**Conclusion:** The progression of hepatic fibrosis in NASH were remarkably attenuated by deficiency of RAGE gene. We clarified that signal transduction pathway of AGE-RAGE system through activation of mDia1, Egr1 and ERK would have important roles for the progression of hepatic fibrosis in NASH.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** (MMPs)-2 and -9 are two of the major matrix metalloproteinases (MMPs) in the circulation and are responsible for degradation of the extracellular matrix (ECM), which is composed primarily of type IV collagen. MMPs are inhibited by tissue inhibitors of metalloproteinases; being TIMP-2 the most effective inhibitor of MMP-2. MMPs have the ability to degrade ECM and their regulation through TIMPs play an important role in the pathogenesis of liver injury and adipogenesis modulation. Obesity is tightly associated with the development of Nonalcoholic Fatty Liver Disease (NAFLD) and metabolic syndrome.
**Aims & Methods:** The aim of this study is to characterize the interplay of MMPs in the different tissues related to NAFLD. 36 human samples from obese patients undergoing bariatric surgery; Plasma (P), visceral adipose tissue (VAT) and liver (L)) were analyzed. Gene and protein expression of MMP-2 and TIMP-2 were studied by qPCR and Western blot. MMP-2 and -9 activity was determined by Gelatin Zymography. Liver fibrosis and steatosis was scored according to Brunt's score or NAS.
**Results:** The highest expression (mRNA and protein) of MMP-2 and TIMP-2) was observed in VAT and Plasma, whereas in the liver the expression was much lower. Regarding the MMP-2 activitiy VAT showed the highest activity, followed by Plasma, and finally Liver. Interestingly, plasmatic MMP-2 activity showed a positive correlation with both Brunt fibrosis score and NAFLD activity score (NAS) ($p = 0.007$ and $p = 0.032$, respectively). No correlation between the MMP-2 activity in tissues (VAT and L) and liver fibrosis was evident. MMP-9 plasmatic activity did not show any significant change.
**Conclusion:** Our study demonstrate that MMP-2 gelatin activity is a good marker for assessing liver fibrosis. Since gelatin activity evaluation is easy and inexpensive, our data suggest the inclusion of MMP-2 in a future panel of biomarkers. Additionally, our data indicates that both VAT and Liver MMP-2 protein contribute importantly to plasmatic MMP2 activity and the latter represents the overall metabolic state of the patient.

**Introduction:** Oxidative stress and metabolic syndrome are major contributors in the pathogenesis of nonalcoholic fatty liver disease (NAFLD). Leptin promotes oxidative stress and fibrogenesis in the liver. Therefore we aimed to evaluate the association between leptin levels, oxidative stress parameters and histopathological findings in NAFLD subjects with and without metabolic syndrome (MS).
**Aims & Methods:** Forty-two patients with no alcohol intake and with biopsy-proven diagnosis of NAFLD were studied (M/F:19/ 23; mean age $44.2 \pm 10.8$ years). Twenty NAFLD patients with MS were compared with 22 subjects without MS. The histopathological findings were evaluated as described by Brunt et al. For the determination of oxidative stress parameters malondialdehyde (MDA), and superoxide dismutase (SOD) activities were measured in serum and as well as in tissue specimens. Glutathione (GH) was measured in tissue homogenates. Nitric oxide (NO) and TNF-alpha receptor (TNF-sRp55) levels were measured in serum. Serum leptin levels were measured by radioimmunoassay. Statistical analysis was done using chi-squared test, Student's t-test, Mann-Whitney test, multivariate regression analysis and the area under receiver operating characteristic (ROC) curve. All statistical analyses were performed using SPSS® statistical software program (Ver.15.0).
**Results:** In bivariate analysis serum leptin levels didn't show any significant correlation with steatosis grade, necroinflammatory grade and stage. Serum leptin levels were neither significantly correlated with serum NO, SOD and MDA levels nor with tissue SOD, MDA and GH levels. Using serum leptin levels the ROC curve for distinguishing between NASH and NAFL didn't show any respective sensitivity and specificity (AUROC 0.48). Serum leptin levels, steatosis grade, necroinflammatory grade and stage were significantly higher in patients with MS ($p = 0.03$, 0.04, 0.004, 0.003, respectively). Patients with MS had significantly higher tissue MDA levels ($p = 0.002$, respectively), and significantly decreased tissue SOD and GH levels ($p = 0.003$ and 0.004) than those without MS. In multivariate regression analysis increase of tissue MDA (OR:1.7; %95 CI:1.02–3.95, $p = 0.035$) and serum NO levels (OR:1.6; %95 CI:1.01–4.2, $p = 0.038$) were risk factors for NASH and increase of leptin activity had preventive effect against NASH (OR:0.049; %95 CI:0.004–0.61, $p = 0.035$).
**Conclusion:** Serum leptin levels did not show any significant correlation with histological findings and oxidative stress parameters. Metabolic syndrome was associated with enhanced oxidative stress, decreased antioxidant levels, and severe histopathological changes. Patients with MS had increased leptin activity with a preventive effect against NASH. Therefore, we can postulate that metabolic syndrome in NAFLD is associated with enhanced oxidative stress and disease severity and leptin may have preventive effect against oxidative stress and against disease worsening.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0554 A CLINICOPATHOLOGICAL COMPARITIVE STUDY OF LEAN VERSUS OVERWEIGHT/OBESE PATIENTS OF NONDIABETIC NONALCOHOLIC FATTY LIVER DISEASE

**S. Budhiraja**, A. K. Jain, V. K. Dixit, S. K. Shukla, P. K. Asati, M. K. Tripathi

**Introduction:** Nonalcoholic fatty liver disease (NAFLD) refers to the accumulation of fat (mainly triglycerides) in hepatocytes that arises due to insulin resistance. NAFLD and metabolic syndrome (central obesity, hypertriglyceridemia, hypertension, impaired glucose tolerance, and low high-density lipoprotein [HDL] cholesterol) commonly coexist, with over 90% of NAFLD patients having at least one of these characteristics. A fraction of NAFLD patients (especially Asians) do not meet weight criteria of obesity. Most low BMI NAFLD patients have central obesity and are metabolically obese, which includes findings of insulin resistance.
**Aims & Methods:** The aim of this study was to compare the clinicopathological and biochemical profile of lean and overweight/obese NAFLD patients with a special emphasis on insulin resistance. This prospective study was conducted in biopsy proven NAFLD patients aged 18 to 75 years in a university hospital in India. On the basis of Asia Pacific criteria, the patients were divided into lean (BMI $< 22.99\,kg/m^2$) and overweight/obese (BMI $\geq 23\,kg/m^2$) NAFLD. Histopathological NASH was defined by NAS (NAFLD activity score) $\geq 5$. Patients with significant alcohol consumption ($> 20\,g$/day for females and $> 30\,g$/day for males), other liver diseases (hepatitis B, C or autoimmune liver disease) and diabetes mellitus were excluded.
**Results:** Among 88 NAFLD patients, 29 (33%) and 59 (67%) were in the lean and overweight/obese group respectively. The mean age was 33.31 years which was similar in both the groups. Metabolic syndrome was present in 60 (68.2%) patients. In the lean and overweight/obese group, 55.2% and 74.6% patients had metabolic syndrome respectively (p 0.06). In the lean group, the mean weight (62.76 kg, $p < 0.0001$), height (1.71 m, $p < 0.0001$), waist circumference (83 cm, $p < 0.0001$), hip circumference (89.14 cm, p 0.003), waist:hip ratio (0.93, $p < 0.0001$) was significantly lower as compared to overweight/obese group (the respective values being 71.25 kg, 1.66 m, 92.47 cm, 94.90 cm, 0.97). The median triglyceride level (190 mg/dl vs 147 mg/dl; p 0.018) and mean VLDL level (50.40 mg/dl vs 33.99 mg/dl; $p < 0.0001$) was significantly higher in the lean NAFLD group. However, the median levels of fasting serum insulin (5.57μU/ml vs 10.83μU/ml; p 0.009) and HOMA-IR (1.37 vs 2.62; p 0.010) were significantly lower in the lean NAFLD group. NASH was present in 59 patients (67%). 75.9% of the lean patients and 62.7% of overweight/obese patients had NASH (p 0.22). There was no difference in the level of ALT, AST: ALT ratio, HDL or total cholesterol in the two groups.
**Conclusion:** Most of the patients with NAFLD were males in the the 4$^{th}$ decade. Lean NAFLD patients had lower mean weight, height, waist:hip ratio. Dyslipidemia was more common in the lean NAFLD group whereas insulin resistance was less in lean NAFLD group. Metabolic syndrome and NASH were equally present in both the groups irrespective of BMI.

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) is the most common liver disease in the western world. Early diagnosis of advanced fibrosis in NAFLD is crucial for preventing cirrhosis-associated complications. The best accurate noninvasive diagnostic tool is still under debate.

**Aims & Methods:** We aimed to compare the diagnostic performance of NAFLD fibrosis score (NFS), FIB-4 index (FIB-4) and transient elastography (TE) for the diagnosis of hepatic fibrosis in patients with biopsy-proven NAFLD. Methods: Patients with biopsy-proven NAFLD were included. Metavir score (F0–F4) was used for grading fibrosis in liver biopsy. TE was measured using the M or XL probe of Fibroscan (Echosens®, Paris, France). NFS and FIB-4 were calculated according to published formulas. Diagnostic performance of NFS, FIB-4 and TE for the diagnosis of hepatic fibrosis was calculated using the area under the ROC curve (AUROC).

**Results:** We included 105 patients, 58% men, with a mean age of $49.8 \pm 12.4$ years. Mean values of NFS, Fib-4 and TE significantly increased according to the degree of hepatic fibrosis in liver biopsy ($p < 0.001$). AUROC for the diagnosis of significant fibrosis (F2 + F3 + F4) for TE, NFS and FIB-4 were 0.809 ($CI_{95\%}$ 0.690–0907), 0.685 ($CI_{95\%}$ 0.560–0.811) and 0.662 ($CI_{95\%}$ 0.545–0.801), respectively. AUROC for the diagnosis of advanced fibrosis (≥F3) and cirrhosis (F4) for TE, NFS and FIB-4 were 0.908 (0.842–0.974), 0.852 (0.734–0.969), 0.807 (0.750–0.872) and 0.849 (0.797–0.891), 0.782 (0.675–0.889), 0.829 (0.675–0.889), respectively.

**Conclusion:** TE was the best accurate noninvasive diagnostic tool for the diagnosis of hepatic fibrosis in patients with biopsy-proven NAFLD, especially for distinguishing patients with significant liver fibrosis (≥F2). The diagnostic performance of NFS and FIB-4 did not differ significantly for the detection of significant or severe fibrosis/cirrhosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0556 NON-INVASIVE ASSESSMENT OF HEPATIC FIBROSIS IN A SERIES OF PATIENTS WITH ALPHA-1-ANTITRYPSIN DEFICIENCY

**A. Bakula**, M. Teisseyre, J. Kmiotek, W. Janczyk, P. Socha

**Introduction:** Transient elastography (FibroScan®, FS) has been recently shown to be a valuable method in detection of liver fibrosis in adults with HBV, HCV, non-alcoholic fatty liver disease. The method seems to be promising mainly in children with liver diseases in whom indications to perform liver biopsy are very limited.

**Aims & Methods:** The aim of the study was to analyze the evaluation of FibroScan in relation to other non invasive tests of hepatic fibrosis and parameters of liver function in children with portal hypertension due to alpha-1-antitrypsin deficiency (ATD PiZZ) compared to ATD patients without portal hypertension, heterozygotes of ATD and healthy controls. We investigated 6 children with ATD PiZZ and portal hypertension aged 3.3(0.8–10.3) y [med (min-max)], 31 asymptomatic PiZZ ATD aged 5.8(1.5–17.9), 8 heterozygotes in ATD (7 PiMZ and 1 PiSZ) aged 5.3(0.8–12.3) and 16 healthy controls aged 6.8(0.4–12.8). Liver function parameters, abdominal ultrasound exam with Doppler and transient elastography were performed in ATD patients. AST/platelet ratio index (APRI), GGTP/platelet ratio index (GAPRI) and FIB-4 index were calculated in ATD groups.

**Results:** Increased liver stiffness in elastography was found in the ATD PiZZ group with splenomegaly compared to ATD without splenomegaly ($p = 0.0001$) and in ATD PiZZ with splenomegaly compared to heterozygotes ($p = 0.002$). Both APRI and GAPRI, but not FIB-4 were significantly higher in the ATD group with splenomegaly compared to ATD group without splenomegaly and ATD heterozygotes.

**Conclusion:** For the first time FibroScan values were assessed in children with liver disease due to alpha-1-antitrypsin deficiency and seem to be clinically useful for predicting liver fibrosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction:
Multi-echo modified Dixon (mDixon) sequence (MR-PDFF) is a safe and non-invasive alternative for the quantification of hepatic fat content. And it has accepted reasonable method to assess the change of hepatic fat amount in phase II study. Recently controlled attenuation parameter (CAP) has been showed good correlation with intrahepatic fat amount compare to liver biopsy as well as MRS data in large cross sectional cohort. However there is little known whether change of CAP scores can be used in clinical trial. We investigated the correlation with CAP and MRS by serial examination in clinical trial setting.

**Aims & Methods:** Sixty-five NAFLD patients were evaluated with MRS and transient elastography including CAP in clinical study. Both MRS and CAP were evaluated after three month probiotic clinical trial in patients with NAFLD.

**Results:** Baseline CAP and MR-PDFF showed good correlation assessing hepatic steatosis ($r = 0.60$, $p < 0.001$). Also, changes of CAP value was also correlated with changes of intra-hepatic fat % using MR-PDFF ($r = 0.35$, $p = 0.008$) in clinical trial setting. Concordance rate of improvement or aggravation was comparable in both two methods. However, the less change amount was small in CAP value, the less concordance rate showed more weak with MR-PDFF. When the change of CAP value after treatment was less than 20, concordance rate with MR-PDFF was decreased to 15/25 (60%).

**Conclusion:** CAP and MRS have a comparable diagnostic value for the hepatic steatosis quantification as well as assessing changes of hepatic fat amount in clinical trial. However, a careful interpretation of the steatosis change using CAP score should be given when the absolute change value was less than 20 in clinical trial setting.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0558 USING OPTICAL METABOLIC IMAGING TO INVESTIGATE MECHANISMS OF PARACETAMOL INDUCED HEPATOXICITY

**X. Liang**, H. Wang, X. Liu, M. Roberts
*School Of Medicine, The University of Queensland, Brisbane/Australia/QLD*

**Introduction:** Paracetamol is the most readily available and widely used painkiller. However, its toxicity remains the most common cause of liver injury. The toxicity of paracetamol has been attributing to its toxic metabolite, N-acetyl-p-benzoquinoneiminie (NAPQI), which could deplete cellular glutathione (GSH) stores and react within cells to increase oxidative stress, leading to mitochondrial dysfunction and cell necrosis.[1] To better understand mechanisms of paracetamol induced liver injury, optical metabolic imaging (OMI) were used to define optical redox ratio of NADH and FAD and in cells in this study to represent the relative rates of glycolysis and oxidative phosphorylation within cells.[2,3] Multiphoton microscopy (MPM) and fluorescence lifetime imaging (FLIM) provide quantitative imaging of biological tissues and organs in vivo and allow direct visualization of cellular events,[4] which could monitor cellular metabolism in paracetamol-induced toxicity.

**Aims & Methods:** BALB/C mice were administered a single dose of paracetamol by gavage. After different time points, livers of mice after paracetamol overdose were collected for MPM-FLIM imaging. The optical redox ratio of liver tissues was calculated using NADH fluorescence intensity divided by FAD fluorescence intensity at pixel to create a redox ratio image. The average fluorescence lifetime of NADH ($\tau$m) of livers was recorded at excitation of 740 nm and emission wavelength of 350 to 450 nm. GSH depletion was measured in different zonations of the liver using mBBr dye for detection of GSH levels. Finally, serum alanine aminotransaminase (ALT) activity was measured and liver tissues were collected for histological examination and necrosis cells were quantified in different zonation.

**Results:** High-resolution images allowed visualization of cellular morphology and cell variability of the optical redox ratio and NADH fluorescence lifetimes in hepatocytes from normal and paracetamol overdose groups. Compared to normal mouse liver, average fluorescence lifetime of NADH and redox ratio of hepatocytes was significantly decreased after paracetamol overdose for 12 and 24 h, reflecting impaired metabolic activity after paracetamol treatment. Furthermore, morphological changes observed in MPM images were consistent with conventional histological results. GSH levels of treatment groups were significantly lower than those of normal livers, with gradually decreasing from periportal to centrilobular zonation. The redox status and NADH fluorescence lifetime altered prior to the changes of ALT activity and cell morphology.

**Conclusion:** Cellular metabolism changes prior to paracetamol-induced cell necrosis. Optical metabolic imaging has significant implications for investigating metabolic mechanisms of paracetamol toxicity.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0559 A NOVEL IN VITRO TEST IMPROVES CAUSALITY ASSESSMENT OF DRUG INDUCED LIVER INJURY IN PATIENTS WITH POLYMEDICATION

**A. Benesic**, D. Dragoi, M. Buchholtz, A. L. Gerbes
*Liver Centre Munich, Department Of Internal Medicine Ii, University Hospital Munich (KUM), Munich/Germany*

**Contact E-mail Address:** andreas.benesic@med.uni-muenchen.de

**Introduction:** Drug-induced liver injury (DILI) is the major cause for acute liver failure in developed countries and accounts for a significant number of drug withdrawals and restrictions of use. However, the idiosyncratic form of DILI (iDILI) is a very challenging diagnosis. In polymedicated patients the identification of the causative agent may be impossible (1,2,3). We have developed a method that makes use of hepatocyte-like cells derived from peripheral blood (MetaHeps®) to diagnose or exclude iDILI (4).
**Aim of this study** was to investigate whether the MetaHeps® test can improve causality assessment in iDILI cases with polymedication.
**Methods:** Clinical data and blood samples were collected prospectively from patients presenting at the Liver Center Munich®, LMU university hospital with acute liver injury and intake of at least one drug with DILI concern (NCT02353455). iDILI was diagnosed by clinical likelihood(4). MetaHeps® were generated and exposed in vitro with the respective drugs. Toxicity was measured by increase in LDH release according to (4).
**Results:** As yet, 83 patients with iDILI were included in the study. In 15 cases a single drug was causing the iDILI episode (18%) while multiple drugs were involved in 68 iDILI events (82%). Seven of these patients showed iDILI at inadvertent re-exposure to one single drug (10%; 8% of total). Clinical causality assessment did not allow unequivocal identification of a single causative drug in 34 cases (50%, 41% of total). MetaHeps® testing was positive in 78 of the iDILI cases (94%). In the patients with positive re-exposure, the MetaHeps® test was positive for the respective drug. Positive test results for more than 1 drug were only found in 6 cases (7%; 6% of total). Interestingly, the combination of involved drugs had synergistic effects on MetaHeps® toxicity in 7 of the polymedicated patients.
**Conclusion:** In polymedicated patients with iDILI the MetaHeps® test seems to improve causality assessment. There is evidence that the test could improve causality assessment in polymedication and further the understanding of drug-drug-interactions in iDILI. Precise case characterization of iDILI events by the MetaHeps® test will help to develop drug-specific safety biomarkers.

## P0560 THE RESPONSE OF HEPATOCYTE AND MACROPHAGE TO ETHANOL-INDUCED TOXICITY: AN IN VITRO CO-CULTURE MODEL

**V. Marin**[1], C. Tiribelli[2], N. Rosso[2]
[1]*Area Science Park, Italian Liver Foundation, Trieste/Italy*
[2]*Centro Studi Fegato- Liver Research Center, Fondazione Italiana Fegato- Italian Liver Foundation, Trieste/Italy*

**Contact E-mail Address:** veronica.marin@csf.units.it

**Introduction:** Macrophage migration Inhibitory Factor (MIF) is a pleiotropic cytokine involved in the pathogenesis of several acute and chronic inflammatory diseases, such as Alcoholic Liver Disease (ALD). Few information is available about MIF regulation between hepatocytes and macrophages in response to ethanol (EtOH).
**Aims & Methods:** The aim of this work is to elucidate if the cross talk between these two cell types has any effect in the hepatic inflammatory response. Co-culture (transwell system) of hepatocytes (HuH7) and differentiated macrophages (THP1+100 nM PMA) were exposed for 24 h to 25 mM EtOH; monoculture of each cell type were used as control (CTRL). We assessed the gene expression of MIF and its receptors CD74, CXCR2, CXCR4 and CXCR7 as well as TNF-$\alpha$. In order to correlate gene expression with MIF functionality we quantified the cytokine released into the culture medium.
**Results:** We confirmed that in hepatocytes, EtOH induced an up-regulation of TNF-$\alpha$. The gene expression of MIF followed the same trend of increase, even if the amount of released MIF was unchanged. The expression of CD74, CXCR2, CXCR4 and CXCR7 were barely detectable in hepatocytes, instead in macrophage monocultures exposed to EtOH did not show any changes. Interestingly, we observed that in the co-culture model only hepatocytes presented a dramatic increase in TNF-$\alpha$ gene expression, whereas macrophages presented a decrease. Moreover, in co-culture both hepatocytes and macrophages increased the release of MIF, with no changes at mRNA level. These data demonstrate that there is a synergic inflammatory response to EtOH when cells are cultured together. We also observed a significant up-regulation of CD74 (both in term of mRNA and protein expression) in co-cultured hepatocytes suggesting that cells respond differently when macrophages are present in the system. Moreover we observed that CXCR4 was very responsive, showing a strong up-regulation in co-cultured hepatocytes. The opposite pattern was observed in co-cultured macrophages, in which the mRNA expression was reduced as compared to the monoculture. No significant changes were observed for CXCR2 and CXCR7.
**Conclusion:** In conclusion, our data suggest that the hepatocyte is the target cell of the EtOH deleterious effect. These results also indicate that injured hepatocytes are able to modulate macrophages response, which once activated, contributes to perpetrate the inflammatory state by increasing the production of MIF.

**Introduction:** Erythropoietin (EPO) is a kind of endogenous protein which exerts tissue protective effects for a wide range of organs. EPO protects tissues through a heterodimer composed of EPO receptor and $\beta$-common receptor, which is pharmacologically distinct from the homodimer receptor that is known to mediate erythropoiesis. However, a very high dose of EPO is required for peripheral administration to achieve tissue protection, which consequently increases the incidence of hypertension and hypercoagulation. Therefore, a novel helix B surface peptide (HBSP) that interacts only with the heterodimer receptor has been developed, which is composed of 11 amino acids derived from the aqueous face of helix B in EPO 3D structure.
**Aims & Methods:** In this study, the protective effect of HBSP in acute liver injury (ALI) induced by carbon tetrachloride ($CCl_4$) was investigated. HBSP (8 nmol/kg) was injected intraperitoneally in C57 BL/6 mice 2 h after $CCl_4$ administration. Serum and liver tissue samples were collected on 24 h after injury. Histological injury was evaluated. Serum alanine aminotransferase (ALT), aspartate aminotransferase (AST) and lactate dehydrogenase (LDH) were detected. Inflammatory cytokines was detected using real-time quantitative PCR. T cells and macrophages infiltration was examined by immunohistochemical staining. Hepatocytes apoptosis were measured by TUNEL assay and cleaved caspase-3 immunohistochemical staining. In in vitro experiment, the human liver cell line $LO_2$ was stimulated by $CCl_4$ with or without HBSP treatment. The glutathione peroxidase (GSH-Px) activity, cell survival and apoptosis were elevated. Furthermore, we examined PI3K/Akt/mTOR pathway to demonstrate the mechanism that HBSP-mediated protection in ALI.
**Results:** HBSP significantly decreased serum ALT, AST, LDH, and pro-inflammatory cytokines in liver tissues after $CCl_4$ injection compared to the $CCl_4$ group. Immunohistochemical staining indicated that the number of CD3, CD8, CD68 positive cells and the expression level of cleaved caspase-3 were significantly decreased by HBSP treatment. Besides, HBSP dramatically reduced apoptosis in vivo. In in vitro study, the activities of GSH-Px and survival rate were increased while the total apoptosis rate was reduced in HBSP-treated group compared to the control group after $CCl_4$ treatment. HBSP activated PI3K/Akt/mTOR pathway, which was confirmed by the PI3K inhibitor LY294002. Furthermore, HBSP could significantly improve the survival rate of acute liver failure mice, which could be reversed by LY294002.
**Conclusion:** HBSP is a potential therapeutic agent against $CCl_4$-induced ALI.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Alcoholic hepatitis (AH) is associated with a high short-term mortality. Static and dynamic prognostic models are essential to determine the best approach to each patient.

**Aims & Methods:** We aimed to select the best potential futility criteria in patients with AH. Retrospective multicentre study including patients with AH diagnosed clinically and/or histologically admitted between January 2012 and December 2015. 28-day mortality (M28) was evaluated and Maddrey Discriminative Function (MDF), CLIF-C ACLF, CLIF-C AD, Model for End-Stage Liver Disease (MELD), MELD-Sodium, Age, Bilirubin, INR and Creatinine (ABIC), Glasgow Alcoholic Hepatitis Score (GAHS) and Child-Turcotte-Pugh(CTP) performances were compared.

**Results:** 91 patients were included (male sex:80.2%, mean age:53.4 ± 9.3 years) with a median follow-up of 20.0 months (IQR 14.0–36.0) and mean alcohol consumption of 146.2 ± 95.9 g/day. 43 (47.3%) patients were started on pentoxifylline (PTX) and 33 (36.3%) on prednisolone (PDN). There were no significant differences on Kaplan-Meier survival curves between patients treated with PDN Vs. PTX. CLIF-C ACLF was significantly superior to predict M28, namely when compared to FDM (AUROC 0.839 Vs. 0.671, p = 0.040). A CLIF-C ACLF > 60 had a positive predictive value (PPV) for M28 of 81.8%. Patients treated with PDN with CLIF-C ACLF > 60 and Lille≥0.45 had a 100% PPV for M28.

**Conclusion:** The CLIF-C ACLF score selects patients with high mortality. Combination of static and dynamic scores (CLIF-C ACLF + Lille) improves M28 predictive ability and may be used as futility criteria, in the absence of indication for liver transplant.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0563 THE NON-STEROIDAL FXR AGONISTS PX20606 AND GS-9674 IMPROVE LIVER FIBROSIS AND PORTAL HYPERTENSION IN RODENT MODELS OF CHOLESTATIC, METABOLIC AND TOXIC LIVER CIRRHOSIS

**P. Schwabl**[1], E. Hambruch[2], T. Reiberger[1], P. Supper[1], D. Bauer[1], B. A. Payer[1], H. Hayden[1], N. Rohr-Udilova[1], C. Kremoser[2], M. Trauner[1]

**Introduction:** FXR agonists show beneficial effects in cholestasis and NASH. We evaluted the non-steroidal FXR agonists PX20606 and GS-9674 in rodent models of toxic (CCl4), and metabolic (NASH) liver fibrosis.

**Aims & Methods:** Toxic model: CCl4 2x/week i.p. for 12weeks. PX20606 (10 mg/kg/day) was given from weeks4–12 of CCl4. NASH model: choline-deficient high-fat diet plus repeated $NaNO_2$ (25 mg/kg i.p., 2x/week) for 10 weeks. GS-9674 (10 mg/kg/day or 30 mg/kg/day) was gavaged from weeks 4–10, with/without propranolol (PROP, 25 mg/kg). At end of treatment, mean arterial pressure (MAP), heart rate (HR), portal pressure (PP) and superior mesenteric artery blood flow (SMABF) were measured. Liver fibrosis was assessed by Sirius Red area (SRA), content of hydroxyproline (HP). Hepatic gene expression was quantified by qRT-PCR.

**Results:** In CCl4 rats, PX treatment ameliorated fibrosis (SRA: 6.99 ± 3.15 vs. 3.97 ± 1.64%; p < 0.001. HP: 415 ± 86 vs. 134 ± 14 μg/g liver;p = 0.002) and decreased AST (555 ± 30 vs. 227 ± 83 IU/ml;p < 0.001) and ALT (538 ± 233 vs. 193 ± 86 IU/ml;p = 0.008). PX decreased PP (11.9 ± 1.4 vs. 9.7 ± 1.4 mmHg;p = 0.037) and increased SMABF (8.88 ± 2.62 vs. 13.81 ± 2.81 ml/min/100 g;p = 0.021), while not affecting MAP or HR. Livers of CCl4–PX rats overexpressed FXR target genes including BSEP (2.5x), SHP (2.3x) and vasodilatory mediators CSH (2.1x) and DDAH (1.7x) while vasoconstrictive endothelin-1 (0.45), PDGF-Rβ (0.51x) and αSMA (0.61x) were reduced. GS-9674 reduced fibrosis in NASH rats in a dose-dependent manner: SRA: VEH:9.62 ± 4.60% vs. GS-9674-10 mg/kg:5.64 ± 4.51% vs. GS-9674-30 mg/kg: 2.94 ± 1.28%;p < 0.001). HP content was reduced by GS-9674-10 mg/kg:6.40 ± 1.33 mg/L and GS-9674-30 mg/kg:6.98 ± 4.74 mg/L vs. NASH-VEH:11.89 ± 2.90 mg/L (p = 0.030). GS-9674-30 mg/kg decreased hepatic col1a1 (-36.5%;p = 0.030) and pdgfr-b (−36.2%;p < 0.001) whereas shp expression was increased (+159%;p < 0.01). GS-9674 decreased PP (11.9 ± 2.1 vs. 8.9 ± 2.2 mmHg;p = 0.020), the combination of GS-9674+PROP reduced SMABF (14.18 ± 3.27 to 10.48 ± 3.74 mL/min/100 g;p = 0.032) while not further decreasing PP.

**Conclusion:** PX20606 ameliorates liver fibrosis and portal pressure in toxic cirrhosis. The novel non-steroidal FXR agonist GS-9674 exerts dose-dependent antifibrotic effects and ameliorates portal hypertension in NASH rats. The addition of propranolol to GS-9674 results in an decrease of mesenteric hyperperfusion.

**Introduction:** Liver cirrhosis is the end-stage liver diseases, which significantly reduces life quality and expectancy in patients with chronic liver diseases. The most common causes of chronic liver injury include hepatitis C virus (HCV), hepatitis B virus (HBV), alcohol, autoimmune hepatitis and many other conditions. The natural course of liver diseases varies considerably between separate individuals. Some individuals develop liver cirrhosis in a relative short span of year, while in others chronic liver damage does not progress through decades. This inter-individual variability might be related to different confounding factors, including clinical, virulent, environmental, and host factors. Over the last 10 years studies have shown that host genetic factors clearly contribute to the progression of liver fibrosis and development of liver cirrhosis. Genome-wide association studies (GWAS) revealed a link between the risk of developing liver fibrosis (LF) or liver cirrhosis (LC) and single nucleotide polymorphisms (SNPs) of PNPLA3, RNF7, MERTK and PCSK7 genes. PNPLA3 Variations in sequences of the genes encoding PNPLA3, RNF7, MERTK and PCSK7 might be functional and may contribute to the progression of liver injury.

**Aims & Methods:** In this study we aimed to evaluate replicate GWAS results and evaluate associations between PNPLA3 (C > G, rs738409), RNF7 (A > C, rs16851720), MERTK (A > G, rs4374383), and PCSK7 (C > G, rs236918) SNPs and LC or LF. The study included 317 individuals with LC, 154 individuals with LF and 498 healthy controls. The diagnosis and etiology of liver fibrosis and cirrhosis was confirmed by laboratory tests, clinical features, liver biopsy and radiological imaging. Liver fibrosis stage in the biopsy was assessed using METAVIR score. PNPLA3, MERTK, PCSK7 and RNF7 SNPs in all groups were detected using real-time PCR TaqMan® method.

**Results:** Genotypes and alleles of MERTK and PCSK7 SNPs were not associated with the risk of developing LF or LC. RNF7 rs16851720 was associated with LC in recessive model comparing CC vs. AA + CA genotype (aOD: 0.26, CI: 0.09–0.81, p = 0.020). PNPLA3 SNP was linked with higher risk of developing LF (aOD: 1.65, CI: 1.22–2.23, p = 0.001) and LC (aOD: 1.92, CI: 1.49–

2.48, p = 5.57*10–7). PNPLA3 rs738409 was associated with higher risk of developing LF and LC when comparing both dominant (aOD: 1.98, CI: 1.44–2.72, p = 2.20*10–5; aOD: 1.67, CI 1.14–2.43, p = 0.008, respectively) and recessive (aOD: 3.94, CI: 2.03–7.67, p = 5.16*10–5; aOD: 3.02, CI: 1.45–6.28, p = 0.003, respectively) inheritance models.
**Conclusion:** PNPLA3 rs738409 and RNF7 rs16851720 were associated with the risk of developing LF and LC and may contribute to progression to end stage liver disease. MERTK rs4374383and PCSK7 rs236918 SNPs were not linked with the risk of LF and LC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0565 IS THERE THE CONNECTION BETWEEN THE SEROTONERGIC SYSTEM AND CHOLINE ALFOSCERATE IN THE CONDITIONS OF EXPERIMENTAL HEPATIC ENCEPHALOPATHY?

E.G. Manzhalii[1], **O. V. Virchenko**[2]
[1]*Department Of Propedeutics Of Internal Medicine No 2Bogomolets National Medical University, Kyiv/Ukraine*
[2]*Biology Subdepartment, Bogomolets National Medical University, Kyiv/Ukraine*

**Contact E-mail Address:** ovirchenko@gmail.com
**Introduction:** Brain serotonin (5-hydroxytryptamine, 5HT) is involved in hypothalamic regulation of energy consumption. That is why it is implicated in the pathogenesis of several metabolic pathologies such as obesity and diabetes mellitus. Several studies have also confirmed its participation in the liver cirrhosis (LC) and hepatic encephalopathy (HE).
**Aims & Methods:** The aim of the study was to establish the state of serotonergic system in the brain and blood in the conditions of LC and concomitant HE in rats and potential impact of standard and novel treatment on the serotonergic system. The study was carried out on four groups of rats: 1st – intact rats and 2nd – $CCl_4$+rats, 3rd – $CCl_4$+standard treatment rats, 4th – $CCl_4$+choline alfoscerate (ChA) rats. Intraperitoneally administration of 1 ml/kg 15% solution of $CCl_4$ in olive oil four times a week for 4 weeks has been done for the modeling of LC and HE in rats. Then the treatment has been performing for one month. The standard administration regimen contained larnamin once daily (75 mg/kg, intraperitoneally (i/p)), rifaximin (10 mg/kg, intragastically (i/g)) and lactulose (1.5 ml/kg, i/g). In the new scheme, animals were treated with lactulose and ChA (15 mg/kg, i/p). In rat brain tissue, 5-HT and tryptophan level, the activity of monoamine oxidases (MAO), tryptophan hydroxylase (TPH), tryptophan decarboxylase (TPDC) and indoleamine-pyrrole 2,3-dioxygenase (IDO) were measured by standard biochemical methods. In rat blood, we estimated the level of 5-HT and tryptophan and the activity of MAO.
**Results:** In the condition of HE, 5-HT in the brain was lower by 60% ($p < 0.05$) as compared with intact, however tryptophan level did not differ. Contrary, in the blood these two parameters were increased by 233% ($p < 0.05$) for 5-HT and 150% ($p < 0.05$) for tryptophan. Standard and novel treatment of HE significantly elevated 5-HT and tryptophan level in the brain and reduced them in the blood. The most pronounced effect was revealed in the 4th group. Thus, ChA increased the level of 5-HT by 101% ($p < 0.05$) and tryptophan by 46% ($p < 0.05$) in the brain and decreased their level by 85% ($p < 0.05$) and 60% ($p < 0.05$) compared with $CCl_4$+rats. It was also found the alteration in the enzymatic activity: the enhancement of MAO in the blood and the fall of the MAO, TPH and IDO activity in the brain, but not the activity of TPDC. The treatment partially restored these parameters to the control values. The ChA had the strongest effect and returned the MAO in the blood to the control benchmark, and increased MAO, TPH and IDO in the brain by 91% ($p < 0.05$), 5.2% ($p < 0.05$) and 4.1% ($p < 0.05$) as for the $CCl_4$+rats.
**Conclusion:** These data suggest the decrease of the 5-HT synthesis in the brain in the conditions of LC and concomitant HE, but its catabolism was not increased because the MAO activity was low and these changes was associated with the elevated level of the 5-HT in the blood. The novel treatment regimen contributed to the normalization of the serotonergic system in the conditions of HE, but the exact molecular mechanisms of such action require unraveling.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0566 REGULATION OF P53 – A POSSIBLE BACTERIAL DEFENSE MECHANISM LEADING TO EPITHELIAL BARRIER DESTABILIZATION IN SPONTANEOUS BACTERIAL PERITONITIS?

**M. Haderer**[1], C. Kunst[2], E. Aschenbrenner[2], K. Pollinger[2], J. Middendorf[1], S. Schlosser[2], M. Müller-Schilling[2]

**Contact E-mail Address:** marika.haderer@ukr.de
**Introduction:** Spontaneous bacterial peritonitis (SBP) is a life-threatening complication in advancing liver cirrhosis. SBP represents a bacterial infection of ascitic fluid without an intra-abdominal source of infection that could be treated surgically. Translocation of intestinal bacteria or bacterial products from the gut to mesenteric lymph nodes is crucial for SBP, with *Escherichia coli* (*E. coli*), Klebsiella pneumoniae, enterococci and streptococci being the most common germs. As soon as a SBP is suspected, patients must be treated with antibiotics. In this context, biomarkers are in the focus of interest, as they are essential for an initiation of antibiosis on time and a reduced mortality of SBP. However, detection systems or biomarkers for early SBP diagnosis are so far not available.
**Aims & Methods:** With regard to the development of early recognition systems, pathomechanisms and signaling pathways of bacterial translocation in SPB were explored. To investigate effects of intestinal bacteria on epithelial cell junctions, monolayers of human intestinal epithelial cell lines Caco-2 (p53 deficient) and HCT-116 (p53 wildtyp, wt) were cocultured with *E. coli* at day 5 to 8 post confluence. Infection with *E. coli* was performed with a MOI of 10 for 4 hours at each day. Western Blot analysis was performed to analyze changes in intracellular protein levels of Occludin, E-cadherin and the p53 family including p53, p63 and p73.
**Results:** *E. coli* stimulation of HCT-116 cells resulted in a strong decrease of the tight junction protein Occludin, the adherens junction protein E-cadherin, and, remarkably, also p53. Consistently, following *E. coli* stimulation Caco-2 cells displayed reduced protein levels of Occludin and E-cadherin. However, in p53-deficient Caco-2 cells this reduction was less distinct compared to p53-wt HCT-116 cells.
**Conclusion:** These results highlight destabilizing effects of E. coli on intestinal cell junctions. Of specific clinical relevance, a regulation of the tumor suppressor p53 by E. coli was demonstrated. With a more distinctive downregulation in HCT-116 epithelial cells, we hypothesize an involvement of p53 in the regulation of epithelial permeability during bacterial infection. Reduced p53 levels in conjunction with destabilized intestinal epithelial integrity following bacterial infection might represent a mechanism to protect bacteria from intestinal immune responses and therefore to promote bacterial translocation in SBP.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0567 IGFBP2–A NOVEL P53-FAMILY TARGET GENE IN HEPATOCELLULAR CARCINOMA

**D. Gschwind**, M. Lohse, C. Kunst, T. Fuertjes, E. Aschenbrenner, K. Pollinger, S. Schlosser, M. Müller-Schilling

**Contact E-mail Address:** dana.gschwind@stud.uni-regensburg.de
**Introduction:** p53 transcription factors (p53, p63, p73) respond to cellular stress signals by transcriptional regulation of a specific set of genes. In a number of tumors, also in hepatocellular carcinoma (HCC), p53 family members exert cancerogenic or tumorsuppressive effects. Depending on their splice variants – with transactivation domain (TA) or dominant negative (DN) – p53 proteins activate or inhibit specific target genes. In previous studies we identified the IGFBP2 gene (Insulin-Like Growth Factor Binding Protein 2) as one out of 7 putative target genes for p53 proteins with prognostic relevance in HCC.
**Aims & Methods:** The aim of this study was to characterize the impact of p53 transcription factors on the IGFBP2 gene. Potential p53 family binding sites in the IGFBP2 locus were identified by database analyses (TRANSFAC, JASPAR, TFBIND, PROMO). Hep3B cells were transfected with rAd-p53, -TAp63, -TAp73, -DNp63 or -DNp73 and transcriptional regulation of IFGBP2 was determined by real time qPCR. Intra- and extracellular IGFBP2 protein levels were analyzed by Western Blot and ELISA. Identified putative binding sites were cloned, mutated and evaluated by luciferase reporter assays to confirm p53 family binding.
**Results:** In total, 12 putative p53 family binding sites were identified within the IGFBP2 locus. Intron 1 contains five putative binding sites for p73 and one for p53; another putative p53 binding site is located within the promoter region. TAp73-transfected Hep3B cells displayed a more than 25-fold increased IGFBP2 expression and 10-fold increased intra- and extracellular IGFBP2 protein levels. Transfection with TAp53 resulted in an up to 7-fold increased IGFBP2 expression. Intron1-dependent luciferase activity was increased by up to 150-fold in TAp73-transfected cells. Moreover, luciferase assays confirmed the identified p53 binding site in intron 1, since luciferase activity (initially induced by up to 20-fold in TAp53 transfected cells) was reduced by up to 90% after mutation and deletion, respectively, of the putative p53 binding sequence.
**Conclusion:** These results identify IGFBP2 as novel target gene for TAp73 and TAp53 in HCC. We demonstrate for the first time, that TAp73 interacts with IGFBP2 signaling, underlining the important link between p53 and IGF pathways. In this context, the p53 family network acts as tumor-inhibiting mechanism, whereas the axis of IGF growth factors is a crucial mediator of cell proliferation. It is suggestive, that the particular balance of these two signaling pathways decides on growth, cancerogenesis and treatment response. Thus, fine-tuning of these pathways might be capable of adjusting a cell's resistance to chemotherapeutic drugs and offers new therapeutic options.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0568 QUINOLINIC ACID AS A PREDICTOR OF OUTCOME IN CIRRHOTIC PATIENTS

**R.a. A.E. El Aidy**, A.M.N. M. Nafee, H. I. Mohammed, H. F. Basha
*Tropical Departement, zagazig, zagazig/Egypt*

**Contact E-mail Address:** ra_s1988@yahoo.com
**Background:** Liver cirrhosis and its complications are major health problem (1). Number of predictors of prognosis of liver cirrhosis was established. The most widely used and applicable ones are Child (2) and MELD (3) scores. There are some deficiencies concerning both of them. Quinolinic acid (QuinA) is a product of the kynurenine pathway, it acts as a neurotoxin, gliotoxin, pro-inflammatory mediator and pro-oxidant molecule(4).
**Aim:** To assess the role of QuinA as a predictor of outcome in patients with liver cirrhosis.
**Patients and methods:** The study included 80 patients with liver cirrhosis and 10 healthy persons as controls. Child-Pugh and MELD scores were calculated. All patients were subjected to complete history taking, full clinical examination, pelvi-abdominal ultrasonography, laboratory investigations; complete blood picture, liver and kidney profiles, coagulation profile, random blood glucose level and serum QuinA by ELISA. Six months follow-up were done for all patients

according to clinical, routine laboratory parameters and ultra sound examination with assessment of mortality
**Results:** After 6 months with assessment of mortality, 20 patients died. There was positive significant correlation between baseline QuinA values and baseline Child and MELD scores. Regarding prediction of complications after 6 months, both Child and MELD scores showed sensitivity more than that of QuinA levels, while QuinA levels showed higher specificity. QuinA values were the most sensitive and specific for prediction of mortality after 6 months when compared to Child and MELD scores.
**Conclusion:** Serum levels of QuinA increased markedly according to progressive liver dysfunction and correlated to high values of Child and MELD scores. QuinA was a specific marker for complications in cirrhotic patients particularly hepatic encephalopathy, while it was an excellent marker for prediction of mortality in those patients. It means that it is a good prognostic marker for prediction of outcome in cirrhotic patients, however its low sensitivity in prediction of complications reduce its value in screening of these complications
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0569 VITAMIN D DEFICIENCY IN LIVER CIRRHOSIS

**O. Gavrilescu**, M. Dranga, M.A. Badea, C. Mihai, C. Cijevschi Prelipcean
*Gastroenterology, University of Medicine and Pharmacy "Grigore T. Popa" Iasi, Iasi/Romania*

**Contact E-mail Address:** otilianedelciuc@yahoo.com

**Introduction:** The presence of vitamin D deficiency (VDD) is now widely recognized to be associated with many systemic disorders, such as chronic liver diseases (1). However, its association with alcoholic liver disease (ALD) has been poorly described.
**Aims & Methods:** The aim of this study was to compare the prevalence of vitamin D deficiency in patients with alcoholic cirrhosis and hepatitis C cirrhosis. We performed a prospective study, conducted over a period of 12 months (October 20114–September 2015). The study enrolled 84 patients diagnosed with liver cirrhosis (42 with hepatitis C cirrhosis and 42 with alcoholic cirrhosis). Serum 25(OH) D levels were measured in all patients enrolled in the study. Severity of vitamin D deficiency was graded as mild (20–30 ng/ml), moderate (7–19 ng/ml) or severe (<7 ng/ml), normal being >30 ng/ml.
**Results:** Of patients, 84% presented some degree of vitamin D deficiency. In the hepatitis C cirrhosis group, 18% had mild, 46% had moderate, and 36% had severe vitamin D deficiency. In the alcoholic cirrhosis group, 22% had mild, 41% had moderate, and 37% had severe vitamin D deficiency. There was no statistical difference between groups regarding vitamin D deficiency (41% vs. 43%). Female gender were independent predictors of severe vitamin D deficiency in chronic liver disease.
**Conclusion:** Chronic liver disease patients are at very high risk of vitamin D deficiency regardless of etiology or severity. This patients have an increased risk for the development of osteoporosis and fractures, reduced muscle strength, an impaired inflammatory response, and malignancy (2). Females are at highest risk of vitamin D deficiency.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0570 IMPROVEMENT OF THE MODELING AND DIAGNOSIS OF HEPATIC ENCEPHALOPATHY IN RATS

**E.G. Manzhalii**[1], O. V. Virchenko[2]
[1]*Department Of Propedeutics Of Internal Medicine No 2 Bogomolets National Medical University, Kyiv/Ukraine*
[2]*Biology Subdepartment, Bogomolets National Medical University, Kyiv/Ukraine*

**Contact E-mail Address:** elinam@ukr.net

**Introduction:** Modeling of liver cirrhosis (LC) and hepatic encephalopathy (HE) in rats has some limitations namely high mortality of lab animals or high duration of LC formation. Diagnosis of HE was accomplished with the model of food conditioned reflex that allowed to evaluate only locomotor activity of animals but not their ability to think and remember.
**Aims & Methods:** The aim of the study was the optimization of the HE modeling and diagnosis. Intraperitoneal administration of 1 ml/kg 15% solution of $CCl_4$ in olive oil four times a week for 4 weeks has been suggested for optimal simulation of HE in rats. The development of HE, namely the ability of animals to memorization, learning and thinking was studied by the formation of a food conditioned reflex in the T-shaped maze. 14 rats were divided into two groups: 1st – intact rats and 2nd – rats pretreated with $CCl_4$. The dynamic of reducing the time of getting animals to the food reinforcement in the maze as a result of remembering the location of food was estimated during 14 days.
**Results:** In the first day of food conditioned reflex study it was established that intact rats reached the food in $157 \pm 47$ sec. Contrary, the time of getting to food of $CCl_4$-rats was 2,1 times ($p < 0.05$) longer that suggests the less activity and lethargy of these animals. In the next 7 days, there were not any changes in the time of getting to food in T-shape maze in the intact group as well as in the group pretreated with $CCl_4$. Since the 7th day we have shown a steady acceleration of finding the food by intact rats. However, there were not registered data about faster food reinforcement in the group of animals that got $CCl_4$ injection. Moreover, in the group of intact rats we have established the decrease in time of finding the food by 92% ($p < 0.05$) as compared with the first day of experiment. Such changes were not obvious for the $CCl_4$-group: we did not find the significant difference between the reaching food of $CCl_4$-rats at the start and at the 14th day of experiment in the T-shaped maze. Thus, we registered that the time of finding the food in the $CCl_4$ group was 21.4 ($p < 0.001$) greater than in the intact group at the 14th day of study in the T-shaped maze. The impairment of food conditioned reflex formation has showed lack of remembering and thinking in rats pretreated with $CCl_4$.
**Conclusion:** We have updated the scheme of modeling LC and HE by the decrease of time of the LC development and the reduction of animal mortality as result of toxic action by $CCl_4$. The improved diagnosis of HE was achieved by using the methodology of forming a food conditioned reflex in rats. This method can be recommended as a basic for HE modeling and can be used for study new treatment strategies of this disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0571 PROGNOSIS OF PATIENTS WITH ESOPHAGEAL VARICES POST BANDING ULCER BLEEDING

**Introduction:** Bleeding from post-endoscopic band ligation (EBL) ulcer is associated with a high mortality, for which outcome and prognostic indicators are unknown.
**Aims & Methods: Aims:** to identify predictors of poor outcome for variceal post-EBL ulcer bleeding and its impact in short and long term mortality; to compare mortality among patients with bleedind from post-EBL ulcer and from esophageal variceal rupture (EVR).
**Methods:** Case control study. Cases: all admissions for post-EBL ulcer bleeding, in a tertiary gastrointestinal service, from January 2003 to December 2015. Controls: EBL treated patients due to acute esophageal variceal hemorrhage. Endpoints: mortality assessed at 7, 28, 90, 180 and 360 days post-therapeutic.
**Results:** A total of 50 post-EBL ulcer bleeding cases were included. Mean age ($57.1 \pm 12.0$); male:female ratio (4.1:1). Cirrhosis etiologies: alcoholic (70.7%), HCV (29.3%) and HBV (15.7%). Child-Pugh-Turcotte (CPT) distribution: A (17.3%), B (46%) and C (36.7%); mean MELD was $14.5 \pm 6.1$. Hepatocellular carcinoma and thrombosis of the portal vein were present in 14% and 24%, respectively. Treatment: endoscopic therapy in 34%, balloon tamponade in 20% and TIPS placing in 8%. Rebleeding in 22% and failure to control hemorrhage in 1 case. Mortality at 7, 28, 180 and 360 days was 2%, 14%, 30% and 34%, respectively, showing no difference from control group (p = n.s). Presence of hepatorenal syndrome (HRS) was associated with mortality at 28 (OR:30 $p < 0.001$), 180 (OR:8 $p = 0.049$) and 360 days (OR:8, $p = 0.005$), while alcoholic cirrhosis and spontaneous bacterial peritonitis (SBP) were associated with mortality at 180 and 360 days. In multivariate analysis, only the HSR (28, 180 and 360 days) and SBP (360 days) were independent risk factors for mortality.
**Conclusion:** Mortality due to post-EBL ulcer bleeding was high, and was not attributable to bleeding-treatment failure. The presence of hepatorenal syndrome and spontaneous bacterial peritonitis were independently associated with poor outcome, regardless of CPT classe.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0572 DOES NON-INVASIVE ASPARTATE AMINOTRANSFERASE/ PLATELET RATIO INDEX (APRI) CORRELATES WITH INVASIVE HEPATIC VENOUS PRESSURE GRADIENT (HVPG) IN CIRRHOSIS?

**V. Kirnake**[1], A. Arora[2], P. Sharma[2], A. Kumar[3]
[1]*Medicine And Gastroenterology, Acharya Vinoba Bhave Rural Hospital and Jawaharlal Nehru Medical College, Wardha/India*
[2]*Gastroenterology And Hepatology, Sir Gangaram Hospital, New Delhi/India*
[3]*Gastroenterology And Hepatology, Sir Gangaram Hosptal, New Delhi/India*

**Contact E-mail Address:** drvijendrakirnake@gmail.com

**Introduction:** Hepatic Venous Pressure Gradient (HVPG) is the only recommended tool to measure portal hypertension and prognosticate complications of cirrhosis. Aminotransferase/platelet ratio index (APRI) is simple noninvasive marker of hepatic fibrosis.

**Aim:** To compare non-invasive APRI score with invasive HVPG for portal hypertension and determine the usefulness of APRI in predicting complication of portal hypertension

**Methods:** APRI and HVPG were measured in consecutive patients of cirrhosis aged 18 to 70 years in the year 2011–2014 admitted to our department.

**Results:** Study included 277 patients with median age 51years (48–63years); 228 (82.31%) males. Etiology of cirrhosis were alcohol 135(48.7%), Viral (12.3%), Cryptogenic/NAFLD 78(28.2%) and others 30(10.8%). Mean CTP score and mean MELD score were $7.33 \pm 1.7$ and $16.85 \pm 6.4$ respectively. Median HVPG was $16.69 \pm 5.43$ mmHg. Maximum Youden's index was 0.479 which corresponded to a cut-off value of 0.876 of APRI. The ROC curve to study the performance of APRI for predicting portal pressure (HVPG $>12$ mmHg) had area under curve 0.753 ($P < 0.001$). APRI of 0.876 had a sensitivity 69.5%, specificity 78.4%, diagnostic accuracy 71.12% and positive predictive value 93.45% for predicting HVPG $>12$ mmHg. There was significant difference (Spearman's Rho = 0.443; $p < 0.001$) in median APRI of patient with HVPG $\leq 12$ mmHg (APRI- 0.66) and those with HVPG $>12$ mmHg (APRI-1.40) respectively. Median APRI in upper GI bleed patient was 1.441 which was significantly higher than non bleeder patient APRI- 0.985($p < 0.001$).

**Conclusion:** APRI score of 0.876 seems to have an acceptable accuracy for prediction of high portal pressure. High APRI will predict more bleeding complications. APRI is a simple, non invasive and cost-effective parameter for diagnosis of high portal pressure in patients with cirrhosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Bacterial infections are a significant cause of morbidity and mortality in cirrhosis. Lectin pathway molecules of the complement system are synthesized in the liver and have a pivotal role in the innate host defense against infectious organisms. Mannose-binding lectin (MBL) and ficolins (FCNs) act as soluble pattern recognition molecules, while mannan-binding lectin serine proteases (MASPs) do as effector molecules in elimination of the pathogens. Low levels of the functional proteins increase the risk of various infectious diseases mostly in immune-deficient conditions but their significance has scarcely been investigated in cirrhosis related bacterial infections.

**Aims & Methods:** Sera of 266 patients with cirrhosis (male: 50%, alcoholics: 63.9%, median age: 56 years and MELD score: 11), and 160 healthy subjects were assayed for the concentrations of a panel of lectin molecules (FCN-2, FCN-3 and MASP-2) by sandwich-type immunoassay. In cirrhosis, a 5-year follow-up observational study was conducted to assess a possible association between lectin levels and development of clinically significant bacterial infections (CSI) and mortality.

**Results:** The FCN-2, FCN-3 and MASP-2 levels were significantly lower in cirrhosis compared to healthy controls (median, 505 vs. 769 ng/ml, 7301 vs. 10797 ng/ml and 212 vs. 412 ng/ml, respectively, $p < 0.001$ for all) and decreased according to disease severity as rated by Child-Pugh stage. In Kaplan-Meier analysis with LogRank test, time to development of CSI was associated with low level of FCN-3 (<4857 ng/ml, $p = 0.028$) but not FCN-2 (<427 ng/ml, $p = 0.068$) or MASP-2 deficiency ($p = 0.368$). Combined FCN deficiency even more than individual molecules were able to predict the development of these episodes. Patients with low level of both FCNs had a cumulative risk of an infection of 52% as compared to 31% with normal level of FCNs ($p = 0.021$). None of the lectin molecules, however, were associated to long-term mortality. In multivariate Cox-regression analysis, clinical factors but not the serum lectin profile remained an independent predictor of CSI. Prior episode of CSI and in a stepwise manner, the disease severity as rated by Child-Pugh stage conferred higher risk for development of CSI (HR: 2.64, 95% CI: 1.74–3.99, $p < 0.001$ and 2.11, 95%CI: 1.52–2.93, $p < 0.001$, respectively).

**Conclusion:** In the present prospective study, diseases severity and prior episode of CSI but not the serum lectin profile were major determinants of the risk of CSI in cirrhosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0574 SAFETY OF DAA THERAPY REGARDING RENAL FUNCTION IN POST-LIVER TRANSPLANT PATIENTS INFECTED WITH HEPATITIS C INDEPENDENT OF PRE-EXISTING RENAL IMPAIRMENT, AND A 100% SVR12 RATE – A SINGLE-CENTRE STUDY

**G. Peschel**[1], L. Baier[2], L. Moleda[3], M. Selgrad[1], M. Scherer[2], M. Müller[1], K. Weigand[4]
[1]*Internal Medicine I, University of Regensburg, Regensburg/Germany*
[2]*Surgery, University of Regensburg, Regensburg/Germany*
[3]*Intrenal Medicine I, University of Regensburg, Regensburg/Germany*
[4]*Gastroenetrology, University of Regensburg, Regensburg/Germany*

**Contact E-mail Address:** georg.peschel@ukr.de

**Introduction:** Direct acting antiviral (DAA) therapy of hepatitis c virus (HCV) infection is yet well established in patients with and without cirrhosis of the liver. In times of low efficiency and Interferon treatment liver transplantation has frequently been necessary in patients with chronic HCV infection, especially for those with advanced cirrhosis or HCC. Patients after liver transplantation with ongoing HCV infection often suffer from renal and hepatic impairment. A major concern when treating HCV patients after liver transplantation is the potential interaction of DAA and immunosuppressive therapy that might result in decreasing renal function.

**Aims & Methods:** In this single-centre study we analysed clinical parameters of 18 HCV infected patients treated with DAA therapy after liver transplantation. The primary endpoints were change of renal function (GFR and creatinine levels) and viral eradication 12 weeks after therapy (SVR 12). For secondary endpoints we investigated the influence of DAA therapy over the time on following parameters: transaminases, bilirubin, INR, ARFI measurement and MELD Score. Subgroup analyses were performed for renal impairment, the type of immunosuppressant and the type of DAA Regime.

**Results:** Form the 18 patients treated 5 suffered of renal impairment grade 2, and 7 patients of renal impairment grade 3. The remaining 6 patients had no/mild renal impairment. No patient was on haemodialysis. Renal function at SVR 12 was neither influenced by the type of immunosuppressant nor the type of DAA regime, nor whether there was pre-existing renal impairment. All patients reached SVR12, regardless of the genotype (4 patients genotype 3; 14 patients genotype 1) or the type of DAA regime (9 patients Daclatasvir and Sofosbuvir / 2 patients additionally ribavirin; 9 patients Ledipasvir, Sofosbuvir / 8 patients additionally ribavirin). In respect of secondary endpoints the type of immunosuppressant had no influence on renal function or SVR12 rate. The levels of transaminases and bilirubin declined as expected. 10 patients had already liver fibrosis greater than F3 in non-invasive measurement before initiation of treatment. Even in this short period of time single point acoustic radiation force impulse imaging (ARFI) improved in 9 patients ($p = 0.012$) and albumin levels tended to increase under therapy ($p = 0.055$). In 7 patients MELD score improved, due to the decrease of bilirubin levels.

**Conclusion:** Over all, DAA-therapy in liver transplant patients was effective and save in this single-centre real-life cohort. Renal function was not influenced by the administered drug combinations, even in patients with pre-existing renal impairment. No safety issues occurred.

**Contact E-mail Address:** nikolauspfisterer@hotmail.com
**Introduction:** Endoscopic band ligation (EBL) is used for primary (PP) and for secondary prophylaxis (SP) of variceal bleeding in cirrhotic patients with gastro-esophageal varices (GEVs). While the addition of non-selective beta-blockers (NSBBs) to EBL is recommended for SP, in PP either EBL or NSBB should be used.
**Aims & Methods:** Retrospective assessment of the efficacy of EBL for PP and SP of variceal bleeding in two tertiary care centers in Vienna. Rebleeding rates and transplant-free survival were assessed with and without concomitant NSBB therapy.
**Results:** 766 patients with GEVs were treated with EBL. Among the 284 patients undergoing sequential EBL for PP, n = 95 (33.5%) received EBL only while n = 187 (65.8%) received concomitant EBL+NSBBs. Among the n = 482 patients on SP, n = 163 (33.8%) received EBL only while n = 306 (63.5%) received EBL/NSBB combination therapy.
In PP, concomitant NSBB therapy did neither decrease bleeding rate (9.0% vs. 10.3% at Y1, 16.2% vs. 13.5% at Y2, 19.3% vs. 14.9% at Y3, log-rank p = 0.747) nor mortality (29.6% vs. 19.2% at Y1, 39.7% vs. 31.8% at Y2, 45.9% vs. 38.3% at Y3, log-rank p = 0.389) as compared to EBL alone. In SP, the combination of EBL/NSBB did not decrease bleeding rates as compared to EBL alone (25.1% vs. 23.7% at Y1, 27.8% vs. 30.4% at Y2, 32.5% vs. 33.8% at Y3, log-rank p = 0.822) but was associated with a significantly lower mortality rate (17.1% vs. 46.2% at Y1, 22.5% vs. 48.7% at Y2, 31.8% vs. 49.7% at Y3, log-rank $p < 0.001$).
**Conclusion:** EBL alone is as sufficient as EBL/NSBB combination for primary prophylaxis of variceal bleeding. In absence of contraindications to NSBB, the EBL should always be combined with NSBB in secondary propylaxis of variceal bleeding, since it improves survival as compared to EBL alone.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Early implantation of a transjugular intrahepatic portosystemic shunt (TIPS) has been shown to improve survival after acute variceal bleeding (AVB) in highly selected patients. However, data on real-life cohorts is scarce.
**Aims & Methods:** To identify and evaluate outcome of adult patients with cirrhosis undergoing early TIPS implantation within 72 hours after AVB at two tertiary care centers in Vienna from 1994–2014.
**Results:** Forty-nine patients with early TIPS after AVB were included. Mean MELD score was: 14.4±4.4. Thirteen patients (26.5%) presented characteristics that were exclusion criteria in previous early TIPS trials ('stringent criteria': n = 3 age > 75, n = 3 CPS > 13, n = 1 HCC > Milan, n = 5 previous beta-blocker/band-ligation, n = 1 renal insufficiency). Bare metal and PTFE-covered stents were used in 32 (65.3%) and 17 (34.7%) patients, respectively. Early rebleeding (< 6weeks) occurred in 8.2% (4/49) patients and 6-weeks bleeding-related mortality was 28.6% (12/49). Bare and PTFE-TIPS patients showed similar early rebleeding rates (9.9% vs. 6.3%, p = 0.627) and bleeding-related mortality (22.6% vs. 11.8%, p = 0.389). Overall rebleeding rate was lower in PTFE-TIPS patients (61.5% vs. 6.3%, p = 0.002; median follow-up of 18.5 months). Survival tended to be longer in patients receiving PTFE-TIPS vs. bare stents (median 21.5 vs. 9.6 months, p = 0.212). Survival was significantly better in patients meeting stringent early TIPS criteria ($p < 0.001$), especially in those with PTFE-TIPS (58.1 vs. 10.7 months in bare stents, p = 0.029).
**Conclusion:** An early TIPS strategy controls acute variceal bleeding in most cases. The use of early PTFE-TIPS for acute variceal bleeding results in a favorable outcome in a real-life cohort of cirrhotic patients fulfilling 'stringent' selection criteria.

## P0577 ACUTE-ON-CHRONIC LIVER FAILURE AN UNDENIABLE ENTITY

**D. Perdigoto**[1], P. Figueiredo[2], C. Sofia[2]
[1]*Gastroenterology, University Coimbra Hospital – Portugal, Coimbra/Portugal*
[2]*Gastroenterology, Coimbra University Hospital, Coimbra/Portugal*

**Contact E-mail Address:** dperdigoto@hotmail.com
**Introduction:** The last 5–7 years in hepatology saw the genesis of a new clinical nosologic entity called Acute-on-chronic liver failure (ACLF). Following the initial theoric idea formal objective criteria were defined based and supported by good quality clinical studies such as CANONIC (Moreau R & Consortium., 2013) that produced strong evidence to justify this new concept. However, the clinical relevance and true independence of this entity has been frequently questioned and challenged.
**Aims & Methods:** The objective was to identify and characterize this clinical condition in a Gastroenterology department including its associated intensive care unit. We performed a single-center prospective study (during 18 months) with inclusion of every patient admitted with acute decompensation of chronic liver disease (CLD). Exclusion criteria considered were: any stage of hepatocellular carcinoma, acute or chronic extra-hepatic severe medical condition that might have contributed to the acute decompensation particularly chronic kidney disease, chronic decompensated heart failure, any oncologic condition and trauma. Exclusion of the patients without, at least, 3 months of follow-up. Identification of the patients with ACLF according to the criteria defined by the study CANONIC. ACLF was graded also with those criteria. Statistics done with SPSS v. 20 (SPSS Inc. v. 20, IBM, Chicago IL).
**Results:** 118 patients enrolled at their first admission in the period of the study (July 2014 – December 2015). The majority were men (76.3%). Mean age of 60.0 ± 11.2 years (36 to 84). The most common etiologies of the CLD were alcohol consumption (81.4%), HCV + alcohol (5.9%), HBV + HCV + alcohol (2.5%) and primary biliary cholangitis (2.5%). There were 39 patients admitted with ACLF (33.1%), the majority with ACLF – grade 1 (61.5%). In the univariate analysis the presence of ascites – odds ratio 3.64 (95% CI 1.66–8.0), infection (spontaneous bacterial peritonitis or sepsis with other cause) odds ratio 4.38 (95% CI 2.36–8.12) and hepatorenal syndrome – odds ratio 4.66 (95% CI 3.11–6.97) all correlated with higher risk of ACLF but the presence of acute upper digestive bleeding (mainly by variceal bleeding) had a negative correlation for ACLF – odds ratio 0.49 (95% CI 0.28–0.88) ($p < 0.05$). In the multivariate analysis the presence of infection or hepatorenal syndrome showed

higher risk for ACLF development ($p < 0.0001$ and $p = 0.002$ respectively). The ACLF group had higher short-term (28-day) and 3 month mortality, respectively 43.6% and 64.1% comparing to the no-ACLF group: 2.5% and 7.6% ($p < 0.0001$).
**Conclusion:** the presence of ACLF is linked to a considerable higher risk of short-term mortality in the patient with CLD. Sepsis and acute kidney injury occur frequently in this condition and can be often present in a subtle/attenuated way so they must be carefully searched and efficiently treated. On the opposite side, in this study, an important clinical event like acute variceal bleeding correlated with lower risk for development of ACLF.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Previous studies have evaluated erectile dysfunction (ED) in patients with chronic liver disease (CLD). However, the association between ED and other complications of liver cirrhosis (LC) has not been widely studied [1].
**Aims & Methods:** The aim of this study was to evaluate the independent risk factors for ED in patients with CLD. This is a cross-sectional study in subjects with CLD in which a simplified version the International Index of Erectile Function questionnaire was applied. Exclusion criteria were as follows: age $>75$ years old and alcohol intake $>40$ g/day. Statistics analysis were performed using IBM SPSS Statistics 22 with $p < 0.05$ deemed to be statistically significant.
**Results:** We included 66 male patients with CLD, median age was 55.5 years (IQR: 47.5–62.0), and 77% were married. Forty three percent of the patients evaluated had liver cirrhosis (LC), mainly Child-Pugh A (64.3%), being alcohol the most frequent etiology (25.8%). Globally, 62.1% of the patients fulfilled criteria for ED, 10.6% characterized as severe ED, and among patients with LC the diagnosis of ED was made in 82% of them. Twenty percent of patients surveyed confirmed that had previously taken drugs not prescribed by a doctor to increase their sexual performance. The presence of ED was associated with LC ($p = 0.006$), severity of LC ($p = 0.014$), presence of esophageal varices ($p < 0.001$), refractory ascites ($p = 0.006$), previous hospitalization due to decompensated cirrhosis ($p = 0.006$), use of diuretics ($p = 0.041$) and smoking habits ($p = 0.003$). In our study, there was no association between the presence of ED and previous episodes of hepatic encephalopathy, presence of diabetes mellitus, dyslipidaemia, hypertension or use of beta-blockers. In a linear regression model that included the following factors: age, smoking habits, previous decompensation, presence of LC and Child-Pugh score, only the latter two variables were independent factors for the presence of ED. The presence of LC was associated with an OR = 5.11 (95% IC: 1.06–16.27) for the diagnosis of ED.
**Conclusion:** The presence of LC, specially in more advanced stages, was an independent risk factor for the presence of ED, apart from other classic factors, such as: smoking habits and diabetes mellitus.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Cirrhotic cardiomyopathy, manifested as an impaired contractile response to stressful stimuli, damaged diastolic relaxation and electrophysiological abnormalities, is a chronic cardiac dysfuntion in patients with liver cirrhosis. Prolonged QT interval represents the most important electrocardiographic (ECG) finding in these patients, being a risk factor for ventricular arrhythmias.
**Aims & Methods:** The aim of this study was to find correlations between ECG changes in cirrhotic patients and prognostic scores for disease severity, and analyze the relationship between the use of non-selective beta blockers (NSBBs) and QTc interval prolongation. This retrospective study conducted in the Clinic of Gastroenterology and Hepatology, Clinical Center of Serbia, Belgrade, included 251 patients with liver cirrhosis, who were consecutively hospitalized in the period from 2013–2015. According to etiology of cirrhosis, the patients were divided into two groups: alcoholic and non-alcoholic. Based on laboratory values and clinical findings, prognostic scores including Model for End-Stage Liver Disease (MELD) and Child-Pugh were calculated, along with a 12-lead ECG in each patient on the day of admission. Heart rate (HR), PQ interval, QT interval, QRS duration, and voltage of QRS complexes in precordial and limb leads were analyzed.
**Results:** Alcoholic liver cirrhosis was diagnosed in 109 (43.43%) and non-alcoholic in 142 (56.57%) patients. There was a statistically significant positive correlation between QTc and MELD and Child-Pugh scores and a negative correlation between the voltage of the QRS complex in the limb leads and the prognostic scores. The average length of QTc in the alcoholic group was $434.16 \pm 42.82$ ms and $410.76 \pm 52.56$ ms in the non-alcoholic group ($p < 0.001$) (Table 1). There were no statistically significant correlations between PQ interval and QRS complexes with MELD and Child-Pugh scores in both observed groups. Similarly, there were no statistically significant differences in QTc prolongation between patients who had and had not received NSBBs (QTc $= 415.17 \pm 56.44$ vs $426.91 \pm 41.40$) ($p = 0.066$).

**Table 1:** Mean values of parameters based on etiology of cirrhosis ($n = 251$)

| Parameter | Alcoholic Cirrhosis | Non-alcoholic Cirrhosis | P-value |
|---|---|---|---|
| MELD | $14.26 \pm 7.02$ | $12.49 \pm 6.64$ | 0.075 |
| HR | $80.14 \pm 20.85$ | $74.83 \pm 15.69$ | 0.023* |
| PQ (ms) | $150.07 \pm 37.97$ | $149.98 \pm 35.82$ | 0.975 |
| QTc | $434.16 \pm 42.82$ | $410.76 \pm 52.56$ | <0.001* |
| QRS (ms) | $92.85 \pm 32.68$ | $91.33 \pm 39.85$ | 0.745 |
| QRS Voltage (precordial leads) | $14.56 \pm 5.60$ | $14.71 \pm 6.56$ | 0.849 |
| QRS voltage (limb leads) | $6.56 \pm 2.81$ | $8.12 \pm 3.30$ | <0.001* |

* Statistically significant, MELD: Model for End-Stage Liver Disease Score, HR: heart rate, OTc: corrected QT for the heart rate.

**Conclusion:** These findings imply that patients with liver cirrhosis have prolonged OTc interval, as a consequence of abnormal ventricular repolarization, and this prolongation is greater in those with alcoholic liver cirrhosis. Voltage of QRS complex in limb leads is lower in patients with advanced liver cirrhosis because of peripheral oedema. Patients who are on NSBBs for portal hypertension do not have an increased risk for ventricular arrhythmias including torsades de pointes.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Nonselective beta-blockers and angiotensin II receptor antagonists are widely used in the pharmacological treatment of portal hypertension. In the last years was reported about antifibrotic effect of angiotensin II receptor antagonists in chronic liver diseases.

**Aims & Methods:** Our study included 115 patients with liver cirrhosis in different stages. 27 patients with compensated liver cirrhosis (Child-Pugh class A) and 28 patients with decompensated cirrhosis (Child-Pugh class B and C) received Losartan 25 mg/day. 29 patients with compensated liver cirrhosis and 31 patients with decompensated cirrhosis received Propranolol 30 – 120 mg/day. Initially and after 6 months of treatment using color duplex Doppler ultrasonography we appreciated portal vein and splenic vein diameter, portal blood flow, portal blood flow velocity and hepatic artery resistance index.

**Results:** After 6 months of treatment we found different changes in different groups of study. Propranolol administration in decompensated liver cirrhosis versus compensated cirrhosis significantly decreased portal blood flow ($17.7 \pm 0.9\%$ vs $12.1 \pm 0.6\%$, $p < 0.05$), portal vein diameter ($16.8 \pm 0.7\%$ vs $11.8 \pm 0.7\%$, $p < 0.05$) and splenic vein diameter ($15.3 \pm 0.5\%$ vs $10.8 \pm 0.7\%$, $p < 0.05$). Portal blood flow velocity and hepatic artery resistance index changed significantly after 6 months of treatment in Propranolol administration groups, but no significant differences were found between these groups ($p > 0.05$). Losartan administration significantly increased portal blood flow velocity in compensated liver cirrhosis versus decompensated cirrhosis ($15.5 \pm 0.8\%$ vs $10.8 \pm 0.7\%$, $p < 0.05$) and significantly decreased hepatic artery resistance index in compensated liver cirrhosis compared with decompensated cirrhosis ($16.8 \pm 0.9\%$ vs $11.2 \pm 0.8\%$, $p < 0.05$). Portal vein and splenic vein diameter, portal blood flow changed significantly after 6 months of treatment in Losartan administration groups, but no significant differences were found between both study groups ($p > 0.05$).

**Conclusion:** Our study indicated that the target of Propranolol administration is portal blood flow that is more increased in decompensated cirrhosis. The main target of Losartan administration is intrahepatic resistance that can be better remodeled in compensated cirrhosis than in advanced liver cirrhosis. Intrahepatic resistance decreases, probably, by antifibrotic effect of Losartan, which is expressed in compensated cirrhosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0581 ULTRASOUND-BASED ELASTOGRAPHIC METHODS FOR THE PREDICTION OF ESOPHAGEAL VARICES IN LIVER CIRRHOSIS

**Introduction:** Ultrasound-based elastographic methods are non-invasive techniques for the evaluation of liver stiffness (LS) that might be also useful in the assessment of portal hypertension.

**Aims & Methods:** The aim of this study was to evaluate the performance of 4 ultrasound based elastographic methods for predicting the presence of esophageal varices (EV) in patients known with liver cirrhosis.

**Material and method**: the study included 130 consecutive subjects diagnosed with liver cirrhosis (with clinical, biological, ultrasound, endoscopical or histological signs of liver cirrhosis), in whom LS was evaluated in the same session by means of 4 elastographic methods: transient elastography (TE) (M and XL probes) (FibroScan, EchoSens), ARFI (VTQ) (Acuson S2000, Siemens), 2D-SWE [Aixplorer, Supersonic Imagining (SSI)] and 2D-SWE. GE (LOGIQ E9, General Electrics Healthcare). Reliable LS measurements were defined as: for TE, VTQ and 2D-SWE. GE-the median value of 10 measurements and for 2D-SWE the median value of 3 measurements acquired in a homogenous area. In 75 patients out of 130 all 4 elastographic methods had valid measurements and were included in the final analysis.

**Results:** 29/75 patients from the study group had EV while 46/75 had not. The mean LS values for patients without EV were lower as compared to those of patients with EV: TE ($23.02 \pm 9.67$ KPa vs. $28.01 \pm 12.81$ KPa, $p = 0.05$), 2D-SWE($20.18 \pm 11.75$ KPa vs. $23.32 \pm 14.45$ KPa, $p = 0.29$), ARFI ($2.50 \pm 0.67$ m/s vs. $2.67 \pm 0.70$ m/s, $p = 0.28$), 2D-SWE. GE ($10.69 \pm 6.52$ KPa vs. $11.47 \pm 6.46$ KPa, $p = 0.60$). TE had the best performance for predicting EV. The following cut-off were establish for predicting the EV (table):

| Elastographic technique cut off | Se | Sp | NPV | PPV | AUROC | |
|---|---|---|---|---|---|---|
| **TE** $\geq$21.1 kPa | 80.8% | 50% | 82.8% | 46.7% | 0.68 | $p = 0.04$ |
| **ARFI(VTQ):** $>3.08$ m/s | 37% | 83.3% | 70.2% | 55.6% | 0.58 | $p = 0.25$ |
| **2D-SWE:** $>13.2$ kPa | 96.3% | 25% | 92.3% | 41.9% | 0.60 | $p = 0.12$ |
| **2D-SWE. GE:** $>13.3$ kPa | 74.7% | 58.3% | 80% | 50% | 0.65 | $p = 0.02$ |

**Conclusion**: LS values assessed by any ultrasound based elastographic methods are higher in patients with EV as compared to those without EV, but TE seems to be the most predictive for the presence of EV.

## P0582 PLATELET COUNT TO PORTAL VEIN DIAMETER RATIO AS A NOVEL PREDICTOR OF ESOPHAGEAL VARICE IN PATIENTS WITH LIVER CIRRHOSIS

**A. Eshraghian**[1], S. Nikeghbalian[1], S.A. R. Taghavi[2], M. R. Fattahi[2], S.A. Malek-Hosseini[1]
[1]*Transplant Research Center, Namazi Hospital, Shiraz University of Medical Sciences, Shiraz/Iran*
[2]*Gastroenterohepatoloy Research Center, Namazi Hospital, Shiraz University of Medical Sciences, Shiraz/Iran*

**Contact E-mail Address:** eshraghiana@yahoo.com

**Introduction:** Patients with liver cirrhosis predispose to several complications with large burden of morbidity and mortality. One of the most fearful complications of liver cirrhosis is development of esophageal varices and subsequent variceal bleeding with considerable mortality. Upper endoscopy is now considered the gold standard modality for diagnosis of esophageal varices. Due to large burden of esophageal varices in cirrhosis, both their early and non invasive detection have been increasingly considered in different studies.

**Aims & Methods:** This study aimed to investigate use of platelet count to portal vein diameter ratio for detection of esophageal varices in patients with liver cirrhosis. Adult patients (>18 years) diagnosed with liver cirrhosis of different etiologies who were referred to Shiraz transplant center for liver transplantation between October 2012 and October 2015 were included in the study. All of these patients have undergone upper endoscopy for screening of esophageal and gastric varices. Color Doppler sonography of abdominal vessels and contrast enhanced abdominal computed tomography (CT) were also performed as routine pre-transplant check up for all cirrhotic patients awaiting liver transplantation. Patients 'characteristics including sex, age, underlying cause of cirrhosis as well as liver function test, coagulation profile, model for end stage liver disease (MELD) score, cell blood count, platelet cunt, size of spleen and diameter of portal vein were recorded using a data gathering form. Patients with isolated gastric varices and those with simultaneous gastric and esophageal varices were excluded.

**Results:** From 989 patients with liver cirrhosis, 524 patients (52.9%) found to have esophageal varices in upper endoscopy. Grade 1, 2 and 3 esophageal varices were found in 183, 198 and 143 patients respectively. In univariate analysis, platelet count, aspartate aminotransferase (AST), total bilirubin and alkaline phosphatase were associated wit esophageal varices ($P < 0.05$). Mean platelet count to portal diameter ratio was $6.64 \pm 0.57$ in patients with esophageal varices and $8.45 \pm 0.79$ in patients without esophageal varices ($P = 0.0001$). Mean platelet to portal vein diameter ratio in patients with grade 1 varices was $5.92 \pm 0.36$ and $6.90 \pm 0.63$ in patients with grade 2 and 3 varices ($P = 0.028$). In logistic regression analysis, Platelet count to portal diameter ratio was independently associated with the presence of esophageal varices ($P < 0.0001$).

**Conclusion:** Platelet count to portal vein diameter ratio can be used as a novel non invasive predictor of esophageal varices in patients with liver cirrhosis. It may also applicable to differentiate grade of esophageal varices in cirrhotic patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0583 RECENT TREND OF VARICEAL BLEEDING IN PATIENTS WITH PORTAL HYPERTENSION AND ITS TREATMENTS

**T. Sato**
*Gastroenterology, Sapporo Kosei Hospital Dept. of Gastroenteroloy, Sapporo/Japan*

**Contact E-mail Address:** taka.sato@ja-hokkaidoukouseiren.or.jp

**Introduction:** Esophageal varices are the most common complication of cirrhosis. Ectopic varices are portosystemic collaterals along the digestive tract outside the gastroesophageal region and are unusual and their frequency has been increasing on a current survey in Japan. In this study, we investigated recent trend of variceal bleeding in patients with portal hypertension and its treatments including ectopic varices.

**Aims & Methods:** One hundred fourteen patients with variceal bleeding and portal hypertension were evaluated retrospectively at Sapporo Kosei Hospital, Japan, from December 2012 to August 2015.

**Results:** Sites of variceal bleeding were as follows; esophageal varices in 56, cardiac varices in 15, fundal varices in 8, and ectopic varices in 35. Ectopic varices were rectal varices in 20, duodenal varices in 4, jejunal varices in 3, gastric body varices in 6 and stomal varices in 2. One hundred thirteen of 114 patients had stigmata of recent bleeding at endoscopy. Patients underwent endoscopic procedures interventional radiology and hemostatic rate was 113 of 114 cases (99.1%). Endoscopic band ligation (EBL) was successfully performed for 49 esophageal varices and endoscopic injection sclerotherapy using 5% ethanolamine oleate (EO) for 5, and EBL plus EIS for 2, respectively. EBL was performed successfully for 6 cardiac varices and EIS using EO for 6, and EBL plus EIS for 3, respectively. EIS using cyanoacrylate was successfully performed for 7 fundal varices and EIS using EO for 1. EIS using EO was performed successfully for 14 rectal varices and EBL for 4, and EBL plus EIS for 2, respectively. EIS using cyanoacrylate was successfully performed for 3 duodenal varices and EIS plus balloon-occluded retrograde transvenous obliteration for 1. EIS using cyanoacrylate was successfully performed for 2 jejunal varices, however, jejunal variceal patient who underwent percutaneous transhepatic obliteration died 2 days after treatment due to poor condition. EBL was successfully performed for 6 gastric body varices. Percutaneous sclerotherapy using EO was successfully performed for 2 stomal varices. No significant complications were observed.
**Conclusion:** Ectopic varices in patients with portal hypertension are considered to be the cause of hemorrhage presenting with gastrointestinal bleeding, and recently, their frequency has been increasing. Endoscopic treatments and interventional radiology have been performed successfully and safety for variceal bleeding including ectopic varices.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0584 REGENERATE: A PHASE 3, DOUBLE-BLIND, RANDOMIZED, PLACEBO-CONTROLLED MULTICENTER STUDY OF OBETICHOLIC ACID THERAPY FOR NONALCOHOLIC STEATOHEPATITIS

**V. Ratziu**[1], A. J. Sanyal[2], L. Macconell[3], R. Shringarpure[3], T. Marmon[3], D. Shapiro[3], Z. Younossi[4]

**Contact E-mail Address:** vlad.ratziu@upmc.fr
**Introduction:** Nonalcoholic Steatohepatitis (NASH) is a slowly progressive chronic liver disease without approved therapies. Patients with NASH and fibrosis are at high risk of increased mortality. Obeticholic Acid (OCA) is a selective and potent farnesoid X receptor (FXR) agonist, that has been shown to improve liver histology, including NAFLD activity score (NAS) and fibrosis, in a Phase 2 clinical trial (FLINT). Furthermore in FLINT, OCA treated patients had significant improvements in select liver biochemistries, markers of inflammation, and select cardiometabolic parameters.
**Aims & Methods:** The ongoing, randomized, global, Phase 3 study REGENERATE, will further evaluate the effect of OCA on liver histology and clinical outcomes in patients with biopsy-confirmed NASH with stage 2–3 fibrosis. 2065 patients will be randomized 1:1:1 to 10 mg OCA, 25 mg OCA or placebo, each added to standard of care. An interim analysis at 18 months will evaluate the effect of OCA on liver histology. Total study duration is driven by time required to accrue a total of 264 outcome events and is estimated to be ~6 years. Safety assessments will include adverse events (AEs), adjudicated cardiovascular events, and hepatic events as well as laboratory assessments. The effect of OCA on NASH and fibrosis severity will also be assessed by multiple noninvasive methods (FIB-4, APRI, transient elastography, magnetic resonance elastography, etc.).
**Results:** The co-primary liver histology endpoints at 18 months include: (I) improvement in fibrosis by ≥1 stage with no worsening of NASH and (II) resolution of NASH with no worsening in fibrosis stage. Further, confirmation of clinical benefit of OCA will be assessed at the end of the study by comparing the time to first occurrence of any of the following adjudicated events: histological progression to cirrhosis; uncontrolled ascites; hospitalization for: variceal bleed, hepatic encephalopathy or spontaneous bacterial peritonitis; hepatocellular carcinoma; liver transplant or eligibility for liver transplant (defined by model for end stage liver disease (MELD) score ≥15); and death.
**Conclusion:** REGENERATE is the first pivotal study in NASH, designed in conjunction with FDA and meant to support approval of OCA for NASH with fibrosis. This robust Phase 3 study is designed to evaluate the effect of OCA on liver histology and effects on progression to cirrhosis, liver-related clinical outcomes and mortality.

## P0585 RISK FACTORS FOR OVERT HEPATIC ENCEPHALOPATHY AFTER TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT IN PATIENTS WITH LIVER CIRRHOSIS

**H. Tong**, H. Wu, B. Wei, H. Huan, L. Zhang, C. Tang
*Department Of Gastroenterology, West China Hospital, Sichuan University, Chengdu/China*

**Contact E-mail Address:** doctortonghuan@163.com
**Introduction:** Transjugular intrahepatic portosystemic shunt (TIPS) is gradually widely applied in the treatment for variceal bleeding and refractory ascites in patients with liver cirrhosis. Although the patients are carefully selected before the operation, hepatic encephalopathy (HE) is still the main complication of TIPS. However, the risk factors for HE after TIPS procedure were seldom studied.
**Aims & Methods:** This study aims to investigate the risk factors for overt HE within 6 months after undergoing TIPS. The patients with liver cirrhosis who received TIPS in our department during 2014–2015 were screened and reviewed. The occurrence of HE and its first episode time during 6 months after TIPS were recorded. In addition, the age, gender, underlying chronic liver disease, data of the complete blood cell count, liver function test, blood ammonia, renal function test, electrolyte and prothrombin time (PT) before TIPS performance were recorded, and Child-Pugh grade and MELD score were also obtained. Furthermore, Cox proportional hazard regression model was utilized to determine the hazard ratios (HRs) of factors described above for overt HE within 6 months after undergoing TIPS.
**Results:** 102 patients were screened, 28 patients were excluded for incomplete data, and 74 patients (gender: male/female 52/22; age: 53.1 ± 11.6 years; Child-Pugh grade: A/B 34/40; MELD score: 5.87 ± 4.50) were finally included in this study. 60 patients and 14 patients received TIPS for variceal bleeding and refractory ascites, respectively. 26 patients (35.1%) experienced overt HE within 6 months after receiving TIPS, with a median first episode time of 21.5 days. The HRs of factors for overt HE were as below: age 1.100 (95% CI: 1.011–1.198, p = 0.028), gender 0.042 (0.001–1.233, 0.066), underlying liver disease [hepatitis virus B infection 8.500 (0.722–100.127, 0.089), hepatitis C infection 19.576 (0.467–821.219, 0.119), alcohol 0.080 (0.004–1.654, 0.102), primary biliary cholangiolitis 2657.450 (11.316–624053.3, 0.005), others 3.307 (0.035–313.085, 0.606)], erythrocyte 10.885 (0.850–139.392, 0.067), leukocyte 0.890 (0.432–1.834, 0.753), platelet 1.018 (0.985–1.051, 0.295), direct bilirubin 1.746 (1.031–2.959, 0.038), indirect bilirubin 0.912 (0.800–1.040, 0.170), alanine transarninase 1.001 (0.933–1.074, 0.980), aspartate aminotransferase 0.912 (0.826–1.006, 0.066), albumin 1.242 (0.991–1.558, 0.060), alkaline phosphatase 1.044 (1.015–1.073, 0.002), blood ammonia 1.030 (0.989–1.072, 0.160), blood urea nitrogen 0.993 (0.689–1.264, 0.656), creatinine 0.948 (0.896–1.003, 0.064), blood sodium 0.837 (0.609–1.151, 0.273), blood potassium 1.314 (0.076–22.600, 0.851), PT 18.422 (1.664–203.986, 0.018), Child-Pugh grade 1.397 (0.333–5.865, 0.648) and MELD score 4.127 (0.117–145.049, 0.435).
**Conclusion:** Age, primary biliary cholangiolitis, direct bilirubin, alkaline phosphatase and PT are the risk factors for overt HE in a 6-month follow-up after TIPS procedure in patients with liver cirrhosis. However, Child-Pugh grade and MELD score are not the risk factors for overt HE after TIPS performance in well-selected patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0586 ACUTE KIDNEY INJURY IN HOSPITALIZED PATIENTS WITH CIRRHOSIS: ASSOCIATION WITH MORTALITY AT 30 DAYS

C. Teixeira, C. Martins, E. Dantas, **D. Trabulo**, A. Alves, I. Cremers, A. P. Oliveira
*Gastroenterology, Centro Hospitalar de Setubal, Setúbal/Portugal*

**Contact E-mail Address:** danieltrabulo@yahoo.com
**Introduction:** Acute kidney injury (AKI) occurs in about 20% of hospitalized cirrhotic patients. The Acute Kidney Injury Network (AKIN) defined AKI as a percentage increase in serum creatinine (sCr) of more than or equal to 50% from the stable baseline value in < 3 months or by an absolute increase in sCr of 0.3 mg/dl in < 48 h.
**Aims & Methods:** Retrospective analysis of cirrhotic patients hospitalized in our department during 2 years. Definition of AKI and staging according to AKIN criteria. Classification of etiology of AKI as pre-renal, parenchymal and hepatorenal syndrome. Evaluation of outcome of AKI (regressive, persistent, progressive). Analysis of association between AKI and mortality at 30 days.
**Results:** 95 patients, 85.3% male, mean age 62.4 years. The main etiologies of cirrhosis were: alcoholic in 71.6% and hepatitis C virus in 14.7%. AKI was present in 42.1% of the patients. Regarding staging: 17.9% AKI 1, 14.7% AKI 2 and 9.5% AKI 3. Etiology of AKI: pre-renal in 75%, parenchymal in 12.5% and hepatorenal syndrome in 12.5%. Concerning AKI outcome: regressive in 72.5%, persistent in 12.5% and progressive in 15%. More patients with AKI were admitted in intensive care unit (17.5%) than patients without AKI (1.85%) (p = 0.007). There were no differences in gender, age, etiology of cirrhosis or Child-Pugh score between patients with or without AKI. In univariate analysis, mortality at 30 days was associated with AKI, Child-Pugh C and infection (p < 0.05). Mortality correlated with AKI outcome (Rs = 0.440; p = 0.000). In multivariate analysis, mortality at 30 days was associated with AKI (p = 0.001; OR = 10.38) and Child-Pugh C (p = 0.018; OR = 4.89).
**Conclusion:** In patients with cirrhosis, AKI was associated with 30-day mortality. Progression of AKI was also associated with a worse outcome. It is therefore essential to early identify the development of AKI and start an adequate treatment to improve outcome.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0587 HEPATITIS C VIRUS INFECTION TREATMENT WITH SOFOSBUVIR-LEDIPASVIR: SUSTAINED VIROLOGIC RESPONSE PREDICTING FACTORS

**M.A. Kopke Tulio**, L. Carvalho, S. Marques, J. Rodrigues, J. Carmo, P. Costa, R. Herculano, F. Augusto, P. Barreiro, M. Bispo, T. Bana, E Costa, L. Lebre, P. Peixe, C. Chagas

**Contact E-mail Address:** mariaanatulio@yahoo.com

**Introduction:** Direct-acting antivirals (DAA) have revolutionized the treatment of hepatitis C virus (HCV) infection, with the available clinical trials showing high sustained virologic response (SVR) rates with short treatment regimes, convenient pharmaceutical forms and high tolerability when compared to previous treatment options. However, additional studies are still necessary in order to evaluate the real tolerability of these agents in the daily clinical practice.

**Aims & Methods:** Our objective was to assess the efficacy and safety of Sofosbuvir-Ledipasvir treatment for HCV-infected patients in the daily practice of a tertiary care centre, as well as to identify SVR predicting factors, in order to ascertain if certain subgroups of patients may be in higher risk of HCV relapse. The group of patients with HCV treated with Sofosbuvir-Ledipasvir between February 2015 and January 2016 at our centre was analyzed.

**Results:** Our sample included 172 patients, 113 males (65.7%) and 59 females (34.3%), with a mean age of 55 years (32–84 years). 117 patients (68%) underwent treatment for 12 weeks and the remaining 55 (32%) for 24 weeks, with 16 patients (9.3%) having concomitant administration of Ribavirin. Genotype distribution was the following: genotype 1 – 77.3% (133/172), genotype 3–2.9% (5/172), genotype 4 – 19.2% (33/172), genotype 5–0.6% (1/172). 75 patients (43.6%) were treatment-naïve. Distribution according to fibrosis stages was as follows: F0 0.6% (1/172), F1 15.7% (27/172), F2 32.6% (56/172), F3 24.4% (42/172), F4 26.7% (46/172). Regarding treatment response rates, 86.6% (149/172) of patients had Rapid Virological Response (RVR), with 30 patients having $<15$ IU/mL viral load, and 96.5% (166/172) of patients had End of Treatment Response (ETR). The global SVR rate was 94.2% (162/172), with the following distribution according to genotype and fibrosis stage: genotype 1–96.2% SVR (98% (100/102) for $\leq$F3 patients and 90.3% (28/31) for F4 patients), genotype 3–80% SVR (4/5 F4 patients), genotype 4 – 87.9% SVR (100% (23/23) for $\leq$F3 patients and 60% (6/10) for F4 patients – only one relapse, one stop treatment for adverse event and two dies for no treatment related event) and genotype 5–100% SVR (1/1 $\leq$F3 patient). Patients with genotype 1 or genotype 4 HCV infection were analyzed in order to identify possible SVR predicting factors (genotypes 3 and 5 were not considered for this analysis due to their reduced proportion in our sample). There was a statistically significant association between SVR and fibrosis stage (98.4% SVR in $\leq$F3 patients and SVR 82.9% SVR in F4 patients, $p < 0.001$) and between SVR and ETR ($p < 0.001$). Moreover, there was a statistically significant association between SVR and RVR when $<15$ IU/mL was considered as negative viral load ($p = 0.005$) but not if $<15$ IU/mL was considered as positive viral load ($p = 0.075$). No association was identified, in our sample, between SVR and naïve status or IL28B ($p = 0.993$ and $p = 0.880$, respectively). Mild adverse events were reported by 35 patients (19.7%), with headache being the most common (6.2% of patients). Two adverse events lead to stop treatment at first week treatment (pancreatitis and diarrhea).

**Conclusion:** In our sample of HCV-infected patients, treatment with Sofosbuvir-Ledipasvir was well tolerated and achieved SVR in more than 98% of non-cirrhotic patients. Fibrosis stage $\leq$F3, ETR and RVR (considering $<15$ IU/mL as negative viral load) were associated to SVR.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0588 TOLL-LIKE RECEPTOR 7 AND INTERFERON LAMBDA 1 IN CHRONIC HEPATITIS C: RELATION TO VIRUS REPLICATION AND LIVER INJURY

H. El-Aggan[1], N. Farahat[2], N. El-Deeb[3], A. Zeid[1], **A. El-Shandidi**[1]

[3]*Pathology, Faculty of Medicine, University of Alexandria, Alexandria/Egypt*

**Contact E-mail Address:** dr-3asem@hotmail.com

**Introduction:** Toll-like receptor 7 (TLR7) can recognize single-stranded RNA viruses like hepatitis C virus (HCV) with subsequent induction of different interferon (IFN) types, including IFN lambdas (IFN-λ), which play an important role in antiviral innate immunity.

**Aims & Methods:** The present work was designed to study the role of TLR7 and IFN-λ1 in chronic hepatitis C (CHC) in relation to virus replication and liver injury. Forty-two treatment-naive patients with CHC and 20 healthy subjects were included in the study. Circulating TLR7-expressing peripheral blood mononuclear cells (PBMC) were identified by color flow cytometry and were expressed as percentages of total lymphocyte count. Quantification of IFN-λ1 levels in serum was performed using enzyme-linked immunosorbant assay. Liver biopsies were examined for assessment of histological activity grade and fibrosis stage according to METAVIR scoring system, and steatosis grade. Immunohistochemical staining was performed using antibodies against TLR7 and IFN-λ1 and was scored semi-quantitatively. The hepatic expression of TLR7 and IFN-λ1 was further classified into: low expression (score 0 or 1) and high expression (score 2 or 3).

**Results:** The percentages of circulating TLR7-expressing PBMC and serum IFN-λ1 levels showed significant increases in patients with CHC compared to healthy subjects ($P = 0.025$ and $P < 0.001$ respectively) and were positively correlated ($P < 0.001$). The hepatic TLR7 and IFN-λ1 expression was low in 35.7% and 23.8% of patients respectively; and was high in 64.3% and 76.2% of patients respectively. The patients with low hepatic TLR7 and IFN-λ1 expression showed significant decreases in the percentages of circulating TLR7-expressing PBMC and serum IFN-λ1 levels; and showed significant increases in serum aminotransferases, viral load and METAVIR histological activity grade and fibrosis stage compared to patients with high hepatic expression ($P < 0.01$). The expressions of TLR7 and IFN-λ1 in the liver were positively correlated in HCV-infected patients ($P < 0.001$).

**Conclusion:** Dysregulation of TLR7/IFN-λ1 signaling pathway seems to play an important role in viral replication and HCV-related liver injury and could be a potential therapeutic target in chronic HCV infection.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The proportion of HCV infected patients over age 65 years in Western countries is increasing. This growth and the advent of new antiviral therapy bring us to consider which is the efficacy and safety in the ''real world'' of a combination of Sofosbuvir and Simeprevir (SOF/SMV) plus a flat dose of ribavirin (RBV) in elderly patients compared to younger patients.

**Aims & Methods:** This study was a multicenter, real-world investigation of once daily treatment with SOF 400 mg+ SMV 150 mg with a flat dose of RBV 800 mg/day for a duration of 12 weeks in treatment naïve or experienced HCV genotype 1-infected patients with compensated cirrhosis. Patients were divided into two groups by age: Group I with less than 65 years of age and Group II aged more than 65 years

**Results:** Of the 262 patients enrolled in the study, 130 (49.6%) were $>65$ years of age (Group II) and 32 $<65$ (Group I). HCV genotype 1a was more frequent in Group I patients compared to Group II (25% vs 5.4% $p < 0.0001$) Sustained virological response at week 4 (SVRw4) and week 12 (SVRw12) was achieved by 94.7% (125/132) of those aged $<65$ years and 97.7% (127/130) of those $>65$. Diabetes was the most common comorbidity in patients $>65$ years compared to younger patients (26.2% vs 12.1% $p < 0.03$) but, this comorbidity did not affect SVR overall. Hepatocellular carcinoma in the Milano criteria was more common in older vs younger patients (16.9% vs 4.5% $p < 0.001$). The most common adverse event (AE) in older patients was a grade 2 anemia (36.2% vs 20.6% $p < 0.01$) but no interruption of antiviral treatment due to anemia was recorded among the older.

**Conclusion:** SOF/SMV plus a daily flat dose of RBV 800 mg for a period of 12 weeks was highly effective and safe in older patients with HCV genotype 1 and cirrhosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0590 DIRECT OBSERVED THERAPY OF CHRONIC HEPATITIS C WITH INTERFERON-FREE ALL-ORAL REGIMENS AT A LOW-THRESHOLD DRUG TREATMENT FACILITY – A NEW CONCEPT FOR TREATMENT OF PATIENTS WITH BORDERLINE COMPLIANCE RECEIVING OPIOID SUBSTITUTION THERAPY

**S. Moser**[1], A. Schütz[2], K. Marchart[2], S. Ambrosch[2], J. Luhn[2], E. Gutic[1], H. Haltmayer[2], M. Gschwantler[1]
[1]*Wilheminenspital Wien 4. Abt. für Medizin, Wien/Austria*
[2]*Suchthilfe Wien gGmbh, vienna/Austria*

**Contact E-mail Address:** dr.stephan.moser@gmail.com

**Introduction:** An important subgroup of people who inject drugs (PWID) receives opioid substitution therapy (OST) under direct observation of a physician or nurse at a low-threshold drug treatment facility or pharmacy on a daily basis. Most of these patients suffer from psychiatric comorbidities and are reluctant or unable to go to specialized hepatitis centers. Our hypothesis was that chronic hepatitis C in these difficult-to-treat patients could be optimally managed if modern, interferon-free regimens were applied together with OST under direct observation of a physician or nurse at a low-threshold drug treatment facility.
**Aims & Methods:** Fifty-two PWID with chronic hepatitis C and borderline compliance (male/female: 41/11; mean age: 39.0 ± 9.7 years; genotype (GT) 1/3/4: 41/10/1) started interferon-free treatment of chronic hepatitis C at the "Ambulatorium Suchthilfe Wien" – a low-threshold drug treatment facility in Vienna, Austria. Four patients were coinfected with HIV and 13 had liver cirrhosis. Patients received antiviral treatment together with OST under direct observation of a physician or nurse. For each patient, the individual treatment regimen was selected according to genotype, fibrosis stage, pretreatment, HIV-status and current reimbursement policy of insurances.
**Results:** Following this concept of directly observed therapy, adherence to antiviral therapy was excellent: Only one scheduled date, out of 3.228 dates (0.03%), for ingestion of the antiviral therapy in combination with OST was missed by the 52 patients. Till now, 23 patients (male/female: 20/3; mean age: 39.3 ± 7.0 years; GT1/3/4: 18/4/1; liver cirrhosis present in 7 patients) have completed treatment and a 12-week follow-up period. Virologic healing of hepatitis C infection (sustained virologic response, SVR12) could be confirmed in all 23 patients (SVR12 rate: 100%).
**Conclusion:** Directly observed therapy of chronic hepatitis C with interferon-free all-oral regimens at a low-threshold drug treatment facility represents a promising new concept for treatment of patients with borderline compliance receiving OST. By this concept chronic hepatitis C can be cured in a group of difficult-to-treat patients, who are unable to be treated at hepatologic centers. It should be stressed that successful treatment of these patients is not only beneficial for themselves but also for the general population because further transmission of the virus may be prevented.

## P0591 PROMOTION OF INTRA-HOSPITAL REFERRAL OF HEPATITIS B AND C VIRUS CARRIERS TO HEPATOLOGY SPECIALISTS BY ELECTRONIC MEDICAL RECORD-BASED ALERT SYSTEM: A CASE STUDY AT A UNIVERSITY HOSPITAL

**M. Enomoto**[1], S. Uchida-Kobayashi[1], H. Fujii[2], A. Iida-Ueno[1], H. Motoyama[1], R. Kozuka[1], A. Hagihara[1], E. Kawamura[1], H. Morikawa[1], Y. Murakami[1], A. Tamori[1], N. Kawada[1]
[1]*Department Of Hepatology, Osaka City University Hospital, Osaka/Japan*
[2]*Department Of Gastroenterology, Osaka City Juso Hospital, Osaka/Japan*

**Contact E-mail Address:** enomoto-m@med.osaka-cu.ac.jp

**Introduction:** Due to advances in antiviral therapy, most patients with chronic viral hepatitis have become treatable. However, because most patients do not have subjective symptoms, there are still a number of hepatitis virus carriers who are not aware of their infection. Although testing for the hepatitis B and C virus (HBV or HCV) is performed in daily practice as a preoperative or pretransfusion screening, it remains unclear whether intra-hospital collaboration regarding hepatitis virus carriers identified by the screening testing occurs appropriately in non-hepatology departments even within a large hospital, such as our university hospital.
**Aims & Methods:** Osaka City University Hospital (having 982 beds in 24 wards) developed an alert system in April 2013 to promote referral of hepatitis B surface antigen (HBsAg)-positive or anti-HCV-positive patients to the Department of Hepatology through electronic medical records. Additionally, we changed the preoperative assessment manual of the Department of Anesthesiology to promote the referral of patients who tested positive to the Department of Hepatology. In this study, we investigated the status of hepatitis virus testing in fiscal 2012, the change in the number of referrals related to hepatitis viruses to the Department of Hepatology between the fiscal years 2012 and 2013, the distribution of patients referred in fiscal 2013, and the subsequent clinical courses of the patients following these referrals.
**Results:** In fiscal year 2012, before the introduction of the system, HBsAg screening testing was performed in 13,004 cases, and anti-HCV was performed in 12,374; 450 (3.46%) patients were positive for HBsAg, and 711 (5.75%) were positive for anti-HCV. Positive results in both tests were found most frequently in the Department of Hepatology, followed by surgery-related departments, such as the Department of Orthopedics, Ophthalmology, and Otolaryngology. Since the introduction of the new system, the number of intra-hospital referrals regarding hepatitis virus infections increased from 18.8 ± 5.7 to 29.0 ± 4.5 per month. A steady stream of referrals originated from departments in which there were more patients who tested positive for the hepatitis virus. Some referred patients had progressed to cirrhosis or hepatocellular carcinoma while they were unaware of the infection.
**Conclusion:** This electronic medical record-based alert system is useful for promoting the intra-hospital referral of hepatitis virus carriers who are detected by screening tests to hepatology specialists and is thus considered to be important in the appropriate management of chronic viral hepatitis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0592 CHANGES IN LIPID PROFILE WITH TREATMENT OF HEPATITIS C WITH DIRECT-ACTING ANTIVIRALS

**M.J. Silva**, T. Capela, R. Vasconcelos Loureiro, V. Borges, C. Bernardes, P. Russo, F. Calinas
*Gastroenterology, Centro Hospitalar de Lisboa Central, Lisboa/Portugal*

**Contact E-mail Address:** mariojorgesilva01@gmail.com

**Introduction:** Chronic infection with hepatitis C virus (HCV) is associated with both a disturbed intrahepatic lipid metabolism and an altered pattern of circulating lipoproteins.
**Aims & Methods:** We aimed to evaluate the impact of treatment of hepatitis C with direct-acting antivirals without interferon (DAA) on serum lipid profile. Analysis of all patients with chronic hepatitis C treated with DAA in one center, from whom measurements of total cholesterol (TChol), low-density lipoproteins (LDL), high-density lipoproteins (HDL) and/or triglycerides (TG) were performed at first day of therapy (baseline), end-of-treatment (EOT) and/or 12 weeks after EOT (PT12). Patients on lipid lowering drugs or with detectable HCV viral load on PT12 were excluded. Hepatitis C treatment regimens were selected according to national and/or EASL recommendations. Statistical analysis performed with STATA® v12.1 and Excel® 2010.
**Results:** Forty-two patients were analysed, 73.8% (31/42) male, median age 55 years (41;72), 14.3% (6/42) of them obese (IMC > 30 kg/m$^2$). Twenty-five (59.5%) patients had HCV genotype 1, 14 patients had HCV genotype 3, and 3 patients had HCV genotype 4. Twenty-nine patients had cirrhosis. All patients were treated with sofosbuvir/ledipasvir, with or without ribavirin, during 12 or 24 weeks, and had HCV viral load < 15UI/mL on EOT. During treatment with DAA (from baseline to EOT), there was a significant rise in mean TChol (from 159.4 mg/dL to 182.5 mg/dL; n = 41; $p < 0.001$) and LDL (from 90.3 mg/dL to 116.4 mg/dL; n = 40; $p < 0.001$), whereas TG decreased significantly (from 100.7 mg/dL to 83.5 mg/dL; n = 41; $p < 0.001$) and HDL levels remained stable (from 45.2mg/dL to 46.1 mg/dL; n = 40; p = 0.63). On PT12, mean TChol levels (171.2 mg/dL vs 151.1 mg/dL; n = 20; $p < 0.01$) and mean LDL levels (105.8 mg/dL vs 79 mg/dL; n = 19; $p < 0.01$) remained significant higher than on baseline; while HDL levels (46.8 mg/dL vs 48.7 mg/dL; n = 19; p = 0.60) and TG levels (94.8 mg/dL vs 91.6 mg/dL; n = 18; p = 0.77) were similar to those on baseline. Similar trends were observed on sub-analyses for HCV genotype and disease stage.
**Conclusion:** We observed significant changes in lipid profile with treatment of hepatitis C with direct-acting antivirals. Further studies are needed, investigating possible influence of treatment regimen and if the observed changes in lipid profile persist in the long-term.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0593 EMERGENCE OF MULTIDRUG-RESISTANT HEPATITIS C VIRUS DURING INTERFERON-FREE THERAPY WITH ASUNAPREVIR AND DACLATASVIR AFTER SIMEPREVIR-BASED TRIPLE THERAPY FOR RECURRENT HEPATITIS C AFTER LIVER TRANSPLANTATION

**Y. Ueda**[1], H. Takeda[1], S. Ohtsuru[1], S. Uemoto[2], H. Marusawa[1]

[2]*Surgery, Kyoto University, Kyoto/Japan*

**Contact E-mail Address:** yueda@kuhp.kyoto-u.ac.jp

**Introduction:** The treatment for hepatitis C virus (HCV) has dramatically changed with the introduction of direct-acting antivirals (DAAs). The efficacy and safety of interferon-free therapy after liver transplantation have been recently confirmed[1)]. However, the emergence of HCV resistance to DAAs is a major obstacle of interferon-free therapy, especially in patients who had prior DAA-containing therapy.
**Aims & Methods:** This study aimed to clarify the dynamic changes of resistance-associated variants during interferon-free therapy with asunaprevir and daclatasvir after simeprevir-based triple therapy for recurrent hepatitis C after liver transplantation. Daclatasvir (60 mg/day) and asunaprevir (200 mg/day) were administered to 15 patients with recurrent hepatitis C genotype 1 b after liver transplantation. Efficacy and safety of this therapy were clarified. Resistance-associated substitutions in NS3 and NS5A region of HCV genome were analyzed before and after the therapy in patients who did not achieve sustained virological response (SVR) by using the ultra-deep sequencing analysis.
**Results:** Eight patients were treatment-naive, and 7 patients were treatment-experienced with peginterferon and ribavirin in 3 patients, and with simeprevir, peginterferon, and ribavirin in 4 patients. SVR was achieved in 9 of the 15 patients, resulting in the 60% SVR rate. In the 6 non-SVR patients, 4 had simeprevir-based triple therapy before this interferon-free therapy. Although none of the 4 patients had resistance-associated substitutions at D168 of NS3 region before simeprevir-based triple therapy, the D168-resistant associated variants became dominant HCV clones at the viral breakthrough or relapse in the simeprevir-based therapy. At 4 to 9 months after the termination of simeprevir administration, interferon-free therapy with asunaprevir and daclatasvir was

initiated. Emergence of multidrug-resistant HCV with resistance-associated substitutions at D168 of NS3 region and at L31, L32, and/or Y93 of NS5A region was observed in the 4 patients during asunaprevir and daclatasvir administration. Sofosbuvir and ledipasvir for 12 weeks successfully eradicated the multidrug-resistant HCV in a case.
**Conclusion:** Interferon-free therapy with asunaprevir and daclatasvir for 24 weeks was well tolerated and resulted in 60% of SVR in liver transplant recipients with HCV genotype 1 b infection. Resistance-associated variants induced by the prior simeprevir administration resulted in the emergence of multidrug resistant HCV and the treatment failure of this interferon-free therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** smaxavier@gmail.com
**Introduction:** Hepatic fibrosis occurs in response to sustained hepatic injury. Withdrawal of the aggressive agent may allow regression of the fibrotic process.
**Aims & Methods:** Aims: Assess the impact of new Hepatitis C treatments in hepatic fibrosis determined by non-invasive biologic scores. Methods: Included patients that systematically concluded treatment with sofosbuvir/sofosbuvir + ledipasvir. Four non-invasive biologic scores (Forns Index, APRI, GUCI e FIB-4) were calculated before the treatment (T0), at the fourth week of treatment (T4) and at the end of treatment (Tfinal). Statistical analysis was preformed with SPSS v21.0, and a value of $p < 0.05$ was considered statistically significant.
**Results:** Twenty eight patients included. Genotype 1 was the most frequent in 64.3%. Previous treatment was performed in 57.1% of patients. At the beginning of treatment, 32.1% of patients were classified as fibrosis stage F4. We found statistically significant differences between score values at T0 and T4 as well as between T0 and Tfinal, as accessed by Forns Index (6.85 vs 6.09, $p < 0.01$ and 6.85 vs 5.92, $p < 0.01$), APRI (1.83 vs 0.48, $p < 0.01$ and 1.83 vs 0.51, $p < 0.01$), GUCI (2.03 vs 0.55, $p < 0.01$ and 2.03 vs 0.57, $p < 0.01$) and FIB-4 (2.71 vs 1.53, $p < 0.01$ and 2.71 vs 1.56, $p < 0.01$). No differences were found between the values of fibrosis at T4 and Tfinal for any score. Only for FIB-4 score did we found significant differences in the variation of score between patients with initial fibrosis F1–3 vs F4 (0.71 vs 2.1, $p = 0.03$).
**Conclusion:** New treatments associate with significant and precocious variation in non-invasive biologic scores for hepatic fibrosis. It becomes relevant to compare these findings with non-invasive physical scores and, eventually, with histology, to assess if analytic improvement translates, in equal proportion, in parenchymal/histologic improvement.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0595 RISK FACTORS FOR PRIMARY SCLEROSING CHOLANGITIS RECURRENCE AFTER LIVER TRANSPLANTATION

**L. Bajer**[1], E. Sticova[2], P. Macinga[1], R. Janousek[3], P. Trunecka[4], J. Spicak[1], P. Drastich[1]

[4]*Transplantcentre, IKEM, Prague/Czech Republic*

**Contact E-mail Address:** lukasbajer1@gmail.com
**Introduction:** Primary sclerosing cholangitis (PSC) is a chronic liver disorder of unknown etiology, characterized by inflammation, fibrosis and stenoses. The disease may progress to cirrhosis and eventually to liver failure and death. For those who develop end – stage liver disease, orthotopic liver transplantation (OLT) remains the only effective treatment currently available. However, recurrent form of PSC (rPSC) often appears in patients after OLT and may eventually lead to graft loss and liver re – transplantation (re – OLT). The aim of our retrospective study was to identify risk factors for rPSC.
**Aims & Methods:** A total number of 115 orthotopic liver transplantations for PSC were performed at Institute for Clinical and Experimental Medicine, Prague, Czech Republic between July 1994 and May 2015. The diagnosis of rPSC was based on histology and cholangiographic findings. We retrospectively analyzed medical records of all PSC patients from our computed database. Only patients with a proper record of pre – OLT ($\leq$12 months) colonoscopy and those monitored for a time period of $\geq$ 60 months post – OLT were included. Input data were analyzed using JMP statistical software. Student's t-test, Fisher's exact test and nominal logistic regression were used to assess the data. A p – value $< 0.05$ was considered as statistically significant.
**Results:** After applying inclusion/exclusion criteria, we analyzed a cohort of 47 patients. 31 were male, 16 female, with median age of 36 (range 15–68) and median follow – up 122 months (range 60–249) after OLT. In 21/47 (44.7%) patients, rPSC was diagnosed during the follow – up. Two patients underwent re – OLT (after 103 and 116 months respectively, both for rPSC). According to performed univariate analysis, presence of de – novo colitis ($p = 0.0002$; OR 27.50, 95% CI 3.13 – 241.94) and OLT for overlap with autoimmune hepatitis (PSC/AIH) ($p = 0.0133$) were significantly associated with rPSC. Presence of HLA-DRB1*04 in the recipient was identified as protective factor for rPSC ($p = 0.0287$). In case of de – novo colitis, statistical significance was further confirmed by nominal logistic regression analysis ($p = 0.0094$; OR 22.00, 95% CI 2.04 – 591.60). Neither gender, nor age, CMV infection, acute cellular rejection (ACR), corticoresistant ACR, use of OKT3, presence of HLA-DRB1*08, history of cholangiocarcinoma, cold ischemia time and length of corticosteroids use were significantly associated with rPSC.
**Conclusion:** Recurrent PSC is an important clinical entity with high prevalence in patients after OLT. De – novo colitis is a significant risk factor associated with rPSC, along with PSC/AIH overlap, while presence of HLA-DRB1*04 in the recipient appeared to have a protective effect on rPSC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0596 HEPATIC COMPUTED TOMOGRAPHY VOLUMETRY FOR NON INVASIVE PREDICTION OF HEPATIC STEATOSIS AND STEATOHEPATITIS IN LIVING RELATED LIVER TRANSPLANTATION

**A. Eshraghian**[1], A. Rasekhi[2], S. Nikeghbalian[1], S.A. Malek-Hosseini[1]

**Contact E-mail Address:** eshraghiana@yahoo.com
**Introduction:** Macrovesicular hepatic steatosis is associated with complications after living related liver transplantation. Therefore, detection of hepatic steatosis in potential organ donors by liver biopsy has an important role to prevent future adverse outcomes. Since liver biopsy is an invasive procedure, several attempts have been made to find a non invasive method for precise estimation of hepatic steatosis.
**Aims & Methods:** This study aimed to investigate the role of hepatic computed tomography (CT) volumetry in detection of hepatic steatosis in living liver donors. A cross sectional study was conducted between August 2012 and August 2015 at Namazi hospital, Shiraz, Iran. Study subjects were healthy individuals who had undergone liver biopsy for evaluation of liver histology as a routine pre-transplant check up before living related liver transplantation. Liver function tests, age, gender, weight, height, fasting plasma glucose, and lipid profile were recorded. Liver biopsy specimens were reviewed by an expert pathologist for hepatic steatosis and steatohepatitis. Spiral abdominal CT scan with intravenous contrast enhancement was performed for all patients. The total volume of liver, volume of left lobe and left lateral segment were recorded. These measures were compared in those with and without hepatic steatosis/steatohepatitis.
**Results:** Totally 177 individuals were included. Sixty four individuals had biopsy proven macrovesicular steatosis. Mean age of individuals with and without hepatic steatosis in liver biopsy were $32.39 \pm 6.53$ years and $31.82 \pm 6.88$ years respectively ($P = 0.6$). In univariate analysis, weight, serum triglyceride, cholesterol, alanine aminotransferase, alkaline phosphatase and fasting plasma glucose were associated with hepatic steatosis ($P < 0.05$). Mean total volume of the liver was $1530.1 \pm 273.3$ $cm^3$ in those with hepatic steatosis and $1395.4 \pm 231.4$ $cm^3$ in those without hepatic steatosis ($P = 0.003$). Mean volume of left lateral segment of the liver was $221.9 \pm 69.9$ $cm^3$ in individuals with hepatic steatosis and $196.3 \pm 64.7$ $cm^3$ in individuals without hepatic steatosis ($P = 0.039$). In logistic regression analysis, neither total liver volume nor volume of left lateral segment of the liver were predictor of hepatic steatosis ($p > 0.05$). Sixteen individuals had steatohepatitis in their liver biopsy. In univariate analysis, higher weight, serum triglyceride, and alanine aminotransferase were associated with hepatic steatohepatitis ($P < 0.05$). Mean total volume of the liver was $1705.2 \pm 256.5$ $cm^3$ in those with hepatic steatohepatitis and $1419.4 \pm 241.2$ $cm^3$ in those without hepatic steatohepatitis ($P = 0.0001$). In logistic regression analysis, higher total volume of the liver was an independent predictor of hepatic steatohepatitis (OR: 1.005; 95% CI: 1.001–1.010, $P = 0.012$). A cut off value of 1531 $cm^3$ for total volume of the liver was predictor of presence of steatohepatitis in liver biopsy of donors (sensitivity = 83%; specificity = 71%; area under curve = 0.809; P-value = 0.0001).
**Conclusion:** CT volumetry can be considered as a non invasive method for prediction of hepatic steatosis of donors in living related liver transplantation. Higher total volume of the liver is an independent factor that predicts hepatic steatohepatitis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0597 PARACETAMOL-INDUCED ACUTE LIVER FAILURE IN A PORCINE MODEL IS ASSOCIATED WITH SIGNIFICANT GUT DYSBIOSIS

**R. Sinha**[1], M. H. Karavolos[2], P. Treskes[3], P. C. Hayes[1], J.N. Plevris[1]

[3]*Hepatology Lab, The University of Edinburgh, Edinburgh/United Kingdom*

**Contact E-mail Address:** rohits78@gmail.com

**Introduction:** Gut dysbiosis is implicated in chronic liver disease, however little is known in the context of acute liver failure.

**Aims & Methods:** In this study, we investigated the changes in the gut microbiome in a porcine model of paracetamol-induced acute liver failure. We induced acute liver failure in seven weight-matched female pigs (*Sus scrofa domesticus*) with a toxic dose[1] of paracetamol 1 gm/kg intravenously. Signs of acute liver failure were evident at 24hours. Animals were monitored and managed for a total study duration of 48 hours following best practice. Stool specimen was collected upon initiation of paracetamol (T = 0) and after 48 hours (T = 48). Microbiome analysis was accomplished using the method described by Wu et. al[2]. DNA was extracted[3]using a QIAamp DNA stool mini-kit (QIAGEN). Pyrosequencing reads were uploaded onto QIIME software (http://qiime.org/), classified, aligned and processed into phylogenetic trees as described previously[3]. Statistical analysis was performed using UniFrac software (http://bmf.colorado.edu/unifrac); by comparing distances within groups to distances between groups[4]. Comparisons was summarised using the t-statistics and significance assessed using 10000 permutations[3]. Sequencing 16 S rRNA gene pool from specimens was used to identify the microbial landscape in the gut and perform grouping by shared sequence characteristics (taxonomical assignment).

**Results:** In established acute liver failure at 48hrs, OTU (Operational Taxonomic Units) observed at the level of family changes in statistically significant abundance were Ruminococceae and Spirochaetaceae. There was a relative increase in the abundance of Fibrobacter intestinalis, and Ruminococus gnavus at the expense of Lactobacillus genus belonging to Firmicutes phylum. Dysbiosis ratio[5] changed significantly ($p = 0.042$) in paracetamol-induced acute liver failure reflecting a rapid shift in gut microbiome. Between the groups (0 h and 48 h), significant OTU difference at the family level [Analysis of similarities (ANOSIM R): 0.242, p-value: 0.0075; Bray-Curtis metrics], with only marginal differences (chi squared metrics) at genus level but no difference at species levels was observed. Wilcoxon test did not reveal any statistical significant trend (increasing or decreasing) in the gut microbiome biodiversity between groups.

**Conclusion:** In paracetamol-induced acute liver failure in pigs we observe an acute onset significant relative change in the autochthonous taxa without alteration to gut microbiome biodiversity. Dysbiosis ratio changed significantly and rapidly in acute liver failure reflecting imbalance of ''good'' vs ''bad'' bacteria.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Transjugular portosystemic shunt (TIPS) implantation was shown to be effective in controlling variceal re-bleeding and refractory ascites in patients with liver cirrhosis[1,2,3]. However, its impact on the outcome of patients on the liver transplant waiting list is less clear. A recent UNOS database analysis has demonstrated a decreased risk of death in patients with TIPS at listing[4], but the optimal time point for TIPS implantation has not been established.

**Aims & Methods:** Here we aimed to retrospectively assess the outcome of patients undergoing TIPS implantation before (pre-listing) or after (post-listing) listing for orthotopic liver transplantation (OLT) at a tertiary care hospital. We retrospectively identified n = 98 patients with TIPS who were on the OLT waiting list between 01/1993–12/2013. 73 patients (74.5%) received a pre-listing TIPS and 25 patients (25.5%) a post-listing TIPS. A control group (n = 60) was matched to assess the differences in post-transplantation outcome according to underlying disease, sex, BMI and age at listing.

**Results:** More patients with post-listing TIPS (28.0%, 7/25) showed clinical improvement and went off-list than patients with pre-list TIPS (8.2%, 6/73, $p = 0.0119$). A similar proportion of patients with pre-list TIPS (19.2%, 14/73) and post-list TIPS (20.0%, 5/25) died on the OLT waiting list. More pre-list TIPS patients (72.6%, 53/73) than post-list TIPS patients (52.0%, 13/25) finally underwent OLT ($p = 0.0580$). MELD score evolution on the OLT list was similar for patients with pre-list and post-list TIPS (Listing-MELD: $15.7 \pm 0.5$ vs. $14.4 \pm 0.9$, p = n.s.; OLT-MELD: $17.5 \pm 0.8$ vs. $19.5 \pm 1.6$; p = n.s,). Mean OP-time was 348.0 (±12.5) minutes and a median of 3 (IQR 0–7) RBCs transfusions were required during OLT for patients with TIPS vs 337.4 (±9.8) minutes and a median of 5 (1.75–8) for patients without a TIPS. Estimated 1-year post-transplant survival was 86.0% in the pre-list TIPS group, 76.2% in the post-list TIPS group and 91.2% in the control group (log-rank $p = 0.1506$).

**Conclusion:** TIPS implantation represents an important tool for the management of portal hypertension with a favorable one-year post-OLT-survival. TIPS should be placed prior to listing to assess the actual need for listing (less delisting with pre-list TIPS) and to optimize the bridging to OLT (higher OLT-rate with pre-list TIPS).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** eshraghiana@yahoo.com

**Introduction:** Post transplant lymphoproliferative disorder (PTLD) is one of the complications that may occur after liver transplantation and threaten both graft and patient survival.

**Aims & Methods:** This study aimed to investigate incidence and survival of PTLD patients after liver transplantation. Shiraz Organ Transplant center is a leading transplant center not only in Iran but also in Middle East and Asia with considerable annual cases of liver transplantation for both adult and pediatric patients. A cross-sectional survey was conducted among adult and pediatric patients (< 18 years) who underwent liver transplantation at Shiraz transplant center, Shiraz, Iran between August 2004 and August 2014. Clinical and laboratory data of patients were collected using a data gathering form containing information regarding age, sex, underlying liver disease, type of allograft (deceased donor, living related donor, split liver transplantation), time of liver transplantation and time of PTLD development, survival of patients from date of liver transplantation, survival after PTLD diagnosis, immunosuppressive regimen and dosage, rejection episodes, EBV status before and after transplantation, presenting sign and symptoms, PTLD histology, multi-organ involvement, modality of treatment, response to therapy, serum level of calcineurin inhibitors including tacrolimus and cyclosporine. Patients received tacrolimus, cyclosporine, mycophenolate mofetile and prednisolone as immunosuppressive therapy during their follow up.

**Results:** There were 40 cases of PTLD in pediatric age group and 13 cases in adult patients. The incidence of PTLD was 6.25% in pediatric patients and 1.18% in adult liver transplant recipients. The post-PTLD survival of patients at 6 months was 75.1% (±SE 6%), at 1 year was 68.9% (±SE 6.5%) and at 5 years was 39.2% (±SE 14.2%). The mean post-PTLD survival in adult patients was $82.94 \pm 18.58$ months. The post-PTLD survival of adult patients at 6 months was 83.9% (±SE 10.4%), at 1 year was 74.6% (±SE 12.8%) and at 5 years was 59.7% (±SE 16.8%). The mean post-PTLD survival in pediatric patients was $42.61 \pm 6.1$ months. The post-PTLD survival of pediatric patients at 6 months was 72.4% (±SE 7.1%), at 1 year was 67.1% (±SE 7.5%) and at 5 years was 24.1% (±SE 18.6%). Multi-organ involvement was significantly associated with lower post-PTLD survival ($104.25 \pm 9.08$ months vs. $27.13 \pm 6.30$ months, $P = 0.002$). EBV-positive patients with PTLD had significantly higher mean survival compared to EBV-negative PTLD patients ($60.58 \pm 7.62$ months vs. $16.72 \pm 5.66$ months, $P = 0.018$). Higher serum tacrolimus level was associated with lower post-PTLD survival in pediatric patients (OR: 1.07; 95% CI: 1.006–1.15; P-value = 0.032) (Table). A serum tacrolimus of 11.1 ng/ml was predictor of post PTLD survival (sensitivity = 90%; specificity = 52%; area under curve = 0.738; P-value = 0.035).

**Conclusion:** Our study is one of the largest series of patients with PTLD after liver transplantation. This study showed that the incidence of PTLD following pediatric liver transplantation was much higher than adult liver transplantation Incidence of PTLD in our liver transplant patients is comparable to other

centers. Transplant physicians may consider adjustment of tacrolimus dose to maintain its' serum level around this cut of point.

**Table:** Cox-regression analysis of association of multiple risk factors and post-PTLD survival of pediatric patients

| | Mean | OR | 95% CI | P-Value |
|---|---|---|---|---|
| Age (years) | 5.05 | 0.94 | 0.82–1.08 | 0.434 |
| Time to PTLD (Months) | 15.63 | 0.96 | 0.91–1.02 | 0.242 |
| Tacrolimus Level | 14.99 | 1.07 | 1.006–1.15 | 0.032 |
| Tacrolimus Dose | 3.81 | 1.06 | 0.67–1.66 | 0.797 |
| Prednisolon Dose | 10.12 | 0.99 | 0.86–1.13 | 0.897 |

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0600 OBLITERATION OF PORTOSYSTEMIC SHUNTS IMPROVES HEPATIC FUNCTIONAL RESERVE

**N. Waguri**, A. Osaki, M. Sato, M. Ogawa, A. Kimura, T. Aiba, O. Yoneyama, K. Furukawa, K. Igarashi
*Gastroenterology & Hepatology, Niigata City General Hospital, Niigata/Japan*

**Contact E-mail Address:** waguri@hosp.niigata.niigata.jp

**Introduction:** Balloon-occluded retrograde transvenous obliteration (B-RTO) has been widely adopted for the management of gastric fundal varices (GV). B-RTO can be a suitable treatment option for refractory hepatic encephalopathy (HE) with large portosystemic shunts (PSS). Percutaneous transhepatic obliteration (PTO) is a useful antegrade obliteration method for PSS that is hard to access by B-RTO. There are many reports that obliteration of PSS leads it to the improvement of the liver function in the short term, however the long-term effects are not well known.

**Aims & Methods:** We retrospectively review the long-term effect on liver functional improvement and the prognosis of the patients who had the obliteration of PSS. We performed PSS obliteration using B-RTO and/or PTO in 63 patients with GV (n = 41) and/or HE (n = 24) between 2005 and 2015 at a single institute. We examined the parameters of hepatic functional reserve such as encephalopathy, ascites, total bilirubin, albumin, prothrombin time, Child-Pugh score, and liver volume in the follow-up period 3, 6, 12, 24, and 36 months after PSS obliteration. We analyzed the survival curve using Kaplan-Meier method, and investigated the preoperative factor which affected a prognosis independently with multivariable analyses.

**Results:** GVs were well-embolized in 40 patients (97.6%), and GV disapeared in all patients successfully treated by B-RTO. PSS in HE patients were well embolized in 20 patients (83.3%). The plasma ammonia level significantly decreased, and HE was improved after PSS obliteration. The serum albumin level was significantly elevated in the long-term follow-up. The median survival was of all cases was 1871 days. Multivariable analyses revealed that cases with cancer and preoperative Child-Pugh B-C grade were predictors of poor prognosis.

**Conclusion:** Significant improvement of the hepatic residual function after PSS obliteration is present in the short term, however, it does not have the permanent effect in all cases. When the PSS obliteration is necessary is the optimal time, however, what we perform it in the time preserved the liver residual function without the cancer is desirable from the viewpoint of long-term survival.

**Contact E-mail Address:** moga.tudor@yahoo.com

**Introduction:** Contrast enhanced ultrasound (CEUS) has become the first line imaging method in our center, used for the characterization of focal liver lesions (FLL), after it proved to be a cost-efficient method (1). We present you a monocentric experience in the evaluation of focal liver lesions by CEUS in daily practice routine in our center.

**Aims & Methods:** The retrospective study performed between September 2009-December 2015, included 2037 patients, in whom CEUS was performed. We evaluated **2427** FLL "de novo. The evaluation by CEUS was considered conclusive if the FLL had a typical enhancement pattern following contrast bolus as described in the European Guidelines for the use of CEUS, issued by the European Federation of Societies of Ultrasound in Medicine and Biology (EFSUMB) (2).

**Results:** From the 2427 FLL examined by CEUS, a positive diagnosis of malignant vs. benign could be established by CEUS in **2138/2427, (88.1%)**: 49.9%(1068) benign and 50.1%(1070) malignant, the latter with typical washout pattern in the late phase. In 289/2427 (11.9%) cases, CEUS was inconclusive, other methods being required (CT, MRI or biopsy) for the final diagnosis. From the total of 2427 lesions evaluated by CEUS, we were able to provide the correct classification in 1931 **(79.6%)** of cases. From all the FLLs evaluated by CEUS, 442 (22.9%) were hepatocellular carcinomas; 490 (25.4%) were liver metastases; 373 (19.2%) hemangiomas; 257 (13.4%) focal fatty liver alterations; 75 (3.9%) focal nodular hyperplasia (FNH); 1.2% (22) Adenomas, 82 (4.2%) hepatic cyst; 48 (2.5%) liver abscesses; 80 (4.1%) regenerative nodules; 0.5% (10) Cholangiocarcinoma; 0.1% (2) other malignant lesions; 2.5% (48) other benign lesions.

**Conclusion:** CEUS demonstrated its efficiency as a good first-line imaging method for the characterization of focal liver lesions detected by ultrasound, with a positive diagnosis in 79.6% cases and differentiation between malignant and benign lesions in **88.1%** % cases.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The incidence of nonalcoholic steatohepatitis (NASH) has significantly increased in the last years, mainly due to modern lifestyle changes. Liver stiffness measurements by means of Transient Elastography (TE) has been widely accepted as a tool for fibrosis assessment not only in chronic viral liver diseases but also in patients with nonalcoholic steatohepatitis.

**Aims & Methods:** The **aim** of the present study was to assess the severity and the dynamics of liver fibrosis in NASH patients.

**Material and methods**: A retrospective study of 890 patients with nonalcoholic steatohepatitis was conducted. The diagnosis of NASH was established based on: ultrasound examination (moderate or severe liver steatosis- "bright liver" with posterior attenuation); biological tests (increased aminotransferases level); no history of alcohol abuse; negative viral hepatitis B or C markers. In each patient ten LS measurements were performed by means of TE, either with the M (3.5 MHz) probe or with XL (2.5 MHz). In patients in which reliable measurements could not be obtained by M probe, XL measurements were performed in the same session. Reliable measurements were defined as: median value of 10 LS measurements with a success rate (SR) $\geq$60% and an interquartile range (IQR) $<$30%. Using the proposed cut-offs by Wong 2010 [1], NASH patients were divided into 3 categories $<$7.9 kPa (absence of severe fibrosis); values ranging between 7.9 kPa and 9.6 kPa ("gray zone" in which biopsy is recommended); and $>$9.6 kPa (severe fibrosis).

**Results:** Out of 890 patients, reliable measurements by either probe were obtained in 76.5%. Older age, female gender and higher BMI were associated with unreliable TE measurements. The analysis of liver fibrosis distribution was performed in 681 NASH patients with reliable LSM. Using the proposed cut-offs, 69.5% of the patients did not have severe fibrosis, 11.5% had F$\geq$2 fibrosis being in the "gray zone" and 19% had severe fibrosis. In 49 patients the dynamics of fibrosis was evaluated. Over a period of at least 2 years, fibrosis progression was observed in 12.2%, 75.6% had stable fibrosis, and 12.2% had an improvement in fibrosis stage.

**Conclusion:** Approximately 20% of NASH patients had LSM compatible with severe fibrosis, therefore LS assessment should be performed systematically in NASH patients.

**Introduction:** The aim of this study was to test performance of quantitative elastographic methods and Enhanced Liver Fibrosis (ELF™) test as potential non-invasive tools for assessment of portal hypertension (PH).

**Aims & Methods:** Patients suspected as having compensated advanced chronic liver disease (cACLD) of different aetiologies based on previous clinical diagnostic work-up were considered candidates for invasive approach in order to confirm the aetiology and stage of liver disease as well as to confirm presence and severity of PH. Hepatic venous pressure gradient (HVPG) served as a reference method for assessment of PH and was measured in each patient by standardized transjugular approach (Fig. 1). All patients had been scanned by transabdominal ultrasound prior to HVPG measurement including elastographic assessment of liver and spleen stiffness (LS and SS) by 2 different methods (Transient elastography (TE; Fibroscan®, Echosense) and Real-time 2-dimensional shear wave elastography (RT-2D-SWE; Aixplorer® US system, Supersonic imagine). ELF™ as a representative of serological tests was performed from single blood specimen taken from each study subject and performed according to manufacturer instructions.

**Results:** Twenty (20) patients (14 male; median age 62 (34–74) years; 8 Non Alcoholic Fatty Liver Disease, 6 Alcoholic Liver Disease, 6 other aetiologies; median fibrosis stage 6 (0–6), mean $4.75 \pm 1.7$ according to Ishak) consecutively underwent HVPG measurement (median value 10.25 mmHg (1.5–22.4)). No major adverse event occurred in relation to HVPG procedure. Liver cirrhosis was histologically confirmed in 14/20 (70%) patients, and clinically significant portal hypertension (CSPH$\geq$10 mmHg) in 11/20 (55%). TE used M probe in 55% and XL probe in 45% of patients. LS correlated significantly to HVPG (Spearmann $\rho = 0.863$ $p < 0.0001$ for RT-2D-SWE and $\rho = 0.77$, $p = 0.0001$ for TE). SS showed significant correlation with HVPG as well (Spearmann $\rho = 0.78$; $p = 0.0002$ for RT-2D-SWE and $\rho = 0.69$, $p = 0.0042$ for TE). Correlation between HVPG and ELF test was also significant ($\rho = 0.62$; $p = 0.0046$). Assessment of LS by RT-2D-SWE and TE had excellent performance for differentiation between patients with or without CSPH (LS cut-off 12.6 kPa; Se 90.9%, Sp 87.5%, PPV 90.9%, NPV 87.5%, AUC 0.94 and 10.4 kPa, Se 90%, Sp 88.9%, PPV 90%, NPV 88.9% AUC 0.89 respectively). The same was observed for SS (cut-off 30.2 kPa; Se 60%, Sp 100%, PPV 100%, NPV 63.6%, AUC 0.81 and 41.8 kPa, Se 66.7%, Sp 100%, PPV 100%, NPV 66.7% AUC 0.85 respectively). At cut-off 9.88 ELF test was able to differentiate between patients with or without CSPH (Se 81.2%, Sp 87.5%, PPV 90%, NPV 77.8%, AUC 0.818).

**Conclusion:** Both elastographic and serological tests demonstrated very strong correlation to portal hypertension as assessed by HVPG measurement. Both group of tests, and both LS and SS showed very good performance for non-invasive diagnosis of CSPH, with lower cut-off values than previously published.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0604 OUTCOMES OF RADIOFREQUENCY ABLATION AND MICROWAVE ABLATION IN LIVER METASTASES: A SINGLE CENTER EXPERIENCE

**Contact E-mail Address:** mocan_tudor@yahoo.com

**Introduction:** Microwave ablation (MWA) and radiofrequency ablation (RFA) have both emerged as promising treatment modalities for liver metastases, but the technical and oncologic differences between these modalities are not fully investigated.

**Aims & Methods:** To evaluate technical success, effectiveness and safety of MWA and RFA in patients with unresectable liver metastases. A retrospective analysis of 42 patients who underwent percutaneous MWA or RFA of liver metastases from 20011 to 2016 at our institution was performed. Peri-interventional and long-term data were reviewed to determine outcomes and patterns of recurrence.

**Results:** A total of 59 tumors were treated, ranging 0.5–4.5 cm in range. Technical success was obtained in all cases. 13 tumors (22%) were treated with MWA and 46 (78%) were treated with RFA. 29 (69%) patients had colorectal metastases, 6 (14.28%) patients had metastatic breast cancer and 7 (16.66%) patients had other types of hepatic metastases. The median follow-up was 300 days. Overall hepatic recurrence rate was 33.2%. Median time to first recurrence was 356 days. There were no complication after MWA while 5 (15.62%) patients in the RFA group had major complication (2 cases of hepatic abscess; 2 cases of arterio-portal fistula and one hematoma). Hepatic recurrence rate was significantly higher in tumors treated with RFA compared to MWA (39.13% versus 7.69%, P: 0.032). However the median follow-up was significantly shorter in the MWA versus RFA treated patients (180 versus 330 days, P: 0.025).

**Conclusion:** Although this was not a matched cohort analysis, overall hepatic recurrences were lower in patients treated with MWA compared to RFA. Longer follow-up time in the MWA may increase the recurrence rate. Moreover MWA seems to be safer than RFA in the long term management of hepatic metastases.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0605 VALIDITY OF ALBI-T SCORING MODEL AS A PROGNOSTIC INDICATOR IN EGYPTIAN PATIENTS WITH HEPATOCELLULAR CARCINOMA

**O. A. Elshaarawy**, A. I. Gomaa, N. Allam, A. Alsebaey, E. Ahmed Rewisha, I. A. Waked
*Hepatology & Gastroenterology Department, National Liver Institute, Shebine Elkom/Egypt*

**Contact E-mail Address:** oelshaarawy@liver.menofia.edu.eg

**Introduction:** The Child-Pugh (CTP) score for evaluation of liver function status has limitations as it relies on individual subjective variables as ascites and encephalopathy that are scored based on arbitrarily defined points. The albumin-bilirubin (ALBI) [1] score eliminates the need for the subjective variables required in the CTP grade and offers more precise selection of patients with HCC for treatment allocation and it is now considered a core for other scores as ALBI-T[2] score after incorporating other factor as TNM stage to reflect the extent of the tumor in ALBI-T score.

**Aims & Methods:** This study was conducted on 415 patients with HCC in a tertiary referral center in Egypt. Baseline characteristics including CTP, BCLC, ALBI[1] & ALBI-T[2] scores were determined. Patients were followed up from the time of diagnosis to the date of death or date of data collection if they remained alive. Overall survival and the received treatment were determined. Survival data were analyzed using Kaplan-Meir Survival curves using log rank test and multivariate analysis.

**Results:** For 415 patients, the mean age was 57 years, 317 were males. At presentation, 65.5% were CTP A, 28% were CTP B and 6.5% were CTP C. Most of patients were ALBI grade 2 (63.6%), 25.5% were ALBI grade 2 A while 38.1% were ALBI grade 2B. ALBI grade 1 & 3 were 21.4% & 15% respectively. Patients with CTP A were classified according to ALBI score to 32.7% & 67.3% ALBI grade 1 & 2 respectively and according to PALBI score to 19%, 45.2% and 35.8% PALBI grades 1, 2 & 3 respectively. The overall survival was 22.8 months; the median survival was better in patients with ALBI grade 1 than ALBI 2 & 3 (33.8, 22.1 and 6.8 months respectively, $P < 0.001$). Moreover, the median survival for ALBI grade 2 A patients was better than ALBI 2B (26.3 vs. 16.9 months respectively, $P < 0.001$). ALBI-T grades 0 &1 patients had better median survival than those of ALBI-T grades 2, 3, 4 & 5(undefined (mean 34.7 months), 30.8, 25.5, 10.7, 6.8 and 5.8 months respectively ($P < 0.001$)). On classifying CTP A patients using ALBI and ALBI-T scores, we found that the median survival increased in CTP A patients after further classification by our tested scores, as it was 28.5 months for all CTP A patients, to be 33.8 months in ALBI grade 1 and 34.7 & 30.8 months ALBI-T grade 0 &1 respectively ($P < 0.001$).

**Conclusion:** ALBI score was found to be an independent prognostic factor that classifies patients with HCC according to liver functions better than CTP score. Further sub classification for ALBI grade 2, were found to be significant to identify patients with better liver functions. However, ALBI-T score was found to be the best total prognostic scoring system for predicting survival of patients with HCC that allow more convenient treatment modalities.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

[2]*Gastroenterology, Centro Hospitalar de São João, Porto/Portugal*

**Contact E-mail Address:** rosacoelhoabrantes@hotmail.com
**Introduction:** ALBI score is a simple and objective tool to assess liver function in patients with hepatocellular carcinoma (HCC) [1,2].
**Aims & Methods:** Our aim was to compare the ALBI score with Child-Pugh and BCLC scores as a mortality predictor. ALBI score was calculated in HCC patients followed in Hepatology consultation between 2010 and 2015. ALBI score results were stratified as: grade 1 (values $< -2.60$), grade 2 (between $-2.60$; $-1.39$) and grade 3 (values $> -1.39$).
**Results:** A total of 167 HCC patients were included (87% male), with a median age of 65 years (IQR: 19), followed for a median period of 15 months (IQR: 4–28). The median ALBI score was $-3.088$ (IQR: $-0.798$), classified as grade 1 and grade 2 in 77% and 23% cases, respectively. The majority of grade 1 patients were Child-Pugh A (71%) and BCLC stage B (41%). Grade 2 patients were Child-Pugh B (44%) and BCLC stage C (34%). The mortality rates at 6, 12 and 24 months were 68%, 56% and 29%, respectively. The ALBI score showed good ability to predict 6-months mortality (area under the curve [AUROC] of 0.73 IC 95% (0.65–0.81) ($p < 0.001$). Considering, a cut-off value of $-3.847$, this score showed high sensitivity (98%) and specificity (92%) predicting 6-month mortality. At 12 and 24 months, despite preserving the capacity to predict mortality, ALBI score showed lower AUROC values (0.67 IC 95% (0.59–0.76) and 0.61 IC 95% (0.51–0.70), respectively). At 6 months, the ALBI score was superior to Child-Pugh and BCLC classifications (AUROC 0.71 IC 95% (0.62–0.80) vs. 0.68 IC 95% (0.58–0.78) vs. 0.68 IC 95% (0.58–0.77), $p < 0.0001$). However, the BCLC classification was superior to the Child-Pugh and ALBI scores predicting mortality at 12 and 24 months (AUROC 0.67 vs. 0.64 vs. 0.66 and AUROC 0.69 vs. 0.64 vs. 0.62, respectively), $p < 0.001$.
**Conclusion:** ALBI score may be a better predictor of short-term mortality in patients with HCC. BCLC classification was superior predicting long-term mortality.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0608 MARITAL STATUS AND SURVIVAL IN PATIENTS WITH PRIMARY LIVER CANCER: AN ANSWER FROM SEER

**X. He**, Z. Lin, L. Sun, Y. Qian
*Department Of Gastroenterology, Sir Run Run Shaw Hospital, Hangzhou/China*

**Contact E-mail Address:** hexingkang1990@163.com
**Introduction:** Primary liver cancer still represents the common cancer and a leading cause of cancer-related death worldwide [1, 2]. The 5-year survival rate for patients with liver cancer is still poor [3]. Marital status, as an important type of social support, has been reported to provide several health benefits for various diseases. Early studies had demonstrated that married persons had greater longevity and overall better health compared with the unmarried (including divorced/separated, widowed and single) [4–6]. Hence, whether marital status is associated with favorable survival among cancer patients has aroused public interest. To our knowledge, no research has reported the relationship between marital status and prognosis of primary liver cancer so far.
**Objective**: Marital status is viewed as an independent prognostic factor for survival in various cancer types. However, its role in primary liver cancer hasn't been thoroughly explored. In this study, we aimed to investigate the impact of marital status on survival outcomes among liver cancer patients.
**Methods:** We used the Surveillance, Epidemiology and End Results (SEER) database to identify 40,809 patients diagnosed with primary liver cancer between 2004 and 2012. Kaplan-Meier analysis and Cox regression were performed to identify the influence of diverse marital status on overall and liver cancer-specific survival.
**Results:** We finally identified 40,809 eligible liver cancer patients between 2004 and 2012, including 21,939 (53.8%) patients were married at diagnosis and 18,870 (46.2%) were unmarried (including the divorced/separated, the widowed, the single). Married patients had better overall and cause-specific survival outcomes compared with patients who were divorced/separated, widowed, single, respectively. The benefit associated with marriage still persisted even after adjusted for known confounders. Widowed individuals were at greater risk of overall and cancer-specific mortality compared to other groups. Similar associations were observed in subgroup analyses according to SEER stage.
**Conclusion:** Results from our study indicated that married persons enjoyed survival benefits and unmarried patients were at higher risk of overall and cancer-specific cancer mortality. We speculated that psychosocial factors and social support may contribute better survival outcomes among cancer patients, especial for the widowed. More social supports and care should be provided for unmarried patients in our clinic practice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Limited studies describe incidental space occupying lesions (SOL) in liver during pretreatment evaluation in chronic hepatitis C (CHC).
**Aims & Methods:** We aim to evaluate the occurrence and nature of SOL) on liver imaging in patients with chronic hepatitis C (CHC) receiving antiviral therapy (AVT) and the role of combination of non-invasive fibrosis scores in its characterization. 1540 patients (from January 2002 to July 2014) with CHC who underwent ultrasound (USG) scan, liver biopsy (LB) and received conventional (pegylated interferon and ribavirin) dual AVT were retrospectively analyzed for the occurrence and nature of SOL prior to initiation of AVT and thereafter.
**Results:** Mean age of patients was $41.9 \pm 9.7$ years (85% males), predominantly genotype 4 (65%) and genotype 1 (11%). Pretreatment LB showed (Scheuer classification) stage-0 fibrosis (F0) in 1.9%, stage-1 (F1) in 32.9%, stage-2 (F2) in 39.5%, stage-3 (F3) in 19% and stage-4 (F4) in 6.6% patients. Median follow-up was 3.5 years (5390 patient-years). Computed Tomography (CT) and Magnetic resonance imaging (MR) scans were performed in 1185 and 560 patients respectively prior to AVT and during follow up. Of the patients with F4 on LB, USG identified cirrhosis in 68%. Of all the patients reported with cirrhosis on USG, F4 was seen in 16.6% and advanced fibrosis (F3 and F4) in 53.4%. Routine pretreatment USG showed fatty liver in 334 (20.8%). Incidental SOL included, cysts in 21 (1.3%), hemangioma in 41 (2.6%) and hypoechoic lesions in 14 (0.9%). CT and/or MR scan did not change diagnosis in most of these SOL, except in two hypoechoic lesions detected pretreatment (one was confirmed as hepatocellular carcinoma (HCC) by CT and another by MR) and one hypoechoic lesion during post AVT follow up (confirmed as HCC in MR). CT and MR identified three and one HCC respectively that were missed on USG against cirrhotic background. Four patients had HCC during pretreatment evaluation and 11 developed HCC during post AVT follow up. The mean alpha fetoprotein (AFP) at diagnosis of new onset HCC on follow up was $63.3 \pm 1173.8$ (vs $16.2 \pm 118.1$ for non HCC patients, $p = 0.001$). Elevated AFP levels were seen in 81.8% of these patients. Independent pretreatment predictors of new onset HCC were pre-AVT albumin (adjusted odds ratio [AOR]= 0.718, confidence interval [CI] = 0.527–0.979, $p = 0.036$) and GGT (AOR = 1.008, CI = 1.003–1.012, $p = 0.001$). We derived a predicting model, 7.86–0.331 (albumin, g/dL) + 0.007(GGT, IU/L) which at a cut off 5.0 has sensitivity of 85.7% and 78.3% in predicting new-onset HCC.
**Conclusion:** Most of the incidental SOL detected in routine pre-AVT USG retained diagnostic consistency with further radiological imaging with CT and MR. A predicting model including pre-AVT albumin and GGT showed high predictive accuracy for development of HCC during post treatment follow up, This model could be applied as a guide to consider further radiologic evaluation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0610 EVALUATION OF SERUM NITRIC OXIDE LEVEL AND TUMOR EXPRESSION OF INDUCIBLE NITRIC OXIDE SYNTHETASE ENZYME IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

and AFP. NO is a product of the conversion of L-arginine to L-citrulline by NOS. iNOS is a class of NOS enzymes that produces much larger amounts of NO and has been detected in many human tumors.

**Aims & Methods:** To evaluate serum NO levels and tumor expression of iNOS in HCC patients. Subjects and Methods: Group (1) 50 patients with liver cirrhosis and HCC. Group (2) 25 patients with liver cirrhosis without HCC. Group (3) 10 normal individuals. History taking, clinical examination and Laboratory investigations (complete liver profile, AFP, NO) were done. Tumor and corresponding peri-tumor iNOS expressions were measured using Immuno-histo-chemistry technique.

**Results:** The median level of nitric oxide was significantly higher in Group (1) than in other two groups with a diagnostic sensitivity of (56%) and specificity of (80%) at a cut-off level of 58.5 $\mu$mol/l. combined usage of both AFP and NO raised the diagnostic sensitivity for HCC up to 64%. The level of tumoral iNOS was significantly higher than peri-tumoral iNOS in overall samples. The level of tumoral iNOS was significantly lower in low grade (I) HCC smears than in high grades (II& III) smears. There was significant positive correlation between serum NO and both tumor iNOS and tumor size.

**Conclusion:** NO can be considered as a novel diagnostic marker for HCC and the simultaneous determination of NO and AFP gave significant improvement in HCC detection. Its significant positive correlation with tumor iNOS suggests that the elevated tumor expression of iNOS is the source for the increased serum levels of NO in these patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0611 HBV-INFECTION IN GERMANY – COSTS IN A REAL-LIFE SETTING

**H. Becker**[1], J.T. Stahmeyer[2], A.L. Orlemann[1], C. Krauth[2], M. Manns[3], H. Wedemeyer[4]
[1]*Department Of Gastroenterology, Medical School Hannover, Hannover/Germany*

[3]*Department Of Gastroenterology, Hepatology And Endocrinology, Hannover Medical School, Hannover/Germany*
[4]*Dept. Of Gastroenterology, Hepatology And Endocrinology, Medizinische Hochschuel Hannover, Hannover/Germany*

**Contact E-mail Address:** becker.hans@mh-hannover.de

**Introduction:** An estimated 500,000 individuals are infected with HBV in Germany but medical costs caused by HBV-infection are not known. In particular costs for diagnosis and monitoring of hepatitis B in different phases of the dynamic disease from chronic hepatitis up to the cirrhotic state and the amount of pharmaceutical costs are not defined. The introduction of nucleos(t) ides (NUC) has replaced treatment with interferons (IFN) which was associated with severe side-effects.

**Aims & Methods:** The aim of the study was to assess the direct medical costs of treating HBV-infection in a real-life setting. Data on resource utilisation of 117 HBV-infected patients was obtained from an outpatient clinic at a tertiary referral center. Patients were categorised in six groups: (1.) low viraemic carriers, (2.) high viraemic carriers, (3.) chronic hepatitis B, (4.) chronic hepatitis B with compensated cirrhosis, (5.) chronic hepatitis B with decompensated cirrhosis, (6.) chronic hepatitis B/D co-infection. Ambulatory care which comprises basic diagnostic procedures and monitoring was categorised in doctor fees, general lab tests, virological diagnostics as well as imaging. Ambulatory costs are based on the German remuneration scheme for outpatient services (EBM). Pharmaceutical costs were derived from German drug directory (Lauer-Taxe). Inpatient care costs were calculated based on German Diagnosis Related Group (g-DRG) listings. The investigation period covered 3.5 years from 07/2009 to 12/2012.

**Results:** Patient characteristics and annual treatment costs of the different groups are shown in **Table 1**. 47% (55 patients) received NUCs, 4.3% (5 patients) IFN only and 6.8% (8 patients) were treated with IFN and NUCs during the study period. Total treatment costs ranged between €221 and €5,609 per year in different patient groups. Low and high viraemic carrier patients caused average annual costs of about €250. Patient groups 3–6 had mean total costs between €3,466 and €5,618 per year predominantly due to antiviral treatment costs. Medications for the treatment of HBV-associated symptoms were of minor importance. Hospitalisation was rare, except in patients with decompensated cirrhosis and with hepatitis D-coinfection.

**Conclusion:** Management of chronic hepatitis B-infection is expensive. Antiviral therapy accounts for the majority of costs. Real-life costs are lower compared to estimated guideline-based treatment costs [1]. Only a quarter of the infected patients are diagnosed and about a quarter of the diagnosed are treated. Nevertheless the economic burden of the disease is high.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** qianqianonline@gmail.com

**Introduction:** Klebsiella pneumoniae-induced pyogenic liver abscess (KP-PLA) mainly occurs in the *Asia-Pacific* region. However, there were only few studies came from mainland China and none of which highlighted critically ill patients. Moreover, the clinical presentation and prognosis of critically ill patients with KP-PLA or invasive KP-PLA syndrome remain unclear.

**Aims & Methods:** The aim of this study was hence to investigate the clinical characteristics of KP-PLA with a focus on critically ill patients in mainland China by retrospective review of medical records in a tertiary teaching hospital. We performed a retrospective analysis of consecutive PLA cases by accessing ICD-9 codes (572.0) of the hospital discharge database from May 1994 to April 2013 and ICD-10 codes (k75.0) from May 2013 to December 2015 at a 2400-bed tertiary teaching hospital in mainland China. We only enrolled critically ill patients with PLA admitted to Intensive Care Units (ICU) during hospitalization and collected the Acute Physiology and Chronic Health Evaluation II (APACHE II) score within 24 hours after transferring to ICU. The pathogenic bacteria isolated from blood and pus were identified and susceptibility testing was performed afterwards. Patient data such as demographics, underlying diseases, clinical features, microbiological findings and clinical outcomes were documented and analyzed.

**Results:** Ninety-seven out of 802 PLA patients were admitted to ICU and were included in this study. Compared with the initial 10 years, there was no significant change in the proportion of PLA patients that became critically ill in recent years (2004–2015) – (12.3% vs. 10.9%, p = 0.681). 43 patients (44.3%) developed septic shock, and 18 patients (18.6%) died eventually. *Klebsiella pneumoniae* (KP) was identified in 72.3% (n = 47) of the culture-positive PLA patients (n = 65), of

which 2 strains showed extended-spectrum beta-lactamases (ESBL) production. KP-PLA was predominately community-acquired (55.3% vs. 16.7%, $p = 0.005$) and less commonly occurred in patients who previously had been diagnosed with cancer (10.6% vs. 44.4%, $p = 0.005$) or underwent hepatobiliary surgery (27.7% vs. 77.8%, $p < 0.001$), as compared with non-KP-PLA. Nine cases of KP-PLA patients (19.1%) developed invasive KP-PLA syndrome with metastatic infection at distant sites, including meningitis ($n = 2$), brain abscess ($n = 1$), lung abscess ($n = 1$), pneumonia ($n = 3$) and other infections ($n = 2$), of which 4 patients died ultimately. Patients with invasive KP-PLA syndrome had higher APACHE II score ($21.9 \pm 6.9$ vs. $14.9 \pm 6.6$, $p = 0.016$.), longer length of hospitalization ($11.7 \pm 10.3$ vs. $8.4 \pm 13.1$, $p = 0.040$) and higher in-hospital mortality (44.4% vs. 18.4%) than patients with non-metastatic KP-PLA.
**Conclusion:** KP-PLA is an emerging infectious disease in mainland China. Even with improved early diagnostic techniques and advanced multidisciplinary management over past 2 decades, there were a substantial number of KP-PLA patients that required ICU support. Patients with invasive KP-PLA syndrome had a more severe disease course with higher mortality. Detection of KP-PLA and its catastrophic metastatic complications in critically ill patients deserve more attention.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0613 CHANGING HAV IMMUNITY IN ADULTS OF IRAN: NEW EVIDENCE FOR NEW POLICY

**K. B. Lankarani**[1], B. Honarvar[2]
[1]*Health Policy Research Center, Shiraz university of Medical Sciences, Shiraz/Iran*
[2]*Health Polciy Research Center, Shiraz University of Medical Sciences, Shiraz/Iran*

**Contact E-mail Address:** lankaran@sums.ac.ir
**Introduction:** Sanitation specially access to safe drinking water is one of the major determinants of hepatitis A (HAV) infection in communities. Iran as a transitional economy has witnessed dramatic improvement in access to safe water and in improvement of sanitation. Previous studies from Iran about two decades ago revealed high level of immunity as early as age 16 years. This study was designed to see the current state of HAV infection in one of the major cities of Iran.
**Aims & Methods:** To determine the age-specific prevalence of immunity to HAV in adults in a major metroplitan of Iran, through a multi stage cluster randomized population based sampling in Shiraz (capital city of Fars province in south of the Iran) among adults $\geq$18 years old were invited to participate. After filling a questionnaire on demographic features, a serum sample for total anti HAV immunoglobulin was taken. The sample size was estimated 500 to cover all neighborhoods of Shiraz, but to be sure about the appropriate number 1000 of inhabitants were invited. Data were analyzed in SPSS software.
**Results:** Of 1000 invitees, 820 participated in this study (response rate 82%) and their mean of age was: $43 \pm 14$ years. 479(58.4%) were female compared to 340(41.5%) who were male. We found that overall immunity against HAV was as $289/820 = 35.2\%$ and HAV immunity was 21.9% in 18–25yrs,31.9% in 26–35yrs, 39.3% in 36–45yrs, 41.4% in 46 55yrs and 30.2% in 56–65yrs age groups. It was also concluded that only age was positively correlated with HAV-Ab immunity (OR = 1.2, 95% CI = 1–1.4, $P < 0.05$) while gender, level of education and co-morbidities did not show any correlation.
**Conclusion:** Epidemiology of HAV has changed in Iran and now HAV vaccination should be a consideration. Further studies to determine the most appropriate age and most appropriate groups to receive this vaccine is warranted
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** mariaanatulio@yahoo.com
**Introduction:** The use of alanine aminotransferase (ALT) and aspartate aminotransferase (AST) in the detection and monitoring of chronic liver disease (CLD) is well established. In the absence of factors such as alcohol consumption or viral infections, the prevalence of non-alcoholic fatty liver disease (NAFLD) and its potential to progress to CLD have gradually been recognized.
**Aims & Methods:** Our aim was to determine the prevalence and etiology of elevated ALT and AST in a sample of military volunteers without known history of liver disease and to correlate ALT elevation with clinical and laboratory parameters associated to the diagnosis of metabolic syndrome and NAFLD. 229 military volunteers were prospectively analyzed. Intervention included a standardized lifestyle assessment questionnaire (comprising present health conditions, family history of liver disease and personal consumption of potentially hepatotoxic substances, namely alcohol, drugs and natural products), collection of biometric parameters (height, weight, waist circumference and blood pressure) and analysis of serum biochemical parameters (general liver disease biomarkers and viral hepatitis serologic tests). The considered variables were statistically correlated to categorized ALT levels (normal $\leq$40 IU/L, normal-high 41–55 IU/L and elevated $>$55 IU/L).
**Results:** From the 229 analyzed volunteers, 205 (89.5%) were males. Given the major gender disproportion, only male individuals were considered for statistical analysis. ALT or AST elevation was present in 18.7% and 28.3% of individuals, respectively, whereas 15.8% showed normal-high levels of ALT. In our sample, 17.6% of individuals had elevated body mass index, 19.5% increased waist circumference and 39.5% hypertension. 59.3% of male volunteers showed elevated total cholesterol, 10.3% HDL-cholesterol, 27.3% elevated triglycerides and 8.5% increased fasting glucose. Categorized ALT levels correlated with body mass index ($p < 0.001$), waist circumference ($p < 0.001$), blood pressure ($p < 0.01$), serum triglyceride levels ($p < 0.001$) and serum total cholesterol levels ($p < 0.01$). No correlation was identified between categorized ALT levels and serum HDL-cholesterol or glucose levels. Furthermore, normal ALT levels were associated to normal body mass index, waist circumference, blood pressure, triglycerides and total cholesterol levels. On the other hand, elevated ALT was associated to obesity, increased waist circumference and hypercholesterolemia. More than half the individuals with ALT elevation had no apparent cause for this elevation.
**Conclusion:** Elevated ALT was common in our sample of military volunteers without known history of liver disease and, in the majority of cases, was associated to metabolic syndrome and NAFLD risk factors, such as obesity and dyslipidemia.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0615 IDENTIFICATION OF PALLIATIVE CARE NEEDS IN HEPATOLOGY – EXPERIENCE OF A MAJOR REFERRAL CENTRE

**J.R. Carvalho**[1], M. Vascocelos[2], P. Marques Da Costa[1], R.T. Marinho[1], N. Fatela[1], F. Ramalho[1]

**Contact E-mail Address:** joana.rita.carvalho@gmail.com
**Introduction:** Chronic liver disease is a major cause of morbidity and mortality that affects active adults of working age. Palliative care policies are not clearly established in chronic liver disease. The NECPAL CCOMS-ICO© is a tool to identify palliative care needs, including in liver disease.
**Aims & Methods:** This prospective single-centre prospective observational study aimed at identifying palliative care needs in hospitalized liver patients in a tertiary Liver Unit. The NECPAL CCOMS-ICO© was applied to all hospitalized patients admitted from 1st August to 30th September 2015.
**Results:** Forty-six patients (80.4 male) with chronic liver disease were included with a median age of 60 years (SD 10.7). Alcoholic abuse was the most prevalent etiology (76%). 47% had a MELD score greater than 15. Using NECPAL tool, 89% of the patients were considered as requiring some type of palliative intervention. Those needs were subjectively identified by clinicians in only 58.6% of the cases. Caregiver perception of palliative care needs was even lower (13%). 14% of the patients were admitted in intensive care unit, all of them considered as needing palliative care by NECPAL. Mortality rate was 21.7%, 40% due to hepatocellular carcinoma. All deaths occurred in patients with MELD score superior to 15.
**Conclusion:** Clinicians and caregivers were not aware of palliative care needs. End of life care needs must be promptly identified and provided, in order to improve quality of life of terminal patients. The NECPAL CCOMS-ICO© represents a feasible and easy to use tool to identify patients in need of palliative care in chronic liver disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Complementary and alternative medicine (CAM) encompasses a huge variety of treatments including homeopathy, herbal medications and acupuncture. We hypothesize that CAM use in liver disease patients is underreported in clinical practice and can lead to relevant pharmacological interactions.
**Aims & Methods:** The aims of this study were to assess the prevalence and type of CAM use, and experiences with CAM use in liver disease patients. We

conducted a cross-sectional survey among the members of the Dutch Liver Patients Association. All members received a questionnaire through Survey Monkey©. The questionnaire included 26 questions about demographics, liver disease, frequency, type, and experiences with CAM use. Results are presented as mean, standard deviation (SD), and frequencies.
**Results:** We received 210 completed questionnaires. Mean age of respondents was 55 years (SD 13.5), 62 (30%) respondents were male and main liver diseases were primary sclerosing cholangitis (n = 50, 24%), primary biliary cholangitis (n = 40, 19%), autoimmune hepatitis (n = 40, 19%), and viral hepatitis (n = 16, 8%). A total of 96 (43%) patients reported CAM use; type of CAM was diverse and silymarin was most frequently reported (n = 16). Up to 35% of CAM users had not divulged CAM use to their physician. The majority of patients (n = 63, 76%) experienced beneficial effects of CAM and 58 patients (71%) would recommend CAM to other patients.
**Conclusion:** Prevalence of CAM use is high (43%) in liver disease patients and 35% of patients do not report CAM use to their physician. Clarity about CAM use can prevent potential harmful interactions with prescribed medication. Physicians should actively ask for CAM use.

## P0617 INCIDENCE AND PREDICTORS OF HEPATITIS C TREATMENT INITIATION AMONG PEOPLE WHO INJECT DRUGS: LONGITUDINAL DATA FROM A GREEK TERTIARY CENTER, 2009–2015

**V. Papastergiou**[1], O. Anagnostou[2], M. Deutsch[1], A. Kourikou[1], D. Zampetas[1], E. Ionas[1], H. Kranidioti[1], G. Kontos[1], S. Manolakopoulos[1]

[2]*Greek Organization against Drugs (OKANA), Athens/Greece*

**Contact E-mail Address:** vasi.pap@hotmail.com
**Introduction:** People who inject drugs (PWID) account for a large burden of hepatitis C virus (HCV) infection. However, they often face several barriers to accessing antiviral treatment. In the era of highly-efficacious direct-acting antivirals (DAAs), knowledge of factors that prevent treatment among PWID is very crucial.
**Aims & Methods:** We retrospectively reviewed consecutive HCV-viraemic PWID visiting a tertiary liver center (January 2009–June 2015). Patients attending a substitution program were managed by a multidisciplinary approach. Kaplan-Meier and Cox regression analyses were used to evaluate treatment initiation and its correlates.
**Results:** A total of 177 PWID (141 males, 41.7 ± 10.6 years, 19.7% cirrhotics, 77.9% treatment-naïve) were included: 74 (41.8%) former drug users, 88 (49.7%) attending substitution programs and 15 (8.5%) active users. Treatment was initiated in 101 (57.1%), with the vast majority (91.1%) receiving peginterferon/ribavirin(PR). The cumulative probability of treatment was 61.8% over 3 years. During the DAA era treatment was prescribed to 15 out of 35 who visited the center. DAAs were prescribed in 9 patients; only 5 cases in an all-oral regimen. There was no impact of calendar time (2009–11 vs 2012–13 vs 2014–15) on treatment initiation incidence (RR: 1.02, 95%CI: 0.78–1.32; P = 0.88). Compared to former drug users, active users were less likely to initiate treatment (RR: 0.17, 95%CI: 0.03–0.91; P = 0.04), whereas no difference was observed for patients under substitution (RR: 0.60, 95%CI: 0.30–1.18; P = 0.14). ALT < 40 IU/L (RR: 0.23, 95%CI: 0.09–0.6; P = 0.002), genotype 1–4 (RR:0.36, 95%CI: 0.17–0.73; P = 0.005) and comorbidities that constitute contraindications to interferon (RR: 0.36, 95%CI: 0.19–0.69; P = 0.002) were inversely related to treatment initiation.
**Conclusion:** In PWID with HCV infection, active drug use and drawbacks pertinent to PR therapy posed significant barriers to treatment. Few PWIDs had been referred and initiated DAAs during 2014–15. In the era of financial crisis delineating the barriers to initiate DDAs should urgently be explored in order to reduce the burden of the disease in this population.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0618 ENDOSCOPIC TREATMENT OF BILIARY STRICTURES FOLLOWING LIVER TRANSPLANTATION- 15 YEARS' EXPERIENCE IN A TERTIARY TRANSPLANT CENTER

**Introduction:** Biliary strictures are a common complication of liver transplantation. The standard treatment is repeated ERCP with placement of increasing numbers of plastic stents. Despite high success rates, some strictures fail to resolve and require surgery as definitive treatment.
**Aims & Methods:** We aimed to find predictors for failure of endoscopic treatment in order to avoid unnecessary procedures in patients who have low probability of recovery under standard treatment. Database of Gastroenterology Department at Tel Aviv Medical Center was retrospectively reviewed, and data regarding patients who underwent liver transplantation and developed biliary strictures was analyzed.
**Results:** 31 patients met the study criteria. 24 (77.4%) resolved with endoscopic treatment and 7 ultimately required surgery. There were no significant differences between stent responders and non-responders regarding demographics, transplant and postoperative hospitalization data, time from transplantation to presentation with stricture, total number of ERCP sessions or maximal number of stents. A significant difference was noted in the time elapsed between the first and the second ERCP, whereby ERCP non-responders required a second urgent procedure sooner than responders (0.99 ± 1 vs. 2.17 ± 1.39 months, p = 0.046). Patients presenting electively had a 95% endoscopic success rate, while those presenting urgently had a 55% failure rate (p = 0.004).
**Conclusion:** This study identified urgent repeat ERCP as a harbinger of ultimate failure of plastic stent treatment for biliary stricture following liver transplant. This finding may assist earlier triage of these patients toward alternative treatment such as metal stents or surgery, thus sparing needless procedures and complications.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Choledocholithiasis is a frequent condition in the elderly. Therapeutic Endoscopic Retrograde Cholangiopancreatography (ERCP) in the elderly patients is increasing as a result of the population ageing.
**Aims & Methods:** To evaluate the efficacy and safety of therapeutic ERCP in the elderly. A retrospective study which included patients with choledocholithiasis who underwent therapeutic ERCP during a 6-year period (2009–2015). The patients were divided in two groups: age ≥75 years and age <75 years. Variables analyzed: gender, antiplatelets/antithrombotic drugs, American Society of Anesthesiologists (ASA) classification, periampullary duodenal diverticulum, diameter of the common bile duct, number of the common bile duct stones, diameter of the larger stone, complete/incomplete common bile duct stone removal, placement of biliary stent and early complications (<30 days): pancreatitis, bleeding, cholangitis, hepatic abscess and death.
**Results:** Two hundred twenty-nine patients were included: 133 female, 123 patients with age ≥75 years. The patients who were ≥75 years were more frequently on antiplatelet drugs (30% vs 22%, p = 0.001) and on antithrombotic drugs (14% vs 6%, p = 0.041), had more commonly an ASA classification >2 (99% vs 90%, p < 0.001), had more frequently a periampullary diverticulum (36% vs 21%, p = 0.012) and presented a higher mean diameter of the common bile duct (14 mm vs 12 mm, p < 0.001) and a higher mean diameter of the larger stone (12 mm vs 10 mm, p < 0.001). The proportion of patients with multiple common bile duct stones was not significantly higher in this group (63% vs 57%, p = 0.294). The rate of complete common bile duct stone removal and of biliary stent placement was similar in the two groups (80% vs 88%, p = 0.137; 20% vs 12%, p = 0.102, respectively). Moreover, there was no significant difference between the two groups regarding overall complications (15% vs 12%, p = 0.601), pancreatitis (4% vs 5%, p = 0.530), bleeding (4% vs 5%, p = 0.530), cholangitis (2% vs 2%, p = 0.570), hepatic abscess (2% vs 0.2%, p = 0.501) and death (0% vs 2%, p = 0.213).
**Conclusion:** Therapeutic ERCP is an effective procedure in the elderly patients with choledocholithiasis. The occurrence of complications is not increased in these patients, although antiplatelet/antithrombotic drugs are more commonly used and their ASA classification is higher. As such, ERCP is a valid therapeutic procedure in the elderly patients with choledocholithiasis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0620 COST IMPACT OF LONG-TERM HEALTH CARE CONSUMPTION AND SICK LEAVE IN PATIENTS WITH PERSISTENT ABDOMINAL PAIN AFTER LAPAROSCOPIC CHOLECYSTECTOMY

**S. Z. Wennmacker**[1], M. Oostendorp[2], M. G. Dijkgraaf[3], G. P. Westert[4], J.P. h. Drenth[5], C. J. h.m. Van Laarhoven[1], P. R. De Reuver[5]

**Introduction:** In the Netherlands, annually 23,000 cholecystectomies are performed against hospital-related costs of 55 million euro.[1] Remarkably, gallbladder removal appears to be ineffective in terms of pain relief, in up to 40% of patients with uncomplicated symptomatic cholecystolithiasis.[2] Although several studies report persistent abdominal pain after cholecystectomy, there is no literature on the actual burden of this pain to the health care system.
**Aims & Methods:** Aim: To determine health care consumption and the related costs in patients with persistent abdominal pain after cholecystectomy. Methods: A prospective multicentre cohort study included patients with uncomplicated symptomatic cholecystolithiasis who had a cholecystectomy between June 2012 and June 2014. Persistent postoperative abdominal pain was reported by 146 of the surveyed 360 patients (40.6%) at 24 weeks after surgery.[2] For these patients health care consumption was assessed in February 2016 using Patients' Experience of Surgery Questionnaire (PESQ), Medical Consumption Questionnaire (iMCQ) and patients' medical records. Sick leave and productivity loss of (un) paid work were assessed using Productivity Cost Questionnaire (iPCQ). Health care consumption was defined as home, primary and secondary care consultations, emergency department and hospital admissions, and medication use. Related costs were calculated according the Dutch "Guideline for performing economic evaluations in health care", using Euro 2014 prices.
**Results:** Complete assessment of health care use was obtained from 124/146 patients (85%). Sixty-nine patients (55.6%) had additional care for persistent abdominal pain after cholecystectomy; 38 patients (30.6%) received primary care with an average number of 3 (SD 2.4) visits, 46 patients (37.1%) received secondary care with an average number of 4.7 (SD 4.5) visits, 20 patients (16%) were admitted in the emergency department, and 11 patients (8.9%) were admitted in the hospital. Forty-two patients (33.9%) had additional diagnostic procedures, which revealed gallstone or surgery related causes in six patients. As treatment, 22 patients (17.7%) reported use of medication; 13 (10%) used analgesia and 12 (9.6%) used proton pump inhibitors. Seven patients (5.6%) needed other additional treatments, of which 3 had an Endoscopic Retrograde CholangioPancreatography with stone extraction. The estimated mean medical costs (excl. medication) for persistent abdominal pain since cholecystectomy were €1239 (SD €3573) per patient. The estimated mean costs of sick leave and productivity loss of paid and unpaid work due to persistent abdominal pain since cholecystectomy were €727 (SD €2163) per patient.
**Conclusion:** Fifty-five percent of patients needed additional care for persistent abdominal pain after cholecystectomy. Optimized indication for cholecystectomy will reduce postoperative pain for patients and partly reduce costs after cholecystectomy for health care system and employers. The gain is that less money is spent on unnecessary surgery, but patients will use other resources as therapy for their symptoms.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0621 A MEASURE OF QUALITY IN MANAGEMENT OF GALL BLADDER POLYPS IN A DISTRICT GENERAL HOSPITAL: THE UNITED KINGDOM EXPERIENCE

**T. Mahmood**
*Mulja-e-Tariq, Ickenham, Middsx/United Kingdom*

**Contact E-mail Address:** tm123@btinternet.com
**Introduction:** Lesions projecting from the gall bladder wall into the gall bladder are called gall bladder polyps. It is usually an incidental diagnosis. Most gall bladder polyps are benign but may be malignant in some cases, therefore an early detection and appropriate treatment of these is required. There are two categories of gall bladder polyps: 1) Benign polyps like cholesterol deposits, inflammatory polyps and epithelial tumours like adenomas or mesenchyma tumours like fibromas, lipomas, haemangiomas etc 2) Malignant polyps like gall blabber carcinoma. It has been suggested that age more than 50 years, presence of Diabetes Mellitus, polyp size more than 1.5 cms specially in solitary sessile hypoehogenic lesions and presence of pain make high risk for polyps to be malignant. However there are no clear guidelines on their management. Pragmatically polyps less than 1 cm in size and asymptomatic are monitored with an ultrasound after 6–12 months. However other studies have suggested that diameter alone is not a safe exclusion criteria and cholecystectomy should be considered for any polyp more than 6 mm in size. This study aims to measure quality in management of gall bladder polyps in a sample district hospital in the United Kingdom. It is in turn dependent upon quality of radiological reporting
**Aims & Methods:** It is a retrospective study. To measure quality of radiological reporting of gall bladder polyps, a check list was devised to see if a) Full description of characteristics of polyps was described. b) Whether it had been documented if patient was symptomatic or not and thus achieved a clinical correlation and c) Polyps more than 6 mm size were monitored bi-annually
**Results:** All patients with a diagnosis of gall bladder polyp in a sample district general hospital of United Kingdom over a period of six months in 2015 were identified through IT records. A total of 34 Patients were studied all of whom had an ultrasound of the abdomen. 27 patients were above 50 years of age while 7 were below 50 years. Only 4 patients were male and 30 were females. The polyp characteristics were fully described in all radiological reports. All reports had indication described by the doctor indicating presence or absence of symptoms. It was not documented whether they had diabetes or not in any patient. Upon further investigations it transpired that 8 patients were not diabetic and in another 06 it could not be determined if they were diabetic, while 20 patients had diabetes mellitus. Regarding monitoring, in 06 patients solitary polyps were found and they were more than 1.5 cm in size. All these patients were referred for surgical opinion. Repeat US scan was arranged in six months' time. Only 02 of them showed progression and had laparoscopic cholecystectomy. Another 23 patients had their repeat ultrasound in 12 months and did not show any progression. All of them had multiple polyps ranging between 0.5 mm to 15 mm. 01 patient had multiple polyps ranging between 0.3 mm-10mm but following first scan no follow up had been arranged. None of the patients had CT, MRCP or EUS as these were not required
**Conclusion:** This study has shown that despite no clear guidelines on management of gall bladder polyp, in a sample district general hospital of United Kingdom, a reasonable pragmatic management plan was being undertaken as a measure of quality. Overall appropriate reporting is undertaken by the radiologists, follow up scans are arranged for patients found to have gall bladder polyps and adequate referrals to surgeons for laparoscopic cholecystectomy are made. However importance of Diabetes Mellitus in this group of patients is being less emphasised. Further studies should be undertaken to see if following the surgery, histology is being checked and documented to have been seen. Also how frequently if at all cancer is picked up in these post-operative samples. Experts in hepato-biliary disease need to provide guidelines to the general hospitals on gall bladder polyp cancer risk stratification. There shall then be clear goals in quality for general hospital to aspire to in management of gall bladder polyps
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0622 THE DIAGNOSTIC PERFORMANCE OF NON-INVASIVE FIBROSIS MARKERS IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS AND PRIMARY BILIARY CHOLANGITIS AND AUTOIMMUNE HEPATITIS VARIANT FORM: IS THERE ANY DIFFERENCE?

**A. Sheptulina**, E. Shirokova, V. Ivashkin
*First Moscow State Medical University n.a. I.M. Sechenov, Moscow/Russian Federation*

**Contact E-mail Address:** sheptulina.anna@gmail.com
**Introduction:** The pathogenesis of primary biliary cholangitis (PBC) and autoimmune hepatitis (AIH) variant form remains poorly understood and it is debated whether this syndrome represents a distinct entity or a variant of PBC or AIH [1]. To the best of our knowledge, there is no published data on the diagnostic performance of non-invasive fibrosis markers in this group of patients.
**Aims & Methods:** The aim of the study was to evaluate and compare the ability of non-invasive fibrosis markers for staging of liver fibrosis in patients with PBC and PBC-AIH variant form, thereby determining the viability of grouping these patients together for the analysis. Ninety-two patients with PBC and 45 patients with PBC-AIH variant form were enrolled in the study and analyzed for the following parameters of liver fibrosis: Fibrosis 4 score (FIB-4), aspartate aminotransferase (AST) to alanine aminotransferase (ALT) ratio (AAR), AST to platelet count ratio (APRI), and platelet count to spleen diameter (PC/SD) ratio. The diagnosis of PBC-AIH variant form was based on the "Paris criteria" [2]. All PBC patients were treated with ursodeoxycholic acid (UDCA), and all patients with PBC-AIH variant form received a combination of UDCA and prednisolone. The diagnostic value of each parameter was evaluated by the area under the receiver operating characteristic curve (AUROC). The AUROCs and standard errors (SE) of non-invasive fibrosis markers in PBC and PBC-AIH patients were compared using Z-statistic.
**Results:** Among the 92 PBC patients (median age [25th – 75th interquartile range] 54 years [49–62]; 92.6% were female), 48 (50.5%) had significant fibrosis (≥F2), 37 (39%) had severe fibrosis (≥F3), and 20 (21.1%) had cirrhosis (F4). In PBC-AIH group (n = 45; median age 50 years [43.5–57]; 93.3% were female) 34 patients (75.6%) had significant fibrosis (≥F2), 27 (60%) had severe fibrosis (≥F3), and 13 (28.9%) had cirrhosis (F4). The AUROCs of the PC/SD ratio, FIB-4, AAR, and APRI were 0.775, 0.686, 0.639, and 0.608 in PBC and 0.711, 0.722, 0.600, and 0.703 in PBC-AIH variant form, respectively, for significant fibrosis (≥F2); 0.776, 0.694, 0.642, and 0.705 in PBC and 0.802, 0.817, 0.699, and 0.780 in PBC-AIH variant form, respectively, for severe fibrosis (≥F3); and 0.806, 0.715, 0.675, and 0.700 in PBC and 0.866, 0.756, 0.626, and 0.705 in PBC-AIH variant form, respectively, for cirrhosis (F4). There were no significant differences in AUROCs of AAR, APRI, FIB-4, or the PC/SD ratio for the prediction of fibrosis ≥F2, ≥F3, or F4 between the PBC and PBC-AIH groups (Table). However, the AUROCs of FIB-4 and the PC/SD ratio tended to be higher in patients with PBC-AIH variant form.

