manure pits (39.9%) and common alleyways (38.2%), while the lowest percentage positive were from gutter cleaners (23.9%); however, these percentages were not statistically different. Statistically, the percentage of *Salmonella*-positive operations from the Dairy 2014 study (39.2%) was not different from the percentage of *Salmonella*-positive operations from the NAHMS Dairy 2007 study (35.8%). *Campylobacter* was identified in at least one sample from 88.5% of operations. There were no differences by herd size or by region in the percentage of operations testing *Campylobacter*-positive. Overall, 54.8% of samples from holding pen floors were *Campylobacter*-positive, followed by 54.3% of samples from common alleyways, 51.1% from parlor exits, 45.5% from gutter cleaners, and 42.6% from common pens, and these locations were more likely to be positive than samples from manure spreaders (19.1%) and flush water (14.0%). A high percentage of US dairy operations can be expected to have *Campylobacter* on the operation. *Salmonella* is not as common, with less than half of operations expected to be positive at a single sampling. The percentage of operations positive for *Salmonella* did not change between the Dairy 2007 and Dairy 2014 studies.

Key Words: *Salmonella*, *Campylobacter*, prevalence

M272 Off-site dairy heifer rearing in the United States.

Jason E. Lombard*[1], Ashley E. Adams[1,2], Charles P. Fossler[1], Natalie J. Urie[1,2], Chelsey B. Shivley[1,2], and Christine A. Kopral[1], *[1]USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO, [2]Colorado State University, Fort Collins, CO.*

The National Animal Health Monitoring System′s Dairy 2014 study collected information regarding off-site rearing of dairy heifer calves. Data for the study were collected via face-to-face interviews on operations in the top 17 dairy states. An objective of the study was to describe the use of off-site heifer-rearing facilities by US dairy operations. Size categories were created based on adult cow populations: small (30–99 cows), medium (100–499 cows), and large (500 or more cows). The percentage of operations that had their heifers raised off-site increased as herd size increased: 5.5% of small, 11.9% of medium, and 44.2% of large operations. Overall 11.7% of operations raised heifers off-site. The majority of small and medium operations (84.9% and 59.0% percent, respectively) sent weaned and non-pregnant heifers to off-site rearing facilities at an average age of 255.4 and 164.7 d, respectively. The majority of large operations (62.8%) sent heifers to off-site facilities as preweaned heifers at an average age of 6.8 d. About a quarter of operations that sent the majority of calves off-site as preweaned heifers (26.6%), provided waste milk to the off-site rearing operation. Additionally, 2-thirds of the rearing facilities (66.8%) fed pasteurized waste milk. More than 4-fifths of operations (84.6%) used off-site rearing facilities within 50 miles of the dairy operation. Approximately 50% of operations in each size category and 53.8% of all operations sent heifers to a single facility where heifers had contact with cattle from other operations. Additionally, 10.6% of operations sent heifers to multiple facilities where they had contact with cattle from other operations. Most operations (69.6%) brought back pregnant heifers at an average age of 21.5 mo. Off-site heifer rearing is an important component of the US dairy industry; however, off-site rearing increases the potential for disease exposure and spread. The development of biosecurity/biocontainment plans based on specific risks associated with stress from shipping and exposure of dairy heifers to cattle from other operations at off-site facilities should reduce disease transmission.

Key Words: off-site heifer rearing, biosecurity, dairy heifer

M273 Management practices that may affect dairy heifer welfare on US dairy operations.

Ashley E. Adams*[1,2], Jason E. Lombard[2], Chelsey S. Shivley[1,2], Natalie J. Urie[1,2], Ivette N. Roman-Muniz[1], Charles P. Fossler[2], and Christine A. Kopral[2], *[1]Colorado State University, Fort Collins, CO, [2]USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO.*

The objectives of this study were to describe housing and management practices that may affect dairy heifer welfare on US dairy operations, and to compare dairy heifer housing and management practices on organic and non-organic dairy operations. This study was conducted as part of the National Animal Health Monitoring System’s Dairy 2014 study, which included dairy operations in 17 states. Data on housing and management practices were collected on 1,261 dairy operations via in-person interviews. A total of 7.4% of operations were certified organic. Organic and non-organic operations differed only in the time at which calves were removed from the dam. On 50.1% of organic operations calves remained with their dam for 12 or more hours, compared with 26.9% of non-organic operations that kept calves with their dams for that long. Individual hutch/pen was the primary housing type for preweaned heifers on 69.6% of operations in 2013 compared with 74.9% of operations in 2006. Most dairy operations (94.3%) disbudded/dehorned calves. A hot iron was the most prevalent method used to disbud/dehorn calves (69.9%); 30.0% of operations that disbudded/dehorned calves gave the calves analgesics and/or anesthetics. Tail-docking was performed on 31.7% of operations, of which 1.1% used analgesia/anesthesia. A band was the most common method of tail-docking (97.0% of operations that tail-docked); 31.9% of operations that tail-docked, docked tails when heifers were less than 2 mo of age, while 44.9% tail-docked when heifers were over 2 years of age. In total, 6.4% of preweaned dairy heifers and 1.9% of weaned dairy heifers died during 2013, compared with 7.8% of preweaned heifers and 1.8% of weaned heifers in 2006. Of preweaned heifers and weaned heifers that died in 2013, 3.5% and 4.2%, respectively, were euthanized. The percentage of operations using an analgesia/anesthesia during disbudding/dehorning increased from 13.8% in 2006 to 30.0% in 2013; however, 70% of dairy operations do not use analgesia/anesthesia when disbudding/dehorning cows, which highlights the need for education regarding pain management during surgical procedures.

Key Words: dairy heifer, welfare, organic

M274 Management practices that may affect dairy cow welfare on US dairy operations.

Ashley E. Adams*[1,2], Jason E. Lombard[2], Ivette N. Roman-Muniz[1], Charles P. Fossler[2], and Christine A. Kopral[2], *[1]Colorado State University, Fort Collins, CO, [2]USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO.*

The objectives of this study were to describe housing and management practices that may affect dairy cow welfare on US dairy operations, and to compare dairy cow housing and management practices on organic (ORG) and non-organic (NORG) dairy operations. This study was conducted as part of the National Animal Health Monitoring System’s Dairy 2014 study, which included data from dairy operations in 17 states. Data on housing and management practices were collected on 1,261 dairy operations via in-person interviews. A total of 7.4% of operations were certified organic. Freestall barns were the primary housing type for lactating cows on 39.0% of operations, while tie-stall or stanchion barns were used on 38.2%. The primary bedding material used in operations with freestall barns were sand (44.0%), sawdust (19.0%), and straw (14.2%). Operations with tie-stall or stanchion barns primarily used straw for bedding (46.4%) or saw dust (25.3%). For organic operations, the predominant flooring types for cows not being milked were concrete (45.0%), pasture (31.1%), and rubber mats over concrete (14.9%). In comparison, the predominant flooring types used on NORG operations were concrete (62.2%) and rubber mats over concrete (21.8%). Fans for cooling dairy cows were used on 59.6% of ORG operations and 77.0% of NORG operations. Sprinklers/misters were used on 12.1% of ORG and 26.3% of NORG operations. A total of 59.8% of operations provided personnel with training in milking procedures, 56.0% in animal handling, 33.4% in management of nonambulatory cattle, 29.8% in surgical procedures, and 20% in euthanasia. In total, 5.6% of dairy cows died during 2013, of which 40.6% were euthanized. While a smaller percentage of ORG operations used concrete as the primary flooring for dairy cows, more NORG operations provided heat abatement, suggesting that there is room to improve cow welfare on both types of operations. This finding is also evidenced by the percentage of dairies that do not train personnel in animal handling, surgical procedures, management of nonambulatory cattle, and euthanasia techniques, all of which may affect dairy cow welfare.

Key Words: dairy cow, welfare, organic

M275 Evaluation of colostrum management, feeding management, and weaning practices on US dairy operations.

Chelsey B. Shivley*[1,2], Jason E. Lombard[2], Ashley E. Adams[1,2], Natalie J. Urie[1,2], Charles P. Fossler[2], and Christine A. Kopral[2], [1]*Colorado State University, Fort Collins, CO,* [2]*USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO.*

The National Animal Health Monitoring System's Dairy 2014 study evaluated colostrum management, feeding management, and weaning practices on 1,261 operations from 17 of the nation's top dairy states. Results from the study indicate that on average heifer calves were given their first feeding of colostrum 3.6 h following birth. The highest percentage of operations (53.2%) administered colostrum by hand, followed by both hand-feeding and suckling the cow (40.5%), and only suckling the cow (6.3%). For the 93.7% of operations that hand-fed colostrum, 87.4% fed colostrum with a bottle, 8.1% with an esophageal feeder, and 4.5% with a bucket. Most dairies (53.0%) fed 2 L of colostrum at the first feeding, and 62.1% of operations fed another 2 L within the first 24 h following birth. About half of all operations (49.3%) stored colostrum, with freezing being the most common method of storage (73.0% of operations). About half of dairies that hand-fed colostrum (53.3%) estimated colostrum quality, with visual appearance being the most common method used (45.1% of operations). Only 6.2% of operations monitored serum proteins to test passive-transfer status. Almost half of dairies (49.9%) fed milk replacer (MR), and 63.2% fed waste milk. Of operations that fed MR, percent protein was 20–24% on 89.2% of operations. About half of operations (56.4%) fed less than 4.7 L of waste milk or MR per day, with most operations (94.6%) feeding twice per day. The highest percentage of operations used bottles and buckets to feed waste milk or MR (77.2% and 72.3%, respectively). On average, heifer calves were first offered water at 17.3 d of age, starter grain at 10.8 d of age, and hay at 36.0 d of age. The average age at weaning was 8.8 weeks, and age was the most commonly used determinant for weaning on 50.2% of operations. These results show that less than 2 thirds of producers are feeding the recommended 3–4 L of colostrum at the first feeding on US dairies, indicating that producer education on colostrum management is warranted.

Key Words: dairy heifer calves, colostrum management, feeding management

M276 Locomotion scoring dairy cows: A comparison among three different locomotion scoring on intra- and interrater reliability.

Ashley E. Adams*[1,2], Jason E. Lombard[2], and Ivette N. Roman-Muniz[1], [1]*Colorado State University, Fort Collins, CO,* [2]*USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO.*

Lameness in dairy cattle is usually identified by judging the locomotion of dairy cows. The objective of this study was to determine differences in intra- and interrater reliability among 3 different locomotion scoring systems for dairy cows. The 3-, 4-, and 5-point locomotion scoring systems were used by 42 observers to score the gait of cows in a set of 45 video clips. Each observer scored the set of clips 4 times, once using each of the 3 scoring systems, then again repeating one of the 3 systems. The order of presentation of the video clips was randomized between each viewing, and participants were randomly assigned to repeat one of the 3 scoring systems. Intra- and interrater reliability were calculated as the weighted kappa coefficient (κw). The mean intrarater reliability for the 3-point system was $\kappa w = 0.57$ (95% CI: 0.43–0.71), for the 4-point system $\kappa w = 0.60$ (95% CI: 0.53–0.68), and $\kappa w = 0.64$ (95% CI: 0.55–0.72) for the 5-point system. The CI for intrarater reliability suggests that no difference exists in κw among the 3 systems. The mean interrater reliability for the 3-point system was $\kappa w = 0.42$ (95% CI: 0.41–0.43), for the 4-point system $\kappa w = 0.43$ (95% CI: 0.42–0.44), and $\kappa w = 0.47$ (95% CI:0.46–0.48) for the 5-point system. These intervals indicate that interrater reliability is greater for the 5-point system when compared with the 3- and 4-point systems. Using a level of acceptable reliability of $\kappa w > 0.60$, none of the scoring systems achieved good reliability for interrater comparisons, while both the 4- and the 5-point scoring systems achieved good intrarater reliability. This result suggest that within observer reliability is adequate for the 4- and 5-point scoring systems, but not for the 3-point system. In contrast, between observer reliability is lacking for the 3 locomotion scoring systems examined in this study. Further analysis is needed to determine if cows are consistently identified as lame and severely lame using the 3 scoring systems.

Key Words: dairy cow, locomotion scoring, reliability

M277 Association between changes in body condition score, NEFA, and BHBA concentrations during the transition period on fertility of Holstein cows.

R. V. Barletta*[1,2], P. D. Carvalho[1], M. Madureira[3], T. A. Del Vale[2], E. R. Madureira[3], A. S. Netto[2], G. M. Baez[1], P. M. Fricke[1], and M. C. Wiltbank[1], [1]*Department of Dairy Science, University of Wisconsin-Madison, Madison, WI,* [2]*Department of Nutrition and Animal Production, School of Veterinary Medicine and Animal Sciences, University of São Paulo, São Paulo, Brazil,* [3]*Department of Animal Reproduction, School of Veterinary Medicine and Animal Sciences, University of São Paulo, São Paulo, Brazil.*

Our objective was to assess the association between body condition score (BCS) change during the transition period with pregnancies per AI (P/AI) and NEFA and BHBA concentrations in Holstein cows in a retrospective cohort study. Holstein cows ($n = 232$) were assessed for BCS (5 point scale; 0.25 point increments) at 21 d before, on the day of, and 21 d after calving. Blood samples were collected 21 and 7 d before, on the day of, and 7 and 21 d after calving and were assayed for NEFA and BHBA concentrations. All cows received a timed artificial insemination (TAI) after a Presynch-Ovsynch protocol at 75 ± 3 DIM. Data were analyzed by logistic regression with GLIMMIX and ANOVA with repeated measures using the MIXED procedures of SAS. Both NEFA and BHBA concentrations after calving differed ($P < 0.01$) for cows that lost, maintained, or gained BCS from 21 d before to 21 d after calving (NEFA: 0.49 ± 0.01; 0.40 ± 0.01; 0.43 ± 0.01 mmol/L; BHBA: 0.72 ± 0.02; 0.70 ± 0.02; 0.67 ± 0.02 mmol/L; respectively). Day of sampling relative to calving also affected ($P < 0.01$) NEFA and BHBA concentrations, with the greatest increase occurring 7 d after calving. Change in BCS after ($P < 0.01$) but not before calving affected P/AI. Cows were grouped based on BCS change after calving as to whether they: 1) lost, 2) maintained, or 3) gained BCS. By design, BCS change after calving differed ($P < 0.01$) among groups and was −0.38; 0.00; and 0.35 for cows in groups 1, 2 and 3, respectively. On the day of calving, BCS differed ($P < 0.01$) among groups and was 2.89; 2.69; and 2.49 for cows in groups 1, 2 and 3, respectively. At 21 d after calving, BCS differed ($P < 0.01$) among groups and was 2.51; 2.69; and 2.85 for cows in groups 1, 2 and 3, respectively. At 32 d after TAI, P/AI differed ($P < 0.01$) for cows that lost [13% (11/84)], maintained [33% (26/80)], or gained [47% (32/68)] BCS. In conclusion, changes in BCS during the transition period affected NEFA and BHBA concentrations during the transition period; however, P/AI was only affected by changes in BCS after calving.

Key Words: body condition score, fertility, transition period

M278 Compost bedded pack on bacterial counts and milk composition in lactating dairy cows. Lorena Castillejos, María Rodríguez, Adriana Siurana, and Sergio Calsamiglia*, *Animal Nutrition and Welfare Service, Department of Animal and Food Science, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

The compost bedded pack dairy barn is an alternative loose housing system that has been implemented in the recent years. The objective of this study was to evaluate the effect of compost bedded pack on bacterial counts in bedding and milk in lactating dairy cows. A field study was conducted in Girona (Spain) between May 2013 and July 2014 in 2 commercial dairy farms (816 and 394 lactating cows). Cows were distributed in equal barns (90 ± 14 and 66 ± 7 cows) with different loose housing system: 2 compost-bedded-pack (compost) barns were compared with 2 conventional-bedded-pack (control) barns, 4 barns per farm. Compost barns were aerated twice daily, but less sawdust was added as bedding material. Farms were visited 6 times (spring, summer and autumn of 2013 and winter, spring and summer of 2014). During each visit, bedding material samples throughout each barn and milk samples of the total production of each barn of the morning and afternoon milking were collected. Data on milk composition (lactose, protein, fat and fat free total solids) and somatic cells count (SCC) were analyzed. Bacterial counts of bedding material were determined for mesophilic aerobic bacteria (total bacteria counts, TBC), other gram-negative, total coliforms, *E. coli*, *Streptococcus* spp., *Strep. agalactiae*, and *Klebsiella* spp. Bacterial counts of milk were determined for TBC, other gram-negative, lactose (-), total coliforms, *E. coli*, coagulase-negative staphylococci, *Staph. aureus*, *Streptococcus* spp., *Strep. agalactiae*, and *Klebsiella* spp. No significant effects in bacterial counts were found in bedding material (TBC $1.1 \times 10^{10} \pm 3.3 \times 10^{9}$ cfu/g) or milk (TBC $5.1 \times 10^{4} \pm 9.3 \times 10^{3}$ cfu/mL). Milk quality (SCC 240,000 ± 173,000 cells/mL) and composition did not change, except for lactose that was higher in compost cows than in control cows (4.91 vs 4.89 ± 0.008%, $P < 0.05$). These results suggest that udder health and milk quality were not compromised when housing lactating dairy cows were in compost barns. Saving of sawdust and manure storage costs without negative effect in milk quality, encourage the implementation of compost barns in dairy farms.

Key Words: compost bedded pack barn, bacterial count, milk composition

M279 Economic impact of nutritional grouping in dairy herds. Afshin S. Kalantari*, Louis E. Armentano, Randy D. Shaver, and Victor E. Cabrera, *University of Wisconsin-Madison, Madison, WI.*

Study's objective was to evaluate the economic impact of nutritional grouping in commercial dairy herds. A dynamic, stochastic Monte Carlo simulation model was developed to represent individual cow DMI, NE_L, and MP requirements and the resulting changes in body energy throughout a year. The amount of energy consumed directly affected the BW and BCS changes in the model. Moreover, to control the range of observed BCS in the model constraints on lower and upper bounds of BCS were set. Cows that would drop to BCS <2.0 were assumed to stay at BCS = 2.0, but at a decreased milk production {New daily milk (kg/d) = daily milk (kg/d) – [deficient NE_L intake (Mcal/d)/NE_L in milk (Mcal/kg)]}, and cows that would reach BCS >4.5 were assumed to stay at BCS = 4.5, but at decreased DMI {New DMI (kg/d) = DMI (kg/d) – [extra NE_L intake (Mcal/d)/dietary NE_L (Mcal/kg)]}. The model was validated by comparing its projections against actual data regarding involuntary culling, BW, BCS, NE_L and MP concentrations of the offered diet. The model was initialized by separate data sets obtained from 5 dairy herds with different herd size and structure. Status of each cow was updated on a daily basis together with the required diet nutrient concentrations. Each month, lactating cows were regrouped according to the studied grouping strategies and their nutrient concentration requirements. The calculated income over feed costs (IOFC, $/cow per yr) of having more than 1 nutritional group among the herds ranged from $51 to $70, with an average of $58 for 2 groups and $70 for 3 groups, when group was fed at average NE_L and average+1xSD MP concentration. The improved IOFC was explained by increased milk sales and lower feed costs. Higher milk sales were a result of fewer cows having a milk loss associated with low BCS in multi-group scenarios. Lower feed costs in multi-group scenarios were mainly due to less RUP consumption. The percentage of total NE_L consumed captured in milk for greater than 1 nutritional group did not show a consistent increase and the values were rather similar among different group numbers. The percentage of N fed that was captured in milk increased with more than 1 group, and was the most important factor for improved economic efficiency of the grouping strategies.

Key Words: stochastic, simulation, nutrition

M280 Influence of calving weight on milk yield of dairy Gyr cows. Manuela Pires Monteiro Gama*[1], Gabriela Geraldi Mendonça[2], Anibal Eugênio Vercesi Filho[3], André Rabelo[4], Lenira El Faro Zadra[3], and Cláudia Cristina Paro Paz[1,3], *[1]Departamento de Genética, FMRP-USP, Ribeirão Preto, SP, Brazil, [2]Instituto de Zootecnia (IZ/APTA/SAA), Nova Odessa, SP, Brazil, [3]Centro APTA Bovinos de Corte, Instituto de Zootecnia (IZ), Sertãozinho, SP, Brazil, [4]ABCGIL – Associação Brasileira de Criadores de Gir Leiteiro, Uberaba, MG, Brazil.*

The weight of cows at calving is not a trait commonly measured by producers, but may influence milk yield and reproduction because of the negative energy balance. The effect of calving weight on milk yield of dairy Gyr cows was analyzed using data from 2 herds comprising 570 records of total yield during lactation of 363 cows that had calved between 2000 and 2014. The contemporary groups containing at least 5 observations were defined as herd and year and season of calving. The latter was divided into dry season (April to September) and rainy season (October to March). The analyses were performed using linear models containing the fixed effects of contemporary group and lactation duration (linear coefficient), and by regression of milk yield on calving weight nested within classes of age at calving (1 to 8), with class 1 corresponding to animals aged 2 to 3 years and so on until animals aged 10 years at calving. The PROC GLM module of the SAS program was used for analysis. The mean calving weight was 434.156 kg and this trait was influenced by age of cow at calving (linear and quadratic effects). The trend of regression indicated an increase in calving weight up to 90 mo, declining thereafter. The effect of calving weight for each class of age at calving presented linear regression coefficients of 5.19, 7.34, 9.33, 8.97, 2.43, −0.93, −3.70 and −4.97, respectively. These results demonstrate an increase in calving weight and total yield until physiological maturity, which occurs in this breed at about 93 mo when production starts to decrease slowly with increasing age of the animal. The influence of calving weight on milk yield is more important for younger cows. This importance decreases for older cows as expected, since they have stopped growing and have reached their maximum genetic production potential. Furthermore, older cows produce less milk compared with younger animals whose genetic potential for milk production and lactation persistence is higher due to the genetic improvement performed.

Key Words: body weight, Zebu, age at calving

M281 Effects of dietary forage and protein levels on the concentration and total load of *Escherichia coli* and *Listeria monocytogenes* in feces of dairy cows. M. Niu*[1], S. Biswas[2], J. A. D. R.N. Appuhamy[1], P. K. Pandey[2], A. Leytem[3], R. Dungan[3], and E. Kebreab[1], *[1]Department of Animal Science, University of California, Davis, Davis, CA, [2]Department of Population Health and Reproduction, University of California, Davis, Davis, CA, [3]USDA-ARS, Northwest Irrigation and Soils Research Lab, Kimberly, ID.*

Escherichia coli and *Listeria monocytogenes* are animal waste borne pathogens. The study aimed to determine if the basic dietary nutrient composition affected total *E. coli* and *Listeria* load and concentration in dairy cow feces. Twelve Holstein cows were assigned to a 2 × 2 factorial arrangement of 2 forage levels [37 (LF) vs. 53% (HF)] and 2 CP levels [15.2 (LP) vs. 18.5% (HP)] in a 4 × 4 Latin square design with 4 periods. After a 14 d adaptation period, total feces mass (kg/cow/d) was determined using total collection approach for 3 d. Six fecal samples were collected periodically to represent the course of a day. Dry matter intake (kg/cow/d), and *E. coli* and *Listeria* concentrations in all feed ingredients were measured to determine pathogen intake via feed. Pathogen concentrations in solid samples were determined as colony forming units (cfu) per gram according to the Bacteriological Analytical Manual recommended by US FDA. Total pathogen load was calculated based on the pathogen concentration and feces mass. Treatment effects were analyzed by a mixed model with the random effect of cow. Concentration of *E. coli* and *Listeria* were measured for all feed ingredients. Estimated average *E. coli* and *Listeria* concentrations in LF and HF diets were 1.4×10^6 and 1.9×10^6, and 3.8×10^4 and 5.4×10^4 cfu/kg of DM, respectively. Interaction effects between dietary fiber and CP contents were found for both *E.coli* concentration ($P < 0.05$) and load ($P < 0.01$) in feces. Fecal *E. coli* concentration and load were greater ($P < 0.05$) in HFHP (5.4×10^6 cfu/g and 6.4×10^{10} cfu, respectively) than HFLP (3.1×10^6 cfu/g and 3.64×10^{10} cfu, respectively). Greater dietary CP content significantly decreased fecal concentration of *Listeria* regardless of dietary fiber content ($P < 0.01$). Concentration of *Listeria* was higher in LP (110.5 cfu/g) than HP (68.2 cfu/g). There was no association between DM, CP, NDF, or starch of feces and *E. coli* or *Listeria*. Dietary forage and CP interactively affect the concentration and total load of *E. coli.* Only dietary CP level affects concentration of *Listeria* in the feces of dairy cows.

Key Words: dairy cow, *E. coli*, *Listeria*

M282 Urinary disposition kinetics and fecal excretion of two intramammary antibiotic preparations in dairy cows. Partha Pratim Ray*, Katharine F. Knowlton, Chao Shang, and Kang Xia, *Virginia Polytechnic Institute and State University, Blacksburg, VA.*

Appropriate assessment of the contribution of antibiotic use in animal agriculture to development of antibiotic resistance in bacterial pathogens and development of efficient mitigation strategies are limited due to a lack of data on the elimination of antibiotics from animals. The objective was to investigate urinary disposition kinetics and fecal excretion of pirlimycin and cephapirin, 2 antibiotics commonly used on dairy farms as intramammary infusion. Three lactating cows were administered 2 doses of pirlimycin (50 mg/cow; 24 h apart), and 3 end of lactation dairy cows were administered cephapirin (1200 mg/cow) intramammary. Feces and urine were collected just before antibiotic infusion and at 2, 4, 8, 12, 16, and 24 h after 1st dose of pirlimycin, at 2, 4, 8, 12, 16, 24, 36, 48, and 72 h after 2nd dose of pirlimycin, and at 2, 4, 8, 12, 16, 24, 36, and 72 h post-cephapirin infusion. Antibiotics were quantified using UPLC-MS/MS. Urinary disposition kinetics parameters were derived by fitting urine concentration-time data into noncompartmental model. Elimination rate constants in urine were estimated using regression analyses of antibiotic concentrations after peak time. The elimination half-life, mean residence time, and elimination rate constant for 1st and 2nd dose of pirlimycin and cephapirin were 11.6 ± 3.6, 20.2 ± 8.8, and 14.9 ± 1.9 h, 22.1 ± 9.3, 33.1 ± 14.5, and 25.2 ± 4.9 h, and 0.039 ± 0.034, 0.038 ± 0.016, and 0.048 ± 0.006 h^{-1}, respectively. Fecal concentration of pirlimycin peaked (252 ± 162 ng/g) at 34.9 ± 9.2 h after the 2nd dose. Despite intramammary administration, antibiotics reached blood and the digestive tract, were excreted in urine and feces, and thus may influence microbial antibiotic resistance in the gut and following excretion. Slow elimination and long residence time of antibiotics indicate that manure may need to be treated to reduce antibiotic loading to the environment. The data obtained in this study will allow development of efficient manure management strategies to reduce the contribution of dairy farms to the challenge of antibiotic resistance.

Key Words: dairy cow, disposition kinetics, intramammary antibiotic preparation

M283 Performance and health of Holstein calves fed different amounts of milk supply with or without a symbiotic complex. Marcos Inácio Marcondes[1], Juana Chagas*[1,2], Roberto D. Sainz[3], Thiago Pereira[1], and Evando Filgueiras[4], *[1]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil, [2]Universidade Federal Rural de Pernambuco, Recife, Pernambuco, Brazil, [3]University of California, Davis, CA, [4]Bioformula Leite, Gioânia, Goiais, Brazil.*

The objective of this study was to evaluate performance and health of Holstein calves fed low or high milk supply (MSP) and with an inclusion or not of symbiotic complex (SYM). Thirty-two Holstein calves (34 ± 7 kg BW) with an age of 6 d were distributed in a randomized block design in a 2 × 2 factorial arrangement. The MSP consisted in: low MSP - 10% BW for the 1st through 8th weeks after birth; and high MSP - 20% BW for the 1st and 2nd weeks after birth, 15% BW for the 3rd and 4th weeks after birth and 10% BW for the 5th and 8th weeks after birth. The SYM tested was Bioformula Leite (prebiotics, probiotics, and fibrolytic enzymes). Solid ration was supplied in addition to milk. Intake, ADG, diet digestibility, and fecal consistency index were evaluated. MSP influenced calf growth ($P < 0.10$), with different final weight (77.8 and 85.0 kg), post-weaning average weight gain (548 and 788 g/d), and final average weight gain (549 and 646 g/d) in calves fed 10% and 20% BW, respectively. MSP affected intake variables; calves fed 10% and 20% BW had pre-weaning dry ration intakes of 291 and 237 g/d, pre-weaning total DM intake of 715 and 1,672 g/d, and total DM intakes over the experimental period of 867 and 1,016 g/d. The digestibility of DM, CP, NDF, and non-fiber carbohydrates were not different for both variables ($P > 0.10$): 0.73, 0.69, 0.77, and 0.92 g/kg, respectively. There was an interaction between MSP and SYM on the digestibility's of DM and NDF ($P < 0.10$). The digestibility of DM (0.728 g/kg) and NDF (0.771 g/kg) of the calves fed 10% BW were not affected by inclusion of SYM ($P > 0.10$). On the other hand, for calves fed 20% BW, inclusion of SYM increased digestibility of DM (0.720 to 0.736 g/kg) and NDF (0.758 to 0.783 g/kg). The use of SYM improved fecal score of the animals ($P < 0.10$; 0.31 and 0.42, respectively). The milk-feeding level is an important factor in animal performance. In addition, the present study demonstrated positive results for the DM and NDF digestibilities, and animal's health; Thereby SYM might be use as an option to control diarrhea.

Key Words: fecal score, milk supply, weaning

M284 Impact of feeding betaine-containing molasses to transition dairy cows during late summer. Ana Paula A. Monteiro*[1], John K. Bernard[1], Stephen Emanuele[2], Randy Davis[2], Charles R. Staples[3], Jundi Liu[1], Geoffrey E. Dahl[3], and Sha Tao[1], *[1]University of Georgia, Tifton, GA, [2]Quality Liquid Feeds, Dodgeville, WI, [3]University of Florida, Gainesville, FL.*

Betaine (tri-methyl glycine) is a natural compound found in sugar beets and serves as a methyl donor when fed to animals. Under heat stress it can act as an osmolyte, reducing dehydration. The objective was to evaluate the effect of feeding betaine-containing molasses on performance of transition dairy cows during late summer. In early September, cows were randomly assigned to betaine (B) or control (C) groups either at dry off (B: n = 10; C: n = 10) or 24 d before calving (B: n = 8; C: n = 8) based on their previous mature equivalent milk yield. Cows were fed a common diet supplemented either with a 28% CP molasses-based liquid supplement made from sugar cane or a 28% CP liquid supplement made of molasses from sugar cane (67%) and condensed beet solubles containing ~30% betaine (33%) for C and B cows, respectively, until 60 d in milk. The liquid supplement was fed at a rate of 1.1 and 1.4 kg DM/d for pre and postpartum cows, respectively. Before calving, all cows were housed in the same free-stall barn without supplemental cooling. After calving, all cows were cooled by misters and fans and were milked thrice daily. Feed intake was recorded daily and BW and BCS were assessed every 2 wk. Milk yield was recorded at each milking and composition was analyzed weekly. Blood samples were collected weekly from a subset of cows to assess hematocrit and concentrations of cortisol, betaine, and metabolites. There were no treatment effects on intake of DM and BW in the prepartum and postpartum periods, but cows fed B had lower ($P = 0.05$) BCS at 4 and 6 wk postpartum compared with C. For those cows enrolled at dry off, B tended to have lower ($P < 0.15$) hematocrit at 8 and 5 wk before calving compared with C, but no difference was detected postpartum. All cows fed B tended ($P < 0.10$) to produce more milk (44.2 vs. 41.5 kg/d) and 3.5% FCM (50.0 vs. 47.0 kg/d) compared with C, but no differences in milk composition were observed. In conclusion, supplementing transition cows with betaine-containing liquid supplement during late summer may prevent dehydration of dry cows based on a trend for lower hematocrit and increase 3.5% FCM yield in early lactation.

Key Words: dairy cow, heat stress, betaine

M285 Growth and behavior of group-fed dairy calves fed once or twice daily in an organic production system. Myrrh-Anna J. Kienitz*[1], Bradley J. Heins[1], and Hugh Chester-Jones[2], *[1]University of Minnesota, West Central Research and Outreach Center, Morris, MN, [2]University of Minnesota, Southern Research and Outreach Center, Waseca, MN.*

Heifer calves (n = 102) were used to evaluate the effect of once or twice daily feeding on growth and behavior of calves in an organic group management system. Calves were assigned to replicate feeding groups of 10 in super hutches by birth order, during 2 seasons from September to December 2013 and March to May 2014 at the University of Minnesota West Central Research and Outreach Center, Morris. Calves in groups were the experimental unit. Breed groups of calves were: Holsteins (HO; n = 26), crossbreds (n = 45) including combinations HO, Montbéliarde, and Viking Red selected for high production, and crossbreds (n = 31) including combinations of HO, Jersey, Normande, and Viking Red selected for robustness. Treatment groups were 1) once daily feeding (1×) or 2) twice daily feeding (2×). Calf groups were fed 6 L per calf/daily (2×, 3 L/feeding) of 13% total solids organic milk then weaned at 60 d when the group consumption averaged 0.91 kg starter/calf daily. Body weight and hip height were recorded at birth, once/wk, at weaning, and at 90 d of age. Hobo Pendant G loggers were applied to the right rear leg of calves to measure total lying and standing time. Data were analyzed using PROC MIXED of SAS. Independent variables for analyses were the fixed effects of birth weight (co-variable), season of birth, treatment group, along with replicate as a random effect. Weaning group performance was gain per day, 1× (0.79 kg) and 2× (0.81 kg; $P = 0.33$); weaning weight, 1× (92.7 kg) and 2× (93.3 kg; $P = 0.80$); and weaning hip height, 1× (95.2 cm), and 2× (95.3 cm; $P = 0.94$). Daily gain to 90 d were 0.85 vs. 0.85 kg, and daily gain to 120 d were 0.85 vs. 0.83 kg for 1× and 2× calves, respectively ($P = 0.62$). For lying time, 1× (988 min/d) and 2× (995 min/d) were not different ($P = 0.57$) from each other. During the evening hours, the 2× calves had lower ($P < 0.01$) lying times (34 min/h for 1×; 28 min/h for 2×) per h because they were fed at 6pm every evening. In summary, group-fed calves fed once per day in an organic production had similar average daily gains and body dimensions compared with calves fed twice per day.

Key Words: organic, calf growth, crossbreeding

M286 The sex ratio of female to male calves may be affected by number of services to achieve conception and lactation number of the lactating dairy cow. Andy Mendes*[1], Michael R. Murphy[2], Peter S. Erickson[3], and David P. Casper[1], *[1]South Dakota State University, Brookings, SD, [2]University of Illinois, Champaign Urbana, IL, [3]University of New Hampshire, Durham, NH.*

Commercial dairy producers get frustrated by the low ratio of female to male calves born because female calves are more valuable than bull calves. The objective of this data analysis was to determine if any parameters could be identified that may be influencing the ratio of female to male calves born on the dairy operation. Data from the University of Illinois and the University of New Hampshire Dairy herds were collected and summarized for calf sex, number of services to achieve conception, and lactation number of the lactating dairy cow when she conceived. Logistical regression procedures were used to analyze the data set via version 9.4 of SAS. The data set was edited to delete those cow observations when the number of services to achieve conception (n = 6) or lactation number (n = 2) were greater than 9. These cows would typically be classified as “do not breed” and sold for harvest. The final data set contained 2,987 calvings, which consisted of 1,406 females and 1,581 males (47.1 and 52.9% for females and males, respectively). The frequency distribution of number of services to achieve conception was highest for first service and progressively declined with increasing services (52.1, 21.7, 10.8, 6.7, 4.2 and 4.7% for 1 to 6 services, respectively). The frequency distribution of calvings by lactation number was highest for 1st lactation cows becoming pregnant with their 2nd calf and declined with increasing lactation number (35.5, 28.2, 17.0, 9.6, 5.0, 2.5, 1.1. 0.1 and 0.3% for lactation number 1 to 9, respectively). Logistic stepwise regression indicated that number of services to achieve conception was significant ($P < 0.02$) in predicting the ratio of female to male calves. Calculation of odds ratios indicated that as the lactation number increased the likelihood of getting a bull calf decreased. These data demonstrate that increasing number of services to achieve conception and age of the cow increase the probability of getting a heifer calf. The earlier in DIM or age a cow conceives will increase the odds of the dairy producer getting a male calf.

Key Words: female, male, sex ratio

M287 Margin over concentrates as a performance indicator for the dairy farms. Aadi Remmik*, *Estonian University of Life Sciences, Tartu, Estonia.*

Margin over concentrates (MoC) was identified as a practical indicator of management performance at dairy farms. It was found to be a more objective metric than income over feed costs (IOFC), yet it has been scarcely used in dairy farm management literature. Estonian University of Life Sciences and partner farmers conducted a study recording data on production processes in 10 midsize (190–750 milking cows) Estonian dairy farms on a monthly basis in 2012–2014. The study included detailed information on feeding and milk output. One of the key objectives of the study was to find reliable performance indicators that would assist dairy farmers in diagnosing and measuring potential weaknesses in farms' production processes. In the study, MoC was calculated as milk sales turnover less cost of concentrate feeds for the milking herd (including dry cows, but excluding youngstock). Concentrate feeds included all feeds except grass, silages (grass and corn), hay and straw. Concentrate feeds were determined the biggest single cost component at the farms (29% of all dairy-related costs on average) and its efficient use has a significant effect on total farm profitability. MoC was found to effectively summarize the financial result of several other metrics, such as milk yield, milk price, percentage of discarded milk, and so on. MoC excludes cost of forage feeds that often lack reliable market price and can have very different physical and nutritional characteristics based of preparation timing, plant material and technology. Dairy farmers could benefit from using MoC as a broad measurement tool for the milk herd performance.

Key Words: dairy, performance, measurement

M288 Factors affecting the success of an embryo transfer program in dairy cattle. Priscila Ferraz*[3], Clay Burnley[4], John Karanja[5], Achilles Vieira-Neto[1], Jose Eduardo P. Santos[1], and Klibs N. Galvão[2], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]Department of Large Animal Clinical Sciences, University of Florida, Gainesville, FL, [3]Escola de Medicina Veterinaria, Universidade Federal da Bahia, Salvador, Bahia, Brazil, [4]Southern Embryo, Athens, GA, [5]North Florida Holsteins, Bell, FL.*

Objective of the study was to evaluate factors affecting pregnancy per embryo transfer (PET) in dairy cattle. A total of 10,634 transfers in 6,734 Holstein dairy cows (primiparous = 2,287; multiparous = 1,907) and heifers (n = 6,440) from a 4,500-cow commercial herd in Northern Florida, were used. Data on collection year (2011–2014), transfer season (fall, winter, spring, summer), semen type [conventional (C), sexed (S)], embryo type (Fresh, Frozen, IVF, IVF-Frozen), embryo developmental stage (4 - morula, 5 - early blastocyst, 6 - blastocyst, 7 - expanded blastocyst, 8 - hatched blastocyst), embryo quality grade (1 - excellent/good, 2 - fair, 3 - poor), recipient parity (N - nulliparous, P - primiparous, M - multiparous), recipient estrous cycle day (5, 6, 7, 8, 9), technician (1, 2, 3, 4), DIM, and milk yield at the time of transfer were collected. The embryos were produced in vivo (superstimulation and uterine flush 7 d after AI) or in vitro (ovum pick-up, fertilization, in vitro culture for 7 d). Pregnancy was diagnosed at 41 ± 3 d of gestation. Data were evaluated by mixed logistic regression using the GLIMMIX procedure of SAS using all data listed as fixed effects and recipient ID as random. PET was affected by embryo type (Fresh = 48.1%, Frozen = 36.6%, IVF = 38.9%, IVF-Frozen = 32.6%; $P < 0.001$), embryo stage (4 = 36.4%, 5 = 34.1%, 6 = 38.2%, 7 = 45.2%, 8 = 37.1%; $P < 0.001$), embryo quality (1 = 42.1%, 2 = 32.6%, 3 = 23.5%; $P < 0.001$), recipient parity (n = 41.9%, $P = 37.7\%$, M = 31.6%; $P < 0.001$), recipient estrous cycle day (5 = 32.6%, 6 = 36.4%, 7 = 40.8%, 8 = 40.4%, 9 = 36.6%; $P < 0.001$), technician (1 = 33.9%, 2 = 33.5%, 3 = 38.0%, 4 = 43.8%; $P < 0.001$), semen type (C = 39.9%, S = 37.7%, $P = 0.03$), transfer year (2011 = 44.2%, 2012 = 41.5%, 2013 = 38.2%, 2014 = 36.5%, $P < 0.001$). In conclusion, PET was affected by year, semen type, embryo type, embryo stage and quality, recipient parity, recipient estrous cycle day, and technician, but not by transfer season, DIM or milk yield at embryo transfer.

Key Words: embryo transfer, pregnancy, dairy cattle

M289 High cow ration recipe: Preparation and feeding times. Yolanda Trillo*[1], Sonia Rodriguez[1], Alfonso Lago[2], and Noelia Silva-del-Rio[1], *[1]UC Davis School of Veterinary Medicine, VMTRC, Tulare, CA, [2]DairyExperts, Tulare, CA.*

The objective of this study was to describe the high cow ration (HCR) recipe preparation and feeding times on 26 California dairies ranging in size from 1,100 to 6,900 cows. Consecutive records from a 12-mo period were extracted from the feeding management software FeedWatch 7.0. The variables included were data, recipe, recipe number, ingredient, loading sequence, start loading time and end loading time. A total of 33 ingredient types were used across dairies. Data set included information from 50,909 recipe loads (487,218 ingredient loads). Descriptive statistics were conducted with SAS 9.3. Across dairies, the median recipe preparation time was [median (range)] 15 min 0 s (9 min 18 s to 27 min 0 s). The interquartile range (IQR = Q_3-Q_1) per dairy was <13 min 30 s (Q_1) and >16 min 58 s (Q_3). At least 20% (up to 68%) of the time, recipe preparation was < 10 min in 5 dairies, and at least 10% (up to 70%) of the time it was >25 min in 4 dairies. Across dairies, the median elapsed time from recipe preparation to start feeding was [median (range)] 3 min 48 s (1 min 54 s to 9 min 0 s). The IQR per dairy was <2 min 30 s (Q_1) and >5 min 10 s (Q_3). On 6 dairies, at least 70% (up to 80%) of the time, recipe preparation to start feeding took <3 min in 6 dairies. On 6 dairies, at least 20% (up to 30%) of the time it took >10 min. Across dairies, the median feeding time was [median (range)] 4 min 12 s (1 min 30 s to 10 min 48 s). The IQR per dairy was <3 min 20 s (Q_1) and >6 min 30 s (Q_3). At least 20% (up to 75%) of the time, feeding took <2 min in 4 dairies; and between 20 to 55% of the time, it was >10 min in 4 dairies. Overall, from recipe preparation to feeding, 25% of the times (Q_1) it took <15 min (n = 10), 15 to 20 min (n = 12) and >20 min (n = 4); and 25% of the time (Q_3) it took <25 min (n = 5), 25 to 35 min (n = 16) and >35 min (n = 5). There were important differences within and across dairies on time elapsed from recipe preparation to feeding. This may have implication on mixing and processing of the HCR recipe.

Key Words: dairy cattle, high cow ration, feeding management software

M290 Using first test milk yield and previous lactation data to assess herd transition cow management in Brazilian dairy farms. J. K. Poncheki[1], J. A. Horst[2], A. A. Valloto[2], and R. Almeida*[1], *[1]Universidade Federal do Paraná, Curitiba, PR, Brazil, [2]Associação Paranaense de Criadores de Bovinos da Raça Holandesa, Curitiba, PR, Brazil.*

The objective of this study was to develop an index to assess the management applied to dairy cows during transition period, known as Transition Cow Index (TCI), using information from official DHIA Paraná herds, Southern Brazil. Data set was assigned by Holstein Cattle Breeders Association from Paraná State (APCBRH) and it had originally 310,007 first monthly test-days collected between 5 and 40 d after calving from 2000 to 2013. To generate this index several information from previous lactation were used. First-lactation data were excluded and animals were categorized in 2nd, 3rd, 4th, and 5th lactation or more. After editing, only Holstein data were kept in the final data set, which had 94,508 first test-days from 445 herds. Pearson correlations among independent variables and milk yield on first test-day were estimated by CORR procedure from SAS. Previous cumulative milk yield was the variable with the highest correlation with the first test-day milk yield (r = 0.42). Previous cumulative milk yield, DIM in prior lactation (linear and quadratic effects), linear somatic cell score at the last test-day of previous lactation, days dry (linear and quadratic effects), lactation number, month of calving, milking frequency and DIM at first test were the independent variables used in GLM procedure from SAS to generate an expected milk yield in the first test-day after calving. The expected daily production was compared with the actual production collected, to generate TCI in kg/d. During the whole period investigated, 50.9% of the analyzed data had positive TCI (above expectations) and 49.1% had negative TCI (below expectations) and the overall TCI average was −0.283 kg/d. The 5 best herds with 100 or more test-days had TCI average of 3.908 kg/d and the 5 worst herds with 100 or more test-days had TCI average of −5.589 kg/d. Transition Cow Index proved to be an efficient tool for evaluation of transition period management of Paraná herds. It is recommended to not overlook individual cows that fail and to use TCI only at herd level.

Key Words: early lactation, fresh cow performance, transition cow index

M291 Differences in rumination time, lying time, and rectal temperature between cows with and without metritis, ketosis, and subclinical hypocalcemia.

I. C. Tsai*, L. M. Mayo, A. E. Stone, B. A. Wadsworth, and J. M. Bewley, *University of Kentucky, Lexington, KY.*

The objective of this study, conducted at the University of Kentucky Coldstream Dairy from June 2014 to January 2015, was to quantify differences in rumination time, lying time, and rectal temperature between cows with and without metritis, ketosis, and subclinical hypocalcemia. Precision dairy farming technologies used for these measurements included: SensOor (Agis Automatisering, Harmelen, the Netherlands) which measured ear movement, feeding time, rumination time, and ear skin temperature; Track-a-Cow (ENGS, Hampshire, UK) which measured lying time and time at the feed bunk; and Precision Xtra (Abbott Laboratories, Abbott Park, Illinois) which measured blood β-hydroxybutyrate (BHBA). Ten days before due date, technologies were assigned to cows. Blood serum samples were collected on 3, 7, 14, and 21 DIM and sent to the University of Kentucky Veterinary Diagnostic Laboratory for calcium analysis. The GLM procedure of SAS (Version 9.3, Cary, NC) was used to evaluate factors affecting metritis, ketosis, and subclinical hypocalcemia. Mean rumination time, lying time, and rumen temperature were calculated for the first 21 DIM. Average lying time percent for cows with subclinical hypocalcemia (63% ± 8%) was greater than for cows without subclinical hypocalcemia (57% ± 9%; $P < 0.002$). Average rectal temperature of metritis cows (39.13 ± 0.22) was higher than for cows without metritis (37.75 ± 0.29; $P \leq 0.05$). No differences in rumination time were observed between cows with or without metritis, ketosis, and subclinical hypocalcemia. Precision dairy farming technologies could be useful for detecting metritis, ketosis, and subclinical hypocalcemia.

Key Words: transition period, metabolic disease, precision dairy farming technology

M292 Bacterial and dry matter content of bedding substrates utilized on Canadian dairy farms.

Ivelisse Robles*[1], David F. Kelton[2], Herman W. Barkema[3], Greg P. Keefe[4], Jean-Philippe Roy[5], Marina A. G. von Keyserlingk[6], and Trevor J. DeVries[1], [1]*Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada,* [2]*Department of Population Medicine, University of Guelph, Guelph, ON, Canada,* [3]*Faculty of Veterinary Medicine, University of Calgary, Calgary, AB, Canada,* [4]*Atlantic Veterinary College, University of Prince Edward Island, Charlottetown, PEI, Canada,* [5]*Faculté de Médecine Vétérinaire, Université de Montréal, Montréal, QC, Canada,* [6]*Animal Welfare Program, University of British Columbia, Vancouver, BC, Canada.*

The objective of this study was to determine the bacteria and DM content of bedding substrates utilized on dairy farms. Seventy-two dairy farms in Ontario, Canada, were visited 3 times, 7 d apart. At each visit, composite samples of the unused and used bedding material were collected for DM determination and bacterial culturing of major pathogen groups (gram-positive, gram-negative, and *Klebsiella* spp.). Bedding substrates were classified by farm as following: sand (n = 12), straw and other dry forage (n = 34), wood products (shavings, sawdust; n = 17), and other (recycled manure solids, compost, digestate, peat moss; n = 10). Tests of bacteria counts and DM content were made between bedding types, as well as between unused and used samples, in a general linear mixed model. DM content of unused bedding varied with type ($P < 0.01$): sand was driest (92 ± 1.4%), followed by straw (88 ± 0.9%) and wood (85 ± 1.2%), while other types were wettest (39 ± 1.6%). DM content of used bedding was reduced ($P < 0.01$) for wood (75 ± 1.7%) and straw (77 ± 1.2%), increased for other types (48 ± 2.3%; $P < 0.01$), and did not change for sand (95 ± 2.1%; $P = 0.17$). Gram-positive bacteria counts did not vary with bedding type ($P > 0.25$) in unused (2.4 ± 1.2 ln cfu/mL) and used (16.1 ± 0.9 ln cfu/mL) samples. Gram-negative bacteria counts in unused bedding varied with type ($P < 0.01$): straw was greatest (12.6 ± 0.6 ln cfu/mL), followed by other types (8.1 ± 1.3 ln cfu/mL), then wood (4.7 ± 0.8 ln cfu/mL), while sand was least (2.4 ± 1.0 ln cfu/mL). Gram-negative counts in used samples were greater ($P < 0.01$) for other types (16.8 ± 1.1 ln cfu/mL), sand (14.2 ± 0.8 ln cfu/mL), and wood (10.0 ± 0.7 ln cfu/mL), while straw did not change (13.4 ± 0.5 ln cfu/mL; $P = 0.17$). *Klebsiella* spp. counts in unused bedding varied with type ($P < 0.01$): straw was greatest (11.4 ± 0.6 ln cfu/mL), while wood (4.2 ± 0.9 ln cfu/mL), other types (3.7 ± 1.4 ln cfu/mL), and sand (2.5 ± 1.0 ln cfu/mL) were similarly ($P > 0.6$) lower. *Klebsiella* spp. counts for used bedding were greater ($P < 0.01$) for other types (12.3 ± 1.3 ln cfu/mL) and sand (11.2 ± 1.0 ln cfu/mL), while wood tended ($P = 0.1$) to be greater (5.4 ± 0.9 ln cfu/mL), and straw did not change (11.4 ± 0.6 ln cfu/mL; $P = 0.99$). Overall, bedding types varied in their DM, particularly between unused and used samples.

Key Words: bedding, dry matter, bacteria count

M293 Risk factors affecting expression of estrus measured by activity monitors in lactating dairy cows.

Augusto M. L. Madureira*[1,2], Bruna F. Silper[2], Liam B. Polsky[2], Eraldo L. Drago Filho[1], Sergio Soriano[3], Alex F. Sica[3], José L. M. Vasconcelos[1], and Ronaldo L. A. Cerri[2], [1]*Sao Paulo State University, Botucatu, SP, Brazil,* [2]*University of British Columbia, Vancouver, BC, Canada,* [3]*Colorado Dairies, Araras, SP, Brazil.*

The objective of this study was to determine risk factors related to increase in physical activity during estrus. Estrus events (n = 2,510) from 1,358 lactating Holstein cows from 2 commercial dairies were recorded. Cows were monitored continuously by 3 automated activity monitors (AAM). A collar-mounted accelerometer (Collar; Heatime, SCR Engineers) and a leg-mounted pedometer (Leg1; Boumatic Heatseeker-TX) were used in farm 1. A second leg-mounted pedometer (Leg2; AfiMilk Pedometer Plus) was used in farm 2. For cows with collar and Leg1, only spontaneous estrus (SE) events were registered (1,099 events; 318 cows). Cows with Leg2-tags were induced to ovulate (IO; 1,411 events; 1,040 cows) through an E2/P4-based TAI protocol. Body condition score (BCS; 1 to 5 scale) was measured at moment of AI. SE cows' also had secondary signs of estrus (clear vaginal mucus, uterine tonus, signs of mounting) recorded. Milk production was recorded at each milking. Ovarian ultrasonography was performed at estrus. Data were analyzed by Pearson correlation and ANOVA. Collar, Leg1 and Leg2 systems' peak of activity (PA) and Collar's duration (DU) were affected by parity as multiparous expressed lower PA (69.3 ± 0.8 vs. 75.9 ± 1.1 index [Collar]; 323.9 ± 6.0 vs. 354.8 ± 8.5% [Leg1]; 323.04 ± 4.6 vs. 336.3 ± 5.3% [Leg2]) and shorter duration (10.7 ± 0.2 h vs. 12.0 ± 0.3 h) than primiparous. Cows with BCS $\leq$2.5 showed less intense estrus measurements (PA and DU). Lactation stage did not influence PA or DU of estrus. Cows that displayed secondary signs of estrus had greater PA and DU measured by Collar and Leg1 systems. Intensity progressively increased as more secondary signs were displayed. Milk production was negatively correlated with PA ($r = -0.20$), but no difference was observed in PA and DU when milk production was categorized into quartiles. Quantitative data from activity monitors can be used to survey estrus behavior in dairy cows, but must be calibrated based on risk factors to ensure accurate behavior interpretation.

Key Words: pedometer, estrus, body condition score

M294 Description of close-up cow recipes in California dairies.

Sonia Rodriguez*[1], Yolanda Trillo[1], Alfonso Lago[2], and Noelia Silva-del-Rio[1], [1]*UC Davis School of Veterinary Medicine, VMTRC, Tulare, CA,* [2]*DairyExperts, Tulare, CA.*

The objective of this study was to describe close-up cow (CU) recipes prepared on 25 California dairies ranging in size from 1,100 to 6,900 cows. Records from a consecutive 12-mo period were extracted from the feeding management software FeedWatch 7.0. The variables included were date, recipe, recipe number, ingredient, loading sequence, target weight, actual weight and tolerance level. Descriptive statistics were conducted with SAS 9.3. Dairies prepared a median of one (n = 24) or 2 (n = 1) CU recipes per day. The median number of ingredients included in the CU recipe ranged from 3 to 5 (n = 18) and 6 to 9 (n = 7); and varied over time within dairy, by one (n = 7), 2 to 3 (n = 2), or zero (n = 16) ingredients. The most commonly used ingredients in CU recipes were rolled corn (n = 19), premix (n = 17; 5 prepared it on farm), liquids (n = 8), mineral-vitamins (n = 7), anionic salts (n = 6) and canola (n = 5). The most common forages included were corn silage (n = 24) and alfalfa hay (n = 20), and some dairies also used straw hay (n = 5) and oat hay (n = 7). The ingredients most frequently added first were alfalfa hay (n = 11), straw hay (n = 5) oat hay (n = 5), premix (n = 2), yeast (n = 1) and wheat (n = 1). The ingredients most frequently added last were corn silage (n = 11), liquids (n = 7), premix (n = 2), mineral-vitamins (n = 2), canola (n = 1), earlage (n = 1) or rolled corn (n = 1). The tolerance level (TL) (kg) of the various ingredients for all dairies enrolled was: 0 (11.2%), 0.5–20 (31.7%), 25–40 (33.5%), 50–75 (18.0%) and 100–150 (5.6%) kg. The TL allowed a deviation from the median formulated target for the various ingredients across dairies of: 0% (11.2%), > 0–2% (14.9%), > 2–5% (25.5%), > 5–10% (18.0%) and > 10% (30.4%). Deviation from target > 10% was allowed on 20 ingredient types on 20 dairies [alfalfa hay (n = 11), rolled corn (n = 8), mineral-vitamins (n = 4), corn silage (n = 3), canola (n = 3) and others (n = 2)]. Corn silage, alfalfa hay, rolled corn and premix were ingredients commonly found on CU recipes. In many dairies, the TL allowed to CU ingredients should be re-evaluated.

Key Words: dairy cattle, close-up cow ration, feeding management software

M295 Agritourism: Demographics and views of customers—In-depth look at Fair Oaks Farms.

Ann Cummins*, Nicole Widmar, Candace Croney, and Joan Fulton, *Purdue University, W. Lafayette, IN.*

This research will use data from 3 mutually exclusive data sets, where all are representative of households in a given sample for age, sex, income, and region of residence. The 3 samples only differ in geographical location (National Survey n = 1004, 5-State Survey n = 1029, Indiana Survey n = 797). Through this presentation, we will highlight the rates of attendance at a variety of agritourism locations (i.e., national parks, museums, amusement parks, livestock farms, pick-your-own farms) and look at the demographics of those who attend these attractions, including an in-depth look at Fair Oaks Farms (FOF). In this survey we have questions which gather respondents self-reported perceptions of how well educated they are about agriculture and livestock production and questions which test their general knowledge level. We will look at consumers who attend livestock agritourism locations to see if they care more about animal welfare but are misinformed about production practices or if they care more about animal welfare and are more informed. The methods used for this research are the survey data collected and analysis via z-scores and cross tabulations. A brief highlight on the national sample includes that 15% of the sample had heard of FOF and 7% had attended FOF, we see that those who had been to FOF tended to be male, from the younger age categories, they tended to have pets, and were more highly concerned about animal welfare. They are less supportive than those who had not been to FOF for the growth of livestock agriculture in their county, but tended to more strongly believe in the importance of agriculture in the state which they reside as well as tended to be high dollar food purchasers in the supermarket.

Key Words: agritourism, consumer demographics, perceptions

M296 Management practices on Virginia dairy farms utilizing automated calf feeders.

Alyssa M. Dietrich* and Robert E. James, *Virginia Polytechnic Institute and State University, Blacksburg, VA.*

The objective of this study was to evaluate management practices and calf performance on 6 Virginia dairy farms using automated calf feeders (Förster Technik, Engen, Germany) in their preweaning programs. Following an initial management survey, farms were visited biweekly for approximately 28 wk. At each visit, facilities were scored on cleanliness of feeders and quality of bedding, calf starter, and drinking water. Weights (estimated by heart girth) and hip heights were measured on calves within approximately 5 d of entering the feeder system or 5 d of being weaned and averaged by farm for each age group to estimate average daily gain (ADG) and average daily height gain (ADH) over the preweaning period. One farm was an exception to this procedure, where farm staff regularly measured hip heights and calf weights with a digital scale and ADG and ADH were calculated for individual calves. Blood was collected from calves 1–7 d of age by jugular venipuncture, transported on ice, and centrifuged to estimate total serum proteins by refractometry. Calf treatment and mortality records were collected at each farm visit. Median lactating herd size was 260, ranging from 110 to 850 cows. Each farm sorted calves by age into 2 pens per feeder, with a mean number of calves ± SD per pen of 10 ± 3. Mean ADG and

ADH ± SD of calves were 0.73 ± 0.11 kg and 0.21 ± 0.05 cm. Mean ± SD serum total protein levels were 5.80 ± 1.04 g/dl. According to treatment and mortality records, mean ± SD morbidity and mortality rates were 61.05 ± 18.48 and 3.14 ± 2.67%. All farms fed milk replacer and utilized a feeding plan with a mean starting allotment of 5.4 L/d, ranging from 4.0 to 6.0 L/d, and a mean peak allotment of 9.0 L/d, ranging from 7.0 to 16.0 L/d. Mean milk replacer concentration was 150 g powder/L water, with a range of 140 to 160 g powder/L water. Mean length of enrollment on the feeder system was 54.3 d, ranging from 48 to 63 d. The information from this study may provide insight to producers using or considering using automated feeders in their calf programs.

Key Words: dairy calves, management, automated calf feeder

M297 Calculation method alters the ratio of milk true protein production to milk urea nitrogen production in late-lactation cows fed four levels of dietary crude protein.

Margaret A. Quaassdorff* and Michel A. Wattiaux, *University of Wisconsin-Madison, Madison, WI.*

Our preliminary data suggested that, using DHIA data only, the ratio of milk protein production (MPP, g/d) to milk urea nitrogen production (MUNP, g/d) might be a reliable and inexpensive indicator of nitrogen (N) use efficiency of dairy cows on commercial dairy farms. Although milk urea N (MUN, mg/dL) is an indicator of N intake and urinary urea-N excretion, it does not reflect milk protein synthesis. Our main objective was to compare 5 methods of calculation of MPP:MUNP ratio with the hypotheses that the ratio would be altered neither by calculation methods that use fewer DHIA variables nor by dietary CP level. Data were from samplings collected from 2 consecutive milkings (pm and am) in wk 12 of a study with 122 Holstein cows (mean ± SD: 303 ± 55 DIM; 761 ± 77 kg BW) fed a 16.2, 14.4, 13.1 or 11.8% CP (DM basis) TMR for 12 weeks. Methods of calculation were as follows: A) daily MPP divided by daily MUNP, where daily values were calculated using 6 DHIA values (milk production, milk protein %, and MUN for am and pm sampling, respectively); B) milk protein % divided by MUN (averages of am and pm for both); C) method B using am values only; D) method B using pm values only; and E) average of methods C and D. Ratios were analyzed in SAS 9.3 with PROC MIXED and single df orthogonal contrasts to compare methods B, C, D and E to method A. Overall, there was no difference between methods A and B, or A and E, but method C overestimated, and method D underestimated the MPP:MUNP ratio relative to method A (see Table 1.). These differences, however, were associated with high MPP:MUNP ratios observed when dietary CP were 13.1 and 11.8%. In this study, the MPP:MUNP ratios remained similar when calculated with average concentrations alone or average concentrations weighted for am and pm milk production.

Contd.

Table 1 (Abstr. M297). Comparison of 5 methods of calculation of MPP:MUNP ratio

	Method					Contrast P-value			
Dietary CP	A	B	C	D	E	A vs. B	A vs. C	A vs. D	A vs. E
16.2% of DM	291	289	309	274	291	0.906	0.222	0.239	0.982
14.4% of DM	333	329	364	304	334	0.838	0.119	0.150	0.946
13.1% of DM	494	480	627	397	512	0.760	0.009	0.043	0.686
11.8% of DM	763	744	1042	647	844	0.884	0.048	0.383	0.536

Key Words: nitrogen use efficiency, MUN, DHIA

M298 Seasonality distributions of number of breedings and conception rate of Florida dairy farms.

Fernanda Ferreira*[1,2] and Albert De Vries[1], [1]*University of Florida, Gainesville, FL,* [2]*Embrapa Gado de Leite, Juiz de Fora, MG, Brazil.*

Florida dairy farms are seasonal in their reproductive performance due to the hot summers. The amount of seasonality across farms has not been quantified, however. The objective was to describe the distribution of seasonality in the number of breedings (NB) and the average conception rate (CR) of dairy farms in Florida. We used reproductive data from USDA-AGIL, collected through DHIA, from the year 2010. Farms with annual NB < 100 and annual average CR > 0.75 were not used. We calculated the ratio of breedings (BR) as the NB in a calendar month divided by the average monthly NB. We also calculated the CR per calendar month for each farm. A sigmoidal function was fitted per farm to measure seasonality as is common in economic studies. The final data set had 36 (BR) and 33 (CR) farms. Goodness of fit of the sigmoidal function was measured by the mean square of errors (MSE). Measures of seasonality were the range (max – min) and minmax ratio (min/max) from the sigmoidal functions. Means and 5th, 25th, 50th, 75th and 95th percentiles are reported as well as Pearson correlations. For the BR, the mean ± SD of MSE were 0.31 ± 0.73. In the fitted model, the mean ± SD of BR were 1.21 ± 1.08. The 5 percentiles were 0.94, 0.98, 0.99, 1.04 and 1.46, respectively. The mean BR range was 1.261 and the 5 percentiles were 0.10, 0.35, 0.695, 1.32 and 2.46, respectively. The mean minmax ratio of BR was 0.45 and 5 percentiles were −0.03, 0.27, 0.49, 0.70 and 0.90. For CR, the mean ± SD of MSE were 0.01 ± 0.01. The mean ± SD of CR were 0.40 ± 0.13. The 5 percentiles were 0.26, 0.30, 0.38, 0.43 and 0.63, respectively. The mean CR range was 0.30 and 5 percentiles were 0.09, 0.21, 0.27, 0.36 and 0.71 respectively. The mean minmax ratio of CR was 0.46 and the corresponding 5 percentiles were 0.05, 0.33, 0.46, 0.58 and 0.80, respectively. Correlations between the ranges and minmax ratios were −0.96 for BR and −0.72 for CR. Maximum values were typically observed around March and minimum values around August for both BR and CR. The sigmoidal function did not necessarily describe the seasonal pattern well. In conclusion, many farms were very seasonal but different measures of seasonality may be needed.

Key Words: seasonality, reproduction, dairy farm

M299 An evaluation of automated milking systems in the Midwest United States. Marcia I. Endres[1] and Jim A. Salfer*[2], *[1]University of Minnesota, St. Paul, MN, [2]University of Minnesota Extension, St. Cloud, MN.*

Automatic or robotic milking systems (AMS) are being adopted by dairy producers in the Upper Midwest United States at a relatively fast rate. There is limited research available on AMS in US dairies. This ongoing study is summarizing data collected from 52 AMS dairy farms in Minnesota and Wisconsin to describe characteristics of AMS systems and investigate factors that may influence AMS efficiency in US farms. Farms were visited once to collect housing and management information and then daily data from the AMS were remotely collected for approximately 18 mo. These data showed that on average cows were milked 2.61 ± 0.30(mean ± SD) times per day, produced 32.25 ± 6.81 kg of milk per day, and consumed 5.03 ± 0.95 kg of concentrate in the AMS per day. The number of cows per robot box was 70.25 ± 14.06 and it was greater for guided flow compared with free flow AMS farms (75.0 vs. 65.5 cows per robot). Forty farms had exclusively free flow cow traffic. Milking speed was 2.24 ± 0.40 L/min and total milk yield per robot unit was 1843.5 ± 490.9 L/day. Total daily milk yield per robot has been suggested to be an important characteristic to assess the efficiency of AMS. Proc CORR in SAS was used to conduct a preliminary analysis of factors associated with yield per robot and milk yield per day. Factors most strongly associated ($P < 0.001$) with yield per robot were milk per cow per day ($r = 0.81$) and average milking speed ($r = 0.76$). Other factors moderately associated ($P < 0.001$) with yield per robot were average concentrate consumed per cow per day ($r = 0.31$) and exit length from the AMS ($r = 0.32$). Protected AMS exit lane was 3.1 ± 2.4 m long and ranged from 0.3 to 8.5 m. Factors associated ($P < 0.001$) with average daily milk yield per cow were milking speed ($r = 0.79$), exit length ($r = 0.51$) and average concentrate consumed per cow per day ($r = 0.41$). Further multilevel regression analysis will provide a clearer picture of factors influencing efficiency of AMS in the United States.

Key Words: automated milking, robotic milking

M300 Factors affecting vaginal temperature in high-producing lactating Holstein cows. Eraldo L. Drago Filho*[1], Augusto M. L. Madureira[1], Liam B. Polsky[2], Sergio Soriano[3], Alex F. Sica[3], Jose L. M. Vasconcelos[1], and Ronaldo L. A. Cerri[2], *[1]Sao Paulo State University, Botucatu, SP, Brazil, [2]University of British Columbia, Vancouver, BC, Canada, [3]Colorado Dairies, Araras, SP, Brazil.*

The aim of this experiment was to evaluate the continuous collection of vaginal temperature for 72 h (every 10 min) in lactating Holstein cows (n = 480; 591 data collections) allocated in one single cross-ventilation barn. Cows were fitted with a thermometer attached to a progesterone intravaginal device before AI. Milk production, DIM, skin thickness, coat color, body condition score (BCS), and pregnancy per AI (P/AI) data were collected and recorded for further analyses. Ambient temperature and humidity was measured for 72 h using a data logger for calculation of the temperature and humidity index (THI). Data were analyzed using ANOVA and Pearson correlations using proc GLM, Corr and Logistic of SAS. Maximum THI (MAX) and percentage of time above a vaginal temperature of 39°C (PCT) were used as data logger responses, class variables were created for MAX and PCT (High vs Low) using the median threshold. There was a low correlation between THI and PCT ($r = 0.01$). Skin thickness was also poorly correlated with PCT ($r < 0.01$). Cows with black color coat spent less time with high vaginal temperatures ($P = 0.05$). Primiparous ($P = 0.04$) and cows with low BCS ($P < 0.01$) had greater PCT. Milk production was affected by parity ($P < 0.01$) and PCT ($P = 0.02$; High = 43.5 vs Low = 41.2 kg/d). There was a milk production by MAX interaction for PCT ($P < 0.01$), whereas only cows in the highest milk production quartile (>50.7kg/d) spent more time with high vaginal temperatures. Among the independent variables included in the model, parity ($P < 0.01$), PCT ($P = 0.03$; 26.1 vs 17.4% for Low and High, respectively) and a PCT by milk production interaction ($P = 0.05$) affected P/AI. The decrease in P/AI in cows with High PCT only occurred in cows with the highest production. In summary, there is a large variability on how individual cows respond to heat stress. Parity, BCS, coat color and milk production affect PCT, particularly under high ambient temperatures. Selection of animals with efficient control of body temperature in spite of high milk production should be further approached as a strategy to maintain adequate fertility.

Key Words: heat stress, milk production, pregnancy per AI

M301 Prepartum activity is associated with increased plasma NEFA and body weight loss in postpartum dairy cows. Yu Zang*, Ida Holásková, and Joseph W. McFadden, *West Virginia University, Morgantown, WV.*

Monitoring physical activity of cattle is an estrus detection tool utilized on dairy farms. Lower than normal dairy cow activity can enhance postpartum metabolic disease risk (e.g., ketosis). Considering that NEFA mobilization and BHBA synthesis can promote metabolic disease, our objective was to investigate the relationship between activity and metabolic health markers in peripartal dairy cows. Seventy-one multiparous Holstein cows (713 ± 65 kg BW) housed in a commercial herd setting were continuously enrolled. Collar mounted activity meters (DeLaval) were worn by cows −45 d before expected calving until 10 DIM. Data were recorded at 1 h intervals. Blood was collected regularly. Plasma variables were measured and insulin sensitivity was estimated using RQUICKI. Cows were retrospectively categorized according to pre- and postpartum activity into those with the lowest (LOW; 25%), modest (MOD; 50%), and highest (HIGH; 25%) activity. Data were analyzed using a mixed model with repeated measures (fixed effects of activity and time). Nonparametric correlations were analyzed. For activity categorized from d −10 to −4, LOW had higher plasma NEFA on d −15 and 1, relative to HIGH (e.g., 744 vs. 367 μM on d 1; $P < 0.01$). LOW had decreased RQUICKI values and glucose levels on d −15 and 1, respectively, relative to HIGH ($P < 0.01$). For activity categorized from d 1 to 7, LOW had higher plasma NEFA on d 1, relative to HIGH ($P < 0.01$). Plasma BHBA and insulin were not modified by activity. Plasma NEFA levels were negatively correlated with previous 24-h activity on d 1 and 4 ($r = -0.33$ and -0.26, respectively; $P < 0.05$). RQUICKI values were positively correlated with previous 24-h activity on d 1 ($r = 0.25$; $P < 0.05$). Similar results were observed on d 1 and 4 when evaluating daytime activity. Prepartum activity was negatively correlated with postpartum BCS loss ($P < 0.01$). Lower prepartum activity of dairy cows is associated with reduced insulin sensitivity, and accelerated NEFA mobilization and BCS loss postpartum. Activity monitoring within large herds has the potential to serve as an inclusive alternative to laboratory NEFA testing.

Key Words: activity, dairy cow, metabolic health

M302 Adding antioxidants to ram sperm improves sperm binding capability after cryopreservation. Jonathan M. S. Costa[1], Wildelfrancys L. Souza[1], Elenice A. Moraes*[1], and James K. Graham[2], *[1]Federal University of San Francisco Valley, Petrolina, PE, Brazil, [2]Colorado State University, Fort Collins, CO.*

Cryopreserved mammalian sperm generally exhibit lower fertility than fresh sperm. An increasing number of antioxidants have been tested in attempts to improve semen quality, but improvements have not often been consistent or repeatable. The objective of this study was to determine if adding several different antioxidant combinations to ram sperm before cryopreservation could improve sperm binding to perivitelline membrane (PM) after thawing. Thirty ejaculates from 3 rams were split and diluted to 200×10^6 sperm/ml in an egg yolk tris diluent containing different antioxidants: control, with no antioxidant; 100 µ*M* Melatonin plus 0,05% ascorbic acid (MEL+AA); 100 µ*M* MEL plus 90µL Trolox C (MEL+TRO); 90µL TRO plus 0,05% AA (TRO+AA); and 100 µ*M* MEL plus 0,05% AA plus 90 µL TRO (MEL+AA+TRO). The samples were then cooled to 5°C, over 2h, and upon reaching 5°C were packaged into 0.5mL straws and frozen in static liquid nitrogen vapor for 15min before being plunged into liquid nitrogen. Straws were thawed for 30s in 37°C water and the motility and zona binding ability were determined using a CASA and fluorescence microscopy, respectively. Prior to binding analysis, sperm were stained with 35 µg/mL Hoechst 33342 for 15 min at 37°C, and then centrifuged at 400g for 5min and the sperm suspended in 1mL TALP and 5-µL aliquots (10,000 sperm prepared) were added to each PM. The membranes and sperm incubated together at 37°C for 2 h in an atmosphere of 5% of CO_2 in air, after which the PM were washed 5 times, placed onto a glass slide and examined using fluorescence microscopy at 400×. The number of sperm bound to the membrane in 6 predetermined fields of each membrane piece was counted. Data were analyzed by ANOVA using Tukey test. All antioxidants combinations maintained higher percentages of total and progressive motile cells after thawing, than control sperm ($P < 0.05$), with MEL+AA+TRO maintaining the highest percentage of motile sperm (49%). Sperm treated with MEL+AA+TRO exhibited the highest the number of sperm binding to the PM after thawing (177.63 cells; $P < 0.05$) compared with other treatments. Adding antioxidants to ram sperm before freezing increased the number of sperm surviving cryopreservation. Supported by FACEPE, CAPES and UNIVASF (Brazil).

Key Words: ascorbic acid, melatonin, vitamin C

M303 Distribution of detected estrus following 14-day CIDR and prostaglandin $F_{2\alpha}$ treatment as a pre-synchronization strategy in dairy heifers. Courtney K. Claypool*[1], Jennifer A. Spencer[1], Saulo Menegatti Zoca[3], Bahman Shafii[1], William J. Price[1], Amin Ahmadzadeh[1], Neil R. Rimbey[2], and Joseph C. Dalton[2], [1]*University of Idaho, Moscow, ID,* [2]*University of Idaho, Caldwell, ID,* [3]*UNESP, Botucatu, Sao Paulo, Brazil.*

Pre-synchronization is an effective management strategy in lactating dairy cows to increase the number of animals in estrus and facilitate AI during a desired time interval. However, it is not a strategy often used in nulliparous dairy heifers. The objective was to characterize the distribution of detected estrus following a 14-d CIDR and prostaglandin $F_{2\alpha}$ (PG) treatment as a pre-synchronization strategy in cyclic dairy heifers. Holstein heifers (n = 119) received a CIDR on d −30, and had the CIDR removed 14 d later on d −16. All heifers then received an Estrotect patch and were observed daily to facilitate detection of estrus. Following removal of the CIDR, 115/119 (96.7%) heifers were detected in estrus within 5 d. The proportion of heifers detected in estrus ± SE for each d after CIDR removal was: d 1: 12.6% ± 3% (15/119); d 2: 55.5% ± 5% (66/119); d 3: 18.5% ± 4% (22/119); d 4: 8.4% ± 3% (10/119); d 5: 1.7% ± 1% (2/119). Four heifers were not detected in estrus. Sixteen d after CIDR removal, all heifers received an injection of PG (25 mg i.m.) upon entry to the AI pen (study d 0). All heifers received tail paint and were observed for behavioral estrus daily. Following PG treatment, 114/119 (95.8%) heifers were detected in estrus within 5 d. The proportion of heifers detected in estrus ± SE for each d after PG treatment was: d 1: 3.3% ± 2% (4/119); d 2: 16.0% ± 3% (19/119); d 3: 59.7% ± 5% (71/119); d 4: 16.8% ± 3% (20/119); d 5: 0% (0). Five heifers were not detected in estrus. For the 2 estrus events observed, peak activity was detected 2 d after CIDR removal and 3 d after PG treatment. Pre-synchronization with a 14 d CIDR and PG protocol appears to be an effective strategy to facilitate detection of a high percentage of dairy heifers in estrus.

Key Words: dairy heifer, pre-synchronization, CIDR

M304 Feeding time variation on California dairies. Yolanda Trillo*[1], Sonia Rodriguez[1], Alfonso Lago[2], and Noelia Silva-del-Rio[1], [1]*UC Davis School of Veterinary Medicine, VMTRC, Tulare, CA,* [2]*DairyExperts, Tulare, CA.*

The objective of this study was to describe the variation of high cow ration (HCR) recipe feeding on 26 California dairies ranging in size from 1,100 to 6,900 cows. Records from a consecutive 12-mo period were extracted from the feeding management software FeedWatch 7.0. The variables included were date, recipe, recipe number, feeding sequence, start feeding time, end feeding time, target weight, actual weight and pen number. Data set included information from 51,195 recipes. Descriptive statistics were conducted with SAS 9.3. The median day-to-day variation on start feeding time [median (range)] was |12| min (|6| to |60| min). The interquartile range ($IQR = Q_3 - Q_1$) per dairy was | <15| min (Q_1) to | >33| min (Q_3). On 23 dairies, at least 70% (up to 93%) of the feedings were done within 15 min from the previous day feeding time. Across dairies, at least 2% of the time feedings were delayed by 60 to 90 min (n = 23; up to 17% of the time), by 90 to 120 min (n = 23; up to 5%), and by >120 min (n = 26; up to 9.6%). On 9 dairies, at least 5% (up to 25%) of the total feedings were delayed at least by 2 h relative to the previous day. On those dairies, delays affected 75 to 100% of the pens, at least once. Feeding delays of 2 h or more were observed in all dairies, ranging from 0.05 to 2% (n = 18), 2 to 5% (n = 7) and 9.6% (n = 1). The median time elapsed between the last feeding to the first feeding of the next day was 23 h 50 min, 14 h 20 min to 23 h 30 min and 15 h 50 min to 19 h 00 min for dairies feeding once a day (n = 2), twice a day (n = 18), and thrice a day (n = 6). The IQR for the time elapsed between the last feeding to the first feeding was <1 h 20 min (Q_1) to >4 h 25 min (Q_3). The median time to complete the first feeding to all HCR pens [median (range)] was1 h 18 min (10 min 58 s to 4 h 24 min). The IQR was <18 min (Q_1) to >45 min (Q_3). At first feeding, the amount of HCR recipe delivered [median (range)] was 49.7% (33.1 to 100%) of the total amount fed per day. The IQR was <1.8% (Q_1) and >19.4% (Q_3). Based on our data, some dairies could improve their time consistency at first feeding.

Key Words: dairy cattle, high cow ration, feeding time consistency

M305 Association among body condition score change, milk yield, and reproductive performance of Holstein cows. Ricardo C. Chebel*[1], Pablo J. Pinedo[2], Jose E. P. Santos[1], Gustavo Schuenemann[3], Guilherme J. M. Rosa[4], Robert Gilbert[5], Rodrigo C. Bicalho[5], Klibs N. Galvao[1], Christopher Seabury[6], John Fetrow[7], William W. Thatcher[1], and Sandra L. Rodriguez-Zas[8], [1]*University of Florida, Gainesville, FL,* [2]*Texas A&M AgriLife Research, Amarillo, TX,* [3]*Ohio State University, Columbus, OH,* [4]*University of Wisconsin, Madison, WI,* [5]*Cornell University, Ithaca, NY,* [6]*Texas A&M University, College Station, TX,* [7]*University of Minnesota, St Paul, MN,* [8]*University of Illinois at Urbana-Champaign, Urbana, IL.*

Objectives were to determine the association among body condition score change from calving to 35 DIM, resumption of cyclicity by 50 DIM and both productive and reproductive performance. Holstein cows (n = 5,175) from 9 dairy herds from the Southwest, Southeast and Midwest of the USA were used in this experiment. Cows were BCS at 3 ± 3 and 35 ± 3 DIM. Cows were classified according to BCS change [Gained(G), No change(NC), Moderate loss(ML) = −0.25 to −0.75, and Extreme loss(EL) < −0.75]. Study personnel examined cows for retained placenta and metritis. Blood sampled at 7 DIM was used to diagnose ketosis (BHB >1.0 mmol/L). Calf gender, occurrence of calving problems (twins, stillbirth, and dystocia), and occurrence of mastitis, displacement of abomasum, and respiratory illness within the first 60 DIM were recorded. Cows were milk thrice daily and average milk yield in the first 90 DIM recorded. Continuous data were analyzed by ANOVA, dichotomous data were analyzed by logistic regression, and pregnancy hazard ratio was analyzed by Cox Proportional Hazard Ratio. The interaction between BCS at 3 DIM and BCS change was associated with milk yield ($P < 0.01$). Among cows calving with BCS < 3.25, milk yield was lowest for cows gaining BCS and cows with extreme BCS loss from 3 to 35 DIM (G = 34.4 ± 0.3,NC = 37.1 ± 0.3,ML = 38.2 ± 0.3,XL = 34.4 ± 4.4kg/d). Among cows calving with BCS = 3.25 to 3.5 (G = 35.4 ± 0.5, NC = 36.3 ± 0.3,ML = 37.9 ± 0.2, XL = 39.1 ± 1.0kg/d) and cows calving with BCS >3.5 (G = 26.0 ± 2.3,NC = 35.0 ± 1.0,ML = 37.5 ± 0.4, XL = 38.5 ± 0.9kg/d) milk yield was greatest when cows had extreme BCS loss from 3 to 35 DIM. Change in BCS from 3 to 35 DIM was associated ($P < 0.01$) with likelihood of cows resuming cyclicity by 50 DIM (G = 78.8%, NC = 76.4%,ML = 74.8%, XL = 75.9%). Although BCS change was not associated ($P < 0.02$) with the probability of pregnancy after first postpartum AI, pregnancy hazard ratio was associated with BCS change from 3 to 35 DIM [G = 1.2 (0.99, 1.56), NC = 1.21 (0.98,1.51),ML = 1.10 (0.90,1.36), EL = referent]. In conclusion, excessive loss of BCS from 3 to 35 DIM was associated with greater milk yield and reduced cyclicity and reproductive performance.

Key Words: Holstein cow, body condition score, reproductive performance

M306 Animal and dietary factors associated with daily rumination time during the periparturient period.

Daniela N. Liboreiro*[1], Luiz Ferraretto[2], Randy Shaver[2], and Ricardo C. Chebel[1,3], *[1]University of Minnesota, St Paul, MN, [2]University of Wisconsin, Madison, WI, [3]University of Florida, Gainesville, FL.*

The objectives of the current experiment were to determine the association among animal and feed factors associated with daily rumination of periparturient dairy cows. Holstein animals (n = 297) were fitted with collars that record minutes of rumination every 2 h and activity every 2 h (SCR) from −21 to 21 d relative to calving. Rumination data were analyzed in 24 h intervals. Animal data collected were parity, twining, calf sex, animal body condition score at −21 d relative to calving, and days relative to calving. Total mixed ration samples were collected twice weekly. Samples from the same week were combined and analyzed for crude protein, neutral detergent fiber, ether extract, ash, and non-fiber carbohydrate. Furthermore, weekly feed samples were evaluated for particle size using a 4-panel particle separator. Physically effective fiber was calculated. Each pen in which study cows were housed had a temperature humidity HOBO and temperature humidity index were calculated. Daily rumination data were analyzed, separately for the prepartum and postpartum periods, by ANOVA using the MIXED procedure of SAS. A stepwise backward elimination procedure was conducted and only independent variables with $P < 0.10$ were kept in the final model. During the prepartum period, non-fiber carbohydrate ($P < 0.01$) was positively associated with daily rumination time and parity ($P = 0.04$), days relative to calving ($P = 0.01$), BCS at −21 d relative to calving ($P = 0.05$), twining ($P = 0.08$), daily average THI ($P < 0.01$), crude protein ($P < 0.01$), neutral detergent fiber ($P < 0.01$), ash ($P < 0.01$), and physically effective NDF ($P = 0.01$) were negatively associated with daily rumination time. During the postpartum period, days relative to calving ($P < 0.01$), crude protein ($P < 0.01$), ether extract ($P = 0.01$), non-fiber carbohydrate ($P < 0.01$) were positively associated with daily rumination time and parity ($P < 0.01$), daily average THI ($P < 0.01$), neutral detergent fiber ($P < 0.01$), ash ($P < 0.01$), were negatively associated with daily rumination time. The findings of the current experiment demonstrate that variability in daily rumination time is dependent on several animal, dietary, and environmental factors.

Key Words: Holstein cow, rumination

M307 Deviation from the formulated target weight for ingredients loaded into the high cow ration on California dairies.

Yolanda Trillo*[1], Alfonso Lago[2], and Noelia Silva-del-Rio[1], *[1]UC Davis School of Veterinary Medicine, VMTRC, Tulare, CA, [2]DairyExperts, Tulare, CA.*

The objective of this study was to describe the deviation from target weight of the various ingredients added into the high cow ration (HCR) on 26 California dairies ranging in size from 1,100 to 6,900 cows. Records from a consecutive 12-mo period were extracted from the feeding management software FeedWatch 7.0. The variables included were date, recipe, recipe number, ingredient, loading sequence, target weight, actual weight and tolerance level (TL, deviation allowed per ingredient during loading). Descriptive statistics were conducted with SAS 9.3. The median TL assigned to ingredients across dairies ranged from 9 to 90 kg. The TL allowed a deviation from the median formulated target for the various ingredients across dairies of 0% (8.7%), > 0–2% (45.2%), > 2–5% (25.5%), > 5–10% (11.6%) and > 10% (9.0%). A total of 2.5% of the observations did not reach the target weight set by TL, and represented from 0.1 to 21.1% of all loads within a given dairy. Across dairies the median deviation from the target weight for the HCR recipe varied from < −2 (n = 2), −2 to < −1 (n = 2), −1 to 0 (n = 6), > 0 to 1 (n = 11), > 1 to 2% (n = 3), > 2% (n = 2). Seven dairies had 20 to 47% of their loads with a deviation from target > 40 kg. On 2 dairies 59% and 27% of the observations had a deviation from target of < −40 kg. Rolled corn and almond hulls were loaded with an interquartile range (IQR = Q_3-Q_1) | < 20| kg on 68% of the dairies. The deviation from target (Q_1) was | < 10| kg on 77% of the dairies. Overall, alfalfa hay, corn silage and canola had a IQR > 20 kg on 60 to 62% of the dairies, and a deviation from target (Q_3) | > 40| kg on 35 to 45% of the dairies. This represents a deviation (as percentage) of 2.1 to 12.9% (alfalfa hay), 2.2 to 5.5% (corn silage), and 2.3 to 7.3% (canola). Some dairies were able to load ingredients very close to the target weight, however, dairy producers should evaluate if readjusting the TL settings of some ingredients might reduce the deviation from target weight.

Key Words: dairy cattle, loading deviations from target, feeding management software

M308 Feeding frequency of the high cow ration recipe on California dairies.

Yolanda Trillo*[1], Alfonso Lago[2], and Noelia Silva-del-Rio[1], *[1]UC Davis School of Veterinary Medicine, VMTRC, Tulare, CA, [2]DairyExperts, Tulare, CA.*

The objective of this study was to describe the feeding frequency of high cow ration (HCR) recipe on 26 California dairies ranging in size from 1,100 to 6,900 cows. Records from a consecutive 12-mo period were extracted from the feeding management software FeedWatch 7.0. The variables included were date, recipe, recipe number, feeding sequence, start time, end time and pen number. Descriptive statistics were conducted with SAS 9.3. The median frequency of feedings per pen within a dairy varied from 1 (n = 2), 2 (n = 10), 1 to 2 (n = 6), 1 to 3 (n = 4) and 2 to 4 (n = 1) times per day. Sixteen dairies had at least 90% of the pens fed the same number of times consistently (80% of the times or more) and 10 dairies had at least 30% of the pens fed the same number of times inconsistently (60% of the times or less). For dairies with a median of 2 feedings per day (n = 18), the time elapsed between the first and second feedings was <3 h (n = 8), from 3 to 6 h (n = 8), and from 6 to 9 h (n = 8). For dairies with 3 feedings per day (n = 6), the time elapsed between the first and the second feeding ranged from 2 to 4 h, and between the second and the third feeding was between 2 to 5 h. Dairies with 1, 2, or 3 feedings per day started feeding at 0300 or 0530 a.m. (n = 2), 0215 to 1030 a.m. (n = 18), and 0200 to 0815 a.m. (n = 6) respectively. The last feeding was done from 0530 a.m. to 1530 p.m. for dairies feeding 2 times (n = 18) and from 0800 a.m. to 1330 p.m. (n = 6) for dairies feeding 3 times. Some dairies were consistent (at least 85% of the time), feeding each recipe load to a single pen (n = 4), 2 pens (n = 2) or 3 pens (n = 2). However, most dairies (n = 18) split a recipe load among a combination of 1, 2, 3, 4, or more than 4 pens. At least 50% of the times, a recipe load was split among 4 or more pens in 3 dairies. One dairy split 37% of the times a recipe load among 8 pens. There was an important variation on the number of feedings per pen within and across dairies. Many dairies were inconsistent on how they split a recipe load among pens.

Key Words: dairy cattle, high cow ration, feeding management software

M309 The effects of milk production class on serum haptoglobin concentrations in mid-lactation Holstein cows with and without clinical mastitis. G. Taasoli*[1], F. Kafilzadeh[1], D. Ghadimi[2], and M. A. Ballou[3], [1]*Department of Animal Science, Razi University, Kermanshah, Iran,* [2]*Institute of Physiology and Biochemistry, MRI, Karlsruhe, Germany,* [3]*Department of Animal and Food Sciences, Texas Tech University, Lubbock, TX.*

This experiment investigated the link between production class and inflammation in mid-lactation Holstein cows with or without clinical mastitis. Forty cows were sampled, 20 positive for clinical mastitis and 20 healthy control cows. Within the mastitis and healthy groups, cows were further classified by level of milk production (Low = 23 to 25 kg/d vs. High = 28 to 35 kg/d). Therefore the experimental design was a 2 × 2 factorial with health status and level of milk production as the main effects (n = 10 cows per health status x level of milk production). All cows were sampled from a single commercial dairy farm with 1200 lactating Holstein cows with an average milk yield of 28 kg/d. Sampled cows were 80 to 120 DIM in their 2nd or 3rd parity. A positive mastitis case was defined as clinical signs and a positive California mastitis test. Cows had ad libitum access to feed and water. A peripheral blood sample was collected from each cow and analyzed for plasma haptoglobin concentrations. Among the healthy cows, plasma haptoglobin concentrations were greater for the high production group compared with the low production group (132 ± 12.9 vs. 93 ± 23.0 µg/mL; $P \leq 0.05$). Although cows with mastitis had greater plasma haptoglobin concentrations compared with the healthy cows, there was no difference ($P = 0.71$) between the low and high milk production groups for cows with clinical mastitis (1,193 ± 238 vs. 1,145 ± 211 µg/mL, high and low, respectively). These data indicate that increased milk production among healthy Holstein cows may cause an increase in low level inflammation when compared with cows that produced less milk. The mild increase in plasma haptoglobin concentrations may be associated with a greater intake of certain nutrients and/or overall metabolic activity. Clinical mastitis caused a large increase in plasma haptoglobin concentrations that was independent of milk production class.

Key Words: inflammation, mastitis, production

Ruminant Nutrition: Beef I

M310 Effect of narasin in mineral mix to Nellore heifers fed with high forage. Renan G. Silva*[1], Marcos V. C. Ferraz Junior[1], Vinicius N. Gouvea[1], Daniel M. Polizel[1], Marcelo H. Santos[1], Alexandre A. Miszura[1], Thiago S. Andrade[1], Mariana F. Westphalen[2], Marcos V. Biehl[2], and Alexandre V. Pires[2,1], *[1]University of São Paulo, Pirassununga, São Paulo, Brazil, [2]University of São Paulo, Piracicaba, São Paulo, Brazil.*

The use of feed additives for ruminants is a further tool that can improve feed conversion in animal protein. The objective of this study was to determine the effect of narasin in mineral mix (MM) of heifers fed high-forage diet. Thirty Nellore heifers (12 mo old) were penned (3 heifers / pen) by BW (222 ± 3.0). Heifers were fed daily with Tifton 85 haylage ad libitum. Experimental treatments were 0 (control); 650 and 1300 mg of narasin / kg MM (0N, 6.5N and 13N, respectively). The variables analyzed were dry matter intake (DMI), and mineral mix intake (MMI) daily, average daily gain (ADG) and feed:gain ratio. The experimental design was a change-over (all pens underwent all treatments) with 3 experimental periods of 28 d. Between periods there was a 7 d wash-out. Heifers were weighed at the beginning and end of each experimental period to determine ADG. The variables ADG and feed:gain were analyzed by PROC MIXED (SAS 9.3), MMI and DMI measures were analyzed as repeated measures over time. Treatments, periods and pens were placed in the model. The addition of narasin in MM did not effected MMI (0N - 60.70 ± 3.05; 6.5N - 55.62 ± 3.18; 13N - 57.44 ± 2.50 g / heifer / d, $P = 0.7497$), corresponding to 0; 7.30 and 15.62 ppm of narasin intake. There was no change on DMI (0N - 4.85 ± 0.09; 6.5N - 4.95 ± 0.11; 13N - 4.78 ± 0.09 kg / heifer / d, $P = 0.6944$). However, adding 1300 mg of narasin / kg MM increased ADG (0N - 0.486 ± 0.02; 6.5N - 0.512 ± 0.02; 13N - 0.582 ± 0.02 kg / d, $P = 0.0181$) and improved feed:gain ration (0N - 12.71 ± 0.85; 6.5N - 11.70 ± 0.85; 13N - 9.50 ± 0.85, $P = 0.0488$) compared with the control group. In conclusion, adding 1300 mg of narasin / kg MM increased ADG and improved the feed:gain ratio.

Key Words: narasin, Nellore, high-forage

M311 Ruminal microbiology of Nellore steers fed different sources of forage in diets with crude glycerin in feedlot. Telma T. Berchielli*, Andressa F. Ribeiro, Yury G. Salcedo, Antonio Jose Neto, Luis G. Rossi, Monaliza O. Santana, Ana Laura E. G. F. Carvalho, Erick E. Dallantonia, and Juliana D. Messana, *Sao Paulo State University, Jaboticabal, Sao Paulo, Brazil.*

The aim of this study was to evaluate the effect of alternative forages for corn silage such as sugar cane and sugar cane bagasse included in a similar forage NDF level (fNDF) in diets with crude glycerin (80.64% of glycerol) on ruminal microbiology. Nine ruminally cannulated Nellore steers (300.0 ± 30kg of BW and 18 ± 2 mo of age) were used in a 3x3 Latin Square experimental design. Experimental periods were 15 d (14 d for adaptation and 1 d for ruminal sampling). Ruminal samples were taken 3 h after feeding. Protozoa population were preserved in formalin and quantified in Sedgewick-Rafter chamber. The technique to quantify total bacteria was qPCR. Data were analyzed using R software (version 3.1.1) as a triple Latin Square design with 3 treatments and 3 animals in 3 simultaneous triplicates. The fixed effects were treatments and Latin Square, and random effects were time, animal and error. The statistical test used was Tukey, and the significance was $P < 0.05$. The protozoa population was not influenced by the different sources of forage with crude glycerin, except *Dasytricha* and *Isotricha*. The concentration of *Dasytricha* population was increased in animals fed with sugar cane which not differed from animals fed with corn silage diet ($P > 0.05$). Additionally, *Isotricha* population concentration increased ($P < 0.05$) in animals fed with sugar cane. The population of fibrolytic bacteria (*Ruminococus flavefaciens*, *Ruminococcus albus* and *Fibrobacter succinogenes)* were similar ($P > 0.05$) among diets. On the other hand, the population of *Selenomonas ruminantium* increased ($P < 0.01$) in animals fed with corn silage. Corn silage and sugar cane included in 15% of fNDF in diets with crude glycerin (10% DM) altered ruminal microorganisms populations.

Key Words: bacteria, corn silage, protozoa

M312 Performance of young Nellore bulls during the dry season with two supplements. Marcella de Toledo Piza Roth*[1], Matheus Henrique Moretti[2], Flavio Dutra de Resende[3,4], Rodolfo Maciel Fernandes[1], Ana Paula de Toledo Piza Roth[2], and Gustavo Rezende Siqueira[3,4], *[1]UNIFEB, Barretos, São Paulo, Brazil, [2]Agroceres Multimix, Rio Claro, São Paulo, Brazil, [3]Agência Paulista de Tecnologia dos Agronegócios, Colina, São Paulo, Brazil, [4]UNESP, Jaboticabal, São Paulo, Brazil.*

The effects of 2 supplements on the performance of Nellore cattle in their post-weaning phase on a marandu-grass pasture during the dry season were evaluated. It was expected that differences would occur in the average daily gain (ADG), thereby modifying the carcass gain (CG) and carcass gain percent (CGP). The experiment was divided into 3 experimental periods (EP) with 35 d each (105 d), beginning in 08/2009. A total of 129 animals aged 8 ± 2 mo, with an initial BW of 204 ± 5.2 kg, were used in the experiment. The following supplements were tested: protein supplement (PS) (1 $g \cdot kg^{-1}$ BW, low-moderate ADG rate) and protein energy supplement (PES) (5 $g \cdot kg^{-1}$ BW, moderate-high ADG rate). Animals were weighed at the beginning and end of the EP (after 16 h deprivation) to determine the ADG. For the calculation of CG, the initial carcass weight was estimated through the equations obtained with 3 animals slaughtered at the onset. The CGP was calculated by dividing the carcass gain by the BW gain. The animals were allocated to a 48.2-ha pasture area (deferred in April 2009) divided into 18 paddocks (9 per treatment). The experimental design was completely randomized, with the paddock considered the experimental unit. To evaluate performance, 9 paddocks were considered per treatment (63 animals), while for the evaluations of carcass and body components, 3 animals were considered per treatment (6 animals); these results were subjected to ANOVA at 10% probability. Treatment PES provided a 44% higher ADG ($P < 0.01$) as compared with PS. The animals ADG was 0.72 kg (PES) and 0.50 kg (PS), resulting in a different BW at the end of the dry season ($P < 0.01$), which was 26 kg greater in the animals fed PES (285 kg) as compared with PS (259 kg). CG was not affected ($P = 0.35$) by the type of supplementation; however, the final carcass weight in the animals fed PES was 14.7% higher than in those which received PS ($P = 0.05$). The CGP (average 547.3 g carcass kg^{-1} BW) was not affected ($P = 0.94$) by the supplements. Supplementation with PES increases the ADG and provides heavier carcasses.

Key Words: average daily gain, protein supplement, protein-energy supplement

M313 Transcriptional profiles of adipose tissue from finishing beef steers fed diets supplemented with *Aspergillus oryzae*.

Kristen M. Brennan*, Daniel E. Graugnard, Allison C. Smith, Tatijana M. Fisher, and Leya F. Spangler, *Alltech Inc., Center for Animal Nutrigenomics and Applied Animal Nutrition, Nicholasville, KY.*

The objective of this study was to compare the transcriptional profiles in adipose tissue of steers fed diets supplemented with *Aspergillus oryzae* (Amaize, Alltech Inc.). Angus-cross steers were randomly assigned to one of 3 treatments ($n = 9$/treatment): basal diet (CON, control), basal diet plus 10g/hd/d of *A. oryzae* introduced gradually during the transition phase (GRAD, gradual), or basal diet plus 10g/hd/d of *A. oryzae* introduced at full level at the end of the transition phase (FULL). For the GRAD treatment, *A. oryzae* was added gradually to the ration by increasing the dose 2.5 g every 3 d until steers were receiving 10g/d at d 19. From receiving until d 21, starter and step-up diets were fed to transition steers to a low-forage finishing ration. On d 140, adipose tissue was biopsied. Samples were analyzed for gene expression using the Affymetrix Bovine Genome Array. Performance did not differ between treatment groups, however GRAD and FULL steers had numerically greater hot carcass weights ($P = 0.54$) and rib eye areas ($P = 0.15$) than CON steers. Relative to CON, there were 930 (396 upregulated, 534 downregulated) differentially expressed genes (DEG) in FULL steers and 425 (196 upregulated, 229 downregulated) DEG in GRAD steers. In FULL steers, DEG categorized to both the oxidative phosphorylation and mitochondrial dysfunction pathways were downregulated, suggesting a decrease in cellular energy production. Key DEG included components of complex I, III, and IV and the ATP synthase subunits. Surprisingly, these pathways were unaffected in GRAD steers. Although performance or carcass characteristics did not differ ($P < 0.05$) between treatment groups, the DEG suggest that, at least in FULL steers, energy production may be decreased. A future study is warranted to examine response to Amaize in terms of steer carcass composition and transcriptional patterns in skeletal muscle.

Key Words: enzyme, gene expression, beef

M314 Earlage: Yield, harvest timing, composition, and in situ digestibility.

L. Brown, S. Soderlund, and F. N. Owens*, *DuPont Pioneer, Johnston, IA.*

To increase return per hectare and profit, production of earlage (ensiled high-moisture harvested chopped corn ears) has increased. Compared with high moisture shelled corn grain (HMSC), yield of DM as earlage is 15 to 19% greater; field grain loss is less, harvest is simpler (grain need not be shelled from the cob), and “built-in-roughage” (cob and husk) reduces the need for added forage with no additional cost of production. Effects of harvest timing on yield, composition, and in situ digestibility were examined. In trial 1, ears from 6 hybrids grown at 2 locations harvested at 3 grain maturities (56 to 87% grain DM) were separated into grain, cob, and husk plus shank portions. Within the optimum harvest moisture for HMSC (minimum of 65% for maximum grain yield and maximum of 74% for adequate fermentation), earlage contained 4.0 to 5.6% less DM. Thereby; the optimum DM range for earlage harvest to parallel HMSC would be 60 to 69% DM. For simplicity, the optimum stage for harvest for earlage can be appraised by DM content of samples of shelled grain (optimum being 65 to 74% DM). Across hybrids and growing locations, ranges in percentage of earlage DM derived from grain, cob, and husk were 81 to 85%, 7.6 to 10.8%, and 5.7 to 8.9%, respectively. Heavier ears had less cob due to incomplete grain fill of cob tips, so high plant density or other factors that decrease ear size increase the percentage of cob in earlage. Irrigation timing and other traits (e.g., stay-green) may alter moisture distribution within ears. In trial 2, ears from 4 hybrids, one being a BMR, were harvested on 6 dates (60.6 to 80.2% DM) and ensiled for 0, 30, 60, 120, or 240 d. NDF content of earlage differed with hybrid and maturity due to changes in the break point between the cob and the shank. In situ NDFD was greater ($P < 0.01$) for the BMR hybrid (67 vs 58 to 62%). Delaying harvest decreased NDF content from 26% to 20% and in situ NDFD at 48 h from 71 to 57% (due to cob maturation) without changing DM disappearance. With longer durations of storage, curvilinear decreases in NDF content (22 vs 24% of DM) and in situ NDFD (60 vs 65% of NDF) were detected, but ranking of hybrids was not altered by fermentation time.

Key Words: earlage, harvest, NDF digestibility

M315 Effect of prenatal trace mineral source on neonatal and growing calf mineral status.

Deborah M. Price*[1], Alex F. Swain[1], Joseph M. Guevera[2], Carley R. Trcalek[2], Meaghan M. O’Neil[1], Max Irsik[2], Owen Rae[2], Matthew J. Hersom[1], and Joel V. Yelich[1], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]College of Veterinary Medicine, University of Florida, Gainesville, FL.*

The effect of cow prenatal trace mineral (TM) supplement source on calf TM status from birth through 30 d of age was examined. Factorial treatment (TRT) arrangements (Angus = AN, $n = 95$ and Brangus = BN, $n = 96$ cows; Inorganic = ING, $n = 98$, and Organic = ORG yeast, $n = 93$) utilized calves born to cows supplemented (3d/wk at a rate of 0.4 kg$\cdot^{-1}$454 kg BW$\cdot^{-1}$d in a pellet) with TM $\geq$90 d before expected parturition. Calf BW were collected at birth ($n = 191$). A subset of calves ($n = 43$) had BW, serum and plasma collected by jugular vein puncture at birth (0 h, before colostrum intake), 12 h, 24 h and 30 d of age. Processed samples were frozen at −20°C and plasma was refrigerated at 4°C until analyzed for TM (serum: Co, Cu, Fe, Mn, Mo, Se, Zn; plasma: Se), by ICP-MS. Data were analyzed in SAS using Proc Mixed and repeated measures, with TRT, breed and time as fixed effects. Breed, TRT, nor interactions affected ($P > 0.34$) BW at birth (36 ± 0.4 kg) and 30 d (69 ± 1.1 kg). With the exception of plasma Se, there were no ($P \geq 0.39$) 3-way interactions. Time affected ($P < 0.02$) all 0–24 h serum and plasma TM except for Co ($P = 0.60$). Calf Mn concentrations were undetectable at 0–24 h, but were 1.9 ± 0.2 ng/mL at 30 d sample. Both serum Se (ING = 57.5 ± 1.7 and 44.7 ± 1.1 µg/mL vs. ORG = 46.5 ± 1.7 and 33.4 ± 1.2 µg/mL) and plasma Se (ING = 149.4 ± 3.2, 129.9 ± 3.2 vs. ORG = 118.7 ± 3.3, 95.4 ± 3.3 ng/mL) were affected ($P < 0.001$) by TM source at 0–24 h and 30 d, respectively. At 30 d, Co was greater ($P = 0.002$) for ING (2.0 ± 0.3 ng/mL) than ORG (0.6 ± 0.3 ng/mL). At 0–24 h, Fe and Se were greater ($P \leq 0.05$) in AN (87.1 ± 5.9 µg/dL and 54.7 ± 1.7 ng/mL) than BN (70.1 ± 5.8 µg/dL and 49.2 ± 1.7 ng/mL). At d 30, AN (40.7 ± 1.2 ng/mL) serum Se was greater ($P = 0.048$) than BN (37.4 ± 1.1 ng/mL). In contrast, BN had greater ($P < 0.01$) Cu (0.3 vs. 0.2 ± 0.01 µg/mL) than AN at 0–24 h and Mo (52.9 ± 8.5 vs. 10.0 ± 1.7 ng/mL) at 30 d, respectively. These data demonstrate calf TM status varies by time, prenatal TM source and breed. Pre-calving nutritional strategies need to consider TM source and calf breed.

Key Words: trace mineral, prenatal nutrition, calves

M316 Effects of feeding a complete pelleted feed consisting of treated corn stover and distillers byproducts on total tract digestion and performance of growing cattle. Jana L. Harding*, Curt J. Bittner, Dirk B. Burken, Galen E. Erickson, and James C. MacDonald, *University of Nebraska Lincoln, Lincoln, NE.*

Two studies evaluated the effect of replacing traditional growing diets with a complete pelleted feed. In Exp. 1, 6 steers were utilized in a 4 × 6 Youden square to evaluate the effects of a complete pelleted feed on total-tract digestion. Four treatments consisted of 2 control diets containing 18% modified distillers grains (MDGS), 18% solubles, and either 60% untreated corn stover (−CON) or 60% alkaline treated corn stover (+CON). The remaining 2 diets were 1 of 2 complete pelleted feeds (Pellet A or Pellet B). Pellets contained alkaline treated corn stover, dry distillers grains, solubles, and supplement. Corn stover used in Pellet A and B were harvested using different methods causing Pellet B to have less stem than Pellet A. In Exp. 2, a 92-d growing study utilized 360 (initial BW = 316 ± 22 kg) yearling steers to evaluate replacing a diet consisting of 60% corn stover, 18% solubles, and 18% MDGS with a complete pelleted feed on growing cattle performance. The pelleted feed was the Pellet A treatment in Exp. 1. Pellets were either pair-fed (Pel-PF) to the control (CON) treatment (CON fed ad libitum) or fed ad libitum (Pel-AL). In Exp.1, differences ($P < 0.01$) in total-tract digestibility of OM (OMD) and NDF (NDFD) between the 4 treatments were observed. Pellet B had the greatest OMD and NDFD (75.55% and 63.93%, respectively) and the −CON had the lowest (67.58% and 54.36%, respectively). The +CON and Pellet A were intermediate and statistically similar to one another ($P \geq 0.22$). In Exp. 2, there were no differences ($P > 0.50$) between the CON and Pel-PF in ending BW, DMI (by design), or ADG (1.29 ± 0.17 and 1.27 ± 0.22 kg/d, respectively). Greater DMI (12.18 ± 0.71 kg/d) and ADG (1.63 ± 0.20 kg/d) were observed for the Pel-AL compared with the CON and Pel-PF treatments ($P < 0.01$). The Pel-AL treatment (0.134) had lower G:F ($P = 0.05$) compared with the CON and Pel-PF treatments (0.143 and 0.140, respectively). Replacing a traditional growing diet with a complete pelleted feed resulted in similar or improved diet digestibility, depending on stover harvesting method. Pelleting increased DMI and ADG if cattle were fed ad libitum but decreased G:F.

Key Words: byproducts, pellet, treated corn stover

M317 Additives in supplements to fed Nellore young bulls in pasture. Erick Escobar Dallantonia[1], Josiane Fonseca Lage*[2], Elias San Vito[1], Gabriela Moraes Delamagna[1], Patricia Baldi Garrido[1], Lutti Maneck Dellevatti[1], Ricardo de Andrade Reis[1], Marco Antonio Alvares Balsalobre[2], and Telma Teresinha Berchielli[1], [1]*Universidade Estadual Paulista Julio de Mesquita Filho, Jaboticabal, São Paulo, Brazil,* [2]*Trouw Nutrition Brazil, Mirassol, São Paulo, Brazil.*

This trial aimed to evaluate the blood parameters and growth of Nellore young bulls finished in pasture in the rainy season supplemented with monensin (MON), virginiamycin (VM) or both associated. Ninety animals were used with the initial BW of 360 kg ± 24.98 kg, receiving daily supplementation in 0.3% of BW, distributed in 12 paddocks of *Brachiaria brizantha* 'Xaraés', with about 2 ha each (3 paddocks/treatment) and fed daily with supplement without additives (SUP), with MON (SUPM - 80 mg/kg), with VM (SUPV - 150 mg/kg) and supplement with MON and VM (SUPMV - 80 and 150 mg/kg, respectively). Supplements had 25% of CP. After 14 d of adaptation, 8 animals were slaughtered as a reference group to obtain the initial dressing percentage (DP) to calculate the carcass gain (CG) at the end of the experiment. The remaining animals (n = 82) were allotted in paddocks (7 animals/paddock). In one paddock were allotted 5 animals, due to the smaller size of the area. Blood was collected after 14 h withdrawal period from feed and water at the 0, 63 and 118 d of feeding. To obtain the ADG, animals were weighted in shrunk. Animals were slaughtered after 140 d of trial. Data were analyzed using the Proc Mixed of SAS with a randomly design (5% of probability). The inclusion of additives in supplements does not affect the insulin ($P = 0.81$) and glucose ($P = 0.29$) concentrations. The inclusion of the additives in supplements does not affect the final BW ($P = 0.11$), hot carcass weight ($P = 0.45$), DP ($P = 0.14$) and CG in relation the ADG ($P = 0.91$). However, the ADG was affected ($P = 0.03$) by inclusion of additives in supplements. Young bulls fed SUPM had similar ADG (0.867 kg/d) in relation young bulls fed SUPV (0.896 kg/d), but lower ADG than animals fed SUP (0.949 kg/d) and SUPMV (0.969 kg/d). Animals fed SUPV had similar ADG than animals fed SUP, but lower than animals fed SUPMV. The inclusion of MON, VM or both associated in supplements to fed bulls in pasture at the rainy season not promotes additional weight in carcass or BW.

Key Words: beef cattle, monensin, virginiamycin

M318 Relationship between infrared thermography and heat production in young bulls. Mario L. Chizzotti[2], Rafael A. Gomes*[1,3], Karina C. Busato[1], Marcio M. Ladeira[1], Matheus C. Galvão[1], Priscilla D. Teixeira[1], Aline C. Rodrigues[1], Antonio Henrique Ribeiro Junior[1], and Maria Helena Oliveira[1], [1]*Universidade Federal de Lavras, Lavras, MG, Brazil,* [2]*Universidade Federal de Viçosa, Viçosa, MG, Brazil,* [3]*Washington State University, Pullman, WA.*

Infrared thermography (IRT) was tested for predicting heat production in Nellore and Angus young bulls. A total of 32 animals with initial body weight (BW) of 380.6 ± 6.1 kg were housed in individual stalls. Eight animals of each breed were fed ad libitum with a whole shell corn (WSC) diet (85% whole shell corn and 15% of a pellet based on soybean meal) or a silage/concentrate (SC) diet (30% silage and 70% concentrate based on corn and soybean meal). After 50 experimental days, skin and eyeball temperatures were obtained by infrared thermal images (Fluke Ti 55ft, Fluke Corporation) and the pictures were analyzed using the software SmartView 3.0. The daily intake was measured and a metabolic trial was conducted with total collection of feces and urine to estimate the metabolizable energy intake (MEI). With 90 d of growth, the cattle were slaughtered. The retained energy (RE) was calculated using comparative slaughter technique. Heat production (HP) was calculated as the difference between MEI and RE. The data were analyzed using the GLM and REG procedures of SAS adopting significance level of 0.05. Angus cattle show greater daily MEI, daily HP and body temperatures than Nellore (Table 1). SC diets show greater MEI and HP, but similar eye and skin temperatures. We found a moderate correlation ($P < 0.05$) between daily HP and maximum (r = 0.46) and average skin (r = 0.47) and maximum (r = 0.44) and average eyeball (r = 0.40) temperatures. We concluded that IRT technique has a potential to be used to evaluate HP in cattle.

Contd.

Table 1 (Abstr. M318). Metabolizable energy intake (Mcal/d), heat production (Mcal/d), and maximum and average temperatures of skin and eyeball (°C) of Nellore and Angus bulls fed whole shell corn (WSC) or a silage/concentrate (SC) diets

	Nellore		Angus			*P*-value

Key Words: Nellore, Angus, metabolizable energy intake

M319 Intake, digestibility and rumen fermentation in beef cattle fed warm-season legume (*Stylosanthes* 'Campo Gande') silage with two dietary protein levels.

Leandro D. Silva, Odilon G. Pereira*, Thiago C. Silva, Sebastião C. Valadares Filho, and Karina G. Ribeiro, *Universidade Federal de Viçosa, Viçosa, MG, Brazsil.*

The *Stylosanthes* 'Campo Grande' (*Stylosanthes capitata + S. macrocephala*) is adapted to tropical conditions and exhibit a nutritional value comparable to other high efficiency feeds being used in the tropics. The objective of this study was to evaluate the nutrient intake, total apparent digestibility, ruminal pH and ammonia concentration and the microbial efficiency of beef cattle fed *Stylosanthes* 'Campo Grande' (StS) or corn silages (CS) with 2 dietary protein levels (PL). Four Nelore rumen cannulated, average (BW) of 449.8 ± 9.47 kg were assigned to a 4 × 4 Latin square with a 2 × 2 factorial design of treatments with 4 16-d periods. The treatments were StS and CS with 2 PL (11% and 13% CP on DM basis). Data were analyzed including in the model the fixed effects of silage (S), PL and the interaction S × PL, and the random effects of animal and period. The intake and digestibility were not affected ($P > 0.01$) by the interaction S × PL. However, the diets containing StS showed lower ($P < 0.01$) TDN intake than CS (4.52 vs. 6.01 kg/d). Similar pattern was observed for DM, OM, CP and NDF digestibilities. The ruminal pH and ammonia concentration were affected ($P < 0.01$) by S and PL, respectively. The microbial efficiency estimated from urinary purine derivatives was not affected ($P > 0.01$) by treatments (average of 75.77 g/kg TDN). The StS resulted in lower TDN intake and lower total apparent digestibility of DM, OM, CP and NDF without affecting the microbial efficiency. Supported by Fapemig, CNPq and INCT-CA.

Key Words: stylo silage, microbial efficiency, ruminal pH

M320 Performance of Nellore bulls supplemented with energy sources associated crude glycerin on finishing phase.

Antonio Jose Neto*, Luis Gustavo Rossi, Erick Escobar Dallantonia, Monaliza de Oliveira Santana, and Telma Teresinha Berchielli, *Department of Animal Science, São Paulo State University, UNESP, Jaboticabal, SP, Brazil.*

The objective of this study was to evaluate the effects of crude glycerin (Gly) combined with energy sources on performance and carcass characteristics of Nellore bulls fed tropical pasture during the finish phase. Sixty Nellore bulls (424 ± 34 kg; 20 ± 2 mo) were distributed in a completely randomized design (5 animals per paddock and 3 paddocks per treatment) with 4 experimental treatments in a 2 × 2 factorial arrangement (high or low starch, with or without a source of oil). The experimental period lasted 133 d, divided in adaptation (21 d) and 4 periods of 28 d each. The animals were allocated into 12 paddocks of 1.8 ha, consisting of *Brachiaria brizantha* 'Xaraés' in the dry season, and supplemented at the rate of $1000\ \mathrm{g \cdot 100\ kg^{-1}}$ of BW, daily, at 1000 h. The supplements were: T1 - Gly with high starch (corn), T2 - Gly with low starch (soybean hulls), T3 - Gly with high starch associated with a source of oil (corn and soybeans), and T4 - Gly with low starch associated with a source of oil (soybean hulls and soybeans). Crude glycerin (83.9% of glycerol), a byproduct from the biodiesel agroindustry, was used in all supplements to replace (28% of DM) corn or soybean hulls. Average daily gain (ADG) was measured by weight changes during successive weightings of the animals in each experimental period. After 133 d of feeding, all the animals were slaughtered with 546 ± 43 kg of shrunk BW and was determined the hot carcass weight (HCW), dressing percent (DP), and daily carcass gain (CrG). Data were analyzed using the PROC MIXED of the SAS with $\alpha = 0.05$ and F-*test*, animal was the experimental unit. There was no interaction between starch × oil for final BW, ADG, HCW, DP, and CrG ($P = 0.11$). However, animals supplemented with oil increased final BW ($P = 0.01$), ADG ($P = 0.02$), HCW ($P < 0.01$), and GrC ($P = 0.01$). Independently of starch level utilized, there was an increase of 7.4% (ADG), and 2.5% (HCW) for animals fed with oil compared with without oil. Oil supplementation associated with Gly may be effective to improve performance and final carcass characteristics of Nellore bulls finished on pasture.

Key Words: beef cattle, glycerol, oil

M321 Ruminal health of feedlot beef cattle fed with crude glycerin during adaptation period or finishing time.

Josimari Regina Paschoaloto*, Jane Maria Bertocco Ezequiel, Marco Tulio Costa Almeida, Ivaldo Monsignati, Vanessa Barbosa Carvalho, Henrique Leal Perez, Antonio Carlos Homem Junior, Henrique Boselli Bussioli, Rhaony Gonçalves Leite, Anibal Garcia Camargo Junior, and Gustavo Leite Vieira, *São Paulo State University, UNESP/FCAV, Jaboticabal, São Paulo, Brazil.*

This trial evaluated the inclusion of glycerin in high concentrate diets as an ingredient is able to of reducing ruminal metabolic problems. Sixty Nellore cattle (initial BW of 300 ± 50kg) were used in a completely randomized block. Diets consisted of corn silage, corn, crude glycerin (83% glycerol), urea, sunflower meal, soybean hulls and mineral. Finishing diets presented 15% of roughage and 85% of concentrate. The crude glycerin derived from vegetable used is soybean oil and 30% was included in the diets of DM. Four treatments were used: glycerin during adaptation step up and finishing period (1) or glycerin just during adaptation period (2); absence glycerin during adaptation and finishing period (3) or absence of glycerin during adaptation and finishing period (4). The animals were housed in individual pens with free access to water. The diets were offered twice daily at 0800 and 1600h. Hepatic abscesses incidence (HAI) was determined according the presence and severity. At harvest rumenitis incidence (RI) was determined, on the entire washed rumen, using a scale of 0 (no lesions noted) to 10 (severe ulcerative). A fragment of 1 $\mathrm{cm^2}$ of each rumen was collected from ventral sac. Manually, the number of papillae per $\mathrm{cm^2}$ of rumen wall (NOP) was determined and 10 papillae were randomly collected from each fragment; scanned, and mean papillae area (MPA) in $\mathrm{cm^2}$ was measured by software for image analysis. RASA in $\mathrm{cm^2}$ was calculated as follows: $1 + (\mathrm{NOP} \times \mathrm{MPA}) - (\mathrm{NOP} \times 0.002)$. The data were analyzed using GLM procedure of SAS statistical software 9.2 and were compared the means by Tukey's test (5%). No significant ($P > 0.05$) effect was observed for RI, HAI, MPA and NOP between diets, however there are difference for ASA and PSA ($P < 0.05$). Diets without glycerin during adaptation showed reduction on absorptive surface area per cm^2 of rumen wall and lower participation of rumen papillae in the total area of absorptive surface (%). Use of glycerin during adaptation led to greater development of ruminal epithelium, which may represent a new technology to control rumen acidification.

Key Words: Nellore, papillae, rumenitis

M322 Feeding behavior of feedlot beef cattle fed with high level of crude glycerin with crude glycerin during adaptation period or finishing time.

Josimari Regina Paschoaloto*, Jane Maria Bertocco Ezequiel, Marco Tulio Costa Almeida, Bruno Henrique Ferreira Araujo, Vanessa Barbosa Carvalho, Henrique Leal Perez, Ivaldo Monsignati, Henrique Boselli Bussioli, Rhaony Gonçalves Leite, Anibal Garcia Camargo Junior, and Gustavo Leite Vieira, *São Paulo State University-UNESP/FCAV, Jaboticabal, São Paulo, Brazil.*

This trial evaluated the inclusion of glycerin in high concentrate diets as an ingredient is able to of reducing ruminal metabolic problems, for this was evaluated the behavior feeding of 60 Nellore cattle (initial BW of 300 ± 50 kg) assigned in a completely randomized block. Diets consisted of corn silage, corn, crude glycerin (83% glycerol), urea, sunflower meal, soybean hulls and mineral. Finishing diets presented 15% of roughage and 85% of concentrate. The crude glycerin derived from vegetable used is soybean oil and 30% was included in the diets of DM. Four treatments were used: glycerin during adaptation step up and finishing period (1) or glycerin just during adaptation period (2); absence glycerin during adaptation and finishing period (3) or absence of glycerin during adaptation and finishing period (4). The animals were housed in individual pens with free access to water. The diets were offered twice daily at 0800 and 1600h with 50% of total in each meal. The data were analyzed using GLM procedure of SAS statistical software 9.2 and were compared the means by Tukey's test considering 5% of significance level. There were no difference treatments among the variables: ruminating time, total idle, ruminating efficiency, bolus number and mastication per day ($P > 0.05$). The exceptions were the variables: dry matter intake, feeding time, feeding dry matter efficiency ($P < 0.05$). Diets with glycerin finishing promoted greater feeding time and lower dry matter intake, probably this effect is due to energy contribution of glycerin, which modulated the animal intake. Glycerin increases the frequency of meals and reduces meal size which is beneficial for ruminal fluid pH. It is concluded, that the use of glycerin results in better synchronization in time between feed intake (acid production) and rumination (saliva production).

Key Words: feed intake, Nellore, ruminating time

M323 Supplementary levels of *Macleaya cordata* plant extract Sangrovit-RS on feedlot performance and carcass traits of finishing bullocks.

Rubén Barajas*[1], Billy J. Cervantes[2], Ingo Rogge[3], Alejandro Plascencia-Jorquera[4], Alejandro Camacho[1], and Marco A. Osuna[1], [1]*FMVZ-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México,* [2]*Ganadera Los Migueles, S.A. de C.V., Culiacán, Sinaloa, México,* [3]*Phytobiotics Futterzusatzstoffe GmbH, Eltville, Germany,* [4]*FMVZ-Universidad de Baja California, Mexicali, Baja California, México.*

Macleaya cordata, is a plant of the *Papaveraceae* family that contains quaternary benzophenathridine and protopine alkaloids, showing systemic anti-inflammatory effects. Despite *Macleaya cordata* plant extract being used in Europe as feed additive for livestock (Sangrovit RS; Phytobiotics, Eltville, Germany), its effects on feedlot cattle performance are not well documented. Hence, 60 bullocks (368 ± SD 44.7 kg) were used to determine the effect levels of *M. cordata* plant extract Sangrovit-RS (S-RS) supplementation level on feedlot performance and carcass traits of finishing bullocks. Animals were crowded by breed in groups of 5 placed in 12 dirt-floor pen and randomly assigned to receive treatments as follows: 1) A 90% concentrate finishing diet (Control); 2) Control plus daily supplementation of 3 g of Sangrovit-RS (SRS)/bullock (SRS3); and 3) Control plus daily supplementation of 8 g of SRS/bullock (SRS8). Results were analyzed as a completely randomized design. Pen was the experimental unit. Body weight at d −21 and hot carcass weight were used as the associated co-variables, for performance and carcass characteristics, respectively. The influence of SRS level was analyzed using unequal spaced polynomials. Feed efficiency (Gain/feed ratio) responded quadratically to inclusion level of SRS ($P = 0.04$), with means of 0.17, 0.19 and 0.15 kg/kg for Control, SRS3, and SR8, respectively; bullocks in SRS3 shown the best response, with 12% improved feed efficiency compared with Control (0.19 vs. 0.17 kg gain/kg DM). Dry matter intake tended ($P = 0.08$) to respond quadratically to SRS supplementation level, with the lowest value for SRS3. Hot carcass dressing was augmented linearly ($P = 0.03$) by SRS level. KPH-fat tended to decreases linearly as SRS intake was increased ($P = 0.11$). Results of this experiment suggest that feeding Sangrovit-RS in doses close to 3 g/day improves feed efficiency of finishing bullocks.

Key Words: feedlot performance, *Macleaya cordata*, sanguinarine

M324 Energy requirements of Nellore and Angus young bulls.

Rafael A. Gomes*[1,3], Mario L. Chizzotti[2], Karina C. Busato[1], Jose Rodolfo R. Carvalho[1], Marcio M. Ladeira[1], Matheus C. Galvão[1], Maria Helena Oliveira[1], Aline C. Rodrigues[1], and Priscilla D. Teixeira[1], [1]*Universidade Federal de Lavras, Lavras, MG, Brazil,* [2]*Universidade Federal de Viçosa, Viçosa, MG, Brazil,* [3]*Washington State University, Pullman, WA.*

Fouty-8 animals with initial body weight (BW) of 380.2 ± 4.73 kg were used to determine energy requirements of Nellore and Angus young bulls using comparative slaughter technique. Four animals of each breed were slaughtered at beginning of the experiment (baseline animals). The remainder were housed in individual stalls. Eight animals of each breed were fed ad libitum with a whole shell corn (WSC) diet (85% WCS and 15% of a pellet based on soybean meal) or a silage/concentrate (SC) diet (30% silage and 70% concentrate based on corn and soybean meal). Other 4 animals of each breed were fed with the SC diet at 50% of feed restriction, based on dry matter intake adjusted for metabolic BW of animals that received the SC diet ad libitum. We measured the daily intake and a metabolic trial was conducted with total collection of feces and urine to estimate the metabolizable energy intake (MEI). At 90 d of growth, the bulls were slaughtered. Heat production (HP) was calculated as the difference between MEI and retained energy (RE). The net energy requirements for maintenance (NE_m) was estimated considering the intercept of the equation $HP = a \times e^{(b \times MEI)}$. The metabolizable energy requirements for maintenance (ME_m) was calculated by iteration, assuming the value which HP and MEI are the same. The efficiency of ME utilization for maintenance (k_m) was obtained as the NE_m divided by the ME_m. The slope of the regression of RE on MEI was assumed to be the efficiency of energy utilization for growth (k_g). The data were analyzed using the GLM and NLIN procedures of SAS adopting significance level of 0.05. NE_m was different between Angus and Nellore (99.8 vs 75.8 kcal/kg $EBW^{0.75}$/d). The ME_m was 150 and 122 kcal/ kg $EBW^{0.75}$ and the k_m was 67 and 62% for Angus and Nel-

lore cattle, respectively. We did not find difference between breeds ($P > 0.05$) in k_g (20%).

Key Words: maintenance, growth

M325 Influence of particle size of sugar cane and concentrate level on intake and digestibility of nutrients, and rumen fermentation in crossbred steers.

T. C. da Silva*, O. G. Pereira, D. R. da Costa, R. M. Martins, M. C. N. Agarussi, L. D. da Silva, K. G. Ribeiro, and S. C. Valadares Filho, *Universidade Federal de Vicosa, Vicosa, Minas Gerais, Brazil.*

The objective of this study was to evaluate the nutrient intake, ruminal and intestinal digestibility, and the ruminal fermentation of beef cattle fed fresh sugarcane (SC) chopped in 2 particle sizes (PS) and 2 levels of concentrate (40 and 60%, DM basis). The treatments were: 1) Fine-chopped sugarcane and 40% C (FSC-40); 2) Fine-chopped sugarcane and 60% C (FSC-60); 3) Coarse-chopped sugarcane and 40% C (CSC-40); and 4) Coarse-chopped sugarcane and 60% C (CSC-60). Four Holstein × Zebu steers (average BW of 510 ± 11 kg) were used, distributed in a 4 × 4 Latin square design, with a 2 × 2 factorial. The experiment lasted 64 d and was divided in 4 periods of 16 d each (10 d for adaptation and 6 d for samples and data collection). Data from intake and digestibility were analyzed including in the model the fixed effects of PS, C and the interaction PS × C, and the random effects of animal and period. For the ruminal fermentation data, a scheme of time-repeated measurements was used considering the sampling time (before feeding, 2, 4 and 6 h after feeding). The geometric means (X_{gm}) were 8.30 and 15.92 mm for the FSC and CSC, respectively. The intake of DM, OM and NDF were affected by the interaction PS × C ($P < 0.05$). The diet containing FSC showed higher intake of these nutrients than CSC-diet when 60% C was added. The amounts of OM and NDF digested in the rumen were affected by the interaction PS × C ($P < 0.05$). The diet FSC-60 had higher amounts of OM and NDF digested in the rumen than the diet CSC-60. The amounts of OM and NDF digested in the intestine were higher in the diets containing 60% than the diets with 40% C ($P < 0.05$). The diet FSC-60 had the lowest ($P < 0.05$) pH (5.75). The ruminal ammonia-nitrogen was affected by sampling time ($P < 0.05$) and had a quadradic behavior. We concluded that fine-chopped sugarcane ($X_{gm} = 8.30$ mm) in diets with 60% of concentrate increases the intake and digestibility of nutrients without compromise the ruminal fermentation of crossbred steers.

Key Words: effective fiber, ruminal digestibility, ruminal pH

M326 Supplementation with a DHA-rich microalgae alters muscle gene expression profiles in finishing beef heifers.

Kristen M. Brennan*[1], Daniel E. Graugnard[1], Allison C. Smith[1], James S. Drouillard[2], and Kate A. Jacques[1], [1]*Alltech Inc., Center for Animal Nutrigenomics and Applied Animal Nutrition,, Nicholasville, KY,* [2]*Kansas State University, Manhattan, KS.*

The objective of this study was to determine gene expression patterns in the muscle tissue of finishing heifers fed diets supplemented with DHA-rich algae. Angus-cross heifers (n = 285; 453 ± 24 kg initial BW) were randomly assigned to one of 4 treatments: control (CON) or 50, 100, or 150 g/d of DHA-rich microalgae (ALG, *Schizochytrium limacinum* CCAP 4087/2, Alltech Inc., Nicholasville, KY). Muscle samples (n = 9 per treatment) were obtained via biopsy from the *Longissimus dorsi* and gene expression was analyzed using the Affymetrix Bovine Gene 1.0 ST Array. Relative to the CON, a total of 2047 differentially expressed genes (DEG, 919 upregulated and 1128 downregulated), 711 genes (343 upregulated and 368 downregulated), 956 genes (440 upregulated and 516 downregulated), were differentially expressed in the 50, 100 and 150 g/d treatment groups, respectively. In the 50-g treatment group, DEG encoding enzymes involved in the synthesis of n-3 PUFA included ELOVL2 (−1.15 fold), ACOX1 (1.19 fold) and SCP2 (1.22 fold). These genes were unchanged in the 100-g and 150-g treatment groups. Biological functions commonly enriched in all 3 treatment groups included cellular development and lipid metabolism. DEG involved in free radical scavenging, including catalase (1.16 fold), superoxide dismutase (1.18 fold) and peroxiredoxin (1.14 fold) were increased in the 150-g treatment group, supporting previous findings that markers of lipid oxidation in muscle were increased in this group. Overall, these results suggest that supplementing finishing heifer diets with ALG alters the expression of genes involved in lipid metabolism and lipid accumulation in muscle tissue, and that these alterations are dose dependent.

Key Words: microalgae, gene expression, omega-3 fatty acid

M327 Influence of a tannins extract preparation supplementation level on the feedlot performance of feedlot bullocks.

Rubén Barajas*[1], Billy J. Cervantes[2], Juan A. Vázquez[2], Alejandro Camacho[1], and Javier A. Romo[1], [1]*FMVZ-Universidad Autónoma de Sinaloa, Culiacán, Sinaloa, México,* [2]*Ganadera Los Migueles, S.A. de C.V., Culiacán, Sinaloa, México.*

Eighty Brahman cross bullocks (399.3 ± SD 19.41 kg) were utilized in a 56-d experiment to evaluate the influence of a tannins extract preparation supplementation level on the feedlot performance of feedlot bullocks. Bullocks were individually weighed and blocked by weight. Groups of 5 bullocks were placed in16 dirt-floor pens (6 × 12 m). Pens within a block were randomly assigned to treatments follows: 1) Finishing diet (13.6% CP, 2.11 Mcal NE_m/kg) formulated with ground corn (Control, CTL); 2) Control added with 2 g of tannins extract preparation/ kg of DM (TE2); 3) Control supplemented with 4 g of tannins extract preparation/ kg of DM (TE4); and 4) Control added with 6 g of tannins extract preparation/ kg of DM (TE6). The tannins extract preparation (TE) was provided as TMP Protein Enhancer + ByPro (Tecnica Mineral Pecuaria, Mexico, that contains 50% of condensed and hydrolysable tannin blend. TE treatments were top dress on the diet in the feed bunk. Results were analyzed by ANOVA for a randomized complete block design. Three orthogonal contrasts were performed: I = 0 vs. 2 + 4 + 6 g of TE/kg DM; II = 0 *vs*. Two g of TE/kg DM; and III = 2 *vs*. Four + 6 g of TE/kg DM. and the linear, quadratic or cubic trend were tested by polynomial contrasts. The final weight of TE2 bullocks was higher than CTL ($P = 0.05$), and a tendency for a quadratic response was observed ($P = 0.10$). TE2 increased 13.8% ($P = 0.05$) the ADG respect to CTL (1.53 *vs*. 1.35 kg/d). ADG show a quadratic tendency ($P = 0.10$). Dry matter intake was not affected by treatments ($P > 0.20$). Feed efficiency tended ($P = 0.06$) to be better in TE2 treatment than CTL (0.174 vs. 0.156 kg gain/kg food). Gain/feed ratio responded in a quadratic manner ($P = 0.05$) as TE supplementation was increased, the best level was calculate by polynomial regression as 3 g of TE by kg of diet DM ($R^2 = 0.3$; $P = 0.05$).It is concluded that performance of feedlot bullocks respond in a quadratic manner to tannins extract supplementary level, and the best response could be expected with addition of 3 g of tannins extract by kg of diet DM.

Key Words: bovine, feedlot performance, tannin

M328 Effect of monensin withdrawal on intake and digestion in *Bos indicus* and *Bos taurus* steers consuming bermudagrass hay.

Natasha L. Bell*1,2, Todd R. Callaway[3], Robin C. Anderson[3], Marcia O. Franco[4], and Tryon A. Wickersham[1], [1]*Texas A&M University, College Station, TX,* [2]*Texas A&M University-Kingsville, Kingsville, TX,* [3]*Southern Plains Agricultural Research Center, Agricultural Research Service, USDA, College Station, TX,* [4]*Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Effects of monensin withdrawal and subspecies of cattle on the utilization of bermudagrass hay (13.7% CP) were evaluated using ruminally cannulated steers (5 *Bos indicus*, BI and 5 *Bos taurus*, BT; 398 kg BW). Subspecies were concurrently subjected to a 2 period, 2 treatment crossover design. Each period consisted of a 42 d adaptation phase with treatments including 0 (CON) or 200 (MON) $mg \cdot hd^{-1}$ monensin, fed in 0.91 kg DDGS daily. Withdrawal of monensin was then evaluated for a 28 d phase following adaptation. Hay, ort, and fecal grab samples were collected d 23–27 after the cessation of MON feeding for determination of intake and digestion. Steers were group housed throughout the trial, but moved to individual covered pens to facilitate sampling. Data were analyzed using the MIXED procedure of SAS 9.3 (SAS Inst. Inc., Cary, NC) with terms in the model including treatment, subspecies, subspecies × treatment and period, with animal as a random effect. No subspecies × treatment interactions were observed ($P \geq 0.15$). A tendency for greater ($P = 0.09$) forage OM intake (FOMI; 21.2 vs 19.2 g/kg BW) and greater ($P < 0.01$) OM digestibility (OMD; 72.4 vs 63.0%) resulted in greater ($P < 0.01$) total digestible OM intake (TDOMI; 16.8 vs 13.2 g/kg BW) in BT vs BI steers. Previous monensin feeding had no effect ($P \geq 0.45$) on FOMI, OMD, or TDOMI. Greater ($P = 0.04$) forage NDF intake (FNDFI; 16.68 vs 14.94 g/kg BW) and greater ($P < 0.01$) NDF digestibility (NDFD; 73.8 vs 65.6%) led to greater ($P < 0.01$) total digestible NDF intake (TDNDFI; 12.9 vs 10.3 g/kg BW) in BT vs BI steers. Previous monensin feeding had no effect on FNDFI, NDFD, or TDNDFI. Increased FOMI, FNDFI, OMD, NDFD, TDOMI, and TDNDFI by BT steers suggest they are better able to utilize the bermudagrass hay offered them than BI steers. Results also indicate that upon treatment withdrawal, no intake or digestibility differences are observed between steers previously fed monensin and control.

Key Words: cattle subspecies, ionophore, digestibility

M329 The influence of pellet size and a pellet binder on rumen fermentation and total tract digestibility in beef heifer.

Katie M. Wood*[1], Faustin Joy[1], John Smillie[1], Rodrigo Kanafany Guzmán[1], Gillian Gratton[1], Tom A. Scott[1], Herbert (Bart) A. Lardner[2,1], and Gregory B. Penner[1], [1]*Dept of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Saskatchewan, Canada,* [2]*Western Beef Development Center, Lanigan, Saskatchewan, Canada.*

Using by-product feeds can be a means of reducing feed costs, however, challenges with the pelleting process may affect pellet quality. The effect of pellet size and durability of a by-product based pellet was evaluated in 8 crossbred ruminally cannulated heifers. The experiment was conducted as a replicated 4 × 4 Latin square design with a 2 × 2 factorial treatment arrangement. Pellets were prepared using a 3.96 mm (SP) or 12 mm (LP) die and contained Nutraflex Plus (3 kg/T) and Ameri-Bond 2X (5 kg/T) as binding agents (B) or no binding agent (NB). Heifers were fed a partial mixed ration (81.8% grass hay and 18.2% oat hull, DM basis) ad libitum and pellet was offered separately at a rate of 0.09% of BW. Heifers were provided 15 d for adaptation followed by 3 d for total fecal and urine collection, rumen fluid sampling and continuous rumen pH measurement using indwelling pH probes. Statistics were conducted using PROC MIXED in SAS with the fixed effect of pellet size, binder inclusion, and the interaction. Tukey's adjusted post hoc mean separation test was used to compare treatment means where significance was declared at $P \leq 0.05$. Heifers fed pellet with binder had increased ($P \leq 0.05$) ADG and G:F, did not differ ($P \geq 0.33$) in DM intake. The molar proportion of acetate was greater (interaction, $P = 0.03$) in heifers fed large pellet with binder (66.0%) compared with small pellet with binder (63.9%) whereas the large and small pellets without binder were intermediate (64.6 and 63.9%, respectively). Propionate was greater (interaction, $P = 0.05$) in heifers fed large pellet (17.7%) with no binder than with binder (15.6%) and was intermediate for heifers fed the small pellet with and without binder (17.6 and 17.2%, respectively). Heifers fed binder had butyrate concentrations that were 0.68% greater ($P = 0.05$) than without binder. Total-tract digestibility was not affected. The results of this experiment indicate that overall digestibility of a by-product based range pellet was not influenced by size or binder; however, pellet size and use of a binder may influence rumen fermentation, ADG, and feed conversion.

Key Words: pellet size, binder, beef

M330 Effect of monensin concentration on rumen pH, short-chain fatty acid absorption, total-tract digestibility, and barrier function in beef heifers.

Katie M. Wood*[1], Ana C. J. Pinto[2], Danilo D. Millen[2], Rodrigo Kanafany Guzmán[1], and Gregory B. Penner[1], [1]*Dept. of Animal and Poultry Science, University of Saskatchewan, Saskatoon, Saskatchewan, Canada,* [2]*São Paulo State University(UNESP), Dracena, São Paulo, Brazil.*

The objective of this study was to evaluate whether the monensin concentration affects DMI, rumen fermentation, short-chain fatty acid (SCFA) absorption across the rumen and total-tract barrier function. Four ruminally cannulated Hereford × Angus heifers were used in a 4 × 4 Latin square design with 24-d periods. Heifers were fed a barley-based finishing diet (76% rolled barley grain, 12% barley silage, 8% mineral and vitamin supplement, and 4% canola meal) containing either 0, 22, 33 or 48 ppm monensin. Urinary recovery of Cr-EDTA was used as an indicator of total-tract barrier function (d 18 to 20). Days 20 to 23 were used to evaluate rumen fermentation and total-tract digestibility measurements, and SCFA absorption was measured on d 24. Data were analyzed using PROC MIXED of SAS with linear and quadratic contrasts. Increasing monensin inclusion decreased DMI linearly (10.0, 9.9, 9.3, and 9.1, kg/d DM respectively, $P = 0.01$), but as the dose of monensin increased, BW, ADG and G:F ratio were not affected ($P \geq 0.11$). Total Cr-EDTA recovery was not ($P \geq 0.61$) affected by increasing dose of monensin, nor was rumen pH (mean, minimum, maximum, duration <5.5, area under curve; $P \geq 0.21$). The acetate-to-propionate ratio decreased linearly (1.9, 1.8, 1.4, 1.3, respectively, $P = 0.03$) as dose of monensin increased. A quadratic response (35.7, 47.5, 41.8, 35.4%, respectively, $P = 0.02$) for the absorption of acetate was detected with a maximal value at 22 ppm. Ethanol soluble carbohydrate digestibility increased linearly (77.2, 84.7, 88.0, 94.0%, respectively, $P = 0.003$) with increasing doses of monensin. Starch digestibility showed a quadratic response (93.8, 93.9, 88.0, 94.0%, respectively, $P < 0.001$), where 33 ppm inclusion had a minimal value. The results from this study indicate that increased monensin inclusion decreases DMI without affecting SCFA concentrations, SCFA absorption, and total-tract barrier function.

Key Words: monensin, digestibility, barrier function

M331 Effects of essential oils and exogenous enzymes on in vitro rumen fermentation kinetics.

Camila Delveaux Araujo Batalha[1], Lucas Jado Chagas[1], João Ricardo Rebouças Dórea*[2], Tiago Sabella Acedo[2], Luis Fernando Tamassia[2], Cristina Simões Cortinhas[2], and Flávio Augusto Portela Santos[1], [1]*University of São Paulo, Piracicaba, SP, Brazil,* [2]*DSM Produtos Nutricionais Brasil SA, São Paulo, SP, Brazil.*

The objective with this trial was to evaluate the combination of essential oils and exogenous enzymes on ruminal DM degradation kinetics in feedlot diets. The treatments were MON (Monensin, Tortuga – 26 mg/kg DM), CRINA (Essential Oils: Crina Ruminants, DSM – 90 mg/kg DM), CRINA+MON (90 and 26 mg/kg DM, respectively), CRINA+RUM (CRINA + α-amylase: Ronozyme RumiStar, DSM – 90 and 560 mg/kg DM, respectively) and CRINA+RUM+P (CRINA+RUM+Protease: Ronozyme Proact, DSM – 90; 560 and 840 mg/kg DM, respectively). The incubated diets were composed by corn (82.5%), sugarcane bagasse (8.5%), soybean meal (5%), mineral (3%) and urea (1%). The experimental design was completely randomized, with 5 treatments and 3 replicates per incubation time. The estimated parameters of rumen degradation kinetics were soluble fraction (A), potentially degradable fraction (B), degradation rate (kd), lag time (Lag), potential degradability after 120 h of incubation time (PD = A+B). The substrate (1 g) was incubated with rumen inoculum (10 mL) and bath culture (90 mL). For each incubation time (0, 2, 4, 8, 16, 24, 48, 72, 96 and 120 h) the flask contents were filtered, dried and weighted to determine de DM disappearance. The rumen degradation parameters were analyzed using SAS system. The A and B fractions and kd were not affected by treatments ($P > 0.05$). The MON diet had higher Lag ($P < 0.05$) in comparison with other treatments. The reduction on lag is related to the increases on dry matter PD for CRINA+MON, CRINA+RUM and CRINA+RUM+P diets, probably because the rumen microorganisms starts the DM degradation earlier, reaching more extension of degradation compared with MON. In conclusion, the use of enzymes (amylase and protease) improves rumen DM degradation.

Table 1 (Abstr. M331). Combination of essential oils and exogenous enzymes on in vitro rumen fermentation kinetics

Parameter	MON	CRINA	CRINA +MON	CRINA +RUM	CRINA +RUM+P	*P*-value	SEM
A	20.16	20.97	19.48	21.79	19.83	0.6986	1.24
B	56.56	57.55	58.22	58.36	58.98	0.7486	1.32
kd	0.0822	0.0687	0.0739	0.0698	0.0723	0.7317	0.0064
Lag	5.34^{a}	3.74^{b}	3.07^{bc}	2.78^{bc}	2.16^{c}	0.0025	0.40
PD	76.71^{c}	78.51^{abc}	77.70^{bc}	80.15^{a}	78.80^{ab}	0.0700	0.73

M332 Effects of essential oils and exogenous enzymes for finishing Nellore cattle in feedlot during the adaptation period.

Murillo Alves Porto Meschiatti[1], Diandra Leziér[1], João Ricardo Rebouças Dórea[2], Tiago Sabella Acedo*[2], Luis Fernando Tamassia[2], Cristina Simões Cortinhas[2], and Flávio Augusto Portela Santos[1], [1]*University of São Paulo, Piracicaba, SP, Brazil,* [2]*DSM Produtos Nutricionais Brasil SA, São Paulo, SP, Brazil.*

The objective with this trial was to evaluate the combination of essential oils and exogenous enzymes during the adaptation period on performance of Nellore bulls finished in feedlot. Three hundred Nellore bulls (initial BW = 330 ± 33 kg) were fed diets containing 82.5% corn, 8.5% sugarcane bagasse, 5% soybean meal, 3% mineral, 1% urea and were randomly allocated to 50 pens. Animals were blocked based on initial BW. The treatments were MON (Monensin, Tortuga – 26 mg/kg DM), CRINA (Essential Oils: Crina Ruminants, DSM – 90 mg/kg DM), CRINA+MON (90 and 26 mg/kg DM, respectively), CRINA+RUM (CRINA + α-amylase: Ronozyme RumiStar, DSM – 90 and 560 mg/kg DM, respectively) and CRINA+RUM+P (CRINA+RUM+Protease: Ronozyme Proact, DSM – 90; 560 and 840 mg/kg DM, respectively). Response variables included: dry matter intake (DMI), average daily gain (ADG), feed efficiency (FE, G:F) after 28 d on feed. The data were analyzed using PROC MIXED of SAS and means were compared by Tukey test considering the block as random effect and treatments as fixed effects. Cattle fed CRINA and CRINA+RUM diets presented greater ($P < 0.05$) DMI in comparison with the other treatments. The improvements on DMI were 7.8% and 9.1% for CRINA and CRINA+RUM, respectively, compared with MON. For ADG the improvements were 14.5% and 23.3% for CRINA and CRINA+RUM, respectively, compared with MON. Feed efficiency was greater ($P < 0.05$) for cattle fed CRINA+RUM diets. In conclusion, the use of essential oils and its combination with amylase improved DMI, ADG during the adaptation period. Nellore bulls were 12.4% more efficient when diets containing Amylase and essential oils were fed compared with monensin diets.

Table 1 (Abstr. 332). Combination of essential oils and exogenous enzymes on feedlot performance of finishing Nellore bulls during the adaptation period

Parameter	MON	CRINA	CRINA +MON	CRINA +RUM	CRINA+ RUM+P	*P*-value	SEM

M333 Shifts in rumen microbiota in response to inoculation with *Propionibacterium acidipropionici* strain P169.

