## Self-assembly of a nano hydrogel colloidal array for the sensing of humidity

Zhe Wang,<sup>a</sup> Min Xue,<sup>\*a</sup> Herong Zhang,<sup>a</sup> Zihui Meng,<sup>\*a</sup> Kenneth J. Shea,<sup>b</sup> Lili Qiu,<sup>a</sup> Tiantian Ji<sup>a</sup> and Tengsheng Xie<sup>a</sup>

Traditional artificial opals are assembled from silica or polystyrene colloids which have poor swellability and a lower response to stimuli. A novel three-dimensional photonic crystal array sensor which has a high stability and desired structural colour was fabricated from the self assembly of nano hydrogel colloids. The nano hydrogel colloids were prepared by co-polymerisation of *N*-isopropylacrylamide, functional monomer acrylic acid and *N*-*tert*-butylacrylamide. The relative humidity from 20% to 100% could be detected rapidly *via* the reflection spectrum of the nano hydrogel colloidal array with a maximum amount of red shift of 24 nm. The response kinetics for humidity of the nano hydrogel colloidal array were investigated, and correspondingly, a rational response mechanism of the compactness of the close-packed structure caused by the swelling of the nano hydrogel colloidal array was discussed. The nano hydrogel colloidal array sensor presented good reversibility and can be reused for at least five rounds.

### Introduction

Photonic crystals (PCs), artificial dielectric array structures with more than two different refractive index materials, can prohibit the transmission of light with certain wavelengths due to its band gap developed by a certain period of ordered form in space. The existence (distance change) of an optical band gap induces the sensitivity of the PC structure to the environmental changes, such as temperature,<sup>1,2</sup> pH,<sup>3</sup> ionic strength,<sup>4,5</sup> light,<sup>6</sup> electric field,<sup>7</sup> strain,<sup>8</sup> organics<sup>9,10</sup> and biomolecules.<sup>11–13</sup> This optical band gap can be modulated in the visible wavelength range while colloidal crystals were used as the matrix for self-assembly, *i.e.*, structural units, located at the submicron scale. Nano colloidal particles prepared from SiO<sub>2</sub>,<sup>14,15</sup> PMMA,<sup>16,17</sup> PS<sup>18</sup> and other composite material<sup>19–21</sup> were more often used to produce the close-packed PC with periodically arranged three-dimensional structures which makes the PC suitable for naked-eye detection application.

Compared to traditional detecting sensors,<sup>22,23</sup> which require expensive sensing elements associated with energy consumption and complex signal demodulation process, sensors that fabricated from photonic crystal material have attracted continuing interest<sup>24–27</sup> because of their visual diffraction signals and remarkable response to external stimuli. Self-assembly is a simple, economical and effective method to

construct PC from mono-dispersed latex spheres.<sup>28,29</sup> However, photonic crystal arrays fabricated by the self-assembly of solid spheres, are difficult to respond to external stimuli by deformation for their small swelling ability and low mass transfer. The common practice of realizing lattice spacing variations in photonic crystal arrays is incorporating responsive gel into photonic crystal arrays to fabricate the opal structure. Smith *et al.* developed an air-stable two-dimension opal PC sensor which was immersed into ethylguanidine perchlorate ionic liquid for visual detection of vapour and ammonia because of the negligible ionic liquid vapour pressure.<sup>30</sup> Barry *et al.* developed a polyacrylamide inverse opal hydrogel to detect ambient humidity variations through an optical change.<sup>31</sup> However, the photonic crystal bandgap after embedding will change due to the filling of the gel medium. Moreover, the filling process often results in damage to the array structure, which requires the operator to be extremely careful.

Soft materials can also be used for the preparation of photonic crystal arrays. Compared to the solid spheres, soft materials<sup>32</sup> with a larger swelling ratio and exposed functional groups on the surface of the particles are easier to respond to external stimuli. Recently, a kind of novel nano hydrogel colloidal (NHC) material with sensing, processing and executive function that hold great promise in nanotechnology for diagnostics, drug delivery, protein separation and bioinspired designing was synthesized as polymer hydrogel colloidal nanoparticles.<sup>33</sup> The NHC has the similar composition of hydrogel nanoparticles that is called plastic antibody.<sup>34</sup> It is capable of combining with target biomolecules for its good biocompatibility and affinity, and can be used as a substitute for