**Table:** Areas under the receiver operating characteristic curves of AAR, APRI, FIB-4, and PC/SD ratio for the prediction of significant fibrosis (≥F2), severe fibrosis (≥F3), or cirrhosis (F4) in PBC patients and patients with PBC-AIH variant form

| Index | Fibrosis category | AUROC (SE) in patients with PBC (n = 92) | AUROC (SE) in patients with PBC-AIH variant form (n = 45) | Z-statistic | p |
|---|---|---|---|---|---|
| AAR | ≥F2 | 0.662 (0.057) | 0.600 (0.086) | 0.601 | 0.548 |
| | ≥F3 | 0.671 (0.060) | 0.699 (0.080) | −0.280 | 0.779 |
| | F4 | 0.673 (0.073) | 0.626 (0.089) | 0.408 | 0.681 |
| APRI | ≥F2 | 0.708 (0.054) | 0.703 (0.088) | 0.048 | 0.961 |
| | ≥F3 | 0.713 (0.055) | 0.780 (0.068) | −0.766 | 0.440 |
| | F4 | 0.715 (0.062) | 0.705 (0.078) | 0.100 | 0.920 |
| FIB-4 | ≥F2 | 0.693 (0.054) | 0.722 (0.075) | −0.314 | 0.753 |
| | ≥F3 | 0.702 (0.056) | 0.817 (0.066) | −1.329 | 0.181 |
| | F4 | 0.729 (0.063) | 0.756 (0.071) | −0.284 | 0.776 |
| PC/SD ratio | ≥F2 | 0.775 (0.050) | 0.711 (0.092) | 0.611 | 0.548 |
| | ≥F3 | 0.776 (0.051) | 0.802 (0.069) | −0.303 | 0.762 |
| | F4 | 0.806 (0.055) | 0.866 (0.055) | −0.711 | 0.441 |

**Conclusion:** The diagnostic performance of non-invasive fibrosis markers for the diagnosis of fibrosis ≥F2, ≥F3, or F4 did not differ significantly between patients with PBC and PBC-AIH variant form. According to our data, patients with PBC and PBC-AIH variant form may be grouped together for the analysis of the diagnostic performance of non-invasive fibrosis markers.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0623 PRIMARY CLOSURE VERSUS T-TUBE AFTER LAPAROSCOPIC COMMON BILE DUCT EXPLORATION FOR CHOLEDOCHOLITHIASIS? A SINGLE CENTER EXPERIENCE

**E. El Hanafy**
*Surgical Departement, Mansoura University, gastroenterology center, Mansoura/Egypt*

**Contact E-mail Address:** dr_ehab_elhanafy@yahoo.com

**Introduction:** Common bile duct exploration (**CBDE**) has the advantage of managing cholecysto- choledocholithiasis by single-stage procedure **(1,2).** There is still a debate about the benefits and drawbacks after t tube usage. The aim of this study is to evaluate the value of primary common bile duct **(CBD)** closure and routine T-tube usage after laparoscopic **CBDE**.
**Aims & Methods:** One hundred ninety two patients underwent laparoscopic **CBDE** by choledochotomy for **CBD** stones. Patients were divided into two Groups. **Group (A):** 55 patients were managed by primary closure of the **CBD**, **group (B):** 137 patients were managed by using T-tube after assumed **CBD** clearance. Demographics, pre-operative radiology, intraoperative findings, and post-operative complications were collected and analyzed between the two Groups
**Results:** There was no statistically significant reduction in the serum bilirubin level in the first postoperative day (POD1) with the use of T-tube between the two Groups: 1.2 (0.9–24 mg/dl) and 2 (0.5–27.2 mg/dl) ($P > 0.223$) in Group (A) and (B) respectively. Also in the third post-operative day (POD3) which was 0.9(0.9–18 mg/dl) and 1.1(0.5–14.5 mg/dl) ($P > 0.154$) in Group (A) and (B) respectively. Wound infection and abdominal collections were significantly more obvious in Group **(B)** patients, **($p < 0.003$)** and **($p < 0.002$)** respectively**.** There was no statistically significant difference in bile leakage between both groups as it was encountered in one patient (1.8%) in Group **(A)** and 4 patients (2.9%) in Group **(B), ($p = 0.066$)**. Residual stones were encountered in 10 patients (5.2%); two patients in group A (3.6%) and eight patients in group B (5.8%). Hospital stay was significantly longer in Group **(B)** patients, 4(3–35 days) versus 3(1–13 days) in group (A) **($p < 0.001$).**

| Variable | Group (A) Primary closure(n = 55) | Group (B) T-tube (n = 137) | P value |
|---|---|---|---|
| **(POD1) Total Bilirubin level on first day** | 1.2(0.9–24) | 2(0.5–27.2) | 0.223 |
| **(POD3) Total bilirubin level on third day** | 0.9(0.9–18) | 1.1(0.5–14.5) | 0.154 |
| **Drain removal (days)** | 1 (1–13) | 2 (2–35) | 0.001 |
| **Hospital stay (days)** | 3 (1–13) | 4 (3–35) | 0.001 |
| **Complications*Clavien-Dindo Classification** | 5 (9%) | 19 (14%) | 0.032 |
| **I** | 1 (2%) | 6 (4%) | 0.008 |
| **II** | 0 (0%) | 1 (0.7%) | 0.032 |
| **IIIA** | 0 (0%) | 1 (0.7%) | 0.032 |
| **IIIB** | 4 (7%) | 11 (8%) | 0.032 |
| **Wound infection** | 0 (0%) | 5 (4%) | 0.004 |
| **Bed side management** | | 4 (3%) | |
| **Surgical management** | | 1 (0.7%) | |
| **Collection** | 0 (0%) | 2 (1%) | 0.003 |
| **Conservative management** | | 1 (0.7%) | |
| **US guided tube drainage** | | 1 (0.7%) | |
| **Bile leakage without residual stones** | 1 (2%) | 4 (3%) | 0.065 |
| **Conservative management** | 1 (2%) | 1 (0.7%) | |
| **(ERCP) management** | 0 | 1 (0.7%) | |
| **Surgical management** | 0 | 2 (1%) | |
| **Residual stones management** | 2 (4%) | 9 (7%) | 0.056 |
| **(ERCP)** | 2 (4%) | 7 (5%) | |
| **Surgery** | 0 | 2 (1%) | |
| **Mortality** | 0 (0%) | 0 (0%) | |

**Conclusion:** We encourage the primary **CBD** closure over the use of T-tube as it provides a more comfortable post-operative course, lower morbidity and a shorter hospital stay.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Aged patients with difficulty tolerating prolonged or frequent endoscopic procedure because of poor general condition and prognosis are seen in a rising frequency. Advantages of long-term endoscopic biliary stenting (EBS) with low risk and high safety without stone removal has been pointed out by us in those cases, despite the popular first choice of stone removal in the treatment of common bile duct stones. Endoscopic papillary large balloon dilatation (EPLBD), on the other hand, making it possible to remove a large number of stones in a single procedure, is used in increasing frequency recently.
**Aims & Methods:** In the present study, prolonged EBS on one hand was compared with standard EST and EPLBD with stone removal on the other, to evaluate the safety and indication of these procedures. Test subjects consisted of 740 patients with common bile duct stones older than 80 years in age, subjected to endoscopic treatment in our hospital over the past 12 years (mean age of 87.3 years, maximum age 108 years). EST with stone removal was performed in 370, long term EBS in 349 and EPLBD with stone removal in 21 (maximum stone size and number; EST 10.0 mm and 3.1, EBS 14.9 mm and 4.7, EPLBD 14.8 mm and 3.5). Duration of the procedure, days of post-treatment hospital stay, and freguency of short-term complications and long-term complications including recurrence of cholangitis were recorded.
**Results:** 1) Mean treatment time was 40.2 minutes for EST, and 50.5 minutes for EPLBD compared to 21.2 minutes for EBS (significantly shorter at $p < 0.01$). 2) Mean Post-treatment Hospital Stay was significantly shorter for EBS 5.0 than 8.9

| ALP Baseline (U/L) LS Mean (SE) at Change 12 Months[b] | 332.7 (119.8) −57.8 (17.4) | 332.7 (159.0) −116.4 (17.2)** | 278.1 (68.4) −141.0 (16.8)*** |
| Baseline Bilirubin (umol/L) LS Mean (SE) at Change 12 Months[b] | 10.6 (8.8) 2.2 (1.1) | 8.1 (7.1) 1.1 (1.0) | 10.0 (7.8) 0.0 (1.1) |

days for EST and 7.2 days for EPLBD ($p < 0.05$, $p < 0.01$). 3) Short-term complications were low; 17.3% for EST, 3.2% for EBS and 0.5% for EPLBD. Serious complications consisted of serious pancreatitis after EST (fatal) and perforation in 1 (laparotomized). 4) Long-term recurrence rate for cholangitis (3 years) was distinctly higher in EBS, 55.5% than in EST, 21.5% ($p < 0.01$). Mean recurrence interval of cholangitis was 2.9 years in EBS, significantly shorter than 5.6 years in EST ($p < 0.01$). 5) Recurrent cholangitis was safely treated in each case without mortality.

**Conclusion:** 1) Long-term EBS caused rather frequent recurrence of cholangitis controlled quickly making prompt repetition possible. This is a safe and non-invasive method providing early ambulation. 2) EPLBD also provides an early ambulation even in cases with large stones but requires a long duration of treatment. 3) Long-term EBS is indicated for aged patients with poor prognosis in the absence of prospect of radical cure, especially those intolerable of a time-consuming endoscopic stone extraction. 4) EPLBD appeared to be especially more desirable than long term EBS for those requiring early ambulation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0625 EFFICACY OF OBETICHOLIC ACID IN THE TREATMENT OF PRIMARY BILIARY CIRRHOSIS BY CONTINENTAL REGIONS

V. Luketic[1], P. Andreone[2], F. Nevens[3], **J. Owens-Grillo**[4], R. Pencek[4], T. Marmon[4], L. Macconell[4]

[4]*Intercept Pharmaceuticals, Inc., San Diego/United States of America/CA*

**Contact E-mail Address:** janet.owens-grillo@interceptpharma.com

**Introduction:** Obeticholic Acid (OCA) is a potent and selective farnesoid X receptor (FXR) agonist under investigation for treatment of primary biliary cirrhosis (PBC). POISE was a placebo-controlled, double-blind, randomized Phase 3 study examining the efficacy of OCA in patients located primarily in Europe (EU) and North America (NA). Differing regional lifestyles, standards of care and other variables may affect disease state or response to treatment.

**Aims & Methods:** This analysis assesses the efficacy of OCA within the EU and NA. Inclusion criteria: PBC diagnosis, Alkaline phosphatase (ALP) ≥1.67x upper limit of normal (ULN) and/or total bilirubin >ULN to <2x ULN, stable UDCA dose or unable to tolerate UDCA. 216 patients were enrolled and treated with Placebo (PBO; EU, n = 49; NA, n = 21), 5–10 mg OCA daily (titration from 5–10 mg was based on efficacy and tolerability; EU, n = 45; NA, n = 20), or 10 mg OCA daily (EU, n = 51, NA, n = 21). Primary efficacy was assessed by a composite endpoint of ALP <1.67 x ULN, ≥15% reduction in ALP, and normal total bilirubin. P-values compare active treatments to placebo using either a Cochran Mantel-Haenszel test or ANCOVA.

**Results:** Demographics were well balanced between the two regions. In the EU patients, 51% (5–10 mg OCA, $p < 0.0001$) and 43% (10 mg OCA, $p < 0.0001$) met the primary endpoint vs 8% in PBO. In the NA patients, 35% (5–10 mg OCA, $p = 0.017$) and 48% (10 mg OCA, $p = 0.010$) met the primary endpoint vs 5% in PBO. Mean (SD) baseline ALP (U/L) was similar between groups, EU: 327.6 (107.7); NA: 314.2 (121.6). The least squares (LS) mean change (SE) in ALP (U/L) in EU Patients was 2.0 (18.3) in PBO, −109.5 (18.3) in 5–10 mg OCA ($p < 0.0001$), −125.6 (18.1) in 10 mg OCA ($p < 0.0001$). The LS mean change (SE) in ALP (U/L) in NA Patients was −57.8 (17.4) in PBO, −116.4 (17.2) in 5–10 mg OCA ($p = 0.001$), −141.0 (16.8) in 10 mg OCA ($p < 0.0001$). Mean baseline total bilirubin was within normal range for both groups but higher in the EU patients: 11.9 umol/L compared to 9.6 umol/L in NA patients. The LS mean change (SE) in total bilirubin (umol/L) in EU Patients was 1.7 (0.8) in PBO, −1.1 (0.8) in 5–10 mg OCA ($p = 0.001$), −1.5 (0.8) in 10 mg OCA ($p = 0.0001$). The LS mean change (SE) in total bilirubin (umol/L) in NA patients was 2.2 (1.1) in PBO, 1.1 (1.0) in 5–10 mg OCA ($p = 0.356$), 0.0 (1.1) in 10 mg OCA ($p = 0.072$). Baseline values are Mean (SD). *$p < 0.05$, **$p < 0.01$,***$p < 0.0001$. [a]P-values for comparing treatments are obtained using CMH General association test stratified by randomization strata factor. [b]P-value for comparing active treatments to placebo is obtained using an ANCOVA model with baseline value as a covariate and fixed effects for treatment and randomization strata factor.

**Conclusion:** OCA was effective in both regions with significantly more patients meeting the primary endpoint and having large reductions in ALP compared to PBO. Bilirubin levels were generally reduced or maintained in normal ranges.

**Contact E-mail Address:** matteogarcovich@yahoo.it

**Introduction:** Non-invasive assessment of liver fibrosis by ultrasound elastography techniques has received increasing attention as a means to evaluate disease progression in chronic liver disease patients. In this study, we assessed the value of shear wave elastography with Supersonic Shear Imaging (SSI) for the prediction of fibrosis stage in a cohort of pediatric patients with nonalcoholic steatohepatitis.

**Aims & Methods:** Consecutive patients scheduled for liver biopsy were studied by using SSI ultrasound system, a non-invasive method of assessing tissue stiffness. The correlations between laboratory findings, liver stiffness and the fibrosis score were analyzed using logistic regression and receiver operating characteristic curve analyses were performed to calculate area under the receiver operating characteristics curves for the presence of "any" (F≥1) or significant (F≥2) fibrosis.

**Results:** SSI was performed in 68 consecutive biopsy-proven nonalcoholic steatohepatitis patients (38 males, 31 females, age 12.6 ± 2.48 years). At the univariate linear analysis, SSI showed a high correlation with liver fibrosis (rho = 0.840, $P < 0.001$), ALT (rho = 0.387, $P = 0.001$) and AST (rho = 0.375, $P = 0.002$), degree of portal inflammation (rho = 0.428, $P = 0.002$), lobular inflammation (rho = 0.379, $P = 0.006$) and a moderate correlation for degree of histologic steatosis (rho = 0.279, $P = 0.020$) and histological hepatocyte ballooning (rho = 0.339, $P = 0.015$). However in the multivariate linear analysis (including all the aforementioned variables) the strong correlation with SSI was confirmed only for fibrosis stage ($P < 0.001$) (adjusted r2 = 0.73). Overall, SSI correctly classified 57 of 68 patients (84%). In particular, the ROC curve drawn to differentiate "any" fibrosis (F≥1) from absence of fibrosis (F0) yielded an AUROC of 0.92 (95% CI: 0.86–0.98), with an optimal cut-off of 5.1 kPa (sensitivity 86%; specificity 95%). The AUROC value for differentiating significant fibrosis (F ≥2) from fibrosis degree of less than F2 was 0.97 (95% CI: 0.95–0.99), with an optimal cut-off value of 6.7 kPa (sensitivity 88%; specificity 96%).

**Conclusion:** To date this is the largest case series evaluating the accuracy of SSI in children with fatty liver disease. SSI is an accurate and reproducible non-invasive technique detecting efficiently the presence of significant liver fibrosis and, less accurately, mild liver fibrosis in pediatric patients with non-alcoholic fatty liver disease. Larger clinical prospective studies are warranted to confirm SSI accuracy and establish threshold values for fibrosis grading in comparison or in combination with other non-invasive methodologies.

**Contact E-mail Address:** veronica.marin@csf.units.it
**Introduction:** NAFLD is a liver disease without a specific pharmacological therapy. Diet and life style changes are considered the best treatments, but patient compliance is the main limitation of this approach.
**Aims & Methods:** The aim of this work is to study the nutraceutical properties of Silymarin, added to High Fat High Carbohydrates Diet (HFHCD), in a NASH juvenile mice model, to assess if this compound could exert positive effects without modifications in dietary habits. Females and males C57BL/6 mice were fed with HFHCD immediately after weaning. After 8 weeks of diet when animals presented signs of NASH, Silymarin (33 mg/animal/day) was added to HFHCD and administrated for further 12 weeks. Animals exposed only to HFHCD for the same period (20 weeks) were used as control. Silymarin effects were assessed in terms of bodyweight, BMI, insulin resistance (HOMA-IR), lipidemia (total cholesterol, LDL and triglycerides-TG), hepatomegaly, hypertrophy of visceral adipose tissue and liver histology. The hepatic expression of genes involved in fibrosis, inflammation and steatosis was also assessed. Fibrosis was detected also though Sirius Red and Fast Green staining. Hepatic oxidative status was quantified in terms of MDA and GSH/GSSG analysis.
**Results:** The addition of Silymarin to the HFHCD decreased the liver weight and the visceral adipose tissue ($p < 0.001$); glycaemia was also reduced ($p < 0.05$) but not the HOMA-IR, since insulin level remained unchanged. Plasma LDL-C, TG, ALT, AST were significantly reduced ($p < 0.05$). Liver histology showed a reduction of steatosis and fibrosis. At the molecular level, Silymarin decreased significantly ($p < 0.05$) the expression of $\alpha$-SMA (hepatic stellate cells activation marker) and Collagen 1A1 confirming its effect in improving the fibrogenesis. A reduction of Sirius red staining indicating a decrease of collagen deposition ($p < 0.01$) was observed in males. Silymarin also reduced DGAT2 ($p < 0.05$), and MCP1 ($p < 0.05$) gene expression, markers of steatosis and inflammation, respectively. Of notice, inflammation was observed only in males while oxidative stress in HFHCD females. Silymarin decreased MDA and improved the GSH/GSSG ratio ($p < 0.05$), confirming antioxidant properties.
**Conclusion:** The addition of Silymarin to the HFHCD exerts beneficial effects mainly on lipidemia, liver damage and fibrosis possibly related to its anti-inflammatory and antioxidant activity. These data may be clinically relevant to overcome the low compliance of the patient to change dietary habits.

**Introduction:** Wilson's disease (WD) is an autosomal recessive disorder of the copper metabolism. The clinical manifestations are very variable with hepatic (from asymptomatic to fulminant liver failure of cirrhosis), neurological, psychiatric, ocular or other organ involvement. In some cases the diagnostic is difficult and a high degree of suspicion is needed for diagnostic orientation.
**Aims & Methods:** The aim of our study was to analyse the presence of diagnostic criteria for WD in childhood and adolescence. We have retrospectively analysed the data from the patients with WD diagnosed or followed-up in our unit during 2006–2015. The diagnosis was done using the clinical features, Kayser-Fleischer ring presence, copper metabolism tests and genetic analysis of ATP7B gene, following the up-to-date WD guidelines.
**Results:** WD was diagnosed in 47 patients (26 males, 21 females), with mean age at diagnosis of 12.30 years (range from 5 to 18.16 years). The clinical presentation was with hepatic disease in 37 patients (78.72%, three with associated autoimmunity and one as an acute hepatitis), haemolytic anaemia in 7 patients (14.89%, three of them with fulminant liver failure), neurologic in two patients (2.26%) and by screening as a relative of an index case in one patient (2.12%). Two patients with liver presentation developed also neurological disease in evolution. Serum ceruloplasmin was decreased in all, but two patients (mean level 10.63 mg/dl) and 24 h-urinary copper excretion was increased in all, but 6 patients (mean level 619.11 mcg/24h). In four cases the d-penicillamin challenge was used to prove WD and in two cases (with fulminant liver failure) sample was not collected due to fatal evolution. Kayser-Fleisher ring was present only in 9 patients (19.14%). Molecular analysis of ATP7B gene confirmed the disease in 42 patients (89.36%), in four patients no characteristic mutations were found and in one patient just one of the allele was mutated.
**Conclusion:** The majority of the children and adolescents with WD in our population had hepatic manifestations as clinical presentation. The existent criteria (including genetic analysis) permitted the diagnosis with certitude in most of the patients from our cohort. Genetic analysis could confirm the diagnosis of WD, but sometimes the results are coming too late, mainly in cases with fulminant liver failure with bad prognosis without emergency liver transplantation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0629 NON-INVASIVE TOOLS FOR LIVER DISEASE ASSESSMENT IN OBESE CHILDREN

**C. Pienar**[1], P. Velea[1], I. Ciuca[1], M. Tudor Voicu[2], A. Popescu[2], I. Sporea[2]

[2]*Gastroenterology And Hepatology, "Victor Babes" University of Medicineand Pharmacy, Timisoara/Romania*

**Contact E-mail Address:** pienar.corina@umft.ro
**Introduction:** Pediatric obesity plays a central role in the etiology of non-alcoholic fatty liver disease (NAFLD), which has become the most common form of chronic liver disease in children. While biopsy remains the golden standard for staging liver disease, several non-invasive tools have been proposed for evaluating it.
**Aims & Methods:** To evaluate the usefulness of Aspartate-aminotransferase to Platelets Ratio Index (APRI) and a point shear wave elastography technique (point SWE) in assessing liver disease in obese children. We conducted a prospective study in 31 children (mean age $11.4 \pm 3.9$, 22.6% girls, mean BMI $22.62 \pm 7.19\,kg/m^2$) divided into 3 groups: obese children ($n = 14$), children with hepatopathies (cystic fibrosis associated liver disease, chronic autoimmune hepatitis, $n = 4$) and controls (normal weight children without liver disease, $n = 13$). Our analyzed variables included aminotransferase levels and platelet count. We performed liver ultrasonography for the assessment of liver steatosis and elastographic measurements of liver stiffness using point SWE – Virtual Touch Tissue Quantification (VTQ), Acuson S2000 Siemens.
**Results:** Overall 22.5% (7/31) children had NAFLD, while 50% (7/14) of the obese children had NAFLD. None of the controls or children with hepatopathies had NAFLD. APRI scores were higher in obese children with NAFLD ($0.2 \pm 0.07$ vs $0.48 \pm 0.16$, $p = 0.009$). VTQ values were similar both in obese children with NAFLD and without NAFLD ($1.37 \pm 0.61$ vs $1.35 \pm 0.72$, $p = 0.3$). For both APRI and VTQ the highest values were found in children with hepatopathies. When compared to the controls, APRI scores were higher in the obese group ($0.32 \pm 0.18$ vs $0.22 \pm 0.11$, $p = 0.16$). We also found higher VTQ values for the obese, when compared with the controls ($1.36 \pm 0.67\,m/s$ vs $1.11 \pm 0.16\,m/s$, $p = 0.5$).
**Conclusion:** APRI and VTQ are useful for liver disease assessment in obese children. VTQ predicts liver disease in obese children, even when ultrasound steatosis or high transaminase levels are not present.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0630 STRUCTURAL CHANGES IN THE LIVER AND FEATURES OF METABOLIC CHANGES IN CHILDREN WITH NONALCOHOLIC FATTY LIVER DISEASE COMBINED WITH BILIARY DYSKINESIA

N. Zavgorodnya[1], **O. Lukyanenko**[2]
[1]*Pediatric Gastroenterology, Institute of Gastroenterology of National Academy of Medical Sciences of Ukraine, Dnipropetrovsk/Ukraine*
[2]*Pediatric Gastroenterology, sirenkolga@gmail.com, Dnipropetrovsk/Ukraine*

**Contact E-mail Address:** sirenkolga@gmail.com
**Introduction: Introduction** Nonalcoholic fatty liver disease is one of the most common causes of chronic liver disease in children and adults [1]. Hepatic insulin resistance is associated with the accumulation of fat in the liver, but also plays a crucial role in the development of colloidal properties of bile disorders due to a glut and excess production of bile salts [2]. There are numerous studies that insulin resistance is also a direct factor in gallbladder motility [3]. Functional disorder of the gallbladder with sphincter of Oddi disorder, according to the Rome III criteria relating to the functional disorders of the biliary system. The etiology and pathogenesis of these disorders do not fully clarified, and diagnostic criteria rather contradictory. Functional disorder of the gallbladder can be a primary link of the organic diseases of the biliary tract [4]. Studies on the influence of a violation of the functional state of the gallbladder on structural features in children with liver steatosis almost nonexistent.
**Aims & Methods:** Purpose – to study structural changes in the liver and features of metabolic changes in children with nonalcoholic fatty liver disease combined with biliary dyskinesia. Materials and methods – 34 children aged 5 to 17 years were examined for the presence of risk factors of hepatic steatosis. Abdominal ultrasonography was performed to diagnose the functional state of gallbladder. Gallbladder contractility index was calculated based on the preprandial and postprandial gallbladder volumes. The presence of liver steatosis was determined using transient elastography with the help of FibroScan® 502 touch (Echosens, Paris, France) with controlled attenuation parameter (CAP) measurement. Biochemical lipid spectrum of the blood, biochemical quality of bile were investigated. Determination of taurocholic, taurodeoxycholic, glicoholic and

glikodeoxyholic bile acids in bile was conducted using the thin layer chromatography. Patients were divided into 4 groups: 1st group consisted of 7 patients with existing hepatic steatosis and gallbladder hypokinesia (20.5%); 2nd – 6 patients with liver steatosis and gallbladder normokinesia (17.65%); 3rd – 11 patients without hepatic steatosis but with gallbladder hypokinesia (32.35%); 4th – 10 patients without hepatic steatosis but with gallbladder normokinesia (29.4%).
**Results:** Combination of liver steatosis and gallbladder hypokinesia was associated with liver parenchyma stiffness increasing and CAP reached the maximum values ($268.2 \pm 32.7$ dB / m). Patients with gallbladder hypokinesia were characterized by the development of type IIa dyslipidemia. Combination of liver steatosis and gallbladder hypokinesia demonstrated reduction of cholic acid content with tauroholic acid growth and reducing of glikoholic acids in the liver and gallbladder bile portions. There were also observed increasing in conjugated with glycine bile acids concentration. Accordingly the ratio between oxidized and recovered fractions corresponding bile acids was altered that could contribute to changes of bile colloidal stability.
**Conclusion:** The combination of nonalcoholic fatty liver disease with gallbladder hypokinesia is accompanied by both liver stiffness and CAP increase, type IIa dyslipidemia development and bile composition alteration.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The documented incidence of pediatric pancreatitis (PP) is very low, less than 1/100,000 in almost all European countries, whereas it is around 3.6–13.2/100,000 in the USA and Australia. Moreover, there are large differences between the countries: the incidence decreases from the USA and Western Europe to Eastern Europe.
**Aims & Methods:** Our aim is to understand the current practice of diagnosis of PP and to develop EBM guidelines that helps to evaluate (in a reliable and cost efficient way) the necessity of pancreatic enzyme measurement (PEM) and abdominal ultrasonography when a child has abdominal pain. The PINEAPPLE trial is a registered (ISRCTN35618458), multinational observational clinical trial and the prestudy protocol is already published (http://www.ncbi.nlm.nih.gov/pubmed/26641250). The PINEAPPLE-R reviews retrospectively the children (patients under 18) records appearing at ER units, whereas, the PINEAPPLE-P subtrial is a prospective part of the study where detailed patients data are collected, PEM and abdominal imaging are performed in all cases. Until now 23644 patients records/PINEAPPLE-R and 188 patients/PINEAPPLE-P were enrolled from eight pediatric centres.
**Results:** PINEAPPLE-R: We analysed and compared 11733 American and 11911 Central-European patients data. All together 8.3% (1970/23644) of the patients appearing at ER unit had abdominal pain. The incidence of abdominal pain was 6.2% in America whereas 10.4% in Central-Europe. The rate of the transabdominal ultrasonography was similar in America and in Central-Europe (28.2% vs. 31.2%). However, concerning PEM, 8-times more measurement were performed in the USA than in Central-Europe (21.6% (157/728) vs 2.8% (35/1242)). Not surprisingly the incidence of pancreatitis was 6.9 times higher in USA (4/728) than in Central-Europe (1/1242). PINEAPPLE-P: 3 pancreatitis of 188 patients with abdominal pain were diagnosed.
**Conclusion:** The PINEAPPLE-R study clearly shows that the number of PEM performed at ER units are unacceptably low in children, which could be the reason of low incidences of PP. More patients are crucially needed for PINEAPPLE-P in order to develop EBM guidelines.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Despite of the rising incidence of pediatric pancreatitis (PP) in the last decade, there is still lack of information (studies) concerning the management of childhood onset pancreatitis. Most of the guidelines are based on clinical trials performed on adults.
**Aims & Methods:** The Pediatric Section of the Hungarian Pancreatic Study Group aimed to initiate a prospective international observational clinical trial (APPLE – Analysis of Pediatric Pancreatitis) (i) to understand the genetic factors of all forms of pancreatitis occurred under 18 (APPLE-R), and (ii) to collect a critical mass of clinical data and biomedical research samples from children suffering from AP (APPLE-P). The study has (i) been discussed and agreed in our latest international meeting (http://pancreas.hu/sites/info/files/conferences/ALPD2014-Program.pdf), (ii) received the relevant ethical permission, (iii) been registered at the ISRCTN registry (ISRCTN89664974) which is a primary clinical trial registry recognised by WHO. The study is open for all centres. All clinical research forms are available at our webpage http://pancreas.hu/en/studies.
**Results:** APPLE-R: 35 acute (AP), 8 recurrent acute (RAP) and 14 chronic pancreatitis (CP) cases were enrolled yet. Concerning the etiology, biliary and drug-induced 9–9%, trauma, acohol 2–2%, postERCP and anatomic 5–5%, other 14% were identified however 54% of the cases still remained idiopathic. In 35 cases, genetic analyses of PRSS1, SPINK1, CFTR and CTRC genes have been completed. Genetic alterations in PRSS1 were found in 4 cases (all CP), in SPINK1 in 6 cases (3 RAP and 3 CP), in CFTR in 1 case (CP) and in CTRC in 18 cases (5 AP, 6 RAP and 7 CP), In 5 CP patients mutations in two genes were observed (3 SPINK1-CTRC, 1 PRSS1-SPINK, 1 CFTR-CTRC. APPLE-P: no data available yet.
**Conclusion:** Positive genetic alteration was found in 95% of the idiopathic and 47% of the non-idiopathic groups. Our result suggest that genetic testing should be performed in all children suffering from pancreatitis. The study is still ongoing, more patients are crucially needed.

## PANCREAS II – POSTER EXHIBITION

### P0633 RISK STRATIFICATION DEPENDING ON THE TIMING OF TRANSMURAL ENDOSCOPIC DEBRIDEMENT AFTER SEVERE ACUTE PANCREATITIS: A RETROSPECTIVE GERMAN SINGLE CENTER ANALYSIS

**C. Meinhardt**, B. Dahl, P. Troschel, D. Scholz, M. Reuther, H. Seifert
*University Clinic of Internal Medicine – Gastroenterology, Klinikum Oldenburg, Oldenburg/Germany*

**Contact E-mail Address:** christian.meinhardt@uni-oldenburg.de

**Introduction:** The mortality due to severe acute pancreatitis (SAP) is mainly caused by late complications such as infected necrosis. In this context, the classic statement, 'ubi pus, ibi evacua' is still valid. Transmural endoscopic debridement is the treatment of choice for post pancreatic infected necrosis. However, there is still no consensus concerning the optimal timing of the transmural endoscopic interventions.
**Aims & Methods:** We sought to determine the interdependence between the timing of the transmural intervention and the mortality rate, severe adverse

events and therapeutic success. A total of 223 patients with severe acute necrotizing pancreatitis received transmural endoscopic debridement from 1999 to 2015. This cohort was divided in 4 groups according to the timing of the intervention (interval from acute pancreatitis to early intervention ≤4 weeks (EI), 5–8 weeks, 9–12 weeks and >12 weeks).
**Results:** EI was associated with a higher mortality rate than interventions after this period (17% vs. 8%, p = 0.0648) and with a significantly lower success rate (76% vs. 89%, p < 0.05). They were generally justified by signs of septic complications, so this subgroup was characterized by significantly more frequent initial ICU treatment as well as higher inflammatory markers at the time of intervention.

| Time of intervention | n | Success | Mortality | Complications | Sepsis | CRP [mg/dl] | Initial ICU |
|---|---|---|---|---|---|---|---|
| **week 0–4** | 53 | 39 (76%) | 9 (17%) | 24 (45%) | 38 (72%) | 21.7 ± 13.3 | 21 (40%) |
| **week 5–8** | 80 | 69 (87%) | 8 (10%) | 36 (45%) | 39 (49%) | 15.2 ± 10.6 | 24 (30%) |
| **week 9–12** | 36 | 32 (89%) | 3 (8%) | 8 (22%) | 18 (50%) | 13.7 ± 9.5 | 7 (9%) |
| **>week 12** | 52 | 48 (92%) | 2 (4%) | 19 (37%) | 7 (13%) | 9.2 ± 9.2 | 2 (4%) |
| **≤4 wk. vs. >4 wk.** | | p < 0.05 | p = 0.0648 | p = 0.3360 | p < 0.0001 | p < 0.0001 | p < 0.01 |

In the EI group patients with lethal outcome had more frequently cardiovascular (33% vs. 5%, p < 0.05), pulmonary (56% vs. 9%, p < 0.01) and/or renal failure (44% vs. 2%, p < 0.01) at disease onset, defined as systolic blood pressure <90 mmHg, paO2 <60 mmHg or mechanical ventilation and serum creatinine level >2 mg/dl, respectively, as compared to surviving patients in this group. Indication for EI was sepsis (lethal outcome: 100%; survivors: 66%; p < 0.05), mean CRP at the time of intervention was 35.2 ± 12.3 mg/dl (lethal outcome) vs. 18.9 ± 11.6 mg/dl (survivors), p < 0.05. The procedure related complication rates did not differ among both groups (44% vs. 45%).
**Conclusion:** Our data show that delayed as opposed to early endoscopic debridement is associated with more favourable outcomes in patients with SAP complicated by infected peripancreatic necrosis. However, the common consensus that interventions should be delayed as long as possible cannot be inferred from these data. The high mortality rate after EI may be due to the severe condition in general of these patients. Under most critical circumstances early transmural interventions may be a life-saving strategy with more than 80% survival. This "early subgroup" comprising our most demanding and complicated patients deserves more detailed and prospective analysis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0634 ACUTE PANCREATITIS IN THE ELDERLY: A CAUSE FOR INCREASED CONCERN? RETROSPECTIVE EVALUATION OF A TERTIARY REFERRAL CENTER

**S.R. R. Fernandes**, C. M. Moura, P. Santos, J. Carvalho, T. Antunes, J. Velosa
*Serviço De Gastrenterologia E Hepatologia, Hospital Santa Maria, Centro Hospitalar Lisboa Norte, Lisboa/Portugal*

**Contact E-mail Address:** Samuelrmfernandes@gmail.com
**Introduction:** Acute pancreatitis is an aggressive and potentially fatal disease. The elderly population is hypothetically at a higher risk for a fatal outcome. Unexpectedly, recent studies have challenged this assumption, stating that although elderly patients may undergo a severe acute pancreatitis course, they present with no increased mortality. We aimed to confirm these findings in a retrospective cohort of acute pancreatitis patients.
**Aims & Methods:** 254 elderly patients (median 77.5 years, range 65–98 years) and 271 controls (median 46, range 15–64 years) with acute pancreatitis admitted to our center were included in this study. Outcomes included mortality, admission to intensive care unit (ICU), length of hospital stay, development of organ failure or persistent organ failure and need for interventional procedures or nutritional support. Statistical analysis was performed with SPSS v21.0.
**Results:** Elderly patients showed higher median Ranson (1, range 0–8 versus 3 range 1–6, p < 0.001) and BISAP scores (0 range 0–3 versus 2 range 0–5, p < 0.001) and longer length of hospital stay (7.5 range 1–33 versus 8 range 1–44, p < 0.001). Mortality (3.4% versus 9.5%, p = 0.008), ICU admission (29.2% versus 53.0%, p = 0.002), organ failure (21.4% versus 52.6%, p < 0.001), persistent organ failure (8.1% versus 16.9%, p = 0.008) and need for interventional procedures (21.1% versus 66.0%, p < 0.001) were also similar in the older population. There was no difference in the length of ICU stay (p = 0.944) or the need for nutritional support (p = 0.444). In logistic regression analysis, every ten years increase in age increased the risk of death by 10.35 (95%CI 10.12–10.59, p = 0.003).
**Conclusion:** In our series, older age was strongly associated with a more severe course of acute pancreatitis. Early recognition and prompt action are essential in this condition. Especial consideration should be given in older patients as the rates of organ failure and persistent organ failure are higher and the need for interventions is significantly increased.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0635 ENDOSCOPIC AND PHARMACOLOGICAL PROPHYLAXIS OF POST-ERCP PANCREATITIS: A META-ANALYSIS AND SYSTEMATIC REVIEW

**S.F. Vadalà Di Prampero**[1], G. Faleschini[2], M. Bulajic[3], D. Berretti[2], M. Marino[2], N. Panic[4], M. Zilli[2]

**Introduction:** Post-ERCP pancreatitis (PEP) is the most common complication following endoscopic retrograde cholangiopancreatography. To provide clinical guidance and a framework for future research in this important field, we performed a systematic review and meta-analysis of the global literature on PEP prevention.
**Aims & Methods:** PubMed, Embase, Science Citation Index, Ovid and the Cochrane Controlled Trials Register were searched by 2 independent reviewers to identify full-length, prospective, randomized, control trials (RCTs) published up until March 2016 investigating the use of pancreatic duct (PD) stents and pharmacological agents to prevent-PEP.
**Results:** Twelve RCTs comparing the risk of PEP after PD stent placement (1369 subjects) and thirty RCTs comparing pharmacological agents over placebo (10251 subjects) met the inclusion criteria and were selected for final review and analysis. Meta-analysis showed that prophylactic pancreatic stents decreased the odds of post-ERCP pancreatitis (OR, 0.28; 95% CI, 0.18–0.42). Pooled analysis showed a significant OR reduction of PEP with rectal administration of Diclofenac (OR, 0.24; 95% CI, 0.12–0.48) compared with placebo. Rectal administration of Indometacin compared with placebo significantly decreased the odds of PEP (OR, 0.59; 95% CI, 0.44–0.79), with significant heterogeneity observed (P = 0.045; $I^2$ = 56%). Subgroup analysis showed a significant reduction with bolus administered somatostatin (OR, 0.23; 95% CI, 0.11–0.49).
**Conclusion:** Pancreatic stent placement, rectal Diclofenac and bolus administration of somatostatin are most effective in preventing post-ERCP pancreatitis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0636 THE UTILITY OF SIRS AND BISAP SCORES FOR PREDICTING SEVERITY, MORBIDITY AND MORTALITY IN PATIENTS WITH ACUTE PANCREATITIS

**P. Kakkadasam Ramaswamy**, A. Yelsangikar, A. Nagar Krishnamurthy, N. Bhat
*Gastroenterology And Liver Diseases, Aster CMI Hospital, Bangalore/India*

**Contact E-mail Address:** drkrpradeep@gmail.com
**Introduction:** A high Systemic Inflammatory Response Syndrome (SIRS) score at admission and a persistently high SIRS at 48 hours have been shown to predict a severe course, presence of pancreatic necrosis, ICU stay and mortality in acute pancreatitis. The Bedside Index for Severity of Acute Pancreatitis (BISAP) Score has been used as predictor of mortality in acute pancreatitis (AP). SIRS can be easily calculated in the emergency room and is also a component of the BISAP score.
**Aim**: The aim of this study was to compare the performance of BISAP with SIRS alone in predicting severity, mortality, length of hospital stay, ICU stay, organ failure, infections and need for interventions in patients with acute pancreatitis.
**Methods**: Consecutive patients admitted with acute pancreatitis from June 2013 to July 2015 were included in the study. A retrospective analysis of prospectively collected data from all patients was carried out. SIRS and BISAP were calculated at admission to the emergency room. As per the Revised Atlanta Classification the patients were classified into Mild, Moderately Severe and Severe Acute Pancreatitis.

**Abstract No: P0636**
**Table 1:** Clinical Characteristics of the two groups

| | SIRS ≤ 1 (n = 37) | SIRS ≥ 2 (n = 38) | P value | BISAP ≤ 1 (n = 40) | BISAP ≥ 2(n = 35) | P value |
|---|---|---|---|---|---|---|
| **Mild Moderately severe Severe** | 31 4 2 | 12 17 9 | 0.0001 | 36 4 0 | 7 17 11 | 0.0002 |
| **Age (years)** | 40.78 ± 17.6 | 39.6 ± 18.1 | 0.69 | 35.3 ± 15.6 | 45.1 ± 19.4 | 0.01 |
| **M/F** | 31/6 | 30/8 | NS | 33/7 | 28/7 | NS |
| **Duration of hospital stay (days)** | 4.86 ± 4 | 11.2 ± 9.7 | 0.0004 | 4.8 ± 3 | 11.9 ± 10.2 | 0.0001 |
| **ICU stay (days)** | 1 ± 1.97 | 4.5 ± 5.9 | 0.001 | 0.75 ± 1.2 | 5 ± 6.1 | 0.0001 |
| **Organ failureTransientPersistent** | 0 2 | 5 9 | 0.0014 | 0 0 | 5 11 | 0.0001 |
| **InfectionPancreaticExtrapancreaticBoth** | 1 0 1 | 2 3 4 | 0.04 | 0 0 0 | 3 3 5 | 0.0001 |
| **Mortality** | 0 | 3 | 0.24 | 0 | 3 | 0.09 |
| **Need for intervention** | 4 | 5 | 1 | 2 | 7 | 0.07 |

**Results:** Seventy-five patients with AP (mean age 40.3 years) were included in the study, 81.3% were male. Forty-three patients (57.3%) had mild AP, 21 patients (28%) had moderately severe AP and 11 patients (14.7%) had severe AP. Three patients with acute severe pancreatitis died, no mortality was seen in the mild AP or moderately severe AP groups. Sixteen patients (21.3%) developed organ failure, 5 patients had transient organ failure and 11 patients had persistent organ failure. Eleven patients (14.67%) developed infections. Six patients developed either pancreatic or extra-pancreatic infection alone, whereas 5 patients developed infection at both pancreatic and extra-pancreatic sites. SIRS $\geq$ 2 at admission had a sensitivity of 81.2 (95%CI 63.5 to 92.8%), specificity of 72% (95% CI 56.3 to 84.6%), PPV 68.4%(95% CI 51.3 to 82.5%) and a NPV of 83.8% (95% CI 67.99 to 93.8%) to predict a moderately severe/severe course of AP. In comparison, BISAP $\geq$ 2 at admission had a better PPV of 80% (95% CI 63 to 91.5%) and NPV of 90% (95% CI 76.3 to 97.2%). The sensitivity and specificity of BISAP $\geq$ 2 was 87.5% (95% CI 71 to 96.4%) and 83.7% (95% CI 69.3 to 93.2%) respectively. BISAP $\geq$ 2 was more accurate in predicting a severe course of AP when compared to SIRS $\geq$ 2 (85.3% vs 76%). Patients with BISAP $\geq$ 2 or SIRS $\geq$ 2 had a significantly longer hospital and ICU stay, higher rate of infection and organ failure (Table 1). Mortality and need for interventions was similar in both the groups.
**Conclusion:** The SIRS and BISAP scores are easy to calculate and both scores can be used for risk stratification of all patients with acute pancreatitis. SIRS $\geq$ 2 and BISAP $\geq$ 2 at admission both correctly predict a severe course of AP, however the BISAP score is more accurate. Both scores accurately predict a longer hospital and ICU stay, greater risk of organ failure and infections in patients with acute pancreatitis. Patients with SIRS $\geq$2 or BISAP $\geq$2 at admission need close monitoring and should be considered for referral to a pancreatic unit.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0637 A NEW SCORING SYSTEM TO PREDICT POST-ERCP PANCREATITIS

**K. Fujita**[1], S. Yazumi[2], Y. Kodama[3], A. Sugahara[1], T. Kawamura[4]

[4]*Health Service, Kyoto University, Kyoto/Japan*

**Contact E-mail Address:** koichifujitarm@gmail.com
**Introduction:** Post-ERCP pancreatitis (PEP) can be sometimes serious and/or fatal. Therefore, it is important to detect high risk patients for adequate preventive strategies. Some risk factors for PEP are known, but there are few reliable methods for predicting whether PEP will develop in an individual patient [1].
**Aims & Methods:** The aim of this study is to develop a practical prediction rule for PEP. This study was designed as hospital-based observational study. From April 2010 to September 2012 at Kyoto University Hospital, Kitano Hospital and Yodogawa Christian Hospital, patients who were referred for transpapillary ERCP were enrolled. Exclusion criteria were under 18 years old, patients with clinical evidence of acute pancreatitis at the time of the procedure, and patients with altered gastrointestinal anatomy. e.g. Roux-en-Y reconstruction. The main outcome was PEP. In addition, we assessed two types of candidate predictive factors. (1) Patient-related factors included younger age ($<$60 years), female gender, history of PEP, chronic pancreatitis, jaundice, periampullary diverticulum, intact papilla and suspect of sphincter of Oddi dysfunction. (2) Procedure-related factors included difficult cannulation (over 15 min), endoscopic sphincterotomy, precut sphincterotomy, endoscopic papillary balloon dilation and pancreatic contrast injection, biliary drainage, pancreatic drainage, stone extraction, common bile duct intraductal ultrasonography (C-IDUS), pancreatic duct IDUS, tissue sampling (biopsy and brushing cytology) from biliary tract and tissue sampling from pancreatic duct. Univariable analysis and multivariable logistic regression were used to detect candidate predictive factors for PEP. Based on the analysis, we constructed several scoring models by changing the detailed settings of model construction. The final model was selected from those candidate models based on the area under the receiver-operating characteristic curve (AUC), visual inspection of the histogram and clinical adequacy.
**Results:** Result from 2738 patients were analyzed. PEP developed in 133 cases (4.9%), 80 mild, 46 moderate, 6 severe and 1 fatal. By univariable analysis, 8 candidate factors were selected; younger age, female gender, history of PEP, intact papilla, difficult cannulation, pancreatic contrast injection, C-IDUS, and tissue sampling from bile duct. Multivariable risk factors with adjusted odds ratios (OR) were female gender (OR: 1.5 [95% CI, 1.1–2.2]), history of PEP (OR: 4.1 [95% CI, 2.0–8.0]), intact papilla (OR: 2.9 [95% CI, 1.8–4.9]), difficult cannulation (OR: 2.32[95% CI, 1.6–3.5]), pancreatic contrast injection (OR: 2.6 [95% CI, 1.7–4.1]),and C-IDUS/tissue sampling from biliary tract (OR:2.1 [95% CI, 1.4–3.1]). A scoring system was constructed from the six clinical variables as below. Female gender: 1 point, history of PEP: 3 points, intact papilla: 2 points, difficult cannulation: 2 points, pancreatic injection: 2 points, C-IDUS/tissue sampling from biliary tract: 1 point. The points were added up to a total score that predicts the risk of pancreatitis. Cases scoring 2 or fewer points had less than a 2% risk of PEP. Those scoring 3 and 4 points had 3.9–5.9% risk, while those scoring 5 between 7 points had 10.3–17.5% risk and more than 7 points had more than 20% risk. AUC of this model was 0.80. When all cases were divided into two groups; a low risk group (scoring 4 points or fewer) and a high risk group (more than 4 points). The sensitivity of this criteria was 66.9%, specificity was 78.3%, positive predictive value was 14% and negative predictive value was 97.8%. All patients with severe PEP belonged to a high risk group.
**Conclusion:** The present study found that female gender, history of PEP, intact papilla, difficult cannulation, pancreatic contrast injection, and C-IDUS/tissue sampling from biliary tract independently increased the risk of PEP. This scoring system will serve as a useful prognostic tool for PEP in clinical practice, although it requires prospective validation with a variety of patients and clinicians.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Severe acute pancreatitis (SAP) is a potentially high-mortality disease for which organ. Organ failure (OF) is among the chief causes of mortality. Pancreatitis-related OFs are either local or systemic. In general, local OF can be divided into three stages: pancreatic ischemia, pancreatic necrosis, and walled-off necrosis (WON). Pancreatic necrosis is caused by pancreatic ischemia, which leads to WON. Systemic OF, including shock states, respiratory failure, renal failure, and heart failure, is the common origin of patient instability. Both local and systemic OFs can be caused by disturbances of coagulation and inflammatory effects. These SAP disorders are related to the development of disseminated intravascular coagulation (DIC). Recombinant human soluble thrombomodulin (rTM) was recently approved for use in treating sepsis- induced DIC[1]. According to a recent study, SAP patients with disturbances of coagulation and treated with rTM showed significantly lower rates of development of WON than those not treated with rTM[2].
**Aims & Methods:** This study investigates whether rTM improves the disturbances of coagulation in SAP, and prevents the development of pancreatic ischemia/necrosis. We retrospectively analyzed 87 successive patients with SAP treated at our hospital from January 2006 to December 2015 at Osaka Saiseikai Nakatsu Hospital. All patient data was gathered from an electronic database. A diagnosis of SAP was determined using the Japanese severity scoring system. The study enrolled patients with SAP whose treatment began within 48 hours of onset. Eighty-seven SAP patients were divided into two groups: SAP patients treated with rTM (380U/kg for 30 min, once daily) (rTM group, 42 patients) and not treated with rTM (control group, 45 patients). JAAM DIC scores, as the coagulation abnormality, were calculated before treatment (admission day = day 0) and after the start of treatment (days 3 and 7). A diagnosis of pancreatic ischemia/necrosis based on conventional contrast-enhanced CT (CECT) was recorded. We assessed the development of WON 4 weeks later based on CT/MRI.
**Results:** On day 0, the condition of patients in the rTM group was significantly worse than the control group in age ($69.8 \pm 14.2$ vs. $61.2 \pm 17.8$ years), APACHE II score ($11.6 \pm 3.8$ vs. $9.1 \pm 5.1$), SOFA score ($4.0 \pm 2.8$ vs. $2.7 \pm 2.5$), and number of OF patients {42.9 (18/42) vs. 17.8 (8/45) [%]} ($p < 0.05$). On day 0, we found no significant differences in rate of pancreatic ischemia/necrosis between the rTM group and the control group {64.3% (27/42) vs. 60.0% (27/45), $p = 0.82$}. On day 0, we found significant differences in coagulation abnormality between the rTM group and the control group (rTM vs. control: $4.8 \pm 1.6$ vs. $2.6 \pm 1.6$ for JAAM DIC score; $51.2 \pm 38.1$ vs. $20.2 \pm 17.6\,\mu g/mL$ for FDP; $27.1 \pm 21.1$ vs. $14.7 \pm 14.2\,\mu g/L$ for TAT; $13.5 \pm 10.0$ vs. $5.6 \pm 4.9\,\mu g/mL$ for D-dimer; $p < 0.05$). On day 7, the following parameters fell for patients treated with rTM: JAAM DIC scores, FDP levels, TAT levels, and D-dimer levels. Univariate analysis shows that identified platelet counts, FDP levels, D-dimer levels, JAAM DIC score did not significantly contribute to pancreatic ischemia/necrosis. A multivariate analysis was performed, incorporating the factors identified by univariate analysis. The JAAM DIC score ($P = 0.047$, OR = 0.651, 95%CI: 0.427–0.995) was the only factor found to contribute to the absence of pancreatic ischemia/necrosis.
**Conclusion:** In this study, lower JAAM DIC scores were related to the absence of pancreatic ischemia/necrosis, a local complication. Treatment with rTM immediately improved disturbances of coagulation, including JAAM DIC scores. rTM may be a candidate as a new therapeutic option beneficial in addressing local complications for SAP patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic transmural drainage (ETMD) of peripancreatic fluid collections(PFC) is an effective alternative to surgical drainage. Conventional drainage using plastic stents has its limitations. Removable wide bore, short metal stents have been used successfully in the past for this purpose, but spontaneous stent migration and tissue erosion secondary to the stents have been reported.
**Aims & Methods:** Assesment of efficacy and safety of a newly designed fully covered bi-flanged metal stent (BFMS) with special anti-migratory flanges and with internal diameter of 14 mm (Hanaro, MI Tech, South Korea) for ETMD. This was a retrospective analysis of prospectively collected data in a single center with adequate experience in EUS guided ETMD. Parameters evaluated were technical success of stent placement, clinical success as defined by radiological resolution of PFC and resolution of symptoms. Feasibility of endoscopic necrosectomy and stent removal was noted. Adverse events including stent migration and stent related tissue erosion were recorded. Patients were followed up with suitable imaging to confirm PFC resolution. Stents were endoscopically removed within six weeks of placement after confirmation of clinical and radiological resolution of PFC.
**Results:** Twelve patients of PFC underwent endoscopic ultrasonography (EUS) guided ETMD using this BFMS underduring a five month period (July – October 2015). Ten were males. Mean age was 37 years (20 – 65). Alcohol was commonest etiology of pancreatitis (8/12, 67%). Nine PFCs were pseudocysts (PPC's) and three were walled off necrosis (WON) with significant debris in the cavity. Technical and clinical success for drainage was seen in all patients (100%). Direct endoscopic necrosectomy (DEN) was performed in 3 (25%) patients. No adverse events were observed. There were no incidences of stent migration or stent related tissue erosion. Mean duration of follow up was10 weeks (4 – 20). All stents were removed within six weeks of placement. At the time of writing the abstract, 4/12(33%) patients had undergone stent removal.
**Conclusion:** The new specially designed anti- migratory BFMS is safe and effective for drainage of PFC. Endoscopic necrosectomy can be carried out through the stent. Stent can be removed endoscopically at the end of the treatment period. No incidences of spontaneous stent migration or stent related tissue erosion were noted in this small series of patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0640 METABOLIC SYNDROME AND ACUTE PANCREATITIS

**I. Mikolasevic**, S. Milic, L. Orlic, G. Poropat, I. Jakopcic, A. Klanac, N. Kristo, D. Stimac

**Contact E-mail Address:** ivana.mikolasevic@gmail.com
**Introduction:** The aim of our study was to investigate the influence of metabolic syndrome on the course of acute pancreatitis determined by disease severity, the presence of local and systemic complications and survival rate.
**Aims & Methods:** 609 patients admitted to our hospital in the period from January 1, 2008 up to June 31, 2015 with the diagnosis of acute pancreatitis were analyzed. The diagnosis and the severity of acute pancreatitis were made according to the revised Atlanta classification criteria from 2012.
**Results:** Of 609 patients with acute pancreatitis, 110 fulfilled the criteria for metabolic syndrome. Patients with metabolic syndrome had statistically significantly higher incidence of moderately severe (38.2% vs. 28.5%; $p = 0.05$) and severe (22.7% vs. 12.8%; $p = 0.01$) acute pancreatitis in comparison to those without metabolic syndrome, while patients without metabolic syndrome had higher incidence of mild acute pancreatitis in comparison to those patients with metabolic syndrome (58.7% vs. 39.1%; $p < 0.001$). Patients with metabolic syndrome had a higher number of local and systemic complications, and higher APACHE II score in comparison to patients without metabolic syndrome. In multivariable logistic regression analysis, the presence of metabolic syndrome was independently associated with moderately severe and severe acute pancreatitis. Comparing survival rates, patients suffering from metabolic syndrome had a higher death rate compared to patients without metabolic syndrome (16% vs. 4.5%; $p < 0.001$).
**Conclusion:** The presence of metabolic syndrome at admission portends a higher risk of moderately severe and severe acute pancreatitis, as well as higher mortality and longer duration of stay in intensive care unit. Given the rising incidence of metabolic syndrome, we can expect even higher incidence of severe acute pancreatitis in the near future. Regarding the fact that most of metabolic syndrome components can be either prevented or improved through lifestyle changes and/or pharmacological agents, a question is raised whether this can also prevent the occurrence of acute pancreatitis, namely severe acute pancreatitis and its complications.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** amandineabrantes@gmail.com
**Introduction:** In Western countries, alcohol abuse is the main aetiology of chronic pancreatitis (CP), representing 70% to 80% of cases. However, only less than 10% of heavy drinkers develop CP. The discovery of involvement of certain genes such as PRSS1, CFTR and SPINK1 in hereditary and idiopathic CP, also raises the question of the role of genetic factors in alcoholic chronic pancreatitis (ACP). Several studies have been conducted in recent years to search this involvement, especially regarding PRSS1, SPINK1, CLDN2 and more recently, CEL, ABO and FUT-2.
**Aims & Methods:** The aim of this work is to investigate whether genetic factors may be protective against the development towards CP or conversely may promote the evolution to CP in alcoholic subjects. A case-control study was conducted. The group of cases included 40 severe alcoholics with CP whilst the group of controls included 76 severe alcoholics without CP. Severe alcoholics were defined to have an alcohol consumption of more than 80 g per day for at least 5 years. DNA extraction was performed from a blood sample taken from each participant. Genotyping of PRSS1, SPINK1, CLDN2, ABO and FUT-2 variants of interest was achieved by a High Resolution Melting (HRM) method. The recently described CEL-HYB allele was genotyped using the previously published long-range duplex PCR assay followed by sequencing.
**Results:** The Single Nucleotide Polymorphism (SNP) rs10273639 of PRSS1 is more frequently found among alcoholics controls ($OR = 0.12$, $CI_{95\%} = [0.04–0.42]$; $p < 0.0001$). The SNP rs12688220 of CLDN2 is significantly associated with ACP ($OR = 2.83$; $CI_{95\%} = [1.08–7.49]$; $p = 0.02$). The SPINK1 p. N34S variant was identified in only 3 cases in the heterozygous state, or 7.5% of cases. The CEL-HYB allele was found in the heterozygous state in 2 cases out of 40 examined (5%). Of the 76 alcoholic controls studied, one carried this hybrid allele in the heterozygous state, or 1.32%. As for SNP rs8176693 of ABO and SNP rs632111 of FUT2, no observable differences of allele frequency were found between cases and controls.
**Conclusion:** This study has allowed us to demonstrate a protective effect of the rs10273639 in PRSS1 and a predisposing effect of rs12688220 of CLDN2. The suggestive predisposing effect of SPINK1 p. N34S variant (as well as the CEL-HYB allele) remains to be tested in larger samples. However, we did not detect any distribution differences of the ABO and FUT2 variants between cases and controls. Recruitment of alcoholic subjects is going in order to confirm or otherwise our results. The identification of susceptibility and protective genes in ACP will allow not only better knowledge of disease initiation and progression but also improved therapeutic management.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0642 IS SURGERY USEFUL TO CURE CHRONIC PAIN IN ALCOHOLIC CHRONIC PANCREATITIS?

**B. Bordacahar**[1], A. Couvelard[2], M. Pierre Vullierme[3], P. Lévy[1], A. Sauvanet[4], P. Ruszniewski[1], V. Rebours[1]

**Contact E-mail Address:** benoit.bordacahar@gmail.com
**Introduction:** Chronic pain is a severe symptom in chronic pancreatitis (CP), leading to morphine addiction and reduced quality of life. Pancreatic surgery is usually performed as a last resort therapeutic option and its outcomes are still widely debated.
**Aim**: To assess pancreatic surgery results performed for chronic pain in patients with alcoholic CP and to determine pathological and morphological markers of therapeutic response.
**Methods**: All patients with alcoholic CP who underwent pancreatic surgery for chronic pain between 2008 and 2015 were included. Clinical data such as tobacco, alcohol and analgesics intake, type of surgical procedure, quality of life (QOL) data at 6 months and 1 year, radiological and pathological features were analyzed.
**Results:** 50 patients were included (men, 88%; age at surgery, 47 years old (32–64)). Surgical procedures were resections (Frey procedure, distal pancreatectomy or whipple procedure; $n = 45$) or drainage (lateral pancreaticojejunostomy $n = 5$). All patients were smokers (pack-year, 30 (10–90)). Postoperative tobacco and alcohol withdrawals were observed in 40% and 80% of the patients, respectively. Opioid intake before surgery, at 6 months and at 1 year was 60 mg (20–500), 20 mg (0–360) and 0 mg (0–360), respectively. QOL at 6 months and 1 year was respectively good (52% vs 54%, NS), average (34 vs 24%, $p = 0.01$) and bad (14 vs 22%, $p = 0.01$). The median delay between CP diagnosis and surgery was 5

years (1–22). Early surgery was associated with lower postoperative opioid intake ($r = 0.35$, $p = 0.01$) opioid withdrawal at 6 months (5.87 versus 4.5 years $p = 0.03$) and at 1 year ($p = 0.09$). At 6 months, opioid withdrawal was associated with an absence of exocrine ($p = 0.06$) and endocrine ($p = 0.08$) pancreatic insufficiency, a pre-operative alcohol withdrawal ($p = 0.08$), an improved quality of life and postoperative smoking cessation ($p = 0.0075$) but not with the type of surgery, nor morphological inflammation. Pathological (neuritis, lymphocytes infiltration, nerve hyperplasia) and radiological (inflammation, pseudocyst, calcifications) features were not associated with postoperative pain changes. Optimal delay between CP diagnostic and surgery allowing opioid withdrawal at 6 months and 1 year was 2 years. Following multivariate analysis, predictive factors for opioid withdrawal at 6 months were a surgery performed within 2 years (OR = 4.228 (1.04–17.17)) and a postoperative smoking cessation (OR = 3.561 (1.021–12.41)). At 1 year, only smoking cessation was predictive for opioid withdrawal, OR = 11.33 (2.677–47.98).
**Conclusion:** A benefit (opioid withdrawal and improved quality of life) depends mainly on complete postoperative smoking cessation and early surgery.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** Marianna.arvanitaki@erasme.ulb.ac.be
**Introduction:** Epidemiology of chronic pancreatitis (CP), as well as natural history, complications and therapeutic management are variable and not well described on a national basis.
**Aims & Methods:** This multicenter prospective observational study including 8 Belgian hospitals could improve the knowledge of these aspects. All patients with CP proven by imaging procedures were eligible. 809 patients were included between 1/9/2014 and 31/8/2015 using a case report form completed once at the time of out-patient visit or in-patient admission. Data collected included epidemiological, etiological items as well as CP complications (exocrine and endocrine insufficiency, pain) and type of treatment.
**Results:** Among the 809 patients, 794 were aged 16-year-old (adult population); the 15 remaining patients consisted the pediatric population. Characteristics of the adult population were the following: a majority of male (74%) and outpatient inclusion rate (69%), mean age at symptoms onset was 46 years and duration of disease was 9 years, median Izbicki pain score (IPS) was 96 (0–195). Main etiological risk factors according to TIGARO classification were alcohol and tobacco (69%) followed by idiopathic cause in 17%. Recurrent acute pancreatitis, genetic, auto immune and obstructive causes were less represented, between 2–4%. Pancreas divisum was identified in 3% of the cases. More patients had stopped alcohol than smoking (47 vs 21%). Benefits from no alcohol abuse were: higher BMI (25 vs 22 $kg/m^2$, $p < 0.01$), lower Izbicki pain score (90 vs 121, $p < 0.01$) and lower inability to work. Benefits from tobacco withdrawal were higher BMI (25 vs 22 $kg/m^2$, $p < 0.01$) and lower Izbicki pain score (82 vs 137, $p < 0.01$). Endocrine and exocrine insufficiencies were reported in 41% and 36% respectively. Diabetes was significantly more important in toxic cause than the others (44 vs 35%, $p < 0.05$) while there was no significant difference concerning exocrine insufficiency. Patients with BMI < 20 $kg/m^2$ had significantly more exocrine insufficiency (44 vs 34%), weight loss (32 vs 16%), pain (IPS: 146 vs 75) and included more current smokers (78 vs 46%) and alcohol drinkers (30 vs 15%), ($p < 0.001$). Concerning the impact of treatment on pain, patients with ongoing endoscopy were associated with highest Izbicki pain score (163/400) compared to patients with previous or no endoscopic treatment (83, 82/400 respectively) as well as patients with initial surgical management without endoscopy (79/400), ($p < 0.001$). 14% of patients had previous surgery and among them, 25% had initial surgery without previous endoscopic treatment. There was a majority of duodenopancreatectomy (30%) or partial resection (19%) followed by pancreatico-jejunostomy (13%). In children, there was a majority of girls (73%); idiopathic and genetic causes were the main risks factor (54 and 34% respectively). A majority of them were under the percentile 50 in the BMI for age percentiles curve. No diabetes and exocrine insufficiency were reported.
**Conclusion:** This nationwide Belgian study about 809 CP patients could provide a useful tool to emphasize the management of these patients in terms of complications and treatment. Cessation of smoking and alcohol and BMI > 20 $kg/m^2$ were associated with better outcome.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0644 MANAGEMENT OF PANCREATOLITHIASIS: A NATIONWIDE SURVEY IN JAPAN

**Introduction:** Prevalence of patients with chronic pancreatitis has been increasing in Japan. Chronic pancreatitis often is associated with pancreatolithiasis. When pancreatic stones develop, pancreatic ductal hypertension can cause pain and pseudocysts, thereby further exacerbating the disease condition. Treatment of pancreatic stones is extremely important. Although surgical and endoscopic treatments remain the conventional therapies for pancreatolithiasis, usefulness of extracorporeal shock-wave lithotripsy (ESWL) has been recognized. In 2014, an application for health insurance coverage of ESWL was approved by the government. We performed a 2-part nationwide survey of prevailing practices in management of pancreatolithiasis.
**Aims & Methods:** In the first part, replies from 566 of 1683 institutions with more than 200 beds were obtained, among these, 282 hospitals treated 4653 patients with pancreatolithiasis between 2009 and 2013. In the second part, clinical data were collected from 1835 patients treated for pancreatolithiasis at 125 hospitals. Patients included 1477 men and 358 women (gender ratio, 4.1). Mean age was 59.9 years (range, 9 to 99). Most often, chronic pancreatitis was alcohol-related (65.4%), idiopathic was the next most common category (17.6%). Statistical analyses included chi-squared tests. Differences associated with probability (p) values below .05 were considered significant.
**Results:** ESWL alone was performed in 103 patients (5.6%); ESWL plus an adjunctive endoscopic procedure (endoscopic sphincterotomy, endoscopic pancreatic sphincterotomy, or endoscopic balloon dilation) 446 (24.3%); endoscopic treatment alone 261 (14.2%); and surgery 168 (24.3%). Other therapies including pancreatic enzyme replacement, antispasmodic drugs, or protease inhibitors, were given to 358 (19.5%). No treatment was considered in 499 (27.2%). Fragmentation of all stones was achieved in 447 of the 549 patients undergoing ESWL (81.4%). Stone clearance was complete in 49.9% of patients treated by ESWL with or without adjunctive endoscopic treatment, and in 48.3% of patients treated only endoscopically. Symptom relief rate was 85.7% after ESWL including adjunctive endoscopic treatment, 80.8% after endoscopic treatment alone, and 92.9% after surgery. Early complication rates within 3 months after ESWL including adjunctive endoscopic treatment, endoscopic treatment alone, and surgery were 8%, 4.5%, and 26.9%, respectively. Rates of late complications occurring over 3 months after ESWL including adjunctive endoscopic treatment, endoscopic procedures alone and surgery were 1.7%, 2.5%, and 8.2%, respectively. Symptom relief rate but also, early and late complication rates for surgery were significantly higher than for ESWL and endoscopic treatment. Among 417 patients treated with ESWL, 61 (14.6%) required surgery, as did 32 (16%) of 200 patients treated endoscopically. Reoperation was required in 11 (6.7%) of 165 patients who were treated with surgery. Need for operation was significantly less frequent after surgery than that for surgery after the other treatments.
**Conclusion:** In Japan, non-surgical treatments were chosen more frequently than surgical treatment for patients with pancreatolithiasis. Appropriate guidelines for clinical management of pancreatolithiasis should improve efficacy and safety
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0645 EXTRACORPOREAL SHOCK WAVE LITHOTRIPSY FOR PANCREATIC DUCT STONES IS EFFECTIVE IN TERMS OF PAIN RELIEF AND USE OF OPIOIDS

**S. Haraldsson**, S. Roug, C. Nøjgaard, S. Novovic, E. Feldager, P. N. Schmidt
*Gastroenterology, Hvidovre Hospital, Hvidovre/Denmark*

**Contact E-mail Address:** stebbihar@gmail.com
**Introduction:** Fragmentation of pancreatic duct stones (PDS) using extracorporeal shock wave lithotripsy (ESWL) allows flow of pancreatic juice, spontaneous passage of small stone fragments, and facilitates endoscopic removal of

larger stones. Studies have shown that ESWL is effective in terms of lowering pain intensity and improving the quality of life. However, studies on use of analgesics before and after the ESWL are limited.
**Aims & Methods:** All consecutive ESWL procedures performed in our department in the period August 2010 to December 2014 were reviewed. We extracted data on demographics, technical details, pain score, and use of analgesics before and after ESWL. Data on the use of analgesics was obtained from hospital records, electronic medicine database, and prescription database. Our aim was to evaluate the use of analgesics before and after the ESWL.
**Results:** Ninety-six patients received 157 (1–7 per patient) ESWL procedures. The mean age was 57 years, 64% being males. Alcohol was the cause of chronic pancreatitis in 71% of the cases. There was a significant reduction in the daily use of opioids, before and after ESWL, and a significant increase in patients with no pain and no use of analgesics, see Table 1. The number and location of stones did not affect the use of analgesics. Table 1 shows the use of analgesics before and after the ESWL.

| Pain and analgesic use | Before ESWL | After ESWL | P-value |
|---|---|---|---|
| No pain and no use of analgesics | 11% | 39% | $<0.0001$ |
| Mild pain but no use of analgesics | 5% | 3% | 0.49 |
| "As needed" use of weak analgesics | 7% | 9% | 0.75 |
| Daily use of weak analgesics | 5% | 3% | 0.49 |
| "As needed" use of opioids | 18% | 17% | 0.90 |
| Daily use of opioids | 54% | 29% | 0.0006 |

**Conclusion:** ESWL is an effective and opioid-saving procedure in the management of pain in patients with PDS.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0646 MALNUTRITION IS A COMMON COMPLICATION IN CHRONIC PANCREATITIS OUTPATIENTS AND SIGNIFICANTLY ASSOCIATED WITH IMPAIRED MUSCLE FUNCTION

**J. L. Poulsen**[1], S.S. S. Olesen[1], L. Kuhlmann[1], H. H. Rasmussen[2], A. Madzak[1], A. M. Drewes[1]
[1]*Centre For Pancreatic Diseases, Aalborg University Hospital, Aalborg/Denmark*
[2]*Centre For Nutrition And Bowel Disease (cet), Department Of Gastroenterology And Hepatology, Aalborg University Hospital, Aalborg/Denmark*

**Contact E-mail Address:** jakob.poulsen@rn.dk
**Introduction:** Malnutrition is a well-known complication of chronic pancreatitis (CP), but little is known about its prevalence, risk factors and health-related consequences in the outpatient setting.
**Aims & Methods:** We investigated the prevalence of malnutrition in CP outpatients and its associated risk factors and influence on muscle function and quality of life. This was a cross-sectional study of CP outpatients. We used bioelectric impedance to measure body composition, and a handheld dynamometer (hand grip strength) and the timed up and go test to investigate muscle function. The EORCT QLQ C30 questionnaire was used to document quality of life. The primary outcome was malnutrition defined as a body mass index $<18.5\,kg/m^2$.
**Results:** A total of 166 patients with CP were enrolled in the study. The median age was 58.6 years (IQR 49.9–66.1) and 70% were men. The prevalence of malnutrition was 10.8% (95% CI; 6.6–16.6). Opioid use ($P=0.036$), exocrine pancreatic insufficiency ($P=0.025$) and female sex ($P=0.041$) were identified as independent risk factors. Patients with malnutrition had decreased handgrip strength compared to patients with normal nutritional state ($28.7\pm11.3$ kPa vs. $38.5\pm12.3$ kPa; $P=0.0016$) and used a longer period of time to complete the time up and go test ($10.3\pm4.6$ sec vs. $8.2\pm4.0$ sec; $P=0.026$). Lean body mass and handgrip strength was significantly correlated ($r=0.57$; $P<0.001$) and this correlation was further strengthened when analysing the patients with malnutrition independently ($r=0.83$; $P<0.001$). Global health status was comparable between groups ($P=0.76$).
**Conclusion:** Malnutrition is a common complication in CP outpatients and significantly associated with impaired muscle function.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0647 "DUODENAL DYSTROPHY", OR "GROOVE PANCREATITIS", OR "PARADUODENAL PANCREATITIS." DOES IT MATTER WHICH NAME YOU CHOOSE? LESSONS OF 71 CASES

**V.I. Egorov**[1], R. Petrov[2], N. Starostina[3], A. Vankovich[4]

[2]*5th City Hospital, Surgical Oncology Moscow/Russian Federation*
[3]*Radiology, 5th City Hospital, Moscow/Russian Federation*
[4]*Hpb, Moscow Clinical Acientific Sentre, Moscow/Russian Federation*

**Contact E-mail Address:** egorov12333@gmail.com
**Introduction:** Different terms were proposed as an umbrella for cystic dystrophy in heterotopic pancreas (duodenal dystrophy, DD), paraduodenal cyst and groove pancreatitis, by reasoning that these conditions mimic pancreatic head tumors and share certain histological evidences. The reasons for amalgamation of these terms in "paradudenal pancreatitis (PD)" are unclear.
**Aims & Methods:** To understand the origin of the DD assessing results of different treatment modalities by 1.prospective analysis of 71 cases of PP or DD (2004–2015), comparing 71 preoperative and 54 histopathological findings; 2. Assessment of clinical presentation and the results of DD treatment.
**Results:** Preoperative diagnosis was correct in all the cases except one, when cystic tumor of the pancreatic head was suspected (1.9%). Patients were presented with abdominal pain (100%), weight loss (76%), vomiting (30%) and jaundice (18%). CT, MRI and endoUS were the most useful diagnostic modalities. Ten patients were treated conservatively, 31 underwent pancreaticoduodenectomies (PD), pancreatico- and cystoenterostomies (8), Nakao procedures (4), duodenum-preserving pancreatic head (DPPH) resections (5), and 12 pancreas-preserving duodenal resections (PPDR). No mortality. Full pain control was achieved after PPRDs in 91%, PDs in 83%, and after DPPHR resections and draining procedures in 18% of cases. Diabetes mellitus developed thrice after PD. In 3 PD cases only moderate pancreatitis was revealed in specimen.
**Conclusion:** 1. Early diagnosis of DD saves pancreas; 2. Late diagnosis "convert" DD in PP and leaves patient only PD; 3. The effectiveness of PPDR proves that DD is an entity of duodenal, but not paraduodenal origin.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0648 GLYPICAN-1 IDENTIFIES CANCER EXOSOMES AND DETECTS VARIOUS DIGESTIVE SYSTEM NEOPLASMS

**Y. Chen**, X. Shen
*Department Of Gastroenterology, Zhongshan Hospital, Fudan University, Shanghai/China*

**Contact E-mail Address:** chen.yanjie@zs-hospital.sh.cn
**Introduction:** Exosomes are kinds of nanovesicles secreted by both healthy and unhealthy cells. They are about 30–100 nm wide and can be found in most of the body fluids, including blood, urine, saliva, breast milk, and so on[1]. The exosomes have been found to contain various proteins and nucleic acids, and play a central role in cancer development[2]. In addition, the proteins and nucleic acids contained in exosomes are less easy to be degraded and had more quantitative advantages as biomarkers comparing the circulating RNAs or DNAs. The heparin sulfate proteoglycan glypican-1 (GPC1) is a membrane anchored protein and has found to be universally and highly expressed in breast cancer[3], pancreatic cancer[4], human gliomas[5], ameloblastoma[6], neuroendocrine tumors[7], and some other solid tumors. Melo et al. and his colleagues found that GPC1 was enriched on pancreatic cancer-cell-derived exosomes[8]. GPC1+ circulating exosomes (crExos) were detected in the serum of pancreatic cancer patients with absolute sensitivity and specificity. It was also found that the level of GPC1+ crExos was correlated with tumor burden and prognosis, indicating GPC1+ crExos may serve as a potential biomarker for pancreatic cancer diagnosis[8].
**Aims & Methods:** In this study, we isolated crExos from patients with pancreatic carcinoma ($n=64$), esophageal squamous cell carcinoma (ESCC, $n=61$), gastric cancer ($n=54$), colorectal cancer ($n=42$), healthy donors ($n=30$), gastrointestinal polyp patients ($n=30$), and pancreatitis patients ($n=7$), and performed flow cytometry (FACS) analysis of crExos of these patients to detect GPC1 protein expression level.
**Results:** We found that digestive tumor exosomes are enriched in GPC1. The GPC1+ crExos level may be a reliable biomarker for detecting of digestive cancer, especially pancreatic carcinoma and CRC. The diagnostic value of GPC1+ crExos is superior to the traditional tumor marker, such as CA199, CEA, and AFP.
**Conclusion:** In summary, we found that GPC1+ crExos level may be a reliable biomarker for detecting of digestive cancer, and the diagnostic value of GPC1+ crExos is superior to the traditional tumor marker, such as CA199, CEA, and AFP.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Establishing the diagnosis of pancreatic ductal adenocarcinoma (PDAC) is important for optimal patient management but can be difficult and relies on imaging and cytology/pathology. A tissue diagnosis is not obtained in a significant proportion of PDAC cases. Hence, an unmet clinical need exists for the diagnosis of PDAC from cytology samples. One potential way of improving the diagnosis is to use immunohistochemistry (IHC) biomarkers as an adjunct to cytology in difficult to diagnose cases.
**Aims & Methods:** A systematic approach was used to identify and validate the best available biomarkers. In the identification phase, a meta-analysis of potential IHC biomarkers investigated in PDAC was performed with sensitivity and specificity as outcome variables. High ranking candidates from meta-analysis were validated by IHC on tissue microarrays (TMAs) of surgical specimens from 99 patients with PDAC. Sensitivity and specificity analyses were performed based on five potential cut-offs from the data generated from TMAs. Two cut-offs namely, 10% positive cells and 20% positive cells were investigated for observer agreement amongst seven pathologists. Finally, high ranking candidates using 10% cut-offs were investigated in twenty cytology samples and sensitivity and specificity analyses were performed.
**Results:** Sixteen biomarkers identified in systematic review were quantified in meta-analysis and the highest ranked biomarkers were KOC, maspin, S100P, mesothelin and MUC1. These biomarkers showed the following sensitivity & specificity in surgical specimens using 10% cut-off: KOC 87% & 97%; S100P 86% & 97%; mesothelin 94% & 88%; MUC1 90% & 35%; and Maspin 98% & 98%. Analysis of a panel of KOC, S100P and mesothelin achieved almost 100% sensitivity and specificity if at least two biomarkers were positive for both 10% and 20% cut-offs.
The investigation of 10% and 20% cut-offs for observer agreement showed reasonable strength of agreement (Kappa $>0.50$) modestly decreasing inter and intra-observer variability in IHC interpretation but 10% is slightly better than 20%. Finally, in cytology samples, 10% cut-off achieved higher sensitivity & specificity values: KOC 92% & 100%; maspin 54% & 100% and mesothelin 72% & 100%. In addition, analysis of a panel of KOC, maspin and mesothelin achieved 82% sensitivity and 100% specificity for 10% cut-off in cytology samples.
**Conclusion:** A panel of KOC, maspin and mesothelin is a suitable diagnostic panel and 10% cut-off is a reasonable cut-off achieving high observer agreement. Their diagnostic accuracies approach those of optimal conventional cytology. These markers may be appropriate for further clinical validation and potentially routine use in difficult cases.

**Introduction:** Pancreatic ductal adenocarcinoma (PDAC) is a leading cause of cancer-related death in Europe. Gemcitabine has been the standard of care for patients with metastatic PDAC. Recently, FOLFIRINOX and nab-paclitaxel+gemcitabine have shown significant survival benefits compared to gemcitabine in clinical trials.
**Aims & Methods:** This study aims to investigate the efficacy of FOLFIRINOX and nab-Paclitaxel+gemcitabine versus gemcitabine monotherapy or gemcitabine-based doublets (gemcitabine+erlotinib, +5-FU, +capecitabine or +cisplatin) in real-life clinical care across different European institutions and to analyze the decision making process among physicians administering these drugs. We conducted a retrospective multinational study including patients with metastatic PDAC receiving palliative chemotherapy from January 2012 through January 2015. In addition, we utilized a web-based questionnaire study, containing 15 questions regarding use of chemotherapy in metastatic PDAC, was sent to 5420 doctors in 19 European countries in June 2015.
**Results:** 634 patients from 8 centers in the UK, Germany, Italy and Hungary were included of which 55% (351) were male and 15% (97) underwent primary resection before systemic recurrence. Analysis showed that Gem-based regimens without nab-Paclitaxel were frequently used in European centers from 2012–2015 (75% vs. 9% for FOLFIRINOX and 3% for nab-Paclitaxel+gemcitabine; 13% other regimens). The median overall survival (OS) in different groups were: FOLFIRINOX 12.0 months (95% CI 8.5–15.5), nab-Paclitaxel + gemcitabine 7.0 months (95% CI 4.7–9.3), other gemcitabine doublets 9.0 months (95% CI 7.4–10.6) and gemcitabine monotherapy, 5.0 months (95% CI 4.4–5.6). FOLFIRINOX was associated with improved survival ($p < 0.001$). 153 valid responses from the questionnaire from 19 countries were analyzed. As first-line therapy, 47% used nab-Paclitaxel+gemcitabine, 42% used FOLFIRINOX and 11% used gemcitabine+/-erlotinib in 2015. Of the intensified regimens, dose reductions were more common for FOLFIRINOX likely due to higher toxicity, as FOLFIRINOX was estimated to be more toxic than nab-Paclitaxel+gemcitabine (neutropenia 88% vs. 68%; polyneuropathy 42% vs. 41%; rapid deterioration 42% vs. 31%). FOLFIRINOX was rated over nab-Paclitaxel+gemcitabine in achieving longer survival with acceptable quality of life (52% vs. 44%, respectively).
**Conclusion:** Intensified regimens are widely available throughout Europe, but used variably in clinical routine dependent on hospital setting and country. A large multicenter retrospective series of patients revealed that in spite of the improvement and availability of intensified regimens, gemcitabine-based treatments were predominantly used in 2012–2015. However, the pan-European questionnaire revealed a more frequent use of intensified regimens indicating an increasing acceptance among European doctors in 2015. In line with previous clinical trial data, nab-Paclitaxel+gemcitabine appears to have a more favorable toxicity profile compared to FOLFIRINOX, and needed de-escalation less often.

**Introduction:** 30–40% of patients (pts) with pancreatic adenocarcinoma (PDAC) are not resectable at the diagnosis because of locally advanced disease. Standard treatment is Chemotherapy (CT) ± Radiotherapy (RT). We evaluated feasibility and safety of endosonography-guided HybridTherm ablation (EUS-HTP) in a preliminary report, showing a trend in tumor size reduction[1].

**Aims & Methods:** Primary aim was to assess the effect of EUS-HTP on tumor growth. Secondary aims were to evaluate tumor induced necrosis and to determine overall survival after EUS-HTP. Consecutive pts with stage III PDAC after CT ± RT were prospectively enrolled and treated by EUS-HTP at our tertiary referral Center. The HTP, a flexible bipolar device combining radiofrequency with cryogenic cooling, was used under EUS guidance. The tumor growth, evaluated by the absolute volume of the tumor mass (ATV), the necrotic volume of the ablated area (ANV), and the overall survival (OS) were evaluated by a radiological and clinical follow-up. Data were analyzed using descriptive statistics and non-parametric tests for group differences and correlation analysis. P-values $< 0.05$ were considered as statistically significant.

**Results:** 35 pts with stage III PDAC were enrolled (21 M; mean age 63.66 years). EUS-HTP was feasible in 26 pts (74.3%); it was not possible in 9 pts because of tumor stiffness or vessel interposition. Six pts received two or more treatments. The application time was dependent on the tumor size ($R = 0.45$; $p = 0.038$) with a mean duration of 125.90 sec (range 30–360). Early complications occurred in 11/26 pts (42%), all mild, except one moderate (endoscopic intervention). Late complications were reported in 6/26 pts (23%), of which 5 were mostly related to tumor progression. CT scans were able to measure the lesion volumes in 25/26 treated pts (96%). No significant changes in the ATV were observed at post-treatment evaluation (mean 44.5 days: $31.65 \pm 26.2$ mm$^3$), compared to the pre-treatment CT scan evaluation ($29.9 \pm 24.5$ mm$^3$). The mean ANV was 12.44 mm$^3$ (range 1.3–56), i.e. 34.9% (range 3–65) of the tissue could be ablated by HTP. There was a significant positive correlation between ablation time and ANV ($R = 0.66$, $p = 0.013$) and also a significant positive correlation between ANV and ATV ($R = 0.92$, $p < 0.0001$). The longer the ablation duration and the larger the ATV were, the larger was the ANV. An analysis of the median survival time for pts treated only once and for those treated two or more times revealed an increase of the survival time from 5 to 9 months ($p = 0.066$). The median post-EUS-HTP OS was 6 months (range 1–22), with 2 pts still alive (3 and 9 months after EUS-HTP).

**Conclusion:** EUS- HTP is a safe treatment, able to obtain disease stability and may improve the mean survival time. These positive results suggest the possibility to include EUS-HTP in the treatment algorythm of stage III PDAC after CT ± RT.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The introduction of minimally invasive pancreatic resection (MIPR) into surgical practice has been slow. Randomized trials in this field are lacking. While valuable and informative, existing cohort studies suffer from selection biases and surgeon opinion. Worldwide utilization of and attitudes towards MIPR remains unknown.

**Aims & Methods:** We developed an international survey in order to gain knowledge on opinions and use of MIPR. The anonymous survey was send out online using Google Docs (Google, Mountain View, CA) to all surgeon members of the International Hepato-Pancreato-Biliary Association, Asian-Pacific Hepato-Pancreato-Biliary Association, Americas Hepato-Pancreato-Biliary Association, European-African Hepato-Pancreato-Biliary Association, Japanese Society of Hepato-Biliary-Pancreatic Surgery and PancreasClub. The survey consisted of 61 questions focusing on both laparoscopic and robot-assisted pancreatic resection; and included demographic information, experience with MIPR, patient selection criteria, learning curve estimates, presumed effect of MIPR on health-care costs, patient quality of life, and education in MIPR. Non-responders received up to two reminders.

**Results:** In total, 435 surgeons from 50 countries completed the survey. Median surgical experience was 12 (Interquartile range (IQR): 6–20) years and responders performed a median of 22 (IQR: 0–450) pancreatic resections as primary surgeon annually. Minimally invasive distal pancreatectomy (MIDP) was performed by 345 (79%) surgeons with a total personal experience of median 20 (IQR: 10–50) MIDPs. Of surgeons performing MIDP, 338 (98%) surgeons considered the overall value of MIDP superior or equivalent to the open approach. Minimally invasive pancreatoduodenectomy (MIPD) was performed by 124 (29%) surgeons with a total personal experience of median 12 (IQR: 4–40) MIPDs. Of surgeons performing MIPD 96 (77%) surgeons considered the overall value of MIPD superior or equivalent compared to the open approach. The most important reason for not performing MIPR was a lack of specific training. 161 (37%) surgeons received training in MIPR whereas 275 (63%) and 350 (81%) felt like they would benefit from training in MIDP or MIPD, respectively. Proctoring on-site was considered as the most important training element by 140 (32%) surgeons and 392 (90%) would consider participation in an international registry.

**Conclusion:** This worldwide survey on MIPR showed that the median annual number of MIPRs performed per surgeon is low. Whereas most surgeons considered MIDP superior or equivalent to open distal pancreatectomy, this was less clear for MIPD. Specific training in MIPR, especially on-site proctoring, with outcomes monitored by an international registry seems required.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0653 WATCHFUL FOLLOW-UP IS ACCEPTABLE, BASED ON CLINICAL OUTCOMES OF MAIN DUCT INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS OF THE PANCREAS

**A. Kubo**, T. Noda, M. Izuta, C. Ogawa, T. Matsunaka, H. Tamaki, M. Shibatoge
*Gastroenterology, Takamatsu Red Cross Hospital, Takamatsu/Japan*

**Contact E-mail Address:** yamato_with_999@yahoo.co.jp

**Introduction:** In the IPMN/MCN international consensus guidelines 2012, main duct IPMN (MD-IPMN) with main pancreatic duct (MPD) dilation of 5–9 mm considered as one of the "worrisome feature" have changed from rather immediate resection to more deliberate observation and evaluation. In the previous guideline, surgical resection is strongly recommended for all surgically fit patients, so natural course for MD-IPMN has been limited and still unclear.

**Aims & Methods:** The aim of this study was to clarify the natural history of MD-IPMN without surgical resection. Method; 1012 patients with IPMNs were treated in our institute from April, 1996 to December, 2014. 43 patients were with MD-IPMN. 32 patients without surgical resection and more than 1 year imaging follow-up were identified and their cases reviewed retrospectively. Evaluation points were 1) initial clinical data, 2) progression rate, 3) outcomes.

**Results:** Of 32 patients, mean age was 75.3 years and male was 56%. Median observation period was 48.2 months (17.2–153.8 months). 1) The initial median size of the MPD dilation is 10 mm (4–25), 14 patients with "worrisome feature", 18 patients with "high-risk stigmata", 4 patients had mural nodules. 2) 14 patients (43.8%) of 32 exhibited progression. 6/14 among "worrisome feature" group, 8/18 among "high-risk stigmata" group. The details of progression were 13 cases with an increasing MPD diameter, 2 cases with an increasing cyst size, and 6 cases with appearance and/or enlargement of mural nodules (included overlapping). Median period to progression was 26.6 months (4.9–98.9). 3) Surgical resection was performed in 4 of 14 patients with progression.3 patients were died (1 of invasive IPMC, 1 of pancreatic cancer and 1 of cancer of other organ). Progression rate by the Kaplan Mayer Curve was 25.5% for 2 years and 48.0% for 5 years.
**Conclusion:** This study suggested we could expect clinical course and progression rate for MD-IPMN without surgical resection and it is no significant difference of progression rate between "Worrisome feature" group and "High-risk stigmata" group. Both group could have been observed, if malignant findings (mural nodule > 5 mm etc.) were not revealed. It is highly important that we decide how long we observe patients with MD-IPMN and when we suggest surgical resection to them.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0654 SYSTEMATIC REVIEW OF RESECTION RATES AND CLINICAL OUTCOMES AFTER FOLFIRINOX-BASED TREATMENT IN PATIENTS WITH LOCALLY ADVANCED PANCREATIC CANCER

**Contact E-mail Address:** s.j.e.rombouts@umcutrecht.nl
**Introduction:** FOLFIRINOX prolongs survival in patients with metastatic pancreatic cancer and may alsobenefit patients with LAPC of which a substantial number may convert into resectable tumors. Previous studies combined LAPC and borderline resectable pancreatic cancer, which hampers the interpretation of outcomes with FOLFIRINOX in LAPC.
**Aims & Methods:** The aim of this review is to provide an overview of the (R0) resection rate and clinical outcomes after FOLFIRINOX-based therapy for locally advanced pancreatic cancer (LAPC). PubMed, Embase and Cochrane were systematically searched for studies published up to August31st, 2015. Primary outcome was (R0) resection rate.
**Results:** Fourteen studies involving 365 patients with LAPC were included. A modified chemotherapy regimen was described in 3 studies and FOLFIRINOX dose reductions in up to 65% of patients. Radiotherapy was given in 57% of all patients. Total resection rate was 28% (77% R0). Mediano verall survival ranged from 8.9 to 25.0 months. Median survival after resection was 24.9 months. Six out of 85 (7%) resection specimens showed a complete pathologic response. Grade 3–4 toxicity occurred in 23% of patients. The resection rate of patients treated with FOLFIRINOX without radiotherapy was 12% (70% R0) with 15.7 months median overall survival and 19% grade 3–4 toxicity.
**Conclusion:** FOLFIRINOX-based treatment for patients with LAPC seems safe and achieves high (R0) resection rates and overall survival, despite the frequent administered modified regimes and dose reductions during treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0655 CLINICAL EFFICACY OF PET/CT IN PATIENTS WITH INCREASED SERUM CA19–9 WITHOUT BILIARY TRACT OR PANCREATIC MALIGNANCY

**K.T. Lee**, J.H. Kim
*Gastroenterology, Samsung Medical Center, Seoul/Korea, Republic of*

**Contact E-mail Address:** ktcool.lee@samsung.com
**Introduction:** Serum CA19–9 level is considered a useful tumor marker for biliary tract and pancreatic malignancy. But, CA 19–9 can be elevated in benign lesion also.
**Aims & Methods:** This study was to determine the clinical efficacy of $^{18}$F-FDG (fludeoxyglucose F 18)-PET/CT in patients with increased serum CA19–9 level without biliary tract or pancreatic malignancy. We enrolled 78 patients who received PET/CT after serum CA19–9 elevation (> 37 U/ml) without biliary tract or pancreatic malignancy. We divided patients into two groups based on whether FDG uptake on PET/CT could explain the cause of CA19–9 elevation.
**Results:** In 45 of 78 patients, the CA19–9 elevation was explained by FDG uptake on PET/CT. Most malignancies were detected by PET/CT except one case. Acute CA19–9 elevation over 200 U/ml for duration of 6 months was an independent factor for diagnostic PET/CT finding. Ten of 45 patients had CA19–9 elevation explained by PET/CT which other screening tests produced inconclusive results. These patients were female and nine cases involved benign diseases.
**Conclusion:** To patient with increased serum CA19–9 level without biliary tract or pancreatic malignancy, PET/CT could be a useful method for explaining the cause of CA19–9 elevation even when other screening tests produced inconclusive results. And CA19–9 elevation over 200 U/ ml for duration of 6 months had greater diagnostic value on PET/CT regardless of malignant or benign disease status.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** In recent years, EUS-FNA as been noted for its high diagnostic accuracy and is on the road to becoming established as a clinically useful technique. On the other hand, there is a need to establish a more safe and efficient method for specimen collection in order to prevent the development of procedural accidents and collect high-quality specimens for genetic exploration. In the present study, we focused on the suction method for collecting specimens by EUS-FNA. The author proposes a method combining the suction and no-suction methods, and compared it with the conventional method in terms of collection of adequate specimens from malignant solid pancreatic tumors.
**Aims & Methods:** The study was conducted in 65 patients who underwent EUS-FNA after providing written consent for this study and received a final diagnosis of malignant solid pancreatic tumor between May 2013 and January 2016. Either 22- or 25-G needles for puncturing, and 20-mL suction syringes were used. Both the "no-suction plus suction method" (NS+S method), consisting of 5 strokes without suction and 10 strokes with suction, and the conventional suction method (S method), consisting of a total of 15 strokes with continuous suction, were used in all the patients. A pathologist conducted microscopic examinations of the specimens under the blinded condition. The adequate specimen collection rate, diagnostic accuracy rate and the level of blood contamination of the tissue specimens were prospectively compared between the two methods.
**Results:** In all, 74 cytology specimens were collected by the NS+S method and 78 cytology specimens by the S method, and a total of 67 histology specimens was collected by the NS+S method and 72 specimens by the S method. The adequate specimen collection rate for cytologic diagnosis was 94.6% by the NS+S method and 98.7% by the S method ($p = 0.15$), and that for histologic diagnosis was 74.6% by the NS+S method and 81.9% by the S method ($p = 0.29$), with no statistically significant difference between the two methods. The overall diagnostic accuracy rate in this study based on the combination of cytology and histology was 89.2% (58 of 65 patients). In a comparison between the NS + S and S methods, the diagnostic accuracy rate based on the combination of cytology and histology was 72.3% for the NS+S method and 86.1% for the S method ($p = 0.052$), tending to be higher for the S method. The low level of blood contamination in the tissue specimens was 40.3% for the NS+S method and 23.6% for the S method ($p = 0.03$), being significantly lower in the NS + S method, especially tumor size ≥29 mm and with a 22 G needle.
**Conclusion:** The NS + S method may allow higher-quality specimens with less blood contamination compared to the S method. However, the optimal suction/no-suction ratio and optimal number of strokes should be determined.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0657 ENDOSCOPIC ULTRASONOGRAPHY OF THE PANCREAS REFLECTS EXOCRINE AND ENDOCRINE FUNCTION

**Introduction:** Non-alcoholic fatty liver disease or non-alcoholic steatohepatitis occurs after pancreatic resection as a result of decreased pancreatic function. Predicting postoperative pancreatic dysfunction and measuring postoperative nutritional complications are important for quality of life. However, pancreatic function tests such as the pancreatic function diagnostic (PFD) test and 75 g oral glucose tolerance test (OGTT) require great care and are not performed in all patients. Endoscopic ultrasonography (EUS) is a popular and less invasive diagnostic tool that shows detailed pancreatic structures. Structural changes correlate with function, therefore, detailed EUS findings are expected to reflect pancreatic function. However, to the best of our knowledge, there are no reports about correlations among pancreatic parenchymal changes shown by EUS, exocrine function and endocrine function. We analysed the correlation between EUS images and the results of the PFD test and 75 g OGTT.
**Aims & Methods:** We analysed 46 patients who underwent pancreatic resection for pancreatobiliary disease. There were 28 men and 18 women, with a mean age of 60 years. Primary diseases were as follows: invasive ductal carcinoma

(n = 16), chronic pancreatitis (n = 12), intraductal papillary mucinous neoplasm (n = 10), bile duct carcinoma (n = 6), serous cystadenoma (n = 1) and mucinous cystadenoma (n = 1). Surgical procedures included pylorus-preserving pancreaticoduodenectomy (n = 31), distal pancreatectomy (n = 8), segmental resection (n = 6), and duodenum-preserving pancreatic head resection (n = 1). All cases were examined during the inactive pancreatitis phase by EUS, and exocrine function was measured by PFD and endocrine function by 75 g OGTT. EUS findings were divided into three types: Group I, high-echoic dots with a small and similar size; Group II, large and homogeneous macule pattern; and Group III, nodular pattern with inhomogeneous sizes.
**Results:** Six patients had Group I EUS findings, 17 had Group II findings, and 23 had Group III findings. The mean results of the PFD test for each group were as follows: Group I, 91%; Group II, 73%; and Group III, 55%, with a significant difference between each group. Correlation between EUS patterns and glucose intolerance by 75 g OGTT was: Group 1, 17%; Group II, 29%; and Group III, 67%. There were significant differences between Groups I and III, and Groups II and III.
**Conclusion:** EUS patterns reflected pancreatic exocrine and endocrine function. EUS images are expected to predict remnant pancreatic function.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0658 ENDOSCOPIC ULTRASOUND (EUS) HAS THE EDGE OVER CT/MRI IN THE DETECTION OF PANCREATIC NEURO-ENDOCRINE TUMOURS (PNETS) IN PATIENTS WITH MULTIPLE ENDOCRINE NEOPLASIA TYPE I (MEN1)

**Introduction:** Early identification of pNETs is a key element to reducing morbidity and mortality in MEN1 patients. Prognosis is associated with tumour size. Many pNETs are small subcentimetre lesions and only become symptomatic when the tumour is large. Conventional radiology is suboptimal in detecting such lesions, thus missing the window to remove them at an earlier stage.
**Aims & Methods:** We compared: (a) linear-EUS detection of pNETs in patients with confirmed MEN1 vs triple-phase contrast-enhanced CT/MRI pancreas and (b) incremental benefit of EUS to cross-sectional imaging for detection of small pNETs and quantity of pNETs in this cohort. Between Jan 2008- Oct 2015, a total of 20 patients with clinically confirmed MEN1 underwent baseline assessment with EUS, CT/MRI and biochemical screening. Data were retrospectively retrieved from the hospital electronic records database. Statistical analysis was performed using SPSS v20 on the size and number of pNET detection by EUS and CT/MRI using the Wilcoxon Signed Rank Test and McNemar Chi-square.
**Results:**

Detection of pNETs in MEN-1 cases

| | CT/MRI pancreas | EUS |
|---|---|---|
| Median pNET size (mm) | 14.5 | 7.1 |
| Smallest pNET size (mm) | 12.7 | 4.6 |
| Total pNETs Detected (%) | 57.9% | 100% |

A total of 28 EUS procedures and an equal number of cross-sectional imaging (CT/MRI) were performed. pNETs were identified in 95% of all 20 MEN1 cases. Overall median pNET size was 7.1 mm on EUS and 14.5 mm on CT/MRI ($p = 0.007$). Median value for smallest pNETs detected by EUS was 4.6 mm and 12.7 mm on CT/MRI ($p = 0.001$). EUS detected more pancreatic lesions/pNETs compared to CT/MRI ($p < 0.001$) in 25 of the 28 procedures (89.3% more). The remaining 3 procedures showed equal numbers of pNETs detection by both modalities. The interquartile range (IQR) for smallest pNET detected by EUS was 3.0–5.0 mm while IQR for CT/MRI lies between 8.3 mm-14.8 mm. EUS detected all 100% cases of pNETs in our series of MEN1 compared to CT/MRI imaging alone which detected 57.9% cases ($p = 0.008$). 14 of 20 patients had FNA performed with a positive yield of 85.7%. In 50% of patients, pNET measured $\leq$10 mm.
**Conclusion:** In MEN1 patients, CT/MRI underestimated the presence of pNETs in approximately half of all cases compared to EUS and was not able to identify small pNETs ($<$ 8 mm) in all but one case. EUS offers higher sensitivity than cross-sectional imaging (CT/MRI) in terms of detecting the number of positive pNET cases as well as a greater number of pancreatic lesions especially subcentimetre ones. EUS should be considered a standard tool in the algorithm for MEN1 workup, instead of an adjunct reserved for diagnostic dilemmas.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Ki-67 is increasingly recognized as a prognostic factor for gastroenteropancreatic neuroendocrine neoplasm (GEP-NEN). The cutoff index of Ki-67, especially for G3 type, is the current hot topic on grading of GEP-NEN. The characteristics of Ki-67 variability and the correlation to the prognosis of GEP-NEN have not been well evaluated.
**Aims & Methods:** A total of 225 GEP-NEN patients treated in Wuhan University Hospital between 2009–2015 were enrolled and reviewed. All the specimens, clinic information, follow-up and survival dada were collected. The correlation among Ki-67 index, the variability of Ki-67 and prognosis of disease were evaluated. The decision tree methods, Kaplan-Meier methods and Cox regression analysis were used.
**Results:** The re-grading of NEN using the Ki-67 index (intervals 0–27.5% ; 27.5–55% ; 55–75% ; 75–100%) in our cohort suggested a risk stratification and prognosis in high-proliferation type of G2-NEN and G3-NEN graded by the WHO classification. Comparing the primary with metastasis specimens, Ki-67 index were elevated in 45% cases and were down-regulated in 10% patient. Ki-67 index keep stable in 45% NEN patients. The rectum was the most variable primary site. While, the G3-NEN present the most variable intervals. The group with Ki-67 variability had a worse prognosis relative to the group without Ki-67 variability ($P = 0.0074$). The GEP-patient could be separated with a promising three-dimensional model as Ki index, variability of Ki-67 and tumor location.
**Conclusion:** G3-NEN group could be further re-stratification into 3 groups with elevated Ki-67 index and worse prognosis. Ki-67 variability indicates a worse prognosis. Ki index, variability of Ki-67 and tumor location could be three important prognostic factors for NEN. The re-assessment of Ki-67 status in metastatic sites may be important for assessing prognosis of GEP-NEN patients, especially for those with primary G3 tumors.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Slit2 and its receptor Robo1 constitute evolutionary conserved axon guidance cues with repellent function in directing neurogenesis, angiogenesis and endocrine development. Transcriptom analysis revealed that mRNA signatures of distinct metastatic phenotypes in patients with pancreatic NETs (pNETs) exhibit differences in several components of the Slit-Robo signalling pathway.
**Aims & Methods:** We thus aimed at delineating the role of Slit-Robo signalling for tumour biology and progression in pNETs. To this end, expression of Slit2 and Robo1 on human pNET tissues was determined by immunohistochemistry and quantitative PCR. In vitro migration and colony formation, as well as metastasis in an orthotopic pNET mouse model were evaluated using pNET cell lines genetically manipulated for restored Slit2 expression or functional inactivation of Robo1 activity.
**Results:** Quantitative PCR indicated a reduction of Slit2 expression in pNET tissues as compared to healthy pancreas. Immunohistochemistry localized expression of the Slit2 receptor Robo1 to epithelial tumour cells of pNETs and hence identified the tumour epithelial compartment with the capacity to respond to secreted Slit2 ligand. Furthermore, reduction of Robo1 mRNA tissue levels correlated to shorter time-to-progression in pNET patients. To experimentally address the function of Slit2-Robo1 signalling, BON and QGP pNET cell lines with divergent endogenous expression of Slit2 were used. Restored Slit2 expression in Slit2-deficient BON cells inhibited proliferation, transwell migration and colony formation in softagar assays. Conversely, disruption of Slit2-Robo1 signalling via lentiviral Robo1 knockdown or sequestration of endogenous Slit2 in QGP cells by a soluble Robo1 decoy receptor stimulated directed migration and colony formation of QGP cells. Mechanistically, restored Slit2-Robo1 signalling in BON cells stimulated, whereas functional inactivation of Robo1 in QGP cells reduced Ras activity. As a consequence of Ras activation, expression of yes-associated protein (YAP) was enhanced, and cell cycle progression was delayed in BON cells with restored Slit2 expression, consistent with a growth suppressive function of Ras in endocrine cells. Conversely, Ras activity rather promoted neuroendocrine differentiation as evidenced by an increase of chromogranin A release by BON cells upon re-expression of Slit2. Ultimately, the incidence of lymphatic metastases and lymphangiogenesis were reduced in mouse orthotopic BON tumours with restored Slit2 expression.
**Conclusion:** Our experimental and translational data assign to Slit2-Robo1 a novel function as metastasis suppressor and identified Ras and YAP as downstream mediators, which link Slit2-Robo1 signalling to growth inhibition and neuroendocrine differentiation. Together, we provide functional evidence, that loss of Slit2-Robo1 activity in pNETs may contribute to a metastatic phenotype in pNET patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0661 NATURAL HISTORY AFTER LONG-TERM FOLLOW UP OF PANCREATIC NEUROENDOCRINE TUMORS (PNET), BASED ON THE DETECTION OF THE PROLIFERATION CELL INDEX (KI-67) OBTAINED BY EUS-GUIDED FINE NEEDLE ASPIRATION (EUS-FNA)

M. F. Brasil[1], **C. D. Nava**[1], J.G. G.G.D.A.L. Cabral[1], J.C. Ardengh[2], G. F. Paduani[1], L. S. Hybner[1]

**Contact E-mail Address:** carolinnava@gmail.com
**Introduction:** PNET have been increasingly detected by imaging methods as computerized tomography (CT), magnetic resonance imaging (MRI) and endoscopic ultrasonography (EUS). The EUS-FNA could be an important tool to assess the prognostic factor in this disease through the determination of Ki-67, especially on a small PNET (< 3.0 cm) where management is still controversial.
**Aims & Methods:** To determine the natural history of PNET smaller than 3.0 cm managed conservatively and the role of Ki-67 in this case. From January 2010 to April 2015, 29 patients with histologically proven PNET were followed by MRI, CT and/or EUS. 19 were operated (Group 1) and 10 are being observed until the present day (Group 2).
**Results:** From the 29 patients studied, 23 (93%) were well differentiated PNET (Grade I – GI) and 2 (7%) were poorly differentiated neuroendocrine tumor (Grade II – GII). There was no statistical difference between groups regarding sex, mean age, symptoms and the localization of the PNET (head 13, body 14 and tail 2). The average size was of 1.5 cm (0.4–2.8 cm). EUS-FNA obtained sufficient material for Ki-67 in 18 patients (94.7%) of group 1 and 9 (90%) of group 2. Ki-67 was positive and < 5% in all cases of group 1 and in all but 1 patient from group 2 (patient with GII PNET). On group 1 there was 1 perioperative death (5.2%), 1 liver metastases (5.2%) which was resected after 24 months, and 17 (89.6%) kept without recurrence. In group 2, there was 1 liver metastasis (10%), 4 maintained hypoglycemic attacks (40%), 1 had tumor growth (10%) of 1.4 to 2.5 cm, being operated lately and 5 kept asymptomatic (50%). The mean tumor growth rate was 0.25 cm per year and no predictive factor of worse outcome was identified.
**Conclusion:** Conservative management of PNET smaller than 3.0 cm was safe. A Ki-67 < 5%, obtained by EUS-FNA on PNET was a reliable approach to choose the treatment strategy on this study. Prospective and larger multicenter studies with long-term follow-up are needed to validate this result.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** One of the most controversial issue in the diagnosis of pancreatic neuroendocrine tumors (pNET) is the accurate prediction of their clinical behaviour. The grading has to be expressed by using the mitotic index and the Ki67 proliferation index.
**Aims & Methods:** The aim of this study was to evaluate the role of the endoscopic ultrasound (EUS) fine needle aspiration (FNA) in the diagnosis and grading of pNET.
**Methods**: We retrospectively reviewed all consecutive patients with a radiological finding suspicious for pNET. A computerized system was used to extrapolate the list of patients between May 2014 and April 2016. In the present study, only patients with FNA were included. FNA was performed with Beacon or Boston Scientific 25 G or 22 G needles. In case of pathological diagnosis different from NET, the patient was excluded from analysis. Adequacy of the aspirated material was assessed by rapid on site evaluation. If any fragment was observed on the slide at macroscopic evaluation, it was placed into formalin for histology evaluation. In patients undergoing surgery the EUS-FNA results were compared with final histological diagnosis.
**Results:** 51 patients undergoing EUS were identified with 38 having also an FNA. Three pts were excluded because the NET was not confirmed after EUS–FNA: one patient had a SPT, one had a SCA, one had a metastasis from renal cancer. Study population included 35 patients: 15 female and 20 male, mean age 59 years (SD 13.6 y). Twenty-five patients (71.4%) had an incidental finding of pancreatic mass, 3 (8.6%) had genetic syndrome, 6 (17.1%) had symptoms like pain, weight loss or jaundice. One case (2.9%) was functioning NET (hypoglycemia). Clinical and technical data are summarized in the Table. The mean size of punctured lesions was 20 mm (SD 13.7) and the localization was the body and tail in 24 patients (68%), neck in 3 (8.6%), head in 3 (8.6%), uncinated process in 5 (14.3%). The 25-G needle was used in 28 patients (80%). The mean number of passages was 1,6 (SD 0.7; range 1–4). In 4 cases a mild self-limited bleeding was observed: one in a solid lesion, one in a solid-cystic lesion, one in a cystic lesion, and one into the pancreatic duct after FNA of a solid lesion infiltrating the pancreatic duct wall. The overall FNA adequacy was 97.1%. One inadequate case was that one with a mild bleeding in which the specimen was too bloody for pathological examination. The ki67 index was obtained in 25 cases (71.4%). Fourteen of 35 patients with pNET (40%) underwent surgery, one patient is waiting for surgery; 2 had chemotherapy; 18 are in follow up. The concordance rate between EUS-FNA grading and the grading on surgical specimen was 85.7% (12 of 14 patients). In two cases an up-grading was observed in the surgical specimen (from G1 to G2, because of a final ki67 of 3% compared to 2% in the FNA).
**Conclusion:** This study has some limitations mainly because of the retrospective design and the lack of histological examination on all FNA specimens. On the other hand, this study confirmed the high accuracy of the EUS-FNA in the diagnosis of pNET and the ability to evaluate the ki67 index on EUS-FNA cytology or histology material.

**Table (P0662)**

**Introduction:** Resection of submucosal tumors by means of endoscopy has been reported using a variety of techniques. However, lesions originating from the pro-pria muscle layer are unlikely to be re-sected completely and safely.

**Aims & Methods:** Here, we report the first series describing the new technique of endoscopic resection for submucosal tumors of the stomach using the simple and safe forcep strip technique. Endoscopic submucosal tumor resection using hot biopsy forcep was attempted in ten consecutive patients in clinical indications for lesion removal. Following injection around the submucosal tumor, the adjacent mucosa or submucosa was grasped with the forceps and pulled away forming a "tent". Electrocoagulating current was applied for dissection of tissue. For repeating described process, the tumor was dissected from the muscularis propria layer and then carefully removed using forcep.

**Results:** All of the ten patients that underwent Forcep Strip Technique for the gastric submucosal tumors were successful, with the complete resection rate of 100%. There was no major bleeding and the procedure time was reduced compared to the conventional methods. No complications occurred and follow-up was unremarkable. It is possible to resect submucosal tumor any part of the stomach (fundus, cardia, body). On histology, all tumors were resected completely (eight gastrointestinal stromal tumor, two leiomyomas).

**Conclusion:** Forcep Strip Method appears to be an easy, safe, and effective procedure for treatment of gastric submucosal tumor originating from the muscularis propria layer.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Patients with gastroesophageal reflux disease (GERD) have an increased number, dilation and tortuosity of the microscopic intra-papillary capillary loops (IPCLs). Recently, an image-enhanced technology called Optical Enhancement system (OE system™) is equipped in Pentax video processor EPK-i7010. It improves visualization of microvessels. Also new high-definition scopes with optical magnification (Magniview™) were developed. The scopes increase the image up to 136 times with a better evaluation of the mucosa.

**Aims & Methods:** To evaluate the diagnosis ability of OE system™ +Magniview™ scopes, to detect minimal esophageal lesions (MEL) (IPCLs) and predict reflux in non-erosive reflux disease (NERD) patients. Methods: Prospective, non-randomized, simple blind study. Patients enrolled had typical GERD symptoms. If esophagus was normal at endoscopy, a pH-impedanciometry was performed to discriminate NERD patients (NG) from non reflux disease (Control group [CG]). Finally an OE system™ +Magniview™ endoscopy was performed. Images were recorded and examined blindly by 3 endoscopists. Biopsies from each esophagus level were done. Images were compared to histology to predict inflammation. Inclusion Criteria: >18 years-old, agree to participate, GERD symptoms (>8 points at GERD questionnaire), absence of Barrett's esophagus or erosive sign (Los Angeles classification: Grade A-D) by

| UE middle third | 75.00 (57.80 – 87.88) | 62.50 (40.59 – 81.20) | 75.00 (57.80 – 87.88) | 62.50 (40.59 – 81.20) | 73.68 |
| UE upper third | 80.56 (63.98 – 91.81) | 66.67 (43.03 – 85.41) | 80.56 (63.98 – 91.81) | 66.67 (43.03 – 85.41) | 75.44 |
| UE in general | 94.44 (81.34 – 99.32) | 61.90 (38.44 – 81.89) | 80.95 (65.88 – 91.40) | 86.67 (59.54 – 98.34) | 82.46 |
| BIOPSY | | | | | |
| UE lower third | 92.31 (74.87 – 99.05) | 64.52 (45.37 – 80.77) | 68.57 (50.71 – 83.15) | 90.91 (70.84 – 98.88) | 77.19 |
| UE middle third | 81.82 (59.72 – 94.81) | 57.14 (39.35 – 73.68) | 54.55 (36.35 – 71.89) | 83.33 (62.62 – 95.26) | 66.67 |
| UE upper third | 89.47 (66.86 – 98.70) | 50.00 (33.38 – 66.62) | 47.22 (30.41 – 64.51) | 90.48 (69.62 – 98.83) | 63.16 |
| UE in general | 96.55 (82.24 – 99.91) | 50.00 (30.65 – 69.35) | 66.67 (50.45 – 80.43) | 93.33 (68.05 – 99.83) | 73.68 |

endoscopy (by neither white light nor I-Scan™). Exclusion Criteria: Barrett's esophagus or erosive sign (Los Angeles classification), history of esophagitis, achalasia, esophageal varices, esophageal cancer, PPI or NSAIDs consumption, coagulopathy, gastric lesions, gastroparesis, history of esophageal/gastric surgery, pregnancy, lactation.
**Results:** 57 patients were analyzed [36 (63.15%) NG, 21 (36.85%) CG] [mean age 48 years old, 46 women (81%)]. The main symptom was regurgitation in 27 cases (47.3%). IPCLs was observed in 94.4% of NG, being the lower third the most affected ($p < 0.05$). In CG 8 patients (38%) had IPCLs ($p < 0.05$ for NG). The IPCLs dilatation was the most common find (91.6%). Unlike IPCLs tortuosity, both dilatation and increased number of IPCLs showed a significant difference between groups. Also both lesions were more common ($p < 0.05$) between patients with inflammation at histology. The ability to predict GERD with OE system™ +Magniview scopes was determined/compared with Ph-Impedanciometry (gold standard). The sensitivity, specificity, PPV, NPV and accuracy was 94.4%, 61.9%, 91.4%, 81.8% and 86.67% respectively. The lower third of the esophagus had the higher sensibility and accuracy (88.9% and 87.72). The Kappa inter and intra-observer value was 0.85 and 0.90 respectively.
**Conclusion:** OE system™+Magniview™ scopes can detect MEL and predict GERD with a high sensitivity and accuracy. The presence of MEL has a high grade of correlation with a histology inflammation.

## P0665 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASMS WITH THE CONTINUOUS USE OF LOW-DOSE ASPIRIN: ANALYSIS OF 101 PATIENTS

**H. Harada**, S. Suehiro, D. Murakami, R. Nakahara, T. Shimizu, Y. Katsuyama, K. Hayasaka
*Gatroenterology, New Tokyo Hospital, Matsudo, Chiba/Japan*

**Contact E-mail Address:** nerimaendo@hotmail.co.jp
**Introduction:** Although the safety of endoscopic submucosal dissection (ESD) for gastric neoplasms has been established, the postoperative bleeding after ESD is one of the major complication. Low-dose aspirin (LDA) is usually used for the prevention for cardiovascular and cerebrovascular diseases. Reportedly, the continuous use of LDA (continued-LDA) seems to be a high risk for bleeding after endoscopic treatment. Guidelines recommend that high risk bleeding endoscopic procedures including gastric ESD are not required to discontinue LDA in patients with a high risk for thrombosis whereas LDA should be discontinued in patients with a low risk for thrombosis. Recent retrospective studies have been described that continued-LDA has not significantly increased postoperative bleeding after gastric ESD compared with discontinued-LDA. However, there has been a limitation, such as small samples. We treated with gastric ESD in 101 patients with continued-LDA and assessed the postoperative bleeding and clinical outcomes compared with discontinued-LDA.
**Aims & Methods:** A total of 480 patients who underwent ESD for gastric neoplasms at the New Tokyo Hospital between August 2008 and October 2015 were enrolled in this study. We categorized patients into three groups: continued-LDA (100 mg/day, n = 101), discontinued-LDA for 5 days or more (n = 46), and without LDA intake (control, n = 333). Multivariate analyses were performed to analyze the differential effect of continued-LDA and discontinued-LDA on postoperative bleeding.
**Results:** The postoperative bleeding occurred in 6.9% (33/480) overall, and in 4.2% (14/333) in the control group. The postoperative bleeding rate in the continued-LDA group was observed to be lower than in the discontinued-LDA group (11.9% [12/101] versus 15.2% [7/46]), but no significant differences were found between the two groups on logistic regression analysis (OR, 1.33; 95% CI 0.49–3.64). Multiple logistic regression analysis showed that no significant differences in postoperative bleeding were found between the two groups (OR, 1.20; 95% CI 0.43–3.36).

**Table:** Logistic regression analysis for postoperative bleeding after gastric ESD between continued-LDA and discontinued-LDA

| | Postoperative bleeding (n = 19) | Non postoperative bleeding (n = 128) | Odds ratio | 95%CI | P value |
|---|---|---|---|---|---|
| LDA, n (%) | | | | | |
| Discontinued | 7(15.2) | 39(84.8) | 1.33 | 0.49–3.64 | 0.58 |
| Continued | 12(11.9) | 89(88.1) | reference | | |

ESD, endoscopic submucosal dissection; LDA, low-dose aspirin; CI, confidence interval.

**Conclusion:** The continuous use of LDA was not an increase for the risk of postoperative bleeding compared with interruption of LDA. The continuous use of LDA is applicable to gastric ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** turaoka@a3.keio.jp
**Introduction:** Endoscopic submucosal dissection (ESD) can remove varying size early stage gastrointestinal tumors en bloc, however, delayed bleeding can occur days after the procedure and success requires reducing a relatively high post-procedure bleeding rate; 1% esophagus, 4.6 to 15.6% stomach and 2.0 to 2.5% colorectum. Gastric ESD-induced ulcers are treated with proton pump inhibitor for at least 8 weeks after ESD in most hospitals. Recently, tissue engineering and regenerative substances have been developed to target the reconstruction of structurally and functionally normal tissues.
**Aims & Methods:** The aim of this study was to assess the safety and efficacy of a novel fully synthetic and self-assembled peptide solution which functions as an extracellular matrix scaffold material that facilitate the reconstruction of normal tissues (PuraMatrixTM, 3-D Matrix, Ltd, Tokyo, Japan) in ESD-induced ulcers. Consecutive patients who underwent esophageal, gastric and colorectal ESDs were prospectively enrolled. This solution was applied to the ESD-induced ulcer using a catheter immediately after the procedure. Post-ESD bleeding was defined as bleeding that required transfusion, endoscopic or surgical intervention, or bleeding that caused the hemoglobin level to fall by 2 g/dl in addition to changes in vital signs. Gastric ulcers were evaluated by

endoscopy and classified as active, healing or scarring stages at 1, 4 and 8 weeks after ESDs. The study endpoints were the rate of post-ESD bleeding, the transitional rate to healing and scarring stages of gastric ESD-induced ulcers.
**Results:** One hundred and twenty-two patients including 26 (21.3%) previously on antithrombotic therapy and 7 (5.7%) requiring heparin bridge therapy with 133 lesions were analyzed. The mean size of en bloc resected specimen was 40.6 ± 15.6 mm. The overall rate of post-ESD bleeding was 1.5% (2/133; 95%CI, 0.4–5.3). Bleeding from esophagus, stomach and colorectum were 0% (0/19), 2.0% (1/51) and 1.6% (1/63), respectively. Transitional rate to healing stage of ESD-induced ulcer at 1 week was 96% (49/51). Further follow up endoscopies demonstrated the scarring stage in 19% (9/48) and 98% (41/42) at 4 and 8 weeks, respectively. There were no adverse effects related with this solution.
**Conclusion:** This novel peptide solution can potentially aid in reducing the delayed bleeding rate by promoting mucosal regeneration and speed of ulcer healing after large mucosal and submucosal resections. Further studies are needed to fully evaluate its efficacy.
**Disclosure of Interest:** T. Uraoka: – No financial relationships relevant to this presentation. – This study was supported by Japan Society for the Promotion of Science of Grant-in-Aid for "Scientific Research (C)".

**Introduction:** Recent endoscopy has evolved into image-enhanced endoscopy (IEE), such as Narrow Band Imaging and Blue Light Imaging. IEE focused on increasing abnormal microvessels in the surface of early cancers. In contrast, hypoxia is one of the functional characteristics in cancer, with strong association to the biological features. The investigation of cancer hypoxia was started in the 1960's, with poor prognosis in hypoxia cases for chemotherapy or radiotherapy. In these many studies, polarographic needle electrodes for direct tumor-tissue were used as oxygen measurements. However, there has been no modality in which hypoxia imaging is visible in real-time and in the whole tumor. Therefore, hypoxia imaging was innovated to visualize directly the biological and functional changes in cancer.
**Aims & Methods:** The aim of this prospective study is to evaluate the visualization of whole feature in early cancers and to predict treatment efficacy for advanced cancers using hypoxia imaging endoscopy. In endoscopic equipment, we utilized a difference of absorption between oxy- and deoxy-hemoglobin in visible light wavelength. The signals converted from laser light were calculated in oxygen saturation (StO2) by processor. Hypoxia imaging was obtained in real-time, displaying two types of StO2 images. One was a pseudocolor image showing StO2 levels as different hues, and the other was an overlay image that overlapped low StO2 levels in blue on a white light illumination image of background mucosa. In the initial clinical trial, hypoxia imaging was analysed in early cancers and adenomas of the pharynx, esophagus, stomach, or colorectum. As the second trial, a prediction of treatment efficacy in advanced cancers of the esophagus, stomach, or colorectum using hypoxia imaging was evaluated between before and after chemotherapy. To compare histologic findings to hypoxia imaging, all patients with early-sided lesions received endoscopic resection immediately after conventional and hypoxia imaging endoscopy, and all patients with advanced cancers were histologically confirmed by biopsy. All lesions were evaluated the prediction of treatment efficacy in StO2 levels obtained from the StO2 map.
**Results:** Forty patients with early-sided lesions were analysed. The hypoxic area was completely corresponded to the portion of early cancer, with clearly visible in cancer edge. Furthermore, 8 colorectal low-grade adenomas were also detected as hypoxia, ranging from 3 to 10 mm in diameter. All esophageal cancers including 2 Barrett's cancers were detected in hypoxia images. Median StO2 differences between neoplastic and non-neoplastic areas in the pharynx, esophagus, stomach and colorectum were −15.4%, −14.5%, −5.1% and −21.5%, respectively. Significant differences of StO2 levels were seen in the esophagus ($p = 0.0078$, $n = 8$) and colorectum ($p = 0.0001$, $n = 14$), but not in the stomach ($p = 0.9341$, $n = 15$) or pharynx ($p = 0.2500$, $n = 3$). In the prediction of treatment efficacy in the 15 advanced esophageal, gastric and colorectal cancers, accuracy before chemotherapy and after 1 curse of individual chemotherapy was 62% and 92%, respectivery.
**Conclusion:** Hypoxia imaging with the laser endoscope enables us to visualize spatial and temporal information of hypoxic conditions in adenoma, early and advanced cancers. Hypoxia imaging illustrates a novel aspect of cancer biology as a potential biomarker and can be widely utilized in cancer diagnosis and prediction of treatment efficacy.

## P0669 HANDS-ON TRAINING ON PORCINE MODELS FOR ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) AND PER-ORAL ENDOSCOPICMYOTOMY (POEM) – DOES IT HELP TRAINING OF PHYSICIANS FOR THESE ADVANCED PROCEDURES?

**A. Bapaye**[1], M. Mahadik[1], N. A. Dubale[1], V. Vyas[1], S. Dorwat[1], P. Desai[2]
[1]*Shivanand Desai Center For Digestive Disorders, Deenanath Mangeshkar Hospital Digestive Diseases & Endoscopy, Pune/India*
[2]*Surat Institute of Digestive Sciences, Surat/India*

**Contact E-mail Address:** amolbapaye@gmail.com
**Introduction:** Expertise in advanced endoscopy procedures – endoscopic submucosal dissection (ESD) and per-oral endoscopic myotomy (POEM) is largely limited to few select centers. A global need for trained physicians competent to perform these advanced endoscopy procedures has been identified. Optimum training in these procedures has been traditionally difficult to obtain due to limited opportunities and ethical issues regarding training on live patients. Our center has considerable experience in performing ESD and POEM and conducts regular endoscopy training programs. We developed a special fresh cadaver porcine model for ESD and POEM training at our center. During a 12-month period, four hands on ESD and POEM training workshops using this model were conducted. Participants were endoscopists with more than 5 years' experience in advanced therapeutic endoscopy including ERCP. This study aims to evaluate the impact of these training courses amongst the participants and their subsequent clinical practices.
**Aims & Methods:** 116 endoscopists participated in a 2-day ESD / POEM workshop with hands on training on specially developed porcine models over 4 training courses conducted over a 12-month period. All participants completed a detailed feedback form at end of the course wherein they had to mention if they would perform these procedures within 6-months. Each physician was contacted by telephonic survey 8-months after the workshop. The questionnaire evaluated the following points – whether they had initiated any of the procedures – ESD or POEM, reason for noninitiation, type of procedure initiated, number of procedures performed to date, difficulties faced during procedure, desire to attend further similar workshops.
**Results:** Of 116 participants, 102 responded via feedback form were inclined to perform these procedures within 6-months. Of these, 88 participants (75.8%) could be contacted for the post workshop telephonic survey. 23/88 (26.1%) confirmed having attempted and 22/88 (25%) successfully performed either ESD or POEM within 6-months. ESD was performed by 15 (17%), POEM by 4 (4.5%) and both ESD & POEM by 3 (3.4%) physicians. No significant adverse events were reported. Amongst 65 physicians who did not initiate any procedure, 40 (61.5%) cited lack of instrumentation and infrastructure as the reason, 9 (13.8%) mentioned lack of suitable patients whereas 12 (18.4%) physicians requested additional hands-on training prior to initiation.
**Conclusion:** The current study shows a significant impact of hands-on training models with 25% participants initiating ESD and POEM. Only 18% participants requested additional training before initiating these procedures. Hands-on training workshops on specially developed fresh cadaveric porcine models may serve as an important platform for aspiring endoscopists who wish to train in these advanced procedures.

## P0670 PRAGUE CLASSIFICATION FOR BARRETTES OESOPHAGUS: A STUDY TO SEE THE DEGREE OF COMPLIANCE BY THE ENDOSCOPISTS

**T. Mahmood**
*Mulja-e-Tariq, Ickenham, Middsx/United Kingdom*

**Contact E-mail Address:** tm123@btinternet.com
**Introduction:** The British Society of Gastroenterology (BSG) guidelines on Barrettes oesophagus were modified in 2015. Firstly, the guidelines focus on precise documentation of the findings. The Prague Classification has been recommended as a standard. This takes into account the circumferential extent (C) as well as the maximal longitudinal extent (M) of the Barrettes segment as measured from the gastro-oesophageal junction. It is therefore called the "Prague CM classification". Secondly, the guidelines have focused on presence or absence of any histological intestinal metaplasia and/or dysplasia in relation to the length of Barrettes segment. This study aims at finding the compliance rate of endoscopists to Prague CM classification for reporting of Barrettes oesophagus. This study focuses only on the first aspect of the guidelines regarding diagnosis of Barrettes oesophagus, as the second aspect (interval surveillance endoscopy) depends on the first after histology is incorporated into the information.
**Aims & Methods:** This is a retrospective study recruiting all the cases who were documented in the endoscopy reports as "Barrettes Oesophagus" upon having gastroscopy in a sample district general hospital of United Kingdom between January 2014 and May 2015. All new and old diagnosis of Barrettes oesophagus in the period of 18 month were included in this study. Endoscopy reports from all professionals doing the upper GI endoscopy in this sample unit were included in the study. Therefore there were reports from the Consultant Gastroenterologists, Consultant Surgeons, Registrars and Nurse Endoscopists included in the study. Data was retrieved from hospital computer records and individual report was analysed in detail.
**Results:** There were 39 patients who had endoscopy and were recorded with a definitive diagnosis of Barrettes Oesophagus. Only 18 (46%) of these had been documented using the Prague CM classification and 21(54%) had no such documentation. In the unit 19 (48.8%) of GI endoscopy was done by the Consultants, 6 (15.3%) by Registrars and 14 (35.9%) by the Nurse Practitioners. When analysis was made based upon the operator, it was seen that 63% of Consultants, 33% of Registrars and 50% of the nurses did not

document Barrettes oesophagus using the Prague CM classification. It is clear that the registrars have done better than the consultants or nurse practitioners in adhering with the guidelines.
**Conclusion:** Our study has shown lack of adherence with BSG guidelines on documentation of Barrettes Oesophagus using Prague CM classification in a sample district general hospital of United Kingdom over a period of 18 months consistently. Whereas the sample represents practice in one district only, more studies are required to see what is happening in other districts. Some possible causes for poor documentation can be; time constraints during busy endoscopy lists, lack of knowledge about the Prague CM classification, not being convinced about the value of using the classification, lack of IT support in the form of endoscopy reporting tool which may not have built in provision for using the classification or simply that the operator could not be bothered. This study has also shown better adherence to the guidelines on documentation by the registrars in comparison to the consultants and the experienced nurse practitioners. Possible causes for this can be; new training techniques in endoscopy which the registrars are more likely to have received recently, In any case the use of Prague CM classification to describe Barrettes Oesophagus has multiple advantages. For example, it enables better planning of interval for surveillance endoscopy. If the segment is below 1 cm in size and there is no histological metaplasia or dysplasia, endoscopy has to be repeated once only. If same findings are seen then patients can be discharged from the surveillance program. If it is more than 3 cms in size, then repeat endoscopy is recommended based upon histological presence or absence of intestinal metaplasia and/or dysplasia. Furthermore the classification enables operator to estimate progression or regression of Barrettes. It also enables a validated universal understanding of the extent of the disease.

## P0671 RISK FACTORS FOR METACHRONOUS GASTRIC CARCINOMA DEVELOPMENT AFTER ENDOSCOPIC RESECTION OF GASTRIC DYSPLASIA; RETROSPECTIVE, SINGLE CENTER STUDY

**H.S. Moon**, J.S. Kim, S.H. Kang, J.K. Sung, H.Y. Jeong
*Dept. Of Internal Medicine, Chungnam National University Hospital, Daejeon/Korea, Republic of*

**Contact E-mail Address:** mhs1357@cnuh.co.kr
**Introduction:** Gastric dysplasia is a known precursor lesion of invasive adenocarcinoma, so endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD) is routinely performed to remove this premalignant lesion. Upon removal of the dysplasia, gastric adenocarcinoma (GAC) can be detected during the follow-up period, but few studies have addressed the factors related to gastric cancer occurrence.
**Aims & Methods:** We determined the occurrence rate of GAC and related factors by evaluating the follow-up results of patients who had been confirmed with gastric dysplasia after endoscopic resection. We retrospectively analyzed the medical records, endoscopic examination records, endoscopic procedure records, and histological records for 667 cases in 641 patients being followed up over 1 year, among the 1,273 patients who had been confirmed with gastric dysplasia after EMR or ESD for gastric mucosal lesions between January 2007 and August 2013at the Chungnam National University Hospital.
**Results:** The mean follow-up period was 33.8 months and the median follow-up period was 29 months (range, 12–87). During the follow-up period, the occurrence of metachronous GAC was 4.0% (27/667). The mean and median interval periods between occurrence of metachronous GAC and endoscopic treatment of GA were 36.3 months and 34 months, respectively (range, 16–71). The factors related to metachronous GAC occurrence after endoscopic resection for gastric dysplasia were male sex (5.3% vs. 1.0%), open type of atrophic gastritis (9.5% vs. 3.4%), intestinal metaplasia (6.8% vs. 2.4%), and high grade dysplasia (8.4% vs. 3.2%). Among these, male sex [OR: 5.05 (1.18–21.68) $p = 0.029$], intestinal metaplasia [OR: 2.78 (1.24–6.23) $p = 0.013$], and high grade dysplasia [OR: 2.70, (1.16–6.26) $p = 0.021$] were independent related factors in a multivariate analysis. Among the 27 GAC cases, 24 cases (88.9%) occurred at locations other than the previous resection sites and 3 cases (11.1%) occurred at the same locations as the previous resection sites.
**Conclusion:** Male sex, intestinal metaplasia, and high grade dysplasia were significantly related to the occurrence of metachronous GAC after EMR/ESD for gastric dysplasia, and most cases occurred at locations other than the previous resection sites.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0672 DOES SHOCK INDEX (SI) CONTRIBUTE IN THE RISK ASSESSMENT OF PATIENTS WITH ACUTE UPPER GASTROINTESTINAL BLEED (AUGIB)?

**S. Naik**[1], D. Forrest[1], S.I. Hussaini[1], S. Gupta[2]

**Introduction:** Patients presenting with acute upper gastrointestinal bleeding (AUGIB) are risk assessed by calculating pre-endoscopy Rockall score (RS). Shock index (SI) [ratio between highest heart rate (HR) and lowest systolic blood pressure (SBP) has been described as an easy-to-use clinical tool that rapidly identifies patients at risk of haemodynamic decompensation (NCEPOD report)[1]. We have shown previously that RS is inaccurately documented in 78% cases[2]. The aim of this study was to compare SI with RS in patients with AUGIB. RS of $<3$ was considered low risk, while $>3$ as moderate to high risk. SI $<0.7$ was taken as low risk and $>0.7$ as moderate to high risk.
**Aims & Methods:** A retrospective analysis was conducted for all patients with AUGIB from January to December 2015 at Croydon University Hospital. Copies of electronic referral forms and endoscopy reports were scrutinised. RS was ascertained from the electronic endoscopy request form while SI was determined by scrutinizing patient observations. Endoscopic findings and therapeutic interventions were also recorded.
**Results:** Of the 195 patients, 123(63%) were male. Presenting symptom was haematemesis including coffee ground vomiting in 85 (44%) patients, melaena in 95(49%), PR bleeding in 15(8%) patients. In 152(78%) patients gastroscopy was performed within 24 hours, 27(14%) between 24–48 hours, 10(5%) in 48–72 hours and 6(3%) $>72$ hours. Endoscopy was abnormal in 144 patients (75%) which included peptic ulcer in 79 patients (55%), varices in 14 (10%), vascular lesions in 7(5%), malignancy in 3, Mallory Weiss tear in 2 and mild inflammation in 41(28%) patients. 143(73%) patients required no endoscopic intervention. Of the remaining 52 patients, variceal banding was performed in 6(3%) patients, adrenaline and endoclips in 9(5%), adrenaline and gold probe in 29 (15%) and APC done in 8 (4%) patients. SI was $<0.7$ in 67(34%) and $>0.7$ in 128(66%) patients. RS was $<3$ in 77(39%) and $>3$ in 118(61%) patients. Endoscopic intervention was required in 3 of 42 patients(7%) with RS $<3$ and SI $<0.7$, 5 of 54 patients(9%) with RS $>3$ and SI $<0.7$, 30 of 50 patients(60%) with RS $>3$ and SI $>0.7$ and 14 of 49 patients(28%) with RS $<3$ and SI of $>0.7$ required treatment. For predicting likelihood of applying endoscopic therapy for AUGIBs, RS $>3$ had a sensitivity of 67%, specificity of 37%, positive predictive value of 35% and a negative predictive value of 69%. SI $>0.7$ had a sensitivity of 84%, specificity of 61%, positive predictive value of 44% and negative predictive value of 91%.
**Conclusion:** This study shows that shock index more accurately predicts the likelihood of a patient with AUGIB requiring endoscopic intervention. SI had a higher sensitivity, specificity, negative and positive predictive value compared to RS. SI indicated a high risk GI bleed in 28% patients who were triaged as low risk bleed on pre-endoscopy RS alone. Limitation of this study is the accuracy of RS documentation which could have affected the comparison.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0673 CREATING A VIRTUAL LESION WITH A POLYPECTOMY SNARE: A SIMPLE AND INEXPENSIVE METHOD TO ASSESS THE "PIG R0 RESECTION RATE" DURING ENDOSCOPIC SUBMUCOSAL DISSECTION TRAINING IN ANIMAL MODELS

J. Jacques[1], R. Legros[2], **S. Geyl**[1], C. Couquet[1], P. Carrier[1], T. Tabouret[1], L. Bianchi[1], M. Debette-Gratien[1], A. Le -Sidaner[1], V. Loustaud-Ratti[1], D. Sautereau[1]

**Contact E-mail Address:** sophiegeyl@hotmail.com
**Introduction:** Animal models have proven efficacious for overcoming the ESD learning curve with satisfactory results and are recommended in western countries because of a lack of recruitment due to epidemiological differences and the lack of available experts to help with hands-on learning and training. Only en-bloc but not R0 resection rates have been evaluated in all animal model studies because a measurable virtual lesion is lacking
**Patients & Methods:** From March 2013 to April 2016 we performed a retrospective analysis of prospective collected data. 73 virtual standardised gastric lesions were resected by ESD. There were created by applying an open polypectomy snare on the gastric mucosa using a soft coagulation current (effect 5) during 3 s. Primary outcome was the evaluability of the specimen that was considered assessable if the virtual lesion was clearly visible during and at the end of the procedure. Pig R0 resection was defined by macroscopic visualization of the entire snare scar on the specimen with a 1 mm macroscopic margin.
**Results:** The creation of the virtual lesions was feasible in 100% of cases. The specimens were assessable in 100% of cases and the lateral margins were easily measured in 100% of cases. The marks around the virtual lesion were visible at

the end of the procedure in 44 specimens (60%) but in 35 (79.5%) cases the marks were considered less visible than the virtual lesion. 63 (86.3%) were considered "R0" resected.
**Conclusion:** After initially learning the technique, one of the most challenging aspects for the endoscopist is to perform a complete resection of a human lesion. ESD is performed after coarsely marking the lesion while learning on an animal model. Then the en bloc resection rate is evaluated but not the R0 resection rate, particularly when the marks are not visible, as in 35% of our cases. The en bloc resection rate is not an actual solid primary outcome, whereas the R0 resection rate is the final goal of ESD. Moreover, this virtual lesion allows the trainee to learn all steps of the procedure including marking around the lesion. The size of the virtual lesion is easily adaptable using different sizes of polypectomy snare, which can be applied in different locations of the pig stomach.
**Conclusion:** Creating a virtual lesion with an open polypectomy snare and a soft coagulation current is an easy, cheap, and reproducible method effective in 100% of cases. That adds the possibility of reliably evaluating the pig R0 resection rate without need of a pathological analysis that could be very useful during ESD training and research. We could imagine a threshold of pig R0 resection rate that would be defined for different locations according to difficulty before a trainee would be considered effective enough to begin human ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic forceps biopsy (EFB) is considered the gold standard and most commonly used for histological diagnosis of gastric cancerous lesions before proper management, however, with considerable discrepancy rate of 27.1–44.5% with final resected specimen. With advancement of endoscopic techniques, magnifying endoscopy with narrow band imaging (ME-NBI) has been widely used in diagnosis of cancerous lesions with relatively high diagnostic efficacy. Different from application of ME-NBI in the esophagus and colorectum, consolidated standard haven't been established for diagnosis of gastric cancerous lesions and there are many diagnostic standard proposed such as MSVS, which was most commonly used. Besides, compared with cancerous lesions in the esophagus and colorectum, high-grade intraepithelial neoplasia (HGIN) even early gastric cancer (EGC) are the most difficult to be subjectively evaluated and diagnosed using ME-NBI. Thus, diagnostic efficacy differed significantly between endoscopists even in Japan [1]. Therefore, for endoscopists especially novice endoscopists, it is common and seems reliable to perform targeted biopsy under guidance of ME-NBI (MNTB) when they were not sure for diagnosis of cancerous lesions using ME-NBI. Actually, studies have shown that MNTB has better diagnostic performance than EFB.
**Aims & Methods:** The aims of this study were to validate diagnostic efficacy of targeted biopsy under guidance of ME-NBI (MNTB) and further evaluate whether it is necessary to perform MNTB when combined with ME-NBI using MSVS diagnostic criteria [2] with a minor adjustment. This study prospectively analyzed 211 gastric lesions suspected of cancerous lesions. gastric lesions were classified as ME-NBI (+) (Definite cancer), ME-NBI (Suspected) (Indefinite but suspected cancer), ME-NBI (-) (Definite non-cancer). After careful observation under ME-NBI view, MNTB would be performed where abnormal or suspiciously abnormal features were observed. If no abnormal structures were detected, biopsy would be performed on the depressed area of gastric lesions or within the demarcation line of lesions. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) of EFB, ME-NBI, MNTB, EFB plus ME-NBI, MNTB plus ME-NBI for diagnosis of cancerous lesions were determined respectively. Accuracy, sensitivity, specificity of EFB and MNTB, EFB plus ME-NBI and MNTB plus ME-NBI were also compared respectively.
**Results:** The accuracy, sensitivity and specificity with 95% confidence intervals were 68.2% (61.4–74.4%), 62.3% (54.1–69.9%), 84.2% (71.6–92.1%) for EFB, 75.4% (68.9–80.9%), 72.7% (64.9–79.4%), 82.5% (69.6–90.8%) for MNTB, 76.8% (70.4–82.2%),73.4% (65.5–80.0%), 86.0% (73.7–93.3%) for ME-NBI, 82.0% (76.0–86.8%), 85.7% (79.0–90.6%), 71.9% (58.3–82.6%) for EFB plus ME-NBI, 84.8% (79.1–89.3%), 89.6% (83.4–93.8%), 71.9% (58.3–82.6%) for MNTB plus ME-NBI respectively. The sensitivity of MNTB was significantly higher than EFB ($P = 0.048$). There was no significant difference in the sensitivity ($P = 0.307$), specificity ($P = 1.000$) and accuracy ($P = 0.337$) between EFB plus ME-NBI and MNTB plus ME-NBI.
**Conclusion:** Though MNTB had higher diagnostic efficacy than EFB in diagnosis of cancerous lesions, it may be not necessary to perform MNTB when combined with ME-NBI. MNTB didn't show better diagnostic performance than EFB in the group of suspected cancerous lesions under ME-NBI. Our study showed that it should arrest our attention because MNTB don't boost cost-effectiveness in diagnosing gastric cancerous lesions and even increase unnecessary waste of medical resources. When we're not sure for diagnosis of cancerous lesions using ME-NBI, we could use the former EFB pathology and endoscopic features to diagnose cancerous lesions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Magnifying narrow-band imaging (M-NBI) is useful in making endoscopic diagnosis of early gastric cancer (EGC). Evaluation of morphological feature of microvessels are key to make diagnosis of EGC in M-NBI, however, interpretation of microvessel patterns is often subjective and needs certain time to achieve expertise. In our project, we aim to develop computer-aided diagnosis (CAD) algorithms to reduce variation and to facilitate learning in interpreting microvessel patterns of EGC in M-NBI.
**Aims & Methods:** In this study, a hundred M-NBI images from 100 EGCs were prepared as a training set. We firstly pre-processed these images with histogram equalization and Gaussian filtering to enhance microvessels. Each image was divided into blocks of $40 \times 40$-pixels size and, for the each block, mean and standard deviation of the gray-level co-occurrence matrix (GLCM) parameter considering four directions were obtained [1]. Then, these GLCM data were defined as the feature vector of the specific image block and used for constructing a database of all defined feature vectors. To reduce the computational complexity, we clustered the feature vectors using the vector quantization (VQ) technique. The test set consisted of other 10 M-NBI images of EGC. An expert who has experience of $>1{,}000$ cases for M-NBI diagnosis delineated the area with irregular microvessels in the M-NBI images and this was served as reference standard. The same algorithms as in the training set were applied to the images in the test set, and the Euclidean distance of feature vectors between the each block in the test set and those in the database was calculated. When the Euclidean distance is less than a threshold value (0.15), the image block was diagnosed as abnormal. The microvessels within the abnormal areas were automatically colored using our previously developed microvessel labeling algorithms.
**Results:** Compared with the expert diagnosis (area_physician), our CAD (area_CAD) achieves the mean precision rate (area_physician area_CAD / area_CAD) of 75% and the mean recall rate (area_physician area_CAD / area_-physician) of 77%, respectively. VQ technique significantly reduced the mean processing time from 18.6 seconds to 2.16 seconds for one image.
**Conclusion:** Our preliminary study demonstrated great potential of CAD in assisting endoscopists to detect abnormal microvessels of EGC in M-NBI images.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** rinori1222@yahoo.co.jp

**Introduction:** Benign, non-neoplastic gastric polyps consist of hyperplastic polyps of foveolar epithelium type and fundic gland polyps. However, recently we have detected a different type of polyp, in the form of multiple white flat lesions (MWFL),which are present from the gastric body to the fundus. There is no report in the literature describing endoscopic findings and clinical significance of these lesions.
**Aims & Methods:** We retrospectively studied the endoscopic findings—including findings by magnification endoscopy with narrow-band imaging (NBI)—and the clinical characteristics of patients with MWFL. The study population consisted of consecutive patients who underwent upper magnifying gastrointestinal endoscopy (GIF-Q240Z, Olympus Co., Ltd., Tokyo) between April 2014 and March 2015 at a single center.by an endoscopist with more than 15 years' experience in performing magnifying endoscopic examinations in the stomach Patients who had undergone total gastrectomy and patients for whom detailed medical notes were not available were excluded from the study. Three types of images (conventional endoscopic images, NBI non-magnified images, and NBI magnified images) recorded onto an endoscopic filing system were reviewed and the endoscopic findings characteristic for MWFLwere investigated. The patients' background clinical information recorded in medical notes was also reviewed, and the clinical data of patients was compared according to whether or not they exhibited MWFL. Chi-square test was used for statistical analysis and statistical significance was set at $p < 0.05$.
**Results:** A total of 177 consecutive patients were included in the analysis. The prevalence of MWFL was 7.3% (13/177 patients). Endoscopic findings characteristic for MWFL were as follows. Conventional white-light endoscopy findings revealed small, white superficial elevated multiple lesions of various sizes with serrated margins in all MWFL patients. By non-magnifying endoscopy with NBI, the background mucosa appeared brown, thus enhancing the contrast with the white lesions and making them easier to identify. By magnifying endoscopy with NBI, a clear demarcation line was present between the lesion and the background mucosa. The microvasculature of the lesions was not clearly visualized. Individual marginal crypt epithelium had an elongated, elliptical appearance with a uniform shape. Comparison between MVFL-positive and -negative patients revealed that the MVFL were frequently present among the elderly ($p = 0.007$) patients and women ($p = 0.089$). Furthermore, The prevalence of MVFL-positive patients who were taking oral antacid medication (100%, 13/13) was higher than that of MVFL-negative patients (53.7%, 88/164) ($p < 0.001$).
**Conclusion:** Endoscopic findings of MWFL are totally different from those of hyperplastic polyps of foveolar epithelium type and fundic gland polyps. The presence of MWFL might be related to the use of antacids such as proton pump inhibitors (PPI). MWFL, therefore, could constitute a new disease entity that endoscopists need to be aware of.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0677 IMPACT OF TIME TO ENDOSCOPY ON MORTALITY IN PATIENTS WITH NON VARICEAL UPPER GI BLEED

**S.A.A. Gardezi**[1], C. Tibbatts[2], A. Foliaki[3]
[1]*Gastroenterology, UHL Cardiff, Cardiff/United Kingdom*
[2]*Gastroeneterology, UHL Cardiff, Cardiff/United Kingdom*
[3]*Upper GI Surgery, UHL Cardiff, Cardiff/United Kingdom*

**Contact E-mail Address:** sanjliajk@gmail.com

**Introduction:** Acute upper GI Bleed (AUGIB) is one of the most common presentations in UK hospitals and is associated with significant morbidity and mortality. Current guidelines recommend early endoscopic intervention (i.e. Within 24 hours) for patients presenting with UGIB.1 Early endoscopy can be beneficial in achieving hemostasis more quickly & decreasing need for transfusions. 2. However aggressive resuscitation before rushing towards an endoscopy has its own importance as inadequate early resuscitation is believed to be a major factor in the persistently high mortality rate in patients with UGIB.3
**Aims & Methods:** We conducted a retrospective study of 696 patients who were admitted to Cardiff and Vale university health board & subsequently treated in endoscopy unit for non variceal upper GI bleed between September 2010 and September 2013. Patients were divided into 3 groups depending upon the time to scope from admission (Within 6 hours, 6–24 hours and more than 24 hours).
**Results:** Our study found that very early endoscopy (i.e. <6 hours) compared to rapid endoscopy (6–24 hours), did not improve outcome and in fact had a significantly worse mortality rate of 16.67% vs 4.62%. Though it can be argued that patients who had a very early endoscopy were more unwell comparatively. When we compared patients in high risk group only i.e. GBS (Glasgow Blatchford >10); results were identical.

Time to scope vs Outcome

| Hours to OGD | Total Number | Death |
|---|---|---|
| <6 hours | 18 | 3(16.67%) |
| 6–24 Hours | 173 | 8(4.62%) |
| >24hours | 505 | 59(11.68%) |

**Conclusion:** Our study reinforced the importance of access to rapid endoscopic intervention within 24 hours, but did not demonstrate the need for very early gastroscopy. This was likely due to the fact that organizing very early endoscopy within 6 h would slow intensive resuscitative efforts leading to worse outcome.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0678 APPLICATION OF A NOVEL ENDOSCOPIC SUTURING COIL IN ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD)

Y. Bi, Y. Liu, **M. Min**, L. Wang
*Gastroenterology And Hepatology, Affiliated Hospital of Academy of Military Medical Sciences, Beijing/China*

**Contact E-mail Address:** minmin823@sina.com

**Introduction:** Endoscopic submucosal dissection (ESD) is a relatively new but widely used medical technique that has been used to remove gastrointestinal mucosal tumors.
**Aims & Methods:** To evaluate a new suture coil technique for endoscopic submucosal dissection (ESD). We performed a retrospective analysis of the treatment and outcomes of 15 patients who underwent ESD for early gastrointestinal cancer between December 2013 and September 2014. The new coil-assisted suturing technique aided in lifting the mucosa, thereby fully revealing the submucosal layer and facilitating submucosal dissection. The suture coil was also used to close postoperative wounds.
**Results:** This new suture coil technique successfully aided in the resection of lesions from all 15 patients. Specifically, the use of the coils to retract the mucosa allowed the submucosal blood vessels to be clearly visualized, intraoperative uncontrollable bleeding did not occur, and the coil-based portion of the procedure was completed in 5–10 min. However, in one patient a small perforation did occur with the use of this new technique, and the perforation was readily stitched using the novel suture coil technique. In two other patients, titanium clips that had the suturing coils attached slipped after being applied, and this required adjustment of the ESD approach. The suturing coils were also found to be effective for wound closing in all of the patients. While one patient did experience minor postoperative bleeding, it was controlled with a hemostatic clip that was applied during a second endoscopy.
**Conclusion:** The proposed novel suture coil technique is straightforward to use, facilitates ESD, and it has the potential to reduce the likelihood of intraoperative and postoperative ESD-related complications.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Diagnosis of range of early gastric cancer (EGC) is essential for ESD, which is a standard treatment for EGC. Recently, it is reported that image-enhanced endoscopy with magnifying endoscopy (IEE-ME) is useful for diagnosis of range of EGC. However, IEE-ME is not considered gold standard for diagnosis of range of EGC yet. We prospectively evaluated whether magnifying endoscopy with blue laser imaging (M-BLI) could be a gold standard for diagnosis of range of EGC.
**Aims & Methods:** 47 patients with 50 tumorous lesions including 34 well-differentiated EGCs and 16 gastric adenomas were enrolled in this study between July 2015 and February 2016. Excluding lesions were diagnosed moderately and poorly differentiated EGC by biopsy specimen before M-BLI. After 50 lesions were detected a clear demarcation line using M-BLI, all of 50 lesions were randomly divided into two groups, which were only M-BLI observation

group (A group N = 25) and M-BLI with additional negative biopsies group (B group N = 25). All of the lesions were resected by ESD. Primary end point was to evaluate diagnostic accuracy of M-BLI and rate of complete resection between two groups. Secondary end point was to evaluate clinicopathological features such as mean age, gender, location, macroscopic type, median tumor size, and finally pathological diagnosis were compared between two groups.
**Results:** Diagnostic accuracy of M-BLI in A group and B group were 100% and 98%, respectively. Rate of complete resection in A group and B group were 100% and 100%, respectively. There was no significantly difference for diagnostic accuracy and complete resection rate between two groups. No significant difference was found in the clinicopathological features between A group and B group as follows; mean age was 72.8 and 72.8, gender (male:female) was 16:9 and 15:10, macroscopic type (slightly elevated: flat: slightly depressed) was 9:1:15 and 13:1:11, median tumor size was 13.1 mm and 15.7 mm, finally pathological diagnosis (adenoma: well differentiated adenocarcinoma: papillary adenocarcinoma: moderately differentiated adenocarcinoma) was 2:20:1:2 and 0:23:0:2, and location (U:M:L) was 0:10:5 and 6:10:9, respectively.
**Conclusion:** M-BLI is an effective tool for diagnosis of the range of EGC. When M-BLI showed clear demarcation lines, there were no need of additional negative biopsy around EGC. Our study suggested that M-BLI can be a gold standard for diagnosis of the range of well differentiated gastric adenocarcinoma.

## P0680 THE IMPACT OF THE UNITED KINGDOM NATIONAL OESOPHAGO-GASTRIC CANCER AWARENESS CAMPAIGN

**S. Pelitari**[1], N. Sharma[1], I. Rahman[2]
[1]*Dept. Of Gastroenterology, Heart of England Trust, Birmingham/United Kingdom*
[2]*Gastroenterology, University Hospital Southampton, Southamtpon/United Kingdom*

**Contact E-mail Address:** stavroulapelitari@gmail.com
**Introduction:** The national oesophago-gastric cancer campaign was launched in late January 2015 for 4 weeks with the intention to raise awareness and increase detection of upper GI cancers.
**Aims & Methods:** The aim of our study was to evaluate the impact of this campaign on the number of 2 week wait (2WW) referrals for gastroscopies, diagnosis of new upper GI cancers and other major pathologies identified during diagnosis. A retrospective audit was undertaken on all patients who were referred through the 2WW pathway for gastroscopy for the month before, during and after the campaign at a district general hospital trust. Data on indication, patient demographic and endoscopic diagnosis was noted. Major pathology was defined as that requiring biopsy and/or repeat procedure.
**Results:** A total of 739 patients were assessed during the study period, with a mean age of 64 years (SD 14.7) and 43% male. The indication for gastroscopy was dyspepsia in 43.3%, dysphagia in 34.9%, both dyspepsia and dysphagia in 5.0% and other indications in 16.6%. There was a 70% increase in the number of 2WW referrals during the campaign over the preceding month, with a sustained increase of 50% the month after. Despite the increase in referrals the incidence and total number of cancer detected, fell from 7.4% (n = 13) before the campaign month, to 2.3% (n = 7) during and 3.4% (n = 9) after (p = 0.02). Findings of major pathology did not significantly change either; 17.0% (n = 30) before, 17.7% (n = 53) during and 15.2% (n = 40) post (p = 0.71). There was no alteration on the tumour stage of cancers detected during or after the campaign. However, the proportion of cancers diagnosed in the <55years of age group increased from 7.7% (n = 1) before to 28.6% (n = 2) during and 11.2% (n = 1) post campaign (p = 0.54).
**Conclusion:** The 'Be clear on cancer' oesophago-gastric campaign significantly increased the number of 2WW referrals for gastroscopies without any increase in detection of new cancers or major pathologies.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0681 SAFETY AND USEFULNESS IN ELDERLY PATIENTS 80 YEARS OR OLDER OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC AND ESOPHAGEAL CANCERS

**Y. Miyamoto**[1], S. Nonaka[1], I. Oda[1], S. Abe[1], H. Suzuki[1], S. Yoshinaga[1], Y. Kawaguchi[2], Y. Saito[3]

**Contact E-mail Address:** bjdoc30@gmail.com
**Introduction:** Endoscopic submucosal dissection (ESD) is a safe and effective treatment modality for early gastrointestinal neoplasms. Given the increasing life expectancy worldwide, there is growing number of elderly patients referred for endoscopic treatment of early gastrointestinal cancer. ESD can be performed in the endoscopy room under sedation administered by endoscopists, however there are currently no guidelines on the best anesthetic modality, particularly in elderly patients, who are at higher risk of complications given frequent concomitant comorbidities, The aim of this study was to assess the safety and effectiveness in elderly patients of ESD for early gastric cancer (EGC) or early esophageal cancer (EEC).
**Aims & Methods:** We retrospectively investigated 2015 consecutive patients with 2276 lesions who underwent ESD for EGC/EEC between January 2011 and December 2015 at our institution. Anesthetic modalities included: i. propofol-based monitored anesthesia care (MAC) administered by the anesthesiologist without intubation; ii. regular sedation by endoscopists with pentazocine hydrochloride plus midazolam or/and propofol; iii. general anesthesia (GA) in the operating theatre. Anesthetic modality was at discretion of the endoscopist and anesthesiologist based on the technical complexity of the case and patient comorbidities [1]. In this study, patients were divided into 2 groups based on age 80 years or older (Group A, n = 255) and less than 80 years (group B, n = 1760). Patient demographics, sedation methods, technical outcomes, adverse events, body movement that required control by a third person during ESD, oxygen saturation (SpO2), sedatives and dosages given were then examined.
**Results:** The group A/B included 183/1367 males and 72/393 females with a mean age of 83.1/67.8 years. In the group A/B, 246/1610 ESDs for 252/1644 EGCs and 35/343 ESDs for 35/345 EECs were performed, in which 204 (80%)/1439 (81.8%) patients were managed by regular sedation by endoscopists, 46 (18%)/311 (17.7%) patients by propofol-based MAC without intubation, and 5 (2%)/10 (0.6%) patients by GA. The median size of EGC and EEC in the group A/B were 15 mm (range, 2.5–89)/12 mm (1–74) (P < 0.001) and 25 mm (7–60)/20 mm (3–100) (P < 0.001), respectively. The proportions of class III in the ASA classification in the group A/B were 1.9% (I-II/III, 250/5)/0.4% (I-II/III; 1752/8), respectively (p < 0.001). Technical outcomes and adverse events for the groups A/B were as follows: median procedure times were 74/76 minutes (range, 10–442/16–425) (p = 0.5); rate of en-bloc resection was 99.6%/99.5% (p = 0.72); perforations occurred in 0.7%/1.3% of patients (p = 0.53) and delayed bleeding in 7.1%/3.8% (p = 0.16). No significant differences in body movement of 47%/43% (p = 0.97), and median SpO2 of 98% (72–100)/98% (57–100) (p = 0.84) were seen in the two groups. Sedation was controlled by using propofol in 183/1334 (74%/83%) ESDs for EGCs and in 35/343 (100%/100%) ESDs for EECs and the remaining were managed by midazolam. Median dose of propofol in the group A/B were 5.6 mg/kg/h (range, 1.2–11.2)/6.7 mg/kg/h (0.5–25.0) (p < 0.0001) while median dose of midazolam in the group A/B were 0.12 mg/kg/h (0.01–0.29)/0.12 mg/kg/h (0.01–0.60) (p = 0.47). Five ESD were discontinued because of laryngeal edema due to the overtube (n = 2), severe esophageal spasm (n = 1) and cardiovascular instability (n = 2).
**Conclusion:** ESD is a safe and effective treatment modality for early EGC and EEC in patients 80 years or older with no differences in the short-term outcomes compared to younger patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** akio_s60@hotmail.co.jp
**Introduction:** Post-endoscopic submucosal dissection (ESD) ulcers are treated with proton pump inhibitors (PPIs). This is because some meta-analyses found that peptic ulcers are curable earlier with PPIs than with H2 receptor antagonists (H2RA) owing to the stronger inhibitory effect of PPIs on gastric acid secretion. Vonoprazan (VPZ) has been available since February 2015 in Japan. VPZ is a potassium-competitive acid blocker, which is a new gastric acid suppressant. VPZ has a more potent and long-lasting anti-secretory effect than conventional PPIs. There is no report examining whether VPZ is superior to PPIs in healing post-ESD ulcers or preventing post-ESD bleeding. We compared the rate of decrease in ulcer size in patients with post-ESD ulcers treated with PPI or VPZ.
**Aims & Methods:** We conducted ESD in 37 patients with gastric tumors, from April 2015 to March 2016. Subjects were randomly divided into the lansoprazole (LPZ) group or VPZ group. Both groups received an anti-ulcer drug orally for 8 weeks; the LPZ group received lansoprazole 30 mg/day and the VPZ group received VPZ 20 mg/day. Patients in both groups underwent upper gastrointestinal endoscopy at 4 and 8 weeks after the start of treatment. The ESD-induced ulcer size was assessed by area ($mm^2$); long and short axes (mm) of an assumed ellipse were measured using an endoscope and measuring equipment to calculate ulcer size (long radius×short radius×$\pi$= ulcer size). Complete healing was defined as ESD ulcer reaching the scar stage (S1 or S2 stage).
**Results:** The LPZ group consisted of 14 men and 3 women with a mean age of 75.6 years, whereas the VPZ group consisted of 12 men and 6 women with a mean age 71.7 years. In the LPZ group, the 17 lesions consisted of 4 in the body, 3 in the angulus, and 10 in the antrum. In the VPZ group, the 18 lesions consisted of 2 in the body, 8 in the angulus, and 8 in the antrum. There were no significant differences in extraneous factors (body mass index, degree of atrophic gastritis, and *Helicobacter pylori* infection status) between the two groups. Mean (SD) ulcer size at baseline was 2927.5 (1978.4) $mm^2$ in the PPI group and 3286.7 (2550.1) $mm^2$ in the VPZ group, and were not significantly different from each other (p = 0.64). Mean (SD) ulcer sizes at 4 and 8 weeks after ESD were 175.8 (289.3) $mm^2$ and 11.2 (9.4) $mm^2$ in the PPI group, and 360.0 (525.2) $mm^2$ and 35.2 (98.3) $mm^2$ in the VPZ group respectively. There were no significant differences between the two groups (p = 0.21 at 4 weeks and p = 0.37 at 8 weeks). The

rates of decrease in ulcer size were 93.5% for LPZ group and 88.6% for VPZ group, at week 4; and 99.2% for LPZ group and 99.6% for VPZ group, at week 8. There were no significant differences between the two groups at week 4 ($p = 0.12$) and week 8 ($p = 0.44$). No patient had complete healing at week 4 in both groups. The rate of complete healing at week 8 was 87.5% for LPZ group and 57.9% for VPZ group, and no statistically significant difference was found between the two groups ($p = 0.053$). There was one patient with post-ESD bleeding in each group.
**Conclusion:** VPZ did not reveal any superiority in healing post-ESD ulcer compared with LPZ; therefore, PPIs might be sufficient for post-ESD ulcer treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0683 OVER-THE-SCOPE CLIP FOR THE MANAGEMENT OF ENTEROCUTANEOUS FISTULA (ECF) AND PERISTOMAL LEAKAGE

**M. Bukhari**, V. Kumbhari, M. Elzein, A. Ismail, Y. Chen, Y. H. Chavez, S. Ngamruengphong, M. Khashab
*Dept. Of Gastroenterology, Johns Hopkins University, Baltimore/United States of America*

**Contact E-mail Address:** mbukhar4@jhmi.edu
**Introduction:** Persistent enterocutaneous fistula (ECF) following enteral tube removal occurs in 10% of patients. Persistent leakage results in cutaneous infection, irritation and dehydration. Several factors can delay the closure of the tract and contribute to persist ECF. Prolonged tube placement for more than six months duration result in epithelialization of the tract which plays a critical role in development of persistent ECF. Hence de-epithelialization may be important in treatment. The over-the-scope clip (OTSC) has been demonstrated to be effective for leaks and perforations with efficacy for fistulae closure being less well established. OTSC is a new class of clipping system that has the ability to precise and easy clouser for large defect upto 30 mm in diamter. There are several case reports and case series of its use in gastrocutaneous fistula but efficacy in large series has not been documented.
**Aims:** To assess the technical success, clinical success, and adverse events when using the OTSC for persistent ECF.
**Methods:** We report a single-center retrospective review of patients with persistent ECF following gastrostomy or jejunostomy tube removal who underwent OTSC closure. Persistent ECF was defined as persistent leakage for more than 1 week after removing the feeding tube. Technical success was defined as satisfactory application of the OTSC resulting in immediate fistula closure. Clinical success was defined as resolution of leakage after placement of the OTSC at last available follow-up.
**Results:** A total 16 patients (mean age 54, 69% Female) were included in the analysis. Fourteen patients had PEG tube and two had jejunostomy tube placement with a median time of percutaneous tube dwell of 22 months (range 1–48). The median duration of persistent ECF was 21 days (range 8–60). The median size of the fistula was 10 mm (range 5–15). ECF was ablated with argon plasma coagulation (APC) prior to OTSC placement in 87.5% of patients. Technical success was achieved in all patients (100%). The median follow up post OTSC placement was 30 days (range 3–120). Overall clinical success was accomplished in 62.5% of cases (10/16 patients) without any adverse events. Two patients who failed OTSC were managed successfully with alternative endoscopic therapies, 3 were managed surgically and 1 died of unrelated causes.
**Conclusion:** Endoscopic closure of ECF using the OTSC with endoscopic ablation of the fistula tract is a moderately effective and safe. About a third of patients fail therapy and can be managed by alternative endoscopic or surgical modalities.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0684 EXPANDING RELATIVE INDICATION OF ESD FOR EARLY GASTRIC CANCER ACCORDING TO THE SURGICAL CASES OF POST NON-CURATIVE ESD

**H. Tomida**[1], T. Ninomiya[2], K. Michitaka[2]
[1]*Dept. Of Gastroenterology, Ehime Prefectural Central Hospital, Matsuyama/Japan*
[2]*Gastroenterology Center, Ehime Prefectural Central Hospital, Matsuyama/Japan*

**Contact E-mail Address:** hideomi.tomida.epch@hotmail.com
**Introduction:** Recently endoscopic submucosal dissection(ESD) for early gastric cancer (EGC) has been gaining popularity. Expanded indication criteria is also accepted at this time in addition to the absolute indication criteria. Criteria of ESD had been decided based on the R0 resection and a very low risk of lymph node (LN) metastasis. On the other hands, the lesion had about 10% risk of the LN metastasis, for example submucosal (SM) invasion over 500 μm, is expected to resect at the 90% probability. With the advance in aged society, ESD is one of the choices of the treatment for the EGC to the patients who are not able to have surgery because of chronic diseases.
**Aims & Methods:** This is the study of 62 patients who underwent gastrectomy after ESD for EGC because the lesion was pathologically over the indication of ESD between March 2007 and February 2016 at our hospital. 17 patients had LN metastasis and/or residual tumor (R1 group), and 45 patients had no LN metastasis and residual tumor (R0 group). We retrospectively analyzed the pathological features between two groups.
**Results:** Regarding the characteristics of patients, in age, gender, location of the lesion, tumor size, there were no significant differences between two groups. In gross type, protruded lesion in R1 group was significantly more frequent than R0 group ($p = 0.04$). Then, we analyzed the character of the lesion according to the depth of invasion and the invasion of the lymphatic vessels. In differentiated adenocarcinoma, 1) 2 of 7 patients that had 500 μm or less SM invasion and over 30 mm in size (2/7:29%), 2) 7 of 37 patients that had over 500 μm SM invasion (7/37:19%), 3) 7 of 31 patients that had invasion of lymphatic vessels (7/31:23%), 4) 7 of 11 patients that had invasion both of SM and lymphatic vessels (7/11:24%), and 5) all 2 patients that had invasion SM and lymphatic vessels with ulcer change (2/2:100%), had LN metastasis. In undifferentiated adenocarcinoma, 2 patients that the lesion of protruded type (Type I) had residual tumor in muscle layer of resected tissue (2/2:100%). 16 patients had differentiated carcinoma including undifferentiated carcinoma, and 12 of them had LN metastasis (12/16:75%). Only 1 of 10 patient with differentiated type without papillary type, SM2 invasion, no lymphatic vessels invasion and resection margin negative had LN metastasis (1/10:10%).
**Conclusion:** With the advancement of endoscopic devices, we have widen the limitation of ESD. In case that the lesion is over the ESD indication, it is better that we recommend the patient to have the gastrectomy because of the high rate of LN metastasis. However, in case the patient have a severe complications, we should think about necessity of the additional gastrectomy based on pathological findings of ESD tissue.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0685 THE EFFECTIVENESS OF THE TRIAMCINOLONE-LOADED THERMOGEL SYSTEM TO PREVENT ESOPHAGEAL STRICTURE AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION IN A PORCINE MODEL

C. Zhang[1], Q. Li[1], L. Yu[2], **M. Xu**[1]
[1]*Endoscopy Center And Endoscopy Research Institute, Zhongshan Hospital of Fudan University, Shanghai/China*
[2]*Macromolecular Science, Fudan University, Shanghai/China*

**Contact E-mail Address:** xumeidong@aliyun.com
**Introduction:** Esophageal stricture, as an important complication of endoscopic submucosal dissection (ESD) in the esophagus, can cause dysphagia, reduce the quality of life significantly. Repeated endoscopic balloon dilation (EBD) was performed before stricture formation to prevent esophageal stricture previously, but repeated EBD increases trauma and cost of the treatment. Then triamcinolone was gradually used in prevention for esophageal stricture after ESD, and was confirmed to be able to prevent stricture occurrence. But there are still advantages of triamcinolone for submucosal injection, for example, it has short duration of drug function, drug function intensity can not continue to cicatrization fastigium, repeated rejection brings patients much inconvenience and pain. The thermogelling PLGA-PEG-PLGA triblock copolymer was verified to be a good drug controlled release carrier.

**Aims & Methods:** The study aimed to discuss the effectiveness of triamcinolone-loaded thermogel system to prevent esophageal stricture after ESD. ESD was performed in middle esophagus in six porcine models, the resected mucosa occupied complete circumference, the longitudinal diameter was 4–5 cm. Gastroscopy was performed on the 1st, 2nd, and 4th week after ESD, the situation of esophageal stricture was observed, porcine models of esophageal stricture after ESD were set up. According to different reagents injecting into the wound after ESD, eighteen porcine models were divided into 3 groups, blank control group (n = 6), triamcinolone injecting group (n = 6) and triamcinolone-loaded thermogel system injecting group (n = 6). Blank thermogel solution was injected in blank control group. The volume of injecting regent in each group is 25 ml. The total dose of triamcinolone was 100 mg in each of the latter two groups. Gastroscopy was performed on the 2nd, 4th, and 8th week after ESD, the situation of esophageal stricture after ESD in the three groups was observed and compared.
**Results:**

**Table 1:** Comparison of severe esophageal stricture between triamcinolone-loaded thermogel system injecting group and blank control group

| | Triamcinolone-loaded thermogel system injecting groupn = 6 | Blank control groupn = 6 | P-value Two-tailed |
|---|---|---|---|
| No or mild esophageal stricture (lumen diameter) 1.0 cm | 3 | 0 | 0.01P0.05 |
| Moderate esophageal stricture lumen diameter 0.5–1.0 cm | 2 | 0 | |
| Severe esophageal stricture lumen diameter 0.5 cm | 1 | 6 | |

On the 4th week after ESD in middle esophagus, the esophageal stricture rate in the six porcine models was 100%, porcine models of esophageal stricture after ESD were set up successfully. According to the gastroscopy result after ESD in the three groups, the rate of moderate and severe esophageal stricture (lumen diameter≤1.0 cm) in blank control group, triamcinolone injecting group and triamcinolone-loaded thermogel system injecting group was 100% (6/6), 83.3% (5/6) and 50% (3/6), respectively. Compared with blank control group, both of triamcinolone injection and triamcinolone-loaded thermogel system injection could not prevent postoperative esophageal stricture completely (P > 0.05, respectively). Compared in esophageal stricture extent, the rate of severe esophageal stricture (lumen diameter < 0.5 cm) in blank control group, triamcinolone injecting group and triamcinolone-loaded thermogel system injecting group was 100% (6/6), 66.67% (4/6) and 16.67% (1/6), respectively. Compared with blank control group, triamcinolone injection could not decrease the degree of postoperative esophageal effectively (P > 0.05), while triamcinolone-loaded thermogel system injection could decrease the degree of postoperative esophageal stricture, the difference was statically significant (0.01 < P < 0.05) (Table 1).
**Conclusion:** Compared with blank control group, both of triamcinolone injection and triamcinolone-loaded thermogel system injection could not prevent postoperative esophageal stricture completely, however, triamcinolone-loaded thermogel system injection could decrease the degree of postoperative esophageal stricture, while triamcinolone injection could not decrease the degree of postoperative esophageal stricture effectively.

## P0686 THE ROLE OF MINIPROBE ENDOSCOPIC ULTRASONOGRAPHY IN THE DECISION OF EARLY GASTRIC CANCER TREATMENT

R. Daegon, D. Kang, H. Kim, C. Choi, S. Park, S. Kim, H. Nam, W. Choi, J. Cho, **J. Park**, S. Lee
*Division Of Gastroenterology, Department Of Internal Medicine, Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of*

**Contact E-mail Address:** mini3763@hotmail.com
**Introduction:** The exact prediction of tumor invasion depth is mandatory to perform endoscopic submucosal dissection (ESD).
**Aims & Methods:** The aim of this study is to evaluate the accuracy of endoscopic ultrasonography (EUS) predicting invasion depth accordingto the degree of authenticity for endoscopic depth prediction and to find the characteristics of lesions associated with abenefit of additional EUS after endoscopy. Between January 2009 and February 2015, 275 well to moderate differentiated early gastric cancer (EGC) in 269 patients underwent EUS and curative treatment. We reviewed their medical records including preoperativeconventional endoscopy (CE) and EUS staging.
**Results:** The accuracy of CE and EUS to identify lesions meeting expanded ESD indications was 90.4% and 91.4% (p = 0.727) for lesion with high degree of certainty, 50.6% and 68.8%, respectively, for low degree of certainty (p = 0.021). Lowdegree of certainty for endoscopic depth prediction (OR 3.168; CI 1.256–7.990), lesions with submucosal invasion on CE staging (OR 3.7, CI 1.3–10.7), ulcer including scar (OR 5.3; CI 1.5–18.5) were associated with a higher accuracy of EUS than CE for identifying lesion meeting expanded ESD indications.
**Conclusion:** In lesions with indefinite endoscopic T staging, submucosal invasion on CE staging and ulcer including scar, EUS staging could be helpful in the decision-making process for treatment of patients with EGCs according to expanded indications.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0687 USEFULNESS OF THE MARGIN AROUND LESION FINDINGS BY MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING IN EARLY GASTRIC CARCINOMA

K. Hamada, **T. Itoh**
*Gastoenterological Endoscopy, Kanazawa Medical University, Ishikawa/Japan*

**Contact E-mail Address:** itotohru@kanazawa-med.ac.jp
**Introduction:** Many endoscopists have reported their own classifications of early gastric carcinoma using magnifying narrow-band imaging. However, there are few reports on the classification of the margin around lesions by magnifying narrow-band imaging. The aim of this study was to advocate the usefulness of the "demarcation area classification" for the diagnosis of early gastric carcinoma.
**Aims & Methods:** 197 lesions that could be investigated by magnifying narrow-band imaging were included in this study. They consisted of 115 early gastric carcinoma and 82 intestinal metaplasia. We suppose that white zone changes (fusion sign and erasure sign) and blood vessel changes (extend sign and draw sign) are indications of early gastric carcinoma findings; we retrospectively investigate this hypothesis to see if it is valid.
**Results:** For the investigation of white zone in demarcation area, both fusion sign (P: < 0.0001) and erasure sign (P: < 0.0001) were observed more often in early gastric carcinoma rather than in intestinal metaplasia. When we diagnosed the lesion with either a fusion sign or erasure sign as early gastric carcinoma, accuracy was 80.7%. For the investigation of blood vessel in demarcation area, both extend sign (P: < 0.001) and draw sign (P: < 0.0001) were observed more often in early gastric carcinoma rather than intestinal metaplasia. When we diagnosed the lesion as early gastric carcinoma with either extend sign or draw sign, accuracy was 59.9%.
**Conclusion:** The estimations of white zone and blood vessel in demarcation area are useful for diagnosis of early gastric carcinoma.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0688 THE TUNNEL + CLIP STRATEGY INCREASES THE EASE AND SPEED OF OESOPHAGEAL ESD: A RANDOMIZED STUDY IN PIGS

J. Jacques[1], **R. Legros**[1], S. Geyl[1], C. Couquet[1], P. Carrier[1], L. Bianchi[1], V. Loustaud-Ratti[1], D. Sautereau[2]
[1]*Hepato-gastro-enterology, CHU Limoges, Limoges/France*
[2]*CHU Limoges Gastroentérologie, Limoges/France*

**Contact E-mail Address:** rom1.legros@gmail.com
**Background and Aims:** Oesophagus is considered as one of the most difficult location in which to perform ESD. Indeed its narrow diameter compromises scope manoeuvrability and the thin wall increases the risk of perforation. However, oesophageal ESD is often essential, as indicated by the epidemiology of early-stage oesophageal cancer in Europe, and the high morbidity associated with oesophageal surgical procedures. Counter-traction methods and tunnel ESD have been previously reported to help during oesophageal ESD. We first reported the combination of the clip-with-line method and the tunnel technique (tunnel + clip strategy) to facilitate oesophageal ESD[1].
**Patients and methods:** From July 2015 to April 2016 we performed a randomized study in pigs comparing oesophageal ESD using the Tunnel + clip strategy vs oesophageal ESD using the tunnel method. After creating a virtual lesion in the oesophagus of 35 kgs anesthetized Landrace mini-pigs with a polypectomy snare using a soft coagulation current, a tunnel was created beneath this lesion after distal and proximal mucosal incision. Then a randomization was performed to finish the procedure with or without adding a clip with line in traction dropped at the proximal entry of the tunnel. Pig R0 resection, monobloc resection, speed of the dissection, perforation were compared. An evaluation of operator comfort and perception of safety (dissection score) was performed using a visual analogue scale (0 = the worst, 10 = the best). We estimated that a sample of 16 resections would provide at least 90% power and an alpha level of 5% to prove an increase of the speed of 50%.
**Results:** Twenty virtual lesions were resected: 10 with the tunnel method and 10 using the tunnel + clip strategy. The speed of dissection was 1.8 faster in tunnel + clip group: 15 $mm^2$/min vs 8.3 $mm^2$/min (p = 0.002). No perforation occurred in each group. The dissection score was significantly higher in the Tunnel + clip group than in the Tunnel group (7.3 vs. 4.7; p = 0.006) indicating that both operators felt more comfortable and safer performing oesophageal ESD using the tunnel + clip strategy. No difference was observed in the rates macroscopic R0 resection (100% vs 70% p = 0.2) and of en bloc resection (100% vs 90%, p = 1) The clip provided considerable assistance in performing the procedure. No macroscopic damage caused by the clipping was reported.
**Conclusion:** The tunnel + clip strategy for oesophageal ESD increases the ease and the speed of oesophageal ESD in pigs compared to the classic tunnel method. The tunnel + clip strategy improves the field of view during oesophageal dissection in particular for the edges of the tunnel. This technique enabled standardisation of the ESD procedure for superficial oesophageal neoplasia. This strategy allows a constant good exposure of the submucosal layer that is key for efficient and safe ESD. This strategy could become the standard for endoscopic resection of superficial oesophageal cancerous lesions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0689 ENDOSCOPIC RESECTION FOR DUODENAL LESIONS: OUTCOMES OF THE 374 PATIENTS FROM A RETROSPECTIVE SINGLE-CENTER STUDY

**Q. Li**, C. Lim, P. Zhou
*Endoscopy Center and Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Shanghai, China, Shanghai/China*

**Contact E-mail Address:** liquanlin321@126.com

**Introduction:** Endoscopy resection (ER), a minimally invasive technique, is becoming increasingly utilized to treat duodenal lesions. Several reports have been published, but mostly involved only a small number of patients.

**Aims & Methods:** The aim of this study was to assess the feasibility, efficacy, and safety of ER for duodenal lesions in a large retrospective study. We retrospectively analyzed the medical records of a total 374 patients with duodenal lesions who underwent ER at our institution from January 2008 to February 2015.

**Results:** The mean lesion size was $12.5 \pm 9.0$ mm. ER was in the form of 51 polypectomys (13.6%), 147 endoscopic mucosal resection (39.3%), and 176 endoscopic submucosal dissection (47.1%). The mean procedure time was $19.8 \pm 14.1$ minutes. The total rates of en bloc resection and complete resection were 94.7% and 89.0%, respectively. Intraoperative bleeding was observed in 1 patient whereas delayed bleeding was observed in 12 patients. 1 patient had intraoperative perforation while 3 patients had delayed perforation. The results of multivariate analyses showed that histopathology ($p = 0.004$) was significantly influencing delayed bleeding; histopathology ($p = 0.000$) and lesion size ($p = 0.027$) for en bloc; and histopathology ($p = 0.000$), lesion size ($p = 0.000$) and treatment methods ($p = 0.004$) for complete resection. During a mean follow-up period of $22.2 \pm 17.8$ months, 2.9% recurrence rate for dysplastic lesion (2/68) was recorded. One patient died from metastases of a primary duodenal adenocarcinoma after additional surgery, resulting in a disease-specific survival rate for dysplastic lesion was 98.5%.

**Conclusion:** ER can be considered as an effective, feasible and minimally invasive method for duodenal lesions.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0690 IMPROVING EFFICIENCY IN THE ENDOSCOPY UNIT: WHAT CAN WE DO TO REDUCE 'DID NOT ATTEND' (DNA) AND LATE CANCELLATION RATES?

**Y. Hussain**, S. Moreea
*Gastroenterology, BTHFT NHS, Bradford/United Kingdom*

**Contact E-mail Address:** yusufhussain@doctors.org.uk

**Introduction:** The demand for gastrointestinal endoscopy is inexorably growing in the UK because of the expanding screening programme for colon cancer, the two week waiting time for suspected GI cancer and the expectation from the NHS Operating Framework that 99% of patients should have their diagnostic tests within 6 weeks. In our endoscopy unit, demand for endoscopy is outstripping capacity and this gap is growing. It is therefore more relevant and important than ever before to improve the efficiency of the unit – the easy targets being increasing the room occupancy rate and decreasing the DNA rate which seems to be increasing.

**Aims & Methods:** To audit the efficiency in the endoscopy unit focusing on room occupancy, DNA and late cancellation rates with a view to implementing changes to improve efficiency. Also to look for patterns in list utility in relation to the day of the week and timing of the list. The standard endoscopy list contains 11 points (gastroscopy/sigmoidoscopy 1 point, colonoscopy 2 points) with evening, screening and teaching lists reduced to 8 points. We interrogated the electronic databases to obtain a number of variables on all endoscopy lists between April 2015 and August 2015 (19 weeks).

**Results:** During the study period a total of 3752 patients (5788 points) were listed for endoscopy. 546/584 lists ran as planned (room occupancy 93.5%) with 38 either cancelled or converted to other procedures. There were 504 (92.3%) weekday lists and 42 (7.7%) weekend lists. The average number of lists run on a working week day was 5.4. Overall 11.9% ($n = 446$) patients did not attend without prior notice and 7.7% ($n = 288$) patients cancelled without sufficient time to rebook the appointment. In total, 19.6% of patient appointments were not undertaken. 35.1% ($n = 195$) of lists ran at full capacity without any patients in the DNA or late cancellation categories. DNA and late cancellation rates did not vary much between week days but were considerably lower for weekday morning (14.7%) and weekend morning (10.1%) appointments compared to afternoon (22.2%) and evening (21.1%) lists. There were 93 acute lists run. These consist of some elective patients and empty spaces for emergency patients. 72.2% of elective acute list capacity was booked and undertaken. All booked elective patients on acute lists were scoped.

