## HIGHLIGHTS

- A PPI network showing protein interaction was produced.
- 3 top biotargets of curcumol against IC were identified.
- Human IC sections showed increased PTK2, p-PTK2<sup>Tyr397</sup> expressions.
- Curcumol-treated IC mice benefited reduced PTK2, p-PTK2<sup>Tyr397</sup> expressions.
- PTK2 may be a potential biomarker for screening and treating IC.

## ABSTRACT

This study was designed to reveal the predictive targets and biological mechanisms of curcumol against interstitial cystitis (IC). By use of available databases and bioinformatic assays, pathogenetic targets of IC and functional targets of curcumol were identified respectively. A network of functional protein-protein interaction (PPI) was produced before screening the main predictive targets, biological processes and signaling pathways of curcumol against IC. In bioinformatic findings, the data of ingenuity pathway analysis (IPA) delineated that curcumol exerted anti-IC benefits through regulating multipronged signaling pathways, including tyrosine protein kinase-2 (PTK2) pathway. Further, optimal 18 biotargets of curcumol against IC were harvested through differential expression analysis. And the predictive targets of receptor tyrosine-protein kinase erbB-2 (ERBB2), epidermal growth factor receptor (EGFR) and PTK2 were the most important molecules. In further validated experiments, PTK2 and phosphorylation PTK2 (p-PTK2) were representatively selected for testing by human and animal IC samples. As results, increased immunoreactive proteins of tumor necrosis factor alpha (TNF- $\alpha$ ), PTK2 and p-PTK2<sup>Tyr397</sup> in human IC sections were observed, accompanied with altered urinary parameters. Interestingly, curcumol-treated IC mice showed that intracellular expressions of PTK2, p-PTK2<sup>Tyr397</sup> in bladder samples were reduced,

accompanied with lowered blood inflammatory cytokines of interleukin 6 (IL-6), TNF- $\alpha$ . In conclusion, the current bioinformatic data and preliminary findings unravel that the predominant targets of curcuminol against IC may be the potential biological markers for screening and treating IC, such as PTK2 molecule.

## Introduction

Interstitial cystitis (IC), a urinary tract infection, refers to the chronic inflammation and stress that disrupt the upper urinary tract functions. Pathological syndromes of IC may have urinary frequency, pain with urination, and dysuria, hematuria, hemorrhage [1,2]. The common cause of infection is *Escherichia coli*. In addition, drug-induced hemorrhagic cystitis is another inflammation of the bladder [3,4]. The main clinical therapy against IC is antibiotic medication by the time- and dose-dependent manners, such as nitrofurantoin, trimethoprim (uncomplicated case), phenazopyridine (complicated case) [5]. However, a long-term treatment of antibiotics may induce drug resistance over time. Therefore, further development of candidate medication to treat IC is needed. Curcuminol, isolated from *Rhizoma Curcumaes*, is a bioactive component with potent pharmacological activities. And it is characterized with potential anti-inflammatory, anti-virus, anti-microbial, and anti-cancer effects [6,7]. Increasing evidences has suggested that curcuminol plays a potent inhibitory effect on the proliferation of human bladder cancer cells [8]. However, the pharmacological study of curcuminol against IC is limited presently. In addition to literature analysis, a predictive tool of network pharmacology can optimize and propose the main functional targets and molecular mechanisms of bioactive component against disease [9]. Therefore, the current study used network pharmacology-analyzed bioinformatic data to uncover the main predictive targets, and correlative biological processes and signaling pathways of curcuminol against IC. In parallel, the samples of clinical IC and curcuminol-treated rats were collected and established to characterize the pathological and pharmacological biotargets, respectively. Together, the graphical abstract of this study design was demonstrated visibly in Fig. 1.

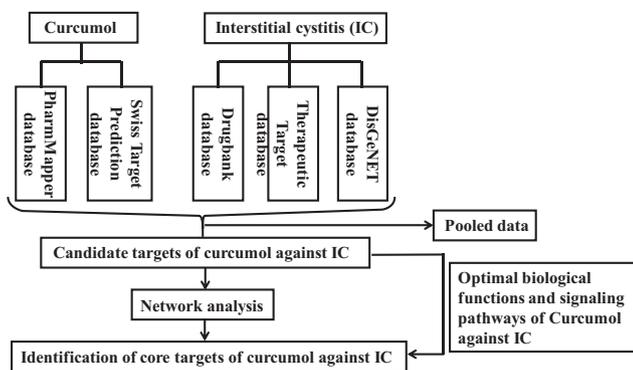

Fig. 1. This study used bioinformatic assays to predict the main biotargets and molecular pathways of curcuminol against IC, followed by experimental validation.

