The crystal structures of two substituted HATN (hexaaazatrinaphthylene) derivatives, namely 2,3,8,9,14,15-hexamethyl- and 2,3,8,9,14,15-hexaphenyl-5,6,11,12,17,18-hexaaazatrinaphthylene (HATNMe_6 and HATNPh_6), are reported. Whereas the structure of the methyl-substituted derivative (HATNMe_6) contains no solvent molecules ($\text{C}_{30}\text{H}_{24}\text{N}_6$), the hexaphenyl-substituted structure (HATNPh_6) contains two molecules of dichloromethane ($\text{C}_{60}\text{H}_{36}\text{N}_6 \cdot 2\text{CH}_2\text{Cl}_2$). This class of planar bridging ligands is known for its electron-deficient systems and its ability to form π – π stacking interactions. Indeed, in both crystal structures strong π – π stacking interactions are observed, but with different packing features. The dichloromethane molecules in the crystal structure of HATNPh_6 are situated in the voids and are involved in C–H···N contacts to the nitrogen atoms of the pyrazine units.

1. Chemical context

Over the last decades, hexaaazatriphenylene (HAT) and its derivatives have shown numerous applications in magnetic materials, semiconductors, sensors and polymers for energy storage (Segura *et al.*, 2015). These electron-deficient, aromatic and planar systems are known for their excellent π – π stacking ability (Alfonso & Stoeckli-Evans, 2001) and their three potential chelating positions to form metal complexes. Therefore, a variety of metal HAT or HATN (hexaaazatrinaphthylene) complexes are known (Kitagawa & Masaoka, 2003). Complexes with ruthenium (HATN; Ghumaan *et al.*, 2007), rhenium (HATN; Roy & Kubiak, 2010), cobalt (HATN; Moilanen *et al.*, 2016) and titanium (HATNMe₆; Piglosiewicz *et al.*, 2005) have been investigated, in particular due to their interesting electrochemical, photophysical and magnetic properties. The synthesis, electrochemical and photophysical properties of the title compounds HATNMe₆ (**1**) (Catalano *et al.*, 1994; Fraser *et al.*, 2011) and HATNPh₆ (**2**) (Gao *et al.*, 2009) have already been published. Herein we report on the corresponding crystal structures of the two HATN derivatives.

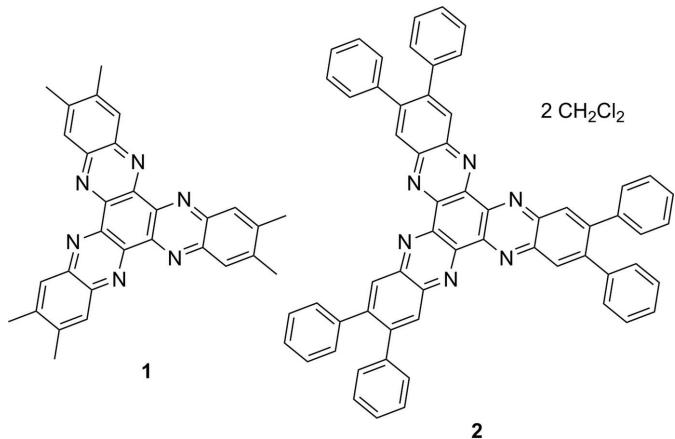

2. Structural commentary

The title compound HATNMe₆ (**1**) crystallizes without solvent molecules in the orthorhombic space group *Pbcn* with four formula units per unit cell and half a molecule of HATNMe₆ in the asymmetric unit, the other half being completed by twofold rotation symmetry (Fig. 1). The molecule is nearly planar with a slight deviation of the outer annulated benzene

OPEN ACCESS

rings [2.25 (6) $^\circ$ for C8–C13 and 4.09 (6) $^\circ$ for C4–C6 i ; symmetry code: (i) $1 - x, y, 1/2 - z$]. The central six-membered ring of **1** exhibits three longer (C1–C2, C3–C3 i : average 1.474 Å) and three shorter (C2–C3, C1–C1 i : average 1.427 Å) C–C bonds. The C–C bonds at the annulated benzene rings show differences in bond lengths. While the outermost bonds (C10–C11 and C6–C6 i , respectively) are elongated (average 1.438 Å) the bonds to the left and right of these bonds (C5–C6, C9–C10, C11–C12) are shortened (average 1.366 Å).

HATNPh₆ (**2**) crystallizes with two molecules of CH₂Cl₂ in the triclinic space group *P*̄*1* with two formula units per unit cell (Fig. 2). The molecule is, aside from the terminal phenyl groups, nearly planar with a slight deviation of the outer annulated benzene rings [9.97 (6) $^\circ$ for C43–C48, 8.96 (6) $^\circ$ for C7–C12, and 4.11 (6) $^\circ$ for C25–C30]. The terminal phenyl groups do not lie in this plane and are twisted [dihedral angles