**Conclusion:** Our study showed an overall efficiency of 80.4% and a room occupancy of 93.5%. This amounts to a significant loss of earnings over the given period and leaves considerable room for improvement. Patients are more likely to attend weekend and AM appointments versus PM or evening appointments. Further study in to the contributing factors is advised as results may yield which can be used to increase efficiency of PM and evening slots. Based on these results a number of measures have been implemented to try and increase efficiency of the endoscopy unit. The following solutions are currently being explored: patient education, overbooking lists by 10%, weekly analysis of future lists to ensure cancellations are replaced, phoning patients five days before their appointments (increased administrative costs) and warehousing a number of pre-assessed patients who can attend at short notice. The authors note that, as has been mentioned in General Practice, it may be that taking a fee from patients, refundable on attendance to endoscopy appointment, is a good solution. However this is not currently viable at this time.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0691 PERCUTANEOUS ENDOSCOPIC JEJUNOSTOMY AS THERAPEUTIC INDICATION IN PATIENTS WITH PARKINSON'S DISEASE

**Z. Durkovicova**[1], M. Szantova[2]
[1]*3rd Internal Clinic, University Hospital, Medical Faculty of Comenius University, Bratislava/Slovak Republic*
[2]*3rd Department Of Medicine, Medical Faculty of Comenius University, Bratislava/Slovak Republic*

**Contact E-mail Address:** zuz.sedlakova@gmail.com

**Introduction:** PEJ is miniinvasive endoscopic procedure for nutritional or therapeutic indication. It is more difficult as PEG from technical point of view. PEJ was used in patients with Parkinson's disease for application of antiparkinsonic medication.

**Aim:** Evaluation of PEJ in patients with Parkinson's disease from therapeutic indication. Jejunal administration of medication (carbidopa and levodopa) was the aim with the continual application of medicine to jejunum and achievement of stable blood levels.

**Patients and Methods:** At the endoscopic ambulance of the 3rd Department of Medicine od Medical University 31 PEJ were done in patients with Parkinson's disease in the period from 1. 1. 2009 till 10. 10. 2015. The indication was the late stage of Parkinson's disease, if deep brain stimulation was contraindicated or non-agreement in levodopa-responsive patients. Hypersensitivity to levodopa/carbidopa, glaucoma, severe kidney, liver or cardiac failure, acute stroke, feochromocytoma, hypertyreosis and con-compliance were contraindication of the procedure.

**Results:** Fruitfulness of implantation PEJ was 100% and medium persistence was 818 days. We achieved higher persistence of PEJ in comparison with the literature (1–2 years). From the gender point of view men: women were: 1:1.2. Medium age was 70 years. Complication in association with the procedure were present in 57.1%, mild in 53.6% severe in 3.6%, comparable with the literature. Obturation of the probe was the most common complication (33.3%), comparable with the literature. It was associated with the small diameter of our probes (9 Fr). The second most common complication was (non)-intended removal of the probe (18.75%), present more frequent as in the literature. The cause was indication diagnosis – advanced stage of Parkinson's disease with demention and limited patient cooperation. Jejunal Levodopa administration with the thin lumen of the probe was the cause of more frequent extraction of the probe as in PEG. Other mild complication (convolution of the probe in stomach, dislocation of PEJ, infection of the dolg and syndrom of implanted target) occured in 10.41%, 12.5%, 4.2% a 2.1%. Frequency of these complication was comparable or lower to the literature. Hemorrhage didńt occure, as all patients had normal coagulative parameters and periprocedural drop-out of the antiagregative medication was done. Severe complication occurred in 2 patients: aspiratory pneumonia, complicated with death (3.2%) and peritonitis (3.2%), with lower frequency compare to the literature. Mortality accompanied with the procedure of in-patients is described in the literature in 25–29%. COPD was the predisposition factor of aspiration in our patient with the severe pneumonia, sepsis and multiorgan failure.

**Conclusion:** PEJ is the apropriate method for antiparkinsonic medication in the late stage of Parkinson's, if other options failed. We had less complications in comparison to the literature except of the obturation and removal of the probe. It is one of the newest indication of PEJ. It improves preservation of the motoric function and avoids to the progressive weight loss of the patients. Continual dosage of the treatment improves the neurologic state of the patients with Parkinson's disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic submucosal dissection (ESD) for early stage gastric neoplasms was recently established in Japan. We usually use proton pomp inhibitors (PPIs) to prevent delayed bleeding after ESD and to induce rapid ulcer healing. Although many reports describe the healing of post-ESD ulcers by PPIs, there is no consensus for the optimal treatment. Recently, a potassium-competitive acid blocker (P-CAB), vonoprazan, has been developed in Japan. However, no study has reported the efficacy of vonoprazan in healing post-ESD ulcers.
**Aims & Methods:** The aim of this study was to compare the efficacy between P-CAB and PPI in healing post-ESD ulcers. This study was designed as a double-blind prospective randomized controlled trial (UMIN000017386). A total of 40 patients with gastric neoplasia (gastric cancer and adenoma) who were treated by ESD at our hospital from April 2015 to January 2016, were enrolled in this study. All patients were randomly assigned to two groups as follows: group A, vonoprazan 20 mg/day; group B, rabeprazole 10 mg/day before ESD; patients took these medications from a day before ESD to 4 weeks after ESD. They underwent esophagogastroduodenoscopy (EGD) after 4 weeks, and the ESD-induced artificial ulcer size was measured just after ESD and 4 weeks after ESD, to calculate the reduction rate. The ulcer reduction rate was calculated as area of ellipse: (ulcer area 4 weeks after ESD)/(ulcer area just after ESD) × 100 (%). In addition, gastric ulcer stage was classified using a 6-stage system Sakita-Miwa classification: active (A1, A2), healing (H1, H2), and scarring (S1, S2). We then compared group A and group B via a reduction rate and gastric ulcer stage.
**Results:** As a result, 18 cases in group A (13 males, 5 females; mean age 69 y), and 15 cases in group B (11 males, 4 females; mean age 70.9 y) were analyzed. No significant differences were observed in mean age, gender, BMI, comorbidity, *Helicobacter pylori* infection, and clinicopathological findings. There were significant differences in mean reduction rate (group A: 93.3%, from $741.3 \pm 666.8 \rightarrow$to $48.0 \pm 52.0 mm^2$; group B: from 96.6%,$1022.4 \pm 640.5 \rightarrow$to $31.0 \pm 19.1 mm^2$, $p < 0.01$). All gastric ulcers 4 weeks after ESD were classified as stage H1 or H2 (H1/H2; group A: 8/10; group B: 6/9), and there were no significant differences in gastric ulcer stage. Regarding the adverse events, post-ESD bleeding was observed in 5.6% of the patients (1/18) in group A, and drug-induced hepatic injury was observed in 6.7% of the patients (1/15) in group B.
**Conclusion:** Rabeprazole was significantly more effective than vonoprazan in healing after ESD ulcers.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0693 DIFFERENTIAL DIAGNOSIS OF DIFFERENTIATED GASTRIC CANCER BY USING RAPID FLOW CYTOMETRY METHOD AS A CLINICAL APPLICATION

**S. Akane**[1], T. Yamada[2], T. Noguchi[2], A. Serizawa[2], S. Kotake[2], N. Ikari[2], N. Kanai[3], T. Shioyama[4], H. Kubo[4], S. Yamamori[4], N. Kobayashi[4], N. Hinata[5], Y. Nagashima[6], Y. Muragaki[1], K. Taniguchi[2], M. Yamamoto[2]

**Introduction:** It is difficult to diagnose gastric cancer because of its various classifications and multiple criteria according to the facility. New approaches were developed to overcome the existing problems such as high resolution endoscopic camera technologies. However, the doctors still encounter the cases being difficult to diagnose, and have to wait for a few days to be ascertained the diagnosis by pathologists. Against this background, we focused on the flow cytometry technique that was much reported in 1980's.[1–3] Cell cycle analysis with flow cytometry was well known as a useful method to study cell division and proliferation in clinical specimens. On the other hand, there were some problems especially in sample preparation and technical requirement. Therefore, we proposed a rapid and simple procedure and an algorithm for quantitative analysis for clinical use.
**Aims & Methods:** 50 specimens taken during gastroendoscopy were measured with flow cytometry according to the previous study. [4] Each DNA histogram was analyzed with quantification method with the following parameters; "malignancy index", the integrated value of G0/G1, S, G2/M, and over G2/M,[5] then evaluated the correlation with the degree of tumor differentiation in 4 groups (normal, and poorly/ moderately/ well-differentiated). All procedures were performed at Tokyo Women's Medical University in 2015.
**Results:** The patient data were as follows; 22 males, 15 females, age from 30 to 94 y. o., 19 normal/ 12 poorly/ 7 moderately/ 12 well-differentiated tissues. Statistically significant differences were observed between well-differentiated and normal tissues ($p < 0.001$), meanwhile there was no difference between poorly or moderately-differentiated and normal tissues ($p = 0.3625$). The accuracy of the discrimination of well-differentiated tissues from normal tissues was 91.7% sensitivity and 90.5% selectivity. Since well-differentiated adenocarcinomas tend to derive homogeneously, it was easy to detect with flow cytometry technique, however, poor-prognosis cancers like poorly-differentiated adenocarcinomas were required higher sensitivity because of its infiltrating progression feature.
**Conclusion:** In this study, we demonstrated the possibility of discrimination of well-differentiated adenocarcinomas from normal tissues during gastroendoscopy using quaintitative flow cytometry method. Flow cytometry analysis has the potential to provide different aspect information of cells from histopathological investigation. We will continue collecting data and additionally evaluate correlation with the prognosis factors in future.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** deep3570@yahoo.co.uk
**Introduction:** Endoscopic submucosal dissection (ESD) is superior to endoscopic mucosal resection(EMR) as it leads to en-bloc resection & reduces risk of recurrence. However, its uptake in the west has been limited due to long learning curve and procedure time. ESD in western hands takes long time and this has become a significant barrier in the adoption of this technique. We believe that if time taken to perform each individaul step of ESD can be established then future research can focus on developing devices which can shorten that time.
**Aims & Methods:** Aim: To establish individual component steps of ESD for Barrett's neoplasia & identify the time required for each component & factors predicting teh procedure time. Methods: A single, experienced, western Endoscopist performed all procedures for suspected Barrett's cancers >2 cm. All procedures were recorded in full on a digital recorder. First 30 procedures were considered as a part of learning curve and not analysed but all consecutive procedures after that were analysed by an independent researcher with knowledge of ESD. Lesion area was calculated based on length of the lesion and the percentage of the oesophageal circumference involved. Using the equation area-$= 2*\pi* r * l *\%$ circumferential involvement / 100. Here r = radius and l = length of lesion. The time for every component of the procedure was recorded: lesion

**Table 1 (P0694)**

| | Lesion evaluation (min) | SM injection | Mucosal incision | SM dissection | Accessory change | Haemostasis control | Post resection evaluation |
|---|---|---|---|---|---|---|---|
| Mean | 19 | 10.1 | 14.9 | 19.3 | 9.0 | 4.5 | 3.8 |
| Median | 20 | 8.9 | 14.8 | 15.5 | 9.2 | 3.9 | 3.8 |
| Range | 5.7–27 | 4.3–24 | 5.9–26.4 | 3.2–64.3 | 3.3–17.5 | 0.7–20 | 1.5–8 |
| | **24%** | **13%** | **18%** | **24%** | **11%** | **5%** | **5%** |

evaluation & marking, submucosal (SM) injection, mucosal incison, SM dissection, haemostasis & post-ESD site evaluation.
**Results:** ESD Component steps & time taken for each step. 29 consecutive videos were examined. All were Barrett's cancers (35% T-1b, 75% T-1a). The mean length was 30 mm (range:10–70 mm), with mean area of 8.2cm$^2$ (range:1.6–23cm$^2$). The mean procedure time was 81 mins (range:45–142 min), equating to 9.9 min/cm$^2$. The time taken for each component of the procedure is shown in Table 1. Only 42% of the time was spent in cutting (Mucosal incision and SM dissection). 24% of time was spent in evaluation and marking the margins. 24% of the time spent in changing accessories & injection. Procedure time was related to lesion area: 100 min for lesions $>10$cm$^2$ vs 72 mins for lesions $<5$cm$^2$($p=0.0056$). Circumferential extension had an effect, with $<25\%$ circumference taking 66 min vs 92 mins for lesions with $>25\%$ circumferential extension ($p=0.0025$)
**Conclusion:** Our data shows that it takes 9.9 min/cm$^2$ to perform ESD for Barrett's cancers. The time taken is directly related to the size and circumferential extent of the lesion. We also found that only 42% of the time is spent performing the actual resection and rest of the time is spent in supporting acts. This information can help focus the future research in reducing the ESD procedure time and also help plan appropriate time and remuneration for current ESD procedures. This data is unique to Barrett's neoplasia as identification of lesion margins is very challenging in Barrett's oesophagus and this is reflected in the fact that almost quarter of the time was spent doing that. Advances in imaging can help shorten this time.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0695 NEW ENDOSCOPIC FINDING OF ESOPHAGEAL ACHALASIA WITH ST SHORT HOOD: "CORONA APPEARANCE"

**H. Shiwaku**[1], K. Yamashita[1], T. Matsuoka[1], T. Ohmiya[1], H. Okada[2], Y. Shiwaku[3], S. Nimura[4], H. Inoue[5], S. Hasegawa[1]

**Introduction:** Detecting esophageal achalasia remains a challenge. We describe the diagnostic utility of "Corona appearance", a novel endoscopic finding specific to esophageal achalasia.
**Aims & Methods:** Following criteria had to be met during lower esophageal sphincter examination using the attached ST Hood short-type for positive Corona appearance: A) Congestion inside the hood, B) Ischemic change around the hood, and C) Palisade vessels outside the hood. Corona appearance and seven conventional endoscopic findings were compared for sensitivity and consistency ($\kappa$-value) among 53 untreated esophageal achalasia patients who underwent endoscopy at our hospital.
**Results:** Corona appearance had the highest sensitivity (91%; $\kappa$-value, 0.71). Other findings in descending order of sensitivity included 1) functional stenosis of the esophagogastric junction (EGJ; 86%; $\kappa$-value, 0.58), 2) mucosal thickening and whitish change (71%; $\kappa$-value, 0.27), 3) abnormal contraction of the esophageal body (59%; $\kappa$-value, 0.32), 4) dilation of the esophageal lumen (58%; $\kappa$-value, 0.53), 5) liquid remnant (57%; $\kappa$-value, 0.51), 6) Wrapping around EGJ (49%; $\kappa$-value, 0.14), and 7) food remnant (30%; $\kappa$-value, 0.88). Even in 22 patients with non-dilated achalasia (grade 1), corona appearance had highest sensitivity (88%) compared to other endoscopic findings ($\kappa$-value, 0.63).
**Conclusion:** Among endoscopic findings using a ST Hood short-type to diagnose esophageal achalasia, corona appearance had the highest sensitivity and its consistency ($\kappa$-value) among endoscopists was substantial compared to other endoscopic findings. Similar results were also seen in cases of non-dilated achalasia. Endoscopic diagnosis of esophageal achalasia with ST Hood short-type is very useful.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0696 FULL THICKNESS RESECTION DEVICE (FTRD): A NOVEL TOOL FOR COLONOSCOPIC ADENOMA RESECTION. FIRST CLINICAL EXPERIENCE FROM TWO TERTIARY REFERRAL CENTERS IN SWITZERLAND

**P.R. Aepli**[1], R. Frei[2], J. Borovicka[2], D. Criblez[1]

[2]*Gastroenterology And Hepatology, Kantonsspital St. Gallen, St. Gallen/Switzerland*

**Contact E-mail Address:** patrick.aepli@luks.ch
**Introduction:** Recently a novel endoscopic tool, the so-called "Full Thickness Resection Device" (FTRD, Ovesco, Germany), has been introduced. FTRD allows colonoscopic full thickness resection (FTR) of certain polyps that are not manageable by established techniques, especially non-lifting lesions measuring up to 30 mm in diameter. In addition, FTR is supposed to have a higher diagnostic accuracy in assessing depth of invasion in early cancer as compared to conventional endoscopic polypectomy techniques.
**Aims & Methods:** We report our first clinical experience with FTRD procedures, assessing technical success, completeness of resection (R0 status), rate of histologically proven FTR and safety. Methods: Retrospective analysis of 18 consecutive patients with colonic polyps treated with FTRD during the period of May 2015 through April 2016.
**Results:** 13 FTRD procedures were performed in the colon, 5 in the rectum. Indications were adenoma recurrence or residual adenoma with non-lifting sign after previous polypectomy (n = 7), treatment-naive adenoma with non-lifting sign (n = 5), staging resection following presumed incomplete polypectomy of early carcinoma (n = 5) and one adenoma located at the appendiceal orifice (n = 1). In one case (polyp at appendiceal orifice) the lesion could not be reached once the FTRD system was mounted, due to diverticulotic narrowing of the sigmoid. In the 17 remaining cases amenable to FTR, resection was en bloc and histologically complete (R0) in 94.1% (16/17) of patients. Complete FTR was achieved in 82.4% (14/17), i.e. 91.7% (11/12) in the colon and 60.0% (3/5) in the rectum. The mean diameter of resection specimens was 2.6 cm (range 1.8–3.2 cm). Two technical failures occurred in the initial phase of the study (one problem of handling, one malfunction of the device). Two post-procedure minor bleedings were seen (one requiring re-colonoscopy and adrenalin injection). Otherwise there were no complications during a one-month-follow-up.
**Conclusion:** According to these preliminary data, the novel technique of colonoscopic full thickness resection by FTRD appears to be feasible, efficacious and sufficiently safe in the treatment of non-lifting polyps of $\leq$30 mm in diameter. FTR is an adjunct to the armamentarium of established colonoscopic polypectomy techniques, as it offers minimally invasive treatment to a group of patients that would otherwise undergo surgery. Limitations include a lower rate of complete FTR in the rectum as compared to the colon. This has to be taken into account when dealing with dysplastic polyps or early carcinoma, where the purpose of FTR includes assessment of depth of invasion. Further prospective studies will have to corroborate this concept.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0697 IMPLEMENTATION OF AN OPTICAL DIAGNOSIS STRATEGY SAVES COSTS AND DOES NOT IMPAIR CLINICAL OUTCOMES OF A FIT-BASED CRC SCREENING PROGRAMME

**Contact E-mail Address:** j.l.vleugels@amc.uva.nl
**Introduction:** With an optical diagnosis strategy, diminutive (1–5 mm) polyps throughout the colon are resected and discarded and diminutive recto-sigmoid hyperplastic polyps (HPs) are left in situ. Implementation of this strategy may result in reduced polypectomy-related complications, direct surveillance interval assignment and cost-savings. Previous modelling studies did not include the serrated neoplasia pathway, were based on primary screening colonoscopies and assumed a rather high percentage of high-confidence predictions. We evaluated the effectiveness and costs of an optical diagnosis strategy compared to polypectomy of all diminutive lesions followed by histopathological diagnosis.
**Aims & Methods:** The Adenoma and Serrated pathway to Colorectal Cancer (ASCCA) model was set up to simulate a biennial faecal immunochemical testing (FIT) screening programme, with referral to colonoscopy of FIT positives, as well as a primary colonoscopy screening programme in individuals aged 55 to 75 years. Surveillance colonoscopies were included in both screening scenarios. For each screening scenario, we compared a histopathological diagnosis strategy to an optical diagnosis strategy. In the latter strategy, diminutive HPs assessed with high-confidence located in the recto-sigmoid are left in situ and diminutive lesions throughout the colon assessed with high-confidence are not sent for histopathology. Based on recent literature, we assumed that 76% of optical diagnoses would be made with high confidence and that 88%, 91% and 88% of respectively adenomas, sessile-serrated polyps and HPs would be accurately characterized. Outcomes of each strategy included discounted life-years, costs and number of colonoscopies.
**Results:** The model predicted that in a FIT-screening programme with a strategy of histopathological diagnosis, 17 days of life are gained in the lifetime of a 20-year old individual compared to no screening. The optical diagnosis strategy led to similar health gains. In addition, it led to cost-savings compared to the histopathological diagnosis strategy. These cost-savings were mainly due to the lower percentage of colonoscopies with polypectomy in which histopathology was required. In the optical diagnosis strategy, histopathological analysis would be performed in $\sim$70% of diagnostic colonoscopies with polypectomy. In surveillance, only $\sim$40% of colonoscopies with polypectomy required histopathological evaluation. Projected to a fully implemented FIT screening programme in the Netherlands, this would result in yearly undiscounted cost-savings of $\sim$€2.5 million. The assigned surveillance intervals were comparable for both strategies. In colonoscopy screening, comparison of both strategies led to similar conclusions, although the additional cost-savings due to the optical diagnosis strategy were higher. This was mainly due to a lower proportion, i.e. $\sim$40%, of diagnostic colonoscopies with polypectomy in which pathology was required.
**Conclusion:** Based on the ASCCA model, an optical diagnosis strategy for diminutive polyps detected within a FIT-based or colonoscopy-based screening programme does not decrease the effectiveness of either screening strategy. However, implementation of this strategy can lead to economic benefits, especially in colonoscopy screening.

**Contact E-mail Address:** federico.iacopini@gmail.com

**Introduction:** Endoscopic resection of superficial neoplasms at the low perineal rectum is difficult due to pain sensibility, narrowness of the anal canal, presence of internal rectal plexus, whereas that of at the ileocecal valve (ICV) due to the various and variable morphology of the ICV itself and ileal involvement. These two anatomic locations are relative contraindications to the conventional endoscopic snare resection (EMR) even for non-invasive cancers due to a high incomplete resection rate. Aim was to assess the feasibility and outcomes of ESD of superficial neoplasms in the low rectum and ICV.

**Aims & Methods:** Retrospective analysis of prospectively collected database in a single nonacademic center. From 1.2010 to 7.2015, all consecutive patients scheduled to ESD for a superficial neoplasm in the low rectum (<10 mm from the dentate line) and at the ICV lip +/- ileal involvement, and no deep SM invasion (Kudo pit pattern type V; Sano microcapillary pattern type 3B) were included. ESD was performed with the standard technique. Follow-up was scheduled at 3 and 6 months within the first year and then yearly. Biopsies were taken from the scar of the resection site if a residual tissue was visible at chromoscopy and/or NBI.

**Results:** A total of 28 neoplasms (7 at ICV; 21 in the low rectum) underwent ESD (Table). Rectal neoplasms involved >50% of the circumference in 9 (43%) cases. Lesions at the ICV had a complete involvement of one lip in 4 (57%) cases and of the ileum for a median of 15 mm in 2 (29%) cases. ESD was en bloc in 22 (79%) with a median operating speed of 14 min/cm$^2$ (range 3–34), was converted to a piecemeal EMR in 5 patients, and incomplete in 1 residual neoplasm in the low rectum that underwent transanal microsurgery. Results according to neoplasm location are reported in the Table. ESD was R0 in 14 (50%) cases A delayed bleeding occurred in one rectal ESD. A curative ESD (comprising R1 due to lateral margins positive for dysplasia but no residue at follow-up) was achieved in 6 (86%) ICV and 14 (67%) rectal lesions. Three patients underwent additional surgery for high-risk pathologic features (2 after ESD, 1 after piecemeal EMR). During follow-up (median 12 months; range 12–32): no recurrence was observed in 14 R0-ESDs; a minute residue was observed in 1 (14%) /7 R1-ESDs and 1 1 (50%) /2 curative piecemeal EMR. An asymptomatic scar of anal canal was observed at digital rectal examination in 2 cases.

| | ICV (n.7) | Low Rectum (n.21) |
|---|---|---|
| size, mm (median, range) | 44 (20–85) | 48 (23–180) |
| morphology: LST-G / NG | 6 / 1 | 19 / 2 |
| scar (prev. resection) | 0 | 6 (29%) |
| ESD en bloc | 6 (86%) | 16 (76%) |
| ESD R0 | 3 (43%) | 11 /52%) |
| ESD R1 (LM / VM) | 3 / 0 | 4 / 1 |
| piecemeal EMR | 1 | 3 |
| T1 high-risk LN metastasis | 0 | 3 |

**Conclusion:** The ESD of large neoplasms at the ICV and in low perineal rectum involving the anal canal is feasible and effective. The complete resection rate is low due to the challenging anatomy of that precludes conducting a mucosal incision far from tumor margins. A careful endoscopic follow-up is mandatory but ESD (even when converted to piecemeal EMR) permitted to avoid incomplete endoscopic resections and unnecessary surgery.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0699 OPTIMIZING WITHDRAWAL TIME AND USE OF FUSE ENDOSCOPE ACHIEVE SIMILAR RESULTS IN TERM OF INCREASING ADENOMA DETECTION RATE. RESULTS OF A PRELIMINARY OBSERVATIONAL STUDY

**G. Manes**, M. Devani, S. Saibeni, I. Arena, G. De Nucci, P. Andreozzi, B. Omazzi
*Ospedale Salvini, Garbagnate/Italy*

**Contact E-mail Address:** gimanes@tin.it

**Introduction:** Colonoscopy outcome is strictly related to the adenoma detection rate (ADR). An endoscopy withdrawal time (WT) >6 min has been suggested to increase the ADR since it allows for accurate evaluation of the several hidden areas of the colon. The FUSE endoscope has been demonstrated also to reduce the rate of missed lesions due to its wide angle view. In the present study we evaluate the impact on the ADR either of the use of a FUSE endoscope or of interventions directed at optimizing WT.

**Aims & Methods:** In a 3-month period 4 expert endoscopists performed 529 colonoscopies either with HD standard endoscope (SE) (n = 264) or with FUSE (n = 265) without a dedicated WT protocol. During a subsequent 2-month period they performed further 250 colonoscopies with standard scopes using dedicated inspection techniques and a minimum 6-minute WT. We compared overall rates of ADR in post-intervention procedures with those in baseline examinations.

**Results:** No differences were observed among the three groups in terms of demographic and clinical characteristics. Mean WT in the pre-intervention phase was 291+/-109 sec in the FUSE group and 260+/-94 in the SE group ($p < 0.01$). Introduction time was also longer for the FUSE (382 +/-187 sec vs 385 +/-184, $p < 0.02$). In the post-intervention phase WT increases to 386+/-69 sec ($p < 0.01$). In the pre-intervention the polyp detection rate was 60.7% (161/265) in the FUSE vs 48.1% (127/264) in the SE group ($p = 0.15$); in the post-intervention the polyp detection rate in the SE increases to 70% (175/250) ($p = 0.027$). Optimizing the WT, the ADR increases from 29.9% to 34.8% in the SE. The ADR achieved by the FUSE in the pre-intervention phase did not differ from the post-interventional ADR obtained by the SE (35.5% vs 34.8%, NS). Increase in the detection rate regarded exclusively small (<1 cm) polyps (40% in the SE pre-intervention group vs 47% in the FUSE group and 53% in the SE post-intervention group).

**Conclusion:** An intervention directed to optimize the withdrawal time determined in our series a significant increase in the number of detected lesions and a trend towards a better ADR. The same results were obtained by the FUSE scope independently of the withdrawal time. These preliminary results are likely to be important since use of FUSE may reduce the duration of colonoscopy without affecting its accuracy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0700 PREDICTORS RELATED TO COLONOSCOPY COMPLICATIONS IN AN ORGANISED COLORECTAL CANCER SCREENING PROGRAMME WITH IMMUNOCHEMICAL FAECAL OCCULT BLOOD TEST

I. Idigoras Rubio[1], **E. Arana-Arri**[2], I. Bilbao[1], J. Fernandez[3], I. Fernandez[3], L. Martinez-Indart[4], I. Gutierrez-Ibarluzea[5], M.I. Portillo Villares[1]

**Introduction:** Colorectal cancer (CRC) is a major cause of morbidity and mortality. CRC screening with biannual faecal occult blood test (FIT) has been shown to reduce CRC mortality. The efficacy of the screening programmes ultimately depends on the accuracy of post-FIT colonoscopy, however we must not underestimate the harms that they can produce.

**Aims & Methods:** Complications in a FIT screening programme occur from diagnostic colonoscopies after positive test results. The aim of this study is to determine which factors are related to these complications. Methods In 2009 the colorectal cancer screening programme started in the Basque Country, with a target population of 586,700 50 to 69 years-old citizens. This programme has a high participation rate (68.5%) and high colonoscopy compliance rate (93.1%). After a positive FIT result, patients underwent colonoscopy with sedation. Data of invitations from January, 2009 to December, 2014 on clinical characteristics of patients, screening history, endoscopic procedure and histology results were collected. Mortality and complications within 30 days after colonoscopy were identified through national registries and were assessed through the review of medical records. Predictors of colonoscopy complications were identified through a logistic regression.

**Results:** After 39,254 colonoscopies, complication rate was 1.1%. 70.4% were men and 61.7% 60–69 years-old. 83.4% had adequate bowel cleansing. 76% had an advanced adenoma (high risk adenoma or CRC). After a diagnostic colonoscopy, the risk of bleeding was 6/1,000 and the risk of perforation 2.8/1,000. The risk of post-polypectomy bleeding was 10/1,000 and perforation 4.6/1,000. No deaths had been reported. Independent predictors of colonoscopy complication were sex (OR:1.48 for men; 95%CI:1.03–2.14), history of abdominal surgery (OR:2.06; 95%CI:1.28–3.31), a colonoscopy performed in the previous 5 years (OR:30.77; 95%CI:4.13–229.32), diverticulosis (OR:2.79; 95%CI:1.84–4.23), polyp size ≥20 mm(OR:2.64; 95%CI:1.59–4.40) and advanced neoplasia in the diagnosis (OR:1.78; 95%CI:1.04–3.02). We found no relationship in: age, body mass index, anticoagulant or antiplatelet therapy and number of polyps removed. The area under ROC curve was 0.73 (95%CI:0.69–0.77). 88.1% of the patients with complications were admitted to hospital. 27.7% of them needed therapeutic colonoscopy and 10.1% surgical treatment. The average stay in hospital was 5 days (IQR: 3–7 days).

**Conclusion:** Colonoscopy, with or without removal of a lesion, is an invasive procedure with a small, but not insignificant risk of major complications. That is why, it is vital to know which aspects predict their appearance in order to implement according countermeasures.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0701 REAL TIME HISTOLOGY AT ENDOSCOPY – VIRTUAL ELECTRONIC CHROMOENDOSCOPY AND PROBE CONFOCAL LASER ENDOMICROSCOPY CAN ASSESS SUBTLE MUCOSAL AND VASCULAR INFLAMMATORY CHANGES IN ULCERATIVE COLITIS PATIENTS

**M. Iacucci**[1], X. Gui[2], O. Akinola[3], R. Panaccione[3], S. Ghosh[3]

**Contact E-mail Address:** iacuccim@yahoo.it

**Introduction:** Inflammation is considered increasingly important in the assessment of disease activity and therapeutic response in ulcerative colitis (UC). Histological assessment is being standardized to reflect disease activity even when endoscopic features are subtle. We have reported that such subtle changes can be detected by iSCAN virtual electronic chromoendoscopy (VCE) scoring.[1] Probe confocal laser endomicroscopy (pCLE) is an endoscopic tool which allows real time histology of mucosa therefore may provide histology- like images.

**Aims & Methods:** We aimed to determine whether pCLE reflected VCE and the mild –chronic subtle changes histological abnormalities in UC patients compared with the newly defined histological ECAP score,[1] and the recently validated Robarts Histology Index (RHI).

**Patients & Methods:** 90 patients (82 UC and 8 Controls) (Male: 54, median age 47 years; Range 19–79 y) were assessed with high definition –iSCAN virtual chromoendoscopy (HD-VCE)(Pentax, Japan) and pCLE (Cellvizio, Paris) after IV fluorescein. The endomicroscopy findings were graded as A) Crypt architecture: (1) normal, (2) irregular, (3) drop-outs, (4) cryptitis, (5) necrosis with crypt abscess; B) Leakage of fluorescein: (1) normal, (2) low density in the lumen of the crypts, (3) among the cells, (4) high density in the lumen of the crypts;C) Vessel architecture: (1) normal, (2) branchless, (3) tortuous, (4) dilated; D) Blood flow: (1) normal, (2) low back and forth flow, (3) high back and forth flow, (4) stagnant. Harpaz grade, the newly ECAP[1] score and the validated Robarts Histology Index (RHI) were used to represent the histological acute and chronic changes of inflammation.

**Results:** The Mayo endoscopy subscore was significantly correlated with pCLE score (rs = 0.79, 95%CI 0.7–0.85; $p < 0.001$). The overall mucosal and vascular pattern iSCAN endoscopic score[1] was significantly correlated with pCLE score (rs = 0.83, 95%CI 0.76–0.88; $p < 0.0001$). pCLE features of leakage of fluorescein (rs = 0.75, 95%CI 0.64–0.87; $p < 0.00001$), vascular architecture (rs = 0.77, 95%CI 0.67–0.84; $p < 0.0001$) and blood flow (rs = 0.80, 95%CI 0.71–0.86; $p < 0.00001$) reflected the endoscopic iSCAN vascular pattern. The Harpaz histology score was correlated with pCLE (rs = 0.59,95%CI 0.44–0.71; $p < 0.0001$). The RHI was also correlated with pCLE (rs = 0.60,95% CI 0.45–0.72; $p < 0.001$). The ECAP score correlated better with pCLE score (rs = 0.70, 95% CI 0.58–0.79; $p < 0.0001$).

**Conclusion:** pCLE can assess grade of inflammation in UC patients, both at VCE and histology levels. The leakage of fluorescein, vessels architecture and blood flow determined by pCLE reflect well the vascular changes seen by VCE. Technological advances in endoscopy are rapidly approximating histology in intestinal inflammation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** ignasipuig@gmail.com

**Introduction:** The prediction of deep submucosal invasion in a colon polyp is a challenge and an important factor in the choice of the best and safest treatment. The NICE classification attempts to resolve this issue, but it has not been validated in vivo.

**Aims & Methods:** Prospective, observational study to assess diagnostic accuracy of the NICE classification for predicting deep submucosal invasion ($>1000\,\mu m$) in polyps $>1$ cm detected during colonoscopies in routine clinical practice. Forty-five endoscopists from 14 Spanish hospitals included all consecutive colonic lesions type 0 in the Paris classification and larger than 1 cm. Characteristics of the patients and the lesions were recorded. Primary outcomes were the diagnostic test (NICE classification: 1/2/3) and the gold standard (blinded histology evaluation based on the Vienna classification). In addition, the degree of confidence of the assessment of the NICE classification (high/low) was also recorded. NICE categories 1 and 2 were grouped in a single category (non-NICE 3) in the statistical analysis. Lesions with deep submucosal invasion evaluated as NICE 3 were considered true positives, and lesions with non-deep

**Table 1. (P0702):** Diagnostic accuracy of NICE classification to predict deep submucosal invasion according to the confidence and morphology

| | N lesions | P of DSI | Se, % (95%CI) | Sp, % (95%CI) | PPV, % (95%CI) | NPV, % (95%CI) |
|---|---|---|---|---|---|---|
| Overall | 846 | 1.3 | 54.5 (51–58) | 95 (94–96) | 12.5 (10–15) | 99.4 (99–100) |
| Confidence | | | | | | |
| High | 760 | 0.9 | 57.1 (54–61) | 97.7 (97–99) | 19 (16–22) | 99.6 (99–100) |

P: prevalence; DSI: deep submucosal invasion

submucosal invasion evaluated as non-NICE 3 were considered true negatives. Sensitivity (Se), Specificity (Sp), Positive Predictive Value (PPV) and Negative Predictive Value (NPV) were calculated. Subanalyses were performed in high/low confidence lesions and in pedunculated (0–Ip)/non-pedunculated lesions, because the significance of deep submucosal invasion in 0–Ip lesions is uncertain.
**Results:** Nine hundred and two lesions (620 patients) were included (50% of the needed sample). Seventeen pT1 awaiting for a specific histological assessment were excluded at the moment. In addition, therty-nine lesions were also excluded for other reasons. Se, Sp, PPV and NPV were 54%, 95%, 12% and 99%. Diagnostic accuracy according to the grade of confidence and the lesions' morphology is shown in table 1.
**Conclusion:** This intermediate analysis shows that the Specificity and Negative Predictive Value of the NICE classification for predicting deep submucosal invasion in routine clinical practice are high. However, Sensitivity and Positive Predictive Value did not achieve acceptable levels. We must wait for the final results to better assess its role in routine clinical practice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Classification of the Laterally Spreading Tumors (LSTs) in the colon and rectum can be useful to predict the risk of containing submucosal invasion. In turn, pre-treatment diagnosis can guide the therapeutic plan: EMR, ESD or surgery. Development of a universal classification of the LSTs is needed for worldwide collaboration. We examined the interobserver agreement (IOA) for classification of LSTs among international experts as a first step towards validation and wide implementation in practice.
**Aims & Methods:** We developed an educational, web-based system to classify the endoscopic aspect of LSTs, using a modified Delphi process. We defined LSTs as large (≥10 mm) laterally superficial growing lesions. We included in the web-based system still images of LSTs using high-definition white-light endoscopy and chromoendoscopy (indigo carmine dye spraying). We asked raters to classify the lesions according to two standardized classifications: A. Kudo Classification, which included granular homogenous (LST-G-H) type; granular nodular mixed (LST-G-NM) type; non-granular flat-elevated (LST-NG-FE) type; or non-granular pseudodepressed (LST-NG-PD) type; and B. Paris classification, which included: Ip, Is, IIa, IIb, IIc and combinations. Raters were blinded to histopathology. We calculated the interobserver agreement (IOA) using Fleiss kappa coefficients with 95% confidence intervals and the proportion of pairwise agreement. Sensitivity analyses were performed to adjust for high impact of single raters.
**Results:** A total of 72 cases were assessed by 13 international (7 Western and 6 Eastern) experts. Overall, there is good interobserver agreement (IOA) for Kudo classification of LSTs into granular vs non-granular type (Fleiss kappa: 0.76 [0.72–0.79], pairwise agreement: 88.2%). The IOA varies by endoscopic type, with good IOA (kappa: 0.76 [0.68–0.84]) for LST-G-NM type vs moderate agreement (kappa: 0.54 [0.47–0.61]) for LST-NG-PD type. The IOA for Paris classification is only moderate (kappa: 0.51 [0.45–0.57], pairwise agreement: 73.5%). The IOA improves with lesion size (kappa: 0.64 for LST ≥30 mm vs kappa: 0.53 for LSTs <30 mm) and improves along the study (from kappa: 0.53 for the first third of cases to kappa: 0.68 for the last third of cases). In total, there were 50 adenomas, 4 early carcinomas and 18 sessile serrated adenomas/polyps. IOA did not differ by histopathology.
**Conclusion:** Using an educational web-based system, a good interobserver agreement was achieved among international experts in classifying colorectal LSTs into granular vs non-granular type. Interobserver agreement was highest for LST-G-NM type and lowest for LST-NG-PD type. Endoscopic classification of LSTs helps to standardize their management to optimize outcomes. Additional training is therefore required to implement the LST classification widely in clinical practice.

**Introduction:** Studies with highly experienced endoscopists revealed a moderate to high accuracy of Narrow-band imaging (NBI) in real time histological characterization of colorectal polyps. Its implementation in the real world remains to be determined, particularly in diminutive polyps (≤5 mm), for which recent guidelines propose "resect and discard" and do "not resect" (for rectosigmoid polyps) strategies.
**Aims & Methods:** To assess the role of NBI for predicting histology of colorectal polyps, using the NICE (NBI-International Colorectal Endoscopic Classification) and WASP classifications (Workgroup Serrated Polyps and Polyposis). Prospective, single-center study of patients undergoing elective colonoscopy (colonoscope CF-H190®, Olympus) between January-February 2016. Colonoscopies were performed by endoscopists with no prior NBI experience, except for a 20-minutes interactive session. Polyp characteristics were recorded: location, size, morphology (Paris classification), NICE/WASP classifications (1p-hyperplastic, 1s-sessile serrated, 2-adenoma, 3-deep submucosal invasive carcinoma) and confidence level in this classification (low: <90% vs high: >90%). Polyp histology was determined by anatomo-pathologists blinded to the NICE/WASP diagnosis. Statistics: Fisher's exact test, logistic regression (SPSS-21).
**Results:** 207 polyps of 95 patients were evaluated; average size 6.3 mm (2–35 mm); 71% 0–Is; 59.4% in the left colon. Histology: hyperplastic polyp −26.6% (n = 55), sessile serrated adenoma −4.3% (n = 9), adenoma −61.4% (n = 127), adenocarcinoma −0.5% (n = 1), inflammatory polyps/normal mucosa −7.2% (n = 15). Type of polyp according to NICE/WASP classifications: 1p – 32.9% (n = 68), 1s – 7.7% (n = 16), 2–59.4% (n = 123). The diagnosis of adenoma by NICE/WASP classifications presented an accuracy, sensitivity, specificity, positive predictive value and negative predictive value of 76.8%, 72.5%, 79.5%, 82.0% and 68.2%, respectively. For polyps ≤5 mm, located on the left colon (n = 76) there was better accuracy (81.3%), with 73.3% of the predictions made with a high confidence level. In multivariate analysis the high level of confidence (p = 0.010) and <3 polyps resected/exam (p = 0.042) were associated with the correct classification by NBI.
**Conclusion:** The application of NBI by inexperienced endoscopists showed moderate accuracy in histology prediction. For diminutive polyps of the left colon, the accuracy and confidence levels were lower than the thresholds recommended by the ASGE guidelines (≥90%). These results justify additional training and monitoring.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The relevance of incidental colorectal focal FDG-PET/CT uptake is debatable. The aim of this study was to investigate the nature of FDG-avid and non-FDG-avid lesions detected at colonoscopy in patients presenting with incidental focal uptake.

**Aims & Methods:** Charts of patients without known history of colorectal disease, who were referred in our endoscopy center for lower GI endoscopic evaluation of incidental colonic focal FDG uptake, were retrospectively reviewed. Patients with segmental or diffuse uptake were excluded. Characteristics of PET/CT images were assessed by a nuclear physician blinded to endoscopic and histopathologic findings to localize FDG uptake and measure maximum standardized uptake values (SUVmax). Endoscopic findings and histologic results were categorized into malignant lesions (adenocarcinoma), high-risk polyps (HRP, polyp $\geq$ 10 mm, with high-grade dysplasia for adenoma, or dysplasia for sessile serrated polyp), low-risk polyps (LRP, adenoma or sessile serrated polyp) or other non neoplastic lesions (NNL, hyperplastic polyps, or various lesions). The colon was divided into 4 segments: rectosigmoid, left, transverse, and right colon. Analyses per-patient, per-FDG uptake and per-lesion were performed. Kruskall Wallis test was used for comparison.

**Results:** From 2005 to 2015, 82 consecutive patients with incidental colonic uptake were referred for colonoscopy. Twelve patients with segmental or diffuse uptake were excluded; 84 focal areas of FDG uptake were detected in the 70 included patients. Colonoscopy was total in 52 (74.3%) and incomplete in 18 patients. The colonic segments with FDG uptake were constantly assessed by colonoscopy and a total amount of 233/280 (83.2%) colonic segments were evaluated with colonoscopy. Among the 84 focal areas, 43 (51.2%) were in the rectosigmoid, 12 (14.3%) in the left colon, 9 (10.7%) in the transverse colon, and 20 (23.8%) in the right colon. The proportions of true-positive (lesion found at colonoscopy at the same location) and false-positive (no lesion at colonoscopy) PET/CT results were 55 (65.5%) and 29 (34.5%). SUVmax values differed significantly between true-positive ($11.4 \pm 0.79$) and false-positive ($8.5 \pm 0.94$) FDG-uptakes ($P < 0.02$). The area under the curve was 0.63. The optimal cut-off SUVmax was 8.9 (sensitivity 55%, specificity 75%). The number of lesions seen at colonoscopy and the number of colonic segments with lesions were 107, and 83, respectively. Among the 83 colonic segments with lesion seen at colonoscopy, FDG-uptake was present in 52 cases and absent in 31 cases. Among the 150 colonic segments without any lesion, FDG-uptake was present in 25 cases and absent in 125 cases. Thus, the distribution of true-positive, false-negative, false-positive, and true-negative FDG-PET/CT results were 22.3%, 13.3%, 10.7%, and 53.7%. Among the 55 true-positive FDG uptakes, there were 14 (25.5%) malignant lesions, 30 (54.5%) HRP, 4 (7.3%) LRP, and 7 (12.7%) NNL. SUVmax did not differ significantly between groups according to histopathologic diagnosis ($p = 0.8$). The 34 non-FDG-avid lesions detected in 31 colonic segments corresponded to 5 (14.7%) HRP, 27 (79.4%) LRP and 2 (5.9%) NNL.

**Conclusion:** Our study demonstrates that two-thirds of sites of FDG uptake correspond to a lesion at colonoscopy and 52% of FDG uptake to advanced neoplasia. Although mean SUVmax values are significantly higher in true-positive than false-postive FDG uptake, individual values did not correlate with histopathologic diagnosis. The majority of non-FDG-avid lesions corresponded to LRP. We conclude that incidental focal colonic FDG uptake should be evaluated by total colonoscopy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0706 ENDOSCOPIC REMOVAL OF EARLY STAGE COLORECTAL CANCER IN A FIT-BASED SCREENING POPULATION: PROGRESS STILL TO BE MADE

**E. Wieten**, E.J. Grobbee, E.J. Kuipers, P. Didden, M.J. Bruno, M.C. w. Spaander
*Department Of Gastroenterology And Hepatology, Erasmus University Medical Center, Rotterdam/Netherlands*

**Contact E-mail Address:** e.wieten@erasmusmc.nl

**Introduction:** Endoscopic recognition and resection of early colorectal cancers (CRCs) is likely to influence the efficacy of CRC screening programs. Patient survival after (endoscopic) resection of early CRC confined to the superficial layers is higher compared to more advanced lesions and prevents a more invasive surgical resection. Literature concerning identification and endoscopic removal of early CRC in a screening setting is limited.

**Aims & Methods:** We therefore assessed if endoscopically resectable CRCs are identified correctly at colonoscopy within the framework of a fecal immunochemical tests (FIT)-based CRC screening program, and what the final treatment and outcomes of these patients were. A random sample of 13,566 persons from the Dutch general population, aged 50–74 years, were invited to participate in a FIT-based screening program, between November 2006 and October 2014. Participants were referred for colonoscopy in case of a positive FIT (cut-off $\geq$10 µg hemoglobin per gram feces). From all detected CRCs, we included endoscopically resectable cancers, defined as a CRC confined to the submucosa, without invasion of the muscularis propria or deeper wall (T1N0M0). Endoscopic resections were considered sufficient, in case of an R0 resection and resection margin $>$1 mm. Dutch guidelines were followed for treatment and surveillance recommendations, which are comparable to American Society for Gastrointestinal Endoscopy guidelines.

**Results:** Twenty patients were diagnosed with a histologically proven T1N0M0 malignant colorectal polyp. These cancers had a median size of 16 mm (range 5–40 mm) and were located in cecum (n = 1), ascending colon (n = 3), descending colon (n = 1), sigmoid (n = 13) and rectum (n = 2). Seven (35%) polyps were identified as potentially malignant before resection based on its endoscopic appearance (table 1). In total, sixteen (80%) primary endoscopic resections were performed and four (20%) primary surgical resections. Reasons for primary surgical resections were (incorrect) suspicion of stadium T2 or more by the endoscopist (n = 3) and familial adenomatous polyposis (n = 1). R0 resection rate with resection margin $>$1 mm, was 50% in the identified CRCs at colonoscopy and in 33% of the non-identified CRCs. Five (71%) patients from the endoscopically identified CRCs underwent surgery and six (46%) from the non-identified CRC (table 1).

**Table 1:** Endoscopy results and additional surgery after diagnosis of endoscopic resectable colorectal cancers detected by FIT in a CRC screening population.

*Patient diagnosed with FAP at initial colonoscopy. In this patient a colectomy was performed subsequent to the initial colonoscopy and in the resected colon a T1N0M0 CRC was found.

**Conclusion:** In this FIT-based CRC screening population, more than half of the endoscopically resectable CRCs were not identified as such during initial colonoscopy. Additional surgery was still required in a substantial part of these patients often due to incomplete and undetermined resection margins. Our findings implicate that improvement in the recognition of early CRC and use of endoscopic resection techniques are mandatory to ensure completeness for proper pathological evaluation and staging.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0707 FULL SPECTRUM ENDOSCOPY (FUSE) VERSUS STANDARD FORWARD VIEWING ENDOSCOPE (SFVE) IN A HIGH-RISK POPULATION

**S. Roepstorff**, S. Hadi, M. Rasmussen
*Digestive Disease Center, Copenhagen University Hospital Bispebjerg, Copenhagen/Denmark*

**Contact E-mail Address:** soeren@roepstorff.info

**Introduction:** Identifying polyps and subsequent polypectomy of adenomas during screening colonoscopies can prevent colorectal cancer (CRC). High adenoma detection rates (ADR) correlate inversely with the risk of interval cancers(1), making ADR the most important quality indicator in colonoscopy. Promising results have been seen with the use of Full Spectrum Endoscopy (FUSE) colonoscope in terms of ADR, but data from a high risk population is limited.

**Aims & Methods:** The purpose of the study was to investigate the diagnostic performance of FUSE compared to a conventional forward viewing endoscope. The primary outcome was CRC detection and ADR. Secondary outcome was

feasibility of FUSE opposed to Olympus standard forward viewing colonoscope (SFVE). 205 consecutive patients participating in the Danish CRC screening program were prospectively included in the study. Participants underwent FUSE colonoscopy on days when the FUSE system was available, while the remaining participants had SFVE. Baseline characteristics in terms of age, gender, ASA score, BMI, anticoagulation/antiplatelet therapy, 1st degree familiar history of CRC, prior colon resection and prior laparotomy were recorded. Following procedural parameters were recorded: completion rate, cecal intubation time, fentanyl and midazolam sedation, CRC detection, ADR, diverticulosis, bowel preparation, patient discomfort and endoscopist difficulty rating. All colonoscopies were performed by two trained endoscopists. Data were analysed using Student t-test, Fishers Exact test, Chi-squared test and Wilcoxon rank sum test.

**Results:** 109 patients were included in the FUSE group and 106 in the SFVE group. Mean age was $64.3 \pm 8.3$ and $64.5 \pm 8.0$ years, 51.4% and 50.0% were male, mean BMI $25.7 \pm 4.5$ and $26.1 \pm 4.5\,kg/m^2$ in the FUSE group and SFVE group, respectively. The two groups were comparable in age, gender, BMI, ASA score, anticoagulation/antiplatelet therapy, 1st degree familiar history of CRC, prior colon resection and prior laparotomy. Completion rate was 18/109 with FUSE and 7/106 in with SFVE ($p = 0.040$). Incompletion was due to pain in 6 vs. 1 ($p = 0.119$), preparation 6 vs. 5 ($p = 1$), malignant stricture 2 vs. 0 ($p = 0.498$), benign stricture 2 vs. 0 ($p = 0498$) and other 2 vs. 1 ($p = 1$) with FUSE and with SFVE respectively. Cecal intubation time was $11.4 \pm 6.7$with FUSE and $9.1 \pm 6.2$ with SFVE ($p = 0.042$, adjusted for bowel preparation, prior surgery, diverticulosis and BMI). CRC detection was 8.5% and 3.0% ($p = 0.126$), ADR was 67.0% and 59.6% ($p = 0.362$), while total adenoma detection was 166 (1.82/patient) and 139 (1.40) ($p = 0.094$) with FUSE and with SFVE respectively. No difference in patient discomfort ($p = 0.781$) was recorded between the two groups. Significant difference in difficulty rating among endoscopists was observed with FUSE compared to SFVE ($p > 0.001$).

**Conclusion:** There is tendency that FUSE colonoscopies identifies a greater number of adenomas compared to SFVE in a CRC screening population. Nonetheless, FUSE colonoscopies has a lower completion rate, longer cecal intubation time and a higher difficulty rating from an endoscopist point of view.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** 2L polyethylene glycol plus ascorbic acid (PEGA) is known to be as effective as standard 4L polyethylene glycol for bowel preparation. However, the volume of this regimen is still large to ingest. Therefore, we evaluated the potential of 1L PEGA with prepackaged low-residue diet (PLD) for an alternative to 2L PEGA. We report the interim results of this ongoing study.

**Aims & Methods:** The subjects were randomly assigned either to PEGA group or PLD group ($n = 100$ for each group). PEGA group received 2L PEGA (a split regimen for morning colonoscopy and a same-day regimen for afternoon colonoscopy). PLD group received PLD on the day preceding colonoscopy and 1L PEGA on the morning of colonoscopy. A questionnaire regarding bowel preparation was administrated on the morning of colonoscopy by telephone. One blinded endoscopist performed colonoscopy and evaluated the degree of bowel preparation using Boston bowel preparation score (BBPS).

**Results:** A total of 128 patients (male 56.3%, mean age 56) completed this study (68 in PEGA group, 60 in PLD group). There was no significant difference in the baseline characteristics such as sex, age, history of abdominal surgery, body mass index, and indication for colonoscopy between the two groups. The palatability of PLD was acceptable (bad taste 6.8%). The proportion of subjects who are willing to undergo colonoscopy with the same bowel preparation regimen used in the present study was higher in PLD group than in PEGA group (96.6% vs. 29.9%, $p < 0.001$). Although total BBPS was significantly higher in PLD group than in PEGA group (median 9 vs. 8, $p = 0.005$), the proportion of adequate bowel preparation (BBPS > 4) was not different between PEGA and PLD groups (98.5% vs. 96.6%, $p = 0.599$). There were no difference in the cecal intubation rate (98.5% vs. 98.3%, $p = 1.0$), cecal intubation time (median 240 seconds vs. 280 seconds, $p = 0.230$), and adenoma detection rate (40.3% vs. 42.4%, $p = 0.857$) between PEGA and PLD groups.

**Conclusion:** 1L PEGA with PLD showed similar efficacy for bowel preparation to 2L PEGA and higher acceptability than 2L PEGA.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0709 A NEW DEVICE FOR ACHIEVING ADEQUATE BOWEL PREP IN POORLY PREPPED PATIENTS RECEIVING A REDUCED PRE-PROCEDURAL PREPARATION

**Contact E-mail Address:** ori_segol@clalit.org.il

**Introduction:** Colonoscopy is the gold standard for evaluating the colon and an effective bowel preparation is essential to perform a quality colonoscopy. Inadequate preparation, estimated as many as 25% of colonoscopy procedures, results in increased rates of missed lesions, earlier repeat procedures, prolonged colonoscopy duration, reduced patient satisfaction and increased costs The MOTUS GI Pure-Vu™ System (Tirat Carmel, Israel) has been designed to improve visualization in an inadequately prepared colon by facilitating intra-procedural cleaning. The Pure-Vu system consists of a disposable single-use over-sleeve and a supporting workstation controller. The disposable over-sleeve fits easily on standard colonoscopes and does not interfere with the working channel or the navigation and advancement of the colonoscope. A foot pedal accessed by the physician controls the workstation to deliver irrigation jets to cleanse and evacuation to effectively remove considerable colon content.

**Aims & Methods:** Fifty procedures from two clinical sites using identical protocols, Carmel Medical Center in Haifa, Israel ($N = 9$) and San Rafael Hospital in Cadiz, Spain ($N = 41$), used the Pure-Vu System in partially prepped patients receiving a colonoscopy for screening, diagnostic or surveillance. The preparation used to ensure an inadequately prepped colon included a spilt dose of two tablets of 5mg Bisacodyl/ Laxadin, diet restrictions (no dried fruit, seeds or nuts) starting 2 days before the procedure and a 24 or 18 hour clear liquid diet prior to the colonoscopy. At 2 and 14 days post procedure a telephone follow-up was conducted to assess patient well-being and capture any adverse events. The study endpoints were: (1) improvement of colon cleansing level as per the Boston Bowel Preparation Scoring (BBPS) when comparing before and after Pure-Vu use, (2) Pure-Vu usability via questionnaire and (3) safety.

**Results:** Fifty subjects (64% males) are included in this analysis. The subjects' age ranges from 26–73 years, and their average BMI was 26. Results were analyzed on both a Per Protocol (PP) and Intent To Treat (IIT) basis due to patient non-compliance with the pre-procedural prep regime The Pure-Vu significantly reduced the number of subjects with an inadequate cleansing level (BBPS score < 2 of at least one colon segment). As per PP analysis, the rate of inadequate cleansing rate improved from (34/49) 69% at baseline to (1/49) 2% after use of Pure-Vu ($p < 0.001$), The mean and standard deviation of the post-treatment BBPS score was $2.96 \pm 0.29$. The cecum was reached successfully in (48/49) 98% of the cases. As per IIT analysis, the rate of adequate cleansing level pre and post procedure was 30% and 96%, respectively. The physicians were satisfied with the device's ease of advancement and found it easy to use and intuitive to operate. No serious adverse events were reported.

**Conclusion:** The Pure-Vu System was found to be simple, safe and effective in cleaning inadequately prepared colons to an adequate level for a thorough exam. Based upon these early results the device is expected to have a role in subjects with an inadequately prepared colon which may help to improve overall quality of colonoscopy, reduce the need to cancel or repeat colonoscopy procedures and improve patient satisfaction by reducing the burden of prep especially in those patients that have difficulty tolerating current prep regimes.

### P0710 ACCURACY OF THE FULL SPECTRUM ENDOSCOPY SYSTEM (FUSE) FOR PREDICTION OF COLORECTAL POLYP HISTOLOGY ACCORDING TO THE REQUIREMENTS OF THE PIVI STATEMENT

**H. Neumann**[1], G.E. Tontini[1], M. Vieth[2], K. Mönkemüller[3]

**Contact E-mail Address:** helmut.neumann@uk-erlangen.de

**Introduction:** In contrast to other endoscopy systems, FUSE uses LEDs to illuminate the tissue, thereby potentially providing more contrast as xenon lamps which emits over a broad spectrum across the visible range. The ASGE PIVI statement proposed that a new technology should provide a negative predictive value (NPV) >90% for adenomatous polyp histology to leave distal diminutive colorectal polyps in place without resection. To our knowledge no prior study has yet evaluated the feasibility of the recently introduced FUSE system for real-time in vivo prediction of polyp histology.

**Aims & Methods:** Prospective assessment of real-time prediction of colorectal polyps by using the FUSE System. Therefore, consecutive patients undergoing screening or surveillance colonoscopy were included. Colorectal lesions were evaluated in real-time by using the FUSE system. Before resection, the endoscopist described each polyp according to size, shape and surface characteristics (pit and vascular pattern, color, depression) and histology was predicted with a level of confidence (high or low).

**Results:** The histology was predicted with high-confidence in 87.6% of polyps. The overall accuracy for prediction of adenomatous polyp histology was 95.6% with sensitivity, specificity, positive and negative predictive value of 97.8%, 87.5%, 96.7%, and 91.3%, respectively. When the prediction was made with high-confidence, the accuracy was 96.9%. Sensitivity, specificity, positive and negative predictive values were 98.8%, 89.5%, 97.5%, and 94.4%, respectively.

**Conclusion:** The FUSE system is accurate enough for in vivo prediction of colorectal polyp histology. These findings need to be evaluated in future prospective, controlled, and blinded clinical trials.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0711 EFFECT OF THE MAGNETIC ENDOSCOPE IMAGER ON COLONOSCOPY PERFORMANCE BY A SINGLE ENDOSCOPIST

**L. B. Materacki**, J. Kennedy, H. Kriel, T. Brooklyn
*Gastroenterology, Cheltenham General Hospital, Cheltenham/United Kingdom*

**Contact E-mail Address:** LBM425@gmail.com
**Introduction:** Colonoscopy is the gold standard investigation for colonic assessment. To maintain clinical excellence in colonoscopy several performance indicators are recognised[1]. Colonic looping is a common patient-related factor which may reduce completion rates. The magnetic endoscope imager (MEI), a device which generates a three-dimensional map of colonoscope orientation, provides feedback regarding tip location and loop formation. MEI may improve colonoscopy outcomes however findings are inconsistent.
**Aims & Methods:** This study aimed to evaluate whether MEI use improves outcomes in colonoscopy completed by a single endoscopist. This retrospective cohort study investigated the effect of MEI on procedure completion, polyp detection, medication doses (sedation, analgesia and buscopan), endoscopist and nurse discomfort scores and patient satisfaction in patients undergoing colonoscopy. Data was obtained by interrogation of electronic colonoscopy records for a single gastroenterologist between December 2009 and November 2014. The equipment used for all colonoscopies was identical in make and age, the only difference being the presence or absence of the MEI. Statistical analysis was completed using Wizard©.
**Results:** 2129 colonoscopies were completed during the study period across three endoscopy units. After exclusion of incomplete data, study groups significantly differed by age demographics. By excluding patients older than 74 y, study groups ($n = 914$ without MEI, $n = 359$ with MEI) had similar age ($p = 0.06$) and gender ($p = 0.962$) characteristics. MEI use did not significantly influence colonoscopy completion (97.2% vs 96.3%, ($p = 0.412$)) or polyp detection (24.8% vs 29.1%, ($p = 0.132$)). Colonoscopies completed without MEI were associated with higher doses of midazolam ($1.618\,mg \pm 0.051$ vs $1.379\,mg \pm 0.097$, $p < 0.001$), fentanyl ($1.313\,\mu g \pm 0.557$ vs $0.348\,\mu g \pm 0.493$, $p = 0.044$), pethidine ($24.858\,mg \pm 0.986$ vs $23.259\,mg \pm 1.784$, $p = 0.104$) and buscopan ($16.247\,mg \pm 0.526$ vs $13.510\,mg \pm 1.041$, $p < 0.001$). Comfort scores and patient satisfaction outcomes were sub-analysed in colonoscopies completed without analgesia or sedation ($n = 244$). MEI use did not significantly affect endoscopist ($p = 0.383$) or nurse discomfort scores ($p = 0.383$ and $p = 0.971$) or patient satisfaction ratings ($p = 0.209$).
**Conclusion:** Real-world use of MEI at colonoscopy did not improve polyp detection or completion rates but was associated with decreased analgesia, sedation and buscopan use. Unsedated colonoscopy was associated with similar comfort and satisfaction scores regardless of MEI use. Endoscopists may anticipate greater discomfort without MEI and overcompensate sedation doses. Medication dosing should remain consistent regardless of MEI availability.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Colonoscopy is the gold standard for the diagnosis and management of colonic pathology. It is well recognised that the quality of bowel preparation (BP) affects the outcome of colonoscopy. Repeat procedures can be stressful for patients.
The aim from this study is to evaluate factors predicting the quality of BP in a large retrospective cohort.
**Aims & Methods:** All patients undergoing colonoscopy at a tertiary unit between 25th March 2014 and 24th March 2015 were retrospectively identified. The quality indicators used were 'excellent' for no setbacks to mucosal overview. The term 'inadequate' was used to describe suboptimal preparation rendering the procedure unfit for purpose with a requirement for repeat procedure. The term 'adequate' was used to describe stages in between. We investigated the effect of the following factors on the quality of BP:
1. Patient age. 2. Location of BP e.g. inpatient vs outpatient. 3. Number of previous colonoscopies. 4. Referral settings e.g. 2-week wait urgent referrals vs. bowel cancer screening program patients. 5. Pre-assessment and extra counselling. 6. Inflammatory bowel disease (IBD) vs. non IBD indication A logistic proportional odds model was fitted for univariate and multivariate analysis. Data was analysed using R statistical software and the visualizing categorical variables R package.
**Results:** We identified 6467 colonoscopies performed by 72 endoscopists. The patients' median age was 60 (range 7–95). Three hundred and two procedures were performed as inpatient. Twenty percent of the patients were targeted and pre-assessed according to need, 7.5 days before the procedure on average. Almost half the patients were colonoscopy naive. The proportion of excellent, adequate and inadequate procedures was 26%, 63% and 11% respectively. Advancing age ($P < 0.001$), inpatient colonoscopy ($P < 0.001$) and previous colonoscopy experience ($p = 0.02$) were independent predictors of poor bowel preparation. Bowel cancer screening and private patients had significantly better bowel preparation ($P < 0.01$) in comparison to other groups.
**Conclusion:** Bowel preparation is essential to achieve quality in colonoscopy. We identified several independent factors predicting its quality. Older and colonoscopy experienced patients did significantly worse. We suggest focused pre- assessment on those groups. Prospective in-depth studies are required in this field.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0713 THE ADENOMA TO POLYP DETECTION RATE QUOTIENT VARIES AMONG DIFFERENT PATIENT POPULATIONS: IMPLICATIONS FOR THE QUALITY METRICS OF COLONOSCOPY

**Contact E-mail Address:** andrea.buda66@gmail.com
**Introduction:** The adenoma detection rate (ADR) is considered the primary quality indicator for colonoscopy and the risk of interval colorectal cancer seems to be inversely related to the endoscopist's ADR. However, ADR calculation is a time-consuming process requiring a combination of endoscopic and histopathological data. The adenoma to polyp detection rate quotient (APDRQ) has been recently proposed as a conversion factor to estimate ADR from polyp detection rate (PDR). Besides issues regarding its calculation, it is still unclear whether different colonoscopy indications may affect its estimation and accuracy.
**Aims & Methods:** Our aim was to calculate conversion factors able to accurately estimate the ADR from the PDR in two different screening populations: average risk patients and patients with a positive fecal immune test (FIT-positive). We retrospectively reviewed colonoscopies carried out by six gastroenterologists from January 2004 to July 2015 in a tertiary referral center for gastrointestinal endoscopy, including only first time colonoscopies on average risk and FIT-positive patients. ADR, PDR and adenoma to polyp detection rate quotient (APDRQ) were calculated for each endoscopist. Mean APDRQs (ADRs/PDRs) for average risk patient population (AVR-APDRQ) and FIT-positive population (FIT-APDRQ) were used as conversion factors to estimate AVR-ADRs and FIT-ADRs of each endoscopist. The main outcome was to measure the strength of the relationship between the estimated and the real ADRs by using Pearson's coefficient, and the average estimated-actual differences.
**Results:** 3686 colonoscopies performed on average-risk patients (2327 female, 63.1%; median age 65, interquartile range 57–72) and 3962 colonoscopies performed on FIT-positive patients (1344 female, 33.9%; median age 63, interquartile range 57–68) were included. The mean AVR-APDRQ and FIT-APDRQ, used as conversion factors, were 0.72 and 0.87, respectively. The correlation between the estimated AVR-ADRs and the actual AVR-ADRs was 0.93 (95% CI, 0.70–1.00; $p = 0.007$), whereas the correlation between the estimated FIT-ADRs and the actual FIT-ADRs was 0.97 (95% CI, 0.83–1.00; $p = 0.002$). Estimated-actual AVR-ADRs difference and estimated-actual FIT-ADRs difference were 0.13% ($SD \pm 1.32$) and 0.02% ($SD \pm 1.32\%$), respectively.
**Conclusion:** In targeted specific populations, the use of a conversion factor applied to the PDR might accurately estimate the ADR. We obtained two targeted conversion factors: 0.72 for average-risk patients, 0.87 for FIT-positive patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0714 CAN A SMALL POLYP SURPRISE A BIG ENDOSCOPIST?

**S. Pietruszka**, P. Wyszyńska, Z. Wojciechowska, A. Szczepanik
*Department Of General & Gi Surgery, Jagiellonian University, Kraków/Poland*

**Contact E-mail Address:** szymon@cela.pl

**Introduction:** Colonoscopy is a significant screening exam for colorectal cancer, providing early detection and potential treatment. The risk of malignancy of large polyps and benign nature of small polyps is generally accepted, however the management of polyps $<10$ mm in diameter including polypectomy technique is controversial and not standardized.

**Aims & Methods:** The aim of the study is to assess the prevalence of malignancy and high grade dysplasia in small 6–9 mm) and diminutive ($<5$ mm) colorectal polyps ($<10$ mm) among patients undergoing screening colonoscopy. We retrospectively analyzed database of 15 631 colonoscopy procedures performed between 2006–2011 in two reference endoscopy centers.

**Results:** The study group included Females = 9476, Males = 6155. The average age of the study group was 54.37 years. In the database there were 4448 patients with polyps found during the procedure and 3943 polypectomy were performed during initial colonoscopy. Among them we found 4245 polyps $<10$ mm in diameter: 3051 (72%) diminutive polyps and 1194 (28%) small polyps. 2 cases of malignancy were discovered in polyps $<5$ mm (0.07%) while malignancy was found in 68 patients with polyps altogether. 26 patients (0.6%) with polyps had high grade dysplasia (most commonly tubular adenoma with HGD), among them 75 cases of HGD were found in small polyps (33 in polyps $<5$ mm (1%) and 42 in polyps 6–9 mm (3.5%).

**Conclusion:** Management of small colorectal polyps is still not standarized and there is no size-based strategy of treatment. Although malignancy is more often found in large polyps, small polyps require attentive approach and adequate removing technique. The cases of high grade dysplasia and malignancy found in polyps smaller than 5 mm can be of great importance to emphasize the necessity to develop a management strategy for small and diminutive polyps.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** jmgonza05@yahoo.fr

**Introduction:** Endoscopic submucosal dissection (ESD) allows resection of superficial digestive tumors, and is expanding in western countries. However, there is a lack of realistic, available and cost-effective way for learning the technique. We propose a newly designed porcine colonic ex-vivo model, with a two-steps evaluation: one with expert assessment during a single-day workshop, one by a learning curve study with inexperienced fellows

**Aims & Methods:** Model: The model consists of a porcine adult (100 kg) ex-vivo colon and rectum (50 cm). To simulate realistic 0-IIa lesions, we pasted standardized 4 cm patches made of small bowel against the mucosa. Then, the specimen was placed in a specifically designed tray mounted with a hermetic valve mimicking the anus and keeping the air inflation once the scope inserted. Expert's assessment: was performed during a one-day workshop with 21 attendees, whom belonged to the French Group of Practitioners in Endoscopy (GRAPHE), used in advanced endoscopic procedures, including ESDs. Among them, 2 had never performed ESD on patients, 8 had performed less than 10 ESD, 4 between 10 and 30, and 7 more than 30. Thus, 12 considered themselves as "still learning", 9 as "advanced or experts". Six endoscopy stations were available, with various dissection devices. Each attendee evaluated, using a visual analogic scale: 1/ the realism of model itself (8 items); 2/ the realism of the ESD procedure (12 items). Finally, 5 questions were dedicated to their impression about the usefulness of this model for teaching ESD. Learning curve study: 5 fellows without experience in ESD were enrolled and performed 18 procedures each, on 4 cm colonic lesions. For each procedure, it was recorded the time for completing the resection (minutes), the number and the volume on injections (milliliters), the number of position change and of perforations. The first 9 procedures were compared to the last 9 to evaluate the improvement of the skills.

**Results:** Expert's assessment: In total, 42 ESD procedures were performed, with a mean of 2.2 per operator, and the type of knife used was equally distributed. Regarding the evaluation of the model, the results were excellent with rate between 70 and 80% for all the items. More, 100% of the attendees believe that such model is useful to improve skills in ESD and that it could provide them more confidence for patient's procedures, and 100% said that it was an excellent model for learning ESD and were very satisfied by the workshop. More, when comparing the groups of "still learning" and "experts", the mean number of procedures was slightly different (1.8 vs. 2.5, respectively), but there was no difference in the results of the model assessment (20 items as well as final questions). Learning curve study: The total number of procedures was 90. Regarding each operator taken separately, it was observed a significant decreasing of mean ESD time, number of injections and total volume of injections for all of them. There was also less position changes and perforations. The overall analysis (45 first procedures vs 45 last) showed a significant improvement in terms of mean total time ($68 \pm 24$ vs. $41 \pm 13$; $p < 0.001$), number of injections ($4.5 \pm 1.9$ vs. $2.7 \pm 0.8$; $p < 0.001$) and total volume of injection ($69 \pm 26$ vs. $42 \pm 14$; $p < 0.001$). It was also observed a decreasing of perforation rate ($n = 13$ vs. 4; $p = 0.09$).

**Conclusion:** In conclusion, the experts considered this model as excellent for teaching and improving skills, and the learning curve study suggested a significant improvement of the performances with time. This two steps evaluation demonstrated that our newly designed ex-vivo model with simulated realistic lesions was effective and could be a useful model for learning ESD.

[6]*Sackler School Of Medicine, Tel Aviv University, Tel Aviv/Israel*

**Contact E-mail Address:** yuliash@tlvmc.gov.il

**Introduction:** Quality in medicine and patients' safety are major issues in in the last decades and became crucial in all aspects of the health system. In 2013, Gastroenterology units in most Israeli hospitals acquired the approval of the Joint Commission International (JCI) organization following prolonged procedure of training and qualification.

**Aims & Methods:** To assess the factors affecting the successful implementation of NAP aimed at improving patients' safety in endoscopy units in 3 JCI- qualified hospitals in central Israel. We used questionnaires and statistically analyzed the data using t-test and Pearson Correlation Coefficient Calculator. We investigated the followings: 1) the association between knowledge and positive attitude of the endoscopy stuff to the NAP regarding hands hygiene, performance of time out before endoscopy and double check of pathology specimens, 2) factors that inhibit or assist in the implementation of the NAP, 3) the differences in performance level parameters of the NAP between physicians and nurses in the endoscopy units.

**Results:** 71 endoscopy units personal participated in the study (64% females and 36% male, 49% nurses and 51% physicians, mean age was $45.7 \pm 9.4$ years). We found no positive correlation between the level of knowledge of each of the NAP (hands hygiene, time out and pathology specimen handling) to their actual implementation, but there was a significant correlation between positive attitude to the NAP and the level of actually performing them. The NAP performance by GI nurses was higher compared to the physicians concerning time out and pathology specimens handling. The major factors that prohibited the implementation of the NAP were former organization habits and work stress. According to the questionnaires, the means to improve implementation of the NAP should be: discussions in stuff meetings of the endoscopy unit, group decision making and consent of the stuff to comment to each other when necessary.

**Conclusion:** Knowledge and positive attitude are not sufficient for successful implementation of NAP in GI endoscopy units. In order to achieve a major change in adopting the new practices we need to abandon former organization habits, to include the stuff in the process of implementation and to reduce work stress by improving time management.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0717 HIGHER NUMBER OF SMALL (<10MM) ADENOMAS DETECTED WITH ENDOCUFF-ASSISTED COLONOSCOPY IN A SCREENING POPULATION

**L. G. Cavallaro**[1], P. Lecis[1], E. Galliani[1], E. Dal Pont[1], A. Giacomin[1], P. Iuzzolino[2], E. Macrì[2], C. Roldo[2], F. Soppelsa[3], S. Di Camillo[3], R. Mel[3], B. Germanà[1]

**Contact E-mail Address:** cavallarolucas@libero.it
**Introduction:** The Adenoma Detection Rate (ADR) is one of the quality measures in screening colonoscopy. The lower the ADR, the higher the risk of cancers after colonoscopy. Moreover, the number of adenoma detected per patient could impact on surveillance. Endocuff is an endoscopic cap with plastic projections which permits to flatten the colonic fold during withdrawal. Endocuff-Assisted colonoscopy (EAC) is potentially able to ameliorate the ADR which is crucial especially in a screening population.
**Aims & Methods:** To compare in a screening population ADR, advanced adenoma detection rate (AADR) and mean number of adenomas per patient (MAP) between EAC and Standard colonoscopy (SC)**.** We compared the performance of SC (from January to December 2014) and EAC (from January to December 2015) both in consecutive Fecal Immunochemical Test (FIT) positive and endoscopical follow-up screening participants. Colonoscopy was performed by the same team of endoscopists in both 2014 and 2015. ADR was defined as the number of colonoscopy with at least one adenoma divided by the total number of colonoscopies; mean number of adenoma per patient was defined as the total number of detected adenomas divided by the number of colonoscopies; AADR as the number of colonoscopy with at least one advanced adenoma (defined as an adenoma of 1 cm or grater, or with villous/tubule-villous or components or with high grade dysplasia) divided by the number of colonoscopies.
**Results:** 579 (298 M, mean age: 60 years, 49–70) and 605 (343 M, 60 ys, 49–70) subjects performed SC and EAC respectively. ADR was 48% in SC and 53% in EAC, p = ns. MAP in SC and EAC was 0.88 (range: 0–8) and 1.1 (range: 0–13) respectively, p = 0.02. Advanced adenoma detection rate was 26% and 23% in SC and EAC respectively, p = ns.
**Conclusion:** EAC increases the number of small (< 10 mm) adenomas detected (but not both ADR and AADR) shortening surveillance intervals in accordance to the current guidelines.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0718 PREVALENCE OF SERRATED ADENOMAS/POLYPS AT COLONOSCOPY IN A REGIONAL HOSPITAL IN QUEENSLAND, AUSTRALIA

**S. John**, A. Azzam, S. Stanley, D. Jones
*Gastroenterology, Logan Hospital, Logan/Australia/QLD*

**Contact E-mail Address:** sneha.john@health.qld.gov.au
**Introduction:** Serrated adenomas or polyps (SSA/P) of the colo-rectum are established precursors of colorectal cancer. Cancers associated with SSA/Ps are often in the proximal colon. These polyps are often flat and barely discernible and account for a significant fraction of post colonoscopy interval cancers. While recent publications suggest that SSA/Ps are more common than previously realised, data on the prevalence of these polyps is limited. Most of the published literature in this area has measured prevalence rates in screening populations and in tertiary centres.
**Aims & Methods:** The aims of our study were 1) to establish the prevalence of SSA/Ps at colonoscopy in a regional centre in South East Queensland 2) To identify the prevalence of SSAs in the younger population ie <40 years. Data was collected from our endoscopy database between July 2014 and December 2015. All procedures performed by Gastroenterologists and Surgeons who performed more than 100 colonoscopies annually were used for the analysis. Histopathology was used for establishing presence of serrated lesions and size. Electronic records stored were interrogated to establish age and gender of the patient and location of the lesion. Prevalence was determined as the proportion of patients with at least one serrated adenoma/polyp.
**Results:** A total of 3173 procedures were identified and were performed by 13 endoscopists (8 physicians, 5 surgeons). 460 SSA/Ps were detected in 309 examinations with a prevalence of 9.7%. 194 patients had polyps in the proximal colon only(62.8%). 82 polyps were greater than 10 mm in size with 85% of them in the proximal colon. Similarly, of all SSA/Ps discovered, 323 (70%) were in the proximal colon. 52.4% of the serrated polyps were discovered in men and 47.6% in women. Analysis of prevalence of SSA/Ps in relation to age was performed and identified that 10.4% of the procedures that detected SSA/Ps were in the under 40 years population. The prevalence of SSA/Ps in this age group was 1%. Details of the distribution across the age groups is provided in the attached table.

| Age Group | Procedures with SSA | Percentage | Prevalence |
|---|---|---|---|
| 20–39 years | 32 | 10.4% | 1% |
| 40–59 years | 118 | 38.2% | 3.7% |
| 60–79 years | 150 | 48.5% | 4.7% |
| 80–100 years | 9 | 2.9% | 0.2% |

**Conclusion:** Serrated adenomas/polyps are more common than realised in our population. In a retrospective analysis of a large number of unselected procedures we identified a prevalence of SSA/Ps of 9.7%. We also identified a significant proportion of procedures for patients less than 40 years where these polyps were discovered. Improvements in image enhancement and quality in colonoscopy with a focus on adenoma detection and withdrawal times may further increase serrated adenoma detection. This is expected to have a positive impact on reducing proximal colon cancers.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0719 HISTOLOGY PREDICTION OF COLORECTAL POLYPS BY NARROW-BAND IMAGING – ACCURACY AND INTER-OBSERVER AGREEMENT IN STATIC IMAGES' EVALUATION

**J. Castela**[1], J. Moleiro[1], R. Vale Rodrigues[2], F. Ávila[1], C. Martins[3], S. Mão De Ferro[1], I. Rosa[1], M. Serrano[3], J. Pereira Da Silva[4], S. Ferreira[5], I. Marques[5], I. Claro[1], P. Lage[5], A. Dias Pereira[5]

**Introduction:** The characterization of colorectal polyps by Narrow-band imaging (NBI), using the NICE classification (NBI-International Colorectal Endoscopic Classification), recently complemented by the WASP classification (Workgroup Serrated Polyps and Polyposis) revealed high accuracy when applied by endoscopists with experience in electronic chromoendoscopy. It remains to determine its applicability beyond the scope of clinical trials.
**Aims & Methods:** To assess the accuracy and inter-observer agreement of the NICE/WASP classifications for predicting the histology of colorectal polyps. NBI photo documentation of polyps detected during colonoscopy (colonoscopes CF-H190®, Olympus, Europe), from January-February 2016. High-quality images selected (Visual Analogue Scale > 6) and reviewed by 8 gastroenterologists and 4 residents, with no previous NBI experience, except for a 20-minutes interactive session. Polyps' images classified as hyperplastic polyp (1p), serrated (1s) or adenoma (2) (NICE/WASP classifications) and a confidence level was assigned to the predictions (low: <90% vs high: >90%). Individual performance, global and inter-observer agreement was evaluated. Statistics: logistic regression, Fleiss Kappa (SPSS-21).
**Results:** 52 images were evaluated, corresponding to 16 hyperplastic polyps (30.8%), 4 serreated (7.7%) and 32 adenomas (61.5%). The adenomatous histology prediction of NICE/WASP classifications revealed an overall accuracy, sensitivity, specificity, positive predictive value and negative predictive value of 80.9%, 95.4%, 71.9%, 96.2% and 68.0%, respectively. Individual accuracy ranged from 63.5% to 92.3%. 70.5% (440/624) of ratings were assigned with a high confidence level. Inter-observer agreement was moderate (Fleiss Kappa 0.53; 95% CI, 0.44–0.62), with no significant difference between specialists (Fleiss Kappa 0.51; 95% CI, 0.42–0.61) and residents (Fleiss Kappa 0.58; 95% CI, 0.49–0.67).
**Conclusion:** The application of the NICE/WASP classifications by endoscopists with no NBI experience showed good accuracy, in spite of high variability and moderate inter-observer agreement. The limitations associated to the use of static images without magnification may have contributed to these results.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic submucosal dissection (ESD) has been proposed as an ideal technique for early colorectal neoplasms that are large and/or with suspected submucosal fibrosis/focal adenocarcinoma. A demanding learning curve for colorectal ESD, together with a low prevalence of easier gastric or esophageal lesions to boost it, have prevented colorectal ESD spreading in Western countries.

**Aims & Methods:** To evaluate outcomes and learning curve progress of colorectal ESD, we completed a prospective analysis of procedures performed in two tertiary centers in Madrid. Previous training included intensive practice in animal model (46 colorectal ESD and a short number of gastric ESD performed without tutoring). We performed a global analysis and also time-framed analysis of the series, specifically assessing initial success, en-bloc & R0 resection rate, speed and complication rate. Perforation was established as any disruption of the muscular layer, regardless of size or identification of peritoneal fat.

**Results:** ESD was attempted in 85 colorectal lesions by a single operator (AH) from November 2012 to April 2016. Rectal lesions comprised 22.4% of the total collection analysed. Anatomical distribution of colonic lesions were as follows: cecum (9, 16.5%), ascending colon (9, 10.6%), hepatic flexure (8, 9.4%), transverse colon (14, 16.5%), splenic flexure (4, 4.7%), descending colon (7, 8.2%), sigmoid colon (9, 10.6%) and colorectal anastomosis (1, 1.2%). Classification according to morphology was: LST Granular mixed type 8 cases (12.1%), LST Granular homogeneus type 36 cases(54.5%) and LST Non Granular type 22 cases (33.3%). Initial success was achieved in 95.3% of the cases, with en-bloc and R0 resection rate of 94.1% and 85.8% respectively. Mean lesion size was 31 mm (range 5–80 mm), with median time to complete procedure 85 min (range 23–260 min). Perforation was the predominant complication, with a global rate of 38.8%. Close to 85% of the perforations were successfully managed endoscopically. Results from the learning curve progression according to 3 consecutive chronological blocs of 25 cases and a last bloc of 10 cases are summarized in table 1. Initial success rapidly increased from 84% to 100%, whereas en-bloc resection rate remained very high from the beginning. Speed of ESD showed a constant advance after the first 50 cases (from 0.16–0.17 $cm^2$/min on the first 50 cases to 0.33 $cm^2$/min on the last 10 cases). Perforation rate remained constantly high along all the learning curve (36–40%). Of note, surgical treatment was required on average 20% of the perforations along the first 50 cases, but a decrease in the following 2 periods analysed (11% and 0%) was remarkable.

| N = 85 | 1–25 | 26–50 | 51–75 | 76–85 | Total(n/%) |
|---|---|---|---|---|---|
| Success | 21(84%) | 25 (100%) | 25 (100%) | 10(100%) | 81(95.3%) |
| En bloc (n/%) | 21(100%) | 24(96%) | 25 (100%) | 10(100%) | 80(94.1%) |
| R0 (n/%) | 21 (100%) | 23 (92%) | 20 (80%) | 9(90%) | 73(85.8%) |
| Speed ($cm^2$/min) Mean (SD) | 0.17(0.13) | 0.16(0.12) | 0.22(0.17) | 0.33(0.15) | 0.21(0.15) |
| Perforation (n/%) | 10 (40%) | 10 (40%) | 9 (36%) | 4 (40%) | 33(38.8%) |
| Surgery after perforation (n/%) | 2/10(20%) | 2/10(20%) | 1/9(11.1%) | 0/10 (0%) | 5 (15.2%) |

**Conclusion:** Colorectal ESD is a demanding technique with a long learning curve in Western setting, as reflected in a high perforation rate observed along the time. Nevertheless, excellent outcomes in terms of success, en-bloc resection rate, speed and endoscopic management of perforations can be accomplished after completing 50 cases. These preliminary results require further analysis with long-term recurrence rate to properly evaluate the real impact of colorectal ESD in the West.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic submucosal dissection for colorectal neoplasms (C-ESD) has become a standard method of treatment. One of the advantages of ESD is that it makes it possible to resect a large tumor in an en block fashion, but a previous report [1] revealed that C-ESD for large lesions ≥50 mm was an independent risk factor for complications.

**Aims & Methods:** In the present study we aimed to evaluate the safety of C-ESD for the lesions ≥ 50 mm. This is a retrospective single-center analysis. We extracted all consecutive C-ESD cases between January 2010 and January 2016 from our database. Out of the extracted cases, we excluded aborted cases and cases where the histopathological result proved to be non-neoplastic or advanced cancer. We divided the remaining cases into two groups: the diameter of the tumor was (A) between 20 mm and 49 mm; (B) ≥ 50 mm. The following factors were assessed and compared between the two groups: patient characteristics, tumor shape, tumor location, pathological results, procedure time, and complications.

**Results:** A total of 327 cases were enrolled in this study. The results were shown in Table 1. Group A contained 285 cases (mean age: 66.9 ± 11.3, male 187/female 98) and group B contained 42 cases (mean age: 64.8 ± 10.5, male 22/female 20). As for macroscopic type, significantly more cases of laterally spreading tumor-granular type (LST-G) were included in group B than A, and no protruded tumors were included in group B ($P < 0.001$). The mean resected tumor diameter were 31.0 ± 8.0 mm in group A and 67.3 ± 15.7 mm in group B. The procedure time was significantly longer in group B than in group A (90.7 ± 52.9 min in group A vs 163.2 ± 76.5 min in group B). En block resection was achieved in 276 cases (96.8%) in group A and 42 (100%) in group B, respectively, but curative resection cases (A: 221, 76.5%; B: 23, 54.8%) were significantly more in group (A). Of the 19 non-curative cases in group B, 18 cases were with horizontal margin positive or unknown, and to date no recurrence has occurred for these cases. As for complications, there were no significant differences in the rate of post-ESD bleeding, perforation and delayed perforation between group A and B (post-ESD bleeding/perforation/delayed perforation: 2.1%/2.8%/0.7% in group A vs 4.8%/4.8%/2.4% in group B).

**Table 1:** The characteristics of patients and tumors, and the resection results

| | Group (A) 20–49 mm | Group (B) ≥ 50 mm | P value |
|---|---|---|---|
| Case number | 285 | 42 | |
| Age, y | 66.9 ± 11.3 | 64.8 ± 10.5 | 0.264 |
| Sex (female/male) | 98/187 | 20/22 | 0.101 |
| Macroscopic type, n (%) | | | < 0.001 |
| LSTG | 118 (41.4) | 38 (90.5) | |
| LSTNG | 131 (46.0) | 4 (9.5) | |
| protruded | 36 (12.6) | 0 (0) | |
| Location, n (%) | | | 0.099 |
| proximal | 143 (50.2) | 16 (38.1) | |
| Distal | 67 (23.5) | 8 (19.1) | |
| Rectum | 75 (26.3) | 18 (42.9) | |
| Tumor diameter, mm | 31.0 ± 8.0 | 67.3 ± 15.7 | |
| Resected specimen diameter, mm | 37.8 ± 8.9 | 72.5 ± 16.9 | |
| Histopathological findings, n (%) | | | 0.001 |
| adenoma | 137 (48.1) | 13 (31.0) | |
| pTis (intramucosal carcinoma) | 101 (35.4) | 28 (66.7) | |
| pT1a (submucosal invasion ≤1000$\mu$m) | 27 (9.5) | 0 (0) | |
| pT1b (submucosal invasion >1000$\mu$m) | 20 (7.0) | 1 (2.4) | |
| Procedure time, min | 90.7 ± 52.9 | 163.2 ± 76.5 | < 0.001 |
| En block resection, n (%) | 276 (96.8) | 42 (100) | 0.611 |
| Curative resection, n (%) | 221 (76.5) | 23 (54.8) | 0.003 |
| Post-ESD bleeding, n (%) | 6 (2.1) | 2 (4.8) | 0.274 |
| Perforation, n (%) | 8 (2.8) | 2 (4.8) | 0.623 |
| Delayed perforation, n (%) | 2 (0.7) | 1 (2.4) | 0.339 |

**Conclusion:** C-ESD for the lesions ≥ 50 mm takes a longer procedure time, but can be performed safely. Almost all of the non-curative cases in group B in this study were caused by lateral positive margin, so there is room for improvement. C-ESD for the lesions ≥ 50 mm can be safely said to be feasible and safe.

**Introduction:** In younger patients (aged <50 yrs) colorectal cancer (CRC) and inflammatory bowel disease (IBD) can present with similar symptoms and both are often diagnosed after significant delay. Clinical decision tools that quantify risk of disease by symptoms, individually or in combination, are increasingly used by clinicians. One possible way of achieving earlier diagnosis of IBD and CRC is to consider which patients aged <50 yrs need specialist assessment for possible serious bowel disease. We identified and quantified features of CRC and IBD in primary care, separately and combined.
**Aims & Methods:** This was a case–control study using electronic primary-care records of UK patients aged <50 years. Cases with primary colorectal cancer or IBD were matched to controls on age, sex and practice. Putative features were identified in the year before diagnosis. Odds ratios (ORs) were calculated for these features using conditional logistic regression, and positive predictive values (PPVs) were calculated.
**Results:** A total of 11239 cases and 26926 controls were studied. Ten features were independently associated with CRC/IBD (all $P < 0.001$): abdominal pain, OR 3.9 (95% confidence interval 3.4–4.5); change in bowel habit, 27.0 (19.0–39.0); diarrhoea, 8.9 (7.5–11.0); rectal bleeding, 42.0 (33.0–55.0); low haemoglobin, 2.5 (2.1–3.1); low MCV, 2.7 (2.1–3.5); raised inflammatory markers, 5.4 (4.6–6.3); raised hepatic enzymes, 1.4 (1.2–1.6); raised white cell count, 1.5 (1.3–1.9); and thrombocytosis, 4.4 (3.4–5.7). PPVs >5% in patients <50 years were found for rectal bleeding in combination with thrombocytosis or raised inflammatory markers, for change in bowel habit with low MCV or low haemoglobin, and for diarrhoea in combination with thrombocytosis.
**Conclusion:** Symptoms of colorectal cancer and inflammatory bowel disease are similar in younger patients presenting in primary care. When associated with abnormal haematology, rectal bleeding and change in bowel habit are strongly predictive of CRC/IBD and can be used to prioritise patients for colonoscopy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0723 NARROW BAND IMAGING (NBI) VS. NBI WITH ACETIC ACID ENHANCEMENT FOR DIFFERENTIATION OF SMALL COLORECTAL POLYPS

**D. Zavyalov**[1], S. Kashin[1], R. Kuvaev[2], E. Kraynova[1], T. Kryukova[3]

[3]*Medical Center of Diagnostic and Prevention, Yaroslavl/Russian Federation*

**Contact E-mail Address:** zavialoff@mail.ru
**Introduction:** Narrow Band Imaging Endoscopy (NBI) is useful for differentiation of adenomas and hyperplasic polyps (HP). However, it is still occasionally complicated for distinguishing polyps using just a NBI, because it's surface is often indistinct. The application of acetic acid for enhancement allows obtain a clearer image.
**Aims & Methods:** To evaluate the diagnostic efficacy NBI and NBI with acetic acid enhancement (NBI+AA) for differentiation of adenomas and HP. We carried out a prospective study that included 261 benign colorectal polyps with size less than 10 mm (the average size of polyp was 4.8 mm). All polyps were detected by the conventional inspection in white light mode. Afterwards 184 polyps have been examined with NBI mode, however 35 polyps (23.5%) were excluded due to the fact that lesions surface was unclean and unsuitable for evaluation by NICE-classification. Ultimately in NBI-group entered 149 cases. In NBI+AA-group 77 polyps were included, all of them were evaluated after the utilization of1.5% acetic acid spray. Eventually 226 cases were involved into the study (73 adenoma and 153 HP). Endoscopy suites were equipped with Evis Exera II CV-180 processors, CF-H180AL and PCF-H180AL colonoscopes (Olympus). In each case the image database has been generated in graphical format.bmp. After completing inclusion of patients in the study, physician, who conducted a colonoscopy, predicts the results of histological findings based on the NICE classification.
**Results:** In both groups (NBI-group vs. NBI+AA-group) the sensitivity of endoscopic prediction compose 84.6vs.92.7% (CI 84.7–97.3% for NBI+AA-group), the specificity 99.1vs.98.6% (CI 92.5–99.7%), the positive predictive value 99.3vs.98.7% (CI 92.9–99.8%), the negative predictive value 81.9vs.92.2% (CI 83.8–99.1%) and AUC 0.92vs.0.96% (CI 91–98%). In NBI-group relative risk was 0.82 ($P < 0.0001$), odds ratio was 0.031 ($P < 0.0007$), in NBI+AA-group 0.93 ($P = 0.05$) and 0.16 ($P = 0.088$) respectively.
**Conclusion:** Both of these methods (NBI and NBI+AA) are highly accurate for distinguishing adenomas and HP of small size. Nevertheless, applying NBI-mode is limited in approximately a quarter of the cases (23.5%) due to indistinct surface of lesions. Acetic acid enhancement increases the value of this method. Usage of acetic acid is cheap, fast, safe and allows avoiding unnecessary biopsies.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0724 ENDOSCOPIC APPLICATION OF REGENERATED OXIDIZED CELLULOSE AFTER RECTAL ENDOSCOPIC RESECTION

**Introduction:** The most common complication of endoscopic resection (ER) of large colorectal polyps is bleeding, especially in patients who must continue anticoagulation medications for thrombophilic or cardiovascular disorders. Oxidized cellulose mesh (Surgicell®) is a well-known and widely available surgical hemostatic agent (mesh). Oxidized cellulose, which has bactericidal activity, exerts its effect as a tissue-apposing device. Oxidized cellulose is used to stop bleeding from liver lacerations, gynecological surgery and in neurosurgical interventions. Therefore, it use in endoluminal GI interventions is appealing, especially in patients on anticoagulant therapy.
**Aims & Methods:** The aim of this study was to evaluate the feasibility of endoscopic application of oxidiced cellulose and the hemostatic efficacy after endoscopic resection (endoscopic submucosal dissection or piecemeal endoscopic mucosal resection). Retrospective, observational, open label, single-center study of patients undergoing endoscopic resection of large rectal and rectosigmoid lesions. After the colorectal epithelial neoplasm removed, oxidized cellulose was applied onto the submucosal surface using one of two methods: a) anoscope or cap-assisted delivery. In both techniques, a hemoclip was advanced through the working channel of the scope and 10 x 10 to 20 x 20 mm large pieces of the oxidized cellulose were grasped with the clip and then delivered and attached to the wound.
**Results:** A total of 16 patients (9 male, 7 female, mean age 65, range 42 to 87) underwent endoscopic resection (ESD, n = 9 or piecemeal EMR, n = 7) of large rectum or rectosigmoid lesions with either primary intent of complete resection or debulking (in the case of large mucin-secreting rectal tumors). All patients were on anticoagulants and/or antiplatelet agents. The mean size of the lesions was 45 mm, range 30 to 120 mm. An endoscopic R0 was achieved in 75%. During follow-up period there were no rectal bleeding episodes or adverse events, despite patients continuing on anticoagulant therapy.
**Conclusion:** Oxidized cellulose mesh can be successfully applied to large resection sites using the cap-assisted or anoscope techniques. Oxidized cellulose mesh effectively decreases hemorrhage and prevents post-endoscopic resection bleeding. Thus, this feasibility study suggests that oxidized cellulose mesh may be a valuable tool to provide hemostasis and prevent bleeding after ESD. Now prospective and randomized studies are warranted.

**Introduction:** Background: It is known that pedunculated colorectal polyps are high risk for post-polypectomy bleeding (PPB), because thick feeding artery runs through their stalks[1]. Therefore, several methods for endoscopic treatment, such as endoloop snare and clips to the stalk, have been performed to prevent PPB in large pedunculated polyps. However, it is relatively difficult for endoscopists and assistants to perform using these methods because of technical tools and limited endoscopic working space. Moreover, if spurting bleeding after polypectomy occurred, it was difficult and time consuming to do hemostasis because of poor visibility due to bleeding. In our hospital, large pedunculated polyps are removed with endoscopic mucosal resection (EMR) method by bipolar electrocauterization. In this method, several benefits are present. The precoagulation with slowly cutting because of electric current flow peculiar to bipolar snare that does not flow through the wall of colon can prevent immediate PPB. Furthermore, if immediate PPB occurred, hemostasis was relatively easy with bipolar hemostatic forceps, because we could observe the bleeding point by large resection space after EMR. Therefore, we consider EMR by

bipolar electrocauterization is a good method for large pedunculated polyps in the respect of a lesser PPB and easier hemostasis. In previous studies, PPB accounted for 5.1–14.4% by monopolar electrocauterization and 1.8–3.1% by bipolar electrocauterization with some preventional methods[2–4].
**Aims & Methods:** The aim of this retrospective study is to investigate the efficacy and safety of removal of large pedunculated colorectal polyps with EMR by bipolar electrocauterization. Methods: We intended consecutive patients with pedunculated colorectal polyps 10 mm or more that were resected with EMR by bipolar electrocauterization in our hospital between May 2013 and October 2015. The data about patients' characteristics and endoscopic findings were evaluable retrospectively. We assessed about PPB and prophylactic hemostasis in pedunculated polyps resected with EMR.
**Results:** A total of 50 polyps in 39 patients were analyzed. The median head and stalk diameter were 15 mm (range, 10–40) and 10 mm (range, 6–20), respectively. The location of polyps was almost in Sigmoid colon. Prophylactic clips before and after EMR were performed at 0 and 1 polyp in all polyps. PPB was observed 5 polyps (10%) in 4 patients, compromised of 3 immediate PPB (6%) in 3 patients and 2 delayed PPB (4%) in 1 patient. The hemostasis of post EMR performed in 37 polyps (74%) by hemostatic forceps and no PPB observed in those polyps.
**Conclusion:** This was the first report about removal of pedunculated polyps with EMR method by bipolar electrocauterization. This method was tolerable safety and efficacy compared with previous studies, and could be one of the choices to remove large pedunculated polyps.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic resection of intra mucosal carcinomas or precancerous lesions is established as a safe method to achieve a high rate of R0 curative resections. However, it has not been shown whether cirrhotic patients could safely benefit from this procedure. Intra-abdominal surgery is a high-morbidity and high-mortality procedure in cirrhotic patients, the main risk being hepatic decompensation. Endoscopic resection could be an interesting alternative to reduce such risks. On the other hand, portal hypertension, especially in esophagus, stomach or rectum can be an impediment to resections, as the submucosal venous dilations easily bleed. Endoscopists and anaesthetists are also precautious regarding clotting factors ant platelets abnormalities. The aim of our study was to assess the safety and effectiveness of endoscopic resections in this case.
**Aims & Methods:** We designed a retrospective, open-label monocenter study. Every patient diagnosed cirrhotic, either through medical imaging, liver biopsy or Transient Elastometry along with physical examination and blood results, admitted in our unit for an endoscopic resection (Endoscopic Submucosal Dissection (ESD) or Endoscopic Mucosal Resection (EMR)) or a Per Oral Endoscopic Myotomy (POEM) between 2009 and 2016, was included. Data on patients' medical history, cirrhosis, blood results, endoscopic procedure, and potential complications were retrieved from medical records. Medical records were fully screened for any clue of retarded complication that would not have been mentioned in the post procedure report. Last medical note was considered end of follow up.
**Results:** To date, 102 resections were included from medical procedures coding records. After medical records analysis, 88 fitted our criteria (cirrhosis + ESD, or EMR, or POEM), in 52 patients (Esophagus n = 32, Stomach n = 25, Duodenum n = 15, Colon n = 14, POEM n = 2). Patient globally had a mild liver disease: the mean MELD score was 9.15. Only 10 patients had a decompensated cirrhosis (defined by ascites presence). Out of the 35 with precise available data, 19 had a history of hepatic decompensation. 36 patients had a history of varices band ligation (no band ligation n = 16, missing data n = 36). The mean follow up duration after resection was 17.35 months (from 0.03 to 52.20). 22 resections were performed in patients with antiplatelet medication. 3 patients had a creatinine clearance below 30 mL/min, 13 between 30 and 60 mL/min, 33 between 60 and 90 mL/min, and 41 over 90 mL/min. There were no cirrhosis decompensation, nor post-endoscopic infections in all 88 cases (0%). 8 bleedings, in 6 different patients occurred: in the Stomach n = 1 (4%), the Duodenum n = 3 (20%) and the Colon n = 4 (28.6%). The overall bleeding rate was 9.1%. The mean MELD score in patients who bled was 10.1 (vs 9.1 in patients who did not bleed), none had a decompensated cirrhosis. All bleedings happened within 48 hours of the procedure, and either spontaneously dried up (n = 5) or were successfully treated in endoscopy (n = 3). 5/8 were carried out in patients with antiplatelet medication (62.5%). The bleeding rate in cirrhotic patient under antiplatelet medication in the overall cohort was 22.7%. Creatinine mean was 110.8 μmol/L and creatinine clearance mean was 66.5 mL/min (vs respectively 83.6 μmol/L and 92.9 mL/min in patients who did not bleed). Among patients who experienced delayed bleeding, 6 had stage III chronic kidney failure (clearance of creatinine between 30 and 60 mL/mn). The bleeding rate in patients with a creatinine clearance below 60 mL/min in the overall cohort (stage III to V chronic kidney disease) was 31.6%. There were no bleeding-associated deaths. No other complication was observed.

| Total: 88 resections | Bleeding (8) | No bleeding (80) |
|---|---|---|
| **Mean Age (year)** | 62.38 | 66.4 |
| **Gender Men** | 6 (75%) | 73 (91.25%) |
| **Women** | 2 (25%) | 7 (8.75%) |
| **Localisation Œsophagus** | 0 (0%) | 32 (40%) |
| **Stomach** | 1 (12.5%) | 24 (30%) |
| **Duodenum** | 3 (37.5%) | 12 (15%) |
| **Colon** | 4 (50%) | 10 (12.5%) |
| **POEM** | 0 (0%) | 2 (2.5%) |
| **Mean Large Diameter (mm)** | 11.83 | 19.6 |
| **Medication antiplatelets** | 5 (62.5%) | 15 (19%) |
| **K vitamin inhibitors** | 0 | 2 (2.5%) |
| **both** | 0 | 4 (5.1%) |
| **Mean Hospital stay (days)** | 4.9 | 4.5 |
| **Mean Hemoglobin drop (g/dL)** | 0.6 | 0.21 |
| **Mean Albumin (g/L)** | 39.2 | 36.8 |
| **Mean Bilirubin (μmol/L)** | 8.3 | 13.6 |
| **Mean Platelets Count (G/L)** | 171 | 166 |
| **Mean INR** | 1.08 | 1.13 |
| **Mean Creatinin (μmol/L)** | 110.8 | 83.6 |
| **Mean Clearance (μmol/mn)** | 66.5 | 92.9 |
| **Mean PT** | 91 | 83.3 |
| **Mean MELD** | 10.1 | 9.1 |
| **CHILD-PUGHA5-A6-B7** | 8 (100%) | 73 (91.25%) |
| **>B8** | 0 (0%) | 7 (8.75%) |
| **Mean Follow up (months)** | 13.22 | 17.78 |
| **Death** | 0 (0%) | (7.6%) (4 patients) |

**Conclusion:** Endoscopic resection does not seem to induce cirrhosis decompensations unlike open abdominal surgery. Our results tend to demonstrate that endoscopic resections are safe and effective in cirrhotic patients. The risk of delayed bleeding is increased in case of association of both cirrhosis and antiplatelet agents with 5 bleedings among the 88 resections.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0727 RISK ASSESSMENT OF ANTICOAGULATION AND ANTIPLATELET THERAPY IN DELAYED POSTPOLYPECTOMY BLEEDING – A COHORT STUDY

**M.P. Costa Santos**, C. Fidalgo, A. Ferreira, C. Palmela, C. Gouveia, R. Ferreira, J. Nunes, R. Loureiro, E. Barjas, L. Glória, A.A. Santos, M. Cravo
*Hospital Beatriz Ângelo, Loures/Portugal*

**Contact E-mail Address:** mariapiacostasantos@gmail.com

**Introduction:** Colonic polypectomy of adenomatous polyps reduces the incidence and mortality from colorectal cancer. However it can be associated with potentially serious complications, such as delayed bleeding.
**Aims & Methods:** The aim of this study was to assess the risk of delayed postpolypectomy bleeding in patients receiving anticoagulation (AC) and/or antiplatelet (AP) therapy. Retrospective cohort study of patients who underwent colonic polypectomy between January and December 2015 after discontinuation of AC and/or AP according to current recommendations. Data collected included patient demographics and antithrombotic therapy, endoscopic technique, lesion characteristics and bleeding incidence.
**Results:** We analysed 913 patients, 63% were women with a mean age of 66.9 ± 10.7 years. Fifty-nine patients were under anticoagulation, 166 were on antiplatelet agents and 5 under dual antithrombotic therapy (AC and AP). Overall 2321 lesions were resected, with a median of 2 (1–18) lesions per patient. The resected lesions had more than 10 mm in 380 cases and 429 patients had lesions located in the right colon. Delayed post-polypectomy bleeding occurred in 11 patients (1.2%), all managed successfully with endoscopy, without need of surgery and without bleeding-related death. The incidence of delayed bleeding

was 0.3% (2/683) in patients without antithrombotic therapy, 1.2% (2/166) in patients receiving AP, 6.8% (4/59) in patients under AC and 60% (3/5) in patients with dual antithrombotic therapy. The risk of delayed bleeding was significantly increased with AC (OR 24,764; 95% CI 4,4437–138,220; $P < 0.001$) and dual antithrombotic therapy (OR 510,75; 95% CI 53.06–4916.23; $P < 0.001$). There was no difference in bleeding risk between patients under antiplatelet drugs and without medication (OR 4,152; 95% CI 0.58–29.70; $P = 0.156$). The incidence of delayed bleeding was similar in patients under warfarine and new oral anticoagulation therapy.
**Conclusion:** The incidence of post-polypectomy delayed bleeding was higher in patients receiving anticoagulant agents. These findings suggest the need of a close surveillance after polypectomy/mucosectomy in these patients, even after a proper interruption of therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0728 PREDICTING ADENOMA DETECTION RATE BY POLYP DETECTION RATE AND INDIVIDUAL ADENOMA-TO-POLYP-DETECTION-RATE-RATIO IN AVERAGE-RISK COLONOSCOPIES

**C. Schramm**[1], I. Scheller[2], J. Franklin[3], M. Demir[1], F. Kuetting[1], D. Nierhoff[1], T. Goeser[1], U. Toex[1], H. Steffen[1]

**Introduction:** Adenoma detection rate (ADR) has been established as a quality indicator for screening colonoscopy.[1] However, it is cumbersome to obtain in routine practice. The adenoma-to-polyp–detection-rate-ratio (APDRR) has been proposed as a practical tool to easily estimate the ADR in routine practice.[2,3]
**Aims & Methods:** The aim of this study was to evaluate the APDRR in order to estimate ADR. We performed a retrospective evaluation of average risk screening and surveillance colonoscopies in a community and tertiary academic hospital setting. Individuals with an increased risk for colorectal cancer, with proven polyps who have been referred for polypectomy, and with a sigmoidoscopy only were excluded. Polyp detection rate (PDR), ADR and APDRR were calculated as previously described.[3] APDRR was either calculated as group average for all endoscopists and the first half of study procedures or individually for each endoscopist and his/her first 25, 50, and 100 colonoscopies. Estimated ADR (ADR_est) was calculated as the product of endoscopist's PDR and either the averaged group APDRR for the second half of study procedures or the individual APDRR of his/her first 25, 50, and 100 colonoscopies for his/her subsequent procedures grouped in portions of 50 procedures. We used Pearson's correlation coefficient (r) to describe the strength of association between ADR and ADR_est. Wilcoxon matched-pair signed-rank was used to test the difference between different prediction models. The root-mean-square error (RMSE) was defined as $\sqrt{(\text{ADR-ADR\_est})^2}$. A p-value $<0.05$ was considered statistically significant.
**Results:** A total of 2,717 patients were analyzed. 45.7% were men, the median age was 61.8 years (interquartile rage 56.2, 68.7). Overall PDR and ADR were 52.6% and 35.1%. The averaged group APDRR for the entire study period was 0.667. RSME between ADR and ADR_est was 5.8% with no significant correlation between both parameters ($r = 0.189$, $p = 0.684$) when the averaged group APDRR was used. In the individual approach using the first 50 colonoscopies to calculate APDRR, ADR and ADR_est correlated significantly in 4 of 5 endoscopists with a mean RMSE of 6.8% (2 of 5 and 3 of 5 endoscopists with mean RMSE of 9.9% and 5.8% using first 25 and 100 colonoscopies as basis for APDRR, respectively). A significant difference in mean RMSE was found in the Wilcoxon matched-pair signed-rank for the prediction model 25 and 50 ($p < 0.001$) as well as prediction model 25 and 100 ($p < 0.001$), but not between prediction model 50 and 100. We did not observe an increasing deviation between ADR and ADR_est over the study period.
**Conclusion:** ADR for subsequent colonoscopies of an individual endoscopist can be reliably predicted by using an individually calculated APDRR. It remains open to discussion at which time interval the individual APDRR should be calculated again. Although the mean RSME was low with the use of the averaged group APDRR, no significant correlation was found between ADR and estimated ADR for this model. Prospective studies would be valuable to verify this promising approach.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** carlasat@hotmail.com
**Introduction:** Despite the existence of several practice guidelines, there is a great amount of uncertainty regarding the periprocedural management of APT when a gastrointestinal endoscopy is scheduled.
**Aims & Methods:** Our objective was to describe the real periprocedural management of APT in outpatients undergoing upper and lower gastrointestinal endoscopies in our hospital, a tertiary referral center for the Valencian Region in Spain. To that purpose, consecutive outpatients scheduled for gastroscopy or colonoscopy in our Unit between January and June 2015 were surveyed. The referral note of each patient (which has a check box asking specifically for APT) was also reviewed. The collected variables were: age, gender, procedure, indication, referral doctoŕs specialty, APT status according to the information provided by the patient and by the referral note, APT indication, modification of APT prior to the procedure (stop/change), person responsible for this change and days of withdrawal if applicable.
**Results:** 668 patients were included [age (median, range) = 62 (19–99)] and 337 (50.5%) were male. A total of 685 procedures were performed (282 gastroscopies and 403 colonoscopies). Six patients underwent gastroscopy and colonoscopy in the same session; therefore 679 questionnaires were finally collected. According to the information provided by the patient, 102 patients (15%) were on APT; but according to the referral note, there were only 95 (14%). The information provided by the patient did not match that stated in the referral note in 37 cases (5.5%). Regarding the type of APT, there was a disagreement in 3 of the 81 patients (3.7%) who had information from both sources. Despite the specific check box, information about APT was lacking in 21 (3.1%) referral notes. Considering only the 95 patients whose referral note stated that they were taking APT, this therapy was modified before the procedure in 37 (39.1%). Specifically, acetylsalicylic acid (ASA) therapy was modified in 26 of 81 patients (32.1%), clopidogrel in 5 of 8 patients (62%), and DAPT in 6 of 6 patients (100%). In 11 of the 26 patients taking ASA (42.3%) the patient self-interrupted therapy, and in 15 (57.7%) a physician ordered the modification. On the other hand, a physician always ordered the modification of clopidogrel and DAPT. No relationship was shown between APT modification and neither the indication of APT (primary/secondary prophylaxis) nor the bleeding risk of the procedure. When a physician modified APT, ASA and clopidogrel were retired more than 5 days before the procedure in 12 (80%) and 4 cases (80%) respectively.
**Conclusion:** 1) The information about APT provided by the patient and the referral note does not match accurately; 2) ASA is interrupted in a significant proportion of cases, against guidelinés recommendations; 3) Physicians modify APT regardless of its indication and without considering the characteristics of the procedure; 4) APT is interrupted sooner than recommended by guidelines.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0730 PREDICT, RESECT AND DISCARD – A QUANTITATIVE ASSESSMENT OF THE RISKS AND COST SAVINGS IN COLORECTAL CANCER SCREENING COMPARING TWO STRATEGIES FROM THE PORTUGUESE HEALTH SYSTEM

**J. Moleiro**, S. Ferreira, M. Serrano, A. Dias Pereira
*Gastrenterology, Portuguese Oncology Institute of Lisbon, Lisbon/Portugal*

**Contact E-mail Address:** joanamoleiro1984@gmail.com
**Introduction:** The "predict, resect and discard" (PRD) strategy, supported by the high diagnostic accuracy of the electronic chromoendoscopy technologies, has established new paradigms for diminutive colonic polyps management: polyps $\leq$5 mm can be resected and discarded without pathologic assessment and rectosigmoid hyperplastic polyps $\leq$5 mm can be left in place.
**Aims & Methods:** Cross-sectional analysis of a colorectal cancer (CRC) screening colonoscopy database (patients $\geq$50 years at average risk for CRC). Demographic and endoscopic data were collected. We intended to analyse up-front costs saving with the PRD strategy when applied to two different strategies of the Portuguese Health System (hospital cost – Governmental Order 234/2015 vs. community colonoscopy package – order of the Minister of Health of June 2015) and the impact in the surveillance intervals.
**Results:** A total of 284 colonoscopies (male-101) were performed in patients with a mean age of 61 years (50–75). Cecal intubation and adenoma detection rate was 97.2% and 27.5% (male: 39.6%; female: 20.8%), respectively. A total of 231 polyps (1–5) were documented in 132 patients: $\leq$5 mm n = 185, 5–9 mm n = 36, $\geq$10 mm n = 10; adenomas n = 120, HP n = 76, SSA n = 9, others n = 26. There were no CRC but 14 patients had high risk adenomas. Hospital cost: 64013.4€ (endoscopic procedure: 29642.5€ (46%), histological examination: 19847.3€ (31%)). Community cost: 47710.54€ (endoscopic procedure: 17341.04€ (36%), histological examination: 19847.3€ (42%)). By direct comparison, CRC screening in the community is 25% less expensive, mainly by reducing 42% the costs of the endoscopic procedure. The adoption of a PRD strategy would result in savings of 24% (15352€: polypectomies-2677€, histological evaluation-12675€) in the hospital regimen and 27% (12675.52€-histological evaluation) in the community package, without negative impact in the surveillance intervals (no villous elements or high-grade dysplasia in polyps $\leq$5 mm). By association the PRD strategy to the community package, total

CRC screening cost in this population would result in a savings of 35935.02€, meaning an overall saving of 45% in relation to the real cost.
**Conclusion:** PRD strategy is a promising approach to reduce costs in the CRC screening. Thus, it should be gathered efforts to the implementation and dissemination of the electronic chromoendoscopy technologies.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0731 DIRECT PERORAL CHOLANGIOSCOPY BY USING A NEWLY DEVELOPED MULTIBENDING ULTRASLIM ENDOSCOPE FOR THE TREATMENT OF DIFFICULT BILE DUCT STONES

**J.H. Moon**[1], Y.N. Lee[2], H.J. Choi[1], M.H. Choi[1], T.H. Lee[1], S. Cha[1], Y.D. Cho[1], S. Park[1]

**Contact E-mail Address:** jhmoon@schmc.ac.kr
**Introduction:** As direct peroral cholangioscopy (POC) by using an ultraslim endoscope provides direct visualization of the bile duct and allows performing of various therapeutic interventions more safely, several accessories have been developed to overcome low success rate of direct POC. In a recent, a multibending ultraslim endoscope was developed as a dedicated cholangioscope for direct POC.
**Aims & Methods:** The aim of this study was to evaluate the usefulness of direct POC by using a newly developed multibending ultraslim endoscope for lithotripsy in patients with difficult bile duct stone. A total of 20 patients, who were unsuccessfully treated for bile duct stones using conventional endoscopy, including mechanical lithotripsy (ML), underwent electrohydraulic lithotripsy (EHL) or laser lithotripsy (LL) under direct POC using a multibending ultraslim endoscope (Olympus Co., Tokyo, Japan). If a direct POC without accessory failed, an intraductal balloon (MTW Endoskopie, Wesel, Germany)-guided direct POC was performed. The success rate of complete stone removal and procedure-related adverse events were evaluated.
**Results:** A successful direct POC using a multibending ultraslim endoscope was achieved in all patients. The fragmentation of stone using 9 EHL or 11 LL was successful in 19 of 20 patients (95.0%). The complete stone removal was achieved in all patients (19/19). There were no procedure-related adverse events except one case of mild bleeding.
**Conclusion:** The direct POC by using a multibending ultraslim endoscope may be effective for the lithotripsy in patients with difficult bile duct stones.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0732 RAPID CARBAPENEMASE RESISTANT ENTEROBACTERIACEAE (CRE) PCR TESTING OF DUODENOSCOPES: FEASIBILITY AND ACCURACY

**R. Pannala**[1], D. O. Faigel[2], B. Baldwin[2], L. J. Miller[3], C. C. Nguyen[1], M..E. Harrison[1], F. Tenover[4], D. Persing[4], T. E. Grys[5]

[4]*Cepheid, Sunnyvale/United States of America/CA*
[5]*Microbiology, Mayo Clinic, Scottsdale/United States of America/AZ*

**Contact E-mail Address:** pannala.rahul@mayo.edu
**Introduction:** Duodenoscope-associated nosocomial transmission of CRE despite high-level disinfection (HLD) is an important health concern. Duodenoscope screening and surveillance by culture may reduce risk of patient exposure but culture is challenging to perform and may require 48–72 hours for results We evaluated the feasibility of testing a duodenoscope before and after manufacturer-recommended manual washing with a rapid PCR test for five genotypic markers of carbapenem resistance (CARBA-R, Cepheid, Sunnyvale, CA) after intentional exposure to three carbapenemase producing bacteria and compared results to culture.
**Aims & Methods:** The distal end of a research use TJF-Q180V duodenoscope (Olympus USA, Center Valley, PA) was immersed for 60 seconds in saline containing about 10e6 CFU per mL bacteria. The organisms (resistance gene) included *E. coli* (NDM), *K. pneumonia* (IMP), *P. aeruginosa* (VIM). During the exposure, the elevator was raised and lowered 10 times. The instrument was then air-dried for 24–48 hrs to mimic persistent contamination or incomplete washing and then a manufacturer-recommended manual washing including scrubbing the endoscope with a sponge in a cleaning agent (Metrizyme, Metrex, Orange, CA) and brushing the elevator and sampling ports, and flushing three times (>10 mL) with the cleaner was performed. The instrument was then rinsed briefly in water and soaked 10 seconds in ethanol (70%). The endoscope was then dried at least 60 minutes but up to 48 hours and sampled. Samples were collected by using a flocked swab (Copan, Murrieta, CA) dampened by saline, gently contacting a broad area around the terminus of the scope, including around the elevator shaft and sample port. The specimen swab was broken off into 10 mL saline and mixed by vortex for 10 seconds. The saline was then sampled with a second flocked swab which was dipped into the saline for 10 seconds and placed into the Cepheid CARBA-R processing buffer. The CARBA-R test was run according to manufacturer insert. A portion of the saline (0.05 mL) was plated to blood agar media and the remaining saline was placed into a blood culture bottle BACTEC/FX, BD, Sparks, MD). Three cycles of the above process were performed.
**Results:** Experiment 1: *E. coli* was used to contaminate the scope. At 24 hours a sample of the scope was culture negative and PCR positive. A manual cleaning was done and PCR and culture were both negative. Experiment 2: *Klebsiella pneumoniae* was used to contaminate the scope. At 48 hours a sample of the scope was culture and PCR positive. A manual cleaning was done and PCR and culture were both negative. Experiment 3: *Pseudomonas* was used to contaminate the scope. At 48 hours a sample of the scope was culture negative and PCR positive. A manual cleaning was done and PCR remained positive while culture was negative. After an additional 24 hours, another manual cleaning was done and PCR and culture were both negative.
**Conclusion:** CARBA-R PCR test is a potential method for rapid surveillance of carbapenemase producing organisms on endoscopes. PCR and culture were negative in all instances after manual cleaning and prior to HLD. Further study is required in the clinical setting to identify predictors of persistent contamination and to identify optimal sampling technique for endoscope surveillance.

### P0733 SPYGLASS DIRECT VISUALIZATION SYSTEM VERSUS DIRECT PERORAL CHOLANGIOSCOPY USING BY A MULIBENDING ULTRASLIM ENDOSCOPE AS A SINGLE-OPERATOR PERORAL CHOLANGIOSCOPY FOR THE MANAGING BILIARY LESIONS: A PROSPECTIVE COMPARATIVE STUDY

**J.H. Moon**[1], Y.N. Lee[2], H.J. Choi[1], H.K. Kim[3], M.H. Choi[1], T.H. Lee[1], S. Cha[1], Y.D. Cho[1], S. Park[1]

**Contact E-mail Address:** jhmoon@schmc.ac.kr
**Introduction:** Single-operator peroral cholangioscopy (POC) has been a new modality for diagnosis and treatment for various bile duct (BD) diseases. Up to date, SpyGlass direct visualization system (SpyGlass) and direct POC (DPOC) using ultra-slim endoscope have been used as a single operator POCs. However, there is no study to comparing two systems.
**Aims & Methods:** In this study, we prospectively compared the procedure success rate of POC using SpyGlass and DPOC for diagnosis and treatment of BD lesions. A total of 21 patients with BD lesions (diameter of CBD≥8 mm) requiring evaluation or treatment using POC were enrolled prospectively. All patients received POC using SpyGlass and mulibending ultraslim endoscope for DPOC. According to the presence of obstructive lesion, all patients were classified as obstructive type (8 patients) or non-obstructive type (13 patients), respectively. Technical and procedural success defined as abilities to visualize bifurcation / obstructive lesions and visualize target lesions / stone fragmentation, respectively.
**Results:** There was no significant differences between the SpyGlass and DPOC in technical success rates (100% vs. 95.2%, P = 0.485) and overall procedural success rate (71.4% vs.90.5%, P = 0.119).The procedural success rates of SpyGlass and DPOC were not different in 8 obstructive type (100%vs. 87.5%, P = 0.5). In 13 non-obstructive type, DPOC showed significantly higher procedural success rate (53.8% vs. 92.3%, P = 0.037). There was no significant difference between SpyGlass and DPOC groups in the success rates of targeted biopsy (80% vs. 100%, P = 0.385) and stone lithotripsy (100% vs. 75%, P = 0.5), respectively.
**Conclusion:** Both SpyGlass and DPOC demonstrated high technical success rates in patients with biliary lesions having dilated BD, but DPOC showed a higher procedural success for non-obstructive BD lesion. The POC using SpyGlass or DPOC according to the characteristics of BD lesion can be considered to improve the success rate of managing biliary lesions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0734 A COMPARATIVE STUDY OF STRATEGIES FOR PREVENTION OF POST-ERCP PANCREATITIS AFTER EARLY PRE-CUT SPHINCTEROTOMY FOR BILIARY ACCESS

T. Ang[1], A.B.E. Kwek[2], **W. J. Li**[1], M. Song[1], P.H. Thurairajah[1]
[1]*Gastroenterology & Hepatlogy, Changi General Hospital, Singapore, Singapore/Singapore*
[2]*Gastroenterology And Hepatology, Changi General Hospital, Singapore/Singapore*

**Contact E-mail Address:** james.li@mohh.com.sg
**Introduction:** Post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis (PEP) is the most common serious ERCP complication. Needle knife precut sphincterotomy (PS) is used to achieve selective cannulation when standard techniques fail. It is associated with a higher risk of complications such as PEP, bleeding and perforation. It is frequently performed after a prolonged attempt at cannulation. If PS is performed early, a skillful endoscopist can avoid

papilla trauma from prolonged cannulation, and the risk of PEP may not be increased. Intravenous somatostatin infusion, rectal diclofenac and pancreatic duct (PD) stenting have been used to reduce the rate of PEP.
**Aims & Methods:** Aim: This study examined the effect of somatostatin, rectal diclofenac and PD stenting in reducing PEP in patients who underwent early PS to achieve selective common bile duct (CBD) cannulation. Methods: The data of patients in a prospective ERCP registry were reviewed. The study period was January 2006 to December 2015. A standardized approach to early PS had been implemented: 1) inadvertent guidewire cannulation of PD > 3 times; 2) presence of impacted CBD stone; 3) inability to achieve deep cannulation within 10 minutes. Patients with PS were enrolled. Exclusion criteria were patients who did not undergo PS and pancreatic ERCP. Measures used for PEP prophylaxis included: 1) none when there was minimal papilla trauma; 2) somatostatin infusion; 3) rectal diclofenac; 4) PD stent. The difference in rates of PEP between the different prophylactic strategies was analysed.
**Results:** During the study period, 2879 ERCP were performed, of which 191 had PS (mean age 66 years [range: 25–97]; 56.5% males). The most common diagnoses were CBD stones (138/191; 72.3%) and pancreatic adenocarcinoma (29/191; 15.2%). ERCP success rate after PS was 178/191 (93.2%). Post PS patients were divided into 4 groups: control with no intervention (57), somatostatin infusion (55), rectal diclofenac (55) and PD stent (24). The decision for not utilizing PEP measures in the first group was due to the endoscopist's assessment of minimal trauma to the papilla. PD cannulation occurred in 99/191 (51.8%). Overall the PEP rate was 6/191 (3.1%) and the severity was mild in all cases. PEP occurred in 6.1% of patients with PD cannulation but not in those without ($p = 0.016$). There was no statistically significant difference in PEP rates in the 4 groups. A trend towards lower rates was noted for the diclofenac and PD stent groups. The PEP rates were 1/57 (1.8%) in control, 4/55 (7.3%) with somatostatin, 1/55 (1.8%) with diclofenac and 0 with PD stent ($p = 0.209$). Post ERCP bleeding occurred in 3/191 (1.6%). There were no ERCP related perforation or mortality. The somatostatin group had significantly higher proportion of patients with guidewire cannulation of PD, compared to the control and diclofenac groups (65.5% vs. 35.1% vs. 34.5%, $p = 0.001$).
**Conclusion:** A strategy of early PS for biliary access was safe and effective. There was no significant difference in PEP rates whether or not prophylactic measures were adopted if there is minimal papilla trauma. A trend towards lower PEP rates was observed in patients who had either rectal diclofenac or PD stenting. These measures may be warranted in the presence of additional risk factors for PEP such as PD cannulation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0735 ENDOSCOPIC MINOR PAPILLA SPHYNCTEROTOMY IS EFFECTIVE FOR THE TREATMENT OF SYMPTOMATIC SANTORINICELE: LONG-TERM RESULTS IN A LARGE SERIES

**S.F. Crinó**[1], M.C. Conti Bellocchi[2], L. Bernardoni[1], G. Malleo[3], R. Manfredi[4], A. Amodio[5], L. Frulloni[5], A. Gabbrielli[1]

**Contact E-mail Address:** stefanofrancesco.crino@ospedaleuniverona.it
**Introduction:** Santorinicele (SC), a cystic dilatation of the intramural portion of the dorsal pancreatic duct, is a rare morphological alteration generally associated with pancreas divisum and acute recurrent pancreatitis. Endoscopic minor papilla sphyncterotomy (EPSm) has been proposed as treatment in few isolated cases or small series with encouraging results but never sistematically investigated.
**Aims & Methods:** The aim of this study is to assess the outcome of endoscopic treatment in a large series with long follow-up. From 2009 to 2015, at the tertiary care center of pancreatic disorders of Verona, 33 patients with SC and acute recurrent pancreatitis (APR) were enrolled for EPSm. The average number of pancreatitis before and after treatment was evaluated. Clinical outcome was analyzed and related with the secretin-enhanced magnetic resonance cholangiopancreatography (s-MRCP) findings performed before the endoscopic procedure. Mean follow-up after sphincterotomy was 41.4 months (range 12–80).
**Results:** The mean number of pancreatitis per year before and after endoscopic treatment was respectively 1.586 (95% CI 1.0548 – 2.1186) and 0.18 (95% CI 0.0029 – 0.3629). EPSm, performed in 30 patients, resulted effective in reducing the average number of pancreatitis ($p < 0.0001$). Only 1 (3.2%) severe EPSm related adverse event was observed (retroperitoneal perforation). Complete response was obtained in 86.6% of patients. Four patients relapsed after a mean time of 13 months from the sphincterotomy. In 3 of them we found another potentially cause of APR. No relation between clinical response and s-MRCP findings was observed.
**Conclusion:** SC, when associated with APR, represents an indication for endoscopic minor papilla sphincterotomy. This procedure is efficacy in reducing the recurrence of pancreatitis in 86% of cases. In non-responder patients, SC may represent a morphological finding not related with APR and another etiology must be searched.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Sphincter of Oddi dysfunction (SOD) in liver transplant (LT) recipients can occur 3–16% of patients, however there is scarce data regarding the specific characteristics, incidence, and long-term outcome of this condition. The aim of this analysis was to estimate the incidence and outcome of SOD in a cohort of LT recipients.
**Aims & Methods:** We reviewed 561 ERCP's performed in LT-patients with duct-to-duct biliary anastomosis at Hospital Clinic, Barcelona from 01/2003 to 01/2015. Information was obtained from electronic health records and a prospectively collected database. SOD in LT recipients was defined as the presence of cholestasis, elevated liver enzymes, dilated bile duct and absence of alternative diagnosis at ERCP. Patients with SOD underwent a biliary sphincterotomy with adequate drainage of contrast and bile. Definite SOD was defined as absence of alternative diagnosis in the following 12 months. Laboratory and clinical findings were obtained immediately before ERCP and 3 months post-ERCP to evaluate the effect of sphincterotomy.
**Results:** 1036 patients underwent LT from 2003 to 2015. 225 LT recipients underwent 561 ERCP's during the study period. Twenty-three patients met the initial criteria of SOD (10.2%). However, during the 12-month follow-up, 10 patients (43%) developed other conditions [biliary anastomotic stricture ($n = 1$), biliary sludge or stones ($n = 3$), chronic graft rejection ($n = 4$), HCV recurrence ($n = 1$) and chronic pancreatitis ($n = 1$)]. Therefore 13 of the 225 patients (5.8%) were diagnosed with definite SOD. Overall incidence was 1.2% among LT recipients. Patients with definite SOD had a significant decrease in bilirubin and alkaline phosphatase after sphincterotomy compared to those without SOD (Table). There were no complications after ERCP.

| | n | Lab enzymes | Pre-sphx | | Post-sphx | | p value |
|---|---|---|---|---|---|---|---|
| | | | Mean | SD | Mean | SD | |
| Definite SOD | 13 | Bilirrubin | 2.0 | 1.0 | 1.3 | 0.9 | .019 |
| | 13 | AP | 623.6 | 374.0 | 344.3 | 241.7 | .003 |
| | 13 | GGT | 378.0 | 240.4 | 245.0 | 266.8 | .087 |
| | 13 | AST | 58.9 | 28.2 | 65.8 | 40.4 | .701 |
| | 13 | ALT | 96.5 | 63.2 | 73.1 | 47.4 | .463 |
| Alternative diagnosis | 10 | Bilirrubin | 7.1 | 6.8 | 5.9 | 7.2 | .386 |
| | 10 | AP | 1357.1 | 995.0 | 1308.4 | 1115.7 | .878 |
| | 10 | GGT | 957.8 | 934.0 | 994.7 | 916.9 | .445 |
| | 10 | AST | 221.8 | 207.5 | 127.8 | 110.3 | .333 |
| | 10 | ALT | 221.2 | 178.7 | 93.3 | 48.3 | .074 |

Pre-Sphx, pre-sphincterotomy; Post-Sphx, post-sphincterotomy; SOD, sphincter of Oddi dysfunction; AP, alkaline phosphatase; GGT, gamma-glutamyl transferase; AST, aspartate aminotransferase; ALT, alanine transaminase.

**Conclusion:** The estimated incidence of definite SOD in LT recipients was 1.2%. More than 40% of the patients with a suspected diagnosis of SOD at ERCP developed other conditions that accounted for cholestasis and abnormal liver enzymes. Biliary sphincterotomy is a safe and effective procedure in these cases as those with definite SOD had a resolution of cholestasis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0737 A PROSPECTIVE COMPARISON OF DIRECT DIGITAL AND BALLOON-ASSISTED CHOLANGIOSCOPY IN COMPLEX BILIARY DISEASE

**K. Herba**, J. Behary, P. I. Craig
*Department Of Gastroenterology And Hepatology, St. George Hospital, Sydney/Australia*

**Contact E-mail Address:** kmherba1@gmail.com
**Introduction:** Direct digital cholangioscopy (DDC) and balloon-assisted cholangioscopy (BAC) are important tools in the evaluation and management of complex biliary disease that have not been sufficiently compared.
**Aims & Methods:** OBJECTIVE: To assess the utility, indications, advantages and disadvantages of DDC compared with BAC in patients with complex biliary disease. METHODS: Prospective single centre observational study of all cholangioscopy procedures performed during a 10 month period (June 2015–April 2016) using either DDC (Spyglass® digital) or BAC (Olympus N180 gastroscope with 5FG MTW balloon). Strictures were dilated if required prior to cholangioscopy. Strictures were considered indeterminate if preceding cross-sectional imaging, and ERCP and/or EUS-acquired cytology or biopsies were negative for malignancy.
**Results:** 25 patients (28 procedures) had DDC and 17 patients (18 procedures) BAC. Median distal CBD diameters were similar, 6 mm in DDC group and 5 mm in BAC group. Cholangioscopy indications are shown in the Table. In general, DDC was used to investigate indeterminate hilar or intrahepatic strictures, particularly primary sclerosing cholangitis (PSC). Moreover, DDC-directed Holmium laser lithotripsy successfully fragmented 7 biliary (4 extrahepatic and 3 intrahepatic) stones but was unsuccessful in 1 pancreatic stone case. In addition, DDC enabled guidewire placement into poorly accessible intrahepatic segments for subsequent directed therapy or biopsies. However, BAC was usually preferred in extrahepatic biliary strictures because of superior optics and lower cost. Technical success rates were high (DDC 96% and BAC 94%) in both groups while median procedural times and biopsy yields were similar (Table). Complications rates were similar, occurring in 3 of 28 (10.7%) DDC procedures (2 cholangitis, 1 pneumonia) and 2 of 18 (11%) BAC procedures (1 cholangitis, 1 localized wire perforation).

**Table:** Indications and Procedural Details

| Indications | DDC (25 patients) | BAC (17 patients) |
|---|---|---|
| Indeterminate strictures: | | |
| - Extrahepatic | 4 | 9 |
| - Hilar and Intrahepatic (PSC) | 12 (7) | 7 (2) |
| Ampullary adenoma intraductal extension | 1 | 1 |
| Holmium laser lithotripsy | 8* | 0 |
| **Procedural Details** | | |
| Technical success / Total Procedures | 27/28 | 17/18 |
| Median procedural time, minutes (range) | 32 (20–82) | 24 (19–43) |
| Adequate histological specimen | 13/14 | 16/18 |
| Benign histology | 12/13 | 15/16 |
| Cholangioscopy-directed guidewire access | 6 | 0 |

*7 biliary and 1 pancreatic duct stone

**Conclusion:** In the era of direct digital cholangioscopy and balloon-assisted cholangioscopy: 1) Both are similar in terms of technical success rates, procedural time, tissue acquisition and complication rates; 2) DDC is particularly useful to manage intrahepatic strictures and for lithotripsy of complex stone disease; 3) Extrahepatic biliary strictures are usually best evaluated by lower-cost BAC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0738 ERCP IN INFANTS, CHILDREN AND ADOLESCENTS IS FEASIBLE AND SAFE – RESULTS FROM A TERTIARY CARE CENTER

J. Felux[1], E. Sturm[2], A. Busch[2], E. Zerabruck[1], F. Graepler[1], N.P. Malek[1], **M. Goetz**[3]
[1]*Innere Medizin, 1 Universitätsklinikum Tübingen, Tübingen/Germany*
[2]*Kinderklinik, Universitätsklinikum Tübingen, Tübingen/Germany*
[3]*Interdisziplinäre Endoskopie, Universitätsklinikum Tübingen, Tübingen/Germany*

**Contact E-mail Address:** martin.goetz@med.uni-tuebingen.de
**Introduction:** Indications for ERCP in children differ from adults, and concerns about potential lower effectiveness and more side effects limit the use of ERCP even in high volume centers. We retrospectively analyzed indications, effectiveness, limitations, and side effects of ERCPs in children $<18$ years.
**Aims & Methods:** From Jan 2012 – Mar 2015, 54 ERCPs (median 1, range 1–7) were performed in 31 children (mean age $7.6 \pm 6.1$ yrs; median weight 22 kg, range 3.3–142.7). Indications were suspected choledocholithiasis ($n = 13$), postoperative complications (15), ductal anomalies (14), tumors (10), and PSC (2). High-end ultrasonography and/or cross-sectional imaging was available for all patients before ERCP. All patients were followed up for at least 3 d.
**Results:** Therapeutic ERCP was performed in 36 children, diagnostic in 18, by adult ERCP expert endoscopists. Endoscopic papillotomy was performed in 16/54 examinations. General anesthesia was preferred, only in 6/54 interventions (in 16 to 17-years old), conscious sedation was used. In two patients, retrograde access to the papilla was necessary (after Roux-en-Y, duodenostomy). Successful intervention (defined as accurate diagnosis and/or adequate therapy) was possible in 87.0% (47/54 ERCPs), and was more often achieved in older children (mean age 10.9 vs. 4.2 years, median weight 34.0 vs. 8.3 kg). Standard duodenscopes were used in children $>20$ kg BW, smaller diameter duodenoscopes (min. diameter 7.5 mm, working channel 2 mm) in smaller children. Similarly, we used .018'', .025'', and .035'' wires. 5 complications were recorded (5/54, 9.3%), and included 4 cases of mild pancreatitis (7.4% PEP rate; incl. 2 pts. with aggravation of preexisting pancreatitis) and 1 aggravation of cholangitis in PSC despite antimicrobial prophylaxis. PEP was noted in 0 of 6 children with protective pancreatic stents vs. 4/43 without pancreatic stents. All complications were managed conservatively. No complications were attributed to mechanical stress on the GI tract.
**Conclusion:** ERCP in children only accounted for 3.3% of our ERCP caseload. Endoscopists must be aware of differing spectrum of pediatric biliary and pancreatic diseases. We underline this point by including the endoscopist and the pediatrician in the ERCP room. Failed cannulation was associated with small dimensions of young children. Accessories for small caliber duodenoscopes are limited, as is navigation at the papilla in babies. Complications were similar to rates reported in adults. Rectal NSAIDs in children were not yet standard in our cohort, but may be considered. Protective pancreatic stents were helpful but necessitate a second endoscopy or plain abdominal radiograph for stent removal or proof of spontaneous passage. In summary, ERCP in children appears to be safe and effective in selected indications. Close collaboration between endoscopists and pediatricians is necessary.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0739 COMPARISON OF MAGNETIC RESONANCE CHOLANGIOPANCREATOGRAPHY AND ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY IN DISEASE SEVERITY ASSESSMENT OF PRIMARY SCLEROSING CHOLANGITIS: IMPACT ON PROGNOSIS

**A. Tenca**[1], K. Lind[2], E. Lantto[2], H. Mustonen[3], M.A. Färkkila[4]

[3]*Helsinki University Central Hospital, Biomedicum, Helsinki/Finland*
[4]*Dept. Of Gastroenterology, Helsinki University Hospital, Helsinki/Finland*

**Contact E-mail Address:** ante14@hotmail.it
**Introduction:** Endoscopic retrograde cholangiography (ERC) has been considered as the gold-standard for the diagnosis of primaring sclerosing cholangitis (PSC), but it might have severe complications (e.q. pancreatitis)[1]. Magnetic resonance cholangiopancreatography (MRCP) is an accurate, cost-effective and non-invasive procedure for the diagnosis of PSC[2]. However, in the majority of the studies on the agreement MRCP-ERC, disease severity as well as the impact on the patients' prognosis was not been evaluated in detail.
**Aims & Methods:** Aims of the study were to evaluate: 1) the agreement between MRCP and ERC in the assessment of PSC severity 2) the impact of the imaging modality on the prognosis. PSC diagnosis was based on patient's history, laboratory findings, histology, ERC, MRCP and clinical follow-up. All PSC patients who underwent MRCP and ERC within 3-month interval ($n = 50$) were collected from PSC register of our hospital ($n = 614$). MRCP was done using either 1.5 Tesla (in 49) or 3 Tesla (10); 3D reconstruction was available in 56. Two gastroenterologists and two radiologists reviewed all ERC and MRCP imaging studies, respectively, by using the modified Amsterdam PSC score; a mean score for intra-hepatic (IH) and extra-hepatic (EH) bile ducts was calculated. The Kendall's tau-b test was used to measure pairwise correlation among the methods; weighted k for inter-rate agreement and the McNemar-Bowker Test to find out differences in between the methods. The prognosis (liver transplantation and death) was evaluated by January 2016.
**Results:** Overall, 59 MRCP and ERC (14 for diagnosis and 45 for follow-up) were performed in 50 patients (male 38, median age at diagnosis 31 years; 6–75) and included in the analysis. The median modified Amsterdam PSC score in

MRCP images was 3 for IH and 2 for EH bile ducts, whereas in ERC images was 3 for IH and 1 for EH bile ducts. The overall diagnostic accuracy in detecting any changes of PSC in IH was 98% (95%CI 91–100%) and in EH 81% (95%CI 69–90%). The agreement in describing disease severity was only fair for IH bile ducts (weighted k 0.347; 95%CI 0.162–0.531), Kendall's tau-b 0.395; SE 0.121, McNemar-Bowker Test p 0.193), especially for early stages of the disease. The agreement for disease severity was also only fair for EH bile duct changes (weighted k 0.305; 95%CI 0.158–0.452; Kendall's tau-b 0.440; SE 0.091; McNemar-Bowker Test p 0.002), especially for severe disease. By the end of follow-up, 10 patients were transplanted (4 for suspicion of malignancy and 6 for end-stage liver disease) and one patient died (cholangiocarcinoma). In these patients the agreement for IH was 91%. The agreement for EH was 64%; 4 patients (MRCP score severe changing and ERC score mild changes) were transplanted for end-stage liver disease.

**Conclusion:** The agreement between MRCP and ERC in detection of any PSC changes was good, but it turned out to be poor when assessing disease severity of bile duct changes. The relatively poor agreement (especially for EH assessment) seems to have an impact on prognosis. MRCP identified better severe EH changes, which related with complications. Future prospective studies confirming this finding are warranted.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic stenting for combined malignant biliary and duodenal obstruction is technically demanding, especially in those with native papilla. However, this procedure can be facilitated when there is guidance from previously inserted stent or percutaneous transhepatic biliary drainage (PTBD) tube.

**Aims & Methods:** This study aimed to evaluate the feasibility and clinical success rate of endoscopic placement of biliary self-expandable metal stent (SEMS) through duodenal SEMS in patients with combined biliary and duodenal obstruction due to inoperable or metastatic periampullary malignancy. A total of 6 patients (4 male and 2 female) with combined malignant biliary and duodenal stricture underwent insertion of biliary SEMS through the mesh of duodenal SEMS from July 2012 to December 2015 at Korea University Ansan Hospital. All patients either had previously inserted biliary SEMS, plastic stent or PTBD for guiding insertion of biliary SEMS. M-duodenal (Bonastent, Korea) SEMS, a specialized SEMS with expandable lattices in the mid portion, were used for duodenal SEMS. Technical and clinical success rate, adverse events, and survival after completion of SEMS insertion were evaluated.

**Results:** The mean age of the patients was 56.3 years (range: 38–82 years). Half (n = 3) of the patients were diagnosed with pancreatic cancer and the remaining 3 patients had either gallbladder cancer (n = 1), ampulla of Vater cancer (n = 1) or common bile duct cancer (n = 1). The duodenal strictures were located in the first portion of the duodenum in 1 patient (type I), in the second portion in 3 patients (type II), and in the third portion in 2 patients (type III). Technical success rate of combined metallic stenting was 100%. Insertion of biliary SEMS was guided by previously inserted biliary SEMS in 4 patients, plastic stent in 1 patient, and PTBD in 1 patient. Clinical success rate was 83.3% (5/6). There were no early adverse events after the procedure. Mean survival period after combined metallic stenting was 118.6 days (range: 56–245 days).

**Conclusion:** Endoscopic placement of biliary SEMS through duodenal SEMS is feasible with high success rates and relatively easy when there is guidance from previously inserted biliary SEMS, pancreatic stent or PTBD. This method can be a good alternative for palliation in patients with combined biliary and duodenal obstruction.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0741 TRANSPANCREATIC SEPTOTOMY – AN ALTERNATIVE TO PRECUT FOR DIFFICULT BILIARY ACCESS?

**D. Branquinho**, N. Almeida, D. Gomes, E. Camacho, S. Mendes, C. Sofia
*Dept. Of Gastroenterology, Coimbra University Hospital, Coimbra/Portugal*

**Contact E-mail Address:** diogofbranquinho@yahoo.com

**Introduction:** Selective cannulation of the common bile duct (CBD) is an essential step in ERCP. However, this may not be achieved in up to 15% of patients. Techniques like precut have adequate success rates, but show higher risk of complications. Transpancreatic septotomy is an alternative facing difficult biliary access.

**Aims & Methods:** Our objective was to evaluate the efficacy and safety of transpancreatic septotomy when compared with precut technique. Between January-2014 and February-2016, alternative techniques to CBD cannulation were used in 70 patients (Septotomy-35 patients, Precut-35; Female-57.1%; Average age-69.5 ± 15.2 years-old). Several variables that could have influenced the success or complication rate were analyzed.

**Results:** The main indication for the procedure was choledocolithiasis, with or without cholangitis (67.2%), followed by CBD strictures (malignant-21.4%; benign-11.4%). The cannulation rate was 83.8% with septotomy and 76.5% with precut (p = 0.47). Biliary stone removal and stent placement was achieved in a similar percentage in both groups (p = 0.49 e 0.51, respectively), while the need to repeat ERCP in the next four months was higher with precut (p = 0.03). The complication rate was not different between the two techniques (17.1% vs. 23.5%; p = 0.51). However, they were more severe with precut, as two patients died following the procedure.

**Conclusion:** These techniques are useful when there is difficult billiary access and obtained a similar success rate. However, there was a lower need to repeat the procedure after performing septotomy. Complication rate was also similar, but more severe outcomes occurred with precut.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0742 INTERNATIONAL MULTICENTER COMPARATIVE TRIAL OF ENDOSCOPIC ULTRASONOGRAPHY GUIDED GASTROENTEROSTOMY VERSUS SURGICAL GASTROJEJUNOSTOMY FOR THE TREATMENT OF MALIGNANT GASTRIC OUTLET OBSTRUCTION

**M. Bukhari**[1], T. Itoi[2], M. Elzein[3], T.H. Baron[4], J. Nieto[5], Y. Chen[1], Y. H. Chavez[1], S. Ngamruengphong[6], V. Kumbhari[3], A. Alawad[3], A. Ismail[1], M. Khashab[1]

**Contact E-mail Address:** mbukhar4@jhmi.edu

**Introduction:** There are limitations to enteral self-expandable metallic stents (SEMS) and surgical gastrojejunostomy (SGJ) in the treatment of patients with malignant gastric outlet obstruction (GOO). EUS-guided gastroenterostomy (EUS-GE) is a novel procedure that potentially offers long-lasting luminal patency without the risk of tumor ingrowth/overgrowth, while avoiding the morbidity of a surgical procedure. Currently there are no studies comparing EUS-GE to SGJ.

**Aims:** To compare the clinical success, technical success, adverse events (AEs), length of hospital stay (LOHS) and reintervention rates in EUS-GE versus SGJ.

**Methods:** This was a multicenter international retrospective comparative study of EUS-GE and SGJ in patients with malignant GOO who underwent either EUS-GE at 6 centres (3 US, 2 Europe, and 1 Asia) between 2013 and 2015 or SGJ at 1 US centre between 2008 and 2010 for the management of GOO. EUS-GE was performed using lumen apposing stents.

Technical success was defined as adequate positioning and deployment of the stent as determined by the endoscopist and confirmed radiographically. Technical success of SGJ was defined as technical feasibility to perform a gastrojejunostomy, clinical success as the ability to tolerate oral intake without vomiting. The need for reintervention (repeat endoscopic or surgical procedures due to recurrent GOO symptoms) was considered a surrogate for recurrent GOO.

**Results:** A total of 93 patients with malignant GOO treated with either EUS-GE (n = 30, 57% men, mean age 70 ± 13.3 year) or SGJ (n = 63, 52% men, mean age 68 ± 9.6 year) were identified: Etiology of GOO was most commonly due to pancreatic cancer (n = 70), followed by ampullary cancer (n = 11), gastric cancer (n = 5), duodenal cancer (n = 1), metastatic cancer (n = 4) and gallbladder cancer (n = 2)). Most patients presented with weight loss (n = 90, 97%) with an average of 6.8 kg (range 2–20.4) loss per patient. The most common location of GOO was at second part of the duodenum (n = 72, 77%). Peritoneal carcinomatosis was present in 13 (43%) patients in the EUS-GE group and 7 (11.12%) patients in the SGJ group (p = 0.001). Although technical success was significantly higher in the SGJ group as compared to the EUS-GJ group (100% vs. 87%, OR 3.4, p = 0.009), clinical success was similar between both groups (90% vs. 87%, OR 1.7, 95%CI (0.44–7.07), p = 0.18). Although rate of AEs was lower in the EUS-GE group, the difference was not statistically significant (16% vs 25%, p = 0.3). The mean LOHS was similar in the EUS-GE group compared to SGJ (11.6 days ± 6.6 vs. 12 days ± 8.2 days,

P = 0.35). The mean length of follow-up was similar in both groups (107.8 ± 70 days in EUS-GE vs. 73.7 ± 156 days in SGE, p = 0.79). Reintervention rate were also not different between the two groups (3% vs. 9%, p = 0.3). Similarly, the mean time to reintervention was similar (88 days vs. 179 days, p = 0.83).

| | EUS-GE (n = 30) | Surgical GJ (n = 63) | p value |
|---|---|---|---|
| Technical success, n (%) | 26 (87) | 63 (100) | 0.009 |
| Clinical success, n (%) | 26 (87) | 57 (90) | 0.18 |
| Re-intervention, n (%) | 1 (3) | 6 (9) | 0.9 |
| Adverse events, n (%) | 5 (16) | 16 (25) | 0.3 |
| Mean length of hospitalization (days), mean±SD | 11.6 ± 6.6 | 12 ± 8.2 | 0.35 |

**Conclusion:** EUS-GE is associated with equivalent efficacy and safety as compared to surgical GJ. This is the first comparative trial between both techniques suggests EUS-GE as a non-inferior but less invasive alter to surgery. Prospective comparative trial is needed to confirm these intriguing results.

**Introduction:** The first report on the performance of a recently introduced flexible 20 gauge ProCore biopsy needle was promising, with a diagnostic yield of >85% (1). However, prior to implementation of this device, its reproducibility should be established, not only in the hands of academic experts, but also in non-academic practice.
**Aims & Methods:** To evaluate the interobserver agreement amongst expert and non-academic pathologists in grading the quality and diagnostic value of specimens obtained with the new flexible 20 G ProCore FNB needle (Cook Medical, Limerick, Ireland). Five international EUS-centers prospectively collected 74 samples (39 solid pancreatic masses and 35 lymph nodes) using the new needle. All samples were independently reviewed by five expert academic and five non-academic pathologists for sufficiency of tissue quality, percentage of target cells present, presence of tissue cores, suitability for additional analysis (i.e. immunohistochemistry), and diagnostic classification (non-diagnostic, benign, neoplastic, or malignant). Agreement was calculated using the Fleiss' kappa statistic and 95% confidence intervals (CIs).
**Results:** Overall, 91% of cases were considered to be of sufficient quality, with moderate agreement among the ten reviewing pathologists ($\kappa = 0.49$, table 1). Agreement was higher within the group of expert academic pathologists (p = 0.02). Interobserver agreement on the diagnostic classification was good amongst both academic ($\kappa = 0.62$; 95% CI 0.57–0.67) and non-academic pathologists ($\kappa = 0.59$; 95% CI 0.55–0.64). Regarding sample quantity, tissue cores were considered present in 70% of cases ($\kappa = 0.37$), with a higher level of agreement among expert pathologists ($p < 0.001$). As for cellularity of the sample, presence of ≥50% of target cells was reported in 78% of cases ($\kappa = 0.31$). In addition, suitability for additional analyses was rated as positive in the majority of samples (76%), with higher agreement among expert academic pathologists ($p < 0.001$). When comparing pancreatic to lymph node samples, agreement on the diagnostic classification was higher for lymph nodes ($\kappa = 0.64$; 95% CI 0.61–0.67) than for pancreatic masses ($\kappa = 0.54$; 95% CI 0.51–0.58, $p < 0.001$). In addition, lymph node specimens provided higher agreement with regard to possibility for additional analysis ($\kappa = 0.51$; 95% CI 0.46–0.56 versus $\kappa = 0.38$; 95% CI 0.33–0.43, $p < 0.001$). Agreement on specimen quality was higher for pancreatic samples ($\kappa = 0.62$; 95% CI 0.57–0.67 versus $\kappa = 0.43$; 95% CI 0.38–0.48, $p < 0.001$).
**Conclusion:** There was good interobserver agreement amongst both expert academic and non-academic pathologists in the assessment of the quality and diagnostic value of specimens obtained with the new 20 gauge ProCore biopsy needle. Follow-up data is required to confirm the diagnostic accuracy of this agreement.

obstruction of the common bile duct after failed endoscopic retrograde cholangiopancreatography (ERCP) or in case of surgically altered anatomy. Endoscopic ultrasound-guided Hepaticogastrostomy (EU-HGS) is a more recently introduced alternative to relieve malignant obstructive jaundice
**Aims & Methods:** The aim of this prospective observational study was to compare the outcome, efficacy and adverse events of EU-HGS and PTBD. From April 2012 to August 2015, consecutive patients with malignant bile duct obstruction who underwent EU-HGS or PTBD in two tertiary-care referral centers were included. The primary endpoint was the clinical success rate. Secondary endpoints were technical success, overall survival, procedure-related adverse events, incidence of adverse events, and reintervention rate.
**Results:** Fifty-one patients (EU-HGS n = 31, PTBD, n = 20) were included. Median survival was 71 days (range 25–75th percentile; 30–95) for the EU-HGS group and 78 days (range 25–75th percentile; 42–108) for PTBD group (p = 0.99). Technical success was achieved in all patients in both groups. Clinical success was achieved in 25 (86%) of 31 patients in the EUS-HPG group and in 15 (83%) of 20 patients in the PTBD group (p = 0.88). There was no difference of adverse events rates between 2 groups (EU-HGS: 16%; PTBD: 10%)(p = 0.69). Four deaths within one month (2 hemorragic and 2 septic) were considered procedure-related (2 in EU-HGS group and 2 in PTBD group). Overall reintervention rate was significantly lower after EU-HGS (n = 2) than after PTBD (n = 21) (p = 0.0001). Length of hospital stay was shorter after EU-HGS (15 days vs 22 days; p = 0.002).
**Conclusion:** EU-HGS can be an effective and safe mini invasive procedure alternative to PTBD with similar success and adverse events rate but a lower number of reintervention and length of hospitalization.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0745 ENDOSCOPIC ULTRASOUND-GUIDED BILIARY DRAINAGE FOR MALIGNANT BILIARY OBSTRUCTION AFTER FAILED ERCP: A SINGLE ITALIAN CENTER EXPERIENCE

**P. Cecinato**, F. Parmeggiani, F. Azzolini, F. Decembrino, G. Sereni, C. Tioli, V. Iori, M. Cavina, R. Zecchini, R. Sassatelli
*Unit Of Gastroenterology And Digestive Endoscopy, Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia/Italy*

**Contact E-mail Address:** paolo.cecinato@asmn.re.it
**Introduction:** Endoscopic ultrasonography-guided biliary drainage (EGBD) has been proposed as an alternative drainage technique for percutaneous transhepatic biliary drainage (PTBD) in patients with obstructive jaundice where endoscopic retrograde cholangiopancreatography (ERCP) has failed.
**Aims & Methods:** All patients afferent to Santa Maria Nuova Hospital in Reggio Emilia, between January 2011 and March 2016, with malignant obstructive jaundice, in whom ERCP had failed, were enrolled. Inclusion criteria are: patients over 18 years old, malignant bile duct obstruction with unsuccessful ERCP drainage. Patients with benign stricture were excluded. The end points were to evaluate technical and clinical success rate, adverse events rate and follow-up of direct transluminal EGBD. Technical success was defined as success of stent placement in the desired location. Early clinical success was defined as a drop in the bilirubin level by 50% at 2 weeks and late clinical success as a drop to below 3 (level that allows patients to undergo chemotherapy) at 4 weeks.
**Results:** In this study we enrolled 29 patients (11 men; median age 72; interquartile range, 61 to 90) underwent EGBD: 21 by intrahepatic approach (IA), 8 extraepatic approach (EA) The reason for EGBD was obscured ampulla by invasive cancer in 37.9% (11/29), postsurgical anatomy in 31.0% (9/29), failed deep biliary cannulation in 24.1% (7/29), hepaticojejunostomy stricture in 3.4% (1/29) and gastric outlet obstruction in 3.4% (1/29). EUS-guided cholangiography was successful and confirmed a distal common bile duct stricture in 26 patients (90%). Technical success in EGBD was achieved in 82.7% (24/29) of patient with a successful cholangiography: 90.5% in IA and 62.5% in EA. Early clinical success was reached in 62.1% (66.7% IA, 50% EA) and late clinical success in 39.9% (38.1% IA, 37.5% EA). Median bilirubin value decrese from 16.5 to 5.1 mg/dl after the procedure. Stent dysfunction occurred in 6 cases (20.6%) while procedure-related severe adverse event occurred in 3 patients (10.3%) with several comorbidities that developped severe cholangitis and died after 3–16 days after the procedure from multiorgan failure
**Conclusion:** EGBD is a safe and effective procedure to provide biliary access and drainage after failed ERCP. EGBD provides a viable alternative to PTBD, and limited available data suggest equivalent efficacy and safety.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** julio.iglesias.garcia@sergas.es
**Introduction:** Endoscopic ultrasound (EUS) is a useful tool for the evaluation of the left adrenal gland, mainly in the context of the staging of lung cancer. Endoscopic ultrasound (EUS)-guided elastography evaluates the stiffness of different tissues, which has been shown to be highly accurate for the diagnosis of malignancy of solid pancreatic lesions and lymph nodes.
**Aims & Methods:** Aim of our study was to evaluate the accuracy of EUS-guided elastography for the diagnosis of malignancy of left adrenal solid lesions.
**Methods:** 32 consecutive patients (mean age 66.1 years, range 46–80, 20 male), who underwent EUS-guided elastography for the evaluation of solid left adrenal lesions over the last 4 years were identified from a prospectively collected endoscopy database, and included in the study. EUS-guided elastography was performed using a convex array echoendoscope (Pentax EG-3870UTK and EG-3270UK), and the HITACHI-PREIRUS and ASCENDUS ultrasound equipment. The elastographic pattern was qualitatively evaluated based on color predominance (green or blue). Final diagnosis was based on surgical histopathology or, in non-operated cases, on EUS-guided fine needle biopsy, imaging assessment (CT scan and/or PET scan), with a minimum clinical follow-up of 6 months. Probability of malignancy according to the elastographic pattern is described.
**Results:** Mean size of left adrenal masses was 31.4 ± 16.8 mm. Malignancy was confirmed by reference methods in 20 cases, whereas the remaining 12 left adrenal masses were finally considered as benign. Three different elastographic patterns were identified: 1) heterogeneous blue-predominant pattern (n = 21), 2) heterogeneous green-predominant pattern (n = 10), and 3) heterogeneous mixed green-blue pattern with geographical appearance and no color predominance (n = 1). Nineteen out of the 20 malignant lesions (95%) showed a blue-predominant pattern; the remaining malignant lesion showed a green-predominant pattern. Nine out of the 12 benign lesions (75%) showed a green-predominant pattern, two showed a blue-predominant pattern, and one had a mixed green-blue pattern. The probability of malignancy of a left adrenal mass showing a blue-predominant pattern is of 91.3%, whereas is as low as 10% in the presence of a green-predominant pattern.
**Conclusion:** EUS-guided elastography is a useful tool for the differential diagnosis of left adrenal masses. It provides specific colour patterns supporting the malignant or benign nature of the lesions.

**Introduction:** Different types of endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA) techniques are used in clinical practice. However, controversy still remains as to which EUS-FNA techniques would result in better adequate specimen and diagnostic accuracy. The aim of our study was to compare specimen adequacy and diagnostic performances according to EUS-FNA techniques (no suction vs. suction vs. capillary suction) in a same patient with pancreatic lesions.
**Aims & Methods:** Patients who referred to EUS-FNA for pancreatic mass lesion were enrolled. Basically, we performed EUS-FNA with three needle passes and applied each pass of different FNA techniques (suction, no suction or capillary suction) which were randomly allocated. Additional needle passes were allowed to obtain an adequate specimen after the initial three needle passes without adequate specimen. EUS-FNA specimens were evaluated by one experienced cytopathologist who was blinded to which EUS-FNA techniques were applied. The specimen adequacy and diagnostic performances for malignancy were compared among EUS-FNA techniques.
**Results:** From Jan. 2014 to Oct. 2015, 113 patients with pancreatic mass were enrolled and 4 patients were excluded due to loss of follow-up after EUS-FNA. Finally, 109 patients (65 males; median age, 67 years) with 327 needle passes were included without technical failure. The cumulative diagnostic accuracy for

**Table (P0748)**

| | | Standard classification 3–4 criteria | 3–4 criteria | >6 criteria |
|---|---|---|---|---|
| Rosemont classification | Indeterminate | 106 (100%) p = 1<br>Rho = 0.9229 | 0 (0%) p = 0.2623<br>Rho = 0.656 | 0 (0%) p = 0.000<br>Rho = 0.3422 |
| | Suggestive | 10 (7.69%) p = 0.3882<br>Rho = 0.599 | 115 (88.46%) p = 0.2207<br>Rho = 0.832 | 5 (3.83%) p = 0.000<br>Rho = 0.314 |
| | Consistent | 1 (1.85%) p = 0.000<br>Rho = 0.375 | 9 (16.67%) p = 0.000<br>Rho = 0.252 | 44 (81.48%) p = 0.1967<br>Rho = 0.8244 |

malignancy for overall needle passes was 61.5%, 84.4% and 91.7% at 1st, 2nd and 3rd pass, respectively. Although high rate of inadequate specimen in EUS-FNA with capillary suction was occurred, there was no significant differences among EUS-FAN techniques and number of needle pass. EUS-FNA with no suction at 2nd needle pass showed statistically high rate of diagnostic accuracy comparing to suction at 2nd pass and no suction at 1st and 3rd pass (P = 0.016, 0.051, 0.034).
**Conclusion:** EUS-FNA with no suction, suction and capillary suction showed similar rate of inadequate specimen. However, further prospective study including variable lesions is needed to validate for optimal application and sequences of EUS-FNA techniques.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0748 CONCORDANCE BETWEEN THE ROSEMONT AND THE STANDARD ENDOSCOPIC ULTRASOUND CLASSIFICATION OF CHRONIC PANCREATITIS

**C. Calviño-Suárez**[1], D. De La Iglesia-García[2], J. Iglesias-Garcia[3], J. López-Díaz[1], J. Lariño-Noia[4], J.E. Domínguez-Muñoz[5]

**Introduction:** Endoscopic ultrasound (USE) is considered the most sensitive technique for the diagnosis of chronic pancreatitis (CP). However, EUS has less than optimal interobserver agreement for the diagnosis of CP. To minimize this inconvenience, two EUS-based classifications are used: the standard classification, which is based on the simple scoring of EUS criteria of the disease (4 parenchymal and 5 ductal), and the Rosemont classification, which includes weighted EUS criteria and stricter definitions for individual features to establish four groups of patients (normal, indeterminate, suggestive and consistent with CP). Aim of our study was to evaluate the concordance between the Rosemont and the standard EUS classifications for the diagnosis of different stages of CP.
**Aims & Methods:** Aim of our study was to evaluate the concordance between the Rosemont and the standard EUS classifications for the diagnosis of different stages of CP.
Methods: Retrospective analysis of a prospectively collected database. CP patients who underwent a EUS between October-2014 and November-2015 were included. EUS was performed by linear Pentax echoendoscopes (EG-3870UTK y EG-3270UK) and HITACHI-ASCENDUS ultrasound equipment. Standard EUS criteria and Rosemont classification of CP were recorded. Data were analyzed by McNemar-test and Spearman correlation-test.
**Results:** 290 patients (mean age 53 years, range 41–61, 222 male) met the inclusion criteria. Table shows patient distribution based on standard and Rosemont criteria, as well as the concordance and correlation between the two classifications. The majority of patients classified as indeterminate, suggestive and consistent with CP according to the Rosemont classification presented 3–4, 5–6 or >6 criteria, respectively. Concordance between the two classifications is lower at advanced stages of the disease due to the mischaracterization of standard parenchymal criteria in the presence of calcifications.
**Conclusion:** Standard and Rosemont EUS classifications of CP correlates significantly at early and moderate stages of the disease. The standard classification does not allow a proper scoring of EUS findings in patients with chronic calcifying pancreatitis.

## P0749 IMPACT OF VISUAL ON-SITE EVALUATION DURING ENDOSCOPIC ULTRASOUND ON FINE NEEDLE ASPIRATION CYTOLOGY

**A. Mariniello**, M. Martino, M. Pandolfi, F. M. Di Matteo
*Gi Endoscopy Unit, Campus Bio-Medico Of Rome, Roma|Italy*

**Contact E-mail Address:** marinielloanna@gmail.com
**Introduction:** Rapid on site evaluation (ROSE) has a deeper impact on Endoscopic Ultrasound (EUS)-guided fine needle aspiration (FNA) adequacy rate[1–2], but a cytopathologist on site is not available in all endoscopic centers. Macroscopic on-site evaluation (MOSE) was suitable to estimate the adequacy of the histologic core specimen obtained by EUS-FNA using a 19-G needle but often a thinner needle is preferred to perform EUS-FNA[3–4].
**Aims & Methods:** The aim of this study was to assess the efficacy of Visual On Site Evaluation (VOSE) in estimating the adequacy of FNA cytological specimens.
Thirty-three patients underwent EUS-FNA for pancreatic solid lesion or for enlarged lymph nodes with 22-or 25-Gauge (G) needle. VOSE was performed assessing each FNA pass in a fixative prepared fluid, evaluating: 1. blood (Ba, absent; B-, little; B+, a lot); 2. macroscopic visible core (MVC), single or multiple, long (>4 mm) or short (≤4 mm), red or white; 3. necrotic or fibrinoid material. When the macroscopic core was absent, the sample was considered inadequate.
**Results:** A total of 125 FNA needle passes was performed: 33 using 22-G and 92 passes using 25-G needle; 100 passes on pancreatic lesions, 25 on lymph nodes. Mean(SD) of needle passes was 3.47(0.81). VOSE results are summered in table 1. Correspondence between VOSE and cytological adequacy was of 91.2%. There was no concordance for 11 samples: 2 samples were adequate for VOSE but inadequate for the cytopathologist and 9 samples were inadequate for VOSE but adequate for the cytopathologist.

**Table 1.:** VOSE results

| | |
|---|---|
| **Presence of blood**, n (%), Ba/B-/B+ | **35**(28)/ **60**(48)/ **30**(24) |
| **Presence of MVC**, n (%) | **107**(85.6) |
| **Single/Multiple**, n (%) | **51**(48)/ **56**(52) |
| **Short/Long**, n (%) | **46**(43)/ **61**(57) |
| **Red/White**, n (%) | **60**(57)/ **47**(43) |
| **Presence of necrosis**, n (%) | **16**(12.8) |

**Conclusion:** VOSE can be an easy and feasible indicator of EUS-FNA adequacy when ROSE is not available
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0750 IN VIVO CHARACTERIZATION OF ABNORMALITIES IN SMALL BOWEL DISEASES USING PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY

**N. Ohmiya**, T. Tahara, M. Nagasaka, Y. Nakagawa, T. Shibata
*Department Of Gastroenterology, Fujita Health University School of Medicine, Toyoake/Japan*

**Contact E-mail Address:** nohmiya@fujita-hu.ac.jp
**Introduction:** Probe-based confocal laser endomicroscopy (pCLE) enables real-time optical biopsy.
**Aims & Methods:** Little is known about the pCLE imaging deep inside the small bowel, therefore we determined its usefulness. Between April 2014 and January 2016, we performed 38 pCLE examinations during double-balloon enteroscopy with intravenous fluorescein in 37 patients with: tumors (n = 10), vascular disorders (n = 6), inflammatory diseases and drug injuries (n = 13), other disorders (n = 4), and normal findings (n = 4). We measured the calibers of capillary and lymphatic vessels at 15 different sites each and compared calibers between pCLE images and histopathology. We also compared pCLE findings with pathologic diagnosis.
**Results:** The inner diameters of capillary vessels beneath the epithelium and in the middle of villi were $16.2 \pm 3.0$ mm and $14.5 \pm 3.1$ mm, respectively, in the pCLE images but were not consistent with formalin-fixed paraffin-embedded histology. In tumors, larger capillary vessels were observed in aggressive malignant lymphoma and metastasis, and a "soccer ball-like pattern" constituting homogenous dark cells packed by polygonal, narrower capillary vessels was characteristic in pCLE images of a malignant lymphoma follicle. Hereditary hemorrhagic telangiectasia and angiodysplasia contained anastomosis of capillary vessels of different calibers. In IgA vasculitis, segmental capillary strictures were observed. Intestinal lymphangiectasia with protein-losing enteropathy contained a reticular network of lymphatic vessels and dilated lymphatic ducts accompanied by numerous cell gaps. pCLE findings corresponded to pathologic diagnosis in 32 examinations (94%).
**Conclusion:** pCLE was useful for in vivo detection of abnormalities of the capillary and lymphatic vessels and epithelium and the diagnosis in various small bowel diseases.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0751 DOUBLE-BALLOON COLONOSCOPY: A 7-YEAR EXPERIENCE FROM EDINBURGH

**D. E. Yung**, A. Koulaouzidis, C. H. Fraser, K. C. Trimble, J.N. Plevris
*The Royal Infirmary of Edinburgh, Edinburgh/United Kingdom*

**Contact E-mail Address:** diana.e.yung@gmail.com
**Introduction:** In experienced hands, conventional colonoscopy fails to achieve caecal intubation in around 5% of patients, mainly due to anatomical factors and/or patient tolerance [1–3]. Recently, it has been reported that double-balloon colonoscopy (DBC) is effective in completing colonic examination in such cases [1,4]. This retrospective study aims to present the utility of DBC from a tertiary care centre in South East Scotland.
**Aims & Methods:** Retrospective study; consecutive patients who underwent DBC without general anaesthesia from Dec 2008–Dec 2015, following incomplete colonoscopy, were included. Information extracted from case notes for initial colonoscopy: indication(s), patient clinical characteristics, procedure data, pathology found, therapeutic interventions and reason for failure to complete examination; and, for DBC: caecal intubation rate, pathology found, endoscopic interventions performed, sedation used and complications. Data are reported as mean (±SD) or median (range).
**Results:** Over the study period, DBC was performed in 57 patients (31 F/26 M; median age 62.9, range 20–89 years). Indications for colonoscopy were obscure GI bleeding in 14 (24.5%), prior abnormal cross-sectional imaging in 4 (7.0%), known or suspected polyps in 21 (36.8%), investigation or surveillance of inflammatory bowel disease in 12 (21.1%), and/or cancer screening in 4 (7.0%). 16/57 (28.1%) patients had previous abdominal or pelvic surgery. 19/57 (33.3%) patients had 2 or more previous failed colonoscopies. Reasons for failure of previous colonoscopies were: technical difficulties (excessive looping/tortuous colon, long colon) (n = 34), patient discomfort (n = 13), fixed angulated colon (n = 5) and/or severe diverticulosis (n = 3). With DBC, caecal intubation was achieved in 55/57 (96.5%) patients. In 29 (50.9%) patients, DBC revealed significant pathology; the majority of these findings 79.3%(23/29) were inaccessible by conventional colonoscopy. Therapeutic interventions (endoscopic mucosal resection, Argon Plasma Coagulation and/or polypectomy) were performed in 22/57 (38.6%) patients. For sedation, the midazolam dose was $2.94 \pm 1.6$ mg and that of Fentanyl $70 \pm 40\,\mu$g; comparable to previous data from our centre [5]. No complications occurred during DBC.
**Conclusion:** DBC is highly effective for completing colonic evaluation in patients with previous incomplete colonoscopy. DBC should be considered as the modality of choice in patients with incomplete colonoscopy in whom follow-up imaging suggests the presence of significant proximal colonic pathology, and as a useful option in any patient in whom standard colonoscopy has been incomplete [3].
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) in patients with altered gastrointestinal anatomy is challenging. The development of short double balloon enteroscopy (DBE) enabled deep access to the blind end of the intestine to perform ERCP. Although ERCP using DBE (DB-ERCP) is an established technique, there have been no reports on the efficacy and safety of DB-ERCP when acute biliary decompression is required.
**Aims & Methods:** The aim of this study was to evaluate this procedure in the urgent care setting. Between July 2007 and January 2016, we performed 144 DB-ERCP procedures in 79 patients with altered anatomy (77 procedures with Roux-en-Y gastric bypass (RYGB), 16 with Billroth II gastrectomy (B-II), 17 with pancreatoduoderectomy (PD), and 6 with pylorus preserving pancreaticoduodenectomy (PPPD), 9 with hepaticojejunostomy, 19 with other procedures). We defined urgent DB-ERCP as performance of the procedure within 24 hours of the diagnosis of pancreaticobiliary disease and nonurgent DB-ERCP as performance of the procedure 24 hours or more after the diagnosis. We retrospectively evaluated the success rate of reaching the blind end, the therapeutic success rate and the occurrence of complications in urgent and nonurgent DB-ERCP.
**Results:** We performed 30 urgent DB-ERCP procedures (28 patients) with altered anatomy (23 with RYGB, 3 with PD, 1 with hepaticojejunostomy, and 3 with other procedures) and 114 nonurgent DB-ERCP procedures (51 patients) with altered anatomy (54 with RYGB, 16 with B-II, 14 with PD, 6 with PPPD, 8 with hepaticojejunostomy, and 16 with other procedures). In urgent DB-ERCP, successful deep insertion of the endoscope to the blind end was accomplished in 27 of 30 procedures (90.0%). Deep biliary cannulation was successful in 21 of 27 procedures reaching the blind end (77.8%). Therapeutic intervention was achieved in all of 21 procedures in which deep biliary cannulation was successful (100%). The overall intention to treat therapeutic success rate was 70%. In nonurgent DB-ERCP, successful deep insertion of the endoscope to the blind end was accomplished in 102 of 114 procedures (89.5%). Deep biliary cannulation was successful in 91 of 102 procedures reaching the blind end (89.2%). Therapeutic intervention was achieved in 90 of 91 procedures in which deep biliary cannulation was successful (98.9%). The overall intention to treat therapeutic success rate was 78.9%. Complications for all the urgent DB-ERCP procedures were observed in 2 of the 30 procedures (6.7%), whereas complications for all the nonurgent procedures were 8 of the 114 procedures (7.0%). No procedure-related death was observed in urgent and nonurgent DB-ERCP.
**Conclusion:** Urgent DB-ERCP is an effective and safe treatment choice for patients with altered gastrointestinal anatomy who require acute biliary decompression.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0753 UTILITY OF SINGLE-BALLOON ENTEROSCOPY FOR THE DIAGNOSIS AND MANAGEMENT OF SMALL BOWEL POLYPS/TUMORS DETECTED IN CAPSULE ENDOSCOPY

**P. Andrade**, M. Marques, H. Cardoso, G. Macedo
*Gastroenterology, Centro Hospitalar de São João, Porto/Portugal*

**Contact E-mail Address:** anapatriciarandrade@gmail.com
**Introduction:** Small-bowel polyps/tumors have been difficult to diagnose as a consequence of the poor accessibility to small bowel (SB). Since the introduction of capsule endoscopy (CE) and overtube-assisted enteroscopy, the number of SB polyps/tumors that are diagnosed has increased. Data regarding the performance of single-balloon enteroscopy (SBE) for the diagnosis and management of SB polyps/tumors detected in CE are scarce.
**Aims & Methods:** We aimed to evaluate the performance of SBE for the diagnosis and management of SB polyps/tumors detected in CE. Among all the SBE performed at our tertiary centre between 2010 and 2015, we analyzed those performed for evaluation of SB polyps/tumors detected in CE. SBE was performed using an oral or anal approach according to the CE results.
**Results:** From 244 procedures, 61 (25%) were performed for evaluation of SB polyps and tumors detected in CE. Twenty-five (41%) patients were male with a mean age of $53 \pm 16$ years; Forty (65.6%) procedures were performed using an oral approach. SBE detected 72% (44/61) of the lesions previously identified in CE. The distribution of the lesions was: 18% proximal jejunum, 25% middle jejunum, 16% distal jejunum, 14% proximal ileum, 7% medium ileum and 20% distal ileum. Histopathological results were: 10 adenomas, 8 hamartomas, 3

adenocarcinomas, 6 inflammatory polyps, 2 follicular lymphomas, 2 inflammatory fibroid polyps, 2 hyperplastic polyps, 1 carcinoid tumor, 1 metastasis of renal cell carcinoma, 3 xanthomas and 6 subepithelial lesions. Polyps/tumor size in CE was the only factor that significantly influenced diagnostic accuracy of SBE: 95% for lesions larger than 10 mm versus 62% for lesions smaller than 10 mm ($p = 0.006$). SBE directly influenced patient's management in 57% (39/61) of the cases.

**Conclusion:** SBE has a good accuracy (72%) for the diagnosis of SB polyps/tumors detected in CE. Diagnostic accuracy increased to 95% for lesions larger than 10 mm in CE. SBE directly influenced patient's management in 57% (39/61) of the cases.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0754 SMALL BOWEL REBLEEDING AFTER A SECOND ENDOSCOPIC TREATMENT IS EVEN HIGHER THAN AFTER THE FIRST ENDOSCOPIC TREATMENT IN PATIENTS WITH OBSCURE GASTROINTESTINAL BLEEDING

**A. Ponte**[1], R. Pinho[2], A. Rodrigues[2], J. Silva[2], J. P. Rodrigues[2], M. Sousa[2], J. Carvalho[2]
[1]*Gastroenterology, Centro Hospitalar Vila Nova Gaia/Espinho, Vila Nova Gaia/Portugal*
[2]*Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia/Portugal*

**Contact E-mail Address:** ana.ilponte@gmail.com

**Introduction:** In western countries, small-bowel vascular lesions (SBVL) represent the most frequent small-bowel finding in patients submitted to balloon-assisted enteroscopy (BAE) for obscure gastrointestinal bleeding (OGIB).[1] The global rebleeding rate of SBVL after a first endoscopic treatment session is 40%, and there is limited data regarding the efficacy of further endoscopic therapeutic sessions in the reduction of the rebleeding rate of SBVL.[2]

**Objective:** Evaluate the rebleeding rate of SBVL, after two endoscopic therapeutic sessions with BAE.

**Methods:** Between July 2007 and August 2015, all patients with rebleeding after a first endoscopic therapeutic session of SBVL who underwent a second BAE therapy session were included. The endpoint was a second episode of rebleeding, defined as the presence of overt OGIB, the need for red blood cells transfusions or a decrease in haemoglobin $\geq 2$ g/dL. Statistical analysis: Kaplan-Meier survival curves. Significance: $p < 0.05$.

**Results:** 17 patients with rebleeding SBVL after a first BAE therapy session were included, 52.9% (n = 9) were men with a median age of 71 years. In 94.1% (n = 16) patients, further endoscopic and/or radiologic exams were performed. A second BAE was performed in 70.6% (n = 12) patients, using an antegrade insertion in 75% (n = 9) of the cases and a retrograde insertion in 8.3% (n = 1) of the cases. The remaining two patients had a complete BAE. Angioectasias were identified in 83.3% (n = 10) of BAE, all classified as type 1 b in Yamamoto's classification.[3] Findings were multiple in 60% (n = 6) of the cases, with a median of 3.5 angioectasias per exam. Argon plasma coagulation was performed in all BAE with angioectasias (n = 10). Rebleeding occurred in 60% (n = 6) of patients after a second BAE therapeutic session, manifested as overt OGIB in 50% (n = 3), need of blood transfusion in 33.3% (n = 2) and haemoglobin drop $\geq 2$ g/dL in 16.7% (n = 1). The rebleeding rate at 1 year was 60%, and no further rebleeding was observed in the remaining period of follow-up.

**Conclusion:** Despite the high rebleeding rate detected shortly after endoscopic therapy, further endoscopic sessions of SBVL might be beneficial due to the relative effective reduction of rebleeding in a group of patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

[2]*Endoscopy, Moscow University Hospital №31Moscow/Russian Federation*

**Contact E-mail Address:** katendo@yandex.ru

**Introduction:** The recent development of new enteroscopic modalities, such as video capsule endoscopy (VCE) and device-assisted enteroscopy, including balloon-assisted enteroscopy (BAE), has given the opportunity to evaluate the small bowel diseases and allows for the most accurate therapy. Suspected small bowel tumors and obscure bleeding was an often reason for the surgery.

**Aims & Methods:** The aim of the study is to evaluate the clinical utility of VCE and BAE in the clinical practice of the surgical hospital. From 14.02.2007 to 28.03.2016 enteroscopy was performed in 473 patients (m-247, f-226, mean age $47.9 \pm 16.9$ years, range 18–84), including 24 postoperative patients with long afferent loop for performing therapeutic ERCP. The indications for small bowel evaluation in 449 pts included: suspected small bowel bleeding – in 164 (36.5%) pts, small bowel tumor – in 88 (19.6%) pts, inflammatory bowel disease (IBD)-in 110 (24.5%) pts, others (carcinophobia, helminthosis, etc.) – in 87 (19.4%) pts. We performed 345 VCE in 328 (73.0%) pts. BAE was performed in 121 (26.9%) pts. Totally we performed 227 BAE by oral approach, including 26 repeated procedures in 11 pts; and 134 BAE by transanal approach, including 6 repeated procedures in 6 pts. Combination (VCE+ BAE) was performed in 133 (40.5%) of 328 pts.

**Results:** BAE was successfully performed in 443 (98.6%) of 449 pts. Using VCE and BAE we were able to reveal small bowel abnormalities – in 255 (57.6%) pts: vessel pathology in 60 (23.5%) pts, tumors in 74 (29.0%) pts, enteropathy – in 92 (36.1%) pts, other disorders – in 29 (11.4%) pts.; no abnormalities in 188 (42.4%) pts. Endoscopic treatment was performed in 63 (24.7%) pts, mostly including the removing of hamartomas in 14 (22.2%) patients with Peutz-Jeghers syndrome and endoscopic hemostasis in 26 (41.3%) patients with vessel pathology. Surgical treatment was performed in 41 (16.1%) pts, mostly because of the small bowel tumors. Capsule retention was the only adverse event, related to VCE, in 6 (1.8%) pts. Adverse events, related to BAE, were revealed in 6 (1.8%) pts: bleeding after biopsy (3), perforation (1) and gastric cardia tears (2).