## Experimental

### Identification of candidate targets of curcuminol against IC

All curcuminol-associated functional targets were collected from the databases of PharmMapper ([http://lilab.ecust.edu.cn/pharmmapper/submit\\_file.php](http://lilab.ecust.edu.cn/pharmmapper/submit_file.php)) and Swiss Target Prediction (<http://www.swisstargetprediction.ch/index.php>). In addition, pathogenetic and therapeutic targets of IC were produced from the databases of DisGeNET (<http://www.disgenet.org/web/DisGeNET/menu/search?0>), Drugbank (<https://www.drugbank.ca/>), Therapeutic Target Database (<https://db.idrblab.org/ttd/>), respectively. Further, the curcuminol-pharmacological targets were pooled with cystitis-pathologic targets before picking up the predictive targets of curcuminol against IC.

### Construction of PPI network and verification of main targets of curcuminol against IC

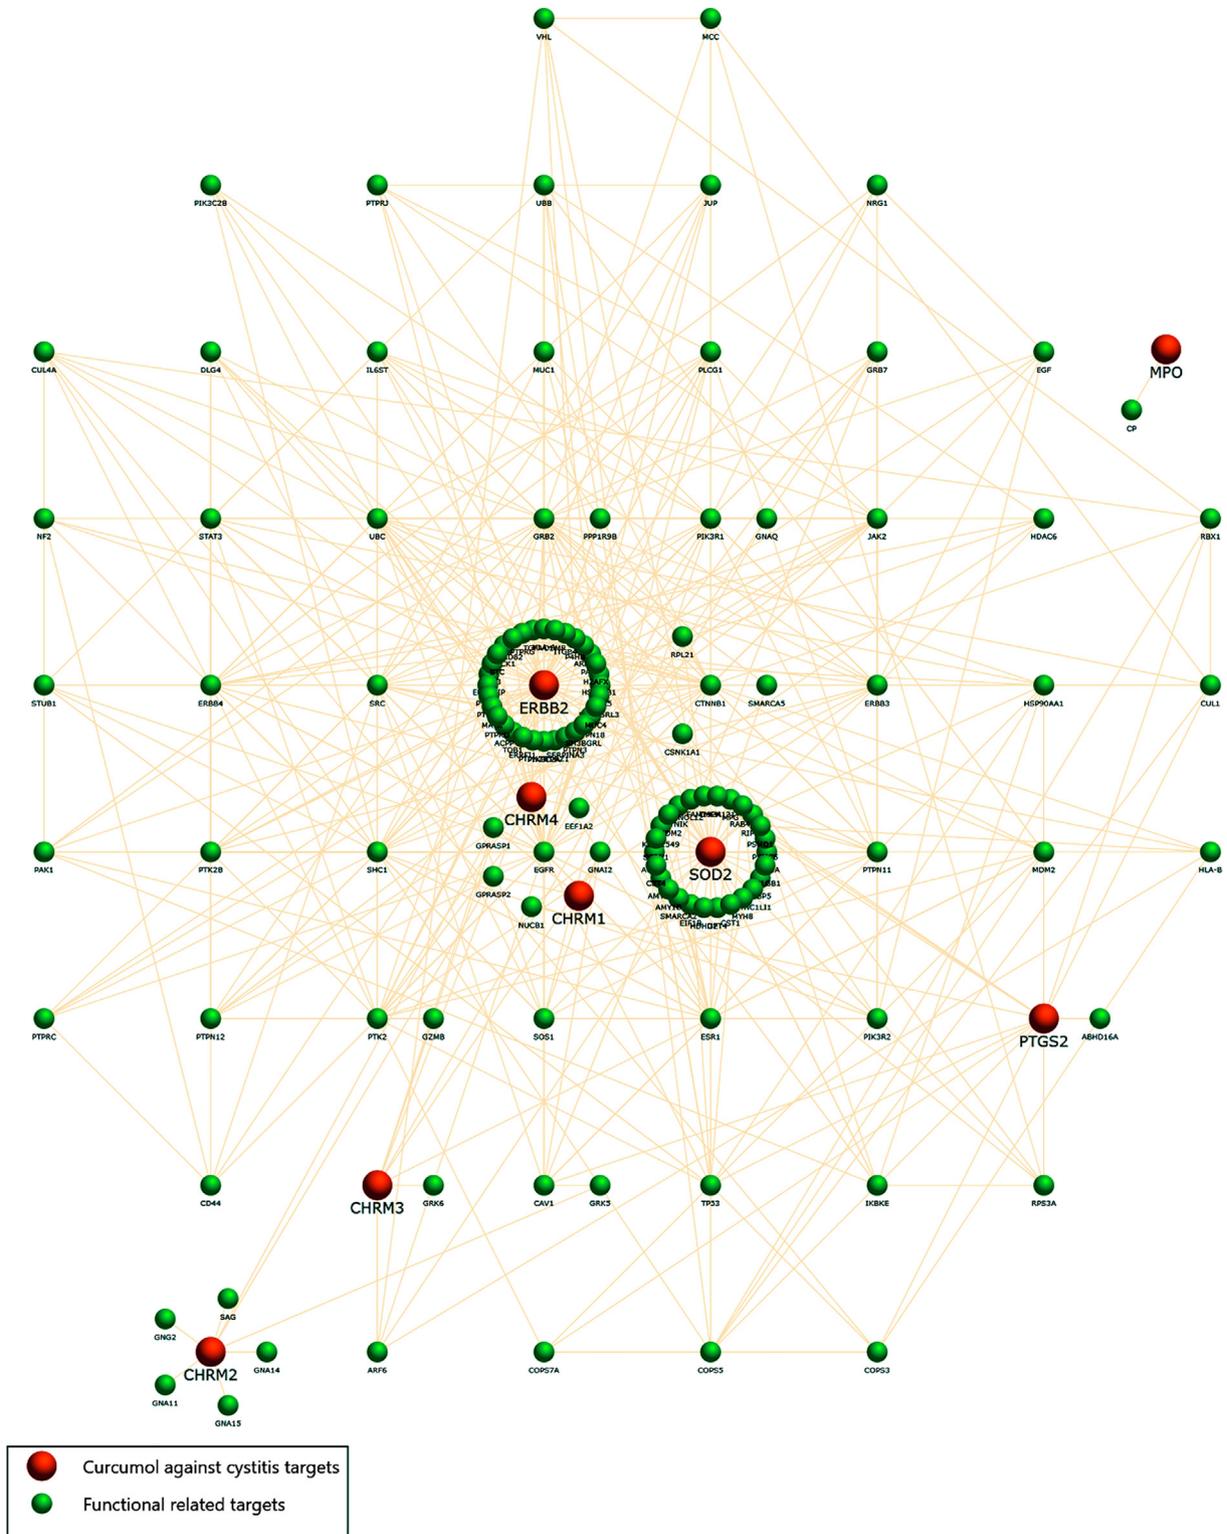

The pooled targets of curcuminol against IC were projected into FunRich\_3.1.3 software (<http://www.funrich.org/>) to establish the target-functional proteins. And a PPI network of predictive targets was constructed. In addition, the identifiable data were further imported to Cytoscape (v3.6.1) (<https://cytoscape.org/>). The network analyzer setting was used to visualize the network targets of curcuminol against IC based on topological parameters. The optimal targets were identified according to the maximum degree values.

### Confirmation of biological processes and molecular pathways of curcuminol against IC

The Database for Annotation, Visualization and Integrated Discovery (DAVID) database (<https://david.ncifcrf.gov/home.jsp>) was used to extract the available biological functions related to core targets. These data were further introduced in the Omicshare Cloud Platform (<http://www.omicshare.com/tools/Home/Soft/gogsea>) to visualize the biological processes and signaling pathways from the core targets of curcuminol anti-IC. And a p-value was used to plot advanced bubble diagrams of biological processes and signaling pathways.

### Human designs

Adult male patients (n = 3) were diagnostically determined as IC through the biochemical, pathological, and medical imaging tests at Department of Urology Surgery. The serological data and clinical imaging were collected for further analyses. Additionally, IC samples of all these cases were surgically isolated during precancerous screening, followed by immunohistochemical and immunofluorescence stains. All principles of this human study were conducted following the guidelines issued by Declaration of Helsinki [10].

