Abstract

The clinicopathological implication and prospective molecular mechanisms of miRNA-145-5p in the metastasis of prostate cancer (PCa) stand unclear. Herein, it is found that miRNA-145-5p expression was remarkably reduced in 131 cases of metastatic PCa than 1371 cases of localised ones, as the standardised mean differences (SMD) was -1.26 and the area under the curve (AUC) was 0.86 , based on miRNA-chip and miRNA-sequencing datasets. The potential targets of miRNA-145-5p in metastatic PCa ($n = 414$) was achieved from the intersection of miRNA-145-5p transfected metastatic PCa cell line data, differential expression of metastatic PCa upregulated genes and online prediction databases. TOP2A was screened as one of the target hub genes by PPI network analysis, which was adversely related to miRNA-145-5p expression in both metastatic PCa ($r = -0.504$) and primary PCa ($r = -0.281$). Gene-chip and RNA-sequencing datasets, as well as IHC performed on clinical PCa samples, showed consistent upregulated expression of TOP2A mRNA and protein in PCa compared with non-PCa. The expression of TOP2A mRNA was also significantly higher in metastatic than localised PCa with the SMD being 1.72 and the AUC of sROC being 0.91 . In summary, miRNA-145-5p may participate in PCa metastasis by binding TOP2A and be useful as a biomarker for the detection of metastatic PCa.

1 | INTRODUCTION

Prostate cancer (PCa) is one of the most common malignant tumours in humans. Among all male cancers, PCa is also the second most frequent cause of cancer-related death, accounting for 20% of newly diagnosed cancers and an estimated 29,430 deaths according to 2020 cancer statistics [1]. Although urologists have made great progress in the diagnosis and therapy of PCa, the metastasis of this cancer remain serious problems that adversely affect the quality of life and survival time of patients with PCa [2–7]. Therefore, clarifying the mechanisms of PCa metastasis is essential, as knowledge of these mechanisms may offer new insights into metastatic PCa diagnosis and therapy.

MicroRNAs (miRNAs) are small (about 22 nucleotides long), endogenous, non-coding single-stranded eukaryotic RNAs that can influence the expression of their target genes post-transcriptionally [8–14]. Abnormal expression of miRNA-145-5p has a reported involvement in multiple cancers, including hepatocellular carcinoma, oesophageal carcinoma and lung cancer. MiRNA-145-5p plays crucial parts in the tumorigenesis and deterioration of hepatocellular carcinoma by targeting RAB18 [15]. Downregulation of miRNA-145-5p expression increased the risk of oesophageal carcinoma, and it was closely associated with the cell differentiation, lymph node invasion and distant metastasis [16]. In lung cancer, miRNA-145-5p modulated the epithelial-mesenchymal transition (EMT) and

This is an open access article under the terms of the Creative Commons Attribution License, which permits use, distribution and reproduction in any medium, provided the original work is properly cited.

promoted metastatic infiltration by aiming ZEB2, which controls lung cancer cell migration [17]. MiRNA-145-5p plays a crucial role in the onset, development and treatment of PCa [18–24]. However, researches on the role of miRNA-145-5p in the metastasis of PCa have been limited. Through the analysis of 14 miRNAs in 14 localised PCa and 5 metastatic PCa, Leite et al. found that miRNA-145-5p was downregulated in metastatic PCa [25]. In another study by Leite et al., the results also demonstrated that miRNA-145-5p expression was reduced in 6 metastatic PCa than 18 localised PCa [26]. Peng et al. performed miRNA chip analysis on 6 localised PCa and 7 metastatic PCa, showing that miRNA-145-5p expression was reduced in metastatic PCa, and further confirmed the result in 16 localised PCa and 13 metastatic PCa using real-time PCR method; over-expression of miRNA-145-5p could reduce the invasion and migration ability of PC-3 cells [27]. However, these results were investigated through a small sample sizes ($n < 20$), without verification with a larger sample sizes, which might reduce the credibility of the results. Moreover, the clinicopathological implication and prospective molecular mechanisms of miRNA-145-5p in metastatic PCa have not been elucidated.

A comprehensive valuation of the expression and distinguishing potential of miRNA-145-5p in metastatic PCa is given, conducted by estimating standard mean deviations (SMDs) and summary receiver operating characteristics (SROCs) based on miRNA-chip and miRNA-sequencing datasets. Gene ontology (GO) and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathways were also generated to investigate the latent molecular characterisations involving miRNA-145-5p target genes in metastatic PCa. Potential hub target genes were screened with protein–protein interaction (PPI) network analyses, and TOP2A having the highest degree of connectivity among the hub genes was selected for in-depth research via the Spearman's correlation analysis, estimating SMDs and SROCs and immunohistochemistry (IHC) of clinical PCa samples.

2 | MATERIALS AND METHODS

2.1 | Data collection of miRNA-145-5p expression in metastatic and primary PCa

We collected the miRNA-145-5p expression data for metastatic and primary PCa from miRNA-chip and miRNA-sequencing datasets. The search terms used for The Cancer Genome Atlas (TCGA), ArrayExpress, Sequence Read Achieve (SRA), Gene Expression Omnibus (GEO), Oncomine databases as well as the existing literature, were provided by our previous study concerning another miRNA in PCa [28]. Studies were counted in if: (1) the studies incorporated two groups (metastatic PCa group vs. localised PCa group or primary PCa group vs. non-PCa group) and (2) the studies were based on human tissues, cell lines or body fluids. The studies were excluded if: (1) no miRNA-145-5p expression data were obtained and (2) the studies had fewer than three samples. The expression data for miRNA-145-5p were normalised using log₂ conversion.

2.2 | Putative target genes of miRNA-145-5p in metastatic PCa

Putative target genes of miRNA-145-5p were derived from the following three evaluations.

2.2.1 | MiRNA-145-5p transfected metastatic PCa cell line data

MiRNA-chip and miRNA-sequencing datasets were selected as qualified studies if they showed gene expression profiles post miRNA-145-5p transfection or silencing in metastatic PCa cell line. Genes with the standard log₂FC > 1 or log₂FC < -1 were filtered as genes directly influenced by the change of miRNA-145-5p.