<sup>a</sup>School of Chemistry & Chemical Engineering, Beijing Institute of Technology, Beijing, 102488, China. E-mail: minxue@bit.edu.cn; mengzh@bit.edu.cn; Fax: +86 10 68913065; Tel: +86 10 68913065

<sup>b</sup>Department of Chemistry, University of California, Irvine, California 92697, USA

antibody. It has been applied in toxins elimination successfully *in vivo* and *in vitro*. The responsive NHCs are a class of polymers which undergoing a volume phase transition in response to minimal environmental stimulus. Besides, temperature-responsive colloidal nanoparticles containing the spatial network structure have a remarkable capacity to adsorb water. There are also substantial hydrophilic groups and hydrophobic groups at side chain, which makes the polymers sensitive to water. In addition, the preparation process of the three-dimensional NHCA is easier than that of the opal or inverse opal PC hydrogel film. However, PC colloidal arrays that was assembled with NHC is rarely reported.

In this study, we focused on the PC array fabricated by hydrogel nanoparticles for the response of humidity. We innovatively constructed a PC sensor fabricated from soft and bio-friendly NHC, and investigated its response to humidity. To a certain extent, this work expanded the materials that could be used for the preparation of photonic crystal. Furthermore, the nano hydrogels have been verified to be capable of binding to specific targets including peptides and proteins,<sup>34,35</sup> which provides the possibility of recognizing biological macromolecules using the as-prepared NHCA in the follow-up study.

## Experimental section

### Materials

*N*-Isopropylacrylamide (NIPAM), acrylic acid (AAc), and *N,N'*-methylenebisacrylamide (BIS) were purchased from J&K Chemicals Co. Ltd.; *N-tert*-butylacrylamide (*t*-BAM) was from Aladdin Chemicals Co. Ltd.; sodium dodecylsulfate (SDS) was from Fuchen chemical reagent factory; ammonium persulfate (APS) was from Beijing Chemical Reagent Co. Ltd. All chemicals were used as received, except that NIPAM was recrystallized by hexane before usage. Water used in the experiment was distilled and purified by an Aquapro purification system. Glass slides (50 × 24 mm and 24 × 24 mm) were purchased from Weiss Experiment Products Co. Ltd. and treated with a H<sub>2</sub>SO<sub>4</sub>/H<sub>2</sub>O<sub>2</sub> (7/3, v/v) solution for 24 h.

### Synthesis and characterization of nano hydrogel colloids

The nano hydrogel colloids (NHC) were synthesized using precipitation polymerization method.<sup>36</sup> NIPAM (139.7 mg), AAc (46.8 mg), *t*-BAM (165.3 mg), BIS (10 mg) and SDS were dissolved in 50 mL water of a total volume. Then the initiator APS (30 mg) was added after the solution degassed by nitrogen for 30 min. The polymerization reaction was carried out at 65 °C for 3 h. The reacting solutions were cooled down to room temperature and then purified by dialysis (14 000 MWCO) in excessive fresh water changed several times per day to remove unreacted monomers and impurities. The as-prepared NHC solution was transferred into the cuvette, and then the hydrodynamic diameters of NHCs were measured by dynamic light scattering (DLS) instrument (Zetasizer Nano ZS, Malvern Instruments Ltd.) at 25 °C. The lower critical solution temperature (LCST) was obtained from a series of as-prepared NHC hydrodynamic diameters measured at different temperatures. The

concentration of hydrogel solution was calculated after lyophilisation of 5 mL polymer sample solution.

### Fabrication and characterization of nano hydrogel colloidal array

The nano hydrogel colloidal array (NHCA) was fabricated *via* a vertical deposition method<sup>37</sup> on a clean glass slide treated with a H<sub>2</sub>SO<sub>4</sub>-H<sub>2</sub>O<sub>2</sub> solution. The glass slide was vertically dipped into a vial containing the NHC solutions (0.3 wt%) at 30 °C under 50% relative humidity in an incubator for 3–4 days. After complete evaporation of water, NHCA were obtained on the glass slide.

Morphology images of the NHCA were obtained with a field emission scanning electron microscope (HITACHI S-4800, Japan) after sputter coating a layer of platinum on the surface of NHCA. Photographs of the as-prepared films on glass slide were taken with a digital camera. Reflection spectrum of the NHCA was recorded using a fiber optic UV-vis spectrometer (Avaspec-2048TEC, Avantes) with an AvaLight-DH-S-BAL light source and an AvaSpec-ULS-TEC fiber optic reflection probe.