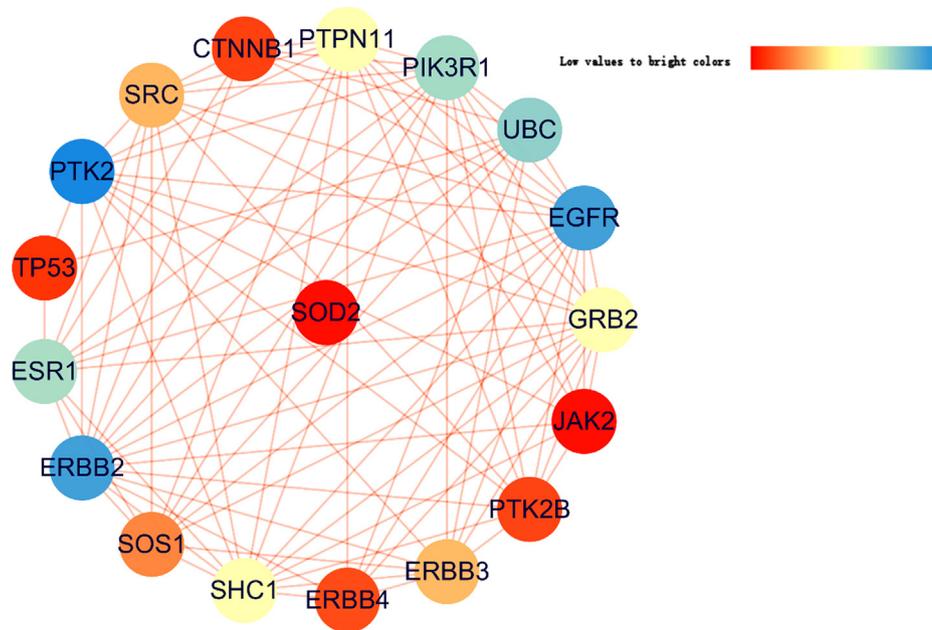

**Fig. 2.** A PPI network was used to construct the targets of curcumol against IC (Red nodes) and functional related targets (Green nodes) before the main targets were identified and collected.

*Animal designs*

Adult female Kunming mice were obtained from the Experimental Animal Unit of Guilin Medical University (Guilin, China). The mice were maintained in animal house under the controlled conditions of  $22 \pm 1$  °C, around  $60 \pm 5\%$  humidity, 12 altered hours in cycled light/dark. The mice were allowed to have filtered water

and rodent chow freely. *The present study was authorized through Institutional Animal Care and Use Committee of the Guilin Medical University.* After acclimatization for at least one week, the anti-cancer drug-induced IC mice by cyclophosphamide (CPS) was established as previously described [11]. Briefly, the fresh-prepared CPS solution were given to mice via oral gavage with 50 mg/kg in body weight every 3 days, followed by curcumol treat-

**Fig. 3.** After being analyzed, the main targets of curcumol against IC were identified and correlated. As a result, 3 top targets were representatively found as ERBB2, EGFR and PTK2 prior to further validation.

ments (40 and 80 mg/kg; w/w) for consecutive 12 days. At the end of experiment, the serum and bladder samples from all mice were isolated for biochemical tests, and stains used for immunohistochemistry and immunofluorescence. For more details, all immunostaining procedures were referenced in previous description [12].

### Statistical analysis

The blood results were expressed as mean  $\pm$  standard deviation (SD). The mice data were assayed through statistical product and service solutions (SPSS) 19.0 software (IL, USA). Multiple comparisons were calculated by using the analysis of variance (ANOVA) with Tukey's post hoc test. The statistical significance was considered as  $P < 0.05$ .

### Results

#### Candidate targets and identification of core targets

After bioinformatic assays, all 64 IC-pathogenic targets and 314 curcumol-therapeutic targets were screened. For further validation, 8 predictive targets were identified ultimately. A PPI network of curcumol against IC was constructed through assaying a function-related protein-protein interaction in these 8 functional targets. As shown in PPI network analysis, the hub network had 137 nodes and 449 edges with interactions and associations (Fig. 2). In topology parameters, the shorter path length and the larger median value indicated the more important targets. After calculation, 18 core targets were optimally obtained. According to the resultant visualization, the predictive targets of ERBB2, EGFR and PTK2 were the most important (Fig. 3).

