The title sulfoxide, $C_{18}H_{20}O_2S$, was prepared by controlled oxidation of *thia*-Dianin's compound using hydrogen peroxide in glacial acetic acid. On recrystallization from glacial acetic acid, it was found to form unsolvated, spontaneously resolved crystals, the initial crystal structure analysis revealing the presence of both sulfoxide epimers in the crystal. On multiple recrystallization a single epimer was observed, with crystallization occurring in the unchanged orthorhombic space group $P2_12_12_1$, with $Z' = 1$. The molecule possesses a *distal* conformation, referring to the juxtaposition of the *p*-hydroxyphenyl substituent with respect to its *syn*-related methyl group, with the sulfoxide oxygen atom *anti* to the aromatic substituent. The molecular packing features $O-H \cdots O$ hydrogen bond chains running parallel to the *b* axis of the unit cell.

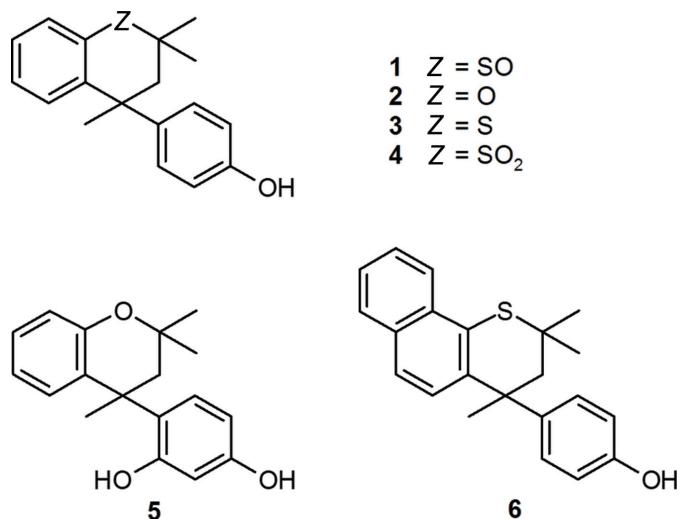

1. Chemical context

A significant body of work in the literature relates to specifically targeted structural modification of Dianin's compound, 4-(4-hydroxyphenyl)-2,2,4-trimethylchroman **2**, (MacNicol, 1984; Finocchiaro & Failla, 1996; Collet & Jacques, 1976; Frampton *et al.*, 2017*a,b,c*). Crystallization of the new compounds has normally resulted in one of two outcomes: formation of clathrates in the space group $R\bar{3}$ (or $R3$) or spontaneous resolution, also a subject of much current interest (Pérez-García & Amabilino, 2007), to form an unsolvated conglomerate in space group $P2_12_12_1$, with $Z' = 1$, in which the individual crystals are formed by supramolecular assembly of a single enantiomer. A notable departure from the above crystallization modes has, however, been found in the case of Dianin's sulfone **4**, (Frampton *et al.*, 1992), which crystallizes unsolvated in the polar monoclinic space group *Cc*, with $Z' = 1$, and these crystals exhibited a significant SHG effect. The present work was undertaken to establish if the corresponding sulfoxide **1** would retain the clathrating ability of its immediate progenitor *thia*-Dianin's compound **3**, or would undergo spontaneous resolution, alternative possibilities being the formation of a polar monoclinic crystal or crystallization in a more frequently encountered space group. Interestingly, the achiral bis-sulfoxide *trans*-(*R,S*)- α,α' -di-*tert*-butylsulfinyl-*para*-xylene undergoes conformational spontaneous resolution in the space group $P2_12_12_1$: on dissolution, rapid conformational racemization occurs at room temperature; however, the authors make the point that at 173 K, from calculations, it

OPEN ACCESS

could be possible to obtain one chiral conformation from a single crystal (Xu *et al.*, 2014). Accordingly, the sulfoxide **1** was prepared by controlled oxidation of **3** as described in Section 5, and its crystal structure determined.

2. Structural commentary

Initial attempts to determine the crystal structure of **1** revealed the presence of both sulfoxide epimers in the crystal in a ratio of approximately 90:10. It was found that multiple

recrystallization of **1** from glacial acetic acid yielded a single epimer, the structure of which is presented here. The crystal structure of **1** is orthorhombic, space group $P2_12_12_1$ with a single independent molecule in the asymmetric unit, ($Z' = 1$), Fig. 1. The molecule possesses a *distal* conformation, this referring to the juxtaposition of the *p*-hydroxyphenyl substituent with respect to the *syn*-related methyl group. The C2—C3—C4—C11 torsion angle is $154.0(2)^\circ$, the corresponding torsion angle for racemic Dianin's compound **2** has a magnitude of 80.67° (Lee *et al.*, 2014) and for 4-(4-hydroxyphenyl)-2,2,4-trimethylchroman-1,1-dioxide **4**, it is 76.8° (Frampton *et al.*, 1992). The expected torsional angle value for a *distal* conformation is 160° whereas that for a *proximal* conformation is 80° . The torsion angle S1—C2—C3—C4, defining the heterocyclic ring chirality, has a value of $-67.3(2)^\circ$. Fig. 2 shows an overlay of **1** (brown) with sulfone **4** (cyan). In this figure, the six aromatic atoms of the chroman unit for each structure have been overlaid using the standard molecule overlay routine in *Mercury* (Macrae *et al.*, 2008), resulting in an r.m.s. displacement of 0.0147 \AA , and this clearly demonstrates the difference between the *distal* and *proximal* conformations of **1** and **4**, respectively. The absolute configuration of **1**, was determined as being *R* at the chiral centre C4 by anomalous dispersion methods, (Parsons *et al.* 2013), the Flack x parameter was determined as $-0.002(7)$ using 1246 quotients $[(I^+) - (I^-)]/[(I^+) + (I^-)]$.

