Purpose: Coronary microembolization (CME) is associated with progressive cardiac dysfunction, myocardial inflammation, and apoptosis. Resveratrol (RES) has a considerable role in cardioprotection. However, the contribution and possible mechanisms of RES in CME have not been clearly understood.

Methods: In the current study, 40 SD rats were randomly selected and categorized into various groups including CME, CME + resveratrol (CME + RES), CME + resveratrol+ LY294002 (CME + RES + LY), and sham groups (10 animals in each group). The inert plastic microspheres (42 μ m) were injected into the rats' left ventricle for developing the CME model. Then resveratrol (25 mg/kg/d) was given to the rats in the CME + RES and CME + RES + LY groups for one week before CME induction. Furthermore, LY294002 (10 mg/kg) was intraperitoneally injected into the rats of the CME + RES + LY group 0.5 hours before CME modeling. The cardiac functions, serum levels of myocardial injury biomarkers, myocardial histopathology, and mRNA and proteins associated with myocardial apoptosis were all assessed 12 hours after surgery.

Results: The results revealed that resveratrol pretreatment alleviated the CME-induced myocardial damage by improving cardiac dysfunction, and lowering the serum level of myocardial injury biomarkers, myocardial microinfarct size, and cardiomyocyte apoptotic index. Pretreatment with resveratrol reduced the level of proteins and mRNAs associated with the pro-apoptosis in myocardial tissues and increased the levels of proteins and mRNAs associated with the anti-apoptosis. Moreover, the combined treatment of resveratrol and LY294002 reversed the observed protective effects.

Conclusion: Resveratrol can inhibit cardiomyocyte apoptosis, thus attenuating the CME-induced myocardial injury by triggering the PI3K/Akt/GSK-3 β cascade.

Keywords: resveratrol, myocardial apoptosis, PI3K/Akt/GSK-3 β , coronary microembolization, cardiac dysfunction

Introduction

Coronary microembolization (CME) commonly occurs during thrombolytic therapy or percutaneous coronary intervention. CME is caused by atherosclerotic unstable plaques rupturing accidentally or small thrombus or plaque debris blocking the distal end of the coronary artery.^{1,2} CME may slow or no-reflow in the myocardium, resulting in fatal arrhythmia and local myocardial contractile failure, both of which

have severe consequences for the patient's cardiac function and prognosis.^{3–5} Microinfarctions occur in the local myocardium during the acute condition of CME, and apoptotic and necrotic cells grow in cardiomyocytes. Many studies have been revealed that the apoptotic process of the cardiomyocytes significantly contributes to CME-induced systolic dysfunction, thus inhibition of cardiomyocyte apoptosis can reduce CME-induced myocardial damage.^{6,7} According to the Kong et al⁸ study on rats, myocardial apoptosis and inflammation can potentially result in cardiac failure and myocardial damage after CME induction. By activating the phosphoinositide 3-kinase (PI3K)/protein kinase B (Akt) pathways, pretreatment with puerarin considerably decreased the CME-induced myocardial inflammation and apoptotic process, thus alleviating myocardial damage and improving cardiac contractile efficiency.⁹

Resveratrol (RES), a polyphenolic compound, found in several plants, has many pharmacological properties. Studies suggested that resveratrol has relatively fewer adverse effects and is highly effective.¹⁰ According to the reported data on cardiovascular diseases, Resveratrol has many cardiovascular-associated therapeutic activities, including platelet aggregates inhibition,¹¹ blood lipid control,¹² anti-oxidative stress,¹³ anti-myocardial ischemia-reperfusion damage, and anti-apoptosis.¹⁴ However, the mechanism of action of resveratrol and its targeting pathway associated with CME-induced myocardial apoptosis has not been clearly understood. Furthermore, Mao et al¹⁵ reported that RES can elevate the Sirtuin-1 (SIRT-1) expression in myocardial tissue, resulting in a significant reduction in p53 acetylation and thereby inhibiting p53's pro-apoptotic activity in myocardial tissues, which leads to the reduction in cardiomyocyte apoptosis induced by CME. Another study reported by Zhang et al¹⁶ demonstrated that resveratrol preconditioning could help patients with cardiac failure after resuscitation. The inhibitory potential of resveratrol against nitrate stress was linked to this effect, which may concern the PI3K/Akt signaling cascade in part. To use resveratrol for CME treatment, an extensive study of the association between resveratrol and cardiomyocyte apoptosis is needed. This study was designed to study whether resveratrol therapy could attenuate myocardial apoptosis (CME-induced) by triggering the PI3K/Akt/GSK-3 β cascade.

Materials and Methods

Preparation of Animals

The Clinical and Animal Research Ethics Committee of Guangxi Medical University approved the use of animals

in this study. All experimental procedures were carried out following the NIH Guidelines for the Use of Laboratory Animals. Forty male Sprague Dawley (SD) rats with 250 to 300g per body weight (8-week-old) were procured from the Experimental Animal Center, Guangxi Medical University. The rats were freely allowed water and food. The temperature and humidity of the animal house were kept at 23 °C, and 50 to 60%, respectively. Furthermore, the light and dark cycle of 12 h dark: 12 h light was maintained.