2.2.2 | Differential expression of metastatic PCa upregulated genes

The search formula for the gene-chip and RNA-sequencing datasets was as mentioned above [28]. The inclusion conditions were the following: (1) The studies involved gene expression data for both a metastatic PCa and a localised PCa group and (2) the study samples were from human tissues, body fluids or cell lines. The exclusion criteria were: (1) Only lncRNA, circular RNA or miRNA expression data were obtained and (2) the studies had fewer than three samples. A total of 10 studies were finally included. The limma R package was leveraged to examine the differentially expressed genes (DEGs) in the gene-chips. The DESeq2 R language package was used to screen the DEGs in the RNA sequencing. The DEGs threshold was set as an adjusted p -value < 70.05 and $|\log_2\text{FC}| > 1$. Herein, the expression of miRNA-145-5p was downregulated in metastatic PCa, so the upregulated genes in metastatic PCa were more likely to be the targets of miRNA-145-5p. Upregulated genes were screened from the DEGs, and the genes that occurred at least three times were selected for subsequent analysis.

2.2.3 | Online prediction databases

The miRNAWalk2.0 program [29] was applied to anticipate the supposed target genes of miRNA-145-5p. Genes identified by at least five prediction tools among 12 were screened for further study. The intersections of these three sources were considered to represent the targets of miRNA-145-5p.

2.3 | GO, KEGG and PPI analyses of potential miRNA-145-5p targets in metastatic PCa

The functions and pathways involving the miRNA-145-5p target genes were identified using GO and KEGG analysis

as well as the database for Annotation, Visualization and Integrated Discovery (DAVID) 6.8. The GO terms and KEGG signal pathways with p -value <0.05 were presented. Search Tool for the Retrieval of Interacting Genes (STRING) and Cytoscape software 3.6.1 were applied to construct a PPI network for miRNA-145-5p target genes. Hub genes were selected based on the degree of connectivity among miRNA-145-5p targets. Among the hub genes, TOP2A having the highest degree of connectivity was selected for further study.

2.4 | Relationship between miRNA-145-5p and TOP2A

The miRNA-145-5p and TOP2A expression data in metastatic and primary PCa were downloaded from the TCGA database. The expression data were normalised by $\log_2(x + 1)$. Spearman's correlations were computed between miRNA-145-5p and TOP2A in both metastatic and primary PCa. Furthermore, the relationships between miRNA-145-5p and TOP2A expression levels in different cancers were evaluated using StarBase v3.0. Negative relationships with $p < 0.05$ were statistically significant.

2.5 | The clinical significance of TOP2A in the metastasis of PCa

2.5.1 | Data collection of TOP2A expression in metastatic and primary PCa

Relevant gene-chip and RNA-sequencing datasets providing TOP2A expression data were collected using the aforementioned search terms for PCa. The inclusion criteria were: (1) the studies enrolled two groups (metastatic PCa group vs. localised PCa group or primary PCa group vs. non-PCa group) and (2) the studies were based on human tissues, body fluids or cell lines. The exclusion criteria were the following: (1) no TOP2A expression data were present and (2) the study had fewer than three samples. TOP2A expression data were normalised by \log_2 -transformation.

2.5.2 | Determination of protein expression of TOP2A in PCa samples by IHC

Four tissue microarrays (PRD1021, PRC1021, PRC481 and PRC961) were purchased from Fanpu (Guilin, China) including 160 PCa tissues from patients aged between 47 and 91 years, as well as 61 non-PCa tissues aged between 54 and 85 years. IHC was conducted as the manufacturers' protocols guided. Rabbit monoclonal anti-TOP2A (1:100 diluted; catalog no. ab109524, Abcam, Cambridge, MA, USA) was the first antibody for IHC. The intensity and the percentage of positive cells were used to calculate an immunoreactive score (IRS) for each sample by multiplying the two scores as previously reported [30].

2.6 | Statistical analysis

The standard mean deviation (SMD) with 95% confidential interval (CI) was used to estimate the differential expression of miRNA-145-5p and TOP2A between two independent groups using stata14.0 software (Stata Corporation, College Station, TX, USA). The pooled effect was determined by a random-effect model if heterogeneity occurred between the studies ($p < 0.05$ or $I^2 > 50\%$); otherwise, a fixed-effects model was applied ($p > 0.05$ or $I^2 < 50\%$). The cause of heterogeneity was explored by subgroup analysis and sensitivity analysis. Begg's test and egger's test were used to detect any publication bias in the included studies. The sensitivity and specificity of each study were determined by creating a receiver operating characteristic (ROC) curve and calculating the cut-off values. A summary receiver operating characteristic (SROC) curve was produced to assess the distinguishing potential of miRNA-145-5p and TOP2A between two independent groups using stata14.0. Scatter diagrams were generated with GraphPad Prism5.0 (GraphPad Software, Inc., La Jolla, CA, USA) to show the expression trends for miRNA-145-5p and TOP2A between two independent groups. The statistics were analysed using SPSS22.0 (SPSS, IBM, Chicago, IL, USA), and the results were shown as mean \pm standard deviation (SD). The differences between two independent groups were compared using independent t -tests. Survival analysis was performed by the Kaplan–Meier method and log-rank test. $p < 0.05$ was the cut-off to be statistically significant. A flow chart of design is presented in Figure S1.