3. Supramolecular features

The structure of **1** is isostructural with the enantiomerically pure amine counterparts of Dianin's and *thia*-Dianin's compound, (*R*)-4-(4-aminophenyl)-2,2,4-trimethylchroman and (*S*)-4-(4-aminophenyl)-2,2,4-trimethylthiachroman, both

of which were obtained by spontaneous resolution (Frampton *et al.*, 2011), and also surprisingly isostructural with the enantiomerically pure forms of 4-(4-hydroxyphenyl)-2,2,4-trimethylchroman, **2** (Lloyd & Bredenkamp, 2005) and 4-(2,4-dihydroxyphenyl)-2,2,4-trimethylchroman, **5** (Beresford *et al.*, 1999). The crystal packing is dominated by the formation of an extended linear hydroxy —OH to sulfoxide O, hydrogen-bonded O—H···O chain along the [010] direction of the unit cell, Figs. 3 and 4, Table 1.

4. Database survey

A search of the Cambridge Structural Database (CSD, Version 5.39 update August 2018; Groom *et al.*, 2016) for the *thia*-Dianin's framework, **3**, yielded 15 hits, all of which were genuine examples of analogues of the material under investigation. Although there are no entries for the empty racemic *R*₃ host of *thia*-Dianin's compound, there are seven entries for

Symmetry code: (i) *x*, *y*—1, *z*.

the following host–guest clathrates: ethanol (HPTHCR; MacNicol *et al.*, 1969), 2,5,5-trimethylhex-3-yn-2-ol (TCHHXO; MacNicol & Wilson, 1971), cyclopentane (METCCP; Hardy *et al.*, 1979) and isopropanol at four different temperatures demonstrating three commensurate phase changes in the host lattice (VANFOI, 371 K, VANFOI01, 295 K, VANFOI02, 200 K and VANFUO, 90 K; Frampton *et al.*, 2017a). *Thia*-Dianin's compound, **3**, was also found in the 1:1 quasi-racemic *R*3 host with Dianin's compound, **2**, in the following three entries: apohost (BIBNAD and BIBNAD01), CCl₄/H₂O host–guest clathrate (HIDQAO) (Frampton *et al.*, 2013). The structure and absolute stereochemistry determination of the resolved S-enantiomer of *thia*-Dianin's compound used in the formation of the quasi-racemates above (BIBNEH; Frampton *et al.*, 2013). Four further examples demonstrating a slightly modified framework include the 6-methyl analogue (HPMTCM; Hardy *et al.*, 1977), the cyclooctane host–guest clathrate of the 8-methyl analogue (MSOCYO10; Hardy *et al.*, 1979), the oxidized sulfone, **4**, (KUTDUY; Frampton *et al.*, 1992) and 4-(4-hydroxyphenyl)-2,2,4-trimethyl-7,8-benzothiachroman **6**, a fused-ring counterpart of *thia*-Dianin's compound (JELROK; Frampton *et al.*, 2017c).

5. Synthesis and crystallization

Preparation of **1**: 4-(4-hydroxyphenyl)-2,2,4-trimethylthiachroman **3** (MacNicol, 1969) (0.25 g, 0.88 mmol) was dissolved in glacial acetic acid (10 mL) and a 50% excess of 30% hydrogen peroxide (0.15 mL, 1.32 mmol) added. After the reaction was left overnight at *ca* 278 K, the precipitated white solid was filtered off, washed several times with ether, and initially recrystallized from aqueous dimethyl sulfoxide yielding 0.168 g, (63%) of product. A further recrystallization from glacial acetic acid gave colourless crystals which were analysed by X-ray diffraction as described in the text. The crystals were obtained by spontaneous resolution on crystallization, yielding a 50:50 mixture of the pure enantiomers. These crystals also incorporated both spontaneously resolved sulfoxide epimers, four further recrystallizations were performed giving a single epimer of purity greater than 99% [500 MHz ¹H NMR, DMSO-*d*₆ solution analysis gave 99.5 (2)% purity] and the very minor residual second epimer was undetectable in the subsequent X-ray analysis. These crystals melted over a wide range, *ca* 513–536 K, possibly arising from sulfoxide epimerization, along with decomposition, at high temperature. MS [EI⁺]: 300.1178, C₁₈H₂₀O₂S, calculated 300.1184; ¹H NMR (400 MHz, DMSO-*d*₆) : δ 0.94 (*s*, 3H), 1.31 (*s*, 3H), 1.67 (*s*, 3H), 2.26 (*q*, 2H, J_{AB} = 0.45 ppm, J_{AB}

= 15.1 Hz), 6.6–7.7 (aromatic, 8H), 9.27 (*s*, 1H); FT-IR (ν_{max} , ATR, cm^{-1}): 3176 (*br*), 3197 (minor) [$\nu(\text{O}-\text{H})$]; 1017 [$\nu(\text{S}-\text{O})$].

6. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2.

The hydrogen atom of the OH group was localized in the difference-Fourier map and refined isotropically. The other hydrogen atoms were placed in calculated positions and refined within the riding model with C—H = 0.95–0.99 Å and fixed isotropic displacement parameters [$U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C})$ for the methyl groups and $1.2U_{\text{eq}}(\text{C})$ for the other groups].

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.
