Received 27 November 2012; accepted 20 December 2012

Key indicators: single-crystal X-ray study; T = 298 K; mean σ(C–C) = 0.004 Å; R factor = 0.043; wR factor = 0.114; data-to-parameter ratio = 11.9.

The title compound, {2-[(2-carbamoylethyl)amino]-3-methylpentanoic acid}, $C_9H_{18}N_2O_3$, is of interest with respect to its biological activity. It was formed during an addition reaction between acrylamide and the amino acid isoleucine. The crystal structure is a three-dimensional network built up by intermolecular N—H···O and O—H···N hydrogen bonds.

N-(*β*-Carboxyethyl)-*α*-isoleucine

Irene Nehls, Olaf Hanebeck, Roland Becker and Franziska Emmerling

Comment

Acrylamide is a water-soluble unsaturated amide, a reactive monomer and an industrial chemical used in many technological applications.

It is also a contaminant in baked and fried starchy food as a result of Maillard reactions involving asparagine and reducing sugars that leads to disseminated human exposure. So people may be exposed to acrylamide in industry as well as in daily life *via* diet and drinking water. Furthermore, it was recently reported a novel method for the determination of acrylamide in particulare-phase outdoor aerosol (Zangrando *et al.*, 2012).

It is known that acrylamide is a neurotoxin and putative human carcinogen. In the last years a lot of different toxicological investigations have been carried out (Besaratinia and Pfeifer, 2007*;* Parzefall, 2008*;* Bowyer *et al.*, 2009;Wang *et al.*, 2010; Mei *et al.*, 2010; Koyama *et al.*, 2011; Lee *et al.*, 2012; Nixon *et al.*, 2012*).* Therefore, acrylamide was included (with a limit value of 0.1μg/*L*) to the numerous substances to be monitored in drinking water according to EU Water Framework Directive (EU 2000). The best method for the determination of acrylamide in water is the liquid chromatography/ tandem mass spectrometry (LC—MS/MS) (Marin *et al.*, 2006; Lucentini *et al.*, 2009; Keramat *et al.*, 2011). In the area of foods GC method with bromination of acrylamide as a derivatization reaction was used (Tareke *et al.*, 2002; Pittet *et al.*, 2004; Castle & Eriksson, 2005; Mizukami *et al.*, 2006; Dias Soares *et al.*, 2009). But also methods such as high-performance thin-layer chromatography (HPTLC) (Alpmann & Morlock, 2008) and a bioassay of dietary acrylamide exposure on the basis of monoclonal antibodies (Preston *et al.*, 2009) were used.

In toxicological investigations it could be proven, that reactions between acrylamide and different amino acids take place *(*Rice, 2005). These reactions and the corresponding adducts can be used also for the analytical determination of acrylamide in drinking water (Perez & Osterman-Golkar, 2003). There the amino acid isoleucine served as a nucleophilic trapping agent. Our group examined the derivatization of acrylamide with isoleucine in the course of the drinking water analysis.

The molecular structure of the reaction product from acrylamide and isoleucine and the atom-labeling scheme is shown in Fig. 1. The absolute configuration has not been determined by anomalous-dispersion effects in diffraction measurements on the crystal, but assigned by reference to an unchanging chiral centre in the synthetic procedure. Each molecule forms six hydrogen bonds to six adjacent molecules leading to a three-dimensional-network structure. In the a-c plane adjacent molecules form strong hydrogen bonds between amino donor groups and oxygen acceptor atoms.Each molecule is further involved in N—H···O bonds parallel the crystallographic b direction. The hydrogen bond network is completed by a further hydrogen bond between a hydroxy donor group and a nitrogen acceptor atom parallel to the a direction. The resulting arrangement together with the hydrogen bonding system (dashed green lines) is shown in Fig. 2.

Experimental

The derivatization of acrylamide (for synthesis, > 99%; Merck, Darmstadt, Germany) with *L*-isoleucine (Biochemica > 99%; Fluka, Deishofen, Germany) was achieved in a water bath at 39 °C. For the reaction 0.4233 g *L*-isoleucin (3.2 mol) were dissolved in water (19.8 g) and temperated to 30 °C. The pH was set to 10 with sodium hydroxide (2*M)* and 0.4562 g (6.4 mol) acrylamide was added. The flask was shaken for two minutes and placed in the water bath for 48 h. Crystallized solids were filtered out, washed with cold methanol, redissolved in small amounts of hot water and at 4 °C for one week to yield light yellow crystals with a melting point of 282 °C and a purity (DSC) of 99.9%.

Refinement

All H-atoms were positioned geometrically and refined using a riding model with d(C—H) = 0.93 Å, U_{iso}=1.2U_{eq} (C) for aromatic C atoms, 0.98 Å, U_{iso} = 1.2U_{eq} (C) for CH, 0.97 Å, U_{iso}= 1.2U_{eq} (C) for CH_2, 0.96 Å, U_{iso} = 1.5U_{eq} (C) for CH_3 hydrogen atoms, and d(N—H) = 0.86 Å, U_{iso}=1.2U_{eq} (N). In the absence of significant anomalous dispersion effects Friedel pairs were merged. The absolute configuration has not been determined by anomalous-dispersion effects in diffraction measurements of the crystal, but assigned as based on an unchanged chiral centre in the synthetic procedure.

$\Delta\rho_{max}$ = 0.42 e Å^{-3}
$\Delta\rho_{min}$ = −0.27 e Å^{-3}

Special details

Geometry. All e.s.d.'s (except the e.s.d. in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell e.s.d.'s are taken into account individually in the estimation of e.s.d.'s in distances, angles and torsion angles; correlations between e.s.d.'s in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell e.s.d.'s is used for estimating e.s.d.'s involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2, conventional R-factors R are based on F, with F set to zero for negative F^2. The threshold expression of $F^2 > \sigma(F^2)$ is used only for calculating R-factors(gt) *etc*. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F, and R- factors based on ALL data will be even larger.