### Humidity sensor response

NHCA slides were placed in a hermetic container (45 cm × 45 cm × 45 cm). Humidity inside the container was controlled using a desiccator containing a large dish of a warm water or supersaturated salt solutions,<sup>30</sup> and a fan to gently circulate the air surrounding the measurement apparatus. Real-time relative humidity (RH) and temperature values was monitored with a digital temperature & humidity sensor (AS105, Guangzhou) probe inside the container after the equilibrium of RH.

To study the response to relative humidity, reflection spectrum of the NHCA at an atmospheric condition or a controlled humidity condition was recorded. The NHCA response time was investigated when exposed to a certain relative humidity (RH) from the atmosphere conditions of RH 20%. Here, the RH considered in the experiment were 50% and 100% respectively. Reversibility of the NHCA was tested by raising and dropping humidity repeatedly.

## Results and discussion

### Characterization of the nano hydrogel colloidal

The monodispersed nano hydrogel colloidal (NHC) could be obtained while the backbone monomer (NIPAM), hydrophobic (*t*-BAM) and hydrophilic monomer (AAc) and the surfactant (SDS) reacted in appropriate ratios. NIPAM as the conventional thermosensitive monomer exhibits lower critical solution temperature (LCST) at 32–34 °C. However, the LCST value of the NHC can be tuned by adjusting the hydrophilic–hydrophobic balance. The LCST value of the corresponding NHC with the formula NIPAM/AAc/*t*-BAM/BIS (38/20/40/2, mol%) was confirmed as 11–12 °C, which was proved by dynamic light scattering (Fig. 1). The lower LCST of NHC indicates that NHC is in a collapsed state above this temperature. That means the temperature-sensitive property of NHC would not interfere with

Fig. 1 The hydrodynamic diameters of the NHC with an optimised monomer molar ratio.

the swelling/shrinkage properties due to water absorption when measuring humidity at room temperature.

The hydrodynamic diameters of NHCs could be controlled by the concentration of surfactant SDS in pre-polymer solution. A series of NHCs with different particle size from 60–600 nm was obtained while the amount of SDS used in the polymerization process was adjusted from 0.02 to 0.1 mg mL<sup>-1</sup>, and the distribution trend of the colloidal size with SDS concentration is displayed in Fig. 2.

During the reaction, electrostatic repulsion force of colloids was enhanced when SDS concentration increased, which results in a shorter chain polymer, therefore, the smaller size of the nanoparticles was obtained. All the NHCs are monodispersed with uniform particle size while their PDI value was below 0.1 monitored by a Zetasizer Nano ZS DLS instrument in aqueous solutions.

#### Characterization of the nanohydrogel colloidal array

A series of 3D NHCA were self-assembled *via* the vertical deposition method<sup>37</sup> with the nano hydrogel colloidal solution, which concentration was confirmed as 6.0–8.1 mg mL<sup>-1</sup> by a Gravimetric analysis after lyophilisation, and then was diluted

Fig. 2 DLS distributions of NHC with different sizes while the concentration of SDS used is from 0.1 mg mL<sup>-1</sup> (purple) to 0.02 mg mL<sup>-1</sup> (red).

to 3.0 mg mL<sup>-1</sup> to prepare the array with a certain thickness. It is an easy, cost-effective and efficient approach for obtaining NHCA from NHCs.<sup>28</sup> The uniform size and fine spherical shape of NHCs together with the regular microstructure of the as-prepared NHCA were proved by the SEM image in Fig. 3(a). In addition, the self-assembly process is strict with the uniformity and sphericity of the colloidal crystals.<sup>38</sup> The structured array also implies high uniform quality of the NHCs. From the cross view of the NHCA in Fig. 3(b), the thickness of typical as-prepared NHCA is three micrometres with about 20 layers. Such a thin array makes the interface between the NHCA and the target larger, the response becomes faster.

Their transmission spectra was also proved by a fiber optic UV-vis spectrometer as presented in Fig. 4. The inserts depict various structural colours of these as-prepared hydrogel colloidal PC shows visible colour from purple, blue, green, orange to red corresponding to the arrays with different particles in 169 nm, 186 nm, 214 nm, 230 nm and 285 nm. Therefore, the PCs covering the full visible wavelength range (400–760 nm) could be obtained with different sizes of the NPs.

