ABSTRACT *Salmonella enterica* is an important global pathogen due to its contribution to human morbidity and death. The presence of *S. enterica* in Southeast Asian informal markets is amplified by cross-contamination between market surfaces and food products. Here, we describe the draft genome sequences of 81 *Salmonella enterica* isolates from informal markets in Cambodia.

Nontyphoidal *Salmonella enterica* causes the most cases of diarrheal disease worldwide and is a pathogen of global importance, particularly in low-income countries (LICs) (1). Major data gaps in LICs stem from inadequate national monitoring and surveillance programs. Whole-genome sequencing (WGS) can provide accurate information on foodborne pathogens (2). The availability of molecular data is crucial for improving food safety outcomes in LICs and understanding foodborne outbreaks and transmission pathways.

Herein, we describe the draft genome sequences of 81 *S. enterica* isolates collected from two Cambodian informal markets (i.e., those escaping food safety oversight). Sixty-four vendors classified by market location (inside versus outside) were sampled during the rainy (June 2018) and dry (January 2019) seasons. For each vendor, samples from three food contact surfaces (FCSs) and three non-food contact surfaces (NFCs) were collected, totaling 384 samples. Screening and isolation of *S. enterica* strains were conducted according to the U.S. Department of Agriculture Food Safety and Inspection Service guidelines (3). Samples were enriched with buffered peptone water, followed by selective enrichments of tetrathionate bile broth and Rappaport-Vassiliadis broth (HiMedia). Selective enrichments were streaked onto xylose-lysine-Tergitol 4 and brilliant green sulfa agar (HiMedia). Typical colonies were tested using the *Salmonella* latex agglutination kit (Oxoid, Basingstoke, UK), and presumptive isolates were confirmed by PCR (4). Genomic DNA was obtained using the DNeasy blood and tissue kit (Qiagen, Hilden, Germany), following the manufacturer's instructions. Libraries were prepared from genomic DNA with the Nextera XT DNA library preparation kit, and WGS was conducted on either a MiSeq or NextSeq sequencer, using a MiSeq reagent kit v2 (500 cycles) or a NextSeq 500/550 high-output kit v2 (300 cycles), respectively (Illumina, San Diego, CA). Minimum sequence quality was represented by average coverage of >30× and Q scores for reads 1 and 2 of >30 (5). Absence of contamination was affirmed with Kraken (6). Default parameters were used for all software unless otherwise specified. *De novo* assemblies were generated with SKESA v2.2 either by NCBI Pathogen Detection or in-house using GalaxyTrakr with standard settings (7, 8). Antibiotic resistance (AMR), stress, and virulence genotypes

^aSamples collected from food contact surfaces (FCSs) are underlined, while the rest were collected from non-food contact surfaces (NFCSS); the location of the vendor is indicated as inside or outside. All isolates belong to BioProject number PRJNA628951.

^bNextSeq run with an average of four lanes.

were available at NCBI Pathogen Detection (9). *Salmonella* pathogenicity islands (SPIs) were identified with SPIFinder (<https://cge.cbs.dtu.dk/services/SPIFinder>) (Center for Genomic Epidemiology). Draft genomes were annotated using the NCBI Prokaryotic Genome Annotation Pipeline (PGAP) (10). The serotype of each isolate was determined *in silico* using SeqSero v1.0 on draft genomes (11). Draft genomes ranged between 4,609,585 and 5,198,930 bp in size, with an average GC content of 52.4%. The number of contigs for each isolate ranged from 23 to 468. A total of 16 *S. enterica* serotypes were identified, including Rissen ($n = 19$); Hvittingfoss ($n = 13$); Corvallis ($n = 10$); Krefeld ($n = 8$); Weltevreden ($n = 6$); Altona ($n = 6$); Mbandaka ($n = 5$); Typhimurium ($n = 3$); Javiana, Uganda, and Derby ($n = 2$ each); and Anatum, Braenderup, Lexington, Virchow, and the potential monophasic variant of *S. enterica* serotype Typhimurium (I 4,[5],12:i:–) ($n = 1$ each). AMR genes, including those encoding for tetracycline, β -lactam, sulfonamide, quinolone, aminoglycoside, phenicol, trimethoprim, and fosfomycin resistance, were identified in 43 of 81 strains. A total of 10 SPIs were detected in 59 genomes (Table 1) (12, 13). The draft genome sequences described will be valuable for understanding the dynamics of *S. enterica* diversity and persistence in informal markets in Cambodia, as well as supporting global epidemiological investigations of outbreaks.

Data availability. This whole-genome shotgun project has been deposited in DDBJ/ENA/GenBank under the accession numbers presented in Table 1. The versions described in this paper are the first versions.

ACKNOWLEDGMENTS

We thank the faculty and students of the Royal University of Agriculture (Phnom Penh, Cambodia) for their valuable insights and resources, which were essential for the completion of this project.

We thank the Horticulture Innovation Lab at the University of California, Davis, for financial support. This project was also supported by the Center for Food Safety and Applied Nutrition at the U.S. Food and Drug Administration through its Genome-Trakr network (<https://www.fda.gov/food/whole-genome-sequencing-wgs-program/genometrakr-network>). This article was made possible through the generous support of the U.S. Agency for International Development. This work was supported by the USDA National Institute of Food and Agriculture, Hatch project 1018371.

The contents of this article are the responsibility of the Horticulture Innovation Lab and do not necessarily reflect the views of the U.S. Agency for International Development or the U.S. Government. The use of trade names and commercial sources is for identification purposes only and does not imply endorsement.