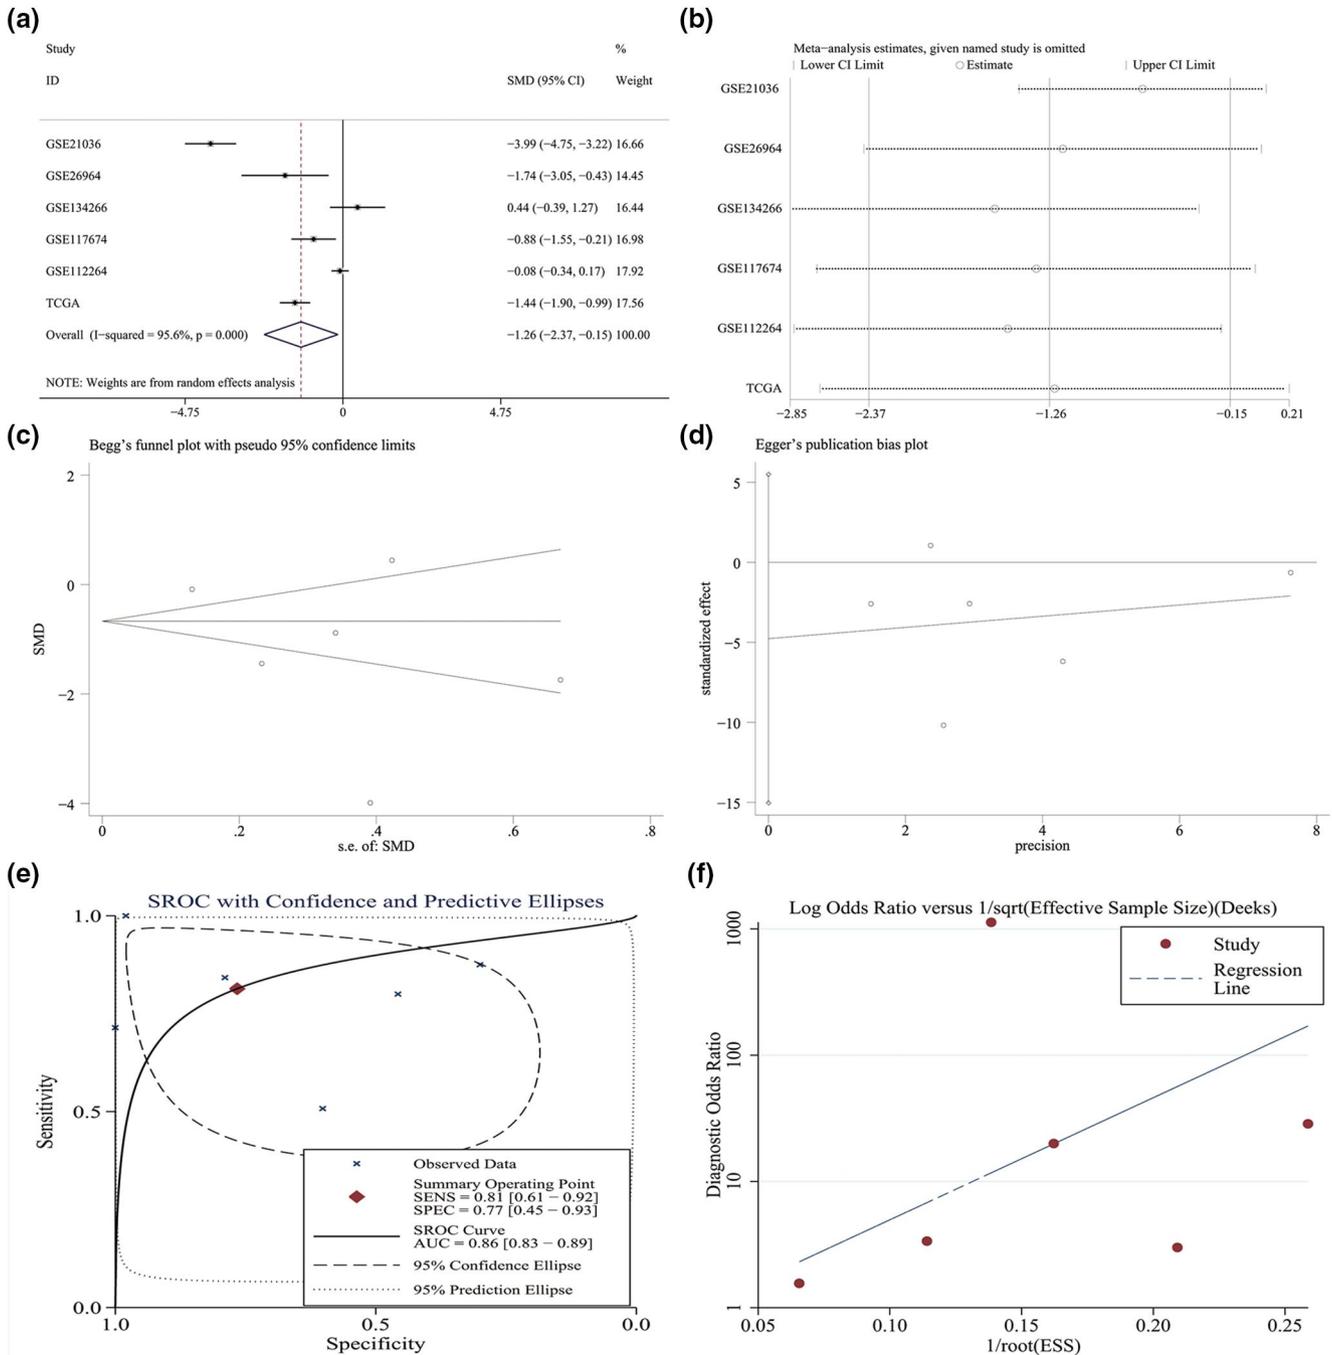

FIGURE 1 The expression level and discrimination potential of miRNA-145-5p in metastatic PCa. (a) Forest plot showing the combined SMD of -1.26 (-2.37 to -0.15), indicating that the expression of miRNA-145-5p in metastatic PCa is lower compared with that of localised PCa. (b) Sensitivity analysis showing the combined SMD is stable. (c) Begg's test showing no publication bias ($p > 0.05$). (d) Egger's test showing no publication bias ($p > 0.05$). (e) SROC curve assessing the discrimination potential of miRNA-145-5p in metastatic PCa. (f) Funnel chart showed no publication bias ($p > 0.05$)

3 | RESULTS

3.1 | The clinical significance of miRNA-145-5p in the metastasis of PCa

A total of six studies that contained miRNA-145-5p expression data were considered eligible (Table 1). The data extracted from the six studies showed a lower miRNA-145-

5p expression in 131 metastatic PCa samples than in 1371 localised PCa samples (SMD = -1.26 , 95% CI: -2.37 to -0.15 , $I^2 = 95.6%$, $p = 0.000$) (Figure 1a). Because the samples are all from the tissues, we only conducted a sensitivity analysis to seek the source of heterogeneity, which indicated that no study had a significant influence on the whole study cohort (Figure 1b). No publication bias was observed (Figure 1c,d). The potential of miRNA-145-5p for

