**Introduction:** Sinusoidal obstruction syndrome (SOS) is a drug-induced liver injury caused by anticancer treatments, such as oxaliplatin-based chemotherapy. Injury of sinusoidal endothelial cells (SECs) and subsequent extravasated platelet aggregation (EPA) initiate development of SOS. Beraprost sodium (BPS) has a protective effect on SECs and antiplatelet effect. The aim of this study was to examine the protective effect of BPS against SECs injury resulting from monocrotaline (MCT)-induced SOS in mice.

**Aims & Methods:** SOS was induced in Crl:CD1 (ICR) mice by intraperitoneal administration of MCT (270 mg/kg). To evaluate the effect of BPS on SOS, the mice were divided into two groups. In the BPS group, BPS (200 $\mu$l/kg) was injected by intraperitoneal administration at 1 hour before, 3 hours after, and 9 hours after MCT administration. The control group received intraperitoneal injections of the same volume of saline at the same time points. All mice were sacrificed at 48 hours after MCT administration and the protective effect on SECs was assessed by determining blood cell count, serum biochemical findings and immunohistochemical stains of sinusoidal endothelial cell antibody (SEC-1) and CD62P (P-selectin). Western blot analysis and real-time polymerase chain reaction (RT-PCR) were also used to examine plasminogen activator inhibitor-1 (PAI-1) and endothelial nitric oxide synthase (eNOS) expression.

**Results:** Platelet count was maintained in the BPS group compared to that in the MCT group (48.2 vs. 4.8 $\times 10^4/\mu$l, $P < 0.001$). Serum transaminase levels and hyaluronic acid (HA) in the BPS group were significantly reduced compared to the levels in the MCT group (AST 129 vs. 1013 IU/L, $P < 0.05$; ALT 90 vs. 923 IU/L, $P < 0.01$; HA 670 vs. 2243 ng/mL, $P < 0.01$). In the MCT group, liver histology showed endothelial damage of the central venule, congestion and obstruction of the sinusoids, and necrosis of hepatocytes in zone 3. In the BPS group, these findings were suppressed. Immunohistochemistry showed a protective effect of SECs on SEC-1 and a decrease in platelet infiltration in the space of Disse on CD62P in the BPS group compared to that in the MCT group. Expression of PAI-1 was significantly lower and expression of eNOS was significantly higher in the BPS group.

**Conclusion:** BPS preserved SECs and suppressed the progression of MCT-induced SOS in mice, suggesting that BPS is useful for the prevention of SOS.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0002 HEPATOCYTE-SPECIFIC DELETION OF HYPOXIA INDUCIBLE FACTOR-2A ATTENUATES FIBROGENIC PROGRESSION IN MICE WITH NON-ALCOHOLIC FATTY LIVER DISEASE

**Introduction:** Hypoxia and hypoxia inducible factors (HIFs) have been implicated in the fibrogenic progression of human and experimental chronic liver diseases, with HIF-1$\alpha$ originally suggested to play a role in the murine models of bile duct ligation and chronic diethylnitrosamine administration. Recently, a mechanistic study based on alternate hepatocyte-specific deletion of HIFs suggested that HIF-2$\alpha$ (rather than HIF-1$\alpha$) may sustain lipid accumulation and liver fibrogenesis in a short-term (two weeks) model of ethanol-related steatohepatitis.

**Aims & Methods:** Since increased HIF-2$\alpha$ expression has been observed in either experimental or human conditions of non-alcoholic fatty liver disease (NAFLD), the present study has been designed to mechanistically investigate the putative pro-fibrogenic role of HIF-2$\alpha$ in experimental NAFLD. Expression and the mechanistic role of HIF-2$\alpha$ have been investigated by means of morphological and molecular biology approach in the methionine/choline deficient diet (MCD) murine model of progressive NAFLD by employing i) wild type C57Bl6J mice and ii) mice carrying hepatocyte-specific conditional deletion of HIF-2$\alpha$ (HIF-2$\alpha$ fl/fl /Alb-Cre mice) vs related littermate (HIF-2$\alpha$ fl/fl mice).

**Results:** HIF-2$\alpha$ hepatic transcript levels were progressively up-regulated during the development of MCD murine model of NASH in parallel with the development of fibrosis, with increased expression being observed by immunohistochemistry mostly in hepatocytes. However, HIF-2$\alpha$ deficiency resulted in: i) a significant decreased expression of major pro-fibrogenic genes, including transforming growth factor $\beta$1, $\alpha$-smooth muscle actin, collagen 1A1, matrix-metalloprotease 2; ii) deleted expression of SerpinB3, a hypoxia and HIF-2$\alpha$-dependent mediator able to directly modulate pro-fibrogenic activity of HSC which is mainly released by hepatocytes in chronic liver diseases. Of interest, no significant up-regulation was observed for HIF-1$\alpha$ levels in mice carrying hepatocyte-specific deletion of HIF-2$\alpha$.

**Conclusion:** Hepatocyte-specific down-regulation of HIF-2$\alpha$ negatively affect liver fibrogenesis, suggesting that a HIF-2$\alpha$-dependent mediator released by hepatocytes like SerpinB3 may have a role in the fibrogenic progression of experimental NAFLD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0004 PROSPECTIVE COMPARISON OF NONINVASIVE TECHNIQUES FOR THE ASSESSMENT OF LIVER STIFFNESS IN A COHORT OF COMPENSATED HCV LIVER CIRRHOSIS

**Introduction:** It is known that the liver biopsy is the gold standard for diagnosing liver fibrosis, but it also can be diagnosed by means of noninvasive techniques, either biological tests or ultrasound based elastographic techniques.

**Aims & Methods:** The aim of this study was to compare the performance of elastographic techniques and biological tests in diagnosing compensated HCV liver cirrhosis. We performed a prospective study, including 100 consecutive patients diagnosed with HCV liver cirrhosis. All patients were evaluated by point ultrasound shear wave elastography (SWE) – {Virtual Touch Quantification [ (VTQ)-Acuson S2000, Siemens], ElastPQ- (Affinity, Philips)}, by Transient Elastography [ (TE)-FibroScan, EchoSens], by 2-dimensional (2D) shear wave elastography (SWE)- [Aixplorer, Supersonic Imagine (SSI)], LOGIC E9 [GE Healthcare, Chalfont St. Giles-UK (2D-SWE GE)]-in the same session, while biological test (FibroTest) was performed within a month. In each patient we performed 10 valid measurements (VM) for TE, VTQ, ElastPQ and 2D-SWE.GE, and 3 for SSI. The following published cut-offs were used to diagnose cirrhosis: TE-12 kPa (1); VTQ-1.81 m/s (2); ElastPQ-12 kPa (3); SSI-13.5 kPa (4); 2D-SWE.GE-12 kPa (5).

**Results:** Our cohort included 100 subjects (60 women and 40 men), mean age of $60 \pm 5.3$, BMI $24.9 \pm 2.2$. Reliable LS measurements by means of point elastography were obtained in 100/100 subjects, by means of TE in 94/100 subjects (94%) and by means of 2D-SWE elastography in 87/100 subjects (87%), so the final analysis included 87/100 subjects (87%). TE elastography had 94.6% accuracy, point elastography – 79.3%, 2D-SWE elastography – 85.1% and FibroTest – 77%. There were no significant statistical differences between FibroTest-point elastography ($p = 0.85$), FibroTest-2D-SWE elastography ($p = 0.24$), TE-point elastography ($p = 0.06$), TE- 2D-SWE elastography ($p = 0.06$), point-2D-SWE elastography ($p = 0.42$) respectively. Significant statistical differences were found only between TE and FibroTest (94.6% vs 77%, $p = 0.0019$).

**Conclusion:** In this preliminary study, all ultrasound based elastographic methods had good performance for the diagnosis of compensated liver cirrhosis and this seem to be similar with FibroTest.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0005 LIVER-SPECIFIC SIRT1 DELETION AGGRAVATES HEPATIC FIBROSIS BY REGULATING BAS METABOLISM AND SUPPRESSES THE EXPRESSION OF IQGAP1

**X. Liu**, H. He, Y. Nie
*Department Of Gastroenterology, xiangya 2nd hospital, changsha/China*

**Contact E-mail Address:** liuxw@csu.edu.cn.

**Introduction:** Hepatic fibrosis is a reversible wound-healing response characterized by the accumulation of extracellular matrix (ECM), in response to the stimulation of liver injury factors, hepatocytes damage and promote the activation of hepatic stellate cells. The of SIRT1 in the liver fibrosis remains poorly understood. Here, we demonstrate the influence and potential mechanisms of SIRT1 in murine liver fibrosis models.

**Aims & Methods:** Liver-specific SIRT1 deletion (SIRT1-LKO) mice and wild type (WT) mice were injected intraperitoneally (IP) 5 ml/kg body weight twice per week for 2 month with 10% CCL4 (dissolved in olive oil). Paraffin-embedded sections of liver tissue were stained with hematoxylin and eosin (H&E) and Masson's Trichrome staining to assess the collagen architecture and the extent of fibrosis. Serum ALT, bile acids concentrations were measured. We used label-free MS to screen differentially expressed proteins. Finally, we explored the potential mechanisms of SIRT1 in liver fibrosis in vitro.

**Results:** SIRT1-LKO mice treated with CCL4 showed more serious liver fibrosis compared with the WT mice according to H&E and Masson's Trichrome staining. Serum levels of ALT, AST were significantly higher in SIRT1-LKO mice than WT mice after CCl4 treatment, while BAs concentration was decreased. In CCl4-treated SIRT1-LKO mice, there was significantly higher expression of $\alpha$-SMA and Collagen 1A1. We analyzed the results of Label-Free mass spectrometry with a bioinformatics approach and discovered candidate gene-IQGAP1, CRABP1 and $\beta$-Catenin. Western blot and immunohistochemical staining were conducted to validate that SIRT1-LKO reduced the decreased expression of IQGAP1 compared with WT mice after treated with CCL4. However, SIRT1 and IQGAP1 were not shown to interact at exogenous level in SIRT1-overexpressing cells by coimmunoprecipitationin. Neither overexpression nor silence of SIRT1 affected the expression of IQGAP1 in L02 cells. These results indicated that SIRT1 influence the expression of IQGAP1 likely through indirect way. In LX2 cell, CDCA and DCA treatment increased IQGAP1 in a dose dependent manner.

**Conclusion:** We define a pivotal role of SIRT1 in liver fibrosis and explore the potential mechanism that SIRT1 prevents activation and proliferation of hepatic stellate cell by regulating bile acids metabolism in hepatocytes and influencing the expression of IQGAP1 in HSCs.

**Introduction:** Chronic inflammation is a key player in the progression from NAFLD to NASH. Morbid obesity is a known risk factor of NAFLD. It has been described that adipose tissue from obese patients has higher Th17 cell content than normal subjects. Th17 cells have been implicated in the pathogenesis of autoimmune and inflammatory diseases. The differentiation of naïve CD4 T cells into Th17 cells is triggered by TGF$\beta$, IL6 and IL1$\beta$, which induce the expression of their characteristic transcription factor Orphan Nuclear Receptor (RORC). After stimulation Th17 cells secrete IL-17 that binding its receptor IL-17RA, propagates a cascade of events that lead to neutrophil recruitment, inflammation and host defense. Periostin, one end-product of this pathway, is a secretory cell adhesion protein recently involved in pathogenesis of fibrosis observed both in vitro and in vivo.

**Aims & Methods:** The aim of the present study is to assess the Th17 immune response contribution to the progression of human NAFLD. Prospectively we included in the study 14 morbidly obese subjects undergoing bariatric surgery (7 men and 7 women with a mean age of 43 years (19–60), mean BMI 46.5). We analyzed mRNA expression of the Th17 pathway (RORC, IL-17, IL-17RA) and Periostin (POSTN) in liver and visceral adipose tissue biopsies. According to the histological assessment, patients were divided according Brunt's score of liver fibrosis F0 (n = 2), F1 (n = 5), F2 (n = 7). Data was correlated with the expression of other markers involved in inflammation (IL1$\beta$; TNF$\alpha$, VEGFA, IL8, IL6) and fibrosis (TGF$\beta$; $\alpha$SMA, COL1A1).

**Results:** We found that adipose tissue of patients with F2 stage of liver fibrosis shows an overexpression of RORC ($p < 0.05$) and IL-17RA ($p < 0.05$) genes respect to F0 group whereas IL17 was overexpressed only in F1 ($p < 0.001$). Moreover, hepatic gene expression of RORC ($p < 0.05$), IL17RA ($p < 0.05$) and Periostin ($p < 0.05$) was higher in the F1 and F2 group compared with the F0. No changes were observed in IL17 hepatic gene expression. All together these results are in line with those observed for inflammation IL1$\beta$; TNF$\alpha$, VEGFA, IL8 and fibrosis markers TGF$\beta$; $\alpha$SMA, COL1A1.

**Conclusion:** In obese patients, the Th17 pathway seems to be involved in the pathogenesis of liver inflammation and progression to fibrosis. Adipose tissue plays an important role as a source of IL17 conferring higher risk of NAFLD to these patients. Our preliminary data, in line with other reported studies, suggests that liver Periostin could be involved in hepatic fibrogenesis.

## P0007 LIVER AND SKELETAL MUSCLE MIR-34A CONTRIBUTES TO MITOCHONDRIAL DYSFUNCTION AND INSULIN RESISTANCE IN EXPERIMENTAL NAFLD

**A.L. Simão**, M.B. Afonso, P.M. Rodrigues, C.M.P. Rodrigues, R.E. Castro
*iMed.ULisboa, Faculty of Pharmacy, Universidade de Lisboa, Lisbon/Portugal*

**Contact E-mail Address:** adlsimao@ff.ul.pt.

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) pathogenesis associates with intracellular lipid accumulation and mitochondrial dysfunction in both the liver and skeletal muscle. In addition, we previously showed that, in human NAFLD progression, insulin resistance (IR) primarily targets the muscle although the liver is also affected. Still, the molecular mechanisms underlying the cross-talk between these organs during disease development remains poorly explored. Recent evidence supports a functional role for microRNAs (miRNA/miRs) in regulating NAFLD pathogenesis. In particular, activation of the miR-34a pro-apoptotic pathway correlates with NAFLD severity. Of note, miR-34a was recently described as a critical regulator of cardiomyocyte function, negatively impacting on cardiac repair and regeneration.

**Aims & Methods:** Our aims were to evaluate the potential role of miR-34a-dependent pathways in the development of mitochondrial dysfunction and IR in both muscle and liver cells in the context of NAFLD, using in vitro and in vivo disease models. C57BL6 mice were fed either a standard or a fast food (FF) diet for 25 weeks, or a methionine and choline-deficient (MCD) diet for 2 and 8 weeks. C2C12 muscle cells were incubated with or without palmitic acid (PA). Liver and skeletal muscle total RNA was used for miR-34a analysis by real-time RT-PCR. Protein levels of Sirtuin 1 (SIRT1), a key direct miR-34a target, mitofusion 2 (Mfn2) and peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1$\alpha$), two important players in mitochondrial dynamics and dysfunction, as well as endoplasmic reticulum stress-associated inositol-requiring enzyme 1$\alpha$ (IRE-1$\alpha$) were analyzed by Western Blot. IR was ascertained by assessing the activation/phosphorylation status of the insulin receptor / insulin receptor substrate 1 / Akt pathway.

**Results:** Mice fed the FF diet developed steatosis, inflammation and IR. MCD diet-fed mice developed steatohepatitis and severe liver damage and fibrosis. miR-34a expression levels were significantly increased in mice livers and skeletal muscle in both in vivo models, as compared with standard diet-fed mice ($p < 0.05$). Concomitantly, expression of SIRT1 was significantly decreased ($p < 0.05$). Further, in MCD-fed mice, expression levels of of PGC-1$\alpha$, which is also a transcriptional coactivator of SIRT1, as well as of mitochondrial fusion protein Mfn2 were significantly reduced ($p < 0.05$). Inversely, mitochondrial fission protein Drp1 and the unfolded protein response sensor IRE-1$\alpha$ were found increased ($p < 0.05$). Finally, incubation of C2C12 cells with PA activated the miR-34a/SIRT1 pro-apoptotic pathway, concomitantly with induction of cell death and IR, as well as reduced ATP levels ($p < 0.05$).

**Conclusion:** In conclusion, activation of the miR-34a/SIRT1 pathway in experimental NAFLD correlates with the development of IR and mitochondrial dysfunction in both liver and skeletal muscle. A better understanding of the overlapping roles of miR-34a in different tissues during NAFLD may help in establishing new therapeutic options (PTDC/BIM-MEC/0873/2012, UID/DTP/04138/2013, SFRH/BD/104160/2014, FCT, Portugal).
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0008 INHIBITION OF CANONICAL WNT SIGNALING PATHWAY BY B-CATENIN/CBP INHIBITOR ICG001 AMELIORATES LIVER FIBROSIS IN VIVO THROUGH SUPPRESSION OF STROMAL CXCL12

**R. Bansal**[1], B. Öztürk[1], G. Storm[2], J. Prakash[1]
[1]*Mira Institute, University of Twente, Enschede/Netherlands*
[2]*Department Of Pharmaceutics, Utrecht University, Utrecht/Netherlands*

**Contact E-mail Address:** r.bansal@utwente.nl.
**Introduction:** Hepatic fibrosis, is a common pathological consequence of chronic liver diseases mainly caused by viral infections, alcohol abuse or metabolic syndrome leading to liver dysfunction, is the growing cause of mortality worldwide. In response to liver injury and altered wound healing response, quiescent hepatic stellate cells (HSCs) undergo characteristic morphological and functional changes and transform to proliferative, contractile and ECM-producing myofibroblasts.
**Aims & Methods:** In this study, we investigated implication of canonical Wnt signaling pathway in hepatic stellate cells and liver fibrogenesis. Activation of canonical Wnt signaling pathway was examined in vitro in activated HSCs (LX2), mouse 3T3 fibroblasts and in vivo in liver fibrosis mouse model. Effects of canonical WNT signaling pathway using $\beta$-catenin/CBP inhibitor ICG001 on fibrotic parameters and contractility were evaluated in TGF$\beta$-activated human HSCs and 3T3 fibroblasts. Effect on cell viability was examined at increasing concentrations of ICG001 using alamar blue assay. Finally, ICG001 was evaluated for efficacy in $CCl_4$-induced liver fibrogenesis mouse model.
**Results:** Canonical Wnt signaling pathway components (Wnt1, Wnt3a, Wnt 10b, FZD1, FZD2 and LRP5/6) were significantly up-regulated in TGF$\beta$-activated HSCs and 3T3 fibroblasts, and in vivo in liver fibrosis mouse model. In vitro, in TGF$\beta$-activated human LX2 cells and 3T3 fibroblasts, ICG001 significantly inhibited expression of major fibrotic parameters (Collagen I, $\alpha$-SMA, Vimentin, TIMP1 and PDGF$\beta$R) and 3D-collagen I gel contractility. No significant effects on cell viability was observed with increasing concentrations of ICG001. In vivo in $CCl_4$-induced acute liver injury mouse model, post-disease intraperitoneal administration of ICG001 (5 mg/kg) significantly attenuated collagen accumulation and HSC activation. Interestingly, ICG001 drastically inhibited macrophage infiltration, intrahepatic inflammation (IL-6, TNF$\alpha$ and CCL2 expression) and attenuated angiogenesis (CD34, CD31, SOX9 and VEGF expression). We further studied role of stromal factor SDF1/CXCL12 and observed complete inhibition of CXCL12 expression both in vitro and in vivo following Wnt inhibition suggesting potential role of CXCL12 in Wnt/b-catenin signaling during liver fibrogenesis. We therefore hypothesized that CXCL12 produced by activated HSCs (regulated by canonical Wnt signaling pathway) potentiates macrophage infiltration and activation leading to liver inflammation, and also promotes angiogenesis.
**Conclusion:** Because no effective treatment for liver fibrosis exists, pharmacological inhibition of Canonical Wnt signaling pathway thereby suppression of stromal factor CXCL12 suggests a potential therapeutic approach targeting activated hepatic stellate cells in liver fibrosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0009 HEPATITIS C CORE REGION MUTATIONS ARE CORRELATED WITH LIVER DISEASE PROGRESSION

**B. Mohar Vitezic**[1], S. Milic[2], M. Čarapina[1], D. Kovač[1], D. Stimac[3], B. Grahovac[1]

**Introduction:** Hepatitis C virus (HCV) core is a complex protein, capable of modifying HCV life cycle, participating in interactions with host proteins, altering cellular signalling pathways and contributing in hepatocarcinogenesis. HCV core region mutations were reported to be associated with advanced liver disease and increased risk of hepatocellular carcinoma.
**Aims & Methods:** The aim of this study was to determinate and compare HCV core region mutations in the serum and liver samples of the same patient at the time of diagnosis. The object was also to investigate the correlation of mutations determined at diagnosis and subsequent liver disease course. HCV RNA was isolated from serum and liver samples of 85 infected patients, collected at the time of diagnosis, at the Department of Gastroenterology, Clinical Hospital Center, Rijeka, Croatia. Viral RNA was transcribed to cDNA and the entire HCV core region was amplified using nested PCR. Amplicons were sequenced with Big Dye Termination v1.1. method on ABI 310 sequencer and compared with referent HCV genotypes from GenBank.
**Results:** Thirty patients were infected with HCV genotype 1 b, 29 patients with 1 a, 26 patients with 3 a. Thirteen patients demonstrated severe hepatitis activity grade, 44 patients moderate and 28 patients mild or minimal. Severe fibrosis stage was determined in 9 patients, moderate in 36 and mild or no fibrosis in 40 patients. Basal viremia above $1 \times 10^6$ IU/ml was determined in 32 patients and below $1 \times 10^6$ IU/ml in 53 patients. We determined identical core region sequence in serum and liver sample in 79 (93%) patients, confirming that serum is adequate material for analysis of viral parameters in chronic hepatitis C. Twenty-nine different core region missense mutations were identified in HCV genotype 1 a group, 106 in HCV genotype 1 b group and 61 in HCV genotype 3 a group. Missense mutations in the core region were determined in all 30 patients with genotype 1 b, ranging from one to nine mutations per patient. In contrary 17 (57%) patients in HCV genotype 1 a group, had no missense mutation in the entire core region. HCV genotype 1 b group represented majority of mutations. Of all 85 patients, 25 (34%) demonstrated more than 3 missense mutations in the core region of the same sample. 19/25 (76%) patients had severe or moderate hepatitis activity grade and demonstrated severe or moderate fibrosis. Genotype 1 b was determined in 13/25 (52%) patients with more than 3 missense mutations. The most frequent missense mutations identified were R70Q, T75A, M91L/C and A147V. R70Q, T75A and M91L were already reported as mutations promoting hepatocarcinogenesis and associated with increased HCC risk. Results of this study indicate significant correlation of HCV genotype 1 b and high basal viremia with presence of R70Q ($p = 2.831 \times 10^{-5}$; $p = 0.0202$), T75A ($p = 1.99 \times 10^{-12}$; $p = 4.384 \times 10^{-5}$) and M91L/C ($p = 1.169 \times 10^{-6}$; $p = 0.0902$) core region mutations. Progressive patohistological liver parameters (severe or moderate hepatitis activity grade and severe or moderate fibrosis stage) were associated with the presence of R70Q ($p = 0.0049$; $p = 0.0018$) and M91L/C ($p = 0.0413$; $p = 0.0223$) mutations.
**Conclusion:** Results of our study confirm that serum is adequate material for chronic hepatitis C viral parameters analysis. The frequency and the type of missense mutations positively correlate with liver disease progressivity. Core region missense mutations found at the time of diagnosis could serve as a prognostic parameter for liver disease subsequent course and patient outcome.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0010 HIGH LEVELS OF SERUM AUGMENTER OF LIVER REGENERATION (ALR) PREDICT BETTER PROGNOSIS OF ACUTE-ON-CHRONIC LIVER FAILURE (ACLF) AND ALR PROMOTER REGION GENETIC VARIANTS ASSOCIATE WITH ACLF RISK

Y. Bi, **M. Min**, Y. Liu
*Gastroenterology And Hepatology, Affiliated Hospital of Academy of Military Medical Sciences, Beijing/China*