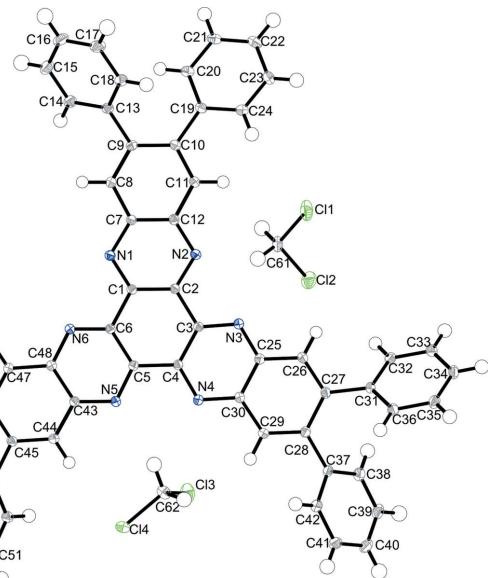

Figure 2

between the least-squares planes of the six-membered central ring system and the phenyl rings: 47.60 (7) $^\circ$ for C49–C54, 54.11 (7) $^\circ$ for C55–C60, 32.99 (6) $^\circ$ for C19–C24, 47.26 (6) $^\circ$ for C13–C18, 46.74 (6) $^\circ$ for C31–C36 and 44.26 (7) $^\circ$ for C37–C42]. The central six-membered ring of **2**, like in HATNMe₆ (**1**), exhibits three longer (C2–C3, C4–C5, C6–C1; average 1.474 Å) and three shorter (C1–C2, C3–C4, C5–C6; average 1.430 Å) C–C bonds. These distances are slightly shorter in comparison with HATN (Alfonso & Stoeckli-Evans, 2001; average 1.48 and 1.43 Å) but still longer than known for HAT(CONH₂)₆ (Beeson *et al.*, 1996; average 1.46 and 1.41 Å). As has been noted for HATNMe₆ (**1**) above as well as for HATN (Alfonso & Stoeckli-Evans, 2001), the annulated benzene ring shows differences in C–C bond lengths. For **2**, the outermost bonds (C9–C10, C27–C28 and C45–C46, respectively) are elongated (average 1.449 Å) and the bonds to the left and right of these bonds (C8–C9, C10–C11, C26–C27, C28–C29, C44–C45, C46–C47) are shortened (average 1.379 Å).

3. Supramolecular features

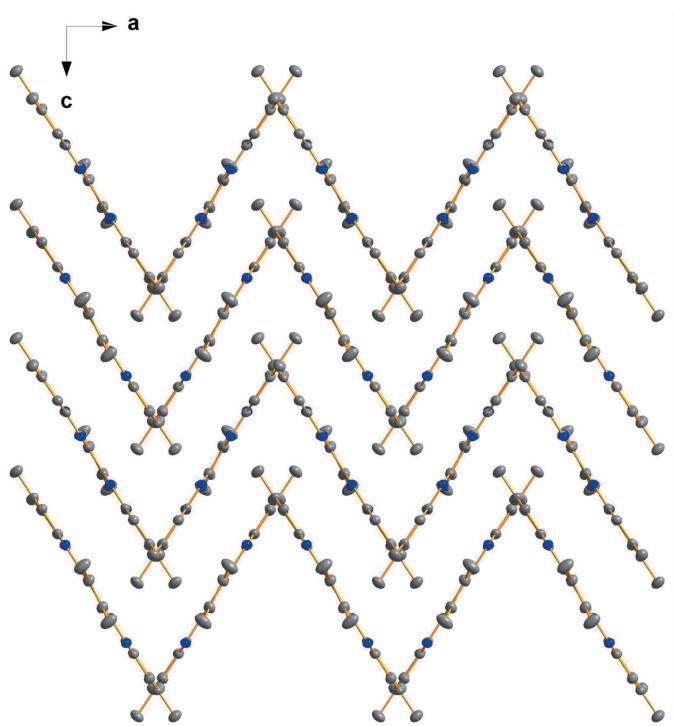

As a result of the π – π stacking ability of trinaphthylene derivatives HATNMe₆ (**1**) and HATNPh₆ (**2**), these molecules stack in layers in their respective crystal structures. In the crystal packing of HATNMe₆ (**1**), a herringbone-like arrangement of molecules is observed (Figs. 3 and 4). Individual molecules are arranged in layers and have a short plane-to-plane distance (defined by the central rings) of 3.3602 (5) Å. However, the π – π overlap occurs only in small areas, as shown by the rather large parallel displacement of the molecules with an angle of 31.52 $^\circ$ and a shift of 5.48 Å between the centroids. The resulting layers within the

**Figure 3**

herringbone-like structure stack at an angle of 63.1° to each other.

