eAppendix 1. Defining Deaths Due to Opioid Overdose, Firearms, and Car Accidents

All opioid overdoses have one of the following underlying cause of death codes: X40-X44 (accidental), X60-X64 (self-harm), X85 (homicide), or Y10-Y14 (undetermined). In addition, opioid-related deaths also contain at least one of the following contributory cause codes: opium (T40.4), heroin (T40.1); other natural and semi-synthetic (T40.2) such as morphine, hydrocodone, or oxycodone; methadone (T40.3); other synthetic (T40.4) such as fentanyl and fentanyl derivatives; or unspecified (T40.6).

Deaths due to firearms have ICD-10 codes: *U01.4 (terrorism); W32-W34 (accidental); X72-X74 (suicide); X93-X95 (homicide); Y22-Y24 (undetermined); and Y35.0 (legal intervention). Deaths due to motor vehicle accidents have ICD-10 codes: V02-V04, V09.0, and V09.2 (pedestrian collisions); V12-V14, V19.0-V19.2, and V19.4-V19.6 (cyclist collisions); V20-V79 (motor vehicle collisions); V80.3-V80.5, V81.0-V81.1, V83-V86, V87.0, V87.8, V88.0-V88.8, V89.0, and V89.2 (other vehicle).

eAppendix 2. False Discovery Rate Adjusted *P* Values

Due to multiple comparisons, some significant findings may be observed due to chance alone. We use false discovery rate adjusted *P*-values, called *Q*-values, to assess this possibility. We present all *P*- and *Q*-values on the online interactive results viewer. However, in the manuscript we present only the *P*-values because for all levels of significance and for all types of comparisons, *P*-values were more conservative (i.e., fewer tests were below the significant threshold). For example, we show sets of *P*- and *Q*-value comparisons for the overall change in mortality (AAPC) as well as each joinpoint segment (APC).

Distribution of Average Annual Percent Change (AAPC) P- and Q-values.

	<1e-04	<0.001	<0.01	<0.025	<0.05	<0.1	<1
P-Value	129	145	167	177	186	193	208
Q-Value	151	178	202	208	208	208	208
Local FDR	131	148	171	184	193	198	208

Distribution of Annual Percent Change (APC) P- and Q-values.

	<1e-04	<0.001	<0.01	<0.025	<0.05	<0.1	<1
P-Value	140	197	254	275	302	330	434
Q-Value	155	222	282	325	351	378	434
Local FDR	112	161	224	246	262	284	389

On the online interactive results viewer, we present *Q*-values and *P*-values together for all results.

eAppendix 3. Details Regarding Joinpoint Models

Below we show the fitted mortality rate for each state (blue lines) and the national average (orange line) by opioid type from each of 208 joinpoint models. We excluded observations when there were both fewer than 100,000 people and fewer than ten deaths. In cases where an observation had fewer than ten deaths (but more than zero deaths) and a population greater than 100,000, the observation was included in the analysis but removed from the public tables and plots in accordance with National Center for Health Statistics data use requirements. The joinpoint model is log-linear, which requires all observations be non-zero and positive. Thus, in cases where there were zero deaths and a population greater than 100,000, we imputed the rate as .1 per 100,000. In addition, each observation is weighted by its precision, thus we imputed the variance of these observations with the minimum variance for that year/state/opioid type. Results were not sensitive to changes in these parameters.

eFigure shows the joinpoint-estimated opioid mortality rate, by opioid type, for each state and for the whole US. There is substantial variation in the opioid epidemic of each state and by opioid type in terms of the epidemic trajectory over time, the current mortality rate, the current growth or decline of the mortality rate, and both the timing and number of joins.

eFigure. Fitted mortality rate, by opioid type and state. Each line represents the joinpoint model fit of opioid-related mortality. Each thin blue line is a state. The thick orange line is the national model. Note the geographic variation in trajectory, current rate of increase, and the start year of the current increases. Interactive plots and tables, by state, are available through the interactive results viewer.

eAppendix 4. Estimating Implied Life Expectancy Lost

We are interested in looking at the effect of opioid overdoses on life expectancy in different populations. In order to do this, it is useful to think about mortality processes over age as a series of decrements: people can die from one of many decrements at any particular age. We want to remove one of these decrements and then see what happens to the resulting life expectancy.

We can think about different types of decrements when calculating elements of a life table. Specifically, we are interested in cause-deleted life tables: these allow you to consider mortality if one cause was completely eliminated. Cause-deleted life tables are based on the assumption that causes of death act independently, and so removing a cause does not change the hazard of dying from other causes. For causes that are often seen together (e.g., cardiovascular disease and obesity), this assumption is clearly violated. For external causes such as car accidents, firearms, and in this case, opioids, this may be a weaker assumption. To avoid issues of early life mortality, we estimate life expectancy after the age of 15. Estimates of life expectancy lost for older ages are also available on the online results viewer described in eAppendix 5.

eAppendix 5. Reproducible Code and Additional Results

All code to reproduce this analysis will be made available online at https://github.com/mkiang/opioid_geographic upon publication of the manuscript. While the code is freely available, the data required are restricted-access and must be requested through the National Association for Public Health Statistics and Information Systems via <https://www.naphsis.org/>.

We provide additional disaggregated results both through the reproducible code as well as through an online interactive results viewer available at:

https://sanjaybasu.shinyapps.io/opioid_geographic/. This online interactive viewer allows users to select the outcome, year, threshold (e.g., P-value, Q-value, or minimum age for Life Expectancy Lost calculation), and state.

eTable 1. Descriptive Statistics of Deaths by Year and Sex

Number of observed deaths, deaths with missing age values (excluded from analysis), mean age at death, and standard deviation of age at death by year and sex.

Year	Male				Female

eTable 2. Overall Opioid Mortality Rate, Annual Percent Change, and Life Expectancy Lost at Age 15 Years by State for 2016

The mortality rate is expressed as deaths per 100,000 population. The Poisson approximation was used to estimate standard errors of the mortality rate. Life expectancy lost at age 15 is estimated using the Chiang method and is the difference between all-cause and cause-deleted life tables for life expectancy at age 15. Annual percent change (APC) is estimated using joinpoint regression and represents the current relative change (in percent) of the mortality rate. Additional disaggregated results for all years is available at: https://sanjaybasu.shinyapps.io/opioid_geographic/.

State	All opioids

eTable 4. Heroin Mortality Rate, Annual Percent Change, and Life Expectancy Lost at Age 15 Years by State for 2016

The mortality rate is expressed as deaths per 100,000 population. The Poisson approximation was used to estimate standard errors of the mortality rate. Life expectancy lost at age 15 is estimated using the Chiang method and is the difference between all-cause and cause-deleted life tables for life expectancy at age 15. Annual percent change (APC) is estimated using joinpoint regression and represents the current relative change (in percent) of the mortality rate. Additional disaggregated results for all years is available at: https://sanjaybasu.shinyapps.io/opioid_geographic/.

State	Heroin			
	Rate (95% CI)	LEL ₁₅	APC (95% CI)	P