The CME Model Categorization and Establishment

Rats were randomized into different groups (10 per group): CME, Sham, CME + resveratrol (CME + RES), and CME + resveratrol + LY294002 (CME + RES + LY). Before inducing CME, rats in the CME + RES and CME + RES + LY groups were given a daily dose of 25 mg/kg of resveratrol (Sigma Chemical Co, St Louis, Missouri) for 7 consecutive days. Previous studies and our preliminary experimental results were used to determine the resveratrol dose.^{17,18} The CME+RES +LY group received a 10 mg/kg intraperitoneal injection of LY294002 (a particular inhibitor of PI3K) (APEX BIO, Houston, USA) 30 minutes before CME surgery. The rats were anesthetized with 30–40 mg/kg intraperitoneal pentobarbital sodium as reported by Chen et al.⁹ To promote aerobic respiration, small animal ventilators were used to keep the rats alive. A thoracotomy was carried out on the left side of the sternum in the 3rd and 4th intercostal spaces. The ascending aorta was then completely isolated and exposed before being clamped for 10 sec via a vascular clamp. The suspension of three thousand polyethylene microspheres (42 μ m diameter, BioSphere Medical Inc., USA) was prepared in 0.1 mL normal saline, followed by rapidly injecting into the cardiac apex of the animals in the CME, CME + RES, and CME + RES + LY groups simultaneously. After normal breathing and heart rate, the chest was cautiously sutured followed by the isolation of the endotracheal tube. Following that, penicillin (800,000 IU) was injected intraperitoneally. The sham group animals were treated with 0.1 mL normal saline instead of microspheres while other experimental and surgical procedures were the same. 12 hours after the procedure, all of the animals in the 4 groups were sacrificed.

Evaluation of Rat Cardiac Function

As reported previously, rats' heart function is at an all-time low 12 hours post-CME modeling.¹⁹ In this regard, the current study evaluated cardiac function simultaneously. The left ventricular fractional shortening, left ventricular ejection fraction, left ventricular end-systolic diameter, and left ventricular end-diastolic diameter (indicated as LVFS, LVEF, LVESd, and LVEDd, accordingly) were all calculated via a 12 MHz transducer on a Hewlett Packard Sonos 7500 ultrasound (Philips Technologies, USA). Furthermore, these parameters were averaged over 3 cardiac cycles, followed by echocardiographic recording in the presence of an expert to obtain their echocardiogram individually.

Tissue Collection and Sample Processing

Each rat was treated with an overdose of anesthesia (60 mg/kg) of pentobarbitone sodium intraperitoneally after 12 hours of CME modeling and cardiac function measurements. Blood was collected from each rat via the abdominal aorta to test serum myocardial injury markers. In the end, all rats were sacrificed and easily removed after cardiac arrest, and each heart tissue was segmented into three sections: upper, mid, and bottom section. The upper and mid sections were then placed at -80°C for RT-qPCR analysis and immunoblotting. Eventually, the bottom sections were fixed in paraformaldehyde (4%), embedded in paraffin, followed by serially slicing into $4\ \mu\text{m}$ small sections for hematoxylin-basic fuchsin-picric acid (HBFP) staining, hematoxylin-eosin (H&E) staining, and TdT-mediated dUTP nick end labeling (TUNEL) staining.

Evaluation of Myocardial Injury Biomarkers in Serum

Before euthanizing the rats, blood samples were obtained from the abdominal aorta 12 hours after CME induction or sham procedure. The cardiac troponin I (cTnI) levels in serum were then measured using standardized ELISA kits (Bio-Swamp Biological Technology Co., Ltd, China) as per the manufacturer's suggested protocol. Furthermore, the creatine kinase myocardial band isoenzyme (CK-MB) and lactate dehydrogenase (LDH) levels were measured using an automated biochemical analyzer (Olympus 5400, Olympus, Japan).

Electron Microscopy of Heart Tissues

After 12 hours of surgery, the animals were euthanized, and then the myocardial tissues were cut into a $1\ \text{mm}^3$ pieces. Myocardial tissue pieces were then treated with glutaraldehyde (3%) for 24 hours at 4°C . The pieces were rinsed thrice with PBS (pH 7.4) before being post-fixed for two hours in osmium tetroxide (1%). Next, the samples were rinsed (multiple times) and dehydrated with PBS and a series of graded ethanol (50~100%), accordingly. Samples were then immersed in resin, further cut into extremely thin sections (50 nm), and stained with lead citrate and uranyl acetate, followed by evaluation and then photographed the observations using a Hitachi H-7650 electron microscope.