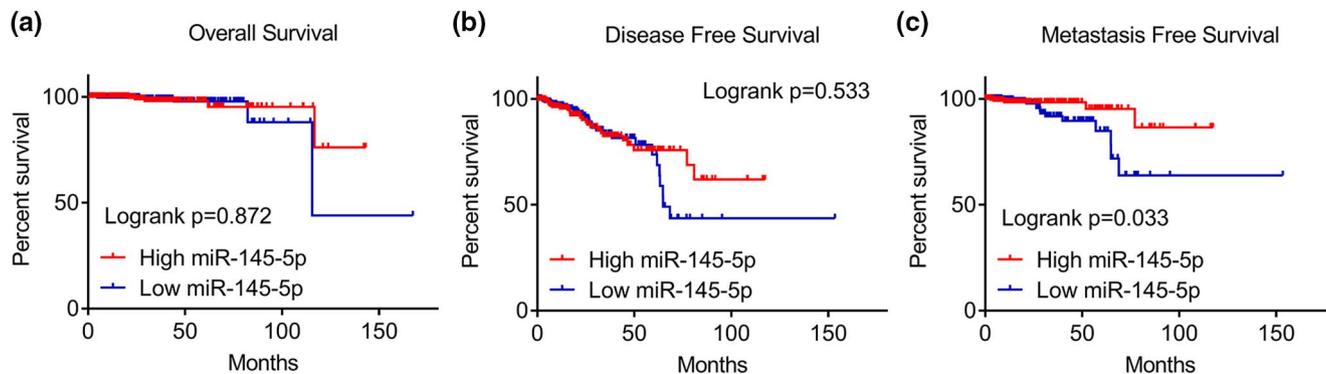

FIGURE 2 Kaplan–Meier analysis of miRNA-145-5p of PCa. (a) no statistical relationship was found between miRNA-145-5p and OS rate ($p = 0.872$). (b) no statistical relationship was found between miRNA-145-5p and DFS rate ($p = 0.533$). (c) PCa with downregulated miRNA-145-5p had a shorter MFS time than did the PCa with upregulated miRNA-145-5p ($p = 0.033$)

distinguishing metastatic PCa from localised PCa was assessed by SROC analysis, which showed area under the curve (AUC) value of 0.86 (0.83–0.89) (Figure 1e). No publication bias was observed (Figure 1f). The scatter diagrams and ROC curves of miRNA-145-5p between metastatic PCa and localised PCa of each study were visualised in Figures S2 and S3. These data indicated a dramatic downregulation of miRNA-145-5p and a moderate potential of miRNA-145-5p for distinguishing metastatic PCa from localised PCa. We also verified the miRNA-145-5p expression between PCa and non-PCa. A total of 26 studies were obtained (Table S1). As expected, we found that miRNA-145-5p expression was remarkably reduced in 1429 PCa samples as compared with 544 non-PCa samples, as the standardised mean differences (SMD) was -0.30 and AUC was 0.76 (Figure S4). The association between miRNA-145-5p and clinical characteristics was analysed in PCa patients using the TCGA database. Downregulated miRNA-145-5p was significantly associated with pathological T, N and M stages, Gleason score and recurrence (Table S2). Survival analysis demonstrated the PCa with downregulated miRNA-145-5p had shorter metastasis-free survival (MFS) time than did the PCa with upregulated miRNA-145-5p, while no statistical relationship was found between miRNA-145-5p and overall survival (OS) rate or disease-free survival (DFS) rate (Figure 2).

3.2 | Putative target genes of miRNA-145-5p in metastatic PCa

3.2.1 | miRNA-145-5p transfected metastatic PCa cell line data

Examination of the GSM610397 (the bone metastatic PCa cell line PC-3) and GSM610398 (the lymph node metastasis PCa cell line LNCap) data with the standard $\log_2FC < -1$, which included gene expression variations after the transfection of miRNA-145-5p mimic in metastatic PCa cell line, gave a total of 8365 and 7603 genes, respectively. After removing the

duplicates, 12,031 genes were determined as candidates influenced by miRNA-145-5p.

3.2.2 | Differential expression of metastatic PCa upregulated genes

Screening of a total of 10 studies identified the differential expression of upregulated genes. In total, 1460 standard genes that occurred at least three times among the differentially expressed upregulated genes were selected for subsequent analysis.

3.2.3 | Online prediction databases

In total, 9163 predicted target genes emerged using at least five prediction tools. These were gathered and the overlap of the three sources was used to obtain an accurate evaluation of the targets of miRNA-145-5p. Ultimately, 414 genes obtained from

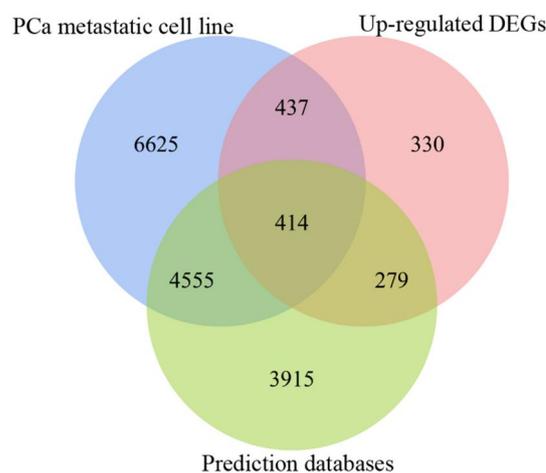

FIGURE 3 A total of 414 genes were selected as potential target genes of miRNA-145-5p