#### Humidity response of the nano hydrogel colloidal array

Due to the intrinsic humidity sensitivity of Aac used as the negative charged monomer in this study, the as-prepared NHCA shows sensitive to humidity. The reflection peak get red shift when the relative humidity (RH) increased. From the colour changes and the reflection peak shifts, the relative humidity could be clearly indicated. Herein, we give a typical example of the NHCA with a green structural colour prepared by nanoparticle of 230 nm responding to the RH from 20% to 50% and 99.9%, respectively.

It is seen from Fig. 5, both reflection peak wavelengths stay the same after a rapid red shift of reflection peak wavelength within equilibrium time of 10 min. Compared with the traditional commercial hygrometers that can achieve the balance within 60 seconds, it takes time for sensors made from polymer material to deform when humidity changes. This time depends on the nature of the material itself. Three-dimensional ordered porous poly(ethylene glycol) hydrogel could expand in 1 min and reach stability after 70 min,<sup>39</sup> while transition time of PAAm-P(St-MMA-AA) PC hydrogel between the dry and fully wetted states was less than 3 min.<sup>19</sup> The NHCA was thin enough

Fig. 4 UV-vis spectra of the NHCA with particle diameter of 169 nm, 186 nm, 214 nm, 230 nm and 285 nm. The inset shows the structure color of the as-prepared NHCA. The photos and data were taken at atmospheric conditions.

Fig. 5 Time dependence of the NHCA exposed to 50% RH (black) and 100% RH (red) from ambient RH of 20%.

to achieve a somewhat short equilibrium time. Red shift of 24 nm and 11 nm was monitored during humidity increase in the black line with squares and red line with dots, correspondingly. The swelling of NHC contribute to the red shift of the reflection peak, and the swell ratio can be calculated by the reflection peak change.

For the NHCA, the reflection obeys Bragg and Snell's law (1):<sup>10,40</sup>

$$m\lambda_{\text{peak}} = 2d_{111}(n_{\text{eff}}^2 - \sin^2 \theta)^{1/2} \quad (1)$$

where,  $m$  is the order of reflection;  $\lambda_{\text{peak}}$  is the wavelength of the reflected light;  $n_{\text{eff}}$  is the mean effective refractive index;  $\theta$  is the angle between the incident light and the normal to the reflection plane.  $d_{111}$  is the lattice spacing between array planes which can be calculated by the diameter of NHC, defined as  $D$  here, as shown in eqn (2).

$$d_{111} = \sqrt{\frac{2}{3}}D \quad (2)$$

In this study, the incident angle  $\theta$  was fixed and the average value of effective refractive index  $n_{\text{eff}}$  was constant. As for the first order diffraction, the value of  $m$  is 1. Therefore, we can get a linearity between the lattice spacing and the diameter  $D$  in eqn (3).

$$\lambda_{\text{peak}} = \alpha D \quad (3)$$

Herein, the linear coefficient is defined as  $\alpha$ . The swelling ratio  $R$  of the NHC in response to humidity could be calculated as eqn (4).

$$R = (\lambda_{\text{peak},1} - \lambda_{\text{peak},0})/\lambda_{\text{peak},0} \quad (4)$$

where,  $\lambda_{\text{peak},1}$  is the wavelength of the reflected light after adsorption equilibrium,  $\lambda_{\text{peak},0}$  is the initial wavelength of the reflected light.

Therefore, the swelling ratios of the NHC is 4.5% and 2.1% respectively corresponding to eqn (4), indicating that NHC has the swelling properties. Compared with the common PC fabricated with solid colloids that need to be embedded with gel, NHCA is easy prepared, which makes it easier for use in the future.

After absorbing water, the structure of the network is swollen, which leads to the increase of the particle size and the shift of the reflection peak. The scheme was shown in Fig. 6. If more water is added, the particles will be dissolved. The PNIPAM exhibits an LCST of 32 °C, while the LCST drops to 11–12 °C for NHC, which contains temperature-sensitive monomer NIPAM and other functional monomers such as acrylic acid. The NHC also has properties of hydrophilicity at low temperature and hydrophobicity at high temperature. Tanaka<sup>41</sup> suggested whether the polymer gel should absorb water depending on the combination of van der Waals forces, hydrogen bonding, electrostatic interaction and hydrophobic interaction. The condition temperature is higher than the LCST of NHC, which means the NHC is in a hydrophobic state. Therefore, we