**Conclusion:** VCE and BAE plays a significant role in the diagnosis and treatment of patients giving the opportunity to be treated endoscopically in 25.0% and to avoid surgery in 83.9% of patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Data on small bowel (SB) mucosal healing (MH) and deep remission (DR) in children with Crohn's disease (CD) are rare. Recently, colon capsule endoscopy (CCE) has been proved effective as "pan-endoscopy" in pediatric CD. This is the first study to prospectively assess MH and DR on the entire GI tract by performing two subsequent CCE over 24 weeks in children with CD in comparison with biomarkers, magnetic resonance enterography (MRE) and SB contrast ultrasonography (SICUS).

**Aims & Methods:** Children with known CD were prospectively recruited and underwent imaging studies followed by CCE, at baseline and after 24 weeks. The Lewis score (LS) and Simple endoscopic score for Crohn's disease (SES-CD) were calculated for SB and colon, respectively. C-reactive protein (CRP) and fecal calprotectin (FC) were also evaluated for their association with clinical activity, imaging and CCE findings. Clinical remission was defined as PCDAI < 10. SB and colonic MH were defined as LS < 135 and SES-CD $\leq 1$, respectively; moderate-to-severe inflammation was defined as LS > 790 or SES-CD > 7. Biomarker remission (BR) was defined as a combination of clinical remission (PCDAI < 10) and normal biomarkers. Deep remission (DR) was defined as a combination of BR and MH. Therapy was calibrated according to CCE results.

**Results:** Forty-eight patients (pts) were recruited, 22 with clinical and biomarker activity and 26 in remission. At baseline CCE confirmed significant inflammation (either in SB or colon) in 18 (82%) of 22 pts with clinical and/or biomarker disease activity, while showed mild lesions and/or normal mucosa in 4 (18%). MRE and SICUS did not demonstrate active disease in 5/18 (23%) with lesions at CCE, but it found nonspecific findings in 2 of 4 with negative CCE. Biomarker levels were elevated with FC in 13 (59%); CRP levels in 10 (45%) and either biomarker in 15 (68%). In the 26 pts with remission, CCE showed SB lesions in 13 (50%) and colonic lesions in 6 (23%). Complete MH and DR were observed in 10 (39%). Imaging studies found lesions only in 7 (27%, $p < 0.05$). At 24-week follow-up, CCE identified DR only in 8/20 (36%) of the active group; while in 12/20 (54%) showed a partial MH. In inactive pts, CCE revealed that only 7/10 pts maintained DR. Of 16 pts in remission and with lesions at baseline, CCE showed that 9 (56%) achieved DR and 5 (44%) a partial MH after a change of therapy. MRE and SICUS had a good concordance in evaluating DR (14/17, 82%) in both groups, but did not identify partial MH (only 8/17, 47%, $p < 0.05$). FC and CRP were not able to accurately evaluate DR in either group.

**Conclusion:** This study shows for the first time that CCE is effective for monitoring DR and MH of the entire GI tract and in directing therapy for pediatric patients with CD.

## P0757 WHICH FACTORS MAY PREDICT THE FAILURE OF A COMPLETE SMALL-BOWEL EXAMINATION IN CAPSULE ENTEROSCOPY?

**A. Ponte**[1], R. Pinho[2], A. Rodrigues[2], J. Silva[2], J. P. Rodrigues[2], M. Sousa[2], J. Carvalho[2]

Introduction

**Introduction/Objectives:** Capsule enteroscopy (CE) represents a valuable tool in the examination of small-bowel, with a higher diagnostic yield compared to radiology and angiography.[1] Nevertheless, the inability of reaching the cecum during the recording time of CE, prevents complete small-bowel assessment which negatively affects its diagnostic yield. Previous studies report that 15–33% of CE are incomplete.[2,3] Therefore, the identification of factors associated with incomplete CE is crucial. The aim of this study was to evaluate predictive factors associated with incomplete CE.

**Methods:** Between June 2009 and February 2016, all patients with incomplete small-bowel examination in CE (Mirocam®) were included. This case group was compared with a control group which consisted of all patients with complete CE examinations submitted to CE between January 2014 and February 2016. Patients with an ileostomy, retained CE and CE directly placed in the duodenum were excluded. Data regarding demography, degree of dependency of patients, past medical and surgical history, medications, CE parameters and its regimen of performance (inpatient/outpatient regimen) was analyzed. Statistical analysis: $X^2$, Student's t-test and binary logistic regression. Significance: $p < 0.05$.

**Results:** One hundred and fifty-three patients were included, 31 cases and 122 controls. Among the parameters analysed, factors significantly associated with incomplete CE included inpatient regimen ($p < 0.0001$), prior abdominal surgery ($p = 0.019$), higher degrees of dependency ($p = 0.008$) and opiate use ($p = 0.019$). In logistic regression, the degree of dependency ($OR = 4.67$; $p = 0.028$), performance of CE in hospitalized patients ($OR = 4.04$; $p = 0.006$) and prior abdominal surgery ($OR = 3.45$; $p = 0.012$) represented the independent predictive factors of an incomplete CE.

**Conclusion:** Patients hospitalized and with higher degrees of dependency and prior abdominal surgeries are more likely to have an incomplete assessment of small-bowel in CE. The recognition of these factors may contribute to the adoption of specific measures to decrease the rate of incomplete exams.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The early timing of the Small Bowel (SB) Capsule Endoscopy (CE) is an independent predictor of positive findings in Obscure GastroIntestinal Bleeding (OGIB). Duodenal delivery of SBCE immediately after normal gastroscopy and colonoscopy may enable significant time savings, and therefore increase the diagnosis yield. However, the quality of SB visualization after immediate duodenal delivery is not known.

**Aims & Methods:** Our aim was to compare the quality of SB visualization after immediate duodenal delivery to the standard procedure (postponed SBCE ingestion after oral preparation). This was a prospective case-control study. After sample size calculation, 48 patients with OGIB were selected. Patients with active hemorrhage on SBCE were excluded, as bowel visualization would likely be altered downstream the bleeding site. Twenty-two cases (group 1) were included and matched to 22 controls (group 2) according to gender, age and type of bleeding (patent/occult). Patients in group 1 received a split 4 L PEG preparation before SBCE was delivered into the duodenum immediately after normal colonoscopy. Patients in group 2 received 1 L of PEG the day before ingesting the SBCE, distant from the initial bidirectional endoscopies. A validated Computed Assessment of Cleansing (CAC) score, based on the automated calculation of the ratio of red and green pixels (R/V) of each frame of each video sequence of the SB, was used for objective comparison.

**Results:** A preliminary study confirmed good correlations between reddish frames (with $CAC > 1.6$) and those deemed adequately cleansed by 2 blinded expert readers. The average time intervals between admission for OGIB and delivered or delayed SBCE, were 4 days for overt bleeding, and 65 days for occult bleeding. The proportions of "adequately cleansed" frames according to the CAC did not differ significantly between the 2 groups ($p = 0.28$). There was no significant difference between the 2 groups terms of SB transit time ($p = 0.53$), total number of SB frames ($p = 0.21$), and rates of complete SB examination.

| | Group 1 (delivery) n = 22 | Groupe 2 (ingestion) n = 22 | p |
|---|---|---|---|
| **Proportion of adequatelycleansed frames (CAC ≥ 1.6)** | | | |
| Over the entire sequence | 43.1% | 50.0% | 0.28 |
| Within the 1st quartile | 57.4% | 59.2% | 0.86 |
| Within the 2nd quartile | 46.6% | 49.9% | 0.88 |
| Within the 3rd quartile | 38.7% | 47.2% | 0.47 |
| Within the 4th quartile | 31.9% | 41.1% | 0.42 |
| **Secondary outcomes** | | | |
| Complete examination of the small bowel: n (%) | 22 (100%) | 21 (95.5%) | ns |
| Mean number of small bowel frames | 12451 | 13800 | 0.21 |
| Mean transit time (minutes) | 267 | 273 | 0.53 |

**Conclusion:** According to an objective CAC score, SBCE delivery into the duodenum in OGIB, immediately after normal bidirectional endoscopies, allows a SB quality of visualization not different to that of the delayed standard procedure, with virtualy no delay and no additionnal preparation for patients. The potential of this approach to increase the diagnostic yield of SBCE in OGID, and to decrease the length of hospital staying, should be evaluated.

**Introduction:** Capsule endoscopy (CE) has become an important tool for the diagnosis of small bowel disease. A major problem of CE is that it is time consuming to read one case. Although few previous studies have showed a supporting role of Pre-Reader in the reading of CE, it remains controversial. In this study, we aimed to show the complement role of low experienced endoscopy trainee (VCE < 20) in the interpretation of CE.

**Aims & Methods:** Before the study, pre-readers was educated about RAPID® for PillCam Software. The 50 educational cases (which including 12 vascular lesions, 21 ulcerative lesions, and 16 neoplastic lesions) were selected from our

hospital. Two Endoscopy trainees, as a pre-reader, interpretated 50 cases of CE and completed the assessment form. After that, highly experienced endoscopists (VCE > 100) reviewed each case individually with reference to the filled out assessment form. Same videos, which didn't include the Pre-Readers assessment form were reviewed by another high experienced endoscopists too. We evaluated the agreement, missed lesion, overcalled, and reading time between two expert groups.
**Results:** At assessment form, which filled up by Pre-reader, agreement (A)/missed lesion(M)/overcalled(O) were observed in 72.3%/ 8.9%/18.8% respectively. The agreement rate was high in vascular and ulcerative lesions, On the other hand, overcalled lesion was high in neoplastic, especially polypoid lesion. Pre-reader's assessment form supported experts to get more abnormal findings (detection rate was improved by 10~20%), however final diagnosis was not changed. Pre-reader's assessment form added more information as well as decreased expert's time significantly.
**Conclusion:** Pre-reader added more information on capsule endoscopy, even though the final diagnosis was not changed. Also, a group of pre-readers could decrease the time spent. In this study, we showed complement role of pre-reader in the reading of CE.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Small bowel capsule endoscopy (SBCE) is a useful diagnostic tool for small bowel Crohn's disease (CD), with a higher diagnostic yield than standard radiological techniques. However, the majority of patients undergoing either modality do not have CD. As with standard endoscopy a tool to help select patients with probable IBD would be clinically useful.
**Aims & Methods:** To correlate a single Fecal calprotectin (FC) concentration with SBCE findings in patients with suspected or known small bowel CD. In this prospective study patients with suspected or known CD scheduled to have a SBCE were requested to give a stool sample for fecal calprotectin (FC) on the day of examination. In addition to FC, CRP (normal < 5 mg/L) and Harvey Bradshaw index (< 5 is normal) was calculated. SBCE was performed as standard and read by experienced gastroenterologists. A SBCE with a Lewis score of >135 or >3 significant ulcers was considered positive for CD. FC was analyzed externally and results reported as ug/g stool. The predictive value of a FC > 50ug/g and 100ug/g for CD was calculated and overall correlation assessed with pearsons r.
**Results:** To date 84 patients have been invited to participate and 53/84(63%) have both a FC and SBCE results available at the time of analysis of which; male = 22 (38%), established CD (n = 5), suspected CD (n = 48), median age was 47yrs (range 17 to 75), median CRP was 1.55 mg/L (range 1 to 28.2) and median FC was 53ug/g (range 19.5 to 774). In all 47% (25/53) had a normal FC <50ug/g, and 35% (19/53) FC > 90 (median 217; range 102.8 to 774) and 9 an indeterminate FC >50 and< 90. Overall 12/53 (22.6%) had a positive SBCE for Crohn's disease. Overall FC was weakly correlated with SBCE, with pearsons's r of 0.4401. The sensitivity, specificity and positive and negative predictive values for FC cut off's of >50ug/g and >100ug/g were; FC >50ug/g 67%, 53%, 31% and 83% and FC >100 ug/g 58%, 71%, 39% and 84%. The sensitivity, specificity and PPV and NPV for a CRP cut off >5 mg/L was; sensitivity 27%, specificity 86%, PPV 37%, NPV 78%. Similarly neither HBI nor CRP correlated with SBCE findings.
**Conclusion:** In our prospective study FC weakly correlated with SBCE findings in both suspected and known CD patients. This may reflect the lack of colonic disease in the majority of our patients. However a FC of <100 ug/g has an adequate NPV at 84%, which was higher than for CRP and may be useful clinically and warrants further investigation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0761 FECAL CALPROTECTIN AS A SELECTION TOOL FOR SMALL BOWEL CAPSULE ENDOSCOPY IN SUSPECTED CROHN'S DISEASE

**S. Monteiro**[1], M. Barbosa[1], T. Cúrdia Gonçalves[1], P. Boal Carvalho[1], M.J. Moreira[1], B. Rosa[1], J. Cotter[2]

**Contact E-mail Address:** sara.s.o.monteiro@gmail.com
**Introduction:** The small bowel capsule endoscopy (SBCE) is a first-line method in patients with suspected Crohn's disease (CD) after a previous negative ileocolonoscopy. Fecal calprotectin (FC) is a non-invasive marker of intestinal inflammation and has demonstrated an excellent diagnostic accuracy in distinguishing inflammatory bowel disease and functional disease.
**Aims & Methods:** The aim of this study was to evaluate the predictive value of the FC in inflammatory activity detected by SBCE in patients with suspected CD and negative ileocolonoscopy. Retrospective study included patients who underwent SBCE for suspected CD between March 2015 and March 2016. FC was measured within one week of SBCE. Inflammatory activity was considered significant when the Lewis score (LS) ≥135. FC was correlated with LS using Spearman correlation. The diagnostic accuracy of FC for significant activity was calculated by area under the curve (AUC).
**Results:** Fifty-five patients were included: 38 females (69.1%), mean age of 38 years. The FC was correlated positively and significantly to LS ($rs = 0.571$, $p < 0.001$). The SBCE detected significant inflammatory activity (LS ≥135) in 27 patients (49.1%). The AUC of FC was 0.864 for significant inflammatory activity (LS ≥135). For values of FC≥100 µg/g, a LS≥135 was found in 22 patients (40%), $p < 0.001$, corresponding to a sensitivity, specificity, positive predictive value and negative predictive value of 81.5%, 85.7%, 84.6% and 82.8%, respectively.
**Conclusion:** The FC has shown a good ability to predict significant inflammatory activity in SBCE in patients with suspected CD. Thus, the FC proved to be a useful tool to select patients with suspected CD for SBCE.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0762 USEFULNESS OF THE NEWLY DESIGNED PLASTIC STENT FOR EUS-GUIDED HEPATICOGASTROSTOMY AND PANCREATIC DUCT DRAINAGE: LARGE CASE SERIES EVALUATION

**T. Tsuchiya**[1], A. Sofuni[1], S. Tsuji[1], K. Kamada[1], R. Tanaka[1], R. Tonozuka[1], M. Honjo[1], S. Mukai[1], M. Fujita[1], K. Yamamoto[1], Y. Matsunami[1], Y. Asai[1], T. Itoi[2]
[1]*Gastroenterology & Hepatology, Tokyo Medical University, Tokyo/Japan*
[2]*Department Of Gastroenterology And Hepatology, Tokyo Medical University, Tokyo/Japan*

**Contact E-mail Address:** tsuchiya@tokyo-med.ac.jp
**Introduction:** Recently, EUS-guided biliary and pancreatic duct drainage has emerged in case of failed ERCP. Apart from established ERCP, there are several obstacles to perform successful drainages. The most big issue is few dedicated EUS-guided devices for EUS-biliary and pancreatic duct drainage. Thus, we developed a new single pigtail plastic stent designed for EUS-guided interventions (EUS-guided hepaticogastrostomy;EUS-HGS and pancreatic duct drainage;EUS-PD) and used as the first-line EUS-guided stent until now.
**Aims & Methods:** The aim of this study is to retrospectively evaluate the feasibility and efficacy of newly designed plastic stent. Thirty-two patients with biliary obstruction due to benign or malignant biliary strictures or common bile duct stones underwent EUS-HGS. And Twenty-two patients with acute recurrent pancreatitis due to main pancreatic duct stricture or stenotic pancreatojejunostomy underwent EUS-PD. Totally a new plastic stent was used in fifty-four patients. EUS-PD and HGS were performed using a 19-gauge or 22-gauge fine-needle. When bile duct dilatation is insufficient, it is possible to use a 0.021-inch guidewire with a 22 G needle. Dilation of the needle tract and anastomotic site was performed by using a standard or tapered catheter, a cautery dilator, an 8F dilation catheter. After tract dilation, new tapered tip and four-fold-flanged single pigtail plastic stent (8F for EUS-HGS, 7F for EUS-PD, total length: 20-cm, effective length: 15-cm, flanges: 4 with apertures, side holes: total 12 holes, distal straight site, 4 holes and pigtail site, 8 holes) was placed.
**Results:** New plastic stent was placed successfully without procedural complication in all cases (54/54, 100%). Treatment success rate was 96.9% (31/32) in EUS-HGS and 100% (22/22) in EUS-PD. In EUS-HGS, bleeding from the punctured gastric wall occurred in one patient three days postoperatively. We exchanged the plastic stent for a fully covered self-expandable metal stent (8 mm in diameter). Hemostasis was achieved and rebleeding did not occur. A mild adverse event of self-limited abdominal pain occurred in three patients. There was no stent migration or dislocation. In EUS-PD, self-limited abdominal pain was observed in three patients, bleeding in one patient one day postoperatively (interventional radiology and transcatheter arterial embolization were needed), and mild pancreatitis in one patient, but there were no stent migration.
**Conclusion:** We designed a new single-pigtail plastic stent dedicated for EUS-guided interventions (EUS-HGS and EUS-PD) and confirmed its technical feasibility and clinical effectiveness. Additional long-term studies involving a sufficient number of patients are warranted.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Recently Lumen-apposing metal stent (LAMS) specifically designed for interventional EUS (Hot-AXIOS$^{TM}$), had significantly changed the technical approach in the setting of EUS-guided drainage.
**Aims & Methods:** The aim of this study was to evaluate the feasibility, safety and efficacy of the Hot-AXIOS$^{TM}$ stent placement in different clinical setting in a tertiary referral center. The Hot-AXIOS stent (Boston Scientific) is a fully covered, nitinol, braided stent with bilateral anchor flanges. We prospectively gathered data from consecutive patients treated with this device between March 2014 and April 2016. Clinical applications are various including pancreatic fluid collection, gallbladder and biliary drainage. Technical success was defined as correct positioning of stent. Clinical success was defined as complete resolution of the pancreatic collection and of the patient's symptoms in pancreatic pseudocyst drainage; radiologic evidence of gallbladder decompression and resolution of clinical symptoms in cholecystitis; serum bilirubin level decreased by 50% or more within 2 weeks after the procedure in biliary drainage.
**Results:** Thirty-nine patients were treated with LAMS (Hot-AXIOS) stent placement. Population cohort was composed of 16 male and 23 female, with mean age of 68.7 years (ranging from 37–95 y). The indication of EUS drainage were: 18 (46.2%) pancreatic collections (2 pancreatic necrosis), 10 (25.6%) acute cholecystitis in patients not fit for surgery, 11 (28.2%) biliary drainage in patient with pancreatic or duodenal neoplasm and papilla of Vater unreachable by ERCP. All stents were successfully positioned. Twenty-six stents were placed transgastric, 13 transduodenal. The stent diameter was 6 mm in 5 patients, 8 mm in 3 patients, 10 mm in 14 patients and 15 in the remaining 17 patients. All patients were treated under deep sedation with propofol, with the linear array Olympus GF-UCT-180 series echoendoscopes, in a single step fluoroless procedure. The mean duration of EUS interventional procedure was 22.3 minutes (ranging for 7 to 50). Three (7.7%) adverse events were observed (one self-limited intra-procedural bleeding during gallbladder drainage and two late re-infections of necrosis in pancreatic collection drainage). There were no major complication. The mean duration of time for stent placement was 3.2 minutes (ranging for 1 to 15). Stent removal was safely performed in 9 out 18 patients treated for PFC, after a median of 3.8 months. No complications occurred during stent removal. Biliary and gallbladder stent were permanently positioned and therefore were not removed. Clinical success was observed in all patients.
**Conclusion:** To the best of our knowledge, this is the first comprehensive analysis of feasibility, safety and efficacy of EUS-guided drainages with new lumen-apposing metal stent (Hot-AXIOS$^{TM}$ system) for multiple indications. Up to now, transmural drainages were performed with devices borrowed from ERCO and not specifically designed for interventional EUS. The availability of new devices, such as Hot-AXIOS$^{TM}$, developed for interventional EUS could significantly change the technical approach of these procedures, allowing an easier, quicker and safer procedures with high technical and clinical success rates. Our results will have to be confirmed by multicenter controlled studies with large populations.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0764 LONG-TERM OUTCOMES OF A NEWLY DEVELOPED HYBRID METAL STENT FOR ENDOSCOPIC ULTRASOUND–GUIDED BILIARY DRAINAGE

**D.H. Cho**, S.S. Lee, D. Oh, T.J. Song, D.H. Park, D. Seo, S.K. Lee, M. Kim
*Gastroenterology, Asan Medical Center, Seoul/Korea, Republic of*

**Contact E-mail Address:** dhcho81@daum.net
**Introduction:** Endoscopic ultrasound–guided biliary drainage (EUS-BD) has been proposed as an alternative in patients whom endoscopic retrograde cholangiopancreatography (ERCP) has failed. Although a fully covered self-expandable metal stent (FCSEMS) has been commonly used for EUS-BD, but migration of the FCSEMS is one of the main limitations of this procedure.
**Aims & Methods:** In the present study, we evaluated the technical and clinical success rate, adverse events and long-term outcomes of the newly developed hybrid stents customized for EUS-BD. From September 2011 to May 2015, a total of 54 consecutive patients with biliary obstruction who were candidates for an alternative technique for biliary drainage because of failed ERCP were enrolled. We conducted a prospective observational study.
**Results:** EUS-guided hepaticogastrostomy (EUS-HGS) was performed in 21 patients, and EUS-guided choledochoduodenostomy (EUS-CDS) was performed in 33 patients. The technical success rate of EUS-BD was 100% (54/54), while the clinical success rate was 94.4% (51/54). Immediate adverse events developed after EUS-BD in 9 patients (16.6%; cholangitis (n = 3), bleeding (n = 2), self-limited pneumoperitoneum (n = 3), and abdominal pain (n = 1)). During the follow-up period (median 143, IQR: 80–239 days), proximal or distal stent migration was not observed, and the mean stent patency duration was 166.3 days in EUS-HGS and 329.1 days in EUS-CDS group, respectively.
**Conclusion:** EUS-BD with the hybrid metal stent is technically feasible and can be an effective treatment for biliary obstruction after failed ERCP. Hybrid metal stents may be used safely in EUS-BD and it can reduce stent-related adverse events, especially stent migrations.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0765 THE ACTUAL IMPACT OF PREOPERATIVE BILIARY DRAINAGE ON POSTOPERATIVE OUTCOME: ANALYSIS OF 1000 CONSECUTIVE PANCREATICODUODENECTOMIES

**Introduction:** Patients with periampullary neoplasms frequently present with obstructive jaundice. Bile obstruction may lead to hepatic dysfunction, coagulation disorders, cholangitis and hepatotoxicity. In the attempt to palliate symptoms and systemic disorders associated with hyperbilirubinemia, a preoperative biliary drain (PBD) is often performed. Several studies have revealed that PBD decreases postoperative mortality and morbidity rates compared to jaundiced patients. However, other studies argued that PBD increases surgical site infection, major surgical complications and mortality rates. Although PBD has been routinely conducted to ensure safe anesthesia and operation, the beneficial effects of PBD remain uncertain. In addition, even when PBD is performed, the selection of either a plastic or a metal stent remains controversial and its prognostic impact on long-term survival is still unknown.
**Aims & Methods:** The aim of this study was to examine the impact of preoperative jaundice and PBD on complications following pancreaticoduodenectomy (PD). We retrospectively analyzed 1000 consecutive patients who underwent PD at our Institution from 2005 to 2014. The population was divided into three groups based on PBD (SG), preoperative jaundice without PBD (JG) and control group (CG).
**Results:** The overall postoperative morbidity and mortality were 60% and 1.9%, respectively. A comparison among the three groups and within CG and SG showed a significantly higher morbidity rate in SG ($p = 0.019$;OR 1.2 and $p = 0.007$;OR 1.2, respectively). No difference was found in the mortality rate. Overall, major complications (Clavien-Dindo $\geq$ III) occurred in 22.7% of patients, with a significantly higher rate in SG (compared to CG, $p = 0.010$; OR 0.8). Abdominal abscess, sepsis and wound infection were found significantly higher in SG ($p < 0.05$). Within the JG a preoperative bilirubin cut-off value of 4 mg/dl seems to predict a worse postoperative outcome: morbidity rate ($p = 0.027$ OR 1.9), grade C fistula ($p = 0.011$ OR 0.8), length of stay ($p = 0.032$ OR 1.0) and reoperation ($p = 0.002$ OR 5.5) rates were significantly higher with preoperative levels greater than 4 mg/dl. There was no significant difference on morbidity and mortality rates in SG and JG patients with Bilirubin levels $\geq$ 4 mg/dl, however the latters showed a higher rate of reoperations ($p < 0.001$ OR 1.5).
**Conclusion:** Obstructive jaundice is one of the commonest symptoms in patients with periampullary tumors. Despite theoretical advantages, the use of PBD remains controversial because it has failed to show an actual clinical benefit, suggesting, on the contrary, an adverse impact on perioperative outcome. Our study demonstrates that stented patients have higher morbidity rate and major complications than controls. Instead, there was not significant difference in morbidity, major complications, and mortality rates between JG and SG. We showed that the PBD does not increase major complications in PD, but resulted in a significant increase in the risk of postoperative infectious complications and wound infections. We also confirm previous findings that a preoperative bilirubin cut-off value of 4 mg/dl in non-stented patients seems to best predict postoperative outcome. We did not find differences between SG and JG patients with Bilirubin levels $\geq$4 mg/dl in morbidity and mortality rates, major complications and lenght of stay between the groups. However, there was a statically significant difference in wound infection and reoperation rate. PBD is associated with infectious complications, so we propose that intraoperative bile cultures should be routinely obtained during PD to tailor antibiotic therapy in case of infectious complications. Patients with preoperative Bilirubin levels $\geq$4 mg/dl should be evaluated for a PBD in order to reduce the complications related to jaundice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** In patients with distal malignant biliary obstruction and concomitant duodenal obstruction, biliary endoscopic palliation can be obtained by EUS-guided biliary drainage either before or after duodenal stent placement. Novel cautery-tipped lumen apposing metal stent (LAMS) have been recently developed for this purpose.
**Aim**: We evaluate the technical success and clinical efficacy of EUS-guided biliary drainage and duodenal stenting performed in a single session in patients with unreachable papilla due to malignant duodenal obstruction.
**Methods**: Retrospective analysis of a prospectively maintained data base aimed to evaluate the technical success (defined as correct positioning of the stent) of the new single session approach. We included 5 consecutive patients referred for malignancy involving both the duodenum and the bile duct. Four were affected by unresectable pancreatic cancer (3M/1 F, mean age 63.8 y) and one by duodenal adenocarcinoma (1 M, 53 y) referred for endoscopic palliation.
**Results:** All the patients were treated with a new single session sequential approach by deployment of LAMS and duodenal stent after failed ERCP. During procedures, patients were deeply sedated with propofol under and carbon dioxide insufflation was used. The linear array Olympus GF-UCT-180 series echoendoscopes at 5–10 MHz in combination with the echoprocessor EU-ME2 were used. Under EUS-guidance, the biliary duct was punctured from the duodenal bulb and hot-axios stent was deployed in a fuoroless and wireless manner. Afterward, the duodenal stent was placed under fluoroscopic during the same section. The procedures were well tolerated; the whole mean procedural time was $45 \pm 5.7$ min (range 38–52 min) and $19 \pm 0.8$ min (range 18–20) for EUS-CDS. All patients had clinical resolution of their jaundice within the first week and started their oral intake the day after the procedure. Overall technical success rate for both EUS-guided choledochoduodenostomy and duodenal stenting was 100%. There were no procedure-related adverse events. Clinical success rate was 100% with mean follow up of 3 months (SD 1.3 m).
**Conclusion:** When a transpapillary biliary drainage is not feasible, EUS-CDS may provide an alternative biliary drainage route away from both duodenal and biliary obstruction. The introduction of specific stent designed for transluminal endoscopic intervention such as LAMS minimizes the risk of bile leakage and stent migration and makes the transmural approach potentially more effective and safe. Single session approach for biliary and duodenal obstruction palliation, using cautery-assisted LAMS, could be proposed as safely and effectively technique in patients with unreachable papilla due to malignant obstruction.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0767 EUS-ASSISTED CHOLEDOCHODUODENOSTOMY WITH METAL STENTS FOR PATIENTS WITH MALIGNANT BILIARY OBSTRUCTION: A COMPARATIVE ANALYSIS OF OUTCOMES BETWEEN TUBULAR AND LUMEN-APPOSING STENTS

**C. De La Serna Higuera**, R. Sanchez-Ocana, I. Peñas-Herrero, P. Gil-Simon, P. Diez-Redondo, V. Busto, R. Amo Alonso, M. Pérez-Miranda

**Contact E-mail Address:** csernah@hotmail.com
**Introduction:** EUS-guided biliary drainage with tubular (plastic or metal) stents is the standard approach for patients with malignant biliary obstruction (MBO) unfit for surgery after failed or unfeasible ERCP. Choledochoduodenostomy (CD) with tubular self-expanding metal stents (tSEMS) have some drawbacks such as migration, shortening, bile leakage or cholecystitis secondary to blockade of cystic duct: all of them could be prevented by means of lumen-apposing metal stents (LAMS). However, LAMS insertion in this setting is technically demanding because of angulation of echoendoscope tip at duodenal bulb and the narrow caliber of biliary lumen. We aimed at comparing efectiveness, safety and technical feasibility between both techniques in a consecutive series of MBO patients.
**Aims & Methods:** Retrospective review of a prospectively maIntained database including all MBO patients who underwent EUS-guided choledochoduodenostomy. Patients receiving full-covered tSEMS (10 x 60 mm) were matched with those drained with LAMS (AXIOS$^{TM}$, Xlumena, CA, USA: 10 x 10 mm & 6 x 8 mm; conventional 'cold' and electrocautery-equipped -'hot'- LAMS) and compared according to sex, age, ASA score, etiology,overall survival time, technical & clinical success and rate of adverse events. Technical success: Stent deployment in the correct position. Clinical success: decrease in bilirubin concentration to less than 50% of the preprocedure values. Statistical analysis was carried using SPSS v 17.0 and results compared by Student's t test for continuos variables and $\chi^2$ test/ Fisher's exact test for categorical variables. P values $\leq 0.05$ were considered significant.
**Results:** 25 patients were included: tSEMS vs LAMS = 13: 12. LAMS Ø 6 mm / 10 mm: 10/2 pts, Hot-LAMS: 6 pts. Inclusion period: tSEMS: Oct'10–Nov'14; LAMS: March'12–Nov'15. Mean follow-up (days): tSEMS/LAMS: 138.2 (20–283) / 116.5 (6–342). No differences were observed with regard to age, sex, ASA score, overall survival time and etiology of malignance. There were neither significant differences tSEMS/LAMS referred to: 1.-Technical success rate: 12/13 (92.30%) vs 11/12 (91.66%); $p = 0.25$, 2.- Clinical success: 11/13 (84.61%) vs 10/12 (83.33%); $p = 0.19$, 3.-Adverse events :2/13 (15.38%) vs 2/12 (16.6%) $p = 0.116$. Adverse events: tSEMS: Early: Biliary duct perforation. Late: acute cholecystitis. LAMS: Early: scant biliay leak, dislodgement of distal flange with rescue by coaxial insertion of a plastic stent. There were no clinical data of stent dysfunction in either group.
**Conclusion:** EUS-guided CD with LAMS appears to provide a highly safe and effective procedure with quite similar results than tSEMS for drainage of malignant biliary obstruction. Further larger, prospective and randomized studies are needed.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0768 EFFICACY AND SAFETY OF ENDOSCOPIC-ULTRASOUND GUIDED BILIARY DRAINAGE; AN UPDATE META-ANALYSIS

**A. Hedjoudje**[1], A. Sportes[2], S. Koch[1], L. Vuitton[1], F. Prat[3]

**Introduction:** Success and event rate of EUS-guided biliary drainage varies with techniques and results from different studies remain inconsistent. We conducted a proportion meta-analysis to evaluate efficacy and safety of EUS-guided biliary drainage and to compare the different procedures and biliary access route.
**Aims & Methods:** We searched MEDLINE, EMBASE,COCHRANE and SCOPUS to identify studies reporting technical success, clinical success and complcation rate of EUS-guided biliary drainage technique with a sample size greater than 5 patients. Weighted pooled rate and 95% confident interval were calculated to estimate clinical effectiveness and safety of EUS-guided biliary drainage procedure.
**Results:** We identified 49 studies with a total of 885 patients (371 choledocho-duodenostomies, 249 hepaticogastrostomies and 336 rendez-vous technique). The overall technical success rate, clinical success rate and complications rate with 95% confidence interval were 88% (83%–91%), 92% (89–94%) and 21% (18–25%) respectively with no publication bias ($p = 0.326$, $p = 0.903$ and $p = 0.203$ respectively). There was no difference in technical and clinical success rate using either intra-hepatic or extra-hepatic approach (OR = 0.98[0.93–1.03] and OR = 0.99[0.90–1.09] respectively).
**Conclusion:** EUS-guided biliary drainage appears to be an effective treatment when ERCP fails with a high success rate and acceptable adverse event rate. There was no significant difference between the intra-hepatic or extra-hepatic approaches. Prospective randomized controlled studies are required to further evaluate the difference between the 2 approaches.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0769 NEWLY DEVELOPED FLOWER-TYPE COVERED SELF-EXPANDABLE METAL STENT FOR PREVENTING CHOLECYSTITIS AND PANCREATITIS: PHYSICAL PROPERTIES

**J.K. Lee**[1], J. Yang[1], J.K. Park[1], K.H. Lee[2], K.T. Lee[3], S. Kang[4]

**Contact E-mail Address:** jongk.lee@samsung.com
**Introduction:** The conventional, cylindrical fully covered self expandable metallic stent (C-CSEMS) has its limitations with high risks of blocking the cystic duct, and the branches of pancreatic ducts in accordance with the stent design and the properties of the covered materials. The need for a new stent design was indispensable, such as a flower type, five-petal shaped design with side grooves, fully covered self-expandable metallic stent (F-CSEMS).
**Aims & Methods:** A comparison study regarding the experimental results for the physical properties accomplished with a conventional e-PTFE covered self-expandable metallic stent (C-CSEMS) and the newly developed flower-type e-PTFE covered self-expandable metallic stent (F-CSEMS). The physical experimental study was performed in between the conventional cylindrical type covered stent and the newly developed flower-type covered stent with the same specification of 8 mm in diameter, 12.5 cm in length, e-PTFE covered material with the cell size of the 2 mm. The main comparison was based on the following factors: flexibility using banding test, shortening rate by loading the stent into the 8Fr. Delivery system and the drainage rate by measuring drained amount of water in 5 minutes.
**Results:** The flexibility was measured through the bending test and the result for F-CSEMS was 0.41 N where as the C-CSEMS was 0.65 N. The fact that F-CSEMS has more flexibility as compared to the C-CSEMS has been proven since the less force it needs for banding the better flexibility it gives. As per the shortening rate, the F-CSEMS stent with the length of 12.5 cm has been loaded into the 8Fr. Delivery system and the final length inside the delivery system was measured as 15 cm. The same length of C-CSEMS has been loaded into the same

8Fr. Delivery system and the final length was approximately 17.9 cm. Therefore, the shortening rate for F-CSEMS was determined as low as 20% where as the C-CSEMS was determined as 30%. The drainage test was performed by draining water outside the stent in a cylindrical tube with the 8 mm of inner diameter and measuring the amount of water that it got drained in 5 minutes. The F-CSEMS drained 100 ml of water through the grooves on the outside of the stent where as the C-CSEMS could not drain anything at all for the whole time.
**Conclusion:** The newly developed flower-type covered self-expandable metal stent has been proved to have more flexibility with less shortening rate of 20% as well as the full drainage of liquid through the special grooves formed outside of the stent design. The animal test has been already done in 2014 and the clinical test will be needed.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0770 RISK FACTORS FOR POSTPROCEDURAL PANCREATITIS AFTER ENDOSCOPIC PAPILLECTOMY

**S.J. Yeo**, C. Cho, J. Heo, M.K. Jung, K.J. Kim, M.H. Kim
*Division Of Gastroenterology And Hepatology, Dept. Of Internal Medicine, Kyungpook National University Medical Center, Daegu/Korea, Republic of*

**Contact E-mail Address:** sekj319@hanmail.net
**Introduction:** Endoscopic papillectomy (EP) is increasingly used as an alternative to surgery for ampullary adenomas and other noninvasive lesions. However, it remains controversial as to which factors were associated with post-papillectomy pancreatitis.
**Aims & Methods:** The aim of this study is to analyze the rates of complications after EP, with a particular emphasis on risk factors associated with pancreatitis, especially endoscopic pancreatic sphincterotomy (EPS) and pancreatic stent insertion. We conducted a retrospective cohort study of all patients who underwent attempted endoscopic papillectomy for known or suspected ampullary tumors between July 2003 and March 2016. Through reviewing procedure reports and medical records, variables for patients and procedures were compared between cases with and without pancreatitis.
**Results:** Endoscopic papillectomy was performed in 93 patients with histological findings of low-grade dysplasia (41.9%), high-grade dysplasia (19.3%), carcinoma (22.6%), and others (18.3%). The rate of post-papillectomy pancreatitis was 10.7% (10/93). In this study, we compared with the categories, no additional procedure versus EPS and no additional procedure versus pancreatic stent insertion and EPS versus pancreatic stent insertion. There was no statistically significant difference in incidence rate of pancreatitis among those three groups, indicating no difference for each method to prevent the complication post-papillectomy pancreatitis ($P = 0.068$) In addition, age, sex, pathologic size, comorbidity, and the resection type were not statistically associated with post-papillectomy pancreatitis.
**Conclusion:** After papillectomy, pancreatic stent insertion ofwith endoscopic pancreatic sphincterotomy may not be effective to prevent post-papillectomy pancreatitis. Further prospective study is needed to confirm this result.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0771 OUTCOMES AND TECHNICAL METHODS OF ENDOSCOPIC THERAPY FOR ACUTE CHOLECYSTITIS IN OUR HOSPITAL

**T. Fujimori**[1], H. Kamada[1], T. Yamashita[1], K. Kobayashi[1], K. Kato[2], T. Masaki[1]
[1]*Gastroenterology And Neurology, Kagawa University, Miki-cho,Kita-gun,Kagawa Prefecture/Japan*
[2]*Kagawa University, Kagawa/Japan*

**Contact E-mail Address:** sannai@med.kagawa-u.ac.jp
**Introduction:** Cholecystectomy is the standard treatment for acute cholecystitis, while in case of increased operative risk, surgery may be postponed or rejected. In such a case, percutaneous or endoscopic gallbladder drainage may be attempted. When percutameous drainage is difficult such as the cases with anticoagulant therapy or anatomical reason, we have performed endoscopic drainage (ETGBS(endoscopic transpapillary gallbladder stent) or ETGBD(endoscopic transpapillary gallbladder drainage) with ETCG(endoscopic transpapillary catheterization into the gallbladder). The aim of the study was to assess the success rate and clinical efficacy,and some technical methods of endoscopic gallbladder drainage in patients with acute cholecystitis.
**Aims & Methods:** A total 36 consecutive patients with acute cholecystitis who received endoscopic drainage between April 2006 and March 2016 were enrolled in the present retrospective study. The technical success rate, clinical success rate, and adverse events rate were evaluated. Technique of ETCG After successful bile duct cannulation, a 0.025 or 0.032-inch guidewire is advanced into the cystic duct and subsequently into gallbladder. (In the lower branch type of cystic duct, seeking of cystic duct is difficult because guidewire is easily bounced to the hepatic side. ENBD tube is useful by fixing pig-tail above the bifurcation) Then catheter is advanced into gallbladder, guidewire is exchanged to the stiff type. Finally, nasobigallbladder drainage tube or stent is placed.
**Results:** The technical success raet was 94%(34/36) and clinical success rate was 100%(34/34). Adverse events rate was 11.1%(4/36:acute pancreatitis(not severe) in 3 cases and injury of cystic duct in 1 case).
**Conclusion:** Ebdoscopic gallbladder drainage with ETCG technique is safe and effective to treat acute cholecystitis with patients who are unsuitable for cholecystectomy or percutaneous drainage. ETCG with ENBD tube is useful especially in the lower branch type of cystic duct.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The number of patients undergoing bariatric surgical procedures is clearly increasing over the last years due to the increasing prevalence of obesity in the general population. Different bariatric surgical procedures are carried out in obese patients, among them gastric sleeve, gastric bypass and duodenal switch. Gastric and duodenal anatomical changes secondary to these procedures may lead to important disturbances in the digestion and absorption processes. The dynamic of the digestive process may be evaluated by the 13 C-MTG breath test
**Aims & Methods:** Aim of our study was to evaluate the digestive function after different bariatric surgical procedures. Methods: A prospective, cross-sectional study was designed. Patients who underwent any bariatric surgical procedure, gastric sleeve, gastric bypass or duodenal switch, were included. Digestive function was evaluated the 13 C-MTG breath test as previously optimized by our group. The dynamic of the digestive process was defined by the cumulative 13CO2 recovery rate (CRR %), the time to 13 C exhalation peak and the curve of 13CO2 exhalation (% digestion from 0–2, 2–4 and 4–6 hours after meal). Data are shown as median and interquartile range and analysed by the Kruskal Wallis and U-Mann Whitney tests. Sample size was calculated and a total of 90 patients should be included.
**Results:** A total of 94 patients were finally included. 35 patients underwent duodenal switch (49 years, range 29–68, 28 female), 36 gastric bypass (52 years, range 28–68, 28 female) and 23 gastric sleeve (51 years, range 22–70, 19 female). The ability to digest food was quantitatively lower after duodenal switch (CCR $29.02 \pm 21.19\%$) than after gastric bypass (CCR $43.75 \pm 9.02\%$) or gastric sleeve (CCR $49.05 \pm 14.04\%$) ($p < 0.01$). Absorption peak was markedly delayed after duodenal switch (13CO2 exhalation peak at 330 min), compared to gastric bypass (150 min) and gastric sleeve (105 min). In accordance with this, nutrients are digested and absorbed late (4–6 hours after meal ingestion) after duodenal switch, intermediate after gastric bypass (2–4 hours after meal ingestion) and early after gastric sleeve (0–2 hours after meal ingestion) ($p < 0.01$).
**Conclusion:** Significant pathophysiological changes in the processes of digestion and absorption of nutrients are described according to particular bariatric surgical procedures. Duodenal switch alters digestive process more than any other procedure. Compared to gastric bypass, gastric sleeve does not affect digestive function significantly. Whether these differences have an impact on the nutritional status, digestive symptoms, quality of life and long-term morbidity after bariatric surgery deserves further studies.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0773 DIFFERENCES IN SURVIVAL AFTER CURATIVE R0-RESECTION FOR KOREAN AND GERMAN GASTRIC CANCER PATIENTS: RESULTS FROM A PROPENSITY SCORE MATCHED ANALYSIS

**D. Reim**[1], Y.W. Kim[2]
[1]*Department Of Surgery, Klinikum Rechts der Isar der TU Muenchen, Munich/Germany*
[2]*Center For Gastric Cancer, National Cancer Center Korea, Goyang/Korea, Republic of*

**Contact E-mail Address:** daniel.reim@tum.de

**Introduction:** Several retrospective analyses on patients undergoing gastric cancer surgery revealed different survival outcomes between Eastern (Korean, Japanese) and Western (USA, Europe) countries. The reasons remain elusive to date and not only ethnical but also and biological differences were proposed in the past. This propensity score matched analysis investigates surgical and oncologic outcomes between two specialized institutions for gastric cancer in Korea and Germany.

**Aims & Methods:** The local prospectively documented databases were screened for patients undergoing curative (R0,M0) primary surgical resection for gastric cancer between 2002 and 2008. Baseline characteristics were compared using $\chi 2$ testing, and two cohorts were matched using a propensity score matching (PSM). Patients' survival was estimated using Kaplan-Meier methods, and multivariable Cox proportional hazard model was used for comparison of survival outcomes.

**Results:** 3563 from Korea and 275 from Germanywere included in the final analysis. Baseline characteristics demonstrated statistically significant differences for age, tumor-location, pT stage, grading, lymphatic vessel infiltration (LVI), comorbidities, number of dissected lymph-nodes (LN), postoperative complications, lymph-node ratio stage and application of adjuvant chemotherapy. After propensity-score-matching (PSM), 215 patients from the German cohort were matched to Korean patients leading to balanced baseline characteristics for both cohorts. Korean patients demonstrated significantly longer survival than those in Germany both before and after PSM. After stratification for each UICC-stage the same trend was detected in any of the the UICC-stages. However, significant survival differences could be detected only for UICC III after PSM.

**Conclusion:** Differences in overall survival between Korean and German gastric cancer patients persist after balancing for possible confounders by propensity score matching.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0774 PERIOPERATIVE TRANSFUSION OF BLOOD PRODUCTS IN GASTRIC CANCER PATIENTS NEGATIVELY INFLUENCES ONCOLOGIC OUTCOME – A RETROSPECTIVE PROPENSITY SCORE WEIGHTED ANALYSIS

**D. Reim**, A. Novotny
*Department Of Surgery, Klinikum Rechts der Isar der TU Muenchen, Munich/Germany*

**Contact E-mail Address:** daniel.reim@tum.de

**Introduction:** The influence of perioperative transfusion (PT) on outcome following surgery for gastric cancer remains controversial, with randomized trials lacking and observational series confounded by patient risk factors.

**Aims & Methods:** Data from 610 patients who underwent curative surgery for gastric cancer(R0/M0) in a German Univeristy hospital from 2001 to 2013 were included. Kaplan-Meier survival curves and Cox proportional hazards regression were applied to determine the association of PT and clinical and patient risk factors for overall and relapse-free survival. Propensity score analysis was performed to adjust for observational biases in reception of PT.

**Results:** Higher UICC/AJCC-stages ($p < 0.001$), postoperative complications and severity according to the Clavien-Dindo-classification ($p < 0.001$), perioperative blood transfusion (PT) ($p = 0.02$), higher age ($p < 0.001$) and neoadjuvant chemotherapy ($p < 0.001$) were related to increased mortality rates. Higher UICC-stages ($p < 0.001$), neoadjuvant chemotherapy ($p < 0.001$) and type of surgery ($p = 0.02$) were independently associated with increased relapse-rates. Patients were more likely to receive PT with higher age ($p = 0.05$), surgical extension to adjacent organs/structures ($p = 0.002$), tumor-location ($p = 0.003$) and female gender ($p = 0.03$). In the adjusted propensity score weighted analysis, PT remained associated with an increased risk of death (HR: 1.30, 95%CI: 1.01–1.68, $p = 0.04$).

**Conclusion:** Due to a potential independent association of perioperative blood transfusions with negative influence on patient survival following oncologic resection, application of blood products should be considered carefully in gastric cancer patients.

**Introduction:** The supraclavicular lymph nodes metastasis has been recognized as distant lymph nodes metastases (M1 LYM) according to UICC 7th.

**Aims & Methods:** The aim of this study is to investigate the usefulness of esophagectomy in patients with supraclavicular lymph nodes metastasis. Two hundred eighty-two patients, who underwent R0 esophagectomy for thoracic esophageal squamous cell carcinoma between 1996 and 2012, were analyzed by univariate and multivariate analysis. The median follow-up duration was 62 (range from 3 to 239) months.

**Results:** There were 252 males and 30 females, with a median age of 63 years (range 39–87 years). Of the 282 patients, 90 (32%) had pT1 cancer, 46 (16%) had pT2 cancer, 134 (48%) had pT3 cancer, and 12 (4%) had pT4 cancer. The number of patients at N status N0/N1/N2/N3 were 107 (38%)/ 87 (31%)/ 61 (22%)/ 27 (9%). Twenty-three patients (7%) had supraclavicular lymph nodes metastasis (M1 LYM). Three-field lymphadenectomy was performed in 173 (61%) patients and Two-field lymphadenectomy was performed in 109 (39%) patients. The median number of resected lymph nodes was 60 (range, 16–151). The overall 5- and 10-year survival rates in all patients were 59% and 44%, respectively. By univariate analysis, gender (male; $p = 0.0032$), post operative complication (absent; $p = 0.0433$),the depth of tumor invasion (pT1,T2; $p < 0.0001$), lymph nodes metastasis (absent; $p < 0.0001$), histopathological grading (G1; $p < 0.0001$), lymphovascular invasion (absent; $p < 0.0001$), tumor length (6 cm $\geq$; $p = 0.0407$), and the number of resected lymph nodes ($\geq$60; $p = 0.0092$) were associated with improved survival. The 5-year survival rate of patients with supraclavicular lymph nodes metastasis was 43%, compared to 61% those without supraclavicular lymph nodes metastasis ($p = 0.0707$). Supraclavicular lymph nodes metastasis did not significantly affect survival. In multivariate analysis, gender (female vs. male: hazard ratio 0.435; 95% confidence interval 0.195–0.835; $p = 0.0102$), post operative complication (absent vs. present: hazard ratio 0.615; 95% confidence interval 0.434–0.863; $p = 0.0047$), the depth of tumor invasion (pT1,T2 vs. pT3,T4: hazard ratio 0.420; 95% confidence interval 0.280–0.622; $p < 0.0001$), lymph nodes metastasis (absent vs. present: hazard ratio 0.596; 95% confidence interval 0.401–0.870; $p = 0.0069$), histopathological grading (G1 vs G2,G3: hazard ratio 0.494; 95% confidence interval 0.341–0.702; $p < 0.0001$), the number of resected lymph nodes ($\geq$60 vs 60$>$: hazard ratio 0.558; 95% confidence interval 0.398–0.777; $p = 0.0005$) were found to be independent prognostic factors. In patients with supraclavicular lymph nodes metastasis, tumor length (8 cm vs. $\geq$8 cm; hazard ratio 0.300; 95% confidence interval 0.092–0.851; $p = 0.0232$), the number of lymph nodes metastasis (3$\geq$ vs. $\geq$4: hazard ratio 0.357; 95% confidence interval 0.112–0.984; $p = 0.0464$) were found to be prognostic factors.

**Conclusion:** Our findings suggest that esophagectomy may be effective some patients with the supraclavicular lymph nodes metastasis, in particular the number of lymph nodes metastasis is 3 or less, or the tumor length is less than 8 cm.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0776 FEASIBILITY AND EFFICACY OF MODIFIED PERORAL ENDOSCOPIC MYOTOMY (LIU-POEM) IN PATIENTS WITH ACHALASIA: A RETROSPECTIVE COMPARISON STUDY

**B. Liu**[1], Y. Guang[2], J. Song[1]

**Contact E-mail Address:** 13704510648@126.com

**Introduction:** Esophageal achalasia is a primary motility disorder involving absence of esophageal peristalsis, failure of the lower esophageal sphincter (LES) to relax, and cardiac diastolic dysfunction. Peroral endoscopic myotomy (POEM) has emerged as one approach to treating esophageal achalasia. Although POEM is credited with high success rates in the treatment of achalasia, the submucosal tunneling is time consuming and commonly requires one-third to two-third of the total operation time. For improvement of POEM procedure, we modified the POEM procedure by limiting myotomy and tunnellization into one step. We named this modified peroral endoscopic myotomy Liu-POEM.

**Aim** To compare Liu-POEM and conventional POEM for the treatment of achalasia, analyze the clinical outcomes of each method, and evaluate the feasibility and efficacy of Liu-POEM.

**Methods** 30 patients with achalasia were included in the Liu-POEM group, and 30 patients were included in the conventional POEM group retrospectively. The clinical characteristics, therapeutic success, procedure-related parameters and adverse events were compared.

**Results:** Liu-POEM was successful in all. Meanoperation time of conventional POEM was 51.2 min (range 24–119 min) and Liu-POEM was 27.2 min (range 15–62 min). The different operation times were statistically significant ($p < 0.001$). Length of myotomy in POEM group was 9.9 cm and the other group was 8.6 cm ($p = 0.054$). The mean number of mucosotomy-closure clips are 12 and 10 using in POEM and Liu POEM procedure respectively ($p = 0.006$). The symptom remission rates were 100% in boths groups. Their Eckardt scores were less than 3. Only 3 patients in POEM groups sufferred mild subcutaneous emphysema, but they recover without any special treatment in one day.

**Conclusion:** Liu POEM and POEM for the treatment of achalasia has the same therapeutic effect. Liu POEM leads to a significant decrease in POEM procedure time and possibly contributing to a lower rate of complications. Further studies have to confirm this.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The most common and the most severe complication to a distal pancreatic resection is the forming of a postoperative pancreatic fistula (POPF). A frequency of 30–60% has been reported. To reduce the frequency of POPF the use of somatostatin, dividing pancreas with a stapler, suturing and/or covering the remaining part of the cut pancreas with glue have all been assessed in trials without any of the methods showing superiority. In previous studies, the combination of stapling technique and resorbable staple line reinforcement has shown both positive and negative influence on POPF frequency. The present study is a prospective, randomized, controlled multicentre trial (RCT) comparing reinforcement with resorbable mesh (The Biodesign™ Surgisis® staple reinforcement, COOK® Medical) or not at the site of stapling division of the pancreas in distal pancreatic resection.

**Aims & Methods:** Patients planned for open or laparoscopic distal pancreatic resection with or without splenectomy, at four Swedish tertiary referral centres, were informed about the study. On accepting to participate they were randomized peroperatively, after confirming that resection could take place, to either reinforcement or not at the division site. Primary outcome was a pancreatic fistula or leakage, in accordance with the definition of a pancreatic fistula made by ISGPF's (International study group of pancreatic fistula), and the number of days to healing/drain evacuation.

**Results:** 105 patients (51 female/54 male) aged 62.9 (28–89), ASA 2 (median) were randomized to either reinforcement (54) or no reinforcement (51) on the stapler instrument dividing the pancreas. In the group with reinforcement 22.2% of the patients developed a fistula (12/54) and in the group without reinforcement 39.2% (20/51) developed a fistula ($p = 0.043$). Once a fistula had occurred there was no difference in healing time/ days to drain removal between the groups.

**Conclusion:** Reinforcing the stapler line with a resorbable mesh when performing a distal pancreatic resection results in a reduced risk of developing a POPF.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0778 RISK-BASED PATIENT SELECTION IN OPEN AND MINIMALLY-INVASIVE DISTAL PANCREATECTOMY: AN ACS-NSQIP STUDY

**Introduction:** Patient selection criteria which optimize outcomes after minimally invasive distal pancreatectomy [MIDP] remain unknown. As a result, widespread adoption of this surgical technique has been delayed with resulting misallocation of its potential benefits. Our two aims were to assess current case selection factors for MIDP and to identify actual risk factors for adverse outcomes compared to open distal pancreatectomy [ODP].

**Aims & Methods:** Retrospective cohort study of elective ODP versus MIDP, using the pancreas-targeted database of the American College of Surgeons National Surgical Quality Improvement Program® (ACS-NSQIP®), collected at 106 participating centers in 2014. Excluded were patients requiring neoadjuvant treatment or having pancreatitis as only diagnosis. The primary outcome was a composite major morbidity metric, reflecting major surgical and medical complications, including extended length of stay, reoperation, and death. Two multivariable models were used to detect currently applied selection factors and to determine actual independent risk factors of composite major morbidity, adjusting for baseline differences and incorporating approach interactions.

**Results:**

**Table:** Perioperative and postoperative outcomes, unmatched cohorts.

| | ODP (472) | MIDP (456) | P-Value |
|---|---|---|---|
| Operative time, median (i.q.r.), min. | 199 (156–266) | 215.5 (162–275) | .166 |
| Multivisceral procedure, No. (%) | 95 (20.1%) | 40 (8.8%) | <.001 |
| Blood transfusion for bleeding (<72 hrs), No. (%) | 65 (13.8%) | 23 (5.0%) | <.001 |
| Mortality within 30-days, No. (%) | 5 (1.1%) | 3 (0.7%) | .508 |
| Unplanned reoperation, No. (%) | 13 (2.8%) | 7 (1.5%) | .201 |
| Length of say, median (i.q.r.), days | 6 (5–7) | 5 (4–6) | <.001 |
| Unplanned readmission, No. (%) | 85 (18.0%) | 52 (11.5%) | .005 |
| Composite major morbidity*, No. (%) | 111 (23.5%) | 61 (13.4%) | <.001 |

In total, 928 patients underwent ODP (472) or MIDP (456) using a laparoscopic or robotic approach. Current selection factors for MIDP were presence of benign disease (odds ratio [OR] 1.56, 95 per cent confidence interval [CI] 1.10–2.21) and body-mass-index between 30–40 (OR 1.41, CI 1.04–1.91). Current selection factors against MIDP were pancreatic ductal adenocarcinoma presence (OR 0.45, CI 0.31–0.64), benign tumor size over 5 centimeters (OR 0.40, CI 0.23–0.67), and multivisceral resection (OR 0.39, CI 0.26–0.59). In patients lacking potential risk factors, MIDP was associated with a significantly lower risk of composite major morbidity compared to ODP (OR 0.37, CI 0.14–0.97). Diabetes was the only risk factor which added significantly to the baseline odds of composite morbidity in MIDP compared to ODP (OR 2.55, CI 1.14–5.71; $P = 0.023$).

**Conclusion:** Current patient selection factors for MIDP in the United States do not mitigate the actual odds of postoperative composite major morbidity. Diabetes was the only patient risk factor associated with significant additive risk of composite major morbidity after MIDP compared to ODP. No other risk factors were identified that justify restricting the utilization of a minimally invasive technique to perform distal pancreatectomy. The mechanism behind the impact of diabetes on outcomes after MIDP requires further study.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0779 ROLE OF EXTERNAL JEJUNAL DRAINAGE AND PERIOPERATIVE SERUM ALBUMIN EVALUATION IN PREDICTION AND MANAGEMENT OF PANCREATIC FISTULA

**M. Gruppo**[1], A. Geron[1], F. Zingales[1], B. Martella[1], V. Beltrame[1], I. Angriman[2], R. Bardini[1]

**Contact E-mail Address:** mario.gruppo@unipd.it

**Introduction:** Despite improvements in surgical techniques, instruments and perioperative management, postoperative pancreatic fistula (POPF) remains a serious complication after pancreaticoduodenectomy (PD). The aim of the

present study was to evaluate the potential role of perioperative clinical variables of patients in predicting pancreatic fistula and the impact of external jejunal drainage in management of complications.
**Aims & Methods:** 52 patients underwent PD for pancreas cancer between 2010 and 2015 at our institution. In all cases a Whipple procedure was performed with external drainage tube in the jejunal segment anastomosed to pancreatic stump and hepatic duct. Pancreatic fistula have been assessed according to ISGPF criteria: grade B and C were defined as "POPF". Surgical complications have been graded according to Clavien scale: grade III-IV-V were considered serious complications. Perioperative clinical variables were evaluated and investigated with univariate and multivariate analyses.
**Results:** 12 patients (23.1%) developed Grade B POPF. No Grade C fistulas were detected. Perioperative (within 30days) deceases were 2 (3.8%), both for heart failure. Second surgery was performed on 3 patients (5.7%): 1 for gastrojejunal leak (1.9%), 1 for splenic artery bleeding (1.9%) and 1 for bilioenteric leak (1.9%). 1 patient (1.9%) developed a splenic artery pseudoaneurysm treated with angiographic embolization, 1 patient (1.9%) developd a self-limited gastrointestinal bleeding. At univariate analysis POPF correlated with soft pancreas ($p = 0.02$), low levels of postoperative day (POD) 1 albumin (mean value $20.66 \pm 2.99$ g/L vs $24.79 \pm 4.10$ g/L in patients without POPF; $p = 0.005$) and POD 1 albumin decrease ($16.33 \pm 5.34$ g/L vs $11.31 \pm 5.05$ g/L in patients without POPF; $p = 0.019$). No significant correlations with POPF were demonstrated for age, surgical time and preoperative albumin levels. These data have been confirmed at multivariate analysis (Tab.1). Other serious complications (grade III-V) were correlated with low level of POD 1 albumin (mean $21.70 \pm 3.14$ g/L vs $24.40 \pm 4.08$ in patients without serious complications; $p = 0.015$) and high POD1 albumin decrease (mean $14.45 \pm 5.42$ g/L vs $11.15 \pm 5.39$ in patients without serious complications; $p = 0.037$).

**Table 1:** Multivariate analyses of clinical variables in relation to postoperative pancreatic fistula grade B or C after pancreaticoduodenectomy.

| Parameters | OR | p-Value |
|---|---|---|
| Age | 2.513 | .091 |
| Preoperative Albumine | 1.198 | .311 |
| POD1 Albumin (g/L) | 5.872 | .005 |
| POD1 Albumin Decrease (g/L) | 4.317 | .019 |
| Surgival Time | 1.096 | .342 |
| Pancreas Consistency | 5.402 | .008 |

POD: post-operative day

**Conclusion:** Postoperative pancreatic fistula significantly correlates with postoperative level and decrease of albumin, demonstrating a latent impairment in metabolic and nutritional status of some patients more prone to develop POPF and other major complications. These data suggest a predictive role of nutritional status assessment that could be useful in postoperative management of patients. Furthermore, external jejunal drainage of bilious, pancreatic and intestinal fluid seems to be helpful in prevention of grade C fistulas, reducing morbidity and promoting a conservative management of patients with POPF.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0780 TOTAL PANCREATECTOMY: SHORT-TERM AND LONG-TERM OUTCOMES OF THE APANCREATIC STATE

**Introduction:** Complete pancreatic resection, or Total Pancreatectomy (TP), represents an increasing indication for diffuse pancreatic disease. While several studies have demonstrated that improvements in the perioperative care have decreased short-term morbidity and mortality, only small series have investigated long-term impact of the apancreatic state. With this study we aim to evaluate short-term and long term outcomes following total pancreatectomy. In particular quality of life (QoL) of long term survival patients has been investigated using validated questionnaires with respect to the indication for surgery.
**Aims & Methods:** Patients who underwent TP between 2000 and 2015 at the Department of General and Pancreatic Surgery, Verona University (VU) and at the Department of Hepatobiliary and Pancreatic Surgery, Johns Hopkins University (JHU), were retrospectively identified from prospectively collected databases. Possible risk factors associated with the development of perioperative complications were evaluated using univariate and multivariate regression models. Long-term outcomes were assessed using an original specific survey, and validated QoL questionnaires: Short Formula36 (SF-36), EORTC-PAN26, Audit of Diabetes-Dependent (ADD) QoL. In particular correlation analyses and linear logistic regressions investigated the association between physical (PCS) and mental composites (MCS) at the SF-36 and results at the DD-AWI and at the PAN-26.
**Results:** 329 patients underwent TP at VU and JHU between 2000 and 2015. Postoperative morbidity was 59.3%, 64 (22.4%) patients experienced major surgical complications (Clavien-Dindo grade III-IV) and 17 (5.1%) patients died within 90 days from TP. At multivariate analysis age ($P = 0.014$, OR 1.041, 95% CI 1.008–1.074) and duration of surgery were independent predictors for major complications ($P = 0.008$, OR 1.005, 95% CI 1.001–1.008). 152 patients with more than 12 months of follow up after surgical resection were enrolled in the cross-sectional study. Among them, 94 replied to the questionnaires. The median follow-up from surgery was 63 months (20–109). SF36 reported no difference in the general health perception ($P = 0.069$) and in the body pain ($P = 0.717$) before and after surgery, while PCS and MCS were both significantly reduced (respectively: $P = 0.047$ and $P = 0.019$). At the EORTC-PAN, the most affected symptoms were digestive symptoms (mean 47.6% SD 31.1) and altered bowel habit (mean 42.8% SD 32.2). The ADD-QoL shows that diabetes has a negative impact in the daily life, with an overall average weighted impact score (AWI) of −1.9 (±2.1). Reduced MCS and PCS were correlated with male gender and a higher score at the PAN 26. Linear regression model shows that persistent abdominal pain after TP was negatively associated with the SF-36 PCS and MCS (PCS: ß −0.38, 95% CI −0.80 to −0.1, $P = 0.004$; MCS: ß −0.351, 95% CI −0.7 to −0.11, $P = 0.007$).
**Conclusion:** Short-term outcomes for TP are aceptable. Age and a long time operation are risk factors associated with major complications after surgery. Patient's General Health perception appears not to be affected from surgery, but when specifically investigated both PCS and MCS are downgraded. Diabetes, digestive symptoms and altered bowel habit mainly affect the QoL after surgey, however they do not significantly correlates with PCS and MCS. The persistence of abdominal pain and its intensity after surgery directly correlate with both physical and mental limitations. Control of abdominal pain may significantly improve QoL outcomes after surgery.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0781 SOLID PSEUDOPAPILLARY TUMOURS OF THE PANCREAS: SPECIFIC PATHOLOGICAL FEATURES PREDICT THE LIKELIHOOD OF POSTOPERATIVE RECURRENCE

**Introduction:** Since their introduction in the WHO classification, the incidence of solid pseudopapillary tumours (SPTs) of the pancreas has progressively increased mainly because of the widespread use of cross-sectional imaging. Few recent studies have analysed the biological behaviour of SPTs, but reliable data on long-term follow-up are needed.
**Aims & Methods:** Retrospective analysis of two Institutions with high case-load, The Department of General Surgery – Pancreas Institute, University of Verona Hospital Trust and the Department of General Surgery, Massachusetts General Hospital, Harvard Medical School was carried out. Data from 131 consecutive resections for SPT performed during the last 3 decades were collected and analysed.
**Results: Results** The majority of patients were female (86.3%) with a median age of 33 (7 – 68) years. The prevalent location was the pancreatic tail (33.5%). Applying the WHO criteria, 16 (12.2%) SPTs were considered malignant due to the presence of at least pancreatic parenchyma invasion (9.9%), perineural invasion (4.6%), and/or angiovascular invasion (2.3%). After a median of 62 months after surgery, only two patients had a recurrence (1.5%). Both of them fulfilled the WHO criteria for malignant SPT (vs. 10.7% of those who did not recur, $p = 0.01$), had an infiltrative growth pattern (vs. 10.8%, $p = 0.01$), pancreatic parenchyma invasion (vs. 9.7%, $p = 0.01$) and capsular invasion (vs. 4.9%, $p = 0.004$).
**Conclusion:** Overall, SPTs are associated with excellent survival results after surgical resection. Disease recurrence is extremely rare, and might occur if the primary tumour presents with either pancreatic parenchyma or capsule invasion.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** normabasurtoa@outlook.com
**Introduction:** Acute cholecystitis is one of the most common causes of surgery in the emergency room services around the world. Since 2007, and later in 2013, it has been used them for this common disease proposed by the Consensus of Tokyo (TG07 and TG13). Gastroenterologist and Surgeons around the World have used as the gold standard to diagnose and determining the severity of the AC and then decide the timely treatment. Unfortunately, we have found there are many differences between Tokyo (TG13) Severity Assessment Criteria and transoperative features in Laparoscopic Cholecystectomy. TG13 grade Acute Cholecystitis in three groups: Grade III (severe) acute cholecystitis is associated with dysfunction of some organs or systems; Grade II (moderate) Acute Cholecystitis is associated with any one of the following conditions (Leukocytosis $>18{,}000/mm^3$, Palpable tender mass in the upper abdominal quadrant, duration of complains $>72$ h or Marked local inflammation) and Grade I: acute cholecystitis does not meet the criteria of ''Grade III'' or ''Grade II''. We have propose a table which collects the macroscopic transoperative features in laparoscopic cholecystectomy in cases of acute cholecystitis and allows to grade the severity of the cholecystitis, and evaluate the the concordance with the ''New diagnostic criteria and severity assessment in Tokyo guidelines'' and histopathological features. The conclusion was that concordance grade DTFT and Tokyo criteria was little almost nill. These findings suggest a reconsideration to stake new classification criteria to grading acute cholecystitis.
**Objective:** To review the database of our study and try to find any explanation about the non concordance between Tokyo criteria, the histopatologycal features and our proposed table of macroscopic transoperative features in laparoscopic cholecystectomy, in cases of acute cholecystitis.
**Methodology:** 91 medical records of patients who were attended with the diagnosis of ''Acute Cholecystitis'' (AC) were reviewed (clinical files, laboratories results and imaging studies, dvds cholecystectomy video). This is a cohort study, it was double blind. At the end we summed all the items and we classified the results in phases ranging from a 1 to a 3 phase according to its score (mild, moderate, and severe severity). A kappa test was realized to assess the degree of agreement between our DTFT and the Tokyo criteria using the software STATA v.13.
**Results:** The medical records of 91 patients treated for acute cholecystitis were reviewed, they were classified according to the criteria for severity of Tokyo in Phase I (mild) 22 pac (24.17%), stage II (moderate) 63 pac (69.23%) are reviewed and Phase III (severe) 6 patients (6.59%). Of these the criteria for classification in grade III was 3 pac (50%) creatinine $>2$ mg/dl; 2 pac (33.33%) neurological deficit; and one pac (16.66%) with platelet $<100{,}000/mm^3$ account. Of the 63 patients classified as Stage II (moderate) variable selection was: 58 pac (92.06%) the evolution of the disease $>72$ hrs, 6 pac (5.52%) leukocytes $>18{,}000/mm^3$. It is noteworthy that the duration of the classification variable condition, obviously would deduce that this affects other systems or organs, however, to review the rest of the parameters are not altered by this variable.
**Conclusion**: Therefore, it may be desirable to rethink the criteria of severity, and this allows to have more consistent with the other scales, which in turn also require review and redefine its variables. It is fair to say that this puts us all on the way to improve and unify criteria and classifications

## P0783 MODIFIED FOLFOX6 AND BEVACIZUMAB AS NEOADJUVANT CHEMOTHERAPY FOR PATIENTS WITH POTENTIALLY CURABLE BILOBAR LIVER METASTASES FROM COLORECTAL CANCER

**A. Maeda**, Y. Kaneoka, Y. Takayama, Y. Fukami, S. Onoe
*Digestive Surgery, Ogaki Municipal Hospital, Gifu, Ogaki/Japan*

**Contact E-mail Address:** omh.amaeda@mac.com
**Introduction:** Even though patients with colorectal cancer (CRC) and liver metastases have a poor prognosis, they can benefit from perioperative chemotherapy and complete extirpation of the diseases. Oxaliplatin-based chemotherapy with bevacizumab has been widely reported to improve outcomes with metastatic CRC.
**Aims & Methods:** The objective of the present study is to elucidate impact of neoadjuvant chemotherapy based on oxaliplatin and bevacizumab on surgical complications and survival benefit after hepatectomy in patients with potentially curable synchronous bilobar liver metastases. Twenty-three patients with potentially curable bilobar liver metastases from CRC were eligible for this prospective single-center, nonrandomized trial during a period between September 2008 and December 2014 (NAC group). The study group consisted of 15 men and 8 women, with median age of 62.1 (range 52 to 79) years. Eligible criteria included synchronous liver metastases and metastatic liver disease developed within one year after resection of the primary lesions. Patients received biweekly oxaliplatin of $85\,mg/m^2$, folic acid of $200\,mg/m^2$, a bolus 5-fluorouracil of $400\,mg/m^2$, and continuous 5-fluorouracil of $2400\,mg/m^2$ for 46 hours (modified FOLFOX6) plus bevacizumab of 5 mg/kg for 6 cycles. The sixth cycle of neoadjuvant chemotherapy (NAC) did not include bevacizumab, resulting in 4 weeks window-time between the last administration of bevacizumab and hepatectomy. No additional postoperative adjuvant chemotherapy was performed. Overall survival (OS) and progression free survival (PFS) rates were compared with 13 patients who underwent hepateictomies for synchronous multiple bilober liver metastasis from CRC without NAC during 2002 and 2008 (non NAC group).
**Results:** Synchronous liver diseases were observed in 20 (87.0%). In the remaining 3 patients, liver metastases developed within one year after primary surgery for CRC. Objective response to NAC was achieved in 6 patients (26.1%), and 21 patients (91.3%) underwent liver resection. Two patients were excluded from hepatectomies because of progressive diseases. The liver surgery included 5 hemihepatecitomies, 10 sectorectomies, and 6 partial resections of the liver with median operative time of 207 minutes and median blood loss of 340 mL without blood transfusion. Median size of the liver tumor was 3.7 cm in diameter and number of the tumors was 3.6. Any posthepatectomy morbidity or morbidity was observed in NAC group. Three- and five-year PFS of the NAC group were significantly better than those of non-NAC group (34.4% and 34.4% respectively (median survival time, 12.8 months) vs. 18.2% and 18.2% (9.0 months), $P=0.038$). And three- and five year OS of NAC group were slightly better without significant difference (72.3% and 21.1% (48.9 months) vs. 41.5% and 16.8% (31.2 months), $P=0.063$). Among the hepatectomized patients of NAC group, 13 patients (61.9%) developed recurrence, and initial recurrent deposits were observed in remaining liver in 6 patients (46.2%), lymph nodes in 6, lung in 4 and peritoneum in 2 (redundant included).
**Conclusion:** Our data suggest that NAC of 6 cycles with modified FOLFOX6 and bevacizumab can be safely administered until 4 weeks before liver resection without increasing perioperative complications and may provide better OS and PFS with good local control of the liver in patients with synchronous bilobar multiple liver metastases from CRC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0784 PERCUTANEOUS TRANSHEPATIC BILIARY DRAINAGE – FIRST STEP IN THE PALLIATIVE TREATMENT OF MALIGNANT BILIARY OBSTRUCTION?

**P. Ignatavicius**[1], R. Riauka[1], G. Barauskas[2]
[1]*Surgery, Lithuanian University of Health Sciences, Kaunas/Lithuania*
[2]*Dept. Of Surgery, Lithuanian University of Health Sciences, Kaunas/Lithuania*

**Contact E-mail Address:** Ignatavicius@gmail.com
**Introduction:** Obstructive jaundice is a frequent complication, occurring in patients with biliary tract and periampullary malignancies. It's a symptom of advanced stage of the disease and poor prognosis. Biliary decompression is necessary in order to prevent patients from more serious complications and allow them to receive further treatment.
**Aims & Methods:** The aim of this study was to evaluate the clinical outcomes and possible benefit of an ultrasound-guided percutaneous transhepatic biliary drainage as the first step in the palliative treatment of malignant biliary obstruction. Retrospective review of patients undergoing percutaneous transhepatic biliary drainage from 2014 to 2015 at the Department of Surgery, Hospital of the Lithuanian University of Health Sciences was performed. Patients were reviewed for demographic features, laboratory tests, complications, outcomes (reduction in serum bilirubin level), hospital stay and mortality rate.
**Results:** During the study period 99 patients (43.4% males ($n=40$)) with median age of $68.67 \pm 11.02$ (range 44–95) received 124 successful biliary drainage procedures for malignant obstructive jaundice. Prior the percutaneous drainage procedure 58 patients (58.6%) were unsuccessfully treated by endoscopic retrograde cholangiopancreatography (ERCP). Forty patients (40.4%) were diagnosed with periampullary tumours, thirty patients (30.3%) had proximal/hilar cholangiocarcinoma and 29 (29.3%) patients had biliary obstruction due to liver metastasis. Acute cholangitis before drainage procedure was present in 52 (52.5%) patients. After drainage procedure total serum bilirubin value decreased in 87 (87.9%) patients (from $293.72 \pm 131.9\,\mu mol$ to

193.11 ± 117.49 μmol, $p < 0.05$). Reduction in the levels of Gamma-glutamyl transferase and Alkaline phosphatase was observed in 94 (94.9%) patients. Seventy patients (70.7%) underwent additional interval procedures. In 62 (88.6%) cases percutaneous transhepatic biliary stenting was performed. The mean hospital stay was 25.49 ± 17.97 days (after percutaneous drainage −19.95 ± 17.28 days). Thirty-four (34.3%) patients developed drainage related complications, with drainage catheter dislocation being most common (70.6% (n = 24)). Hospital mortality rate reached 27.3% (n = 27) with no drainage-related deaths.
**Conclusion:** Percutaneous transhepatic biliary drainage is safe and effective method to reduce malignant obstructive jaundice, when other drainage methods are unavailable. Percutaneous transhepatic biliary drainage acts as a first step in further palliative treatment of these diseases.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0785 RBC DISTRIBUTION WIDTH (RBC-DW) AND ACUTE CHOLECYSTITIS. CORRELATION BETWEEN THE RBC DISTRIBUTION WIDTH (RBC-DW) AND THE DESCRIPTIVE TRANSOPERATIVE FEATURES TABLE (HGM), THE NEW DIAGNOSTIC CRITERIA AND SEVERITY ASSESSMENT IN TOKYO GUIDELINES

**J.L. De-Leon-Rendon**[1], R. Gaxiola-Werge[1], N.E. Basurto-Acevedo[2], S.L. Briones-Fraga[3], H.J. Rivera-Cadena[2], A. Reding-Bernal[4]

**Contact E-mail Address:** bass_spl@hotmail.com
**Background:** Acute cholecystitis is one of the most common causes of surgery in the emergency room services around the world. Since 2007 and later 2013, the diagnostic criteria and severity assessment criteria have been used for this widespread disease. Nevertheless, a description of transoperative features hasn't been standardized, so it has been impossible to classify or grade acute cholecystitis. Nowadays, with the aid of our proposed "Descriptive transoperative features table" (DTFT), we are now able to grade the severity of acute cholecystitis. The rheologic changes of red blood cells (RBC) and their physiopathological role during inflammation are not completely understood. Previous studies have founded important alterations in RBC shape and functional disturbances during sepsis and inflammation. We have noticed that there are many differences between the Tokyo Classification (2013), the transoperative features and Histopathology features. Our objective was to study the variations of RBC distribution width (RBC-DW) in patients with acute cholecystitis and its relation with the severity of each case.
Aims & Methods:
**Objective**: To study the variations of RBC distribution width in patients with acute cholecystitis and its relation with the severity of each case and to find the concordance with the "New diagnostic criteria and severity assessment in the Tokyo guidelines", the table in which the macroscopic transoperative features of laparoscopic cholecystectomy and histopathological features.
**Methodology**: Sixty-two medical records of patients who were attended with the diagnosis of "Acute Cholecystitis" (AC) were reviewed (clinical files, laboratories results and imaging studies, and cholecystectomy videos). This is a cohort study, it was double blind. In the stage, we added all the scores and classified the results in phases ranging from phase I to a phase III according to their score (mild, moderate, and severe severity). A kappa test was done to assess the degree of agreement between The RBC Distribution Width (RBC-DW) and our DTFT, the Tokyo criteria and histopatological features using the software STATA v.13.
**Results:** There were 62 patients: 39 women (in the range of 21 to 79 years old) with a mean age of 56.75 years, and 23 men (range of 28 to 76) with a mean of 55.38 years. They were grouped according to the Tokyo criteria in: mild, 13 (20.96%); moderate, 43 (69.35%); and severe 6 (9.67%); DTFT criteria I: 13 (20.96%), II: 29 (46.77%), III: (29.03%) and IV: 1 patient; and by histopatological features: Acute Cholecytitis (AC) non gangrenous: 23 (37.09%), CA with microscopic foci of necrosis: 35 (56.45%) and acute gangrenous cholecystitis 4 (6.15%). The RBC-DW was in normal range in the most of cases, except in fase III of Tokyo criteria where it was elevated in 66.6% of the cases. According to the kappa index, the degree of agreement between RBC-DW, Tokyo criteria,DTFT criteria and histopathological features criteria was fair.
**Conclusion**: We also concluded that we need to study a bigger population to acutely describe an association between this variables and RBC-DW. The relationship between RBC-DW and severity assessments scores has to be defined with future studies. And we suggest a reconsideration be taken if we want to advance a new set of classification criteria for grading acute cholecystitis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0786 CONTEMPORARY APPROACHES TO CHOOSING SURGICAL TREATMENT FOR PATIENTS WITH COMPLICATED FORMS OF CHRONIC PANCREATITIS

V. I. Pylypchuk[1], **V. Galyuk**[2]
[1]*Surgery Of Post Diploma Faculty, Ivano-Frankivsk National Medical University, Ivano-Frankivsk/Ukraine*
[2]*Surgery #1Ivano-Frankivsk National Medical University, Ivano-Frankivsk/Ukraine*

**Contact E-mail Address:** dr.galyuk@gmail.com
**Introduction:** Cronic pancreatitis (CP) is a progressing inflammatory process in the pancreas that results in complete destruction of gland tissue, derangement of digestion, development of diabetes mellitus, and manifest pain syndrome. Over the last thirty years, we have witnessed a more than double increase in the number of CP patients.
**Aims & Methods:** We analyzed the results of surgical treatment of 144 patients with complicated forms of CP who underwent surgical treatment at the department of surgery of the Ivano-Frankivsk Regional Clinical Hospital, Ukraine, among them 133 (92.3%) men and 11 (7.7%) women aged 21 to 72. To diagnose CP and its complications we used: laboratory tests, ultrasonography, endoscopic retrograde cholangiopancreatography, computer tomography, magnetic resonance cholangiopancreatography, intraoperative measurement of bile pressure. The quality of patients' life in the remote postoperative periods was considered the criterion of surgical treatment efficiency. Assessment of the remote results of surgical treatment was done by examining the patients, ultrasonography, and filling out the «Short Form Medical Outcomes Study» (SF-36) questionnaire, which allows assessing physical and psychoemotional conditions of the surveyed separately.
**Results:** Surgical treatment was applied to 144 patients with CP. In 54 (37.5%) patients, CP was complicated by dysfunction of adjacent organs. Particularly, these were biliary hypertension (BH) in 36 (25%) patients and chronic duodenal obstruction (CDO) in 8 (5.5%) patients. In 5 (3.5%) patients, BH was combined with CDO, and another 5 (3.5%) patients had a combination of BH, CDO and venous hypertension (VH) of the portomesenteric area. Indications for surgical treatment were as follows: persistent pain syndrome and inefficiency of pharmaceutical treatment; manifest duct hypertension due to fibrotic CP with dilatation of pancreatic ducts and pancreatic juice hypertension in hem or calculous CP with manifest intrapancreatic hypertension – 48 (33.3%) patients; fibrocystic CP with formation of retention cysts, pseudocysts and external fistula of the pancreas – 27 (18.7%) patients; fibrous-degenerative CP with involvement of adjacent organs and their dysfunction (BH, CDO, VH, and their combination) −54 (37.5%) patients; pancreatic pseudotumor and assumption of a pancreas tumor – 10 (6.9%) patients. Resection surgeries were performed in (43.4%) patient (pancreaticoduodenal resection (PDR) – 5 (3.5%), Frey's procedure – 44 (30.5%), Berne modification – 2 (1.4%), distal pancreas resection – 10 (7%). Draining operations were performed in 74 (51.4%) patients, palliative surgeries – in 9 (6.2%) patients. In 16 patients with CP accompanied by signs of BH, intraoperative monitoring of biliary pressure was performed, which allowed determining the appropriateness of the surgery for the elimination of BH.
**Conclusion:** The results of surgical treatment were traced in 43 (29.8%) patients in the period from 6 to 36 months and appeared to be good and satisfactory. Life quality indicators were better in patients who underwent resection surgeries on the pancreas.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0787 IMPACT OF PRE-TRANSPLANT SARCOPENIA AND SEQUENTIAL CHANGES IN SARCOPENIC PARAMETERS AFTER LIVING DONOR LIVER TRANSPLANTATION

**T. Kaido**[1], Y. Hamaguchi[2], S. Okumura[1], A. Kobayashi[1], H. Shirai[1], S. Yagi[1], Y. Tamai[2], N. Inagaki[3], S. Uemoto[1]

**Introduction:** Sarcopenia is characterized by muscle mass depletion and decrease in muscle power or physical activity. We reported that preoperative low skeletal muscle mass was an independent risk factor for survival after living donor liver transplantation (LDLT) in a retrospective study (1).
**Aims & Methods:** The present study prospectively investigated the impact of pretransplant sarcopenia on survival after LDLT. Moreover, we examined sequential changes in sarcopenic parameters after LDLT. Seventy-two consecutive adult patients who underwent LDLT at our institute between January 2013 and October 2015 were enrolled in this study. Median patient age was 55 (range, 21–68), 38 (53%) were male, median MELD score was 18 (range, 6–41). Sarcopenia was assessed by the measurement of skeletal muscle mass (SMM) obtained by a multifrequency body composition analyzer (InBody 720®) and handgrip strength (HS). We defined patients with sarcopenia as those with low SMM (< 90% of the standard SMM) and low HS (< 26 kg for men, < 18 kg for women). The impact of pretransplant sarcopenia on short-term survival and sequential changes in sarcopenic parameters including SMM and HS were analyzed.
**Results:** The overall survival rate in patients with preoperative sarcopenia (n = 10) was significantly lower than that in patients without sarcopenia (n = 62) (1-year overall survival rate; 56% versus 98%, resepctively) ($p < 0.001$). SMM worsened after LDLT and did not recover to preoperative levels until 1 year after LDLT. In contrast, HS recovered to preoperative levels at 6 months after LDLT following sharp decrease at 1 month after LDLT. According to preoperative sarcopenia, postoperative HS in patients without sarcopenia tended to be lower compared to patients with sarcopenia, while postoperative SMM did not differ between patients with sarcopenia and those without sarcopenia.
**Conclusion:** Prospective analysis clarified that pretransplant sarcopenia had negative impact on short-term survival after LDLT. The recovery of handgrip strength preceded that of SMM.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The role of intestinal microbiota in inflammatory bowel disease (IBD) development and exacerbation has been widely studied, but is still poorly understood. Microbiota have thus become a potential pharmacological target in IBD therapy. Silver preparations are well known of their broad spectrum of antimicrobial and anti-inflammatory actions. The activity of silver nanoparticles depends on their size and shape, which affect the interaction with biological membranes in microbiota and the host, and the immune system of the host.
**Aims & Methods:** Aims: The aim of this study was to investigate the effect of newly developed silver nanoparticle aqueous suspensions varying in shape and size, NanoAg1 and NanoAg2 (spherical shape, 294 nm in diameter and irregular shape, 122 nm in diameter, respectively) in the mouse models of experimental colitis. Methods: NanoAg1 and NanoAg2 were synthesized by a one-step chemical reduction in aqueous medium with the involvement of tannic acid. UV-Vis spectroscopy and atomic force microscope microphotographs were made to confirm the size and the shape of nanoparticles. To assess the anti-inflammatory activity of tested compounds, semi-chronic mouse models of inflammation induced by DSS addition to drinking water and intracolonic (i.c.) administration of TNBS were used. Macroscopic score, ulcer score, colon length, weight and thickness, as well as, microscopic score were recorded. Moreover, in all experiments the level of myeloperoxidase (MPO) activity was determined as an indicator of neutrophil infiltration in the colonic tissue. The effect of silver nanoparticles on colonic microbiota was studied ex vivo by recording the number of total bacteria, *Escherichia coli*, *Lactobacillus species* and *Clostridium perfringens* in stool content.
**Results:** NanoAg1 and NanoAg2 (0.05 mg/dm$^3$, 100 μL/animal, i.c., once daily) significantly ameliorated colitis in DSS- and TNBS-induced mouse models of colonic inflammation, as indicated by reduced macroscopic, ulcer and microscopic scores. However, the anti-inflammatory effect was dependent on the shape and diameter of silver nanoparticles, as indicated by weaker effect of NanoAg1 than NanoAg2. The MPO activity was reduced after i.c. installation of NanoAg1 and NanoAg2. In addition, administration of NanoAg2, but no NanoAg1 modulated colonic microbiota, as indicated by reduced number of *E. coli* and *C. perfringens*, and increased number of *Lactobacillus* sp.
**Conclusion:** We propose a novel adjuvant therapeutic strategy to induce remission in IBD, based on the treatment with silver nanoparticle aqueous suspensions and modulation of colonic microbiota.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0789 MACROPHAGES BEHAVIOUR AGAINST ADHERENT AND INVASIVE E. COLI (AIEC) ISOLATED FROM CROHN'S DISEASE PATIENTS IN RELATION WITH HOST FACTORS SUSCEPTIBILITY

**Introduction:** Crohn's disease (CD) is a chronic inflammatory bowel disease which altere quality of life, leads to significant disability, and slightly increased mortality rate. The pathophysiology of the CD remains imperfectly elucidated. The most recent hypothesis considered CD as resulting from an abnormal interaction between microbiota and host immune system influenced by genetics and environmental factors. Ileal lesions of CD patients are abnormally colonized by adherent-invasive *E. coli* (AIEC) able to survive in macrophage cell lines. The macrophages play a pivotal role in the elimination of pathogenic bacteria via autophagy which is one of the main pathways responsible for the elimination of intracellular bacteria and which play a key role in CD. We recently reported that macrophages from CD patients could have an impaired ability to restrict intracellular AIEC replication.
**Aims & Methods:** In the present study we aimed to understand why macrophages from CD patients have a deficient control regarding AIEC infection in searching a correlation between AIEC replication and several CD genetics polymorphisms especially those related to autophagy. Peripheral blood monocyte-derived macrophages (MDM) were obtained from 95 CD patients, 30 ulcerative colitis patients and 15 healthy volunteers, genotyped for ULK, XBP1, CYLD, USP40, LRRK2, NOD2, IRGM and ATG16L1 mutations. The numbers of intracellular bacteria were determined at 1 h and 10 h post-infection using gentamicin assay. Cytokine secretion was quantified by ELISA. Factors (including clinical factors, current therapies, CDAI, SCCAI, CRP, vitamin D and fecal calprotectin values, genetics polymorphisms...) associated with AIEC uptake/survival/replication were investigated using multivariate analysis.
**Results:** The bacteria uptake and ability to survive and replicate within MDM were significantly higher for AIEC reference strain LF82 comparatively to the non-pathogenic *E. coli* K-12 regardless macrophages origin. The AIEC uptake (1 h post-infection) within MDM did not differ according to MDM origin. The AIEC survival (10 h post-infection) within MDM from CD patients was higher than AIEC survival within MDM from UC patients and helathy volunteers ($p = 0.0019$). In multivariate analysis, AIEC survival within MDM from CD patients was positively correlated with IL1-$\beta$ secretion ($p < 0.0001$) and was decreased in the presence of ULK1 ($p = 0.046$) and XBP1 ($p = 0.014$) mutations. AIEC were able to replicate within MDM from CD patients but not within MDM from UC patients or healthy volunteers ($p < 0.001$). In multivariate analysis, AIEC intracellular replication was increased in CD patients with IRGM mutation ($p = 0.045$).
AIEC infection of MDM from CD patients induced an increased secretion of pro-inflammatory cytokines/chemokines IL-1$\beta$, IL-8, IL-6 and TNF-$\alpha$ compared to both basal secretion and K-12 infection.
**Conclusion:** ULK-1, XBP-1 and IRGM polymorphisms are implicated in macrophages deficiency to control intracellular AIEC replication leading to disordered inflammatory response. Our results highlighted the implication of Crohn's disease ULK-1, XBP-1 and IRGM polymorphisms in macrophages abnormalities which are suspected to account for some immunological defects associated with the development of Crohn's disease. Further work is required in Crohn's disease patients to phenotypically characterized MDM and to define how ULK-1, XBP-1 and IRGM could modulate AIEC uptake/survival/replication within MDM. This may lead to develop new therapeutic strategy based on manipulation of macrophage phenotype and on host-pathogen interaction in selected patients.

### P0790 THE EFFECT OF ORAL S1P RECEPTOR MODULATOR (FTY720) ON COMPLEMENT CASCADE AND NUMBER OF NORMAL STEM CELLS TRAFFICKING IN PERIPHERAL BLOOD IN A MURINE MODEL OF ULCERATIVE COLITIS

**Introduction:** FTY720 (fingolimod) is oral sphingosine-1-phosphate (S1P) receptor agonist with documented immunomodulatory function. FTY720 was shown to be clinically effective in the treatment of multiple sclerosis and colitis in IL-10-deficient and $CD4^+CD62L^+$ cell-transfer animal model. Another S1P receptor modulator (RPC1063) was effective in induction of clinical remission and mucosal healing in TOUCHSTONE (1) study in patients with moderate to severe ulcerative colitis (UC). Based on these results S1P receptor modulators have been proposed as novel therapeutic option for the treatment of UC. We have previously documented that the number of normal stem cells (SCs) circulating in peripheral blood increases in patients with inflammatory bowel disease (IBD) (2) and reported that these SCs could be implicated in tissue/organ regeneration (3,4). However the effect of S1P modulators on normal SCs mobilization in UC is currently unknown.
**Aims & Methods:** In the current study we investigated the effect of FTY720 on components of complement cascade and number of normal SCs mobilized into peripheral blood (PB) in UC. Male, 8-week-old, C57BL/6J mice were administered FTY20 after induction of colitis with dextran sulfate (DSS). The disease activity index (DAI) was monitored daily by measuring the body weight, stool consistency and rectal bleeding. Bone marrow (BM) derived SCs expressing Sca-1, CD45, c-kit and lack of lineage specific markers were identified by fluorescence-activated cell sorting (FACS) analysis. Plasma levels of complement cleavage fragments (C5a), intestinal fatty acid binding protein (I-FABP) and vascular endothelial growth factor (VEGF) were measured by ELISA. S1P plasma levels were measured by liquid chromatography. BM-derived PB MNCs were tested for their ability to form granulocyte-monocyte (CFU-GM) and erythroid (BFU-E) colonies. Histopathological analysis of intestinal tissue specimens was performed.
**Results:** FTY20 administration was followed by decrease in disease activity index (DAI) of mice with DSS colitis. The administration of FTY720 resulted in reduced egress from BM into PB of all populations of SCs studied. FTY720 administration was associated with lower levels of serum S1P, decreased expression of plasma I-FABP (marker of intestinal permeability) and VEGF vascular markers. The plasma levels of complement cascade (CC) fragments were not manipulated by FTY720 treatment. The intestinal gross pathology revealed less advanced damage of epithelial cells and increased vessel formation in intestines of FTY20 treated animals.

**Conclusion:** Beneficial effect of FTY720 administration in murine model of DSS colitis is associated with reduced egress of inflammatory cells into PB, decrease in intestinal permeability and increase in angiogenesis. Decrease in mobilization and trafficking of SCs in PB in UC after FTY720 treatment is also observed.

**Introduction:** Pouchitis is a common complication after ileal pouch–anal anastomosis (IPAA). However, there is a poor correlation between symptoms and endoscopic appearance and many pouch patients can have debilitating symptoms in the absence of overt inflammation. It remains unknown whether these clinical symptoms are independently associated with the microbiota.
**Aims & Methods:** The objective of this work was to examine if the clinical components of the pouch activity scoring systems are associated with microbiota. Pouch biopsies from 202 patients (50%male) post IPAA were included. Illumina MiSeq sequences were processed using QIIME pipeline v1.9. Microbiome functions were imputed using Picrust software. Clinical phenotyping was performed and patients were classified using both clinical and endoscopic components of the Pouch Activity Scale. Associations were performed using linear regression adjusting for age, gender and antibiotic use, first in patient with endoscopic inflammation ($n = 99$) and second in patient with no inflammation ($n = 103$). Scoring for symptoms examined 24 h stool frequency, urgency, incontinence and rectal bleeding as described by PAI score
**Results:** In the absence of inflammation, presence of symptoms was associated with Firmicutes ($q < 0.04$) and 24 h stool frequency was associated with an undefined Clostridiales species among others ($10^{-6} < q < 10^{-5}$). In the inflamed individuals, 24 h stool frequency was associated with Bacillales ($q < 0.02$) and with an unknown species of Lachnospiraceae ($q < 0.05$). Picrust analysis in inflamed groups showed that 24 h stool frequency was associated with synthesis/biofilm formation ($q < 0.05$).
**Conclusion:** These findings indicate that in patients with an IPAA, the composition of mucosa associated microbiota of the pouch contribute to clinical symptoms, in particular stool frequency, independently of endoscopic disease activity.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0792 PHARMACOKINETICS AND PHARMACODYNAMICS FOLLOWING ORAL ADMINISTRATION OF PTG-100, A PEPTIDE ANTAGONIST OF INTEGRIN A4B7

**Introduction:** The $\alpha4\beta7$ integrin is a clinically validated target in inflammatory bowel disease (IBD) as reflected by the FDA-approval of the humanized monoclonal antibody vedolizumab (Entyvio®) for the treatment of moderate-to-severe ulcerative colitis and Crohn's disease. Vedolizumab binds to $\alpha4\beta7$ on circulating memory/effector T cells in the blood and blocks their homing to intestinal tissues that express the ligand MAdCAM-1. PTG-100 is a novel oral $\alpha4\beta7$ antagonist peptide that has minimal systemic absorption and is therefore largely restricted to the gut tissues. PTG-100 is currently in a Phase 1 study in normal healthy volunteers and will be developed for patients with ulcerative colitis. The aim of these studies was to characterize the pharmacokinetic (PK) properties and pharmacodynamic (PD) activities of PTG-100 in mice and cynomolgus monkeys to support the clinical development of PTG-100.
**Aims & Methods:** We conducted PK and PD studies in mice, rats, and cynomolgus monkeys, with peptide concentrations measured by mass spectrometry. We measured $\alpha4\beta7^+$ memory T cell receptor occupancy, surface expression, and cell numbers in whole blood using Fluorescence Activated Cell Sorting (FACS) to assess PD activity. Cell trafficking in blood and gut lymphoid tissues was measured by FACS or immunohistochemistry (IHC).
**Results:** Oral dosing of PTG-100 in normal or dextran sodium sulfate (DSS)-treated mice and rats showed a dose-dependent exposure in the small intestine, colon, and Peyer's Patches (PP), with very low exposure in the blood and urine. Oral bioavailability (%F) in mice was $<0.5$, indicating that PTG-100 is largely gut restricted. PK studies in cynomolgus (cyno) monkeys showed that oral bioavailability of PTG-100 was $<0.5$ and up to 40% in feces. Daily dosing with PTG-100 in murine DSS colitis models showed a dose-dependent reduction in $CD4^+$ $CD44^{high}$ $CD45RB^{low}$ $\beta7^+$ T cells in the mesenteric lymph node (MLN) and PP, and concomitant increase in the spleen and blood as measured by FACS. There was also a strong reduction of $\beta7^+$ cell and polymorphonuclear cell infiltration into lamina propria lesions of the distal colon. At these pharmacologically active doses, $\alpha4\beta7$ receptor occupancy (RO) in the blood, MLN and PP ranged from 46–81% at 4 h post dose. PTG-100 also induced a strong downregulation of $\alpha4\beta7$ integrin surface expression on $CD4^+$ effector T cells in murine blood. In normal cynos, once daily oral dosing of PTG-100 resulted in a dose-dependent increase in RO of memory T cells and an increase of $\alpha4\beta7$ memory $CD4^+$ T cell numbers in the peripheral blood.
**Conclusion:** PTG-100 is a novel oral $\alpha4\beta7$-selective antagonist being developed for the treatment of patients with ulcerative colitis. It is largely gut restricted and alters the trafficking of gut-homing T cells in mice and cynomolgus monkeys. These studies showed that PTG-100 induced downregulation of $\alpha4\beta7$ expression on memory T cells in the blood may be an additional and important mechanism for inhibiting T cell trafficking. Together, these results support clinical development of PTG-100.

**Introduction:** The pathophysiology of ulcerative colitis (UC) is characterized by an excessive induction of the endoplasmic reticulum stress (ERS) in epithelial cells (IEC) of colonic mucosa. Moreover, an excessive proteolytic activity has been described in IEC in course of UC.
**Aims & Methods:** We aimed to investigate the impact of the ERS on trypsin-like activity (TLA) in enterocytes and goblet cells, and its reflection on the intestinal barrier function. Human cell lines Caco2 (enterocyte) and HT29MTX (Goblet cell) were stimulated with Thapsigargin (10 µg/mL) and Tunicamycin (20 µg/mL) to induce ERS. TLA in the supernatant was analyzed at 2, 4, 6 and 24 hours and mRNA expression of serine proteases from cell lysates was analyzed at 6 and 24 hours. The impact of ERS on intestinal barrier function was evaluated by measuring the paracellular permeability (transwell system), IL8 secretion and the mRNA expression of anti-microbial peptides (AMP). To assess the role of the serine proteases released by ERS on the intestinal barrier function, human cells lines were treated with serine proteases inhibitors (AESBF 20uM and Leupeptin 50uM). In addition, the involvement of Proteases Activated Receptor (PAR) -1, -2, -3 and -4 after ERS induction was evaluated by measuring their mRNA expression in the presence or absence of antagonists.
**Results:** Inducing ERS by Thapsigargin or Tunicamycin enhanced the secretion of Trypsin-like proteases by Caco-2 and HT29MTX cells at 2, 4, and 6 hours, but not at 24 hours, probably due to inducer depletion. This activity was prominent in the apical side of IEC. At 6 and 24 hours, the expression of the three main Trypsin-like proteases (PRSS1, 2 and 3) mRNA was increased in IEC. Next, we have evidenced that ERS increased permeability, the release of IL-8 at apical and basolateral side of the epithelium and mRNA expression of the Resistin Like Molecule $\beta$ (RLM $\beta$), known as a proliferative IEC and AMP molecule. Serine protease inhibitors inhibited the ERS-increased permeability and RLM$\beta$ mRNA overexpression, while they aggravated IL-8 secretion. In addition, protease inhibitors also suppressed the increased mRNA expressions of PRSS1, 2 and 3. Lastly, ERS increased the PAR-2, -3 and -4 mRNA level while it downregulated PAR-1 expression.
**Conclusion:** Our results show that ERS induces the release of Trypsin-like activity in the apical side of enterocytes and muco-secreting cells. The deregulation of proteases leads to destabilization of the epithelium homeostasis. Although PAR-1 expression was downregulated by ERS, it mediated the impact of serine proteases released by ERS to alter the IBF. These results evidence a crosstalk between ERS and serine proteolytic activity to destabilize the IBF, playing a potential role in UC development.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0794 EFFECTS OF HUMAN AMNION-DERIVED MESENCHYMAL STEM CELL TRANSPLANTATION AND CONDITIONED MEDIUM ENEMA IN RATS WITH TRINITROBENZENE SULFONIC ACID-INDUCED COLITIS

**Introduction:** Mesenchymal stem cells (MSCs) have been reported to be a valuable cell source in regenerative medicine, and bone marrow represents a major source of MSCs. Recently, it has been shown that MSC can be easily isolated from human amnion, which is generally discarded after delivery, and a large amount of cells can be obtained. We have previously reported that intravenous administration of human amnion-derived MSCs (hAMSCs) provided significant improvement in rats with colitis induced by dextran sulfate sodium or g-irradiation. In addition, conditioned medium (CM) obtained from MSCs contains a variety of humoral factors to improve damaged tissues. In this study, we investigated the effects of hAMSCs and CM in rats with 2,4,6-trinitrobenzene sulfonic acid (TNBS)-induced colitis.
**Aims & Methods:** hAMSCs were isolated and expanded by digestion with collagenase, followed by culturing in uncoated plastic dishes. CM was collected by culturing subconfluent hAMSCs with serum-free MEMa for 48 hrs. CM gel was prepared by mixing CM with 2% carboxymethyl cellulose. On day 0, 200 $\mu$l of TNBS (15 mg/rat) in 30% ethanol was intrarectally administered to the ten-week-old male Sprague-Dawley (SD) rats. One-million hAMSCs were intravenously administered 3 hrs after TNBS treatment, and rats were sacrificed on day 7 for histological examination and quantitative PCR. In another experiment, 400 $\mu$l of CM gel was intrarectally administered 3 hrs after TNBS treatment, and day 1 and day 2.
**Results:** hAMSC transplantation and CM gel enema significantly improved the endoscopical score, and tended to improve the histological score. Quantitative PCR demonstrated that the expression levels of TNF-$\alpha$, CXCL1 and CCL2 tended to be decreased by hAMSC transplantation and CM gel enema. Infiltrations of CD68-positive macrophages and myeloperoxidase-positive neutrophils were significantly decreased by hAMSC transplantation and CM gel enema.
**Conclusion:** Transplantation of hAMSCs and CM gel enema provided significant improvement in rats with colitis induced by TNBS. hAMSCs or CM from hAMSCs may be new therapeutic strategies inflammatory bowel disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** There is recent evidence of increased naïve and central memory T lymphocytes ($T_N$ and $T_{CM}$) mucosal infiltration of the inflamed gut in Inflammatory Bowel Disease (IBD), while $T_N$ and $T_{CM}$ cells were thought to migrate exclusively to secondary lymphoid organs (SLOs). Ectopic formation of tertiary lymphoid organs (TLOs) containing peripheral lymph node adressin $(PNAd)^+$ high endothelial venules (HEVs) might explain the homing of these lymphocytes to the gut, as PNAd is the ligand of L-selectin which is expressed on $T_N$ and $T_{CM}$ lymphocytes.
**Aims & Methods:** The aim of this study was to investigate the presence of PNAd expressing HEVs and TLOs in the inflamed intestinal mucosa of newly diagnosed, untreated, IBD patients in relation to the presence of $T_N$ and $T_{CM}$ lymphocytes. Thirty-nine newly diagnosed, untreated IBD patients and eight healthy controls were prospectively included. Intestinal biopsy samples were analysed by immunohistochemistry for blood vessels (CD31) and PNAd expression (MECA-79), the density of MECA-$79^+$ vessels was calculated and the presence of lymphoid follicles was assessed. Different lymphocytes subsets in the tissue samples were identified by flowcytometric immunophenotyping, including $T_N$ ($CD45RA^+CD27^+$), $T_{CM}$ ($CD45RA^-CD27^+$) and effector memory T cells ($CD45RA^-CD27^-$).
**Results:** A statistically significant higher number of extra-follicular $PNAd^+$ vessels were found in the inflamed colon of patients with ulcerative colitis (median density of 3.05 $PNAd^+$ vessels/$mm^2$ (IQR 0–6.39)) and ileum of patients with Crohn's disease (median density of 1.40 $PNAd^+$ vessels/$mm^2$ (IQR 0–4.34)) compared with healthy controls (median density of colon: 0 $PNAD^+$ vessels/$mm^2$ (IQR 0–0, $p = 0.033$) and ileum: 0 $PNAd^+$ vessels/$mm^2$ (IQR 0–0.50, $p = 0.033$)). The heterogeneity of extra-follicular $PNAd^+$ vessels in IBD patients allowed classification in two different groups: $HEV^{high}$ and $HEV^{low}$. A high density of $PNAd^+$ HEV-like vessels was associated with increased numbers of $T_N$ and $T_{CM}$ in the inflamed gut mucosa (median 87% (IQR 82–93%) of total T cell population), compared with the inflamed mucosa of patients from the $HEV^{low}$ group (58% (IQR 38–81%) $p = 0.003$). The number of colonic follicles was higher in $HEV^{high}$ patients (median 0.54/$mm^2$ (IQR 0.28–0.84)) when compared with $HEV^{low}$ patients (median 0.25/$mm^2$ (IQR 0.08–0.45) $p = 0.031$) and controls (0.31/$mm^2$ (IQR 0.23–0.45) $p = 0.043$).
**Conclusion:** For the first time, evidence has been delivered of extra-follicular HEV-like vessels and TLOs, strongly associated with $T_N$ and $T_{CM}$ cell mucosal infiltration, in a subgroup of newly diagnosed IBD patients. Different T cell migration phenotypes based on TLO formation in the early phase of IBD might allow risk-stratification of patients and enable more effective, individualized treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0796 TOLL-LIKE RECEPTOR 9 MODIFIES INTESTINAL SEROTONERGIC SYSTEM

**Introduction:** Toll-like receptor 9 (TLR9) is expressed in intestinal epithelial cells, which recognize microbiota developing different responses [1]. Several studies have shown that TLR9 seems to be involved in Inflammatory Bowel Diseases (IBD) due to an inappropriate defensive response against microorganisms [2]. Moreover, intestinal serotonergic system is also altered in IBD, where extracellular serotonin (5–HT) levels are increased [3]. 5-HT bioavailability is mainly regulated by the serotonin transporter (SERT), expressed in enterocytes [4].
**Aims & Methods:** The aim of the present study was to analyse whether TLR9 activation affects SERT expression and activity, and expression of other elements from the serotonergic system (TPH1, TPH2 and 5-HT receptors). Human enterocyte-like Caco-2 cells, and ileum and colon from $TLR9^{-/-}$ mice and Dextran Sulphate Sodium (DSS) mouse colitis model were used as experimental models. mRNA expression was determined by RT-qPCR, and protein expression by western blot.
**Results:** TLR9 activation in Caco-2 cells decreased SERT mRNA and protein expression. TLR9 activation also reduced SERT activity by different intracellular pathways, depending on activation period. Indeed, TLR9 long-time activation altered 5-HT uptake through ERK pathway, whereas short-time activation modified SERT by p38/MAPK pathway. Moreover, 5-HT addition to culture media increased TLR9 protein expression in the brush-border membrane of Caco-2 cells. In $TLR9^{-/-}$ mice were observed different expression patterns. SERT was not modified in ileum, but increased in colon. TPH1 was increased in ileum, and TPH2, in colon. Regarding 5-HT receptors, 5HT2A, 5-HT2B, and 5-HT3 were increased in ileum; however, 5-HT1A, 5-HT2A and 5-HT4 were increased in colon. In both ileum and colon of DSS mice, TLR9 and 5-HT7 mRNA expression were increased, whereas SERT expression was diminished.
**Conclusion:** Our results suggest that TLR9 modulates intestinal serotonergic system. Indeed, TLR9 activation decreases SERT function and expression by different pathways. In part, this is corroborated by the decreased expression of SERT in colon of TLR9 knockout mice and altered 5-HT receptors expression. Finally, SERT and TLR9 are inversely disturbed in DSS mice colitis model.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The role of gut microbiota on the etiopathogenesis of IBD, both Crohn's disease (CD) and ulcerative colitis (UC), is not well known. Most studies of human gut microbiota rely on the non-invasive collection of stool samples. However, the analysis of the fecal microbiota may not reflect the role of the mucosa-associated microbes. Mucosa-associated germs live in close proximity to the intestinal epithelium and are in contact with the cells of the innate immune system directly involved in the inflammatory response
**Aims & Methods:** Aim of this study was to investigate the genotypes of Bacteroidetes microbiota from colon biopsies of IBD patients and to determine their relationship with the endoscopic activity of the disease. Methods:
A single-center, observational cross-sectional study was designed. Consecutive patients with Crohn's disease (CD) and ulcerative colitis (UC) who attended the Endoscopy Unit of Santiago de Compostela for colonoscopy were included. Colonic biopsies were taken to characterize microbiota by using a restriction fragment length polymorphism (RFLP) analysis on PCR products targeting the 16SrRNA genes of Bacteroidetes digested with HinfI, PciI, DpnII and AciI. Inactive UC was defined as a Mayo endoscopic score of 0. Inactive CD was defined as a SES-CD $<= 2$. The association of endoscopic activity with demographic (gender, age and smoking habits) and analytical (VSG, PCR and platelets) factors was also evaluated. The results were expressed as prevalence and analyzed using logistic regression.
**Results:** 52 consecutive IBD patients (28 CD and 24 UC) were included. 33 patients showed endoscopic activity of the disease (20 CDa and 13 UCa). A total of eight genotypes of Bacteroidetes called N1, C1-C5, CB 10 and CB13 were detected. N1 is probably a strain of Bacteroides dorei, and C1 and C2 B.vulgaris strains. While the presence of N1 and C1 genotypes was consistent in patients with active and inactive IBD, the percentage of C4 genotypes in patients with UCa and CDa was very high (81.8%) compared to patients without activity (36.8%) ($p = 0.001$). C3 genotype was observed in 4/19 inactive IBD patients and in 12/33 of active IBD patients ($p = 0.24$). Other genotypes were found sporadically in IBD biopsies. No differences were observed between the genotype of patients with CD or UC. After multivariate analysis, C4 genotype in colon biopsies was associated with endoscopic activity of the disease (OR 8.58, 95%CI 2.16 to 34.08) ($p = 0.02$).
**Conclusion:** The presence of genotype C4 of Bacteroidetes is associated with the endoscopic activity of IBD, both CD and UC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0798 GENETIC DIFFERENCES IN THE OUTER MEMBRANE PROTEINS SEQUENCE AMONG COMMENSAL AND ADHERENT-INVASIVE E. COLI STRAINS

**Contact E-mail Address:** c.camprubi4@gmail.com
**Introduction:** Outer Membrane Proteins (OMPs) usually play a role in antibiotic resistance of *Escherichia coli* by making the bacterium less permeable when decreased expression or variations in pore conformation occur. Moreover, OmpA has been implicated in the invasion ability of Adherent Invasive E. coli (AIEC) pathotype by binding the receptor Gp96, overexpressed in Crohn's disease patients (1). An indirect role in AIEC adhesion and invasion has also been suggested for OmpC (2).
**Aims & Methods:** The aim of this study was to identify gene mutational patterns in OMPs among a collection of AIEC and non-AIEC strains, to determine possible associations between them and antibiotic resistance or AIEC pathogenicity. The genes of OMPs ompA, ompC and ompF were sequenced from a collection of 22 AIEC and 29 non-AIEC strains tested for resistance to 27 antimicrobials. For comparison, genes from AIEC, UPEC, MNEC, APEC, EAEC, EHEC, ETEC and commensal strains were retrieved from GenBank. Phylogenetic tree analysis and allele identification was performed using MEGA5 (Neighbour-joining, Poisson correction distance and 10,000 bootstrap replicates). The genetic differences were annotated using as reference the LF82 strain. Then, they were analysed statistically according to AIEC pathotype, phylogroup origin, and antibiotic resistance by the $\chi^2$ test and non-parametric tests were used to evaluate amino acid variability regarding the invasion index.
**Results:** The OmpA protein sequence shared a 93.2% of similarity among the strain collection. For OmpF and OmpC was 92.4% and 83.4%, respectively. Phylogenetic tree analysis clustered the strains in 9 groups for OmpA, 2 for OmpF and 12 for OmpC. Most of the variation occurred in the extracellular loops, a total of 22 amino acid changes in OmpA, 28 in OmpF and 61 in OmpC were found. The distribution of amino acid variants was similar between AIEC and non-AIEC. However, despite not reaching statistical significance, higher invasion indices were observed in strains with specific amino acids changes in position 114 of the OmpA sequence, in position 115 of OmpF and in different positions across OmpC extracellular loops 2, 5 and 7. Amino acid variants of each porin (3 of the variable positions of OmpA, 2 of OmpF and 16 of OmpC) correlated with phylogroup origin of the strains, being A phylogroup the one resembling more to B1 and B2 to D ($p < 0.05$). Resistance to $\beta$-lactams amoxicillin-clavulanate and ticarcillin-clavulanate was more frequently observed in strains with P131 OmpA variant ($p = 0.024$), tetracycline and doxycylin resistance with OmpF variations in P264_274 ($p = 0.010$) and streptomycin resistance with OmpC P191 and P220 variants ($p < 0.05$).
**Conclusion:** In conclusion, no amino acid changes in OmpA, OmpF and OmpC were found distributed specifically and across all AIEC, but some amino acid variants correlated with higher invasion ability what could depict pathoadaptative mutations associated with virulence. Additional molecular studies are needed to evaluate the finding of site-specific mutants presenting particular resistance phenotypes.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0799 ANTIBIOTICS-MEDIATED INCREASE IN LARGE INTESTINAL PROTEASE ACTIVITY IS ASSOCIATED WITH IMPAIRED INTESTINAL BARRIER FUNCTIONS AND AGGRAVATION OF SPONTANEOUS COLITIS

**H. Yoon**, M. Schaubeck, D. Haller, G. Hörmannsperger
*Chair Of Nutrition And Immunology, Ziel – Institute For Food & Health, Technische Universität München, Freising-Weihenstephan/Germany*

**Contact E-mail Address:** hongsup.yoon@tum.de
**Introduction:** Early exposure to antibiotics (AB) has been associated with increased risk for later development of inflammatory bowel diseases (IBD) but the causal relevance and pathophysiological mechanisms are unknown. Specific AB treatments induce a major increase of the large intestinal protease activity (liPA) via the elimination of bacteria that mediate the physiological inactivation of pancreatic proteases in the large intestine.
**Aims & Methods:** We hypothesized that the AB-mediated rapid increase in liPA may impair the large intestinal barrier and promote the development of chronic inflammation. In order to investigate this hypothesis, we treated wildtype (WT) and interleukin 10 deficient (IL10-/-) mice with vancomycin/metronidazole (V/M) and investigated the impact of this AB therapy on the liPA, the intestinal barrier function and the subsequent susceptibility towards dextran sodium sulfate (DSS)-induced and spontaneous colitis.
**Results:** V/M-mediated elimination of anti-proteolytic bacteria in the large intestinal ecosystem resulted in a rise of large intestinal pancreatic trypsin (~20x) and liPA (~5–10x), being comparable to the levels observed in GF mice. Transwell and Ussing chamber analyses using large intestinal epithelial cells or cecal tissue revealed that the high proteolytic activity in cecal supernatants (CS) from V/M-treated or GF mice significantly impaired the epithelial barrier function in a serine protease dependent way. In WT and IL10-/- mice, the acute V/M-mediated increase in liPA was associated with impaired large intestinal barrier functions (Ussing chamber) and increased translocation of orally applied FITC dextran (4 kDa) to the systemic circulation. Importantly, oral co-administration of a serine protease inhibitor, AEBSF, maintained normal intestinal barrier functions in V/M-treated WT mice. Repeated short term V/M treatments of WT mice ($2 \times 7$ days, at 4 and 8 weeks of age) resulted in chronically increased liPA but did not affect later susceptibility towards DSS-induced colitis (at 12 weeks). However, analogously V/M-treated IL10-/- mice showed accelerated development of chronic colitis, systemic inflammation and large intestinal tumor formation.
**Conclusion:** V/M treatment results in a rapid and major increase in liPA which is detrimental to the intestinal barrier. Pulsed V/M treatments mediated a chronic increase in liPA as well as accelerated colitis development in IBD susceptible mice. These findings demonstrate that specific AB therapies can indeed promote the development of IBD in disease susceptible organisms and indicate that the increase in liPA may contribute to this long-term adverse effect.

**Introduction:** Neutrophils dependent oxidative stress (OS) in the intestinal mucosa plays an important role in ulcerative colitis (UC) disease. Several antioxidants inhibit the inflammatory responses in intestinal tracts system. Therefore, we investigated reactive oxygen species (ROS) and antioxidants levels in tissue specimens and their correlation with disease activity.

**Aims & Methods:** In total, 44 UC patients (M/F 23/21, mean age $41.2 \pm 11.8$) were compared with 33 controls (M/F 18/15, mean age $48.23 \pm 15.12$). Clinical disease activity was estimated according to Truelove–Witts Index values $<150$, 150–220, and $>220$ corresponded to mild, moderate, and severe, respectively. OS was estimated based on malondialdehyde (MDA), superoxide dismutase (SOD), glutathione peroxidase (GPX), and myeloperoxidase (MPO) levels in tissue specimens using the thiobarbituric acid-trichloroaceticacid assay for MDA-phenyltetrazolium chloride assay for SOD, method of Paglia and Valentine for GPX, and tetramethyl benzidin assay for MPO measurement. Chi-square test, Student's t-test, Mann–Whitney test, multivariate regression analysis, and the area under receiver operating characteristic (ROC) curve were used for statistical analysis

**Results:** In controls, MDA levels correlated positively with GPX, MPO, and SOD levels ($r = 0.68$, $p = 0.02$; $r = 0.72$, $p = 0.02$; $r = 0.42$, $p = 0.03$, respectively). MDA level of patients with mild AI correlated positively with GPX and SOD levels ($r = 0.73$, $p = 0.01$ and $r = 0.82$, $p = 0.01$, respectively). Patients with mild and moderate AI had similar MDA levels as the controls. Patients with severe AI had significantly higher MDA and MPO levels than the controls did ($p = 0.03$ and 0.004, respectively), but in patients with high AI, MDA levels correlated inversely with the GPX and SOD levels ($r = -0.79$, $p = 0.01$ and $r = -0.68$, $p = 0.03$, respectively). The ROC curves revealed statistically significant discriminative power of MDA and MPO levels for high AI (AUROC = 0.69 and 0.58, respectively). Tissue MDA ($B = 0.22$, $p = 0.006$), and MPO levels ($B = 1.48$, $p = 0.03$), were independently associated with high AI. Increased MDA (OR 1.48; %95 CI, 1.08–2.16, $p = 0.04$) was risk factor for disease severity and increase of SOD- and GPX activity had preventive effect against high AI (OR 0.008; %95 CI, 0.001–0.98, $p = 0.04$ and OR 0.006; %95 CI, 0.02–0.67, $p = 0.045$, respectively).

**Conclusion:** Our findings show that UC patients with enhanced oxidative stress and subsequent depletion of antioxidant capacity have increased risk for severe clinical activity. Therefore, therapeutic interventions with antioxidant agents should be considered for the treatment in UC patients with high clinical activity index

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0801 AQUAPORIN EXPRESSION AND LOCALIZATION IN COLONIC BIOPSIES FROM COLLAGENOUS COLITIS PATIENTS

**Introduction:** Collagenous colitis (CC) is an inflammatory bowel disease and common cause for watery diarrhoea. The diarrhoeal mechanisms in CC are poorly understood as well as the mode of action how budesonide effectively reduces stool frequency and improves stool consistency. Aquaporins are water channels responsible for absorption and water balance in the colon as well as water homeostasis inside cells. We therefore investigated aquaporins in colonic biopsies of CC patients with active disease and in clinical remission under budesonide therapy.

**Aims & Methods:** The aquaporin expression was assessed using qPCR on colonic biopsies. The aquaporins investigated were AQP1, AQP3, AQP4, AQP6, AQP7, AQP8, AQP9, AQP10 and AQP11. We also investigated the sodium/hydrogen exchanger 1 (NHE1).

**Results:** qPCR analysis of the colonic biopsies revealed a significant decrease in the mRNA expression of AQP1, AQP8, AQP11 and NHE1 in CC-patients compared to healthy controls. For AQP1 and AQP11 there were, however, no significant differences observed during budesonide treatment, compared to controls. We observed a significant increase in the expressions of AQP8 and NHE1 within the patient group during treatment. The clinical improvement seen in CC patients during treatment associates with restoration of AQPs expression.

**Conclusion:** CC patients showed a decreased expression level of AQP1, 8, 11 and NHE1 compared to healthy controls. During budesonide treatment the expression was re-established for AQP1 and 11 and significantly increased for AQP8 and NHE1 indicating an involvement of AQPs in CC. This is to our knowledge the first observation of AQP dysregulation in CC patients.

## P0802 ALTERED HUMAN DENDRITIC CELL PHENOTYPE AND SUBSET COMPOSITION IN THE BLOOD AND GASTROINTESTINAL TRACT OF ULCERATIVE COLITIS PATIENTS

**D. Bernardo**[1], M. Chaparro[1], I. Mora-Gutierrez[2], A.C. Marin[1], P.M. Linares[1], A. Diaz-Guerra[1], F. De La Morena[1], M. Jimenez[1], J. P. Gisbert[1]

**Contact E-mail Address:** d.bernardo.ordiz@gmail.com

**Introduction:** Dendritic cells (DC), the most potent antigen presenting cells, determine the outcome (pro-inflammatory/tolerogenic) of antigen-specific adaptive immune responses. In the gastrointestinal tract, DC promote the mechanisms of immune tolerance towards the nutrients and the commensals while initiate immune responses against invading pathogens. Changes in their immunity/tolerance balance have been related with the development of inflammatory bowel diseases, including ulcerative colitis (UC).

**Aims & Methods:** Our aim was to characterize human DC (both circulating and intestinal) from endoscopically active UC patients and healthy controls. To that end, we performed a prospective, single centre study were intestinal biopsies were obtained from the inflamed colon and non-inflamed terminal ileum (TI) from UC patients. The colon and TI from non-inflamed healthy controls without autoimmune diseases, infections or malignancies were also sampled. Blood samples were obtained from the same patients/controls on the same day of the colonoscopy. All samples were immediately processed in the laboratory and characterized by flow cytometry.

**Results:** Human intestinal DC were identified within singlet viable $CD45^+$ cells as $HLA\text{-}DR^+CD11c^+CD14^-CD64^-$ and divided into subsets based on the expression of CD103 and SIRP$\alpha$. $CD103^-SIRP\alpha^+$ DC were the main intestinal subset and together with $CD103^+SIRP\alpha^+$ DC were $CD1c^+ILT3^+$. CCR2 was expressed in all $CD103^-SIRP\alpha^+$ DC with expression being variable on the $CD103^+SIRP\alpha^+$ subset, where it was inversely correlated with CD103 expression. $CD103^+SIRP\alpha^-$ DC constituted a minor subset and were $CD141^+ILT3^-CCR2^-$. Circulating DC were identified within the $HLA\text{-}DR^+CD14^-CD16^-CD19^-$ fraction as plasmacytoid (pDC, $CD123^+$) and myeloid (mDC, $CD11c^+$), being the later divided into mDC1 ($CD1c^+$) and mDC2 ($CD141^+$). mDC1 and pDC were $SIRP\alpha^+ILT3^+CCR2^+$ while mDC2 were $SIRP\alpha^-ILT3^-CCR2^-$. $CD1c^+$mDC (but not pDC or $CD141^+$mDC) were recruited in a CCR2-deppedent manner by the human colon before they subsequently up-regualted CD103 and down-regulated CCR2 expression in time. In UC patients, the numbers of intestinal $CD103^+SIRP\alpha^+$ DC were reduced. CCR2 expression was lower in both $CD103^+SIRP\alpha^+$ and $CD103^-SIRP\alpha^+$ subsets while HLA-DR intensity was also lower in all intestinal DC subsets. Such differences were indeed observed in both the inflamed colon and the non-inflamed (TI) tissue from UC patients compared with the matched tissue from the healthy controls with no differences between the inflamed and non-inflamed areas in UC patients. Circulating mDC1, mDC2 and pDC from UC patients also had lower HLA-DR expression in comparison with healthy controls.

**Conclusion:** Human intestinal DC subset composition and their phenotype are altered in both inflamed (colon) and non-inflamed (TI) intestinal segments in UC patients as well as in their circulating counterparts compared to healthy controls. Future studies will determine whether such differences are also resembled into a different functionality and should identify the mechanisms responsible for such differences.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0803 THE ROLE OF PLATELETS IN INFLAMMATORY BOWEL DISEASE

**S. Bourke**[1], A. Chauhan[2], T. Iqbal[3], P.F. Lalor[1]
[1]*Centre For Liver Research, University of Birmingham, Birmingham/United Kingdom*

[3]*Gastroenetrology, University Of Birmingham Queen Elizabeth Hospital, Birmingham/United Kingdom*

**Contact E-mail Address:** SPB120@student.bham.ac.uk

**Introduction:** Inflammatory Bowel Disease (IBD) is a chronic relapsing inflammatory disorder of the GI tract, thought to be caused by an uncontrolled immune response to commensal gut bacteria in genetically susceptible individuals. Patients with IBD have higher platelet counts and an increased risk of thrombosis than matched controls. Retrospective reviews have noted improvements in disease activity among patients taking antiplatelet therapy, and murine models have highlighted that Clopidogrel confers protection against mucosal damage. It is therefore possible that platelets play an active role in the disease pathogenesis through interaction with a plethora of immune cells.

**Aims & Methods:** Patients with Crohn's Disease undergoing therapeutic resections at Queen Elizabeth Hospital, Birmingham, donated tissue sections from both macroscopically active and non-active diseased regions. Matched blood samples were taken for Flow Cytometric analysis of activated platelets. Immunohistochemical staining to detect the presence of endogenous platelets within diseased samples, and functional adhesion assays were used to elicit the key integrins involved in platelet-immune cell interactions.

**Results:** Patients with Crohn's Disease had a significant decrease in the percentage of activated platelets compared to controls ($P < 0.02$), measured using percentage of P-Selectin positive platelets. The hypothesis that populations of activated platelets undergo sequestration within diseased bowel was supported by immunochemical staining. Immunohistochemical staining highlighted the

presence of Podoplanin-positive structures, likely to be macrophages, within diseased bowel, highlighting the importance of the podoplanin-CLEC-2 interactions in immune cell recruitment. Functional adhesion assays have highlighted key roles for P-Selectin in the interaction between platelets and immune cells.
**Conclusion:** These interactions show promise as novel therapeutic targets in the management of Inflammatory Bowel Disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0804 LOSS OF PRDX6 AMELIORATES DSS-INDUCED ACUTE AND CHRONIC COLITIS

**H. Melhem**[1], S. Lang[2], K. Atrott[3], G. Rogler[4], I. Frey-Wagner[2]
[1]*Gastroenterology Unit, University hospital of Zurich, Zurich/Switzerland*
[2]*Division Of Gastroenterology And Hepatology, University Hospital Zurich, Zürich/Switzerland*
[3]*Gastroenterology And Hepatology, University Hospital Zurich, Zurich/Switzerland*
[4]*Klinik Für Gastroenterologie, UniversitätsSpital Zürich, Zürich/Switzerland*

**Contact E-mail Address:** Hassan. Melhem@usz.ch
**Background:** An imbalance between cellular antioxidant defense system(s) and reactive oxygen species (ROS)-driven oxidative stress has been implicated in the pathogenesis of inflammatory bowel disease (IBD). Peroxiredoxin (Prdx) 6, a protective protein with GSH peroxidase and acidic calcium-independent phospholipase A2 activities, maintains an appropriate redox balance by clearing ROS and thereby optimizing gene regulation.
**Aims:** We therefore hypothesized that loss of Prdx6 would lead to enhanced susceptibility to DSS induced acute and chronic intestinal inflammation.
**Design:** To investigate the impact of Prdx6 in intestinal inflammation, we used wild type (WT), Prdx6 knock-out mice ($Prdx6^{-/-}$) and transgenic mice ($Prdx6^{+/+}$), expressing a constitutively active form of Prdx6. Acute and chronic colitis was induced by dextran sulfate sodium (DSS) in WT, $Prdx6^{-/-}$, and $Prdx6^{+/+}$ mice. Colitis was evaluated clinically, histologically and endoscopically. Changes in the mRNA expression of cytokines and antioxidants enzymes were evaluated by RT-qPCR.
**Results:** $Prdx6^{-/-}$ mice exposed to acute and chronic DSS showed a significant decrease in the clinical parameters or in the colon levels of pro-inflammatory cytokines compared to WT mice. In DSS-induced acute and chronic colitis, colon levels of antioxidant enzymes were significantly increased in $Prdx6^{-/-}$compared to WT mice. In addition, total GSH level was increased in $Prdx6^{-/-}$ mice exposed to DSS as compared with the WT. However, overexpression of Prdx6 in mice does not influence the acute and the chronic colitis even a trend towards an amelioration of some cytokines expression in the chronic model.
**Conclusion:** Our data show that the antioxidant Prdx6 deficiency does not affect negatively the DSS-induced acute and chronic colitis but is associated with increased antioxidants enzymes suggesting a critical role of Prdx6 and several compensatory mechanisms during acute chronic colitis. Thus, our finding indicates that cells require well balanced of antioxidant gene to limit excessive inflammation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0805 THE ROLE OF DIPEPTIDYL PEPTIDASES IN INFLAMMATORY BOWEL DISEASE

[4]*Gastroenterology & Hepatology, Flinders Medical Centre, Adelaide/Australia/SA*
[5]*Gastroenterology, Basil Hetzel Institute, Adelaide/Australia/SA*

**Contact E-mail Address:** s.jaenisch@outlook.com
**Introduction:** Inflammatory bowel disease (IBD) is a chronic, multi-factorial disease that includes complex interactions between host genetics, the intestinal microbiome and lifestyle factors. Dipeptidyl Peptidase (DPP)-IV is a ubiquitously expressed type-II integral membrane glycoprotein that has been implicated in the immuno-pathogenesis of inflammatory disease including IBD.
**Aims & Methods:** This study retrospectively investigated the role of DPP-IV and other related serine proteases in human IBD. The mRNA expression of DPPIV, DPP8, DPP9, DPP2 and fibroblast activation protein (FAP) was determined in colonic biopsies collected from Crohn's Disease (CD), Ulcerative colitis (UC) and healthy patients (n = 8/group) at the Queen Elizabeth Hospital. RNA was isolated from colonic biopsies using the spin-column technique and cDNA was then synthesized using a reverse transcriptase kit. Relative mRNA expression was quantified using SYBR green technologies. Gene expression data was expressed as the average relative-fold change determined by the comparative Ct method. Sera samples were collected from CD (n = 96) and UC (n = 54) patients at Flinders Medical Centre between 2008 & 2015. Plasma samples from healthy adult donor's (n = 11) were collected at the Women's and Children's Hospital. DPP enzyme activity was quantified by colorimetric enzyme activity assay using the substrate H-Ala-Pro-pNA. Enzyme activity is expressed as median units of activity (U)/mg of protein (range).
**Results:** There was a 6-fold decrease in DPPIV gene expression in CD and UC patient biopsies. DPP8 & DPP9 gene expression was down-regulated 2.5 fold in both CD and UC samples. DPP2 gene expression was unchanged in UC patients; however, in CD patients, there was 3-fold decrease. FAP expression was unchanged in CD patients; conversely, FAP was upregulated 3-fold in UC patients. DPP enzyme activity in the sera was unchanged between healthy 0.41U/mg (0.24–1.11), CD 0.46U/mg (0.14–1.73) and UC 0.54U/mg (0.28–1.23) patient groups.
**Conclusion:** The current study indicates that there is differential DPP gene expression in human IBD; however, further studies are needed to decipher how these changes correspond to disease pathogenesis. Although there was no significant differences in enzyme activity between patient groups, the retrospective data that we have analysed does not specify active and inactive disease. The range of enzyme activity within patient groups suggests that DPP enzyme activity may correspond to disease parameters. We are currently undertaking a prospective study in adult IBD patients to delineate the mechanism of DPPs in the pathogenesis IBD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0806 ROLE OF EXTRINSIC PRIMARY AFFERENTS AND ASIC 3 IN PELVIC CROSS-ORGAN SENSITIZATION

**K. Atmani**[1], L. Langlois[2], G. Gourcerol[3], M. Meleine[1]
[1]*Biology, INSERM U1073, Rouen/France*
[2]*Université De Rouen, Inserm U1073, Rouen/France*
[3]*Dept. Of Digestive Physiology, CHU Rouen Hopital C. Nicolle Dept. de Physiologie Digestive, Rouen Cedex/France*

**Contact E-mail Address:** karim.atmani1@univ-rouen.fr
**Introduction:** Irritable bowel syndrome and bladder pain syndrome are both characterized by pain in response to organ distension. Epidemiologic studies showed that these two syndromes are often overlapped. Since these pelvic organs share a common extrinsic innervation, it is likely that those syndromes involve a cross-sensitization of the bladder and the colon in response to mechanical distension of the gut.
**Aims & Methods:** The aim of this project was to develop and characterized a rodent model of bladder-colon sensitization. Double retro-labelling was performed to indentify extrinsic primary afferent neurons innervating both the colon (Fluororuby) and the bladder (Flurogold) in the S1–L6 dorsal root ganglia of Sprague Dawley rats. The phenotype of the colon/bladder co-innervating primary afferents was assessed using immunochemistry directed against TRPV4 and ASIC 3. Cross-organ sensitization was obtained in Sprague Dawley rats using echography-guided intravesical administration of acetic acid (0.75%) under brief isoflurane anesthesia. Colonic sensitivity was assessed in conscious rats by measuring abdominal contraction during isobaric colo-rectal distension.
**Results:** Immunohistochemistry showed that 73.1% of extrinsic primary afferents co-innervating the colon and the bladder expressed ASIC 3, and 53.8% expressed TRPV4. By contrast, extrinsic primary afferents innervating the colon or the bladder were positive for ASIC 3 in 39.3 and 42.6%, and for TRPV4 in 70.5 and 57.8% of the case, respectively. Based on these results, colonic hypersensitivity to colorectal distension was observed after intravesical administration of acetic acid (0.75%). This effect started 1 h post-injection and lasted up to 24 h, and was not longer seen after 3 days after injection. Colonic sensitization by intravesical acetic acid administration was prevented by S1 intrathecal administration of APETx2 (2.2$\mu$M), an ASIC 3 blocker.
**Conclusion:** We developed an acute pelvic cross-organ sensitization model in conscious rat. In this model, cross-organ sensitization is likely to involve S1–L6 extrinsic primary afferents co-innervating the colon and the bladder through an ASIC 3 pathway.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0807 INDIAN MIGRANTS HAVE A HIGHER INCIDENCE OF ULCERATIVE COLITIS, MORE SEVERE DISEASE PHENOTYPE AND YOUNGER AGE OF PRESENTATION IN SECOND GENERATION MIGRANTS COMPARED WITH CAUCASIANS: RESULTS FROM A 1-YEAR PROSPECTIVE POPULATION-BASED INCEPTION COHORT STUDY

**Contact E-mail Address:** r.misra15@imperial.ac.uk
**Introduction:** The world-wide incidence of inflammatory bowel disease (IBD) is increasing. Migration influences disease epidemiology. South Asians are the predominant migrant group in the UK with a previously reported highest ulcerative colitis (UC) incidence of 17.2/100.00) and a pan-colonic phenotype.[1] These studies were retrospective and last performed over 10 years ago.[2]
**Aims & Methods:** We aimed to compare the incidence of IBD and disease phenotype of UC at diagnosis between Indians and Caucasians within our catchment area of approximately 500,000 people. All new diagnoses of IBD between February 1st 2015–January 31st 2016 were recorded. Demographic data, ethnicity, smoking status, faecal calprotectin and Simple Clinical Colitis Activity Index (SCCAI) were completed at diagnosis. Data was collated on the validated Epicom database. Information on population size and ethnicity was obtained from 2011 Census data.

**Results:** Eighty-eight patients fulfilled Copenhagen diagnostic criteria for IBD. Eleven living outside the catchment area were excluded. 48/77 were male (Table 1). The predominant ethnic group was Indian (33 cases) with a median age at presentation of 36 years (IQR 29–51) compared with 23 Caucasian cases at 40 years (IQR 33–61.5). The crude incidence of IBD, UC and Crohn's in the Indian group was 26.4, 19.4 and 6.6/100,000 cases respectively compared with 10.7, 7.1 and 2.8/100,000 cases inthe Caucasian group. Average time between symptom onset and diagnosis was 97 days (65–129, 95%CI) for Indians and 56 days (31–81, 95% CI) for Caucasians ($p < 0.001$). Further analysis compared UC between Indians and Caucasians: 50% and 47% had extensive colitis at diagnosis, 81% and 41% never smoked. The median age at diagnosis of first generation Indians was 49 years (IQR 36–65) and was lower in the 2nd generation Indian group compared to Caucasians. (26 years, IQR 20–34 vs 40 years, IQR 33–63, $p < 0.0001$). Indian patients had higher mean SCCAI scores (6.8 vs 4.3), higher mean calprotectin at diagnosis (907 vs 708 ug/g) and lower mean vitamin D levels at diagnosis (16.6 vs 29.8 ng/mL). They also required steroids within 3 months in 8/33 cases vs 2/23 ($p = 0.17$) in Caucasians.

**Table 1:** Demographic and Clinical data comparing Indian and Caucasian groups

| | Caucasian | Indian | Other |
|---|---|---|---|
| **M/F** | 13/10 | 19/14 | 17/5 |
| **Median age at presentation (years)** | 40 (33–62) | 36 (29–51) | |
| **Crude Incidence (cases/100,000)** | | | |
| **IBD** | 10.7 | 26.4 | |
| **UC** | 7.0 | 19.4 | |
| **CD** | 2.8 | 6.6 | |
| **Time to diagnosis (days, 95% CI)** | 56 (31–81) | 97 (65–129) | |
| **Disease phenotype** | | | |
| **E1** | 5 | 9 | |
| **E2** | 4 | 3 | |
| **E3** | 8 | 12 | |
| **1st vs 2nd generation** | - | 19/13 | |
| **Median Age at diagnosis 1st/2nd generation (years)** | - | 41/26 | |
| **Vitamin D (ng/mL, 95% CI)** | 29.8 (14.7–44.5) | 16.6 (9.9–23.2) | |
| **SCCAI at diagnosis (95% CI)** | 4.3 (2.4–6.2) | 6.8 (5.5–6.8) | |
| **Smoking** | | | |
| **Never** | 7 | 18 | |
| **Former** | 8 | 0 | |
| **Current** | 2 | 4 | |
| **Calprotectin before treatment (ug/g, 95% CI)** | 708 (367–1049) | 907 (638–1176) | |
| **Treatment** | | | |
| **Steroids within 3 months** | 2 | 8 | |
| **5-ASA** | 7 | 5 | |
| **Hospital admission** | 3 | 5 | |

**Conclusion:** We report the highest incidence of UC in the Indian migrant population in the literature. The higher SCCAI and calprotectin indicate a more aggressive disease phenotype however the significant delay in diagnosis maybe a confounding factor. Second-generation migrants presented at a younger age than first generation migrants and Caucasians. Migrants have a potential genetic predisposition enhancing susceptibility to environmental exposure. Further studies in first and second-generation migrants examining the impact of factors such as diet on the microbial and metagenomic profille may help to explain the more aggressive disease phenotype and decipher the role of genetics and environment within this group.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Perianal Crohn's disease (PCD) is a frequent dreaded condition during Crohn's disease that predicts a disabling course and drastically alters quality of life of patients. Natural history of PCD remains poorly describes, mainly based on retrospective studies from referral centers. The Aims of the present study were to assess the incidence, outcomes and predictors of onset of PCD.
**Aims & Methods:** All incident cases of patients diagnosed with possible CD ($n = 370$) were registered from 1994 to 1997 in Brittany, a limited area in France. At diagnosis were recorded clinical features, endoscopic lesion per ileocolic segment (according to the CDEIS), radiologic and histologic data. All charts of patients were reviewed from the diagnosis to the last clinic in 2015. Cumulative incidence of PCD and each elementary PCD lesions were estimated using the Kaplan-Meier method. Independent predictors of all outcomes were identified using a Cox proportional hazards model.
**Results:** Among the 370 incident cases, 39 had not Crohn's disease and 272 of the 331 cases with CD (82%) were reviewed with a median follow-up of 12.8 years. During the follow-up period, 87 (32%) of patients developed PCD. Cumulative probabilities of PCD occurrence were 22%, 29%, 32% and 24% at 1 year, 5 years, and 10 years and 15 years, respectively. Rectal involvement at diagnosis was independently associated with an increased risk of PCD occurrence ($HR = 1.72$, $p = 0.01$) Cumulative probabilities of perianal ulceration were 14%, 17%, 19% and 21% at 1 year, 5 years, 10 years and 15 years, respectively. No predictor of anal ulceration onset was observed. Conversely ileal disease at diagnosis was associated with less occurrence of anal ulceration ($HR = 0.53$, IC95 [0.29–0.99]). Cumulative probabilities of fistulizing perianal Crohn's disease were 11%, 16%, 19% and 20% at 1 year, 5 years, and 10 years and 15 years, respectively. Perianal ulceration prior to anal fistula ($HR = 13.7$, IC95 [7.33–24.8]) and rectal superficial and/or deep ulceration at diagnosis ($HR = 2.1$, IC95 [1.2–3.65]) were predictors of fistulizing perianal disease occurence. Anal stenosis was never observed without prior history of perianal lesion. Anal stenosis was describe in 13 patients (4%) concomitant to anal ulceration or following fistulizing perianal disease.
**Conclusion:** PCD are frequently observed during Crohn's disease for broadly one third of patient. These data underline the need to early treat patient with rectal involvement and anal ulceration to avoid the onset of fistulizing perianal disease.

## P0809 CLOSTRIDIUM DIFFICILE INFECTION WORSEN OUTCOME OF HOSPITALIZED PATIENTS WITH INFLAMMATORY BOWEL DISEASE

**Y. Chen**, T. Zhang
*Gastroenterology, Nanfang Hospital, Southern Medical University, Guangzhou/China*

**Contact E-mail Address:** yechen_fimmu@163.com

**Introduction:** The prevalence of *Clostridium difficile* infection (CDI) in inflammatory bowel disease (IBD) patients has been reported increasing rapidly over the past several decades in North America and Europe. However, the exact global epidemiology is hindered due to lack of data from developing countries.
**Aims & Methods:** In the present study, we sought to evaluate the prevalence and risk factors of CDI and the impact of CDI on IBD patients. A total of 646 hospitalized adult IBD patients were enrolled; and their fresh stool specimens were acquired and used for *Clostridium difficile* detection. Clinical data were collected to evaluate IBD disease progression with two years following-up. Potential risk factors including demography, IBD disease characteristics within one year and pre- and in-hospital concomitant medication use within six months were recorded.
**Results:** The incidence of CDI in CD patients (12.7%) was significantly lower than that in UC patients (19.3%); and the most common toxin type was $A^+B^+$ strains. Length of stay, hospitalization times and bowel surgery rate were significantly higher in CDI than non-CDI group either in CD or in UC patients. Moreover, more patients in CDI-CD group were still in active and even clinical moderate or severe CD stage than non-CDI-CD group after two years following-up. Fistula, antibiotics and infliximab usage were likely to increase the CDI rate in CD patients, while risk factor in UC patients was infliximab treatment.
**Conclusion:** CDI is a growing public health issue and may influence the IBD course, increase the expenditure even delay remission of IBD patients. Increasing attention need to be paid to complication of IBD by CDI urgently.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Colorectal cancer (CRC) is perhaps the most undesirable adverse outcome in inflammatory bowel disease (IBD).

**Aims & Methods:** The aim of this study is to estimate the rate of CRC in a single center cohort of IBD patients and to identify potential predisposing factors. A retrospective review of the endoscopy charts of the period 1996–2016 was conducted. All patients enrolled exhibited both endoscopic and histologic documentation of IBD. Patient and disease (Montreal classification) characteristics, change in location and behaviour of IBD, location of CRC and treatment with imunomodulators and antiTNFalpha agents were recorded. As index colonoscopy was defined the one that established IBD diagnosis.

**Results:** So far, 550 IBD patients having undergone 1805 colonoscopies have been registered. Males are 279 [50.7%]. Median age at IBD diagnosis is 41 years [IQR: 27–55, range: 2–89]. Median follow-up period is 37.2 months [IQR: 3.5–94.6, range: 0–504.4]. Ulcerative colitis (UC) was diagnosed in 274 [49.8%], Crohn's disease (CD) in 272 [49.5%] and IBD unclassified in 4 [0.7%] patients. IBD location changed in 49 UC [17.9%] and in 32 CD [11.7%] patients. CD behaviour progressed to a worse state in 21 [7.7%] patients. Eight patients [1.5%] developed CRC; 2 with CD ileocolitis (both in the right colon) and 6 with UC of who 4 were classified as having extensive colitis (two rectal, one in the right and one in the left colon) and 2 as having left-sided colitis (both in the left colon). None of these patients had been operated for IBD. A non-passable colonic stenosis was already known before CRC diagnosis in only one patient while no apparent stenosis had been detected in the rest. Two patients with CRC received azathioprine for more than 3 years, whereas none was treated with an anti-TNFalpha agent.

**Conclusion:** The rate of CRC is low in our cohort of IBD patients and compatible with literature data regarding Caucasian populations. No association was observed with specific predisposing factors that were studied.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0812 IMPACT OF BIOLOGICAL THERAPY ON IBD HOSPITALIZATIONS OUTCOMES: REPORT FROM AN ITALIAN TERTIARY CENTRE BETWEEN 2000 AND 2013

**Introduction:** In recent years the management of Inflammatory bowel disease (IBD) is changing, in particular, due to the introduction of biological therapy. New advances in this context made progressively possible to manage these conditions in the outpatient setting. While the advantages of biological therapy are unquestionable, there is still controversy if they can truly modify disease outcomes.

**Aims & Methods:** Aim of the study was to describe IBD admissions and outcomes variations between the pre- and post- biologic era in an Italian tertiary centre between the years 2000 and 2013. All hospitalizations for Crohn's disease (CD) or ulcerative colitis (UC) were indentified from Policlinico "A. Gemelli" between 2000 and 2013 using ICD-9-CM codes for IBD. Hospitalization outcomes were stratified in 3 groups (elective restaging, therapy administration or unrelated). Surgery and complications related to IBD during the hospitalization were also evaluated. For CD the year 2003 was used as "cut-off" for pre- and post- biologic era, while 2007 was used for UC, as those were the years of introduction of biologics at Policlinico "A. Gemelli". Statistical analysis was performed by Chi2 test for qualitative variables and the Student's t test for quantitative variables. Statistical significance was defined for p values less than 0.05.

**Results:** Between the years 2000 and 2013 an overall of 8834 admissions were recorded at "Policlinico A. Gemelli" for IBD, specifically, 52.3% CD and 47.7% UC. Hospitalizations due to IBD increased reaching a peak in 2006, with a downward trend in the following years. Analyzing hospitalization outcomes we found a statistically significant difference between pre- and post- biologic groups for both CD and UC, with a relative increase in the therapy administration group. A surgical procedure was required in 10.8% of admissions, in particular 11.0% for CD and 10.7% for UC, without difference between pre- and post-biologic era in both the diseases. Complications occurred in 28.7% of admissions, 31.6% for CD and 25.5% for UC. The most common complications were fistula (10.1%) for CD and osteo-articular manifestations for UC (6.6%). We did not find differences in the overall occurrence of complications between pre- and post-biologic era in both the diseases, however we noted a variation in the incidence of single complications.

**Conclusion:** Hospitalizations due to IBD are now decreasing, consistently with the hypothesis that introduction of biologic therapy is associated with a progressive switch to the outpatient management. However, initial necessity of hospitalization for patients receiving biologics may explain the relative raise in admissions for therapy administration in the post-biologic era. About 11% of admitted patients underwent a surgical procedure related to IBD. We did not find difference in surgical procedure occurrence after biologic introduction for both diseases. About 23% of admitted patients presented an IBD-related complications, which were also slightly more frequent in CD. Introduction of biologics is associated with variation in the incidence of IBD-related complications.

## P0813 PREVALENCE OF IRON DEFICIENCY WITHOUT ANAEMIA IN INFLAMMATORY BOWEL DISEASE AND ITS IMPACT ON THE QUALITY OF LIFE

**C. González Alayón**, C. Pedrajas Crespo, S. Marín Pedrosa, J.M. Benítez Cantero, E. Iglesias Flores, V. García Sánchez
*Gastroenterology, University Hospital Reina Sofía, Córdoba/Spain*

**Contact E-mail Address:** carlosalayon@hotmail.com

**Introduction:** Iron deficiency without anaemia (IDWA) is a common finding in patients with inflammatory bowel disease (IBD). The real magnitude of this issue and its consequences are unknown, although it is underestimated.

**Aims & Methods:** To determine the prevalence of IDWA, identifying factors related to this condition and its impact on quality of life of patients. We evaluate the medical approach of this situation. We carried out an observational, transversal and single-centre study from population-based Córdoba IBD cohort. Consecutive patients were included from April to June 2015, and demographics, clinical and laboratory data were collected. IDWA was defined as ferritin levels $< 30$ or $< 100$ ng / mL with absence or presence of inflammatory activity respectively, with normal levels of hemoglobin. Univariate and multivariate analysis was performed to identify predictor factors, comparing IDWA patients with those without iron deficiency. The quality of life was assessed with the IBDQ-9 and FACIT-F questionnaires. The medical management was assessed.

**Results:** 127 patients (58.3% men and 41.7% women, mean age $42.27 \pm 12.08$ years) diagnose with IBD were included. The prevalence of IDWA was of 37%, normal iron deposits with normal levels of hemoglobin was 50.4% and 12.6% anaemia. In multivariate analysis the female gender (OR = 2.8, 95% CI: 1.2–6.6, $p = 0.015$) and inflammatory activity (OR = 9.4, 95% CI: 2.5–35.9, $p = 0.001$) were the variables associated with IDWA. Excluding the patients with anaemia, the group with IDWA had a worse quality of life (with a lower score in IBDQ-9 and FACIT-F questionnaires which decreased 6.55 and 4.26 points, respectively, compared to the group with normal deposits). Extreme fatigue was higher in the IDWA group, 64.7% versus 35.3%. In less than 30% of cases, an active therapeutic approach (like oral iron supplements) was performed.

**Conclusion:** Over one third of patients with IBD showed IDWA. Factors as the female gender and the inflammatory activity of the disease were associated with a higher prevalence of this complication. The IDWA had a negative impact on the quality of life of patients. An active and optimized therapeutic approach is required.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** christina.christ@immundiagnostik.com

**Introduction:** Vedolizumab (VLZ), an $\alpha4\beta7$ integrin antagonist, is a therapeutic monoclonal antibody recently approved for use in moderate to severe ulcerative colitis and Crohn's disease. As for TNFa agonists, measurement of serum levels is indispensable for the optimization of VLZ therapy. Typically, ligand binding assays (LBA), such as enzyme-linked immunosorbent assays (ELISAs), are used to measure serum antibody levels. However, LBAs may have significant limitations, including procurement or generation of the binding reagents, interference from matrix components, and drug antibodies. To overcome these limitations, we have developed a reliable tandem liquid chromatographic mass spectrometric (LC-MS/MS) method to quantify VLZ serum levels.

**Aims & Methods:** Serum analyses were performed on an ultra performance liquid chromatography (UPLC)-MS/MS system (Ultimate 3000 Binary RSLC system, Thermo Scientific, Waltham, MA, USA) coupled to a TSQ Vantage triple quadrupole mass spectrometer (Thermo Scientific, Waltham, MA, USA) with an H-ESI II ionization source. The analytical column was an Acquity UPLC BEH Shield RP C18 2.1 mm × 50 mm column with 1.7$\mu$m particle size. The mobile phases were KM9600LMA and KM96LMB. VLZ was extracted from serum by a modified ''pellet digestion'' technique. Tryptic peptides for quantification were identified for VLZ using a selective reaction monitoring (SRM) mass spectrometry method.

**Results:** Sensitivity for VLZ was determined to be 1.6$\mu$g/mL. The standard curves showed high reproducibility and sensitivity. Intra- and inter-assay precision were 10.46% and 7.67%, respectively, and accuracy was within 20%. There was no significant interference from lipemic, hemolyzed, or rheumatoid factor (Rf) serum.

**Conclusion:** A general LC-MS/MS method approach using immunocapture was developed, qualified, and applied to VLZ quantification in serum, with an affinity purification time of one hour. The method has been demonstrated to be accurate, precise and robust. The LC-MS/MS method may also be applied to other protein-based drugs to accurately detect serum drug levels.

**Introduction:** The aetiology of Crohn's disease (CD) and ulcerative colitis (UC) is not known. Recent data suggest that vitamin D (VD) plays an important role in IBD. Pathways that are influenced by VD in IBD are poorly understood.

**Aims & Methods:** The aim of this study was to analyse the influence of 25(OH) VD serum concentration on the expression of mRNA proinflammatory cytokines (IL-6,IL-23, TNF$\alpha$, CCR1), regulatory cytokines (IL-10,TLR2,CCR9, CD 207) and transcription factor Fox3P in colonic mucosal samples from IBD patients. We performed a cross-sectional study. The cohort consisted of 87 IBD patients (47 CD and 40 UC) followed at the IBD centre of University Hospital Bratislava-Ružinov. We performed colonoscopy in each patient and took biopsies from inflammed and if applicable also from non-inflammed mucosa from sigma (CD, UC) and terminal ileum (CD). Serum concentration of 25(OH) VD was assessed in each patient at the time of colonoscopy. mRNA was extracted from mucosal biopsy samples for each cytokine and isolated by RLT buffer. mRNA was reversely transcribed. We normalized expression of the target genes to the expression of the house-keeping gene (GAPDH). Then we analysed the correlation between serum concentration 25(OH) VD and the expression of mRNA of inflammatory cytokines from biopsies samples.

**Results:** In CD we observed a positive correlation of serum concentration of 25(OH) VD and mRNA expressions levels of TNF$\alpha$ ($r = 0.41$, $p = 0.043$), IL-6($r = 0.45$, $p = 0.023$), IL-10($r = 0.44$, $p = 0.027$), IL-23($r = 0.55$, $p = 0.023$), TLR 2($r = 0.041$, $p = 0.042$) in inflammed mucosa of terminal ileum. A positive correlation was also observed with CCR5($r = 0.042$, $p = 0.011$) and CCR1($r = 0.33$, $p = 0.027$) in non-inflammed mucosa from sigma. We also found a positive correlation between 25(OH) VD and IL-23($r = 0.45$, $p = 0.011$), TLR4($r = 0.42$, $p = 0.017$), CD 207($r = 0.42$, $p = 0.017$), CCR1 ($r = 0.52$, $p = 0.002$), CCR5 ($r = 0.51$ $p = 0.003$) and CD 206($r = 0.43$, $p = 0.014$) in non-inflammed mucosa of sigma in UC.

**Conclusion:** According to our results, VD significantly influences the levels of expression of several inflammatory cytokines including TNF$\alpha$ in colonic mucosa of patients with CD as well UC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0816 DEVELOPMENT OF A DIAGNOSTIC SCORING SYSTEM TO PREDICT MICROSCOPIC COLITIS

**J. S. Kane**[1], R. Sood[2], G. R. Law[3], D. J. Gracie[2], N. To[2], M. J. Gold[4], A.C. Ford[2]

**Contact E-mail Address:** jackjohnkane@googlemail.com

**Introduction:** Many patients presenting with diarrhoea undergo colonoscopy with random biopsies to rule out microscopic colitis (MC), if the colonoscopy is macroscopically normal. However, the yield of taking biopsies in individuals with diarrhoea is low (1). Accurate predictors of MC could identify at-risk individuals, and avoid the need to take biopsies in a substantial proportion of patients, saving money for the health service. We previously derived and validated a diagnostic scoring system for MC based on clinical information alone but this was based on retrospective data (2).

**Aims & Methods:** The aim of this study was to validate the original scoring system in a prospective cohort of patients, and to assess whether incorporating further clinical features could improve its performance. Consecutive adults with loose stools undergoing colonoscopy in Leeds, UK were included. Demographic and symptom data were collected prospectively. Patients with a diagnosis of microscopic colitis including both collagenous and lymphocytic colitis, after histological examination of biopsy specimens, were compared with those with normal biopsies. The diagnostic scoring system described previously, which assigned scores for female gender, current use of proton pump inhibitors or non-steroidal anti-inflammatory drugs, age $\geq$ 50 years, weight loss and the absence of abdominal pain, was applied. In addition, the incorporation of other factors, including other drugs that may be associated with MC (statins and selective serotonin re-uptake inhibitors), number of stools, nocturnal passage of stools, and duration of loose stools, into the scoring system was assessed. Sensitivities, specificities, and positive and negative predictive values were calculated for the modified scoring system.

**Results:** In total, 242 patients (mean age 51.0 years, 163 (67.4%) female), 26 (10.7%) of whom had MC, were included. A cut off of $\geq$4 on the original scoring system had a sensitivity of 92.3% and specificity of 35.2% to detect MC. After including the additional clinical factors, nocturnal passage of stools and duration of loose stools $<$6 months were both found to be significant predictors of MC. Incorporating these variables into a modified scoring system using a cut off of $\geq$6 identified MC with 95.7% sensitivity and 46.0% specificity.

**Conclusion:** Incorporating nocturnal passage of stools and duration of loose stools into our original scoring system may improve ability to predict MC, and avoid random colonic biopsies in a greater proportion of patients with loose stools. Future studies in clinical practice could use this scoring system, alongside biochemical or faecal markers, in the diagnostic pathway for MC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0817 THE ROLE OF FAECAL CALPROTECTIN IN A PRIMARY CARE REFERRAL PATHWAY IN THE UK

M. Tan[1], Y. Subramaniam[1], C. Cheong[1], F. Hasan[1], G.W. Moran[2], **W. Fateen**[2], A. Jawhari[1]

**Introduction:** Faecal calprotectin (FCP) is a clinically useful surrogate marker of intestinal inflammation in Inflammatory Bowel Disease (IBD). Multiple studies confirmed its high negative predictive value (NPV) and low positive predictive value (PPV) for a diagnosis of IBD. This indicates a possible clinical utility in primary care settings to avoid unnecessary referrals to secondary care.
**Aims & Methods:** To evaluate the clinical impact of FCP in a population-based setting in a diagnostic referral pathway for primary care practitioners. Methods. we investigated the outcome of all FCP tests performed in primary care from 1st of May 2015 till 31 of August 2015 in a population-based setting including 703.983 individuals residing in the city of Nottingham, East Midlands. Descriptive statistics were used to summarize the patient demographics and referrals to secondary care. We analysed the impact of GP interpretation of FCP in the context of the clinical presentation and reviewed all electronic records of referrals to secondary care. We used area under the receiver operating characteristic (AUROC) curve for this group to obtain negative and positive predictive values with an FCP cut off of 50 ug/g. The test was considered positive for detection of IBD if the outcome was diagnosis of ulcerative colitis (UC) or Crohn's disease (CD).
**Results:** The total number of tests performed was 809 on 731 patients with no previous history of IBD. There was a female predominance with a ratio of 1.7. The median age was 40 years(IQR = 26). FCP levels were low (< 50ug/g), medium (50–200ug/g) or high (> 200ug/g) in 398, 202 and 131 patients respectively. 23.9%, 42.6% and 71.8% of the patients who had low, medium and high FCP in primary care respectively were referred to secondary care. The total number of referrals was 275 patients. A similar female predominance (ratio = 1.6) and age group (median = 40, IQR = 29) was maintained in the referred cohort. IBD was then confirmed in 10 patients with CD and 5 patients with UC. Twelve patients had high, three had medium and none had a low FCP on presentation to primary care. In the cohort referred to secondary care, FCP had a NPV and PPV of 100% and 8% respectively with a specificity of 37% and a sensitivity of 100%. Ninety-five patients referred with negative FCP had further investigations at the discretion of the hospital clinician: 58 colonoscopies, 19 gastroscopies and 3 MRI small bowel. None of which was diagnosed with IBD.
**Conclusion:** FCP maintains its high NPV and low PPV in real life primary care practice. Of the patients referred to secondary care with a negative FC none had an eventual diagnosis of IBD. A considerable proportion of patients with a negative FCP at presentation were still investigated in secondary care. Our data indicates that FCP may be a reliably good negative test to be used in a primary care referral pathway. Further education of its use is needed for both primary and secondary clinicians to avoid unnecessary referrals and invasive investigations in low risk subgroups
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0818 COLONOSCOPY SURVEILLANCE IN LONG-STANDING INFLAMMATORY BOWEL DISEASE IN A GENERAL DISTRICT HOSPITAL AND COMPARISON BETWEEN WHITE LIGHT ENDOSCOPY AND CHROMOENDOSCOPY IN DETECTING DYSPLASIA DURING SURVEILLANCE

**S. Pelitari**, G. Marinopoulos, N. Sharma
*Dept. Of Gastroenterology, Heart of England Trust, Birmingham/United Kingdom*

**Contact E-mail Address:** stavroulapelitari@gmail.com
**Introduction:** The increased risk of colorectal cancer in the Inflammatory Bowel Disease (IBD) population along with the global IBD incidence rise highlights the importance of colonoscopy surveillance programme. Recent guidelines advocate use of chromoendoscopy as a preferable mode used for surveillance.
**Aims & Methods:** The aim of our study was to assess adherence of our IBD population with disease > 10 years to colonoscopy surveillance and also compare chromoendoscopy with white light endoscopy against their ability to detect dysplasia. Data from our trust IBD registry were analysed retrospectively. From a total IBD population of 2254 patients, 820 were identified as having IBD for 10 years or more and were included. Two groups, one receiving chromoendoscopy and one white light endoscopy for surveillance performed in real-life practice, were compared. Data were analysed according to number of patients having a dysplastic lesion in endoscopy with Z-score test. Type of lesion and grade of dysplasia were also taken into account.
**Results:** Out of 820 patients, 610 were suitable for surveillance; n = 449 with Ulcerative colitis (UC)/indeterminate colitis (IC) and n = 161 with Crohn's colitis (CD). Colonoscopy surveillance was initiated in n = 216 (48.1%) of the UC/IC group and n = 105 (65.2%) of CD patients. Surveillance was not continued as per guideline (with maximum interval of 5 years) in n = 37 patients (29.8%) of UC/IC and n = 13 (22.4%) of CD patients. Average time of initiating surveillance was 13 years. Only 18% of surveillance colonoscopies performed using chromoendoscopy. Chromoendoscopy (CE) was performed in 59 patients during 2012–2015. 38 were male with mean age 59 (SD 13.6). A similar group of 59 patients were white light endoscopy (WLE) was performed was randomly selected from our initial sample. A total of 16 dysplastic lesions (2 with high grade dysplasia (HGD) and 14 with low grade dysplasia (LGD)) were detected in 12 patients in the CE group and 12 lesions (1 HGD and 11 LGD) were detected in 9 patients in the WLE group but results didn't reach statistical significance(p = 0.47). In the CE group 7 lesions were due to flat dysplasia (43.75%) compared to only 1 flat lesions in the WLE group (8.3%) (p = 0.02).
**Conclusion:** Adherence to guidelines for colonoscopy surveillance was poor both for UC/IC and CD population. Similarly low rates (44%-54%) were observed in studies of other European countries like the Netherlands, Ireland and France. Reasons for poor uptake of surveillance need to be identified. The number of dysplastic lesions found was greater with CE. In addition CE was found to be superior to WLE in identifying flat dysplastic lesions in IBD surveillance population. This reflects results from recent meta-analysis included in the SCENIC international consensus on surveillance in IBD but larger randomized trials are still required.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0819 ENDOSCOPY SIGNIFICANTLY IMPROVES OUTCOME PREDICTION IN ACUTE SEVERE COLITIS

**S.R. R. Fernandes**, P. Santos, C. M. Moura, P. Marques Da Costa, J. Carvalho, L. A. Correia, J. Velosa
*Serviço De Gastrenterologia E Hepatologia, Hospital Santa Maria, Centro Hospitalar Lisboa Norte, Lisboa/Portugal*

**Contact E-mail Address:** Samuelrmfernandes@gmail.com
**Introduction:** Up to one-third of patients with acute severe colitis will present an insufficient response to systemic steroids and will require rescue therapy or surgery. Delay in surgery has been associated with increased postoperative complications. Early recognition of patients who will show an insufficient response is therefore of the utmost importance.
**Aims & Methods:** To compare several endoscopic index in the setting of acute severe Ulcerative Colitis. We evaluated consecutive patients admitted with acute severe colitis according to the Truelove & Witts criteria. For each patient the Mayo endoscopic subscore, the Ulcerative Colitis Endoscopic Index of severity (UCEIS) and the Ulcerative Colitis Colonoscopic Index of Severity (UCCIS) were determined. Outcomes included the need for medical rescue therapy, steroid refractoriness and surgery.
**Results:** We included 76 patients, median age 34.5 years (15–80) with median Truelove & Witts score of 4 (2–5). 20 patients (26.3%) required rescue therapy (16 with Infliximab and 4 with Cyclosporine), 26 patients (34.2%) were colectomized and 3 patients (3.9%) died. Median endoscopic scores were: Mayo 3 (1–3), UCEIS 5 (2–7) and UCCIS 45.8 (13.8–59.8). Only UCEIS and UCCIS were predictors of surgery (AUC 0.723, p = 0.002 and AUC 0.733, p = 0.001) but only the UCCIS adequately predicted unresponsiveness to steroids (AUC 0.675, p = 0.009). A compound outcome including steroid refractoriness, surgery and death was also only predicted by UCCIS (AUC 0.644, p = 0.045). In a logistic regression model including age, gender, disease extension, Truelove and Witts score, C-reactive protein and endoscopy, the UCEIS (OR 2.47 CI95% [1.18–5.16], p = 0.016) and the UCCIS (OR 1.12 CI95% [1.023–1.23] but not the Mayo were predictors of the need for surgery.
**Conclusion:** In this retrospective study, endoscopic severity was an excellent predictor of important outcomes in acute severe colitis. The UCCIS appear to perform better than the UCEIS in all outcomes. The complexity of the former can represent the greatest barrier to its implementation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0820 RISK OF COLORECTAL ADENOMAS IN PATIENTS WITH MICROSCOPIC COLITIS: A CASE-CONTROL STUDY

**Introduction:** Previous case-control studies have shown a low rate of colorectal polyps in patients with microscopic colitis (MC), but the control groups used were heterogeneous (1–3).
**Aims & Methods:** The aim of the study was to evaluate this association in comparison with a control group with chronic diarrhoea and a control group of individuals of average risk.
One hundred patients with MC (Group A) (age, 62.1 ± 1.5; 68% women; 44 aged between 50–70 years) and 200 patients with chronic diarrhoea and normal colon histology (Group B), matched for age and sex were included. Diagnostic colonoscopy including multiple colonic biopsies was performed in the same period of time. Reports of colonoscopy and histology of both index colonoscopy and previous colonoscopies were reviewed. Colorectal polyps (number and size) and their histology were recorded. A control group from a population screening program for colorectal cancer by colonoscopy (COLONPREV study) matched for age and sex (Group C), was randomly selected (n = 88; age 50 to 70 years). A conditional logistic regression (1 case with 2 controls) was performed.
**Results:** 15% of patients in Group A and 18.5% in Group B had adenomas (OR = 0.76; 95% CI = 0.4–1.5; p = 0.43). In the 50 to 70 years age group, the presence of adenomas was: Group A, 13.9%, Group B, 18.2% and Group C, 29.5%. The OR of the analysis of Group A vs Group C was 0.33 (95% CI = 0.12–0.93; p = 0.036), and Group B vs Group C was 0.45 (95%CI = 0.20–0.98; p = 0.047). The frequency of advanced adenomas was: Group A 4% (OR = 0.26, 95%CI = 0.08–0.85 vs Group C), group B 5% (OR = 0.33; 95%CI = 0.1–0.8 vs Group C), and Group C 13.6% (1 patient with colorectal cancer).
**Conclusion:** Patients with MC have a low rate of colorectal adenomas and lesser histological severity as compared to the average risk population. However, the absence of differences with the group of chronic diarrhoea and normal colonic histology suggests more an effect of chronic diarrhoea than of colonic inflammation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0821 POST-INDUCTION SERUM INFLIXIMAB TROUGH LEVEL WAS ASSOCIATED WITH MUCOSAL HEALING AFTER INITIATING THERAPY IN CROHN'S DISEASE

J. Tang, **G. Xiang**, M. Zhi, P. Hu
*Gastroenterology, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou/China*

**Contact E-mail Address:** helengao818@163.com
**Introduction:** Serum infliximab trough level(S-IFX) and antibody were documented to correlate with clinical response. Aim of this study was to identify relationship between trough levels, antibodies and mucosal healing (MH) in a cohort on maintenance infliximab therapy.
**Aims & Methods:** 108 patients were retrospectively enrolled. All received a scheduled maintenance therapy after response to infliximab induction. S-IFX and antibodies were tested in at 14 weeks after initiating treatment. Endoscopic activities were evaluated at 14 and 52 weeks.
**Results:** At week 14, S-IFX was 4.78 ± 6.16ug/ml and 19% (21/108) of patients developed antibodies. S-IFX was significantly lower in patients with antibody (1.49 ± 3.05ug/ml vs 5.58 ± 6.46ug/ml, P < 0.01). 52 of 102 patients reached MH. S-IFX were higher in patients with MH (6.26 ± 7.78ug/ml vs 3.32 ± 3.80ug/ml, P = 0.02). But there was no statistical difference on MH between ATI positive and negative groups (36% vs 54%, P = 0.17). During 52 weeks follow up, 28% (30/108) patients lost of response to infliximab. The patients who lost of response had lower S-IFX and higher ATI positive rate than patients had sustained response (2.16 ± 3.05ug/ml vs 6.50 ± 8.02ug/ml, P = 0.03; 48% vs 23%, X = 5.11,P = 0.02). At week 52, 73 patients had undergone endoscopy and 31 patients reached MH. Patients with MH had relatively higher S-IFX than who did not reach MH (7.77 ± 9.13ug/ml vs 2.99 ± 3.23ug/ml, P < 0.01), but no statistical difference for antibodies between two groups (31% vs 45%,P = 0.30). S-IFX had a predictive value on MH in 52 weeks follow up. When S-IFX > 2.5ug/ml, the sensitivity for predicting MH at 52 wks were 87%, and the specificity were 61%(AUC = 0.73,P < 0.01).
**Conclusion:** Post-induction serum IFX trough level could predict MH in CD patients undergoing IFX treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Assessment of tissue healing has become of paramount importance in patients treated for inflammatory bowel disease. The aim of our study was to prospectively identify, at diagnosis, factors predictive of mucosal healing in ulcerative colitis (UC) patients treated with anti-TNFα.
**Aims & Methods:** All consecutive patients with UC who had corticosteroid-refractory or corticosteroid-dependent disease and were eligible for treatment with anti-TNFα agents (infliximab, adalimumab, golimumab), according to the current ECCO guidelines were considered for enrolment in the study. Patients on azathioprine received anti-TNFα treatment, immunomodulatory- and anti-TNFα-naïve patients received combination therapy with azathioprine and anti-TNFα, whereas anti-TNFα monotherapy was offered to patients aged less than 25 and over 65 years and in those who refused combination therapy. Patients on combo who discontinued azathioprine shortly after initiation of treatment for drug-related adverse events were grouped with the anti-TNFα monotherapy treated patients. The duration of azathioprine co-treatment in combo was 6 months. Patients who consented to participate in the study underwent ileocolonoscopy with biopsies of the affected areas and assessment of UC disease activity (total Mayo score calculation) prior to and at 3 and 12 months after initiation of anti-TNFα treatment. Complete mucosal healing (CMH) was strictly defined as endoscopic sub-score 0. In a subgroup of patients the mucosal expression of T helper (Th) cell lineage-specific transcription factors (T-bet, Gata3, Rorc, FoxP3) and the concentration of cytokines in the serum (IL-10, IL-6, IFN-γ, IL-17A) were measured by real-time RT-PCR and ELISA respectively and their predictive value for mucosal healing at 1 year was examined.
**Results:** From September 2010 till January 2015, 67 UC patients treated with infliximab (n = 56), adalimumab (n = 5) or golimumab (n = 6) were enrolled in the study. At the end of 1 year, only 29 (43.3%) patients achieved CMH. Patients receiving anti-TNFa and concomitant azathioprine treatment for the first 6 months showed higher rates of CMH, as compared to those receiving anti-TNF monotherapy and those that discontinued azathioprine during the first month because of side-effects [CMH: 28 patients with combination therapy and 1 in monotherapy; without CMH: 30 patients with combination therapy and 8 in monotherapy; p = 0.03]. In the subgroup of 12 patients in whom immunological markers were sought, responders had significantly lower baseline expression of the transcription factor T-bet that defines type 1 (Th-1) adaptive immunological responses (p < 0.05). Finally, responders had significantly lower baseline serum concentration of IL-6 (p < 0.05).
**Conclusion:** Immunomodulator use, lower baseline mucosal expression of T-bet as well as lower baseline serum concentration of IL-6 are associated with complete mucosal healing in UC patients treated with anti-TNFα.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0823 CLINICAL SIGNIFICANCE OF PERIPHERAL BLOOD TH17 CELLS IN EVALUATING DISEASE ACTIVITY OF INFLAMMATORY BOWEL DISEASE: A MULTI-CENTER CLINICAL STUDY

**N. Gao**, R. Li, W. Chen
*Department of Gestroenterology, First Affiliated Hospital of Soochow University, Suzhou, Jiangsu, China, SUZHOU/China*

**Contact E-mail Address:** carrie_gn@126.com
**Introduction:** Th17 cells play important roles in immuno-inflammatory responses. The relationship between Th17 cells and inflammatory bowel disease (IBD) is a new hot spot of related studies.
**Aims & Methods:** Aims: To investigate preliminarily the role of Th17 cells in the pathogenesis of IBD and the clinical significance of peripheral blood Th17 cells in evaluating disease activity. Methods: Peripheral blood mononuclear cells were collected in 162 IBD patients recruited from 5 hospitals, including 78 Crohn's disease (CD) and 84 ulcerative colitis (UC), and also 80 healthy volunteers. The proportion of Th17 cells in peripheral blood $CD4^+$ T cells was detected with flow cytometry after stimulated by PMA and ionomycin. Simultaneously, two clinical inflammatory markers, ESR and serum CRP were measured.
**Results:** The proportion of peripheral blood Th17 cells was significantly higher in CD group (2.51%±1.59%) and UC group (4.15%±2.75%) than in control group (1.44%±0.73%, P all <0.05), and that in UC group was significantly higher than in CD group (P < 0.01). Furthermore, the proportion of peripheral blood Th17 cells in IBD patients was significantly higher in active stage than in remission stage (CD: 3.39%±1.56% vs. 1.48%±0.81%, P < 0.01; UC: 5.77%±2.77% vs. 2.18%±0.59%, P < 0.01). In Spearman rank correlation coefficient analysis, the proportion of peripheral blood Th17 cells in active stage CD and UC was correlated significantly with ESR ($r_s = 0.851$, P < 0.05; $r_s = 0.817$, P < 0.05) and CRP ($r_s = 0.793$, P < 0.05; $r_s = 0.873$, P < 0.05).
**Conclusion:** Th17 cells might be involved in the pathogenesis and development of IBD, especially UC. Measurement of the proportion of peripheral blood Th17 cells is beneficial for the evaluation of disease activity of IBD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** We have reported that a quantitative fecal immunochemical test (FIT) could predict mucosal status of UC as well as or better than fecal calprotectin (Fcal). Additionally, the cost and time benefit of FIT are superior to those of Fcal. However, the usefulness of Fcal has been well-verified for detecting the changes of mucosal inflammation of UC patients in the world. Although it is desirable to weigh the two markers for more precise estimation of mucosal status of UC, there is no any assay which can measure levels of the two markers easily. In recent days, we've invented the break-through assay which could measure levels of the hemoglobin and calprotectin simultaneously by a single sampling probe with latex agglutination turbidimetric immunoassay (LATIA) reagents.
**Aims & Methods:** The aim of this study is to evaluate the usefulness of a novel fecal calprotectin assay (Fcal-LATIA). Consecutive UC patients who underwent scheduled colonoscopy between March 2015 and February 2016 were requested to bring fecal samples with the OC-Auto Sampling Bottle 3 (Eiken Chemical, Japan) for the examination of FIT and Fcal. Levels of FIT and Fcal were analyzed from the same samples. FIT levels were determined with OC-SENSOR DIANA (Eiken Chemical, Japan) according to manufacturer's instruction (using the LATIA reagent). Fcal levels were determined by two methods, conventional enzyme-linked immunosorbent assay (ELISA) and newly developed LATIA reagent. For ELISA, Fcal levels were determined with commercially available ELISA kit (Immundiagnostik, Germany) according to manufacturer's instruction. For LATIA, the levels were determined with OC-SENSOR DIANA using the LATIA reagent. The measuring time of OC-SENSOR DIANA is about 10 minutes per 1sample. The mucosal status of UC patients was assessed via the Mayo endoscopic subscore (MES) classification. Evaluation was performed at each portion of the colorectum (cecum and ascending colon combined, transverse colon, descending colon, sigmoid colon, and rectum).
**Results:** In total, 120 UC patients were evaluated in conjunction with the fecal marker and colonoscopic findings. First, we evaluated the correlations between Fcal-LATIA and Fcal-ELISA, a significant correlation was also observed between the Fcal-LATIA values and Fcal-ELISA values (Spearman rank correlation coefficient: 0.96, $p < 0.0001$). Secondly, the correlation between fecal markers (FIT, Fcal-LATIA, Fcal-ELISA) and colonoscopic findings were analyzed. All of these fecal markers were significantly correlated with the maximum MES (Spearman rank correlation coefficient, FIT: 0.75, $p < 0.0001$, Fcal-LATIA: 0.58, $p < 0.0001$, Fcal-ELISA: 0.60 $p < 0.0001$). When mucosal healing was defined as MES 0 alone, the sensitivity and specificity of FIT was better than those of Fcal by two methods. Whereas the sensitivity and specificity of Fcal by two methods is similar. (The cutoff determined by ROC analysis: $<50$ ng/mL for FIT, $<220$ μg/g for Fcal-LATIA, and $<280$ μg/g for Fcal-ELISA: Sensitivity: 0.90 vs. 0.77 vs. 0.83, Specificity: 0.80 vs. 0.80 vs. 0.75) (The standard cutoffs: $<100$ ng/mL for FIT and $<250$ μg/g for Fcal: Sensitivity: 0.93 vs. 0.77 vs. 0.77, Specificity: 0.80 vs. 0.80 vs. 0.75). Similar AUCs were obtained by ROC analysis for the FIT and two Fcal results (0.86 vs. 0.83 vs. 0.84).
**Conclusion:** A novel Fcal assay using the LATIA reagent is a rapid assay, and correlated significantly with conventional Fcal assay (ELISA). In addition, Fcal-LATIA was effectively predicted mucosal healing in UC patients. A novel assay Fcal-LATIA, simultaneously measured with FIT, could help a fine quality practice for UC patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0825 MEASURING APPARENT DIFFUSION COEFFICIENT VALUES IN COLLAPSED AND DISTENDED SMALL BOWEL LOOPS HAS A POTENTIAL IN EXCLUDING INFLAMMATORY BOWEL DISEASE IN PATIENTS WITHOUT BOWEL PREPARATION: A STUDY IN HEALTHY SUBJECTS

**Introduction:** Up to 15% of patients suspect for inflammatory bowel disease (IBD) do not meet strict diagnostic criteria due to overlap of clinical, visual and morphological data[1]. Around 80% of such patients either Crohn's disease or ulcerative colitis develops within next several years but the diagnosis remains uncertain[2]. MR enterography (MRE) benefits in assessment of bowel inflammatory lesions however insufficient bowel distention degrees decreases accuracy of MRE and its use is limited in general anesthesia patients where oral preparation is contraindicated (e.g., small children, claustrophobic and uncooperative patients) as well as in patients with contraindications to butylscopolamine administration. It is known that inflamed bowel walls presents lower apparent diffusion coefficient (ADC) values in diffusion – weighted imaging (DWI) than in intact bowel walls[3,4] but research data refer to distended bowel loops, and no data are available about ADC differences between collapsed and distended bowel walls in one and the same bowel segments.
**Aims & Methods:** The aim was to measure and compare ADC values in collapsed and distended intestinal loops of high signal intensity (SI) in DWI images in subjects without evidence of IBD as well as compare the calculated values with literature data. ADC values of collapsed and distended bowel walls with high SI in DWI images were measured in 42 patients (13–67 y.o.) with no previous diagnosis of inflammatory bowel disease (IBD) and with fecal calprotectin level $<260$ μg/g. Magnetic resonance enterography (MRE) exams were performed by 1.5 T MRI system. MRE protocol included DWI sequences with b values of 0, 100 and 600. Bowel filling was achieved with 1.51 of 2.5% mannitol orally over 40 minutes before scanning; peristalsis was reduced with butylscopolamine 20 mg intravenously. Sites of collapsed and distended jejunal and ileal loops were identified and graded as 'collapsed jejunum', 'distended jejunum', 'collapsed ileum' and 'distended ileum'. 2 ADC measurements were recorded in each of the filling grade of jejunum and ileum. Differences between filling grades within one bowel site were assessed with t-test.
**Results:** There was statistically significant difference between ADC values of collapsed and distended intestinal loops with high SI on DWI. The mean ADC values in collapsed bowel loops were lower than in distended loops subsequently being in jejunum 1.84 $mm^2/s$ ($SD = 0.54$) in collapsed state and 2.73 $mm^2/s$ ($SD = 0.60$) in distended state ($p < 0.0001$) whereas the mean ADC value in ileum for collapsed state was 2.46 $mm^2/s$ ($SD = 0.81$) and 2.89 $mm^2/s$ ($SD = 0.64$) for distended ileum ($p = 0.0075$). Comparing to the literature data ADC values in collapsed bowel loops were higher than in bowel with inflammatory changes.
**Conclusion:** The results are perspective and helpful as a control group of potentially healthy subjects and could benefit in improving diagnostic accuracy of distinction between intact and inflamed bowel loops in MRE exams of patients without bowel preparation in clinical situations where maintaining adequate bowel filling is a problem.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** One of the key challenges for managing Crohn's disease is knowing when to start and stop immunosuppressive medications. No single biomarker for disease activity exists although Magnetic Resonance Enterography (MRE) is increasingly implemented. The MaRIA score is a validated MRE activity score based on quantifying structural changes in the bowel associated with inflammation such as wall thickening and contrast enhancement and is considered to be one of the 'gold-standard' MRI methods for assessing disease activity[1]. However it is time consuming to use and changes with treatment often lag behind clinical response. An alternative approach is to measure small bowel motility i.e. bowel function rather than structure. Quantified motility assessment is rapid (~60 seconds per case), with previously demonstrated good inter-reader agreement[2,3]. Single site retrospective studies have suggested reduced motility is correlated with Crohn's disease activity but prospective validation is lacking.