Measurement of Myocardial Microinfarct Size

HBFP staining is considered an important staining approach for detecting myocardial ischemia in its earlier stages. Post staining via HBFP, the erythrocytes and ischemic cardiomyocytes were colored red, while the nucleus and cytoplasmic parts of healthy cardiomyocytes were colored blue, and yellow, correspondingly. Using a DMR-Q550 pathological image analyzer (Leica, Germany), five non-overlapping fields were randomly picked from each section to compute the infarction area. Subsequently, using the following calculations, the percent relative ischemic area was measured as: $\text{ischemic area}/\text{total area} \times 100\%$.²⁰

TUNEL Staining for the Evaluation of Myocardial Apoptosis

TUNEL apoptosis detection kit (Roche, USA) was used to quantitatively analyze cardiomyocyte apoptosis to evaluate the apoptotic index, as suggested by the guidelines provided by the manufacturer. In this procedure, the normal cell nuclei were found to be light blue in myocardial tissues while the cells that were apoptotic in nature were found to be yellow-brown. In addition, five randomly chosen fields in each slice were selected for evaluating the number of apoptotic as well as total cardiomyocytes in distal non-infarcted, micro-infarcted, and marginal infarcted regions. The rate of myocardial apoptosis was evaluated using the formula: $\text{apoptotic cardiomyocytes}/\text{total cardiomyocytes} \times 100\%$.²¹

Immunofluorescence (IF) Staining

Post 12 hours of CME modeling, rats were euthanized. Thick sections ($4\ \mu\text{m}$) were prepared, followed by

immunofluorescence staining as suggested by the manufacturer. These sections were rinsed thrice in PBS, and then they were blocked in BSA for 0.5 hours at ~25 °C, followed by incubating the sections with following primary antibodies for 24 hours (at 4 °C): cleaved caspase-3 (#9661, Cell Signaling Technologies, Danvers, MA, USA), Bax (ab53154, Abcam, Cambridge, UK), and Bcl-2 (ab194583, Abcam) followed by five times washing with PBS. The sections were then subjected to incubation with fluorescent secondary antibodies at ~25°C for 50 minutes. DAPI was used for counterstaining of nuclei for 7 minutes. A fluorescence microscope (Olympus, Japan) was employed to obtain the images.

qRT-PCR Analysis

The TRIzol RNA extraction method was carried out for obtaining the total RNA from the heart tissues, as suggested by the instructions provided by the manufacturer. Next, the NanoDrop (Thermo Fisher Scientific Inc., USA) was employed to measure the concentration of the total RNA. The PrimeScript™ RT reagent Kit with a gDNA Eraser (Perfect Real Time) (TaKaRa, Japan) was employed for the synthesis of cDNA. Moreover, the ABI PRISM-7500 system (CA, USA) was used to perform qRT-PCR using the TB Green® Premix Ex Taq™ II (TaKaRa, Japan). The relative expression of the target genes was evaluated by the $2^{-\Delta\Delta Ct}$ method and GAPDH was used as an endogenous control. Table 1 indicates all the sequences of primer.

Western Blotting Assay

A lysis buffer was utilized to extract the total protein from the heart sample, followed by measuring its concentration by

bicinchoninic acid (BCA) assay kit (PC0020, Solarbio, China). The separation of equal quality proteins was carried out by using 10~15% SDS-PAGE. These proteins were electrophoretically moved onto PVDF membranes. Furthermore, 5% BSA or skimmed milk were used for membrane blockage (60 min), followed by incubation with the underlined primary antibodies with a dilution of 1: 1000 at 4 °C for 24 hours: p-PI3K, total PI3K, total GSK-3β, total Akt, p-GSK-3β, p-Akt, cleaved caspase-3, Bax, GAPDH, or Bcl-2. Abcam provided the primary antibodies against total PI3K (ab40776), p-PI3K (Tyr607) (ab182651), Bax (ab53154), and Bcl-2 (ab194583). While the primary antibodies against p-Akt (Ser473) (#9271), total Akt (#9272), p-GSK-3β (Ser9) (#9322), total GSK-3β (#9315), GAPDH (#5174), and cleaved caspase-3 (#9661) were provided by Cell Signaling Technology. Post incubation for 24 hours, a 1×TBST buffer solution was used for membrane washing (five times) at room temperature, followed by treating with secondary antibodies (ab6721, 1:10000, Abcam) conjugated with horseradish peroxidase for 2 hours. An enhanced chemiluminescence detection system (Pierce, Rockford, IL) was employed for detecting the protein band in each group. The ImageJ software (NIH, USA) was used for determining the level of expressions.

Statistical Evaluation

The SPSS version 23.0 (IBM, Chicago) was employed to conduct the statistical analyses, and the obtained data were indicated as mean ± standard deviation (SD). One-way ANOVA was used to compare multiple groups, followed by the Student-Newman-Keuls post hoc analysis. A *P*-value < 0.05 was regarded as statistically considerable.

Results

Resveratrol Enhanced Cardiac Functions Following CME

Figure 1 shows the echocardiographic results obtained from each group of rats. Relative to the sham group, the CME group had considerably impaired cardiac contractility with elevated LVEDd and LVESd but decreased LVFS and LVEF (*P* < 0.05). On the contrary, treatment with resveratrol considerably improved the dysfunction of the heart, as shown by lower values of LVEDd and LVESd but elevated LVFS and LVEF in the CME+RES group, relative to the CME group (*P* < 0.05). LY294002 treatment reversed the cardioprotective effects of resveratrol.

