Background: Diabetic retinopathy (DR) is one of the most prevalent consequences of diabetes mellitus (DM). Much emphasis has been focused on the link between DR and cardiovascular disorders in patients with type 2 diabetes (T2DM). However, there is little information about the relation between the degree of DR and coronary atherosclerosis severity in Egyptian patients.

Aim: To assess the correlation between the degree of DR and the coronary atherosclerosis severity in T2DM.

Patients and Methods: This work included 140 diabetic patients with T2DM who underwent diagnostic coronary angiography because of suspected coronary artery disease (CAD). All participants were evaluated by history, fundus assessment, laboratory tests (lipid profile and glycated hemoglobin [HbA1c]), and selective coronary angiography. The severity of coronary artery lesion was detected by Gensini score and vessel score.

Results: Patients with DR had a significantly higher Gensini score (67.86 ± 44.56 versus 5.93 ± 9.02 , $P < 0.001$) and a vessel score (2.29 ± 0.86 versus 0.50 ± 0.66 , $P < 0.001$). There was a significant relation between the degree of DR, Gensini score ($P < 0.001$), and vessel score ($P < 0.001$), as both scores increased according to the severity of DR. The presence and degree of retinopathy were the only independent factors linked to the severity score in multivariate linear regression analyses ($P < 0.001$).

Conclusion: The presence and degree of DR are independent predictors of severe coronary atherosclerosis. Therefore, when evaluating whether a patient with T2DM is at high risk for CAD, the DR degree should be taken into consideration.

Keywords: diabetic retinopathy, coronary atherosclerosis, type 2 diabetes mellitus, coronary angiography

Introduction

Microvascular consequences of diabetes mellitus (DM), such as diabetic retinopathy (DR), are prevalent and severe.¹ DR severity increases the risk of vision loss and other ocular proliferative disorders, such as macular degeneration.²

Adults with DM are more likely to die from atherosclerosis cardiovascular disease (ASCVD) as a result of their elevated glycemic levels.³ Thus, DM is usually regarded as an ASCVD risk factor. For people with diabetes, ASCVD is the leading cause of death, accounting for 70% of mortality.⁴ Myocardial infarction (MI) and silent myocardial ischemia are more common in people with type 2 DM (T2DM). About 30% of patients with acute MI do not complain of chest pain.⁵

Factors known to increase the risk of ASCVD, such as hypertension, hyperlipidemia, and degree of glycemic control in patients with T2DM, are the same factors that lead to the development of DR. Therefore, the relation between DR and ASCVD has been observed.⁶ ASCVD was linked to the presence of DR due to comparable pathophysiological pathways.^{7,8} However, other studies^{9,10} showed that this connection diminishes following correction for established ASCVD risk variables. Many papers studied the relation between DR and ASCVD either by using stress-resting 99mTc SestaMIBI myocardial perfusion scintigraphy¹¹ or by examining carotid intima-media thickness as a marker of atherosclerosis.¹² However, we found scarce data in Egypt about the relation between the degree of DR and the severity

of CAD detected by coronary angiography, which is the gold standard test for the detection of CAD. The question of whether the increased risk of ASCVD is connected with each stage of DR is still debated. As a result, the primary goal of our research paper is to assess the relationship between the degree of DR and the severity of coronary atherosclerosis in T2DM patients.

Patients and Methods

This study is an observational prospective two-center study using 140 diabetic patients with type 2 DM who underwent diagnostic coronary angiography because of suspected coronary artery disease (CAD) in the Cathlab of Internal Medicine Department, Sohag University and the Cathlab Unit of Cardiology Department, Ain Shams University between September 2020 and September 2021. Its protocol conformed to the ethical guidelines of the Declaration of Helsinki. The study was accepted by Sohag Faculty of Medicine's Ethics Board under IRB registration number Soh-Med-22-02-25. Each subject signed an informed written permission form.

Type 2 DM was diagnosed according to the American Diabetes Association (ADA) guidelines¹³ using glycated hemoglobin (HbA1c) cut point of 6.5%. Patients were previously diagnosed with DM if their doctor told them they had DM or were already on regular anti-diabetic medications. Individuals with type 1 DM, hypertension, previous coronary artery bypass surgery, pregnancy, and non-diabetic retinopathy were excluded.