Elnaz Azad*[1], Nelmy Narvaez[2], Hooman Derakhshani[1], Awfa Y. Alazzeh[2,3], Yuxi Wang[2], Tim A. McAllister[2,1], and Ehsan Khafipour[1], [1]*Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada,* [2]*Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada,* [3]*Department of Clinical Nutrition, College of Applied Medical Sciences, University of Hail, Hail, Saudi Arabia.*

Inoculation of cattle with *Propionibacterium acidipropionici* strain P169, a commensal rumen bacterium known for its lactate and glucose utilizing properties, has been reported to modify the profile of ruminal VFAs in favor of increased propionate production. The objective of this study was to document shifts in rumen microbiota as a result of rumen inoculation with P169. Eight ruminally cannulated steers (434 ± 33 kg) were either not inoculated (control) or inoculated with P169 (1×10^{11} cfu/head/day) by including it in the diet for 101 d. Rumen samples from liquid and solid fractions were collected every 3 wks. Genomic DNA was extracted and subjected to qPCR for quantification of P169 and Illumina sequencing of the V4 region of the 16S rRNA gene for community profiling. On average, 36,250 high quality sequences were generated per sample, resulting in identification of 16 and 15 bacterial phyla in liquid and solid fractions, respectively. No significant difference was detected in α-diversity indices between treatments. While PERMANOVA analysis of the UniFrac distances of microbial communities revealed distinct clustering of rumen liquid from solids ($P = 0.03$), β-diversity did not differ between treatments. Quantitative PCR identified a trend for an increase ($P = 0.06$) in the abundance of P169 in inoculated steers. Partial Least square discriminant analysis of sequence data found that the proportion of members of the Firmicutes (Clostridiaceae, Lachnospiraceae, and Ruminococcaceae, and *Phascolarctobacterium*), Bacteroidetes (Bacteroideales, families

RFP12 and BS11), and Synergistetes (Pyramids) were increased ($P < 0.05$) in response to P169 ($R^2 = 0.86$, $Q^2 = 0.57$). Data suggest that while inoculation with P169 altered the proportions of bacteria within the rumen, it did not change the α or β diversities of bacteria in either liquid or solid bacterial communities.

Key Words: *Propionibacterium acidipropionici* (P169), rumen microbiota, 16S rRNA sequencing

M334 A comparative assessment of dried distillers grain, ionophore, bambermycin, saponin, and condensed tannin for methane emission abatement in beef cattle.

M. A. Fonseca*[1], L. O. Tedeschi[1], T. R. Callaway[2], and W. L. Crossland[1], [1]*Texas A & M University, College Station, TX,* [2]*USDA-ARS, College Station, TX.*

The objectives of this study was to assess in vitro (IV) potential abatement of CH_4 production rate of 4 commercially available products [ionophore (I), bambermycin (B), saponin (S), and condensed tannin (CT)] when fed in combination with dried distillers grain (DDG) on growing feedlot type diets. The IV gas production technique was used to determine the fermentability of 3 base diets with 3 levels of DDG (0, 20, and 40% DM). Diets contained alfalfa hay, ground corn, and Bermudagrass hay. The 15 diets (DDG0, DDG20, DDG40, I0, I20, I40, B0, B20, B40, S0, S20, S40, CT0, CT20, and CT40) were incubated in duplicates, 6 times each (15 × 2 x 6 × 2; n = 360 bottles), and the alfalfa hay was incubated alone in each run as standard. Blanks (n = 2 bottles/incubation time), containing rumen fluid and medium only, were used to adjust the CH_4 production. Methane was computed as adjusted CH_4 concentration divided by the amounts of NDF (CH_4NDF, mM/g NDF), NFC (CH_4NFC, mM/g NFC), fermentable carbohydrate (FCHO = sugar + starch + available NDF) (CH_4FCHO, mM/g FCHO), OM (OM = 100 – Ash) (CH_4OM, mM/g OM), and fermentable OM (FOM = OM – Ash) (CH_4FOM, mM/g FOM). . The PROC MIXED of SAS (SAS Inst., Cary, NC) was used to analyze the CH_4 data assuming a completed randomized design. Diets, products, and products within levels were assumed to be fixed factors and replicate within diet to be random. The convergence method was REML. Products affected CH_4 production for total concentration ($P = 0.0003$), Adj CH_4 ($P < 0.0001$), CH_4NDF ($P < 0.0001$), CH_4NFC ($P < 0.0001$), CH_4FCHO ($P < 0.0001$), CH_4FOM ($P < 0.0001$), and CH_4OM ($P < 0.0001$). Ionophores had the greatest effect ($P > 0.05$) among all tested products to further decrease CH_4 production, being the only significantly different from the DDG control diets. Levels (0, 20 and 40% DM) of DDG were not significant ($P > 0.2076$) in decreasing CH_4 production. This is probably because the fat content in the diets were not high enough. Previous IV data from our laboratory had shown that responses in CH_4 mitigation due to fat content in the diet was only significant when DDG levels were over 50% or 7.3% EE in the diet. These IV results suggested that ionophores have the potential to further decrease methane production from ruminants fed DDG based diet.

Key Words: greenhouse gas emissions, dried distillers grain (DDG), methane mitigation

M335 Effect of dietary supplementation of β-mannanase in Hanwoo growing heifers.

Jakyeom Seo[1], Jeongsoo Park*[1], Junsung Lee[1], Jae-Hwan Lee[2], Jung-Jin Lee[2], Dong Keun Kam[3], and Seongwon Seo[1], [1]*Department of Animal Biosystem Sciences, Chungnam National University, Daejeon, Republic of Korea,* [2]*CTC Bio Inc., Seoul, Republic of Korea,* [3]*Cargill Agri Purina Inc., Seongnam, Republic of Korea.*

Supplementation of β-mannanase, an enzyme that breaks down mannan, in a diet composed of high mannan contained feedstuffs (e.g., palm kernel meal, copra meal, soy hull; HMCF) improves utilization of feeds not only in monogastric animals, but also in goats and Holstein calves. No study, however, has been conducted to evaluate the effect of β-mannanase supplementation in Hanwoo (*Bos taurus coreanae*) growing heifers. Moreover, little is known whether β-mannanase supplementation also has beneficial effects in conventional corn-soy based diets (CS). The objective of this study was thus to investigate the effect of supplementation of β-mannanase in Hanwoo growing heifers fed a diet composed of either a CS or HMCF based concentrate mix. For this purpose, a feeding trial was conducted for 12 weeks using a total of 40 Hanwoo growing heifers (BW: 236.2 kg ± 1.1 kg, 11 mo of age). Total mixed rations (250 g/kg of ryegrass and 750 g/kg of concentrate mix) were offered ad libitum. The experimental design was 2 × 2 factorial approach with 2 different concentrate mixes (CS or HMCF based) and with or without a commercial feed β-mannanase (800,000 U/kg DM) product (CTCZYME, CTC Bio Inc., Seoul, Korea) at a level of 1 g/kg in concentrate mixes. In both diets, supplementation of β-mannanase significantly increased ADG of Hanwoo heifers by 95 g/d on average (111 g/d or 90 g/d for CS and HMCF, respectively; $P < 0.05$). No significant difference was observed in DMI among treatments ($P > 0.10$), and thus, β-mannanase supplementation tended to decrease feed conversion ratio (DMI/ADG) by 1.3 on average ($P = 0.06$). The ADG of CS (943 g/d) was significantly greater than that of HMCF (854 g/d), as expected ($P < 0.05$). These results indicated that supplementation of β-mannanase enhanced growth rate and feed efficiency of Hanwoo heifers regardless of the basal diets. Therefore, we conclude that supplementation of β-mannanase can be beneficial to improve the feed utilization in Hanwoo growing heifers.

Key Words: β-mannanase, growing heifer, growth rate

M337 Calculating residual feed intake using high-frequency partial body weights.

Ann Kenny*[1], David Benfield[2], Camiel Huisma[2], and Kevin Garossino[2], [1]*University of Missouri, Columbia, MO,* [2]*GrowSafe Systems Ltd., Airdrie, AB, Canada.*

Residual feed intake (RFI) calculations were compared using either conventional chute weighing (CW) or partial body weights (PBW) collected with specialized data acquisition systems (DAS). Per-second PBW, CW and feed intake (FI) data of beef cattle (n = 3743) from 49 contemporary groups located throughout Canada, Australia and USA was compiled. Data for PBW and FI was collected using automated DAS which non-invasively collected per-second information on individual animals while eating or drinking (GrowSafe Systems Ltd., Airdrie, AB, Canada). Chute weights were taken at varying time points while cattle were on feed. Total BW was converted from PBW using a constant conversion factor. Correlations of RFI calculation, between FI and metabolic weight ($W^{0.75}$) and between FI and ADG using CW, PBW or a combination of CW and PBW (COMB) were examined. Paired T-Tests were performed to compare calculated R^2 values. Linear regression on CW and PBW demonstrated a high degree of correlation ($R^2 = 0.962$), which remained similar when data were sorted by sex (Bull n = 5077 $R^2 = 0.962$; Heifer n = 4942 $R^2 = 0.953$; Steer n = 4331 $R^2 = 0.972$). The R^2 values of the calculated RFI were greater (0.614 vs 0.590; $P = 0.0016$) for CW compared with PBW. The correlation between FI and ADG also had greater R^2 values for CW vs COMB ($P = 0.0224$). The correlation between FI and $W^{0.75}$ tended to have lower R^2 values for PBW compared with CW ($P = 0.0551$) and COMB ($P = 0.0551$). Comparison of individual animal RFI calculations using PBW or CW identified differences in RFI values of greater than one standard deviation (SD) in 2.7% of animals and greater than 2 SD in 0.2% of animals. These differences were associated with chute weight errors and nonlinear growth. RFI rankings within contemporary groups changed < 23% in 90% of animals evaluated when weighing techniques were compared. The use of DAS for collecting PBW and FI measurements was determined to be a viable method for RFI ranking of animals within contemporary groups. High-frequency PBW information also provided the ability to calculate RFI with better rejection of errors caused by incorrect chute weights and issues caused by nonlinearity in growth.

Key Words: residual feed intake, body weight

M338 Effect of different supplementation strategies on grazing and ingestive behavior in cattle finished on pasture. Guilherme Felipe Berti[1], Rodolfo Maciel Fernandes[2], Matheus Henrique Moretti[2], Mauricia Brandao Silva[3], Paloma Helena Gonçalves[1], Michele Aparecida Prado Alves[1], Flávio Dutra Resende[4,2], and Gustavo Rezende Siqueira*[4,2], [1]*Centro Universitario de Barretos, Barretos, Sao Paulo, Brazil,* [2]*Universidade Estadual Paulista, Jaboticabal, Sao Paulo, Brazil,* [3]*Universidade Estadual Paulista, Botucatu, Sao Paulo, Brazil,* [4]*Agencia Paulista de Tecnologia dos Agronegocios, Colina, Sao Paulo, Brazil.*

The objective of this observational study was to describe grazing and ingestive behavior of Nellore cattle under field conditions fed 2 grain supplementation strategies during the dry season. Forty-eight finish Nellore bulls (±340 kg of initial body weight and ± 20 mo of age) were blocked by body weight and assigned to 6 paddocks of 2.4 ha each of *Brachiaria brizantha* 'Marandu' pastures. The experiment was conducted as a randomized complete block experiment with 2 treatment factors for 140 d from May to September 2012. Treatment factors consisted of 2 levels of grains supplementation - 1.5% BW/daily (DMI) (SUPL1.5) and 2.0% BW/daily (DMI) (SUPL2.0) offered once a day (at 8 a.m.). Were evaluated the animals daily grazing time and time spent near the trough (min/day) during continuous 72h after supplementation, with intervals of 5 min. The observation occurred in 2 different period – Day (8 a.m. until 7:59 p.m.) and Night (8 p.m. until 7:55 a.m.). Data were analyzed using the MIXED procedure of SAS with sampling time serving as a repeated measure. Paddocks served as the experimental unit. The SUPL1.5 animals had greater ($P < 0.01$) grazing activity than SUPL2.0 (298.5 min and 244.2 min, respectively). Although, SUPL2.0 animals spend 20% more time near to the trough compared with SUPL1.5 animals ($P < 0.01$). Period significantly affected grazing time, with animals spend more time in grazing activity during the day (166.6 min) compared with the night (104.7 min; $P < 0.01$). The time spend near to the trough was greater during the day period ($P < 0.01$), increased rapidly in the firsts 3 h after the grain supplementation. This study indicates that the high supplementation (2.0% of the body weight) decrease the grazing time and increase the time spent near to the trough. Supported by CNPq/BELLMAN.

Key Words: beef cattle, grazing behavior, finishing pasture supplementation

Ruminant Nutrition: Dairy I

M339 The effect of decreasing dietary cation-anion difference in the prepartum diet on urine pH and plasma minerals in multiparous Holstein cows. B. M. Sweeney*[1], C. M. Ryan[1], T. Stokol[2], K. Zanzalari[3], D. Kirk[3], and T. R. Overton[1], *[1]Department of Animal Science, Cornell University, Ithaca, NY, [2]Department of Population Medicine and Diagnostic Sciences, Cornell University, Ithaca, NY, [3]Prince Agri Products Inc., Quincy, IL.*

The objective of this study was to determine the effect of decreasing dietary cation-anion difference (DCAD) in the prepartum period on prepartum urine pH and peripartum plasma mineral concentrations. Multiparous Holstein cows (n = 89) were allocated randomly to one of 3 prepartum diets formulated with decreasing DCAD: CON (+17.5 mEq/100 g DM), MED (+3.6 mEq/100 g DM), or LOW (−10.9 mEq/100 g DM), beginning 24 d before expected parturition. Analyzed DCADs were +18.3, +5.9, and −7.4 mEq/100 g DM. Cows were fed a common postpartum diet from parturition until 63 d in milk (DIM). Blood was collected 1 × /wk prepartum, 2 × in 24 h postpartum, 1 × /d until 5 DIM, and 3 × /wk until 14 DIM. Repeated measures analyses were conducted using the MIXED procedure of SAS with linear and quadratic effects of decreasing prepartum DCAD as contrasts. There was a quadratic effect on urine pH (CON = 8.20, MED = 7.84, LOW = 5.98; $P < 0.01$). There tended to be an interaction between DCAD and parity (2nd lactation vs. 3rd and greater) for prepartum Mg ($P = 0.08$) such that Mg decreased with decreasing DCAD for older cows ($P < 0.05$) but not for 2nd lactation cows. Postpartum Ca increased linearly with decreasing DCAD (CON = 8.84, MED = 8.89, LOW = 9.19; $P < 0.01$) with greater increases through 5 DIM (DCAD × Day; $P = 0.06$). There tended to be an interaction between DCAD and parity ($P = 0.06$) such that Ca was increased more for older cows fed lower DCAD levels (CON = 8.68, MED = 8.63, LOW = 9.16; $P < 0.01$) than for 2nd lactation cows. Postpartum P tended to decrease linearly ($P = 0.08$). For 2 d postpartum cows fed LOW had lower Mg (DCAD × Day; $P < 0.01$). Incidence of hypocalcemia (HC, plasma Ca < 8.5 mg/dL) was significantly different at 1 DIM ($P = 0.02$). When parity groups were analyzed separately, incidence of HC in older cows was decreased by decreasing prepartum DCAD at 0.6 ($P = 0.07$), 1 and 2 DIM ($P < 0.01$) but did not differ for 2nd lactation cows. Decreasing prepartum DCAD improved Ca status, decreased incidence of HC, and had varied effects on other minerals over the periparturient period.

Key Words: hypocalcemia, dietary cation anion difference, transition cow

M340 Canola meal in dairy cow diets with varying concentration of starch sources. Nadeesha K. Jayasinghe[1], Kenneth F. Kalscheur*[2], Jill L. Anderson[1], and David P. Casper[1], *[1]Dairy Science Department, South Dakota State University, Brookings, SD, [2]US Dairy Forage Research Center, USDA-ARS, Madison, WI.*

Synchronization of the degradability of non-structural carbohydrate and rumen degradable protein has been identified as an effective method of increasing intestinal AA flow through increased microbial protein synthesis and more efficient ruminal fermentation, thereby increasing performance of dairy cows. Therefore, the objective was to determine the performance of lactating cows fed either corn and barley starches at varying proportions in diets containing canola meal as the major source of supplemental protein. Twelve multiparous and 4 primiparous Holstein cows (94 ± 25 DIM) were used in a 4 × 4 Latin square design with 28-d periods. The ratio of starch from ground corn and rolled barley within each treatment was 100:0, 67:33, 33:67, and 0:100. Diets contained 36% corn silage, 20% alfalfa haylage, and 44% concentrate (DM basis). Varying proportions of corn and barley had no effect ($P > 0.10$) on dry matter intake (26.5 kg/d) or milk production (41.2 kg/d). Milk fat percentage (3.52%) and yield (1.42 kg/d) and milk protein percentage (2.95%) and yield (1.21 kg/d) were not affected by starch. Lactose percentage (4.86, 4.83, 4.90, and 4.88%, for 100:0, 67:33, 33:67, and 0:100, respectively) and MUN (14.8, 14.5, 15.4, and 15.1 mg/dL) responded cubically ($P < 0.05$) to the changes in dietary starch proportions. Treatments did not affect energy-corrected milk (40.6 kg/d) nor feed efficiency (1.53). Increasing the proportion of barley to corn had no effect on the molar proportion of ruminal acetate and butyrate, however, propionate increased quadratically as barley increased in the diets ($P < 0.01$). Ruminal ammonia concentration averaged 11.5 mg/dl and was not affected by starch source. Apparent total-tract digestibilities of DM, OM, and NDF decreased linearly ($P < 0.05$) and, CP and ADF tended to decrease linearly ($P < 0.10$) when the proportion of barley starch increased in the diet. Total-tract digestibility of starch was not affected by starch source and averaged 95.5%. Overall, lactation performance was not affected by feeding varying proportions of corn and barley when the diets were formulated with canola meal as the primary protein supplement.

Key Words: canola meal, starch source, lactating dairy cow

M341 Dietary grape marc supplementation alters the milk protein and fatty acid profile produced by pasture-based dairy cattle. Reuben Harland[1], Aysha Morrow[1], Roland Harrison[1], Jana Kraft[2], and Sabrina L. Greenwood*[1,2], *[1]Lincoln University, Lincoln, New Zealand, [2]The University of Vermont, Burlington, Vermont.*

Grape marc (GM) is a byproduct of the wine-making industry and is a rich source of polyphenols. This experiment evaluated the efficacy of feeding supplementary GM to late-lactation dairy cows fed pasture-based diets as a means to manipulate the milk fatty acid (FA) and protein content produced. The effects of condensed tannins (CT) within GM were determined through the feeding of polyethylene glycol (PEG), a CT inhibitor. Forty late-lactation Friesian x Jersey cows were used in a 4 × 2 factorial design, receiving either (1) pasture only (control), (2) pasture + 350 g PEG/cow/d, (3) pasture + 2 kg DM GM/cow/d, (4) pasture + 2 kg DM GM/cow/d + 350 g PEG/cow/d, (5) pasture + 4 kg DM GM/cow/d, (6) pasture + 4 kg DM GM/cow/d+ 350 g PEG/cow/d, (7) pasture + 6 kg DM GM/cow/d, or (8) pasture + 6 kg DM GM/cow/d + 350 g PEG/cow/d. Cows were offered increasing amounts of GM for 10 d and maintained on the full amount of supplement for a further 6 d. Milk yield was determined at each milking. Milk samples were collected at a.m. and p.m. milking on d 0 and 16 and analyzed for milk components (milk fat, protein, and lactose), protein profile (α-, κ- and β- casein, α-lactalbumin, and β-lactoglobulin variants A and B) and FA profile by ANOVA using GenStat. Total milk and component yields were not affected by GM or PEG ($P > 0.05$). Of the short-chain FA analyzed (n = 13; C4 to C15), 63% were negatively affected ($P < 0.05$) by GM inclusion and 15% increased with PEG intake. PEG positively affected 25% of long-chain FA (n = 24; C17 to C26), while 29% were negatively affected by GM and 8% were positively affected by GM. Inclusion of GM did not affect the content (mg/mL) of any milk protein analyzed. Cows that received dietary PEG had lower α- ($P = 0.06$) and β- ($P = 0.02$) casein content than those not receiving PEG. In conclusion, GM negatively affected the profile of some short-chain (de novo synthesized) and long-chain (diet-derived) FA, the effects of which could not be fully eradicated by dietary PEG inclusion (CT inhibition). Dietary PEG inclusion decreased the content of α- and β- casein, suggesting that diet CT can increase the output of these proteins in milk.

Key Words: casein, fatty acid, byproduct

M342 Integrating nutrient and hormonal effects on mTOR phosphorylation in the mammary cell.

Juan J. Castro Marquez* and Mark D. Hanigan, *Virginia Tech, Blacksburg, VA.*

The objective of this work was to integrate experimental data on the effect of insulin, EAA and acetate into a model of transcription control in the mammary cell. Current representations of milk protein synthesis consider energy and dietary protein effects separately with no regulation other than by limiting production when supply of either is short. In reality, protein synthesis is simultaneously affected by EAA, energy substrates and hormones, by upregulating the initiation and elongation phases of mRNA translation. A central element to this process is the mammalian target of rapamycin (mTOR) which transfers nutritional and hormonal signals onto translation initiation and elongation proteins that, through phosphorylation, modulate protein synthesis. Phosphorylation data for protein kinase B (Akt), AMP activated protein kinase (AMPK), mTOR, eukaryotic elongation factor binding protein (4EBP1) and eukaryotic elongation factor 2 (eEF2) from a series of experiments in MACT cells and lactogenic mammary tissue slices conducted over the past 5 years was used to build a dynamic model representing each one of the above signaling proteins in their phosphorylated and dephosphorylated states. Akt and mTOR phosphorylation reactions were defined as Michaelis-Menten, whereas AMPK, 4EBP1 and eEF2 representations used mass action kinetics. Inference was based on resampling with replacement and resulting nonparametric confidence intervals (CI). The affinity constants for insulin effects on Akt (CI = 6.6, 32.8 ug) and isoleucine on mTOR (CI = 90, 443 uM) were within physiological concentration ranges, but the rate constant for acetate effects on AMPK was null (CI = 2.71×10^{-9}, 9.8×10^{-8}). Sensitivity analysis coefficients indicate isoleucine was the strongest driver (0.71) of mTOR phosphorylation compared with insulin (0.01) and acetate (0.01). Phosphorylated Akt, AMPK, mTOR, 4EBP1 and eEF2 were predicted without bias and had errors of 16, 33, 29, 28 and 33%, respectively. Insulin and isoleucine effects seem to be well represented but more work is needed to improve our understanding of the role of acetate and other AA on mTOR regulation.

Key Words: mTOR, casein, modeling

M343 Prediction of daily energy status in early and mid lactation using milk and body traits.

Päivi Mäntysaari*[1], Tuomo Kokkonen[2], Martin Lidauer[1], and Esa A. Mäntysaari[1], [1]*Natural Resources Institute Finland, Green technology, Jokioinen, Finland,* [2]*Department of Agricultural Sciences, University of Helsinki, Helsinki, Finland.*

Monitoring cow's energy status at the individual level in early lactation is important for management, but also for breeding purposes. Energy status of a cow can be estimated by calculating the energy balance (EB) from cow's energy intake and output. Alternatively, indicator traits such as body weight (BW) and body condition score (BCS) changes and milk fat-protein ratio (FP) have been proposed. However, precision of these predictions has been low. This may be related to the lack of precision in estimated EB itself, because standard estimates for energy requirements are used in its calculation. We used the plasma nonesterified fatty acids (NEFA) concentration as a biomarker of energy mobilization and energy status, and addressed associations between NEFA concentration and energy status indicators. The data included 10032 daily BW, intake and milk, 279 BCS, and 261 NEFA measurements of 56 Nordic Red primiparous dairy cows. Plasma samples for NEFA were collected twice on lactation wk 2 and 3 and once on wk 20. The milk samples were taken on the same days as NEFA samples and on monthly test days. Daily BWs were smoothened by a regression model with fixed effect of days in milk and random animal part. The NEFA concentration on wk 20 was considered as base level and deviations from base level (dNEFA) were used in calculations. The mean (±sd) ECM (kg/d), milk fat and protein (%), BW (kg) and BCS (1–5) were 30.3 (±4.60), 4.43 (±0.51), 3.59 (±0.32), 574 (±53), and 3.19 (±0.38), respectively. On lactation wk 2 and 3 the average NEFA concentrations were 0.704 (±0.363) and 0.526 (±0.275), and 0.123 (±0.035) mmol/l on lactation wk 20. From all indicators daily BW change had the highest correlation (0.57) with NEFA, followed by daily FP (0.53) and BCS change (−0.20). To predict dNEFA by available indicators, a multiple linear regression model was developed. The best fit was achieved with a model including BW change, FP, BCS and its change, BCS*BCS change, and days in milk. The correlation between predicted and observed dNEFA was 0.77, which was higher than the correlation (0.69) between dNEFA and EB.

Key Words: dairy cow, energy balance

M344 Performance of dairy calves receiving probiotic containing *Bacillus subtilis* and *Bacillus licheniformis*.

Thais M. Torrezan[1], Jackeline T. Silva[1], Nathalia B. Rocha[1], Evangelina Miqueo[1], Fernanda L. M. Silva[1], Samyra Baldassin[1], and Carla M. M. Bittar*[1,2], [1]*University of Sao Paulo, ESALQ, Piracicaba, Sao Paulo, Brazil,* [2]*CNPq, Brasilia, DF, Brazil.*

Methods to improve calf growth and health, with reduced antibiotics use are essential for a successful and profitable dairy. This study evaluated the performance and fecal pH of dairy calves receiving milk replacer supplemented or not with probiotic. Twenty-four newborn Holstein male calves were utilized in a randomized blocks experimental design, and distributed into 2 treatments: Control: no probiotic supplementation; Supplementation of 2g/d of a *Bacillus subtilis* (1.6×10^9 cfu) and *Bacillus licheniformis* (1.6×10^9 cfu) containing probiotic (Bioplus, Chr. Hansen), via milk replacer. Calves were individually housed, with free access to water and starter (20% CP and 80% TDN), and received 4L/d of milk replacer (FeedTech, DeLaval, 21.6:15.5, 12.5% solids) until the eighth week of life, when weaned. Feed intake was monitored daily; while body weight, height withers, heart girth, hip width and fecal pH were weekly measured. Data were analyzed as repeated measures, considering treatment, age, and their interaction effects. There were no probiotic supplementation effects on growth and starter intake ($P > 0.05$). As animals were growing, all parameters were significantly affected by age ($P > 0.05$); however, there were no treatment and age interaction effect ($P > 0.05$). On the other hand, probiotic supplementation tended to reduce fecal pH, suggesting a change in intestine microorganisms and probably a reduction on pathogens growth.

Contd.

Table 1 (Abstr. M344). Performance of calves receiving milk replacer supplemented with probiotics

	Treatment			P <[1]		
Iten	Control	Probiotic	SEM	T	A	T × A
Initial BW, kg	36.54	35.47	0.82	0.48	—	—
Weaning BW, kg	57.22	56.64	1.99	0.89	—	—
ADG, kg	0.39	0.44	0.03	0.49	0.0001	0.81
Average starter intake, g/d	372.8	362.0	28.6	0.89	0.0001	0.72
Withers height, cm	78.8	79.2	0.2	0.68	0.0001	0.98
Heart girth, cm	81.1	80.7	0.4	0.71	0.0001	0.39
Hip width, cm	22.0	22.1	0.09	0.68	0.0001	0.86
Fecal pH	6.75	6.79	0.04	0.07	0.001	0.02

[1] T = treatment effect; A = age effect; T × A = treatment and age interaction effect.

M345 Growth performance in Crossbred (Holstein x Gyr) calves differing in phenotypic residual feed intake on pre-weaned period.

Juliana Mergh Leão*[1], Fernanda Samarini Machado[2], Mariana Magalhães Campos[2], Juliana Campos Carneiro[3], Paulo Campos Martins[1], Isabela Carvalho Costa[4], Paulo Sérgio Dornelas Silva[4], Brenda Karoline Alcântara Faria[3], Juliana Aparecida Mello Lima[2], Rayanne Soalheiro de Souza[1], and Sandra Gesteira Coelho[1], [1]*Universidade Federal de Minas Gerais-UFMG, Belo Horizonte, Minas Gerais, Brazil,* [2]*Embrapa Dairy Cattle, Juiz de Fora, Minas Gerais, Brazil,* [3]*Instituto de Ciências Agrárias da UFMG, Montes Claros, Minas Gerais, Brazil,* [4]*Instituto Federal de Educação, Ciência e Tecnologia do Sudeste de Minas Gerais-IFSEMG, Rio Pomba, Minas Gerais, Brazil.*

The aims of this study were to quantify the variation in residual feed intake (RFI) of calves F_1 (Holstein × Gyr) until 60 d of age and evaluate their productive performance. Eighteen calves received colostrum after birth (10% of body weight) and were housed in individual sand bed stalls in the experimental farm of Embrapa Dairy Cattle (Coronel Pacheco, Brazil). All animals were subjected to the same nutrition management which consisted of 6 L of whole milk (TS; 11.75%) in equal amounts twice a day. Solid diet consisting of 95% of concentrated (88% DM; 20% CP and 3% Fat), 5% Tifton 85 hay (81% DM; 13.4% CP; 72.8% NDF; 32.3% ADF) and water were provided ad libitum from the first day of life. Feed solid diet, milk and water intakes were measured daily and body weight and morphometric measurements (withers height, hip height, chest circumference and rump width) were done at birth and at 60 d of age. RFI was calculated for each animal as the difference between actual DMI and expected DMI. Expected DMI was computed for each animal by regressing average daily DMI on mean $BW^{0.75}$and ADG over a 60 d period. Twelve animals were ranked according to the RFI into 2 groups: low (efficient) and high (inefficient). The data were analyzed in a completely randomized design by ANOVA using GLM procedure of SAS. High RFI calves had DMI 12.39% higher than the low group ($P < 0.05$). There was no difference in ADG, water intake and rump width between RFI groups ($P > 0.05$).Withers height, hip height, chest circumference were higher ($P < 0.05$) for the low RFI group.

Contd.

Table 1 (Abstr. M345). Main effect means and SE to intake and growth performance parameters in crossbred (Holstein x Gyr) calves differing in phenotypic residual feed intake (RFI)

Parameters	Low RFI	High RFI	SE	P-value
RFI, kg DM/d	−0.13	0.07	—	—
ADG, kg/d	0.730^{a}	0.746^{a}	0.02	>0.05
DMI, kg/d	0.941^{b}	1.074^{a}	0.03	<0.05
Water intake, L/d	1.00^{a}	1.38^{a}	0.20	>0.05
Milk intake, kg/d	0.803^{a}	0.795^{a}	0.04	>0.05
Hip height, cm	92.25^{a}	91.87^{b}	0.96	<0.05
Chest circumference, cm	94.00^{a}	93.50^{b}	1.33	<0.05
Rump width, cm	25.67^{a}	25.50^{a}	0.40	>0.05
Withers height, cm	88.20^{a}	87.25^{b}	0.89	<0.05

Means within rows followed by the same letter are not significantly different ($P \geq 0.05$).

Key Words: measurement, body weight, efficiency

M346 Dietary grape marc supplementation lowers urinary nitrogen excretion from pasture-based dairy cattle.

Aysha Morrow[1], Reuben Harland[1], Roland Harrison[1], Jana Kraft[2], and Sabrina L. Greenwood*[1,2], [1]*Lincoln University, Lincoln, New Zealand,* [2]*The University of Vermont, Burlington, Vermont.*

On-farm nitrogen (N) losses in pasture-based dairy systems are an environmental issue. Grape marc (GM) is a byproduct that contains condensed tannins (CT) and low crude protein concentrations, constituents that alter N partitioning in ruminants. The objective of this experiment was to determine if GM could decrease the urine N concentration and the urine N output (g N/d) from cows grazing a typical perennial ryegrass/white clover pasture. A second objective of the current experiment was to determine if the CT in GM are a component causing any changes in fecal and urine N concentrations through the use of polyethylene glycol (PEG), a CT inhibitor. The experiment was arranged in a 4 × 2 factorial design, including 4 levels of GM supplementation (0, 2, 4, and 6 kg DM/cow/d) and 2 levels of PEG (0, and 350 g/cow/d) in addition to their daily pasture allowance. Forty Friesian x Jersey crossbred multiparous cows in late lactation were evenly divided into one of 8 treatment groups. Cows were fed increasing amounts of GM for 10 d and fed the full treatment amounts of GM for a further 6 d. The pasture DMI were estimated for each treatment group daily, and intakes of GM and PEG were determined for each cow daily. Urine, feces, plasma and milk samples were collected on d 0, 10, and 16 of the trial. Fecal N % and DM % were analyzed, as well as urine N %, and concentrations of urine ammonia, urine urea-N, plasma urea-N, and milk urea-N. Estimated urine N excretion (g N/d) was calculated. Results were analyzed using GenStat. The dietary inclusion of PEG decreased fecal N % ($P < 0.001$), while dietary supplementation with GM lowered urine N % ($P = 0.005$) and urine urea ($P = 0.003$) concentrations. Cows fed GM also had lower plasma urea-N ($P = 0.024$) and milk urea-N ($P = 0.026$) concentrations. There was a tendency toward lower ammonia (mmol/L; $P = 0.09$) and N excretion in urine (g N/d; $P = 0.08$) due to the supplementation of dietary GM. These results indicate that the dietary inclusion of grape marc is effective at increasing fecal N and reducing urine N concentrations and that the CT within GM aids in increasing fecal N loss.

Key Words: nitrogen loss, environment, byproduct

M347 Energy expenditure and methane emission in dairy heifers using the face-mask method. Carlos Alberto Alves Oliveira Filho[1], Fernanda Samarini Machado[2], Alexandre Lima Ferreira[2], Luiz Gustavo Ribeiro Pereira*[2], Thierry Ribeiro Tomich[2], Mariana Magalhães Campos[2], José Augusto Gomes Azevêdo[3], Rogério Martins Maurício[4], Alexandre Vieira Chaves[5], and Camilla Flávia Portela Gomes Silva[6], *[1]Universidade Estadual do Sudoeste da Bahia, Itapetinga, Bahia, Brazil, [2]Embrapa Dairy Cattle, Juiz de Fora, Minas Gerais, Brazil, [3]Universidade Estadual de Santa Cruz, Ilhéus, Bahia, Brazil, [4]Universidade Federal de São João Del Rei, São João Del Rei, Minas Gerais, Brazil, [5]Faculty of Veterinary Science, Sydney, New South Wales, Australia, [6]Instituto Federal de Educação, Ciência e Tecnologia Baiano, Santa Inês, Bahia, Brazil.*

The aim of this study was to evaluate the effect of feeding levels (FL) and breed (B) on energy expenditure as heat production (HP) and methane emission in dairy heifers using the face-mask method. Twenty-four heifers, 8 Holstein, 8 Gyr and 8 Holstein-Gyr crossbreed (F_1) with average live weight (LW) of 440 ± 88 kg and average age of 27.5 ± 0.8 mo, were housed in tie stall and randomly distributed to the treatments in a 2 × 3 factorial design (feeding level of 1.17% LW or 1.46% LW, on dry matter (DM) basis and breed). The diet was offered as a total mixed ration (700g/kg of corn silage and 300g/kg of concentrate, on DM basis). O_2 consumption, CO_2 production and CH4 emission data were measured using Sable System (Sable Systems, Henderson, NV) coupled with a face-mask for 30 min per day, for 3 d. Heart rate (HR) (beat/min) was registered over 72 h using Polar Equine transmitter (model RS800CX G3, Polar Electro Enc.). Three measurements of oxygen pulses (O2P) (mL O_2/beat) were registered. Total daily O2 consumption (L/d) was calculated as O2P times daily mean HR. Daily HP was calculated as total daily O_2 consumption times the constant 20.47 KJ/L of O_2. Data were subjected to ANOVA and means were compared by Student-Newman-Keuls test ($P < 0.05$). No effect of the interaction between B and FL was observed for any of the variables analyzed. HR, O2P and HP (kcal/kg $LW^{0.75}$) did not differ among B and FL. F_1 heifers presented higher DM intake (DMI) and higher daily mean gain (DMG) in comparison to Holstein and Gyr breeds (6.18, 5.36 and 4.14 kg DM/d; 674.3, 480.8 and 435.4 g/d, respectively). Animals fed at 1.46% LW level presented higher DMI, DMG, BW and methane emission (g/d). Methane emission was higher for F_1 animals (161.3 g/d), but did not differ from Holstein breed (141.1 g/d). Animals from Gyr breed fed at 1.17% LW presented lower DMI, DMG and BW as well as inferior CH4 production (98.3 g/d). This research project was funded by FAPEMIG, CAPES, CNPq and Embrapa.

Key Words: greenhouse gas, heat production, zebu

M348 Methane production in dairy cows consuming corn milling co-products. K. G. Saathoff*[1], C. J. R. Jenkins[1], S. C. Fernando[1], D. Hostetler[2], and P. J. Kononoff[1], *[1]Department of Animal Science, University of Nebraska-Lincoln, Lincoln, NE, [2]The School of Veterinary Medicine and Biomedical Sciences, University of Nebraska-Lincoln, Lincoln, NE.*

A study using 4 multiparous Holstein dairy cows, which were 93.5 ± 22.2 DIM, was conducted to determine the effect of conventional and corn milling co-products, specifically dried distillers grains and solubles (DDGS), on milk production, composition, and methane production. A 4 × 4 Latin square was utilized and included 4 treatments, namely a zero control (C) and diets that contained 30% of the diet DM as either conventional DDGS (ConDG), or 15% reduced fat DDGS (RFDG) or a mixture (Mix) of 15% conventional DDGS and 15% reduced fat DDGS. In all 3 treatment diets, DDGS were included in replace of corn and soybean meal. Cows were housed and fed in individual stalls and fed once per day and milked twice per day for 4–28 d periods. During the last 2 d methane production was measuring using indirect calorimeters. Cows consuming DDGS consumed more ($P = 0.05$) feed (22.7, 24.8, 26.4 and 27.3 ± 1.57 for the C, RFDG, Mix and ConDG respectively). Likely in response feed intake, milk yield was also increased ($P < 0.01$) by feeding DDGS (29.4, 39.4, 38.2, and 38.0 ± 3.22 for the C, RFDG, Mix and ConDG respectively). The concentration of fat in the milk was not affected ($P = 0.47$) by treatment and averaged 3.41 ± 0.29%. In comparison, protein in milk was higher ($P = 0.05$) in consuming DDGS (2.74, 2.85, 2.95 and 2.91 ± 0.12 for the C, RFDG, Mix and ConDG respectively). Although total methane was not different ($P = 0.69$) across treatments averaging 443.8 ± 20.6 L/d, cows consuming DDGS produced less ($P = 0.01$) methane per unit of milk produced (14.6, 11.3, 12.1 and 12.1 ± 0.84 kg milk/kg feed for the C, RFDG, Mix and ConDG respectively). Results of this study further support the notion that corn milling co-products may be used to replace both corn and soybean meal in dairy rations and also suggest that doing may also result in less methane per unit of milk produced.

Key Words: methane, dried distillers grains and solubles

M349 Implementing multi-variate statistical process control to detect variability on a commercial dairy farm. Robb W. Bender*[1,2], James A. Barmore[2], David E. Cook[1], and David K. Combs[1], *[1]University of Wisconsin-Madison, Madison, WI, [2]GPS Dairy Consulting LLC, Calmar, IA.*

The objective of this study was to characterize variability in both individual animal and pen data in data streams on a well-managed commercial dairy farm. Additional objectives were to assess the effect of outside events on the variability of data streams and utilize multi-variate statistical process control (SPC) to improve detection time of out-of-control data streams. A 1,400-cow dairy in Eden, Wisconsin, was equipped with milk meters and rumination/activity collars to record individual cow milk production, rumination, physical activity, and pen-based feed intake. Data were collected over a 3 mo period. Milk production was analyzed for out-of-control data points via the Shewhart procedure, and rumination, physical activity and feed intake were analyzed multivariately via the MVP procedures of SAS. On this dairy, milk production averaged 45.1 kg, with a standard deviation of 1.3 kg among days within a pen, 11.5 kg among individual cows within a pen, and 20.1 kg among days within individual cows. Rumination (min per day) averaged 441.6 min, with a standard deviation of 14.0 among days within a pen and 120.7 min among individual cows within a pen. Physical activity (measured in arbitrary units) averaged 489.2, with a standard deviation of 17.1 among days within a pen, 103.4 among individual cows within a pen. Feed intake (DMI kg/cow/d) averaged 26.6 kg, with a standard deviation of 1.8 kg among days within pens. Multi-variate SPC increased sensitivity when compared with individual single-variate SPC analyses. Out-of-control milk production values were preceded by a deviation from normal variance in the multi-variate analysis of rumination, physical activity, and feed intake. Thus, multi-variate SPC could be used as an early determinant of extreme variability in data streams on a commercial dairy.

Key Words: statistical process control, variation, dairy

M350 Evaluation of apparent starch digestibility in commercial dairy herds. R. A. Silva[1], J. H. Carneiro[1], I. Q. Carvalho[2], J. F. Santos[3], R. B. Navarro[4], P. F. Menegucci[5], M. Caetano[6], D. P. D. Lanna[7], and R. Almeida*[1], *[1]Universidade Federal do Paraná, Curitiba, PR, Brazil, [2]Fundação ABC, Castro, PR, Brazil, [3]Castrolanda Cooperativa Agroindustrial, Castro, PR, Brazil, [4]Capal Cooperativa Agroindustrial, Arapoti, PR, Brazil, [5]Chr. Hansen, Valinhos, SP, Brazil, [6]University of Adelaide, Roseworthy, SA, Australia, [7]ESALQ/USP, Piracicaba, SP, Brazil.*

The objective of this study was estimate the apparent total-tract starch digestibility (ATTSD) in dairy herds, as well as its correlation with corn ensiling time. There were 20 commercial herds in the Paraná State, South Brazil, TMR-fed with predominantly Holstein cows. In all herds, only the high-producing groups were included in the study, with an average milk yield of 41 ± 6 L/cow/d, representing 33 ± 13% of lactating cows, and a total of 1655 cows. To check the influence of silage fermentation time on the starch digestibility, each farm was sampled in 2 distinct periods; fall season when most producers were using corn silage (CS) with short ensiling time (132 ± 132 d), and spring season with CS of longer ensiling time (260 ± 46 d). In each period 3 samples were collected per herd; TMR, CS and feces. Starch contents were determined in quadruplicate by enzymatic colorimetric method. To estimate ATTSD 2 equations were used: only with fecal starch as input (Eq1 = 100 × (1–0.0125 × %fecal starch)); and using lignin as marker (Eq2 = 1 − ((%TMR lignin/%fecal lignin) × (%fecal starch/%TMR starch))) × 100). The average values of 40 samples of corn silage and TMR were 31.15 ± 3.44% DM, 42.36 ± 3.86% NDF, 21.19 ± 2.11% ADF, 2.49 ± 0.68% lignin, 30.45 ± 4.29% starch, and 45.38 ± 3.75% DM, 34.99 ± 3.21% NDF, 16.72 ± 2.16% ADF, 1.92 ± 0.66% lignin, 27.02 ± 4.37% starch, respectively. The average fecal starch content was 3.40 ± 3.1% and 3.93 ± 2.50% for spring and fall samples, respectively. Apparent TTSD estimates were 95.42 ± 2.38% and 95.43 ± 5.15% to Eq1 and Eq2, respectively, with a high correlation between them ($r = 0.83$; $P < 0.01$). Positive correlation between ensiling time and ATTSD calculated by Eq2 was also detected ($r = 0.31$; $P < 0.05$), showing that CS with longer fermentation contributes positively to the increased starch utilization. We also observed moderate negative correlation between CS dry matter and ATTSD ($r = -0.28$; $P < 0.05$), indicating that dried CS reduces TTSD. In general, dietary starch was efficiently utilized, but some factors such as ensiling time and plant maturity influence starch digestibility of the dairy cow diets.

Key Words: corn silage, fecal starch

M351 Effects of partial replacement of corn and alfalfa silage with tall fescue hay on total-tract digestibility and lactation performance in lactating dairy cows. Robb W. Bender*, Fernanda Lopes, David E. Cook, and David K. Combs, *University of Wisconsin-Madison, Madison, WI.*

Our objective was to evaluate the effects of partial replacement of corn and alfalfa silage with tall fescue hay on total-tract NDF digestibility and lactation performance in dairy cows. Twenty-four primi- (75 ± 35 DIM) and 40 multi-parous (68 ± 19 DIM) Holstein cows were blocked by parity and randomly assigned to 1 of 4 treatment groups in a pen equipped with 32 feeding gates to record intake by cow. Each gate was randomly assigned to 1 treatment group, thus each cow had access to all 8 gates within the respective treatment and cow was the experimental unit. Treatments were formulated to partially replace corn silage (CS) and alfalfa silage (AS) with tall fescue hay (TF) as follows (DM basis): 67% CS and 33%AS (control), 60%TF and 40%AS (60TF40AS), 60%TF and 40%CS (60TF40CS), and 33%TF and 67%CS (33TF67CS). The experiment was a 7-week continuous lactation trial with a 2-week covariate period. Data were analyzed using the MIXED procedure of SAS. The model included parity, treatment, week, and relevant interactions as fixed effects and cow within treatment as a random effect. Dry matter intake and milk production did not differ, and averaged 23.5 and 41.4 kg/d, respectively. Fat concentration, protein yield and concentration, and SCC did not differ and averaged 4.00%, 1.28 kg/d, 3.15%, and 92.3, respectively among all treatments. Fat yield was greater ($P < 0.01$) for the control (1.65 kg/d), 60TF40AS (1.66 kg/d), and 33TF67CS (1.66kg/d) treatments compared with the 60TF40CS treatment (1.50 kg/d). Total-tract dry matter digestibility and total-tract organic matter digestibility did not differ, and averaged 67.9% and 70.0%, respectively. Total-tract NDF digestibility was lowest ($P < 0.01$) for control (40.8%), and greater ($P < 0.01$) for 60TF40CS (51.2%) than 60TF40AS (45.9%). 33TF67CS (46.7%) had similar total-tract NDF digestibility to the latter 2 treatments. Inclusion of highly digestible tall fescue grass hay has the potential to replace corn silage and alfalfa silage without influencing DMI and production.

Key Words: NDF, fiber digestion, dairy cow

M352 Methyl-donors choline and methionine differentially alter hepatic methyl carbon metabolism. Tawny L. Chandler*[1], Courtney L. McCourt[1], and Sandra J. Bertics[1], Barbara A. Barton[2], and Heather M. White[1], *[1]University of Wisconsin-Madison, Madison, WI, [2]Balchem Corporation, New Hampton, NY.*

Overlap in hepatic methyl pathways highlights a role for potential competition and compensation of methyl donors. The objective of this experiment was to examine the regulation of genes controlling methyl group transfer in response to increasing concentrations of choline chloride (CC), DL-Met (dLM), and added fatty acids (FA). Primary hepatocytes isolated from 4 Holstein calves were maintained as monolayer cultures for 24 h before treatment with CC (33, 100, 200, 450 μM) and dLM (16, 30, 100, 300 μ*M*), with or without a 1 m*M* FA cocktail in a factorial design. Concentrations mimicked expected physiological concentrations. After 24 h, media was collected for quantification of reactive oxygen species (ROS) by fluorometric assay and cells were collected for quantification of gene expression. Data were analyzed using PROC MIXED of SAS 9.4 with linear and quadratic contrasts in a model with fixed effect of treatment and random effects of calf. Interactions were not significant and therefore only main effects are discussed. Met can be generated from betaine via BHMT, or from homocysteine via MTR which also serves as the final step in regeneration of met after methyl-group donation. Increasing dLM concentration did not alter BHMT expression but did decrease ($P = 0.003$) MTR expression. Increasing concentration of CC did not alter BHMT but did increase ($P = 0.02$) MTR expression, suggesting that CC plays a key role in regeneration of met after methyl group donation. FA increased ($P = 0.05$) BHMT expression but decreased ($P = 0.0001$) MTR expression, which favors regeneration of met that is coupled with downstream glutathione production, which may aid the cell with oxidative stress associated with FA metabolism. Both CC and dLM decreased ($P = 0.02$) expression of MAT1A, the enzyme that generates SAM from met. PEMT expression was not affected by CC or dLM suggesting that dLM was not used to generate phosphatidylcholine. ROS tended to decrease ($P = 0.08$) with increasing CC treatment but was not changed with dLM treatment. These data suggest that CC may play a critical role in donating methyl groups and in decreasing ROS within the hepatocyte.

Key Words: choline, methionine, methyl-donor

M353 The effect of nitrate or live yeast culture on methane mitigation in a continuous culture system. Caitlyn M. Massie*[1], Benjamin A. Wenner[1], Amanda M. Gehman[2], Zhongtang Yu[1], Kelly C. Wrighton[1], and Jeffrey L. Firkins[1], *[1]The Ohio State University, Columbus, OH, [2]Alltech, Nicholasville, KY.*

Nitrates have been successfully fed to dairy cows to decrease methane emissions in several experiments. In the nitrate assimilatory pathway, bacteria reduce nitrate to nitrite to ammonia. Because the second step can be rate-limiting, nitrite accumulation poses health risks such as methemoglobinemia, which would hinder adoption of nitrate feeding to compete with methanogens for H_2 while assimilating the N from nitrate into microbial protein. The yeast *Saccharomyces cerevisiae* has the potential to anaerobically respire nitrite through its cytochrome c oxidase; it also can stimulate populations of bacteria that express nitrate and nitrite reductases. For this project, 4 dual flow continuous culture fermenters were used in 5 periods with 7 d of adaptation and 3 d of sampling. Fermenters were fed 40 g DM (50:50 ratio of concentrate:alfalfa pellet). Treatments were arranged in a 2 × 2 factorial with NO_3 (1.5% of DM) or urea as an isonitrogenous control and without or with Yea-Sacc (Alltech Inc., Nicholasville, KY) fed at a recommended 0.010 g/d. Gas production was measured over 3 d by closed circuit respirometry; 1 fermenter's gas production was omitted for all periods (unrelated to treatment). Objectives were to test the hypothesis that the combination of live yeast culture and nitrate would mitigate methane production in continuous culture compared with the control (a statistical interaction). However, there were no interactions ($P > 0.10$). The main effect of nitrate decreased ($P < 0.05$) CH_4 emission compared with urea control (29.6 vs 21.0 mmol/d). There was no difference ($P > 0.10$) for H_2 emission for nitrate or yeast (averaging 0.149 mmol/d; SEM = 0.051), but the main effect of nitrate was decreased ($P < 0.01$) for aqueous H_2 concentration compared with urea (1.23 vs 1.88 μM). Total VFA production (averaging 148 mmol/d; SEM = 15) and acetate:propionate (averaging 3.37, SEM = 0.12) did not differ ($P > 0.10$) among treatments. Nitrate decreased methanogenesis without affecting H_2 variables. No interactions were detected, but live yeast might offer a useful protection against incompletely adapted rumen microbial populations.

Key Words: dairy, methane, yeast

M354 Performance, heat production and methane emission in dairy heifers under different nutritional plans. Carlos Alberto Alves Oliveira Filho[1], Fernanda Samarini Machado[2], Alexandre Lima Ferreira[2], Luiz Gustavo Ribeiro Pereira*[2], Thierry Ribeiro Tomich[2], Mariana Magalhães Campos[2], José Augusto Gomes Azevêdo[3], Rogério Martins Maurício[4], Alexandre Vieira Chaves[5], and Camilla Flávia Portela Gomes Silva[6], *[1]Universidade Estadual do Sudoeste da Bahia, Itapetinga, Bahia, Brazil, [2]Embrapa Dairy Cattle, Juiz de Fora, Minas Gerais, Brazil, [3]Universidade Estadual de Santa Cruz, Ilhéus, Bahia, Brazil, [4]Universidade Federal de São João Del Rei, São João Del Rei, Minas Gerais, Brazil, [5]University of Sydney, Sydney, New South Wales, Australia, [6]Instituto Federal de Educação, Ciência e Tecnologia Baiano, Santa Inês, Bahia, Brazil.*

This study aimed to evaluate the effect of feeding levels (FL) and breed (B) on performance, heat production (HP) and enteric CH_4 emission in dairy heifers. Thirty 6 heifers, 12 Holstein, 12 Gyr and 12 crossbreed Holstein-Gyr (F1) with average live weight (LW) of 445.8 ± 98 kg and average age of 27.5 ± 0.8 mo, were housed in tie stall and randomly distributed to the treatments in a 3x3 factorial design (feeding levels of 1.95% LW, 1.46% LW and 1.17% LW, on dry matter (DM) basis and breeds). The diet was offered as a total mixed ration (700g/kg of corn silage and 300g/kg of concentrate, on DM basis; 140g of crude protein (CP) per kg of DM). Respiratory exchanges (oxygen consumption and CO_2 and CH_4 production) were measured over 2 periods of 24h using 4 open-circuit respiration chambers and a Sable System (Sable Systems, Henderson, NV) of Embrapa's Bioenergetic Laboratory (Coronel Pacheco, Minas Gerais, Brazil). The equation from Brouwer was used to estimate HP. Data were subjected to ANOVA and means were compared through the Student-Newman-Keuls test ($P < 0.05$). Significant effects were found for the interaction between B and FL for DM, organic matter (OM) and neutral detergent fiber (NDF) intakes (kg/d, %LW and g/kg $LW^{0.75}$) and enteric methane emissions (L/day, g/kg DMI, g/kg OMI and g/kg NDFI). Animals fed at 1.17% LW level presented lower HP (kcal/kg $LW^{0.75}$), feeding efficiency (FE) (kg LW/kg DM_{ing}) and CH_4 emission (L/kg $LW^{0.75}$). Gyr breed presented lower heat production (132.5 kcal/kg $LW^{0.75}$) and CH_4 emission (2.03 L/kg $LW^{0.75}$). For Gyr heifers, FE was higher than Holstein heifers but did not differ ($P > 0.05$) from F1 animals (0.11 and 0.10 Kg LW/kg DMI, respectively). F1 heifers presented higher ($P < 0.05$) daily mean gain (DMG), but did not differ ($P > 0.05$) from Holstein breed (0.81 and 0.67 kg/day, respectively). Animals fed at the level of 1.17% of LW presented lower DMG (0.40 kg/day). This research project was funded by Fapemig, CAPES, CNPq and Embrapa.

Key Words: greenhouse gas, respirometric chamber, zebu

M355 Effects of rumen-protected choline and B vitamins during the transition period on serum metabolites and milk composition in periparturient dairy cattle. C. M. Melo[1], L. C. Copetti[1], O. F. Stuani[2], R. Locatelli-Dittrich[1], and R. Almeida*[1], *[1]Universidade Federal do Paraná, Curitiba, PR, Brazil, [2]Safeeds Nutrição Animal, Toledo, PR, Brazil.*

The effects of rumen-protected choline and B vitamins (RPB) on β-hydroxybutyrate (BHBA), nonesterified fatty acids (NEFA), total cholesterol, triglycerides, HDL, LDL and VLDL and milk fat to protein ratio (FPR) were evaluated in periparturient dairy cows. In a commercial farm in Southern Brazil, 132 Holstein cows (104 multiparous and 28 primiparous) were blocked by parity, expected day of calving and body condition score (BCS). The supplementation period was 18 d pre and 21 d postpartum. Cows in the treatment group were individually top-dressed with 100 g/d Vicomb (Jefo, Quebec, Canada), to provide 20.9 g of rumen-protected choline plus protected riboflavin and folic acid, while the control cows (CON) were supplemented with corn meal. Five blood samples were collected from each animal (14 d and 7 d before calving, at calving, 7 d and 14 d after calving). Additionally 4 samples were collected (3, 5, 7 and 10 d after calving) for BHBA analysis using a Precision Xtra meter. Milk samples to estimate FPR were collected on d 7, 14 and 21 after parturition. Data were analyzed using MIXED procedure of SAS with a model containing the effects of block, treatment, time, and treatment × time interaction as fixed effects and cow within treatment as a random effect. The incidence of hyperketonemia (BHBA concentration ≥1.2 mmol/L) was 25.0% (16/64) for RPB and 30.0% (19/63) for CON. Body weight and BCS did not differ ($P > 0.05$) between RPB and CON cows in all 3 observations (21 d before calving, at calving, and 21 d after calving). No differences on serum metabolites between RPB and CON cows were detected ($P > 0.05$). NEFA concentrations peaked ($P < 0.01$) at calving; 0.82 ± 0.04 mmol/L, whereas BHBA peaked ($P < 0.01$) at 7 d after calving; 0.78 ± 0.05 mmol/L. The lowest cholesterol concentration was at calving; 73.78 ± 1.53 mg/dL. Finally no milk FPR differences ($P > 0.05$) were observed between RPB and CON cows in the first 3 weeks after calving; 1.29 *vs*. 1.31. In the particular conditions of this on-farm trial with low incidence of hyperketonemia no benefits on RPB supplementation were detected.

Key Words: cholesterol, ketosis, lipoproteins

M356 Microbial protein synthesis of Jersey heifers supplemented with chitosan or omega-6 fatty acids source.

Murilo Vendramini[1], Helder Amaral[1], Hayne Araki[1], Marcia Vaz[2], Dargon Salvia[1], Euclides Oliveira[1], Rafael Goes[1], Marcelo Barros[2], Bruno Secundino[1], and Jefferson Gandra*[1], *[1]Faculdade de Ciências Agrárias, Universidade Federal da Grande Dourados, Dourados, MS, Brazil, [2]Faculdade de Ciências da Saúde, Universidade Federal da Grande Dourados, Dourados, MS, Brazil.*

The objective of this study was to evaluate the microbial protein synthesis of Jersey heifers supplemented with chitosan or omega-6 fatty acids (FA) source. Eight animals (average body weight of 158.62 ± 1.75 kg, mean ± SD) were used in replicated 4 × 4 Latin square experimental design, balanced and contemporary, in 2 × 2 factorial arrangements. The experimental period consisted of 18 d (12 d for adaptation and 6 d for data collection) and 5 d were used for wash out. The experimental diets were (1) control (CO), without omega-6 FA and chitosan supplementation; (2) whole raw soybean (WRS, source of omega-6 FA) with 200 g/kg of DM of WRS); (3) chitosan (CHI), with 2 g/kg of DM of chitosan; (4) chitosan and WRS (CHWS), with chitosan and WRS in the same level used in previously cited treatments. The diets were formulated according to the NRC (2001) to achieve weight gain of 700 g/day. Spot urine samples were collected on d 17 of each period 4 h after feeding. The analyses were performed according to Chen and Gomes (1992). Data were analyzed using PROC MIXED of SAS 9.3.Interaction effect ($P < 0.05$) was observed between CHI and WRS for uric acid (mmol/L), which CHI reduced (1.74 mmol/L) and CHIWS increased uric acid (3.34 mmol/L). Animals fed CHI presented decrease ($P < 0.05$) in total purine and absorbable purine derivatives. The output of microbial nitrogen and protein (g/d) was reduced ($P < 0.05$) when heifers were supplemented only with CHI. Animals fed CHI presented decrease in the output of microbial nitrogen and protein in 31.55, 35.53 and 15.07% when compared with CO, WRS and CHWS, respectively. The chitosan supplementation reduced the microbial protein synthesis of dairy Jersey heifers.

Key Words: nitrogen metabolism, purine derivative, rumen manipulation

M357 Nutritional value of hemp byproducts as ruminant feeds.

George N. Gozho* and Jan C. Plaizier, *University of Manitoba, Winnipeg, MB, Canada.*

Hemp byproducts have potential as ruminant feeds, especially now that very low tetrahydrocannabinol (THC) hemp varieties contents are available in Canada. Three hemp by-products, i.e., hemp meal, hemp bran, and hemp meal fines, were, therefore, analyzed for their value as ruminant feeds. These values were compared with ruminant feeds that these byproducts may replace, including canola meal, soybean meal, and grain screenings. Analyses included proximate analysis, in vitro dry matter digestibility (IVTDMD) analysis using the Dairy II system, and in situ rumen degradability using Dacron bags. The rumen in situ dry matter digestibilities were fitted to an exponential equation using the SAS nonlinear regression procedure. Calculated parameters included washing loss (A), potential digestibility after washing (B), potential total digestibility (A + B) and digestibility rate (c). Results showed that hemp meal contained less CP, and more fiber and fat, and had lower in situ and in vitro dry matter digestibilities than soybean meal. Hemp meal had a similar CP content, contained more fiber and fat, and had lower in situ and in vitro dry matter digestibilities than canola meal. Hemp bran had a very high fiber content and was less digestible than grain screenings. Hemp seed fines had a similar chemical composition than hemp meal, but it was more digestible than hemp meal. Hemp meal could be an alternative for other high protein feeds, but its relatively low digestibility must be taken into account.

Table 1 (Abstr. M357). Evaluation of hemp byproducts for ruminant feeds

	Hemp meal	Hemp bran	Hemp seed fines	Canola meal	Soybean meal	Grain screenings
CP, % DM	36.2	15.9	29.1	37.1	52.9	10.3
NDF, % DM	56.5	76.2	52.1	30.1	10.5	49.7
ADF, % DM	34.0	56.0	29.6	18.0	5.5	27.5

Key Words: hemp byproduct, ruminant, feed

M358 Effect of corn type, particle size, enzymes, and time ensiled on chemical composition of rehydrated corn silage.

Naina M. Lopes*[1,2], Marcos N. Pereira[2], and Felipe C. Cardoso[1], *[1]University of Illinois, Urbana, IL, [2]Universidade Federal de Lavras, Lavras, MG, Brazil.*

Utilization of enzymes have been reported to improve feedstuff quality for dairy cows. The objective of this study was to evaluate 2 corns, Flint (F) and Floury (D); 2 particle sizes, grinded Fine (Fi) or Coarse (Co); application of 3 enzyme combination, amylase (A), protease (P) and both (AP); during 3 times of ensiling (TP) at 1, 3, or 5 mo in a complete randomized design resulting in 36 treatments. Each of the 5 silos for each treatment (replicates) consisted of 1kg of corn at 35% moisture and were stored in vacuum sealed bags at environmental temperature. Enzymes used were 650 g/t of amylase and 200 g/t of protease or the combination of the 2. Corn weight, pH and temperature were measured at time of bag opening. Samples were analyzed for starch, crude protein (CP) and prolamin concentration. Statistical analysis was performed using the MIXED procedure in SAS. Corn F had higher ($P < 0.001$) CP (9.52 vs. 7.61%DM) and prolamin (9.70 vs. 8.3 2%DM) before ensiling than D. On TP5, F had increased prolamin concentration (7.95%DM, $P = 0.003$) than D (4.91%DM). Corn F had lower weigh variation (11.34 vs. 12.12 g, $P < 0.0001$), lower starch concentration (65.03 vs. 66.63%DM, $P = 0.01$) and lower NFC ($P < 0.0001$) than D. Particle size Co had lower DM (29.28 vs. 29.41%; $P = 0.04$), higher weigh variation (12.12 vs. 11.34 g, $P = < 0.0001$) and higher pH (4.07 vs. 3.98, $P < 0.0001$) than Fi. Enzymes P and AP had lower prolamin concentration for A (6.09%DM), P (4.62%DM) and AP (4.92%DM, $P < 0.0001$); for starch, A had lower concentration for A (64.40%DM), P (65.30%DM) and AP (67.80%DM, $P = 0.0002$). Enzyme A had lower NFC, for A (8.75%DM), P (8.86%DM) and AP (8.89%DM, $P < 0.0001$). Corn weight increased with time 1.73g in TP1, 11.4g inTP3 and 22.02g in TP5 ($P < 0.0001$). Corn CP decreased ($P = 0.04$) with time ensiled from TP1 to TP 3 by 0.35%DM. Prolamin concentration changed ($P =$

0.01) during time of ensiling, 5.19, 4.0 and 6.43%DM for TP1, TP3 and TP5, respectively. In conclusion, P seemed to have reduced the matrix starch protein. Small particle size, enzyme and time ensiled, made F better feed but not as good as D.

Key Words: matrix starch protein, amylase, protease

M359 Nitrogen balance of Jersey heifers supplemented with chitosan or omega-6 fatty acids source.

Murilo Vendramini[1], Helder Amaral[1], Maria Gabriela Lobo[1], Marcia Vaz[2], Natalia Silva[1], Euclides Oliveira[1], Rafael Goes[1], Marcelo Barros[2], Caio Takiya[3], and Jefferson Gandra*[1], *[1]Faculdade de Ciências Agrárias, Universidade Federal da Grande Dourados, Dourados, MS, Brazil, [2]Faculdade de Ciências da Saúde, Universidade Federal da Grande Dourados, Dourados, MS, Brazil, [3]Departamento de Nutrição e Produção Animal, Universidade de São Paulo, Pirassununga, Brazil.*

The objective of this study was to evaluate the nitrogen balance of Jersey heifers supplemented with chitosan or omega-6 fatty acids (FA) source. Eight animals (average body weight of 158.62 ± 1.75 kg, mean ± SD) were used in replicated 4 × 4 Latin square experimental designs, balanced and contemporary, in 2× 2 factorial arrangements. The experimental period consisted of 18 d (12 d for adaptation and 6 d for data collection) and 5 d were used for wash out. The experimental diets were (1) control (CO), without omega-6 FA and chitosan supplementation; (2) whole raw soybean (WRS, source of omega-6 FA) with 200 g/kg of DM of WRS); (3) chitosan (CHI), with 2g/kg of DM of chitosan; (4) chitosan and WRS (CHWS), with chitosan and WRS in the same level used in previously cited treatments. The diets were formulated according to the NRC (2001) to achieve weight gain of 700 g/day. Blood samples were collected on d 15 of each period before feeding, by puncture of coccygeal vein and immediately centrifuged at 2000 g × 15 min, supernatant serum was transferred do tubes and submitted to analyses. Spot urine samples were collected on d 17 of each period 4 h after feeding. For the evaluation of nitrogen compounds were dosed concentrations of urea and creatinine (mg/dL) in blood and urine by enzymatic colorimetric method. Data were analyzed using PROC MIXED of SAS 9.3.Animals fed CHI presented lower ($P < 0.05$) concentration of urea and higher ($P < 0.05$) concentrations of creatinine (0.80 mg/dL) in blood than other diets. Higher concentration of urea (43.12 mg/dL) was observed for heifers fed WRS and lower concentration of creatinine than others experimental diets. The renal clearance of urea (24 h period) presented highest value ($P < 0.05$) for animals fed WRS and lowest ($P < 0.05$) for animals fed CHI. Fractional urea excretion (%) was highest for animals fed CHI and lowest for animals fed WRS. Chitosan and omega-6 FA source supplementation altered the nitrogen balance of dairy Jersey heifers.

Key Words: rumen manipulation, renal clearance, soybean

M360 Effects of amylase and protease on degradability and gas production of rehydrated corn grain silage.

Naina M. Lopes*[1,2], Marcos N. Pereira[2], and Felipe C. Cardoso[1], *[1]University of Illinois, Urbana, IL, [2]Universidade Federal de Lavras, Lavras, MG, Brazil.*

Protein starch matrix is a physical barrier to starch digestion in corn grain. The objective of this study was to evaluate 2 corns, Flint (F) and Floury (D); 2 particle sizes, grinded Fine (Fi) or Coarse (Co); application of 3 enzyme combinations, amylase (A), protease (P) and both (AP); during 3 times of ensiling (TP) at 1, 3, or 5 mo in a complete randomized design resulting in 36 treatments. Each of the 5 silos for each treatment (replicates) consisted of 1kg of corn at 35% moisture and were stored in vacuum sealed bags at environmental temperature. Enzymes used were 650 g/t of amylase and 200 g/t of protease or the combination of the 2. Samples were analyzed for in vitro degradability for 18 h and fermentation of gas production for 24 h (Ankom RFS, Ankom Tech.). Statistical analysis was performed using the MIXED procedure in SAS. Corn F had lower soluble fraction (Fs) degradability (6% of incubated, $P < 0.0001$) but higher degradable fraction (Fd, $P = 0.02$) than D (42 and 43% of incubated, respectively). Corn Co had higher indigestible fraction (Fi, 53% of incubated, $P = 0.002$) then Fi (51% of incubated). Enzyme P resulted in higher ($P < 0.0001$) Fd (43% of incubated) and AP (44% of incubated) than A (39% of incubated). Addition of AP reduced Fi portion and increased the rate of degradation ($P < 0.0001$) over time. Time points 3 and 5 had higher Fd (30% on TP1 vs. 50% on TP3 and 5; $P = 0.002$) than TP1, thus, the rate of degradation increased in the last month of ensiling (from 0.02 to 0.04; $P = 0.004$). Timepoint 3 had a higher ($P < 0.0001$) absolute pressure 37.42 psi for TP1, 42.81 psi for TP3 and 38.08 psi for TP5 and cumulative pressure 9.77 psi for TP1, 16.5 psi for TP3 and 8.92 psi for TP5 ($P < 0.0001$). Data from gas production were divided in 2 periods: 0–12 h and 12–24 h. Period 1 (6.17 psi) had lower ($P < 0.001$) gas production than period 2 (17.30 psi). In conclusion, corn ensiled and treated with enzymes for 3 mo had improved in vitro degradability than non-ensiled corn. Treated corn has great potential to improve farmer's profitability when fed to cattle.

Key Words: enzyme, corn fermentation, gas production

M361 Stereo microscopy and scanning electron microscopy of manure samples from late lactation dairy cows when fed cobalt-lactate in a high-forage total mixed ration.

Jon P. Pretz*[1], Jianping Wu[2], Madam Jao[2], Bill Holloway[3], Del Davis[3], and David P. Casper[1], *[1]South Dakota State University, Brookings, SD, [2]Gansau Agricultural University, Lanzhou, Gansu, China, [3]Ralco Inc., Marshall, MN.*

Feeding higher Co amounts showed increased ruminal fiber digestion. Cobalt-lactate is a highly rumen soluble source of Co and has demonstrated increased ruminal molar acetate concentrations and decreased ruminal ammonia concentrations when lactating dairy cows were fed a high forage ration (Pretz et al., 2014). These results indicated increased fiber digestion and synthesis of microbial protein. Twenty-four late-lactation (μ = 238 DIM and 36.5 kg milk) Holstein dairy cows (10 primiparous and 14 multiparous), were block by milk yield, DIM, and parity and randomly assigned to 1 of 2 treatments being: 1) control (C): ration containing cobalt carbonate fed at 58 mg/cow/d and 2) (T): ration containing 5 g/cow/d of a 1% Co-lactate product (Co-Max). Total mixed rations (TMR) were 70% forage (60% alfalfa baleage and 40% corn silage) and 30% of the respective experimental grain mix on a DM basis. Lactational responses were previously reported. This study further evaluated the total-tract nutrient digestion by collecting TMR and manure samples for measuring nutrient digestibility via internal markers (acid insoluble ash and iron). In addition, manure samples were submitted for stereo microscopy and scanning electron microscopy evaluation. Manure samples were collected at 4 h intervals for 3 consecutive d from each cow during wk 3 and 4. Total-tract DM (53.7 and 56.8% for C and T, respectively), CP (63.8 and 64.0%), NDF (46.3 and 48.9%), and ADF (39.8 and 42.9%) digestibility coefficients were numerically greater, but not significantly ($P > 0.10$) different for cows fed T compared with cows fed C. Stereo microscopy demonstrated that manure samples from cows fed T were more transparent than manure samples from cows fed C. Scanning electron microscopy indicated small visible improvements in digestibility of fiber components observed as appearance of hollow pits in the fiber particles. Feeding additional Co as cobalt-lactate visu-

ally appeared to increase digestibility of fiber particles when evaluated by stereo and scanning electron microscopy.

Key Words: scanning electron microscope, cobalt-lactate, stereo microscopy

M362 Plasma metabolites of Jersey heifers supplemented with chitosan or omega-6 fatty acid source. Helder Amaral[1], Murilo Vendramini[1], Leticia Parangaba[1], Grazilele Rosa[1], Caio Takiya[2], Euclides Oliveira[1], Rafael Goes[1], Antonio Machado[1], André Santos[1], and Jefferson Gandra*[1], *[1]Faculdade de Ciências Agrárias, Universidade Federal da Grande Dourados, Dourados, MS, Brazil, [2]Departamento de Nutrição e Produção Animal, Universidade de São Paulo, Pirassununga, Brazil.*

The objective of the present study was to evaluate plasma metabolites of blood of Jersey heifers supplemented with chitosan or omega-6 fatty acids (FA). Eight Jersey heifers (average body weight of 158.62 ± 1.75 kg, mean ± SD) were used in replicated 4 × 4 Latin square experimental design, balanced and contemporary, in 2 × 2 factorial arrangement. The experimental period consisted of 18 d (12 d for adaptation and 6 d for data collection) and 5 d were used for wash out. The experimental diets were (1) control (CO), without omega-6 FA and chitosan supplementation; (2) whole raw soybean (WRS, source of omega-6 FA) with 200g/kg of DM of WRS); (3) chitosan (CHI), with 2 g/kg of DM of chitosan; (4) chitosan and WRS (CHWS), with chitosan and WRS in the same level used in previously cited diets .The diets were formulated according to the NRC (2001) to achieve weight gain of 700 g/day. Blood samples were collected on d 15 of each period before feeding, by puncture of coccygeal vein and immediately centrifuged at 2000 g × 15 min, supernatant serum was transferred do tubes and submitted to analyses of cholesterol (CHO), low density cholesterol (LDL), high density cholesterol (HDL) urea and blood urea nitrogen (UN) by enzymatic colorimetric method. Data were submitted to PROC MIXED of SAS 9.3. The CHI diet decreased ($P < 0.05$) and WRS increased ($P < 0.05$) blood concentrations of TC, LDL, urea and UN. Heifers presented blood concentration (mg/dL) of TC (78.12 and 131.25), LDL (44.15 and 92.35), urea (35.50, 43.12) and UN (16.54 and 20.09) for fed CHI and WRS, respectively. Interaction effect for HDL blood concentration was observed ($P < 0.05$) between CHI and WRS. The animals fed CHWS presented higher concentration (46.37 mg/dL), than WS (32.87 mg/dL), CO diet (28.00 mg/dL), and CH (23.75 mg/dL).Chitosan and omega 6 fatty acid influenced plasma metabolites of Jersey dairy heifers.

Key Words: alternative rumen modulator, metabolic profile, rumen manipulation

M363 Effect of top-dressing rumen-protected methionine in lactating Holstein cows: I. Profile of plasma amino acids, milk yield, and milk composition. Mateus Z. Toledo*[1], Giovanni M. Baez[1], Eduardo Trevisol[1], Nelson E. Lobos[1], Alvaro Garcia-Guerra[1], Jerry N. Guenther[1], Daniel Luchini[2], Randy D. Shaver[1], and Milo C. Wiltbank[1], *[1]University of Wisconsin-Madison, Madison, WI, [2]Adisseo, Alpharetta, GA.*

Experimental objectives were to evaluate the effects of supplementation with rumen-protected methionine (RPM) from 31 ± 2 until 127 ± 2 DIM on circulating amino acid concentrations and lactation performance of dairy cows. Holstein cows (n = 309) were housed in a freestall barn, milked twice daily, fed a basal diet formulated to 16.7% CP to deliver 2521 g of metabolizable protein (MP) with 6.93 lysine as % of MP and randomly assigned to once daily top-dressing with either: 1) RPM, 21.2 g of Smartamine M mixed with 38.8 g of dry distillers grains (2.34 methionine as % of MP) or 2) Control (CON), 60 g of dry distillers grain (1.87 methionine as % of MP). Plasma was assayed for free amino acids by gas chromatography using a commercial kit (EZ:faast, Phenomenex). Amino acid data were analyzed using a linear mixed model with repeated measures. Milk yield and composition were determined monthly and analyzed using a linear mixed model with treatment as a fixed effect and enrollment week as a random effect. Cows treated with RPM had increased milk protein content at all 3 milk tests (mean 58.7, 86.0, 113.5 DIM) (2.96 vs. 3.03%, $P = 0.003$; 3.02 vs. 3.07%, $P = 0.02$; 3.05 vs. 3.12%, $P = 0.02$) with no difference in milk yield. Blood samples were collected from a subset of cows (n = 8 CON; n = 12 RPM) at 0, 3, 6, 9, 12, 18, and 24 h after feeding RPM. Plasma methionine did not differ between treatments at 0 ($P = 0.37$) and 3 h ($P = 0.50$) but was greater in RPM cows at 6 ($P = 0.03$) and 9 h ($P < 0.0001$), peaking at 12 h (52.4 vs 26.0 nmol/mL, $P < 0.0001$), decreasing by 18 h ($P = 0.12$), and back to basal by 24 h ($P = 0.44$). Plasma lysine ($P = 0.47$) and histidine ($P = 0.42$) were unaffected by treatment. Another subset of cows (n = 16 CON; n = 24 RPM) was evaluated at 12 h after top-dressing. Cows fed RPM had increased methionine in both primiparous (23.9 vs. 46.4; $P = 0.007$) and multiparous (23.5 vs. 38.7; $P = 0.02$) cows. Thus, top-dressing RPM resulted in a surprisingly large but acute change in circulating methionine and a small but consistent change in milk protein content.

Key Words: methionine, dairy cattle, milk protein

M364 Milk protein and fat production are regulated by histidine and glucose supply in the lactating dairy cow. John Doelman*[1,2], Michelle Carson[1], John P. Cant[2], and John A. Metcalf[1], *[1]Nutreco Canada Agresearch, Guelph, ON, Canada, [2]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada.*

The lactational response to essential amino acid (EAA), histidine and glucose supply was determined in 6 early lactation fistulated dairy cows (92 ± 17 DIM) fed a diet to provide an NE_L of 6.9 MJ/kg DM and 11.7% crude protein. Treatments consisted of abomasal infusions of saline (Sal), 1 kg/d glucose (Glc), 563 g/d of an EAA mix (equivalent to EAA in 1kg casein) with (EAA + Glc) and without (EAA) glucose, or EAA less histidine with (–His + Glc) and without glucose (–His) in a 6 × 6 Latin square design. Data were analyzed using the MIXED procedure in SAS where period and treatment were fixed effects and cow a random effect. Milk yield was significantly increased in response to EAA + Glc compared with Sal ($P < 0.001$), while the removal of histidine from EAA + Glc significantly decreased milk yield ($P < 0.001$). Compared with Sal, milk protein yield increased 146 g/d ($P < 0.001$) in response to EAA. The –His treatment decreased milk protein yield 266 g/d ($P < 0.001$) compared with EAA, and EAA + Glc generated an increase of 346 g/d over –His + Glc ($P < 0.001$). Milk protein concentration increased 0.21 and 0.23 percentage points during EAA and EAA + Glc infusion compared with Sal ($P \leq 0.003$), while the imbalance created with the omission of histidine, with and without glucose, significantly reduced milk protein concentrations to below those observed for Sal ($P \leq 0.002$). With the exception of the complete EAA treatment, milk fat yield was significantly greater for –His compared with all other treatments ($P \leq 0.03$). Milk fat concentration was 0.99 and 1.08 percentage points greater for –His compared with Glc ($P < 0.001$) and EAA + Glc ($P < 0.001$). Supplemental glucose did not stimulate a milk protein response and amplified the negative effects of a histidine deficiency. Additionally, histidine deficiency generated a positive milk fat response while glucose

supplementation inhibited milk fat production. These results demonstrate the effect of histidine and glucose supply on lactation performance.

Key Words: amino acid, dairy cow, milk protein

M365 Development of an in vitro subacute ruminal acidosis (SARA) model. Allan B. Chestnut*[1], Jim M. Aldrich[1], Tammy K. Miller Webster[2], Wenping Hu[1], Wibe B. Fokkink[1], and Howard G. Bateman[1], [1]*Provimi North America, Brookville, OH,* [2]*Rumen Fermentation Profiling Laboratory, West Virginia University, Morgantown, WV.*

To test efficacy of additives to reduce SARA, a protocol was developed to model SARA conditions using an in vitro continuous culture fermentor system at the Rumen Fermentation Profiling Laboratory, West Virginia University. A BASE diet was formulated with a 60:40 forage:concentrate (F:C) ratio (DM basis). Inclusion of corn silage, alfalfa balage, grass hay, ground corn (GC), SBM, corn gluten meal, corn gluten feed, soybean hulls, dried molasses, sodium bicarbonate and a mineral-vitamin supplement were, respectively, 36.1, 12.1, 12.1, 11.00, 13.7, 1.0, 1.0, 8.3, 2.0, 2.0 and 1.8% of DM. Mean particle size of GC was 870 µm (SD = 2.7). In Trial 1, diet SARA1 was formulated by reducing the BASE diet F:C ratio to 52:48. Corn was increased to 20.9% with 50% (DM basis) of the GC replaced with steam flaked corn (SFC). Treatments were: BASE diet fed as 25-g meals 4 times daily for 10 d (B) and BASE diet fed as 25-g meals 4 times daily for 7 d followed by the SARA1 diet fed as 50-g meals 2 times daily for 3 d (S1). Treatments were replicated in triplicate. Data collected the last 3 d included pH at 30-min intervals and NDF digestibility. Daily average pH were calculated for each fermentor. All data were analyzed using PROC MIXED of SAS. Average and minimum pH were analyzed with a repeated-measures model. Fermentor was treated as a random variable and AR(1) was selected as the appropriate covariance structure. Average pH of S1 (6.25) vs B (6.28) was similar ($P = 0.15$). Minimum pH of S1 (6.06) vs B (6.15) tended to be less ($P = 0.08$). NDF digestion was less ($P < 0.01$) for S1 (41.5%) vs B (46.6%). In Trial 2, treatment S1 was replaced with S2 by altering the SARA1 diet to create SARA2 as follows: corn replaced sodium bicarbonate and the GC:SFC ratio changed to 1:2. Trial 2 protocol was similar to Trial 1. Average pH of S2 (6.17) was less ($P < 0.05$) than B (6.30). Minimum pH of S2 (5.88) was less ($P < 0.01$) than B (6.18). NDF digestion was less ($P < 0.01$) for S2 (30.5%) vs B (40.4%). It was concluded that using the tested protocol with diets BASE and SARA2 provided an appropriate SARA model.

Key Words: subacute ruminal acidosis, in vitro, model

M366 Association of peripartal nutritional strategy with concentration of postpartum β-hydroxybutyrate in dairy cows. Allison B. Lawton*[1], Sabine Mann[2], Winfield S. Burhans[3], Daryl V. Nydam[2], Christine A. Rossiter-Burhans[4], Michael Tetreault[4], and Thomas R. Overton[1], [1]*Department of Animal Science, Cornell University, Ithaca, NY,* [2]*Department of Population Medicine and Diagnostic Sciences, College of Veterinary Medicine, Cornell University, Ithaca, NY,* [3]*Dairy-Tech Group, South Albany, VT,* [4]*Poulin Grain, Newport, VT.*

The objective was to determine the effect of transition cow nutritional management on β-hydroxybutyrate (BHBA) concentration of postpartum dairy cows. Commercial Holstein herds (n = 64) based in New York and Vermont were enrolled in a prospective cohort study in one of 6 herd nutritional strategy groups: 1) low energy dry cow (<16% starch), high energy lactating (>25% starch) (L-H); 2) Step-up dry (far-off < 16% starch, close-up > 16% starch), high energy lactating (S-H); 3) high energy dry (>16% starch), high energy lactating (H-H); 4) low energy dry, step-up fresh (fresh < 25% starch, high > 25% starch) (L-S); 5) step-up dry, step-up fresh (S-S); 6) high energy dry, step-up fresh (H-S). Blood samples were collected from 972 cows, 3–14 DIM and BHBA concentration measured using a Precision Xtra meter. Concentrations of BHBA were log-transformed and a multivariable linear model was used to assess the fixed effects nutritional strategy, season, and parity on BHBA concentration with farm as a random effect. The proportion of cows with hyperketonemia (HYK; BHBA ≥1.2 mmol/L) in each nutritional strategy as well as risk group (low: <15%, moderate: ≥15%, <40%, high: ≥40% of sampled cows HYK) was evaluated. Multiparous cows had higher BHBA concentrations than primiparous (0.61 [0.57–0.67 CI] vs. 0.48 [0.43–0.53 CI] mmol/L, $P < 0.0001$) and concentrations were higher in summer compared with winter (0.61 [0.56–0.67 CI] vs. 0.48 [0.44–0.53 CI] mmol/L, $P < 0.0001$; Table 1). Overall, a step-up approach to both dry and fresh diets led to the highest BHBA concentration among all strategies in this study.

Key Words: transition period, β-hydroxybutyrate, nutritional strategy

M367 Evaluation of rumen outflow in dairy cows by use of reticular and omasal sampling as an alternative to sampling from abomasal cannula. José Esler Freitas Jr.*[1], Tiago Dell Vale[2], Vitor Pereira Bettero[2], Marjorye Kametani[2], Pablo Gomes Paiva[2], Rodrigo Gardinal[2], Caio Seiti Takiya[2], Filipe Zanferari[2], Thiago T. H. A. Vendramini[2], Elmerson Ferreira Jesus[2], Gustavo Delfino Calomeni[2], and Francisco Palma Renno[2], *[1]Department of Animal Science, Federal University of Bahia, Salvador, Bahia, Brazil, [2]Department of Nutrition and Animal Production, Faculty of Veterinary Medicine, University of São Paulo, Pirassununga, São Paulo, Brazil.*

The aim of this study was to evaluate the effects rumen outflow in dairy cows fed unsaturated fatty acid by use of reticular and omasal sampling as an alternative to sampling from the abomasal canal. Four Holstein dry cows cannulated in the rumen and abomasum (602 ± 21 kg of body weight; mean ± SD) were assigned randomly into a 4 × 4 Latin square design experiment, fed the following diets: (1) control (C), without unsaturated fatty acid supplementation; (2) soybean oil (SO), addition of 3% of refined soybean oil in DM basis of total diet; (3) whole raw soybean (WS), addition of 16% of whole raw soybeans in DM basis of total diet; and (4) calcium salts of unsaturated fatty acids (CSFA), addition of 3% of CSFA in DM basis of total diet. Nutrient flow was calculated using the reconstitution system based on 3 markers (cobalt-EDTA, ytterbium chloride and indigestible NDF). Large and small particles and the fluid phase were recovered from digesta collected of different sites. Samples were collected 8 times during 20 4 h and were combined into one pool sample for further reconstitution. Data were analyzed using PROC MIXED of SAS 9.1 using the Tukey test to test pair wise comparisons. The DM flow was higher ($P < 0.01$) to abomasum compared with reticulum and omasum (4.0; 4.0 and 4.8 kg to sites reticulum, omasum and abomasum respectively). However, the NDF flow was higher ($P < 0.01$) (1.5; 1.2 and 1.4 kg to reticulum, omaso and abomasums respectively), to reticulum compared with omaso and abomasums. There was no difference for the 18:3 flow. The 18:2 flow was higher (50.9; 10.3 and 24.3 g to sites reticulum, omasum and abomasum respectively), to reticulum compared with omaso and abomasums, and 18:1 flow was less ($P < 0.01$) for to omasum compared with reticulum and abomasum. The reticular sampling technique provided reliable estimates for DM flow and fatty unsaturated fatty acids in dairy cows

Key Words: dairy cow, omasal sampling, nutrient flow

M368 Feed milk value and protein supply to dairy cows of new co-products (carinata meal) from bio-fuel processing in comparison with canola meal. Yajing Ban*, David A. Christensen, John J. McKinnon, and Peiqiang Yu, *Department of Animal and Poultry Science, College of Agricultural and Bioresources, University of Saskatchewan, Saskatoon, Saskatchewan, Canada.*

Brassica carinata is a newly developed oilseed for bio-fuel production in Canada. The bio-fuel processing results in a large amount of co-products (carinata meal), which could potentially be utilized as a protein source for animal feed. However, there is little research on metabolizable protein characteristics of carinata meal for dairy cattle. The objectives of this study were to determine differences among carinata meal, extruded carinata meal and canola meal for dairy cattle in terms of (1) rumen protein degradation, (2) intestinal digestion of protein, (3) total truly digestible protein supply, and (4) feed milk value. The animal trial was carried out in University of Saskatchewan dairy research facility. Statistical analyses were performed using PROC MIXED procedure of SAS 9.3 with significance declared at $P \leq 0.05$. The results indicated that extruded carinata meal had higher rumen degraded protein than canola meal ($P \leq 0.05$). Intestinal digestible protein was the highest in canola meal but the lowest in extruded carinata meal ($P < 0.0001$), while total digestible protein was the highest in extruded carinata meal but the lowest in canola meal ($P < 0.0001$). Extruded carinata meal had the most truly absorbed rumen-synthesized microbial protein in the intestine and degraded protein balance, but had the least truly absorbed rumen undegraded feed protein and truly digested protein in the small intestine ($P \leq 0.05$). The canola meal was the highest in truly absorbed rumen undegraded feed protein in the small intestine but the lowest in truly absorbed rumen-synthesized microbial protein in the intestine and degraded protein balance ($P \leq 0.05$). Feed milk values had no significant difference in carinata meal and canola meal using the Dutch DVE/OEB model. In NRC model, canola meal was the highest in FMV. The results indicated that carinata meal could be used as a potential protein supplement. Extrusion processing seems to have a negative effect on protein utilization and production in dairy cattle.

Key Words: carinata meal, metabolizable protein characteristics, feed milk value

M369 Dairy calves changes in serum total protein and albumin concentration according to time after colostrum intake. Nathalia B. Rocha[1], Fernanda L. M. Silva[1], Jackeline T. Silva[1], Carolina C. F. Monteiro[2], Marília R. Paula[1], and Carla M. M. Bittar*[1,3], *[1]University of Sao Paulo, ESALQ, Piracicaba, SP, Brazil, [2]Universidade Federal de Pernambuco, Recife, PE, Brazil, [3]CNPq, Brasilia, DF, Brazil.*

Determination of serum total protein (TP) is being used as a tool to evaluate failure of passive immune transfer in dairy calves. However, time of evaluation recommendation is not well established. The objective of this study was to evaluate these changes, aiming a better recommendation of the better time to assess TP in neonatal calves. Blood form 47 cows was drawn just after calving, as well as from the calves at 0 (before colostrum feeding), 1, 2, 4, 6, 12, 24, 48, 72, 96 and 120h after colostrum intake. Crossbred calves (Holstein × Gir and Jersey × Gir) were separated from their mothers and 3L of high quality colostrum were fed. Hematocrit was determined and samples were centrifuged for determination of TP using a refractometer and albumin and TP using a commercial enzymatic kit. Regression curves were constructed for each parameter according to time, using SAS PROC REG. Correlations between mother TP at calving and calf TP at different times were also calculated using SAS PROC CORR. Quadratic regressions showed higher R^2 for all parameters. Total protein concentration estimated by the protein refractometer was higher than that determined by enzymatic method, as shown by the higher intercept in both linear and quadratic prediction equation (Table 1). Correlation between cow's TP at calving were positive and significant only at time 0 ($r = 0.2989$; $P < 0.05$) and 1h ($r = 0.24591$; $P < 0.1$). The quadratic behavior of the regression analysis of TP, by both methods, suggest that the maximum time after colostrum feeding for a better evaluation of passive immune transfer is around 12–24h after colostrum feeding.

M370 Relationship between rumen methanogens and methane production in crossbred Holstein-Gyr steers.

Shirley Motta de Souza[1], Daniela Batista Oss[2], Luiz Gustavo Ribeiro Pereira*[1], Cláudia Braga Pereira Bento[2], Hilário Cuquetto Mantovani[2], Marcos Inácio Marcondes[2], Fernanda Samarini Machado[1], Thierry Ribeiro Tomich[1], Mariana Magalhães Campos[1], Adriana Santana Carmo[1], Ellen de Almeida Moreira[1], Sávio Augusto Toledo Moreira[1], and Pedro Braga Arcuri[4], *[1]Brazilian Agricultural Research Corporation-Embrapa (Dairy Cattle), Juiz de Fora, MG, Brazil, [2]Federal University of Viçosa, Viçosa, MG, Brazil, [3]Federal University of Minas Gerais, Belo Horizonte, MG, Brazil, [4]EMBRAPA Liaison Officer for Multilateral, Regional & National Entities in Europe, Rome, Italy.*

The aim of this study was to evaluate the bacterial community composition by denaturing gradient gel eletrophoresis (PCR-DGGE). Eighteen steers Holstein × Gyr with average body $8\,155 \pm 5$ kg d^{-1} were randomly distributed in a completely randomized design with 3 treatments and 6 repetitions. The diet was calculated for average daily gain of 1.2 kg/d and an average weight of 240 kg, using the requirements for crossbred steers estimated by BR-Corte. Forage:concentrate ratio (based on DM) used was 60:40 and the animals received dietary treatment 1.2% MS of BW; 1.9% MS of BW and ad libitum intake, as maintenance, intermediate and high gain treatment, respectively. The daily feed intake was recorded and animals were weighed weekly each 28 d. The production of methane enteric by the animals was measured by open-circuit respiration chambers for 2 consecutive 24-h days. To assess the genetic diversity of the ruminal microbial community, 50 mL of rumen fluid samples were collected at the slaughter. DNA was extracted and processed by phenol-chloroform and bead beating method. PCR reaction used universal primers to amplify the V3 region to amplify the 16S rRNA of archaea Nested-PCR was performed to amplify a shorter region of the archaea 16S rRNA, using the primers ARC344f-GC/517r for archaea. PCR-DGGE patterns were analyzed using BioNumerics software 5.1 with which hierarchical cluster comparisons were carried out to group similar profiles and to generate a binary matrix of band classes. All the images were normalized using the internal control samples and the comparison among whole profiles was performed using the Dice similarity coefficient. The total number of the detected bands represented the species richness. Shannon-Wiener index was calculated based on relative band intensity and the total of number bands of each DGGE profile. The statistical analyses were done using the software R. The methane emission was affected by the treatments ($P < 0.05$) but there was no effect of the treatments on the richness index also by Shannon-Wiener ($P > 0.05$). No differences in archaeal population were detected between treatments.

Key Words: archaea, greenhouse gas, global warning

M371 Evaluation of different oral rehydration protocols for dairy calves affected by diarrhea.

Evangelina Miqueo[1], Thais M. Torrezan[1], Nathalia B. Rocha[1], Jackeline T. Silva[1], Marília R. Paula[1], Samyra Baldassin[1], and Carla M. M. Bittar*[1,2], *[1]University of Sao Paulo, ESALQ, Piracicaba, SP, Brazil, [2]CNPq, Brasilia, DF, Brazil.*

Different oral rehydration therapies are used to restore the electrolyte level in diarrheic dairy calves. Most of them demand great amount of labor and time, however the use of commercial supplements administered with the liquid diet may make it easier. The objective of this study was to evaluate 3 rehydration protocols to determine the most effective in restoring electrolytes and water while maintaining animal performance. Thirty male Holstein bull calves were blocked by birth weight and serum total protein 24 h after birth, and distributed to one of 3 protocols of oral rehydration when presenting fecal score higher than 3 in a scale of 1 to 5: (1) Common electrolytes oral solution: 25 g dextrose, 10 g of sodium bicarbonate and diluted 5 g of sodium chloride in 1 L of water supplied at 10:00 and at 14:00); (2) commercial electrolyte solution vial for calves added to the milk replacer; and (3) Common electrolytes oral solution containing 2.2 g of glutamine and glutamate diluted in 1 L of water supplied at 10:00 and 1L at 14:00 h. All animals received 4 L/d milk replacer divided into 2 meals (7 h and 17 h) and were weaned with 56 d. Starter concentrate and water intake were measured daily and calves were weighed weekly. Although there were no significant differences among treatments for consumption, weight gain and days in diarrhea, voluntary water intake was significantly higher for diarrheic calves that received Glutellac, which together with the simplicity of use, represent the major advantages of this method of rehydration.

Table 1 (Abstr. M371). Performance of dairy calves receiving different rehydration treatments when presenting diarrhea

Item	Dextrose solution	Commercial electrolytes	Dextrose + AA solution	SEM	$P <$
Total DMI, g/d	713	747	670	41.3	0.41

M372 Pretreatment with saturated and unsaturated fatty acids regulates [1-^{14}C] C16:0 metabolism in Madin-Darby bovine kidney cells.

Katherine E. Boesche*, Stephanie L. Koser, and Shawn S. Donkin, *Purdue University, West Lafayette, IN.*

Metabolic fates of fatty acids (FA) may be influenced by circulating FA concentration. Previous work in our lab demonstrated an ability of C18:3n-3 *cis* to ameliorate gene expression of pyruvate carboxylase (PC) after depression by either C16:0 or C18:0. PC catalyzes oxaloacetate (OAA) synthesis and ostensibly links gluconeogenesis and FA metabolism. Our objective was to determine effects of copresence of saturated and unsaturated FA pretreatments on cellular partitioning of [1-^{14}C] C16:0 metabolism to CO_2 or acid-soluble products (ASP) in Madin-Darby bovine kidney (MDBK) cells. Cells at 80% confluence were exposed for 21h to either individual FA bound to BSA (C16:0,

C18:0, C18:1n-9 *cis* or C18:3n-3 cis) or FA cocktails in 10:90, 25:75, 50:50, 75:25 or 90:10 ratios for combinations of C16:0: C18:3n-3 *cis* or C18:0: C18:3n-3 *cis* or C18:1n-9 *cis*: C18:3n-3 *cis*. Total pretreatment FA concentration was 1.0 m*M*. Following pretreatment, cells were then incubated in the presence of 1.0 m*M* [1-^{14}C] C16:0 for 3h. Pretreatments with either C16:0 alone or C18:0 alone significantly ($P < 0.01$) depressed subsequent oxidation of [1-^{14}C] C16:0 to ASP by 62.7% and 41.2%, respectively, compared with C18:3n-3 *cis* pretreatments. Pretreatments with C18:1n-9 *cis* either alone or in any combination with C18:3n-3 *cis* did not significantly ($P > 0.10$) depress subsequent oxidation of [1-^{14}C] C16:0 to ASP. Similar patterns were seen with [1-^{14}C] C16:0 oxidation to CO_2. ASP production from [1-^{14}C] C16:0 was positively correlated ($r = 0.68$, $P < 0.01$) with PC gene expression levels while CO_2 production from [1-^{14}C] C16:0 did not show a correlation ($r = 0.30$, $P > 0.10$) with PC expression. Activation of PC gene expression by unsaturated FA may play a critical role in setting the capacity for OAA synthesis and determining metabolic fates of FA. Results show the regulation of ketone production by bovine kidney cells in response to saturated and unsaturated FA pretreatments.

Key Words: fatty acid oxidation, ketogenesis, pyruvate carboxylase

M373 $Ca(OH)_2$-treated corn stover as an alternative for haycrop forage or corn silage in diets for lactating dairy cows.

Brittany A. Casperson*[1], Aimee E. Wert-Lutz[2], and Shawn S. Donkin[1], [1]*Purdue University, West Lafayette, IN,* [2]*ADM Alliance Nutrition, Quincy, IL.*

Nutritive value of crop residues may be improved through prestorage treatment with $Ca(OH)_2$. The objective of this experiment was to determine the effect of maximal substitution of either haylage or corn silage with $Ca(OH)_2$-treated corn stover on feed intake, milk production and milk composition in lactating dairy cows. Corn stover was processed by chopping, rehydrating, and treating with 6.6% $Ca(OH)_2$ (DM basis), and stored in bag silos. Six mid-lactation multiparous Holstein cows were assigned to one of 2 groups and randomized within group to a Latin Square design to receive a TMR without any added $Ca(OH)_2$-treated stover (CON), a TMR where $Ca(OH)_2$-stover replaced alfalfa haylage at 15% of the diet (HYLGsub), or a TMR where $Ca(OH)_2$-stover replaced corn silage at 19% of the diet DM (CSsub). Diets were evaluated in a 3 × 3 replicated Latin square consisting of 3 21-d periods. Cows were individually fed in tie stalls. The first 14 d of each period were used for diet adaptation followed by 7 d of data collection. Milk production was not different ($P = 0.77$) among treatments. DMI was reduced ($P < 0.05$) for HYLGsub and CSsub diets when compared with CON (24.5, 21.8, 20.6 ± 1.0 kg/d for CON, HYLGsub, and CSsub, respectively). Milk fat percent was decreased ($P < 0.05$) with inclusion of $Ca(OH)_2$-treated corn stover (3.92, 3.66, 3.69 ± 0.15%, CON, HYLGsub, and CSsub, respectively) and milk fat yield tended to decrease ($P = 0.09$). Milk protein percentage was reduced ($P < 0.05$) by $Ca(OH)_2$-treated corn stover inclusion (3.27, 3.16, and 3.11 ± 0.06% for CON, HYLGsub, and CSsub, respectively) but milk protein yield was unaffected ($P = 0.32$). Energy-corrected milk production per unit of DMI (kg/kg) was greater ($P < 0.05$) for cows fed diets containing $Ca(OH)_2$-treated corn stover (1.12, 1.26, and 1.30 ± 0.05 CON, HYLGsub, and CSsub, respectively). Results show that $Ca(OH)_2$-treated corn stover can replace haycrop forages or up to 31% of the corn silage in diets for dairy cows without negatively impacting milk production while simultaneously improving the efficiency of conversion of feed to milk.

Key Words: corn stover, alternative forage, feed conversion efficiency

M374 Composition of rumen microbiota alters following diet-induced milk fat depression in dairy cows.

Elnaz Azad[1], Daniel E. Rico[2], Hooman Derakhshani*[1], Kevin J. Havartine[2], and Ehsan Khafipour[1], [1]*Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada,* [2]*Department of Animal Science, Penn State University, University Park, PA.*

An experiment was conducted to explore the effect of diet-induced milk fat depression (MFD) on the global profile of rumen microbiota. Eight ruminally cannulated cows were subjected to time-course induction of and recovery from diet-induced MFD in a replicated design with 3 periods of 21 d. Briefly, MFD induction followed control and recovery followed MFD. A high-fiber, low-oil diet was fed during the control and recovery periods, and a low-fiber, high-oil (LFHO) diet was fed during the induction period. Whole ruminal digesta samples were collected and subjected to high-throughput Illumina sequencing of the V3-V4 hypervariable regions of bacterial 16S rRNA gene. On average, 40,562 high-quality sequences were generated per sample. Taxonomic classification of sequences unraveled the presence of 15 different bacterial phyla across all samples, among which Bacteroidetes (46.96%), Firmicutes (35.95%), Proteobacteria (7.5%), Spirochaetes (2.64%), and Fibrobacteres (2.10%) were identified as predominant members of rumen microbiota. When compared with control and recovery-associated communities, the diversity of rumen microbiota was significantly decreased following consumption of LFHO diet ($P < 0.001$). Moreover, PERMANOVA analysis of weighted UniFrac distances of microbial communities also revealed distinct clustering pattern for LFHO-associated microbiota compared with control and recovery diet ($P = 0.002$ and $P = 0.007$, respectively). Based on linear discriminant analysis effect size (LEfSe), the proportions of several members of rumen microbiota were also found to be significantly ($P < 0.05$) altered in response to dietary-induced MFD; the proportion of family Succinivibrionaceae (Proteobacteria) and genera *Shuttleworthia* and *Catonella* (Firmicutes) were found to be significantly increased in response to LFHO diet, while fibrolytic genera, such as *Fibrobacter* (Fibrobacteres) and *Ruminococcus* (Firmicutes) were found to be relatively more abundant during the control/recovery periods. Here, we demonstrated the complex dynamics of rumen microbiota that underlie diet-induced MFD.

Key Words: milk fat depression, 16S rRNA sequencing, rumen microbiota

M375 Effects of *Saccharomyces cerevisiae* fermentation product on rumen fermentation during heat stress.

Kristy L. Dorton*, Tracy Werner, Jason Lin, Abigail Souder, Adam M. Brainard, Joan Butler, and Ilkyu Yoon, *Diamond V, Cedar Rapids, IA.*

Effects of *Saccharomyces cerevisiae* fermentation product (SCFP; Original XPC) on rumen volatile fatty acid (VFA) and lipopolysaccharide (LPS) concentrations during heat stress were measured in a crossover experimental design consisting of 2 28 d-periods. Eight cannulated Jersey cows (nonlactating, non-pregnant) were housed in tie stalls containing individual feed bins and an automatic watering system. Cows were fed a mixture of chopped grass hay and a grain mix twice daily and 1 of 2 treatments. Treatments consisted of 14 g Control (grain mix) or 14 g SCFP and were fed before the morning feeding. The THI of the barn was maintained at 80 to 83 during the trial. Rumen fluid samples were collected from 5 locations within the rumen (cranial dorsal, cranial ventral, central rumen, caudal dorsal, and caudal ventral) every 3 h from 0900 h to 2100 h on d 26, 27 and 28, composited within cow, and strained. Samples were analyzed for VFA and LPS concentrations. Data were analyzed using the fit model procedure of JMP. Cows supplemented with SCFP had greater ($P < 0.0001$) concentrations of total VFA, acetate, propionate, and butyrate than control cows (103.46 vs. 95.19; 69.14 vs. 63.78; 18.75 vs. 17.21; 12.16 vs. 10.80 mM, respectively). Molar proportions of acetate and propionate were not affected by treatment. Molar proportion of butyrate was higher ($P < 0.002$) for cows supplemented with SCFP than control cows (11.72 vs. 11.32%, respectively). Molar proportions of valerate, isobutyrate and isovalerate were lower ($P \leq 0.007$) for cows supplemented with SCFP (1.01 vs. 1.08; 1.18 vs. 1.27; 1.11 vs. 1.20%, respectively). Although not significantly different, cows supplemented with SCFP tended to have lower trend ($P = 0.16$) LPS concentrations than control cows (17,327 vs. 20,156 endotoxin units). Results show that SCFP can maintain better rumen function in cows subjected to heat stress as indicated by higher rumen VFA concentrations. This effect could be the result of stabilized rumen microbial populations, as indicated by the reduced tendency of LPS concentrations in the rumen.

Key Words: *Saccharomyces cerevisiae* fermentation product, VFA, LPS

M376 Peroxisome proliferator-activated receptor β/δ regulates glucose uptake in bovine mammary epithelial cells. Jayant Lohakare*[1,2], Johan Osorio[2], and Massimo Bionaz[2], [1]*College of Animal Life Sciences, Kangwon National University, Chuncheon, South Korea,* [2]*Oregon State University, Corvallis, OR.*

A previous study showed that Peroxisome Proliferator-Activated Receptor β/δ (PPARβ/δ) activation inhibits glucose uptake in bovine aortic endothelial cells. We hypothesize that inhibition of PPARβ/δ can increase glucose uptake in immortalized bovine mammary alveolar cells (MACT) and increases lactose synthesis. To test our hypothesis, we treated MACT cells with PPARβ/δ synthetic agonist (GW501516) and antagonist (GSK3787) and assessed PPARβ/δ activation, live and dead cell count, and glucose uptake. MACT cells plated at 10,000 cells/well in 96 well plates were transfected with a PPAR Response Element (PPRE X3-TK-luc) plasmid using 0.3 μL/well of TransIT-X2 Dynamic Delivery System (Mirus) in Opti-MEM media without fetal bovine serum (FBS). Cells were treated 24h after transfection in triplicates with 10 and 1,000 n*M* of GW501516, GSK3787, or a 1:1 combination of them plus ethanol as control in high-glucose DMEM medium with 10% FBS. After 24 h of treatment, a nuclear staining (NucBlue Live) was added and 2 images/well were obtained using an inverted fluorescent microscope (DMI6000B, Leica Microsystems, Germany). Luciferase activity was measured via a luminometer and normalized by the number of viable cells measured using CellProfiler software. Glucose concentration in the medium was measured using a Blood Glucose Meter kit (Safeway) and glucose uptake/viable cell was estimated. Data were analyzed using GLIMMIX of SAS. Significance was declared with $P < 0.05$. More than 2-fold increase of luciferase compared with control ($P < 0.001$) was observed with both doses of GW501516 and a dose-dependent decrease of luciferase was observed with GSK3787. The number of viable cells was negatively affected by 10 n*M* of GSK3787 ($P < 0.05$) but was positively affected with 1,000 n*M* of GSK3787 (16,990 vs. 20,966 ± 521 cells/well). No effect on cell viability was observed with GW501516. There was a tendency ($P = 0.06$) for an overall effect of treatments on glucose uptake. Cells treated with GW501516 had a lower glucose uptake (7.2 vs. 10.4 ± 1.6 ng/cell) compared with cells treated with GSK3787. In conclusion, the use of 1,000 n*M* of GSK3787 successfully inhibited PPARβ/δ activity and increased glucose uptake in MACT cells. It remains to be determined if the increase in glucose uptake observed results in higher lactose synthesis.

Key Words: PPARβ/δ, mammary alveolar cells (MACT), glucose uptake

M377 Estimation of biohydrogenation in dairy cows fed unsaturated fatty acids by use of reticular and omasal sampling as an alternative to sampling from abomasal cannula. José Esler Freitas Jr.*[1], Tiago Dell Vale[2], Vitor Pereira Bettero[2], Marjorye Kametani[2], Pablo Gomes Paiva[2], Rodrigo Gardinal[2], Caio Seiti Takiya[2], Filipe Zanferari[2], Thiago T. H. A. Vendramini[2], Elmerson Ferreira Jesus[2], Gustavo Delfino Calomeni[2], and Francisco Palma Renno[2], [1]*Department of Animal Science, Federal University of Bahia, Salvador, Bahia, Brazil,* [2]*Department of Nutrition and Animal Production, Faculty of Veterinary Medicine, University of São Paulo, Pirassununga, São Paulo, Brazil.*

The aim of this study was to evaluate the biohydrogenation in dairy cows fed unsaturated fatty acid by use of reticular and omasal sampling as an alternative to sampling from the abomasal canal. Four Holstein dry cows cannulated in the rumen and abomasum (602 ± 21 kg of body weight; mean ± SD) were assigned randomly into a 4 × 4 Latin square design experiment, fed the following diets: (1) control (C), without unsaturated fatty acid supplementation; (2) soybean oil (SO), addition of 3% of refined soybean oil in DM basis of total diet; (3) whole raw soybean (WS), addition of 16% of whole raw soybeans in DM basis of total diet; and (4) calcium salts of unsaturated fatty acids (CSFA), addition of 3% of CSFA in DM basis of total diet. Nutrient flow was calculated using the reconstitution system based on 3 markers (cobalt-EDTA, ytterbium chloride and indigestible NDF). Large and small particles and the fluid phase were recovered from digesta collected of different sites. Samples were collected 8 times during 20 4 h and were combined into one pool sample for further reconstitution. Data were analyzed using PROC MIXED of SAS 9.1 using the Tukey test to test pair wise comparisons. There were not effects of sampling sites, on biohydrogenation of 18:3 (85.6; 97.9 and 93.2% of intake for to digesta reticular, omasal and abomasal respectively). However, the biohydrogenation of C18:2 (84.2; 93.4 and 85.1% of intake for to digesta reticular, omasal and abomasal respectively) ($P < 0.01$) and C18:1 (63.2; 83.7 and 62.9% of intake for to digesta reticular, omasal and abomasal respectively) were overestimated by use sampling omasal in relation to use reticular sampling and abomasal ($P < 0.01$).The reticular sampling technique provided reliable estimates for biohydrogenation of 18:2 and 18:1. The omasal sampling technique can overestimate to biohydrogenation.

Key Words: dairy cow, fatty acid, linoleic acid

M378 Milk odd- and branched-chain fatty acid profile is affected by lactation stage in dairy cows. Eric Baumann*, P. Yvan Chouinard, Yolaine Lebeuf, and Rachel Gervais, *Université Laval, Quebec, QC, Canada.*

The odd- and branched-chain fatty acid (OBCFA) profile of milk fat has emerged as an interesting, non-invasive tool for evaluating rumen fermentation. These fatty acids are synthesized by different rumen microbial populations, absorbed in the intestine, and taken up by the mammary gland to be incorporated in milk fat. It is well known that milk fat composition is influenced by stage of lactation; proportion of short chains (de novo synthesis) being low initially and increasing with days in milk. However, literature is scarce about the specific effects of stage of lactation on milk OBCFA concentrations. Seven Holstein dairy cows were followed during the experiment. Five data collection and sampling periods were conducted on d 60 to 70, d 120 to 130, d 210 to 220, and d 300 to 310 of a lactation, and on d 5 to 15 of the subsequent lactation. During that period, cows were fed total mixed rations based on grass/legume and corn silages, cracked corn, soybean meal, and corn gluten meal, and formulated to meet their energy and nutrient requirements according to NRC (2001). The results indicate that stage of lactation do affect expression of various milk OBCFA; these effects would need to be considered in the development of models aiming to predict rumen parameters based on milk OBCFA.

Table 1 (Abstr. 378). Milk fat concentrations (mg/g) of individual OBCFA

Key Words: milk fat synthesis, odd- and branched-chain fatty acids, stage of lactation

M379 Ruminal and production effects of supplementing high and low forage dairy rations with a live yeast culture.

Maegan E. Weatherly*[1], Amanda M. Gehman[2], Amanda M. Lisembee[2], Joey D. Clark[1], Laurel L. Ball[2], and Jeffrey M. Bewley[1], *[1]University of Kentucky, Lexington, KY, [2]Alltech Inc., Nicholasville, KY.*

The objective of this study was to assess the effect of yeast supplementation in high and low forage diets on rumen and production parameters. Four, ruminally fistulated, multiparous, mid-lactation, Holstein cows were housed in a tie-stall barn at the University of Kentucky Coldstream Dairy from October 29, 2013 to February 7, 2014. A 4 × 4 Latin square design with a 2 × 2 factorial arrangement of treatments was used. Cows were assigned to 1 of 4 treatments each period including (1) low forage (LF), (2) low forage with 10 g/d yeast (Yea-Sacc; Alltech Inc., Nicholasville, KY; LFY), (3) high forage (HF), or (4) high forage with 10 g/d yeast (HFY). Periods 1 to 3 consisted of 21 d and period 4 was 18 d. Treatment periods were followed by a 7-d washout period where cows were gradually adjusted to the next ration. Dry matter intake was recorded daily. Daily rumination was recorded using HR Tags (SCR Engineers Ltd., Netanya, Israel). Rumen papillae were biopsied from each cow once per feeding period and analyzed for expression of enzymatic genes and transcriptional regulators. The GLM procedure of SAS (Version 9.3 SAS Institute, Inc., Cary, NC) was used to evaluate the fixed effects of cow, period, forage, yeast, and the interaction of forage and yeast on each parameter. Rumen papillae gene expression data were analyzed using a MIXED model in SAS. Rumination time and DMI were the only production parameters significantly influenced by treatment ($P < 0.01$). Dry matter intake was 17.05, 13.41, 19.44, and 20.29 ± 1.40 kg/d for cows on the LF, LFY, HF, and HFY treatments, respectively. Rumination time was 442.88, 323.09, 433.34, and 475.50 ± 21.93 min/d for cows on the LF, LFY, HF, and HFY treatments, respectively. Expression of peroxisome proliferator-activated receptor γ, sterol regulatory element-binding transcription factor 1, and oxoglutarate dehydrogenate ornithine carbamoyl transferase were significantly upregulated by yeast supplementation ($P \leq 0.05$). The upregulation of genes that affect metabolism of VFA during yeast supplementation may suggest the importance of this product on rumen stabilization.

Key Words: yeast, rumen papillae gene expression, rumination

M380 Effects of milk replacer and multivitamin-mineral supplementation on metabolism and rumen development in heat-stressed dairy calves.

Steven J. Blair*[1], Cathleen C. Williams[1], Bruce F. Jenny[1], Ashley H. Dolejsiova[1], and Thomas J. Earleywine[2], *[1]Louisiana State University, Baton Rouge, LA, [2]Land O'Lakes Animal Milk Products, Shoreview, MN.*

Seventy-one neonatal Holstein calves (40 female; 31 male) were used in a randomized block design with a 2 × 2 factorial arrangement of treatments to evaluate the effects of milk replacer (MR) feeding management alone or in combination with a multivitamin and electrolyte supplement on growth performance and mitigation of heat stress in southeast Louisiana. Milk replacer treatments consisted of Land O'Lakes Herdmaker Supreme (20% CP, 20% fat; CON) and Land O'Lakes Warm Front (27% CP, 10% fat; WF). Supplemented calves received either 0 or 20 mL of Palamountains Calf Boost (CB) in MR once daily. Calves were offered MR treatments and water and calf starter (20% CP) ad libitum beginning on d 2. All milk replacer was mixed at 15% solids. Calves consuming CON were fed 2.28kg MR twice daily. Calves on WF were fed 2.72kg MR twice daily for the first 3 weeks of life, and 3.86kg twice daily until weaning. Beginning on d 42, MR feeding was reduced to 1 time per day for all treatment groups to decrease MR intake by 50%. On d 49 calves were weaned. Calves remained in their hutches until d 56 to determine immediate post weaning performance. Blood was collected on d 14, 28, 42, and 56 for analysis of plasma urea nitrogen (PUN), glucose, and β-hydroxybutyrate (BHBA), as well as rumen fluid for analysis of volatile fatty acids (VFA) and pH. Data were analyzed using the PROC MIXED procedure in SAS. A main effect of milk replacer composition on PUN was observed, with calves fed WF having greater concentrations ($P < 0.05$) than CON. Glucose concentrations decreased ($P < 0.05$) as calves aged. There was no treatment effect ($P > 0.05$) on plasma BHBA, but concentrations increased ($P < 0.05$) as calves aged. Likewise, there was no treatment effect ($P > 0.1$) on rumen acetate, propionate, butyrate, and total VFA concentrations; however, concentrations increased ($P < 0.05$) as calves aged. No effects of treatment or time were observed ($P > 0.05$) for rumen pH. These data indicate that milk replacer composition and feeding management and multivitamin mineral supplements do not affect negatively metabolism or rumen development in young dairy calves.

Key Words: calf milk replacer, multivitamin-mineral supplement, heat stress

M381 Validation of a radio frequency system for monitoring feeding behavior and intake of feed and water in young cattle.

Baltazar Ruas de Oliveira Júnior[1], Marcelo Neves Ribas[2], Fernanda Samarini Machado[3], Juliana Aparecida Mello Lima[1], Luigi Francis Lima Cavalcanti[2], Mario Luiz Chizzotti[4], Rafael Alves de Azevedo*[1], and Sandra Gesteira Coelho[1], *[1]Federal University of Minas Gerais, Belo Horizonte, MG, Brazil, [2]CNPq, RHAE–SEVA Engenharia, Projeto Intergado, Contagem, MG, Brazil, [3]EMBRAPA Dairy Cattle,* *Juiz de Fora, MG, Brazil, [4]Federal University of Viçosa, Viçosa, MG, Brazil.*

The objective was to validate a radio frequency system for monitoring individual feeding behavior, water and feed consumption in young cattle housed in group. Thirty 5 Holstein-Gyr crossbred heifers, fitted with an ear tag containing a unique passive transponder, were distributed in 3 groups of 12, 12 and 11 animals per period and had free access to 12 electronic feed bins and 2 electronic water bins (Intergado, Contagem, Brazil). The system documented the visit duration and feed and water intake by recording animal's identification tag, bin number, initial and final times of visits, and the difference of feed/water weight at start and end for each bin visit. Feed bins were monitored by time-lapse video recording over 4 d and the water bins over 6 d. Video data on animal behavior were compared with those generated by the system. Feed and water consumption were measured using an external scale. For each feed bin, 2 feeding events were monitored using manual weighing's immediately before and after the animal's visit and the difference between them was assumed as feed intake (n = 24 observations). For water bins there were made 60 manual weighing's. These data were compared with those recorded by the system. Video and manual weighing data were regressed on the electronic feeding behavior and feed and water intakes data to evaluate system's precision and accuracy. The system showed a high specificity (98.98 and 98.56% for the feed and water bins, respectively) and sensitivity (99.25 and 98.74%, respectively) for identifying animal's presence or absence. Duration of feed and water bins visits, and feed and water consumption per visit estimated by the system were highly correlated and precise ($R^2 = 0.917$, 0.963, 0.973 and 0.986, respectively) when compared with observed video and manual weighing data. Feed daily intake per visit registered electronically and manual weighing differed by less than 150 g. It was concluded that Intergado system is a useful tool for monitoring feeding behavior, water and feed intakes in young cattle housed in group.

Key Words: electronic monitoring, heifer, precision farming

M382 Evaluation of two techniques used to dislodge bacteria from particles contained in rumen digesta.

Jared V. Judy*, Chad J. R. Jenkins, Samodha C. Fernando, and Paul J. Kononoff, *University of Nebraska-Lincoln, Lincoln, NE.*

The objective of this study was to estimate the concentration of bacterial crude protein (BCP) in pellets isolated from ruminal digesta using a preparatory step of either blending or shaking to dislodge bacteria from rumen particles. Using a completely randomized design, 2 multiparous, lactating Holstein cows (DIM 229 ± 7d, DMI 36.1 ± 2.5 kg/d, milk yield 37.7 ± 5.6 kg/d) (mean ± SD), fitted with ruminal cannulas were fed the same diet once daily at 0930 h. Two hours post feeding, approximately 2.5 kg of rumen contents were collected from each cow, then thoroughly mixed and separated into 2 aliquots (blend or shake) then samples were strained through 4 layers of cheesecloth. Particle associated bacteria were separated from the solid portion of rumen contents by adding and equal amount of McDougal's buffer as was collected in the filtrate and physically shook or blended in a commercial blender for 1 min., followed by straining through 4 layers of cheesecloth. Fluid collected after shaking or blending, as well as fluid retained from the initial straining where combined together. Each sample underwent differential centrifugation which yielded bacterial pellets consisting of fluid associated bacteria and particle associated bacteria. DNA was then extracted from bacterial pellets and from the non-centrifuged samples of rumen content particles. The DNA from the bacterial pellets and samples of rumen content were subjected to real-time PCR using the TaqMan assay. Primers and a probe were designed from the DNA encoding part of the 16S rRNA for bacteria. The concentration of BCP using these 2 methods to dislodge bacteria did not differ ($P = 0.42$) (13.9 ± 5.0 and 7.5 ± 1.9 mg BCP/g DM for shake vs. blend, respectively). Results suggest that BCP concentration is not different between shaking or blending to dislodge bacteria, however, further research should examine and attempt to identify the large amount of analytical variation observed in both techniques.

Key Words: bacteria, bacterial crude protein, rumen

M383 Effect of an exogenous fibrolytic enzyme on the performance of dairy cows consuming a diet with a high proportion of bermudagrass silage.

Andres A. Pech Cervantes*, Kathy G. Arriola, Jorge E. Zuniga, Ibukun M. Ogunade, Yun Jiang, Thiago F. Bernardes, Charles R. Staples, and Adegbola T. Adesogan, *Department of Animal Sciences, University of Florida, Gainesville, FL.*

We previously reported that milk production by dairy cows was increased by adding specific xylanase-rich (XYL) and xylanase-cellulase enzymes to corn silage-based diets containing 0 or 10% bermudagrass silage. This study examined effects of adding XYL on the intake and performance of lactating dairy cows consuming a TMR formulated with a greater proportion of bermudagrass silage. Endoglucanase and xylanase activities of XYL were 3,283 and 46,281 µmol/min/mL, respectively. Forty lactating Holstein cows (16 multiparous and 24 primiparous; 21 ± 3 DIM; BW 589 ± 73 kg) were stratified by milk production and parity and assigned randomly to Control and XYL diets. The TMR (CP of 16.2% of DM, NDF of 36.4% of DM, and NE_L of 1.65 Mcal/kg of DM) contained 20% bermudagrass silage, 25% corn silage, and 55% concentrate (DM basis). Immediately before the a.m. (0700 h) and p.m. (1300 h) feedings, the enzyme was sprayed on the XYL diet at the rate of 1 mL/kg of TMR DM in a Calan data ranger and mixed. A second data ranger was used to feed control cows. Cows were fed experimental diets for 70 d after they were fed a common diet for a 9-d covariate period. The experiment had a randomized complete block design. The statistical model included effects of enzyme, parity, week, and their interactions as well as covariate milk production or DMI. The random effect was cow nested within treatment. Application of XYL did not ($P > 0.10$) affect milk yield (35.1 vs. 36.2 kg/d), DM intake (24.0 vs 23.7 kg/d for XYL and Control), fat-corrected milk (FCM) (36.1 vs. 36.9 kg/d), yields of milk fat (1.29 vs. 1.31 kg/d) and protein (1.07 vs. 1.08 kg/d), milk fat concentration (3.65 vs. 3.61%), and body weight change (0.26 vs. 0.33 kg/d) compared with control cows. However, cows fed the diet treated with XYL had greater milk protein concentration ($P = 0.01$; 3.02 vs. 2.95%) and tended to have less feed efficiency ($P = 0.06$; 1.52 vs. 1.57 kg of FCM/kg of DMI) compared with cows fed the control diet. Adding XYL to a diet containing 20% bermudagrass silage and 25% corn silage did not improve DM intake or milk production.

Key Words: bermudagrass silage, milk, enzyme

M384 Effects of intensive whole-milk feeding in calves on subsequent feeding behavior of dairy heifers.

Camila Flávia de Assis Lage[1], Mariana Magalhães Campos[2], Fernanda Samarini Machado[2], Paulo Campos Martins[1], Luigi Francis Lima Cavalcanti[3], Marcelo Neves Ribas[3], Luiz Gustavo Ribeiro Pereira[2], Thierry Ribeiro Tomich[2], Rafael Alves de Azevedo*[1], and Sandra Gesteira Coelho[1], *[1]Federal University of Minas Gerais, Belo Horizonte, MG, Brazil, [2]EMBRAPA Dairy Cattle, Coronel Pacheco, Minas GG, Brazil, [3]CNPq, RHAE–SEVA Engenharia, Projeto Intergado, Contagem, MG, Brazil.*

This study aimed to evaluate the effects of intensive whole milk feeding in calves on subsequent feeding behavior of 58 Holstein-Gyr females. Up to 56 d of age, calves received 6 L/d of 4 different liquid diets consisting of whole milk with the increasing addition of milk replacer (Sprayfo Violet SSP) to adjust the concentration of total solids (TS) to 13.5 (n = 15), 16.1 (n = 15), 18.2 (n = 13), 20.4% (n = 15). After weaning, animals were randomly housed in 4 paddocks, each one equipped with 3 electronic feed bins and one electronic water bin (INTERGADO, Brazil) in Embrapa Dairy Cattle facilities, Brazil. The diet (70% corn silage and 30% concentrate, 195 g of CP/kg, DM basis) was fed ad libitum, twice a day, until 210 d of age. Only events with registered intake were used, and the following results were calculated: Ingestion rate (IR, g/s), average bunk visit duration (AVD, min), daily visit duration (DVD, h) and daily visit frequency (VF, events). Due to the natural right skewness of IR and AVD distributions, their daily median, instead of mean, were used to represent their trends across study period. All variables were analyzed as a completely randomized design with repeated measures using linear mixed model approach. Age and TS were evaluated as fixed effects, while animals as random. The necessity to model error dependence and heteroscedasticity was evaluated by monitoring Schwarz criterion. The effect of TS was decomposed into orthogonal polynomials of linear and quadratic degrees. Significance was declared at $P < 0.05$. All variables were consistently influenced by animal's age, where IR was increased as animals become older (0.837 ± 0.075 g/s at 100 d old versus 1.617 ± 0.072 g/s at 210 d old). An interaction effect between TS and age was detected for IR, where TS linear increased IR for animals older than 190 d of age. None of visit variables were affected by TS levels (AVD = 3.70 ± 0.37 min, DVD = 2.50 ± 0.12 h, VF = 35.16 ± 3.21 events). Intensive whole-milk feeding in calves caused minor effects on subsequent feeding behavior of dairy heifers.

Key Words: milk replacer, intake, precision farming

M385 Comparison of the RQUICKI estimate of insulin sensitivity with glucose and insulin tolerance in periparturient dairy cows.

Sina Saed Samii*, J. Eduardo Rico, Alice T. Mathews, Cassandra L. Orndorff, Amanda N. Davis, and Joseph W. McFadden, *West Virginia University, Morgantown, WV.*

The revised quantitative insulin sensitivity check index (RQUICKI) has been utilized to evaluate insulin resistance in dairy cows; however, discrepancies between RQUICKI and direct measurements of insulin sensitivity are documented. Our objective was to compare RQUICKI with glucose and insulin tolerance in non-fasted peripartal dairy cows. Multiparous Holstein cows were grouped by BCS at d −28 prepartum: lean (BCS 2.91 ± 0.13; n = 7) or overweight (OVER; BCS 4.03 ± 0.21; n = 7). Diets were formulated to meet nutrient requirements. An intravenous insulin challenge (0.1 IU/kg BW; ITT) was performed on d −26 and −13, relative to expected calving, and 5 DIM. An intravenous glucose challenge (0.3 g/kg BW; GTT) was performed 24 h post- ITT . Blood and milk were collected routinely. Data were analyzed using a mixed model with repeated measures (fixed effects of BCS and day). Effects are presented as changes relative to lean cows, unless described otherwise. OVER had lower DMI, and lost more BCS and BW postpartum ($P < 0.05$). Adiposity had no effect on milk yield, milk protein yield, and SCC; however, milk fat yield was greater in OVER ($P < 0.05$). OVER had increased plasma NEFA and BHBA ($P < 0.05$). Prepartum plasma insulin levels were higher in OVER ($P < 0.05$). Although plasma glucose levels declined with time ($P < 0.01$), BCS did not modify plasma glucose. RQUICKI values were lower for OVER pre- and postpartum ($P < 0.05$). Postpartum cows had lower insulin-stimulated glucose disposal, relative to prepartum cows ($P < 0.01$). Following insulin-stimulated glucose disappearance, return to basal glucose in OVER was delayed by 60 min ($P < 0.05$). BCS had no effects on GTT; however, post-glucose challenge area under the curve (AUC) for 180 min and clearance rate (%/min) for the first 30 min were lower for postpartum cows, relative to prepartum cows ($P < 0.05$). Before and after calving, OVER experienced greater glucose-stimulated reductions in NEFA and AUC for 180 min following glucose challenge ($P < 0.05$). Observed inconsistencies between RQUICKI and tolerance testing may be due to direct measurements in the fed state.

Key Words: glucose tolerance, insulin resistance, transition cow

M386 Evolving the plasma free AA dose-response technique to determine bioavailability of Met in RP-Met supplements.

Devan L. Chirgwin*[1], Nancy L. Whitehouse[1], Andre F. Brito[1], Charles G. Schwab[2], and Brian K. Sloan[3], *[1]University of New Hampshire, Durham, NH, [2]Schwab Consulting, LLC, Boscobel, WI, [3]Adisseo, Alpharetta, GA.*

The plasma free AA dose-response technique has been proposed as the standard approach for arriving at estimates of efficacy for rumen-protected Lys supplements. Results of the first replicate of a 5 × 5 Latin square study, reported last year [J. Dairy. Sci. (97(E-Suppl. 1):763], confirmed that a positive relationship also exists between increasing amounts of absorbed Met and plasma Met and total sulfur AA (TSAA) concentrations. The objective of adding a second replicate was to complete the study, and using the combined data set, to determine if using plasma Met or TSAA concentrations (μM) is the more precise response parameter and whether expressing either as a % of total AA (TAA) or total essential AA (TEAA) would reduce the error of calculated estimates of Met-bioavailability. Experimental protocol was as previously described: namely, 5 rumen-cannulated Holstein cows (74–222 DIM) were fed a Met-deficient basal diet with identical treatments. Combined data were analyzed using PROC MIXED and PROC REG of SAS. Outlier analysis, using ± 2.0 SD away from the mean for plasma Met and TSAA concentrations, resulted in removal of all data for one cow. Plasma Met and TSAA concentrations (μ*M*), and both expressed as %TAA and %EAA, were regressed on 0, 12, and 24 g of infused Met and 0, 15, and 30 g of fed Met. Slopes (and associated CV, %) for infused and fed Met were 1.40 and 1.04 (3.68 and 1.85) for Met, 0.067 and 0.048 (4.92 and 3.18) for Met as %TAA, and 0.152 and 0.112 (4.48 and 3.22) for Met as %TEAA. Corresponding values for total TSAA were 2.00 and 1.64 (1.58 and 2.57) for μ*M* concentrations, 0.108 and 0.079 (2.79 and 2.48) for %TAA, and 0.234 and 0.184 (2.67 and 3.48) for %TEAA, respectively. Estimates of bioavailability (and 95% CI) of the RP-Met supplement for the 6 respective methods of expression were 74.4 (2.1), 71.6 (1.9), 73.7 (1.3), 81.8 (3.3), 72.7 (1.3) and 78.6 (2.3). We conclude the plasma free AA dose-response technique is precise, and because Met is a precursor to other sulfur AA, TSAA (μ*M*) is the most appropriate response parameter for estimating Met bioavailability of RP-Met supplements.

Key Words: methodology, methionine, bioavailability

M387 Effects of intensive whole-milk feeding in calves on subsequent performance and feed efficiency of crossbred dairy heifers.

Camila Flávia de Assis Lage[1], Mariana Magalhães Campos[2], Fernanda Samarini Machado[2], Paulo Campos Martins[1], Luigi Francis Lima Cavalcanti[3], Marcelo Neves Ribas[3], Luiz Gustavo Ribeiro Pereira[2], Thierry Ribeiro Tomich[2], Rafael Alves de Azevedo*[1], and Sandra Gesteira Coelho[1], *[1]Federal University of Minas Gerais, Belo Horizonte, MG, Brazil, [2]EMBRAPA Dairy Cattle, Coronel Pacheco,*

MG, Brazil, [3]CNPq, RHAE – SEVA Engenharia, Projeto Intergado, Contagem, MG, Brazil.

This study aimed to evaluate the effects of intensive whole-milk feeding in calves on subsequent performance and feed efficiency in growing heifers. Up to 56 d of age, Holstein-Gyr calves received 6 L/d of 4 different liquid diets consisting of whole milk with the increasing addition of milk replacer (Sprayfo Violet SSP) to adjust the concentration of total solids (TS) to 13.5 (n = 15), 16.1 (n = 15), 18.2 (n = 13), 20.4% (n = 15). After weaning, animals were housed in 4 paddocks, each one equipped with 3 electronic feed bins and one electronic water bin (Intergado, Brazil) in the experimental farm of Embrapa Dairy Cattle, Brazil. The same diet (70% corn silage and 30% concentrate, dry matter basis; 195 g of CP/kg of DM) was fed in ad libitum, twice a day, until 210 d of age. Daily feed intake (DFI) and water intake (WI) were registered by the electronic system. Average daily gain (ADG) was determined from regression of weekly BW measurements so feed conversion (FC) could be calculated. Longitudinal data was analyzed as a completely randomized design with repeated measures using linear mixed models, where animal's age and TS were fixed effects while animal was considered a random effect. The necessity to add random components to model error dependence and heteroscedasticity was evaluated based on Akaike's Information Criterion. Initial body weight, air temperature and humidity were added as co-variables. Average and cumulative results were analyzed by linear regression, where only the fixed effect of TS was evaluated ($\alpha = 0.05$). DFI and WI were only influenced by age, however in both cases an interaction effect was observed, although none supplementation level caused a steady superiority across period for any variable. This result was corroborated by cumulative DFI and WI that were not influenced by TS. ADG was decreased by increasing nutritional management (e.g., 916 ± 30 and 833 ± 29 g/d for animals with 13.5 and 20.4%, respectively), what also reflected in a higher FC to animals in higher TS (13.19 ± 0.45 vs 14.55 ± 0.44 in animals that received 13.5 and 20.4% of FD, respectively).

Key Words: milk replacer, feeding, performance

M388 Immediate and long-term effects of niacin feeding to fresh dairy cows: 1. Ketosis and fertility.

J. M. Havlin*[1], P. H. Robsinson[1], and J. E. Garrett[2], *[1]University of California, Davis, Davis, CA, [2]Qualitech, Chaska, MN.*

During the fresh period after calving through ~21 d postpartum, dairy cows are often in negative energy balance (NEB) due to high energy demands to support rapidly rising milk output at a time of relatively low dry matter intake (DMI). This NEB makes cows susceptible to ketosis, fatty liver, metritis, and displaced abomasum, which can lead to decreased performance and eventual culling. A possibility to reduce the extent of NEB is to feed niacin (Ni) as nicotinic acid (NA) to reduce milk fat production, thereby minimizing body weight loss to reduce ketogenesis, all to reduce the extent of NEB thereby creating a more successful lactation. Multiparity Holstein cows (672) on a California dairy farm were used from 14 d pre-calving through 150 d in milk (DIM). While in the close-up dry pen (−14 to 1 DIM), cows were comingled and fed the same total mixed ration (TMR), in the fresh pens (1 to ~22 DIM) cows were fed the same TMR, except for inclusion of ruminally protected (RP) Ni (rumen escape estimate = 66%), in separate pens at 0, 3.5, 7 or 14 g NA/cow/d. Cows were comingled in the high pen (~23 to 150 DIM) and fed the same TMR. DMI was tabulated by treatment in the fresh pens, blood samples were collected for NEFA and BHBA analysis during the dry and fresh periods, and fertility data was tabulated through 150 DIM. Feeding 3.5 g/d RPNi increased DMI from 19.3 to 21.5 kg/d in the fresh period, but RPNi at 14 g/d reduced it to below Control cows (Quadratic $P = 0.07$). Ketosis prevalence (% cows with BHBA $\geq$ 1.44 mg/dl) decreased from 36 to 20% in the fresh period with 3.5 g/d, but RPNi at 14 g/d did not differ from levels of Control cows (Quadratic $P = 0.06$). Niacin feeding had no effect on any fertility measure, with averages for 1st service conception (%) being 44.6 ± 4.38, pregnancy (%) being 76.2 ± 3.70 and services/conception being 1.58 ± 0.082. Short-term fresh period RPNi feeding at the 3.5 g/d level reduced the incidence of ketosis caused by NEB, but feeding higher levels removed those benefits. No RPNi feeding level during the fresh period affected fertility parameters through 150 DIM.

Key Words: niacin, ketosis, fertility

M389 Effects of supplementation with a rumen-protected lysine product on production in high-producing dairy cows.

Meagan Cooney*[1] and Izuru Shinzato[2], *[1]phdR&D, East Troy, WI, [2]Ajinomoto Heartland, Chicago, IL.*

The objective of this study was to determine the effects of supplementation and withdrawal of a rumen-protected lysine product, AjiPro-L 2nd generation (2G), on production performance of high-producing dairy cows. Ninety-six multiparous Holstein cows averaging 2.9 ± 1.3 lactations and 83.6 ± 36.7 DIM at the commencement of the trial were assigned at random to one of 12 pens that received either a negative control ration (n = 4), positive control ration with added metabolizable lysine from an animal protein (n = 4), or AjiPro-L 2G added metabolizable lysine from a rumen-protected amino acid (n = 4). The 8wk experimental period consisted of 2 periods; a 4-wk treatment period followed by a 4-wk carryover period. During the treatment period, animals received negative, positive or AjiPro-L 2G treatments, whereas during the carryover period all animals received the positive control treatment. Milk yield, energy-corrected milk yield, water consumption and DMI were recorded daily and milk composition was measured weekly. Data from only cows that completed the entire duration of the study were used in the analysis. Days in milk categories of either high (114 ± 17.7) or low (53 ± 21.3) were also analyzed. Results showed that water consumption and DMI was significantly increased compared with baseline ($P < 0.05$) and MUN levels were significantly decreased compared with baseline ($P < 0.01$) for animals receiving AjiPro-L 2G during the treatment period. When comparing DIM categories, results revealed a significant difference ($P < 0.05$) in change of milk production, ECM, pounds of fat and pounds of lactose in comparison to baseline across treatments. For these parameters, high DIM animals receiving AjiPro-L 2G had greater milk yield, and the least reduction of ECM, pounds of fat, and pounds of lactose from baseline compared with the positive and negative treatments. During the carryover period all parameters measured, except for MUN ($P < 0.05$), were not different between treatments compared with baseline. Under the conditions of this experiment, supplementation of AjiPro-L 2G had the greatest effect on cows averaging 114 DIM in which milk production and milk components were maintained in post-peak cows.

Key Words: rumen-protected lysine, dairy cow, production performance

M390 Immediate and long-term effects of niacin feeding to fresh dairy cows. 2. Body condition and milk production.

J. M. Havlin*[1], P. H. Robsinson[1], and J. E. Garrett[2], *[1]University of California, Davis, Davis, CA, [2]Qualitech, Chaska, MN.*

During the fresh period after calving through ~21 d postpartum, dairy cows are often in negative energy balance (NEB) due to high energy demands to support rapidly rising milk output at a time of relatively low dry matter intake (DMI). Multiparity Holstein cows (672) on a California dairy farm were used from 14 d pre-calving through 150 d in milk (DIM). While in the close-up dry pen (−14 to 1 DIM), cows were comingled and fed the same total mixed ration (TMR), in the fresh pens (1 to ~22 DIM) cows were fed the same TMR, except for inclusion of ruminally protected (RP) Ni (rumen escape estimate = 66%) in separate pens at 0, 3.5, 7 or 14 g nicotinic acid/cow/d. Cows were comingled in the high pen (~23 to 150 DIM) and fed the same TMR. Milk production and body condition (BCS) was measured every 2 wk in the fresh pen and every 4 wk in the high pens. At 7 ± 3.9 DIM, there was no effect of RPNi on milk (39.3 ± 0.89 kg) or component yields. However at 21 ± 3.9 DIM there were quadratic trends ($P < 0.20$), with highest outputs at 3.5 g/d feeding and lowest at 14 g/d. However at the 1st high pen milk sampling after cessation of RPNi feeding (48 ± 8.0 DIM), milk and component yields slumped for cows previously fed 3.5 g/d resulting in lower yields vs Control (53.2 vs 51.8 kg milk/d; 1.75 vs 1.67 kg fat/d), but over the next 3 mo they converged with Control. In contrast, milk and component yields of cows previously fed 14 g/d rebounded on the 1st high pen milk sampling after cessation of feeding RPNi resulting in higher yields vs Control (53.2 vs 55.3 kg milk/d; 1.75 vs 1.82 kg fat/d). There was no effect of RPNi feeding on BCS during the fresh period, but BCS of cows previously fed 3.5 g/d decreased more than Control cows in high pens, maintaining a lower BCS through ~80 DIM, but by 150 DIM there was no difference with Control. In contrast the BCS of cows previously fed 14 g/d decreased from the fresh period through 150 DIM. RPNi had small effects on animal performance while supplemented, but cessation of feeding caused short-term rebound carry-over effects. However, performance of cows on all RPNi levels had largely converged by 150 DIM.

Key Words: niacin, milk, BCS

M391 Lactational performance of cows fed extruded linseed on commercial dairy herds. Amélie Beauregard*[1,2], Marie-Pierre Dallaire[1], Rachel Gervais[1], and P. Yvan Chouinard[1,2], *[1]Université Laval, Quebec, QC, Canada, [2]Insitute of Nutrition and Functional Foods, Quebec, QC, Canada.*

The objective of this study was to determine the effect of feeding extruded linseed (EL) on milk yield and milk composition, including fatty acid profile, and enteric methane output on commercial settings. Thirty dairy herds averaging 55 cows and 30.1 kg of milk/d with 4.0% fat and 3.3% protein were recruited for this study. Twenty-eight herds had Holstein cows, while 2 herds had Jersey and Holstein cows, and all of them were located in the province of Quebec, Canada. A first group of 15 herds was randomly selected to be used as control (CTL). Cows from the remaining 15 herds were fed between 200 and 900 g of EL (mixture of linseed:wheat bran, 70:30; Valorex, Combourtillé, France) per cow per day (average 700 g/d) according to their lactation stage and their level of production. Diet compositions were then adjusted to cover the animals' nutrient requirements. The feeding trial was 6 mo in length, and data collected during a 2-mo interval before the experimental period were used as covariates. Actual milk yield was higher in herds fed EL as compared with CTL (28.5 vs. 27.4 L/d; $P = 0.01$). Milk fat content was similar between treatments (4.08 kg/hL; $P = 0.20$), but milk fat yield tended to be higher in herds fed EL as compared with CTL (1.15 vs. 1.12 kg/d; $P = 0.09$). Feeding EL decreased milk protein content (3.30 vs 3.37 kg/hL; $P < 0.01$), but had no effect on milk protein yield (0.94 kg/d; $P = 0.17$) when compared with CTL. Milk fat contents of *cis*-9,*cis*-12,*cis*-15 18:3 (6.72 vs 4.79 mg/g; $P < 0.01$), and other fatty acids of the n-3 family (18:4, 20:4, 20:5, 22:5, 22:6; $P \leq 0.05$) were higher in herds fed EL as compared with CTL. Methane output, as estimated using a proprietary equation (WO 2009 156453 A1) based on milk yield and fatty acid profile, was 9.4% lower in dairy herds fed EL as compared with CTL (12.9 vs. 14.2 g/L milk; $P < 0.01$). In conclusion, feeding moderate amount of EL (700 g/d, providing 200 g of oil) was efficient to mitigate methane emission while maintaining animal performance and increasing the n-3 FA content in milk fat.

Key Words: cow, extruded linseed, methane

M392 Bacterial communities in the gastrointestinal tract of preruminant dairy calves. Janet E. Williams*, William I. Loucks, Elizabeth D. Benda, Nicola F. Beatty, Katelyn M. Steinkamp, Matthew E. Doumit, and Mark A. McGuire, *University of Idaho, Moscow, ID.*

Nutritional factors are known to influence the development of the gastrointestinal (GI) tract in preruminants. However, the effect of different lipid sources on the bacterial communities in the GI tract of young calves has not been well described. Therefore, the aim of this study was to utilize high-throughput sequencing to investigate the GI microbiota of preruminant calves fed supplemental polyunsaturated fatty acids. Calves (n = 8) were fed milk (4 L per d) plus 3% supplemental oil containing either palm oil or a combination of conjugated linoleic acid and flaxseed oil in a ratio of 1:2 (CLA/FLAX) for 50 d beginning 3–6 d after birth. After euthanasia, digesta samples from the rumen, omasum, abomasum, duodenum, cecum, and large intestine (LI) were collected. DNA was extracted using the Qiagen DNA Stool Mini kit and bacterial DNA amplified using primers targeting the V1-V3 hypervariable region of the 16S rRNA gene. Amplicons were sequenced using an Illumina MiSeq v3 paired-end 300-bp protocol for 600 cycles. Sequences were processed and classified using the custom python application dbcAmplicons. Principal coordinate analysis at the genus level revealed 3 clusters: (1) rumen, omasum, abomasum; (2) duodenum; (3) cecum and LI. All 3 clusters had large proportions of reads that could not be classified at the genus level: 1) 39.9% ± 1.9; 2) 76.2% ± 5.4; 3) 56.4% ± 2.6. Clusters 1 and 2 were enriched in *Prevotella* (24.4% ± 1.6 and 7.2% ± 2.7, respectively) and *Succinivibrio* (8.7% ± 1.4 and 2.8% ± 2.1, respectively) while Cluster 3 had similar proportions of *Prevotella* (6.2% ± 2.2), *Bacteroides* (6.2% ± 1.9), and *Oscillibacter* (4.3% ± 0.6). Using generalized linear mixed models, rumen, omasum, and abomasum bacterial communities from calves fed palm oil had greater ($P < 0.05$) abundances of *Succinivibrio* (13.10% ± 1.9 vs 4.1% ± 1.0), *Oscillibacter* (2.7% ± 0.4 vs 1.1% ± 0.3), and *Paraprevotella* (2.5% ± 0.4 vs 1.4% ± 0.3), and lower ($P < 0.05$) abundances of *Prevotella* (20.4% ± 1.8 vs 28.4% ± 2.1) as compared with those from calves fed CLA/FLAX. The implications of different ruminal bacterial composition on growth and tissue development in preruminant calves warrant further research.

Key Words: preruminant, microbiome, gastrointestinal

M393 Application of tri-axial accelerometers to determine the grazing behavior of dairy cows in a commercial dairy herd. Pieter J. M. Raedts*, Rajneet S. Sohi, Indunil Kulatilleke, and Markandeya Jois, *La Trobe University, Melbourne, Victoria, Australia.*

In grazing dairy farming systems measurement of feed intake is problematic, especially due to lack of practical methods to determine the quantity of pasture that cows graze. Our aim was to measure relative DM intake by grazing behavior using tri-axial accelerometers. Tri-axial accelerometers (ActiGraph) were set to continuous recording at 60 Hz and attached to collars around the neck of 10 lactating dairy HF and

HF-Jersey cross cows (HF 82.5% to 100%) on a commercial dairy herd in Northern Victoria, Australia. After 16 full days of recording, the sensors were removed from the collars and recorded RAW data downloaded from the sensors. The 16 d RAW data were used to determine grazing time, bites and intensity. Occasional observational data of cow behavior was used to validate behavior of cows as determined from the activity counts. All cows in the herd were offered the same ration (flat-feeding), consisting of approximately 1/3rd of DM as concentrate and 2/3rd of DM as forage. Forage was predominantly grazed pasture. Herd test results during the trial provided data regarding milk production and somatic cell count (SCC) of individual cows. The data set (n = 10) showed AVG per day grazing time of 340 min (265 to 397), 21,390 grazing bites (16,409 to 25,810) and 541,957 counts for grazing intensity (345,094 to 641,808). Two cows had a high SCC (>2,500,000/mL), indicating subclinical mastitis, and were excluded from the data set used for correlations. The cows (n = 8) had an AVG daily milk yield of 30.6 L (17.7 to 39.1) and 108 d in lactation (62 to 134). The correlation between number of daily bites and daily milk yield was $R^2 = 0.80$, while grazing time (minutes per day) had a correlation to milk yield of $R^2 = 0.69$. These results suggest that tri-axial accelerometer sensors are useful in determining grazing behavior of lactating dairy cows.

Key Words: grazing, bites, lactating

M394 Effect of acetate and *trans*-10,*cis*-12 CLA on milk production in lactating dairy cows.