Figure 1 Echocardiography of rats in each group ($n = 6$, per group). The cardiac function parameters of left ventricle ejection fraction (LVEF), left ventricle fractional shortening (LVFS), left ventricular end-diastolic diameter (LVEDd), and left ventricular end-systolic diameter (LVESd) were measured quantitatively. Data were presented as the mean \pm standard deviation (SD). * $P < 0.05$ versus the sham group; # $P < 0.05$ versus the CME group; & $P < 0.05$ versus the CME + RES group. **Abbreviations:** CME, coronary microembolization; RES, resveratrol; LY, LY294002.

Resveratrol Lowered the Myocardial Injury Biomarkers in the Serum

The serum levels of cTnI, CK-MB, and LDH were used to determine myocardial damage following CME induction, and the results are shown in Figure 2. The obtained

findings revealed that the rats in the CME group had considerably elevated levels of serum cTnI, CK-MB, and LDH relative to the sham group. While pretreatment with resveratrol substantially reduced myocardial damage post CME, as evidenced by lower serum levels of cTnI, CK-

Figure 2 Resveratrol reduced the serum levels of myocardial injury markers ($n = 6$, per group). (A) The levels of cTnI in the four groups. (B) The levels of CK-MB in the four groups. (C) The levels LDH in the four groups. Data were presented as the mean \pm SD. * $P < 0.05$ versus the sham group; # $P < 0.05$ versus the CME group; & $P < 0.05$ versus the CME + RES group.

MB, and LDH in the CME + RES group relative to the CME group. The combined therapy of resveratrol and LY294002 reversed the effects of resveratrol on serum cTnI, CK-MB, and LDH expression levels.

CME Histopathology

H&E and HBFP staining indicated sporadic subendocardial ischemia in the sham group with no visible infarction, however, numerous microinfarctions were found in the CME, CME + RES, and CME + RES + LY groups, as indicated in Figure 3A and B. Furthermore, H&E staining revealed that the nuclei of cardiomyocytes vanished or dissolved in areas of microinfarction (caused by CME),

along with cytoplasmic red staining and degeneration. In addition, peripheral inflammatory cell infiltration, erythrocyte exudation, peripheral myocardial edema, and arteriole microembolism were observed. Remarkably, resveratrol administration considerably reduced these conditions. While the combined therapy of resveratrol and LY294002 considerably reversed these beneficial effects. The microinfarct lesions were mostly wedge-shaped, localized, and non-transmural, as indicated by the HBFP staining. They were mostly found in the left ventricle and subendocardium. The CME + RES group had a considerably smaller infarct size ($P < 0.05$) than the CME group, suggesting that resveratrol pretreatment could have attenuated