**Aims & Methods:** This prospective study evaluates the predictive accuracy of quantified MRI small bowel motility to assess inflammatory activity in Crohn's disease against histopathological and endoscopic reference standards. Performance against conventional magnetic resonance index of severity (MaRIA) scoring is further provided for context.

82 subjects with CD (42 male, median age 32.5 years, range 16 to 70 years) were recruited prospectively from two European centres as part of the VIGOR++ study, undergoing ileocolonoscopy and MR enterography separated by median 5 days (range 0 to 14).

The CD Endoscopic Activity Index (CDEIS–endoscopic standard) was scored at the terminal ileum (TI), and a histopathological activity score based predominantly on the presence of ulceration and volume and distribution of acute inflammatory cells (eAIS–histopathological standard) was derived from multiple biopsies from the distal terminal ileum. TI motility was quantified using a validated software algorithm4 based on image registration applied to a breath hold 2D "cine" acquisition (BTFE, slice thickness 1 cm, temporal resolution 1.1 images/s).

The TI MaRIA score was calculated by two experienced readers blinded to the clinical and motility data. A motility cut-off score (0.30) was pre-selected from a prior, retrospective study5 and the sensitivity and specificity of Motility and MaRIA ($\geq$11) for disease activity (defined as eAIS $\geq$1 or CDEIS $\geq$4) calculated. Motility was correlated with reference standards using Spearman's rank and Receiver Operating Characteristic (ROC) area under the curves (AUC) were constructed. Diagnostic performance was compared using McNemar's test.

**Results:** Against eAIS, motility had sensitivity and specificity of 92.3% (95% CI 81.5–97.86%) and 75.6% (95% CI 60.4–87.1%) for activity. Sensitivity but not specificity was significantly higher than MaRIA (80.0% P = 0.03 and 79.1% P = 1.0, respectively). Against CDEIS, motility had sensitivity and specificity of 93.3% (95% CI 81.7–98.6%) and 74.0% (95% CI 60.4–85.0%), significantly higher (sens) & lower (spec) respectively than MaRIA (82% P = 0.03 and 83.7% P = 0.05). Motility had moderate negative correlations with eAIS ($R = -0.61$, $p < 0.001$) and CDEIS ($R = -0.59$, $p < 0.001$) and demonstrated a ROC AUC of 0.87 (eAIS) and 0.86 (CDEIS), respectively.

**Conclusion:** In this dual site prospective study, quantified motility appears a valid biomarker for endoscopic and histopathological activity in CD.

**Introduction:** The early identification of primary non-response to anti-TNFα therapy facilitates the timely management of patients with inflammatory bowel disease (IBD). A recent, pilot study to detect prognostic markers of early response to anti-TNFα therapy identified the two genes coding for the calprotectin subunits (S100A8, S100A9) to be among the most highly expressed gene transcripts in non-responders.

**Aims & Methods:** This retrospective study tests the hypothesis that measurements of faecal calprotectin (FCAL) pre- and post- anti-TNFα induction can predict primary non-response in both Crohn's disease (CD) and ulcerative colitis (UC). Outcomes were assessed at 6 months based on clinical activity scores and the use of corticosteroids: (a) Remission: Harvey Bradshaw Index (HBI) < 5 or SCCAI < 3, off corticosteroids > 2 months; (b) Response: drop in HBI or SCCAI > 3, off corticosteroids; (c) non-response. ΔFCAL (and ΔCRP respectively) was calculated as (FCALpost induction – FCALpre induction)*100/FCAL pre induction.

**Results:** At 6 months, 23 (72%) CD and 10 (56%) UC patients had responded. In remission were 17(53%) and 5 (28%) respectively. Comparing non-responders to combined response and remission groups, the area under the curve of ΔFCAL to predict outcomes at 6 months was 0.97 for CD and 0.96 for UC. Using ROC analysis, a Δ70% returned a sensitivity and specificity of 99% and 96%, respectively (likelihood ratio, LR = 23) in CD. For UC a Δ70% had a sensitivity and specificity of 88% and 86%, respectively (LR = 6).

**Conclusion:** A drop in FCAL < 70% after induction predicts primary non-response to anti-TNFα in both CD and UC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Perianal fistula, a common complication of Crohn's disease (CD), affect up to one third of patients during the course of their disease. It is associated with significant impairment in quality of life and is an independent predictor of inflammatory bowel disease -related work disability. Mostly perianal fistula is evaluated after perianal symptoms appeared.

**Aims & Methods:** In this study, we investigated the clinical characteristics of perianal fistula in CD patients without perianal symptoms. All CD cases diagnosed initially in our hospital were evaluated perianal fistula using magnetic resonance imaging (MRI) from Oct. 2014 to Oct 2015. The medical records were studied retrospectively.

**Results:** 152 cases were categorized into three groups, 59 cases of no perianal fistula CD (NF-CD) (38.8%), 44 asymptomatic perianal fistula CD (AF-CD) (28.9%) and 49 symptomatic perianal fistula CD (SF-CD) (32.2%). Both groups of AF-CD and SF-CD showed shorter period of disease duration than that of NF-CD [12.0 (6.0,24.0) vs 24 (8, 57), P = 0.05 and 14 (6.5,24) vs 24 (8, 57), P = 0.025], higher value of hs-CRP [10.90 (10.34,11.30) vs 10.13 (3.45,11.47), P = 0.027, and 10.69 (8.94,11.44) vs 10.13 (3.45,11.47), P = 0.041], and much higher score of rectal SE-SCD [1.5 (0, 4) vs 0 (0, 3), P = 0.013 and 3 (0,4) vs 0 (0, 3), P = 0.008]. Other clinical indices of the three groups were comparable. Compared with the patients of SF-CD, those of AF-CD had more types of simple fistula (18.2% vs 4.1%, P = 0.043), more low fistula (22.7% vs 4.1%, P = 0.007), more inter-sphincteric fistula (86.3% vs 51.0%, P < 0.001), and less number of fistula (50.0% vs 75.5%, P = 0.011).

**Conclusion:** Asymptomatic perianal fistula in CD is not uncommon and should be considered when patient who has shorter disease duration, significant higher value of hs-CRP or severe rectal disease. Asymptomatic perianal fistula may be on early stage of symptomatic perianal fistula in CD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0829 DERMATOLOGICAL COMPLICATIONS OF ANTI-TNF THERAPY IN INFLAMMATORY BOWEL DISEASE

**P. Andrade**, S. Lopes, R. Gaspar, A. C. Nunes, F. Magro, G. Macedo
*Gastroenterology, Centro Hospitalar de São João, Porto/Portugal*

**Contact E-mail Address:** anapatriciarandrade@gmail.com

**Introduction:** The broader use of anti tumor necrosis factor (TNF) agents in Inflammatory Bowel Disease (IBD) has been associated to a high rate of adverse reactions. Dermatological complications are among the most common adverse reactions.

**Aims & Methods:** We assessed the cumulative incidence of dermatological complications in a large cohort of IBD patients treated with anti-TNF agents and its impact on patient's therapeutic management. A single tertiary-center observational retrospective study. All consecutive adult IBD patients treated with anti-TNF agents between 2006 and 2015 were identified. Patients who developed at least one dermatological complication while under anti-TNF therapy were included.

**Results:** Among 732 patients treated with anti-TNF agents, 211 (29%) developed at least one dermatological complication: 59% women with a mean age of $42 \pm 13$ years, 85% with Crohn's disease. Sixty-seven percent were under infliximab and 64% under combination therapy. Median follow-up time was 34 (11–71) months. Dermatological complications recorded were: infections (46.9%, 99/211), psoriasiform lesions (18.5%, 39/211), eczema and injection site reactions (16.6%, 35/211), vasculitis (5.2%, 11 / 211), neoplasias (1.9%, 4/211) and others (10.9%, 28/211). The most common cutaneous infections were bacterial (45%) and fungal (36%). Infectious complications led to a delay superior to 7 days in next dose of anti-TNF in 25 (12%) patients. Three (3%) patients with infectious complications and 12 (31%) patients with psoriasiform lesions definitely discontinued anti-TNF therapy. All patients with cutaneous malignancy discontinued therapy with anti-TNF.

**Conclusion:** Dermatological complications affected almost one-third of IBD patients treated with anti-TNF agents. Infections were the most common dermatological complication, but psoriasiform lesions induced by anti-TNF agents were the most common cause for anti-TNF therapy definitive discontinuation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0830 MR ENTEROCOLONOGRAPHY EVALUATION FOR SMALL BOWEL STRICTURES IN PATIENT WITH CROHN'S DISEASE: COMPARISON WITH BALLOON ENTEROSCOPY

**F. Toshimitsu**, K. Takenaka, M. Kimura, K. Matsuoka, M. Nagahori, K. Ohtsuka, M. Watanabe
*Gastroenterology And Hepatology, Tokyo Medical and Dental University, Tokyo/Japan*

**Contact E-mail Address:** fujii-vn@mbg.nifty.com

**Introduction:** Crohn's disease (CD) is a lifelong inflammatory bowel disease. Evaluating the extent and severity of the disease is critical to determine appropriate therapeutic strategies in patients with CD. Magnetic resonance (MR) enterography (MRE) / MR enterocolonography (MREC) can examine not only intra-luminal changes, but also extra-luminal abnormalities without ionizing radiation and anesthesia, which makes it appropriate for frequent examinations in CD. MR imaging is one of the most recommended technique for detection of small bowel lesions of CD. However, the accuracy for strictures in the deep small intestine is not validated.

**Aims & Methods:** The aim of this study is to evaluate the impact of stricture findings indicated by MREC and the patient outcomes using balloon-assisted enteroscopy (BAE) reference. A total of 200 CD patients with established CD were prospectively examined both MREC and BAE. Among them 75 patients were indicated strictures with BAE. The presence of strictures in the small bowel by MR was compared with endoscopic findings. Moreover, the relations between MR findings, surgical outcomes and the impact of endoscopic balloon dilation (EBD) were evaluated.

**Results:** MREC detected strictures in 45 patients (60%) and could not in 30 patients (40%). Major strictures (diameter $< 10$ mm or with internal fistula) ($p = 0.001$), long strictures ($p = 0.017$), and pre-stenotic dilatation ($p = 0.002$) were predictors of strictures detection by MREC. Surgery was observed in 16 (34%) patients with strictures both on MREC and BAE (MREC-positive-BAE-positive), on the other hand 4 (13%) patients without strictures on MREC but with strictures on BAE (MREC-negative-BAE-positive). The surgery-free rates in MR-negative-BAE-positive group were significantly lower than MREC-positive-BAE-positive group at 6 months (short-term outcome, $p = 0.008$) and 1 year (mid-term outcome, $p = 0.043$). The corresponding rates at 2 years (long-term outcome) did not differ between those groups ($p = 0.065$). In the MREC-positive-BAE-positive group, the patients who were performed with EBD showed significantly higher surgery-free rates than those who were not ($p = 0.037$).

**Conclusion:** MREC specificity for small bowel strictures was clinically sufficient; and MREC procedure could detect critical strictures, which was a predictive factor for surgical intervention. But MR-negative-BAE-positive strictures were also associated with an increased risk over 1-year follow-up.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Fatigue is increasingly recognized as an important complaint of patients with inflammatory bowel disease (IBD) (1). Optimal management of fatigue in patients with IBD is not yet known, and the course of fatigue during concentional treatment has not been widely studied in patients with ulcerative colitis.

**Aims & Methods:** The aim was to investigate potential changes in the severity of fatigue in a cohort of patients with ulcerative colitis receiving conventional drug treatment over 3 months. Furthermore to assess whether depression, disease symptoms, disease activity, and inflammatory or other selected biological markers were associated with changes in fatigue. Patients with newly diagnosed ulcerative colitis were included in an observational cohort study and received conventional non-biological drug treatment for 3 months. Colonoscopy was performed at diagnosis and after 3 months. Disease activity was assessed by Mayo score and measurement of serum C-reactive protein (CRP) and fecal calprotectin levels. Fatigue was rated using the fatigue visual analog scale (fVAS). Mood was assessed with the hospital anxiety and depression scale (HADS). Associations between fVAS scores and the variables: time, age, CRP, fecal calprotectin, hemoglobin, ferritin, Mayo scores, Mayo endoscopic scores, and HADS depression subscale (HADS-D) scores were explored.

**Results:** In the 82 included patients, median fVAS scores decreased from median (range) 40 (0–94) to 22 (0–81) after 3 months, $p = 0.001$. The prevalence of significant fatigue (defined as fVAS scores $\geq$ 50) was reduced from 40.2% to 20.7%. The fVAS scores were non-significantly lower for patients in remission compared to patients with active disease, $p = 0.13$. All disease activity markers were reduced; Mayo score from median (range) 7 (2–12) to 2 (0–11), CRP from 7 mg/L (1–117) to 1.9 mg/L (1–43) and fecal calprotectin levels, from 773 mg/kg (0–5466) to 58 mg/kg (18–2241), $p = 0.001$ for all differences. HADS-D remained unchanged from median (range) score 2 (0–10) at baseline to 1 (0–13), $p = 0.59$, whereas hemoglobin levels increased after 3 months from mean (SD) 13.7 g/L (1.5) to 14.6 g/L (1.4), $p = 0.001$. Decreased fVAS scores were associated with lower ferritin levels ($p = 0.011$), Mayo scores ($p = 0.035$) and HADS-D ($p = 0.001$) scores. There were no associations between fVAS scores and CRP, fecal calprotectin, or Mayo endoscopic scores. Colonic disease distribution did not influence fatigue significantly.

**Conclusion:** Disease activity and fatigue improved after 3 months of conventional treatment for ulcerative colitis. Over time, persistence of more severe fatigue was associated with more ulcerative colitis symptoms, but not with objective disease activity markers or colonic disease distribution. A clinical setting of standard treatment regimens and medical attention may thus alleviate fatigue in IBD patients.

**Introduction:** Crohn's disease is associated with accumulation of progressive structural bowel damage (SBD) that may lead to stenotic or penetrating complications and frequent need for surgery. The data pertaining to the degree of progression of SBD in both active and quiescent disease is scarce. The Crohn's Disease (CD) Digestive Damage Score (Lemann Index, LI) is a novel tool for evaluation of SBD, that incorporates clinical, endoscopic and imaging data for the entire digestive tract.
**Aims & Methods: Aims:** To evaluate the progression of SBD in patients with quiescent Crohn's disease. **Methods**: Patients with known quiescent small bowel CD – for at least 3 months (CDAI < 150) were prospectively recruited and underwent repeated magnetic resonance enterography (MRE) and capsule endoscopies (CE). LI was used to assess the grade of CD-related SBD at baseline and follow-up evaluation. The gastrointestinal tract was divided to segments [esophagus, stomach, and duodenum; 20 segments for small bowel; 6 segments for colon and rectum]. Findings at MRE and CE were divided into stricturing and penetrating lesions, scored and adjusted for anatomical coefficients. Only patients who remained in clinical remission and underwent $\geq 2$ MRE evaluations were included. SBD was identified as LI > 4.8, and progression of SBD as $\Delta$ LI > 0.3.
**Results:** Fifty nine patients were enrolled; 44 remained in clinical remission and 36 underwent 2 MREs and were included in the analysis. The average interval between MRE scans was$14.8 \pm 2.5$ months.SBD was detected in 5/36 patients (13.9%) on both MRE examinations. LI was similar at baseline and follow-up ($2.6 \pm 3.7$ vs $2.5 \pm 3.8$, $p = 0.97$). There was a negligible change in LI between evaluations ($0.008 \pm 1.27$). Progression of SBD ($\Delta$LI > 03) was demonstrated in 13/36 (36.1%) and regression – in 11/36 (30.6%) of patients. Changes in SBD were not associated with biologic or immunomodulator treatment.
**Conclusion:** In patients with quiescent CD, structural bowel damage was stable, with a negligible change during a 14 months follow-up

[2]*Nephrology, Oujda University Hospital, Oujda/Morocco*

**Contact E-mail Address:** sahareelmahjoubi27@gmail.com
**Introduction:** Renal involvement in chronic inflammatory bowel disease (IBD) remains an extra-digestive event that is relatively rare, occurring in 4–23% of cases. It has several aspects from simple abnormality of the urinary sediment to nephropathy and renal failure.
**Aims & Methods: Aims:** To assess the prevalence of renal disease in IBD and analyze its clinical and biological characteristics.
**Patients and methods:** Renal function (blood creatinine and creatinine clearance according to MDRD formula), the Urine culture and 24 h proteinuria were performed for 120 patients. If renal tests show abnormalities, renal ultrasound and a blood and urine electrolytes are evaluated.
**Results:** Renal involvement has been discovered in 36 patients or 30% of the cases. These are 20 women and 16 men with a sex ratio F/M of 1.25. The mean age was $40.2 \pm 13$. Ulcerative colitis was the most common, present in 19 cases (52.8%). Crohn's disease was found in 11 patients (30.5%) and indeterminate colitis in 6 cases (16.7%). Maintenance therapy was based on azathioprine for 16 patients (44.4%), salicylates for 13 patients (36%), anti-TNF and 6 Mercaptopurine for 2 patients (5.5%) respectively and methotrexate for 1 patient. The Urine culture showed a urinary infection in 9 cases (25%) and aseptic leukocyturia in 16 cases (44.4%). Crystals was found in 4 patients (13%), microscopic hematuria in 10 patients (27.7%) and macroscopic in 4 patients (11%). A positive proteinuria was found in 8 patients (22.2%). Furthermore, renal failure and kidney stones were discovered in 2 patients (5.5%) respectively.
**Conclusion:** Renal involvement during chronic inflammatory bowel disease is probably underestimated due to its silent and asymptomatic nature. Its screening must be systematic and regular to identify nephropathy in an early stage.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0834 THE ECONOMIC BURDEN OF INFLAMMATORY BOWEL DISEASE

**J. Bonello**[1], S. Chetcuti[1], M. Farrugia[1], J. Burisch[2], P. Ellul[1]

[2]*Nortz Zealand University Hospitla, Department of Gastroenterology, Frederikssund/Denmark*

**Contact E-mail Address:** johnbonello89@gmail.com
**Introduction:** Spiraling health-care costs are always a highly topical issue. Patients with inflammatory bowel disease are diagnosed earlier on in life and thus require a lifetime of investigations, treatment and follow-up.
**Aims & Methods:** Our aim was to calculate the economic burden of patients diagnosed with inflammatory bowel disease in 2010 in Malta. Patients diagnosed with inflammatory bowel disease on histology at endoscopy, in 2010 at Mater Dei Hospital were included in this study. Their case notes were reviewed. Costs were calculated over 5 years since diagnosis. Data was obtained for inpatient hospital stays, outpatient visits, blood tests, radiological tests, surgery, endoscopy and medications.
**Results:** 58.7% of patients had ulcerative colitis (UC). The rest (41.3%) had Crohn's disease (CD). The male to female ratio was almost 1.1. Mean age of diagnosis was 36.7 years (SD±20.9). Females were statistically more expensive to manage than males ($p < 0.019$). There was no significant statistical correlation between age at diagnosis and cost of treatment. None of this cohort required any surgical intervention. Mean cost per patient for 5 years since diagnosis were as follows:

| Cost | CD/UC | Mean (€) | Standard Deviation | Significance (P value) |
|---|---|---|---|---|
| **Inpatient stays** | CD | 1903 | 1338 | 0.254 |
| | UC | 4441 | 2811 | |
| **Outpatient visits** | CD | 399 | 197 | 0.101 |
| | UC | 301 | 187 | |
| **Blood Tests** | CD | 1021 | 480 | 0.054 |
| | UC | 708 | 576 | |
| **Imaging** | CD | 512 | 344 | 0.008 |
| | UC | 125 | 200 | |
| **Endoscopies** | CD | 1099 | 595 | 0.010 |
| | UC | 547 | 341 | |
| **Medications** | CD | 12952 | 7049 | 0.012 |
| | UC | 7831 | 5249 | |
| **Total** | CD | 16442 | 7416 | 0.005 |
| | UC | 9906 | 6939 | |

The cost of CD management per patient per year (€3288) was higher than UC (€1981). Proportion of costs in the management of inflammatory bowel disease was as follows: medications 75.3%, blood tests 6.7%, endoscopies 5.8%, inpatient stays 8.5%, outpatient visits 2.6%, imaging 1.2%.
**Conclusion:** Current trends point towards possible more aggressive medical management leading to a higher financial investment in medications rather than surgery. 5-year cost of CD was higher than that of UC across all categories except for inpatient management of UC. CD remains more expensive to treat probably due to the presence of more complicated disease requiring more investigations and use of biological drug therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0835 RISK FACTORS OF CLINICAL RELAPSE IN PATIENTS WITH ULCERATIVE COLITIS IN CLINICAL AND ENDOSCOPIC REMISSION

**M. Calafat Sard**[1], T. Lobatón[1], A. Hernández-Gallego[2], M. Mañosa Ciria[1], P. Torres-Rodríguez[1], E. Cabré[1], I. Ojanguren[2], E. Domènech[1]

[2]*Department of Pathology, Hospital Universitari Germans Trias i Pujol, Badalona/Spain*

**Contact E-mail Address:** margalidasard.calafat@gmail.com

**Introduction:** Patients with ulcerative colitis (UC) in endoscopic remission have a better disease outcome with fewer complications. It has been suggested that histological features have a prognostic value in the outcome of these patients.
**Aims & Methods: Aim:** To assess the role of histology as a risk factor for clinical relapse in patients with UC in clinical and endoscopic remission. **Methods**: This was a retrospective observational study including patients with left/extensive UC who underwent a colonoscopy with biopsies between January 2005 and June 2014 and were in clinical remission (partial Mayo score 0–1, without rectal bleeding) and endoscopic remission (Mayo endoscopic subscore 0–1) while on stable treatment and free of steroids within the previous 3 months. Regarding histology, basal plasmacytosis, the presence of intraepithelial neutrophils (acute activity), the architectural alterations, and an increased mononuclear infiltrate, were evaluated. Other variables including UC flare within 12 months prior to inclusion,Mayo endoscopic subscore grade 1, biological activity (increased C-reactive protein) and treatment at the time of endoscopy, were also analysed as potential risk factors of clinical relapse. Clinical relapse was defined as the presence of symptoms together with the need for treatment optimization.
**Results:** 157 patients were included: 38% women; median age 54 years (IQR 44–65); 65% with extensive UC; 87% with Mayo endoscopic subscore = 0 and 18% presented a flare within 12 months prior to inclusion. Median time in clinical remission previous to the inclusion was 38 months (IQR 19–105) and median time of follow-up was 39 months (IQR 18–64). 31% presented clinical relapse during follow-up with a median time for relapse of 3.3 years (IQR 1.55–5.4). The cumulative probability of CR at 1, 3 and 5 years was 7%, 22% and 29%. Regarding histology: 10%, 17%, 54%, and 60% presented basal plasmocytosis, acute activity, architectural changes and mononuclear infiltrate, respectively. In the multivariate analysis (Cox), acute activity and flare within 12 months prior to inclusion showed a significant association with clinical relapse at 12 months of follow-up (RR = 7.69; 95% CI 2.03–29.05 p = 0.003-). Similar results were obtained when considering the whole follow-up period (RR = 1.97; 95% CI 1.01–3.82 p = 0.046-).
**Conclusion:** In UC patients in clinical and endoscopic remission, the presence of intraepithelial neutrophils in colonic biopsies and a shorter time of clinical remission constitute risk factors for clinical relapse. A closer monitoring is therefore recommended in these patients. Further prospective studies need to clarify whether treatment optimization is justified in this context.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0836 NO IRON AND NO ANEMIA: WHO ARE THESE CROHN'S PATIENTS AND WHAT IS THEIR EVOLUTION?

**T. Cúrdia Gonçalves**[1], S. Monteiro[1], M. Barbosa[1], M.J. Moreira[1], J. Cotter[2]
[1]*Gastroenterology, Hospital da Senhora da Oliveira, Guimarães/Portugal*

**Contact E-mail Address:** tiagomcg@hotmail.com

**Introduction:** Despite many studies on anemia in Crohn's Disease (CD) exist, the knowledge about iron deficiency without anemia (IDWA) is still scarce.
**Aims & Methods:** The aim of this study was to characterize CD patients with IDWA, as well as to analyze its evolution during the follow-up. Patients with CD which have had at least one episode of IDWA between January/2011 and December/2014 were analyzed. Two subgroups were analyzed regarding the definition of iron deficiency: one group with serum ferritin $<30\mu g/L$ and no evidence of inflammation, and another group with serum ferritin between 30–$100\mu g/L$ when inflammation was evident. Besides description of the patients' evolution during the follow-up, demographic and clinical differences between the two groups were evaluated using the $\chi^2$ and Fisher's exact tests.
**Results:** From the 136 analyzed patients, 97 (71.3%) were female and the mean follow-up time was 42 ± 16 months. Regarding the evolution during the follow-up, 43 patients (31.6%) developed anemia, 51 (37.5%) resolved the iron deficiency, 35 (25.7%) had persistent IDWA, and in 7 patients (5.2%) recurrence of IDWA was confirmed after an initial period of resolution. Only 8 patients (5.9%) received iron supplementation for IDWA. There were no significant differences between the two groups regarding gender (p = 0.849), disease extension (p = 0.91) or behavior (p = 0.056), age at diagnosis (0.401), perianal (p = 0.571) or upper gastrointestinal tract involvement (p = 0.749), family history (p = 0.051) or smoking habits (p = 0.555). Although the development of anemia was not significantly different between groups (p = 0.957), resolution of IDWA was significantly more common in those patients with serum ferritin levels between 30–$100\mu g/L$ (p = 0.025).
**Conclusion:** Although about one-third of the patients with CD will have only transient IDWA, another third of the patients will develop iron deficiency anemia during the follow-up. This fact highlights the importance of the exhaustive identification and follow-up of this clinical situation, particularly in those with lower levels of serum ferritin, in which the spontaneous recuperation is not so frequent.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0837 ANORECTAL FUNCTION AND QUALITY OF LIFE IN IBD PATIENTS WITH PERIANAL DISEASE: A PROSPECTIVE OBSERVATIONAL STUDY

**Introduction:** Anorectal complications are a common feature of patients affected by inflammatory bowel disease (IBD) [1], with a huge impact on their quality of life (QoL) [2]. Up to now the anorectal function of IBD patients has been poorly investigated[3], with results often contrasting[4, 5]. Aim of this prospective observational study was to analyze the anorectal function and the QoL of IBD patients, and to compare the results with healthy volunteers.
**Aims & Methods:** Patients were assessed by a physical and clinical examination (including the Wexner score, the Harvey Bradshaw score, the Clinical Mayo score), anorectal manometry, three-dimensional endoanal ultrasound (3D-EAUS), and endoscopy. The patients' QoL was evaluated by administration of the Inflammatory Bowel Disease Questionnaire (IBDQ).
**Results:** From January to April 2016, 24 IBD patients (14 males; mean age 38.9 ± 12.8 years) and 20 healthy volunteers (10 males, mean age 42 ± 10.7 years) were enrolled in the study. Eighteen patients were affected by Crohn's disease (CD), and 6 by ulcerative colitis (UC), with a mean Harvey Bradshaw score and a mean Clinical Mayo score of, respectively, 6.5 ± 3.8 and 2.6 ± 2.6. Thirteen patients had a history of perianal fistula, while 7 were affected by fecal incontinence (mean Wexner score 8.6 ± 3.7). Fecal incontinent patients had a longer duration disease (p = 0.024), and a higher bowel movements number (p = 0.024). The 3D-EAUS was normal in all healthy volunteers, while 21/24 IBD patients had at least a pathological features (fistula, sphincter lesion, fibrosis). At the anorectal manometry, the maximum anal resting pressure was lower in IBD patients when compared to controls (84.9 ± 43.5 mmHg versus 128.4 ± 10.2 mmHg, p < 0.0001), while the maximum squeeze pressure was higher in IBD patients (166.8 ± 55.8 mmHg versus 122.9 ± 12.2 mmHg, p = 0.0001); the rectoanal inhibitory reflex was present in 20 out 24 IBD patients, and in all healthy volunteers; 19 out 24 IBD patients had a dyssynergic defecation pattern; rectal sensations did not differ between IBD patients and the control group. No differences emerged at the anorectal manometry between CD or UC patients, while the presence of rectal inflammation (p = 0.026) and incontinence (p = 0.040) was associated to a lower maximum anal resting pressure. Overall, the mean IBDQ score was 164.0 ± 36.7, but it was lower in UC patients when compared to CD patients (140.8 ± 44.1 versus 170.4 ± 32.9, p = ns); the score was not significantly influenced by the presence of rectal inflammation and a perianal fistula, but it was lower in patients with fecal incontinence (p = 0.030).
**Conclusion:** Anorectal function was impaired in IBD patients with perianal disease. Specific features emerged at the anorectal manometry, and should be better investigated. The perianal disease negatively affect patients' QoL.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0838 PARALLEL TEMPORAL CHANGES IN HARVEY-BRADSHAW INDEX, TNFA AND INTESTINAL FATTY ACID BINDING PROTEIN (I-FABP) IN RESPONSE TO INFLIXIMAB (REMICADE) IN CROHN'S DISEASE

**A. K. Al-Saffar**[1], C. H. Meijer[1], V. R. Gannavarapu[1], G. Hall[1], H. Diaz[1], M. Lördal[2], T. Ljung[1], P.M. Hellström[1], D. Webb[1]

**Introduction:** Crohn's disease (CD) is characterized by increased intestinal mucosal permeability and inflammation. Unlike ulcerative colitis, CD can occur throughout the gastrointestinal (GI) tract, including the small intestine. Beyond lowering tumor necrosis factor alpha (TNFa), the ultimate biological outcome of anti-TNFa (Remicade) therapy in CD should display evidence of mucosal healing (e.g., improved mucosal epithelial integrity). Intestinal fatty acid binding protein (I-FABP) is highly and selectively expressed in the mucosal epithelium of human intestine (1) and has therefore been used as an indicator of small intestinal barrier integrity (2). It was reasoned that I-FABP might be elevated in active CD and might then serve as an indicator of mucosal healing to monitor treatment outcomes.

**Aims & Methods:** The primary aims were to determine if 1) I-FABP is elevated in active CD and 2) I-FABP parallels Remicade induced lowering of circulating TNFa and Harvey-Bradshaw Index (HBI) as a more direct indication of mucosal healing. Methods: A local biobank containing serum from 47 CD patients that underwent Remicade therapy between the years 2000 and 2004 was investigated for blood draws suitable for monitoring changes in TNFa, HBI and I-FABP. From this, serum from 11 CD patients were identified which included naive samples drawn on the first occasion of Remicade infusion (Inf1) and at two later occasions along with matching follow-up visit serum and HBI data. Remicade infusion occurred on days 1 (Inf1), 14 (Inf2) and 42 (Inf3). Follow-up visits (F1, F2 and F3) each occurred one week after infusions. Serum drawn at Inf1 was used as a reference time point to normalize data from which TNFa and HBI would be expected to decline with successful treatment. In addition to the CD patient samples, serum from 33 healthy adult subjects with normal gut permeability, assessed by lactulose:mannitol ratios $\leq$0.7 were assayed for I-FABP by ELISA (Hycult Biotech, The Netherlands). CD patient circulating TNFa was assayed by ELISA (Meso Scale Diagnostics, USA) and compared to 63 healthy subjects. Significance threshold was set as $P < 0.05$ using t-test for paired data (before and one week after treatment) or Mann-Whitney U test when comparing CD to healthy subjects.

**Results:** One of the 11 subjects (9%) was a strong outlier on several parameters and tested positive for anti-Remicade antibodies already at Inf 1. This patient was excluded, reducing sample size to $n = 10$. At Inf1, serum TNFa was 1.5 fold ($2.34 \pm 0.22$ vs $1.58 \pm 0.09$ ng/L, $P < 0.001$) and I-FABP was 2.3 fold ($2.02 \pm 0.23$ vs $0.86 \pm 0.17$ µg/L, $P < 0.001$) higher than healthy subjects. On each follow-up day, TNFa was lower than the prior infusion day as well as the subsequent Remicade infusion day, demonstrating that the drug effect was clearly identifiable in these 12–16 year old samples and was transient, returning to levels of Inf1 day by the time of next infusion. HBI values followed the same trend. TNFa and HBI were statistically significant across most time points. I-FABP also followed this trend, with F1 being statistically lower than Inf1 ($P < 0.05$) and the next two follow-ups approaching statistical significance relative their preceding infusion days ($P = 0.08$ and $P = 0.15$). Decreased I-FABP on follow-up visits was consistent in 8 out of 10 patients. Based on 3 power calculations from the I-FABP data organized as 3 independent before-after datasets, it was estimated that a sample size of 25 CD patients is desirable to obtain significance ($P < 0.05$) for all 3 follow-up visits relative preceding infusion days. Combining I-FABP data for all 3 infusion days into one group and all follow-ups into a second group ($n = 30$) yielded a significant difference ($P < 0.005$).

**Conclusion:** Despite concerns about stability partly stemming from its short half-life in blood (~10 min), I-FABP was clearly higher in CD than healthy controls with a magnitude comparable to TNFa in biobank samples stored over 12 years. A parallel drug effect of Remicade on TNFa, HBI and I-FABP was found. I-FABP may be useful to monitor treatment progress at the level of mucosal epithelial barrier integrity.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Patients suffering from inflammatory bowel diseases (IBD) are risked to have abnormal body composition. Altered body composition can affect body fat, muscle mass and bone mineral content as well. The risk of decreased bone mineral density content and osteopenia related bone fracture is well known among IBD patients. Tumor necrosis factor inhibitors has a known beneficial effects to bone turnover in rheumatoid arthritis patients, however its not prowed in IBD.

**Aims & Methods:** Our study involved 40 IBD outpatients (33 Crohn's disease, 7 ulcerative colitis); 24 of these received adalimumab (160/80/40 mg every other week) and 16 were treated with infliximab (5 mg/kg at week 0, 2, 6, and subsequently every 8 weeks). Body composition and bone mineral content was measured by bioelectrical impedance analysis (BIA) with an InBody 720 device. The screening was recorded prior to initiating biologicals and 3, 6 and 12 months afterwards. Baseline bone mineral content was recorded with DEXA and laboratory parameters related to bone metabolism were measured at the induction phase of biologicals.

**Results:** At the end of the 12 months observational period, 27 of 40 patients were on biologicals. Baseline bone mineral content measuerd by BIA imporved significantly during the follow up time (month 0, 3, 6 and 12: $2.90 \pm 0.62$ kg; $2.99 \pm 0.68$ kg; $2.95 \pm 0.61$ kg; $2.95 \pm 0.64$ kg; $p < 0.05$, respectively). We also observed significal improvement in total mineral content ($3.54 \pm 0.75$ kg; $3.63 \pm 0.82$ kg; $3.59 \pm 0.74$ kg; $3.59 \pm 0.80$ kg; $p < 0.05$; resp.) and in body cell mass parameter ($34.04 \pm 7.97$ kg; $35.11 \pm 8.24$ kg; $34.80 \pm 7.68$ kg; $34.60 \pm 8.47$; $p < 0.05$; resp.). At the end of induction therapy bone metabolism related laboratory parameters improved as well ($\beta$-crosslaps: $561.00 \pm 302.30$ pg/ml vs. $530.30 \pm 381.48$ pg/ml; $p < 0.05$; osteocalcin: $27.43 \pm 16.78$ ng/ml vs. 36.77 vs. 25.93 ng/ml; at week 0 and 12, resp.)

**Conclusion:** Significant improvement was observed in bone parameters measured by BIA during anti-TNF therapy among IBD patients. Our finding suggests that biompedance analyses may have a role in follow up of bone mineral content as it is less expensive and more easily accessible than other methods.

**Introduction:** Anti-tumor necrosis factor (TNF)-alpha agents are widely used for the treatment of both inflammatory bowel disease (IBD) and psoriasis. Paradoxically, anti-TNF therapy has been associated to the development of psoriasis in IBD patients, which may lead to treatment discontinuation.

**Aims & Methods:** We analysed all cases of psoriasis induced by anti-TNF therapy in a large cohort of IBD patients and assessed its impact on patients' therapeutic management. A retrospective observational study of IBD patients treated with infliximab or adalimumab between 2006 and 2015. IBD patients who developed psoriasis while under treatment with ant-TNF agents were included. Patient's characteristics, duration and type of anti-TNF therapy, lesions characteristics and outcome were analysed.

**Results:** Among 732 IBD patients, 39 (74% women, mean age $38 \pm 11$ years) developed anti-TNF induced psoriasis (cumulative incidence 5.3%). Thirty-seven (95%) had Crohn's disease, 49% were under adalimumab and 51% under infliximab. Median time until the diagnosis of psoriasis after starting anti-TNF agent treatment was 15 (IQR 4–26) months. The most common lesions were plaque psoriasis (51%) or inverse psoriasis (28%) and the most frequent rash location was palmoplantar (31%), scalp (28%) or trunk (26%). Fifty-one percent of patients improved with topical treatment and 49% required systemic therapy (PUVA or methotrexate). Two (5%) patients switched anti-TNF agent but there was a severe recurrence of lesions in both cases, thus anti-TNF therapy was definitely discontinued. Globally, 31% of the patients permanently discontinued therapy with clinical improvement in 81% of cases.

**Conclusion:** The cumulative incidence of anti-TNF induced psoriasis in this large cohort of IBD patients was 5.3%. Half of the patients had a favourable response to topical therapy, but in almost 1/3 of the patients it was necessary to permanently discontinue anti-TNF therapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0841 ETROLIZUMAB TREATMENT DOES NOT MODIFY LEVELS OF VCAM-1 IN ULCERATIVE COLITIS PATIENTS

**Introduction:** Etrolizumab, an anti-$\beta$7 monoclonal antibody, targets the integrins $\alpha4\beta7$ and $\alpha E\beta7$ and inhibits the interaction of $\alpha4\beta7$ with MAdCAM-1 and VCAM-1, and $\alpha E\beta7$ with E-Cadherin. IBD patients have higher levels of expression of MAdCAM-1 and ICAM-1 in the gut tissue compared to controls. Expression levels of VCAM-1 (Jones, 1995; Panés, 2003), an adhesion molecule

**Abstract No: P0842**

**Table:** Summary of PMS response and PMS remission by treatment group over time (A), and at Wk 2 as predictors of efficacy endpoints at Wk 8 (B)

| A. | | Wk 2 | Wk 4 | Wk 8 |

Patients with missing data were treated as non-responders.***$p < 0.0001$ vs placebo, based on the Cochran-Mantel-Haenszel chi-square test stratified by study, prior treatment with tumour necrosis factor inhibitors, corticosteroid use at baseline and geographic region, used to test the treatment difference between tofacitinib 10 mg BID and placebo in PMS remission and PMS response.+++$p < 0.0001$, based on the chi-square test for the association between predictor at Wk 2 and clinical outcome at Wk 8.BID, twice daily; CI, confidence interval; PMS, partial Mayo score; Wk, week.

involved in cell trafficking across the blood-brain barrier, are reported to be similar between IBD patients and controls. We demonstrated that etrolizumab treatment in patients with moderate-to-severe ulcerative colitis (UC) modulates MAdCAM-1 and E-Cadherin in serum and colonic tissue (Vermeire, 2014; Fuh, 2015; unpublished data) whereas natalizumab has been shown to decrease serum VCAM-1 in multiple sclerosis patients (Millonig, 2010).

**Aims & Methods:** The aims of this study were to explore the role of etrolizumab treatment on VCAM-1 and ICAM-1 serum levels and expression in colonic tissue among patients in the Phase 2 EUCALYPTUS study. Phase 2 UC patients were randomized into one of 3 different treatment arms during an induction period of 10 weeks: placebo (n = 36), 100 mg dose (n = 28), and 300 mg dose (n = 34). Soluble VCAM-1 and ICAM-1 were measured at baseline and during the treatment period using commercially available ELISA assays and tissue expression was assessed in biopsy tissue by qPCR.

**Results:** No differences were observed in serum soluble VCAM-1 and ICAM-1 levels between etrolizumab-treated arms and the placebo arm. Similar results were observed in VCAM-1 expression in colonic tissue on Day 43 and Day 71. In colonic biopsies, there was no dose-proportional decrease of ICAM-1 expression in the etrolizumab-treated arm. However, levels of ICAM-1 expression in colonic tissue of clinical responders, in both etrolizumab- and placebo-treated arms, decreased significantly compared with non-responders at Day 43; in etrolizumab-treated responders/remitters, this reduction was maintained through Day 71. There were no consistent differences in VCAM-1 expression in colonic biopsies between placebo-treated responders and non-responders or between etrolizumab-treated remitters, responders and non-responders.

**Conclusion:** Lack of changes in VCAM-1 levels in both colonic tissue and serum is consistent with the mechanism of action of etrolizumab which does not block interaction of $\alpha 4\beta 1$ with VCAM-1. The observed downmodulation of ICAM-1 expression is likely due to a decrease in tissue inflammation and not to direct targeting of the pathway. These and prior data indicate that etrolizumab modulates expression of gut-specific MAdCAM-1 and suggests that it does not affect lymphocyte trafficking to CNS via VCAM-1 modulation. **Introduction:** Tofacitinib is an oral, small molecule JAK inhibitor that is being investigated for ulcerative colitis (UC). Two Phase 3 randomised placebo-controlled studies (OCTAVE Induction 1, NCT01465763; OCTAVE Induction 2, NCT01458951) demonstrated efficacy of tofacitinib 10 mg twice daily (BID) vs placebo as induction therapy for patients with moderate to severe UC.[1]

**Aims & Methods:** We investigated how response and remission based on partial Mayo score (PMS) at Week (Wk) 2 correlate with clinical efficacy endpoints at Wk 8. Patients in both studies were randomised (4:1) to receive treatment with tofacitinib 10 mg or placebo BID for up to 9 wks. Patients were ≥18 years old with moderately to severely active UC defined at baseline by Mayo score of ≥6, rectal bleeding subscore ≥1 and endoscopic subscore ≥2. Patients had previous failure or intolerance to treatment with ≥1 of corticosteroids, thiopurines, or tumour necrosis factor inhibitors (TNFi). Primary endpoint was remission at Wk 8 defined as Mayo score ≤2, no subscore >1 and rectal bleeding subscore of 0. Secondary endpoints included clinical response (decrease from baseline Mayo score of ≥3 points and ≥30%, plus decrease in rectal bleeding subscore ≥1 or absolute subscore ≤1) at Wk 8, mucosal healing (Mayo endoscopic subscore ≤1) at Wk 8 and PMS at Wks 2, 4 and 8. Exploratory endpoints included PMS response (PMS ≥2 decrease from baseline) and PMS remission (PMS ≤2 with no individual subscore >1 at Wks 2, 4 and 8). The chi-square test was used to test whether PMS response and remission at Wk 2 correlated with remission, mucosal healing and clinical response at Wk 8. Sensitivity was defined as the proportion of patients who achieved Wk 2 PMS response or PMS remission among Wk 8 responders. Specificity was defined as the proportion of patients who did not achieve PMS response or PMS remission at Wk 2 among Wk 8 non-responders.

**Results:** Treatment difference with tofacitinib 10 mg BID vs placebo was achieved at Wks 2, 4 and 8: of 905 patients treated with tofacitinib 10 mg BID, 53.9%, 66.6% and 69.1% achieved PMS response, and 21.3%, 34.0 and 43.2% achieved PMS remission at Wks 2, 4 and 8, respectively (Table A). Both PMS response and PMS remission, at Wk 2, were significantly associated ($p < 0.0001$) with all three clinical efficacy endpoints: clinical response; mucosal healing; and remission at Wk 8 (Table B). Similar results were obtained in both subpopulations of TNFi-naïve and -experienced patients.

**Conclusion:** In patients with moderate to severe UC treated with tofacitinib 10 mg BID, tofacitinib demonstrated induction efficacy based on PMS as early as Wk 2, the first time point measured in this study. Efficacy at Wk 2 is a good predictor of efficacy at Wk 8, regardless of prior TNFi therapy. Patients who have not achieved remission or response at Wk 2 based on PMS may still achieve improvements in Mayo score at Wk 8.

**Introduction:** Etrolizumab, an anti-$\beta7$ monoclonal antibody that targets the integrins $\alpha4\beta7$ and $\alpha E\beta7$, has shown efficacy in patients (pts) with moderate-to-severe ulcerative colitis (UC). Serum drug levels in etrolizumab-treated pts from the Phase 2 EUCALYPTUS study demonstrated linear kinetics in drug exposure. Target engagement was measured as receptor occupancy (RO) by flow cytometry; complete RO was observed at the time of initial assessment at Day 5 after the first dose in both dose cohorts (Vermeire, 2014).
**Aims & Methods:** The aim of this study was to assess the relationship between drug levels and RO with levels of MAdCAM-1, the ligand for $\alpha4\beta7$, in the serum of EUCALYPTUS pts. Pts enrolled in the EUCALYPTUS study were randomized (1:1:1) into 3 different treatment arms: a 100 mg etrolizumab dose cohort (100 mg at week 0, 4, and 8), a 300 mg dose cohort (loading dose of 420 mg at week 0 and 300 mg at week 2, 4 and 8) or a placebo control. The study included a treatment period of 10 weeks (last dose given on week 8) followed by 18 weeks of safety follow-up/drug wash-out. Biomarker data was analysed from 112 pts (n = 40 placebo, n = 34 at 100 mg, and n = 38 at 300 mg + loading dose).
**Results:** Serum analysis indicated a gradual and significant decrease from baseline of soluble MAdCAM-1 in etrolizumab-treated pts (mean ± SE, day 5: –19 ± 4%, day 29: –67 ± 3%) with no significant changes observed in the placebo arm. There were no apparent dose-dependent differences in the decrease of soluble MAdCAM-1 levels in the two etrolizumab arms. After the last dose at week 8, during the wash-out phase, a decrease in serum drug concentration levels (to < 1 μg/mL) was associated with a loss of RO, and concurrent increase in soluble MAdCAM-1. Baseline levels of MAdCAM-1 did not predict etrolizumab responses, and post-dose levels did not correlate with clinical responses or remission to etrolizumab treatment.
**Conclusion:** Etrolizumab-treated UC pts demonstrated a significant decrease in serum MAdCAM-1 compared to placebo. While the drop in soluble MAdCAM-1 was not correlated with response, nor did baseline levels of soluble MAdCAM-1 predict responses to treatment, the decrease in serum MAdCAM-1 levels can potentially be used as a surrogate for RO. In the Phase 2 study, the $\alpha E$ component of $\alpha E\beta7$ was identified as a biomarker that may predict responses to etrolizumab treatment. Further work in the Phase 3 studies will explore biomarkers predictive of responses to etrolizumab treatment. Funded by Genentech.

### P0844 DEVELOPMENT AND ANALYTICAL CHARACTERIZATION OF GP2017, A PROPOSED ADALIMUMAB BIOSIMILAR

**M. Schiestl**[1], C. Roesli[2]
[1]*Sandoz GmbH, Kundl/Austria*
[2]*Hexal AG, Oberhaching/Germany*

**Contact E-mail Address:** martin.schiestl@sandoz.com
**Introduction:** As many of the biologic agents used to treat inflammatory bowel diseases will lose patent protection during the next few years, biosimilars are becoming an increasingly important focus of development. The demonstration of biosimilarity is based on the evaluation of all physicochemical, biological, nonclinical and clinical data; i.e. the totality of the evidence.[1] For new drugs, the major goal is to describe the product analytically and then determine clinical properties. By contrast, the overall aim of biosimilar development is to prove that the biosimilar and originator product contain essentially the same active substance, and confirm the expectation that both products will elicit the same clinical effects. Since analytical tools are a highly sensitive means of comparing two products, comprehensive physicochemical and biological characterization of the proposed biosimilar and originator product serves as the foundation of the overall comparability exercise.
**Aims & Methods:** The aim of this study is to describe the techniques and approaches used to characterize and compare the physicochemical and structure-function properties of GP2017, a proposed adalimumab biosimilar, with its originator product. Multiple batches of the originator were sourced and analyzed using state-of-the-art analytical methods to define the development target for GP2017. A manufacturing process was iteratively designed and modified to develop a product with quality attributes and biological function within the predetermined variability ranges of the originator. GP2017 and the originator were analyzed with respect to primary and higher-order structure as well as post-translational modifications. Binding of GP2017 and the originator to recombinant tumor necrosis factor-$\alpha$ (TNF$\alpha$) and a panel of human Fc$\gamma$ and FcRn receptors was analyzed using surface plasmon resonance-based assays. Cell-based bioassays were used to compare levels of TNF$\alpha$ neutralization, binding of membrane-bound TNF$\alpha$, complement-dependent cytotoxicity, antibody-dependent cellular cytotoxicity and apoptosis.
**Results:** Multiple orthogonal analytical methods showed similarity between GP2017 and the originator. The amino acid sequences of GP2017 and the originator were identical, protein folding was indistinguishable and post-translational modifications including glycosylation, C-terminal variants, methionine oxidation and deamidation were also similar. At the in vitro level, the binding affinity of GP2017 to TNF$\alpha$ was within the predetermined variability range of the originator. Binding affinities of GP2017 to the tested panel of receptors were similar to the originator and both products had similar bioactivity in terms of cytotoxicity and apoptosis inhibition.
**Conclusion:** The observed physicochemical and functional similarity between GP2017 and the originator, as part of the totality of the evidence, demonstrate that the biological component of both products is essentially the same active substance. GP2017 is therefore a suitable candidate to move into the next stages of biosimilar development; i.e. nonclinical, pharmacokinetic and confirmatory clinical studies.
**Disclosure of Interest:** M. Schiestl: Paid employee of Sandoz GmBH
C. Roesli: Paid employee of Hexal AG

**Introduction:** Extraintestinal manifestations (EIMs) in patients (pts) with Crohn's disease (CD) are associated with morbidity and impaired quality of life.[1] This analysis evaluated effects of adalimumab (ADA) on median time to first recurrence of EIMs following initial resolution in pts with EIMs; predictors of initial resolution and sustained resolution (time to first recurrence of EIMs) were also assessed.
**Aims & Methods:** EIM data were pooled from 11 open-label (OL) or double-blind induction, maintenance, and OL extension studies in adult and pediatric pts with CD (age 13–17 years old). The ADA group included pts who received blinded or rescue OL ADA in randomised trials and those who received OL ADA in non-randomised trials. The placebo (PBO) group included pts randomised to PBO, including those who received OL ADA induction before randomisation to PBO. Data from PBO pts who received OL ADA rescue therapy after randomisation were censored from that point. In 10 studies, question 4 of the Crohn's Disease Activity Index was used to evaluate EIMs at scheduled and unscheduled visits; in 1 study, a separate form was used. Sustained resolution, defined as median time to first recurrence following initial resolution, was calculated for any EIM and for musculoskeletal EIMs (arthritis/arthralgia). A log-rank test was used for between-group comparison. A Cox model was used to determine predictors of resolution (data from 10 studies) and sustained resolution (data from 11 studies) in pts with any EIM or with arthritis/arthralgia.
**Results:** For pts with EIMs at baseline who achieved resolution, sustained resolution was significantly longer for the ADA group vs the PBO group for any EIM ($P < 0.001$) and for musculoskeletal EIMs ($P < 0.001$; **Table 1**).

**Table P0846**

| Patient | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 |
|---|---|---|---|---|---|---|---|---|---|---|
| Age (yrs), Gender | 33, f | 51, m | 57, m | 21, m | 50, m | 47, f | 32, m | 21, m | 50, m | 23, m |
| Primary Diagnosis | PSC | PSC | PSC | AISC | PSC | PSC | AISC | AISC | AISC | PSC |
| Age at OLT (yrs) | 20 | 40 | 52 | 20 | 48 | - | - | - | - | - |
| IBD extent | pancolitis | pancolitis | pancolitis | pancolitis | pancolitis | pancolitis | pancolitis | pancolitis | pancolitis | pancolitis |
| Disease duration (yrs) | 10 | 5 | 25 | 6 | 15 | 1 | 10 | 7 | 4 | 1 |
| Duration of IBD pre-OLT (yrs) | Post | Post | 20 | 5 | 13 | | | | | |
| Immunosuppression | Tac | Tac, MMF, Pred | Tac | Pred | Aza, Tac, Pred | Pred | Aza | | | |
| , Pred | Pred | | | | | | | | | |
| , MMF | Pred, Aza | Mercap | | | | | | | | |
| Prior Anti-TNF use | Yes | Yes | Yes | Yes | No | Yes | Yes | No | Yes | No |
| Time from OLT to VDZ (yrs) | 13.3 | 10.8 | 4.2 | 0.9 | 1.6 | - | - | - | - | - |
| SCCAI | 7 | 8 | 7 | 12 | 10 | 6 | 5 | 9 | 3 | 4 |
| Mayo endoscopy score | 2 | 2 | 2 | 2 | 2 | 2 | 3 | 3 | 3 | 2 |
| Duration of VDZ (m) | 10.8 | 7.3 | 13.4 | 5.1 | 4.1 | 4.4 | 7.1 | 1.4 | 8.7 | 7.4 |
| Maintenance therapy | Yes | Yes | Yes | Yes | Yes | Yes | Yes | No | Yes | Yes |

Predictors of resolution for any EIM were: ADA treatment (P = 0.003), younger age (P < 0.001), moderate (vs severe) disease activity at baseline (P < 0.001), lower baseline levels of albumin (P = 0.013), and higher baseline levels of C-reactive protein (CRP; P = 0.026). Predictors of resolution for arthritis/arthralgia were the same except for CRP (P = 0.052). Predictors of sustained resolution for any EIM were ADA treatment (P < 0.001), male sex (P = 0.031), and shorter disease duration (P = 0.010). Predictors of sustained resolution for arthritis/arthralgia were ADA treatment (P < 0.001), younger age (P = 0.050), and shorter disease duration (P = 0.029).

**Table 1:** Median Time to First Recurrence of Any EIM and Musculoskeletal EIMs Following Initial Resolution

| | | Time to First Recurrence | | |
|---|---|---|---|---|
| EIM | Treatment group (n) | Median, d | 95% CI | P |
| Any EIM | PBO (137) | 57 | 43–70 | <0.001 |
| | ADA (848) | 136 | 113–169 | |
| Musculoskeletal (arthritis/arthralgia) | PBO (130) | 57 | 36–71 | <0.001 |
| | ADA (808) | 141 | 113–169 | |

**Conclusion:** ADA treatment was effective for achieving sustained resolution of EIMs in pts ≥13 years old with CD. ADA treatment and shorter disease duration were among the predictors of sustained resolution for any EIMs and musculoskeletal EIMs.

## P0846 VEDOLIZUMAB IN INFLAMMATORY BOWEL DISEASE ASSOCIATED WITH AUTOIMMUNE LIVER DISEASE PRE- AND POST-LIVER TRANSPLANTATION: A CASE SERIES

**T.Y. Lim**, P. Pavlidis, S. Gulati, T. Pirani, M. Samaan, G. Chung-Faye, P. Dubois, P. Irving, M. Heneghan, B. Hayee
*Gastroenterology, King's College Hospital, London/United Kingdom*

**Contact E-mail Address:** llty24@gmail.com

**Introduction:** Inflammatory bowel disease (IBD) associated with primary and autoimmune sclerosing cholangitis (PSC and AISC respectively) appears to represent a distinct clinical entity in comparison to 'classical' ulcerative colitis (UC) and Crohn's disease (CD). The course of IBD appears to be influenced by liver transplantation (LT): typically following an indolent course pre-LT, while an aggressive phenotype may be seen in up to 50% of patients post-LT and de novo disease reported in up to 25%. Anti-TNF therapy can be efficacious but systemic complications remain a real concern, while evidence for other therapeutic interventions is limited to pre-clinical models and small case series. Vedolizumab (VDZ), a humanised monoclonal antibody directed against the $\alpha 4\beta 7$ integrin is appropriate for induction and maintenance of remission of moderate to severe IBD, either naïve or refractory to anti-TNF agents. In this case series, we report our experience of VDZ for patients with PSC/AISC-IBD pre- and post-LT.

**Aims & Methods:** Patients were identified from a prospectively kept database at 2 tertiary hospitals. The diagnosis of liver disease was based on established diagnostic criteria and confirmed with a liver biopsy in all patients. IBD clinical activity was assessed using the Simple Clinical Colitis Activity Index (SCCAI) at baseline and end of follow-up (as all patients had only colonic involvement and were therefore classified as ulcerative colitis for the purposes of this report). A clinical response was defined as a drop in SCCAI > 3 with remission defined as a total score < 3. Quality of life (QoL) was assessed by the IBD-control-8 questionnaire. Faecal calprotectin (FCAL) and endoscopic activity (Mayo endoscopic sub-score) are also provided.

**Results:** Ten patients were identified with PSC/AISC-IBD. Table 1 summarises the disease characteristics and outcomes. There were 7 (70%) with previous primary or secondary non-response to anti-TNF agents. The median interval between LT and initiation of VDZ therapy was 4.2 (1, 13) years. Five patients were on corticosteroids for active IBD before induction (median dose 40 [20–40] mg/day) and were successfully weaned in 4/5 (80%). Surgery was required for one patient during induction due to acute severe colitis. The median duration of VDZ therapy in the 9 patients who received maintenance was 7.4 [1.4–12.5] months. Overall a clinical response was seen in 4/10 (40%) one of whom achieved clinical remission (sustained to last follow-up). In responders, a drop in faecal calprotectin (μg/g; median 708 [60–2696] vs. 90 [32–960], p = 0.03 by Wilcoxon test) and improvement in QoL scores were observed [5 (0, 13) vs. 13 (8, 16), p = 0.03]. Abnormalities in liver biochemistry were seen in two post-LT patients, but both had recurrence of their liver disease prior to VDZ initiation. No infective complications were attributed to VDZ use. There were no malignancies identified during the follow-up period.**Conclusion:** This is the first case series of VDZ use in PSC/AISC-IBD patients pre- and post-LT. Therapy has been well tolerated by all patients and no safety signals have been identified during the follow-up period despite concomitant immunosuppresants. VDZ shows promise as a safe and efficacious treatment in PSC/AISC-IBD, even in the post-LT setting. As experience increases, taking into account its potential beneficial effects for autoimmune liver disease as well as the infectious complications associated with anti-TNF use, it seems likely that VDZ will become the treatment of choice for IBD in this patient group.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Rheumatologic, dermatologic and inflammatory bowel disorders (IBD) can affect women of childbearing potential. Infliximab ([IFX], Innovator) is approved for the treatment of rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), Crohn's disease (CD), ulcerative colitis (UC) and psoriasis (PsO). To characterize pregnancy outcomes in patients treated with IFX (Innovator), data obtained from maternal exposure to IFX (Innovator) are presented.

**Aims & Methods:** Dataset includes individual patient cases within the company safety database through 23 August 2015. Cases originated from various sources, including spontaneous reporting, clinical studies, and registries. Cases include prospectively reported (ie, pregnancy outcome not known when first reported) maternal exposures to IFX (Innovator) during pregnancy or within 2 months prior to conception with a known pregnancy outcome in RA, PsA, AS, CD, UC, or PsO pts. Birth outcome was stratified by grouped indication.

**Results:** 1362 prospective pregnancy reports with reported outcomes (103 in RA, PsA, and AS; 1023 in IBD (CD & UC); 33 in PsO) were identified. Mean maternal age was 29.7 years. Of the 1362 pregnancy reports, 1115 (81.9%) resulted in live births, 147 (10.8%) in spontaneous abortion (SA), 72 (5.3%) in elective/induced abortion, 12 (<1%) in abortion scheduled, 1 (<1%) in unspecified abortion, 9 (<1%) in ectopic pregnancy, 3 (<1%) in C-section, 1 (<1%) in molar pregnancy and 2 (<1%) in still births. Of the 1115 live births, 25 (2.2%) congenital anomalies (CA) and 85 (7.6%) preterm births were reported (Table). Of the 1362 prospective pregnancy reports, 695 (51%) reported first trimester (T1) exposure to IFX (Innovator). Among 695 reports of the T1 IFX (Innovator)-exposure, 592 (85.2%) pregnancies resulted in live births, 68 (9.8%) in SA, 23 (3.3%) in elective/induced abortion, 4 (<1%) in abortion scheduled, 3 (<1%) in ectopic pregnancy, 3 (<1%) in C-section, 1 (<1%) in molar pregnancy, and 1 (<1%) in still birth. Of the 592 pregnancies resulting in live births with T1 IFX (Innovator)-exposure, 11 (1.9%) CA and 40 (6.8%) preterm births were reported (Table). In characterizing the reports by indication, the percentage of CA among live births was 7.1% (6/84) in rheumatological indications, 1.8% (15/832) in IBD, and 0% (0/23) in PsO. The average maternal age for the rheumatological indications was 30.5 years.

**Table:** Summary of pregnancy reports with known outcomes in patients treated with IFX (Innovator) for RA, PsA, AS, CD, UC and PsO

| Pregnancy Outcome | All IFX (Innovator)-exposed pregnancies n, (%) | T1 IFX (Innovator)-exposed pregnancies n, (%) |
|---|---|---|
| Total no of reports with known outcome | 1362 | 695 |
| Live birth | 1115 (81.9) | 592 (85.2) |
| Congenital anomalies | 25 (2.2) | 11 (1.9) |
| Preterm birth | 85 (7.6) | 40 (6.8) |
| Abortion | | |
| Spontaneous | 147 (10.8) | 68 (9.8) |
| Elective/Induced | 72 (5.3) | 23 (3.3) |
| Scheduled | 12 (<1) | 4 (<1) |
| Unspecified | 1 (<1) | 0 |
| Ectopic pregnancy | 9 (<1) | 3 (<1) |
| Still birth | 2 (<1) | 1 (<1) |
| C-section | 3 (<1) | 3 (<1) |
| Molar pregnancy | 1 (<1) | 1 (<1) |

**Conclusion:** Pregnancy outcomes among pregnancies with T1 IFX (Innovator)-exposure did not differ from the pregnancy outcomes among all prospectively reported pregnancies exposed to IFX (Innovator). Higher percentages of CA were reported among rheumatological indications in comparison to IBD and PsO. The combined rate of CA among pregnancies with IFX (Innovator) exposure was comparable to US general population (3%)[1]. Potential confounders will be further characterized. Limitations of this analysis include lack of a direct comparison group and missing data in the reports.

## P0848 CROHN'S DISEASE (CD) PATIENTS WITH HIGH BODY MASS INDEX PRESENT MORE FREQUENT AND RAPID LOSS OF RESPONSE TO INFLIXIMAB

**L. Guerbau**[1], R. Gerard[1], N. Duveau[2], P. Desreumaux[1], M. Boualit[1], J. Branche[1], V. Maunoury[1], L. Libier[1], S. Cattan[1], C. Gower Rousseau[1], A. Cotteau-Leroy[3], M. Nachury[1], B. Pariente[1]

**Introduction:** Infliximab (IFX), a tumor necrosis factor (TNF) antagonist, is effective in patients with luminal and perianal Crohn'sdisease (CD) (1). Nevertheless, up to 40% of patients with an initial response to IFX lose the benefit within the first year. Excess of fat tissue may have pharmacological effects on TNF antagonists. The aim of our study was to determine whether the body mass index (BMI) affects response to IFX during the first year of treatment in CD patients.

**Aims & Methods:** We performed a retrospective and observational study at a tertiary referral center including all luminal CD patients who started IFX between January 2010 and May 2014. BMI was calculated before initiation of IFX and patients were divided into 3 groups according to the WHO BMI categories: BMI $< 25\,kg/m^2$ (normal BMI), $25\,kg/m^2 \leq BMI \leq 30\,kg/m^2$ (overweight) and BMI $> 30\,kg/m^2$ (obesity). The following data were recorded during the first year of follow-up: optimization of IFX treatment, delay of IFX optimization, rate of mucosal and/or morphological healing, occurrence of an intestinal resection surgery, introduction of corticosteroid (CT) and/or immunosuppressant (IS) therapy and IFX treatment withdrawal. The occurrence of one of the three previous events (occurrence of surgery, CT or IS introduction, and IFX withdrawal) was considered as a pejorative event. A descriptive statistical analysis was performed on the population selected, including median calculation and range interquartile for the continuous data and percentages for discrete variables. The independence between two variables was investigated by the chi square test. Student's test was performed for comparison between groups.

**Results:** One hundred and forty patients were included, with 21 patients (15%) overweight and 23 patients (16%) obese. The median BMI at baseline was $22\,kg/m^2$. Characteristics ill introducing IFX were comparable between the three groups (phenotype and location of the CD diagnosis according to the Montreal classification, clinical activity Disease score according to the Harvey Bradshaw, CRP, and existence of IS treatment at the introduction of IFX). At 12 months from the beginning of IFX treatment, the rate of IFX optimization was significantly higher in overweight and obese patients than in the normal BMI group: 48%, 44% and 20% respectively ($p = 0.0002$). Furthermore, the optimization period was significantly shorter in these same patients: 8.5, 8, 17 months respectively ($p = 0.03$). There was no significantly difference between overweight and obese patients regarding the rate and time optimization IFX ($p = 1.0000$ and $p = 0.93$ respectively) and there was no significant difference between the three groups concerning the others parameters.

**Conclusion:** We report the first study demonstrating a loss of response to IFX more frequent and faster in obese and overweight CD patients. These Results suggest that these types of patients justify an IFX induction with higher doses and close control of residual IFX concentrations.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0849 OUTCOMES OF EMERGENCY ADMISSIONS WITH ULCERATIVE COLITIS IN ADULTS IN ENGLAND BETWEEN 2004 AND 2014

**J. Rees**[1], J. Mytton[2], F. Evison[2], P. Patel[3], R. Cooney[4], N. Trudgill[1]

**Contact E-mail Address:** jamesrees@doctors.org.uk

**Introduction:** Between 2008 and 2014, the UK national audit of adult ulcerative colitis (UC) admissions revealed a fall in mortality from 1.54 to 0.75%, a rise in anti-TNF therapy in steroid non-responders from 12 to 43%, and a fall in emergency surgery from 12 to 11%.

**Aims & Methods:** Hospital Episode Statistics (HES) is an administrative database of data on all elective and emergency care episodes in hospitals in England. Using HES, patients aged between 18 and 60 years coded with a first emergency admission with UC were identified. The influence of demographic factors, comorbidity and infused anti TNF therapy on mortality, surgery and emergency readmissions was examined using multivariate logistic regression.

**Results:** Between 2004 and 2014, 17,344 patients (47.5% female and mean age of 36 (IQR 26–45)) were identified. Mortality was 0.13% at 30-days, 0.17% in hospital and 0.55% within 1 year. During admission, 11.5% of patients had surgery (median time to surgery 6 days (IQR 1–17)) and 1.93% had infused anti-TNF therapy. Surgery during admission fell non-significantly from 12.4 to 11.7% between 2004 and 2014, but the fall in surgery within a year between 2004 and 2013 was significant (OR 0.65 (95% CI 0.52–0.83) $p < 0.001$). Anti-TNF therapy rose from 0.9 to 4.6% between 2006 and 2014. In-hospital and 1 year mortality fell from 0.25 and 0.69% in 2004 to 0.14 and 0.56% in 2014 but this was not statistically significant. Patients aged 35–60 had a higher in-hospital (3.69 (1.37–9.94) p 0.010) and 1-year mortality (2.68 (1.66–4.33) $p < 0.001$) than those aged 18–34. Increased comorbidity was associated with 30-day mortality (29.73 (9.89–89.41) $p < 0.001$) and non-white patients had a lower 1-year mortality (0.59 (0.38–0.92) $p = 0.010$). Females were less likely to have surgery during admission (0.67 (0.61–0.74) $p < 0.001$) or within 1 year (0.87 (0.79–0.96) $p < 0.001$), but gender was not associated with mortality. Patients aged 35–60 (1.17 (1.06–1.29) p 0.001) and those of non-white ethnicity (1.27 (1.12–1.42) $p < 0.001$) were more likely to have surgery during admission. Patients given anti-TNF therapy during admission were more likely to need surgery at the time (1.40 (1.03–1.89) $p = 0.031$) and within 1 year (1.44 (1.04–2.00) $p = 0.030$). Emergency readmissions within 30 days were associated with younger age (35–60 years 0.89 (0.81–0.97) $p = 0.011$) and increased comorbidity (1.78 (1.22–2.62) $p = 0.003$).

**Conclusion:** For patients with a first emergency admission for UC, there was no change mortality between 2004 and 2014. Rates of anti-TNF therapy during emergency admission have increased and surgery decreased over time. Older men and non-white ethnicity were associated with surgery during admission and the use of anti-TNF agents was associated with an increased risk of surgery, likely reflecting severe colitis.

**Disclosure of Interest:** J. Rees: Received a £10,000 grant from Merck Sharpe & Dohme (MSD) to contribute to HES access. Abstract also accepted as a poster presentation at BSG Liverpool June 2016
All other authors have declared no conflicts of interest.

## P0850 SYSTEMATIC REVIEW – MANAGEMENT OF CHRONIC REFRACTORY POUCHITIS IN ADULTS UNDERGOING RESTORATIVE PROCTOCOLECTOMY WITH ILEOANAL POUCH ANASTOMOSIS FOR ULCERATIVE COLITIS

**J. P. Segal**[1], N.S. Ding[1], S.K. Clark[2], A. L. Hart[1]
[1]*Gastroenterology, St Marks Hospital, Harrow/United Kingdom*
[2]*Department Of Surgery, St Marks Hospital, London, United Kingdom, Harrow/United Kingdom*

**Contact E-mail Address:** Jonathansegal1@nhs.net

**Introduction:** Restorative proctocolectomy (RPC) with ileal pouch anal anastomosis (IPAA) is considered the procedure of choice in patients with ulcerative colitis (UC) refractory to medical therapy. This approach is popular amongst patients since it restores intestinal continuity and avoids the necessity for a long-term stoma. The incidence of pouchitis is 20% at one year and up to 40% at 5 years. 10 to 15% of patients with pouchitis experience chronic pouchitis, which is classified as either 'treatment responsive' or 'treatment refractory'. Often in refractory unresponsive pouchitis trial medications have been utilized, usually unlicensed. This review summarises the 19 trials looking at the treatment of chronic pouchitis and builds on the cochrane review in 2015 which summarised the 2 randomised control trials in the management of chronic pouchitis.

**Aims & Methods:** Aims: To determine the efficacy of various oral and topical medical therapies for the treatment of chronic refractory pouchitis in patients undergoing IPAA for ulcerative colitis. Methods: A computer-assisted search of MEDLINE and EMBASE was carried between 1966 and February 2016 by two independent researchers. Manual searches of the reference list from the potentially relevant studies were performed in order to identify additional studies that may have been missed using the computer-assisted search strategy. Abstracts from conferences were also manually searched from 1965–2016 in order to identify unpublished studies. Outcomes: The proportion of patients with clinical improvement or remission of pouchitis. Remission was defined according to individual study and remission endpoints ranged from 15 days to 10 weeks. Chronic pouchitis was defined differently in each study with the majority defining it as symptoms for at least 4 weeks despite either antibiotics or steroid therapy.

**Results:** The literature search identified a total of 2954 studies. Two authors (JPS and NSD) independently reviewed the titles and abstracts of these studies. After screening 16 were included in the study. 4 additional papers were included after manual reference searching. A total of 19 papers were considered eligible. Antibiotics: Low-quality evidence suggests that tinidazole and ciprofloxacin were better than mesalazine in inducing remission in chronic pouchitis but not significantly, rifaxamin and ciprofloxacin for 15 days had an 33% success rate at achieving remission in chronic pouchitis and combination of metronidazole 400 mg or 500 mg twice daily and ciprofloxacin twice daily for 28 days had an 82% remission rate. Low-quality evidence also supports that metronidazole was significantly better than placebo at decreasing stool frequency. Steroids: Low-quality evidence suggests that oral beclomethasone 5 mg once daily for 8 weeks then tapered by 5 mg every 2 weeks until suspension can induce remission in 80% of patients and budesonide induced remission in 75% of patients. Biologics: Pooling low-quality evidence suggests that infliximab can induce remission in 21/50 (42%) at 1 year and 12/24 (50%) at 10 weeks using infliximab. Adalimumab at 10 weeks had a remission rate of 5/7 71% at 10 weeks. Tacrolimus: Pooling low-quality evidence suggests that tacrolimus in both enema form and tablet form may have benefit in achieving remission for chronic pouchitis. Tacrolimus: enemas induced clinical remission with significant reductions in PDAI at 8 weeks. Other Therapies: Low-quality evidence suggests that alicaforsen enemas at week 6, can induce remission in 7/12 patients (58%). Other treatments such as faecal transplantation, elemental diets did were not able to induce remission significantly in the above literature

**Conclusion:** The treatment of chronic refractory pouchitis remains difficult and is largely empirical. Our knowledge of the treatment of this condition is based on small studies with often poor study designs and small numbers. There may be room for larger multi-centre trials in order to generate larger study populations and therefore more meaningful data. There is also room for larger randomised control trials to aid the management of chronic refractory pouchitis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** haggaiby@gmail.com

**Introduction:** Anti-drug antibodies (ADA) may hamper infliximab (IFX) efficacy. Factors determining the appearance of ADA in some but not all individuals are still poorly understood. It has been suggested that ADA formation is triggered by low drug levels in the serum, yet no clear causality was hitherto demonstrated.

**Aims & Methods:** We aimed to define whether exposure to low IFX level triggers ADA formation and investigate whether other factors are related to immunogenicity. To test this, C57BL/6 mice received intra-peritoneal IFX injection in escalating doses. Serum drug levels (SDL) and ADA level were measured using ELISA. To test whether a rapid decrease of IFX levels rather than low levels per se triggered ADA formation, human TNF (hTNF) was injected intra-venously in escalating doses after administration of a fixed IFX dose, allowing for IFX-hTNF complex formation. SDL, IFX-hTNF complexes and ADA were measured. Evidence for IFX-TNF complexes in human tissue of IFX-treated patients was sought utilizing a novel ELISA.

**Results:** In mice, SDL correlated well with injected IFX dose. Two weeks after IFX injection, all mice in the higher IFX dose group developed ADA, while no ADA were detected in mice injected with the lower dose. SDL predicted ADA formation (AUC 0.748 (CI 0.657–0.839), $P < 0.0001$) and SDL of $>9.35\,\mu g/ml$ was 9.2 times more likely to produce positive ADA than SDL $<9.35\,\mu g/ml$ (OR 9.2, CI 3.43–24.81, $P < 0.0001$). Repeated low IFX dose injections every 2 weeks did not elicit any ADA response. Human-TNF injection after IFX elicited a rapid decline in SDL and appearance of measurable IFX-hTNF complexes, followed by boosted ADA appearance in all mice a week thereafter. IFX-hTNF complex level strongly predicted ADA (AUC 0.944 (CI 0.851–1.000), $p = 0.003$). Injection of mice with in-vitro formed IFX-hTNF complexes elicited similar in-vivo robust ADA formation. In-vitro stoichiometric experiments with different IFX/hTNF ratios (3:2 to 3:0.01) confirmed propensity for IFX-hTNF complex formation. Various IFX-hTNF complex sizes were demonstrated by western blotting. Finally, IFX-TNF complexes were found in human intestinal tissue of IFX-treated patients.

**Conclusion:** Higher IFX doses were more immunogenic in C57BL/6 mice. The presence of IFX-hTNF complexes boosted ADA appearance in mice and their presence was demonstrated in human intestinal tissue. Stochastic formation of IFX-TNF complexes may explain the variable time course of ADA formation in IFX-treated patients depending of IFX/TNF ratios.

**Introduction:** Patient-reported outcomes (PROs), such as the stool frequency and rectal bleeding components of the partial Mayo score, have received increasing attention as important treatment goals for ulcerative colitis (UC).[1–4] GO-COLITIS is a multicentre, open-label, single-arm, phase 4 study (NCT02092285; 2013–004583–56) that measured efficacy of subcutaneous golimumab (GLM) in anti-TNF-$\alpha$–naïve UK patients with moderate to severe UC despite conventional treatment. Results of the PROs of the partial Mayo score from the 6-week induction phase are presented here.
**Aims & Methods:** Adults with UC ≥3 months, moderate to severe disease (partial Mayo score 4–9 or Mayo score 6–12) at baseline (BL), Mayo rectal bleeding subscore ≥1, and Mayo endoscopy subscore ≥2 (if full Mayo was used) were included. Patients received GLM on day 0 (200 mg) and day 14 (100 mg) during the 6-week induction phase, followed by GLM 50 mg or 100 mg every 4 weeks during the 48-week maintenance phase as per the Summary of Product Characteristics, with 12-week follow-up. Measurements taken at BL and week 6 included the PRO components of the Mayo score.
**Results:** Overall, 205 patients were enrolled (mean [range] age, 39.3 [18–79] years; male, n = 123 [60%]) and received one (n = 2) or two doses (n = 203) of induction GLM. This resulted in pronounced improvements from BL to week 6 in the stool frequency (mean change, –1.1; SD, 1.0), rectal bleeding (mean change, –1.1; SD, 0.9), and physician global assessment (mean change, –1.1; SD, 0.9) subscores of the Mayo score (all $P < .0001$). Improvements in stool frequency and rectal bleeding subscores included increased proportions of patients with normal scores and decreased proportions with severe scores at week 6 versus BL (**Table**).

| | Baseline (n = 205) | Week 6 (n = 198) |
|---|---|---|
| Stool frequency | | |
| Normal | 3 (1.5%) | 54 (27.3%) |
| 1–2 stools more than normal | 16 (7.8%) | 61 (30.8%) |
| 3–4 stools more than normal | 64 (31.2%) | 40 (20.2%) |
| 5 or more stools more than normal | 122 (59.5%) | 43 (21.7%) |
| Rectal bleeding | | |
| No blood seen | 6* (2.9%) | 111 (56.1%) |
| Streaks of blood with stool less than half the time | 77 (37.6%) | 57 (28.8%) |
| Obvious blood with stool most of the time | 94 (45.9%) | 24 (12.1%) |
| Blood alone passed | 28 (13.7%) | 6 (3.0%) |

*Protocol violations, but included in primary analysis.

**Conclusion:** During the GO-COLITIS induction phase, patients with moderate to severe UC experienced significant improvements from BL to week 6 in the PROs of the partial Mayo score. These changes parallel the significant improvements found in the physician global assessment and patient-reported quality of life (EQ-5D/IBDQ) at week 6 versus BL.[5] The rectal bleeding and stool frequency PROs of the Mayo score could thus be a simple and noninvasive way for patients with UC to monitor their response to treatment in daily clinical practice.

**Introduction:** A global rise in the prevalence of inflammatory bowel disease has been reported, especially in countries with previously low incidence rates, such as China. Inflammatory bowel disease is associated with an imbalance in gut microbiota, including reduced bacterial diversity and Firmicutes abundance. The gut microbiota differs among human populations because of variation in genetic polymorphisms, diet, lifestyle, and environmental conditions.
**Aims:** This study was performed to identify gut microbiome patterns in a Chinese population with inflammatory bowel disease (IBD) and to investigate if any specific gut microbiome markers are associated with the activity of IBD and the response to infliximab treatment. Methods: We enrolled 51 Chinese patients with ulcerative colitis (UC), 72 with Crohn's disease (CD) and 73 healthy volunteers as control (HC) for cross-sectional comparison of gut microbiota using stool samples. Gut microbial communities were profiled by sequencing the 16S rRNA V4 region. These data were analyzed and compared with Givers's RISK cohort and PRISM cohort to investigate cross-cohorts and cross-ethnics microbial patterns associated with IBD. Furthermore, 16 CD patients were treated with infliximab (IFX) for 30 weeks and their faecal microbiota patterns were analyzed before and after treatment.
**Results:** Compared to healthy controls, IBD patients showed increased abundance of *Actinobacteria*, *Proteobacteria*, *Bacilli*, *Veillonella*, *Granulicatella*, *Enterococcus*, *Lactobacillus*, *Streptococcus*, *Rothia*, *Morganella* and decreased abundance of *Firmicutes*, *Turicbacter*, *Coprococcus*, *Lachnospira*, *Roseburia*, *Faecalibacterium*, *Ruminococcus*, *Phascolactobacterium* and *Clostridiales*. Increase in Actinobacteria and Proteobacteria and decrease in Firmicutes were strongly correlated with CD and UC severities ($p < 0.05$). Comparison to the RISK and PRISM cohorts suggests that patterns of gut microbiome dysbiosis are universal in IBD patients despite the ethnic and region differences. The predictive modelling of IBD diagnosis performs well across cohorts and ethnics groups. For IFX-treated CD patients, gut microbiota showed restored diversity as well as a significant increased trend of Clostridiales abundance in the reponse group (n = 9), compared with those in the relapse group (n = 7). Using a machine learning model including mainly two orders of Clostridiales and bacteroidales, the microbiota alone can predict the treatment outcome to 86.5% accuracy.
**Conclusion:** Gut microbiota offers potential but universal biomarkers for early diagnosis of IBD, disease activity evaluation and IFX-treatment outcome prediction, which may pave the way to the usage of gut microbiota to stratify IBD patients and apply personalized treatment for optimal outcomes.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Treatment options in steroid-dependent, chronic-active ulcerative colitis (UC) with insufficient response or intolerance to immunosuppressants and/or biologicals are limited. The ART trial intended to document efficacy and identify refractory UC subpopulations which could benefit from Granulocyte/Monocyte adsorptive (GMA) apheresis (Adacolumn®). At week 12, clinical remission and response rates were 37.2% and 53.2% respectively (ITT Population; N = 95) [1]. We report final calprotectin and endoscopy results which objectively substantiate the reported clinical remission and response rates at Week 12 and Week 24.

**Aims & Methods:** This was a prospective multicenter cohort trial conducted in the UK, France and Germany. 95 patients (18–75 years) with steroid-dependent active UC (Clinical Activity Index (CAI) $\geq$ 6; Endoscopic Activity Index (EAI) $\geq$ 4) and insufficient response or intolerance to immunosuppressants (IS) and/or TNF inhibitors were included. Patients received at least 5 and up to 10 GMA aphereses in a single induction series over up to 10 weeks. Primary endpoint was the clinical remission rate (CAI $\leq$ 4) at week 12. We calculated the proportions of patients with calprotectin above and below cut-offs of 200, 250, 300, 400 and 600 mg/kg at Weeks 12 and 24, as well as EAI subscores using McNemar's test in the ITT population at week 12.

**Results:** Logistic regression analyses did not show correlation of remission or response at 12 weeks to age, gender, duration of disease, previous failed anti-TNF, previous failed immunosuppression, baseline steroid intake, number of apheresis used or smoking status. 94% of patients had calprotectin values above the reference range at Baseline. Median values decreased from Baseline (890.5) to Week 12 (555.0) and further to Week 24 (492.5; median difference: 221.0 [95% CI: −461, −52.0]). All 95% Confidence Intervals excluded zero, indicating statistically significant changes from Baseline. 25% and 39.2% of patients achieved calprotectin levels $<$200 mg/kg at Week 12 and Week 24, respectively. Statistically significant decreases for calprotectin were found comparing baseline to Week 12 at cut-off values 200 mg/kg [p = 0.0325]; 300 mg/kg [p = 0.0412] and 600 mg/kg [p = 0.0164]; as well as at Week 24 at cut-off values 200 mg/kg [p = 0.0003]; 300 mg/kg [p = 0.0105] and 600 mg/kg [p = 0.0124]; respectively. Results for the PP Population demonstrated a similar pattern. Mean EAI at Baseline was 8.7; the mean change at Week 12 was −2.2 [95% CI: −3.0, −1.4] for the ITT Population and −2.5 [95% CI: −3.4, −1.7] for the PP Population. All 95% CIs excluded zero, indicating statistically significant changes from Baseline. Statistically significant decreases were subsequently found for EAI subscores Granulation scattering reflected light, [p = 0.0029]; vulnerability [p $<$ 0.0001] and mucosal damage [p = 0.0003] at week 12 in the ITT population. Better EAI results in the PP population paralleled CAI improvement in PP by number of apheresis sessions applied [p $<$ 0.05].

**Conclusion:** We describe a cohort of steroid-dependent moderate to severe active UC patients with failure or intolerance to previous treatment with IS and/or anti-TNF, treated with GMA apheresis induction therapy. Clinical benefit was seen in over 50% of patients at week 12. This is paralleled by a statistically significant improvement of mucosal damage parameters Calprotectin and EAI subscores. GMA apheresis may be a safe alternative treatment option in UC patients with failure or intolerance to immunosuppressants and TNF-inhibitors.

**Introduction:** Vedolizumab (VDZ), a humanized monoclonal antibody against the $\alpha4\beta7$-integrin is effective in inducing and maintaining remission in Crohn's disease (CD) and ulcerative colitis (UC). The aim of this study was to determine 54-week efficacy of VDZ in inflammatory bowel disease (IBD) patients in a real-world clinical setting.

**Aims & Methods:** This observational, multicenter registry from 6 academic, 2 community centers and one IBD practice assessed real-world clinical outcome data for IBD patients newly treated with VDZ. The primary endpoint was clinical remission (CR) (CD HBI $\leq$ 4/UC pMayo $\leq$ 1 without rectal bleeding) at week 54. Secondary endpoints included week 30 and 54 clinical response (HBI / pMayo score drop $\geq$3) and steroid-free remission.

**Results:** A total of 127 adult patients with CD (n = 67, median HBI 9 (5–30)) or UC (n = 60, median pMayo 6 (5–9)) were analyzed. Only 9.0% of CD and 18.3% of UC patients were anti-TNF naïve. At week 54, 20.9% of CD patients and 25.0% of UC patients achieved CR (all based on non-responder imputation). If CD patients did not respond to VDZ or UC patients did not enter CR by week 14, probability of CR at week 54 was 7% and 10%, respectively. Clinical remission at week 54 was significantly more frequent in anti-TNF naïve UC patients (OR 5.250 (1.277–21.583) or patients without steroid dependency (OR 11.762 (1.403–98.630)). Decline of CRP or fecal calprotectin values predicted 54-week remission in UC. VDZ treatment was stopped in 69/127 patients (56.4%) (median week 18 (range 2–49)). Lack of response was the main reason for discontinuation of VDZ. Most common AEs were arthralgia, nasopharyngitis and fatigue.

**Conclusion:** VDZ was clinically effective in 20–25% of initially enrolled patients, who continued treatment beyond induction therapy and were in clinical remission after one year. A better substance specific patient stratification – as earlier treatment of anti-TNF-naïve or steroid independent patients – may enhance VDZ efficiency in every-day clinical practice.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0856 PATTERNS OF DOSE ESCALATION AMONGST PATIENTS WITH ULCERATIVE COLITIS AND CROHN'S DISEASE TREATED WITH VEDOLIZUMAB VS. INFLIXIMAB IN THE UNITED STATES (US)

M. Raluy-Callado[1], Q. Li[1], M. Luo[2], K. Lasch[2], **J.M. Khalid**[3]
[1]*Evidera, London/United Kingdom*
[2]*Takeda Pharmaceuticals, Chicago/United States of America*
[3]*Takeda Development Centre Europe Ltd, London/United Kingdom*

**Contact E-mail Address:** mona.khalid@takeda.com

**Introduction:** The infliximab (IFX) label in the US recommends dose escalation (DE) for patients with Crohn's disease (CD) who initially respond and then lose response. Vedolizumab, a monoclonal antibody to the $\alpha4\beta7$ integrin was approved for use in patients with moderately-to-severely active ulcerative colitis (UC) and CD in May 2014 with a maintenance dosing regimen of 300 mg every 8 weeks. This study investigated the proportion of UC and CD patients who experience maintenance DE of vedolizumab (VDZ) vs. IFX in a real-world clinical practice setting in the US.

**Aims & Methods:** This retrospective cohort study used data from 1/6/2014 – 3/11/2015 in the US Explorys Universe electronic health records database. Adult patients with $\geq$ 12 months of available medical history, diagnosed with UC (ICD-9-CM 556.xx) or CD (ICD-9-CM 555.xx), and who received $\geq$ 5 infusions (including 3 for induction and $\geq$ 2 for maintenance) of VDZ or IFX were included. The 1st observed infusion defined the index date. Given that 8 weeks (56 days) is the standard maintenance dosing schedule, DE was defined as occurring when a patient received $\geq$ 2 maintenance infusions during an interval of 7–52 days since last infusion. DE was assessed at 180 days and 210 days after treatment initiation and results were stratified by prior biologic use.

**Results:** Among 101 VDZ and 228 IFX patients who qualified for the 180-day analysis, the mean age was 43 years for VDZ and 44 years for IFX and the proportion of females was 60.4% in VDZ and 50.4% in IFX. DE during 180 days was statistically significantly lower in VDZ compared with IFX (4.0% VDZ vs. 21.5% IFX, $P < 0.05$). Among 71 VDZ and 27 IFX with prior biologic treatment, DE was 5.6% VDZ and 25.9% IFX, $P < 0.05$. Among those without a prior biologic, DE was 0% VDZ and 20.9% IFX, $P < 0.05$. Among 96 VDZ and 213 IFX patients who qualified for the analysis of DE during 210 days, DE was observed in 5.2% VDZ and 25.8% IFX, $P < 0.05$. Among 68 VDZ and 24 IFX with prior biologic treatment, DE was 5.9% VDZ and 29.2% IFX, $P < 0.05$. Among those without a prior biologic, DE was 3.6% VDZ and 25.4% IFX, $P < 0.05$.
**Conclusion:** Results from this US database study suggest that a higher proportion of IBD patients with prior biologic treatment experienced DE than those without. In addition, patients treated with VDZ were less likely to experience DE than patients treated with IFX. This could, in part, reflect the guidance in the US IFX label to increase the dose for patients with CD who initially respond and then lose response.

## P0857 THE EFFECTIVENESS OF TREATMENT OF PATIENTS WITH LUMINAL FORM CROHN'S DISEASE MESENCHYMAL STROMAL CELLS OF THE BONE MARROW – 7 YEARS OF OBSERVATION

O. Knyazev[1], **N. Fadeeva**[1], A. Kagramanova[1], I. Ruchkina[1], A. Konoplyannikov[2], A. Parfenov[1], O. Boldyreva[1], A. Lishchinskaya[1], A. Babayan[1], N. Orlova[1]
[1]*IBD, Moscow Clinical Research Center, Moscow/Russian Federation*
[2]*Cells Therapy, Medical Radiological Research Center, Obninsk/Russian Federation*

**Contact E-mail Address:** chueva@mail.ru
**Introduction:** Anticytokine therapy with anti-TNF-alpha drugs contributes to the achievement of stable remission of Crohn's disease (CD). For the treatment of CD are also using mesenchymal stromal cells (MSCs). **Objective:** To examine the long-term efficacy (7 years) therapy mesenchymal stromal cells (MSCs) from the bone marrow of patients with luminal Crohn's disease (CD).
**Aims & Methods:** 80 patients with luminal form CD (terminal ileitis, colitis and ileokolit) were divided into two groups. The first group of patients aged 19 to 58 years old (Me-29) (n = 34) received the culture of MSCs under the scheme (0–1–2–3, then every 26 weeks). The second group of patients with CD (n = 46) aged 20 to 62 years (ME-28) received standard anti-inflammatory therapy with 5-aminosalicylic acid (5-ASA), glucocorticosteroids (GCS) and immunosuppressive (IS). Evaluation of the effectiveness of therapy on the level of the index of activity of Crohn's disease (CDAI < 150 point) was carried out at 12, 24, 36, 48, 60, 72 and 84 months after initiation of therapy.
**Results:** Among the patients in 1st group relapse in the 12 months of observation occurred in 4/36 patients (11.76%). In 2nd group, relapse occurred in 5/46 (10.8%) (p = 0.82). After 24 months in the 1st group of patients receiving MSC, relapse occurred in 6/34 (17.6%). In the 2nd group of patients relapse in 19/27 (41.3%) (p = 0.044). After 36 months in 1st group patients with a relapse of the disease in 11/34 (32.3%). In the 2nd group relapse 29/46 (63.1%) (p = 0.01). After 48 months in 1st group, receiving MSCs, relapsed in 15/34 (44.1%). In the 2nd group relapse in 33/46 (71.7%) (p = 0.023). After 60 months in the 1st group relapse in 19/34 (55.9%). In the 2nd group relapse 40/46 (86.9%) (p = 0.004). After 72 months in 1st group relapse 25/34 (73.5%). In 2nd group relapse of the CD in 45/46 (97.8%) (p = 0.001). After 84 months in 1st group relapse CD in 29/34 (85.3%). In the 2nd group of patients CD relapse occurred in 46/46 (100.0%) (p = 0.011).
**Conclusion:** MSCs transplantation helps to maintain a long-term clinical remission in patients with luminal Crohn's disease compared with GCS/IS therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0858 POSTOPERATIVE INFECTIOUS COMPLICATIONS IN CROHN'S DISEASE: RESULTS FROM PRACTICROHN STUDY

**Contact E-mail Address:** gutierrez_anacas@gva.es
**Introduction:** Crohn's disease (CD) surgery is related to postoperative complications in 11 to 14% of all cases. Infectious complications (ICs) are the most common. The aim of this study is to describe the prevalence and factors associated with the ICs in a cohort of patients with CD.
**Aims & Methods:** PRACTICROHN was a study that included patients aged ≥18 years-old from 26 centers who underwent CD-related ileocolonic or ileorectal resection with ileocolonic or ileorectal anastomosis between January 2007 and December 2010. Clinical data and treatments, including surgery was retrospectively collected from medical records. Analyzed ICs were: intra-abdominal abscess, wound infection, catheter-related sepsis and extra-abdominal infections.
**Results:** 364 patients were analyzed (mean age 32 years [SD13], 50% men). Median time from CD diagnosis to surgery was 6 years (IQR 1–12). Indication for surgery was: stenosing (n = 169, 48%), penetrating (n = 114, 45%), penetrating + stenosing (n = 51, 14%) and resistance to treatment (n = 21, 6%). 69 patients presented some IC (18%), with a hospitalization median of 19 days IQR (10–30) vs 9 days IQR (7–12) in patients without IC ($p < 0.001$). The most frequent IC were wound infection (n = 33, 28%) and abscess (n = 28, 24%); extra-abdominal infections (n = 12, 10%) and infections of the catheter (n = 4, 3%). None of them were associated with mortality. ICs were more frequent in patients in which perforation was the reason for surgery (n = 11, 39% vs n = 27, 20% p = 0.048). No differences in ICs were observed related to age, gender, smoking habit location or length of intestinal resections. No treatment was correlated with a higher rate of ICs. Table 1.

| Treatment received | No IC | IC | p |
|---|---|---|---|
| Corticosteroids, n(%) | 70 (24.48) | 20 (29.85) | 0.452 |
| Immunosuppressants, n(%) | 133 (45.70) | 32 (47.76) | 0.866 |
| Anti-TNF, n(%) | 49 (16.84) | 15 (22.39) | 0.372 |

**Conclusion:** One in five patients who underwent a CD related surgery presented some postoperative IC, being perforation the most related cause of surgery associated with these complications. None of the treatments were associated with the presence of ICs.

**Introduction:** ABP 501 is being developed as a biosimilar candidate to adalimumab. Demonstration of biosimilarity requires totality of evidence based on a step-wise approach, starting with structural and functional characterization followed by toxicology and pharmacokinetic (PK) assessments. A clinical study confirms efficacy, safety, and immunogenicity. Extrapolation may allow a biosimilar to be labeled for use in indications for which the reference product is approved but the biosimilar has not been studied in the biosimilarity clinical trials. Evidence from analytical[1] and PK comparisons[2] indicates that ABP 501 is similar to adalimumab. Results of two phase 3 studies have confirmed clinical similarity[3,4]. Adalimumab exerts its effects by binding tumor necrosis factor-α (TNFα) and inhibiting pro-inflammatory signaling; this is the primary mechanism of action for all indications. Additional mechanisms may play a role in inflammatory bowel diseases (IBD), such as binding to cell surface membrane-bound TNFα (mbTNFα) or through Fc-mediated effector functions. To support extrapolation to IBD, specific functional studies explored similarity of ABP 501 to adalimumab in these mechanisms.
**Aims & Methods:** Binding of ABP 501 and adalimumab to soluble TNFα (sTNFα) and mbTNFa were tested. Blocking of TNFα-induced caspase activation and IL-8 secretion and blocking of lymphotoxin-α (LTα; TNFβ) bioactivity (ie, specificity) were also assessed. To confirm similarity in Fc-mediated functions, antibody-dependent cell-mediated cytotoxicity (ADCC) and complement-dependent cytotoxicity (CDC) were tested, as was inhibition of proliferation in a mixed lymphocyte reaction (MLR). Multiple lots of ABP 501, adalimumab sourced from the United States (US) and adalimumab sourced from the European Union (EU) were compared.
**Results:** The mAbs similarly bind sTNFα [108% mean relative binding for ABP 501, 111% for adalimumab (EU), 112% for adalimumab (US)] and similarity is also demonstrated in neutralization of sTNFα activity and specificity against LTα. These assessments reflect on signaling outcomes important to all indications. Binding to mbTNFα is similar [103% mean relative binding for ABP 501, 106% for adalimumab (EU), 105% for adalimumab (US)] and functionally adalimumab and ABP 501 similarly inhibit proliferation in an MLR. Similarity in ADCC [85% mean relative activity for ABP 501, 87% for

**Abstract No: P0860**

**Table:** Market share (M/S) of biosimilar infliximab in five European countries in 2015

| | France | Germany | Spain | UK | Italy |
|---|---|---|---|---|---|
| **Biosimilar price per vial (€) (RP price per vial (€))** | 434.4 (434.4) | 551.9 (580.1) | 402.2 (536.3) | 478.2 (531.3) | 428.01 (570.68) |
| **Q1 M/S %*** | **0.0** | **2.0** | **4.4** | **0.1** | **0.3** |
| **Q1 Biosimilar vials sold (RP vials sold)** | **67(180,614)** | **2,440(122,429)** | **3,508(80,640)** | **132(112,194)** | **169(61,601)** |
| **Q2 M/S %** | **0.7** | **9.2** | **15.5** | **3.6** | **6.5** |
| **Q2 Biosimilar vials sold (RP vials sold)** | 1,246 (179,752) | 10,765 (117,254) | 11,379 (73,474) | 4,130 (113,978) | 3,616 (55,392) |
| **Q3 M/S %** | **5.8** | **12.5** | **17.4** | **11.8** | **15.7** |
| **Q3 Biosimilar vials sold (RP vials sold)** | 10,684 (183,970) | 14,879 (118,625) | 12,974 (74,506) | 13,248 (112,136) | 8,554 (54,523) |
| **Q4 M/S %** | **10.7** | **17.2** | **22.7** | **25.3** | **28.8** |
| **Q4 Biosimilar vials sold (RP vials sold)** | 19,272 (180,538) | 19,964 (116,291) | 16,695 (73,585) | 26,023 (102,941) | 14,247 (49,419) |

*M/S for biosimilar infliximab = (biosimilar infliximab vials sold/RP vials sold) × 100%

adalimumab (EU), 86% for adalimumab (US)] and CDC [100% mean relative activity for ABP 501, 94% for adalimumab (EU), 94% for adalimumab (US)] is also demonstrated.

**Conclusion:** The totality of evidence shows that ABP 501 is similar to adalimumab in multiple functional assessments, including of mbTNFα-mediated activities that have been suggested to be important for efficacy in IBD. These results, along with previous analytical, PK, and clinical similarity results, provide support for ABP 501 extrapolation to all approved adalimumab indications.

### P0860 PHARMACOECONOMIC ANALYSIS OF BIOSIMILAR INFLIXIMAB (CT-P13) IN FIVE EUROPEAN COUNTRIES IN 2015

**S. Han**, S. Yun, S. Yoon
*Celltrion, Incheon/Korea, Republic of*

**Contact E-mail Address:** SeongHee. Han@celltrion.com

**Introduction:** Biosimilar infliximab (CT-P13) was recently approved by the US Food and Drug Administration in April 2016, following its approval by the European Medicines Agency in 2013. Due to its lower price compared with the infliximab reference product (RP), it is possible that use of biosimilar infliximab could offer a method to reduce the economic burden associated with biologic therapy and increase the number of patients accessing treatment.

**Aims & Methods:** This study aimed to analyse the real-world pharmacoeconomic effects of biosimilar infliximab use in Europe in 2015. To evaluate market share for biosimilar infliximab, surveys were conducted by IMS Health in France, Germany, Spain, UK and Italy (with market share defined as the number of vials of biosimilar infliximab sold, expressed as a percentage of the number of RP vials sold). To evaluate costs, public prices for biosimilar infliximab and RP in France, Spain, UK and Italy were used; prices in Germany were calculated according to IMS Health sales data.

**Results:** In the first quarter of 2015, market share of biosimilar infliximab in France, Germany, Spain, UK and Italy was 0, 2.0, 4.4, 0.1 and 0.3%, respectively (Table 1). Market share in the fourth quarter was 10.7, 17.2, 22.7, 25.3 and 28.8%. For 2015, total cost savings associated with biosimilar infliximab use in Germany, Spain, UK and Italy were €1,354,954, 5,974,960, 2,311,602 and 3,793,025, respectively. There were no cost savings in France as public prices for biosimilar infliximab and RP were the same. With the cost savings calculated, it was estimated that use of biosimilar infliximab instead of RP could allow up to 1,085 extra patients in Spain per year to access biologic therapy.

**Conclusion:** This study has shown the real-world cost savings that were associated with use of biosimilar infliximab in five European countries in 2015. Due to its cost competitiveness, biosimilar infliximab has rapidly entered into use, while the market share of RP has decreased. Even though the price of biosimilar infliximab and RP are the same in France, use of biosimilar infliximab has grown gradually in that country. Competition between the two products may drive down costs of both biosimilar infliximab and RP. As the market share of biosimilar infliximab increases, the economic burden in each country is expected to reduce, allowing more patients to access biologic therapy.

**Contact E-mail Address:** zsuzsa.kurti@gmail.com

**Introduction:** Therapeutic drug monitoring (TDM) measuring drug trough levels (TL) and antidrug antibodies (ADA) may aid the therapeutic decision in patients with inflammatory bowel disease (IBD) who loose response to anti-TNF therapy.

**Aims & Methods:** Our aim was to evaluate the frequency and predictive factors of loss of response to adalimumab therapy and the role of the therapeutic drug monitoring to predict the loss of response in adalimumab treated IBD patients. 74 IBD patients (with 94 TDM measurements, CD/UC 59/15, male/female 32/42, mean age CD/UC: 38/31 years, mean duration of adalimumab therapy CD/UC: 147.6/43.7 weeks) were enrolled in this consecutive cohort from two referral IBD centres in Hungary. Demographic data were comprehensively collected and a harmonized monitoring strategy was applied. Previous and current therapy, laboratory data and clinical activity at the time of the TL and ADA measurement were recorded. Patients were evaluated either at the time of suspected LOR or during follow-up. TDM measurements were done by commercial ELISA (LISA TRACKER, Theradiag, France).

**Results:** Among 74 IBD patients, the probability of ADA positivity and low TL ($<4.5\ \mu g/mL$) was 8.1% and 13.8% in the first year and 11.4% and 28.8% and in the second year after start of adalimumab therapy in Kaplan-Meier analysis. The frequency of previous and current steroid and azathioprine exposure were 95.9%/29.7% and 73.3%/53.3% and previous anti-TNF therapy was present in 74% (in CD 69%, in UC 93.3%) in the IBD cohort. Dose intensification was needed in 38.7% during the study period. The combination of normal TL and no ADA, normal TL and high ADA, low TL and no ADA and low TL and high ADA were observed in 63.5%, 6.8%, 23% and 6.8% at TDM measurement. Predictors of the dose intensification were female gender ($p = 0.06$, HR: 2.1), concomitant steroid therapy ($p = 0.01$, HR: 2.57) and ADA positivity ($p = 0.005$, HR: 3.26) with Cox-regression model ($p < 0.05$). Predictors of loss of response were female gender ($p = 0.004$, HR: 4.9), dose intensification ($p = 0.009$, HR: 3.75) and there was a positive trend for concomitant steroid therapy ($p = 0.06$, HR: 2.71) and previous anti-TNF therapy ($p = 0.15$, HR: 2.39). Predictors remained unchanged if the 94 TDM episodes were analysed separately.

**Conclusion:** Our results suggest that ADA development, low TL and need for dose intensification are frequent during adalimumab therapy and support the use of routine TDM assessment in IBD patients. Female gender, concomitant steroid therapy and ADA positivity were predictors of dose intensification and female gender and dose intensification predicted loss of response.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Vedolizumab (VDZ) is an effective agent recently approved by both FDA and EMA for the treatment of ulcerative colitis (UC) and Crohn's disease (CD).

**Aims & Methods:** The aim of this study was to describe our real-life experience with VDZ in a large national cohort of patients with inflammatory bowel diseases (IBD), and specifically, to assess its efficacy for induction of clinical remission, steroid-free clinical remission and discontinuation of systemic corticosteroids by week 14.

**Methods:** Patients with IBD and treated with VDZ were prospectively enrolled. Those receiving$\geq$ 4 infusions (week 0, 2, 6,14) were included, as well as patients discontinuing VDZ earlier due to primary non-response or adverse effects (AE). Clinical, laboratory and endoscopic data were collected. Clinical remission was defined as Harvey Bradshaw index (HBI) $<5$ for CD, partial Mayo score $<2$ or Simple Clinical Colitis Activity Index (SCCAI)$<4$ for UC; physician's global assessment (PGA) was used when clinical scores were unavailable.

**Results:** A total of 166 patients receiving VDZ between January and November 2015 were included; after exclusion of patients that did not complete the induction protocol or did not have sufficient clinical data, 110 patients (CD-67,UC −35; unspecified IBD (IBD-U) – 4, pouchitis −2, ileostomy-2) were retained for analysis; For CD, the mean age at treatment onset was $39.6 \pm 17.7$ years, and mean disease duration was $12.8 \pm 9.4$ years. For UC and IBD-U, the mean age at treatment onset was $34.3 \pm 44$ years, and mean disease duration was $8.0 \pm 31$ years. Most patients (95.4%) failed at least one previous biologic therapy. For CD, clinical remission was achieved in 25/67 (37%) and steroid-free remission in 18/67 (26.5%) of the patients by week 14; 10/19 (52.6%) of the patients receiving systemic corticosteroids at onset of VDZ therapy discontinued steroids. VDZ was discontinued by 16/67 (23.8%) before week 14 due to primary non-response. Fifteen patients (22.4%) were hospitalized during VDZ treatment and 9/67 (13.4%) required surgery. For UC and IBD-U (combined), clinical remission was achieved in 14/39 (35.3%) and steroid-free remission in 9/39 (23%) of the patients by week 14; 9/18 (50%) of the patients discontinued systemic steroids. VDZ was discontinued for primary non-response in 9/39 (23%) of the patients. Seven (17.9%) patients were hospitalized and 5/39 (12.8%) were referred for colectomy. The main AEs observed included CMV Colitis, *Clostridium difficile* and campylobacter infection [1/110 (0.8%) patients each], transient hearing loss, skin rashes and fever within 24 hours of VDZ infusion [2/110 (1.6%) patients each].

**Conclusion:** In a large cohort of IBD patients with refractory disease, VDZ was effective in induction of clinical remission and steroid-free clinical remission. Treatment had a favorable safety profile. Thus, in accordance with recently published data, VDZ is an effective real-life therapy for IBD.

**Introduction:** Vedolizumab (VDZ), a gut-selective monoclonal anti-integrin antibody, is approved for the treatment of moderate-to-severely active Crohn's disease (CD) and ulcerative colitis (UC) in adults.

**Aims & Methods:** This study aimed to provide a systematic summary of recently published reports describing real-world effectiveness and safety of VDZ to date. MEDLINE-, Cochrane- and Embase-indexed publications and conference abstracts (n $\geq$10) were searched from 1 January 2014 to 1st April 2016, to identify studies reporting VDZ outcomes. Reports for patients $<18$ years of age or on off-label VDZ use were excluded.

**Results:** 51 reports were identified (4 manuscripts and 47 conference abstracts) describing a total of 5,775 VDZ patients. The majority of VDZ-treated patients had prior exposure to $\geq$1 anti-tumour necrosis factor (TNF) therapy; definitions of clinical remission differed between studies (partial Mayo score, simple clinical colitis activity index, Harvey-Bradshaw index, Crohn's disease activity index, clinician assessment). In UC, real-world clinical remission rates at week 14 ranged from 24–55% (6 studies). Three UC VDZ studies reported steroid-free clinical remission rates at week 14 ranging from 19%–36%. In 2 UC studies not reporting clinical remission rates, marked reductions in disease activity scores (DAIs) from baseline at week 14 were observed. Mucosal healing was observed in 57–72% of patients in 4 UC studies (Table 1). In CD, real-world clinical remission rates at week 14 ranged from 14–38% (7 studies). Three CD studies reported steroid-free clinical remission rates between 19%–31% at week 14. In 3 CD studies not reporting clinical remission rates, marked reductions in DAIs from baseline at week 14 were observed. Mucosal healing was observed in 17–30% of patients in 4 CD studies (Table 1). VDZ patients experiencing adverse events (AEs) ranged from 4–42% (13 studies); rates of infection ranged from 4–13% (7 studies). One study reported serious AEs in 8% of VDZ patients (2% of VDZ patients experienced a serious infection).

**Conclusion:** Real-world clinical effectiveness and safety data for VDZ confirm benefit for moderate-to-severely active UC and CD in largely anti-TNF-refractory populations. Evidence from larger VDZ cohorts over longer periods are required to support these findings and support the efficacy and safety outcomes in subpopulations of patients, including those naive to biologic therapy already demonstrated in the GEMINI studies.

**Introduction:** Infliximab (IFX) is a source of potential immunogenicity for patients, with the occurrence of anti-infliximab antibodies (ATI) and different autoantibodies such as antinuclear (ANA), anti-double-stranded DNA (anti-dsDNA), or anti-extractable nuclear antigens (anti-ENA) antibodies. Recently introduced biosimilar IFX seems to be identical to the original drug from the clinical and pharmacological points of view. However, even minor modification of molecular structure could potentially alter the immunogenicity of the drug.
**Aims & Methods:** To compare the incidence of immunogenicity of IFX in patients treated by biosimilar and original preparation. Sera from 60 previously IFX-naive patients treated by the biosimilar IFX (Remsima$^{TM}$) and 71 patients treated by the original preparation (Remicade®) were analyzed at treatment weeks 2 and 14 (W2 and W14) on ATI, ANA, anti-dsDNA and anti-ENA antibodies. ATI were detected by ELISA (Shikari, Matriks Biotek, Turkey). ANA and anti-dsDNA were detected by indirect immunofluorescence (ImmunoConcepts, USA and Orgentec, Germany, respectively), anti-ENA antibodies were analyzed by ELISA (Immco, USA). A chi-square statistic was used to investigate whether distributions of measured qualitative variables differ between two groups. P-values $< 0.05$ were considered significant.
**Results:** No significant difference in proportion of patients with positive ATI and ANA were observed at W2 between original and biosimilar IFX. None of patients was positive for anti-dsDNA and anti-ENA at W2. Similarly, at W14 the proportion of patients with positive anti-bodies (ATI, ANA, anti-dsDNA and anti-ENA) was not different comparing therapy with original and biosimilar IFX (Table 1).

**Table 1.**

| | | ATI | ANA | ANA in high titre (≥1:640) | Anti-dsDNA | Anti-ENA |
|---|---|---|---|---|---|---|
| | Biosimilar IFX | 3% | 18% | 2% | 0% | 0% |
| **W2** | Original IFX | 10% | 14% | 3% | 0% | 0% |
| | p-value | ns | ns | ns | ns | ns |
| | Biosimilar IFX | 7% | 30% | 18% | 3% | 2% |
| **W14** | Original IFX | 11% | 38% | 17% | 3% | 3% |
| | p-value | ns | ns | ns | ns | ns |

**Conclusion:** Original and biosimilar IFX have comparable immunogenicity in patients with inflammatory bowel disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0865 RISK FACTORS ASSOCIATED WITH THE NEGATIVIZATION OF ANTI-HBS ANTIBODIES IN INFLAMMATORY BOWEL DISEASE PATIENTS

**A.C. Marin**[1], M. Chaparro[1], M. Ramas[1], A. Garre[1], P.M. Linares[1], J. Villagrasa[2], D. Bernardo[1], J. P. Gisbert[1]

**Introduction:** The vaccine against hepatitis B (HBV) is less effective in patients with inflammatory bowel disease (IBD) than in the healthy population. Furthermore, it has been suggested that anti-HBs antibodies negativization rate following a successful vaccination is higher in such patients compared with healthy controls. The aim of this study was therefore to evaluate the anti-HBs negativization rate in a cohort of IBD patients and to investigate the risk factors associated to such loss.
**Aims & Methods:** Inclusion criteria: IBD patients not infected by HBV who were successfully vaccinated (determined as titres of anti-HBs $>10$ IU/L following vaccination) between 2008 and 2010. Follow-up period: from the date of vaccination until 2016. Procedures: Anti-HBs titres were retrospectively collected from the clinical history of the patients. Events were considered as negativization if antibodies titres were $<10$ IU/L at any serology. Statistical analysis: Logistic regression was applied, being the dependent variable the negativization of anti-HBs, and possible risk factors were investigated as covariates (type of IBD, gender, smoking habit, age of the patients at vaccination, anti-HBs titres after vaccination, and treatment with immunosuppressants or biologics).
**Results:** 95 patients were included (65% Crohn's disease, 52% female, 26% smokers, median of the age at vaccination: 38 years). During vaccination, 24% of patients were treated with immunosuppressants and 15% with biologics. Median follow-up was 23 months (range: 4–135 months) and the prevalence of negativization was 25%. The proportion of patients who lost antibody titles was significantly higher among those who had anti-HBs $<100$ IU/L (measured at 1–6 months after vaccination) compared to those with anti-HBs $>100$ IU/L (78% vs. 22%; $p < 0.01$). The predictive model of developed negativization (shown in the table) corroborated that titles of anti-HBs $>100$ IU/L were associated with a reduced probability of negativization, while treatment with biologics during vaccination markedly increased the risk of losing anti-HBs.

| | B | S.E. | p value | OR | 95% C.I.for OR |
|---|---|---|---|---|---|
| Anti- HBs $>100$ IU/L | −2.8 | 0.9 | $<0.01$ | 0.06 | 0.01–0.36 |
| Biologics | 1.6 | 0.7 | 0.02 | 5.16 | 1.2–21.18 |

**Conclusion:** Negativization of anti-HBs antibodies in IBD patients is much more common in patients with low post-vaccine antibody titres and in those treated with biologics during vaccination.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0866 AZATHIOPRINE IN THE MAINTAINANCE OF STEROID-FREE REMISSION IN INFLAMMATORY BOWEL DISEASE PATIENTS: EFFICACY AND SAFETY IN FIVE YEARS OF FOLLOW-UP

**C. Cassieri**[1], R. Pica[1], E.V. Avallone[1], G. Brandimarte[2], M. Zippi[1], P. Crispino[1], D. De Nitto[1], G. P. Lecca[2], P. Vernia[1], P. Paoluzi[1], E.S. Corazziari[1]

[2]*Division Of Internal Medicine And Gastroenterology, ''Cristo Re'' Hospital, Rome/Italy*

**Contact E-mail Address:** claudio.cassieri@libero.it
**Introduction:** Purine analogue azathioprine (AZA) is widely used for induction and maintenance of remission in steroid dependent patients with inflammatory bowel disease (IBD). The treatment must be withdrawn in 5–30% of patients due to the occurrence of adverse events.
**Aims & Methods:** We investigated its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients three year after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985–2014, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2–2.5 mg/kg.
**Results:** Out of 2684 consecutive IBD outpatients visited in the index period, AZA was prescribed to 398 patients, 216 (54.3%) were affected by Crohn's disease (CD) and 182 (45.7%) by ulcerative colitis (UC). One hundred and thirty-eight patients with a follow-up $<60$ months were excluded from the study. Two hundred and sixty patients were evaluated, 145 (55.8%) with CD and 115 (44.2%) with UC. One hundred and forty-six (56.2%) were male and 114 (43.8%) female (average age of $34.85 \pm 14.92$ SD years, range 14–74 y.). Five year after the institution of treatment, 135 (51.9%) patients still were in steroid-free remission (86 CD vs 49 UC, 59.3% and 42.6%, respectively, $p = 0.0087$), 71 (27.3%) had a relapse requiring retreatment with steroids (29 CD vs 42 UC, 20% and 36.5%, respectively, $p = 0.0033$), 54 (20.8%) discontinued the treatment due to side effects (30 CD vs 24 UC, 20.7% and 20.9%, respectively). Loss of response from 1$^{st}$ to 5$^{rd}$ year of follow-up was low, about 18%.
**Conclusion:** Five years after the onset of treatment 52% of patients did not require further steroid courses. After the first year loss of response was low in four subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0867 IS FECAL CALPROTECTIN THE BETTER TOOL TO MONITOR DISEASE ACTIVITY IN PREGNANT IBD PATIENTS?

**M. Julsgaard**[1], L. Ambrosius Christensen[1], C.L. Hvas[1], J. Fallingborg[2], L. Svenningsen[3], J. Kjeldsen[4], M.P. Sparrow[5], S. Wildt[6], S. Bell[7]

**Contact E-mail Address:** mjn@clin.au.dk
**Introduction:** Active inflammatory bowel disease (IBD) increases the risk of adverse pregnancy outcomes, and maintaining clinical remission during pregnancy is of pivotal importance. It is difficult to validate IBD activity indexes in pregnant women because several parameters are affected by and change throughout pregnancy, e.g. laboratory markers, nausea, and stool frequency. Levels of fecal calprotectin (FC) greater than 100 microgram/gram have been found to predict Crohn's disease activity with greater accuracy than C-reactive protein (CRP) among non-pregnant patients.[1]Few, if any, studies have examined FC in pregnant IBD women as a marker for disease activity.

**Aims & Methods:** Pregnant women with IBD who received treatment with anti-TNF-alpha were prospectively recruited from seven tertiary hospitals in Denmark and Australia. Disease activity was assessed prospectively by a physician global assessment (PGA) as active or in remission in the 6 months pre-conception period, in each trimester and the first 6 months post-partum. We investigated if FC levels greater than 100 microgram/gram and/or CRP greater than 10 mg/L correlated with PGA of disease activity in the pre-conception period, in each trimester of pregnancy and/or postpartum. Demographics, disease activity and medication were prospectively documented. Blood and stool samples were obtained to determine CRP and FC, respectively. Pearson's chi-squared test was applied for comparison.
**Results:** Of the 42 pregnant IBD patients recruited, 33 (79%) had Crohn's disease and nine (21%) had ulcerative colitis. A total of 161 fecal samples and 192 blood samples were collected during the five periods of investigation. Disease activity was observed in the pre-conception period in 17 (40%); 1st trimester, 13 (31%); 2nd trimester 15 (36%); 3rd trimester, 17 (40%); and postpartum, 17 (40%). FC was significantly correlated with disease activity at all five periods of investigation ($p < 0.001$). In contrast, CRP was not correlated with disease activity at any time point ($p > 0.05$) apart from 2nd trimester ($p = 0.01$).
**Conclusion:** Our data suggest that FC is superior to CRP as a monitoring tool for disease activity during pregnancy among women with IBD. FC testing can be performed noninvasively and easily which is of great importance during pregnancy. These data should assist clinicians in the management of pregnant IBD patients.

**Introduction:** Vedolizumab is a fully humanized monoclonal IgG1 antibody targeting $\alpha 4\beta 7$ integrin that has shown its efficacy in patients with inflammatory bowel disease (IBD) even after failure of anti-TNF therapy. However, its effect as a third line therapy in real-life circumstances remains to be established.
**Aims & Methods:** In this prospective, multicentric, observational cohort study we aimed to evaluate the effects of vedolizumab induction therapy in a real-life setting. 150 consecutive adult IBD patients with moderate to severe disease and known primary or secondary failure/intolerance to at least two biologicals were included in a compassionate early access program. Vedolizumab (300 mg intravenously) was administrated at weeks 0, 2, 6 and optionally at week 10 for Crohn's Disease (CD) patients. Efficacy was evaluated by physician's assessment at week 10 for Ulcerative Colitis (UC) and week 14 for CD. In case of response, maintenance therapy was started. Remission was defined based on Harvey-Bradshaw index (HBI) or CDAI for CD patients and total Mayo score for UC patients.
**Results:** In this study, data from 121 patients (80.6%; mean age $40.7 \pm 13.4$ y; mean disease duration $13.3 \pm 8.7$ y; 54% concomittant oral steroids at week 0) are presented of which 79 patients had CD (62.3% female; mean HBI 15.7, mean CDAI 306.9) and 42 patients were known with UC (41.5% female; mean total Mayo 9.6). Based on physician's assessment at week 10 for UC and week 14 for CD, we report a clinical response in 62/79 or 78.5% of patients with CD and 31/42 or 73.8% of patients with UC with no difference between steroid users and non-users (73.1% clinical response in concomittant steroid use versus 80% in steroid free patients). Clinical remission was found in 34.2% of CD patients (defined as CDAI $\leq 150$ or HBI $\leq 4$) but in only 5.9% of UC patients (Mayo score $\leq 2$). Clinical response according to changes in disease activity score was found in 68% of UC patients (defined as a drop in Mayo score with 3 points and at least 30% from baseline) and 69.7% CD patients (CDAI drop $> 100$ or HBI $>/= 3$). No deaths were reported during the course of this study. Nine patients needed colectomy because of non-response ($n = 6$), acute subobstruction ($n = 1$) or perforation during colonoscopy ($n = 1$). In one patient ileostomy and drainage of a perirectal abscess was required.
**Conclusion:** In this retrospective cohort study studying the real life effects of third line administration of vedolizumab in IBD patients intolerant/resistant to at least two biologicals, approximately 70% achieved a clinical response after 10 to 14 weeks.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0869 ULCERATIVE COLITIS: DISEASE COURSE AND PROGNOSIS DURING THE FIRST YEAR OF DISEASE

**S.R. R. Fernandes**, L. A. Correia, J. Velosa
*Serviço De Gastrenterologia E Hepatologia, Hospital Santa Maria, Centro Hospitalar Lisboa Norte, Lisboa/Portugal*

**Contact E-mail Address:** Samuelrmfernandes@gmail.com
**Introduction:** Ulcerative Colitis (UC) is a chronic immune-mediated disease affecting the colon and rectum. While the majority of patients will present a mild and moderate disease, approximately 15% will require hospitalization and 5% will be refractory to conventional management and potentially require surgery.
**Aims & Methods:** We sought to evaluate the clinical course of patients with UC during the first year of diagnosis and determine potential predictors of the need of anti-TNF therapy and surgery. This was a single-center, retrospective study including patients with an established diagnosis of UC. Demographic and clinical data were retrieved from patient's medical charts. Logistic regression analysis were performed in order to evaluate potential predictors of the need for surgery or biologic therapy.
**Results:** 395 patients with UC were included in this study. Patient's characteristics are presented in Table 1. In the first year following diagnosis, 336 (85.1%) required therapy with aminosalycilates, 202 (51.1%) steroids and 48 (12.2%) with thiopurines. Ten patients (2.5%) required biologic therapy and 9 patients (2.3%) underwent surgery. During the first year of disease, 47 patients (11.4%) developed an episode of severe acute colitis (SAC). Colectomy was more common amongst this group (OR 35.4 IC95% [11.0–114.8], $p < 0.001$). In regression analysis, extensive disease was the only independent predictor of requiring anti-TNF therapy (OR 3.813 IC95%[1.194–12.172], $p = 0.024$) and surgery IC95%(OR 8.353 [1.131–61.671], $p = 0.037$).
**Conclusion:** A subgroup of patients with UC present with an early aggressive severe course. The extension of inflamed bowel and developing an episode of ASC represent important prognostic factors.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0870 THE INCIDENCE OF SUBOPTIMAL THERAPY AFTER INITIATING A SECOND TUMOUR NECROSIS FACTOR ANTAGONIST IN PATIENTS WITH ULCERATIVE COLITIS: A MULTI-COUNTRY CHART REVIEW

**Introduction:** Patients with ulcerative colitis (UC) treated with tumour necrosis factor antagonists (anti-TNF) may require treatment modifications (i.e., dose

escalation, switch to another anti-TNF, surgery, or addition of other medications). Such changes can be used as surrogate of loss of response and may be considered as indicators of suboptimal therapy.
**Aims & Methods:** Our aim was to quantify the incidence of suboptimal therapy among adult patients with UC treated with a second anti-TNF using data from real-world clinical practices. A retrospective chart review study conducted in six countries (Canada, France, Germany, Italy, UK, and Spain) recruited UC patients initiating anti-TNF therapy between June 2009–2013. We measured the incidence of suboptimal therapy over two years and time to the first indicator of suboptimal therapy among patients who switched from initial anti-TNF to a second anti-TNF. Indicators of suboptimal therapy with a second anti-TNF included anti-TNF dose escalation (assessed >4 months after index to allow for initial dose optimization), augmentation with aminosalicylates, immunomodulators, or corticosteroids, discontinuation of anti-TNF therapy, switching to another anti-TNF, and UC-related surgery. Time to the first occurrence of the indicator of suboptimal therapy was measured using the Kaplan-Meier Method, where patients were censored after discontinuation of therapy or at the end of the follow-up period.
**Results:** The study included a total of 538 UC anti-TNF naïve patients of which 111 (20.6%) patients had initiated a second anti-TNF [mean age (SD): 40.7 (14.9) years, 45% female]. Median duration with the first anti-TNF therapy was 9.8 months. 73.8% of patients had reported moderate to severe UC with a median duration of UC of 5.2 years. The majority of patients had left-sided or distal UC and pancolitis (35.1% and 50.0%, respectively). At the time of initiation of the second anti-TNF therapy, 69.4% of patients had an ongoing treatment with at least one non-biologic therapy. The proportion of patients on adalimumab, infliximab and golimumab as a second anti-TNF were 83.8%, 9.0%, and 7.2%, respectively. Within two years after initiating a second anti-TNF therapy, 51.4% patients had at least one indicator of suboptimal therapy. Discontinuation (27.9%) and dose escalation (17.1%) were the most frequent indicators of suboptimal therapy. Median time to at least one of the indicators of suboptimal therapy was 14.3 months (95% CI: 9.0 – 25.0).
**Conclusion:** Over half of UC patients treated with a second anti-TNF therapy experienced at least one indicator of suboptimal therapy within 2 years of therapy. The most common indicators were dose escalation and discontinuation with anti-TNF therapies. Future research should determine the potential for alternative therapies to improve treatment response rates among patients who experience loss of response with anti-TNF therapies.

## P0871 PROBIOTICS ARE LESS EFFECTIVE THAN MESALAZINE IN MAINTAINING REMISSIONS IN IBD

**A. Sydorchuk**, R. Sydorchuk, L. Sydorchuk, I. Sydorchuk, O. Plehutsa
*Bukovinian State Medical University, Chernivtsi/Ukraine*

**Contact E-mail Address:** rsydorchuk@ukr.net
**Introduction:** The role of gut microbiota has become more appreciated in recent years emphasizing the IBD etiology. Probiotics are widely discussed for IBD and thought to work by altering the composition of the intestinal microbiota, the epithelial barrier function of the intestine, and have important immunoregulatory activity. Expanding this idea, probiotics have been subject for intensive research, mainly focusing on bifidobacteria and lactobacteria. However, existing reports of probiotic use in IBD are contradictory and even confusing.
**Aims & Methods:** The aim of this study is to compare therapeutic efficacy of standard treatment with mesalazine and novel probiotic strains with potent immunological features. Ninety-eight patients (34 CD, 64 UC) participate in the study. Colonic resistance studied in mucosal bioptates. Specially designed (T73) strain of P. Shermani with high antagonistic/immunoregulatory potential was orally given triple daily in a form of suspension containing $10^{12}$–$10^{14}$ bacteria/day. Patients without probiotic treatment formed second group (57.14%), they received mesalazine 1500 mg ($3 \times 500$ mg) daily as a basis therapy. Study duration was 50 weeks, treatment efficacy evaluated according to WGO, ECCO Guidelines and patients were assessed by clinical and endoscopic activity indices as well as by biopsies. The primary endpoint of the study was to compare efficacy in prevention of relapses.
**Results:** Systemic oral probiotic use significantly improved colonic resistance. There were relapses in 16 of 56 (28.57%) patients in second group (with mesalazine) and in 19 of 42 (45.24%) in probiotic group ($p = 0.007$). No statistically significant variations between UC and CD patients inside groups were found. CDAI score at the end of study was $12.37 \pm 5.14$ points lower in mesalazine group ($p > 0.05$). Abdominal pain, stool, and drug use for symptomatic therapies improved in both groups, too. Endoscopic picture and biopsies presented no specific differences between groups after study. Safety profiles and tolerability were satisfactory for both groups and without significant differences.
**Conclusion:** Probiotics are living microorganisms that exert health effects on the host; their use in IBD is promising. Our study shows that probiotic treatment of IBD patients with P. Shermani is safe but lacks efficacy in maintaining remission equivalent to the gold standard in IBD treatment – mesalazine. However, this study has limitations in both volume and control. Further controlled trials are needed to clarify whether probiotics alone are sufficient enough to prevent IBD relapses. At that point use of probiotics may have good potential when applied as an addition to mesalazine, acting on different mechanisms of IBD pathogenesis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Biosimilar infliximab (IFX) has been approved in European Union for treatment of inflammatory bowel disease (IBD) since September 2013. The approval process included the extrapolation of clinical data from other indications, namely rheumatoid arthritis and ankylosing spondylitis. The data from clinical practice are therefore desirable to confirm the efficacy and safety of biosimilar IFX in IBD population.
**Aims & Methods:** The aim was to evaluate efficacy and safety of biosimilar IFX in patients with Crohn's disease (CD) and ulcerative colitis (UC) naïve to anti-TNF therapy. Data from consecutive patients with CD and UC starting on biosimilar IFX since January 2015 at our center were analyzed. Patients were assessed as non-responders (NR), partial responders (PR), or complete responders (CR) based on clinical, endoscopic, and laboratory parameters. Besides clinical and endoscopic evaluation, C-reactive protein (CRP) levels, faecal calprotectin (FC), blood count, IFX trough levels (TL), and antibodies-to-infliximab (ATI) were measured. All adverse events were also recorded. Final analysis was performed at week 38 (W38).
**Results:** One hundred and nineteen IBD patients (CD, 90; UC, 29, female 55.5%) were included into this analysis. The mean disease duration at anti-TNF therapy start was 6.2(±6.3) years. Thirty seven percent of patients had history of extra-intestinal manifestations, 27.7% were treated surgically in past, and 31.1% of CD patients had a history of perianal disease. By week 38, 84.1% of CD, and 65.2% of UC patients were assessed as CR or PR. Perianal disease was improved in 88% of patients. Among UC patients, one half of them achieved mucosal healing (Mayo endoscopic subscore 0 or 1) by W38. Therapy was intensified in11.9% of CD and 23.5% of UC patients. The mean IFX trough level at W38 was $4.5 \pm 5.5 \mu$g/mL, and 10% were positive for ATI. Therapy with biosimilar IFX was discontinued in 7 CD (7.8%) and 6 (20.7%) patients. Observed adverse events included mainly skin lesions (16), joint pain (14) and infectious complications (14). Fife patients were hospitalized for disease exacerbation, and 7 underwent surgery.
**Conclusion:** Both efficacy and safety of biosimilar IFX in this cohort of anti-TNF naive IBD patients seems to be comparable to that observed previously with originator IFX.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0873 CORRELATION BETWEEN ENDOSCOPIC AND HISTOLOGICAL HEALING IN ADULTS WITH MODERATE TO SEVERE CROHN'S DISEASE: DATA FROM EXTEND

**W. Reinisch**[1], J. Colombel[2], P. Rutgeerts[3], K. Geboes[3], G. R.a.m. D'Haens[4], J. Petersson[5], S. Eichner[5], J. Maa[5], A. M. Robinson[5]

**Introduction:** Clinical remission and endoscopic healing are regarded as important treatment targets for patients with Crohn's disease (CD), but do not take into account histopathological healing. Concordance between endoscopy and histology scores for patients with CD is not well known.

**Aims & Methods:** We assessed the agreement between complete endoscopic healing and histological healing at baseline (BL) and week 52 in the colon and ileum segments of patients with moderate to severe CD randomized in the EXTEND study (N = 129). Concordance of each of the Simple Endoscopic Score for CD (SES-CD) subscores (ulcer size, ulcerated surface, and affected surface) measured in pooled samples from 3 colon segments (sigmoid/left, transverse, right colon) or ileum with Colonic Global Histologic Disease Activity Scores (CGHAS) for the colon samples or with Ileal Global Histologic Disease Activity Scores (IGHAS) for the ileal samples was performed using kappa statistic. Complete endoscopic healing was defined as SES-CD ulcer size subscore = 0, ulcerated surface subscore = 0, and affected surface subscore = 0 in the colon segments or in ileum. The SES-CD subscores in each of the colon segments had to = 0 to qualify as complete endoscopic healing. Two biopsies from each ileocolonic segment were evaluated for 8 histological variables, including epithelial damage, architectural damage, mononuclear cells in lamina propria, neutrophils in epithelium, erosion or ulceration, granuloma, proportion of ≥6 biopsy samples that were affected. Individual variables were scored independently and summed up to create CGHAS/IGHAS scores ranging from 1 (least severe) to 16 (most severe)[1, 2]. Histologic healing was defined as CGHAS or IGHAS ≤2. Centrally read SES-CD and CGHAS/IGHAS were used and patients were analyzed regardless of randomized treatment, disease location, and whether they had ulcers at BL. Data are reported as-observed.

**Results:** Fair/moderate to high agreement was observed at BL and week 52 between SES-CD subscores (ulcer size, ulcerated surface or affected surface) and CGHAS (for colon segments)/ IGHAS (for ileum) scores (Table). At week 52, for patients with evaluable colonic biopsies, SES-CD subscores = 0 were observed in 68% (53/78, data as observed) of patients for ulcer size and ulcerated surface, and by 65% (51/78) for affected surface subscores. CGHAS≤2 in the colon was observed in 67% (52/78) of patients. Of the patients with SES-CD subscores = 0 for ulcer size or ulcerated surface in the colon, 83% (44/53) also had CGHAS ≤2; the corresponding value for patients with affected surface = 0 was 84% (43/51). Similarly, for patients with evaluable ileal biopsies, 68% (52/77) of patients had SES-CD subscore = 0 for the 3 subscores evaluated and 75% (58/77) had IGHAS≤2 at week 52. Of the patients with SES-CD subscores = 0 in the ileum, 96% (50/52) also had IGHAS≤2. Concordance between SES-CD components and IGHAS/CGHAS scores is shown in the Table.

**Conclusion:** A high degree of concordance between SES-CD subcores and IGHAS/CGHAS was observed at week 52, as the majority of patients with complete endoscopic healing (using a very stringent SES-CD definition) also had histological healing. There was a greater concordance in the ileum than in the colon.

**Table:** Degree of Agreement (kappa values) Between SES-CD Subscores and IGHAS/CGHAS at Baseline and Week 52

| | BL N = 121 | | | Week 52 N = 78 | | |
|---|---|---|---|---|---|---|
| | CGHAS > 2 | CGHAS≤2 | κ* | CGHAS > 2 | CGHAS≤2 | κ* |
| Ulcer size = 0 | | | | | | |
| No | 75 | 1 | 0.37 | 17 | 8 | 0.50 |
| Yes | 30 | 15 | | 9 | 44 | |
| Ulcerated surface = 0 | | | | | | |
| No | 75 | 1 | 0.37 | 17 | 8 | 0.50 |
| Yes | 30 | 15 | | 9 | 44 | |
| Affected surface = 0 | | | | | | |
| No | 77 | 1 | 0.39 | 18 | 9 | 0.51 |
| Yes | 28 | 15 | | 8 | 43 | |
| | BL N = 113 | | | Week 52 N = 77 | | |
| | IGHAS > 2 | IGHAS≤2 | κ* | IGHAS > 2 | IGHAS≤2 | κ* |
| Ulcer size = 0 | | | | | | |
| No | 50 | 10 | 0.55 | 17 | 8 | 0.68 |
| Yes | 15 | 38 | | 2 | 50 | |

## P0874 TUBERCULOSIS IN INFLAMMATORY BOWEL DISEASE PATIENTS UNDER TREATMENT WITH ANTI TNF ALFA AGENTS: A FREQUENT COMPLICATION DESPITE RIGOROUS SCREENING

**R. Vadan**, M. L. Cojocaru, C. Gheorghe, M. Diculescu, I. Stanel, N. Zamfirescu, L.S. Gheorghe
*Gastroenterology, Fundeni Clinical Institute, Bucharest/Romania*

**Contact E-mail Address:** roxanavadan@yahoo.com

**Introduction:** Although screening strategies for tuberculosis (TB) are applied to all patients before starting biologic therapy with anti TNF alfa agents, the risk of TB reactivation/infection remains a problem, especially in countries with high prevalence of infection. Our objectives were to evaluate the frequency of latent TB before and of active TB during biological treatment in patients with inflammatory bowel diseases (IBD).

**Aims & Methods:** Patients with IBD and biological treatment from Fundeni Clinical Institute, Bucharest, Romania were evaluated retrospectively. Demographic data (sex, age, rural/urban residence, profession), diagnosis (type, extension, severity of bowel disease), the results of TB screening (PPD test, Quantiferon), treatment, were noted. Patients diagnosed with active TB were contacted by phone and time of onset, TB symptoms, treatment, laboratory and radiological tests were noted.

**Results:** 156 patients with Crohn's disease and 45 with ulcerative colitis, 104 men, with mean age 39.1 years were included in the study. 100 received Infliximab and 101 Adalimumab. 42 (20.89%) patients had latent TB at screening, before starting anti TNF therapy: 23 patients were Quantiferon positive, 9 both PPD test and Quantiferon positive, 4 only PPD test positive. All received prophylactic treatment with Hydrazide. Seven patients were diagnosed with active TB after a mean time of 13+/−0.3 month form the start of biologic therapy, 5 being in remission and 2 with mild flares of IBD at the time of TB diagnosis. One patient received concomitantly immunosuppression, one oral cortisone, the rest being on anti TNF monotherapy. All cases were pulmonary TB: 3 pleurisy, 3 pneumonic, one miliary. Only one patient had latent TB at screening. Two patients had TB contact. The symptom present in all patients was cough, 4 patients had dyspnea, 3 had fever, 2 nocturnal sweating. Quantiferon test was positive for all.

**Conclusion:** Although 1 of 5 patients with IBD and indication for biological treatment have latent TB, most of the cases with active TB were diagnosed in patients with negative TB screening. To avoid delays in diagnosis patient's training regarding the most frequent symptoms and Quantiferon test can help.

**Introduction:** Several guidelines and consensus are available for the therapeutic management of patients with ulcerative colitis (UC). The application of such criteria in daily practice improves the quality of care and increases patient satisfaction, however only few studies have evaluated the use of evidence-based therapy by physicians in their clinical practice.
**Aims & Methods:** The aim was to assess the adherence to UC management guidelines by Italian gastroenterologists. A multicentre prospective observational study on the adherence to the guidelines in UC was conducted in 26 gastroenterology (GI) units across Italy. Consecutive outpatients with a flare of UC were enrolled in the study. A questionnaire was administered to the attending physicians consisting of two sections, the first included questions about the GI unit, personal experience in inflammatory bowel disease (IBD), number of IBD/UC patients followed by the unit, the second included questions on the extension and severity of UC, specific medical treatment undertaken and adherence to the guidelines.
**Results:** Most of the centres (73%) were provided with an IBD outpatient clinic and a GI ward, 61.5% of the attending physicians classified themselves as gastroenterologists specialized in IBD. Five hundred seventy-two patients (325 males) were enrolled by high (40.9%), medium (37.9%) and low (21.2%) IBD volume units, and included 41.2% extensive colitis (mild-moderate: 79.1%, severe: 19.9%), 48.3% left-sided colitis (mild-moderate: 88.0%, severe: 12.0%), 10.5% proctitis (mild-moderate: 93.3%, severe: 6.7%). Mean age of patients: 49.3 yrs (range 18–87), mean age at diagnosis 40 yrs (range 8–79). In 88.8% of flares the management was considered by the attending physicians based on guidelines regardless of the physician's experience in IBD. Physicians from high IBD volume units referred more to ECCO guidelines (89.3% vs 63%). Rectal 5-ASA in left-sided and extensive colitis was less prescripted in low IBD volume unit (55% vs 80%) and by less experienced physicians (53% vs 76%). Conversely, physicians with less experience prescribed more anti-TNF therapy for mild–moderate UC (27% vs 10%).
**Conclusion:** The adherence of Italian gastroenterologists to the guidelines for the management of UC is high. In clinical practice, the size of IBD unit and the physicians experience in IBD may affect the compliance with guidelines.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0876 SKIN SIDE-EFFECTS OF BIOLOGIC THERAPY AND SYSTEMIC DRUGS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES

K. Juzlova[1], K. Koblova[1], J. Hercogova[1], **M. Bortlik**[2], D. Duricova[2], M. Kolar[2], M. Lukas[2]

**Contact E-mail Address:** MBortlik@seznam.cz
**Introduction:** Crohn's disease and ulcerative colitis count among inflammatory bowel diseases (IBD). Currently, biologic therapy is the most advanced and most effective anti-inflammatory strategy in IBD treatment. Most common side effects of the treatment include skin manifestations. According to some authors the prevalence reaches about 20% of patients undergoing biological treatment. The biologic therapy becomes increasingly frequent therapeutic option in patients with IBD and as a result skin complications occur more frequently.
**Aims & Methods:** To compare the incidence of skin reactions in patients with IBD treated with biologic therapy with the incidence in IBD patients with other systemic treatment. The study was performed between 2009 and 2015 and 221 subjects were enrolled. All patients involved in the project suffered from Crohn's disease or ulcerative colitis and exhibited a skin reaction during the treatment. 167 subjects treated with biological agents with skin reaction were enrolled as cases. 54 patients treated with other systemic drugs such as azathioprine, methotrexate, mesalazine, sulfasalazine, and corticosteroids were included in the control group.
**Results:** Atopic dermatitis was interestingly the most frequent dermatosis that we diagnosed in both groups. In the case of occurrence of psoriasis, palmoplantar pustulosis and bacterial skin infections, we noticed some differences between the group of patients treated by biologic agents and the group with other systemic drugs. These differences did not reach the level of statistical significance.

Skin side-effects of IBD treatment

| | Biologic therapy | Other immunosupressants |
|---|---|---|
| **Atopic dermatitis** | 76 | 20 |
| **Psoriasis** | 16 | 2 |
| **Pyodermia** | 12 | 1 |
| **Palmoplantar pustulosis** | 9 | 1 |
| **Total** | 167 | 54 |

**Conclusion:** In some skin reactions, discontinuation of biologic therapy is necessary, in other cases the therapy may continue but the cooperation with a dermatologist is needed. We would like to help gastroenterologists and dermatologists with the management and raise their awareness in terms of skin diseases.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0877 SYNERGY RESEARCH: INVESTIGATING THE COMBINED ACTION OF CHAMOMILE, MYRRH AND COFFEE CHARCOAL ON CHEMOKINE RELEASE OF ACTIVATED HUMAN MACROPHAGES

**Contact E-mail Address:** cica.vissiennon@uni-leipzig.de
**Introduction:** The herbal medicinal product Myrrhinil-Intest®, a combination of myrrh (Commiphora molmol E.), chamomile flower (Matricaria recutita L.) and coffee charcoal (Coffea Arabica L.) is used for the treatment of gastrointestinal complaints. Clinical data suggest its use for the maintenance therapy of inflammatory bowel disease [1]. In vitro studies revealed, that chemokine signaling of human macrophages is influenced by the plant extracts as part of an anti-inflammatory strategy. However, the occurrence of synergistic effects remains unexplored.
**Aims & Methods:** The present study aims to investigate the combined effect of the plant extract on chemokine (CXCL13 release) from activated human macrophages. The single effect of myrrh (MY), chamomile flower (KA) and coffee charcoal extract (CC) on CXCL13 release from LPS (100 ng/ml)-stimulated human macrophages was investigated after 24 hours incubation time using an ELISA test system. The inhibitory effect was characterized by calculation of IC50 values. Budesonide served as positive control. To characterize the combined effect, IC50 values were used to prepare combinations of two plant extracts in different concentrations (0–100%) and proportions to each other (3:1; 1:1; 1:3). Interpretation of the data was based on isobologram analysis and calculation of a combination index (CI; $= IC50_{comb.}/IC50_{single}$).
**Results:** LPS-induced CXCL13 release from human macrophages was inhibited after treatment with MY ($IC50 = 19\,\mu g/ml$), KA ($IC50 = 82\,\mu g/ml$) and CC ($IC50 = 106\,\mu g/ml$) whereby the extent of inhibition was comparable to budesonide. All combinations of two plant extracts resulted in synergistic effects with varying magnitude (CI from 0.87 to 0.46). The combination of CC and KA (ratio of 1:1) exhibited the strongest synergistic effect ($CI = 0.46$). Increasing amounts of CC resulted in increased synergistic activity ($CI_{coffee\ charcoal/myrrh\ (1:3)} = 0.73$; $CI_{coffee\ charcoal/myrrh\ (1:1)} = 0.60$; $CI_{coffee\ charcoal/myrrh\ (3:1)} = 0.51$).
**Conclusion:** Synergistic effects between all plant components contribute to the anti-inflammatory activity of the herbal combination.
**Disclosure of Interest:** C. Vissiennon: Author Cica Vissiennon is employed by Repha GmbH Biologische Arzneimittel. Financial funding for the experiments has been provided by Repha GmbH Biologische Arzneimittel.

**Contact E-mail Address:** AKohn@scamilloforlanii.rm.it
**Introduction:** Limited real-world data are available regarding the effects of adalimumab (ADA) on Italian patients with moderate to severe ulcerative colitis (UC).
**Aims & Methods:** INSPIRADA was a single-arm, multi-country, open-label study that evaluated the effect of ADA on patients with UC treated according to usual clinical practice. Adults with active moderate to severe UC who failed immunosuppressive therapies and experienced rectal bleeding within 7 days of baseline (BL) were enrolled. Prior use of anti-TNF was allowed. Patients received 160/80 mg ADA at Week 0/2 followed by 40 mg of ADA every other week at Week 4 to Week 26. Patients who did not respond to ADA by Week 8 (PGA score $\geq$2 and did not achieve Simple Clinical Colitis Activity Index [SCCAI] response, defined as a decrease of $\geq$2 points compared to BL) were to discontinue ADA. Patients who lost response at or after Week 8 could escalate to 40 mg ADA weekly. Clinical outcomes included SCCAI response and remission (defined as an SCCAI $\leq$2). HRQoL (EQ-5D-5 L and SIBDQ), treatment satisfaction with medication (TSQM), and work productivity and activity impairment (WPAI) were measured from BL to week 26. Change (defined as 6 mo after start

of ADA vs 6 mo before) in health care resource use was calculated. Data for the intent-to-treat population in Italy were analysed. Missing data were imputed using last observation carried forward.
**Results:** Data from 48 Italian patients (39.6% female, mean age 41.3 yrs) were analysed. Mean SCCAI at BL was 8.0. At week 2, 83.3% achieved SCCAI response and 31.3% achieved SCCAI remission. At week 8, 75.0% achieved SCCAI response, 43.8% were in remission and 37.5% had no blood in stool. At week 26, 66.7% achieved SCCAI response, 41.7% were in remission and 45.8% had no blood in stool. Significant improvements, as early as within 2 weeks, in SIBDQ (15.7 points, $p < .001$), EQ-5D-5 L (0.13 index score and 19.5 VAS points, both $p < .001$), all 4 WPAI domains (−23.6%, −27.1%, −32.7%, −26.2%, all $p < .001$), and 2 of 4 TSQM domains (21.9%, 23.3%, all $p < .001$) occurred from BL to week 26. Significant decreases in number of hospitalization (UC-related:−0.21; all-cause: −0.23, both $p < .05$), all-cause hospitalization length of stay (-2.19 days, $p < .05$), and UC-related outpatient visit (-2.0, $p < .001$) occurred in the 6 mo period after starting ADA compared to 6 mo before starting ADA. No new safety signals were identified from the evaluation of adverse events.
**Conclusion:** Real-world rates of response, remission and improvements in HRQoL with ADA for Italian patients with moderate to severe UC were clinically meaningful. ADA improved work productivity, increased patient satisfaction with therapy and reduced health care resource use for these patients.

## P0879 ULCERATIVE COLITIS: ARE WE DEVALUING ITS PROGRESSIVE CHARACTER?

**P. Massinha**, F. Portela, S. Campos, M. Ferreira, S. Mendes, A. m. Ferreira, C. Sofia
*Gastroenterologia, Centro Hospitalar e Universitário de Coimbra, EPE, Coimbra/Portugal*

**Contact E-mail Address:** massinha@iol.pt
**Introduction:** Ulcerative Colitis (UC) is a chronic disease but its progressive character, with structural damage is insufficiently studied.
**Aims & Methods:** To analyze a group of patients without bias referral, as the clinical course the morphological damage and functional status. We evaluated patients diagnosed with UC established between 01–01–2000 and 31–12–2004, residing in direct referral area of the hospital, having determined medication use, colectomy rate, structural damage (''lead pipe'', stenosis, pseudopolyp, fibrous bridges) or functional anorectal (Prospective evaluation with Cleavland Clinic Incontinence Score, CCIS and Fecal Incontinence Quality of Life, FIQL).
**Results:** We identified 104 patients, 47% female, mean age at diagnosis of $38 \pm 17$ years, 24% proctitis, left colitis 57%, 19% pancolitis. In 3 patients it has not been possible to obtain follow-up data. Of the studied patients, 56% were in need of corticosteroid therapy, 38% of immunosuppressants and 16% of anti-TNFs. After a mean follow-up of $13 \pm 2$ years, it was met structural damage in 25 patients (25%), protocolectomy in 5%, ''lead pipe'' in 15%, 16% pseudopolyp stenoses and 3% fibrous bridges. It was reference to anorectal disorders in 49% (mostly self-limited and previous episodes of incontinence) but including persistent incontinence in 10%. There was an increased incidence of structural damage and anorectal dysfunction in patients who needed corticosteroid therapy ($p = 0.001$), immunosuppressants ($p < 0.001$) and anti-TNF ($P = 0.002$) and a correlation between structural damage and anorectal dysfunction ($p < 0.05$). There is no correlation between age and anorectal dysfunction, including incontinence episodes.
**Conclusion:** CU is a disease with structural and functional consequences in a significant subset of patients. This should be incorporated in the definition of the therapeutic strategy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0880 SAFETY PROFILE OF ANTI-TNF ALPHA THERAPY IN THE ELDERLY – A COMPARATIVE STUDY

**C. Bernardes**, P. Russo, D. Carvalho, J. Saiote, J. Ramos
*Dr., Hospital De Sto António Dos Capuchos, Lisbon, Portugal, Lisbon/Portugal*

**Contact E-mail Address:** carlosfbernardes@gmail.com
**Introduction:** TNF alpha is a key cytokine in immune regulation and defense against infections and malignancies. The ageing process has been associated with immune system functional changes, which could increase susceptibility to adverse events (AE). Advanced age has been suggested as a risk factor for infectious complications among patients with Inflammatory Bowel Disease (IBD) treated with anti-TNF alpha agents; however, safety data regarding biological therapy in elderly patients with IBD is still limited.
**Aims & Methods:** The aim of this study was to evaluate the AE of elderly patients with IBD treated with an anti-TNF alpha agent. A retrospective analysis was conducted in all IBD patients $\geq$ 60 years old treated with Infliximab (Group A) between 2006 and 2014. A control group of patients with <30 years old (Group B) was randomly selected. The probability of a causal association between each AE and the drug was determined by using an imputability score based in chronologic and clinical criteria and then classified as ''not related'', ''doubtful'', ''possible'', ''likely'' or ''definite''.
**Results:** Twenty patients were included in each group. The mean age at the beginning of Infliximab therapy was of 63 and 21 years and the mean treatment time with the drug was of $39 \pm 29$ months (total of 482 infusions) and of $41 \pm 26$ months (total of 504 infusions) in group A and B, respectively. Patients in group A had more comorbidities, the most prevalent being hypertension (45%), dyslipidemia (20%) and diabetes (15%). An annual rate of 1.1 AE/patient (group A) and 1,0 AE/patient (group B) was recorded. In both groups, 10 patients had at least one infection and 4 patients had at least one infusion reaction. Serum sickness-like disease occurred in 6 patients of group A and in 1 patient of group B. Thirteen severe AE had an association that was at least possible with the drug: 8 in group A and 5 in group B. Mortality was null and only 1 event resulted in permanent disability and/or progressive disease.
**Conclusion:** In this series, the annual rate of AE related to anti-TNF alpha therapy was low in both groups. With the exception of serum sickness-like disease, which was more frequent among elderly patients, the range of events was similar. Although severe AE related to the drug were rare, their occurrence was higher in individuals with $\geq$ 60 years old.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Iron deficiency (ID) and iron deficiency anaemia are common complications in IBD patients with significant detrimental effects on Quality of Life. Anaemia in IBD is attributable to chronic blood loss and/or impairment of iron intake and absorption. International guidelines favour the use of intravenous (IV) iron supplementation in IBD patients, since oral supplements are frequently poorly tolerated and have been shown to exacerbate inflammation. Ferric carboxymaltose (FCM) is a recently-developed IV iron preparation that has been shown in clinical trials to be safe and effective. Ferinject® (FCM, 50 mg ferric iron(III)/ml suspension) allows application of single doses up to 1,000 mg per week, infused over 15 minutes.
**Aims & Methods:** For post-marketing surveillance (PMS), a prospective non-interventional study (NIS) was performed from Nov 2008 to Aug 2010, aiming to assess the efficacy of ferinject® in clinical practice in a large cohort of IBD patients. In addition, the study investigated the tolerability of ferinject® under routine conditions and the influence of rapid, high-dosed application on time and effort of physicians and patients. Primary endpoints were normalisation of Hb or increase of 2 g/dL, and normalisation of serum ferritin and transferrin

saturation (TSAT). AEs, clinical symptoms and disease activity indices (CD:CDAI/UC:CAI) were also analysed. 223 Subjects were enrolled at 101 centres based on indication and therapy requirements according to the German Physician's Circular and Summary of Product Characteristics (age ≥18 y., ID based on chronic IBD, therapeutic necessity for iron substitution). All patients were ferinject®-naïve.
**Results:** Of 223 subjects (127 CD; 97 UC) treated, 193 patients who received at least one dose of FCM were included in the safety analysis, and 150 in the efficacy evaluation (Wk 12–14 or study termination). Mean total iron dose was 1,139 mg (range: 100 mg-4,800 mg). 76.7% of doses were between 500 mg and 2,000 mg. No adverse drug reactions, SAEs or deaths were observed. Mean Hb increased from 10.0 to 12.3 g/dL. Normal Hb or improvement ≥2 g/dL was achieved by 63.3% of patients. Ferritin increased from 52$\mu$g/L to 103$\mu$g/L, TSAT from 15% to 25%, and mean serum iron from 6.1 to 12.4$\mu$mol/L. The differences in Hb, ferritin, TSAT and serum iron are statistically significant ($p = 0.0001$). Median single dose was 500 mg FCM, median infusion frequency was 2, median duration was 15 min, median dilution was 250 mL. Clinical scores showed that QoL improved due to massive reduction of symptoms of anaemia.
**Conclusion:** Ferinject®-therapy has proven to be effective and safe in a large cohort of patients with IBD-associated anaemia in routine daily practice, and provides a sufficient refill of iron stores. These results are similar to those obtained from controlled clinical trials. Rapid, high-dose application offers increased convenience for physicians and reduces patients' time lost from work.

## P0883 BIOLOGICAL THERAPY FOR IBD IN THE ELDERLY: SENSE, SCIENCE OR SENSIBILITY?

**B. H. Miller**[1], B. Crooks[1], J. Scott[1], U. Nosegbe[1], J. K. Limdi[2]
[1]*Gastroenterology, Pennine Acute Hospitals NHS Trust, Manchester/United Kingdom*
[2]*Gastroenterology, The Pennine Acute Hospitals NHS Trust, Bury, Greater Manchester/United Kingdom*

**Contact E-mail Address:** bmiller@doctors.org.uk
**Introduction:** The role of biological therapies in the decisive induction and maintenance of remission of moderate-severe inflammatory bowel disease (IBD) is established through pivotal trials. There is a lack of data on their use in older patients.
**Aims & Methods:** Our aim was to review the use of biological therapy in older IBD patients at our institution, including patient demographics and adverse events. We conducted a retrospective study of patients aged 60 and above with IBD treated with a biological agent atour institution. Data was collected using electronic case records and included demographics, disease characteristics (Montreal classification), treatment and adverse events.
**Results:** Of 47 patients who were treated with a biologic, 24 were male. The median age at diagnosis of IBD was 60 (range 26–84) and the median age at most recent follow up was 70 (range 60–86). Twenty six patients had Crohn's disease (CD), 19 had Ulcerative Colitis (UC) and 2 IBD Unclassified (IBDU). Disease classification was as follows: CD-L1(7), L2 (9) and L3 (10). 20 patients had B2 disease. For UC-E1 (2), E2 (9) and E3 (8). At most recent review 42 patients were still receiving a biological agent, 16 were on Adalimumab, 25 on Infliximab and 1on Vedolizumab. Of the 5 patients no longer on a biologic all had received Infliximab. The mean duration betweendiagnosis of IBD and commencement of biological agent was 98 months (range 0–480) at a median age of 66 (range 53–84). At most recent follow up 18 patients were on a concomitant immunomodulator; 16 were on Azathioprine and 2 on Methotrexate. Of 16 patients on Adalimumab, 14 had prior Infliximab and were switched due to adverse drug reactions (Leucopenia (1), Infusion reaction (3), Other (4)), patient convenience (4) or inadequate response (2). One patient had Vedolizumab following reactivation of pulmonary TB on Infliximab. Another patient treated with Infliximab died from Cryptococcalmeningitis. Sixteen patients had prior IBD related surgery; 5 had surgery after starting a biologic. On most recent follow up 16 patients had active symptoms and 20 patients had evidence of endoscopic remission or improvement with another 9 still demonstrating moderate or severe disease.
**Conclusion:** Data on Anti-TNF therapy in older patients with IBD are conflicting and may reflect disparate practice evenwith comparable disease severity. There is an urgent need for real world data and consensus guidelines enablingclinicians to make personalised decisions (as evidence based as possible) in the holistic, considered and optimalmanagement of older patients with IBD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0884 COMPARISON OF THE EFFECTIVENESS AND COMPLICATIONS OF INFLIXIMAB AND ADALIMUMAB IN COMBO THERAPY WITH IMMUNOMODULATORS FOR CROHN'S DISEASE

**A. Budzynska**[1], M. Gawron-Kiszka[2], E. Nowakowska-Dulawa[1], M. Hartleb[1]

**Contact E-mail Address:** budzynskaagnieszka@poczta.onet.pl
**Introduction:** TNF$\alpha$ antagonists are currently the most effective therapy for induction and maintenance of remission in Crohn's disease (CD). However, their beneficial effect is not uniform and both the relapses and adverse events may lead to early termination of therapy. There are still doubts what treatment strategy is the most effective.
**Aim:** Comparison of the effectiveness and complication rate of one-year therapy with infliximab (IFX) and adalimumab (ADA) combined with immunomodulators.
**Materials and Methods**: The prospective one-center study included 55 patients (24 females) enrolled in 2014–2015 into Polish National Programme of biologic therapy for CD who failed to respond to conventional therapy (44.8%), showed drug-related side effects (24.1%) or presented perianal fistulas (31%). Nearly all patients received corticosteroids before considering biologics and all patients were treated with immunomodulators (azathioprine or 6-mercaptopurine). Forty-one patients (75%) received IFX and 14 (35%) received ADA. The effect of treatment was assessed with clinical, laboratory, and endoscopic response.
**Results:** There were no differences between IFX and ADA in subjective response to treatment: improvement was reported respectively in 70.8% and 50% of patients, no change in 12.5% and 33.3% of patients and exacerbation was experienced by 16.7% and 16.7% of patients ($p = 0.3$). The Crohn's Disease Activity Index significantly decreased in both groups after one-year therapy (from 342 to 165 in IFX, $p = 0.02$ and from 427 to 73 in ADA group, $p = 0.04$. CRP levels decreased in IFX treated patients (from 22.5 to 9.7 mg/dl; $p = 0.02$); but not in ADA group (from 17.1 to 11.5 mg/dl; $p = 0.3$). Hemoglobin concentration increased after termination of therapy only in IFX group (from 12.6 to 13.7 g/dl, $p = 0.001$) as well. Improvement in endoscopic lesions were detected in similar percentage of patients (56% in IFX and 83% in ADA group, $p = 0.2$). Mucosal healing was achieved in comparable number of patients (25% in IFX and 33% in ADA group, $p = 0.7$). Similar number of patients terminated therapy before scheduled time (22% in IFX and 29% in ADA groups, $p = 0.6$). There were no significant differences between IFX and ADA groups in adverse events: viral infection occurred in 8.3% and 7.7%, bacterial infection in 12.5% and 16.7%, fungal infection in 4.2 and 0%, tuberculosis in 4.2% and 0%, anemia in 25% and 23.1%, leucopenia in 8.3% and 15.4%, liver dysfunction in 4.2% and 7.7%, and fever in 16.7% and 30.8% of patients. Four patients in IFX group and one in ADA group required surgery during biologic therapy ($p = 0.4$).
**Conclusion:** These data demonstrate similar effectiveness and safety of combo one-year therapy with IFX and ADA. Efficacy of both regimens was proved by reduced disease activity, decreased inflammatory biomarkers and improved blood count. Deep remission was achieved in 1/4 of infliximab and 1/3 of adalimumab treated patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Inflammatory bowel disease (IBD) presents in childhood/adolescence in up to 25% of patients. Guidelines recommend structured paediatric to adult transition when moving patients to adult IBD services; however, there is little published objective data on the benefits of such a structured transition programme.
**Aims & Methods:** The primary aim of TRANSIT was to compare the impact of structured transition vs. no transition on measurable, objective indicators of disease control. A retrospective case note review and cross-sectional patient survey of outcomes following the first visit involving the adult IBD services (the index visit) was conducted in 11 UK centres. Eligible patients with a confirmed diagnosis of IBD before age 16 years who were subsequently under the care of adult services for 12–36 months were recruited. 'Transition patients' had attended ≥2 structured transition service visits and 'non-transition patients' had not attended any transition visits. Predefined outcome measures included IBD disease flares (defined as any Crohn's disease [CD] or ulcerative colitis [UC]-related hospitalisations, or increase in CD/UC therapy), steroid treatment and hospital visits/admissions. Data were collected for the 12-month period before

(pre-index) and after (post-index) the index visit. Patients completed 7 questionnaires at the point of recruitment.
**Results:** The study recruited 95 transition patients (median age 19.6 [interquartile range (IQR): 18.7–21.0] years; 47% female; 78% CD; median of 2.0 (IQR: 2.0–3.0) transition visits; median 2.1 [IQR: 1.4–3.2] years since index visit) and 34 non-transition patients (median age 19.3 [IQR: 18.2–21.3] years; 41% female; 74% CD; median 2.3 [IQR: 1.5–4.5] years since index visit). Most patients were in remission in the pre-index period, with 24 transition patients (25%) and 13 non-transition patients (38%) having ≥1 flare; post-index, 27 transition patients (28%) and 16 non-transition patients (47%) had ≥1 flare ($p > 0.05$). The mean number of flares/patient were similar in transition (0.4 [standard deviation (SD): 0.9]) and non-transition patients (0.4 [SD: 0.8]) pre-index, but significantly different post-index (non-transition: 1.0 [SD: 1.4] vs. transition: 0.6 [SD: 0.9]; $p < 0.05$). Mean flares/patient post-index were significantly different in females (transition: 0.4 [SD: 0.8]; non-transition: 1.2 [SD: 1.5]; $p < 0.05$) but not males (transition: 0.5 [SD: 0.9]; non-transition: 0.9 [SD: 1.4]; $p > 0.05$). Post-index, 67/95 transition patients (70.5%) remained steroid-free compared with 14/34 non-transition patients (41.2%; $p < 0.05$). Hospital visits/admissions pre-index were similar in transition and non-transition patients. However, significantly more non-transition patients had A&E visits leading to admission compared with transition patients post-index (see table). There were significantly fewer non-transition patients with post-index outpatient visits compared to transition patients. Patient-reported measures were similar in transition and non-transition patients.
**Conclusion:** These data suggest that adolescent patients undergoing structured transition to adult IBD services have a reduction in IBD flares, are more likely to remain in steroid-free remission and are less likely to have an emergency admission during the first 12-months post-index compared with patients not receiving structured transition care. This dataset is supportive of the current guidelines recommending transition as an integral part of adolescent IBD care.

**Introduction:** The use of accelerated step-up or anti-TNF before first remission and after or in combination with immunomodulators (IM) remains controversial in paediatric Crohn's disease (CD).
**Aims & Methods:** Five-year follow-up data from BELCRO (Belgian observational prospective cohort of paediatric CD) were analysed. Disease severity was scored as inactive, mild or moderate-to-severe on a 3-point scale based on PCDAI and/or PGA scores at diagnosis and monitored yearly. Univariate analyses were performed between patients treated with anti-TNF before or after first remission and correlations were assessed between treatment variables and the outcomes average disease severity and sustained remission, defined as inactive disease for ≥ 2 yrs follow-up.
**Results:** Of 66 anti-TNF exposed patients (median (IQR) age 13.1 (11.5 – 15.2) yrs, 50% male), 47% had accelerated step-up and 5% never reached remission. Accelerated step-up was associated with older age (13.3 (12.1 – 15.9) vs. 12.5 (10.2 – 14.1) yrs; $p = .02$), higher average disease severity (1.8 (1.6 – 1.9) vs. 1.6 (1.3 – 1.8); $p < .01$) but similar disease location and severity at diagnosis compared to anti-TNF after first remission. Delay to steroids and IM and duration of steroids was similar in both groups, but delay to anti-TNF or combination therapy and duration of IM was shorter with anti-TNF before first remission, resulting in longer duration of anti-TNF but similar duration of combination therapy. Time to first remission was longer in the accelerated step-up group but delay to and duration of sustained remission was similar in both groups.

Univariate analyses of treatment and outcome variables between patients treated with anti-TNF before or after first remission (no correction for multiple testing).

| Treatment or outcome variable, median (IQR) in yrs | Anti-TNF before first remission (n = 31) | Anti-TNF after first remission (n = 32) | P value |
|---|---|---|---|
| Delay to first steroids | 0 (0 – 0.05) | 0 (0 – 0.01) | .60 |
| Duration of steroids | 0.4 (0.3 – 0.6) | 0.4 (0.3 – 1.0) | .96 |
| Delay to first immunomodulator | 0.08 (0.01 – 0.16) | 0.09 (0.01 – 0.46) | .55 |
| Duration of immunomodulator | 2.0 (1.2 – 2.7) | 3.9 (2.0 – 4.8) | **.02** |
| Delay to first biological | 0.6 (0.4 – 0.9) | 2.1 (1.4 – 3.3) | < **.0001** |
| Duration of biological | 4.6 (4.0 – 4.9) | 2.7 (1.6 – 3.6) | < **.0001** |
| Delay to combination | 0.6 (0.2 – 1.0) | 2.4 (1.5 – 3.5) | < **.0001** |
| Duration of combination | 1.0 (0.5 – 2.0) | 1.3 (0.6 – 2.1) | .57 |
| Time to first remission | 1.5 (1.1 – 3.0) | 0.5 (0.3 – 0.8) | < **.0001** |
| Time to sustained remission | 3.1 (2.6 – 4.0) | 2.7 (2.0 – 3.6) | .14 |
| Duration of sustained remission | 2.1 (1.4 – 4.0) | 2.7 (1.3 – 4.6) | .45 |

Rates of surgery and hospitalisations for CD were similar and at 5 yrs, inactive disease (68% vs. 69%, $p = .93$) was similar and IM use (24% vs. 59%; $p < .01$) lower in the group treated with anti-TNF before first remission. Accelerated step-up correlated with average disease severity (AUC = .70; $p < .01$) but not sustained remission (no correction for multiple testing). No other correlations were found between treatment and outcomes.
**Conclusion:** Accelerated step-up was prescribed for more severe disease and in older children not remitting on IM. IM exposure was limited compared to anti-TNF upon relapse despite IM. Only patient age was associated with initial response to IM. Sustained remission was similar for all children needing anti-TNF.

## P0887 THE ASSOCIATION BETWEEN PEDIATRIC-ONSET INFLAMMATORY BOWEL DISEASE AND BONE MINERAL DENSITY IN ADULTHOOD

**A. Guz Mark**[1], F. Rinawi[2], R. Shamir[1], A. Assa[2]
[1]*Institute Of Gastroenterology, Nutrition And Liver Diseases, Schneider Children's Medical Center, Petach Tikva/Israel*
[2]*Institute Of Gastroenterology, Nutrition And Liver Diseases, Schnider Children's Medical Center, Petach Tikva/Israel*

**Contact E-mail Address:** anatguz@gmail.com

**Introduction:** Inflammatory bowel disease (IBD) is known to pose a risk for low bone mineral density (BMD) in both children and adults.

**Aims & Methods:** We aimed to evaluate the impact of pediatric-onset IBD on BMD in adulthood. Records of patients diagnosed with pediatric IBD were retrospectively reviewed. Patients who had documentation of dual energy X-ray absorptiometry (DXA) scans after the age of peak bone mass accrual (females-18 years, males- 20 years) were included. BMD was expressed as z-score and defined as the lower between lumbar and femoral-neck BMD for each patient.

**Results:** 61 patients with pediatric-onset IBD were included. Median age at diagnosis was 15.3 years (IQR 14–16.5). Median age at first DXA scan in adulthood was 21.9 years (IQR 20.2–27.3). Mean BMD z-score was −1.12 (±1.04). Overall, 44.3% (n = 27) had osteopenia (BMD z-score ≤ -1), and 8.2% (n = 5) had osteoporosis (BMD z-score ≤ -2.5). This deviation from normal distribution of BMD was statistically significant ($p < 0.001$). Bone status showed no correlation with age, disease severity, height z-score and vitamin D status at diagnosis, type of IBD or duration of disease. Significant correlation ($r = 0.306$, $p = 0.05$), was identified between low weight z-score at diagnosis and abnormal bone status in adulthood. Thirty six patients had at least 2 DXA scans during follow-up. During a median interval of 3.6 years there was no significant change in BMD between first and last measurement.

**Conclusion:** Osteopenia and osteoporosis are frequent in adult IBD patients with pediatric-onset disease. BMD does not significantly change over time in these patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0888 REMISSION INDUCTION IN CORTICOSTEROID-NAÏVE CHILDREN AND ADOLESCENTS WITH ACTIVE ULCERATIVE COLITIS BY ADSORPTIVE LEUCOCYTAPHERESIS AS MONOTHERAPY OR IN COMBINATION WITH LOW-DOSE PREDNISOLONE AFTER FAILURE OF FIRST-LINE MEDICATIONS

**T. Tanaka**, M. Akagi, H. Goishi, T. Iiboshi, T. Kajihara, T. Miura
*Dept. Of Gastroenterology, Akitsu Prefectural Hospital, Hiroshima/Japan*

**Contact E-mail Address:** tomotaka@c.do-up.com

**Introduction:** In patients with active ulcerative colitis (UC), myeloid lineage leucocytes are known to show activation behaviour and increased survival time, including the CD14+CD16+ monocyte phenotype, which releases tumour necrosis factor-$\alpha$. Therefore, selective depletion of myeloid leucocytes by adsorptive granulocyte/monocyte apheresis (GMA) with an Adacolumn should promote remission, or enhance drug efficacy. Potentially, GMA should be a relevant option in paediatrics and adolescents in whom drug therapy has limitations.

**Aims & Methods:** This study was to evaluate the efficacy of GMA in children and adolescents with active UC in whom conventional first-line medications had failed. Between 2010 and 2015, a total of 30 consecutive patients, age 11–19 years, body weight 33–55.5 kg were given mesalazine (n = 23) or sulphasalazine (n = 7) as a first-line medication. Twenty patients relapsed or did not respond and received GMA with the Adacolumn, 2 sessions in the first week, then weekly, up to 11 sessions. Patients who achieved a decrease of ≥5 in the clinical activity index (CAI) continued with GMA while non-responders received GMA in combination with prednisolone (PSL). At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her or his own control.

**Results:** At entry, all 30 patients were corticosteroid naïve and none had deep UC lesions together with extensive loss of the mucosal tissue at the affected sites. Ten patients achieved stable remission with the first-line medications and did not receive GMA. Six patients did not respond well to the first 5 GMA sessions and received PSL (0.5 to 1.0 mg/kg bodyweight) together with GMA, while 12 patients responded well to GMA with stable remission and 2 withdrew from GMA to receive high dose PSL (up to 2 mg/kg bodyweight). At entry, the average CAI was 14.2 ± 0.4 (n = 28), range 11–17, and the average endoscopic index was 9.2 ± 0.4, range 7–11. The corresponding values at week 12 were 2.1 ± 0.2, range 1–4 ($P < 0.001$) and 2.4 ± 0.2, range 1–4 ($P < 0.001$). PSL was tapered to 0 mg within 3 months. Therefore, at week 12, all 30 patients were in clinical remission, majority with mucosal healing (complete remission).

**Conclusion:** In the past, GMA in patients with deep ulcers and extensive loss of the mucosal tissue (a major GMA non-responder feature) has not been associated with significant efficacy. In this study, GMA in young corticosteroid naïve patients with active UC refractory to the first-line medications was associated with clinical remission and mucosal healing, while in non-responders to GMA monotherapy, addition of a low dose PSL enhanced the efficacy of GMA and tapering of the PSL dose was not associated with UC relapse. Therefore, the majority of young steroid-naïve UC patients who fail to respond to first-line medications should respond well to GMA and be spared from pharmacologicals. Additionally, GMA has a good safety profile, which is a favourable feature in clinical practice setting.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0889 PREDICTING DISEASE COURSE OF PEDIATRIC CROHN'S DISEASE: ROLE OF CLINICAL, ENDOSCOPIC AND IMAGING FINDINGS AT THE DIAGNOSIS

**M. Aloi**[1], F. Civitelli[1], S. Oliva[1], E. Casciani[2], G. D'Arcangelo[1], A. Spatoliatore[1], F. Viola[1], S. Cucchiara[1]

[2]*Radiology, Sapienza University of Rome, Rome/Italy*

**Contact E-mail Address:** marina.aloi@uniroma1.it

**Introduction:** Identifying the factors related to a more severe disease course in pediatric Crohn's disease (CD) may lead to an optimal and individualized use of therapeutic options and possibly to a change in the natural history of the disease.

**Aims & Methods:** Aims of this study were to evaluate the predictive value of clinical, laboratory, endoscopic and imaging factors at the diagnosis for the risk of surgery and complicated disease course in children with CD. In this single-centre, prospective, longitudinal study, children newly-diagnosed with CD were enrolled and followed for 3 years. At baseline all patients underwent a clinical evaluation (Pediatric Crohn Disease Activity Index, PCDAI), laboratory exams (including C-Reactive Protein [CRP] and Erythrocyte Sedimentation Rate [ESR]), Magnetic Resonance Imaging (MRI) and ileocolonoscopy. Disease location and behavior were defined by Paris classification[1]. Simple endoscopic score for Crohn's disease (SES-CD)[2] was used to evaluate the severity of endoscopic lesions. Rate of surgery at maximum follow up was the primary outcome evaluated.

**Results:** Fifty patients (64% males, median age 12.7 ± 2.9 years) were enrolled. Mean SES-CD at the diagnosis was 15.3 ± 10.6. A SES-CD graded as severe (> 15) was present in 20/50 (40%) patients. MRI showed ulcers in 7/50 (14%) patients, stenosis in 20/50 (40%), pre-stenotic bowel dilation in 14/50 (28%), abscesses in 3/50 (6%) and fistulas in 7/50 (14%). The presence of stenosis at ileocolonoscopy ($p = 0.009$) and fistulae at MRI ($p = 0.05$) correlated with the need of resection surgery at follow-up. At a multivariate analysis, penetrating disease [r 0.65(0.40 to 0.81);$p < 0.0001$], perianal involvement [0.41 (0.15 to 0.62);$p = 0.002$], stenosis at ileocolonoscopy [r 0.30 (0.03 to 0.53);$p = 0.02$] and fistulas at MRI [r 0.41 (0.15 to 0.62);$p = 0.002$] at the diagnosis increased the surgical risk at follow-up, while inflammatory behavior (B1 according to Paris classification) (r −0.4 (−0.6 to −0.1); $p = 0.006$) and ESR > 25 mm/h (r −0.3 (−0.5 to −0.03); $p = 0.03$) were negatively associated.

**Conclusion:** Penetrating behavior at the diagnosis and perianal disease along with the presence of stenosis at ileocolonoscopy and fistulas at MRI are independent predictive factors of the surgical risk in children with CD. An inflammatory behavior and high ESR seem to correlate with a milder disease course

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0890 THE CLINICAL BURDEN OF TRANSITION IN INFLAMMATORY BOWEL DISEASE

**K. Siau**, A. Klonis, H. Steed
*Department Of Gastroenterology, New Cross Hospital, Wolverhampton, Wolverhampton/United Kingdom*

**Contact E-mail Address:** keith@siau.org

**Introduction:** Transition in inflammatory bowel disease (IBD) is a planned movement of adolescents from paediatric to adult services. Most work focuses on engagement of the patients, encouragement of effective communication and awareness of the surrounding psychosocial factors and patient experience of transition. The data on clinical outcomes is sparse, although clearly important in a high-risk population who already have one poor prognostic risk factor: age.
**Aims & Methods:** We aimed to assess the clinical changes taking place during the 12months after transition. Adolescent patients diagnosed in pediatrics and transitioned to New Cross Hospital adult IBD service, UK between 2009–2015 were identified and notes retrospectively reviewed for a 12 month follow up period.
**Results:** 28 patients were included for analysis, with a median age of 16.8 at time of first adult clinic. The average transition interval was 143 days. 12 had ulcerative colitis (UC), of whom 8 had pancolonic disease. 8 of 16 patients with Crohn's Disease (CD) had perianal disease and 2 had surgery pre-transition. Eight of the 28 suffered extraintestinal manifestations of IBD. Twenty-five of 28 had been treated with steroids and 21 with a second-line immunomodulator. 11 CD patients had been exposed to one or more biologic. At the time of transition 11 were reported and handed over with active disease. 4 patients were assessed in a joint clinic. This group then had a total of 165 outpatient appointments between them in 12 months, 14 patients having between 1–4 each and 14 having between 5–10 each. The number of did not attend (DNA) appointments were 64 (39%). Within 12 months of adult transition 14 had MRI scans, 17 had endoscopy procedures. 14 CD and 8 UC patients required pharmacological escalation of IBD therapy (Table 1). 6 required surgery and 5 had medical hospital admissions. After 12 months of adult transition 22 patients were deemed to be in clinical remission.

