ABSTRACT

The Data in Brief contains data on the electrokinetic mobility of PTFE and silica particles in aqueous suspensions as a function of pH and temperature. Furthermore, the concomitant conductivities and pH values are reported both for systems in the absence and presence of PTFE particles as a function of temperature and are compatible with the associated research paper “The influence of temperature on the charging of Polytetrafluoroethylene surfaces in electrolyte solutions” (Barisic et al.). The trend of the electrokinetic charging with temperature can be inferred from this for both kinds of particles. The data on the evolution of the pH and the measured conductivities are valuable input for future models that simulate the charge of inert surfaces at variable temperature.

Specifications table

Subject area	Chemistry
More specific subject area	Physical and colloid chemistry
Type of data	Tables
How data was acquired	Laser-Doppler (PALS) device for electrokinetic mobility and conductance (Nanobrook 90 plus PALS, Brookhaven), pH and conductivity electrodes.
Data format	Raw data.
Experimental factors	Silica and PTFE particles were used as received. Suspensions and solutions were prepared at room temperature with the respective salts and acids. No specific treatment.
Experimental features	The Brookhaven PALS device was used to measure the electrokinetic mobility and conductance as a function of temperature for a given suspension over a range of temperatures (from room temperature, where the suspension was prepared to lower temperature). The pH and conductivity of suspensions of given salt, acid and particle concentration and solutions containing salt and acid identical to those of the suspensions were measured as a function of temperature starting from low temperature.
Data source location	Karlsruhe, Germany
Data accessibility	Data is with this article.
Related research article	A. Barisic, J. Lützenkirchen, G. Lefevre, T. Preocanin, The influence of temperature on the charging of Polytetrafluoroethylene surfaces in electrolyte solutions, Coll. Surf. A, in press [1].

Value of the data

- The experimental data in combination with each other can be used to infer the variation of the isoelectric point of PTFE particles and silica particles (AEROSIL380) as a function of temperature [1].
- Conductivity data of suspensions and concomitant solutions can be used as quantitative tests of models to describe the charging of PTFE particles as a function of pH and temperature [1].
- The data involve a more comprehensive data set than the currently available one [2] for hydrophobic surfaces.
- The data can be used to construct charging models for a range of temperatures and modelers can benefit from the temperature-dependent data.
- The data can help to unravel the origin of the charging of inert surfaces in electrolyte solutions, which is currently under debate, and to inspire even more comprehensive experimentation on the effect of temperature.

1. Data

The shared data involve the pH, electrophoretic mobility, the conductivity and the conductance of solutions and suspensions (containing particles of interest, i.e. PTFE or silica particles) as a function of temperature. In the experiments, we vary the initial pH of the solution and the salt composition. Tables 1–3, 6, 7, 11 and 12 present data on the electrophoretic mobilities and the conductance of the respective suspension for negative, uncharged, and positive surfaces. Tables 4, 5, 8–10, 13 and 14 include the corresponding conductivities and pH values. Table 8 a and b show the reproducibility in terms of pH measurements. Table 10 a, b, c, and d show reproducibility in terms of conductivity measurements.

Fig. 1a shows an example pertaining to Table 2 for a negatively charged surface, while Fig. 1b shows the same kind of data for the positively charged surface (Table 11). The tables include the relevant experimental error estimates.

The trends in electrophoretic mobility are inverted based on the average values.

2. Experimental design, materials, and methods

The electrokinetic mobilities were measured using the Brookhaven Zeta-PALS equipment. This set-up also measures conductance. The settings in most cases were such that the temperature was varied from room temperature down to low temperatures. In some cases, it was also chosen to start an experiment directly at a lower temperature to observe whether the starting point would affect the results. These experiments were done both with PTFE particles and AEROSIL380 particles.

Separate pH and conductivity measurements were obtained using the SurPass equipment. The pH and conductivity were measured starting at low temperature and letting the temperature slowly increase to room temperature. This was done for defined solutions in terms of salt and acid composition

Table 1

Electrophoretic mobility (and standard deviation) and conductance of a PTFE suspension in 10 mM NaCl as a function of temperature. At room temperature the pH of the PTFE suspension was 4.

both with and without PTFE particles of known mass. In some experiments, a known mass PTFE particles were added to a solution with known volume (at room temperature) that had reached a given temperature.

PTFE particles were Microdispers-200 obtained from Polysciences Europe (Hirschberg, Germany). AEROSIL380 particles were obtained from EVONIK (Germany). All chemicals were reagent grade. Solutions were made using MilliQ water.

The pH and conductivity electrode of the SurPass equipment were calibrated as described in the manual of the set-up. The data were collected in the premeasurement option "record".

The data are all presented as the raw data in terms of tables.