**Contact E-mail Address:** minmin823@sina.com.
**Introduction:** Acute-on-chronic liver failure (ACLF) is a newly formed clinical entity characterized by acute decompensation of cirrhosis, liver failure, and a high mortality risk. Although it is know that both, acute and chronic hepatic insults could result in ACLF and hepatitis B virus infection and continuous alcohol intake damage the liver and induce ACLF, the defined risk factors have not yet been fully clarified. Clinical management of ACLF includes antiviral treatment, liver transplantation, liver dialysis, and replacement therapy according to the recommendations by the Asian Pacific Association for the Study of the Liver (APASL).
**Aims & Methods:** This study investigated serum augmenter of liver regeneration (ALR) levels' association with prognosis of hepatitis B virus (HBV)-related acute-on-chronic liver failure (ACLF). Then, the association of ALR single nucleotide polymorphisms (SNPs) with risk of HBV-related ACLF was assessed.
**Results:** A total of 100 ACLF, 100 mild-to-moderate chronic hepatitis B (CHB) infection, 100 liver cirrhosis (LC), and 100 hepatocellular carcinoma (HCC), and 100 healthy donors were enrolled. Serum ALR levels were detected using ELISA and 19 ALR promoter region SNPs were genotyped using PCR. The association between SNPs and ACLF risk was analyzed by the logistic regression model.
**Conclusion:** Serum ALR levels were $2.58 \pm 1.67$, $0.68 \pm 0.24$, $1.53 \pm 0.97$, $1.74 \pm 1.29$, and $0.72 \pm 0.29$ in ACLF, CHB, LC, HCC, and NC, respectively ($F = 7.028$, $P < 0.01$). Compared to healthy control, ACLF and HCC patients had dramatically elevated levels of serum ALR ($P < 0.01$ and $P = 0.035$, respectively). High levels of serum ALR predicted a better ACLF prognosis (OR, 6.4; 95% CI, 2.126–19.585; $P < 0.001$). Furthermore, four of the 19 ALR promoter region SNPs (G-721A, T-1199C, C-559A, and T-1285C) were associated with risk of developing ACLF ($P < 0.05$). However, none of these 19 SNPs was associated with serum ALR levels in ACLF patients ($P > 0.05$).
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0011 THE ROLE OF SARTANS (TELMISARTAN OR OLMESARTAN) IN DECREASE OF INTERLEUKIN-6 LEVEL IN PATIENTS WITH STEATOHEPATITIS COMBINED WITH ARTERIAL HYPERTENSION AND OBESITY

E. Sklyarov[1], **O. Bochar**[1], V. Bochar[2]

**Contact E-mail Address:** bovotar@ukr.net.
**Introduction:** Non-alcoholic fatty liver disease (NAFLD) is one of the most widely spread chronic liver diseases of non-viral and non-alcoholic etiology. In recent years, a steady increase in the incidence of non-alcoholic steatohepatitis, which ranks 2nd among chronic liver diseases, is seen. In 14–20% of cases, NAFLD is combined with cardiovascular pathology, in particular – with arterial hypertension and coronary heart disease. An important role in the progression of these comorbid conditions is played by cytokines, especially interleukin-6. This pro-inflammatory cytokine stimulates the hepatic lipogenesis and is associated with obesity and insulin resistance.
**Aims & Methods:** The aim of the study was to assess the dynamics of interleukin-6 level and lipid spectrum of the blood in patients with steatohepatitis combined with arterial hypertension and obesity during administration of olmesartan or telmisartan in complex treatment with atorvastatin. The study enrolled 44 patients with steatohepatitis combined with arterial hypertension and obesity. Women and men were of equal average age – $55.6 \pm 1.5$. After initial tests for blood lipid spectrum and interleukin-6 level, all patients were divided into 2 groups. Throughout 12 weeks, the patients received sartans in standard dosages: 1st group – telmisartan, 2nd – olmesartan. In both groups, treatment was combined with atorvastatin.
**Results:** The therapy was effective in 17 (77.3%) patients in the 1st group and in 13 (59%) patients of 2nd group. Comparison of IL-6 levels in patients, who received both telmisartan and olmesartan, revealed a significant decrease of IL-6 level ($p < 0.001$). In addition, the study showed that 12 week-long administration of olmesartan or telmisartan in complex treatment with atorvastatin resulted in a significant decrease in levels of total cholesterol ($p < 0.01$) and LDL cholesterol ($p < 0.05$). At the same time, there was no significant difference in the levels of triglycerides and HDL cholesterol ($p > 0.05$).
**Conclusion:** Administration of olmesartan or telmisartan in complex treatment with atorvastatin in patients with steatohepatitis combined with arterial hypertension and obesity leads to inhibition of inflammatory responses which follow the course steatohepatitis. This is proven by the significant decrease of interleukin-6 level in both groups of patients ($p < 0.001$). In addition, the given combination of drugs significantly improves lipid metabolism by reducing the levels of total cholesterol ($p < 0.01$) and LDL cholesterol ($p < 0.05$).
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0012 BACTERIAL ENDOTOXIN SIGNIFICANTLY DETERIORATE CONSEQUENCES OF EXPERIMENTAL LIVER INJURY THROUGH "EXPLOSION" OF CYTOKINES

**A. Sydorchuk**[1], R. Sydorchuk[1], P. Fomin[2], L. Sydorchuk[1], I. Sydorchuk[1]

[2]*National State Medical University, Kyiv/Ukraine*

**Contact E-mail Address:** rsydorchuk@ukr.net.
**Introduction:** Liver injury causes extensive immunological pro-inflammatory response characterized by significant growth of IL-1$\beta$, TNF$\alpha$, IL-6 and other pro-inflammatory mediators. Gram-negative bacteria infection exposes immune cells to lipopolysaccharide (LPS) from the bacterial cell membrane that induces a rapid cytokine response, which is essential for the activation of host defences against the invading pathogens. Following idea that microbial endotoxins cause similar immune reactions to liver injury we hypothesize that these effects may combine and/or even multiply.
**Aims & Methods:** The aim of this study is to determine the aetiology role for inflammatory/immunologic changes following liver injury emphasizing bacterial endotoxin as an experimental background for treatment corrections. Liver injury was modelled experimentally in 87 Wistar rats under general anaesthesia; sutures were applied immediately. Forty-five rats (51.72%) additionally received *S.typhimurium* endotoxin intraperitoneally. Twenty healthy rats formed control. Liquid chromatography and ELISA were used for determination of cytokines (TNF-$\alpha$, TGF-$\beta$1, IL-1$\beta$, and $\gamma$-INF) levels in liver tissue homogenates taken 24 hrs after injury.
**Results:** Aseptic liver injury alone cause minor changes in cytokines levels in liver homogenates compared to control: IL-1$\beta$ grew insignificantly ($55.72 \pm 8.30$ pg/g of homogenated hepatic tissue under liver injury compared to $45.37 \pm 5.82$ pg/g in healthy control rats, $p > 0.05$); TNF-$\alpha$ – $39.26 \pm 4.89$ pg/g and $47.63 \pm 6.47$ pg/g, $p > 0.05$, respectively; gamma-interferon ($\gamma$-INF) – $112.9 \pm 7.62$ pg/g and $123.9 \pm 10.75$ pg/g, $p > 0.05$; TGF-$\beta$1 – $204.5 \pm 12.17$ pg/g and $196.2 \pm 6.42$ pg/g, $p = 0.06$. Endotoxin added intraperitoneally caused explosive growth of cytokines in liver tissue homogenates: IL-1$\beta$ increased over 80% to $74.27 \pm 8.09$ pg/g, $p < 0.01$; TNF-$\alpha$ grew 45% to $56.91 \pm 6.53$ pg/g, $p < 0.05$; $\gamma$-INF level ($419.16 \pm 30.68$ pg/g) raised 3.7 times compared to liver injury without endotoxin, $p < 0.001$. In contrast, TGF-$\beta$1 remained almost unchanged – $236.16 \pm 25.68$ pg/g, $p > 0.05$.
**Conclusion:** Although liver injury is generally accompanied by pro-inflammatory tendencies, though they are generally insignificant in case of isolated aseptic and immediately cured trauma. However, this presents the ideal, theoretic condition; raised endotoxin level is inevitable in case of real clinical situation related to acute trauma or chronic liver disease. Changes of microbiome and rapid release of endotoxin play an even more important role than the liver injury itself, which rather acts as a trigger factor. Obtained data shows that better control of microbial lipopolysaccharide-endotoxin influence must be ensured in order to achieve sufficient results and prevent further liver inflammation. This may be valid for not only trauma itself but also any liver injury including surgery and possibly autoimmune disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0013 FUNGAL INFECTIONS IN CIRRHOTIC PATIENTS – MARKER FOR AN ADVERSE OUTCOME?

**D. Branquinho**, A. Oliveira, C. Gregório, C. Sofia
*Dept. Of Gastroenterology, Coimbra University Hospital, Coimbra/Portugal*

**Contact E-mail Address:** diogofbranquinho@yahoo.com.
**Introduction:** Liver cirrhosis is increasingly being considered a state of immunosuppression and sepsis is nowadays seen as a major threat for these patients. Due to increased use of broad-spectrum antibiotics, particularly for the prophylaxis of spontaneous bacterial peritonitis, fungal infections are a growing concern in Hepatology.
**Aims & Methods:** Our objective was to evaluate the impact of fungal infections on the prognosis of decompensated cirrhotic patients. Two groups of decompensated cirrhotic patients were compared (2010–2014). Group A included patients with a documented fungal infection. Group B patients had no evidence of fungal infection. Clinical, biochemical and microbiological data was collected. Short and long-term prognosis of the two groups was compared.
**Results:** A total of 86 patients were included (Group A–34; Group B–52). In both groups, there was a predominance of male patients (Group A–70.6%; B–90.4%), with similar average age (A-$64.8 \pm 8.3$; B-$63.2 \pm 7.8$ years-old). Group B patients had more severe liver disease, as 76% were classified as Child-Pugh Class C vs 41.2% in group A ($p < 0.0001$); average MELD score was also higher in group B (16.9 vs 18.7; $p > 0.05$). Patients with fungal infections (Group A) had a significant longer length of stay (LOS) – 22.6 vs 10.2 days ($p < 0.001$). The mortality rate as inpatients and in the 3 months following discharge was also much higher in group A (inpatient mortality: 52.9% vs 4%, $p < 0.0001$; 3 month mortality: 29.4% vs 9.6%, $p = 0.0001$).
Further analysis of group B revealed that admission was mainly due to portosystemic encephalopathy (23%), followed by spontaneous bacterial peritonitis (17.6%) and urinary sepsis (17%). Fungal infections were caused by *Candida albicans* in 64.7%, while other Candida species were responsible for the remaining cases. About two-thirds involved the urinary tract. Fluconazol and Anidulafungin were the preferred antifungal agents (70.6% and 18.5%, respectively). The average number of antibiotics used before the diagnosis of fungal infection was 1.5 (0–4).
**Conclusion:** In our study, fungal infections were undoubtedly associated with an adverse outcome, with longer LOS and significantly higher mortality rates, despite occurring in patients with less severe liver disease. In decompensated cirrhotic patients, especially if exposed to broad-spectrum antibiotics, careful search for fungal infections and appropriate treatment should be systematically adopted.

**Introduction:** The bacterial overgrowth in the intestine, disruption of the balance in the gut microbiota (dysbiosis) may have an effect on NAFLD pathogenesis. The purpose of the present study is to compare the gut microbiota of the patients with NAFLD and the healthy controls by quantitative Real Time PCR (qPCR) analysis. Gut microbiota is affected by environmental and specific dietary patterns. This is the first study in Turkish NAFLD patients with diverse cultural dietetic habits. In order to understand the potential role of gut dysbiosis and subsequent translocation of bacterial products, serum endotoxin levels were also analyzed.
**Aims & Methods:** The stool and serum samples from 52 NAFLD patients and 38 healthy controls have been collected. qPCR analysis of *Akkermansia muciniphila*, *Faecalibacterium prausnitzii*, *Lactobacillus spp.*, *Bifidobacterium spp.*, *Bacteroides fragilis* group was performed. Serum endotoxin levels were also determined by Chromogenic LAL Assay. Dietary habits were analysed by nutritional questionnairs.
**Results:** *Akkermansia muciniphila* and *Bacteroides fragilis* group were significantly lower in patients with NAFLD as compared with the healthy control ($p < 0.001$). No significant difference was determined in terms of *Lactobacillus spp.*, *Bifidobacterium spp.* and *Faecalibacterium prausnitzii* counts. Moreover, significantly elevated endotoxin levels were determined in NAFLD patients (9.04 EU/mL in NAFLD group; 2.75 EU/mL in control group; $p < 0.05$).
**Conclusion:** *Akkermansia muciniphila* and *Bacteroides fragilis* group has been known to have beneficial effects on gut barrier function. These two bacterial groups were decreased in Turkish NAFLD patients. Decreased levels of these bacteria were also shown in metabolic syndrome, which is frequently associated with NAFLD. NAFLD patients have also increased endotoxin levels which indicate a translocation of bacterial products as a result of increased gut permeability.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0015 RETROSPECTIVE ANALYSIS OF THE MICROBIAL EPIDEMIOLOGY OF SPONTANEOUS BACTERIAL PERITONITIS AND BACTERIASCITES IN PATIENTS WITH LIVER CIRRHOSIS

**Introduction:** Current guidelindes recommend the use of 3rd generation cephalosporines for antibiotic therapy of spontaneous bacterial peritonitis (SBP). Response rates to this therapy are reported with 76–98%. Bacterial translocation of grampositive bacteria including enterococcae and specific local resistance patterns may result in inferior response rates to 3rd generation cephalosporines. Knowledge on local microbial epidemiology privides evidence to optimize antibiotic therapy.
**Aims & Methods:** Microbial epidemiology of ascitic fluid cultures and resistance patterns obtained from patients with liver cirrhosis between 2013–2015 at a tertiary care center (Krankenanstalt Rudolfstifung, Vienna) were retrospectively analyzed.
**Results:** In total 482 ascites cultures of 200 cirrhotic patients were analyzed. Median age was 62.2 (31.2–91.8) years, the majority (73%, M:146/F:54) were men, and the main etiology was alcoholic liver disease (83% ALD), followed by viral hepatitis (8.9%), autoimmunie (0.8%), and cryptogenic (7.3%). Thirty-one (6.4%) of ascitic fluid cultures reveiled positive results, and 12.5% of all patients (25/200) had at least one positive culture result. While 17 (3.5%) of patients had bacteriascites, 58 (12%) of patients had SBP – among those 47 (81%) had no germ isolated at their asicitic fluid culture. The most common species were *Streptococcus spp.* (n = 7/22.6%) followed by *Candida spp.* (n = 6/19.4%), *E. coli* and *Staphylococci* (n = 5/16.1%) and *Enterococci* (n = 3/9.7%). 28% of all bacteria were resistant towards aminopenicillines/betalactamase-inhibitors. There was a resistance rate of 18.5% of all germs towards 3rd generation cephalosporines.
**Conclusion:** Considering the local microbial epidemiology, the initial empirical antibiotic treatment for SBP should have good efficacy from grampositive bacteria including Enterococci. The recommendation for empiric antibiotic therapy of patients with liver cirrhosis with inherent immunosuppression should be adapted according to local resistance rates.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0016 THE ADAPTOR PROTEINS CARDIF/STING NEGATIVELY REGULATE THE PROLIFERATION OF LIVER REGENERATION AFTER PARTIAL HEPATECTOMY IN MICE

**S. Schulze**, M. Lu, B. Holzmann, H. Friess, N. Hüser, D. Hartmann
*Department Of Surgery, Klinikum rechts der Isar, Technische Universität, Munich/Germany*

**Contact E-mail Address:** sarah.schulze@tum.de.
**Introduction:** The innate immune system is of crucial importance for the regulation of liver regeneration. Nucleic acid sensors are know to play a major role within this context, however, there is only limited knowledge on the role of central adaptor proteins, such as CARDIF and STING, during liver regeneration. The aim of the present study was to analyze CARDIF and STING during liver regeneration. Our hypothesis states that these known modulators of the innate immune system have an influence on liver regeneration by direct activation of CARDIF/STING-dependent cytosolic sensors.
**Aims & Methods:** In order to examine the influence of these two proteins on liver regeneration, we use a newly established CARDIF/STING knockout mouse model and compared it to a C57BL/6 mice control cohort. A 2/3 partial hepatectomy (PH) was performed in both groups and mice were analyzed at eight designated timepoints after surgery (n = 80 mice in total). Liver regeneration was quantified by liver-to-body weight ratio, while proliferation was determined by BrdU staining. Additionally, RNA- and protein levels of proliferation markers were analyzed in resected tissues while pro-inflammatory cytokines were measured in murine serum.
**Results:** CARDIF/STING knockout mice showed a significantly impaired liver regeneration after PH. Additionally, we detected a strong difference in BrdU staining at several time points after PH underlining an inhibition of proliferation in the absence of CARDIF and STING. Expression analysis of Interleukin-6 (IL-6) revealed a significant decrease in the wild type cohort after PH. In addition, the membrane-bound form of the IL-6 receptor was found to be increased in the control group 2, 4 and 8 h after PH, while the soluble form of the receptor was significantly increased 12 h post-PH. In CARDIF/STING knockout mice, the proliferation marker Cyclin D1 was decreased until 24 hours after surgery, while $p21^{Cip1}$ expression, which is associated with a cell cycle arrest, was increased 8 h post-PH.
**Conclusion:** Together, these data provide the first experimental evidence that CARDIF/STING knockout mice show a delayed liver regeneration. These data support the concept that CARDIF and STING play a major role in liver regeneration during physiological conditions. In the absence of these two proteins, we observed a modulated immune response which lead to a negative regulation of the proliferative capacity in liver after partial hepatectomy. This finding could impact on the future development of molecular therapies making use of the innate immune system.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0017 THE ROLE OF GENETICALLY MODIFIED HSCS IN LIVER REGENERATION AFTER ACUTE LIVER DAMAGE

**E.I. Sharipova**[1], A. Titova[1], A. Shafigullina[1], E. Garanina[2], M.O. Mavlikeev[1], G. Pevnev[1], G.R. Burganova[3], A.A. Gumerova[4], M.A. Titova[1], A. Rizvanov[1], A.P. Kiyasov[1]

**Introduction:** Actual problem of modern hepatology is to find a new treatment for liver diseases. Nowadays gene and cell therapy methods using hepatic stellate cells (HSCs) that are thought to be regional stem cells of the liver, are considered as a new perspective approach. It is assumed that using genetically modified cells that express and overexpress therapeutic factors, could reduce the therapeutic dose of transplanted cells and enhance therapeutic effects of these cells. However, it remains unclear, the influence of genetically modified cells, in this case HSCs, on liver regeneration and therapeutic effects of these cells after transplantation into the organism.
**Aims & Methods:** We aimed to study the role of genetically modified HSCs (by using the adenoviral vector Ad5-optHGF-optFGF4-RFP) on liver regeneration after transplantation into the rats with acute liver damage. Genetic modification of HSC was carried out by using adenoviral vector Ad5-optHGF-optFGF4-RFP, which contains hepatocyte growth factor (HGF), fibroblast growth factor-4 (FGF-4), and red fluorescent protein (RFP). We selected the classical model of acute liver damage – partial hepatectomy (PH). Genetically modified HSC were injected into portal vein during the PH operation. Control group of animals have received the same cells without PH operation. The animals were sacrificed after 1, 2, 3, 5, 7, 14, 28 days after the transplantation of HSC. Paraffin slices were stained by immunohistochemistry with antibodies to RFP, desmin – marker of HSC and a-SMA – myofibroblast marker.
**Results:** RFP + cells were detected in parenchyma in both groups even at first days after transplantation. They varied in shape and location in the liver in different days of experiment. Small oval-shaped RFP + cells were stained from the first day near the portal tracts. At the same time hepatocyte-like RFP + cells were also found here from the first day. Maximal number of such cells was found on the 5th day after transplantation in both groups, but in the experimental group average number of cells was higher than in control. Coincidently, the intensity

and quickness of hepatocyte repopulation in liver were higher in the group of animal after PH. Number of desmin + cells increased more in the experimental group comparing with the control one. In both groups a-SMA-positive cells were not detected.
**Conclusion:** Genetically modified HSCs, which is transduced by HGF and FGF-4 genes, save their viability after transplantation into the rat after PH, migrate and integrate into the liver parenchyma. These cells have a positive influence on the process of liver regeneration without the risk of liver fibrosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0018 ANGIOTENSIN II TYPE 1 RECEPTOR GENE A1166C POLYMORPHISM IS ASSOCIATED WIT NON ALCOHOLIC FATTY LIVER DISEASE AND PREDICTS ITS SEVERITY

**A. Eshraghian**[1], S. Iravani[2], P. Azimzadeh[2]

[2]*Gastroenterology And Hepatology, AJA University of Medical Sciences, Tehran, Tehran/Iran*

**Contact E-mail Address:** eshraghiana@yahoo.com.
**Introduction:** The pathogenesis of non alcoholic fatty liver disease (NAFLD) has not been well demonstrated yet, however, genetic predisposition is probably of major importance. Angiotensin II type I receptor (AGTR1) have been known to be involved in the process of liver fibrosis and metabolic syndrome.
**Aims & Methods:** This study aimed to investigate the association between AGTR1 A1166C polymorphism and NAFLD. A cross-sectional study was conducted between March 2014 and March 2015 among healthy adult individuals referred to our radiology clinic for abdominal ultrasonography. NAFLD was diagnosed by an expert radiologist based on the presence of these ultrasonographic findings: hepatorenal echo contrast, liver brightness, deep attenuation, vascular blurring and the absence of hepatitis B surface antigen or antibody to hepatitis C virus, 2) alcohol consumption (>20 g/day), 3) history of other causes of liver disease, and 4) medications known to produce fatty liver disease during the last six months prior to the study. Participants' characteristics and their lab data including liver function tests, lipid profile, fasting plasma glucose (FPG) were also recorded. AGTR1 A1166C polymorphism was checked in subjects with NAFLD and healthy controls using TaqMan allelic discrimination method.
**Results:** Fifty eight subjects with NAFLD were compared with 88 individuals without NAFLD. Mean of all anthropometric indices including BMI, weight, height, waist circumference and hip circumference were significantly higher in subjects with NAFLD compared to those without NAFLD ($P < 0.05$). Mean total cholesterol was significantly higher in subjects with NAFLD in comparison to the controls in univariate analysis ($P = 0.018$). Higher serum ALT was also a predictor of NAFLD ($38.56 \pm 17.61$ versus$20.76 \pm 6.40$ IU/L) ($P = 0.0001$). Metabolic syndrome was detected in 31 (53.44%) individuals in NAFLD group and in 27 (19.01%) in control group ($P < 0.001$) (OR: 3.51, 95% CI: 1.84–6.66). Multivariate logistic regression analysis of risk factors showed that body mass index (BMI), metabolic syndrome, waist circumference, hip circumference and serum ALT were independent predictors of NAFLD in our study population. The frequency of AA and CC genotypes of AGTR1 gene was significantly higher in patients with NAFLD compared to controls ($P = 0.029$ and $P = 0.042$ respectively). Furthermore, C allele was more detected in subjects with NAFLD compared to healthy controls (OR: 2.1; 95% CI: 1.23–3.61, P-Value = 0.006). CC genotype (OR: 10.62; 95 %CI: 1.05–106.57, P-Value: 0.045) and C allele (OR: 6.81; 95 %CI: 1.42- 32.48, P-Value: 0.016) were also predictors of severe fatty liver disease in our study population.
**Conclusion:** Our results provide the first evidence that AGTR1 gene A1166C polymorphism not only is associated with NAFLD and but also may predict its severity. Multivariate regression analysis for the NAFLD predictors.

| | OR | (95% CI) | P-value |
|---|---|---|---|
| Body mass index (BMI) | 7.74 | (1.25-3.73) | 0.005 |
| Waist circumference | 9.26 | (0.68–0.92) | 0.002 |
| Hip circumference | 5.21 | (1.02–1.39) | 0.022 |
| Metabolic syndrome | 15.21 | (9.74–14.43) | <0.001 |
| Alanine aminotransferase (ALT) | 26.46 | (1.19–1.50) | <0.001 |

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Progressive growth of hepatic cysts can lead to symptomatic hepatomegaly in polycystic liver disease (PLD).
**Aims & Methods:** Our primary aim was to determine at which threshold of liver volume PLD patients become symptomatic. As a secondary objective we investigated which symptoms are associated with higher liver volume. We used the PLD questionnaire (PLD-Q), a validated questionnaire that assesses frequency and discomfort of PLD-related symptoms, to determine the symptom burden. In a cohort of 291 PLD patients that have completed the PLD-Q and rated themselves as symptomatic or not (NCT02173080), we have defined the PLD-Q cut-off value of being symptomatic with receiver operating characteristic (ROC) analysis. The optimal PLD-Q cut-off score was 31 points with an area under the curve (AUC) of 0.832 ($p < 0.001$). Next, we used baseline data of PLD patients from two prospective studies (DIPAK observational study and CURSOR randomized controlled trial (NCT02021110). All patients completed the PLD-Q and had liver volume imaging (CT or MRI) measured by segmentation. In order to determine the liver volume cut-off value for being symptomatic, we used the PLD-Q cut-off value from the previous step in another ROC analysis with liver volume as independent variable. Spearman correlations were calculated between symptoms and liver volume.
**Results:** We included 82 of the 131 patients from the prospective studies (main exclusions: no PLD n = 26, no PLD-Q n = 7 or no imaging n = 8). Most patients were female (n = 67) with a mean age of 48 years. Median liver volume was 3879 mL (IQR: 2452 – 5891). Cut-off liver volume for being symptomatic was 3472 mL (AUC 0.805, $p < 0.001$) with a sensitivity of 80% and a specificity of 73%. This cut-off volume has a positive and negative predictive value of 66% and 82% respectively. Dissatisfaction with abdomen size was strongly correlated with liver volume (r = 0.63). Fullness, early satiety, pain in rib cage, shortness of breath, limited mobility, anxiety about the future and, problems with intercourse correlated moderately (r = 0.40–0.59). There was a weak correlation with lack of appetite, pain in side and tiredness (r = 0.20–0.39). Nausea (r = 0.17, p = 0.146) and abdominal pain (r = 0.17, p = 0.127) were not correlated with liver volume.
**Conclusion:** Patients with liver volumes equivalent to two times the normal size are likely to develop PLD-related symptoms. In patients with smaller livers, other causes that lead to similar symptoms should be considered. Most PLD-related symptoms are associated with larger liver volume, except for nausea and abdominal pain.