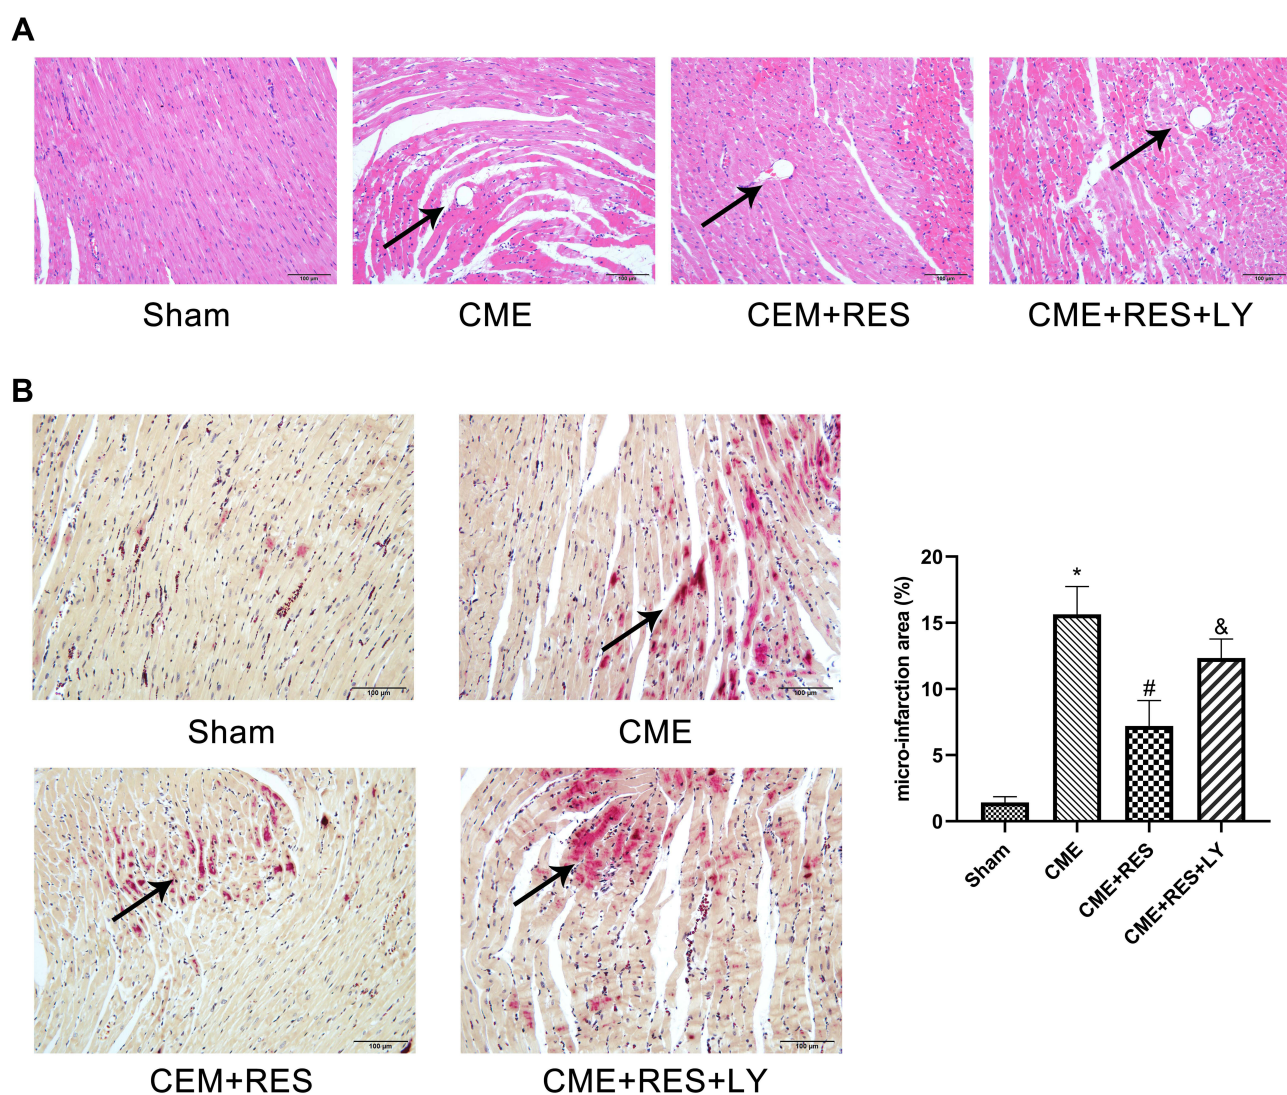

Figure 3 Histopathological examination of myocardial tissues through HE and HBFP staining ($\times 200$ magnification; bar = 100 μm) ($n = 6$, per group). **(A)** HE staining. Microspheres were observed in the CME, CME+RES, and CME + RES + LY groups but not in the sham category. The arrows indicate the microspheres. **(B)** HBFP staining. An ischemic myocardium is highlighted in red. The arrows indicate the microinfarct area. Data were presented as the mean \pm SD. * $P < 0.05$ versus the sham group; # $P < 0.05$ versus the CME group; & $P < 0.05$ versus the CME + RES group.

the myocardial microinfarct region post CME induction in rats. The effect of resveratrol on the myocardial microinfarct area was eliminated when a combination of resveratrol and LY294002 was used.

Resveratrol Decreased CME-Induced Mitochondrial Injury

Myocardial mitochondria in the CME group had considerably vacuolated degeneration and swelling, as indicated by the transmission electron microscopy (TEM) analysis of heart tissues. However, post-treatment with resveratrol, the ultra-structural variations observed in the CME group were considerably reduced, and the mitochondrial integrity was maintained, as depicted in Figure 4. A combined treatment of resveratrol and LY294002 reversed the protective effect of resveratrol on mitochondria. These findings suggested that resveratrol pretreatment can help to mitigate mitochondrial damage.

Resveratrol Decreased the Apoptotic Process of Cardiomyocyte Post CME

TUNEL staining was carried out to evaluate the apoptotic process in cardiomyocytes, and the results are shown in

Figure 5. Normal and apoptotic nuclei were found to be light blue and yellow-brown (TUNEL positive), accordingly. In the sham group, myocardial apoptosis was sometimes noticed in the papillary and subendocardium muscles. In comparison to the sham group, the number of TUNEL-positive cells elevated considerably in the CME group ($P < 0.05$). Following CME induction, the underlined apoptotic cardiomyocytes were mostly found in the myocardial peri-infarct and micro-infarct areas. Furthermore, the TUNEL positive cells in the peri-infarct and micro-infarct zones of rats were considerably decreased in the CME +RES group ($P < 0.05$). The anti-apoptotic effects of resveratrol were reversed by the combined therapy of resveratrol and LY294002.