Natalie L. Urrutia*, Michel Baldin, Jackie Y. Ying, and Kevin J. Harvatine, *The Pennsylvania State University, University Park, PA.*

During CLA-induced milk fat depression (MFD) acetate and glucose are spared from milk fat synthesis and are available for other metabolic uses. Acetate is the major carbon source spared and although acetate deficiency does not cause milk fat depression the effect of acetate supply on lactation and the effect of spared acetate during MFD is not clear. The objective of this study was to compare the effect of CLA and acetate equivalent to that spared during MFD on milk production. Nine multiparous, lactating, ruminally cannulated Holstein cows (244 ± 107 DIM; mean ± SD) were randomly assigned to treatments in a 3 × 3 Latin square design. Experimental periods were 14 d in length and included 4 d for treatment and 10 d for washout period. Cows received the following treatments: control (CON), acetate [ACE; continuous infusion of 7 *M*/d acetate pH 6.1 (rumen)], or CLA [10 g/d *trans*-10,*cis*-12 CLA (abomasal)]. Milk samples were collected on the last 2 d of treatment for determination of fat, lactose and protein concentration, and milk fatty acid profile. Data were analyzed using the fit model procedure of JMP Pro. The model included the random effects of cow nested in sequence, sequence and period and the fixed effect of treatment. Dry matter intake, protein and lactose yield and percentage were not affected by treatments. Milk yield tended to be increased 11% in ACE ($P = 0.09$) compared with CON (22.8, 23.4 and 25.4 kg/d for CON, CLA and ACE, respectively). Milk fat yield increased 20% in ACE ($P = 0.04$) and decreased 23% in CLA ($P < 0.02$) and milk fat percent was decreased 30% by CLA ($P < 0.001$), but was not affected by ACE compared with CON. Concentration and yield of de novo FA ($P < 0.001$), while concentration of preformed FA (>C16) was increased by CLA ($P < 0.001$), compared with CON. Yield of de novo FA, palmitic acid and total C16 FA was increased by ACE ($P < 0.05$ for all) and concentration of palmitic acid was higher ($P < 0.05$) in ACE, compared with CON. In conclusion, acetate supply has an effect on milk production and milk fat synthesis, and spared acetate during MFD may improve energy status.

Key Words: acetate, CLA, milk fat synthesis

M395 Exogenous fibrolytic enzyme in dairy cows diets: Milk yield and composition.

Thiago Henrique da Silva*[1], Caio Seiti Takyia[1], Thiago Henrique Anibale Vendramini[1], Filipe Zanferari[1], Elmeson Ferreira de Jesus[2], and Francisco Palma Rennó[1], [1]*University of São Paulo, Pirassununga, São Paulo, Brazil,* [2]*São Paulo State University, Jaboticabal, São Paulo, Brazil.*

Exogenous fibrolytic enzymes can be a feature to improve fiber digestion and performance of dairy cows. This study was aimed to evaluate the effect of exogenous fibrolytic enzymes on milk yield and composition. Twenty-four Holstein cows (180.2 ± 54.3 DIM; 662.6 ± 88.2 kg BW) were assigned in a replicated 4 × 4 Latin square design, with 21-d periods. Dietary treatments were: 0 (control), 8 (low), 16 (middle) and 24 (high) g of enzyme/cow/day (Fibrozyme, Alltech Inc., Nicholasville, KY) of total mixed ration based on corn silage. Milk yield was recorded by a computer twice daily at 0600 and 1600 h. Milk sample was collected proportionately to a.m. and p.m. milking, and analyzed for fat, protein and lactose by near infrared reflectance spectroscopy. Data were subjected to ANOVA and simple polynomial regression using the SAS software, version 9.0. There was no effect of fibrolytic enzyme supplementation on milk yield (30.24 vs. 30.22 vs. 30.52 vs. 29.89 kg/d) and 3.5% fat-corrected milk (FCM) yield (30.96 vs. 31.70 vs. 31.33 vs. 30.71 kg of 3.5% FCM/d) for control, low, middle and high supplementation, respectively. Also, milk composition was not affected ($P > 0.05$) by enzyme supplementation just like yield fat, protein and lactose. A possible explanation for these results is that animals were not with energy challenge. Results of present study indicated that the use of exogenous fibrolytic enzymes did not improve performance of mid-lactation dairy cows.

Key Words: digestion, fiber, energy

M396 Milk urea:allantoin ratio is a useful marker of efficiency of protein utilization in dairy cows.

Pieter J. M. Raedts*, Devin A. Benheim, Ashlee J. Hammond, Jargal Menghe, and Markandeya Jois, *La Trobe University, Melbourne, Australia.*

Dietary protein is extensively degraded in the rumen into ammonia some of which which is in turn used by rumen bacteria to synthesize microbial protein. Excess ammonia is converted to urea in the liver and excreted in urine and milk. Microbial protein (MCP) is digested and absorbed as amino acids and nucleic acids. Nucleic acids are degraded in the liver into allantoin and excreted in the urine and milk. The ratio of urea to allantoin therefore is an indicator of efficiency of utilization of protein in the feed. Our aim was to investigate the efficiency of protein utilization by determining the urea:allantoin ratio in the milk of cows in the 1, 2, 3 and 6+ months of lactation. Herd test milk was collected from 44 Holstein Friesian (HF) and HF-Jersey cross cows (HF 75% to 100%) on a commercial dairy herd in Northern Victoria, Australia. The herd consisted of 2 cohorts, one in early lactation and one in the second half of lactation. All cows in the herd were offered the same ration (flat-feeding), consisting of approximately one-third of DM as concentrate and two-thirds of DM as grass based forage. Part of the forage was grazed pasture consisting predominantly of perennial English ryegrass (*Lolium perenne*) with a scattering of clover and some weeds. The milk was analyzed for urea concentration by an enzymatic method. Allantoin concentration was determined using high performance liquid chromatography. The MUN:MAC ratio was significantly different ($P < 0.05$) between cows in 1st month of lactation (27.92 ± 2.28) and cows in 2nd, 3rd or 6+ months in lactation (34.84 ± 1.68, 43.89 ± 5.35, 45.60 ± 3.42, respectively). This ratio was also significantly different ($P < 0.05$) between cows in 2nd month of lactation and 6+ months of lactation. Cows in the first month of lactation had a significantly higher MAC and lower MUN ($P < 0.05$) than cows 3 or more months in lactation. These results indicate that cows in early lactation are more efficient in the utilization of dietary protein

Key Words: milk, urea, MUN

M397 Use of chloride concentration to identify ration sorting by dairy cattle.

Heidi Rossow*, *University of California, Davis, Davis, CA.*

Currently differences in proportions of particle sizes between the ration fed and the residual ration indicates if dairy cattle are sorting their feed. However, results using the Penn State Particle Sorter (PSPS) can be variable depending on the dry matter of the ration and how vigorously and consistently PSPS is shaken for each sample. Examining differences in chloride concentration (CC) of the ration between the ration fed and residual ration may be an easier and more accurate method to assess ration sorting by dairy cattle. Therefore, the objective of this study is to examine if CC in the ration fed compared with the residual ration could also be used to assess ration sorting by dairy cattle. Ten samples each of the ration fed and the residual ration were collected from 2 pens, including cows close to calving and cows 30–200 d in milk, from 5 dairies in Tulare County CA. Total CC, and CC from each tray of the PSPS was measured by soaking 30 g of sample in 200 mL of de-ionized water for 2 h and then measuring CC using an Oakton waterproof SaltTestr meter (Oakton Instruments, Vernon Hills IL) with a range of 0 to 1% chloride. Overall CC increased with decreasing particle size with means (standard deviations) of CC of 0.195% (0.048), 0.254% (0.041), 0.264% (0.055) and 0.277% (0.080) for top, middle, screen and bottom trays of the PSPS, respectively. Statistics were performed using Proc GLM (SAS Institute, 2013) with CC and PSPS % from each tray regressed on sample type (ration fed or residual ration) for each dairy and pen and if different ($P < 0.05$), then the ration was sorted. For 8 pens representing 4 dairies, results for sorting (fed vs residual) were consistent between PSPS and CC. However for 1 dairy (2 pens), CC indicated sorting and PSPS did not. Therefore, results from CC and PSPS indicate that CC maybe an equivalent method to identify ration sorting but more research needs to be done to determine why results were not consistent on 1 dairy.

Key Words: chloride concentration, ration sorting, Penn State particle sorter

M398 Pre- and postweaning performance of nursery calves offered texturized calf starters with varying protein levels for 56 days.

Bruce Ziegler*[1], David Ziegler[2], Hugh Chester-Jones[2], Daniel Schimek[1], and Sarah Schuling[1], [1]*Hubbard Feeds, Inc., Mankato, MN,* [2]*University of Minnesota Southern Research and Outreach Center, Waseca, MN.*

One hundred and four (2 to 5 d old) individually fed Holstein heifer calves (39.5 ± 0.69 kg BW) were randomly assigned to 1 of 4 treatments to evaluate pre- (d 1–42) and postweaning (d 43–56) calf performance when fed texturized calf starters varying in crude protein (CP) level. Texturized calf starter (CS) treatments were 1) 15% CP; 2) 18% CP; 3) 21% CP, and 4) 24% CP, as-fed. All calves were fed 0.28 kg of milk replacer (MR; 20% protein:20%fat) in 1.99 L water twice daily for the first 35 d and once daily from d 36 to 42. From d 1 to 14, 1:1 neomycin:oxytetracycline was added to the MR solution to provide 22 mg/kg BW/d. Calf starter and water were fed free choice throughout the trial. Linear (L) and quadratic (Q) contrasts were used to differentiate effects of CS CP level on growth performance. There were no differences among treatments in average daily gain pre- or postweaning. There was a Q effect of treatment on daily gain for d 1 to 56 ($P < 0.01$). Daily gains were 0.71, 0.76, 0.76, and 0.70 kg for the 15%, 18%, 21% and 24% CP CS treatment, respectively. There was a Q effect for hip height gain ($P = 0.02$). Hip height gains were 10.2, 11.1, 11.0 and 9.9 cm for the 15%, 18%, 21% and 24% treatments, respectively. Preweaning CS intake was similar across treatments. Postweaning CS intake linearly decreased with increasing CP levels, d 43 to 56 ($P < 0.01$) and overall ($P < 0.03$). Preweaning gain/feed increased with CS CP level up to 21% CP then decreased (Q; $P = 0.04$). A similar overall 56 d response in gain/feed occurred (Q; $P = 0.05$). Gain/feed d 1 to 56 was 0.53, 0.55, 0.56, and 0.55 kg for 15%, 18%, 21% and 24% CP treatments, respectively. Fecal scores, scouring days and treatment costs were similar among treatments. b-Hydroxybutyrate levels at 42 d were the lowest in calves fed the 15% CP CS. Calf starter intake decreased with increasing CP levels but did not directly relate to calf performance. Under the conditions of this stud, there was no benefit of feeding CS CP levels above 21%.

Key Words: calf performance, calf starter, crude protein

M399 Pre- and postweaning performance and health of dairy calves fed milk replacers vs. pasteurized waste milk.

David Ziegler*[1], Hugh Chester-Jones[1], David Cook[2], and Julian Olson[2], [1]*University of Minnesota Southern Research and Outreach Center, Waseca, MN,* [2]*Milk Products, Chilton, WI.*

The objectives of this study were to compare pre- (d 1 to 49) and post weaning (d 50 to 56) performance of calves fed a milk replacer (MR) formulated with similar crude protein (CP) and fat (F) concentrations to pasteurized waste milk (PWM) and a combination of PWM and a low (F) and high CP MR. One hundred and five (2 to 5 d old) individually fed Holstein heifer calves (38.8 ± 0.73 kg) were randomly assigned to 1 of 4 milk treatments. Milk treatments included 1) all-milk, non-medicated MR 20% CP: 20% F fed at 0.34 kg in 2.38 L of water 2x daily from d 1 to 42 and 1x daily from d 43 to weaning at d 49 (CON); 2) all-milk, non-medicated MR 26% CP: 31% F supplemented with additional fatty acids fed as in CON (MRS); 3) pasteurized waste milk 28.4% CP: 30.1% F fed as in CON, feeding rate was adjusted daily based on measured solids (PWM); 4) PWM fed 2× daily with 0.22 kg solids supplemented with 0.12 kg of an all milk non-medicated 24% CP: 7% F MR as in CON, adjusted for solids as in PWM (WMS). Calf starter (CS;18%CP) and water were fed free choice d 1 to 56. Waste milk was collected twice a week from one farm then sampled, cooled, and pasteurized before each feeding. Calves fed PWM and WMS avg. 0.85 kg/d gain vs. 0.72 kg/d for calves fed CON and MRS ($P < 0.05$) for the 56 d study. Hip height gain avg.13 cm for PWM and WMS vs.11 cm for CON and MRS ($P < 0.05$). There were no differences in intake of milk solids, avg. 29.7 kg for 49 d. Intake of CS, d 1 to 56, was highest for WMS (48.2 kg) with CON and PWM being intermediate (avg. 38.2 kg) and MRS the lowest (31.9 kg; $P < 0.05$). Gain/feed was highest ($P < 0.05$) for PWM (0.69 kg) with MRS (0.65 kg) being intermediate and CON and WMS the lowest ($P < 0.05$; avg. 0.64 kg).There were no differences in daily fecal scores across treatments. Days with fecal scores = 4 and health costs were higher ($P < 0.05$) for MRS vs. CON, PWM and WMS. From d 57 to d 84 there were no differences in ADG across treatments. Under conditions of this study calves fed WMS had greater CS intake than CON, MRS and PWM. Calves fed MRS did not enhance performance over CON.

Key Words: calf performance, milk replacer, pasteurized waste milk.

M400 Evaluation of the effects of direct-fed microbials, microbial fermentation products, and digestive enzymes on milk yield and milk components in dairy cattle in the tropics. Karen Espino-Mercado, Coral Castillo-Caballero, Jaime Curbelo-Rodríguez, and Guillermo Ortiz-Colón*, *University of Puerto Rico at Mayaguez, Mayaguez, PR, Puerto Rico.*

The effect of direct-fed microbials, fermentation products (FP) and digestive enzymes on milk yield and milk composition was evaluated in dairy cattle. Lactating Holstein dairy cows (n = 40) from a commercial dairy herd were divided in 4 groups (n = 10 each) and blocked by days in milk (DIM; < 100 DIM or ≥100 ≤ 171 DIM) and balanced by parity number. Animals had a 2-week adaptation period. The balanced groups were randomly assigned to one of the following treatments: Control (C): 21g wheat middling; Treatment 1 (T1): 21g of a commercial mixture of *A. oryzae* FP, *B. subtilis* FP, *L. acidophilus* FP, yeast and amylase. Treatment 2 (T2): 18g Wheat middlings + 3g of a commercial mixture of *A. niger* FP, *A. oryzae* FP, α amylase, pectinase, endo- glucanase, β- glucanase, xylanase, and mannanase. Treatment 3 (T3): 11g Wheat middlings + 10g of a commercial mixture of *B. subtilis*, amylase and α amylase. Each treatment was top-dressed on the pelleted feed offered at the parlor during every morning milking. Milk production by cow was collected twice a day for 14 weeks using the AfiLab AfiMilk system. Milk urea nitrogen (MUN) and ketone body concentrations in milk by cow was collected once a week for 14 weeks using the Porta BHB milk ketone test and MUN was determined by the Teco Diagnostic Vet- MUN Reagent strips. There was no interaction between treatment, parity and/or period ($P > 0.10$). Average milk production (kg/cow/per day) during the experiment was C 21.4 ± 2.12; T1 19.7 ± 2.11; T2 19.8 ± 2.23; T3 21 ± 2.11 ($P > 0.05$). Average milk BHB concentration (μmol/L) per treatment was C 90.29 ± 13.08; T1 100.39 ± 12.04; T2 89.71 ± 13.12; T3 99.17 ± 12.57 ($P = 0.2121$). Treatment neither had an effect on MUN. Mean MUN (mg/dL) per treatment was C 8.42 ± 1.3; T1 8.38 ± 1.20; T2 8.58 ± 1.44; T3 8.63 ± 1.26 ($P = 0.8533$). In conclusion, in this experiment under tropical conditions, DFM, FP and digestive enzymes, resulted in no change in milk production, MUN and BHB concentrations in milk.

Key Words: direct-fed microbial, digestive enzyme, fermentation product

M401 Phosphorous excretion and digestibility in Jersey and Holstein consuming corn milling co-products. Gabriel Garcia Gomez*, Alison Foth, and Paul Kononoff, *University of Nebraska-Lincoln, Lincoln, NE.*

Excess dietary phosphorous (P) in dairy cows diet may result in increased excretion of this mineral. Additionally, P accumulation in the soil may be a result of high concentrations of P when manure is applied to cropland. The objective of this study was to evaluate P intake, digestibility and excretion when dairy cows consumed rations containing reduced fat distillers grains (RFDDGS). Data from this study originated from an energy balance study in which RFDDGS was included at 28.8% of the ration DM. In this study, corn was reduced from 22.9 to 8.95% and soybean meal was reduced from 14.8 to 0% of the ration DM in the control and co-product (Co-P) diet, respectively. The study included 8 Holstein (BW = 693.8 ± 12.9 kg) and 8 Jersey (BW = 429.1 ± 13.0kg) multiparous, lactating cows (93 ± 20 DIM) in a repeated switchback design. The concentration of P in the test treatments were 0.44% and 0.59% ± 0.01% DM for the control and Co-P diet, respectively. The intake and excretion of P was estimated through feed sampling and total collection of feces. All feed and fecal samples were analyzed for P. Concentration of P in feces was lower in control diet compared with Co-P (0.97 vs. 1.27 ± 0.05%, respectively; $P < 0.01$). Excretion of P was less for cows fed the control diet compared with the Co-P diet (62.34 vs. 89.70 ± 3.82 g/d, respectively; $P < 0.01$). The excretion of P per kg of milk yield was higher in cows fed Co-P diet compared with control diet (21.7 and 15.8 ± 1.29 g/kg, respectively; $P < 0.01$). There was no difference between Holstein and Jersey in concentration of P in the feces (1.16 vs. 1.08 ± 0.07%, respectively; $P = 0.36$), digestibility (32.3 versus 29.0 ± 2.83%, respectively; $P = 0.40$) and P efficiency (19.4 vs. 18.0 ± 1.63g/kg, respectively; $P = 0.55$) across treatments. Results of this study suggest that rations formulated containing RFDDGS should be adjusted for P to reduce P excretion by dairy cows.

Key Words: phosphorus, excretion, digestibility

M402 Variability in diets of lactating dairy herds . Maria P. Turiello*[1], Marco Sambataro[1], Agustin Turiello[1], Claudina Vissio[1], and Alejandro Relling[2,3], [1]*Universidad Nacional de Rio Cuarto, Facultad de Agronomia y Veterinaria, Cordoba, Argentina,* [2]*Universidad Nacional de La Plata, Facultad de Ciencias Veterinarias, Buenos Aires, Argentina,* [3]*IGEVET CCT CONICET, Buenos Aires, Argentina.*

The objective of this study was to determine daily ration and feed bunk variability in physical composition of TMR offered to lactating cows in dairy herds. Four commercial herds (12 pens) in the south of Cordoba province, Argentina, were visited during 3 consecutive days on February. Fresh TMR offered in the morning was sampled to assess particle size distribution with a Penn State Particle Separator. Two samples were taken at the beginning and 2 at the end of the feed bunk to determine TMR variability for each wagon. Daily ration variability was expressed as CV, and calculated by dividing the SD of each particle length % over the 3 d period by the average of them over the same period. The effect of place at the feed bunk on particle size distribution was analyzed with linearized mixed models using the mixed procedure of InfoStat. Place at the feed bunk (beginning vs end) was included as a fix effect. Herd and mixer wagon within herd were included in the model as random effects. The greatest daily CV was found with long and fine particles (17.4 and 17.6% respectively) but all of them where greater than 8%. We observed a great variability and a significant difference between places of TMR samples in the short particle size sieve (Table 1). These results may be indicating heterogeneity on the feed delivered due to procedures of loading and mixing the TMR. It is very important to determine factors of management and infrastructure associated with variability of TMR to improve consistency and then to increase profitability of dairy farms.

Table 1 (Abstr. M402). Distribution (mean ± SD) of particles

	Mixer wagon		
Particles (%)	Beginning	End	*P*-value
Long	17.0 ± 2.84	17.6 ± 2.85	0.52
Medium	34.8 ± 3.80	34.1 ± 3.80	0.34
Short	35.7 ± 2.01	34.4 ± 2.01	0.05
Fine	12.5 ± 2.16	13.9 ± 2.16	0.11

Key Words: TMR variability, particle size distribution

M403 Mineral blood serum status of Holstein cows during the warm and cold seasons.

Pedro Meda-Alducin*, Maximino Huerta-Bravo, Gustavo De la Torre-López, Baldomero Alarcón-Zúñiga, and Raymundo Rangel-Santos, *Posgrado en Producción Animal, Departamento de Zootecnia, Universidad Autónoma Chapingo, Texcoco, México.*

Heat stress decreases productive and reproductive performance of dairy cows, and it may be related to mineral status. The aim was to quantify serum concentrations of Cu, Zn, Fe, Ca, Mg and K in Holstein cows during warm (WS, ITH = 72) and cold seasons (CS, ITH = 56). Cows (n = 240) with 2 to 6 lactations and 30–60 DIM, milked 3 times per day were selected from 3 commercial dairy farms (F1-F3) in an arid zone of México. Cows were fed similar diets during both seasons, within farm, with a total mixed ration (corn silage, flaked corn, soybean meal, wheat bran, concentrated, alfalfa and wheat hay, molasses and minerals, according to NRC (2001) requirements. Blood samples were obtained from coccygeal vein with Vacutainer tubes, serum was separated by centrifugation at 3000 rpm during 15 min, and stored at −20°C until their analysis. Mineral content was quantified using an atomic absorption spectrophotometer. Data were analyzed using a lineal model with a 2x3 season x farm arrangement. The interaction season x farm effected ($P < 0.001$) all minerals studied. Concentrations of Cu, Zn, K and Mg in blood serum of cows were not dependent on season. However, Fe was higher ($P < 0.05$) during CS compared with WS in the cows from the 3 farms, while the reverse was true for Ca. Overall, Cu, Zn, Fe, Ca, Mg and K concentrations in blood serum were below the normal range in 65, 35, 26, 0, 35 and 38% of cows during the WS, while corresponding values during the CS were 42, 45, 4, 40, 52 and 38%.It is concluded that the dairy cows studied have several mineral problems that depend more of the interaction season × farm than season. It is recommended to study water quality.

Table 1 (Abstr. M403). Means of minerals (mg/L) in blood serum of Holstein cows in warm and cold seasons

		Mineral (mg/L)					
Season	Farm	Cu	Zn	Fe	Ca	Mg	K
Warm	1	0.92^{a}	0.94^{a}	1.60^{c}	105.53^{a}	18.23^{b}	173.58^{c}
Cold	1	0.84^{a}	0.69^{a}	1.97^{b}	94.95^{b}	20.30^{a}	234.81^{a}
Warm	2	0.77^{b}	0.80^{a}	1.68^{c}	108.38^{a}	19.02^{b}	194.11^{b}
Cold	2	0.78^{b}	0.92^{a}	2.01^{b}	60.27^{c}	10.96^{c}	128.62^{d}
Warm	3	0.68^{c}	0.87^{a}	1.55^{c}	112.64^{a}	20.49^{a}	126.81^{d}
Cold	3	0.88^{a}	0.89^{a}	2.64^{a}	89.16^{b}	18.36^{b}	222.67^{a}
$P > F$		<0.001	<0.001	<0.001	<0.001	<0.001	<0.001
SEM[1]		0.03	0.08	0.08	1.83	0.33	3.88

Key Words: mineral diagnosis, heat stress, Holstein cows

M404 Effects of rumen-protected methionine or choline supplementation on vaginal discharge and uterine cytology of Holstein cows.

Cassandra S. Skenandore*[1], Diego A. Velasco Acosta1,2, Zheng Zhou[1], Maria I. Rivelli[1], Marcio N. Corrêa[2], Daniel Luchini[3], and Felipe C. Cardoso[1], *[1]University of Illinois, Urbana, IL, [2]Federal University of Pelotas, Pelotas, Brazil, [3]Adisseo S.A.S., Alpharetta, GA.*

Fertility in dairy cows has been declining in recent years. Supplementation with methionine has been shown to improve reproductive health. Seventy-one pregnant Holstein cows entering their 2nd or greater lactation were fed the same basal diet and randomly assigned to 4 treatments from 21 d before calving to 30 DIM. From −21 d to calving cows were fed a close-up diet. From calving to 30 DIM cows were fed a fresh cow diet, and from 30 to 72 DIM a high cow diet. Treatments were: CON (n = 16, fed the basal diets with a Lys:Met = 3.5:1), MET (n = 20, fed the basal diets + Smartamine M to a Lys:Met = 2.9:1), CHO (n = 16, fed the basal diets + 60 g/d Reashure), and MIX (n = 19; fed the basal diets plus Smartamine M to a Lys:Met = 2.9:1 and 60 g/d Reashure). Starting at d 31 cows were randomly re-assigned to 2 treatments: (CON; n = 36, fed the basal diet with a Lys:Met = 3.4:1) or (SM; n = 36, fed the basal diet + Smartamine M to a Lys:Met = 2.9:1). Cows were evaluated at 4, 7, 10, 13, 15, 17, and 30 d after calving for the presence of secretion by inserting the Metricheck device into the cow's vagina. Sample appearance was scored from 0 to 3 and smell was scored 0 or 3 according to Sheldon et al. (2006), and combined in a final score (S). On 15, 30, and 72 d after calving, the uterine endometrium of all cows was sampled using an endocervical brush (cyto-brush) and streaked onto slides. Each slide was examined and counted by the same person for the presence of endometrial polymorphonuclear (PMN) cells. Statistical analysis was performed using the MIXED procedure of SAS. There was no treatment effect ($P = 0.16$) for S up to 17 DIM. Cows receiving MIX had a lower (0.38 ± 0.3, $P = 0.03$) S at 30 DIM than CON (1.15 ± 0.3), MET (1.08 ± 0.4), or CHO (2.11 ± 0.4). There were no treatment differences ($P = 0.93$) for the percentage of PMN cells at 15 or 30 DIM. At 72 DIM, cows in SM had lower (5.33 ± 3.6%, $P = 0.01$) PMN cells than CON (10.17 ± 3.6%). In conclusion, supplementing cows with Smartamine M after 30 DIM seems to have beneficial effect on cows' uterine health.

Key Words: methionine, endometritis, PMN

M405 Milk yield and composition in cows fed calcium salts of polyunsaturated fatty acids of different particle sizes.

Maxime Leduc*[1,2], Rachel Gervais[1], Yolaine Lebeuf[1,2], and P. Yvan Chouinard[1,2], *[1]Université Laval, Québec, QC, Canada, [2]Institue of Nutrition and Functional Foods, Québec, QC, Canada.*

Feeding unsaturated fatty acids (FA) as Ca salts (CS) has been proposed as a way to protect ruminal microbes from the adverse effects of dietary oils. However, ruminal dissociation of CS may limit the efficiency of this protection. Industrial processes used to obtain CS of FA lead to the production of commercial feeds with a range of different particle sizes. We hypothesized that feeding CS as large particles will improve their inertness in the rumen and improve animal performance. CS of unsaturated FA were obtained from Virtus Nutrition LLC (Corcoran, CA). On a FA basis, the preparation contained 22.4% 18:1 n-9, 14.7% 18:2 n-6, 31.9% 18:3 n-3. The product was sieved through a 1.9-mm screen, and the retained particles were identified as coarse CS (CCS). The small particles were ground through a 0.864-mm sieve, and identified as fine CS (FCS). A mixture of unprotected FA, as triglycerides, with a composition similar to that of the CS served as control. Eight Holstein cows were used in a 4 × 4 Latin square design. Treatments were: 1) ruminal dosing of unprotected FA (negative control; N-CTL); 2) ruminal dosing of FCS; 3) ruminal dosing of CCS; and 4) abomasal dosing of unprotected FA (positive control; P-CTL). Treatments were adjusted to provide 600 g FA per day, and were offered daily in 2 equal boluses for 14 d, followed by 14-d washout intervals. Pre-planned contrasts were used to compare CCS with i) N-CTL; ii) FCS; and iii) P-CTL. Milk yield was 30.0 kg/d for CCS, and was similar in cows fed N-CTL (29.4 kg/d; $P = 0.70$) or FCS (29.6 kg/d; $P = 0.82$), and lower in cows fed P-CTL (25.8 kg/d; $P = 0.01$). Milk fat content was 3.48% for CCS, and was lower in milk from cows fed N-CTL (3.01%; $P < 0.01$) or FCS

(3.15%; $P = 0.03$), and higher in milk from cows fed P-CTL (3.84%; $P < 0.01$). Concentrations of trans-10, cis-12 18:2 in milk was 0.41 mg/g of fat for CCS, and was higher for N-CTL (0.69 mg/g; $P < 0.01$) or FCS (0.69 mg/g; $P < 0.01$), and was similar for P-CTL (0.35 mg/g; $P = 0.29$). In conclusion, feeding CCS prevented ruminal production of trans-10, cis-12 18:2 and maintained a higher milk fat content as compared with unprotected FA or FCS.

Key Words: dairy cow, Ca salt, fatty acid

M406 Using the NRC (2001) model to examine the relationships between predicted supplies of metabolizable Met and Lys and actual yields of milk and milk protein: A subject revisited.

Nancy L. Whitehouse*[1], Andre F. Brito[1], Charles G. Schwab[2], and Brian K. Sloan[3], *[1]University of New Hampshire, Durham, NH, [2]Schwab Consulting, LLC, Boscobel, WI, [3]Adisseo, Alpharetta, GA.*

We previously reported relationships between predicted supplies of MP, MP-Met, and MP-Lys (NRC, 2001) and yields of milk and milk protein. The original database consisted of model evaluations of 464 diet treatments from experiments published in the *Journal of Dairy Science* (JDS) from 1976 through 2003. Results indicated yields of milk and milk protein were more accurately predicted by supplies of the first limiting AA rather than by supplies of MP. To establish a more robust database, an additional 550 diet treatments from experiments published in JDS in 2004–2014 were evaluated. For the current analysis, the following criteria were imposed: NE_L allowable milk ≥ MP allowable milk, MP allowable milk within ± 6 kg of actual milk yield, MP balance between −250 to 100 g/d, Lys ≤7.2% of MP, and Met ≤2.4 of MP. To develop the regression equations for MP-Met, and to help ensure that Met was more limiting than Lys, the Lys/Met ratio in MP had to be ≥3.20/1. To generate the regression equations for MP-Lys, the Lys/Met ratio in MP had to be ≤3.15/1. It was preferred this ratio be ≤3.00/1, but that was too restrictive for the available data set. The PROC REG procedure of SAS was used to generate the regression equations. The resulting regression equations describe the relationship between measured milk yields and MP, MP-Met and MP-Lys supplies: MP (n = 455): $y = 0.01397x + 1.76875$, $R^2 = 0.74$; MP-Met (n = 260): $y = 0.84054x - 1.18403$, $R^2 = 0.78$; and MP-Lys (n = 29): $y = 0.25722x - 1.48198$, $R^2 = 0.70$. The equations describing the relationship between milk protein yields and MP, MP-Met and MP-Lys were MP (n = 455): $y = 0.47131x - 67.02527$, $R^2 = 0.82$; MP-Met (n = 260): $y = 28.47206x - 178.08057$, $R^2 = 0.86$; and MP-Lys (n = 29): $y = 9.07155x - 217.19663$, $R^2 = 0.85$. In contrast to the previous equations, these are linear in nature and biologically more correct. We conclude these updated Met and Lys regression equations more accurately predict relationships between MP-Met and Lys supplies and milk and milk protein yields, and can be used by NRC users to determine if milk and milk protein yields are potentially being limited by these 2 AA.

Key Words: methionine, lysine

M407 Milk fatty acid profile in cows fed calcium salts of polyunsaturated fatty acids of different particle sizes.

Maxime Leduc[1,2], Rachel Gervais*[1], Yolaine Lebeuf[1,2], and P. Yvan Chouinard[1,2], *[1]Université Laval, Québec, QC, Canada, [2]Institue of Nutrition and Functional Foods, Québec, QC, Canada.*

Feeding unsaturated fatty acids (FA) as Ca salts has been proposed as a way to protect them against ruminal biohydrogenation. However, dissociation of Ca salts in the rumen limits the efficiency of this protection. Industrial processes used to obtain Ca salts of FA lead to the production of commercial feeds with a range of different particle sizes. We hypothesized that unsaturated FA in large particles are physically protected against ruminal biohydrogenation. Calcium salts of polyunsaturated FA were obtained from Virtus Nutrition LLC (Corcoran, CA). On a FA basis, the preparation contained 22.4% 18:1n-9, 14.7% 18:2n-6, 31.9% 18:3n-3. The product was sieved through a 1.9-mm screen. The retained particles were saved, and identified as coarse Ca salts. The particles less than 1.9-mm were ground through a 0.864-mm sieve, and identified as fine Ca salts. A mixture of unprotected FA, as triglycerides, with a composition similar to that of the Ca-salts served as control. Eight Holstein cows were used in a 4 × 4 Latin square design. Treatments were N-CTL) ruminal dosing of unprotected FA, used as negative control; FCS) ruminal dosing of fine Ca salts; CCS) ruminal dosing of coarse Ca salts; and P-CTL) abomasal dosing of unprotected FA, used as positive control. Treatments were adjusted to provide 600 g FA per day, and were offered in 2 equal boluses at 1000 and 1600h for 14 d, followed by 14-d washout intervals. Pre-planned contrasts were used to compare CCS with i) N-CTL; ii) FCS; and iii) P-CTL. Milk fat content of 18:2n-6 was 25.4 mg/g for CCS, and was lower in cows fed N-CTL (16.5 mg/g; $P = 0.01$) or FCS (15.0 mg/g; $P < 0.01$); and higher in cows fed P-CTL (35.2 mg/g; $P < 0.01$). The concentrations of 18:3n-3 in milk fat was 28.9 mg/g for CCS, and was lower in cows fed N-CTL (7.0 mg/g; $P = 0.01$) or FCS (14.6 mg/g; $P = 0.08$, tendency); and higher in cows fed P-CTL (92.2 mg/g; $P < 0.01$). In conclusion, feeding CCS appeared to have partially prevented ruminal biohydrogenation, and increased milk fat content of polyunsaturated FA as compared with dietary unprotected oil or FCS.

Key Words: dairy cow, Ca salt, unsaturated fatty acids

M408 The effect of linseed oil supplementation on rumen microbiota composition in lactating dairy cows.

H. M. Tun*[1], E. Khafipour[1], and C. Benchaar[2], *[1]Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada, [2]Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada.*

The effect of linseed oil (LO) supplementation to red clover silage (RCS)- or corn silage (CS)-based diets on rumen microbiota composition was studied in 12 rumen-cannulated lactating dairy cows in a 4 × 4 Latin square design (35-d periods) with a 2 × 2 factorial arrangement of treatments. Rumen liquid and solid samples were collected on d 18 of each period. DNA was extracted and V4 region of 16S rRNA was amplified and subjected to illumina paired-end sequencing. In both rumen liquid and solids, the LO supplementation reduced bacterial α-diversity in CS-based diet but not in RCS ($P < 0.05$). The LO supplementation altered the β-diversity of rumen microbiota in both CS- and RCS-based diets though the magnitude of shift was greater in CS. The LO supplementation reduced the abundances of several bacterial phyla including Actinobacteria, Chloroflexi, Fibrobacteres, Firmicutes, Plantomycetes, SR1, Spirochetes and Tenericutes, and increased the abundances of Bacterioidetes, Elusimicrobia, Lentisphaerae, Proteobacteria and Synergistetes in the CS-based diet ($P < 0.05$) but did not change the proportion of the abovementioned phyla in the RCS-based diet. The LO supplementation reduced methanogenic *Methanobrevibacters* in both diets, but the magnitude of depression found to be greater in CS compared with RCS. The LO supplementation increased *Methanosphaera* population with a greater magnitude in the CS-based diet compared with RCS ($P < 0.05$). The LO supplementation also negatively affected the proportion of several beneficial rumen bacteria including *Bifidobacteria*, *Fibrobacter* and *Mollicutes* with greater magnitude in the CS-based diet compared with RCS ($P < 0.05$). Data mechanistically explains how

LO supplementation differentially affected CH_4 emission and animal production in CS- vs. RCS-based diets observed in the parallel study to this. The LO supplementation more effectively reduced the CH_4 emission (26%) in CS vs. RCS (9%), which might be due to greater reduction in *Methanobrevibacters*. Also, LO supplementation reduced DMI, fiber digestion, and yields of milk fat and protein only in the CS-based diet, which might be due to its negative effect on fibrolytic populations.

Key Words: linseed oil, rumen microbiota, methane emission

M409 The effects of linseed oil supplementation on fecal microbiota in lactating dairy cows.

H. M. Tun*[1], E. Khafipour[1], and C. Benchaar[2], [1]*Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada,* [2]*Agriculture and Agri-Food Canada, Dairy and Swine Research and Development Centre, Sherbrooke, QC, Canada..*

The effect of linseed oil (LO) supplementation to red clover silage (RCS)- or corn silage (CS)-based diets on rumen microbiota composition was studied in 12 rumen-cannulated lactating dairy cows in a 4 × 4 Latin square design (35-d periods) with a 2 × 2 factorial arrangement of treatments. Fecal samples were collected on d 24–29 of each period and pooled. DNA was extracted and V4 region of 16S rRNA was amplified and subjected to Illumina paired-end sequencing. DNA was extracted and V4 region of 16S rRNA was amplified and subjected to illumina paired-end sequencing. The feces from cows fed RCS-based diets had greater microbial α-diversity compared with CS, but LO supplementation did not affect α-diversity of microbial community. In contrast, the LO supplementation altered the β-diversity of fecal microbota only in the CS-based diet ($P = 0.001$). Among 17 bacteria phyla found in fecal samples, the LO supplementation reduced both Actinobacteria and Bacteroidetes populations and increased Fimicutes under the CS-based diet ($P < 0.05$). However, under the RCS-based diet, the LO supplementation showed no significant effect on any of bacterial phyla. In CS-based fed cows, LO supplementation suppressed abundances of 2 genera from Bacteriodales family, unclassified RF16 and unclassified Rikenellaceae, as well as the genus SHD231 in Anaerolinaceae family ($P < 0.05$). The 16S rRNA sequencing generated taxa belonged to Euryarchaeota in which no archaeal genera were found to be associated with LO supplementation. Data suggest that LO supplementation only affected fecal microbiota in the CS-based diet and that the source of the basal forage diet influences the effectiveness of LO supplementation and composition of microbiota even in the hindgut of dairy cows.

Key Words: linseed oil, fecal microbiota, methane emission

M410 Effects of acetate, and propionate infusion and pH on VFA production.

Sandip Ghimire*[1], Benjamin A. Wenner[2], Richard A. Kohn[3], Jeffrey L. Firkins[2], and Mark D. Hanigan[1], [1]*Virginia Polytechnic Institute and State University, Blacksburg, VA,* [2]*The Ohio State University, Columbus, OH,* [3]*The University of Maryland, College Park, MD.*

Four continuous culture fermenters were used to determine the effect of varying VFA concentrations and pH on VFA production. The treatments were applied in the fermenters over 4 periods in a 4 × 4 Latin square design. The 4 treatments were: control, 20 mmol/d acetate infusion (INFAC), 7 mmol/d propionate infusion (INFPR), and low pH (LOWPH). For the LOWPH, buffer composition was adjusted to lower pH by 0.5 units compared with control (ranging from 6.62 to 6.97). The fermenters were fed 40 g of a pelleted 50:50 alfalfa: concentrate diet once daily. After 7 d of adjustment, filtered liquid effluent (4 mL) was sampled at 0, 2, 4, 6, 8, 12, 16, and 22 h after feeding for VFA concentration analysis. Acetate and butyrate production were not affected by treatments. Production of propionate was higher in LOWPH ($P < 0.05$) compared with control and INFPR (Table 1). The hourly production of propionate was not different between treatments ($P > 0.1$) except at 2 h when it was higher in LOWPH compared with INFPR ($P > 0.05$). The acetate to propionate ratio (AP ratio) in INFPR was higher than other treatments ($P < 0.05$). The AP ratio of LOWPH was lower than control. These results reveal that propionate production was increased by low pH, and higher concentration of propionate increased the AP ratio in continuous culture, thus affecting VFA recycling.

Table 1 (Abstr. M410). Effect of acetate infusion, propionate infusion, and low pH on VFA production[1]

VFA (mmol/d)	INFAC	INFPR	LOWPH	Control	SE	*P*-value
Acetate	88	93	89	91	5.2	0.56
Propionate	34.7^{ab}	30.8^{b}	38.4^{a}	33.4^{b}	1.8	0.01
Butyrate	15.3	15.4	14.1	14.7	0.9	0.12
Acetate: Propionate	2.55^{ac}	3.03^{a}	2.32^{c}	2.73^{b}	0.1	<0.01

[1] Production was calculated after subtracting infused VFA from entry rate.

Key Words: fermenter, VFA, pH

M411 Effect of linseed meal on animal performance and oxidative stability of omega 3 enriched milk in Holstein dairy cows.

Daniel E. Rico*, Rachel Gervais, Lauriane Schwebel, Yolaine Lebeuf, and Yvan Chouinard, *Département de Sciences Animales, Université Laval, Quebec, QC, Canada.*

Linseed meal antioxidants could help prevent oxidative degradation of omega-3 enriched milk. Six Holstein dairy cows (120 ± 30 DIM, 36.3 ± 6.5 kg milk/d; Mean ± SD) were used in a replicated 3 × 3 Latin Square design (20-d periods; 14 d of adaptation) investigating the effect of linseed meal on animal performance and oxidative stability of omega-3 enriched milk. Linseed oil was abomasally infused continuously to all cows at 243 ± 23 g/d, and dietary treatments were: 1) Linseed meal (16.5% of DM; LS), Canola meal (16.5% of DM) + 7000 units of vitamin E/kg DM (VE), Canola meal (16.5% of DM; CON). Milk yield was recorded and sampled for composition analyses on the last 3 d of each period. Oxidation measurements were done in fresh milk collected on d 17. Data were analyzed using the MIXED procedure of SAS (SAS 9.3, The SAS institute, Cary, NY) including the random effects of period and cow, and the fixed effects of square and treatment. Preplanned contrasts were CON vs. LS and VE vs. LS. Milk yield and fat corrected milk were not affected by treatment and averaged 34.2 ± 2.3 and 32.8 ± 2.3 (mean ± SE), respectively. Milk fat concentration tended to be lower in LS (3.76%) relative to CON (4.00%; $P = 0.06$), but was no different from VE (3.73%). Milk protein concentration was higher in LS (3.38%) compared with CON (3.30% $P = 0.01$), and was not different from VE (3.38%). The concentration of lactose and the yields of fat, protei, and lactose were not different among treatments. The concentration of C18:3 n-3 was not affected by treatment and averaged 5.1 ± 0.79% of total milk fatty acids. Treatments had no effect on the concentration of dissolved oxygen, redox potential or conjugated diene hydroperoxides of fresh milk, which averaged 5.5 ± 0.17 mg/L of milk, 148.5 ± 24.1 mV and 0.92 ± 0.06 mmol/L, respectively. However, VE reduced milk concentrations of the volatile lipid oxidation products propanal, hexanal, and 1-octen-3-one by >73% ($P < 0.05$) and tended to reduce hept-*cis*-4-enal concentrations by 90% ($P = 0.06$) relative to

LS, whereas there were no differences between LS and CON. Vitamin E may help prevent oxidative degradation of milk moderately enriched in omega-3, whereas linseed meal has no effect.

Key Words: dairy cow, omega-3, linseed meal.

M412 Effect of potassium carbonate and soybean oil supplementation on lactational performance in early-lactating dairy cows fed a high-concentrate diet.

A. Rene Alfonso Avila*[1], Edith Charbonneau[1], P. Yvan Chouinard[1], Gaëtan F. Tremblay[2], and Rachel Gervais[1], [1]*Université Laval, Quebec, QC, Canada,* [2]*Agriculture and Agri-Food Canada, Quebec, QC, Canada.*

Research suggests that the decrease in milk fat synthesis observed in dairy cows fed rations high in concentrates or supplemented with vegetable oils could be prevented by increasing dietary cation-anion difference (DCAD) and/or potassium supply. The objective of this study was to evaluate the effect of potassium carbonate (K_2CO_3) on lactational performance of early-lactating dairy cows fed diet supplemented with soybean oil (SBO). Eight primiparous and 20 multiparous Holstein cows averaging 39 ± 9 DIM (Mean ± SD) were used in a randomized complete block design (7 blocks) based on DIM and number of calving with a 2 × 2 factorial arrangement of treatments. Within each block, cows were fed a basal diet formulated to achieve 40% forage (58% corn silage) and 60% concentrate (47% non-fibrous carbohydrates), with 0 (DCAD: +95 mEq/kg) or 1.5% K_2CO_3 (DM basis; DCAD: +316 mEq/kg), and 0 or 2% SBO. Effects of K_2CO_3, SBO and their interaction were evaluated. Treatment period was 28 d in length, plus 1 wk pretreatment collection period, used as covariate and the last 5 d used for data and sample collection. Dry matter intake was not affected by treatments (24.8 ± 1.2 kg/d; $P = 0.56$), but milk yield was increased when SBO was added to the diet (41.8. vs 38.6 kg/d; $P = 0.01$). Milk protein content was decreased by SBO (3.02% vs. 3.23%; $P = 0.01$), but a similar milk protein yield was observed among treatments (1.26 ± 0.01 kg/d; $P = 0.19$). Milk fat percentage (3.30 ± 0.07%; $P = 0.21$) was not affected by treatments. Feeding SBO tended to decrease milk fat yield, exclusively when cows were fed a diet without K_2CO_3 (0% K_2CO_3: 1.26 vs. 1.33 kg/d, 1.5% K_2CO_3: 1.31 vs. 1.34 kg/d; interaction: $P = 0.09$). 4% fat-corrected milk was increased with K_2CO_3 supplementation in cows fed SBO diets (37.4 vs. 35.0 kg/d), whereas the opposite effect was observed for cows receiving diets without SBO (35.4 vs. 36.9 kg/d; interaction: $P = 0.06$). Milk urea nitrogen was decreased by SBO (14.2 vs. 16.2 mg/dL; $P = 0.03$) and K_2CO_3 (13.9 vs. 16.5 mg/dL; $P = 0.01$). In conclusion, the effect of K_2CO_3 on milk production and composition is affected by dietary unsaturated fatty acid supplementation.

Key Words: DCAD, milk fat synthesis, potassium carbonate

M413 Ratio between plasma sphingolipids reveals acyl-chain specific changes during the transition from pregnancy to lactation in Holstein cows.

Sina Saed Samii*, J. Eduardo Rico, Alice T. Mathews, and Joseph W. McFadden, *West Virginia University, Morgantown, WV.*

The ratio between sphingolipids is a means to understand sphingolipid biology, an analysis utilized in biomedicine to study ceramide-mediated insulin resistance. Our objective was to evaluate whether the ratio between plasma sphingolipids in dairy cows is modified during the peripartum. Multiparous Holstein cows were grouped by BCS at d −28 prepartum: lean (BCS 2.91 ± 0.13; n = 7) or overweight (OVER; BCS 4.03 ± 0.21; n = 7). Diets were formulated to meet nutrient requirements. Blood was collected routinely from d −21 to 21. LC/MS was used to profile 37 Cer, monohexosylceramides (GlcCer), lactosylceramides (LacCer), and SM in plasma. Log-transformed data were analyzed using a mixed model with repeated measures (fixed effects of BCS and day). Nonparametric correlations were analyzed. NEFA mobilization increased during transition, more so in OVER ($P < 0.01$). Ratio of C16:0-SM to C16:0-Cer (C16:0 SM:Cer) increased during transition ($P < 0.01$) and tended to be lower in OVER ($P < 0.1$). C18:0 SM:Cer reached a nadir at calving ($P < 0.01$). In contrast, C24:0 and C22:1 SM:Cer progressively decreased with time ($P < 0.01$). C16:0, C22:0, and C26:0 Cer:GlcCer decreased during transition ($P < 0.01$). C18:0 Cer:GlcCer tended to display a biphasic response (increased then declined; $P = 0.08$). Neither BCS nor day modified C24:0 Cer:GlcCer. C16:0 and C18:0 GlcCer:LacCer increased and decreased, respectively, as calving approached ($P < 0.01$). After calving, C24:0 GlcCer:LacCer declined until d 21 ($P < 0.05$). C18:0 and C24:0 SM:Cer, C16:0 and C20:0 Cer:GlcCer, and C18:0 and C24:1 GlcCer:LacCer were negatively correlated with NEFA (r = −48 to −0.22; $P < 0.01$). In contrast, C16:0 GlcCer:LacCer was positively correlated with NEFA (r = 0.57; $P < 0.01$). C18:0 and C26:0 Cer:GlcCer were negatively correlated with estimated insulin sensitivity (RQUICKI; r = −0.35 to −0.29; $P < 0.01$), whereas, C20:0 Cer:GlcCer and C18:0 GlcCer:LacCer were positively correlated with RQUICKI (r = 0.19 to 0.29; $P < 0.05$). Research will need to determine whether changes in plasma fatty acids are related to the ratio between acyl-chain specific sphingolipids.

Key Words: ceramide, dairy cow, sphingomyelin

M414 Effects of feeding protected unsaturated fatty acids (Persia Fat) on Insulin resistance parameters of fresh Iranian Holstein dairy cows.

Hamed Khalilvandi-Behroozyar[1], Mehdi Dehghan-Banadaky*[2], Mohammad Ghaffarzadeh[3], Kamran Rezayazdi[2], and Essa Dirandeh[4], [1]*Department of Animal Science, Urmia University, Urmia, West Azerbaijan, Iran,* [2]*Department of Animal Science, University of Tehran, Karaj, Alborz, Iran,* [3]*Chemistry and Chemical Engeenering Research center of Iran, Tehran, Iran,* [4]*Department of Animal Science, Sari University of Agriculture and Natural resources, Sari, Mazandaran, Iran.*

The onset of insulin resistance (IR) in fresh dairy cows, will promote sparing of glucose, but the ability of insulin to inhibit HSL and suppress NEFA release from adipose may be impaired. The aim of this study was to evaluate the effects of feeding different FA in dairy cows on IR parameters. Twenty-four multiparous Iranian Holstein cows were used −30 d to 50 DIM. Dietary treatments consisted of (1) Prilled Palm (PO) [Energizer RP10, 2 and 2.25% DM in pre- and postpartum]; (2) Ca-salts of sunflower oil [Persia Fat-SO]; (3) Ca-salts of fish oil [Persia Fat- FO] and (4) equal amounts of Persia Fat-FO and Persia Fat-SO (2.2 and 2.5% of dietary DM in pre- and postpartum). Cows were weighed on 2 consecutive days to determine the doses of glucose for IVGTT(20 DIM, by administering 0.25 g/kg BW glucose i.v.) and insulin for insulin challenge (by 0.1 IU/kg BW insulin i.v. followed by saline). Blood samples were collected at −30 to180 min relative to administration of glucose and 120 min to insulin. The areas under the curve (AUC) of glucose and insulin during IVGTT and IC were calculated using the trapezoidal method. The parameters obtained from IVGTT and IC, were analyzed using PROC MIXED of SAS. The model included the fixed effects of treatment and sequence, and the random effects of period and cow within sequence. A covariate was used to adjust for differences in glucose concentration before the challenges. Statistically significant lower glucose and higher Insulin concentration in PO fed cows, in line with higher TNF-α and glycerol levels can be a hint to lower insulin sensitivity compared with Persia Fat fed animals. Accordingly, PO impaired glucose and NEFA CR (%/min) during IVGTT and glucose, insulin and NEFA during IC, reflecting lower responsiveness to insulin. The highest and lowest AUC (mg/dL) for glucose, NEFA and insulin during IVGTT, determined for PO and Persia Fat- Fish fed animals, respectively. After IC data support lower response to insulin in the case of glucose, NEFA and Insulin according to lower clearance rate for PO fed animals than Persia Fat. NEFA AUC30 (mEq/L) values were −13817 for PO vs. −16338, −18275 and −19462 for SO, Mix and FO. Overall, data support the idea that feeding rumen protected PUFA can modulate insulin resistance in fresh dairy cows.

Key Words: inflammation, palm oil, fish oil

M415 A novel method to determine rumen biohydrogenation kinetics of alpha-linolenic acid (18:3 n-3).

Michel Baldin*[1], Natalie L. Urrutia[1], Daniel E. Rico[2], Kelsie Baxter[1], Yun Ying[1], and Kevin J. Harvatine[1], [1]*Penn State University, University Park, PA,* [2]*Université Laval, Québec, QC, Canada.*

Biohydrogenation (BH) of unsaturated fatty acids (FA) has been extensively studied in vitro allowing inferences on BH pathways and kinetics. However, BH rates and intermediates formed in vitro may not parallel BH pathways in vivo. The objective was to develop an in vivo method to determine the rate of α-linolenic acid (18:3 n-3) BH and identify intermediates formed. Eleven rumen cannulated high-producing Holstein cows [40 ± 6 kg milk/d (Mean ± SD)] were fed at a rate of 6%/h of expected total DMI a diet balanced to 29% NDF and 5.9% EE (1.5% soybean oil). A single bolus consisting of 200 g of flaxseed oil (53% 18:3) and 15 g of tridecanoic acid (13:0) was mixed with rumen contents and rumen digesta was collected at −1, 0.1, 0.5, 1, 2, 3, 4, 6 and 8 h relative to the bolus. Samples were immediately placed in dry ice, stored at −20°C, freeze-dried, methylated and analyzed by gas chromatography using 17:1 and 19:0 as internal standards. Data were first analyzed using PROC Mixed with repeated measures for time point comparison. Second, the disappearance of 13:0 and 18:3 was fit to a single exponential decay model using the nonlinear procedure of JMP Pro. The bolus increased total fat in the rumen from 4.3 to 6.0% and enriched 13:0 concentration from 0.04 to 2.2% of FA and 18:3 concentration from 2.0 to 11.3% of FA. The fractional rate of disappearance of 13:0 was 0.4%/min (r^2 = 0.98) and of 18:3 was 2.5%/min (r^2 = 0.99), with 18:3 reaching pre-bolus concentration within 4 h. Assuming that 13:0 disappeared only by passage, 18:3 disappeared by passage and biohydrogenation, and the rate of passage of 13:0 and 18:3 are the same, the extent of bolused 18:3 BH was 85%. The concentration of *cis*-9,*trans*-11,*cis*-15 18:3 peaked at 1.2% of FA at 1 h (8-fold increase), *trans*-11,*cis*-15 18:2 peaked at 3.9% of FA at 2 h (13-fold increase), and *trans*-11 18:1 peaked at 6.6% FA at 3 h (43% increase). The in vivo method resulted in the expected extent of biohydrogenation and biohydrogenation intermediates, but the rate of ruminal biohydrogenation of 18:3 was much higher than that commonly observed in vitro.

Key Words: biohydrogenation, fatty acid

Ruminant Nutrition: General I

M416 Samples dried with commercial dry matter techniques differ in volatile compound contents. Donald Meyer*[1], Lynn Nagengast[1], Dustin Sawyer[1], and John Goeser[1,2], *[1]Rock River Laboratory, Watertown, WI, [2]University of Wisconsin-Madison, Madison, WI.*

On-farm feed dry matter techniques determine DM by difference between original feed weight and a dried weight. Oven DM techniques, though, have been documented to volatilize more than water, leading to underestimated feed DM measures. The objective of our work was to evaluate if feeds, dried through commercially adopted DM techniques, differ in total volatile compound content relative to undried. Corn ($n = 14$), grass ($n = 5$), legume ($n = 15$) and small grain silages ($n = 14$) were collected, divided into equal subsamples using a riffle-splitter, vacuum-sealed, and frozen until analyzed. Subsamples were thawed and then handled according to 5 different drying treatments; undried (CTL), on-farm type forced-air oven dry, 60 min (KOS), 50C for 48h forced-air oven dry (OV), freeze-dry (FD) or sequential microwave-NIR (LAB). Following treatment, and to assess DM technique non-water losses, undried and corresponding dried samples were analyzed for volatile fermentation products by HPLC (lactic, acetic, propionic, butyric, succinic, and formic acids, and ethanol). Each constituent was expressed as a % of DM, using sequential microwave-3 h 105°C oven dry as a standard DM. Fermentation products were then summed to determine total volatile compounds (TV). Technique difference from CTL represents significant non-water loss and a DM measure error. The resulting data were not normally distributed and were log-transformed before being evaluated using the Fit Model procedure in SAS JMPv11.0. Feed, drying treatment and their interaction were treated as fixed effects and assessed using backward-elimination. Significance was declared at $P < 0.05$. Feed type and drying treatment were significantly related to TV. Results presented here are converted back to % of DM. The TV means were compared using Tukey's test, finding legume and corn silage (5.1 and 4.9) differed from small grain (3.6), which differed grass silage (1.80). The TV was the greatest for CTL (4.43) and was not significantly different from LAB, KOS, or FD (4.18, 3.67, and 3.13, respectively). The CTL differed ($P < 0.05$) from OV (2.7) while KOS and FD did not differ from OV. Results suggest OV underestimates feed DM.

Key Words: silage, dry matter, volatiles

M417 Comparison of in situ and in vitro methods for predicting in vivo fiber digestion. David E. Cook*[1], John P. Goeser[1,2], Lynn Nagengast[2], and David K. Combs[1], *[1]Department of Dairy Science, University of Wisconsin-Madison, Madison, WI, [2]Rock River Laboratory Inc., Watertown, WI.*

Our objectives were to compare potentially digestible NDF (pdNDF) and pdNDF digestion rate (k_d), using in situ (IS) or traditional in vitro (TR) assays, and compare subsequent estimates of total-tract NDF digestibility (TTNDFD) to in vivo (IV) TTNDFD measurements. High and low digestible corn silages (HDCS and LDCS) and alfalfa silage (AS) previously characterized for pdNDF, k_d and TTNDFD by in vivo analysis were utilized. For the IS and TR analyses, samples were incubated for 6, 12, 24, 30, 48, 72, 96, 120, and 240h. For TR, 0.5g dried, 1mm ground feed was weighed into flasks and digested with Van Soest buffer. Rumen fluid was collected from 2 cannulated, lactating cows consuming a high forage diet. Rumen fluid was held under CO_2, processed and used to immediately inoculate samples. For IS, 0.5g dried, 2mm ground feed was weighed in Ankom F57 bags. TR samples were digested in each of 2 separate runs and IS in each of 3 cannulated, lactating cows consuming a high forage diet. The NDFD data from both methods were modeled using nonlinear option of SAS JMP (v11.0) to determine pdNDF and associated k_d for each digestion method. The k_d (%/h) and concentration of pdNDF (% of NDF), using IS were 2.39 and 88.4 for HDCS, 2.24 and 83.5 for LDCS, and 5.54 and 65.5 for AS, respectively. The k_d and pdNDF using TR were 4.64 and 74.93 for HDCS, 9.82 and 56.29 for LDCS, and 5.28 and 69.84 for AS, respectively. Total-tract NDF digestibility (TTNDFD) was predicted using the following equation: $pdNDF(k_d/(k_d+k_p))$. The k_p (2.67%/h) was derived from a meta analysis of in vivo passage rates for pdNDF. HDCS, LDCS, and AS TTNDFD were 46.4, 42.3, and 49.2 for IS; and 52.8, 51.5, and 49.2 for TR. Weighted averages of the feed TTNDFD values were used to predict TMR TTNDFD for comparison with in vivo observations. Resulting TMR TTNDFD were then compared across techniques using a linear model within JMP. Main effects were IS, TR and IV. Means for each technique were compared using student's *t*-test. The TTNDFD determined from TR (50.7) differed ($P < 0.01$) from IS (46.3) and IV (43.6). Estimates of total-tract NDF digestion based on TR, k_d, and pdNDF overestimated TTNDFD measured in vivo.

Key Words: total tract, NDF, digestion

M418 Response to iso-alpha acids from *Humulus lupulus* (hops) extract on fermentation by rumen microbes in continuous culture fermenters. Isaac J. Salfer*, Samuel W. Fessenden, and Marshall D. Stern, *University of Minnesota, St. Paul, MN.*

Iso-α acids from hops (*Humulus lupulus)* derived from the brewing industry have been shown to exhibit bacteriostatic properties against gram-positive bacteria. Previous research using whole or ground hops has shown promising results for decreasing hyper-ammonia producing bacteria in the rumen. However, hops contain additional fermentable substrate and other metabolites including tannins, β-acids and xanthohumol that confound the direct effects of iso-α-acids on rumen fermentation. Research using strictly iso-α acids in rumen culture is limited. The objective of this study was to examine the direct effects of iso-α acids on fermentation by rumen microbes using a dual-flow continuous culture system. Eight fermenters were used in 2 consecutive 10-d periods consisting of 7 d of adaptation followed by 3 d of sampling. Fermenters were provided with a basal diet consisting of 44% corn silage, 14% alfalfa hay, 13% ground corn, 11% protein mix, 10% corn gluten feed, 5% cottonseed and 3% liquid vitamin and mineral supplements on a DM basis. This diet provided substrate for ruminal microbes maintained in continuous culture at a rate of 75 g of DM/L of fermenter volume/day. Iso-α Extract (IE) solution was added to the artificial saliva buffer to supply 0 (CON), 600 (LOW), 1200 (MED) and 1800 (HIGH) mg of IE/kg of diet DM/day. There was no effect ($P > 0.05$) on DM, OM, NDF or ADF digestion (%). Volatile fatty acid (VFA) metabolism was not affected by IE treatment ($P > 0.05$), with total VFA concentrations of 105.5, 93.4, 87.9 and 103.6 mM for the CON, LOW, MED and HIGH treatments, respectively. Similarly, N metabolism was not affected ($P > 0.05$) by IE level, with the CON, LOW MED, and HIGH treatments resulting in nitrogen concentrations of 7.4, 5.3, 7.6 and 6.8 mg N/dL of rumen fluid, respectively. No significant effects ($P > 0.05$) on fermenter pH were observed. In conclusion, administration of IE had no effects on measurements of fermentation by ruminal microbes maintained in continuous culture fermenters.

Key Words: rumen, continuous culture, hops

M419 Sodium salicylate depresses fermentation by ruminal microbes in vitro.

Abigail J. Carpenter*, Claudio F. Vargas-Rodriguez, Jacob A. B. Jantz, and Barry J. Bradford, *Kansas State University, Manhattan, KS.*

The administration of the anti-inflammatory medication sodium salicylate (SS) after calving has been shown to increase whole-lactation milk production in multiparous cows; however, treatment with SS is associated with hypoglycemia following its administration in some circumstances. We hypothesized that decreased glucogenic substrate supply from fermentation may contribute to decreased blood glucose concentrations in SS-treated cattle. We performed a 24-h batch culture experiment to determine the effects of SS on rumen microorganisms in vitro. Strained and pooled fluid from 3 heifers was combined in a 2:1 ratio with McDougall's buffer, and 150 mL of the inoculum was added to each flask (n = 5/treatment). Blank flasks (n = 5) contained inoculum alone, while each treated and control flask contained 2.5 g of fermentation substrate. Before inoculum was added to the flasks, 1 mL of premixed treatment mixtures were added to achieve the desired final amount of SS (CON = 0 mg, LOW = 125 mg, MED = 250 mg, HI = 375 mg). Gas production was measured with the ANKOM^{RF} Gas Production System. Dry matter disappearance (DMD) was significantly depressed by inclusion of SS ($P < 0.05$), with HI having a lower DMD than LOW ($P < 0.05$), and MED intermediate (CON = 48%, LOW = 37%, MED = 30%, HI = 23% of DM; SEM = 2%). Final pH was not different between LOW and CON, but MED and HI had higher final pH than CON (CON = 6.31, LOW = 6.36, MED = 6.42, HI = 6.45; SEM = 0.01, $P < 0.05$). No differences were observed due to treatment for volume, rate, or lag in gas production ($P \geq 0.28$). These results indicate that SS may have an inhibitory effect on rumen microorganisms in vitro, which is counterintuitive considering previous findings that SS administration in early lactation increases 305-d milk production, but consistent with previous observations of decreased blood glucose concentrations in SS-treated cows.

Key Words: sodium salicylate, fermentation, rumen modification

M420 Comparison of different four methods for determining in vitro digestibility of annual ryegrass.

Mariano Alende*[1,2], Louisa Bowen[1], Prabha Ranasinghe[1], Gabriela Volpi-Lagreca[1,2], Gustavo Lascano[1], and John Andrae[1], [1]*Clemson University, Clemson, SC,* [2]*INTA, Anguil, Argentina.*

Multiple in vitro methods have been developed to assess forage digestibility but little is known regarding agreement in disappearance among them. This study compared 3 different rumen in vitro apparent digestibility (AD) methods (Daisy^{II} [D], Batch Culture [BC] and the Ankom Gas Production System [G]) at 4 incubation times ([IT];12, 24, 36 and 48 h). Additionally, results obtained at 24 h were compared with those obtained from dual-flow continuous fermenters [CF]. Annual ryegrass (*Lolium multiflorum*; 33.8% NDF, 16.6% CP, 91.1% OM, 27.3% WSC) was clipped from an ungrazed pasture, dried (<60°C) and ground in a Wiley mill (1 mm). Three runs of each method were conducted using rumen fluid from a cannulated Holstein cow in mid-lactation fed a 34% corn silage, 6% grass hay and 60% grain mix diet. Ankom F57 acetone pre-rinsed bags containing 0.5 ± 0.01 g of sample were used for D, BC and G. Digestibility coefficients in CF were estimated in 3 periods (7-d adaptation, 3-d collection) ran simultaneously with the other methods. The same buffer was used for all 4 methods. Data were analyzed using Mixed procedure of SAS in a model including method, IT and period as a random factor, with IT as repeated measure. Means within each IT were compared by PDIFF function. Results are presented in Table 1. Results indicate that D predicts higher AD than G and BC at IT greater than 12 h. Digestibility estimated using CF was similar to the obtained with BC and G at 24 h. We conclude that different in vitro digestibility methods could yield different results.

Table 1 (Abstr. M422). Dry matter digestibility (%) data of annual ryegrass samples assessed by 4 in vitro methods at 4 incubation times

	Incubation time (h)			
In vitro method	12	24	36	48
Daisy^{II}	58.35	70.92^{a}	75.93^{a}	79.85^{a}
Batch culture	52.88	61.29^{b}	68.14^{b}	71.82^{b}
Gas Production System	51.23	58.89^{b}	64.01^{b}	66.44^{b}
Continuous fermenter		58.97^{b}		

^{a,b}Means within each column with a different letter indicate significant differences ($P < 0.05$).

M421 The effect of dietary inclusion of sugar and type of sugar on ruminal short-chain fatty acid and glucose uptake across the ovine ruminal epithelium.

Katie M. Wood*[1], Christine L. Rosser[1], Matthew E. Walpole[1], Rodrigo Kanafany Guzmán[1], Beth Mason[2], Timothy Mutsvangwa[1], and Gregory B. Penner[1], [1]*Dept of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada,* [2]*Saputo Dairy Products Canada Ltd., Saint-Léonard, QC, Canada.*

The objective was to determine whether sugar inclusion and the type of sugar (lactose; LAC or sucrose; SUC) as a replacement for starch influences ruminal glucose and short-chain fatty acid (SCFA) uptake by the rumen epithelium. Eighteen Suffolk × Arcott wethers were randomly assigned to 1 of 3 diets: control (CON), LAC (whey permeate), and SUC (molasses). Sugar content was 6% of DM for LAC and SUC and partially replaced barley grain ensuring NSC was balanced among treatments. After 31d, lambs were killed and the caudal-ventral blind sac was collected and washed using a pre-heated buffer solution. The tissue was then stripped of the underlying muscular layer and mounted in Ussing chambers under short-circuit conditions. The uptake of ^{14}C-butyrate, ^{14}C-propionate and ^{3}H-acetate under non-inhibited conditions and conditions that inhibit protein-mediated uptake were measured. The uptake of ^{14}C-glucose was evaluated without inhibition and when phlorizin (0.5 m*M*; inhibitor of sodium-linked glucose transporter; SGLT-1), or phloretin (0.5 m*M*; inhibitor of facilitated glucose transporters) were included. Data were analyzed using PROC MIXED in SAS and contrasts used to evaluate the effect of sugar (CON vs. sugar) and type (LAC vs. SUC). Acetate uptake was reduced ($P = 0.04$) for lambs fed sugar due to a reduction in passive diffusion ($P = 0.02$), whereas protein-mediated uptake did not differ ($P = 0.24$). Propionate uptake was not affected by sugar inclusion; however, lambs fed LAC tended ($P = 0.098$) to have greater propionate uptake and had greater ($P = 0.043$) protein-mediated propionate uptake than those fed SUC. Lambs fed LAC tended ($P = 0.10$) to have greater protein-mediated and passive uptake of butyrate than those fed SUC. Glucose uptake was increased 1.7 times for lambs fed sugar compared with those fed CON ($P = 0.012$). The SGLT-1 uptake tended to be greater for lambs fed sugar than those fed CON ($P = 0.09$).

The results of this study indicate that the type of sugar included in diets may influence SCFA and glucose uptake by the rumen epithelium.

Key Words: rumen, absorption, glucose

M422 Evaluation of three rumen-protected lysine sources produced in two different batches using a modified three-step in vitro procedure.

Haley E. Larson*[1], Izuru Shinzato[2], Makoto Miura[3], Samuel W. Fessenden[1], Isaac J. Salfer[1], and Marshall D. Stern[1], [1]*University of Minnesota, Saint Paul, MN,* [2]*Ajinomoto Heartland, Inc., Chicago, IL,* [3]*Research Institute for Bioscience Products & Fine Chemicals, Ajinomoto Co., Inc., Kawasaki, Japan.*

A standardized 3-step in vitro procedure for evaluating rumen-protected lysine (RPL) sources was modified by Ajinomoto Co. Inc. and the University of Minnesota to estimate bioavailability of lysine within RPL products. The objective of this study was to evaluate variation between batch and source of RPL products AjiPro-L (A) and 2 other commercial products (B and C). Each RPL product was replicated 3 times in 3 runs to evaluate consistency of results within and between runs using the procedure. One gram of product from each RPL source, taken from one of 2 batches (2013, 2014) was individually weighed into a Dacron polyester bag. Bags were incubated in media bottles in a shaking water bath at 39$^?$C for 30 h. Simulation of ruminal (20 h), abomasal (2 h) and intestinal (8 h) digestion was accomplished by immersing solutions at 20, 22 and 30 h. At each time point, a 10-mL aliquot of buffer was collected and analyzed for lysine concentration using a Bioflow BF-7 biosensor (Oji Scientific Instruments Co., Ltd., Japan). Statistical differences ($P < 0.05$) were identified using a one-way ANOVA. Differences ($P < 0.001$) were observed between the 3 product sources for rumen insoluble lysine (RIL) and abomasal insoluble lysine (AIL). Intestinally available lysine (IAL) for product A differed from B and C ($P < 0.001$). Results showed variation between 2013 and 2014 batches of product sources A and B for RIL and IAL, and product sources B and C for AIL ($P < 0.001$). The release efficiency (RE) of RIL for each product source differed between years ($P < 0.001$). Within each run of the procedure, there was no variation observed between replicate samples ($P > 0.05$). Variation was observed between runs for RIL ($P < 0.002$), AIL ($P < 0.001$) and RE ($P < 0.03$), with no variation between IAL ($P > 0.05$). The modified 3-step procedure demonstrated differences between product types and batches within the same product source. The procedure was consistent between replicates of a run demonstrating its ability to compare differences in bioavailability of RPL products.

Key Words: in vitro, rumen-protected lysine

M423 Duodenal infusion of casein but not glutamic acid increases nitrogen retention in cattle provided continuous duodenal infusion of cornstarch.

Ethan J. Blom*[1], Derek W. Brake[1], and David E. Anderson[2], [1]*South Dakota State University, Brookings, SD,* [2]*University of Tennessee Knoxville, Knoxville, TN.*

Our objective was to quantify effects of increases among small intestinal starch digestion in response to greater postruminal flows of glutamic acid (Glu) on N retention. Five steers (351 ± 11 kg BW) were fed (5.1 ± 0.06 kg DM/d) a soybean hull-based diet formulated to provide adequate ruminally available N, moderate amounts of RUP, and small amounts of starch (0.8% DM). Cattle were placed in a 5 × 5 Latin square with 12-d periods. Cattle received (DM basis) continuous duodenal infusion of raw cornstarch (1.5 ± 0.08 kg/d), and either 0 (control), 30.9 ± 0.59, 62.4 ± 1.16, 120.4 ± 3.39 g/d Glu or 407 ± 18.3 g/d casein (a positive control). Data were analyzed with Mixed procedures of SAS; linear and quadratic effects of Glu were determined and the positive control was compared with the negative control by a *t* test. Nitrogen intake from feed was not different ($P \geq 0.23$). Infusate N increased from 0 to 13 g/d with greater amounts of Glu (Linear < 0.01) and casein provided 61 g N/d ($P < 0.01$). Similarly, total N intake was greater when cattle were provided casein ($P < 0.01$), but was not affected by Glu (Linear = 0.75). Increases in postruminal Glu did not affect urinary N excretion ($P \geq 0.30$), but casein increased urinary N excretion ($P < 0.01$). Fecal N excretion was not different ($P \geq 0.55$) despite reduced ileal flow of starch in response to greater postruminal flows of Glu (Linear = 0.04) or casein ($P = 0.07$). Glutamic acid had little impact on N retention ($P \geq 0.95$) despite increases in small intestinal starch digestion (Linear = 0.02), but casein increased N retention ($P < 0.01$). It is possible that increases in energy available for gain from increased small intestinal starch digestion in response to greater postruminal flow of Glu are used for purposes other than protein gain; however, it is likely that increases in energy available for gain exceeded capabilities for N deposition under conditions of our experimental model, because N retained as a proportion of N intake was not different when cattle were provided Glu ($P \geq 0.83$) or casein ($P = 0.38$).

Key Words: nitrogen retention, glutamic acid, cattle

M424 Rumen fermentation responses to phytogenic medicinal oils.

Barbara J. M. Lemos*, Flavia M. Souza, Edemilson C. Conceição, Victor R. M. Couto, and Juliano J. R. Fernandes, *Universidade Federal de Goias, Goiania, Goias, Brazil.*

The effects of oils extracted from the trunk of *Copaifera langsdorffii* (Copaiba; 21.3% β-caryophyllene, a essential oil), and from the fruit of *Pterodon emarginatus* (Sucupira; 5.3% β-caryophyllene) on rumen fermentation were evaluated in 2 independent in vitro experiments at doses CONTROL, LOW, MEDIUM and HIGH (0, 30, 300, and 3000 mg/L of buffered rumen fluid, respectively). The oils were dissolved in 2.5 mL of ethanol, also added to CONTROL. The incubation was repeated 4 times in each experiment. The diet (50:50 concentrate:roughage ratio, 90% DM, 20% CP, 2.2% EE, 36% NDF) was ground (1 mm) and incubated using filter bags for 3, 6, 12, 24, 48, 72 and 96 h. Rumen fluid was collected from a cannulated Holstein steer fed the same concentrate:roughage ratio diet. Samples of culture fluid collected after 96 h were analyzed for $N\text{-}NH_3$ and VFA concentrations. The disappearance data of DM were used to calculate the degradability of DM (Orskov et al., 1980). The HIGH dose of *C. langsdorffii* oil, showed degradability of parameter b (potential degradability of the DM assumed to be degraded over time) 29% lower than CONTROL (63.4 *vs* 45.3%; $P = 0.002$) and the potential degradability (a + b, amount of DM which can be degraded within the rumen given sufficient time) was 15% lower than CONTROL (87.9 *vs* 75.2%; $P = 0.001$). No responses of *C. langsdorffii* oil was observed ($P > 0.05$) on effective degradability (at rates of passage of 5 and 8%/h) and on constituents of culture fluid ($N\text{-}NH_3$, total VFA, acetate, propionate, isobutirate, butirate, isovalerate, valerate and acetate:propionate ratio). In the *P. emarginatus* oil study, the response on parameter b was 45% lower for HIGH dose compared with CONTROL dose (60.4 *vs* 32.1%; $P < 0.001$). The potential degradability was affected by *P. emarginatus* doses ($P = 0.013$), it was similar to CONTROL and LOW doses (highest values, 83.0 and 83.4%, respectively), intermediate to MEDIUM (73.3%) and lower to HIGH dose (64.8%; 22% lower than CONTROL dose, $P = 0.023$). There were no effects ($P > 0.05$) of *P. emarginatus* oil on effective degradability and constituents of culture fluid. In conclusion, these phytogenic oils were able to modify microbial fermentation in the rumen environment.

Key Words: degradability, feed additive, in vitro

M425 Effect of thyme (*Thymus vulgaris*) and peppermint (*Mentha piperita*) on digestibility of a finishing diet in lambs.

H. Khamisabadi[1,2], F. Kafilzadeh[1], B. Charaien[2], and G. Taasoli*[1], [1]*Department of Animal Science, Razi University, Kermanshah, Iran,* [2]*Research Centre of agriculture and natural resource of Kermanshah, Kermanshah, Iran.*

This experiment was conducted to study the effect of addition of 2 medicinal plants, peppermint or thyme, on digestibility of a finishing diet in lambs. Eighteen male lambs (initial body weight 21.6 ± 1.5 kg) were randomly assigned to one of 3 diets: control (with no additive), peppermint (control diet plus 3% of peppermint) or thyme (control diet plus 3% of thyme), for a 90-d finishing period. Lambs were fed individually and digestibility of nutrients were determined using insoluble ash method during 5 d of fecal sampling from all lambs. The ratio of concentrate:forage was 70:30. Diets were isocaloric and isonitrogenous. Data were analyzed as a completely randomized design with means compared using Duncan's test (SAS v9.2). Addition of peppermint or thyme to diets had no effect on digestibility of CP, ether extract, NDF and ADF but improved DM intake and digestibility of calcium and phosphorus ($P < 0.05$). Supplementation with peppermint or thyme could increase performance of finishing lambs through improved feed intake. Results are given in Table 1.

Table 1 (Abstr. M425). Effect of peppermint and thyme on DMI (g/d) and in vivo nutrient digestibility (%) of a finishing diet in lambs

Item	Peppermint	Thyme	Control	SEM	*P*-value
DM intake	$1,494.4^a$	$1,488.5^a$	$1,185.5^b$	40.6	0.001
Nutrient digestibility					
Crude protein	77.65	75.17	76.96	0.667	1.14
Ether extract	77.93	75.43	76.58	0.074	1.28
NDF	58.04	59.50	65.19	0.424	2.20
ADF	49.76	45.96	50.13	0.183	2.56
Calcium	53.98^a	44.21^a	37.30^b	2.99	0.05
Phosphorus	66.65^a	53.61^a	50.66^b	2.99	0.03

M426 Abomasal infusion of glucose increases intramuscular lipid content and acetate incorporation into fatty acids in subcutaneous adipose tissue relative to ruminal acetate infusion.

Terronica L. Blackmon*, Tryon A. Wickersham, Jason E. Sawyer, Rhonda K. Miller, and Stephen B. Smith, *Texas A&M University, College Station, TX.*

We hypothesized that abomasal infusion of glucose, which would provide more glucose for absorption from the small intestine, would promote intramuscular (i.m.) adipose tissue development to a greater extent than ruminal infusion of acetate, propionate, or glucose. At 22 mo of age, Angus crossbred steers (n = 24) were fitted with ruminal cannulas and adapted to a standard, corn/sorghum finishing diet over a 2-wk period. Subsequently, the steers were infused with isocaloric amounts (3.76 Mcal/d) of glucose, propionate, or acetate. Glucose was infused either into the rumen (control group) or into the abomasum, whereas propionate and acetate were infused into the rumen. Relative to abomasal glucose infusion, acetate infusion decreased DM, OM, DE, and GE intake ($P \leq 0.05$). USDA marbling scores were greater in acetate-infused steers than in than in ruminal glucose-infused steers ($P = 0.04$) and abomasal glucose-infused steers ($P = 0.08$). Ruminal propionate-infused steers had lower subcutaneous (s.c.) fat thickness over the 12th thoracic rib ($P \leq 0.10$) and lower USDA yield grades ($P \leq 0.05$) than ruminal acetate-infused steers and ruminal glucose-infused steers ($P = 0.05$). The lowest proportions of palmitic acid and palmitoleic acid in s.c. adipose tissue was observed in ruminal glucose-infused steers. Acetate infusion decreased the lipid content of i.m. adipose tissue ($P = 0.09$) and decreased the in vitro incorporation of acetate into fatty acids in s.c. adipose tissue relative to abomasal glucose infusion, ruminal glucose infusion, or propionate infusion ($P \leq 0.02$). Carcass data, lipogenesis, and fatty acid composition were analyzed using the General linear mixed models of SPSS statistics. The rate of glucose incorporation into fatty acids was greater in i.m. adipose tissue of propionate-infused steers than in abomasal or ruminal glucose-infused steers ($P \leq 0.07$). In summary, abomasal infusion of glucose did not promote higher marbling scores but did cause the greatest amounts of i.m. adipose tissue lipid, whereas propionate infusion promoted the greatest rates of fatty acid synthesis from glucose in i.m. adipose tissue.

Key Words: glucose, beef quality, lipogenesis

M427 Effects of increased inclusion of algae meal with differing fatty acid profiles on lamb total-tract digestibility.

Rebecca S. Stokes*, Daniel D. Loy, Megan L. Van Emon, and Stephanie L. Hansen, *Department of Animal Science, Iowa State University,Ames, IA.*

Heterotrophic microalgae can be manipulated to contain specific fatty acids; however, it is unknown how these differences may affect nutrient digestibility in ruminants. Algae meal (ALG) contains delipidated algae (57% DM basis) and soyhulls (43%). To determine the impact of replacing corn with ALG of differing fatty acid profiles, high oleic acid (HE) or high lauric acid (HL), on nutrient digestibility, 10 whiteface wethers (27.9 ± 0.87 kg) were used in a replicated 5 × 5 Latin square. There were 5 periods, with 10 d of adaptation and 5 d of fecal and urine collection. Sheep ($n = 2$ sheep·diet^{-1}·period^{-1}) received one of 5 finishing diets containing corn, 35% corn silage, 5% hay, 10% soybean meal, and 5% micro ingredients: a corn-based control (CON), 18% HE ALG (18HE), 36% HE ALG (36HE), 18% HL ALG (18HL), and 36% HL ALG (36HL). Both the HE and HL ALG were similar in nutrient composition except for fat (15.8 and 8.19%, respectively) and K (1.6 and 5.4%, respectively). Pooled SEM and LSMEANS are reported. Intake of DM linearly ($P < 0.01$) increased as either ALG increased in the diet; however, DMI was less ($P < 0.01$) for 18HE-fed lambs vs. 18HL-fed lambs. Urine output linearly ($P < 0.001$) increased as ALG increased in the HL-fed lambs and was less ($P < 0.001$) for 36HE-fed lambs vs. 36HL-fed lambs. Digestibility of DM linearly ($P \leq 0.04$) decreased as both HE and HL ALG increased in the diet (75.2, 73.9, 70.1, 73.2, and 72.7 ± 0.82% for CON, 18HE, 36HE, 18HL, and 36HL, respectively). Lambs fed 36HE had less ($P = 0.03$) DM digestibility than those fed 36HL. Digestibility of NDF linearly ($P = 0.04$) increased in lambs fed HL diets (47.7, 51.6, 54.5 ± 2.18 for CON, 18HL, and 36HL, respectively). Fat digestibility linearly ($P \leq 0.02$) increased as either ALG increased in the diet; however, digestibility was less ($P < 0.001$) for 36HE-fed lambs than 36HL-fed lambs. Both ALG are highly digestible and could serve as viable feedstuffs in feedlot diets. Due to varying inclusions of fat and K within the strains of algae it was difficult to ascertain if the fatty acid profile had any effect on nutrient digestibility.

Key Words: algae, digestibility, sheep

M428 Urine pH, serum calcium, and dry matter intake evaluated in Jersey cows fed anionic salts or Animate. Tyler J. Schell*[1], Shelby A. Armstrong[1], Derek J. McLean[1], Ken P. Zanzalari[1], James D. Chapman[1], and Lane O. Ely[2], [1]*Phibro Animal Health Corporation, Quincy, IL,* [2]*University of Georgia, Athens, GA.*

Negative DCAD diets have been proven beneficial for reducing incidence of periparturient diseases in dairy cows, however maintaining dry matter intakes (DMI) have been an issue with these strategies. Twelve non-pregnant, nonlactating Jersey cows (464 kg ± 19 kg BW) were used in a crossover design study to evaluate the effect of diets fully acidified (−15 mEq/100g DM) with either an anionic salt mix (SM) or Animate (AN) on urine pH, serum calcium and DMI when fed continuously for 21 or 24 d. Cows were randomly assigned to diet (6 h/diet) at the onset of the study. The first feeding period was 24 d (P1) and the second was 21 d (P2), with a 7-d wash-out non-anionic (NA) diet period between P1 and P2. In P1, P2 and NA urine pH and DMI were recorded daily. Urine samples were collected mid-stream, 4–6 h post-feeding and pH measured. Anionic diets were offered in grain mixes and adjusted daily to maintain a urine pH between 5.5 and 6.0. Blood samples were taken on d 0 (diet assignment), 7, 14, 21, 24 in P1 and 7, 14 and 21 in P2. Diets were balanced using NDS Professional, fed as TMRs 1x/d in Calan gates and orts recorded. To insure adaptation to diets, data recorded in the last 4 d in P1, P2 and NA were averaged and compared across periods using PROC GLM and significance tested to $P < 0.05$. Urine pH in P1 and P2 for cows fed the SM and AN were 5.8 ± 0.14 and 5.66 ± 0.14, respectively, and were different from the NA (6.52 ± 0.14, $P = 0.001$). Serum calcium (mg/dL) was similar for cows fed SM or AN in P1 (9.32 ± 0.19 vs. 9.37 ± 0.2) and P2 (9.33 ± 0.21 vs. 9.2 ± 0.24) and not different from the NA (9.18 ± 0.12). Prior to start of P1, cows averaged 8.95 ± 0.18 kg DM. During P1 and P2, cows fed AN had greater DMI (+0.79 kg/d) than when fed the SM diets ($P = 0.027$). Comparing the last 4 d of P1 and P2, cows fed the AN diets consumed more DM (+1.16 kg/d, +1.02 kg/d, respectively) than when fed the SM diets ($P = 0.001$) but DMI was not different from the NA period (8.94 ± 0.19kg). In conclusion, Animate was equally effective as anionic salts for reducing urine pH and maintaining serum calcium levels in Jersey cows; however, DMI were significantly improved.

Key Words: dry matter intake, Animate, Jersey cow

M429 Nonlinear models to describe the transit of particles through the ruminant digestive tract: Evaluation of models and theoretical implications. Ricardo Augusto Mendonça Vieira*, Marcelo Cabral da Silva, Tadeu Silva de Oliveira, and Alberto Magno Fernandes, *Universidade Estadual do Norte Fluminense, Campos dos Goytacazes, RJ, Brazil.*

Fecal profiles (n) of the particulate markers Cr (n = 52) and La (n = 30) and the fluid marker complex Co-EDTA (n = 57) were obtained from digestion kinetic studies with cows, steers, and sheep with the aim of evaluating mathematical models designed to interpret marker excretion profiles in feces. The models evaluated were the multicompartmental model of Dhanoa et al. (1985), the Gamma model described as GN by Pond et al. (1988), and the GNG1 model proposed by Matis (1972). Models were fitted by ordinary nonlinear least squares and evaluated on the basis of the Akaike information criterion and derived measures (information-likelihood criteria). Despite remarkable differences in terms of information-likelihood measures, the models were quite similar in terms of visual adherence to observed time profiles and presented overlapping interval estimates for compartment mean retention times. The major relative numerical discrepancies observed among the models were related to the mean and variance of the transit time for the first appearance of the marker in feces. The model with the best performance in mimicking the marker profiles was the GN model; the GNG1 model and the multicompartmental model were almost equivalent in terms of information-likelihood. Therefore, we derived a mathematical model to account for digestibility (D) and fill (Q) of the ruminoreticular digesta whenever the best model used to interpret marker studies, chosen based on information-likelihood criteria, was the GN model. Therefore, the GN model solutions for D and Q are as follows: $D = [k/(\lambda + k)]\ \Sigma_i[\lambda/(\lambda + k)]^{i-1}$, and $Q = AF/(\lambda + k)\ \Sigma_i[\lambda/(\lambda + k)]^{i-1} + UFN/\lambda$, for $i = 1, 2, \ldots, N$. In the models, k, λ, A, and U are the fractional rate of the pool of escapable particles in the rumen, the fractional escape of particles from the rumination pool to the escapable pool, the fiber fraction available for digestion, and the unavailable fiber fraction, respectively. F is the average daily intake rate, and N is the order of time dependency. Funded by CNPq, CAPES, and FAPERJ.

Key Words: ruminant digestive tract, kinetics, mathematical model

M430 Supplementation of grazing cow's diet with corn oil and palm kernel oil: ruminal fermentation, milk production and fatty acids profile. Jair Esteban Parales, Martha Lucia Pabón, and Juan Evagenlista Carulla*, *Universidad Nacional de Colombia, Bogotá, Cundinamarca, Colombia.*

The effects of supplementing corn oil (CO) alone or combined with palm kernel oil (PKO) to grazing cows on ruminal fermentation, milk production and its fatty acid (FA) profile were studied. Six multiparous Holstein cows (597 ± 11.5 kg BW, 160 ± 29 d in milk) were assigned to a double Latin square design (3 cows × 3 diets × 3 periods × 2 squares). Three diets were evaluated: a control (C) without oil and 2 with oil addition (720 g/cow/day), one with CO, and the other with CO:PKO (75:25; COKP). Each trial period lasted 28 d (21 for adaptation and 7 for sample collection). Cows strip grazed a *Pennisetum clandestinum* pasture (3 kg DM/100 kg LW/d) and received daily corn silage (0.9 kg DM), concentrate (4.2 kg DM) and chromium oxide (9 g). Rumen fluid was collected on d 28th, milk samples on d 15, 18 and 21 of each period and feces from d 15 to 21. Milk production was recorded daily. Milk FA and ruminal VFA were determined by GC and Cr in feces and concentrate by AA. Methane production was estimated using ruminal VFA concentration. Data were subjected to ANOVA using GLM procedure of SAS and comparisons among means using Tukey's test. Voluntary intake and digestibility of the diet were similar among treatments as well as the molar proportions of acetate, propionate, and butyrate. Total VFA (m/L) was lower (C = 94.7 vs CO = 72.2 and COKP = 74.0, $P < 0.001$) for the diets with oils resulting in lower estimated methane production ($P < 0.01$). Addition of oils increased milk production (l/d) (C = 21.4 vs CO = 23.6 and COKP = 23.9; $P < 0.01$) and milk fat (%) (C = 3.15 vs CO = 3.40 and COKP = 3.40; $P < 0.05$). De novo synthesized FA (g/100 g FA) in milk was higher for the control treatment (C = 68.5 vs. CO = 52.2 and COKP = 58.6; $P < 0.01$). Conjugated linoleic acid (CLA) (g/100g FA) in milk was higher for the oil diets but decreased by addition of CPK (C = 0.68 vs CO = 1.56, and COKP = 1.01; $P < 0.01$). Supplementation with CO or COKP in diets of grazing dairy cows increased milk production without affecting voluntary intake or the digestibility of the diet but CO addition resulted in higher milk CLA.

Key Words: methane, CLA, *Pennisetum clandestinum*

M431 Effect of rumen-protected carbohydrate supplementation on blood and plasma metabolites in finishing steers during heat stress.

Juan P. Russi*[1,3], Elias Peruzzo[1], Nicolas DiLorenzo[2], and Alejandro E. Relling[1], [1]*Facultad de Cs Veterinarias, UNLP, Buenos Aires, Argentina,* [2]*University of Florida, Marianna, FL,* [3]*RUPCA LLC, Merced, CA.*

Finishing steers during the summer can be challenging due to the effects of high temperatures and humidity on DMI. The objective of this study was to evaluate the inclusion of a rumen-protected carbohydrate (RUPCA) (US Patent # 8,507,025) on blood metabolites of finishing steers during heat stress. Temperature humidity Index average measured every day during the experiment was 72 ± 4.9. Crossbred steers (n = 135; 355 ± 20kg) were used in a 62-d experiment. Steers were blocked by initial BW and placed into 15 pens. Steers within blocks were randomly assigned to 3 treatments. T0) fed 91.4% of a basal diet (% DM), 22.3% corn silage, 65.9% dry corn, 0.6% sunflower meal, 0.5% urea, 2% minerals and vitamins and 8.6% of a supplement containing (% DM) 58.1% soybean meal, 38.9% soluble carbohydrates, 2% urea and 1% minerals salts, T1) fed the basal diet plus 4.3% supplement and 4.3% RUPCA and T2) fed basal diet plus 8.6% RUPCA. The supplement and RUPCA consisted of the same ingredients, differing on the processing of the carbohydrate (i.e., protected or not from ruminal degradation). Blood samples were taken from jugular vein prior morning feeding on d 0, 15, 39, and 62 and analyzed for glucose, insulin, urea and NEFA concentrations. Data were analyzed as a randomized complete block design with repeated measures using a mixed model of SAS. Initial body weight was used as a covariate. Treatment × day interactions were found for insulin ($P = 0.01$) and urea ($P = 0.02$) plasma concentrations. There were no differences on plasma concentration of insulin, NEFA or urea among treatments ($P > 0.10$). T0 showed higher blood glucose concentration ($P = 0.05$). The results suggest that including RUPCA might help to mitigate the negative effects of heat stress on blood metabolites, potentially improving animal performance. Results are shown in Table 1.

Table 1 (Abstr. M431).

Item	T0	T1	T2	SEM	*P*-value Trt	 Day	 Trt × day

M432 Effect of rumen-protected carbohydrate supplementation on performance, blood and plasma metabolites in growing heifers.

Juan P. Russi*[1], Elias Peruzzo[1], Nicolas DiLorenzo[2], and Alejandro E. Relling[1], [1]*Facultad de Cs Veterinarias, UNLP, Buenos Aires, Argentina,* [2]*University of Florida, Mariana, FL.*

The objective of this study was to evaluate the inclusion of a rumen-protected carbohydrate (RUPCA) (US Patent # 8,507,025) on performance, blood and plasma metabolites in growing heifers. Crossbred heifers (n = 135; 136 ± 14kg) were used in an 84-d experiment. Heifers were blocked by initial BW, placed into 15 pens and fed a diet comprised of (DM basis) 38.8% corn silage, 41.5% dry corn, 2% minerals and vitamins mix, and 17.7% supplement or RUPCA, which varied depending on treatments. The supplement and RUPCA consisted of the same ingredients (58.1% soybean meal, 38.9% soluble carbohydrates, 2% urea and 1% mineral salt), differing in the processing of the carbohydrate (i.e., protected or not from ruminal degradation). Heifers within blocks were randomly assigned to 3 treatments: T0) 17.7% supplement (100% unprotected carbohydrate), T1) 8.85% supplement and 8.85% RUPCA, and T2) 17.7% RUPCA (100% protected carbohydrate). Body weight was measured on d 0, 21, 42, 63, and 84. Pen DMI was measured weekly from d 21 to 84. Blood samples were taken on d 0, 42, 63, and 84 from jugular vein prior morning feeding and analyzed for glucose, insulin, urea and NEFA concentrations. Data were analyzed as a randomized complete block design with repeated measures using a mixed model of SAS. Treatment × day interaction were found for DMI ($P = 0.02$), ADG ($P < 0.0001$) and G: F ($P < 0.0001$) and with T1 having the lowest DMI ($P < 0.05$) and the greatest G:F ($P < 0.05$). No differences were found in the concentrations of blood glucose ($P > 0.91$), plasma insulin ($P = 0.82$), plasma NEFA ($P = 0.802$) or plasma urea ($P = 0.336$). Feeding RUPCA to growing heifers improved G:F through lower DMI without altering ADG, blood or plasma metabolites. Results are shown in Table 1.

Table 1 (Abstr. M432).

Item	T0	T1	T2	SEM	*P*-value Trt	 Day	 Trt × day
DMI, kg/d	6.9^{a}	5.9^{b}	6.8^{a}	0.06	<0.0001	<0.0001	0.02

M433 Nonlinear parameter estimation in R and SAS: Similarities and discrepancies of both statistical programs based on a case study of digestion kinetics and animal growth curves.

Ricardo Augusto Mendonça Vieira*[1], Leonardo Siqueira Glória[2], and Fabyano Fonseca e Silva[2], [1]*Universidade Estadual do Norte Fluminense, Campos dos Goytacazes, RJ, Brazil,* [2]*Universidade Federal de Viçosa, Viçosa, MG, Brazil.*

Growth, digestion, and passage kinetics in ruminants were studied as reference problems of nonlinear phenomena in animal science to be analyzed using nonlinear models. The statistical packages R and SAS were compared in terms of their nonlinear parameter estimation by ordinary nonlinear least squares and maximum likelihood algorithms. The assessed programs included the nls2, nlsLM, and nlme functions of R, and the NLIN, %NLINMIX macro of SAS. The quality of fit of the models was evaluated through likelihood criteria. The NLIN, nls2, and nlsLM functions yielded nonlinear parameter estimates that were almost equal in terms of scale; nevertheless, the interval estimates obtained with nls2 and nlsLM were within those estimated with PROC NLIN, despite the fact that the approximate confidence intervals are estimated using the same Student's *t*-test in both R and SAS. The degradation of fiber and passage kinetics of particulate markers were predicted with very small numerical differences both in terms of scale and dispersion estimates. For the nonlinear mixed-effects models used to interpret growth data, the nlme (R) and %NLINMIX macro (SAS) algorithms differed in terms of the value of the likelihood function whenever heterogeneous variances, correlations, and weighting variances were fitted; nonetheless, when assuming independence and homoscedasticity, the results of the log-likelihood function were identical. The number of possible models fitted to the growth profiles was 28 with nlme function of R, whereas with %NLINMIX macro of SAS, only 13 possible models were fitted. Fortunately, the conclusions reached by fitting growth models to lamb growth data with either R or SAS were the same. Nonetheless, because each fitting experience is unique, there is no guarantee that the same conclusions would be achieved because the programs do not behave equally in the case of fitting nonlinear mixed models with different correlation and variance structures combinations. Funded by CNPq, CAPES, and FAPERJ.

Key Words: nonlinear phenomena, R-project, SAS software

M434 Effect of crude glycerin in supplement on rumen microbial profile of Nellore steers consuming low quality pasture during the dry season.

Elias San Vito*, Pablo Castagnino, Erick E. Dallantonia, Yury T. Granja-Salcedo, Lutti M. Delevatti, and Telma T. Berchielli, *University Estadual Paulista-UNESP, Jaboticabal, São Paulo, Brazil.*

The effect of crude glycerin (CG) - 80% of glycerol - inclusion as a substitute to corn grain in supplements on rumen fluid protozoa numbers, and relative proportion of cellulolytic bacteria and methanogenic archaea of rumen-cannulated Nellore steers (n = 10; BW = 408.8 ± 38.5 kg) on low quality pasture, in the dry season was studied. Treatments were constituted by 5 levels of CG in the supplement: 0, 7, 14, 21 and 28% DM of CG. Animals were supplemented, daily at 1000 h in a ratio of 700 g/100 kg of BW. Supplement consisted of corn grain, soybean meal, urea, gluten meal and mineral mix. Bacteria and protozoa samples were collected on the d 11 of each experimental period, 3 h after supplementation, in the solid and liquid extracts in different parts of the rumen. Real-time PCR was used to quantify microbial population. Methanogens and cellulolytic bacteria were expressed as a proportion of total rumen bacterial 16S rDNA. Ciliate protozoa species were identified and quantified (#/mL) in a Sedgewick-Rafter chamber. Data of ciliated protozoa were log10-transformed and analyzed in a replicated Latin square design using the MIXED procedure of SAS. Bacterial proportions were analyzed using the software R, with data compared between treatments (with or without 28% DM of CG in the supplement) using the Wilcoxon test, considered significant effects at $P < 0.05$. The inclusion of CG in supplement did not affect ($P > 0.05$) rumen protozoa number (6.52, 4.46, 3.02, 2.95, 1.73, 2.16 and 1.67 for the genera *Entodinium, Dasytricha, Isotricha, Eremoplastron, Eudiplodinium, Elytroplastron*, and *Polyplastron*). The inclusion of CG had no effect in the rumen relative proportion of *Ruminococcus albus* ($P = 0.237$), *Ruminococcus flavefaciens* ($P = 0.129$), and methanogens ($P = 0.151$) with mean values of 0.0046, 0.0044, and 0.0169. However, increased ($P = 0.003$) *Fibrobacter succinogeneses*, with mean values of 0.0033 and 0.0296 for 0% DM and 28% DM of CG in the supplements, respectively. Inclusion up to 28% DM of CG in the supplement did not interfere negatively on rumen microbial profile, increased relative proportion of *F. succinogenes* of Nellore steers in low quality pasture.

Key Words: pasture, cellulolytic, glycerol

M435 Effect of crude glycerin in supplement on rumen microbial profile of Nellore steers grazing tropical grass during the rainy season.

Telma T. Berchielli*, Elias San Vito, Pablo Castagnino, Yury T. Granja-Salcedo, and Erick E. Dallantonia, *University Estadual Paulista-UNESP, Jaboticabal, São Paulo, Brazil.*

The effect of crude glycerin (CG) - 80% of glycerol - inclusion as a substitute to corn grain in supplements on rumen fluid protozoa numbers, and relative proportion of cellulolytic bacteria and methanogenic archaea of rumen-cannulated Nellore steers (n = 10; BW = 490 ± 47 kg) grazing tropical grass, during the rainy season was studied. Treatments were constituted by 5 levels of CG in the supplement: 0, 7, 14, 21 and 28% DM of CG. Animals were supplemented daily at 1000 h in a proportion of 300 g/100 kg of BW. Supplement consisted of corn grain, soybean meal, urea, gluten meal and mineral mix. Bacteria and protozoa samples were collected on the d 11 of each experimental period, 3 h after supplementation, in the solid and liquid extracts in different parts of the rumen. Real-time PCR was used to quantify microbial population. Methanogens and cellulolytic bacteria were expressed as a proportion (%) of total rumen bacterial 16S rDNA. Ciliate protozoa species were identified and quantified (#/mL) in a Sedgewick-Rafter chamber. Data of protozoa were log10-transformed and analyzed in a replicated Latin square design using the MIXED procedure of SAS. Bacterial proportions were analyzed using the software R, with data compared between treatments (with or without 28% DM of CG in the supplement) using the Wilcoxon test, the effects of treatments were considered significant at $P < 0.05$. The inclusion of crude glycerin in supplement did not affect ($P > 0.05$) rumen protozoa number (6.8, 5.6, 5.2, 2.4, 2.0, and 3.6 for the genera *Entodinium*, *Dasytricha*, *Isotricha*, *Eremoplastron*, *Diploplastron*, and *Polyplastron*). The inclusion of CG decreased the relative proportion of *Ruminococcus albus* ($P = 0.047$) and *Ruminococcus flavefaciens* ($P = 0.036$), with mean values of 0.0702 and 0.0174; 0.0411 and 0.0073 respectively for 0% DM and 28% DM of CG in the supplements. However, had no effect on *Fibrobacter succinogenes* ($P = 0.420$), and methanogens ($P = 0.150$) with mean values of 0.0199 and 0.1791, respectively. Inclusion of CG at the level of 28% of DM in the supplement negatively affect the rumen cellulolytic bacteria *R. albus* and *R. flavefaciens* of Nellore steers grazing tropical grass.

M436 Improvement in saccharification yield of mixed rumen enzymes by identification of recalcitrant cell wall constituents using enzyme fingerprinting.

Ajay Badhan[1], Yuxi Wang*[1], Robert Gruninger[1], Justin Powlowski[2], Adrian Tsang[2], and Tim McAllister[1], [1]*Agriculture and Agri-Food Canada, Lethbridge Research Centre, Lethbridge, AB, Canada,* [2]*Centre for Structural and Functional Genomics, Concordia Univ, Montreal, QC, Canada.*

Identification of factors that limit plant cell wall digestion of forages and the development of enzymatic approaches that improve hydrolysis could play a key role in improving the production efficiency of ruminants fed these feeds. Enzyme fingerprinting and FTIR analysis of barley silage and total-tract indigestible fiber residue (TIFR) in heifers' feces were used to identify cell wall components resistant to digestion. The results identified acetyl xylan esterases as key to enhance ruminal digestion, and that polysaccharide-lignin complexes are principal components in TIFR. Enzyme pre-treatment to enhance glucose yield from hydrolyses of barley straw and alfalfa hay by mixed rumen enzymes (MRE) was subsequently developed. The enzymes for pre-hydrolysis were recombinant acetyl xylan esterases (AXE16B_ASPNG and AXE16A_ASPNG), polygalacturonase (PGA28A_ASPNG), α-arabinofuranosidase (ABF54B_ASPNG) all from *Aspergillus niger*, feruloyl esterase (FAE1a) from *Anaeromyces mucronatus* (expressed in

E. coli), endoglucanase GH7 (EGL7A_THITE) from *Thielavia terrestris* (produced in *A. niger*). Lyophilized cell-free rumen fluid from cows fed forage diet was used as source of MRE. The study was conducted using micro assays in combination with simplex lattice mixture models that were designed using Design of Experiment statistical software. Fungal hemicellulases and auxiliary enzymes initiated degradation of structural polysaccharides upon application and improved the in vitro saccharification of alfalfa and barley straw by MRE. The analysis model predicted 75% (SEM: 2.8%) higher relative glucose yield from alfalfa pretreated with PGA28A_ASPNG and ABF54B_ASPNG in 1:1 ratio. Whereas, prehydrolysis of barley straw with a mixture of 50% EGL7A_THITE and 50% FAE1a increased glucose release by 100% (SEM: 1.8%) upon incubation with MRE. The results showed that microassays in combination with simplex lattice statistical experimental design can be used to predict effective enzyme pretreatments that can enhance plant cell wall digestion by MRE, and strengthen the rationale of developing specific enzyme pretreatments for forages, depending on their structure and composition.

Key Words: enzyme fingerprinting, saccharification, plant cell wall

M437 Effect of dietary protein level and vigna hay supplementation on production and efficiency of lactating dairy cows. Elmer Edgardo Corea-Guillén[1], J. M. Aguilar-Aguilar[1], N. P. Alas-Avelar[1], E. A. Alas-García[1], J. M. Flores-Tensos[1], and Glen A. Broderick*[2], [1]*Universidad de El Salvador, San Salvador, El Salvador,* [2]*Broderick Nutrition & Research LLC, Madison, WI.*

This trial assessed whether dietary content of CP or supplementation with vigna hay (*Vigna sinensis*) would improve milk production or efficiency of lactating cows. Thirty-two multiparous Holstein cows were blocked by DIM into 8 squares of 4 cows in a replicated 4 × 4 Latin square with a 2 × 2 arrangement of treatments: 15.5 or 17% CP, and with or without vigna hay (16.6% CP), which replaced 12.5% of dietary DM from sorghum silage (8.4% CP). Soybean meal was fed to adjust dietary CP; diets contained about 50% forage and 50% concentrate, and 38% NDF. Cows within squares were randomly assigned to treatment sequences and fed diets for 3-wk periods; data from the last week were analyzed using the mixed procedures of SAS. Table 1 reports LS-means. Diet did not alter yield of milk or milk components. Higher dietary CP increased DMI but also increased MUN and reduced N efficiency without improving yield. Supplementing dietary sorghum silage with vigna hay maintained production, reduced DMI and MUN, and increased milk/DMI, N efficiency and apparent NDF digestibility. Daily income over feed cost (IOC) averaged $0.85/cow more on the vigna hay diets. Results from this trial indicated that replacing a portion of dietary forage with vigna hay improved nutrient and economic efficiency of milk production.

M438 In vitro effects of a commercial blend of functional oils on rumen fermentation, methane production, and methanogenic archaea. Ahmad Reza Seradj[1], Joan Torrent*[2], Gabriel de la Fuente[1], and Joaquim Balcells[1], [1]*University of Lleida, Lleida, Catalonia, Spain,* [2]*Oligo Basics, Cary, NC.*

A complete randomized block design trial with 4 in vitro incubation sets were prepared to evaluate the effect of a commercial blend of functional oils (FO) containing cashew nut shell liquid and castor oil as active ingredients (Essential, Oligo Basics Agroind. Ltda., Cascavel, Brazil) on rumen fermentation, methane production and methanogenic archaea. Bottles of 120 mL were filled with 600 mg of concentrate (same as given to 4 rumen liquid donor steers), and 80 mL of an incubation solution including rumen inoculum, mineral, buffer and reducing solutions under a CO_2 stream. Sealed bottles were incubated at 39 ± 1°C for 24 h and either dosed with 500 µg of FO/g DM of basal diet or not (control). The headspace pressure was measured and sampled (0.1 mL) at 2 h intervals, up to 12 h and then 24 h post incubation to determine gas and then methane concentration using GC. The pattern of cumulative gas/methane production (y) was fitted to the model: $y = a(1 - e^{-b(t-c)})$, being a the potential cumulative gas/methane production (mL); b the production rate (mL/h) and c the lag time (h). After 12 and 24 h, 2 bottles per treatment per set were sampled for NH_3-N, volatile fatty acid (VFA) concentration and molecular analyses. The DNA was extracted using a QIAamp Kit. Specific primers were used to determine absolute abundance (Log_{10} gene copy number/ g fresh sample) of total bacteria and hydrogenotrophic methanogenic archaea (HMA) and the relative abundance ($2^{(-\Delta Ct)}$) of HMA in relation to total archaea using qPCR (*CFX96* Touch). Bottles supplemented with FO showed a tendency (14.26 vs. 13.50 SEM 0. 284; $P = 0.06$) to decrease methane production (mL/g DM substrate) and reduced the methane ratio (CH_4/gas; v/v; 0.093 vs. 0.089 SEM 0.0011; $P = 0.049$), where the discrete lag time for gas production increased (0.04 vs.0.12 SEM 0.024; $P = 0.047$). Addition of FO improved rumen fermentation, increasing molar proportion of propionate (33.5 vs. 34.3 SEM 0.24; $P = 0.024$) and decreasing NH_3-N concentration (305.3 vs. 284.4 SEM 5.95; $P = 0.022$) and relative abundance of HMA (17.8 vs. 14.7 SEM 0.96; $P = 0.032$).

Key Words: fermentation, functional oil, methanogenic archaea

M439 The influence of feeding oscillating dietary crude protein contents on milk production and nitrogen utilization in lactating dairy cows.

Jolet Köhler* and Timothy Mutsvangwa, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

There is increasing public pressure on intensive dairy operations to reduce nitrogen (N) excretion into the environment, which can be achieved by adopting feeding practices that enhance the efficiency of N utilization. One such feeding strategy is feeding diets with oscillating crude protein (CP) contents, and studies with finishing beef cattle and growing sheep have reported improvements in N retention when oscillating CP diets are fed compared with static CP diets. This experiment was conducted to determine: 1) the effects of feeding oscillating CP diets on N balance and milk production in dairy cows; and 2) the optimum frequency of oscillating dietary CP concentration (i.e., 24, 48, or 72 h). Eight Holstein cows (714 ± 36 kg of BW; 114 ± 15 DIM) were used in a replicated 4 × 4 Latin square design with 30-d periods (consisting of 18 d of dietary adaptation and 12 d of sample and data collection). Treatments were a diet containing 17% CP fed on a continuous basis (designated STATIC), and diets containing 14% and 20% CP that were fed on an oscillating basis at 24 (OSC-24), 48 (OSC-48), or 72 (OSC-72) h. Diets were fed twice per day as TMR. The actual CP contents were 17.8% for the STATIC, and 14.9 and 20.3% for the oscillating CP diets, which deviated from the target CP concentrations due to variations in forage CP content. Dry matter intake (mean = 26.6 kg/d) and milk production (mean = 36.4 kg/d) were not affected ($P \geq 0.57$) by diet. Milk contents and yields of fat, protein, and lactose were unaffected ($P \geq 0.33$) by diet. Although N intakes were similar across dietary treatments, retained N was greater ($P = 0.02$) in cows fed the OSC-48 diet compared with those fed the STATIC and OSC-24 diets. Apparent total-tract DM, organic matter, CP, NDF, and ADF digestibilities did not differ ($P > 0.05$) among diets; however, cows fed the OSC-72 diet had greater ($P = 0.02$) apparent total-tract fat digestibility compared with those fed the STATIC and OSC-24 diets. Our results demonstrate that feeding oscillating dietary CP diets on a 48-h basis improves N efficiency by enhancing N retention when compared with feeding a static CP diet or an oscillating dietary CP on a 24-h basis.

Key Words: milk production, nitrogen utilization, oscillating crude protein

M440 Effect of guanidinoacetic acid on metabolism of cattle.

Mehrnaz Ardalan*[1], Erick D. Batista[1,2], Cheryl K. Armendariz[1], and Evan C. Titgemeyer[1], [1]*Department of Animal Sciences and Industry, Kansas State University, Manhattan, KS,* [2]*Departamento de Zootecnia, Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

Guanidinoacetic acid (GAA) is the precursor of creatine, which is produced by hepatic methylation of GAA. We evaluated the metabolic response of cattle to post-ruminal supplementation of GAA with and without methionine (Met) supplementation as a source of methyl groups. Six ruminally cannulated Holstein heifers (520 ± 49 kg initial BW) were fed twice daily a diet containing 6 kg/d rolled corn, 4 kg/d alfalfa hay, and 50 g/d trace-mineralized salt. The experiment used a split-plot design. All treatments were infused continuously to the abomasum. The main plot treatments were 0 or 12 g/d of L-Met arranged in a completely randomized design; 3 heifers received each treatment throughout the entire experiment. Subplot treatments were 0, 10, 20, 30, and 40 g/d of GAA, with treatments provided in sequence from lowest to highest level using 6-d periods for each level. Blood and urine samples were collected on d 6 of each period. Met supplementation increased plasma Met ($P < 0.01$). GAA supplementation linearly increased plasma Arg (% of total AA), suggesting a sparing of Arg for GAA synthesis. GAA supplementation linearly increased plasma concentrations of GAA and creatinine ($P < 0.001$) and increased plasma creatine at all levels of GAA except when 40 g/d of GAA was supplemented with no Met (GAA quadratic × Met, $P = 0.07$). Plasma homocysteine was not affected by GAA supplementation when heifers received 12 g/d Met, but it was increased in response to 30 or 40 g/d of GAA when no Met was supplemented (GAA linear × Met, $P = 0.003$); increases did not suggest a dangerous hyperhomocysteinemia. Urinary GAA and creatine concentrations were increased by all levels of GAA when 12 g/d Met was provided and by GAA supplementation up to 30 g/d when no Met was provided, but 40 g/d GAA did not increase urinary concentrations of GAA or creatine when no Met was supplemented (GAA quadratic x Met, $P \leq 0.06$). Data suggest that post-ruminal GAA supplementation increased creatine supply to cattle. An apparent methyl group deficiency, demonstrated by increases in plasma homocysteine, developed when 30 or 40 g/d of GAA was supplemented, but it was ameliorated by 12 g/d Met.

Key Words: creatine, guanidinoacetic acid, methionine

M441 Canola meals produced in different years have similar contents of rumen-undegraded protein.

Glen A. Broderick*[1], Stefania Colombini[2], and Sara Costa[2], [1]*Broderick Nutrition & Research LLC, Madison, WI,* [2]*University of Milan, Milan, Italy.*

When evaluating protein degradability in canola meal (CM) produced in 2011 and 2012 we observed that CM from different processing plants differed in rumen-degraded protein (RDP) and rumen-undegraded protein (RUP), estimated using the Michaelis-Menten inhibitor in vitro method (MMIIV). However, these analyses were conducted in 2 different years and may have been influenced by methodological changes over time (e.g., degradative activity of rumen inoculum may have altered between years). Three CM samples were collected from each of 12 Canadian production plants in each of 2 years (2013 and 2014; total = 72). Meals were analyzed chemically and for protein degradation rate, RDP and RUP by MMIIV, assuming passage rates of 0.16 and 0.06/h for soluble and insoluble proteins, respectively (Colombini et al., J. Dairy Sci. 94:1967–1977, 2011). Half of the meals from both years were analyzed in each of 3 MMIIV incubations; a total of 6 incubations were conducted. Differences among plants and years were assessed with the Proc Mixed procedure of SAS, and LSM over all plants for each year are in Table 1. As seen in 2011 and 2012, there were large differences in RUP among plants (data not shown). There were differences by year ($P \leq 0.04$) in DM and protein fraction degraded at $t = 0$ (FD_0); CP in CM from 2013 was 1.8 percentage units greater than 2014 ($P < 0.01$). Theta (unadjusted degradation rate) was not different between years ($P = 0.50$). However, adjusting Theta for FD_0 resulted in differences in degradation rate by year ($P = 0.03$) and trends ($P = 0.06$) for differences in RDP and RUP. The results suggest that apparent differences among production years in RUP content of CM may be due to small differences in protein already degraded before incubation.

Contd.

Table 1 (Abstr. M441). Composition and degradability of canola meals from 2 years

M442 Enteric methane emissions of crossbred heifers fed mixtures of *Pennisetum purpureum* grass and *Leucaena leucocephala*.

A.T. Piñeiro-Vázquez*[1], J.R. Canul-Solis[1], J.A. Alayón-Gamboa[2], A.J. Ayala-Burgos[1], F.J. Solorio-Sánchez[1], C.F. Aguilar-Pérez[1], and J.C. Ku-Vera[1], *[1]Faculty of Veterinary Medicine and Animal Science, University of Yucatán, Mérida, Yucatán, México, [2]The College of the Southern Frontier, Campeche, México.*

The aim of the work was to assess feed intake, apparent digestibility and methane (CH_4) emissions of crossbred heifers fed a basal ration of *Pennisetum purpureum* grass mixed with increasing amounts of chopped forage of the tropical legume *Leucaena leucocephala*. Five crossbred (*Bos indicus* × *Bos taurus*) heifers with an average live weight of 295 ± 6 kg were used. Heifers were randomly allotted to 5 treatments (0, 20, 40, 60 and 80% *L. leucocephala* on a DM basis) in a 5 × 5 Latin square design. The DM intake, DM digestibility and CH_4 production (L/day) were determined in 24 h periods, while heifers were housed in open-circuit respiration chambers. Data were analyzed with PROC GLM of SAS. Dry matter intake (DMI) and organic matter intake (OMI) were similar ($P > 0.05$) between treatments registering an average of 7.0 and 6.5 kg/day and an intake of 98.7 g DM/kg$^{0.75}$/day. Dry matter digestibility (DMD) was similar ($P > 0.05$) between treatments registering an average of 492.3 g/kg. Organic matter digestibility (OMD) was similar between the control treatment (without *L. leucocephala*) and treatments with incorporation of 20 and 40% of *L. leucocephala*, however, with 60 and 80% incorporation, OMD was significantly different ($P \leq 0.05$) compared with the control treatment. Molar proportions of acetic and propionic acids in the rumen were significantly ($P \leq 0.05$) affected, observing a difference between treatments with incorporation of *L. leucocephala* and the control treatment. A linear ($P = 0.0005$, 0.0004 and 0.0022) reduction was observed in enteric CH_4 emissions when expressed as DM, OM, and NDF (L/kg) respectively, as the level of *L. leucocephala* was increased, additionally a reduction of 61.3, 61.7 and 53.1% was observed in CH_4 emissions (L/kg) when expressed per unit of DMI, OMI and NDFI respectively, with 80% incorporation of the legume in ration DM compared with the control treatment. These data point out toward the potential of *L. leucocephala* to reduce CH_4 emissions in cattle fed a basal ration of *P. purpureum* grass.

Key Words: methane emissions, respiration chamber, feed intake

M443 Effect of dietary crude protein content on milk yield and composition in dairy cows fed diets based on rehydrated corn silage and sugar cane silage.

Marcos André Arcari, Cristian Marlon de Magalhães Rodrigues Martins, Juliano Leonel Gonçalves, Danylo Oliveira Sousa, Bruna Gomes Alves*, Alessandra Módena Orsi, and Marcos Veiga dos Santos, *Universidade de São Paulo, Pirassununga, SP, Brazil.*

The aim was to evaluate the effect of dietary crude protein (CP) content on milk yield and composition for dairy cows fed with rehydrated corn silage (RCS) and sugar cane silage (SS). Fifteen Holstein cows were distributed in 3 contemporary 3 × 3 Latin square design and diets consisted of 600g / kg dry matter (DM) of SS, 400g / kg DM of RCS and CP levels (135, 161 and 186 g CP / kg DM) contained 89.9, 120.8 and 180.5 g soybean meal; 21.2, 40.4 and 50.5 g corn meal gluten and 6.7, 8.8 and 7.9 g urea / kg DM. The dry matter intake was 18.7 kg, 21.0 kg and 20.5 kg DM respectively. The data were analyzed using the MIXED procedure of SAS, were treatment effect was decomposed into 2 orthogonal polynomial contrasts (linear and quadratic). The CP content linearly increased the milk yield ($P = 0.0005$) (27.65, 29.88 and 30.32 L / day) [Y = 20.6593 (SE = 2.3976) + 0.5509 (SE = 0.1350) × CP] and 3.5% fat-corrected milk ($P = 0.0002$) (27.90, 30.63, 31.46 L / day) [Y = 18.6007 (SE = 2.8809) + 0.7275 (SE = 0.1643) × CP). There was a linear increase in the milk concentrations of fat ($P = 0.045$) (3.53, 3.64 and 3.71g / 100mL) [Y = 3.0605 (SE = 0.2827) + 0.03627 (SE = 0.01675) × CP), protein ($P = 0.025$) (2.82, 2.87 and 2.9g / 100mL) [Y = 2.6042 (SE = 0.1305) + 0.01728 (SE = 0.007107) × CP), casein ($P < 0.0001$) (2.08, 2.17 and 2.32g / 100mL) [Y = 1.4634 (SE = 0.06818) + 0.04644 (SE = 0.003836) × CP), total solids ($P = 0.011$) (11.91, 12.24 and 12.23%) [Y = 11.0888 (SE = 0.4023) + 0.06661 (SE = 0.02284) × CP), milk urea nitrogen (12.71, 18.44 and 18.95 mg / dL) [Y = −3.6595 (SE = 2.4423) + 1.2998 (SE = 0.1440) × CP) and casein percentage:milk protein ratio ($P < 0.0001$) (73.78, 75.61 and 79.88%) [Y = 58.0580 (SE = 3.4810) + 1.1727 (SE = 0.2044) × CP) for cows fed 135, 161 and 186 g CP / kg DM, respectively. And, there was a quadratic effect on the lactose content ($P = 0.005$) [Y = 1.8836 (SE = 0.8580) + 0.3406 (SE = 0.1127) × CP - 0.01091 (SE = 0.003650) × PB^2). The increase in dietary CP content when cows were fed with RCS and SS caused an increase on milk yield and its main compounds solids.

Key Words: milk, protein, rehydrated corn silage

M444 Effects of levels of whole cottonseed and soybean oil on intake and ruminal fermentation in Nellore steers.

Vinicius N. Gouvea*[1], Marcos V. Biehl[2], Marcos V. C. Ferraz Junior[1], Jose A. Faleiro Neto[1], Elizangela M. Moreira[1], Marcelo H. Santos[1], Renan G. Silva[1], Mariana F. Westphalen[2], Alexandre A. Miszura[1], Daniel M. Polizel[1], and Alexandre V. Pires[2,1], *[1]University of Sao Paulo, Pirassununga, SP, Brazil, [2]University of Sao Paulo, Piracicaba, SP, Brazil.*

In this study 6 ruminally cannulated Nellore steers (407 ± 24 kg BW) were used in a 6 × 6 Latin square design to evaluate 5 levels of whole cottonseed (0, 8, 16, 24 and 32% DM basis respectively treatments WC0; WC8; WC16; WC24 and WC32) plus a negative control diet – WCO + soybean oil (treatment SO; to reach the WC0 diet at the same fat content of WC32). Isonitrogenous (14% CP) diets containing 20% roughage 80% concentrate were formulated to provide the same amount of ruminally degradable protein. The 26-d experimental periods consisted 21-d for adaptation followed by 5-d for collection. Increasing WC linearly decreased DMI ($P < 0.01$; 7.9; 7.21; 6.77; 6.06; 6.18 kg/d respectively for WC0; WC8; WC16; WC24 and WC32).

No differences were observed between S0 and WC0 ($P = 0.23$; 7.17 *vs* 7.90 kg/d respectively) nether between S0 and WC32 ($P = 0.08$; 7.17 *vs* 6.18 kg respectively). Increasing WC increased quadratically the pH ($P < 0.001$; 6.24; 6.44; 6.54; 6.65; 6.56 respectively for WC0; WC8; WC16; WC24 and WC32). The SO inclusion increased the pH compared with WC0 diet ($P < 0.05$; 6.37 *vs* 6.24 respectively). Even with the same fat content WC32 diet presented higher pH than SO diet ($P < 0.001$; 6.56 *vs* 6.37 respectively). Total volatile fatty acids (VFA) linearly decreased with WC inclusion ($P < 0.001$; 107; 94.4; 87.0; 79.8 and 79.0 m*M* respectively for WC0; WC8; WC16; WC24 and WC32). The SO inclusion did not change total VFA compared with WC0 diet ($P = 0.22$; 102 *vs* 107 m*M* respectively). The SO inclusion increased the total VFA compared with WC32 diet ($P < 0.001$; 102 *vs* 79 m*M* respectively). Acetate:propionate (A:P) ratio linearly decreased with WC inclusion ($P < 0.001$; 2.60; 2.62; 2.22; 2.23; 1.88 respectively for WC0; WC8; WC16; WC24 and WC32). The SO inclusion did not change the A:P ratio compared with WC0 diet ($P = 0.73$; 2.66 *vs* 2.60 respectively) but compared with WC32 the SO increased the A:P ratio ($P < 0.005$; 2.66 *vs* 1.88 respectively). Intake and rumen fermentation parameters were negatively affected by the levels of WC inclusion in the diets but the main reasons for that not seems only related with the increased fat content.

Key Words: beef, fatty acid, feedlot

M445 Effect of lipid sources with different fatty acid profiles on rumen metabolites of feedlot Nellore steers.

Juliana Duarte Messana*, Giovani Fiorentini, Pablo S. Castagnino, Roberta C. Canesin, and Telma T. Berchielli, *UNESP - Univ. Estadual Paulista, Jaboticabal, SP, Brazil.*

The aim of this study was to investigate the effect of diets containing lipid sources with different fatty acid profiles on ruminal pH, NH_3-N, volatile fatty acids (VFA) and microbial protein synthesis. Ten Nellore steers with initial body weight of 268 ± 27 kg, ruminally cannulated, were used in a double 5 × 5 Latin square design (20 d of each period). Dietary treatments were: without fat (WF), palm oil (PO), linseed oil (LO), protected fat (PF; Lactoplus), and whole soybeans (WS). The roughage feed was corn silage (600 g/kg on a DM basis) plus concentrate (400 g/kg on a DM basis). To evaluate rumen fermentation parameters, rumen fluid samples (approximately 80 mL) were collected manually on the last day of the experimental period (20 d), both before supplying the diet (time zero) and 1, 2, 4, 6, 8, 10, 12, and 14 h after feeding. Microbial protein synthesis was calculated via urinary total excretion of purine derivatives (allantoin + uric acid). The diet with PF and WF increased the concentration of NH_3-N ($P < 0.001$); however, the diet did not change in VFAs ($P > 0.05$), such as the molar percentage of acetate (ACE), propionate (PROP), butyrate and the ACE:PROP ratio. There was a tendency ($P = 0.06$) to change ruminal pH values and total VFA ($P = 0.092$) with lipid diets. The higher NH_3-N and tendency to reduce pH values in the WF and PF diets could be linked to the higher DMI (nitrogen and organic matter), and consequently higher ruminal fermentation. The higher production of microbial N ($P = 0.030$) was in the animals fed WF, LO and WS, whereas animals of the PO diet had the lowest production. The higher microbial protein synthesis was found in animals on the diet with LO and WS ($P = 0.040$). Diets with some type of protection (PF and WS) caused less disturbance on ruminal fermentation.

Key Words: pH, ruminal fermentation, volatile fatty acid

M446 The effect of carbohydrate source in a urea-based liquid supplement on ruminal fermentation and methane production of wintering beef cows fed low-quality forage.

A. C. Conway[1], J. J. Michal[1], J. S. Chang[2], B. Carter[3], M. E. Benson[1], T. Bodine[4], and K. A. Johnson*[1], [1]*Department of Animal Sciences, Pullman, WA,,* [2]*Korea National Open University, Seoul, Korea,* [3]*Perfomix Nutrition Systems, Nampa, ID,* [4]*Northwest Research & Nutrition, LLC, Yakima, WA.*

The objectives of this study were to investigate the effects of 2 readily fermentable carbohydrate (RFC) sources in a urea-based liquid supplement on ruminal fermentation characteristics. Four ruminally cannulated Angus cows were fed 11.8 kg of bluegrass straw (BGS), 0.78 kg chopped triticale (TRIT), and 0.56 kg supplement on a DM basis. The experiment was performed in a Latin square design with repeated measures. Treatments were alfalfa hay (CON), a molasses-urea liquid supplement (MOL), a glycerol-urea liquid supplement (GLY) and a mixture of MOL and GLY (50/50). Ruminal fluid samples were collected at 0, 2, 4, 8, 12, 16, 20, and 24 h after feeding to analyze pH, VFA, and ruminal ammonia (NH_3-N) concentration. Ruminally incubated samples of BGS and TRIT were removed at 0, 6, 12, 24, 48, and 72 h after feeding to assess digestibility. Ruminal fluid was collected for bacterial speciation. Disappearance of BGS DM, OM and CP were unaffected ($P < 0.05$). Disappearance of NDF (48.2, 48.5, 50.3 versus 44.2 ± 2.0, respectively) and ADF (47.1, 47.5, 49.0 versus 43.9 ± 3.4 respectively) in BGS increased 4–6% with MOL, GLY, and 50/50 ($P = 0.03$) compared with CON. There was no treatment effect for digestibility of TRIT ($P < 0.05$). Total VFA concentration, VFA ratios, and ruminal pH were unaffected ($P < 0.05$), but MOL, GLY, and 50/50 increased NH_3-N concentration ($P = 0.007$). Average CH_4 emissions (192.13 ± 25.6 g/d) and methane yield (g CH_4/g gross energy intake; 5.2–5.5%) were unaffected ($P < 0.05$). Microbial species varied over time ($P < 0.01$) but not with RFC source. The improved fiber degradation in BGS indicates a GLY-based supplement is as effective as the standard MOL-based liquid supplement for wintering cows.

Key Words: liquid supplement, glycerol, methane

M447 Effect of varying type of forage and feeding times of rumen degradable nitrogen sources on the production, digestibility, feeding behavior and rumen metabolites of lactating dairy cows.

Mustafa Hajilou*[1], Hamid Reza Mirzaei Alamouti[1], Mehdi Ganjkhanlou[2], Hamid Amanlou[1], and Mehdi Dehghan Banadacki[2], [1]*Department of Animal Science, University of Zanjan, Zanjan, Iran,* [2]*Department of Animal Science, Campus of Agriculture and Natural Resources, University of Tehran, Karaj, Iran.*

This study was designed to evaluate effects of varying type of forage and feeding times of rumen degradable nitrogen sources on milk production, digestibility, feeding behavior and rumen metabolites of lactating dairy cows. Twelve multiparous (100 ± 10 d in milk) Holstein dairy cows were used in incomplete Latin square design (five 21-d periods) with a 2 × 3 factorial arrangement of treatments. All diets had a 50:50 forage-to-concentrate ratio, contained 16% CP, and were formulated to be equal in rumen-degradable protein. Treatments include different alfalfa hay-to-corn-silage ratios (35:15 and 15:35) and different feeding times of the rumen degradable nitrogen sources: 1- total mixed ration (TMR) was offered once daily in the morning (0900); 2- part of soybean meal was offered at 2100; 3- part of urea was offered at 2100. Data were analyzed using the mixed procedures of SAS. Diets based on corn silage and feeding soybean meal at night increased milk and ECM yield ($P < 0.05$) (ALFA1 = 32.06, ALFA2 = 33.95, ALFA3 = 32.25, CORN1 =

32.69, CORN2 = 34.17, CORN3 = 33.91; SEM = 0.55). Dry matter, organic matter and neutral detergent fiber digestibility numerically increased in cows feed corn silage diets ($P < 0.09$) and not affected by feeding times of rumen degradable nitrogen sources ($P < 0.25$). Feeding urea at night increased ruminating and chewing time (min/d and min/kg of NDF intake) in alfalfa hay based diets ($P < 0.05$), but not in corn silage based diets. Standing ruminating (min/d) was higher for alfalfa hay fed cows ($P < 0.01$) and resting ruminating (min/d) was higher for corn silage fed cows ($P < 0.01$). Total volatile fatty acids and molar proportions not affected by treatments ($P > 0.15$). Corn silage based diets improved milk production and digestibility.

Key Words: forage, Holstein dairy cow, nitrogen source

M448 Effects of intravenous infusion of olive oil, safflower oil, and flaxseed oil on milk fatty acid composition in dairy cows.

C. Bai*, C. J. Ao, Khas-Erdene, P. Gao, Y. Zhang, F. Y. Mi, T. L. Zhang, J. Wen, and Y. K. Zheng, *College of Animal Science, Inner Mongolia Agricultural University, Hohhot, Inner Mongolia, P. R. China.*

The objective of this study was to determine the effects of intravenous infusion of olive oil, safflower oil and flaxseed oil in various combinations on milk fat composition in lactating dairy cows. Eight Chinese Holstein cows (101 ± 11 DIM) were used in a replicated 4 × 4 Latin square design. Each period lasted 12 d with 5 d of infusion and 7 d of adaptation. Treatments were jugular vein infusion of 1) 170 g/d of oil mixture contained olive and safflower oil (43.10% *cis*-9 C18:1, 42.58% *cis*-6 C18:2 and 1.08% n-3 C18:3, OS); 2) 167 g/d of oil mixture contained olive and flaxseed oil (43.69% *cis*-9 C18:1, 13.89% *cis*-6 C18:2 and 29.94% n-3 C18:3, OF); 3) 161 g/d of oil mixture contained safflower and flaxseed oil (15.12% *cis*-9 C18:1, 44.72% *cis*-6 C18:2 and 30.50% n-3 C18:3, SF); and 4) 224 g/d of oil mixture contained olive, safflower and flaxseed oil (33.02% *cis*-9 C18:1, 32.94% *cis*-6 C18:2 and 22.63% n-3 C18:3, OSF). Treatment emulsions were consisted of water, oil mixture, 10 g/L of soy lecithin and 25 g/L of glycerol. The volume of the emulsion was 2 L/d per cow. Infusion process lasted for 6 h per day. Milk samples were collected twice daily during the last 2 d of each 5 d infusion period. Data were analyzed by using the Mixed procedure of SAS. Significance was declared at $P < 0.05$. Milk fatty acid from OF had greater concentration of *cis*-9 C18:1 (26.29%) compared with 21.80% from SF and 22.25% from OSF (SEM = 1.04). The concentration of *cis*-6 C18:2 from OF (4.36%) had the lowest level ($P < 0.0001$) compared with 6.77%, 7.07% and 7.00% from OS, SF and OSF (SEM = 0.21), respectively. The concentration of n-3 C18:3 in OS (0.66%) was lower ($P < 0.0001$) than in OF (3.57%), SF (3.26%) and OSF (3.34%), SEM = 0.13. The concentrations of C18:0 and short- and medium-chain fatty acids were not changed through treatments, whereas C16:0 was lower ($P = 0.0202$) in treatment OF (30.70%) than in treatment OS (32.62%), SEM = 0.74. Infusion of different oil combinations increased target fatty acids in milk and markedly altered milk fat composition.

Key Words: intravenous infusion, milk fatty acid, dairy cow

M449 Pelleting-induced changes at different conditioning temperatures and times on metabolic characteristics of the proteins and feed milk value of co-products from bio-oil processing.

Xuewei Huang, Tom Scott, Colleen Christensen, Yajing Ban, Xinxin Li, and Peiqiang Yu*, *Department of Animal and Poultry Science, University of Saskatchewan, Saskatoon, SK, Canada.*

The dramatic increase in bio-oil production in Canada has resulted in millions of tonnes of different types of co-products: carinata meal and canola meal. Little research has been conducted to determine pelleting induced changes at different conditioning temperature and time on the metabolic characteristics of the proteins in co-products from bio-oil processing in dairy cattle. The objectives of this study were to investigate the effects of conditioning temperature (70, 80 and 90°C), time (50 and 75 s), and interaction (temperature × time) during the pelleting process on the metabolic characteristics of the proteins, feed milk value, the total truly absorbed protein supply (DVE), and degraded protein balance (DPB) to dairy cattle and to compare between unprocessed mash and pellets in true protein supply to small intestine of dairy cows. The DVE/OEB system was applied in determining metabolic characteristics of the proteins, feed milk value, DVE and DPB values. The data were analyzed with a randomized complete block design (RCBD) with a 3 × 2 factorial arrangement. Statistical analyses were performed through MIXED procedure of SAS 9.3. The results showed that the unprocessed co-product from bio-oil processing is a good source of the truly digested protein in small intestine (DVE: 170 g/kg DM) with DPB of 115 g/kg DM. It was unexpectedly found that the pelleting process under current conditions did not increased but reduced DVE and increased DPB values. Within pelleting processed treatments, there was no interaction ($P = 0.64$) between conditioning temperature and time on the metabolic characteristics of the proteins. However, increasing conditioning temperature tended to decrease DPB ($P = 0.051$) values of co-product pellets. Feed milk value of the co-products was reduced after pelleting process as well (3.4 vs. 3.0 kg milk per kg feed). In conclusion, pelleting with relative low temperature (70–90°C) decreased DVE, feed milk value, and increased DPB of co-products compared with raw co-products. Increasing conditioning temperature during pelleting tended to decrease the potential N loss of pelleted co-products.

Key Words: feed technology, bio-oil processing co-product, protein

M450 Ruminal fermentation of Nellore steers fed different sources of forage in diets with crude glycerin in feedlot.

Andressa F. Ribeiro, Antonio Jose Neto*, Luis G. Rossi, Erick. E. Dallantonia, Ana Laura E. G. F. Carvalho, Monaliza. O. Santana, Manuela. B. Abra, Juliana D. Messana, and Telma T. Berchielli, *Sao Paulo State University, Jaboticabal, SP, Brazil.*

This study investigated the effect of alternative forages for corn silage such as sugar cane and sugar cane bagasse included in a similar forage NDF level (fNDF) in diets with crude glycerin (80.64% of glycerol) on ruminal fermentation of Nellore feedlot steers. Nine ruminally cannulated Nellore steers (300.0 ± 30kg of BW and 18 ± 2 mo of age) were used in a 3x3 Latin Square experimental design with 3 treatments and 3 animals in 3 simultaneous triplicates to evaluate the effect of different sources of forage in diets with crude glycerin (80.64% of glycerol) on ruminal pH and ammonia-N concentration. Experimental periods were 15 d (14 d for adaptation and 1 d for ruminal sampling). The treatments were different sources of forage (fixed 15% of NDF from forage; fNDF): corn silage (CS), sugar cane (SC) and sugar cane bagasse (SB), in diets with 10% (DM) of crude glycerin. Ruminal contents were obtained at 0, 2, 4, 6, 8, 10, and 12 h after feeding. Data were analyzed as a triple Latin Square design and repeated measurements on time using the PROC MIXED procedure of SAS. The least squares means were generated and compared ($P < 0.05$) using Tukey's test. The pH values of animals fed with SB (6.40) were greater compared with CS (6.08; $P < 0.05$), which did not differ from animals fed with SC (6.27; $P > 0.05$). Animals fed with SC presented lower values of NH_3-N (11.54; $P < 0.05$) compared with animals fed with CS (15.42) and SB (15.40). Sugar cane and sugar cane bagasse included in 15% of fNDF in diets with crude glycerin (10% DM) altered ruminal parameters, however, maintained adequate conditions for animal performance.

Key Words: byproduct, corn silage, sugar cane

M451 Comparison of ruminal microbial diversity and richness in whole rumen content, rumen liquid and solid fractions.

Shoukun Ji*, Yajing Wang, Zhijun Cao, Gibson Maswayi Alugongo, Haitao Shi, and Shengli Li, *State Key Laboratory of Animal Nutrition, China Agricultural University, Beijing, China.*

Whole rumen content, fluid or solid fractions have been used often to assess the rumen microbial diversity and richness; however, the suitability of using each fraction assessing the ruminal microbial diversity and richness has not been evaluated. To compare the bacterial profiles in each fraction, samples of rumen content from 6 cows were collected via fistula and squeezed through 4 layers of cheesecloth to get liquid and solid fractions before analyzing with the next generation sequencing technique. Results showed that the Operational Taxonomic Units (OTUs) numbers (4897 ± 582, 5253 ± 855 and 4860 ± 615 for whole content, liquid and solid fraction, respectively) and Simpson indices (0.99 ± 0.008, 0.99 ± 0.006 and 0.99 ± 0.004 for whole content, liquid and solid fraction, respectively) among whole content, liquid and solid fractions were similar ($P > 0.05$). No statistical difference was found among the inner- or inter-group similarities for each kind of samples using Bray-Curtis metric ($P > 0.05$). At Phylum level, Bacteroidetes and Firmicutes were the predominant bacteria and accounted for more than 90% of the microbes in all samples in our study. However, richness of Bacteroidetes in liquid fraction was 64.29 ± 0.03% which was higher than that in solid fraction as 48.25 ± 0.04% ($P < 0.05$), while that of Firmicutes was 31.72 ± 0.03% in liquid fraction which was lower compared with that of solid fraction as 44.71 ± 0.05% ($P < 0.05$). At genus level, on analyzing the top 9 bacteria (accounting for more than 43% in quantity in all samples), the fold change values of liquid fraction versus whole content (liquid/whole) were 0.51, 0.73, 0.76, 0.82, 1.07, 1.19, 1.20, 1.35, and 1.38 for *Coprococcus*, *Succiniclasticum*, *Butyrivibrio*, *Shuttleworthia*, YRC22, *Prevotella*, *Ruminococcus*, CF231, and *Oscillospira*, respectively. These findings indicate that using whole, fluid, or solid fractions to assess the microbial diversity generate similar results. However, the richness of predominant bacteria in phylum and genus may differ depending on the sample fraction type.

Key Words: rumen microbial diversity, rumen microbial richness, rumen content fraction

Small Ruminant I

M452 Chemical composition and quality of fresh lamb from rationally grazed hair and wool x hair sheep lambs as influenced by soy hull supplementation. Beruk B. Lemma*[1], Jung Hoon Lee[1], Stephan A. Wildeus[2], Govind Kannan[1], and Brou Kouakou[1], [1]*Fort Valley State University, Fort Valley, GA,* [2]*Virginia State University, Petersburg, VA.*

This study was conducted to evaluate the effects of soy hull supplementation on the quality characteristics of fresh lamb from hair and wool × hair sheep lambs. Forty-seven lambs (5-mo old), 23 purebred hair sheep (Barbados Blackbelly or BB, BW = 16.2 ± 1.9 kg; St. Croix or SC, BW = 19.5 ± 2.0 kg) and 24 crossbred wool (Dorset, D) × hair (BB; BW = 21.7 ± 2.3 kg or SC; BW = 21.7 ± 2.9 kg) sheep lambs of both sexes rotationally grazed predominately tall fescue with or without soy hull supplementation during summer. Soy hull was provided at 2.0% of BW at individual feeding stations. After 90 d of grazing, lambs were harvested using standard procedures. After 24 h cooler storage (2°C), longissimus muscle (LM) pH was measured in individual carcasses. Each carcass was fabricated to obtained 2.5-cm thick loin chops for meat quality analysis. All data were analyzed as a completely randomized design with a 2 × 2 x 2 factorial treatment arrangement: breed type (pure- or cross-bred), supplement (with or without soy hull), and sex (male or female). The CIE L* (lightness), a* (redness), and b* (yellowness) values of lamb chops were significantly influenced by supplementation, sex, and their interaction. Chops from supplemented lambs had higher ($P < 0.001$) CIE a* values than those from grazed-only lambs. The LM from supplemented lambs had higher ($P < 0.001$) protein (22.4 vs 21.4%) and fat contents (2.88 vs 2.47%) than that from grazed-only lambs. The percent metmyoglobin and thiobarbituric acid reactive substances (TBARS) values of LM from lamb chops were significantly affected by sex, breed type, and breed type × sex. The LM from purebred lambs had a higher ($P < 0.05$) level of TBARS (0.32 vs 0.27 mg MDA/kg) than that of crossbred lambs. Chops from supplemented lambs had lower ($P < 0.01$) shear values than those from grazed-only lambs. The results indicate that soy hull supplementation can improve color and texture property of fresh hair sheep lambs grazing fescue pasture regardless of breed type.

Key Words: hair and wood sheep, meat quality, soy hull

M453 Effects of feeding entrapped fish oil in a chemically treated protein matrix on milk composition of lactating goats. Jung Hoon Lee*[1], Christina R. Alfred[1], Beruk B. Lemma[1], Brou Kouakou[1], and Byung J. Min[2], [1]*Fort Valley State University, Fort Valley, GA,* [2]*Tuskegee University, Tuskegee, AL.*

Because of the potential benefit to human health, there is considerable interest in increasing omega-3 fatty acid contents in milk fat. However, efforts to increase the levels of eicosapentaenoic (EPA; C20:5n-3) and docosahexaenoic (DHA; C22:6n-3) acids had limited success because they undergo biohydrogenation in rumen. This study investigated the effect of entrapped fish oil (EFO) containing EPA and DHA acids on milk and milk fat compositions of lactating goats. The EFO were prepared with fish oil, defatted soy flour, and acetaldehyde. Nine Saanen lactating goats (4 yr old; BW = 48.3 ± 2.26 kg) were divided into groups of 3 and randomly assigned to 3 diets using a 3 × 3 Latin square design with 14-d periods. The 3 diets consisted of 95% basal diet containing alfalfa meal, yellow corn and soybean meal, plus 5.0% lipid from either poultry fat (PF), fish oil (FO) or EFO. Each period consisted of a 10-d adjustment to assigned diets followed by 4-d of milking collection. The designated diet was provided once daily ad libitum at individual feed stations. The collected milk samples from each goat were analyzed for basic nutrient, α-tocopherol and fatty acid composition. All data were analyzed as a 3 × 3 Latin square design. Lactating goats fed a PF containing diet had a higher ($P < 0.01$) content of milk fat compared with goats fed either a FO- or an EFO-containing diet (3.98 vs 3.34 or 3.22%). No significant differences were found in the amount of α-tocopherol (0.87–0.90 µg/mL) in the milk samples from the 3 different diets. Compared with lactating goats fed PF-diet, goats fed either FO- or EFO- diets had higher ($P < 0.01$) concentrations of EPA (C20:5n-3, 0.30 vs. 0.81 or 1.66%), docosapentaenoic (C22:5n-3, 0.24 vs. 0.77 or 0.98%), and DHA (C22:6n-3, 0.32 vs. 1.21 or 1.86%) in milk. Furthermore, the concentration of EPA in milk from goats fed EFO-diet was higher ($P < 0.01$) than that from goats fed a FO-diet. The results indicate that feeding lactating goats with entrapped fish oil in a chemically treated protein matrix might increase the deposition of omega-3 fatty acids in their milk.

Key Words: lactating goat, milk fat, eicosapentaenoic and docosahexaenoic acids

M454 Fatty acid composition and α-tocopherol content of blood serum from lactation goats fed entrapped fish oil in a chemically treated protein matrix. Christina R. Alfred*[1], Jung Hoon Lee[1], Beruk B. Lemma[1], Brou Kouakou[1], and Byung J. Min[2], [1]*Fort Valley State University, Fort Valley, GA,* [2]*Tuskegee University, Tuskegee, AL.*

This study evaluated the effects of feeding entrapped fish oil containing eicosapentaenoic (EPA; C20:5n-3) and docosahexaenoic (DHA; C22:6n-3) acids in chemically treated protein on fatty acid compositions and a-tocopherol concentrations of blood serum in lactating goats. The entrapped fish oil (EFO) were prepared with fish oil, defatted soy flour, and acetaldehyde. Nine Saanen lactating goats (4 yr old; BW = 48.3 ± 2.26 kg) were divided into groups of 3 and randomly assigned to 3 diets using a 3 × 3 Latin square design with 3 14-d periods. Experimental diets consisted of 95% basal diet, containing alfalfa meal, yellow corn and soybean meal, with 5.0% of oil/fat from either poultry fat (PF), fish oil (FO) or EFO. The designated diet was provided once daily ad libitum at individual feed stations. Blood samples were collected from individual goats at the end of each feeding period which were analyzed for α-tocopherol and fatty acid composition. All data were analyzed as a 3 × 3 Latin square design. Average daily intake of diet containing EFO was lower ($P < 0.01$) than diets containing either PF or FO (1.04 vs 2.56 or 1.90 ± 0.300 kg). Consequently, the ADG of goats fed EFO diet was lower ($P < 0.05$) than the other 2 diets. The blood serum from goats fed EFO diet tended ($P = 0.08$) to have a higher amount of a-tocopherol (2.31 vs 1.89 or 1.90 µg/mL) than did those from goats fed either PF or FO diet. Compared with goats fed PF-diet, goats fed either FO- or EFO- diet had higher ($P < 0.01$) concentrations of EPA (C20:5n-3, 1.76 vs 10.57 or 13.23%), docosapentaenoic (C22:5n-3, 1.32 vs 2.02 or 1.93%), and DHA (C22:6n-3, 1.95 vs 4.58 or 5.38%) acids in blood serums. Furthermore, the concentrations of EPA and DHA in blood serums from either EFO- or FO-diet fed goats were similar even with a limited intake of EFO-diet. Thus, feeding lactating goats with entrapped fish oil in chemically treated protein might protect n-3 fatty acids and a-tocopherols from ruminal degradation and subsequently increased those contents in the blood serum of lactating goats.