## P0020 LNCRNA PROFILE IN NAFLD AND IDENTIFICATION OF A PROTECTIVE NOVAL LNCRNA FLRL2 IN NAFLD

**Y. Chen**, C. Xu, C. Yu, Y. Li
*Department Of Gastroenterology, the First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou/China*

**Contact E-mail Address:** 11218285@zju.edu.cn.
**Introduction:** Non-alcoholic fatty liver disease (NAFLD) is one of the most prevalent chronic liver diseases worldwide with unclear mechanism. Long noncoding RNAs (lncRNAs) have recently emerged as important regulatory molecules in liver diseases.
**Aims & Methods:** To further understand the pathogenesis of NAFLD, lncRNA and mRNA microarray was conducted in NAFLD mice model. Potential target genes of significantly changed lncRNA were predicted using cis/trans-regulatory algorithms, followed by Gene Ontology analysis and KEGG pathway enrichment analysis. NAFLD mice model and NAFLD AML12 cell model were used in further experiments. Real-time qPCR and Western Blot were adopted in effect test after manipulations with certain siRNA or shRNA transfection. Oil Red O/ HE staining and total triglyceroil kit were applicated in celllular steatosis evaluation. Dual luciferase assay was used in identifying promoter activity of certain genes.
**Results:** In current analysis, 89 up-regulated and 177 down-regulated mRNAs were identified, together with 291 dysregulated lncRNAs. Bioinformatic analysis of these RNAs has categorized these RNAs into pathways including arachidonic acid metabolism, circadian rhythm, linoleic acid metabolism, Peroxisome Proliferator Activated Receptor signaling pathway, sphingolipid metabolism, steroid biosynthesis, tryptophan metabolism and tyrosine metabolism were compromised. Quantative PCR of 9 mRNAs and 8 lncRNAs of interest (named as fatty liver related lncRNA, FLRL) was conducted and verified previous microarray results. Several lncRNAs, such as FLRL1, FLRL6 and FLRL2 demonstrated to be likely a key player in circadian rhythm targeting Per3, Per2 and Arntl. While FLRL8, FLRL3 and FLRL7 showed their potential role in PPAR signaling pathway through interaction with Fabp5, Lpl and Fads2. Mechanism of FLRL2 as well as its potential target circadian rhythm gene Arntl was investigated. Western blot and qPCR both revealed a decreased trend of FLRL2 as well as Arntl in NAFLD in vivo, in vitro models. Overexpression of FLRL2 reverses lipid accumulation, ER stress and lipogenesis, which are main

pathophtsiological changes in NAFLD. In the mean while, shRNA knock down of FLRL2 lead to excerbation caused by FFA treatment, a classical NAFLD cell model. Bioinformatic analysis pointed to potential cis-interaction of FLRL2 and Arntl gene. Both knock-down or knock in of FLRL2 caused possitive feedback of Arntl expression. As a clock protein, Arntl has been identified to be a Sirt1-regulator through transcriptoin level. Dual luciferase assay has proved interaction between Arntl and Sirt1 gene promoter, which was inhibited in NAFLD cellular model and rescued by Arntl overexpression. Similar with FLRL2, inhibition of Arntl led to NAFLD excerbation, while overexpression played a protective role, measured by ER stress, lipid accumulation and over-lipogenesis.
**Conclusion:** This is the first study focusing on NAFLD lncRNA profile in rodent model and also first time in identification of NAFLD-related FLRL2 as well as mechanism exploration. We characterized global changes in lncRNAs and mRNA in NAFLD. 89 up-regulated and 177 down-regulated mRNA were identified, and 291 dysregulated lncRNAs, with 111 increased and 180 decreased were discovered. Function of these changes hasn't be fully elucidated, but potential pathways involved were predicted, such as arachidonic acid metabolism, circadian rhythm, linoleic acid metabolism, PPAR signaling pathway, sphingolipid metabolism, steroid biosynthesis, tryptophan metabolism, tyrosine metabolism. Among all changed lncRNAs, FLRL2 showed potential role in NAFLD pathogenesis through Arntl-Sirt1 axis. Current study provided new insight into pathogenesis of NAFLD, involving lncRNAs. Further study will focus on the molecular mechanism of these changes as well as interacting pattern of FLRL2 and Arntl.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0021 NON-ALCOHOLIC FATTY LIVER DISEASE ASSOCIATED WITH METABOLIC SYNDROME: MAJOR RISK FOR ATHEROSCLEROSIS

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) affects about 1 billion people worldwide. Those with non-alcoholic steatohepatitis (NASH) have increased mortality rates compared to the general population. Cardiovascular diseases are the leading cause of death in NASH patients. Identifying those which are at higher risk for developing cardiovascular events is of major importance, both in terms of prognosis, as in the terms of therapeutic attitude.
**Aims & Methods:** Our aim was to identify those patients which are at higher risk for developing cardiovascular events, by quantifying subclinical atherosclerosis in patients with NAFLD and MS. Through this, we tried to identify a screening strategy for cardiovascular disease and to identify an optimal moment for initiating therapeutic intervention. We included patients with NAFLD and metabolic syndrome (MS), which we divided into 4 arms: patients with NAFLD and with MS, patients with NAFLD without MS, patients with MS without NAFLD and controls. We performed ultrasound measurement of the carotid intima-media thickness (common carotid artery, 1 cm before the bifurcation). Values above 0.06 were considered increased. Values above 0.12 cm were considered as atherosclerotic plaques. We used Fibromax for evaluating NAFLD severity (presence of NASH, degree of fibrosis and steatosis). We performed liver enzymes determination, lipid profile, glycaemic profile and antropometric measurements. We determined the levels of IL-6, IL-18, adiponectine and leptine. For statistical analyses we performed chi-squared test, Fisher exact test, Kruskal-Wallis and Mann-Whitney tests, ANOVA test, Spearman's rank correlation coefficient using R Foundation for Statistical Computing, IBM SPSS v.19 and Statistics v.6.0.
**Results:** We included 157 patients in all 4 arms, with no significant differences regarding the age ($F(3.153) = 2.74$, $p = 0.05$) and sex ($\chi2(1) = 2.99$, $p = 0.392$). Patients with NAFLD and MS had intima-media thickness values greater than those with NAFLD without MS ($U = 708.5$, $p = 0.002$) and greater than controls ($U = 498$, $p < 0.001$). Between intima-media thickness values in those with isolated MS and in those with NAFLD with MS, no significant differences were found ($U = 407.5$, $p = 0.21$). In all patients with NAFLD, with and without MS, there was a correlation between the value of intima-media thickness and the presence of NASH ($U = 225$, $p = 0.025$), the degree of steatosis ($\rho = 0.296$, $p = 0.027$) and the degree of fibrosis ($\rho = 0.466$, $p < 0.001$). We identified in all patients with NAFLD, with and without MS, a positive monotonous correlation between the degree of steatosis and leptin ($\rho = 0.3$, $p = 0.025 < 0.05$). These levels of leptin were higher in those with more severe steatosis. Also in this group of patients we identified a good positive correlation between the interleukin 18 and the presence of NASH ($\rho = 0.701$, $p < 0.001$). Those with NASH had higher values of interleukin 18. The presence of atherosclerotic plaque has been influenced by the the degree of fibrosis ($U = 131$, $p < 0.001$). The sex of the patients ($\chi2(1) = 0.30$, $p = 0.638$) and the level of total cholesterol ($U = 738$, $p = 0.438$), LDL-cholesterol ($t(91) = 0.67$, $p = 0.505$), HDL-cholesterol ($t(93) = 0.75$, $p = 0.458$), and triglycerides ($U = 803.500$, $p = 0.911$) did not affect the presence of atherosclerotic plaque, nor on the entire group of patients or on each arm. In the logistic model for the prediction of the risk for developing atherosclerotic plaque, the degree of fibrosis was a predictor with a positive effect on the presence of atherosclerotic plaque ($p = 0.004$, adjusted $OR = 7.19$).
**Conclusion:** The patient with NAFLD was found to be atypical for the development of cardiovascular risk. The association between NAFLD and MS predisposes to an increased cardiovascular risk. The development of MS in patients with NAFLD implies the acceleration of atherosclerosis and thus increasing the cardiovascular risk. The determination of leptin, interleukin 18, as well as performing ultrasound measuring of the carotid intima-media thickness may be useful to quantify the severity of liver disease. The characterization of the liver disease and, especially the grading of fibrosis, has proved to be an important prognostic factor for cardiovascular disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0022 CAUSES OF DEATH IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE: RESULTS FROM A TERTIARY HOSPITAL IN SOUTH CHINA

**J. Ye**, M. Li, W. Yanqin, B. Zhong
*Gastroenterology, The First Affiliated Hospital Of Sun Yat-Sen University, Guangzhou/China*

**Contact E-mail Address:** 1044050245@qq.com.
**Introduction:** Non-alcoholic fatty liver disease (NAFLD), which would progress to cirrhosis and hepatocellular carcinoma, is the most rapidly increasing hepatic diseases worldwide and has become the leading cause of chronic liver disease in China. There is no published data related to NAFLD mortality from Chinese subjects.
**Aims & Methods:** This cross-sectional study was designed to analyze the causes of death and clinical characteristics among death cases with NAFLD in south China. The clinical information of patients who died during hospitalization in the First Affiliated Hospital of Sun Yat-sen University from January 2009 to December 2011 was collected from medical records. NAFLD was diagnosed only if fatty liver was confirmed by imaging examination, either by ultrasound, computed tomography or magnetic resonance imaging. Exclusion criteria included overdrinking and with other liver disease. ICD-10 death classification was used to investigate the cause of all deaths. Clinical and laboratory tests for patients were analyzed and compared with the other death cases without NAFLD.
**Results:** In total, 694 patients had available radiological data, including 102 (14.6%) of patients with NAFLD and 592 controls. Of NAFLD group, 70 (68.6%) were males and the median death age was $66.53 \pm 23.45$ years. The most frequent death cause was cardiocerebral vascular diseases (39.2%) followed by extrahepatic malignancy (32.3%) , infection (6.9%) and liver related disease (3.9%) . The percentage of patients died of cardiocerebral vascular diseases (39.2%) was significant higher in NAFLD group than that of controls (13.8%, $p = 0.027$), while the rate of NAFLD patients died of liver related disease (3.9%) showed obvious lower than that of controls (13.8%, $p = 0.005$) . According to whether death cause is cardiocerebral vascular diseases (CVD), NAFLD were divided into 2 subgroups, CVD group and non CVD group. CVD group had significantly higher total cholesterol levels ($6.43 \pm 0.63$ mmol/L vs $6.02 \pm 0.87$ mmol/L, respectively, $P = 0.011$) and higher triglyceride ($2.44 \pm 0.82$ mmol/L vs $2.05 \pm 0.76$ mmol/L, $P = 0.015$) and higher LDL- cholesterol ($3.79 \pm 0.43$ mmol/L vs $3.62 \pm 0.35$ mmol/L, $P = 0.031$) compared with non CVD group. There was no difference of body mass index, liver function, blood routine test, blood pressure, fasting serum glucose levels, serum uric acid levels, HDL-cholesterol levels among the two subgroups.
**Conclusion:** Cardiocerebral vascular disease is the predominant death cause in NAFLD participants. Cardiocerebral vascular diseases account for a higher proportion of death cause but liver-related diseases less in NAFLD patients than individuals without NAFLD. NAFLD patients who died of cardiocerebral vascular diseases may have more severe dyslipidemia than those of other death cause.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0023 THE EFFICACY AND SAFETY OF VILDAGLIPTIN TREATMENT FOR NONALCOHOLIC FATTY LIVER DISEASE IN TYPE 2 DIABETES MELLITUS

**M. Celikbilek**[1], Z.T. Ozdemir[2], A. Aktas[2], T. Yildirim[2], H. I. Serin[3]

**Introduction:** It is known that dipeptidyl peptidase-4 inhibitors were useful for the treatment of type 2 diabetes mellitus (DM). However, effects of these drugs on liver function and glucose metabolism in nonalcoholic fatty liver disease (NAFLD) have not been well determined. Except the improvement of glycemic control observed in type 2 DM; dipeptidyl peptidase IV (DPP-4) inhibitors have also been reported to have non-glycemic actions with decreasing receptor for advanced glycation end-products (RAGE) expression [1], vascular relaxation and increasing nitric oxide release [2] reducing lipid and protein oxidation [3] improving hepatic steatosis [4] or anti-inflammatory actions [5]. We evaluated the effect of vildagliptin on nonalcoholic fatty liver which has a widespread use in the treatment of diabetes.
**Aims & Methods:** The aim of this study was to evaluate the effect of vildagliptin on liver functions and hepatic steatosis and also to evaluate efficacy and safety of vildagliptin in NAFLD patients with type 2 DM.Fifty-four patients with Type 2 DM, whom were newly started vildagliptin treatment and diagnosed as NAFLD by ultrasonography, were prospectively enrolled from June 2014 to June 2015 in Bozok University Hospital, Yozgat, Turkey. All patients were subjected to lifestyle intervention of diet and physical exercise after the diagnosis of T2DM. Patients aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma glutamyl transferase (GGT), alkaline phosphatase (ALP), HbA1c,

waist circumference (WC), body mass index (BMI), triglyceride (TG), low-density lipoprotein (LDL), high-density lipoprotein (HDL), and demographic characteristics were recorded before, 3 and 6 months after the initiation of treatment. Liver non-invasive assessment tools such as, Fatty Liver Index (FLI), FIB-4 score, APRI Score, were also evaluated. Vildaliptin treatment was given 100 mg per day.

**Results:** Characteristics of patients were given in Table 1 during and pretreatment time. HbA1c was reduced from $8.48 \pm 1.43\%$ to $7.87 \pm 1.35\%$ ($P < 0.001$). There were no significant difference between patients AST, GGT, ALP, HDL and FIB-4 score before and after treatment values ($P > 0.05$). HbA1c was reduced from 8.95% (8.07–10.35) to 7.00% (6.27–8.10) ($P < 0.001$). During vildagliptin treatment, ALT levels improved from $30.91 \pm 26.48$ to $25.94 \pm 14.8$ IU/L ($P = 0.048$). The serum levels of TG and LDL decreased with statistical significance ($P < 0.05$). WC and BMI were also decreased ($P < 0.001$). FLI and APRI score improved at 6 months after the initiation of vildagliptin. All the patients could take vildagliptin of 100 mg/day without reduction necessitated by related side-effects.

**Conclusion:** Our preliminary study results showed that vildagliptin treatment have positive effect on blood sugar regulation, body composition, ALT and non-invasive liver tools for the treatment of T2DM complicated with NAFLD. Our results indicated that vildagliptin is effective and safe in NAFLD patients with Type 2 DM.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Hyperferritinemia is a common finding in routine laboratory tests.

**Aims & Methods:** To develop and validate a diagnostic algorithm for high iron overload (HIO) based on laboratory and genetic variables.

We collected a retrospective cohort with all consecutive patients between 2001–2008 studied by Magnetic Resonance Imaging (MRI) to determine liver iron concentration (LIC). This cohort served as the derivation set. We analyzed all variables using univariate statistics with the MRI acting as the gold standard. We studied the best combination of the diagnostics variables to build the algorithm. We validated the algorithm in a prospective cohort, collecting all patients referred to our hospital for study of iron metabolism alteration between 2009–2013 (validation set). HIO is considered if the Hepatic iron index (LIC/age) > 1.9 (estimated by MRI).

**Results:** Retrospective cohort: 242 patients (198 men/44 women), mean age 52.4 (SD 13.3). Thirty six of them had HIO. Nearly half of the patients (117/242 = 48.4%) had both Transferrin saturation index (TSI) and Ferritin elevated and 28 (11.5%) were C282Y homozygous. The final algorithm was as follows: We consider a patient as having HIO with the simultaneous occurrence of TSI and Ferritin elevated and C282Y homozygosis. HIO is discarded if TSI or Ferritin are within normal values. The rest should be studied by MRI.

Prospective cohort: 312 patients (272 men/40 women), mean age 55 (SD 13.5). Mean ferritin 729.6 (SD 449.6), mean TSI 40.8 (SD 15.8).

The nosological characteristics of the algorithm in this validation study are: 9 out of 312 (2.9%) were TSI and Ferritin elevated with C282Y homozygosis. Seven of them proved to have HIO by MRI, PPV = 77.8% (45.3 to 93.7). 218 (69.9%) had TSI or Ferritin within normal values. Eleven of them had HIO NPV = 95% (91.2 to 97.2). 85 patients of our sample (27.2%), less than 1/3, needed to have a diagnostic MRI for HIO.

**Conclusion:** MRI is not necessary in 72.8% of the patients for HIO diagnosis. MRI is indicated in patients not C282Y homozygous with raised TSI and Ferritin.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0025 INCREASED FREQUENCY OF KERATIN 8/18 VARIANTS IN CHINESE NON-ALCOHOLIC FATTY LIVER DISEASE PATIENTS: AN ASSOCIATION WITH METABOLIC DISORDERS

**R. Li**, J. Ye, W. Yanqin, M. Li, B. Zhong
*Gastroenterology, The First Affiliated Hospital Of Sun Yat-Sen University, Guangzhou/China*

**Contact E-mail Address:** lyric_mg@sina.com.

**Introduction:** Non-alcoholic fatty liver disease (NAFLD) has the highest incidence of liver disease in Chinese population. Patients with NAFLD not only suffered from liver damage but a multisystem disorder with effects on the cardiovascular system, endocrine system, and kidneys. Keratins 8 and 18 (K8/K18) variants are considered to be involved in kinds of liver disorders and associated with the severity. Our study is the first to identify increased frequency of K8/K18 variants in NAFLD patients.

**Aims & Methods:** We analyzed the entire K8/K18 coding regions (15 exons and exonic-intronic boundaries) in 131 NAFLD patients and 173 controls. PCR-amplified samples were analyzed by DNA sequencing.

**Results:** We identified keratin heterozygous variants in 6 of 131 NAFLD patients (4%), including 2 amino-acid-altering heterozygous variants and 4 non-coding heterozygous variants. One novel amino-acid-altering heterozygous variant (K18 N193S) and three non-coding variants were observed. We found increased frequency of variants in NAFLD patients versus controls (4% vs. 0.58%, $P = 0.021$). Notably, keratin variants significantly associated with homeostatic model assessment-insulin resistance (HOMA-IR) in NAFLD patients (14.3% variants in NAFLD with IR versus 0.58% in control group, $P < 0.001$; 14.3% variants in NAFLD with IR versus 0.00% in NAFLD without IR, $P < 0.001$). Moreover, HOMA-IR and total cholesterol (TC) are higher in patients with keratin variants (HOMA-IR $2.93 \pm 1.26$ vs. $3.92 \pm 1.48$, $P = 0.029$; TC $5.76 \pm 1.03$ vs. $6.84 \pm 1.79$, $P = 0.015$).

**Conclusion:** There is an increased frequency of keratin 8/18 variants in NAFLD patients, and high levels of IR and TC of variant carriers are found suggesting an association with the severity of metabolic disorders.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0026 ASSESSMENT OF THE CLINICAL IMPACT OF MULTIDRUG-RESISTANT BACTERIA IN CIRRHOTIC PATIENTS

**A.G. G. Antunes**[1], C. Teixeira[2], A. Vaz[1], C. Martins[2], P. Queirós[3], A. Alves[2], B.M. Santos Peixe[1], A. P. Oliveira[2], H. Guerreiro[1]

[3]*Gastroenterology, Centro Hospitalar do Algarve, Faro/Portugal*

**Contact E-mail Address:** sergiogiao@hotmail.com.

**Introduction:** Bacterial infections are common in cirrhotic patients and are associated with poor prognosis. Literature reports an increasing incidence of infections by multidrug-resistant bacteria (MDR) in this group of patients, compared to the general population. The real clinical impact of these bacteria on short and medium term prognosis is not fully established. [1–2].

**Aims & Methods:** 1) to analyze at admission the incidence of MDR-bacteria in patients with decompensated cirrhosis; 2) to identify predictive factors for its development; 3) to study its impact in 30 and 90-day mortality. Retrospective cohort study, conducted in 2 centers that evaluated hospitalizations for decompensated cirrhosis between 2011 and 2014. We excluded patients without microbiological cultures at admission. MDR-bacteria were defined as strains resistant to at least three of the main antibiotic families including beta-lactam. Diagnosis of infections at admission (<24 h) was made according to conventional criteria.

**Results:** We identified a total of 779 hospitalizations, from those 349 patients met criteria for infection at admission (nosocomial: 27.5%). The 30 and 90-day mortality was 17.7% and 37.3% respectively. The most common infection was spontaneous bacterial peritonitis (n = 122), followed by urinary tract infections (n = 93) and pneumonia (n = 55). We obtained a total of 161 microbiological isolations (gram negative bacteria: 52.2%) from which 67 were considered to be MDR-bacteria; in 18.18% of the community-acquired infections was isolated a MDR-bacteria and 20.93% in the nosocomial-acquired group. There was no predominance of any gram class when evaluated MDR-bacteria ($p = 0.525$), and the most frequent isolated bacteria were extended spectrum beta lactamase positive *Escherichia coli* (n = 22), *Enterococcus faecalis* (n = 16) and methicillin resistant *Staphylococcus aureus* (n = 8). No statistical significantly difference was noticed between centers, when analyzed microbiological isolations rate. In multivariate analysis, we failed to identify risk factors for the development of MDR-bacteria (studied variables: hospitalization in the last 3 months; primary or secondary prophylaxis of spontaneous bacterial peritonitis; use of systemic antibiotics and gastrointestinal bleeding in the last month; continuous use of proton pump inhibitors in the last 3 months). In the univariate analysis, MDR-bacteria isolation were not associated with increased mortality at 30 ($p = 0.159$) neither at 90 days ($p = 0.673$), but they were associated with an increased length of hospitalization (MDR = 17.88 vs multidrug-susceptible strains = 13.80 days; $p = 0.045$).