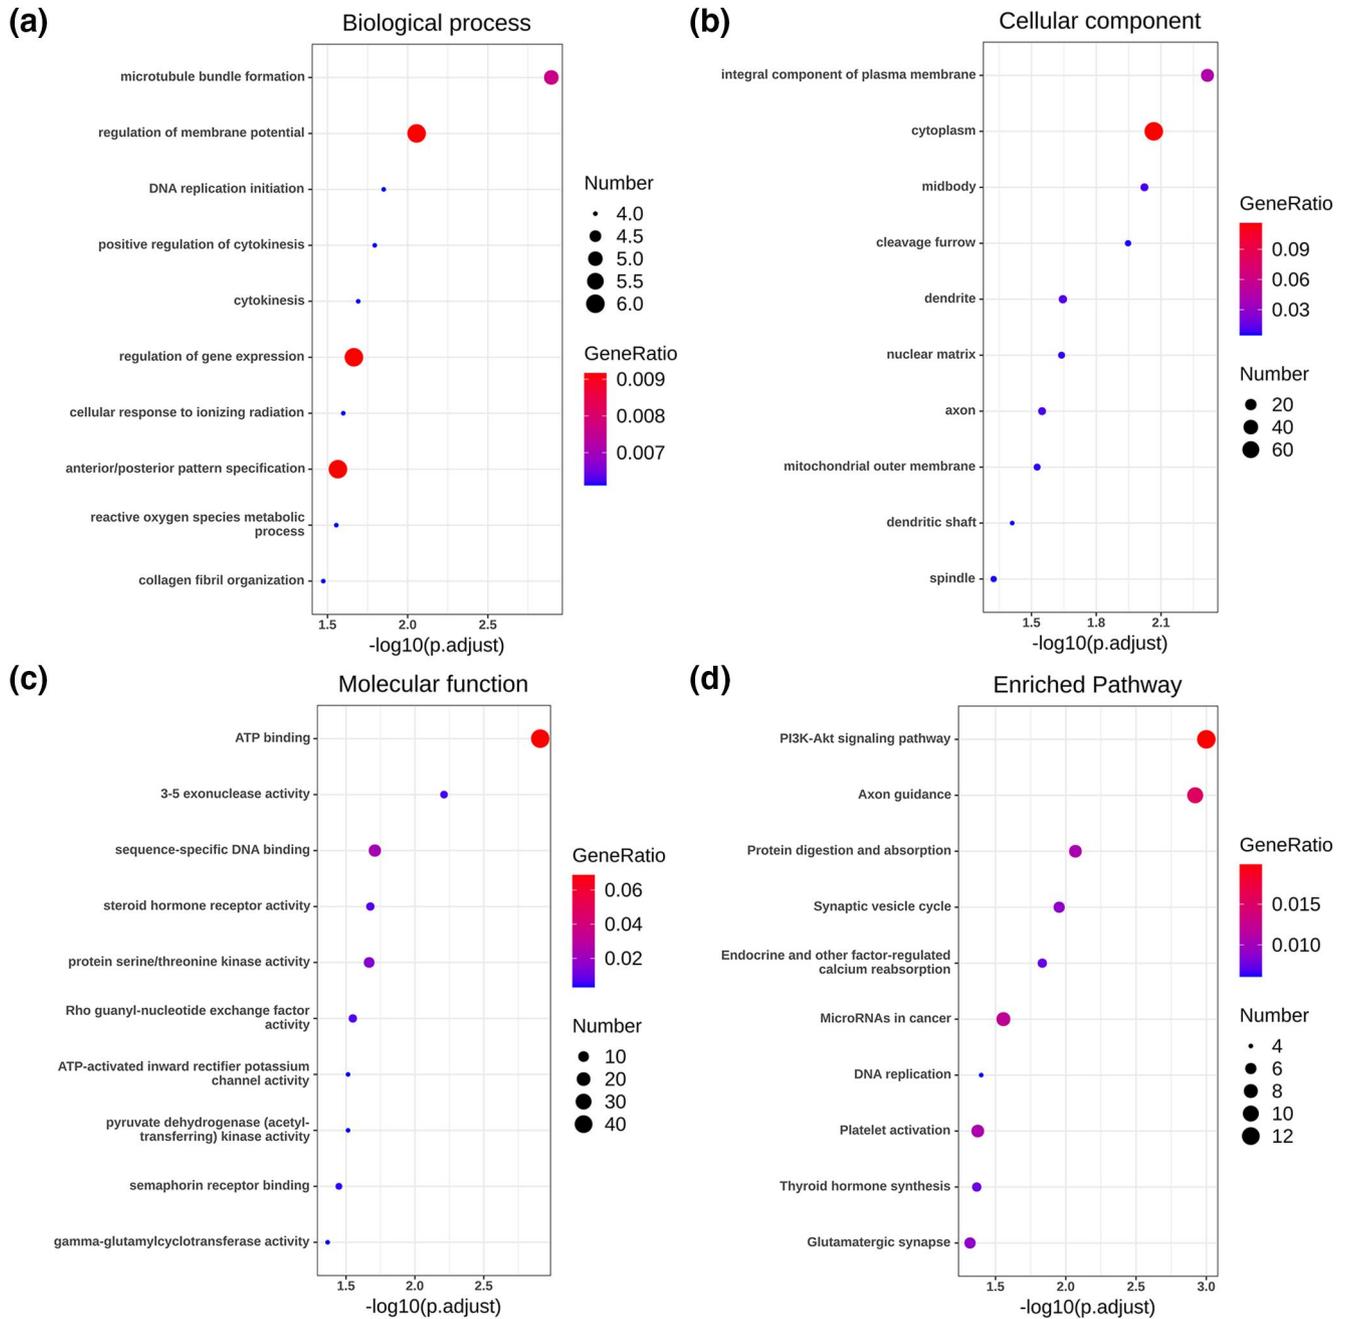

FIGURE 4 Functional and pathway enrichment analyses of the target genes of miRNA-145-5p. (a) Biological processes. (b) Cellular component. (c) Molecular function. (d) Kyoto Encyclopedia of Genes and Genomes analysis

the overlapping results from the three sources, were gathered for subsequent analysis (Figure 3).

3.3 | GO, KEGG and PPI analyses of the putative targets of miRNA-145-5p in metastatic PCa

GO enrichment using DAVID showed that the 414 intersected potential targets were enriched most significantly in the subsequent pathways: microtubule bundle formation,

regulation of membrane potential and DNA replication initiation in the biological process (BP) (Figure 4a); integral component of plasma membrane, cytoplasm and midbody in the cellular component (CC) (Figure 4b); ATP binding, 3'-5' exonuclease activity and sequence-specific DNA binding in the molecular function (MF) (Figure 4c). The KEGG pathway analysis suggested that the PI3K-Akt signalling pathway was most significant (Figure 4d). The PPI network analysis defined ten genes (TOP2A, RRM2, PBK, BIRC5, PRC1, FANC1, MCM10, TRIP13, SMC4 and RAD51AP) as the hub genes in metastatic PCa, and TOP2A

fluids and cell lines needs further verification. Richardsen et al. found that miRNA-145-5p was not correlated to Gleason grade [44]. Our study indicated miRNA-145-5p was decreased in high Gleason grade patients (≥ 8) than low Gleason grade patients (≤ 7). For the relationship between miRNA-145-5p and prognosis, Larne et al. found the PCa with downregulated miRNA-145-5p had a shorter median survival time than did the PCa with upregulated miRNA-145-5p [19]. Aygeris et al. reported the loss of miRNA-145-5p expression resulted a shorter DFS time of PCa patients [31]. No statistical significance was found between miRNA-145-5p and OS rate or DFS rate in PCa patients using the TCGA database. Additional research is needed to further confirm the clinical effects of miRNA-145-5p in PCa.