Key Words: lactating goat, blood serum, eicosapentaenoic and docosahexaenoic acids

M455 Fatty acid composition of different fat depots from meat goats supplemented with tannin-rich pine bark. Beruk B. Lemma*[1], Jung Hoon Lee[1], Byeng R. Min[2], Govind Kannan[1], and Brou Kouakou[1], *[1]Fort Valley State University, Fort Valley, GA, [2]Tuskegee University, Tuskegee, AL.*

This research assessed the effect of feeding ground pine bark (PB, *Pinus* spp.), containg up to 13% condensed tannins (CT) on a DM basis, on different fat depots in meat goats. Twenty-four intact male Kiko goats (8 mo of age; BW = 39.7 ± 2.55 kg) were grazed in a winter rye grass-dominant pasture, and supplemented either bermudagrass hay (BG) or PB pellet. Each supplementation (n = 12 goats/treatment) consisted of alfalfa pellet (16.9% CP, 3.30% ether extract or EE, 48.7% NDF), molasses, and mineral mixtures with either BG (20.5% CP, 4.44% EE, 40.9% NDF) or PB powder (9.10% CP, 3.35% EE, 59.0% NDF), which was provided at 1.5% of BW at individual feeding stations. After 50 d grazing, goats were harvested. Intramuscular, subcutaneous, and kidney fats were obtained from each carcass. Total lipids from each fat depot sample were extracted by the chloroform-methanol method. Extracted lipids were prepared for the fatty acid methyl esters (FAME) and then analyzed by a gas chromatography. All data were analyzed as a completely randomized design. Palmitic (C16:0), stearic (C18:0), oleic (C18:1n9), and linoleic (C18:2n6) acids were the major fatty acids in the intramuscular fats from goats supplemented with either BG-hay or PB-pellet (85.9 vs 86.0% of total fatty acid). The subcutaneous and kidney fats consisted mainly of myristic (C14:0), C16:0, C18:0, and C18:1n9 acids, which accounted for 79.1 and 81.9% vs 85.3 and 84.7% of total fatty acids in the BG-hay and PB-pellet supplemented goats, respectively. No significant differences were found in these major fatty acids in the 3 different fat depots from goats fed either BG-hay or PB-pellet. However, compared with goats fed BG-hay, goats fed PB-pellet had lower ($P < 0.05$) concentrations of margaric (C17:0), margaroleic (C17:1n9), and conjugated linoleic (C18:2, *CLA*) acids in intramuscular fats; a higher ($P < 0.05$) concentration of eicosapentaenoic (C20:5n3) acid in subcutaneous and kidney fats. The results indicate that the supplementation of PB did not change the major fatty acids in the different fat depots in meat goats.

Key Words: goat, pine bark, fatty acid profile

M456 Influence of dietary condensed tannins from pine bark and/or sericea lespedeza on chemical composition and quality of goat meat. Travet Witherspoon[1], Jung Hoon Lee*[2], Beruk B. Lemma[1], Byeng R. Min[3], Govind Kannan[2], and Brou Kouakou[2], *[1]1Thomasville High School, Thomasville, GA, [2]Fort Valley State University, Fort Valley, GA, [3]Tuskegee University, Tuskegee, AL.*

Even though pine bark (PB) and sericea lespedeza (SL) contain a high amount of condensed tannins (CT), they have been recognized as an economical source of nutrients for goats. Yet their effect on the quality of goat meat (chevon) has not been intensively studied. This study was conducted to determine the quality characteristics of chevon from meat goats fed CT-containing PB and/or SL diets. Twenty-four Kiko × Boer male goats (8 mo of age; BW = 37.3 ± 2.56 kg) were randomly assigned to a feeding trial. Goats were randomly divided into 4 groups with 6 goats in each group. Each group was assigned randomly 1 of 4 diets: 30% bermudagass (BG) hay (control, BG-diet); 30% PB pellet (PB-diet); 30% SL pellet (SL-diet); and 15% PB + 15% SL pellet (PS-diet) with the remainder of each diet made up of 70% alfalfa pellets mixed with a commercial molasses-based sweet feed. After a 50 d feeding trial, goats were slaughtered using standard procedures. After 24 h cooler storage (2°C), longissimus muscle (LM) pH was measured from individual carcasses and each carcass was fabricated to obtained 2.5-cm thick loin chops for meat quality analysis. All data were analyzed as a completely randomized design. The LM pH values of goats fed the 4 different diets were not significantly different. Chops from goats fed a PB-diet had higher ($P < 0.05$) CIE L* (lightness) and a* (redness) values than those from goats fed the other 3 different diets. The LM from goats fed a PS-diet had higher ($P < 0.05$) moisture and ash contents than that from goats fed a PB- and a BG-diet, respectively. Furthermore, the LM from goats fed a PB-diet had higher ($P < 0.05$) percent metmyoglobin and thiobarbituric acid reactive substances (TBARS) values than that from goats fed the other diets. Compared with goats fed BG-diet, goat fed either a SL- or a PB-diet had lower ($P < 0.05$) shear values (3.74 vs 3.26 or 3.03 ± 0.13 kg) in cooked loin chops. The results indicate that a diet containing higher amounts of dietary tannins from PB might improve the texture property and color of goat meat, whereas the resulting chevon might be more susceptible to the lipid oxidation.

Key Words: chevon quality, pine bark, sericea lespedeza

M457 Fatty acid composition of different fat depots from meat goats supplemented with either tannin-rich pine bark and sericea lespedeza alone or in combination. Christina R. Alfred[1], Jung Hoon Lee*[1], Travet Witherspoon[2], Beruk B. Lemma[1], Byeng R. Min[3], Govind Kannan[1], and Brou Kouakou[1], *[1]Fort Valley State University, Fort Valley, GA, [2]Thomasville High School, Thomasville, GA, [3]Tuskegee University, Tuskegee, AL.*

In vitro studies showed that dietary tannins inhibit the growth of microorganisms that are responsible for ruminal biohydrogenation of fatty acids. Both pine bark (PB) and sericea lespedeza (SL) contain high amounts of condensed tannins (CT). However, their effect on the fatty acid profile of different fat depots in meat goats has not been studied. This study was conducted to determine the fatty acid composition of different fat depots from meat goats fed CT-containing either PB and SL alone or in combination diets. Twenty-four crossbred (Kiko × Boer) goats (BW = 37.3 ± 2.56 kg) were randomly assigned to one of 4 diets: 30% bermudagass (BG) hay (control, BG-diet); 30% PB pellet (PB-diet); 30% SL pellet (SL-diet); and 15% PB + 15% SL pellet (PS-diet) with the remainder of each diet made up of 70% alfalfa pellets mixed with a commercial molasses-based sweet feed. After 50 d feeding, goats were harvested. Intramuscular, subcutaneous, and kidney fats were obtained from each carcass. Total lipids from each fat sample were extracted, and prepared for the fatty acid methyl esters (FAME). The FAME were analyzed by a gas chromatography. All data were analyzed as a completely randomized design. Compared with goats fed BG-diet, goats fed either PB- and SL-diet had a lower ($P < 0.05$) concentration of stearic (C18:0) acid (16.93 vs 14.93 or 15.01%) in intramuscular fat. Goats fed PB-diet had higher concentrations of linoleic (C18:2n-6; 5.55 vs 8.21%) and linolenic (C18:3n-3; 0.57 vs 0.91%) acids in intramuscular fat compared with goat fed BG-diet. In kidney fat, goats fed either PB- or SL-diet had a lower ($P < 0.05$) concentration of margaroleic (C17:1n-9) acid (0.45 vs 0.33 or 0.36%), but goats fed PB-diet had higher a concentration of C18:2n-6 (2.50 vs 5.48%) acid compared with goats fed BG-diet. Goats fed PS-diet had a higher concentration of C18:2n-6 acid (1.48 vs 2.75%) in subcutaneous fat compared with those fed BG-diet. The results indicated that goats fed PB might increase the deposition of C18 polyunsaturated fatty acids in fresh goat meats.

Key Words: pine bark, sericea lespedeza, fatty acid profile of goat

M458 Influence of reproductive stage and breed on the hemogram of sheep. Leilson R. Bezerra*[1,2], Jacira N. C. Torreão[1], Carlo A. T. Marques[1], Marcos J. Araujo[1], and Ronaldo L. Oliveira[2], [1]*Federal University of Piauí, Bom Jesus, Piauí, Brazil,* [2]*Federal University of Bahia, Salvador, Bahia, Brazil.*

The objective with this study was to evaluate the influence of reproductive stages (pregnancy, puerperium) and breed (Santa Inês and Morada Nova) on the hemogram. We used 20 Santa Inês sheep and 20 Morada Nova sheep diagnosed with positive pregnancy and distributed in a completely randomized design, factorial arrangement 2 × 2 (reproductive stage × breed) a in a split-plot arrangement over time (blood collection). During the experimental period, the animals were kept in paddocks containing *Andropogon gayanus*, which was enclosed in the late afternoon for supplementation consisting of cracked corn (70%), soybean meal (25%) and mineral supplement (5%), based on the dry matter. Blood samples were collected by jugular venipuncture every 14 d in the morning before the animals were released to pasture, starting from 1st day of gestation up to the 90th day of lactation (when the lambs were weaned). The hemogram analysis consisted of global erythrocyte counts, packed cell volume or hematocrit, hemoglobin, mean corpuscular volume (MCV), mean corpuscular hemoglobin concentration (MCHC), total plasma proteins (TPP) and total leukocyte counts. The means were compared with the Student-Newman-Keuls test, and was considered significant effect when $P < 0.05$. There was no influence of breed in erythrocyte count ($P = 0.4718$) and TPP ($P = 0.2609$). The Morada Nova breed showed higher hemoglobin ($P < 0.0001$) and hematocrit ($P = 0.0024$) and total leukocyte count ($P < 0.0001$) than Santa Inês breed. There was increased in global erythrocyte counts ($P < 0.0001$) in pregnancy and a reestablishment during the puerperium period. The pregnancy period reduced hemoglobin ($P < 0.0001$), hematocrit ($P = 0.0024$), MCV ($P < 0.0001$) and MCHC ($P < 0.0001$) and puerperium period increased hematocrit ($P = 0.0356$) and total leukocyte count ($P = 0.0243$). The TPP also increased ($P < 0.0001$) during pregnancy period to compensate for the high nutritional requirements of the fetus, and these levels remained high until the end of the puerperium phase when the lambs were weaned. There is recuperation of blood values such as TPP in puerperium, which increase during this period to compensate for the high nutritional demands of the fetus in pregnancy.

Key Words: hemoglobin, indigenous sheep, parturition

M459 Production and chemical composition of milk from goats fed different levels of buriti oil. Leilson R. Bezerra*[1,3], Jasiel S. Morais[1,2], Ronaldo L. Oliveira[3], Aderbal M. A. Silva[2], and Ricardo L. Edvan[1], [1]*Federal University of Piauí, Bom Jesus, Piauí, Brazil,* [2]*Federal University of Campina Grande, Patos, Paraíba, Brazil,* [3]*Federal University of Bahia, Salvador, Bahia, Brazil.*

Buriti (*Mauritia flexuosa*) oil can be a great energy source for goats in lactation. This study aimed to determine the most effective level of buriti oil to use in supplements for lactating goats. Eight Anglo-Nubian crossbreed goats in 50 d of lactation were grouped into 2 4 × 4 double simultaneous Latin squares being 4 experimental periods of 21 d each, with 16 adaptation days and 5 d data collection. The treatments were 4 diets containing 0–15, 30 or 45 $g \cdot kg^{-1}$ of buriti oil in the total diet. The diets, a total mixed ration, were composed of corn silage and concentrate made with: corn, soybean, mineral supplement and buriti oil and were formulated according to NRC (2007) recommendations to lactating goats with production of 2 $kg^{-1} \cdot goat^{-1} \cdot day^{-1}$ and 4% milk fat. Animals were fed twice a day immediately after milking, at 8:00 and 16:00 h. The data were submitted to ANOVA and regression, using the MIXED model procedure from the statistics program SAS 9.1.2. The dry matter intake was reduced linearly ($Y = -0.16x + 2.1$, $r^2 = 0.914$) by the addition of buriti oil ($P < 0.05$). The milk production and milk production corrected for 4% of fat were not affected by the addition of buriti oil, but the corrected milk production of total solids ($Y = 0.033x + 1.152$, $r^2 = 0.898$) were increased linearly ($P = 0.0378$). In regards to milk constituents, the fat milk ($Y = 0.237x + 4.465$, $r^2 = 0.985$) was increased linearly ($P < 0.0001$) by the buriti oil levels in the total diet. The mean concentrations of total protein (37.63 $g \cdot day^{-1}$) casein (31.80 $g \cdot day^{-1}$) lactose (45.09 $g \cdot day^{-1}$) and urea (18.74 $mg \cdot dL^{-1}$) were not affected by the addition of buriti oil in diet ($P > 0.05$). The inclusion of buriti oil at 45 $g \cdot kg^{-1}$ in a total mixed ration increases corrected milk production of total solids and milk fat of Anglo-Nubian crossbreed goats.

Key Words: fat milk, nutrition, palm tree

M460 The effects of administering a fibrolytic probiotic made from moose rumen bacteria to neonatal lambs. Suzanne L. Ishaq*[1], Christina J. Kim[1], and André-Denis G. Wright[2], [1]*University of Vermont, Burlington, VT,* [2]*University of Arizona, Tucson, AZ.*

The present study investigated the effect of a fibrolytic probiotic using bacteria isolated from the rumen of the North American moose (*Alces alces*). Bacteria from moose were chosen for their ability to digest a variety of plant polysaccharides and lignin. Twenty 5-d old lambs (mean 5.9 ± 0.2 kg) were divided into probiotic and control groups, with probiotic receiving 5 bacterial isolates orally through weaning (9 wk), after which the lambs were put on pasture. Neither weight gain nor wool quality was improved in lambs given a probiotic, however, dietary efficiency was increased as evidenced by the reduced feed intake (and rearing costs) without a loss to weight gain. Total VFAs were not significantly different between groups. Acetate, propionate, butyrate, and ethanol were significantly ($P < 0.05$) higher in experimental lambs at certain weeks. The acetate to propionate ratio was statistically lower in the experimental group at wk 9, 11, and 15, which was previously shown to indicate increased dietary efficiency. Sampling coverage decreased over time, while Shannon, Inverse Simpson, CHAO, and ACE increased over time, which is a function of the increasing diversity of microbiota as the rumen develops. The experimental group had a higher diversity at the beginning of the experiment. Bacteroidetes was the most prevalent phylum (38–73% of total sequences) in both groups for the duration of the study, with the exception of the first sampling of the control group. Firmicutes was the second most prevalent (23–59%). In the control group, Bacteroidetes increased while Firmicutes decreased for the first 3 sampling points, while the experimental had a general trend of decreasing Bacteroidetes and increasing Firmicutes over time. *Prevotella* was the most prevalent genus, followed by *Butyrivibrio* and *Ruminococcus*. Protozoal densities increased over time and stabilized, but methanogen densities varied greatly in the first 6 mo of life for lambs. This is likely due to the changing diet and bacterial populations in the rumen.

Key Words: lamb, probiotic, moose

M461 Factors affecting feed efficiency in dairy goats. Tadeu Silva de Oliveira*[1], Ricardo Augusto Mendonça Vieira[1], Danielle Ferreira Baffa[2], Aberto Magno Fernandes[1], and José Carlos Pereira[2], [1]*Universidade Estadual do Norte Fluminense-Darcy Ribeiro, Rio*

de Janeiro, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.

The objective of this study was to present some factors affecting feed efficiency in dairy goats. For our study, individual and average data from performance experiments with lactating goats were used. The following variables were evaluated: gross feed efficiency, adjusted feed efficiency, dry matter intake, milk-yield, 3.5% fat-corrected milk yield, dry matter digestibility, dietary neutral detergent fiber content, different roughage-to-concentrate ratios and body weight. The statistical analyses involved the application of descriptive and dispersion measures besides Pearson correlation coefficient PROC CORR and linear regression analysis PROC MIXED of SAS. However, because average daily gain (ADG) and dry matter intake (DMI) are variables of normal distribution, and because their division generates a Cauchy distribution variable it is more appropriate to generate a normal distribution variable from the transformation of the 2 variables according PROC TRANSREG of SAS. The analyzed variables were highly correlated with feed efficiency. The dry matter intake, dietary NDF content, roughage to-concentrate ratio and live weight had a negative correlation ($P < 0.05$) with feed efficiency, indicating that increase in these variables inversely affecting FE, reducing it. In contrast, milk yield, 3.5% fat-corrected milk yield and dry matter digestibility positively affected ($P < 0.05$) FE. Fat corrected milk yield was positively correlated with FE (R = 0.89; $P < 0.001$) as was milk yield (R = 0.83; $P < 0.001$). Feed efficiency (FE) increased by 0.061 points with every 1-L increase in milk yield. Fat corrected milk is a better indicator of feed efficiency because of the difference in energy represented my milk fat percentage. In conclusion, among these factors, standardization of the milk fat appeared to be the most efficient in describing the feed efficiency in lactating goats. Funded by FAPERJ, CAPES, and CNPq.

Key Words: dry matter intake, goat, milk yield

M462 Variation of masses of body fat and protein and visceral organs of alpine goats in the first eight weeks of lactation. Tadeu Silva de Oliveira*[1], Ricardo Augusto Mendonça Vieira[1], Marcelo Teixeira Rodrigues[2], Aberto Magno Fernandes[1], and Danielle Ferreira Baffa[2], *[1]Universidade Estadual do Norte Fluminense-Darcy Ribeiro, Rio de Janeiro, Brazil, [2]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The use constant values to represent the loss of energy due to mobilization of fat and protein as considered by INRA (1989), AFRC (1993) and Morand-Fehr and Hervieu (1999) does not reflect in a reliable dynamic mobilization. It should be considered that most data used for that inference were based on short-term calorimetric studies. Thus, it is essential to quantitatively know low body energy reserves are transformed into milk energy, and low energy mobilized and consumed concur for energy balance in the lactation course. This study aimed to measure changes of body fat and protein masses, and also quantify mass-changes of visceral organs of Swiss Alpine does throughout the first 8 weeks of lactation. Fifty-one multiparous does were allotted in a completely randomized design with 6 replications and 8 treatments (weeks of lactation). Animals were slaughtered sequentially to measure the mass of fat and protein retained in the body, as well as the weight of the visceral organs. The data were analyzed by using the MIXED procedure of SAS, in which 2 covariance structures (homogeneous and heterogeneous variances) and the likelihood of linear, quadratic, and cubic models were evaluated. The empty body weight (EBW) decreased ($P < 0.05$) over the 8 weeks of lactation (from 56.8 to 35.6 kg) and carcass fat also decreased ($P < 0.05$) from 5.16 to 2.10 kg and from 9.1 to 5.9% of EBW. Body fat reduced from 24.13 to 13.51%, as well as protein (from 14.18 to 14.75%), mostly because of the mobilization of noncarcass fat (from 28.58 to 15.73%) and protein (from 12.42 to 13.20%). The visceral fat mass was mobilized with greater intensity from the third to the eighth week of lactation, i.e., 4.33 kg reduced to 1.40 kg in the period or 7.57% reduced to 3.01% of EBW. There was no effect ($P > 0.05$) on liver mass, rumen, omasum, abomasum, small intestine, and large intestine during the first 8 weeks of lactation, but there was a decrease ($P < 0.05$) in the uterus (from 1.63 to 0.14 kg) and mammary gland masses (from 2.84 to 1.48 kg). In conclusion, Swiss Alpine does in early lactation mobilized energy reserves not only from carcass and internal fat but also from visceral organs. Funded by FAPERJ, CAPES and CNPq.

Key Words: adipose tissue, goats, mobilization

M463 Meat composition and yield of carcass and non-carcass components in crossbred lambs fed frying soybean oil. F. O. Scarpino-van Cleef*, E. H. C. B. van Cleef, M. T. C. Almeida, A. P. D'Aurea, H. L. Perez, and J. M. B. Ezequiel, *São Paulo State University, Jaboticabal, São Paulo, Brazil.*

Twenty-four crossbred uncastrated male Santa Ines × Dorper lambs (24.9 ± 2.4 kg BW) were used to evaluate meat composition and yield of carcass and non-carcass components when fed diets containing supplementary oil sources. Treatments consisted of a control diet (CON) containing 40% corn silage, 10.8% corn grain, 9.8% soybean hulls, 37.45% sunflower meal, 0.55% urea, 1.4% mineral premix, and 2 diets containing additional 6% soybean oil (SOY) or 6% residual soybean frying oil (FRY). Lambs were blocked by initial body weight (BW), and randomly assigned to 24 individual feedlot pens. Animals were harvested when they reached 35 kg BW. Carcass and edible non-carcass components were separated and weighed. Total edible non-carcass components yield (TENC) was obtained as the sum of weights of blood, tongue, lungs + trachea, liver + gall bladder, heart, kidneys, gastrointestinal tract (reticulum, rumen, omasum, abomasum and intestines), and abdominal and kidney fats. Total yield of usable products (TUP) was calculated as the sum of hot carcass weight and TENC. A sample of *Longissimus* muscle was collected between 12th and 13th ribs, and evaluated for moisture, crude protein, ether extract and ash contents. Data were analyzed as a randomized block design using a mixed model, and the contrasts control × oil treatments and soybean oil × frying oil were evaluated. TENC values were 6.62, 6.56, and 6.35 kg; and TUP values were 22.27, 21.58, and 22.19 kg for CON, SOY and FRY, respectively ($P > 0.10$). The weight of the liver of oil-fed lambs was greater than the ones fed CON ($P = 0.04$). The weight of the spleen tended to be greater in lambs fed FRY ($P = 0.06$), while the other individual non-carcass components were not affected by treatments. The ether extract of meat tended to be greater in lambs fed diets containing oil, regardless the source ($P = 0.07$). The meat moisture, mineral matter, or crude protein contents were unaffected by dietary oil supplementation. Data indicate soybean-frying oil is a potential alternative energy ingredient in diets for feedlot lambs and that the inclusion of 6% of this oil does not depreciate carcass and edible non-carcass components yields, and it increases meat intramuscular fat slightly.

Key Words: byproduct, lipid, non-carcass component

M464 Milk production, quality, and components measured in lactating dairy goats supplemented with OmniGen-AF. Angela D. Rowson*[1], Shelby A. Armstrong[1], Lane O. Ely[2], and Derek J. McLean[1], *[1]Phibro Animal Health Corporation, Quincy, IL, [2]University of Georgia, Athens, GA.*

OmniGen-AF (OG) is a nutritional supplement that supports immune function in ruminant species. Forty-four, second parity lactating dairy goats were used to determine the effects of feeding OG on milk production, quality and components. Goats (63.5 ± 4.8 kg BW) were housed on a commercial goat dairy in Wisconsin. Does were randomly assigned to 1 of 2 diets: 1) Control (CT; n = 22), and 2) OG (n = 22). CT does were fed a complete commercially available feed pellet (dry pellet: CP 14%, fat 3%, fiber 11.2%; lactating pellet: CP 16%, fat 3.4%, fiber 8.1%) twice a day and had ad libitum access to alfalfa hay. OG does were fed the same diet but with 6 g/h/d of OG added to the pellet. Both diets met the nutrient requirements of the does including the diet without OG. Diets were initiated at dry-off (67–94 d prepartum) and continued for the entire lactation. Does were crossbreds (Saanan, Nubian, Alpine and LaMancha) with all breeds equally represented in both groups. DHIA milk testing was performed every 28 d during lactation, resulting in a total of 10 tests. Milk production, % fat, % protein, fat corrected milk (FCM), energy corrected milk (ECM), SCC, and somatic cell score (SCS) data were collected at each test. Mean milk produced per day was significantly greater ($P < 0.05$) for OG does than CT does (3.65 vs. 3.3 kg/h/d, respectively). Mean FCM was 3.59 kg/h/d for OG goats vs. 3.15 kg/h/d for CT goats ($P < 0.01$). Mean ECM was 3.82 kg/h/d for OG goats and 3.39 kg/h/d for CT goats ($P < 0.02$). Mean milk % fat was significantly greater ($P < 0.05$) for OG does (3.93%) compared with CT does (3.66%). The mean SCC for OG does was 847,060 mL^{-1} vs. 1,167,100 mL^{-1} for CT does ($P < 0.1$). Further analysis of the last 2 test dates (mean days in milk = 239.7 and 266.8) indicated OG does had lower SCC [1,348,090 mL^{-1} ($P < 0.1$) and 2,003,630 mL^{-1} ($P < 0.05$)] than CT does (2,471,090 mL^{-1} and 5,057,630mL^{-1}). There were no differences ($P > 0.1$) in mean % protein or mean SCS between the 2 groups. These results, including improved milk production, quality and select components, suggest enhanced mammary health in lactating dairy goats supplemented with OG.

Key Words: goat, milk, OmniGen-AF

M465 Effect of increasing levels of concentrate on nutrient digestibility and growth performance in lambs. Michelle de Oliveira Maia Parente[1], Ruan Mourão Silva Gomes*[1], Wesclley Jesus dos Santos Sodré[1], Henrique Nunes Parente[1], Miguel Arcanjo Moreira Filho[1], Nágila Maria de Carvalho Almeida[1], Rosane Cláudia Rodrigues[1], Jocélio dos Santos Araújo[1], and Daniel Louçana da Costa Araújo[2], [1]*Universidade Federal do Maranhão, Chapadinha, Maranhão, Brazil,* [2]*Universidade Federal do Piauí, Teresina, Piauí, Brazil.*

Quality and quantity of feed are the major factors in increasing ruminant productivity under tropical conditions. Increase in energy density in diets by providing larger quantities of concentrate feeds may improve feed efficiency and animal performance contributing to higher overall efficiency of utilization of dietary energy for body weight gain. Therefore, the objectives were to determine the effects increasing levels of concentrate on performance, intake and digestibility of lambs. Fifteen crossbred lambs (initial BW of 18.2 ± 3.2 kg and 100 d old) were used in a randomized complete block design according to initial BW and age. Lambs were penned individually during 45 d and fed an isonitrogenous (16.6 ± 0.55 CP, DM basis) diet. Increasing levels of concentrate were 40, 60, or 80% corresponding to the experimental diets C40, C60 and C80, respectively. Data were analyzed using SAS PROC Mixed procedure and means compared by Tukey Test. Effects were declared significant at $P \leq 0.05$. No effect were observed on Dry matter (DM) intake (0.76, 0.87 and 0.85 kg/d for C40, C60 and C80) and crude protein (CP) intake (0.14, 0.16 and 0.15 kg/d or C40, C60 and C80). The DM digestibility was greater ($P \leq 0.01$) for lambs fed C60 and C80 diets (80.18, 87.53 and 88.16% for C40, C60 and C80, respectively), while CP digestibility was unaffected ($P \geq 0.05$) by concentrate levels (91.03, 92.21 and 91.56% for C40, C60 and C80, respectively). The Neutral Detergent Fiber (NDF) intake decreased for lambs fed C80 diet ($P \leq 0.05$) while NDF digestibility was unaffected ($P \geq 0.05$). ADG and G:F were greater ($P \leq 0.01$) with increasing concentrate levels. Average daily gain was 60.1, 126.1 and 232.6 g/d while G:F was 0.08, 0.14 and 0.23 for C40, C60 and C80, respectively. It is concluded that supplementation of concentrate between 60 to 80% improves DM digestibility and performance of crossbred lambs without affect DM intake.

Key Words: average daily gain, energy density, feed efficiency

M466 Feeding behavior of lambs fed increasing levels of concentrate in the diet. Michelle de Oliveira Maia Parente[1], Wesclley Jesus dos Santos Sodré[1], Ruan Mourão da Silva Gomes*[1], Miguel Arcanjo Moreira Filho[1], Grazieli Silva Oliveira[1], Alayne Andrade Cutrim[1], Arnaud Azevêdo Alves[2], and Viviany Lúcia Fernandes dos Santos[3], [1]*Universidade Federal do Maranhão, Chapadinha, Maranhão, Brazil,* [2]*Universidade Federal do Piauí, Teresina, Piauí, Brazil,* [3]*Universidade Ferederal do Rio Grande do Norte, Natal, Rio Grande do Norte.*

The study of ingestive behavior is a highly important tool in the evaluation of diets, because through it is possible to acquire knowledge of the possible relationships existing between foods and animal, allowing us to adjust the feeding management of animals to obtain better productive performance. The objective of this trial was to determine the effects increasing levels of concentrate on feeding behavior of lambs. Fifteen crossbred lambs (initial BW of 18.2 ± 3.2 kg and 100 d old) were used in a randomized complete block design according to initial BW and age. Lambs were penned individually during 45 d and fed an isonitrogenous (16.6 ± 0.55 CP, DM basis) diet. Increasing levels of concentrate were 40, 60, or 80% corresponding to the experimental diets C40, C60 and C80, respectively. Animals were monitored every 5 min during 24 h, on the 23th day of the experiment, according to the activities: eating, rumination, idle and other activities. The feed and rumination efficiencies, expressed as g DM/hour were obtained by dividing the average daily intake of dry matter by the total time spent eating and/or ruminating in 24 h, respectively. Orthogonal polynomials for diet responses were determined by linear and quadratic effects. Effects were declared significant at $P \leq 0.05$. There was a quadratic response ($P \leq 0.05$) for time spent in eating. The levels of concentrate did not affect ($P \geq 0.05$) the eating efficiency (149.3, 182.3 and 226.1 g DM/h for C40, C60 and C80), time spent in idle (505.0, 493.0 and 589.0 min/d for C40, C60 and C80) and water intake (1.8, 2.5 and 2.5 kg/d for C40, C60 and C80). The time spent in other activities (133.0, 185.0 and 220.0 min/d for C40, C60 and C80) and rumination efficiency (92.4, 116.5 and 132.4 g DM/h for C40, C60 and C80) tended to linearly increase ($P = 0.07$) with high concentrate levels. However, the time spent in rumination (495.0, 462.0 and 391.0 min/d for C40, C60 and C80) tended to linearly decrease ($P = 0.06$) with high concentrate levels. It is concluded that high concentrate levels (C80) changed the feeding behavior of lambs, especially for time spent for eating

Key Words: eating efficiency, idle, rumination efficiency

M467 Efficacy of Rumatel (morantel tartrate) against gastrointestinal nematode infections in lactating dairy goats. Angela D. Rowson*[1], Shelby A. Armstrong[1], Brian P. Schnell[2], and Lane O. Ely[3], [1]*Phibro Animal Health Corporation, Quincy, IL,* [2]*University of Wisconsin, Madison, WI,* [3]*University of Georgia, Athens, GA.*

Rumatel (morantel tartrate) is an FDA-approved anthelmintic safe for use in goats and has no milk withhold. The objective of this study was to evaluate the efficacy of Rumatel on the removal of gastrointestinal nematodes (GIN) in lactating dairy goats. Twenty second-lactation crossbreed does (59 – 68 kg; mean days in milk = 128.5) from a south-central Wisconsin commercial herd were used in this study. Goats were housed in a pole barn with roll-up curtain sides on a bedded pack with continual access to pasture. A complete feed pellet was provided to the does twice a day and alfalfa hay was fed ad libitum. Goats had not been dewormed for 7 mo. Fecal pellets were collected from the rectum of each doe at 2 different time points, once immediately before the administration of Rumatel and again 14 d later. Fecal samples were analyzed for GIN using the McMaster's technique for fecal egg counts. Eligible samples [≥25 *Trichostrongyle* spp. eggs/gram of feces (EPG)] were further analyzed using the Peanut Agglutination test. Conjunctival examinations were conducted on all does using the FAMACHA card as a color reference (scored 1 – 5) at each fecal collection. Goats were dewormed once using Manna Pro Positive Pellet Goat Dewormer (morantel tartrate: 880 g/ton) immediately following the first fecal collection. Does were group-fed the product with enough pellet provided for each goat to consume 0.68 kg (0.66 g of morantel tartrate). Means were compared with a Student's *t*-test. Feeding Rumatel resulted in significantly lower ($P < 0.01$) EPG of total nematodes, *Trichostrongyle* spp., and *Haemonchus contortus*. Fecal egg counts were 176.3, 167.5, and 166.1 EPG, respectively, before deworming and 20.0, 20.0, and 14.7 EPG after deworming. Rumatel treatment also lowered the percentage of goats with *H. contortus* infections from 74.7% to 29.6% ($P = 0.001$) and decreased FAMACHA scores from 3.5 to 2.65 ($P = 0.001$). Results indicate that Rumatel is an efficacious anthelmintic for lactating dairy goats for GIN like *Trichostrongyle* spp., including *H. contortus*.

Key Words: goats, *Haemonchus contortus*, Rumatel

M468 Determining the critical time to measure fasting heat production of Saanen goats. Ana Rebeca Castro Lima*, Kleber Tomás de Resende, Márcia Helena Machado da Rocha Fernandes, Izabelle Auxiliadora Molina de Almeida Teixeira, Thiago Henrique Borghi, José Mauricio dos Santos Neto, and Carolina Isabel Soriano Oporto, *Unesp, Jaboticabal, São Paulo, Brazil.*

The objective of this study was to establish the physiological parameters of Saanen goats at absorptive and post absorptive statuses, to determine the required period of fasting for these animals. Gas exchange was recorded by an open-circuit face-mask respirometry. Six nonlactating and non-pregnant Saanen (49.2 ± 3.2 kg) goats were used in this experiment, allocated to individual pens and fed the same total mixed ration (19,5% of crude protein, 10 MJ per kg DM of metabolizable energy, ME). Gas exchange was measured in groups of 3 animals each and each data collection period lasted 6 d. During feeding period (3 d), each group was submitted to a double Latin square (3 × 3) with 3 animals and 3 h window in the morning (7.00–9.00h; 9.00–11.00h; 11.00–13.00h) and evening (13.00–15.00h; 15.00–17.00h; 17.00–19.00h). After the 3-d feeding period, animals were subjected to fasting (no feed, only water) and gas exchange measurement was performed for 30 min periods at 12, 20, 36, 44, 60, and 68 h after fasting. To evaluate the decay of methane during fasting, methane production was fitted to a nonlinear logistic model. The critical time to reach the asymptote, or to measure fast heat production (FHP), was obtained when the upper limit of the standard error of mean of minimum methane produced and when CH_4 production became equivalent. During the feeding period, Saanen goats' drank 3.34 ± 0.53 L/d of fresh water and consumed 848.6 ± 40.2 g/d of dry matter, the daily heat production, averaged 557.4 ± 38.7 kJ/kg$^{0.75}$ BW and their FHP was 236.0 ± 19.7 kJ/kg$^{0.75}$ BW. After fasting, methane production decreased exponentially and the critical time to measure FHP was 47 h of fasting for Saanen goats when methane production was statistically equal to zero. Taken together, our results suggest that the ideal period to measure FHP should be between 40 and 60 h of fasting for goats fed at maintenance levels. The results presented herein are relevant for future energy metabolism studies in goats.

Key Words: heat production, indirect calorimetry, methane

M469 Calcium and phosphorus accretion rate in Saanen goat kids of different genders. José Maurício dos Santos Neto*, Kléber Tomás de Resende, Márcia Helena Machado da Rocha Fernandes, Izabelle Auxiliadora Molina de Almeida Teixeira, Julian André Castillo Vargas, Ana Rebeca Castro Lima, Fernanda Oliveira de Miranda Figueiredo, Rafael Fernandes Leite, Paula Fernanda Varella dos Santos, and Carolina Isabel Soriano Oporto, *São Paulo State University (Unesp), Jaboticabal, São Paulo, Brazil.*

Calcium (Ca) and phosphorus (P) constitute an essential part of goat diets, being necessary for adequate growth and physiological function; however, studies about their accretion rate in goats are still scant, especially regarding the differences among genders. In this sense, we evaluated and compared the Ca and P accretion rate in intact males, castrated males and females, weighting from 15 to 30 kg of body weight (BW). We used 58 Saanen goat kids (20 intact males, 20 castrated males and 18 females) fed ad libitum and housed in individual pens, with an initial BW of 15.85 ± 0.11 kg. The diet consisted of 45% forage (dehydrated corn plant) and 55% concentrate. The animals of different genders were assigned in a completely randomized design and slaughtered at 16.6 ± 0.40 kg BW, 23.1 ± 1.33 kg and 31.2 ± 0.58 kg BW. Allometric equations used to calculate the relationships between macromineral quantities and empty body weight (EBW) were generated and compared among genders by NLINMIX procedure (SAS Institute Inc., Cary, NC 9.4). The Ca and P accretion rate were estimated by the first derivative of these allometric equations. The Ca and P accretion rate did not differ among genders ($P > 0.05$) and decreased from 11.04 to 11.01 g of Ca and from 6.96 to 5.98 g P per kg of EBW gain, when kids grown from 15 to 30 kg BW, respectively. Because Ca and P mostly concentrate in skeletal tissue, absence of difference may indicate that bone development in Saanen goats are similar among genders, and presumably, those animals have reached bone maturity early in life.

Key Words: body composition, comparative slaughter, macromineral

M470 Effects of milk replacer feeding time on growth performance, nutrient digestibility and serum profiles in early-weaned lambs. Jian-min Chai, Hai-chao Wang, Qi-yu Diao, Tao Ma, Min-li Qi, Yan Tu, and Nai-feng Zhang*, *Feed Research Institute, Chinese Academy of Agricultural Sciences, Key Laboratory of Feed Biotechnology of the Ministry of Agriculture, Beijing, China.*

This study was conducted to evaluate the effect of milk replacer feeding time on growth performance, nutrient digestibility and serum profiles in early-weaned lambs. Forty-eight newborn Hu lambs (2.53 ± 0.13 kg; 24 male and 24 female) were divided into 4 treatments: ewe-reared (ER) or weaned at 10, 20, or 30 d post birth (EW10, EW20, and EW30) and fed milk replacer (MR). All liquid feed were eliminated at 60 d of age (d 60). Creep feed was offered ad libitum to all lambs from d 15 to 90. Lambs were weighed on d 60 and 90. The data of liveweight (LWT), average daily gain (ADG), feed (including creep and MR) intake, nutrient utilization and serum parameters were analyzed as completely randomized design using one-way ANOVA. Duncan's method for multiple comparisons was used if the overall F test for the measurement was significant ($P < 0.05$). The results indicated that lambs of EW10, EW 20, and EW 30 had higher LWT (22.1, 21.4, and 20.2 vs 18.5 g), ADG (225.1, 219.6, and 208.6 vs 177.6 g/d), and creep feed intake (512.9, 412.1, and 413.0 vs 370.3 g/d) ($P < 0.001$) than those in ER group. There were no differences between treatments in the apparent digestibility of dry matter (DM), organic matter (OM), nitrogen (N), phosphorus (P) ($P > 0.05$) from d 50 to 60. The apparent digestibility of DM, OM, N and P of EW20 and EW30 groups were significantly higher ($P < 0.05$) than that of EW10 and ER groups from d 80 to 90. Lambs in the EW10 group had higher concentration of albumin, serum urea nitrogen, and immunoglobulin G than those of other groups ($P < 0.05$). In conclusion, early weaning could improve creep intake, growth performance, and nutrient utilization of Hu lambs. Time of early weaning significantly increased the growth of lambs.

Key Words: early weaning, milk replacer, lamb

M471 Seasonal weight loss tolerance biomarkers to in dairy goats: An approach for breed selection.

Mariana Palma[1], Lorenzo Hernández-Castellano[2,3], Noemi Castro[2], Anastasio Arguëllo[2], Juan Capote[4], Manolis Matzapetakis[1], and Andre M. de Almeida*[5], *[1]Instituto de Tecnologia Química e Biológica António Xavier, Universidade Nova de Lisboa, Oeiras, Portugal, [2]Department of Animal Science, Universidad de Las Palmas de Gran Canaria, Arucas, Canary Islands, Spain, [3]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [4]Instituto Canario de Investigaciones Agrarias, Valle Guerra, Canary Islands, Spain, [5]Instituto de Biologia Experimental e Tecnológica, Oeiras, Portugal.*

Goat milk and dairy products are an important nutritional and economic resource in Tropics. However, the yearly production of milk is affected by the scarcity of pastures during the dry season, which leads to seasonal weight loss (SWL) in ruminants. The aim of the work is to identify physiological markers indicative of SWL tolerance in 2 dairy goat breeds, with different SWL tolerance levels. The results will help to define breed selection strategies in drought prone regions. Nuclear magnetic resonance (NMR) was used to compare the observable metabolome present in aqueous extracts of mammary glands and milk serum from 2 dairy goat breeds; tolerant to dry environment (Majorera) and susceptible (Palmera). Ten Palmera and 9 Majorera dairy goats in mid lactation were used in this study. Animals were divided in 4 experimental groups (Majorera control, Palmera control, Majorera restricted and Palmera restricted). Milk samples were collected daily, after milking from the whole available milk, and mammary gland biopsies were collected after 23 d. Aqueous fractions were obtained by tissue aqueous/organic extraction and milk serum was obtained by ultra-centrifugation. We collected ^{1}H NMR spectra (1D-NOESY and CPMG) from the aqueous extract of the mammary gland, and the milk serum. ^{1}H NMR Spectrum deconvolution was used for metabolite profiling analysis and has led to the identification of 47 compounds in the aqueous fraction of mammary gland extracts. Lactose, glutamate, glycine, lactate and glucose were found to be the most abundant. Statistical evaluation using principal component analysis (PCA) and partial least squares (PLS) revealed differences between control and restricted animals, although no differences between breeds were observed. Preliminary profiling analysis of milk serum samples resulted in the identification of 20 metabolites.

Key Words:goat, undernutrition, nuclear magnetic resonance metabolomics

M472 An NGS-based gene expression profile study in the goat mammary gland: Effect of undernutrition in two breeds with different levels of adaptation to nutritional stress.

José Parreira[1,2], Joana R. Lérias[1], Lorenzo E. Hernández-Castellano[3,4], Mariana Palma[2], Noemi Castro[4], Anastasio Argüello[4], Juan Capote[5], Susana S. Araújo[1,2], and André M. de Almeida*[1], *[1]Instituto de Biologia Experimental Tecnológica, Oeiras, Portugal, [2]Instituto de Tecnologia Química e Biológica (I.T.Q.B.), Universidade Nova de Lisboa, Oeiras, Portugal, [3]Veterinary Physiology, Vetsuisse Faculty, University of Bern, Bern, Switzerland, [4]Department of Animal Science, Universidad de Las Palmas de Gran Canaria, Arucas, Canary Islands, Spain, [5]Instituto Canario de Investigaciones Agrarias, Valle Guerra, Canary Islands, Spain.*

Goat milk has a high relevance worldwide, particularly in the tropics. Consequently, dairy goat productivity performance is very important for animal production and the dairy industry. Undernutrition during the dry season causes Seasonal Weight Loss (SWL), a relevant constraint for animal production. Knowledge on the genetic factors regulating milk production is limited and the impact of feed restriction, in this mechanism has been poorly addressed. A Systems Biology approach can provide a new and comprehensive insight on the molecular mechanisms underlying milk production, under feed restriction, as well as the regulation of the several biological processes involved. With such strategy, the identification of specific biomarkers and metabolic pathways involved could be used to develop new strategies to overcome this constraint. The objective of this work is to understand the molecular mechanisms by which goat breeds are adapted to SWL. We report a preliminary study of a quantitative differential analysis of mammary glands transcriptome using the Illumina high-throughput transcriptome sequencing (RNA-Seq). Two Canary Island (Spain) goat breeds were used; Majorera (SWL tolerant) and Palmera (SWL susceptible), with different productivity performances. We studied the impact of nutritional restriction on the transcriptome of mammary gland secretory tissue. Results show that a concerted reprograming of genes expression occurs as result of the stress imposed, irrespective to the breed. Also suggesting a different behavior of both breeds in response to the treatment applied. Moreover, an enrichment analysis of the differentially expressed genes provided some insight into what biological processes are related with the response to SWL during lactation. Finally, a validation of the RNA-Seq assay using RT-qPCR was performed on candidate genes differentially expressed, for instance glycerol kinase (GK) and adrenoreceptor β 2 (ADRB2). The knowledge obtained through this project will be useful to release new genomic resources as well as shed some light into the genes and regulatory networks underlying milk production under nutritional stress.

Key Words: dairy goat, undernutrition, transcriptomics

M473 Digestibility of diets containing calcium salts of fatty acids in Saanen goats.

Bruna Susan de Labio Molina, Claudete Regina Alcalde*, Bruna Hygino, Ludmila Couto Gomes, Caroline Isabela da Silva, Ana Paula Silva Possamai, and Rodrigo de Souza, *Universidade Estadual de Maringá, Maringá, Paraná, Brazil.*

According on the fat source included in the diets for goats, the availability of nutrients can be improved. The objective was to evaluate the inclusion of calcium salts of fatty acids (CSFA) in diets of Saanen goats on the digestibility of dry matter and nutrients. Five Saanen goats (63.23 ± 9.08 kg body weight and ± 105 d of lactation) were distributed in a Latin square design (5 × 5). The treatments were diets: control (without CSFA) and the other with: 6.25, 12.50, 18.75, and 25.0 g of CSFA g/kg DM, respectively. The ingredients that were: ground corn, soybean meal, protected fat (calcium salt linked with long chain fatty acids containing

1,760 g/kg total digestible nutrients, 820 g/kg ether extract, 100 g/kg calcium, 260 g/kg oleic acid, and 420 g/kg linoleic acid), and mineral-vitamin supplement. The oat hay was utilized in a proportion of 570 g/kg DM for all the treatments. The rations were adjusted to provide 700 g of total digestible nutrients/kg DM and 155 g of crude protein/kg DM. The internal marker used to estimate the digestibility was the indigestible acid detergent fiber. After 15 d for the animals to adapt to the diets, samples of feces from the exit of the rectum were collected during 6 consecutive days to obtain a composite sample per animal for each period. Calcium salts of fatty acids showed a quadratic effect on digestibility of dry matter; organic matter; neutral detergent fiber and total carbohydrate with improvement from the minimum points of 13.2; 13.3; 16.9 and 14.6 g of CSFA/kg of dry matter, respectively. Crude protein digestibility and non-fiber carbohydrates digestibility were not influenced by treatments, however, for the ether extract digestibility there was a positive linear response as function of the calcium salts of fatty acids in diets. A quadratic effect was observed on total digestible nutrients with the minimum point of 9.8 g of CSFA/kg DM. In conclusion, the inclusion of 25.0 g calcium salts of fatty acids/kg DM in diets of Saanen goats shows a better response for the total digestible nutrients.

Key Words: digestion, goat, indigestible ADF

M474 Loin characteristics of feedlot lambs fed different sources of non-protein nitrogen and carbohydrate.

Ricardo D. Kliemann*, Jean C. S. Lourenço, Larissa Goltz, Juliana M. Lima, Dayanna Pastal, Tiago M. Santos, Sergio R. Fernandes, and Américo F. Garcez Neto, *Federal University of Paraná, Palotina, Paraná, Brazil.*

The formulation of balanced diets has been a way to optimize the nutrient use by different animals and to get carcasses with high proportion of muscles and proper fat content to attract potential consumer markets. The proportion of these tissues in the carcass can be estimated by measurements in the *Longissimus dorsi* (*L. dorsi*) muscle. Characteristics of *L. dorsi* in feedlot lambs fed different sources of carbohydrates (CHO) and non-protein nitrogen (NPN) were evaluated. It was used 20 non-castrated crossbred lambs with 4 mo of age and 26 kg of body weight. The diets were composed by 57% of grass hay (*Brachiaria* hybrid) and 43% of concentrate. The hay was harvested at late mature stage with high (72.4%) neutral detergent fiber and low (4.9%) crude protein. Four concentrates were formulated from the combination of 2 CHO (ground corn: starch; whey permeate: lactose) and 2 NPN (fast and slow release urea) sources. After cooling, loin of the left half of carcasses was separated and measurements in the *L. dorsi* were made. The measurements were loin eye width (LEW), loin eye depth (LED), loin eye area (LEA), minimum fat thickness (MinFT), maximum fat thickness (MaxFT). The LEW:LED ratio was also calculated. It was used a completely randomized design with 4 treatments and 5 replicates. Data were analyzed by ANOVA following a 2 × 2 factorial scheme. LED (2.57 ± 0.06 cm), LEA (10.37 ± 0.31 cm^2), MinFT (0.76 ± 0.09 mm), MaxFT (1.69 ± 0.12 mm) and LEW:LED ratio (2.12 ± 0.06) were not ($P > 0.05$) affected by the diets. It was found an interaction ($P < 0.05$) between CHO and NPN for LEW. The LEW was smaller ($P < 0.05$) for feedlot lambs fed whey permeate and fast release urea (4.98 cm) than for those fed whey permeate and slow release urea (5.78 cm). The mean LEW was 5.39 ± 0.10 cm. Differences in the LEW did not change the LEA, which may be inferred that the association of whey permeate with slow and fast release urea resulted in the same muscle development. The association of CHO and NPN with concentrates of closest potential degradation rates does not influence the proportions of muscle and fat of lambs fed low quality forage at finishing.

Key Words: fat, muscle, sheep

M475 Blood metabolites of feedlot lambs fed different sources of non-protein nitrogen and carbohydrate.

Ricardo D. Kliemann*, Larissa Goltz, Jean C. S. Lourenço, Eduardo M. Nascimento, Dayanna Pastal, Tiago M. Santos, Sergio R. Fernandes, and Américo F. Garcez Neto, *Federal University of Paraná, Palotina, Paraná, Brazil.*

The levels of blood metabolites of feedlot lambs fed low quality forage and different sources of carbohydrate (CHO) and non-protein nitrogen (NPN) in the concentrate feed was evaluated. Twelve non-castrated male lambs with 4 mo of age and 23.5 kg BW were used. The experimental design was 4 × 3 incomplete Latin square replicated 3 times, with 4 treatments (diets) and 3 periods of 21 d. The diets were composed by 57% of grass hay (*Brachiaria* hybrid) and 43% of concentrate. The hay was harvested at late mature stage with high fiber (72.4% NDF) and low protein (4.9% CP). Four concentrate feeds were formulated from the combination of 2 CHO (ground corn: starch; whey permeate: lactose) and 2 NPN (fast and slow release urea) sources. The diets were isoenergetic (2.32 Mcal/kg ME) and isoproteic (11% CP), and fed at 1.5 times the ME requirement. At the end of each period, blood samples were collected after fasting (feed for 14 h) to assess the serum levels of total proteins (TP), albumin (Alb), creatinine (Creat), urea, glucose (Glu), cholesterol (Chol), triglycerides (TG) and β-hydroxybutyrate (BHBA). Data were analyzed by ANOVA and means were compared by LSD test ($P < 0.05$). Serum levels of TP (61.7 g/L), Alb (31 g/L), Creat (0.91 mg/dL), Glu (64 mg/dL) and BHBA (0.12 mg/dL) were not affected by the diets. Serum urea was higher in lambs fed corn and fast release urea (29.9 mg/dL), and lower in those fed whey permeate independent from NPN source (25.4 mg/dL). High levels of serum urea can be related to high production of ammonia in the rumen due to the differences in degradation rates between corn and fast release urea, and by the higher CP of corn (9%) compared with whey permeate (3%). Maybe the whey permeate was fermented faster than corn resulting in greater MP production and less ammonia in the rumen. Serum levels of Chol and TG were higher in lambs fed corn (45.2 and 24.6 mg/dL) compared with those fed whey (34.6 and 17.1 mg/dL), which was caused by the lipid fraction of corn (5.4%). The inclusion of corn or whey permeate in the concentrate feed affects the protein and energy metabolism of lambs fed low quality forage.

Key Words: cholesterol, metabolism, urea

M476 Multi-scale straightness index analysis of goat behavior.

Terry A. Gipson*[1], Kenneth M. Andries[2], Terry Hutchens[2], and Myron E. Evans[3], [1]*American Institute for Goat Research, Langston University, Langston, OK,* [2]*Kentucky State University, Frankfort, KY,* [3]*University of Kentucky Cooperative Extension, Grayson, KY.*

Multi-scale straightness index (MSSI) has been proposed for determining behavioral states such as resting, grazing, or commuting in wildlife but its suitability in livestock is not known. Therefore, the objective of this study was to apply MSSI to a herd of grazing goats. On a random sample of 13 mature Boer-cross females from a herd of 120, GPS collars that recorded a fix every 5 min were fitted for 3 consecutive days in August, 2012. The study area was a 40-ha unimproved hill pasture. The fix records were post-processed and imported into ArcMap. Boundaries of the pasture, including a 7-m external buffer, were constructed as shapefiles. Only fixes (average of 804 ± 15.2 fixes/goat) within the

boundary and buffer shape-files were exported to a spreadsheet for the calculation of MSSI using granularity (g) from 1 to 12 and window (w) from 1 to 36 with the constraint that w/g must be an integer, yielding a total of 110 g-w combinations. Within daytime (D) and nighttime (N) periods, MSSI were calculated for each g-w combination yielding 868,707 MSSI for D and 541,599 MSSI for N. LSmeans for each g-w combination were estimated using mixed model analysis with collar as random effect and day (1, 2, or 3) as repeated measure. A linear-linear-linear grafted polynomial analysis was conducted to ascertain ridge points for g-w combinations (between 2 break points). The first linear segment for both D and N represented targeted travel and accounted for 11% of the MSSI; however, the g/w ratio was 1 so this was straight line travel between 2 points. The last linear segment represented highly tortuous travel indicating most probably grazing or resting. This segment was 81% and 85% of the MSSI with an average MSSI of 0.17 ± 0.083 and 0.08 ± 0.050 for D and N, respectively. The middle linear segment represented targeted travel and accounted for 8% and 4% of the MSSI with an average MSSI of 0.53 ± 0.108 and 0.41 ± 0.119 for D and N, respectively. For the targeted travel segment, g averaged 1 for both D and N and w averaged 5 and 3 for D and N, respectively. Even in a herd of goats familiar with the terrain, targeted travel account for a small percentage of behavior and was only for a short duration.

Key Words: goat, GPS, multi-scale straightness index (MSSI)

M477 Effects of high heat load on BW, DMI, rectal temperature, and respiration rate of Katahdin sheep and Boer and Spanish goat wethers.

Mengistu Urge[1,2], Ryszard Puchala[1], Terry A. Gipson[1], Tilahun Sahlu[1], and Arthur L. Goetsch*[1], [1]*American Institute for Goat Research, Langston University, Langston, OK,* [2]*School of Animal and Range Sciences, Haramaya University, Dire Dawa, Ethiopia.*

Thirty-three yearling Katahdin sheep (K) and Boer (B) and Spanish (S) goat wethers were used to determine conditions such as an appropriate heat load index (HLI) for a method of evaluating differences in resilience to high HLI among different small ruminant species, breeds, ecotypes, and individuals. Grass hay was consumed ad libitum with concentrate (80% corn, 20% soybean meal) at 0.5% BW. After a baseline period (1) with thermo-neutral conditions, target HLI were 80, 90, 95, and 100 (e.g., 42.0°C, 40% relative humidity) during the day and 70, 77, 81, and 85 at night in subsequent 1-wk periods (2–5). Actual values averaged 66, 80, 92, 97, and 101 during day (0700 to 1900 h) and 66, 75, 84, 86, and 89 at night in periods 1–5, respectively. Final period BW was not markedly affected by HLI (100.2, 99.7, 103.1, and 101.3% of baseline; SE = 0.74), and hay DMI also was generally similar to the baseline (95.0, 72.4, 93.6, and 96.4% in periods 2–5, respectively; SE = 3.69). Rectal temperature at 0600, 1300, and 1700 h was lowest for Katahdin in periods 3 (39.4, 39.2, and 39.6°C) and 4 (39.9, 39.6, and 40.0°C for Boer, Katahdin, and Spanish, respectively; SE = 0.07) but similar at other times. There was an interaction in respiration rate between animal type and period (71, 105, and 105 in period 2, 93, 101, and 104 in period 3, 121, 139, and 129 in period 4, and 105, 126, and 109 breaths/min in period 5 for B, K, and S, respectively; SE = 4.75). Rectal temperature and respiration rate were much lower at 0600 (38.7, 38.9, and 38.8°C and 34, 77, and 56 breaths/min) than at 1300 (39.7, 39.6, and 39.9°C and 127, 137, and 135 breaths/min) and 1700 h (40.1, 39.7, and 40.2°C, SE = 0.07, and 131, 139, and 144 breaths/min for B, K, and S, respectively, SE = 4.4). In conclusion, in some periods K exhibited greater ability than B and S to increase respiration rate and minimize rectal temperature at high HLI; periods longer than 1 wk at high HLI are required for evaluating changes in BW and DMI; and variables such as rectal temperature and respiration rate may be more meaningful when measured in the afternoon than morning.

Key Words: goat, sheep, heat load

M478 Effects of mixing different breeds to evaluate electric fence strand additions to barbed wire fence to contain growing meat goat kids.

Yoko Tsukahara*, Terry A. Gipson, Jerry Hayes, Ryszard Puchala, Tilahun Sahlu, and Arthur L. Goetsch, *American Institute for Goat Research, Langston University, Langston, OK.*

A method of evaluating electric fence strand addition to cattle barbed wire fence for goat containment would be useful to promote co-grazing. Therefore, 38 Boer (B) wethers (6.3 mo of age and 22.1 kg BW initially), 41 B doelings (6.3 mo and 21.4 kg), 40 Spanish (S) wethers (6.7 mo and 17.8 kg), and 40 S doelings (6.8 mo and 18.4 kg), were used to evaluate effects of grouping, single breed (SGL) and breeds combined (COM), on behavior (e.g., pen exit and shock) when exposed to barbed wire fence with different electric strand additions. Five 2.4 × 3.7 m evaluation pens had 1 side of barb wire strands at 30, 56, 81, 107, and 132 cm from the ground. Fence treatments (FT) were electrified strands (6 kV) at 15 and 43 (LH), 15 and 23 (LM), 15 (L), 23 (M), and 43 cm (H). For adaptation, kids were exposed in evaluation pens to no electric strands (NES), NES, LH at 0 kV, LH at 6 kV, and NES in wk 1, 2, 3, 4, and 5, respectively. Then kids were divided into 2 replication sets per grouping (2 B-SGL, 2 S-SGL, 2 B-COM, and 2 S-COM); each of the 5 pens consisted of 4 or 3 animals for 1 h exposure to FT while observing behavior visually and with video surveillance. There were no main effects of grouping. Fence treatment affected ($P < 0.01$) the percentage of animals receiving a shock (59.4, 44.5, 34.4, 22.8, and 6.2%; SE = 8.53), exiting with shock (37.5, 35.8, 31.3, 19.6, and 3.1%; SE = 7.63), and exiting without shock (0.0, 14.9, 50.0, 67.7, and 76.3% for LH, LM, L, M, H, respectively; SE = 7.56). There was an interaction ($P = 0.01$) between FT and grouping in pen exit (50.0, 25.0, 75.0, 85.7, and 42.9% with B-COM, 12.5, 77.8, 87.5, 75.0, and 100% with B-SGL, 62.5, 62.5, 75.0, 87.5, and 75.0% with S-COM, and 25.0, 37.5, 87.5, 100.0, and 100.0% with S-SGL for LH, LM, L, M, and H, respectively; SE = 14.83). In conclusion, in contrast to previous findings with mature does, these results do not provide clear evidence supporting notable effect of method of grouping growing meat goat kids for evaluating effectiveness of various electric strand additions to barbed wire fence for goat containment, indicating appropriateness of either method.

Key Words: behavior, fence, goat

M479 Diet selection patterns and ingestive behavior of feedlot lambs fed different sources of non-protein nitrogen and carbohydrate.

Jean C. S. Lourenço*, Ricardo D. Kliemann, Larissa Goltz, Caroline Dell'Agnolo, Dayanna Pastal, Tiago M. Santos, Sergio R. Fernandes, and Américo F. Garcez Neto, *Federal University of Paraná, Palotina, Paraná, Brazil.*

The mixture of carbohydrates (CHO) and non-protein nitrogen (NPN) with different ruminal degradation may affect the feeding behavior and feed selection by ruminants. This study was carried out to evaluate the ingestive behavior and diet selection by feedlot lambs fed different sources of CHO and NPN. It was used 20 non-castrated crossbred lambs with 4 mo of age and 26 kg of body weight. The diets were composed by 57% of grass hay (*Brachiaria* hybrid) and 43% of concentrate. The hay was harvested at late mature stage with high (72.4%) neutral detergent fiber and low (4.9%) crude protein content. Four concentrate feeds were formulated from the combination of 2 CHO (ground corn:

starch; whey permeate: lactose) and 2 NPN (fast and slow release urea) sources. Orts samples were taken to determine the proportion of leaves (LVS), stems (STS) and leaf:stem ratio, and activities of eating (EAT), ruminating (RUM) and resting (RES) were recorded. The efficiency of rumination (RE) and dry matter intake (IE) were also calculated. It was used a completely randomized design with 4 diets and 5 replicates. Data were analyzed by ANOVA following a 2 × 2 factorial scheme. LVS (56.2 ± 2.7%), STS (43.8 ± 2.7%), leaf:stem ratio (1.60 ± 0.16), EAT (318 ± 8 min), RUM (537 ± 11 min), RES (585 ± 14 min), RE (1.82 ± 0.06 g DM/min) and IE (3.10 ± 0.11 g DM/min) were not affected ($P > 0.05$) by diets. The mixture of CHO and NPN with more distinct potential degradation rates (ground corn + fast release urea; dry whey permeate + fast release urea) did not increase ($P > 0.05$) the selection of LVS, neither the mixture of sources with closest potential degradation rates (ground corn + slow release urea; dry whey permeate + fast release urea) reduced the RUM. It is possible that these results were not effective to increase the ruminal degradation of low quality forage. Such hypothesis is supported by the similarity of RE values between diets. In the present study the association of CHO and NPN with similar or distinct degradation rates does not influence the diet selection and the ingestive behavior.

Key Words: degradation rate, rumination, sheep

M480 Carcass characteristics of feedlot lambs fed different sources of non-protein nitrogen and carbohydrate.

Jean C. S. Lourenço*, Larissa Goltz, Ricardo D. Kliemann, Douglas Bloedorn, Dayanna Pastal, Tiago M. Santos, Sergio R. Fernandes, and Américo F. Garcez Neto, *Federal University of Paraná, Palotina, Paraná, Brazil.*

A balanced supply of nutrients can be regarded a way to support an increase of body weight and a tool to improve the carcass grade at slaughter. In that context carcass weight, yield and fat covering can be changed by the quality of different diets affecting not only the carcass parameters but also the meat value of the lambs. The carcass grade and weight at slaughtering and its parameters were evaluated on feedlot lambs fed different sources of non-protein nitrogen (NPN) and carbohydrates (CHO). It was used 20 non-castrated lambs with 4 mo of age and 26 kg of body weight. Lambs were fed ad libitum for 45 d. The diets were composed by 57% of grass hay (*Brachiaria* hybrid) and 43% of concentrate. The hay was harvested at late mature stage with high (72.4%) neutral detergent fiber and low (4.9%) crude protein. Four concentrates were formulated from the combination of 2 CHO (ground corn: starch; whey permeate: lactose) and 2 NPN (fast and slow release urea) sources. Slaughter weight (SW), body condition score (BCS), hot carcass weight (HCW), cold carcass weight (CCW), fat thickness (FT), hot carcass yield (HCY), cold carcass yield (CCY) and chilling losses (CL) were measured. A completely randomized design was used with 4 diets and 5 replicates. Data were analyzed by ANOVA following a 2 × 2 factorial scheme. SW was higher ($P < 0.05$) for lambs fed corn (31.3 kg) than for those fed whey (29.4 kg) suggesting that the starch intake was more effective in improving low quality forage degradation than lactose. However, BCS (3.0 ± 0.1), HCW (12.34 ± 0.41 kg), CCW (11.87 ± 0.37 kg), HCY (40.7 ± 0.5%), CCY (39.2 ± 0.5%), FT (1.23 ± 0.10 mm) were not influenced ($P > 0.05$) by diets. CL was higher ($P < 0.05$) for diets with slow release urea (4.01%) compared with those with fast release urea (3.65%) suggesting higher muscle water retention for diets with urea of faster degradation. For this reason, we can recommend the use of a concentrate diet composed of fast release urea and corn for finishing lambs. Because these feed ingredients are usually cheaper, this will also reduce the cost of fattening.

Key Words: fattening, sheep, slaughter weight

M481 Weight and cutting yield of feedlot lambs fed different sources of non-protein nitrogen and carbohydrate.

Larissa Goltz, Jean C. S. Lourenço, Ricardo D. Kliemann, Bruna N. Zuffo, Dayanna Pastal, Tiago M. Santos, Sergio R. Fernandes, and Américo F. Garcez Neto*, *Federal University of Paraná, Palotina, Paraná, Brazil.*

Diets formulated with feed of different ruminal degradation rates can affect the performance and feed efficiency of lambs. In that condition is expected that the carcass weight and its cuts are also influenced changing the potential income for farmers. This work was carried out to evaluate the weights and yield of carcass cuttings of feedlot lambs fed diets of different carbohydrate (CHO) and non-protein nitrogen (NPN) sources. It was used 20 non-castrated crossbred lambs with 4 mo of age and 26 kg of body weight. The diets were composed by 57% of grass hay (*Brachiaria* hybrid) and 43% of concentrate. The hay was harvested at late mature stage with high (72.4%) neutral detergent fiber and low (4.9%) crude protein. Four concentrate feeds were formulated from the combination of 2 CHO (ground corn: starch; whey permeate: lactose) and 2 NPN (fast and slow release urea) sources. The diets were isoenergetic (2.32 Mcal/kg ME) and isoproteic (11% CP). The lambs were slaughtered at the end of trial after 45 d with a mean body weight of 30.4 ± 1.0 kg. After cooling, the left half of carcasses was separated into 6 commercial cuts of meat: neck, breast, ribs, shoulder, loin and leg. It was recorded the weight of each cut and its proportion in relation to the half carcass. A completely randomized design was used with 4 treatments and 5 replicates. Data were analyzed by ANOVA following a 2 × 2 factorial scheme between CHO and NPN. The weights of neck (0.57 ± 0.02 kg), breast (0.63 ± 0.02 kg), ribs (0.85 ± 0.03 kg), shoulder (1.19 ± 0.04 kg), loin (0.64 ± 0.02 kg) and leg (2.05 ± 0.07 kg) were not influenced ($P > 0.05$) by the treatments. The same pattern was found to the yield of neck (9.7 ± 0.2%) breast (10.6 ± 0.3%), ribs (14.3 ± 0.2%), shoulder (20.1 ± 0.2%), loin (10.8 ± 0.2%) and leg (34.6 ± 0.3%). The association of CHO and NPN with concentrates of closest degradation rates (whey permeate + fast release urea; ground corn + slow release urea) do not increase ($P > 0.05$) the weight neither change the yield of cuts of meat in the lamb carcass when low quality forage is added to the diet during the finishing.

Key Words: slow release urea, sheep, whey permeate

M482 Effect of *Acacia mearnsii* tannin extract on intake and digestibility by sheep fed a tropical grass hay plus concentrate.

S. C. Avila*[1], G. V. Kozloski[1], T. Orlandi[1], M. P. Mezzomo[1], and D. L. Harmon[2], [1]*Universidade Federal de Santa Maria, Santa Maria, Rio Grande do Sul, Brazil,* [2]*University of Kentucky, Lexington, Kentucky.*

Tannins are plant polyphenols with the capacity to form complexes mainly with proteins reducing their degradation in the rumen and, thus, have the potential to increase the metabolizable protein supply and/or to decrease the urinary N losses by ruminants. However, tannins might also decrease feed intake and digestibility. Moreover, the nutritional effect of tannins is dependent on the tannin source. Six Texel wethers (67.0 ± 6.53 kg) fed ad libitum Tifton hay (*Cynodon* sp.) and 12 g/kg body weight (dry matter (DM) basis) of concentrate were used in a crossover design with 2 21 d periods to evaluate the effect of dietary inclusion of a tannin extract from *Acacia mearnsii* on feed intake, digestibility and N excretion. The concentrate was composed of cracked corn grain (0.36), wheat bran (0.36) and soybean meal (0.28) with or without 10 g/kg DM of tannin extract of *Acacia mearnsii*. Total feed, refusals, feces and urinary excretion were measured during the last 7 d of each experimental period. The concentrate represented in average 0.40 of total DM intake. Total intake (g/day) of organic matter (OM, 1720 ± 132.0), neutral detergent fiber (NDF, 1039 ± 78.8) and N (38.2 ± 3.29), as well as the apparent digestibility of OM (0.77 ± 0.031), N compounds (0.82 ± 0.020) and NDF (0.72 ± 0.038) and urinary N excretion (21.4 ± 2.33 g/day) were not affected by tannin extract inclusion. Tannin extract reduced ($P < 0.05$) the proportion of fecal N from endogenous origin (0.81 vs 0.76) and the true digestibility of N compounds (0.97 vs 0.95). These results indicate that tannin inclusion can affect N digestion. Further studies are needed to optimize the amount of tannin for each diet.

Key Words: consumption, digestion, nitrogen compound

M483 Probiotic supplementation affects resilience to parasites in goats.

Mulumebet Worku*, Kingsley Ekwemalour, Emmanuel Asiama, Hamid Ismail, and Sara Adjei-Fremah, *North Carolina A&T State University, Greensboro, NC.*

The objective of this study was to evaluate resistance and resilience to gastrointestinal parasites in goats following supplementation with probiotics. Improving resistance and resilience to gastro-intestinal parasites is essential to combating the threat to the small ruminant industry from anthelmintic resistance. Following initial screening for infection, female SpanishXBoer goats were assigned to 4 groups of 4 (n = 16), one week post weaning. Goats were drenched daily with 10 mL sterile water containing recommended doses of either CorPET (treatment I)-a probiotic from the mushroom Coriolus versicolor (Mycology Research Laboratories, Ltd., Netherlands), Fastrak microbial pack (treatment II) or ruminant gel(treatment III) (Conklin Company, Inc. Shakopee, MN). A control group of age-matched goats received sterile water (treatment IV) for an 8 week period. Samples were collected weekly. Body weight, Body condition and FAMACHA scores were evaluated. Fecal samples were used for Hemonchus and coccidia egg counts to evaluate resistance. Blood samples were used to measure Packed cell volume (PCV) and for isolation of total RNA using Tri-reagent. The Nanodrop spectrophotometer was used to evaluate RNA concentration and purity. Data were analyzed using SAS PROC MIXED for repeated measures analyses. The effect of treatment on fecal egg count was variable. Treatment with commercial probiotics significantly increased body weight in wk 8, improved FAMACHA scores in wk 7,PCV was improved by treatments II and III in wk 5 ($P < 0.05$).There was no effect on body condition score.Transcription of total RNA in blood increased during periods of high parasite egg output and were not affected by treatment ($P > 0.05$). Thus probiotic supplementation may affect resilience to parasite infection in goats in a time and marker specific manner.

Key Words: goat, probiotic, resilience

M484 Determination of the grazing activity energy cost in Boer goat wethers using a portable indirect calorimety method.

Marie E. Brassard[1,2], Ryszard Puchala*[1], Tilahun Sahlu[1], and Arthur L. Goetsch[1], [1]*American Institute for Goat Research, Langston University, Langston, OK,* [2]*Université Laval, Québec, QC, Canada.*

Heat energy (HE) of small ruminants in free-moving settings such as grazing is often measured indirectly from heart rate (HR) and the ratio of HE to HR determined when situated once or periodically in a stationary calorimetry system. Therefore, feasibility of use of a portable indirect calorimetry system with goats while grazing, for a direct estimate of HE based on gas exchange without reliance on HR, was investigated in this experiment. Ten yearling Boer goat wethers (44.4 ± 0.95 kg) were used to determine HE and the grazing activity energy cost (GAEC) while standing or grazing Sudangrass pasture with a portable indirect calorimetry system. The method entailed use of a partial face mask that allowed unrestricted grazing to measure oxygen consumption and carbon dioxide emission for 30 min while restrained in a stanchion near the grazing area, followed by 60 min of grazing with other members of the group. The face mask was attached to a 15-m tether along with a corrugated plastic hose through which exhaled air was passed to a FlowKit Mass Flow Generator and FoxBox Respirometry System (Sable System, Las Vegas, NV) that were carried by a researcher who allowed unrestricted goat movement. Prior to measurements, animals were trained to become accustomed to presence of personnel and use of the equipment, with observed grazing behavior similar among all animals of the group. Measurement periods were during morning and afternoon grazing bouts. Heat energy while restrained was 18.7 kJ/kg $BW^{0.75}$/h or 446 ± 10.7 kJ/kg $BW^{0.75}$/d. Grazing HE increased to 35.1 kJ/kg $BW^{0.75}$/h or 843 ± 39.3 kJ/kg $BW^{0.75}$/d, implying that the GAEC was 16.4 kJ/kg $BW^{0.75}$/h. Goats spent 8.5 h/d grazing; therefore, the daily GAEC was 138 ± 17.3 kJ/kg $BW^{0.75}$. A very similar GAEC of (165 ± 10.4 kJ/kg $BW^{0.75}$/d) was determined from the difference in HE estimated indirectly from HR between times when grazing a 0.8-ha pasture and confined in nearby 1.2 × 1.2 m pens and fed fresh forage. In conclusion, this method offers promise for relatively simple and direct estimates of the sizable fraction of total HE comprised by GAEC.

Key Words: goat, grazing, heat energy

M485 Effects of two heart rate-based methods of estimating the grazing activity energy cost of Boer goat wethers.

Marie E. Brassard[1,2], Ryszard Puchala*[1], Terry A. Gipson[1], Tilahun Sahlu[1], and Arthur L. Goetsch[1], [1]*American Institute for Goat Research, Langston University, Langston, OK,* [2]*Université Laval, Québec, QC, Canada.*

There are different methods to estimate the grazing activity energy cost (GAEC) of ruminants from heart rate (HR), regarding both treatment differences and contribution to total heat energy (HE). The primary objective of this experiment was to investigate differences between 2 such methods. Ten yearling Boer goat wethers (44.4 ± 0.95 kg) consuming fresh Sudangrass ad libitum while grazing a 0.8-ha pasture or confined in nearby 1.2 × 1.2 m pens were used in a crossover. Heart rate measured over 24 h in 5-min intervals and the ratio of HE to HR previously determined for each animal with a stationary calorimetry system for 24 h while consuming grass hay was used to estimate HE. A GPS collar and leg activity monitor were used when HR was measured to determine HE while resting-lying (L), resting-standing (S), grazing (G), and walking (W); behavior in confinement was L or S. The grazing activity method (GAM) was based on time spent in the different activities multiplied by corresponding HE values, with GAEC assumed the sum of differences between S, G, and W relative to L. The confinement method (COM) entailed subtracting total HE while confined from that when grazing. There were differences ($P < 0.01$) in percentage of the day spent in the 4 activities (33.8, 53.9, 11.4, and 0.9%; SE = 2.44) and the associated daily HE (241, 322, 75, and 6 kJ/kg $BW^{0.75}$; SE = 17.9), although HE per unit time only tended ($P = 0.099$) to vary (707, 598, 472, and 636 kJ/kg $BW^{0.75}$ on a daily basis for G, L, S, and W, respectively; SE = 65.8). Total daily HE (642 and 482 kJ/kg $BW^{0.75}$; SE = 17.2) and

HE while lying (598 and 450 kJ/kg $BW^{0.75}$; SE = 18.1) were greater when grazing than confined ($P < 0.01$). Daily GAEC was considerably greater ($P < 0.01$) for the COM vs. GAM expressed in kJ/kg $BW^{0.75}$ (165 and 46; SE = 14.0) and relative to HE when confined for COM and of L on a daily basis for GAM (35 and 8%; SE = 3.5). In conclusion, method of estimation can have substantial effect on GAEC. Greater L HE per unit time when grazing than confined may contribute to lower GAEC for GAM than for COM, although factors such as dietary and environmental conditions will influence accuracy of COM.

Key Words: activity, energy, goat

M486 The effects of variation in birth weight of littermates on lamb performance.

Jennifer L. Juengel*[1], George H. Davis[1], Roger Wheeler[2], and Peter D. Johnstone[1], *[1]AgResearch, Invermay Agricultural Centre, Mosgiel, New Zealand, [2]AgResearch, Woodlands Research Station, Invercargill, New Zealand.*

The objective of this study was to assess the relative importance of lamb birth weight (BW) and variation between BW of littermates (VAR) on lamb performance. Records from lambs born into twin (n = 4160) or triplet (n = 1279) litters from 1988 to 2005 were analyzed. Data collected for each lamb included dam, sire, sex, BW, birth date, lamb fate, and weaning weight and date. Data were analyzed with REML with BW and VAR grouped into classes (BW (kg): ≤2, >2–3, >3–3.5, >3.5–4, >4–5, >5; VAR (kg): 0–0.1, >0.1–0.35, >0.35–0.5, >0.5–0.75, >0.75–1.00, > –1.3, >1.3). The model included BW, VAR, sex and year of birth as fixed effects with sire of lamb included as a random effect. Overall, 85.3% of twins and 74.7% of triplet lambs survived to weaning. For both twin and triplet lambs, BW was associated with survival ($P < 0.001$) with lambs < 2 kg having very low survival rates (<40%). For triplets and the larger of twin lambs, VAR was not associated with survival. However, VAR did affect survival of the smallest lamb in twin litters ($P < 0.001$) with lambs with VAR > 1.3 kg being less apt to survive (67.8%) compared with those from litters of smaller VAR (range 80.4–86.2% survival). Growth rate of twin and triplet lambs was affected by BW ($P < 0.001$). As BW increased, growth rate also increased. For triplet born and raised lambs, VAR did not affect growth of the lamb. Surprisingly, twin lambs from litters with high VAR had slightly greater growth rate than those from lambs of low VAR ($P < 0.05$). Given the strong effect of BW on lamb performance, the large data set of twins was examined to determine whether variation in ovulation rate or pattern influenced BW. While year born, lamb birth date and sex and ewe age and weight before mating affected BW of the lamb ($P < 0.001$), neither ovulation rate nor pattern (i.e., both ova released from one ovary or one from each) were associated with BW of the lambs. In summary, the BW was strongly associated with survival and growth of the lamb. The litter VAR had little or no effect on survival and did not negatively affect growth of the lamb. Thus, birth weight, but not variability in birth weight within a litter, appears to be a major driver of lamb performance.

Key Words: sheep, lamb survival, lamb growth

M487 Effect of different rearing systems on growth, nutrient utilization and serum indices of early weaned Hu twin lambs.

Hai-chao Wang, Jian-min Chai, Yan Tu, Nai-feng Zhang, Tao Ma, Bo Wang, and Qi-yu Diao*, *Feed Research Institute of Chinese Academy of Agricultural Sciences, Key Laboratory of Feed Biotechnology of the Ministry of Agriculture, Beijing, China.*

This experiment was conducted to study the effect of different rearing systems on growth, nutrient utilization and serum indices of early weaned Hu twin lambs. Twenty-four pairs of newborn Hu male twin lambs were equally divided into 2 groups according to paired experiment design. In each pair, one lamb was artificially reared (AR) with milk replacer, while the other one was ewe reared (ER). Body weight was recorded and blood samples were collected every 10 d. Two digestion trials were undertaken during d 45 to 55 and d 75 to 85 with 4 pairs of lambs from each group. On d 60 and 90, another 3 pairs of lambs from each group at each time point were euthanized for weighing gastrointestinal organs. The data of body weight and serum indices (total protein, cholesterol, glucose, triglyceride, albumin, blood urea nitrogen, alkaline phosphatase activity, and immunoglobulin) were analyzed using PROC ANOVA with repeated measure, while the others were analyzed using PROC paired *t*-test of SAS 9.1. The results showed that the BW of lambs in ER group was higher than that in AR group on d 30 ($P < 0.05$). No difference was observed in the final BW of AR group and ER group (21.02 vs 21.92 kg, $P > 0.05$) or the overall average daily gain (205.97 vs 217.01 g/d, $P > 0.05$). On d 60, the proportion of the rumen to 4 stomaches (weight basis) of lambs in AR group was higher ($P < 0.05$) while that of omasum and abomasum were lower ($P < 0.05$) than those in ER group. The proportion of small intestine was higher in AR group than that in ER group ($P < 0.05$). There was no difference in the nutrient digestibility ($P > 0.05$) or the serum concentration of total protein, cholesterol, glucose, triglyceride, albumin, blood urea nitrogen, alkaline phosphatase activity, and immunoglobulin (G, A, and M) ($P > 0.05$). In general, lambs reared with milk replacer achieved the same growth performance as their ewe-reared counterparts.

Key Words: lamb, milk replacer, growth performance

M488 Preliminary results of the feedlot performance of South African Boer goats.

Tertius S. Brand*[1,2], Daniel A. van der Merwe[2], Louw C. Hoffman[2], and Emiliano Raffrenato[2], *[1]Directorate: Animal Sciences, Department of Agriculture, Western Cape Government, Elsenburg, South Africa, [2]Department of Animal Sciences, Stellenbosch University, Stellenbosch, South Africa.*

Goats are more commonly reared in extensive production systems in South Africa and are directly marketed from the farm at a weight of less than 30 kg. This study was performed to determine the effect of dietary energy content on the production of South African Boar goats in a feedlot system to be able to increase marketing weight. In this trial, 53 Boer goats were randomly divided into 3 dietary treatments that varied in energy content, giving a low, 11.3 MJ ME/kg feed (18 goats), medium, 12.0 MJ ME/kg feed (16 goats) and high energy diets, 12.7 MJ ME/kg feed (19 goats). The diets were equal in terms of crude protein (17.0%), calcium (0.86%) and phosphorus (0.36%). These goats were reared in individual pens for a period of 8 weeks, where the trial diets were fed on an ad libitum basis and growth and feed intake were monitored. Initial body weight was 22.4 kg and after 8 weeks the goats on the medium diet had gained the most weight, weighing 34.6 kg followed by the low energy (33.4 kg) and the high-energy diets (31.4 kg). The difference between the 3 treatments were significant at $P = 0.01$. The average daily gains differed significantly ($P = 0.036$) with goats on the medium energy diet attaining the highest ADG of 0.253 kg/day, while goats on the high-energy diet had the lowest ADG of 0.183 kg/day. This suggests that the energy content of the medium energy diet is probably close to the energy requirements of the goats, while the low diet does not contain sufficient energy to maintain higher growth rates. Goats are also not adapted to digest feeds with high-energy contents

and therefore can probably not use the excess energy for growth. Feed intake differed between the 3 treatments ($P < 0.001$) with the goats on the low energy diet having the highest DMI of 1.456 kg/day which decreased with an increase in dietary energy content (1.112 kg/d for the high energy diet). The feed intake for the medium energy group was intermediate at 1.284 kg/d. The feed conversion ratio (FCR) did not differ significantly for the 3 treatments and was calculated to be 6.61 kg feed/kg weight gain. Goats fed the medium energy diet displayed the best growth at a moderate feed intake, even though the FCR between the diets did not differ significantly.

Key Words: Boer goat, dietary energy, feed intake

Swine Species

M489 Long-term effects of dietary calcium montmorillonite on swine productivity in a conventional farm in Japan.

Fang Chi*[1], Munetaka Oi[2], Tomohiro Furuichi[2], San Ching[1], and LeAnn Johnston[1], [1]*Amlan International, Chicago, IL,* [2]*Toyoura Veterinary Clinic, Kanagawa, Japan.*

Dietary clay (Calibrin-Z; CZ), has been shown to enhance weanling pig performance due to its barrier function in the intestine. An 18-mo trial was conducted to investigate the long-term feeding effects of CZ in swine. Sixteen crossbred sows (3.2 parities) were randomly assigned to 2 TRT. The sows were fed an antibiotic free diet with 0 (CON) or 0.1% CZ during the trial. The farrowings were between Nov 2012 and Mar 2013, and from Apr to Aug 2013. Litter size and weaning weights were recorded (sow was the experimental unit). Weaned pigs from approximately 1/2 of the litters (362 pigs) were divided into 2 TRT in a split-plot arrangement based on sow TRT, and fed diets with 0 or 0.1% CZ until slaughtered (litter was the experimental unit). Pigs were weighed and blood samples collected at weaning, d-60, 90, 140, and end of trial. Feeds were formulated to meet Japanese feeding standards for swine. Total born from the 2 farrowings was not different ($P > 0.05$) averaging 12.7 for the sows fed the CON vs. 14.4 piglets for the sows fed 0.1% CZ. However, total pigs born in the second litter was numerically higher (12.5 vs. 15.8; $P > 0.05$) when CZ was fed. This improvement in the size of the second litter suggests that feeding 0.1% CZ for a longer period may have positive effects on sow reproductive performance. The combined data of 2 cycles of G-F pig performance, showed pigs fed 0.1% CZ diets needed 4.9 fewer days to reach market weight (166.8 vs. 161.9 d; $P < 0.01$) although ADG was not improved (840 vs. 864 g; $P > 0.05$). Total feed consumption was lower in pigs fed the CZ diets (308.6 vs. 287.4 kg; $P < 0.01$), and therefore, an improvement of FCR (2.92 vs. 2.75; $P < 0.05$) was obtained when pigs consumed diets containing 0.1% CZ. There were no differences ($P > 0.05$) in the serum biochemical markers concentrations, such as total protein, albumin, GOT, GTP, γGTP and IgG etc. In conclusion, pigs fed commercial diets containing 0.1% Calibrin-Z under normal conditions in Japan may increase numbers of total born and born-alive, and improve FCR in growing-finishing phases.

Key Words: sow litter size, growing-finishing, calcium montmorillonite

M490 Effect of dietary micronutrient on the transcriptome of boar semen.

Dianelys Gonzalez-Pena*, Robmay Garcia, and Robert V. Knox, and Sandra L. Rodriguez-Zas, *University of Illinois at Urbana-Champaign, Urbana, IL.*

Micronutrients are important co-factors or substrates to enzymes that protect and repair DNA against damage or methylation. Micronutrient deficiency could induce genomic instability and changes in DNA leading to cell apoptosis and degenerative diseases. The objective of this study was to compare the sperm transcriptome of boars receiving a diet supplemented with high amounts of methylating micronutrients (methionine, choline, betaine, vitamin B6, folate, and vitamin B12) relative to boars with non-supplemented diet. Semen mRNA from 4 boars was profiled and single-end reads were mapped to the *Sus scrofa* reference genome (UCSC susScr3) using Tophat v2.012. In total, 477 transcripts from 446 genes were tested and 73 transcripts from 72 genes were differentially expressed between the supplemented and non-supplemented boars using Cufflink v2.2.1 (P-value <0.05). Among the differentially expressed transcripts, 89% of those from boars with the supplemented diet were overexpressed relative to those from non-supplemented boars. The porcine seminal protein II (PSP-II) was under-expressed; meanwhile, the AWN protein (AWN) was overexpressed in boars with the supplemented diet relative to non-supplemented. PSP-II encodes a protein with paradoxical functions: in vitro PSP-II enhances viability, motility and mitochondrial activity of highly-extended boar spermatozoa; in vivo PSP-II triggers the recruitment of polymorphonuclear leukocytes and T cells in the uterus of the sow after mating. AWN encodes a sperm surface-associated protein that participates in sperm adhesion to the egg. Functional analysis of the differentially expressed genes using DAVID identified one category cluster (enrichment score >6) related to cellular metabolism and biosynthetic process, structural constituents of ribosomes and structural molecular activity. The limited differentially expressed transcripts and the solely functional category enrichment suggest that methylating micronutrients in high quantities had no impact on the transcriptome of sperm cells.

Key Words: micronutrient, transcriptome, semen

M491 Effects of supplementing high-fiber diets with a multicarbohydrase enzyme on net portal flux of essential amino acids and urea-nitrogen in growing pigs.

Atta K. Agyekum*[1], Elijah Kiarie[2,1], and Charles M. Nyachoti[1], [1]*Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada,* [2]*DuPont Industrial Biosciences, Marlborough, Wiltshire, UK.*

The present study investigated the effects of adding a multicarbohydrase enzyme (MC; 4000 units/g xylanase, 1000 units/g α-amylase, 500 units/g protease, 150 units/g β-glucanase) to a high-fiber diet on net portal fluxes of essential AA (EAA) and urea-N in growing pigs. Five female pigs (22.8 ± 1.6 kg BW), with permanent catheters in the portal vein, ileal vein and carotid artery, were fed 3 isocaloric/nitrogenous diets at 4% of their BW once daily at 0900 h for 7 d in a replicated 3 × 3 Latin square design. The diets contained corn and soybean meal with 0% (CTRL) or 30% distillers dried grains with solubles (DDGS; HF) produced from a 1:1 mixture of wheat and corn. The third diet was supplemented with MC in addition to the 30% DDGS (HF+MC). On d 7, para-amino hippuric acid was infused into the ileal vein (to measure flow rate) and blood was sampled from the portal vein and carotid artery for 7 h after feeding to assay EAA and urea-N. Portal absorption of nutrients was derived by multiplying the porto-arterial plasma concentration differences by portal vein plasma flow. Diet had no effect ($P > 0.10$) on postprandial portal vein plasma flow rate and net urea-N flux, but portal urea-N was lower ($P < 0.05$) during the first h and tended to be lower ($P = 0.07$) over the 7 h in pigs fed CTRL. Postprandial portal Arg, Ile, Leu, Trp, and Val were lower ($P < 0.05$) in HF-fed pigs from 30 to 240 min than CTRL-fed pigs and MC supplementation tended ($P < 0.10$) to or improved ($P < 0.05$) portal fluxes of those AA. Further, pigs fed CTRL had higher ($P < 0.05$) net portal fluxes of the above-mentioned AA from 30 to 120 min postprandial. Also, CTRL-fed pigs had higher ($P < 0.05$) net portal fluxes of most EAA and pigs fed HF+MC had higher ($P < 0.05$) Lys and similar Met and Phe ($P > 0.10$) net portal fluxes compared with CTRL-fed pigs. The results showed that supplementing the HF diet with MC improved net portal appearance and fluxes of some EAA in growing pigs.

Key Words: fibrous diet, multicarbohydrase, net portal flux

M492 Lifetime reproductive performance of South African Mukota sows following bio-stimulation protocols.

Dennis O. Umesiobi* and Matthew C. Achilonu, *Central University of Technology, Free State, Bloemfontein, South Africa.*

Bio-stimulation is the stimulus evoked by the presence of a male which induces sexual and oestrus expressions in females through genital stimulation, pheromones, and or other external cues. The aim of this study was to comparatively evaluate the effects of 2 bio-stimulation methods on lifetime reproductive performance of sows, arranged in a 2x3 factorial experiment. Thirty sows were assigned per group to each of 2 bio-stimulation protocols, twice daily (08:30 to 09:00 and 16:00 to 16:30) per 30 min duration in a 4-week observation per parity over 3 parities. The bio-stimulation protocols involved (1) fence-line boar exposure (FBE): in which sows were exposed to fence-line boars during oestrus detection and (2) physical boar exposure (PBE): in which sows received physical contact with the boar during oestrus detection. Following the bio-stimulation applications to each sow treatment group, oestrus was synchronised in sows by a single subcutaneous injection of P.G. 600 (400 IU PMSG with 200 IU HCG/5 mL dose/animal; Intervet Inc., Millsboro, DE). After the onset of oestrus, sows on each treatment were artificially inseminated using semen from the same boars and collections. All experimental females received inseminations of 3.5×10^9 sperm/80 mL at 24 h after onset of oestrus. Physical boar exposure before oestrus induction (PG600) evoked the highest ($P \leq 0.01$) reproductive performance in sows in parity 3 compared with those in parity 2 and 1, respectively. Sows that received physical boar exposure in parity 3 produced a higher ($P \leq 0.05$) oestrus expressions (98 ± 23.1 vs. 77.5 ± 25.5%), Non-return rate (92.1 ± 6.3 vs. 74.4 ± 3.5%), farrowing rate (88.2 ± 16.5 vs. 63.8 ± 7.1%,), litter size (12 ± 0.02 vs. 8 ± 0.05) and live piglets (10 ± 0.05 vs. 6.5 ± 0.02), respectively compared with those from sows that received fence-line boar exposure in parity 3. Results suggest that direct exposure of boars to sows before artificial insemination following oestrus induction progressively enhances the lifetime reproductive performance in South African Mukota sows.

Key Words: boar effect, reproductive longevity, Mukota pigs

M493 Improved piglets performance with protected sodium heptanoate.

M. Puyalto*[1], P. Honrubia[1], M. I. Gracia[2], and J. J. Mallo[1], [1]*Norel S.A., Spain,* [2]*IMASDE Agroalimentaria S.L., Spain.*

The objective of the present study was to evaluate the effect in piglets productive parameters of sodium heptanoate protected with hydrogenated palm fatty acids distillate sodium salt (HEPT'ON) in a control diet without any additive. Thirty-two 21-d-old piglets (6.5 ± 0.5 Kg) were randomly divided in 2 groups: control (C) and 70% Na-heptanoate protected (HEPT'ON) 3 kg/t (21–35 d) and 1 kg/t (36–49 d). Every treatment was replicated 4 times and each replicate consisted of 4 piglets in the first 2 weeks and 3 piglets in the second 2 weeks of the trial. Mash feeds and water were offered ad libitum. BW, ADG, ADFI and FCR were recorded for every period. At the end of each period (35 d and 49 d), one piglet per replicate was euthanized and samples from the ileum and cecum were taken to analyze gut microflora. Data were analyzed as a completely randomized design by GLM of SPSS v. 19.0. Piglets receiving sodium heptanoate protected with hydrogenated PFAD sodium salt (HEPT'ON) tended to have higher final body weight (15.997 kg vs 14.201 kg; $P = 0.0686$). The use of HEPT'ON resulted in a tendency to improve FCR ($P = 0.0660$). Also the ADG was numerically improved in this group ($P = 0.0686$). No significant differences were observed in count of *Lactobacillus* and *E. coli*. We can conclude that the use of sodium heptanoate protected with hydrogenated PFAD sodium salt may be able to improve productive parameters in piglets compared with the control treatment. Further research is needed.

Key Words: protected sodium heptanoate, piglets

M494 Effects of dietary supplementation organic medicinal charcoal (Olga Black) on aflatoxin adsorption capacity, digestibility, population of *Lactobacillus* and *E. coli* in feces, and the fecal odor emission by In vitro and In vivo.

Kwang-Sik Kim*[1], Jin-Ho Cho[2], Ki Hyun Kim[1], and Young Hwa Kim[1], [1]*National institute of animal science, Cheonan, Chungnam, Korea,* [2]*Chungbuk National University, Cheongju, Chungbuk, Korea.*

This study was performed to evaluate effects of dietary supplementation organic medicinal charcoal (OMC: Olga Black) on aflatoxin adsorption capacity, digestibility, population of *Lactobacillus* and *E. coli* of feces and the fecal odor emission by in vitro and in vivo in finishing pig diet. Exp 1. the aflatoxin adsorption capacity of OMC, pyroligneous charcoal (PC), and coconut tree charcoal (CC) was measured using the ELISA test kit. The aflatoxin absorption capacity was 100, 10 and 20% in OMC, PL and CC, respectively ($P < 0.05$). The effects of OMC on digestibility of dry- and organic matter were evaluated by in vitro prediction methods (Boisen, 1991). Treatments of in vitro and in vivo included: 1) CON (basal diet contaminated with 1,543ppb of deoxynivalenol and 596ppb of zearalenone); 2) OMC (basal diet + 0.25% Olga Black; 3) PC (basal diet + 0.50% Pyroligneous Charcoal); 4) CC (basal diet + 0.50% Coconut tree Charcoal). The digestibility of OMC on dry matter was significantly higher than CON, PC, and CC ($P < 0.05$). The digestibility of OMC on organic matter was significantly higher than CON ($P < 0.05$). Exp 2. a 10-d trial with 20 [(Yorkshire × Landrace) × Duroc)] finishing pigs (BW = 81 ± 3.3 kg) was conducted to investigate the population of *Lactobacillus* and *E. coli* in feces, and the fecal odor (NH_3, H_2S, total mercaptans, and acetic acid) in vivo. The fecal NH_3 and H_2S emissions of OMC were significantly lower than CON, PC, and CC ($P < 0.05$). Several *Lactobacillus* in feces of OMC and CC were significantly higher than CON and PC ($P < 0.05$). Several fecal *E. coli* of OMC and CC were lower than CON and PC ($P < 0.05$). It was thought that organic medicinal charcoal is useful as a feed additive in pig diets because it improves the digestibility of feed and the fecal odor, and has positive effect on the population of microorganism in feces.

Key Words: swine, organic medicinal charcoal, fecal

M495 Effect of a functional feed additive on the stress nervous modulation response—Application on both the feeding behavior and performance of lactating sows and their litters.

Mónika Kormondi[1], Bertrand Medina*[2], and Tamás Tóth[1,3], [1]*Adexgo Ltd., Balatonfüred, Hungary,* [2]*Laboratoires Phodé, Terssac, France,* [3]*Department of Animal Nutrition, University of West Hungary, Mosonmagyaróvár, Hungary.*

Recently, the effects of a 1-week administration of cyclic terpene (d-limonene) on neurotransmitters as well as its expected anti-stress effect were evaluated on mice. Considering this, the preliminary aims of Laboratoires Phodé were to investigate the effect of specific and purified fractions of natural plant extracts (*Citrus* sp.) characterized by a high level of D-limonene (135000 ppm) on the feeding behavior (total feed intake through the lactation phase) and performance of lactating sows and their litters (piglet weaning weight). The trial was performed on sows (n = 98, Topigs genetic stock, ALW = 262 ± 26.6 kg) over 3 repetitions from farrowing (d0) to inseminating period (d36). Control (CTL) and Treated (VéO) groups of sows were completed by setting lactation pairs under the same housing (individual farrowing pens) and feeding conditions (lactating feed: 17.1% CP, 5.57 Mcal/kg ME with a twice-a-day dispensing). The administration of the functional feed additive (VéOPremium, Laboratoire PHODÉ, France – 250 g/MT) was started with a 4-d pre-feeding period before the sows were moved to the farrowing barn (d-4). Data were analyzed under non-parametric tests (Kolmogorov-Smirnov test, Levene-test, independent-samples *t*-test) using SPSS 13.0 for Windows. There were no significant differences ($P > 0.05$) between groups regarding the body weight loss of lactating sows. The average lactating FI was significantly higher (+ 4.7%, $P \leq 0.05$) in the VéO group compared with the CTL one (157 ± 6.3 vs 150 ± 8.3 kg, respectively). Regarding the average number of weaned piglet/litter of sow, no significant difference was observed between groups (12.25 vs 12.3 piglets/litter, for both VéO and CTL groups, respectively). The average live-weight (ALW) of piglets at weaning showed significantly heavier value (+6.5%, $P \leq 0.05$) in the VéO group (ALW = 7.37 ± 0.72 kg) although the piglets were weaned after 26.1 d on average, while the average number of days from birth to weaning was 26.6 in the control group (ALW = 6.92 ± 0.77 kg). These results suggest that the administration of these specific and purified fractions of natural plant extracts are able to support higher sow feed intake and piglet weaning weight ($P \leq 0.05$) through lactation phase.

Key Words: botanical extract, lactating sow, stress

M496 Improved piglets performance with sodium heptanoate. M. Puyalto*[1], P. Honrubia[1], M. I. Gracia[2], and J. J. Mallo[1], [1]*Norel S.A., Spain,* [2]*IMASDE Agroalimentaria S.L., Spain.*

The objective of the present study was to evaluate the effect in piglets productive parameters of sodium heptanoate in a control diet without any additive. Forty-eight 21-d-old piglets (6.5 ± 0.5 kg) were randomly divided in 2 groups: control (C) and 98% Na-heptanoate (NaC7) 3 kg/t. Every treatment was replicated 6 times and each replicate consisted of 4 piglets. Mash feeds and water were offered ad libitum. BW, ADG, ADFI and FCR were recorded for every period. At the end of each period (35 d and 49 d), one piglet per replicate was euthanized and samples from the ileum and cecum were taken to analyze gut microflora. Besides, samples of duodenum, jejunum and ileum epitheliums were obtained to determine their development status. Data were analyzed as a completely randomized design by GLM of SPSS v. 19.0. Piglets receiving sodium heptanoate had higher final body weight without significative differences (16 Kg vs 16.2 Kg; $P = 0.7583$). However the use of NaC7 resulted in an improvement ($P = 0.0431$) in the FCR (1.416 vs 1.324) when compared with the control treatment. No significant differences were observed in count of *Lactobacillus* and *E. coli*. Neither were there significant differences in villi height; however, there was a tendency to show deeper crypts in duodenum ($P = 0.1058$) in the animals that received the sodium heptanoate (441.1 µm vs 374.3 µm). We can conclude that the use of sodium heptanoate is able to improve productive parameters in piglets compared with the control treatment.

Key Words: sodium heptanoate, piglet

M497 Feeder space may affect pig performance in the early growing-finishing period. David Solà-Oriol, Patricia Romero, Deborah Temple, Laia Blavi*, and Josep Gasa, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

The number pigs fed per feeder space decrease along the whole growing period. However moving pigs from the weaning to the growing-finishing facilities is a challenging period and feeder space may affect performance, growth and homogeneity of pigs. The aim of the present work was to study the effect feeder type in terms of feeder space (2 or 5) at the start of the growing period. At weaning a total of 264 28-d-old piglets [Pt × (LD × LW)] were distributed into 24 pens (11 piglets/ pen) according to sex and initial body weight (BW) for the transition period (T; 28 to 64d). During T period, a commercial INOX lidded hopper was used (3 feeder spaces of 17cm/pen). When pigs moved to the growing facilities, the 24 pens were maintained and split into 2 groups of 12 according sex, BW and feeder type. Two different commercial concrete hoppers differing in feeder space were used (2 feeder space of 23cm or 5 feeder space of 18cm/pen) Pigs were feed the same diets during T and growing (G) period. Feed was offered ad libitum in mash form. Therefore, 2 experimental treatments were performed at the start of the growing period (64 to 92d) according to feeder space and sexes taking into account the same conditions from 28 to 64d. Individual BW was recorded at 28, 64 and 92d of age and average daily gain (ADG) and coefficient of variation (CV) of the pen were calculated. Behavioral measures and lesion scoring were also monitored on d 74 of age. No sex effect was observed for the T and G ($P > 0.10$). Higher BW (33.1 vs 32.5kg; $P = 0.061$) and ADG (583 vs 562g/d; $P = 0.062$) were observed for the animals raised in the 5 feeder space hoppers compared with the 2 feeder spaces. Moreover, the CV of the animals at the end of T was reduced (12%) along G with a 5 feeder spaces while increased (1.2%) with 2 feed spaces. Finally, no differences were observed in terms of aggressions and lesions due to feeder space during G period. It is concluded that feeder space may affect growth performance and body weigh homogeneity in growing pigs.

Key Words: feeder space, performance, pig homogeneity

M498 The effect of inmunocastration on growth performances and carcass quality of heavy males and gilts. Maria A. Latorre*[1], Argimiro Daza[2], Alvaro Olivares[3], Jesus Suarez-Belloch[1], and Clemente J. Lopez-Bote[3], [1]*Universidad de Zaragoza, Zaragoza, Spain,* [2]*Universidad Politecnica de Madrid, Madrid, Spain,* [3]*Universidad Complutense de Madrid, Madrid, Spain.*

A trial was carried out with 48 Duroc × (Landrace × Large White) pigs intended for dry-cured ham; 24 males and 24 gilts of 46.3 and 42.9 kg BW, respectively. For that end, surgically castrated males are used to avoid sexual odour and minimum levels of fat thickness, measured at Gluteus medius muscle (GM; >16 mm), are required to improve the ripening process and ham quality. Currently, the main problems are the future prohibition in EU of this type of castration and the lack of fat in gilts. The effect of immunization against GnRH on growth performances and carcass quality was evaluated. There were 4 experimental treatments; surgically castrated males (CM), immunocastrated males (IM), entire gilts (EG) and immunocastrated gilts (IG). The CM had been castrated at 5 d of age. Inmunization was carried out in both sexes with 2 injections of Improvac (Zoetis) with an interval of 4 weeks (1st: 44.6 kg BW, 2nd: 70.6 kg BW, as average). The replicate was a pen with 3 pigs (n = 4) for performance traits and the animal (n = 12) for carcass traits. A commercial diet, based on barley, wheat, and vegetable meals and containing 13.74 MJ DE/kg, 14.1% CP, and 0.75% Lys, was provided ad libitum through the trial. Pigs were slaughtered at 127 kg BW. Data were analyzed by ANOVA and the statistical model included the sex as main effect. Duncan test was used to compare pairs of means. From 1st to 2nd injection, the EG grew faster than IG with CM and IM being intermediate ($P < 0.001$) but this effect disappeared after. At the end of the trial, the CM had higher feed:gain ratio than the other treatments ($P < 0.05$). No effect of immunocastration was observed on carcass yield but the IG had wider fat depth at GM and lower lean yield than EG with CM and IM being intermediate ($P < 0.05$). Intramuscular fat content was not affected by sex. It is concluded that the immunization against GnRF might be a good strategy to improve some traits desirable in pigs intended for dry-cured ham because, in gilts, it increased fat depth and, in males, it reduced feed:gain ratio in comparison with those surgically castrated.

Key Words: pig immunocastration, growth performance, carcass quality

M499 Is the lactation period the main variable responsible for reducing the efficiency of the swine production?

Sergi López-Vergé, David Solà-Oriol, Laia Blavi*, and Josep Gasa, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Pig body weight (BW) homogeneity across the entire production cycle plays an important role in the swine industry because it directly affects efficiency and farm occupation time, mainly in regards to the growing-finishing facilities. The aim of this study was to know if the BW variability is equally distributed along the pig productive life or is primarily important at one particular stage. A total of 433 crossbreed piglets [Pietrain × (Landrace ×x Large White)] from 40 litters were used. All diets were offered ad libitum. During the nursery period, piglets were fed a diet formulated to contain 11.0 MJ/kg NE, 20.2% CP and 1.37 Lys. Thereafter, the animals were moved to a growing-finishing facility. Pigs were fed the same commercial growing and finishing diets (10.0 MJ/kg NE, 16.0% CP, 0.95 Lys). All animals were individually weighed from birth until slaughter at d 2 (CF; cross fostering), d 28 (weaning), d 42 (14 d post-weaning), d 63 (35 d post-weaning) and every 3 weeks until pigs were slaughtered. The relationship between BW at one stage and the next succeeding one along the whole cycle was analyzed by using the CORR procedure of SAS. Moreover, the variability at all periods was calculated taking into account the coefficient of variation (CV, %) by using the MEANS procedure of SAS. A strong relationship was observed between 2 consecutive steps along the whole production cycle (Pearson Correlation Coefficient (r) ranging from 0.85 to 0.96 ($P < 0.001$) until the first group of pigs were slaughtered), except for the lactation period (from birth to weaning, r = 0.46, $P > 0.001$). At the same time, the CV was higher at the first stages (22.17% until 35 d post-weaning) and then decreased until slaughter (8.42%). Results showed that the events occurred in the first stages of pig life, but especially during the lactation period (in terms of variability), have a huge effect along the subsequent performance of pigs, suggesting a more accurate management for the smallest piglets just after birth.

Key Words: correlation, piglet, variability.

M500 Evaluation of the efficacy of sodium heptanoate or butyrate in front of an enterotoxigenic *Escherichia coli* (ETEC) K88 oral challenge in piglets.

P. López-Colom[1], L. Castillejos[1], M. Puyalto[2], J. J. Mallo*[2], and S. M. Martín-Orúe[1], [1]*Animal Nutrition and Welfare Service, Departament de Ciència Animal i dels Aliments, Universitat Autònoma de Barcelona, Bellaterra, Barcelona, Spain,* [2]*Norel S.A., Madrid, Madrid, Spain.*

This study evaluated the efficacy of sodium heptanoate (HEPT'ON) or sodium butyrate (GUSTOR BP70; Norel S.A.) against ETEC K88 in weanlings. A total of 72 3-week-old piglets were divided into 24 pens and 3 experimental groups: Plain diet (CTR); supplemented with GUSTOR BP70 (BUT); or supplemented with HEPT'ON (HPT), both at 3 kg/t and containing 70% of acid salt protected with vegetable fat. Intake and weight were monitored along 15 d. After one week, animals were orally inoculated with ETEC K88 ($1x10^9$ cfu) and fecal consistency and rectal temperature evaluated afterward. On d 4 and 8 post inoculation (PI) one animal per pen was euthanized to evaluate inflammatory response (TNFα and Pig-MAP) and counts of enterobacteria and *E. coli* in ileal-colonic contents and ileal mucosa scrapes. No significant differences were seen in performance although numerical values were higher for the experimental diets (217, 264 and 243 g ADFI and 117, 123 and 124 g ADG for CTR, BUT and HPT). No significant differences were found in fecal consistency, rectal temperature and inflammatory markers. Regarding microbiological changes, no significant differences were observed between treatments in the colon. Nonetheless, in ileum digesta, there were numerical differences ($P = 0.126$) with higher number of enterobacteria in both acids treatments at d 4 PI, that was correlated to an increase in the number of enterobacteria and *E. coli* recovered from the ileal scrapes (4.30, 5.88 and 5.46 log cfu *E. coli* for CTR, BUT and HPT, $P = 0.003$). This increase, however, was not found at d 8 PI when even a decrease in the numerical values of *E. coli* in ileal digesta was seen for BUT treatment (6.58, 6.01 and 6.93 log cfu for CTR, BUT and HPT, $P = 0.036$) that also showed a tendency to improve the colonic consistency ($P = 0.099$). These results suggest the potential of BUT to improve the recovery of the animals after an ETEC challenge. More studies under field conditions with a higher number of animals would be needed to confirm the numerical differences found in performance.

Key Words: *Escherichia coli* K88, sodium heptanoate, sodium butyrate

M501 The use of multiple imputation for the accurate measurements of individual feed intake by electronic feeders.

Shihui Jiao*[1], Christian Maltecca[1], Yijian Huang[2], and Kent A. Gray[2], [1]*North Carolina State University, Raleigh, NC,* [2]*Smithfield Premium Genetics, Rose Hill, NC.*

Obtaining accurate individual feed intake records is a key first step in achieving genetic progress toward a more efficient pig for nutrient utilization. Feed intake records collected by electronic feeding systems contain errors (extreme values or outliers), which are due to feeder malfunction or animal movements. In this study, we introduce a new feed intake data editing strategy to replace errors and missing observations occurring in feed intake data, based on multiple imputation methods. Compared with the well-established linear mixed model (LMM) approach, multiple imputation either by using conditional distribution (MI) or by chained equation (MICE) results in increased accuracy of data adjustment in simulated phenotypes with artificially introduced errors. Feeder visit records in the simulated data sets were sampled from a data set including individual pig feed intake visits collected by Smithfield Premium Genetics from year 2004 to 2013. Three scenarios were considered in the analysis with 5%, 10% and 20% error visits simulated. Each scenario was replicated 5 times. Accuracy of the error-adjustments was measured as correlation between the true error-free daily feed intake (DFI) or average daily feed intake (ADFI), and the adjusted ones. Multiple imputation methods outperformed the linear mixed model approach in all scenarios with average accuracies of 96.71%, 93.45% and 90.24% obtained with MI and 96.84%, 94.42% and 90.13% obtained with MICE, compared with 91.0%, 82.63% and 68.69% using LMM for DFI with simulated error rate 5%, 10% and 20%, respectively. Similar results were obtained for ADFI. In conclusion, multiple imputation was introduced in this study as a more accurate

and flexible error-adjustment method for feed intake data collected by electronic feeders.

Key Words: feed intake, electronic feeder, multiple imputation

M502 Effect of using nonconventional legumes (narbon vetch, black chickpea, and winter pea) as protein sources in piglet diets.

Eduardo de Mercado[1], Jose Gómez-Fernández[1], Cristina Tomás[1], Emilio Gómez-Izquierdo[1], Eva Guillamón[2], Alejandro Varela[2], Pacual López[3], and Maria A. Latorre*[4], *[1]Centro de Pruebas de Porcino, ITACYL, Hontalbilla, Segovia, Spain, [2]Departamento de Tecnología de los Alimentos, INIA, Madrid, Spain, [3]Copiso Soria Sociedad Cooperativa, Soria, Spain, [4]Universidad de Zaragoza, Zaragoza, Spain.*

A trial was carried out to study the effect of the partial substitution of soybean meal (SBM) by alternative protein sources: black chickpea (*Cicer arietinum*; BC), narbon vetch (*Vicia narbonensis*; NV), and winter pea (*Pisum sativum*; WP) on growth performance of piglets during starter period. The anti-nutritional factors are the main handicap of including in a diet a high proportion of legumes with no previous treatment. The protease inhibitors (PI) (trypsin inhibitor; TI and chymotrypsin; CI) interfere in the absorption of proteins affecting feed intake and feed efficiency in young pigs. A total of 192 animals (96 barrows and 96 gilts), from PIC L-65 sires x Topigs 20 dams, of 11.6 ± 0.56 kg BW and 42 ± 2 d of age were used in the experiment. Piglets were allocated according to sex and initial BW. Four diets were provided: 1) control with 21% SBM, 2) 24% BC + 14.4% SBM, 3) 20% BC + 5% NV + 13.2% SBM and 4) 24% WP + 5% NV + 11.4% SBM. Diets had a similar nutritional profile (10.24 MJ NE/kg, 18% CP, and 1.25% Lys). Trial lasted 20 d (23.35 ± 1.42 kg BW as average). Data were analyzed as a random factorial design 2 (sexes) × 4 (diets) by GLM of SAS. Each experimental treatment was replicated 4 times considering the box, with 6 piglets, as the replicate. The PI content in the experimental diets was 1.03, 2.41, 1.57, and 1.13 units TI/mg feedstuff, and 1.85, 2.66, 2.24, and 2.60 units CI/mg feedstuff for diet 1, 2, 3, and 4, respectively. No significant difference was detected for any variable studied between barrows and gilts. The average daily gain was not affected by diet ($P = 0.42$) but piglets fed diets 1, 2 and 3 ate more feed than those fed diet 4 (898, 951, 876 vs 836 ± 25.7 g/d, respectively; $P < 0.001$). Diet 4 provided better feed to gain ratio than diets 1 and 2, with diet 3 in an intermediate position (1.54, 1.58, 1.51, and 1.44 ± 0.034 g/g, for diets 1, 2, 3, and 4, respectively; $P < 0.005$). Although more studies are necessary, we can conclude that black chickpea, narbon vetch, and winter pea can substitute partial soybean meal in piglet diets during the starter phase.

Key Words: nonconventional legume, piglet, productive performance

M503 Effects of breed, sex, and birth weight on growth and carcass composition traits in pigs.

L. L. Lo*[1], C. C. Tsai[1], and R. S. Lin[2], *[1]Chinese Culture University, Taipei, Taiwan, Republic of China, [2]National I-Lan Univesity, I-Lan, Taiwan, Republic of China.*

Effects of breed, sex, and birth weight on growth and carcass composition traits were investigated using purebred Duroc, Landrace, and Yorkshire, respectively. Twenty-three sets of thee littermates, consisting of a boar, gilt, and barrow for each of 3 breeds was used. All pigs were classified into 3 groups based on their birth weights (BWT): small (mean = 1.15 kg), medium (mean = 1.50 kg), and big (mean = 1.75 kg). Gilts and barrows from each littermate were slaughtered at 103.40 kg (SD = 13.98 kg) of body weight. A mixed model that included fixed effects of breed, sex, birth group, interaction of breed and sex, and random effect of animal was used. Breed significantly affected growth traits. Landrace pigs had the highest ($P < 0.05$) overall average daily gain than in other 2 breeds. The overall average daily gain was 608.93 ± 7.87 g, 649.00 ± 7.82 g, and 603.38 ± 8.61 g for Duroc, Landrace, and Yorkshire, respectively. Heavier pigs at birth showed significant advantage ($P < 0.05$) on overall average daily gain (small = 595.99 ± 12.00 g, medium = 615.64 ± 6.17 g, large = 649.68 ± 7.65 g). Carcasses from Landrace pigs had thinner average backfat and tenth rib backfat thickness than those from Duroc breeds. Duroc pigs however had heavier ($P < 0.05$) ham weight than that of Landrace pigs indicated the carcass characteristics of Duroc breed. Most carcass composition traits did not show the sex effect except for fat percentage and weight of tenderloin ($P < 0.05$). Pigs with heavier birth weight had larger ($P < 0.05$) Boston butt. In conclusion, the results suggest that breed, sex, and birth weight are important sources of variation for growth and carcass composition traits of pigs.

Key Words: birth weight, carcass, pig

M504 Reducing malodorous compounds on swine in vitro fermentation using probiotics.

Yeon Jae Choi, Lovelia L. Mamuad, Seung Hyun Kim, and Sang Suk Lee*, *Sunchon National University, Suncheon, Jeonnam, South Korea.*

Bacteria play a significant role in odor production. Thereby, we evaluated different bacteria for their ability to reduce malodorous compounds in swine using in vitro fermentation. Fresh cultures of *Lactobacillus plantarum* KACC 91016 (T1), *L. brevis* ATCC 14869(t) (T2), *Bacillus subtilis* KACC 10112 (T3), *Saccharomyces cerevisiae* KACC 30068 were used in this study. One hundred milliliters of anaerobic salt medium containing 10% fresh swine feces was transferred to serum bottles containing 1g DM of 50:50 soluble starch to casein ratio and inoculated with or without (control) 1mL of different microbial cultures and incubated for 24h. Highest ($P < 0.05$) total gas production was observed in T1 and lowest in control. Opposite was observed in hydrogen sulfide (H_2S) concentration, wherein lowest ($P < 0.05$) H_2S was observed in T1 and highest in control with 17.80% and 22.20%, respectively. Also, lower percent methanethiol, dimethyl sulfide and trimethylamine were observed in treated compared with control. Highest ($P < 0.05$) concentration of total fatty acids, propionate, and butyrate were also observed in T1 and the highest ($P < 0.05$) acetate was observed in T3. Among the bacteria used, addition of *L. plantarum* is the most effective for reducing malodorous compounds

Key Words: n vitro, malodorous compounds in swine, probiotic

M505 Relationship between birth weight and subsequent piglet performance: A meta-analytic study.

Eloiza Lanferdini[1], Ines Andretta[2], Leonardo da Silva Fonseca[1], Rennan Herculano Rufino Moreira[1], Vinicius de Souza Cantarelli[1], Rony Antônio Ferreira[1], Alysson Saraiva[3], Cesar Augusto Pospissil Garbossa[1], and Márvio Lobão Teixeira de Abreu*[2], *[1]Universidade Federal de Lavras, Lavras, Minas Gerais, Brazil, [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil, [3]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The aim of this study was to evaluate the effect of birth weight of piglets on subsequent performance through a meta-analysis. The database totaled 2,691 piglets (15 articles published between 2002 and 2014). Average birth weights were 1.785, 1.511 and 1.129 kg for heavy, medium and light piglets, respectively. The selected database publications contained results of experiments with at least 2 weight groups of piglets at birth and performance results. The meta-analysis was based on 3 sequential analysis: graphic, correlation and variance-covariance. The birth weight of piglets was positively correlated with body weight in the subsequent phases and with weight gain during the lactation period. On the other hand, the age at slaughter to reach 110 kg correlation with birth weight of piglets was negative. The birth weight of piglets affected ($P < 0.05$) body weight and weight gain in the subsequent phases. Heavy piglets at birth showed an increase ($P < 0.05$) of 6.6 kg in the slaughter weight, at 150 d of age, compared with light piglets. Piglets with medium weight at birth reached similar weight at slaughter ($P > 0.05$) compared with heavy piglets and showed a difference ($P < 0.05$) of 5.2 kg compared with light piglets. The different birth weight of piglets had no influence ($P > 0.05$) on feed intake in the subsequent phases of growth. Feed efficiency improved ($P < 0.05$) in medium and heavy piglets at birth in the growing and finishing phases. The slaughter age to reach 110 kg of live weight decreased ($P < 0.05$) in the piglets born with medium and heavy weight, respectively, compared with piglets with low birth weight. Heavy piglets at birth (1.785 kg) performed better by increasing weight gain, and consequently greater final body weight and fewer days (10–12 d) to reach slaughter weight compared with light piglets (1.129 kg). Above 1.50 kg at birth the pig performance until slaughter is not influenced by birth weight.

Key Words: animal growth, meta-analysis, pig production

M506 Meat quality of finishing pigs from sows supplemented with arginine during gestation. Leonardo da Silva Fonseca[1], Eloiza Lanferdini[1], Rennan Herculano Rufino Moreira[1], Rhuan Fillipe Chaves[1], Peter Bitencourt Faria[1], Marianne Kutschenko[2], Eduardo Terra Nogueira[2], Alysson Saraiva[3], Cesar Augusto Pospissil Garbossa[1], and Márvio Lobão Teixeira de Abreu*[1], *[1]Universidade Federal de Lavras, Lavras, Minas Gerais, Brazil, [2]Ajinomoto Animal Nutrition, Limeira,São Paulo, Brazil, [3]Universidade Federal de Viçosa, Viçosa, Minas Gerais, Brazil.*

The aim of this study was to evaluate carcass traits and meat quality of finishing pigs from sows supplemented with arginine during gestation. Piglets of 48 sows from parities 2 to 6 fed gestation diets with or without 1.0% L-arginine (Ajinomoto) supplementation from 30 to 60 d of gestation and from 80 d of gestation until farrow were used. Twenty 4 pigs (6 males and 6 females per treatment), selected by average weight (96.17 kg ± 3.74 for the pigs from control sows and 103.67 kg ± 4.05 for the pigs from arginine fed sows) were slaughtered at 150 d of age. *Longissimus dorsi* temperature and pH at the 12th rib were measured 45 min and 24 h after slaughter on the left half of the carcass. Loin eye area and the fat area were evaluated by drawing the outline of the muscle and the fat at the tenth rib on a paper and then scanning and measuring the area through ImageJ IJ 1.46r. *Longissimus dorsi* samples were collected and cooled to perform the color ratings. Saturation indices (C*) and hue angle (h*) were determined. Pigs from sows fed arginine during pregnancy were 7.80% heavier ($P < 0.05$) at 140 d of age. The drip loss was negatively affected ($P < 0.05$) by arginine supplementation which was 3.40% higher compared with the control group. This feature may negatively influence the product choice by the consumer as it is one of PSE meat characteristics. The loin depth of the control group was 13.70% lower ($P < 0.05$), however the loin eye area and the loin fat area were not affected ($P > 0.05$). L*, a*, b*, C*, and h* values as well as shear force and cooking loss were not affected ($P > 0.05$) by arginine. Dietary supplementation of gestating sows with arginine increase pig weight and loin depth at slaughter; however, drip loss is also increased.

Key Words: amino acid, carcass, nutrition

M507 Growth curve analysis of placental and fetal growth influenced by adjacent fetal sex status under crowded uterine conditions in pigs. Brad A. Freking* and Clay A. Lents, *USDA, ARS, US Meat Animal Research Center, Clay Center, NE.*

Intrauterine position and sex of adjacent fetuses in litter bearing species have been implicated in physiological and behavioral differences in males and females. Our objective was to establish growth curves for fetal and placental weight gain as influenced by sex status of flanking fetuses under crowded uterine conditions. Gilts were subjected to unilateral-hysterectomy-ovariectomy surgery at 160 d of age and mated at approximately 280 d of age. Gilts were assigned to be harvested at d 45, 65, 85, or 105 of gestation. A total of 297 pregnancies were evaluated in 4 contemporary groups. Position in the uterus relative to the cervix, fetal weight, and placental weight were recorded at harvest. Data were coded to test when each fetus was adjacent to 0, 1, or 2 opposite sex fetuses after removal of the first and last fetuses in each litter to remove bias of ends not being flanked on both sides. After this editing a total of 343, 651, and 303 fetuses were included in the analyses for 0, 1, or 2 opposite sex flanking fetuses, respectively. Nonlinear analyses fitted a logistic function ($Wt = Ae^{tk}$) to the fetal and placental weight data to establish unique growth curves for each flanking sex status code. Two parameters were estimated representing the initial weight at day zero (A) and a slope parameter (k) with respect to time of gestation (t). Gauss-Newton method was used in the NLIN procedure to generate solutions. A 4 df F-test was calculated to compare the ability of code-specific functions to account for more variation than the pooled function. The null hypothesis of a single pooled function to describe fetal weight was rejected ($F = 2.49$; $P < 0.05$) but not for placental weight ($F = 0.80$; $P > 0.1$). Code specific growth curves indicated placental weight separated only in the latter stage (d 105) of gestation whereas fetal weights separated as early as d 65 of gestation. Fetal growth development in pigs is influenced by sex status of adjacent fetuses, with increased growth by those surrounded by the same sex, and could be a potential source of variation in behavioral and reproductive differences later in life.

Key Words: pig, fetal growth, survival

M508 Effect of mineral sources on reproductive performance in sows. Tsung-cheng Tsai*[1], Gary A. Apgar[2], Mark J. Estienne[3], Mark Wilson[4], and Charles V. Maxwell[1], *[1]University of Arkansas, Fayetteville, AR, [2]Southern Illinois University, Carbondale, IL, [3]Virginia Tech, Blacksburg, VA., [4]Zinpro Inc., Eden Prairie, MN.*

Sows (n = 245 from 3 stations) were blocked by parity [Pty 1: parity 1 ; Pty 2: parity 2 and 3; Pty 3: parity ≥4) and initial BW, and then randomly assigned to corn-SBM diets supplemented with either inorganic [IM: 120 ppm Zn (ZnO), 30 ppm Cu ($CuSO_4$), and 50 ppm Mn ($MnSO_4$)] or the same total level of minerals with AA complex of Zn, Cu and Mn (OM) replacing 50% of the IM in iso-mineral based diets which also provided 120, 165, 0.3, 0.3 ppm of inorganic Ca, Fe, I, and Se, respectively. Gestation (3391 kcal/kg of ME; 0.65% SID lysine) and lactation (3348 kcal/kg; 1.00% SID lysine) diets were formulated to meet 1998 NRC nutrient recommendations. Sow individual BW (at breeding, 110 d, 48 h postpartum, and weaning) and Intake (gestation: breeding to 110 d; lactation: postpartum to weaning) were collected to calculate ADG, ADFI and G:F ratio. During gestation, IM fed sows gained less weight (60.4 vs. 64.6 kg, $P = 0.054$), consumed less feed (263.5 vs. 264.8 kg, $P = 0.047$), and had lower G:F ratio (0.27 vs. 0.29, $P = 0.044$) than OM fed sows. In lactation, sows fed IM had higher ADFI in wk 2 (5.85 vs. 5.19 kg/d, $P = 0.021$), and weaned more light BW piglets per litter (<3.63 kg; 6.55 vs. 3.23%, $P = 0.047$) than those fed OM, whereas number born alive (11.4 vs. 10.9, $P = 0.238$), number weaned (10.2 vs. 9.8, $P =$

0.184), piglets pre-weaning ADG (0.27 vs. 0.27 kg/d, $P = 0.767$), and the percentage of pre-weaning mortality (13.1 vs. 12.9%, $P = 0.923$) were similar for IM and OM fed sows, respectively. Of all parities, the Pty 1 and 2 sows gained more BW in gestation (66.1 and 67.5 vs. 53.9 kg, $P < 0.001$) then Pty 3. In addition, the Pty 1 sows had lower overall lactation intake (99.0 vs. 124.7 and 126.2 kg, $P < 0.001$) when compared with Pty 2 and 3 sows. Sows of Pty 2 delivered 8.9% heavier average BW piglets [1.67 vs. 1.50 (Pty 1) and 1.52 (Pty 3) kg, $P < 0.001$), and had 11.5% higher piglet ADG [0.29 vs. 0.26 (Pty 1 and 3) kg/d, $P < 0.001$). Results of current study demonstrate that supplemental organic minerals improved gestation weight gain, G:F ratio, and produced more full value weaned pigs.

Key Words: organic and inorganic minerals, sow, reproductive performance

M509 Transcriptome profile of boar spermatozoa as revealed by RNA-sequencing.

Jean M. Feugang*[1], Shengfa S. Liao[1], William S. Sanders[2,3], Jingqiao Lu[4], Mark A. Crenshaw[1], Scott T. Willard[1,5], and Peter L. Ryan[1,6], *[1]Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State, MS, [2]Department of Computer Science & Engineering, Mississippi State University, Mississippi State, MS, [3]Institute for Genomics, Biocomputing, and Biotechnology, Mississippi State University, Mississippi State, MS, [4]School of Medicine, Emory University, GA, [5]Biochemistry, Molecular Biology, Entomology and Plant Pathology, Mississippi State University, Mississippi State, MS, [6]Pathobiology and Population Medicine, Mississippi State University, Mississippi State, MS.*

High-throughput RNA sequencing (RNA-Seq) overcomes the limitations of the current hybridization-based techniques to detect the actual pool of RNA transcripts in spermatozoa. The application of this technology in livestock can speed the discovery of potential predictors of male fertility. As a first step to identify novel gene products of fertility importance in pigs, we conducted a RNA-sequence analysis of boar spermatozoa. Fresh semen of 8 fertile boars (3 ejaculates/boar) were purchased from a commercial stud and pure motile spermatozoa were obtained through a discontinuous percoll gradient. Total sperm RNA were extracted using commercial kits with an in-column DNase digestion. The purity and integrity of RNA samples were checked and those with high quality parameters were used for deep-RNA sequencing to produce millions of short cDNA reads using Illumina RNA-Seq technology. Resulting reads were aligned to the pig reference genome to produce a genome-scale transcription map that consisted of both the transcript structure and the expression level of each gene (fragments per kilobase of exon per million fragments mapped). Total of 18,357 sequence tags were successfully mapped to all pig chromosomes and mitochondrial genome. Five chromosomes (2, 1, 6, 7, and 13) comprised the highest density of mapped transcripts (42%), while the bottom lowest density (8%) was found in chromosomes 10, 18, 16, 11, and Y. The Y chromosome and mitochondrial genome contained only 0.07% and 0.08% of total mapped sequence tags. Structural annotation revealed a diverse population of sperm transcripts comprising both coding and non-coding RNAs. Approximately 12,355 of sequence tags were annotated with ENSEMBL and rRNAs (e.g., 5s and 7sk), snRNA (e.g., U1 and U6), miRNAs (e.g., mir127 and mir935), and mitochondrial RNA (e.g., ND6 and CO1) constituted the most abundant sequence tags. We further confirmed the presence of selected genes (e.g., AQP11 and AQN-1) through RT-PCR. The findings revealed a large pool of coding and non-coding RNA in mature boar spermatozoa. The full investigation of this RNA population will allow for the identification of those having critical roles during fertilization and early embryogenesis.

Key Words: gamete, reproduction, swine

M510 Effects of chicken egg anti-F4 antibodies supplementation on performance and diarrhea incidences in enterotoxigenic *Escherichia coli* K88$^+$ challenged piglets.

Kolawole R. Aluko*[1], Deepak Ettungalpadi Velayudhan[1], Lin Fang[2], and Charles M. Nyachoti[1], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]Zyme Fast System Inc., Winnipeg, MB, Canada.*

This study was conducted to evaluate the effects of feeding diets supplemented with spay-dried whole egg containing anti-F4 antibodies (SDWE) against recombinantly produced F4 antigens to piglets challenged with enterotoxigenic *Escherichia coli* K88 (ETEC). Twenty-seven individually housed piglets [(Yorkshire × Landrace) × Duroc, 7.27 ± 0.47 kg initial BW] weaned at 21 ± 1 d were randomly allotted to 3 dietary treatments (n = 9) consisting of a wheat-soybean meal basal diet containing either 0 (control egg powder; CEP), 0.1% (SDWE1) or 0.4% (SDWE2) SDWE for a 14-d study. After a 7-d adaptation period, all pigs were weighed, blood samples collected and then orally challenged with 6 mL (2×10^9 cfu/mL) of freshly grown ETEC inoculum on d 8. Pigs had ad libitum access to feed and water throughout the study. Blood was sampled at 24 h and 48 h post-challenge to determine plasma urea nitrogen (PUN) content and diarrhea incidences and fecal consistency scores were recorded from d 9 to d 12. On d 14, all pigs were weighed and then killed to obtain intestinal tissue samples for villus height and crypt depth measurements. During the pre-challenge period, pigs fed the SDWE2 diet had higher ($P < 0.05$) ADG and G: F compared with CEP but there were no differences among treatments in any of the performance response criteria during the post-challenge period. Incidences of diarrhea were similar among treatments although piglets fed SDWE-containing diets recovered from diarrhea within 48 h (with fecal consistency score of 0.0) of ETEC compared with CEP pigs. Also, fecal shedding of ETEC, PUN content and intestinal histomorphology were similar among treatments. The results show that SDWE at 0.4% supported greater piglet performance before challenge although there was no benefit of SDWE supplementation at either 0.1% or 0.4% evident during the post-challenge period.

Key Words: ETEC K88$^+$, chicken egg anti-F4 antibodies, recombinant F4 antigens

M511 Combined effects of chitosan and probiotic supplementation on performance and diarrhea incidences in enterotoxigenic *Escherichia coli* K88$^+$ challenged piglets.

Kolawole R. Aluko*[1], Deepak Ettungalpadi Velayudhan[1], Aike Li[2], Yulong Yin[3], and Charles M. Nyachoti[1], *[1]University of Manitoba, Winnipeg, MB, Canada, [2]Academy of State Administration of Grain, Beijing, China, [3]Institute of Subtropical Agriculture, Chinese Academic of Sciences, Changsha, China.*

The aim of this study was to investigate the combined effects of chitosan oligosaccharide (COS) and a microencapsulated *Enterococcus faecalis* probiotic (PRO) on growth performance and diarrhea incidences in enterotoxigenic *Escherichia coli* K88 (ETEC) challenged piglets in a 14-d study. Thirty piglets [(Yorkshire × Landrace) × Duroc], 7.19 ± 0.52 kg initial BW weaned at 21 ± 1 d were allotted to 5 treatment groups (n = 6) consisting of a corn-soybean meal diet with no additive (negative control, NC), the NC + 0.25% chlortetracycline (positive control, PC), NC + 400 mg/kg COS (COS), NC + 100 mg/kg PRO (PRO) and NC +

a combination of COS and PRO (CPRO). The basal diet was formulated to meet the NRC (2012) nutrient specifications for 5 to 10 kg BW pigs. Pigs were individually housed in cages, acclimated to treatments for a 7-d period and had ad libitum access to feed and water throughout the study. On d 8, pigs were weighed, blood samples were collected and then orally challenged with 6 mL (1×10^{11} cfu/mL) of freshly grown ETEC inoculum. Post-challenge, blood was sampled at 24 h and 48 h to determine plasma urea nitrogen (PUN) and diarrhea incidences and fecal consistency scores were recorded from d 9 to d 12. On d 14, all pigs were weighed and then killed to obtain intestinal tissue samples for histomorphometric measurements. Growth performance responses were similar among treatments during the pre- and post- challenge periods. There were no significant differences in PUN content, incidences of diarrhea and fecal consistency scores among treatment. The intestinal histomorphology results did not differ significantly among treatments except for PC with increased ($P = 0.0003$) villus-crypt ratio compared with the NC. Therefore, under the conditions of the present study, supplementing pig starter diet with 400 mg/kg COS or 100 mg/kg PRO or their combination had no effect against ETEC-induced diarrhea and did not improve growth performance in ETEC challenged piglets compared with control group.

Key Words: ETEC K88$^+$, chitosan oligosaccharide, *Enterococcus fecalis* probiotic

M512 Yeast cell wall supplementation in the diet of weaned piglets and its effect on performance and diarrhea incidence.

Amadeo A. Alcantara*[1], Kim C. P. Isiderio[1], and Melina A. Bonato[2], [1]*College of Veterinary Medicine, University of the Philippines Los Baños, Los Baños, Philippines,* [2]*ICC Industrial Comércio Exportação e Importação Ltda., São Paulo, Brazil.*

The objective of this study was to evaluate effects of yeast cell wall (YCW) supplementation in weaned piglet's diet on performance and diarrhea incidence. Trial 1 was conducted on a swine farm which recently recovered from hog cholera disease, and 120 piglets, 28-d old (avg. 8.37 kg) were distributed in an randomized complete block design (RCBD), with 2 treatments (0 and 2 kg/MT of YCW from *Saccharomyces cerevisiae*), being 8 reps for control group and 7 for YCW group, of 8 piglets in each. The 2nd trial was conducted on a swine farm where the low disease profile was relatively stable for the past 2 years, and 100 piglets, 28-d old (avg. 7.53 kg) were distributed in RCBD, with 2 treatments (same as 1st trial) each having 5 reps with 10 piglets in each. The periods were 20 and 21d, respectively, for 1st and 2nd trials, divided into booster (28–30d) and pre-starter diets (31–47d 1st trial, and 31–48d 2nd trial). The parameters measured in both trials were: body weight (BW, kg), body weight gain (BWG, kg), average daily feed intake (ADFI, kg), feed:gain (F:G) and mortality (M, %). Diarrhea incidence (DI) was observed in 1st trial, and given a corresponding score from zero to 3 in order of increasing severity. The data were analyzed using the GLM (SAS), and means were compared by Kruskall-Wallis test for non-parabolic data. The YCW supplementation in the diet of weaned piglets resulted in no differences ($P > 0.05$) in performance parameters analyzed for both trials. However, the groups supplemented with YCW, numerically had improved BWG (+6.3; +6.4%) and F:G (+7%; 13.2%), respectively, for both trials. There were no differences ($P > 0.05$) between treatments for DI score. For control group, 90.36% of the population has 0 score at the beginning, which suggests a normal type of feces, and at the final week of the experiment, it minimally increased to 93.05%. For YCW group, there was an increase in the number of animals having a 0 score, from 82.58% to 93.79%, at the last week of the experiment. Supplementation of YCW at 2 kg/MT to diets of weaned piglets had numerical, but no significant, positive benefits when considering BWG, F:G, and DI, compared with control treatment.

Key Words: body weight, *Saccharomyces cerevisiae*

M513 Yeast cell wall supplementation in the diet of weaned piglets and its effect on gut health.

Amadeo A. Alcantara*[1], Glorilyn M. Valesco[1], Cellito C. Mendoza[1], and Melina A. Bonato[2], [1]*College of Veterinary Medicine, University of the Philippines Los Baños, Los Baños, Philippines,* [2]*ICC Industrial Comércio Exportação e Importação Ltda., São Paulo, Brazil.*

The objective of this small-scale study was to evaluate effects of yeast cell wall (YCW) supplementation in weaned piglet's diet on gut health and integrity. The trial was conducted with 12 piglets, 28-d old (8.5 ± 1.5 kg), distributed in a complete randomized design, with 2 treatments (0 and 2kg/MT of YCW from *Saccharomyces cerevisiae*), 6 reps, 1 piglet in each. On d 1 of trial, *E. coli* was inoculated at 9.8×10^8 cfu/mL per pig. The experimental period was 14 d, where on d 1, 1 animal of control group (CG) was killed for baseline values; on d 7, 3 piglets from each treatment were killed; and on d 14, the remaining piglets were killed. Intestinal samples were collected from jejunum on d 1, 7, and 14 and measured under the light microscope for villus height (VH,µm), villus width (VW,µm), mucosal thickness (MT,µm), crypt depth (CD,µm) and villous surface area (VSA,µm^2). Also scanning electron microscopy (SEM) was performed. The jejunal samples were also used to determine *E. coli* (JEC) and total coliform counts (JCC). On d 4, 7, 11, and 14 of the trial, fecal samples of all pigs were also collected for *E. coli* (FEC) and total coliform count (FCC). The data were analyzed using the GLM (SAS), and means were compared by *t*-test ($P = 0.05$). Overall (d 7 and 14), the YCW-treated piglets differed ($P < 0.05$) from baseline piglet for VH, VW and CD. The CG had better results ($P < 0.05$) for VH, VW, CD and VSA at 7th d post-infection. However, at 14 d post-infection, YCW supplementation had improved ($P < 0.05$) VH, CD and VSA. Although there were no statistical differences ($P > 0.05$) between treatments for MT at d 14, it was numerically improved (+16.2µm) for piglets supplemented with YCW. For SEM, YCW group appeared to have less erosion in villi apices and better microvilli surface, when compared with CG at d 7 and 14. The JEC, JCC, FEC and FCC average of YCW group and CG showed a significant increase ($P < 0.05$) among the days post-infection, compared with the baseline values; however, the averages of YCW group were significantly lower ($P < 0.05$) than the CG. These results demonstrated that YCW supplementation at 2 kg/MT to weaned piglets decreased jejunal and fecal *E. coli* counts and improved intestinal integrity.

Key Words: *Saccharomyces cerevisiae*

M514 Effect of chronic heat stress on mRNA expression of heat shock protein 70, uncoupling protein 3, and cytochrome p450 in pigs.

Verónica Montesinos, Margarita Cota, Miguel Cervantes, Ernesto Avelar, Salvador Espinoza, and Adriana Morales*, *Instituto de Ciencias Agrícolas, Universidad Autónoma de Baja California, Mexicali, Baja California, México.*

Exposure of pigs to sudden increases in ambient temperature (AT), causing heat stress (HS) provokes cellular and molecular changes to cope with HS and maintain homeostasis. Abundance of mRNA coding for heat shock protein 70 kDa (HSP70) involved in the folding of proteins during heat stress, uncoupling protein 3 (UCP3) involved in heat generating in mitochondria, and cytochrome p450 (Cp450) involved in redox equilibrium, is affected in animals under acute HS. But it is not clear whether those alterations are maintained in pigs with chronic exposure to HS. An experiment was conducted with 18 pigs (30–35 kg BW) to analyze the effect of chronic HS on mRNA expression of HSP70, UCP3, and Cp450. There were 3 treatments: 1) pigs housed inside an AT controlled room (24 ± 2°C) and fed ad libitum (TNL), 2) as in 1 but feed restricted (TNR), 3) pigs housed under natural HS conditions (27.1 to 39.6°C, average 33.3°C). Feed intake in HS pigs was restricted to 95% of ad libitum intake, and that of TNR pigs was similar to HS pigs. Body temperature (BT) was recorded every 15 min with a device implanted under the skin of 4 pigs per treatment. At the end of the 21-d study, all pigs were killed and samples of liver, and longissimus (LM) and semitendinosus (SM) muscles were collected to analyze the mRNA expression of HSP70, UCP3 and Cp450. The BT of TNL, TNR, and HS pigs was 38.4, 37.7 and 39.0°C, respectively. It was higher in HS pigs compared with TNL and TNR ($P < 0.05$). Expression values ($\times 10^{-4}$) for HSP70 in TNL, TNR, and HS pigs were liver, 2.03, 4.08, 7.66; LM, 2.47, 5.2, 4.69; SM, 2.10, 2.31, 2.23, respectively; for UCP3 were LD, 4.58, 4.92, 3.57; SM, 3.46, 2.42, 6.04. Expression values ($\times 10^{-3}$) for Cp450 in liver were 3.59, 1.77, 1.68. Chronic HS did not affect the expression of HSP, UCP3 or Cp450 in pigs. Although BT of pigs exposed to chronic HS remains higher than in TN pigs, the lack of effect on gene expression may suggest that pigs became acclimated at or before 21 d of natural exposure to HS.

Key Words: pig, heat stress, gene expression

M515 Influence of CLA supplementation on body composition of finished pigs.

Kyle J. Stutts*, Ginger G. Vann, Mark J. Anderson, Jessica L. Leatherwood, Marcy M. Beverly, and Stanley F. Kelley, *Sam Houston State University, Huntsville, TX.*

Twenty-four pigs (Large White × Landrace; 128.2 to 134.1 kg) of similar breeding were utilized in a randomized complete block design to evaluate the effects of dietary supplementation of conjugated linoleic acid on body composition of mature, finished pigs. Pigs were blocked by BW and sex and were randomly assigned and evenly distributed between a treatment (n = 12; TRT) or control group (n = 12; CON) for an 84-d feeding trial. Diets were formulated to be isocaloric and isonitrogenous and consisted of a CON diet of a commercially available concentrate (Producers Cooperative, Bryan, TX) with an additional 2% of the total diet of soybean oil, or the TRT diet that consisted of the same pelleted concentrate with an additional 2% of the total diet of oil containing CLA. The CLA source (BASF Corp., Florham Park, NJ) being utilized contained 55% CLA (mixture of *cis*-9, *trans*-11; *trans*-10, *cis*-12; and *trans*-9, *trans*-11 isomers) yielding a CLA supplementation of 1.1% of the total diet. Oil was top-dressed and mixed into feed immediately before feeding. Pigs were fed at 12-h intervals at 3.5% BW per day in concentrate. Body weight was obtained every 7 d with the intake of concentrate adjusted accordingly. Fat thickness (cm) was measured at 14-d intervals via ultrasonography at the 10th and last ribs. Longissimus muscle area (LMA) was collected via ultrasonography at d 0 and 84. Data were analyzed using the mixed procedure of SAS. Overall effects were analyzed using repeated measures and data from individual days were analyzed using fat thickness from d 0 as a covariate. CLA supplementation had no effect on body composition. Overall, there was no difference between treatments in BW ($P = 0.98$), 10th rib fat thickness ($P = 0.07$), last rib fat thickness ($P = 0.17$), or LMA ($P = 0.96$). Additionally, there were no treatment × time interactions for the variables measured. These data indicate that CLA supplemented at 1.1% of the diet when mature pigs are fed at 3.5% BW has no effect on body composition or BW. Further studies are needed to fully elucidate dietary CLA supplementation to alter body composition when fed to mature pigs.

Key Words: CLA, swine, fat thickness

M516 Effect of acute water and feed deprivation at weaning and subsequent heat stress on serum stress markers and ileal mucosa gene expression in nursery pigs.

Nathan L. Horn*[1], Guy Miller[2], Frank Ruch[3], Carrie R. Little[3], Kolapo M. Ajuwon[1], and Olayiwola Adeola[1], [1]*Purdue University, West Lafayette, IN,* [2]*Biomatrix, Princeton, MN,* [3]*JBS United, Sheridan, IN.*

The current experiment was conducted to investigate the effect of a feed and water deprivation event at weaning and subsequent heat stress event on serum stress markers and expression of selected genes in the ileum. Mixed-sex pigs were allotted on the basis of IBW (6.97 kg ± 0.89) in a RCBD with treatments in a split-plot arrangement and consisting of the whole-plot factor of with or without a 24-h feed + water deprivation event at weaning (deprivation event) and the sub-plot factor of with or without a cyclic 3-d heat stress event starting 27 d post-weaning. On 1, 27, and 30 d post-weaning one pig from each pen was selected for blood and ileal mucosa collection to determine serum cortisol, corticotrophin releasing factor (CRF), and endotoxins; and mucosal gene expression measurement of tumor necrosis factor α (TNF-α), interleukin 6 (IL-6), interleukin 8 (IL-8), glucose transporter 2 (GLUT2), claudin 1 (CL-1), occludin (OC), and zonula occludens 2 (ZO-2) by RT PCR. There was an increase ($P < 0.05$) in serum CRF and endotoxins and a tendency for an increase ($P = 0.09$) in serum cortisol due to the deprivation event 1 d post-weaning. Furthermore, serum endotoxins and CRF tended to increase ($P < 0.10$) due to the deprivation event on 27 and 30 d post-weaning, respectively. Gene expression of GLUT 2 tended to decrease ($P = 0.07$), CL-1 tended to increase ($P = 0.10$), and OC decreased ($P = 0.05$) due to the deprivation event 1 d post-weaning. Expression of IL-8 and OC genes decreased ($P < 0.05$) due to the deprivation event 27 d post-weaning and OC and ZO-2 gene expression tended to decrease ($P = 0.07$) due to the heat stress event 30 d post-weaning. Results from the current experiment show that a post-weaning feed and water deprivation event impacts serum stress markers and mucosal gene expression throughout the nursery period and a subsequent heat stress event affects tight junction gene expression although an interaction of deprivation event by heat stress was not observed.

Key Words: feed and water deprivation, heat stress, nursery pig

M517 The growth of Tamworth × Berkshire pigs farrowed outdoors and reared in a hoop structure.

H.-S. Park[1], N. Whitley[2], and S.-H. Oh*[1], [1]*Department of Animal Sciences, North Carolina A&T State University, Greensboro, NC,* [2]*Cooperative Extension Program, North Carolina A&T State University, Greensboro, NC.*

The objective was to investigate the growth of Tamworth- or Berkshire-sired pigs from Berkshire sows at the North Carolina Agricultural and Technical State University Farm. The location features a humid subtropical climate with subtropical summer temperatures and mild winters and an average annual precipitation of approximately 110 cm. Forty-four purebred Berkshire females were used to produce crossbred and purebred Berkshire pigs. Females were given altrenogest (Matrix) for estrus synchronization for 14 consecutive days at 7 ml for gilts and 9 ml for sows. Thirty-three females were detected in heat and artificially inseminated, which resulted in 10 farrowed sows. Each sow farrowed in a 15-m^2 paddock in June 2014. Total number born were 67 in Tamworth × Berkshire (TB) and 51 in Berkshire × Berkshire (BB), respectively.

Number born alive were 53 in TB, and 35 in BB. Pigs were weaned at 4 weeks of age. Body weights from 43 weaned Tamworth × Berkshire (TB) crossbred pigs were recorded from 6 sows, and weights from 28 weaned Berkshire × Berkshire (BB) purebreds were recorded from 4 sows as a control group. Birth weights (BW) were recorded at 3 d of age, and then body weights were recorded every 4 weeks from their birthdate to 20 weeks of age; weaning weight (WW), 8 weeks of age (W8), 12 weeks of age (W12), 16 weeks of age (W16), and 20 weeks of age (W20). Data were analyzed with repeated measures ANOVA using SAS PROC GLM. Least squares means of weights in TB were 1.90 ± 0.06kg (BW), 8.11 ± 0.29kg (WW), 19.11 ± 0.58kg (W8), 34.80 ± 1.10kg (W12), 54.49 ± 1.51kg (W16), and 79.16 ± 1.96kg (W20), respectively. Least squares means of weights in BB were 1.80 ± 0.08kg (BW), 7.78 ± 0.36kg (WW), 16.99 ± 0.74kg (W8), 31.58 ± 1.39kg (W12), 52.04 ± 1.91kg (W16), and 79.78 ± 2.48kg (W20), respectively. Body weights were significantly greater for TB compared with BB only for W8 and W12 ($P < 0.05$). More research is needed regarding breed types used in alternative production systems.