**Conclusion:** 1) we identified a high and worrisome prevalence of MDR-bacteria in our sample (42.1% of the total bacterial microbiological isolations; community-acquired infections: 18.18%); 2) we failed to identify risk factors for its development, possibly because of the retrospective nature of our study, the heterogeneity of the infections that were evaluated and patients could had a previous colonization by MDR-bacteria without developing an active infection until an unbalancing event occurred; 3) microbiological isolation of a MDR-bacteria was not associated with a higher 30 or 90-day mortality. The results of this study which derive from a two-center retrospective experience, with a specific epidemiological pattern of multiresistance, cannot be fully generalized; however it indicates an alarming pattern of infections by MDR-bacteria on community-acquired infections, challenging the current international guidelines for bacterial infections in cirrhotic patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Variceal hemorrhage is a frequent and severe complication in patients with cirrhosis and portal hypertension. Transjugular intrahepatic portosystemic shunts (TIPS) are used for treatment of severe acute variceal bleeding episodes or in patients with failure of secondary prophylaxis.
**Aims & Methods:** In this retrospective cohort study, cirrhotic patients undergoing TIPS implantation in two specialized centers in Vienna in 1994–2014 for secondary variceal bleeding prevention were included. Variceal re-bleeding events, TIPS patency, mortality and transplant free survival (TFS) were evaluated.
**Results:** 286 cirrhotic patients received TIPS for secondary prophylaxis of variceal bleeding. During a median (transplant-free) follow-up of 821 days, 67 patients (23%) experienced at least one re-bleeding event. Patients with isolated esophageal varices were at highest risk of re-bleeding (85% occurred in esophageal varices, 0% in isolated gastric varices, 15% in unspecified locations). Patients with expanded polytetrafluorethylene (ePTFE)-covered stents ($n = 167$) were at significantly lower risk for variceal re-bleeding than patients with bare-metal stents [$n = 119$; 14% vs. 37%, respectively, $p < 0.001$; OR at 1 year: 0.259 (95% confidence interval: 0.123–0.542, $p < 0.001$)]. Conversely, revisions due to shunt dysfunction were more common in bare metal than in ePTFE- stents (24% vs. 14%, respectively; log-rank: $p = 0.011$). More patients without re-bleeding within 1 year received non-selective beta blockers (NSBB) than re-bleeders (16% vs 6%, $p = 0.059$). Although overall transplant-free survival was similar between groups (47.4 vs. 43.6 months for ePTFE vs Bare stents; log-rank: $p = 0.968$), patients with ePTFE-covered stents were at lower risk of overall 1- and 2-year mortality compared to patients with bare stents (19% vs. 31%, $p = 0.020$ and 29% vs. 40%; $p = 0.041$, respectively).
**Conclusion:** TIPS prevent variceal re-bleeding in up to 77% of all patients. ePTFE stents are more effective at preventing variceal re-bleeding than bare-metal stents due higher patency rates. As a result, 1- and 2-year mortality rates were lower in ePTFE stents.

### P0029 CYSTATIN C A REAL-TIME BIOMARKER FOR GLOMERULARFILTRATION RATE IN CRITICALLY-ILL PATIENTS WITH END STAGE LIVER DISEASE

**E. M. Abdelaal**[1], E. S. Tharwa[2], S. Abbas[2], M. a. Eljaky[2]

[2]*Hepatology, Liver Institute Menofia University, Shibin Elkom/Egypt*

**Contact E-mail Address:** eabdelaal@yahoo.com.

**Introduction:** Parameters allowing regular evaluation of renal function in critically ill patients such as serum creatinine and blood urea are not optimal. Sudden changes in glomerular filtration rate (GFR) are not followed by parallel changes in serum creatinine and are at risk of developing renal dysfunction.
**Aims & Methods:** The aim of study was to analyze the utility of serum cystatin C as a real-time biomarker of renal function in critically-ill patients with end stage liver disease (ESLD). **Patients and Methods:** serum creatinine, cystatin c and 24 hours creatinine clearance were determined daily to 300 patients (220 male and 80 female) critically ill patients with ESLD. The serum levels of creatinine and cystatin c were correlated with the creatinine clearance daily. The diagnostic value of serum creatinine and cystatin c to identify GFR under 80 ml/min per 1.73 $m^2$ was evaluated using receiver operating characteristic (ROC) curve analysis.
**Results:** Thirty out of 300 patients (10%) had serum creatinine above the upper limit of normal, while 85 out of 300 patients (28.3%) had serum cystatin c above the upper limit of normal. Statistically the ability of serum cystatin c to identify a creatinine clearance rate 80 ml/min per 1.73 $m^2$ was better than that of serum creatinine (areas under the ROC curve: for cystatin c 0.925, and for creatinine 0.613).
**Conclusion:** Serum cystatin c is an accurate easy and useful marker, better than serum creatinine to detect early renal dysfunction in real-time before acute renal injury in critically-ill patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0031 NEW TREATMENT WITH SULODEXIDUM FOR PORTAL VEIN THROMBOSIS IN PATIENTS WITH LIVER CIRRHOSIS

**I. Copaci**[1], L. Micu[1], S. Ioanitescu[1], G. Chiriac[1], I. Lupescu[2]

**Introduction:** Vitamin K antagonists and low-molecular weight heparin are not ideal drugs for patients with cirrhosis and portal vein thrombosis. New drugs must be investigated, based on the concept of rebalanced hemostasis in patients with liver disease.
**Aims & Methods:** We intended to assess the safety and efficacy of sulodexidum to treat portal vein thrombosis (PVT) in cirrhotic patients. From June 2010 to March 2013, 810 patients with liver cirrhosis admitted to our clinic received Doppler ultrasound examination as a part of routine workup. In the presence of PVT, spiral CT or magnetic resonance was performed to exclude concomitant hepatocellular carcinoma and to evaluate the extension of thrombosis in the portal-splenic-mesenteric axis. 94 patients diagnosed with non-neoplastic PVT and cirrhosis were prospectively enrolled (50 in the treatment group with sulodexidum 2 tb/day and 44 in the control group). In 55.3% of patients, PVT was an occasional finding, 12.8% presented with acute abdominal pain, while in 32.1% with bleeding from gastro-esophageal varices. In this last group, treatment was started after endoscopic eradication of varices by band ligation. In the treatment group, 16 patients (32%) had complete PVT and 34 pts (68%) had partial PVT. The mean MELD score was 14.6. Therapy was administered for a median period of 12 months and individuals were followed for a median time of 19 months.
**Results:** Complete recanalization of the portal vein occurred in 24% vs 0% of subjects, partial recanalization in 38% vs 27.2% of pts, and no response in 38% vs 72.8%. No significant side effects, particularly bleeding complications, were observed during therapy. The median value of platelets was 58, 000/$mm^3$ and 55, 000/$mm^3$ at the end of treatment. 4 of 28 pts who stopped treatment showed re-thrombosis of the portal vein at 1, 4 and 6 months. In univariate analysis, previous bleeding caused by portal hypertension and time between diagnosis and initiation of treatment $< 14$ days were positively associated with PV recanalization. Decompensation occurred during the study period significantly more in placebo than in sulodexidum treated patients [placebo 18/44 (40.9%) vs 11/50 (22%); $p = 0.01$].
**Conclusion:** Sulodexidum demonstrated to be safe and effective in the treatment of PVT in patients with liver cirrhosis, and delayed liver decompensation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0032 IS IT TIME TO CONSIDER ANTITHROMBOTIC PROPHYLAXIS IN CHRONIC LIVER DISEASE?: USEFULNESS OF CHA2DS2-VASC SCORE, HAS-BLED SCORE AND PLATELET COUNT

**E. Soares**, M. Gravito-Soares, C. Lérias, S. Lopes, D. Gomes, P. Figueiredo, C. Agostinho, L. Tomé, C. Sofia
*Gastroenterology, Coimbra University Hospital, Coimbra/Portugal*

**Contact E-mail Address:** es18497@gmail.com.
**Introduction:** Liver plays a central role in maintaining hemostasis. The imbalance between coagulation-anticoagulation can occur in Chronic Liver Disease (CLD). Antithrombotic prophylaxis in CLD remains to be established.
**Aims:** To evaluate the prevalence and predictive scores of vascular events in CLD and prognostic implication.
**Methods:** Case-control retrospective study of 200 patients with CLD, divided in 3 groups: with thrombotic events, bleeding events and with no thrombotic or bleeding events. The variables included, prior to vascular events, were age, gender, coagulation parameters, CLD prognostic scores (Child-Turcotte-Pugh (CPT), MELD, Na-MELD, APRI, AST/ALT ratio, ALT/AST ratio, Age to platelet index, Bonacini cirrhosis discriminant score, Pohl score, king score, FIB-4, FI score), predictive scores of bleeding (HAS-BLED) and thrombotic (CHA2DS2-VASc), and overall or vascular events-related mortality.
**Results:** About half (99/200) of patients developed vascular events, thrombotic in 32.3% (32/99) and hemorrhagic in 77.8% (77/99), with both of them in 10 patients. After multivariate analysis, the independent predictors of bleeding events in CLD were high HAS-BLED score ($3.9 \pm 1.0$vs$3.0 \pm 1.1$; OR 2.105; $p < 0.001$) and low platelet count ($93.3 \pm 45.9$vs$118.2 \pm 67.1$; OR 1.008; $p = 0.006$); and of thrombotic events were high CHA2DS2-VASc score ($3.0 \pm 2.0$vs$1.4 \pm 1.4$; OR 1.1773; $p < 0.001$) and high platelet count ($141.6 \pm 78.6$vs$102.3 \pm 55.0$; OR 1.009; $p = 0.002$). The best cut-off of HAS-BLED score was 3 (AUROC 0.707; $p < 0.001$; S63.6%; Sp65.6%), CHA2DS2-VASc 2 score was 2 (AUROC 0.731; $p < 0.001$; S75.0%; Sp60.5%) and platelet count was 103 (AUROC 0.648; $p = 0.008$; S62.5%; Sp61.3%). The remaining prognostic scores and other parameters of coagulation or liver function has not been associated with the development of vascular events. Only thrombotic events were associated with increased overall mortality and vascular events-related mortality (37.5% vs 21.4%; $p = 0.046$ and 18.8% vs 4.8%; $p = 0.012$).
**Conclusion:** Vascular events are common in CLD and include not only bleeding events, but also thrombotic events. Patients with CHA2DS2-VASc score $\geq 2$, HAS-BLED score $< 3$ and platelet count $> 103$ could benefit of prophylactic antithrombotic therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0033 CONTINUOUS PROTON PUMP INHIBITOR THERAPY INCREASES THE RISK OF BACTERIAL INFECTION IN CIRRHOTIC PATIENTS

**A.G. G. Antunes**[1], A. Vaz[1], P. Queirós[2], T. Gago[1], J. Roseira[1], B.M. Santos Peixe[1], H. Guerreiro[1]

[2]*Gastroenterology, Centro Hospitalar do Algarve, Faro/Portugal*

**Contact E-mail Address:** sergiogiao@hotmail.com.
**Introduction:** Patients with cirrhosis have a high risk for developing bacterial infections. Worse liver function, history of recent hospitalization, previous spontaneous bacterial peritonitis and gastrointestinal bleeding are well documented risk factors for its development. Although proton pump inhibitors (PPI) are associated with dysbiosis and with increased intestinal permeability and transitory bacteriemia, it still remains unknown whether continuous PPIs exposure increases the risk for bacterial infections and literature reports conflicting results.[1–3].
**Aims & Methods:** 1) to evaluate if continuous exposure to PPIs is a risk factor for bacterial infections in cirrhotic patients with ascites; 2) to assess the effect of PPIs exposure in 30 and 90-day mortality. Retrospective cohort study that evaluated hospitalizations secondary to cirrhosis decompensation between 2010 and 2014 in a tertiary center. Only patients with ascites and microbiological cultures at admission were considered. Past medical history was reviewed: PPI exposure was defined as continuous exposure for at least 3 months; previous hepatic function was assessed by past medical history review and it was expressed according to Child-Pugh score. A multivariate analysis was conducted by binary logistic regression aiming risk factors for the presence of bacterial infections at admission.
**Results:** 571 admissions were evaluated, gastrointestinal bleeding was present in 137 episodes and 252 met criteria for infection at admission. The most common infection was spontaneous bacterial peritonitis (SBP, $n = 100$), followed by urinary tract infection ($n = 62$) and pneumonia ($n = 33$). When analyzed medical history: 51% were previously classified as Child-Pugh C patients; 127 had recent hospitalization ($< 3$ month), 51a previous SBP (47 doing secondary prophylaxis) and 9 a recent gastrointestinal bleeding episode ($< 1$ month); at admission an active neoplasia was present in 71 episodes (hepatocarcinoma $n = 65$); 180 met criteria for continuous exposure to PPI and 29 were taking beta-blockers. In multivariate analysis Child-Pugh C ($p = 0.000$; OR = 2.971), recent hospitalization ($p = 0.000$; OR = 3.188) and continuous exposure to PPIs ($p = 0.002$; OR = 1.924) were independent risk factors for bacterial infections. When analyzed the effect of previous PPIs exposure: 30-day mortality after admission was not statistically significant different ($p = 0.095$) between groups, but PPIs exposure was associated with a higher 90-day mortality ($p = 0.000$; OR = 1.893).
**Conclusion:** In our sample continuous exposure to PPIs was an independent risk factor for bacterial infections in cirrhotic patients with ascites and it was associated with a higher 90-day mortality. Therefore, the prescription of PPIs in cirrhotic patients with ascites should be considered carefully.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** paulacrfsousa@gmail.com.
**Introduction:** The benefit of the use of beta-blockers (BB) in the primary and secondary prevention of variceal bleeding in cirrhosis is a known fact. Additionally, a reduction on the risk of ascites, hepatorenal syndrome and spontaneous bacterial peritonitis (SBP) was also associated with BB in some studies. On the other hand, there are studies that indicate a detrimental effect of the use of BB in patients with decompensated cirrhosis, namely refractory ascites or SBP. As such, the existence of a "window of opportunity" in the natural history of cirrhosis for the use of BB was hypothesized.
**Aims & Methods:** The aim of this study was to evaluate the impact of the use of BB in patients hospitalized for decompensated cirrhosis. We performed a retrospective study with inclusion of all patients admitted in a gastroenterology and hepatology unit due to decompensated cirrhosis (ascites, variceal bleeding, encephalopathy, renal failure, jaundice and bacterial infections) between 01-01-2013 and 31-12-2015. Patients were evaluated in two different groups according to use of BB at admission. Demographic, clinical and therapeutic data, prognostic scores and hospitalization outcome were collected. Patients with incomplete medical records were excluded from the analysis. Statistical analysis was performed with SPSS 20.0.
**Results:** We identified 164 admissions fulfilling inclusion criteria, 34 of which (20.7%) corresponding to patients medicated with BB. Both groups (with and without BB) were homogeneous regarding demographic features, cirrhosis aetiology and Child-Turcotte-Pugh and MELD scores at admission. There were no differences in the duration of hospitalisation [median (interquartile range – IQR); with BB: 8 days (5–14); without BB: 8 days (6–11); $p = 0.74$)] or in the in-hospital mortality (with BB 14.7%; without BB 11.5%; $p = 0.57$) between the 2 groups. In the sub-analysis by reason for admission, there was a tendency to greater mortality in patients admitted for ascites medicated with BB [5.8% vs 1.5%; $p = 0.052$; OR 21; confidence interval 95% 1.27–346).
**Conclusion:** The use of BB in patients with decompensated cirrhosis admitted for ascites may lead to an increase in in-hospital mortality.
**Disclosure of Interest:** P. Ministro: Medical advisor for Abbvie, Ferring, MSD and Hospira.

## P0035 EFFICACY OF TOLVAPTAN WITH CELL-FREE AND CONCENRATED REINFUSION THERAPY FOR REFRACORY ASCITES IN PATIENTS WITH ADVANCED LIVER DISEASE

**T. Ichikawa**, N. Machida, H. Sasaki, I. Aoki
*Dept. Of Gastroenterology And Hepatology, Itabashi Chuo Medical Center, Tokyo/Japan*

**Contact E-mail Address:** ichikawtakeshi@gmail.com.
**Introduction:** In Japan, adding of tolvaptan (TLV), an oral vasopressin V2 receptor antagonist to conventional diuretics has been used for refractory ascites in patients with cirrhosis, however the effectiveness of TLV is limited in end-stage liver disease. Serial paracentesis provide relief of symptoms but also promote loss of albumin and hypovolemia, which may cause renal dysfunction. Cell-free and concentrated ascites reinfusion therapy (CART) is a treatment which maintains

albumin by filtration, concentration, reinfusion of drained ascites and avoids complications due to paracentesis. CART is listed in the clinical practice guideline for liver cirrhosis in Japan, however the efficacy of TLV with CART for the treatment of refractory hepatic ascites has not been elucidated.
**Aims & Methods:** The aims of this study were to identify predictors associated with the response to TLV in patients with decompensated cirrhosis and to evaluate the efficacy of TLV with CART in non-responders. TLV was administered to 28 liver cirrhosis patients with persistent ascites despite conventional diuretics. Responders who were defined as ≥1 kg body-weight reduction in 1 week continued to receive TLV. Non-responders underwent CART in addition to the treatment with TLV. Conventional diuretics continued throughout. We assessed predictors that contributed to the response to TLV using univariate analysis and multivariate logistic regression analysis. Changes in the clinically relevant parameters were evaluated prior to the use of TLV and 1 month later.
**Results:** Responders to TLV were 19 (67.9%) patients. Gender (male: 47 vs 89%, respectively in responders and non-responders, $p = 0.026$), etiology of cirrhosis (HCV: 42 vs 0%, $p = 0.021$, alcohol: 26 vs 78%, $p = 0.010$), baseline BUN (19.3 vs 44.2 mg/dl, $p = 0.024$) and baseline creatinine (0.88 vs 1.94 mg/dl, $p = 0.009$) were associated with response to TLV. By multivariate analysis, we determined that higher level of BUN ($p = 0.046$) was the independent predictor of non-response to TLV along with male gender ($p = 0.008$). In non-responders, the mean volume of collected ascites was 6543 ml per session, and non-responders underwent CART at the mean 1.3 sessions for 1 month in each patient. In patients treated using TLV with CART, estimate glomerular filtration rate (eGFR) significantly increased from 47.5 to 54.3 ml/min/1.73 $m^2$ 1 month after administration of TLV ($p = 0.020$) and the serum level of albumin was almost identical to that prior to administration of TLV (2.87 at baseline vs 2.94 mg/dl 1 month after administration of TLV, $p = 0.137$). TVL with CART alleviated symptoms such as abdominal fullness in all the patients. There were no serious adverse events during the entire treatment period.
**Conclusion:** Higher level of BUN is the predictor of non-response to TLV in patients with advanced liver disease. In non-responders to TLV, CART with TLV keeps serum level of albumin and avoids renal dysfunction; therefore, TLV with CART is useful for refractory ascites in patients with decompensated cirrhosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Spontaneous bacterial peritonitis (SBP) is the most frequent and life-threatening infection in patients with decompensated liver cirrhosis. Diagnosis should be prompt and treatment must not be delayed until the microbiology results are available. Mean platelet volume (MPV) is one of the most widely used surrogate markers of platelet activation. MPV might be helpful in early diagnosis of SBP which may result in improved patient outcome.
**Aims & Methods:** The current study was conducted to assess the potential role that MPV may have in the diagnosis of SBP in cirrhotic patients with ascites together with other inflammatory markers; ESR &CRP. The current study is a case control study that was conducted from May 2015 to March 2016 at the Endemic Medicine and Hepatology departments, in both Ain Shams and Cairo Universities. Three groups were included in the study. Group I (SBP group) included 100 patients with liver cirrhosis and ascites complicated by SBP, group II (non-SBP group) included 98 patients with liver cirrhosis and ascites without SBP and group III included 50 healthy subjects to serve as a control group. Patients were subjected to thorough history taking, clinical examination and laboratory evaluation. ESR, CRP and Complete blood picture including MPV was done at time of diagnosis of SBP.
**Results:** Platelet count was significantly lower in SBP group than in non-SBP group (median 116.5 vs. 150 with P value $< 0.01$). On the other hand, ESR, CRP and total leucocytic count (TLC) in ascitic fluid were significantly higher in SBP group compared to non-SBP group (median 37.5 vs. 12, 12 vs. 5 and 530 vs. 60 respectively with p value $< 0.01$). On the other hand, hemoglobin, bilirubin, albumin, INR, creatinine and Child-Turcotte-Pugh (CTP) Score showed no statistically significant difference between SBP and non-SBP groups. The MPV was significantly higher in SBP group vs. non-SBP group and healthy control group (8.5, 7.9 and 8.3 respectively and P value $< 0.0001$). On constructing ROC curve for the MPV; at a cutoff value of 8.4 fl, MPV had 73% sensitivity and 85.7% specificity for detecting SBP with overall accuracy 79.3%, [AUC = 0.84 with negative predictive value (NPV) and positive predictive value (PPV) for MPV of 75.7 and 83.9%, respectively]. Regarding ESR; at a cutoff value of 20, ESR had 78% sensitivity and 63.4% specificity for detecting SBP with overall accuracy of 70.7%, [AUC = 0.845 with negative predictive value (NPV) and positive predictive value (PPV) for MPV of 73.8 and 68.5%, respectively]. Regarding CRP; at a cutoff value of 7, MPV had 66% sensitivity and 67.4% specificity for detecting SBP with overall accuracy 66.6%, [AUC = 0.71 with negative predictive value (NPV) and positive predictive value (PPV) for MPV of 66% and 67.3%, respectively].
**Conclusion:** MPV is increased in SBP in cirrhotic patients with ascites than the other inflammatory markers; ESR & CRP. It can be used as an accurate predictor test of ascitic fluid infection.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0037 EVALUATION OF AN ALTERNATIVE MODEL TO MELD FOR ANTICOAGULATED PATIENTS WITH CIRRHOSIS: MELD-XI (EXCLUDING INR)

**P. Sousa**[1], D. Martins[1], J. Pinho[1], J. Fernandes[2], R. Araújo[1], E. Cancela[1], A. Castanheira[1], P. Ministro[1], A. Silva[1]

**Introduction:** The concept of the existence of a "natural anticoagulation" state in patients with cirrhosis is outdated, and it's now widely accepted that there is a dynamic and precarious hemostatic balance in this group of patients. Therefore, anticoagulant agents such as warfarin are being increasingly used in cirrhotic patients. However, one of the most used prognostic models, the Model for End-stage Liver Disease (MELD) is based on the values of bilirubin, creatinine and INR, and no modification exists for anticoagulated patients. As such, there might be an overestimation of risk in these group of patients when using MELD, so that a new model not including INR is necessary. MELD-XI (eXcluding INR) is a model based exclusively on bilirubin and creatinine, and may be a potential alternative.
**Aims & Methods:** The aim of this study was to compare MELD and MELD-XI scores on the evaluation of risk of mortality in patients admitted for decompensated cirrhosis. We performed a retrospective study with inclusion of patients admitted in a gastroenterology and hepatology unit for decompensated cirrhosis (including but not limited to patients with acute-on chronic liver failure) between 2013 and 2015. Patients with hepatocellular carcinoma, portal vein thrombosis and those submitted to liver transplantation within 3 months of admission were excluded from the analysis. MELD score was calculated according to the formula and criteria defined by United Network for Organ Sharing. MELD-XI was calculated according to the formula 5.11xLn (bilirubin) + 11.76xLn (creatinine) + 9.44 previously described. Mortality within 3 months of admission (M3) was evaluated. Statistical analysis was performed with SPSS 20.0.
**Results:** One hundred and twenty three hospital admissions corresponding to 87 patients were identified. MELD-XI had a weak discrimination power for M3 with an area under the receiver operating characteristics curve (AUROC) of 0.68 [confidence interval (CI) 95% 0.57–0.79; $p = 0.006$) versus 0.73 (CI 95% 0.63–0.84; $p = 0.001$) for MELD. On the sub-analysis by type of decompensation, MELD-XI had the best discrimination power for M3 in the sub-group of patients with ascites with an AUROC of 0.87 (CI95% 0.0–1.0; $p = 0.028$). We performed a Spearman correlation to ascertain the relationship between the two models, in order to understand if the exclusion of INR had a significant impact on the prognostic model. There was a positive, statistically significant and strong correlation between MELD and MELD-XI ($r = 0.90$; $p < 0.001$).
**Conclusion:** In this population both MELD and MELD-XI had a weak discrimination power for the prediction of mortality at 3 months. However the correlation between the two models was strong, so in anticoagulated patients MELD-XI can be a valid alternative to MELD.