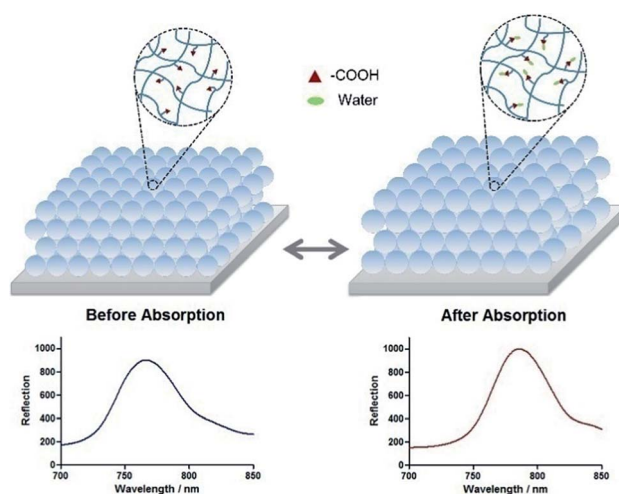

Fig. 6 Sketch diagram of the detection mechanism for the target by the NHCA.

Fig. 7 UV-vis spectra of the as-prepared hydrogel colloidal PCs with humidity change. (a) Water absorption (b) water desorption. The NHCA were assembled from NHC of 230 nm.

proposed that water absorption at NHCA is mainly due to the contribution of the acrylic acid component.

The shifts and intensity changes of reflection peak in response to humidity were monitored, which discloses the particle swelling behavior as shown in Fig. 7. A red shifts and intensity increase of reflection peak when increasing humidity and a blue shifts and intensity decrease of reflection peak when decreasing humidity was observed.

As the ambient humidity increases, the carboxyl groups in the polymer chains within the colloid formed a more stable bond with the water molecules. The initially dry hydrogel colloids swelled to a degree that the PC on the glass slide was close-packed and the compactness of the close-packed structure was strengthened until reaching equilibrium, and *vice versa*.

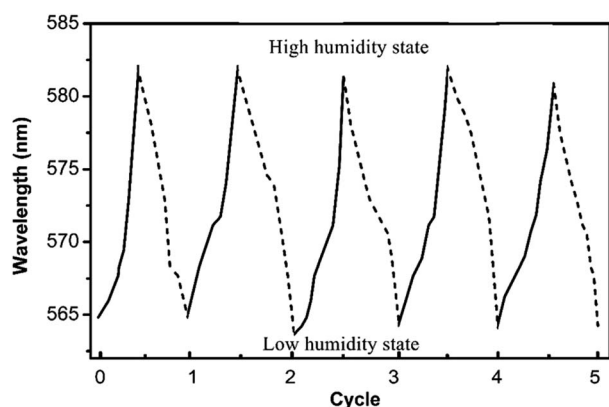

Fig. 8 Reversible wavelength changes of UV-vis reflection peak of the nanohydrogel colloidal PC with relative humidity by alternately exposing to increasing (the solid lines) and decreasing (the dashed lines) relative humidity conditions (between 20% and approaching 100%).

The NHCA showed a reversible reflective wavelength shift according to the swelling and shrinkage behaviour of the NHC when the humidity changed, which makes it a potential tool to detect the humidity sensitively and quickly.

### Reversibility of the nano hydrogel colloidal array in response to humidity

The NHCA fabricated from the soft nano-hydrogel particles is stable and reusable. The reversibility of the NHCA was evaluated on the humidity response by cycle method of humidity (Fig. 8). It was shown that the NHCA could retain its initial response to humidity after 5 rounds relative humidity recycles from 20% to 100%, which means the sensor presents good stability and reversibility and can be used many times in humidity range.

## Conclusions

Compared with the conventional photonic crystal, soft and uniform nano hydrogel colloids dispersed in water with bio-friendly, stable physical and chemical properties, were self-assembled to get a 3D-array. This nano hydrogel colloidal array with a bright structure color can be used as a humidity sensor. The response mechanism of the sensor is based on the changes in the compactness of close-packed structure and refractive index of the array of the hydrogel colloids, which can also be applied to biomolecules for response. Full wavelength coverage will meet different requirements. Further work on optimizing the performance to realize naked-eye detection as well as diminishing the response time is under way.