Key Words: Tamworth, Berkshire, growth

M518 Effect of postcervical artificial insemination with semen supplemented with oxytocin in sows in warm weather. Juan M. Romo, Javier A. Romo, Ruben Barajas, Hector R. Guemez, and Juan M. Uriarte*, *Universidad Autónoma de Sinaloa, Culiacan, Sinaloa, Mexico.*

To determine the effect of applying semen doses spiked with oxytocin by post-cervical insemination, on the reproductive performance of sows serviced during the months of June to October (max. registered ambient temperature of 46°C and 28 min) in northwest Mexico, 223 multi parturient sows were inseminated. Sows were assigned randomly to be serviced twice with semen from same boar(s) in 1 of 2 treatments: (1) serviced with a reduced dosage equivalent to 1.5 × 10,000,000,000 viable spermatozoa cell diluted in 40 mL of semen dose (CONT, n = 111) and (2) similar to CONT plus addition of 4 IU oxytocin to semen at service time (OXY, n = 112). Sows were serviced from June to October, using an intrauterine semen delvery device. Total number born and total number born alive were counted at farrowing. Results were compared using X^2 analyses. Treatment had no effect on litter size with 11.0 vs. 10.8 ($P = 0.577$), or on number born alive with 9.8 vs. 9.6 for CONT and OXY, respectively. OXY enhances ($P = 0.03$) 9.6% the farrowing rate, with means values of 84.68 vs. 93.75 for CONT and OXY, respectively. These results sugest that the addition of oxytocin to semen at serviced time improves farrowing of multi parturient sows serviced during summer-autumn in northwest Mexico, without effects on other reproductive performance variables.

Key Words: sow, postcervical insemination

Animal Health: Reproductive health and acute immune responses

20 Efficacy of nonsteroidal antiinflammatory drugs for the treatment of acute puerperal metritis in dairy cows. Alina Pohl and Wolfgang Heuwieser*, *Clinic of Animal Reproduction, Freie Universität Berlin, Berlin, Germany.*

Acute puerperal metritis (APM) in dairy cows is often treated with antibiotics. An increasing antibiotic resistance is well documented and associated with decreasing clinical efficacy, animal welfare and economic consequences. Hence, there is a significant need to encourage prudent use of antibiotics and alternative therapies to antibiotics. The objective of this study was to compare the efficacies of ketoprofen and ceftiofur for the treatment of APM. Between June 2013 and February 2015, a total of 610 dairy cows from 6 farms in Germany were enrolled. Inclusion criteria was a rectal temperature (RT) ≥ 39.5°C and a reddish-brown fetid vaginal discharge within the first 10 DIM. Cows meeting the inclusion criteria were randomly allocated to treatment with ketoprofen (3 mg/kg of BW, n = 300) or treatment with ceftiofur (1 mg/kg of BW, n = 310), both on 3 consecutive days. Rectal temperature was recorded daily for a period of 7 d after enrollment. Cows that showed RT ≥39.5°C on d 4 to 7 after inclusion received an extended treatment with ceftiofur for 3 (ketoprofen group) or 2 (ceftiofur group) more days. Between 21 and 34 DIM, cows were examined with the Metricheck device and vaginal discharge was categorized on a 5-point scale according to the presence of pus. A total of 51 cows (34 from ketoprofen group, 17 from ceftiofur group) were excluded from analysis due to concurrent disease (n = 15), additional medication of APM (n = 11), and due to missing protocol compliance (n = 25). Cows of the ketoprofen group (54%) received an extended treatment more often than cows of the ceftiofur group (30%; $P < 0.01$). Occurrence of purulent vaginal discharge was similar for both treatment groups (ketoprofen: 57.8%, ceftiofur: 55.3%, $P = 0.62$). More than half of the cows initially treated with ketoprofen needed ceftiofur treatment. However, there is potential of reducing antibiotic use by utilizing ketoprofen for the treatment of APM as up 46% of cows treated with ketoprofen did not need extended treatment. Animal welfare and economic aspect need to be considered.

Key Words: acute metritis, treatment, antibiotic

21 Intrauterine cephapirin infusion is associated with better reproduction performance in cows with purulent vaginal discharge and cytological endometritis. José Denis-Robichaud*[1] and Jocelyn Dubuc[2], [1]*Department of Population Medicine, University of Guelph, Guelph, Ontario, Canada,* [2]*Faculté de M*édecine *V*étérinaire, Université de Montréal, Saint-Hyacinthe, Québec, Canada.

The objectives of this study were to quantify the effect of an intrauterine infusion of cephapirin on the reproductive performance at first service of postpartum dairy cows affected by purulent vaginal discharge (PVD) or cytological endometritis (ENDO) using different diagnostic strategies and to determine if the presence of prolonged anovulation would influence the magnitude of treatment benefit. A total of 2,259 Holstein cows in 28 herds were enrolled in a randomized clinical trial. At 35 (±7) DIM, cows were diagnosed for PVD (purulent vaginal discharge or worse using the metricheck device) and ENDO (≥6% polymorphonuclear cells using the cytobrush technique or at least small amounts of leukocytes using the leukocyte esterase colorimetric test). Regardless of reproductive tract disease status, cows were randomly assigned to receive an intrauterine cephapirin infusion or no treatment. Serum progesterone was measured at 35 and 49 (±7) DIM (14 d apart); cows were considered to have prolonged anovulation if progesterone was <1 ng/mL at both times. Statistical analyses were conducted using multivariable mixed logistic regression models adjusted for confounders and herd clustering effect. Intrauterine cephapirin treatment was associated with an increased first service pregnancy risk in cows diagnosed with PVD (no treatment: 15.4%; treatment: 31.4%; $P < 0.05$) and ENDO (cytobrush: no treatment: 16.2%, treatment: 24.4%, $P < 0.05$; leukocyte esterase: no treatment: 15.8%; treatment: 25.1%, $P < 0.05$), but not in cows unaffected by any form of reproductive tract disease (no treatment: 34.8%; treatment: 32.6%; $P = 0.5$). The effect of cephapirin treatment in anovular cows (no treatment: 21.0%; treatment: 26.4%; $P = 0.26$) was numerically lower than in cyclic cows (no treatment: 22.7%; treatment: 34.1%; $P < 0.05$). Overall, an intrauterine infusion of cephapirin improved first service pregnancy risk in cows with postpartum reproductive tract disease and this effect was influenced by postpartum anovulation status.

Key Words: dairy cows, endometritis, treatment

22 Potential role of lactic acid bacteria in the regulation of *Escherichia coli* infection and inflammation of the bovine endometrium. Sandra Genís*[1], Àlex Bach[1,2], Francesc Fàbregas[1], Marta Terré[1], and Anna Arís[1], [1]*Department of Ruminant Production, Institut de Recerca i Tecnologia Agroalimentàries (IRTA), Torre Marimon, Caldes de Montbui, Barcelona, Spain,* [2]*Institució Catalana de Recerca i Estudis Avançats (ICREA), Barcelona, Spain.*

About 40% of dairy cattle develop uterine disease at postpartum, causing infertility. Some studies indicate that uterine infection, predominantly by *Escherichia coli* in the first week postpartum, is associated with metritis. Metritis is an inflammation of the uterus in which the cow fails to completely clear bacterial contaminants and reducing postpartum inflammatory processes. The aim of this study was to evaluate the potential role of 4 lactic acid bacteria (LAB; *Lactobacillus rhamnosus*, *Pediococcus acidilactici*, *Lactobacillus reuteri*, and *Lactobacillus sakei*) in the modulation of *Escherichia coli* infection and its respective inflammation response by endometrial cells. Primary endometrial epithelial cells were isolated from a fresh endometrium of a healthy cow and cultured at 8×10^4 cells/well in 24-well plates to evaluate the effects of LAB at 3 different doses. Cell extracts were obtained with TriZol. Pro-inflammatory status was assessed by qPCR quantification of IL8, IL1β, TNFα, and IL6 gene expression. Internalization of *Escherichia coli* was determined by direct enumeration on MacConkey agar plates. Data were normalized and analyzed by an ANOVA. *Lactobacillus sakei* and *Lactobacillus reuteri* had a positive effect preventing *E. coli* infection (87% and 78% respectively, $P < 0.001$) but were associated with a dose-variable effect on tissular inflammation that could further exacerbate the pro-inflammatory status of the endometrium. *Pediococcus acidilactici* clearly decreased ($P < 0.001$) *E. coli* internalization up to an 83% reduction and slightly reduced the inflammation (up to 3.2-fold in IL1β expression, $P < 0.001$). However, the pro-inflammatory cytokines IL8 and IL1β decreased significantly ($P < 0.001$) up to 85.1 and 5.2 folds, respectively, in the presence of *L. rhamnosus*. In conclusion, these results demonstrate a clear beneficial effect of *P. acidilactici* and *L. rhamnosus* in the modulation of endometrial infection and inflammation in cattle.

Key Words: *Escherichia coli*, LAB bacteria, metritis

23 Uterine microbiota from calving until establishment of metritis in dairy cows.

Soo Jin Jeon*[2], Achilles Vieira-Neto[1], Mohanathas Gobikrushanth[2,6], Rodolfo Daetz[2], Rodolfo Mingoti[1], Ana Carolina Parize[2], Sabrina Freitas[2], Antonio Nelson da Costa[5], Rodrigo Bicalho[3], Svetlana Lima[3], Kwang C. Jeong[1,4], and Klibs N. Galvão[2], *[1]Department of Animal Sciences, University of Florida, Gainesville, FL, [2]Department of Large Animal Clinical Sciences, University of Florida, Gainesville, FL, [3]Department of Population Medicine and Diagnostic Sciences, Cornell University, Ithaca, NY, [4]Emerging Pathogens Institute, University of Florida, Gainesville, FL, [5]Departamento de Zootecnia, Universidade Federal do Ceará, Fortaleza, Ceara, Brazil, [6]Department of Agricultural, Food and Nutritional Science, University of Alberta, Alberta, Canada.*

Objective was to characterize the progression of uterine miocrobiota from calving until establishment of metritis. Uterine swabs were collected at 0 (20 min from calving), 2, 4, 6, and 8 d postpartum (DPP) from 92 cows. Twelve cows were diagnosed with metritis at 4, 6, or 8 DPP (6 ± 2 DPP), and 12 healthy cows were selected for comparison. Swabs (n = 72) collected at 0, 2, and 6 ± 2 DPP were used for metagenomic sequencing of 16S rRNA gene on the Illumina MiSeq platform. A heat map showed that uterine microbiota was established in cows shortly after calving. The microbiota changed rapidly from 0 to 6 ± 2 DPP by decreasing the abundance of Proteobacteria and increasing the abundance of Bacteroidetes and Fusobacteria. At 6 ± 2 DPP, abundance of Bacteroidetes was significantly higher in metritic cows than healthy cows ($P < 0.01$). Although most genera were shared, healthy and metritic cows could be discriminated based on relative abundance at 0, 2, and 6 ± 2 DPP using discriminant analysis ($P < 0.01$). Also, discriminant analysis showed that *Bacteroides, Filifactor, Porphyromonas, Fusobacterium,* and *Arcanobacterium/Trueperella* were important predictors of metritis. Furthermore, *Bacteroides* and *Fusobacterium* were significantly correlated with uterine discharge score ($r_s = 0.51$ and $r_s = 0.49$, respectively; $P = 0.02$). Likewise, at species level, *Bacteroides heparinolyticus* and *Fusobacterium necrophorum* were the main bacteria for the development of metritis because they were both prevalent (16.8% and 20.2% in metritic cows; 7.0% and 15.8% in healthy cows) and correlated with uterine discharge score ($r_s = 0.42$ and $r_s = 0.42$, respectively; $P \leq 0.05$). In addition, there was a second (*Fusobacterium gonidiaformans, Helcoccocus ovis,* and *Filifactor villosus*) and third (*Bacteroides pyogenes, Porphyromonas levii* and others) line of bacteria that acted synergistically with the main bacteria causing metritis.

Key Words: dairy cow, metritis, 16S metagenomics

25 Association among health and fertility and survival of high-producing dairy cows in three geographic regions of Chile.

Pablo Pinedo*[1,2], Pedro Melendez[3], Sushil Paudyal[4], Felipe Arias[5], Ricardo Krauss[5], Hernando Lopez[6], Alejandro Luco[5], and Cristian Vegara[5,6], *[1]Texas A&M AgriLife Research, Amarillo, TX, [2]Department of Veterinary Pathobiology, College of Veterinary Medicine & Biomedical Sciences, Texas A&M University System, College Station, TX, [3]Department of Veterinary Medicine and Surgery, College of Veterinary Medicine, University of Missouri-Columbia, Columbia, MO, [4]West Texas A&M University, Canyon, TX, [5]ABS Chile Ltda., Santiago, Chile, [6]ABS Global Inc., DeForest, WI.*

The objective was to analyze the association between disease occurrence during early lactation and reproductive performance and survival of dairy cows in high-producing herds, under different management practices in 3 geographic regions of Chile. Data included 30,157 lactation records of cows calving between January, 2013 and June 2014, maintained under different production systems: Dry lot (DL; n = 3,881 cows in 6 herds); freestall (FS; n = 21,421 cows in 13 herds); grazing (G; n = 1,211 cows in 3 herds); and freestall/grazing (FG; n = 4,244 cows in 5 herds). Cows were also classified according to geographic location: central area (C, n = 6,375 cows); south-central area (SC, n = 17,073 cows); and south area (S, n = 7,309 cows). Logistic regression and ANOVA were used for the analyses (PROC GLIMMIX and PROC GLM, SAS), considering cow as the experimental unit. Covariables offered to the models included lactation number, cow, and herd milk yield. Average milk yield (305 ME) per cow was 11,793, 12,632, and 6,876 kg for C, CS, and S regions, respectively and 10,603, 12,270, 6,899, and 9,261 kg for DL, FS, G, and FG systems. The odds (95% CI) of pregnancy at 150 DIM (P150) and the odds of survival until 150 DIM (S150) for cows that had at least 1 disease event within 50 DIM were 0.82 (0.77–0.88) times the odds of pregnancy and 0.21 (0.17–0.26) times the odds of survival for healthy cows. The odds (95% CI) of P150 for cows under grazing systems were 1.48 (1.24–1.77), 1.07 (0.9–1.28), and 1.29 (1.09–1.52) times the odds of P150 for cows under DL, FG, and F systems, respectively. The odds (95% CI) of S150 for cows under grazing were 5.15 (3.0–8.8), 3.18 (1.88–5.40), and 2.0 (1.19–3.33) times the odds of S150 for cows under DL, FG, and F systems. The odds (95% CI) of P150 and S150 for cows located in the S area were 1.03 (0.95–1.11), and 1.11 (1.03–1.19) times the odds of P150 for cows in C, and SC areas and 1.42 (1.23–1.66), and 1.37 (1.20–1.60) times the odds of S150 for cows in C, and SC areas. Data suggested that cow's health status, geographic location, and production system had a significant association with reproductive performance and survival in this population of Chilean high-producing cows.

Key Words: dairy, health, fertility

26 Bovine viral diarrhea diagnostic testing results in the Intermountain West—Comparison between test methods, age, sex and beef versus dairy breeds.

David J. Wilson*, Thomas J. Baldwin, E. Jane Kelly, Arnaud VanWettere, and Gordon Hullinger, *Utah State University, Logan, UT.*

Bovine viral diarrhea (BVD) is an important cause of respiratory, gastrointestinal, and reproductive disease in cattle. The objectives were to calculate prevalence of BVD ("detected" test results) among all bovine samples tested for BVD at the Utah Veterinary Diagnostic Laboratory from 2009 to 2013, and to compare results by sex, age, dairy vs. beef breeds (if provided) of the cattle, and BVD test methods. For necropsied animals, most were tested by Ag capture ELISA, but fetuses were usually tested by PCR. Cattle were mainly from Utah, but also from surrounding states in the Intermountain West of the United States. This was not a planned experiment, but Chi-squared was used to test for significant differences in BVD prevalence between age, sex, breed and test methods. BVD was detected in 105/8,975 samples (1.2%), including 22/180 necropsies (12.2%). Test methods and results are given in Table 1. There were no significant differences in BVD detection by age or sex. Dairy breeds ($P = 0.07$), all necropsied animals, and those tested with PCR were significantly more likely to test as "detected" with BVD. The overall prevalence of >1% and the 8% prevalence in aborted fetuses demonstrates that despite the low reported prevalence of persistently infected cattle, BVD remains an important bovine disease.

Table 1 (Abstr. 26). Results by BVD test method, by age, sex, or breed, and by dairy versus beef breeds

Item	Tested, no.	BVD detected, no. (%)
BVD test method		
Ag Capture ELISA	7,692	79 (1.0)
Serum ELISA	1,195	19 (1.6)
PCR	88	7 (8.0)*
Necropsy (all methods)[1]	180	22 (12.2)*
Age, sex or breed		
Male	215	5 (2.3)[2]
Female	382	9 (2.4)[2]
Fetus	36	3 (8.3)[2,3]
Calf	579	29 (5.0)[2,4]
Immature	183	4 (2.2)[2,5]
Adult	75	4 (5.3)[2,6]
Dairy[7]	754	25 (3.3)†
Beef[8]	1,600	26 (1.6)†

[1] Subset of above 3 categories.
[2] NSD among sex, age, or by test method within sex, age or breed.
[3] All 3 by PCR at necropsy.
[4] Twenty-seven by Ag Capture ELISA, including 16 of 114 necropsies (14.0%).
[5] Three by serum ELISA, 1 by Ag Capture ELISA, of 6 necropsies (16.7%).
[6] Two by serum ELISA, 2 by Ag Capture ELISA, of 24 necropsies (8.3%).
[7] 95.0% Holsteins, 3.8% Jerseys.
[8] 60.0% Angus, 22.8% "Beef."
*Higher prevalence of "BVD detected" results, $P < 0.0001$.
†$P = 0.07$.

27 Preweaning plane of nutrition and *Mannheimia haemolytica* dose influence inflammatory responses to a combined bovine herpesvirus-1 and *Mannheimia haemolytica* challenge in postweaned Holstein calves.

K. P. Sharon*[1,2], Y. L. Liang[1], N. C. Burdick Sanchez[2], J. A. Carroll[2], P. R. Broadway[2], and M. A. Ballou[1], [1]*Department of Animal and Food Sciences, Texas Tech University, Lubbock, TX,* [2]*USDA-ARS, Livestock Issues Research Unit, Lubbock, TX.*

To determine whether previous plane of milk replacer nutrition (PON) and *M. haemolytica* (MH) dose influences inflammatory responses to a combined viral-bacterial respiratory challenge, Holstein calves (1d of age; n = 30) were assigned to treatments in a 2 × 3 factorial with preweaned PON and dose of MH as main effects (n = 5/treatment). Calves were fed either a low (LPN; n = 15) or a high PON (HPN; n = 15) from birth through weaning. Calves fed the LPN were fed 445 g DM/d of milk replacer until weaning, and HPN calves were fed 830g DM/d of milk replacer from 1 to 10d and 1080g from 11d until weaning. Calf starter and water were offered ad libitum. Calves were step-down weaned beginning at 54d and moved into an enclosed barn at 70d. Indwelling rectal temperature (RT) devices and jugular catheters were inserted at 80d. Calves were challenged with 1.5×10^8 PFU/mL/nostril of bovine herpesvirus-1 (BHV-1) at 81d and with 10^6, 10^7, or 10^8 cfu of MH at 84d. Blood samples were collected at varying intervals respective to BHV-1 and MH challenges. There was a PON × MH interaction ($P < 0.01$) on RT, where calves receiving 10^8 MH had the greatest increase among HPN calves, but the least among LPN calves. Haptoglobin (Hp) concentrations were greater ($P = 0.04$) in LPN vs HPN calves after BHV-1 challenge. There was a time x MH interaction ($P < 0.01$) for Hp concentrations after the MH challenge, where calves receiving 10^7 MH had the greatest Hp concentrations at 24 h, and calves receiving 10^8 MH the greatest at 144h. During the BHV-1 challenge, neutrophil concentrations (PMN) and change in total leukocytes were greater ($P < 0.01$) among LPN vs HPN calves. After the MH challenge PMN were greatest ($P \leq 0.05$) in calves receiving 10^8 MH at 5 and 24h. During the MH challenge calves receiving 10^8 MH had the greatest ($P < 0.05$) IL-6 and TNFα concentrations. These data demonstrate that LPN calves responded more severely to a combined viral-bacterial respiratory challenge and greater doses of MH increase the acute inflammatory response and prolong inflammation.

Key Words: health, nutrition, respiratory

28 Plasma leptin concentrations are increased during a vaccine-induced acute-phase response in beef cattle.

Rodrigo Marques*[1], Reinaldo Cooke[1], Murilo Rodrigues[1], Bruno Cappellozza[1], Sergio Arispe[2], and David Bohnert[1], [1]*EOARC, Oregon State University, Burns, OR,* [2]*Malheur County Extension, Oregon State University, Ontario, OR.*

The objective of this experiment was to evaluate if a vaccine-induced acute-phase reaction also results in increased plasma leptin concentration, which would explain a potential DMI decrease in vaccinated beef cattle. Eighteen yearling Angus × Hereford heifers were ranked by BW and allocated to 2 groups, which were randomly assigned to a crossover design containing 2 periods of 7 d and the following treatments on d 0 of each period: (1) vaccination against *Mannheimia haemolytica*, bovine rhinotracheitis virus, and bovine viral diarrhea Types 1 and 2 viruses (VAC; BoviShield One Shot; Zoetis, Florham Park, NJ), or (2) saline-injected control (CON). Heifers were maintained in individual pens, offered grass hay for ad libitum consumption, in addition to 3.5 kg/d (DM basis) of a corn-based supplement. During Period 1, hay and concentrate intake were evaluated daily. During Period 2, blood samples were collected before (- 2 and 0 h) and at 2, 4, 6, 8, 12, 16, 24, 36,48, 60, 72, 96, 120, 144, and 168 h after treatment administration. All samples were analyzed for plasma haptoglobin concentration. Samples collected from 0 to 48 h were also analyzed for plasma cortisol, insulin and leptin concentrations. Plasma variables were analyzed using the mean result from samples collected at −2 and 0 h as covariate. Treatment × day interactions were detected ($P < 0.01$) for hay and total DMI, given that these parameters were reduced ($P \leq 0.05$) in VAC compared with CON on d 0 and 1. Treatment × hour interactions were detected ($P \leq 0.02$) for all plasma variables. Plasma cortisol concentrations were greater ($P \leq 0.05$) in VAC compared with CON from 2 to 16 h. Plasma insulin concentrations were greater ($P \leq 0.05$) in VAC compared with CON from 4 and 16 h. Plasma leptin concentrations were greater ($P \leq 0.03$) in VAC compared with CON from 6 to 16 h. Plasma haptoglobin concentrations were greater ($P \leq 0.02$) in VAC compared with CON from at 16 to 120 h. In conclusion, plasma leptin concentration was increased during a vaccine-induced acute-phase reaction, which may explain the decrease in DMI observed herein in vaccinated cattle.

Key Words: cattle, acute-phase reaction, leptin

29 Effect of an early-life LPS challenge on a subsequent LPS challenge in Holstein bull calves.

Aimee L. Benjamin*[1], Filiz T. Korkmaz[1], Theodore Elsasser[2], and David E. Kerr[1], [1]*University of Vermont, Burlington, VT,* [2]*USDA-ARS, Beltsville, MD.*

The variable innate immune response between animals can be due to a variety of causes. Infections during the neonatal period could affect an animal's innate response phenotype. Ten Holstein calves were used to investigate the sustained effects of neonatal LPS exposure on the innate immune system. At 8d of age, 5 calves received an IV infusion of LPS (0.5 μg/kg), while the remaining 5 received saline. A subsequent dose of

LPS (0.25 µg/kg) was given to all 10 calves at 30 d of age to determine if there was any lasting effects from the first LPS challenge. Skin biopsies were collected from all calves at 22 d of age to isolate dermal fibroblasts for a cell model to explore genetic and/or epigenetic changes that may have resulted from the early life LPS treatment. Two hours after the first challenge, LPS-treated calves had greater ($P < 0.05$) plasma IL-6 (14.4 ± 2.8 vs. 0.6 ± 0.3 ng/mL) and TNF-α (3.2 ± 1.0 vs. 0.2 ± 0.1 ng/mL) compared to calves that had received saline, respectively. Response curves of these plasma cytokines from measurements at 0, 1, 2, 3, 5, and 7 h following the second LPS challenge were similar ($P > 0.05$) between groups. Rectal temperatures were not significantly different between the treatment groups in either challenge. Dermal fibroblasts isolated from LPS- or saline-treated calves produced similar ($P > 0.05$) levels of IL-6 (318.4 ± 96.8 vs. 359.3 ± 54.6 pg/mL) and IL-8 (183.6 ± 33.8 vs. 157.1 ± 11.7 pg/mL), respectively, in response to a 24h LPS challenge (500 ng/mL). Although the fibroblasts produced much greater levels of IL-6 (5178.6 ± 637.9 vs. 5353.4 ± 853.1 pg/mL) and IL-8 (1554.2 ± 96.8 vs. 1596.9 ± 93.4 pg/mL), respectively, in response to a 24h challenge with IL-1b (10 ng/mL), there was no early-life treatment effect. There was substantial inter-animal variation in clinical symptoms following the LPS challenges, but the early-life exposure to LPS at 8d of age did not clearly influence the response to a subsequent LPS challenge in 30-d-old calves, or affect the ability of fibroblasts to respond in vitro to LPS or IL-1b. More work is needed to determine how early-life exposure to infection may influence an animal's innate immune response.

Key Words: neonatal, variation

30 ACTH-test reactivity affect disposition for storage of fat depots in dairy cows during the transition period. Lena Ruda[1], Claudia Raschka[1], Lea Fieguth[1], Asako Kinoshita[1], Anja Schacht[1], Marion Piechotta[1], Korinna Huber[2], Akos Kenez[2], Ulrich Meyer[3], Sven Dänicke[3], and Juergen Rehage*[1], *[1]Clinic for Cattle, University of Veterinary Medicine Hannover, Hannover, Germany, [2]Department of Physiology, University of Veterinary Medicine Hannover, Hannover, Germany, [3]Institute of Animal Nutrition, Friedrich-Loeffler-Institute, Braunschweig, Germany.*

It is generally recommended to adjust feeding requirements to avoid overconditioning of dairy cows at calving because high body condition is a major risk factor for ketosis in early lactation. However, beside feeding and environmental factors individual disposition for high body condition appears to have also a genetic and epigenetic background. The individual reactivity of the hypothalamic-pituitary-adrenal axis (HPA-axis) and the release of cortisol as tested in the ACTH-test varies considerably between cows. Thus, the aim of the study was to test the relationship between HPA-axis reactivity and body condition in dairy cows during the transition period. In 22 pluriparous German HF dairy cows, kept in freestalls with cubicles and fed a TMR based on grass and corn silage and concentrate, an ACTH challenge was performed on d 100 postpartum (pp). Before and after injection of ACTH (80µg) cortisol concentrations were measured in blood samples taken in short-term intervals from indwelling jugular vein catheters from which baseline and peak concentrations and AUC were assessed. Results were used in a regression analysis (SAS statistical package) and correlated with sonographically estimated subcutaneous fat mass (SC fat) assessed at d –42 before parturition, and at d 1, d 21, d 100 pp. Cows were also classified according the AUC cortisol results into high (HR; n = 7), intermediate (IR; n = 8), and low (LR; n = 7) responder and fat mass was tested for differences by ANOVA. Significant linear negative correlations were found between AUC and peak cortisol concentrations from ACTH challenge and SC fat at d –42, d 1, d 21 and d 100. In HR compared with LR cows in average SC fat was significantly less at d –42, d 1, d 21 and d 100 and gain before and loss of SC fat after parturition was lower. Cows with high reactivity of the HPA-axis are leaner during the whole transition period, gain less before and lose less SC fat after parturition. Dynamics in body condition appears to be closely correlated with HPA axis reactivity during the transition period in dairy cows. This work was funded by the German Research Foundation.

Key Words: ACTH-test, BCS, dairy cows

31 Use of an ex vivo/in vitro laminitis model to elucidate the role of endotoxins during equine and bovine laminitis. Nicole Reisinger*[1], Simone Schaumberger[2], and Gerd Schatzmayr[1], *[1]Biomin Research Center, Tulln, Austria, [2]Biomin Holding GmbH, Herzogenburg, Austria.*

Laminitis is one of the most common causes for lameness in horses and ruminants. The pathology of laminitis is still not fully understood. As it is a multifactorial disease, several substances and toxins such as endotoxins are discussed as possible trigger factors. The aim of our study was to test the influence of endotoxins on the lamellar integrity of hoof explants. Furthermore, the potential difference of effects of endotoxins on the lamellar integrity of hooves from horses and ruminants was investigated. Explants from hooves (n = 3) and claws (n = 3) were cultivated at 37°C and 5% CO2 with D-MEM as culture medium. Lipopolysaccharides (LPS) of *Escherichia coli* O55:B5 were added to the equine [0, 2.5, 10, 100 µg/mL] and bovine [0, 1, 10, 100 µg/mL] explants for 24 h. After incubation, explants were tested for their integrity by measuring the force [Newton], which is needed to separate the explants (= separation force). Therefore, the explants were connected to a force transducer with clamps. Viability of explants was tested with the water-soluble tetrazolium (WST-1) assay. There was no effect on separation force when equine explants were incubated with 2.5 µg/mL LPS. Separation force of equine explants incubated with 10 and 100 µg/mL LPS was significantly decreased ($P < 0.005$) by 45% and 49%, respectively, compared with control explants. Similar to equine explants, there was no effect on separation force when bovine explants were incubated with 1 µg/mL LPS. Separation force of bovine explants incubated with 10 and 100 µg/mL LPS was significantly decreased ($P < 0.005$) compared with control explants. A reduction by 50% and 65% for LPS was observed, respectively. All explants were viable after 24 h incubation. In our study a concentration dependent reduction of separation force of explants incubated with LPS was observed. Similar effects of LPS were observed in explants from both species. Although laminitis has never been induced by endotoxins alone in animal experiments, our data suggest that endotoxins might play an important role during the onset of laminitis. The presented model could be used to test other potential trigger factors of laminitis and the interaction between these factors.

Key Words: laminitis, endotoxins, in vitro

Bioethics Symposium: Effects of science, government, and the public in directing the future of animal agriculture

32 Role of science in the future of animal agriculture. Paul H. Hemsworth*, *University of Melbourne, Parkville, Victoria, Australia.*

Animal welfare is a state within the animal. Scientists use 2 main conceptual frameworks for understanding animal welfare: biological functioning and affective state. These 2 frameworks were initially seen as competing, but more recently biological functioning is recognized to include affective experiences and affective experiences are recognized as products of biological functioning. While science provides us with the ability to understand how the body responds to physical challenges and affective states, our ability to monitor some affective states is under-developed. Thus most studies have used the biological functioning framework to infer compromised animal welfare, on the basis that suboptimal biological functioning accompanies negative affective states. There is increasing societal interest in providing domesticated animals with the opportunity for positive affective experiences and this will also be a major focus for animal welfare science in the early 21st century. Furthermore, animal welfare science will continue to identify conditions and strategies to prevent and ameliorate negative states in farm animals, and extend the range of animal welfare indicators for use on-farm in risk assessment and management, welfare benchmarking and welfare auditing. Science thus should provide the facts, but what society, groups or individuals do with these facts is a philosophical decision. Exclusion of science can result in emotive or self-interested arguments from sectional groups dominating community debate. This is not to say that such arguments should be ruled out; quite the reverse, as they reflect, in part, current community values. However, they should contribute to, not pre-empt, the debate. Furthermore, these ethical questions should include other considerations, such as our duties toward animals and human health, economic, social and environmental consequences. Thus, in resolving the question of whether or not a particular animal use is acceptable, science provides the means to understand the impact of each animal use on the animal and has a prominent role in underpinning decisions on animal use and the attendant conditions and compromises.

Key Words: animal welfare, science, role

33 Update on the US Technical Advisory Group to the International Organization for Standardization (ISO) Working Group 16—Welfare of Food-Producing Animals. Craig A. Morris*, *United States Department of Agriculture, Agricultural Marketing Service, Washington, DC.*

World Organization for Animal Health (OIE) Member Countries mandated the organization to take the lead internationally on animal welfare and, as the international reference organization for animal health, to elaborate recommendations and guidelines covering animal welfare practices, reaffirming that animal health is a key component of animal welfare. However, there can be impediments to the ability of the OIE to assure worldwide adherence the codes they develop; especially in the developing world. In 2011 to respond to this issue, the International Organization for Standardization (ISO) and the OIE established a Memorandum of Understanding to strengthen cooperation in all fields of mutual interest, including animal welfare. The ISO is a worldwide federation of national standards bodies and the work of preparing ISO standards is usually carried out through ISO Technical Committees. The ISO took on this work to help facilitate the international adoption of OIE codes, such as those dealing with animal welfare, through the private sector implementing seller or buyer requirements. The ISO committee structure is broken down into Technical Committees (TCs) and the ISO assigned this work on animal welfare to TC34 (Food Products) with the creation of a Working Group (WG) 16. To participate in WG16, experts from the United States formed a Technical Advisory Group that is chaired by Dr. Morris of the United States Department of Agriculture. WG16 is currently working toward the development of the ISO's first Technical Specification (TS) in this area of animal welfare and plans for it to be complete by the end of 2015. The objective of this work is to have the private sector use this TS to not only further the international adoption of the OIE codes, but serve to better the living conditions of animals raised for food around the world while not impeding the international trade of animal products. This presentation will update attendees on the progress being made by the ISO in this important area.

Key Words: bioethics, animal welfare, ISO

34 Effect of consumer choices on food animal production practices in the future. Charlie Arnot and J. J. Jones*, *Center for Food Integrity, Gladstone, MO.*

The application of technology in food and agriculture has provided countless benefits to society. Innovation and technology help us meet one of humanity's most basic needs—the need to provide safe, nutritious food for our children and our children's children. Today, our challenge is not just better technology, but finding better ways to support the informed public evaluation of those technologies and our food production system. Consumer choice is playing an increasing role in the food system. No matter what science says, many issues remain contentious because the social decision-making process is complex. The ability to break down the communication barriers is critical to fostering informed decision making that encourages technology and innovation in society's best interest. The Center for Food Integrity's 2014 research, combined with previous research provides great insight into how consumer choice— consumer decision-making—will have many effects on animal agriculture.

Key Words: consumers, choice, food

35 US consumer perceptions of animal use for food, recreation, and more: Are feelings about Bambi the deer, Bessie the cow, and Buster the dog more related than we thought? Elizabeth Byrd* and Nicole Widmar, *Purdue University, W. Lafayette, IN.*

This research seeks to link sentiments about various animal uses, such as pets, circus animal, and racing dogs, to sentiments and perceptions of livestock animal welfare. A national-scale survey was used to explore linkages between animal uses and species. Researchers, marketers and livestock industries alike have also sought to uncover relationships between observable demographics (sex, age, education, pet ownership) and views of livestock practices. If owning a pet and/or interacting with animals in general is related to increased concern for livestock welfare, what else may be affecting consumers' perceptions of livestock rearing? Is the approval of using animals for working dogs, such as service/therapy or police/military, related to sentiments toward farm animals? When asked, 92% of US consumers agree it is acceptable to have animals as pets or for service/therapy animals. A total of 93% of US consumers agree with using animals to produce eggs, but only 67% agree with keeping zoo animals. Is the approval of hunting and various hunting practices related to concern for food/farm animal welfare? More broadly, are sentiments toward animal species related and does it depend whether or not they are produced and consumed for food or even the perceived average age of those animals? Do those respondents who believe dairy cows have a long life expectancy on a farm also report increased concern for their welfare? Respondents reported the average life expectancy of a dairy cow on a dairy farm to be 9.71 years and the average life expectancy of an egg laying hen to be 5.29 years. Understanding how consumers' sentiments toward animal uses are related to each other and to key socio-demographic factors will provide valuable insight into the minds of consumers and provide guidance for the agricultural industry in understanding, communicating with, and meeting the demands of consumers.

Key Words: animal use, consumer demand, preferences

36 Willingness to pay for pork chops and chicken breasts: Are hunters (and those who approve of hunting) different (from the average US consumer)?

Elizabeth Byrd*, Nicole Widmar, and John Lee, *Purdue University, W. Lafayette, IN.*

Consumers, in general, are concerned about how their food, especially meat, is raised. This concern extends to animal welfare practices and the social and environmental impacts of production. Recently, studies have focused on consumer willingness to pay (WTP) for various production process attributes, such as gestation crate-free hog production, cage-free egg production, and rBST-free milk production. However, most studies have been limited to general samples of US residents or consumers. Other research has linked demographics, including pet ownership, to increased concern for pig welfare (McKendree, Croney, and Widmar, 2014). Relationships with animals, even those that are not consumed for food, are related to consumers' level of concern for farm animal welfare. Studies have explored the public's acceptance of lethal management of wildlife and feral animals. We seek to determine how views of wild animals, both consumptive and non-consumptive, may affect the level of concern for livestock animal welfare. Concern for animal welfare can extend to include WTP for attributes of the production process that affect animal welfare. The next step is to determine how interactions with wild animals, in terms of hunting (or approval of hunting), are related to concern for farm animal welfare. Preliminary results indicate those who regularly hunt are willing to pay less for animal welfare attributes such as cage or crate free production and antibiotic free production. For example, non-hunters have a mean WTP of $3.13/lb for USDA-verified crate-free pork chops, but those who regularly hunt are not WTP anything. Likewise, non-hunters are willing to pay more than twice what hunters are willing to pay for USDA-verified antibiotic-free production. The goal of this analysis is to determine how consumers' outdoor activities and key demographic factors (sex, pet ownership, and opinions on hunting) are related to the relative importance of food values for meat purchases and WTP for animal welfare production process attributes.

Key Words: animal welfare, consumer demand, preferences

37 Willingness to pay for pork chops and bacon: Effects of perceived farm sizes and information shocks.

Ann Cummins*, Nicole Widmar, Joan Fulton, and Candace Croney, *Purdue University.*

This research utilizes a willingness to pay (WTP) model for a variety of pork, specifically pork chop and bacon, attributes. There has been an identified gap between consumer's perceptions and the reality of even something as simple as the size of pig farm which pork originated from. This presentation explores the effect of the perceived size of pig farm on consumers' WTP for verified pork attributes. The data for this analysis is from a nationally representative survey (in terms of age, sex, income, and region of residency). A total of 1,004 respondents and 10,040 choice situations were obtained. Along with a collection of demographic, educational, perceptions about farming, and other information is used as part of the analysis, participants experienced a simulated shopping experience (designed choice experiment) where they made purchasing decisions about certified pork products with different attributes. The attributes included price per pound, permitted use of individual crates or stalls, farm size, antibiotic use, and certification entity. The choice experiment methodology is used for this analysis and the random parameter logit model is used to estimate the consumers' WTP for the different pork product attributes. The first set of analyses look at the average WTP for these two pork products in relation to individual consumer's self-reported perception of the farm size on which they believe most pigs raised for pork are raised (which they provided before entering the simulated shopping experience). The second set of analyses uses the choice experiment data, but in addition uses an information shock, in which a subset of approximately half of the respondents were randomly selected and given an information shock with included NASS statistics on the true pig farm size in the U.S. These responses are then compared between perceived size of pig farms in the US, the information shock, and consumers' WTP for pork verified attributes including farm size. We find that certain consumer segments are willing to pay statistically significant and positive amounts for the verified attributes studied. Further, there are differences in those WTP values amongst pork products, verifying parties, and the specific attributes in question.

Key Words: bacon, pork chops, willingness to pay

Breeding and Genetics Symposium: Relevance of modeling in the genomics era

38 Is complex modeling important in the age of genomic selection? Guilherme J. M. Rosa*, *University of Wisconsin, Madison, WI.*

Statistical methodology has always played a fundamental role in modern animal breeding and genetics. For example, regression and ANOVA techniques have been developed and applied extensively in the context of estimation of genetic parameters and prediction of genetic merit for complex traits. Later, linear mixed model approaches such as best linear unbiased prediction (BLUP) and residual maximum likelihood (REML) estimation of (co-)variance components became prevailing in the analysis of pedigreed data, given their flexibility to accommodate unbalanced data, complex genetic relationships and overlapping generations. Several extensions of mixed models techniques have also been applied in animal breeding, such as the analysis of binary and count data, growth curves, survival models, and gene mapping in outbred populations. These complex models have been frequently implemented using Bayesian and MCMC techniques, facilitated by recent advances in computing technology. More recently, accessibility to genomic technologies has allowed fine mapping of causative loci, high throughput functional genomics studies, and whole-genome prediction of complex traits in livestock species. However, advancements in genomic technologies have also brought several new challenges from data-storage and data-mining standpoints, given the dimensionality of current data sets. Nowadays, not only efficient computer algorithms are required for data storage and data management, but also carefully tailored data mining tools are essential to deal with issues of multiple testing, potential of over fitting, spurious associations, and nonlinearities and complex interactions inherent to genomic data. In this presentation I will review some of the contemporary statistical and data mining methods currently used in animal breeding and genetics, for both prediction and causal inference, with especial emphasis on mixture regression models and graphical models, and the incorporation of biological knowledge into the analyses. Through some examples, I will illustrate the importance of complex modeling in the age of genomic selection.

Key Words: statistical models, genomic data, animal breeding

39 BLUP, REML, and other tools in the age of genomic selection. Esa A. Mäntysaari* and Martin Lidauer, *Natural Resouces Institute Finland, Green Technology, Jokioinen, Finland.*

Onset of genomic selection changed the focus of animal evaluation experts into estimation of genomic breeding values (GEBV). This was because of enormous potential of genomic information, but also because of similar intellectual challenges in methodologies. Still, also GEBV rely on phenotypes as a source of information. The GEBVs and the ordinary estimated breeding values (EBV) have the same need of well-defined models to attain accurate and unbiased results. Milk and component yield EBVs can illustrate the value of accuracy. Although $\mathrm{EBV}_{\mathrm{protein}}$ or $\mathrm{EBV}_{\mathrm{fat}}$ can be used as a indirect estimates of $\mathrm{EBV}_{\mathrm{milk}}$ (correlations to milk EBV 0.91 and 0.79), the $\mathrm{GEBV}_{\mathrm{milk}}$ trained on protein (fat) gave validation reliability of 0.27 (0.10), while the training on milk gave $R^2 = 0.45$. In this presentation we discuss particulars of breeding value estimation models and approaches for estimation of variance components (VC). The examples used are the joint Nordic test day model and the multiple trait-across country (MACE) model. The Nordic test day model is used to evaluate bulls and cows in Finland, Sweden and Denmark for 4 breeds: Holstein, Red Dairy Cattle, Jersey and FinnCattle. The challenges are the varying production conditions and admixed populations. The model is a multilactation, multitrait (milk, protein, fat) random regression. In every evaluation run the heterogeneity of variance is estimated for each trait and herd-year. During the implementation, VC for 1,827 parameters were estimated for each country and breed combination. Estimation was done using Monte Carlo REML and EM-algorithm. Most genomic evaluations rely on genotype exchange and MACE results for training. Accuracy of MACE depends on the assumed correlations across countries. Currently Interbull estimates correlations among breeding values of bulls from 31 countries, 6 breeds and 40 traits. The largest single VC estimation is for the Holstein production traits involving all countries. The challenges are computing, and the lack of genetic ties among smaller countries. Current estimation is by subsets of countries, but another alternative is to use MC REML and all countries simultaneously.

Key Words: breeding value estimation, variance components

40 Practical implications for genetic modeling in the genomics era for the dairy industry. Paul M. VanRaden*, *Animal Genomics and Improvement Lab, Agriculture Research Service, USDA, Beltsville, MD.*

Genetic models convert data into estimated breeding values and other information useful to breeders. The goal is to provide accurate and timely predictions of the future performance for each animal (or embryo). Modeling involves defining traits, editing raw data, removing environmental effects, including genetic-by-environmental interactions and correlations among traits, and accounting for nonadditive inheritance or nonnormal distributions. Data included phenotypes and pedigrees during the last century and genotypes within the last decade. Genomic data can include markers, haplotypes, and causative effects such as insertions, deletions, or point mutations; most models also include polygenic effects because the markers do not track causative variants perfectly. Total numbers of known variants have increased rapidly from thousands to hundreds of thousands to millions. Nonlinear models add precision for traits influenced by major genes, but linear models work well for traits with more normally distributed genomic effects. Numbers of genotyped animals in US dairy evaluations increased rapidly from a few thousand in 2009 to about 1 million in 2015. Most are young females that will contribute to estimating allele effects in the future, but only about 100,000 have phenotypes so far. Traditional animal models may become biased by genomic preselection because Mendelian sampling of phenotyped progeny and mates is no longer expected to average 0. Single-step models that combine pedigree and genomic relationships can account for such selection, but approximations and new algorithms are needed to avoid excessive computation. Traditional animal models may include all breeds and crossbreds, but most genomic evaluations are still computed within breed. Inclusion of inbreeding, heterosis, dominance, and interactions can improve precision. Multitrait genomic models may be preferred for traits with many missing records or when foreign records are included as pseudo-observations, but most countries use multitrait traditional evaluations followed by single-trait genomic evaluations. A final goal is to explain how the models work so that breeders can more confidently apply the predictions in their selection programs.

Key Words: genetic evaluation, genomic selection, mixed models

41 Experiences in bioinformatics. Luc L. Janss*, *Aarhus University, Tjele, Denmark.*

Knowledge from bioinformatics research can in principle be used to improve genomic predictions. Examples are use of the QTLdb database with collected QTL mapping results, the use of genomic feature annotations, and pathway or Gene Ontology (GO) data. There are, however, several hurdles to appropriately use this information and include it in genomic models for analysis of livestock data. A limitation in the use of QTL mapping results is that results from classical linkage analysis studies have wide confidence intervals such that for any trait a large part of the genome will be tagged as "QTL region". Despite this limitation, SNPs in QTL regions can be found to explain more variance than those outside QTL regions, which is for instance shown for milk and fat yield in dairy cattle, but not for protein yield. A limitation of genomic feature annotations is that this information is not covering the whole genome and is not directly related to traits, or, for pathway or GO data, is mostly categorized in fundamental biological processes. This makes it difficult to attach genuine prior information to this data. The common approach to use this kind of bioinformatics data is to simply try which features or GO groups explain more variance or predict better. This leads to results such as that SNPs in/near genes (but not necessarily from the coding parts of genes) explain more variance in phenotypes. A final significant hurdle to use this information is that our animal populations are highly structured and include relatives. This leads to long-range LD and LD between chromosomes, which effectively spreads QTL effects over the whole genome. This creates a polygenic image of the trait architecture, which matches the assumptions of GBLUP that all SNPs contribute equally, and makes genomic relationships the main driver for genomic prediction within animal populations. Better modeling, notably a separation of effects of linkage and LD in genomic prediction, allows more meaningful inferences from bioinformatics data, and potentially allows to improve genomic predictions where relationships are weak; for example, across breed.

Key Words: bioinformatics, genomic feature, genomic prediction

42 Practical implications for genetic modeling in the genomics era for the beef industry. Andy D. Herring*, *Texas A&M University, College Station, TX.*

The beef cattle industry is based on valuation of phenotypes, and its supply chain components vary across global region. In many areas, producers maintain ownership of animals until sale to an abattoir, yet in many other regions distinct industry segments (cow-calf, grower/stocker, finisher/feedlot, packer) exist where animal ownership changes across segment. Commodity cattle (of unknown genetic and/or management background) have different value potential as compared with cattle with known background. The utility of genomic data and analyses are, and will remain, different regarding these 2 types of cattle. Many genomic approaches have calculated molecular breeding values of animals; however, most beef industry managers other than seedstock producers would much rather have predicted phenotypes (predictions that could be collectively based on breeding value, non-additive genetic value, and environmental value) for improved management and marketing decisions. Current US beef industry trends show increasing carcass (and mature cow) weight and carcass quality grade, but static incidence of respiratory disease in feedlots, and no improvement in percent calf crop weaned in beef herds. Trends for more prevalent and less costly genomic data will also continue. There appears to be large potential to genomically characterize beef cattle for production-related physiological systems (health, growth, body composition, fertility, nutrient utilization) as well as potential interactions for optimal economic management and production system assessment. Better understanding of these systems and their components will require knowledge beyond the DNA sequence including RNA regulatory elements and products and protein function and structure; the roles of fetal programming and epigenetics on economically important traits in beef production remain largely unknown and need investigation. Resource cattle populations with detailed phenotypes and banked biological samples, and that evaluate multiple components of beef cattle production systems remain critically important; partnerships of industry groups and research institutions can assemble large, informative data sets. The incorporation of genomic data into economic assessments is also encouraged.

Key Words: genetic modeling, beef cattle production systems

Comparative Gut Physiology and Nonruminant Nutrition Symposium: The gut–brain axis—Sensing and signaling

43 Nutrient and non-nutrient sensing in the gastrointestinal tract. Soraya P. Shirazi-Beechey*, *University of Liverpool, Institute of Integrative Biology, Liverpool, UK.*

The intestinal epithelium is a major interface with the outside world. This interface is separated from the body's internal milieu by a single layer of epithelial cells consisting of absorptive enterocytes, goblet, enteroendocrine and Paneth cells. These cells are exposed, at the luminal domain, to an external environment that is continuously changing by types and amounts of nutrients, microorganisms, microbial products, gastrointestinal secretions and potentially toxic chemicals. The intestinal epithelium constantly monitors the composition of its contents to optimize nutrient absorption, as well as defending threats to its integrity. In recent years significant advances have been made in the understanding of the molecular recognition events involved in sensing the luminal contents of the gastrointestinal tract. The sensing of various nutrients in the gastrointestinal tract is accomplished by several G-protein coupled receptors, expressed on the luminal membrane of enteroendocrine cells. Sensing of nutrients by these receptors leads to secretion of hormones that control vital physiological functions such as food intake, nutrient digestion and absorption, intestinal barrier function and insulin secretion. The intestine also contains approximately 1000 different species of bacteria and has to discriminate between pathogenic and commensal bacteria to maintain a balance between immune protection and inflammatory over-reactions. A class of proteins known as pattern recognition receptors, in particular toll-like receptors (TLRs 1–10) play a key role in the recognition of microbes via detection of conserved molecular features. The sensory receptors that face the lumen of the intestine and are responsive to luminal contents provide a unique therapeutic opportunity. In my talk I will present data on the role of the gut expressed taste 1 receptor (T1R) family in intestinal nutrient sensing and the contribution of TLR9-recognition of bacteria in control of gut hormone release. The impact of these findings to animal nutrition will be discussed.

Key Words: intestine, taste 1 receptor (T1R), toll-like receptor 9 (TLR9)

44 Effects of supplemental amino acids in low-protein diets on intestinal tight junction and amino acid transporters in growing pigs. S. J. Zhang*[1,2], W. Parnsen[1], and S. W. Kim[1], [1]*Department of Animal Science, North Carolina State University, Raleigh, NC,* [2]*College of Animal Science and Technology, China Agricultural University, Beijing, China.*

This study was to determine the effects of supplemental AA in low-protein diets on tight junction and AA transporters in the small intestine of growing pigs. 72 pigs (19.7 ± 1.1 kg, 36 barrows and 36 gilts) were allotted to 3 treatments with 8 pens per treatment (3 pigs per pen, 4 barrow pens and 4 gilt pens) using sex and initial BW as blocks: NC (supplemental Lys, Met, and Thr at 18% CP), PC (supplemental Lys, Met, and Thr at 16% CP), and PCT (PC + 0.05% Trp). The NC and PC diets had AA to meet the NRC 2012 requirements (0.98% Lys, 0.55% Met + Cys and 0.59% Thr) whereas PCT diet had additional 0.05% Trp exceeding the requirement. After 4 wk feeding, 24 pigs (1 pig per pen with median BW) were euthanized to obtain duodenum and jejunum to quantify tight junction proteins (claudin-1, occludin-1, and ZO-1) and jejunum to quantify mRNA of AA transporters (CAT-1, $b^{0,+}$AT, rBAT, y^+LAT, 4F2hc, and B^0AT). Tight junction proteins were separated by Western blot and bands densities were measured. The mRNA of AA transporters was quantified by a real-time PCR. Data were analyzed using the Mixed procedure of SAS. Treatment and sex were the fixed effects and initial BW was a random effect. Pigs in PCT had increased ($P < 0.05$) claudin-1 in duodenum and jejunum compared with pigs in NC and PC. No difference in ZO-1 in duodenum and jejunum was detected among treatments. Pigs in PC had decreased ($P < 0.05$, 39.3%) occludin-1 in duodenum compared with pigs in NC. There was no difference in occludin-1 between PC and PCT. Pigs in PC and PCT had increased ($P < 0.05$) mRNA concentrations of CAT-1 (2.29 and 1.92 fold), 4F2hc (2.76 and 2.45 fold), and B^0AT (2.12 and 2.26 fold, respectively) compared with pigs in NC. Collectively, use of supplemental amino acids (Lys, Met, Thr, and Trp) in low protein diet to meet the NRC 2012 requirements could increase AA transporters in jejunum and additional 0.05% Trp exceeding the NRC 2012 requirements enhanced intestinal tight junction.

Key Words: amino acid transporters, low-protein diet, tight junction

45 The emerging role of bile acids as nutrient-sensing signals. Ignacio R. Ipharraguerre*[1,2], [1]*Institute of Human Nutrition and Food Science, University of Kiel, Kiel, Germany,* [2]*Lucta S.A., Montornes del Valles, Spain.*

Traditionally, bile acids (BA) have been viewed as detergent molecules involved in the intestinal digestion and absorption of lipids and hepatic maintenance of cholesterol homeostasis. During the last 15 years, however, it has become clear that BA are important regulatory molecules with systemic endocrine functions that signal changes in luminal nutrients and microbial activity during the fed-fast cycle. The regulatory actions of BA are primarily mediated by the nuclear receptor FXR (farnesoid X receptor), the G-protein coupled receptor TGR5 and cellular signaling pathways (AKT and ERK1/2). These proteins are highly expressed in the liver as well as enterocytes, endocrine cells and enteric neurons in the small intestine. Surprisingly, BA receptors are also present in several tissues outside the biliary tree including adipose tissue, pancreas, and immune cells. In mice, via interaction with these sensors and pathways, BA control the expression of genes and concentration of circulating hormones involved in the regulation of lipid and glucose metabolism, energy expenditure, intestinal integrity, motility, and immune homeostasis, gut microbial growth, and inflammation. In pigs, evidence from seminal studies indicates that BA signaling is implicated in the intestinal secretion of glucagon-like peptides, gut mucosal growth and protection, nutrition-related liver disease, and changes in host weight and metabolism resulting from variations in gut microbiota. It is important to note that BA differ in their ability to activate signaling pathways and that the composition of the BA pool varies remarkably among non-ruminant animals. In fact, all non-ruminant species of interest (e.g., pig, chicken, rabbit, horse) have unique BA signatures. In view of these differences and the emerging role of BA as regulatory molecules, the study of their involvement in signaling outside the enterohepatic circulation and in mediating reciprocal communication between the host and its microbiota will become a relevant and expanding field of research in animal nutrition and physiology.

Key Words: bile acid signaling, FXR, TGR5

46 The role of gut peptides in the gut-brain-axis of livestock.

Andrew P. Foote*, *USDA-ARS, US Meat Animal Research Center, Clay Center, NE.*

Gut peptides are small hormones produced within the gut that are involved in many biological processes including, but not limited to, appetite regulation, mucosal growth, and metabolism regulation. Some peptides, such as cholecystokinin (CCK) and xenin-25 may affect appetite by altering gut motility through cholinergic pathways, but most of the hunger/satiety signals are processed through the brain. Ghrelin is a peptide produced mostly in the gastric stomach or abomasum and increases before a meal. The ghrelin receptor is expressed in neurons in the arcuate nucleus of the hypothalamus and binding leads to the release of neuropeptide Y and agouti-related peptide, thereby stimulating appetite. While ghrelin is thought to serve as a hunger signal in meal fed animals, it may also be involved in the variability of DMI in ad libitum fed animals. Other gut peptides, including peptide YY, oxyntomodulin, and glucagon-like peptide-1 (GLP-1), act as satiety signals and are inhibitory to ghrelin. These peptides stimulate neurons in the arcuate nucleus to release α-melanocyte-stimulating hormone (α-MSH) and cocaine and amphetamine regulated transcript (CART), thereby decreasing appetite. The actions of gut peptides are not limited to appetite regulation. Glucagon-like peptide-2 (GLP-2) is a potent stimulator of intestinal mucosa growth and gut blood flow, and could be important for gut health of livestock. Glucose-dependent insulinotropic polypeptide (GIP) increases insulin secretion and regulates lipid metabolism. Because the complete functions of many gut peptides in livestock species are not known, studying their regulatory roles is critically important in nutritional physiology and animal health.

Key Words: appetite regulation, metabolism regulation, gut function

47 Nutrient sensing by glucagon-like peptide-1 secreting cells.

Frank Reimann*, *Institute of Metabolic Science & MRC Metabolic Diseases Unit, University of Cambridge, Cambridge, UK.*

Glucagon-like peptide-1 (GLP-1) is an enteroendocrine hormone secreted by L-cells found throughout the intestinal epithelium, but with increased frequency in the ileum and colon. GLP-1 acts as an incretin, boosting postprandial insulin secretion, inhibits glucagon secretion and is anorexigenic. Using transgenic mouse models allowing labeling and manipulation of GLP-1 and GLP1R expressing cells we investigated molecular mechanisms underlying hormone secretion and responses in the GLP-1 axis. L-cells are electrically excitable cells, displaying an increased action potential firing rate when nutrients are available. This can be achieved by electrogenic nutrient uptake, for example by the sodium coupled glucose transporter (SGLT-1) or the proton coupled dipeptide transporter (PepT1). L-cells isolated from knockout mice for these transporters have attenuated responses to glucose and dipeptide, respectively. Lipid derived molecules and bile acids, by contrast were shown to be detected by the G-protein coupled receptors FFAR1 and TGR5 (GPBAR), predominantly coupling to increases in cytosolic Ca^{2+} and cAMP, respectively. In the distal intestine, where most nutrients are likely to be processed by the intestinal microbiota, L-cells can be shown to respond to short chain fatty acids (via FFAR2/3) and indole, with the latter inhibiting voltage gated potassium channels and ATP-production, resulting in stimulatory and inhibitory signals respectively. Distal L-cells also differ from small intestinal L-cells in that they co-secrete peptideYY (PYY) and the orexigenic peptide Insulin-like peptide-5 (Insl5), whereas duodenal/jejunal L-cells co-express glucose-dependent insulinotropic polypeptide (GIP, the other incretin) and cholecystokinin (CCK). It is hoped that an improved understanding of the gut hormone signaling will facilitate the development of new therapies that harness endogenous gut hormone reserves for the treatment of metabolic disease.

Key Words: glucagon-like peptide-1 (GLP-1), hormone secretion, nutrient sensing

48 Effect of feeding rate and glucose provision on plasma glucagon-like peptide 2 concentration in dairy calves.

Sarah Y. Morrison*[1], Juan. J. Castro[1], Kristen M. Glosson[1], Jens. J. Holst[2], James K. Drackley[1], and Ignacio R. Ipharraguerre[3,4], [1]*University of Illinois, Urbana, IL,* [2]*Department of Biomedical Sciences, University of Copenhagen, Denmark,* [3]*Institute of Human Nutrition and Food Science, University of Kiel, Germany,* [4]*Lucta SA, Barcelona, Spain.*

Glucagon-like peptide 2 (GLP-2) may have therapeutic potential in young calves encountering stressors, such as weaning and diarrheal disease, because of its pleiotropic actions on intestinal mucosal and barrier function. During diarrhea, feed intake decreases, which is a major negative effector of GLP-2 secretion and increases intestinal atrophy. We determined the effects of feeding rate and supplementation with potential GLP-2 secretagogues in milk replacer (MR) on GLP-2 concentration [GLP-2] in calf plasma. Three days after birth, male Holstein calves (n = 45) were randomly assigned to 1 of 12 treatments arising from factorial combination of feeding rate (FR) and supplement type. Feeding rates were 25, 50, 75, and 100% of standard feeding level on d 5 (1.5% of BW as DM). Supplement treatments were Control: MR, no supplement; GLC: MR plus glucose (220 mg/kg BW per day); and 3OMeGLC, MR plus 3-O-Methyl glucose (6 mg/kg of BW per day). A commercial MR (12.5% solids) was fed twice daily at 10% of BW for d 1–2 and 12% of BW for d 3–5. On d 6–7 calves were fed the FR plus supplement treatments. On d 8, calves were fed 0, 25, 50, and 75% of respective MR allowance on d 5 plus supplement treatments, and plasma was obtained at −15, 15, 30, 60, 90, and 240 min relative to feeding for determination of [GLP-2]. No starter was fed but water was offered ad libitum. Generalized linear models with normal and Poisson distributions were used to analyze [GLP-2] and fecal score data, respectively. As designed, MR intake differed ($P < 0.0001$) among treatments. Occurrence of diarrhea did not differ among treatments. For log [GLP-2], there was a quadratic effect of FR ($P = 0.0003$) and effect of supplement, with 3OMeGLC greater than GLC but not control ($P = 0.002$). Increasing FR increased ($P < 0.0001$) area under the curve for [GLP-2] after feeding; calves fed the 25% rate had the lowest area under the curve and calves fed 100% had the greatest (10,188 vs. 22,023 pg·h/mL). Feeding rate had a significant effect on GLP-2 with calves allotted greater MR intakes having greater plasma [GLP-2].

Key Words: glucagon-like peptide 2, feeding rate, glucose

49 The brain within the gut—Activation of enteric cells and sensory neurons.

John B. Furness*[1], David M. Bravo[2], Jeremy J. Cottrell[1], and Frank R. Dunshea[1], [1]*University of Melbourne, Parkville, Australia,* [2]*InVivo Animal Nutrition & Health, Talhouët, Saint-Nolff, France.*

For optimal digestive efficiency, the contents of the gastrointestinal tract need to be detected and the information needs to be conveyed to control systems: the gut endocrine system, the nervous system and the immune and tissue defense systems. The contents include nutrients, products of digestion, bacteria, viruses, fungi and potentially injurious substances in foods. Sensory neurons that innervate the gut lining detect hormones released from enteroendocrine cells (EEC) and also detect other signals, for example cytokines and other substances released when the gut is inflamed, and contractile activity of the gut. There are 4 classes of enteric sensory neurons, intrinsic primary afferent neurons (IPANs), with cell bodies in the gut wall, vagal primary afferent neurons, spinal primary afferent neurons and intestinofugal neurons, and within each class there are subclasses that detect different sensory signals. From a comparative point of view, the functioning of the enteric nervous system (ENS) is similar between species, although there are some differences in its organization, as will be discussed. The ENS works in concert with CNS reflex and command centers to control digestive function, so it cannot be considered in isolation. There is bidirectional information flow between the ENS and CNS. The major type of sensory ENS neuron is the IPAN. These neurons have distinctive shapes and electrophysiological characteristics, similar to primary afferent neurons of dorsal root ganglia. Their axons in the mucosa sense the chemical environment of the lumen and mucosal distortion. They also detect toxins (they are nociceptive neurons). Other processes of the neurons are sensitive to muscle movement. Their outputs are to other enteric neurons (interneurons and motor neurons) and to intestinofugal neurons. The major functions they control are gut movements, water and electrolyte secretion and blood flow.

Key Words: enteric nervous system, sensory neurons

50 Xylanase supplementation in feed reduces incretin and PYY levels in piglets.

Katherine May*[1], Saoirse E. O'Sullivan[2], John M. Brameld[1], Helen V. Masey O'Neill[3], Tim Parr[1], and Julian Wiseman[1], *[1]School of Biosciences, University of Nottingham, Loughborough, Leicestershire, UK, [2]School of Medicine, University of Nottingham, Derby, Derbyshire, UK, [3]AB Vista Feed Ingredients, Marlborough, Wiltshire, UK.*

The objective of this study was to investigate the effects of xylanase supplementation on gut hormone production in newly weaned piglets. In experiment 1, 32 female Camb12 weaned piglets (8.8 ± 1.38 kg, mean ± SD) were randomly assigned to 1 of 2 diet groups in period 1 (0–2 wk postweaning; P1), a control diet (Co) or the same diet supplemented with xylanase (XS). During period 2 (2–6 wk postweaning; P2) half the pigs were kept on their original diet while the rest were swapped onto the other diet, resulting in 4 groups. At the end of P2 the pigs were culled by electrical stun and exsanguination at which point blood samples were collected using EDTA coated tubes. The samples were centrifuged at 3000 g for 10 min at 4°C and the plasma was aliquoted and stored at −80°C for further analysis. A Human Metabolic Hormone Milliplex HMHMAG-34K kit (Merck Millipore) was used to assess the concentrations of PYY, PP, Insulin, C-Peptide and GIP (total) in the plasma. In experiment 2, 16 female Camb12 weaned piglets (9.2 ± 0.95 kg) were assigned to the same 2 diet groups as in experiment 1 (Co and XS). After P1, the pigs were culled and blood samples taken as in experiment 1; however, protease inhibitors were added to the collection tubes so extra gut hormones could be analyzed [amylin (active), ghrelin (active) and GLP-1 (active)]. The data were tested for normality and analyzed with the appropriate parametric or non-parametric test (one/two-way ANOVA or Kruskal-Wallis), significance was accepted at $P < 0.05$. In experiment 1, XS in P2 significantly decreased plasma PYY concentrations ($P = 0.008$). In experiment 2, XS significantly decreased plasma GIP ($P = 0.027$) and GLP-1 ($P = 0.002$) concentrations in P1. GIP and GLP-1 are known as incretin hormones that affect pancreas function. In conclusion, xylanase supplementation to newly weaned piglets affects the production of certain gut hormones. The effect was dependent upon the timing of supplementation as different hormones were affected between P1 and P2.Further trials are needed to investigate whether there are longer-term effects when the piglets are grown to a commercial slaughter weight.

Key Words: gut hormone, piglet, xylanase

51 Perinatal nutrition and the gut–brain axis.

Ryan N. Dilger*, *University of Illinois, Urbana, IL.*

There exists a need to better understand complex interrelationships between dietary intake and cognitive function, and animal models are critically important in this endeavor. The field of nutritional neuroscience has, as a primary goal, the application of findings to the human clinical setting, and therefore, models that closely mimic the human condition are highly valued. Thus, based on similarities in patterns of brain development and structure, the pig has emerged as a biomedical and preclinical model for studying human brain development and cognitive function. Building upon the storied history of using the neonatal pig as a research model for studying pediatric nutrition and metabolism, recent emphasis has been placed on understanding how signaling mechanisms in the gut, being largely synonymous with microbial interactions, influence neurodevelopment and brain function. As a precocial species, the young pig can be artificially reared with relative ease, thus providing strict control over dietary intake. Moreover, validated methods to assess learning and memory using behavioral assays now exist, and these outcomes provide a powerful and integrated view of how nutrition influences brain development. Sensitive neuroimaging sequences are also available, and along with cellular and molecular techniques optimized for the pig, there exists a fruitful area to generate new knowledge of how early-life nutrition influences neurodevelopmental processes. As such, nutritional strategies to alter the delivery of specific components to the brain, or influence the microbial composition or production of bioactive compounds in the gastrointestinal tract, are currently being tested. There are many advantages to extending the field of pediatric nutrition research by integrating outcomes related to the microbiome, routes of information transfer between the gut and brain, and processes associated with cognitive function and brain development, and the young pig will play a pivotal role in these investigations.

Key Words: nutrition, neuroscience, pig

52 Effects of increasing standardized ileal digestible tryptophan:lysine ratio on performance and ileal expression of cytokine mRNA in weaned pigs challenged with *Escherichia coli* K88.

B. Jayaraman*[1], A. Regassa[1], W. K. Kim[1], J. K. Htoo[2], and C. M. Nyachoti[1], *[1]University of Manitoba, Winnipeg, Manitoba, Canada, [2]Evonik Industries AG, Nutrition Research, Hanau-Wolfgang, Germany.*

A study was conducted to determine the optimal standardized ileal digestible (SID) tryptophan:lysine (Trp:Lys) ratio in piglets challenged with *Escherichia coli* K88 (*E. coli* K88) and fed antibiotic-free diets. Thirty individually housed mixed-sex pigs (Duroc × [Yorkshire × Landrace]) with an initial BW of 6.41 ± 0.4 kg and weaned at 21 ± 1 d were randomly assigned to 5 dietary treatments with 6 replicates per treatment. Dietary treatments consisted of increasing levels of SID Trp:Lys ratios (16, 18, 20, 22 and 24%). Diets were corn-wheat-soybean meal-based with a constant SID Lys of 1.18% that was set to be the second limiting AA but adequate in other AA. Pigs had ad libitum access to feed and water for 13 d. Piglets were fed the experimental diets for 6 d and on d 7, they were orally challenged with 6 mL of *E. coli* K88 (2×10^9 cfu/mL). Body weights and pen feed disappearance were recorded weekly to determine ADG, ADFI and G:F. On d 13, all pigs were euthanized to obtain ileal tissue samples to measure mRNA expression of tumor necrosis factor-α (TNF- α) and interleukin-10 (IL-10) using qRT-PCR. During the pre-challenge period, increasing dietary SID Trp:Lys increased (linear, $P < 0.05$) ADG (157, 162, 173, 179 and 201 g) and G:F (0.71, 0.73, 0.74, 0.81 and 0.84). During the post-challenge period, there was an increasing trend (linear, $P = 0.076$) in ADG (177, 180, 208, 210 and 213 g), whereas there was no effect on G:F ($P > 0.10$). The optimal SID Trp:Lys determined using the broken-line regression analysis for ADG and G:F in piglets subjected to *E. coli* K88 challenge was 21 and 24.2%, respectively. The expression of pro-inflammatory cytokine, TNF-α mRNA, linearly decreased ($P = 0.10$) with increasing SID Trp:Lys ratio. The expression of anti-inflammatory cytokine, IL-10 mRNA, increased (linear and quadratic, $P < 0.01$) with increasing SID Trp:Lys ratio. In conclusion, in antibiotic-free starter diets, an average optimal SID Trp:Lys of 22.6% optimized performance and immune status of piglets under *E. coli* challenge.

Key Words: tryptophan:lysine, *Escherichia coli* K88, piglet

53 Effect of dietary intervention of probiotic *Lactobacillus helveticus* MTCC 5463 on fecal beta-glucuronidase activity in geriatric volunteers.

Suja Senan*[1], Jashbhai Prajapati[2], Chaitanya Joshi[2], Sreeja V[2], Manisha Gohel[3], Sunil Trivedi[3], Rupal Patel[3], Himanshu Pandya[3], Ajay Phatak[3], Uday Shankar[3], and Hasmukh Patel[1], [1]*South Dakota State University, Brookings, SD,* [2]*Anand Agricultural University, Anand, Gujarat, India,* [3]*H. M. Patel Center for Medical Care & Education, Karamsad, Gujarat, India.*

Probiotics may reduce the risk for the onset of colorectal cancer by modulating the activity of fecal bacterial enzymes that catalyze the liberation of procarcinogenic substances in the intestine. The aim of this study was to investigate the influence of probiotic *Lactobacillus helveticus* MTCC 5463 (5463) on fecal microbial-related functions in geriatric volunteers. The subjects were randomized into 2 groups, fed either fermented drink containing 5463 (test group) or without 5463 (placebo group). The volunteers consumed 200 mL of the product once a day for 4 weeks. Fecal samples were collected in sterile plastic containers at the beginning and end of the intervention period. β-glucuronidase was considered as the marker enzyme for anti-colonic carcinogenesis activity, and measured in terms of unit activity per mg of protein in fecal samples. Total fecal protein was determined by Folin-Lowry method with bovine serum albumin as a standard. The data were analyzed with Student's *t*-test, and the levels of significance were expressed as p values. The mean β-glucuronidase activity was reduced in test group from 1.40 to 0.73 (μg/min/mg of protein) while in case of placebo group, no effect on enzyme activity was observed. Enzyme β-glucuronidase activity in the feces of all subjects in the probiotic group, were highly significant ($P < 0.001$), whereas the placebo group showed nonsignificant differences ($P = 0.40$). We were able to demonstrate consistent reduction in the fecal β-glucuronidase activity in the probiotic group. Results suggested that the metabolic activity of the fecal flora was altered by 5463 therapy, which further decreased procarcinogenic enzyme levels in the large intestine. Probiotic MTCC 5463 interaction with the geriatric host microbiome, affects β-glucuronidase activity, which can be exploited as an alternate therapy against colonic carcinogenesis.

Key Words: probiotics, geriatics, β-glucuronidase

54 Brain–gut interactions in stress.

Jackie D. Wood*, *The Ohio State University, Columbus, OH.*

Stress can be viewed as exposure of an animal to a hostile environment that compromises bodily homeostasis. Stress of this nature can occur in many forms, examples of which are extremes in environmental temperature, fear, predator attack and crowding. Elevation of heart rate, blood pressure, respiration rate and emotional agitation are among the many bodily manifestations of stress. In the gut, they can include diarrhea, constipation, incontinence, gastric regurgitation and gastrointestinal mucosal inflammation. Corticotropin-releasing factor (CRF) is a neuropeptide that plays a major role in the body's overall responses to stress, including the gut. The physiology of central CRF signaling pathways in stress-induced changes in gastrointestinal motility and gastric acid secretion has been well characterized. Recent work elucidates how the physiology of peripheral CRF-related mechanisms contribute to stress-induced changes in gut motility and intestinal mucosal function. Acute stress, intramural CRF release and experimental application of selective CRF_1 receptor agonists evoke excitatory responses in neurons in the enteric nervous system (i.e., the brain-in-the-gut). Enteric neurons express CRF and its receptors. Exposure to acute and chronic stresses increases intestinal ion secretion and mucosal permeability to macromolecules and evokes diarrhea. Effects of stress on intestinal mucosal function are mimicked by peripheral injection of CRF and blocked by peripheral injection of non-selective peptide CRF receptor antagonists. CRF mRNA knock down in the enteric nervous system prevents intestinal responses to environmental stress in rodents. These findings constitute strong evidence that activation of peripheral CRF receptors in the enteric nervous system is a key mechanism involved in stress-related alterations of gut motility and mucosal function. In the cotton-top tamarin (*Siquinus oedipus*) model for ulcerative colitis and associated colon cancer, evidence suggests that environmental stress initiates the inflammatory response, which is then sustained by factors in the feces.

Key Words: stress, CRF, enteric nervous system

Extension Education Symposium: Extension and industry outreach for tomorrow's producers

55 Developing partnerships between academia and industry. Todd R. Bilby*, *Merck Animal Health, Fort Worth, TX.*

Partnerships between academia and industry continue to be an important aspect of aiding in providing educational and research opportunities to advance the agriculture industry. Funding for applied research and extension continues to be difficult to both secure funds and develop long-term strategic partners. Understanding what industry partners are seeking in terms of strategic initiatives and corporate missions will be important in securing a long-term partner. In addition, extension needs to develop programs and other opportunities that will target a broad geography, deliver science-based outcomes, and aid in the implementation of these outcomes utilizing the latest technologies. Industry partners are actively seeking academic partners with a strong reputation in their field of interest who can deliver within a timely manner on tasks set forth by both parties. Academia would benefit by using more power of persuasion, salesmanship, and clearly illustrating to an industry partner the ROI for both parties. Once the right partner is chosen, articulation and documentation of terms, executing a contract that respects the integrity and commitment of all parties as well as timely delivery of outcomes is imperative to continued collaboration. Some significant roadblocks in negotiations between academia and industry occur during the processes of valuation, IP ownership, indemnification, royalties and conflict of interest. Often, academia representatives do not have enough information to understand the market factors during negotiations, however, industry has proprietary issues that restrict corporations from sharing information with regard to risk mitigation and value assessment for given products and markets. Lack of knowledge surrounding industry constraints coupled with the inability to share knowledge from industry can make negotiations and partnerships difficult. Enhanced appreciation for constraints, instead of focus on incentives, is required to share ideas and develop long-term partnerships.

Key Words: academia, industry, partnership

56 What I've seen and done on both sides: Academia and Industry. Larry Corah*, *Certified Angus Beef, Wooster, OH.*

There has been a progressive change in the evolution of information transfer in animal agriculture over the past 70 years. During the era of 1930s to 1960s, information flow centered on university research ≫ > transferred to the local county agent ≫ > and then shared with the producer. Starting in the 1960s to 1970s, that process started to change. Numerous commercial companies started adding expertise to support product research, the advent of consultants occurred, universities started filling extension positions with greater research expertise and focus and a new era of information flow started as these industry specialist and consultants played a much more active role. Today we find an even greater role of industry in technology transfer as they explain new R&D findings which coupled with reduced funding and staff downsizing at many universities which has resulted in a more educated clientele looking for information in new ways. Where are we heading? There are numerous opportunities for both industry and academia which likely will lead to greater partnership opportunities driven by varying needs. From a university perspective funding needs will likely drive partnerships. From an industry perspective, many companies are starting to recognize the important and needed role universities play in educating undergraduates and graduate students who fill vital staffing industry needs. These collaborations will also expand in areas of mutual research interests and how that research is transferred to clientele groups.

Key Words: technology transfer, academia, industry

57 Training of students: Real-world experience on farm, in extension, and industry. Robert E. James*, *Virginia Tech, Blacksburg, VA.*

Significant challenges exist in training students to enter employment in the animal industry. Farm numbers continue to shrink while farm size and complexity has increased. Excellent opportunities exist for graduates with proficiency in communication and problem solving and are able to integrate sophisticated technical knowledge to practical problems on the farm. The challenges are many. Reductions in faculty, particularly in extension and more applied research and teaching positions, are common in our universities. Students are increasingly from urban and suburban backgrounds with little previous agriculture experience but considerable interest in food production. Declining state and federal support for undergraduate education and more applied graduate research are additional challenges. However, many new opportunities are available to provide needed training experiences. Summer internships are common for students at dairy farms and in industry positions in sales, market research and technical support. The North American Intercollegiate Dairy Challenge Contest and Academy has been successful in fostering better communication of students with dairy industry partners. Over 4,500 students have participated since its inception in 2002. Employment on campus dairy farms provides opportunities for non-traditional students to obtain farm experience. On farm research at the university and on commercial dairies expands student perspectives. Training graduate students presents similar challenges. In the past, formula funding permitted research to address timely research needs of our animal industries. However, these funds have been replaced with competitive grants directed toward specific narrow problems. Students begin their graduate studies with less input into research project design and have less time for exposure to our farms. Industry sponsored management research enables students to conduct on farm research on commercial farms. Farm sponsored check off programs such as the Virginia Set-aside program direct funds toward more applied research.

Key Words: students, extension, industry

58 Retaining qualified extension faculty: An administrator's perspective. Gregory P. Lardy*, *North Dakota State University, Fargo, ND.*

Retaining qualified faculty for extension positions is an important factor in the success of animal, dairy, and poultry science departments. To be successful in an extension appointment requires a unique combination of skills. I believe the following skills are critical: (1) sound technical training, (2) excellent written and oral communication skills, (3) a thorough understanding of the industry one is hired to serve and a desire to serve that industry, (4) excellent time management skills, (5) ability to translate scientific knowledge to practical applications in a systems approach, and (6) the ability to develop and maintain relationships with clientele. Candidates with these skills have an improved probability of being successful. Retaining highly qualified faculty requires support from multiple levels of the institution. Factors affecting retention include (1) a positive departmental culture, (2) a competitive salary and benefits package, (3) clear job expectations and provision of resources required to effectively carry out the job duties including an institutional culture that supports and values extension programming, (4) a stimulating and challenging work environment, and (5) a departmental, college, and institutional culture that helps the faculty member balance the demands of work and family life and fosters professional development. In my experience, having a positive departmental culture is the most important. Department heads and chairs have a very direct effect on departmental culture (both positive and negative). Administrators and promotion and tenure committees at the departmental and college level must place a high value on extension programming in order for faculty with extension appointments to feel valued. Promotion and tenure documents at the department, college, and institutional level should reflect the scholarship of extension programming. Recruitment and retention of extension faculty is a multi-faceted challenge and one that requires commitments at the departmental, college, and institutional level to be successful. In my experience, hiring candidates with the right combination of skills and developing a positive departmental culture are the most important means to improving success.

Key Words: extension, faculty, recruitment

59 Development of mobile applications in extension.

R. Lawton Stewart, Jr.*[1] and G. Cliff Lamb[2], *[1]The University of Georgia, Athens, GA, [2]The University of Florida, Marianna, FL.*

Mobile computing devices such as smartphones and tablets are quickly becoming the principal means of communication in the United States. The adoption of smartphone and tablet technology among adults over the age of 18 has increased from 35 and 8%, respectively, in 2011 to 55 and 42%, respectively, in 2014. This growth is visible in the agricultural field as well. A search of currently available mobile computing applications (apps) for agriculture revealed 42, 28, 19, and 11 apps are available for crops, livestock, spraying, and pests, respectively. Given that the role of extension is to extend lifelong learning opportunities through unbiased, research-based education, the utilization of apps provides an excellent opportunity to serve clientele. This technology can improve the power to disseminate information, make informed science-based decisions, and collect data. However, when considering the use of this technology for an Extension program, several aspects of implementing this technology should be addressed. Most attempts at Extension-based apps are based on currently available informative publications for dissemination of information, or spreadsheet-based decision aids for decision-aid tools. This development is initiated by the need of information in the field, however, the challenge often becomes getting information transferred to an app-accessible format. The most common form is an app available through application distribution platforms specific to a smartphone mobile operating system (e.g., Apple iTunes and Google Play). These require app-specific programing and approval through the distributor; however, once downloaded to a mobile device, are accessible independent of a data connection. Another avenue is to develop a mobile-friendly website. This makes the information or decision aid available on any operating platform, however requires a data connection by the device. Finally, the impact of this technology should be quantifiable to allow extension personnel to measure the effect of their program. This can be performed through download statistics for mobile apps, or through website analytics for mobile-friendly websites. With the increased availability of information through mobile devices, mobile device applications are an excellent tool for extension personnel.

Key Words: mobile app, extension, decision-aid tools

60 Social media to deliver extension.

Alison Van Eenennaam*, *University of California, Davis, CA.*

The use of social media in public engagement and extension is a relatively new phenomenon, and many scientists are cautious about using it professionally. A recent survey of 4,000 researchers carried out by the Pew Research Center found less than half of the researchers ever used social media, 24% use it to blog about science, and only 12% said they currently use it to follow experts in their field. Depending upon the target audience, social media may or may not be a useful tool to deliver extension information. Social media gives opportunities to reach a much wider public audience than traditional extension meetings, but it may not always be the best approach to reach more traditional agricultural clientele who typically are an older demographic. One issue with the professional use of social media is the difficulty of objectively documenting impact. Although the number of followers or page views is an easy metric to report, it does not really evaluate impact. Merit and promotion evaluation systems will need to evolve to reflect the increased use of social media in extension programs, and appropriately reward academics for time spent effectively using these forms of communication. The UC Davis Animal Biotechnology and Genomics Extension program incorporates the use of social media including websites, YouTube educational videos, and the use of Twitter. For extension work in controversial areas, educators need to be prepared for the unpredictable nature of social media audiences. Several high-profile "public shamings" following an ill-advised tweet provide cautionary case studies of one of the risks of using social media, especially when discussing controversial topics. Although Twitter is useful for directing interested followers to a website or alerting them to an upcoming meeting, it is difficult to explain the nuances of complex topics in 140 characters, and maintaining a civil and respectful dialog can sometimes be challenging. Extension educators can certainly benefit from the expansive reach of social media and magnify the reach of their programs, and the next generation of educators will likely increasingly do so in the future. As with all extension communication, great care should be given to wording to ensure the professional dissemination of science-based information using social media.

Key Words: social media, Twitter, YouTube

Forages and Pastures: Forages for livestock systems

61 Forage-finished steer performance and carcass characteristics from grazing high-energy forages during the finishing period. Rachel M. Martin*[1], Jason E. Rowntree[1], Kim A. Cassida[1], Joseph Paling[1], and Douglas Carmichael[2], [1]*Michigan State University, East Lansing, MI,* [2]*Michigan State University AgBio Lake City Research Center, Lake City, MI.*

The research objective was to compare high-energy forage options during the finishing period for Upper Midwestern forage-finished beef production systems. Twelve 0.80-ha pastures were randomly assigned to 1 of 3 forage treatments including: mixed pasture (MIX); simple cereal grain/brassica mixture (SIMP); and complex cereal grain/brassica mixture (COMP). Red Angus-influenced steers (BW = 439 kg ± 15.6, n = 24) were stratified by BW and randomly assigned to 1 of 12 paddocks and were grazed for a 64 d finishing period. Steers had *ad libitum* access to water and free choice mineral, and were given access to strips in each grazing treatment. Fasted BW was measured on d 0, 34, and 64. At the end of the finishing period, steers were slaughtered under Federal Inspection and carcass data were collected 48 h post-mortem. Data were analyzed using Proc Mixed (SAS v 9.4) where paddock was the experimental unit. There was a treatment by period interaction for d 64 BW ($P < 0.01$) where steers on MIX and COMP had greater BW (517 kg ± 8.1 and 514 kg ± 8.1, respectively) than SIMP (490 kg ± 8.1). Steers in MIX and COMP had similar d 0 to 64 BW gains (78 ± 4.3 kg, and 74 ± 4.3 kg), however steers in COMP had greater ($P < 0.01$) d 34 to 64 BW gains than MIX and SIMP (48 ± 1.6 kg versus 34 ± 1.6 kg and 31 ± 1.6 kg, respectively). Although d 64 BW were similar for COMP and MIX, there was a decided advantage ($P < 0.01$) for steers in COMP for HCW and dressing percent (295 kg ± 5.6 and 57.29% ± 0.55). Although there were no differences for LM area, marbling score or USDA yield grade, carcasses from steers in COMP had numerically greater means (69.7 ± 2.8 cm^2, 483 ± 16.9, and 2.5 ± 0.2, respectively) for each carcass trait when compared with MIX and SIMP. These data indicate that steers grazing MIX and COMP had reasonable gains and carcass merit and these systems can be a viable component of forage-finishing systems in the Upper Midwest.

Key Words: beef, forage-finished, grass-finished

62 Using weekly pasture growth and utilization measurements to make management decisions on Oregon dairies. Troy W. Downing*, *Oregon State University, Corvallis, OR.*

The use of weekly pasture cover measurements have been shown useful in New Zealand dairies to estimate daily growth rates, determine grazing rotation, calculate feed inventories and they have been used for feed budgeting. The objectives of this study were to take weekly pasture growth measurements to estimate growth and utilization and to learn how to use this information to make management decisions on Oregon dairies. Additionally, all conserved feed fed was recorded daily and milk solids shipped were recorded and these data were used to estimate the percentage of milk produced from pasture. This study was done on one dairy for a 3-year period. Pastures were measured and mapped and total standing DM was estimated weekly in 22 pastures using a calibrated rising plate meter. Paddocks grazed and residual pasture covers were recorded daily and forage cover measurements were entered into management software. Paddock grazing and residual heights were also included in the electronic recordkeeping. Measurements started in March and continued until the end of November for all 3 years. Weekly grazing wedges were developed and were used to make grazing decisions that week. Estimated dry matter yields for all paddocks each year averaged 18695 ± 3451, 17848 ± 3966 and 17306 ± 5058 kg/ha for each consecutive year. Daily pasture DM growth averaged 47, 49 and 56 kg/ha per day for each of the growing seasons. During year 1 the dairy averaged 1219 kg of milk solids per hectare from grass, 888 kg milk solids for year 2 and 962 kg of milk solids per hectare in year 3. Pasture accounted for 85, 72, and 80% of the total DM consumed on the dairy during the 9 mo grazing season for year 1, 2, and 3, respectively.

Key Words: rotational grazing, rising plate meter, pasture management

63 Evaluation of sound-based detection of rumination in grazing dairy cows. Santiago A. Utsumi*[1], Julio R. Galli[2], Diego Milone[3,4], Hugo L. Rufiner[3,4], and Leonardo Giovanini[3,4], [1]*Michigan State University, East Lansing, MI,* [2]*Universidad Nacional de Rosario, Santa Fe, Argentina,* [3]*Universidad Nacional del Litoral, Entre Rios, Argentina,* [4]*CONICET, Argentina.*

Individualized monitoring of rumination time (RT) could be used to guide nutritional recommendations for improved production, health and well-being of dairy cows. One commercial application is the QWES-HR Tag system (HR Tags), which uses a microphone and microprocessor in neck collars for sound-based detection of RT; filtered sounds in 12 × 2 h intervals are automatically integrated for estimation of 24 h moving RT, but inaccurate detection or processing of sounds could significantly affect estimations. A study was conducted to compare the automatic detection of RT by HR Tags against observed values obtained by supervised inspection of 24-h soundtracks. The RT of 5 lactating Holstein cows on ryegrass/white clover or orchardgrass/white clover pastures was monitored for 6 non-consecutive days, using 2 sound-based methods (1) HR Tags and, (2) Acoustic Halters, which included a digital recorder and one directional microphone pressed to the animal's forehead (Control). Five halters were used with halters rotated across cows according to a completely randomized design. Cross-validation of HR Tags (24-h and 2-h periods) was conducted by inspection of the root of the mean squared prediction error (RMSPE) and concordance correlation coefficient (CCC) between methods. The HR Tags consistently underestimated RT by 18%, regardless of the period of measurement (Table 1). Similarly, high RMSPE and low CCC indicated limited accuracy and low precision by HR Tags, which were slightly improved for 24 h evaluations (Table 1). Further research is needed to improve the automatic sound-based detection of rumination by commercial HR Tags.

Table 1 (Abstr. 63). Estimation of 24-h and 2-h rumination time by 2 acoustic methods

Rumination time/ measurement period		Control	HR Tags
24 hour (n = 29)	Mean (min)	534	437
	SE (min)	19.2	25.4
	RMSPE (min)	90.7	
	CCC (%)	36.6	
2 hour (n = 349)	Mean (min)	44.3	36.3
	SE (min)	1.7	1.2
	RMSPE (min)	30.6	
	CCC (%)	23.8	

Key Words: acoustics, grazing behavior, rumination

64 Evaluation of forage quality of five grains for use in sprouted fodder production systems for organic dairy cattle.

Bradley J. Heins*[1], James C. Paulson[2], and Hugh Chester-Jones[3], *[1]University of Minnesota, West Central Research and Outreach Center, Morris, MN, [2]University of Minnesota Extension, Rochester, MN, [3]University of Minnesota, Southern Research and Outreach Center, Waseca, MN.*

The objective of the study was to evaluate 5 grains for use in sprouted fodder productions systems at the University of Minnesota's West Central Research and Outreach Center, Morris, MN. Forage mass, mold score, dry matter, and forage quality were evaluated for varieties of sprouted organic barley, oats, wheat, rye, and triticale harvested at 7 d after the start of sprouting. During September 2014, on every Monday for 6 weeks, 28 fodder trays (0.6 m x 1.8 m) from a FarmTek Fodder Pro system were filled with 4.1 kg of pre-soaked grain, which was soaked for 24 h. Each tray was automatically watered 3 times a day for 4 min each time. On the seventh day, each tray was harvested, weighed, and visually scored on a 1 to 5 scale for mold by one observer. Ten random samples from each sprouted grain each week were saved for dry matter and forage quality analysis. Sprouted forage samples were sent to Rock River Laboratory, Inc., Watertown, Wisconsin, and were analyzed by wet chemistry for DM, CP, NDF, and TDN. Data were analyzed using the MIXED procedure of SAS. Independent variables for analyses were the fixed effects sprouted grain, and date of harvest and replicate were random effects. Sprouted barley (9.3 kg), oats (9.0 kg), and wheat (8.8 kg) had greater ($P < 0.05$) forage mass per tray than sprouted rye (7.8 kg) and triticale (6.3 kg). Mold scores were lower ($P < 0.05$) for sprouted barley (0.04) and oats (0.03) compared with sprouted rye (2.8) and triticale (4.8). Sprouted barley DM (15.4%) was lower ($P < 0.05$) than sprouted oat (19.1%), rye (19.8%), triticale (24.2%), and wheat (18.9%) DM. Concentrations of CP averaged 15.6%, 13.1%, 12.8%, 17.0%, and 17.9% for sprouted barley, oats, rye, triticale, and wheat, respectively, and they were different ($P < 0.05$) from each other. The NDF was greater ($P < 0.05$) for sprouted barley and oats (34.4% and 44.8%, respectively) compared with sprouted rye, triticale, and wheat (23.6%, 20.4%, and 26.7%, respectively). Sprouted triticale (79.7%) had higher TDN than sprouted oats (71.8%), which was the lowest for TDN. In summary, the results show that sprouted barley has the highest forage quality for fodder production systems.

Key Words: sprouted fodder, NDF, forage quality

65 Protein quality of grass silage as affected by silage additives and its effects on dairy cow performance.

Elisabet Nadeau*[1], Björn Johansson[2], Wolfram Richardt[3], and Michael Murphy[2], *[1]Swedish University of Agricultural Sciences, Skara, Sweden, [2]Lantmännen Feed Division, Malmö, Sweden, [3]LKS mbH, Lichtenwalde, Germany.*

This experiment was conducted to evaluate the effects of improved protein quality of grass silage by additive use on dairy cow intake and performance. Grass from the first regrowth was wilted to 33% DM before being precision chopped and treated with the inoculant Kofasil Duo (*Lactobacillus plantarum/Lactobacillus buchneri*, 200,000 cfu/g) or with the chemical additive Kofasil Ultra K (sodium nitrite, hexamine, potassium sorbate, sodium benzoate and sodium propionate, 2 L/T, Addcon Europe GmbH), which were compared with a control without additive. The forage was ensiled in hard-pressed round bales before being fed to 48 dairy cows (150 DIM) in a continuous trial for 9 wk using 8 cows per treatment. Cows were blocked according to breed, parity, DIM and milk yield. The silage contained 15% CP, 47% NDF, 3.3% WSC, 8.2% lactic acid, 2.1% acetic acid and 0.25% NH3-N of DM with minor differences between treatments. Rumen undegradable protein (RUP) of the silage at 5% passage rate was 22, 23 and 24% of CP for control (C), inoculant (I) and salt-based (S) additive, respectively. Diets were isonitrogenous (15.1% of DM) and isoenergetic (11.4 MJ/kg DM) varying in RUP (4.7% (high) and 2.5% (low) of DM). Concentrate UDP was 2.9 and 8.6% of DM. Dietary forage proportion of the TMR was 58% of DM. Data were analyzed using PROC MIXED of SAS with RUP, silage and week as fixed factors and block as a random factor. High RUP diet had higher milk yield than low RUP diet (29.4 vs. 27.9 kg; $P < 0.05$). The DM intake was not affected by RUP and silage treatment. Yields of milk and ECM were higher for the I and S diets than for the C diet at low RUP (28.9 vs. 26.0 kg milk, $P < 0.01$; 30.6 vs. 27.1 kg ECM, $P < 0.001$) whereas there was no effect of additive treatment in the high RUP diet. Milk fat and protein did not differ between silage treatments. Feed efficiency was higher for the I and S diets than for the C diet at the low RUP (1.6 vs. 1.3 kg of ECM/kg DM intake, $P < 0.001$) but not at the high RUP. The increased milk yield and feed efficiency when fed a diet with low RUP can partly be explained by increased RUP of the I and S silages.

Key Words: additive, protein quality, silage

66 Effects of type and level of energy supplementation on stocker cattle performance from annual ryegrass.

Carla J. Weissend*, Courteney M. Holland, Kaleb B. Marchant, Samantha R. Sechler, and Russell B. Muntifering, *Auburn University, Auburn, AL.*

Supplementation of high-quality grazed forage with high-energy feedstuffs can improve animal performance and enable increased stocking rates. However, the extent of performance improvement and direction of forage utilization response may be dependent upon supplementation level and whether the supplement is a high-starch or highly-digestible-fiber feedstuff. For these reasons, a grazing experiment was conducted to determine the type and level of supplementation with select high-energy feedstuffs that yield optimum animal performance and forage utilization from annual ryegrass (*Lolium multiflorum*). Twenty 0.81-ha pastures were each grazed by 4 crossbred steers (235 kg ± 15 kg initial BW) between Feb. 6 and May 15, 2014. Cracked corn (CC), pelleted citrus pulp (CP) or pelleted soybean hulls (SH) were fed at rates of 0.25, 0.50 and 0.75% of steer BW daily (2 rate × supplement replicates per treatment, including replicate pastures in which steers received no supplement). Steers were weighed every 28 d following an overnight shrink. Forage mass was measured every 28 d using the destructive harvest/disk meter dual-sampling method. Data were analyzed as a completely randomized design by the PROC GLM procedure of SAS 9.2 using pasture as the experimental unit. There were no supplement type × level interactions ($P > 0.05$) observed for either ADG or net forage mass change (FMC). Steers receiving CC and SH supplementation had greater ($P < 0.05$) ADG (1.30 and 1.23 kg/d, respectively), and steers receiving CP tended ($P = 0.07$) to have greater ADG (1.20 kg/d) than steers receiving no supplement (0.95 kg/d). Steers supplemented at 0.25 and 0.75% BW had greater ($P < 0.05$) ADG (1.23 and 1.30 kg, respectively) than steers receiving no supplement (0.95 kg/d). Net FMC over the entire grazing season increased ($P < 0.05$) in pastures grazed by steers receiving CC (+38 kg DM/ha) compared with those grazed by steers receiving SH (−277 kg/ha). There were no differences in net FMC between any of the supplementation types or levels and the unsupplemented control. Patterns of net FMC response indicate relative underutilization of forage by steers receiving CC (i.e., substitution effect of supplementation) compared with steers receiving SH or CP.

Key Words: beef cattle, ryegrass, supplementation

67 Performance of *Bos indicus* versus *Bos taurus* stocker cattle grazing 'Coastal' bermudagrass supplemented with distillers dried grains.

W. Brandon Smith*[1], F. M. "Monte" Rouquette[1], Joel L. Kerby[1], Luis O. Tedeschi[2], Jamie L. Foster[3], Jason P. Banta[4], Kimberly C. McCuistion[5], and Tanner J. Machado[5], [1]*Texas A&M AgriLife Research, Overton, TX,* [2]*Texas A&M University, College Station, TX,* [3]*Texas A&M AgriLife Research, Beeville, TX,* [4]*Texas A&M AgriLife Extension, Overton, TX,* [5]*Texas A&M University-Kingsville, Kingsville, TX.*

The objective of this study was to evaluate performance of "long yearling" stocker steers grazing 'Coastal' bermudagrass (*Cynodon dactylon* [L.] Pers.) and supplemented daily with titrated levels of DDG. Steers (n = 63 [7 testers per pasture; 4 Brahman, 3 other], 352 ± 7.6 kg initial BW, approx. Fifteen mo of age) were stratified by BW within source (Overton or McGregor) and known sire breed type (Angus or Charolais, both with Brahman crossbred dams; or purebred Brahman) and allocated randomly to 1 of 9 paddocks (1.3 ± 0.17 ha), and paddocks were allocated randomly to 1 of 3 levels of DDG supplementation for the 96-d study: 0.00, 0.25 or 1.00% BW hd^{-1} d^{-1}. Animals were group-fed daily at 0800 h, and bunk space was allowed at a minimum of 61 cm hd^{-1}. Forage mass was assessed by destructive harvest of four 0.09-m^2 quadrats throughout each pasture on 21-d intervals. Steers were weighed every 21 d, and grazers were added to each pasture based on visual and numerical assessments to maintain vegetative growth while preserving ad libitum intake and selection. Data were analyzed using SAS PROC MIXED. Average daily gain was greater ($P < 0.05$) from steers offered 1.00% BW daily (0.97 kg d^{-1}) compared with those offered 0.00 or 0.25% BW daily (0.71 and 0.69 kg d^{-1}, respectively), and *Bos indicus* steers gained more (0.93 kg d^{-1}; $P < 0.05$) than *B. taurus* steers (0.72 kg d^{-1}). Supplement to gain ratio was not different among treatments ($P = 0.29$) or species ($P = 0.76$). Pastures in which supplement was offered at 1.00% BW tended to sustain more ($P = 0.06$) AU (363-kg steer) per ha (8.8 AU ha^{-1}) compared with 0.00% pastures (6.3 AU ha^{-1}), with 0.25% pastures intermediate (8.2 AU ha^{-1}). Additionally, pastures supplemented at 1.00% BW supported more ($P < 0.05$) gain per unit area (851 kg ha^{-1}) than pastures supplemented at 0.00 or 0.25% (431 and 575 kg ha^{-1}, respectively). Thus, supplementation of stocker calves with DDG at the 1% level, especially *B. indicus*, may be a viable option for increased performance from stocker cattle, as well as increased stocking density, on bermudagrass pastures, depending on the economic factors of the current market.

Key Words: Coastal bermudagrass, DDG, stocker

68 Interaction between a tannin-containing legume and endophyte-infected tall fescue seed on lamb feeding behavior and physiology.

Juan J. Villalba*[1], Casey Spackman[1], Ben Goff[2], James L. Klotz[3], and Jennifer W. MacAdam[1], [1]*Utah State University, Logan, UT,* [2]*University of Kentucky, Lexington, KY,* [3]*USDA-ARS, Lexington, KY.*

It was hypothesized that a tannin-rich legume like sainfoin reduces the negative postingestive effects of ergot alkaloids in tall fescue. Thirty-two 3-mo-old lambs were individually penned and randomly assigned to a 2 × 2 factorial experimental design with 2 legume species (sainfoin [SF; tannins] or cicer milkvetch [CIC; no tannins]) and a ration (seed:beet pulp:alfalfa, 50:30:20) containing 2 types of tall fescue seed (endophyte-infected [E+;1,745 ppb ergovaline] or endophyte-free [E–]). For a 10-d baseline period, all groups were fed their respective supplemental legumes (17 to 25 g DM/kg BW) and ad libitum amounts of E–. In an ensuing 10-d testing period, the protocol was the same but half of the lambs received E+ instead of E-. Daily feed intake and rectal temperatures were measured for both periods and jugular blood was extracted at the beginning and end of the testing period. Subsequently, all lambs had choices between their respective legume (SF; CIC) and seed-containing rations (E+; E–). Response variables were analyzed using a mixed effects model, which included legume, ration and day as fixed effects and lamb as a random factor. All groups consumed similar amounts of E– during baseline ($P > 0.10$). However, lambs ate more E– than E+ during testing ($P < 0.05$) and lambs offered SF ate more E+ than lambs offered CIC ($P < 0.05$). Groups fed E– during baseline and testing periods had similar rectal temperatures ($P > 0.10$). However, lambs fed E+ had lower rectal temperatures when supplemented with SF than with CIC ($P < 0.05$). Lambs fed E+ had a greater concentration of hemoglobin and number of red blood cells than lambs fed E– ($P < 0.05$). Plasmatic concentrations of cortisol and prolactin did not differ between treatments ($P > 0.10$). All lambs preferred their respective rations over their respective legumes and they preferred E– over E+ ($P < 0.05$). In summary, SF increased intake of E+ and reduced rectal temperatures relative to CIC supplementation. However, SF did not lead to changes in preference for E+ or improvements in other physiological parameters assessed.

Key Words: ergot alkaloids, ingestive behavior, prolactin

69 Effect of a combination of lactic acid producing bacteria and fibrolytic enzymes on the ensiling characteristics of cool season grasses: A farm-scale application.

Jeffrey M. Chilson*, Chia-Yu Tsai, Kirk C. Ramsey, Richard Scuderi, and Pedram Rezamand, *University of Idaho, Moscow, ID.*

In prior research, using a combination inoculant containing homofermentative lactic acid bacteria and fibrolytic enzymes we showed an improvement in rumen DM degradation, lactic acid production and rate of pH decline, for alfalfa using small scale setting. The objective of the present study was to test the effectiveness of the inoculant on the quality of ensiled mixed cool season grasses (orchard, oat, mountain brome and Italian rye grasses) in a farm scale setting. Grasses were harvested and the windrows randomly assigned to either the control (Con) or inoculant (Trt). The Con was treated with water only and Trt was treated with an equal amount of water plus the inoculant. Control was baled, and wrapped first, followed by Trt. On d 86, 88, 90, 92, 94, 3 bales from each group were removed, weighed, core samples taken and composite samples prepared for analysis. Composite samples were analyzed for pH, lactic acid, DM, and NDF. Statistical analysis was conducted using a T-Test, on SAS v. 9.4. Initial DM did differ between Con and Trt ($P = 0.03$; 52.3 vs. 58.4 ± 1.9%) possibly related to temperature change (start 16°C, finish 32°C) during baling. Initial pH was not different between Con and Trt. Initial NDF was not different between groups ($P = 0.15$; 60.02 vs. 58.29 ± 0.72%). Final pH was not different between Con and Trt, either ($P = 0.45$; 5.24 vs. 5.36 ± 0.12). DM loss was numerically greater for Con, but not significant, either on kg/bale basis ($P = 0.39$; 91.7 v. 85.9 ± 12.5kg) or as a percent/bale basis ($P = 0.32$; 24.9 vs. 20.9 ± 3.0%). Lactic acid production was not different between groups ($P = 0.14$; 40.89 vs. 75.24 ± 19.88 μmol/g DM). There was, however, a significant difference in final NDF between Con and Trt ($P = 0.04$, 55.25 vs. 57.84 ± 0.81%). Whereas Trt showed greater NDF, Con had numerically greater DM loss, possibly indicating that Con lost more soluble nutrients during ensiling. Furthermore, final pH for both Con and Trt were above desired pH of 4.00–4.20, which could indicate that fermentation was in part inhibited by the high initial DM.

Key Words: inoculant, silage, grass

70 Structural changes and texture development in milk protein concentrates induced by high hydrostatic pressure.

Lee Cadesky*[1], Markus W. Ribeiro[1], Mukund V. Karwe[2], and Carmen I. Moraru[1], *[1]Cornell University, Ithaca, NY, [2]Rutgers University, New Brunswick, NJ.*

Milk protein concentrate (MPC) and micellar casein concentrate (MCC), obtained by membrane filtration, are increasingly available. This research focuses on utilizing high hydrostatic pressure (HHP) to induce structural modifications of milk proteins in MPC and MCC and enable the creation of new textures that may find application in milk protein based products. MPC and MCC powders were reconstituted by dispersing the powders in water to 2.5 and 10% casein (w/v), and allowed to fully hydrate. The concentrates were packaged in flexible pouches and subjected to 15 min HHP treatments at 150, 250, 350, and 450 MPa, at temperatures below 25°C, in a 10 L HHP unit. Pressure induced structural changes to casein micelles in HHP treated samples were assessed by (a) evaluating the renneting behavior of the protein concentrates using dynamic rheology; (b) mineral and proteomic profiling of ultracentrifugation supernatants. The study was replicated, and significant differences among treatments were assessed by statistical analyses. In all samples, HHP treatment increased calcium levels in the serum as compared with untreated controls ($P < 0.05$). HHP treatments at 250 and 350 MPa resulted in levels of serum calcium over 3.5 times higher than in untreated samples. HHP above 250 MPa induced significant ($P < 0.05$) concentration and pressure dependent changes in MCC and MPC. In both 10% MCC and 10% MPC, HHP above 350 MPa led to the formation of weak gel structures. HHP treatment also increased G' values of rennet gels and reduced coagulation times, which indicates a destabilization of casein micelles following pressure treatment. In 10% MCC, maximum gel strength was observed after 150 MPa treatment, with G' of 140 Pa as compared with 45 Pa in untreated samples. For 10% MPC, HHP treatment enabled rennet coagulation, which did not occur in untreated samples. MPC renneted gels were weak, with 450 MPa treatment resulting in the strongest gels (G' of 36 Pa). These observations suggest that HHP treatment of milk protein concentrates can be used for developing new types of dairy-based, protein rich foods with unique structure and texture.

Key Words: high-pressure processing, proteins, rheology

71 Solubilization of rehydrated frozen highly concentrated micellar casein concentrate for use in liquid food applications.

Ying Lu*[1], Donald McMahon[1], Lloyd Metzger[2], Anil Kommineni[2], and Almut Vollmer[1], *[1]Western Dairy Center, Utah State University, Logan, UT, [2]Midwest Dairy Foods Research Center, South Dakota State University, Brookings, SD.*

Highly concentrated micellar casein concentrate (HC-MCC), a potential ingredient for protein fortification, containing ~20% casein with most whey proteins removed by microfiltration, diafiltration, and vacuum evaporation of skim milk. Our objective was to determine the conditions needed to obtain complete solubility of thawed frozen HC-MCC in water, and to understand its gelation upon cooling. Dispersibility (ability to pass through a 250-μm mesh sieve), suspendability (percentage of protein not sedimented at 80 × g within 5 min), and solubility (percentage of protein not sedimented at 20,000 × g within 5 min) were measured at various mixing conditions. Gelation upon cooling from 50°C to 5°C was monitored based on storage (G′) and loss (G″) modulus and gelled HC-MCC examined using transmission electron microscopy. Thawed HC-MCC was added to water (3% of protein) using high shear (7,500 rpm) for 1 min or low shear (800 rpm) for 30 min at 4, 12, 20, or 50°C and at pH 6.4 to 7.2. The HC-MCC completely dispersed at 50°C, or at ≤ 20°C followed by overnight hydration at 4°C. Suspendability at 50°C was ~90%, while mixing at ≤ 20°C followed by overnight hydration yielded only ~57%. Solubility followed a similar trend with ~83% at 50°C and only ~29% at ≤ 20°C. Mixing HC-MCC in 60 mM trisodium citrate increased dispersibility to 99%, and both suspendability and solubility to 81% at 20°C. Cold gelling temperature, defined as temperature at which G′ = G″, was positively correlated (R^2 = 0.97) with protein level in HC-MCC. Gelation occurred at 38, 28 and 7°C with 23, 20, and 17% of protein, respectively. Gelation was reversible upon heating. In micrographs of gelled HC-MCC, casein micelles were observed to be within the normal range and close packed together with only ~20 to 50 nm space between them. We propose that cold gelation of HC-MCC occurs when the kinetic energy of the casein micelles is sufficiently reduced to inhibit their mobility in relation to adjacent casein micelles. Understanding solubilization of rehydrated frozen HC-MCC and its rheological property can help designing process systems for using it as a potential ingredient in liquid food.

Key Words: casein micelle, microfiltration, solubility

72 Development of a method for characterizing high-protein dairy powders with an ultrasonic flaw detector.

Mary Hauser* and Jayendra Amamcharla, *Kansas State University, Manhattan, KS.*

When choosing a high-protein dairy powder such as milk protein concentrate (MPC), dissolution behavior is an important property to consider. Current methods for testing powder dissolution are time consuming, difficult to reproduce, and subjective. Ultrasound spectroscopy is a rapid and precise method, but expensive equipment and skilled technicians are needed. An economical alternative is to use an ultrasonic flaw detector (UFD). The objective of study was to develop a method to characterize the dissolution behavior of MPC with an UFD. The experimental setup included an UFD (Epoch LTC) in pulse-echo mode and a 1MHz immersion transducer that was kept a constant distance from the reflector plate. Powder concentration, stirring speed, UFD settings, and path length were optimized. To validate the method, 2 batches of MPC80 from a commercial manufacturer were procured and stored at 25°C and 40°C for 4 weeks. MPC was slowly added to water at a 5% concentration. During the dissolution, A-Scan data from UFD was acquired to calculate velocity and attenuation. Focus beam reflectance measurement (FBRM) and solubility index were used as reference methods. Velocity had a trend of fluctuating and then stabilizing with fluctuation time increasing with storage time. Due to the variation in fluctuation, the standard deviation from 900 to 1800s was set as a parameter. Day 0s standard deviation was 0.01 m/s and increased to 0.1 m/s after 4 wk at 40°C. During dissolution, attenuation increased and then gradually decreased. From the attenuation, 3 parameters were extracted. The area under the curve from 0 to 1800s showed the most changes. From Day 0 to wk 4 at 40°C, the area decreased from 100 to 110 Np·s/m to below 30 Np·s/m. After comparing all the data, it was observed that fresh powders dispersed quickly, had a low standard deviation and a larger area. As the MPC aged at 40°C, the particle dispersion rate decreased and an increase in standard deviation and reduction in area were observed. Overall, the UFD can be a low cost method to characterize the dissolution behavior of dairy powders.

Key Words: ultrasonic flaw detector, milk protein concentrate, solubility

73 The effect of spray-drying parameters on the flavor of skim milk powder.

C. W. Park*, M. A. Stout, and M. A. Drake, *Southeast Dairy Foods Research Center, North Carolina State University, Raleigh, NC.*

Unit operations during production influence the sensory properties of skim milk powder (SMP). Off-flavors associated with SMP decrease consumer acceptance of ingredient applications. Previous work has shown that spray drying parameters such as inlet temperature and feed solids concentration affect physical and sensory properties of whole milk powder and whey protein concentrate. The objective of this study was to determine the effect of inlet temperature and feed solids concentration on the flavor of SMP. Pasteurized skim milk was evaporated to 50% total solids by a falling film evaporator. The condensed milk was then spray dried at either 160, 210, or 260°C inlet temperature and either 30, 40, or 50% total solids in a randomized order. Warm deionized water was added to achieve 30 and 40% solids condensed milk. The entire experiment was replicated 3 times. Flavor of the SMP was evaluated by sensory and instrumental analyses, which included descriptive analysis and solvent extraction with solvent-assisted flavor evaporation followed by gas chromatography mass spectrometry. Surface free fat and particle size were also analyzed. Both main effects (30, 40, 50% solids and 160, 210, and 260°C inlet temperature) and interactions between solids concentration and inlet temperature were investigated. Interaction effects were not significant ($P > 0.05$). Decreasing inlet temperature decreased overall aroma, sweet aromatic and cooked flavors, and 2-acetyl-1-pyrroline and furaneol concentrations and increased cardboard flavor and hexanal, heptanal, nonanal, furfuryl alcohol, and 2,4-decadienal concentrations ($P < 0.05$). Increasing solids concentration increased sweet aromatic flavor and 2-acetyl-1-pyrroline concentration, while 30% solids concentration increased cardboard flavor and hexanal, nonanal, DMTS, and furfuryl alcohol concentrations compared with 40 or 50% solids ($P < 0.05$). Particle size increased and surface free fat decreased with increasing inlet temperature and solids concentration ($P < 0.05$). These results demonstrate that increasing inlet temperatures and solids concentration during spray drying decrease off-flavor intensities in SMP.

Key Words: skim milk powder, spray drying, flavor

74 Using membrane filtration to fractionate acid whey into value-added ingredients.

Bang Chen*[1], Karen E. Smith[2], John A. Lucey[2,1], Rebecca Kalscheuer[2], and Michael Molitor[2], [1]*University of Wisconsin-Madison, Madison, WI,* [2]*The Wisconsin Center for Dairy Research, Madison, WI.*

There has been a huge expansion in acid whey production due to the rapid growth in Greek yogurt manufacture, therefore it is critical to find an economically feasible way to process acid whey. The objective of this study was to determine the suitability of novel experimental nanofiltration (NF) membranes to reduce the calcium content of acid whey, so that value added streams (e.g., lactose) could be produced from this whey. Approximately 1,000 L of acid whey was obtained from a local Greek yogurt manufacturer for each trial. A 10,000 Da UF membrane was used to produce a permeate stream (i.e., remove any residual proteins). Acid whey was then processed by one of 4 different NF membranes. Three novel NF membranes were evaluated for divalent ion permeation and compared with a control NF membrane. Permeates were concentrated to 1× and 2×, and were sampled at processing pressures of 1380, 2760 and 4140 kPa, and at operating temperatures of 4, 21, 43 and 54°C. Flux also was recorded. Total solids, lactose, galactose, lactic acid and calcium contents of the NF permeates/ retentates were determined. The calcium/lactose ratio in the permeate was determined. We wanted a high ratio of calcium to lactose in the permeate so that we could successful reduce the ash content of acid whey while retaining lactose. Higher temperatures and higher pressures yielded higher rates of component permeation for each type of membrane. The novel NF membranes had higher permeation of all components, compared with the control NF membrane. Lactose and calcium permeated the novel NF membranes to differing degrees, in contrast to the control NF membrane. Permeates were further concentrated (6×) by 1 of 2 novel membranes, or a control membrane. The composition of final concentrates and samples taken during the process of concentration were analyzed. The results indicated that the novel membranes had good retention of lactose while calcium permeation increased as the permeate concentration increased. Lactose hydrolysis tests were performed on NF concentrates of acid whey by utilizing a commercially available lactase enzyme with an acidic pH optimum. The end product of this hydrolysis was a dairy syrup with enhanced sweetness.

Key Words: acid whey, membrane processing, nanofiltration

75 Hydrodynamic cavitation as a tool to improve texture, mouthfeel, and creaminess in formulated and high-protein, low-fat Greek yogurts.

Gopinathan H. Meletharayil* and Hasmukh A. Patel, *South Dakota State University, Brookings, SD.*

Greek yogurt (GY) manufacturing involves a straining step that generates acid whey, which has led to processing and environmental concerns. Non-strained yogurt (GSY) can be the solution to this problem. However, GSY is unacceptable to consumers because of its tart astringent taste, gritty and chalky texture and lack of creamy mouthfeel, taste, and flavor. We explored the use of hydrodynamic cavitation in conjunction with CO_2 treated functional milk proteins to develop a low fat GSY having rheological and organoleptic profiles similar to GY. CO_2 treated milk retentate was added to skim milk and NFDM base to yield 9% (w/w) protein and 17% (w/w) total solids. The mixture was heated to 90°C for 10 min followed by cooling to 42°C. The milk was fermented with yogurt culture to pH 4.6, followed by rapid cooling to less than 10°C. The yogurt was then subjected to hydrodynamic cavitation using an APV cavitator (SPX Flow Technology, Denmark). Rheology, large deformation studies, % lactic acid (LA) organic acid profiles using HPLC, graininess using microscopy and organoleptic profile (mouthfeel and creaminess) using sensory panel were investigated. Experimental data were tested for ANOVA and statistical significance ($P < 0.05$) was determined, using statistical software SAS. Hydrodynamic cavitation reduced the consistency coefficient of GSY to values similar to those obtained in commercial GY. Cavitation of GSY reduced the number of grains from 2389 to 35 grains/g compared with 293 grains/g in commercial GY. There was no significant difference in the LA content between the cavitated GSY and commercial GY. Organic acid profiles of the strained and non-strained cavitated yogurts were superimposable. GSY subjected to hydrodynamic cavitation had better mouthfeel and creaminess compared with commercial GY. Based on these results, it can be concluded that the combination of CO_2 treated proteins and hydrodynamic cavitation can be used as a promising solution to manufacture GSY with rheological and organoleptic profiles better or similar to GY. This processing innovation will help to reduce processing times, capital investments and more importantly the vexing problem of acid whey disposal.

Key Words: hydrodynamic cavitation, Greek yogurt, texture

76 Engineering of infant formula emulsions to enhance protein thermal stability through Maillard conjugation. Kamil P. Drapala*, Daniel M. Mulvihill, and James A. O'Mahony, *School of Food and Nutritional Sciences, University College Cork, Cork, Ireland.*

Comfort-type infant formula (IF) emulsions are frequently manufactured using whey protein hydrolysate (WPH) ingredients; however, stability of these emulsions to heating is often poor. The objective of this study was to improve heat stability of such emulsions by conjugation of WPH with maltodextrin (MD) through wet heating. Model IF emulsions (1.55% protein, 3.50% oil, 7.00% carbohydrate) were prepared using whey protein isolate (WPI), WPH, heated WPH or WPH-MD conjugate. The conjugate was prepared by heating a WPH/MD solution (5.00% protein and 5.00% maltodextrin, pH 8.2) at 90°C for 8 h; heated WPH was prepared in a similar manner but in the absence of MD. Emulsions were heated at 75°C or 95°C for 15 min using a rheometer, with viscosity data recorded throughout the heat treatments, or at 100°C for 15 min using an oil bath. Emulsions were recovered after all heat treatments and changes in viscosity, fat globule size distribution (FGSD) and microstructure, determined using confocal laser scanning microscopy (CLSM), were used to monitor the effects of heating on the structure/stability of the emulsions. Emulsions with similar, monomodal size distributions (mean oil droplet diameter ≤ 1.0 μm) were formed with all protein ingredients (no significant differences, $P < 0.05$). Heat stability of emulsions increased in the order WPH < WPI $\ll$ heated WPH $\lll$ WPH-MD conjugate. A sharp increase in viscosity during heating at 75°C (WPH) or 95°C (WPI) and significantly higher viscosity ($P < 0.05$) post-heat treatment (as compared with initial viscosity) indicated structural rearrangement/coagulation in the WPH and WPI stabilized emulsions; no changes in viscosity on heating were observed for emulsions stabilized with heated WPH or WPH-MD conjugate. After heat treatment at 100°C, flocculation and coalescence of oil droplets in emulsions stabilized by heated WPH were mediated by protein aggregation (as evidenced by CLSM analysis) while no changes in FGSD or microstructure were observed in emulsions stabilized by WPH-MD conjugate. Modification of WPH through conjugation with MD yielded a protein ingredient with superior thermal stability in oil-in-water IF emulsions.

Key Words: protein-carbohydrate conjugation, emulsion thermal stability, infant formula

77 Improvement of the physicochemical and functional properties of whey protein hydrolysates by conjugation. Eve M. Mulcahy*, Daniel M. Mulvihill, and James A. O'Mahony, *School of Food and Nutritional Sciences, University College Cork, Cork, Ireland.*

Proteins can be modified by enzymatic hydrolysis to alter their functionality. The objective of this study was to determine the effect of conjugation on selected physicochemical functionalities (i.e., solubility and solution clarity/heat stability) of either intact whey protein isolate (WPI) or hydrolysed whey protein isolate (WPH). Conjugation of WPI or WPH (degree of hydrolysis of 8%) with maltodextrin (dextrose equivalent value of 6; MD6) was achieved by heating solutions of 5% WPI or WPH and 5% MD6, initial pH of 8.2, at 90°C for up to 24 h. Samples were taken after 3, 5, 8 and 24 h of heating; the greatest reduction ($P < 0.05$) in available amino groups (21.0% reduction in AAG, measured by the o-phthaldialdehyde assay) occurred during the first 8 h of heating for WPH-MD6, with a considerably smaller decrease in AAG between 8 and 24 h of heating, which was consistent with the limited (0.8%) reduction of AAG in WPI-MD6 after 8 h. The number of amino groups available to react with the carbonyl groups of MD6 were 55% higher in WPH than in WPI which contributed to a greater extent of conjugation with the former. Unheated WPI had a protein solubility of 87.3% at pH 4.5; WPI-MD6 conjugate solutions (8 h of heating) had a protein solubility of 40.0% at pH 4.5 while WPH-MD6 conjugate solutions (8 h of heating) had enhanced protein solubility of 78.6% at pH 4.5. Unheated WPI increased in turbidity after thermal treatment for 3 min at 85°C, with 40 m*M* NaCl (48.5% decrease in transmission compared with control) while WPI-MD6 and WPH-MD6 conjugates retained, to a greater extent, solution clarity after heating (3.5 and 0.2% decrease in transmission compared with respective controls). Conjugation of WPH with MD6 resulted in higher levels of conjugation than for WPI and resulted in a conjugate with enhanced functional properties including improved solubility and lower levels of turbidity development in a heated high ionic strength environment compared with unconjugated WPI and conjugated WPI-MD6.

Key Words: conjugation, whey protein hydrolysate, physicochemical functionality

78 Novel application of a fungal catalase preparation to control spore-forming bacteria in the dairy industry. Nuria Garcia-Fernandez*[1,2] and Ashraf Hassan[1], *[1]Dairy Science Department, South Dakota State University, Brookings, SD, [2]Midwest Dairy Foods Research Center, South Dakota State University, Brookings, SD.*

Spores can resist pasteurization, germinate, and grow in the dairy products during storage, causing spoilage. The aim of this work was to investigate the antimicrobial properties of several catalase preparations (Cat) against spore-forming bacteria isolated from dairy sources and their possible applications in milk and cleaning of separation membranes. The antimicrobial activity of a food-grade (FG) commercially available Cat produced by *Aspergillus niger*, a non-food-grade Cat (NFG), and a Cat from bovine liver (BL) against *Bacillus sporothermodurans* (Bs), *Geobacillus stearothermophilus* (Gs), *Bacillus mojavensis* (Bc), *Bacillus licheniformis* (K1), and *Bacillus* spp. (10/1) was assessed by the agar diffusion assay and broth microdilution. The effect of FG Cat on biofilms formed by 2 single strains of slime-producing *Bacillus* (Bc and K1) and a cocktail of 4 strains (Bc, Bs, Gs and 10/1) was studied alone (150 mg/mL) and after a pretreatment with 0.1% Tween 20-PBS buffer. Last, a cocktail of 10^3 spores/mL of 4 strains of *Bacillus* (Bc, Gs, Bs, and 10/1) inoculated in UHT milk was challenged with 0, 6.25 and 12.5 mg/mL of FG Cat for 30 min and the number of survivors was determined. The FG and NFG Cat inhibited the growth of vegetative cells of all tested species of *Bacillus* at 12.5 mg/mL with inhibition zones of up to 25 mm, while BL did not show any inhibition. The FG Cat reduced the number of viable cells in one-day-old Bc and K1 biofilms by 2 and 4.87 log cfu/cm^2 respectively ($P < 0.05$). While the application to a 3-d-old multispecies biofilm reduced the viable counts by only 0.73 log cfu/cm^2, a pretreatment with Tween 20 followed by FG, resulted in a 1.18 log cfu/cm^2 reduction ($P < 0.05$). The FG Cat at 12.5 mg/mL reduced the number of germinating spores in milk by 36.7%. The FG Cat lost antimicrobial activity after heating at 100°C for 10 min. This works describes for the first time the antimicrobial activity of Cat preparations against bacterial spores, which would create new opportunities for the dairy industry to control germination and outgrowth of spore-forming bacteria (patent pending).

Key Words: catalase, antimicrobial, *Bacillus*

79 Impact of buttermilk serum fractions on the rennet coagulation properties of bovine milk. M.-P. Gauvin*[1], M. Britten[1,2], and Y. Pouliot[1], [1]*STELA Dairy Research Center, Institute on Nutrition and Functional Foods (INAF), Université Laval, Québec, Québec, Canada,* [2]*Food Research and Development Center (FRDC), Agriculture and Agri-Food Canada, St-Hyacinthe, Québec, Canada.*

Buttermilk is the aqueous phase obtained after churning of cream into butter. Its composition is similar to that of skim milk except for higher proportion of milk fat globule membrane (MFGM) components. These components seem to interfere with rennet coagulation of milk. The purpose of the present study was to separate buttermilk serum into 3 fractions using centrifugation and determine the effect of each fraction on milk rennet-induced coagulation. Buttermilk and pasteurized skim milk (control) were centrifuged (31,000 *g*, 34°C, 1 h). Three distinct layers of the supernatants were collected: low-density opalescent (LDO), clear (CL) and high-density opalescent (HDO) layers. Protein and fat in these fractions were characterized by gel electrophoresis (SDS-PAGE) and estimation of phospholipid content by colorimetric phosphorus assay after fat extraction by the Mojonnier procedure. Casein micelles from skim milk were collected by centrifugation (31,000 *g*, 20°C, 1 h), redispersed in the different fractions and used to monitor rennet aggregation and coagulation kinetics using dynamic light scattering and rheology. MFGM protein and residual casein micelles were mainly concentrated in the HDO fraction. This fraction from buttermilk contained 3 times more MFGM protein than the same fraction from skim milk, but 35% less casein. Phospholipids were also concentrated in this fraction, 200 mg/100 g and 17 mg/100 g, representing 43 and 39% total fat of this fraction in buttermilk and skim milk, respectively. All buttermilk serum fractions, especially HDO, showed negative effect on rennet coagulation kinetics. Compared with the results obtained with their respective CL fraction (which is the LDO and HDO-depleted fraction), buttermilk HDO slowed down the aggregation rate (−62%) while skim milk HDOL increased it (+42%). In addition, the growth of casein aggregates was rapidly stopped in presence of buttermilk HDO fraction. This suggests that components in this fraction from buttermilk interfere with the aggregation of renneted casein micelles and more investigation is underway to determine the role of MFGM components.

Key Words: buttermilk, MFGM, rennet-induced coagulation

80 Automated detection of estrus using multiple commercial precision dairy farming technologies in synchronized dairy cows. L. M. Mayo*, W. J. Silvia, G. Heersche, I. C. Tsai, B. A. Wadsworth, A. E. Stone, and J. M. Bewley, *Department of Animal and Food Sciences, University of Kentucky, Lexington, KY.*

Detecting dairy cattle estrus helps determine optimal breeding time. Dairy cattle estrus varies in length and intensity, increasing the need for accurate and continuous estrous detection. The objective of this study was to evaluate precision dairy farming technologies (PDFT) for estrous detection. The estrous detection efficiency of PDFT is predicted to be greater than traditional visual observation of estrus. Estrus was synchronized in 24 lactating Holstein dairy cows using a modified G7G-Ovsynch protocol (last GnRH injection withheld to permit expression of estrus) beginning 45 to 85 DIM. Resumption of ovarian cyclicity at enrollment, presence of a corpus luteum (CL) on the day of the final injection (designated experimental day 0), regression of the CL by d 5, and presence of a new CL on d 11 were verified by transrectal ultrasonography. Cows were observed for estrous behaviors for 30 min, 4X per day, on days 2 to 5. Blood samples were collected on d −2, −1, 0, 1, 2, 5, 7, 9, and 11 to quantify progesterone to verify luteal regression and ovulation. Potential periods of estrus (gold standard) were defined by the temporal pattern of progesterone (>1.0 ng/mL on d −2, −1 and 0, <1.0 ng/mL on d 2, and >1.0 ng/mL on d 9 and 11). Detection of estrus by PDFTs, an estrous behavioral scoring system, and by visual observation of standing estrus were compared to the gold standard (Table 1). Sensitivity and specificity for detection of estrus was similar among all PDFT. Only 56% of cows that ovulated were observed standing by visual estrous detection. All systems tested are capable of detecting estrus at least as effectively as visual observation.

Table 1 (Abstr. 80). Detection of estrus using alerts generated by PDFT[1] and visual observation (n=24)

Detection method	TP	FP	TN	FN	Sensitivity (%)	Specificity (%)
Afimilk AfiAct Pedometer Plus	16	0	6	2	89	100
GEA CowScout (leg version)	15	0	6	3	83	100
ENGS Track A Cow	14	0	6	4	78	100
Agis SensoOr	14	0	6	4	78	100
Estrus behavioral score[2]	12	1	5	6	67	83
Standing behavior	10	0	6	8	56	100

[1] Sensitivity = TP/(TP + FN) and specificity = TN/(TN + FP); where TP = true positive, TN = true negative, FP = false positive, and FN = false negative.

[2] Scoring system as defined by Van Eerdenburg et al. (1996).

Key Words: automated estrus detection, precision dairy technology, estrous behavior

81 Effect of nutrition and management practices on de novo fatty acid synthesis in northeastern US dairy herds. Melissa E. Woolpert*[1,2], Catarina Melilli[3], Kurt W. Cotanch[1], Heather M. Dann[1], Rick J. Grant[1], Larry E. Chase[3], and David M. Barbano[3], [1]*William H. Miner Agricultural Research Institute, Chazy, NY,* [2]*University of Vermont, Burlington, VT,* [3]*Cornell University, Ithaca, NY.*

This study investigated the effects of management practices and dietary chemical characteristics on de novo fatty acid (FA) concentrations in bulk tank milk from commercial dairy herds. De novo FA are synthesized primarily from rumen fermentation products acetate and butyrate. It was hypothesized that farms with higher de novo FA concentrations will prioritize management and nutrition that promote rumen health. Herds (n = 44) located in Vermont and northern New York State were selected based on high (HDN; 25.8 ± 1.0; mean ± SD) or low (LDN; 23.6 ± 0.9) de novo FA expressed as a proportion of total FA (relative %) in bulk tank milk. Management practices were assessed during one visit to each farm in March or April, 2014. Total mixed ration samples were collected and analyzed by NIR for chemical composition. Data were analyzed using the MIXED procedure of SAS with de novo group as the fixed effect, farm as the random effect, and breed as the covariate in the model. Milk (26.3 vs. 22.7 kg/d, SE = 1.3, $P = 0.06$), fat (1.1 vs. 0.9 kg/d, SE = 0.1, $P < 0.01$), true protein (0.9 vs. 0.7 kg/d, SE < 0.1, $P < 0.01$), and de novo FA (25.6 vs. 23.7 relative %, SE = 0.2, $P < 0.01$) were higher for HDN vs. LDN farms, respectively. Days in milk (170 ± 7 d; least squares means ± SE), freestall bunk space (41 ± 3 cm), manure score (2.8 ± 0.0), and freestall feeding frequency (1.5 ± 0.4 times/d) were not different between groups. However, tiestall feeding frequency (4.8 vs. 2.8 times/d, SE = 0.7, $P < 0.1$), freestall stocking density (1.05 vs. 1.20 cows/stall, SE = 0.06, $P = 0.07$), and body condition score (3.07 vs. 2.95, SE = 0.04, $P < 0.01$) were different between HDN vs. LDN herds, respectively. Dietary DM (40.7 ± 2.0), CP (16.0 ± 0.6%), ADF (22.9 ± 1.0%), NDF (37.5 ± 1.3%), starch (21.7 ± 1.5%), ash (8.5 ± 0.4%), and forage to concentrate ratio (1.47 ± 0.14) were not different ($P > 0.12$) between groups. However, dietary ether extract was lower in HDN herds (3.5 vs. 4.5%, SE = 0.2, $P < 0.01$). Overcrowded freestalls, reduced feeding frequency, and greater dietary ether extract content compromised de novo FA synthesis thereby decreasing milk fat and protein yields.

Key Words: stocking density, milk protein, milk fat

82 Pregnancy outcomes based on milk pregnancy-associated glycoprotein levels. Erin M. Wynands*, Stephen J. LeBlanc, and David F. Kelton, *University of Guelph, Guelph, Ontario, Canada.*

Timely diagnosis of pregnancy and pregnancy losses is economically important. A commercially available pregnancy-associated glycoprotein (PAG) milk assay (Idexx Laboratories Inc.) is offered through routine Dairy Herd Improvement (DHI) testing for diagnosis of pregnancy. The objective of this observational study was to describe the relationship between PAG at various stages of gestation and the likelihood of successful calving. The hypothesis was that higher PAG levels would be associated with successful calving. Data were collected from CanWest DHI for all cows with a milk PAG assay between January 1 and May 31, 2013. The PAG milk assay result is reported as a relative PAG level (S-N value). Cows that tested pregnant (PAG >0.25 according to the manufacturer's cut-point; 6196 cows in 967 herds) were included in this analysis. A dichotomous outcome of calving between 270 and 290 d after the relevant insemination was determined for each cow with 5139 successful outcomes. There was a significant interaction between days in gestation (DIG) at time of PAG assay and PAG, so the data were stratified by DIG. Milk PAG levels increased after breeding, decreased at 45–75 DIG, then increased through the remainder of gestation. For cows ≤45 DIG (n = 793) increasing PAG level was associated with an increased likelihood of calving ($P = 0.01$). For cows > 45 and ≤75 DIG (n = 1653) relative PAG levels ($P = 0.001$) and linear score ($P = 0.01$) were negatively associated with the outcome, while test-day milk yield was positively associated with the outcome ($P = 0.01$). For cows >75 DIG (n = 3750) relative PAG level ($P = 0.001$), and milk yield ($P = 0.005$) were positively associated with full-term pregnancy; linear score was negatively associated with the outcome ($P = 0.05$). These results indicate that while higher PAG levels are positively associated with a positive calving outcome in general, a decrease in PAG level around 45–75 d in gestation was associated with a successful pregnancy outcome.

Key Words: pregnancy-associated glycoprotein, pregnancy diagnosis

83 Prepartum dietary cation-anion difference (DCAD) and 25-hydroxyvitamin D_3 supplementation modulate β-defensin responses in postpartum dairy cattle. Kathryn Merriman*[1], Natalia Martinez[1], Rachel Rodney[2], Jessi Powell[1], Mercedes Kweh[1], Nathaniel Elliott[1], Jose Santos[1], and Corwin Nelson[1], *[1]University of Florida, Gainesville, FL, [2]SBScibus, Camden, Australia.*

Postpartum hypocalcemia has been associated with suppressed neutrophil and lymphocyte function in dairy cattle. It was hypothesized that mitigation of postpartum hypocalcemia would enhance activation of host-defense mechanisms during the postpartum period. The objective of this study was to determine the effects of pre-partum DCAD in combination with vitamin D supplementation on expression of a cluster of β-defensin (DEFB) host-defense genes. Pregnant dry Holstein cows (n = 51, multiparous) of 255 d gestation were blocked by parity and randomly assigned to 4 prepartum diets of positive (+130 mEq/kg) or negative (−130 mEq/kg) DCAD and either 3 mg vitamin D_3 or 3 mg of 25-hydroxyvitamin D_3 (25D) per 11 kg of DM/d. Treatment diets were fed for the last 21 d of gestation, and, upon calving, cows were fed the same lactation ration for the first 49 DIM. Peripheral blood neutrophils and monocyte cultures were collected at d 0 and d 3 of calving and stimulated with 75 ng/mL of 25D and a combination of 100ng/mL of lipopolysaccharide (LPS) and 75 ng/mL of 25D. The mRNA transcripts of DEFB genes were quantified by real-time PCR, and data were analyzed with a general linear mixed model to test for fixed effects and interactions of experimental variables. Neutrophil gene expression of DEFB4 ($P \leq 0.05$), DEFB5 ($P \leq 0.05$), DEFB7 ($P = 0.1$), and DEF10 ($P = 0.1$) was greater in cows fed the negative DCAD. Neutrophils had lower expression of DEFB3, DEFB4, DEFB7, DEFB10, and lingual antimicrobial peptide in response to LPS at d 3 of calving compared with d 0, ($P \leq 0.05$). Cows supplemented with vitamin D_3 showed greater DEFB3, DEFB4, DEFB5, DEFB7, and DEF10 gene expression in monocytes ($P \leq 0.05$) than 25D supplemented cows. In conclusion, pre-partum DCAD and 25D affect neutrophil and monocyte β-defensin responses and have implications for improving transition cow immunity.

Key Words: defensin, DCAD, vitamin D

84 Effects of elevated subcutaneous adipose stores on fractionated peripheral blood mononuclear cells and polymorphonucleocytes fatty acid profile and polymorphonucleocytes gene expression in periparturient dairy cow. Cynthia M. Scholte*, Zahra Mohammadi-Amiri, Bahman Shafii, and Pedram Rezamand, *University of Idaho, Moscow, ID.*

During the periparturient period, elevated circulating nonesterified fatty acids (NEFA) affect not only the circulating fatty acid (FA) composition, but also that of the peripheral blood mononuclear cells (PBMC) and polymorphonucleocytes (PMN). The changes to specific lipid fractions, however, remain unknown. We hypothesize elevated lipid mobilization will alter FA profiles and therefore gene expression of pro-inflammatory mediators. Starting −28 d before calving, treatment cows (n = 18) received a dry cow ration with an additional 10 kg of corn / head per day, while the control cows (n = 16) received the dry cow ration (no additional corn) with an additional 400 mg of monensin / head per day to minimize lipid mobilization. Postpartum, treatment cows were fasted for 8 h on d +3. Plasma samples were collected on d −28, +3, +12, and +21 relative to parturition to isolate PBMC and PMN for analysis of fatty acid methyl ester (FAME) of cells' NEFA and phospholipids (PL) fractions. Isolated PMN were analyzed using real-time q-PCR for caspase-1 (CASP), interleukin-8 receptor (IL-8R), and L-selectin (SELL). Data were analyzed as repeated measures ANOVA using mixed model procedures in SAS (9.3) with significance declared at $P \leq 0.05$. Several FA concentrations of NEFA and PL fractions in PBMC and PMN changed over time. Eicosanoid precursor C20:4 in the NEFA fraction of PBMC were greater in treatment than control cows (0.51 vs. 1.29 ± 0.27 g/100g FAME; $P = 0.02$). In contrast, C20:4 of PBMC in PL fraction were greater in control animals (10.06 vs. 8.18 ± 0.56 g/100g FAME; $P = 0.02$). Anti-inflammatory C20:5 concentrations in the PL fraction of PMN were greater in the treatment group and multiparous animals in a treatment across parity effect ($P = 0.05$). Although gene expression of CASP, IL8-R and SELL in PMN changed over time ($P < 0.0001$), no treatment effect was detected. In summary, dietary manipulation altered FA profiles within PBMC and PMN fractions, but did not alter gene expression in PMN.

Key Words: lipid mobilization, immune cell, fatty acid

85 Cows at a high risk for subacute rumen acidosis exhibit different feeding behavior. Kira Macmillan*, Xiaosheng Gao, and Masahito Oba, *University of Alberta, Edmonton, Alberta, Canada.*

Previous studies reported that cows fed the same diet have a large variation in rumen pH; cows at a high-risk of sub-acute rumen acidosis (SARA) have a lower pH for a longer period of time than low-risk cows. The objective of this study was to determine if feeding behavior is different between cows with a high or low risk for SARA. We hypothesized that high-risk cows would eat longer during each meal, contributing to a lower pH. Sixteen ruminally cannulated lactating cows (DIM = 265 ± 36; BW = 632 ± 80 kg) were fed a diet consisting of 35% forage and 65% concentrate once daily to increase the risk of SARA. After a 17-d diet adaptation period, ruminal pH was measured every 30 s over a 24-h period. Cows were classified as high or low risk to SARA based on an acidosis index (area of pH <5.8/DMI). Feeding behavior of animals was observed for the same 24-h period; each animal was checked every 5 min and each behavior seen was assumed to last for 5 min. The 24-h observation period was split into 3 8-h time periods following feeding, and eating behavior was summarized for each period. All response variables were evaluated for the group effect using the PROC TTEST procedure of SAS. Minimum pH ranged from 5.13 to 6.10 among the 16 cows fed the same diet. The 7 high-risk cows had a higher acidosis index than the 9 low-risk cows (8.03 vs. 0.11, $P = 0.002$). Despite no significant difference in DMI ($P = 0.87$), high-risk cows spent more time eating in the first 8-h period after feeding (186 vs. 153 min, $P = 0.014$) and less in the third 8-h period (19 vs. 43 min, $P = 0.012$) than low-risk cows. In the third period, high-risk cows spent more time ruminating (243 vs. 197 min, $P = 0.012$). Average meal duration was longer for high-risk cows (92 vs. 59 min, $P = 0.011$). Our results suggest that feeding behavior may be a contributing factor to SARA, where cows with a high-risk for low rumen pH eat for longer periods of time during the first 8-h after feeding. Increasing feeding frequency to encourage distribution of eating throughout the day may be an effective approach to mitigate SARA, which warrants further investigation.

Key Words: subacute rumen acidosis, feeding behavior

86 Factors associated with aerobic plate count, coliform count, and log reduction of bacteria in automated calf feeders.

Alyssa M. Dietrich*[1], Whitney A. Knauer[2], Sandra A. Godden[2], Christina S. Petersson-Wolfe[1], and Robert E. James[1], [1]*Virginia Tech, Blacksburg, VA,* [2]*University of Minnesota, St. Paul, MN.*

As automated calf feeders become more widely adopted, there is a need for research on sanitation management. The objective was to identify factors associated with bacteria counts and log reduction (LR) as a result of circuit cleaning (CC) in milk/replacer samples collected from automated calf feeders (Förster Technik, Engen, Germany). It was hypothesized that increased cleaning is associated with low bacteria counts and increased LR. Six VA and 4 MN dairy farms (14 feeders) were visited weekly for 7 mo. Samples of milk/replacer were collected aseptically from each feeder, iced, and frozen at −5°C. For a 4-wk period, VA farms were instructed to collect and freeze samples immediately before and after CC. Samples were thawed and plated on Petrifilms to find $\log_{10}$ aerobic plate count (APC) and $\log_{10}$ coliform count (CCP). From a model of state, farm(state), LSM ± SE APC was 3.84 ± 0.26 and 5.02 ± 0.21 $\log_{10}$ cfu/mL ($P < 0.01$), and CCP was 0.62 ± 0.47 and 2.89 ± 0.39 $\log_{10}$ cfu/mL ($P < 0.01$) for MN and VA. The LSM by farm ranged from 3.30 to 5.51 $\log_{10}$ cfu/mL APC and 0.07 to 3.82 $\log_{10}$ cfu/mL CCP. The LR of APC (LRAPC) and CCP (LRCCP) after CC was 0.78 ± 0.82 and 0.67 ± 1.17 $\log_{10}$ cfu/mL (mean ± SD). By regression, each $\log_{10}$ increase in pre-CC APC and CCP increased LRAPC and LRCCP by 0.45 $\log_{10}$ cfu/mL ($P < 0.01$). Farms with higher pre-CC APC and CCP cfu/mL performed more CC/wk and used more mL detergent/L water ($P < 0.05$). More mixer cleanings (MCHE)/d lowered pre-CC APC cfu/mL ($P < 0.05$), whereas use of silicon hoses increased pre-CC CCP cfu/mL ($P = 0.04$), and use of bleach decreased pre-CC CCP cfu/mL ($P < 0.01$). By stepwise regression with farm in the model, more days since last MCHE increased LRCCP ($P < 0.01$) within farm. Number of calves, milk L/d, and feeder visit frequency were not associated with LR of bacteria within farm. LR was more dramatic at high pre-CC bacteria, which was reduced by more MCHE/d and use of bleach.

Key Words: bacterial count, automated calf feeders

87 Effects of supplementing slow-release urea in combination with steam-flaked corn or high-moisture corn on ruminal fermentation and lactational performance of dairy cows.

B. M. Tye*[1], K. Neal[1], S. Y. Yang[1], J.-S. Eun[1], A. J. Young[1], and K. Mjoun[2], [1]*Department of Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, UT,* [2]*Alltech, Brookings, SD.*

Associative effects between slow-release urea (SRU) and different types of corn grains [i.e., steam-flaked corn (SFC) vs. high-moisture corn (HMC)] need to be investigated to improve N utilization and lactational performance of dairy cows. This experiment was performed to test a hypothesis that supplementing SRU (Optigen, Alltech, Nicholasville, KY) in HMC-based diet would improve microbial fermentation and nutrient utilization by lactating dairy cows due to a better synchronous supply of dietary N and ruminally fermentable carbohydrates. Eight multiparous Holstein cows (32 ± 8.2 DIM) were used in a duplicated 4 × 4 Latin square design, and within each square, cows were randomly assigned to a sequence of 4 diets during each of the 4 21-d periods (14 d of treatment adaptation and 7 d of data collection). The 4 dietary treatments included: SFC without SRU, SFC with SRU, HMC without SRU, and HMC with SRU. Data were analyzed with a model that included the fixed effect of type of corn grain, SRU supplementation, and their interaction with cow and period as the random effects. Supplementing SRU with SFC but not with HMC increased intake of DM and CP, resulting in tendencies for an interaction between corn grain (CG) and SRU supplementation (CG × SRU; $P = 0.06$). Milk yield did not differ among treatments (39.0 ± 0.37 kg/d). Milk true protein concentration increased with SFC with SRU, whereas it decreased with HMC with SRU ($P = 0.01$). Dietary treatments did not affect ruminal concentration of volatile fatty acids and ammonia-N. Feeding HMC tended to increase feed efficiency for milk production ($P = 0.09$) and N utilization efficiency for milk N ($P = 0.10$), but supplementing SRU did not influence the efficiency parameters. Supplementing SRU with either SFC or HMC resulted in minor effects on ruminal fermentation and lactational performance possibly due to relatively less dietary concentrations of the corn grains (13.6% DM on average) in high-forage diets (60% of the diet DM). However, feeding HMC improved feed and N utilization efficiency for milk production.

Key Words: steam-flaked corn, high-moisture corn, slow-release urea

88 Regulation of microRNA-221 gene expression in ovarian theca cells of cattle: A possible role in follicular development.

Cheyenne L. Robinson*, Luis F. Schutz, Morgan L. Totty, and Leon J. Spicer, *Oklahoma State University, Stillwater, OK.*

Cystic ovarian follicles result in reproductively inefficient dairy cows. Fibroblast growth factor-9 (FGF9) gene expression in granulosa cells (GC) is downregulated in cystic vs. non-cystic follicles in cattle. FGF9 is thought to act as an intraovarian regulator by stimulating proliferation and reducing steroid production by GC and theca cells (TC). Analysis using Affymetirx GeneChip bovine Genome Arrays (n = 8) revealed that microRNA-221 (*MIR221*) in TC was upregulated by FGF9. We selected this gene for further study due to recent evidence indicating *MIR221* is involved in cell proliferation, angiogenesis and cancer. We hypothesized that *MIR221* is regulated during follicle growth and by steroids and hormones that induce cAMP. Three experiments were conducted to evaluate hormonal regulation of *MIR221* mRNA in TC and its possible role in follicular development using sensitive real-time PCR (*U6* as housekeeping gene). TC were isolated from large (>8 mm) follicles (n = 6 to 8 per pool) collected from an abattoir, cultured for 48 h in medium with 10% fetal calf serum, and then treated in serum-free medium for an additional 24 h. Data were analyzed via GLM procedure of SAS. Exp. 1 tested effects of cAMP pharmacologic agents (dbcAMP at 0.1 mg/mL; forskolin at 4.1 μg/mL) on FGF9-induced *MIR221* mRNA abundance; neither affected ($P > 0.10$) *MIR221* expression whereas FGF9 increased ($P < 0.05$) *MIR221* abundance 1.94-fold. Exp. 2 tested the effect of 300 ng/mL of steroids (estradiol; androstenedione) and phytoestrogens (genestein; α- and β-zearanol) on *MIR221*; none of the treatments influenced ($P > 0.10$) MIR221 mRNA levels (3.45 ± 0.62 relative abundance). In Exp. 3, follicular fluid (FF) was collected from ovaries obtained at an abattoir, and *MIR221* mRNA abundance measured; *MIR221* mRNA was 3-fold greater ($P < 0.05$) in FF aspirated from small (1 to 5 mm) follicles compared with FF from large follicles. These novel results indicate *MIR221* is increased by FGF9 but not regulated by steroids or cAMP. Greater levels of *MIR221* in FF of small vs. large follicles suggest a role for FGF9-induced *MIR221* in follicular development.