## P0038 INCIDENCE AND PREDICTORS OF REBLEEDING AFTER BAND LIGATION IN PATIENTS WITH ACUTE ESOPHAGEAL VARICEAL BLEEDING

**V. Anapaz**[1], J. Carvalho, E. Branco[2], M. Cardoso[2], R. Carvalho[2], L. Santos[3], A. Martins[2], J. Reis[2]
[1]*Gastroenterology, Hospital Professor Doutor Fernando Fonseca, Amadora/Portugal*
[2]*Gastroenterology, Hospital Professor Doutor Fernando da Fonseca, Lisbon/Portugal*
[3]*Gastroenterology, Hospital Professor Doutor Fernando Fonseca, Lisbon/Portugal*

**Contact E-mail Address:** vera_anapaz@hotmail.com.
**Introduction:** Variceal bleeding (VB) occurs in 25 to 40% of patients with portal hypertension. Endoscopic variceal ligation (EVL) is the method of choice for the treatment of esophageal varices but there are no specific guidelines about the number of bands per treatment. Some authors reported that the fewer bands placed the more rebleeding risk. Rebleeding occurs in the first few weeks after EVL, with a range of mortality of 30–50%.
**Aims & Methods:** The primary aim for this study was to assess incidence and risk factors contributing to variceal rebleeding (VRB) after EVL, and the role of the number of rubber bands in relapse. We also analyzed the correlation between the VRB and the use of proton pump inhibitors (PPIs), beta-blockers (BB), the Child Turcotte Pugh classification (CTP) and MELD score. This was a retrospective study in patients with liver cirrhosis and VB admitted to our Unit between January 2012 and December 2015.
**Results:** We included 75 patients, of whom 88% ($n = 66$) were male, with an average age of $60.51 \pm 11.39$ years old. 61% of patients had alcoholic cirrhosis and 12% viral etiology. An average of 6.48 (3–12) bands was placed in the first session of EVL. Active bleeding was observed in 38.6% patients. After the procedure 90% were treated with PPIs and 68% with BB. The most common comorbidities were diabetes mellitus ($n = 31$) and essential hypertension ($n = 24$). We observed VRB in 24% of patients ($n = 18$), and was higher in patients with CTP class B and C ($n = 15$, $p = 0.015$) and in patients with less than 6 bands placed ($n = 13$, $p = 0.018$). There was no statistical difference between the VRB with use of PPIs, BB, MELD score or hepatocellular carcinoma at time of diagnosis.
**Conclusion:** This study results contradict the literature regarding the influence of a higher number of bands as a bleeding predictor factor in VRB. In our group we concluded that the CTP B our C class was a VRB predictor.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0039 MORTALITY AFTER THE FIRST ADMISSION FOR HEPATIC ENCEPHALOPATHY

**M. Silva**, A. Albuquerque, H. Cardoso, A. Peixoto, R. Gaspar, G. Macedo
*Departments Of Gastroenterology, Centro Hospitalar São João, Faculty of Medicine of the University of Porto. Porto, Portugal, Oporto/Portugal*

**Contact E-mail Address:** marcocostasilva87@gmail.com.
**Introduction:** Port-systemic hepatic encephalopathy (PSHE) is one of the most common complications in liver cirrhosis. The development of hepatic encephalopathy negatively impacts patient survival. The occurrence of encephalopathy severe enough to lead to hospitalization is associated with a survival probability of 42% at 1 year of follow-up.
**Aims & Methods:** AIMS: Assess the factors associated with increased one year mortality after hospital admission for PSHE. METHODS: Retrospective analysis of admissions for EHPS of patients with liver cirrhosis, between October 2011 and October 2014. Only the onset episode was included. Patients were followed during 1 year. Descriptive statistics, uni and multivariate analysis, logistic regression and ROC curves analysis were performed using IBM SPSS Statistics 22 with $p < 0.05$ deemed to be statistically significant.
**Results:** During the period of the study there were 120 patients discharged with onset PSHE, 78% were men with a mean age of $59 \pm 14$ years, 97% had Child-Pugh B/C, 55% had alcoholic liver disease and 10% had hepatocellular carcinoma. The overall mortality rate during the first year of follow-up was 46%. These patients were 80% men with mean age of $59 \pm 17$ years. Mortality was higher in patients with higher MELD, MELD-Na and Child-Pugh scores ($p < 0.001$), hepatocellular carcinoma ($p = 0.033$), ascites ($p = 0.008$) and readmission for PSHE ($p = 0.025$). Patients with hyponatremia ($p = 0.006$) and higher initial degree of PSHE ($p = 0.036$) in onset episode also had a higher mortality rate. Patients who underwent antibiotic therapy in the first admission for PSHE ($p < 0.001$) had a lower mortality. In the multivariate analysis, there was an independent association between mortality in the follow-up and higher MELD score ($OR = 1.2$; $p = 0.001$), Child-Pugh C ($OR = 3.5$, $p = 0.008$) and readmission for PSHE ($OR = 3.1$, $p = 0.02$).
**Conclusion:** Our data reveals to be similar to that found in the literature, showing that PSHE requiring hospitalization was associated with a poor prognosis, with a one year mortality rate of 46%. The readmission for PSHE and higher Child-Pugh and MELD scores were independently associated with a higher mortality rate.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** rosacoelhoabrantes@hotmail.com.
**Introduction:** Sexual activity is a crucial component of human relationships and has an important impact on quality of life [1]. Despite of its importance, it is rarely evaluated in clinical practice, especially in patients with chronic liver disease (CLD).
**Aims & Methods:** The aim of this study was to evaluate the importance of this issue in a population with chronic liver disease (CLD). This is a cross-sectional study based on an opinion questionnaire, in male consecutive patients, followed as outpatients in a Hepatology Department. The sexual dysfunction was also assessed through the simplified version of the International Index of Erectile Function questionnaire. Statistics analysis were performed using IBM SPSS Statistics 22 with $p < 0.05$ deemed to be statistically significant.
**Results:** A total of 67 male patients were surveyed, 57% with liver cirrhosis, median age of 56 years (IQR: 48–62) and median number of years of education was 7 years (IQR: 5–12). Forty-one patients (62.1%) fulfilled criteria for erectile dysfunction (ED). Sixty-four percent of patients considered that the sexual dysfunction issue should be asked during the Hepatology consultation. The majority of patients (73%), described themselves as being ''very comfortable'' to address this issue, with no statistically significant differences between patients with or without ED (ED: 87.5% vs. Non-ED: 91.3%, $p = 1.000$). Evaluating all the patients surveyed, 45.3% did not consider that the CLD could interfere with ED. However, in 62.1% of the patients whose assessment was consistent with ED, 62.1% considered that CLD could interfere with their sexual dysfunction ($p < 0.001$). When asked about the association between the use of drugs, only 32.5% reported that the medication they took could negatively correlate with his sexual function, and 50% of those who used beta-blockers reported a positive association between therapy and the presence of ED ($p = 0.148$). The answers did not differ statistically significantly with the level of education and marital status.
**Conclusion:** The majority of patients with ED positively correlated this condition with liver disease. The high prevalence of ED in this cohort highlights the importance of addressing this issue at the Hepatology consultation in order to provide a specific treatment for this condition.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0041 REAL-LIFE PRACTICE OF CHRONIC HEPATITIS C PATIENTS TREATED WITH DIRECT ACTING ANTIVIRALS (DAAS) IN A TERTIARY CENTER OF PORTUGAL

**S. Vitor**[1], S.R. R. Fernandes[1], P. Alexandrino[1], R.T. Marinho[2], J. Velosa[2]
[1]*Gastroenterology And Hepatology Department, Hospital de Santa Maria, Lisboa/Portugal*
[2]*Faculdade de Medicina da Universidade de Lisboa, LISBOA/Portugal*

**Contact E-mail Address:** sivvitor@gmail.com.
**Introduction:** The use of new DAAs deeply changed the treatment of chronic hepatitis C virus (HCV) infection in terms of efficacy and tolerability. However, there is still lack of information regarding the real-life data.
**Aims & Methods:** Our aims are to investigate clinical and laboratorial impact, effectiveness and adverse effects of these drugs in real-life practice, in a tertiary center of Portugal. This observational prospective study included all patients who underwent treatment with DAAs (including sofosbuvir) in our department since February 2015. The patients variables were collected in terms of demography and HCV infection baseline characteristics (genotype, viral load, elastography, laboratorial tests and previous treatments). Regarding the treatment, data about therapeutic regimens, sequencial laboratorial follow-up and adverse effects were collected. The variables were compared before and after treatment for

patients who achieved 12 weeks post-treatment evaluation, corresponding to the sustained virological response (SVR) time. The statistic analysis used the logistic-binary regression test and Kaplan-Mayer curves, depending on the specific analyzed variables.
**Results:** A total of 642 were included in our study in which SVR was achieved in 96.7%. The average of age was 53.8 years-old and 64.5% were men. The genotypes related to HCV infection were: 1 in 70.2%, 2 or 3 in 12.8% and 4 in 16.8%. Cirrhotic patients (elastrography > 12.5 Kpa) represented 34.1% of the sample. The majority of patients were treated with sofosbuvir-ledipasvir combination (n = 580; 90.3%) and in 21.9% of patients ribavirin was used in concomitancy. The genotypes 1 and 4 revealed better outcomes in terms of SVR analysis, 97.1 and 95.7, respectively. The genotype 3 achieved 90.2% of SVR. During the treatment the hemoglobin and platelet count decreased independently on ribavirin use ($p < 0.001$). And the liver tests before and after treatment showed a decreased in ALT ($p < 0.001$), GGT ($p < 0.001$) and ALP ($p = 0.004$) levels. Preliminary study of elastrography values revealed a decreased of fibrosis in cirrhotic patients ($p = 0.002$; N = 44). There was no relation between viral load at 2 and 4 weeks of treatment and the final response status. Adverse effects with therapy withdrawal were rare and occurred in 5 patients (0.8%).
**Conclusion:** Treatment with DAAs was highly effective and safe in our patients. Almost all liver tests were improved after this therapy. Evaluation of viral load at 2 and 4 weeks of therapy did not predict the final response.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0042 GENDER-DEPENDENT DRUG–DRUG INTERACTIONS (DDIS) WITH NOVEL ALL ORAL HCV THERAPIES IN GERMAN REAL WORLD: LOW FREQUENCY OF DDIS WITH ELBASVIR (EBV) AND GRAZOPREVIR (GRZ)

**P. Buggisch**[1], H. Löhr[2], G. Teuber[3], H. Steffens[4], M. Kraus[5], P. Geyer[6], B. Weber[7], T. Witthöft[8], U. Naumann[9], E. Zehnter[10], D. Hartmann[11], B. Dreher[11], M. Bilzer[11]

[10]*Gastroenterological Practice, Dortmund, Germany, Dortmund/Germany*
[11]*MSD Pharma GmbH, Haar/Germany*

**Contact E-mail Address:** buggisch@ifi-medizin.de.
**Introduction:** A high frequency of clinically relevant DDIs between the regular outpatient medications and direct-acting antivirals (DAAs) has been reported for HCV treatment with sofosbuvir (SOF) in combination with simeprevir (SMV), daclatasvir (DCV) or ledipasvir (LDV) (30–40%) while patients (pts) treated with ombitasvir/paritaprevir/ritonavir (OBV/PTV/r) ± dasabuvir (DSV) had a risk > 60% (Clin Infect Dis 2016; 62: 561–567). However, the number of DDIs might have been overestimated in this single center study at a tertiary referral center because of a high frequency of severe cases. We therefore assessed the clinical relevance of DDIs between the regular outpatient medications and the above HCV therapies together with the recently approved therapy with EBV/GRZ in a large multicenter real-world cohort.
**Aims & Methods:** From April 2012 until January 2014, regular outpatient medications were documented from 505 pts with HCV G1 infection by 91 medical practices and hospital outpatient departments in Germany. Clinically relevant DDIs (co-administration of drugs contraindicated or may require dose adjustment/closer monitoring) were assessed based on information available at www.hep-druginteractions.org and the prescribing information for each drug in April 2016.
**Results:** The mean age of 505 enrolled pts was 47 years, 60% male, 12% were under opioid substitution, 4% had HIV co-infection, 8% had cirrhosis and 34% had failed prior antiviral therapy. 43% of pts did not take any drugs regularly while 48% reported the regular intake of 1–3 drugs and 9% of 4 or more drugs. The following frequencies of relevant DDIs between the regular outpatient medications and the different antiviral regimens were found: SOF/SMV 28%, SOF/DCV 28%, SOF/LDV 31%, OBV/PTV/r 42% and OBV/PTV/r + DSV 41%. In contrast, a low DDI frequency of only 5% was found for EBV/GRZ. Interestingly, higher frequencies of DDIs were observed in female pts when compared with male pts: SOF/SMV 35 vs. 24%, SOF/DCV 39 vs. 21%, SOF/LDV 35 vs. 29%, OBV/PTV/r 55 vs. 33%, OBV/PTV/r + DSV 54 vs. 33% and EBV/GRZ 7 vs. 3%.
**Conclusion:** Clinically relevant DDIs between the regular outpatient medications and SOF or OBV treatment regimens are a common problem in pts undergoing HCV G1 treatment in German real life. DDIs seem to occur more frequently in female pts suggesting a role for gender-related outpatient medications. Compared to SOF or OBV treatment regimens, there is a 6–8 fold lower frequency of clinically relevant DDIs between outpatient medications and the novel HCV therapy with EBV/GRZ.

**Contact E-mail Address:** gepapath@med.uoa.gr.
**Introduction:** Several clinical trials and real-life cohorts have shown that therapy with DAAs is safe, well tolerated and effective in the majority of CHC patients. The main limitation of DAAs is their potential for DDIs, the probability of which has not been properly assessed in routine clinical practice.
**Aims & Methods:** We aimed to determine the risk of possible DDIs with all HCV agents in 500 consecutive CHC patients (mean age 49 ± 14 years, M/F: 322/178) seen in 2015 at the outpatient liver clinics of 5 tertiary liver centers in Greece (100 patients from each center). Patients with HIV coinfection were excluded. Patients' demographics and habits, laboratory parameters, HCV and liver disease characteristics as well as concomitant diseases and chronic use of drugs were collected from patients' records. All concomitant drugs chronically used by the patients were classified into those with no/no clear data for DDIs, potential DDIs and contraindication for each of the HCV agents according to the HEP Drug Interaction Checker (University of Liverpool).
**Results:** In total, 326 (65%) patients reported no chronic drug use. Patients with contraindications to HCV agents due to DDIs were 30 (6.0%) for paritaprevir/ritonavir/ombitasvir ± dasabuvir (3D/2D), 26 (5.2%) for boceprevir/telaprevir (BOC/TPV), 10 (2.0%) for simeprevir (SMV), 2 (0.4%) for sofosbuvir (SOF) or daclatasvir (DCV) or ledipasvir/sofosbuvir (LDV/SOF) and none for peginterferon (pegIFN) or ribavirin (RBV) ($P < 0.001$). Contraindications due to DDIs or potential DDIs were present more frequently for NS3 protease inhibitors containing agents (22.8–27.0%) than NS5A inhibitors ± SOF (16.8–17.4%, $P \leq 0.040$ vs NS3 inhibitors) than SOF (11.8%, $P < 0.001$ vs NS3 inhibitors; $P \leq 0.030$ vs NS5A inhibitors) or RBV (11.2%, $P \leq 0.014$ vs NS3/NS5A inhibitors) than pegIFN (7.6%, $P < 0.001$ vs NS3/NS5A inhibitors; $P = 0.033$ vs SOF; $P = 0.065$ vs RBV) (Table). Contraindications/Potential DDIs were present more frequently in patients ≥ 50 than < 50 years old for all HCV agents ($P \leq 0.034$), with F3-F4 than F0-F2 fibrosis for all agents ($P \leq 0.014$) except pegIFN and RBV, with F4 than F0-F3 fibrosis for all agents ($P \leq 0.019$) or with genotype (G) 1/4 than 2/3 for all agents ($P \leq 0.036$) except pegIFN, LDV/SOF and 3D/2D (Table)..
**Conclusion:** In the current DAAs era, the potential for DDIs represents one of the main challenges in the management of CHC patients in routine clinical practice, being present more frequently compared to the pegIFN + RBV era. Contraindications/Potential DDIs are present more frequently (~25%) for NS3 inhibitors, but also for NS5A inhibitors (17%) and SOF (12%); their probability is higher for patients with priority for DAAs therapy (eg advanced liver disease) and therefore caution is always warranted.

## P0044 SOFOSBUVIR PLUS RIBAVIRIN FOR TREATMENT OF CIRRHOTIC HCV PATIENTS GENOTYPE-4

**S. Abd-Elsalam**[1], M. Sharaf-Eldin[1], Y. Ahmad[2], S. Tawefeek[3]
[1]*Tropical Medicine Department, Tanta University, Tanta/Egypt*
[2]*Internal Medicine, Alazhar University, Cairo/Egypt*
[3]*Internal Medicine, National Research Center, Cairo/Egypt*

**Contact E-mail Address:** sherif_tropical@yahoo.com.
**Introduction:** Egypt has the highest hepatitis C virus prevalence in the world. Sofosbuvir is a new highly effective drug for treatment of hepatitis C virus (HCV) infection. Compared to previous treatments, sofosbuvir-based regimens provide a higher cure rate, fewer side effects, and a two- to four-fold reduced duration of therapy.
**Aims & Methods:** The aim of the study was to evaluate the antiviral efficacy, safety, and tolerability of sofosbuvir (SOF) plus ribavirin (RBV) in Egyptian patients with liver cirrhosis due to chronic hepatitis C virus (HCV) infection. We studied 2400 cirrhotic Egyptian patients with chronic HCV infection treated with dual therapy with Sofosbuvir and ribavirin for 24 weeks. Efficacy was determined by assessment of serum HCV RNA. Any adverse events during treatment were recorded.
**Results:** 2400 cirrhotic egyptian patients with chronic HCV infection treated with sofosbuvir and ribavirin for 24 weeks were enrolled in the study, their mean age (SD) was 53.9 + 6.5 years, 64.54% were males, they were all cirrhotics, 3.41% were treatment-experienced; baseline mean HCV RNA was 4.33 x $10^6$IU/ml. Overall, 94.37% completed the full course of therapy. Overall, SVR12 rates were 71.2%. The most common adverse events were fatigue, myalgia, headache, insomnia, and anemia. 135 patients stopped treatment permanently due to appearance of complications prevented continuation of treatment (44 cases with hepatic encephalopathy with sever elevated bilirubin and 91 cases with ascites).
**Conclusion:** Sofosbuvir and ribavirin is safe and effective treatment for HCV patients with liver cirrhosis. However, further studies are needed to establish the most optimal treatment regimen for this population.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Infection by hepatitis C virus (HCV) in kidney transplant recipients is associated with an increased progression of hepatic fibrosis. Studies in kidney transplant patients demonstrate that HCV infection is associated with higher rates of rejection and increased risk of mortality. Causes directly related to HCV, such as glomerulonephritis and increased risk of diabetes may affect the outcome of the graft. At this moment, eradication of HCV infection with the direct-acting antivirals (DAAs) is feasible after kidney transplantation with few treatment-related side effects.
**Aims & Methods:** Objective: Analyse the effectiveness and safety of new therapeutic regimens in the treatment of HCV in kidney transplant recipients. Methods: Prospective cohort study of kidney transplant recipients with HCV infection undergoing treatment with the new DAAs. The primary endpoint was sustained virologic response at 12 weeks after completion of therapy (SVR12). The secondary endpoint was the treatment-related side effects.
**Results:** Thirteen kidney transplant recipients were included (69.2% male, mean age 55 ± 8 years) with HCV infection, with a median viral load at the time of treatment initiation of 6.65 log (IQR 3.99 – 7.43 log), proposed for 12 (n = 6) or 24 weeks (n = 7) of treatment with the following regimens (fourteen treatments in thirteen patients).

| | |
|---|---|
| Sofosbuvir + Ledipasvir | N = 8 |
| Sofosbuvir + Ribavirina | N = 3 |
| Sofosbuvir + Daclatasvir (±Ribavirina) | N = 2 |
| Ombitasvir-paritaprevir-ritonavir + Dasabuvir | N = 1 |

Nine (69.2%) patients were infected with genotype 1 (**33**.3% subtype 1 a) and 4 (30.8%) with genotype 3. Three had advanced fibrosis and five had cirrhosis. Three patients were previously treated with interferon. All patients had rapid virologic response (undetectable viremia at week 4 after starting DAA therapy). The eight patients who have completed follow-up up to 12 weeks post-treatment achieved SVR12 (100%).
At week 4 after completing DAA therapy, 9/9 patients obtained undetectable viremia. In all regimens with ribavirin it was necessary to reduce the dose and start erythropoietin. One patient suspended sofosbuvir + ribavirina due to severe anaemia and later was started on sofosbuvir + daclatasvir. A HCV genotype 1 a cirrhotic patient with had suspended the treatment (sofosbuvir + ledipavir) at week 5 due to septic shock (lower limb cellulitis) but SVR12 was still achieved. Serum levels of calcineurin inhibitors were monitored and adjusted to maintain therapeutic levels. Acute kidney injury by cyclosporin intoxication occurred in the patient undergoing treatment with Ombitasvir-paritaprevir-ritonavir + Dasabuvir, since the usual dose of the immunosuppressant was not reduced at the start of treatment. There has been no rejection of the graft during the study.
**Conclusion:** The new regimens with DAAs are associated with high rates of SVR in kidney transplant recipients and rare serious adverse events in a group historically difficult to treat.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** . The response to treatment in hepatitis C virus (HCV) infection varies between individuals. Whereas some variation may be attributable to viral and environmental variables, it is probable that host genetic background also

plays a significant role. It has been shown that cytokine genes are polymorphic, and some of these mutations may influence the production of cytokines and affect the host immune response in HCV infection. Information about treatment predictors, and even the response rates, in children with chronic hepatitis C (CHC), genotype 4 is limited.
**Aims & Methods:** The aim of this study was to investigate the ability of different factors including the genotype polymorphism of a panel of cytokines in predicting the response to Pegylated interferon (PEG-INF) and ribavirin (RBV) in a group of Egyptian children with CHC, genotype 4.
**Methods:** 57 children aged 5–17 years (48 males & 9 females) with previously untreated CHC, Genotype 4 were analyzed for single nucleotide polymorphisms of interleukin (IL) IL-28B, IL-10, IL-6, interferon-gamma (IFN- $\gamma$), tumor necrosis factor-alpha (TNF- $\alpha$), transforming growth factor-beta (TGF- $\beta$) by polymerase chain reaction using sequence-specific primers (PCR-SSP). They received a dose of PEG-INF alfa-2 a (Reiferon Retard®) equivalent to the dose licensed for adults based on calculated conversion to body surface area (BSA) {BSA/1.73 × 160ug/week} plus RBV (15 mg/kg/day) for 48 weeks. The primary end point was sustained virologic response (SVR). Pretreatment liver biopsy was done and evaluated using METAVIR fibrosis and activity scores.
**Results:** The majority of studied children (82.5%) have low baseline viral load (< 600, 000 IU/ml). Concerning fibrosis, 30 children had no fibrosis (F0), 21 had (F1) and only 6 had (F2). The frequencies of different dimorphic polymorphisms were as follows: IL-28B- 12979860 C/T 82.5%, C/C 12.2%, T/T 5.3%; IL-10-1082 G/G 40%, A/A 37.5%, G/A 22.5%; IL-10-819 C/T 47.5%, C/C 45%, T/T 7.5%; IL-10-592 C/C 55%, C/A 37.5, A/A 7.5%; IL-6-174 G/G 67.5%, G/C 17.5%, C/C 15%; IFN $\gamma$ + 874 T/A 40%, T/T 35%, A/A 25%; TNF-$\alpha$ G/G 72.5%, G/A 25%, A/A 2.5%; TGF-$\beta$ codon10 T/T 40%, T/C 35%, C/C 25%. Overall, SVR was attained by 71.9% (41/57) of all children with higher response rate in older chidren (> 11ys) [86.4 vs. 62.8% P = .05]. 77% of studied males attain SVR, versus 44% of females (p = .045). 87% of those with early virologic response (EVR) attained SVR (p = 0.000). AFs were generally mild or moderate in severity, primarily flu-like symptoms. Dose was modified because of hematological AFs in 24% of children. However, all children continued their treatment. SVR was not influenced by any of the studied cytokine polymorphism except for the polymorphism of IL-10-1082, where the G/A genotype which was significantly associated with bad response to treatment (p = 0.016). A multivariate logistic regression analysis showed that male sex, viral genotype 4 b and 4 e and achievement of EVR are independent predictors of SVR. No effect of other factors like viral load, duration of infection, presence of auto antibodies, high ALT levels, stage of fibrosis or degree of necroinflammatory activity was observed on SVR in this population infected with genotype 4.
**Conclusion:** Treatment with PEG-IFN alfa-2 a and RBV should be considered for children with CHC genotype 4 because it provides high response rates with improved tolerability and alleviates the long-term consequences of hepatitis C during adulthood when treatment is associated with additional negative prognostic factors.EVR, is a strong predictor of SVR in children as in adult. However, SVR in this population does not seem to be influenced by cytokine gene polymorphisms.