All participants were subjected to the following:

- History taking, including age, sex, smoking history [current, former, or never], duration of DM, and family history of CAD.

- Thorough clinical examination.

- Body mass index (BMI) assessment: By dividing the (weight in kilograms) by the (height in meters)². Obesity was defined as BMI of 30 or more, overweight was defined as BMI from 25 to 29.9, while BMI from 18.5 to 24.9 was considered normal.¹⁴

- Laboratory investigation, including complete blood count (CBC), HbA1C, estimated glomerular filtration rate (eGFR), serum creatinine, total cholesterol (TC), and triglyceride (TG). CBC was performed by CELL-DYN 3700 (Abbott Laboratories, diagnostic division IL, USA). Biochemical tests for TC, TG, and creatinine were done by Cobas C 311 chemistry analyzer system (Roche Diagnostic, G mbH Indianapolis, IN, USA). HbA1c was done by architect i000 SR system (Abbott Laboratories, diagnostic division IL, USA). GFR was estimated using Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) formula.¹⁵ We defined dyslipidemia according to American Heart Association guidelines if the patient was on statin therapy and /or TC > 200 mg/dl and/or TG level > 150mg/dl.¹⁶

- Resting twelve leads surface electrocardiography to detect signs of myocardial ischemia using a regularly calibrated Fukuda instrument, Japan (Cardimax FX 8200).

- Fundus examination was carried out using the ophthalmoscope and fluorescein angiography by an expert ophthalmologist after full pupil mydriasis using Tropicamide 1.0% eye drops, 5 mL of 10% to 20% concentration of fluorescein dye injected in antecubital vein to reach the systemic circulation. Fluorescein dye reached the retinal vessels and glowed by the stimulation of blue light at a wavelength from 465 to 490 nm. The emission of the yellowish green light between 520 and 530 nm was captured by the camera of the angiography (TRC-50DX, Topcon Medical Systems, Oakland, NJ). Before fluorescein dye injection, color fundus and red-free photographs were obtained, followed by early and late fluorescein angiography photographs with the documentation of the posterior pole and the peripheral retina over 10 min.

Patients were distributed into two groups based on the American Academy of Ophthalmology;¹⁷ group A with retinopathy and group B without retinopathy. DR was divided into two main classes: non proliferative DR (NPDR) and proliferative DR (PDR). According to retinal findings, the NPDR further fell into three categories; mild, moderate, and severe.

- Selective coronary angiography was done via the femoral artery approach using Seldinger's technique.¹⁸ Multiple views were taken to visualize the left ascending coronary artery (LAD), left circumflex artery (LCX) (both at least four views), and right coronary artery (RCA) (at least two views) using the Toshiba instrument (Biplane Infinix CB, Japan).

The severity of coronary artery lesion was detected by the Gensini score¹⁹ and vessel score. Vessel score is the vessel number with significant stenosis [reduction of luminal diameter by 50% or more in any major epicardial coronary artery, including the left main (LM) coronary artery]. The score range from 0 to 3 depends on the involved vessels. The left main (LM) artery stenosis is considered a two-vessel disease.

In order to calculate the Gensini score, each coronary stenosis was assigned a severity score based on the degree of luminal constriction and its geographic significance. The radiological appearance of concentric lesions and eccentric plaques was studied (reduction of 25%, 50%, 75%, 90%, 99%, and total occlusion were given a Gensini score of 1, 2, 4, 8, 16, and 32, respectively).

This score was then multiplied by a factor that took into account the importance of the lesion position in the coronary arterial tree, such as 5 for LM coronary artery, 2.5 for proximal LAD coronary artery and proximal LCX artery, 1.5 for the mid region of LAD artery, 1 for distal left LAD, mid and distal region of LCX artery and RCA, and 0.5 for any other branches. These scores were calculated by one of the investigators without any knowledge about the retinopathy degree.

