### 2 ABSTRACT

Background. The efficacy of SARS-CoV-2 convalescent plasma (CCP) for preventing infection in exposed, uninfected
 individuals is unknown. CCP might prevent infection when administered before symptoms or laboratory evidence of
 infection.

- 6 Methods. This double-blinded, phase 2 randomized, controlled trial (RCT) compared the efficacy and safety of
- 7 prophylactic high titer (≥1:320 by Euroimmun ELISA) CCP with standard plasma. Asymptomatic participants aged ≥18
- 8 years with close contact exposure to a person with confirmed COVID-19 in the previous 120 hours and negative SARS-
- 9 CoV-2 test within 24 hours before transfusion were eligible. The primary outcome was new SARS-CoV-2 infection.
- 10 **Results.** 180 participants were enrolled; 87 were assigned to CCP and 93 to control plasma, and 170 transfused at 19
- sites across the United States from June 2020 to March 2021. Two were excluded for screening SARS-CoV-2 RT-PCR
- 12 positivity. Of the remaining 168 participants, 12/81 (14.8%) CCP and 13/87 (14.9%) control recipients developed SARS-
- 13 CoV-2 infection; 6 (7·4%) CCP and 7 (8%) control recipients developed COVID-19 (infection with symptoms). There were 14 no COVID-19-related hospitalizations in CCP and 2 in control recipients. Efficacy by restricted mean infection free time
- 15 (RMIFT) by 28 days for all SARS-CoV-2 infections ( $25\cdot3$  vs.  $25\cdot2$  days; p=0.49) and COVID-19 ( $26\cdot3$  vs.  $25\cdot9$  days; p=0.35)
- 16 was similar for both groups.
- Conclusions. Administration of high-titer CCP as post-exposure prophylaxis, while appearing safe, did not prevent SARS CoV-2 infection.

- 21 Running title: SARS-CoV-2 exposure plasma prophylaxis or SARS-COV-2 PEP with convalescent plasma
- 22
- 23

- 1 Background
- 2 Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is responsible for Coronavirus Disease 2019 (COVID-19)
- 3 and the pandemic that has claimed millions of lives [1]. Especially at the pandemic's onset, effective preventive
- 4 strategies were limited. Even by 2022, many have not been vaccinated, and some do not respond to vaccination [2, 3].
- 5 The urgency of effective prevention is highest within households of SARS-CoV-2 infected persons since 10-50% will be
- 6 secondarily infected. Passive immunotherapy using preformed antibodies is effective as post-exposure prophylaxis (PEP)
- 7 against many infections [4-7]. Combinations of monoclonal antibodies (mAb) are effective as COVID-19 PEP [8, 9].
- 8 COVID-19 convalescent plasma (CCP) may confer protection during early infection and in those without antibodies[10-
- 9 12]. CCP has some advantages over mAb's, including ease of procurement, low cost, and resilience against viral variants
- 10 [13]. This study sought to evaluate the safety and efficacy of CCP containing anti-SARS-CoV-2 antibodies as PEP.
- 11 Methods
- 12 Study design and Participants
- 13 A randomized, double-blind, placebo-controlled clinical trial was conducted to compare the safety and efficacy of 14 transfusion of CCP (intervention) with SARS-CoV-2 non-immune control plasma.
- 15 Asymptomatic participants aged ≥18 years who had a close contact exposure to a person with confirmed COVID-19 in
- 16 the previous 120 hours and did not have SARS-CoV-2 vaccination, and past or active SARS-CoV-2 infection were eligible.
- 17 The applied definition of close contact exposure was that used by Centers for Disease Control and Prevention (CDC)
- 18 during the study period. Transfused participants positive by RT-PCR at screening were excluded from analyses.
- 19 Participants were enrolled at 19 US centers between June 11, 2020 to June 23, 2021. Approval was obtained from the
- 20 Institutional Review Boards at Johns Hopkins University School of Medicine functioning as single IRB for all participating
- sites. The protocol was additionally approved by the Department of Defense (DoD) Human Research Protection Office.
- 22 An independent data and safety monitoring board provided oversight and reviewed efficacy and safety as the study was
- conducted. All participants provided written informed consent. Trial registration: Clinicaltrial.gov NCT04323800.
- 24
- 25 Randomization to treatment arm and masking
- 26 Eligible subjects were randomized 1:1 to receive a unit of CCP or control plasma using central interactive web-based
- 27 systems. CCP and control plasma were in standard plasma bags, with identical labels.
- 28 Intervention
- 29 CCP donors were eligible for collection if they had a history of a positive molecular assay test result for SARS-CoV-2 30 infection, met standard criteria for blood donation, and had SARS-CoV-2 positive antibody levels after diluting 1:320 titer 31 by Euroimmun ELISA, [Mountain Lakes, NJ] at screening. CCP was collected at various US locations. After qualification, the donor CCP antibody levels were later characterized in research laboratories by full length ancestral spike and 32 33 receptor-binding domain (RBD) endpoint titers, live virus growth neutralization assays and Euroimmun arbitrary unit 34 (AU) at the manufacturer's recommended dilution of 1:101[14]. Control was standard SARS-CoV-2 non-immune plasma 35 collected before January 1, 2020, or seronegative for SARS-CoV-2. Transfusions were performed at outpatient clinical research facilities. Individuals were followed for 90 days with visits at days 0 (transfusion), 1, 3, 7, 14, 28, 60, and 90. 36
- Nasal swabs were collected at screening (days -1 to 0) and at days 1, 7, 14, and 28. Assessments for COVID-19