## P0048 PERFORMANCE OF CONTRAST ENHANCED ULTRASOUND (CEUS) IN THE DIAGNOSTIC OF FOCAL LIVER LESIONS – MONOCENTRIC EXPERIENCE

R.L.D. Sirli, C. Ivascu-Siegfried, T. Voicu Moga, **A. Popescu**, M. Danila, I. Sporea
*Department Of Gastroenterology And Hepatology, Victor Babes University of Medicine, Timisoara/Romania*

**Contact E-mail Address:** alinamircea.popescu@gmail.com.
**Introduction:** Focal liver lesions (FLLs) are often found by ultrasonography in asymptomatic patients and also during follow-up in chronic liver diseases and in oncologic patients. In the last years CEUS is used more and more for FLLs' assessment considering that is non-irradiant, less expensive than sectional imaging and also that it can be used in patients with renal failure.
**Aims & Methods:** The aim of this study was to evaluate the diagnostic performance of contrast enhanced ultrasound (CEUS) in assessing FLLs in a large monocentric experience. The study included 721 patients (57.8% male, mean age 59.6 ± 13.1 years) with 874 FLLs (mean diameter of 4.5 ± 3.1 cm), which were first characterized by CEUS and then were finally evaluated by a 'gold-standard' method (contrast enhanced CT, contrast enhanced MRI or histology). The CEUS diagnosis was based on the FLLs' enhancement pattern following contrast bolus, according to the European Guidelines for the use of CEUS (1). Using the ''gold-standard'' methods, we calculated the sensitivity (Se), Specificity (Sp), and accuracy (Ac) of CEUS for the diagnostic of FLLs.
**Results:** From de 874 FLLs, CEUS was conclusive for the benign vs. malignant nature of the lesions in 776 (88.8%) cases. Using CT, MRI or histology, we established the final diagnostic of the lesions as follows: 246 (28.1%) hepatocellular carcinomas (HCC), 223 (25.5%) liver metastasis, 124 (14.2%) hemangiomas, 30 (3.4%) adenomas, 37 (4.2%) hepatic abscesses, 16 (1.9%) cholangiocarcinomas, 55 (6.3%) focal nodular hyperplasias (FNH), 36 (4.1%) regenerative nodules, 3.3% (29) focal fatty liver alterations (FFLA), 15 (1.8%) liver cysts, 38 (4.3%) other benign lesions, 25 (2.9%) other malignant lesions. For benign liver lesions, CEUS had 78.3% Se, 94.8% Sp, and 87.4% Ac. For the diagnostic of malignant lesions, CEUS had 82.9% Se, 86.4% Sp, and 84.2% Ac. For HCC, CEUS had a 65% Se, 91.4% Sp, and 81.8% Ac. For the diagnostic of liver metastases, CEUS had 74.4% Se, 93.2% Sp, and 86.7% Ac. For liver hemangiomas, CEUS achieved 73.3% Se, 95.6% Sp and 91.1% Ac. For FNH CEUS had 72.7% Se, a 97.3% Sp and a diagnostic Ac of 95%.
**Conclusion:** CEUS is a reliable diagnostic, being able to differentiate between malignant and benign lesions in 88.8% cases. The best accuracy was observed for diagnosing hemangiomas and FNHs (91 and 95%, respectively), and the lowest for HCCs (approximately 82%).
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0049 TRANSIENT ELASTOGRAPHY FOR DIAGNOSIS OF CLINICALLY SIGNIFICANT PORTAL HYPERTENSION IN PATIENTS WITH ALCOHOL-RELATED LIVER CIRRHOSIS

**E. Liusina**[1], C. Pavlov[2], V. Ivashkin[1]
[1]*Chair Of Internal Disease, Propedeutics, Gastroenterology And Hepatology, Sechenov First Moscow State Medical University, Moscow/Russian Federation*
[2]*Scientific And Educational Clinical Center Of Innovative Therapy, Sechenov First Moscow State Medical University, Moscow/Russian Federation*

**Contact E-mail Address:** eka-lusina@yandex.ru.
**Introduction:** Worldwide, up to 50% of liver cirrhosis is due to alcohol consumption [1]. Clinically significant portal hypertension (CSPH) is a main complication of liver cirrhosis. Hepatic venous pressure gradient (HVPG) measurement is the gold-standard method to assess the presence of CSPH, defined as HVPG ≥ 10 mmHg [2]. However, its use in clinical practice is limited as it is expensive and invasive. Esophageal varices are one of the first findings of CSPH. In patients with virus-related compensated cirrhosis, non-invasive methods are considered to rule-in EV, but the diagnostic value of transient elastography (TE) for EV in alcohol-related liver cirrhosis remains to be ascertained (Baveno VI consensus) [3].
**Aim:** To establish the diagnostic value of liver and spleen stiffness measurements in patients with compensated alcohol-related liver cirrhosis for diagnosis esophageal varices (EV).
**Methods:** 74 patients previously diagnosed with compensated liver cirrhosis due to alcohol intake (N = 26) and HCV infection (N = 48); 48% were males; mean age 50.9 years. All patients underwent TE measurements of both liver and spleen for the assessment of liver stiffness (LS) and spleen stiffness (SS) as well as abdominal ultrasonography measurements of the size of liver and spleen, upper endoscopy for EV assessment, and blood sampling. Statistical analysis was performed using nonparametric methods (Mann-Whitney u-test).
**Results:** In HCV-related liver cirrhosis, significant difference was observed in all parameters in patients with and without esophageal varices. Patients with EV had higher LS 27.9 (IQR 21–45) kPa vs 20.6 (IQR 16–26.2) kPa and SS 74.2 (IQR 52–75) kPa vs 38.6 (34–53.5) kPa than those without EV, as well as spleen diameter, platelet count ($p < 0.05$). However, no statistically significant difference of LS, SS, or spleen diameter was observed in patients with alcohol-related liver cirrhosis according to presence of EV. Moreover patients with alcoholic liver cirrhosis but without EV had significantly higher median of platelet counts $210*10^9$/ml (IQR 192–350) vs 98 (IQR 76–153) than those with EV and the same etiology of liver cirrhosis.
**Conclusion:** TE of liver and spleen is a non-invasive tool for diagnosis of EV in HCV-related liver cirrhosis. However, this finding could not be applied for liver cirrhosis due to other etiologies (e.g. alcohol-related). No correlation between spleen size and stiffness was found in alcohol-related liver cirrhosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Steatosis is the most common liver disease in developed countries, being related to other disorders such as diabetes and metabolic syndrome. Biopsy represents the standard of reference in diagnosis steatosis, but it is an invasive technique. As a non-invasive option, CT measurements on liver and spleen may be used, with a 0.9 threshold on their ratio being proven as diagnostic.
**Aims & Methods:** Our aim was to develop a new method based on ultrasound measurements in the liver and the right kidney allowing to detect steatosis using the CT method as reference standard. We retrospectively reviewed images of patients who performed both ultrasound and CT within 10 days. For each patient, we measured CT density of both liver and spleen by placing a region of interest (ROI) of 100 pixel in the same slice; the liver:spleen ratio was calculated. Similarly, measurements on both liver and right kidney in a single ultrasound image were obtained using ImageJ software (Java; developed by the National Institute of Health); the kidney:liver ratio was calculated. The correlation between ratios obtained on CT and ultrasound was estimated using the Spearman correlation coefficient, while the diagnostic performance of the new method based on ultrasound was calculated using ROC analysis. Patients with a CT ratio $< 0.9$ were considered as affected by steatosis. Thresholds were given for nearly-95% sensitivity or nearly-95% specificity.
**Results:** A total of 45 patients [median age 56 years (IQR 50–74 years)] were analyzed, 14 (31%) having steatosis according to CT ratio. The median CT ratio was 1.10 (IQR 0.87 –1.24), while the ultrasound ratio distribution was 0.98 (0.82 –1.13). The correlation between the two ratios was 0.524 ($P < .001$). At ROC analysis, AUC was 0.840. Thresholds for nearly-95% sensitivity and nearly-95% specificity were 1.16 (25% specificity) and 0.75 (50% sensitivity), respectively.
**Conclusion:** We developed a new ultrasound-based method to rule out liver steatosis showing a high diagnostic performance. After validation, patients with a right kidney:liver ratio (measured with this method) higher than 1.16 may avoid biopsy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** isporea@umft.ro.
**Introduction:** The severity of liver disease should be assessed prior to therapy. Noninvasive evaluation of liver fibrosis can be performed using biological test like FibroTest or by using ultrasound based elastographic methods like Transient Elastography (TE).
**Aims & Methods:** The aim of the study was to evaluate the accuracy of these tests (FibroTest and TE) for predicting HCV liver cirrhosis (LC), in naïve or treatment-experienced patients, with compensated liver disease.
**Patients and methods:** The study included 206 consecutive patients previously diagnosed with compensated HCV LC based on clinical, biologic, ultrasonographic, morphologic, laparoscopic or endoscopic (esophageal varices) criterias, who were considered for interferon free treatment (Viekirax/Exviera). Liver fibrosis was assessed during a two week period by means of TE (using M or XL probe) and by FibroTest. For TE reliable measurements were defined as median value of 10 liver stiffness measurements, with a SR $\geq 60\%$ and an IQR $< 30\%$. For diagnosing cirrhosis by means of TE we used a cut-off value 12.5 kPa [1] and for FibroTest a value of 0.75.
**Results:** Out of 206 patients, reliable measurements by TE were obtained in 89.8%, so that the final analysis included 194 patients (having valid TE and FibroTest). According to FibroTest cut-off, 74.2% (144/194) patients were correctly classified, while according to TE cut-off – 92.3% (179/194) patients ($p < 0.0001$). Out of the 194 cirrhotics, 2.1% were misclassified by TE as having significant fibrosis (F2) and 6.2% with severe fibrosis (F3). When we evaluated the performance of FibroTest, 5.7% of patients with LC were misclassified as having F2, 16.5% as having F3 and 2.6% as having F3/F4, 1% as having F1-F2.14% (7/50) patients misclassified by FibroTest had grade I esophageal varices and 2% (1/50) had grade II esophageal varices.
**Conclusion:** The accuracy of FibroTest for predicting HCV liver cirrhosis in naïve or treatment-experienced patients, with compensated liver disease was significantly lower than of TE (74.2% vs. 92.3%; $p < 0.0001$).

[3]*Department Of Gastroenterology And Hepatology, Victor Babes University of Medicine, Timisoara/Romania*

**Contact E-mail Address:** ruxi2323@yahoo.com.
**Introduction:** Accurate staging of liver fibrosis is highly important for patients with chronic liver diseases for treatment, prognosis and for long-term follow-up. Transient Elastography-TE (Fibroscan; Echosens, Paris, France), the first and the most widely used method for liver stiffness assessment, is the only ultrasound-based elastographic technique validated and recommended in some guidelines for diagnosis and management of patients with chronic liver disease [1, 2].
**Aims & Methods:** The aim of this study was to evaluate the diagnostic performance of a point shear wave elastography using ARFI technique - ElastPQ, in patients with B and C chronic hepatopathies, using Transient Elastography (TE) as the reference method, since it is a validated method for liver fibrosis assessment [1, 2]. .
**Subjects and methods:** The study included 228 consecutive subjects with chronic hepatopathies (26% HBV, 74% HCV) from whom 51% had liver cirrhosis. Liver stiffness (LS) was evaluated in the same session by means of 2 elastographic methods: TE (Fibroscan, Echosens) and ElastPQ (Philips, Affinity) techniques. Reliable LS measurements were defined as follows: for TE – the median value of 10 LS measurements with a success rate $\geq 60\%$ and an interquartile range $< 30\%$. For ElastPQ – the median value of 10 LS measurements in the liver parenchyma, at least 1 cm below the capsule, avoiding large vessels. For TE M and XL probes were used. For differentiating between stages of liver fibrosis we used the following cut-off values for TE [3]: mild fibrosis ($F \geq 1$)-6.1 kPa, significant fibrosis ($F \geq 2$)-7.2 kPa, severe fibrosis ($F \geq 3$)-9.6 kPa and for liver cirrhosis ($F = 4$)-14.5 kPa.
**Results:** Reliable liver stiffness measurements were obtained in 90.7% (207/228) by means of TE and in 98.7% (225/228) with ElastPQ. In the final analysis 205 patients were included. The ElastPQ values ranged from 2.32 to 44.07 kPa (median = 10.42 kPa). Based on TE cut-off values [3] we divided our cohort into 4 groups: F1: 62/205 (30.2%); F2: 14/205 (6.8%); F3: 32/205 (15.6%); $F = 4$: 97/205 (47.4%). The areas under the receiver operating characteristic curve were: 0.903 for patients with mild fibrosis ($F \geq 1$), 0.953 for moderate fibrosis ($F \geq 2$), 0.967for severe fibrosis ($F \geq 3$) and 0.947 for cirrhosis ($F = 4$). The best cut-off values for discriminating mild, moderate, severe fibrosis and cirrhosis were 6.4, 7.2, 8.5 and 9.9 kPa, respectively. In our cohort there was a very good correlation between measurements obtained by Transient Elastography and ElastPQ ($r = 0.85$, $p < 0.001$).
**Conclusion:** ElastPQ is a method that seems to be good for the diagnosis of all stages of liver fibrosis in patients with chronic hepatopathies, with good diagnostic accuracy.
**Disclosure of Interest:** I. Sporea: Ioan Sporea participated in an Advisory Board for Siemens and received speaker fees from Philips, Siemens and General Electric.

**Contact E-mail Address:** sherif_tropical@yahoo.com.

**Introduction:** Portal vein thrombosis is a common complication after Transarterial Chemoembolization (TACE) in Hepatocellular Carcinoma (HCC) because HCC may be highly vascular with significant arteriovenous shunting, both into the portal venous system and hepatic venous system.

**Aims & Methods:** This is the first clinical trial to evaluate the role of low molecular weight heparins (LMWH) with TACE in HCC for prevention of thromboembolism complications (portal vein thrombosis). This study was conducted on 40 patients with HCC requiring Transarterial chemoembolization who presented to the Tropical Medicine Department Tanta University and Interventional Radiology Department of Ain Shams University Hospitals starting from April 2015. Patients were divided in two groups: Group I included 20 patients with HCC treated by TACE only. Group II included 20 patients with HCC treated by TACE and adjuvant dose of LMWH. Radiological Assessment of efficacy of procedure and detection of portal vein thrombosis as a complication was done using ultrasound abdomen and pelvis and triphasic spiral CT with contrast.

**Results:** This study was conducted on 40 patients with HCC requiring Transarterial chemoembolization who presented to the Tropical Medicine Department Tanta University and Interventional Radiology; their age ranged between 43 to 74 years, 28 males and 12 female, 26 patients (65%) were child A and 14 patients (35%) were child B. Right hypochondrial pain was the most frequent symptom, 37 patients (92.5%) were seropositive to HCV and 3 patients (7.5%) were HBsAg positive. The tumor was single in 45% of patients, two nodules in 37% and three nodules in 18% of patients with AFP more than 400 ng|ml in 60% of patients. In 57% of patients tumors were located in the right lobe and portal vein was patent in all patients before the procedure The incidence of portal vein thrombosis after TACE was more in group I than group II with Seven cases in group I & only one case in group II.

**Conclusion**: LMWH with TACE in hepatocellular carcinoma is strongly recommended for prevention of thromboembolism complications (portal vein thrombosis). However, larger randomized controlled studies are needed to confirm these obvious findings.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0055 DRUG-ELUTING BEADS VERSUS CONVENTIONAL CHEMOEMBOLIZATION FOR THE TREATMENT OF UNRESECTABLE HEPATOCELLULAR CARCINOMA: A META-ANALYSIS

**A. Facciorusso**, M. Di Maso, N. Muscatiello
*Gastroenterology, University of Foggia, Foggia/Italy*

**Contact E-mail Address:** antonio.facciorusso@virgilio.it.

**Introduction: Background:** Despite the promising results of earlier studies, a clear superiority of drug-eluting beads transarterial chemoembolization over conventional chemoembolization in unresectable hepatocellular carcinoma patients has not been established yet.

**Aims & Methods:** To evaluate the efficacy and safety of the two treatments in unresectable hepatocellular carcinoma patients computerized bibliographic search on the main databases was performed. One-year, two-year, three-year survival rates were analyzed. Hazard ratios from Kaplan-Meier curves were extracted in order to perform an unbiased comparison of survival estimates. Objective response and severe adverse event rate were analyzed too.

**Results:** Four randomized-controlled trials and 8 observational studies with 1449 patients were included in the meta-analysis. Non-significant trends in favor of drug-eluting beads chemoembolization were observed as for 1-year (odds ratio: 0.76, 0.48–1.21, $p = 0.25$), 2-year (odds ratio: 0.68, 0.42–1.12, $p = 0.13$) and 3-year survival (odds ratio: 0.57, 0.32–1.01, $p = 0.06$). Meta-analysis of plotted hazard ratios confirmed this trend (hazard ratio: 0.86, 0.71–1.03, $p = 0.10$). Pooled data of objective response showed no significant difference between the two treatments (odds ratio: 1.21, 0.69–2.12, $p = 0.51$). No statistically significant difference in adverse events was registered (odds ratio: 0.85, 0.60–1.20, $p = 0.36$).

**Conclusion:** Our results stand for a non-superiority of drug-eluting beads chemoembolization with respect to conventional chemoembolization in hepatocarcinoma patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0056 EFFICACY OF LOW-DOSE CAPECITABINE AND SORAFENIB IN PATIENTS WITH ADVANCED ALFA-FETOPROTEIN SECRETING HEPATOCELLULAR CARCINOMA: A ONE-YEAR EXPERIENCE

**A. S. Hanafy**
*Internal Medicine, Zagazig University, Zagazig/Egypt*

**Contact E-mail Address:** amrhanafy@zu.edu.eg.

**Introduction:** The continued appearance of new cases of hepatocellular carcinoma (HCC) with horribly increasing incidence makes it the fifth common worldwide solid tumor; unfortunately, most of the cases present in advanced or inoperable stage. In Egypt, the majority of patients are due to HCV, and actually, they are presenting late with reduced median survival, and therapy in most cases is palliative. The treatment options either curative in the form of hepatic resection or liver transplantation and palliative to include transcatheter arterial chemoembolization (TACE) which is associated with partial response in 10–55%, radioembolization, and medical therapy with sorafenib which is an oral multikinase inhibitor that had led to significant lengthening of short term-survival when compared to placebo. The increasing number of patients presented with advanced HCC with no other eligible treatment options that can be offered for them as surgery, local ablative therapies or chemoembolization will put us in a challenging situation.

**Aims & Methods:** Evaluation of the efficacy of low-dose capecitabine combined with sorafenib which are potentially safe and effective drugs based on previous studies, in subset of Egyptian HCV patients presented with advanced HCC who were unfit for surgical or locoregional therapies. 15 patients with advanced HCC, unfit for surgical or locoregional intervention, with PS $< 2$ recieved Capecitabine 500 mg/day with sorafeneb 200 mg twice daily till normalization of AFP then the treatment was modified to capecitabine 250 mg every other day and sorafenib 400 mg once daily. They were followed every 3 months for size, number of focal masses and AFP. 30 patients were selected as control group, they received supportive therapy ($n = 15$) or sorafenib only ($n = 15$).

**Results:** After 10 months of therapy, 6 patients showed complete response (40%) with complete recanalization of portal vein ($n = 2$) and treatment was stopped and the others showed partial portal vein recanalization so treatment is continued till now. 1 patient (6.7%) showed recurrence of the disease and died after one month, 8 patients showed partial response (53.3%) and still on treatment. The control groups showed a highly significant reduction in survival when compared to patients who received capecitabine and sorafenib ($12.9 \pm 2.1$, $7.9 \pm 0.9$, $4.5 \pm 1.3$ months, $p = 0.000$).

**Conclusion:** Combined low-dose capecitabine and sorafenib proved to be safe with low toxicity profile and deserves further attention as a convenient, outpatient-based chemotherapy regimen in patients with advanced HCC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** HCC is a world-leading cause of mortality with HBV being its major etiologic factor and a worldwide geographic distribution similar to that of HBV. Previous data from Lebanon identified HBV in 51% of cirrhosis and 48% of HCC. The prevalence of HBV infections in Lebanon is decreasing in relation to vaccination, and preventive measures.
**Aims & Methods:** We aimed at studying the etiologic changes in HCC, and the prognostic implications. We compared two periods 1999–2005 (90 consecutive patients), and 2006–2015 (88 patients).
**Results:** Patients were males in respectively 85 and 78%. The etiology showed a stable prevalence of alcohol and HCV related liver disease, whereas we noted a decrease in HBV from 54 (62%) to 43 (48.9%), and an increase in Idiopathic/NAFLD from 10 (10.9%) to 17 (27.3%). Although we noted no differences in terms of severity of underlying liver disease or characteristics of the tumors, HCC occurred in the absence of cirrhosis in 14.8% in 2007–2015 as compared to 2.2% in the previous period ($p = 0.007$). The eligibility for a curative treatment increased from 21.1% to 35.2% ($p = 0.013$). We noted no difference in survival based on time periods with the exception of a better survival in the newer period for patients undergoing a curative resection or ablative therapy.
**Conclusion:** In conclusion we note that we have a changing etiologic epidemiology of HCC in Lebanon, with HBV decreasing, a steady HCV and an increase in the incidence of NAFLD related HCC. These results highlight the positive impact of our national hepatitis program for vaccination, screening, and treatment in decreasing the incidence of HBV and later HCV.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0058 HEPATIC RESECTION IS SUPERIOR TO TACE AND PERCUTANEOUS ABLATION IN B1-B2 SUBGROUPS OF PATIENTS WITH INTERMEDIATE STAGE HEPATOCELLULAR CARCINOMA

**Z.A. Sparchez**[1], P. Radu[1], I. Groza[1], C. Iancu[2], N. Al Hajjar[3]

**Contact E-mail Address:** zsparchez@gmail.com.
**Introduction:** In hepatocellular carcinoma **(HCC)** the intermediate BCLC stage (BCLC-B stage) is characterized by a high clinical heterogeneity. For a tailored treatment, in 2012 it was suggested that the BCLC-B stage should be divided into 4 sub-stages according to the tumour burden (IN or OUT the Up-to-seven criterion) and the Child-Pugh scores (A5 to B9). In B1-B2 stages hepatic resection (HR), percutaneous ablation (PA) and transarterial chemoembolization (TACE) are the proposed treatment.
**Aims & Methods:** To investigate the efficacy of the above mentioned treatments in term of survival in a Romanian cohort of BCLC – B patients with HCC.
**Methods:** Treatment indications for 200 newly diagnosed HCC patients BCLC-B stage referred to our service between 01.2009–01.2014 were analysed retrospectively. Patients were grouped according to the proposed BCLC–B sub-classification model. Baseline patient and tumour characteristics, therapy options and overall survival (OS) were analysed for the B1-B2 subgroups.
**Results:** Of the 200 patients with BCLB B 151 were in B1 + B2 substages, 42 (27.8%) in B1 and 109 (72.2%) in B2. HR was used in 46 pts (23%), 23 in B1 (54.7%) and 23 in B2 (21%), PA in 13 cases, 5 in B1 (11%) and 8 in B2 (7.9%) and TACE in 16 patients, 7 in B1 (16.6%) and 9 in B2 (8.25%). Sorafenib was used in 35 (32%) B2 patients. Patients treated by HR had larger tumors but better liver function. In the B1 + B2 group patients treated by HR had a significantly higher median survival (47 months) in comparison with thosed treated by PA (22 months), TACE (25 months) but also sorafenib (27 months) (p-value for linear trend: $< 0.001$). B1 patients treated with HR had a better median survival (47 months) compared with those treated with: PA (27 months, $p = 0.017$), TACE (26 months, $p = 0.33$) or BSC (16 months, $p < 0.001$). The 1, 3, 5-year survival rates were 81%, 47%, 7% for HR; 64%, 32% and 0% for TACE; 52%, 0%, 0% for PA; and 0%, 0%, 0% for BSC respectively. HR was superior in terms of survival also in B2 patients (46 months median survival) when comparing to TACE (24 months, $p < 0.05$), PA (10 months, $p < 0.001$), Sorafenib (27 months, $p = 0.117$) or BSC (10 months, $p < 0.000$). The 1, -3, -5-year survival rates were 71%, 42%, 7% for HR; 51%, 0% and 0% for TACE; 50%, 0%, 0% for PA; 59%, 0%, 0% for Sorafenib; and 0%, 0%, 0% for BSC respectively. The perinterventional overall 1-month mortality was higher in HR group (4.34%) in comparison with TACE (0%) and PA (0%). The mortality was higher in B2 resected patients (8.9%) in comparison to B1 (0%) but without statistical significance ($p = 0.15$).
**Conclusion:** In our cohort of patients, hepatic resection was used as curative treatment in 23% of patients included in the B1 and B2 sub-stage. In this group of patients HR provided a significant longer survival in comparison to TACE and PA. To decrease the perinterventional mortality a proper selection of patients with careful attention to liver function, degree of portal hypertension and coagulation is mandatory.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[3]*Sungkyunkwan University Of Medicine, Department of Medicine, Seoul/Korea, Republic of*