12 Month Post Transition Outcomes

| | UC | CD | Overall | p-value |
|---|---|---|---|---|
| **n** | 12 (43%) | 16 (57%) | 28 | |
| **Clinics within 12 months** | 4 | 5.2 | 4.7 | 0.14 |
| **Steroids** | 4 (33%) | 7 (44%) | 11 (39%) | 0.57 |
| **Surgery** | 0 | 6 (38%) | 6 (21%) | 0.02 |
| **Admissions** | 1 (8%) | 3 (19%) | 4 (14%) | 0.61 |
| **Medical Escalation of IBD therapy** | 8 (67%) | 14 (88%) | 22 (79%) | 0.13 |
| **Immunomodulator dose escalation** | 3/9 (33%) | 4/15 (27%) | 7/24 (29%) | 0.10 |
| **Immunomodulator introduction** | 2 (17%) | 2 (13%) | 4 (14%) | 1.00 |
| **Biologic dose escalation** | 0 | 3/9 (33%) | 3/9 (33%) | 0.51 |
| **Biologic introduction** | 1 (8%) | 3 (19%) | 4 (14%) | 0.61 |
| **Active IBD (at last paediatric clinic)** | 3 (25%) | 8 (50%) | 11 (39%) | 0.25 |
| **Active IBD (12 months after first adult clinic)** | 1 (8%) | 5 (31%) | 6 (21%) | 0.19 |
| **Clinic DNA within 12 months** | 5 (42%) | 6 (38%) | 11 (39%) | 1.00 |

**Conclusion:** Adolescents have a high burden of disease and despite being handed over in an apparent state of remission, rates of requirement for pharmacological escalation and surgical intervention remain high. Engagement remains an issue. A more formalised process of clinical transition is required between pediatric and adult units to maximise clinical disease management and stability while moving them to an environment where engagement, developmental maturity, abstract reasoning, helicopter parenting etc are all complex factors in this small but heavily burdened group.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0891 PEDIATRIC CROHN'S DISEASE AND ITS DISABILITY OVER TIME: A STUDY PERFORMED WITH A NEW PEDIATRIC LÉMANN INDEX. PRELIMINARY DATA FROM A TERTIARY PEDIATRIC IBD CENTER

**Introduction:** Crohn's disease (CD) is a chronic and progressive condition that, due to disease complication, leads to surgical resection in the majority of cases. Recently, a panel of expert developed the Lémann Index (LI), a new tool aimed to assess the progressive bowel damage due to disease course. The aim of LI is to assess structural bowel damage due to CD based on stricturing lesions, penetrating lesions and surgical resection. However, in the pediatric population we should also take into account also peculiar characteristics, such as intestinal length and the pattern of growth of the patient.
**Aims & Methods:** The aim of our study was to measure the LI in a pediatric cohort at diagnosis as well as the trend of LI during time. We chose segments of 10 cm for small bowel, instead of 20 cm as proposed in adults. Moreover, we decided to adjust the final score considering growth failure, using different values based on weight and height at diagnosis and at the last evaluation. We called this new score pediatric LI (P-LI).
We retrospectively selected 47 consecutive pediatric patients who were firstly diagnosed at our hospital by abdominal Magnetic Resonance Imaging, colonoscopy and upper GI endoscopy, and in case of perianal disease, a pelvic magnetic resonance immaging. Patients were aged between 6 to 17 years. We evaluated the P-LI at diagnosis and calculated the difference between P-LI at diagnosis and at the last pediatric outpatient visit or at transition to adult outpatient.
**Results:** We included a total of 47 CD pediatric patients (23 male, median age 18 years, range 11–27, median age at diagnosis 12 years, range 7–17) who were followed-up for a median of 41 months (range 4–120). Among them, 30 (63.8%%) patients had a stable P-LI during the follow up, whereas 17 (36.2%) had an increase in P-LI during time. Considering the overall population there was no statistical significant difference between median P-LI at beginning and at the end of follow-up (4.6, range 0.6–15 vs 3, range 0.3–31.7. $P = 0.064$). Subdividing patients who underwent surgical resection ($n = 12$, 25.5%) and those who did not ($n = 35$, 74.5%) we found a significant difference between median P-LI at the beginning and at the end of follow up in both groups (4.4, range 1–12.8 vs 15.3, range 8.3–31.7, $P = 0.0002$; 4.6, range 0.6–15 vs 1.6, range 0–18.5, $P = 0.001$) with a disease regression in the no surgery group. Moreover, analyzing data from patients who utilized anti-TNF therapies ($n = 22$, 46.8%), we found no significant difference between LI at the beginning and at the end of follow-up (5, range 1–15 vs 4.2, range 0.6–12.8, $P = 0.3$).
**Conclusion:** Our data suggest that the P-LI we devisd is a useful tool to evaluate CD in the pediatric population and to assess disease progression. In children avoid a surgical resection is extremely important because medical therapy is able to reverse the disease progression

**Contact E-mail Address:** francoscaldaferri@gmail.com

**Introduction:** Transition clinic programs for inflammatory bowel disease (IBD) is an emerging challenge nowadays, however few models have been proposed for a better management of transition-IBD and few information exists on determining factors for successful experiences.
**Aims & Methods:** Aim of our study was to evaluate efficacy of the adopted transition model. Secondary end points were to evaluate predictive factors of success/failure and to evaluate retrospectively the transition program. Proposed model is based on three meetings every four-six weeks: the first in pediatric centre (Bambino Gesù Children's Hospital); the second in the adult centre (Agostino Gemelli General Hospital), with pediatric gastroenterologists; the last in the adult centre with only adult gastroenterologists. During the first visit, the pediatric gastroenterologist proposes the transition; the second time pediatric gastroenterologist presents patient to adult gastroenterologist; in the third meeting, adult gastroenterologist proposes the own follow up program. Questionnaires (General, GQ, transition clinic, TCQ, IBD yourself, self efficacy, VAS based) were used. About nine months after the transition, we made a telephone follow-up and contacted patients who have visited at least once the transition clinic at the Agostino Gemelli General Hospital. Inclusion criteria were: patients with ulcerative colitis (UC) or Crohn's disease (CD) with low disease activity or remission. Transition was considered successful if three steps were reached form patients.
**Results:** Twenty patients were enrolled; age 18–25 years (mean age 20.2, M/F 12/8; UC/CD 10/10); eleven/20 (55%, 8 M/3 F) immediately accepted the second check at adult gastroenterology centre; 5 patients refused transition and 4 patients delayed the transition. Three patients (F)/11 refused follow up in the proposed centre. In eight patients (40%, 8 M) this model was successful. Based on questionnaires, patients elegible referred to be independent and ready to be transferred. They reached high scores in the self-efficacy scale. They appeared to have a good level of knowledge on IBD but low scores about treatments. Young patients who interrupted the transition program felt more independent at VAS-based questionnaire, they totalized higher scores in the self-efficacy scale and referred lower levels of confidence in adult gastroenterologist. Patients who completed the transition program totalized higher scores in the resilience scale, had better scores of wellbeing perception and had lower anxiety scores. Patients who failed the transition program were mostly women. The perceived utility of the transition program was scored 7.3 on a VAS scale. 90% of contacted patients was glad to have had this experience and would repeat it or suggest it.
**Conclusion:** Proposed transition program seems to be feasible. Patients resistant or failing were more likely female, with high self-efficacy scores, lower confidence in adult gastroenterologist and worse wellbeing perception. Psychological

scores together with a systematic approach could help in selecting patient more difficult to candidate to the transition program.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0893 FREQUENCY, CHRONOLOGICAL ORDER OF APPEARANCE AND ANTI-TNF TREATMENT OF EXTRAINTESTINAL MANIFESTATIONS IN PEDIATRIC PATIENTS WITH INFLAMMATORY BOWEL DISEASE

**Introduction:** There is a paucity of data on the prevalence, type, chronological order of appearance, and treatment of extraintestinal manifestations (EIM) in pediatric patients with inflammatory bowel disease (IBD).
**Aims & Methods:** Since 2008, the Pediatric Swiss IBD Cohort Study has collected data on the pediatric IBD population from university centers (5), community hospitals (4), and private practices (2) across Switzerland. Data on 329 patients (173 with CD, 156 with UC/IC) were analyzed.
**Results:** A total of 55 patients (16.7%) suffered from at least one EIM (39 CD, 12 UC and 4 IC patients). Median IBD duration was 5.2 years (range 0.9–15.1). Of the 55 patients, 39 (70.9%), 12 (21.8%), three (5.5%) and one patient (1.8%) experienced one, two, three and four EIM, respectively. Prevalence of EIM was significantly lower than that observed in the adult IBD population (16.7% vs. 29.3%, $p < 0.001$). (1) EIM were more frequently observed in CD patients (39/173, 22.5%) when compared to UC/IC patients (16/156, 10.3%, $p = 0.003$). The most prevalent EIM were peripheral arthritis (47.3%) and aphthous stomatitis (43.6%) followed by uveitis (10.9%), erythema nodosum (EN, 9.1%) and axial spondylarthropathy (AS, 9.1%). While 28.9% of all EIM appeared before the diagnosis of IBD, the majority of EIM occurred once IBD diagnosis was established (53.9%). The remaining proportion of EIM appeared at the time of IBD diagnosis. Peripheral arthritis, uveitis, pyoderma gangrenosum (PG) and psoriasis were significantly more likely to occur after IBD diagnosis than before. The median time between IBD diagnosis and occurrence of EIM was 1 month (range −37.5 – 149.0). Thirty-one of the 55 patients with EIM (56.4%) were treated with one or more anti-TNF agents (a total of 41 anti-TNF treatments). IBD patients with EIM were more likely to be treated with anti-TNF compared to those without EIM (56.4% vs. 38.6%, $p = 0.013$). However, in only 3 cases, anti-TNF was started for management of EIM. Under anti-TNF treatment, 23 EIM appeared in 19 patients (61.3%) with most of them showing improvement or stable disease course with continuation of anti-TNF. Peripheral arthritis and uveitis showed good clinical response rates to anti-TNF (61.5% and 66.7%, respectively), while those of the other EIM were ≤50%.
**Conclusion:** In a cohort of pediatric IBD patients, EIM were frequently encountered; however, prevalence seems to be lower than that observed in the adult population. The majority of EIM occurred after diagnosis of IBD. EIM were more likely to be observed in CD patients when compared to UC patients. The most frequent EIM were peripheral arthritis and aphthous stomatitis. Anti-TNF were more likely to be started in patients with EIM when compared to those without EIM. Response rates to anti-TNF strongly depended on underlying EIM and were best for peripheral arthritis and uveitis. Development of EIM under anti-TNF treatment was frequent, although disease course was usually benign.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Crohn's disease (CD) is a chronic inflammatory disorder that affects the gastrointestinal tract, predominantly involving the small intestine and colon. Up to 66% of patients with Crohn's disease have small-bowel involvement at diagnosis. In approximately 90% of patients with small-bowel Crohn's disease, the disease involves the terminal ileum. Ileocolonoscopy is gold standard in diagnosis of ileocolonic disease but skip lesions and proximal involvement can be evaluated only be meaning of capsule endoscopy (VCE) and or MR enterography (MRE).
**Aims & Methods:** Our aim was to correlate findings obtained from MRE and VCE with Paediatric Crohn's disease Activity Index (PDCAI) at the time of disease presentation. At single-centre, tertiary care hospital centre we prospectively enrolled consecutive paediatric patients with newly diagnosed Crohn's diseases admitted to the Department of Pediatrics in Clinical Hospital Centre Rijeka from December 2010 to December 2015. All the patients had undergone upper and lower endoscopy in deep sedation. PCDAI was made at the time of admission. All patients after endoscopy investigation with suspected small bowel involvement underwent MRE and VCE. MRE and VCE findings were evaluated by using Crohn disease MRI index (CDMI) score and the Capsule Endoscopy Crohn's Disease Activity Index (CECDAI or Niv score) respectively. VCE was performed using PillCam SB 3 with Rapid software. MR enterography protocol was performed on 1.5 T MRI system with combined built in spine array coli and two wrapped around flexible surfce coils. We performed next sequences: HASTE (ST = 100 mm), true FISP: +FS/-FS, HASTE: +FS/-FS; ST = 6 mm, true FISP (axial), DWI, after contrast administration (Gadolinium), VIBE and true FISP, T1. Statistical analysis were performed using Spearman's coefficient of rank correlation.
**Results:** A total of 38 patients, 13 girls (34.2%), median age 14 (95%CI 13–15) were evaluated. During the VCE examination, cecum was reached in all patients. According to PCDAI, 11 patients (28.9%) had inactive disease, 17 (44.7%) had mild disease, while 5 (13.1%) had moderate and 5 (13.1%) severe disease. We found statistically significant correlation between PCDAI-CECDAI ($R = 0.595$; 95%CI 0.31–0.77; $P = 0.0003$) and PCDAI-CDMI ($R = 0.501$; 95%CI 0.18–0.72). In addition CECDAI and CDMI have significant correlation ($R = 0.480$; 95%CI 0.18–0.69; $P = 0.0026$).
**Conclusion:** PCDAI is clinically well-established parameter in evaluating disease severity, but with no adequate reliability in detecting mucosal inflammation. Mucosal inflammation can be be assessed with VCE and MRI, which both have statistically significant correlation with clinical activity index.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Administration of systemic lipopolysaccharide (LPS) induces rapid epithelial cell apoptosis at the small intestinal villus tip in wild-type mice. This response is increased in animals lacking the NF-κB1 subunit and decreased in mice lacking the NF-κB2 subunit[1]. Here we examine the transcriptomic events that underlie LPS induced small intestinal epithelial cell death, and the differences between these genotypes.
**Aims & Methods:** Groups of C57BL/6 (WT), *Nfkb1*$^{-/-}$ and *Nfkb2*$^{-/-}$mice were treated with 125 μg/kg LPS by intraperitoneal injection for 1.5 h, and euthanased by cervical dislocation. Total RNA was isolated from small intestinal mucosal scrapes. RNA sequencing was performed using the Illumina MiSeq platform. Principal component analysis was used to compare the effects of LPS on small intestinal transcriptomics. Differentially regulated genes were identified using DESeq2. $Log_2$ fold changes of +/- > 0.6, and adjusted $p < 0.01$ were considered significant. Pathway analysis was performed using the iPathwayguide platform.
**Results:** Principal components (PC) 1 to 4 showed clear distinction between genotypes. There was also a clear shift as a result of LPS treatment associated with PCs 2 and 3 for WT and *Nfkb1*$^{-/-}$ mice. An LPS associated shift for *Nfkb2*$^{-/-}$ mice was less apparent. Differential gene expression and pathway analysis provided a consistent narrative to PCA analyses. LPS administration resulted in 1253 differentially regulated genes in WT mice. Pathway analysis identified 63 pathways that were perturbed; most significant of which were cytokine-cytokine receptor interaction, MAPK signalling pathway, PI3K-Akt and NF-κB signalling. In *Nfkb1*$^{-/-}$mice, LPS administration caused differential expression of 185 genes and 33 pathways, 13 of which were also perturbed in LPS-treated WT mice. Intriguingly, despite similar pathological phenotypes, the pathways that were most significantly perturbed in WT mice by administration of LPS were not identified in similarly treated *Nfkb1*$^{-/-}$ mice. Administration of LPS to *Nfkb2*$^{-/-}$ mice had minimal impact on the small intestinal transcriptome; only 3 genes (Tnfaip3, Nfkbia and Phlda1) were differentially expressed between untreated

and LPS treated *Nfkb2*$^{-/-}$ mice. As *Nfkb1*$^{-/-}$mice are known to exhibit a spontaneous inflammatory phenotype, we compared the small intestinal transcriptome of untreated WT mice to that of untreated *Nfkb1*$^{-/-}$mice. *Nfkb1*$^{-/-}$ mice had 2361 differentially expressed genes and 70 perturbed pathways compared to WT mice. Of these, 29 pathways were also perturbed in WT mice administered LPS.
**Conclusion:** These data support the findings of morphological studies of LPS induced small intestinal apoptosis, they confirm a transcriptomic basis for resistance to LPS induced small intestinal pathology in *Nfkb2*$^{-/-}$ mice. Transcriptomic responses of *Nfkb1*$^{-/-}$ mice to LPS at first appear blunted compared to WT mice, however, a number of the pathways affected by LPS administration in WT mice are disrupted in untreated *Nfkb1*$^{-/-}$ mice. This reflects the spontaneous inflammatory state of *Nfkb1*$^{-/-}$ mice, which may influence the severity of LPS induced small intestinal pathology in these animals.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Reactive oxygen species have been implicated in the pathogenesis of many gastrointestinal (GI) diseases including inflammatory bowel disease (IBD), colitis and associated cancers and possibly linked to gut dysfunction in ageing. How different region of gut react to, and handle elevated levels of free radicals in young and aged is unclear.
**Aims & Methods:** The aim of this study was to examine the effect of oxidants on sensory nerve activity in the small and large intestine of young (3- months) and aged (22- months) mice. We hypothesised that there would be regional differences between small and large intestine in susceptible to oxidative stress. Experiments were conducted in-vitro from jejunum and colon of male C57BL/6 J mice. Epithelial cells were isolated from each segment; RNA was extracted and used to determine differential gene expression in jejunum and colon of young and aged mice by quantitative PCR, $n = 3$. We focused on some members of transient receptor potential (Trp) channels because of evidence for their role in sensing oxidative stress (Trpa1, Trpm2, Trpc5, Trpc6). Dihydroethidium (DHE) dye was used (oxidative marker) on fresh tissue sections from jejunum and colon to evaluate the levels of superoxide anion in aged and young group, $n = 6$. Sensory nerve recordings were performed on isolated jejunum and colon from young and aged mice, data are presented as mean±SEM spikes$^{-1}$ with $n = 6$. Statistical analysis was performed using Student's t-test and ANOVA (two way) as appropriate. $P < 0.05$ was considered as significant.
**Results:** Quantitative PCR analysis indicated deferential gene expressions of oxidative sensors Trpa1 and Trpm2 (4-fold and 2-fold change respectively) in aged colonic epithelial cells compared to young. Higher levels of superoxide anion were found in sections treated with DHE in colon of aged group compared to young (unpaired t-test, $p < 0.007$). Ramp distension of segments of intestine evoked a biphasic increase in afferent discharge, which represents the activation of low threshold (LT), wide dynamic range (WDR) and high threshold (HT) mechanosensitive afferent fibres. Baseline nerve firing remained unchanged in jejunum and colon between young and aged group. Nerve firing in response to distension was attenuated with age only in colon, especially in WDR and HT components between 30 and 60 mmHg, $P < 0.05$. To examine the regional difference in response to oxidative stress, the mitochondrial inhibitor Antimycin A (20 μM) was applied intraluminally to jejunum and colon of young and aged mice. Afferent hyperactivity in response to Antimycin A was observed only in colon of young and aged group. Nerve firing in response to distension was significantly increased by Antimycin A (20 μM), mainly the WDR & HT component ($P < 0.001$). Similarly, baseline nerve activity was enhanced, $P < 0.02$. Trpa1 antagonist HC030031 (30 μM) failed to block the Antimycin A- induced hyperactivity of colonic afferents in young and aged mice.
**Conclusion:** This study suggests that colon is more vulnerable to ageing and responds to oxidants less efficiently than the small intestine. The ability of small intestine to handle oxidants seems to be preserved during ageing. The regional difference between jejunum and colon could be due to chronic accumulation of ROS in the tissue.

**Contact E-mail Address:** moonone70@hanmail.net
**Introduction:** Radiotherapy for malignant abdominopelvic disease results in radiation-induced enterocolitis. However, there is no well-established preventive strategy. The aim is to evaluate the suppressive effect of rebamipide, sucralfate and rifaximin on ionizing radiation (IR)-induced acute inflammation and apoptosis in the intestine of mouse.
**Aims & Methods:** Thirty ICR mice were divided into (1) a vehicle-treated control group before sham IR, (2) a vehicle-treated group before IR, and (3–5) rebamipide, sucralfate or rifaximin-treated groups before IR. The intestine was resected at 4 hours after 4 Gy IR to the abdominopelvis. Pro-/anti-inflammatory and pro-/anti-apoptotic factors were investigated.
**Results:** NAMPT was down-regulated after IR, which was attenuated by rebamipide, sucralfate and rifaximin ($p < 0.05$). Activation of NF-$\kappa$B and phosphorylation of MAPKs were induced by IR, which were suppressed by rebamipide, sucralfate, and rifaximin ($p < 0.05$). TNF-$\alpha$, IL-1$\beta$, and IL-6 were increased by IR, while attenuated by rebamipide, sucralfate, and rifaximin down to similar level of control group ($p < 0.05$). The iNOS, COX-2 and PGE2 were significantly induced by IR, which were attenuated by rebamipide, sucralfate, and rifaximin ($p < 0.05$). ICAM-1 was corresponded to above mentioned results. [$Ca2^{+}$] oscillation was increased by IR, which was attenuated by rebamipide, sucralfate, and rifaximin. Proapoptotic gene (Bax, c-Myc) and antiapoptotic gene (Bcl-2, Bcl-xL) expressions were potently suppressed and induced, respectively, by rebamipide, sucralfate, and rifaximin. The release of cytochrome C was increased by IR, while it was attenuated by rebamipide, sucralfate, and rifaximin ($p < 0.05$). Caspase 3 and caspase 7 were also elevated by IR compared to control group, however, they showed decline by rebamipide, sucralfate, and rifaximin ($p < 0.05$).
**Conclusion:** This study demonstrated that rebamipide, sucralfate, and rifaximin have the suppressive effects on IR-induced acute inflammation and apoptosis in the intestine of mouse. Rebamipide, sucralfate, and rifaximin may have beneficial effects in preventing acute radiation-induced enterocolitis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Graft-versus-host disease (GVHD) is a common complication after allogeneic hematopoietic cell transplantation (allo-HCT) that mainly affects the skin, the liver and the gastrointestinal tract. When allo-HCT patients develop gastrointestinal manifestations it is critical to establish a diagnosis in order to define the correct therapeutic approach.
**Aims & Methods:** Our aim was to ascertain the role of lower gastrointestinal (LGI) endoscopy and histology in patients with clinical suspicion of gastrointestinal GVHD. We performed a retrospective study from January 2012 to December 2015 that included allo-HCT patients who underwent lower gastrointestinal endoscopy because of de novo digestive complaints suspected to be GVHD. We analyzed demographic, clinical, endoscopic and histologic variables to assess the role of endoscopy and biopsies in the final diagnosis and therapeutic strategy.
**Results:** During the considered period, 275 patients underwent allo-HCT. A LGI endoscopy was performed to 59 of these patients, 55% male, mean age $41 \pm 18$ years. Nearly half (48%) was already diagnosed with GVHD before the onset of gastrointestinal complaints. The digestive manifestations were diarrhea (95%), abdominal pain (35%) and lower GI bleeding (28%); half the patients concomitantly presented with upper GI symptoms. Biopsies were taken in all cases, even in the absence of endoscopic findings (19%). Gastrointestinal GVHD was the histological diagnosis in 66% of the cases, of which 68% (21 patients) were new diagnosis of GVHD. These results led to therapeutic modifications in 59% of the patients, which all had favorable clinical outcomes.
**Conclusion:** In allo-HCT patients with de novo digestive complaints, LGI endoscopy proved to be useful to confirm previously diagnosed GHVD, to exclude other causes of GI symptoms and to identify new cases of GVHD. Lower gastrointestinal endoscopy modified the clinical course of the disease once it motivated therapeutic adjustments in more than half of the patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Colon ischemia (CI) is a common form of intestinal ischemia, resulting in severe morbidity occasionally. Until now, specific biological markers to predict early diagnosis of CI have not been identified. We evaluated stromal derived factor-1 (SDF-1) as a new biomarker for CI.

**Aims & Methods:** Serum SDF-1 levels were assessed prospectively in four groups; Group1 healthy controls (n = 13), Group 2, CI with cardiovascular disease (CVD) (n = 23), Group 3 CI without CVD (n = 21) and Group 4 with irritable bowel syndrome (n = 42). The levels of serum SDF-1 were analyzed with ELISA.

**Results:** The serum SDF-1 was elevated in all CI (group 2 and 3) at admission (43.8 pg/mL, range 0.1–454.9), compared with group 1 (0.1 pg/mL, range 0.1–37.65) and group 4 (0.1 pg/mL, range, 0.1- 58.6) ($P = 0.1$) but it was not significantly important. The serum SDF-1 at admission (102.7 pg/mL, range, 0.1–454.9) in group 2 were more elevated than that of group 1 (0.1 pg/mL, range 0.1–37.65), group 4(0.1 pg/mL, range, 0.1- 58.6) and that at admission in group 3 (0.1 pg/mL, range, 0.1- 134.07) ($P = 0.2$). In multivariate regression analysis, CVD showed association with SDF-1 levels ($P < 0.05$).

**Conclusion:** Serum SDF-1 would be a valuable biomarker for diagnosis of colon ischemic with cardiovascular disease.

## P0900 ACYL-HOMOSERINE LACTONE QUORUM SENSING MOLECULE ACTIVATES THE BITTER TASTE RECEPTOR, T2R138, IN ENTEROENDOCRINE CELLS

**Introduction:** Bitter taste receptors (referred as T2Rs) detect bitter taste, a warning signal to protect the organism from harmful food constituents. T2Rs are also expressed in enteroendocrine (EEC) cells and are likely to serve as transducers for the detection of luminal contents. The bitter taste receptor T2R38 acts as sentinel in bacteria recognition to regulate immune defense in the airway, where it is activated by acyl-homoserine lactone (AHL) quorum-sensing molecule, a product of gram-negative bacteria. In the gut, we have shown that T2R38 in humans and its counterpart T2R138 in mouse is upregulated in obesity, which is associated with intestinal dysbiosis and inflammation. In addition, manipulation of gut dysbiosis with antibiotics reversed obesity-induced T2R138 overexpression. Furthermore, there is a high correlation between T2R138 expression and different species of bacteria.

**Aims & Methods:** In this study, we tested the hypothesis that T2R138 in EEC cells senses luminal bacteria or bacterial products by examining whether the bacteria-produced quorum-sensing molecule, AHL, activates downstream signaling effectors associated with T2R138 transduction in mouse STC-1 cells, a model for EEC cells. Specifically, we compared the effect of AHL and the selective T2R138 ligand, phenylthiocarbamide (PTC) on intracellular $Ca^{2+}$ concentration ($[Ca^{2+}]_i$) since we previously showed that PTC induces increase in $[Ca^{2+}]_i$ in different models of EEC cells, including STC 1 cells. STC-1 cells were treated with PTC (0.1–10 mM), or AHL (0.01–0.5 mM) and $[Ca^{2+}]_i$ was measured by calcium fluorometry using fura-2 AM. The T2R138 antagonist, Probenecid and transfection of STC 1 cells with siRNA (10–50 mM) targeting mT2R138 were used to assess whether AHL and PTC activate the same bitter taste receptor pathway.

**Results:** AHL similarly to PTC induced a rapid and transient increase in $[Ca^{2+}]_i$ followed by a slower return to baseline in STC1 cells, effect inhibited by Probenecid. Silencing of T2R138 with siRNA significantly reduced $Ca^{2+}$ signaling in response to 3 mM PTC or 0.1 mM AHL ($p < 0.05$ vs. non targeting). Furthermore, sequential exposure of STC 1 cells to either PTC followed by AHL or AHL followed by PTC showed a reduction of the $[Ca^{2+}]_i$ response to the second application of either PTC or AHL indicating they activate the same signaling pathway.

**Conclusion:** Our results indicate that PTC and AHL activate the same signaling pathway and support our hypothesis that intestinal T2R138 senses bacterial products to mediate a functional response in EEC cells. We hypothesize that the direct or indirect activation of intracellular signal transduction pathways in EEC cells in response to bitter receptor agonists or bacterial products triggers the release of GI peptides that activate enteric or afferent fibers and/or modulate the activity of adjacent or distant target cells.

**Introduction:** The association of Streptococcus bovis (SB) endocarditis and colon carcinoma has been reported previously. However the relationship between SB bacteraemia (SBB) and colorectal neoplasia (CRN) or other gastrointestinal conditions is still under controversy and maybe underestimated.

**Aims & Methods: Aims** Determine risk factors SBB-associated and evaluate the association between SBB and CRN and other gastrointestinal conditions. **Methods** Retrospective case-control study of all patients with SBB registered in microbiological system (cases), between 2000–2013. They were compared with asymptomatic subjects with no SBB or personal/familial history of CRN, who underwent screening colonoscopy. Cases were paired with controls for gender and age (±3years) in a proportion of 1:2. Variables evaluated included clinic, laboratorial, pathologic, comorbidities, CRN risk, temporal relation of CRN and SBB diagnosis and mortality.

**Results:** Included 57 patients with SBB (mean age: $72.3 \pm 13.8$vs$71.8 \pm 13.3$yo; $p = 0.825$); male gender: 66.7%vs66.7%; $p = 1.000$). About 74.0%(42/57) of SB were detected in the last 6 years of study. All patients underwent colonic imagiological and/or endoscopic evaluation. An half of patients performed echocardiogram, with endocarditis diagnosis in 25.6%(vs0.0%; OR 1.33; $p < 0.001$), being 28.6% previously diagnosed and 64.3% concomitant to SBB. CRN prevalence was higher in cases (61.4%vs3.5%; OR43.75;$p < 0.001$): 47.4% adenomas with low-grade dysplasia (vs3.5%; OR24.75, $p < 0.001$), 1.8% adenomas with high-grade of dysplasia (vs0.0%; $p = 0.156$) and 12.3% invasive carcinomas (vs0.0%; OR1.14; $p < 0.001$). In case of adenoma diagnosis, 70.0% presented ≥2 adenomas and 18.5%(vs0.0%; OR1.08; $p = 0.004$) with location in the colon right-sided. Relatively to invasive carcinomas, 57.1% were located in sigmoid/rectum. Four cases had concomitant diagnosis to SBB, 5 cases previously ($3.6 \pm 2.3$years) and 5 cases posteriorly ($2.4 \pm 1.7$years). About 77.0% (vs57.0%; $p = 0.010$) had benign gastrointestinal conditions, ≥2 in 45.6% (vs35.1%; $p = 0.183$). Biliary lithiasis (38.6%vs8.8%; OR6.54; $p < 0.001$), splenic infarction (3.5%vs0.0%; OR1.04; $p = 0.044$), liver hemangioma (7.0%vs0.0%; OR1.08; $p = 0.004$), chronic liver disease (14.0%vs1.8%; OR13.39; $p = 0.001$), esophageal varices (8.8%vs1.8%; OR5.39; $p = 0.029$), ischemic colitis/perianal abscess (3.5%vs0.0%; OR1.04; $p = 0.044$) and Clostridium difficile infection (5.3%vs0.0%; OR1.05; $p = 0.013$) were the most common SBB-associated conditions. Other gastrointestinal neoplasia than CRN occurred in 8.8%(vs2.6%; $p = 0.172$) with significate association for pancreatic and hepatocellular carcinomas (3.5%vs0.0%; OR1.04; $p = 0.044$). After multivariate analysis, independent risk factors to SBB were atrial hypertension (59.6%vs22.8%; OR4.61; $p = 0.004$), alcoholism (22.8%vs5.3%; OR10.10; $p = 0.004$), cerebrovascular disease (15.8%vs4.4%; OR4.27; $p = 0.043$), acute myocardial infarction (12.3%vs1.8%; OR7.25; $p = 0.042$), endocarditis (OR1.23; $p = 0.030$), chronic liver disease (OR11.36; $p = 0.028$), kidney dialysis (17.5%vs2.6%; OR12.99; $p = 0.038$) and osteoarthrosis (12.3%vs3.5%; OR6.85; $p = 0.018$). Mortality rate was 45.6%(26/57) with one case related to SB endocarditis. One patient died due to sepsis in early CRN post-operative and no CRN recurrence was registered.

**Conclusion:** SBB prevalence has been increasing. CRN was significant higher in SBB patients, suggesting a major role in colorectal carcinogenesis and an important indicator of occult neoplasia with 60.0% of CRN diagnosed previous or concomitant with SBB. All patients with SBB should perform colonoscopy, even if asymptomatic and a close follow-up in first years after SBB diagnosis. The high association with other benign and malign gastrointestinal conditions suggest the necessity of further investigation beyond colonoscopy or echocardiogram. High mortality seems to be related with multiple comorbidities.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0902 THE ASSOCIATION BETWEEN SMOKING DURATION AND ABSTINENCE WITH ODDS OF COLORECTAL ADENOMAS

**N. Fliss Isakov**, S. Zelber-Sagi, R. Kariv
*Gastroenterology, Tel Aviv Sourasky Medical Center, Tel Aviv/Israel*

**Contact E-mail Address:** naomishfi@gmail.com

**Introduction:** Colorectal cancer (CRC) is a common and lethal disease, known to develop gradually from its precursors, the most common are adenomatous polyps. Smoking is an established risk factor for colorectal neoplasia but the association with smoking duration and abstinence is yet to be established.

**Aims & Methods:** To evaluate the association between smoking parameters and odds of colorectal adenomas diagnosis in colonoscopy. A case control study among 40–70y patients at low-medium risk for CRC, undergoing screening or alarming symptoms colonsocopy. Cases with colorectal polyps and controls with no current or previous polyps were evaluated for demographic, lifestyle, anthropometric, clinical and metabolic parameters. Severe or GI background illness were exclusion criteria.

**Abstract No: P0903**

**Table:** Characteristics of CRC cases and non-CRC individuals in 2002 and 2014.

| | 2002N = 1,126,644 CRC N = 921 n (%) | Non-CRCN = 1,125,723 n (%) | 2014N = 1,758,198 CRCN = 1330 n (%) | Non-CRCN = 1,756,868 n (%) |
|---|---|---|---|---|
| **Age at start date (years)** | | | | |
| 40–49 | 32 (3.5) | 330,063 (29.3) | 68 (5.1) | 577,167 (32.9) |
| 50–59 | 115 (12.5) | 305,523 (27.1) | 215 (16.2) | 464,427 (26.4) |
| 60–69 | 244 (26.5) | 234,955 (20.9) | 334 (25.1) | 374,036 (21.3) |
| 70–79 | 355 (38.5) | 174,098 (15.5) | 421 (31.7) | 229,621 (13.1) |

| **Bowel screening** | 34 (3.7) | 11,472 (1.0) | 190 (14.3) | 187,548 (10.7) |

*Body mass index $\geq$30 kg/m$^2$. CRC, colorectal cancer.

**Results:** Among 724 participants, multivariate analysis revealed that relative to never smokers, smoking (ever) and pack years (PY) were significantly associated with colorectal adenomas (OR = 1.85, 95% 1.35–2.53 and OR = 1.02, 95%CI 1.01–1.03). Relative to current smokers, participants who stopped smoking showed decreased association with adenomas (OR = 0.50, 95%CI 0.31–0.81). Smoking abstinence for more than 5 years before colonoscopy was associated with reduced odds for adenoma (OR = 0.80, 95%CI 0.66–0.97) compared to less than 5 years, and even more so when abstinence duration exceeded 25 years (OR = 0.33, 95%CI 0.16–0.68).
**Conclusion:** These results highlight the need to better define smoking habits in order to predict colorectal neoplasia and recommend appropriate screening. These results call for further validation in additional studies of larger samples.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0903 SECULAR TRENDS IN COLORECTAL CANCER IN THE UNITED KINGDOM

L. Cea Soriano[1], M. Soriano-Gabarró[2], **L.A. García Rodríguez**[1]
[1]*Spanish Centre for Pharmacoepidemiologic Research, Madrid/Spain*
[2]*Epidemiology, Bayer Pharma AG, Berlin/Germany*

**Contact E-mail Address:** luciaceife@gmail.com
**Introduction:** Registry data show survival of colorectal cancer (CRC) in the United Kingdom (UK) is poor compared with other European countries and the United States[1], yet these data sources lack information on patient comorbidities and medications used, which could help explain these differences.
**Aims & Methods:** Using The Health Improvement Network primary care database in the UK, we aimed to describe secular trends in CRC incidence and characteristics of CRC cases. Among individuals aged 40–89 years from 2000–2014, we identified first ever cases of CRC and calculated incidence rates (IRs) with 95% confidence intervals (CIs). For all CRC cases and non-cases in two separate calendar years (2002 and 2014), we obtained data on demographics, and characteristics in relation to entry into the study year (start date): body mass index (any time up to start date), morbidities and bowel screening (at start date or within 5 years prior) and current medication use (use 0–30 days prior start date).
**Results:** CRC IRs per 10,000 person-years (pyrs) were relatively constant across the study period; 9.27 in 2000, 10.65 in 2007 and 8.79 in 2014. IRs were higher in men than women, 11.44 versus (vs.) 7.40 per 10,000 pyrs in 2000, and 9.39 vs. 7.38 per 10,000 pyrs in 2014. As shown in the Table, a rise was seen in the proportion of CRC cases diagnosed at <60 years. Prior bowel screening increased in both CRC cases and non-cases. Greater rises in obesity, hypertension, atrial fibrillation and current use of proton pump inhibitors, anti-hypertensives and warfarin, were seen among CRC cases compared with non-cases. Current use of low-dose aspirin remained the same in CRC cases and decreased slightly in non-cases.
**Conclusion:** CRC incidence has remained relatively stable in the UK over the last decade. The increased prevalence of some comorbidities and medication use among CRC cases should be considered when evaluating patterns in CRC survival.

**Introduction:** Most colorectal cancers are classical adenocarcinomas (AC). Less frequent histological subtypes are mucinous adenocarcinomas (MAC) and signet-ring cell carcinomas (SC), which differ from AC in clinicopathology and prognosis. Aim of this study was to define relevant characteristics of mucinous and signet ring cell colorectal cancer on a European population based cohort.
**Aims & Methods:** All newly diagnosed AC, MAC, and SC between 1998 and 2012 within the catchment area of the Munich Cancer Registry were evaluated regarding clinical, histopathological and survival data. The Munich Cancer Registry is a WHO approved population based clinical cancer registry, and member of the International Agency for Research on Cancer (IARC) as well as European Network of Cancer Registries (ENCR), thus warranting thorough data documentation and validation. Cumulative incidence was used to calculate time to locoregional recurrence and distant recurrence.
**Results:** AC occurred in 25,172 patients (90%), MAC in 2,724 (9.7%), and SC in 160 (0.6%). AC were less frequently localized in the proximal colon (34%) compared to MAC (57%, $p < 0.001$) and SC (76%, $p < 0.001$). Both, MAC and SC had higher T, N, and M categories, lymphatic invasion, and worse grading ($p < 0.001$ for each). There were significant differences regarding the 10-year cumulative incidence of locoregional recurrence ($p < 0.001$), and distant recurrence ($p < 0.001$). For AC, the five year overall survival was 59% (95% confidence interval 58.0; 59.3), for MAC 52% (50.2; 54.2), and for SC 40% (32.1; 48.5; $p < 0.001$). However, MAC or SC did not remain independent prognostic factors for overall survival compared to AC upon multivariable analysis ($p = 0.981$).
**Conclusion:** This large European population based cohort of patients with colorectal AC, MAC, and SC shows for the first time different specific histopathological characteristics and recurrence patterns. MAC and SC are diagnosed at more advanced tumor stages and therefore entail reduced survival rates.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0905 INDICATION FOR COLONOSCOPY CORRELATES WITH STAGING AT TIME OF COLORECTAL CANCER DIAGNOSIS

**Introduction:** **B**urgenland **PRE**vention trial of colorectal cancer **D**isease with **I**mmunologi**C**al **T**esting (B-PREDICT) aims to reduce colorectal cancer (CRC) incidence. All inhabitants of Burgenland aged between 40 and 80 years are included in annual fecal immunochemical test (FIT)-based screening. FIT positive tested individuals were subjected to colonoscopy. Recently, test results of 12 years screening were evaluated to assess the CRC stage in correlation with the indication for colonoscopy.

**Aims & Methods:** B-PREDICT, initiated in 2003 was expanded to the whole province Burgenland in 2006. Annually, more than 150,000 individuals aged between 40 and 80 years are invited to participate in FIT screening. In total, 1,400,000 stool sample containers were delivered to the target group and 547,672 used sample containers were returned, reflecting a participation rate of 39.1%. A qualitative assay was used until 2009, that was replaced by a quantitative system (OC-Sensor, Mast Diagnostica, Germany, cut-off 50 ng hemoglobin/mL) in 2010. In total, 2,160 patients with initial diagnosis (ID) of CRC were recorded during the observation period. 1,301 colonoscopies, performed within 30 days before ID were analyzed to assess the correlation of indication for colonoscopy and staging or tumor size at time of ID.

**Results:** Observed distributions of UICC stage within the different indication groups were: for stage I CRC, 26% screening colonoscopy, 29% positive guaiac test and 38% positive FIT. Pre-testing with FIT was only exceeded by 62% follow-up care after adenoma finding and 88% planned polypectomy. Stage IV CRCs were most frequently diagnosed in the indication suspected malignancy (46%) followed by diarrhea (41%), loss of weight (40%) and abdominal pain (34%) compared to the less frequent indications screening colonoscopy (23%), FIT (11%) and guaiac test (8%). Regarding tumor size, T1 CRC detection rate of indication positive FIT (31%) was only exceeded by the two particular subgroups follow-up care after adenoma (43%) and planned polypectomy (57%). Guaiac test and follow-up after CRC (both 22%) were followed by screening colonoscopy (20%). In symptomatic patients, most T3 colorectal tumors were detected due to anemia (58%), obstipation (50%), abdominal pain (49%), loss of weight (45%), abnormal defecation (41%) and hematochezia (38%).

**Conclusion:** The factor indication for colonoscopy correlates with stage and tumor size at time of ID. Diagnosis of CRC within the subgroup of FIT-triggered colonoscopies is beneficial regarding both, stage and size of tumor.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0906 PATIENT SEX IS ASSOCIATED WITH LYMPH NODE METASTASIS IN T1 COLORECTAL CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

**K. Ichimasa**[1], S. Kudo[1], H. Miyachi[1], Y. Kouyama[1], F. Ishida[1], T. Baba[1], A. Katagiri[1], K. Wakamura[1], T. Hayashi[1], T. Hisayuki[1], T. Kudo[1], M. Misawa[1], Y. Mori[1], S. Matsudaira[1], Y. Kimura[1], Y. Kataoka[2]

**Introduction:** About 10% of patients with T1 colorectal cancers have lymph node metastases (LNM), requiring node dissection along with surgical resection. Previously identified risk factors for LNM include lymphovascular invasion, histologic grade, tumor budding and degree of submucosal invasion. Recently, patient sex was also reported to affect the occurrence of LNM.(1)

**Aims & Methods:** The aim was to assess whether patient sex was predictive of LNM in T1 colorectal cancer. We searched public databases, including PubMed, EMBASE and the Cochrane Central Register of Controlled Trials, utilizing keywords related to "T1 colorectal cancer" and "lymph node". All relevant studies reporting the adjusted odds ratio or risk ratio of LNM in relation to patient sex were included. The quality of the studies was classified according to the Quality in Prognosis Studies tool. A random-effects model was used and the quality of the evidence was evaluated using the Grading of Recommendations Assessment, Development and Evaluation approach. Meta-analyses were performed using Stata ver. 13.0 (Stata Corp., College Station, TX).

**Results:** The initial database search identified 2,492 publications; of these, 36 studies reported un-adjusted results. Four of the 36 studies reported adjusted results and fulfilled the inclusion criteria for this meta-analysis. Three studies were graded as having a moderate risk of bias, and one had having a low risk of bias. The meta-analysis showed that female sex was related to increased risk of LNM (relative risk 2.45, 95% confidence interval 1.03–3.88). The I-squared statistic was 0.901, classified as very low (+OOO) and was downgraded by the risk of bias, inconsistency and publication bias.

**Conclusion:** Female sex correlated with LNM in patients with T1 colorectal cancer. T1 colorectal cancer in male and female patients might be oncologically different.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Muir-Torre syndrome (MTS) is a rare genetic condition with an autosomal dominant inheritance. MTS is the combination of skin tumours (such as sebaceous adenomas (SA), sebaceous carcinomas (SC) and keratoacanthomas (KA)) and visceral malignancy. MTS is considered a subtype of Lynch syndrome (LS), usually associated with MSH2 mutations.

**Aims & Methods:** The aim of this study was to characterize MTS families from a Portuguese centre. Retrospective analysis of 9 consecutive families with MTS followed in a specialized centre between 1997 and 2014. We collected demographic data, tumour types, age at diagnosis and DNA mismatch repair gene mutations.

**Results:** Of 9 families, 8 had MSH2 and one MLH1 pathogenic germline mutations. There were 35 mutation carriers (21 F;14 M) and 71.4% of those developed a total of 61 tumours [mean number of tumours per patient: $2.44 \pm 1.94$ (1–10); mean age: $53.2 \pm 14.3$ years). LS spectrum tumours: colorectal (44%), endometrial (12%), KA (8%), SC (5%), SA (5%), urothelial (3%), stomach (3%), ovarian (2%), small bowel (2%) and brain (2%). We also found tumours not belonging to LS spectrum such as other skin tumours (8%), prostate (3%), breast (2%) and neuroendocrine neoplasias (2%). There were 25 index tumours (mean age: $43.9 \pm 13.2$ years); colorectal was the most frequent (52%), followed by endometrial (16%), KA (8%), SC (4%), urothelial (4%), stomach (4%), ovarian (4%), small bowel (4%) and brain (4%). In 2 cases the index tumour was KA/SC and those patients developed also other neoplasias not associated with LS.

**Conclusion:** The presence of skin tumours such as SA/SC/KA should raise awareness for the diagnosis of MTS, especially because they may present as an index tumour. The identification of MTS families has an important impact in patient management and surveillance strategies.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0908 THE ASSOCIATION OF LOW PENETRANCE VARIANTS IN DNA REPAIR GENES WITH COLORECTAL CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

**Contact E-mail Address:** na2412@ic.ac.uk

**Introduction:** Approximately 35% of colorectal cancers (CRC) are attributable to heritable factors. With only 6% contributed by known hereditary syndromes, the remainder of this risk may be due to lower penetrance variants. Genomic stability relies not only on accurate mechanisms of DNA replication but also on the repair of damage caused by replication errors or the environment. Complex conserved DNA repair pathways have evolved which include Base Excision Repair (BER), Nucleotide Excision Repair (NER), Mismatch Repair (MMR), Reverse Repair (RR) and Double-Strand Break (DSB) repair. It is thought that mutations in DNA repair and replication genes are present in over 58% of cancer cell lines and therefore it is expected that those with DNA repair mutations will be at increased risk of CRC. However the role of low penetrance polymorphisms of DNA repair in CRC risk genes is unclear.

**Aims & Methods: Aim**: To perform a systematic review and meta-analysis to assess the association of DNA repair gene polymorphisms with the risk of CRC. **Methods**: A systematic literature review of the Pubmed and HuGENet databases was conducted and studies were included/excluded based on pre-specified criteria. The per allele model was used to assess the risk attributed to each identified variant, by calculating pooled odds ratios. Heterogeneity was investigated by subgroup analyses for ethnicity and tumour location. Publication bias was investigated using funnel plots and Egger's test. Statistical analysis was conducted using the R program (version 3.2.4).

**Results:** 64 polymorphisms in 26 different DNA repair genes were identified. Meta-analyses were conducted for 22 of these polymorphisms in 17 genes, including between 1706 to 9682 cases per polymorphism. 6 polymorphisms were significantly associated with the risk of colorectal cancer. Subgroup analysis revealed ethnicity was not a source of heterogeneity, however tumour location was significantly associated with OGG1 and CRC risk (Table 1). Egger's test revealed no publication bias.

**Table 1:** Polymorphisms significantly associated with CRC and subgroup analysis for tumour location.

| Pathway | Gene | Polymorphism | Odds Ratio | 95% CI |
|---|---|---|---|---|
| BER | APE1 | rs1130409 | 1.15 | 1.06–1.24 |
| BER | PARP1 | rs1136410 | 1.16 | 1.04–1.30 |
| NER | ERCC5 | rs17655 | 1.11 | 1.05–1.18 |
| NER | XPC | rs2228001 | 1.08 | 1.01–1.15 |
| DSB | RAD18 | rs373572 | 1.32 | 1.16–1.49 |
| RR | MGMT | rs12917 | 0.81 | 0.68–0.98 |
| **Subgroup Analysis for rs1052133** | | | | |
| **Pathway** | **Gene** | **Analysis Type** | **Odds Ratio** | **95% CI** |
| BER | OGG1 | Colon vs Control | 0.93 | 0.81–1.05 |
| | | Rectum vs Control | 1.176 | 1.03–1.34 |
| | | Colon vs Rectum | 0.79 | 0.67–0.92 |
| | | Rectum vs Colon | 1.26 | 1.09–1.47 |

**Conclusion:** The 6 polymorphisms associated with a significant association with CRC risk fell within the BER, NER, RR and DSB repair pathways confirming their importance in CRC risk. Interestingly, no polymorphisms within the MMR pathway were found to be associated with significant risk of CRC in meta-analysis. Advances in the identification of new polymorphisms and genotype technique would allow for more accurate gene analysis. Knowledge of which DNA repair gene polymorphisms have a role in CRC will allow risk assessment and/or treatment to be tailored to suit the needs of each individual patient, affording a more personalised approach to medicine.

## P0909 DIETARY EMULSIFIERS INDUCED LOW-GRADE INTESTINAL INFLAMMATION FAVORS COLONIC CARCINOGENESIS

**B. Chassaing**[1], E. Viennois[2], D. Merlin[1], A. Gewirtz[1]
[1]*Institute For Biomedical Sciences, Georgia State University, Atlanta/United States of America*
[2]*Veterans Affairs Medical Center, Decatur/United States of America*

**Contact E-mail Address:** bchassaing@gsu.edu
**Introduction:** Colorectal cancer (CRC) is among the most common human malignancies and has been firmly linked to chronic intestinal inflammation, giving rise to the term of "colitis-associated cancer" (CAC). The development of CAC in patients suffering from IBD is one of the best characterized examples of an association between intestinal inflammation and carcinogenesis. Intestinal microbiota is playing an important role in the development of colorectal carcinogenesis, mainly by providing pro-inflammatory signaling that can favor the development of cancer. We recently described that emulsifiers, detergent-like molecules that are a ubiquitous component of processed foods, disrupt mucus-bacterial interactions and induced low-grade inflammation (1).
**Aims & Methods:** Colitis-associated cancer susceptibility was analyzed in mice subjected to a chronic exposure to commonly used emulsifier, carboxymethylcellulose and Polysorbate 80. Tumor burden, proliferation/apoptosis balance, inflammatory marker lipocalin-2 and microbiota pro-inflammatory potential were analyzed.
**Results:** Emulsifier consumption induce low-grade intestinal inflammation, associated with microbiota encroachment, altered species composition and increased pro-inflammatory potential. Those emulsifier-induced perturbation of the microbiota/host relationship promote colonic carcinogenesis, with an increased tumor burden. through a pro-inflammatory environment. Moreover, the altered intestinal microbiota associated with emulsifier consumption was sufficient to drive alterations in some major proliferation and apoptosis pathways.
**Conclusion:** We found here that emulsifier-induced low-grade intestinal inflammation and proliferation/apoptosis balance alteration lead to an exacerbation of AOM/DSS-induced carcinogenesis. These findings support the concept that a perturbed host-microbiota interactions resulting in intestinal inflammation can promote colonic carcinogenesis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** An elevation of prostaglandin E2 (PGE2) level, a product of arachidonic acid (AA, 20:4 n-6) and cyclooxygenases 2 (COX2), is a hallmark in colorectal carcinoma (CRC). While omega-6 polyunsaturated fatty acid (n-6 PUFA) metabolites have mostly pro-inflammatory properties, anti-inflammatory effects are generally attributed to n-3 PUFA metabolites. Recent studies indicated an increase of n-6 PUFA levels and a decrease of n-3 PUFA levels in CRC. Besides, a downregulation of the 15-lipoxygenase (LOX) pathway of the arachidonic acid (AA, 20:4 n-6) cascade has also been described in CRC cells. The role of 15-LOX in the context of carcinogenesis in the colon is still controversial. Several studies postulated tumor suppressing properties of 15-LOX while other investigations suggested pro-inflammatory roles of 15-LOX and its metabolites [1–3]. However, a detailed insight of lipid metabolite changes has not yet been revealed.
**Aims & Methods:** With the help of liquid chromatography-tandem mass spectrometry (LC–MS/MS) we investigated LOX metabolite profile in normal human colon tissue as compared to colorectal carcinoma and adenoma tissue, respectively. After written informed consent according to the declaration of Helsinki, colonoscopy was performed and each patient underwent biopsies of macroscopically intact colon mucosa. In case of adenoma or carcinoma representative tissue biopsies were taken. All samples were immediately quick frozen on dry ice and then stored at −80°C. Lipid metabolite extraction and subsequently quantification by LC-MS/MS was carried out according as described previously [4]. Concentrations of lipid metabolites are expressed in pmol/g tissue.
**Results:** We investigated lipid profile changes in human colorectal carcinoma (n = 9) and adenoma (n = 34) tissue biopsies, focusing on n-6 – and n-3 PUFA metabolites as well as on all known branches of the AA cascade. Human colon adenoma tissue showed significant increased levels of AA derived lipid mediators prostaglandin E2 (PGE2) and 15-hydroxyeicosatetraenoic acid (15-HETE) compared to healthy tissue. Levels of the EPA- derived metabolite 15 - hydroxypentaenoic acid (15-HEPE) and the DHA- derived metabolite 17 hydroxydocosahexaenoic acid (17-HDHA), known as the precursors /pathway indicators of resolvins and protectins, were elevated in adenoma tissue. Human colon carcinoma tissue also showed an increased level of 15-HETE. 15-HEPE and 17-HDHA were also increased in carcinoma tissue.
**Conclusion:** The approach presented here shows the simultaneous quantification of AA, EPA and DHA derived cascade metabolites by liquid chromatography/tandem mass spectrometry and provides a detailed insight into lipid metabolite profile changes from colon tissue to colonic adenoma and carcinoma tissues.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0911 BMI-1 PROMOTES INVASION AND MIGRATION OF COLON CANCER STEM CELLS THROUGH DOWN-REGULATION OF E-CADHERIN

**Z. Zhang**, W. Sha, Q. Wang
*Gi, Guangdong General Hospital, Guangzhou/China*

**Contact E-mail Address:** 503274480@qq.com
**Introduction:** Colorectal cancer is the second leading cause of cancer-related mortality in America according to NCCN (National Comprehensive Cancer Network) in 2015(1). It's reported that 15%-25% colorectal patients have had hepatic metastases before diagnosed and over half finally have metastasis. Although the five year survival rate of colon cancer patients after radical surgery is often more than 50%, it drops to less than 10% after metastasis. Cancer stem cell (CSC) is a new theory which appears in recent years about the occurrence, development, metastasis and recurrence of tumors. They are defined as a subpopulation of cancer cells which have the features such as self-renewal, differentiation abilities, metastatic potential, and resistance to conventional chemoradiotherapy (2–4). The discovery of markers of CSCs facilitates the screening and studying of many tumors including the blood, pate, thoracic, abdominal, and genital system cancers. Epithelial mesenchymal transition (EMT) is considered to appear during cancer invasion and migration, or tumor progression. In the process, epithelial cells lose their epithelial

characteristics and adopt mesenchymal appearance or characteristics (5). The down-regulation or loss of E-cadherin, a transmenbrane protein important for cell-cell junction, is treated as the hallmark of EMT (6). The Polycomb group (PcG) of proteins consists of a kind of transcriptional repressors that orchestrate changes in chromatin structure to regulate gene activity (7). Many of PcG proteins are confirmed to alter in human cancers, such as Bmi-1. Bmi-1 was previously known as transcriptional repressor targeting the Ink4a/Arf gene locus; and also described as an oncogene in many solid tumors, playing a critical role in the maintenance of CSCs (8). However, it is rarely reported concerning Bmi-1 and CCSCs at present.

**Aims & Methods:** The aim of this study was to reveal the mechanisms that Bmi-1 promoted invasion and migration of colon cancer stem cells (CCSCs) using colon cancer cell line HCT116. Sphere formation media (SFM) and magnetic cell sorting (MACS) were used to enrich and screen CCSCs. CD133 and CD44 were regarded as markers of CCSCs and they were found to co-express in colon cancer cell line HCT116. Colony formation assay, cell proliferation and viability assays with Cell Counting Kit-8 (CCK8), and nude mice transplantation tumor assay were used to identify CCSCs.

**Results:** $CD133^{+}CD44^{+}$ HCT116 cells showed higher cloning efficiency, greater proliferation ability and viability, and stronger tumorigenicity; thus acting as CCSCs for subsequent studies. In addition, the invasion and migration abilities of $CD133^{+}CD44^{+}$ HCT116 cells obviously decreased when Bmi-1 was silenced by small interfering RNA (siRNA). RT-PCR and Western Blot analysis suggested Bmi-1 impacted negatively on E-cadherin.

**Conclusion:** In summary, Bmi-1 promoted invasion and migration of CCSCs through down-regulation of E-cadherin, probably by inducing EMT. This may offer a new target for cancer therapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Colorectal cancer and metabolic syndrome shared several risks like obesity, lack of physical activity, and insulin resistance, but the association between these two disease is still unclear.

**Aims & Methods:** The objective of this study was to assess the association of colorectal adenoma with metabolic syndrome (MS). We retrospectively study 289 participants who underwent screening colonoscopy in the University of Hong Kong – Shenzhen hospital from January 2014 to June 2015. The Associations between smoking, drinking, physical activity, aspirin taking, BMI, waist circumference, MS, blood pressure, free blood glucose (FBG), triglyceride (TG), cholesterol (CHOL), high-density lipoprotein (HDL) and colorectal adenoma were evaluated.

**Results:** 159 participants were recruited in adenoma group (AG) and 130 participants in normal group (NG). AG had a bigger body mass index (BMI) [$(23.5 \pm 3.19)$ versus $(22.7 \pm 2.83)$,$P = 0.05$], bigger waist circumference [$(83.4 \pm 10.3)$ versus $(79.6 \pm 13.)$,$P = 0.015$], higher serum HDL level (mmol/L) [$(1.31 \pm 0.286)$ versus $(1.23 \pm 0.271)$,$P = 0.044$], and higher serum CHOL level (mmol/L) [$(5.4 \pm 0.986)$ versus $(5.04 \pm 1.14)$,$P = 0.018$] than NG. No significant differences were existed when comparing hip circumference and waist-hip ratio, as well as serum FBG and TG. The rate of MS in AG is higher than NG (23.3% versus 12.3%,$P = 0.017$), as well as comparing rate of overweight or obesity (35.2% versus 23.1%,$P = 0.025$), hypertension (23.8% versus 14.3%,$P = 0.046$) and hypercholesteremia (40.3% versus 24.6%,$P = 0.017$). But no significant difference were existed in comparison of hyperglycemia, hypertriglyceridaemia or abnormal serum HDL ($P > 0.05$).

**Conclusion:** Metabolic Syndrome increases the risk of having colorectal adenoma. The mechanism may be related to higher serum CHOL and HDL, and causing elevated catabolism of cholesterol. Screening colonoscopy should be enhanced for people diagnosed of MS, especially having central obesity and hypercholesterolemia, to early diagnose and treat colorectal adenoma and prevent colorectal cancer.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Transanal endoscopic microsurgery (TEM) and endoscopic mucosal resection (EMR) are the most common resection techniques for large non-pedunculated rectal polyps. Despite thorough preoperative endoscopic investigation, unexpected rectal cancer is occasionally encountered at pathological examination of the resected specimen. Little is known about the prevalence and characteristics of unexpected cancer in those lesions that appear benign. This study describes the prevalence of unexpected rectal cancers, the lesion and procedural characteristics and its subsequent treatment and recurrence rates.

**Aims & Methods:** Patients included in this post-hoc analysis were selected from a multicentre randomized controlled trial (TREND study) investigating the recurrence of neoplasia after treatment of rectal polyps with either EMR or TEM between 2009–2013. Patients with a non-pedunculated rectal polyp of $\geq$ 3 cm located between 1–15 cm from the anal verge without endoscopic suspicion of invasive growth, were eligible. If histopathology of the resected specimen revealed invasive growth, patients were excluded from the TREND study and included in this analysis. Data concerning patient, lesion and procedural characteristics as well as additional therapy and surveillance were collected.

**Results:** Unexpected rectal cancer was found in 27/204 included patients in the TREND study (13%); 15 were initially treated with EMR and 12 with TEM. The majority consisted of a T1 cancer ($n = 22$, 81.5%) but also 3 T2 (11.1%) and 2 T3 cancers (7.4%) were detected. The mean lesion size was $47 \pm 11.6$ mm, 18 (78.3%) cancers were moderately to well differentiated and lymphatic or vascular invasion was not detected. Patient and lesion characteristics were similar either between the resection techniques or between malignant and benign lesions included in the TREND study. Resection procedures of malignant lesions were more often assessed as being irradical compared to benign lesions (25.0% vs 8.5%, OR 3.60 (95% CI 1.32–9.84), $p = 0.02$). The success of submucosal lifting during EMR was also lower (60.0% vs 93.1%, $p < 0.001$). Patients initially treated

with EMR received completion surgery in 80.0%, which consisted in 50% of TME (66.7% LAR, 33.3% APR) and in 50% of TEM. Five patients (41.7%) initially treated with TEM received completion surgery, which was according to the TME principle (20% LAR, 80% APR) in all patients. After a mean follow up of 4.4 ± 1.2 years, all patients were alive and one malignant recurrence was detected. Distant metastases were found in 3 patients (11%), whom all underwent surveillance after treating a T1Sm3 carcinoma with TEM.
**Conclusion:** Despite careful lesion assessment, unexpected cancers were encountered in 13% of patients treated for large non-pedunculated rectal polyps. This might impact the strategy how to treat these polyps in the future, since incomplete procedural resection and non-lifting sign during EMR occurred more often in the cancers.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0915 CLINICOPATHOLOGIC AND ENDOSCOPIC FEATURES OF EARLY STAGE COLORECTAL SERRATED ADENOCARCINOMA

**D. Hirano**[1], S. Tanaka[1], S. Oka[1], B. Kazuki[2], Y. Ken[2], K. Sumimoto[2], N. Yuki[2], T. Yuzuru[2], A. Naoki[2], S. Kenjiro[2], N. Hayashi[1], S. Fumio[3], K. Chayama[4]

**Introduction:** Serrated adenocarcinoma (SAC) is considered to be one of several end-points of the serrated neoplasia pathway. Recently, SAC has been described as distinct variant of colorectal carcinomas, accounting for approximately 7.5% of all advanced colorectal carcinomas, and it has been well known to have a worse prognosis than conventional carcinoma. However, there are no reports about the clinicopathologic features in the early stage of SACs.
**Aims & Methods:** The aim of this study was to clarify clinicopathologic and endoscopic differences in early stage SACs. A total of 40 consecutive SACs in 40 patients at Hiroshima University Hospital during the period from January 2009 until January 2016 were enrolled. The histologic diagnosis of SAC was decided according to the World Health Organization (WHO) classification. In this study, we defined more than 5% of serrated morphology in the cancerous area as SAC, and classified 2 groups as SAC with all serrated morphology (Group A, n = 17) and SAC with non-serrated morphology (Group B, n = 23) in the cancerous area. We examined the clinicopathologic characteristics between 2 groups as follows: gender, age, location (proximal colon/ distal colon/ rectum), tumor size, invasion depth (Tis, T1a, T1b). We also examined the endoscopic findings between 2 groups as follows; tumor surface color (same as normal mucosa, white, red), macroscopic type (protruded, superficial), pinecone-like findings, varicose microvecicular, pit pattern, and NBI magnifying finding (JNET classification, Dig Endosc 2016) at the cancerous area. We also classified the serrated components close to carcinoma into 4 types; sessile serrated adenoma (SSA type), traditional serrated adenoma (TSA type), unclassified type, and non-serrated component type.
**Results:** In clinicopathologic characteristics, there were significantly differences in average tumor size (Group A 27.6 mm vs. Group B 43.1 mm), incidence of T1 carcinoma (Group A 71% vs. Group B 13%), the incidence of tumor color of same as normal mucosa (Group A 47% vs. Group B 17%) between 2 groups ($p < 0.01$). Depth (Tis/T1a/T1b) of SACs was shown in Group A (5/1/11) and Group B (20/1/2), respectively. In SACs smaller than 10 mm, there were no submucosal invasive SACs. However, in SACs larger than 20 mm, the incidence of T1 carcinoma in Group A (70%) was significantly higher than that in Group B (13%) ($p < 0.05$). There were no significant differences in gender, age, location, between 2 groups. In endoscopic findings, there were significant differences in JNET Type 3 (Group A 18% vs. Group B 0%, $p < 0.01$), type V pit pattern (Group A 70% vs. Group B 39%, $p < 0.01$) between 2 groups. There were no significant differences in macroscopic type, pinecone-like findings, varicose microvecicular between 2 groups. Average tumor size of TSA type (42.6 mm) was significantly larger than SSA type (17.2 mm) or non-serrated component type (18.3 mm). SACs with SSA type located in the proximal colon in all cases. The incidence of submucosal invasion of SSA type (80%), Unclassified type (100%) and Non-serrated component type (100%) was significantly higher than that of TSA type (11%).
**Conclusion:** Serrated morphology in the cancerous area and background of non-TSA components indicated the aggressive behavior in early stage SACs.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0916 DIAGNOSTIC ACCURACY OF FECAL IMMUNOCHEMICAL TEST IN PATIENTS AT HIGH-RISK FOR COLORECTAL CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

**A. Katsoula**[1], P. Paschos[2], A. Haidich[3], A. Tsapas[4], O. Giouleme[1]

**Contact E-mail Address:** anastkatsoula@gmail.com
**Introduction:** Fecal immunochemical test (FIT) is an alternative screening procedure for individuals in average risk for colorectal cancer (CRC), with increased adherence, safety and low cost. However, evidence on performance of FIT in high-risk population is inconsistent. Thus, we performed a systematic review and meta-analysis to assess the diagnostic accuracy of FIT for CRC and advanced neoplasia (AN: CRC or advanced adenomas) in asymptomatic high-risk population.
**Aims & Methods:** We systematically searched MEDLINE, EMBASE, Database of Abstracts of Reviews of Effects, Health Technology Assessment Database, Cochrane Library and grey literature sources through February 2016. We included diagnostic studies that assessed the accuracy of FIT for CRC in patients with family history of CRC or personal history of colorectal cancer or advanced adenoma. We accepted studies that utilized colonoscopy or longitudinal follow-up as reference standard. Quality of the studies was assessed using the QUADAS-2 tool.
**Results:** Thirteen studies with 6250 participants assessed the diagnostic accuracy of FIT for AN, while eight of those (4840 patients) provided data specifically for CRC. Nine studies evaluated quantitative FITs, while only four evaluated a qualitative FIT. Only five studies were deemed at low risk of bias. FIT sensitivity for CRC ranged from 0.25 to 1.00 (median 0.84) and specificity from 0.76 to 0.95 (median 0.89). Due to substantial heterogeneity, we synthesized diagnostic accuracy by means of hierarchical summary ROC (HSROC) model, and calculated summary estimates only for subgroups that used the same cutoffs. In studies using cut off values less than 15$\mu$gHb/g feces FIT pooled sensitivity was 97% (95% CI 71 to 100), specificity 91% (95% CI 90 to 92), positive likelihood ratio 10.6 (95% CI 8.9 to 12.5) and negative likelihood ratio 0.03 (95% CI 0.00 to 0.40). In four studies using cut off values 15 to 25$\mu$g/g pooled sensitivity was 93% (95% CI 73 to 99), specificity 94% (95% CI 91 to 96) positive likelihood ratio 15.1 (95% CI 9.5 to 23.9) and negative likelihood ratio 0.07 (95% CI 0.02 to 0.32). Finally, we calculated respective diagnostic accuracy summary estimates for AN (Table 1).

**Table 1:** FIT diagnostic accuracy for advanced neoplasia (colorectal cancer or advanced adenomas) in asymptomatic patients at high-risk.

| | Cut-off used for advanced neoplasia ($\mu$g Hb/g feces) $< 15$ | $15 \leq x \leq 25$ |
|---|---|---|
| Number of studies | 8 | 5 |
| Number of participants | 3959 | 2712 |
| Sensitivity (95% CI) | 60 (39 to 78) | 42 (32 to 54) |
| Specificity (95% CI) | 92 (90 to 94) | 97 (95 to 98) |
| Positive likelihood ratio (95% CI) | 7.9 (5.4 to 11.5) | 13.1 (9.2 to 18.6) |
| Negative likelihood ratio (95% CI) | 0.43 (0.26 to 0.72) | 0.60 (0.50 to 0.72) |

**Conclusion:** FIT has high overall diagnostic accuracy and can be used in patients at high risk for colorectal neoplasia for establishing the diagnosis of colorectal cancer or advanced neoplasia. Nevertheless, it can only rule out colorectal cancer, at either one of the cut-offs assessed.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0917 DIMETHYLARGININE SERUM CONCENTRATIONS EFFECTIVELY IDENTIFY SUBJECTS WITH COLORECTAL CARCINOMA

**Introduction:** Along the progression from normal colonic mucosa to colorectal cancer systemic metabolic pathways may be affected. We aimed to identify metabolic features and possible biomarkers of colorectal carcinoma and advanced adenoma.
**Aims & Methods:** According to the results of screening colonoscopy 399 patients were allocated to one of 3 groups: colorectal carcinoma (CRC, n = 47), advanced adenoma (AA, n = 55), control (CTRL, n = 297). The serum metabolite profile of all subjects was obtained by API 4000 triple quadrupole mass spectrometer (ABSciex) using the AbsoluteIDQTM p180 kit (BIOCRATES Life Sciences). Significant differences in metabolomics analyses

were determined by Significance Analysis of Microarrays (SAM) using false discovery rate (FDR).
**Results:** The metabolite profile of CRC was markedly different from the other two groups while AA und CTRL were found to largely overlap. In particular, CRC showed significantly higher levels of total dimethylarginine (TDMA), spermine, acyl carnitines C16, C16-OH, sphingomyelin (SM) C22:3 and SM C20:2 (adjusted $p < 0.001$). For differentiation between CRC and subjects without carcinoma biomarker analysis based on Receiver Operating Characteristic (ROC) was conducted. For TDMA an area under the curve (AUC) of 0.923 was found. After exclusion of 18 subjects with eGFR $<60$ ml/min as a potential confounder of TDMA serum concentrations an AUC of 0.934 (95% CI: 0.897–0.970) was calculated. Apart from TDMA, the other above mentioned metabolites showed an AUC of 0.926. Combining all of the most significant, in particular TDMA, spermine, SM 22:3, SM 20:2, C16 and C16-OH, an AUC of 0.955 was obtained for distinguishing CRC from AA or CTRL group members.
**Conclusion:** TDMA serum concentrations may serve as a potential biomarker for the identification of colorectal carcinoma. Its role in colon carcinogenesis needs to be investigated further.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0918 GAS CHROMATOGRAPHY SENSOR PLATFORM FOR DIAGNOSING COLONIC NEOPLASIA USING FAECAL SAMPLES

**A. Bond**[1], R. Aggio[1], B. M. Corfe[2], S. Lewis[3], R. Hough[1], C. Probert[1]

**Contact E-mail Address:** ashleybond@doctors.org.uk
**Introduction:** Colorectal cancer (CRC) remains a leading cause of mortality and morbidity worldwide. The incidence has increased by 6% in the last decade and it is the third most common malignancy in the UK, accounting for approximately 15,000 deaths annually, with a 50–55% 5-year mortality rate[1]. Data from the UK Bowel Cancer Screening Programme (BCSP) has clearly demonstrated that detection of CRC at an earlier stage and identification of advanced pre-malignant adenomas can reduce future cancer-associated mortality and morbidity. Currently the BCSP utilises stool-based markers (gFOBt) as a pre-screen prior to colonoscopy which has a sensitivity of 54% and specificity of 80%[2]. Here we propose a platform for the diagnosis of colonic neoplasia.
**Aims & Methods:** Stool was collected from symptomatic patients and those within the BCSP due to undergo colonoscopy. Subsequent outcomes were classified as no-neoplasia, adenoma, cancer and higher-risk adenoma (individual lesion $>1$ cm). The platform is composed of a gas chromatography coupled to a metal oxide gas sensor (OdoReader) and a computer algorithm. The OdoReader separates the volatile organic compounds (VOCs) present in faecal samples, while the computer algorithm identifies resistance patterns associated with specific medical conditions and builds mathematical models to classify unknown samples.
**Results:** A total of 161 faecal samples were analysed, of these 78 had no neoplasia, 18 cancer, 67 at least 1 adenomatous polyp of any size and 18 had higher risk adenomatous disease.

**Table 1:** Results of the repeated double cross-validation applied to faeces samples.

| Comparison | Mean accuracy (%) | Median accuracy (%) | Mean sensitivity (%) | Median sensitivity (%) | Mean specificity (%) | Median specificity (%) |
|---|---|---|---|---|---|---|
| No neoplasia v Adenoma | 72.32 | 71.42 | 72.87 | 71.42 | 71.76 | 71.42 |
| No neoplasia v Cancer | 78.38 | 83.33 | 80.61 | 75 | 76 | 66.66 |
| No neoplasia v Higher risk adenoma | 86.3 | 87.5 | 84.6 | 100 | 88 | 100 |
| High risk adenoma v cancer | 93.36 | 100 | 97.38 | 100 | 89.33 | 100 |

**Conclusion:** This is the first description of an investigation for the positive diagnosis of colonic neoplasia using this methodology. The platform presented here classified samples with accuracies up to 93%. These schemes provide an estimate of out-of-sample predictive accuracy for similar populations. Therefore, the results reported here indicate a successful differentiation of neoplastic and non-neoplastic disease which are superior to FOBt.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0919 USE OF CT COLONOGRAPHY (CTC) IN SELECTED PATIENTS REFERRED ON A SUSPECTED COLORECTAL CANCER PATHWAY TO A UK UNIVERSITY TEACHING HOSPITAL – ASSESSING THE POTENTIAL FINANCIAL BENEFITS OF A STRAIGHT TO TEST MODEL

**T. Garvey**[1], C. Kane[1], A. Plumb[2], R. Vega[1], E. Seward[1]
[1]*Gastroenterology, University College London Hospital, London/United Kingdom*
[2]*Centre For Medical Imaging, University College London, London/United Kingdom*

**Contact E-mail Address:** tgarvey02@qub.ac.uk
**Introduction:** Demands on endoscopy units are rising, with particular pressure coming from changes in the NICE guidance[1] lowering the threshold for suspicion of cancer. Colonoscopy effectively excludes colorectal cancer as a cause for a patient's symptoms but may result in cross-sectional imaging further along the diagnostic pathway and CT colonography (CTC) may address both issues. We propose to pilot a straight to test (STT) model where patients 75 years and over undergo CTC as routine, and assessed the potential financial benefit of this in a UK university teaching hospital.
**Aims & Methods:** Data from 2-week wait referrals for suspected colorectal cancer to UCLH between June 12th 2014 to November 17th 2014 was analysed retrospectively from hospital systems. Data was collected from the time of referral until discharge from the pathway. Using the NHS tariffs (to nearest £) for each investigation/procedure, we calculated the potential financial benefit by directly comparing actual costs incurred versus the potential costs using the STT model.
**Results:** In total, 505 patients were referred, with 477 of these patients sent for further tests; 353 referred for endoscopy (332 colonoscopy), and 110 referred for CTC. The average age of patients for endoscopy was 59.3 years versus 71 years for CTC. In the endoscopy group, 46 patients were aged 75 or older (13%). Table 1 details the costs incurred (excluding staging CT).

**Table 1:** Patients 75 or older who had lower GI endoscopy

| Investigation/Procedure (Tariff in £) | No of patients | Total Cost (£) |
|---|---|---|
| Colonoscopy (433) | 31 | 13423 |
| Colonoscopy + biopsy (465) | 4 | 1860 |
| Therapeutic colonoscopy (469) | 10 | 4690 |
| Flexible sigmoidoscopy (309) | 1 | 309 |
| CTC post endoscopy (238) | 3 | 714 |
| CT abdomen/pelvis (A/P) post endoscopy (137) | 3 | 411 |
| CT Chest/A/P post endoscopy (135) | 1 | 135 |
| | | Total = 21542 |

Had all 46 patients had a CTC initially, this would have resulted in a cost of £10948 and follow-up costs for endoscopy would have been as per further procedures as in Table 1 (£1860 + £4690 + £309), resulting in a total of £17807. In the 5-month period analysed, a potential saving of £3735 (i.e. £21542 − £17807) using the STT model, representing a potential annual saving of £8964.
**Conclusion:** The data demonstrates that potentially ≈ £9000 per annum could be saved by using a STT model to CTC for patients aged 75 years or over in the suspected colorectal cancer pathway. This also would have eased pressure on endoscopy capacity, by diverting patients to excess radiology capacity. Additional factors that could further increase financial savings include careful referral to endoscopy after CTC[2] and stricter adherence to guidelines regarding polypectomy after CTC[3]. These could yield a greater financial benefit as a result of lower conversion rates to endoscopy and associated costs. CTC also offers extra-colonic organ review and may reduce the need for further imaging to explain the patients' symptoms, and account for the 13% in our analysis who required a CT post endoscopy. In our analysis, approximately one-third of patients are estimated to require an endoscopy procedure after CTC in the STT model. Although having two procedures rather than one potentially increases patient distress and inconvenience, it does allow targeted therapeutic colonoscopy, potentially on the same day as the CTC. STT has been demonstrated to reduce outpatient clinic appointments[4], thereby reducing costs which were not analysed in this patient cohort. It does, however, require a trained nurse to screen referrals and discuss the investigation with patients by telephone. Obviously this incurs some expenditure but is associated with greater patient satisfaction[4]. We have embarked on a trial of this novel STT pathway and look forward to presenting the results in the future.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Data regarding diagnostic yield of colonoscopies according to Positive Fecal Inmunochemical Test (FIT) and Rectal Bleeding after excluding anal pathology by external inspection (RB) are scarced.

**Aims & Methods:** Aim. To compare the diagnostic yield of neoplasia when colonoscopy is performed after a positive FIT and in the evaluation of RB. Patients and methods. Retrospective study of colonoscopies performed: 1) within a screening program after positive FIT (Sentinel Gold test) result, 2) as diagnostic evaluation in symptomatic patients (non-screening group) after positive FIT result and 3) due to rectal bleeding after excluding anal pathology. The study was performed between January 1st 2014 and June 30th 2015 in Hospital Clínico Universitario Lozano Blesa, Zaragoza (Spain). Age and sex-adjusted Odds Ratios were calculated by logistic regression analysis.

**Results:** A total of 1.387 colonoscopies (54.1% men) were performed; 524 (37.8%) in colon cancer screening program, 507 (36.6%) due to RB and 356 for diagnostic evaluation after Positive FIT. There were more men in screening group (61.5%) than in the other 2 groups: 48.6% in RB and 50.3% in FIT non-screening group ($p < 0.001$). In 640 (53.9%) colonoscopies neoplasia (adenoma or carcinoma) was found. Neoplasia was more frequent in screening colonoscopies (61.1%) than in those performed by diagnostic evaluation (47.2%) or RB (30%) ($p < 0.001$); (OR = 1.7 IC 95% = 1.3–2.3)($p = 0.002$) compared to FIT in non-screening group; (OR = 2.8, IC95% = 2.1–3.7)($p = 0.000$) compared to RB group. Adenoma was found in 600 (43.3%) colonoscopies and was more frequent in screening colonoscopies (60.1%) than in those performed by diagnostic evaluation (42.1%) or RB (26.6%) ($p < 0.001$); (OR = 2.0 IC 95% = 1.5–2.7)($p = 0.002$) compared to non-screening group and (OR = 3.3 IC95% = 2.5–4.4)($p = 0.000$) compared to RB group. Advanced neoplasia (carcinoma or advanced adenoma) was found in 181 (13%) colonoscopies and was more frequent either in screening colonoscopies (16.4%) or in those performed by diagnostic evaluation (15.4%) than in RB (7.9%) ($p < 0.001$), with no differences between screening and diagnostic group; (OR = 1.7 IC 95% = 1.2–2.6)($p = 0.008$) compared to non-screening group and (OR = 1.6, IC95% = 1.0–2.5)($p = 0.046$) compared to RB group. Carcinoma was found in 89 (6.4%) colonoscopies: 33 (6.3%) in screening group, 34 (9.6%) in those performed by diagnostic evaluation and 22 (4.3%) in RB (p NS). In screening group 78.8% of them were diagnosed in early stages (I or II), compared to 58.8% in diagnostic evaluation and 54.5% in RB (p NS).

**Conclusion:** The yield of neoplasia is low when colonoscopy is performed due to RB. Neoplasia rates found in colonoscopies after a positive FIT are higher than in colonoscopies performed because of RB. FIT is a reasonable option in the diagnostic evaluation of patients prior to colonoscopy.

**Contact E-mail Address:** saitoitsyo@yahoo.co.jp

**Introduction:** In Japan, colorectal cancer (CRC) screening was launched as a national policy for both sexes aged over 40 years in 1992. As a screening tool, 2-day FIT has been widely accepted.

**Aims & Methods:** The objective of this study is to verify the CRC screening by 2-day FIT with cut-off value of 20$\mu$g hemoglobin/g stool and by comparing the screening history. 2,709 cases, who were detected between 2001 and 2013, were analyzed by screening history, age, locations, sizes, and Dukes group.

**Results:** 1,058(39.1%) cases were detected by the first time screening group and 1,651(60.9%) cases were detected by the repeated screening group. In the first-time group, 823(77.8%) cases were between 50 and 74 years old, and 1,211(73.3%) cases were between 50 and 74 years old in the repeated group. The proportion of cases with the age of 50–74-year-old was significantly higher in the first time group than in the repeated group. With regard to the locations of CRCs, in the first-time group, 309 cases were in the rectum (R), 390 cases were in the sigmoid colon(S), 58 cases were in the descending colon (D), 89 cases were in the transverse colon (T), and 160 cases were in the ascending colon (A/C). In the repeated group, 459 cases were in R, 462 cases were in S, 64 cases were in D, 191 cases were in T, and 411 cases were in A/C. The proportion of D+T+A/C was significantly higher in the repeated group than in the first time group. 992 cases in the first time group and 1,538 cases in the repeated group were reported for sizes. In the first-time group, 586 cases were 1–24 mm, 291 cases were 25–49 mm, and 115 cases were over 50 mm. In the repeated group, 1,040 cases were 1–24 mm, 396 cases were 25–49 mm, and 102 cases were over 50 mm. The size of detected cancers by the repeated group was significantly smaller than by the first time group. In the first-time group, 455 cases were intra-mucosal Dukes A, 281 cases were Dukes A, 137 cases were Dukes B, 139 cases were Dukes C, and 34 cases were Dukes D. In the repeated group, 831 cases were intra-mucosal Dukes A, 444 cases were Dukes A, 137 cases were Dukes B, 139 cases were Dukes C, and 30 cases were Dukes D. The proportion of intra-mucosal Dukes A was significantly higher by the repeated group than by the first time group.

**Conclusion:** Repeated FIT screening might be more efficient to detect CRCs in the proximal colon, smaller CRCs, and CRCs of intra-mucosal Dukes A.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

[2]*Gastroenterology, Dongguk University Ilsan Hospital, Goyang/Korea, Republic of*

**Contact E-mail Address:** jjg79@naver.com

**Introduction:** The utilization of positron emission tomography (PET) with computed tomography (CT) has increased exponentially, with increment of cancer and health examination. As an increasing number of unexpected incidental FDG uptake are reported, detection of colonic premalignant lesions besides colon cancer accidently is increased. The aim of this study was to assess the usefulness of PET-CT to detect colonic premalignant lesions, especially colonic advanced adenoma (villous or >10 mm adenomas, high grade dysplasia).

**Aims & Methods:** We retrospectively analyzed the records of 1,011 consecutive patients (1,233 pairs of examinations), who underwent an FDG PET-CT scan and colonoscopy simultaneously within a 1-year interval for various reasons at our center. We did not make clear the order of the incident and excluded the cases in which polyps were removed the lesions by polypectomy or biopsy before PET-CT and the interval between the two examinations exceeded a 1 year. Accuracy and predictive value of PET-CT were analyzed in all polyps and in advanced groups respectively.

**Results:** We included 996 pairs of examinations (excluded cases: 105 previous polypectomy, 102 > 1year interval, 30 no pathologic confirmation). We found that 99 foci revealed meaningful lesions on the same sites in both PET-CT and colonoscopy. The positive and negative predictive values of PET-CT to detect colonoscopic abnormalities were 81.8% (99/121) and 58% (508/875) respectively. The sensitivity and specificity of PET-CT for overall adenoma was 21% and 95.8% each. Moreover, the sensitivity of PET-CT for advanced adenomas was 85% (68/80). The rate of false positive was 4% (22/530) and the lesions were often related to physiologic uptake such as bowel retention and inflammation. The false negative results represented 78.8% (367/466) when there were the lesions on same site in both PET-CT and colonoscopy. Tubular adenoma with low-grade dysplasia was most frequent finding (19.2%). A difference in the mean SUVmax between false-positive (6.2) and true-positive colonic FDG foci (8.2) was statistically significant ($p < 0.01$).
**Conclusion:** PET-CT revealed relatively high positive predictive value and negative predictive value. Especially, the sensitivity for advanced adenomas (85%) was higher than overall sensitivity (21%). However, PET-CT does not seem sensitive tool for colonic premalignant lesions because of the rate of false negative results (78.7%). Nevertheless, the sensitivity for advanced adenomas was significantly high. Thus, we should pay particular attention to detect the lesions detected by PET-CT of high-intensity focal FDG uptake through colonoscopy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** A large number of studies on several cancers (prostate, colon, breast, lung, and others) have been published confirming that patients with cancer have lower NKA compared to healthy control subjects. Low NKA has been linked to a higher risk of cancer and has been reported in CRC patients, with lower activity associated with metastatic disease. The cancer-associated drop in NKA has been demonstrated, either using the Research Use Only Cytotoxicity Assays ($^{51}$Cr cytotoxicity gold standard assay or immunofluorescence assay) or more recently using a novel simple blood test, a commercially available in vitro diagnostic device (IVDD) which measure NKA in a small volume of whole blood (Koo et al, 2013;Lee et al, 2014).
**Aims & Methods:** The aim of this study is to evaluate the sensitivity, specificity, positive and negative predictive values of the IVDD in patients with CRC and adenomatous polyps (AP) Method: The current study measured NKA with a new commercially available blood test in 869 consecutive subjects presenting for screening of CRC or prescribed colonoscopies. Blood was drawn on the day of colonoscopy prior to the procedure and the biological assay performed as per the manufacturer's directions.
**Results:** In the 762 evaluable subjects, statistically significant differences were found between the NKA of patients positive for CRC (n = 21), confirmed by colonoscopy and pathological verification, and that of patients negative for CRC (n = 741) (CRC mean 344.2 pg/mL (SD:881.7), CRC-negative mean 731.5 pg/mL (SD:1019.3), p = 0.001; CRC median 87.0 pg/mL (IQR:49.0–151.0), CRC-negative median 294.8 pg/mL (IQR: 98.7–895.5), $p \leq 0.001$). In this population, the prevalence was 2.8% for CRC and 13.4% for AP≥10 mm. Receiver Operator Characteristics (ROC) analysis of the data show that the optimum cut-off for detection of CRC is 181.3 pg/mL, with an area under the curve of 71%. At a cut-off of 200 pg/mL, sensitivity of the IVDD for detection of CRC was 85.7%, with a specificity of 59.6%, positive and negative predictive values of 5.7% and 99.3% respectively (see Table 1). At a cut-off of 500 pg/mL, statistical analysis of the IVDD for detection of AP10 mm (n = 102) showed a sensitivity of 56.9%, a specificity of 35.0%, positive and negative predictive values of 11.9% and 84.0% respectively. Results of NKA and Colonoscopy Findings.
**Conclusion:** The present study using a new simple blood test confirms that the measurement of NKA may be a useful tool in clinical practice to assess the risk of CRC. This blood test, which demonstrated high sensitivity and negative predictive value for CRC, could be a valuable new tool for the detection of CRC.

**Contact E-mail Address:** christian.stoess@tum.de

**Introduction:** Approximately 20% of all patients with colorectal cancer present with distant metastases at the time of diagnosis. During the last years, whenever feasible, complete resection (R0) of the primary tumor as well as of all metastases has been propagated because of substantially improved survival rates for this approach. However, the prognostic role of resection of the primary tumor remains a matter of debate in the case of non-resectable multiple metastases. This meta-analysis evaluates the current literature regarding the risks and benefits of palliative resection of the primary colorectal cancer in the metastasized setting.
**Aims & Methods:** A Medline/PubMed search was performed in March 2016 in order to identify original studies that compare asymptomatic stage IV colorectal cancer patients who were treated with primary tumor resection (with or without systemic or palliative intended antitumoral therapy) versus patients who were treated without primary tumor resection (with or without systemic or palliative intended antitumoral therapy; with or without palliative surgical procedures other than tumor resection). The identified studies were analyzed according to the PRISMA statement. Baseline characteristics as well as morbidity, mortality and overall survival for the two groups were compared.
**Results:** Of 37,413 screened articles, finally 56 studies with a total of 148,151 patients met the inclusion criteria. All articles were retrospective reports. 94,456 patients underwent palliative primary tumor resection and 53,695 received non-surgical therapy of the primary tumor. Primary tumors of the colon were significantly more often resected than primary tumors of the rectum (71% versus 49%, $p < 0.001$). There was no significant difference in overall morbidity (17 studies, 14% for resection group versus 15% for non-resection group, HR = 1.14, 95%CI 0.77–1.68, $I^2 = 73\%$) or in the rate of bowel obstruction during treatment (4 studies, 11% for resection group versus 19% for non-

CI: Confidence Interval /*Negative test if value for NKA is 200 pg/mL or more / **Neoplasia = all patients with either adenomatous polyps (any size) or CRC; Advanced Neoplasia = all patients with either adenomatous polyps of 10 mm or more or CRC.

resection group, HR = 0.37, 95% CI 0.11–1.23; $I^2$ = 82%). The resection group had a significantly reduced 30-day mortality (18 studies, HR = 0.63, 95% CI 0.42–0.96, $I^2$ = 55%), as well as a reduced risk of death due to any cause (28 studies, HR = 0.51, 95% CI 0.48–0.54, $I^2$ = 80% for adjusted analysis; 12 studies, HR = 0.50, 95% CI 0.44–0.56, $I^2$ = 78% for unadjusted analysis). Heterogeneity was high, although all studies except one estimated improved survival for the resection group.
**Conclusion:** The present level IIb evidence reveals a prognostic benefit for resection of the primary tumor in the palliative treatment of stage IV colorectal cancer patients. However, these results are clearly challenged by a high rate of heterogeneity and only retrospective data reporting. The outcomes of the currently ongoing randomized controlled trials SYNCHRONOUS, GRECCAR 8, and CAIRO 4 are eagerly awaited in order to further elucidate this question.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0925 ARE ENDOSCOPIC SUBMUCOSAL DISSECTIONS OF CECAL TUMOR INVOLVING THE ILEOCECAL VALVE AND APPENDICEAL ORIFICE FEASIBLE?

**K. Hotta**[1], K. Shinoki[2], K. Imai[1], S. Ito[1], Y. Yamaguchi[1], N. Kawata[1], M. Tanaka[1], N. Kakushima[1], K. Takizawa[1], H. Ishiwatari[1], H. Matsubayashi[1], H. Ono[1]
[1]*Division Of Endoscopy, Shizuoka Cancer Center, Nagaizumi/Japan*
[2]*Depratment Of Gastroenterology, Toshiba Rinkan Hospital, Sagamihara/Japan*

**Contact E-mail Address:** k.hotta@scchr.jp
**Introduction:** The ileocecal valve (ICV) and the appendiceal orifice (AO) are considered difficult sites for endoscopic tumor resections because of their complicated morphologies[1]. Additionally, little is known about the outcomes of endoscopic submucosal dissection (ESD) of these sites[2].
**Aims & Methods:** The aim of this study was to evaluate the feasibility and outcomes of ESD of ICV and AO lesions as compared to those of the other cecal lesions. This was a multicenter retrospective analysis involving two referral hospitals (Shizuoka Cancer Center, Toshiba Rinkan Hospital). Cecal lesions treated by ESD were divided into three categories: those involving the ICV (ICV), those involving the AO (AO), and those involving other sites (Ce). Rates of procedural success, complications, and recurrences were analyzed. All evaluated cases were followed by at least one surveillance colonoscopy post-operatively. A P value $<.05$ was considered statistically significant; $P>.05$ was considered not significant (n.s.).
**Results:** A total of 115 patients (median age 69 years, 55 women) with cecal lesions (ICV 24, AO 12, and Ce 79) were treated by using ESD between March 2007 and September 2015. Of the 24 ICV lesions, 8 were located on the upper lip, 9 were on the lower lip, and 7 on the both lips. Completion rates of ESD of ICV, AO, and Ce were 100%, 100%, and 95%, respectively (n.s.). En-bloc resection and en-bloc resection + R0 rates were 92% and 83% for ICV, 83% and 75% for AO, and 89% and 73% for Ce, respectively (n.s.). Mean procedural times (min) of ICV, AO, and Ce were 86, 123, and 90, respectively (n.s.). Immediate and delayed perforation rates were 4.2% and 0% for ICV, 8.3% and 0% for AO, and 7.6% and 5.1% for Ce, respectively (n.s.). Two patients with delayed perforation in the Ce group underwent emergent surgery and the others were treated conservatively. Local recurrence occurred in only two patients in the ICV group and in none in the other two groups ($P < .001$). Both patients were treated with surgical resection. Retrospective review of the films revealed poor endoscopic visualization of the proximal tumor margins, and initial surgical margins of ESD specimens were positive in both patients. No stenosis was occurred after ESD in all patients including ICV group.
**Conclusion:** Our results suggest that ESD of lesions involving ICV and AO is a feasible treatment option because the procedural success and complication rates are similar to those of ESD of other cecal lesions. Local recurrence rate after ESD of ICV lesions was significantly higher than that after ESD of other cecal lesions. Therefore, ESD for ICV lesions with poor tumor margin visibility should be done cautiously.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** kouyuta1101@gmail.com
**Introduction:** The recurrence of T1 colorectal cancers is relatively rare, but some cases do develop even after surgery. In addition, their prognostic factors remain obscure.
**Aims & Methods:** The aim of this study is to clarify whether the surgical resection could reduce the risk of recurrence and to investigate the prognostic factors for T1 colorectal cancers by reviewing their long-term outcomes. We analyzed 1050 patients with T1 colorectal cancers resected at our unit from April 2001 to June 2015. Until February 2016, 932 patients were followed up over a mean period of 50.3 months. Of these, 239 cases met the curative criteria for endoscopic resections as follows: well or moderately differentiated adenocarcinoma, no vascular invasion, budding grade 1, slightly invasive submucosal cancer, and negative margin (Group A). The other 693 cases were out of the curative criteria, and initial or additional surgical resection with lymph node dissection was performed in 583 cases (Group B). But 110 cases were followed up without additional surgery because of their complications or refusal (Group C). Disease-free survival was calculated using the Kaplan–Meier method, and the differences were compared using the log-rank test. And also, to clarify the prognostic factors for T1 colorectal carcinomas, we analyzed the association between recurrence and clinicopathological features using the Cox regression analysis.
**Results:** The recurrence rate in Group A was 0% (0/239), 1.03% (6/583) in Group B, and 3.64% (4/110) in Group C. The risk of recurrence in Group C was higher than that in Group B ($p = 0.016$). Among 10 lesions with recurrences, 6 lesions were located in the rectum, and 6 lesions were poorly differentiated adenocarcinoma or mucinous carcinoma ($p = 0.006$, HR = 6.35, and $p = 0.012$, HR = 9.47).
**Conclusion:** Surgical resection reduced the risk of recurrence. But even after surgical resections, some lesions developed recurrences. More careful surveillance is recommended especially for rectal lesions and also lesions with poorly differentiated adenocarcinoma or mucinous carcinoma.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Oxaliplatin-based hepatic arterial infusion chemotherapy (HAIC) for the treatment of liver metastases (LM) from colorectal cancer (CRC) is only used in few experienced centers. Our aim was to evaluate the efficacy and the safety of HAIC in a retrospective multicentric study conducted in 4 centers which have developed this technic for 5 years.
**Aims & Methods:** Clinical, biological and radiological data of all patients treated in 4 institutions with HAIC for unresectable LM from CRC from October 2011 to January 2016 were retrospectively analyzed. Toxicity data were graded using the NCI-CTCAE V4.0 classification. RECIST criteria were used for response rate analysis. Progression-free and overall survivals were estimated using the Kaplan-Meier method.
**Results:** Sixty-one patients with unresectable LM from CRC were included. Median age was 58 years (range 30 to 81 years). Patients were treated in first line, second line, third line, fourth line and beyond in respectively 4.9%, 50.8%, 19.7% and 24.6% of cases. Oxaliplatin was used for HAIC and a median of 6 courses (range 1 to 18) has been delivered in combination with systemic 5FU-Leucovorin in 43.3% of patients, or in combination and with 5FU-Leucovorin plus other IV chemotherapies or monoclonal antibodies in 55% of patients. Grade 3–4 clinical toxicities were reported in 16% of patients, including 9.8% of grade 3–4 neurotoxicity. Grade 3–4 biological toxicities were reported in 24.6% of patients including 22.2% of neutropenia. Catheter-related complications were observed in 31.1% of patients. Objective tumor response rate was 21.3%, tumor control rate was 70.5%, and hepatic tumor control rate was 73.7%. Median hepatic progression-free survival (PFS), median PFS and overall survival (OS) were respectively 9.0, 6.0 and 13.8 months. The secondary R0-resection rate was 16.4% with a 2-year survival of 80%.
**Conclusion:** These data confirm the feasibility and the safety of HAIC using oxaliplatin in centers which have recently developed this technic. The results in

term of hepatic PFS, PFS and OS, as well as the rate of secondary resections of LM, are promising.

## P0928 CHARACTERISTICS OF THE NON-RESPONDER GROUPS OF THE COLORECTAL CANCER SCREENING PILOT STUDY IN LATVIA

U. Kojalo[1], **D. Santare**[2], I. Kojalo[2], M. Leja[2]
[1]*Statistical Unit, Riga Stradins University, Riga/Latvia*
[2]*Faculty Of Medicine, University of Latvia, Riga/Latvia*

**Contact E-mail Address:** daiga.santare@inbox.lv
**Introduction:** Colorectal cancer is the third most common cancer worldwide and the most common cancer of the digestive tract both globally and in Latvia. Colorectal cancer screening programme in Latvia is opportunistic and with unacceptably low participation rate. Invitation-based colorectal cancer screening (CRC) pilot study took place in Latvia in 2011.
**Aims & Methods:** The objective of the study was to identify and describe the reasons for unwillingness to participate in colorectal cancer screening in Latvia for the groups of non-participation. The non-responders for a faecal occult blood test-based colorectal cancer screening pilot study in Latvia were addressed by asking them to fill out a questionnaire detecting the reasons for non-participation. 8149 questionnaires were sent to all non-responders. A questionnaire was completed and sent back by post by 1191 respondents (14.7%). The results were weighted by age, gender and place of living. Adjusted odds ratio (OR) and 95% confidence interval (CI) was calculated comparing each group with the rest of the sample.
**Results:** Two main categories of reasons for non-participation were identified: reasons related to patient only and reasons related to screening. Screening-related reasons were divided into two subgroups: test related and screening organization related. Results for patient-related reasons group demonstrated highest proportion of participants in oldest age group 70–74 OR = 1.9 (CI 1.2–3.0), they were living in small town or rural area, OR = 1.5 (CI 1.1–2.1), having no opinion about the screening program OR = 2.2 (CI 1.2–3.8). Patients belonging to this group more likely had not visited their general practice doctor (GP) for a while, OR = 1.7 (CI 1.0–2.8) or even never had visited him or did not have a GP, OR = 28.6 (CI 2.8–295.3). They most likely will not participate in CRC screening next year: answer "very unlikely" OR = 9.1 (CI 4.7–17.5). Test-related group was never informed about screening program, OR = 1.6 (CI 1.0–2.6) and claimed that there is not enough information about screening, OR = 1.7 (CI 1.1–2.7) and more likely received guaiac test OR = 1.7 (CI 1.1–2.6). Screening-related group was informed about screening program by their GPs, OR = 1.4 (CI 1.1–1.6), visited their GPs several times a year, OR = 1.6 (CI 1.1–2.4) and more likely will participate in the CRC next year.
**Conclusion:** Differences in groups' characteristics should be taken into account when organising an information campaign about colorectal cancer screening programme. (The study was funded in part from ESF project 2009/0220/1DP/1.1.1.2.0/09/APIA/VIAA/016).

**Introduction:** The leucovorin (FOL) and fluorouracil (5-FU) plus oxaliplatin (l-OHP; FOLFOX) or FOL and 5-FU plus irinotecan (SN-38; FOLFIRI) are widely used as first-line chemotherapy in the treatment of advanced CRC. However, second-line chemotherapy must be abandoned in certain cases due to disease progression, adverse effects or high medical cost in clinical setting. Therefore, the most effective regimen should be selected as first-line chemotherapy. We reported that individualization of first-line treatment (FOLFOX/FOLFIRI/Dual /Poor responder) was possible using CD-DST and individualized first-line therapy with the CD-DST may improve the prognosis of patients with unresectable CRC, especially in poor responders (UEGW: 2014; P1538, 2015; P1681).
**Aims & Methods:** In this prospective study, we evaluated the overall survival (OS) of super responder and medium responder in dual responder, moreover, adequate first-line chemotherapy group and inadequate first-line chemotherapy group in poor responder. Between Mar. 2008 and Dec. 2015, we obtained tumor specimens from 120 CRC patients without preoperative chemotherapy. CD-DST was performed and the growth inhibition rate (IR) was determined by incubation for 24 h with 5-FU and l-OHP (6.0 and 3.0 $\mu$g/ml, respectively) and 5-FU and SN-38 (6.0 and 0.2 $\mu$g/ml, respectively). The cumulative distribution of IR values under each condition was evaluated on the basis that the clinical response to FOLFOX and FOLFIRI is equivalent (approximately 50%). [1] All patients were divided into 4 cohorts: FOLFOX and FOLFIRI responder (dual responder), FOLFOX responder, FOLFIRI responder, and poor responder. Dual responder were divided into 2 cohorts: super responder (the upper 15.9%: one standard deviation) and medium responder. [2] All patients were divided into 3 cohorts: FOLFOX recommended, FOLFIRI recommended, and both regimens recommended. First-line regimens were selected by the attending physician. The OS of super responder and medium responder in dual responder, moreover, the group treated with adequate first-line chemotherapy and the group treated with inadequate first-line chemotherapy in poor responder were evaluated Kaplan-Meier method.
**Results:** In 2 regimens, the distributions of IR% in all patients showed the normal distribution. There were 39 unresectable CRC patients with chemotherapy. [1] In 4 cohorts: The median survival time (MST) of dual responders (n21) and poor responders (n13) was 1,025 and 810 days, respectively. The MST of super responders (n11) and medium responders (n10) was 927 and 1025 days, respectively. The long-term survivor (over 2700 days) belonged to only super responder. [2] In 3 cohorts: In poor responder, the MST of the group treated with adequate first-line chemotherapy (n5) and the group treated with inadequate first-line chemotherapy (n8) was 810 and 337 days, respectively (p = 0.02), moreover, the frequency of chemotherapy of the group treated with adequate first-line chemotherapy and the group treated with inadequate first-line chemotherapy was 22.8 and 11.0 times days, respectively (p = 0.04). Limitation: The periods of observation of 4 patients in super responder were less than 150 days.
**Conclusion:** Administration of the recommended first-line regimen using CD-DST for unresectable CRC patient is important for improvement in the further prognosis. It is most important to administrate adequate first-line regimen, especially in poor responders.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Self-expandable metal stents (SEMS) for colonic decompression were first introduced for palliative purposes in patients with obstructing rectal cancer [1]. Thereafter, indications of SEMS have been expanded to their use as a 'bridge to surgery', relieving colonic obstruction before surgical resection [2]. However, it is still unclear whether SEMS as a bridge to surgery benefits patients with left-sided CRC obstruction [3–7].
**Aims & Methods:** This study therefore compared outcomes of SEMS as a bridge to surgery (SEMS group) and direct surgery (OP group) in patients with left-sided CRC obstruction. Of 113 patients who underwent curative surgery for left-sided CRC obstruction at Asan Medical Center between 2005 and 2011, 42 underwent direct surgery and 71 underwent SEMS insertion followed by elective surgery. After 1:1 propensity score matching, 42 patients were enrolled in both the SEMS and OP groups, and their postsurgical outcomes were compared.
**Results:** The 3 and 5 year overall survival rates were similar in the SEMS (87.0% and 71.0%, respectively) and OP (76.4% and 76.4%, respectively) groups (P = 0.931; Fig. 2a). Similarly, the 3 and 5 year recurrence-free survival rates were similar in the SEMS (91.9% and 66.4%, respectively) and OP (81.2% and 71.2%, respectively) groups (P = 0.581). Only one of the 42 patients in the SEMS group experienced a technical failure of the SEMS, making the technical success rate 97.6%. The clinical success rate of SEMS was 92.9%. SEMS-associated perforation occurred in two patients (4.8%). Elective surgery was performed a median 13.5 (interquartile range, 11.0) days following SEMS insertion. Analysis of CRC surgery showed that six patients in the OP group and three in the SEMS group required two-stage operations, a difference that was not statistically significant (P = 0.483). The rate of temporary stoma formation at discharge was similar in the two groups. Postsurgical complication rates were similar in the SEMS and OP groups (9.5% vs. 16.7%, P = 0.344). The need for postoperative admission to the intensive care unit and the median length of hospital stay following surgery were similar in the two groups.
**Conclusion:** In conclusion, these findings suggest that, if inserted cautiously by qualified endoscopists, SEMS as a bridge to surgery does not have deleterious effects on long-term oncological outcomes in patients with left-sided CRC obstruction and can achieve similar outcomes to the direct surgery.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic stenting with self-expandable metal stents (SEMS) is often performed as a bridge to surgery (BTS) or as palliative therapy (PAL) for malignant colorectal obstruction. This procedure was covered by the National Health Insurance of Japan in January 2012, and now the WallFlex colonic stent and Niti-S colonic stent can be used in Japan. This study aimed to compare the efficacy and safety of the WallFlex colonic stent and the Niti-S colonic stent.
**Aims & Methods:** A total of 78 patients (82 lesions, male/female: 34/38, average age: 73.6 years) underwent endoscopic SEMS placement between November 2011 and April 2016 at Kure Medical Center and Chugoku Cancer Center. The WallFlex colonic stent was used in 36 patients (38 lesions: Group W), and the Niti-S colonic stent, in 42 patients (44 lesions: Group N). Stratified analysis of clinical background, technical success rate, procedure time, clinical success rate, and complications was performed to compare Group W with Group N.
**Results:** Endoscopic SEMS placement was attempted in 78 patients (BTS: 46 patients [59%], PAL: 32 patients [41%]). In Group W, an SEMS was placed in 18 patients (50%) as BTS and in 18 patients (50%) as PAL; in Group N, an SEMS was placed in 28 patients (67%) as BTS and in 14 patients (33%) as PAL. The technical success rate was 100% in both groups. The overall clinical success rate was 91% (71/78): 86% (31/36) in Group W and 95% (40/42) in Group N. Complications within 7 days included abdominal pain (3/36, 8%), poor expansion (1/36, 3%), and fever (1/36, 3%) in Group W, and perforation due to obstructive colitis (2/42, 5%) in Group N. Complications after 8 days included stent-related perforations (4/35, 11%) and stent occlusion (1/35, 3%) in Group W and stent occlusion (2/40, 5%) in Group N. Three patients with stent occlusion were treated with in-stent restenosis using an SEMS, and obstruction-related symptoms improved in all 3 cases. All 4 patients with stent-related perforations had undergone palliative stenting with the WallFlex colonic stent, and the stent-related perforation rate in Group W was significantly higher than that in Group N. On retrospective analysis, predicting perforation on the basis of diagnostic imaging would have been difficult in 2 cases of perforation due to obstructive colitis in Group N. However, 1 of the 2 patients had extreme abdominal pain, with high lactic acid levels on blood gas analysis. The other patient received chemotherapy, including bevacizumab, before obstructive colitis. The median stent patency period was 105.5 days (range 0–942 days) in the palliative stent population; 72% (23/32) of patients maintained stent patency until death or end of follow-up. There was no significant difference in stent patency probability between Group W and Group N.
**Conclusion:** Technical and clinical success rates were very high in both groups. The risk of stent-related perforation was lower when using the Niti-S stent. However, in cases of obstructive colitis, because it is difficult to predict perforation by diagnostic imaging, the risk of perforation should be carefully evaluated with reference to diagnostic indications such as lactic acid levels.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0932 TINED LEAD TEST STIMULATION TO PREDICT LONG-TERM BENEFIT FROM SACRAL NERVE STIMULATION IN PATIENTS WITH CHRONIC CONSTIPATION (TILTS-CC)

Y. Yiannakou[1], **K. J. Etherson**[1], H. Close[2], A. Kasim[2], M. Mercer-Jones[3], S. Plusa[4], R. Maier[2], S. Green[1], J. Cundall[1], C.H. Knowles[5], J. Mason[2]

**Introduction:** The primary objective was to assess the value of the tined lead active/sham testing to predict long-term benefits of sacral nerve stimulation (SNS) for patients with chronic constipation. Secondary objectives included quantifying placebo response during temporary testing, efficacy of permanent SNS, any baseline predictors of response and the effect of SNS on quality of life.
**Aims & Methods:** This study used a randomised double-blind 2-period cross-over design. Tined lead testing was performed over a 6-week period. The cross-over design alternated each patient between ACTIVE and SHAM sub-sensory stimulation periods with an intervening washout. Based on response to treatment patients were classified as discriminate responder (improved with ACTIVE only), indiscriminate responder (improved with SHAM) or non-responder. Discriminate or indiscriminate responders proceeded to IPG (implanted pulse generator) and permanent SNS. Follow-up was for 6 months in all patients with a 3-month assessment in IPG patients.
**Results:** 45 patients were randomised, of whom 29 (64.4%) were responders to the testing phase. Of these, 27 were implanted with a permanent IPG. During the testing phase, 7 (18%) were discriminate responders, 22 (56%) were indiscriminate responders and 10 (26%) were non-responders. At 6 months there was no significant difference between discriminate and indiscriminate responders (60% vs 57%, p = 0.76) in the primary endpoint (a => 0.5 reduction in PAC SYM). Results showed no significant differences during the testing phase by timing or sequence, supporting the success of blinding. The study was terminated prematurely due to a persistent and unacceptably high serious infection rate: 10 infections, of which 9 were severe and led to removal of the lead (n = 6) or IPG (n = 3). Among permanently implanted patients there was a modest improvement in PAC SYM (−1.03, 95%CI −1.39 to −0.07) at 3 months, but benefit reduced by 6 months (−0.69, 95%CI −1.00 to −0.37).
**Conclusion:** In patients with constipation: (1) temporary testing is a poor predictor of response to SNS at 6 months; (2) there appears to be a strong and prolonged placebo response to both the testing phase and follow-up; (3) the extended testing period is associated with unacceptably high infection rates. Prolonged failure to recruit to the planned sample size and small sub-group numbers mean that further conclusions about SNS benefit at 6 months cannot be drawn. This abstract presents independent research funded by the National Institute for Health Research (NIHR) under its Research for Patient Benefit (RfPB) Programme (Grant Reference Number PB-PG-1010-23212). **Introduction:** Observational studies show a strong association between delayed intestinal transit and intestinal methane production. Experimental data suggest a direct inhibitory activity of methane on the colonic and ileal smooth muscle. The archaeon *Methanobrevibacter smithii* is the predominant methanogen in the human intestine. Certain statins can inhibit archaeal methane production without affecting other gut organisms as demonstrated in livestock and humans.

**Aims & Methods:** The aim of this trial (NCT02495623) is to assess the efficacy of a proprietary modified release lovastatin lactone in lowering intestinal methane production. Subjects with irritable bowel syndrome with constipation (IBS-C) and a breath methane value >10 parts per million (ppm) at screening were randomly assigned to receive placebo, SYN-010 dose 21 mg or SYN-010 dose 42 mg orally once daily for 28 days. The primary endpoint was the change from baseline in the area under the curve (AUC) of breath methane production at Day 7, based on a 180-minute lactulose breath test (LBT). Secondary efficacy assessments included change in methane AUC at Day 28, stool frequency and consistency, abdominal pain, bloating, and safety data. A necessary normalisation of the severely left-skewed breath test data, not pre-specified in the statistical analysis plan, was accomplished by square root transformation; paired t-tests were performed allowing each subject to serve as their own control. The analyses of the clinical outcomes were performed with untransformed raw data.

**Results:** 63 subjects were enrolled in the trial. After 7 days statistically significant (SS) reductions in breath methane levels were seen in the 42 mg dose arm ($p = 0.02$ but not the 21 mg dose arm ($p = 0.64$). In contrast, after 28 days both dose arms, 21 mg and 42 mg, showed SS reductions ($\Delta$) of breath methane levels, except for placebo (Table). Placebo $\Delta$ – 31.0, $p = 0.15$, SD 74.3; 21 mg dose $\Delta$ – 22.6, $p = 0.03$, SD 55.0; 42 mg dose $\Delta$ −34.3, $p = 0.01$, SD 59.0; Unit: ppm*hours. Percentage of weekly abdominal pain intensity and stool frequency responses are shown in the Table. The definition of these outcomes are consistent with the FDA IBS guidance. A SS improvement in the stool frequency response for the 21 mg dose group was apparent. The 42 mg dose group was numerically better (see Table). No serious adverse events were observed.

Breath Methane and Clinical Outcomes

| | Dose | Placebo | 21 mg | 42 mg | Combined |
|---|---|---|---|---|---|
| | Number | 22 | 22 | 19 | 41 |
| | Decrease in Methane | | | | |
| **Day 7** | Mean (SD) | -10.6 (53.5) | 11.2 (52.4) | -34.6 (63.7) | |
| | p-value | 0.88 | 0.64 | 0.02 | |
| **Day 28** | Mean (SD) | -31.0 (74.3) | -22.6 (55.0) | -34.3 (59.0) | |
| | p-value | 0.11 | 0.03 | 0.009 | |
| | Abdominal Pain Intensity Response (Improvement)* | | | | |
| | Mean (SD) | 10.7 (30.2) | 14.8 (25.2) | 29.0 (37.9) | 21.3 (32.1) |
| | p-value | - | 0.26 | 0.08 | 0.11 |
| | Stool Frequency Response (Improvement)** | | | | |
| | Mean (SD) | 16.3 (22.8) | 41.3 (36.5) | 22.4 (28.7) | 32.5 (34.1) |
| | p-value | - | 0.02 | 0.54 | 0.07 |

*An Abdominal Pain Intensity Weekly Responder is defined as a patient who experiences a decrease in the weekly average of worst abdominal pain in the past 24 hours score (measured daily) of at least 30 percent compared with baseline weekly average. **A Stool Frequency Weekly Responder is defined as a patient who experiences an increase of at least one complete spontaneous bowel movement (CSBM) per week from baseline.

**Conclusion:** This is one of the first trials to target a specific component of the intestinal microbiome. It shows that SYN-010 has the potential to reduce intestinal methane production as measured by breath test in patients with IBS-C. This study was not powered to show improvement in clinical parameters. The unexpected finding of SS improvement in stool frequency response for the 21 mg dose group and encouraging trends in other clinical parameters are therefore particularly noteworthy. Further development of SYN-010 appears warranted.

**Contact E-mail Address:** ching.lam@nottingham.ac.uk

**Introduction:** Irritable bowel syndrome (IBS) is a heterogenous condition. Non-invasive biomarkers which could identify the mechanism of disease in subtypes of IBS coud be valuable.

**Aims & Methods:** Our aim was to assess gut transit, small bowel water content and colonic regional volumes of different clinically defined IBS subtypes both fasted and post-prandially using MRI scans. 34 healthy volunteers (HV), 30 IBS with diarrhoea (IBS-D), 16 IBS with constipation (IBS-C) and 11 IBS with mixed bowel habit (IBS-M) underwent whole gut transit and small and large bowel volumes assessment with MRI scans from $t = 0$ to $t = 360$ min.

**Results:** Median (IQR)**:** See table 1. Fasting small bowel water content in IBS-D and IBS-M were 20 (10–47) and 21 (10–35), significantly less than HV at 44 (15–70) mL, $p = 0.02$ as was the postprandial area under the curve (AUC) $p < 0.01$. The fasting transverse colon volumes in IBS-C were significantly larger at 253 (200–329) compared to HV, IBS-D and IBS-M whose values were 165 (117–255), 212 (103–274) and 169 (119–227) mL respectively, $p = 0.02$. Whole gut transit time (WGTT) for IBS-C was prolonged at 69 (51–111), compared to HV at 34 (4–63) and IBS-D at 34 (10–77) h, $p = 0.02$. Bloating score (VAS 0–10 cm) correlated with transverse colon volume at $t = 405$ min, Spearman $r = 0.21$, $p = 0.04$.

**Conclusion:** The constricted small bowel in IBS-D & IBS-M and the dilated transverse colon in IBS-C point to significant differences in underlying mechanisms of disease.

**Disclosure of Interest:** R. Spiller: I have received research funding from Lesaffre and Ironwood and free drug for clinical trial from Norgine. I also acted on Advisory Boards for Almirall, Astellas, Ibsen and Danone.

## P0935 ABNORMAL BALLOON EVACUATION TEST DOES NOT IDENTIFY WHICH PATIENTS WILL RESPOND TO BIOFEEDBACK; ANORECTAL MANOMETRY OR EMG, AND STRUCTURAL EVALUATION ARE NEEDED

**G. Chiarioni**[1], O. Palsson[2], S. Heymen[2], M. Simrén[3], F. Cidoni[1], W. E. Whitehead[4]

**Introduction:** The utility of anorectal manometry (ARM) and pelvic floor EMG for diagnosing functional defecation disorder and selecting patients for biofeedback treatment has been challenged. Our aim was to determine whether patients with different causes of difficult defecation are equally responsive to biofeedback.

**Aims & Methods:** In 132 patients with an abnormal balloon evacuation test (BET > 2 min) and fewer than 3 complete spontaneous bowel movements per week (CSBM), digital rectal examination, ARM, pelvic floor EMG, and defecography were used to classify 33 as obstructed defecation (OD), 20 as dyssynergic defecation only (DD; paradoxical contraction or inability to relax pelvic floor muscles when attempting to defecate), 10 as inadequate rectal propulsion only (IRP; rectal pressure <45 mmHg when attempting to defecate), and 67 as combined DD and IRP (DD/IRP). A nurse who was unaware of the diagnostic test results provided all patients with 5 biofeedback training sessions designed to teach relaxation of pelvic floor muscles simultaneously with contraction of abdominal wall muscles when evacuating. Primary outcomes were self-ratings of improvement in constipation symptoms on a 7-point scale (“markedly worse” to “markedly better”), and changes in CSBMs.

**Results:** (1) OD patients reported less improvement ($p < .001$) than DD, IRP, or DD/IRP patients, which were similar to each other. (2) OD patients increased CSBMs by a smaller amount than the other 3 groups ($p < .001$), which were similar. (3) Most other symptoms of difficult defecation (straining, hard stools, sensations of incomplete defecation or anal obstruction, <3 stools/week, painful defecation, Bristol Stool Scale scores, and ratings of life interference) improved less in the OD group compared to the other groups (all $p < .05$). (4) Anal canal resting and squeeze pressures and rectal sensory thresholds revealed no differences between groups.

**Conclusion:** The BET is insufficient for identifying patients who should be treated with biofeedback. Physical examination, ARM, EMG, and defecography provide additional utility.

## P0936 SIGNIFICANCE OF PUSH TEST AND BALLON EXPULSION TEST ESTABLISHED BY HIGH-RESOLUTION ANORECTAL MANOMETRY (HRAM) AND ITS SIGNIFICANCE FOR DYSSYNERGIC DEFECATION DIAGNOSTICS

**O. Storonova**[1], A. Trukhmanov[2], V. Ivashkin[3]
[1]*Neurogastroenterology &motility;, First Moscow Sechenov Medical University, Moscow/Russian Federation*

**Contact E-mail Address:** storonova@yandex.ru

**Introduction:** The lack of disclosure of the external anal sphincter (AS), or a paradoxical tension during the push test and inability of the patient to expel the balloon from the rectum considered as direct evidence of dyssynergic defecation by some researchers. Meanwhile other authors detect these patterns in healthy individuals. It is of interest to determine the importance of these parameters for the diagnosis of dyssynergia of the pelvic floor muscles.

**Aims & Methods:** To determine the frequency of dyssynergia and its prevalent type in asymptomatic healthy subjects. 26 asymptomatic healthy adults (18 women, 8 men) median age was 35.03 years (19–59) were studied. We performed them a high-resolution anorectal manometry (HRAM) using a 20 channels silicone water-perfused catheter (Solar GI, MMS, Netherlands). The following HRAM parameters were analyzed: push relaxation percentage of external anal sphincter (EAS) during push test, success of balloon expulsion test (BET) on left lateral decubitus position with latex balloon inflated to 50 mL. The statistical analyses were performed using Statistica for Windows 6.0 (StatSoft Inc.).

**Results:** Push relaxation percentage of EAS was 21.38 (-38.1; 77.3). According to dyssynergia classification (Rao S., 2004) signs of dyssynergia were identified in 9 persons (34.6%): I type was established in 6 (23.08%), type III in 3 persons (11.5%). 15 subjects (57.7%) were not able to expel the balloon. Push relaxation of EAS was positively correlated with successful results of BET ($r = 0.61$, $P = 0.001$) and positively correlated with I type of dyssynergia ($r = 0.77$, $P = 0.00$).

**Conclusion:** In asymptomatic healthy adults investigation by HRAM revealed signs of dyssynergia of pelvic floor muscles (predominantly I type). More than half of the subjects failed to comply with the expulsion of the balloon from the rectum. Therefore, these indicators cannot be considered as the only diagnostic criteria of dyssynergic defecation and should be confirmed by other methods of the pelvic floor muscles functional state examination.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0937 IMPROVEMENT OF BOWEL HABITS AND PATIENT'S SATISFACTION – A POOLED ANALYSIS OF MOST RECENT BISACODYL AND SODIUM PICOSULFATE TRIALS

**S. Niedermeier**[1], H. Weigmann[2], E. Richter[3], P. Kammann[1]

**Contact E-mail Address:** sabine.niedermeier@boehringer-ingelheim.com

**Introduction:** The prescription-free laxatives bisacodyl (BIS) and sodium picosulfate (SPS) are metabolized to form the same locally acting active metabolite bis-(p-hydroxyphenyl)-pyridyl-2-methane (BHPM). Both laxatives are well recognised as safe and effective treatment options for patients suffering from constipation.

**Aims & Methods:** The aim of this post-hoc analysis was to investigate the extent to which diphenyl methane laxatives (BIS/SPS) lead to objective (bowel movement frequency) and subjective improvements (Patient Assessment of Constipation Quality of Life (PAC-QOL©)) in patients suffering from chronic constipation (Rome III criteria). A pooled analysis was performed with the two recent clinical trials [1, 2], in which a total of 735 patients were randomized in a SPS/BIS:placebo ratio of 2:1. The analysis is based on 718 (SPS/BIS: 468, placebo: 250) patients constituting the full analysis set (FAS) = treated patients providing post-treatment data for the primary endpoint 'mean number of complete spontaneous bowel movements (CSBMs)/week over 4 weeks'.

**Results:** With laxative treatment, the mean number of CSBMs/week increased from 1.0 (baseline week) to a weekly mean of 4.4 over 4 weeks compared to an increase from 1.1 to 1.8 with placebo. Over the 4 weeks of treatment, 59.4% of laxative treated patients achieved a mean number of $\geq 3$ CSBMs/week compared to only 22.4% in the placebo group.

The PAC-QOL© overall score as well as all four subscale scores improved remarkably stronger after 4 weeks of treatment with BIS/SPS compared to placebo ($p < 0.0001$ for all). The items showing the highest odds ratio (OR) within each of the main four subscales were: "physical discomfort": feeling of heaviness (OR = 5.9), "psychosocial discomfort": eating less and less (OR = 3.0), "worries and concerns": being more and more bothered by not being able to open bowels (OR = 3.8) and "satisfaction": having had fewer bowel movements than desired (OR = 7.6).

The highest mean treatment difference between BIS/SPS and placebo was observed in the subscale "satisfaction" with the corresponding single PAC-QOL© items providing odds ratios in the range of 4.2 to 7.6. Notably, 64.3% of the patients in the active group showed a clinically relevant improvement $\geq 1$ point [3] in PAC-QOL© subscore "satisfaction" compared with 26.1% receiving placebo ($p < 0.0001$). Those results are in the range of improvements to be seen with prescription laxatives such as prucalopride for which corresponding improvements in this PAC-QOL© subscore were reported in 45.8% of the treated patients compared with 21.5% with placebo [4].

**Conclusion:** The data analysed show that chronic constipated patients receiving bisacodyl or sodium picosulfate experienced a significant improvement in their bowel habits and in their disease-related quality of life compared to placebo. Thus, the diphenyl methane laxatives investigated were demonstrated to offer a significant benefit for constipated patients not only with respect to the laxative effect itself but also in terms of their well-being.

## P0938 GOOD AGREEMENT BETWEEN ORO-ANAL TRANSIT TIME MEASURED BY WIRELESS MOTILITY CAPSULE AND RADIOPAQUE MARKERS IN PATIENTS WITH FUNCTIONAL BOWEL DISORDERS

**K. Engstrand**, P. Jerlstad, A. Lidén, G. Näslin, G. Ringström, M. Simrén, H. Törnblom
*Dept Of Internal Medicine & Clinical Nutrition, Sahlgrenska Academy, University Of Gothenburg, Inst of Medicine, Gothenburg/Sweden*

**Contact E-mail Address:** karin.engstrand@vgregion.se

**Introduction:** The wireless motility capsule (WMC) is a relatively new technique for transit measurements, where most studies performed until now have compared the agreement with scintigraphy or radiopaque markers (ROM) studies in cohorts of constipated patients, but less so in patients with other bowel habits.

**Aims & Methods:** The aim of this study was to evaluate the agreement between oroanal transit time (OATT) measured with WMC and ROM, and to describe segmental transit time in patients with functional bowel disorders (FBD) with different predominant bowel habits. We prospectively included patients with a FBD (Rome III criteria). Both procedures were performed during the same time period with the WMC study starting day 1 and the ROM study starting day 2. Medications with an effect on GI motility were discontinued at least 48 h before the investigations. On day 1, the patients swallowed a WMC after ingesting a standardized energy bar (260 kcal). Six hours later the patients were allowed to continue with their habitual diet. Day 2–6 the patients swallowed 10 ROM in the morning, day 7 the intake of ROM was divided into 5 in the morning and 5 in the evening in order to optimize detection of accelerated transit. Flouroscopy was used in the morning of day 8 to count the remaining ROM. OATT was categorized as normal, accelerated or delayed by use of normal values for healthy men and women without GI symptoms(1, 2).

**Results:** We included 52 patients with a FBD (41 women), median age 39 (range 20–69) years): 43 (83%) patients had irritable bowel syndrome (IBS) (constipation (IBS-C) 22, diarrhea (IBS-C) 13, mixed bowel habits (IBS-M) 8) and 9 (17%) had functional constipation (FC). One patient could not swallow the WMC and three patients did not complete the WMC study because of a long transit time (categorized as delayed transit). Two patients chose not to start the ROM investigation, which means that we had complete data from 48 WMC studies and 50 ROM studies. Segmental transit times measured by the WMC are shown in Table 1. FC patients had longer gastric emptying time than IBS-D ($p = 0.003$) and IBS-M ($p = 0.02$). There were no differences in small bowel transit time between the groups. FC patients also had longer colonic transit time (CTT) and OATT than all the IBS subgroups, IBS-C ($p = 0.02$ and 0.01 respectively), IBS-D ($p = 0.001$ for both) and IBS-M ($p = 0.002$ for both). Additionally, IBS-C patients had longer CTT and OATT than IBS-D ($p = 0.01$ for both). Among the 47 patients who had evaluable data from both investigations there was a significant correlation between OATT measured by the WMC and ROM (Spearmańs rho 0.56; $p < 0.0001$), and the classification of OATT (accelerated-normal-slow) was identical in 42 of 49 patients (Cohens kappa = 0.70; $p < 0.0001$) that could be classified by both investigation types.

**Table 1:** Segmental transit (median (range)) measured with WMC (GET = Gastric emptying time, SBTT = Small bowel transit time, CTT = Colonic transit time, OATT = Oro-anal transit time).

| | GET (h) | SBTT (h) | CTT (h) | OATT (h) |
|---|---|---|---|---|
| IBS-C | 2.6 (0.7–19.7)$_{n=22}$ | 4.7 (3–11) $_{n=22}$ | 31 (0.6–156)$_{n=20}$ | 49 (12–167)$_{n=20}$ |
| IBS-D | 2.3 (1.1–4.5)$_{n=13}$ | 4.2 (1.4–6.3)$_{n=13}$ | 19 (4–68) $_{n=13}$ | 25 (10–72)$_{n=13}$ |
| IBS-M | 2.3 (1.3–4) $_{n=7}$ | 5.6 (3.6–7.4)$_{n=7}$ | 22 (16–42) $_{n=7}$ | 29 (24–51) $_{n=7}$ |
| FC | 3.6 (2.7–7.2)$_{n=9}$ | 5.6 (3.5–22)$_{n=9}$ | 87 (44–216)$_{n=7}$ | 108 (53–223)$_{n=7}$ |

**Conclusion:** There is a good agreement between OATT measured by WMC and ROM in patients with functional bowel disorders, and the vast majority of patients are classified into the same categories of normal or abnormal transit with both techniques. The WMC study was well tolerated by patients with functional bowel disorders and has the advantage of providing additional data regarding segmental transit time, as well as pH and pressure data.

### P0939 WHAT IS MISSED AND WHAT IS STILL NEEDED FOR EFFICIENT TREATMENT OF CHRONIC CONSTIPATION?

**D. Carter**[1], R. Dickman[2]
[1]*Gastroenterology, Sheba Medical Center Dept. of Gastroenterology, Ramat Gan/Israel*
[2]*Sackler Faculty Of Medicine, Tel Aviv University, Tel Aviv/Israel*

**Contact E-mail Address:** dr.dancarter@gmail.com

**Introduction:** Constipation is a common complaint affecting 15% of the general western population. Abundant treatment options are available, though there is no one suitable treatment option for all. Several national societies have released recommendation for the evaluation and treatment of chronic constipation. However, the common practices of GI specialists (GS) and family practitioners (GP) for treating chronic constipation are not well defined, and there are still unmet needs for effective treatment of constipation.
**Aims & Methods:** Aim: To compare the common practices of GPs and of GS specialist for the treatment of constipation, and to examine the conceived limitations of the available treatment options.
Methods: During January to February 2016, an internet survey was sent nationwide and at random to 290 GS and 1312 GPs to assess how treatment strategies and limitations for treatment options for constipation. We assessed for the burden of constipation, indications for referral for a GI consultation, criteria for treatment selection and main unmet needs.
**Results:** 40 GI specialists (18%) and 132 FP (10%) returned the questionnaire. Both groups treat 10–11 patients/week (mean age 41–50 years). The common indications for GI consultation were presence of warning signs (weight loss in26%, new onset constipation 17%, occult blood loss 16%, rectal bleeding 16%, anemia 12%) and unresponsiveness to therapy (24%). Both GPs and GS stated that the most desired effect of therapy was improvement in number of bowel movements and bloating, followed by rapid improvement in the GPs and desire for prescription of the same medication by the GS. GS regularly used polyethylene glycol as first line of therapy, biascodyl as second line and Prucalopride as a third line. GPs used osmotic laxatives (PEG and lactulose) and biascodyl as treatment options for all 3 lines off therapy. About 56% of the GS and 50% of the GPs stated that they would consider prescribing a new medication, if it had high efficacy, rapid action and did not cause addictive response.
**Conclusion:** The awareness to the possible treatment options and to the recommended order of prescription differs between GS and GPs. There are still unmet needs for optimizing the treatment of constipation.

[3]*Digestive System Research Unit, University Hospital Vall Ďhebron, Digestive System Research Unit, University Hospital Vall dHebron, Departament de Medicina. Universidad Autónoma de Barcelona, Ciberehd, Barcelona, Barcelona/Spain*

**Contact E-mail Address:** cmalagelada@gmail.com

**Introduction:** Automatic and non-invasive diagnostic methods for the evaluation of digestive function have been developed in our laboratory using images obtained by internal (endoscopic capsule) and external (abdominal magnetic resonance) imaging techniques. We applied these combined methodologies to patients with cystic fibrosis. Cystic fibrosis is a multisystem disease caused by mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) protein. The loss of CFTR in the gut results in a dehydrated and acidified intestinal milieu, which consequently impairs small bowel motility and clinically manifests as intestinal obstruction and small intestinal bacterial overgrowth. However, intestinal motor dysfunction in CF has only been evidenced by indirect transit tests.
**Aims & Methods:** Aim: To prove the consistency between parameters of gut function detected by external and internal imaging. Methods: Eight patients (3 men, 5 women; age range 23–38 years) with CF were studied on two separate days with the endoscopic motility capsule procedure (PillCam SB2, Given Imaging) and with an abdominal magnetic resonance (MR). Both studies were performed after a 48 h low-residue diet and without bowel preparation. Morpho-functional analysis of the images was performed with specific, previously validated, computer vision programs based on machine learning techniques.
**Results:** Abnormal intestinal motility was detected in six patients (75%) by endoluminal image analysis. Patients with CF exhibited a low number of intestinal contractions as compared to normal values in healthy subjects ($2.0 \pm 0.3$ vs $5.2 \pm 0.3$ contractions/min; $p < 0.001$), less endoluminal motion ($13 \pm 3$ vs $4 \pm 1\%$ static sequences; $p < 0.001$) and greater retention of turbid content ($61 \pm 8$ vs $28 \pm 4\%$ of small bowel images; $p < 0.001$). Ileal perimeter, measured in MR images, correlated inversely with the contractile activity ($R = -0.85$; $p = 0.015$) and with the presence of intraluminal content ($R = 0.80$; $p = 0.030$) measured by endoluminal imaging analysis.
**Conclusion:** Morpho-functional analysis of internal and external imaging techniques reflect analogous views on gut function.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0941 LEVATOR ANI TENDERNESS IN PATIENTS WITH DYSSYNERGIC DEFECATION

**G. Chiarioni**[1], O. Palsson[2], S. Heymen[2], C. Pedrazzani[3], W. E. Whitehead[4]
[1]*Gastroenterology, AOUI Verona, Verona/Italy*
[2]*Unc Center For Functional GI And Motility Disorders, University of North Carolina at Chapel Hill, Chapel Hill/United States of America/NC*
[3]*Division Of General And Hepatobiliary Surgery, University of Verona, Verona/Italy*
[4]*Dept. Of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC/United States of America*

**Contact E-mail Address:** chiarioni@tin.it

**Introduction:** Recently we reported the surprising finding that patients with levator ani syndrome share many pathophysiologic features with dyssynergic defecation (DD): Among 94 patients with a primary complaint of chronic proctalgia who had tenderness on digital rectal exam, 86%% exhibited paradoxical contraction of pelvic floor muscle when straining to defecate and 87% could not evacuate a 50-ml water-filled balloon. Moreover, improvement in these parameters was associated with reductions in rectal pain
**Aims & Methods:** Aim: To further explore the hypothesis of shared pathophysiology by determining whether patients with DD report tenderness when traction is applied to the levator ani muscles. Methods: 242 patients with chronic constipation referred to an ambulatory GI practice in Verona, Italy, were evaluated by physical examination including palpation of the levator muscles by standard protocol, questionnaire, balloon evacuation test (BET), and (if they failed to respond to fiber treatment) by anorectal manometry (ARM). Patients were diagnosed DD if they failed to relax anal canal pressures and anal EMG on ARM and also failed to evacuate a 50-ml water filled balloon within 2 minutes. The last 148 of 242 referrals had a second physical exam by an independent physician to assess reliability of tenderness assessment.
**Results:** Three subjects were excluded for technical reasons and 41 due to a positive response to fiber supplements, leaving 198 for analysis. Average age was 45 years and 94% were female. Constipation type was DD in 44.4%, normal transit (NT) in 28%, slow transit (ST) in 11%, and outlet obstruction in 14.1%; 5 had dyssynergia on manometry but normal BET. Tenderness on digital rectal exam was reported by 87/198 patients (43.9%). 71.2% of DD reported tenderness compared to 23.4% of patients with other types of constipation ($p < .001$). 73.6% of patients reporting tenderness also reported that they had pain with 25% or more of their defecations vs. 15.3% for those without tenderness ($p < .001$). Patients reporting tenderness were also younger (41.8 vs. 47.6 years, $p = .007$). Two independent physician examiners agreed on the assessment of tenderness in 93.5% of cases.
**Conclusion:** These data provide further support that the pathophysiology of DD is similar to that of levator ani syndrome because 71.2% of patients with DD report tenderness on palpation of the levator ani muscles and 73.6% of those with tenderness during digital rectal exam report pain during defecation. Assessment of levator ani tenderness is reliable (93.5% agreement). [Supported in part by R01 DK31369]

[5]*Dept. Of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC/United States of America*

**Contact E-mail Address:** opalsson@med.unc.edu

**Introduction:** The new Rome IV diagnostic criteria for fecal incontinence (FI) require higher minimum frequency of accidental leakage of stool than the Rome III criteria (2+ times vs. 1+ times a month). The population prevalence of Rome IV FI and associated symptom and demographic risk factors are unknown.

**Aims & Methods:** A three-country general population survey conducted on behalf of the Rome Foundation was used to assess national FI rates, prevalence difference between demographic groups, and the association of FI with stool consistency abnormalities and urge. This secure internet survey included the Rome IV Diagnostic Questionnaire for Adults and demographic questions, and was completed by a sample of individuals age 18 years and older in the US, UK and Canada (2,100 in each country) provided by Qualtrics (Provo, Utah). Quota-based sampling was used to ensure equal proportion of sex (50%/50%) and age groups (40% age 18–39, 40% 40–64, 20% 65+) across countries, and to control education distributions (30% maximum with college degree or equivalent). Chi-Square analysis was used to compare FI rate differences between countries, and demographic and symptom subgroups. Latest national census figures were used to calculate correction weights for age (in 5-year bins) and gender proportions, and to obtain census-adjusted FI prevalence estimates for each country.

**Results:** Data from 5,931 of 6,300 total survey completers were retained for analysis (49.2% female; mean age = 47.4, range 18–92; 1,949 US, 1,994 UK, 1,988 Canada) after 369 inconsistent responders were eliminated. Sex or age group proportions were not significantly different between countries due to quota-based sampling. Of the total sample, 16.1% reported some FI symptoms, but 3.3% met Rome IV FI criteria. FI rate was higher ($p < 0.05$) in females than males in the UK (3.5% vs. 2.0%) and Canada (4.0% vs. 2.2%), but not in the US (4.0% vs. 4.4%). National raw and census-weighted (in parentheses) FI rates were 4.2% (4.2%) in the US, 3.2% (2.8%) in Canada and 2.7% (3.1%) in the UK. Individuals aged 18–34 and 35–49 years had significantly lower ($p < 0.01$) FI rates compared to those aged 50–64 and 65+ in Canada and the UK (see Table), but those age group differences were not significant in the U.S. Among individuals meeting Rome IV FI criteria, FI prevalence was significantly increased by the presence of frequent (>20% of BMs) loose stools (OR = 9.10, 95% CI = 6.53–12.66), urgency (OR = 10.66, 95% CI = 7.55–15.08), and hard stools (OR = 2.66, 95% CI = 2.00–3.55).

**Table:** General Population Rome IV FI Prevalence Rates in the US, Canada and UK.

| | Age 18–34 | Age 35–49 | Age 50–64 | Age 65+ | Total Sample | Total Sample Census-adjusted |
|---|---|---|---|---|---|---|
| US (n = 1,949) | 3.8% | 3.5% | 4.8% | 4.4% | 4.2%[2] | 4.4% |
| Canada (n = 1,998) | 0.5%[1] | 1.8%[1] | 4.6% | 5.9% | 3.2% | 2.9% |
| UK (n = 1,994) | 1.4%[1] | 1.4%[1] | 4.1% | 4.1% | 2.9% | 3.2% |

[1]Significantly lower than the rate in the 2 older age groups. [2]Significantly higher than the UK rate.

**Conclusion:** This first population assessment of Rome IV fecal incontinence shows that the condition is present in 3–4% of the general adult population. It tends to be more common in women than men and to be more prevalent after age 50. Frequent hard and loose stools and frequent urgency to defecate are all associated with increased FI risk. **Contact E-mail Address:** marcocostasilva87@gmail.com

**Introduction:** HIV and human papilloma virus (HPV) infection are known risk factors for the development of anal dysplasia (AD). The risk of anal cancer in men who have sex with men (MSM) infected with HIV has increased in the recent years. Current recommendations for AD screening are based on expert opinion and have not proven their benefit yet.

**Aims & Methods:** The authors intend to evaluate the results obtained after implementation of a systematic cytological screening program in a cohort of patients with HIV infection. This is a prospective study of patients receiving anal dysplasia screening in 2011, in a tertiary referral center. Included male patients with HIV infection, age >18 years, MSM or with oral/genital warts. The patients were followed prospectively until March 2016. Descriptive statistics was performed using IBM SPSS Statistics 22.

**Results:** During the period of the study there were 59 patients (mean age 50 ± 5 years, with median of 30 (IQR: 6–65) months duration of HIV infection (51% patients on antiretroviral therapy)). The median follow-up time was 49 (IQR: 47–53) months (lost follow-up in 9 cases). The results of the initial anal cytology tests were: 40 (71%) negative for intraepithelial lesion or malignancy (NILM), 6 (11%) atypical squamous cells of uncertain significance (ASCUS), 8 (14%) low-grade squamous intraepithelial lesion (LSIL) and 2 (4%) high-grade squamous intraepithelial lesion (HSIL). During follow-up, 27 (46%) patients were referred to proctology consultation and in 19 (32%) cases excision/biopsy of a suspicious lesions on anoscopy was performed. During follow-up, were detected 13 (22%) cases of AD: 7 (54%) low-grade dysplasia (LGD), 4 (31%) high-grade dysplasia (HGD) and 2 (15%) carcinoma in situ (CIS). All patients with HGD were treated with argon plasma destruction and the patients with CIS were treated with combination of radiotherapy and chemotherapy.

**Conclusion:** The implementation of an AD screening programme in HIV infected male patients, MSM or with oral/genital warts, may prevent morbidity and mortality associated with delayed diagnosis of anal cancer. More studies are necessary in order to determine the periodicity of screening programs and evaluate its cost-effectiveness.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0944 ANAL CONDYLOMAS: PREDICTORS OF RECURRENCE AND PROGRESSION TO HIGH-GRADE DYSPLASIA / CARCINOMA IN SITU

**A. Peixoto**, M. Silva, R. Castro, R. Coelho, A. Albuquerque, J.A. Sarmento, G. Macedo
*Gastroenterology, Centro Hospitalar de São João, Porto/Portugal*

**Contact E-mail Address:** armandoafp5@gmail.com

**Introduction:** Anal condylomas with dysplasia are precursors of anal squamous cell carcinoma, appearing in the context of chronic infection with human papilloma virus (HPV). However, there are few studies concerning predictors of recurrence and progression to high-grade lesions (high-grade dysplasia – HGD and carcinoma in situ – CIS).

**Aims & Methods:** The aim was the evaluation of clinical characteristics and predictors of recurrence and progression to HGD / CIS in patients with anal condylomas. We performed a retrospective analysis of all biopsies and subsequent excision of anal condylomas performed in proctology consultation between 2011–2015, in a single center.

**Results:** During the study period 152 biopsies/excisions of anal condylomas were performed in 82 patients followed for 9 ± 12 months. Patients were mostly men (80%) with a mean age of 39 ± 11 years, and 76% had HIV infection (mostly in asymptomatic phase −95%, and under therapy −82%). In 61% of cases there was previous history of condylomas, 39% with prior dysplasia (HGD 65%). The most frequent HPV genotypes were 16 (49%), and 18 (27%). In 66% of biopsies/excisions dysplasia was detected, with 33% of high-grade dysplasia (HGD) and carcinoma in situ in 2%. The most applied treatments included argon plasma (83%) and excision with a scalpel (12%) without evidence of complications. There was a 64% recurrence rate. Presence of HGD/CIS was the sole predictor of recurrence. The predictors of high-grade lesions were shorter time to recurrence ($p = 0.003$), HPV-16 ($p < 0.001$) and previous HGD/CIS ($p = 0.035$).

**Conclusion:** In patients with anal condylomas there is a high frequency of high-grade lesions, including HGD. Such cases need close monitorization due to the

high risk of early recurrence. The identified predictors can aid in the stratification of that surveillance.

## P0945 PHASIC AND CONTINUOUS PROTOCOLS IN ANORECTAL MANOMETRICAL ASSESSMENT OF RECTAL SENSITIVITY: AGREEMENT AND CORRELATION WITH CLINICAL PRESENTATION

C. Peleman[1], K. Van Malderen[1], W. Verlinden[2], **H. De Schepper**[1]
[1]*Laboratory Of Experimental Medicine And Pediatrics, University of Antwerp, Antwerp/Belgium*
[2]*Department Of Gastroenterology Hepatology, Antwerp University Hospital, Antwerp/Belgium*

**Contact E-mail Address:** heiko.deschepper@uza.be
**Introduction:** Anorectal manometry is used in the evaluation of patients presenting with faecal incontinence, constipation or combination of both. It is useful in refining the diagnosis and guiding the management of these disorders. However, there is lack of consensus on the method and interpretation of anorectal manometry. With regards to the assessment of rectal sensitivity by manometry, phasic inflation of the balloon is considered the gold standard, although continuous inflation is now suggested because of the presumably more physiological nature. Cut-off values have only vaguely been defined for both methods of inflation.
**Aims & Methods:** The aim of the present study was to assess correlation and agreement between phasic and continuous methods of manometrical rectal sensitivity assessment, and their correlation with the clinical presentation. We retrospectively assessed rectal sensitivity on anorectal manometry with both phasic and continuous inflation of the anorectal probe in patients presenting to our tertiary care 'Pelvic clinic' with complaints of constipation, faecal incontinence or both. Impaired rectal sensitivity was defined as a first urge to defecation above cut-off value 40 mmHg for phasic and 150 mmHg for continuous inflation. Patients also filled in a questionnaire to correlate their clinical image with results from the two methods of rectal sensitivity assessment.
**Results:** Two hundred and eighty-two patients were included. The inflation pressures associated with first urge to defecation of phasic and continuous methods were significantly correlated (Spearman's rho 0.465, $p < 0.001$). Using the cut-off values stated above, continuous inflation reached sensitivity 16.1% and specificity 97.4% compared to phasic inflation as gold standard. Furthermore, only slight agreement was reached between phasic and continuous inflation using these cut-off values, indicated by Cohen's kappa 0.173. By means of a ROC curve, a new cut-off value of 84.5 mmHg for continuous inflation was defined, yielding the highest Youden index. However, despite this new cut-off value only moderate agreement was reached, indicated by Cohen's kappa 0.429. Impaired rectal sensitivity on phasic inflation was significantly correlated with self-reported constipation ($r_s = 0.151$, $p = 0.001$), manual evacuation of faeces ($r_s = 0.108$, $p = 0.017$) and bloating ($r_s = 0.107$, $p = 0.02$). Impaired rectal sensitivity on continuous inflation was significantly correlated with constipation ($r_s = 0.171$, $p = 0.002$).
**Conclusion:** Our results show a strong correlation between values of continuous and phasic inflation during manometrical rectal sensitivity assessment. However, there is low agreement between the two methods when using currently published cut-off values. Optimizing the cut-off value of continuous inflation increased agreement only moderately. Phasic inflation seems to be correlated with more clinical characteristics of constipation, compared to continuous inflation and thus might be more interesting to use as a diagnostic tool.

**Contact E-mail Address:** dario.gambaccini@gmail.com
**Introduction:** Conventional water perfused manometry (WPM) identifies the functional defecatory disorders (FDD) according to the defecatory patterns suggested by Rao. Unfortunately manometric data are often conflicting with clinical data, and balloon expulsion test (BET) or defecography need to be performed to reach a correct diagnosis. High resolution anorectal manometry (HRAM) and three-dimensional HRAM (3D-HRAM) allow a better evaluation of the endoanal and endorectal pressure and the anorectal dynamics providing a better diagnostic accuracy. On the basis of the indexes used by esophageal high-resolution manometry we identified a new parameter potentially useful for the evaluation of FDD: the Recto-Anal Delta-Contractile Integral (RAD-CI).
**Aims & Methods:** The aims of the study were: – to evaluate the possible correlation between WPM and 3D-HRAM parameters – to evaluate correlation between RAD-CI, traditional Rectoanal gradient (RAG) and BET 21 FDD diagnosed by using WPM, BET and/or defecography (15 type I, 6 type II), underwent 3D-HRAM (Manoscan 360TM, Medtronic – USA). Endoanal and endorectal pressure values obtained during the push straining were used to calculate the contractile integral (CI) which is a measure of duration and intensity. Endoanal CI was evaluated on a space including the anal canal for the whole duration of the push straining. By using the function "isobaric contour" pressures lower than mean resting pressure of the anal canal were excluded. Endorectal CI was calculated on a 10 mm space for the whole duration of push straining. RAD-CI was the difference between endoanal CI (proportionally correlated to 10 mm) and endorectal CI.
**Results:** Correlation between 3D-HRAM and WPM were found regarding: maximum resting ($r = 0.53$, $p < 0.05$), squeeze pressure ($r = 0.85$, $p < 0.001$), RAIR ($r = 0.76$, $p < 0.001$), volume for costant sensation ($r = 0.55$, $p < 0.05$) and maximum tolerated volume ($r = 0.63$, $p = 0.005$). RAD-CI showed significantly lower values in patients with positive BET ($p < 0.05$) (Tab.1).

**Table 1.**

| Correlation with BET | POSITIVE | NEGATIVE | p |
|---|---|---|---|
| RAG (mmHg) | $-50.3 \pm 28.1$ | $-30.1 \pm 28.5$ | 0.17 |
| RAD-CI mmHg*cm*s | $-1259 \pm 221$ | $639.5 \pm 689.2$ | 0.02* |

**Conclusion:** Also in the evaluation in dyssynergia 3D-HRAM shows a substantial agreement with WPM. RAD-CI could be an important index in the evaluation and classification of dyssynergic defecation. This study shows that RAD-CI has a positive correlation with BET, better than RAG. Additional studies are required on a larger number of patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0947 PERCEPTIONS OF CURRENT TREATMENTS FOR FECAL INCONTINENCE

**Introduction:** Faecal incontinence (FI) is a common and socially stigmatizing condition, but fewer than 30% of people with FI consult for medical or surgical treatment. Multiple behavioral, medical and surgical treatments have been shown to be effective by controlled trials, but data on patients' opinions of these options is limited.
**Aims & Methods:** This study aimed to explore perceptions of the effectiveness and safety of, and willingness to undergo treatment with, sacral nerve stimulation (SNS), biofeedback (BIO), and anal dextranomer injection (INJ) in a population sample reporting FI at least twice per month. Of 254 survey responders, 76 inconsistent responders and 14 subjects previously undergoing BIO, SNS, or INJ were eliminated, leaving 164 for analysis (72%). A 54-question survey enquiring about demographics, FI features and perceptions of BIO, SNS and INJ was distributed online (Qualtrics, Provo, Utah, USA) to individuals with FI in the US general population in March 2016. Perceived effectiveness and safety were rated on a 0–10 scale from "not at all" to "completely" effective or safe, and willingness to undergo each treatment was rated on a 0–10 scale from "definitely not" to "yes, definitely". Free text fields were included to collect data on "worries or concerns" that would prevent the subject from participating in each treatment. FI severity was assessed with the Fecal Incontinence and Constipation Scale (FICA), which has a range of 0–13.
**Results:** Complete data was available for 164 subjects with self-reported FI at least twice per month (112 F, median age 43, range: 18–82). The median FICA score was 8 with 119 (73%) respondents reporting either moderate or severe symptoms (FICA severity score >10). There was no difference in perceived effectiveness scores for SNS, BIO and INJ (means: SNS 5.6, BIO 6.1, INJ 5.7, p = ns). However, BIO was perceived to be safer than INJ ($p < .001$), and INJ was perceived to be safer than SNS ($p < .005$); average safety ratings were SNS 5.0, BIO 7.5, INJ 5.7, $p < .001$). Patients were more willing to try BIO than INJ ($p < .001$) and they were more willing to try INJ than SNS ($p < .005$). Average ratings of willingness to try these treatments if they were offered for free were SNS 5.5, BIO 7.4, INJ 6.2, $p < .001$). Regression analysis demonstrated that greater symptom severity and greater perceived effectiveness significantly predicted willingness to try each treatment ($F[12,151] = 15.23$, $p < .0001$). Free text descriptions of concerns about SNS included infection risk, use of electricity, and potential nerve damage; for BIO, embarrassment, time constraints, and discomfort; and for INJ, risk of infection, damage to the anus, and pain.

**Conclusion:** SNS, BIO and INJ are perceived to be equally effective by individuals with FI in the community. However, due to safety concerns individuals report being more willing to try BIO than either INJ or SNS. Commonly cited fears about accepting treatments for FI include infection, discomfort, and embarrassment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0948 ANORECTAL COMPLICATIONS IN PATIENTS WITH HEMATOLOGIC DISEASES – A SINGLE CENTER EXPERIENCE

**R. Vasconcelos Loureiro**[1], V. Borges[2], C. Bernardes[3], T. Capela[2], P. Russo[3], M. J. Silva[2], M. J. Bettencourt[1]

[3]*Dr., Hospital De Sto António Dos Capuchos, Lisbon, Portugal, Lisbon/Portugal*

**Contact E-mail Address:** loureiro.rafaela@gmail.com
**Introduction:** Proctologic diseases, such as anal sepsis, were responsible for elevated mortality rate (69%) in patients with hematologic diseases.
**Aims & Methods:** Characterization of proctologic diseases in patients with hematologic diseases admitted in the haematology department; analysis of risk factors, therapeutic management and clinical outcome. Retrospective review of all patients admitted to the Haematology Department and observed by anorectal symptoms in the Proctology Departement (January 2010 to September 2015). Analyzed demographic data and clinical outcome, during a 30 days period of follow-up.
**Results:** Eighty-four patients were included, 63.1% (n = 53) males, median age of 56 years. Fifty-four patients (64.3%) were admitted due to acute myeloid leukemia and 82.1% (n = 69) had active hematologic disease. Eighty (95.2%) underwent chemotherapy in previous 15 days. The main proctologic complaints were proctalgia (83.3%, n = 70) and rectal bleeding (46.4%, n = 39). More than half of patients (64.3%, n = 54) had fever and, 67.9% (n = 57), severe neutropenia (< 500 cells/uL). Most patients (67.9%, n = 57) had "no septic" complications: anal fissure, hemorrhoidal disease (including hemorrhoidal thrombosis) and anorectal ulcer, and conservative treatment was adopted, with complete symptoms remission. Twenty-seven patients (32.1%) had "septic" complications: anorectal abscess, perianal fistula and perianal cellulitis; 15 underwent fistula cannulation and seton placement, or surgical drainage/debridement. There were 2 deaths (2.4%), one related to perianal sepsis.
**Conclusion:** In this study, majority of patients had "non-septic" proctologic complications, and had complete symptoms remission with conservative treatment. Surgical debridement or proctologic procedures should be reserved for "septic" complications, which have a better prognosis now than in the past.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0949 POTENTIATION OF LOPERAMIDE AND RACECADOTRIL ANTI-DIARRHOEAL PROPERTIES BY SACCHAROMYCES BOULARDII CNCM I-745 IN A MOUSE MODEL

**P. Girard**, Y. Pansart, M. Verleye
*Pharmacology, Biocodex, Compiegne/France*

**Contact E-mail Address:** p.girard@biocodex.fr
**Introduction:** Loperamide and racecadotril are potent anti-diarrhoeal drugs whose mechanisms of action involve the peripheral opioid system in the gut wall. Unlike loperamide that mainly acts on the mu opioid receptor subtypes, racecadotril inhibits enkephalinase and interacts with the delta opioid receptor subtypes (Faure 2013). Main side effects involve constipation for loperamide and headache for racecadotril.
**Aims & Methods:** Our objective was to study the combinations of loperamide or racecadotril with another anti-diarrhoeal drug in order to enhance their anti-diarrhoeal efficacies while reducing concomitantly side effects. For this purpose, the probiotic yeast *Saccharomyces boulardii* CNCM I-745 was combined with loperamide or racecadotril in the model of endotoxins-induced diarrhoea in mice. Diarrhoea was induced by intravenous injection of endotoxins (Lipopolysaccharides from *Escherichia coli*) at 0.25 mg/kg in fasted CD1 mice (Masso et al., 1994). Loperamide (oral route) or racecadotril (intraperitoneal route) and *S. boulardii* (oral route) were given 30 min before endotoxins, and diarrhoea was assessed every hour during 7 hours, according the following score: 0 for clean anus without faeces or with normal faeces, or 1 for soiled anus with unformed or liquid faeces. ED50 of each compound was determined in groups of 12 animals according to the method of Tallarida (2001).
**Results:** Single loperamide administration induced an anti-diarrhoeal effect with ED50s values of $2.62 \pm 0.56$, $3.29 \pm 0.80$ and $4.88 \pm 0.73$ mg/kg at 1, 2 and 7 h respectively after injection of endotoxins. Single S. boulardii administration decreased the percentage of mice showing diarrhoea by around 50% at the doses of 2 and 3 g/kg, one hour after endotoxins injection. Combination of several doses of loperamide with S. boulardii at 3 g/kg showed a significant reduction of loperamide ED50s with anti-diarrhoeal values of $0.76 \pm 0.16$, $0.82 \pm 0.18$ and $0.97 \pm 0.17$ mg/kg at 1, 2 and 7 h respectively, after endotoxins injection. This combination allowed to reduce at least 3 fold the loperamide administered dose while keeping the same anti-diarrhoeal efficacy. Single racecadotril administration induced an anti-diarrhoeal effect with ED50s values of $157.4 \pm 8.5$, $240.0 \pm 6.9$ and $> 300$ mg/kg at 1, 2 and 7 h respectively after injection of endotoxins. Combination of several doses of racecadotril with S. boulardii at 3 g/kg showed a significant reduction of racecadotril ED50s with anti-diarrhoeal values of $58.4 \pm 16.1$ and $104.6 \pm 12.8$ mg/kg at 1 and 2 h respectively, after endotoxins injection. This combination allowed to reduce at least 2 to 3 fold the racecadotril administered dose while keeping the same anti-diarrhoeal efficacy.
**Conclusion:** These results show that combination of S. boulardii CNCM I-745 with loperamide or racecadotril significantly potentiates their anti-diarrhoeal efficacies in the mouse endotoxins-induced diarrhoea model. These compounds interact synergistically through their different mechanisms of action. These findings suggest that these combinations could be effective in the treatment of acute diarrhoea and could reduce loperamide or racecadotril consumption and side effects.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Fecal immunochemical test (FIT) is the preferred strategy for colorectal cancer screening. In limited-resource countries, there are few well-trained endoscopists, which is incomparable with the screening colonoscopy volume. (Table 1) The Asia-Pacific Colorectal Screening system (APCS) score based on simple clinical risk factors has been developed and validated. Score 4–7 is defined as high risk. FIT and APCS have been individually shown to predict the risk of colorectal neoplasm.

**Abstract No: P0951**

**Table 1:** Different aspects of GI training in evaluated countries

| Country of training (N° of participants) | Length of postgraduate training (years) | Average number of total diagnostic procedures performed [Mean ± SD] | | | | Trainees performing interventional endoscopic procedures (%) | | | | | Trainees very or fully confident in each field at the end of training (%) | | | | | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | Upper endoscopy | Colonoscopy | ERCP | EUS | >30 Hemostatic procedures for non-variceal bleeding | >30 Hemostatic procedurs for variceal bleeding | >50 polipectomy procedures | >10 EMR procedures | >30 PEG placements | Ward clinical activities | Outpatient clinic activities | Luminal endoscopy | Ultrasound | ERCP | EUS |

**Table 1:** Asia-Pacific colorectal screening system score

| Clinical risk factors | Criteria | Points |
|---|---|---|
| Age | below 50 years | 0 |
| | 50–70 years | 2 |
| | above 70 years | 3 |
| Gender | Female | 0 |
| | Male | 1 |
| Family history of colon cancer in the first degree relative | Absent | 0 |
| | Present | 2 |
| Smoking | Never | 0 |
| | Current/ past | 1 |

**Aims & Methods:** We aimed to determine the value of the combination of FIT and APCS score in stratifying asymptomatic subjects for screening colonoscopy. We conducted a multicenter study from 6 university hospitals in Thailand between October 2013 and February 2016. Asymptomatic subjects with aged 50–75 years, who participated in a health promotion program, were recruited. All subjects were evaluated for APCS score. FIT was done within 3 days prior to colonoscopy. Quantitative FIT with cut-off hemoglobin of 100 ng/dl was referred as positive. Subjects were divided into 4 groups according to the FIT and APCS results; group I = positive FIT with high risk, group II = positive FIT with non-high risk, group III = negative FIT with high risk, group IV = negative FIT with non-high risk. All underwent colonoscopy and adenoma detection rates (ADRs), advanced ADRs, and cancer detection rates (CDRs) were compared among the 4 groups. The results of FIT and APCS score were blinded to the performing endoscopists.
**Results:** A total of 1,120 subjects (mean age $60.5 \pm 7.1$yrs, female = 62%) were enrolled. The detection rate of adenomas, advanced adenoma, and cancer were 409(37%), 86(8%) and 7(0.6%) respectively. Regarding APCS score, 338 (30%) and 782(70%) subjects were classified as high risk, non-high risk, respectively. Advanced ADR was significantly higher in high risk subjects than in non-high risk subjects (10.4% vs. 6.5%, $p < 0.05$) There were 78(7%) subjects with positive FIT. Subjects with positive FIT had a significantly high advanced ADR compared to subjects with negative FIT (23% vs. 6.5%, $p < 0.001$). In combination of FIT and APCS, 30(2.7%), 49(4.4%), 308(27.5%) and 733(65%) subjects were stratified into group I, II, III and IV, respectively. There were significant differences of ADR and advanced ADR among 4 groups ($p < 0.001$). ADRs were 67%, 59%, 40% and 32% in group I, II, III and IV, respectively ($p < 0.001$). Group I had significantly higher advanced ADR (30%) than group II (22%), group III (8.4%) and group IV (5.5%), ($p < 0.001$).
**Conclusion:** The use of a combination of clinical risk scores and FIT is helpful to prioritize screening colonoscopy. Subjects with positive FIT with high-risk scores should be the first group undergoing for colonoscopy. However, a cost-effectiveness analysis is needed to evaluate the benefit of offering colonoscopy for the rest.

**Introduction:** There is currently no universal European training program in Gastroenterology and Hepatology. The European Board of Gastroenterology and Hepatology (EBGH) have produced guidance[1] regarding expected competences for European Gastroenterology (GI) trainees but it is unclear as to whether these have been incorporated national curricula. The last evaluation of gastroenterology training across Europe dates back to 2002. [2]
**Aims & Methods:** Our aim was to update the picture of gastroenterology training across Europe to identify differences and similarities between current programs. We developed a web-based 90-point questionnaire composed of 5 sections to investigate different aspects of gastroenterology training including: institutional rules, clinical activities, endoscopy, ultrasound, academic activities including scientific research, financial/socio-economic/employment issues and pitfalls of training programs. Physicians in their last year of GI training or who had recently finished their training, from 16 European countries (Belgium, Croatia, Denmark, France, Germany, Greece, Italy, Lithuania, Netherlands, Poland, Portugal, Romania, Russia, Serbia, Sweden, UK), were invited to participate in the survey. In 10/16 (62%) countries, physicians were identified through national societies of GI trainees/young gastroenterologists.
**Results:** A total of 143 physicians answered the survey (last-year trainees 33%, newly graduated gastroenterologists 77%). Overall, major differences in several aspects of training were identified among all evaluated countries, including access to postgraduate training (local or national application) and its duration (Table 1). Trainees undertake a final exam to complete their training in 11/16 (69%) countries. A minimum number of procedures is required to graduate in 9/16 (56%) countries. Overall European trainees dedicate a median of 12 months of their training period to endoscopy (Interquartile range – IQR: 6–25) but only a median of 3 months (IQR 0–6) to ultrasound training. The actual workload of trainees is usually higher than that forecast by training programmes and up to 13% of trainees complete their training without the supervision of a mentor. Overall, 70–89% of trainees performed a total number of diagnostic endoscopic procedures that fulfills the requirements of EBGH. However, large differences were found between and within countries, especially for interventional procedures (Table 1). Only 52% of trainees have access to pancreatobiliary endoscopy during their training. More than 30% of trainees attend few (<10) academic lessons/year. Approximately 48% of trainees do not receive reimbursement for congress-related expenses. Nearly 66% of trainees dedicate ≤10 hours/month to scientific research, and 80% of trainees undertake research during their free time. Average monthly salaries range from 1200–5200€ which differs considerably among Countries. In 12/16 (75%) countries trainees are paid for night duties and maternity leave. Only a minority of trainees percieve that they are very or fully confident in several GI activities (Table 1). Finally, 86% of trainees believe that GI educational programs should be homogenised across Europe.
**Conclusion:** In this large survey of senior trainees and newly graduated gastroenterologists, considerable differences in several aspects of GI training programs were found both between and within 16 European countries. Nevertheless, there has been some improvement in convergence and adherence to EBGH requirements since 2002.[2] Practical training in ultrasound and interventional endoscopy appear to be still insufficient in most countries. In addition there are significant discrepancies between research opportunities and activities, and support for trainees. Such dissimilarities may lead to disparities in quality of training and, consequently, of healthcare across countries. A higher homogenisation of educational programs and training opportunities across Europe is, therefore, strongly desirable.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Colonoscopy is considered the standard of care for investigating large-bowel and terminal-ileum disease in teenagers and children. The diagnostic accuracy of colonoscopy requires thorough visualization of the colonic mucosa, making bowel preparation a vital element of the procedure. The PEG has showed an option of more secure and more efficacy in the bowel prepare to teenagers and children above two years old. Although there is not gold standard for bowel prepare.
**Aims & Methods:** This study aims to evaluate the effectiveness of PEG 3350 for colonoscopy colon preparation in children and teenagers, considering the measures as followed: full-dose and split-dose. It was conducted as a prospective, randomized controlled trial with children aged 2–18 years undergoing elective colonoscopy. Patients were randomly assigned to receive PEG 3350 for either one (full dose) or two (split dose) days. Children with known fecal impaction, metabolic, cardiac or renal disease were excluded. Subjects reported the tolerability and side effects of PEG 3350 via a survey. Effectiveness of the bowel preparation was assessed using a two bowel cleansing scale during colonoscopy.
**Results:** 52 patients were evaluated aged 02–18 and were scheduled for colonoscopy at the Brasilia Jose Alencar Children's Hospital from November 2014 to October 2015 and were divided into two groups: A) Full-dose with 26 patients and B) Split-dose with 26 patients. The full dose preparation had a success rate of 61.5% and with preparation of Split dose achieved in 92.3% success rate, with statistical significance ($p < 0.0187$) among compared groups. Adverse symptoms in the colon preparation using full dose achieved 11.5% rate of patients and in the case of Split dose it had have a 19.2% rate of patients

**Table Abstract No: P0954**

| Device storage temperature Collection Picker/HM-JACKarc | % difference of Hb concentration 1–7 days OC-SENSOR Autosampling Bottle 3/ PLEDIA | FOB Gold/ SentiFIT 270 | Extel Hemo Auto-MC | |

| | **n** | 12 | 10* | 10* |
| **19°C** | **Average** | 6.4 | −10.1 | −4.8 |
| | **Min** | −35.4 | −19.5 | −19.4 |
| | **Max** | 18.7 | −2.2 | 8.9 |
| **30°C** | **Average** | −31.2 | −32.8 | −22.5 |
| | **Min** | −92.4 | −60.7 | −48.4 |
| | **Max** | 45.0 | −15.8 | 7.7 |

*Two samples gave results below the analytical range.

with no statistical significance if we compare the two groups ($p < 0.703$), and without presenting severe symptoms.
**Conclusion:** This current comparative study was conduct at the Brasilia Jose Alencar Children's Hospital showing a statistical superiority of using of PEG 3350 in two days compared with a only one day. It is important to comment that the colon preparation of two days was effective and secure indicating to be a gold standard for bowel preparation in children and teenagers. There was difference between protocols was observed, the 2 d protocol was superior. Side effects were minimal. Allowing to establish bowel preparation colonoscopy, safe and effective for children and adolescents.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0953 THE BURDEN OF GASTROINTESTINAL MORBIDITY AND HEALTH RESOURCE UTILIZATION IN YOUNG ADULTS

**D. Carter**[1], L. Katz[2]
[1]*Gastroenterology, Sheba Medical Center Dept. of Gastroenterology, Ramat Gan/Israel*
[2]*Sackler Faculty Of Medicine, Tel Aviv University, Tel Aviv/Israel*

**Contact E-mail Address:** dr.dancarter@gmail.com

**Introduction:** The reported burden of gastrointestinal (GI) morbidity in the Western world is extensive, and close to 20% of the general population is affected annually. The reported burden of GI morbidity in Israel is unknown.
**Aims & Methods:** Aim: To examine the prevalence of GI reported symptomatology, morbidity and utilization of health system resources in a cohort of young adults.
Methods: The study population included all young adults (18–26 years old) who served in the IDF between the years 2005–2015. Comprehensive data regarding their GI-related symptoms, diseases, emergency department visits and diagnostic procedures were obtained from medical records in order to estimate the burden of GI-related morbidity. Summary statistics and frequencies were recorded.
**Results:** A total of 824,476 young adults (38.9% females) were included in the study. During an average follow-up of 2.3 years, 44.2% had at least one GI-related symptom (682 recorded symptoms per 1000 follow-up years) and 48.3% were diagnosed with at least one GI-related disease (656 recorded diseases per 1000 follow-up years). The most common symptoms were abdominal pain, diarrhea, nausea and vomiting, dyspepsia and anemia and nutritional deficiencies (275, 101, 83, 74 and 63 per 1000 follow-up years, respectively). The most common diagnosed diseases were GI-related infections, small intestine disorders (e.g. Celiac), perianal problems, liver-related diagnoses and irritable bowel syndrome (272, 169, 76, 25 and 24 per 1000 follow-up years, respectively). Precancerous conditions and cancer were rare (0.61 per 1000 follow-up years). The emergency room referral rate was 5.5% (37 visits per 1000 follow-up years). Endoscopic procedures were performed in 1.8% (13.5 endoscopies per 1000 follow-up years) and 0.4% had a radiologic exam (3 per 1000 follow-up years).
**Conclusion:** GI diseases are a source of substantial morbidity and utilization of health resources in young Israeli adults
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0954 FIT SAMPLE STABILITY FOR HAEMOGLOBIN-POSITIVE FAECES USING THREE ANALYSIS SYSTEMS OVER SEVEN DAYS

**C. Piggott**[1], C. John[2], H. Bruce[1]
[1]*NHS Bowel Cancer Screening Programme Southern Hub, Guildford/United Kingdom*
[2]*Southern Hub, NHS Bowel Cancer Screening Programme, Guildford/United Kingdom*

**Contact E-mail Address:** carolyn.piggott@nhs.net

**Introduction:** Automated quantitative faecal immunochemical test (FIT) for haemoglobin (Hb) systems include a faecal sampling device (with preservative buffer), laboratory analyser and reagent kit. In colorectal cancer screening programmes faecal samples are usually collected at home and posted back to the laboratory for testing. Samples can be in transit for several days and subjected to a variety of temperatures.
**Aims & Methods:** We investigated the likely effect of sample return time on Hb concentration using naturally Hb-positive faeces stored for seven days at 19°C or 30°C and analysed on three different FIT systems. Twelve Hb-positive samples were taken from stools provided for calprotectin analysis and mixed for two minutes using wooden sticks. Two FIT sampling devices for each of the three FIT systems (Extel Hemo Auto-MC Collection Picker (Kyowa Medex Co. Ltd), FOB Gold (Sentinel Diagnostics), and OC-SENSOR Autosampling Bottle 3 (Eiken Chemical Co.)), were loaded with faeces from the twelve samples. After mixing and incubation for 24 hours at room temperature, Hb was measured using the HM-JACKarc, SentiFIT 270 and OC-SENSOR PLEDIA analysers, respectively. One of the sampling devices for each sample was then stored in the dark at room temperature (15–23°C) for seven days and one stored in the dark at 30°C for seven days. After mixing the samples, Hb was re-measured on days 3, 5 and 7. The samples stored at 30°C were allowed to cool to room temperature before analysis.
**Results:** The average percentage difference between the Hb concentration on day 1 and day 7 was calculated for each FIT system. The minimum and maximum percentage differences were also calculated.
**Conclusion:** Faecal samples that were positive for Hb collected and stored in the OC-SENSOR Autosampling Bottle 3 devices showed the lowest average percentage change over seven days at 19°C (negative percentage difference), followed by the FOB Gold device (positive percentage difference) and the Extel Hemo Auto-MC Collection Picker (negative percentage difference). At 30°C OC-SENSOR Autosampling Bottle 3 devices gave the lowest average percentage change over seven days, followed by the FOB Gold device and the Extel Hemo Auto-MC Collection Picker. All three devices showed negative average percentage differences at 30°C.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0955 REFERRALS TO A TERTIARY HOSPITAL: A CLINICAL SNAPSHOT OF PATIENTS WITH FUNCTIONAL GASTROINTESTINAL DISORDERS AND EFFECTIVENESS OF PRIMARY CARE MANAGEMENT

**E. C. Linedale**[1], A. Mikocka-Walus[2], P. R. Gibson[3], J. M. Andrews[1]
[1]*Medicine, The University of Adelaide, Adelaide/Australia/SA*
[2]*Health Sciences, University of York, Heslington/United Kingdom*
[3]*Medicine, Monash University, Melbourne/Australia/VIC*

**Contact E-mail Address:** ecushla.linedale@adelaide.edu.au

**Introduction:** Although current guidelines recommend that functional gastrointestinal disorders (FGID) can be effectively diagnosed and managed in primary care [1] tertiary care referrals exceed capacity.

**Aims & Methods:** This study aimed to utilise referrals to tertiary care as a window to the effectiveness of FGID management in primary care in Australia. Consecutive patients with likely FGID referred to one gastroenterology outpatient department (2013–2015) were invited to participate in a RCT of a novel care pathway. Patients completed an intake survey and a standard panel of screening tests. Referral quality was assessed with content analysis, and general practitioners (GP) surveyed to explore referral reasons.

**Results:** 111 patients (64% female, mean 42 [SD 15] y) responded; 90 intervention, 21 waitlist control. 60% were tertiary educated and 61% employed. Symptom duration was >2 y (64%) and 44% reported psychological co-morbidities. 52% experienced persistent/distressing symptoms with reduced daily functioning in 17% of these. 66% had never seen a gastroenterologist, yet 18% had previously consulted more than once. 37% had consulted their GP in the last 4 weeks for these symptoms and 87% were using at least one treatment (medications, 35% prescription, 36% over the counter,17% complementary and alternative; 23% diet; 32% >1 treatment type) with little/no improvement in 69%. 40% were dissatisfied and 36% only partially satisfied with management (Table 1). Dissatisfaction was related to both the lack of provision of a diagnosis (70%) and effective treatment options ($p < .001$ for each). Treatment costs in the previous 4 weeks varied between $0 (in a third) and $1300. Table 1. Range of statements made by patients regarding dissatisfaction with management.

"(GP) has offered no assistance, has told me I need to learn to live with it" Pt 99
"Have no diagnosis, nor any idea how to treat it" Pt 106
"I've seen different GP's and at this stage, all they have been able to offer me are various tests. This has been going on for a few years" Pt 29
"No results, constant hand balling. Ultimately no relief and now on a 12 month waiting list for the next step" Pt 85
"I don't have medicine to fix the problem. I'm not sure what the doctors think about my problems. I'm not getting much explanations. Looks all my problems is an enigma" Pt 73

Referrals lacked information required for safe triage such as age (49%), gender (27%), symptom duration (50%) and clinical alarms (71%). GPs underreported alarms (13% GPs vs 86% patients) with 34/90 patients subsequently receiving prompt GE review after screening, due to a change in triage category. 61 GPs completed the survey. Reasons for referral were repeat presentations (n = 32), diagnostic uncertainty (n = 19), to ensure nothing is missed (n = 19), patient request (n = 17), treatment failure (n = 16) and patient fears (n = 14). 28 GPs were confident their patient had a FGID yet referred for confirmation (n = 24) and treatment advice (n = 4). 20 were "unsure", 7 "not confident" and 5 confident in an alternate diagnosis (3 unable to suggest what this was).

**Conclusion:** This window into primary care management of patients with likely FGID indicates that the majority of patients have long-term, distressing symptoms and yet have not received a diagnosis (70%) or previously seen a gastroenterologist (66%); although a third seek repeat specialist consultation. These data suggest that GPs lack confidence in diagnosing and managing FGID and we propose that education and structured support tools may be an effective strategy to facilitate primary care management of FGID.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0956 GP PARTICIPATION IN INCREASING UPTAKE IN BOWEL CANCER SCREENING: THE PEARL PROJECT

**P. Butler**[1], S. Duffy[2], K. Reed[3], M. Chesters[4], S. Stanley[4], S. Rickard[4], R. Roope[4], S. Benton[1]

[3]*Southern Hub, NHS Bowel Cancer Screening Programme, Guildford/United Kingdom*
[4]*Wessex Senate And Strategic Clinical Network Primary Care, NHS, Southampton/United Kingdom*

**Contact E-mail Address:** piers.butler@nhs.net

**Introduction:** Uptake of bowel cancer screening in England is about 56%, a figure that has changed little since the programme began in 2006. The NHS Bowel Cancer Screening Programme (BCSP) in England is organised centrally, without the direct involvement of general practitioners (GPs). There is however evidence to suggest that people are more likely to be screened if they are encouraged to do so by their GP. The Practice Endorsed Additional Reminder Letter (PEARL) project is a collaboration between the BCSP Southern Hub and a group of Wessex GPs working for Macmillan Cancer Support in partnership with the Wessex Strategic Clinical Network.

**Aims & Methods:** Wessex practices with BCSP uptake below 55% (prevalent episodes 2008–2013) were invited to participate. Between September 2014 and October 2015, subjects registered with participating practices who had not returned a test kit within 30 days of a standard reminder letter were identified on the BCSP database and their GPs asked to identify those who should not be sent a further reminder (end-of-life-care etc.). The Hub then confirmed that GP-included subjects remained non-respondent and a second reminder letter was sent out with the appropriate GP letterhead and signature. 25 non-PEARL practices were selected, matched to the 25 PEARL-registered practices by previous prevalent participation rates and number of invitees. Comparison of uptake in these two groups was performed using Mantel-Haenszel estimation conditioning, producing relative risk and 95% confidence intervals.

**Results:** The intervention significantly increased the probablillity of uptake by 4% in absolute terms from 50% to 54%, a proportional increase of 8% (RR = 1.08, 95% CI 1.05–1.11, $p < 0.001$). Restricting analysis to subjects who had not completed a kit by the index date (date PEARL reminder letter was sent, or would have been sent if in a participating practice), also showed that the intervention had a significant effect (RR = 2.96 [2.37–3.69]).

**Conclusion:** The PEARL intervention significantly increased uptake both as a proportion of all invitees or only those invitees who had not completed a kit by the index date. The extra work required at the Hub and practices will be evaluated and recommendations made about the viability of rolling this process out nationally within the BCSP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0957 POST-POLYPECTOMY BLEEDING AMONGST PARTICIPANTS OF NEW ZEALAND BOWEL SCREENING PILOT PROGRAMME

**H.S. Chan**, P. Frankish
*Gastroenterology Dept, Waitemata District Health Board, Auckland/New Zealand*

**Contact E-mail Address:** huisynchan@hotmail.com

**Introduction:** The New Zealand Bowel Screening Pilot (NZBSP) Programme was implemented from year 2012 to 2015. Subjects aged 50 to 74 eligible for publicly funded healthcare from Waitemata District Health Board area were invited to participate in the programme.

**Aims & Methods:** To evaluate post-polypectomy bleeding (PPB) complications in NZBSP Programme. Demographics, polyp characteristics, polypectomy techniques, PPB clinical parameters, resource utilisation and management outcomes were analysed.

**Results:** Of 7643 participants who underwent colonoscopy under NZBSP Programme, 53 presented with PPB over the four-year period, overall PPB rate was 0.7%. PPB rate was highest in first year at 1.5%, with rates of 0.4%, 0.4% and 0.6% noted over each consecutive year. Antithrombotic agents were managed per local guidelines prior to these colonoscopy, including Clopidogrel (n = 3), Warfarin (n = 5, 3 had bridging Enoxaparin) and Dabigatran (n = 3). Median polypectomy rate was 3 polyps per participant. Median size of largest polyp resection was 12 mm (range 3–50 mm), 15 of these were 20 mm or larger, 24 were located in right colon. Hot snare method was employed in 91%, 8/48 (17%) were piecemeal endoscopic mucosal resections. 12 patients had early PPB (intra-procedural and up to 24 hours), median interval to onset of PPB was 2 days (range 0–16). Median hospital stay was 2 days (range 0–34), 16 patients (30% PPB cases, 0.2% overall participants) received red blood cell transfusions, 2 required additional blood products. Computed tomography angiography was performed in 3 patients, of these 1 proceeded to embolisation and 2 had repeat endoscopy; computed tomography of abdomen was performed in another participant. Repeat endoscopy rate was 17% (5 colonoscopies and 4 flexible sigmoidoscopies): endoscopic therapies were applied in 7 procedures, 1 polypectomy ulcer required no therapy and 1 had proximal bleeding and proceeded to surgery. Surgical management rate of PPB was 7.5% (3 right hemicolectomies and 1 Hartmann's procedure).

**Conclusion:** The NZBSP Programme has similar polypectomy-related bleeding rate when compared to other larger series bowel cancer screening programme[1].

### P0959 THE IDRI STUDY: EFFECT OF DYNAMIC, DIAGNOSE SPECIFIC CHECKLISTS ON REFERRAL QUALITY IN GASTROENTEROLOGY- A RANDOMIZED CROSS-OVER STUDY

**S.L. Eskeland**[1], L. Aabakken[2], T. De Lange[3]

**Contact E-mail Address:** sigesk@vestreviken.no

**Introduction:** The quality of referral letters in gastroenterology is variable, with a significant proportion of low quality. This is a challenge for consultants assessing referral letters and prioritizing the patients for appropriate examinations/consultations. Some studies have shown effect of checklists on referral quality, but none has examined this in a standardized setting.

**Aims & Methods:** The aim of the study was to assess the effect of dynamic, diagnose specific interactive checklists on the quality of GPs' referral letters. In order to reduce confounding by organizational- or patient- variation the assessment was performed in a standardized setting. An Electronic Patient Record (EPR) simulator was developed, and 8 patient cases were made using the most common reasons for referral from the National Prioritization Guideline in gastroenterology. The patient cases were incorporated in the EPR-simulator, allowing doctors to chat with the virtual patients to obtain a medical history and results from relevant examinations and work-up. From April 2014 to October 2014, 45 GPs were invited to perform virtual consultations and randomized to generate referral letters either by using dynamic, diagnose-specific check list or a free text format. After an interval of 3–12 months, the GPs repeated the process in a cross-over design with the opposite referral- type. Referrals were assessed using a Thirty Point Score (TPS) for referral quality.

**Results:** From April 2014 to July 2015, 25 GPs completed both rounds of the study. Participating GPs were an average of 52.3(range 33–63) years old, 60 %female. Average TPS was 22.1(21.3–22.9) in the checklist-group and 15.4(14.6–16.3) in the free-text group($p < 0.001$). Individual TPS for each indication is shown in the table.

**Conclusion:** The results from this study indicate that there is a considerable positive effect of check-lists on referral quality in gastroenterology. These results are most likely valid also for other medical specialties.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Gastrointestinal bleeding is the commonest cause of iron deficiency anaemia (IDA). Guidelines on the management of IDA due to GI bleeding are outdated and lack information on the use of high-dose IV iron formulations in this context.

**Aims & Methods:** Aim: To gain expert consensus on the optimal management of GI bleeding associated IDA. Methods: An e-Delphi study was conducted among 27 European experts in gastroenterology and IDA (senior academics and senior clinicians from 7 European countries) under the direction of a study chairman and steering group. The experts completed a non-directive narrative questionnaire about their clinical practice and opinions on the optimum management of IDA due to GI bleeding, including the place of high dose IV iron formulations in iron replacement therapy. Narrative questionnaire results were analysed to identify unique propositions about the optimal management of IDA due to GI bleeding. The resulting pool of propositions was used to formulate a Delphi questionnaire with 126 propositions, focussing on those most relevant to the study aim. The Delphi questionnaire was completed on-line by the 27 experts using the Delphi Process Research Unit e-portal. Analysis determined the level of agreement between the 27 experts on each of the 126 propositions. If there was at least 75% agreement on the correctness of a proposition, it was considered to be supported by a consensus. Free text comments were listed and subjected to qualitative analysis.

**Results:** There was a consensus in support for 53 of the 126 propositions tested. Five important themes were identified: 1/ There is a need for new guidelines on the management of IDA in patients with GI bleeding, including practical advice for non-specialists and the identification of "Red Flags" for iron replacement therapy. 2/ Choice of iron formulation to treat IDA in GI bleeding should be based on clinical considerations (primary GI disorder, pathophysiology, presence of inflammation, presence of comorbidity and malabsorption). 3/ Use of blood test threshold values is not a sufficient basis for determining the most appropriate type of iron therapy to use (high dose IV or traditional oral). 4/ Oral iron therapy is not always an appropriate first line treatment in cases of IDA due to GI bleeding. 5/ Timely iron supplementation can reduce the need for blood transfusion.

**Conclusion:** Our study suggests that the current use of IV iron by experts in the field is driven by clinical considerations rather than by target laboratory test results or treat/no-treat thresholds. The use of high dose IV iron formulations is logical because compliance is certain, the onset of beneficial effects is fast, the formulations are well tolerated and efficient to use, as shown by evidence from RCTs. New guidance is needed on the optimal management of IDA in patients with GI bleeding including advice on the use of high-dose IV formulations of iron.