- 1 (symptomatic infection) were conducted at screening, transfusion, and days 1, 3, 7, 14, 28, and 60. Safety assessments
- 2 were continued to day 90. Viral testing was performed using RT-PCR that targeted the SARS-CoV-2 nucleocapsid gene.
- 3 Recipient antibody levels were measured by RBD endpoint titers.

### 4 Primary Outcome

- 5 The primary efficacy outcome was incident SARS-CoV-2 infection by study day 28 by positive RT-PCR testing conducted
- 6 on collected nasal swabs or by clinical RT-PCR testing conducted outside the study.

## 7 Secondary efficacy outcomes

- 8 Disease severity was measured to day 28 using a clinical event scale (supplementary material) and evaluated using an
- 9 ordinal logistic model. Efficacy for preventing SARS-CoV-2 infection and COVID-19 was examined based on donor
- antibody titer through characterization of donor IgG, including end point titers and area under the curve (AUC) using a
   standardized ELISA to measure IgG against the spike and receptor binding proteins and anti-SARS-CoV-2 IgG against
- 12 recombinant S1 domain of the SARS-CoV-2 spike protein (Euroimmun) as previously described [14].

# 13 Safety assessments

- 14 The Common Terminology Criteria for Adverse Events (CTCAE) 5.0 was used for grading of adverse events (AE). The
- 15 safety outcomes were monitored throughout the study, including transfusion-related serious AEs (SAEs) (i.e. severe
- 16 transfusion reactions, acute respiratory distress syndrome and grade 3 or 4 adverse events). The masked independent
- 17 medical monitor evaluated AEs, SAEs and changes in baseline safety laboratory values.
- 18 Data management and statistical analyses
- The pre-specified primary analysis of cumulative SARS-CoV-2 infection was conducted using a time-to-event analysis to
   compare the restricted mean survival time, referred to henceforth as restricted mean infection free time (RMIFT).
- We calculated and compared the restricted mean survival times by 28 days and risk difference (RD) by treatment arm in 21 a modified intention to treat (mITT) analysis. We performed the primary analysis according to the participants' original 22 randomized treatment groups excluding those who did not receive a transfusion of study plasma and those who were 23 later found to have been test positive at transfusion [15]. Analyses were adjusted for variables potentially related to the 24 outcome in order to increase estimate precision (statistical analysis plan; supplementary material) [15]. Demographic 25 26 and clinical variables were measured at baseline. To determine which pre-specified candidate variables to include, we conducted variable selection by random survival forest in the entire sample (i.e., not including an indicator term for 27 treatment arm) and masked to treatment allocation. This algorithm was implemented on the mITT sample to identify 28 the prognostic baseline variables for the entire sample. 29
- 30 Baseline characteristics are reported as proportions or medians with interguartile ranges (IQR) for continuous variables.
- 31 Time-to-event analysis was computed from the time of transfusion until development of a positive molecular test for
- 32 infection. Analyses were repeated using only clinical illness with COVID-19 as the outcome. Targeted minimum loss-
- 33 based estimation (TMLE) was used for difference in RMIFT by 28 days and risk of infection. Time scale was days from
- transfusion. A one-sided test with type I error of 0.05 was used to determine statistical significance.
- 35 A secondary outcome was disease severity by day 28 using a clinical event scale ranging from no infection to death. The
- 36 most severe status by the day 28 visit was ascertained using a TMLE estimator for ordinal outcomes and adjusted for the
- 37 pre-specified candidate variables selected by the algorithmic approach [16, 17].