Ren and colleagues found that low level of WT-p53 accelerated the metastasis of PCa through inhibiting miRNA-145-5p expression to promote EMT [45]. In Guo et al.'s study, miRNA-145-5p was reported to target HEF1 repressing invasion and EMT in PCa [46]. miRNA-145-5p and ZEB2 could form a negative feedback loop, which accelerated the progression and metastasis of PCa [47]. However, research on miRNA-145-5p expression in metastatic PCa is limited. Only a few studies with small sample size ($n < 20$) results indicated that miRNA-145-5p was reduced in metastatic PCa [25–27], and these results have not been verified by large sample. Herein, we observed downregulated miRNA-145-5p expression in 131 metastatic PCa samples than in 1371 localised PCa samples. Besides, miRNA-145-5p had good distinguishing

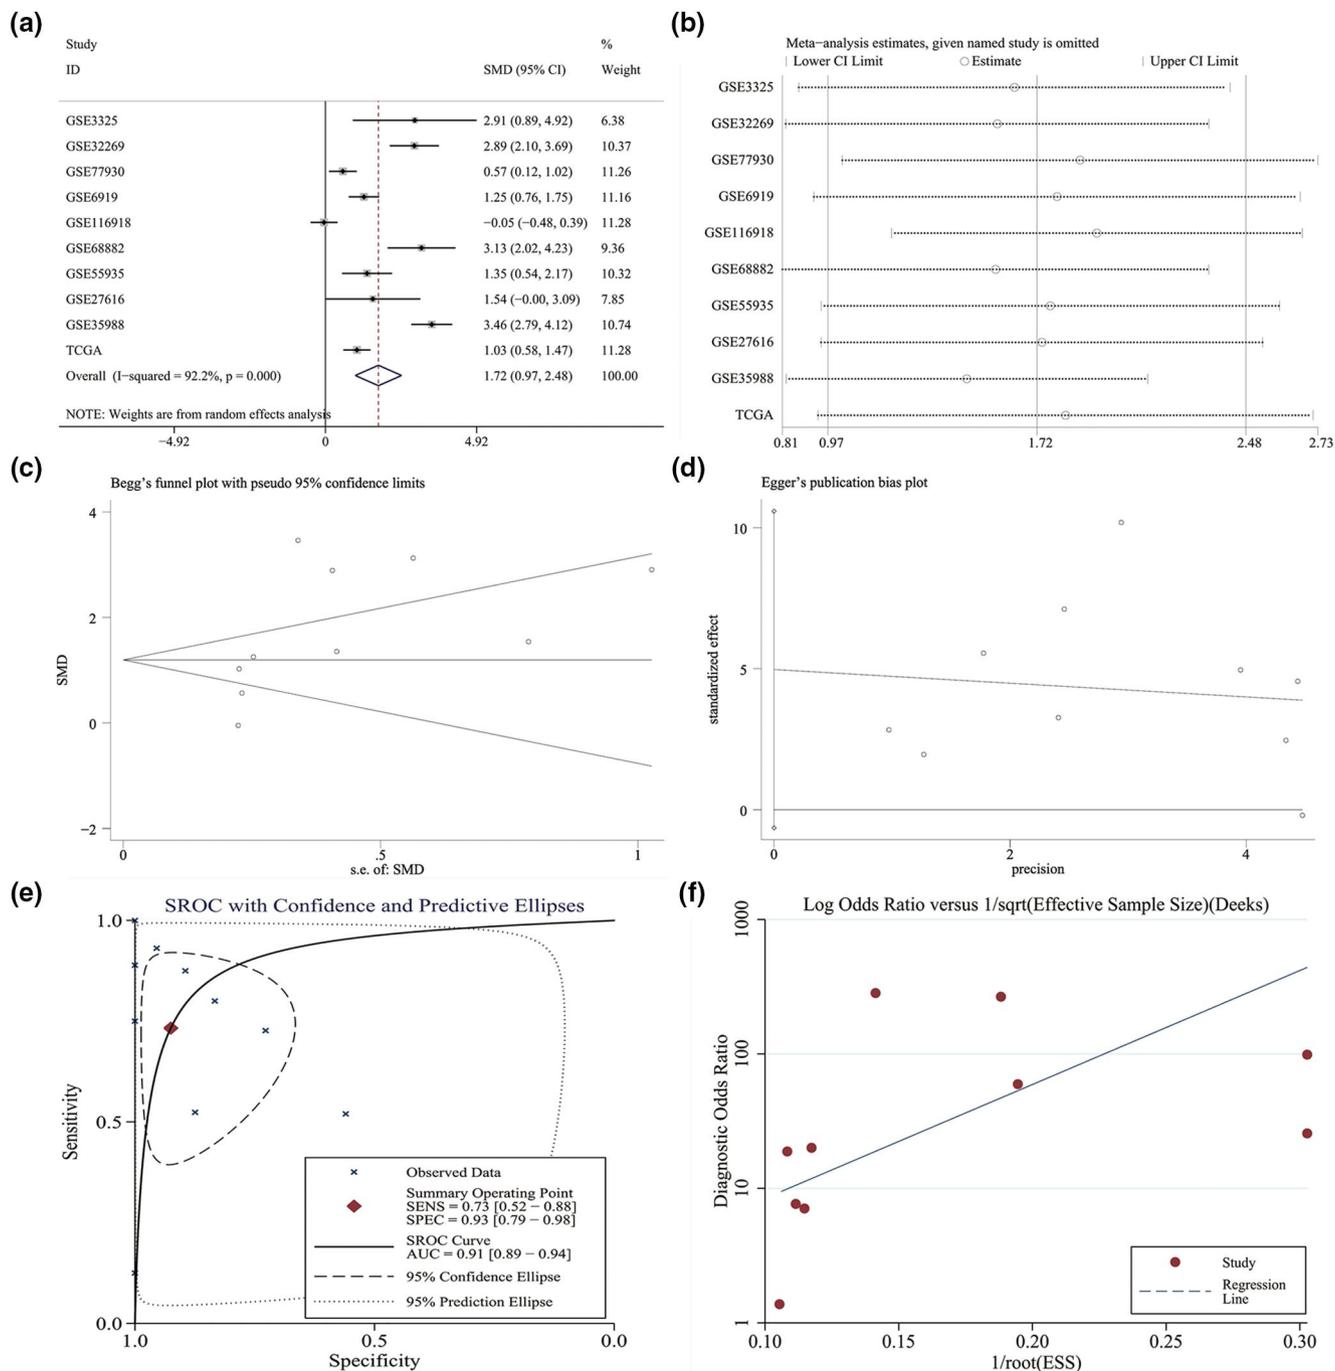

FIGURE 7 Expression level and discrimination potential of TOP2A in metastatic PCa. potential in metastatic PCa, and downregulated miRNA-145-5p predicted poor MFS in PCa patients. MiRNA-145-5p might serve as a clinical biomarker in metastatic PCa.