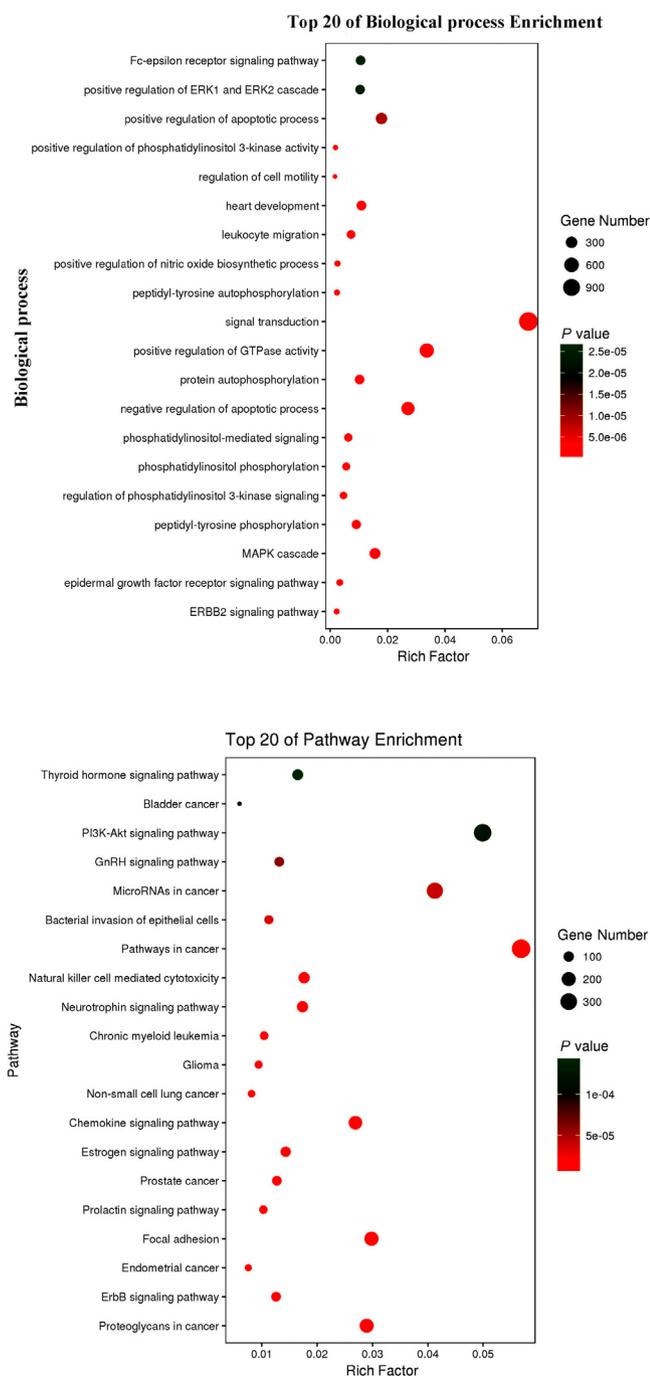

#### Biological function and signaling pathways of curcumol against IC

As results, the top 20 biological function enrichments were obtained through DAVID database and omicshare cloud platform. As shown in Fig. 4, the results showed that the biological processes

from the predictive targets of curcumol against IC were principally linked to regulating the ERBB2 signaling pathway, epidermal growth factor receptor (EGFR) signaling pathway, MAPK cascade, peptidyl-tyrosine phosphorylation, regulation of phosphatidylinositol 3-kinase signaling phosphatidylinositol phosphorylation (PI3-K), phosphatidylinositol-mediated signaling, negative regulation of apoptotic process, protein autophosphorylation, positive regulation of GTPase activity, signal transduction, peptidyl-tyrosine autophosphorylation, positive regulation of nitric oxide biosynthetic process, leukocyte migration, heart development, regulation of cell motility, positive regulation of phosphatidylinositol 3-kinase activity, positive regulation of apoptotic process, positive regulation of ERK1 and ERK2 cascade, Fc-epsilon receptor signaling pathway. In addition, the signaling pathways were chiefly involved in the Proteoglycans in cancer, ErbB signaling pathway, Endometrial cancer, Focal adhesion, Prolactin signaling pathway, Prostate cancer, Estrogen signaling pathway, Chemokine signaling pathway, Non-small cell lung cancer, Glioma, Chronic myeloid leukemia, Neurotrophin signaling pathway, Natural killer cell mediated cytotoxicity, Pathways in cancer, Bacterial invasion of epithelial cells, MicroRNAs in cancer, GnRH signaling pathway, PI3K-Akt signaling pathway, Bladder cancer, Thyroid hormone signaling pathway, respectively.