- 1 A pre-specified sensitivity analysis was restricted to participants who remained infection-free up to day 4 to account for
- 2 people with early and still undetectable infection when CCP was administered and for an expected lag between
- 3 transfusion and effect from passive antibody transfer. Since protocolized RT-PCR testing was not performed on days 2
- 4 and 3, it is possible that infected asymptomatic patients were included in this analysis.

#### 5 Donor antibody titers

Analysis for donor spike antibody titer was conducted for AUC as a continuous variable: controls were assigned a value
of zero. To model antibody effect, a flexible Weibull time to event model was used[18] to estimate the hazard ratios. To
allow for non-linearity, both natural cubic splines and fractional polynomials were assessed choosing the model with the
lowest Akaike Information Criterion (AIC) [19]. Data on days from donation to transfusion were collected and compared
in the CCP vs placebo group.

### 11 Safety

- 12 Rates of severe transfusion reactions, AEs, grade 3 or 4 AEs, and death were evaluated by treatment arm; 95%
- 13 confidence intervals (CI) were calculated using skewness-corrected asymptotic score for exact CI[20], using the R
- 14 package 'ratesci'.

### 15 Conditional Power Analysis

- 16 The trial did not meet the target sample of 500 participants as enrollment stopped with widespread vaccine availability.
- 17 The sample size calculation is provided as supplementary material. A conditional power analysis, using the R package
- 18 'gsDesign', was conducted to assess the likelihood of providing evidence for the efficacy of convalescent plasma.

#### 19 Results

Of 1,138 participants screened, 180 (15.8%) were eligible and consented to the study and 170 were transfused (82 CCP;
88 control plasma; Figure 1). Of those transfused, two were excluded from efficacy analyses for baseline SARS-CoV-2

22 RT-PCR positivity. Table 1 lists participants' demographic and baseline characteristics. Median time from exposure to

23 transfusion was 2 days (IQR 1-4). Seven participants (3 CCP recipients) did not complete all study components.

CCP from 70 unique donations was transfused to 82 recipients; the IgG inverse endpoint titers to protein S were > 1,000
 except for a single unit at 540. More than 85% of the plasma units were hospital qualified EUA high titer by Euroimmun

- 26 Arbitrary units  $\geq$ 3·5, international spike binding arbitrary units/mL  $\geq$  60, RBD AUC>900 and virus 3-day culture
- 27 neutralization  $\geq$  8 International units/mL (appendix Figure S1).

# 28 Primary Outcomes

- Of the 168 participants in the mITT analyses, 12/81 (14·8%) CCP and 13/87 (14·9%) control recipients tested positive for SARS-CoV-2 RNA. Three were positive on day 1 post-transfusion and 3 on days 2-3. The RMIFT by 28 days was 25·3 days for CCP and 25·2 for control recipients (p=0·47. The RD was 0·01 (p=0·42) lower for CCP. Excluding infections through day 3, the RMIFT was 26·6 days for CCP and 25·8 for control recipients (p=0·15). The RD was 0·04 (p=0·21) lower for CCP.
- 33 Six (7.4%) CCP and 7 (8%) control recipients had COVID-19 (4 and 5 after day 3 from transfusion). The RMIFT by 28 days
- 34 was 26.3 for the CCP and 25.9 days for the control recipients. The RD between groups was 0.012 lower for CCP.
- 35 Excluding infections through day 3, the CCP group was consistently, but not significantly, better than control (difference
- in RMIFT =0.7 days, p=0.14; RD=0.017). Cumulative incidence of confirmed SARS-CoV-2 infections and of COVID-19,
- using a time-to-event analysis to compare the restricted mean survival (infection free) time are shown in figures 2 and 3.