Key Words: theca cells, cattle, microRNA-221

89 Feeding a rumen-degradable amino acid can enhance milk production.

Kayla M. Hultquist* and David P. Casper, *South Dakota State University, Brookings, SD.*

The study objective was to determine if feeding a rumen degradable AA can increase milk production comparable to growth hormone (GH). Eight multiparous late-lactating (255 ± 26.4 d in milk) Holstein dairy cows were blocked by milk yield (34.1 ± 8.25 kg/d) and randomly assigned to 1 of 4 treatments in a replicated 4 × 4 Latin square design having 21 d periods with 7 d for dietary adaptation and 14 d for data collection. Treatments were control (C), Posilac (rBST), and valine fed at 40 (V40) and 80 g/d (V80). Cows were fed a total mixed ration (TMR) with a distillers grains carrier at 113.4 g/d containing none or added AA. Rumen and blood samples were collected during wk 2 and 3 for volatile fatty acids and endocrine assays. Dry matter intake was similar ($P > 0.10$) (21.3, 22.0, 22.8, and 21.5 kg/d for C, rBST, V40, and V80, respectively) for cows receiving all treatments, but milk yield (22.0, 26.1, 25.2, and 24.9 kg/d), FCM (22.1, 25.4, 24.4, and 24.3 kg/d), and ECM (22.7, 26.1, 25.1, and 24.9 kg/d) were significantly ($P < 0.05$) increased for cows receiving rBST, V40, and V80 compared with C cows. Milk yield improvements were similar ($P > 0.10$) between rBST, V40, and V80. Milk fat percentages (3.51, 3.36, 3.32, and 3.38%) were highest ($P < 0.05$) for cows receiving C compared with cows receiving V40, while cows receiving other treatments were intermediate and similar ($P > 0.10$). Milk protein percentages (3.20, 3.12, 3.15, and 3.13%) were greatest ($P < 0.05$) for cows receiving C compared with cows receiving rBST. Ruminal isobutyric acid (1.01, 1.05, 1.28, and 1.49 molar %) concentrations were increased ($P < 0.05$) for cows receiving V40 and V80 compared with cows receiving C and rBST treatments. Plasma IGF-1 concentrations (60.4, 106.1, 65.9, and 58.3 ng/mL) were greater ($P < 0.05$) for cows receiving rBST compared to cows receiving other treatments. Plasma GH concentrations (1.78, 1.99, 1.55, and 1.45 ng/mL) were greater ($P < 0.05$) for cows receiving rBST compared with V40 and V80 cows, while C cows were intermediate and similar ($P > 0.10$). This study suggests that feeding a rumen degradable AA can increase milk yield comparable to rBST.

Key Words: milk production, dairy cow, growth hormone

90 Investigation of a new anti-slip flooring technology to address slips and falls by dairy cows.

Nancy Franco-Gendron*[1], Renée Bergeron[1], Walt Curilla[2], Sabine Conte[3], Trevor J. DeVries[4], and Elsa Vasseur[1], [1]*Organic Dairy Research Center, University of Guelph, Alfred Campus, Alfred, Ontario, Canada,* [2]*AB Silikal Hygienic Floors, Diamond Hard Surfaces Inc., Calgary, Alberta, Canada,* [3]*Centre de Recherche et de Développement sur le Bovin Laitier et le Porc, Agriculture and Agri-Food Canada, Lennoxville, Quebec, Canada,* [4]*Department of Animal and Poultry Science, University of Guelph, Kemptville Campus, Kemptville, Ontario, Canada.*

Freestall dairy facilities are known to have issues with slips and falls by cows caused by the combination of smooth flooring and manure slurry. Eighteen Holstein dairy cows (parity 1 to 6) selected to maximize gait range were evaluated on various flooring types to test the hypothesis that flooring with greater anti-slip properties will improve cattle's ease of movement. Cows were trained and randomly assigned to walk on 6 flooring types covered with thin coat of manure 3x/wk for 6 wks; 2 controls: rubber mat (Animat), traction milled concrete (Agri-Trac), and 4 different coated treatments: Red (Silikal 0.7–1.2 mm quartz with 1 seal coat), Green (Silikal 0.7–1.2 mm, 2 seal coats), Yellow (Silikal 0.4–0.8 mm, 1 seal coat) and Orange (Silikal 0.4–0.8 mm, 2 seal coats). Cows were filmed walking a straight corridor and a corridor with a turn (5 passages/corridor). Cows had 2 accelerometers on their rear legs to measure the average acceleration of a passage. Reflective markers were placed on both right hooves before walking the straight corridor measuring stride length, foot height, swing and stance time via kinematics. Steps taken, passage time and time/steps were recorded for the curved corridor. Stride for cows on the straight corridor was longer for rubber (1.54 ± 0.026 m; mean ± SE) compared with all other treatments: 1.44 ± 0.041 m for Red (Wilcoxon sign rank test: S = 54; $P = 0.003$), 1.38 ± 0.027 m for Green (S = 68; $P < 0.0001$), 1.48 ± 0.031 m for Yellow (S = 43; $P = 0.02$), and 1.46 ± 0.033 m for Orange (S = 47; $P = 0.01$). Stride of cows walking on the straight corridor was shorter on groove concrete (1.41 ± 0.034 m) compared with Yellow (S = −52; $P = 0.02$), but no differences were found with the other treatments. The time taken per step for cows on the curve corridor was not different between flooring (Kruskal-Wallis test: $X^2 = 0.9$; $P > 0.1$). In conclusion, longer strides or faster pace reflects cow ease of movement on a particular flooring type. Based on these 2 variables, cow ease of movement was greater on rubber versus coating treatments, but was better on the Yellow treatment compared to concrete. Other aspects of ease of movement like acceleration or gait need to corroborate these first findings.

Key Words: dairy cows, welfare, flooring

91 2,4-Thiazolidinedione improves liver function but does not affect insulin sensitivity and expression of genes in adipose and mammary tissue of lactating dairy goats.

Fernanda T. da Rosa*[1], Johan Osorio[1], Francisco Y. Rivera[1], Erminio Trevisi[2], Charles T. Estill[1], and Massimo Bionaz[1], [1]*Oregon State University, Corvallis, OR,* [2]*Universita Cattolica del Sacro Cuore, Piacenza, PC, Italy.*

Previous studies have shown that daily injection of 2,4-thiazolidinedione (TZD) in lactating dairy goats decreases milk somatic cell count but does not affect milk fat yield. The latter could be due to a lipogenic competition between adipose and mammary tissues, owing to an activation of peroxisome proliferator-activated receptor gamma (PPARγ), a potential TZD target, in the adipose tissue. This study investigated the hypothesis that activation of PPARγ improves the response to mastitis and increase milk fat synthesis. To test this, 24 Saanen goats received either TZD or saline and intramammary infusion of either bacteria or saline (6 goats/group). A metabolic and inflammation profiling in blood (including insulin), adipocyte size by histology, and expression by RT-qPCR of PPARγ target genes in adipose tissue obtained through biopsy and in mammary epithelial cells (MEC) isolated from milk were assessed. In MEC, expression of *CCL2* and *IL8* was also measured. Data were analyzed by GLIMMIX of SAS with Mastitis, TZD, and Time and all interactions as main effects. Significance was determined by Tukey-adjusted $P < 0.05$. Mastitis induction decreased myeloperoxidase but TZD treatment increased haptoglobin, cholesterol, paraoxonase, γGT, and myeloperoxidase in blood compared with saline, indicating a positive effect on liver and increased neutrophil host defense capability. Insulin sensitivity (estimated using QUICKI) was not affected by TZD but overall was lower in mastitic goats. Adipocyte size increased over time but was not affected by treatments. Sub-clinical mastitis increased expression of *CCL2* and decreased expression of *FASN* in MEC but increased expression of *FASN* and *SREBF1* in adipose. No overall effects of TZD on expression of PPARγ target genes were observed in MEC and adipose tissue. In summary, the data revealed limited effects of TZD on the response of goats to mastitis. Furthermore, the data does not support TZD being a strong PPARγ agonist and insulin sensitizer in dairy goats but indicates that it might improve directly or indirectly the liver function and inflammatory response.

Key Words: goats, mastitis, 2-4-thiazolidinedione

92 Inferring the causal effect of number of lambs born on milk yield in dairy sheep using propensity score methods. Vera C. Ferreira*, Bruno D. Valente, David L. Thomas, and Guilherme J. M. Rosa, *University of Wisconsin, Madison, WI.*

Assigning causal interpretation to associations obtained from observational data is challenging as they are prone to confounding. Number of lambs born (prolificacy) in dairy sheep may be considered a potential factor contributing to milk yield (MY). However, inferring this effect using traditional regression or ANOVA techniques can generate spurious results if confounder variables affect both the outcome (MY) and treatment (prolificacy). Propensity score (PS) methods tackle this issue by balancing baseline covariate distributions between treatment levels, allowing unbiased inference of marginal effects. This method belongs to the framework of causal models dealing with potential outcomes. It intends to mimic aspects of randomized trials, in which the difference among treatment groups is causally meaningful. Under the assumption that ewe prolificacy affects MY, our objective was to estimate the magnitude of such a causal effect using PS based on Matched Samples. Data comprised 4,319 records from 1,534 crossbred dairy ewes. The set of potential confounders was composed by lactation number (1th, 2nd and 3th – 6th) and dairy breed composition (<.5, 0.5-.75 and > 0.75 of East Friesian or Lacaune). For the treatment variable, single lamb birth was assigned to Group 0, while multiple birth (2, 3 or 4 lambs) was assigned to Group 1. MY represented the volume of milk produced for the whole lactation (mean = 268.5 L and SD = 116.4 L). The R package “nonrandom” was used. A total of 1,166 pairs of treated/nontreated individuals with similar PS values were formed. The criterion for similarity was defined by a caliper size equal to 20% of the sd in the PS logit (0.13) and a ratio of treated/untreated = 1. All covariates were deemed balanced after matching (cutoff for standardized bias = 0.2). The estimated causal effect of prolificacy on MY was 20.52 L, se = 3.77 L, 95% CI = 13.13–27.91 L. This means that ewes that gave birth to a single lamb would be expected to have MY increased by 20.52 L if they had given birth to multiple lambs and all other variables were held constant. This implies that any management practice that increases (decreases) prolificacy would affect MY positively (negatively).

Key Words: causal inference, milk yield, prolificacy

93 The effect of somatic cell score on milk yield of dairy cattle in the southeastern United States. Derek T. Nolan* and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

The objective of this study was to quantify the effect of somatic cell score (SCS) on milk yield of dairy cattle. Collection of Dairy Herd Information cow records included: herd, days in milk (DIM), parity, birth date, calving date for each parity, and SCS. Records were collected from 6 states in the Southeast (Tennessee, Kentucky, Virginia, Georgia, Florida, and Mississippi). To be included in the data set, cows must have been within one standard deviation of the mean age of the parity group and have DIM between 240 and 305 d. Herds containing less than 5 cows that met the criteria were not included in the analysis. As a result, 10,333, 5,917, 3,213, and 3,266 cows were included from 468, 357, 238, and 244 herds in the analysis of parities 1, 2, 3, and 4 respectively. The GLM procedure of SAS version 9.3 (SAS Institute Inc. Cary, NC) was used to analyze the following model: $Y_{ijklmn} = S_i + H_j + M_k + D_l + A_m + I_n + E_{ijklmn}$, where Y_{ijklmn} = lactation milk yield, S_i = effect of the *i*th state, H_j = effect of the *j*th herd, M_k = effect of *k*th calving season, D_l = effect of the *l*th days the cow was in lactation, A_m = effect of the *m*th age at calving, I_n = effect of *n*th SCS, and E_{ijklmn} = residual error. Analysis of parities 1 to 4 occurred separately. Herd was a random effect in the model; all other variables were considered fixed. For every 1-unit increase in SCS, a milk yield loss of −113.58, −209.89, −214.42, and −252.09 kg/lactation occurred for parities 1, 2, 3, and 4 respectively. Overall, first-parity cows have half of the milk production loss from a unit increase in SCS than older parity cows. The Southeast Quality Milk Initiative project is supported by Agriculture and Food Research Initiative Competitive Grant no. 2013-68004-20424 from the USDA National Institute of Food and Agriculture.

Key Words: somatic cell score, milk yield, Southeast Quality Milk Initiative

94 Effect of early lactation increased milking frequency on milk yield and local regulators of mammary cell activity. Diana K. Hardin*[1], Andrea J. Lengi[1], Hollie H. Schramm[2], and Benjamin A. Corl[1], *[1]Department of Dairy Science, Virginia Tech, Blacksburg, VA, [2]Department of Large Animal Clinical Sciences, Virginia-Maryland Regional College of Veterinary Medicine, Blacksburg, VA.*

Increased milking frequency (IMF) during early lactation increases milk yield not only during the IMF period, but also during continuing lactation after a return to twice daily milking (2×). The increase in milk yield is locally regulated within the mammary gland; however the mechanism for the increase in milk yield is unknown. The objective of this study was to demonstrate a difference in milk and component yield, both during the IMF period and throughout remaining lactation, and examine potential local regulation mechanisms that increase production due to early lactation IMF. Eight multiparous dairy cows were assigned to unilateral frequent milking [2× left udder half and 4-times-daily milking (4×) right udder half] for the first 21d of lactation. Both udder halves were milked 2× for the remainder of lactation. Milk weights from each udder half were recorded at 7, 14, 21, 60, 120 and 180 DIM. Mammary biopsies were obtained from each rear quarter at 21 DIM, and tissue was used to measure protein and mRNA expression. During the IMF period, between 0 and 21 DIM, 4× milking increased milk yield 5.5 ± 0 0.5 kg/d more than 2× ($P < 0.05$). Between 60 and 180 DIM, the 4× half tended to produce 4.4 ± 0.9 kg/d more than the 2× half ($P < 0.1$). Overall, between d 0 and d 180, IMF increased milk yield by 4.6 ± 0.5 kg/d more than 2× ($P < 0.05$). The 4× gland had reduced phosphorylated and activated Akt (phospho:total Akt) compared with the 2× gland ($P < 0.05$). There was no significant difference between the mRNA expression of IGF-1 or IGFBP-5 between 4× and 2× milking. There was no significant difference between total and phosphorylated STAT5, however the 4× gland tended to have increased activation of STAT5 (phospho:total STAT5) compared with the 2× gland ($P < 0.06$). There was no significant difference between the expression of total, phospho, or activated STAT3. We conclude that early lactation IMF significantly increased milk yield throughout lactation, and this increase in milk yield may be regulated by changes in cell activity resulting from activation of STAT5.

Key Words: milking frequency, lactation, STAT5

Lactation Biology Symposium: Mammary gland biology revisited

95 Mammary gland growth—It's not just estrogen. Russell C. Hovey*[1], Grace E. Berryhill[1], Josephine F. Trott[1], and Adam L. Lock[2], [1]*University of California, Davis, Davis, CA,* [2]*Michigan State University, East Lansing, MI.*

The mammary gland goes through a coordinated series of developmental states during postnatal life in preparation for lactation. These changes ultimately reflect a changing endocrine environment alongside local alterations in the microenvironment. A longstanding assumption has been that estrogens serve as the first essential component for any of these developmental changes to be realized in the mammary glands. Indeed, estrogens can initiate the onset of allometric growth during puberty, and they subsequently potentiate the effects of other endocrine cues on the mammary epithelium during lobulo-alveolar development throughout gestation. More recent evidence from our laboratory indicates that alternative pathways are equally effective in promoting growth of the mammary glands independent of a primary role for estrogens. One fascinating example is the ability of dietary *trans*-10,*cis*-12 conjugated linoleic acid (10,12 CLA) to promote allometric growth of the mammary ducts of ovariectomized mice. In subsequent studies we showed that the specific effects of this dietary fat are independent of estrogenic action, and are mediated through IGF-I receptor signaling. The relevance of these findings is emphasized by the fact that this dietary intervention mimics several aspects of the metabolic syndrome manifest in obese humans. At the same time, additional findings from our laboratory indicate that prolactin and progesterone have synergistic effects on epithelial growth and morphogenesis independent of any role for estrogens, which are partly mediated by changes in the local microenvironment. These data collectively support the notion that while estrogens are clearly mitogenic for the growing and developing mammary glands, they are not necessarily requisite. These findings have potential implications for our understanding of mammary growth in all mammals including livestock, as well as direct relevance to the regulation of mammary cancers.

Key Words: prolactin, progesterone, lipid

96 Body condition of gilts at the end of gestation affects their mammary development. Chantal Farmer*[1], Marie-France Palin[1], and Michel Vignola[2], [1]*Agriculture and Agri-Food Canada, Dairy and Swine R&D Centre, Sherbrooke, QC, Canada,* [2]*Nutreco Canada, St-Elzéar, QC, Canada.*

The goal of this project was to determine if changes in body condition that incur during gestation affect mammary development of gilts on d 110 of gestation. Gilts of a similar BW (138.1 ± 8.2 kg) and backfat thickness (BF, 16.4 ± 1.0 mm) at mating were fed different amounts of a commercial gestation diet to create 3 groups of animals based on body condition at the end of gestation. These were low (LO; 12–15 mm, n = 13), medium (ME; 17–19 mm, n = 13), and high (HI; 21–26 mm, n = 13) BF. All gilts were weighed and had their BF measured ultrasonically at P2 the day of mating and on d 30, 50, 100 and 110 of gestation. Blood samples were obtained on d 109 of gestation to measure IGF-1 and adiponectin concentrations. Gilts were then slaughtered on d 110 to collect mammary glands for compositional analyses. The MIXED procedure of SAS using a univariate model (3 levels) was used for statistical analyses and means were compared using the Tukey's test. As expected, BW and BF were similar across all groups at mating ($P > 0.10$). Treatment differences were present for both variables as of 30 d of gestation onward ($P < 0.01$). Neither IGF-I nor adiponectin concentrations were affected by treatment ($P > 0.10$). Mammary extraparenchymal tissue weight was lesser in LO than in ME or HI gilts (1074.7, 1360.2 and 1578.4 ± 64.3 g, respectively, $P < 0.01$) and tended to be lesser in ME than in HI gilts ($P = 0.06$). Weight of parenchymal tissue was also affected by treatment ($P < 0.05$), being lesser in LO than HI gilts ($P < 0.05$), and tending to be lower in LO than ME gilts ($P = 0.12$). Values for LO, ME and HI gilts were 1058.6, 1369.6 and 1443.9 ± 198.7 g, respectively. Mammary cell number (DNA) in parenchyma was not affected by treatment, whereas metabolic activity (RNA) was greater in LO than HI gilts ($P < 0.05$). Total parenchymal fat was also lesser in LO than ME or HI gilts ($P < 0.001$). Body condition of gilts therefore has an impact on mammary development at the end of gestation. Thanks to Swine Innovation Pork for partial funding.

Key Words: backfat thickness, gilt, mammary development

97 Autocrine-paracrine regulation of the mammary gland. Samantha R. Weaver and Laura L. Hernandez*, *University of Wisconsin-Madison, Madison, WI.*

The mammary gland has a remarkable capacity for regulation at a local level, particularly with respect to its main function: milk secretion. Regulation of milk synthesis has significant affects animal and human health, at the level of both the mother and the neonate. Control by the mammary gland of its essential function, milk synthesis, is an evolutionary necessity and is therefore tightly controlled at a local level. For at least the last 60 years, researchers have been interested in elucidating the mechanisms underpinning the mammary gland's ability to self-regulate, largely without the influence from systemic hormones or signals. By the 1960s, researchers realized the importance of milk removal in the capacity of the gland to produce milk and that the dynamics of this removal, including emptying of the alveolar spaces and frequency of milking, were controlled locally as opposed to through systemic hormonal regulation. Using both in vitro systems and various mammalian species, including goats, marsupials, humans, and dairy cows, it has been demonstrated that the mammary gland is largely self-regulating in its capacity to support the young, which is the evolutionary basis for milk production. Local control occurs at the level of the mammary epithelial cell through pressure and stretching negative-feedback mechanisms and also in an autocrine fashion through bioactive factors within the milk which act as inhibitors, regulating milk secretion within the alveoli themselves. It is only within the last 20 to 30 years that potential candidates for these bioactive factors have been examined at a molecular level. Several factors, including parathyroid hormone related protein (PTHrP), growth factors (transforming growth factor, insulin-like growth factor, epidermal growth factor) and serotonin (5-HT), are both synthesized within and act upon the gland, and posess dynamic receptor activity resulting in diverse effects on growth, calcium homeostasis, and milk composition. This review will focus on the autocrine-paracrine regulation of the mammary gland, with an examination of both foundational work and the progress made within the last 10 to 20 years of research.

Key Words: lactation, milk, secretion

98 New insights in the importance of prolactin in dairy ruminants. Pierre Lacasse*[1], Séverine Ollier[1], Vanessa Lollivier[2], and Marion Boutinaud[2], [1]*Dairy and Swine R&D Centre, Sherbrooke, QC, Canada,* [2]*INRA, Agrocampus Ouest, UMR1348 PEGASE, Saint Gilles, France.*

In most mammals, prolactin (PRL) is essential for maintaining lactation and its suppression inhibits lactation. However, the involvement of PRL in the control of ruminant lactation is less clear because inconsistent effects on milk yield have been observed with short-term suppression of PRL by bromocriptine. Therefore, several experiments were conducted to assess the galactopoietic role of PRL. In an initial experiment, cows in early lactation received daily injections of the dopamine agonist quinagolide (QUIN) for 9 weeks. QUIN reduced milking-induced PRL release and caused a faster decline in milk production. Milk production was correlated with the amount of PRL released at milking. QUIN reduced mammary epithelial cell activity, survival and proliferation. In goats, QUIN did not affect either basal or milking induced PRL release and milk production, whereas injection of cabergoline, another dopamine agonist, caused a decrease of 28% of milk yield the day after the injection. In another experiment, cows were injected for 5 d with QUIN; QUIN + injection of bPRL at milking time; or vehicles. Again, milk, protein and lactose yield were decreased by QUIN. Although PRL injections were not sufficient to restore milk yield, they tended to increase milk protein and lactose yields and increased the viability of milk purified mammary epithelial cells. In late lactation cows, QUIN decreased milk production within the first day of treatment and induced a more rapid changes in several markers of mammary gland involution after drying-off. Similarly, injection at drying-off of cabergoline hastened mammary involution and enhanced mammary gland remodeling. Recently, we stimulated PRL secretion with daily injection of the dopamine antagonist domperidone for 5 weeks. Milk production increased gradually and was greater in domperidone-treated cows during the last 4 weeks of the treatment period. Milk production of both groups became similar again 5d after the last injection. In conclusion, these data, combined with those from other studies, provide a good body of evidence that PRL is galactopoietic in dairy ruminants.

Key Words: prolactin, milk production, cows

99 Regulation of cell number in the mammary gland via the control of the exfoliation process in milk in ruminants. Lucile Hervé[1,2], Vanessa Lollivier[1,2], Hélène Quesnel[1,2], and Marion Boutinaud*[1,2], [1]*INRA UMR1348, Saint Gilles, France,* [2]*Agrocampus Ouest UMR1348, Rennes, France.*

Milk yield is partly influenced by the number of mammary epithelial cells (MEC) in the mammary gland. It is well known that MEC number varies due to cell proliferation and apoptosis. The exfoliation of MEC from the mammary epithelium into milk is another process which might influence MEC number in the mammary tissue. Yet, little is known about the control of MEC exfoliation process. The rate of MEC exfoliation can be assessed by measuring the milk MEC content through flow cytometry analysis or through an immuno-magnetic method for MEC purification. Various experimental models were used to affect milk yield and study the rate of MEC exfoliation. Reducing milking frequency from twice to once daily increased MEC loss per day in goat but not in cow milk. An increased daily rate of MEC exfoliation was also observed during short days as compared with long days or in response to an endotoxin-induced mastitis in cows. Other animal models were designed to investigate the endocrine control of the exfoliation process and its link with milk production. Suppression of ovarian steroids by ovariectomy resulted in a greater persistency of lactation and a decrease in MEC exfoliation. Administering prolactin inhibitors enhanced MEC loss while exogenous prolactin tended to prevent this negative effect of prolactin inhibitors. These findings suggest that prolactin could regulate MEC exfoliation. In most of these studies, variations of MEC exfoliation were associated with variations in milk yield and changes in mammary epithelium integrity. Exfoliation of MEC could be a process that regulates MEC number in the mammary tissue, and thereby could influence milk yield and lactation persistency.

100 Mammary response to infection: A critical balance between pathogen elimination and collateral damage. David E. Kerr*, *University of Vermont, Burlington, VT.*

Mastitis is an inflammatory disease of the mammary gland. The disease is generally classified as sub-clinical (no obvious signs) or 3 levels of clinical disease including: mild (abnormal milk); moderate (abnormal milk with swelling or redness of the gland); severe (abnormal milk, gland inflammation, with systemic signs of illness). Recent large-scale studies indicate that mild, moderate, and severe forms make up approximately 60%, 30%, and 10% of clinical cases of mastitis, with severe mastitis predominately caused by gram-negative bacteria. Efforts to reduce severe mastitis are of utmost importance to dairy animal welfare, and these cases are associated with greatest milk production losses. Experimental challenge studies under controlled conditions reveal animal-to-animal variation in the severity of the resulting mastitis. This suggests a genetic basis to disease severity and the potential for finding genetic markers for use in breeding programs to produce animals with a reduced tendency to develop severe mastitis. However, the evolving field of epigenetics suggests that in utero and early life environments can modify gene expression and thus modify an animal's phenotype. Our approach is to develop a cell culture challenge model predictive of an animal's innate response phenotype. Such a model could potentially be used with cells from young animals to determine their response phenotype and thus facilitate selection of herd replacements. In our dermal fibroblast model, the cells are cultured under controlled conditions and then challenged with LPS to determine innate response magnitude. This model has revealed breed differences (Angus vs. Holstein) and epigenetic differences in samples from the same animals (i.e., same genotype) collected at 5 and 16 mo of age. Further, animals with low vs. high fibroblast response phenotype produce less BSA in milk following experimentally induced mastitis. Future studies employing this and other model systems, combined with well-controlled disease challenges of extreme phenotypes will lead to a greater understanding of factors contributing to animal variation in the severity of response to mammary infection.

101 Blood-derived proteins in milk during the colostral period: Active or passive transfer? Samantha K. Wall*[1], Josef J. Gross[1], Evelyne C. Kessler[1], Kris Villez[2], and Rupert M. Bruckmaier[1], [1]*Veterinary Physiology, Vetsuisse Faculty University of Bern, Bern, Switzerland,* [2]*Swiss Federal Institute of Aquatic Science and Technology, Dübendorf, Switzerland.*

Colostrum has a different composition than milk in established lactation. This difference is in part due to the partially open blood-milk barrier, which prevents the interdiffusion of blood and milk components. In the first days of lactation, α-lactalbumin (LALBA), a milk protein, is typically present in blood and several blood-derived proteins are present in milk such as IgG_1 (very high concentration), IgG_2, serum albumin (ALB), and lactate dehydrogenase (LDH). With the exception of IgG_1, which is transferred by active transcellular transport, other proteins are

thought to pass paracellularly through the temporarily open barrier. This study aimed to examine the decline patterns of each protein relative to IgG_1, to distinguish between paracellular and transcellular transport through the blood-milk barrier during the first days of lactation. Ten Holstein cows were milked at 4 h after parturition, the next 5 consecutive milkings, and the afternoon milking on d 5, 8, 10, and 14 of lactation for a total of 10 milking time points and blood samples were taken in parallel. Blood and milk samples were analyzed for the concentrations of LDH, ALB, IgG_1, IgG_2 and LALBA. Protein concentration curves were generated from all 10 time points and were evaluated using the tau time constant model to determine the rate of decline of the slope of each protein. When examining blood-derived proteins in milk, the concentration of IgG_1 declined significantly faster than the proteins IgG_2 and LDH. Interestingly, the decline of ALB was not statistically different from IgG_1 nor IgG_2 and LDH. IgG_1 concentration in milk far exceeded levels in plasma, and this protein exhibited a recovery increase in plasma during the experimental period. IgG_2, ALB, and LDH concentrations in milk did not reach plasma levels. Plasma LALBA followed a different pattern, declining significantly slower than all blood-derived proteins in milk. These results indicate that there is active transport of only IgG_1, with a sharp decline at parturition, compared with IgG_2, ALB, LDH, and LALBA which are following the closure of the blood-milk barrier.

Key Words: colostrum, blood-milk barrier, blood-derived protein

Meat Science and Muscle Biology

102 Timing of exposure to high-concentrate diets vs. pasture on lipogenic enzyme gene expression of steers at slaughter.

Brandon M. Koch*[1], Emanuel A. Oliveira[2], and Susan K. Duckett[1], *[1]Clemson University, Clemson, SC, [2]Universidade Estadual Paulista, Jaboticabal, SP, Brazil.*

Forty Angus steers (278 ± 21.4 kg) were used to evaluate the effect of feeding strategy during stocker (P1) and finishing (P3) phases on the relative mRNA expression of lipogenic enzymes. Steers were randomly assigned to 2 feeding treatments during P1 (111 d): high-concentrate diet (cracked corn, corn silage, and soybean meal) or high-quality pasture (winter annuals, alfalfa, and non-toxic fescue). An intermediate phase (P2) consisted of 98 d where all steers grazed high-quality pastures. At the start of P3 (until 568 kg BW), each group from P1 was randomly divided into 2 groups that received either a high-concentrate diet or grazed high-quality pastures resulting in 4 treatments (FPF, FPP, PPF, PPP). At slaughter, s.c. adipose tissue samples were collected from each steer and flash frozen for later analysis. No differences were observed for the relative expression of Acetyl CoA carboxylase, carnitine palmitoyltransferase 1A, or glucose transporter type 4 mRNA ($P > 0.162$). An interaction between P1 and P3 ($P = 0.048$) was observed for stearoyl CoA desaturase (SCD) mRNA with 107-, 140-, 10-fold increases for FPF, PPF, FPP, respectively, compared with PPP. Steers on a high-concentrate diet during P3 had greater relative expression of fatty acid synthase (FASN) mRNA ($P < 0.001$) with 59- and 21-fold increases for FPF and PPF treatments, respectively compared with PPP. Similarly, elongase-5 (ELOVL5) and elongase-6 (ELOVL6) mRNA expression increased ($P < 0.001$) when finished on a high-concentrate diet, with FPF and PPF treatments having 18- and 10-fold increases, respectively, for ELOVL5, and 8 and 5-fold increases, respectively, for ELOVL6, when compared with PPP. Adiponectin receptor 1 adipocyte protein 2, and lipoprotein lipase expression were all downregulated when cattle received a high-concentrate diet during P1 ($P < 0.018$). Glycerol-3-phosphate acyltransferase was highly upregulated when steers were finishing on a high-concentrate diet ($P < 0.001$; 56- and 33-fold increase for FPF and PPF, respectively, when compared with PPP). Feeding high-concentrate diets upregulates key lipogenic genes that enhance MUFA content of beef.

Key Words: gene expression, lipogenic

103 Effects of high-concentrate diets during stocker and finishing phase on lipid fractions in longissimus muscle.

Adriana Pordomingo, Gabriela Volpi Lagreca, Brandon M. Koch, and Susan K. Duckett*, *Clemson University, Clemson, SC.*

Twenty Angus steers (278 ± 21.4 kg BW) were used to evaluate the effect of high concentrate diets during stocker and finishing phases on lipid fractions [neutral lipid (NL), phospholipid (PhL) and free fatty acid (FFA)] in longissimus muscle. Steers were randomly assigned to 2 treatments: (1) high quality forage grazed during all phases (PAST) or (2) high concentrate diets fed during early stocker (111 d) phase and finishing phase (77 d) with an intermediate period on high quality forage (98 d) between stocker and finishing periods (FPF). Steers were slaughtered at a similar live weight endpoint (568 kg BW). Longissimus muscle samples were obtained from each animal. Lipids were extracted from the LM, separated into lipid fractions (NL, PhL, and FFA) and fatty acid composition of each fraction analyzed by GLC. Feeding of high concentrates during the stocker phase and finishing phase increased ($P < 0.05$) total fatty acid content of the LM compared with PAST (4.96% vs. 3.38%, respectively). On a gravimetric basis, FPF had greater NL and FFA content than PAST. However on a percentage basis, the lipid fractions were similar ($P > 0.05$) between PAST and FPF. Overall, the LM contained 93.7% NL, 5.0% PhL, and 1.6% FFA. In the NL, FPF had greater ($P < 0.05$) concentrations of MUFA, n-6 PUFA, and n-6 to n-3 ratio of PUFA compared with PAST. The PAST had greater ($P < 0.05$) concentrations of n-3 fatty acids in NL than FPF. In the PhL, PAST had greater ($P < 0.05$) MUFA and n-3 PUFA compared with FPF. The PhL fraction of FPF had greater ($P < 0.05$) concentrations of n-6 PUFA and higher ratio of n-6 to n-3 PUFA. Fatty acid composition of FFA fraction did not differ ($P > 0.05$) between treatments. These results indicate that PAST finished beef has increased n-3 PUFA concentrations in the LM due to greater accumulation of n-3 PUFA in both NL and PhL fractions and not because of a greater PhL contribution to the total lipid fraction.

Key Words: beef, high concentrate diet, fatty acid

104 Feeding microalgae meal *(Schizochytrium limacinum* CCAP 4087/2) to finishing cattle I: Effects on visceral and subcutaneous adipocyte size and *Longissimus lumborum* muscle fiber characteristics.

Kelsey J. Phelps*[1], John M. Gonzalez[1], Derris D. Burnett[1], Christian A. Alvarado-Gilis[1], Mathew A. Vaughn[1], Caleb P. Weiss[1], Cadra L. Van Bibber-Krueger[1], Justin E. Axman[1], Jake D. Thieszen[1], Kate A. Jacques[2], and James S. Drouillard[1], *[1]Kansas State University, Manhattan, KS, [2]Alltech Inc., Nicholasville, KY.*

The objective of this study was to examine effects of feeding microalgae meal *(*MA*; Schizochytrium limacinum* CCAP 4087/2) on visceral adipocyte, subcutaneous adipocyte, and *Longissimus lumborum* (LL) muscle fiber characteristics. Heifers (36 pens; 8 heifers/pen) were blocked by initial pen BW (4014 ± 223 kg) and assigned within strata to 1 of 4 treatments. Treatments consisted of 0, 50, 100, and 150 $g \cdot heifer^{-1} \cdot d^{-1}$ of MA (Alltech Inc., Nicholasville, KY) added to a basal diet consisting of steam-flaked corn, wet corn gluten feed, alfalfa hay, glycerin, and supplement. Heifers were harvested on d 89 of the study and visceral and subcutaneous adipose tissue were collected from approximately the 13th rib of 3 heifers selected at random from each pen. The strip loin from the left side of the same randomly selected heifers was removed and transported to Kansas State University for analysis. One 1.27-cm steak was removed from the 13th-rib end of each loin for measurement of muscle fiber characteristics of the LL. There were no treatment × depot interactions for cross-sectional area or diameter of subcutaneous and visceral adipocytes ($P > 0.33$). Increasing MA in the diet did not affect cross-sectional area or diameter of visceral or subcutaneous adipocytes ($P > 0.56$) and did not affect distribution of LL myosin heavy chain type I, IIA, and IIX muscle fibers or cross-sectional area of fibers ($P > 0.16$; Table 1). Supplementing microalgae meal does not affect visceral and subcutaneous adipocyte size or muscle fiber characteristics of the LL.

Contd.

Table 1 (Abstr. 104). Cross-sectional area (μm^2) of adipocytes and muscle fibers in heifers fed microalgae meal

	Algae, g·heifer^{-1}·d^{-1} DM				
Item	0	50	100	150	SEM
Subcutaneous adipocyte	9,962	9,395	9,632	9,899	523
Muscle fiber					
Type I	2,601	2,321	2,289	2,521	119
Type IIA	2,794	2,692	2,710	2,676	139
Type IIX	4,171	3,809	3,954	4,020	181

105 Feeding microalgae meal *(Schizochytrium limacinum* CCAP 4087/2) to finishing cattle II: Effects on *Longissimus lumborum* fatty acid profile and meat quality. Kelsey J. Phelps*[1], John M. Gonzalez[1], Christian A. Alvarado-Gilis[1], Derris D. Burnett[1], Mathew A. Vaughn[1], Sara M. Ebarb[1], Caleb P. Weiss[1], Cadra L. Van-Bibber Krueger[1], Justin E. Axman[1], Kate A. Jacques[2], and James S. Drouillard[1], *[1]Kansas State University, Manhattan, KS, [2]Alltech Inc., Nicholasville, KY.*

Effects of feeding microalgae meal *(*MA; *Schizochytrium limacinum* CCAP 4087/2) on fresh meat quality were examined. Heifers (36 pens; 8 heifers/pen) were blocked by initial pen BW (4014 ± 223 kg) and assigned within strata to 1 of 4 treatments. Heifers were fed diets containing steam-flaked corn, wet corn gluten feed, alfalfa hay, glycerin, supplement, and 0, 50, 100 or 150 g·d^{-1} MA (Alltech, Inc., Nicholasville, KY). Heifers were harvested on d 89 of the study and strip loins were collected from 3 randomly selected heifers per pen. One 1.27-cm steak was removed from the 13th-rib end of each loin for fatty acid analysis. Loins were weighed, vacuum packaged, and aged for 14 d. Loins were reweighed and fabricated into 2.54-cm steaks for analysis of lipid oxidation and color stability during retail display, Warner-Bratzler shear force, and sensory attributes. Feeding MA did not affect concentrations of C16:0, C18:0, C18:3n-3, or total fatty acids within loins ($P > 0.16$), but increased concentrations of C18:2n-6c and C20:5n-3 (linear, $P < 0.01$) and C22:5n-3 and C22:6n-3 (quadratic, $P < 0.02$). There were treatment × day interactions for all color attributes and TBARS during display ($P < 0.01$). From d 0 to 2 of display, increasing MA decreased L* (linear, $P < 0.03$). For the remainder of display, increasing MA tended to decrease L* (quadratic, $P < 0.07$). From d 2 to 4 of display, increasing MA decreased a* (linear, $P < 0.04$). For the remainder of display, increasing MA decreased a* (quadratic, $P < 0.02$). Surface oxymyoglobin decreased and surface metmyoglobin increased with increased MA (d0–4, linear, $P < 0.05$; d5–7 quadratic, $P < 0.04$), and lipid oxidation was elevated on d 0 and 7 of display with increased MA (quadratic, $P < 0.01$). Treatments did not affect loin purge loss, loss of weight during cooking, or shear force ($P > 0.15$). For sensory panel, off-flavors increased (quadratic, $P < 0.01$) with increased MA. Increases in measures of oxidation in response to feeding microalgae meal suggest that it may be prudent to include antioxidants in diets of microalgae-fed cattle to preserve oxidative stability of meat.

Key Words: omega-3, color, sensory

106 Intratesticular injection of zinc solution effectively castrates male pigs without affecting pork quality. Jason K. Apple*[1], Tsung-Cheng Tsai[1], Hae-Jin Kim[1], Min Wang[2], Brian P. Corbett[2], Tim M. Johnson[1], and Charles V. Maxwell[1], *[1]Department of Animal Science, University of Arkansas Division of Agriculture, Fayetteville, AR, [2]Ark Science Inc., Irvington, NY.*

Zinc gluconate neutralized by Arg (Zeuterin; Ark Science Inc., Irvington, NY) is directly injected into the testes of dogs and has a 99.6% sterility rate; thus, a study was designed to test the effects of intratesticular injections of a Zn solution (Testrin (T); Ark Science Inc.) as a method of castration in swine. Within 10 litters, 7-d-old male pigs (birth weights of 1 kg, or greater) were assigned randomly to 1 of 3 intratesticular T dosages: 0.15 (n = 1/litter), 0.20 (n = 2/litter), or 0.30 mL/testicle (n = 2/litter). Scrotal area was thoroughly cleansed before T was administered by deep intratesticular injection using a sterile syringe and a sterile 28-gauge (1.26-cm long) needle. A surgically-castrated male (B) and an intact female (G) from each litter were designated as industry controls. Pigs were weaned at 21 d, mixed, and subsequently moved first to an off-site nursery then to a grower-finisher unit. Live weights were recorded at birth, weaning, and at the end of the study to calculate ADG, and scrotums were palpated monthly to monitor testicle growth. One month after injection, the proportion of pigs receiving 0.15, 0.20, and 0.30 mL/testicle with at least 1 testicle was 88.9, 95.0, and 70.0%, respectively, and declined to 55.6 (end of trial), 40.0 (end of trial), and 0% (4 mon after injection), respectively. Testrin-injected pigs were heavier ($P < 0.05$) at weaning than B, but neither pre-weaning ($P = 0.549$), post-weaning ($P \geq 0.185$), nor overall ADG ($P = 0.262$) differed among treatments. Carcasses of T-pigs were heavier ($P = 0.015$) than B, but fat depths, LM area, and calculated fat-free lean yield were similar ($P \geq 0.333$) among treatments. Although the LM from G and males treated with 0.20 mL T/testicle were darker (lesser L* value; $P < 0.05$) than the LM from B, LM color ($P \geq 0.071$), drip and cooking losses ($P \geq 0.370$), marbling ($P = 0.164$), firmness ($P = 0.185$), and shear force values ($P = 0.378$) did not differ among T-treated males, B, and G. Results indicated that male pigs can be effectively castrated by intratesticular injections of 0.30 mL T/testicle, and produce carcasses of equal composition and quality to B and G.

Key Words: castration, intratesticular injection, pork quality

107 Prediction of red meat yield and trimmable fat yield from beef carcasses utilizing bioelectrical impedance analysis. Angela N. Schmitz*[1], Lee-Anne J. Walter[1], Wade T. Nichols[2], John P. Hutcheson[2], and Ty E. Lawrence[1], *[1]West Texas A&M University, Canyon, TX, [2]Merck Animal Health, Summit, NJ.*

An experiment was performed utilizing bioelectrical impendence technology (BIA) to predict red meat and trimmable fat yields for over-finished beef carcasses. Fifty-six single-sired steers were finished to above typical slaughter weights (603.5 kg ± 48.1 kg; 2.0 ± 0.7 cm 12th rib back fat) before harvest. After a 24-h chill period, standard grading procedures were used to derive a calculated yield grade for each animal (3.7 ± 0.9). Measures of BIA [resistance (Rs, 160.2 ± 16.5 ohms), reactance (Xc, 44.6 ± 4.8 ohms)] were quantified by introducing an alternating electrical current between positive (detector) and negative (source) electrodes placed at opposite ends of the right side of each carcass. Source electrodes introduced current through the carcass and detector electrodes detected any decrease in voltage caused by resistance to electrical current. Other measured variables included temperature (Tp, 3.1 ± 0.7°C), length between electrodes (L, 118.7 ± 5.1 cm), and hot carcass weight (HCW, 381.0 ± 32.8 kg). Impedance (I; $(Rs^2 + Xc^2)^5$; 166.3 ± 17.0) electrical volume (EVOL; L^2/Rs; 89.4 ± 16.8), resistive density (RsD; $RSW^2/(L^2/Rs)$; 392.4 ± 63.0), and reactive density (XcD; $RSW^2(L^2/Xc)$; 108.9 ± 16.3) were derived from measured variables. Correlations were calculated between dependent and independent variables. Stepwise regression procedures were used to develop models for prediction of percentage red meat yield (RMY%) and trimmable fat yield (TFY%). Pearson correlation coefficients indicate that RMY was highly correlated ($P < 0.05$) to RsD ($r = -0.65$), XcD ($r = -0.51$), Tp ($r = -0.46$), HCW ($r = -0.39$), EVOL ($r = 0.30$), Rs ($r = -0.30$), and I ($r = -0.28$) whereas FY was correlated ($P < 0.05$) with RsD ($r = 0.75$), XcD ($r = 0.60$), HCW ($r = 0.57$) and Tp ($r = 0.50$). Regression models indicate that 65% and 72% of the variation in RMY% and TFY% may be attributed to BIA measures. By comparison, the calculated USDA yield grade accounted for 50.0% and 61.0% of the variation in RMY% and TFY%, respectively. These results suggest that BIA technology can be utilized as a predictor of beef carcass composition.

Key Words: beef, bioelectrical impendence technology (BIA), zilpaterol

108 Dietary lysine affected the expression of genes related to lipid metabolism in skeletal muscle of finishing pigs. Taiji Wang*, Naresh Regmi, Jean M. Feugang, Mark A. Crenshaw, John R. Blanton Jr., and Shengfa F. Liao, *Department of Animal and Dairy Sciences, Mississippi State University, Mississippi State, MS.*

It has been reported that some amino acids can function as signaling molecules to regulate skeletal muscle growth in mammals. This study was conducted to identify those genes that may be regulated by amino acid lysine and responsible for muscle growth and meat quality of pigs. Nine crossbred barrows (94.4 ± 6.7 kg BW) were randomly allotted to 3 dietary treatments (3 pigs/treatment). Three corn and soybean-meal based diets were formulated to meet the NRC (2012) requirements for nutrients except for lysine, whose concentrations were 0.43, 0.71, and 0.98% for Diets 1 (lysine deficient), 2 (lysine adequate), and 3 (lysine excess), respectively. After 5 weeks on trial, pigs were killed and muscle samples collected from *longissimus dorsi* (between the 10th and 12th ribs). Total RNA was extracted from 50 mg of each sample using a TRIzol reagent. Porcine Gene 1.0 ST Array (Affymetrix, Inc.) was used to quantify the expression levels of 19,211 genes. Raw microarray data were normalized with gcRMA algorithm and analyzed with ANOVA using Partek Genomics Suite (Partek Inc.). A total of 674 transcripts were differentially expressed ($P < 0.05$); 60 out of 131 transcripts ($P < 0.01$) belong to 59 genes and 71 were unannotated. GO Enrichment analysis of this 59-gene set identified 11 genes in 5 categories of molecular functions: binding, catalytic activity, transcription regulator activity, transporter activity, and molecular transducer activity. Interestingly, 4 genes are associated with lipid metabolism: PSPH: lipid binding and key enzyme for serine (precursor of phospholipids and glycolipids) synthesis; CFD: stimulating glucose transport for triglyceride accumulation and inhibiting lipolysis; ME1: associated with backfat thickness and meat quality; SCD: playing a key role in intramuscular fat formation. It appears that lysine can regulate the expression of multiple genes, and at least 4 genes are related to lipid metabolism. Further studies are needed to elucidate the association of dietary lysine level with the expression levels of these genes and the gene network for lipid metabolism. (Supported by USDA Hatch/Multistate Project 233803)

Key Words: lysine, muscle, gene expression

109 Transcriptomic and metabolomic assessment of growth promoter effects on porcine muscle growth. John Brameld*[1], Kevin Ryan[1], Hannah Williams[1], Doug Harris[2], David Brown[1], Richard Emes[1], Tom Giles[1], Chungui Lu[1], Charlie Hodgman[1], and Tim Parr[1], *[1]University of Nottingham, Nottingham, UK, [2]Zoetis, Kalamazoo, MI.*

This study compared the effects of growth hormone (GH) and β-adrenergic agonist (BA) on porcine muscle transcriptome and blood metabolome. Duroc × (Landrace × Large White) gilts (77 ± 7.1 kg, n = 165) were all fed a high protein/energy diet ad libitum, with the GH group receiving an intramuscular injection, 10mg once every 2d of porcine GH (Reporcin, Zamira), the BA group receiving Ractopamine at 20mg/kg feed, whereas the control group just had feed. Pigs were treated for 1, 3, 7, 13d (n = 10 per treatment for each period) and 27d (n = 15 per treatment for each period). After each treatment period muscles were harvested and blood collected, then plasma immediately prepared. The remaining carcass was incinerated. Plasma was analyzed by Metabolon's biochemical platform technology. Total RNA from LD was extracted and subjected to transcriptome analysis (Agilent pig microarray) followed by gene cluster analysis using MaSigPro. Gene expression was verified by quantitative RT-PCR. Protein expression was determined by Western blot. Treatment groups were compared by 2-way ANOVA (Genstat). The BA treatment increased Vastus Lateralis weight ($P < 0.001$), and induced a switch to faster muscle fiber type in Longissimus dorsi (LD), as myosin heavy chain isoform IIB gene expression was increased ($P < 0.001$). Within 1d of treatment plasma fatty acids were increased in BA, but not GH ($P < 0.05$). Both GH and BA decreased certain plasma amino acids, such as lysine ($P < 0.05$), but only GH decreased the concentration of others, such as serine ($P < 0.05$) and glycine ($P < 0.05$). Only GH increased glucose ($P < 0.05$) but there was no effect of either GH or BA on lactate ($P > 0.1$). Predominant effect of treatment was a BA coordinate increase in LD serine synthesis pathway gene expression (PHGDH, $P < 0.001$; PSAT, $P < 0.001$; PSPH, $P < 0.001$) by 3d, which was confirmed at the protein level, as PHGDH was increased with BA at 7d ($P < 0.001$). The effect of GH and BA treatment on metabolism appears to lead to differential effects on muscle mass, with BA potentially elevating serine synthesis, which could lead to the generation of metabolites required for growth.

Key Words: growth promoters, pig, transcriptomics

110 Molecular factors underlying the discrepancy of marbling between Nellore and Angus beef. Taiane Martins[1], Walmir Silva[1], Letícia Sanglard[1], Ivan Carvalho Filho[1], Ygor Cassani[1], Nick Serão[2], Mario Chizzotti[1], Marcio Ladeira[3], and Marcio Duarte*[1], *[1]Federal University of Vicosa, Vicosa, MG, Brazil, [2]Iowa State University, Ames, IA, [3]Federal University of Lavras, Lavras, MG, Brazil.*

Studies have reported that intramuscular adipogenesis and fibrogenesis may concomitantly occur in skeletal muscle of beef cattle. Thus, we hypothesized that the discrepancy of intramuscular fat content in beef from Nellore and Angus bulls was associated with differences in intramuscular adipogenesis and fibrogenesis during the finishing phase. To test our hypothesis, longissimus muscle samples of Nellore (n = 6; BW = 372.5 ± 37.3 kg) and Angus (n = 6; BW = 382.8 ± 23.9 kg) bulls with 20 mo of age were collected for analysis of gene and protein expression, and chemical quantification of intramuscular fat and collagen. Least squares means were estimated for the effect of breed and differences were considered at $P \leq 0.05$. A greater intramuscular fat content was observed in skeletal muscle of Angus compared with Nellore cattle ($P < 0.01$). Despite the lack of differences in gene expression of adipogenic markers *Zfp423* ($P = 0.62$), *PPARγ* ($P = 0.42$), and *C/EBPα* ($P = 0.14$), a greater protein expression of PPARγ was observed in skeletal muscle of Angus compared with Nellore cattle ($P = 0.05$). A greater abundance of adipo/fibrogenic cells, evaluated by the PDGFRα content, was observed in skeletal muscle of Angus than Nellore cattle ($P = 0.05$). No differences in fibrogenesis were observed in skeletal muscle of Angus and Nellore cattle, which is in accordance with the lack of differences in intramuscular collagen content in beef from both breeds ($P = 0.16$). These findings demonstrate that difference in intramuscular fat content is associated with a slightly enhanced adipogenesis in skeletal muscle of Angus compared with Nellore cattle, but no difference in fibrogenesis.

Key Words: adipocyte, collagen, intramuscular fat

111 Effect of rearing system on meat quality, lipid, and amino acid profiles of lambs. Jian-min Chai[1], Hai-chao Wang[1], Qi-yu Diao[1], Kai-dong Deng[2], Yan Tu[1], Min-li Qi[1], and Nai-feng Zhang*[1], *[1]Feed Research Institute of Chinese Academy of Agricultural Sciences, Key Laboratory of Feed Biotechnology of the Ministry of Agriculture, Beijing, China, [2]College of Animal Science, Jinling Institute of Technology, Nanjing, Jiangsu, China.*

To determine the effect of rearing system on meat quality, lipid and amino acid profiles of lambs, 24 Hu lambs (12 rams and 12 ewes) were randomly divided into 2 treatments: ewe-reared (ER) or weaned at d 10 and fed milk replacer (MR). Ewe milk or MR was available from 0 to 60 d and a creep feed was offered ad libitum to all lambs from d 15 to 90. The fatty acid and amino acid composition of the diet and meat samples were determined by gas chromatography and automated dedicated amino acid analyzer, respectively. All data were analyzed using *t*-test procedure of SAS. Lambs fed MR had a greater growth rate ($P = 0.03$) and creep feed intake ($P < 0.001$) than those in ER treatment. Lambs fed MR had a greater harvest weight ($P = 0.003$), HCW ($P = 0.004$) and fat thickness over L *dorsi* ($P = 0.05$) compared with those of ER treatment. The meat of lambs in MR treatment had lesser L* ($P = 0.04$) and b* ($P = 0.02$). There was no difference ($P = 0.82$) in a* values between the 2 treatments. Lambs fed MR had greater ether extract content ($P = 0.003$) than that in ER treatment. No differences were found in crude protein ($P = 0.58$) and ash ($P = 0.11$) between 2 treatments. The content of unsaturated fatty acids and monounsaturated fatty acids in meat were greater ($P = 0.02$) for MR treatment compared with ER treatment. On the contrary, the proportion of saturated fatty acids in ER treatment was greater ($P = 0.03$) than that in MR treatment. The proportion of C14:0 of ER lambs was greater ($P = 0.01$) than that in MR treatment, while the proportion of C18:0 ($P = 0.003$), C18:2 ($P = 0.04$), C18:3 ($P = 0.008$) and the ratio of polyunsaturated fatty acids ($P = 0.002$) and saturated fatty acids (P/S) ($P = 0.03$) were lesser than those of MR treatment. The proportion of leucine ($P = 0.003$), alanine ($P < 0.001$), tyrosine ($P = 0.002$), and proline ($P < 0.001$) were greater, while histidine ($P = 0.014$) was lesser for lambs of MR treatment compared with those of ER treatment. In conclusion, the MR rearing system could increase meat production and improve the proportion of lipid and amino acid profiles of lambs.

Key Words: meat quality, lipid, amino acid profile

112 The effects of growth-promoting agents on ovine metabolism and growth. Shaker Al-Doski*[1], Tim Parr[1], Krystal Hemmings[3], Zoe Daniel[1], David Brown[1], Doug Harris[2], Chungui Lu[1], Charlie Hodgman[1], Sean May[1], and John Brameld[1], *[1]University of Nottingham, Nottingham, UK, [2]Zoetis, Kalamazoo, MI, [3]University of Derby, Derby, UK.*

This study sought to investigate the short-term effects of bovine growth hormone (GH) and β-adrenergic agonist (βA), on lamb liver and muscle, particularly protein and energy metabolism. Wether lambs (120 d old) were all fed a high protein/energy diet ad libitum, with the GH group (n = 10) receiving a single subcutaneous injection of bovine GH (Posilac, Monsanto, 3.75mg/kg BW) on d 1; the βA group (n = 10) receiving βA (cimaterol) at 10mg/kg in the feed, whereas the control group (C, n = 11) only had ad libitum feed. After 6 d sheep were slaughtered blood was collected, plasma immediately prepared, and subsequently analyzed using Metabolon's biochemical platform technology. Samples of Longissimus dorsi (LD) and Supraspinatus (SS) muscles were snap frozen in liquid nitrogen and stored at −80°C until analysis, the remaining carcass was incinerated. From extracted total RNA first strand cDNA was generated using random primers. Gene expression was determined by quantitative RT-PCR analysis relative to total cDNA, as measured using oligreen. Protein expression was determined by Western blot. Treatment groups were compared by one-way ANOVA (Genstat) and post hoc Dunnett's test. Although there were no significant effects of βA and GH in body weight of lambs ($P = 0.122$), βA, but not GH, significantly increased the weights of both SS ($P < 0.01$) and ST ($P < 0.05$). In the blood, GH significantly increased the concentration of more fatty acids than βA ($P < 0.05$), both GH and βA significantly decreased certain plasma amino acids ($P < 0.05$). Treatment with βA, but not GH, increased mRNA expression of genes involved in glycolysis ($P < 0.05$) and the serine synthesis pathway ($P < 0.05$) in both SS and ST, but decreased expression of genes in the TCA cycle ($P < 0.05$). Effects on the serine pathway were confirmed as protein levels for PHGDH were significantly increased with βA ($P < 0.001$). It appears that GH and βA have differential effects on metabolism that lead to differential effects on muscle mass over this short time frame. Treatment with GH has wider effects on whole body metabolism, while βA appears to have more specific effect on both muscle metabolism and its growth.

Key Words: growth promoter, sheep, transcriptomics

Nonruminant Nutrition: Enzymes and processing

113 Comparative efficacy of xylanases on energy and nutrient digestibility in growing pigs fed corn- or wheat-based diets. Elijah Kiarie*[1,2], Luis F. Romero[1], Susan Arent[3], Rikke Lorentsen[3], and Hans H. Stein[4], *[1]DuPont Industrial Biosciences-Danisco Animal Nutrition, Marlborough, Wiltshire, UK, [2]Department of Animal Science, University of Manitoba, Winnipeg, MB, Canada, [3]DuPont Nutrition Biosciences–Enzyme Research & Development, Brabrand, Arhus, Denmark, [4]Department of Animal Sciences, University of Illinois, Urbana, IL.*

Microbial xylanases differ with respect to source, substrate specificities, and biochemical characteristics, but these differences are rarely considered in their evaluation for animal feed applications. Therefore, an experiment was conducted to determine effects of 5 xylanases on apparent ileal (AID) and apparent total-tract digestibility (ATTD) of energy and nutrients in growing pigs fed diets based on corn plus 40% corn distillers dried grains with solubles (DDGS) or wheat plus 25% wheat co-products. The 5 xylanases (XA, XB, XC, XD and XE) were mono-component preparations of endo-1,4-β-xylanase produced by different fungal organisms except XC, which was of bacterial origin. Xylanases were fed at 75 mg of xylanase protein/kg of feed. All diets also contained microbial phytase (500 units/kg). All xylanases and phytase were provided by Danisco Animal Nutrition, Marlborough, Wiltshire, UK. Twelve ileal cannulated barrows (29.3 kg BW) were allotted to two 6 × 6 Latin squares with 6 corn-based and 6 wheat-based diets in each square. Corn and wheat diets had similar levels of insoluble (11.6 vs. 11.0%) non-starch polysaccharides (NSP), but corn diets contained less soluble NSP (1.3 vs. 1.9%) and starch (31.1 vs. 39.0%) than wheat diets. Corn diets containing XD or XE had greater ($P < 0.05$) AID of GE (68.5%) than the control diet (64.6%) or diets containing XB (64.3%) or XC (64.3%), whereas in wheat diets, the diet containing XE had lower ($P < 0.05$) AID of GE (67.9%) compared with diets containing XA, XC, and XD that all had an AID of 72.8% (interaction, $P < 0.05$). Wheat based diets had greater ($P < 0.05$) AID of GE and nutrients compared with corn diets. There was no main effect of diet and no interactions between xylanase and diet for ATTD of GE, but diets containing XE or XD had greater ($P < 0.05$) ATTD of GE compared with the control diets and diets containing XC, whereas results for diets containing XA and XB were intermediate. These data indicate that not all xylanase sources are similar in efficacy at the pig gut level, which may be a result of the unique characteristics of each xylanase.

Key Words: digestibility, xylanase, pig

114 Effects of supplemental xylanase on digesta viscosity, gut health, and growth performance of nursery pigs. Hongyu Chen*[1], Rafael Cabrera[2], and Sung Woo Kim[1], *[1]North Carolina State University, Raleigh, NC, [2]Huvepharma Inc., Peachtree City, GA.*

A total of 40 pigs (10.7 ± 1.2 kg initial BW at 6 wk of age) were used in a 21 d trial to evaluate the effects of supplemental xylanase (Huvepharma Inc., Peachtree City, GA) in nursery diets on digesta viscosity, gut health, and growth performance. Pigs were individually housed and randomly allotted to 4 dietary treatments in a 2 × 2 factorial arrangement (n = 10 per treatment, 0 or 1,500 EPU/kg xylanase and 0 or 30% DDGS as 2 factors). Body weight and feed intake were recorded weekly. Plasma samples were collected on d 19 to measure tumor necrosis factor-α (TNF-α) and malondialdehyde (MDA). On d 21, all pigs were euthanized to collect tissues from duodenum, jejunum, and colon for morphology and to measure TNF-α, and MDA concentrations. Distal jejunal digesta were collected to measure viscosity. During the entire period, supplementation of xylanase increased ($P < 0.05$) ADG (616 to 660 g/d) of nursery pigs whereas DDGS (0 or 30%) did not affect ADG (628 vs. 648 g/d, respectively). There was no interaction between the 2 factors indicating that the effect of xylanase on ADG was independent to the use of DDGS in the nursery feed. On wk 3, ADFI was increased ($P < 0.05$) when fed DDGS (1,141 to 1,267 g/d) and there was an interaction ($P < 0.05$) between 2 factors indicating that xylanase decreased ADFI when DDGS was used in the feed. Use of DDGS increased ($P < 0.05$) viscosity (1.86 to 2.38 cP), whereas supplemental xylanase reduced ($P < 0.05$) viscosity (2.27 to 1.96 cP) of jejunal digesta. Plasma TNF-α was decreased ($P < 0.05$, 108.45 to 69.87 ng/mL) by supplemental xylanase. Use of DDGS reduced ($P < 0.05$) villus height:crypt depth ratio (1.46 to 1.27) in duodenum. Supplemental xylanase increased ($P < 0.05$) the crypt depth (360 to 404 µm) in duodenum. Collectively, this study indicates that supplemental xylanase (1,500 EPU/kg) improved growth performance and inflammatory status of nursery pigs by reducing digesta viscosity and plasma TNF-α regardless of the use of DDGS in nursery diets.

Key Words: digesta viscosity, pig, xylanase

115 Effects of supplemental xylanase on growth, gut health, and ileal nutrient digestibility in nursery pigs fed corn-soybean meal-based diets with two dietary energy levels. I. Park*[1], H. Chen[1], J. Tyus[2], J. J. Wang[2], and S. W. Kim[1], *[1]North Carolina State University, Raleigh, NC, [2]BioResource International Inc., Durham, NC.*

This study was conducted to determine the effects of supplemental xylanase (Xylamax, BioResource International, Inc., Durham, NC) on growth performance, gut health, and ileal nutrient digestibility in nursery pigs fed corn-soybean meal based diets with 2 dietary energy levels. Pigs (60 barrows and 60 gilts weaned at 21 d of age) had a 4-d adaptation period after weaning. On 25 d of age (7.77 ± 0.63 kg BW), pigs were allotted to 4 treatments (2 × 2 factorials arrangement: 3,427 or 3,323 kcal ME/kg of feed and 0 or 1,400 U of enzyme/kg feed) with 10 pens (5 barrow and 5 gilt pens, and 3 pigs per pen) per treatment in a randomized complete block design, and the feeding period lasted for 3 wks. Growth performance was measured weekly. Titanium dioxide (0.3%) was added to diets from d17 to 21 as an indigestible marker. Blood samples were taken on d 20 to measure tumor necrosis factor-α (TNF-α) and malondialdehyde (MDA). On d 21, 24 pigs (1 from each pen and 6 pens per treatment) were euthanized to obtain the duodenal and jejunal mucosa to measure TNF-α and MDA. Jejunal and ileal digesta were collected to measure viscosity and ileal nutrient digestibility. Data were analyzed using the Mixed procedure in SAS with pen as the experimental unit using treatments and sex as fixed effects and initial BW as a random effect. The G:F was improved ($P < 0.05$) by increasing dietary ME (0.774 to 0.800) and xylanase supplementation (0.775 to 0.799), respectively. Dietary energy levels and xylanase supplementation did not affect viscosity and ileal nutrient digestibility. High ME diet increased ($P < 0.05$) the concentrations of MDA in jejunal mucosa (0.74 to 1.25 nmol/mg protein) and plasma (16.89 to 23.79 µ*M*). Supplemental xylanase decreased ($P < 0.05$) MDA (1.02 to 0.88 nmol/mg protein) and TNF-α (3.03 to 2.50 pg/mg protein) concentrations in duodenal mucosa. Collectively, supplemental xylanase (1,400 U of enzyme/kg feed) in corn-soybean meal based pig diets enhances growth performance and gut health of nursery pigs as indicated by increased feed efficiency and reduced MDA and TNF-α concentrations in duodenal mucosa, respectively.

Key Words: growth performance, gut health, xylanase

116 Porcine in vitro digestion and fermentation characteristics of wheat and wheat millrun without or with xylanase and β-glucanase blend.

Tofuko A. Woyengo*[1,2], Elijah Kiarie[3,4], and Ruurd T. Zijlstra[1], *[1]University of Alberta, Edmonton, AB, Canada, [2]South Dakota State University, Brookings, SD, [3]Danisco Animal Nutrition-DuPont Industrial Biosciences, Waukesha, WI, [4]University of Manitoba, Winnipeg, MB, Canada.*

A study was conducted to determine porcine in vitro digestion and fermentation characteristics of the wheat and wheat millrun without or with a with xylanase and β-glucanase blend (XB, Danisco UK Ltd., Marlborough, Wiltshire, UK) that supplied 4,880 units of xylanase and 608 units of β-glucanase per kilogram of treated feedstuff in a completely randomized design. Samples were hydrolyzed in 2 steps using pepsin and pancreatin. Subsequently, residues were incubated in a buffer solution with minerals and fresh pig feces as inoculum. Gas production was measured for 72 h, and modeled to estimate kinetics of gas production. Concentration of VFA per unit weight of residue incubated or feedstuff was measured in fermented solutions. In vitro digestibility of DM (IVDDM) for wheat (77.7%) was greater ($P < 0.05$) than that for wheat millrun (63.2%). Feedstuff and XB interacted ($P < 0.05$) on IVDDM such that XB supplementation increased ($P < 0.05$) IVDDM for wheat, but not for wheat millrun. Total gas production of residue incubated for wheat (176.6 mL/g DM) was greater ($P < 0.05$) than that for wheat millrun (117.4 mL/g DM). Also, total VFA production per unit weight of residue incubated for wheat (3.12 mmol/g DM) was greater ($P < 0.05$) than that for wheat millrun (2.16 mmol/g DM). However, XB did not affect total gas production and total VFA production per unit weight of residue incubated. Total VFA production per unit weight of feedstuff for wheat (0.79 mmol/g DM) was lower ($P < 0.05$) than that for wheat millrun (0.93 mmol/g DM). Feedstuff and XB tended to interact ($P = 0.096$) on total VFA production per unit weight of feedstuff such the XB decreased $P < 0.05$) total VFA production per unit weight of feedstuff for wheat but not for wheat millrun. In conclusion, wheat was more digestible by porcine pepsin and panceatin than wheat millrun, whereas wheat millrun was more fermentable than wheat. The XB supplementation increased the digestion of wheat, but had limited effect on the digestion and fermentation of wheat millrun.

Key Words: wheat and wheat millrun, in vitro fermentation, pig

117 Supplemental effects of β-mannanase on growth performance, ileal nutrient digestibility, and gut health of nursery pigs.

Hongyu Chen*, Inkyung Park, Shihai Zhang, and Sung Woo Kim, *North Carolina State University, Raleigh, NC.*

A total of 84 pigs (17.6 ± 2.8 kg initial BW at 6 wk of age) were used in a 40-d trial to evaluate effects of dietary supplemental β-mannanase (400 U/kg feed, CTCBIO Inc., Seoul, Korea) on growth performance, ileal nutrient digestibility and gut health of nursery pigs. Pigs were allotted to 2 treatments (14 pens per treatment, 3 pigs per pen) based on a randomized complete block design with sex and initial BW as blocks. Experimental diets were corn (phase 3: 50%, phase 4: 57%), soybean meal (phase 3: 27%, phase 4: 20%), and 20% DDGS based with or without 400 U β-mannanase/kg feed. Growth performance (ADG, ADFI, and G:F) was recorded weekly. Plasma was collected on d 35 to quantify tumor necrosis factor-α (TNF-α) and malondealdehyde (MDA). On d 35, 0.3% titanium oxide was added as an indigestible marker to the diets for an additional 4 d feeding. On d 40, 16 pigs (1 pig per pen, 8 pens per treatment) were euthanized to collect digesta from jejunum, ileum, and colon (to measure viscosity and pH value) and to collect tissues from duodenum, jejunum and ileum (for morphology, TNF-α, and MDA evaluation). Supplementation of β-mannanase reduced ($P < 0.05$) viscosity of jejunal digesta (2.52 to 1.97 cP, respectively). Supplementation of β-mannanase improved ($P < 0.05$) G:F during phase 3 (0.593 to 0.617) and overall period (0.572 to 0.589), pH of colon digesta (5.99 to 6.33), and ileal digestibility of NDF (31.3 to 41.1%) and ADF (26.8 to 38.7%). Supplementation of β-mannanase increased ($P < 0.05$) ileal villus height (377 to 432 μm), decreased ($P < 0.05$) jejunal crypt depth (249 to 212 μm), and improved ($P < 0.05$) villus height:crypt depth ratios in jejunum (1.58 to 2.10) and ileum (1.65 to 2.02). Supplementation of β-mannanase tended to reduce ($P = 0.078$) TNF-α concentration (7.94 to 6.46 pg/mg) in jejunal mucosa. Collectively, dietary β-mannanase (400 U/kg) could improve feed efficiency by decreasing digesta viscosity and increasing nutrient digestibility, and could also maintain gut health by improving gut morphology and reducing inflammatory response.

Key Words: digesta viscosity, nutrient digestibility, β-mannanase

118 Effect of superdosing two sources and two levels of phytases on pig performance when supplemented to commercial nursery diets.

Chris Sparks*[1], Rafael A. Cabrera*[1], Gene Gourley[2], and Emily Weber[2], *[1]Huvepharma US Inc., Peachtree City, GA, [2]Gourley Research Group LLC, Webster City, IA.*

The objective of this study was to determine the effect of superdosing 2 sources and levels of phytases on nursery pig performance in a commercial setting. Phase 1 (crumble/meal mix), phase 2 (common meal) and phase 3 diets were corn-SBM with 4, 10, and 20% DDGS respectively and contained 0.47, 0.40, and 0.35% av. P respectively. They were budgeted at 5.7 and 6.4 kg/pig for phase 1 and 2 and until they moved out of the nursery for phase 3. Six experimental diets were fed: Positive Control (PC), Negative Control (NC, PC minus 0.12% av. P), 500 and 1000 FTU/kg of Optiphos 2000 (Huvepharma USA, Inc.); and 500 and 1000 Quantum Blue 5G (AB Vista) were added to the NC. We had 10 pens per treatment and 21 pigs/pen. Pigs (Geneticpork Fertilis 25 female x PIC Line 359 Sire) were sourced out of a sow farm negative to PPRS, PED virus and *M. hyopneumonea*. Pens were weighed at 7 d interval. Pens were the experimental units and we found no gender by treatment interactions therefore gender was removed from the model. The ANOVA was performed using SAS statistical software (SAS Institute, Cary, NC). From d 0 to 44 (Overall), all phytase treatments had higher ($P < 0.01$) final pig BW, increased ($P < 0.01$) ADG, and higher ($P < 0.01$) ADFI when compared with either PC or NC. Positive Control and NC treatments were not different for those traits. All phytase treatments had decreased ($P = 0.03$) FCR when compared with the PC but were not different than the NC. There were not significant differences in any performance traits between Optiphos and Quantum Blue. Increasing the levels of phytases from 500 FTU/kg of complete feed to 1000 FTU/kg of complete feed with either source did not result in improved performance. In this trial, 500 FTU/kg of complete feed performed as well as 1000 FTU/kg of complete feed of either Optiphos or Quantum Blue for commercially raised nursery pigs.

Key Words: nursery pig, superdosing, phytase level

119 Effects of superdosing of microbial phytase in diets for weanling pigs.

T. D. Crenshaw*[1], O. Adeola[2], M. J. Azain[3], S. K. Baidoo[4], S. D. Carter[5], G. M. Hill[6], S. W. Kim[7], P. S. Miller[8], M. C. Shannon[9], and H. H. Stein[10], *[1]University of Wisconsin, Madison, WI, [2]Purdue University, Lafayette, IN, [3]University of Georgia, Athens, GA, [4]University of Minnesota, Minneapolis, MN, [5]Oklahoma State University, Stillwater, OK, [6]Michigan State University, East Lansing, MI, [7]North Carolina State University, Raleigh, NC, [8]University of Nebraska, Lincoln, NE, [9]University of Missouri, Columbia, MO, [10]University of Illinois, Urbana-Champaign, IL.*

An experiment using 390 crossbred pigs (20 replications of 3 or 4 pigs/pen) was conducted at 10 research stations to assess the effects of superdosing phytase on nursery pig growth performance. Corn-soybean meal phase 2 nursery diets were fed for 21-d from 8.5 to 17.6 kg BW. A common premix was formulated using the NCCC42 formulations, and mixed at a central location. Diets were formulated to contain 1.35% standardized ileal digestible (SID) Lys. The positive control diet contained 0.8% Ca, 0.69% P and 0.40% standardized total-tract digestible (STTD) P. The negative control diet contained 0.50% Ca, 0.42% P and 0.18% STTD P. Dietary phytase (Ronozyme HiPhos) was added to the negative control diet premix to provide 0, 500, 1,500 or 3,000 phytase units (FTU)/kg complete diet. On d21, one pig per pen was killed and the 3rd and 4th metacarpals from the right front foot were analyzed for total bone ash. Data were analyzed using the Glimmix procedure of SAS. Pigs were randomly selected based on weight, age, sex, and ancestry. Station by treatment effects were observed for ADG in wk 2 and for the entire period, and for ADFI in wk 2, wk 3, and for the entire period. Body weight gain linearly increased as increased concentrations of phytase were added to the negative control diet (360, 440, 450, and 470 g/d; $P < 0.01$), but ADFI (640, 710, 700, 720 g/d) was not affected during the 21-d study. A linear increase ($P < 0.05$) in G:F was observed as phytase additions increased (0.56, 0.62, 0.64, 0.65 g/g for pigs fed diets containing 0, 500, 1,500, or 3,000 FTU of phytase). Percent bone ash also increased (linear, $P < 0.01$) as addition of phytase increased (44.6, 48.4, 49.2, and 50.6% for pigs fed diets containing 0, 500, 1,500 or 3,000 FTU of phytase, respectively). Percent bone ash was not different between pigs fed the positive control diet and the negative control diet containing 3,000 FTU/kg of phytase (51.1 vs. 50.5%, respectively). In this 21-d study, feeding phase 2 nursery diet containing up to 3,000 FTU/kg resulted in similar growth performance and bone ash percentage as pigs fed a positive control diet containing 0.8% Ca, 0.69% P and 0.40% STTD P.

Key Words: phosphorus, pig, phytase

120 Effect of water-to-feed ratio on the digestibility of diets fed to growing-finishing pigs.

Cinta Sol*, Lorena Castillejos, Ramon Muns, and Josep Gasa, *Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain.*

Dilution rates water to feed may affect the apparent total-tract digestibility (ATTD) of barley-wheat diets fed to growing-finishing pigs. The experiment lasted 52 d and it was divided in 2 studies of 26 d each. In the first study 16 female pigs (46.7 ± 1.98 kg of body weight, BW) were individually allotted and assigned to 1 of 4 treatments (n = 4). Treatments consisted in 4 water-to-feed ratios: in dry form (CON), with no added water, and ratios of 0.6:1, 2.1:1 and 2.7:1. In the second study the same animals (65.4 ± 3.14 Kg of BW) were again assigned to 4 new treatments: CON and 1.35:1, 2.7:1 and 3.5:1 ratios. Each pen was provided with a free-choice nipple drinker. Diet was fed close to "ad libitum" trying to avoid refusals, a 0.3% of TiO_2 was added to the feed as an indigestible marker and fecal grab samples were collected from the rectum twice a day the 2 last days of each study. Data of ATTD of OM, GE and nutrients were analyzed by one-way ANOVA using the GLM procedure of SAS and differences among mean values were assessed by the Tukey *t*-test. In the first study, pigs fed diets with ratios 2.1:1 and 2.7:1 had higher organic matter digestibility (OMd) and gross energy digestibility (GEd) than CON ($P < 0.05$). Pigs fed diets with a ratio of dilution 2.7:1 also had higher ($P < 0.05$) intake of digestible organic matter (DOMi) and digestible energy (DEi) than pigs fed CON. In the second study, pigs fed water diluted diets (the 3 ratios) had better OMd and GEd than CON ($P < 0.05$) but no differences were found in DOMi. Compared with CON, the dilution of 3.5:1 also showed a higher ($P < 0.05$) digestibility coefficients for crude protein (CP), ether extract (EE) and crude fiber (CF) and the dilution 1.35:1 and 2.7:1 also for CF. Using a quadratic regressions approach, the maximum feed OM and GE digestibility coefficient was found with dilution rates of 1.83:1 and 2.70:1 for the first and second study, respectively. In conclusion, the water-to-feed ratio which optimized OM and GE digestibility varies depending on the age of the animals; being lower ratios better for young pigs and higher for finishing pigs. Despite the fact that dilution rates below 2.5–2.7:1 are not usually achieved in liquid feeding commercial farms.

Key Words: water-to-feed ratio, growing-finishing pig, nutrient digestibility

121 Effects of pelleting and extrusion on energy digestibility in pig diets containing different levels of fiber.

Oscar J. Rojas*[1], Ester Vinyeta[2], and Hans H. Stein[1], *[1]University of Illinois, Urbana, IL, [2]Bühler AG, Uzwil, Switzerland.*

An experiment was conducted to determine effects of pelleting, extrusion, and extrusion plus pelleting on energy and nutrient digestibility in diets containing low, medium, or high levels of fiber. Three diets were formulated: (1) a low fiber diet contained corn and soybean meal; (2) a medium fiber diet contained corn, soybean meal, and 25% distillers dried grains with solubles (DDGS); and (3) a high fiber diet contained corn, soybean meal, 25% DDGS, and 20% soybean hulls. Each diet was divided into 4 batches after mixing and the treatments included the following: (1) no further processing; (2) pelleted at 85°C; (3) extruded at 115°C using a single screw extruder; and (4) extruded at 115°C and then pelleted at 85°C. Thus, 12 different diets were produced. A total of 24 growing pigs (initial BW: 26.5 ± 1.5 kg) with a T-cannula fitted in the distal ileum were allotted to the diets in a split-plot design with 8 pigs allotted to the low fiber diets; 8 pigs were allotted to the medium fiber diets; and 8 pigs were allotted to the high fiber diets. Diets were fed to the pigs during 4 14-d periods. Within each type of diet, the 8 pigs were fed the diets produced using the 4 processing technologies. Thus, there were 8 replicate pigs per diet. Each of the 4 14-d periods consisted of 5 d for adaptation, 5 d of fecal collection, and ileal digesta were collected on d 13 and 14 of each period. Results indicated that pelleting, extrusion, or extrusion and pelleting improved ($P < 0.05$) the apparent ileal digestibility (AID) of starch and most indispensable AA. In most cases, there were no differences between the pelleted, the extruded, and the extruded plus pelleted diets. The apparent total-tract digestibility (ATTD) of energy and the ME of the diets were also improved ($P < 0.05$) by pelleting and by the combination of extrusion plus pelleting, and extrusion alone improved ATTD of energy and ME in the low fiber and the high fiber diets. Results of this experiment indicate that energy utilization may be improved by pelleting or extrusion or by the combination of the 2 technologies, but the response to extrusion seems to be greater in diets that are relatively high in fiber.

Key Words: extrusion, fiber, pelleting

122 Mix time does not affect growth performance in finishing pigs fed meal and pelleted diets with high inclusion (32% DDGS and 32% wheat midds) of alternative ingredients.

Megan E. Morts*, Joe D. Hancock, C. Greg Aldrich, Charles R. Stark, Joel D. McAtee, and Kayla L. Kohake, *Kansas State University, Manhattan, KS.*

A total of 200 finishing pigs (average initial BW of 72 kg) were used in a 51-d growth assay to determine the effects of mix time in meal and pelleted diets with high inclusion of alternative ingredients (32% DDGS and 32% wheat middlings) on growth performance and carcass measurements. The pigs were sorted by gender and ancestry and assigned to pens (5 pigs/pen and 10 pens/treatment) in a completely randomized design. The diets (907 kg batches) were blended in a Hayes & Stolz twin-shaft double-ribbon mixer. All ingredients (corn, soybean meal, DDGS, wheat middlings, limestone, salt, vitamin mix, mineral mix, crystalline amino acids, and tylosin) were added to the stopped mixer. Mix times were 0 and 180 s before transfer to sack-off or being pelleted before transfer to sack-off. Treatments were arranged as a 2 × 2 factorial with main effects of diet form (meal vs. pellets) and mix time (0 vs. 180 s). Diets were formulated to at least 120, 120, and 110% of requirements for essential amino acids, vitamins, and minerals, respectively, as suggested in the NRC (2012) Nutrient Requirements of Swine. Feed and water were consumed on an ad libitum basis until the pigs were harvested (avg BW of 119 kg) at a commercial abattoir for collection of carcass data. There were no interactions among diet form and mix time ($P = 0.45$ or greater). Pelleting improved ($P < 0.01$) ADG and G:F, but did not affect ($P = 0.49$ or greater) hot carcass weight (HCW), last rib backfat thickness (BF), or dressing percentage (dress %). Mix time did not affect ($P = 0.17$ or greater) ADG, G:F, HCW, BF, or dress %. In conclusion, increasing mix time from 0 to 180 s in meal or pelleted diets with high inclusion of DDGS and wheat middlings did not improve growth performance or carcass characteristics.

Table 1 (Abstr. 122). Effects of diet form (meal vs. pellet) and mix time (0 vs. 180 s) on performance and carcass traits

	Mash		Pellet			*P*-value		
Item	0 s	180 s	0 s	180 s	SE	Form	Mix	Form x Mix
ADG, g	909	893	969	944	28	0.01	0.17	0.76
G:F, g/kg	294	298	312	319	5	0.01	0.31	0.78
HCW, kg	87.4	86.9	88.2	88.1	3.2	0.49	0.84	0.90
Dress %	73.3	72.9	72.8	73.1	0.5	0.71	0.98	0.45
BF, mm	23	22	23	22	2	0.76	0.54	0.66

123 Effect of sieving methodology on determining particle size of ground corn, sorghum, and wheat by sieving.

Julie R. Kalivoda*, Cassandra K. Jones, and Charles R. Stark, *Kansas State University, Manhattan, KS.*

Particle size determination by sieving is a standard method used to estimate the geometric mean (dgw) and geometric standard deviation (Sgw) of feedstuffs. However, the method allows for variation in time of sieving, sieve agitator setup, and the use of dispersing agent (fumed silica). The objectives of this experiment were to determine which method of particle size analysis best estimates the particle size of cereal grain and assess analytical variation within each method. Treatments were arranged in a 4 × 3 × 3 × 2 factorial design with 4 sieving methods: (1) 10 min with sieve agitators (10A), (2) 15 min with no sieve agitators (15N), (3) 15 min with sieve agitators (15A), or (4) 15 min with sieve agitators and a dispersing agent (15AS), 3 cereal grains (corn, wheat, or sorghum), 3 grinds (coarse, medium, or fine), and 2 mills (hammermill or roller mill). Mill parameters were adjusted to achieve 3 grinds with coarse being the largest and fine being the smallest. Samples were analyzed for particle size according to ASAE S319.3. Data were analyzed using GLIMMIX procedure of SAS with 4 replicates per treatment. Interactions were removed from the model if $P > 0.05$. The main effects of method, grain, grind size, and grind method all differed ($P < 0.01$) for both dgw and Sgw. All methods were significantly different from one another ($P < 0.05$; 587, 615, 576, and 541 for dgw and 2.23, 2.09, 2.27, and 2.63 for Sgw for 10A, 15N, 15A, and 15AS, respectively). All grains differed from one another, with corn having the smallest dgw and Sgw ($P < 0.05$; 537 and 2.28, 550 and 2.34, 652 and 2.31, respectively for corn, sorghum, and wheat dgw and Sgw). Hammermill ground grain had a smaller dgw and larger Sgw than roller mill ground grain ($P < 0.05$; 415 and 2.62 vs. 744 and 1.99, respectively). As expected, varying grind size resulted in different dgw ($P < 0.05$), but Sgw was also affected as the coarse and medium grinds had greater Sgw than the fine grind (2.36 and 2.35 vs. 2.23, respectively). In summary, the particle size analysis method of 15AS provided the lowest dgw and highest Sgw, suggesting that all particles had reached their appropriate spot within the sieve stack and thus was the most accurate of the tested methods.

Key Words: corn, grain, particle size analysis

Physiology and Endocrinology: Reproduction and estrous synchronization

124 Characterization of endometrial immune cells adjustments along pregnancy in the cow. Ana Carolina Furlanetto Mançanares[1], Gabriela de Paula Figueiredo[2], Rodrigo da Silva Nunes Barreto[1], Daniele dos Santos Martins[2], Flávio Vieira Meirelles[2,1], and Lilian J. Oliveira*[1], *[1]Faculdade de Medicina Veterinária e Zootecnia, Universidade de São Paulo, Pirassununga, SP, Brazil, [2]Faculdade de Zootecnia e Engenharia de Alimentos, São Paulo, SP, Brazil.*

Successful of embryo implantation requires synchronization between maternal and fetal factors to promote endometrial receptivity. In this scenario, the maternal immune system may play an important role in the establishment as well in the development of conceptus until onset of parturition in eutherian mammals. Our study aimed to identify and quantify the subpopulations of immune cells in the bovine pregnant endometrium. We hypothesized that the endometrial immune cells pool change as pregnancy progresses. Samples from early (33 ± 1.5 d), mid (170 ± 16.9 d) and late pregnancy (227 ± 10.8 d) were obtained from a local abattoir (n = 5, per group). Cryostat sections were labeled for CD4 (T helper), CD8 (T cytotoxic), CD14 (macrophage), CD25 (activation T cells) and WC1 (γd). The samples were analyzed under epifluorescence microscope. The number of positive cells was counted and normalized to the total number of cells per mm^2 in 5 random fields for each group/marker. Data were analyzed separately for each marker by least square ANOVA using the GLM procedure of SAS. The WC1$^+$ cells were most prominent in the endometrial stroma, with greater cell number in mid than in early and late stages of pregnancy ($P < 0.01$). Moreover, CD4$^+$ ($P = 0.09$) and CD8$^+$ ($P < 0.01$) decreased in number in late pregnancy, whereas CD25$^+$ cells were low only in mid-pregnancy ($P = 0.02$). CD14$^+$ cells increased, respectively, 3- and 4-fold in mid and late stages of pregnancy ($P < 0.01$). Our results show that there is a deviation of endometrial immune cells subpopulations during pregnancy in the cow. In early pregnancy, there is a predominance of immune cells involved in regulation of immune response (CD3, CD4 and CD8) to allow embryo attachment and survival; whereas in mid-pregnancy, number of cells with trophic function are increased (CD14 and WC1) likely to allow placental development. In late pregnancy, there is a recruitment of cells involved in inflammatory response to induce placental detachment and parturition (CD14 and CD25).

Key Words: endometrial immune cell, pregnancy, bovine

125 Expression of nonclassical MHC-I isoforms is deregulated in cloned placenta. Rodrigo Silva Nunes Barreto[1], Felipe Perecin[2], Flávio Vieira Meirelles[2], Flávia Thomaz Verechia Pereira[3], Maria Angelica Miglino[1], and Lilian J. Oliveira*[1], *[1]Faculdade de Medicina Veterinária e Zootecnia, Universidade de São Paulo, São Paulo, SP, Brazil, [2]Faculdade de Zootecnia e Engenharia de Alimentos, Pirassununga, SP, Brazil, [3]Campus Experimental de Dracena, Universidade Estadual Paulista, Dracena, SP, Brazil.*

Trophoblast cell evades the maternal immune recognition by expressing non-classical (NC) MHC-I isoforms, in humans and mice. In the cow, MHC-I proteins are expressed from 120 d of pregnancy, however in clones MHC-I expression can begin as early as d 35. This abnormal expression of MHC-I in clones may play a role on high rates of embryo/fetal losses in this model. Our study aimed to determine expression of MHC-I and its NC isoforms in normal and cloned bovine pregnancy. Samples of normal and cloned bovine placenta in early (n = 5) and term (n = 6) pregnancy were used for immunolocalization of MHC-I by IHC, using antibodies for bovine MHC-I (IL-A88) and murine NC isoform (Qa-2). Also, the expression of classical MHC-I (JSP-1) and NC isoforms (NC1–4) was analyzed by qRT-PCR. Data were analyzed by least square ANOVA using the GLM procedure of SAS. The model included main effects (group and animal) and standard errors. In normal placenta, NC1 was equally expressed in early and late pregnancy, whereas in clones, NC1 tended to increase expression in late pregnancy ($P = 0.07$). NC2 was higher expressed during early pregnancy in clones than early normal pregnancy ($P = 0.03$) and both normal and clone late pregnancies ($P = 0.04$). For NC3 expression showed interaction between type and stage of pregnancy ($P = 0.01$). The expression of NC3 was higher in later in normal pregnancy ($P < 0.01$), while in clones the NC3 expression was higher in early stages ($P = 0.04$). Neither NC4 and JSP1 showed changes in expression among groups. Immunohistochemistry analysis showed that IL-A88 stained the maternal epithelium and non-invading trophoblast but not trophoblast giant cells. In early pregnancy, IL-A88 staining was weak in normal and almost absent in cloned placenta. At term, IL-A88 staining increased in normal placenta. For Qa-2, no staining was detected in early pregnancy in normal whereas the cloned placenta showed strong staining. Furthermore, in the term pregnancy the Qa-2 staining did not differ between normal and cloned placenta. Altogether, our data suggest that the MHC-I expression is dysregulated in clone pregnancy, which may contribute to their low pregnancy rates and success.

Key Words: nonclassical MHC, bovine, cloned placenta

126 Behavioral and hormonal pattern around estrus and the characteristics of preovulatory follicles of repeat breeder dairy cows. Uzi Moallem*[1], Maya Zachut[1], and Pankaj Sood[1,2], *[1]Department of Ruminants Science, Volcani Center, Bet Dagan, Israel, [2]Department of Veterinary Gynecology and Obstetrics, Palampur, India.*

Repeat breeding in dairy cows results in large economic loss; however, the etiology of this phenomenon remains elusive. The objectives were to examine the behavioral and endocrine patterns around estrus, and the characteristics of preovulatory follicles in repeat breeder (RB) vs. normal (CTL) cows. The CTL cows were >60 d in lactation, cycling and not inseminated, and a cow was considered as RB if it did not become pregnant after at least 4 successive inseminations (average 7.0 ± 2.0), with normal intervals. A total of 27 and 31 cycles in 12 RB and 18 CTL cows, respectively, were synchronized. Data were analyzed as repeated measurements by the MIXED procedure of SAS, and the model included the effects of treatment, cow and cluster. Behavioral estrus and ovulation were observed in 81.5 and 83.8% of the synchronized cycles in the RB and CTL cows, respectively. The RB and CTL cows had similar estrus durations of 21.4 and 19.6 h, respectively, but estrus was more intense in the RB, as indicated by numerically higher overall activity indexes and higher peak neck activity. The interval from PG injection to estrus onset (i.e., proestrus) was 8.2 h shorter in RB than in CTL cows (47.9 and 56.1 h, respectively; $P < 0.007$), but the average preovulatory follicle size was similar. Plasma estradiol (E$_2$) concentration at peak was numerically higher (21%) and the AUC tended to be higher in the RB than in the CTL cows. Also, LH secretion during the period from 18 to 3 h before the LH peak was lower in RB than in CTL: 2.5 and 4.6 ng/mL, respectively ($P < 0.01$). In another study, 16 preovulatory follicles (8 CTL and 8 RB) were aspirated 48 h after PG injection. No differences were observed in androstenedione and progesterone (P$_4$) in follicular fluid, but concentrations were 1.7 fold higher ($P < 0.005$)

and E_2/P_4 ratio tended to be higher ($P < 0.07$) in RB than in CTL cows. In conclusion, better estrus expression, similar follicular diameter and higher E_2 in RB indicate that the etiology of repeat breeding lies beyond these parameters. However, short proestrus and subdued LH concentrations before the LH peak, which could impair oocyte competence and development, are first reported in RB cows.

Key Words: repeat breeders, estrus intensity, LH secretion

127 Effects of dry period length on onset of ovarian activity and ovarian cyclicity in the subsequent lactation. Juncai Chen*[1], Nicoline M. Soede[1], Gerrit J. Remmelink[2], Bas Kemp[1], and Ariette T. M. Van Knegsel[1], [1]*Adaptation Physiology Group, Wageningen University, Wageningen, the Netherlands,* [2]*Livestock Research, Wageningen University and Research Centre, Wageningen, the Netherlands.*

Negative energy balance (NEB) caused by high milk yield and insufficient feed intake in early lactation has been related to compromised cow health and fertility. Recent studies show that the NEB in early lactation could be alleviated by omitting or shortening dry period in dairy cows. It can therefore be hypothesized that omitting or shortening dry period improves fertility in dairy cows. The objective of this study was to evaluate the effects of dry period length on onset of ovarian activity and ovarian cyclicity in Holstein-Friesian dairy cows within 100 d in milk (DIM). The cows (60 primiparous and 108 multiparous) were randomly assigned to one of 3 dry period lengths (0, 30, and 60 d). Milk samples were collected 3 times a week for progesterone concentration analysis until 100 DIM after calving. Onset of luteal activity (OLA) was defined as the occurrence of at least 2 succeeding milk samples with progesterone concentrations ≥2 ng/mL. Normal resumption of ovarian cyclicity was defined as onset of first luteal activity occurring within 45 DIM, and followed by regular ovarian cycles of 18 to 24 d in length. Data are expressed as percentage or LSMEANS ± SEM. Within 100 DIM postpartum, cows with a 0-d dry period had greater incidence of normal resumption of ovarian cyclicity compared with cows with a 60-d dry period (53.2% vs. 26.0%; $P = 0.01$). Cows with a 30-d dry period tended to have greater incidence of normal resumption of ovarian cyclicity compared with cows with a 60-d dry period (47.7% vs. 26.0%; $P = 0.09$). In addition, cows with a 0-d dry period tended to have shorter interval from calving to first commencement of luteal activity (23.1 vs. 28.9 ± 2.0 d; $P = 0.07$) compared with cows with a 60-d dry period. Overall, our results demonstrate that omitting dry period improves resumption of ovarian cyclicity within 100 DIM in the subsequent lactation.

Key Words: continuous milking, progesterone, ovulation

128 Effect of extending the duration of the postpartum voluntary waiting period on reproductive performance of lactating dairy cows. Matias L. Stangaferro*[1], Robert Wijma[1], Magdalena Masello[1], Mark J. Thomas[2], and Julio O. Giordano[1], [1]*Department of Animal Science, Cornell University, Ithaca, NY,* [2]*Dairy Health & Management Services, Lowville, NY.*

Our objective was to investigate the effect of extending the duration of the voluntary waiting period (VWP) on reproductive performance of lactating dairy cows. Holstein cows [n = 1,082; 434 primiparous (PP) and 648 multiparous (MP)] from 3 commercial dairy farms in New York were blocked by parity and total milk production in their previous lactation (MP only) and were randomly assigned to receive first timed AI (TAI) service at 60 ± 3 (SVWP) or 88 ± 3 DIM (LVWP) after synchronization of ovulation with the Double-Ovsynch protocol (GnRH-7 d-PGF-3 d-GnRH-7 d- GnRH-7 d-PGF-56 h-GnRH-16 h-TAI). Pregnancy diagnosis was conducted by rectal palpation or transrectal ultrasound 39 and 90 d after AI. Data for pregnancies per AI (P/AI) at 39 d after TAI, pregnancy loss (PL) from 39 to 90 d after AI, and percentage of cows pregnant up to 150 DIM were analyzed by logistical regression using PROC GLIMMIX of SAS. Models included the effect of treatment, parity, and their interaction. Farm was included as a random effect in all models. At 39 d after TAI, P/AI were greater ($P < 0.01$) for cows in the LVWP (46.0%; 228/496) than cows in the SVWP (38.4%; 225/586) group. Pregnancies per AI were greater ($P < 0.01$) for PP (49.5%; 215/434) than for MP (36.7; 238/648) cows. Pregnancy loss, was similar ($P = 0.88$) for cows in the LVWP (4.5%) and the SVWP (4.7%) group, and for PP (4.6%) and MP (4.6%) cows ($P = 0.97$). The percentage of cows pregnant by 150 DIM was similar ($P = 0.23$) for cows in the LVWP (62.6%; 278/444) and the SVWP (69.6%; 261/375) group but were greater ($P < 0.01$) for PP (74.5%; 222/298) than for MP (62.6%; 278/444) cows. The interaction between treatment and parity group did not affect ($P > 0.05$) P/AI, PL, or percent pregnant by 150 DIM. We conclude that extending the duration of the VWP from 60 to 88 DIM for cows receiving TAI after synchronization with the Double-Ovsynch protocol increased overall P/AI. Also, the initial differences in P/AI after first service were compensated by earlier re-insemination of cows in the SVWP group. Supported by New York Farm Viability Institute project AOR13006.

Key Words: timed AI, first service, dairy cow

129 Cows under heat stress have increased uterine size, reduced circulating progesterone, and decreased fertility compared with cows in cooler conditions. Giovanni M. Baez*[1,2], Rafael V. Barletta[1], Eduardo Trevisol[1], Jerry N. Guenther[1], João P. Ferreira[3], and Milo C. Wiltbank[1], [1]*University of Wisconsin-Madison, Madison, WI,* [2]*Universidad Francisco de Paula Santander, Cucuta, NS, Colombia,* [3]*São Paulo State University, Botucatu, SP, Brazil.*

Seasonal differences in progesterone (P4) concentrations and pregnancies per AI (P/AI) have been demonstrated in lactating dairy cows. Moreover, an association between uterine size and P/AI has been recently reported. Our objective was to evaluate seasonal differences in uterine size, circulating P4, and fertility in primiparous and multiparous dairy cows. Lactating Holstein cows (n = 704) were synchronized to receive timed AI (TAI) on d 81 ± 3 of lactation by using the Double-Ovsynch protocol (GnRH-7d-PGF-3d-GnRH-7d-GnRH-7d-PGF-56h-GnRH-16h-TAI). At the time of the last injection of PGF, uterine diameter was determined at the greater curvature using ultrasound, uterine length was determined by rectal palpation, and uterine volume was calculated. Circulating P4 at final PGF and GnRH were evaluated to assure synchronization of all cows used in the final analysis (n = 616; primiparous (P), n = 289; multiparous (M), n = 327). At the same time, respiratory rate (number of breaths per minute, BPM) and body temperature was determined in all cows. Fischer's exact test and *t*-test were used to analyze categorical and continuous variables respectively, and logistic regression analysis was used to calculate probabilities of P/AI related to uterine volume. There was a clear delineation in average respiratory rate (40 to 28 BPM) indicating a change of season (hot (H) n = 226 (112 P, 114 M), cool (C) n = 390 (177 P, 213 M). Uterine volume was greater in H than C season for all cows (150.3 ± 2.9 vs. 131.2 ± 1.9 mm^3, H vs. C, $P < 0.0001$), and for P (134.6 ± 4.1 vs. 122.0 ± 2.8, $P = 0.009$) or M (165.7 ± 4.2 vs. 138.8 ± 2.6, $P < 0.0001$) cows. Circulating P4 was lower during H than C season in P (7.5 ± 0.3 vs. 8.1 ± 0.2, $P = 0.08$) and M (6.0 ± 0.3 vs. 6.8 ± 0.2, $P = 0.02$) cows. The P/AI was reduced in H vs. C for all cows (38.5% vs. 47.7%, $P = 0.02$), and for P (41.1%

vs. 56.5%, $P = 0.03$) but not for M (36.0% vs. 40.4%, $P = 0.21$) cows. Logistic regression analyses indicated a relationship between uterine volume and P/AI for M cows in H ($P = 0.03$) and C ($P = 0.03$) seasons but for P cows only in C season ($P = 0.02$) with greater uterine volume associated with reduced P/AI. Thus, heat stress is associated with an increase in uterine size. Greater uterine size partially explains differences in fertility within parities and seasons.

Key Words: fertility, uterine size, heat stress

130 Effect of heat stress during pregnancy on intact and adrenal de-medullated fetuses: Placental, fetal, and mammary development in ewes.

Antoni Macko*, Sean Limesand, and Robert Collier, *University of Arizona, Tucson, AZ.*

It is well established that heat stress during mid- and late-gestation induces intrauterine growth retardation (IUGR) and decreased milk yield in the subsequent lactation in cattle and sheep. We hypothesized that elevated fetal adrenal norepinephrine (NE) secretion contributes to impaired mammary development in heat stressed pregnant ewes. Pregnant ewes were assigned to one of 4 treatment groups that were a combination of control (C) or hyperthermia-induced IUGR (I) and surgical sham (S) or bilateral fetal adrenal demedullation (D) at 98 d gestational age (dGA; term = 148 dGA)(n = 4 CS, 4 CD, 6 IS, and 4 ID fetuses). At 134 dGA, fetal plasma NE was measured, animals were euthanized, and fetal and placental weights obtained. Ewes' mammary glands were collected, weighed and prepared for analyses of DNA content, and histological evaluation to quantify the numbers of alveolar units per microscopic field and mammary epithelial cells per alveolus. Data were analyzed by Proc Mixed ANOVA, SAS 9.3. In the IS group, fetal plasma NE was 4-fold higher ($P < 0.05$) and placental, fetal and maternal mammary weights and mammary DNA were lower ($P < 0.05$) compared with the CS group and these parameters were partially reversed in the ID group. Placental weight: CS 337 ± 34, CD 271 ± 39, IS 160 ± 36, ID 215 ± 50 g; Fetal weight: CS 3495 ± 214, CD 3343 ± 233, IS 1746 ± 330, ID 2574 ± 296 g; Mammary wet weight: CS 3043 ± 445, CD 2496 ± 345, IS 785 ± 300, ID 1326 ± 316 g; Mammary dry weight: CS 343 ± 34, CD 353 ± 59, IS 192 ± 44, ID 278 ± 58 g; Mammary DNA content: CS 3043 ± 456, CD 2946 ± 353, IS 868 ± 353, ID 1327 ± 322 ng/µl. There were no treatment effects on the number of alveolar units per field: CS 33.6 ± 9.6, CD 17.3 ± 4.0, IS 16.5 ± 5.0, ID 28.5 ± 3.9; or number of cells per alveolus: CS 6.5 ± 1.0, CD 7.5 ± 2.0, IS 8.2 ± 0.3, ID 6.4 ± 1.0. We conclude that heat stress during gestation reduces placental, fetal and mammary development and fetal adrenal de-medullation partially reverses these effects. We also propose that an endocrine signal from the placenta regulates maternal mammary growth during gestation and this signal is responsive to fetal catecholamines.

Key Words: heat stress, placenta, mammary gland

131 Timing of GnRH administration based on estrous response in beef heifers following administration of the 14-d CIDR-PG protocol with split-time AI.

Brianne E. Bishop*, Jordan M. Thomas, Jillian M. Abel, Mark R. Ellersieck, Scott E. Poock, Michael F. Smith, and David J. Patterson, *University of Missouri, Columbia, MO.*

The experiment was designed to evaluate timing of GnRH administration in beef heifers based on estrous status with split-time AI. Estrus was synchronized in 816 heifers across 4 locations by using the 14-d CIDR-PG protocol (CIDR insert [1.38 g progesterone] on d 0 with removal on d 14; 25 mg $PGF_{2\alpha}$ [PG] 16 d after CIDR removal on d 30; and 100 µg GnRH depending on treatment). Estrous detection aids (Estrotect) were applied at PG on d 30, with estrus recorded at 66 and 90 h after PG on d 33 and 34, respectively. Treatments were balanced across locations using tract score and weight. Timing of insemination was based on expression of estrus 66 h after PG. Heifers in each treatment that exhibited estrus by 66 h were inseminated; whereas, AI was delayed 24 h until 90 h after PG for heifers failing to exhibit estrus by 66 h. Heifers in treatment 1 were administered GnRH 66 h after PG irrespective of estrus expression; whereas, in treatment 2, heifers were administered GnRH coincident with delayed insemination only if not detected in estrus at 66 h after PG. Data were analyzed using PROC FREQ in SAS. There was no effect of treatment on overall estrous response (1 = 85%; 2 = 87%; $P = 0.49$) or AI pregnancy rate (1 = 55%; 2 = 58%; $P = 0.54$). There were no differences between treatments in estrous response at 66 h (1 = 70%; 2 = 69%; $P = 0.64$); and pregnancy rate resulting from AI for heifers inseminated at 66 h was not influenced by GnRH (1 = 62%; 2 = 64%; $P = 0.65$). Furthermore, there were no differences between treatments in estrous response during the 24 h delay period (1 = 50%; 2 = 58% $P = 0.22$), or pregnancy rate resulting from AI (1 = 40%; 2 = 44%; $P = 0.55$). In summary, when split-time AI is used in conjunction with the 14 d CIDR-PG protocol, administration of GnRH at AI to heifers that exhibit estrus by 66 h after PG is not warranted. These data suggest, however, that among heifers for which AI is delayed based on failure to exhibit estrus by 66 h after PG, timing of GnRH administration (66 vs. 90 h after PG) may be more flexible.

Key Words: estrous synchronization, split-time artificial insemination, beef heifer

132 Timing of GnRH administration based on estrous response in beef cows following administration of the 7-d CO-Synch + CIDR protocol with split-time AI.

Brianne E. Bishop*, Jordan M. Thomas, Jillian M. Abel, Mark R. Ellersieck, Scott E. Poock, Michael F. Smith, and David J. Patterson, *University of Missouri, Columbia, MO.*

The experiment was designed to evaluate timing of GnRH administration in beef cows based on estrous status with split-time AI. Estrus was synchronized in 622 cows across 6 locations by using the 7-d CO-Synch + CIDR protocol (100 µg GnRH + CIDR insert [1.38 g progesterone] on d 0; 25 mg $PGF_{2\alpha}$ [PG] at CIDR removal on d 7; and 100 µg GnRH depending on treatment). Estrous detection aids (Estrotect) were applied at CIDR removal and PG on d 7, with estrus recorded at 66 and 90 h after PG on d 10 and 11, respectively. Treatments were balanced across locations; cows within location were randomly assigned to one of 2 treatments based on age, BCS, and days postpartum. Timing of AI was based on expression of estrus 66 h after PG. Cows in each treatment that exhibited estrus by 66 h were inseminated; whereas AI was delayed 24 h until 90 h after PG for cows failing to exhibit estrus by 66 h. Cows in treatment 1 were administered GnRH 66 h after PG irrespective of estrus expression; whereas in treatment 2, cows were administered GnRH coincident with delayed AI only if not detected in estrus at 66 h after PG. Data were analyzed using PROC FREQ in SAS. Treatment affected overall estrous response (1 = 85%; 2 = 90%; $P = 0.04$) but did not affect total AI pregnancy rate (1 = 58%; 2 = 57%; $P = 0.89$). There were no differences between treatments in estrous response at 66 h (1 = 73%; 2 = 75%; $P = 0.47$); and pregnancy rate resulting from AI for cows inseminated at 66 h was not influenced by GnRH (1 = 63%; 2 = 59%; $P = 0.50$). Estrous response during the 24 h delay period differed between treatments (1 = 45%; 2 = 61% $P = 0.04$), although AI pregnancy rate for cows inseminated at 90 h did not differ (1 = 44%; 2 = 49%; $P = 0.51$). In summary, when split-time AI is used in conjunction with the 7 d CO-Synch + CIDR protocol, administration of GnRH at AI to cows that exhibit estrus by 66 h after PG is not warranted. These data indicate that delayed administration of GnRH to 90 h coincident with AI among cows failing to exhibit estrus by 66 h after PG results in a greater overall estrous response.

Key Words: estrous synchronization, split-time artificial insemination, beef cow

133 Influence of estrus expression prior to fixed-time AI on embryo survival to maternal recognition of pregnancy.

Emmalee J. Northrop*[1], Olivia L. Amundson[1], Brittany N. Richardson[1], Anthony K. McNeel[2], Robert A. Cushman[2], and George A. Perry[1], *[1]Department of Animal Sciences, South Dakota State University, Brookings, SD, [2]USDA-ARS, US Meat Animal Research Center, Clay Center, NE.*

Estradiol has been reported to play a critical role in pregnancy establishment and embryonic survival. Our objective was to focus on the role of preovulatory estradiol in embryo survival from fertilization to maternal recognition of pregnancy. Estrus was synchronized in beef cows (n = 29) with the CO-Synch protocol and artificially inseminated (d 0). Blood was collected to determine estradiol (d −2 to 0) and progesterone (d 0 to 16) concentrations. Cows were then divided into 2 groups based on expression of estrus (estrus and no estrus). On d 16 uteri were flushed to collect embryos. Total cellular RNA was extracted from blood leukocytes (d 16) to measure the expression of interferon-stimulated genes (ISG): ISG-15, OAS-1, and MX2. Flush media was analyzed for protein and glucose concentrations. Data were analyzed by PROC MIXED. There was an effect of estrus, time, and estrus by time ($P < 0.01$) on circulating concentrations of estradiol, but there was no effect of estrus ($P = 0.85$) or estrus by time ($P = 0.26$) on circulating concentrations of progesterone. There was no difference in embryo recovery rate ($P = 0.97$; 45% vs. 44%). When corrected for volume of flush media, there was no difference between estrus and no estrus for uterine flush protein ($P = 0.51$; 218 ± 94 vs. 124 ± 104 mg/mL); or glucose (1960 ± 274 vs. 2003 ± 304 mg/dL) content between estrus and no estrus. There was no difference ($P > 0.20$) in d 16 expression of ISG-15, OAS-1, or MX2 between estrus and no estrus animals, nor a difference between cows an embryo was or was not recovered from. However, there was a tendency for cows in which an embryo was recovered from to have greater concentrations of protein ($P = 0.056$; 314 ± 104 mg/mL) and glucose ($P = 0.09$; 2347 ± 303 mg/dL) in uterine flushes compared with cows in which an embryo was not recovered (28 ± 94 mg/mL and 1616 ± 274 mg/dL). In summary, there were no differences between cows that did or did not express estrus in ISG expression, or in protein or glucose concentration of uterine flushes. Therefore, the increased embryo survival to d 30 of gestation among cows that express estrus is not associated with embryo survival until maternal recognition.

Key Words: embryo survival, estradiol, fixed-time AI

134 Post insemination interventions: Effect of human chorionic gonadotropin, gonadotropin-releasing hormone, and progesterone on ovulation and conception rates in Nili-Ravi buffaloes.

Ali Husnain, Umair Riaz, Muhammad Ilyas Naveed, Mubbashar Hassan, Mian Abdul Sattar, and Nasim Ahmad*, *Department of Theriogenology, University of Veterinary and Animal Sciences, Lahore, Punjab, Pakistan.*

We hypothesized that enhancing luteal tissue (or progesterone) would improve conception rate in Nili-Ravi buffaloes. The objective of the present studies were to standardized the dose of human chorionic gonadotropin (hCG) for ovulation induction on 7 d post insemination (experiment 1) and to see the effect of standardized dose of hCG, GnRH and exogenous progesterone (CIDR insert) on ovulation and conception rates in Nili Ravi buffaloes (experiment 2). In experiment 1, ovaries of the adult Nili Ravi buffaloes were scanned and mapped 7 d post synchronized estrus to confirm the presence of corpus luteum (CL) and dominant follicle (>8 mm) and assigned randomly to treatments of saline, or 500, 1000, 1500, 2000, 2500, or 3000 IU hCG (IVF-C, LG, Korea; i.m., n = 47) and ovulation induction or accessory CL, was confirmed a week later with ultrasound. Ovulation incidence in response to ≥2500 IU hCG was more (100%) than that of other doses or saline. The minimum effective dose was determined through dose response curve. In experiment 2, ovarian responses and conception rates were assessed by minimal effective dose of hCG (2500 IU, n = 58), GnRH (n = 28), CIDR insert for a week (1.38 g, n = 26) and control (n = 44) on 7 d post AI in previously CIDR synchronized in Nili-Ravi buffaloes. Overall significance was determined with Chi-squared and association between groups was checked using Z test in SAS software. More buffaloes were induced to ovulate with hCG (95%) and GnRH (80%) when compared with control and CIDR insert ($P < 0.05$). Conception rates were significantly higher ($P < 0.05$) in hCG (62%; 36/58) treated buffaloes compared with control (32%; 14/44). In contrast, these were non-significant in GnRH (50%; 14/28) and CIDR (42%; 12/26) treated buffaloes when compared with control. In conclusion 2500 IU of hCG is sufficient to induce the accessory CL and this treatment enhance the conception rate when given 7 d post insemination in Nili-Ravi buffaloes.

Key Words: progesterone, conception rate, Nili-Ravi buffaloes

135 Relationships between hair coat shedding and hair cortisol concentrations and age at first calving in crossbred beef heifers.

Rhonda C. Vann*[1], Michael Robinson[2], Scott T. Willard[2], Thomas H. Welsh, Jr.[4], and Ronald D. Randel[3], *[1]MAFES-E.G. (Gene) Morrison Brown Loam Branch Experiment Station, Raymond, MS, [2]Department Animal & Dairy Science, Mississippi State University, Mississippi State, MS, [3]Texas A&M AgriLife Research Center, Overton, TX, [4]Texas A&M Department of Animal Science, College Station, TX.*

The objective was to evaluate the relationships among hair coat shedding, hair length and hair cortisol concentrations to age at first calving. Spring born (n = 101) crossbred beef heifers (7 to 8 mo. of age) were evaluated for hair length (HL; 1 = short and 5 = long), hair luster (HST; 1 = glossy, healthy appearance and 5 = dull and unthrifty), hair shedding (HS; 1 = short, slick hair, sheds early and 5 = long, late shedding, or full winter coat) at weaning. Calves were weighed, blood samples collected for evaluation of serum cortisol concentrations pre-weaning and at weaning by RIA. At weaning, hair samples were collected over the shoulder, rib and hip area (7.6 cm x 12.7 cm clipped area) for evaluation of hair cortisol concentrations. Hair samples were washed and dried overnight, samples ground using a Retsch mixer miller (200 mm for 10 min), sonicated (at 25 Hz) and incubated 8 h at room temperature. The supernatant was pipetted off and dried under a stream of atmospheric air. Samples were reconstituted before quantification of cortisol using Salimetrics cortisol EIA assay. Data were analyzed using PROC CORR and PROC Mixed of SAS. Hair cortisol concentrations at the rib, hip and shoulder were ($P < 0.001$) greater in cattle with a red or brown coat color compared with cattle with black coat color. Hair length, HST or HS were not influenced by hair coat color ($P > 0.10$). Hair length, HST and HS were negatively correlated with adjusted 205-d weaning weight ($P < 0.006$) and serum cortisol ($P < 0.001$). Hair length, HST, HS or hair cortisol concentrations were not correlated with age at first calving ($P > 0.10$). Calving day of the year was negatively correlated with hair coat luster ($P < 0.04$) and tended to be negatively correlated with hair length ($P < 0.07$). Pregnancy status was not influenced by hair cortisol concentrations or HL, HST or HS ($P > 0.10$). In summary, hair cortisol concentrations were influenced by hair coat color. However, hair cortisol concentrations and hair length, luster or hair coat shedding were not adversely associated with age at first calving.

Key Words: hair coat shedding, hair cortisol concentrations, beef heifers

Production, Management, and the Environment I

136 Changes in milking procedures on US dairy operations: 1996–2014. Jason E. Lombard*[1], Charles P. Fossler[1], Ashley E. Adams[1,2], Chelsey B. Shivley[1,2], Natalie J. Urie[1,2], Christine A. Kopral[1], and Lindsey P. Garber[1], *[1]USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO, [2]Colorado State University, Fort Collins, CO.*

The National Animal Health Monitoring System conducted national dairy studies in 1996, 2002, 2007, and 2014. In all 4 studies, information regarding milking procedures was collected via face-to-face interviews. Although the states participating in each study varied slightly, the goal for all the studies was to account for close to 80% of dairy operations and 80% of dairy cows in the US. An objective of this study was to describe how milking facilities and practices have changed over the last 18 years. In 1996, the average herd size on US dairies was 70 cows, and by 2014 herd size had more than doubled to about 160 cows. During this time, the average bulk-tank somatic cell count decreased from 300,000 to approximately 200,000 cells/mL. Although the majority of operations (52.8%) still milk cows in a tie stall or stanchion barn, parlor use increased from 28.8% of operations in 1996 to 45.7% in 2014. In 1996, 54.9% of cows were milked in a parlor compared with 86.0% in 2014. Although the percentage of operations that milked cows twice daily has remained around 90% since 1996, the percentage of operations that milked 3 times per day nearly doubled from 5.8% in 1996 to 10.2% in 2014. Glove use during milking has almost doubled at both the operation level (32.9% of operations in 2002 and 59.1% in 2014) and at the cow level (48.7% of cows in 2002 and 87.9% in 2014). Forestripping all cows has increased from 44.5% of operations in 2002 to 71.5% in 2014. From 1996 to 2014, compounds containing iodine were the most frequently used pre-milking and post-milking teat disinfectants. Automatic take-off use increased from 36.0% of operations in 2002 to 49.1% in 2014, while operations using a backflush system has remained between 6 and 7% since 2002. The US has seen an increase in dairy herd size over the past 18 years, and this increase is associated with more cows being milked in parlors, more operations using gloves and checking for mastitis via forestripping, and an improvement in milk quality, as evidenced by lower somatic cell counts.

Key Words: milking practice, parlor, milk quality

137 Assessing the farm-level cost of mastitis. Jacqueline Holland*[1], Jason Lombard[2], Joleen Hadrich[1], and Christopher Wolf[3], *[1]Dept. of Agricultural and Resource Economics, Colorado State University, Fort Collins, CO, [2]USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO, [3]Department of Agricultural, Food, and Resource Economics, Michigan State University, East Lansing, MI.*

Although mastitis is the most common disease of dairy cattle, estimates of financial losses due to mastitis vary within the literature. The objective of this research is to create a cost-calculation tool that allows dairy producers to estimate their farm's losses due to mastitis, and to provide dairy managers with more accurate information for making decisions about mastitis control and prevention. The tool takes into account direct and indirect loss components, including fatalities; early culling; milk-yield loss; and costs for treatment, labor, and replacement animals. The tool allows dairy producers to input their herd information (e.g., mastitis prevalence, treatment costs) into a cost worksheet and obtain an estimate of the cost of mastitis on their operation. Information from the National Animal Health Monitoring System's Dairy 2014 study was used to estimate mastitis prevalence, outcome percentages, as well as treatment and labor costs at the farm level. All operations in the study had at least one case of clinical mastitis; overall, 24.1% of cows were affected with mastitis during 2013. Of affected cows, 72.9% recovered, 24.0% were sold, and 3.1% died. The operation average cost of treating a single case of mastitis in 2013 was $42.05. Additionally, cow-level records from DHIA Dairy Records Processing Centers (DRPCs) throughout the US were used to determine milk-yield losses due to mastitis, as milk-yield reduction accounts for the largest loss associated with mastitis. A hierarchal model using cow-level lactation information from the DRPCs was used to construct milk-yield curves of varying production levels, taking into account herd effects. The construction of yield curves through the hierarchal model allows for the comparison of cows based on lactation average somatic cell counts, thus establishing a loss value. The resulting mastitis-cost estimation tool focuses on determining an accurate cost of mastitis, which justifies investment in mastitis prevention measures.

Key Words: mastitis losses, mastitis management, animal health economics

138 Associations between housing and management practices on the incidence of lameness, hock lesions, and thin cows on US dairy operations. Ashley E. Adams*[1,2], Jason E. Lombard[2], Ivette N. Roman-Muniz[1], Charles P. Fossler[2], and Christine A. Kopral[2], *[1]Colorado State University, Fort Collins, CO, [2]USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO.*

The objective of this study was to determine the association among different on the incidence of lameness, hock lesions, and thin cows on US dairy operations. This study was conducted as part of the National Animal Health Monitoring System's Dairy 2014 study, which included dairy operations in 17 states. Size categories were assigned as follows: small (30–99 cows), medium (100–499 cows), and large (≥500 cows). Trained assessors visited 192 dairy operations between March and July 2014, and recorded locomotion and hock scores (on a 3-point scale), and the number of thin cows (BCS <2.25) on a total of 22,773 cows (average 119 cows per farm). The majority of dairy cows (90.3%) were considered to be sound (LS = 1), 6.9% were mild/moderately lame (LS = 2), and 2.8% were severely lame (LS = 3). Similarly, most dairy cows (87.3%) had no hock lesions (HS = 1), 10.1% had mild lesions (HS = 2), and 2.6% had severe hock lesions (HS = 3). A limited percentage of cows (4.2%) were thin. Univariate comparisons were performed using PROC LOGLINK, which accounts for study design and weighting. Statistical significance was declared at $P < 0.05$. Herd size had an effect on all parameters examined, with the percentage of cows scored as LS2, LS3, HS2, HS3, and thin increasing as herd size decreased. Additionally, the percentage of cows scored as LS2, HS2, and HS3 differed by housing type, primary flooring type, and primary bedding material used, and cows scored LS3 differed by housing type and primary bedding used. Operations that housed cows on pasture had fewer LS2 and LS3 cows than those that housed cows in tie-stalls or freestalls, whereas operations that housed cows in open/dry lots had fewer HS2 and HS3 cows than those that housed cows in tie-stalls, freestalls, or on pasture. Feeding a TMR and having a nutritionist balance rations for dairy cows was associated with a lower percentage of thin cows. Although herd size

was found to be an important indicator of the percentage of LS2, LS3, HS2, HS3, and thin cows on dairy operations in the US, other housing and management practices were also found to have an effect.

Key Words: dairy cow, lameness, hock lesions

139 Management of nonambulatory dairy cows on US dairy operations.

Ashley E. Adams*[1,2], Jason E. Lombard[2], Ivette N. Roman-Muniz[1], Charles P. Fossler[2], and Christine A. Kopral[2], [1]*Colorado State University, Fort Collins, CO,* [2]*USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO.*

The objective of this study was to describe practices used on US dairy operations for the management and care of nonambulatory dairy cattle. This study was conducted as part of the National Animal Health Monitoring System's Dairy 2014 study, which included dairy operations in 17 states. Information on the management of nonambulatory dairy cows was collected on 1,261 dairy operations via in-person interviews. For the purpose of this study, nonambulatory cows were defined as those unable to stand at any time during a period of at least 24 h. The majority of operations (76.5%) had at least one nonambulatory cow in 2013, with an average of 2.6% of US dairy cows becoming nonambulatory during the year. Less than a quarter of all operations (22.6%) had written guidelines for handling nonambulatory cattle: 57.1% of large dairies (≥500 cows) had written guidelines, compared with just 24.1% of medium dairies (100–499 cows), and 15.5% of small dairies (30–99 cows). After becoming nonambulatory, cows were offered water within 1 h on 62.6% of operations, within 4 h on 83.0%, and within 12 h on 92.6% of operations; 2.6% of operations did not offer nonambulatory cows water. Food was offered to nonambulatory cows within 1 h on 60.6% of operations, within 4 h on 81.3%, and within 12 h on 91.6% of operations; 3.4% of operations did not offer food to nonambulatory cows. Cows were offered shelter within 1 h after becoming nonambulatory on 65.5% of operations, within 4 h on 80.1%, and within 12 h on 84.9% of operations; 9.1% of operations did not offer shelter to nonambulatory cows. Of nonambulatory cows, 30.0% recovered, 49.7% were euthanized, and 17.7% died. Of those that were euthanized, 59.1% were euthanized within 2 d of being recognized as nonambulatory. With 17.7% of nonambulatory cattle dying, and 41.9% being nonambulatory for 2 d or more before being euthanized, an opportunity exists for dairy producers to improve in this area. Implementing written guidelines, including the identification of cows that qualify for humane euthanasia, may help ensure the welfare of nonambulatory dairy cattle.

Key Words: dairy cattle, nonambulatory, management practices

140 Morbidity and mortality of preweaned dairy heifer calves.

Natalie J. Urie*[1,2], Jason E. Lombard[1], and Chelsey B. Shivley[1,2], [1]*USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO,* [2]*Colorado State University, Fort Collins, CO.*

During the calf component of the National Animal Health Monitoring System's Dairy 2014 study, information was collected on morbidity and mortality in preweaned dairy heifers. In addition, data were collected on birthing parameters, serum IgG, and treatments administered. Data have been collected from 851 calves on 89 farms in 12 of the nation's top dairy states. These results from the interim analysis are based on approximately 25% of the total number of calves expected to be enrolled in the study. The objective of the study was to assess morbidity and mortality of preweaned dairy heifers in the US to aid management decisions and increase heifer survival. Of the 851 calves, 33.4% experienced at least 1 disease event, and 6.1% had more than 1 disease event. The maximum number of disease events reported was 6. Clinical signs of morbidity were classified as dull; dehydrated; gastrointestinal; respiratory; lameness; and neurological. Gastrointestinal signs were observed in 18.0% of calves, while dullness was reported in 13.3% of calves and respiratory signs in 10.6%. Of the 33.4% of calves with clinical signs, 93.3% received treatment. Medications, including antibiotics, were administered to 82.4% of calves and electrolytes were administered to 35.6% of calves. Interestingly, of the 5.4% of calves that died, 39.1% died without displaying clinical signs before dying. The average age at death was 22.8 d, with a range from 3 to 78 d. Birthing parameters, including calving-ease score, number of calves born, and disinfection of the navel were not associated with morbidity or mortality. Serum IgG was collected and calves were classified as excellent ≥15.0 g/L (71.2%); fair 10.0–14.9 g/L (11.4%); or failure <10.0 g/L (17.4%) of passive transfer. Calves with fair passive transfer had higher levels of morbidity (44.3%) compared with calves with excellent passive transfer (30.4%). Serum IgG categories were not associated with mortality. High serum IgG levels were associated with decreased morbidity. Digestive and respiratory diseases were the 2 most common causes of morbidity in preweaned heifer calves.

Key Words: preweaned dairy calf, morbidity, mortality

141 Evaluation of colostrum quality and passive transfer status of dairy heifer calves on US dairy operations.

Chelsey B. Shivley*[1,2], Natalie J. Urie[1,2], Deborah M. Haines[3,4], Jason E. Lombard[2], and Manuel F. Chamorro[3], [1]*Colorado State University, Fort Collins, Colorado,* [2]*USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, Colorado,* [3]*Research and Technical Services, The Saskatoon Colostrum Company, Saskatoon, SK, Canada,* [4]*Department of Veterinary Microbiology, Western College of Veterinary Medicine, Saskatoon, SK, Canada.*

Passive transfer of immunity is essential for the short- and long-term health of dairy calves. The objective of this study was to evaluate colostrum quality and the passive-transfer status of US dairy heifer calves. This study was conducted as part of the calf component of the National Animal Health Monitoring System's Dairy 2014 study, which included 92 dairy operations in 13 states. Dairy 2014's calf component is a yearlong longitudinal study focused on dairy heifer calves from birth to weaning; data were collected on 851 calves. The results from the interim analysis are based on approximately 25% of the total number of calves expected to be enrolled in the study. The mean colostrum IgG level was 74.9 g/L (SE 1.2), with 66.3% of samples having IgG levels above 50 g/L. The mean serum IgG level was 22.2 g/L (SE 0.4), and 71.2% of calves had serum IgG levels above 15 g/L. The highest percentage of calves (60%) received colostrum from their dam. Pasteurized colostrum was fed to 9.6% of calves. On average, colostrum was fed within 3.4 h following birth. The mean volume of colostrum fed at first feeding was 3.0 L, and the mean volume of colostrum fed in the first 24 h of life was 4.5 L. The highest percentage of calves (63.7%) were fed colostrum by bottle, while 31.3% were fed colostrum by esophageal feeder. Backward elimination model selection in Proc Mixed was used to determine which colostrum management factors were most important for determining serum IgG levels. The model using initial results included grams of total colostrum fed at the first feeding, the number of hours following birth that calves received their first colostrum feeding, and the calves' birth weight. Serum IgG increased with more grams of total colostrum fed at first feeding; serum IgG decreased as the number of hours from birth to first feeding increased; serum IgG also decreased as birth weights increased. These results show that feeding appropriate amounts of high-quality colostrum shortly following birth is crucial to the passive-transfer status of dairy calves.

Key Words: dairy heifer calf, colostrum quality, passive transfer

142 Evaluation of the Brix refractometer for measuring colostral and serum IgG concentrations.

Manuel F. Chamorro*[1], Ron Sargent[1], Deborah M. Haines[2,1], and Jason Lombard[3], [1]*The Saskatoon Colostrum Company Ltd., Saskatoon, Saskatchewan, Canada,* [2]*Western College of Veterinary Medicine, Saskatoon, Saskatchewan, Canada,* [3]*Center for Epidemiology and Animal Health USDA, Fort Collins, CO.*

The objective of this study was to evaluate the use of a digital Brix refractometer to assess the levels of IgG in maternal colostrum and to measure passive transfer in newborn calves. Colostrum (n = 1,590) and serum (n = 1,756) samples from 1- to 5-d-old calves were collected from 130 dairy farms across the US from April through December 2014. Colostrum and serum IgG were determined by radial immunodiffusion (RID), and a digital refractometer was used to indirectly estimate IgG concentrations by %Brix. The mean IgG colostrum level was 76.7 g/L (SEM ± 0.84) with a range of 3.0 to 227.4 g/L. The mean %Brix in colostrum samples was 23.3 (SEM ± 0.12) with a range of 2.3% to 40%. The mean IgG serum level was 21.8 g/L (SEM ± 0.26) with a range of 0.1 to 79.3 g/L. The mean %Brix in serum samples was 9.1 (SEM ± 0.02) with a range of 6.4% to 18.7%. The %Brix in colostrum and serum samples was highly correlated with IgG levels in colostrum and serum (r = 0.76 and r = 0.85, respectively). A receiver-operating characteristic curve was created to plot the true positive rate against the false positive rate for consecutive %Brix values for colostrum and serum samples. Compared with a cut-point of 50 g/L IgG (consistent with good quality) as determined by RID in colostrum samples, the lowest false-positive rate occurred at 22% Brix, with a combined sensitivity and specificity of 78% and 84%, respectively. The positive predictive value (PPV) and negative predictive value (NPV) of 22% Brix were 94% and 53.5%, respectively. For serum samples, the optimal combination of sensitivity (88.8%) and specificity (90.6%) compared with a cut-point of 10 g/L (consistent with adequate passive transfer) occurred at 8.4% Brix. The PPV and NPV of 8.4% Brix were 98.3% and 56.9%, respectively. The digital brix refractometer is a convenient method to assess colostrum quality and adequacy of passive transfer in calves at the herd level. However, individual %Brix values below these threshold values underestimate the actual IgG level in about 45% of the samples.

Key Words: colostrum IgG, serum IgG, Brix

143 Prevalence of *Cryptosporidium* and *Giardia* in preweaned dairy heifer calves.

Natalie J. Urie*[1,2], Jason E. Lombard[1], Ronald Fayer[3], Monica Santin-Duran[3], and Chelsey B. Shivley[1,2], [1]*USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO,* [2]*Colorado State University, Fort Collins, CO,* [3]*USDA:ARS:NEA:BARC: Environmental Microbial and Food Safety Lab, Beltsville, MD.*

As part of the calf component of the National Animal Health Monitoring System's Dairy 2014 study, fecal samples were collected from 782 calves on 87 farms in 11 of the top dairy states. These results from the interim analysis are based on approximately 25% of the total number of calves expected to be enrolled in the study. The samples were examined for *Cryptosporidium* (*Crypto*) and *Giardia* by immunofluorescence microscopy. Samples were collected from 612 calves in the East [IA, MI, MN, MO, NY, OH, PA, VT, VA, WI] and from 239 calves in the West [CA, CO, WA]. Calves were from 3 to 54 d of age at the time of sampling, with a mean age of 22 d. Overall, 48.2% of calves were infected with *Crypto* and 36.5% were infected with *Giardia*. One fifth of calves (20.0%) were infected with both *Crypto* and *Giardia*; 28.3% were infected with *Crypto* only, and 16.5% were infected with *Giardia* only. Approximately one-third of calves (35.3%) were not infected with either organism. *Crypto* was detected in 54.1% of calves 21 d of age or younger (n = 442) and in 40.6% of calves older than 21 d of age (n = 340). *Giardia* infection also differed between age groups: *Giardia* was detected in 32.4% of calves 21 d of age or younger and in 41.8% of calves older than 21 d of age. The percentage of samples positive for *Crypto* was similar between the East and West (47.4 and 50.2%, respectively). A higher percentage of calves in the East were infected with *Giardia* compared with calves in the West (40.0 and 27.8%, respectively). Calves were sampled from March through December 2014; 29.5% were sampled in April–June (spring), and 58.6% were sampled in July–September (summer). Only 11.9% were sampled during October–December (fall). The prevalence of *Crypto* was not different between seasons. *Giardia* levels differed among the seasons with a prevalence of 36.8% in the spring, 33.8% in the summer and 48.4% in the fall. *Giardia* prevalence in calves was lower than *Crypto*, but *Giardia* was more prevalent in the East region and during the fall. Species and assemblage identification for *Crypto* and *Giardia*, respectively, for these and additional samples await molecular applications.

Key Words: calves, *Cryptosporidium*, *Giardia*

144 Evaluation of average daily gain in preweaned dairy heifer calves based on different liquid diets and management practices.

Chelsey B. Shivley*[1,2], Natalie J. Urie[1,2], and Jason E. Lombard[2], [1]*Colorado State University, Fort Collins, CO,* [2]*USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO.*

The objective of this study was to evaluate average daily gain (ADG) in US dairy heifer calves based on different liquid diets and management practices. This study was conducted as part of the calf component of the National Animal Health Monitoring System's Dairy 2014 study, which included 123 dairy operations in 13 states. Dairy 2014's calf component is a yearlong longitudinal study focused on dairy heifer calves from birth to weaning; data were collected on 851 calves from 92 operations. The results from the interim analysis are based on approximately 25% of the total number of calves expected to be enrolled in the study. Liquid diets were categorized by type (i.e., milk replacer, waste/whole milk, or a combination of the 2 (combination)) and by volume (i.e., > 4.9 kg/d or ≤ 4.9 kg/d). The mean ADG was 0.7 kg per day, and calves were fed liquid diets an average of 58.8 d. Backward elimination model selection was used to determine which diet and management practices significantly affected ADG. Using initial results, the model included liquid diet ($P = 0.004$), disease ($P < 0.001$), housing ($P = 0.0189$), and dehorning ($P = 0.001$). After controlling for other independent variables in the model, calves fed a combination diet gained, on average, 0.14 kg/day more than calves fed any milk replacer or a low volume of milk. Calves fed a high volume of milk outgained calves fed milk replacer or a low volume of milk by 0.15 kg/day. Calves without any disease events gained 0.07 kg/day more than calves with one or more disease events. Calves housed in groups gained 0.15 kg/day more than calves housed individually. Preweaned heifer calves that were dehorned gained 0.11 kg/day more than calves that were not dehorned. These initial results indicate the type of liquid diet fed, the amount fed, as well as other management practices unrelated to feeding, affect ADG.

Key Words: dairy heifer calf, average daily gain, liquid diet

145 Prevalence of *Campylobacter* spp. in bulk tank milk and filters from US dairies.

Laura P. Del Collo*[1,3], Jeffrey S. Karns[1], Debabrata Biswas[3], Jason E. Lombard[2], R. Camilla Kristensen[2], Charles P. Fossler[2], and Jo Ann S. Van Kessel[1], [1]*USDA-ARS-NEA Environmental Microbial and Food Safety Laboratory, Beltsville, MD,* [2]*USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO,* [3]*Dept. of Animal and Avian Sciences, University of Maryland, College Park, MD.*

Campylobacter spp. is an important zoonotic bacterial pathogen that caused the majority of US outbreaks associated with nonpasteurized milk from 2007 to 2012. Bulk tank milk and milk filter samples were collected from 234 dairy operations in 17 top dairy states from March through July 2014 as part of the National Animal Health Monitoring System's Dairy 2014 study. Overall, 234 bulk tank samples and 396 milk filter samples were collected. Bulk tank and milk filter pairs were collected from 231 operations, and only bulk tank samples were collected from 3 operations. Bulk tank milk and buffered peptone water extracts of milk filters were enriched in Bolton Broth and struck onto mCCDA plates. A real-time PCR method was used to determine the presence of pathogenic species (*C. jejuni*, *C. coli*, and *C. lari*) in enrichments and to confirm isolates. Analysis of prevalence (%) incorporated operation weights to reflect the population from which samples were collected. Positive operations were those with either a positive milk filter or a positive bulk tank sample (or both). PCR indicated the presence of pathogenic *Campylobacter* spp. in enrichments from 24.3% of operations, while isolates were obtained from 12.0% of operations. *Campylobacter* was more frequently identified in samples from operations in the west region than in the east region (46.5% and 21.8%, respectively) and was more common in medium and large operations than in small operations (42.8%, 47.3%, and 4.9%, respectively). Based on multiplex PCR analysis, 41 (91.3%) of the *Campylobacter* isolates were *C. jejuni,* 3 were *C. lari*, and 1 was identified as *C. coli.* This first national survey of *Campylobacter* spp. in bulk tank milk and milk filters suggests that pathogenic *Campylobacter* spp. are common on US dairies and, therefore, are a continued risk for foodborne disease outbreaks.

Key Words: *Campylobacter*, bulk tank milk, milk filter

146 *Salmonella* Dublin antibodies in bulk-tank milk on U.S. dairy operations.

Jason E. Lombard*[1], Belinda S. Thompson[2], Paul D. Virkler[2], Bettina Wagner[2], R. Camilla Kristensen[1], and Charles P. Fossler[1], [1]*USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO,* [2]*Animal Health Diagnostic Center, College of Veterinary Medicine, Cornell University, Ithaca, NY.*

Bulk-tank milk was collected and tested for antibodies to *Salmonella* Dublin during the National Animal Health Monitoring System's Dairy 2014 study. Information regarding management practices and dairy-cow health and productivity was also collected via 2 face-to-face interviews. One objective of the Dairy 2014 study was to estimate the herd-level prevalence of *Salmonella* Dublin antibodies and associated factors. A single bulk tank sample was collected from 230 operations from March through July 2014. After adjusting for study design and incorporating weighting procedures, estimates indicated that 8.0% of dairy operations had *Salmonella* Dublin antibodies present in bulk-tank milk. A higher percentage of operations with 500 or more cows (39.2%) had bulk-tank antibodies compared with operations with 100–499 cows (2.1%), and 30–99 cows (1.0%). In the West region (CA, CO, ID, TX, WA), 52.1% of bulk tanks were antibody positive, and in the East region [IA, IN, KY, MI, MN, MO, NY, OH, PA, VT, VA, WI] 2.8% of operations were antibody positive. Although bulk tanks in closed herds were not at lower risk of being antibody positive, bulk tanks on a higher percentage of operations that reared heifers offsite (20.6%) were antibody positive compared with bulk tanks on operations that did not raise heifers offsite (6.0%). In addition, bulk tanks on operations that reared heifers offsite and commingled heifers with cattle from other operations were at higher risk of being antibody positive (28.0%) compared with bulk tanks on operations in which heifers did not have contact with other cattle at the offsite facility (3.2%). Operations with *Salmonella* Dublin antibodies detected in bulk-tank milk had rolling herd average milk production of 10,764 kg compared with 9,672 kg for operations in which antibodies were not detected. Operation-level mortality of pre-weaned and weaned heifers did not differ by Dublin result. Results suggest that large operations, operations in the West and operations that raise heifers offsite are more likely to have *Salmonella* Dublin antibodies detected in milk.

Key Words: *Salmonella* Dublin, bulk milk, prevalence

147 Prevalence of *Salmonella* and *Listeria monocytogenes* in bulk tank milk and filters from US dairies.

Jo Ann S. Van Kessel*[1], Jeffrey S. Karns[1], Jason E. Lombard[2], R. Camilla Kristensen[2], and Charles P. Fossler[2], [1]*USDA-ARS-NEA Environmental Microbial and Food Safety Laboratory, Beltsville, MD,* [2]*USDA:APHIS:VS:Center for Epidemiology and ANimal Health, Fort Collins, CO.*

Zoonotic bacterial pathogens are frequently isolated from the feces of dairy animals and their environments; therefore, bulk tank milk (BTM) and meat from culled dairy animals are at risk for contamination. As part of the National Animal Health Monitoring System's (NAHMS) Dairy 2014 study, 234 BTM and 396 milk filter (MF) samples were collected from 234 operations in 17 states from March through July 2014. BTM and MF pairs were collected from 231 operations, and only BTM samples were collected from 3 operations. Samples were enriched for *Salmonella* and *Listeria* spp. in selective broths. The presence of *Salmonella* was determined by real time PCR, and positive enrichment broths were struck onto selective agar for isolation. *L. monocytogenes* was distinguished from other *Listeria* species via the presence of phosphatidylinositol-specific phospholipase. Analysis of prevalence (%) incorporated operation weights to reflect the population from which samples were collected. Positive operations were those with either a positive MF or a positive BTM sample (or both). PCR analysis indicated that 18.6% of operations were positive for *Salmonella*. *Salmonella* isolates were obtained on 96.5% of these PCR-positive operations. Sixteen *Salmonella* serotypes were identified, with multiple serotypes detected on 9 operations. The most common serotypes were Cerro, Montevideo, Kentucky, and Newport, which were isolated from 33, 8, 5, and 5 operations, respectfully. *Listeria* spp. were isolated from 20.0% of operations and *L. monocytogenes* was isolated from 3.0% of operations. Prevalences of *Salmonella* and *L. monocytogenes* increased as herd size increased. The 2014 prevalences of *Salmonella* and *L. monocytogenes* are significantly lower than the prevalences from the NAHMS 2007 Dairy study (28.1% for *Salmonella*, 7.1% for *L. monocytogenes*). A significant presence of *Salmonella* and *L. monocytogenes* in BTM or MF samples indicates potential health risks to raw milk consumers.

Key Words: *Salmonella*, *Listeria*, bulk tank milk

148 Dry-off procedures on US dairy operations. Jason E. Lombard*[1], Gosia Zobel[2], Ashley E. Adams[1,3], Charles P. Fossler[1], Chelsey B. Shivley[1,3], Natalie J. Urie[1,3], and Christine A. Kopral[1], *[1]USDA:APHIS:VS:Center for Epidemiology and Animal Health, Fort Collins, CO, [2]University of British Columbia Animal Welfare Program, Vancouver, BC, Canada, [3]Colorado State University, Fort Collins, CO.*

The National Animal Health Monitoring System′s Dairy 2014 study collected information via face-to-face interviews from 17 states. An objective of the study was to describe dry-off procedures on US dairy operations. Size categories were created based on number of lactating and dry cows: small (30–99 cows), medium (100–499 cows), and large (500 or more cows). During 2013, the operation average dry period length was 57.1 d. Almost all operations (98.8%) dried off at least some cows based on a set schedule, and 81.3% of operations dried off at least some cows based on a minimum milk-production level. Overall, 88.1% of cows were dried off on a set schedule and 11.9% were dried off based on milk production. Almost 3-fourths of operations (73.6%) abruptly stopped milking some cows at dry-off, while 47.5% of operations gradually stopped milking some cows at dry-off. However, only 10.2% of cows experienced gradual cessation of lactation, while 89.8% experienced abrupt cessation. At dry-off, 15.0% of operations performed a California Mastitis Test; 65.7% reduced the quality/energy content of feed; 10.9% restricted access to feed; and water was restricted on 3.9% of operations. More than 3-fourths of operations (80.3%) treated all cows with dry-cow intramammary antibiotics and, overall, 93.0% of cows were treated. Cephapirin benzathine was the single most commonly administered antibiotic (31.6% of cows dry-treated). Alcohol pads were used to clean teat ends before administering dry-cow antibiotics on 90.3% of operations. Dry-cow intramammary antibiotics were not used on 9.2% of operations. Internal teat sealants were used on 37.3% of operations, while external teat sealants were used on 14.5%. The percentage of operations using sealants on all cows increased as herd size increased. The operation average cost of antibiotics and sealants used at dry-off was $13.09 per cow. Gradual cessation of milking, which may reduce new intramammary infections during dry-off, is infrequently practiced in the US. Most cows are treated with antibiotics at dry-off, but this practice may be examined due to pressure to reduce antibiotic use in livestock and poultry.

Key Words: dry-off procedure, antibiotic, teat sealant

Ruminant Nutrition: Dairy calves

149 Effects of intensive whole-milk feeding in calves on subsequent growth of dairy heifers.

Camila Flávia de Assis Lage[1], Mariana Magalhães Campos[2], Fernanda Samarini Machado[2], Paulo Campos Martins[1], Luigi Francis Lima Cavalcanti*[3], Marcelo Neves Ribas[3], Luiz Gustavo Ribeiro Pereira[2], Thierry Ribeiro Tomich[2], Rafael Alves de Azevedo[1], and Sandra Gesteira Coelho[1], *[1]Federal University of Minas Gerais, Belo Horizonte, Minas Gerais, Brazil, [2]EMBRAPA Dairy Cattle, Coronel Pacheco, Minas Gerais, Brazil, [3]CNPq, RHAE – SEVA Engenharia, Projeto Intergado, Contagem, Minas Gerais, Brazil.*

The effects of intensive whole milk feeding in calves on subsequent growth of Holstein-Gyr females was evaluated. Up to 56 d old, calves received 6 L/d of 4 different liquid diets consisting of whole milk with increasing addition of milk replacer (Sprayfo Violet SSP) to adjust the concentration of total solids (TS) to 13.5 (n = 15), 16.1 (n = 15), 18.2 (n = 13), 20.4% (n = 15). After weaning, animals were randomly housed in 4 paddocks, each one equipped with electronic feed and water bins (Intergado, Brazil) in Embrapa Dairy Cattle facilities, Brazil. Diet (70:30, corn silage:concentrate, 195 g CP/kg, DM basis) was fed ad libitum, twice a day, until 210 d old. The withers height (WH), hip height (HH), rump width (RW) and chest circumference (CC) measures were carried out fortnightly using a flexible tape measure and a teletape (Ketchum, Canada). WH and CC were analyzed as a completely randomized design with repeated measures using nonlinear mixed models approach. A regression model ($Y(age) = A+(B-A)\exp[-\exp(-c \times age)]$, where Y = response at a specific age, A = asymptote as age $\rightarrow\infty$, $B = Y_{(0)}$, and c = logarithm of the rate constant) was fit to the data, where age and function parameters were allocated as fixed effects while animal was considered as random. It was evaluated the necessity of adding random terms to model error dependence and heteroscedasticity by monitoring Schwarz criterion, estimates stability and correlation. HH and RW, due to their linear growth pattern, were analyzed by linear mixed models, allowing polynomial models of first and second degree orders to model variable change over time ($\alpha = 0.05$). All variables were steadily influenced by age, but only WH and CC were influenced by TS. For both responses, the c parameter was linearly increased by TS, revealing that a more intensive feeding strategy increases the growth rate of these 2 traits. TS influenced all CC parameters, where increasing total solid level caused a linear decrease of A, while increased B. TS effects over parameters A and B should be interpreted with parsimony, because animals in the present study had not achieved their mature weight.

Key Words: milk replacer, intensive farming, heifer

150 Effect of bacteria level in colostrum on dairy heifer serum IgG concentration.

Christine Cummins and Emer Kennedy*, *Teagasc, Ireland.*

Storage of colostrum >4°C increases total bacterial count (TBC) which may compromise passive transfer of immunity. This experiment investigated the effect of colostrum stored at varying temperatures, to induce a difference in bacteria levels, on the rate of passive transfer of immunoglobulin G (IgG) in dairy heifer calves. Colostrum was collected immediately postpartum from Holstein-Friesian (HF) cows, tested for IgG concentration, and assigned to 1 of 5 treatments: (1) pasteurized, (2) fed when freshly collected, (3) stored at 4°C for ≥48 h (fridge), (4) stored at 13°C ≥48 h, and (5) stored at 22°C ≥48 h. Colostrum fed to each calf was tested for TBC, using serial dilution and IgG concentration using radial immunodiffusion (RID; Triple J Farms, WA). Seventy-five HF and HF × Jersey (JEX) heifer calves were removed from their dam and assigned to a treatment immediately postpartum at Teagasc Moorepark Research Farm, from 3 Feb to 25 Mar 2014. A randomized block design accounting for breed, birth date and birth weight (BW) was used. Calves were fed 8.5% of their BW in colostrum via stomach tube within 2 h. Calf blood samples were collected at 0 and 24 h of age and analyzed for IgG concentration using RID. Data were checked for normality and the MIXED procedure in SAS was used to examine the effect of treatment on serum IgG concentration. Pasteurised colostrum had a TBC <9,000 cfu/mL, fresh colostrum had 68,000 cfu/mL; both below the recommended level of 100,000 cfu/mL. Colostrum stored at 4°C had a TBC > 2 million cfu/mL, currently not recommended for feeding. Colostrum stored at 13°C and 22°C had significantly higher ($P < 0.01$) TBCs (>92 and >1000 million cfu/mL, respectively). Colostrum stored at 22°C had the lowest IgG concentration (62 g/L). The overall average colostrum IgG concentration across all treatments was 97 g/L. Zero-hour serum contained no IgG. Serum IgG of calves at 24 h from the pasteurised, fresh and 4°C treatments were similar, but were significantly higher ($P < 0.05$) than colostrum from the 13°C and 22°C treatments. Colostrum with high levels of bacteria reduced IgG absorption in dairy calves. Colostrum should be stored ≤ 4°C to minimize bacterial growth and improve subsequent passive transfer of IgG.