We screened 414 miRNA-145-5p target genes using three different methods, which increased the reliability of the targets. The KEGG pathway analysis revealed the most significant pathway closely associated with metastatic PCa as PI3K-Akt signalling pathway. Previous literature reported PI3K-AKT

signalling pathway activation was related to PCa metastasis [48–51]. Two studies have shown that miRNAs (miRNA-133a-3p and miRNA-188-5p) suppressed PCa metastasis via inhibiting PI3K/AKT signalling pathway [52,53]. Although there is no research report on the connection between miRNA-145-5p and PI3K-AKT signalling pathway in metastatic PCa, we believe that the role of miRNA-145-5p in PI3K/AKT signalling pathway is worth studying.

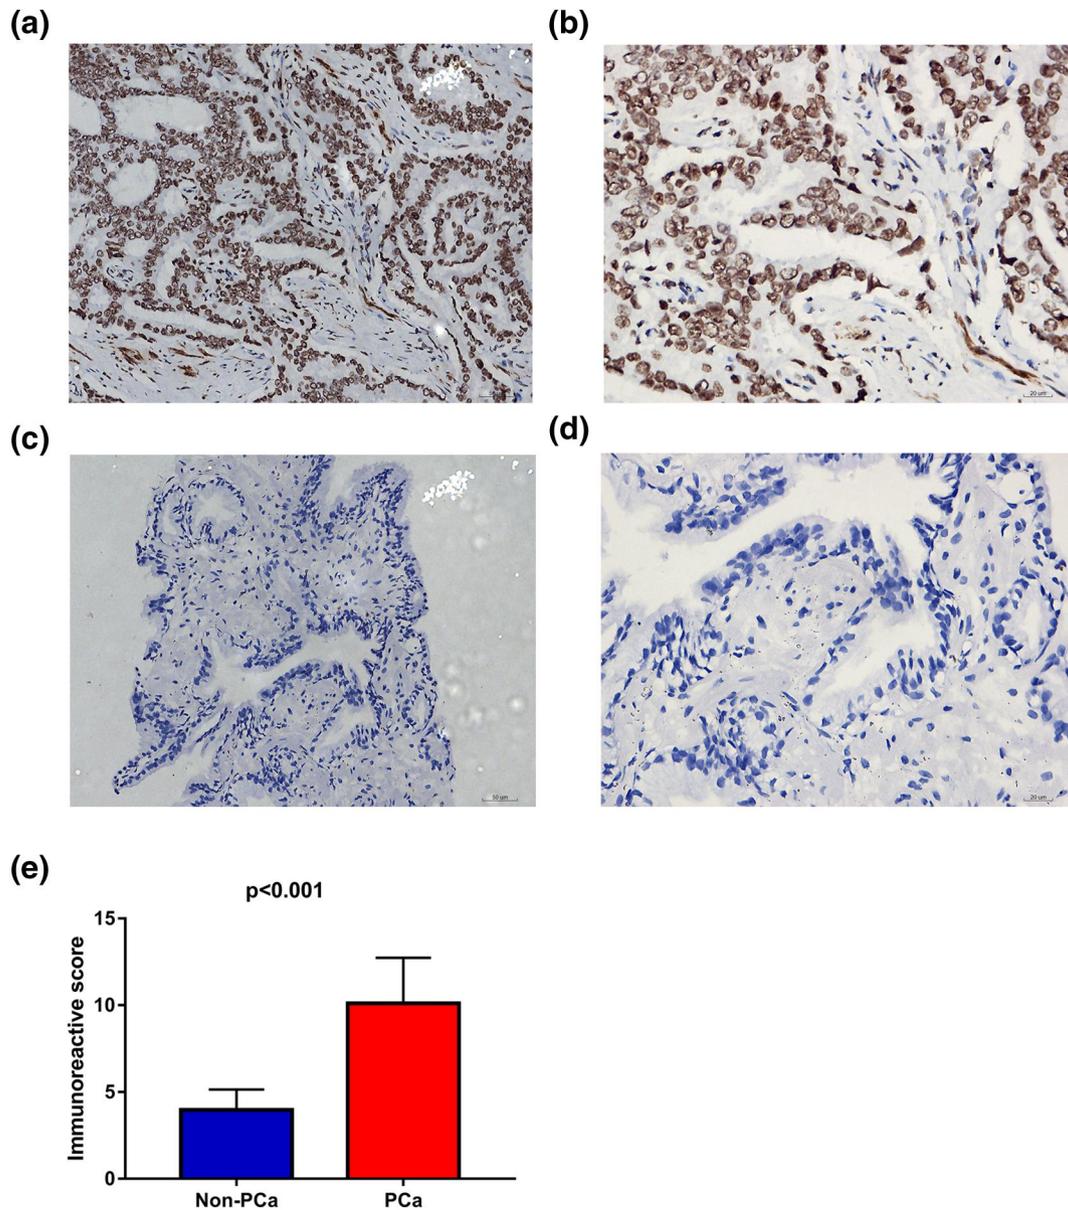

FIGURE 8 TOP2A protein expression in PCa and non-PCa tissues by immunohistochemical staining. (a), (b) PCa tissues stained intensely for TOP2A (magnification, $\times 200$ lower and $\times 400$ upper). (c), (d) non-PCa tissues stain medium for TOP2A (magnification, $\times 200$ lower and $\times 400$ upper). (e) Histogram showing the expression of TOP2A proteins in PCa and non-PCa tissues based on immunoreactive score