- 1 Conditional power analyses were conducted since the target enrollment (500 transfused) was not reached. Had target
- 2 enrollment been reached it is unlikely that statistically significant results would have been achieved, with chances for
- 3 significant differences in RMIFT and RD calculated as 0.3% and 0.6% respectively.

### 4 Adverse Events

- 5 There were 86 reported AEs, of which 28 occurred with CCP and 58 with control plasma; 17/86 events were grade 3 or 4
- 6 Five participants required hospitalization (2 for COVID-19) all with control plasma (Supplemental Materials). CCP
- 7 recipients had a lower proportion of any AEs (p=0.005), and severe AEs (p=0.06) (Table 2).

### 8 Clinical Severity Score

- 9 Two control participants required hospitalizations for COVID-19 (Table 3). The distribution of clinical severity was similar
- 10 between the two groups for all events after transfusion (OR 0.99) and for events >3 days after transfusion (OR 0.94).

### 11 Relationship between donor antibody levels and infection

- 12 The donor antibody levels measured by binding to SARS-CoV-2 proteins or by virus neutralizations as well as the interval
- 13 from plasma donation to transfusion was comparable in those infected or not infected when limiting analysis to those
- 14 developing infection > 3 days after transfusion (Supplemental Figure 1 and 2). Pharmacokinetic analysis on 24
- 15 participants showed recipient antibody levels to be 4% or a 25-fold reduction from donor antibody levels with a 7-day
- 16 recipient half-life measured over 14 days (Figure 4).

### 17 Discussion

This randomized, placebo-controlled, double-blinded trial evaluated the efficacy and safety of a unit of high antibody titer CCP for prevention of SARS-CoV-2 infection following recent, close contact exposure to a person with COVID-19. In this sample of outpatients, CCP did not reduce SARS-CoV-2 infection in participants transfused up to 120 hours following exposure.

- The findings contrast with successful use of mAbs for PEP [8]. Inability of CCP to prevent infection cannot be ascribed to 22 the absence of specific antibody to SARS-CoV-2, as both CCP and mAbs contain SARS-CoV-2 specific antibodies. 23 Insufficient antibody dose in the CCP used is one explanation for lack of efficacy as PEP. The amount of immunoglobulin 24 in the casirivimab/imdevimab dose is 12 grams, likely exceeding the amount of viral-specific antibodies in a unit of high-25 26 titer plasma. The concentration of antibodies in the casirivimab/imdevimab PEP trial was 22-25 mg/L which is about 150 times that needed for neutralization of many variants [21, 22]. CCP used in this study had geomean neutralizing 27 international units/mL of 1:27, which when diluted about 30-fold after transfusion, resulted in 10-100 lower neutralizing 28 29 capacity than mAbs. Neutralization potency of CCP may be impacted by multiple factors including time of plasma collection, distance from location of use, severity of illness and age. The impact of viral variants on efficacy of plasma 30 collected earlier in the pandemic may be most profound with variants such as delta and omicron. Those would not have 31 impacted the results of this trial. It is possible that low levels of the delta variant were present at the clinical sites during 32 33 this trial, however, the treatment phase was completed prior to widespread circulation of those variants in the US. 34 Qualitative differences between the products could also affect efficacy. For CCP, much of the neutralizing capacity is in 35 IgM [23], a large molecule with poor tissue penetration; mAbs are entirely IgG, which has better tissue penetration[24].
- Breakthrough SARS-CoV-2 infections despite vaccination provide insight as to why CCP did not prevent infection. Serum
   IgG is unlikely to prevent upper airways infection, presumably because of insufficient concentration within respiratory
   airway mucosa during initial infection when the epithelium is intact. As infection progresses an inflammatory response