**Contact E-mail Address:** luismaia.gastro@gmail.com
**Introduction:** Acute nonvariceal upper gastrointestinal haemorrhage (ANVUGIH) is a common condition with significant associated morbidity and mortality. Although performance of endoscopic haemostasis improves the outcomes, evidence sustaining benefits for very early endoscopy is scarce.
**Aims & Methods:** Our aims were to evaluate the impact of out-of-hours presentation and the timing of endoscopy on the outcomes of patients presenting with ANVUGIH to the emergency department. We performed a retrospective analysis of consecutive patients undergoing upper gastrointestinal endoscopy (UGIE) due to ANVUGIH between January 2010 and June 2013 in our centre. Inpatients were excluded. Timing of UGIE (first 6 hours, 6 to 12 hours or later than 12 hours after admission) and daytime (8–20 h) versus out-of-hours (20–8 h) presentation were compared for mortality, need for urgent surgery and rebleeding.
**Results:** From January 2010 to June 2013 there were 453 episodes of ANVUGIH (64% males, mean age 66.4 years). Slightly more than half (55%) of UGIE were performed out-of-hours, 34% in the first 6 hours after admission and 36% between 6 and 12 hours after admission. Global 30-day mortality rate was 6.2%. No predictors of outcomes were found for daytime ANVUGIH. For out-of-hours ANVUGIH, haemoglobin less than 7 g/dL was an independent predictor of in-hospital and 30-day need for urgent surgery, rebleeding and mortality; Rockall score >7 predicted in-hospital and 30-day mortality and personal history of neoplasia predicted 30-day mortality. Patients presenting with out-of-hours ANVUGIH were more likely to undergo endoscopic haemostasis. Timing of UGIE was not a predictor of mortality or other outcomes.
**Conclusion:** Endoscopy during the first 6 hours after admission did not improve mortality, rebleeding and the need for surgery. In out-of-hours ANVUGIH, highly qualified care should be provided for patients with higher Rockall score and lower haemoglobin levels.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0962 A COMPARATIVE STUDY OF RISK ASSESSMENT SCORES FOR ACUTE UPPER GI BLEEDS, IN PREDICTING NEED & TIME FOR INTERVENTION

**S.A.A. Gardezi**[1], C. Tibbatts[2], A. Foliaki[3]
[1]*Gastroenterology, UHL Cardiff, Cardiff/United Kingdom*
[2]*Gastroeneterology, UHL Cardiff, Cardiff/United Kingdom*
[3]*Upper GI Surgery, UHL Cardiff, Cardiff/United Kingdom*

**Contact E-mail Address:** sanjliajk@gmail.com
**Introduction:** While managing patients with acute upper GI bleed (AUGIB) a simple numerical score can be helpful to identify high risk groups & need for intervention as recommended by NICE. Recent NCEPOD report for AUGIB reported that only 32% patients had a Pre-endoscopy risk assessment performed. Two commonly used scoring systems in UK are GBS (Glasgow Blatchford score) and RCS (Rockall score). Recent comparisons have shown that the GBS was superior in identifying need for hospital-based intervention1 while RCS was better in predicting mortality.2
**Aims & Methods:** We conducted a retrospective study of 893 patients, admitted to the hospital and treated in endoscopy unit of Cardiff & Vale health board between September 2010 to September 2013 with AUGIB. We calculated the GBS and pre & post endoscopy RCS for each and compared several outcomes.
**Results:**

Time to scope vs outcome in Patients with GBS >10 (High risk)

| Hours to OGD | Total | Ther Intervention | Died |
|---|---|---|---|
| >24Hrs | 240 | 61(25.4%) | 45(18.75%) |
| 6–24Hrs | 108 | 52(48.1%) | 8(7.4%) |
| <6 hrs | 14 | 8(57.14%) | 4(28%) |

Overall, GI bleed related mortality was only 3.1% in our study, with chronic liver disease being one of the main risk factor. GBS was superior in identifying patients suitable for safe discharge with outpatient management. The GBS was also better at predicting the need for endoscopic intervention. Our study also found that very early endoscopy (ie <6 hours) compared to rapid endoscopy (6–24 hours), did not improve survival in the highest risk patients (ie GBS>10), and in fact had a significantly worse mortality rate of 28% versus 7.4%.
**Conclusion:** The GBS score is superior to the pre-endoscopy Rockall in rationalising need & timeliness of intervention. The post-Rockall score is shown to be the better predictor of mortality. This study also reinforced the importance of access to rapid endoscopic intervention within 24 hours, but did not demonstrate the need for very early gastroscopy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[3]*Information Sciences And Decision In Health (cides) And Cintesis, Faculty of Medicine of Porto, Porto/Portugal*

**Contact E-mail Address:** luismaia.gastro@gmail.com
**Introduction:** Mallory-Weiss syndrome (MWS) is a frequent cause of upper gastrointestinal bleeding (UGIB). Although classically considered mild and self-limited, recent evidence suggests that mortality can be substantial.
**Aims & Methods:** In this study we aimed to analyse the prevalence, patient characteristics, endoscopic treatment and main outcomes of patients admitted for MWS and to compare them to those of peptic ulcer bleeding. We performed a retrospective single-centre cohort of consecutive patients with upper non-variceal gastrointestinal bleeding due to all causes between January 2010 and June 2013. Patient demographic characteristics, endoscopic variables and outcome parameters, including rates of haemostasis, recurrent bleeding, surgery and mortality were analysed. Comparative analysis was performed between MWS and peptic ulcer bleeding.
**Results:** Seventy-two patients with UGIB due to MWS (69.4% male, mean age 61.1years) and 347 with peptic ulcer bleeding (70.0% male, mean age 64.6 years) were evaluated. In the MWS cohort, hematemesis was the commonest form of presentation (88.9%) and almost half of the patients were haemodynamically unstable (45.8% presented tachycardia or hypotension). Endoscopic haemostasis was performed in 40 patients (55.6%; including 19.4% adrenaline injection only, 5.6% hemoclipping only and 29.1% combined therapy) with no immediate complications. 30-day rebleeding, surgery and mortality rates were respectively 2.8 (n=2), 0.0 (n=0) and 2.8% (n=2, only 1 due to rebleeding). No predictors of outcome could be found. When compared with peptic bleeding, MWS patients presented more frequently with hematemesis (91.4% vs 53.9%, p=0.000) and higher haemoglobin (11.3 g/dL vs 8.6 g/dL, p=0.000). The proportion of anticoagulated patients was twice as high (18.8% vs 9.9%, p=0.032). In-hospital and 30-day mortality for all causes (p=0.423 and p=0.244, respectively) or related to bleeding (p=0.303) was similar, despite a trend towards lower mortality due to MWS (2.8% vs 6.1%). Significant differences were noted in relation to lower need for surgery (p=0.012) and rebleeding (p=0.026) in MWS patients.
**Conclusion:** MWS commonly presents as hematemesis and the majority of patients need endoscopic haemostasis due to maintained bleeding. Although rebleeding and surgery rates are lower, mortality is comparable to that of peptic ulcer bleeding, stressing the need for high standard quality care and management.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0964 THE ROLE OF ENDOSCOPIC HEMOSTASIS FOR PERIAMPULLARY DIVERTICULAR BLEEDING

K.B. Kim[1], **Y. Choi**[1], Y. Oh[1], E.B. Kim[2], K. Kim[1], J. Han[1], S.M. Yoon[1], H.B. Chae[1], S.M. Park[1], S.J. Youn[1]

**Contact E-mail Address:** cyongh20@hanmail.net
**Introduction:** Upper gastrointestinal bleeding (UGIB) is gastrointestinal emergency that results in substantial morbidity and mortality. Timely and precise bleeding control after resuscitation is necessary. Endoscopic hemostasis has also continued to evolve. However, endoscopy often fail to visualize the exact focus of bleeding when there is massive bleeding, large amount of bloody debris impairing the endoscopic view, or the location such as periampullary diverticulum is difficult to approach.
**Aims & Methods:** This study is aimed to evaluate the role of endoscopic hemostatic modalities for periampullary diverticular bleeing. There was a lack of data for endoscopic control of periampullary diverticular bleeding because the incidence was low, precise targetting for bleeding focus was difficult. We examined the successful endoscopic hemostasis or other hemostatic modalities such as angioembolization for the periampullary diverticular bleeding. The patients' medical records were retrospectively analyzed during 5 years [Apr. 2011 ~ Mar. 2016] in our hospital.
**Results:** During 5 years, 2,237 cases [1,583 patients: male 1,171 (73.9%), female 412 (26.0%), mean age 61.4 ± 14 years)] were treated with endoscopic hemostasis. 199 cases (8.9%) were lower gastrointestinal hemorrhage and 2,038 cases (91.1%) were upper gastrointestinal hemorrhage (including 654 cases (29.2%) of variceal bleeding). Periampullary diverticular bleedings were happened to 7 patients [male 4, female 3, mean age 80 ± 11 years]. There were 4 Dieulafoy's lesions and 3 ulcerative lesions in periampullary diverticulum. 3 patients were treated with radiologic angioembolization as initial hemostatic modality and 4 patients were treated with endoscopic hemostasis (3 hemoclippings and 1 band ligation). Angioembolization is followed by hemoclipping for 1 patient. 2 of 4 endoscopic hemostasis were done by cap-assisted endoscopy. All 7 patients were recovered without rebleeding.
**Conclusion:** This study was limited by being single center observational study. However, the endoscopic hemostasis for periampullary diverticular bleeding could be considered as alternative to surgery or angioembolization.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** ivan.budimir.zg@gmail.com
**Introduction:** To compare the performance of the AIMS65 score and Glasgow Blatchford score (GBS) in predicting specific clinical end-points and the need for blood transfusion in patients with variceal bleeding.
**Aims & Methods:** Between January 2008 and December 2013, we retrospectively analyzed 225 consecutive hospitalized patients managed for endoscopically confirmed UGIB (upper gastrointestinal bleeding). The GBS and AIMS65 score were calculated. Discriminative ability for each score was assessed using the receiver operated characteristics curve(ROC) analysis.
**Results:** A total of 225 patients (mean age 61.3 years), frequently diagnosed with alcoholic cirrhosis(195/86.7%), presented with variceal bleeding during the study period. The overall 30-day hospital mortality rate was 17.3%, rebleeding rate was 9.8%, and median hospital stay was 6(1–35) days. Red blood cell transfusion was required in 171(76%) patients with an average of 3.2 red blood cell transfucion packs. Initial hemostasis was achieved with N-butyl cyanoacrylate (151/79.1%) and endoscopic variceal ligation(40/20.9%). There was no statistically significant difference among AIMS65 score and GBS in predicting mortality [(AUROC 0.70(CI 95% 0.62 to 0.77) vs 0.64(CI 95% 0.55 to 0.71)] or rebleeding rate[AUROC 0.74(CI 95% 0.67 to 0.81) vs 0.60 (CI 95% 0.51 to 0.67).] The GBS was superior in predicting the need for blood transfusion compared to AIMS65 score[AUROC 0.75(CI 95% 0.67 to 0.82) vs 0.61(CI 95% 0.53 to 0.66)].
**Conclusion:** The AIMS65 score and GBS are comparable but not useful for predicting outcome in patients with variceal bleeding. The GBS is superior in predicting the need for transfusion compared to AIMS65 score.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** solemiooh@gmail.com
**Introduction:** DA-5204 (Stillen 2X®) is a new formulation of DA-9601 (Stillen®) with gastro-retentive system (floating technique) that is in the treatment of acute or chronic gastritis. This technique is improved usage of DA-9601 from t.i.d. to b.i.d.. DA-9601 is a phytopharmaceutical derived from *Artemisia princeps*, which has antioxidative and anti-inflammatory actions.
**Aims & Methods:** The study aimed to evaluate the endoscopic efficacy ratio, endoscopic cure ratio and safety for DA-5204. In this multicenter (21 investigational sites), double-blinded, stratified randomized, active controlled, parallel group, non-inferiority trial, 421 patients with acute or chronic gatritis over a 2-week period were randomly assigned to groups for coincidential treatment with DA-5204 (90 mg, b.i.d.) (209 patients for full analysis) or DA-9601 (60 mg, t.i.d.) (212 patients fo full analysis). The primary endpoint was the endoscopic efficacy ratio (used modified Lanza Score) and the secondary endpoint cure ratio and gastric symptoms (epigastric pain, heartburn, reflux, nausea, vomiting, belching and bloating).
**Results:** At week 2, endoscopic efficacy ratio with DA-5204 and DA-9601 were 42.1% (88/209) and 42.5% (90/212), respectively. The difference between th groups was −9.8%, indicating non-inferiority of DA-5204. In secondary

endpoint, endoscopic cure ratio with DA-5204 and DA-9601 were 37.3% (78/209) and 37.3% (79/212), gastric symptoms were 40.4% (84/209) and 40.8% (86/212), respectively. Finally, adverse event ratio od safety issue were not different in both groups (8.4% vs. 8.8%), significantly. Serious adverse events were not reported in both groups.
**Conclusion:** In evaluation of efficacy and safety, DA-5204 (b.i.d.) was equal to DA-9601 (t.i.d.) in patients with acute or chronic gastritis. We should have to get more data with continuous clinical studies. In addition, we will develop a qd (once a day) formulation through formulation studies.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0967 IN-HOSPITAL AND DELAYED MORTALITY IN A SINGLE CENTER SERIES OF UPPER GASTROINTESTINAL BLEEDING, A CRITICAL ANALYSIS

**E. Redondo Cerezo**, R. Jimenez-Rosales, J. G. Martinez-Cara, F. Valverde-Lopez, M. Ubeda-Muñoz, J.L. Ariza-Fernandez, A. Caballero-Mateos, P. Jervez-Puente, M. Lopez De Hierro, J. De Teresa
*Gastroenterology, Hospital Virgen de las Nieves, Granada/Spain*

**Contact E-mail Address:** eredondoc@gmail.com
**Introduction:** Upper gastrointestinal bleeding is a common cause of hospitalization, with an estimated annual incidence ranging from 50 to 150 cases per 100000 people, and with morality rates ranging from 2% to 15% of the admitted patients. Factors found to be predictors of mortality include advanced age, low hemoglobin level, low systolic blood pressure, blood in a gastric aspirate, severe comorbidities (neoplasm, cirrhosis), worsening health status, rebleeding, hypoalbuminemia, elevated creatinine, elevated serum aminotransferase levels, onset of bleeding while inpatient, and active bleeding or other stigmata of recent hemorrhage at the time of endoscopy. However, mortality is not always caused by the gastrointestinal bleeding itself, but by the worsening of previous comorbidities, misbalances in their chronic treatment, or by other disease in which upper GI bleeding is only an intercurrent outcome.
**Aims & Methods:** The aim of this study is analyze inpatient and delayed 6 months mortality in patients with a previous admission because of an upper GI bleeding. This was a prospective cohort study on consecutive patients admitted to the "Virgen de las Nieves" University Hospital emergency room for the management of upper GI hemorrhage over 36 months from January 2013 to January 2016. All patients received upper endoscopy and information regarding patients' demographic data, comorbidities, current medications (including antiplatelet drugs, NSAIDS and oral anticoagulants), clinical presentations, hemodynamics, admission laboratory test results, and endoscopic findings was collected. Interventions were recorded, including the need for blood transfusion and the number of packed red cells units per patient, endoscopic therapy, radiologically guided hemostasis, and surgery. Clinical outcomes documented were in-hospital and delayed 6-months mortality, rebleeding, bleeding persistence.
**Results:** 449 patients were included (304 males; aged $64.32 \pm 16.7$). Presenting symptoms were melena ($n = 309$; 68.8%), hematemesis ($n = 236$; 52.7%), and hematochezia ($n = 43$; 9.6%). Overall in-hospital mortality was 9.8% ($n = 44$) but the GI hemorrhage specific mortality rate was $n = 23$ (5.1%). Among patients who died in the first admission, the main causes were hemorrhagic shock followed by hepatic encephalopathy. Active bleeding was observed in 60%, and 31% presented with esophageal varices, 22% gastric ulcers and 18% duodenal ulcers. Only 6% had neoplasms. In patients with delayed mortality 31% had an active bleeding in the first admission, 34% had esophageal varices, 25% a gastric ulcer but only 9% a duodenal ulcer. Neoplasms were found in 6% of patients. In this group, the leading causes of mortality were neoplasms and variceal bleeding. However, cardiovascular causes of mortality accounted 33% (Table 1). Delayed mortality was related with any type of hemorrhagic events ($p < 0.0001$). Considering most of cardiovascular or hemorrhagic delayed events preventable, we observed that half of the patiens with a delayed mortality ($n = 22$) had a potentially preventable cause (Myocardial infarction (4), stroke (4), bleeding esophageal varices (8), heart failure (3) and gastric ulcer bleeding (3)). Factors related with this mortality were AIMS65 > 2 at admission ($p < 0.0001$; HR: 1.775; 95%CI: 1.166–2.702). Age was not related with risk in our cohort. AIMS65 showed a good prognosis prediction ability regarding delayed preventable deaths (AUC 0.745; 95%CI: 0.642–0.849).

**Table 1:** Cause of delayed (6months) mortality

| | |
|---|---|
| Neoplasms | 11 (25.4%) |
| Variceal bleeding | 8 (17.8%) |
| Myocardial infarction | 6 (13.3%) |
| Heart failure | 5 (11.1%) |
| Stroke | 4 (8.9%) |
| Haemorrhagic shock | 3 (6.7%) |
| Surgical complications | 3 (6.7%) |
| Cirrhosis, encephalopathy | 2 (4.4%) |
| Biliary disease (cholangitis, pancreatitis) | 2 (4.4%) |
| Aspiration pneumonia | 1 (2.2%) |

**Conclusion:** Acute and delayed mortality in upper GI bleeding have different patterns. While cirrhosis complications are important in both groups, especially esophageal varices, advanced neoplasms have an important role in delayed mortality. In this last group of patients, there are a subgroup which mortality could be considered non-malignant or preventable. In patients with no malignancies, AIMS65 was a good predictor of mortality, and could select a subset of patients in which an intensive follow-up and therapy should be established.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0968 ACUTE NECROTIZING ESOPHAGITIS: A RETROSPECTIVE CASE SERIES

**C. Martins**, C. Teixeira, É. Gamito, A. P. Oliveira
*Gastroenterology, Setúbal Hospital Center, Setubal/Portugal*

**Contact E-mail Address:** cmartins1@campus.ul.pt
**Introduction:** Acute necrotizing esophagitis (ANE), which presents as a black esophagus on endoscopy, is a rarely described entity. Its incidence has not yet been established, and its multifactorial etiology remains unknown.
**Aims & Methods:** The aim of the study was to establish the incidence, risk factors, clinical presentation, endoscopic features, complications and outcomes of the disease. A retrospective analysis of clinical, laboratory, endoscopic and histological data and the clinical course in 17 patients with acute necrotizing esophagitis was carried out over a 5-year period (from 2010 to 2014).
**Results:** ANE was diagnosed in 17 of 11 023 upper gastrointestinal endoscopies (0.15%) carried out during the 5-year period. The average age of the patients was 77.6 years (range 53–90), with no gender predominance (53% females versus 47% males). 88% of the patients had comorbid conditions, particularly hypertension (59%) and ischemic heart disease (41%). In 86% of cases, ANE became evident with upper gastrointestinal bleeding, without hemodynamic instability in the majority of cases (82%). The lesions predominantly affected the lower two-thirds of the esophagus (65%), and there were coexisting abnormal endoscopic findings in 88% of cases. Hypoalbuminemia was observed in 16 patients (94%) with average values of 2.1 g/dL, reflecting a poor nutritional status. Empirical supportive therapy, including oral nutritional rest, proton pump inhibitors and broad-spectrum antibiotics was provided. Endoscopic remission was documented in 5 cases. Esophageal stricture in one case was the only reported complication. Seven patients (41%) died of other causes (coexisting illnesses).
**Conclusion:** In this series, the prevalence of ANE was 0.15%. It is a serious clinical entity that should be considered in the differential diagnosis of upper gastrointestinal bleeding, particularly in elderly patients. The prognosis depends more on the patient's advanced age and on comorbid illnesses than on the course of the esophageal lesions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0969 PREDICTION OUTCOME OF ACUTE NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING: PROGNOSTIC VALUE OF NON-INVASIVE RISK ASSESSMENT SCORES

**E. Soares**, M. Gravito-Soares, C. Lérias, C. Sofia
*Gastroenterology, Coimbra University Hospital, Coimbra/Portugal*

**Contact E-mail Address:** es18497@gmail.com
**Introduction:** Non-variceal gastrointestinal bleeding (NVGB) remains a common and challenge disease for gastroenterologists. Predicting the outcome in the moment of patient admission is crucial in the best management of NVGB.
**Aims & Methods: Aims:** Determine the prognostic value of usual scores used in NVGB, particularly the pre-endoscopic ones. **Methods:** Retrospective case-control study of 121 NVGB. Compared patients with worse prognosis(Group 1), defined by intra-hospital mortality, re-bleeding and hemodynamic instability at presentation; need of endoscopic therapy(Group 2); and early and late (<1 month of index event) refractory to endoscopic therapy(Group 3) with controls. Evaluated clinical and biochemical variables, non-invasive prognostic scores [admission Rockall score(aRS), Glasgow-Blatchford score(GBS), modified Glasgow-Blatchford score(mGBS), AIMS-65] and invasive prognostic scores [total Rockall score(tRS)].
**Results:** Worse prognosis occurred in 47(38.8%) patients with intra-hospital mortality in 13.2%(16/121), 28.9%(35/121) of re-bleeding and hemodynamic instability in 22.3%(27/121). Endoscopy therapy was performed in 70.2%(85/121) of patients with therapeutic refractory in 50 patients (41.3%). Relatively to patients with worse prognosis(Group 1), the prognostic scores had a similar predictive value (AUROC0.632–0.716;$p < 0.015$), being the tRS (AUROC0.716;$p < 0.001$), mGBS (AUROC0.705;$p < 0.001$) and AIMS-65 (AUROC0.688;$p < 0.001$). Patients with endoscopic therapy need(Group 2), the best prognostic scores were tRS (AUROC0.834;$p < 0.001$), mGBS (AUROC0.733;$p < 0.001$) and GBS (AUROC0.725;$p < 0.001$). The prognostic scores AIMS-65 (AUROC0.702;$p < 0.001$), mGBS (AUROC0.696;$p < 0.001$) and tRS (AUROC0.682;$p = 0.001$) showed best accuracy in predicting refractory to endoscopic therapy(Group 3).
**Conclusion:** There are many scores to predicting outcome in NVGB. The non-invasive prediction of worse outcome in NVGB is better defined by mBGS and

AIMS-65 scores. The mGBS is the best prognostic score in selecting patients who needs endoscopy and/or hospital admission.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0970 POPULATION PREVALENCE OF ROME IV AND ROME III FUNCTIONAL DYSPEPSIA IN THE UNITED STATES (US), CANADA AND THE UNITED KINGDOM (UK)

**O.S. S. Palsson**[1], M. Simrén[2], M. Van Tilburg[3], A. D. Sperber[4], W. E. Whitehead[5]

[4]*Ben-Gurion Univ. of the Negev, Tel Aviv/Israel*
[5]*Dept. Of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC/United States of America*

**Contact E-mail Address:** opalsson@med.unc.edu
**Introduction:** The new Rome IV diagnostic criteria for functional dyspepsia (FD) are similar to Rome III except they do away with several qualifiers for diagnosing the Epigastric Pain Syndrome (EPS) variant. It is unknown how the new criteria will affect the prevalence and demographic distribution of FD in the general population.
**Aims & Methods:** We aimed to characterize and compare Rome IV and Rome III FD prevalence in the general adult population across multiple countries by using data from a large three-country internet survey conducted on behalf of the Rome Foundation. The survey included the Rome IV Diagnostic Questionnaire for Adults, the Rome III diagnostic questions for FD, and demographic and health history questions, and was completed in 2015 by a community sample of individuals aged 18+ in the US, UK and Canada (2,100 in each country). Quota-based sampling ensured equal proportion of sex (50%/50%) and age groups (40% aged 18–39, 40% aged 40–64, 20% aged 65+) across countries, and controlled education distributions (30% maximum with college degree or equivalent). Latest national census figures were used to calculate correction weights for age (in 5-year bins) and gender proportions and obtain census-adjusted FD prevalence estimates for each country.
**Results:** Of 6,300 total response sets, 5,931 were judged valid for analysis (49.2% female; mean age = 47.4 years, range 18–92; 1,949 US, 1,994 UK, 1,988 Canada) after data from inconsistent responders were eliminated. Sex and age group proportions were equivalent between countries since the sampling was quota-based. Raw and census-weighted (in parentheses) FD prevalence by Rome IV vs. Rome III criteria was 11.9% (12.7%) vs. 9.4% (10.0%) in the US, 8.4% (8.7%) vs. 7.2% (7.3%) in Canada, and 7.6% (7.7%) vs. 5.9% (6.0%) in the UK. FD prevalence was significantly higher for Rome IV vs. Rome III criteria in the total sample (raw sample prevalence 9.3% vs. 7.5%, $p < 0.0001$). The US sample had higher ($p < 0.05$) Rome III FD rate than the other countries, and a higher Rome IV rate than the UK. In the total sample, women had substantially higher FD rates than men (Rome IV: 11.3% vs. 7.3%; $p < 0.0001$. Rome III: 9.9% vs. 5.1%; $p < 0.0001$), and individuals aged 65+ had lower FD rates than younger ones (Rome IV: 5.4% vs. 10.3%; $p < 0.0001$. Rome III: 4.8 vs. 8.2; $p < 0.0001$). The distribution of IBS prevalence across age and sex groups is presented in the Table. Among individuals who met Rome IV FD criteria, 61.5% classified as having Postprandial Distress Syndrome (PDS), 17.6% as EPS and 20.9% as both. With Rome III criteria, 77% of FD cases classified as PDS, only 0.5% as EPS (due to the multiple symptom exclusions required by Rome III), and 22.5% as neither.

**Table:** Population Rome III and Rome IV FD rates (%) by sex and age groups in the US, UK and Canada survey samples (without census weighting).

| Rome III FD: | Age 18–34 | Age 35–49 | Age 50–64 | 65+ | All age groups |
|---|---|---|---|---|---|
| US Females (n = 962) | 14.5% | 14.9% | 12.6% | 8.9% | 12.9% |
| US Males (n = 987) | 6.9% | 7.8% | 5.0% | 4.7% | 6.1% |
| UK Females (n = 976) | 9.4% | 7.5% | 7.3% | 2.5% | 7.3% |
| UK Males (n = 1018) | 2.2% | 6.0% | 6.5% | 2.8% | 4.5% |
| Canada Females (n = 980) | 7.9% | 8.6% | 13.7% | 7.1% | 9.6% |
| Canada Males (n = 1008) | 5.3% | 6.4% | 4.3% | 3.8% | 4.9% |
| Total Sample (N = 5,931) | 7.8% | 8.6% | 8.3% | 4.8% | 7.5% |
| **Rome IV FD:** | **Age 18–34** | **Age 35–49** | **Age 50–64** | **Age 65+** | **All age groups** |
| US Females (n = 962) | 17.2% | 17.4% | 13.4 | 8.3% | 14.4% |
| US Males (n = 987) | 13.8% | 8.3% | 8.8% | 5.1% | 9.5% |
| UK Females (n = 976) | 13.6% | 7.9% | 9.5% | 2.5% | 9.3% |
| UK Males (n = 1018) | 5.8% | 6.4% | 8.5% | 2.8% | 6.0% |
| Canada Females (n = 980) | 10.7% | 10.2% | 11.6% | 8.2% | 10.4% |
| Canada Males (n = 1008) | 8.5% | 6.9% | 4.6% | 5.9% | 6.5% |
| Total Sample (N = 5,931) | 11.8% | 9.6% | 9.4% | 5.4% | 9.3% |

**Conclusion:** In the three nations sampled, 7.7% to 12.7% of the adult population meets Rome IV FD criteria and 6.0% to 10.0% meets Rome III FD criteria. FD is more prevalent in the US than in Canada or the UK, and is female-predominant and less common in older adults (age 65+). EPS emerges as a more prevalent FD subtype in Rome IV compared to Rome III due to easing of diagnostic restrictions. [Supported by the Rome Foundation]

## P0971 LOW YIELD REPEAT UPPER GI ENDOSCOPY FOR DYSPEPSIA PATIENTS: CONSECUTIVE SERIE FROM A TERTIARY REFERRAL CENTER

S. Carvalhana, **S. Bernardo**, L. Freitas, C. Ferreira, L. C. Ribeiro, J. Velosa
*Serviço De Gastrenterologia E Hepatologia, Hospital Santa Maria, Centro Hospitalar Lisboa Norte, Lisbon/Portugal*

**Contact E-mail Address:** soniamcb@hotmail.com
**Introduction:** In patients with persistent dyspeptic symptoms, the benefit of repeating upper gastrointestinal endoscopy is unclear.
**Aims & Methods: Objectives of the study:** To evaluate endoscopic and histological findings in patients who undergo endoscopy for dyspeptic symptoms; evaluate how frequently endoscopy was repeated and whether there were changes in endoscopic/histologic findings in patients with persistent dyspeptic symptoms. **Methods:** Retrospective cohort study of all patients with dyspepsia scheduled for upper gastrointestinal endoscopy (UGE) between January 2010 and December 2012; Endoscopic follow-up until December 2015. Exclusion criteria: Prior gastric surgery or alarm symptoms highly suggestive of neoplasia. We defined organic cause for dyspepsia as peptic ulcer disease (PUD), gastroesophageal reflux disease or malignancy. Some patients had more than one positive endoscopy findings.
**Results:** The study sample included 2150 patients with average age of $54 \pm 16$ years of whom 62% were female. The average follow-up was $4.6 \pm 0.9$ years. Endoscopic/histologic findings at baseline endoscopy: normal or insignificant findings in 69.3% (1491), erosive gastroduodenitis in 14.4%, esophagitis in 7.1%, gastric polyp in 4.4%, PUD in 3.4%, Barret's esophagus in 1.2%, portal hypertension in 0.6%, malignancy in 0.7% and dysplasia in 0.3%. Patients aged $\geq$ 50 years had a trend for higher prevalence of organic cause of dyspepsia compared to those aged $<$50 years (66.0% vs 34.0%; OR 1.27; 95% CI:0.96–1.68, $p = 0.056$). Just 1/16 patients (6.2%) with malignancy at baseline endoscopy was $<$50 years old. Biopsies at baseline endoscopy were taken in 70% (1504) of patients: *H. pylori* infection in 41% (615), non-atrophic gastritis in 80% (1206) and atrophic gastritis in 19% (281). A subsequent endoscopy was performed in 83 patients for reasons other than dyspepsia, and these patients were not considered in the further analysis. UGE was repeated in 21.9% (452/2067 patients). The median time to subsequent endoscopy was 24 months (range 2–70) years and median number of UGEs/patient was 2 (range 1–10). The endoscopic/histologic findings in patients with subsequent UGE for persistent dyspepsia were: normal or insignificant findings in 78.6%, erosive gastroduodenitis in 11.9%, gastric polyp in 7.7% esophagitis in 3.3%, PUD in 2.4%, malignancy in 0.2% and dysplasia in 0.2%. The diagnostic yield of endoscopy in detecting organic causes for dyspepsia was higher for the initial UGE (11.3%) than the subsequent UGE (OR = 2.6; 95% CI: 0.92–7.5, $p = 0.07$), even when considering only patients aged $\geq$50 years (52.4% vs. 47.6%).
**Conclusion:** The diagnostic yield of UGE in patients with dyspepsia without alarm symptoms for organic causes was low with almost 2/3 of patients having a normal baseline endoscopy. However, there is a trend for a higher diagnostic yield for organic causes for dyspepsia in patients aged $\geq$50 years. Repeating endoscopies in patients with persistent dyspepsia does not seem to be clinically justified.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Carbon monoxide (CO), hydrogen sulfide ($H_2S$) and nitric oxide (NO) are endogenous mediators. CO is produced via activity of constitutive heme oxygenase (HO)-2 and inducible by inflammation and oxidative stress HO-1. $H_2S$ is produced endogenously by cystationine-$\gamma$-lyase (CSE), cystationine-$\beta$-synthase (CBS) and 3-mercaptopyruvate sulfurtransferase (3-MST). Both, CO and $H_2S$ were shown to protect gastric mucosa against injury induced by topical irritants, such as ethanol or stress. We investigated if CO and $H_2S$ exert gastroprotection against aspirin (ASA)-induced gastric damage in animal model and whether increased bioavailability of CO or $H_2S$ can affect this injury via regulation of gastric microcirculation, lipid peroxidation and expression of antioxidative enzymes in gastric mucosa. Moreover, we investigated involvement of NO in the mechanism of CO-mediated gastroprotection.
**Aims & Methods:** Male Wistar rats were pretreated with A) vehicle, B) CORM-2 (5 mg/kg i.g.) alone or in combination with NO synthase (NOS) inhibitor, L-NNA (10 mg/kg i.p.), C) ZnPP (10 mg/kg i.p.), an inhibitor of HO-1 or D) NaHS (5 mg/kg i.g.), $H_2S$ donor, E) D,L-propargylglycine (PAG, 30 mg/kg i.g.), an inhibitor of CSE. Next, ASA in the dose of 125 mg/kg was administered i.g. to induce gastric damage. The area of ASA-induced gastric mucosal damage was evaluated macroscopically by planimetry. Gastric blood flow (GBF) was measured by laser Doppler flowmeter. CO content in gastric mucosa and COHb level in blood samples were determined by gas chromatography. Protein and mRNA expression for Nrf-2, HO-1, HO-2, CSE, CBS, 3-MST, inducible NOS (iNOS), glutathione peroxidase (GPx)-1, superoxide dysmutase (SOD)-1 were measured by Western Blot and/or real-time PCR. Malonylodialdehyde (MDA) level was measured using spectrophotometric assay.
**Results:** In gastric mucosa with aspirin-induced damage, HO-1 and iNOS mRNA and protein expressions were increased in paralel to Nrf-2, while HO-2, CSE and 3-MST expression was downregulated. CORM-2 and NaHS but not ZnPP or PAG decreased ASA-induced gastric damage, and this effect was accompanied by the increase of GBF. CORM-2 significantly enhanced mRNA and protein expression for Nrf-2, HO-1, CSE, CBS, GPx-1, SOD-1 and increased CO content in gastric mucosa and COHb level in blood. However, NaHS decreased mRNA and protein expression for iNOS, HO-1 and Nrf-2, increased expression for GPx-1 and SOD-1 but did not affect expression for CSE, CBS, 3-MST and CO content in gastric mucosa. MDA level was decreased after NaHS or CORM-2 administration as compared with vehicle-control group. Interestingly, L-NNA did not affect protective effect of CORM-2 and CO-induced reduction of lipid peroxidation.
**Conclusion:** We conclude that CO and $H_2S$ are important components of protective and physiological gastric mucosal barrier. Increased bioavailability of CO produced by HO-1/Nrf-2 pathway or released from CORM-2 and increased $H_2S$ content after NaHS or enhanced biosynthesis prevent gastric mucosa against ASA-inudced gastric damage via upregulation of gastric microcirculation, downregulation of lipid peroxidation and antiinflammatory properties of these gaseous molecules. This study was supported by a grant from National Science Centre in Poland (UMO-2014/15/N/NZ4/04564).

## P0973 USE OF DISTENSIBILITY TESTING TO DEMOSTRATE PYLORIC FUNCTION IN A PORCINE MODEL

**Introduction:** Pyloric sphincter function is still relatively poorly understood. Its role in digestive function and in disease require investigation and enquiry in order to understand its function. The functional lumen imaging probe (FLIP) is a relatively new technique which uses a distensible cylindrical balloon to characterise valvular regions in the digestive tract. However to date there are very few studies to determine if FLIP can be useful in measuring pyloric sphincter function.
**Aims & Methods:** The aim of this study was to identify if new information on the function of the pylorus could be identified by inflating a FLIP probe in the pylorus using a distensibility protocol. With local ethics approval two anaesthetised pigs were used for this study (28 kg). With the pigs in the supine position the gastroscope was advanced into the stomach with a clear view of the pylorus. The EndoFLIP(R) catheter was then inserted into the biopsy channel and pushed out of the distal end of the endoscope. The probe was then placed straddling the pyloric sphincter and its position was confirmed by filling 20 ml of liquid into the balloon and observing the classic hourglass shape on the system screen. The balloon was then deflated and the pressure was set to 0 mmHg in order to establish a baseline. A stepwise inflation protocol was then carried out to 20 ml, 30 ml, 40 ml and 50 ml. Each step was held for at least 20 sec. The protocol was repeated. Then a ramp distension from 0 to 50 ml was carried out and immediate deflation at the same rate. After 1.5 ml of neostigmine was injected intraveniously and a wait of 5 minutes the stepwise and ramp protocols were repeated. After 30 mins a test distension identified that the effects of the neostigmine were no longer apparent and a further set of stepwise and ramp distensions carried out. Then using a feeding tube a mixture of 300 ml of baby formula and 150 ml of water was infused into the stomach and the stepwise protocol was repeated immediately after and again after a 30 min interval.
**Results:** Table 1 shows the results for densibility index (minimum CSA/pressure) at 30 ml, 40 ml and 50 ml volumes for the two pigs studied. The higher value the higher distensibility.

**Table 1.**

| Pig1 | Baseline | Post Neostigmine | 1 hr Post Neostigmine | Immediate Post Food | 30mins Post Food |
|---|---|---|---|---|---|
| 30 ml | 17 | 18 | 10.8 | 45.4 | 19.1 |
| 40 ml | 13.8 | 12 | 11.3 | 40.5 | 17.5 |
| 50 ml | 7 | 8.3 | 8.3 | 9.3 | 10.5 |
| Pig 2 | | | | | |
| 30 ml | 19 | 5.4 | 9.6 | 33.3 | 15.9 |
| 40 ml | 9.1 | 6.4 | 8.3 | 21.4 | 9.5 |
| 50 ml | 6.6 | 5.5 | 7.3 | 10.3 | 6.7 |

**Conclusion:** These results show that using EndoFLIP we can clearly see how the pyloric sphincter behaves like a valve, Using Neostigmine we were able to provoke a decrease in the distensibility of the pylorus in the two pigs. By placing food in the stomach during the test we have been able to show that in both pigs the pylorus became more distensible (more relaxed) as indicated by the increase in the distensibility index. This technique shows promise as a method to determine pyloric function in health and disease. However further studies are needed to verify this.

## P0974 ACCELERATION OF EXPERIMENTAL GASTRIC ULCER HEALING BY MELATONIN. EVIDENCE FOR THE INTERACTION OF MELATONIN WITH MEL RECEPTORS AND MUCOSAL REGENERATING FACTORS EGF AND IGF-1 AND THEIR RECEPTORS

**Introduction:** Melatonin is a pineal gland hormone with a potent reactive oxygen metabolite scavenging and antioxidant activities also produced in abundant amounts by gastrointestinal mucosa. This indoleamine plays an important role in protection against noxious agents and the mechanism of gastric ulcer healing. However, the expression of G-protein coupled melatonin receptors Mel1 and Mel2 in normal and/or ulcerated gastric mucosa and their relationship with trophic physiological factors including epidermal growth factor (EGF), insulin like growth factor-1 (IGF-1), and their receptors (IGF-1 R and EGF-R) during the course of gastric ulcer healing have been little studied.
**Aims & Methods:** To determine the effect of treatment with melatonin and expression of Mel1 and Mel2 receptors, growth factors EGF and IGF and their receptors during ulcer healing, GU were produced in rats by a focal, serosal application of 100% acetic acid. Rats with GU were treated 9 days with vehicle (saline) and melatonin (20 mg/kg-d i.g.) Rats were euthanized at different time intervals post-GU induction and the gastric blood flow was examined at ulcer margin and non-ulcerated gastric mucosa, the area of GU was measured by planimetry and the mucosal specimens were collected for the quantitative histology and the Mel1-, Mel2 receptors, EGF-R, IGF-1 and IGF-1 R and signal quantification were assessed using Metamorph 7 image system.
**Results:** Melatonin significantly decreased the size of GU and increased the GBF at ulcer margin at day 9$^{th}$ upon ulcer induction compared with vehicle ($p < 0.05$). In non-ulcerated stomach, Mel1 and Mel2 were expressed in: a) neuronal and glial cells of submucosal and myenteric plexuses, b) endothelial cells of blood vessels and c) in epithelial progenitor cells and surface epithelium. Signal intensity was highest in the neuronal cells ($100 \pm 4$ IU) followed by endothelial cells ($56 \pm 3$ IU; $p < 0.01$) and epithelial cells ($44 \pm 3$ IU; $p < 0.01$). Expression of Mel1 in epithelial cells was 2.1 fold stronger than Mel2 ($p < 0.01$). In the scars of healed GU neuronal cells in submucosal plexus were significantly reduced ($p < 0.001$) and Mel1 and Mel2 were reduced and/or absent. Regenerated mucosa of GU scar was lined with dilated, irregular glands, which either expressed both Mel1 and Mel2 (1.8-fold less than Mel1;

$p < 0.01$) or were Mel1 and Mel2 deficient (~24% of glands). Expression of EGF-R, IGF-1 and IGF-1 R in regenerated epithelium of GU scar was mostly co-localized with Mel1. Quantitatively expression of EGF-R was > than IGF-1 R and > IGF-1.

**Conclusion:** 1) In normal stomach, melatonin receptors Mel1 and Mel2 are expressed in neuronal cells of submucosal and myenteric plexuses, endothelial cells of blood vessels, and in epithelial progenitor cells and surface epithelium; 2) melatonin accelerates ulcer healing via an increase in gastric microcirculation around the ulcer; 3) in scars of healed GU expression Mel1 and Mel2 is significantly reduced in neuronal cells and this is improved by treatment with melatonin; 3) expression of Mel1 and Mel2 is increased ($p < 0.01$) in regenerated epithelium, where it co-localizes to EGF-R, IGF-1 and IGF-1 R, indicating their local interactions during GU healing; 3) a lack of Mel1 and Mel2 in some regenerating glands may indicate an existence of 2 distinct cell lineages, and 4) differential distribution of Mel1 and Mel2 receptors in gastric mucosa indicates targets for melatonin hormonal (e.g. endothelial cells) as well as paracrine and autocrine actions.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0975 A NEW GASTRIC ACID SUPPRESSOR, "VONOPRAZAN", IS EFFECTIVE IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE REFRACTORY TO PROTON PUMP INHIBITORS

**K. Matsumoto**[1], H. Yamashita[2], A. Okada[3]

**Contact E-mail Address:** matsuk84com@yahoo.co.jp

**Introduction:** Acid suppression is the mainstay of therapy for gastro-esophageal reflux disease (GERD), and proton pump inhibitors (PPIs) are the first choice of treatment. However, approximately 30% of patients with GERD experience persistent symptoms while taking PPIs. Previous reports have showed that the acid suppression ability of PPIs is affected by the following: (1) there is a large variation in efficacy among patients because of the cytochrome P450 (CYP) 2C19 genotype; (2) PPIs are unable to continuously control acid secretions for a period of 24 h; and (3) acid suppression is lower in patients without *Helicobacter pylori* infection than in those with the infection. Taking these finding into consideration, PPIs may be insufficient for controlling reflux symptoms in patients with GERD. Vonoprazan (VPZ) belongs to a new class of gastric acid-suppressing agents developed in Japan. It has potent and long-lasting anti-secretory effects resulting in a greater acid suppression than conventional PPIs (1).

**Aims & Methods:** The aim of this study was to investigate the effect of switching from PPIs to VPZ in patients with GERD, who have persistent symptoms despite treatment with PPIs. Sixteen patients with GERD, who have persistent reflux symptoms (heartburn and/or regurgitation at least once a week) despite treatment with PPIs were enrolled in this study. All patients were endoscopically diagnosed with non-erosive reflux disease. Patients received VPZ 20 mg daily for 4 weeks, and were assessed for the severity of heartburn (score 0–3), regurgitation (score 0–3), and summation of the heartburn and regurgitation scores (reflux symptoms score, range 0–6) before, and after 2 weeks and 4 weeks of VPZ administration. The primary endpoint was the therapeutic effect of switching from PPIs to VPZ. Complete resolution was considered when the reflux symptoms score was zero. Data were described as mean (SD). Categorized data were analyzed by $\chi 2$ test or Fisher's exact. Changes in symptom scores were analyzed using one-way analysis of variance (ANOVA). A P value of $<0.05$ was considered as significant.

**Results:** The heartburn scores at baseline, and at 2 and 4 weeks after treatment were 1.81 (1.83), 1.25 (1.12), and 1.0 (0.81) respectively. There was a significant difference between the scores at baseline and after 4 weeks ($p = 0.049$). Regurgitation scores at baseline, and at 2 and 4 weeks after treatment were 1.62 (0.88), 1.25 (1.06), and 1.06 (0.85) respectively; the scores were not significantly different from each other ($p = 0.236$). Reflux symptoms scores were 3.43 (1.26) at baseline, 2.50 (1.96) at 2 weeks, and 2.06 (1.61) at 4 weeks. A tendency for reduction in the reflux symptoms score was found at 2 weeks and at 4 weeks; however, it was of no statistical significance ($p = 0.063$). Four patients (25.0%) had complete resolution by week 2 while five patients (31.2%) had complete resolution by week 4.

**Conclusion:** The results of this study indicate that switching from PPIs to VPZ may be an effective therapy for patients with PPI-refractory reflux symptoms.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** oliv00e@naver.com

**Introduction:** Irritable bowel syndrome (IBS) and functional dyspepsia (FD) show considerable overlap.

**Aims & Methods:** The present study aimed to investigate the clinicodemographic features of FD, IBS and FD-IBS overlap. It also evaluated the potential risk factors for FD-IBS overlap including genetic polymorphism such as SLC6A4 5-HTTLPR, ADRA2A 1291C > G, GNB3 825C > T, CCK1R intron 779 T > C and TRPV1 945 G > C. Study subjects were prospectively recruited at Gastroenterologic clinic of Seoul National University Bundang Hospital between 2003 and 2014. Three hundred and fifty four FD patients and 278 controls were enrolled.

**Results:** The prevalence of IBS in FD was 35.7% (110/308) and that of FD in IBS was 70.5% (110/156). Patients with the FD-IBS overlap showed severer degree of bloating, nausea and general abdominal discomfort than either FD or IBS-alone patients (all $P < 0.05$). In multivariable analyses, nausea, postprandial fullness, SLC6A4 5-HTTLPR L/L and ADRA2A-1291 G/G were risk factor for the FD-IBS overlap among the patients with FD ($P < 0.05$). Among patients with IBS, increasing age, single/unmarried status, nausea, bloating and feeling of incomplete emptying were significantly associated with an increased risk of the overlap. Among patients with both FD and IBS, IBS-C was more common in PDS group than EPS (55% and 0%, $P = 0.035$).

**Conclusion:** The prevalence of FD-IBS overlap was considerably high and its symptom severity was severer compared to the single disorder. SLC6A4 5-HTTLPR and ADRA2A- 1291 polymorphism might be risk factors for the overlap in patients with FD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0977 THE PREDICTIVE VALUE OF A DISTINCT LABORATORY SCORE IN THE PREDICTION OF DELAYED GASTRIC EMPTYING AND AUTONOMIC NERVE DYSFUNCTION IN PATIENTS WITH AUTOIMMUNE GASTRITIS

I. Soykan[1], **Ç. Kalkan**[2]
[1]*Ankara University, Faclty of Medicine, Ankara/Turkey*
[2]*Gastroenterology, Ankara University, Faclty of Medicine, Ankara/Turkey*

**Contact E-mail Address:** isoykan@medicine.ankara.edu.tr

**Introduction:** Symptoms of patients with autoimmune gastritis are proteiform and some patients may present with symptoms suggestive of delayed gastric emptying (GE). Signs of autonomic nervous system dysfunction exist in patients with autoimmune diseases. Some of the patients with autoimmune gastritis may have delayed GE causing upper gastrointestinal (GI) symptoms and this situation may be related to autonomic nerve dysfunction.

**Aims & Methods:** The aims of this study were to investigate the predictive value of two scoring systems in the differentiation of delayed gastric emptying and deranged autonomic nerve function in patients with autoimmune gastritis. 154 patients (106 women) diagnosed as having autoimmune gastritis and 65 functional dyspepsia patients whose gastric emptying test were available, were analyzed by using two laboratory based scoring systems: "global score" (hemoglobin, mean corpuscular volume, gastrin, vitamin $B_{12}$ and chromogranin A) and "simple score" (hemoglobin, mean corpuscular volume, gastrin).

**Results:** The mean "simple score" was $4.82 \pm 0.94$ for autoimmune gastritis patients with delayed gastric emptying and $0.72 \pm 0.60$ for patients with normal gastric emptying ($p < 0.001$, AUC: 97.2, PPV: 97.6% and NPV: 100%). The mean "global score" was $7.42 \pm 0.81$ for AIG patients with delayed gastric emptying and $1.176 \pm 0.98$ ($p < 0.001$) for patients with normal gastric emptying (AUC: 98.8, positive predictive value: 99.1% and negative predictive value: 82.6%). Mean simple score was significantly lower in patients with normal autonomic nerve function compared to patients with deranged autonomic nerve function ($0.908 \pm 0.409$ vs $3.55 \pm 1.88$ $p < 0.001$, AUC: 88.3, PPV: 97.5% and NPV: 66.6%, 95% CI 88.4–99.7).

**Conclusion:** Our results showed that this model may help physicians while evaluating AIG patients and deciding which patients need gastric emptying test. Therefore, we suggest that gastric emptying study should be ordered in patients who are fulfilling the criteria proposed by these scoring systems.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** jqcht884@ybb.ne.jp

**Introduction:** Gastrin is an acid secretion-stimulating hormone, which is affected by several factors including pH in the stomach, mucosal injury and gender[1), 2)]. Proton pump inhibitors (PPIs) are commonly adopted for disorders caused by hyperacidity, and the use of PPIs is known to lead hypergastrinemia[3)]. Although H.pylori infection is known to induce hypergastrinemia[4)], the data of the gastrin levels in the patients with atrophic gastritis taking long-term PPIs is still lacking.

**Aims & Methods:** To investigate the factors elevating serum gastrin levels, we conducted this study. H. pylori status was determined by the presence of serum H. pylori IgG and serum gastrin levels were measured by RIA. Atrophic gastritis was assessed by upper gastrointestinal endoscopies performed by experienced endoscopists.

**Results:**

| Conparison items | | p |
|---|---|---|
| Use of PPIs | | |
| Non-drug users (n = 91) | PPI users (n = 175) | |
| 88.4 (66.9–166.2) | 219.1 (143.5–425.4) | < 0.001 |
| Gender | | |
| Men (n = 61) | Women (n = 205) | |
| 151.7 (86.3–286.3) | 226.1 (121.6–466.7) | 0.001 |
| H.pylori infection | | |
| Controls (n = 143) | Infected (n = 123) | |
| 153.3 (80.6–333.2) | 185.2 (109.5–336.9) | 0.064 |

323 patients (84 men and 239 women) were enrolled. Median serum gastrin levels were higher in PPI users than non-antacid users (219.1 vs. 88.4 $p < 0.001$) and in women than men (226.1 vs. 151.7 $p = 0.001$). The gender difference was confirmed in the subgroup taking PPIs ($p = 0.001$), but not among the non-users. There was no significant difference in gastrin levels among three kinds of PPIs (lansoprazole, rabeprazole, and esomeprazole). Multivariate analysis revealed that gastrin levels over 150 pg/ml were significantly associated with PPI use (OR = 7.23 CI 4.02–13.01) and women (OR = 2.32 CI 1.16–4.62). H.pylori infection and atrophic gastritis were not associated with hypergastrinemia.

**Conclusion:** Each PPI was associated with hypergastrinemia equivalently and the serum gastrin levels in PPI users were higher than $H_2$ antagonist users. Serum gastrin levels in women were higher than men, and the differences were greater especially in PPI users.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Reactivators of acetylcholinesterase (AChE) are essential in the treatment of organophosphate intoxication. Wider clinical use of several AChE modulators is limited because of the significant side effects, including serious gastrointestinal toxicity. Our research team has synthesised our own priority compound K027, 1-(4-carbamoylpyridinium)-3-(4-hydroxyiminomethylpyridinium)-propane dibromide. This novel oxime AChE reactivator was already tested in vitro and on small laboratory animals with excellent results. K027 might thus be a candidate for human therapeutic use in the event of industrial poisoning or catastrophic situations. The small adult pig can be used in experiments as an omnivorous representative due to its relatively very similar gastrointestinal functions in comparison to man. The aim of this study was to evaluate the effect of K027 on porcine oesophageal manometry.

**Aims & Methods:** Ten mature experimental pigs entered the study (Sus scrofa f. domestica, 3–4-month old; 5 males, 5 females; mean weight $32.0 \pm 4.6$ kg). All recordings were performed under general anaesthesia in the morning after 24 hours of fasting. Water-perfused disposable catheters were used (MMS G-88402, conventional 12 French, 8 channels with central lumen; MMS – Medical Measurement Systems B.V., Enschede, the Netherlands). Catheters were introduced into the oesophagus through mouth, their correct position was verified endoscopically. Basic oesophageal manometry was performed for 10 minutes by means of the Polygraf UPS 2020 (UPS-2020 manometry system from MMS – Medical Measurement Systems B.V., Enschede, the Netherlands). After this baseline period, K027 (1500 mg i.m.) was administered. Trial manometry started 19 minutes later (at the $t_{max}$ point, with $C_{max}$ 106 $\mu$g/mL). Dry swallowing was induced by massage of lower part of the neck. All evaluated parameters were assessed as an average measure of four consecutive values.

**Results:** Male and female pigs were comparable in age and weight. In female pigs, there were higher baseline pressures of the lower esophageal sphincter ($19.2 \pm 13.0$ vs. $13.0 \pm 1.6$ mm Hg; NS) and peristaltic wave pressures ($34.2 \pm 11.5$ vs. $21.6 \pm 3.4$ mm Hg; $p = 0.046$). Mean relaxation of the lower esophageal sphincter was $96.7 \pm 5.4\%$, duration of relaxation was $6.7 \pm 6.1$ seconds. Mean duration of peristaltic wave was $2.3 \pm 1.0$ seconds. These two time intervals were longer in female pigs, however, the difference did not reach a statistical significance. K027 did not produce any significant changes of the principal manometry indices (1 – type 2 error beta < 0.8).

**Conclusion:** Oesophageal manometry in experimental pigs is feasible. Porcine resting and relaxed pressures of the lower esophageal sphincter are fully comparable with healthy human subjects. Evocable swallowing is doable and oesophageal peristalsis is quantifiable. K027, a novel AChE reactivator, caused only non-significant minor changes of the major parameters of porcine oesophageal manometry.

## P0980 BRAIN MECHANISMS UNDERLYING THE EFFECT OF MOTILIN RECEPTOR AGONIST ERYTHROMYCIN ON HUNGER FEELINGS IN HEALTHY VOLUNTEERS

**D. Zhao**[1], A.C. Meyer-Gerspach[1], E. Deloose[2], N. Weltens[1], J. Iven[1], I. Depoortere[1], J. Tack[1], L. Van Oudenhove[1]

**Introduction:** We have previously shown that infusion of 40 mg of the motilin receptor agonist, erythromycin (EM), induces peaks in fasting hunger ratings, accompanied by a premature gastric phase III of the migrating motor complex (MMC). It is likely that the sensation of hunger during motilin receptor stimulation results from changes in brain activity in regions involved in the regulation of appetite and food intake.

**Aims & Methods:** Aim of the study: To explore the neural and hormonal responses to intravenous EM infusion and its influence on eating behavior measurements and hedonic food intake in healthy volunteers. Methods: Thirteen healthy right-handed women were recruited for this counterbalanced 2-visit study. On each study day, subjects were given a 275 kcal standard breakfast after an overnight fast. Hundred-and-five minutes after breakfast, intravenous cannulas were inserted into a vein on both forearms; 10 minutes later subjects entered the magnetic resonance (MR) scanner for a 10 minutes adaptation period after which MR images were acquired for 50 minutes. Ten minutes after the start of scanning, 40 mg EM or saline were intravenously infused over 20 minutes. Blood was taken from the other cannula before and every 10 minutes after the start of the infusion until the end point of the study to measure plasma motilin levels. Hunger ratings (visual analogue scale) were obtained every 5 minutes during scanning. After scanning, subjects drank chocolate milkshake ad libitum as a measure of hedonic eating. Preprocessing and analysis were performed in SPM12. The effect of EM versus saline infusion on brain responses in a priori defined regions of interest (ROI) was assessed using one-way ANOVA, with time (1 min bins) as within-subject factor, at a voxel-level threshold of pFWE-corrected < 0.05 combined with an extent threshold of kE > 10. The ROIs consisted of brain regions involved in homeostatic and hedonic control of feeding. Percentage change of the plasma motilin levels (compared to baseline) was calculated using the mixed model procedure from SAS 9.2.

**Results:** EM infusion deactivated left anterior cingulate cortex, left thalamus, and right insula. In contrast, activation of left caudate, left orbital frontal cortex, left putamen, left amygdala, midbrain, and accumbens were observed during EM infusion. The effects started 10–15 minutes and reached a peak 35 minutes after the start of infusion. Plasma motilin levels increased significantly higher after saline infusion than after EM infusion ($p < 0.0001$, mixed model). In addition, hunger ratings (increase from baseline) and milkshake intake ($p < 0.0001$, and $p = 0.044$, respectively, paired Student's t- test, one-tailed) were significantly higher after EM compared to saline. Furthermore the peak in hunger ratings coincided with the peak in the brain responses.
**Conclusion:** Intravenous infusion of the motilin agonist EM affects hunger ratings, hedonic food intake and activity in brain regions related to homeostatic and hedonic control of appetite and feeding. The effect seems not to be mediated via stimulation of motilin release.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0981 SOMATIZATION IS THE KEY LINK IN THE OVERLAP BETWEEN FUNCTIONAL GASTROINTESTINAL DISORDERS AND OTHER FUNCTIONAL SOMATIC SYNDROMES

**M.P. Jones**[1], D. Mcnaughton[1], A. Beath[1], N.J. Talley[2]
[1]*Psychology, Macquarie University, North Ryde/Australia/NSW*
[2]*University of Newcastle Faculty of Health PVC Office, Callaghan/Australia*

**Contact E-mail Address:** mike.jones@mq.edu.au
**Introduction:** Functional gastrointestinal disorders are often associated with pain and result in reduced quality-of-life for individuals affected. They are also associated with elevated anxiety[1] and a tendency to somatization [2] in which psychological distress receives apparent somatic expression. Similar findings have been reported in other functional somatic syndromes such as chronic pain and fibromyalgia. The extent to which these associations are specific to gastrointestinal disorders has not been studied.
**Aims & Methods:** This study aimed to 1) estimate the overlap between functional gastrointestinal (GI) and extra-GI conditions within individuals, 2) compare level of GI and extra-GI symptom burden in sufferers of GI and extra-GI disorders and 3) compare the correlation between somatization and symptom burden in sufferers of GI and extra-GI disorders. A similar pattern of correlation in GI and extra-GI groups would suggest a common role for somatization in symptom burden for both GI and extra-GI functional conditions. Individuals were sampled from gastroenterology clinics, chiropractic clinics and community samples screened for GI symptoms occurring more than rarely. Standard diagnostic criteria for applied to GI disorders (Rome III) and extra-GI conditions (chronic pain, lower back pain, fibromyalgia, chronic fatigue). All individuals completed standardized measures of GI and extra-GI symptom burden, including the gastrointestinal symptom rating scale (GSRS). Due to overlap, individuals were categorized as meeting criteria for FGID only, extra-GI only, both FGID and extra GI or neither. The final group did not meet criteria but did experience GI or extra GI symptoms and are considered subsyndromal.
**Results:** A total of 133 individuals were recruited and grouped as per Table 1. 23% did not meet formal criteria for either gastrointestinal or extra-GI syndromes so are considered subsyndromal. Among individuals who qualified for FGID or extra-GI syndromes 39% met criteria for both. Mean GSRS scores were higher in groups meeting FGID criteria but only by degree. Somatic pain intensity scores were highest in groups meeting extra-GI criteria but also elevated in FGIDs (Table 1).

**Table 1:** Overlap, burden and psychological associations. Table entries are a) mean (SD) or b) Pearson correlation coefficient

| Measure | Sub-syndromal (n = 31) | FGID (n = 20) | Extra-GI (n = 40) | Both (n = 38) |
|---|---|---|---|---|
| GSRS[a] | 28.8 (9.8) | 42.0 (14.4) | 31.1 (11.7) | 41.9 (14.1) |
| Somatic pain[a] | 29.9 (20.4) | 40.5 (21.8) | 32.4 (18.4) | 43.6 (21.0) |
| Anxiety[a] | 12.5 (4.0) | 12.3 (3.5) | 11.6 (3.9) | 12.0 (4.6) |
| Somatisation[a] | 24.5 (5.1) | 27.2 (3.7) | 24.9 (4.6) | 27.6 (4.9) |
| $r_{GSRS/somatization}$[b] | 0.45 | 0.52 | 0.55 | 0.45 |
| $r_{Pain/somatization}$[b] | 0.63 | 0.41 | 0.38 | 0.21 |

The correlation between somatization and both gastrointestinal symptoms burden (GSRS) and extra-GI somatic pain intensity was moderate to strong in all groups including those who did not meet criteria but were subsyndromal (Table 1).
**Conclusion:** There is substantial overlap between GI and extra-GI somatic disorders. Although somatization levels are elevated in FGIDs compared with extra-GI syndromes the correlation between somatization and both somatic pain and GSRS is relatively similar across conditions. This suggests that somatization may be a common factor in the brain-gut connection across FGID and extra-GI functional somatic syndromes.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** There are no studies examining a possible relationship between achalasia and neurodegenerative/ demyelinating diseases of central nervous system. Although both achalasia and neurodegenerative/demyelinating processes are not considered hereditary, a number of genetic variations have been shown to increase the risk of both conditions. For example, HLA-DQB1-insertion (chromosome 6) may be strongly associated with both achalasia and multiple sclerosis suggesting that autoimmune processes are involved in their etiopathogenesis. Several other findings (e.g. inflammatory infiltrate, Lewýs bodies, north-south gradient etc.) are also described in patients with achalasia as well as with neurodegenerative/demyelinating diseases.
**Aims & Methods:** The aim of our prospective study was to examine a prevalence of neurodegenerative/demyelinating diseases in a cohort of consecutive patients with confirmed esophageal achalasia. Achalasia was diagnosed by high resolution manometry, endoscopy and X-ray. One hundred and forty consecutive patients with achalasia (female/male, mean age) have been questioned so far by using a detailed questionnaire about the occurrence of neurological symptoms or diseases in their personal or family history. Those with suspicion of a neurological disease were referred for MR imaging of the brain and for detailed neurological examination.
**Results:** A total of 51 out of 140 patients (35.4%) described a presence of neurological symptoms – most often visual disturbances in 33.3% (17 pts.), paresthesia of limbs in 23.5% (12 pts.) and hypotension in 19.6% (10 pts.). A total of 6 patients (4.3%) have definitely been diagnosed with a neurodegeneration/demyelinating disease (multiple sclerosis have 3 patients, Lebeŕs optic neuropathy 1 patient, Parkinsoń disease 1 patient and Allgrove syndrome). Furthemore, 7 patients with positive questionnaire have been diagnosed with other neurological diseases (tetany, carpal tunnel syndrome, epilepsy). A total of 38 patients with positive questionnaires are still awaiting MR examination. In addition, 14 patients (27.4%) of those 51 patients with the presence of neurological symptoms (vs. 0 from 89 patients without any neurological symptoms) have positive family history of a neurodegenerative or a demyelinating disease.
**Conclusion:** Our preliminary results show an increased prevalence of at least 4.3% of neurodegenerative/demyelinating diseases in patients with achalasia (vs. approx. 1.4% in the Czech controls) and also a high prevalence of these disorders in family history.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0983 CONCURRENT AUTOIMMUNE DISEASES AND ASSOCIATED FACTORS IN PATIENTS WITH AUTOIMMUNE GASTRITIS

I. Soykan[1], **Ç. Kalkan**[2]
[1]*Ankara University, Faclty of Medicine, Ankara/Turkey*
[2]*Gastroenterology, Ankara University, Faclty of Medicine, Ankara/Turkey*

**Contact E-mail Address:** isoykan@medicine.ankara.edu.tr
**Introduction:** Autoimmune gastritis (AIG) is an autoimmune and inflammatory disorder of the oxyntic mucosa characterized by autoantibodies directed against structures containing $H^+/K^+$-ATPase and intrinsic factor, with subsequent loss of parietal cells. Autoimmune gastritis may be associated with other organ-specific autoimmune disorders, but the prevalence of this association is not entirely quantified.
**Aims & Methods:** The aims of this study were to investigate the prevalence of autoimmune disorders and evaluate the factors that might affect this association in patients with autoimmune gastritis. 320 patients with autoimmune gastritis were retrospectively studied and data on concomitant autoimmune diseases, serum gastrin and chromogranin A levels, Anti Hp IgG, antiparietal cell antibodies, presence of enterochromaffin cell hyperplasia and gastric atrophy were gathered for each patient and associations between autoimmune gastritis and studied parameters were explored through descriptive statistics and logistic regression analysis.
**Results:** Of the 320 atrophic body autoimmune gastritis patients, 171 (53.4%) had an associated autoimmune disorder. Autoimmune thyroiditis was the most common concurrent disease, diagnosed in 116 patients (36.2%). Multivariate analysis showed that, presence of enterochromaffin cell hyperplasia (odds ratio [OR] 9.445, 95% confidence [CI], 4.42–20.22) serum gastrin (OR 3.1, 95% CI. 1.46–6.60) and serum chromogranin A (OR 4.14, 95% CI, 2.01–8.52) levels remained significantly associated with the coexistence of an autoimmune disease.
**Conclusion:** Concurrent autoimmune diseases are common in patients with autoimmune gastritis. Autoimmune thyroiditis is the most encountered disease. These data suggest that patients with autoimmune gastritis should be investigated for the presence of an autoimmune disease, in particular patients with enterochromaffin cell hyperplasia and those with serum gastrin and chromogranin A levels above cut-off values.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0984 EFFECT OF INTRAGASTRIC FAT INFUSION ON THE GENERALIZATION OF REWARD SENSITIVITY

**D. Zhao**[1], M. Van Gils[2], M. Moeni-Jazani[3], M. Tuk[4], J. Tack[1], L. Warlop[5], L. Van Oudenhove[1]

**Contact E-mail Address:** dongxing.zhao@med.kuleuven.be

**Introduction:** We have previously shown that subliminal intragastric infusion of a small amount of medium chain fatty acids influences eating behavior. It is unknown whether the reward sensitivity to an exteroceptive sensory stimulus can be generalized from one domain to another domain. Thus interoceptive sensory stimulus such as intragastric fat infusion might also influence reward sensitivity within and across domains.

**Aims & Methods:** Aim of the study: To explore whether the interoceptive sensory stimulus from the food domain will generalize the exteroceptive reward sensitivity within the food domain, and in the financial domain in healthy males. Methods: Fifty nine healthy heterosexual male were recruited for this counterbalanced 2-visit study. On each study day, subjects came to the lab after an overnight fast. A feeding tube was inserted in to the fundus of the stomach via the nose. After a 10-minutes adaptation period, they were lead to a computer for an online survey (Qualtrics, Provo, Utah, USA). Hunger rating and unpleasant feeling from the tube (visual analogue scale) were obtained via the survey, after which either 2.5 g lauric acid emulsified with 250 mL phosphate buffered water (350 mOsm/L) or physiological saline was infused within 2 minutes in each visit. From the start of the infusion, subjects were shown a neutral film with landscape for 10 minutes as a filler. At the end of the film the feeding tube was removed and another hunger rating was obtained via the survey. Subjects were then shown 10 high caloric and 10 low caloric food pictures in a random order, which they needed to rate on a 7-point scale "How much would you like to eat this food right now?", with end points 'totally not' and 'certainly yes'. Next, subjects completed an intertemporal discounting task in which they specified how much money they would require in one week, one month, three months, six months and one year, instead of receiving 15 euro now, using the standard instructions in a fixed order. Area under the discounting curve (AUC) was calculated as a measure of subjects' impatience for receiving smaller-sooner amount of money. Lastly, subjects were asked to guess what they were administered intragastrically (fatty acids or saline). We treated the AUC, and ratings of food picturesas dependent variables, and fat versus saline condition as within subject factor for the analysis. Moreover, we included subjects' absolute change in hunger feelings (after – before infusion) as covariate in our mixed model in SAS 9.2.

**Results:** 21 out of 59 subjects gave a wrong post hoc guess about the content of the intragastrically infused substance. Subjects with incorrect guess gave lower discounting rate after fat infusion compared to saline, while this effect didn't exist in the correct estimation group ($p = 0.02$, $p = 0.32$, respectively, mixed model). Furthermore the discounting rate increases in the incorrect estimation group, and decreases in the correct estimation group when the change of hunger rating is larger ($p = 0.02$, $p = 0.02$, respectively). In addition, regardless of the post hoc estimation, subjects' ratings to both high caloric and low caloric food were lower after fat infusion, even after controlling for the unpleasant feeling of the tube ($p = 0.04$, $p = 0.04$, respectively).

**Conclusion:** A subliminal sensory stimulus from the food domain decreases financial discounting rate, and this effect vanished if the sensory stimulus reached conscious level. The interoceptive stimulus of intragastric fatty acid decreases the sensitivity to exteroceptive food cues.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0985 RELATIONS AMONG AUTONOMIC NERVE FUNCTION AND GASTRIC EMPTYING IN PATIENTS WITH AUTOIMMUNE GASTRITIS

Ç. Kalkan[1], A. Maden[1], **I. Soykan**[2]
[1]*Ankara University Faculty of Medicine, Ankara/Turkey*
[2]*Ankara University, Faculty of Medicine, Ankara/Turkey*

**Contact E-mail Address:** isoykan@medicine.ankara.edu.tr

**Introduction:** Autoimmune gastritis (AIG) is an autoimmune and inflammatory disorder of the oxyntic mucosa characterized by autoantibodies directed against structures containing $H^+/K^+$-ATPase and intrinsic factor, with subsequent loss of parietal cells. Signs of autonomic nervous system dysfunction exist in patients with autoimmune diseases between 24% and 100%. Some of the patients with AIG may have delayed GE causing upper gastrointestinal (GI) symptoms and this situation may be related to autonomic nerve dysfunction.

**Aims & Methods:** The purposes of this study were: (i) to define whether the autonomic nervous system dysfunction exists and determine the frequency and characteristics of dysautonomia in patients with AIG, (ii) to evaluate the association of autonomic nerve function characteristics with of GE based on radionuclide GE studies in patients with AIG. 75 patients (50 women, mean age $56.73 \pm 11.77$) diagnosed as having autoimmune gastritis were investigated by means of autonomic nervous system and gastric emptying tests. All patients underwent a standardized scintigraphic gastric emptying study and five tests evaluating autonomic nervous system. Patients with autonomic nervous system dysfunction were then analyzed and compared by means of existence of delayed gastric emptying and gastrointestinal symptoms.

**Results:** 62 patients had autonomic nervous system dysfunction (14 mild, 40 moderate and 8 severe autonomic dysfunction. The mean total score of autonomic tests was $3.85 \pm 2.35$. Total autonomic score of patients ($n = 60$) with delayed gastric emptying was significantly higher than patients ($n = 15$) with normal gastric emptying ($4.68 \pm 1.7$ vs.$1.53 \pm 0.58$, $p < 0.001$). Mean gastroparesis cardinal symptom index was significantly higher in patients ($n = 60$) with delayed gastric emptying half-time compared to patients ($n = 15$) with normal gastric emptying half-time ($1.89 \pm 1.16$ vs $0.4 \pm 0.3$, $p < 0.001$).

**Conclusion:** Most of patients with autoimmune gastritis have autonomic nerve dysfunction. There is a close relation between autonomic nervous system dysfunction and delayed gastric emptying. Gastroparesis cardinal symptom index has a high sensitivity and specifity in predicting both autonomic nerve function and delay in gastric emptying.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0986 DETAILED ANALYSIS OF A SINGLE U.S. CENTER EXPERIENCE WITH PERORAL ENDOSCOPIC MYOTOMY (POEM) SUGGESTS ITS EFFICACY AND SAFETY WITH SIGNIFICANT OCCURRENCE OF POST-PROCEDURAL GASTROESOPHAGEAL REFLUX

**Y. Haito Chavez**[1], S. Ngamruengphong[2], Y. Chen[3], M. Bukhari[3], G. Hajiyeva[4], A. Ismail[4], A. Kamal[4], G. Aguila[5], V. Kumbhari[4], V. Singh[3], M. Khashab[4]

**Contact E-mail Address:** yamihaito@hotmail.com

**Introduction:** POEM was introduced as a new effective therapeutic option for esophageal achalasia and other spastic esophageal disorders. It is currently believed that POEM is associated with low rates of post-procedural reflux and formal esophageal acid exposure testing is rarely performed after POEM.

**Aims & Methods:** To report outcomes of POEM performed by a single gastroenterologist at a single US center, including procedural adverse events (AEs) and gastroesophageal reflux (GER). Methods: All patients who underwent POEM at our institution were included. Clinical response was defined by decrease in Eckardt score to $\leq$3. AEs were graded according to the ASGE lexicon's severity grading system.

**Results:** A total of 104 patients (mean age 49.5 y, 48 females) underwent POEM from 11/2011 to 10/2015 for the treatment of achalasia (type I 10, type II 69, type III 15) or spastic esophageal disorders (n = 10) (table 1). POEM could not be completed in 1 patient due to extensive submucosal fibrosis resulting from prior therapies. The mean length of the procedure was 81.4 min (range 22–210) (table 2). The mean myotomy length was 11.6 cm (esophageal 8.3 cm, cardia 3.3 cm). A total of 83 (79.8%) patients underwent anterior myotomy while the remainder underwent posterior myotomy. The median length of hospital stay was 1.7 days (range 1–13). Among 75 patients with mean follow up period of 407 days (range 21–1447), clinical response was observed in 63 patients (84%) (86.6% vs. 62.5%, achalasia group vs. spastic disorders group, $p = 0.08$). There was significant decrease in Eckardt score after POEM (7.8 vs. 1.7, $p < 0.0001$). The mean lower esophageal sphincter (LES) resting pressure (mmHg) and the residual LES pressure (mmHg) decreased significantly after POEM (41.8 vs. 22.4, $p < 0.0001$ and 26.6 vs 11.5, $p < 0.0001$). A total of 16 adverse events occurred in 13 (12.5%) patients (5 mucosotomies, 2 pneumoperitoneum, 2 pneumothorax, 1 pulmonary embolism) (table 2): 13 complications were rated as mild, 3 moderate, and none severe. All mucosotomies were successfully treated with endoscopic closure. PH-impedance testing was completed in 47 patients following POEM: 32 (68.1%) had abnormal acid exposure with a mean De-Meester score of 81.53. Positive symptoms correlation was present in only 30% of patients.

**Conclusion:** POEM was successfully completed in 99% of the cases, even when extended indications (extremes or age, previous interventions, or sigmoid esophagus) were used. Adverse events were infrequent (12.5%) and could be managed intraprocedurally. There were no mortalities. Significant improvements in Eckardt scores and LES pressures were seen. However, post-POEM GER occurs in two thirds of patients and is most commonly silent. We, therefore, recommend formal esophageal acid exposure testing in all patients after POEM to avoid long-term complications due to caustic acid injury.

**Introduction:** Although endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) to early esophageal cancers has been performed widely, esophageal stenosis after ESD could lead dysphageal symptoms and result in decreasing quality of life [1][2]. Esophageal stenosis may impair esophageal motility, however there has been no study regarding whether EMR/ESD would affect esophageal motility so far.

**Aims & Methods:** The aim of this study is to evaluate the esophageal motility using high-resolution manometry (HRM) before and after EMR/ESD, prospectively. Patients who scheduled to undergo endoscopic therapy of esophageal tumor were prospectively enrolled. Symptom score evaluation (Eckardt score, Dysphagia score) and HRM (Star Medical, Inc, Tokyo, Japan) was performed before and after endoscopic resection(ER). Based on Chicago classification as categories of esophageal motors dysfunction [3], HRM results are expressed as DCI; Distal Contractile Integral(>20.0) (mHg-cm-s), CFV; Contractile Front Velocity (cm/s), IBP; Intrabolus Pressure (mmHg), IRP; Integrated Relaxation Pressure (mmHg), DL; Distal Latency (sec). We divided patients into two groups, patients who underwent more than 2/3 circumference resection (group A) and less than 2/3 circumference resection (group B). This study was approved by the ethical committee. (UMIN Clinical Trials Registry: UMIN000015829)

**Results:** Out of 27 enrolled patients, 22 patients (male/female; 17/5, mean age; 66, range; 52–80) were able to be analyzed (group A: 11, group B: 11). Symptom scores worsened in 72.7% of group A, but not in group B. Result of HRM were, DCI (beforeER/ afterER): ($1462 \pm 1144$/ $2104 \pm 1615$) ($p < 0.05$), CFV: ($5.3 \pm 2.5$/ $3.6 \pm 0.5$) (p: 0.08), IBP: ($4.8 \pm 6.7$/ $4.0 \pm 6.9$), IRP: ($7.5 \pm 5.6$/ $10.3 \pm 7.7$), DL: ($6.7 \pm 1.9$/ $7.6 \pm 0.8$) in group A, respectively. DCI: ($2322 \pm 1145$/ $2583 \pm 1517$), CFV: ($4.6 \pm 2.0$/ $4.6 \pm 2.2$), IBP: ($7.1 \pm 6.8$/ $8.6 \pm 8.0$), IRP: ($12.9 \pm 7.9$/ $11.2 \pm 7.2$), DL: ($6.9 \pm 1.0$/ $6.9 \pm 0.6$) in group B, respectively.

**Conclusion:** There were no significant differences of esophageal motility before and after esophageal endoscopic resection in group B. However, significant increase of DCI and tending to decrease of CFV was observed in group A indicating that massive esophageal endoscopic therapy impaired esophageal motility.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0988 DELAYED GASTRIC EMPTYING IS ASSOCIATED WITH INCREASED RISK OF CARDIOVASCULAR DISEASE INDEPENDENT OF THE AETIOLOGY OF GASTROPARESIS

**A. Gaus**[1], P. Layer[1], V. Andresen[1], J.J. Holst[2], J. Keller[3]

**Introduction:** Patients with diabetic gastroparesis have an increased risk of cardiovascular disease (CVD) which is partly attributed to autonomic neuropathy as a common risk factor. Moreover, diabetics have decreased ghrelin secretion which also has been shown to influence both, gastric emptying velocity and the risk of CVD. It is unknown, whether – independent of the aetiology of gastroparesis – there is an association between gastroparesis and CVD and whether autonomic neuropathy and decreased ghrelin release may be of pathophysiological importance.

**Aims & Methods:** This prospective study aimed to investigate the association between gastric emptying (GE), cardiovascular risk, autonomic neuropathy and ghrelin release. Patients with symptoms compatible with gastroparesis underwent a standardized $^{13}$C-octanoic acid breath test for calculation of GE half time (T½) and cumulative $^{13}$C-exhalation, measurement of ghrelin release in response to the test meal, heart rate variability (HRV) measurements and rigorous evaluation of cardiovascular risk factors to calculate the probability of a major cardiovascular event during the next 10 years (CVR) using evaluated software.

**Results:** 83 patients (59 females) participated, including 15 diabetics. In 5 patients GE was accelerated (T½ < 50 min), in 19 delayed (T½ > 150 min). The probability for a major cardiovascular event was significantly different in patients with accelerated (CRV, mean±SD: 0.8 ± 0.7%), normal (12.4 ± 17.4%) and delayed (24.2 ± 20.3%) GE ($p = 0.004$). Reduced HRV correlated with slower GE ($p < 0.019$), and 4 out of 5 patients with severely delayed GE (T½ > 250 min) had HRV results compatible with manifest autonomic neuropathy. Only 2 of these were diabetics. Postprandial ghrelin release correlated directly with HRV ($p = 0.034$) and inversely with GE time ($p = 0.006$). Multiple linear regression analysis revealed that, of commonly accepted risk factors for CVD (including diabetes), only male sex was an independent risk factor for reduced ghrelin release.

**Conclusion:** Not only patients with diabetic gastroparesis, but also with other aetiologies have an increased risk for CVD. This might partly be explained by autonomic neuropathy and/or reduced ghrelin release. Moreover, increased prevalence of CVD might contribute to the increased mortality rate in gastroparesis shown before (1). Further studies are needed to clarify whether a diagnosis of gastroparesis should trigger the search for CVD, also in non-diabetic patients.

**Introduction:** Peroral endoscopic myotomy (POEM) has been demonstrated to be safe and effective for treating achalasia. Though most groups perform POEM on the anterior wall of the esophagus with patients in the supine position, some groups perform it on the posterior wall with patients in the left lateral position. However, little is known about the comparison between the two different methods of POEM.

**Aims & Methods:** Aim: To compare the safety and efficacy of anterior myotomy and posterior myotomy for the treatment of achalasia. Methods: From August 2015 to January 2016, a total of 30 consecutive achalasia patients without prior treatment or sigmoid-type esophagus were prospectively recruited. They were randomized into anterior or posterior group. Clinical data about general characteristics, operative parameters, pre- and postoperative Eckardt score, esophageal manometry results, 24-hour PH test, adverse events were collected and compared between the two groups.

**Results:** There are 15 patients in each group, and all of them underwent POEM successfully. The mean operation time was significantly shorter in posterior group compared with the anterior group (41.3 ± 12.0 min vs. 49.7 ± 8.8 min, $P < 0.05$). Treatment success (defined as an Eckardt score ≤3) was achieved in 100% of the 30 patients during a median follow-up of 6 months (3∼8 months). Mean Eckardt score decreased significantly from 6.3 ± 1.5 (baseline value) to 0.7 ± 0.6 ($p < 0.001$). Postoperative mean basal LES pressure and 4sIRP were significantly lower compared to the preoperative values (39.3 ± 6.7 mmHg and 29.1 ± 5.5 mmHg vs 14.3 ± 3.8 mmHg and 10.4 ± 2.8 mmHg, respectively, $p < 0.01$). Adverse events were seen in 13.3% (4/30) of the cases, namely 1 subcutaneous emphysema in the posterior group, and 1 subcutaneous emphysema and 2 arrhythmia (nodal tachycardia and supraventricular tachycardia) in the anterior group. The 2 subcutaneous emphysema was spontaneous absorbed within 3 days without additional intervention. The arrhythmias were seen on the monitor during myotomy procedure and it returned to normal sinus rhythm after myotomy completed. There was no significant difference between the 2 groups in terms of treatment success, pre- and postoperative esophageal manometry, Eckardt score and adverse events ($P > 0.05$).

**Table 1:** Comparison of characteristics between the two groups

| | Anterior myotomy (n = 15) | Posterior myotomy (n = 15) | P |
|---|---|---|---|
| Sex, M/F | 7/8 | 5/10 | 0.710 |
| Age, year | 44.3 ± 13.9 | 41.9 ± 13.4 | 0.634 |
| Disease course, year | 5.1 ± 4.8 | 4.3 ± 4.7 | 0.574 |
| Achalasia type, I/II/III | 2/13/0 | 1/13/1 | 0.513 |
| Pre-POEM Eckardt score | 6.3 ± 1.5 | 6.1 ± 0.8 | 0.655 |
| Pre-POEM LESP, mmHg | 41.6 ± 8.0 | 38.8 ± 6.7 | 0.218 |
| Pre-POEM 4sIRP, mmHg | 29.6 ± 4.7 | 28.2 ± 5.4 | 0.421 |
| Operative time, min | 49.7 ± 8.8 | 41.3 ± 12.0 | 0.021 |
| Complications | 20% (3/15) | 6.7% (1/15) | 0.315 |
| Subcutaneous emphysema | 6.7% (1/15) | 6.7% (1/15) | 1.000 |
| Arrhythmia | 13.3% (2/15) | 0% (0/15) | 0.483 |
| Hospital stay, day | 4.8 ± 0.6 | 5.1 ± 1.1 | 0.391 |
| Follow-up, month | 6 (3∼8) | 6 (3∼8) | 0.941 |
| Post-POEM Eckardt score | 0.73 ± 0.59 | 0.67 ± 0.61 | 0.765 |
| Post-POEM LESP, mmHg | 15.8 ± 3.8 | 13.6 ± 3.7 | 0.198 |
| Post-POEM 4sIRP, mmHg | 11.2 ± 3.3 | 10.0 ± 2.5 | 0.335 |
| GERD symptom, % | 13.3% (2/15) | 20% (3/15) | 1.000 |
| PH test, % | 26.7% (4/15) | 33.3% (5/15) | 1.000 |
| Esophagitis, % | 13.3% (2/15) | 13.3% (2/15) | 1.000 |

**Conclusion:** The treatment efficacy and manometry outcomes were comparable between the two groups, but a posterior myotomy could reduce the procedure time. Although the overall adverse events were comparable, arrhythmia may be seen during POEM in the anterior group.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0990 ABNORMAL INTRA-BOLUS PRESSURE CORRELATES WITH ESOPHAGO-GASTRIC DYSFUNCTION AND WITH INCREASING AGE – A STUDY USING HIGH-RESOLUTION MANOMETRY

**Introduction:** High-Resolution Manometry (HRM) is currently considered the gold standard to assess esophageal peristalsis and esophago-gastric junction (EGJ) function. Indeed, with the use of this technology novel validated metrics have been developed to define clinically relevant esophageal motility abnormalities. On the other hand, among these novel metrics, there are few features whose interpretation and utility are still challenging. In particular, the intrabolus pressure (IBP) has been initially regarded as an indirect measure of bolus transit trough the EGJ.
**Aims & Methods:** We aimed to investigate the frequency of abnormal IBP and the factors implicated in its development in consecutive patients with esophageal symptoms. We included consecutive patients with esophageal symptoms (i.e. heartburn, regurgitation, dysphagia, non-cardiac chestpain) referring to our motility laboratory. Patients with gastro-intestinal surgery, achalasia or scleroderma were excluded. All patients underwent esophagogastroduodenoscopy off-antisecretory drugs (discontinued at least 30 days before the endoscopy) to assess the presence of esophageal mucosal lesions and HRM with 5-min baseline recording and 10 single water swallows. The diagnostic criteria for manometry agreed with the Chicago Classification vers. 3. We stratified these patients according to their IBP value (i.e. abnormal if $\geq$ than 17 mmHg according to literature) in two groups: patients with normal and those with abnormal IBP values. Data were expressed as mean and standard deviation. A t-test and x2-test were performed and a p-value $<0.05$ was considered statistically significant.
**Results:** Overall 200 patients (95 Male/105 Female, $56 \pm 15$ years) with esophageal symptoms were enrolled ($n = 80$ with heartburn, $n = 30$ with regurgitation, $n = 40$ with dysphagia, $n = 50$ with non-cardiac chestpain). Abnormal IBP is quite common in patients with dysphagia and non-cardiac chestpain, whereas is less frequent in patients with heartburn and/or regurgitation ($p < 0.05$). Patients with abnormal IBP had a mean age higher than patients with normal IBP ($60 \pm 13$ vs $50 \pm 16$; $p < 0.001$), but no difference was found in terms of gender distribution and BMI ($p = ns$). As to HRM characteristics, patients with abnormal IBP had similar mean Distal Contractile Integral (DCI) than those with normal IBP ($2287 \pm 10538$ vs. $2100 \pm 1497$; $p = 0.9$), but a lower esophageal sphincter (LES) resting pressure ($22 \pm 11$vs $33 \pm 16$; $p < 0.001$) and an increased IRP ($22 \pm 11$vs$33 \pm 16$; $p < 0.001$). No differences were found in terms of distal latency ($6.7 \pm 1.5\%$ vs $6.4 \pm 2.0\%$; $p = 0.14$), peristaltic swallow ($70 \pm 34\%$ vs $78 \pm 27\%$; $p = 0.07$), abnormal type of swallow such as failed, ineffective, and fragmented ($p = ns$) and EGJ morphologies ($p = ns$).
**Conclusion:** Patients with abnormal IBP values presented an increased IRP and LES resting pressure compared to patients with normal IBP values, suggesting that a reduced EGJ compliance may play an important role in its determination. Further, we observed that IBP values increase with ageing and this phenomenon could be explained by the anatomic and functional alterations age-related. Further studies investigating the diagnostic and pathogenetic role of abnormal IBP are required.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0991 POSTPRANDIAL INTRAGASTRIC PH LEVELS ARE ELEVATED FOR SIGNIFICANTLY LONGER ON REFLUX MONITORING IN PATIENTS WITH CONFIRMED GASTROPARESIS

**Introduction:** Many patients present to gastroenterology services with multiple upper GI symptoms. Complaints of postprandial retrosternal/epigastric discomfort with regurgitation are common and can suggest gastro-oesophageal reflux disease, gastroparesis, or both. Disentangling the differentials can be difficult on clinical history alone. The need for several tests to exclude each diagnosis has cost and time implications for clinicians and patients. It is known that intragastric pH rises from baseline ~1 to a median of 4.5 during a meal and gradually returns to fasting-state as the buffer (i.e ingested food) leaves the stomach. We aimed to establish if reflux monitoring, where intragastric pH is recorded routinely, could also detect longer periods of high pH postprandially in subjects with confirmed gastroparesis compared to those with normal gastric emptying.
**Aims & Methods:** From our database of patients seen in our tertiary referral GI physiology unit, we identified patients with confirmed delayed gastric emptying on $^{13}$C-octanoic acid breath test from 2009–2015 who had also undergone 24-hour reflux monitoring off PPI (combined pH-impedance). Another group of symptomatic patients with normal gastric emptying times on breath test, who also had reflux monitoring, were identified as controls. We interrogated reflux monitoring traces for baseline fasted pH, then measured the time taken for intragastric pH to return to baseline from the end of self reported mealtimes. Median times for return of postprandial intragastric pH to baseline were compared between groups.
**Results:** 57 eligible patients with gastroparesis (38 female, age range 13 to 70 years, median 39) were identified and compared with 45 subjects with normal gastric emptying times (32 female; age range 18–72, median 45 years). Median baseline fasting intragastric pH in those with normal gastric emptying and gastroparesis was 1.2 and 1.3 respectively. The median duration for postprandial intragastric pH to return to baseline for the control group was 62 minutes (95% CI: 51–70 min) compared to 109 min for the gastroparesis group (95% CI: 74–127). The difference between the two groups was significant ($p = 0.0002$).
**Conclusion:** Intragastric pH is elevated for longer periods postprandially in patients with gastroparesis. The intragastric pH data readily captured on reflux monitoring can be useful to identify patients with simultaneous pathological reflux and delayed gastric emptying. A prospective sudy where $^{13}$C-octanoic acid breath testing using standardised meal is performed with concurrent reflux monitoring is currently underway at our unit.

**Introduction:** Peroral endoscopic myotomy (POEM) has been rapidly gaining ground as a treatment for achalasia. Although POEM is a safe and effective treatment, a subset of patients has persistent or recurrent symptoms after POEM. It is currently not known how these patients can be managed best.
**Aims & Methods:** This study aimed to examine the efficacy of different retreatments after failed POEM and to identify predictors of retreatment success. In three tertiary care hospitals in Europe and the USA all achalasia patients with recurrent or persistent symptoms after POEM (Eckardt symptom score $>3$) were identified between 2011 and 2015. Retreatment success was defined as an Eckardt score $\leq 3$ persisting for at least six months. Retreatment failure was defined as Eckardt $>3$, also if patients developed recurrent symptoms after a symptom-free period.

**Abstract No: 0993**

**Table 1:** Main HRM results and statistical analisys (ANOVA and Bonferroni tests).

| | Percentage of failed swallows | | | | | p |
|---|---|---|---|---|---|---|
| | Group A (17) ≤30% | Group B (11) 40% | Group C (10) 50% | Group D (8) 60% | Group E (8) ≥70% | |
| Mean age (IQR) | 44.5 (16.2) | 43.2 (16.8) | 51.3 (7.2) | 39.8 (13.6) | 47.1 (18.1) | 0.57 |
| **P > 0.05 for all pairwise comparisons** | | | | | | |
| DCI mean (IQR) | 1255.5 (577.8) | 1466 (623.5) | 1153 (577) | 598 (582) | 284 (235) | 0.0001 |
| **P < 0.001 between A vs D; A vs E; B vs D; B vs E; C vs D and C vs E** | | | | | | |
| DCI-MRS (IQR) | 1653 (541.8) | 1578 (502) | 1241 (828) | 472 (507) | 119 (221) | 0.0001 |
| **P < 0.001 between A vs D; A vs E; B vs D; B vs E; C vs D and C vs E** | | | | | | |
| MRS/WS ratio (IQR) | 1.3 (0.6) | 1.1 (0.2) | 1.1 (0.3) | 0.6 (0.6) | 0.5 (0.3) | 0.0001 |

P < 0.001 between A vs D; A vs E; B vs D; B vs E; C vs D and C vs E

**Results:** From a cohort of 441 patients that underwent POEM, we identified 43 achalasia patients (14 females; mean age 42 years, range 17–84) with an Eckardt >3 after POEM. Before POEM, most patients had either received no treatment (22 patients; 51%) or endoscopic dilatations (17 patients; 40%). Median relapse time of symptoms after POEM was 6 months (IQR 3–20). The majority of patients (34 patients; 79%) received one or more retreatments after POEM. The other nine patients started a modified diet or refused treatment. Overall, in 17 patients (50%), the final retreatment was effective for at least six months, but efficacy differed for the choice of treatment. Laparoscopic Heller myotomy was effective in 45% of patients, and re-POEM in 63% of patients. Pneumatic dilatation (PD) with a 30 mm balloon was never long-term effective, PD 35 mm was effective in 22% of patients. When PD 35 mm was not effective, PD 40 mm also was not effective. No complications of retreatments occurred. On univariate logistic regression, patients with successfull retreatment were more often female patients ($p = 0.038$) and had a higher initial Eckardt score ($p = 0.041$), compared to patients with failed retreatment.

**Conclusion:** In our cohort of patients with POEM failure, laparoscopic Heller myotomy and re-POEM showed a modest efficacy, whereas pneumodilatation showed a poor efficacy.

**Introduction:** The last version (3.0) of Chicago Classification took anarbitrary decision and defined ineffective esophageal motility (IEM) when 50% or more wet swallows (WS) result failed (DCI < 100 mmHg/cm/s) or weak (100 < DCI < 450 mmHg/cm/s) during standard manometric protocol.

**Aims & Methods:** The aim of this study was to compare patients with different frequency of failed/weak WS, provocative test (MRS, 3 ml x 5times in 10 sec) and MRS/WS ratio to better define the IEM diagnosis. We retrospectively evaluated 59 outpatients who underwent: upper endoscopy, high-resolution manometry (HRM) with 5-min baseline recording, 10 single water swallows of 5 mL each, and 1 MRS in supine position, and 24-h impedance and pH monitoring for unresponsive heartburn. We excluded patients with achalasia, scleroderma, absent peristalsis and prior surgery. MRS/WS ratio was calculated according to medical literature. All patients were sub-grouped based on the percentage of failed/weak WS as follows: a) ≤30%; b) 40%; c) 50%; d) 60% and e) ≥ 70% failed or weak WS. All data were expressed in median and IQR. ANOVA with Bonferroni test has been applied for statistical analysis.

**Results:** Male were more represented in groups C (60%), D (75%), E (75%) ($p = 0.03$), whereas mean age was similar in all groups ($p = 0.57$). Erosive esophagitis was more represented in groups C (70%), D (50%), E (50%) ($p = 0.018$). Acid exposure time increased progressively from group A to E (A 4.3 [IQR 5.6]; B 8.2 [8.4]; C 9 [5.7]; D 9.1 [11.3]; E 10.2 [7.4]; $p = 0.014$). Total number of reflux events was higher in C and D groups (A 45.3 [IQR 20.7]; B 49 [85]; C 96 [71]; D 80 [37.5]; E 57.5 [76.7]; $p = 0.008$). Mean DCI during WS, DCI-MRS and MRS/WS ratio were progressively lower from A to E group ($p < 0.001$ with ANOVA). The Bonferroni test showed significant differences between A, B, C, versus D and E ($p < 0.001$). Details are reported in table 1.

**Conclusion:** Data on GERD evidence at impedance-pH monitoring demonstrated that IEM should be considered as clinically relevant when the frequency of failed or weak WS is ≥60%.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The recently published grading and classification system for eosinophilic esophagitis (EoE) evaluates the presence and severity of exudates, rings, edema, furrows, and strictures (EREFS). To date, the score for the EREFS grading system has not been developed.

**Aims & Methods:** We aimed to develop and validate an endoscopic score based on the EREFS system. Adult EoE patients in Switzerland and the United States underwent esophagogastroduodenscopy. The endoscopists recorded the severity of EoE-associated endoscopic features in accordance with the EREFS system. Five expert endoscopists reviewed the grading of EoE-associated endoscopic features and provided an Endoscopist Global Assessment (EndoGA) of endoscopic EoE activity (on a Likert scale from 0 to 10). In order to develop a score based on EREFS grading system, linear regression was used to quantify the way mean of EndoGA provided by five experts varied with the severity of endoscopic features. The regression based score was developed in a group of 153 adult patients with EoE (72.5% male, median age, 38 years) and validated in an independent group of 120 EoE patients (60.8% male; median age, 40.5 years).

**Results:** The mean of the difference between the highest and the lowest EndoGA rating provided by the five expert endoscopists for a given patient was 2.5 (IQR 1.0–3.6, range 0–6.5); white exudates contributed most to differences in EndoGA ranking among expert endoscopists. In the EREFS-based score, variations in severity of endoscopic features explained 92% of the EndoGA variability. The predicted EndoGA increased most, if patient had severe rings (regression coefficient of 2.5) and severe white exudates (coefficient of 3.0), and least, if patient presented with furrows (coefficient of 0.7). In the validation patients, the mean difference between EndoGA and EREFS score

was 0.13. The proposed EREFS based score ranges from 0 to 9 with various EoE-associated features graded as follows: edema (absent = 0, present = 1), rings (absent = 0, mild = 1, moderate = 2, severe = 2.5), white exudates (absent = 0, mild = 1, severe = 3), furrows (absent = 0, present = 0.5); strictures (absent = 0, low-grade = 1, intermediate-/high-grade = 2).
**Conclusion:** For a given set of endoscopic features, endoscopists differ with respect to overall impression of endoscopic disease activity with white exudates being the source of most inconsistencies in EndoGA ranking among experts. We developed and validated an EoE endoscopy score based on the EREFS grading and classification system. The utility of the score for the purposes of observational studies and clinical trials needs to be further evaluated.gov number, NCT00939263.

**Introduction:** Eosinophilic oesophagitis (EO) has emerged as a leading cause for dysphagia and food bolus. Expert consensus recommends that oesophageal biopsies be taken in all those who present with these symptoms, where no other cause is identified at endoscopy.
**Aims & Methods:** The aim of this study was to assess the incidence of EO in this group and review the frequency of oesophageal biopsies in accordance to this guidance.
All index gastroscopies undertaken for dysphagia or food bolus, from September 2014 to September 2015 at our trust, were retrospectively analysed. Patient demographics, endoscopic diagnosis, frequency of oesophageal biopsies in a normal oesophagus or suspected EO cases and the incidence of EO were noted.
**Results:** A total of 1017 cases fulfilled the inclusion criteria (97% dysphagia and 3% food bolus). Incidence of cancer was 6% (n = 59), with further causal oesophageal pathology identified in 41% (n = 416). In the 53% (n = 542) of cases with a normal oesophagus, biopsies were only taken in 10% of cases (n = 56) and in 20% (n = 6) of food bolus patients. The incidence of EO was 6.8% (n = 13) in the biopsied group, giving an overall incidence of 1.3% for those who presented with dysphagia or food bolus. Median age of diagnosis for EO was 45 years (range 21–73) and 69% were male (n = 9). Only 6 cases were suspected endoscopically (Schatzki ring n = 2, stricture n = 1, furrows n = 3). 62% (n = 8) of EO patients had a history of atopy and 39% (n = 5) serum eosinophilia. Median duration of symptoms was 5 years (range 0.1–10yrs).
**Conclusion:** The overall incidence of EO in our study group was low compared to published literature, this is likely to be reflected by the low frequency of biopsies being undertaken in this at-risk group. Awareness in recognising endoscopic features of EO and the need for screening, through biopsy, in this cohort of patients' needs to be increased among all endoscopists.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0996 INFLUENCE OF FOUR DIFFERENT BIOPSY FORCEPS MODELS ON QUANTITY AND QUALITY OF EPITHELIAL AND SUBEPITHELIAL TISSUE SAMPLING IN EOSINOPHILIC ESOPHAGITIS

**Introduction:** Eosinophilic esophagitis (EoE)-associated histologic alterations encompass the entire thickness of the esophagus including the subepithelial layer, which is not routinely sampled. As such, information about underlying subepithelial fibrosis that may impact esophageal compliance if often missing.
**Aims & Methods:** We evaluated four biopsy forceps models by assessing the following parameters: 1) success rate with which subepithelial tissue was sampled; 2) the amount of tissue biopsied; 3) quality of biopsy orientation; and 4) complications. The following forceps were used: static jaw (Olympus, FB-11K-1 and FB-45Q-1), alligator jaw (Olympus, FB-210 K), and large capacity (Boston-Scientific, Radial Jaw 4). One gastroenterologist took 240 esophageal biopsies from 30 adult EoE patients. One pathologist calculated the surface area of epithelial and subepithelial layers in H&E-stained biopsies.
**Results:** Subepithelial tissue was sampled with the following success rate: 96.7% (static jaw FB-11K-1); 92.5% (static jaw FB-45Q-1); 80% (alligator jaw); 55% (large capacity). The median ratios of the surface area of the epithelial to that of subepithelial tissue sampled were as follows: $2.05 \pm 2.52$ (static jaw FB-45Q-1); $2.56 \pm 4.96$ (static jaw FB-11K-1); $4.01 \pm 5.06$ (alligator jaw); and $5.83 \pm 7.25$ (large capacity). A larger surface area of subepithelial tissue was obtained using the static jaw forceps when compared to that using alligator jaw ($p < 0.001$ and $p = 0.037$) and the large capacity forceps ($p < 0.001$). When large capacity forceps were used, the highest rate of poorly oriented biopsies (27.5%) was observed. No esophageal perforations or hemorrhages occurred.
**Conclusion:** The static jaw forceps allowed to sample subepithelial tissue in >90% of biopsies and appear to be superior to alligator or large capacity forceps in sampling larger amount of subepithelial tissue. Sampling deeper biopsies is safe.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0997 EFFICACY OF TOPICAL STEROIDS IN EOSINOPHILIC ESOPHAGITIS: A METAANALYSIS

**S. Miehlke**[1], P. Wohlmuth[2], A. Madisch[3], A. Morgner[2]

**Introduction:** Eosinophilic esophagitis (EoE) is a chronic inflammatory allergen-mediated disease with increasing frequency. Recommend therapeutic options include elimination diets and topical steroids. The aim of this analysis was to determine the efficacy of topical steroids in the treatment of EoE based on recent randomized controlled trials.
**Aims & Methods:** We searched Pubmed and Embase for randomized controlled trials on topical steroids for treatment of active EoE fully published until 12/2015. Treatment effects were calculated as mean difference of eosinphil counts before and after treatment.
**Results:** 9 studies (budesonide n = 3, fluticasone n = 6) with a total of 416 Patienten were included. In placebo-controlled trials (n = 6) topical steroids were associated with a significant reduction of esophageal eosinophilc counts (standardised mean difference, SMD: −0.864 [−1.274, −0.454], $p < .001$). There was a moderate heterogenity between studies ((I^2 = 49.82%; Q(df = 5) = 9.86, p-val = 0.0793), which was mainly caused by differences in patient's age. There was no significant difference between budesonide und fluticasone trials (SMD = 0.389 [−0.437, 1.214], p = 0.3561). Placebo-controlled trials showed stronger effects than trials using PPI or prednisolone as comparator (p = 0.0021). The patient's age and gender had no significant influence on the efficacy of topical steroids.
**Conclusion:** Topical steroids are effective and well tolerated for the treatment of eosinophilic esophagitis independent of the patient's age and gender.

**Introduction:** Eosinophilic oesophagitis (EoE) is a chronic condition of the oesophagus characterized by a dense eosinophilic infiltrate defined as >15 eosinophils/high power field (eos/hpf). The aim of this study was to capture the prevalence of EoE in a tertiary referral centre in London, to identify factors associated with a positive diagnosis and interrogate optimal response to therapy.
**Aims & Methods:** From February 2013 to November 2015, all patients presenting with solid food dysphagia to University College Hospital had a high resolution white light endoscopy. Those with cancer, achalasia, postoperative stricture or endotherapy for Barrett's were excluded. Endoscopy, histology and clinical data were collected. >15oes/hpf were defined as positive for EoE. A separate histopathology search identified patients with >15eos/hpf and no dysphagia. A prospective follow-up was conducted in focusing on therapy and response in those with >15 eos/hpf.
**Results:** Out of the 1566 patients with dysphagia, 524 were excluded for reasons stated. 736/1042 (71%) had oesophageal biopsies. Of those, 67 (9.1%) had more than 15eos/hpf. Another 14 patients with >15eos/hpf with symptoms other than dysphagia were identified from histology records, making the total number with eosiniphilia 81. The mean number of biopsies taken in those with >15eos/hpf (6.3) was greater than those with <15eos/hpf (5.1; p = 0.003). EoE patients were more likely to be male (70%) and younger ($43 \pm 16$ years) compared to nonEoE (40% male, $p < 0.0001$; $59 \pm 16$ years, $p < 0.0001$). Typical endoscopic features were found in 39 (48%) EoE patients; rings/furrows in 26 (32%) and strictures in 15 (18%). 42/81 (52%) were treated with PPIs only of which 19 (45%) clinically responded. 18 (22%) patients had both PPI and topical steroids (12 had steroids after PPI failure) while 8/81 (10%) had steroids only. Clinically 14/26 (54%) responded optimally to topical steroids, 13 of which had dysphagia. Overall, response to steroids occurred in those with a higher eosinophilia (53 vs 24, p = 0.004) and all 9 with ≥40eos/hpf had a complete response. Furthermore, typical EoE findings at endoscopy was more likely to be associated with a poor response to PPIs ($p < 0.0001$).
**Conclusion:** A higher number of biopsies taken raises the diagnostic yield; however still up to 1/3 patients in a modern referral centre have no biopsies taken. EoE should be excluded in those with no dysphagia and refractory reflux symptoms. Although PPIs are provided as first-line therapy, a positive response to steroids is more likely in those with higher numbers eos/hpf, while those with

fewer numbers and no endoscopic features could be considered for PPI therapy first. Such findings might be a useful tool to help tailor therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0999 SIX-FOOD ELIMINATION DIET EFFECTIVELY INDUCES AND MAINTAINS REMISSION IN ADULTS WITH EOSINOPHILIC OESOPHAGITIS

**Contact E-mail Address:** susanagrodrigues@gmail.com
**Introduction:** Adults present with eosinophilic oesophagitis (EoO) most frequently with food impaction and dysphagia, and due to growing evidence it is increasingly diagnosed.
**Aims & Methods:** Aims: To evaluate the efficacy of the 6-food elimination diet (SFED) in inducing and maintaining remission and identify clinical, demographic, histological and endoscopic findings in adults diagnosed with EoO. In addition, the study evaluated the efficacy of SFED in maintainance of remission in adults with EoO diagnosed in pediatric age. Methods: Clinical, demographic, histological and endoscopic findings were retrospectively analyzed before and after SFED (wheat, soy, nuts, seafood, egg and food with cow milk) in 27 adults (17 diagnosed at adult age, 10 pediatric cases) followed in a tertiary centre clinic.
**Results:** Most patients were male (83%) and 52% had an atopic background. Dysphagia or food impaction were th presenting symptom in 94% of patients. Furrowing was the only endocopic finding present in all cases. Skin testing and IgE levels did not identify food triggers in most patients. In 88% of cases SFED induced clinical and histological remission. Food with cow milk were the most frequently identified trigger (82%). Around 90% adults diagnosed in pediatric age maintained clinical and histological remission over time with SFED (median time follow up 3.5 years).
**Conclusion:** SFED induced clinical, endoscopic and histological remission in 88% of adults with EoO. Remission was maintained in adults diagnosed with EoO with SFED. SFED is an effective and long-lasting treatment option for adults with EoO.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1000 DIFFERENTIATION OF EOSINOPHILIC ESOPHAGEAL MYOSITIS FROM EOSINOPHILIC ESOPHAGITIS

**Introduction:** Eosinophilic esophagitis (EoE) is a Th2-mediated allergic disease of the esophageal epithelium. We previously reported a case series for eosinophilic esophageal myositis (EoEM)—a novel eosinophilic gastrointestinal disorder (EoGID) as eosinophilic infiltration localized in the esophageal muscle layer.[1] EoEM was diagnosed by peroral endoscopic muscle biopsy (POEM-b), which is a new histopathological diagnosing method developed from peroral endoscopic myotomy (POEM).
**Aims & Methods:** Four patients (mean age $54.0 \pm 17.7$[SD] y; all men) were diagnosed with EoEM in our case series July 2014 through February 2016. In the same period, four other patients ($53.5 \pm 15.6$ y, 3 men) were diagnosed with EoE. The clinical features and histopathology of EoEM were investigated to differentiate it from EoE.
**Results:** Those patients with EoEM had suffered from medicine (calcium blockers and proton pump inhibitors)-resistant chest pain and dysphagia, and initially three were diagnosed with Jackhammer esophagus, and one with Nutcracker esophagus on high-resolution manometry (HRM). Conventional endoscopy and mucosal biopsy samples of the esophagus showed no characteristic findings (no eosinophils in the epithelium [maximum number, $0 \pm 0$/ high-power field [HPF]). Thereafter, POEM was performed to resolve the esophageal spastic contraction and POEM-b for histopathological assessment. In the muscle layer samples obtained by POEM-b, severe eosinophil infiltration was observed ($46.8 \pm 16.5$/HPF). In contrary, severe eosinophil infiltration ($38.5 \pm 11.3$/HPF) was observed in the esophageal epithelium of EoE. And HRM showed failed perstalsis in those patients with EoE.
**Conclusion:** Our study indicates that HRM is a useful tool to raise a first suspicion of EoEM. The EoEM histological pattern displays clear differences from that of EoE.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1001 THE PREVALENCE OF JOINT HYPERMOBILITY IN DIFFERENT PHENOTYPES OF REFLUX DISEASE: INCREASED IN OESOPHAGEAL HYPERSENSITIVITY

A. Y. Nasr, A. Fikree, Q. Aziz, **D. Sifrim**
*Neurogastroenterology, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London/United Kingdom*

**Contact E-mail Address:** d.sifrim@qmul.ac.uk

**Introduction:** Joint hypermobility (HM) refers to increased flexibility of the joints which is present in 5–17% of the population, and is assessed by clinical examination or validated hypermobility questionnaire. HM is associated with gastro-oesophageal reflux (GOR) symptoms (1). The aim of the study was to determine the prevalence of joint hypermobility in a large number of well-phenotyped patients with symptoms of GOR disease.

**Aims & Methods:** A cross-sectional study of patients attending our GI physiology unit for investigation of reflux symptoms over 4 years was undertaken. Patients completed the validated joint hypermobility questionnaire; scores $\geq 2$ out of 5 represented HM (2). Information from gastroscopy and physiology testing was used to determine whether patients had pathological GOR, hypersensitive oesophagus (no pathological reflux but positive correlation with reflux symptoms), or functional heartburn (no pathological reflux, no reflux-symptom association). Patients who were on proton pump inhibitors were excluded. Hypermobility questionnaire data from a group of 250 healthy volunteers was obtained from another study (3).

**Results:** 899 patients with complete data were included. HM was present in 18% of healthy controls. The prevalence of HM and the demographic characteristics of the patients in each reflux category is shown in Table 1. HM prevalence was highest in patients diagnosed with hypersensitive oesophagus (35%), and this was increased compared to HM prevalence in pathological GOR (22%, $p = 0.003$), functional heartburn (14%, $p < 0.0001$) and healthy controls (18%, $p = 0.0002$). HM prevalence in pathological GOR and functional heartburn was not significantly different to that in controls ($p = 0.2$ for both). Even after adjustment for age and gender, HM prevalence in hypersensitive oesophagus was significantly increased compared to that in other reflux diagnoses (17%): ORadj 2.06, CI:1.3–3.3, $p = 0.003$.

**Table 1:** HM prevalence and demographics in each reflux category

| | Pathological GOR n = 367 | Hypersensitive oesophagus n = 133 | Functional heartburn n = 399 |
|---|---|---|---|
| Females n, (%) | 187 (51%) | 88 (66%) | 254 (64%) |
| Median age (IQR) | 50 (38–60) | 43 (31–53) | 49 (38–59) |
| HM prevalence n, (%) | 81 (22%) | 47 (35%) | 55 (14%) |

**Conclusion:** The prevalence of HM in patients with hypersensitive oesophagus was almost twice as high as in healthy controls, whereas the prevalence in other phenotypes of reflux disease (pathological GOR and functional heartburn) was not significantly different to controls. This suggests that HM is over-represented in and associated with oesophageal hypersensitivity. Hypermobile patients may represent a distinct subgroup within the hypersensitive oesophagus category.

**Introduction:** Population-based MEGRE study (7812 subjects in 6 cities of Russia) performed in 2005–2006 showed that the average prevalence of GERD (Mayo Clinic Questionnaire) proved to be 13.3%.

**Aims & Methods:** The aims of the multicenter study are to determine the current prevalence, clinical spectrum of GERD and usage of medications for GERD treatment among in the urban population of Russia. Self-completion study questionnaire was performed on randomly selected 1734 patients of primary health care in the cities of Russia (Moscow, Kazan, Tver, Ryazan): 1059 females, 675 males, average age $46.1 \pm 14.4$ years. The questionnaire assessed the frequency, intensity of heartburn and regurgitation, medications consumption and frequency of their administration. Major symptoms (heartburn and/or regurgitation) were defined as "frequent symptoms" when occurring at least once a week or more. Patients were defined as having GERD if they reported frequent heartburn and/or regurgitation.

**Results:** Frequent heartburn was reported by 459 (26.5%), frequent regurgitation - by 281 (16.2%) of respondents. Prevalence of GERD among primary care patients was 30.8%. Importantly, we found that only 71.7% of subjects with GERD had seen a physician for this symptom. No difference was found in prevalence of frequent heartburn and/or regurgitation among women and men. Respondents with GERD took following medications for the last year to relieve the symptoms: PPIs −47.6%, $H_2$-blockers −20.4%, antacids −82.8%, alginates −24.2%, prokinetics −16.5%. Patients took the drugs at least once a week or more: PPIs −40.8%, $H_2$-blockers −15%, antacids −66.7%, alginates −17.8%, prokinetics −12.5%. PPIs were recommended by physician in 81.6% of cases, $H_2$-blockers – in 83.5%, antacids −65.2%, alginates −69%, prokinetics −82.8%.

**Conclusion:** Preliminary results of this study indicate a high prevalence of GERD among primary care patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1003 QUALITATIVE EVALUATION OF THE COMPOSITION OF REFLUXATE BY 24-HOUR MULTICHANNEL ESOPHAGEAL INTRALUMINAL IMPEDANCE AND PH-MONITORING AND ITS RELATIONSHIP WITH EXTRAESOPHAGEAL REFLUX DISEASE

**S. Konecny**[1], R. Kroupa[2], T. Pavlik[3], J. Dolina[1]

**Contact E-mail Address:** stefan.konecny@fnbrno.cz

**Introduction:** Gastroesophageal reflux disease (GERD) is a disease caused by backflow of gastric contents into the esophagus due to the failure of physiological antireflux mechanisms and can lead to esophageal and extraesophageal symptomatology. Extraesophageal reflux (EER) is a condition where refluxate penetrate above the upper esophageal sphincter (UES) in to the oral cavity, pharynx, upper and lower respiratory tract and leads to pathological changes like e.g. hoarseness, chronic cough, vocal fold granuloma, globus pharyngis, laryngitis, pharyngitis, rhinosinusitis, otitis media, laryngeal tumors, bronchial asthma, COPD, sleep apnea and noncardiac chest pain. GERD can cause these symptoms directly by aspiration or indirectly by neurally mediated vagal reflex.

**Aims & Methods:** The examinations were carried out using 24-hour multichannel intraluminal impedance and pH esophageal monitoring (MII-pH), which compared to the more commonly used conventional pH-monitoring can accurately detect reflux episodes at all pH levels and divide the episodes to acid reflux ($pH < 4$), weakly acidic reflux (pH 4–7) and nonacid reflux ($pH > 7$), and also provides information of the composition of refluxate (liquid, gas and mixture). We evaluated results of the examinations from 200 patients in two groups. The first group included 100 patients (56 female and 44 male, mean age 47.8 years (range 12–71 years) with GERD and typical esophageal symptomatology. In the second group were 100 patients (56 female, 44 male, mean age 45.8 years (range 16–72 years) with EER symptoms, 52 patients were sent for examination by ENT specialist, 31 patients were from pulmonary clinic, 16 patients were from allergology department and one patient was sent from cardiology clinic. We evaluated DeMeester score, the number of reflux episodes by pH (acid, weakly acid and non acid), simultaneously the state of matter (liquid, gas, mixed) and the rate of penetration in the UES area. Statistical data were evaluated using Mann-Whitney test, Fisher's exact test and Wilcoxon paired test.

**Results:** We found a statistically significant difference ($p < 0.001$) in the value of DeMeester score that were significantly lower in the group with EER (median 21.6 vs. 45 in the GERD group). Further, in the group with EER against the group with GERD we observed significantly less episodes of mixed acid reflux ($p < 0.05$) and total acid reflux ($p < 0.05$) and higher number of mixed weakly acid reflux episodes ($p < 0.01$) gaseous weakly acid reflux episodes ($p < 0.01$) and total weakly acid reflux episodes ($p < 0.01$) and increased total number of gaseous reflux episodes ($p < 0.05$). Furthermore, in the group with EER against the group with GERD we observed significantly higher number of liquid ($p < 0.05$), mixed ($p < 0.05$), gaseous ($p < 0.001$) and overall ($p < 0.01$) reflux episodes in the level of electrode Z1 (UES). Also, we observed an increased fraction of non acid reflux episodes in the group with EER (27% versus 15% of patients with GERD), but without statistical significance ($p = 0.055$). We also compared the components of the acid and weakly acid reflux within groups of patients with GERD and EER, where we have seen in the group with GERD statistically significantly more episodes of mixed acid reflux against mixed weakly acid reflux ($p < 0.001$) and lower values of gaseous component of acid reflux against the gaseous component of weakly acid reflux ($p < 0.001$). In the group with EER as in the group with GERD were fewer episodes of gaseous acid reflux against the gaseous weakly acid reflux ($p < 0.001$), but a larger total number of reflux episodes of weakly acid to acid reflux ($p < 0.001$).

**Conclusion:** Patients with EER symptoms have more weakly acid reflux episodes and fewer acid reflux episodes compared to a group of patients with classical GERD symptoms while we found minor differences in the frequency of individual components of refluxate. We also observed lower values of DeMeester score, a higher number of gaseous reflux episodes and generally significantly higher number of penetration of refluxate of all states of matter to the UES area. These differences can suggest different pathophysiological mechanism of

symptoms of EER and GERD and also the necessity of different therapeutic approach to both groups in the future.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1004 STUDY OF THE PREVALENCE OF GERD SUBTYPES IN THE NATURAL POPULATION WITH HIGH ESOPHAGEAL CANCER INCIDENCE OF CHINA

**Introduction:** There have been few studies on the prevalence of GERD subtypes in the natural population in China.
**Aims & Methods:** The aim of the research is to study the prevalence of reflux esophagitis (RE) and non-erosive reflux disease (NERD) in the natural population with high esophageal cancer incidence of China combined the questionnaire screening and endoscopy examine. A population-based, randomized, cross-sectional study was conducted by site investigation of residents between 20~70 years old in Hua County of the Henan province, an area with high esophageal cancer incidence. Those with self-reported history of cancer, cardiovascular disease, mental disorder, etc. were excluded. All the subjects underwent Gerd Q investigation, the blood test, gastro-endoscopy with routine lodine dye and esophageal biopsy. According to the Los Angeles classification, RE was classified into four grades: LA-A, LA-B, LA-C and LA-D. NERD was diagnosed if Gerd Q score≥8 without esophageal mucosal damage. The data was inputted in the database and analyzed.
**Results:** Total 3291 residents (56.61 ± 7.62yrs, M: F = 1624:1667) completed the protocol. There were 19 subjects were identified to suffered from esophageal cancer, 3 gastric cancer, 31 gastric ulcer, 24 duodenal ulcer and 1 complex ulcer. ① Total 15.80% (520/3291,58.35 ± 7.15yrs, M:F = 328:192, P < 0.001) subjects were considered GERD with positive Gerd Q screening or/and endoscopy examine. ②10.15% (334/3291) subjects (M:F = 177:157, P = 0.166) were found positive with Gerd Q scores ≥8. The Gerd Q positive rate were 1.96% (1/51) in subjects with age less than 40yrs, 6.89% (59/856) in 41~50yrs, 9.03% (108/1196) in 51~60yrs and 13.97% (166/1188) in 61~70yrs, respectively (p < 0.001). Among them, 90 were RE, so the rest of 7.41% (244/3291) were diagnosed as NERD (58.51 ± 7.21yrs, M:F = 110:134, P = 0.183). The prevalence rate of NERD were 1.96% (1/51) in subjects with age less than 40yrs, 5.26% (45/856) in 41~50yrs,7.02% (84/1196) in 51~60yrs and 9.60% (114/1188) in 61~70yrs. ③276 subjects (8.39%, M:F = 218:58, P < 0.001) were identified as RE. Among them, 3.92% (129/3291) were LA-A grade RE, 4.32% (142/3291) were LA-B, and 0.15% (5/3291) was LA-C. None LA-D was detected. The detective rate of RE were 6.54% (56/856) in subjects with age 41~50yrs, 7.53% (90/1196) in 51~60yrs and 11.28% (134/1188) in 60~70yrs (P < 0.001). In addition, among 276 RE, 67.39% (186/276) were negative with Gerd Q investigation, and 28.26% (78/276) met the definition of silent RE.
**Conclusion:** The prevalence of GERD was 15.80% in the natural population with high esophageal cancer incidence of China. The prevalence of male was higher than that of female. The detective rates of RE and NERD were 8.39% and 7.41%, respectively. The age was older, prevalence rate was higher for both RE and NERD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1005 LIFESTYLE FACTORS AND GASTRO-ESOPHAGEAL REFLUX DISEASE: A CASE-CONTROL STUDY IN ALBANIAN ADULTS

**I. Kellici**[1], A. Kocollari[2], S. Gjika[2], S. Prifti[2], L. Cakerri[1], B. Kraja[1]
[1]*Department Of Biomedical Sciences, Faculty of Medicine, University of Medicine, Tirana/Albania*
[2]*University Service Of Gastrohepatology, University Hospital Center Mother Teresa, Tirana/Albania*

**Contact E-mail Address:** indkel1@gmail.com
**Introduction:** The prevalence of Gastro-Esophageal Reflux Disease (GERD) in a population-based sample of Albanian adults has been recently estimated at 12% (1), which is lower than in many western European countries. Furthermore, GERD different environmental and lifestyle factors may contribute to its pathophysiology.
**Aims & Methods:** The aim of our study was to assess the association of GERD with lifestyle factors among adult men and women in Albania, a south-east European country still in the process of transition. A case-control study was conducted in 2013–2014 including 248 consecutive patients diagnosed with GERD at the Endoscopy Unit of the Regional Hospital Durres (142 men and 106 women, mean age: 46.5 years), and 273 GERD-free population-based controls (169 men and 104, mean age: 46.4 years; 85.3% response). A structured questionnaire included information about socioeconomic characteristics, behavioral factors and symptoms. Multivariable-adjusted binary logistic regression was used to assess the independent associations of lifestyle factors with GERD.
**Results:** GERD was positively associated with smoking, alcohol intake and physical inactivity. A similar positive association was found with body mass index and waist-to-hip ratio. Upon adjustment for socioeconomic characteristics, behavioral factors and anthropometric indices we found a negative association between GERD and daily intake of fruits, vegetables, whole-grain bread, boiled foods and olive oil (OR = 0.10, 95% CI: 0.03–0.31, OR = 0.14; 95% CI: 0.05–0.45, OR = 0.08; 95% CI: 0.02–0.26, OR = 0.06, 95% CI: 0.01–0.30 and OR = 0.03; 95% CI: 0.01–0.20, p < 0.05, respectively). There was no relationship between GERD and daily intake of tea, coffee, meat and butter.
**Conclusion:** We obtained evidence on the lifestyle correlates of GERD in Albania and the understanding of these modifiable risk factors can help to design the prevention and treatment strategies.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1006 PATHOLOGIC ACID REFLUX IS NOT A COMMON FINDING IN PATIENTS WITH SEVERE DENTAL EROSIONS

**A. Josefsson**[1], A. L. Krarup[2], P. Jerlstad[3], K. Jonsson[1], H. Törnblom[3], M. Simrén[3]

**Contact E-mail Address:** axel.josefsson@vgregion.se
**Introduction:** Previous studies have shown that dental erosions might be a common finding in patients with gastroesophageal reflux disease (GORD), some studies reporting numbers as high as 32.5% (Loffeld, *Digestion* 1996). However results are conflicting and studies regarding the prevalence of pathologic acid reflux in patients with severe dental erosions of unknown etiology are lacking.
**Aims & Methods:** We retrospectively reviewed all patients referred to our department for an ambulatory 24 h pH registration between 2007 and 2015. In all, 1063 pH registrations were performed and 54 of these were referred due to severe dental erosions of unknown etiology. pH registrations were performed by a transnasally placed catheter with the pH sensor placed 5 cm above the proximal border of the lower esophageal sphincter, position determined by use of oesophageal manometry. A pathologic pH registration was defined as total acid exposure (pH < 4) of more than 4% of the registration time. A symptom association probability (SAP) ≥95% was considered positive. Baseline demographic data and symptoms suggestive of GERD (chest pain, acid regurgitations or retrosternal discomfort) were registered, both as indicated by the dentist in the referral note and by the patient during the registration. The results obtained in the patient group were compared with a group of 24 healthy controls (Krarup 2013).
**Results:** We included 54 patients (34 males (63%)), median age 41 years (range 16–71). GORD symptoms were mentioned by the dentist in the referral note of four (8%) patients, and during the 24 h pH registration by 13 (24%) patients. In all, 8 patients (15%) had a pathologic pH registration, a positive SAP in the 13 patients with symptoms was found in 53%, and the diagnostic yield in all was 16.5% (patients with either positive SAP or pathologic pH registration). Of the four patients with GORD symptom identified by the referring dentist, one had a pathologic pH registration (25% vs 15% in the rest of the cohort p = 0.5), and only this patient also had a positive SAP. Patients who reported GORD symptoms during the registration were significantly more likely to have a pathologic pH registration, compared to those without symptoms, 38.5% vs .7.5% (p = 0.006). Comparing patients with controls, patients were significantly older (41 vs. 29.5 years, p = 0.002) but the gender distribution was similar (64% vs. 63% men, p = 0.8). There were no significant differences between patients and controls with regard to proportion of time with pH < 4 (2% (0–25%) (median (range)) vs 0.9% (0–9.1%); p = 0.21), or acid exposure time in recumbent and upright positions (upright 2% (0–30%) vs 1.2% (0–12.5%); p = 0.18, recumbent 0% (0–26%) vs 0% (0–8.2%); p = 0.7). However in patients with GORD symptoms there was a significant difference in pathologic pH registration compared with controls (38.5% vs 8.5% p = 0.025). Duration of pH < 4 was significantly lower in upright position (6% (1–30%) vs. 1.2% (0–12.5%); p = 0.006) but not significantly for total (2% (0–18%) vs. 0.9% (0–9.1%); p = 0.077) or recumbent position (1% (0–8%) vs. 0% (0–8.2%); p = 0.25). Patients without any GORD symptoms (41/54), had a pathologic pH registration to the same extent as in controls (7.5% vs 8.5% p = 0.88).
**Conclusion:** In patients referred for 24 h pH registration because of dental erosions, pathologic acid reflux is not more common than in healthy controls. A careful symptom analysis before referral could possibly better identify patients who would benefit of 24 h pH registration in order to identify acid reflux as a putative cause of their dental erosions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1007 EXPRESSION OF LNCRNA CCAT2 IN PLASMA AS POTENTIAL BIOMARKER FOR DIAGNOSIS OF ESOPHAGEAL SQUAMOUS CELL CARCINOMA

**X. Zhou**[1], G. Zhang[2]
[1]*Dept. Of Gastroenterology, Jiangsu Province Hospital, Nanjing/China*

**Introduction:** Recent studies suggested that lncRNAs are stably detectable in the plasma or serum of tumor patients. Consequently, they can be identified as biomarkers for cancer patients. Identification of these markers that can be routinely monitored to predict the disease onset of cancer patients and prognosis of cancer patients would increase their median survival. We tested whether CCAT2, which was reported to be highly expressed in tissues of esophageal squamous cell carcinoma (ESCC), could also be regarded as a potential stable biomarker in the serum of ESCC patients.
**Aims & Methods:** 10 lncRNAs, which previously found to be over-expressed in ESCC, were selected as candidates for subsequent circulating lncRNA assay. After validating in 20 pairs of tissues and plasma in training set, CCAT2 was finally selected for further analysis in another 100 patients and 100 controls. We also used ROC curve to identify the sensitivity and specificity of this test.
**Results:** Plasma level of CCAT2 was significantly higher in ESCC patients compared with controls ($p < 0.0001$). By receiver operating characteristic curve (ROC) analysis, the area under the ROC curve (AUC) was 0.837; $p < 0.0001$; sensitivity, 83.3%; specificity, 73.3%. Furthermore, CCAT2 expression distinguished early stage ESCC from controls with AUC of 0.782; sensitivity, 62.2%; specificity, 89.5%. Additionally, plasma levels of CCAT2 were significantly lower in postoperative patients than preoperative ones ($p = 0.001$).
**Conclusion:** In conclusion, plasma CCAT2 could be regarded as a potential biomarker for ESCC diagnosis, particularly for early tumor screening.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Insulin resistance and hyperinsulinemia could have a role in the growing incidence of Esophageal Adenocarcinoma (EAC) and its precancerous lesion Barrett's Esophagus, related to gastro-duodenum-esophageal reflux disease. These metabolic alterations are strictly linked to central obesity. Obesity condition is characterized by chronic systemic inflammation, increased levels of insulin like growth factor 1 (IGF1), steroids and peptides, that are showed to increase the risk of cancer. Furthermore, Human Epidermal growth factor receptor 2 (HER2) signaling activation is known to have a pivotal role in EAC carcinogenesis. A relationship between insulin and HER2 signaling was already demonstrated for breast cancer and it could be hypothesized also in this context.
**Aims & Methods:** The aim of this study was to evaluate the role of hyperinsulinemia in EAC pathogenesis, in the absence of any other confounding factor associated with obesity. To this purpose, we used the transgenic MKR murine model characterized by marked hyperinsulinemia and severe insulin resistance. Importantly, mice are not obese. Mice underwent duodenum-esophageal anastomosis in order to induce chronic reflux. Serum levels of glucose, insulin, C-peptide, leptin and IL-6 were quantified by Luminex-X-Map Technology. IR/IGF1R metabolic and mitogen signal pathways were analyzed in esophageal tissue. HER2 expression was evaluated by immunohistochemistry. Insulin signal and HER2 expression were evaluated also in insulin-treated OE19 human esophageal adenocarcinoma cell line.
**Results:** 29 normo-insulinemic wild type and 29 hyperinsulinemic MKR mice were sacrificed 30 weeks after surgically-induced reflux. 75.9% of MKR mice developed EAC compared with 34.5% of wild type ($p = 0.002$). The higher insulin concentration in MKR mice compared to wild type was responsible for insulin signal increase in esophageal tissue: IR and IGF1R were respectively two-fold and six-fold increased in MKR compared to wild type mice. A moderate HER2 expression was found in wild type neoplastic tissue, while a strong expression was found in MKR neoplastic esophageal tissues. In vitro, in absence of any other growth factor, insulin was able to induce HER2 overexpression and activation.
**Conclusion:** Hyperinsulinemia seems to have a pivotal role in EAC cancerogenesis related to chronic reflux independently from obesity condition. The insulin pro-cancinogenic mechanism could be also mediated by HER2 activation that, as known, could promote cell proliferation and invasion, inhibition of apoptotic mechanisms that, finally, are responsible for tumor onset and development.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1009 IMMUNONUTRION BEFORE ESOPHAGECTOMY: IMPACT ON IMMUNESURVEILLANCE MECHANISMS

M. Scarpa[1], **A. Kotsafti**[1], M. Scarpa[1], M. Fassan[2], M. T. Nardi[3], E. Pinto[1], F. Cavallin[1], R. Alfieri[1], M. Cagol[1], M. Rugge[4], I. Castagliuolo[5], C. Castoro[1]

**Introduction:** Esophageal adenocarcinoma is the fastest rising upper gastrointestinal malignancies in Western world and its outcome remains poor. Immunonutrition has been reported to improve the immune status of perioperative cancer patients. No data are known about the impact of immunonutrition on the immune microenvironment of esophageal adenocarcinoma. Mucosal immunesurveillance mechanisms might play a role in local recurrence after esophagectomy.
**Aims & Methods:** This study aimed to assess whether immunonutrition enriched in arginine, EPA & DHA and nucleotides could impact the immune cells responses in the local immune microenvironment of esophageal adenocarcinoma patients. Mucosal samples from healthy esophagus were obtained from 17 patients in QOLEC trial who had oral immunonutrition (Impact(®), Nestlé) for 5 days before esophagectomy were compared to those obtained from 65 patients who had esophagectomy and no supplementation. Markers of activation of antigen presenting cells (CD80, CD86 expression), innate immunity (TLR4, MyD88 expression) and cytotoxic lymphocyte infiltration (CD8, CD38, CD69 and CD107) were measured with imunohistochemistry and RT-PCR. Non parametric statistics was carried on.
**Results:** In healthy esophageal mucosa in patients having oral immunonutrition CD80 mRNA levels tended to be higher compared to patients who had no supplementation ($p = 0.08$). Moreover, in patients who had immunonutrition TLR4 mRNA were significantly higher than in those who had no supplementation ($p = 0.009$). Finally, in patients having oral immunonutrition lymphocyte infiltration (CD8+) and degranulation (CD107+) were significantly increased ($p = 0.04$ and $p < 0.001$, respectively).
**Conclusion:** Immune modulating nutrition seems to activate all the main immune surveillance mechanisms [1] in healthy mucosa of patients having esophagectomy for cancer. These results suggest possible impact of immunonutrition on adenocarcinoma local recurrence after esophagectomy and encourage the design of adequately powered clinical trials.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** berit.sunde@ki.se
**Introduction:** Dysphagia, often accompanied by significant weight loss, is the main symptom leading to the diagnosis of esophageal cancer (Lagergren and Lagergren, 2013). Due to the elasticity of the esophageal wall, esophageal cancer usually gives no symptoms until the tumor obstructs the larger part of the lumen, and often the disease has then already reached an advanced stage (Rubenstein and Shaheen, 2015). A currently common clinical problem is how to manage dysphagia and secure nutrition during neoadjuvant treatment. In a recent pilot study from our group we showed that dysphagia in esophageal and junctional cancer decreased significantly already after the first cycle of platin based neoadjuvant chemotherapy, and decreased even more after completed nCT and nCRT (Sunde et al 2014). Though there is still a gap in knowledge regarding how nCT compared with nCRT affects dysphagia.
**Aims:** To investigate patient reported dysphagia before and after neoadjuvant treatment comparing neoadjuvant neoadjuvant chemotherapy (nCT) and neoadjuvant chemoradiotherapy (nCRT). Furthermore we aimed to explore the association between dysphagia relief and histological response on the two neoadjuvant therapy options.
**Methods:** A multicentre randomized controlled trial acronymed NeoRes comparing nCT with nCRT before surgery. Studypopulation was among 181 patients randomized in Sweden and Norway that answered dysphagia items using European Organisation for Research and Treatment of Cancer (EORTC)- esophageal specific instrument QLQ OES24/OG25 (n = 152). Histologic response was reported according to Chirieac Tumor Regression Grade.
**Statistics:** Data were analysed according to the EORTC manual. SAS proc mixed model was constructed to analyse repeated data with dysphagia effect and dysphagia-treatment adjusted with gender, age and histologic response. The distribution of characteristics between the two group treatment groups (nCRT and nCT) was described and compared, using Chi-square and Mann-Whitney U test where appropriate.
**Results:** Among 91 patients answering both dysphagia questionnaire before and after neoadjuvant treatment (patients with stent excluded) we found that in nCT a mean dysphagia score was before treatment 41(32–51) and decreased to 25(12–39) after neoadjuvant treatment, with a mean score difference on −16 and a p-value = 0.018. In nCRT arm mean score before neoadjuvant treatment was 41(30–50) and decreased to 28(17–39) after neoadjuvant treatment with a mean score difference −13 with a p-value = 0.081. In comparison between the arms nCT versus nCRT no score difference was detected between the groups (difference = 3). In both arms a statistical significant reduction was seen in problem to eat solid food. In nCT we detected a decrease from mean 60 before treatment to mean 31 after neoadjuvant treatment (p = 0.002) and nCRT mean 58 before treatment to 36 after neoadjuvant treatment (p = 0.005). Among patients without dysphagia we detected in nCRT arm a statistical significant increase of dysphagia (p = 0.006) after neoadjuvant treatment but stable among patients with nCT (p = 0.15). In comparsion between the arms nCT versus nCRT the increased dysphagia after neoadjuvant treatment in cohort without dysphagia had mean difference of 14 and a p-value = 0.008. In the other comparsions no difference were detected between the arms. We detected no association between dysphagia response and histologic response (p = 0.473).
**Conclusion:** Dysphagia improved after nCT, while not statistically significant after nCRT. In both arms a statistically significant ability to eat solid food was detected. In nCRT arm we detected a statistical significant increase of dysphagia. No correlation between change of dysphagia score and histologic response was detected using generalized linear mixed effect model.

## P1011 THE CLINICAL AND SERVICE IMPACT OF THE NATIONAL OESOPHAGO-GASTRIC CANCER AWARENESS CAMPAIGN: A LOCALITY ANALYSIS FROM COUNTY DURHAM

**S. Koo**[1], B. Awadelkarim[1], S. Choudhary[1], A. Dhar[2]

[2]*Gastroenterology, County Durham and Darlington NHS Foundation Trust, Co. Durham/United Kingdom*

**Contact E-mail Address:** sara.koo@gmail.com
**Introduction:** The UK national 'Be clear on cancer (BCOC)' campaigns led by Public Health England aim to improve public awareness of symptoms of cancer with a view to make an early diagnosis and reduce deaths arising from advanced disease. The 2015 national campaign for oesophago-gastric (OG) cancer ran from 26 January to 22 February with a key message of 'Having heartburn, most days, for 3 weeks or more could be a sign of cancer – tell your doctor' and a secondary message of 'Food sticking when you swallow could be a sign of cancer – tell your doctor.' The initial analysis of endoscopic outcomes of the national campaign suggested no significant increase in diagnosis of OG cancers. A locality impact analysis has not been reported so far.
**Aims & Methods:** This study is aimed as an impact analysis of the BCOC Oesophago-gastric cancer campaign in a specific locality of South Durham Hospitals (Darlington Memorial and Bishop Auckland[DA(CG1]). It aims to assess two aspects of the campaign: (1) clinical gain of a diagnosis of OG cancer and (2) the service impact of the increase in endoscopy demand as 2WW and routine referrals. Methods: Upper GI endoscopic data was captured from an electronic Endoscopy Scheduling software, as additions to gastroscopy waiting lists at two periods of time: 4 weeks after the OG campaign, in March 2015 and 4 months after the campaign, in July 2015. These included referrals from general practitioners for upper gastrointestinal symptoms in February/March 2015 (to coincide with the campaign period) and June/July 2015 (to coincide with a non-campaign period). Referrals for variceal screening, Barrett's surveillance, inpatient referrals or patients already known to secondary care were excluded. Of 760 cases, 407 were selected.
**Results:** There were a total of 284 referrals (2WW-149, urgent[DA(CG1] −66, routine-69) during the campaign period, which was 2.2 times greater than non-campaign period of 123 referrals (2ww-79, urgent-9, routine-35). The age distribution of cases was similar during both periods, with patients aged 61–80 having highest referral rates. Gender distribution was fairly similar across both periods for 2ww and routine referrals. However, there were 2.4 times more females referred urgently during the campaign period compared to male patients. During the campaign, despite an increase in referrals, there was no significant incease in OG cancer diagnosis. Only 2 OG cancers (1 oesophageal squamous cell carcinoma, 1 gastric adenocarcinoma) were diagnosed from 2ww referrals, while none was diagnosed from urgent or routine referrals. These 2 patients presented with dysphagia and weight loss. During the non-campaign period however, 3 malignancies were detected from 2ww referrals. Only one was an OG cancer (gastric adenocarcinoma), the other two had normal gastroscopies with malignancy detected on imaging (lymphoma, metastatic adenocarcinoma of unknown origin). There was no impact on average waiting time from referral to endoscopy for urgent referrals during both periods (29–42 days). The main impact on waiting times was seen for routine referrals: an increase from 29–42 days during non-campaign period to 43–56 days during the campaign period.
**Conclusion:** A national Oesophago-gastric cancer awareness campaign produces a significant increase in the number of referrals for gastroscopy, which has an impact on routine waiting times. The campaign has not shown any increase in diagnosis of OG cancers, thereby indicating that other strategies need to be considered for reducing deaths due to these cancers.

## P1012 ESOPHAGEAL STRICTURES AFTER CHEMORADIOTHERAPY FOR ESOPHAGEAL CANCER; PREDICTORS AND SURVIVAL RATE

**N. Nishide**, T. Nishina, S. Hori, S. Nadano, H. Ishii
*Gastroenterology, Shikoku Cancer Center, matsuyama/Japan*

**Contact E-mail Address:** n.nishide@shikoku-cc.go.jp
**Introduction:** Chemoradiotherapy (CRT) has been an important role in the treatment of inoperable esophageal cancer. Esophageal strictures sometimes occur after CRT, which cause patients dysphagia. Although there are several studies about esophageal strictures, their clinical courses are unknown.
**Aims & Methods:** The aim of this study was to clarify the predictors for esophageal strictures and examine survival rate. This study was a retrospective and single-center study. Sixty patients with esophageal cancer received CRT between April 2011 to October 2013. We clarified predictors of the esophageal strictures after CRT by comparing the patients with stricture and those without it, and examined a 3-year survival rate. Strictures were defined as the condition that the endoscope (9.8 mm in diameter) did not pass thorough. This study was approved by the institutional review board of our hospital.
**Results:** Esophageal strictures occurred in 16 of 60 patients (27%). In the univariate analysis, longitudinal diameter (7.2 ± 0.5 cm vs 5.0 ± 0.3 cm), the proportion of tumor to the whole esophageal lumen (3/4< / <3/4:p = 0.006), and tumor depth (T3-T4 / T1-T2:p = 0.002) were significant predictors of esophageal strictures. The multivariate analysis revealed that longitudinal diameter of ≧7.0 cm (OR, 6.11; 95CI, 1.50−29.11) and tumor depth of T3-T4 (OR, 6.15; 95CI, 1.42−35.69) were significant predictors. The 3-year survival rate of the patients with strictures was 31% and that without strictures was 67%. The

survival rate of the patients with esophageal stricture was significantly lower than the rate without stricture (p=0.002).
**Conclusion:** Longitudinal diameter of 7.0 cm and tumor depth of T3-T4 were significant predictors for esophageal strictures after CRT. The survival rate of the patients with esophageal strictures was significantly lower than the rate without strictures.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1013 CLINICAL EFFICACY OF POLYGLYCOLIC ACID SHEET TO PREVENT ESOPHAGEAL STRICTURE AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION

**Introduction:** Stricture after endoscopic submucosal dissection (ESD) for superficial esophageal neoplasm with a mucosal defect involving more than three-quarters of the circumference is frequent. This prospective cohort study examined the clinical efficacy of application of polyglycolic acid (PGA) sheet with fibrin glue for the prevention of esophageal stricture after ESD.
**Aims & Methods:** We conducted a prospective study on eight patients with superficial esophageal neoplasm treated by ESD, who had a more than three-quarter including whole circumferential defect. After resection, PGA sheets were placed over the mucosal defect. Endoscopy was performed 2 days, 4 weeks, and 8 weeks after ESD, and esophagogram was performed 8 weeks for evaluating the degree of stenosis. In addition, dysphagia scoring scale at 8 weeks was investigated. Results were compared with a historical control group of nine patients who underwent ESD without PGA. The primary endpoint was the post-ESD stricture rate. Secondary endpoints included dysphagia score, degree of stenosis, the number of endoscopic balloon dilation sessions, and the occurrence of adverse events.
**Results:** Compared with the historical control group, the study group had a significantly lower stricture rate (12.5%, 1/8 patients vs. 66.7%, 6/9 patients; $P = 0.024$). There was a lower 8-week dysphagia score in PGA group than control group ($0.63 \pm 1.41$ vs. $2.22 \pm 1.56$; $p = 0.044$). In addition, frequency of severe stenosis was 12.5% and 55.6% in PGA and control group, respectively ($p = 0.054$). Number of EBD sessions was lower in PGA group with borderline level of statistical significance ($0.25 \pm 0.70$ vs. $2.00 \pm 2.24$; $p = 0.052$). There was no serious adverse event in both groups.
**Conclusion:** PGA application showed favorable outcome for the prevention of stricture after ESD for superficial esophageal neoplasm.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1014 CLINICAL OUTCOMES OF ENDOSCOPIC RESECTION FOR SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA IN CERVICAL ESOPHAGUS

**Introduction:** Since the cervical esophagus (CE) is the narrowest portion of the esophagus, it is difficult to observe endoscopically due to anatomical constriction and gag reflex. Therefore, most of the CE cancers were detected at advanced stage, and often required total laryngectomy to achieve cure. Although the clinical benefit of endoscopic resection (ER) for superficial cancer in the thoracic esophagus is clarified, little is known for lesions in the CE because of low detection rate in superficial cancer.
**Aims & Methods:** The aim of this study was to clarify the clinical outcomes of ER for superficial squamous cell carcinoma (SSCC) of the CE. We enrolled consecutive patients with SSCC lesions in the CE who underwent ER at the National Cancer Center Hospital East between January 2009 and June 2015. The indication criteria of ER was as follows; 1) invasion depth was limited within SM1, 2) absence of clinical lymph node or distant metastasis. The definition of the CE referred to UICC TNM Classification, 7th Edition. An esophageal stricture (ES) was defined that endoscope with ordinary diameter could not pass through and endoscopic balloon dilation was required due to stricture symptom. We retrospectively analyzed clinocopathological factors and clinical courses after ER for SSCC in the CE. This study was approved by the institutional review board in our institution.
**Results:** A total of 33 patients (29 male and 4 female; median age of 69 years; range 49–85) with 37 lesions were enrolled. In the past histories, thoracic esophageal cancer and head and neck cancer (HNC) were found in 21 (64%) and 16 (49%) patients, respectively. 8 patients had other synchronous cancers (7 HNCs and one gastric cancer). 20 lesions limited in the CE, and the remaining 17 lesions extended to the upper thoracic esophagus. Conventional endoscopic mucosal resection and endoscopic submucosal dissection were performed in 10 and 27 lesions, respectively. Of the 37 lesions, 35 (95%) were resected en bloc, and 19 lesions were treated with ER under general anesthesia. In addition, 7 patients underwent simultaneously ER for another superficial HNC. Serious complications involving perforation or bleeding required intervention or transfusion were not observed. Median size of lesion was 16 mm in diameter (range: 3–52), and depth of tumor invasion; EP/LPM/MM/SM1/SM2 were 20/9/4/0/4 lesions, respectively. The luminal circumferences of mucosal defects after ER; $<1/2$ / $\geqq 1/2$ and $<3/4$ / $\geqq 3/4$ were 15/11/11, respectively. While a total of 12 patients developed ES, all of them recovered with repeated balloon dilation. Of the 12 patients, 10 had 3/4 or larger mucosal defect after ER, with ES rate of 91%. At the median follow-up period of 23 (range: 4–68) months after ER, local recurrence was detected in one (3%) patient alone. Metachronously superficial thoracic esophageal cancer was detected in 9 (27%) patients, and superficial HNC was detected in 7 (21%). All lesions were detected with follow-up endoscopy, and all of them except for one were treated with ER or partial resection under organ preservation. No lymph node or distant metastasis was detected in all patients, and no patients required laryngectomy and died with primary esophageal cancer in the CE.
**Conclusion:** Conclusion: Clinical benefit of ER for SSCC in the CE could be clarified because of curative potential under organ preservation. Careful observation in follow-up endoscopy after ER would be very important not only for early diagnosis of local recurrence but also for early detection of metachronous thoracic esophageal cancer and HNC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1015 ENDOSCOPIC ULTRASOUND (EUS) FOR PSEUDOACHALASIA, HISTORY REVISITED!

**C. T.W. Chia**[1], I. Koumoutsos[2], I. Nasr[2], S. Demartino[2], J. Meenan[2]

**Contact E-mail Address:** tzechris@gmail.com
**Introduction:** Pseudoachalasia is an infrequent secondary form of achalasia which can result from malignant or benign tumours, postoperative complications or paraneoplastic syndromes. Management can be vastly different between achalasia and pseudoachalasia, making it important to exclude the latter condition. Oesophago-gastro-duodenoscopy (OGD), high resolution manometry (HRM), barium oesophagram, CT scan and EUS play complementary roles to procure a diagnosis of achalasia and exclude pseudoachalasia.
**Aims & Methods:** This is one of the few studies that aims to evaluate the role of EUS in excluding pseudoachalasia for patients referred for achalasia workup. Data was collected retrospectively from hospital electronic records from 2008 to 2015. Our study group comprised 77 patients (female = 44, male = 33) with a mean age of 62 years. All cases had a prior OGD and EUS performed. Only cases with a non-diagnostic OGD (including negative esophageal biopsies) were included. Cases with obvious mass seen on OGD were excluded. Work up included the following:(A) classic achalasia symptoms, (B) normal OGD, (C) positive HRM +/-barium for achalasia/gastro-oesophageal junction outflow obstruction (GOJ-OO) and (D) had CT scan performed. Yield of excluding pseudoachalasia with addition of EUS was analysed in 4 groups: (1) A+B, (2) A+B+C, (3) A+B+D and (4) A+B+C+D. Cases referred without information on manometry, barium or CT findings were excluded appropriately in the subgroup analysis. Surveillance was performed within 6–12 months to detect any missed cases of pseudoachalasia. Statistical analysis was performed using SPSS V20 using the McNemar Chi-Square and Cochran's Q.
**Conclusion:** In excluding pseudoachalasia, additon of EUS to a well complemented workup (typical symptoms, OGD, HRM and/or CT scan) may not yield statistically significant benefit. However, EUS demonstrated good sensitivity and excellent specificity, PPV and NPV for pseudoachalasia detection clinically and should be considered on a case-by-case basis especially in any diagnostic dilemma.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** It has become possible to resect the superficial esophageal cancer of whole circumferential extension in en bloc fashion by ESD along with advancement of the ESD technique. However postoperative stenosis is sure to be developed, a countermeasure has been desired. Steroid injection or oral steroid administration is performed for extensive resection of non-whole circumference, and its effectiveness has been reported. But countermeasures for the entire circumference resection are not sufficient.

**Aims & Methods:** The aim of this study was to clarify the efficacy of modified oral steroid therapy which has done in our hospital and to clarify the current situation and challenges. Consecutive 25 patients underwent ESD of the entire circumference for superficial esophageal cancer from April 2010 to April 2015. Three patients were excluded because of additional surgery after ESD. So 22 patients were included in this study. Until January 2013 oral steroid had been administered for total 8 weeks, which was scheduled that 30 mg steroid was administered for 2 weeks, 25 mg for 2 weeks, and then 20 mg. 15 mg, 10 mg, 5 mg for 1week as an original method. Modified method, which was scheduled that 30 mg steroid was administered for 3 weeks, and then steroid was reduced in each 5 mg in 3 weeks interval, has been conducted since February 2013. Eleven patients were administered in original method, and 11 patients were in modified method.

**Results:** Four lesions were located at the upper site of the esophagus, 13 were at the middle, 5 were at the lower. All cases except 3 cases were performed ESD under general anesthesia. Procedure time was 114 minutes in average. There was no adverse event including post ESD bleeding and perforation. In the original method, esophageal stricture, which scope cannot pass through and dilatation was needed, prophylactic dilatation was performed in 2 patients. The median number of dilatation was 25, and mean number was 19.4. In the modified method, esophageal stricture and followed by balloon dilatation was developed in 4 patients (36%). The median number of dilatation was 0, and mean number was 6.2. Pneumonia and oral herpes infection were observed in 2 and 1 patients respectively as an adverse event in the original method, Candida esophagitis and arthritis were observed in 7 and 1 patients respectively in the modified method.

**Conclusion:** It was conducted safely to resect entire circumference of the esophagus by ESD. The frequency of esophageal stricture was lower in the modified method compared with original method, the number of balloon dilatation in the modified method was statistically lower than that in the original method (p = 0.028). Prophylactic measures for adverse events of steroid such as pneumonia should be paid attention.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Thanks to recent development in upper GI endoscopy have enabled us to find superficial esophageal squamous cell carcinoma (ESCC). High-resolution endoscopy and image-enhanced endoscopy techniques such as magnifying endoscopy with NBI system allow detailed observations of microvessels pattern in superficial esophageal carcinoma, and we can estimate the depth of tumor invasion. Our indication of endoscopic treatment such as ESD for superficial ESCC is that depth of tumor is EP (epithelial layer), LPM (proper mucosal layer) regardless of the size. Even if the depth of tumor is MM (muscularis mucosae layer) or SM1 (surface layer of submucosa), the tumor is indication of diagnostic ESD. We assess the pathological data after diagnostic ESD, evaluate the risk of lymph node metastasis and decide the additional treatment, such as surgery and chemoradiotherapy (CRT). Estimation of the tumor invasion of lateral spreading (size is over 5 cm) superficial ESCC is difficult because of the size of tumor and accuracies are relatively lower compared to small lesions. Thus diagnostic ESD is the one of the options of treatment even for lateral spreading (size is over 5 cm) ESCC. Some of the patients have to undergo additional treatment because tumor is invaded to submucosal layer or lymphvascular invasion. On the other hand, wide resection by ESD could cause the delay of additional treatment because of the treatment for esophageal stricture after ESD. Thus, treatment strategy for lateral spreading ESCC has to include additional treatment after ESD.

**Aims & Methods:** From January 2010 to December 2014, 49 cases of lateral spreading superficial ESCC were resected by surgery (n = 17) or ESD (n = 32) in our hospital. Diagnosis, treatment methods and outcomes are evaluated. Our indications for additional treatment (surgery or CRT) after ESD are the cases of is over pT1b (SM), and even if the depth of tumor is MM pathologically invasive type, poorly differentiated ESCC or angiolymphatic invasion is indication of additional treatment, because of the high risk of lymph node metastasis.

**Results:** In 49 cases of lateral spreading superficial ESCC, 32 cases were treated by ESD and 17 cases were treated by surgery. Average age in ESD group is 67.8 years old (50–85 years old). Average size of tumor treated by ESD is 59.4 mm (50–85 mm). The depth of tumor invasion is pT1a-EP in 3 cases, pT1a-LPM in 12 cases, pT1a-MM in 11 cases, pT1**b**-SM1 in 1 case and pT1b-SM massive in 3 cases. Accuracies of estimated the depth of tumor invasion by preoperative endoscopic diagnosis for EP/LPM and MM/SM1 are 76.5% and 53.3%, respectively. Four of 32 cases of ESD underwent additional therapy (3 for surgery and 1 for CRT), because three cases are pT1b-SM2 and one case in pT1a-MM and lymphvascular invasion. In one case of 3 cases underwent surgery has lymph-node metastasis. Rate of stricture after ESD is 20.0% for sub-circumference ESD and 77.8% for circumference ESD even though injection of steroid. Average time and duration for control of esophageal stricture by Baloon Bougie is 13.5 times (4–32 times) and 18 weeks (7–32 weeks). No cases died by recurrence after ESD. Average age in surgery group is 65.7 years old (51–78 years old). Average size of tumor treated by surgery is 76.5 mm (50–130 mm). Seven cases in 17 (41.2%) have lymph node metastasis. Rate of lymph node metastasis is 0% (0/2 cases) for pT1a-LPM, 42.9% (3/7 cases) for pT1a-MM, 100% (1/1 case) for pT1b-SM1 and 42.9% (3/7 cases) for pT1b-SM massive. One case died by recurrence after surgery and 48 cases were survived without any recurrences.

**Conclusion:** Most of strictures after sub-circumference ESD could be prevented by steroid injection. However control of strictures after circumference ESD is difficult and takes long time. Thus, diagnostic ESD should not be performed for circumferencial lesions of lateral spreading superficial ESCC for the patients who want to undergo CRT for additional treatment after ESD, and undergo CRT without diagnostic ESD. Diagnostic ESD for circumferencial lesions for the patients who want to undergo surgery for additional treatment is acceptable. Long survival could be obtained by ESD or surgery for the patients of lateral spreading ESCC by our treatment strategy.

**Introduction:** *Helicobacter pylori* (*H. pylori*) is a risk factor for gastric cancer. Gastric cancer is believed to be a disease of the elderly, and rarely occurs in young patients. The aim of this study was to analyze the clinicopathological and prognostic factors in young (aged < 40 years) gastric cancer patients according to *H. pylori* infection.
**Aims & Methods:** A total of 515 young (aged < 40 years) patients with gastric cancer from 2003 to 2015 were enrolled in this study. The clinicopathological features of the young gastric cancer patients with *H. pylori* infection were compared with those of the young gastric cancer patients without *H. pylori* infection. The overall survival was the main outcome measure. The survival curves were constructed using the Kaplan-Meier method, Univariate analysis was performed using the log-rank test, and multivariate analysis was performed using with Cox regression.
**Results:** Of the 515 patients, those with *H. pylori* infection were assigned to the HP group (n = 257), and those without *H. pylori* infection were assigned to the non-HP group (n = 258). Kaplan-Meier analysis showed that the prognosis of gastric cancer in young patients with *H. pylori* infection was poorer than that in young patients without *H. pylori* infection (log-rank test, p = 0.021). The 5-year survival rates were higher in the non-HP group than in the HP group (88.3% vs. 79.7%, $p < 0.05$). The relative risk of death in the HP group compared to that of the non-HP group, after correction for age and gender, was 2.62 (95%CI: 1.46–4.81; p = 0.02). In univariate and multivariate analysis, pathologic differentiation, stage and cell type were related to gastric cancer in young patients with *H. pylori* infection ($p < 0.05$).
**Conclusion:** In young gastric cancer patients with *H. pylori* infection, the prognosis was poorer than that of young gastric cancer patients without *H. pylori* infection. The 5-year survival rates were higher in the non-HP group than in the HP group (88.3% vs. 79.7%, $p < 0.05$). The relative risk of death in the HP group compared to that of the non-HP group, after correction for age and gender, was 2.62 (95%CI: 1.46–4.81; p = 0.02).

**Contact E-mail Address:** frontierassa@hanmail.net
**Introduction:** Although early gastric cancer (EGC) confined to mucosal layer, the risk of lymph node (LN) metastasis may be different according to characteristics of tumor including histologic type. However, there is little information about the LN metastasis risk for histologic type with poorly cohesive components such as poorly cohesive carcinoma (PCC) and mixed adenocarcinoma (MAC).
**Aims & Methods:** Of 692 EGC patients who had undergone gastrectomy with LN dissection, 147 (21.2%) EGCs were confirmed as mucosal cancer with poorly cohesive components.
**Results:** 147 EGCs were classified as PCC group (n = 127, 86.4%) and MAC (n = 20, 13.6%) based on WHO classification. PCC group had LN metastasis in 8 (6.3%). LN metastasis was detected in 2 PCCs > 20 mm in size and without ulceration, 2 PCCs ≤ 20 mm in size and with ulceration, and 4 PCCs > 20 mm in size and with ulceration. In addition, lymphovascular (LV) invasion was found in 2 PCCs > 20 mm in size and with ulceration. However, there was no LN metastasis or LV invasion in lesions ≤20 mm in size and without ulceration. No LN metastasis or LV invasion was detected regardless of ulceration and tumor in MAC group.
**Conclusion:** The risk of LN metastasis is little for histologic type with poorly cohesive components in EGC with mucosal invasion, less than 20 mm in size, and no ulceration. Considering tumor size, depth invasion, and the presence of ulceration in EGC, ESD can be treatment modality even in PCC or MAC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1020 EPIDEMIOLOGY AND CLINICAL MANAGEMENT OF PATIENTS WITH GASTRIC MALT LYMPHOMA: THE FIRST POPULATION-BASED STUDY IN FRANCE

**Introduction:** Gastric marginal zone B-cell lymphomas of mucosa-associated lymphoid tissue (GML) is a rare disease whose clinical management has not been well standardized until recently. Our aim was to describe the principal epidemiological and clinical characteristics of GML in the general, non selected, French population.
**Aims & Methods:** All new cases of GML diagnosed between 2002 and 2010 in 11 French areas covered by registries were included. Pathology reports were verified and if necessary reviewed by an expert pathologist. Data were collected retrospectively from medical files. Age adjusted incidence rate was calculated and survival estimated using Kaplan- Meier method.
**Results:** Among 423 eligible cases, 7 (1.7%) were excluded after verification because of false diagnosis. Incidence rate of GML was 0.40 per 100,000 person-years (IC95% [0.36–0.44]). Among 416 patients with confirmed GML, 50.2% were males, with median age of 67 years (range 24–97) and 40 (9%) had a personal history of cancer. The median number of biopsies at diagnosis was 6 (range 1–20), and histological analysis by a referent pathologist was made in 56% of patients. Staging was performed in 340 patients, by CT-Scan (93%), endoscopic ultrasound (45%), or bone marrow biopsy (62%). Disease stage was indicated for 338 patients: 76% were at loco-regional- and 24% at advanced stage. *H. pylori* was searched in 393 patients (94%), and 57% of them were *H. pylori* (+) at diagnosis. Treatments were analysed in 339 out of 416 patients: 33 had no treatment and 44 cases were excluded because of histological transformation into high-grade lymphoma observed early after diagnosis putting in doubt initial histological typing as small cell GML. Out of 339 patients, 200 were *H. pylori* (+) and 193 of them (94%) received at least 1 line of eradication treatment. 190 patients received at least one other treatment (143 chemotherapy +/- immunotherapy, 25 radiotherapy and 5 surgery). A complete remission was obtained in 238 patients (70%). The 5-year overall survival was 82% (IC95% [77–85]), and was significantly higher in *H. pylori* (+) (87%)(IC95% [82–91]) than in *H. pylori* (-)(75%) %)(IC95% [67–81]) patients.
**Conclusion:** In the general population, the diagnosis of GML is sometimes difficult, with a risk of underestimating the degree of malignity, and is made at more advanced stages as compared to the patients included in clinical studies. The prognosis is better for *H. pylori* (+) than *H. pylori* (-) patients. This study underlines the importance of following the recent European guidelines in the clinical management of GML.

**Introduction:** Magnified narrow-band imaging (ME-NBI) endoscopy is effective for differentiation benign and neoplastic gastric lesions. VS-classification (by K. Yao et al., Japan) is the most effective and widespread for this reason, but it is not easy to determine irregularity of microsurface and microvascular pattern.
**Aims & Methods:** Aim: to define the most important and easy high-definition narrow-band imaging (HD-NBI) and ME-NBI endoscopic features of the surface (pits) and vessels of gastric mucosa for differentiation benign and neoplastic gastric lesions. Materials and methods: We prospectively selected and described 220 HD-NBI (n = 175) and ME-NBI (n = 45) quality endoscopic images by 4 clinical (age, gender, etc.), 14 macroendoscopic (localization, size, microtype, etc.) and 16 microendoscopic parameters of microsurface and microvascular pattern. 220 images included 141 photos of benign lesions (hyperplastic polyps, erosions, ulcers, focuses of intestinal metaplasia) and 79 photos of neoplasia (low

and high grade IEN, EGC Tm, Tsm, GC Tmp). We compared benign and neoplastic lesions by 34 parameters with Fisher's exact test and Cramer's conjugation coefficient.
**Results:** We determined 17 statistically significant endoscopic parameters for differentiation benign and neoplastic lesions with accuracy 95% (94 and 97% respectively) by inhomogeneous Bayes sequential diagnostic procedure. Then we selected 6 the most significant, easy and objective endoscopic signs and we got differentiation benign and neoplastic lesions with accuracy 94% (92 and 96% respectively). The features of benign lesions: thickness of vessels in the lesion is even and more/same to surrounding mucosa, smooth edges of vessels, the ratio of pit and vessels thickness $P \leq V$, there are not demarcation line and bright dark vessels in the lesions by NBI visualization. The features of neoplastic lesions: thickness of vessels in the lesion is uneven and less to surrounding mucosa, uneven edges of vessels, the ratio of pit and vessels thickness $P > V$, there are demarcation line and bright dark vessels in the lesions by NBI visualization. We checked these 6 microendoscopic features for differentiation 40 endoscopic images (21 benign, 19 neoplastic) by 3 experts (accuracy 100%), 2 doctors with small experience (accuracy 92–95%, interobserver agreement (IA) $k = 0.75$) and 2 doctors without experience in HD-NBI endoscopy (accuracy 95–98%, IA $k = 0.85$). We also used computer analysis of endoscopic images to differentiate irregular vascular pattern in expert opinion and so determined the neoplasia with accuracy 85%.
**Conclusion:** In accordance with the analysis six microendoscopic features of gastric lesions were proven most significant for effective differential diagnosis between benign and neoplastic epithelial gastric lesions. These features can be successfully used by nonexperience doctors and also for creating the decision support system, including through the computer analysis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1022 TREATMENT STRATEGY OF ENDOSCOPIC RESECTION FOR SYNCHRONOUS DOUBLE EARLY GASTRIC CANCER: SIMULTANEOUS RESECTION VS. TWO-STAGE RESECTION

**H. Suzuki**[1], I. Oda[1], M. Sekiguchi[1], Y. Tanaka[2], K. Inoki[1], S. Abe[1], S. Nonaka[1], S. Yoshinaga[1], Y. Saito[1]
[1]*Endoscopy Division, National Cancer Center Hospital, Tokyo/Japan*
[2]*Endoscopydivision, National Cancer Center Hospital, Tokyo/Japan*

**Contact E-mail Address:** harusuzu@ncc.go.jp
**Introduction:** With the recent advances in endoscopic examinations, the number of patients with synchronous early gastric cancers (EGCs) fulfilling the indications for endoscopic resection (ER) has increased. There are several treatment strategies of ER for synchronous double EGCs, such as simultaneous ER carried out in the same session and two-stage ER carried out on separate days; however, the optimal treatment strategy has not yet been clarified [1].
**Aims & Methods:** The aim of this study was to clarify the optimal treatment strategy of ER for synchronous double EGCs by comparing the clinical outcomes of simultaneous ER and two-stage ER. A total of 1,398 patients with 1,690 EGCs in the normal stomach underwent ER (endoscopic submucosal dissection (ESD)/endoscopic mucosal resection (EMR) = 1,681/9) at our hospital from 2010 to 2014. Among 156 patients with 342 synchronous multiple EGCs, there were 133 patients with 266 synchronous double EGCs. In this study, 87 patients with 174 synchronous double EGCs treated by simultaneous ER in the same session (simultaneous ER group; 87 sessions with 174 resections [ESD/EMR = 169/5]) and 20 patients with 40 synchronous double EGCs treated by two-stage ER on separate days (two-stage ER group; 40 sessions with 40 resections [ESD/EMR = 40/0]) were included after excluding 26 patients with 52 adjacent, synchronous double EGCs in whom both the lesions were resected as one piece simultaneously. We retrospectively compared the clinicopathological findings and technical outcomes between the simultaneous ER group and the two-stage ER group. Synchronous double EGCs were defined as the double EGCs diagnosed at the same time.
**Results:** The clinicopathological findings in the simultaneous ER group vs. two-stage ER group were as follows; mean age (yr): $72.1 \pm 7.2$ vs. $72.3 \pm 8.8$ (NS [Not significant]); gender: male/female = 73/14 vs. 17/3 (NS); ASA physical status classification: class 1 or 2/class 3 = 71/16 vs. 14/6 (NS); mean tumor size (mm): $13.3 \pm 9.6$ vs. $20.5 \pm 12.3$ ($P < 0.0001$); present of ulceration: 2.3% (4) vs. 15% (6) ($P = 0.0026$); proportion of cases with lesions in the lower-third of the stomach: 44.3% (77) vs. 25% (10) ($P = 0.0254$). The technical outcomes were as follows; mean specimen size (mm): $34.6 \pm 11.9$ vs. $43.7 \pm 12.1$ ($P < 0.0001$); mean procedure time per resection (min): $55.7 \pm 41.3$ vs. $99.7 \pm 60.1$ ($P < 0.0001$); mean procedure time per session (min): $111.1 \pm 54.2$ vs. $99.7 \pm 60.1$ (NS); en-bloc resection: 99.4% (173) vs. 100% (40) (NS); R0 resection: 97.7% (170) vs. 95% (38) (NS); delayed bleeding per resection: 2.3% (4) vs. 7.5% (3) (NS); delayed bleeding per session: 4.6% (4) vs. 7.5% (3) (NS); perforation per resection: 2.3% (4) vs. 2.5% (1) (NS); perforation per session: 4.6% (4) vs. 2.5% (1) (NS); delayed bleeding and/or perforation per resection: 4.6% (8) vs. 10% (4) (NS); delayed bleeding and/or perforation per session: 8.0% (7) vs. 10% (4) (NS). All complications were managed conservatively.
**Conclusion:** Simultaneous ER appears to be preferable especially for synchronous double EGCs that are technically easy to resect, such as lesions that are non-ulcerative, small and located in the lower-third of the stomach, because of the favorable technical outcomes [2].
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1023 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR NON-AMPULLA DUODENAL NEOPLASIA

**T. Oyama**, A. Takahashi, N. Yorimitsu
*Endoscopy, Saku Central Hospital Advanced Care Center, Nagano/Japan*

**Contact E-mail Address:** oyama@coral.ocn.ne.jp
**Introduction:** Duodenum is one the most difficult area for safe ESD, because of poor maneuverability, narrow space and thin proper muscle layer. Furthermore, the incidence of delayed complications including perforation and bleeding have been reported higher than that of gastric or esophageal ESD.
**Aims & Methods:** The aim of this study is to clarify the result of duodenal EMR/ESD, and the effect of suture for ESD ulcer to prevent delayed complications. Patient and method: A consecutive 111 duodenal neoplastic lesions treated by EMR/ESD from May 2001 to June 2015 were enrolled to this retrospective study. Male and Female were 84 and 31, respectively. Mean age was 60 (37–86). Bulbs, second and third portion were 8, 93 and 10, respectively. Adenocarcinoma and adenoma were 88 and 23, respectively. 0-I, 0-IIa and 0-IIc were 1, 59 and 51, respectively. Size of tumor and resected specimens were 9 (2–70) and 6 (8–58) mm, respectively. EMR, hybrid ESD (Mucosal incision, submucosal dissection + snaring) and ESD were performed for 19, 89 and 7 patients, respectively. Eight cases were followed up without closure (open group), and remaining 103 patients were followed up after closure of EMR/ESD ulcer by clip, endo-loop or laparoscopic assist (closed group).
**Results:** 1. Perforation during procedure: the number of perforation during EMR, hybrid ESD and ESD were 0, 1 (1/89) and 0%. The only perforated case was treated by clipping without surgery. 2. En-bloc resection rate of EMR, hybrid ESD and ESD were 75% (12/16), 93% (82/88) and 100% (7/7), respectively. 3. R0 resection rate were 69% (11/16), 84% (75/88) and 100% (7/7), respectively. R0 is defined as En-block resection, horizontal and vertical margin were negative. Therefore, piecemeal resected cases were judged as R1. The result of ESD and hybrid ESD is better than EMR. 4. Local recurrence rate were 19% (3/16), 0 and 0%, respectively. 5. 96 of 103 cases in closed group could be closed completely by clips. The average number of clips was 7.7. And remaining seven patients were treated combination by clip and ENPD/ENPD, laparoscopic closure and/or covering technique by Neoveil. 6. Delayed bleeding rate of closed and open groups were 2.8% (3/103) and 50% (4/8), respectively ($p < 0.0001$). All of three cases those tumor size was 21 mm or bigger in open group caused delayed bleeding. 7. Delayed perforation rate of closed and open groups was 0% and 13% (1/8), respectively ($p = 0.0012$).
**Conclusion:** Closure of EMR/ESD ulcer is effective to prevent delayed bleeding and perforation after duodenal EMR/ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1024 DKK-2, A MODULATOR OF WNT-SIGNALING PATHWAY, IS OVEREXPRESSED IN GASTRIC CANCER

**M. Selgrad**[1], J. Bornschein[2], M. Vieth[3], P. Malfertheiner[4]

**Contact E-mail Address:** michael.selgrad@ukr.de
**Introduction:** Gastric cancer (GC) still ranks as one of the most common malignancies worldwide with high morbidity and mortality. The dickkopf gene family comprises four secreted proteins (DKK1–4), which modulate the Wnt-signaling pathway that plays a major role in gastrointestinal carcinogenesis. DKK-2 acts either as an activator or inhibitor of this pathway, but its role in gastric cancer is uncertain.
**Aims & Methods:** To evaluate the gene expression of DKK-2 in GC and normal gastric mucosa. Biopsies from a prospective cohort of 56 patients with gastric cancer (32 intestinal type, 24 diffuse type) and 20 non-cancer controls were analysed for DKK-2 and ß-catenin gene expression. From cancer patients, biopsies from tumour, adjacent normal and tumour-distant mucosa were retrieved, while antrum and corpus biopsies were obtained from healthy volunteers. DKK-2 transcript levels were quantified by realtime RT-PCR and protein expression was analyzed using immunohistochemistry (IHC).
**Results:** DKK-2 was expressed in 33.4% (diffuse type) and 40.7% (intestinal type) of GC samples, while no expression was seen in non-cancer controls. Gene expression was most increased in tumour compared to tumour-adjacent, and tumour-distant mucosa ($P < 0.001$). DKK-2-transcript levels were 88- and 6-fold increased in GC of the intestinal and diffuse type, respectively compared to the adjacent tumour-free mucosa ($P = 0.001$). The expression levels of DKK-2 and ß-catenin correlated significantly in tumor specimens ($r = 0.431$; $p = 0.002$). IHC confirmed protein expression of DKK-2 in 58.9% of the GC-samples ($P = 0.113$).
**Conclusion:** DKK-2 expression in GC is upregulated in tumour samples compared to adjacent normal and tumour-distant mucosa. This implies a functional role of DKK-2 in the Wnt-signaling pathway of gastric carcinogenesis. This

seems to account especially for the intestinal type of GC. Whether it may play a role in the clinical setting (i.e. clinical translation) should be further investigated.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1025 LOW-PASS FILTER VISUALIZES MARGINAL CRYPT EPITHELIUM OF GASTRIC MUCOSA WITH HIGH SENSITIVITY IN MAGNIFYING ENDOSCOPY WITH NARROW-BAND IMAGING

**K. Yoshida**[1], Y. Sasaki[2], N. Hanabata[1], T. Mikami[1], H. Kijima[3], S. Fukuda[1]

**Contact E-mail Address:** kyoshida@hirosaki-u.ac.jp
**Introduction:** White zone visualized by magnifying endoscopy with narrow-band imaging (M-NBI) corresponds to stratified alignments of the gastric marginal crypt epithelium. White zone is, however, not necessarily traced even under the presence of crypt alignments. We have noticed that white zone has been effectively visualized by using low-pass filter even in cases with poor visual discrimination.
**Aims & Methods:** The aims of this study are to present an image processing method or low-pass filter for white zone and to compare detection sensitivity for crypt alignments between the image processing and visual evaluation. Eleven specimens of endoscopic submucosal resection from 8 patients with gastric cancer were used. M-NBI was taken serially along the line of interest. The pictures were processed by low-pass filter for white zone area (%), and visually classified into the presence (WZ+) or absence of white zone (WZ-) by a single endoscopist. The formalin-fixed-specimen was sliced along the same line of interest. The histological pictures was processed for averaged epithelial area (μm×mm) at 1 mm intervals.
**Results:** A total of 123 intervals were analyzed. In cancer intervals, 36 intervals were visually classified as WZ- and 30 as WZ+. In background, 11 intervals were visually classified as WZ- and 46 as WZ+. In cancer, white zone area was significantly lower in WZ- ($28.4 \pm 10.7\%$) than in WZ+ ($32.9 \pm 4.6\%$, $p = 0.0126$). In background, white zone area did not significantly differ between WZ- ($30.5 \pm 6.3\%$) and WZ+ ($33.5 \pm 4.3\%$, $p = 0.2508$). When the presence or absence of crypt alignments are defined as averaged epithelial area $\geq 20$ or $< 20$, respectively, detection sensitivity for crypt alignments in visual evaluation was 50% in cancer and 81% in background, and that in the image processing method was 100% both in cancer and background.
**Conclusion:** Low-pass filter was found to detect crypt alignments with a higher sensitivity than visual evaluation, possibly allowing auto-detection of early gastric cancer through pattern classification of crypt alignments.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1026 ENDOSCOPY GUIDED DA VINCI® ROBOTIC GASTRIC SURGERY FOR EARLY GASTRIC CANCER

**W.J. Ko**[1], G.W. Song[2], J.Y. Cho[2]
[1]*Digestive Disease Center, CHA University, Seongnam/Korea, Republic of*
[2]*Digestive Disease Center, CHA University, Seongnam/Korea, Republic of*

**Contact E-mail Address:** wisred@naver.com
**Introduction:** Endoscopic resection has been an optimal treatment for selected patients with early gastric cancer (EGC) based on advances in endoscopic instruments and techniques. This study aims to evaluate the result of endoscopy guided da Vinci® Robotic full-thickness gastric resection (ERFTGR) with sentinel lymph node basin dissection (SLND) under indocyanine green and infrared in cases of EGC with high risk of lymph node metastasis.
**Aims & Methods:** This was a prospective, pilot study at a single academic center. Of 70 patients with EGC, 12 met the following criteria: 1) differentiated mucosal/submucosal cancer with an ulcer, between 3 and 4 cm by endoscopic imaging; 2) undifferentiated mucosal/submucosal cancer without an ulcer, between 2 and 3 cm by endoscopic imaging; 3) patients who had undergone previous ESD whose pathological reports recommended an additional gastrectomy due to a risk for LNM. The main outcome measure was technical success.
**Results:** All cases were resected en bloc with negative surgical margins. Previous forceps biopsy results revealed that 7 cases were undifferentiated adenocarcinoma. Three of the 10 cases were suspected submucosal cancer by endoscopic and EUS findings. The other 2 cases that had undergone previous ESD whose pathological reports recommended an additional gastrectomy due to positive vertical margin. After ERFTGR with SLND, 2 patients were observed lymph node metastasis and were underwent standard gastrectomy. ERFTGR with SLND was conducted without perioperative adverse events.
**Conclusion:** ERFTGR with SLND could be a bridge between ESD and conventional gastrectomy with respect to preventing an extensive gastrectomy in patients with EGC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Pepsinogen 1 (PG1) is a non-invasive test for diagnosis of body chronic atrophic gastritis (with a negative predictive value of 98%) but the upper cut-off to make the diagnosis is controversial, as in Europe is claimed to be under 30 mcg/l, while in Japan is considered under 70 mcg/l. Furthermore there is a "gray zone ", of not clear interpretation, in which patients with PG1 values ranging between 30 and 50 mcg/l could show histologic finding of CAG.
In the literature it's claimed that PG1 are increasing after PPI administration, within one week from the start of the therapy.
**Aims & Methods:** To identify patients with body chronic atrophic gastritis (CAG) in a population group showing serological PG1 levels borderline (30–50 mcg/l) by means of a PPI –test. 42 patients (M: F = 19: 23, mean age: 54.7 years) with a common finding of PG1 < 60 mcg/l were divided into 5 groups according with the values of PG1: Group A (n = 6, PG1 < 30 mcg/l), Group B (n = 15, PG1 30–35 mcg/l), Group C (n = 14, PG1 35–39 mcg/l), Group D (n = 5, PG1 40–49 mcg/l), Group E (n ° 2, PG1 50–60 mcg/l). The determination of PG1 values was made by using a commercial kit (Biohit Oyj, Helsinki, Finland). In every patients a full dose of PPI (40 mg of esomeprazole, once a day before breakfast) was administered for seven days. At the end of PPI administration the PG1 determination was repeated. An increase of less than 10% of PG1 values after PPI test was considered POSITIVE test in confirming the diagnosis of body atrophic gastritis. All patients underwent on upper G.I. endoscopy with gastric biopsies for diagnosis of gastritis, according with OLGA staging.
**Results:** In Group A levels of PG1 resulted not increased in 6 patients out of 6, in Group B in 11 patients out of 15, in Group C in 5 out of 14, in Group D in 3 to 5 and in Group E all the subjects showed an increase >10% of PG1 values from baseline. The correspondence between serology and histology to assess diagnosis of body atrophic gastritis was as follows: Group A 6/6; Group B: 14/15; Group C 13/14; Group D: 5/5; Group E 2/2.
**Conclusion:** The diagnosis by serology of CAG is filling 100% with the histological diagnosis, when PG1 values are less than 30 mcg/l, while in the range between 30 and 50 mcg/l ("gray zone") the use of PPI test can allow us to identify the true subjects with CAG from normal people, by using the "PPI Test" as previously described.

[2]*Haematology, Centro Hospitalar de Lisboa Central, Lisbon/Portugal*
[3]*Gastroenterology, Centro Hospitalar de Lisboa Central, Lisbon/Portugal*
[4]*Pathology, Centro Hospitalar de Lisboa Central, Lisbon/Portugal*

**Contact E-mail Address:** loureiro.rafaela@gmail.com
**Introduction:** Gastrointestinal tract is the most commonly involved site in extranodal lymphomas. Majority are primary gastric lymphomas and 50% of these are diffuse large B-cell non-Hodgkin's lymphoma (DLBCL).
**Aims & Methods:** Evaluation of overall survival and potential prognostic factors, in patients with primary gastric DLBCL. Retrospective analysis of patients with gastric DLBCL diagnosed in a tertiary center, during a 11 years period. Analyzed demographic data, immunohistochemical characteristics, *H. pylori* infection status (HP), biological markers, staging, therapeutic approach, prognosis and survival.
**Results:** Thirty-six patients were included, 52.8% (19/36) males, median age of 69 years. Most of gastric DLBCL (n = 30, 83.3%) weren't associated with MALT component. In 33 patients in whom it was possible to determine Lugano staging, 15 (45.5%) were in stages I/II and 18 (54.5%) in stages III/IV. Twenty-four of the 32 patients (75.0%) underwent chemotherapy (CT) and 8/32 (25.0%) underwent

surgery with or without chemotherapy associated. The mean follow-up time was 39 months (mín.0; máx.123). Most patients, 66.7% (18/27), achieved complete remission; 1/27 (3.7%) had partial remission and 8/27 (29.6%) had no response or had disease progression. The overall survival at 1, 2 and 5 years was 61.1%, 45.7% and 34.5%, respectively. The univariate analysis showed that elevated $\beta$2-microglobulin ($>3$ mg/ml) (HR: 3.53, $p=0.065$), low albumin ($\leq 3.5$ g/dL) (HR: 0.14, $p=0.002$) and a high (3, 4 and 5) International Prognostic Index (IPI) (HR: 4.03, $p=0.012$), are associated with worse survival. There was no significant association between gender, age at diagnosis, immunohistochemical phenotype, HP infection, LDH, hemoglobin, platelets, Lugano staging and treatment modality and survival.
**Conclusion:** In this population, the $\beta$2-microglobulin values, albumin, and IPI were prognostic predictors factors.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1029 GASTROINTESTINAL STROMAL TUMORS: NATURAL HISTORY AND OUTCOMES IN THE IMATINIB ERA

**A. Peixoto**, M. Silva, A. L. Santos, P. C. Moreira, S. Lopes, G. Macedo
*Gastroenterology, Centro Hospitalar de São João, Porto/Portugal*

**Contact E-mail Address:** armandoafp5@gmail.com

**Introduction:** Before the advent of imatinib, the gastrointestinal stromal tumors (GISTs) were associated with a disease free survival rate of disease of 50% at 5 years, but the actual natural history of the disease is understood.
**Aims & Methods:** Our objective was to characterize the natural history and outcomes of GISTs in the imatinib era. For that, we performed a retrospective evaluation of patients with GISTs diagnosed in a tertiary referral center between January 2000 and June 2015.
**Results:** We included 131 patients, 55% female, with a mean age of $64 \pm 14$ years, followed for a median of 30 months (IQR: 11–68). 64% of cases had gastric involvement. Most patients (57%) had symptoms at diagnosis, including gastrointestinal bleeding (38%). 20% of the diagnoses were accidental. At diagnosis 55% were in stage I and 16% in IV (TNM classification). 92% of the tumors were c-Kit positive. According to the NIH risk classification, 28% of the tumors were classified as high risk. The accuracy of cytology in patients who underwent endoscopic ultrasound (21%) was 54%. 95% of patients were operated (complete resection: 89%). Imatinib was initiated in 25% of patients, as adjuvant therapy in 69%. 75% reported adverse effects, and 16% developed resistance that was associated with the presence of lymph node involvement ($p=0.025$) and positive immunohistochemistry for DOG-1 ($p=0.017$). The recurrence rate was 4%, and was associated with age at diagnosis ($p=0.037$), tumor size ($p=0.028$), presence of metastases ($p=0.019$) and high-risk lesions ($p=0.036$). Survival at 1, 3 and 5 years was 87%, 71% and 61%, respectively. One year's mortality was significantly associated with tumor size ($p=0.021$), stage IV at diagnosis ($p=0.003$), non-complete resection ($p=0.002$) and palliation with imatinib ($p=0.035$). Similar associations were observed at the 3 and 5 years.
**Conclusion:** In the imatinib era there is an increased long-term survival in comparison with previous epidemiological data, and reduced recurrence rates. In more advanced cases survival remains limited in the short term.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1030 FEASIBILITY OF PRECUT COAGULATION WITH AN ENDO-KNIFE ALONE ON GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION: A CASE-CONTROL STUDY

**Y. Horikawa**[1], T. Toyonaga[2], H. Mizutamari[1], N. Mimori[1], Y. Kato[1], S. Fushimi[1], S. Okubo[1]

**Introduction:** Intraoperative bleeding is a serious problem during gastric endoscopic submucosal dissection. The presence of a clear view, without bleeding, during the procedure helps the surgeon monitor the progress, and prevents injuries ulcer base or perforation by over-coagulation. Precut coagulation (PCC) with hemostatic forceps is reported to be effective to reduce intraoperative bleeding. Otherwise, this method involving the frequent replacement of devices, the use of PCC with knife alone would ensure a smoother procedure.
**Aims & Methods:** We aimed to assess the effectiveness of PCC with endo-knife alone at a super-low output setting. In this case-control study, we compared the hemostasis condition during ESD in 40 pairs of consecutive superficial gastric lesions that were treated via PCC with Hemostatic forceps (Control group) or the Flush knife BT at a super-low output setting (Knife group). The primary outcome was the frequency of major bleeding. The secondary outcomes included procedure time, en bloc resection rate, and adverse event rate.
**Results:** The average frequency of major bleeding was no significant difference between Group C and Group F ($1.30 \pm 1.30$ vs. $1.60 \pm 1.34$, $p=0.35$). The procedure time, the en bloc resection rate, and adverse event rates were similar in both groups. Lesions located at the upper-third of the stomach required the repeated hemostasis ($p=0.01$).
**Conclusion:** The use of PCC with the Flush knife BT alone, at a super-low output setting, prevented serious intraoperative bleeding in the same as using hemostatic forceps. Hence, this technique could ensure a smooth and safe procedure during gastric ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Multifocal atrophic gastritis (MAG) is considered to be precancerous conditions and associated with an increased risk for gastric cancer. To diagnose MAG and establish its extent, three methods can be used: endoscopy, histological assessment of biopsy specimens, and serology. Serum analysis of PG 1, G-17 and *H. pylori* antibodies (GastroPanel, Biohit), has been considered to be the promising tool for screening of precancerous conditions and early cancer of the stomach (1).
**Aims & Methods:** To assess the accuracy of non-invasive screening of atrophic gastritis (AG) and EGC with use of biomarkers compared to endoscopy and histology. We saved up 7 years' experience of investigation of patients with gastric dyspepsia, serum samples were obtained from 635 dyspeptic patients followed by high-resolution chromoendoscopy with biopsy sampling from antrum and corpus. The specimens of serum were investigated for IgG *H. pylori*, G-17 and PG I using the GastroPanel. The statistical analysis is made by MedCalc V9. After histology examination all patients were selected into 3 groups: AG ($n=252$), non-atrophic gastritis (NAG) ($n=352$) and EGC ($n=31$). Patients with AG were divided into antrum AG (AAG), $n=202$, and MAG, $n=50$.
**Results:** The dispersion analysis revealed that the PG 1 in patients with EGC ($45.02 \pm 8.23$) was lower than in the groups of patients with NAG ($114.02 \pm 8.0$) and AG ($82.70 \pm 6.60$), $p < 0.05$, in cases with AAG ($97.95 \pm 7.39$) it was higher than in the MAG group ($46.23 \pm 7.05$), $p < 0.05$. G-17 level in patients with EGC ($21.07 \pm 3.06$) was higher than in the groups of patients with NAG ($12.67 \pm 2.04$) and AG ($9.14 \pm 1.66$), $p < 0.05$. In patients with AAG the G-17 level - $7.74 \pm 1.65$ and in the MAG - $19.95 \pm 4.70$ respectively, $p=0.005$. There are no differences between biomarkers levels in patients with MAG and EGC. Distinctions the biomarkers at patients depending on process localization (body, antrum) and type a gastric cancer (intestinal, diffusion) it wasn't received. MAG was diagnosed in all patients with EGC, that's why the assessment of diagnostic accuracy of serological method was performed in this group. ROC-analysis determined that G-17 as well as PG 1 authentically diagnose MAG: G-17 AUC = 0.737, SE = 0.0862, 95%CI 0.590–0.805, PG 1 AUC = 0.779, SE = 0.0646, 95%CI 0.647- 0.850.