Pretreatment with Resveratrol Decreased Apoptotic Markers

qRT-PCR and immunoblotting were employed to determine the expression of Bax, Bcl-2, and cleaved caspase-3 in the rats' myocardium of each group to confirm the existence of apoptotic process in cardiomyocytes following CME. The results are shown in Figure 6A and B. The transcriptional and translational levels of cleaved caspase-

3 and Bax were considerably elevated in the CME group relative to the sham group, while the transcriptional and translational levels of Bcl-2 were considerably reduced ($P < 0.05$). Furthermore, in comparison with the CME group, the transcriptional and translational levels of cleaved caspase-3 and Bax were considerably decreased in the CME+RES group, whereas the transcriptional and translational levels of Bcl-2 were considerably elevated ($P < 0.05$). However, when resveratrol was combined with LY294002, the impact of resveratrol on the expression of Bax, Bcl-2, and cleaved caspase-3 was reversed. Furthermore, the IF findings from myocardial tissues showed consistency with the results obtained from qRT-PCR and immunoblotting, as depicted in Figure 7. These findings indicated that resveratrol pretreatment could effectually minimize the CME-induced apoptotic process in cardiomyocytes.

Attenuation of Myocardial Apoptosis by Resveratrol Linked with the PI3K/Akt/GSK-3 β Signaling Cascade

Immunoblotting showed no considerable variations in total PI3K, total Akt, or total GSK-3 β between the four groups,

as depicted in Figure 8. As compared with the sham group, myocardial expression of p-Akt, p-PI3K, and p-GSK-3 β was considerably decreased in the CME group ($P < 0.05$), while in the CME+RES group, myocardial expression of p-Akt, p-PI3K, and p-GSK-3 β was considerably elevated ($P < 0.05$) relative to the CME group. Moreover, the influence of resveratrol on the expression of p-Akt, p-PI3K, and p-GSK-3 β was reversed by the combined treatment of resveratrol and LY294002. These results indicate that resveratrol pretreatment could efficiently decrease myocardial apoptosis following CME, which was linked with the stimulation of the PI3K/Akt/GSK-3 β cascade.

Discussion

The data provided in this work demonstrate the following 3 points. Firstly, myocardial apoptosis was found to be a critical factor in myocardial damage and cardiac dysfunction in rat following CME modeling. Secondly, resveratrol pretreatment effectively suppressed CME-induced myocardial apoptosis and myocardial injury. Thirdly, triggering of the PI3K/Akt/GSK-3 β signaling cascade was found to be an important factor in resveratrol's protective mechanism against CME-related myocardial injury. Generally, the study for the first time revealed that