- 1 permits transudation of serum (and IgG) into tissues. Our results contrast with those of a study using the same plasma
- 2 supply, which found that CCP administered early in COVID-19 reduced hospitalization by 54% [25]. The large amount of
- 3 immunoglobulin in plasma after prophylactic mAb administration or vaccination is presumably sufficient to prevent
- 4 progression of infection to severe disease. However, the amount of specific antibody after a unit of CCP may be
- 5 insufficient to affect the course of initial infection, especially if much of the neutralizing antibody is IgM. This is
- 6 consistent with animal studies reporting antibodies' inefficiency at reducing virus in nasal tissues [26]. Notably, two
- 7 control participants were hospitalized for COVID-19 (one with hematological disease and hypogammaglobulinemia).
- 8 Though the numbers are small, none of those who received CCP progressed to hospitalization, which is consistent with
- 9 findings that early treatment with passive immunotherapy (CCP or mAbs) reduces disease progression [10].
- 10 Our study affords insight into the optimal timing of CCP administration. Although numerous clinical trials and
- 11 observational studies were initiated early in the pandemic, these —overwhelmingly— focused on hospitalized patients
- 12 with severe COVID-19, collectively demonstrating little if any benefit in advanced disease [27]. By contrast, findings from
- 13 large observational studies of hospitalized patients suggested a mortality benefit when CCP was administered early [11].
- 14 Two clinical trials of CCP in outpatients (i.e., those with early infection) have also shown benefit. One showed a
- 15 significant reduction in progression of respiratory disease in older patients with COVID-19 who received CCP [10]. In the
- 16 US, the largest trial to date of outpatient CCP use demonstrated a 54% relative risk reduction in hospitalization relative
- 17 to controls [25]. Another trial enrolled patients with COVID-19 who presented to the emergency room (ER) [28]. It failed
- 18 to show a significant difference between the CCP and control arms, but the high number of patients (n=25) who were
- 19 hospitalized during the index visit, suggests that the trial may have selected for a population with more advanced
- 20 disease [28]. Our study, which focused on PEP refines our understanding of when CCP is optimally effective, thus
- strengthening extant guidelines that recommend early use of qualified CCP following diagnosis [29].
- Historically, convalescent serum was used for prophylaxis of measles [4] and mumps [5] where it was demonstrated to
  prevent measles and mumps-related orchitis. These viruses are acquired by the respiratory route, but disease
  manifestations are systemic [5]. For both measles and mumps, success of serum prophylaxis was measured by
  prevention of systemic disease (rash and orchitis). These experiences suggest that it may be easier to prevent systemic
  disease with antibodies than against respiratory tract-only disease. A similar pattern is found with pneumococcal
  vaccine, in which antibodies are more effective in preventing sterile site than respiratory tract disease [30].
- In this study, CCP was associated with substantially fewer Grade 3/4 and severe AE's than control plasma. The reason for 28 this finding is unclear. As there were two hospitalization for COVID-19 in control recipients and none in CCP a possible 29 explanation could be protection from severe disease in those developing COVID-19 [25]. Early in the pandemic, there 30 were concerns about antibody-dependent enhancement (ADE) of infection [31, 32]. While ADE has not been reported in 31 CCP studies to date, almost all were conducted in hospitalized patients [33] and do not rule out the possibility of ADE in 32 early infection when endogenous antibody responses are lacking. In this study, CCP was administered before or very 33 34 early in the course of infection and there was no evidence of ADE. This strongly suggests that ADE is not a significant 35 concern [31, 32, 34].
- The study had limitations. The logistical challenges were formidable and frequently changed with the evolving pandemic. Enrollment declined precipitously with widespread vaccine availability. Previously vaccinated individuals were ineligible for participation, and guidance to defer vaccination until 90 days after receipt of CCP deterred potential subjects. The enrollment goal of 500 total participants was not achieved. However, conditional power analyses for the primary endpoint of infection suggest that results may not have significantly differed had the trial achieved target enrollment.

- 1 In conclusion, this RCT of high titer CCP given to participants exposed to, but not infected with SARS-CoV-2, within 120
- 2 hours demonstrated that CCP did not provide evidence of efficacy. Acknowledging the challenges of enrollment in the
- 3 setting of vaccine availability, the ongoing evolution of SARS-CoV-2 with loss of multiple treatment and prevention
- 4 options, could renew interest in new studies of CCP as PEP. Such studies should consider a higher dose of antibodies
- 5 (i.e., collected from donors who have a history of SARS-CoV-2 infection and have also previously been vaccinated)
- 6 and/or transfusion with multiple CCP units. Further, studies would best target populations most at risk, including the
- 7 immunocompromised or elderly, with greater emphasis on clinical rather than laboratory outcomes.

#### 8 NOTES

#### 9 Supplementary Data

- 10 Supplementary materials are available at Clinical Infectious Diseases online.
- 11 Consisting of data provided by the authors to benefit the reader, the posted materials are not copyedited and are the
- 12 sole responsibility of the authors, so questions or comments should be addressed to the corresponding author.