Statistical Analysis

Frequency and percentage distributions were calculated for qualitative data, and the mean and standard deviation (SD) were calculated for quantitative data using the Statistical Package for Social Sciences (SPSS) version 22 (IBM Corp.; Armonk, NY, USA). Significance was defined as a p -value < 0.05 . The following tests: Student's t -test, Mann–Whitney U -test, Chi-Square test, Kruskal–Wallis test, and Spearman Correlation test were used.

Results

This work included 140 patients with T2DM with a mean age of 55.40 ± 8.798 years (ranging from 35 to 70). The majority were males numbered 92 (65.7%). The mean age in the DR group was 57.28 ± 9.20 years, ranging from 35 to 70 years. In the non-DR group, the mean age was 53.41 ± 7.94 years, ranging from 39 to 68 years. Age was significantly higher in the DR group ($p=0.005$). The duration of DM was significantly higher in the DR group ($P < 0.001$). There was no significant difference between both groups, considering sex, presentation, and risk factors for CAD (Table 1).

Patients with DR had a higher significant HbA1C, creatinine, and TC levels ($p < 0.001$, $p=0.043$, and $p=0.007$, respectively), while eGFR was significantly lower in the DR group ($p=0.004$). There was no significant difference between both groups, considering hemoglobin and TG level (Table 2).

Among the DR group, all patients had evidence of significant CAD by coronary angiography: 39 (54.2%) of them had a three-vessel disease (Figure 1A and B), 15 (20.8%) had a two-vessel disease, and 18 (25%) patients had a single-vessel disease. In contrast, among the non-DR group, 28 (41.2%) patients had angiographic evidence of significant CAD; no patients had a three-vessel disease, 6 (8.8%) patients had a two-vessel disease, and 22 (32.4%) patients had a single-vessel disease. By comparing the coronary angiography scores between the two groups, DR patients had a significantly higher Gensini score (67.86 ± 44.56 versus 5.93 ± 9.02 , $P < 0.001$), and vessel score (2.29 ± 0.86 versus 0.50 ± 0.66 , $P < 0.001$), as shown in Table 3. There was a significant relation between the degree of DR and Gensini score ($P < 0.001$) and vessel score ($P < 0.001$) as both scores increased according to the severity of DR, as shown in Table 4.

The univariate analysis of the correlation for the CAD severity by Gensini score showed that the presence of DR ($r=0.814$, $P < 0.001$), grade of DR ($r=0.891$, $P < 0.001$), age ($r=0.238$, $P=0.005$), HbA1C ($r=0.729$, $P < 0.001$), eGFR ($r=-0.176$, $P=0.038$), serum TC level ($r=0.225$, $P=0.007$), and duration of DM ($r=0.725$, $P < 0.001$) were significantly related to the severity score. Multivariate linear regression analysis revealed that the factors independently related with Gensini score were the severity of retinopathy ($P < 0.001$), age of the patient ($P=0.007$), and duration of DM ($P=0.036$). In a similar manner, the characteristics that were shown to be strongly connected to the vessel score were determined to be significant in the univariate correlation analysis were the presence of DR ($r=0.770$, $P < 0.001$), grade of DR ($r=0.807$, $P < 0.001$), age of patient ($r=0.249$, $P=0.003$), HbA1C ($r=0.661$, $P < 0.001$), eGFR ($r=-0.168$, $P=0.048$), serum TC level ($r=0.230$, $P=0.006$), and duration of DM ($r=0.690$, $P < 0.001$). The presence and degree of retinopathy

were the only independent factors linked to the severity score in multivariate linear regression analyses ($P < 0.001$) (Table 5).

The severity of retinopathy was found to be significantly valid for the identification of the severity of ASCAD in T2DM patients. The sensitivity, specificity, and AUC were 84.6%, 86.7%, and 0.867, respectively ($p < 0.001$) (Figure 2).

Discussion

The microvascular consequences of DM include diabetic retinopathy. A patient with diabetes' time to acquire DR is between five and ten years. DR is linked to CAD and frequent and late consequences of DM.²⁰

Diabetic complications include the retina, perhaps neuropathy, and nephropathy and enhance the morbidity and mortality risk in patients with cardiovascular disease (CVD).²¹

The results of this research paper showed that the presence and severity of DR were highly correlated with the presence of severe coronary atherosclerosis in diabetic patients. People with type 2 DM with DR, according to these results, were a particularly high-risk group for CVD. As a result, they needed a customized treatment plan targeting lowering CVD risk factors, improving metabolic control, and monitoring CVD over time.