Table 4

pH of a solution (a) and pH of a PTFE suspension (b) containing 0.1 mM KNO₃ as a function of temperature. At room temperature the pH of the PTFE suspension was 4.8. The mass concentration in the PTFE suspension was 0.35 g/L.

278.15	0.04	0.09	12860
276.15	0.02	0.07	12123

Table 12

Electrophoretic mobility (and standard deviation) and conductance of an Aerosil380 suspension in 10 mM NaCl as a function of temperature. At room temperature the pH of the Aerosil380 suspension was 2.7.

T (K)	μ ($\mu\text{m/s}/\{\text{V/cm}\}$)	σ_{μ} ($\mu\text{m/s}/\{\text{V/cm}\}$)	G (μS)
297.15	0.38	0.08	3683
294.15	0.35	0.06	3387
292.15	0.32	0.07	3210
289.15	0.31	0.04	2939
287.15	0.29	0.04	2799
285.15	0.28	0.07	2653
283.15	0.27	0.06	2530
279.15	0.27	0.06	2270
276.15	0.25	0.04	2084

Table 13

pH and conductivity of a solution (a) and conductivity of a PTFE suspension (b) containing 0.1 mM KNO_3 as a function of temperature in lower temperature ranges. The experiment was started at 8 °C and measurements were stopped at about 15 °C. At room temperature the pH of the PTFE suspension was 1.65. The mass concentration in the PTFE suspension was 0.5 g/L.

T (K)	pH	κ (mS/m)
(a)		
281.36	1.490	677.9
282.88	1.538	695.3
284.29	1.566	713.5
285.26	1.582	726.5
286.07	1.592	737.0
286.80	1.599	745.9
287.48	1.605	753.9
(b)		
281.04	1.543	767.1
282.26	1.566	787.2
283.28	1.580	803.6
284.15	1.590	817.7
284.97	1.598	830.5
285.73	1.605	842.2
286.44	1.617	852.7

Table 14

pH and conductivity of a solution (a) and pH and conductivity of a PTFE suspension (b) containing 0.1 mM KNO_3 as a function of temperature in lower temperature ranges. The experiment was started at 17 °C and measurements were stopped at room temperature. At room temperature the pH of the PTFE suspension was 1.65. The mass concentration in the PTFE suspension was 0.5 g/L.

T (K)	pH	κ (mS/m)
(a)		
290.26	1.599	785.5
291.12	1.608	794.9
291.88	1.614	803.0
292.53	1.619	810.2
293.11	1.623	816.5
293.62	1.627	822.1
294.24	1.632	829.1
(b)		
290.34	1.619	907.9
291.15	1.624	919.2
291.86	1.628	928.4
292.48	1.632	936.8
293.04	1.634	944.7
293.52	1.638	951.4
294.17	1.642	961.8

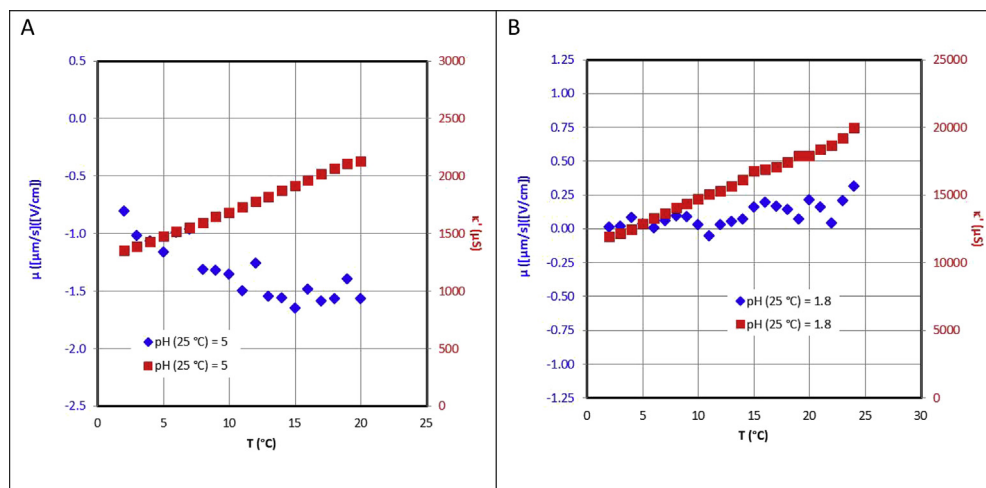

Fig. 1. a) Electrophoretic mobility and conductance of a PTFE suspension in 10 mM NaCl as a function of temperature. At room temperature the pH of the PTFE suspension was 5. b) Corresponding plot for a net positive surface, where the pH of the suspension at room temperature was 1.8.