#### 13 Acknowledgments.

- 14 The authors gratefully acknowledge the study participants who generously gave of their time and biological specimens.
- 15 Initiation of this work was catalyzed by grants from Bloomberg Philanthropies and the State of Maryland

#### 16 Financial Support.

- 17 This study was funded principally by the U.S. Department of Defense's Joint Program Executive Office for Chemical,
- 18 Biological, Radiological and Nuclear Defense (JPEO-CBRND), in collaboration with the Defense Health Agency (DHA)
- 19 (contract number: W911QY2090012), with additional support from Bloomberg Philanthropies, State of Maryland, the
- 20 National Institutes of Health (NIH) National Institute of Allergy and Infectious Diseases 3R01AI152078-01S1, NIH National
- 21 Center for Advancing Translational Sciences U24TR001609-S3 and UL1TR003098, the Division of Intramural Research
- 22 NIAID NIH, Mental Wellness Foundation, Moriah Fund, Octapharma, HealthNetwork Foundation and the Shear Family
- 23 Foundation. The study sponsors did not contribute to the study design; the collection, analysis, and interpretation of
- 24 data; manuscript preparation, and the decision to submit the paper for publication.

### 25 Potential conflicts of Interests.

The authors report-KG- grants or contracts unrelated to this work and paid to institution from NIHI, personal fees from 26 Aspen Institute, Teach for America and UpToDate; TG- paid consultant for Fresenius Kabi USA and reports <\$5,000 of JNJ 27 28 stock; AC- Scientific Advisory Board of Sabtherapeutics (cow-derived human immunoglobulins COVID-19 treatment and 29 other infectious diseases) and Ortho Diagnostics Speakers Bureau, and consulting fees from Ortho Diagnostics and Pfizer, and payment for expert testimony from King & Spalding LLP, and leadership or fiduciary role with American 30 Society for Microbiology, and part owner of Melatech; EB- time is funded in part by National Heart Lung and Blood 31 32 Institute (NHLBI) through grant 1K23HL151826, member of the FDA Blood Products Advisory Committee, Abbot 33 Laboratories, Grifols Diagnostic Solutions, personal fee for invited educational presentations for Terumo BCT (honoraria for educational webinar) and advisor for California Institute for Regenerative Medicine (convalescent plasma program), 34 35 and unpaid participation as invited member for a Data Safety Monitoring Board for the following trial: "Assessment of 36 safety and efficacy of COVID-19 Convalescent Plasma for treatment of COVID-19 in adults in Uganda; A Phase III 37 randomized controlled trial; SS research grants from Ansun, Astellas, Cidara, Emergent Biosolutions, F2G, Gilead, Merck, Scynexis, Zeteo, Shionogi and Shire, personal fees from Adagio, Adamis, Celltrion, Immunome, Intermountain Health and 38