Key Words: calf, IgG, colostrum

151 Performance of calf reared on waste milk or nonmedicated milk replacer contained sodium butyrate and *Bacillus amyloliquefaciens.*

O. V. Vazquez-Mendoza[1], A. E. Kholif[2], M. M. Y. Elghandour[3], A. Z. M. Salem*[3], V. L. Garcia-Flor[4], and T. A. Morsy[2], *[1]Norel México S.A. de C.V., Parque Industrial El Marqués, Querétaro, México, [2]Dairy Science Department, National Research Centre, Giza, Egypt, [3]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma del Estado de México, Toluca, Estado de México, Mexico, [4]Centro de Ciencias Agropecuarias, Universidad Autónoma de Aguascalientes, Aguascalientes, México.*

More interest is paid for the accelerated growth programs for dairy calves through enhancing early nutrition programs based on greater rates of liquid feeding for better mammary gland development and milk production. Appropriate supply of nutrients for calves through liquid feed including milk or milk replacer is essential for better performance and welfare. In a completely randomized design, the nutritional and economic efficiencies, and growth performance of 18 Holstein female dairy calves (41 ± 3.7 kg BW, 1 d old) fed either pasteurized waste milk (PWM) or calf milk replacer (CMR) were tested. Calves were fed colostrum (IgG; 70–100 mg/mL) within the first 2 h of life at the rate of 10% of their BW, and then offered 2 L every 12 h for 3 d, without access to solid feed. Calves were fed individually on PWM (n = 9) or CMR containing *Bacillus amyloliquefaciens* and sodium butyrate (n = 9) twice daily at 0900 and 1600 h for 60 d. From the fourth day, calves were offered pelleted starter feed (180 g CP and 338.2 g of NDF/kg DM) in the morning at 0900 h. Water was provided ad libitum. Health condition, body measurements, fecal bacteriological analysis and economic analysis were measured. No differences were observed for liquids and total starter intakes; however, calves fed on PWM consumed more ($P < 0.05$) starter DM during the period from d-16 to d-45 with greater metabolizable energy intake. Greater ($P < 0.05$) BW changes

for PWM-calves than CMR-calves during the period from d-30 to d-60; with higher ($P < 0.05$) average daily gains during the period from d-16 to d-60. Health conditions did not differ between calves with greater faces score and lower cough score for CMR-calves. Calves fed CMR had greater fecal number from *Klebsiella oxytoca* and *Proteus vulgaris* with the same count of *E. coli*. Greater economic evaluation ($P < 0.0001$) for CMR-calves than PWM-calves were obtained. It could be concluded that the CMR can be used efficiently rather than PWM without reducing feed efficiency and with more profits in feeding dairy calves during the pre-weaning period.

Key Words: calf, health condition, milk replacer

152 Effects of colostrum feeding programs on passive immunity, health, and performance of Holstein dairy calves.

Weina Shi and Zhijun Cao*, *China Agricultural University, Beijing, China.*

The objective of this study was to investigate effects of 4 colostrum feeding programs on passive transfer of immunity, health, and growth performance of Holstein dairy calves before 70 d age. Experiment 1, 76 newborn Holstein calves (24 bulls and 52 heifers) were blocked by colostrum quality and sex and assigned randomly to 4 treatments. Calves were housed in individual hutches and were moved to the heifer pens at the age of 9 week. Colostrum feeding programs were as follows: calves in T_{322} were fed 3 L at 0 h (birth), 2 L at 6 h, and 2 L at 12 h; calves in T_{402} were fed 4 L at 0 h and 2 L at 12 h; calves in T_{400} were fed 4 L only at birth; calves in T_{220} were fed 2 L at 0 h and 2 L at 6 h. Blood sample collected at 24 h after birth showed that serum total protein (TP, g/dL) and IgG (mg/mL) levels were significantly higher for calves in T_{322} (TP = 6.11 g/dL, IgG = 22.49 mg/mL, $P < 0.01$) and T_{402} (TP = 5.89 g/dL, IgG = 19.99 mg/mL, $P < 0.05$) compared with calves in T_{400} (TP = 5.56 g/dL, IgG = 16.05 mg/mL) and T220 (TP = 5.58 g/dL, IgG = 16.31 mg/mL). At 48 h after birth, serum TP and IgG levels were significantly higher for calves in T_{322} (TP = 6.37 g/dL, IgG = 25.61 mg/mL, $P < 0.01$) and T_{402} (TP = 6.12 g/dL, IgG = 22.61 mg/mL, $P < 0.01$) compared with calves in T_{400} (TP = 5.58 g/dL, IgG = 16.30 mg/mL) and T_{220} (TP = 5.66 g/dL, IgG = 17.24 mg/mL). Experiment 2, 40 heifers in experiment 1 were involved. Results showed that the incidence and frequency of diarrhea and the fecal index tended to be greater ($P > 0.05$) in T_{400} and T_{220} than in the other 2 treatments. At the first week post-weaning, calves from T_{322} (1536.54 g/d, DM, $P < 0.01$) and T_{400} (1321.23 g/d, DM, $P < 0.01$) had significantly higher starter intake than that of calves from T_{220} (1162.01 g/d, DM). These results suggest that colostrum feeding program 322 (3 L at 0 h, 2 L at 6 h, and 2 L at 12 h) and 402 (4 L at 0 h and 2 L at 12 h) can improve passive Immunity, health, and growth performance of Holstein dairy calves compared with the other 2 feeding programs. Further research is needed to evaluate the influence of colostrum feeding programs on later growth, reproduction and lactation performance of dairy cattle.

Key Words: colostrum, passive immunity, growth performance

153 Influences of SmartCare in milk replacer and XPC in calf starter on the performance and health of preweaning Holstein calves challenged with *Salmonella enterica* serotype Typhimurium.

Tyler L. Harris*[1], Yu Liang[1], Matt D. Sellers[1], Jeff A. Carroll[2], Ilkyu Yoon[3], Mark F. Scott[3], and Michael A. Ballou[1], *[1]Department of Animal and Food Sciences, Texas Tech University, Lubbock, TX, [2]USDA-ARS, Lubbock, TX, [3]Diamond V, Cedar Rapids, IA.*

This study investigated how supplementing milk replacer with SmartCare (SC) and calf starter with original XPC (XPC) would affect performance and health following an oral challenge with *Salmonella enterica* serotype Typhimurium. The study was performed in 2 35 d periods with 30 Holstein bull calves per period. In each period, calves were blocked by location in the barn and randomly assigned to treatments that included: CON: base milk replacer and calf starter with no added products, SC: milk replacer with 1 g SC/calf/d and base calf starter, and SC+XPC: milk replacer with 1 g SC/calf/d and calf starter with 0.5% XPC. Calves were fed 350 g of milk replacer at 0700 and 1700. Calf starter and water were offered ad libitum and recorded daily. Calves were challenged with 10^8 cfu of sulfamethazine-resistant *Salmonella enterica* orally on d 14 of the study. Fecal *Salmonella* shedding was determined on d 14 to 21, and d 24, 28, and 35 using selective media. Blood samples were collected on d 0, 7, 14, 16, 18, 21, 24, 28, and 35 and analyzed for hematology. Contrasts were analyzed to determine SC and XPC effects. All data were reported as CON, SC, and SC+XPC, respectively. The LSMeans with various superscripts differ ($P \leq 0.05$). Calf starter intake (0.178^a, 0.218^{ab}, $0.254^b \pm 0.022$ kg) was improved in both SC and SC+XPC (SC contrast $P = 0.029$; XPC contrast $P = 0.035$). Average daily gain (0.48^a, 0.48^a, $0.58^b \pm 0.028$ kg) was greater among SC+XPC calves vs. the other treatments (XPC contrast, $P = 0.001$). Post challenge, the SC+XPC calves had a lower neutrophil to lymphocyte ratio (0.81^a, 0.83^a, $0.69^b \pm 0.051$) vs. CON and SC calves (XPC contrast, $P = 0.005$). The SC+XPC calves also had lower hematocrits (35.1^a, 35.3^a, $33.4^b \pm 0.54\%$) and hemoglobin concentrations (10.8^a, 10.6^a, $10.1^b \pm 0.16$ mg/dL) after the challenge. Fecal *Salmonella* shedding tended to be reduced by both SC and SC+XPC (3.21, 2.84, 2.42 ± 0.279 d shedding; SC and XPC contrasts $P \leq 0.071$). Calves fed both SC in milk replacer and XPC in calf starter had improved performance and enteric health.

Key Words: calf, health, yeast culture

154 Effect of feed type and presentation on feeding behavior, intake, and growth of dairy calves fed a high level of milk.

Morgan A. Overvest*[1], Renee Bergeron[2], Derek B. Haley[3], and Trevor J. DeVries[1], *[1]Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [2]Department of Animal and Poultry Science, University of Guelph, Campus d'Alfred, Alfred, ON, Canada, [3]Department of Population Medicine, Ontario Veterinary College, University of Guelph, Guelph, ON, Canada.*

The objective of this study was to assess the effect of different feed types and method of feed presentation in the first 12 wk of life on the feeding behavior, intake and growth of calves fed a high milk level. Forty-eight neonatal Holstein calves (~24 h old) were individually housed and randomly assigned to 1 of 4 treatments: silage-based total mixed ration (TMR), concentrate (CON), and chopped hay and concentrate presented in 2 manners: mixed (MIX) or separate (SEP). All calves were offered 12L/d of acidified milk replacer until d 38 at which time step-down weaning by 1 L/d began. At d 50 calves no longer received milk and all calves on SEP and CON treatments were offered the MIX diet until the end of the trial while TMR and MIX calves did not change feeds. Feed intakes were recorded daily and calves were weighed 2x/wk. For the last 2 d during wk 3, 5, 7, 9, and 11 video recordings were analyzed for time spent feeding. Data were summarized by week and analyzed in a repeated measures general linear mixed model. In the preweaning stage (d 1–37) ADG was similar for all calves (1.1 kg/d; SE = 0.05; $P = 0.16$). TMR calves had lower ADG than calves on the other 3 treatments during both the weaning (d 38–49; 0.2 vs. 0.7 kg/d; SE = 0.06; $P < 0.01$) and post-weaning (d 50–84; 0.5 vs 1.2 kg/d; SE = 0.09; $P <$

0.01) stages. This result is related to the lower DMI of calves fed TMR in comparison to MIX, SEP and CON calves in the weaning (0.2 vs. 0.5 kg/d; SE = 0.07; $P < 0.01$) and post-weaning (1.8 vs. 2.8 kg/d; SE = 0.17; $P < 0.01$) stages. It should be noted that, given DM content of the feeds (TMR = 52%, all other diets = 89%), the as-fed intake of the calves was actually similar ($P \geq 0.40$) across treatments in all 3 stages. Interestingly, TMR calves spent more time feeding during the postweaning stage than MIX, SEP and CON calves (308 vs 194 min/d; SE = 16.0; $P < 0.001$). It appears that during weaning and post-weaning, calves fed TMR were attempting to maximize their nutrient intake, but were unable to match that of those in other treatments due to the high moisture content of their feed, and thus were unable to perform at a similar level.

Key Words: dairy calf, weaning, feeding behavior

155 Extensive, noninvasive measurements of body temperature and posture in neonatal Holstein dairy calves bedded with deep straw in response to changes in ambient temperature and amount of milk replacer fed.

T. Mark Hill*, H. Gale Bateman, II, F. Xavier Suarez-Mena, James D. Quigley, and Rick L. Schlotterbeck, *Nurture Research Center, Provimi North America, Cargill Premix and Nutrition, Brookville, OH.*

Posture of calves can be influenced by nutrition and ambient temperature. Calf tail vein temperature (a proxy for body temperature) and standing time were extensively measured in 14 male calves (46 ± 1.5 kg initial BW) between 4 and 18 d of age. Thermocrons (Maxum Integrated Products Inc.) were taped to the tail vein to capture temperatures hourly. Accelerometers (Onset Computer Corp.) were attached to a plastic ankle bracelet and taped to the medial side of the right, rear leg to record posture every minute. Calves were fed free-choice dry feed and water and a 27% CP, 17% fat (DM) milk replacer fed at 2 rates (0.66, LOW, and 1.0 HIGH, kg DM daily) in 2 equal meals fed at 0600 and 1600 h. Calves were bedded with deep straw and maintained in an unheated, naturally ventilated, curtain-sided nursery with a well-drained rock floor. Ambient temperature averaged 2.5°C (daily averages ranged from −2.4 to 8.1°C). Data were analyzed as repeated measures in a randomized ANOVA to test MR rate and with linear regression analysis to test ambient temperature and time. Mean calf temperature was 38.4 ± 0.11°C and it changed diurnally with a 0.5°C daily range being highest at night ($P < 0.05$). Calf temperature was 0.1°C greater for calves fed a HIGH vs. LOW rate and it increased 0.02°C per 1°C ambient temperature ($P < 0.05$). Standing time averaged 299 ± 17 min/d and it increased 7.1 min daily with age and decreased 2.6 min daily per 1°C ambient temperature ($P < 0.05$). Standing bouts (a standing plus lying event) averaged 16.2 ± 0.5 daily and decreased 0.3 bouts daily per 1°C ambient temperature ($P < 0.05$). Bouts were 2.8 more daily for caves fed at the high vs. low rate and these extra bouts occurred during the AM and PM meals ($P < 0.05$). Standing time and bouts changed over the 24-h day and were greatest during the AM and PM meals, intermediate during the day between meals, and were the least overnight ($P < 0.05$). Feeding more milk replacer slightly increased body temperature and increased standing bouts during meals. A greater body temperature and less standing time overnight suggests that calves bedded with deep straw during cold temperatures conserved body heat by lying.

Key Words: calves, posture, temperature

156 Commercial dairy farm evaluation of highly digestible corn grain for calf starters when calves are fed pasteurized waste milk.

David P. Casper*[1] and Mark Kirk[2], [1]*South Dakota State University, Brookings, SD,* [2]*Masters Choice, Anna, IL.*

New corn hybrids have been developed by Masters Choice (MC) that vary in energy density and starch digestibility. These MC hybrids have lower starch densities due to an altered starch structure, which allows for greater ruminal and intestinal starch digestion. Our previous work (Casper et al. 2014) had demonstrated improved nutrient digestibilities, feed efficiency, and reduction in cost of gain when feeding a calf starter (CS) based on MC corn when calves were fed an accelerated milk replacer (28:18 CP:fat). Forty-five (1 to 3 d old) Holstein heifer calves raised on a large commercial Eastern South Dakota Dairy Operation were randomly assigned to 1 of 3 CS to evaluate growth performance of Holstein heifer calves through 7 wk of age from mid-June 15 through mid-August, 2013. Treatments were: 1) Control (C) CS: containing 40% (DM basis) conventional ground shelled corn 24% CP; 2) MC CS: containing (40% DM basis) MC corn and 24% CP; and 3) Standard commercially available CS (S) being fed at the dairy operation containing 16% conventional corn and 16.5% CP. All CS were fed as a pellet. Colostrum was fed the first 3 d of life and then pasteurized waste milk was fed twice daily at a rate of 3.78l L/d for 2–13 d, 5.68 L/d for 14–35 d, and once daily at 2.85 L/d for 35–42 d of age. Feedings were reduce to 1x/d at 35 d to facilitate weaning at 42 d and the study ended at 49 d. Calves were housed in individual poly hutches with ad libitum CS and water. Data were analyzed as a completely random design using the PROC MIXED procedure of SAS Version 9.4. Initial body weights were similar ($P > 0.08$) for calves fed all CS (38.8, 37.5, and 34.9 kg for C, MC, and S, respectively). Body weight gains (18.0, 16.8 and 13.6 kg) and average daily gains (0.34, 0.32, and 0.28 kg/d) were greater ($P < 0.03$) for calves fed C and MC compared with calves fed S CS. Calves fed MC CS gained greater ($P < 0.03$) more body length (4.6, 12.9, and 6.4 cm) than calves fed C or S. Feeding a higher CP CS improved growth rates, but MC CS further increased body length when fed pasteurized waste milk during the summer heat stress.

Key Words: waste milk, corn hybrid, calf starter

157 Vitamin D status of dairy calves fed pasteurized whole milk.

Jessica L. Powell*[1], Kathryn E. Merriman[1], Mary E. Drewnoski[2], and Corwin D. Nelson[1], [1]*University of Florida, Gainesville, FL,* [2]*University of Nebraska, Lincoln, NE.*

Calves need vitamin D to support bone growth and immunity. Feeding dairy calves pasteurized whole milk is a common practice, but the vitamin D status of milk-fed calves has not been widely appreciated. The objectives of this study were to determine serum 25-hydroxyvitamin D (25D) concentrations of dairy calves fed pasteurized whole milk and the effects of subcutaneous vitamin D injections on serum 25D concentrations of milk-fed dairy calves. Two experiments were conducted on 2 separate farms and serum 25D concentrations were measured using a 25D ELISA. In the first experiment, 23 Holstein calves received a vitamin AD&E (1200 IU α-tocopherol, 400,000 IU retinyl-palmitate, and 40,000 IU vitamin D_3; n = 11) or saline injection (n = 12) at birth, and were fed pasteurized whole milk and housed indoors. Serum 25D concentrations of the control calves were 8.1 ± 1.0, 11.2 ± 2.6, 13.0 ± 3.2, and 13.3 ± 1.6 ng/mL (mean ± SE) at 0 d, 7 d, 22 d, and 37 d of age, respectively. In contrast, serum 25D concentrations of the vitamin AD&E treated calves were the same as control calves at birth (10.0 ± 1.0 ng/mL), greater at 7 d and 22 d (25.4 ± 2.8 and 24.9 ± 3.4 ng/mL,

respectively; $P < 0.05$), and not different from controls at 37 d (14.3 ± 1.6 ng/mL; treatment x time interaction, $P < 0.05$). In the second experiment, 13 Holstein bull calves received either 80,000 IU of vitamin D_3 via subcutaneous injection at birth and once weekly for 3 weeks (n = 5) or no injection (control, n = 8), and were fed pasteurized whole milk and housed under shaded structures. Serum 25D concentrations of the non-treated calves were 13.4 ± 3.3, 5.1 ± 3.4, 8.0 ± 4.1, and 8.7 ± 4.9 ng/mL (mean ± SE) at 0 d, 7 d, 14 d, and 21 d of age, respectively. In the vitamin D-treated calves, serum 25D was the same as control calves at birth, but was increased to 25.6 ± 4.4, 38.1 ± 5.2, and 41.2 ± 6.2 ng/mL (mean ± SE) at 7 d, 14 d and 21 d of age, respectively (treatment x time interaction, $P < 0.01$). In conclusion, milk-fed dairy calves, particularly if housed indoors or under shade, are at risk for vitamin D deficiency (serum 25D < 10 ng/mL) if they do not receive supplemental vitamin D, and continuous vitamin D supplementation is needed to maintain vitamin D status of calves.

Key Words: dairy calf, nutrition, vitamin D

158 Gradual weaning affects pre- and postweaning feed intake, growth, and gastrointestinal development in Holstein calves fed an elevated plane of nutrition during the pre-weaning stage.

Michael A. Steele*[1,2], Leonel Leal[3], Michelle Carson[1], John H. Doelman[1], and John A. Metcalf[1], [1]*Nutreco Canada AgResearch, Guelph, Ontario, Canada,* [2]*University of Alberta, Edmonton, Alberta, Canada,* [3]*Nutreco Research and Development, Boxmeer, the Netherlands.*

The short and long-term benefits of feeding elevated quantities of milk have been recently been established and these feeding strategies have been implemented in many production systems worldwide. The objective of this study was to characterize the effect of abrupt and gradual weaning when calves are fed an elevated plane of nutrition (1.35 kg/d milk replacer) in a twice-daily feeding scheme. At total of 55 calves were randomly assigned to treatments of abrupt (0 d step-down) or gradual (12 d step-down) weaning at 48 d of life. Calves were housed and sampled in individual pens for the duration of the experiment. Milk, starter, straw and water intake was measured on a daily basis. Bodyweight was measured every 6 d until d 35 and every 3 d thereafter, while blood, rumen fluid and fecal matter was collected on d 35, 48 and 54 of the experiment. Although the growth rates of the step-down calves were lower from d 35 to weaning (0.48 ± 0.08 vs. 1.00 ± 0.10 kg/d; $P < 0.01$), the post-weaning average daily gain was greater compared with the abruptly weaned group (0.86 ± 0.12 vs. 0.15 ± 0.10 kg/d; $P < 0.01$). Total rumen volatile fatty acid concentration was greater in the step-down group compared with the abrupt group on the day of weaning on d 48 (76.84 ± 1.28 vs. 46.72 ± 0.78 mmol; $P < 0.01$). Fecal starch percentage was lower postweaning compared with the abruptly weaned calves on d 54 (2.97 ± 1.28 vs. 6.67 ± 1.22%; $P < 0.05$), whereas serum amyloid A concentration was not affected by weaning strategy. These results showcase the benefits of a step-down feeding scheme from an overall energy balance standpoint in twice daily feeding schemes, presumably due to the increased opportunities for the gut to adapt before weaning.

Key Words: calf, weaning, development

159 Effects of pre- and postweaning nutrition on growth, efficiency, and rumen fermentation of Holstein calves.

Tana S. Dennis*[1], Michael W. Grott[1], Brad W. Shelton[1], and Tamilee D. Nennich[1,2], [1]*Purdue University, West Lafayette, IN,* [2]*Famo Feeds, Freeport, MN.*

The objective of this study was to evaluate the interaction of preweaning and postweaning nutrition on calf performance, blood metabolites, and rumen fermentation. Holstein calves (43.5 ± 5.1 kg BW at birth; 39 heifers and 18 bulls) were assigned at 1 d of age to 1 of 4 treatments in a randomized complete block design with a 2 × 2 factorial arrangement of treatments. Preweaning milk replacer (MR) treatments were a 22% CP, 20% fat (as-fed basis) MR (C) or 28% CP, 20% fat MR (H), with weaning based on starter intake. Postweaning treatments were low NFC (27% NFC on DM basis; LC) or high NFC (42% NFC; HC) grower diets fed individually for ad libitum intake from 12 to 28 wk of age. Weights, skeletal measurements, and blood were taken every 2 wk during the preweaning period. Postweaning, BW were taken every 2 wk and skeletal measurements, blood, and rumen fluid were collected monthly. Pre- and postweaning periods were analyzed separately and overall from birth to 28 wk. Calves fed H were 15 d older, 18.0 kg heavier, and consumed 58% more DM through weaning compared with C ($P < 0.01$); however, feed efficiency (FE) was similar between H and C from birth to weaning ($P = 0.24$). From weaning to 11 wk, DMI was 53% greater for C ($P < 0.01$); however, ADG from weaning to 11 wk was similar, resulting in greater ADG from birth to 11 wk for H ($P < 0.01$). Hip height, hip width, and heart girth increased 2.7, 3.6, and 3.7%, respectively, for H over C at 8 wk ($P < 0.01$). Postweaning, ADG was improved for HC ($P = 0.01$), resulting in an 8.7 kg advantage in BW at 28 wk ($P = 0.04$). Total DMI was similar between postweaning treatments, and FE was significantly improved for HC from 12 to 28 wk ($P < 0.01$). Rumen fermentation and blood profiles were altered in favor of decreased acetate ($P = 0.09$), increased butyrate ($P = 0.01$), and reduced rumen NH_3 and plasma urea N ($P < 0.01$) for HC. Overall, calves fed H^{+}HC were 12.4 kg heavier at 28 wk compared with calves fed H^{+}LC, but similar in BW to calves fed C+HC. These results suggest calves fed a high plane of nutrition preweaning should continue to receive high planes of nutrition postweaning to maintain growth advantages.

Key Words: dairy calf, weaning, growth

160 Commercial dairy farm evaluation of milk replacers with different protein sources and concentrations.

K. A. Froehlich*[1], U. Salga Vegas[1], C. Soderholm[2], and D. P. Casper[1], [1]*South Dakota State University, Brookings, SD,* [2]*Milk Specialties Global, Eden Prairie, MN.*

High protein (accelerated) milk replacers (MR) have increased skeletal frame growth and average daily gain (ADG) in dairy calves. However, high protein MR often cost more money than dairy producers are willing to spend for the improved performance. Our objectives were to determine the growth performance of calves fed a 24/20 (protein/fat) MR made from alternative protein sources that equal the cost of a 20/20 all milk protein MR. Eighty-eight Holstein calves raised on a South Dakota (SD) commercial dairy operation were blocked by birth date and randomly assigned to 1 of 3 treatments consisting of a control 20:20 all milk protein MR (C20), 24:18 all milk protein MR (C24), and a 24:18 alternative protein MR (A24) where the CP sources were based on 11% milk, 5% wheat, and 8% plasma. Colostrum was fed the first 3 d of life and then MR was fed at a rate of 0.68 kg/calf/d at twice daily for 35 d via bottle. Feedings were reduce to once daily at 36 d to facilitate weaning at 42 d. All MR had neomycin and oxytetracycline added at 1,330 g/ton each and supplemented with SAF Mannan. Calves were housed in individual poly-dome hutches bedded with straw with ad libitum access to a 20% CP calf starter (CS) and water. Calves fed all 3 MR were similar ($P > 0.10$) in ADG (0.59, 0.63, 0.63 kg/d for C20, C24, and A24, respectively). Gains in body weight, hip width, wither

height, and body length during the 56 d study were similar ($P > 0.10$) among calves fed all MR. Calves fed C24 MR had greater ($P < 0.05$) gains in hip height than calves fed C MR (6.2, 10.6 and 8.5 cm) with calves fed A24 being intermediate. Calves fed A24 MR tended ($P < 0.08$) to have greater gains in heart girth (15.8, 16.8 and 18.0 cm) than calves fed C20 with calves fed C24 being intermediate. Feeding a MR having more protein can support greater frame growth. The use of wheat and plasma protein to replace portions of all milk protein in MR can result in better frame growth when calves are raised on a commercial dairy. Thus, feeding a 24/18 MR can be cost neutral to the feeding of a 20/20 MR, but potentially support improved frame growth.

Key Words: calf, wheat protein, plasma protein

Ruminant Nutrition: Dairy rumen fermentation

161 Methanogenesis reduction ability of monensin and essential oils from two Nigerian citrus species. Musibau A. Bamikole[1,2], Ibukun M. Ogunade*[1], Felipe Amaro[1], Yun Jiang[1], Thiago F. Bernardes[1], Darren D. Henry[3], Vania R. Vasconcelos[1], F. O. Ugiagbe[2], U. J. Ikhatua[2], Nicolas DiLorenzo[3], and Adegbola T. Adesogan[1], *[1]University of Florida, Gainesville, FL, [2]University of Benin, Benin City, Nigeria, [3]North Florida Research and Education Center, University of Florida, Marianna, FL.*

The effects of essential oils from sweet orange (*Citrus sinensis*, EOS) and tangerine (*Citrus tangerina*, EOT) on rumen fermentation, methane production and digestibility were studied. A corn silage-based TMR (0.5 g; CP 16.6%; NDF 35.9%) was treated with EOT or EOS at rates of 0 (Control), 10 (Low), 20 (Med) and 30 (High) μL/50 mL of rumen fluid-buffer inoculum (ratio 1:2) and with monensin (0.6 mg/50 mL). Each suspension was incubated in a 120-mL gas-tight culture bottle in triplicate at 39oC for 24 h in each of 2 runs. Fermentation parameters, gas and methane production, in vitro DM digestibility (DMD), and fermentation efficiency (FE; DMD $g\ kg^{-1}$/gas volume) were measured. Data for each EO were separately analyzed with the Glimmix procedure of SAS. Adding EOS or EOT did not depress DMD (g/kg; 541 and 548, respectively) but adding monensin did (555 vs. 526; $P < 0.05$). Gas volume (mL/g DM) was increased by Low EOS or EOT (84.5 vs. 92.8 and 96.3) and decreased by High rates or monensin (75.3, 73.6 and 66.8), respectively. Hence, FE was reduced by Low EOS or EOT (6.58 vs. 5.81 and 5.70) and increased by High rates or monensin (7.52, 7.43 and 7.92), respectively. Methane production (mg/g DM digested) was increased by Low EOS and EOT (11.4 vs. 14.4 and 15.3) and reduced by High rates and monensin (7.10, 7.10 and 6.58; decreases of 37.7, 37.7 and 42.2%), respectively. Ammonia-N concentration (mg/dL) was increased by Med EOS (21.43) and EOT (20.6) versus monensin (4.63) or Control (11.3). Ruminal pH was increased by monensin (5.66 vs 5.75) but not by EOT (5.63 – 5.72) or EOS (5.67 to 5.71). Total VFA concentrations (mmol) of EOS (54.7 to 69.2), EOT (68.24 to 121.8), monensin (71.0) and control (80.2) treatments did not differ ($P > 0.05$). Monensin decreased acetate molar proportion and increased that of valerate, and Low EOT reduced the molar proportion of propionate. High doses of EO from *Citrus sinensis* and *Citrus tangerina* reduced in vitro methane production without adverse effects on feed digestibility and VFA production. By comparison, monensin reduced methane production and digestibility.

Key Words: essential oil, citrus, in vitro fermentation

162 Changes in fermentation and biohydrogenation intermediates in continuous cultures fed corn grains differing in rates of starch degradability. Kaylin Young[1], Louisa Bowen[1], Mariano Alende[1], Gustavo Lascano[1], Mark D. Holt[2], and Thomas Jenkins*[1], *[1]Clemson University, Clemson, SC, [2]Matrix Nutrition LLC, Chandler, AZ.*

Excessive amounts of starch in diets for lactating dairy cattle is a known risk factor for milk fat depression but little is known about how these risks are altered by differences in rates of starch degradability (K_d) in the rumen. The objective of this study was to compare accumulation of biohydrogenation intermediates causing milk fat depression, including conjugated linoleic acid (CLA), when corn with low or high K_d were fed to continuous cultures. Diets contained (DM basis) 50% forage (alfalfa pellets and grass hay) and 50% concentrate with either no added fat (LF) or 3.3% added soybean oil (HF). Three LF and 3 HF diets contained corn sources with either low, medium, or high K_d (48.4, 66.2, or 84.0% in a 7 h in vitro test) giving 6 diet treatments with a 2 × 3 factorial arrangement. Each diet was fed to dual-flow continuous fermenters 3 times daily at 0800, 1600, and 2400 h. Diets were fed for 4 10 d periods, with 7d for adaptation and 3 d for sample collection. No fat × starch interactions occurred ($P > 0.05$) so main effects are presented. Starch effects were tested by linear (L) or quadratic (Q) contrasts. The LF and HF treatments differed ($P < 0.05$) in acetate (53.0 vs. 49.0 mol/100 mol), acetate/propionate (2.00 vs. 1.70), *trans*-10 18:1 (2.7 and 13.6% of total), and *trans*-10,*cis*-12 CLA (0.15 and 0.41% of total), respectively. Increasing starch K_d from low to high increased ($P < 0.05$) culture pH (L, 6.22, 6.23, 6.38) and acetate (Q, 48.7, 50.6, 53.9 mol/100 mol) but decreased ($P < 0.05$) butyrate (Q, 16.4, 15.0, 12.2) mol/100 mol). Changes in biohydrogenation intermediates (expressed as % of total fatty acids) from low to high K_d included decreases ($P < 0.05$) in *trans*-11 18:1 (Q, 8.58, 4.78, 4.46) and *cis*-9,*trans*-11 CLA (Q, 0.40, 0.34, 0.20) but an increase ($P = 0.07$) in *trans*-10,*cis*-12 CLA (L, 0.23, 0.24, 0.37). The results show that increasing the starch K_d in continuous culture while holding starch level constant causes elevation of some biohydrogenation intermediates linked previously to milk fat depression.

Key Words: lipid, biohydrogenation, starch

163 Effects of functional oils and monensin supplementation on ruminal fermentation and milk production and composition in Holstein cows under heat stress. Maurício F. Martins[1], Arlindo S. Netto[1], Paulo R. Leme[1], Maria G. Pinheiro[2], Joan Torrent*[3], Katiéli C. Welter[1], and Isadora Arruda[4], *[1]Univ. São Paulo, Pirassununga, SP, Brazil, [2]Agência Paulista de Tecnologia dos Agronegócios, Riberão Preto, SP, Brazil, [3]Oligo Basics USA LLC, Cary, NC, [4]Univ. Estadual Paulista, Botucatu, SP, Brazil.*

Eight Holstein lactating cows (68 ± 3.46 d in milk) were assigned to 2 contemporary Latin squares in a 2 × 2 factorial design during the summer months. The 4 treatments were (1) no additive, (2) monensin supplementation at a rate of 30 mg/kg DM, (3) supplementation of 0.5 g/kg DM of a commercial blend of functional oils containing cashew nut shell liquid and castor oil as active ingredients (Essential, Oligo Basics Agroind. Ltda., Cascavel, Brazil), and (4) supplementation of both monensin and functional oils at the rates supplemented in treatments 2 and 3. Average temperature heat indexes ranged between 70 and 90. Whereas the inclusion of functional oils increased intake (15.30 vs. 16.67 kg; $P < 0.001$), monensin decreased it (16.89 vs. 15.57 kg; $P < 0.001$). Feeding functional oils increased 3.5% fat corrected milk ($P < 0.001$) but only when cows were not supplemented with monensin (interaction monensin × functional oils: $P < 0.01$). Also, the supplementation of functional oils increased both the protein and fat yield ($P < 0.01$) and the protein percentage in the milk ($P < 0.01$). Monensin supplementation improved milk production efficiency ($P < 0.01$) but decreased fat percentage ($P < 0.05$) and total solids in milk ($P < 0.01$). Only the supplementation of monensin changed the ruminal fermentation parameters, increasing propionate ($P < 0.05$), and consequently decreasing the acetate to propionate ratio ($P < 0.05$). Rectal and skin temperatures were not affected by any treatment. However, the respiratory frequency was increased by the supplementation of functional oils ($P < 0.05$). In conclusion, whereas the inclusion of functional oils improved the cows' productive parameters without altering rumen fermentation, monensin supplementation decreased the amount of milk fat.

Key Words: functional oil, monensin, heat stress

164 Shifts in methanogen archaea and anaerobic fungi in the rumen of dairy cows during the transition period.

Sanjay Kumar*, Nagaraju Indugu, Bonnie Vecchiarelli, and Dipti Pitta, *Department of Clinical Studies, School of Veterinary Medicine, New Bolton Center, University of Pennsylvania, Kennett Square, PA.*

Anaerobic rumen fungi (ARF) play an important role in the degradation of dietary plant cellulosic material. Subsequent decomposition products (mainly H_2 and CO_2) are utilized by other microbes, including methanogens. In the present study, we investigated the shift in ARF and methanogenic communities in dairy cows fed S1 diet (80% forage) 4 weeks before calving and moved to S2 diet (50% forage) after calving. Five cows from 2 study groups (SG: primiparous and multiparous) were sampled for ruminal contents before and after calving using a stomach tube. The genomic DNA from all rumen samples were amplified using archaeal and fungal specific primers, sequenced on a 454 Jr Roche platform and analyzed using QIIME pipeline. Approximately 18,317 and 35,582 reads were analyzed from 20 archaeal and ARF communities, respectively, resulting in 180 and 310 OTUs for archaea and ARF, respectively. Community comparisons (the Bray-Curtis distance matrix) revealed the effect of diet ($P < 0.001$) on ARF composition, while archaea communities differed between primiparous and multiparous cows ($P < 0.05$). Among ARF lineages, genus *Cyllamyces* was higher on S2 diet whereas, *Cecomyces* and *Orpinomyces* were higher on S1 diet, irrespective of parity. *Methanobrevibacter* showed >95% abundance across all samples. A co-occurrence analysis using dice index was performed, incorporating taxa from bacteria (published recently) and archaea and fungi from this study to determine the effect of diet and parity on inter-microbial relationships within the rumen. The coexistence patterns both within and between bacteria, archaea and ARF were more influenced by SG than by diets. In conclusion, the findings presented here indicate the influence of dry matter intake, stage of production and parity on rumen microbial communities.

Key Words: anaerobic fungi, co-occurrence, diet

165 Effects of stocking density and source of forage fiber on short-term responses in ruminal fermentation and behavior of Holstein dairy cows.

Mackenzie A. Campbell*[1,2], Kurt W. Cotanch[1], Catherine S. Ballard[1], Heather M. Dann[1], and Richard J. Grant[1], [1]*The William H. Miner Agricultural Research Institute, Chazy, NY,* [2]*The University of Vermont, Department of Animal Science, Burlington, VT.*

Understanding the interaction of stocking density and diet is vital for dairy cow well-being and ruminal health. Multiparous (n = 11) and primiparous (n = 5) ruminally cannulated Holstein cows (116 ± 84 d in milk and 46 ± 9 kg milk/d) were assigned to 1 of 4 pens to determine the short-term effects of stocking density and source of forage fiber on ruminal fermentation and behavior. Pens were assigned to treatments in a 4 × 4 Latin square with 14-d periods using a 2 × 2 factorial arrangement. Two stocking densities (STKD; 100 or 142% of stalls and headlocks) and 2 diets (straw; S and no straw; NS) resulted in 4 treatments: (1) 100NS, (2) 100S, (3) 142NS, and (4) 142S. Dietary forage content consisted of 39.7% corn silage and 6.9% haycrop silage versus 39.7% corn silage, 2.3% haycrop silage, and 3.5% chopped straw (dry matter; DM basis) for NS and S, respectively. Both diets were formulated for 16% crude protein, 28% neutral detergent fiber (NDF), and 28% starch (DM basis). Alterations in forage fiber source resulted in physically effective NDF values of 18.8% and 20.1% for NS and S, respectively. Ruminal pH measurements were recorded on d 12–14 of each period using indwelling pH loggers. Time spent feeding and ruminating were measured using 72-h direct observation on d 8–10 of each period. Data were analyzed using the MIXED procedure in SAS with pen as the experiment unit. Eating time (248 min/d, SEM = 9) and rumination time (496 min/d, SEM = 23) did not differ ($P > 0.05$) among treatments. Higher STKD tended ($P < 0.07$) to have a lower mean and maximum pH and significantly reduced ($P < 0.01$) time that pH <5.8. Area under the curve (AUC) and time spent below pH 5.8 were significantly reduced with S. Higher STKD reduces ruminal pH and S tends to counteract this effect.

Table 1 (Abstr. 165). Ruminal pH in Holstein cows fed 2 stocking densities (STKD; 100 or 142% of stalls and headlocks) and 2 diets (straw; S and no straw; NS)

	100%		142%			*P*-value		
Item	NS	S	NS	S	SEM	STKD	Diet	STKD × Diet
Mean pH	6.17	6.13	6.09	6.10	0.03	0.07	0.62	0.39
Minimum pH	5.70	5.67	5.62	5.59	0.05	0.11	0.53	0.95
Maximum pH	6.63	6.58	6.56	6.53	0.04	0.07	0.22	0.68
ph <5.8, h/d	2.29	1.90	4.12	2.77	0.41	<0.01	0.01	0.10
AUC <5.8, pH units × min/d	0.38	0.19	0.58	0.34	0.10	0.06	0.03	0.75

Key Words: overcrowding, physically effective fiber, ruminal pH

166 Rumen bacterial communities in three breeds of dairy cattle shift from early to peak lactation.

Melissa L. Bainbridge*[1], Laura M. Cersosimo[1], André-Denis G. Wright[2], and Jana Kraft[1], [1]*University of Vermont, Burlington, VT,* [2]*University of Arizona, Tucson, AZ.*

Rumen bacteria form a dynamic, complex symbiotic relationship with their host, degrading fibrous forages to provide volatile fatty acids (VFA) as energy to the animal. The objective of this study was to characterize rumen bacteria and VFA in 3 breeds of primiparous dairy cattle, Holstein (HO, n = 7), Jersey (JE, n = 8), and HO x JE crossbred (CB, n = 7), at early (3 DIM) and peak lactation (93 DIM). All cows were fed a consistent TMR at a 70:30 forage to concentrate ratio. Rumen digesta were collected via esophageal intubation at 3 and 93 DIM. Microbial DNA was extracted and sequenced using Illumina MiSeq (v. 3) following PCR amplification of the V1-V3 region of the 16S rRNA gene. Sequences were analyzed using Mothur. The 16S copy numbers of rumen bacterial densities were quantified by real-time PCR. Data were analyzed using a repeated measures general linear mixed model in SAS. Breed (B) had no effect on rumen VFA, however, molar concentrations of acetate, butyrate, and propionate were lower at 93 DIM (74.7, 10.7, and 20.8 m*M*, respectively) than at 3 DIM (93.8, 14.7, and 26.9 m*M*, respectively; $P < 0.01$). The quantity of bacteria in rumen digesta was unaffected by B or lactation stage (LS). Overall, Bacteroidetes (Bd) was the predominant phylum, accounting for 54–78% of total bacteria, followed by the phyla Firmicutes (Fc; 19–42%) and Proteobacteria (1–4%). *Prevotella* was the predominant genus of the Bd phylum and was unaffected by B, however, *Prevotella* species did increased with LS (49.8% vs. 67.3% for 3 DIM and 93 DIM, respectively; $P < 0.01$). At 93 DIM there was a lower abundance of Fc (38.5%) than at 3 DIM (25.0%; $P < 0.01$), with bacteria belonging to the genera *Butyrivibrio* and *Coporococcus* decreasing from 3 DIM (1.74% and 1.33%) to 93 DIM (0.26% and 0.30%; $P < 0.01$). Bacteria belonging to the genera *Mogibacterium* and *Ruminoccocus* within the Fc phylum were affected by B ($P < 0.05$), HO had less *Mogibacterium* species than CB and JE (0.58% vs. 1.22% and 1.26%), and HO had higher abundance of *Ruminoccocus* species than CB and JE (2.3% vs. 1.5% and 1.3%; *P* <

0.05). In conclusion, LS had a greater effect on bacterial communities and VFA than host genetics.

Key Words: volatile fatty acid, bacterial diversity

167 Effect of 3-nitrooxypropanol on ruminal fermentation, methane and hydrogen emissions, and methane isotopic composition in dairy cows.

Laiz F. de Matos[1], Michael T. Harper[1], Juliana Lopes*[1], Fabio Giallongo[1], Joonpyo Oh[1], Danielle Gruen[2], Alexander N. Hristov[1], Maik Kindermann[3], and Stephane Duval[4], *[1]Department of Animal Science, The Pennsylvania State University, University Park, PA, [2]Department of Earth, Atmospheric and Planetary Sciences, Massachusetts Institute of Technology, Cambridge, MA, [3]DSM Nutritional Products, Animal Nutrition and Health, Basel, Switzerland, [4]DSM Nutritional Products France, Research Centre for Animal Nutrition and Health, Saint Louis Cedex, France.*

The objective of this crossover experiment was to investigate the effect of a methane inhibitor, 3-nitrooxypropanol (3NOP), on rumen fermentation and enteric CH_4 emission in lactating dairy cows. Six ruminally-cannulated late-lactation (235 DIM; SD = 20 d) Holstein cows were assigned to 2 treatments: control and 3NOP (60 mg/kg DMI). Each experimental period consisted of 10 d for adaptation and 4 d for sample collection. Compared with the control, 3NOP decreased ($P < 0.001$) CH_4 emission by 31% (487 vs. 335 g/d, respectively) and increased ($P < 0.001$) that of H_2 from 0.005 to 1.33 g/d. CH_4 emissions per kg of DMI or milk yield were also decreased ($P < 0.001$) 34 and 37%, respectively, by 3NOP. The isotopic composition of CH_4 was similar between treatments: control, $\delta^{13}C_{CH4} = -20.91 \pm 0.32$‰, $\delta D_{CH4} = -266.92 \pm 0.14$‰, and $\Delta^{13}CH_3D = -1.96 \pm 1.78$‰; and 3NOP, $\delta^{13}C_{CH4} = -24.91 \pm 1.72$‰, $\delta D_{CH4} = -266.94 \pm 0.27$‰, and $\Delta^{13}CH_3D = -1.72 \pm 2.97$‰. Concentrations of total VFA and propionate in ruminal fluid were not affected by treatment. Acetate concentration tended to be lower ($P = 0.08$) and acetate:propionate ratio was lower ($P < 0.001$) for 3NOP compared with the control. Butyrate and isovalerate concentrations tended to be or were increased ($P \leq 0.08$) by 3NOP. Methanogenic archaea (*Methanobrevibacter, Methanosphaera*, and *Methanomicrobium*) were not affected ($P \geq 0.46$) by 3NOP. *Prevotella* spp., the predominant bacterial genus in ruminal contents (22 to 23% of the total isolates), was also not affected ($P = 0.54$) by 3NOP. Compared with the control, *Ruminococcus* and *Clostridium* spp. were decreased ($P \leq 0.03$) and *Butyrivibrio* spp. was increased by 3NOP: 8.2 vs. 6.5%, 6.2 vs. 4.1%, and 3.6 vs. 4.8%, respectively. This experiment demonstrated that a substantial inhibition of enteric CH_4 emission in dairy cows resulted in increased H_2 emission and decreased acetate concentration, but had no effect on rumen archaea. The isotopic composition of CH_4 was similar between the 2 treatments, supporting the conclusion that there was little to no change in the metabolic strategy of the rumen archaeal population.

Key Words: methane, 3-nitrooxypropanol, archaea

168 Divergent fermentation patterns of grass fructan, inulin, and glucose.

Mary Beth Hall*, *US Dairy Forage Research Center, USDA-ARS, Madison, WI.*

Fructans are an important nonfiber carbohydrate in cool season grasses. Their fermentation by rumen microbes is not well described, though such information is needed to understand their nutritional value to ruminants. Fermentation kinetics and product formation from orchardgrass fructan (phlein; PHL), chicory inulin (INU), and glucose (GLC) were compared when fermented in vitro with mixed rumen microbes. Studies were carried out as randomized complete block designs. All rates given are fractional exponential. Significance was declared at $P < 0.05$, and tendency at $0.05 \leq P < 0.10$. Rate of substrate disappearance tended to be greater for GLC than for PHL and INU which tended to differ from each other (0.74, 0.62, and 0.33 h^{-1}, respectively). Disappearance of GLC had almost no lag time (0.04 h) whereas the fructans had lags of 1.4 h. The maximum microbial N accumulation (a proxy for cell growth), tended to be 20% greater with PHL and INU than with GLC. The N accumulation rate with GLC (1.31 h^{-1}) was greater than with PHL (0.75 h^{-1}) and INU (0.26 h^{-1}) which also differed. More microbial glycogen (+57%) was accumulated with GLC than with PHL, though accumulation rates did not differ (1.95 and 1.44 h^{-1}, respectively); little glycogen accumulated with INU. Rates of organic acid formation were 0.80, 0.28, and 0.80 h^{-1} for GLC, INU, and PHL, respectively, with PHL tending to be greater than INU. Lactic acid production was more than 7-fold greater for GLC than for the fructans. The ratio of microbial cell carbon to organic acid carbon tended to be greater with PHL (0.90) and INU (0.86) than with GLC (0.69) indicating a greater yield of cell per amount of substrate fermented with fructans. Reduced microbial yield with GLC may relate to the greater glycogen production which requires ATP, and lactate production which yields less ATP; together, these processes could have reduced ATP available for cell growth. Acetate molar proportion was less with GLC than with fructans, and less for PHL than for INU. Rumen microbes ferment PHL differently than other plant sugars or fructans.

Key Words: rumen fermentation, fructans, glycogen

169 The effect of lactic acid bacteria as probiotics or silage inoculants on in vitro rumen digestibility, total gas and methane production.

Jennifer L. Ellis*[1,2], Andre Bannink[3], Ida K. Hindrichsen[4], Robert D. Kinley[1], Wilbert F. Pellikaan[1], Nina-Lotte Milora[4], and Jan Dijkstra[1], *[1]Animal Nutrition Group, Wageningen University, Wageningen, the Netherlands, [2]Centre for Nutrition Modelling, Department of Animal and Poultry Science, University of Guelph, Guelph, ON, Canada, [3]Animal Nutrition, Wageningen UR Livestock Research, Wageningen, the Netherlands, [4]Chr. Hansen A/S, Hørsholm, Denmark.*

Lactic acid bacteria (LAB) included as a probiotic or silage inoculant may affect rumen fermentation, OM digestibility and methane (CH_4) emissions in cattle. Therefore, 2 in vitro gas production trials were conducted to pre-screen several potential LAB inoculants at several inoculation levels, using different LAB mixtures, and on different silage substrates. In Experiment 1 the dose-response effects of 3 LAB inoculants added as probiotics (0.0, 5×10^5, 1×10^6 and 5×10^6 cfu/mL) on in vitro total gas and CH_4 production were examined using grass silage as the substrate. In Experiment 2, 3 LAB inoculant mixtures were examined while varying the substrate. Substrates were inoculated with LAB before ensiling, and were ryegrass/clover (RCS), corn (CS) and ryegrass (RS) silage. Data were analyzed with proc MIXED of SAS with LAB inoculant × dose as a fixed effect, and dose was analyzed via orthogonal polynomial contrasts (Experiment 1), and using substrate, inoculation and substrate × inoculation as fixed effects (Experiment 2). Results showed that not all LAB affected in vitro fermentation. In Experiment 1, *L. plantarum* (LP) but not *L. lactis* (LL) or a 1:1 mixture of LL and LP, resulted in significant increases in OM digestibility ($P = 0.023$), and there was a trend for several dose related responses. In Experiment 2, LAB showed both strain and substrate-specific responses. In RS, an inoculation of a mixture of *L. plantarum*, *L.buchneri* and *L. lactis* (LM1) increased OM digestibility, while inoculations of *L. buchneri* and *L.lactis* (LM2) and *L. plantarum*, *L. lactis* and *E. faecium* (LM3) decreased OM digestibility in RCS (inoculation $P < 0.001$). These effects were generally mirrored by changes in gas and CH_4 production. In CS, no effects were observed on OM digestibility, total gas or CH_4 production. From these results we conclude that LAB may be most effective in grass based silages (compared with corn) for altering OM digestibility, and that the LP treatment from Experiment 1, or the LM1 treatment from Experiment 2, may be most promising for evaluation in vivo.

Key Words: in vitro, lactic acid bacteria, cattle

170 Influence of diet change frequency on growth, rumen fermentation, and behavior of prepubertal dairy heifers. Tana S. Dennis*[1], Jason E. Tower[1], Hans F. P. Schmitz[1], Amanda M. Mosiman[1], and Tamilee D. Nennich[1,2], [1]*Purdue University, West Lafayette, IN,* [2]*Famo Feeds, Freeport, MN.*

The objective of this study was to evaluate the effects of diet change frequency on dairy heifer performance, rumen fermentation, and feeding behavior. Ninety Holstein heifers (141.8 ± 11.7 kg of BW) in 15 pens were randomly assigned to treatments designed to change diets using rapid (30 to 60% hay; 1STEP), moderate (30 to 45 to 60% hay; 2STEP), or gradual steps (30 to 40 to 50 to 60% hay; 3STEP). Heifers were fed for 84 d, and diets were changed every 2 wk starting on d 28. Weights were taken every 2 wk, and skeletal measurements and blood samples were collected monthly. Rumen fluid was collected esophageally 6 h after feeding (2 heifers/pen) to determine pH, NH_3, and volatile fatty acids (VFA) 2 wk after each diet change. Behavior was evaluated using scan-sampling before and after diet changes for 30 min before and 120 min following feed delivery. Data were analyzed with pen as the experimental unit. On d 84, 3STEP heifers were heavier than 1STEP ($P = 0.05$) and tended to be heavier than 2STEP ($P = 0.06$). Daily gain was significantly improved for 3STEP after the second diet change ($P < 0.01$), but lower after the last diet change compared with 1STEP and 2STEP ($P = 0.05$). Feed intake was greater ($P = 0.02$) for 3STEP from d 35 to 63, yet similar among treatments from d 63 to 84. Skeletal growth was similar with the exception of heart girth, which was greatest for 3STEP on d 84 ($P = 0.01$). Blood glucose was greatest for 3STEP after the first diet change ($P = 0.02$) and greatest for 2STEP after the last diet change ($P = 0.04$). Rumen fermentation profiles were altered following the first diet change, as proportions of acetate ($P < 0.01$) and isoacids ($P = 0.10$) were greatest and total VFA, propionate ($P < 0.01$), and valerate ($P < 0.01$) were lowest for 1STEP. Heifers fed using 1STEP spent 51% more time feeding than 3STEP heifers 3 d after the first diet change ($P < 0.01$). Time spent feeding was 18% ($P = 0.01$) and 14% ($P = 0.01$) greater 6 d before the second diet change for 1STEP and 2STEP, respectively, compared with 3STEP. Rapid diet changes appear to alter rumen fermentation and feeding behavior, which potentially reduces performance of growing dairy heifers.

Key Words: heifer, feeding, growth

171 Effects of rumen inoculum adapted and unadapted to *Saccharomyces cerevisiae* fermentation product, culture pH, and starch fermentability on the biohydrogenation of unsaturated fatty acids in batch culture. Yan Sun*, Michael S. Allen, and Adam L. Lock, *Michigan State University, East Lansing, MI.*

The effect of rumen fluid (RF) inoculum either unadapted (U-RF) or adapted (A-RF) to *Saccharomyces cerevisiae* fermentation product (SCFP; Diamond V Original XPC) on the biohydrogenation (BH) of unsaturated fatty acids (FA) at 2 pH levels and starch sources with different fermentabilities (SF) were evaluated. Rumen inocula for batch cultures were collected at the end of each 4-wk feeding period in a crossover design (n = 6). U-RF or A-RF cultures (4 replicates/treatment) were incubated for 24 h at pH 5.8 or 6.2 and included alfalfa hay (55% of DM), and either dry ground corn (DC) or high moisture corn (HMC) as starch sources (45% of DM). The alfalfa hay was treated with corn oil (2% of DM) to increase the total unsaturated FA content of cultures. Effects of RF, culture pH, SF, and their interactions were determined. For main effects of treatments, A-RF compared with U-RF and pH 6.2 compared with pH 5.8 increased extent of BH for *cis*-9,*cis*-12 18:2 (41 vs. 38% and 47 vs. 32%, respectively; both $P < 0.001$) and NDFD (14 vs. 12% and 16 vs. 10%, respectively; both $P < 0.001$). Compared with DC, HMC increased BH extent for *cis*-9,*cis*-12 18:2 (41 vs. 39%, $P = 0.06$), and decreased NDFD (12 vs. 14%, $P < 0.001$). Overall, compared with U-RF, A-RF decreased *trans*-10,*cis*-12 18:2 (CLA) by 17% ($P < 0.001$), and increased *trans*-10 18:1 by 10% ($P < 0.001$). HMC compared with DC, and pH 5.8 compared with pH 6.2, increased content of CLA by 15 and 56%, respectively (both $P < 0.01$), and increased *trans*-10 18:1 by 23 and 26%, respectively (both $P < 0.001$). RF interacted with SF for CLA and *trans*-10 18:1 (both interactions $P < 0.01$); in particular, for cultures containing HMC, A-RF decreased the content of CLA and increased the content of *trans*-10 18:1 compared with U-RF. Results demonstrate that under the conditions tested, rumen fluid from cows adapted to SCFP (A-RF) had positive effects on the extent of BH of unsaturated FA and NDFD. A-RF decreased CLA across culture pH, especially when HMC was the starch source.

Key Words: culture pH, dry ground corn, high moisture corn

172 Effects of *Saccharomyces cerevisiae* fermentation products on performance of mid-lactation dairy cows. Subash Acharya*[1], Jon P. Pretz[1], Ilkyu Yoon[2], Mark F. Scott[2], and David P. Casper[1], [1]*South Dakota State University, Brookings, SD,* [2]*Diamond V, Cedar Rapids, IA.*

This study was conducted to evaluate *Saccharomyces cerevisiae* fermentation products (Diamond V Original XPC and 2 prototypes) on production efficiency of mid-lactation dairy cows. Eighty mid-lactation (164.5 DIM ± 67.5) Holstein cows (56 multiparous and 24 primiparous) were blocked by parity, days in milk, and milk production, and randomly assigned to one of 4 treatments. Treatments consisted of (1) Control (C): corn silage and haylage based ration; (2) XPC: C ration with Original XPC added at 14 g/hd per day; (3) Prototype 1 (P1): C ration with Prototype 1 added at 5 g/hd per day; and (4) Prototype 2 (P2): C ration with Prototype 2 added at 19 g/hd per day. Treatments were mixed with dried distillers grains and then mixed into a TMR at 454 g/hd/d. The study lasted for 70 d. The first 14 d of the study (d −14 to 0) was used to train cows to use the Calan gate feeding system and cows were fed the C ration during this period. Treatment effects were continuously monitored for the 8 wk experimental period. Dry matter intakes (DMI) were similar ($P \geq 0.10$) when cows were fed all treatments (25.7, 26.1, 25.1, and 26.2 kg/d for C, XPC, P1, and P2, respectively). Milk production (33.3, 34.4, 35.5, and 36.8 kg/d) was improved ($P < 0.05$) for cows fed P2 compared with cows fed C, with cows fed other supplements being intermediate and similar. Feed efficiency (Milk/DMI) was improved ($P < 0.08$) for cows fed P1 and P2, compared with cows fed C and XPC (1.30, 1.34, 1.49 and 1.41kg/kg). Milk fat content was reduced ($P < 0.05$) for cows fed P2 (4.17, 3.93, 4.08, and 3.85%) compared with cows fed C, with cows fed other treatments being intermediate. Milk protein and lactose percentages were similar ($P \geq 0.10$) among treatments. Cows fed P2 had lower ($P < 0.05$) molar percentages of ruminal acetate (63.8, 64, 63.1, and 62.3%) and greater ($P < 0.05$) propionate (18.9, 19.3, 19.7, and 20.6%) than cows fed other treatments. Supplementing a dairy ration with *Saccharomyces cerevisiae* fermentation products can improve milk production and feed efficiency of mid-lactation cows.

Key Words: dairy cow, *Saccharomyces cerevisiae* fermentation product, milk production

Small Ruminant: Nutrition

173 Blood chemistry, milk yield and composition, and milk fatty acids profile of lactating Anglo-Nubian goats fed *Moringa oleifera* leaf as a protein source.

T. A. Morsy*[1], A. E. Kholif[1], G. A. Gouda[1], A. Z. M Salem[2], S. M. Kholif[1], and A. M. Kholif[1], *[1]Dairy Science Department, National Research Centre, Giza, Egypt, [2]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma del Estado de México, Toluca, Estado De México, Mexico.*

Low availability and increased price of protein sources are a serious problem for animal producers. Therefore there is a need to find alternative ingredients for protein sources. *Moringa oleifera* leaf contains about 25% crude protein (CP) with low degradability, which make it a good source of protein in ruminant diets. In a 4 × 4 Latin square design, 16 lactating Anglo-Nubian goats (36.2 ± 0.7 kg BW) were used to evaluate the effect of replacing sesame meal (259.0 g CP/kg DM; 279.1 g neutral detergent fiber (NDF)/kg DM) with *M. oleifera* (241.2 g CP/kg DM; 336.6 g NDF/kg DM) at 0% (control-M0), 50% (M50), 75% (M75) and100% (M100). The experimental period consisted of 17 d for adaptation + 5 d for milk yield and sampling. All goats were sampled for blood at the last day of the experimental period 4 h after morning feeding. Goats were hand milked daily at 0900 and 2100 h for determination of milk yield. There was no effect of treatment on serum total proteins, albumin, globulin, glucose, creatinine, and triglycerides concentrations, with quadratically increasing GOT and GPT concentrations ($P < 0.05$) and decreasing urea-N (linear, $P = 0.0339$; quadratic, $P < 0.0001$) and cholesterol (linear, $P = 0.0009$; quadratic, $P < 0.0001$) concentrations. Milk yield and energy corrected milk were linear increased ($P < 0.001$) when goats fed on Moringa vs. control. Milk yield was greatest for M75 which had also higher total solids, solids not fat, and lactose versus other treatments. Milk components yield were increased with goats fed Moringa compared with control ($P < 0.01$). Moringa treatments increased ($P < 0.01$) milk fat content from C14:1, C18:1n-9 *trans*, C18:1n-9 *cis*, C18:2 *trans*-10,*cis*-12, and C18:2 *cis*-9,*trans*-11 with decreased C16:0 concentrations. Moreover, decreased ($P < 0.05$) saturated with increased unsaturated fatty acids and conjugated linoleic acids (CLA) were obtained when goats fed Moringa diets vs. control. It could be concluded that replacing 75% of sesame meal with *M. oleifera* as a protein source increased milk yield with enhancing milk content of healthy fatty acids (CLA and n-3), without detrimental effects on animal performance.

Key Words: milk fatty acid, milk composition, *Moringa oleifera*

174 *Moringa oleifera* leaf as a protein source in the diet of Anglo-Nubian goats affects feed intake, digestibility, and ruminal fermentation.

A. E. Kholif*[1], G. A. Gouda[1], A. Z. M. Salem[2], T. A. Morsy[1], and S. M. Kholif[1], *[1]Dairy Science Department, National Research Centre, Giza, Egypt, [2]Facultad de Medicina Veterinaria y Zootecnia, Universidad Autónoma del Estado de México, Toluca, Estado De México, Mexico.*

Recently, the availability and price of concentrates especially of protein sources are a serious problem for animal producers especially small farms. Therefore there is a need to find alternative ingredients for protein sources. *Moringa oleifera* leaf contains about 25% crude protein (CP) with low degradability, which make it a good source of protein in ruminant diets. Therefore, in a 4 × 4 Latin square design, the effect of including *M. oleifera* leaf as a protein source in diets of Anglo-Nubian goats on intake, digestibility and ruminal fermentation given was evaluated. Sixteen goats (36.2 ± 0.7 kg BW) were fed 4 diets (n = 4 goats) where sesame meal (259.0 g CP/kg DM; 279.1 g neutral detergent fiber (NDF)/kg DM) was replaced with *M. oleifera* (241.2 g CP/kg DM; 336.6 g NDF/kg DM) at 0% (control-M0), 50% (M50), 75% (M75) and100% (M100). The experimental period consisted of 17 d adaptation + 5 d for feed intake measurements and feces collection. Water was always available to goats. All goats were sampled for rumen liquor at the last day of each experimental period after 0, 3 and 6h of morning feeding. Goats fed on M75 and M100 diets increased feed intake of all nutrients (linear, $P < 0.001$; quadratic, $P < 0.05$). Moreover, increased dry matter (quadratic, $P = 0.0014$), organic matter (linear, $P = 0.0117$), and crude fibers (linear, $P = 0.0119$; quadratic, $P = 0.0018$) digestibility were obtained with goats fed on M75. However, goats fed on Moringa (M50, M75, M100) had a linearly decreased CP digestibility ($P < 0.0001$). Diets nutritive values as total digestible nutrients ($P = 0.0049$), digestible CP ($P = < 0.0001$), metabolizable energy ($P = 0.0054$) and net energy of lactation ($P = 0.0049$) were quadratically decreased with M50, M75 and M100 vs. M0. Goats fed on Moringa diets had increased ($P < 0.05$) ruminal pH, volatile fatty acids, propionate and methane production vs. control. It could be concluded that inclusion of *M. oleifera* leaf as a protein source at 75% of sesame meal increased feed intake, nutrients digestibility and ruminal fermentation of Anglo-Nubian goats.

Key Words: digestibility, *Moringa oleifera*, ruminal fermentation

175 Effect of dietary forage-to-concentrate ratios on urinary excretion of purine derivatives and microbial nitrogen yields in the rumen of Dorper crossbred sheep.

Tao Ma*[1], Kai-dong Deng[2], Yan Tu[1], Nai-feng Zhang[1], Cheng-gang Jiang[1], and Qi-yu Diao[1], *[1]Feed Research Institute, Chinese Academy of Agricultural Sciences/Key Laboratory of Feed Biotechnology of the Ministry of Agriculture, Beijing, China, [2]College of Animal Science, Jinling Institute of Technology, Nanjing, Jiangsu, China.*

This study investigated the effects of various dietary forage-to-concentrate ratios (F: C) on urinary excretion of purine derivatives (PD) and microbial nitrogen (MN) yields from the rumen of Dorper ´ thin-tailed Han crossbred sheep. Twelve Dorper × thin-tailed Han crossbred ram lambs (47.2 ± 1.0 kg) fitted with ruminal and duodenal cannulas were randomly assigned to 12 levels of dietary F:C in a balanced incomplete block experimental design (12 lambs × 4 periods). Digestibility trials were conducted and MN was estimated using either ^{15}N or PD as markers. Urinary excretion of allantoin and total PD increased ($P < 0.05$) with decreasing F:C. Urinary excretion of uric acid or xanthine plus hypoxanthine was unaffected by F:C ($P > 0.05$). MN yields estimated using ^{15}N as a marker were greater than those predicted from urinary PD (12.5 vs. 11.5 g/d, $P < 0.05$), but the former was more variable than the latter (SE = 0.66 vs 0.45, respectively). A linear correlation existed between MN estimated by ^{15}N and urinary excretion of PD: MN (g/d) = –0.521 + 1.493 × PD (mmol/d) ($r^2 = 0.86$). The purine nitrogen index (PNI: PD nitrogen/urinary N) was linearly correlated with nitrogen capture efficiency calculated from either ^{15}N or PD ($r^2 = 0.60$ and 0.77, respectively). Results suggest that urinary PD is an accurate indicator of MN from the rumen of Dorper crossbred sheep, and PNI reflected the conversion of nitrogen degradation to MN in the rumen.

Key Words: forage-to-concentrate ratio, microbial N yield, purine derivative

176 Effects of reducing dietary cation-anion difference plus vitamin D on plasma Ca and its modulators and growth performance of goats.

Wen-xuan Wu*, Lun-qin Zhu, Xing-zhou Tian, and Ruo-yu Liu, *College of Animal Science, Guizhou University, Guiyang, Guizhou Province, China.*

This study was conducted to evaluate the effects of reducing dietary cation-anion difference (DCAD; $Na^+K\text{-}Cl^-S$, mmol/kg DM) with vitamin D (VD) supplementation on plasma levels of Ca and its modulators, and ration palatability for goats. Eighteen healthy female goats were randomly allocated to 3 treatments with 6 goats per treatment and were fed 3 DCAD levels at 150, −150, −150 for control, treatment 1, and treatment 2, respectively. Anionic salts were included to reduce DCAD level for treatment 1, and VD was added in treatment 1 for treatment 2. Urine pH; plasma Ca, P, PTH, CT, $1,25\text{-(OH)}_2D_3$, vitamin D receptor (VDR), Ca-binding protein (CaBP-D9k) concentrations; and dry matter intake (DMI) were measured in the trial. Urine pH was reduced ($P <$ 0.05) as DCAD decreased for treatment 1 (6.71) and treatment 2 (6.67) over control (7.63). Compared with control, plasma Ca was increased for treatment 1 ($P > 0.05$) and treatment 2 ($P < 0.05$). There was no difference in plasma P and PTH for control, treatment 1, and treatment 2 ($P > 0.05$). Treatment 2 had increased plasma $1,25\text{-(OH)}_2D_3$ relative to control and treatment 1 ($P < 0.05$) and tended to reduce plasma CT over treatment 1 ($P < 0.1$). Moreover, reducing DCAD plus VD for treatment 2 resulted in higher plasma VDR and CaBP-D9k than that of control ($P < 0.05$). Levels of DMI were unaffected among 3 treatments ($P >$ 0.05). These results suggested that plasma Ca homeostasis could be more available to maintain by reducing DCAD plus VD in the present study.

Key Words: dietary cation-anion difference, plasma Ca, goat

177 Iodine supplementation of the pregnant ewe alters serum IgG concentration and expression of genes associated with antibody transfer in the ileum of the newborn lamb.

Fiona M. McGovern*[1], Torres Sweeney[2], Francis P. Campion[1], Marion T. Ryan[2], Stephen Lott[1], and Tommy M. Boland[1], [1]*School of Agriculture and Food Science, University College Dublin, Dublin, Ireland,* [2]*School of Veterinary Medicine, University College Dublin, Dublin, Ireland.*

Ruminant neonates require the passive acquisition of maternal immunoglobulins (Ig) derived from colostrum, to confer immunity against infectious disease in early life. Excess iodine in the diet of the pregnant dam is known to negatively affect neonatal serum IgG concentrations. This experiment examined the mechanisms underpinning the reduced IgG in the progeny of iodine supplemented dams at 24h postpartum. In a randomized complete block design, twin bearing ewes were split into 2 dietary groupings (n = 32 per group). The first group had no iodine supplement and the second was supplemented with 26.6mg per ewe per day of supplementary iodine in the form of calcium iodate for the final 4 weeks of gestation. Ewes were hand milked at 1, 10, and 18 h postpartum and colostrum intake of the lambs was recorded. At 24h postpartum a subset of lambs (n = 12 per group) were euthanized. Duodenal and ileal sections were collected to determine morphology and the expression of a panel of genes associated with antibody transfer. At 24h postpartum and fortnightly until 28 d postpartum IgG concentration was quantified from the serum of the remaining progeny. Iodine supplementation had no effect on colostrum yield, composition or lamb colostrum intake within the first 18h postpartum ($P > 0.05$). Despite this, the progeny from the iodine-supplemented ewes had lower serum IgG concentrations up until d 28 postpartum ($P > 0.001$) when compared with the progeny of the non-supplemented dams. Progeny of supplemented dams had increased expression of *PIGR* and *FCAMR* while the expression of *B2M*, *THRB* and *ALB* declined in the ileum when compared with non-supplemented progeny ($P < 0.05$). A reduction in villus height and villus height:crypt depth ratio was observed in the ileum of the supplemented progeny ($P < 0.01$). In conclusion, the results of this study presents novel data describing the relationship between maternal iodine nutrition and the subsequent failure of passive transfer leading to reduced serum IgG concentrations

Key Words: lamb, immunoglobulin G, ileal gene expression

178 Metabolizable energy requirements of maintenance, energy efficiency of weight gain and fat deposition in Pelibuey and Katahdin ewes in tropical Mexico.

Jose Valentin Cardenas Medina*, Pablo Ivan Duarte Arzapalo, Dahaivis Mena Arceo, and Olivier Santiago Ramos Trejo, *Instituto Tecnologico de Tizimin, Tizimin, Yucatan, Mexico.*

The objective was to estimate metabolizable energy requirements for maintenance (ME_m), energy efficiency of weight gain (EEWG) and fat deposition, in Pelibuey and Katahdin ewes in Yucatan, Mexico. Eight non pregnant, non lactating, multiparous ewes, with average live weight and standard deviation of 35 ± 2 kg, were distributed in a complete randomized design with a 2 × 3 factorial arrangement, 2 breeds and 3 feed levels (100, 120 kcal of ME $kg^{0.75}$ and ad libitum), during 3 periods of 28 d each; the diet were composed of 50% ground *Panicum maximum* hay and 50% of a concentrate, based on corn, wheat and soybean meal, containing 2.0 $Mcal/Kg^{-1}$ of ME and 10% of CP. Feed intake was measured by offered-rejected daily food weighing, to asses ME intake (MEI), ewes were weighed every 14 d, to asses changes in live weight (CLW) and thickness of subcutaneous fat (SF) was measured between 12th and 13th dorsal vertebra. The EM_m was estimated by regressing values of CLW against MEI ($Y = B0 + B1 \times X$), EEWG was estimate as gram of weight gain (WG) per Mcal of MEI. There were no differences ($P > 0.05$) between breeds in EM_m (110 ± 4 and 122 ± 4 $kcal/kg^{0.75}$, for Pelibuey and Katahdin; MEI [$kcal/kg^{0.75}$] = 119.748 + 0.264107 × WG, r = 0.81) and EEWG (33 ± 8 and 17 ± 8 g/Mcal of MEI, for Pelibuey and Katahdin); differences were found ($P < 0.01$) in average SF despite ewe breed (5.6 ± 0.2 and 4.7 ± 0.2 mm, for Pelibuey and Katahdin). There are not difference between breeds in energy requirements for maintenance and weight gain, but difference in body composition could be advantageous for Pelibuey ewes, fat reserves could be used with high efficiency for maintenance and lactation during dry season, in sheep systems in tropical Mexico.

Key Words: sheep, energy, requirement

179 Effect of dry matter content and feeding level on dry matter digestibility and intake of perennial ryegrass fed to sheep.

Brian Garry*[1,2], René Baumont[3], Tommy Boland[2], Michael O'Donovan[1], and Eva Lewis[1], [1]*Teagasc, AGRIC Moorepark, Fermoy, Co. Cork, Ireland,* [2]*School of Agriculture and Food Science, University College Dublin, Dublin, Ireland,* [3]*INRA, UMR1213 Herbivores, Saint Genès Champanelle, France.*

Optimising animal performance from pasture requires a high intake of highly digestible grass. In vivo dry matter digestibility (IVDMD) of grass is affected by the level of dry matter intake (DMI). The objective of this experiment was to analyze the effect of dry matter (DM) content of grass on IVDMD at 2 feeding levels in wether sheep. A Latin square design, with 4 periods and 4 treatments, was used. There were 4 sheep per treatment per period (n = 16) with 4 treatments in a 2 × 2 factorial grass type; wilted or fresh grass offered at one of 2 feeding levels; ad libitum or maintenance. Each 12-d period consisted of a 6 d adaptation phase and a 6 d measurement phase (MP). Grass was cut daily each morning. Approximately half the grass was artificially wilted for 5 h using a centrifugal fan at 18°C (wilted). The other half of the grass was stored at 4°C (fresh). The fresh and wilted grass was fed to the sheep daily at 4 p.m. The DM content of the wilted and fresh grass was 27.8% and 18.6%, respectively. Ad libitum sheep were offered 110% of the previous day's DMI. Maintenance fed sheep were fed 40 g grass DM/kg metabolic BW. Sheep were housed in stalls to allow for individual feeding and total fecal collection. During the MP in each period, a sample of the grass fed to and feces voided by each sheep was collected daily. The daily grass and feces samples were dried and bulked to give one sample per treatment and per sheep per period. Data were analyzed using a mixed model procedure in SAS. Period, feeding level, grass type and their interactions were fixed effects and sheep was a random effect. Wilted grass (757 g/kg) had greater IVDMD than fresh grass (746 g/kg; $P < 0.01$) and maintenance level feeding (759 g/kg) resulted in greater IVDMD than ad libitum (744 g/kg; $P < 0.001$). When fed ad libitum, wilted grass (1.50 kg DM/day) resulted in greater DMI than fresh grass (1.40 kg DM/day; $P < 0.05$) but fresh grass had greater fresh weight intake than wilted grass ($P < 0.001$). This indicates that reducing perennial ryegrass moisture content results in increased IVDMD and increased DMI in sheep fed indoors.

Key Words: digestibility, intake

180 Effects of feeding varying levels of deoiled distillers dried grains with solubles on dry matter intake, rumen fermentation, blood chemistry profile, growth, feed efficiency and carcass quality of meat goats.

Jarvis G. Scott*, Nar K. Gurung, Byeng R. Min, Errol G. Rhoden, and Wendell H. McElhenney, *Tuskegee University, Tuskegee, AL.*

The feeding value of deoiled distillers dried grains with solubles (D-DDGS) has been investigated for dairy, beef cattle, pigs and poultry, but no study has been conducted with meat goats. Objectives were to determine the effects of feeding varying levels of D-DDGS on dry matter intake, rumen fermentation, select blood metabolites, growth, feed efficiency and carcass quality. Twenty-four (24) Kiko wethers (26.67 ± 1.21 kg with initial BW and 5 to 6 mo of age) were randomly assigned to one of the 4 experimental diets (n = 6) containing 50% bermudagrass hay plus 50% concentrate mix with 0, 10, 20 or 30% D-DDGS in the diet on an as-is basis. The body weights were recorded every 4 weeks. The rumen volatile fatty acid were determined at the beginning, mid-point and at end of the trial while blood chemistry profiles were determined at the beginning and end of the trial. After 84 d, goats were slaughtered for carcass traits evaluation. Data were analyzed using the MIXED procedure of SAS. There was quadratic response in dry matter intake ($P < 0.05$) with increasing level of D-DDGS but no differences ($P = 0.49$) were detected in ADG (111.8, 128.4, 140.3 and 98.9 g/day for control, 10, 20 and 30% D-DDGS, respectively. Similarly, no significant differences ($P > 0.05$) were observed for gain to feed ratios among treatments. Molar proportion of acetate (A), propionate (P), and A: P increased linearly ($P < 0.05$) while the overall rumen pH response was quadratic ($P < 0.05$). The blood chemistry profile showed that gamma-glutamyl transferase and glucose decreased linearly ($P < 0.05$) with D-DDGS while the trend was reversed ($P > 0.05$) with aspartate aminotransferase, creatine kinase and cholesterol. However, both rumen volatile fatty acid and blood chemistry profile were within the normal range. There were no significant differences ($P > 0.05$) between treatments for percent transport loss, percent carcass shrink, 12th rib fat thickness, LMA and dressing percent. The findings suggest that up to 30% of D-DDGS can be included in the diet for meat goats without any compromise in rumen fermentation, performance and carcass quality.

Key Words: goat, D-DDGS, performance

181 Economic analysis of feedlot finished lambs receiving diets based on different *Cynodon* hay grasses.

Euclides Reuter Oliveira[1], Flávio Monção[2], Andreia Gabriel[1], Jefferson Gandra*[1], Rayanne Souza[1], Lais Moura[1], Loan Silva[1], Leandro Silva[1], Vadim Carbonari[1], and Thais Lemos[1], [1]*Universidade Federal da Grande Dourados, MS, Brazil, Dourados, MS, Brazil,* [2]*2Universidade Estadual Julio de Mesquita, Jaboticabal, SP, Brazil.*

This study aimed to evaluate the economic viability of the performance of crossbred lambs (1/2 Santa Inês+ 1/2 Sulfolk), feedlot, fed different diets of hay *Cynodon dactylon*. The experiment was conducted at the agricultural sciences college, Federal University of Grande Dourados. Thirty non-castrated, crossbred Suffolk lambs were used, identified with ear tags, with an average age of 90 d, with average body weight (21.5 kg ± 1.61). The animals were blocked by weight and randomly assigned to one of the 6 hays. Hays of each cultivar (Jiggs, Vaquero, Tifton 68 Coast-cross, Tifton 85, and Russell) were harvested at 42 d of age or stage of maturity were fed as 60% of the diet with a standard concentrate making up 40% of the diet. The treatment diets were distributed in a fully randomized block with 5 replications. Means were analyzed as mixed models using the MIXED procedure of SAS software, 9.2 version, and the average compared by Scott Knot test at 5% probability. The intake of dry matter varied from 0.858 kg for Tifton 68 to 1.06 kg for Jiggs. There were significant differences between diets for total cost on feeding, and the Jiggs presented the highest values ($17.11/animal). The animals fed Tifton 68 hay showed higher net income ($41.84/ animal and $44.70), when the animal was sold for slaughter in the refrigerator or alive for rearing in contrast to the other treatments. The animals fed diets with hay Tifton 68 had a higher rate of return (2.16%) and profitability (34.63%) compared with the other diets. In conclusion, the use of Tifton 68 hay in diets of lambs in finishing stage, feedlot, brings higher economic returns compared with other diets containing *Cynodon* hay grasses.

Key Words: economic, hay, lamb

182 Effect of concentrate supplementation during early lactation on intake, rumen function and milk production of twin suckling ewes.

Francis P. Campion*[1], Fiona M. McGovern[1], Eva Levicnik[3], Aileen McCarron[1], Philip Creighton[2], and Tommy M. Boland[1], [1]*University College Dublin, Dublin, Ireland,* [2]*Teagasc Athenry, Co. Galway, Ireland,* [3]*University of Ljubljana, Ljubljana, Lithuania.*

Ewe milk production peaks approximately 3 weeks postpartum, with intake potential peaking approximately 6 weeks postpartum. The aim of this study was to investigate the effect of concentrate supplementation on ewe DMI during early lactation. Fifty-four twin suckling ewes were allocated to one of 3 dietary treatments (n = 18) in a randomized block design on d 7 (+/ 2 d) of lactation as follows: GO: Ad-lib zero grazed grass, GC: Ad-lib zero grazed grass and 500g fresh weight (FW) of concentrate feed for 49 d postpartum and GC21: Ad-lib zero grazed grass and 500g FW of concentrate feed for 21 d postpartum. Ewes were penned with their progeny from 72 h postpartum until d 49 lactation. Lambs were offered free access to a creep area bedded with straw and were offered fresh water and zero grazed grass. Grass was harvested each morning using a single chop zero grazer from perennial ryegrass based swards with an average pre-grazing herbage mass of 1100kg DM/

ha with an average DM, protein and neutral detergent fiber content of 18.0, 18.4 and 45.0% respectively. Individual ewe intakes were recorded daily from d 7 to 49 of lactation. Rumen fluid samples were taken before and 7 d post-dietary introduction to assess rumen fermentation. Milk yield and composition was measured at 7 d intervals starting on d 14 (± 2 d) of lactation. Statistical analysis was carried out using generalized least squares means in SAS v9.4. Ewes from GO treatment had higher grass DMI (1.96kg) compared with GC (1.65kg) ewes ($P < 0.05$) and tended to have higher grass DMI than GC21 (1.84kg) ewes ($P < 0.10$). However, total DMI did not differ between treatments ($P > 0.05$). Rumen pH for GC and GC21 ewes decreased between d 0, 6.65, and d 7, 6.09 ($P < 0.01$). Milk production tended to be lower during early lactation for GC21 (1.85kg) ewes compared with GC (2.11kg) ewes ($P < 0.10$). No difference was observed between treatments in milk fat, protein or net energy ($P > 0.05$). Concentrate supplementation did not lead to increased DMI but rather acted as a substitute for grazed grass.

Key Words: DMI, milk yield, rumen function

183 An investigation into the effect of crude protein intake, dry matter intake and body reserve mobilization on the ewe colostrum and IgG production in the first 18 hours postpartum.

Francis P. Campion*[1], Fiona M. McGovern[1], Philip Creighton[2], Alan G. Fahey[1], and Tommy M. Boland[1], *[1]University College Dublin, Dublin, Ireland, [2]Teagasc Athenry, Co. Galway, Ireland.*

Colostrum is essential to neonatal survival and future performance, providing energy and immunity in early life. Late gestation nutrition has been shown to influence colostrum production and immunoglobulin G yield (IgGY). This study aims to determine the key drivers of colostrum production, specifically the relationship with dry matter intake (DMI), crude protein intake (CPI), and body reserve mobilization during the final 6 weeks of gestation. Data from 7 late pregnancy nutrition studies carried out over 12 years using twin-bearing ewes were merged into a single data set. All studies recorded ewe colostrum production and IgGY at one, 10 and 18 h postpartum. Regression coefficients were estimated using PROC MIXED (SAS v9.4). The model included the fixed effects of ewe, year, ewe breed (Belclare, Leicester and Suffolk crosses) and time point as well as the continuous variables of gestation length, maternal age, average lamb birth weight (BW), live weight change (LWC) and body condition score change (BCSC) during late gestation. Colostrum volume changed by 0.02 l for every 10 g change in CPI ($P < 0.01$), and 0.02 l for every 100 g change in DMI ($P < 0.01$). Body reserve mobilization (LWC and BCSC) did not influence colostrum volume ($P > 0.10$). Breed ($P < 0.01$), time point ($P < 0.01$), breed by time point interaction ($P < 0.01$) and maternal age ($P < 0.05$) had significant effects on the effect of CPI and DMI on the volume of colostrum produced by the ewe. The IgGY was also driven by CPI and DMI ($P < 0.05$). Each 10g change in CPI gave a 0.50 g change in IgGY ($P < 0.05$) and there was 0.80 g change in IgGY for each 100 g change in DMI ($P < 0.01$). Breed did not influence IgGY ($P > 0.10$) despite a breed by time point interaction ($P < 0.01$). Gestation length did not affect colostrum volume or IgGY ($P > 0.10$). These results indicate that intake as opposed to body reserve mobilization is the major driver of colostrum production by the ewe.

Key Words: colostrum, immunoglobulin, gestation

184 Biochemical parameters of newborn goats raised from Saanen does supplemented with selenium and vitamin E during the transition period.

Brenda Barcelos*[1], Arlindo Saran Netto[1], Talita Lara Conti[2], Eduardo Harry Birgel Junior[1], Vanessa Martins Storillo[3], Daniela Becker Birgel[1], and Flávio R. B. Ribeiro[4], *[1]University of Animal Science and Food Engineering, Pirassununga, São Paulo, Brazil, [2]Centro Universitário Anhanguera, Leme, São Paulo, Brazil, [3]College of Veterinary Medicine and Animal Science, São Paulo, São Paulo, Brazil, [4]Cooperative Agricultural Research Center, Prairie View A&M University, Prairie View, TX.*

The objective of this study was to evaluate biochemical parameters of newborn goats from does that were supplemented with Selenium and Vitamin E. Twenty 4 kids from Saanen does that were supplemented starting on the fourth month of pregnancy until birth. The animals received the treatments based on the dams treatments and were divided into 3 groups: Control milk (base diet with 50% forage and 50% concentrate); Se milk (2.5 mg of Se/kg Dm added to the diet) and Sev milk (2.5 mg of Se/kg DM and 1000 IU/day of vitamin E/kg DM). The kids started receiving ad libitum access to feed from 7 d postpartum. The experiment took 28 d. After birth blood samples were collected before ingesting of colostrum and 48 h, 7, 14, 21 and 28 d postpartum. Blood samples were analyzed for serum protein analysis, albumin, gamma-glutamyl transferase (GGT), total cholesterol, high density lipoproteins (HDL), low density lipoproteins (LDL), triglycerides, aspartate aminotransferase (AST), creatine phosphokinase (CK), glucose, lactate, urea, creatinine, β-hydroxybutyrate (BHB), nonesterified fatty acids (NEFA) and total antioxidant status (TAS). The experimental design was a complete randomized design with repeated measures, with 8 replications. Data were analyzed by ANOVA and the means were compared by Tukey test ($P \leq 0.05$). There was no significant effect of treatment ($P > 0.05$) for the parameters of GGT, LDL, triglycerides, CK, glucose, urea, creatinine, BHB, NEFA and TAS. For serum protein and albumin parameters the Sev treatment provided significant increase ($P < 0.05$) when compared with the other treatments. There was a significant effects for Sev treatment ($P < 0.05$) for lactate, total cholesterol, HDL and AST, showing, therefore, a better oxidant activity in the group treated with selenium and vitamin E.

185 The effects of feeding frequency on pig performance, behavior, and tissue accretion rates.

Jessica D. Colpoys*, Anna K. Johnson, and Nicholas K. Gabler, *Iowa State University, Ames, IA.*

Recent research suggests that feeding frequency may affect feed efficiency in pigs. Therefore, our objective was to compare 2 divergent feeding patterns and their effects on pig performance, tissue accretion, body composition and behavior. Following a 3 d acclimation to individual pens, 48 gilts were randomly blocked by body weight (55.9 ± 5.2 kg on test BW) into 2 feeding treatments; 1) ad libitum access or 2) twice daily gilts that were allowed to eat ad libitum between 0800 and 0900 h and again from 1700 to 1800 h. Performance was recorded weekly for 55 d and ADG, ADFI, and G:F was recorded and calculated. Body composition was assessed in 12 gilts per treatment using dual x-ray absorptiometry (DXA) at day −3 and 55, and tissue accretion rates were calculated. Video was recorded on d 51 and continuously watched from 7:00–19:00 h to assess the time pigs spent standing, sitting, lying and eating. Performance and DXA data were analyzed using the Mixed procedure and behavior data were analyzed using the Glimmix procedure of SAS. The model included the fixed effect of treatment, covariate of on test BW, and pig as the experimental unit. Gilts fed twice daily had lower ADG and ADFI compared with ad libitum gilts ($P \leq 0.01$); however, no treatment difference in G:F was observed ($P = 0.41$). No treatment differences were observed in body composition at d 55. However, gilts fed twice daily had lower fat (twice = 297 vs. ad libitum = 339 g/d), lean (twice = 673 vs. ad libitum = 737 g/day), and protein (twice = 136 vs. ad libitum = 149 g/d) daily accretion rates compared with ad libitum gilts ($P = 0.01$). No difference in bone accretion was observed. Gilts fed twice daily spent less time lying and eating compared with ad libitum gilts ($P \leq 0.05$). However, treatments did not differ in duration of time spent sitting or standing ($P \geq 0.19$). In conclusion, twice daily feeding resulted in reduced growth, tissue accretion, and lying behavior compared with ad libitum feeding. However, feeding frequency did not alter feed efficiency. This pig performance can be partly explained by the differences in caloric and nutrient intake.

Key Words: feed efficiency, feeding frequency, pig

186 Relationships between nursery stocking density and feeder space allowance with subsequent gilt estrous characteristics.

E. B. Cook*, W. L. Flowers, and M. T. Knauer, *North Carolina State University, Raleigh, NC.*

The objective of the study was to determine the effect of nursery stocking density (STOCK) and feeder space (FS) on gilt estrous traits. Composite Landrace × Large White PIC gilts (n = 230) were weaned at 37 d of age and 9.6 kg. Gilts were randomly assigned to a nursery STOCK of 0.42 or 0.21 m^2 and a FS of 14.35 or 7.175 cm per pig in a 2 × 2 factorial arrangement. After 33 d in the nursery, gilts were moved to the finisher weighing 23.7 kg. In the finisher, gilts were remixed and housed 15 per pen (0.84 m^2 per pig). Starting at 181 d of age, gilts were penned daily with a mature boar for 7 min and estrous symptoms recorded. At 188 d of age, gilts were allotted 7 min of fence-line boar contact daily until breeding. Measurements of gilt reproductive performance included: whether or not a gilt reached puberty (Pubertal), age at puberty, puberty weight, vulva width at puberty (Vulva_Width1), length of estrus at puberty (LOE1), vulva width at second estrous (Vulva_Width2), and length of estrus at second estrous (LOE2).Data were analyzed in SAS using PROC MIXED for continuous traits and PROC GLIMMIX for the categorical trait Pubertal. Fixed effects included STOCK, FS, the interaction between STOCK and FS, nursery room and age at first boar exposure. Stocking density and FS LSMEAN estimates for gilt estrous traits are shown in Table 1. Length of estrus at puberty tended ($P = 0.08$) to be greater for pigs stocked at 0.21 m^2 when compared with 0.42 m^2 (1.74 vs. 1.57 d). Yet no other estrous characteristics were affected by STOCK or FS ($P \leq 0.22$). Results suggest nursery STOCK and FS have little effect on subsequent gilt estrous characteristics.

Table 1 (Abstr. 186). Effect of nursery stocking density and feeder space on subsequent gilt estrous characteristics

	Stocking density, m^2			Feeder space, cm/pig		
Trait	0.42	0.21	SE	14.35	7.175	SE
Pubertal, %	79.4	74.5	4.0	78.7	75.3	4.0

187 Relationships between nursery stocking density and feeder space allowance with gilt growth performance.

E. B. Cook*, W. L. Flowers, and M. T. Knauer, *North Carolina State University, Raleigh, NC.*

The objective of the study was to determine the effect of nursery stocking density (STOCK) and feeder space (FS) on gilt growth performance. Composite Landrace × Large White PIC gilts (n = 500) were weaned at an average age and weight of 39.3 d and 9.6 kg, respectively. Gilts were randomly assigned to either 5 or 10 pigs per pen to achieve a STOCK of 0.42 or 0.21 m^2 and FS of 14.35 or 7.175 cm per pig in a 2 × 2 factorial arrangement. In 2013 and 2014 pigs remained in the nursery for 33 and 45 d, respectively, and left at an average weight of 23.7 and 39.0 kg, respectively. In the finisher, pigs were randomly placed into groups of 15 gilts per pen (0.84 m^2). Data were analyzed in SAS using PROC GLM. Fixed effects included STOCK, FS, year, nursery room and the interaction between year and room. All interactions between STOCK and FS were $P \geq 0.24$. In 2013 nursery ADG did not differ ($P = 0.27$) between STOCK. However, in 2014 nursery ADG was greater ($P < 0.01$) for pigs stocked at 0.42 m^2 when compared with 0.21 m^2. Overall nursery ADG was greater ($P < 0.01$) for pigs stocked at 0.42 m^2 when compared with 0.21 m^2 and numerically greater ($P = 0.21$) for pigs housed with 14.35 cm of FS when compared with 7.175 cm. Overall finishing ADG tended ($P = 0.08$) to be greater for pigs previously housed with 7.175 cm of FS when compared with 14.35 cm. In 2013 wean-to-finish ADG did not differ ($P = 0.84$) between STOCK. However, in 2014 wean-to-finish ADG tended ($P < 0.08$) to be greater for pigs stocked at 0.42 m^{2}when compared with 0.21 m^2. Overall wean-to-finish ADG was greater ($P = 0.03$) for pigs stocked at 0.42 m^2 when compared with 0.21 m^2. Results suggest nursery FS, but not STOCK, affected subsequent finishing growth rate.

Contd.

188 Apparent total-tract digestibility (ATTD) of total dietary fiber (TDF) between and within high fiber feed ingredients in finishing pigs.

Zhimin Huang*, Pedro Urriola, and Gerald Shurson, *University of Minnesota, St. Paul, MN.*

Fibrous ingredients, such as distillers dried grains with solubles (DDGS), are a price competitive source of energy in swine diets, but TDF may decrease nutrient digestion and absorption as well as energy utilization. However, we know little about the effects of ATTD of TDF on nutrient digestibility and energy utilization. Therefore, the objective of this study was to evaluate the effect of different fiber sources on ATTD of TDF and GE of finishing pigs. A total of 34 barrows and 2 gilts (Large White × Danish Landrace) with an average BW of 84.0 ± 7.2 kg were used in a changeover design with 2 consecutive 13-d periods, and involving 10-d of adaptation and 3-d of fecal and urine collection. During each period, the 36 pigs were allotted to 4 blocks by BW, 9 pigs in each block were fed 9 different experimental diets. Diets were formulated to contain similar concentration of TDF, from 3 sources of 3 ingredients (wheat straw, WS; soybean hulls, SBH, and DDGS). TiO_2 (0.5%) was used in diets as an indigestible marker. The direct procedure was used to measure ATTD of DM, GE, CP, acid ether extract (AEE), and TDF in the diets. Results showed that ATTD of DM, GE, and TDF of pigs fed the diet with SBH (87.4, 86.8%, and 78.9%) were greater ($P < 0.01$) than those fed DDGS (82.6, 80.1%, and 43.0%), which were greater ($P < 0.01$) than those fed WS (75.1,75.8%, and 26.7%). The ATTD of DM and GE were ($R^2 = 0.84$ and $R^2 = 0.85$) correlated with ATTD of TDF among diets. Between sources of the same ingredient, we observed differences ($P < 0.01$) in ATTD of TDF among 3 DDGS sources (36.0, 43.1, and 49.8%), but not for WS, or SBH. Among sources of DDGS, the correlation between ATTD of DM and GE to ATTD of TDF was poor ($R^2 = 0.62$ and $R^2 = 0.51$). In conclusion, ATTD of TDF is a good predictor of ATTD of DM and GE among fibrous ingredients, but it is less predictive among sources of the same ingredient because ATTD of TDF does not affect ATTD of GE, CP, or AEE.

Key Words: apparent total-tract digestibility, pig, total dietary fiber

189 Net portal-drained viscera flux of volatile fatty acids in Iberian and Landrace pigs.

Gonzalez-Valero Lucrecia[1], Rojas-Cano Maria Luz[1], Lachica Manuel[1], Ranilla Maria Jose[1], and Fernandez-Figares Ignacio*[2], [1]*Estacion Experimental del Zaidin-CSIC, Granada, Spain,* [2]*Universidad de Leon. Dept. Produccion Animal, Leon, Spain.*

Iberian pigs are traditionally reared outdoors where they feed on acorns and herbage. The capacity of volatile fatty acids (VFA) absorption could be of importance for these animals although it has never been determined. The aim of the present work was to evaluate the capacity of VFA absorption in Iberian compared with Landrace gilts fed a standard corn-soybean meal diet (160g/kg; 14.25 MJ ME/kg DM), using arterio-venous preparations. Iberian and Landrace gilts (30 kg BW; n = 4 Landrace and 6 Iberian) were used. Diets were formulated with protein of high biological value and offered at 85% ad libitum. Gilts were fasted for 24 h prior surgery. Catheters were implanted in the portal and mesenteric veins and carotid artery. Then, pigs were placed in metabolism cages and fed the diet for 6 d. On d 7, *p*-aminohippuric acid (PAH) was continuously infused through the mesenteric vein and pigs were offered 25% of their daily intake. Blood was withdrawn simultaneously from portal vein and carotid artery at 0, 0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 5 and 6 h after feeding, centrifuged for plasma harvest and stored at −20°C until analysis for PAH and VFA. Compared with Landrace, Iberian gilts had greater net portal absorption (μmol/min) of acetic acid (252 vs. 178; $P = 0.000$), butyric acid (17.0 vs. 12.7; $P = 0.007$) and isovaleric acid (10 vs. 4.7; $P = 0.010$), and lower of valeric acid (−8.5 vs. 12.9; $P = 0.007$), than Landrace gilts. No differences ($P > 0.10$) in net portal absorption of propionic (146 vs. 153), isobutyric (13 vs. 9) and caproic (4.5 vs. 5.5) acids were found. The greater capacity of net portal absorption of VFA in Iberian pigs could constitute a meaningful contribution to the energy requirement for maintenance and constitute an advantage when fed outdoors fibrous rich feeds.

Key Words: net portal absorption, volatile fatty acids, Iberian pig

190 Effects of a phytogenic feed additive in a protein-reduced diet in growing/finishing pigs.

Carina Schieder*[1], Christiane Schwarz[2], Christine Hunger[1], Barbara Rueel[1], Jose Soto[3], and Karl Schedle[2], [1]*Biomin Holding GmbH, Herzogenburg, Austria,* [2]*University of Natural Resources and Life Sciences, Vienna, Institute of Animal Nutrition, Products, and Nutritional Physiology, Vienna, Austria,* [3]*Biomin USA Inc., San Antonio, TX.*

The experiment was conducted to evaluate the efficacy of a phytogenic feed additive (PFA) on body weight gain, carcass composition and quality of 72 fattening pigs [(Large White × Landrace) × Piétrain)]. Animals were distributed into 3 treatment groups with 3 replicates of 8 pigs per replicate, with an initial weight of 32.2 ± 0.4 kg. Control group (CON) and one phytogenic group (PFA+normal; Digestarom® Finish 150 ppm, BIOMIN Phytogenics GmbH, Germany) received a diet containing 17% and 15% CP in the growing and finishing period, respectively. Another phytogenic group (PFA+low; Digestarom Finish 150 ppm) received a ration with a reduced protein content (−0.4% CP) throughout the whole growing and fattening period. Feed and water was provided ad libitum. At 73.2 ± 0.6 kg of BW, feed changed from growing to finishing diet. Body weight was measured weekly and individual feed intake was recorded daily. Pigs were slaughtered at 117.5 ± 0.2 kg and carcass composition and quality were evaluated. Data were analyzed with procedure GLM (SAS 9.4) and a multiple comparison was conducted with Tukey's range test. Results for the whole fattening period show significantly improved gain:feed ratio ($P < 0.05$; 0.389 and 0.388 in PFA+normal and PFA+low, respectively, compared with 0.368 in CON). Average daily feed intake was 2298 g/d in the CON compared with 2288 g/d in the PFA+normal and 2275 g/d in the PFA+low group. Daily weight gain tended to be higher ($0.05 < P < 0.10$) in the PFA+normal and PFA+low group (889.0 and 881.7 g/d) compared with CON (844.5 g/d). Carcass composition and quality parameters did not differ significantly ($P > 0.05$) between treatments besides conductivity of meat which has been improved for PFA+low group compared with CON 1 h post mortem (4.35 vs. 5.02 mS/cm, respectively). Overall, the supplementation of a PFA improved the performance of pigs and a protein reduction was efficiently compensated through the supplementation of PFA.

Key Words: fattening pig, nutrient-sparing, phytogenic feed additive

191 Effect of milky derived flavor inclusion in creep-feed diets on suckling piglet performance and litter homogeneity.

Laia Blavi*[1], David Solà-Oriol[1], Francisco Javier Crespo[2], María del Mar Serra[2], and José Francisco Pérez[1], *[1]Animal Nutrition and Welfare Service, Department of Animal and Food Sciences, Universitat Autònoma de Barcelona, Bellaterra, Spain, [2]Interquim S.A (Ferrer Health Tech), Barcelona, Spain.*

Hyper-prolific sows provide a higher number of piglets born per litter and year but, this promotes greater within-litter birth weight variation with high percentage of small animals. It was hypothesized that the inclusion of a milky derived flavor into the creep-feed (CF) would improve the number of eaters, creep-feed intake, piglet performance and litter homogeneity. A total of 35 litters (418 piglets) of Landrace × Large White sows were used. At cross-fostering (max 48 h after birth) all litters were standardized and were distributed into 3 experimental treatments; a basal CF (2480 kcal/kg, 1.53% digestible Lys) diet without flavor (T1), and 2 different milky derived flavors (T2 and T3) according to number of piglets, litter weight and coefficient of variation (CV). Creep-feed was offered from d 2 to d 28 and indigo carmine (5g/kg) was used as indigestible marker to register the number of creep-feed eaters on d 7, 14, 21 and 28. Creep-feed disappearance and individual BW were registered on d 2, 7, 14, 21 and 28 to calculate the within litter CV and the average daily weight gain (ADG) and mortality rate. No differences ($P > 0.10$) in BW (6.9 kg), CF disappearance (1571 g) and the number of eaters (4.1 piglets per litter) were observed among treatments. However, lower ($P < 0.05$) CV was observed for piglets fed the T2 (0.16 and 0.17%) than those fed the T3 (0.21 and 0.20%) and T1 (0.25 and 0.26%) diets on d 21 and 28, respectively. In addition, animals categorized as small (<180 g/d at 28 d) in T2 presented higher ADG ($P < 0.001$) than T1 (153.5 g/d vs 119.1 g/d, respectively from d 0 to 28). Higher ($P < 0.01$) piglet mortality was observed in litters fed T1 than T2 and T3 (6.9, 3.0 and 4.1%, respectively). These results suggest that the use of a milky derived flavor in the creep-feed improves growth in small piglets and may reduce the CV of the BW within the litters and piglet mortality obtaining higher homogeneity BW at weaning.

Key Words: flavor, creep-feed, piglet

192 Effects of cathelicidin-BF on growth performance, intestinal morphology and inflammation in weanling piglets.

Hongbo Yi*, Caihua Yu, Haiwen Zhang, Huahua Du, and Yizhen Wang, *Institute of Feed Science, College of Animal Sciences, Zhejiang University, Hangzhou, Zhejiang, China.*

The objective of this study was to investigate the effects of cathelicidin-BF (C-BF) derived from the Chinese endemic genera *Bungarus fascia* on postweaning diarrhea, growth performance, intestinal morphology and inflammation in weanling piglets. Eighteen piglets (Duroc × Landrace × Yorkshire) were weaned at 21 d with an initial BW of 6.63 ± 0.13 kg and randomly assigned to one of 2 treatments to give 3 pens per treatment and 3 piglets per pen. Piglets were intraperitoneally injected with normal saline (control group) or 0.55 mg/kg BW C-BF (C-BF group) once a day and offered diets and water on an ad libitum basis for 7 d. Diarrheal index was scored twice daily according a 4-point system (0, normal; 1, soft feces; 2, mild diarrhea; and 3, severe diarrhea). The ADG, ADFI and G:F were calculated at the end of study. All piglets were euthanized to determine serum immunoglobulin, serum cytokines, intestinal morphology and intestinal inflammation. Our data showed that C-BF treatment increased ADFI (245.4 vs. 157.9 g/d, $P < 0.05$) and ADG (181.9 vs. 112.9 g/d, $P < 0.05$) compared with control group. Meanwhile, C-BF treatment reduced diarrheal index compared with control (0.47 vs. 1.67, $P < 0.05$). Serum IgG, IL-6, IL-22 and TNF-α production were decreased ($P < 0.05$) by C-BF treatment. C-BF increased ($P < 0.05$) villus height of jejunum and reduced ($P < 0.05$) crypt depth of ileum. We demonstrated that C-BF reduced ($P < 0.05$) the expression of the inflammatory cytokines TNF-α, IL-6 and IL-8, but increased the expression of the anti-inflammatory cytokine IL-10 ($P < 0.05$) in the jejunum. Furthermore, we demonstrated that C-BF suppressed inflammation by downregulating the nuclear factor-κB (NF-κB) signaling pathway in the jejunum. In summary, these data suggest that intraperitoneal injections of C-BF ameliorated postweaning diarrhea and improved growth performance along with suppressing intestinal inflammation by downregulating the NF-κB signaling pathway in weanling piglets.

Key Words: cathelicidin-BF, weanling piglet, intestinal inflammation

193 Improving growth performance of weaning pigs with different dosages of combined natural growth promoter products.

Jose A Soto*[1] and Attila Kovacs[2], *[1]Biomin America Inc., San Antonio, TX, [2]Biomin Holding GmbH, Herzogenburg, Austria.*

A combination of organic acids OA (formic, propionic and acetic), phytochemical (PC) and permeabilizing substance (PS) which alters the permeability of the outer membrane in gram-negative bacteria, has shown synergistic effect on the inhibition of bacterial growth in vitro as well as improved growth performance in weaning pigs in vivo. The aim of the trial was to determine the efficacy of the combination of OA, PC and PS in the form of combined natural growth promoter (NGP) Biotronic Top3, at 3 different levels (0.1, 0.15, and 0.2%) on the growth performance of wean pigs. 600 pigs weaned at 28 d were assigned to 4 treatments: (1) basal diet, (2) basal diet combined with 0.1 NGP, (3) basal diet combined with 0.15 NGP and (4) basal diet combined with 0.2% NGP with 6 replicates by treatment. Starter diet from d 28 to d 56 (ME 14.00 MJ/kg, CP 17%, Met 0.45% and Lys 1.40%) and grower diet from d 56 to d 71 (ME 13.4 MJ/kg, CP 17.50%, Met 0.36% and Lys 1.20%) were fed. BW of the animals was recorded at d 28, 56 and 71. ADG and FCR were calculated. Dietary supplementation of NGP at inclusion levels of 0.1, 0.15 and 0.2% enhanced growth performance. The BW (kg) was improved on d 56 (quadratic $P < 0.01$; 17.2^{a}, 18.4^{b}, 18.7^{b} and 18.9^{b} for 0, 0.1, 0.15 and 0.2% of NPG, respectively) and d 71 (quadratic $P < 0.01$; 26.9^{a}, 28.1^{b}, 28.3^{b}, and 28.3^{b} for 0, 0.1, 0.15 and 0,2% of NPG, respectively) as well as feed intake (g/d) (quadratic $P < 0.01$; 762^{a}, 804^{b}, 816^{c}, and 818^{c} for 0, 0.1, 0.15 and 0.2% of NPG, respectively). ADG (g) ($P < 0.1$) was only numerically different among treatments (439, 458, 465, and 465 for 0, 0.1, 0.15, and 0.2% of NPG, respectively). There were no differences in FCR ($P > 0.1$). Diet supplemented 0.15% combined NGP had the highest final BW and ADG tended to be greater compared with other groups. The supplementation with the combined NGP at a level of 0.15% was most beneficial.

Key Words: natural growth promoter, organic acids, phytochemical

194 The effects of exogenous protease enzyme on growth performance, nutrient digestibility, blood profiles, fecal microflora, fecal gas emission, and fecal score in weanling pigs.

Glenmer B. Tactacan*[1], Se-young Oh[1], Jin H. Cho[2], and In H. Kim[3], [1]*Innovation and Development Department, Jefo Nutrition, Saint-Hyacinthe, Quebec, Canada,* [2]*Department of Animal Science, Chungbuk National University, Cheongju, Chungbuk, Korea,* [3]*Department of Animal Resources and Science, Dankook University, Cheonan, Korea.*

Although exogenous protease enzymes have been used in poultry quite extensively, this has not been the case in pigs. In general, due to their better fermentative capacity and longer digesta transit time in the gut, pigs have greater capacity to digest nutrients than poultry. In young pigs however, the digestion of nutrients, particularly of dietary proteins is marginally incomplete. Therefore, a study was conducted to elucidate the effects of a commercial protease enzyme supplemented in weanling pig diets. The indices of growth, nutrient digestibility, blood profiles, fecal microflora, fecal gas emission and fecal scores were measured during the study. A total of 50 weanling pigs (6.42 ± 0.60 kg) at 28 d of age were randomly assigned to receive 1 of 2 dietary treatments: (1) basal diet (corn-soy based) with no supplemental protease, and (2) basal diet + 200 g/ton protease for 42 d. A completely randomized block design consisting of 5 replicate pens per treatment with 5 pigs per pen was used. Growth performance in terms of bodyweight and average daily gain in pigs fed with protease enzyme (27.04 vs. 25.75 ± 0.25 kg and 491 vs. 460 ± 6 g; $P < 0.05$) was increased significantly, but gain per feed was similar between treatments. Compared with the control, protease supplementation increased ($P < 0.05$) the apparent total-tract nutrient digestibility (84.66 vs. 81.21 ± 0.91 DM and 84.02 vs. 80.47 ± 0.95 N) and decreased ($P < 0.05$) the NH_3 emission (2.0 vs. 1.2 ± 0.14 ppm) in the feces. Except for a decreased ($P < 0.05$) in blood creatinine level, no differences were observed in RBC, WBC, lymphocytes, urea nitrogen, and IgG concentrations between treatments. Fecal score and fecal microflora (*Lactobacillus* and *E. coli*) were also similar between the control and the protease-supplemented diets. Overall, the supplementation of protease enzyme in weanling pigs resulted to improved growth rate and nutrient digestibility. Exogenous protease enzyme reduced fecal NH_3 emission, thus, potentially serving as a tool in lowering noxious gas contribution of livestock production in the environment.

Key Words: protease, nutrient digestibility, weanling pig

195 Maternal betaine supplementation during gestation attenuates hepatic cell cycle and proliferation through epigenetic regulation of the STAT3-dependent pathway in newborn piglets.

Demin Cai*, Mengjie Yuan, Yimin Jia, Yun Hu, and Ruqian Zhao, *Nanjing Agricultural University, Nanjing City, China.*

Betaine, which donates methyl groups through methionine metabolism for DNA and protein methylation, is critical for epigenetic gene regulation especially during fetal development. Here we fed gestational sows (8 per group) with control or betaine supplemented diets (3 g/kg, from the first day of gestation to parturition) to explore the effects of maternal betaine on hepatic cell proliferation in neonatal piglets. Newborn piglets were individually weighed immediately after birth and the piglets from the same litter were kept together in the warm creep area. One male piglets of the mean body weight were selected per litter and killed for tissue sampling before suckling. Neonatal piglets born to betaine-supplemented sows demonstrated a reduction of cell number and DNA content ($P < 0.05$) in the liver, which was associated with significantly downregulated hepatic expression of cell cycle regulatory genes ($P < 0.05$), cyclin 2 (CCND2) and presenilin1 (PSEN1). Moreover, STAT3 binding to the promoter of *CCDN2* and *PSEN1*genes was lower ($P < 0.05$) in betaine-exposed piglets, which was accompanied by strong reduction ($P < 0.05$) of STAT3 mRNA and protein expression along with its phosphorylation at Tyr^{705} and Ser^{727} residues ($P < 0.05$). Also, prenatal betaine exposure significantly attenuated upstream kinases ($P < 0.05$) of STAT3 signaling pathway (phospho-ERK1/2, phospho-SRC and phospho-JAK2) in the liver of neonates. Furthermore, the repressed *STAT3* expression in the liver of betaine-exposed piglets was associated with DNA hypermethylation ($P < 0.05$) and more enriched repression histone mark H3K27me3 ($P < 0.05$) on its promoter, together with significantly upregulated expression ($P < 0.05$) of H3K27me3 and enhancer of zeste homolog 2 (EZH2) protein, as well as miR-124a ($P < 0.05$) which targets STAT3. Taken together, our results suggest that maternal dietary betaine supplementation during gestation inhibits cell proliferation in the liver of neonatal piglets through epigenetic regulation of hepatic *CCDN2* and *PSEN1* genes via a STAT3-dependent pathway.

Key Words: cell cycle and proliferation, STAT3, epigenetic regulation

ADSA-SAD (Student Affiliate Division) Undergraduate Competition: Dairy Foods

196 Organic versus conventional milk production systems. Savannah B. Meade* and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

In the past decade, organic farming has increased in popularity. Many consumers who support organic farming believe that organic products differ in composition from conventionally produced products. Additionally, organic milk supporters often believe that organic dairy farming is more beneficial to cows and the environment. The milk is produced without antibiotics, added hormones, synthetic chemical treatment or genetic modification. This leads many consumers to believe that organic milk has potential human health benefits. Milk composition is affected by many factors. Studies comparing organic vs. conventional milk are sparse. A recent *Journal of Dairy Science* review covers the individual factors that affect milk composition and provides an overview of a few studies that compare organic and conventional milk. Factors influencing milk composition, such as nutrition, breed, and stage of lactation, have been studied individually, but are difficult to compare simultaneously. Some studies have shown that organic milk has higher levels of omega-3 fatty acids and conjugated linoleic acid, but it is unclear as to whether these differences are truly beneficial. Milk fatty acids are often researched when considering organic vs. conventional milking systems because fatty acids respond rapidly and are very sensitive to changes in the diet of cattle. Studies also discuss the use of antibiotics, the presence of hormones, and genetic modification factors that many organic consumers base their purchases on. More research needs to be conducted to determine whether one production system is more beneficial to human health than the other. Organic consumers pay a higher market price for their products, and as of now, no proven benefits for purchasing organic milk have been demonstrated. No major health differences between organic and conventional dairy products have been proven.

Key Words: organic milk production, conventional milk production, milk composition

197 Postmortem factors relevant to veal quality. Sloane Garcia* and Chad Carr, *University of Florida, Gainesville, FL.*

Veal represents a relatively minor percentage of the meat industry as a whole. During the past half century the veal industry has undergone considerable changes in production practices. Currently, grain-fed and heavier calves are the norm and many farms are converting to individual pens as opposed to group housing which, in addition to improving the conditions for the animals, has also improved the public's perception of the industry. (1) It is generally accepted that meat quality is the most important indicator of financial returns on the product. In today's world, the industry places strong emphasis on lean color in spite of the absence of scientific evidence validating a direct effect on quality. (2) This presentation will discuss the effects of post-mortem factors on veal quality. Factors associated with meat quality include carcass grade, aging, and packaging. According to the USDA, milk fed calves produced carcasses that were lighter in lean color and fatter, however these graded scores do not directly correlate with palatability. (1) Color determination plays a large role in quality determination, but data continues to show a poor relationship between color and taste. Attempts at quality improvements should evaluate factors such as aging and packaging for determining veal quality. Aging veal results in increases in tenderness, decreases in shear force, and increases in lightness and redness. Type of packaging and the time interval between slaughter and packaging has a profound effect on meat quality and shelf life. For example, packaging veal within 24 hours post-mortem yielded a product that was lighter and had a longer shelf life than similar meat that was packaged later. (3) In conclusion, the veal industry should be evaluating factors that directly affect quality of the product. Less emphasis should be placed on color when, ultimately, taste and tenderness of the meat should be the determining factors in assessing the value of the product. Public education may be in order because often the consumer's perception of veal quality is based solely on the color of the meat in spite the lack of scientific evidence correlating veal color with meat quality.

Key Words: dairy, food, veal

198 Probiotics in yogurt and human health. Erin M. Sole* and Gustavo J. Lascano, *Clemson University, Clemson, SC.*

Gastrointestinal diseases are becoming increasingly prevalent in the medical society today with approximately 60 to 70 million Americans affected by gastrointestinal diseases every year. One method of combatting these diseases is through the use of probiotics. Therefore, the aim of this presentation is to provide a review of the literature and a summary of what probiotics and yogurt are, how probiotics are selected, factors that influence the effectiveness of probiotics in yogurt, and how probiotics can benefit human health. A systematic literature research was conducted to further investigate this topic. Databases used included Google Scholar and the *Journal of Dairy Science*. One of the primary vectors for human consumption of probiotic is through fermented dairy products, especially yogurt. The bacteria of the genera *Lactobacillus* and *Bifidobacterium* are added to the yogurt either before or following fermentation and have been proven to positively affect gut health by improving the balance between beneficial and harmful bacteria. Although probiotics are not essential for survival, probiotics are highly recommended as they improve gut health, especially under conditions that decrease the normal microflora of the intestines, such as chronic and acute diseases, antibiotics, and age.

Key Words: probiotic, yogurt, microbiology

199 Protein pricing and promoting: A renewed outlook on milk. Jessica M. Sentelle*, David R. Winston, and Benjamin A. Corl, *Virginia Tech, Blacksburg, VA.*

Fluid milk consumption in the United States has steadily declined over the past several years. Whole milk consumption has declined the most by product as seen by data from USDA ERS. As consumers' tastes and preferences change, innovation in the dairy food industry must occur to sustain demand for dairy products. Recent promotions, such as "milk life" promote the nutritional aspects of milk. Fairlife ultra-filtered milk was recently introduced to capitalize on a growing demand for high protein drinks for the physically active consumer. After developing a patented cold-filtration process for milk, Select Milk Producers started a partnership with Coca-Cola to develop and distribute their dairy based protein drinks. Their products are offered in 4 varieties (whole, reduced fat, fat free, and chocolate); they are priced higher than conventional fluid milk. To obtain an ultra-filtered milk product, the founders of Fairlife use a patented cold filtration process that first concentrates the milk, and then sterilizes the concentrate. The process differs from ultra-high temperature (UHT) processing and manages to avoid the characteristic burnt flavor of UHT milk (Maron and Corby, 2012). Milk components are separated to obtain a final product with twice as much protein, more calcium, less sugar, and no lactose. In a systematic review, Pasiakos et al. suggests that protein supplementation can enhance muscle mass and performance with adequate exercise procedures. This shows that high protein dairy drinks will be beneficial for active consumers. Ultrafiltration allows the separation of lactose to pick up a new class of lactose-intolerant consumers as well. In conclusion, consumption of fluid dairy products is steadily declining. As consumers' tastes and preferences change, innovation in the dairy food industry must occur to sustain demand for dairy products. Ultrafiltration and the new cold filtration process allow the separation and concentration of milk components to create a specialized product for different consumers. Pricing and promotion of new dairy products is very important to convey the proper message and increase demand.

Key Words: milk protein, lactose, ultrafiltration

200 Reinventing sweetness in dairy products.

Halee L. Wasson* and Dale R. Olver, *Pennsylvania State University, University Park, PA.*

In recent years, high levels of sugars in dairy products have created health concerns among consumers. According to the Mid-Atlantic Dairy Association, the average American consumes less than 2 servings of dairy each day. This indicates that many school children and others are missing out on the vital nutrient package provided by dairy products. In fact, chocolate milk has been removed from some school lunch programs due to its high sugar content. As a result, dairy researchers and manufacturers are challenged to identify acceptable alternatives for sweetening. Recent studies have focused on chocolate milk and ice cream to identify methods that reduce sucrose content while maintaining flavor. Research at North Carolina State University demonstrated that reductions up to 30% of sugar content in chocolate milk did not influence acceptability among young consumers. These researchers also investigated ways to use lactose hydrolysis to reduce sucrose content in chocolate milk. However, they found that the additional lactose needed to achieve the sweetness of sucrose did not result in a reduction of calories. Reducing the sugar content in ice cream can be even more challenging. This is because along with being a sweetener, sucrose plays a vital role in Freezing Point Depression Factor (FPDF). The FPDF is important to ensure the desired hardness is reached to maintain ice cream's scoopable properties. Researchers have studied the effects of using erythritol and maltodextrin as sucrose substitutes in ice cream. Erythritol is a sugar alcohol known for its zero calorie status, but it has a high FPDF. Maltodextrin has a similar molecular weight, solubility, and FPDF as sucrose. With these alternative sweeteners and others, it is still possible for ice cream to maintain key attributes such as being scoopable or holding its shape on a stick. The findings of these studies present potential solutions to alter the sugar content in dairy products while maintaining functionality and flavor.

Key Words: chocolate milk, ice cream, lactose hydrolysis

201 How fair is Fairlife?

Sarah Genest* and Cathleen C. Williams, *Louisiana State University, Baton Rouge, LA.*

Coca-Cola is now distributing a new dairy product called Fairlife. It is milk that has 50% more protein, 30% more calcium, and half the sugar of regular milk. It is also lactose free. Recently, the consumption of soft drinks as well as milk has been declining. In the past 10 years, consumption of soft drinks has decreased 20%. Since 1970, consumption of milk has decreased by 37%. Coca-Cola believes that the recent interest in healthier food and drinks will drive consumers to buy Fairlife milk. A Coca-Cola executive even stated that she believed that Fairlife milk would make it "rain money." Milk is composed of water, fat, lactose, protein, and vitamins and minerals. Fairlife makes milk with more protein and calcium and less sugar by using cold filtration. The milk is pasteurized at a higher temperature than regular milk, but for a shorter time period. Then the cold filtration is used to separate the components of milk based on their molecular size. After this is completed, a larger ratio of protein and calcium are added into the milk. Lactase, an enzyme that breaks down lactose is also added. This ensures that Fairlife milk is lactose free. Fairlife was created by Sue and Mike McCloskey. They founded Select Milk Producers which is made up of family-owned farms. Their motto is "from grass to glass." They grow crops and formulate their own cow feed. The cows used to produce milk have freestanding stalls and are protected from harsh weather conditions. After the milk is collected, it is then loaded on Fairlife trucks and it brought to the plant in Michigan with only milk from that one dairy. It is processed and bottled in the same plant and then distributed to stores nationwide.

Key Words: cold filtration, milk, Fairlife

ADSA Foundation PhD Symposium: Meeting the present and future demand for employees with a PhD

202 Current and anticipated supply of people with PhDs. J. R. Knapp*, *Fox Hollow Consulting LLC, Columbus, OH.*

There is a growing concern among employers in academia and industry regarding the adequacy of PhD training programs for animal scientists in the US in terms of the number of graduates as well as their preparedness. Data from the National Center for Education Statistics and USDA Food and Agricultural Education Information System show that the number of PhDs awarded from animal, dairy, and poultry science departments has declined by nearly 40% in the past 2 decades. Currently, ~150 PhDs are awarded per year in animal science, 80 to 90 of whom are US citizens. While some non-citizens may seek employment and stay in the US, the majority return home. The decline in graduate students is associated with decreased funding for animal agricultural research, the declining numbers of animal science faculty at land grant universities, increased undergraduate enrollment, and the expansion of departmental programming to meet changing societal demands. Although a recent National Research Council publication noted that agricultural research funding to the land-grant universities has been flat in real dollars, the reality is that less funding is available to principal investigators (PIs) to support their research programs and graduate training now than in the past due to increased indirect cost rates charged by universities as well as expansion in administrations. Also, whereas graduate assistantships from formula funds and tuition waivers were the normal way of funding graduate training in the 1980s, today PIs often must cover tuition, stipend, and benefits from their research funds at costs of \$50,000 to \$70,000 per graduate student per year. The likelihood of increased federal funding for agricultural research and graduate training in the future is low, and new approaches to funding and operating graduate training are needed. Industry will need to take a larger role in these approaches. Also, significant redundancy exists among the land-grant agricultural experiment stations; regionalization would lead to more efficient use of limited research funding. Consistent availability and effective use of funding for graduate training will be needed to increase the number of animal science PhDs to a sustainable level for our field.

Key Words: graduate training, research funding, future of agriculture

203 What can industry and academia do to help maintain viability of dairy/animal science departments at land-grant institutions? Kenneth G. Odde*, *Kansas State University, Manhattan, KS.*

Animal and dairy science departments at land-grant universities have long served their livestock industries through teaching, research and extension. The number of livestock producers has declined dramatically, and the number of students with farm and ranch backgrounds majoring in animal or dairy science has declined simultaneously. Additionally, Colleges of Agriculture and Departments of Animal Science and Dairy Science have become smaller and less influential components of land-grant universities. As the livestock producer constituency has declined in size, the power of livestock organizations to influence state funding levels and priorities for that state funding has also diminished. Other forces affecting departments include increased emphasis on federally funded research, rising standards for scholarship productivity for faculty members to achieve tenure and promotion, loss of livestock units in proximity to campus, loss of faculty positions, particularly tenure-track positions, greater investment of scarce resources in compliance, and greater emphasis on universities protecting intellectual property and capturing full research costs. The potential exists for stronger relationships between industry and university departments that will ultimately strengthen departments. The strong relationship requires that departmental leadership fully understands the needs and constraints of industry. Likewise, industrial organizations must also understand the nature of universities, and the variables that affect departmental and faculty behavior.

Key Words: animal science, dairy science, animal industry

204 Graduate student perspective: Concerns with pursuing a PhD. Curtis W. Park*, *North Carolina State University, Raleigh, NC.*

College students are in a time of life that requires a lot of decisions that will affect their future careers. Attending graduate school and whether to pursue a PhD is a critical decision students have to make. In order for more students to pursue a PhD in a dairy science related field, more must be done to inform them of the job opportunities available. Some students are intimidated by getting a PhD simply because they do not know what is required for the degree. A survey was conducted with both the ADSA Student Affiliate Division (undergraduates) and the ADSA Graduate Student Division to assess what students consider when making this important decision. The results from this survey will be discussed, as well as insights on how to better engage students early in their educational career, to help those who are thinking of pursuing a PhD in a dairy science-related field.

Key Words: PhD, graduate student

205 Industry–university partnerships in research and graduate student training.

Michael L. Day*, *Department of Animal Sciences, The Ohio State University, Columbus, OH.*

Industry partnerships for graduate education provide opportunities that benefit students' future careers, a means to meet industry needs for employees with advanced research and technical expertise, and a method to train adequate numbers of scientists for academia and industry, especially given escalating costs of graduate education. The OSU Office of Sponsored Programs (OSP; with M. L. Day as PI) and Select Sires Inc. (SSI) have had a cooperative training partnership program to train graduate students in bovine reproduction, with an emphasis in male reproduction, since 2010. The partnership was the result of recognition by the PI and SSI that the number of students trained in male reproduction was limiting and that needs for scientists with this expertise in industry and academia were unlikely to be fulfilled. This partnership provides a platform to leverage resources of OSU and SSI to study male reproduction. Inherent to all partnerships, especially given that the training affects the student's career, having a thoughtful agreement is crucial to protect interests of all parties. Hence, the resources of OSP were instrumental to develop this program. Key aspects of the agreement give guidance as to intellectual property, inventions, patents, publication of results, and so on. Costs of the graduate stipend and tuition are equally shared by SSI and the Animal Sciences department. Consensus between the PI and SSI scientists is necessary for admission into the program. One member of the student's advisory committee must be from SSI and the specific research hypotheses are determined by consensus to ensure needs of the student, PI, and SSI are met, and to affirm the research is comprehensive and high quality. Supply and travel costs for research are paid by SSI and matched "in-kind" by OSU. An important aspect of the agreement, for the student's protection, is that they are not obligated to be employed by SSI upon graduation. Two graduate degrees, with a third in progress, have resulted from this program. This model of university–industry collaboration has been very effective in producing young scientists to meet emerging needs in the area of male reproduction.

Key Words: graduate education, industry, partners

206 Opportunities for PhD student training support at the National Science Foundation.

Steven Ellis*, *National Science Foundation, Arlington, VA.*

In 1950, the National Science Foundation (NSF) was created to "… promote the progress of science; to advance the national health, prosperity, and welfare; and to secure the national defense." The NSF has been a strong supporter of graduate education throughout its history. For example, some of the NSF's first awards were to support graduate training, and extensive support for PhD training is still offered through the NSF Research Traineeship program (NRT) and the Graduate Research Fellowship Program (GRFP). In 2015, the NRT expects to award almost $37.9M and the GRFP is expected to award roughly $333M in new and continuing awards (pending availability of funds). Additional support for the costs associated with graduate and postdoctoral training is available through fellowships and awards funded by core programs, special solicitations, and related activities in the research directorates. Understanding the NSF structure, priorities and merit review process are critical to securing support through these programs because each funding agency has a distinct set of goals and objectives. Researchers associated with the ADSA (or other member societies associated through FASS) can find very relevant funding opportunities in all of the NSF research directorates. However, those submitting proposals should recognize and emphasize the basic, fundamental aspects of their research proposals and activities. Merit review at the NSF centers around the intellectual merits of a proposal, and the broader impacts of the proposed work. So, although NSF does not have an explicit emphasis on food production or agricultural efficiency, animal production systems are potentially excellent experimental systems to reveal basic biologic processes, advance complex technical or engineering principles, and even elucidate economic factors. Putting any proposed effort in context with an over-arching and broadly relevant scientific scope can result in a compelling and fully competitive research proposal that includes support for student training. Such activities also represent excellent student training opportunities that will supply the future demand for PhDs with interdisciplinary skill sets.

Key Words: research funding, National Science Foundation (NSF)

207 Research funding opportunities available through Foundation For Food and Agricultural Research.

Christopher Mallett*[1,2], [1]*Cargill, Wayzata, MN,* [2]*Foundation for Food and Agricultural Research, Washington, DC.*

The objective of this presentation will be to give an overview of the Foundation for Food and Agricultural Research (FFAR) and research funding opportunities available through the foundation. Authorized by Congress as part of the 2014 Farm Bill, the foundation operates as a non-profit corporation seeking and accepting private donations to fund research activities that focus on problems of national and international significance. The US Congress provided $200 million for the Foundation, which must be matched by non-federal funds as the Foundation identifies and approves projects. The foundation will leverage public and private resources to increase scientific and technological research. Research funded by the FFAR is addressing issues including plant and animal health; food safety, nutrition and health; renewable energy, natural resources, and environment; agricultural and food security; and agriculture systems and technology.

Key Words: USDA, Foundation for Food and Agricultural Research (FFAR), research funding

208 Dairy Management Inc.'s role in funding PhD research.

David R. McCoy*, *Dairy Management Inc., Rosemont, IL.*

Dairy Management Inc. (DMI) is funded by America's nearly 49,000 dairy farmers, as well as dairy importers. DMI and its related organizations work to increase demand for dairy through research, education and innovation. US dairy farmers provide 15 cents per hundred pounds of milk, and importers provide 7.5 cents per hundred weight equivalent to the National Dairy Promotion and Research Program. Part of those funds go to DMI for use in funding dairy promotions as well as research. The research funds are used to provide for graduate student salaries and supplies at several universities. The legislation that established DMI limits us to studies on the utilization of milk and dairy products and the creation of new products, so that the utilization of milk and dairy products may be encouraged, expanded, improved or made more acceptable. DMI also has developed consortia of industry, academia, and government agencies to leverage more funding into dairy research. Through the combination of dairy farmer/ importer contributed funds and consortia project funding, DMI and the associated state and regional check-off programs contract for a significant portion of the dairy foods research in the US

Key Words: funding, Dairy Management Inc.

209 Funding opportunities for PhD programs in animal, dairy and poultry science at the USDA National Institute of Food and Agriculture.

Mark A. Mirando*, Adele M. Turzillo, and Ray Ali,
USDA National Institute of Food and Agriculture, Washington, DC.

A variety of opportunities exists to support PhD programs through funding provided by the USDA National Institute of Food and Agriculture (NIFA). NIFA competitive grant programs generally have broad eligibility and, thus, are readily available to support PhD programs across a wide range of institutions and programs, although eligibility is restricted to entities within the US A major funding opportunity for PhD students is the Predoctoral Fellowship Program of the Agriculture and Food Research Initiative (AFRI) Food, Agriculture, Natural Resources and Human Sciences Education and Literacy Initiative. This program provides support for up to 2 yr and $79,000 in total costs/grant for stipends, tuition, fees, fringe benefits, supplies, and travel. Individual students apply for the fellowships, thereby gaining valuable experience in preparing and submitting a grant proposal. Funding for PhD programs, including allowances for international training, is also available through NIFA’s Food and Agricultural Sciences National Needs Graduate and Postgraduate Fellowship Grants Program. In that program, mentors apply for funding to support one or more fellowships totaling $79,500/fellow over 3 yr, with grant awards limited to 3 yr and $262,500 in total costs. Support for PhD students can also be included in applications to most other NIFA competitive grant programs. Those with greatest relevance to animal agriculture include, but are not limited to, the AFRI Foundational Program, AFRI Food Security Challenge Area, Organic Research and Extension Initiative, Organic Transitions Program, Biotechnology Risk Assessment Grants Program, and Beginning Farmers and Ranchers Development Program. Information about these and other NIFA funding opportunities is available at http://www.nifa.usda.gov/fo/funding.cfm. Funding support for PhD students may also be available through capacity-funded research and extension programs provided by NIFA to institutions (e.g., Hatch, Evans-Allen, Smith-Lever); however, these funds are subject to legislative and institutional restrictions, and thus, may not be readily available to support PhD programs at all institutions.

Key Words: federal funding, competitive grants, PhD program

ADSA Multidisciplinary and International Leadership Keynote (MILK) Symposium: Global dairy perspective—Production, processing, people, politics, and priorities

210 Role of milk and milk production in reducing poverty and malnutrition in emerging market countries. Jim Yazman*, *US Agency for International Agriculture, Washington, DC.*

Milk is the food that unites humans with the more than 5,000 other members of the Mammalia class. Milk supplies critical nutrients for newborns and is valued as a dietary component for all age groups. Expanding global trade in milk and milk components reflects an important role as a traditional foodstuff and in food product innovation. The rapidly expanding and urbanized middle class in emerging market countries is driving increased demand for milk and dairy products. The international development community and government partners are working to improve food security for vulnerable populations, including reducing high rates of malnutrition in adolescent, pregnant and nursing women and infants through diversification of diets. Milk and milk products are recognized by nutritionists as key components of diversified diets. Families grazing livestock across semi-arid lands often manage milking animals to supply milk for women and young children. In higher-potential areas, conversion of forage and crop by-products to milk and dairy products is a key income generation strategy for the poor, with women often controlling milk income. The US Agency for International Development (USAID) and other development partners recognize the potential of milk production and marketing to transform the lives of the rural poor. The Feed the Future initiative (www.feedthefuture.gov) is the US Government's contribution to the global effort to improve income, food security and nutrition in poor households. Implemented in in Africa, Asia and Latin America and the Caribbean, Feed the Future strategies enhance household income by linking families to dairy value chains while increasing the availability, access and utilization of milk as a nutrient-rich animal-source food. Pastoralists as well as sedentary smallholder producers are assisted to increase milk-derived income as well as produce milk for home consumption. Dairy producers in emerging market countries face several challenges in an increasingly globalized dairy market: accessing technology and services; meeting raw milk quality standards; and control of production diseases, especially mastitis.

Key Words: food security, malnutrition

211 Meeting 2050 global milk demand while freezing the environmental footprint of dairy production. Roger A. Cady and Howard B. Green*, *Elanco, Greenfield, IN.*

The Food and Agriculture Organization (FAO) of the United Nations projects that the global milk demand in 2050 will exceed 1 billion metric tonnes (MT), an increase of nearly 60% compared with 2010 production levels. The increase in milk solids demand will be 50 million MT, more than any other animal-sourced food except poultry products. The primary sources of human consumed dairy products are cattle and water buffalo (96%). Combined global milk production from these 2 species more than doubled from 1961 to 2010 (331.5 million MT to 692.0). However, milk production has not kept pace with human population growth, resulting in 6% less bovine milk produced per capita than in 1961. Milk production must grow more in the next 35 years than it has in the past 50. Furthermore, growth must occur without increasing the environmental footprint of milk production. Between 1961 and 2010, milk supply from dairy cattle increased primarily due to increased cows (54%). Since 2007, 82% of supply increase is due to a larger cattle population. That contrasts to an average annual yield increase of only 9.7 kg/cow/yr of cattle milk since 1961. Every additional cow to the population adds between 9 and 13 MT of CO_2e (accounts for additional replacement heifers and bulls) to the atmosphere annually. To meet 2050 demand and freeze the environmental impact of milk production requires increasing yield by at least 45 kg/cow/yr annually between now and 2050. This compares to sustained annual increases in developed countries of 130 kg/cow/yr and over 200 kg/cow/yr in some countries with developing dairy industries. In regions where milk production increases are limited, increased trade will be required to source milk from more resilient production regions.

Key Words: dairy, environment, sustainability

212 Global dairy: African perspective. Pieter H. Henning*[1] and Lourens J. Erasmus[2], *[1]Meadow Feeds, Johannesburg, South Africa, [2]University of Pretoria, Pretoria, South Africa.*

Africa is often seen as a "dark continent" yet it has the potential to be a continent of "milk and honey." The objectives of this presentation are to describe the dairy industry in Africa, highlight the challenges faced, and propose how they may be met. The human population of Africa is just over 1 billion. The 8 leading "dairy" countries in Africa together have approximately 37 million dairy cows. Average milk production varies from 0.12 to 6.45 tons/cow/year, and annual per capita consumption ranges from 8 to 241 kg milk equivalent (ME). Comparative figures for the United States are 9.2 million dairy cows, 9.44 tons/cow/year and 259 kg ME/capita. Growing urbanization and westernization are increasing the demand for milk and dairy products in Africa. This is further supported by a rapidly expanding supermarket industry. There is good potential for even more growth in demand. Africa is currently a net-importer (ca 6 million tonnes/year) of dairy products. Cows, though, are abundant in Africa and there is great scope to increase milk production from the continent's cow population. Growth in dairy farming will also contribute to improved livelihood for many African people. However, serious challenges in respect of infrastructure, animal husbandry practices, genetic material, animal nutrition and cow health have to be met if Africa's dairy potential is to be realized. Africa has the intellectual potential but needs to learn and apply suitable technical knowledge and skills. The internet, cell phone, and tablet have revolutionized communication and can play a significant role in the transfer of this knowledge and skills to the emerging African dairy farmer. Politics still remain a stumbling block in some African countries. Two priorities for the dairy industry in Africa are infrastructure creation (from milk collection to final products) and the transfer of appropriate technical knowledge and skills to create successful dairy farmers, whether small or big. The latter priority, especially, poses a challenging opportunity for first-world dairy organizations, such as ADSA, and its members.

Key Words: Africa, dairy industry, technical challenge

213 Dairy in China: Present status and future prospects. Jiaqu Wang*, *Chinese Academy of Agricultural Sciences, Beijing, China.*

China's dairy industry has made tremendous progress in the past 20 years, with cows and milk production growing >10% /yr. In 2000, total number of dairy cattle was <5 million producing 8.27 million tons of milk. In 2014 there were 14.98 million producing 37.25 million tons of milk. Dairy was the most rapid growing section among all livestock production. Herd size shifted from 5 cows in 1995 to a larger present size, with 40% of dairy cows in herds >50 cows. Over 70% of milk is produced and processed in northern China. Dairy industry international trade has shown strong activities since China became a WTO member. Animal importation increased from 37453 cows in 2009 to 99348 cows (2011) and 195000 cows (2014). Importation of dairy products grew more significantly. In 2009, China imported 596999 tons of dairy products, but increased to 1,880,000 tons in 2014. 88% was dry products, mainly milk powder and whey. Seventy percent of the imported milk powder was from New Zealand with Australia, EU and USA also important dairy trade sectors. China exported 20000 to 25000 tons of dairy products annually in the past 5 years. Annual urban dairy product consumption increased from 15 kg/ person (2000) to 23 kg/person (2012), while consumption in rural areas remains relatively low and stagnant (<10 kg/person). Dairy processing plants are becoming larger with Yili and Mengniu processing 10,000 tons of raw milk daily. Currently, raw milk production is from 3 models: Cropping area model (70% of milk; small family farms, local feeds, local raw milk stations), suburban area model (20%; near stable consumer markets) and pasture model (10%). Average annual productivity is 5500 kg /cow. Low productivity means low efficiency and high cost. It is reflected in high raw milk prices ($0.8/L in 2013). China will be the world market center of dairy products in the future due to the rapid growing demand of the huge population. More international trade of dairy products will encourage information and technology exchanges, which will help improve quality and efficiency of domestic production. China's dairy industry must be ready for international competition and cooperation. Standards, policies and legislations will be critical for such prospects.

Key Words: China, dairy production, dairy product

214 Brazil: Recent growth, importance and future of dairy markets. Marcelo Pereira de Carvalho*, *AgriPoint Consultoria, Piracicaba, SP, Brazil.*

This presentation will offer an overview of recent and expected future developments of milk and dairy markets in Brazil, which have expanded significantly in the last 15 years. Since 2000, per capita consumption moved from 122 to 176 kg/year in 2014 (in milk-equivalent terms). As population grew from 173 million to 203 million in the same period, total market increase almost 70% or 14,6 billion kg in volume. This growth was accomplished mainly by domestic production, which expanded from 19,7 billion kg (2000) to 34,3 billion (2013). From 2001 to 2013, the amount of milk delivered to dairy companies for processing increase 6,5x more than the amount unprocessed, a rate of growth of 5,4% per year. Cheese production increased from 440.000 metric tons in 2000 to nearly 1 million tons in 2013, a growth of 6,6% per year, reaching 5 kg/person/year. In the last 10 years, fresh dairy products doubled its market size, from 780.000 tons in 2003 to 1.450.000 tons in 2013, reaching 7,5 kg/person/year. Fluid milk market grew 2,3% per year, with a gradual replacement of raw and pasteurized milk by UHT milk. Income growth and better income distribution were the most important drivers for this growth. Since 1994, minimum wage grew 2x more than milk prices. From 2004 to 2013, salaries grew 72% over inflation, with 17 million new jobs created. Middle class expanded from 33% to 42% of total population. What are the challenges? Economic performance is lagging behind what Brazil experienced during the last decade and past income gains are being challenged. Also, more strict regulation regarding labeling and claims may negatively affect innovation. There have been milk quality problems, suggesting weak supply chain coordination. Productivity, production per farm, cost of production and overall farm efficiency also factors that need to be greatly improved. Anti-dairy groups are not an important factor yet, but there is a growing number of health professionals not recommending dairy products. Brazil is a large and still growing dairy market, but a more challenging environment demands a more active approach to ensure market expansion.

Key Words: consumption, markets, trend

ADSA Southern Section Symposium: Maximizing forage quality in the Southeast

215 Improving corn silage quality in the Southeast and throughout the United States. Donna M. Amaral-Phillips*, *University of Kentucky, Lexington, KY.*

Corn silage has been called the king of stored forages for good reason. Dry matter yields and milk production potential per acre consistently surpass other forage crops while allowing farmers to harvest large amounts of quality feed over a relatively short harvest period. Corn raised for silage can be used in combination with other forage crops to allow for the implementation of double or even triple cropping systems. Thus, increasing the number of dairy cattle supported by each acre of farmland and increasing utilization of nutrients applied to soils through manure applications (i.e., phosphorus). Seed companies have improved the genetics of corn hybrids used for silage, especially as they relate to NDF digestibility. These genetic improvements have increased the nutritional value of these crops, which is even more important under the extended heat stress conditions and resulting decreased dry matter intakes of the Southeast. Environmental temperatures in excess of 32°C and limited rainfall during tasselling and pollination decrease grain development in the corn plant, resulting in a lower energy crop and presenting challenges for meeting the energy needs of high producing dairy cows. Harvesting corn for silage at the proper dry matter content and particle size can affect packing density and quality of silage available at feedout. Starch digestibility can be improved with the proper use of kernel processors on silage choppers. Silage management at harvest and feedout also affects feed quality and dry matter losses.

Key Words: corn silage, forage, corn

216 The effect of forage quality on health and performance of dairy cattle. Adegbola T. Adesogan*, *University of Florida, Gainesville, FL.*

Forages constitute a major portion of the diet of dairy cattle; therefore, factors that affect forage quality can determine the performance and health of the cows. The quality of southeastern forages is relatively low because the prevailing high temperatures favor fiber deposition. This factor coupled with heat stress reduces the productivity of dairy cows in the southeast. Consequently, strategies that increase the quality and utilization of southeastern forages are needed critically. Though effective at increasing forage utilization, strategies like kernel processing and chemical treatment have not been widely adopted. Other approaches such as application of fibrolytic enzymes have given variable results but strategic supplementation with yeast or yeast culture is often effective. Recent studies have shown that milk production was increased by replacing conventional corn silage with shredlage, BMR hybrids or mutant hybrids with lower ferulic acid concentrations. Similar research is needed for other high yielding warm-season grasses adapted to the southeast. Forage-related factors that can reduce the performance and health of dairy cows can be classified as those occurring during the growth or storage of the forage. Compounds such as nitrates, glycosides and alkaloids can accumulate in growing forages during inclement weather or under inadequate management. In addition, forage stressors such as disease, hail, pests and lodging can result in mycotoxin contamination by invasive fungi, which can reduce milk production and safety. In addition, poorly managed silage can reduce milk safety and predispose cows to low milk production and diseases due to accumulation of harmful compounds like mycotoxins, nitrates and biogenic amines or pathogens like *Listeria*, *Bacillus*, *Clostridia* and molds. Microbial inoculants and chemical additives can increase forage preservation, prevent accumulation of harmful compounds and inhibit growth of pathogens but their effects on milk production by dairy cows have been variable.

Key Words: forage quality, milk, health

217 Warm season annual grasses for dairy cattle. J. K. Bernard*, *University of Georgia, Department of Animal and Dairy Science, Tifton, GA.*

Warm season annual grasses are commonly used by dairy producers in their forage programs for grazing, green chop, hay, or silage production. Most warm season annual grasses require less water to grow and are more drought and heat tolerant than corn. These characteristics along with improved varieties that have improved DM yield and higher fiber digestibility have increased the interest in their use for dairy cattle. The incorporation of the brown-midrib 6 gene (*bmr*) in varieties increases in fiber digestibility and energy to support production compared with non-*bmr* varieties. Warm season annuals grasses are susceptible to nitrate toxicity during drought conditions. Prussic acid toxicity is an issue for members of the sorghum family during early growth and after stress from frost. Of the warm season annuals, forage sorghum is used more frequently for silage production. It is susceptible to lodging, but new brachytic dwarf varieties have shorter internodes, reducing lodging potential while providing forage with greater leaf to stem ratio. Diets based on *bmr*-6 forage sorghum silage have supported milk yield comparable to that of corn silage based rations when balanced for fiber content. Pearl millet silage support similar DMI and milk yield, and higher milk fat percent compared with corn silage; however, other trials reported reduced ADG or milk yield when fed to growing heifers or lactating cows. Differing responses may be partially attributed to differences in fermentation of the silages produced from pearl millet, which is more challenging to ensile if water-soluble carbohydrate concentrations are low. Data on *bmr* sorghum-sudangrass are limited and suggest that these forages can support solids-corrected milk yield similar to that of corn silage-based diets. Warm season annual grasses can be effectively incorporated into forage systems for dairy cattle. Improved varieties, especially *bmr* varieties, can support acceptable milk yield.

Key Words: dairy cattle, warm season annual, milk yield

218 Forage systems for Southern dairy production. John G. Andrae*, *Clemson University, Clemson, SC.*

Forages are the major component of lactating dairy rations and make up an even greater proportion of replacement heifer and dry cow diets. Due to the wide range in climate, soils, irrigation availability, and cow management (i.e., confinement vs. grazing vs. hybrid systems), a "cookie-cutter" approach to designing forage systems for southern US dairy production is impossible. Consequently, forage systems are driven by local conditions and management preferences and often vary markedly even within a community. Traditional forage systems comprised of corn, alfalfa and/or small grains silage are common regionwide; however, rising fertilizer input costs and risks associated with drought and irrigation water have increased plantings of forage sorghum and pearl millet. Tropical corn hybrids, Tifton 85 bermudagrass, and adapted non-dormant alfalfa varieties have also improved silage and green chop options for confinement forage systems. Baleage as a production practice has increased the feasibility of harvesting high quality forage when traditional silage equipment is prohibitively expensive or where custom harvesters are unavailable. Grazing dairies have also recently increased some areas. Forage systems for these dairies vary depending on region and range from non-toxic tall fescue, alfalfa, bermudagrass and orchardgrass based perennial systems to annual systems including ryegrass, crabgrass, pearl millet and sorghum × sudangrass. Systems regionwide will be reviewed to provide an overview of their diversity and uses.

Key Words: forage, silage, grazing

219 Environment and crop management as determinants of forage yield and quality in the Southeast.

Gonzalo Ferreira*, *Virginia Polytechnic Institute and State University, Blacksburg, VA.*

After the summer and spring drought of 2012, increasing interest has emerged to use alternative species to maize (*Zea mays*) to produce forages in dairy production systems. Sorghum species (*Sorghum* sp.) are characterized for having greater water use efficiency, water potential, and transpiration and photosynthetic rates under drought conditions. In addition to this, sorghum shows higher turgor potential than corn at the same water status. Despite all these attributes, the land surface planted with corn for silage is substantially greater than that of sorghum for silage in the Southern region. Potential evapotranspiration is substantially greater in the Southern than in the Midwest region. Therefore, to minimize the adverse effects of drought and heat stress, in the Sothern region adequate crop management should be prioritized. Drought stress around silking diminishes kernel development by negatively affecting pollination, mainly through an increased anthesis-to-silking interval. Kernel development is also negatively affected when high temperatures (≥35°C) occur during the lag phase of kernel development. High temperatures immediately after silking limit starch accumulation within the kernels, and increases the rate of kernel abortion as well. Therefore, in regions with extended periods of temperatures greater than 35°C, choosing early maturity corn hybrids, or delaying planting date, should be considered to avoid drought and heat stress during silking and kernel development. Planting density can also affect yield of corn for silage, although this effect depends on the crop rotation system and time of harvesting. Corn silage yield increased at high corn planting densities when an extended fallow and abundant precipitations occurred during the crop cycle. However, no differences in corn silage yields were observed when different corn planting densities were used in more intensive (i.e., double-crop) rotation systems. The effects of corn planting density on nutritional quality are also dependent on environment, although these effects are likely dependent on harvesting time. In summary, adequate crop management strategies should be carefully considered to ensure and maximize yield and quality of corn silage in the Southern region.