**TABLE 1:** Criterion values and coordinates of the ROC curve (MAG)

| Criterion | Sensitivity | 95% CI | Specificity | 95% CI |
|---|---|---|---|---|
| G-17 > 9.3 | 70.29 | 36.2–87.1 | 74.55 | 59.3–84.1 |
| PG 1 ≤ 64 | 80.57 | 50.6–95.1 | 62.78 | 47.9–74.1 |

**Conclusion:** Level of PG 1 ≤ 64 and G-17 > 9.3 have been shown as accurate biomarkers for MAG associated with high risk for gastric cancer. GastroPanel is currently being used to enhance the yield of endoscopic screening programs designed to identify individuals with high cancer risk who are indicated to undergo endoscopic examination.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** doc0224@chol.com
**Introduction:** Subepithelial tumors (SETs) in the gastrointestinal tract are often incidentally found during endoscopic examinations. Although the utility and safety of endoscopic resection (ER) of SETS in the esophagus and stomach have been described, data about the ER of duodenal SETs remain scant. Therefore, we aimed to investigate the clinical outcomes associated with the ER of duodenal SETs, and to assess possible predictive factors for incomplete resection.
**Aims & Methods:** We conducted a retrospective observational study of 62 patients (64 lesions) that underwent ER of duodenal SETs between June 2005 and December 2015 at the Pusan National University Hospital. The therapeutic outcomes from endoscopic submucosal dissection (ESD) and procedure-related complications were analyzed.
**Results:** Endoscopic mucosal resection (EMR) was performed in 38 tumors, EMR with a ligation device (EMR-L) in 18, and endoscopic submucosal dissection (ESD) in 8. The overall en-bloc resection and complete ER rates were 96.9% (62/64) and 100% (64/64), respectively. The complete pathologic resection rate was 76.6% (49/64). Multivariate logistic regression analyses determined that the macroscopic type (Yamada type I or II; odds ratio [OR] 6.460, 95% confidence interval [CI] 1.569–37.458, P = 0.027) and the treatment method (ESD; OR 7.178, 95% CI 1.291–39.323, P = 0.024) were independently associated with incomplete pathologic resection. The procedure-related bleeding and perforation rates were 6.3% and 4.7%, respectively. No recurrences were observed in patients who had undergone complete ER at a median follow-up period of 20 months (range, 6–112 months).
**Conclusion:** In conclusion, ER is an effective, safe, and feasible treatment for duodenal SETs, especially when the SET is located in the deep mucosal layer and/or the submucosal layer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** gasong@pusan.ac.kr
**Introduction:** Literature on the comparison of quality of life (QOL) in patients who have undergone endoscopic resection (ER) and surgical treatment is limited. We evaluated changes in the QOL after treatment for early gastric cancer (EGC), and compared these changes by the treatment procedure (endoscopic resection [ER] vs. surgery).
**Aims & Methods:** We reviewed baseline characteristics and questionnaire results of patients who underwent ER or surgery for EGC that were prospectively collected by the Korean Gastric Cancer Cohort study. The validated Korean version of the European Organization for Research and Treatment of Cancer 30-item core QOL questionnaire and its gastric module were used. We compared the QOL outcomes at pretreatment, and 1 year and 2 years after ER and surgery.
**Results:** In this study, 2.283 patients were included; 542 and 1.741 patients underwent ER and gastrectomy, respectively. Patients in the ER group were more likely to report a better QOL, except for the global QOL, after treatment than those in the surgery group. All the symptom domains were better in the ER group in terms of the absolute score and symptomatic percentage. In the surgery group, role functioning, diarrhea, dysphagia, eating restriction, anxiety, and body image scores deteriorated at 1 year and recovered at 2 years, except diarrhea did not recover to the baseline level. In the ER group and the surgery group, a high proportion of patients generally suffered from anxiety throughout the follow-up period. In the surgery group, the percentage of symptoms such as diarrhea, dysphagia, eating restriction, body image, and pain (gastric module) increased at 1 year and decreased at 2 years postoperatively, but not to the baseline level. Although the global QOL significantly improved postoperatively, patients who underwent ER had slight improvement at 1 year but deterioration at 2 years.
**Conclusion:** ER for EGC results in a better QOL than surgery, specifically in terms of symptom-related QOL, not the global QOL. Therefore, physicians should not ignore the global QOL of patients with EGC after ER, even if the patients received noninvasive treatment and had fewer symptoms.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1034 CLINICAL USEFULNESS OF MAGNIFYING ENDOSCOPY FOR NON-AMPULLARY DUODENAL TUMORS

**T. Mizumoto**[1], Y. Sanomura[1], S. Oka[2], K. Kuroki[3], M. Kurihara[3], Y. Yoshihuku[3], S. Tanaka[1], K. Chayama[2]

**Contact E-mail Address:** mizumoto@hiroshima-u.ac.jp
**Introduction:** A recent increase of the number of case reports on primary non-ampullary duodenal tumor has coincided with advances in the field of endoscopic examination. However, there have been few reports about magnifying endoscopic findings for these tumors.
**Aims & Methods:** The aim of this study was to investigate the clinical usefulness of magnifying endoscopy using narrow-band imaging (ME-NBI) and crystal violet (pit pattern) for non-ampullary duodenal tumors. We enrolled consecutive 103 patients with 103 primary non-ampullary duodenal tumors which were observed by ME-NBI and pit pattern before endoscopic resection at Hiroshima University Hospital until December 2014. Images of ME-NBI were

classified into 2 grades (Type B or Type C) according to the Hiroshima classification (Gastrointest Endosc 2009), and images of pit pattern were classified into 2 grades (regular or irregular). We retrospectively analyzed the clinicopathological features and endoscopic findings of ME-NBI and pit pattern between 2 histological grades according to the Vienna classification (Category 3; 73 tumors, Category 4; 30 tumors).
**Results:** The tumor size with Category 4 was significantly larger than that with Category 3 (Category 3; 10.0 mm vs. Category 4; 13.0 mm). There were no significant differences in location (incidence of second portion, Category 3; 73% vs. Category 4; 80%), and macroscopic type (incidence of depressed type, Category 3; 16% vs. Category 4; 26%) between 2 histological grade. In ME-NBI, Type C tumors with Category 4 (83%, 25/30) had significantly higher frequency than Type B tumors with Category 4 (17%, 5/30). In pit pattern, irregular tumors with Category 4 (77%, 23/30) had significantly higher frequency than regular tumors with Category 4 (23%, 7/30). The accuracy of Type C with ME-NBI for Category 4 was 87% (90/103), the sensitivity was 83% (25/30), the specificity was 89% (65/73), the positive predictive value (PPV) was 76% (25/33), and the negative predictive value (NPV) was 93% (65/70), respectively. The accuracy of irregular pit pattern for Category 4 was 84% (87/103), the sensitivity was 77% (23/30), the specificity was 88% (64/73), the PPV was 72% (23/32), and the NPV was 90% (64/71), respectively. There were no significant differences between ME-NBI and pit pattern for diagnosing histological grade. The accuracy, sensitivity, and specificity of Type C for Category 4 were 89% (75/84), 82% (18/22) and 92% (57/62) in flat elevated/protruded type, and 79% (15/19), 88% (7/8) and 73% (8/11) in depressed type, respectively. On the other hand, the accuracy, sensitivity, and specificity of irregular pit pattern for Category 4 were 87% (53/84), 82% (18/22) and 89% (55/62) in flat elevated/protruded type, and 74% (14/19), 63% (5/8) and 82% (9/11) in depressed type. There was no significant difference for diagnosing histological grade between ME-NBI and pit pattern, regardless of macroscopic type.
**Conclusion:** Our study showed that ME-NBI and pit pattern had the equivalent diagnostic ability for diagnosing histological grade of non-ampullary duodenal tumors. ME-NBI may be more useful because of its simple procedure without time consuming.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1035 LONG NONCODING RNA MALAT1 PROMOTES AGGRESSIVE GASTRIC CANCER THROUGH MMP1 OVER-EXPRESSION AND TRANSCRIPTIONALLY ACTIVATED BY C-JUN

**X. Zhou**[1], G. Zhang[2]
[1]*Gastroenterology, Johns Hopkins Hospital, Baltimore/United States of America/MD*
[2]*Dept. Of Gastroenterology, Jiangsu Province Hospital, Nanjing/China*

**Contact E-mail Address:** zhouxiaoying0926@sina.cn
**Introduction:** Recently long non-coding RNAs (lncRNA) have emerged as new gene regulators and prognostic markers in several cancers including gastric cancer (GC), however, the detailed mechanisms remain largely unknown. In this study, we investigated the contributions of the lncRNA MALAT1, a highly conserved long noncoding RNA, in GC progression and its role in posttranscriptional regulation.
**Aims & Methods:** We analyzed MALAT1 expression levels by real-time reverse transcription PCR in 100 gastric tissues (50 GC tissues and 50 adjacent normal mucosa), and in four GC cell lines compared with epithelial cells. Transient RNAi-mediated knockdown and pcDNA-mediated overexpression of MALAT1 was performed. Stable shRNA-mediated knockdown and lentiviral-mediated overexpression of MALAT1 was to study the role of MALAT1 on in vivo tumorigenicity and metastatic burden in the context of xenograft assays. Proteomic profiling was performed to decipher differential protein expression in cells with different MALAT1 expression levels. One of the differentially regulated proteins, MMP1 was subsequently validated and its function evaluated through xenograft assays.
**Results:** We found that MALAT1 expression was higher in human GC tissues where it was associated with reduced patients' survival. MALAT1 silencing decreased GC cell proliferation and invasion and increased apoptosis. Mechanistic investigations showed that MALAT1 was transcriptionally activated by c-Jun and that it interacted with MMP1. MMP1 and MALAT1 had a positive relationship, both at expression level and in function. Direct interaction between the two was confirmed through RNA immunoprecipitation coupled with quantitative real time PCR. MMP1 was confirmed to be promoter of GC pathogenesis and as functionally similar to MALAT1 lncRNA.
**Conclusion:** MALAT1 expression may serve as a potentially important disease biomarker for the identification of highrisk GC patients. Moreover, our findings provide mechanistic evidence for MALAT1 over-expression and the ensuing malignant phenotype in both cultured and xenografts GC cells.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Gastric cancer is one of the most common malignancies worldwide and the second most frequent cause of cancer-related death in China. Protein regulator of cytokinesis 1 (PRC1) is involved in cytokinesis and plays key roles in microtubule organisation in eukaryotes.
**Aims & Methods:** This study was aimed to analyze the expression and to investigate the functional role of PRC1 in gastric tumorigenesis. The expression of PRC1 was evaluated by qRT-PCR, Western blot and immunohistochemistry. The biological function of PRC1 was determined by CCK-8 proliferation assays, monolayer colony formation, xenografted nude mice and cell invasion assays by shRNA-mediated knockdown in AGS and HGC27 cells. The regulation of PRC1 expression by piperlongumine was also investigated.
**Results:** PRC1 was up-regulated in primary gastric cancers. Overexpression of PRC1 in gastric cancers was associated with poor disease specific survival and overall survival. PRC1 knockdown in AGS and HGC27 cell lines suppressed proliferation, reduced monolayer colony formation, inhibited cell invasion and migration ability, and induced cell cycle arrest and apoptosis. PRC1 depletion selectively postponed cytokinesis in AGS cells instead of in HGC27 cells possibly due to the induction of GADD45a in AGS cells. Inhibition of PRC1 also suppressed tumor growth in vivo. We finally demonstrated that piperlongumine targets PRC1 via a p53-dependent manner in gastric cancers, thus suggesting that PRC1 is a novel downstream target of piperlongumine in gastric cancer.
**Conclusion:** Our findings supported the oncogenic role of PRC1 in gastric carcinogenesis. PRC1 might serve as a prognostic biomarker and potential therapeutic target for gastric cancer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** gasenko@inbox.lv
**Introduction:** Various clinical guidelines**,** including Kyoto global consensus are recommending particular steps, including 'search-and-treat' strategy for *H. pylori* to prevent gastric cancer, however little of this has been implemented to clinical practice.
**Aims & Methods:** The aim of the study was to identify how much of these recommendations have penetrated to practice. A web-based questionnaire was develop and distributed globally via number of international organizations and national professional societies. Questionnaire was available online for 5 months (October 2015 - February 2016) in three languages - English, Russian and German.
**Results:** Altogether 886 responses from 75 countries were received; of the responders 570 (64%) were men; mean age 47 years. There were 606 gastroenterologists and 65 epidemiologists among the responders. The majority were involved in cancer screening (66%), performing endoscopies (67%), and prescribing *H. pylori* eradication therapies (83%). Altogether 79.8% of the responders disagreed that the burden of gastric cancer is a disappearing problem and is not requiring any active intervention. 'Search-and-treat' strategy in the responder's country was considered appropriate by 44.4%, inappropriate – by 24.3%, but 31.3% of the responders were unsure. No difference between gastroenterologists (46.9% positive responses) and epidemiologists (45.5%) was revealed ($p = 0.84$). Population-based screening for gastric cancer was considered appropriate in the respective home-country by 62.2%, in other areas, but not the home-country – by 27.6%, but inappropriate – by 10.2% of the responders. Pepsinogen detection was considered an appropriate screening strategy by 26.1% of the responders, inappropriate – by 50.3%, but the remaining 23.6% considered it useful only in particular settings. No differences were observed in the responses of gastroenterologists and epidemiologists. When asked about volatile marker testing in exhaled air, only 23.4% considered that this approach is readily applicable for gastric cancer screening purpose; the major reason for this response was insufficient evidence (53.3%). The attitude towards *H. pylori* vaccination was as follows: 4.6% of the responders were eager to start vaccination immediately, 55.9% were supporting vaccination, but considered that more data is required; 12.0% were negative, but 27.6% did not have the opinion.
**Conclusion:** In general, the attitude of the specialists corresponds well to the guidelines, yet not always to the clinical practice, in particular in the case of 'search-and-treat' strategy. No substantial differences in the attitude were revealed between gastroenterologists and epidemiologists. Funding. The research was conducted within the HORIZON 2020 project SNIFFPHONE and was supported from the Project No.4 of National Health Program in Latvia BIOMEDICINE 2014–2017.

**Introduction:** Methionyl-tRNA synthetase (MARS) are responsible for cellular protein synthesis and cell viability in various process of tumorigenesis. We hypothesized that genetic variants in MARS might play an important role in the development of gastric cancer.
**Aims & Methods:** A case-control study was conducted including 2211 gastric cancer cases and 2266 cancer-free controls to evaluate the associations of 13 potentially functional polymorphisms in MARS with gastric cancer risk.
**Results:** We found significant associations with the risk of gastric cancer for rs511752 [odds ratio (OR) 0.85, 95% confidence interval (CI): 0.76–0.96, P = 6.21E-03]; rs542278 (OR = 0.84, 95% CI: 0.75–0.95, P = 6.80E-03) and rs508904 (OR = 0.88, 95% CI: 0.78–0.99, P = 3.15E-02). We further observed significant multiplicative interactions between rs511752 and drinking (P = 0.041). Combined analysis of these three SNPs showed a significant allele-dosage association between the number of risk alleles and gastric cancer risk (P for trend = 1.91E-4). Compared with individuals with "0–2" risk alleles, those carrying"3," "4," or "5 or more" risk alleles had a 1.32, 1.48, or 1.60 folds risk of gastric cancer, respectively.
**Conclusion:** These findings indicate that genetic variants in MARS might modify the individual susceptibility to gastric cancer in Chinese population.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1039 LNCRNA HOTAIR ACTS AS A COMPETING ENDOGENOUS RNA TO PROMOTE CISPLATIN RESISTANCE IN GASTRIC CANCER VIA MIR-126/PI3K/ AKT/ MRP1 PATHWAY

**J. Yan**
*Gastroenterology, the First Affiliated Hospital of Nangjing Medical University, Nanjing/China*

**Contact E-mail Address:** jsyj0220@163.com
**Introduction:** Long non-coding RNAs (lncRNAs) have been reported to be involved in many cancer pathological conditions, including cisplatin resistance. However, the function of lncRNA-HOTAIR in cisplatin resistance for gastric cancer (GC) remain elusive. The aim of the study is to identify a novel mechanism that HOTAIR regulates the sensitivity of GC cells to cisplatin.
**Aims & Methods:** HOTAIR expression in GC cells and tissues was quantified by quantitative reverse transcription-PCR (qRT-PCR). The GC cell lines were transfected with pc-HOTAIR, si-HOTAIR, or their respective controls and we investigated the formation of cisplatin resistant phenotype of GC cells and possible molecular mechanisms.
**Results:** We found that HOTAIR was significantly up-regulated in cisplatin resistant GC cells and GC tissues compared with parental GC cells and non-cancerous gastric tissues. Besides, overexpression of HOTAIR could enhance proliferation, decrease apoptosis, and promote G1/S transition in GC cells. Furthermore, HOTAIR was found to directly bind to miR-126, promote miR-126 targets VEGFA and PIK3R2, then activate PI3K/AKT/MRP1expression.
**Conclusion:** Our findings revealed that HOTAIR can act as a competitive endogenous RNA to promote cisplatin resistance in GC and it will be a valuable predictor for treatment and target for reversal of cisplatin resistance in human GC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1040 NUCLEAR EXPRESSION OF MASPIN CORRELATES WITH POOR PROGNOSIS IN PATIENTS WITH GASTRIC CANCER AND IS AS A POSSIBLE INDUCTOR OF EPITHELIAL MESENCHYMAL TRANSITION

**S. Gurzu**[1], J. Orlowska[2], Z. Szentirmay[3], H. Sugimura[4], I. Jung[1]
[1]*Pathology, University of Medicine and Pharmacy of Tirgu-Mures, Romania, Tirgu-Mures/Romania*

[3]*Pathology, National Institute of Oncology, Budpest/Hungary*
[4]*Tumor Pathology, Hamamasu School of Medicine, Hamamatsu/Japan*

**Contact E-mail Address:** simonagurzu@yahoo.com
**Introduction:** Maspin (mammary serine protease inhibitor) is a member of the serine protease inhibitor family that was previously proved by our team to exert p53-mediated pro-proliferation or tumor suppressor roles in several epithelial tumors such as colorectal, gastric carcinomas, or Merkel cell carcinoma. Its role is exerted based on the subcellular location in the cancer cells but the exact pathomechanism is unknown.
**Aims & Methods:** The aim of this study was to explore the possible role of maspin in epithelial mesenchymal transition (EMT), based on its expression in the tumor core and tumor front. Methods: We performed a retrospective analysis of 333 consecutive cases diagnosed between 2003–2012 in three departments of Pathology from Romania, Hungary, and Poland. The grade of tumor cells discohesivity was counted based on the number of tumour cells clusters in the invasion front, similar to the budding quantification in the colorectal cancer. The immunohistochemical (IHC) stains were done with Maspin and the following EMT-related antibodies: E-cadherin, N-cadherin, $\beta$-catenin, SLUG, and the stem cells marker CD44. The IHC quantification was performed in the tumor core and the invasion front.
**Results:** In the tumor core, Maspin was negative in 24.92% (n = 83) of the cases and presented nuclear only expression in 15.31% (n = 51) of the cases. The other cases revealed cytoplasm only positivity (26.13%) or mixed cytoplasm and nuclear Maspin expression (33.64%), independently by the pT stage. The Kaplan-Meier survival analysis showed that nuclear only expression of maspin and lymph node metastases were independent indicators of poor prognosis and low survival in patients with gastric cancer. Nuclear only expression in the tumor core and tumor front were correlated with presence of lymph node metastases ($p < 0.0001$), high grade of discohesivity in the invasion front ($p = 0.01$), E-cadherin loss in the invasion front ($p = 0.001$), nuclear expression of $\beta$-catenin in both core ($p = 0.002$) and front ($p = 0.02$), and CD44 positivity in more than 50% of the tumor cells ($p = 0.003$). SLUG expression was seen in 306 out of the 333 cases (91.89%) and N-cadherin in 67 of the cases (20.12%) without correlation with the other examined markers.
**Conclusion:** This is the first report revealing a possible role of nuclear maspin in EMT of gastric cancer cells. It can explain the negative prognostic role of nuclear maspin in these carcinomas and might serve as a predictive marker for EMT inhibition.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The Popeye domain containing (POPDC) gene family comprises three highly conserved, developmentally-regulated transmembrane proteins, POPDC1–3 (1). POPDC1/BVES (also called blood vessel epicardial substance) and POPDC3, encode proteins that regulate cell-cell adhesion and cell migration during epithelial-mesenchymal transition. POPDC1/BVES and POPDC3 were recently found to be downregulated in gastric carcinoma in humans and have been linked to the mechanism of gastric tumorogenesis (2).

**Aims & Methods:** Aims: In this work, we examined the possibility that POPDC1/BVES and POPDC3 may serve as predictive markers for gastric tumorogenesis and analyzed the expression levels of these genes in intestinal metaplasia, a premalignant stage of gastric carcinoma. Methods: mRNA was isolated from formalin fixed paraffin embedded endoscopic gastric biopsies of 16 normal, 24 intestinal metaplasia, and 8 carcinoma patients. Only *Helicobacter pylori* negative biopsies from the gastric antrum were included in the study. The expression levels of POPDC1/BVES, POPDC3 as well as CDX2 (a biomarker for gastric premalignancy) were assessed by quantitative RT-PCR using RPLP0 as the normalizing mRNA. The biopsies were also stained for POPDC1/BVES.

**Results:** Compared to normal biopsies, we found a statistically significant reduction in the expression levels of POPDC1/BVES and POPDC3 in intestinal metaplasia as well as in the carcinoma biopsies. The expression levels of CDX2 were elevated in both, the intestinal metaplasia and the carcinoma biopsies. Correlation analysis indicated a high correlation between POPDC1/BVES and POPDC3 transcript levels whereas a negative correlation was found between the levels of POPDC1/BVES and CDX2 mRNA transcripts. Preliminary evaluation of POPDC1/BVES immunostaining suggested lower incidence of POPDC1/BVES labeling in the luminal surface of gastric glands of intestinal metaplasia, compared with normal tissues.

**Conclusion:** This is the first demonstration that POPDC1/BVES and POPDC3 are downregulated in intestinal metaplasia suggesting them as potential players in and biomarkers for gastric tumorogenesis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Acetaldehyde is a key cause of alcohol hangover symptoms and a well known Group 1 carcinogen to humans (WHO). It is metabolized by Aldehyde dehydrogenase (ALDH2), which is genetically deficient in 30–50% of Eastern Asians. Local acetaldehyde exposure to gastric mucosa is a key event in the pathogenesis of gastric cancer. It is closely associated with major risk factors, including alcohol drinking, ALDH2 deficiency, achlorhydria, *H. pylori* infection, and tobacco smoking. Recently, a variety of anti-hangover products are commercially available, however, almost none of them has been proven to show enhanced metabolizing capacity of ALDH 2 in a live subject.

**Aims & Methods:** We aimed to test a specific anti-hangover product of interest. The enzyme activities of the anti-hangover substance were examined by in-vitro & in-vivo experiments to measure the amount of NADH formation which is generated through catalytic conversion of alcohol and acetaldehyde, by using a spectrophotometer at 340 nm. Powder sample of a commercial anti-hangover product (South Korea) was used as the experimental substance. In-vivo examination tested the ethanol and acetaldehyde concentration in blood of rats with oral infusion of experimental substance before or after ethanol intake. In first test, twenty four SD male rats were randomly assigned into one of four groups: group1 received only saline, group2 was subjected to ethanol only, group 3 received ethanol with substance (73 mg/kg), and group 4 ethanol with substance (220 mg/kg). Oral dosing of 50% ethanol (3 g/kg body weight) was given 30 minutes after substance gavages, followed by time-dependent collection of rat's blood when zero, 1, 3, 5, and 8 hours after dosing of ethanol. In second test, similar examination was repeated with two groups including ethanol only ($n = 6$) and ethanol with substance (220 mg/kg) ($n = 6$). The differentiator of second in-vivo test was that experimental substance be given 1 hr after ethanol gavage, approximately near maximum level of blood acetaldehyde.

**Results:** In vitro measurements of the activities of alcohol dehydrogenase & aldehyde dehydrogenase within the anti-hangover substance were 1.84 unit/g and 0.28 unit/g, respectively. The enzyme activities in rats' blood under the substance that was given 30 minutes before ethanol intake are as follows: after 1 hour of ingestion of ethanol, the concentration of ethanol in blood showed maximum values for all testing group, but decreases by 15.5% ($p < 0.246$) and 28.3% ($p < 0.011$) were observed for testing groups of dosing substance 73 and 220 mg/kg, respectively. In the case of a group with dosing 220 mg/kg, meaningful decrease in the concentration of ethanol through all measurement times was observed compared to a group of ingestion of ethanol only. With acetaldehyde level in blood, the maximum values for all testing groups were measured 1 hr after ethanol ingestion, demonstrating no significant differences among testing groups. However, the concentration of acetaldehyde in blood for ethanol only group started to decease after 3 hours, in contrast, those of groups with anti-hangover substance have shown concentration-dependent reduction after one hour. As for a group of dosing substance 220 mg/kg, meaningful level of decreases were observed after 3 hours ($p < 0.01$) and 5 hours ($p < 0.05$). Finally, the cases with oral intake of substance 220 mg/kg after 1 hr of ethanol intake have shown more significant and obvious decreases in blood acetaldehyde concentration through the period of all measurement times.

**Conclusion:** Oral intake of anti-hangover substance has significantly enhanced alcohol or acetaldehyde-metabolizing capacity in rat model, potentially suggesting increased ALDH 2 capacity within circulation. Using this substance, further animal researches on prevention of gastric cancer are recommended to conduct.

**Introduction:** Gastric mucosa undergoes a series of changes including of chronic gastritis, atrophic gastritis, intestinal metaplasia and dysplasia, before progressing into gastric cancer, in which process *H. pylori* infection plays a major role. As pH measurement of gastric juice is very difficult, there is rare report regarding the relationship between this process and acid secretion.

**Aims & Methods:** The aim of this study is to evaluate the correlations among pH of gastric juice, atrophic gastritis, intestinal metaplasia, pepsinogen I/II ratio, *H. pylori* infection and clinical diagnosis. From October 2005 to March 2013, a total of 46 subjects were enrolled. Gastric biopsies and stomach juices were collected from subjects who underwent standard endoscopy at Seoul National University Bundang Hospital. Histological atrophic gastritis (AG) and intestinal metaplasia (IM) were assessed by updated Sydney system in the body and antrum, respectively. *H. pylori* infection was determined by any one of modified Giemsa stain, CLOtest and culture. We categorized gastric juice pH as $pH < 3$ ($n = 28$) and $pH \geq 3$ ($n = 18$) because the subject number was small. Pepsinogen test was performed by determined using a latex agglutination method (HBi Corp, Seoul, Korea).

**Results:** *H. pylori* infection state was found significantly lower in the $pH < 3$ group (21.4%) than that of $pH \geq 3$ group (Table). However, the clinical diagnosis was not different in the two gastric pH groups. The subjects with $pH \geq 3$ in gastric juice showed AG in the body more frequently than $pH < 3$ group ($p = 0.047$) (Table). However, this difference was not found in case of antral AG. Similarly, subjects with $pH \geq 3$ in gastric juice showed IM in the body more frequently than $pH < 3$ group ($p = 0.051$). However, this difference was not found in case of antral IM. Pepsinogen I/II ratio did not show any correlation with pH of gastric juice.

**Table:** Characteristics of 46 subjects

| Variables | pH < 3 (n = 28) | pH ≥ 3 (n = 18) | p-value |
|---|---|---|---|
| pH (mean ± SD) | 1.79 ± 0.45 | 5.46 ± 1.58 | |
| M/F, n (%) | 19/9 (67.9/32.1) | 15/3 (83.3/16.7) | 0.243 |
| Age (mean ± SD), years | 58.5 ± 13.7 | 56.0 ± 11.1 | 0.522 |
| *H. pylori* infection state | 6 (21.4%) | 11 (61.1%) | **0.007** |
| Clinical diagnosis | | | 0.332 |
| Control, DU, BGU | 10 (35.7) | 4 (22.2) | |
| Gastric dysplasia/cancer | 18 (64.3) | 14 (77.8) | |
| Atrophic gastritis | | | |
| Antrum | n = 20* | n = 14 | 0.738 |
| Present, n (%) | 10 (50) | 8 (57.1) | |

DU: duodenal ulcer; BGU: benign gastric ulcer *Remaining 8 subjects showed inapplicable finding for histological atrophic gastritis.

**Conclusion:** *H. pylori* infection affected gastric juice pH, which showed good relationship with AG and IM in the body. These results suggest of close relationship of *H. pylori* infection on the acid secretion by way of AG and IM in the body.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1044 POTENTIAL ROLE OF MICRORNA-126 IN THE DIAGNOSIS OF CANCERS: A SYSTEMATIC REVIEW AND META-ANALYSIS

**J. Yan**
*Gastroenterology, the first affiliated hospital of nangjing medical university, Nanjing/China*

**Contact E-mail Address:** jsyj0220@163.com
**Introduction:** Cancer has become a major public concern all over the world and early diagnosis of cancer is of great benefit for treatment and prognosis. Several studies have investigated the association between abnormal circulating microRNA-126 (miR-126) expression and the risk of various cancers, but the results are inconsistent. Therefore, this meta-analysis was carried out to assess the potential diagnostic value of miR-126 for cancer.
**Aims & Methods:** Relevant studies were searched from PubMed, Embase, and Web of Science and we calculated the pooled sensitivity, specificity, positive likelihood ratio (PLR), negative likelihood ratio (NLR), diagnostic odds ratio (DOR), and area under the summary receiver operator characteristic curve (AUC) to assess the diagnostic value of miR-126 for cancer detection.
**Results:** A total of 745 cancer patients and 749 controls from 11 studies of 7 papers were contained in this meta-analysis. The summary estimates revealed that the pooled sensitivity was 68% (95% confidence interval (CI): 60%-75%), the specificity was 76% (95% CI: 65%-85%), the PLR was 2.87 (95% CI: 1.96–4.21), the NLR was 0.42 (95% CI: 0.35–0.52), the DOR was 7 (95% CI: 4–11), and the AUC was 0.77 (95%CI: 0.73–0.80). Moreover, the sample type, cancer type, sample size, and quality score might be sources of heterogeneity.
**Conclusion:** Results from this systematic review and meta-analysis suggested that miR-126 had great potential to be a noninvasive biomarker in the diagnosis of cancer. However, more well-designed studies with larger sample size on the diagnostic value of miR-126 for cancer are needed in the future.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1045 POLYPOID LESIONS OF NON-TYPICAL VARICEAL MORPHOLOGY SEEN IN UPPER GI ENDOSCOPY, IN PATIENTS WITH PORTAL HYPERTENSION. OUTCOMES OF INVESTIGATION WITH ENDOSCOPIC ULTRASOUND

**D. E. Sigounas**, A. Shams, J.N. Plevris, P. C. Hayes
*Centre For Liver & Digestive Disorders, Royal Infirmary of Edinburgh, Edinburgh/United Kingdom*

**Contact E-mail Address:** dsigounas@gmail.com
**Introduction:** Gastroduodenal polypoid lesions are frequently seen in upper GI endoscopy in patients with portal hypertension (PH). Although in certain cases the appearance is typical of ectopic varices, in other cases the true nature of the visualized lesion remains uncertain. The optimal strategy to clarify diagnosis is not clearly defined.
**Aims & Methods:** The aim of this study was to investigate such lesions routinely with endoscopic ultrasound (EUS) and report the outcome of EUS assessment. All patients with PH referred for EUS due to uncertain polypoid lesions seen in upper GI endoscopy, between June 2008 and November 2015, were included. The degree of confidence regarding their true nature varied. Data on aetiology of PH, severity of cirrhosis (if present), demographic characteristics, lesion location, presence of other signs of PH, endoscopic impression and outcome of investigation with EUS and pathology (if appropriate/available) were retrospectively collected after reviewing the EUS reports and hospital electronic database. Final diagnosis was categorized in 3 main groups: 1. Varices, 2. Polyp with underlying vessel/varix and 3. Non-vascular lesions. Patients with known or confidently diagnosed varices at index endoscopy that were referred only to further assess the extent of portal hypertension or facilitate intervention for variceal obliteration were excluded.
**Results:** A total of 36 patients (26 male) were included. PH aetiology was alcoholic liver disease (ALD) or non-alcoholic fatty liver disease (NAFLD) in the majority of patients (83.3%). Most lesions were seen in distal stomach and duodenum (69.4%), while in almost all patients (94.4%) there were other findings of PH. Varices were found in 27.8% of patients, while an equal number were found to have polyps with underlying vessels. Comparing the presumed diagnosis at index endoscopy with the final EUS assisted diagnosis, revealed a poor ability to predict the actual nature of the lesion, since only 42.1% of lesions considered to be polypoid/neoplastic were found to be non-vascular under EUS and 50% of those considered to be submucosal lesions where confirmed as varices.
**Conclusion:** 1.The endoscopist should have a high index of suspicion regarding varices when performing endoscopy in patients with PH. 2. Obtaining biopsies in cases where the true nature of lesions is uncertain should be avoided, as in such cases it is impossible even for experienced endoscopists to accurately categorize them thus significantly increasing the risk of bleeding from varices.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1046 HEREDITARY HEMORRAGIC TELANGIECTASIA: CHARACTERIZATION OF A LARGE COHORT OF PATIENTS WITH DIGESTIVE MANIFESTATIONS

**P. Marques Da Costa**[1], L.C. Meireles[1], N. Fatela[1], C. Baldaia[2], R. Palma[1], L. A. Correia[1], H. Cortez-Pinto[1], J. Velosa[2]
[1]*Gastroenterology And Hepatology Department, Hospital de Santa Maria, Lisboa/Portugal*
[2]*Faculdade de Medicina da Universidade de Lisboa, Lisboa/Portugal*

**Contact E-mail Address:** pedroavmcosta@gmail.com
**Introduction:** Hereditary haemorrhagic telangiectasia (HHT) is a rare autosomal dominant disease affecting 1 in 5000 habitants. It's characterized by the appearance of arteriovenous malformations (AVMs) at micro and macrovascular level, throughout the gastrointestinal (GI) tract, liver, lung and brain. As a result, in the setting of GI bleeding or liver function abnormalities these patients are often evaluated in our clinical practice.
**Aims & Methods:** We aimed at characterizing the phenotypic patterns and disease severity of a cohort of patients admitted, during the past 15 years, to a gastroenterology department of a tertiary medical centre. Medical records were reviewed for demographic, biochemical, endoscopic, radiological and genetic analysis variables collection.
**Results:** Nineteen patients with HHT according to the curacao criteria were identified. Mean age: 61.2 ± 17 years, mostly male (M/F:12/7). No previous diagnosis was present in 26.3% (n = 5) of patients. The vast majority (84% n = 16) reported epistaxis and 52% (n = 10) had at least one previous episode of GI bleeding. Angiodysplasias were distributed through the GI tract: upper 56% (n = 9/16); mid portion 87.5% (n = 7/8); lower 33% (n = 5/15). Visceral AVMs location: hepatic 58% (n = 10/17); pulmonary 27.2% (n = 3/11) and cerebral 33% (n = 3/10). A relevant proportion of our patients had not been submitted to complete endoscopic (16%) and organ (hepatic: 10%, pulmonay: 42% and cerebral: 47%) investigation. Laboratory abnormalities were mostly biochemical cholestasis 36.8% (n = 7) without aminotransferase changes. Portal hypertension: oesophageal varices 31% (n = 5/16); thrombocytopenia 21% (n = 4/19); ascites 44% (n = 8/18). Other complications: thrombotic events 25% (n = 4/16); visceral/articular abscess 15.7% (n = 3/19); idiopathic thrombocytopenic purpura 5.2% (n = 1). Genetic analysis was only available for 2 patients. Overall mortality was 36.8% (n = 7/19) with 10% (n = 2) directly consequence of a HHT complication.
**Conclusion:** This cohort of HHT patients demonstrates a high phenotypic variability as well as a non-negligible disease associated mortality within the specific group of patients with GI manifestations of HHT. It also highlights that there is a need for a protocol based approach in the evaluation and clinical care of this complex set of patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1047 MECHANISM UNDERLYING STRESS-RELATED MUCOSAL DAMAGE: UPPER OPTICAL GASTROSCOPY

**O. Semyachkina-Glushkovskaya**, A. Abdurashitov, I. Agranovich
*Biology, Saratov State University Department of Biology, Saratov/Russian Federation*

**Contact E-mail Address:** glushkovskaya@mail.ru

**Introduction:** The association between stress and gastrointestinal (GI) diseases are well established. The pathogenesis has not been completely clarified, but strong evidence points to disorders of neural and endothelial regulation of the upper GI tract as the major cause.

**Aims & Methods:** The aim: To study the adrenergic and nitroergic mechanisms underlying stress-related mucosal damage (SRMD). The study was carried out on mongrel rats (n = 96) with experimental model of SRMD and patients with erosive gastritis (EG, n = 27) and ulcer bleeding (UB, n = 30). Gastric blood flow was measured using Laser Doppler flowmetry. Nitric oxide (NO) level in epithelium of stomach was analyzed by spectrophotometry.

**Results:** Chronic (4 months) social stress (overpopulation) was accompanied by superficial mucosal damage and primarily erosions in 83% of rats (61 of 73). Additional daily stress (2 hours immobilization) during 1 month in all rats (n = 61) with stress-related injury (SRJ) induced development of stress-related ulcer bleeding (SRUB). In first step of our work we studied role of adrenergic system in development of SRMD. Submucosal infusion of phenylephrine, tyramine, yohimbine caused the drop in gastric blood flow which was the same in healthy rats and rats with SRI and SRUB. Submucosal infusion of isoproterenol induced dilation of gastric vessels which was 2-fold higher in rats with SRI and 5-fold greater in rats with SRUB vs. healthy group. In clinical study we found that patients with EG showed vasoconstriction after submucosal adrenaline injection in stomach but patients with UB – vasodilation. It is known that one of mechanisms underlying adrenomadiated vasorelaxation is activation of NO production. In second step of our work we studied role of NO system in development of SRMD. In rats with SRI and rats with SRUB level of NO in epithelium of stomach was 2-fold and 5-fold higher vs. healthy rats. In clinical study using endoscopic biopsy we found that NO level in epithelium of stomach was higher 1.5-fold in patients with EG and 4-fold greater in patients with UB. Submucosal infusion of L-NAME (10 mg/kg) caused long-term suppression of acid secretion in rats with SRJ and SRUB. NO blockade by L-NAME (10 mg/kg, per os) during 1 month in rats with SRI (n = 23) was accompanied by decrease in number of rats with SRUB (9 of 23).

**Conclusion:** Development of SRMD is accompanied by increase in vasodilator effect of adrenergic influences on stomach and increase in NO production in gastric epithelium. Blockers of NO synthesis may be the novel acid-suppressive pharmacological agents. The research was supported by Grant of Russian Ministry of Science and Education 17.488.2014 K.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1048 SUPERIOR MESENTERIC ARTERY SYNDROME: A TRUE AND MISDIAGNOSED CLINICAL ENTITY

R. Bardini[1], S. Rampado[2], S. Degasperi[2], I. Angriman[2], **A. Ganss**[2]
[1]*Department Of Surgery, Oncology And Gastroenterology, University Of Padua, School Of Medicine, Chirurgia Generale, Padova/Italy*
[2]*Department Of Surgery, Oncology And Gastroenterology, University Of Padova, Chirurgia Generale, Padova/Italy*

**Contact E-mail Address:** angelica.ganss@yahoo.it

**Introduction:** Superior Mesenteric Artery Syndrome (SMAS) is a rare cause of duodenal obstruction, resulting from the compression of the third duodenum between superior mesenteric artery and aorta. Still most clinicians are not aware of this disease and patients are often misdiagnosed. Clinical presentation consists of aspecific gastrointestinal symptoms. The diagnosis is mostly reached by a process of exclusion and the clinical suspect needs to be confirmed radiologically by barium swallow and CT/MR angiography.

**Aims & Methods:** We propose our experience in 39 patients with history of chronical gastrointestinal disorders, who underwent surgical correction for SMAS. Aim of the study was to analyze clinical presentation and diagnosis of SMAS and to assess surgical outcome. Between October 2008 and March 2016 we prospectively collected demographic and clinical data of consecutive SMAS patients. Symptoms were scored on a Likert scale using a detailed questionnaire about abdominal pain, bloating, regurgitation, nausea, and vomiting. The diagnosis was assessed through barium swallow, CT/MR-angiography, endoscopy. Diagnostic criteria at angiogram are: aorto-mesenteric angle $\leq 22^{\circ}$, distance $\leq 8$ mm. All patients underwent duodenojejunostomy, with or without a distal resection of the duodenum. At follow up, symptom score and quality of life were evaluated and a barium swallow was performed.

**Results:** Thirty-nine patients (11 M/28 F, mean age $38 \pm 14$ years) complained of a long clinical history (mean 91 months; range 12–138) of aspecific digestive symptoms. Mean BMI was $17.9 \pm 2.8$, weight loss $9 \pm 7$ kg. Eight patients (21%) had been previously studied for GERD elsewhere and fundoplication had been performed; in 8 patients (21%), one or more bouts of acute pancreatitis had occurred. Once SMAS was suspected clinically, upper gastrointestinal series and CT/MR angiography confirmed the diagnosis. Barium swallow showed a gastroduodenal dilation in 17 cases (44%) and a slow contrast progression in 13 (33%); mean aorto-mesenteric angle was $12 \pm 6^{\circ}$, distance was $6 \pm 2$ mm. All patients underwent laparotomic duodenojejunostomy; in 32 of them (82%), a distal duodenum resection was added. Ten patients (26%) also underwent a fundoplication for GERD. Mortality was nil, while in 6 patients (15%) a complication occurred: melena (2), acute pancreatitis (2), intestinal obstruction by abdominal adhesion (1) and hemoperitoneum (1). In all patients a water-soluble contrast swallow was performed on postoperative day 6, and since no anastomotic leak was recorded, realimentation was started on mean postoperative day 7; patients were discharged after $11 \pm 7$ days. Barium swallow at 2 months showed a delayed gastroduodenal emptying in 10 patients (26%), while a wide and pervious anastomosis was demonstrated in all series (100%). At a mean follow-up of $34 \pm 16$ months, symptom score significantly dropped ($p < 0.0001$) and an increase in BMI ($p < 0.0001$) was recorded [Table].

| | Before Surgery | After Surgery | P value |
|---|---|---|---|
| Symptom Score | $34 \pm 10$ | $15 \pm 13$ | $< 0.0001$ |
| BMI (kg/m$^2$) | $17.9 \pm 2.8$ | $19.4 \pm 3.1$ | $< 0.0001$ |
| Weight gain (kg) | $-9 \pm 7$ | $6 \pm 1$ | $< 0.0001$ |
| PPI therapy | 29/39 (74%) | 12/39 (31%) | 0.0002 |
| Prokinetic therapy | 24/39 (62%) | 10/39 (26%) | 0.02 |

**Conclusion:** We suggest to consider SMAS as a differential diagnosis in subjects with aspecific digestive symptoms, especially if a clinical history of acute pancreatitis or surgical treatment for GERD is recorded. In patients with chronical upper gastrointestinal symptoms and a radiological diagnosis of SMAS, surgical bypass improves symptoms and quality of life.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1049 SUPERIOR MESENTERIC ARTERY SYNDROME AND ACUTE PANCREATITIS

R. Bardini[1], S. Rampado[2], S. Degasperi[2], **A. Ganss**[2]
[1]*Department Of Surgery, Oncology And Gastroenterology, University Of Padua, School Of Medicine, Chirurgia Generale, Padova/Italy*
[2]*Department Of Surgery, Oncology And Gastroenterology, University Of Padova, Chirurgia Generale, Padova/Italy*

**Contact E-mail Address:** angelica.ganss@yahoo.it

**Introduction:** Superior mesenteric artery syndrome (SMAS) is a rare cause of chronic duodenal obstruction, due to the compression by superior mesenteric artery and aorta on the third duodenum. Recent studies report SMAS as a rare cause of recurrent acute pancreatitis.

**Aims & Methods:** Thirty-nine consecutive SMAS patients were addressed to our Department between October 2008 and March 2016; eight of them complained of a past clinical history of acute pancreatitis. Demographic and clinical data were prospectively collected; previous surgical and endoscopic procedures were also recorded. Symptoms of SMAS were scored on a Likert scale using a detailed questionnaire about abdominal pain, bloating, regurgitation, nausea, and vomiting. The diagnosis was assessed through barium swallow, CT/MR-angiography, endoscopy. Diagnostic criteria at angiogram are: aorto-mesenteric angle $\leq 22^{\circ}$, distance $\leq 8$ mm. All patients underwent duodenojejunostomy with a distal resection of the duodenum. At follow up, symptom score was collected, quality of life was evaluated and a barium swallow was performed. Moreover, BMI, weight gain, serum lipase and amylase activity were also collected and considered in determining outcome. The aim of our study was to investigate the occurrence of acute pancreatitis in a larger group of patients who were surgically treated for SMAS, and to assess medical history and final outcome.

**Results:** Eight patients (1 M/7 F, mean age $42 \pm 16$ years) complained of a long clinical history (mean 57 months; range 12–78) of aspecific digestive symptoms and acute pancreatitis, presenting with 1 or more episodes of abdominal pain, nausea, vomiting and serum amylase increase. In 5 of these patients a cholecystectomy had been previously performed elsewhere, while 2 had undergone more than one endoscopic retrograde cholangiopancreatography (ERCP) with biliary sphincterotomy. After these procedures, patients still complained of abdominal pain, bloating, nausea, vomiting, regurgitation, dyspepsia and weight loss (mean $10 \pm 5$ kg); mean symptom score was $36 \pm 9$, BMI $16.5 \pm 2.6$. Barium swallow showed a gastroduodenal dilation in 5 cases (63%) and a slow contrast progression in 4 (50%); at CT/MR-angiography, mean aorto-mesenteric angle was $10 \pm 7^{\circ}$, distance was $6 \pm 4$ mm. All patients underwent a duodenojejunostomy with distal duodenum resection. Postoperative mortality was nil, while 2 complications occurred: an acute pancreatitis, successfully treated conservatively; and a small-bowel obstruction caused by adhesion formation, that required adhesiolysis. In all patients a postoperative water-soluble contrast swallow was performed, and since no anastomotic leak was recorded, they started realimentation on mean postoperative day 10 and were discharged after $14 \pm 8$ days. Barium swallow at 2 months showed delayed gastroduodenal emptying in 2 patients (25%) and regular anastomosal transit in all series (100%). At a mean follow-up of $31 \pm 14$ months, symptom score dropped to $15 \pm 11$ ($p < 0.05$) and an increase in BMI $18.4 \pm 3.9$ was recorded. No recurrence of acute pancreatitis occurred and pancreatic enzyme activity was normal in all patients.

**Conclusion:** The association of SMAS and recurrent acute pancreatitis is a rare but possible and potentially life-threatening condition. We suggest to consider SMAS as a differential diagnosis in patients with recurrent acute pancreatitis of unknown origin and aspecific digestive symptoms. In these patients, endoscopic papillotomy (ERCP) should not be performed; surgical treatment is indicated to relieve symptoms and improve quality of life.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** An inverse association between *Helicobacter pylori* (*H. pylori*) infection and esophageal eosinophilia has been lately suggested. However, data are based on retrospective studies or small prospective studies, with histology or serology as diagnostic tests for *H. pylori* infection.

**Aims & Methods:** Aims: to evaluate the association between *H. pylori* infection and eosinophilic esophagitis (EoE), whether this association was different between responders and nonresponders to PPI therapy, besides elucidating the existence of potential confounding factors for this association. Methods: Prospective multicenter case-control study conducted in Spain and Italy. Controls: patients undergoing upper endoscopy due to esophageal symptoms, without eosinophils on esophageal biopsies. Patients: EoE defined according to available guidelines. All EoE patients underwent an 8-week high-dose PPI trial. Patients with clinic and histologic remission (< 15 eos/HPF) on PPIs were defined as PPI-responsive esophageal eosinophilia (PPI-REE). Atopic status was defined by the presence of any of these conditions: asthma, rhinoconjunctivitis, food allergy, oral allergy syndrome, atopic dermatitis, anaphylaxis, urticaria or angioedema. Positive *H. pylori* infection: urea breath test, rapid urease test or histology. In case of negative results with invasive tests, a confirmatory urea breath test was performed.

**Results:** A total of 243 individuals [75 controls, 168 EoE patients (42% responders to PPI therapy) ] have been included. Compared to controls, EoE patients showed a significantly lower rate of *H. pylori* infection (28% vs. 43%, $p = 0.01$). No differences in *H. pylori* status were observed between responders and nonresponders to PPI therapy (29% vs. 26%, $p = 0.58$). The presence of atopic status was significantly higher in patients vs. controls (72% vs. 34%, $p < 0.001$) and in EoE patients vs. PPI-REE patients (65% vs. 42%, p 0.009). When individuals were stratified according to their atopic status, the rate of *H. pylori* infection was significantly higher in overall non-atopic vs. atopic individuals (49% vs. 23%, $p < 0.001$), controls (54% vs. 23%, p 0.009) and patients (43% vs. 22%, $p = 0.01$). *H. pylori* infection was significantly less common in atopic vs. non-atopic PPI-REE patients (19% vs. 44%, p 0.024). However, this difference could not be confirmed in non-atopic vs. atopic EoE patients (24% vs. 37%, p 0.2), because of the small numbers of non-atopic EoE patients.

**Conclusion:** An inverse association between *H. pylori* infection and EoE was confirmed. *H. pylori* infection was significantly more common in non-atopic controls and patients. These data suggest that the former inverse association might be casual, whereas the gastric microorganism may actually protect against atopy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1051 SURVEILLANCE OF HELICOBACTER PYLORI RESISTANCE TO ANTIBIOTICS IN FRANCE IN 2014

A. Ducournau[1], L. Bénéjat[1], E. Sifré[2], E. Bessède[1], P. Lehours[1], **F. Megraud**[2]

**Contact E-mail Address:** francis.megraud@chu-bordeaux.fr

**Introduction:** The outcome of *Helicobacter pylori* eradication therapies is very much dependent on the antimicrobial susceptibility of the strains. Given the difficulty of offering tailored treatments in some areas, it is important to have accurate knowledge of the prevalence of *H. pylori* resistance which is evolving over time.

**Aims & Methods:** Our aim was to perform a survey of antimicrobial resistance in France in 2014. Gastric biopsy specimens obtained from patients during upper digestive endoscopy were sent to a central laboratory for *H. pylori* culture and antimicrobial susceptibility testing. A real-time PCR detecting the bacterium and the mutations leading to clarithromycin resistance was also performed.

**Results:** Seventy-five gastroenterologists, distributed throughout the different regions of France, enrolled 984 patients. Among the 783 patients with no previous eradication treatment, 266 (33.9%) were *H. pylori* positive. The strains showed high resistance to clarithromycin (22.2%), moderate to levofloxacin (15.4%), high to metronidazole (45.9%), very low to amoxicillin and rifamycin (<1%), and nil to tetracycline. There were 187 patients who received a previous *H. pylori* treatment, of which 115 were *H. pylori* positive. Among the 81 who received other treatment than Pylera®-proton pump inhibitor (PPI), 79% were resistant to clarithromycin, 17.3% to levofloxacin and 72.8% to metronidazole. The corresponding figures for the 34 who received Pylera®-PPI were 61.7%, 11.8% and 91.2%, respectively. None of the patients having received Pylera®-PPI developed resistance to tetracycline. Real-time PCR detected all *H. pylori* patients for whom culture was positive and 30 others. The mutations found were essentially A2142/2143G (150) while there were six A2142C and two A2142T. A double population (mutants + wild type) was observed in 21 cases.

**Results:** Seventy five gastroenterologists, distributed in the different regions of France, enrolled 984 patients. Among the 783 patients who never had eradication treatment before, 266 (33.9%) were *H. pylori* positive. The strains showed high clarithromycin resistance (22.2%), moderate to levofloxacin (15.4%), high to metronidazole (45.9%), very low to amoxicillin and rifamycin (<1%), and nil to tetracycline. There were 187 patients who received a previous *H. pylori* treatment, of which 115 were *H. pylori* positive with very high resistance to clarithromycin (73.9%) and metronidazole (78.3%). None of the patients having received Pylera®-proton pump inhibitor developed resistance to tetracycline. Real-time PCR detected all *H. pylori* patients for whom culture was positive and 30 others. The mutations found were essentially A2142/2143G (151) while there were five A2142C and two A2142T. A double population (mutants + wild type) was observed in 21 cases.

**Conclusion:** This study shows that *H. pylori* resistance to clarithromycin is still increasing and already above the threshold indicating an abandon of its use. However, the progression is slower than in the previous decade probably because of a more prudent use of antibiotics including macrolides during these last years.

**Introduction:** Primary resistance rates of *Helicobacter pylori* (*H. pylori*) to clarithromycin in Northern and Eastern Europe historically have been low; however, monitoring of antibacterial resistance is crucial for maintenance of effective regional treatment strategies.

**Aims & Methods:** The study evaluated primary antibiotic resistance of *H. pylori* strains in adults and children in Lithuania within the period 2013–2015. We also aimed to compare them with previous *H. pylori* resistance rates reported in the years 2007–2008 In total 434 patients (242 adults and 192 children) from Lithuanian University of Health Sciences Kaunas Clinics and Childrens' Hospital, Affiliate of Vilnius University Hospital Santariskiu Clinics who were referred to upper gastrointestinal tract endoscopy due to dyspeptic symptoms, unclear cause anemia, abdominal pain were included in the study. Patients who had previously underwent *H. pylori* eradication therapy, had been using proton pump inhibitors (PPI), antibiotics or bismuth compounds for the last 4 weeks period were excluded from the study. During upper endoscopy two biopsies of gastral mucosa were obtained for culture of *H. pylori*. Biopsies were stored at -80°C until analysis and cultured on agar plates with 7% lysed and defibrinated horse blood. E-tests were performed for amoxicillin (MIC ≥ 0.125 mg/l), metronidazole (MIC ≥ 8 mg/l), clarithromycin (MIC ≥ 0.5), ciprofloxacin (MIC ≥ 1 mg/l), rifampicin (MIC ≥ 1 mg/l) and tetracycline (MIC ≥ 1 mg/l).

**Results:** *H. pylori* grew in 67 (28%) of 242 adult samples: resistance to clarithromycin was found in 2 (3%) cases, to metronidazole – 22 (32.8%), tetracycline - 2 (3%), ciprofloxacin - 5 (7.5%), rifampicin - 5 (7.5%). Multidrug resistant were 6 (9%) strains among adults. *H. pylori* was cultured in 94 (49%) of 192 children samples. Among children resistance to clarithromycin was determined in 33 (34%) cases, to metronidazole – 21 (21.6%) and 11 strains were multidrug resistant (11.3%). No cases of amoxicillin resistance have been detected among children and adults. Among adult patients resistance of *H. pylori* to metronidazole, clarithromycin and ciprofloxacin remained stable during 2008–2015. Meanwhile, the prevalence of clarithromycin resistance in children has increased significantly comparing previously reported 16.8% to 34% ($p < 0.05$).
**Conclusion:** There are no significant changes in the susceptibility of *H. pylori* to the most of widely used antibiotics in adults over the last years in Lithuania; however, increase in clarithromycin resistance among children seems to be dramatic. These trends might be linked with changes in national policies for treatment of pneumonia with macrolides in children.

## P1053 SCREENING OF PRECANCEROSIS AND EARLY GASTRIC CANCER IN NATURAL POPULATION OVER FORTY YEARS OLD, SHENGZE, CHINA: ROLE OF SERUM GASTROPANEL

**Y. Dang**, G. Zhang
*Department Of Gastroenterology, The First Affiliated Hospital of Nanjing Medical University, Najing/China*

**Contact E-mail Address:** yeani_hi@126.com
**Introduction:** Screening and early diagnosis of gastric cancer play important roles in reducing the mortality of gastric cancer.
**Aims & Methods:** The specific aims of this study were 1) to estimate the prevalence of precancerosis and early gastric cancer among natural population aged over forty in Shengze District, Jiangsu, China, 2) to identify risk factors of *H. pylori* infection and precancerous lesions, 3) to estimate the prevalence of precancerous lesions in moderate and high risk population.
**Study design:** Observational, cross-sectional.
**Methods:** 8647 residents aged over forty in 4 villages of Shengze were enrolled from 2014 to 2015. Pepsinogen I (PG I), Pepsinogen I (PG II), Gastrin-17 and serum Hp antibody were applied to screen for high risk individuels. Screened positive participants were referred to a clinical visit. Definite diagnosis was made based on endoscopic examination and histopathological test. Multivariate logistic regression was used to predict potential determinants of a definite positive diagnosis. Odds-ratios and confidence intervals were provided. Inverse probability weights generated from a propensity score model were used to adjust for non-attendance.
**Results:** Anti-Hp positive rate was 51.2%. Independent Risk factors for *H. pylori* infection were female, BMI, family member and smoking. Endoscopic information for 1300 out of the 2391 moderate and high risk individuals were obtained, representing a response rate of around 54.37%. Among them, 14 were atrophic gastritis, 233 were atrophic gastritis with intestinal metaplasia (IM), 136 were IM, and 29 were dysplasia. Remarkably, three HGIN, 2 early gastric cancer and 2 advanced gastric cancer were detected. The prevalence of gastric cancer in this region was 81/100,000. Prevalence of precancerous lesions in males was higher than that in females. The highest prevalence was found in men aged 60 to 69yr old. Risk factors identified from weighted and unweighted multiple logistic regression were smoking, Hp antibody, abnormal PG I and PGR, and G-17 level.
**Conclusion:** A relative higher overall prevalence of gastric cancer was detected in Shengze as compared to worldwide. Prevalence may be further reduced with appropriate interventions, in particular advice against the eradication of *H. pylori*.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1054 RESIDE IN A RURAL AREA AND BEING WOMAN COULD INCREASE THE RISK OF HELICOBATER PYLORI ERADICATION FAILURE, USING THE CLASSIC TRIPLE THERAPY

**E. Peña-Galo**[1], J. Gotor[1], Y. Harb[2], M. Alonso[2], J. Alcedo[1]
[1]*Department Of Digestive Diseases, Miguel Servet University Hospital, Saragossa/Spain*
[2]*Department Of Digestive Diseases, Barbastro Hospital, Huesca/Spain*

**Contact E-mail Address:** empenag@gmail.com
**Introduction:** The rate of *Helicobacter pylori* (Hp) resistance with antibiotics treatments varies according to the geographical area. It is unknown whether factors like gender, economic level, nationality or residence place influence the therapeutic failure with the standard therapy.
**Aims & Methods:** Aim: to evaluate the influence of socioeconomic and demographics factors on the outcomes of triple therapy with omeprazole, clarithromycin and amoxicillin for 7 days (OCA-7), in *Helicobacter pylori* eradication treatment. Method: An observational and retrospective study was carried on in two health sectors from Spain (380,000 and 108,000 inhabitants respectively), between 2006 and 2010. Cases were selected using 13C-urea breath test (UBT) positive previously to first eradication treatment with OCA-7 like inclusion criteria. Patients without following eradication checking by UBT were excluded. The socioeconomic and demographics variables (gender, urban/rural residence place, nationality, and economic status) were collected using the e-medical records. Our target variable was eradication testing with negative UBT at least 4 weeks after ending OCA-7 treatment. A univariate and multivariate regression model was developed. Ethics considerations: the personal information was anonymized.
**Results:** A total of 990 UBT were obtained; of these 794 (80.2%) were positive and 604 had selection criteria. The age mean was 50 years, 55.8% of women, 21.4% lived in rural areas, most prevalent nationality was Spanish (82.8%) and 17.3% were considered as high economic level. 441 (73.4%) of the patients had a successful eradication outcome. Women were significantly associated with mayor rates of eradication failure (OR:2.03; CI 95% 1.37, 3.03) in a model of regression adjusted by age and provenance. In a second model adjusted by gender and age, live in a rural area reached a significant association (OR:1.58; CI 95% 1.01, 2.51). Age and gender adjusted Odds Ratio for eradication failure comparing middle-low economic level vs high-level was 1.10 (95% CI 0.65, 1.86), and the same one was 0.74 (95% CI: 0.41, 1.33.) for another nationality vs Spanish.
**Conclusion:** 1. Under adult population with high prevalence of *Helicobacter pylori* infection, where OCA-7 is used as eradication treatment, the probability of eradication failure is higher in women and rural areas. 2. The economic level and nationality not demonstrate to be associated in the eradication treatment failure.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1055 H.PYLORI VACA GENOTYPE IS A PREDOMINANT DETERMINANT OF IMMUNOLOGIC RESPONSE TO H. PYLORI CAGA

**Introduction:** *H. pylori*-related peptic ulcer disease and gastric adenocarcinoma are commonly associated with cagA+ *H. pylori* strains. However, seropositivity against CagA varies among different studies with positivity below of 50%.

**P1053**

Histopathology diagnosis of respondents

| Histopathology diagnosis | N | Male(%) | age(mean ± SD) | Hp(%) | Moderate risk Group(%) | High risk Group (%) |
|---|---|---|---|---|---|---|
| Chronic gastritis | 925 | 44.1 | 56.28 ± 9.50 | 56.2 | 77.98 | 37.29 |
| Atropic gastritis | 14 | 50.0 | 57.44 ± 9.73 | 64.3 | 0.99 | 0 |
| Atrophic gastritis with IM | 233 | 80.7 | 60.76 ± 9.98 | 69.1 | 16.96 | 20.90 |
| Intestinal metaplasia | 136 | 47.8 | 58.84 ± 9.81 | 70.6 | 10.61 | 10.73 |
| Hyperplastic polyp | 32 | 31.2 | 61.8 ± 11.59 | 65.6 | 2.58 | 2.82 |
| Dysplaisa | | | | | | |
| Mild | 26 | 61.5 | 61.52 ± 9.91 | 73.1 | 2.08 | 2.26 |
| Moderate | 3 | 33.3 | 70.70 ± 14.57 | 100.0 | 0.20 | 0 |
| HGIN | 3 | 66.7 | 67.00 ± 14.53 | 100.0 | 0.20 | 0.56 |
| Early gastric cancer | 2 | 50.0 | 72.50 ± 14.85 | 100.0 | 0.10 | 0.56 |
| Advanced gastric cancer | 2 | 50.0 | 72.00 ± 2.83 | 50.0 | 0.10 | 0.56 |

**Aims & Methods:** In the prospective study, we aimed to identify potential factors related to *H. pylori* CagA-immunological response specifically with focus on *H. pylori* genotype. *H. pylori* isolates, and systematically collected clinical, histological and serological data were analyzed from 99 subjects. Gastric biopsy specimens were obtained during upper GI endoscopy and were used for *H. pylori* cultivation and histological evaluation (Sydney classification). Serological profile (anti-*H. pylori*, anti-CagA) was further correlated with *H. pylori* isolates (cagA, EPIYA, vacA s/m genotype) and mucosal IL-8 mRNA expression. Subsequently, selected *H. pylori* strains were evaluated by using co-culturing model with AGS cells for CagA expression and IL-8 expression induction.
**Results:** Thirty patients (30.3%) out of total 99 microbiologically confirmed *H. pylori*-infected patients were seropositive for CagA. Seropositivity was strongly associated with the histological phenotype of gastritis, increased inflammation according to the Sydney score, IL-8 expression and cagA mRNA expression. VacA s and m polymorphisms were the major determinants for positive (vacA s1m1) or negative (vacA s2m2) anti-CagA serology that further correlated with inflammatory potential in vitro using AGS cells. In addition, in vitro co-culturing analyses confirmed functional CagA, while showing only partial correlation with CagA seropositivity, suggesting other factors as a co-determinants of the immunological response.
**Conclusion:** *H. pylori* vacA polymorphism strongly correlates with serological response to *H. pylori* cagA+ strains. Furthermore, vacA genotype was the main determinant of inflammatory potential in ex vivo and in vivo settings. The CagA-IgG positivity has a low predictive value for the infection with cagA+ *H. pylori* in a region with high vacA s1m2/s2m2 genotype prevalence.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1056 CAN BACTERIAL VIRULENCE FACTORS PREDICT ANTIBIOTIC RESISTANT HELICOBACTER PYLORI INFECTION?

**D. Brennan**[1], M. Feighery[2], C. Treacy[1], E. Fahy[1], J. Omorgbe[1], M. Hussey[1], D. Tighe[1], G. Holleran[1], C. O'Morain[1], D. Mcnamara[1], S. Smith[1]
[1]*Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin/Ireland*
[2]*School Of Pharmacy, Trinity College Dublin, Dublin/Ireland*

**Contact E-mail Address:** dbrenna9@tcd.ie
**Introduction:** Virulence factors produced by *H. pylori* contribute to the pathogenicity of the organism. Cytotoxin-associated gene A (cagA) and vacuolating-associated gene A (vacA) are the main *H. pylori* virulence factors. The frequency of virulence factor genotype differs across countries and recent data suggests that the cagA and vacA virulence factors may influence *H. pylori* treatment outcome.
**Aims & Methods:** To evaluate the impact of virulence factor genotype (vacA and cagA) on the prevalence of primary *H. pylori* antibiotic resistance. Following ethical approval and informed consent, DNA was isolated from gastric biopsies of treatment naïve adult patients infected with *H. pylori* (determined by histology) at Tallaght Hospital. Virulence factor genotyping was performed using PCR and genotypic susceptibility to clarithromycin and levofloxacin was tested using the GenoType HelicoDR assay (Hain Lifesciences). The chi-squared test was used to assess correlations between *H. pylori* genotypes and drug susceptibilities. A result was considered significant if a value of $p \leq 0.05$ was obtained.
**Results:** A total of 50 samples from *H. pylori* positive patients, average age 47.6 years, 56% male (n = 28), were analysed. 38% (n = 19) of samples possessed the cagA gene. The most common vacA genotype was the moderately virulent S1/M2 genotype at 36% (n = 18), followed by the highly virulent genotype S1/M1 at 34% (n = 17), the S2/M2 genotype at 28% (n = 14) and the S2/M1 genotype at 2% (n = 1). A clarithromycin resistant genotype was observed in 38% (n = 19) of samples. A levofloxacin resistant genotype was observed in 6% (n = 3). Resistance to both agents was found in 6% (n = 3) samples. The clarithromycin resistance rate in the $cagA^-$ group was significantly higher than in $cagA^+$ (48.3% vs 21.1%, $\chi = 3.74$, $p = 0.05$, OR 0.2844). There was no significant difference in either the clarithromycin or levofloxacin resistance rate between vacA genotypes.
**Conclusion:** $CagA^-$ and vacA S1/M2 are the dominant genotypes in *H. pylori* strains in our cohort. Infection with $cagA^-$ *H. pylori* may predict clarithromycin resistance. This may be because $cagA^+$ bacteria replicate at a higher rate and are therefore more susceptible to clarithromycin, so will be eradicated faster. Further study is planned to investigate the clinical relevance of virulence factors in *H. pylori* infection.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1057 LONG-TERM CHANGES OF EXTENT OF CHRONIC ATROPHIC FUNDIC GASTRITIS AFTER H. PYLORI INFECTION OBSERVED IN AUTOFLUORESCENCE IMAGING VIDEOENDOSCOPY

**N. Uedo**[1], K. Aoi[2], R. Ishihara[3], E. Toth[4]

[3]*Department Of Gastrointestinal Oncology, Osaka Medical Center for Cancer and Cardiovascular Diseases, Osaka/Japan*
[4]*Skåne University Hospital, Malmö/Sweden*

**Contact E-mail Address:** uedou-no@mc.pref.osaka.jp
**Introduction:** Long-term infection of *H. pylori* causes subsequent changes in the gastric mucosa from inflammatory cell infiltration, glandular atrophy, intestinal metaplasia, dysplasia and cancer. Eradication of *H. pylori* improves inflammatory cell infiltration and, in part, glandular atrophy but whether areas that involved by glandular atrophy and intestinal metaplasia recover or not is unknown. Autofluorescence imaging videoendoscopy (AFI) visualize areas with chronic atrophic fundic gastritis (CAFG) including glandular atrophy and intestinal metaplasia in the gastric corpus as green mucosa in endoscopic images.
**Aims & Methods:** In this study we investigated changes of extent of CAFG after *H. pylori* eradication. Among consecutive patients with history of endoscopic treatment of early gastric cancer who visited an outpatient clinic between July 2013 and August 2014, those who received endoscopy with AFI more than two times with an interval of 2 years or longer were enrolled in this study. Patients with no evaluable AFI images of the corpus, the lesion in the corpus lesser curvature, history of gastric resection, negative and unknown *H. pylori* infection status at initial endoscopy were excluded. At least one downward and one retroflex view of AFI images of the corpus were identified for each patient. Extent of CAFG was graded by consensus of two endoscopists according to the Kimura-Takemoto classification as C-1, C-2, C-3, O-1, O-2, and O-3.
**Results:** A total of 101 patients (median age of 73 years old, 81 man and 20 women) with positive *H. pylori* infection at initial endoscopy were enrolled in this study. 43 patients received successful eradication therapy and 58 patients did not receive eradication therapy. During median (range) follow-up period of 5 (2–8) years, CAFG reduced in 9 (21%) patients in the eradication group and 7 (12%) in the non-eradication group; CAFG increased in 7 (16%) in the eradication group and 5 (9%) in the non-eradication group; and CAFG did not change in reminders (73%, 74/101) in either group (p = NS). Limitation of this study is retrospective design and inclusion of many patients with severe CAFG at initial endoscopy.
**Conclusion:** In majority of patients in this study, extent of CAFG did not improve significantly after eradication of *H. pylori*.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1058 EFFECTS OF HELICOBACTER PYLORI STATUS ON DYSPEPSIA, PEPTIC ULCER, HEALTH CARE USE OR QUALITY OF LIFE - HEP-FYN 13-YEAR FOLLOW-UP

**M. Bomme**[1], J.M. Hansen[1], M. Wildner-Christensen[1], J. Hallas[2], O.B. Schaffalitzky De Muckadell[1]
[1]*Dept. Of Gastroenterology, Odense University Hospital, Odense/Denmark*
[2]*Clinical Pharmacology, University of Southern Denmark, Odense/Denmark*

**Contact E-mail Address:** maria_bomme@hotmail.com
**Introduction:** There is evidence that eradication of *Helicobacter pylori* (Hp) improves the prognosis of the hp positve individual with dyspesia and peptic ulcer disease (PUD) (1,2).
**Aims & Methods:** The aim of this study was to evaluate the long-term effect of Hp screening in Hp positive individuals and the effect of awareness of Hp status in Hp negative individuals. The long-term effects were evaluated as the effect on dyspepsia prevalence, PUD incidence, health resource use, and quality of life in the screening group compared to the control group. This cohort study is based on the HEP-FYN study; a randomized controlled clinical trial where 20,011 individuals aged 40−65 years were invited and randomized to either Hp screening and eradication (screening group) or the control group. At baseline 12,530 were enrolled. In the screening group 1,007 individuals (17.5%) were tested positive and offered Hp eradication therapy and 4,742 were Hp negative. At the 13-year follow-up those controls, who had participated in the 5-year follow-up were invited to Hp $^{13}$C-Urea breath test. Both groups received questionnaires and additionally valid national register data were accessed for all randomized individuals.
**Results:** The Hp negative screened at baseline (aware) had a lower risk of dyspepsia at the 13-year follow-up (OR 0.78 (0.68−0.90)). However, they had a higher OR of incident PUD than controls (OR 1.88 (1.21−2.93)). No difference in dyspepsia prevalence was seen in the Hp positive. In the Hp positive cohort 11 of 876 (1.3%) individuals in the screened group and 3 out of 383 controls (0.8%) had PUD during the 13-year follow-up (OR 1.61 (0.45−5.81)). Both self-reported use of ASA/NSAID, and use of LDA and ASA/NSAID based on register data were higher in the screened group. Screening and eradication at baseline had no effect on dyspepsia related visit to GP nor did decrease use of PPI or antacids. In fact the self-reported use of ulcer drugs and antacids daily was higher and the number of endoscopies and outpatient visits were higher in the screened group in both cohorts. The SF36 mental health summary (MCS) was significantly higher in controls in both cohorts at follow-up indicating higher quality of life in controls.
**Conclusion:** The Hp negative screened at baseline (aware) had a lower risk of dyspepsia at long-term. The risk of PUD was higher in the screened group compared to the unscreened group. No health effects in favor of screening and eradication of Hp positve were observed. Selection bias due to loss of follow-up could explain the results.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1059 EFFICACY OF MULTIPLEX PCR-BASED DETECTION OF HELICOBACTER PYLORI INFECTION IN PATIENTS WITH PEPTIC ULCER BLEEDING

**S.J. Han**, Y.S. Cho, I. Chung, Y. Jung, T.H. Lee, S. Park, S. Kim
*Internal Medicine, Soonchunhyang university hospital, Cheonan, Cheonan/Korea, Republic of*

**Contact E-mail Address:** c99892@schmc.ac.kr

**Introduction:** The diagnostic accuracy of histological and rapid urease tests (RUT) to detect *Helicobacter pylori* (*H. pylori*) infection in patients with peptic ulcer bleeding (PUB) often produce conflicting results. Multiplex PCR is a sensitive, accurate method of diagnosing *H. pylori* infection.

**Aims & Methods:** This study was conducted to assess the diagnostic values of endoscopy-based tests, such as RUT, multiplex PCR, and histology to detect *H. pylori* infection in patients with peptic ulcer bleeding. We prospectively enrolled 120 patients with gastric or duodenal ulcer diagnosed during endoscopic examination for evaluation of upper gastrointestinal bleeding. The patients were categorized into two groups according to the presence (bleeding group, $n = 53$) or absence (non-bleeding group, $n = 67$) of blood in the endoscopic finding. Prevalence of *H. pylori* infection and the sensitivity of the RUT, multiplex PCR and histology were compared.

**Results:** *H. pylori* infection was detected in 75 (62.5%) of 120 patients. The positive rates in RUT, multiplex PCR, and histology were 50.8%, 60.0%, and 36.8%. There was no significant difference in the prevalence of *H. pylori* infection between bleeding and non-bleeding group (66.0% vs. 59.7%, $p = 0.476$). The sensitivities of the RUT (71.4%) and histology (42.4%) in the bleeding group were significantly lower than RUT (90.0%) and histology (74.4%) in the non-bleeding group ($p = 0.039$ and $p = 0.006$). In the bleeding group, the sensitivity of multiplex PCR (94.3%) was significantly higher than RUT (71.4%) and histology (42.4%) ($p = 0.021$ and $p < 0.001$), and the sensitivity of multiplex PCR and RUT were not significantly different in the non-bleeding group.**Conclusion:** Recent bleeding in patients with peptic ulcer decreased the sensitivity of RUT and histology in the detection of *H. pylori* infection. In contrast, multiplex PCR was the most reliable method among the biopsy-based test to detect *H. pylori* infection in patients with peptic ulcer bleeding.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Villous atrophy, crypt hyperplasia and increased intraepithelial lymphocytes are histologic features of gluten-induced enteropathy, but they can be also found in other conditions. Our aim was to evaluate by validated morphometry (1) the architectural and inflammatory changes in the duodenum of patients with inflammatory bowel disease (IBD).

**Aims & Methods:** We evaluated serum samples, paraffin embedded and frozen duodenal biopsy samples from 18 IBD patients (ulcerative colitis or Crohn's disease), 13 newly diagnosed celiac disease (CD) patients and 6 controls with dyspepsia. All patients were on a gluten-containing diet. None of the IBD patients had disease specific involment of the upper gastrointestinal tract. IBD patients and controls had negative serum endomysial antibodies and did not show duodenal IgA deposits targeting transglutaminase. All patients were checked for *Helicobacter pylori* (HP) using rapid urease test during endoscopy. Paraffin embedded biopsy samples were assessed for villous height (VH), crypt depth (CrD) and villous height to crypt depth ratio (VH:CrD), while the density of CD3 and $\gamma\delta$ T cell receptor bearing intraepithelial lymphocytes (IELs) were measured in the corresponding frozen duodenal samples. The study was approved by the Ethical Committee of "Carol Davila" University of Medicine and Pharmacy, Bucharest.

**Results:** Villous atrophy with duodenal villi less than 300 μm in length was seen in 6/13 (46.15%) measurable samples of IBD patients, while crypt hyperplasia defined as over 200 μm was seen in 9/13 (69.23%). Mean VH was 316.3 μm in the IBD group, compared to 143.5 μm in the CD group and 388.3 μm in controls ($p < 0.01$). Mean CrD values were 210, 300 and 188 μm respectively ($p = 0.05$), while VH:CrD was 1.61, 0.90 and 2.14 respectively ($p = 0.03$). A subgroup analysis in the IBD patients after HP status showed a VH to CrD ratio of 1.18 in the HP positive subgroup and 1.98 in the HP negative subgroup ($p = 0.0055$). Regarding the inflammatory changes, an increased density of CD3+ IELs (>37 cells/mm epithelium) was present in 10/16 measurable samples of IBD patients (62.5%) and increased $\gamma\delta$ IELs (>4.3 cells/mm epithelium) were also present in high proportion, 13/16 (81.25%). However, mean number of CD3 and $\gamma\delta$ IELs were significantly lower in the duodenum of IBD and controls compared to CD patients (43.8, 40 and 78.8 for CD3; 7.8, 8 and 28.7 respectively for $\gamma\delta$ IELs, both $p < 0.01$). There was no difference in duodenal inflammation of IBD patients when considering subgroup analysis after HP status.

**Conclusion:** Our results show that IBD patients, when infected with HP, have morphologic changes in the duodenum similar to those seen in CD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1061 EFFICACY OF 7-DAY GENOTYPIC RESISTANCE-GUIDED TRIPLE THERAPY FOR HELICOBACTER PYLORI ERADICATION: PROSPECTIVE TRIAL IN A HIGH-RESISTANCE SETTING

N. Mathou[1], S. Lycousi[2], **V. Papastergiou**[1], K.D. Paraskeva[1], A. Giannakopoulos[1], E. Evgenidi[1], J. Karagiannis[1]

[2]*Microbiology, "Konstantopoulio" General Hospital, Athens/Greece*

**Contact E-mail Address:** vasi.pap@hotmail.com
**Introduction:** *Helicobacter pylori* (*H. pylori*) eradication rates with empirical triple therapies are rapidly declining, thus alternative treatment strategies are urgently needed. The efficacy and applicability of genotypic resistance to guide the choice of antibiotics in triple therapies have not been reported. We trialed the efficacy of a 1-week genotypic resistance-guided triple therapy in a high-resistance setting in Greece.
**Aims & Methods:** Consecutive adult patients undergoing upper endoscopy for the evaluation of gastrointestinal symptoms were prospectively assessed for inclusion. Eligible patients were those who tested positive for *H. pylori* by either rapid urease testing or histology. Gastric biopsy specimens from eligible subjects were tested with a reverse hybridization multiplex polymerase chain reaction (PCR) line probe assay (GenoTypeHelicoDR, Hain Lifescience GmbH, Germany). The 23 S rRNA gene was analyzed with three-point mutations (A2146G, A2146C, A2147G) for clarithromycin, and gyrA gene (codons 87 and 91) for fluoroquinolone susceptibility testing. A genotypic resistance-guided triple therapy was given for 7 days comprising esomeprazole (40 mg b.i.d), amoxicillin (1 gr b.i.d) and either clarithromycin (500 mg b.i.d) in the absence of 23 S rRNA mutation, levofloxacin (500 mg b.i.d) in the presence of 23 S rRNA mutation and wild type gyrA, or rifabutin (150 mg b.i.d) in presence of both 23 S and gyrA mutations. Eradication status was determined by the $^{13}$C-Urea breath test.
**Results:** Of 84 patients screened for eligibility, 28 (33.3%) were enrolled in the study (14/28 males, mean age: 56 years, non-ulcer dyspepsia: 24/28) of whom 10/28 reported a previous history of *H. pylori* treatment. All patients were *H. pylori* positive by PCR. Genotypic resistance to clarithromycin and fluoroquinolones was detected in 14/28 (naïve: 8/18, experienced: 6/10) and 4/28 (naïve: 2/18, experienced: 2/10) patients respectively. There were no cases of dual clarithromycin/fluoroquinolone resistance. All but two patients returned for eradication confirmation. The eradication rates were 92.9% (26/28) in intention-to-treat (ITT) and 100% (26/26) in per-protocol analysis. All (18/18) antibiotic-resistant *H. pylori* strains were successfully eradicated; the ITT eradication rate was 100% in patients reporting a previous *H. pylori* treatment history.
**Conclusion:** Irrespective to treatment status, a genotypic resistance-guided triple therapy, given for 7 days, achieves excellent eradication rates. Future clinical and economic evaluation data are awaited to better characterize the position of molecular susceptibility testing for *H. pylori* eradication in clinical practice
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1062 THE INVESTIGATION OF OPTIMAL H.PYLORI ERADICATION TREATMENT USING VONOPRAZAN, A NOVEL POTASSIUM-COMPETITIVE ACID BLOCKER

**S. Egawa**[1], K. Kozumi[2], E. Yoshida[2], E. Kimura[2], F. Sano[2], C. Torizumi[2], E. Tsumano[2], A. Shimayoshi[2], M. Horie[2], K. Iwahashi[2], D. Nakamatsu[2], M. Murata[2], M. Miyazaki[2], M. Oshita[2]
[1]*Internal Medicine, Osaka Police Hospital, Osaka/Japan*
[2]*Internal Medicine, Osaka Police Hospital, Osaka/Japan*

**Contact E-mail Address:** egawasato@gmail.com
**Introduction:** Vonoprazan, a novel potassium-competitive acid blocker, was reported as a component of first-line triple therapy for *Helicobacter pylori* eradication. A phase three randomized, double-blind, multicentre study in Japan revealed that the first-line eradication rate was 92.6% with vonoprazan versus 75.9% with lansoprazole.
**Aims & Methods:** The aim of this study was to investigate the relationship of patients characteristics (age, gender, renal function, degree of gastric atrophy) with success rate of *H. pylori* eradication. In our hospital, from April 2015 to March 2016, 380 *H. pylori*-positive patients with atrophic gastritis or peptic ulcer received first-line triple therapy with vonoprazan (VPZ) 20 mg in combination with amoxicillin (AMX) 750 mg plus clarithromycin (CLR) 200 or 400 mg. Ninety five patients received triple therapy with lansoprazole (LPZ) 30 mg in combination with AMX 750 mg plus CLR 200 or 400 mg in the last 3 months before using VPZ in our hospital. All treatment were administered orally twice daily for 7 days, and then followed up for an additional >4weeks and evaluated for *H. pylori* status by the C-13 urea breath test.
**Results:** The first-line eradication rate was 85.8% (326/380) in the vonoprazan group versus 55.8% (53/95) in the lansoprazole group, with the significant difference ($p < 0.01$, Chi squared test). Serum creatinine (Crn) level were measured before *H. pylori* eradication, and the median value was 0.75 mg/dl. Between Crn > 0.75 subjects and Crn < 0.75 subjects, the eradication rate was compared. In VPZ group, *H. pylori* eradication rate of Crn > 0.75 subjects was significantly higher than that of Crn < 0.75 subjects. ($p < 0.05$) In LPZ group, *H. pylori* eradication rate was not differed between Crn > 0.75 subjects and Crn < 0.75 subjects. Therefore there is a possibility that success rate of the first-line regimen including VPZ might be improved by administrating higher dose. Age, gender, and degree of gastric atrophy had no significant relation to *H. pylori* eradication rate both in VPZ and LPZ group.
**Conclusion:** Our results suggested that optimal dose of *H. pylori* eradication treatment for patients with normal renal function might be higher than that of the present vonoprazan regimen.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1063 UNSATISFACTORY EFFICACY OF LEVOFLOXACIN TRIPLE THERAPY IN THE FIRST AND SECOND LINE TREATMENT OF HELICOBACTER PYLORI INFECTION- A SYSTEMIC REVIEW AND META-ANALYSIS

**J. Liou**[1], P. Chen[2], J. Lin[3], M. Wu[4]

[4]*National Taiwan University Hospital, Taipei/Taiwan*

**Contact E-mail Address:** dtmed046@pchome.com.tw
**Introduction:** Levofloxacin triple therapy has been used for the first line and second line treatment of *Helicobacter pylori* (*H. pylori*) infection for more than 10 years. Although earlier trials reported high efficacy of this therapy, recent trials show that the eradication rate of levofloxacin triple therapy were lower than 80–85%.
**Aims & Methods:** Therefore, we aimed to systemically review the efficacy of levofloxacin triple therapy in the first and second-line treatment and to assess the time trend and factors that might affect its efficacy. Prospective trials reporting the efficacy of levofloxacin triple therapy in either the first line or second line treatment of *H. pylori* infection in adults were searched from the PubMed and Cochrane database from Jan 2000 to Sep 2015. Meta-analysis was performed to calculate the cumulative eradication rate and the efficacies in subgroups.
**Results:** Of the 322 articles identified, a total of 4574 patients from 41 trials, including 16 trials in the first-line treatment and 25 trials in the second line treatment were eligible for analysis. The cumulative eradication rate was 77.3% (95% confidence intervals (CI):74.7%-79.6%) and showed a trend of decreasing efficacy with time. The eradication rate was 80.7% (95% CI 77.1%-83.7%) in the first line treatment and 74.5% (95% CI:70.9%-77.8%) in the second line treatment. The efficacies of levofloxacin triple therapy before 2008, between 2009~2011, and after 2012 were 77.4%, 79.6% and 74.8%, respectively. The eradication rate was higher when levofloxacin was given once daily (80.6%, 95% CI 77.1%-83.7%) than twice daily (73.6%, 95% CI 69.7%-77.2%). The efficacy was significantly higher in levofloxacin susceptible strains than resistant strains (81.1% vs. 36.3%, risk ratio 2.18, 95% CI 1.6–3, $p < 0.001$).
**Conclusion:** The efficacy of levofloxacin triple therapy has been lower than 80% in many countries and is not recommended when the levofloxacin resistance is higher than 10%.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1064 HELICOBACTER AND DUODENAL ULCERATION IN 2015: HOW METICULOUS ARE WE AT ASSESSING, ERADICATING AND RETESTING FOR HELICOBACTER?

**A. Masding**, K. Besherdas
*Gastroenterology, Barnet General Hospital, Royal Free London, London/United Kingdom*

**Contact E-mail Address:** aekmasding@gmail.com
**Introduction:** The association between *Helicobacter pylori* (HP) and duodenal ulcer (DU) is well recognised. Studies have demonstrated the presence of HP in up to 95% of DU patients, with the remainder mostly related to use of non-steroidal anti-inflammatory drugs (NSAIDs). Detection of HP infection at endoscopy is commonly undertaken via the rapid urease test, however, there is a significant false negative rate in patients with an acutely bleeding DU. Thus, together with the high prevalence of HP infection in DU, some advocate empirical use of HP eradication therapy. Ulcer recurrence following successful HP eradication is low, however there is increasing evidence of antibiotic resistance, likely to cause treatment failure. Consequently, retesting to confirm HP eradication in patients with DU should be performed, a recommendation by The Scottish Intercollegiate Guidelines network (also endorsed by the British Society of Gastroenterology).
**Aims & Methods:** Aim: To identify the rate of detection and eradication of HP in patients with DU at the time of diagnosis and to determine rate of retesting to confirm HP eradication in these DU patients in real-life clinical practice.
A single centre (large north London hospital) retrospective analysis of 93 consecutive patients diagnosed with DU at upper GI endoscopy between September 2010 and September 2015. Data was obtained from the GI audit tool within the Unisoft endoscopy reporting software. Electronic patient records were used to scrutinise endoscopic HP testing, provision of eradication therapy and retesting to confirm eradication. Subgroup analysis for complicated DU was undertaken. Complicated DU was defined as symptoms of haematemesis, malaena or anaemia, or endoscopic signs of visible vessels, blood clots, a red spot, surrounding altered or fresh blood, perforation and obstruction.
**Results:** 93 patients were diagnosed with DU during the study period (age 30–98 years, M:F 1.9:1). 35% patients (n = 33) were tested for HP at endoscopy using the rapid urease test, of which 30% (n = 10) were positive. 60% of patients positive for HP received eradication therapy (n = 6). 83% (n = 77) were complicated DUs, of these 22% (n = 17) received eradication therapy. 3% patients (n = 3) were assessed for confirmation of *H. pylori* eradication. This included 2 patients with complicated DU.
**Conclusion:** From this study we conclude that the majority of patients diagnosed with DU have complicated ulcers. The testing for HP in DU patients is not routinely undertaken. More than one-third of HP-positive patients and three-quarters of complicated DU patients do not receive eradication therapy. Retesting of HP pylori following eradication therapy is extremely poor. To reduce morbidity and mortality associated with HP-related ulcer recurrence, we recommend empirical HP eradication therapy in all patients with DU, followed by retesting to confirm success in complicated DU.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1065 POTASSIUM-COMPETITIVE ACID BLOCKER–BASED THIRD-LINE TRIPLE THERAPY IN HELICOBACTER PYLORI ERADICATION AND STUDY OF THE DIVERSITY OF ANTIMICROBIAL SUSCEPTIBILITIES

**Y. Yano**[1], H. Mizuta[1], M. Kira[1], Y. Matsumura[1], T. Kitagawa[1], M. Hashiba[1], N. Okamoto[1], H. Takeuchi[1], M. Ono[1], T. Saibara[2]

**Contact E-mail Address:** jm-yukari_y@kochi-u.ac.jp

**Introduction:** The *Helicobacter pylori* (HP) eradication rate with potassium-competitive acid blocker (P-CAB)-based triple therapy is reportedly more effective than that with proton pump inhibitor (PPI)-based triple therapy for both first- and second-line treatment. However, the effectiveness of third-line eradication with P-CAB-based triple therapy has not been clarified.
**Aims & Methods:** The aim of this study was to clarify the eradication rate of P-CAB-based triple therapy and verify the antimicrobial susceptibility test using multiple strains from indivisual patients. Thirty patients were referred to our hospital for third-line therapy because of second-line eradication failure or penicillin allergy. Among them, 18 patients who underwent upper endoscopy and had a positive HP culture test result were investigated in this study. We performed biopsies from the corpus and antrum of the stomach in all patients, cultured HP, and identified 6 strains at each part (total of 12 strains per patient). The sensitivity of HP to four antimicrobial drugs (amoxicillin, clarithromycin, metronidazole [MNZ], and sitafloxacin [STFX]) was examined. After endoscopy, all patients were treated with the following third-line P-CAB-based triple therapy regimen: P-CAB 20 mg twice daily, MNZ 250 mg twice daily, and STFX 100 mg twice daily for 7 days. A urea breath test was performed after 8 weeks.
**Results:** The eradication rate of third-line triple therapy was 66.7% (12/18). The eradication rate of third-line triple therapy after second-line failure was only 53.8% (7/13). The sensitivity tests of the 12 HP strains to antimicrobial drugs revealed that all patients simultaneously had both drug-sensitive and drug-resistant strains. Additionally, the minimum inhibitory concentration of drug resistance in each strain differed even in the same patients. A four-drug-resistant strain was detected in one patient in whom third-line therapy failed. In particular, the eradication rates tended to be low in patients with STFX-resistant strains. Almost all patients with second-line failure had some MNZ-resistant strains.
**Conclusion:** P-CAB-based third-line triple therapy was less effective than conventional PPI-based triple therapy for HP eradication. Our antimicrobial resistance study indicates that MNZ-resistance might not contribute to the eradication rate associated with P-CAB-based third-line therapy. However, we found low eradication rates in patients with multidrug-resistant strains, especially STFX-resistant strains. Moreover, bacterial susceptibility to antimicrobial drugs differed among the strains colonized in the same patients. Regarding to effective eradication therapy, it is important to know the great diversity of drug-susceptibility among individual HP strains in the stomach.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** marthekcharles@gmail.com

**Introduction:** *Helicobacter pylori* is a gram negative pleomorphic bacillus associated with gastritis, peptic ulcer disease and gastric adenocarcinomas. *H. pylori* is difficult to cultivate thus making susceptibility testing laborious. CLSI (Clinical and Laboratory Standards Institute) does not currently provide clinical breakpoints for *H. pylori*, other than for Clarithromycin, to classify strains as sensitive or resistant. It is known that resistance to antibiotics is an important cause of treatment failure. Treatment is often based on expert recommendation but rarely based on antibiogram profile. The goal of this study was to evaluate the susceptibility patterns of isolates from Edmonton and Northern Alberta patients.
**Aims & Methods:** Patients scheduled for gastroscopy underwent gastric biopsies for *H. pylori* infection. From February 2012 to October 2015, gastric biopsies were submitted in urea broth and saline. *H. pylori* was isolated from saline and antimicrobial susceptibility testing was performed by E-test (Ampicillin, Tetracycline, Metronidazole, Levofloxacin, Moxifloxacin and Clarithromycin). Interpretation of susceptibility was conducted using European Committee on antimicrobial susceptibility testing clinical breakpoints[1]. A chart review was also conducted to identify prior antimicrobial treatments.
**Results:** During the study period, 183 patients underwent gastric biopsy for *H. pylori* infection, and a total of 205 biopsies were sent for culture. The positivity rate by culture was 21% of patients (42 isolates, 39 patients). In this cohort 90% (35 patients) were previously treated for *H. pylori*. Resistance to one or more antimicrobial agent was found in 88% of positive patients (38 isolates); 33% (14 isolates) were resistant to three or more antibiotics. The majority of isolates from patients that were previously treated with Clarithromycin/ Metronidazole or triple therapy (Lansoprazole/ Amoxicillin/ Clarithromycin) were found to have resistance to Clarithromycin and Metronidazole. The rate of resistance to ampicillin 10% and tetracycline 0% was low; It was 31% for levofloxacin, 79% for Clarithromycin and 76% for Metronidazole. Overall, 64% of the isolates were resistant to Clarithromycin and Metronidazole.
**Conclusion:** This study showed the difficulties of *H. pylori* susceptibility testing due to low recovery rates of the organism from gastric biopsies. It also highlights the need for locally generated susceptibility data to better tailor therapy for each patient. Meanwhile, it also reflects the need for adequate treatment guidelines that reflect susceptibility patterns. Culture and susceptibility testing can be useful for adequate therapy for *H. pylori* eradication and antibiotic stewardship.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** jvafaeemanesh@yahoo.com

**Introduction:** Proton pump inhibitor based triple therapy with two antibiotics for *Helicobacter pylori* (*H. pylori*) eradication is widely accepted, but this combination fails in a considerable number of cases. Some studies have shown that cranberry inhibit the adhesion of a wide range of microbial pathogens, including *H. pylori*. The aim was to assess the effect of cranberry on *H. pylori* eradication with a standard therapy including lansoprazole, clarithromycin and amoxicillin (LCA) in patients with peptic ulcer disease (PUD).
**Aims & Methods:** In this study, *H. pylori*-positive patients with PUD were randomized into two groupsas one by one: Group A: a 14-day LCA triple therapy with 30 mg lansoprazole bid, 1000 mg amoxicillin bid and 500 mg clarithromycin bid; Group B: a 14-day 500 mg cranberry capsules bid plus LCA triple therapy. $A^{13}C$-urea breath test was performed for eradication assessment 6 weeks after completion of the treatment.
**Results:** 200 patients (53.5% males, between 23 and 77 years, mean age $\pm$ SD: $50.29 \pm 17.79$ years) could continue treatment protocols and underwent $^{13}C$-urea breath testing. *H. pylori* eradication was achieved in 74% in Group A (LCA without cranberry) and in 89% in Group B (LCA with cranberry), ($p = 0.042$).
**Conclusion:** The addition of cranberry to LCA triple therapy for *H. pylori*, has higher rate of eradication than the standard regimen alone (up to 89% and significant).
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1068 HELICOBACTER PYLORI ERADICATION EFFECT ON LIVER FAT CONTENT IN PATIENT WITH NON-ALCOHOLIC FATTY LIVER DISEASE

**A. H. Arnaout**
*Faculty Of Medicine, Zagazig University, Zagazig/Egypt*

**Contact E-mail Address:** Ahmedhamouda1977@gmail.com

**Introduction:** *Helicobacter pylori* (HP) infection role in nonalcoholic fatty liver disease (NAFLD) pathogenesis is controversial.

**Aims & Methods:** This study aimed to evaluate the effect of HP eradication on liver fat content (LFC), liver function tests (LFT), lipid profile, and homeostasis model assessment-IR (HOMA-IR) index in NAFLD. Patient with dyspepsia and increased serum levels of aminotransferases enrolled in the study. Exclusion criteria were factors affecting aminotransferases levels or HP treatment regimen. Patients with elevated aminotransferases levels and ultrasound findings of fatty liver disease were supposed for NAFLD. NAFLD liver fat score used to classify NAFLD, those with score greater than -0.64 and positive results for urea breath test (UBT), were included. Patients underwent lifestyle modifications and HP eradication. Alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), triglyceride (TG), cholesterol (CHOL), high and low-density lipoprotein (HDL, LDL), fasting serum glucose (FSG), LFC, and HOMA-IR were checked at baseline, after eight weeks and twenty four weeks.

**Results:** One hundred twenty patients (58 males) with the mean age of 45.39 ($\pm$9.24) were included with repeated ANOVA measurement showed a significant reduction in anthropometric measurements, laboratory parameters (except for HDL) and LFC in both groups during the study; however, no significant difference was observed between the groups.

**Conclusion:** HP eradication per se might not affect LFT, lipid profile, LFC, and insulin resistance in dyspeptic NAFLD patients

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Guanylate cyclase C (GC-C) is an intestinal receptor activated by bacterial heat-stable enterotoxins (ST), the endogenous ligands guanylin (GN) and uroguanylin (UGN) and the drug linaclotide. Familial GUCY2C diarrhea syndrome (FGDS) was diagnosed in a Norwegian family (n = 32) in 2012(1), and is caused by an activating mutation in the GUCY2C gene encoding GC-C. This activation results in increased secretion of chloride and water to the intestinal lumen, explaining the diarrhea. The patients also have an increased risk of Crohn's disease (CD, 20%). Downregulation of the GC-C pathway has previously been demonstrated in patients with IBD, including lower tissue density and gene expression of GN, which was inversely related to inflammation (2). Whether activation of GC-C affects the content of guanylins in intestinal tissue and the levels of these hormones in plasma is not known.

**Aims & Methods:** Plasma from 27 fasting patients with FGDS, 35 with CD, 24 with diarrhea- predominant Irritable Bowel Sydrome (PI-IBS-D) and 29 HC were collected and analyzed for proguanylin (ProGN) and prouroguanylin (ProUGN) using ELISA-kit (BioVendor, Karasek, Czech Republic). We performed immunhistochemistry using commercial antibodies towards GN and UGN in biopsy tissue from non-inflamed terminal ileum (FGDS n = 11, HC n = 16), and density of immunoreactive cells was quantified using computerized image analyses (3).

**Results:** Significantly lower fasting plasma levels of ProGN and ProUGN were found in FGDS and CD patients compared to the HC group ($p < 0.001$, $p = 0.013$ respectively). The plasma levels of both GN and UGN in PI-IBS patients were not significantly different from those in HC or other patient groups, ($p > 0.05$), but levels were below HC and above those observed for FGDS and CD patients. The density of GN immunoreactive cells in terminal ileum of FGDS patients was significantly higher than in HC ($P = 0.02$). Density of immunoreactive UGN cells could not be determined due to failure of UGN antibody binding. The ileal biopsies of all FGDS patients with one exception showed no signs inflammation on histological examination.

**Conclusion:** FGDS and CD patients have significantly lower plasma levels of both ProUGN and ProGN compared to HC. In FGDS patients, this finding was not associated with inflammation in the ileal mucosa nor reduced density of GN immunoreactive cells in terminal ileum, pointing to other mechanisms for the observed reduction of plasma guanylins. The increased density of GN immunoreactive cells in terminal ileum of FGDS patients may indicate impaired GN secretion from epithelial cells to plasma.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Familial GUCY2C diarrhea syndrome (FGDS) is a novel autosomal dominant disorder caused by an activating missense mutation in *GUCY2C*, encoding guanylate cycalse C. Activation of the guanylate cyclase C pathway, with increased formation of cellular cyclic guanosine monophosphate (cGMP), eventually results in increased secretion of chloride ions ($Cl^-$) and water into the

intestinal lumen. FGDS patients also have abnormal contractility of the small intestine, and increased risk of Crohn's disease (20%) and intestinal obstruction (25%) (1). Small intestinal hormones; namely serotonin and peptide YY (PYY) affect intestinal motility and fluid secretion. The densities of serotonin- and PYY-immunoreactive cells have shown abnormalities in other gastrointestinal disorders such as irritable bowel syndrome (2) and inflammatory bowel disorders (3).
**Aims & Methods:** The aim of the study was to investigate whether there are changes in the densities of enteroendocrine cells immunoreactive to chromogranin A (CgA), serotonin and PYY in the terminal ileum of FGDS patients compared to healthy controls. Biopsies sampled from the terminal ileum (non-inflamed mucosa) of 11 FGDS patients and 16 healthy controls were fixed in paraformaldehyde, embedded in paraffin and cut into 5 $\mu$m thinned sections. The sections were immunostained for CgA, serotonin and PYY with ultraView Universal DAB Detection Kit using the BenchMark Ultra immunohistochemistry/in situ hybridization staining module. The density of the immunoreactive cells were quantified using computerized image analysis (4).
**Results:** There was a significant lower density of PYY ($P < 0.011$), but not serotonin and CgA, immunoreactive cells in the terminal ileum of FGDS patients compared to healthy controls (Table 1).

**Table 1:** Densities of immunoreactive cells in the terminal ileum of healthy controls and FGDS patients.

Endocrine cell densities (cells/mm$^2$)

| Hormone | Control | Patient | P-value |
|---|---|---|---|
| **Chromogranin A** | $163.4 \pm 8.0$ | $164.9 \pm 24.6$ | 0.77 |
| **Serotonin** | $63.1 \pm 4.4$ | $70.0 \pm 13.4$ | 0.75 |
| **PYY** | $46.4 \pm 4.5$ | $25.3 \pm 5.8$ | $<0.011$ [a] |

Data are presented as the mean $\pm$ SEM. a: $P < 0.05$.

**Conclusion:** PYY acts as an anti-diarrheal agent by inhibiting cyclic adenosine monophosphate (cAMP) dependent agonists, and also inhibits intestinal motility. Both cGMP and cAMP activate the cystic fibrosis transmembrane regulator, and may cause diarrhea by increased secretion of $Cl^-$ and water from the enterocytes. FGDS patients have lower PYY immunoreactive cell densities than healthy controls. Further investigation of the relevance of PYY and PYY immunoreactive cell densities to the pathogenesis of FGDS is warranted.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1071 BORONIC ACID ARRAY FOR RAPID IDENTIFICATION OF INCREASED SMALL INTESTINAL PERMEABILITY

A. Resendez[1], P. Panescu[1], R. Zuniga[1], I. Banda[1], B. Singaram[1], **D. Webb**[2]

**Introduction:** There is need for low_cost and rapid, high-throughput tests for gut mucosal permeability. We are a multidisciplinary group of organic chemists and gastroenterology experts that is synthesizing and characterizing new chemistries for this purpose. When incorporated into organic molecules, boronic acids bind different sugars and sugar alcohols with different affinities. This variation depends on the positions where boronic acids are attached. A novel boronic acid appended viologen (BBV) sugar receptor library consisting of three synthesized BBVs (abbreviated "4,4'-o-BBV", "4,7'-o-PBBV" and "pBoB") was incorporated into a two component fluorescent assay for intestinal mucosal permeability relevant sugars (lactulose, rhamnose, 3-O-methyl-D-glucose, xylose) and sugar alcohols (mannitol, sorbitol, erythritol, galactitol).
**Aims & Methods:** The aims were to establish binding characteristics for the different permeability analytes and determine ability of the sensor library to discriminate between normal versus increased intestinal permeability (e.g., low versus high lactulose:mannitol ratios) in assay buffers and human urine. Principle component (PCA) and linear discriminant (LDA) analyses were applied to data obtained from samples spiked with known sugar concentrations and mixtures with different ratios.
**Results:** Compared to our previous work (1), twofold reductions in lower limits of detection (LLOD) and quantification (LLOQ) for lactulose were achieved with one of the BBV receptors, 4,7'-o-PBBV (LLOD 41 $\mu$M, LLOQ 72 $\mu$M). The array exhibited sharp discrimination between sugar alcohols (e.g., mannitol) and lactulose, establishing a fluorescence-based differential receptor system. It was further possible by LDA analysis to statistically segregate lactulose:mannitol ratios within a narrow range (0.1 – 0.5) that was sufficient to discern healthy versus increased small intestinal permeability. Segregation between other permutations of permeability markers was also achieved.
**Conclusion:** This proof-of-concept demonstrates that low_cost and rapid tests can be achieved using BBV sugar receptor arrays to discern normal from elevated tight junctional permeability using the most commonly used sugar and sugar alcohol markers. Flexibility to pick and choose different permutations of permeability markers for different clinical study goals or in vitro drug safety screening of large drug libraries (e.g., Caco-2, IPEC-J2, IEC-18) is not only possible, but technically and economically feasible. Because this chemistry is both rapid and reversible, it can be adapted to real-time and online monitoring of changes in permeability to multiple analytes, which is currently under development.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Increased intestinal permeability (IP) has been observed in a number of autoimmune diseases and may account for a susceptibility to disease triggers. We previously showed that IP in healthy subjects is not associated with the makeup of the fecal microbiota.
**Aims & Methods:** The objective of this work was to investigate if functional capacities of fecal microbiota are associated with intestinal permeability. Subjects were given a solution of two saccharide probes, lactulose and mannitol High-pressure liquid chromatography analysis of timed urine collection allows for the calculation of, the lactulose–mannitol ratio (LacMan ratio) based on the fractional excretion of lactulose divided by that of mannitol. Bacterial DNA extracted from the stool of 1098 healthy subject was sequenced for the V4 hypervariable region of the 16S rRNA using Illumina MiSeq platform. The function of the fecal microbial communities was then imputed using PICRUSt V0.1 after a rarefaction step to 30,000 sequences per sample. The PICRUSt precalculated table of gene counts based on OTUs was used to identify the gene counts in the organisms present in the stool samples. The Kyoto Encyclopedia of Genes and Genomes (KEGG) and clusters of orthologous groups (COG) databases were used to identify gene families. Association was performed using a linear regression controlling for age, gender and smoking status. Bacterial functions with a mean count $<10$ were excluded.
**Results:** Among 3,773 KEGG and 3,618 COG functions, we found several nominal associations with IP. Using KEGG database, we found 25 associations with IP ($p < 10^{-4}$). The most significant associations involved tyrosine metabolism and degradation of aromatic compounds (K01826). Ten associations were obtain using COG database, the most significant involved in tellurite resistance (COG3615), and DNA uptake process and recombination (COG4469) ($p < 7.78 \times 10^{-4}$).
**Conclusion:** Multivariate analysis controlling for major contributing factors to IP allowed us to identify that while the specific microbial taxa do not appear to be associated with IP while microbial community functions are likely contributing to IP in healthy humans. Submitted on behalf of GEM Project research team
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1073 DYSBIOSIS AND STABILITY OVER TWO YEARS IN PATIENTS WITH IRRITABLE BOWEL SYNDROME

**Introduction:** There is increasing knowledge of a possible role for gut microbiota in the pathophysiology of at least subgroups of irritable bowel syndrome (IBS) patients. Fluctuations in IBS activity should be reflected by changes in gut microbiota and categorization into a status of dysbiosis or no dysbiosis if there is a causal relationship. In the present study, on defined IBS patients, dysbiosis status was studied at baseline and after two years.

**P1073**

**Table 1:** DBT = dysbiosis both times (2013 and 2015). NHD= never had dysbiosis. *Fisher's exact test. ** Abundance was measured semi-quantitatively as low, normal or high.

| | **Comparison of DBT (n = 33) vs NHD (n = 10)** Test 1 | Test 2 | **Comment** | **Agreement in abundance between test 1 and 2 (%) for DBT**** |
|---|---|---|---|---|
| | p-value | | | |
| **Bacteria** | | | | |
| Ruminococcus albus/bromii | 0.66 | 0.66 | | 76 |
| Ruminococcus gnavus | 1.00 | 1.00 | | 85 |
| Faecalibacterium prausnitzii | 0.07 | 0.24 | DBT lower at test 1 | 57 |
| Lactobacillus | 0.17 | 1.00 | | 85 |
| Streptococcus sanguinis and S. salivarius | 1.00 | 0.61 | | 85 |
| Dialister invisus | 0.73 | 0.04 | DBT higher at test 2 | 67 |

| Shigella/Escherichia | 0.02 | 0.24 | DBT lower at test 1 | 52 |
| Bifidobacterium | 0.04 | 1.00 | DBT lower at test 1 | 52 |
| Bacteroides/Prevotella | 0.60 | 0.01 | DBT higher at test 2 | 61 |
| Firmicutes (Bacillli) | 0.85 | 0.86 | | 63 |
| Firmicutes (Clostridia) | 1.00 | 0.59 | | 58 |
| Proteobacteria | 0.29 | 1.00 | | 70 |

**Aims & Methods::** Sixty-three patients with IBS according to Rome III criteria were recruited to receive education about treatment options for IBS by a gastroenterologist and to be tested for dysbiosis using the GA-map$^{TM}$ Dysbiosis Test. This is a semi-quantitative 16SrRNA-based analysis of fecal bacteriae (Genetic Analysis, Oslo, Norway). The dysbiosis test was repeated two years later. Dysbiosis is defined by a dysbiosis index, DI (1–5), which is calculated by an algorithm based on the abundance and profile of bacteria. DI 3 or higher is defined as dysbiosis. The abundance of bacteria was measured as low, normal or high. All patients were seen by a gastroenterologist at the 2-year follow-up. The present abstract compares the bacterial profile in patients with dysbiosis, those without dysbiosis and any changes in dysbiosis status after two years according to the present definition of dysbiosis.
**Results:** Out of 63 IBS patients at baseline, 60 also provided stool samples after two years. Ten (17%) tested negative for dysbiosis at both rounds (never had dysbiosis=NHD), 33 (55%) had dysbiosis both times (DBT), 8 (13%) went from no dysbiosis to having it, and 9 (15%) went from dysbiosis to losing it. With focus on the first two groups: abundance of Faecalibacterium prausnitzii, Shigella/Escherichia and Bifidobacterium was significantly lower (Fisher's exact test 0.07, 0.02, 0.04) in the DBT group than the NHD group at baseline, while abundance of Dialister and Bacteroides was significantly higher in the DBT group (0.04, 0.009) after two years (Table 1). In the DBT group, the abundance of Ruminococcus gnavus, Lactobacillus, Strectococcus sanguinis and Alistipes species showed high agreement between visits 1 and 2 (82–85%), but low agreement (52–57%) for Faecalibacterium prausnitzi, Shigellea/Escherichia and Bifidobacterium species (Table 1).
**Conclusion:** Fifty-five percent of the patients had dysbiosis at baseline and after two years while 17% tested negative both times. Fifteen percent got dysbiosis and 13% lost it. Some bacteria were very stable, while others were more unstable. To test the stability may be of interest in possible future studies to treat specific disturbances in the gut microbiota.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1074 THE INFLUENCE OF PROTON PUMP INHIBITER IN HUMAN MICROBIOTA AND METABOLIC PRODUCTION RELATED TO ADVERSE EVENTS

**T. Kato**, I. Tsuchiya, A. Nakajima
*Department Of Gastroenterology And Hepatology, Yokohama City University, Yokohama/Japan*

**Contact E-mail Address:** t.kato222@gmail.com
**Introduction:** Proton pump inhibitor (PPI) is widely used for treatment against upper GI disorders, but the attention towards its adverse effects are rarely discussed. Wallace at el. has reported that PPI exacerbates NSAID-induced small intestinal injuries in rodent models [1], and that the reduction of Bifidobacterium due to PPI treatment was related to this.
**Aims & Methods:** Our aim was to figure out how the microbiome change in human, and to analyze the difference of metabolic production after PPI use. We collected fecal samples from 21 healthy male volunteers before and after 14 days of 20 mg daily omeprazole intake. The volunteers were restricted to eat foods that would affect the microbiome. The microbiome of the fecal samples were assessed using next generation sequencing platform (Illumina MiSeq). The metabolome of same samples were also analyzed.
**Results:** Microbiome analysis showed that Actinobacteria phylum ($p = 0.016$), especially Bifidobacterium genus ($p < 0.01$) was significantly reduced after PPI use. Metabolomics analysis revealed that some of the metabolic productions increase, and some decrease significantly after PPI use.
**Conclusion:** Our results showed that the same dysbiosis occurs in human subjects as rodent models, and this suggests that PPI use may exacerbate small intestinal injuries also in human. In addition, there were also changes among the metabolic production. Further study may reveal the pathogenesis of the PPI related adverse effects.
**Disclosure of Interest:** T. Kato: This research was supported by a grant from Biofermin Pharmaceutical Co., Ltd.
A. Nakajima: This research was supported by a grant from Biofermin Pharmaceutical Co., Ltd.

## P1075 PRESENCE OF SMALL INTESTINAL BACTERIAL OVERGROWTH IN PATIENTS WITH ACTIVE HELICOBACTER PYLORI INFECTION ASSESSED BY FUNCTIONAL BREATH TESTING

**D. Enko**, G. Kriegshäuser
*Institute Of Clinical Chemistry And Laboratory Medicine, General Hospital Steyr, Steyr/Austria*

**Contact E-mail Address:** dietmar.enko@gespag.at
**Introduction:** The aim of the present study was to investigate the presence of small intestinal bacterial overgrowth (SIBO) in patients with active *Helicobacter pylori* infection assessed by functional breath testing.
**Aims & Methods:** In total, 109 patients with gastrointestinal complaints, who were referred for the *Helicobacter pylori* $^{13}$C-urea breath test ($^{13}$C-UBT) by general practitioners and specialists, were also tested for the presence of SIBO by the glucose hydrogen ($H_2$)/methane ($CH_4$) breath test (HMBT). The Fisher's exact test was performed to compare the $^{13}$C-UBT with the glucose $H_2/CH_4$ breath test results. A detailed anamnesis was carried out about the history of *Helicobacter pylori* infection, eradication therapies, proton pump inhibitor-intake and co-morbidities.
**Results:** A total of 36/109 (33.0%) patients had a positive *Helicobacter pylori* $^{13}$C-UBT, and 35/109 (32.1%) patients had a positive glucose HMBT. Interestingly, 19/36 (52.8%) individuals with a positive $^{13}$C-UBT also had a positive glucose HMBT, whereas only 16/73 (21.9%) patients with a negative $^{13}$C-UBT showed a positive glucose HMBT ($p = 0.002$), respectively. Overall 13/38 (34.2%), 4/12 (33.3%), 1/2 (50.0%), and 1/2 (50.0%) patients, who had completed one, two, three and four eradication therapies, were diagnosed with SIBO by HMBT, respectively.
**Conclusion:** In the present study active *Helicobacter pylori* infection was found significantly associated with the presence of SIBO as determined by functional breath testing. In addition SIBO rates appeared to have increased after completed eradication therapies. However, further longitudinal studies are warranted, to fully elucidate the relationship and treatment modalities of coincident *Helicobacter pylori* infection and SIBO.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Table 1:** Summary of results

| | Racecadotril 100mg | | Loperamide 2.0mg | | p-value |
|---|---|---|---|---|---|
| | ITT (n = 112) | PP(n = 100) | ITT (n = 111) | PP (n = 110) | |
| **Diarrhea Resolution rate (% of patients)** | | | | | |
| **25%** | 7 h | 6 h | 5 h | 5 h | ITT: 0.25 |
| **50%** | 16 h | 15 h | 17 h | 16 h | PP: 0.39 |
| **75%** | 31.5 h | 31.5 h | 32 h | 32 h | |
| **Spontaneous abdominal pain** | 80 (91%) | 77 (97%) | 80 (85%) | 79 (85%) | ITT: 0.23 PP: 0.0048* |
| **Pain on abdominal palpation** | 48 (89%) | 47 (100%) | 57 (92%) | 56 (92%) | ITT: 0.58 PP: 0.044* |
| **Abdominal distension** | 33 (88%) | 37 (100%) | 34 (87%) | 33 (87%) | ITT: 0.87 PP: 0.022* |
| **Nausea** | 49 (98%) | 47 (100%) | 34 (100%) | 33 (100%) | ITT: 0.41 |
| **Anal burning** | 25 (96%) | 24 (100%) | 25 (100%) | 24 (100%) | ITT: 0.38 |
| **Clinical success** | 97 (87%) | 94 (94%) | 88 (79%) | 88 (79%) | ITT: 0.33 PP: 0.0032* |

*Statistically significant differences All AEs were mild or moderate. The occurrence of treatment related AEs was significantly less common in the racecadotril than in the loperamide group (3.5% vs. 17%). Abdominal distension, was reported significantly more often under therapy with loperamide than with racecadotril (10% vs. 2%, p = 0.0001). Constipation did not occur in the racecadotril group, but 3 cases in the loperamide group.

## P1076 A MULTI-CENTER, RANDOMIZED, CONTROLLED TRIAL TO ASSESS THE EFFICACY, SAFETY AND TOLERABILITY OF RACECADOTRIL VERSUS LOPERAMIDE IN THE TREATMENT OF ACUTE DIARRHEA IN ADULTS

**Contact E-mail Address:** marion.eberlin@boehringer-ingelheim.com
**Introduction:** The primary endpoint was the duration of diarrhea, in hours, under the treatment of racecadotril vs. loperamide. Secondary objectives were the assessments of clinical success, diarrhea associated symptoms and adverse events.
**Aims & Methods:** A multi-center, randomized, single-blind study in adult Chinese outpatients, aged between 18 and 70, with acute diarrhea was conducted according to GCP, relevant national guidelines and the Declaration of Helsinki. Patients received racecadotril 100 mg tid p.o. or loperamide 2.0 mg tid p.o. until recovery (defined as 12 hours with no stools or 2 consecutive normal stools) or for a maximum of 3 days. Clinical success was defined as complete resolution of all symptoms of acute diarrhea. The occurrence of constipation was defined as no stools during 36 or more consecutive hours after diarrhea resolution.
**Results:** A total of 223 patients were entered into the study. Among 13 withdrawals, 4 patients were lost to follow-up and 9 patients were protocol violators (poor medication compliance, no exact time to resolution of diarrhea despite resolution of diarrhea).
Diarrhoea resolved rapidly with both racecadotril and loperamide. Analysis of the per protocol population showed a significantly greater reduction of spontaneous abdominal pain, pain on abdominal palpation and abdominal distension with racecadotril. As for the resolution of nausea, anal burning and anorexia, both treatments were similar to each other and of no significant difference. Clinical success was significantly higher in the per protocol analysis favoring the patients being treated with racecadotril (table 1).
**Conclusion:** Both medications were rapidly effective in the treatment of acute diarrhea in adults. In terms of time to resolution of diarrhea, they were similar to each other and no significant differences were demonstrated. However, a significantly higher clinical success rate was achieved with racecadotril than with loperamide. With racecadotril abdominal symptoms, typically associated with diarrhea, resolved more effectively and a lower occurrence of AEs was observed, especially for abdominal distension and constipation.

**Contact E-mail Address:** mariaesteve@mutuaterrassa.cat
**Introduction:** Celiac disease (CD) is under diagnosed. Primary care physicians can play an active role in the finding of patients with CD using simple tools such as a POCT based on the detection of deamidated gliadin peptide antibodies (DGP). This test has previously shown to have similar sensitivity and specificity as standard serologic analysis of antibodies to tissue transglutaminase (ATTG) (1).
**Aims & Methods:** Aim: 1. To assess the effectiveness of a strategy of adult case-finding in primary care for CD in terms of new diagnosis compared with the same period of previous year; 2. To evaluate if this strategy was cost-effective. Methods: Case finding in a primary care setting by testing for CD by using the POCT (Simtomax) in subjects with predefined signs and symptoms or belonging to at-risk groups. Inclusion criteria: Age >14 years, to be on a gluten containing diet. Exclusion criteria: testing for antiendomysial (AEA) and ATTG during the previous year and previous diagnosis of CD. POCT was performed simultaneously with coeliac serology (AEA and ATTG). Duodenal biopsies for histology and gammadelta cells (by flow cytometry) were obtained if POCT and/or ATTG were positive. Sensitivity (S), specificity (E), PPV and NPV were assessed. Cost-effectiveness of diagnostic strategies using serology or POCT was compared.
**Results:** We included 350 patients (76% women; age 42 ± 1). The POCT was positive in 29 (8.2%). Of these, ATTG was positive in 3/29 (2 Marsh 3, 1 Marsh 1). Of the 26 with POCT+ and ATTG- the histology showed 1 Marsh 3 (AEA- and increase gammadelta). S of POCT for CD was 100% (40–100), E 93% (89–95), PPV 14% (4.5–33), NPV 100% (98.5–100). Prevalence of CD was 1.1% (4/350; 95%CI, 0.3–3.4), doubling the observed in the previous year. POCT followed by duodenal biopsy if positive was the most cost-effective approach (serology, 13724€/case of CD detected; POCT, 7600€/case of CD detected; using the NHS tariffs).
**Conclusion:** The high NPV of POCT allows ruling out CD in primary care. The prevalence of CD using a case-finding strategy was three times higher than in the general adult population in Catalonia. POCT was the most cost-effective approach in routine clinical practice in primary care.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** nicola.imperatore@alice.it
**Introduction:** Potential coeliac disease (PCD) of adults still remains an almost unexplored area.
**Aims & Methods:** 1) to explore the prognostic role of Marsh grade (0 vs 1) in adult PCD patients; 2) to evaluate the effects of a gluten containing diet (GCD) in asymptomatic PCD patients. We prospectively enrolled all consecutive adult PCD patients diagnosed at our tertiary center, who completed a 6-year follow-up period. According with Marsh grade they were divided into Group 0, comprising subjects with Marsh 0 and Group 1, including Marsh 1-patients. Symptomatic patients started gluten free diet (GFD), while asymptomatic subjects were kept on GCD and were followed-up to evaluate serological and clinical features, development of villous atrophy and immune-mediated disorders (IMD).
**Results:** 56 PCD patients were enrolled (21 [37.5%] in Group 0 and 34 [62.5%] in Group 1). Forty-three patients were symptomatic (15 in the Group 0 and 28 in the Group 1, P = NS) and started GFD. Among them, 8 (28.5%) in Group 1 developed IMD during the follow-up, but none patient in Group 0 (P = 0.03; OR = 4.2 [95% IC 0.5–37.5]). The remaining 13 asymptomatic PCD patients kept on GCD. During the follow-up, 69% developed CD-related symptoms, 46% became atrophic and 61% developed IMD, without significant differences between the two groups. Interestingly, confronting patients kept on GCD with

those on GFD, we found that the first ones had a higher risk of developing IMD than patients on GFD (61% vs 18%, P = 0.03, OR = 3.3 [95% IC 1.04–10.5]).
**Conclusion:** Although PCD with normal mucosa seems to be a milder disease, GCD leads to a high risk of developing atrophy, and, especially, a significant risk in developing IMD than patients on GFD. Adult PCD patients should early start GFD despite symptoms.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1079 MAY MUCOSAL TRANSCRIPTOMIC ANALYSIS PREDICT THE DEVELOPMENT OF GLUTEN-RELATED DISORDERS AMONG MICROSCOPIC ENTERITIS?

**G. Losurdo**[1], D. Piscitelli[1], L. Montenegro[1], F. Giorgio[1], A. Giangaspero[1], A. Iannone[1], A. Amoruso[1], M. Barone[1], M. Principi[2], E.G. Ierardi[1], A. Di Leo[1]

[2]*Energency And Organ Transplantation, University of Bari, bari/Italy*

**Contact E-mail Address:** giuseppelos@alice.it
**Introduction:** To evaluate: i. mucosal baseline mRNA expression of tissue transglutaminase 2 (tTG2), interferon gamma (IFN$\gamma$), Toll-like receptor 2 (TLR2) and Myeloid differentiation factor 88 (MyD88) in patients with microscopic enteritis (ME), ii. their predictive value for the diagnosis of underlying disorder in a 2-year follow-up, iii. and their accuracy in discriminating the development of celiac disease (CD) and gluten sensitivity (GS).
**Aims & Methods:** We retrospectively enrolled 89 patients with ME of different etiology, which was defined within a 2-year follow-up. Baseline histological examination had been performed on Hematoxylin–Eosin stained sections and immunohistochemistry of CD3 had been used for intraepithelial lymphocyte count (IELs). ME was defined according to the criteria of Bucharest Consensus Conference. For each patient, formalin-embedded biopsy samples of the duodenum referred to the period of ME diagnosis were retrieved. Real-time polymerase chain reaction (RT-PCR) was used to detect the amount of mRNA coding for tTG2, IFN$\gamma$, TLR2 and MyD88. Control group was represented by duodenal healthy specimens from 15 dyspeptic subjects. Comparisons among continuous variables were performed by One way analysis of variance (ANOVA) and Bonferroni's test. The $\chi 2$ test was used for categorical variables. Pearson's test was used to evaluate correlations. Receiver operating curves (ROC) were drawn for all four markers to estimate sensitivity and specificity in discriminating the development of CD and GS.
**Results:** After a mean period of follow up of $21.7 \pm 11.7$ months, the following diagnoses were achieved: gluten related disorders in 48 subjects (31 CD; 17 GS) and non-gluten related ones in 41 (29 Irritable Bowel Syndrome – IBS; 12 Others). CD patients had the highest tTG2 levels ($8.3 \pm 4.5$) compared to GS ($3.6 \pm 2.7$), IBS ($3.5 \pm 1.8$), other ME ($5.3 \pm 2.3$) and negative controls ($1.001 \pm 0.089$). The ANOVA plus Bonferroni analysis showed that CD > Other ME > GS=IBS > negative controls. A cut off of 2.258 was able to discriminate between CD and GS with a sensitivity of 52.94% and a specificity of 87.1%. CD patients had the highest IFN$\gamma$ levels ($8.5 \pm 4.1$) compared to GS ($3.3 \pm 2.8$), IBS ($3.3 \pm 2.6$), other ME ($4.6 \pm 2.1$) and negative controls ($1.001 \pm 0.15$), with CD > Other ME > GS=IBS > negative controls. A cut off of 1.853 was able to differentiate CD and GS with a sensitivity of 47.06% and a specificity of 96.77%. Patients with non gluten-related causes of ME exhibited the highest TLR2 levels ($6.1 \pm 1.9$), greater than GS ($3.1 \pm 1.8$), IBS ($3.5 \pm 2.0$), CD ($4.1 \pm 2.4$) and negative controls ($1.006 \pm 0.18$), with Other ME > CD=GS=IBS > negative controls. TLR2 were unable to predict the development of CD or GS. Patients with CD expressed MyD88 levels similar to non gluten-related causes of DL ($7.8 \pm 4.9$ and $6.7 \pm 2.9$), higher than GS ($4.2 \pm 2.3$), IBS ($4.3 \pm 2.4$), and negative controls ($0.99 \pm 0.17$), thus CD=Other DL > GS=IBS > negative controls. A cut off of 3.722 was able to differentiate CD and GS with a sensitivity of 52.94% and a specificity of 74.19%.
**Conclusion:** Our results suggest that a single marker is unable able to predict a discrimination among ME underlying conditions as well as between CD and GS. Mucosal transcriptomic levels of tTG and IFN$\gamma$ may predict the development of CD more than GS with high specificity, despite an expected low sensitivity. TLR2 do not discriminate the development of CD from GS. MyD88 show that intestinal permeability is more marked increased when a severe intestinal damage underlies ME.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1080 FLOW CYTOMETRIC ANALYSIS OF ABERRANT INTRA-EPITHELIAL LYMPHOCYTES IN REFRACTORY COELIAC DISEASE

**A. Schiepatti**[1], R. Ciccocioppo[1], E. Betti[1], F. Biagi[1], L. Vanelli[2], C. Picone[2], C. Alvisi[1], G.R. Corazza[1]
[1]*1st Dept. Of Internal Medicine, University of Pavia, Pavia/Italy*
[2]*Clinic Cytometry Laboratory, Department Of Hematology, IRCCS Foundation Policlinico San Matteo, University of Pavia, PAVIA/Italy*

**Contact E-mail Address:** salinana@hotmail.it
**Introduction:** Coeliac disease (CD) is a chronic gluten dependent enteropathy characterized by an increased mortality, mainly due to its complications: refractory coeliac disease (RCD), ulcerative jejunitis and enteropathy associated T-cell lymphoma (EATL). These complications share a common origin as suggested by aberrant intraepithelial T-lymphocytes (IELs) (CD3-, CD45+, CD103+, CD7+, CD4-, CD8-, cytCD3+) [1]. In the last years flow cytometry (FC) analysis of duodenal IELs emerged as the best tool to identify this aberrant monoclonal T-cell population [2]. It was also shown that a percentage of aberrant IELs > 20% predicts evolution of RCD into overt EATL [3].
**Aims & Methods:** To evaluate the reproducibility of the FC analysis of IELs. To see if high levels of aberrant IELs (> 20%) can predict development of EATL and mortality in Italian patients with RCD. From February 2012 to March 2016 IELs were isolated from 26 duodenal biopsies of 13 patients affected by RCD (9F, age at complication $54 \pm 13$ years; follow-up from complication median 44 months, 12–55, 25°-75°) and immunophenotyped using FC. In 7 patients FC was repeated in different times during follow-up. Patients were divided into two groups according to the percentage of aberrant IELs (cut off value > 20%). Survival and development of EATL were then assessed in the two groups.
**Results:** In the 7 patients in whom FC was repeated more than once almost identical results of the immunophenotype of IELs were obtained, suggesting a stability of the IELs phenotype. Increased aberrant IELs (> 20%) were found in 5/13 RCD patients and 3 of them died (2 EATL, 1 RCD type 2). In the group without increased aberrant IELs (< 20%) no patients died (median follow-up 44.5 months, 35.25–67.25, 25°-75°), but one patient developed an EATL.
**Conclusion:** FC is a reproducible tool in the diagnostic workout of RCD patients. We confirm that high levels of aberrant IELs (> 20%) increase the risk of poor outcomes in RCD patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1081 LONG-TERM RECOVERY OF HEALTH STATUS OF PATIENTS WITH CELIAC DISEASE

**F. Casellas Jorda**[1], J. López Vivancos[2]
[1]*Digestive Research Unit, Hospital Universitari Vall DHebron, Barcelona/Spain*
[2]*Internal Medicine, Hospital General de Catalunya - Universitat Internacional Catalunya, Sant Cugat del Vallés/Spain*

**Contact E-mail Address:** fcasellas@vhebron.net
**Introduction:** The symptomatic celiac disease has important biological and psychosocial consequences due to their impact on patient's expectations, habits and health-related quality of life. The introduction of gluten-free diet improves biological changes, symptoms and quality of life of celiac disease patients. Despite its beneficial effect, maintenance of the gluten-free diet also has a negative impact on the life of celiac disease patients due to the restrictions, difficulties in diet follow-up and additional economic costs. We do not know how quality of life changes over time with gluten-free diet.
**Aims & Methods:** Our aim was to determine if celiac disease patient's quality of life remains stable during the follow-up of gluten-free diet. Methods: Prospective observational study in a cohort of celiac disease patients diagnosed by positive serology and duodenal biopsy, with good clinical and serological response to gluten-free diet. Quality of life was evaluated by administering the generic questionnaire EuroQol-5D. In a sub-group of patients, the specific questionnaire CD-QOL was also administered. Patients were visited twice, at entry in the study and after 12 months. In a group of patients, results were compared with those of the EuroQol-5D administered 10 years before, with the disease already treated.
**Results:** Sixty-five patients, with a median age of 40 years and 6 years of evolution since diagnosis were included. Twenty-one also completed the CD-QOL and in another11 EuroQol-5D was compared with that obtained 10 years before. According to the Morisky scale, complete adherence to diet was referred by 86% of patients. The perception of quality of life remained stable, with a median score of the visual analogue scale basal and after 12 months of 80 vs 80 (p = ns). The median tariff of the EuroQol-5D also persisted unchanged (0.87 vs 1.0 after 12 months, p = ns). The median global score of the CD-QOL also persisted unchanged during the year of follow-up (79 vs 76, p = ns). Results of the EuroQol-5D obtained 10 years before also were similar (VAS 83 and tariff 0.87, p = ns).
**Conclusion:** The quality of life of celiac disease patients on gluten-free diet remains stable during long term follow-up.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1082 DENTAL ENAMEL DEFECTS, DENTAL CARIES, ORAL LICHEN PLANUS IN PATIENTS WITH CELIAC DISEASE - PROSPECTIVE COHORT STUDY INTRODUCTION:

**N.S. Behl**[1], A. B. Behl[2]
[1]*Department Of Gastroenterology, FORTIS HOSPITAL, Ludhiana/India*
[2]*Department Of Oral Medicine And Radiology, B.J.S Dental College, Ludhiana, Ludhiana/India*

**Contact E-mail Address:** drnitinbehl@gmail.com
**Introduction:** Celiac disease (CD) can be associated with various oral manifestations. No large study clarifying the exact relation and role of gluten-free diet (GFD) on these manifestations. We prospectively studied these objectives in large cohort of patients.
**Aims & Methods:** Total of 264 CD patients were enrolled for 1 year in tertiary care referral hospital along with controls (n = 269). History of oral lesions was taken and dental examination was done. Enamel defects were classified as to Aine classification. After institution of gluten-free diet (GFD), patients were followed for 3 year.

**Results:** CD patients had significantly more enamel defects. Enamel defects were more common in patients with mixed dentition as compared to permanent dentition. Dental caries were similar in frequency in celiac patients as compared to controls. Oral lichen planus was more common in celiac patients. After institution of GFD at three-year follow up, no significant improvement occurred in enamel defects but improvement in oral lesions was seen.
**Conclusion:** This study proves the association of CD with dental enamel defects in childhood. After 3 year of GFD, improvement occurred in lichen planus. Hence, CD should be added to differential diagnosis of dental enamel defects, lichen planus. All physicians and dentists must be aware of these associations. The diagnosis of celiac disease can sometimes be made from a smile.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1083 CELIAC DISEASE WITH NEGATIVE HLA-DQ2.5/8 IN SPAIN: SYSTEMATIC REVIEW AND META-ANALYSIS

**F. Fernández-Bañares**[1], C. Nuñez[2], B. Arau[3], R. Dieli-Crimi[2], M. Rosinach[4], M. Esteve[4]
[1]*Gastroenterology, Hospital Universitari Mutua de Tarrassa, CIBERehd, Terrassa/Spain*
[2]*UGC of Immunology, San Carlos Institute for Health Research (IdISSC), Madrid, Spain., Madrid/Spain*
[3]*Gastroenterology, Hospital Universitari Mutua de Tarrassa, Terrassa/Spain*
[4]*Gastroenterology, Hospital Universitari Mutua Terrassa, Terrassa/Spain*

**Contact E-mail Address:** ffbanares@mutuaterrassa.es
**Introduction:** More than 90% of celiacs carry the heterodimer HLA-DQ2.5. The DQ8 heterodimer is commonly observed in DQ2.5 negative celiacs. Only a small number of celiacs are DQ2.5/8 negative, many of whom encode half of DQ2.5 heterodimer. The European genetic cluster on celiac disease (CD) showed that 6% of celiacs were DQ2.5/8 negative (93% of them encoded half of DQ2.5 heterodimer) (1).
**Aims & Methods:** To perform a meta-analysis of the presence of negative HLA-DQ2.5/8 CD in Spain.
Studies evaluating the HLA-DQ2.5/8 profile in CD patients in Spain were included. Bibliographies until March 2016 were searched. Inclusion criteria were: 1.Diagnosis of CD with villous atrophy using ESPGHAN criteria; 2. Full description of DQ2.5/8 haplotypes. Studies with duplicated data were excluded. Frequency of negative genetic celiac study was determined. Meta-analyses were performed using the inverse-variance method. A random effects model was used when heterogeneity (I2 statistic) was present. An $I2 > 76\%$ was considered as considerable heterogeneity.
**Results:** The electronic search retrieved a total of 199 publications, from which 44 were selected for a more thorough revision. Finally, 14 studies were included, which comprise 3167 patients with CD. The overall frequency of negative HLA-DQ2.5/8 was 3% (95% CI, 2–4; 2963 patients; $I^2$ 81%), after excluding 2 outlier studies, with doubts about genotyping was correct. Remaining heterogeneity was due to only one study, after excluding it $I^2$ was 36% without changing the overall frequency. Among 105 negative DQ2.5/8 CD patients, the presence of half of the DQ2.5 heterodimer was observed in 80 (55 DQB1+ and 25 DQA1+; in 5 was not described) (80/100, 80%; $p = 0.022$ vs the European study). Thus, at least 20 out of the 105 patients had both alleles of DQ2.5 negative. The overall frequency of being negative for the two alleles of DQ2.5 and for DQ8 was 1% (95% CI, 0–1; 2450 patients; $I^2$ 28%).
**Conclusion:** In Spain, 3% of celiacs are DQ2.5/8 negative. The frequency of CD with the two alleles of HLA-DQ2.5 and DQ8 negative is higher in Spain than in the European study.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** mzwcislo@su.krakow.pl
**Introduction:** Celiac disease is a multisystemic, autoimmune disorder, triggered by gluten ingestion, occurring in genetically predisposed patients. Clinical outcome includes several extraintestinal manifestations with neurologic ones. Neurologic complications are observed in about 10% of patients but previous studies confirmed presence of subclinical changes of autonomic nervous system activity. Aetiology of neurologic involvement in celiac disease is complex and not fully explored. Presence of anti-ganglioside antibodies have been described in the serum of celiac patients with peripheral neuropathy and cerebellar ataxia. Neuron-specific enolase is a marker of autonomic nervous system and its increased levels has been described in several disorders.
**Aims & Methods:** Aim of the study was to evaluate the anti-ganglioside M1 antibodies and neuro-specific enolase serum concentrations in neurological asymptomatic celiac patients and its correlation with activity of disease and duration. 34 celiac patients (70% females, mean age 34 years, $41.2 \pm 16.6$) without neurological symptoms and 34 healthy volunteers (mean age 34 years, $35.8 \pm 9.5$) were tested for the anti-ganglioside M1 antibodies and for neuron-specific enolase concentrations in serum by ELISA.
**Results:** In celiac patients mean level of anti-ganglioside M1 antibodies was significantly higher in comparison to control, group ($1.59 \pm 1.07$ vs $.83 \pm .67$, $p < .001$, Mann-Whitney test). The neuron-specific enolase serum concentration was not significantly higher in celiac group (5.2vs 3.76, $p = .659$, Mann-Whitney test). In celiac group neuron-specific enolase level and anti-ganglioside M1 antibodies level did not correlate with age (respectively $R = -.02$, $p = .926$, and $R = .15$, $p = .422$, Spearman's rank).
**Conclusion:** Presence of anti-ganglioside M1 antibodies in neurologic asymptomatic celiac patients might be the marker of development of subclinical changes in nervous system. Further investigations are needed.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1085 PREVALENCE OF CELIAC DISEASE IN PATIENTS WITH AUTOIMMUNE THYROID DISEASE – A META-ANALYSIS

**Contact E-mail Address:** ml3228@cumc.columbia.edu
**Introduction:** Several screening studies have indicated an increased prevalence of celiac disease (CD) among individuals with autoimmune thyroid disease (ATD) but estimates have varied substantially.
**Aims & Methods:** The aim of this study was to examine the prevalence of CD in patients with ATD. A systematic review of articles published in PubMed Medline or EMBASE until September 2015 was done. Non-English papers with English-language abstracts were also included, as were research abstracts without full text available when relevant data were included in the abstract. Search terms included "celiac disease" combined with "hypothyroidism" or "hyperthyroidism" or "thyroid disease". Fixed-effects inverse variance-weighted models were used. Meta-regression was used to examine heterogeneity in subgroups.
**Results:** A pooled analysis, based on 6,024 ATD patients, found a prevalence of biopsy-confirmed CD of 1.6% (95% CI = 1.3–1.9%). Heterogeneity was large ($I^2 = 70.7\%$). The prevalence was higher in children with ATD (6.2%; 95%CI = 4.0–8.4%), than in adults (2.7%) or in studies examining both adults and children (1.0%). CD was also more prevalent in hyperthyroidism (2.6%; 95%CI = 0.7–4.4%) than in hypothyroidism (1.4%; 95%CI = 1.0–1.9%).
**Conclusion:** About 1 in 62 patients with ATD have biopsy-verified CD. We argue that patients with ATD should be screened for CD given this increased prevalence.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1086 SERUM ANGIOPOIETIN-2 IS AN ACCURATE CAPSULE ENDOSCOPY SCREENING TOOL FOR THE DETECTION OF SMALL BOWEL ANGIODYSPLASIA

**G. Holleran**, M. Hussey, O. O'Dwyer, S. Smith, D. Mcnamara
*Trinity College Dublin, Dublin/Ireland*

**Contact E-mail Address:** grainneholleran@gmail.com
**Introduction:** Small bowel angiodysplasia (SBA) accounts for 50% of cases of obscure gastrointestinal bleeding (OGIB). SBAs bleed recurrently with a proportion of patients dependent on red cell transfusions and a significantly impaired quality of life. Although treatment options are limited, an early diagnosis and directed therapy can significantly improve outcome. CE is the most sensitive diagnostic tool for SBA, however the indication for CE not only includes OGIB, but Iron Deficiency Anaemia (IDA), suspected small bowel

Crohn's disease, malabsorption etc, placing a large demand on the service. Due to the varied presentation of SBA and intermittent nature of bleeding it can be difficult to clinically prioritise patients for CE. We have previously presented an association between SBA and serum alterations in Ang1, Ang2 and TNF$\alpha$ levels, however it is unknown whether these angiogenic factors are driven by bleeding overall or whether they are specific for SBA.

**Aims & Methods:** To determine whether alterations in serum angiogenic factors are specific for SBA, and whether they could be used as screening tools to prioritise patients for CE. Blood samples were prospectively collected from all patients undergoing CE for the investigation of OGIB and IDA at our Hospital over a 12 month period. Haemoglobin (Hb) level and renal function were measured in the hospital laboratory and serum samples were stored at $-80^{\circ}$C for batch analysis. Levels of Ang1, Ang2 and TNF$\alpha$ in serum were measured using commercially available ELISA kits. Based on CE reports patients were divided into 3 groups–SBA, other abnormalities, and normal small bowel. Results of each factor were expressed as a mean/median and compared between groups, and analysed for association with clinical factors using a Mann Whitney U test. The potential for serum Ang1/Ang2 as a CE screening tool was explored using Receiver Operator Characteristic (ROC) curve analysis.

**Results:** A total of 120 patients were included; 53% (n = 64) Male, with a mean age of 63 years. Hb levels were lower in patients with positive findings than in the normal group (11.2 g/dL vs 12.3 g/dL, $p < 0.02$). Levels of each factor are outlined in Table 1. In keeping with our previous findings patients with SBA have significantly elevated serum levels of Ang2 compared to non-SBA patients, with a trend towards lower levels of Ang1 and TNF$\alpha$. In addition, serum Ang2 levels even when controlled for anaemia and chronic kidney disease were selectively elevated in patients with SBA. As a CE screening tool for SBA, we established a cutoff Ang2 level of 2600 pg/ml, giving a sensitivity of 84% and negative predictive value of 87%. Although the positive predictive value for SBA was only 50%, of these false positives; 50% had significant findings (including enteritis, polyps and a small bowel tumour) which would warrant an expedited CE, making the true false positive rate only 26%. Although the Ang1/Ang2 ratio was also specific for SBA over other conditions, the ROC was similar to that of Ang2 alone, conferring no additional benefit to the need for the use of 2 markers.

| | SBA n = 40 Mean age = 73 Mean Hb = 11.2 | Abnormal n = 40 Mean age = 60 Mean Hb = 11.3 | Normal n = 40 Mean age = 55 Mean Hb = 12.7 |
|---|---|---|---|
| **Ang1(pg/ml)**Median P value compared to SBA | 40976 | 44770 0.33 | 47639 0.04 |
| **Ang2(pg/ml)**Median P value compared to SBA | 3759 | 2261 < 0.004 | 2620 < 0.003 |
| **TNF$\alpha$(pg/ml)**Median P value compared to SBA | 5.76 | 9.76 0.12 | 10.14 0.13 |

**Conclusion:** Serum Ang2 levels are specifically elevated in patients with SBA compared to other causes of OGIB. In our cohort a cutoff level of 2600 pg/ml would be an effective CE screening test at initial referral to prioritise patients likely to have SBA and other significant findings, with an earlier diagnosis potentially directing treatment and improving outcome.

## P1087 CROHN'S DISEASE DIAGNOSED BY CHANCE IN PATIENTS SUBJECTED TO CAPSULE ENDOSCOPY FOR THE INVESTIGATION OF OBSCURE GASTROINTESTINAL BLEEDING

N. Viazis, A. Tsigaridas, M. Galanopoulos, L. Varytimiadis, **E. Tsoukali**, C. Pontas, I. Tziortziotis, C. Hatzievangelinou, F. Gkeros, G. Mantzaris
*Depatment Of Gastroenterology And Hepatology, Evangelismos Hospital, Athens, Athens/Greece*

**Contact E-mail Address:** tsoukali_emmanouela@yahoo.gr

**Introduction:** According to the European Society of Gastrointestinal Endoscopy guidelines, small bowel capsule endoscopy (SBCE) is the method of choice for the investigation of suspected Crohn's disease (CD), in patients with a non-diagnostic initial ileocolonoscopy. Our aim was to compare the number of cases with findings suggestive of CD amongst patients subjected to SBCE for the investigation of obscure gastrointestinal bleeding (OGIB) and compare this figure with the number of cases subjected to SBCE for suspected CD.

**Aims & Methods:** Retrospective analysis of data collected prospectively between March 2003 and December 2015. During this period, 3025 patients were subjected to SBCE in our Department for the investigation of a) OGIB (n = 1396, 46.1%), b) suspected small intestinal CD (n = 552, 18.2%), because of abdominal pain and/or chronic diarrhoea, positive inflammation markers, but a negative upper GI endoscopy and ileocolonoscopy and a negative history of aspirin and/or non steroid anti-inflammatory drugs intake, and c) proximal small bowel involvement in patients with known CD (n = 411, 13.6%)

**Results:** Among the 552 patients subjected to SBCE because of suspected CD, lesions suggestive of CD (apthoid or deep ulcers with focal or diffuse inflammation of the jejunal and/or ileal mucosa) were seen in 211 (38.2%) patients [139 (25.2%) patients with chronic diarrhoea and 72 (13.0%) patients with abdominal pain respectively]. Notably, the ileocaecal valve had not been intubated in 52 (24.6%) of the 211 patients. Among the 1396 patients investigated for OGIB, lesions suggestive of CD were seen in 209 (14.9%) and again in 71/209 (33.9%) the ileocaecal valve had not been intubated during the preceding colonoscopy. Focusing on the group of patients with unexplored terminal ileum during the preceding ileocolonoscopy and lesions suggestive of CD at SBCE, there was a statistically significant difference between those with OGIB over patients with suspected CD (p = 0.03). Because most of the patients included in the study were referred to our Department only for SBCE, we cannot estimate the proportion of patients with OGIB and lesions suggestive of CD in whom the diagnosis of CD was finally confirmed by prospective follow-up.

**Conclusion:** In a substantial number of patients subjected to SBCE for the investigation of OGIB, lesions suggestive of CD are seen by chance, in the absence of clinical suspicion for CD. This is especially true in patients in whom the terminal ileum has not been investigated during the preceding colonoscopy. Although the clinical significance of these findings is not known, a meticulous follow-up of these patients is deemed mandatory.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1088 REBLEEDING RATE AFTER ENDOSCOPIC TREATMENT OF SMALL BOWEL ANGIODYSPLASIAS WITH SINGLE-BALLOON ENTEROSCOPY: PREVALENCE AND RISK FACTORS

**P. Andrade**, M. Marques, H. Cardoso, G. Macedo
*Gastroenterology, Centro Hospitalar de São João, Porto/Portugal*

**Contact E-mail Address:** anapatriciarandrade@gmail.com

**Introduction:** Small bowel angiodysplasias are the most common cause of obscure gastrointestinal bleeding in the Western world. Safety and efficacy of short-term endoscopic treatment with argon plasma coagulation (APC) have been demonstrated, but data on the long-term effectiveness of this procedure are still scarce.

**Aims & Methods:** We aimed to evaluate the rebleeding rate after endoscopic treatment of small bowel angiodysplasias with single-balloon enteroscopy and analyse potential risk factors for rebleeding. Between 2010 and 2015, all consecutive patients who were treated with single-balloon enteroscopy with APC due to small bowel angiodyspalsias were included. Rebleeding was defined as recurrence of obscure gastrointestinal bleeding or a decrease in haemoglobin $\geq$ 2 g / dL. Risk factors for rebleeding were analysed.

**Results:** Thirty-one patients were included, 76.5% male, with a mean age of 69.1 $\pm$ 15.8 years. Rebleeding rate after a median follow-up time of 25.0 (IQR 12.1–36.5) months was 35.5% (11/31). Among patients with rebleeding, 36.4% (4/11) had obscure GI bleeding and 63.6% (7/11) a haemoglobin decrease $\geq$ 2 g/dL. Among those patients with recurrent bleeding, 1 or 2 additional endoscopic treatment sessions successfully controlled rebleeding in 81.8% (9/11) of patients. Treatment with oral anticoagulants was the only factor significantly associated with increased risk of rebleeding (57.1% versus 17.6% in patients without anticoagulation, p = 0.028).

**Conclusion:** After a median follow-up of 25.0 months, the rebleeding rate after endoscopic treatment of small bowel angiodysplasias with single-balloon enteroscopy with APC was 35.5%. Patients under treatment with oral anticoagulants had the higher risk of rebleeding.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1089 EXRESS VIEW READING EFFICIENTLY REDUCES READING TIME FOR SMALL BOWEL CAPSULE ENDOSCOPY: A PROSPECTIVE MULTICENTRIC STUDY

**Introduction:** Reading capsule endoscopy films is a time-consuming exercise and reducing the reading time is of high priority for gastroenterologists. Beside the Medtronic capsule, no express reading algorithm has been validated prospectively at the present time. We report a prospective evaluation of an "express view" reading mode for Intromedic° capsule system.

**Aims & Methods:** On hundred patients with occult or overt gastrointestinal bleeding were prospectively included after negative bidirectional endoscopy at ten participating centers. All patients had a capsule endoscopy (Medtronic°, Seoul) examination of the small bowel and the films were read in normal mode, a second reading was performed in express view mode in a second center. For each lesion, the precise location, nature and relevance were collected. Discordant results between the 2 readings will be reviewed by an expert board to confirm discordance or reclassify into concordant cases. We report results of the first 36 cases. Complete data of the series will be presented at the congress.

**Results:** Thirty-six patients from 4 centers (mean age 64.5 yrs) had a capsule endoscopy. Table1 shows the diagnostic yield, transit time measurement and evaluated transit times at both normal and express view reading. Both modes allowed a high diagnostic yield. Discordance (lesion relevance, type of lesion,

presence of lesion) between the 2 readings occurred in 17 cases and corresponded mostly to different interpretations of the same lesions.

| | Normal reading | Express view |
|---|---|---|
| Pts with possible small bowel diagnosis (%) | 21 (58%) | 22 (61%) |
| P2 lesions nb (nb / % pts) | 26 (13 / 36%) | 15 (12 / 33%) |
| Mean reading time | 34.6 min (14–90) | 18.5 min (4–40) |
| Gastric transit time (mean) | 71.6 min | 58.4 min |
| Small bowel transit time (mean) | 218.2 min | 191.9 min |

**Conclusion:** Express view reading allows an important shortening of Intromedic° capule film reading with a high diagnostic yield. Discrepancies between 2 capsule readings are usual and require expert checking to clarify the exact sensitivity and specificity of the 2 modes of reading. Express view may represent a satisfying new informatic algorithm to reduce capsule endoscopy reading time.

**Introduction:** Patients with chronic gastro intestinal ischemia (CGI) suffer from severe postprandial abdominal pain due to insufficient postprandial increase of mesenteric blood flow, usually caused by atherosclerotic stenosis of the supplying gastrointestinal arteries. The diagnosis of CGI remains challenging as chronic abdominal pain due to other causes is common and stenosis of the mesenteric arteries are often asymptomatic due to extensive collateral circulation. Hence, a reliable non-invasive test to assess the hemodynamics of the mesenteric vessels is needed. In cardiovascular radiology, cardiac blood flow is measured using Magnetic Resonance (MR) imaging. This technique has not yet been explored to quantify intestinal blood flow.
**Aims & Methods:** We aimed to determine the feasibility of flow measurements using MR imaging to assess the hemodynamics of the mesenteric arteries and portal vein and establish a set of reference values under fasting and feeding conditions in healthy volunteers. Therefore, healthy volunteers underwent MR flow measurements of the abdominal aorta at a level just above the celiac trunk (AA), the celiac artery (CA), superior mesenteric artery (SMA), and portal vein (PV) on a 1.5 Tesla MR scanner during both inspiration and expiration. An ECG-gated, velocity-encoded cine gradient-echo sequence was used to measure blood flow using a 32-channels surface coil. First, we performed MR flow measurements in fasting state. Consecutively, blood flow was assessed 10, 20, 30 and 40 minutes after oral intake of 400 mL (600 kcal) nutritional drink.
**Results:** Nine healthy volunteers aged $\geq$ 50 years (3 male) underwent MR flow measurements. Median blood flow in mL/stroke of the AA, PV and SMA increased significantly postprandially compared to baseline, both during expiration (AA 47.0 vs. 58.2, $p = 0.028$; PV 24.3 vs. 40.3, $p = 0.008$; SMA 4.9 vs. 13.2, $p = 0.011$) and inspiration (AA 38.2 vs. 47.6, $p = 0.046$; PV 21.6 vs. 33.3, $p = 0.008$; SMA 3.4 vs. 14.3, $p = 0.021$). Blood flow of the CA also increased postprandially, both during expiration and inspiration, but these results were not statistically significant. See table. The relative increase in blood flow was most prominent in the SMA (expiration 169%, inspiration 321%) and these values at baseline and maximal postprandial flow overlap completely during both inspiration and expiration.

Median and IQR of MR flow measurements in mL/stroke of abdominal aorta (AA), portal vein (PV), celiac artery (CA) and superior mesenteric artery (SMA) before (0 minutes) versus after nutritional drink at maximal postprandial flow (max flow). * P-value $<0.05$ is considered significant

| | T = 0 median (IQR) | T max flow (min) | Max flow median (IQR) | p-value |
|---|---|---|---|---|
| **AA expiration** | 47.0 (40.3–53.4) | 30 | 58.2 (47.0–80.1) | 0.028* |
| **AA inspiration** | 38.2 (28.6–43.9) | 20 | 47.6 (37.1–55.7) | 0.046* |
| **CA expiration** | 10.1 (7.0–13.0) | 10 | 11.0 (7.3–16.4) | 0.374 |

(continued)

Continued

Median and IQR of MR flow measurements in mL/stroke of abdominal aorta (AA), portal vein (PV), celiac artery (CA) and superior mesenteric artery (SMA) before (0 minutes) versus after nutritional drink at maximal postprandial flow (max flow). * P-value $<0.05$ is considered significant

| | T = 0 median (IQR) | T max flow (min) | Max flow median (IQR) | p-value |
|---|---|---|---|---|
| **CA inspiration** | 7.7 (6.5–13.2) | 40 | 9.0 (3.8–11.1) | 0.086 |
| **SMA expiration** | 4.9 (3.2–5.7) | 40 | 13.2 (11.0–14.2) | 0.011* |
| **SMA inspiration** | 3.4 (1.1–6.9) | 30 | 14.3 (7.5–17.3) | 0.021* |
| **PV expiration** | 24.3 (21.5–26.6) | 20 | 40.3 (30.0–48.2) | 0.008* |
| **PV inspiration** | 21.6 (20.8–30.1) | 30 | 33.3 (28.5–41.2) | 0.008* |

**Conclusion:** It is feasible to non-invasively assess the hemodynamics of the mesenteric arteries and portal vein using MR flow measurements. We have established a set of reference values under fasting and feeding conditions. Further research is needed for the applicability of this technique in the diagnostic work-up of CGI, starting with pre- and postprandial MR flow measurements in patients with CGI.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1091 A PROSPECTIVE, QUANTITATIVE ASSESSMENT OF PAIN AND QUALITY OF LIFE BEFORE AND 3 AND 12 MONTHS AFTER VASCULAR TREATMENT FOR CHRONIC MESENTERIC ISCHEMIA

**L. Wymenga**[1], L. Everlo[1], P. B. Mensink[1], M. Brusse-Keizer[2], E. J. Stassen[3], R. H. Geelkerken[4], J. J. Kolkman[1]

[4]*Vascular Surgery, Medisch Spectrum Twente, Enschede/Netherlands*

**Contact E-mail Address:** l.f.wymenga@gmail.com
**Introduction:** There are no prospective data on pain or health-related quality of life (HRQOL) in patients treated for chronic mesenteric ischemia (CMI). This prospective study was designed to determine the change of pain intensity and HRQOL in CMI patients treated for atherosclerosis or celiac artery compression.
**Aims & Methods:** Patients with CMI treated with percutaneous mesenteric artery stenting or retroperitoneal endoscopic release of the arcuate ligament in celiac artery compression syndrome between August and December 2013 were enrolled. For pain we used the visual analogue scale for pain intensity (VAS-PI, graded 0–100 mm). We assessed overall pain, postprandial pain and pain after exercise in the preceding week. We also assessed the number of pain free days, and use of analgetics for abdominal pain. For HRQOL we used the 36-item Short Form Health Survey (SF-36). All parameters were obtained before (baseline; BL) and at three (FU3) and twelve months (FU12) after the intervention.
**Results:** Thirty patients were included, 80% female, mean age 57 (range 20–90) years. Diagnoses were single vessel (n = 8) and multi-vessel intraluminal atherosclerotic stenoses or occlusions (n = 15), and celiac artery compression (n = 7). The VAS-overall pain improved from median 60 (IQR 48–72) at BL to 2 (IQR 0–4) at FU3 and 10 (IQR 0–40) at FU12, $p < 0.0001$. At these time-points the postprandial VAS improved from 74 (IQR 67–84) to 2 (IQR 0–40) and 10 (IQR 0–48), $p < 0.0001$. The VAS-pain after exercise improved from 65 (IQR 50–80), to 4 (0–20) and 10 (IQR 0–35), $p < 0.0001$. Analgetic use for abdominal pain decreased from 74% to 17% and 19% of patients ($p < 0.009$), the number of pain free days per week increased from median 0.9 (IQR 0–2) to 6 (IQR 1–7) at FU3 and 7 (IQR 0–7) at FU12, $p < 0.0001$. In all cases the difference between BL and FU3 and F12 was highly significant, but no significant difference between FU3 and FU12 was seen. Of the three diagnosis groups the differences showed similar significant improvements from BL to FU3 and FU12 for single- and multivessel atherosclerosis, but not for CACS patients. The HRQOL measured with SF-36 improved for five of eight dimensions (role physical, bodily pain, vitality, social functioning and mental health) and the both (physical and mental) component summary scores.
**Conclusion:** This prospective study showed marked pain reduction after 3 and 12 months, associated with improved quality of life. The magnitude of change underscores the potential benefit CMI patients may experience from restore of the mesenteric artery inflow.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Obesity is a widespread problem, is considered to be an inflammatory condition. Probiotic strains could modify inflammation and recently were hypothesized to be effective to treat obesity. Our recent studies have demonstrated the ability of previously selected and characterized Lactobacillus delbrueckii subsp. bulgaricus IMV B-7281, L. casei IMV B-7280, Bifidobacterium animalis VKB and B. animalis VKL strains to assimilate cholesterol in vitro [1] and to normalize microbiota spectrum in cases of Staphylococcus infection [2].
**Aims & Methods:** The aim was to study the influence of Lactobacillus and Bifidobacterium probiotic strains on cholesterol levels in serum and the gut microbiota on mouse obesity model. Experimental studies were conducted on female BALB / c mice aged 6–8 weeks (17–24 g). For modeling obesity mice during 21 days were receiving a high-calories diet (HCD); after 22 days, these mice started to receive usual diet and L. delbrueckii subsp. bulgaricus IMV B-7281, L. casei IMV B-7280, B. animalis VKL, B. animalis VKB (each strain separately) or compositions B. animalis VKB / B. animalis VKL (in the ratio 1: 1) or B. animalis VKB / B. animalis VKL / L. casei IMV B-7280 (at 1: 1: 2 ratio). The probiotic strains were suspended in sterilized saline. Mice were treated with these strains and compositions at a dose of 1 x $10^6$ cells daily to the animal orally during 7 days. We organized 7 groups of BALB/c mice (12 mice in each group), that include 2 control groups (intact mice that received normal diet (control 1) and HCD-treated mice (control 2)) and 5 groups of mice that received HDC and probiotic strains in monocultures or their compositions. Body weight was measured once a week. Blood samples and feces were taken on the 7, 15 and 21$^{st}$ days from HCD start and on the 4, 9, 15, 21 and 30$^{th}$ days from the beginning of probiotic strains introduction.
**Results:** We established that 3 weeks of HCD diet leads to an increasing of body weight in mice up to $6.8 \pm 0.3$ g and free cholesterol level in the blood serum from $4.82 \pm 0.36$ to $12.33 \pm 0.77$ and also leads to significant changes of gut microbiota spectrum (increased the number of gram-positive cocci - staphylococci, streptococci, and microscopic fungi, but reduced the number of Lactobacillus spp., Bifidobacterium spp.). Under the influence of all probiotic bacteria and compositions we observed decreasing the level of serum cholesterol from the 4$^{th}$ day of treatment in mice receiving HCD, but under the influence of L. casei IMV B-7280 and L. delbrueckii subsp. bulgaricus IMV B-7281 in monoculture and L. casei IMV B-7280 / B. animalis VKB / B. animalis composition we observed a complete normalization of cholesterol level on the 9$^{th}$, 15$^{th}$ and 21$^{st}$ day respectively. Thus, L. casei IMV B-7280 demonstrated most effective hypocholesterolemic activity, dramatically reducing the level of serum cholesterol even compared with the levels in intact mice. After strains and compositions entering to HDC-treated mice a we observed gradual normalization of body weight, the most ($5.8 \pm 0.6$ g) in the group of mice treated with L. casei IMV B-7280. Treatment with all strains and compositions reduced the total amount of gram-positive bacteria and microscopic fungi in the intestinal contents, but significantly increased the number of Lactobacillus spp., Bifidobacterium spp. and coliform bacteria.
**Conclusion:** L. delbrueckii subsp. bulgaricus IMV B-7281, L. casei IMV B-7280, B. animalis VKB and B. animalis VKL in monoculture and in the various compositions are promising to create probiotic preparations for the prevention and treatment of metabolic diseases, which progress is accompanied by violation of cholesterol metabolism and gut microbiota spectrum.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** brunosander@hotmail.com

**Introduction:** The conventional Intragastric Balloon (IGB) for usage within up to 06 months has been used for more than 25 years in more than 80 countries, as an aid for weight loss. More recently, an adjustable intragastric balloon has been approved for usage within up to 12 months. That brought us a questioning on which procedure should be recommended and in what situations each one should be applied.
**Aims & Methods:** This study compares the usage of two types of liquid balloons available in Brazil, analyzing which of them offer better conditions for weight loss, with a lesser incidence of complications and intercurrences. Data were collected among 868 patients of 05 different private centers, 695 made use of the 06 months conventional balloon and 173 made use of the 12 months adjustable balloon. Study period took place between January 2015 and March 2016. We have analyzed the mean weight loss on both types of balloon during the study period, also the BMI variation, the percent EWL (Excess Weight Loss), the percent of early removals and incidence of ulcers, as well as other intercurrences, which were divided by period of time, considering each type of balloon. Data were analyzed using Student t-test, and andTukey post-test. The level of significance was set at $p < 0.05$.
**Results:** Usage of 06 months balloon has shown results very similar to results with a 12 months balloon, regarding weight loss. The mean Percent EWL was more than -59.10% (±39.32%) [6 months] versus 59.61% (±33.45%) [12 months]. Mean weight loss was -18.57 kg (±8.33 kg) [6 months] versus -20.54 kg (±10.27 kg) [12 months]. Mean variation of BMI was -4.91 kg/m$^2$ (±2.91 kg/m$^2$) [6 months] versus -5.68 kg/m$^2$ (±3.48 kg/m$^2$) [12months]. Removal due to initial intolerance was little higher with the 06 months balloon than with the 12 months balloon (2.7% 6 months balloon versus 1.8% 12 months balloon). Nonetheless, regarding intercurrences and complications, the 12 months balloon presented a higher incidence of gastric perforation (0.6% versus 0.1%), bleeding due to Dieulafoy lesion (0.6% versus 0.1%) and ulcers (16.8% versus 0.3%). The appearance of ulcers was higher from the sixth month of balloon usage (61.1%) and the most used approach was changing the balloon or a dose increase of IBP (89.7%). In 10.3% of ulcer cases, the IGB removal was necessary.
**Conclusion:** The 06 months Intragastric Balloon has presented similar results concerning weight loss and BMI variation when compared to the 12 months Adjustable Intragastric Balloon, however, with the latter, the incidence of ulcers, bleedings and gastric perforation is higher than with the conventional 06 months balloon.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Exercise improves metabolic dysregulation. However, the roles of exercise on gut microbiota have seldom been investigated.
**Aims & Methods:** We conducted an in vivo study to examine how exercise influences metabolic dysregulation and gut microbiota in different diets. C57BL6 mice were divided into four groups: normal diet without exercise (NS group, N = 6), normal diet with exercise (NE group, N = 4), high fat diet without exercise (HS group, N = 6) and high-fat diet with exercise (HE group, N = 4). Body weight, blood sugar, and glucose tolerance tests were compared. The differential DNA expression levels of Bacteroides spp. and Firmicutes spp. in stool specimens were analyzed by using quantitative polymerase chain reaction.
**Results:** After 16 weeks of experiment, body weight gain was significantly greater in high fat diet groups than normal diet groups. Body weight gains between the exercise and non-exercise groups were not significantly different. HE group showed a greater improvement in the glucose tolerance ability ($92.5 \pm 15.2$ mg/dL) compared with the HS group ($165 \pm 28.3$ mg/dL) ($P < 0.05$). In the stool specimens, we found that exercise significantly increased the amount of Bacteroides spp, especially in the NE group (NE: $6.70 \pm 4.86$; HE: $2.43 \pm 0.96$; NS: $2.29 \pm 0.96$; HS: $0.81 \pm 0.49$, $P < 0.01$). On the contrary, increased amount of Firmicutes spp. was observed in the stool specimens of HS group (NE: $0.50 \pm 0.75$; HE: $0.46 \pm 0.17$; NS: $0.51 \pm 0.24$; HS $1.51 \pm 0.68$, $P < 0.01$).
**Conclusion:** Exercise improves glucose tolerance ability in mice with high fat diet. In addition, the gut microbiota was changed with increased Bacteroides spp. by exercise in both diet groups, especially in the normal diet group.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1095 CD24 KO MALE MICE AS A MODEL SYSTEM OF EARLY ONSET OBESITY IN MEN WITH INSULIN HYPER-SENSITIVITY

**Introduction:** The heat stable (HSA)/CD24gene encodes for a heavily-glycosylated cell surface protein.The role of CD24in carcinogenesis is being extensively investigated. Its role in diabetes and obesity is not clear.PPAR$\gamma$ is a regulator of adipogenesis that plays a role in insulin sensitivity, lipid metabolism, and adipokineexpression.
**Aims & Methods:** Aim: To assess gender-dependent changes in CD24/HSA KO mice fed with normal and high-fat diet (HFD). Methods: Body weight (BW), water and food consumption were closely monitored from birth in HSA+/+ ($N > 120$) andHSA-/- ($N > 120$) mice for one year. The experiment was repeated twice. Insulin (0.5 IU/kg) sensitivity and glucose (1 gr/kg) tolerance was determine thrice. Adipose tissuefrom kidney (KF), testicular (TF), and liver (LF) were isolated from KO and WT mice. High-throughput sequencing of stool 16S rRNA genes was assessed in the enteric microbial populations of the KO and WT mice, male and female, normal and HFD consumers. $N = 10$ in each group. Taxa analysiswas performed on the core taxa prevalent in more than >25% of samples. Extraction of vascular fraction from adiposetissues was performed and primary cultures of adipocytes were established. Fecal transplantation was used todetermine whether sensitivity to insulin or weight gain is dependent on the murine gut microbiota.
**Results:** Water and food consumption was similar for the KO and WT mice in normal andHFD. Mean BWof the KO was higher than that of their WT littermates, particularly in males and surprisinglywith greater insulin sensitivity (10–20%) and glucose uptake (30%). It remained valid for mice fed with HFD. No suchdifferences were observed among females. Significant differences in BW, KF, TFand LF were demonstrated between CD24 KO and WT mice. Aadipocytes size of the KO ($8258 \pm 2359$ uM2) was significantly higher thanthat of the WT ($5471 \pm 2030$ uM2) mice ($P < 3.51$ E-09) (Fig.3). PPAR$\gamma$ expression was higher (x1.5) in CD24 KO mice. Enteric bacterial populations were significantly different between KO and WT mice (normal diet) by unweighted ($R = 0.32$, $P < 0.01$) $\beta$-diversity analysis. These differences became more apparent when mice were kept on HFD by weighted ($R = 0.43$, $P < 0.01$) and un-weighed $\beta$-diversity analysis ($R = 0.31$, $P < 0.01$) as well as by specific bacterial taxa (Fig.4). Moreover, when the wt male mice were systemically treated with anti-CD24 mAbs, the phenotype of the KOmice was restored to that of the KO mice.
**Conclusion:** 1. CD24 negatively regulate PPAR$\gamma$ expression in male. 2. The association between CD24 and insulinsensitivity, and the oncogenic potential of CD24, suggest a possible mechanism for diabetes as a cancer risk factor. 3. CD24KO male mice may serve as a model of male early obesity and insulin sensitivity. 4. mAb to CD24 can be used in diabetic patients as they improve insulin sensitivity.

**Introduction:** There is accumulating evidence for the benefit of a diet low in fermentable oligosaccharides, disaccharides, monosaccharides and polyols (FODMAPs) in the management of irritable bowel syndrome (IBS) symptoms. Whether FODMAPs alter the gastric accommodation (GA) response to nutrients, and whether this contributes to symptom generation and induces changes in emotion, remains to be assessed.
**Aims & Methods:** The objectives were to assess the impact of different FODMAPs on the intragastric pressure (IGP) response to nutrient ingestion (which reflects GA), symptom generation and on emotions. A high resolution manometry and infusion catheter were positioned in the proximal stomach of healthy volunteers (HV) and IBS patients. After a stabilization period of at least 10 minutes and when the participant was in a late phase II of the hunger cycle, a FODMAP or control solution (fructans and glucose, respectively) was intragastrically infused at 60 mL/min until maximal satiation (0–5 scale), three days to one week apart in a single-blind randomised cross-over order. Questionnaires on gastrointestinal symptoms and mood and emotion were collected before infusion and then every 15 minutes up to 3 hours. Positive and negative affect were assessed before infusion, immediately after infusion and then every hour up to 3 hours after infusion. IGP data were presented as change from baseline, whereas symptom and psychological scores were presented as absolute score (mean ± SEM). Data were analysed using linear mixed models and repeated measures ANOVA.
**Results:** Twenty healthy volunteers (19–32 y, 10 men, 18–44 BMI) and 19 IBS patients (18–55 y, 4 men, 18–32 BMI) were included. Nutrient volume tolerance did not differ significantly within groups. However, although not significant, IBS patients had a lower nutrient volume tolerance compared to healthy controls (fructans: $p = 0.059$, glucose: $p > 0.05$). GA was significantly inhibited in HV following fructan infusion compared to glucose ($p = 0.002$) and significantly higher in IBS compared to HV for both solutions (fructans: $p = 0.012$, glucose: $p = 0.021$). Regarding gastrointestinal symptoms, fructans induced significantly more flatulence and cramps in IBS compared to HV ($p = 0.026$ and $p = 0.015$, respectively). Throughout the study, fructans were associated with significantly higher fatigue scores in IBS patients ($p < 0.010$). In addition, tension scores were significantly higher in IBS ($p < 0.002$), whereas the feeling of being in control was significantly lower in the patient population ($p < 001$), both for fructans and glucose. Finally, IBS patients reported higher scores for negative affect throughout the study compared to HV ($p < 0.035$).
**Conclusion:** IBS patients have a differential IGP response compared to HV. In addition, these results confirm that FODMAPs are involved in symptom generation in IBS patients and show that IBS patients are characterized by a more negative psychological state in comparison with HV. Unraveling the sensory, neural and/or hormonal pathways involved in the differences in gastric physiology requires further mechanistic studies.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1097 THE FEATURES OF POSTPRANDIAL ABDOMINAL HEMODYNAMICS IN PATIENTS WITH VISCEROPTOSIS

**E. Ljaljukova**[1], M. Rozhkova[2], G. Nechaeva[1], M. Livzan[1]

**Contact E-mail Address:** lyalukova@yandex.ru
**Introduction:** Abdominal circulation has important physiological significance, providing nutriment and function of the digestive system, maintaining nutritional hemostasis.
**Aims & Methods:** Aim: to study features of abdominal hemodynamics in patients with visceroptosis. Materials and methods. The study included 69 patients (mean age $22.28 \pm 3.7$ years) with visceroptosis and 52 patients without visceroptosis (control group). Patients are matched by sex and age. Exclusion criteria: presence of operations on digestive organs in history, medication affecting ciculation.Patients underwent doppler ultrasound common hepatic artery, splenic artery, superior mesenteric artery, portal vein fasting and 30 minutes after food sample standardized by protein (14 g), fat (10 g) (45 g).
**Results:** It was not detected when assessing abdominal blood fasting differences in hemodynamic parameters.In carrying out food samples in the postprandial period in patients with visceroptosis recorded lower volumetric flow rate for all vessels: the portal for vene1124.0 [1030.0–1419.0] ml / min against 1373.0 [1136.0–1567.5] ml / min in the control group ($U = 433.5$; $Z = -2.1$; $p = 0.0342$) at the common hepatic arteri 341.0 [295.0–394.0] ml / min vs. 412 in the comparison group, 0 [331.0–521.0] mL / min ($U = 335.0$; $Z = -2.3$; $p = 0.0218$) at the splenic artery 396.0 [292.0–538.0] ml / min versus the comparison group at 502.0 [394.0–594.0] mL / min ($U = 328.0$; $Z = -2.1$; $p = 0.0399$), in superior mesenteric artery 988.0 [837.0–1272.0] mL / min versus 1136.5 in the comparison group [992.0–1465.0] mL / min ($U = 1625.5$; $Z = -2.2$; $p = 0.0314$). blood flow changes correlated with the degree of visceroptosis: for portal vein from any ptosis ($rs = -0.21$; $p < 0.05$), according to the common hepatic artery from gastroptosis ($rs = -0.38$; $p < 0.05$) by the superior mesenteric artery from kolonoptosis ($rs = -0.86$; $p < 0.05$) and peripheral vascular resistance: on the common hepatic artery ($rs = -0.46$; $p < 0.05$); by splenic artery ($rs = -0.33$; $p < 0.05$), the superior mesenteric artery ($rs = -0.79$; $p < 0.05$).
**Conclusion:** Patients with visceroptosis in postprandial low blood flow volume is recorded for abdominal aortic vessels. The factor that determines a lower volumetric flow rate is the length of the mesenteric vessels, undergoing the greatest changes during ptosis. Food sample reveals a latent deficiency of blood flow in patients with visceroptosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1098 EFFECTIVENESS OF BETA-CRYPTOXANTHIN FOR NONALCOHOLIC STEATOHEPATITIS

**B. Matsuura**[1], S. Yamamoto[1], T. Miyake[2], S. Furukawa[3], Y. Hiasa[2]

**Contact E-mail Address:** bmatsu@m.ehime-u.ac.jp
**Introduction:** We previously reported that in nonalcoholic steatohepatitis (NASH) patients there was an excess intake of carbohydrates/energy and low intakes of protein/energy, polyunsaturated fatty acid and zinc. We also reported that a two-year interventional diet, consisting of 30–35 kcal/kg of ideal body weight, 55% of carbohydrate/energy, 20% of protein/energy, 1.0–2.0 of ratio of polyunsaturated to saturated fatty acid, and sufficient amounts of vitamins and zinc, would be effective for improving anthropometric and biological parameters in NASH patients. There have been a few reports in

NASH patients about effectiveness of carotenoids, especially beta-cryptoxanthin (b-crypt).
**Aims & Methods:** In this study, we clarified intake and serum concentration levels of b-crypt in NASH patients, and conducted a clinical trial to assess whether b-crypt would inhibit the progression of NASH. A priori approval for the study was obtained from the Ehime University Hospital Research Ethics Board and UMIN Clinical Trials Registry. All subjects provided written informed consent.
**Results:** Intake and serum levels of b-crypt were significantly lower in NASH patients (n = 30) than in nonalcoholic fatty liver (NAFL) patients (n = 30) and healthy controls (n = 15). We randomly assigned NAFLD patients to receive the trial beverage containing 3 mg of b-crypt (n = 20) or placebo (n = 20) beverage for 12 weeks. In both NASH and NAFL patients, serum GGT levels were significantly reduced with b-crypt therapy, as compared with placebo. Serum oxidative LDL and interleukin (IL)-6 levels were significantly decreased and serum SOD and IL-10 levels were significantly increased in both NASH and NAFL patients who received b-crypt therapy. We also randomly assigned NASH patients to receive the trial beverage containing 3 mg of b-crypt, 12 mg of Zn and 30 mg of a-tocopherol enriched beverage (n = 20) or only 3 mg of b-crypt enriched beverage (n = 20). Both trial beverages had same effects.
**Conclusion:** These data suggest that b-crypt therapy may be effective for improving anti-oxidant and anti-inflammation in NASH patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1099 A RANDOMIZED PATIENT -BLIND CONTROLLED PHASE III STUDY TO COMPARE THE EFFICACY AND SAFETY OF INTRAVENOUS FERRIC CARBOXYMALTOSE (FERINJECT®) WITH PLACEBO IN PATIENTS WITH ACUTE ISOVOLEMIC ANEMIA AFTER GASTRECTOMY

**Introduction:** Acute isovolemic anaemia is a decreased haemoglobin (Hb) concentration with normal or even increased blood volume after gastric cancer surgery. Unfortunately this condition is largely overlooked, undiagnosed and under-treated which may negatively influence both short and long-term outcomes. We therefore assessed if intravenous iron used in the postoperative setting may efficiently correct anaemia and confer clinical benefits in this population.
**Aims & Methods:** This randomized controlled trial was conducted in 7 centres across Korea to evaluate the efficacy and safety of FCM in treating of acute isovolemic anaemia post gastrectomy. The study group was administered FCM (1.000 mg for body weight ≥50 kg or 500 mg iron if <50 kg). The placebo group received 0.9% normal saline (200 mL for bodyweight ≥50 kg or 100 mL if <50 kg). Pts with a serum ferritin level of <15 ng/mL and Hb-level <10 g/dl at week 3 received an additional dose of 500 mg iron or 100 mL normal saline. The primary endpoint was the number of responders at 12 weeks. Secondary endpoints included Hb and iron parameter evolution, percentage of patients requiring alternative anaemia management and the safety of FCM. Quality of life (QoL) was assessed using the EORTC QLQ-C30 and STO22 questionnaires at 3 and 12 weeks. Pts were blinded to treatment throughout the study to minimise bias.
**Results:** 430 gastric cancer pts with Hb 7 to <10 g/dl at 5–7 postoperative days after oncologic resection were assessed for efficacy. At baseline, the mean Hb concentration was 9 and 9.2 g/dL for the FCM and placebo arms respectively. At end of study, 92% of pts receiving treatment with FCM achieved a Hb increase of at least 2 g/dL or Hb > 11 g/dL versus 54% in the placebo arm (p = 0.001). Significant correction of anaemia and iron parameters in favour of FCM was observed at all time points (Table 1). The estimated blood loss for each group was 187 and 192 mL (FCM and placebo; p = 717). Alternative anaemia management was required in 4 pts in the study group and 18 patients in the placebo group (1.8% vs. 7.1%; p = 0.006). QoL improvements were observed for the global quality of life, fatigue and dyspnoea components of the EORTC QLQ C30 questionnaire. FCM was well tolerated with no severe, serious or anaphylactic reactions reported.

**Table 1:** Laboratory Parameters

| Time-point & Parameter | FCM | Placebo | p-value |
|---|---|---|---|
| **Baseline** | | | |
| Hb (g/dL) | 9 | 9.2 | 0.010 |
| serum ferritin (ng/mL) | 115.9 | 137.1 | 0.094 |
| TSAT (%) | 10.8 | 10.5 | 0.662 |
| **3 week** | | | |
| Hb (g/dL) | 11.6 | 10.6 | 0.001 |
| serum ferritin (ng/mL) | 508.8 | 75.6 | 0.001 |
| TSAT (%) | 29.8 | 13.9 | 0.001 |
| Hb ≥ 10 g/dL | 210(96.8) | 155(71.1) | 0.001 |
| Hb ≥ 11 g/dL | 165(76.0) | 90(41.3) | |

**Conclusion:** Administration of FCM for managing acute isovolemic anaemia post gastrectomy is effective in correcting anaemia and iron deficiency with minimal toxicity profile. The treatment also appears to be beneficial for patients, especially in relation to fatigue and dyspnoea.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1100 CONVENTIONAL CONTINUOUS INSULIN INFUSION THERAPY OF PERIOPERATIVE MANAGEMENT AFTER ESOPHAGECTOMY

**K. Yamada**, K. Nohara, S. Yamashita, D. Souma
*Surgery, National Center for Global Health and Medicine, Tokyo/Japan*

**Contact E-mail Address:** kayamada@hosp.ncgm.go.jp
**Introduction:** In diabetes patients of esophagectomy is high rate morbidity (anastomotic leakage and infection) because of insulin resistance, hyperglycemia and surgical diabetes. On the other hand, intensive or conventional insulin therapy was controversial. Variability of blood glucose and severe hypoglycemia was influenced the mortality in ICU patients.
**Aims & Methods:** To evaluate the influence of diabetes on perioperative complication with conventional continuous insulin infusion therapy after esophagectomy.
Patients and Methods: 1. A total 64 cases (Sep 2013–July 2014) were underwent esophagectomy. About hyperglycemia more than 180 mg/dl, we started continuous insulin infusion therapy and managed blood glucose between 110–150 mg/dl. 2. We retrospectively discussed factors affecting morbidity of perioperative complications after esophagectomy in diabetes.
**Results:** 1. Among 64 patients, 27 (42%) patients (Group HG) used continuous insulin infusion therapy for hyperglycemia (180 mg/dl). 37(58%) patients (Group NG) did not use insulin. 2. Group HG patients had no increased risk for morbidity compared with Group NG. Rate of perioperative complications were Clavien-Dindo classification IIIb: HG: NG 18% vs. 22%, leakage: 10% vs. 8.3%, infectious disease: 46% vs. 38%. 3. Compared with patients with comorbidities, those with ≥2 comorbidities including diabetes had a statistically significance for anastomotic leakage ($p < 0.05$).
**Conclusion:** This study revealed no increased risk for morbidity in patients with diabetes using conventional continuous insulin infusion therapy. However, more than 2 comorbidities including diabetes revealed increased risk for anastomotic leakage after esophagectomy. We will start closed loop system for perioperative blood glucose concentration.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Polymorphism rs58542926 c.449 C > T v TM6SF2 (transmembrane 6 superfamily member 2) is one of genetic factors predisposing to development of non-alcoholic fatty liver disease (NAFLD).
**Aims & Methods:** We aimed to evaluate the influence of both recipient and donor TM6SF2 rs58542926 genotypes on development of steatosis in liver transplant (LT) recipients. The study group included 272 adult LT recipients transplanted between 1995 and 2010, in whom occurrence of steatosis was evaluated by liver biopsy during first 5 post-transplant years. We analyzed TM6SF2 rs58542926 and PNPLA3 (patatin-like phospholipase 3) rs738409 genotypes of recipients and donors, and clinical and laboratory data. Patients with steatosis (≥5%; grade 1–3) were compared to patients without steatosis (<5%, grade 0).