Karyopharm (consultant, advisory board and data safety monitoring board member), participation on a Data Safety 1 2 Monitoring Board or Advisory Board for Adagio, Adamis, Amplyx, Immunome, Intermountain Health, Janssen, 3 Karyopharm, Reviral, and stock options from Immunome; DSu- grants or contracts unrelated to this work from NIH/NIAID (R01Al150763 Dual artemisinin action combats resistance; NIH R21TR001737 Quantum model repurposing of 4 5 cethromycin for liver stage malaria; NIH R01AI111962 Optimized Combination Antimalarial Drug Therapy), founder, 6 board member and stock options from AliguantumRx, DSMB member NIAID SMC/ISM Intramural 2018, medical royalties for malaria test (Binax Inc/D/B/A Inverness), consultant on malaria diagnosis for Masimo and Hemex Health and 7 consulting fees for legal malaria case (Mabrey Firm 2019 and Ressler and Ressler 2018), and patents (Issued-USP 8 9 9,642,865 May 9, 2017 New angiogenesis inhibitors; Issued-USP 9,568,471 February 14, 2017 Malaria Diagnosis in Urine; Issued-USP 7,270,948 September 18, 2007 Detection of malaria parasites by laser desorption mass spectrometry; 10 Pending SALTS AND POLYMORPHS OF CETHROMYCIN FOR THE TREATMENT OF DISEASE Patent Application (Application 11 #20210163522); and Pending- Macrolide compounds and their use in liver stage malaria and related disease Application 12 PCT/US2015/046665); EC- research grants from Gilead Sciences and Merck Sharp and Dohme (funds paid to UC 13 Regents), payment or honoraria for lectures, presentations, speakers bureaus, manuscript writing or educational events 14 from Gilead Sciences, and advisory board member for Gilead Sciences; JC- consultant for Merck and Co. and Resverlogix; 15 SKa- educational product development for Integritas Communications Group; GM- research grants from Teva, Sanofi 16 Regeneron, Astra Zeneca, Alk Abello, Genentech, Propeller Health, GlaxoSmithKline and Novartis, and honoraria paid to 17 author for HCPLive educational presentation, and position as Secretary/Treasurer (March 2019-February 2020), 18 President-Elect (March 2020-February 2021), and President (March 2021-February 2022) of the American Academy of 19 Allergy, Asthma and Immunology (payments made to institution during term as President) and Director of American 20 Board of Allergy and Immunology (2020-2025), Co-Chair of American Board of Allergy and Immunology Continuous 21 Assessment Program Examination Committee (2020-2022) (honoraria paid to author); CS- research grants from Centers 22 for Disease Control and Prevention, Merck and Pfizer; DJ- grants or contracts unrelated to this work from National Eve 23 Institute, National Institutes of Health and National Center for Advancing Translational Research, National Institutes of 24 Health; Board of Directors of the American Uveitis Society, speaking honoraria from Retina Society, Controversies in 25 26 Ophthalmology, University of Rochester, Wills Eye Hospital, LSU School of Medicine and Icahn School of Medicine at Mt. 27 Sinai, and participation on a Data Safety Monitoring Board or Advisory Board for National Eye Institute Intramural Branch. DSh reports numerous grants supporting ongoing and completed research unrelated to this manuscript from the 28 NIH; and is a member of DSMB for the Pelvic Floor Disorders Network (stipend support for meeting activities 4/year). DH 29 reports consulting fees from Neurotrope. MH reports grants or contracts unrelated to this work from NIH National 30 Center of Advancing Translational Sciences (NCATS) (KL2TR001426), NIH National Institute of Allergy and Infectious 31 Diseases (NIAID) (UM1AI069501) and Insmed Inc, and is a member of the AIDS Clinical Trials Group (ACTG) Tuberculosis 32 Transformative Science Group (TB TSG) Study Monitoring Committee. OL reports grants or contracts unrelated to this 33 34 work from Division of Intramural Research, NIAID, NIH. VC reports stock/stock options from spouse's employer and under spouse's name from Pfizer. DT reports board membership with Excision Bio and board membership (DSMB) with 35 Merck and Co (paid to author); employment with JHU; various expert testimony paid to author; honoraria for CME 36 programs only, paid to author (no service on corporate speakers bureau); royalties from UpToDate; and stock/stock 37 options with Excision Bio. NM reports participation as HyazOUT and UtahONE combined DSMB member for NIH National 38 Center for Advancing Translational Sciences (NCATS) U24TR001609-S3. All other authors report no relevant disclosures. 39

- 1 Figure Legends
- 2 Figure 1: Consort Diagram: Intention to treat analysis, including all transfused individuals. Those lost to
- 3 follow-up between transfusion to end of follow-up contributed to the time at risk. Individuals with
- 4 positive RT-PCR on day of transfusion were removed from analysis. \* One randomized participant was
- 5 found ineligible after randomization.
- 6
- 7 Figure 2: Cumulative incidence of confirmed infections and COVID-19.
- 8
- 9 Figure 3: Cumulative incidence confirmed SARS-CoV-2 infections and COVID-19 occurring after day 3.
- 10
- 11 Figure 4: The RBD AUC in the 24 donor plasma units were graphed at Day 0. Recipient participants
- 12 (n=24) who were seronegative at screening and who did not acquire infection were measured for RBD
- protein antibody area under the curve (AUC) levels at day 1 (n=24), 7 (n=21) and 14 (n=20) after
- 14 infection. Geometric means are shown. The recipient day 1 RBD levels were 4% of donor plasma levels.
- 15 The half-life over days 1-14 is 7 days, half-life from day 1-7 is 4.5 days and over day 7 to 14 is 11.3 days.