Patients with DR, especially with a severe degree, have a higher risk of CVD, which is in line with our results.^{22–25} Our research was unique in excluding hypertensive patients from the study, leaving DM as the only cause of retinopathy. Researchers showed that T2DM with DR or nephropathy was more likely to have carotid plaques. The degree of microangiopathy corresponded with the severity of carotid atherosclerosis in a large

cohort of people with diabetes. DR patients also had more severe coronary atherosclerosis and plaque vulnerability.^{26,27}

Vasa vasorum alterations in people with T2DM have been likened to those in the retina, with early stages characterized by endothelial dysfunction and capillary loss and later stages characterized by ischemia and angiogenesis, leading to plaque neovascularization.^{28,29}

The imaging of coronary artery stenosis using computed tomography (CT) angiography is a stronger predictor of risk than conventional risk variables in asymptomatic T2DM patients.^{30,31} DR and coronary stenosis are linked to coronary CT angiography, which is notable. The Gensini and vessel scores in individuals with DR were significantly higher than in non-DR patients.

Our study results showed a significant relation between the degree of DR and the severity of CAD. This finding agreed with the results of Um et al,⁸ who reviewed 175 sheets of patient records retrospectively. According to the severity of DR, patients were grouped into three categories: 38 patients had no DR, 88 had NPDR, and 49 had PDR. Comparing the dual-source CT findings to diabetic retinopathy severity illustrated that the DR severity was associated with a higher significant acute coronary syndrome rate and the number of stenotic arteries.

Our research paper showed a link between the severity of CAD and the progression of DR. As a second, coronary angiography, the procedure we utilized to determine the severity of CAD, is considered the gold standard. Our results were in harmony with Attia et al,³² who reported that DR was a major risk factor for enhancing coronary atherosclerosis. They reported that patients with DR had a significantly higher Gensini score and number of diseased vessels than non-DR patients examined by coronary angiography. They included patients with hypertension, but we excluded hypertensive patients as a possible etiology of retinopathy. In our research, we studied the relation between the degree of DR and the angiographic severity of CAD. Patients with advanced DR had a more severe CAD and a higher Gensini score than those