The molecules of HATNPh₆ (**2**) form centrosymmetric dimers that are stacked perfectly parallel by van der Waals interactions but with a parallel displaced π -stacking. The plane-to-plane distance (defined by the central rings) within a dimer of 3.2518 (5) Å is shorter compared to the corresponding distance in **1**. This distance, as well as the short centroid-to-centroid distance of 3.4018 (7) Å are both at the lower limit of ranges known for metal complexes with

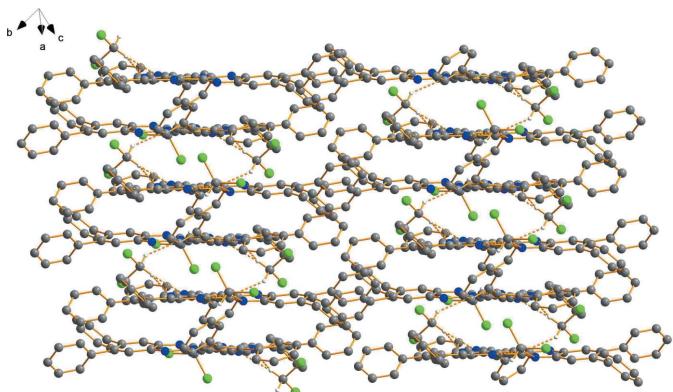

**Figure 4**

aromatic nitrogen-containing ligands (Janiak, 2000). The plane-to-plane distance between adjacent dimers is 3.15 Å. The parallel displacement between the layers (Fig. 5) is much shorter than for HATNMe₆ (**1**), with an angle of 16.8° and a shift of approximately 1 Å. Comparing the plane-to-plane distances of the title compounds with related derivatives like HATN (Alfonso & Stoeckli-Evans, 2001; 3.66 Å) and HAT(CONH₂)₆ (Beeson *et al.*, 1996; 3.31 Å), the dimers of HATNPh₆ (**2**) have the shortest contact and the shortest displacement in π -stacking. Further interactions between the terminal phenyl rings and the pyrazines rings interconnect the dimers. The dichloromethane solvent molecules are located near the electron lone pairs of the N atoms in the voids of the packed molecules. They bridge two molecules of **2** and consolidate the crystal packing through weak C—H···N hydrogen-bonding interactions (Table 1, Fig. 6).

4. Synthesis and crystallization

Hexaketocyclohexane octahydrate and 4,5-diphenyl-1,2-diamine were prepared according to published procedures (Fatiadi & Sager, 1962; Shao *et al.*, 2012; Gao *et al.*, 2009).

Synthesis of 1. HATNMe₆ was synthesized by a published procedure (Catalano *et al.*, 1994). Crystals suitable for single crystal X-ray diffraction were obtained by slow evaporation of a benzene solution of **1**.

Synthesis of 2. HATNPh₆ was synthesized based on a literature method (Gao *et al.*, 2009). 4,5-diphenyl-1,2-diamine (1.8 g, 6.9 mmol) and hexaketocyclohexane octahydrate (0.54 g, 1.72 mmol) in 100 ml acetic acid were heated up to 373 K for 36 h under a nitrogen atmosphere. After cooling to room temperature the reaction mixture was filtrated and the resulting yellow solid was washed with plenty of water and 2 M KOH solution. The solid was suspended in a mixture of dichloromethane (100 ml) and a saturated K₂CO₃ solution

(100 ml) overnight in order to remove all traces of acetic acid. After filtration and washing with water, the solid was dried in a vacuum to give **2** as a yellow solid in 72% yield. Crystals suitable for single crystal X-ray diffraction were obtained by slow evaporation of a CH₂Cl₂ solution of **2**.

5. Refinement

Crystal data, data collection and structure refinement details are summarized in Table 2. Hydrogen atoms bound to C atoms were located from difference-Fourier maps but were subsequently fixed to idealized positions using appropriate riding models.

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Cell parameters from 9893 reflections
 $\theta = 2.3\text{--}30.0^\circ$
 $\mu = 0.29 \text{ mm}^{-1}$

$T = 100 \text{ K}$
Block, yellow
 $0.30 \times 0.12 \times 0.10 \text{ mm}$

Data collection

Bruker APEX-II CCD
diffractometer
Radiation source: sealed tube
 φ and ω scans
Absorption correction: multi-scan
(SADABS; Krause *et al.*, 2015)
 $T_{\min} = 0.970$, $T_{\max} = 1.000$
87137 measured reflections

14377 independent reflections
11804 reflections with $I > 2\sigma(I)$
 $R_{\text{int}} = 0.043$
 $\theta_{\max} = 30.0^\circ$, $\theta_{\min} = 1.4^\circ$
 $h = -13 \rightarrow 13$
 $k = -23 \rightarrow 23$
 $l = -25 \rightarrow 25$

Refinement

Refinement on F^2
Least-squares matrix: full
 $R[F^2 > 2\sigma(F^2)] = 0.039$
 $wR(F^2) = 0.107$
 $S = 1.02$
14377 reflections
649 parameters
0 restraints
Primary atom site location: structure-invariant
direct methods

Secondary atom site location: difference Fourier map
Hydrogen site location: difference Fourier map
H-atom parameters constrained
 $w = 1/[\sigma^2(F_o^2) + (0.050P)^2 + 1.2P]$
where $P = (F_o^2 + 2F_c^2)/3$
 $(\Delta/\sigma)_{\max} = 0.001$
 $\Delta\rho_{\max} = 0.84 \text{ e \AA}^{-3}$
 $\Delta\rho_{\min} = -0.84 \text{ e \AA}^{-3}$

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Fractional atomic coordinates and isotropic or equivalent isotropic displacement parameters (\AA^2)