Key Words: corn silage, drought stress, heat stress

ADSA-SAD (Student Affiliate Division) Undergraduate Competition: Dairy Production

220 The effects of heat stress on reproductive fertility: An effective solution.

Alexandra T. Lemus* and Peter J. Hansen, *University of Florida, Gainesville, FL.*

By virtue of its high metabolic heat production (4–5 times maintenance), the lactating dairy cow is very sensitive to heat stress. A rise in body temperature of 1–2°C can have negative effects on various aspects of reproductive function. Heat stress can reduce luteinizing hormone and steroid hormone secretion, alter folliculogenesis, disrupt oocyte quality and inhibit embryonic development. The net result is reduced expression of estrus and low fertility. Effects on oocyte quality take place over a broad time frame. The ovarian follicle requires about 4 mo to develop from the primary stage to ovulation. The effects of heat stress on the oocyte within the follicle can persist for as long as 103 d. This stress in turn alters the integrity of the follicle and consequently makes it more difficult for the fertilized oocyte to develop into a blastocyst. The newly formed embryo is also susceptible to maternal heat stress. After 2–3 d, however, the embryo becomes increasingly resistant to heat stress and by d 7, when embryo transfer is ordinarily performed, elevated temperature has little effect on the embryo. Still another effect of heat stress is the depression of estrus behavior where both the duration and the intensity of estrus decrease resulting in an increased percentage of missed estruses. The combined effects of reduced detection of estrus and reduced fertility after insemination result in lower conception rates during warm months. These negative effects of heat stress can be bypassed by incorporation of 2 reproductive technologies. Ovulation synchronization protocols such as Ovsynch allow farmers to predict the time of ovulation without the need for estrus detection. Fertility is improved when synchronization is performed in conjunction with embryo transfer. Embryo transfer bypasses causes of infertility due to loss of oocyte competence and damage of the early embryo due to elevated maternal body temperature. The d 7 embryo used for transfer has acquired resistance to heat stress; therefore, maternal heat stress no longer affects the embryo.

Key Words: fertility, embryo transfer, synchronization

221 Effects of colostrum and milk intake on future performance in dairy calves.

Katherine M. Kelly*, Donna M. Amaral-Phillips, and Jeffery M. Bewley, *University of Kentucky, Lexington, KY.*

The first 56 d of a calf's life are critical for improving future milk production. Doubling birth weight within the first 56 d increases future milk production. Colostrum harvested from the mother within 10 h after calving loses 27% of IgG (Jaster, 2004). Consuming 4 L of colostrum compared with 2 L improves average daily gain (ADG), which has a direct effect on milk production (Soberan et al., 2012). Insulin found in colostrum affects gut absorption and growth (Van Amburgh et al., 2011). Without immunity from colostrum, calves that are given antibiotics, due to illness, are 2.5 times more likely to die within the first 2 years of life (Soberan et al., 2012). Milk intake also affects ADG. Calf metabolizable energy (ME) requirement is about 2.34 Mcal/d for a 50 kg calf, to support maintenance. Conventional feeding systems provide the calf with reduced amounts of milk so the calf will began eating calf starter sooner. Conventional feeding systems provide the calf with enough ME for maintenance (Drackley, 2011). Higher intakes of whole milk provide the calf with enough dietary fat to support maintenance and growth (Van Amburgh, 2011). Increased growth increases milk production in Holstein calves during their first lactation and decreases age at first breeding (Khan et al., 2010). Through increased colostrum and milk intakes, milk yields and production life can be increased.

Key Words: calf performance, colostrum, milk intake

222 The effects of feeding heat-treated colostrum to dairy calves.

Rebecca N. Klopp* and Dale R. Olver, *Pennsylvania State University, University Park, PA.*

Heat-treated (HT) colostrum offers many benefits when fed to dairy calves. Calves are born agammaglobulinemic because the placenta does not allow antibodies to pass from the dam to the fetus. As a result, neonatal calves rely on passive absorption of antibodies from colostrum in the first few hours after birth to protect them from infectious diseases. The most prevalent of the colostral antibodies is IgG. This antibody is commonly used as an indicator to show that immunity through passive absorption was achieved. In the past, commercial pasteurizers were used to process both waste milk and colostrum, and they achieved temperatures of at least 63°C to reduce risks of microbial contamination from collection and storage. However, heating colostrum to this temperature reduced IgG concentrations and increased viscosity. Recent studies have demonstrated that heating colostrum to a lower temperature (60°C) for up to 120 min drastically decreased bacterial populations while still maintaining IgG levels and viscosity. Research also shows that calves have a reduced risk for illness when fed HT colostrum compared with fresh colostrum because the heat treatment process significantly reduces total coliform counts. Calves that are fed HT colostrum will more efficiently absorb immunoglobulins compared with calves fed unheated colostrum. Plasma samples taken from calves showed that IgG concentrations in calves that were fed HT colostrum increased by 18.4% with a 21% increase in apparent efficiency of absorption compared with calves fed fresh colostrum. Heat treating colostrum is a continually improving technique resulting in an increased rate of IgG absorption in dairy calves.

Key Words: heat-treated colostrum, calves

223 Rumen development in dairy calves.

Morgan Richard* and Cathleen C. Williams, *Louisiana State University, Baton Rouge, LA.*

At birth, a dairy calf's rumen is not yet developed physically or metabolically. Thus, the calf functions as a monogastric animal until 4 to 8 weeks of life. In order for a calf to transition to a ruminant, the rumen must be able to support fermentation. This development of the rumen is necessary for successful weaning and is primarily affected by dietary change. The rumen changes physically by increasing mass and growth of papillae. At birth, a calf's rumen is only 25% of the stomach capacity, but a mature cow's rumen can compose up to 80% of its stomach. The physical stimulation of feed in the rumen can cause increases in rumen weight and muscular development. However, physical bulk alone has not been proven to promote papillary development. When calves drink milk they stimulate the opening of the esophageal groove. This closure keeps milk from entering the reticulo-rumen and prevents fermentation in the rumen. Calves should be given free choice water to produce the liquid environment needed for microbial growth. Besides liquid and muscular

action, the ingredients needed in rumen development consist of bacteria, absorptive ability of the tissue and substrate. A newborn calf has a sterile rumen, but by 2 d after birth microbes are colonized. These microbes influence growth and development. The earlier dry feed and forage is given to calves, the earlier microbial development occurs. Higher rumen metabolic activity and increased Volatile Fatty Acid concentrations are a direct reflection of the nutrient substrate required for rumen microbes. The fermentation end products of butyrate and propionate are responsible for the growth of ruminal papillae. In conclusion, early consumption of dry feed develops the calf rumen physically and metabolically by promoting growth of rumen epithelium and mobility.

Key Words: dairy calves, rumen development

224 The effect of automated calf feeders on calf welfare. Kelly H. Leatherman*, David R. Winston, and Robert E. James, *Virginia Tech, Blacksburg, VA.*

The dairy calf usually spends its first 6 to 8 weeks in individual pens. The reasons for this practice are to provide individual calf care and to prevent disease. However, there is a push from consumers to consider the welfare of dairy calves by moving away from individually housed, limit fed calves to a system of group housed calves fed ad libitum. The inclusion of an automated calf feeder into a farm's calf rearing program would, if managed correctly, provide the opportunity to increase the overall welfare of dairy calves. Group housed calves tend to be more relaxed when introduced to new situations and are quieter during the weaning process as opposed to their individually housed counterparts (Vieira et al., 2010). By using automated calf feeding systems, calf growers can offer more milk, more often to calves. Calves on automated calf feeders with an ad libitum milk feeding program consume up to 10 kg of milk per day (Jensen and Weary, 2002) which is similar to how a calf would nurse if left with the cow. Calf growing programs that incorporate an automated calf feeder can greatly increase the welfare of pre-weaned calves though increased nutrition and reduced stress.

Key Words: automatic calf feeder, calf management

225 Effectiveness of DHIA herd testing frequency on management decisions and dairy herd performance. Lauren E. G. Clemency*, Kasimu Ingawa, Steven Washburn, John Clay, and Shannon Davidson, *North Carolina State University, Raleigh, NC.*

Statistical analyses indicate that more data points usually improve the reliability of results; hence the objective of this study is to test the hypothesis that higher testing frequency of a dairy herd by Dairy Herd Improvement Associations (DHIA) affects management decisions and herd performance. Higher frequency of DHIA testing provides more information that can be used to make management decisions, thereby enhancing the decision making process; consequently, resulting in improved dairy herd performance. DHIAs are a farmer-owned organizations originating in 1905 as Newaygo Dairy Testing Association, the first Cow Testing Association (CTA) in the US; it assumed its current name, Dairy Herd Improvement Association in 1927. Throughout its more than 100-year history, the core focus of DHIA has not changed from being the means for dairy cattle genetics improvement in the United States. Basically, dairy farm data are periodically collected on each cow and processed into reports which dairy farmers use to manage their herds. Such records include milk and fat weights, percent butterfat, milk fat price, reproduction parameters, weights of different roughages and grains fed, etc. Values of performance variables are computed to determine periodic profits or losses for each cow in the herd. The National DHIA reports a declining trend in DHIA dairy herd testing participation in the last 11 years; in 2004, about 25,077 dairy herds were on test compared with 17,875 as of 1/1/2015. However, number of dairy cows on DHIA test increased during the same period which indicates shrinking number of dairy farms but an increase in dairy farm size. The report also indicates the Holstein breed to be the predominant breed of DHIA testing. A preliminary study by Minnesota DHIA indicated a production increase resulted from a higher frequency of DHIA dairy herd testing, however, variation due to management approach was not considered. In this study, higher frequency of dairy herd DHIA testing resulted in more valuable herd management information and that management approach should be considered when analyzing how the information should be used to manage dairy herds.

Key Words: DHIA, testing, reports

226 Hyperkeratosis: A costly consequence of milking equipment. Kayla J. Alward* and Jillian F. Bohlen, *University of Georgia, Athens, GA.*

Milking a cow causes stress to the teats and damage that is normal, but that can become severe due to variations in cow genetics, management, and equipment. Problems with the teats can be assessed through teat conditioning and may be the result of regular milking or faulty equipment. One alteration of the teat due to milking is hyperkeratosis, which is a thickening of the skin that lines the teat canal, characterized by excessive keratin growth. This excessive growth leaves an area for bacteria to hide and breed, which cannot be sanitized, and increases the risk of mastitis or intramammary infections (IMIs). The severity of the hyperkeratosis is drastically increased due to milking equipment factors. Duration of milking or over-milking, milk flow rate, liner closed phase, vacuum level and the amount of time the cups are on the teats all contribute to hyperkeratosis. The total time that the milk flow rate is less than 1.0 kg/min per day is the main contributing factor to hyperkeratosis severity. Faulty milking equipment has the potential to further exacerbate issues with hyperkeratosis by exposing the teat end to a higher number of bacteria than normal. Once present, these IMIs decrease producer profits by reducing total milk production, increasing somatic cell counts, treatments, cull rates, and milk lost due to treated cows. Although average somatic cell count (SCC) has fallen in herds over the past 20 year, national estimates still cite a to $300 per cow per year loss to elevated SCC. Comprehensive teat assessment and milking equipment checks are an effective way to help minimize incidences of hyperkeratosis. Understanding how and when to do both may help producers to reduce profit loss to IMIs as a result of hyperkeratosis due to milking equipment.

Key Words: hyperkeratosis, milking equipment, mastitis

ADSA-SAD (Student Affiliate Division) Undergraduate Competition: Original Research

227 Use of green vegetative index maps to predict nutritional quality variation of corn silage. Eleonor L. Cayford*[1], Leyang Feng[2], Shao Yang[2], and Gonzalo Ferreira[1], *[1]Department of Dairy Science, Virginia Polytechnic Institute and State University, Blacksburg, VA, [2]Geography Department, Virginia Polytechnic Institute and State University, Blacksburg, VA.*

The objective of this study was to evaluate the use of remote sensing techniques to anticipate the nutritional variation of corn silage. Cornfields (i.e., fields) from 3 commercial dairy farms located in Pittsylvania, Montgomery, and Washington counties in Virginia were used. Fields had an approximate surface of 25, 10, and 54 ha, respectively. Landsat images were obtained from the US Geological Survey online EarthExplorer system for the months Apr to Sep from 2000 to 2014. The spatial resolution of the images is 30 m. Visual assessment of cloud contamination in and around the 3 fields was made using red band (R_{red}) and near infrared band (R_{nir}) imagery. Images were then made into subsets using the field boundaries to calculate the normalized difference vegetation index (NDVI). Normalized difference vegetation index maps were derived for all images as follows: $NDVI = (R_{nir} - R_{red})/(R_{nir} + R_{red})$. This NDVI equation produces values in the range from −1 to 1, where positive values indicate vegetated areas and negative values represent non-vegetated areas, such as water, clouds, or snow. The NDVI values for each pixel of all images were calculated under ArcGIS/Arcpy environment. Low, mid, and high NDVI values within a field were represented by red, yellow, and green pixels, respectively. Coordinates for a single red, yellow, and green area within each field were obtained. At harvesting time, each of the 3 selected areas within each field was reached using a GPS, and 3 samples composed of 8 plants were cut 15 cm above ground (3 areas × 3 samples = 9 samples per field). Whole-plants were weighed, chopped, mixed, and ensiled in bags for 60 d. Nutritional composition of corn silage was performed by wet chemistry. Data was analyzed as a randomized complete block design, where field and NDVI were blocks and treatments, respectively. Dry plant biomass was similar among NDVI areas (270 g/plant; $P > 0.39$). Concentrations of DM (28.3%; $P > 0.25$), ash (4.55; $P > 0.38$), CP (10.5%; $P > 0.29$), NDF (41.3%; $P > 0.49$), and ADF (25.3%; $P > 0.89$) did not differ among NDVI areas. In conclusion, differences in NDVI in cornfields did not correspond with differences in nutritional composition of corn silage.

Key Words: corn silage, nutritional variation, normalized difference vegetation index

228 Processed water and its effect on daily intake and growth in dairy calves. Patrick J. Neff*[1], Matt C. Claeys[1], and Tamilee D. Nennich[1,2], *[1]Purdue University, West Lafayette, IN, [2]Famo Feeds, Freeport, MN.*

There are potentially bacteria and minerals in well water that could reduce the growth and health of preweaned calves. The objective of this study was to determine the effects of providing dairy calves processed drinking water on calf growth, starter intake, and water intake, as well as determine the efficacy of a novel water processing system on water mineral levels. Sixteen Holstein heifers (49.9 ± 7.7 kg of BW) were assigned to 1 of 2 drinking water treatments in a randomized complete block design and blocked by birth date. Treatments were either conventional well water (CONV) or processed water using a novel processing system (PRO). Water was sampled 1×/mo for analysis of minerals. Calves were fed 1.9 L of a 22:20 milk replacer with 0.70 kg/d of powder being fed 2×/d and a 20% CP texturized calf starter. Body weights, hip width (HW), hip height (HH), and heart girth (HG) were measured every 2 wk. Calves began treatments at 2 wk, were weaned at 8 wk, and ended the study at 10 wk of age. Starter and water intake were determined daily. Data were analyzed as repeated measures using PROC MIXED in SAS with calf as the experimental unit. Water mineral content was similar between treatments with sulfates averaging 45.3 ppm in CONV and 35.0 ppm in PRO, chlorides averaging 14.0 and 11.7 ppm in CONV and PRO, respectively, total dissolved solids of 330.3 ppm in CONV and 259.3 ppm in PRO, and sodium levels of 6.3 for CONV and 5.0 ppm for PRO, respectively. In this study, growth results were similar for calves regardless of treatment. The average BW for calves over the study was 155.2 kg for CONV and 156.8 kg for PRO ($P = 0.63$) and ADG was 0.79 and 0.83 kg/d for CONV and PRO ($P = 0.43$), respectively. Starter intake for CONV averaged 1.2 kg/d and 1.3 kg/d for PRO ($P = 0.74$) with feed efficiencies averaging 1.01 kg starter intake/kg gain overall ($P = 0.86$). Average water intakes were 2.0 and 2.2 kg/d for CONV and PRO ($P = 0.50$), respectively. The HH averaged 89.9 cm ($P = 0.80$), HW averaged 20.9 cm ($P = 0.43$), and HGC averaged 96.5 cm ($P = 0.67$). In this study, both treatments showed similar results for water mineral levels, water intake, starter intake, and growth.

Key Words: dairy calves, water, growth

229 Calving detection in dairy cattle using a novel vaginal temperature device. Megan C. Hardy*, Denise L. Ray, Joey D. Clark, and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

Parturition detection and dystocia prevention represent major challenges to dairy farmers. A potential solution is a vaginal thermometer used to detect calving. The objective of this study was to assess the Vel'Phone vaginal thermometer (Vel'Phone, Medria, Chateaubourg, France) for calving prediction accuracy and to characterize temperature and behavior before calving time. Primiparous (n = 40) and multiparous (n = 55) Holstein cows were enrolled in the study, conducted at the University of Kentucky Coldstream Dairy from May 2013 to August 2014. The Vel'Phone thermometer was vaginally inserted into each animal before the expected calving date. Vel'Phone service provided text messages displaying daily temperature reports, as well as impending calving and thermometer expulsion alerts. The Vel'Phone collected temperature data to investigate precalving temperature decreases. Alert timing data were collected to assess the Vel'Phone's calving prediction ability. Video monitoring recorded calving time and behavior (Barn Cams, Oconomowoc, WI). The MEANS procedure of SAS 9.3 (SAS Institute, Inc., Cary, NC) was used to calculate the average time between impending calving alerts, expulsion alerts, and calving time. The FREQ procedure of SAS created alert-frequency distributions. The GLM procedure of SAS was used to assess the effects of calf weight, calf sex, parity, calving ease, and season on precalving temperature decreases. A gradual temperature decrease of 0.6°C was seen at 48 h before parturition. Calf weight, calf sex, parity, calving ease, and season did not have a significant ($P < 0.05$) effect on precalving temperature decreases. Results indicate temperature decreases 48 h before parturition and thermometer expulsion alerts could be useful in calving detection technology.

Key Words: vaginal temperature, calving detection, precision dairy technology

230 Consideration of *DGAT1* interactions with DNA markers improved genetic predictions .

Amber N. Gabel* and Chad D. Dechow, *The Pennsylvania State University, University Park, PA.*

DGAT1 is a major gene influencing yield in cattle with effect magnitudes that vary by breed, implying that *DGAT1* interacts with other parts of the genome. This study aims to determine whether consideration of interactions between *DGAT1* and single nucleotide polymorphisms (SNP) could improve the accuracy of genomic predictions for fat yield in Holsteins. The initial data set included 1,143 305-d fat yield records from 358 Holstein cows in 11 herds that were genotyped for *DGAT1* and 45,187 SNPs. A series of analyses included a random animal effect, a fixed *DGAT1* effect, a single fixed SNP effect, and a fixed interaction of *DGAT1* with the same SNP. This analysis was repeated for each SNP, 191 of which significantly interacted with *DGAT1* ($P < 0.05$). The significant SNP were then included in a single analysis and backward eliminated until a group of 41 significant *DGAT1* × SNP interactions remained. To evaluate whether consideration of the interactions improved genetic prediction, 5 data sets were created where all data from 2 to 3 herds was eliminated. Breeding values were subsequently estimated for those cows whose data were excluded. A sixth validation data set was created where data from the youngest cows was excluded. Four breeding values were estimated for each validation data set: EBVBASE (random animal effect only), EBVDGAT1 (EBVBASE plus DGAT1 effects), EBVSNP (EBVDGAT1 plus SNP effects), and EBVI (EBVSNP plus *DGAT1* × SNP effects). Validation models were more significant when 305-d yield was regressed on EBVI ($F = 37.41$) than on EBVSNP ($F = 14.03$), EBVDGAT1 ($F = 14.51$), or EBVBASE ($F = 0.84$) for the young cow validation data. Validation models were also most significant when 305-d fat yield was regressed on EBVI in 4 of the 5 validation groups where data were excluded from specific herds. Similarly, the correlation between EBVI and EBV from a full model with all data included was highest in 4 of the 5 herd validation analyses (mean = 0.48, range = 0.29 to 0.64) and for the young cow evaluation (0.54), whereas the lowest was always EBVBASE (range = −0.10 to 0.27). Consideration of SNP interactions with *DGAT1* may yield more accurate genomic predictions for fat yield.

Key Words: *DGAT1*, fat

231 Effectiveness of treating subclinical ketosis in dairy cows.

Albert J. Brown*[1], Maurice L. Eastridge[1], Leon D. Weaver[2], and K. J. Chapman[2], [1]*The Ohio State University, Columbus, OH,* [2]*Bridgewater Dairy, Montpelier, OH.*

Ketosis is a major metabolic disorder of dairy cattle in the United States. There are various viewpoints on whether it is cost effective to treat subclinical cases of ketosis (SCK) with propylene glycol (PPG) and dextrose in comparison to treating animals that become clinically ketotic. For this trial, there was a control group and 2 treatment groups. Control cows had <1.2 m*M*/L β-hydroxybutarate (BHBA) and did not receive treatment. Treatment 1 cows were deemed SCK, defined by a blood BHBA of 1.2 to 2.9 m*M*/L and received 250 mL 50% dextrose solution intravenously and 300 mL PPG orally for 3 d. Treatment 2 cows also were SCK (same criteria as Trt 1) but did not receive the PPG and dextrose. Cows with > 2.9 m*M*/L BHBA were not enrolled in the trial. To determine treatment, blood was drawn from the tail vein/artery at 4 d in milk (DIM) and tested for BHBA using a Precision Xtra Meter (Abbott Laboratories, Abbott Park, IL). NEFA and BCS (1 = thin, 5 = fat) were recorded −14 to −3 d prepartum. Data were analyzed using the PROC GLM procedure with repeated measures of SAS (2012), with significance at $P < 0.05$ and trends at $P < 0.10$. Prepartum NEFA were similar between Trt 1 and 2 but lower for control (316, 300, and 240 µEq/mL, respectively). BHBA at 4 DIM was similar for Trt 1 and 2 but lower for control (1.66, 1.69, and 0.70 m*M*/L, respectively), with a similar pattern at 11 DIM (1.34, 1.46, and 0.69 m*M*/L, respectively). BCS at 11 DIM was higher for Trt 1 cows (3.45) than control (3.33) and Trt 2 cows (3.31). Milk yield during the first 90 DIM was similar for control and Trt 1 cows (42.7 vs. 42.1 kg/d, respectively), but milk yield was lower for Trt 2 cows (41.2 kg/d) compared with control cows and tended ($P = 0.06$) to be lower than for Trt 1 cows. Cows with SCK postpartum were showing signs of altered energy metabolism prepartum. Treatment for SCK had minimal effect on BHBA, appeared to increase BCS, and tended to increase milk yield. Additional data on health events and cost of treatments will provide further evidence to the effectiveness of treatment of SCK.

Key Words: ketosis, subclinical ketosis, propylene glycol

232 Assessing the impact of bovine fecal contamination in water on health and management practices.

Sarah J. Thomsen*[1], Jillian F. Bohlen[1], and J. Brooks Crozier[2], [1]*University of Georgia, Athens, GA,* [2]*Roanoke College, Salem, VA.*

The objective of the experiment was to determine the survival and then relationship between *E. coli* O157:H7 and a bovine fecal marker in river water in a set of sequential experiments. Microcosms of river water and sediment were created in 500-mL sampling bottles. In the first module, *E. coli* O157:H7 was inoculated into water samples (125 mL sediment, 400 mL water); in another experimental setup, 1 g of dairy cattle manure was inoculated into the microcosms (150 mL sediment, 300 mL water). Both setups had control groups. Throughout a period of one week, samples were collected; on d 7, an initial sample was collected and all were shaken to represent a disturbance in the water and sampled again. All samples underwent DNA extraction and polymerase chain reaction, utilizing the specific markers *eae* gene in *E. coli* and bovine *Bacteroides* in the manure to indicate presence or absence. In both experiments, data supported presence of the desired markers after inoculation 24 h, but were absent by the end of the week. However, both experimental setups were also positive for the markers 2 out of 3 times in the samples when shaken after one week. This data supports the theory that markers remain present in the sediment even after one week. These data were then used to consider different management practices to better human and herd health, in addition to farm efficiency, with the hope to reduce fecal contamination into water sources. The goal of the experiment was to examine the survival of a harmful strain of *E. coli* and a bovine fecal marker. The bovine fecal marker was used as pathogenic fecal coliforms like *E. coli* can be transferred through bovine feces. This makes bovine feces not only a home but a mobile mechanism by which harmful and zoonotic pathogens may contaminate water supplies. These contaminations may be direct or by indirect sources such as runoff. These realities generate health concerns for both humans and animals with a need to minimize fecal deposition and access to water sources through best dairy management practices.

Key Words: *E. coli*, water, fecal contamination

Animal Behavior and Well-Being Symposium: Novel and multidisciplinary approaches to animal welfare

233 Opportunities and challenges of interdisciplinary approaches to quantifying welfare. Peter D. Krawczel*, *The University of Tennessee, Department of Animal Science, Knoxville, TN.*

There is a growing interest within the United States in ensuring management systems and strategies for animal agriculture are not only highly productive and cost efficient, but also provide for the welfare of animals raised within them. The benefit of this situation is the chance for an empirical approach to evaluating welfare across animal agriculture to make a valuable contribution to the public discourse. The overall objective of this presentation will be to address the challenges and opportunities to using interdisciplinary approaches to quantifying welfare. To narrow the scope of this paper, and provide a more cohesive narrative, examples from dairy production will be used to demonstrate the main concepts. The discussion of opportunities will focus on the interaction between traditional approaches to measuring welfare, such as behavior and productivity, and novel aspects of sleep, immune function, reproduction, or sociology. Sleep research on dairy cows provides a means to demonstrate how biologists, ethologists, and engineers can collaborate to redefine how the lying behavior of a dairy cow is assessed. Moving beyond ideas of immunosuppression and into the approaches to evaluate dysfunction of immune function may provide a more accurate assessment of the effect of a management strategy on a dairy cow or calf. End points commonly used to evaluation reproductive parameters, such as return to cyclicity in early lactation, could provide a means to evaluate the welfare of postpartum dairy cows. Finally, incorporation of sociologists provides a means to understand producers' attitudes toward disease, pain, housing, and other factors that can alter dairy cow welfare. The discussion of the challenges of engaging in a multidisciplinary approach will focus on pain mitigation and immune function. These areas will be used as examples of the difficulties that might be encountered when the collection of one response variable affects another.

Key Words: welfare assessment, multidisciplinary, dairy cow

234 Animal welfare as a source of confounding and variation in science. Amy L. Stanton*, *University of Wisconsin-Madison, Madison, WI.*

It has been well established that chronic stress has a negative impact on the welfare of animals under our care. From the stereotypic behaviors observed in high numbers in zoo and laboratory animals to the decreased milk let-down observed in roughly handled dairy cows the effect of housing and handling practices have been demonstrated clearly by the animals in our care. Although the impact of rough handling and barren environments have been studied many of the more subtle effects that are unique to animal science, especially non-traditional laboratory species, have not been examined as closely. The objective for this paper is to review the effect of common data collection systems and environments on management, behavior, and welfare of agriculture research animals and through this introduce a source of variation. The 3 R's of ethical animal science—Replace, Reduce, and Refine—are used to minimize the impact of research on animals and to reduce the number of animals used in research. Animal behavior and the associated welfare consequences may be sources of variation in many research studies. As an example, to collect physiological measures it is often necessary for animals to be housed in systems that vary greatly from non-research animals. These different housing and handling methods are not studied as extensively in animal agriculture and may be having more of a negative effect on welfare than expected. For this reason, it is important that we understand the effect that different research practices have on animals and accompanying research results. Many of our agriculture species are social animals that have evolved as a prey species. However, many studies require isolation and extensive human observation. Both of which alter animal behavior and welfare. Alternatively, measurement devices, such as feeding gates, may affect normal behavior. Differences in social dominance, prior experiences, and temperament can alter the ability of animals to learn to interact with these systems. For these reasons, an understanding of animal behavior is essential to minimize welfare effects and the accompanying variation in study results.

Key Words: welfare, behavior, research

235 Interaction between coping style/personality, social stress, and disease risk. J.M. Koolhaas*, *University of Groningen, Groningen, the Netherlands.*

Ecological studies in feral populations of mice, fish and birds start to recognize the functional significance of phenotypes that differ individually in their behavioral and neuroendocrine response to environmental challenge. Within a species, the capacity to cope with environmental challenges largely determines the individual survival in the natural habitat. Recent studies indicate that the individual variation within a species may buffer the species for strong fluctuations in the natural habitat. A conceptual framework will be presented that is based on the view that the individual variation in aggressive behavior can be considered more generally as a variation in actively coping with environmental challenges. Highly aggressive individuals adopt a proactive coping style, whereas low levels of aggression indicate a passive or reactive style of coping. Similar coping styles have now been identified in a range of species including cattle, pigs and horses. They can be considered as trait characteristics that are stable over time and across situations. Evidence will be presented that a proactive coping style is best in a stable environment; these animals heavily rely on predictions. Reactive coping is more suited to variable environmental conditions because it is characterized by a continuous use of environmental input. Because the 2 extreme coping styles are adapted to different environmental conditions, there is differential stress vulnerability. Serious health problems may develop when coping fails. Social stress studies show that proactive individuals are resilient under stable environmental conditions but vulnerable when outcome expectancies are violated. Reactive individuals are in fact rather flexible and seem to adapt more easily to a changing environment. The health consequences of this interaction between individual coping style and social environment will be illustrated with examples from the cardiovascular system and the immune system. It will be argued that understanding animal welfare and the individual vulnerability to stress related disease requires a fundamental understanding of the functional individual variation as it occurs in nature and the underlying neurobiology and neuroendocrinology.

Key Words: coping style, welfare, individual differentiation

236 Of nature and nurture: The role of genetics and environment in behavioral development. T. Bas Rodenburg*, *Behavioural Ecology Group, Wageningen University, Wageningen, the Netherlands.*

The behavioral characteristics of an individual are determined by its genes and by its physical and social environment. Not only the individual's early life and current environment is of importance, but also the environment of previous generations. Through epigenetic processes, stress in parents and even grandparents can translate in changes in behavioral and physical characteristics of the offspring. This can also result in an increase in damaging behavior, such as feather pecking in laying hens. We have recently shown that stressed flocks of laying hen parent stock lay smaller eggs and that the offspring that hatched from these eggs were more fearful and showed more severe feather pecking already at one week of age. This effect depended on the genetic background of the hens: it was much more pronounced in the white laying hens than in the brown birds. Apart from epigenetics, also maternal hormones excreted before egg-laying or during pregnancy have effects on behavioral development of the offspring. Recent studies even indicate that epigenetic and hormonal effects may go hand in hand, where parental stress leads to changes in gene expression in genes involved in hormonal responses. The environment in which an individual is born and in which it spends its first weeks of life also has considerable impact on behavioral development. Absence or presence of maternal care has been shown to have strong effects in laying hens: we found that maternal care resulted in birds that were less fearful and developed less damaging behavior when they were adult. In these experiments, we also studied effects of genetic selection on low mortality in group housing. We found that effects of selection on low mortality and of maternal care were additive in most cases, with birds selected for low mortality and reared with a foster mother having the best performance. This illustrates that in our approaches to breed and rear animals for good performance in group housing systems, an approach where genetic selection is combined with improvement of rearing and housing conditions of both parent stock and offspring has the largest chance of success.

Key Words: behavioral development, genetic selection, early-life environment

Animal Health: Swine health and transition cows

237 Protected sodium butyrate may reduce *Salmonella* spp. excretion in contaminated fattening pig farms. M. Puyalto*[1], R.C. Mainar-Jaime[2], S. Andres-Barranco[3], E. CREUS[4], and J. J. Mallo[1], *[1]Norel S.A., Spain, [2]Department of Animal Pathology, University of Zaragoza, Zaragoza, Spain, [3]Agrifood Research and Technology Centre of Aragon, Spain, [4]Agrofestiic S.L., Spain.*

The objective of this study was to assess the level of *Salmonella* shedding and exposure in a fattening unit when protected sodium butyrate was added to the diet of the pigs. The study was carried out in a commercial *Salmonella*-infected fattening unit (8 pens, 110 pigs). Feed with 70% sodium butyrate protected with vegetable fat (3 kg/t) was administrated to animals from 4 randomly selected pens throughout the whole fattening period (4 mo) (TG). Pigs from the remaining 4 pens were fed with regular diet without additive (CG). Individual serum and fecal samples were collected at 30, 60, and 90 d of fattening period and at slaughter. Bacteriology on fecal samples was performed following the ISO 6579:2002 protocol. Serum samples were analyzed by means of an indirect ELISA and 3 cutoff values were used (OD% ≥ 10, ≥ 20 and ≥ 40). Chi-squared analyses were performed to compare microbiological and serological results between groups at different time periods. A difference was considered significant when the one-tail P-value was ≤ 0.05. In addition, a repeated measures analysis was used to estimate differences in mean OD%, after taking into account sampling times and the interaction treatment × time. The levels of shedding were significantly lower for TG when compared with CG for all samplings but the second one (60 d). No significant differences between groups were observed when cut-off values of OD% ≥ 10 or %OD ≥ 20 were used. However, when OD% ≥ 40 was considered, significant differences in seroprevalence were observed for the sampling just before slaughter (CG 89.6% vs. TG 48%). Overall, a lower mean OD% value was observed for samplings at 60 and 90 d, and at slaughter in the TG (71, 66, and 46%, respectively) compared with the CG (88, 87, and 83%, respectively). The results indicate that the use of protected sodium butyrate at 3 kg/t may reduce the shedding of *Salmonella* spp. under this farm conditions, and therefore the risk of contact of the animals with this pathogen, as suggested by serological results.

Table 1 (Abstr. 237). Number of positive *Salmonella* animals/no. of total animals (% positive *Salmonella*)

Treatment	30 d	60 d	90 d	Slaughter
CG	19/29 (65.5%)	5/21 (23.8%)	7/21 (33.3%)	36/48 (75%)
TG	12/28 (42.8%)	2/21 (9.5%)	1/22 (4.5%)	29/50 (58%)
P (one-tail)	0.04	0.2	0.01	0.05

Key Words: *Salmonella* spp., sodium butyrate protected

238 Rapid cooling after acute hyperthermia alters intestinal morphology and may negatively affect pig health. J. S. Johnson*, A Sapkota, and D.C. Lay Jr., *USDA-ARS Livestock Behavior Research Unit, West Lafayette, IN.*

Heat stress (HS) reduces livestock welfare and productivity and can negatively affect pig health. The study objective was to determine the effects of 2 HS recovery methods (rapid vs. gradual cooling) on pig welfare after acute hyperthermia. In 4 repetitions, 36 barrows (88.7 ± 1.6 kg BW) were exposed to thermoneutral conditions (TN; n = 3/rep; 19.5 ± 0.1°C) for 6h, or HS (36.4 ± 0.1°C) for 3h, followed by a 3h recovery period of rapid cooling (HSRC; n = 3/rep; immediate TN exposure and water dousing) or gradual cooling (HSGC; n = 3/rep; gradual decrease in HS room temperature to TN). To evaluate heat dissipation, a thermal circulation index was calculated using gastrointestinal tract (T_{GI}), ambient (T_A), and skin (T_{SKIN}) temperatures collected every 15 min [TCI; $(T_{SKIN} - T_A)/(T_{GI} - T_{SKIN})$]. In repetitions 1 and 2, blood was collected at 60, 180, 210 and 240 min for lipopolysaccharide (LPS) analysis, and then pigs were euthanized at 360 min and duodenum, ileum and colon tissue was collected to determine intestinal morphology. HS treatment reduced ($P < 0.02$) TCI in HSRC (−0.69) and HSGC pigs (−0.64) compared with TN controls (1.31); however, during recovery HSRC reduced TCI ($P < 0.01$; 53.5%) compared with HSGC and TN treatments. In the duodenum and ileum, HSRC and HSGC treatment reduced villus height ($P < 0.01$; 29.4 and 21.1%, respectively) and increased crypt depth ($P < 0.01$; 56.9 and 32.2%, respectively) and villus width ($P < 0.01$; 30.5% and 32.5%, respectively) compared with TN controls. In addition, HSRC reduced duodenal and ileal villus height ($P < 0.01$; 27.6 and 38.2%, respectively) and increased crypt depth ($P < 0.01$; 43.8 and 35.2%, respectively) compared with HSGC pigs. While no colon crypt depth differences were observed for HSRC and HSGC pigs (156.8 µm), crypt depth was reduced ($P < 0.01$; 37.1%) in HSRC and HSGC pigs compared with TN controls. During HS, circulating LPS was similar for all treatments ($P < 0.57$; 56.2 EU/mL); however, during recovery HSRC pigs had increased circulating LPS ($P < 0.05$; 68.5 and 52.4%, respectively) compared with TN and HSGC pigs. In summary, rapid cooling after acute hyperthermia reduces heat dissipation capacity, damages intestinal tissue, and increases circulating LPS compared with gradual cooling.

Key Words: heat stress, pig, recovery

239 Mycotoxin-contaminated diets affect immunity parameters of piglets. Simone Schaumberger*, Sabine Masching, and Ursula Hofstetter, *Biomin Holding GmbH, Herzogenburg, Austria.*

Important aspects of more than one multi-mycotoxin in feed, are the synergistic and additive effects which may result in negative effects on immunity and liver health of animals. The aim of the feeding trial was to investigate the effects of a multi-mycotoxin contaminated diet on immune parameters and liver health in weanling piglets. Twenty-four female weanling piglets were randomly assigned to 2 groups with 12 piglets each. Piglets were assigned to a vaccination program including hog cholera, pseudorabies and foot and mouth disease. Naturally mycotoxin contaminated corn was used to prepare the feed. Groups were as following: negative control group (A) and a mycotoxin contaminated (ZEN 1183 ppb, DON 1740 ppb, FUM 988 ppb) feed group (B). Parameters evaluated included antibody titers for pseudorabies referred to as sample to negatives ratio (S/N 0.6 was defined as positive), plasma CD4+/CD8+, IL-2, TNF-α, IgA, IgG, IgM, total plasma protein (TP) and liver enzymes (ALT, AST). The ratio of S/N in group B was significantly higher compared with group A at d 42 ($P < 0.05$). There were no significant differences of plasma CD4+/CD8+ among the 2 groups. The plasma IL-2 levels of group B were significantly lower than group A at d 14, 28 and 42 ($P < 0.05$). The plasma TNF-α level of group B was significantly lower than group A at d 28 and 42 ($P < 0.05$). The IgA, IgG levels of group B were significantly lower than group A at d 28 and 42 ($P < 0.05$). There was no significant difference of IgM among the 2 groups. Plasma TP levels of group B were significantly lower than group A at d 14, 28 and 42 ($P < 0.05$). Liver enzymes AST and ALT of group B were significantly higher compared with group A at d 14, 28 and 42 ($P < 0.05$). To conclude, the combination of mycotoxins can damage the liver and impair immune response in weanling piglets. The decreased antibody titer against pseudorabies and the increase of S/N ratio in the group fed with mycotoxin-contaminated diet, suggests animal's decreased protection against pseudorabies when mycotoxins are present. This points to the need for greater awareness of a multiple mycotoxin contamination in feed and the protection of animals against said toxins.

Key Words: mycotoxin, piglet, immunity

240 Butyrate enhances disease resistance of piglets through up-regulated gene expression of endogenous host defense peptides.

Haitao Xiong*, Bingxiu Guo, and Yizhen Wang, *College of Animal Sciences of Zhejiang University, Hangzhou, Zhejiang, China.*

Dietary substances can manipulate the expression of endogenous host defense peptides (HDPs), which may provide a promising strategy for disease control and prevention, especially for antibiotic-resistant infections. We hypothesized that butyrate can induce HDP expression, which likely contributes to the elimination of *Escherichia coli* O157:H7 in the intestine and reduces the severity of inflammation caused by *E. coli* O157:H7 challenge. Piglets treated with or without butyrate (2 g/kg of diet) 2 d before *E. coli* O157:H7 challenge was employed to investigate the relationship among porcine HDP expression, status of inflammation and *E. coli* O157:H7 load in feces. The effects of butyrate on HDP gene expression, antibacterial activity of 3D4/2 macrophages and IPEC-1 cells, and phagocytic capacity of 3D4/2 and polymorphonuclear (PMN) leukocytes in vitro were also examined. Data were represented as mean ± SEM. One-way ANOVA or Student's *t*-test was used to compare differences between treatment groups, $P < 0.05$ was considered statistically significant. Results showed that butyrate treatment (1) alleviated clinical symptoms of *E. coli* O157:H7-induced hemolytic uremic syndrome and severity of intestine inflammation, (2) significantly reduced *E. coli* O157:H7 load in feces 24 h after the last inoculation ($P < 0.01$), (3) significantly upregulated multiple HDPs, such as pBD2, pBD3, PMAP23, PR-39, and PG1–5 ($P < 0.05$), but not all HDPs, in vitro and in vivo, and (4) enhanced the antibacterial activity of macrophage 3D4/2 and IPEC-1 and the phagocytic capacity of 3D4/2 and PMN cells in vitro. Our findings indicate that butyrate enhances disease resistance, promotes clearance of *E. coli* O157:H7, and alleviates clinical symptoms of hemolytic uremic syndrome and inflammation partially by affecting endogenous HDP expression.

Key Words: butyrate, *E. coli* O157:H7, host defense

241 The effect of antiseptic compounds on umbilical cord healing and infection rates in neonatal piglets from a commercial facility.

Amanda L. Robinson*, Jessica D. Colpoys, Glenn D. Robinson, Elizabeth A. Hines, Leo L. Timms, Erika M. Edwards, Kenneth J. Stalder, Anna K. Johnson, and Howard D. Tyler, *Iowa State University, Ames, IA.*

Umbilical cord antiseptics are often not used in swine production systems. The objective of this study was to determine if treating the umbilical cord with antiseptics reduces infection and enhances healing within the first 48 h after birth in newborn piglets. A total of 421 mixed sex commercial piglets from a breed-to-wean sow farm were enrolled. Piglets were alternately assigned by birth order within a litter to 4 treatment groups; (1) iodine (2%), (2) trisodium citrate (10%), (3) a dry dip created using an antibacterial peptide (nisin) mixed with talc, and (4) no treatment. All treatments were applied within 1 h of birth. At birth, stall conditions (wet/dry and clean/dirty) were evaluated on a 3-point scale (3 = most dirty or most wet and 1 = dry or clean). Prior to treatment, diameter of the umbilical cords (as an indicator of cord drying and healing) was determined using digital calipers. As a potential indicator of umbilical infections, surface temperature of the umbilical stump, along with a reference point at the midpoint of the sternum, was measured using a dual laser infrared thermometer. These measurements were repeated at 24 ± 1 h of age and at 48 h of age. In addition, umbilical stump redness and swelling (indicators of infection) were evaluated visually at 24 and 48 h. All data were analyzed using mixed model methods. Models included the fixed effects of umbilical diameter at birth, sex (female or male), stall conditions and treatment. No treatment differences were noted between dips on change in diameter of the umbilical cord during the first 24 h (6.60 ± 0.057 mm at birth vs. 3.25 ± 0.072 mm at 24 h). There was no difference in umbilical cord stump surface temperature, redness or swelling at 24 h or 48 h. Stall conditions at birth did not affect the change in umbilical diameter, surface temperature of the umbilical stump, or visual indications of infection. In conclusion, there was no benefit observed when applying an antiseptic treatment on piglet umbilical cords to improve healing or reduce the incidence of infections during the first 48 h of life.

Key Words: piglet, umbilical cord, antiseptic

242 Porcine hepcidin protects piglet intestinal epithelial cells by aggregating *Escherichia coli* K88.

Huahua Du*, Dan Liu, and Zhenshun Gan, *Zhejiang University, Hangzhou, China.*

Hepcidin is a liver-expressed iron-regulating hormone that also is an antimicrobial peptide. Though the iron regulatory function of porcine hepcidin (pHepc) has been extensively investigated, the studies on the relationship between pHepc and bacteria are limited. The aim of current study was to evaluate its antibacterial activity against *Escherichia coli* K88 (*E. coli* K88) and investigate the effect of pHepc on bacterial infection in vitro. The antibacterial activity against pathogen bacteria was evaluated via radial diffusion, colony forming count, transmission electron microscopy (TEM) and DNA binding assays. Invasion assay and immunofluorescence microscopy were employed to determine its effect on bacterial infection. The results showed that pHepc exerted an iron-independent bacteriostatic activity against *E. coli* K88 in a dose-dependent manner. pHepc-treated *E. coli K88* exhibited longer cells and cytoplasm unevenly distribution. To determine whether pHepc inhibited bacterial infection, piglet intestinal epithelial cells were challenged with pHepc-treated or untreated *E. coli* K88. The ability of pHepc-treated bacteria to invade IPEC-1 epithelial cells was impaired. pHepc significantly reduced 33.5% amount of *E. coli* K88 which adhered or invaded to cells ($P < 0.05$). Another human epithelial colorectal adenocarcinoma cell Caco-2 exhibited the same inhibition pattern by pHepc treatment ($P < 0.05$). By scanning electron microscopy (SEM), pHepc-treated *E. coli* K88 was aggregated, and higher magnification revealed a net-like meshwork of fibrils emanating from the bacterial surface that entangled the bacteria. It suggested that pHepc could afford protection against infection of *E. coli* K88 by a novel aggregation strategy, which will contribute broadly to piglet innate immunity.

Key Words: porcine hepcidin, *E. coli* K88, aggregation

243 Limited sun exposure increases 25(OH)D serum concentration and affects mRNA expression of the vitamin D enzymes in liver and kidney of growing pigs at high altitude.

Samanta R. Fensterseifer*[1], D. Enette Larson-Meyer[2], Bennett C. Ingold[2], Kathleen J. Austin[1], Kacey C. Myers[1], and Brenda M. Alexander[1], *[1]Department of Animal Science, University of Wyoming, Laramie, WY, [2]Department of Family and Consumer Sciences, University of Wyoming, Laramie, WY.*

Traditional confinement production management limits exposure of pigs to sunlight. With vitamin D primarily obtained from the diet, producers risk suboptimal vitamin D status. Ten weanling pigs (67.6 ± 6.1 kg; 76d ± 11) were randomly divided into control (CON, $n = 5$, traditional swine confinement) or sun (SUN, $n = 5$, exposed to one hour of sunlight at solar noon for 2-weeks during the summer solstice and fall equinox) groups. Blood samples were collected via cranial cava venipuncture before and after the 2-week sunlight exposure to determine serum concentration of 25-hydroxyvitamin D [25(OH)D]. Following fall sun exposure, pigs were slaughtered and liver and kidney tissue collected and frozen. Expression (mRNA) of vitamin D binding protein (VDBP), vitamin D receptor (VDR) and the enzymes CYP2R1 and CYP27B1 were determined. Serum 25(OH)D concentration did not differ ($P = 0.1$) before summer sunlight exposure (39.5 ± 2.6 ng/mL). Sunlight exposure increased ($P = 0.001$) serum concentration of 25(OH)D by 54.5% in SUN pigs during summer exposure, with 25(OH)D 87.5% greater ($P = 0.001$) compared with CON pigs (66.5 ± 4.8 vs 35.5 ± 2 ng/mL, respectively). Serum 25(OH)D concentration returned to CON values ($P = 0.3$) by the fall exposure period (45.1 ± 2.1 ng/mL). Following fall sun exposure, serum 25(OH)D concentration was again increased ($P < 0.001$) in SUN compared with CON pigs (80.8 ± 3.3 vs. 39.9 ± 3 ng/mL). CYP27B1 mRNA expression was decreased in kidney ($P = 0.03$) but increased in the liver ($P = 0.05$) of SUN pigs when compared with CON pigs. The relative mRNA expression of VDBP, VDR and CYP2R1 did not differ ($P > 0.05$) among pigs. In conclusion, 2-week sunlight exposure at high altitude during the summer solstice and fall equinox increases serum concentration of 25(OH)D and influences expression of CYP27B1 in kidney and liver of sun exposed pigs. Limited sun exposure enhances vitamin D status in confinement-raised pigs and may improve health and production outcomes dependent on vitamin D.

Key Words: vitamin D, sun exposure, pig

244 Relationship between left displacement of the abomasum and daily milk yield in high-producing Chilean dairy cows.

Pedro G. Melendez*[1], Catalina Romero[2], Maria P. Marin[2], Mario Duchens[3], Patrick Pithua[1], and Pablo J. Pinedo[4,5], *[1]University of Missouri-Columbia, Columbia, MO, [2]University Santo Tomas, Viña del Mar, Chile, [3]University of Chile, Santiago, Chile, [4]Texas A&M AgriLife Research, Amarillo, TX, [5]Texas A&M University System, College Station, TX.*

Left displacement of abomasum (LDA) is a metabolic disease affecting dairy cows within the first 30 DIM. Dairy farms in central Chile, consisting of Holstein cows maintained under confinement, use advanced technology including computerized record keeping systems. These farms have well-established postpartum health monitoring programs and LDA is regularly diagnosed. However, due to a scarcity of immediate veterinary assistance, many cows with LDA are treated conservatively by administering oral fluids, anti-inflammatory drugs and/or antibiotics. The hypothesis was that cows with LDA treated conservatively would produce less milk than cows with LDA treated surgically. The objective was to compare daily milk production among cows with LDA that received a conservative treatment, had surgery (right omentopexy or toggle suture) or were not affected (negative controls). Data between 2010 and 2012 from 4 high-producing dairies in Central Chile were analyzed. Cases ($n = 146$) were categorized as treated surgically (DAs, $n = 72$), treated with toggle suture (DAt, $n = 16$), or treated conservatively (DAc, $n = 58$). For each case, 2 healthy contemporary cows (controls) were selected at random and matched by farm, parity and DIM (±15 d; $n = 289$). A mixed model for repeated measures was developed for the analysis of daily milk yield up to 90 DIM with the corresponding covariance structure based upon the best goodness of fit criteria. The mean and median DIM for LDA diagnosis was 13 and 9 d, respectively. Average daily milk up to 90 DIM was 43.0 kg/d for controls, 30.4 kg/d for DAs, 30 kg/d for DAt, and 14.2 kg/d for DAc. Controls produced more milk than DAs, DAt, and DAc group ($P \le 0.01$). DAs and DAt produced a similar amount of milk ($P > 0.05$), but more milk than the DAc group ($P \le 0.01$). It is concluded that cows with LDA receiving conservative treatment produced substantially less milk than control cows (30 kg/d) and cows with LDA treated with surgery or toggle suture (16 kg/d). Furthermore, control cows produced more milk than cows with LDA treated with surgery or toggle suture (13 kg/d). In light of these results, it is recommended that all cows developing LDA should be treated surgically or with toggle suture.

Key Words: displaced abomasum, treatment

245 Comparison of hematological parameters in dairy cows during periparturient period.

Samir Kumar Dash*[1], Hemant Dasharath Kadam[1], Asmita Anant Kulkarni[1], Mohua Das Gupta[1], Narayan Laxman Phadke[1], and Arun P. Phatak[2], *[1]BAIF Development Research Foundation, Central Research Station, Uruli Kanchan, Pune, Maharastra, India, [2]Waterford, CA.*

The periparturient period ranging from 3 wk before calving to 3 wk after calving presents enormous physiological challenges for the dairy cows. It is a period that is affected by metabolic stressors, major changes in endocrine status and altered immune function which together results in an increased risk of diseases including hypocalcaemia, ketosis, hepatic lipidosis, laminitis, mastitis, retained placenta and metritis. The present investigation was undertaken in Central Cattle Breeding Farm, Central Research Station, BAIF, India to study the hematological changes in puerperal period in 30 cows of HF pure, JE pure and their crosses under tropical conditions to compare the Hgb, TLC and CBC/diff. count 10 d before and 10 d after parturition to assess the extent of metabolic changes, infection and stress. The results were analyzed using ANOVA. The study revealed a nonsignificant difference and decrease in the Hgb count from 11.41 ± 0.30 to 10.59 ± 0.30 which may be due to the increased blood supply to fetus and milk adipose tissues with hemorrhagic loss during calving. The TLC count displays a significant ($P < 0.05$) increase from 8.57 ± 0.39 to 10.00 ± 0.58 in postpartum period confirming the reports of previous studies which states that there is a decrease in immunity level due to stress and rise in infection. Neutrophil count increased from 47.03 ± 1.77 to 51.27 ± 2.14 nonsignificantly as the infection in postpartum period may rise. Eosinophil count, Lymphocyte and monocyte level did not reveal any significant changes. It can be concluded that due to lower hemoglobin, hemorrhagic stress and lower immunity due to rise in infection, the animal's health and production are always under threat; hence careful attention is required during the periparturient period.

Contd.

Table 1 (Abstr. 245). Blood parameters in Holstein cows 3 wk pre- and post-calving

Parameter	Hgb (g %)	TLC ($\times 10^3$)	Neutrophil (%)	Eosinophil (%)	Lymphocyte (%)	Monocyte (%)
Pre	11.41 ± 0.30	8.57 ± 0.39	47.03 ± 1.77	6.07 ± 0.43	44.03 ± 1.86	2.73 ± 0.17
Post	10.59 ± 0.30	10.00 ± 0.58	51.27 ± 2.14	5.57 ± 0.42	40.70 ± 2.18	2.53 ± 0.20
“F”	0.0572	0.0454	0.1299	0.5808	0.2494	0.5318

246 Characterizing the effect of feed restriction on biomarkers of leaky gut.

Sara K. Stoakes*[1], Erin A. Nolan[1], David J. Valko[1], Mohannad Abuajamieh[1], Jake Seibert[1], Maria V. Sanz Fernandez1, Patrick J. Gorden[1], Howard B. Green[2], Katie M. Schoenberg[2], William E. Trout[2], and Lance H. Baumgard[1], *[1]Iowa State University, Ames, IA, [2]Elanco Animal Health, Indianapolis, IN.*

Study objectives were to determine the magnitude of feed restriction (FR), which causes “leaky gut” and characterize the temporal consequences on production and blood variables. Twenty-three lactating Holstein cows (157 ± 46 DIM; 713 ± 54 kg BW; parity 2–4) were enrolled in 2 experimental periods. Period 1 lasted 5 d (ad libitum feed intake) and served as baseline for period 2 (P2), which lasted 5 d during which cows received one of 5 dietary treatments: 100% of ad libitum feed intake (AL; n = 3), 80% of ad libitum feed intake (AL80; n = 5), 60% of ad libitum feed intake (AL60; n = 5), 40% of ad libitum feed intake (AL40; n = 5), or 20% of ad libitum feed intake (AL20; n = 5). As the magnitude of FR increased, milk yield, MUN, and milk lactose content decreased linearly ($P < 0.01$) whereas milk fat content linearly increased ($P = 0.02$). Heart rate declined linearly with increasing FR ($P < 0.02$) while respiration rate declined similarly for all FR treatments ($P = 0.02$). Body weight loss increased linearly with increased FR ($P < 0.01$). Both plasma insulin and BUN decreased, whereas NEFA increased linearly with greater FR ($P < 0.01$). Lipopolysaccharide binding protein, haptoglobin, and serum amyloid A tended to increase linearly with increasing FR ($P = 0.09$, $P = 0.07$, $P = 0.10$, respectively). Circulating lymphocytes increased with increasing FR ($P = 0.04$). AL40 and AL-fed cows were killed to determine the effect of FR on intestinal histology. Jejunum villus width, jejunum goblet cell area, ileum height and ileum crypt depth were or tended to be reduced ($P = 0.03$, 36%; $P = 0.02$, 52%; $P = 0.06$, 22%; $P = 0.03$, 28%, respectively) in AL40 cows compared with AL controls. Liver weight tended to be decreased (15%; $P = 0.07$) in AL40 compared with AL cows. Liver fat and moisture percentages did not differ between treatments. In summary, FR tended to increase circulating acute phase proteins, which we speculate is due to an increase in leaky gut as demonstrated by the deterioration in intestinal architecture. Consequently, FR appears to be a simple and viable model to study intestinal integrity and barrier function.

Key Words: lipopolysaccharide, intestinal integrity, feed restriction

247 Neutrophil function is dysregulated over the transition period.

Mallory A. Crookenden*[1], Caroline G. Walker[1], Axel Heiser[6,5], Juan J. Loor[2], Kasey M. Moyes[3], Jane K. Kay[1], Susanne Meier[1], Alan Murray[5], Venkata S. R. Dukkipati[5], Murray Mitchell[4], and John R. Roche[1], *[1]DairyNZ, Hamilton, New Zealand, [2]University of Illinois, Champaign-Urbana, IL, [3]University of Maryland, College Park, MD, [4]University of Queensland, Brisbane, Queensland, Australia, [5]Massey University, Palmerston North, New Zealand, [6]AgResearch, Palmerston North, New Zealand.*

There is a high incidence of infectious and metabolic disease in the transition period. During this time, there is a period of observed immunosuppression that appears to be ‘natural’. The effect of parturition on neutrophil function is of particular interest; we hypothesized that neutrophil dysfunction occurs around the transition period, as evidenced by altered gene expression. To determine this, we extracted neutrophils from peripheral blood of 45 cows at 5 time points: 1 wk pre-calving (−1 wk), day of parturition (d 0), and post-calving at wk 1, 2, and 4. Key pathways of neutrophil function were investigated by qRT-PCR. The ‘bovine immune panel’ (BIP) included 96 targets for detection with Fluidigm 96.96 integrated fluidic circuits and the Biomark HD system. Data were analyzed using SAS 9.3; the effect of time was analyzed using a mixed model approach to repeated measures ANOVA and Tukey’s *t*-test for pairwise comparisons between weeks. Data were submitted for pathway enrichment analysis using the protein analysis through evolutionary relationships tool. The top 3 pathways enriched from gene targets on the BIP included inflammation signaling (14-fold enrichment, $P < 0.001$), apoptosis signaling (19-fold enrichment, $P < 0.001$), and interleukin/cytokine signaling (18-fold enrichment, $P < 0.001$). Biological processes enriched at −1 wk, d 0, and 1 wk post-calving included the immune system process, response to stimulus, and the immune response. The immune response process was most highly enriched (8-fold enrichment, $P < 0.05$) at 1 wk post-calving, which coincided with greatest NEFA concentration (1.08 ± 0.52) and, therefore, greatest NEB. No biological processes were enriched at 2 wk or 4 wk post-calving. Results indicate that the gene expression profile of neutrophils is altered over the transition period. This provides insight into neutrophil activity around parturition and the increased susceptibility to disease during this time.

Key Words: neutrophil, transition period, dairy cow

248 The effects of grain-induced subactue ruminal acidosis on blood plasma proteomic characterization in dairy cows.

S. C. Li*[1], A. M. Danscher[2], P. Azevedo[1], P. H. Andersen[3], P. Ezzati[4], J. A Wilkins[4], E. Khafipour[1], and J. C. Plaizier[1], *[1]Department of Animal Science, University of Manitoba, Winnipeg, Manitoba, Canada, [2]Department of Large Animal Sciences, University of Copenhagen, Copenhagen, Denmark, [3]Department of Clinical Sciences, Swedish University of Agricultural Sciences, Uppsala, Sweden, [4]Manitoba Centre for Proteomics & Systems Biology, Winnipeg, Manitoba, Canada.*

Subacute ruminal acidosis (SARA) resulting from excessive grain feeding to dairy cows is accompanied by an immune response and has been associated with impaired liver function and blood composition. We, therefore, investigated the proteome in blood plasma to discover potential biomarkers for SARA. Four lactating Danish Holstein cows were used in a study that included a 4-week control period followed by a one-week SARA challenge period. During the control period, all cows received a total mixed ration (174 g crude protein/kg DM; 192 g starch/kg DM; 6.28 MJ NE_L/kg DM) ad libitum. During the SARA period, 40% of the ration was gradually substituted with grain pellets (50:50 wheat:barley) within 3 d to induce SARA. This SARA induction diet was then fed for another 4 d. Rumen pH was monitored with indwelling pH probes to verify that cows had rumen pH lower than 5.6 for 3 h daily during the SARA induction. Blood samples were obtained from the jugular vein at 7 h post-feeding on d 4 before SARA induction and on the second of 4 SARA-induction days. The blood plasma samples were then processed for the enrichment of low molecular weight serum proteins using acetonitrile precipitation before mass spectrometry-based proteomic analysis on a nano-RPLC-MS/MS system. The analysis identified 14 high-confidence proteins with significant quantitative differences between control and SARA periods as defined by MS intensity, of which 9 were potential differentially expressed (PDE) proteins LASP1, TMSB4, and the precursors of KNG1, APOE, SERPINA3–8, CRP, SERPINF2, SERPIND1 and CATHL4 reportedly involved in acute phase response, cytoskeletal proteins, blood coagulation, cholesterol transport, liver disease, and innate immune defense molecules. Among these PDE proteins, LASP1 and the precursors of APOE, SERPINA3–8, SERPINF2, SERPIND1 and CATHL4 were upregulated and others were downregulated ($P < 0.05$). These results suggest that it may be possible to identify proteins that are differentially expressed during SARA. Studies are ongoing to validate the possible candidates and identify additional proteins for the understanding of ethological concepts of SARA.

Key Words: dairy cow, SARA, plasma proteome

Animal Health Symposium: Understanding and reducing the impact of various stressors on immune responses and health of cattle

249 Understanding what stresses a dairy cow and the effect on immunity.

Michael A. Ballou*, *Texas Tech University, Department of Animal and Food Sciences, Lubbock, TX.*

Dairy cows experience stress at many times in their life and these stressful events increase the risk for negative health and productive outcomes. A better understanding of what causes stress and the impacts on the immune system will aid in developing management strategies that either reduce stress or attenuate the risk for disease. Cows are creatures of habit and this consistency gives her control. Take away this control and the more stressed she becomes. Stress generally suppresses many inflammatory leukocyte, neutrophil, and lymphocyte responses that create holes in the immune system, which microorganisms capitalize on to cause disease. An early lactating dairy cow is a great example of homeorhesis, whereas she is able to adapt to a new physiological state and environmental conditions. However, when that change is abrupt and/or dramatic, such as parturition and initiation of lactation, the cow can become stressed because the adaptation lags. The metabolic demands during the initiation of lactation play a major role in the dysfunctional immune system, and the effects are likely both direct and indirect. Direct effects are considered if nutrient demands of leukocyte responses are not met / prioritized or an increase in a metabolite, such as NEFA or BHBA, inhibits leukocyte function. Another example of a direct effect would be the negative effect of hypocalcemia on neutrophil function. The indirect effects are considered the physiological adaptations that need to occur in the cow that causes stress because they are a significant deviation and happen abruptly. Since some of the stress during the transition period is unavoidable, the focus should be to limit microbial exposure and any additional stressors that may have additional negative effects on immunity. Some factors that can contribute to additional stress include: high stocking density, poor cow comfort, dirty environment, comingling cows and heifers, and poor feed and bunk management. It is called the transition period because many changes are occurring and this increases the risk for stress. The stressors are multifactorial; therefore, a systematic approach to improving transition cow health is required.

Key Words: dairy, health, stress

250 Stress, immunity, and management of calves.

Lindsey E. Hulbert* and Sonia J. Moisá, *Department of Animal Sciences and Industry, Kansas State University, Manhattan, KS.*

Despite many advances in management and housing of dairy calves, 1 in 10 US dairy heifers die before weaning. A better understanding of the internal and external stimuli that contribute to the calf's physiological and behavioral responses to stressors is needed to reduce the risk of morbidity and mortality. Feeding calves their first meal is crucial, as successful passive transfer reduces mortality by 60%. There appears to be sexually dimorphic immune and stress responses in young cattle, but more research is needed to determine if this is caused by human-bias for female calves. After that first feeding, 1 in 10 heifers and most bull-calves in the US are transported to specialized calf-raising facilities, yet there is a lack of information of the newborn calf stress response during transit and handling. Whether calves are raised off-site or at a calf-ranch, individual housing systems are commonly used in the US to reduce the risk of pathogen exposure and provide individual feeding and healthcare. However, there may be health, growth, and social benefits for calves in alternative systems that have increased space-allowance or group housing. Disbudding and castration are typically performed at an early age for dairy calves, during the pre-wean stage. These stressors often take place when the calf has decreased passive-transfer Ig and immunity is developing. There is limited availability of pain-mitigation through anesthetics and analgesics, but there is evidence that analgesics attenuate supressed leukocyte function during these procedures. Milk replacer (MR) and milk quality may alter immunity. Solid-feed intake is a primary measure for determining "weaning-readiness," but some MR formulas may influence the calf's oral behaviors before weaning, therefore alternate weaning-methods may need to coincide with alternate MR formulas. The calf's behavioral and stress response at weaning may influence its immunity during the transition from individual to group housing (commingling). Alternate commingling strategies and nutritional supplements may help with this transition, but more research is needed to explore feasible alternatives. Optimizing the calf's health and well-being at these early-stages may improve its long-term health and behavioral strategies.

Key Words: calves, stress, immunity

251 Effects of late-gestation heat stress on immunity and performance of calves.

Geoffrey Dahl*[1], Ana Monteiro[2], and Sha Tao[2], *[1]University of Florida, Gainesville, FL, [2]University of Georgia, Tifton, GA.*

Heat stress effects during lactation are well characterized and include reductions in dry matter intake, milk yield and metabolic shifts that reduce the efficiency of milk production. Similarly, when dry cows are heat stressed they experience lower intake, reduced mammary growth and compromised immune function that ultimately results in a poorer transition into lactation and lower milk yield. Recently, we have focused on the effects of late gestation heat stress on calf survival and performance, with a series of studies examining preweaning growth and health, and later reproductive and productive responses, in an attempt to quantify acute and persistent effects of in utero stress. Calves born to dams heat stressed when dry have lower body weight at birth, are shorter at weaning, and do not achieve the same level of weight or height accumulation to 12 mo of age observed in calves from dams that are cooled when dry. Some of the reduced growth may result from the lower immune status observed in calves heat stressed in utero, which begins with poorer apparent efficiency of immunoglobulin absorption and extends to lower survival rates through puberty. However, heat stressed calves also have permanent shifts in metabolism that may lead to greater peripheral accumulation of energy and less lean growth relative to those from cooled dams. Comparing reproductive performance in calves heat stressed versus those cooled in utero, we observe that the cooled heifers require fewer services to attain pregnancy and become pregnant at an earlier age. Tracking the milk production in calves that were heat stressed in utero versus those cooled in late gestation revealed a significant reduction of yield in the first lactation, approximately 5 kg/d through 35 weeks of lactation, despite similar bodyweight and condition score at calving. These observations indicate that a relatively brief period of heat stress in late gestation dramatically alters the health, growth, and ultimate performance of dairy calves. Thus, it is critical to effectively manage heat stress of dry cows to avoid negative effects on the calf.

Key Words: in utero heat stress, growth, health

252 Social stressors and their effects on immunity and health of periparturient dairy cows.

Ricardo C. Chebel*[1,2], Paula R. B. Silva[2], Karen Luchterhand[2], and Marcia Endres[2], [1]*University of Florida, Gainesville, FL,* [2]*University of Minnesota, St. Paul, MN.*

Management practices during the periparturient period have been the focus of much research recently because during this period immune function, metabolism and health of cows are severely challenged. Responses to stress are often classified as behavioral, immunological, neuroendocrine, and autonomic. In production systems, understanding all facets of stress response is important to correctly predict the consequences of stressors to the health and performance of animals and to prevent costly managerial changes that have minimal impact on animal well-being and performance. Common stressors faced by periparturient animals are: regrouping, stocking density, and, for nulliparous animals, commingling with parous animals. In conventional dairies, feeding strategies during the periparturient period often require several group changes during the most challenging period of an animal's life. Traditional weekly regrouping of prepartum cows increases competitive behavior at the feed bunk but it does not affect innate and adaptive immunity, metabolic parameters, health and production, as long as stocking density is not overwhelming and nulliparous and parous animals are housed separately. Stocking density of prepartum animals is often overlooked because these are non-productive animals. Although severe overstocking (200% of feeding space) of commingled nulliparous and parous pregnant animals produces important neuroendocrine and metabolic changes, when prepartum nulliparous and parous animals are housed separately, stocking densities of up to 100% of feed space do not seem to affect innate and adaptive immunity, metabolic parameters, and performance. In recent experiments, when animals were ranked based on feed bunk displacement, submissive animals were more likely to be diagnosed with metritis than dominant animals despite not presenting significant differences in metabolic parameters. With the advent of new technologies that monitor rumination, activity, and lying behavior, it may be possible to more easily identify submissive animals and create strategies to prevent diseases.

253 Metabolic and physiological stressors during the periparturient period and effects on immunity and health of dairy cows.

José E. P. Santos*, Eduardo S. Ribeiro, and Natalia Martinez, *University of Florida, Gainesville, FL.*

During early postpartum, high-producing dairy cows undergo a period of extensive tissue catabolism because of negative nutrient balance. Homeorrhetic controls assure that nutrients are partitioned to favor lactation at the same time that homeostasis secures survival. However, unrestrained metabolic disturbances often lead to diseases which, in turn, dramatically decrease both productive and reproductive performance. In early lactation, dairy cows are more susceptible to diseases, particularly those that affect the uterus, such as metritis, and the mammary gland, such as mastitis. It is thought that calving and the increase in nutrient demands with the onset of lactation affect the immune system causing a temporary dysregulation in immune function. Humoral and cellular immunity are usually depressed at the same time that inflammation is enhanced with parturition. Negative nutrient balance has been associated with compromised immune function in dairy cows, and low concentrations of glucose, insulin, and insulin-like growth factor (IGF)-1 associated with elevated concentrations of nonesterified fatty acids and ketone bodies can have disruptive and detrimental effects on immune cells. Reductions in blood concentrations of Ca and antioxidant vitamins that typically occur around parturition are also linked with impaired immune competence and increased risk of uterine diseases. Nevertheless, experimentally-induced negative nutrient balance alone have minor effects on the leukocyte function, does not seem to affect the clinical symptoms associated with an intramammary endotoxin infusion, and have minor effects on immunocompetence of cows challenged to develop mastitis. The disagreement between experimental models that use nutrient restriction to study negative nutrient balance and immunity and the observations of immunosuppression in periparturient dairy cows suggests that changes in immune function are complex; they likely involve nutritional imbalances associated with the physiological and endocrine state of the cow that leads to the dysregulation of the immune system and increased risk of diseases.

Key Words: dairy cow, health, immunity

Bovine tuberculosis (TB) and paratuberculosis (Johne's disease) Symposium: What we know and what we need to know

254 A three-year study of bovine tuberculosis in an enzootic area, the Nile Delta. Adel M. Talaat*[1], Hazem A. Abdelaal[1], and Essam A. Nasr[2], *[1]University of Wisconsin-Madison, Madison, WI, [2]Veterinary Serum and Vaccine Research Institute, Cairo, Egypt.*

Bovine tuberculosis (BTB) is a chronic infectious disease characterized by the formation of granulomatous lesions in organs, mainly lungs and lymph nodes. BTB is caused by slowly growing bacilli, mainly *M. bovis*. In developed countries, BTB in animals is significantly in decline with rates that reached down to <0.001% in cattle herds in the United States. In developing countries, BTB represent a major problem with a prevalence that could reach up to 10 to 15% of cattle herds in some parts of Africa. In Egypt, BTB transmission among animals and from animals to humans represents a major problem because of the complexity of animal husbandry and animal trade. In this study, our teams in both the United States and Egypt used the single intradermal comparative skin test (SICST) to examine the herd level prevalence of BTB in 5 different regions within the Nile Delta of Egypt. During the years of 2012–2015, several farms were visited where SICST was conducted on all animals in the herd alongside collecting all of the historical background of disease prevalence in these farms. As expected, farms with a known history of risky management behavior (e.g., introduction of new animals without testing, or not testing at all for BTB) were associated with high level of BTB prevalence that reached up to 45% in some herds. Interestingly, clinical health condition of animals and milk yield were not associated with the BTB herd-level prevalence. However, where BTB was enzootic, the highest percentage of SICST-positive animals (average 14%) were among the 6–12 mo of age while newly testing farms identified the highest percentage of SICST positive (60%) in animals above 24 mo of age. This result highlights the importance of periodical testing and intervention to control BTB in dairy herds. Overall, the prevalence of BTB among total number of 2799 examined animals was 7.3% during the 3 years screening project. Recommendation to reduce the BTB in these herds included the frequent testing of animals using SICST, especially before restocking of a dairy herd.

Key Words: bovine tuberculosis, prevalence, enzoology

255 Host genomics—What have we learned? Holly L. Neibergs*, *Washington State University, Pullman, WA.*

The study of the genomic variation in cattle has been undertaken to identify loci that allow the prediction of cattle susceptible to *Mycobacterium avium* ssp. *paratuberculosis* (MAP) infection. The application of this information is to assist in disease prevention through selective breeding of cattle that are less likely to become infected should MAP exposure occur. A genetic predisposition to MAP infection in cattle was established through differences in prevalence of MAP infection found across breeds and across sires. Heritability estimates for susceptibility to MAP infection have been computed from family and genomic studies and typically range from 0.01 to 0.18, although higher estimates have been reported. Candidate gene and genome wide association studies have both been used to identify the loci associated with MAP infection. Phenotypes of susceptible and non-susceptible cattle have been based on serum ELISA, milk ELISA, fecal culture, tissue culture, PCR of tissue or feces or a combination of these diagnostic methods. The disparity in the sensitivity of the diagnostic methods affects the reliability of the controls, and the stage of MAP infection at which the animal is diagnosed. These differences make comparisons across studies difficult, as genomic studies are sensitive to phenotypic differences. Consequently, few studies have identified the same susceptibility loci in independent cattle populations. This lack of agreement across studies is most likely due to small sample sizes (most studies have less than 500 cases and 500 controls), the lack of consistency in the definition of phenotypes, and the polygenic nature of the disease which could result in different genes having a different level of effect within and across breeds. Identifying loci associated with MAP infection offers a permanent preventative strategy to lower the prevalence of bovine paratuberculosis and to have a better understanding of the disease etiology. To obtain concordant results, larger studies with a consistent phenotype are needed and must be followed with independent validation and functional studies. This will allow genomic prediction to deliver its translational promise to assist in preventing MAP infection in cattle.

Key Words: host genomics, bovine paratuberculosis

256 Johne's disease and bovine tuberculosis: Updates on control and prevention. Scott J. Wells*[1], Kimberley L. VanderWaal[1], Catalina Picasso[1], Eva A. Enns[1], Meggan Craft[1], Federico Fernandez[2], Andres Gil[3], Julio Alvarez[1], Lucas Dominguez[1], and Andres Perez[1], *[1]University of Minnesota, St Paul, MN, [2]Ministerio de Ganadería, Agricultura y Pesca, Montevideo, Uruguay, [3]Facultad de Veterinaria, Universidad de la República, Montevideo, Uruguay.*

While improved understanding of within-herd transmission of *Mycobacterium avium* ssp. *paratuberculosis* through conduct of longitudinal herd control studies has led to identification of effective long-term herd control measures, between-herd transmission continues unabated in many cattle herds through movements. Cattle movements serve as one important contributor to transmission of *Mycobacterium bovis* between herds, pointing to the need to better understand the role of cattle movements in disease transmission. Although complete cattle movement and traceability information is not available in the United States, the origin and destination farms for cattle movements in some countries, such as Uruguay and Spain, are captured in official cattle traceability systems. This information can be critical to understanding the risk of disease spread in the endemic cattle populations, which could be adapted to improve understanding of transmission in US cattle. In Uruguay, while the prevalence of *M. bovis* in cattle has been low since implementation of an active surveillance program, multiple outbreaks were reported during 2011–2013. In our study, Uruguayan cattle movements were evaluated using network analysis to understand cattle flows and identify high-risk farms for surveillance and control. Farms represented nodes in the network, which were linked based on the frequency and number of cattle moved. The distribution of in-movements and out-movements from farms was severely right-skewed, and the 10% most highly connected farms accounted for 72–83% of cattle moved each year. In comparison, during the time when bovine tuberculosis was identified in Minnesota (2008 to 2011), 20% of farms performed 90% of the movements. This heterogeneity in movement patterns indicates that some farms are likely critical for disease spread. In Uruguay, farms that experienced outbreaks of *M. bovis* during this period engaged in substantially more movements than the population average. Results from these studies highlight the importance of collecting livestock movement data, and of integrating and coordinating actions for infectious diseases to understand the vulnerability of livestock trade networks to infectious diseases.

Key Words: bovine tuberculosis, cattle, movement

257 MDA outreach: Communicating for a change. Julia M. Smith*, *University of Vermont, Burlington, VT.*

If a veterinary practitioner has tried to persuade a client to take action and nothing happens, is the problem that the client did not listen well or that the practitioner did not communicate well? An understanding of a few communication and behavior change models can enhance one's ability to make change a reality. Key principles of risk communication and social marketing of behavior will be discussed in the context of controlling mycobacterial diseases of animals (MDA). Risk communication can be understood as the process of sharing information and opinion about something hazardous, where uncertainty is a characteristic feature of the risk. When addressing Johne's disease or bovine tuberculosis, the disease is the hazard and uncertainty is associated with disease progression, detection, and success of control strategies. An approach known as message mapping can be a useful tool when developing risk communication messages. According to Prochaska's stages of change model, the process of converting a decision-maker into a change-maker takes time and involves distinct changes in attitude toward doing something new or different. To have the most effective conversations, it is important to identify at what stage of change the decision maker is and to tailor one's key points accordingly. Selling someone on behavior change to prevent or control a disease is a lot like selling someone on buying the latest gadget. The Academy for Educational Development has developed a process for marketing behavior change using the BEHAVE framework. This framework involves asking a few more questions before developing a strategy designed to achieve a behavior change. The strategy guides the development of a marketing plan. An essential element of a BEHAVE-based marketing plan is prototyping and pre-testing messages and aspects of the plan. When practicing risk communication and social marketing of behavior, it is essential to actively listen to the client or potential change-maker. Converting a decision-maker into a change-maker makes all the difference in controlling diseases such as *Mycobacterium avium* ssp. *paratuberculosis* and *Mycobacterium bovis*.

Key Words: risk communication, stages of change, social marketing of behavior

258 Zoonotic potential of bTB and MAP—Nothing to worry about…right? Tim Bull*, *Institute of Infection and Immunity, St George's University of London, London, UK.*

The threat of mycobacterial zoonotic transmission (particularly bTB) has driven expensive eradication efforts and large culling projects. In the absence of reliable vaccines however, the cost and complexity of programs needed to secure eradication from domestic herds and wildlife maintenance reservoirs has had limited progress. Few have succeeded in eradication and some arguably increased transmission rates. As a result bTB and MAP remain prevalent in domestic animals and wildlife reservoirs. Given the opportunity and a favorable host susceptibility these mycobacteria can cause disease in humans. Acute bTB infection is a potentially life threatening disease clinically indistinguishable from tuberculosis. Pasteurization remains an effective defense reflected by the fact that most human bTB cases are either a result of direct animal contact or re-activation from an older latent infection. For MAP, the issue is less clear cut. Despite significant indications that MAP invades, is present and persistent in many humans and has the capacity in susceptible individuals to trigger inflammatory bowel conditions such as Crohn's disease, the role of MAP as a direct human pathogen is still not widely accepted. Worryingly MAP survives pasteurization and prevalence is such that viable MAP is now significantly present in retail and dried infant formula milk. If MAP is truly a human pathogen, current ineffectual MAP control methods are permitting an extensive, unchecked, worldwide, chronic exposure to humans, some of whom are susceptible to developing disease. Latency and persistence are important characteristics of mycobacterial disease evoking long term immunological influences promoting disease. These states have been difficult to quantitate due to dormant unculturable phenotypes. Better tests are needed but the likelihood is that the extent of bTB and MAP disease burden in humans is not yet fully evident. The threat from bTB and MAP to human health thus remains tangible. Only vigilance currently prevents many potential animal reservoirs becoming re-seeded. Failure to improve screening and eradication tools will continue to allow global spread, increase the risk of human exposure and ensure more trouble is in store.

Key Words: bovine tuberculosis, paratuberculosis, zoonotic potential

Breeding and Genetics: EAAP Genetics Symposium: Breeding for environmental sustainability

259 Breeding goals to deal with climate change and food security. Eileen Wall*, *Scotland's Rural College (SRUC), Edinburgh, UK.*

In today's world, livestock production systems need to deliver a secure supply of food (locally and globally) with ever increasing competition for resources (land, water, feed/food, energy). As the competition for resources increases, the costs of production can increase and therefore farmers are challenged to improve efficiencies within their systems with both short and long-term sustainability in mind, trying to balance the profitability of the farming system while minimizing any negativity externalities of that production system (e.g., greenhouse gas emissions (GHG), animal welfare, land capability). As with the rest of society, livestock systems also need to consider potential climate change impacts in their longer term management options. Climate change is expected to have detrimental effects on milk yield and quality, fertility and health, putting further pressure on the sustainability of the sector and introducing new challenges for breeding goals and animal welfare. As climate change advances, indirect effects of weather on wider agricultural systems will become more important. An animal's ability to 'cope' with extreme weather could be further compromised if climate change decreases the availability of these resources, as predicted. This would result in increased competition for the water and nutrients needed to maintain cows' production and fitness. Therefore, incorporating longer-term challenges in our livestock breeding goals (e.g., climate resilience, optimizing production within farming system) is a crucial and timely goal. This paper takes an interdisciplinary approach to quantifying the potential output from livestock systems (dairy and beef) under projected climate change. This will be extended to breeding goals that optimize productivity and climate resilience while meeting GHG targets and wider goals for animal health and welfare. The results could be used to provide solutions to key challenges limiting the efficiency, productivity and sustainability of the livestock sectors.

Key Words: breeding goal, climate change, livestock efficiency

260 Genomic selection for the high-hanging fruit in livestock breeding programs. Donagh P. Berry*[1], Yvette de Haas[2], Roel F. Veerkamp[2], Mike Coffey[3], and Mario P. L. Calus[2], *[1]Animal & Grassland Research and Innovation Centre, Teagasc, Moorepark, Co. Cork, Ireland, [2]Animal Breeding and Genomics Centre, Wageningen UR Livestock Research, Wageningen, the Netherlands, [3]Animal and Veterinary Sciences, SRUC, Easter Bush Campus, Easter Bush, Edinburgh, UK.*

Genomic selection has by now been adopted for most of the "low-hanging" traditionally measured traits in developed breeding programs. The benefit of incorporating genomic information into genetic evaluations, however, is greatest for economically important traits not routinely recorded and thus where only low accuracy of selection is being achieved using traditional approaches. Irrespective of species, difficult to measure traits (i.e., the high-hanging fruit) include feed intake and efficiency, environmental footprint, product quality, and animal health and disease. Options to develop genomic predictions for these high hanging fruits include (1) collation of (inter)national databases which in themselves are too small to achieve high accuracy of predictions, (2) exploitation of low-cost, easy to measure predictors, (3) development of an optimal reference population based on phenotypic and genomic diversity (and possible financial incentives or investment in collection of same), and (4) detection and exploitation of the causal mutations. A successful international initiative (gDMI) based on the collation of feed intake data from 9 countries in dairy cows concluded that exchange of phenotypic and genomic information can augment the accuracy of genetic/genomic evaluations. Such an approach should also be embarked on for other breeds and species. Steps should, however, be taken now in anticipation of such an initiative including the exchange of germplasm between research centers or the use of a pan-global list of sires. Maximizing phenotypic and genomic diversity (within the constraints of relatedness to the candidate population) could improve the accuracy of genomic predictions; whole populations could be screened using low-cost predictor traits (e.g., sensors, mid-infrared spectroscopy) and divergent animals collated to a centralized unit for deep phenotyping. Combining transcriptomic and genomic data could aid in the detection of causal mutations. Successful genomic selection will also require a re-evaluation of current phenotyping strategies and may include measurements on the parents themselves (e.g., feed intake on bulls) as currently undertaken in other species or half-/full-sibs (e.g., deliberate infection with pathogens).

Key Words: genomic selection, phenotype, breeding scheme

261 Statistical approaches to increase resilience of animals towards environmental challenges and to increase homogeneity of animal products. Han A. Mulder*[1], Ewa Sell-Kubiak[1], Juanma Herrero-Medrano[1,2], Pramod K. Mathur[2], and Egbert F. Knol[2], *[1]Animal Breeding and Genomics Centre, Wageningen University, Wageningen, the Netherlands, [2]TOPIGS Norsvin BV, Beuningen, the Netherlands.*

In animal husbandry, there is a growing demand for animals that need less labor and are capable to handle diseases or other environmental challenges. For various markets, homogeneity of animal products is desired and uniform animals would ease management, e.g., less fluctuation in production in spite of challenges. Furthermore, due to globalization of breeding programs animals need to be capable to perform in a wide range of environments. Here we show 2 statistical approaches that can be used to breed for resilience and uniformity: a reaction norm model to breed for resilience and a double hierarchical generalized linear model (DHGLM) to breed for uniformity. Both were applied to reproduction traits such as total number of born piglets and number of piglets born alive in sow lines. For the reaction norm model, we first developed a challenge load indicator to estimate the level of challenge, based on drops in production. Subsequently, we used this challenge load indicator as a covariate in the reaction norm analysis. We found genetic correlations of 0.5–0.85 between healthy and diseased periods indicating substantial reranking of animals, or in other words genetic variation in resilience. We applied a DHGLM to total number born and found substantial genetic variation in residual variance of litter size with a genetic coefficient of variation at variance level of 0.17. Using deregressed variance EBV, we found a few highly significant genomic regions affecting the variance of litter size. These genomic regions could be utilized in genomic selection. Both statistical approaches can yield breeding values that could be used to select for increased resilience and uniformity of animal production. Due to its low heritability, accuracies of breeding values for resilience and uniformity are low, though substantial genetic variation is present. Accuracy of breeding values for these traits can be enhanced by genomic selection.

Key Words: statistical modeling, resilience, uniformity

262 The role of sustainable commercial pig and poultry breeding for food security.

Pieter W. Knap*[1], Anne-Marie Neeteson-Van Nieuwenhoven[2], and Santiago Avendaño[2], [1]*Genus-PIC, Schleswig, Germany,* [2]*Aviagen, Newbridge, UK.*

The worldwide demand for animal products is increasing: global meat consumption is projected to double in the coming 35 years. At the same time, availability of resources such as land and water are decreasing. This requires livestock production to increase its productivity and its reproductive efficiency, and to reduce its environmental impact. Animal breeding must support this. Livestock breeding goals should then broaden in a balanced way, focusing on productivity and efficiency, subject to certain external constraints and internal restrictions. External constraints are due to feed availability and environmental load (which calls for genetic improvement of livestock feed efficiency, reproductive efficiency, gross production levels, and liveability), and to animal welfare (which calls for genetic improvement of liveability, adaptability and health). Internal restrictions are due to genotype by environment interaction (which calls for data recording at the producer level and using those data for genetic evaluation at the nucleus level), antagonisms between traits (which calls for wide data recording and balanced breeding goals incorporating all possibly antagonistic traits), and selection limits (which calls for proper strategies for restriction of inbreeding rate, and optimization of genetic contributions and mate allocation within populations). Commercial poultry and pig breeding goals have been evolving in that direction since the 1950s, and this logically extrapolates toward a shift of focus on animal robustness, feed efficiency, and product quality traits. At the same time, selection technology is becoming more powerful at a very fast rate, mainly due to molecular genetics tools. As a result of both these developments, animal breeding can make an increasing contribution to sustainable food security.

Key Words: food security, pig breeding, poultry breeding

Forages and Pastures: Grasses and silages

263 Maturity is a larger driver of fatty acid content in summer annuals than nitrogen fertility.

Caleb P. Goossen*, Sidney C. Bosworth, Heather M. Darby, and Jana Kraft, *University of Vermont, Burlington, VT.*

Summer annual forages are a potentially important supplement for summer grazing. The C_4 photosynthetic pathway allows increased mid-season growth relative to C_3 perennial pasture. Maximizing grazing availability is important to I) producers seeking to optimize the fatty acid content of their dairy products, and II) organic dairy producers that must satisfy the National Organic Program 30% minimum pasture rule. Although total fatty acid (FA) and polyunsaturated fatty acid (PUFA) content responses to nitrogen (N) fertility and harvest timing have been considered in C_3 forage species, to our knowledge no studies have enumerated the FA profiles of summer annual forage species. This experiment was conducted over two years (2013 and 2014) at two Vermont locations (loamy sand and silt loam, respectively) to assess the effects of N fertility and harvest timing on total FA and PUFA content of sudangrass (*Sorghum* × *drumondii* 'Hayking'*)* and pearl millet (*Pennisetum glaucum* 'Wonderleaf'). The experiment was a split-plot design, with harvest height whole plot treatments (60 cm vs. 90+ cm) and N fertility sub-plot treatments (39, 79, 118, and 157 kg N/ha). A measure of leafiness—the proportion of leaf blades relative to the entire plant as dry matter (DM)—was recorded, as most FA from vegetative forages are found in chloroplast thylakoid membranes. At both locations in 2013, harvests at 60 cm instead of 90+ cm resulted in higher total FA concentration (17.2 vs. 12.6 g/kg DM, $P < 0.001$) and a greater proportion of PUFA (62.3 vs. 57.7 g/100g total FA identified, $P < 0.001$). At the loamy sand location however, both total FA and PUFA effects of harvest height were present only in sudangrass (interaction effect, $P < 0.0001$). The loamy sand location was the only to show a sub-plot effect of increasing N fertility, with a total FA gain of only 1.9 g/kg DM from the lowest N level to the highest ($P = 0.0478$). Leafiness was positively correlated with PUFA content in sudangrass and pearl millet (r = 0.645 and 0.503, respectively). PUFA and total FA content of summer annual forages are primarily driven by maturity. Nitrogen fertility effects were confined to the low fertility soil location.

Key Words: summer annual forage, PUFA, n-3 fatty acid

264 Effect of grazing seedhead-suppressed tall fescue pasture on the vasoactivity of serotonin receptors.

James L. Klotz*[1], Glen E. Aiken[1], Amanda M. Egert[2], and David L. Harmon[2], [1]*USDA-ARS, Forage-Animal Production Research Unit, Lexington, KY,* [2]*Department of Animal and Food Sciences, University of Kentucky, Lexington, KY.*

Previous research has demonstrated that exposure to ergot alkaloids reduces vasoactivity of serotonin (5HT) receptors. Chemical suppression of tall fescue seedhead production is a tool to reduce the level of exposure to ergot alkaloids by a grazing animal. Therefore, the objective was to evaluate contractility of lateral saphenous veins biopsied from mixed breed steers following a 87–101 d grazing period on 3-ha pastures of bermudagrass (BG; n = 5; 340 ± 9 kg), or standard endophyte-infected tall fescue that was not sprayed (UNSUP; n = 5; 300 ± 6; 0.56 ppm ergovaline) or sprayed (SUP; n = 5; 294 ± 9 kg; 0.24 ppm ergovaline) with herbicide containing aminopyralid and metsulfuron-methyl (Chaparral; Dow AgroSciences). To evaluate contractility, biopsied veins were mounted in a multimyograph and exposed to increasing concentrations of a tall fescue seed extract (EXT; ergovaline source); and $5HT_{1B}$ (CP9), $5HT_{1D}$ (L), and $5HT_{2A}$ (TCB) agonists. All contractility data were normalized to a maximal response of 1×10^{-4} M norepinephrine and were analyzed as a split plot treatment design using SAS for effects of pasture treatment, agonist concentration, and the interaction. There was no contractile response to any concentration of CP9 in any of the pasture treatments. There were pasture × concentration interactions for contractile responses to TCB ($P < 0.01$) and EXT ($P < 0.01$). For both EXT and TCB, BG veins were more vasoactive to the higher concentrations ($P < 0.05$) and there were no differences between UNSUP and SUP veins. There was also a pasture × concentration interaction for the contractile responses to L ($P < 0.01$). However, these responses were not sigmoidal and reached a zenith at 5 × 10–7 and 1 × 10–6 M. At these concentrations, the response was greatest for UNSUP ($P < 0.05$) and did not differ between SUP and BG veins. Although lower levels of ergovaline in SUP pastures did not alter vasoactivity of $5HT_{2A}$ or $5HT_{1B}$ receptors in the lateral saphenous vein, elevated vasoactivity of $5HT_{1D}$ in UNSUP veins suggests that lower ergovaline levels in SUP pastures reduces the vascular effects of ergot alkaloids at this receptor.

Key Words: ergot alkaloid, cattle, serotonin receptor

265 Microbial count, fermentation, and aerobic stability of regular- and brown midrib-corn hybrids ensiled with and without a combo inoculant.

Juan J. Romero*[1], Yuchen Zhao[2], Youngho Joo[3], Jinwoo Park[3], Marco A. Balseca-Paredes[1], Adam J. Heitman[1], and Miguel S. Castillo[1], [1]*Department of Crop Science, North Carolina State University, Raleigh, NC,* [2]*Department of Animal Nutrition and Feed Science, China Agricultural University, Beijing, China,* [3]*Department of Animal Science, Gyeongsang National University, Jinju, Korea.*

The objective was to evaluate the effects of a combo inoculant on microbial count, fermentation, and aerobic stability of 4 hybrids of corn. Treatment design was the factorial combination of 4 corn-types ensiled with (INO) and without (CON) inoculant. Corn-types were TMF2R737, F2F817 (A and B, respectively; from Mycogen), P2089YHR, and P1449XR (C and D, respectively; from Pioneer). The NDF digestibility of A and C conventional hybrids was ~56.5% compared with 65.5% for B and D brown midrib hybrids. The inoculant added contained *Lactobacillus buchneri* and *Pediococcus pentosaceus* (4×10^5 and 1×10^5 cfu/g of fresh corn). Experimental design was a complete randomized block design (3 field blocks) with treatments replicated 2 times (2 plots) within blocks, for a total of 16 experimental units within block. Corn from each plot was chopped, treated or not with inoculant, packed into 7.6L bucket silos, and stored for 100 d. At d 0 there were differences due to hybrids solely. The %DM was 44.0, 38.3, 42.1, and 41.3 for A, B, C, and D, respectively; lactic acid bacteria (LAB) count (log cfu/g of fresh corn) was greatest and similar for B and D (7.7) compared with A (6.7) and C (7.1 ± 0.07); yeast count was greatest in D (6.8 vs. 6.6 ± 0.02) and mold count was lowest in C compared with the others (5.7 vs. 5.9 ± 0.05); and pH was higher for A (5.81) vs. C (5.60) and D (5.70), but B (5.79 ± 0.04) was only higher than C ($P \leq 0.05$). At opening, INO increased LAB (from 6.2 to 6.6 ± 0.08) and pH (from 3.80 to 4.02 ± 0.01), and decreased yeast (from 5.10 to 3.74 ± 0.18, $P \leq 0.05$) compared with CON. Aerobic stability (h) was extended by INO compared with CON (181 vs. 35 ± 1.1) but to a lesser extent for B (73 vs. 36 ± 1.2; $P \leq 0.05$). The DM recovery (%) was higher for A (95.8) vs. B (93.4) and D (93.1), but C (95.0 ± 0.6) was only higher than D (P

≤ 0.05). The results indicate that corn-hybrid had an effect on %DM and DM recovery, and that the combo inoculant used improved silage conservation to different extents depending on hybrid type.

Key Words: corn, microbe, inoculant

266 In vitro digestion kinetics of NDF from stockpiled Tifton 85 bermudagrass as influenced by N fertilization.

Samantha R. Sechler*, Courteney M. Holland, Carla J. Weissend, Mary K. Mullenix, and Russell B. Muntifering, *Auburn University, Auburn, AL.*

Productivity and nutritive value of stockpiled bermudagrass are influenced by N fertilization and environmental conditions. Intake of forage DM and DE are highly correlated with kinetics of NDF digestion; yet, NDF digestion kinetics of stockpiled bermudagrass have not been extensively investigated. Therefore, a study was conducted to evaluate effects of N fertilization and seasonal changes in nutritive value on NDF digestion kinetics from stockpiled bermudagrass. Replicate (n = 2) pastures of Tifton 85 bermudagrass were cut on Aug 1 and fertilized with 56 (56N), 112 (112N) or 168 (168N) kg N/ha. Stockpiled forage was sampled monthly beginning on Oct 24, 2012 and analyzed for kinetic parameters of NDF digestion using in vitro fermentation. Undigested NDF residues were recovered at 3, 6, 9, 12, 18, 24, 48 and 72 h of incubation. Potential extent of NDF digestion was assumed complete at 72 h. Rates of NDF digestion were determined by least-squares regression of ln % potentially digestible NDF remaining vs. time; solution of the first-order kinetic equation to equal 100% potentially digestible NDF remaining yielded estimates of lag time. Data were analyzed as a completely randomized design using the PROC MIXED procedure of SAS 9.2. No N fertilization × sampling date interactions ($P > 0.05$) were observed for any kinetic parameters measured. Potential extent of NDF digestion was greatest ($P < 0.05$) in Oct (75.6%), least ($P < 0.05$) in Jan (47.8%), and intermediate but not different ($P > 0.05$) between Nov (61.1%) and Dec (59.0%). Potential extent of NDF digestion was greatest ($P < 0.05$) for 168N (63.2%) and least ($P < 0.05$) for 56N (58.8%). Rates of NDF digestion were not affected ($P > 0.05$) by N fertilization, but were greater ($P < 0.05$) in Oct (0.069 h^{-1}) and Nov (0.068 h^{-1}) than in Jan (0.063 h^{-1}). Lag time was less ($P < 0.05$) for the 168N (7.3 h) than 56N (9.1 h) and 112N (8.8 h) treatments. Lag time was least ($P < 0.05$) in Oct (6.0 h), intermediate ($P < 0.05$) in Jan (7.8 h), and greatest but not different ($P > 0.05$) between Nov (10.5 h) and Dec (9.4 h). Potential extent of NDF digestion was the kinetic parameter most affected by N fertilization and seasonal changes in stockpiled Tifton 85 bermudagrass.

Key Words: bermudagrass, digestion kinetics, neutral detergent fiber

267 Variation in aerobic stability of maize silage with and without microbial inoculant.

Ida K. Hindrichsen* and Nina Milora, *Chr. Hansen A/S, Hørsholm, Denmark.*

Forages to be ensiled for subsequent feeding to dairy cows are often contaminated with spoilage microorganisms that negatively affect feed quality and feed safety. Aerobic instability due to these spoilage organisms can cause heating and significant DM loss. *L. buchneri* improves aerobic stability, but because it grows slowly it is often combined with homofermentative strains to achieve a fast reduction in pH early in fermentation. Efficacy of silage inoculants can vary depending on forage type, harvest time, management etc. In the current study it was aimed at keeping the experimental conditions equal between experiments and to test the efficacy of a dual-purpose silage inoculant. Three samples of chopped whole maize were collected from farms in 2012 and 2013 on the day of harvest. Aerobic stability, microbial population and dry matter loss of the maize was measured using the same methodology. Briefly, maize was inoculated with a combination of *L. buchneri* and *L. lactis* (150,000 cfu/g) or pure tap water and allocated into 1 kg bags, vacuum packed and stored for 15 weeks at 25°C. Then silage was placed in a polystyrene container (1.2 L; 274 kg/m^3) with 1 cm diameter hole in top and bottom. The change in temperature was recorded continuously for 6.5 d using a data logger placed in the middle of each sample. Results showed that the pooled freshly harvested maize was very similar in microbial composition between the farms and years. All samples were highly contaminated with yeast and mold, while epiphytic total lactic acid bacteria were lower than the inoculated. The effect of the silage inoculant varied considerably among the 3 maize samples. Acetate concentration after 15 weeks of anaerobic fermentation was significant ($P < 0.05$) for all inoculated samples compared with control. The aerobic stability varied considerably between the different control samples (46 h, 75 h, >156 h). Inoculation significantly increased ($P < 0.05$) aerobic stability of the unstable samples (72 h, >156 h, >156 h). This study showed that maize with similar quantities of spoilage organisms in the fresh maize can vary widely in their aerobic stability.

Key Words: aerobic stability, maize silage, silage inoculant

268 A comparative study of lignin assays and relationship with grass digestibility.

Alejandro Vargas Velásquez* and Romualdo Shigueo Fukushima, *Department of Animal Nutrition and Production (VNP), Faculty of Veterinary and Animal Science (FMVZ), University of São Paulo, Pirassununga, São Paulo, Brazil.*

Accurate determination of lignin is essential to understand the mechanism by which it inhibits carbohydrate digestion. Available analytical procedures have repeatedly produced conflicting results. The gravimetric methods ADL, potassium permanganate lignin (PL) and KL were compared against the spectroscopic acetyl bromide lignin method (ABL). Grass species *Brachiaria brizantha* 'Marandú' and 'Xaraés', *Panicum maximum* 'Mombaça' and *Pennisetum purpureum* 'Cameroon' and 'Napier' were harvested at 7 maturity stages. A completely randomized experimental design with duplicate analysis for the lignin assays was used. A randomized block design was used for the in vitro experiment. Highly significant effects for maturity, lignin method and their interaction on lignin content were observed. The ADL yielded the lowest values (28.05 to 103.05 g/kg DM) in all species. Values for PL were in accordance to previous observations from our laboratory and other authors (65.45 to 160.65 g/kg DM). The KL values observed (61.35 to 136.20 g/kg DM) were approximately double the values observed for ADL. Values for ABL were higher than all corresponding values from the other methods. Strong negative correlations between lignin contents and IVDMD or IVNDFD were observed for all methods. Higher correlations were observed for IVDMD than for IVNDFD, contrary to what could be expected, because lignin affects the CW digestibility but not the cellular contents. Regression analysis of ADL, KL and ABL produced negative slopes when plotted against IVDMD and IVNDFD. The PL method failed to reliably estimate the digestibility of tropical grasses, possibly because of other substances (pectin, tannins or flavonoids) solubilized by the $KMnO_4$ solution. Although ADL and KL had similar correlations with digestibility and therefore, estimate digestibility of forages with similar accuracy, these methods use strong acids and require determination of ash in the lignin residues, increasing time and cost of analysis. The ABL method has no need for corrections and is a fast and a convenient method for determination of total lignin content in plants, thus, a good option for routine laboratory analysis.

Key Words: lignin, acetyl bromide, digestibility

269 Using Bayesian inference to delineate diet composition of mixed forages.

Napoleón Vargas Jurado*[1], Amy E. Tanner[2], and Ronald M. Lewis[1], [1]*University of Nebraska, Lincoln, NE,* [2]*Virginia Tech, Blacksburg, VA.*

Diet preferences in grazing animals are important for range management and ecology. However, estimating the composition of diet mixtures is challenging. The plant-wax marker technique, combined with nonnegative least squares (NNLS), has traditionally been used to estimate diet composition across herbivore species. More flexible methods, such as the normal compositional model (NCM) under Bayesian inference, offers an alternative approach for predicting diet composition. The efficiency of NCM was assessed by simulation. Mean *n*-alkane (C_{27}, C_{29}, C_{31}, C_{33}) and long-chain alcohol (LCOH; $C_{26}OH$, $C_{28}OH$, $C_{30}OH$) concentrations (mg/kg) were obtained for 11 subsamples for each of 2 forages – tall fescue and red clover – by gas chromatography. The CV of those measures was 10.7%, which was used to derive a common SD (20 mg/kg). Forage mixtures ranging from 0.10 to 0.90 fescue, in 0.10 increments, were simulated from a Gaussian distribution. Values for each *n*-alkane and LCOH, using their respective mean and the common SD, were drawn independently. For each mixture, 100 sets of observations were generated. Data were analyzed using NNLS and NCM. For the *n*-alkanes and LCOH alone and in combination, efficiency was assessed by normalized mean squared error (NMSE), mean average difference (MAD), and coverage of 95% CI. For both types of markers, both methods accurately predicted the forage mixtures, although more so with NCM. The NMSE for the NNLS were 0.032%, 0.019% and 0.012% for *n*-alkanes, LCOH and their combination, respectively; for NCM, those respective values were 0.028%, 0.011% and 0.008%. Similarly, MAD for NNLS were 1.29%, 0.92% and 0.75% for *n*-alkanes, LCOH and their combination, respectively; for NCM, the respective values were 1.22%, 0.74% and 0.63%. Coverage was high for the combined markers: 97.1% for NCM and 91.2% for NNLS. Given the scenario used, the NCM more accurately predicted forage mixtures. In the current study, a common SD was assumed. Such is doubtfully the case in practice, and the NCM methodology can accommodate non-trivial covariance structures among markers and better model differences in variation for individual markers. Such extensions are underway. The NCM approach provides a robust tool for estimating forage mixtures.

Key Words: plant-wax markers, Bayesian inference, diet composition

270 Interaction of isoflavones and endophyte-infected tall fescue seed extract on vasoactivity of bovine mesenteric vasculature.

Yang Jia*[1], David L. Harmon[1], and James L. Klotz[2], [1]*Department of Animal and Food Sciences, University of Kentucky, Lexington, KY,* [2]*USDA-ARS, Forage-Animal Production Research Unit, Lexington, KY.*

It is hypothesized that isoflavones may attenuate ergot alkaloid-induced vasoconstriction and possibly alleviate diminished contractility of vasculature after exposure to ergot alkaloids. The objective of this study was to determine if incubation of bovine mesenteric vasculature with formononetin (F), biochanin A (B), or an ergovaline-containing tall fescue seed extract (EXT) and their combinations affect ergotamine (ERT) induced contractility. Multiple segments of mesenteric artery and vein supporting the ileal flange of the small intestine were collected from Angus heifers at slaughter (n = 5, BW = 639 ± 39 kg). After cleaning and sectioning, duplicates of each vessel type were incubated in tissue culture flasks at 37°C with a 50-mL volume of Krebs-Henseleit buffer containing: only buffer (Control); or 1×10^{-6} *M* EXT; F; or B; and combinations of 1×10^{-6} *M* EXT+F; 1×10^{-6} *M* EXT+B; 1×10^{-6} *M* F+B; or 1×10^{-6} *M* EXT+F+B. After incubation for 2 h, sections were mounted in a multimyograph chamber. The ERT dose responses were normalized to 0.12 *M* KCl. Pretreatment with F, B, and F+B without EXT resulted in similar contractile responses to ERT in mesenteric artery and the incubations containing EXT resulted in a complete loss of vasoactivity to ERT. In mesenteric artery pretreated with EXT, treatments that contained B had higher contractile responses ($P < 0.05$) at ERT concentrations of 1×10^{-7} *M* and 5×10^{-7} *M*. Also, treatments containing B tended ($P < 0.1$) to have greater responses than treatments without B at ERT concentrations of 1×10^{-6} *M*, 5×10^{-6} *M*, and 5×10^{-5} *M*. In mesenteric vein pretreated with EXT, treatments containing F had greater contractile responses to ERT at 1×10^{-5} *M*, 5×10^{-5} *M*, and 1×10^{-4} *M* ($P < 0.05$). These data indicated that F and B at 1×10^{-6} *M* and their combination did not affect the overall contractile response to ERT in mesenteric vasculature. However, F and B may alleviate the reduction of vasoconstriction caused by prior exposure to alkaloids in endophyte-infected tall fescue seed extract.

Key Words: ergot alkaloid, isoflavone, mesenteric vasoconstriction

271 Proximate and fiber composition of leaves and stems of *Pennisetum purpureum* varieties fertilized with animal manure.

Victoria O. Ojo*, Sarafadeen T. Adewuyi, Alaba O. Jolaosho, Adebayo O. Oni, and Oludotun O. Adelusi, *Federal University of Agriculture, Abeokuta, Ogun State, Nigeria.*

An experiment was conducted at the Organic Research Farm, Federal University of Agriculture, Abeokuta between September 2013 and March 2014 to evaluate the influence of manure type and season on the chemical composition of plant fractions of *Pennisetum purpureum* varieties. The experiment was a split-split plot design with 4 manure types: swine (10.16 kg), cattle (22 kg), poultry (7.92 kg)/plot and control) were applied in one application as the main plot, 4 varieties of *P. purpureum* (green, purple, S13and S15) as the sub-plot and 2 seasons (early and late dry season) as the sub-sub plot with 3 replicates. An area of land of 53m × 11m was divided into individual plot size of $2m^2$ after land clearing and was sown with *P. purpureum* stems. The level of manure application was determined according to the nitrogen need of the soil which contained: total N (0.15%), organic C (1.31%), and available P (32.87 mg kg-1). Forage subsamples were harvested after 12 weeks of growth, weighed and oven-dried. Analysis of proximate and fiber contents of leaves and stem fractions was carried out and data obtained were analyzed using GLM procedure of SPSS Statistics 20. Results from this experiment showed ($P < 0.05$) CP content of *P. purpureum* leaves was highest in early dry and late dry seasons for swine manure (25.94%, 21.94%) compared with control (24.86%, 21.83), cattle (25.53%, 18.49%) and poultry (24.19%, 18.04%) respectively. *P. purpureum* variety Local green had the highest ($P < 0.05$) CP content (23.32%) in leaf fractions while *P. purpureum* variety purple had the highest ($P < 0.05$) CP (4.73%) in stem fractions. Cellulose contents of leaf (42%) of the grasses harvested in the early dry season was higher ($P < 0.05$) than those harvested in the late dry season. The ADL content were lower ($P < 0.05$) in the leaves than in the stem fractions in all the parameters measured. Feeding values of all the varieties (DDM, DMI, RFV and FI) were higher ($P < 0.05$) in the leaf fractions than stem fractions. It could therefore be concluded that swine manure is a good source of nutrient for sown pasture production and the use of animal manures maintained the quality of the grasses throughout the dry season.

Key Words: manure, leaf, stem

272 Effects of inoculated lactic acid bacteria on aflatoxin B_1 in corn silage.

Zhengxin Ma*, Felipe X. Amaro, Juan J. Romero, and Adegbola T. Adesogan, *Department of Animal Sciences, University of Florida, Gainesville, FL.*

The objective was to determine the effect of adding viable and unviable silage inoculant bacteria on binding of aflatoxin B_1 (AFB_1) and silage quality. A corn hybrid was harvested at 35% DM, chopped to achieve a theoretical length of 1.9 cm and treated in quadruplicate with deionized water (Con) or 30 µg/kg of AFB_1, or with a mixture of AFB_1 and viable, heated or acid-treated forms (1×10^9 cfu/g) of *Lactobacillus plantarum* R2014 (Lp), *L. buchneri* R1102 (Lb), or *Pediococcus acidilactici* EQ01 (Pa). Each of the inoculants was incubated for 1 h in 30 mL of phosphate-buffered saline (pH 7.3) at 37°C (viable) or 85°C (heated) or in 30 mL of 0.003 *M* HCl (pH 2.5) at 37°C (acid-treated) before application. Silages (3 kg) were stored for 21 d in polythene bags. Concentrations of AFB_1 were measured after 0, 24, 48, and 72 h of ensiling and silage samples from d 21 were analyzed for chemical composition, pH, volatile fatty acids and lactate. The experiment had a completely randomized design. Data were analyzed using the GLIMMIX procedure of SAS (SAS Institute Inc., Cary, NC). The AFB_1 concentration decreased linearly ($P < 0.05$) to 0.35 µg/kg or less within 3 d of ensiling across treatments. Bacterial inoculation did not ($P > 0.05$) increase the AFB_1 reduction. Treatment with AFB_1 reduced ($P = 0.03$) the CP concentration (8.83 vs. 8.25%) and increased ($P < 0.001$) butyric acid concentration (0.37 vs. 0.62%) but inoculation prevented ($P < 0.05$) these effects. Treatment with viable Lp increased ($P < 0.05$) the acidification of the forage in the first 3 d and the lactic acid concentration on d 21 (1.52 vs. 3.97%). However, inoculation with viable Lb or Pa did not ($P > 0.05$) affect the chemical composition, suggesting that typical beneficial effects of these bacteria were attenuated by AFB_1. The spiked aflatoxin was reduced to a safe level within 3 d of addition. Inoculation with bacteria did not increase AFB_1 removal but viable Lp prevented the increase in butyric acid and decrease in CP caused by the toxin.

Key Words: aflatoxin B_1, lactic acid bacteria, silage

273 In vitro digestibility of dried cassava peel, mushroom degraded cassava peel and silage from guinea grass.

Bolanle T. Akinyemi*, Moronfolu Ige, Alaba O. Jolaosho, Moses O. Arigbede, And Shamsideen O. Iposu, *Federal University of Agriculture, Abeokuta, Abeokuta, Ogun State, Nigeria.*

This study was carried out to determine the quality and in vitro digestibility of dried cassava peel, mushroom degraded cassava peel when mixed with 40% of silage from guinea grass and the grass at different levels. Samples from dried cassava peel, mushroom degraded cassava peel (SMS), silage and grass was collected and the nutritional potential was investigated by determining the chemical composition and the level of digestibility. The result shows that there was a significant difference ($P < 0.05$) on the in vitro gas production of dried cassava peel, mushroom-degraded cassava peel and when mixed with 40% of silage from guinea grass and the grass at different levels. The highest gas production of whole samples was from 100%CP having the ($P < 0.05$) value of 56.25 mL/200 mg of DM and the lowest was from which had the ($P < 0.05$) value of 26.50 mL/200 mg of DM. The highest gas production of diets was from Diet 6 (40% grass + 50% cassava peel + 10% PKC) having the ($P < 0.05$) value of 59.00mL/200mgDM and the lowest was from Diet 2 (40% silage + 50% cassava peel + 10% PKC), which had the ($P < 0.05$) value of 17.50 mL/200 mg of DM. Diet 6 had the highest values for metabolizable energy (ME), organic matter digestibility (OMD) and short-chain fatty acids (SCFAs; 7.26 $MJ \cdot kg^{-1}$, 59.93% and 0.82 µmol respectively). Diet 3 has the lowest value for ME, OMD and SCFAs (3.84 $MJ \cdot kg^{-1}$, 35.79% and 0.22 µmol respectively). The highest methane gas production of whole samples was from 100%CP having the ($P < 0.05$) value of 26.33 mL and the lowest was from 100%SMS which had the ($P < 0.05$) value of 12.88 mL. The highest gas production of Diets was from Diet 1 having the ($P < 0.05$) value of 25.00 mL and the lowest was from Diet 3 which had the ($P < 0.05$) value of 11.25 mL. The diet having 40% grass + 50% cassava peel + 10% PKC had the highest nutritional qualities. It is therefore concluded from this study that the use of cassava peel as substrate for producing edible mushroom improved the potential feeding value of the resultant substrate.

Key Words: silage, mushroom degraded cassava peel, in vitro digestibility

274 Carry-over effect of an individual feeding strategy on milk production of Holstein cows managed for extended lactation. Charlotte Gaillard*[1], Nicolas C. Friggens[2], Martin R. Weisbjerg[1], and Jakob Sehested[1], *[1]Aarhus University, Foulum, Tjele, Denmark, [2]AgroParisTech, INRA UMR 0791 MoSAR, Paris, France.*

Feeding can induce significant individual variation in cows' milk production. Previous studies showed that an increase of energy density of the ration for a short period in early lactation induced greater total milk yield and persistency, defined by the shape of the lactation curve. The objective of our feeding strategy was to reduce the intensity of mobilization and thereby to sustain the mobilization for a longer period. We hypothesized that a supply of energy during the mobilization period of each individual cow will have a positive carry-over effect on milk production. A total of 53 Holstein cows performed extended lactations (461 ± 7 d). They were housed in free stalls with access to a milking robot. The group 1 (G1) were fed a control partially mixed ration, with a 60:40 forage:concentrate ratio (energy density 11.8 ± 0.1 MJ of ME/kg of DM), for the full lactation. The group 2 (G2) received a diet enriched in energy (ratio 50:50, energy density 12.1 ± 0.1 MJ of ME/kg of DM) followed by the control diet. The diet shift of G2 was defined individually when DIM ≥42, and live weight gain ≥0 kg/d on a 5 d average. The production data were smoothed using the fda package in R software. The daily smoothed data and the associated slopes were analyzed using a linear mixed effects model with parity and treatment as fixed effects. From calving to 42 DIM, an interaction indicated that the ECM of multiparous G2 was higher than for G1 (42.8 vs. 40.1 ± 1.5 kg ECM/d), while the primiparous presented opposite effects (29.0 vs. 32.5 ± 2.2 kg ECM/d) ($P = 0.02$). The 300 d following the shift in diet, G1 and G2 had similar ECM (35.0 ± 1.0 kg ECM /d, $P = 0.76$) but the curves had different slopes. From 0 to 100 d from shift, the ECM increased for the primiparous G2 while it decreased for the primiparous G1 (+0.008 vs. −0.01 ± 0.007 kg ECM/d, $P = 0.04$). From 201 to 300 d from shift, the ECM decreased faster for G2 than for G1 (−0.06 vs. −0.04 ± 0.008 kg ECM/d, $P = 0.02$). To conclude, the treatment had a 100-d positive carry-over effect only on primiparous persistency, as well as a 300 d negative carry-over effect on the ECM persistency for all the cows.

Key Words: extended lactation, persistency, individual feeding strategy

275 Moisture, temperature, cow health, and bedding bacteria relationships in compost bedded pack barns. Elizabeth A. Eckelkamp*, Joseph L. Taraba, Robert J. Harmon, Katherine A. Akers, and Jeffrey M. Bewley, *University of Kentucky, Lexington, KY.*

Attracting global interest, the compost bedded pack barn (CB) is a loose housing system bedded with shavings or sawdust, without the stalls and partitions found in freestall and tie-stall housing. The objective of this study was to assess relationships among compost bedded pack (CB) moisture and temperature, ambient weather conditions, cow hygiene, mastitis indicators, and bedding bacterial counts. The CB moisture and temperature are affected by ambient conditions, which in turn alter the conditions experienced by the cow and the bacteria in the bedding. The study was conducted using data from 8 CB farms in Kentucky from May 2013 to May 2014. Biweekly, one observer hygiene scored 50 cows per farm and collected CB internal temperature at 20 cm depth (CIT), moisture, nutrient profile, and bedding samples for bacteriological culture from 9 areas in each barn. Somatic cell count and high SCC prevalence (HSP, percent of cows with SCC ≥200,000 cells/mL) were collected from DHIA. The MIXED procedure of SAS 9.3 (SAS Institute, Inc., Cary, NC) was used to assess fixed effects for all models. Stepwise backward elimination was used to remove non-significant interactions ($P \geq 0.05$) with all main effects remaining in the models regardless of significance. Internal temperature increased with increasing BTHI ($P < 0.01$) and decreased with increasing milk yield ($P < 0.01$). Compost moisture content decreased with increasing BTHI ($P < 0.01$). Herd hygiene score decreased with increasing BTHI ($P < 0.01$) and increased with increasing CB moisture ($P = 0.02$). Herd SCC and HSP both increased with increasing BTHI ($P < 0.01$), but did not change with compost factors. Staphylococcus ($P = 0.01$), streptococcus ($P = 0.01$), and bacillus ($P = 0.03$) species growth in the bedding decreased with increasing CIT while coliform species growth ($P = 0.02$) increased with increasing CIT. Maintaining higher internal temperature did not reduce all bedding bacteria levels. In CB farms, BTHI affected cow hygiene and udder health indicators more than CB moisture and CIT.

Key Words: compost bedded pack barn, bedding bacteria, somatic cell count

276 Effect of dry period length and dietary energy source in dairy cows on natural antibody titers and somatic cell count in milk. Novi Mayasari*[1,2], Wilke Rijks[1], Ger de Vries Reilingh[1], Gerrit Remmelink[3], Bas Kemp[1], Henk Parmentier[1], and Ariette van Knegsel[1], *[1]Adaptation Physiology Group, Department of Animal Science, Wageningen University, Wageningen, Gelderland, the Netherlands, [2]Faculty of Animal Husbandry, Universitas Padjadjaran, Bandung, West Java, Indonesia, [3]Livestock Research, Wageningen University and Research Centre, Wageningen, Gelderland, the Netherlands.*

Omission of the dry period of cows improved energy balance (EB) and showed variable effects on somatic cell counts (SCC) and natural antibodies (NAb) in milk. A glucogenic diet compared with lipogenic diet enhanced plasma NAb binding keyhole limpet hemocyanin (KLH). NAb in milk were associated with SCC. It was hypothesized that during negative energy balance, NAb either have a role or reflect in inflammatory processes and are associated with SCC. The objective was to study effects of dry period length and dietary energy source on titers of NAb binding KLH and lipopolysaccharide (LPS) in milk, SCC and mastitis. In total, 167 Holstein-Friesian dairy cows were randomly assigned to treatments. Treatments consisted of 3 dry period lengths: 0-, 30- or 60-d and 2 early lactation diets (glucogenic or lipogenic), in a 3 × 2 factorial design. Cows enrolled in this study were clinically healthy and had SCC in milk < 250,000 cell/mL. Milk samples for NAb and SCC measurement were sampled weekly and 4 times per week, respectively, from wk 1 until 14 postpartum. The data collected were statistically analyzed using ANOVA and logistic regression. Cows with a 0-d dry period had higher titers of IgG and IgM binding KLH and LPS and higher SCC in milk compared with cows with a 30- or 60-d dry period ($P < 0.01$). Mastitis incidence was 17% and did not differ between dry period lengths or lactation diets. A glucogenic diet showed higher titers of IgM binding LPS and tended to have higher titers of IgG binding LPS in milk compared with a lipogenic diet ($P < 0.01$ and $P = 0.08$, respectively).

Higher titers of IgG and IgM binding KLH and IgG binding LPS were associated with increased risk of high SCC ($P < 0.05$). Higher IgG and IgM binding KLH and LPS were also associated with increased risk of mastitis ($P < 0.05$). The results demonstrate that cows with a 0-d dry period and fed a glucogenic diet showed high titers of IgG binding LPS in milk. Moreover, we can conclude that IgG and IgM binding KLH or LPS in milk might be additional valuable tools to detect increased risks for mastitis in dairy cows.

Key Words: dry period, somatic cell count, antibodies

277 Towards a better understanding of the effect of genetic merit for milk production on post-partum cyclicity of first lactation dairy cows.

Nicolas Bedere*[1], Luc Delaby[1], Vincent Ducrocq[2], Ségolène Leurent-Colette[3], and Catherine Disenhaus[1], *[1]INRA-Agrocampus-Ouest UMR 1348 PEGASE, Saint-Gilles, France, [2]INRA UMR 1313 GABI, Jouy-en-Josas, France, [3]INRA UE 326 Domaine Expérimental du Pin-au-Haras, Exmes, France.*

Milk genetic merit is known to affect commencement of luteal activity (CLA) in dairy cows. This effect is considered to be due to energy exported in milk production. We hypothesize that cows with genetic predisposition to export milk energy through milk yield would have degraded cyclicity compared with those exporting energy through fat and protein contents. This study aimed to identify and quantify the effect of breed and genetic groups on postpartum cyclicity of primiparous dairy cows. From 2006 to 2013, an experiment was conducted on 194 primiparous dairy (Holstein) and dual purpose (Normande). Within breeds, cows were classified into 2 groups with regards to their estimated breeding value (EBV). Cows with high EBV for milk yield were included in a "Milk" group (MG) and those with high EBV for fat and protein content were included in a "Content" group (CG). Within breeds, exported milk energy and weight loss were similar for cows in both MG and CG groups. Interval from calving to CLA was studied performing survival analyses (Weibull regression). Progesterone profile, milk yield and body condition were analyzed using Chi^2-test and ANCOVA. Holstein cows produced more milk (+1450 kg, $P < 0.001$) and lost more body weight (BW: −1.4kg/wk, $P < 0.01$) than Normande ones. Normande and Holstein cows had different baseline hazard functions for CLA, Normande cows having earlier CLA than Holstein ones. Within breeds, cows in the CG group had earlier CLA (associated HR = 2.0, $P = 0.001$) than cows in the MG group. For Holstein only, BW loss from wk 1 to 14 of lactation tended to be associated with later CLA ($P < 0.1$). Within breeds, no effect of milk yield on CLA was observed. Prolonged luteal phases were frequent (18% of cows) and neither associated with breed nor with differences between MG and CG. Interovulatory intervals were longer for Holstein than for Normande cows (+1.7 d, $P < 0.001$) because of a longer luteal phase and a longer interluteal interval. To conclude, this study showed that cows with genetic predisposition to export milk energy through fat and protein contents had earlier CLA than those exporting milk energy through yield.

Key Words: genetic merit, cyclicity, primiparous cows

278 Forage yield, quality, and digestibility when intercropping vining soybean with MasterGraze seed corn at different seeding rates.

Ishwary Acharya*[1], David Casper[1], Xingyou Gu[2], and Ahamed Charif[2], *[1]Dairy Science Department, South Dakota State University, Brookings, SD, [2]Department of Plant Science, South Dakota State University, Brookings, SD.*

The production of forage resulting from the intercropping of corn and soybean at planting has the potential to yield greater quantities of digestible nutrients to meet the nutrient requirements of lactating dairy cows. A field plot experiment was conducted to measure forage yield, nutrient concentration and digestibility when intercropping MasterGraze (MG) seed corn and vining (V) soybean lines at different seeding rates. A randomized complete block design with 5 different seeding rates [100:0 (T1); 67:33 (T2); 50:50 (T3); 33:67 (T4), and 0:100 (T5) of V and MG] with 3 replicates was used to determine the optimal intercropping seeding rates. Forage was hand harvested 97 d after planting during the 2014 growing season, inoculated, packed into plastic buckets, weighed, and ensiled for 60 or 90 d. Buckets were then re-weighed, opened, and samples of forage collected. Fresh, 60- and 90-d ensiled forage samples were submitted to a commercial laboratory (Analab Inc., Fulton, IL). Fresh forage yield was greatest ($P < 0.05$) for T5 (all MG) compared with other ratios of MG and V (40.7, 78.0, 75.6, 75.5 and 80.9 T/ha for T1, T2, T3, T4, and T5, respectively). Fresh DM yield (16.5, 22.0, 21.1, 20.2, and 18.7 T/ha) and digestible DM (12.3, 15.2, 14.7, 14.1 and 13.9 T/ha) were similar ($P > 0.05$) across all V:MG ratios. Fresh CP yield (3.74, 2.29, 2.14, 1.97, and 1.18 T/ha) was greatest ($P < 0.05$) for T1 compared with other treatments and T2 greater ($P < 0.05$) than T5 with remaining ratios being intermediate and similar. Fresh digestible fiber yield was similar ($P > 0.10$) for all V:MG ratios (3.78, 5.55, 6.02 5.22, and 6.45 T/ha). The 60 d DM ensiling loss (5.23, 1.34, 1.22, 1.71 and 1.97%) was greatest ($P < 0.05$) for T1 compared with the other V:MG ratios. The 60 d ensiling digestible DM yield (12.3, 15.6, 14.9, 14.0 and 12.9 T/ha) was greatest ($P < 0.05$) for T2 and lowest for T1 with other ratios being intermediate. In conclusion, the intercropping of V and MG holds great potential for increasing the production of forages to meet the nutrient requirements of lactating dairy cows.

Key Words: corn, soybean, yield

279 Intravaginal administration of prostaglandin $F_{2\alpha}$ induces luteolysis in lactating dairy cows.

Robert Wijma*, Matias L. Stangaferro, and Julio O. Giordano, *Department of Animal Science, Cornell University, Ithaca, NY.*

Our objectives were to test the efficacy of $PGF_{2\alpha}$ (PGF) to induce luteolysis and evaluate progesterone (P4) dynamics after intravaginal (IVG) administration in lactating dairy cows. Our hypothesis is that PGF given IVG will induce luteolysis. In 2 experiments, cows were synchronized using Ovsynch (GnRH-7 d-PGF-56 h-GnRH) to induce ovulation and the formation of a corpus luteum (CL). Cows with at least 1 CL ≥ 15 mm 8 d after Ovsynch remained in the study. In Exp 1, cows (n = 31) stratified by parity and number of CL received: 5 mL of saline solution IVG (SAL-IVG, n = 6), 25 mg of PGF im (PGF25-im, n = 7), 25 mg of PGF IVG (PGF25-IVG, n = 6), 50 mg of PGF IVG (PGF50-IVG, n = 6) and 125 mg of PGF IVG (PGF125-IVG, n = 6). In Exp 2, cows (n = 32) stratified as in Exp 1 received: SAL-IVG (n = 7), PGF25-im (n = 7), PGF25-IVG (n = 6), PGF50-IVG (n = 6) as in Exp 1 whereas another group received 2 IVG boluses of 25 mg of PGF 12 h apart (PGF25–2X-IVG, n = 6). Blood was collected at −1 h, 0 h, every 6 h up to 24 h, and then every 12 h up to 96 h after treatment (trt). Concentrations of P4 after treatment were analyzed by ANOVA with repeated measures using PROC MIXED of SAS. Mean separation was conducted with LSD method. In Exp 1, P4 concentrations from −1 to 96 h were affected by trt ($P < 0.01$), time ($P < 0.001$) and trt by time ($P < 0.001$). From 12 to 96 h, all PGF groups had less P4 ($P < 0.05$) than SAL-IVG cows. In Exp 2, from −1 to 96 h P4 concentrations were affected by trt ($P < 0.001$), time ($P < 0.001$) and trt by time ($P < 0.001$). From 12 to 96 h all PGF groups had less ($P < 0.05$) P4 than SAL-IVG cows. From 60 to 96 h, PGF25–2X-IVG and PGF25-im tended ($P < 0.1$) to or had less ($P < 0.05$) P4 than PGF25-IVG. When data from Exp 1 and 2 were combined, P4 concentrations from −1 to 96 h were affected by trt ($P < 0.001$), time ($P < 0.001$) and trt by time ($P < 0.001$). Concentrations of P4 in all the PGF groups were less ($P < 0.05$) than in the SAL-IVG group from 6 to 96 h. At 60 h, the PGF25–2X-IVG group had less ($P < 0.05$) P4 than the rest of the groups. We conclude that it is possible to induce luteolysis in lactating dairy cows by intravaginal administration of PGF. Two 25-mg boluses 12 h apart were more effective than one bolus of 25, 50 or 125 mg of PGF and as effective as a 25-mg bolus of PGF im.

280 Dry period plane of energy: Effects on glucose tolerance in peripartum dairy cows.

Sabine Mann*[1], Francisco A. Leal Yepes[2], Thomas R. Overton[2], Joseph J. Wakshlag[3], Bethany P. Cummings[4], and Daryl V. Nydam[1], *[1]Department of Population Medicine and Diagnostic Sciences, College of Veterinary Medicine, Cornell University, Ithaca, NY, [2]Department of Animal Science, College of Agriculture and Life Sciences, Cornell University, Ithaca, NY, [3]Department of Clinical Sciences, College of Veterinary Medicine, Cornell University, Ithaca, NY, [4]Department of Biomedical Sciences, College of Veterinary Medicine, Cornell University, Ithaca, NY.*

Overfeeding energy during the dry period may affect peripartal insulin sensitivity of dairy cows. The objectives were to describe the effect of different dry period dietary energy strategies on glucose tolerance and on concentrations of insulin, glucagon, glucose, β-hydroxybutyrate (BHBA) and nonesterified fatty acids (NEFA) in the peripartum period. To test our hypothesis that dry period plane of energy leads to changes in glucose tolerance, cows (n = 84) were blocked by expected calving date and randomized into 3 treatment groups 57 d before expected parturition: a TMR formulated to supply 100% of energy requirements (C), or 150% of requirements (H), or 100% for the first 28 d of the dry period followed by a TMR supplying 125% of energy requirements until calving (I). At 28 and 10 d pre-, as well as 4 and 21 d postpartum, intravenous glucose tolerance tests (IVGTT; 0.25 g glucose/kg) were performed and the area under the curve (AUC) of glucose and insulin were estimated. Baseline samples were analyzed for concentration of insulin, glucose, NEFA, glucagon and BHBA. Mixed-effects ANOVA were carried out (SAS, v. 9.3). The AUC for glucose and insulin was not different among groups at any time point ($P > 0.10$). Differences in baseline values were most notable on d 4 postpartum (Table 1) and indicated increased postpartum lipolysis and ketogenesis in group H whereas we detected a tendency for lower glucose concentration despite higher glucagon concentration in this group. In conclusion, these findings suggest that prepartum plane of energy had an effect on the hormonal regulation of gluconeogenesis and ketogenesis (as reflected by the concentrations of insulin and glucagon), but did not lead to a detectable effect on peripartal glucose tolerance as assessed by IVGTT.

Contd.

Table 1 (Abstr. 280). Mean (95% CI) baseline concentrations on day 4 postpartum

Item	C	I	H	*P*-value
Glucose (mg/dL)	60 (57–62)^{a}	58 (56–61)^{ab}	56 (53–58)^{b}	0.09
Insulin (μIU/mL)	2.1 (1.2–3.6)^{a}	2.3 (1.3–4.1)^{a}	1.1 (0.5–1.7)^{b}	0.08
Glucagon (pg/mL)	120 (108–132)^{A}	117 (105–129)^{A}	137 (127–150)^{B}	0.01
NEFA (mEq/L)	1.37 (1.26–1.48)^{A}	1.38 (1.27–1.50)^{A}	1.63 (1.52–1.74)^{B}	0.002
BHBA (mmol/L)	0.75 (0.64–0.88)^{A}	0.83 (0.71–0.97)^{AB}	1.0 (0.85–1.2)^{B}	0.06

Row values with different superscript letters differ ($^{A,B}P < 0.05$; $^{a,b}P < 0.10$) in Tukey's HSD.

281 Infusion of 5-hydroxytryptophan increases serum calcium and mammary gland calcium pump activity during the transition period.

Samantha R. Weaver*[1], Austin P. Prichard[1], Elizabeth L. Endres[1], Stefanie A. Newhouse[2], Rupert M. Bruckmaier[3], Matt S. Akins[1], and Laura L. Hernandez[1], *[1]University of Wisconsin-Madison, Madison, WI, [2]University of Wisconsin-Platteville, Platteville, WI, [3]University of Bern, Bern, Switzerland.*

Hypocalcemia during the transition period in dairy cows has detrimental effects on animal health, welfare, and production. While clinical hypocalcemia affects 2 to 5% of cows in the US, approximately 50% of cows succumb to subclinical hypocalcemia. Serotonin (5-HT) has been suggested as a therapeutic target for prevention of hypocalcemia. Our objective was to determine the effects of pre-partum intravenous (IV) administration of a 5-HT precursor on calcium homeostasis postpartum in multiparous dairy cows. We hypothesized that the treatment would increase serum calcium and calcium transport into the mammary gland. Twelve (avg. lactation number 3.67 ± 0.43) Holstein cows were IV infused for 5.75 ± 0.82 d pre-partum, beginning approximately 7d before their predicted calving date until calving, with saline (CTL; n = 6) or 1.0 mg/kg 5-hydryoxytryptophan (5-HTP; n = 6), the immediate precursor for 5-HT synthesis. Mammary gland biopsies were performed approximately 2 weeks pre-partum, and d1 and d7 postpartum. Blood and urine were collected daily from the first biopsy through d14 and on d30 of lactation. Colorimetric assays were performed for total calcium in serum and relative mammary mRNA expression was evaluated by RT-PCR. All statistical analysis was performed in SAS using a mixed model ANOVA. Cows infused with 5-HTP had decreased feed intake postpartum compared with CTL ($P = 0.0004$; 34.75 ± 1.6 kg CTL vs. 30.25 ± 2.8 kg 5-HTP) and overall decreased milk yield ($P = 0.0054$; 18.35 ± 1.07 kg CTL vs. 17.10 ± 1.04 kg 5-HTP), although colostrum milk yield was not different ($P = 0.88$). Serum total calcium tended to increase in 5-HTP cows for 14d postpartum ($P = 0.07$; 2.89 ± 0.09 m*M* 5-HTP vs. 2.66 ± 0.09 m*M* CTL). Basolateral mammary epithelial cell calcium sensing receptor (CaSR) mRNA was increased in 5-HTP compared with CTL cows ($P = 0.035$), as was apical calcium pump plasma membrane calcium ATPase2 (PMCA2) ($P = 0.018$) on d 1 and d 7 of lactation. These results suggest that 5-HTP treatment prepartum increases postpartum circulating calcium concentrations and calcium transport in the mammary gland.

Key Words: serotonin, calcium, hypocalcemia

282 The use of gene expression in milk fat as an indicator of trace mineral status in dairy cows.

M. J. Faulkner*[1], E. H. Wall[2], and W. P. Weiss[1], [1]*OARDC, The Ohio State University, Wooster, OH,* [2]*Pancosma, Geneva, Switzerland.*

No non-invasive methods exist to accurately evaluate Cu, Zn, and Mn status in dairy cows. Thirty lactating Holstein cows were used to determine whether intake and source of Cu, Zn, and Mn affected erythrocyte Cu/Zn SOD activity and expression of genes in milk fat that are related to Cu and Zn transport. Cows were fed a diet void of supplemental Cu, Zn, and Mn (9, 41, and 41 mg/kg, respectively) for 30 d and then fed 1 of 3 diets for 30 d. One diet (UNSUP) contained no supplemental Cu, Zn, and Mn (9, 41, and 41 mg/kg); one diet (SUL) contained Cu, Zn, and Mn from sulfates (total concentrations = 17, 59, and 54 mg/kg, respectively); one diet (GLY) contained Cu, Zn, and Mn in the glycinate form (B-Traxim 2C, Pancosma; total concentrations = 20, 66, and 58 mg/kg). Data were analyzed using a mixed model with treatment and parity as fixed effects. Using the NRC (2001) model and absorption coefficients (AC), UNSUP provided about 82% of requirements for Cu and Zn for primiparous cows and 95% for multiparous cows. Assuming an AC of 0.05 and 0.20 for Cu and Zn from supplements, supplemented diets provided 1.3 to 2.3 times more absorbed Cu and Zn than requirements. Total RNA was extracted using Tri Reagent from milkfat samples collected on d 60. Expression of 1 Zn transport gene (ZnT4), 2 Zn and Mn transport genes (Zip3 and Zip8), 2 Cu transport genes (ATP7B and CCS), 1 heavy-metal binding gene (MT), and 2 reference genes (KEAP1 and ADSL) were analyzed using qPCR. Activity of SOD was higher ($P = 0.04$) in primiparous than multiparous cows, but was not affected by diet. Expression of CCS, a protein that transports Cu to SOD, and SOD were negatively correlated ($P < 0.06$). Expression of most genes was not affected by treatment; however, MT expression was greater ($P = 0.04$) in primiparous compared with multiparous cows, and Zip8 expression tended ($P = 0.10$) to be greater in cows fed supplemental Cu, Zn, and Mn regardless of source. When supplemental Cu, Zn, and Mn were fed, cow requirements were exceeded and no differences were observed between mineral sources. Zip8 has potential to detect cows with deficient trace mineral status.

Key Words: trace mineral, dairy cow, gene expression

283 Feed efficiency and performance of lactating Holstein dairy cows fed two different concentrations of dried distillers grains with solubles.

Eric D. Testroet*, Stephanie Clark, and Donald C. Beitz, *Iowa State University, Ames, IA.*

Dried distillers grains with solubles (DDGS) has become more nutritionally consistent as the industry has evolved. The objective of this study, therefore, was to evaluate the feed efficiency of lactating Holstein dairy cattle fed 2 different concentrations of DDGS. Thirty cows were fed 0, 10, and 20% DDGS dietary dry matter (DM) as a total mixed ration. Cows were stratified by parity and days in milk into 3 treatment groups of 10 cows in a 3 × 3 Latin square with repeated measures. We hypothesized that feeding 20% DDGS by dietary DM would negatively influence production and efficiency. Feeding DDGS had no consistent effect on dry matter intake (DMI), with the control diet being intermediate to the 10 and 20% diets (25.22, 24.03, and 26.37 kg/day, respectively; $P < 0.0001$). Milk yield was unaffected by feeding DDGS; feeding DDGS, however, caused milk fat depression (3.45, 2.94, and 2.68%; 0, 10, and 20%, respectively; $P < 0.0001$) and reduction of daily fat yield (1.35, 1.15, 1.04 kg/day; $P < 0.0001$) that resulted in decreases in 3.5% fat-corrected milk (FCM) yield (36.20, 32.97, and 31.32 kg/day; $P < 0.0001$) and energy-corrected milk (ECM) yield (40.95, 38.12, and 36.72 kg/day; $P < 0.0001$). Both protein (3.58, 3.62, and 3.65%; $P = 0.0409$) and lactose percentage (5.07, 5.15, and 5.17%; $P = 0.0067$) were increased when cows were fed 20% DDGS; neither protein nor lactose yield, however, was affected. Protein efficiency decreased for cows fed 20% DDGS (35.42, 36.21, and 32.76%; $P < 0.0001$), likely resulting from heat-damaged protein. All measures of energetic efficiency [ECM/DMI, kg ECM/net energy for lactation (NE_L) intake (mcal), and gross energy (GE) of milk produced (mcal)/NE_L caloric intake (mcal)] were decreased when cows were fed 20% DDGS, but not when cows were fed 10% DDGS (ECM/DMI: 1.66, 1.64, and 1.41; kg ECM/NE_L: 1.02, 1.03, 0.89; GE of milk/NE_L caloric intake: 0.65, 0.66, 0.56; $P < 0.0001$). These results indicate that, with the exception of an approximate 0.5% loss of milk fat, the DDGS used in this study can be effectively fed at 10%, but not at 20%, of dietary DM without a loss in feed efficiency.

284 Including sunflower seed in prepartum diet positively influenced postpartum ovarian function without affecting uterine health.

R. Salehi*[1], M. G. Colazo[2], U. Basu[1], A. Ruiz-Sanchez[1], and D. J. Ambrose[1,2], [1]*University of Alberta, Edmonton, Alberta, Canada,* [2]*Alberta Agriculture and Rural Development, Edmonton, Alberta, Canada.*

We investigated the influence of prepartum dietary oilseed supplementation on postpartum (pp) uterine inflammatory status (UIS) based on polymorphonuclear cells (PMN): normal (≤8% PMN) or subclinical endometritis (SCE; > 8% PMN), and associations among SCE, pro/anti-inflammatory cytokine gene expression and resumption of ovarian cyclicity. We hypothesized that feeding a diet containing sunflower seed (SUN; high linoleic acid) will induce pro-inflammatory effects in the early pp uterus facilitating early resumption of cyclicity. During late gestation (last 5 wk), Holstein cows received 1 of 3 diets supplemented with 8% DM rolled sunflower seed (SUN; n = 10) or canola seed (CAN; high oleic acid; n = 9), or no oilseed (CON; n = 9). Ovaries were scanned 2×/wk until 35 d pp to record first appearance of a 10 (DF) or 16 mm (PreOVF) follicle, and ovulation. Endometrial cell sampling was done 25 ± 1 d pp for cytology and gene expression. Data were analyzed using PROC MIXED, CORR and REG of SAS. Prepartum diets did not influence SCE incidence (SUN: 4/10; CAN: 4/9; CON: 3/9). The mRNA expressions of interleukin (IL)-1β, IL-6, IL-8, IL-10, tumor necrosis factor (TNF)-α and interferon (INF)-γ were not affected ($P > 0.05$) by either prepartum diet or diet × UIS interaction. Feeding SUN prepartum hastened ($P < 0.05$) the establishment of PreOVF and increased the proportion of cows ovulating within 35 d pp. Regardless of prepartum diet, cows with SCE had higher ($P < 0.05$) mRNA expression of IL-1β, IL-8, IL-10 and TNF-α than normal cows. The intervals from calving to DF formation and first ovulation were not affected by UIS; however, PreOVF formed earlier ($P < 0.01$) in normal (13.2 ± 0.9) than in SCE (18.7 ± 1.4 d) cows. The mRNA expression of IL-1β, IL-8, IL-10 and TNF-α were positively correlated with each other ($P < 0.01$) and with PMN% ($P < 0.07$). The interval to PreOVF was determined by IL-1β, IL-8, IL-10, IFN-γ expression, PMN%, and the interval to DF. In summary, feeding SUN prepartum positively influenced pp ovarian function without affecting UIS. Increased endometrial expression of pro-inflammatory cytokines is likely linked to delayed establishment of PreOVF.

Key Words: endometritis, ovarian function, cytokine

285 Pretreatment with saturated and unsaturated fatty acids regulates [1-^{14}C] C16:0 metabolism in Madin-Darby bovine kidney cells.

Katherine E. Boesche*, Stephanie L. Koser, and Shawn S. Donkin, *Purdue University, West Lafayette, IN.*

Metabolic fates of fatty acids (FA) may be influenced by circulating FA concentration. Previous work in our lab demonstrated an ability of C18:3n-3 *cis* to ameliorate gene expression of pyruvate carboxylase (PC) after depression by either C16:0 or C18:0. PC catalyzes oxaloacetate (OAA) synthesis and ostensibly links gluconeogenesis and FA metabolism. Our objective was to determine effects of co-presence of saturated and unsaturated FA pretreatments on cellular partitioning of [1-^{14}C] C16:0 metabolism to CO_2 or acid-soluble products (ASP) in Madin-Darby bovine kidney (MDBK) cells. We hypothesized that the ratio of saturated to unsaturated FA pretreatments regulates [1-^{14}C] C16:0 partitioning to CO_2 or ASP. Cells at 80% confluence were exposed for 21h to either individual FA bound to BSA (C16:0, C18:0, C18:1n-9 *cis* or C18:3n-3 *cis*) or FA cocktails in 10:90, 25:75, 50:50, 75:25 or 90:10 ratios for combinations of C16:0: C18:3n-3 *cis* or C18:0: C18:3n-3 *cis* or C18:1n-9 *cis*: C18:3n-3 *cis*. Total pretreatment FA concentration was 1.0 m*M* and was applied in triplicate to 3 cell replicates. Following pretreatment, cells were incubated in the presence of 1.0 m*M* [1-^{14}C] C16:0 for 3h before CO_2 and ASP collection. Data were analyzed using PROC MIXED of SAS. The model accounted for fixed effects of pretreatment and random effects of replicate. Pretreatments with either C16:0 or C18:0 alone significantly ($P < 0.01$) depressed subsequent oxidation of [1-^{14}C] C16:0 to ASP by 62.7% and 41.2%, respectively, compared with C18:3n-3 *cis* pretreatments. Similar patterns were seen with [1-^{14}C] C16:0 oxidation to CO_2. ASP production from [1-^{14}C] C16:0 positively correlated ($r = 0.68$, $P < 0.01$) with PC gene expression from previous experiments. CO_2 production from [1-^{14}C] C16:0 did not correlate ($r = 0.30$, $P > 0.10$) with PC expression. In conclusion, activation of PC gene expression by C18:3n-3 *cis* may play a critical role in setting the capacity for OAA synthesis and determining metabolic fates of FA. Results show a regulation of ketone production by MDBK cells in response to saturated and unsaturated FA pretreatments.

Key Words: fatty acid oxidation, ketogenesis, pyruvate carboxylase

286 A novel method to determine rumen biohydrogenation kinetics of alpha-linolenic acid (18:3 n-3).

Michel Baldin*[1], Natalie L. Urrutia[1], Daniel E. Rico[2], Kelsie Baxter[1], Yun Ying[1], and Kevin J. Harvatine[1], *[1]Penn State University, University Park, PA, [2]Université Laval, Québec, QC, Canada.*

Biohydrogenation (BH) of unsaturated fatty acids (FA) has been extensively studied in vitro but BH rates and intermediates formed in vitro may not parallel BH pathways in vivo. The objective was to develop an in vivo method to determine the rate of α-linolenic acid (18:3 n-3) BH and identify intermediates formed. Eleven rumen cannulated high-producing Holstein cows [40 ± 6 kg milk/d (Mean ± SD)] were fed at a rate of 6%/h of expected total DMI a diet balanced to 29% NDF and 5.9% EE (1.5% soybean oil). A single bolus consisting of 200 g of flaxseed oil (53% 18:3) and 15 g of tridecanoic acid (13:0) was mixed with rumen contents and rumen digesta was collected at −1, 0.1, 0.5, 1, 2, 3, 4, 6 and 8 h relative to the bolus. Samples were immediately placed in dry ice, stored at −20°C, freeze-dried, methylated and analyzed by gas chromatography. Data were first analyzed using PROC Mixed with repeated measures for time point comparison. Second, the disappearance of 13:0 and 18:3 was fit to a single exponential decay model using the nonlinear procedure of JMP Pro. The bolus increased total fat in the rumen from 4.3 to 6.0% and enriched 13:0 from 0.04 to 2.2% of FA and 18:3 from 2.0 to 11.3% of FA. The fractional rate of disappearance of 13:0 was 0.4%/min ($r^2 = 0.98$) and of 18:3 was 2.5%/min ($r^2 = 0.99$), with 18:3 reaching pre-bolus concentration within 4 h. Assuming that 13:0 disappeared only by passage, 18:3 disappeared by passage and biohydrogenation, and the rate of passage of 13:0 and 18:3 are the same, the extent of bolused 18:3 BH was 85%. The concentration of *cis*-9,*trans*-11,*cis*-15 18:3 peaked at 1.2% of FA at 1 h (8-fold increase), *trans*-11, *cis*-15 18:2 peaked at 3.9% of FA at 2 h (13-fold increase), and *trans*-11 18:1 peaked at 6.6% FA at 3 h (43% increase). In conclusion, the in vivo method resulted in the expected extent of biohydrogenation and biohydrogenation intermediates, but the rate of ruminal biohydrogenation of 18:3 was much higher than that commonly observed in vitro. The method developed provides an in vivo assay of ruminal biohydrogenation for use in future experiments.

Key Words: biohydrogenation, fatty acid

287 Effects of feeding algae rich in docosahexaenoic acid (DHA) on lactation and reproductive performance of dairy cows.