#### Case reports of patients with IC

To reveal the clinical and histopathological characteristics of IC, human data and samples were used to assay. In urinary examination, these IC patients showed positive urinary protein, bacterial infection, and visible epithelial cell shedding (Table 1). As shown in clinical computed tomography (CT) screening, chronic cystitis with urinary tract infection was observed. In addition, histopathological stains resulted in elevated intracellular expression of TNF- $\alpha$  in these IC sections. In order to characterize the predictive target of PTK2 in human samples, histopathological and immunofluorescent stains were conducted for further validation. As a result, the IC sections showed increased expressions of PTK2, p-PTK2<sup>Tyr397</sup> in bladder tissues (Fig. 5).

**Fig. 4.** After data analyses in DAVID tool, top 20 biological processes and signaling pathways of curcumol against IC were showed respectively prior to further bioinformatic discussion.

#### Experimental study of PTK2 targets in curcumol-treated mice

To further validate the predictive PTK2 targets of curcumol against IC *in vivo*, well-established CPS-induced IC in mice were used for experimental assays. As results, CPS-lesioned mice showed reduced body weights, and elevated contents of lactate dehydrogenase (LDH), IL-6, TNF- $\alpha$  in sera ( $P < 0.05$ ). Interestingly, high dose of curcumol treatment beneficially increased body mass, and lowered blood contents of LD, IL-6, TNF- $\alpha$  ( $P < 0.05$ ) (Table 2). In histopathological observation with hematoxylin-eosin (HE) stains, CPS-lesioned mice exhibited morphological changes, inflammatory infiltration, and necrotic cells in bladder tissues.

**Table 1**  
Clinical parameters of urinary tests in IC patients.

Clinical indicators	Case data	Clinical standards
UP	Positive	Negative
pH	6.5 $\pm$ 0.4	4.5–8.0

Cond.	12.77 $\pm$ 1.81	5–38
Total	155246 $\pm$ 99709.97	0–40,000

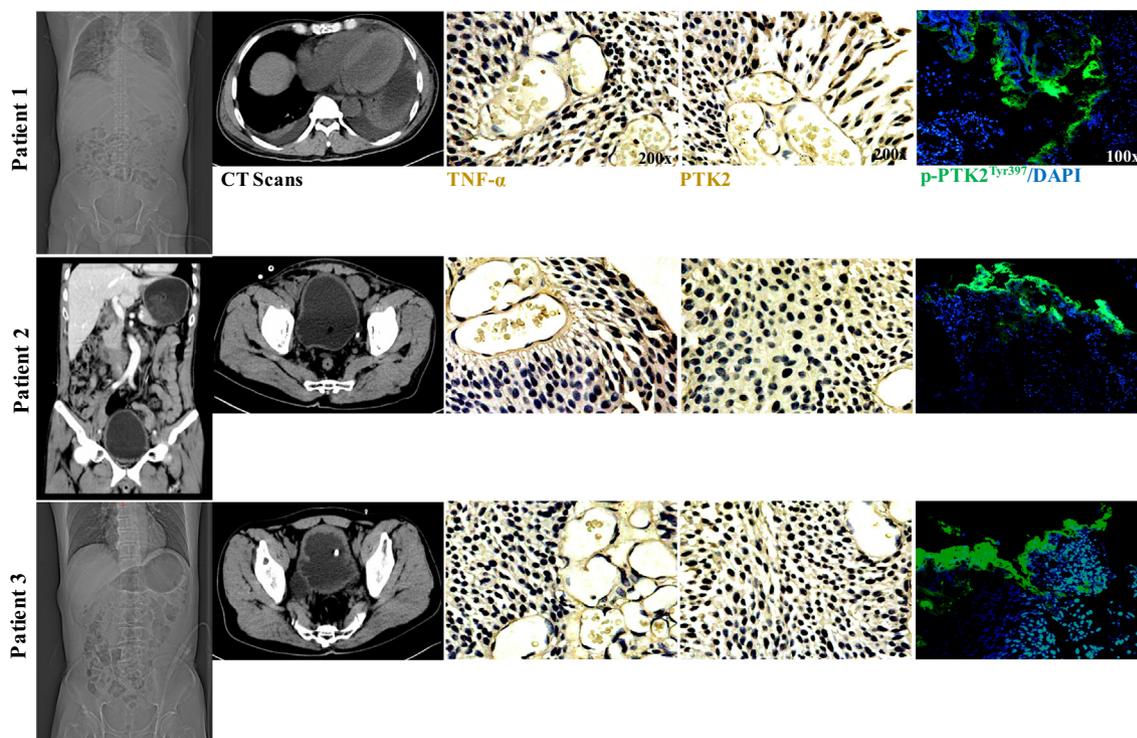

Abbreviations: UP, urinary protein; RBC, red blood cell; WBC, white blood cell; EC, epithelial cells; CAST, cast; BACT, bacteria; X.TAL, crystallization; YLC, yeast cell; SRC, small round epithelial cells; P.CAST, pathological cast; Cond, conductivity; TOTAL, total count.