The results from the PPI network analysis identified 10 hub genes, and TOP2A having the highest degree of connectivity was selected as the potential targets for miRNA-145-5p. TOP2A had a significantly reverse relationship with miRNA-145-5p in both PCa and metastatic PCa. TOP2A encodes topoisomerase II α , a nuclear enzyme that manipulates the DNA topological structure and cell cycle. This enzyme is a biomarker of cell proliferation in both tumour and non-tumour cells. Recent studies have revealed that TOP2A plays a vital role in the genesis of many malignant tumours. TOP2A expression was upregulated in colon cancer than non-cancer, and knockdown of TOP2A could inhibit cancer cell growth and invasion [54]. In breast cancer, TOP2A amplification was correlated with sensitivity to

anthracycline-based neoadjuvant chemotherapy, and TOP2A was identified as a predictive marker [55]. Pei et al. found a significant correlation between upregulation of TOP2A and pancreatic metastasis and with poorer survival in patients with pancreatic cancer [56]. Consistent with the results by calculating the pooled SMD in 1768 PCa samples and IHC of 221 clinical PCa samples, TOP2A has been reported to be upregulated in PCa, which accelerated the onset and progression of PCa via different biological mechanisms [57–61]. At present, the clinical significance of TOP2A is controversial. Malhotra et al. reported that TOP2A was not associated with pathologic T stage and Gleason grade [59]. In our study, TOP2A expression was increased in T3/4 and higher Gleason grade (≥ 8) patients. For the correlation

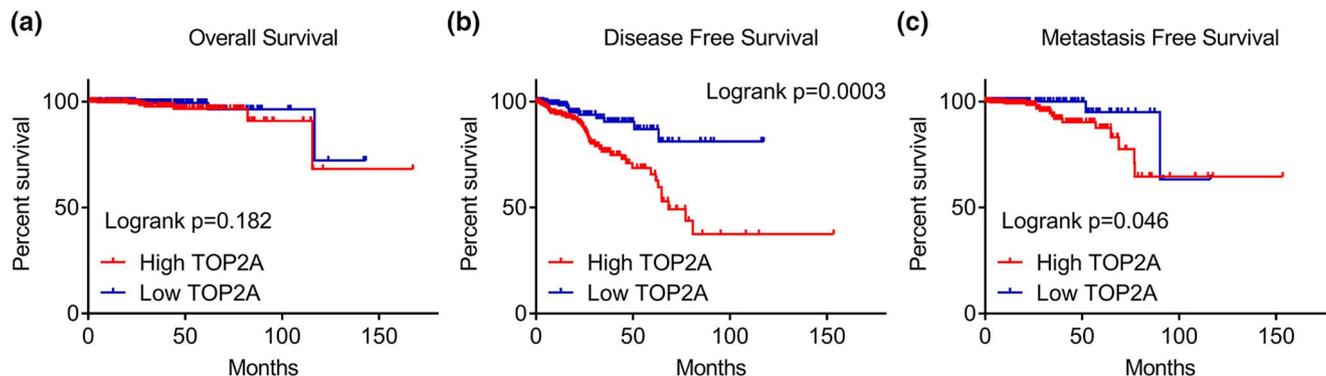

FIGURE 9 Kaplan–Meier analysis of TOP2A of PCa. (a) OS rate of PCa patients with high TOP2A versus low TOP2A expression was no difference ($p = 0.182$). (b) Statistical correlation was observed between TOP2A and DFS rate ($p = 0.0003$). (c) Statistical correlation was observed between TOP2A and MFS rate ($p = 0.046$)

between TOP2A and prognosis, several studies indicated that upregulated TOP2A in patients was associated with a shorter time to biochemical recurrence [59,61,62]. Li et al. found that TOP2A was increased in secondary PCa and TOP2A overexpression resulted a shorter OS time of PCa patients. Amanda et al. reported that TOP2A overexpression was significantly related to OS rate of PCa patients [63]. The result showed that the OS rate of PCa patients with high TOP2A versus low TOP2A expression was no difference. The clinical significance of TOP2A in PCa needs further study.

For metastatic PCa, high expression of TOP2A in PCa patients was associated with poorly differentiated primary disease, indicating that patients with high TOP2A expression might be more prone to suffer a progressive and metastatic disease [62]. Xuefeng et al. reported that TOP2A was high expression in metastatic PCa compared with primary PCa, and TOP2A mediated EMT and cancer stem cells regulating metastasis of PCa [64]. An involvement of TOP2A in epigenetic regulation has been reported through EZH2, and TOP2A was increased in four murine metastatic PCa samples compared with three murine primary samples [65]. However, these studies were conducted through a small sample, which reduced the credibility of results. Herein, TOP2A was dramatically elevated in 303 metastatic PCa samples compared with 943 localised PCa samples. In addition, TOP2A had an outstanding distinguishing potential in metastatic PCa, and high expression of TOP2A predicted unfavourable MFS time in PCa patients. TOP2A may be useful as a biomarker for metastatic PCa.

Although we have obtained valuable findings, our research does have some limitations. First, the clinical significance of miRNA-145-5p in metastatic PCa have not been verified by our the clinical specimens from our institute. Second, we paid more attention to investigating the clinical significance and prospective molecular mechanisms of miRNA-145-5p in metastatic PCa; however, the biological functions of miRNA-145-5p and TOP2A in metastatic PCa and the relationship between miRNA-145-5p and TOP2A need to be further verified through both in vitro and in vivo experiments.

In conclusion, the results based on miRNA-chip and miRNA-sequencing datasets indicated that downregulation of miRNA-145-5p might promote PCa metastasis. TOP2A was determined as a potential target gene of miRNA-145-5p in metastatic PCa; this finding should be confirmed by further studies. In addition, miRNA-145-5p and TOP2A might serve as clinical biomarkers in metastatic PCa.

ACKNOWLEDGEMENTS

This work was supported by the National Natural Science Foundation of China (grant number 81760485), Fund of Natural Science Foundation of Guangxi, China (2018GXNSFAA281175), Medical Excellence Award Funded by the Creative Research Development Grant from the First Affiliated Hospital of Guangxi Medical University and Guangxi Degree and Postgraduate Education Reform and Development Research Projects, China (JGY2019050). The authors are thankful for the use of the GEO, ArrayExpress, Oncomine, SRA and TCGA databases and the software used in the study.
