

Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.

Impact of the COVID pandemic on quality measures in a pediatric echocardiography lab

Quality metrics
Appropriate use criteria
COVID

ABSTRACT

Background: The COVID pandemic necessitated an altered approach to transthoracic echocardiography, especially in COVID cases. Whether this has effected echocardiography lab quality is unknown.

Objectives: We sought to determine whether echocardiography lab quality measures during the COVID pandemic were different from those prior to the pandemic and whether quality and comprehensiveness of echocardiograms performed during the pandemic was different between COVID and non-COVID patients.

Methods: The four quality measures (diagnostic errors, appropriateness of echocardiogram, American College of Cardiology Image Quality metric and Comprehensive Exam metric in structurally normal hearts) reported quarterly in our lab were compared between two quarters during COVID (2020) and pre-COVID (2019). Each component of these metrics was also assessed in randomly selected echocardiograms in COVID patients and compared to non-COVID echocardiograms.

Results: For non-COVID echocardiograms, the image quality metric did not change between 2019 and 2020 and the comprehensive exam metric improved. Diagnostic error rate did not change, and appropriateness of echocardiogram indications improved. When COVID and non-COVID echocardiograms were compared, the image quality metric and comprehensiveness exam metric were lower for COVID cases (image quality mean 21.3/23 for non-COVID, 18.6/23 for COVID, $p < 0.001$ and comprehensive exam mean 29.5/30 for non-COVID, 27.7/39 for COVID, $p < 0.001$). In particular, systemic and pulmonary veins, pulmonary arteries and aortic arch were not adequately imaged in COVID patients. For studies in which a follow-up echocardiogram was available, no new pathology was found.

Conclusions: At our center, though diagnostic error rate did not change during the pandemic and the proportion of echocardiograms ordered for appropriate indications increased, imaging quality in COVID patients was compromised, especially for systemic and pulmonary veins, pulmonary arteries and arch. Though no new pathology was noted on the small number of patients who had follow-up studies, we are paying careful attention to these structures to avoid diagnostic errors going forward.

1. Introduction

Early during the coronavirus diseases (COVID) pandemic, the American Society of Echocardiography made recommendations for performing transthoracic echocardiograms (TTE) in pediatric patients that had suspected or confirmed COVID infection [1]. The guidelines emphasized the need to minimize the duration of exposure to these

patients, performing problem-focused studies, paying attention to the established Appropriate Use Criteria for initial and follow-up examinations when applicable, and maintaining quality of images during the scans [1–3]. These guidelines led us to adopt a more focused and abbreviated protocol for TTEs on patients with confirmed or suspected COVID. However, the impact of these changes on various components of quality of TTEs remains unknown. In our echocardiography lab, we aim

Abbreviations: TTE, Transthoracic echocardiogram; IQM, Image Quality Metric; CEM, Comprehensive Echocardiographic Exam Metric; COVID, Coronavirus disease.

at performing a comprehensive TTE examination during the initial evaluation and follow the standards defined by the American Society of Echocardiography [4,5] and the American College of Cardiology Quality Network cardiovascular imaging metrics [6]. In addition, the 2014 Appropriate use Criteria for Initial Outpatient evaluation has been integrated into our electronic TTE ordering system since 2017 [7].

The purpose of this study was to determine the impact of changes made during COVID pandemic on the TTE imaging quality, comprehensiveness, diagnostic error rate and appropriateness of TTE orders in patients with and without COVID infection.

2. Methods

The study was approved by the Institutional Review Board of Children's Healthcare of Atlanta. Data were retrospectively collected for four quality measures that were reported on a quarterly basis in our lab prior to the pandemic: 1) diagnostic error rate based on the number of major diagnostic errors on TTE for all patients that undergo cardiac surgery; 2) appropriateness of indication for initial outpatient TTE evaluation based on the 2014 Appropriate Use Criteria document [6], which has been integrated into the electronic health system at our center since May 2017 and incorporated into feedback for physicians on the appropriateness of TTE orders [7]; 3) initial TTE Image Quality Metric (IQM) and 4) Comprehensive Echocardiographic Exam (CEM) [6]. IQM and CEM have been defined by the Quality Network of the American College of Cardiology and were adopted by our center in Jan 2019. For IQM and CEM, we evaluate 20 randomly selected TTEs performed on patients with structurally normal hearts during each quarter. The components of IQM scoring are comprised of image orientation, 2D imaging, color flow imaging and spectral Doppler display, with a maximum total score of 23. CEM scoring is based on imaging of vessels, valves, ventricles, veins, atria and situs, with a maximum total score of 30. TTEs performed by trainees were excluded.

All four quality measures were compared between two similar quarters (April to June and July to September) in pre-COVID (2019) and COVID era (2020). Additionally, IQM and CEM of 40 randomly selected TTEs in patients with suspected or confirmed COVID were compared with those of non-COVID patients during the same timeframe. Records were reviewed to look for any missed echocardiographic findings if a follow-up TTE was performed on these patients. The number of images and study time was compared between COVID and non-COVID patients. The location in which the TTEs were performed in patients with suspected or confirmed COVID was also recorded.