**Contact E-mail Address:** shis4u@naver.com.
**Introduction:** Transarterial chemoembolization (TACE) is performed with curative intent in some patients with early stage hepatocellular carcinoma (HCC) in real clinical practice. As radiological complete response (CR) after TACE does not always match histological total necrosis, scheduled second TACE has been tried for early stage tumor with complete response after first TACE, which lacks sufficient supporting data.
**Aims & Methods:** A total of 178 patients with early stage HCC, defined by Barcelona Clinic Liver Cancer stage (BCLC) 0 or A, who were initially treated with TACE and showed CR by mRECIST criteria at one month follow-up computed tomography (CT) were analyzed. Among them, 90 patients received scheduled second TACE in absence of viable tumor at one month follow-up CT, while 88 patients were monitored without TACE until viable lesions are detected (on-demand approach).
**Results:** During a median 4.6 years of follow-up (range: 0.4 – 8.8 years), mortality was observed in 71 patients (39.9%), with a 5-year survival rate of 60.4%. Overall and local tumor recurrence was observed in 135 (75.8%) and 103 (57.9%) patients. The overall and local recurrence-free survival rate at 1 year was 44.4% and 56.2%. In multivariable model, treatment strategy (scheduled second TACE vs. on-demand) was independent factor associated with survival [hazard ratio (HR) (95% confidence interval (CI)): 0.56 (0.34–0.93), $p = 0.025$], along with underlying liver disease, Child-Pugh class, and BCLC stage. BCLC stage was more advanced for those who received scheduled second TACE. When stratified according to the BCLC stage, scheduled second TACE was associated with favorable overall survival rate (62.1% vs. 39.1% at 5-years) and local recurrence free survival rate (31.9% vs. 10.5% at 2-years) in BCLC stage A patients, but not in BCLC 0 patients.
**Conclusion:** Scheduled second TACE was associated with better survival and lower local recurrence rate for BCLC A stage tumor showing CR after initial TACE. Scheduled second TACE strategy may play a significant role for this subset of early-stage HCC patients, which warrants further validation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0060 HEPATIC VENO-OCCLUSIVE DISEASE (VOD) AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) IN PEDIATRIC PATIENTS: ROLE OF LIVER STIFFNESSS

**F. Ravaioli**, A. Colecchia, G. Marasco, R. Masetti, K. Kleinschmidt, A. Prete, A. Pession, D. Festi
*Department Of Medical And Surgical Science, University of Bologna, Bologna/Italy*

**Contact E-mail Address:** federicoravaioli1991@gmail.com.

**Introduction:** VOD is a clinical syndrome characterized by hepatomegaly, ascites, weight gain and jaundice which can develop more frequently in the first 30 days after HSCT and that is associated with >80% mortality. Incidence has been estimated to be 13.7% (range 0%–62.3%). In this syndrome, sinusoidal endothelial cells and hepatocytes in the zone 3 of the hepatic acinus are damaged by toxic metabolites generated during the conditioning regimen leading to post-sinusoidal portal hypertension (PH) that dominates clinical conditions. To date, VOD diagnosis is based primarily on established clinical criteria (modified Seattle or Baltimore criteria) and no predictive factor are known. Liver stiffness measurement (LSM) by Fibroscan® is a safe, accurate and non invasive method used to better identify liver fibrosis and PH degree in chronic liver disease patients.
**Aims & Methods:** The aim of our study is to verify the role of LSM by Fibroscan® in predicting VOD development in a pediatric population who underwent HSCT. We prospectively included all patients with hemato-oncologic disease with indication for allo and auto-HSCT who underwent total-body irradiation (TBI) or busulfan-based conditioning regimen, referred to our Hemato-Oncologic Pediatric Unit of Sant'Orsola Hospital from November 2014 to April 2016. At enrollment (before pre-HSCT chemotherapy) all patients underwent laboratory tests, routine abdomen ultrasonography examination (US) and LSM. Subsequently laboratory tests and LSM were performed at 7–10 days (T1), 17–20 days (T2) and 27–30 days (T3) after transplantation. All examinations were conducted bedside for minimizing infection risks.
**Results:** Overall 20 pediatric patients (14 males, 6 females, mean age: 137 months, min. 54, max 245) were enrolled; 4 patients (20%) of studied population developed VOD. No evident differences were observed at baseline LSM between patients who developed VOD and those who did not. LSM values sudden increased in the measurement made before VOD diagnosis and these values were also different from baseline and from previous one.
**Conclusion:** Our data show that the increase in LSM values seems to predict VOD development in patients who underwent HSCT. In fact, LSM values suddenly increased, respect to the previous measurement, some days before the onset of the disease, in absence of altered laboratory tests or clinical symptoms suggestive of VOD disease. According to the relevance of early diagnosis on clinical outcome, further studies are needed to confirm the predictive role of liver stiffness measurement for an early VOD diagnosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[2]*Special Minimally Invasive Surgery, The First Hospital of Lanzhou University, Lanzhou/China*
[3]*Department Of Gastroenterology, Kyoto Second Redcross Hospital Japan, Kyoto/Japan*

**Contact E-mail Address:** flexzhu6910@sina.com.

**Introduction:** Periampullary diverticula (PAD) is known to be associated with an increased frequency of pancreatobiliary diseases [1]. Our previous study has demonstrated that PAD is an important factor for the occurrence and recurrence of common bile duct (CBD) stones [2]. It is widely accepted that the presence of PAD can be a technical obstacle to cannulation and requires skillful endoscopy manipulation [3–4]. Nevertheless, there has been little study about large scale appraisal of therapeutic effectiveness and safety of endoscopic retrograde cholangiopancreatography (ERCP) procedure when CBD stones combined with PAD.
**Aims & Methods:** This study was to investigate the optimal ERCP method for common bile duct stones combined with periampullary diverticula. Retrospective analysis of the first session therapeutic ERCP cases including two endoscopy centers (The first hospital of Lanzhou University, Gansu, China and Kyoto Second Red Cross Hospipal, Japan) between January 2012 and January 2015. Clinical data of all cases include the following properities: gender, age, with or without PAD, whether or not there was difficulty to remove stones, residual rate of CBD stone, post-ERCP complication. ERCPs were performed by experienced endoscopists who performed over 200 biliary interventions per year. Group of EST plus papillary balloon dilation was conducted at The First Hospital of Lanzhou University, a teaching hospital of Gansu in China. EST group was performed at Kyoto Second Red Cross Hospipal in China. Patients were placed under conscious sedation with meperidine and midazolam.
**Results:** A total of 3.196 (2, 309 Chinese, 887 Japanese) therapeutic ERCPs were enrolled in the final analysis. Of this total, 1, 491 patients (1, 259 Chinese, 232 Japanese) had CBD stones without PAD and 612 patients (459 Chinese, 153 Japanese) had CBD stones with PAD. In all of the data, there were no statistically significant between sex, but patients with PAD were significantly older than those without PAD ($67.61 \pm 13.51$ vs $60.85 \pm 16.82$, $P < 0.0001$). Whether from Chinese, or from Japanese, the rate of CBD stone with PAD was significantly higher than CBD stone without PAD (79.14% vs 72.82%, $P = 0.0025$; 68.61% vs 34.94%, $P < 0.0001$, respectively). Compared with EST, both the rate of difficulty to remove out stones and residue of CBD stones were significantly lower in EST plus EPBD than in EST (74.51% vs 32.46%, $P < 0.0001$; 27.45% vs 8.16%, $P < 0.0001$; respectively) on condition that CBD stones combined with PAD, but the post-ERCP complications had no significant difference between EST and EST plus EPBD (7.17% vs 13.38%, $P = 0.05$) (Table 1).

**Table 1:** Out-come of different ERCP methods for CBD stones with PAD between two groups.

| Index | EST plus EPBD group (The first hospital of Lanzhou University) | EST group (Kyoto Second Red Cross Hospital) | Chi-square | P value |
|---|---|---|---|---|
| Rate of difficulty to remove stone (n, %) | 124 (32.46) | 114 (74.51) | 78.2146 | <0.0001 |
| Rate of residual stone (n, %) | 28 (8.16) | 42 (27.45) | 32.4729 | <0.0001 |
| Rate of post-ERCP Complication (n, %) | 19 (13.38) | 16 (7.17) | 3.8534 | 0.0496 |

**Conclusion:** EST plus papillary balloon dilation was an optimal ERCP procedure for common bile duct stones in patients with periampullary diverticula.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The accumulating evidence strongly suggests that the gut microbiota play an important role in the regulation of energy balance and weight in mammals and may influence the progression of obesity. (1) On the other hand, it is well known that bile acids are the most important regulators of the gut microbiome. (2) Together, these might suggest that pharmacological alteration of bile acid composition can modify the gut microbiota and thus, can provide the relevant therapeutic avenue for obesity and other metabolic disorders.
**Aims & Methods:** We investigated whether the ursodeoxycholic acid (UDCA), a commonly used therapeutic agent for the hepatobiliary disorders, can reduce the weight gain. Furthermore, we also demonstrated the effects of UDCA on the intestinal dominance of Firmicutes, which is known as a condition prone to obesity. The 6 weeks-old male Sprague Dawley (SD) rats were divided into 3 groups: the U10 (a group intraorally administered with 10 mg/kg UDCA), the U15 (a group with 15 mg/kg UDCA) and the control (a group with a saline as a vehicle). During a total of 3 weeks-administration of UDCA, a time course of lipid-related serological parameters e.g., triglycerides (TG), total cholesterol (TCH), and high-density lipoprotein (HDL) and a body weight were analyzed. To investigate the modulating effects of UDCA on the ratio of Firmicutes to Bacteroides, quantitative polymerase chain reaction (qPCR) methods using rat fecal materials were fulfilled after 3 weeks-administration of UDCA.
**Results:** The weight gain of U10 and U15 were significantly reduced compared with that of control and these were dose- and time-dependent manner. Using qPCR, we revealed the ratio of Firmicutes to Bacteroides in fecal materials of U10 and U15 were significantly reduced than that of control after 3 weeks-administration of UDCA. Finally, we demonstrated that the serum level of TG and TCH were decreased, whereas the level of HDL was elevated in U10 and U15 at all time point of experiment and these were also dose-dependent.
**Conclusion:** Taken together, we suggest that UDCA can reduce weight gain via preventing the intestinal dominance of Firmicutes. To address the possible mechanism for these alterations in composition of gut microbiota, further investigation might be needed.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Acute pancreatitis is a multifactorial pathology with possible involving of genetic factors. Pancreatitis itself has strong and diverse impact on digestive system. Acute pancreatic inflammation frequently leads to cholestasis, though prediction of this complication remains tricky. There are multiple studies of the candidate genes' polymorphisms for acute and exacerbated chronic pancreatitis, depicting its understanding as a multifactorial pathology involving genetic factors. But the role of immune system, especially polymorphism of genes that regulate the inflammatory response in the pathogenesis of biliary/pancreatic inflammation is often left beyond attention. Study of different genetic polymorphisms may create a strong background for individualized therapies of biliary disorders.
**Aims & Methods:** The aim of the study is to find changes of biochemical parameters of cholestasis syndrome in patients with acute non-necrotizing pancreatitis, depending on the polymorphism of genes of interleukin 4 (IL-4, (C-590T), TNF-$\alpha$ (G-308A), PRSS1 (R122H) and CFTR (delF508C), etiologic factor and gender. Genetic studies performed for 101 patients, among them 19 (18.8%) were women and 82 (81.2%) men. There were 64 (63.37%) patients with alcoholic pancreatitis genesis (AGP) and 37 (36.63%) – with biliary (BGP). The genotypes distribution among examined patients and healthy people for the selected genes has been determined. The possible associative links of indicated genes polymorphism with the increased activity of gamma-glutamyl transferase, alkaline phosphatase, bilirubin and its fractions levels, the etiology of disease (alcoholic or biliary) and gender have been searched for.
**Results:** Distribution of genotypes among examined patients and healthy people was as follows: the PRSS1 (R122H) gene in all groups was represented by GG-genotype (100%); CFTR (delF508) gene – in 3 persons with NM-genotype (2.97%) and 98 with NN-genotype (97.03%); in control group of healthy people were registered only NN carriers; TNF-$\alpha$ (G-308A) gene: 81.19% with GG-genotype and 18.81% GA-genotype; the IL-4 (C-590T) gene among patients was represented in 58 (57.43%) patients by CC-genotype, in 34 (33.66%) – by CT-genotype, in 9 (8.91%) – by mutation TT-genotype, among healthy – in 26 (65%), 11 (27.5%) and 3 (7.5%), respectively ($\chi^2 < 1.0$, $p > 0.05$).
**Conclusion:** This study does not establish clear association of polymorphisms of PRSS1 (R122H), CFTR (delF508) and TNF-$\alpha$ (G-308A) genes with the increased activity of cholestatic syndrome, pancreatitis etiology and gender. However, the activity of cholestasis syndrome was higher, mainly in carriers of the TT-genotype of IL-4 gene (rs 2243250) and was characterized by 1.9 and 1.58 times growth of the gamma-glutamyl transferase (with biliary genesis) and 2.06 and 1.53 times (among women), total bilirubin - 1.85 and 2.13 times (with alcoholic genesis) and 1.66 and 1.87 times (among men), direct bilirubin - 2.81 and 3.22 times (with alcoholic genesis) and 2.47 and 2.96 times (among men) compared to the C-allele carriers, respectively.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Obeticholic Acid (OCA) is a selective and potent farnesoid X receptor (FXR) agonist developed for treatment of primary biliary cirrhosis (PBC). 216 patients were randomized and dosed in a double-blind (DB), placebo-controlled, phase 3 PBC trial (POISE); 198 patients completed the DB phase of the trial and 193 (97%) patients enrolled in the open-label long-term safety extension (LTSE).
**Aims & Methods:** The LTSE aim is to assess the continued durability of OCA on the markers of cholestasis and safety. Inclusion criteria for the DB phase: PBC diagnosis, ALP $\geq$ 1.67x ULN and/or total bilirubin > ULN to <2x ULN, stable UDCA dose or unable to tolerate UDCA. During the DB phase, patients were randomized to: daily Placebo (PBO), 5 to 10 mg OCA titration group (titration after 6 months based on response/tolerability), or 10 mg OCA. In the LTSE, all patients were to be initially treated with 5 mg OCA regardless of DB treatment with the option to increase OCA dose up to 10 mg after 3 months. This analysis focuses on patients receiving $\leq$10 mg OCA daily. The LTSE phase is currently in progress with 170 total patients completing through 18 months (PBO, n = 41; Titration OCA; n = 45; 10 mg OCA, n = 50; all for patients receiving $\leq$10 mg OCA daily). LTSE demographics: mean age 56 y; female: 91%; white 94%.
**Results:** All OCA groups had significant reductions in ALP, GGT, ALT and AST (Table 1) after 12 months of treatment. In OCA Titration and 10 mg groups, this response was durable through an additional 18 months of the LTSE. For PBO, mean bilirubin increased during the DB period. OCA Titration and 10 mg groups sustained no increase in mean bilirubin in the DB or LTSE. Overall OCA was safe and well-tolerated; pruritus was the most common adverse event (AE) associated with OCA. Patients on OCA in the DB period showed a decrease in crude incidence of pruritus in the LTSE, from 56–68% (12 months DB treatment) to 19–36% (ongoing LTSE treatment). PBO subjects who initiated OCA in the LTSE saw an increase in pruritus consistent with initiation of OCA. While receiving OCA, initial changes in lipoprotein levels were sustained throughout the LTSE. Unrelated to OCA, 1 patient died as a result of sepsis secondary to endocarditis after a prosthetic aortic valve replacement.

**Table 1:** Laboratory changes through the double-blind and LTSE study period.

| Original Treatment Group | Placebo | OCA Titration | 10 mg OCA |
|---|---|---|---|
| **ALP (U/L)** | | | |
| DB Baseline | 310.3 (96.8) | 314.7 (122.1) | 307.7 (97.8) |
| Δ DB 12 mo | -12.1 (80.4) | -106.1 (87.0)*** | -122.0 (74.9)*** |
| Δ LTSE 18 mo | -97.8 (69.6)*** | -111.3 (90.3)*** | -106.8 (91.4)*** |
| **Bilirubin (μmol/L)** | | | |
| DB Baseline | 11.0 (6.4) | 10.6 (6.0) | 10.9 (7.1) |
| Δ DB 12 mo | 1.5 (4.3)* | −0.6 (3.5) | -1.2 (4.7) |
| Δ LTSE 18 mo | 1.9 (14.0) | −0.3 (3.9) | -1.3 (4.5) |
| **GGT (U/L)** | | | |
| DB Baseline | 329.4 (506.6) | 267.0 (177.8) | 277.0 (229.3) |
| Δ DB 12 mo | -16.0 (190.6) | -149.4 (157.1)*** | -188.3 (166.8)*** |
| Δ LTSE 18 mo | -176.7 (406.4)** | -161.7 (156.0)*** | -143.3 (157.0)*** |
| **ALT (U/L)** | | | |
| DB Baseline | 55.7 (31.5) | 65.4 (42.5) | 57.0 (43.3) |
| Δ DB 12 mo | -5.3 (19.6) | -23.8 (22.7)*** | -25.0 (28.3)*** |
| Δ LTSE 18 mo | -22.1 (25.0)*** | -25.8 (27.1)*** | -17.5 (57.5)* |
| **AST (U/L)** | | | |
| DB Baseline | 47.3 (18.2) | 54.1 (27.6) | 51.1 (34.4) |
| Δ DB 12 mo | 1.9 (35.0) | -12.9 (15.1)*** | -14.3 (20.5)*** |
| Δ LTSE 18 mo | -10.4 (15.2)*** | -13.1 (17.9)*** | -12.7 (32.4)** |

*$p < 0.05$, **$p < 0.01$, ***$p < 0.0001$. Values are Mean (SD). P-values for the within treatment comparisons are obtained using a paired t-test. All patients represented received ≤ 10 mg OCA.

**Conclusion:** OCA treatment improves liver biochemistry, most notably ALP and GGT, which is sustained throughout the course of the LTSE. Pruritus was the most common AE, but its incidence appeared to lessen with longer treatment.

## P0065 EUS FOR SUSPECTED CHOLEDOCHOLITHIASIS. FIRST RESULTS OF A CHANGE IN STRATEGY REGARDING INDICATION AND TIMING OF ERCP

**R. Quispel**[1], M. Van Der Voort[1], L. M. Van Driel[1], B. Veldt[1], M.J. Bruno[2]
[1]*Gastroenterology, Reinier de Graaf, Delft/Netherlands*
[2]*Department Of Gastroenterology & Hepatology, University Medical Center Rotterdam, Rotterdam/Netherlands*

**Contact E-mail Address:** r.quispel@rdgg.nl.
**Introduction:** Endoscopic ultrasonography (EUS) is a diagnostic modality with excellent diagnostic accuracy for diagnosing common bile duct (CBD) stones. In studies showing these performance characteristics, any EUS with positive findings was instantly followed by an ERCP. In a recent retrospective study, the proportion of positive findings at ERCP in the group of patients with EUS-confirmed bile duct stones was relatively low (58%). This appeared to be related to both the time interval between EUS and ERCP (median 4 days, interquartile range 1–15) allowing for spontaneous stone and sludge passage, as well as the decision to regard biliary sludge as an indication for performing an ERCP. In the current prospective study, we aim to re-evaluate the time interval and the proportion of positive findings on ERCP. Moreover, we adopted a more conservative attitude towards patients with mild symptoms and a non-dilated CBD with sludge at EUS.
**Aims & Methods:** Between January 2015 and March 2016, 40 out of 100 (40%) consecutive patients undergoing EUS for suspected bile duct lithiasis had positive findings. Patients with CBD stones on EUS all underwent an ERCP with endoscopic sphincterotomy. In patients with suspected sludge, a non-dilated CBD on EUS and mild symptoms, we discussed with the patient either to perform an ERCP or to adopt a watchful waiting strategy. Patients with CBD sludge on EUS opting for the conservative strategy were followed regularly at the outpatient clinic. Data were compared to our retrospective series.
**Results:** Thirty-four out of 40 (85%) patients with positive findings during EUS had one or more CBD stones. Six of those only had sludge in the CBD. For the latter indication, ERCP and sphincterotomy was performed in only one patient. In the remaining 5 patients, a watchful waiting strategy was adopted. None these patients developed cholangitis, pancreatitis or developed any indication for ERCP for biliary symptoms at six months follow-up. In patients in whom an ERCP was performed, 26 of 35 (74.3%) had positive findings. This was substantially higher compared to our retrospective series. The time interval between EUS and ERCP was 2 days (interquartile range 1–8) which was significantly shorter compared to our retrospective series (4 days, $p = 0.05$). Sludge was detected and removed in 3 out of 35 cases (8.5%), and one or more stones were found in 23 out of 35 cases (66%). The one patient with CBD sludge at EUS had an unremarkable ERCP. Patient characteristics including age, gender and cholecystectomy history were comparable in both the retrospective and prospective cohorts.
**Conclusion:** Shortening the time interval between EUS and ERCP results in a higher proportion of positive findings at ERCP as expected. Although evidence is still limited, a more conservative approach, i.e. not immediately performing an ERCP in patients with mild non-specific symptoms with sludge in a non-dilated CBD, appears justifiable without an apparent increase in the incidence of biliary complications.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0066 NEW METHOD TO INSERT LARGE CALIBER PLASTIC AND SELF-EXPANDING METAL STENTS DURING BALLOON OVERTUBE ENTEROSCOPY (BAE) ASSISTED ERCP

**P.T. Kroener**[1], Á. Martínez-Alcalá[1], I. Jovanovic[1], M. A. D'Assuncao[1], H. Neumann[2], K. Mönkemüller[1]
[1]*University of Alabama, Birmingham/United States of America/AL*
[2]*Department Of Medicine I, University Hospital Erlangen, Erlangen/Germany*

**Contact E-mail Address:** thomaskroner@gmail.com.
**Introduction:** BAE-assisted techniques have greatly enhanced our ability to perform ERCP in patients with surgically altered upper gastrointestinal (GI) tract anatomy. However, even with newer endoscopes it is impossible to advance self-expanding or larger diameter stents through the working channel, thus impeding successful therapeutic interventions in some patients. We have developed a novel technique (''BAE-ERCP rendezvous and overtube-in-situ'') to place large diameter self-expanding metal stents.
**Aims & Methods:** The aim of this study is to demonstrate a new method to deliver self-expanding metal stents (SEMS) and large diameter stents in patients with surgically altered upper GI tract anatomy. Retrospective, observational, cohort study at a single tertiary, academic institution during a 3-year period evaluating patients with complex post-surgical anatomy and undergoing BAE-ERCP. Description of endoscopic technique: The technique consists of utilizing the overtube as a ''giant working channel'', inserting a wire into the bile ducts, removing the scope, and then inserting the self-expanding stent over the wire, through the overtube under fluoroscopic control. In addition, the overtube may be left in situ to allow for insertion of standard or ultraslim scopes to perform direct cholangioscopy, laser lithotripsy and stone removal. In addition, SEMS can be placed percutaneosuly, under direct endoscopic vision, especially if the scope/overtube are in twisted and angled positions, thus impeding the use of the working channel to advance accessories towards the bile duct.
**Results:** We performed a total of 105 BAE-ERCPs in 90 patients. The BAE-ERCP rendezvous and overtube-in-situ technique was utilized 10 times in 8 patients (8.8%, female n = 4, male n = 4, mean age 54.4, range 22–82). Indications were cholangitis n = 4, choledocolithaisis n = 6, cancer obstructing the hepaticojejunostomy (HJ) n = 2. The post-surgical anatomy was Roux-en-Y HJ n = 5, RY gastric bypass n = 1, Billroth II n = 1. Four patients had undergone a liver transplant, three patients had undergone Whipple's operation for pancreatic cancer, one patient had undergone RY hepaticojejunostomy for a choledocal cyst during childhood. The technique was successful in all patients. In 50% patients other interventions such direct cholangioscopy, dilation and EHL could be performed using this new technique. The mean duration of the procedure was 65 minutes, range 45 to 125 min. There were no major adverse events.
**Conclusion:** The BAE-ERCP rendezvous and overtube-in-situ and rendezvous technique is a useful method to perform therapeutic interventions such as insertion of large caliber stents and self-expanding metal stents in patients with surgically altered upper GI anatomy and in whom traditional BAE-ERCP is impossible. To the best of our knowledge this is the largest experience using this technique. The working channel of DBE and SBE enteroscopes is too small for passage of larger accessories and the deployment of larger diameter stents. The flexibility of the overtube used for enteroscopy an left in-situ allows for smooth passage of the stent delivery system usig radilogical guidance. Knowledge of this level IV ERCP technique is important for those endoscopists performing therapeutic ERCP in patients with surgically altered upper GI tract, as it will likely increase the success rate of BA-ERCP and should thus be added to the therapeutic arsenal of the biliary endoscopist.