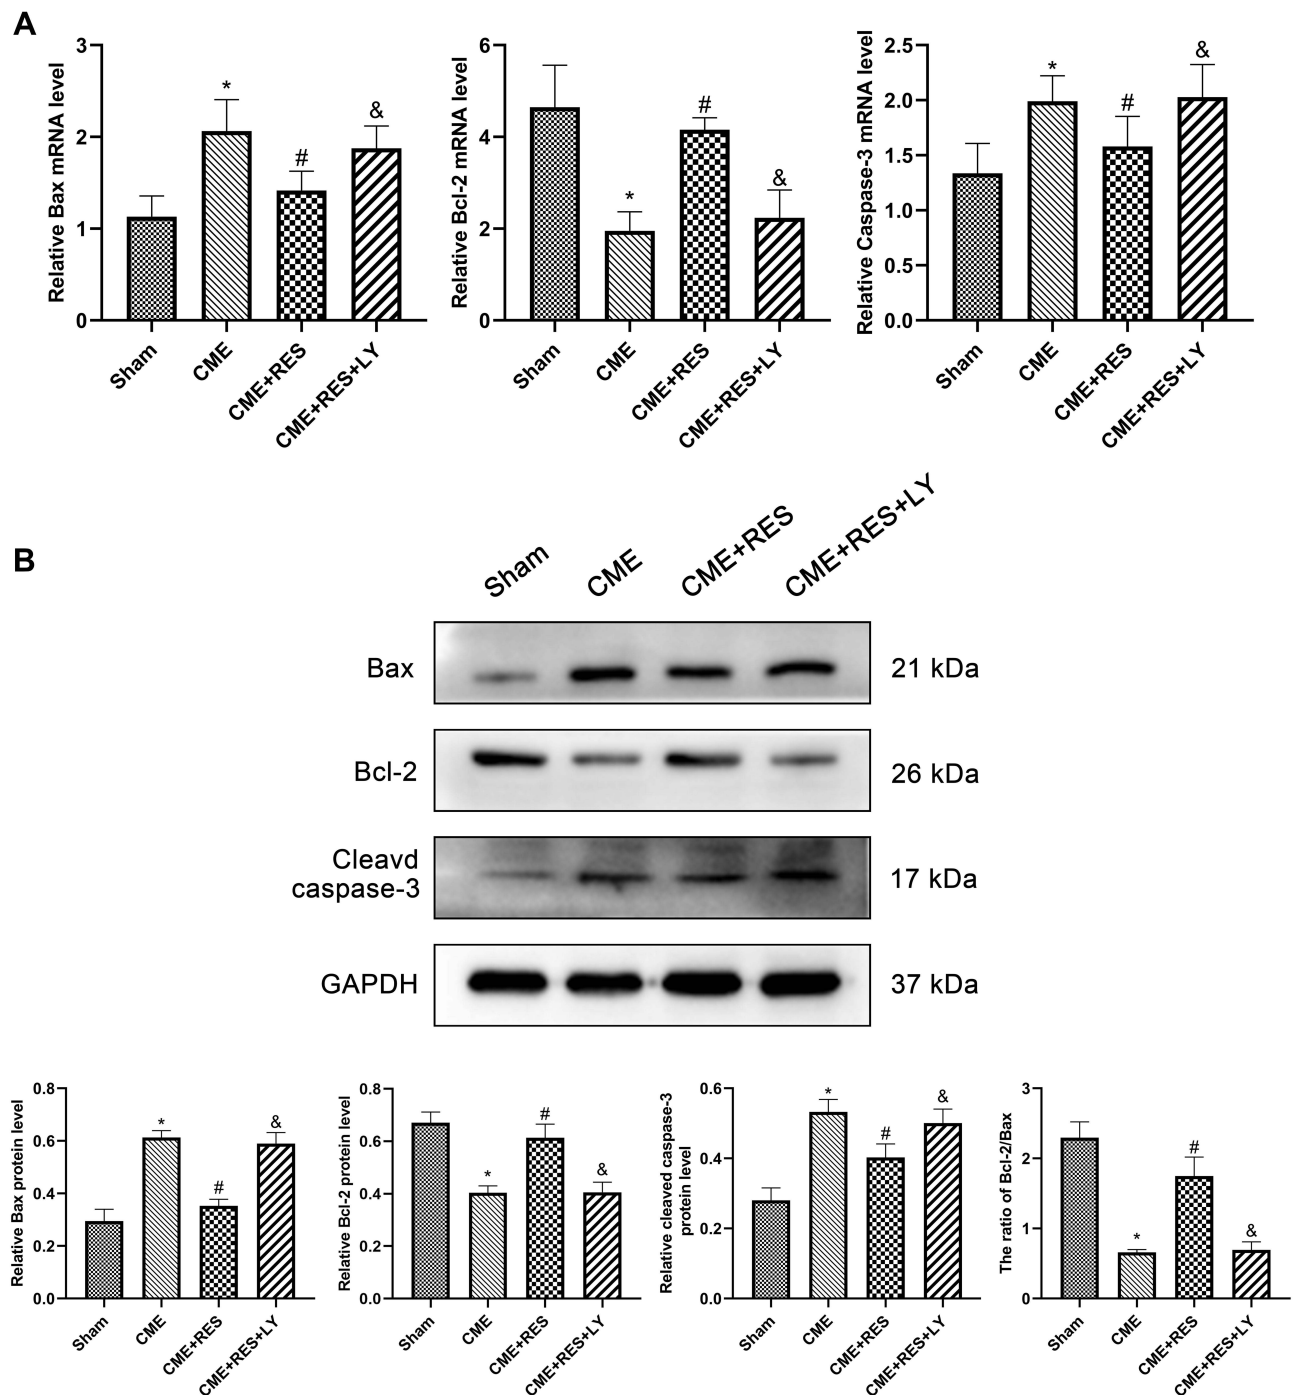

Figure 6 Pretreatment with resveratrol attenuated CME-induced myocardial apoptosis. **(A)** The mRNA expression levels of Bcl-2, Bax, and cleaved caspase-3 in cardiac tissues ($n=6$, per group). **(B)** The protein expression levels of Bcl-2, Bax, and cleaved caspase-3 in cardiac tissues ($n=3$, per group). Abbreviations: CME, coronary microembolization; RES, resveratrol; LY, LY294002.

resveratrol can attenuate CME-induced myocardial apoptosis by controlling the PI3K/Akt/GSK-3 β cascade, thus alleviating CME-associated cardiac dysfunction and decreasing myocardial damage. As a result, resveratrol

pretreatment can be useful in the treatment of myocardial injury induced by CME.

CME became a focus of interest approximately a decade ago,²² when it was revealed that CME and its

sequelae are common iatrogenic consequences of percutaneous coronary procedures.²³ Moreover, myocardial apoptosis has an important role in myocardial damage and advanced cardiac dysfunction following CME. Hence, inhibiting myocardial apoptosis has the potential to considerably decrease cardiac dysfunction.^{24,25} In the current study, the obtained results suggested that our CME rat model indicated a high level of serum markers, increased microinfarct areas, cardiac dysfunction, and apoptotic

cardiomyocytes in peri-infarct and microinfarct areas, which showed consistency with the pathophysiological variations of CME.

Resveratrol is a powerful antioxidant widely found in many plants including peanuts, and grapes. It has potent biological activity against aging, inflammation, and apoptotic process.²⁶ Furthermore, because of its extensive pharmacological influence, diverse mechanisms, and higher efficacy, it has the potential to be used in