However, curcumol-treated mice showed reduced CPS-induced cytotoxicity in bladder cells, such as decreased necrotic cells and inflammatory lesions. Followed by immunohistochemical staining, CPS-lesioned bladders in mice resulted in increased intracellular expression of TNF- $\alpha$ , while curcumol-treated mice showed reduced endogenous TNF- $\alpha$  expression in bladder sections.

In addition, immunofluorescence staining was used to check intracellular expressions of PTK2, p-PTK2<sup>Tyr397</sup>. As results, CPS-lesioned mice showed elevated PTK2, p-PTK2<sup>Tyr397</sup> expressions in bladder sections. After cotreatment with curcumol, the cellular expressions of PTK2, p-PTK2<sup>Tyr397</sup> were down-regulated in comparison with those in CPS-lesioned controls (Fig. 6).

#### Discussion

In this study, a bioactive component-target-disease network was constructed by using the network pharmacology-based bioinformatics. And resultant 18 core targets were identified through further analysis. According to the bioinformatic results, predictive ErbB2, EGFR and PTK2 were the most important targets of curcumol against IC. Tyrosine protein kinases (PTKs) are a group of functional enzymes that can catalyze the phosphorylation of substrate tyrosine residues, and these molecules play the key roles in cellular signaling pathways [13,14]. It is believed that the parathyroid hormones (PTHs) signaling is mainly involved in cell growth and proliferation through modulating the PTKs-MAPK pathway [15]. Mitogen-activated protein kinase (MAPK) functions as a “bridge” connecting extracellular stimuli and intracellular gene expression. It functionally regulates tumor growth and metastasis, as well as biologically participates in cell proliferation, differentiation and apoptosis through a series of effectors’ activation and inactivation [16,17]. The biomolecules of ErbB2, EGFR and PTK2 belong to PTK family, and it is a transmembrane protein with tyrosine kinase activity [18,19]. EGFR is a receptor protein that distributes on the membrane of epithelial cells. When combined with ligands, EGFR activates the downstream signaling molecules and induces the biological effects, such as cell proliferation, differentiation and migration. In addition, EGFR plays a promotive role in transformation of malignant cells [20,21]. PTK2, known as focal adhesion kinase (FAK), is a non-receptor protein tyrosine kinase located in the cytoplasm. Functionally, the activation of PTK2 is to promote the formation of tumor, and it also has other biological activities of regulating cellular apoptosis and stress [22,23]. Recently, some studies have found that PTK2 is positively expressed in bladder

**Fig. 5.** Clinical characteristics of patients with IC. As results, medical CT scans showed urocytic lesions with chronic cystitis, urinary tract infection. Further, immunohistochemical staining showed visible expression of cellular TNF- $\alpha$  in IC sections. And the immunofluorescent stains displayed increased expressions of PTK2, p-PTK2<sup>Tyr397</sup> in IC sections.

<sup>b</sup>  $P < 0.05$  compared to CPS group.