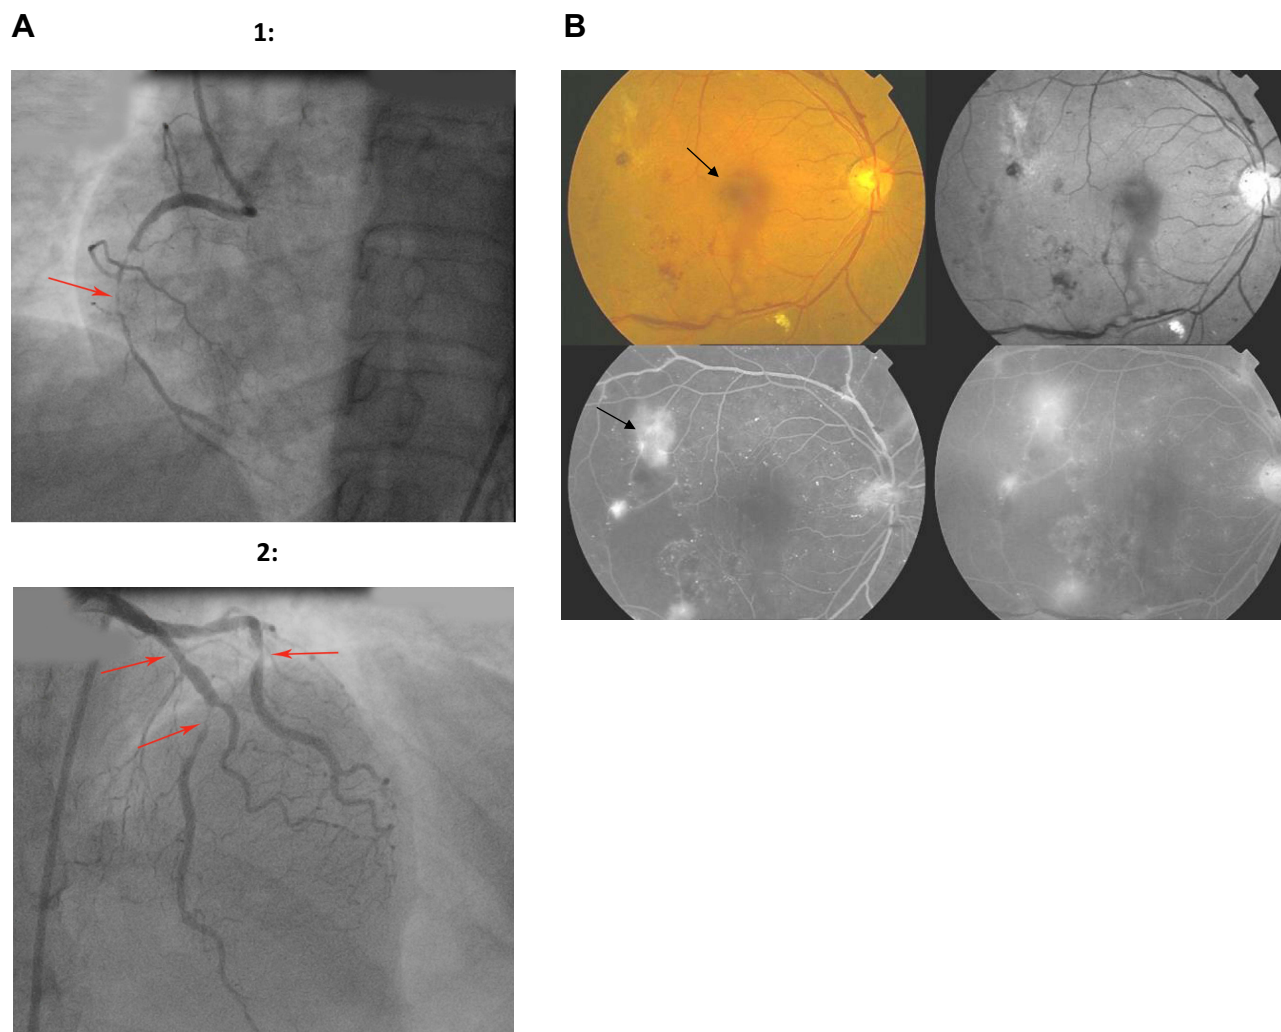

Figure 1 (A) Images of a 51-year-old male patient who had 3 vessel disease (red arrows) and high Gensini score. RCA shows 99% stenosis in mid-segment (1), LAD shows 50% stenosis in the proximal segment and 99% stenosis in mid-segment, and LCX shows 99% stenosis in mid-segment (2). (B) High-risk proliferative diabetic retinopathy (PDR); color fundus photography (upper-left) and Red-free photography (upper-right) showing mild vitreous hemorrhage (black arrow) with retinal neovascularizations; Fundus fluorescein angiography, early (lower-left) and late (lower-right) highlighting the sites of retinal ischemia and leakage from retinal neovascularizations (black arrow).

with mild or no DR. Also, we noticed significant correlations between the degree of DR and the number of diseased vessels and the Gensini score. This finding was consistent with the results of Shereef and Kandeel.³³ However, they included patients with acute coronary syndrome (ACS), excluding patients with stable CAD, despite the value of detecting CAD severity in this category of patients for early risk stratification and the management plan. A study by Rong et al³⁴ found that subclinical coronary atherosclerosis associated with DR was independent of the traditional risk factors for CAD. They assessed coronary atherosclerosis using coronary 64-slice multidetector computed tomography angiography (MDCTA), but we utilized coronary angiography. Previous studies^{35,36} examined the relation between advanced glycation end products (AGEs) and the progression of vascular atherosclerosis. They measured the serum concentrations of AGEs in type 2 DM patients and proposed that AGEs were associated with the development of CAD, as well as DR and nephropathy.