cardiovascular diseases. A previous study showed that resveratrol can inhibit the apoptotic process (stimulated by hypoxia) in H9c2 cells and has a direct anti-apoptosis effect on cardiomyocytes by elevating the expression of SIRT-1 *in vitro*.²⁷ Furthermore, in mice with myocardial ischemia/reperfusion injury, resveratrol enhanced cardiac function and reduced apoptotic process and infarct size, as revealed by the previous study.²⁸ Another study by Mao et al¹⁵ found that resveratrol is essential for myocardial defense in CME-induced myocardial injury, as evidenced by increased SIRT-1 expression in myocardial tissue, which lowers p53 acetylation in myocardial tissue, reducing p53's pro-apoptotic activity and, as a result, decreasing the apoptotic process in CME-induced cardiomyocytes. Resveratrol also reduced cellular apoptosis, elevated the Bcl-2 expression, and lowered the Bax, and cleaved caspase-3 expression. In this study, rats developed left ventricular systolic dysfunction and increased cardiomyocyte apoptosis after CME modeling. These results, like earlier studies, indicate that apoptotic process in cardiomyocyte have a key role in the irreversible injury of cardiomyocytes caused by CME. However, after resveratrol pretreatment, cardiac function was improved and cardiomyocyte apoptosis was reduced in CME rats. These results validate the conclusion that resveratrol improves cardiac function by inhibiting CME-induced cardiomyocyte apoptosis.

Furthermore, PI3K/Akt is not only an important signaling pathway that mediates apoptosis, growth, and survival, but also a common pathway for a variety of cardiovascular drugs to achieve myocardial protection. Activated PI3K inhibits programmed cell death in cells, and Akt, a direct downstream target of PI3K that mediates the PI3K-dependent cell-survival response, is also related to anti-apoptosis.²⁹ Bcl-2 expression is increased when the PI3K/Akt cascade is stimulated, and Bcl-2 can regulate the apoptotic process by this mechanism. The elevated Bcl-2 expression can attenuate cytochrome C release which results in the formation of a stable Bcl-2/Bax heterodimer with Bax, hence attenuating the apoptotic process induced by Bax. On the contrary, the apoptotic process has been enhanced by a higher expression of Bax.³⁰ Recently reported data have revealed that many factors phosphorylate GSK-3 β through considerably triggering the PI3K/Akt cascade, attenuating the GSK-3 β protein's biological activity and, as a result, enhancing the survival of cells.^{31,32} The PI3K/Akt/GSK-3 β cascade has been reported as an effective endogenous negative feedback

mechanism in the cell which results in a compensatory reaction against unfavorable stimuli to attenuate the apoptotic and inflammatory processes.^{33,34} The reported studies suggested that the stimulation of the PI3K/Akt/GSK-3 β cascade markedly decreased myocardial inflammation, apoptotic process, and myocardial damage, however, it might have opposing effects when it is not activated.^{35,36}

In this study, the data suggested that the pretreatment with resveratrol elevated the expression of Bcl-2, p-Akt, p-PI3K, and p-GSK-3 β post CME induction in rats. However, resveratrol considerably attenuated the cleaved caspase-3 and Bax levels. Furthermore, the protective effects of resveratrol were substantially reversed when it was combined with LY294002. Moreover, the data of the current study demonstrated that the attenuation of the PI3K/Akt/GSK-3 β cascade resulted in a decrease in cardiac function and elevation in serum cTnI levels, myocardial apoptosis, and microinfarct size, suggesting that the cardioprotective effects of resveratrol could be reversed by LY294002. In general, the results showed that the PI3K/Akt/GSK-3 β cascade was correlated with the resveratrol's protective effects against CME-induced myocardial injury. As a result, resveratrol will likely protect the heart by triggering the PI3K/Akt/GSK-3 β cascade and attenuating the myocardial apoptosis.

There are some limitations to this study. In this study, the physical microembolic spheres were injected into coronary microvessels to establish a CME rat model. However, because these plastic microspheres lack biological features like vascular or thrombotic activity, the pathological alterations produced by this plastic material in the CME model differ from those generated in atherosclerosis during clinical practice. Further, this study evaluated the impact of resveratrol on myocardial apoptosis triggered by CME and the PI3K/Akt/GSK-3 β cascade by using pretreatment with resveratrol and the LY294002. However, to better understand the effects of resveratrol on the PI3K/Akt/GSK-3 β cascade in CME, inhibitors or agonists of PI3K downstream molecules are required. It cannot be ruled out whether other signaling cascades are involved in myocardial damage caused by CME, which requires further investigation.

Conclusions

In brief, the current study demonstrated that resveratrol can significantly reduce CME-induced myocardial damage and cardiomyocyte apoptosis, most likely by triggering the PI3K/Akt/GSK-3 β signaling cascade. As a result, our

findings revealed that resveratrol may be a candidate therapeutic agent for cardioprotection against CME in clinical applications. These results may also serve as a theoretical basis for further evaluating the impact of resveratrol on CME patients.

Acknowledgments

This study was supported by the National Natural Science Foundation of China (Grant No.81770346) and the Project for Innovative Research Team in Guangxi Natural Science Foundation (Grant No.2018GXNSFGA281006).

Drug Design, Development and Therapy

Dovepress

Publish your work in this journal

Drug Design, Development and Therapy is an international, peer-reviewed open-access journal that spans the spectrum of drug design and development through to clinical applications. Clinical outcomes, patient safety, and programs for the development and effective, safe, and sustained use of medicines are a feature of the journal, which has also

been accepted for indexing on PubMed Central. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