2.1. Statistical analyses

Statistical analyses were performed using SAS software version 9.4 (SAS Institute, Cary, North Carolina), and statistical significance was assessed at the 0.05 level. Normality of continuous variables was assessed using the histogram, normal probability plots and Anderson-Darling test for normality. Descriptive statistics are presented as counts and percentages for categorical variables and as median (25th, 75th percentile) for continuous data with skewed distributions or mean \pm standard deviation for those with normal distributions. Non-normal continuous data were compared using Wilcoxon rank-sum tests, normal continuous data were compared using *t*-tests and comparisons between categorical variables were performed using chi-square tests, or the Fisher exact test when expected cell counts were <5 .

3. Results

The quarterly volumes of TTEs performed at the hospital during pre-COVID and COVID study period were similar (2687 ± 37 vs. 2700 ± 425 , $p = 0.97$). The average quarterly volume of initial outpatient TTEs performed in our clinics was also similar (1524 ± 130 vs. 1170 ± 524 , $p = 0.45$). A comparison of quality measures between the pre-COVID and

COVID era is shown in Table 1. There was no statistically significant difference in the mean IQM score between pre-COVID and COVID era in non-COVID patients with structurally normal hearts. However, the mean CEM score improved from pre-COVID to COVID era, specifically for imaging of coronary sinus (29/40 vs. 38/40, $p = 0.006$), tricuspid regurgitation jet evaluation by Doppler in two views if available (34/40 vs. 40/40, $p = 0.011$) and evaluation adequate for measurement of aortic valve, aortic root, and aortic sinotubular junction diameters measured in parasternal long-axis view (30/40 vs 37/40, $p = 0.034$). There was no significant change in major diagnostic error rate between the pre-COVID and COVID era (0.02 % vs. 0.01 %, $p = 0.18$). Overall, there was an improvement in appropriateness of TTE orders in the COVID era, with the proportion of TTEs with indications rated Appropriate increasing from 90.3 % to 92.1 %, $p = 0.028$ (Table 1). There was no significant change in the TTEs ordered for indications rated Rarely Appropriate. Among the TTEs ordered for indications rated Rarely Appropriate, there was an increase in the proportion of those related to syncope, (5/37 (13.5 %) vs 7/17 (41.2 %), $p = 0.035$) and palpitations and arrhythmias (8/37) 21.6 % vs. 10/17 (58.8 %), $p = 0.007$) in COVID era compared to pre-COVID era, and a decline in those related to chest pain (10/37 (27 %) vs. 0/17 (0 %), $p = 0.02$). Clinic notes of patients with TTE for indications rated Rarely Appropriate were reviewed for any history of COVID or MISC-related concerns, but none were noted.

In the COVID era, the initial TTE IQM mean score was significantly less in COVID patients compared to non-COVID patients, 18.6 ± 2.5 vs 21.3 ± 1.5 , $p < 0.001$, (Table 2). The specific components of IQM that were worse in COVID patients included image orientation for subcostal sagittal view, brightness level, balanced penetration resolution, presentation of region of interest, frame rate and gain level for color-Doppler, scale adjustment and gain level for spectral-Doppler. The mean CEM score was also significantly lower in COVID patients compared to non-COVID patients, 27.7 ± 3.7 vs. 29.5 ± 0.8 , $p < 0.001$, (Table 3). Imaging of the systemic and pulmonary veins, pulmonary arteries and aortic imaging (arch sidedness and branching, arch imaging by Doppler, and abdominal aorta by Doppler) scored significantly lower in COVID patients compared to non-COVID patients. Of the 40 studies in COVID patients, 5 were performed in the emergency department, 20 in the acute care floor and 15 in the critical care unit. The study location was not associated with IQM or CEM results. The number of images acquired per study was significantly less in COVID vs non-COVID patients (96 ± 28.7 vs 118 ± 18 , $p = 0.0002$), though the scanning time was similar (29 ± 13 vs 33 ± 12 , $p = 0.11$). A complete follow-up TTE was available in 20 out of 40 COVID patients, and no pathology was noted on these TTEs.

Table 1
Comparison of quality measures between pre-COVID and COVID Era.

Metric	Pre-COVID Era April-Sept 2019	COVID Era April-Sept 2020	P-value
Image Quality Metric Mean (SD), (Total score 23)	21.5 (2.0)	21.3 (1.5)	0.529
Comprehensive Exam Metric Mean (SD), (Total score 30)	28.4 (1.7)	29.0 (0.9)	<0.001
Diagnostic Errors N (%)	15/665 (0.02 %)	9/694 (0.01 %)	0.180
Appropriateness Ratings N (%)

4. Discussion

In this study from a large tertiary care pediatric center, the image quality and comprehensiveness of TTEs performed in COVID patients were significantly impacted by the changes adopted during the pandemic. However, the quality was maintained in non-COVID patients receiving initial complete evaluation at our center.