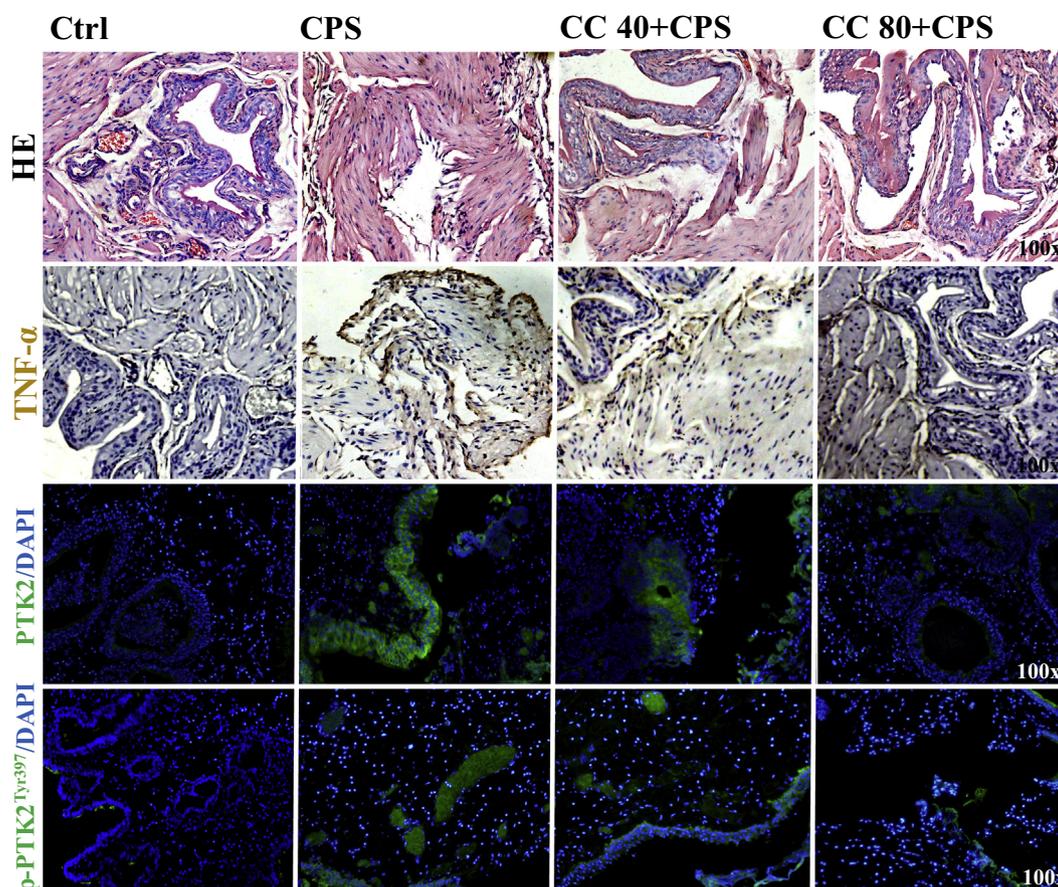

cancer cells, and the over-expression of PTK2 facilitates the neoplastic cells to escape from apoptotic signals, gradually promoting tumor growth, metastasis [24,25]. Interestingly, these functional molecular pathways from literature review were similarly proposed in this study. However, the experimental investigation of PTK2 in interstitial cystitis is not yet conducted. Based on bioinformatic findings, the current study predicted the core targets of curcumol against IC through a network pharmacology method. As a result, a key biotarget of PTK2 was representatively selected for further validation in human samples. In addition to positive detection of TNF- $\alpha$  expression in IC sections, intravesical PTK2, p-PTK2<sup>Tyr397</sup> were markedly up-regulated through immunostaining. The activated PTK2 were positive correlation with cystitis conditions in urinary tests. These clinicopathological findings indicated that intracellular over-expression of PTK2 might be a key pathological promoter in development of IC. Further, PTK2 might be a potential therapeutic target for IC.

To further validate experimental study *in vivo*, CPS-induced IC mice were used to evaluate the pharmacological activities of

curcumol against IC. As results, curcumol-treated mice showed reduced inflammatory cytokines (IL-6, TNF- $\alpha$ ) in sera and suppressed intracellular cytotoxicity, characterized with down-regulated expressions of PTK2, p-PTK2<sup>Tyr397</sup> in bladder cells. Therefore, this study can be reasoned that the anti-IC activities of curcumol might benefit from the anti-inflammatory effects through suppressing intravesical PTK2 and phosphorylation bioactivities.

## Conclusions

Collectively, these bioinformatic and experimental findings demonstrate that predictive targets of curcumol against IC may be mainly linked to inhibition of inflammation-associated pathways and inactivation of intracellular PTK2 activity in bladder cells. It highlights that bioinformatic method based on network pharmacology may predict the biological markers for IC screening and treating. Interestingly, PTK2 may be a potential biomarker for curcumol treating IC.

**Fig. 6.** Anti-IC activities of curcumol on CPS-lesioned mice. As showed in HE stains, CPS-lesioned mice resulted in morphological changes in bladder tissues. And increased expression of intracellular TNF- $\alpha$  in the bladder were observed in CPS-lesioned mice by using immunohistochemical stain. Interestingly, curcumol-treated mice showed bladder morphological improvement, and reduced TNF- $\alpha$  expression. As showed in immunofluorescence staining, CPS-lesioned mice resulted in elevated PTK2, p-PTK2<sup>Tyr397</sup> expressions in bladder sections. However, down-regulated expressions of TNF- $\alpha$ , PTK2, p-PTK2<sup>Tyr397</sup> in the bladder cells of curcumol-treated mice were observed, accompanied with ameliorative histomorphology in bladder tissues.