Therefore, it is plausible to suppose that there is at least one common pathway in the development of DR and diabetic atherosclerotic lesions.

Table 3 The Relation Between the Diabetic Retinopathy and the Presence and the Severity of Coronary Atherosclerosis in Type 2 Diabetic Patients

		Group A DR Group (n=72)		Group B Non-DR Group (n=68)		p-value

Egypt is a developing country like India. Our results were in line with the results of a study done on T2DM Indian patients with established CVD. The authors reported a strong relation between DR and CVD. They found that patients with DR had higher cardiovascular events, cerebrovascular events, mortality, and all-cause mortality.³⁷ Their study was retrospective, and they excluded patients recently discharged from the intensive care unit. In contrast, our study was prospective, and we included patients with ACS.

One of the study's limitations includes the observer bias in ophthalmoscopic and angiographic results. A larger number of patients may also be needed for more accurate statistical data.

Table 5 The Correlation Between Gensini Score and Vessel Score with Different Parameters

	Gensini Score		Vessel Score	
	<i>r</i>	<i>p-value</i>	<i>r</i>	<i>p-value</i>
Age	0.238	0.005	0.249	0.003
Hb A1C %	0.729	0.000	0.661	0.000
Creatinine (mg/dl)	0.054	0.528	0.059	0.489

DM duration	0.725	0.000	0.690	0.000
Presence of DR	-0.814-	0.000	-0.770-	0.000
Degree of DR	0.891	0.000	0.807	0.000

Note: $p \leq 0.05$ is considered statistically significant.

Abbreviations: DR, diabetic retinopathy; HbA1c, glycated hemoglobin; eGFR, estimated glomerular filtration rate; DM, diabetes mellitus; *r*, correlation of the coefficient.

Conclusion

The presence of DR is an independent predictor of severe CAD. Thus, when evaluating whether a patient with T2DM is at high risk for CVD, the DR degree should be taken into consideration. Our findings have important therapeutic implications since the priority will be for individuals with a severe degree of DR when doing a CAD screening.

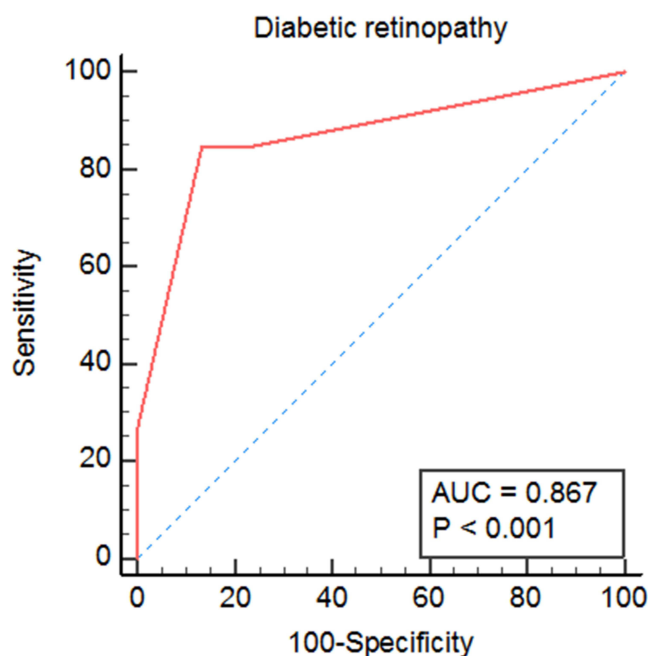

Figure 2 ROC curves of diabetic retinopathy as predictors of the severity of ASCAD in T2DM patients.

Diabetes, Metabolic Syndrome and Obesity: Targets and Therapy

Dovepress

Publish your work in this journal

Diabetes, Metabolic Syndrome and Obesity: Targets and Therapy is an international, peer-reviewed open-access journal committed to the rapid publication of the latest laboratory and clinical findings in the fields of diabetes, metabolic syndrome and obesity research. Original research, review, case reports, hypothesis formation, expert opinion and commentaries are all considered for publication. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.