It is known that severe acute respiratory syndrome coronavirus-2 infection that causes COVID has rapid transmission and is associated with high morbidity and mortality. Given this concern, cardiovascular imaging societies have recommended considering the use of focused and abbreviated protocols and using laptop size echocardiography machines in these patients [1]. In addition, there have been other system-wide

Table 3

Comparison of comprehensive echocardiogram examination quality metric between non-COVID and COVID patients in 2020.

Variable	Non-COVID N = 40	COVID N = 40	P-value

changes that were continuously evolving during the pandemic including closure of the clinics, lack of sedation for TTEs in uncooperative infants and toddlers, changes in staffing, telemedicine and remote reading that could have impacted quality of care in non-COVID patients. Therefore, this study not only evaluated patients with suspected or confirmed COVID, but also non-COVID patients who had initial complete evaluation with TTE. Studying the effect of each of these factors on various quality measures would have been quite challenging as these are hard to objectively capture in a retrospective manner. Fortunately, we did not find any significant changes in IQM in non-COVID patients during the pandemic and noted improvement in CEM. These two metrics were implemented at our center in January 2019, and since then, the sonographers have been receiving quarterly feedback on their studies. The improvement in CEM may be reflective of our educational efforts regarding these metrics.

It was not surprising that the CEM was affected in COVID patients given the use of abbreviated protocols. Initial evaluation in COVID patients had significantly deficient imaging of pulmonary veins, pulmonary arteries, arch situs, arch Doppler, and abdominal aorta Doppler. If a subsequent study was performed on these patients, attempt was made to image the structures that were not captured on the initial scan. IQM was lower in COVID patients due to suboptimal image orientation, brightness level, improper adjustment of Doppler gains and scale. At our center, we did not use laptop size machines to perform TTEs in COVID patients included in this study. One could speculate that the need to complete the study quickly to reduce exposure to the patient could have

resulted in lack of effort for image optimization and hence the lower IQM. Though no pathology was noted in the COVID patients who had a subsequent study, it was a small sample size (20/40). A study in 171 adult patients with suspected or confirmed COVID evaluated the scanning time and acquisition of minimum data set, and compared it to 50 controls from the pre-pandemic period [8]. They reported a significant reduction in median scanning time from 14 min (IQR 10–16 min) to 6 min (IQR 4–8 min) while following the abbreviated protocol. The number of images also reduced from a median of 55 (IQR 39–66) to 25 (17–36). Importantly, there was no difference in the proportion of studies that met the minimum data set (47/50 (94 %) in controls vs. 158/171 (92.4 %) in COVID patients). In contrast to this study, in our study, even though the number of images decreased in COVID patients, the decrease in average scanning time did not reach statistical significance, and this could be related to a relatively small sample size.

Quality of cardiovascular imaging can impact patient outcomes [9,10]. Fortunately, we did not observe any change in the diagnostic error rate. One of the steps in providing quality care with TTE is appropriateness of the study indications. Though, overall there was an improvement in appropriateness of TTE orders for initial outpatient evaluation, there was an increase in the proportion of TTEs ordered for the Rarely Appropriate indications related to syncope, palpitations and arrhythmias. We speculated that these findings may reflect heightened concern for the cardiac complications of COVID and lower threshold to obtain an echocardiogram given the ongoing COVID pandemic. However, upon review of clinic notes, no such association was found. Surprisingly, during the pandemic, no TTEs were ordered for chest pain indications rated Rarely Appropriate. Anecdotally, anxiety-related chest pain has been a common presentation in cardiology clinics through the pandemic and despite that we did not notice a rise in TTEs for indications rated Rarely Appropriate for chest pain. It is important to note that the overall number of indications rated Rarely Appropriate is quite small and the differences noted for specific indications may not be clinically meaningful.

This study is limited by its retrospective nature and restriction of the data to two quarters of the ongoing COVID pandemic. Being a single-center study, the results may not be generalizable. The factors that could have influenced the imaging metrics were difficult to capture objectively for statistical analysis. The representative sampling of TTEs assessed for IQM and CEM quality metrics was relatively small since we used the existing data from our quality assurance process for the echocardiography lab. Nevertheless, some important differences were noted in COVID patients compared to non-COVID patients that have been helpful in our educational efforts to improve quality of care during the pandemic.

5. Conclusion

During the COVID pandemic, the diagnostic error rate has not changed, and the proportion of TTEs ordered for appropriate indications has increased. However, unlike non-COVID patients, the image quality as well as the exam comprehensiveness has decreased in those with suspected or confirmed COVID. In our center, this information has served as a guide to assure that adequate imaging of systemic and pulmonary veins, pulmonary arteries and the aorta is performed on the initial or subsequent studies.