## P0067 TEMPORARY PLACEMENT OF BILIAY PIGTAIL STENTS AFTER UNCERTAIN COMMON BILE DUCT STONES CLEARANCE IN ERCP

**J. Garcia Cano**[1], L. Taberna-Arana[2]
[1]*Department Of Digestive Diseases, Hospital Virgen De La Luz, Cuenca/Spain*
[2]*Department Of Family Practice, District Health of Cuenca, Cuenca/Spain*

**Contact E-mail Address:** jegarca59@gmail.com.
**Introduction:** Sometimes it is difficult to ascertain that after an ERCP session for Common Bile Duct (CBD) stones removal, a complete clearance has been achieved. Failure in total stone extraction can lead to severe cholangitis. There are several methods to verify full CBD stones removal such as occlusion cholangiography, cholangioscopy or intraductal ultrasound. Occlusion cholangiography must be performed carefully for the risk of biliary overdistension and the other methods are not available in many units.
**Aims & Methods:** After ERCP for CBD stones extraction with uncertain complete stone clearance a 7 F, 7 cm long double pigtail stent was inserted. If both patient's condition and liver biochemistry improved, the stent was removed by gastroscopy a month later. After stent removal instructions were given to the patient and relatives for early recognition of cholangitis or CBD obstruction (e.g. dark urine).
**Results:** 24 patients were included prospectively in the study. CBD stone size ranged 9–13 mm. All patients had biliary sphincterotomy and 15 (62.5%) had also sphincteroplasty with balloons up to 15 mm in diameter during the same procedure. Choledocholithiasis tried to be removed with extraction balloons. Doubts about complete CBD stone extraction came about for the following reasons: patient instability and need for a quick procedure (9 or 38%), poor fluoroscopy quality (5 or 21%) and total number of visualized extracted stones less than expected (10 or 41.5%). Two mild pancreatitis and a mild hemorrhage occurred after the procedures. No cholangitis was seen. Uneventful pigtail stent removal was performed a month later and no complications were reported. This group of 24 patients was compared with an historic cohort of 115 previous patients in whom stents were not inserted. Three jaundice episodes and four cholangitis were observed after ERCP for CBD stone extraction in the historic non-stented patients (7/115 or 6%) compared with none in the present group with stents ($p < 0.05$).
**Conclusion:** Insertion of temporary plastic pigtail stents in patients with uncertain complete stone removal in ERCP appears a simple and safe procedure that prevents complications. In this study the stents were removed a month later by gastroscopy without further ERCPs.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0068 ASSESSMENT OF SHORT SINGLE-BALLOON ENTEROSCOPE (SHORT-SBE) FOR THERAPEUTIC ERCP IN PATIENTS WITH ALTERED GASTROINTESTINAL ANATOMY

**Y. Tanisaka**, S. Ryozawa, H. Iwano, M. Harada, T. Kobatake, S. Arai, Y. Mashimo
*Gastroenterology, Saitama Medical University International Medical Center, Saitama/Japan*

**Contact E-mail Address:** tanisaka@saitama-med.ac.jp.
**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) in patients with altered gastrointestinal anatomy is technically challenging. We performed ERCP in such patients using a short single-balloon enteroscope (Short-SBE, Olympus), which has a 3.2-mm working channel and a 152-cm working length and for which conventional accessories are available.
**Aims & Methods:** This study aimed to assess the efficacy and safety of ERCP using a Short-SBE in patients with altered gastrointestinal anatomy. The present retrospective study included 67 patients (range, 37–87 years) and 105 procedures comprising Roux-en-Y reconstruction (55 patients and 73 procedures), Billroth II gastrectomy (7 patients and 16 procedures), and reconstruction by the modified Child method (5 patients and 16 procedures) performed using a Short-SBE. The success and complication rates of each procedure were evaluated.
**Results:** The blind end was reached in 91.4% of procedures (96/105). Of the failed procedures, six were caused by jejunum invasion. Among 96 procedures in which the blind end was reached, cholangiography was successfully performed 93.8% of procedures (90/96). Treatment was successful in 91.7% of procedures (88/96). Successfully performed therapeutic interventions included nasobiliary drainage (n = 2), plastic stent placement (n = 14), self-expandable metallic stent placement (n = 11), tumor biopsy (n = 2), and stone extraction (n = 59) using endoscopic sphincterotomy (n = 1) endoscopic papillary balloon dilation (n = 4), endoscopic papillary large-balloon dilation (n = 19), and choledochojejunostomy dilation (n = 9). Complications that occurred in 10.5% of procedures (11/105) included minor perforation (n = 2) during choledochojejunostomy dilation, mild pancreatitis (n = 5), and mild cholangitis (n = 4). No complications associated with the use of short SBE were observed in the present study.
**Conclusion:** ERCP using a short-SBE is effective and safe in patients with altered gastrointestinal anatomy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0069 ROLE OF SPYGLASS$^{TM}$-CHOLANGIOSCOPY: FIRST CLINICAL EXPERIENCES IN SWITZERLAND

G. Semadeni, **R. Frei**, C. Meyenberger, M.C. Sulz, J. Borovicka
*Gastroenterology/hepatology, Kantonsspital St. Gallen, St. Gallen/Switzerland*

**Contact E-mail Address:** remus.frei@kssg.ch.
**Introduction:** Direct cholangioscopy enables not only the direct diagnostic visualisation of the biliary tract, such as the workup of stenosis, but offers also the possibility in treating complicated choledocho- or hepaticolithiasis via cholangioscopic electrohydraulic lithotripsy (EHL). The SpyGlass$^{TM}$ DS cholangioscope (Boston Scientific) is attached to a duodenoscope, inserted into the working channel of the duodenoscope and advanced into the biliary tract as a single operator system. It has got a 10Fr diameter and a working channel of 1.2 mm. The tip of the SpyGlass$^{TM}$ catheter is steerable in 4 directions.
**Aims & Methods:** Prospective inclusions of direct cholangioscopies with SpyGlass$^{TM}$ DS cholagioscope at a tertiary referral centre in Switzerland.
**Results:** Since September 2015, 14 cholangioscopies were performed in 11 patients (3 female, 8 male; mean age 62; ASA I-II; general anaesthesia (3), conscious sedation (11)). Overall, indications were stenosis (6), hepatico-/choledocholithiasis (4), stent dislocation (2), recurring haemobilia (1) and bile leakage (1). The following interventions were performed: electrohydraulic lithotripsy (EHL) with stone removal (2), percutaneous transhepatic cholangiography with cholangioscopy via PTC and EHL of hepaticolithiasis (2) in a patient with hepaticolithiasis after Kasai procedure in childhood for biliary atresia, and stent extraction (1). In diagnostic cholangioscopies, indications were stenosis (6), in one case with known PSC, recurring haemobilia (1), and postoperative bile leakage (1). Visual examination without additional cytology was able to define inflammatory aetiology of stenosis in 5 patients. Additional cytology confirmed this visual diagnosis in 1 case, but was false negative in one case of suspected cholangiocellular carcinoma (CCA) which was confirmed during surgery. In the case of recurring haemobilia with several unsuccessful prior ERCs, diagnosis of a CCA was made by direct cholangioscopy.
**Conclusion:** First experiences with SpyGlass$^{TM}$ -Cholangioscopy in clinical practice show a therapeutic as well as a diagnostic benefit due to its high resolution imaging. Its simple application (single operator system) is a relevant factor in clinical practice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0070 BALLOON-OVERTUBE ENTEROSCOPY ASSISTED (BAE) VERSUS LAPAROSCOPY-ASSISTED ERCP IN BARIATRIC POST-ROUX-EN-Y GASTRIC BYPASS PATIENTS: A COMPARATIVE STUDY

**U. Kumar**[1], P.T. Kroener[2], I. Jovanovic[2], J. P. Gutierrez[2], H. Neumann[3], K. Mönkemüller[2]
[1]*Gastroenterology, University of Alabama, Birmingham/United States of America/AL*
[2]*University of Alabama, Birmingham/United States of America/AL*
[3]*Department Of Medicine I, University Hospital Erlangen, Erlangen/Germany*

**Contact E-mail Address:** ukumar@uabmc.edu.
**Introduction:** Data on balloon enteroscopy–assisted ERCP (BAE-ERCP) versus laparoscopy-assisted ERCP in post–Roux-en-Y gastric bypass (RYGB) patients are scarce.
**Aims & Methods:** The aim of this study was to compare BEA-ERCP with laparoscopy-assisted ERCP post-RYGB patients. This is a retrospective, observational, comparative, non-randomized, cohort study of consecutive patients at a single tertiary, academic institution during a 3-year period evaluating patients with Roux-en-Y gastric bypass undergoing BAE-ERCP or laparoscopy-assisted ERCP.
**Results:** A total of 31 patients underwent 35 procedures (29 female, 2 male, mean age 52.4 years, range 32 to 67). A total of 19 patients underwent laparoscopy-assisted ERCP and 12 patients underwent BAE-ERCP. There were no statistically significant differences in age (51.5 vs. 52.1 years), gender (9 vs. 5%), indication for ERCP (choledocolithiasis in 73 vs. 67%, suspected sphincter of Oddi dysfunction, 26 vs. 27%). Laparoscopy-assisted ERCP was superior to BAE-ERCP in papilla identification (100% vrs 67%, $p < 0.01$). The ERCP success rate was also higher in the laparoscopy-assisted ERCP group as compared to the BAE-ERCP group (89% vs. 50%, $p < 0.01$). Deep cannulation of the common bile duct failed in one patient undergoing laparoscopy-assisted ERCP, in another patient it was impossible to remove the large impacted stones within the CBD. In three patients undergoing BAE-ERCP it was impossible to perform therapeutic biliopancreatic interventions despite successfully entering the biliodigestive limb. Although the procedure duration was much longer during laparoscopy-assisted ERCP (the mean total time including operation was 190 minutes), the total ERCP time was similar (laparoscopy-assisted ERCP 63 minutes, range 22 to 110 min. vs. BAE-ERCP with a mean of 65 min, range 45 to 125 min). The hospital duration was 2.3 days in the laparoscopy-assisted ERCP group and 1.2 day in the BAE-ERCP group ($p = 0.02$). There were no major complications in the BAE-ERCP group. In patients undergoing laparoscopy-assisted ERCP there were two post-ERCP pancreatitis and one severe post-sphincterotomy bleeding requiring blood transfusion and surgical re-intervention.
**Conclusion:** LA-ERCP offers a higher chance of therapeutic success in patients with Roux-en-Y gastric bypass. Nevertheless, as BAE-ERCP also leads to therapeutic success in about 50% of cases, and thus, starting with BAE-ERCP may offer a stepwise approach and avoid more invasive procedure, longer hospitalization and possibly be more cost-effective than LA-ERCP.

**Contact E-mail Address:** jaihoonyoon@gmail.com.

**Introduction:** We investigated whether periampullary diverticulum (PAD) would be different effects aspect of post endoscopic retrograde cholangiopancreatography (ERCP) pancreatits (PEP) according to type and size of PAD. The aim of this study was to investigate risk factors for PEP, including three types of PAD.
**Aims & Methods:** Consecutive ERCP procedures for extractions of common bile duct stones were studied at one university hospital in Chucheon, Korea from Jan 2007 to July 2015. We reviewed the medical charts of 959 patients, PAD were classified into three types by the location of ampulla of Vater: type 1, inside the diverticulum; type 2, on the margin of diverticulum; type 3, outside the diverticulum. PAD size was divided to Group 1 (larger than diameter of ampulla of Vater (AoV)), Group 2 (similar with diameter of AoV) and Group 3 (smaller than AoV).
**Results:** One hundred sixty-two patients had PAD including 6 (3.7%) in type 1, 107 (66.0%) in type 2, and 49 (30.2%) in type 3. PEP was developed in 61 patients, the frequency of PEP was different from diverticulum type (3.3% in type 1; 82.0% in type 2; 14.8% in type 3, $p = 0.003$). The size of diverticulum was not different for PEP (31.1% in Group1, 47.5% in Group2, 21.3% in Group3, $p = 0.161$). By univariate nanalysis, CBD size (OR 0.898, 95% CI 0.85 – 0.94, $p = 0.0001$) and cannulation time (OR 1.028, 95% CI 1.010–1.046, $p = 0.002$), diverticulum type 2 (OR 2.899, 95% CI 1.72 – 8.8, $p = 0.001$) was associated with PEP. By multivariate analysis, the risk factors for PEP were diviericulum type2 (OR 4.34, 95% CI 1.49 – 12.55, $p = 0.007$).
**Conclusion:** Periampullary ampullary diverticulum, type 2 is only independent risk factor for PEP in our study.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Recent reports have described the efficacy of plastic stent (PS) placement inside the bile duct for malignant biliary strictures. However, the superiority of intraductal PS placement (IS) over PS placement across the sphincter (conventional PS placement [CS]) and uncovered metallic stent placement above the sphincter of Oddi (MS) is unclear.
**Aims & Methods:** The aim of this study was to evaluate the efficacy of IS, and compare its efficacy with the efficacies of CS and MS for malignant biliary strictures. This retrospective study included 25 patients (28 procedures) with an unresectable malignant hilar or middle bile duct obstruction, who underwent IS between January 2008 and December 2015 at our institution. The indication for IS was a distance of at least 3 cm between the lower end of the stricture and the sphincter. We compared the efficacy of IS with the efficacies of CS (22 patients [32 procedures]) and MS (12 patients [12 procedures]). Among the 25 patients who underwent IS, the origins of the malignant biliary stricture were gallbladder cancers in 9 patients, intrahepatic cholangiocarcinomas in 7 patients, bile duct cancers in 3 patients, pancreatic cancers in 3 patients, and others in 3 patiets. We evaluated complications associated with stent placement, stent patency (functional) periods, and stent removability at occlusion. We modified a 7-Fr Flexima biliary stent (Boston Scientific Co., Boston, MA) and attached a nylon thread (size 2/0) to the distal end for removal. If insertion was difficult due to winding or narrowing of the intrahepatic bile duct (ex. B3 and B6), we placed a Flexima nasobiliary drainage tube (7.5Fr), cut to the appropriate length, as an internal stent. All stent placements were performed after preoperative nasobiliary drainage.
**Results:** The overall technical success rates in the IS, CS, and MS groups were all 100%. The success rates for reducing or maintaining the serum bilirubin level (total bilirubin $< 2.0$ mg/dL) were as follows: IS, 96.4% (27/28); CS, 100%; MS, 100%. The median patency duration was greater in the IS group than in the CS group (138 days vs. 44 days, $P < 0.001$, log-rank test); however, the patency duration was not significantly different between the IS and MS groups (138 days vs. 231 days, $P = 0.46$). In the IS group, there were no early complications associated with stent placement; however, delayed complications were observed in 3 patients from this group (2 had cholecystitis with gallstones and 1 had stent migration to the hepatic side). Additionally, in the IS group, 11 patients developed stent occlusion (dysfunction). The causes of occlusion were sludge deposition in 6 patients, reflux cholangitis in 1 patient, bending of the stent in 1 patient, tumor overgrowth in 1 patient, dislocation to the duodenal side in 1 patient, and migration to the hepatic side in 1 patient. In 9 patients from the IS group, stent replacement was attempted and was performed successfully. There were no complications associated with stent removal. Besides IS, the factors associated with PS patency period were the number of stents and usage of anticancer agents (multiple stents 100 days vs. single stent 44 days, $P = 0.034$, usage of anticancer agents 78 days vs. no usage 61 days, $P = 0.024$, log-rank test). Furthermore, multivariate analysis showed a significant difference in IS ($P < 0.0001$, Cox proportional hazard model).
**Conclusion:** The patency period is longer with IS than with CS for malignant biliary obstruction. Additionally, the patency period tends to be shorter with IS than with MS; however, the difference might not be significant. Additionally, complications are relatively minor with IS, and the stent can be removed if dysfunction occurs. Therefore, IS is an effective option for malignant hilar and middle bile duct obstructions, and it is as effective as MS.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0073 HUMAN EQUILIBRATIVE TRANSPORTER 1 (HENT1) EXPRESSION IS NOT PREDICTIVE FOR GEMCITABINE OUTCOME IN PATIENTS WITH ADVANCED BILIARY TRACT CANCER

**J.K. Lee**[1], D.K. Jang[1], J.H. Son[2], J.W. Lee[2], S.H. Lee[2], J.K. Ryu[2], Y. Kim[2], K. Lee[2]

**Contact E-mail Address:** jeromee1971@yahoo.co.kr.

**Introduction:** Human equilibrative nucleoside transporter 1 (hENT1) is the major transporter responsible for gemcitabine uptake into cells. hENT1 expression has been proposed as one of predictive biomarkers for gemcitabine sensitivity in patients with pancreatic cancer. However, the prognostic roles of hENT1 expression in patients with advanced biliary tract cancer (BTC) have not been evaluated so far. The aim of this study was to investigate the association between the expression of hENT1 and disease outcome in patients with advanced BTC treated with gemcitabine.
**Aims & Methods:** Pathological specimens were collected from 101 BTC patients who received first-line palliative chemotherapy with gemcitabine at Seoul National University Hospital between 2006 and 2013. Immunostainings with Rabbit Anti-Human hENT1 monoclonal antibody (Clone SP120) were performed in those specimens. Interpretations were classified as negative, mild, and moderate, according to the immunostain intensity. The patients were divided into two groups according to hENT1 expression, and compared in terms of overall survival (OS), progression-free survival (PFS), and response rate (RR).
**Results:** Immunostainings of specimens from 101 patients (60 males; mean age, $61.6 \pm 9.2$ years) were interpreted by a single pathologist independently. Twenty-one (20.8%) gallbladder cancers, 18 (17.8%) extrahepatic, and 62 (61.4%) intrahepatic cholangiocarcinomas were included. They consisted of 27 (26.7%) locally advanced and 74 (73.3%) metastatic cancers. Positive hENT1 expression was observed in 49 (48.5%) patients, who showed median $8.77 \pm 1.15$ months of OS and $3.80 \pm 0.68$ months of PFS, with no significant difference compared with the negative group. RR of positive group (49.0%) was also not significantly different from that of negative group (48.1%). When negative and mild intensity were classified as low expression, OS, PFS, and RR were also not significantly different between low and high expression group.
**Conclusion:** There was no evidence supporting the use of hENT1 as a predictive marker for gemcitabine efficacy in patients with advanced BTC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0074 ROLE OF THE NEW GENERATION SINGLE-OPERATOR CHOLANGIOSCOPY IN THE DIAGNOSIS OF INDETEREMINATE BILIARY LESIONS: A SINGLE TERTIARY CENTRE PROSPECTIVE STUDY

**N. L. h. Bekkali**[1], A. Winstanley[2], G. J. m. Webster[1]
[1]*Gastro, UCLH, London/United Kingdom*
[2]*Histopathology, UCLH, London/United Kingdom*

**Contact E-mail Address:** noorbekkali@hotmail.com.

**Introduction:** Recent improvements in cholangioscopy include a 4-fold increase in visual acurity for the Spyglass DS cholangioscope compared with previous version. The accuracy of cholangioscopy views and guided sampling (SpyBite) using the new generation Spyglass has yet to be evaluated.
**Aims & Methods:** Prospective single-arm, single-centre study collected data from all patients referred to our tertiary centre to undergo ERCP with cholangioscopy between June 2015 and March 2016. All patients were discussed in the pancreatobiliary multidisciplinary meeting before and after the procedure. The aim of this study is to compare the diagnostic accuracy between brush, endobiliary biopsies, SpyBite and cholangioscopic impression by the endoscopist (likely benign/malignant).

**Results:** A total of 92 patients underwent cholangioscopy; n = 25 (27%) for indeterminate strictures, n = 66 (72%) for stones, n = 2 other. The mean age of the group with strictures (12 males) was 56 +/- 16 years. Stricture location: distal CBD n = 8 (36%), mid CBD n = 3 (14%), CHD n = 2 (9%), hilum n = 6 (27%), intrahepatic n = 2 (9%) or extensive cholangiopathy n = 1 (5%). Two patients had normal mucosa and no biopsies were taken. One patient had a PD stricture. 12 patients had a relevant past medical history: PSC n = 5, IgG4 n = 1, possible metastatic cancer n = 3, other auto-immune disease n = 2 and previous biliary surgery n = 1. Results showed brush cytology sensitivity 53%, specificity 100%, positive predicitive value (PPV) 100%, negative predictive value (NPV) 25%; SpyBite sensitivity 67%, specificity 100%, PPV 100% and NPV 58%; cholangioscopic views 100% sensitivity, 73% specificity, PPV 77% and NPV 100%. One patient developed mild post-ERCP pancreatitis and one patient had abdominal pain following endoscopy without proven pancreatitis or perforation.
**Conclusion:** The new generation cholangioscope has shown a significant improvement in diagnostic yield which appears to relate to improved visualisation in addition to histological confirmation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0075 DEVELOPMENT OF AN EXTERNAL-TO-INTERNAL CONVERTIBLE ENDOSCOPIC BILIARY DRAINAGE DEVICE

**A. Mori**[1], S. Ito[2], M. Sawada[2], T. Yumura[2], H. Hachiya[2], S. Hayashi[2], N. Ohashi[2]

[2]*Gastrorenterology, Ichinomiya Nishi Hospital, Ichinomiya/Japan*

**Contact E-mail Address:** a-mori@anzu.or.jp.
**Introduction:** Endoscopic nasobiliary drainage (ENBD) for a malignant biliary stricture has some advantages over endoscopic retrograde biliary drainage (ERBD) which is the internal drainage. ENBD, allowing external drainage, enables not only drainage but also cytological and bacteriological examination. It also contributes to diagnosis by enabling detailed cholangiography after drainage. However, ENBD may cause stress due to naso-pharyngeal discomfort. ERBD obviates this stress, but it makes the above-mentioned examinations almost impossible. Therefore, we have developed an external-to-internal convertible endoscopic biliary drainage (ETI-EBD) device that enables both, internal and external drainage with a single endoscopy. Herein, we report the method and the feasibility of this device.
**Aims & Methods:** The ETI-EBD device consists of 3 parts, comprising a 5-Fr ENBD tube (250 cm) (ENBD-t), an 8.5-Fr ERBD tube (7 cm) (ERBD-t), and an 8-Fr pusher tube for ERBD (230 cm) (P-t). The ERBD-t and the P-t are mounted over the ENBD-t. The ERBD-t is positioned 12 cm from the distal end of the ENBD-t. The P-t is placed between the proximal end of ERBD-t and about 10 cm of the proximal end of the ENBD-t. The proximal end of P-t is firmly fastened to the ENBD-t. Insertion of the ETI-EBD device was similar to that of the conventional ENBD-t. After passing the guidewire through the stricture in the bile duct under ERCP, the device was inserted over the guidewire through the endoscopic channel. When the proximal end of the ERBD-t was inserted to the papilla, the duodenal endoscope was withdrawn, leaving the device in place. Then, the device was exchanged from the mouth to the transnasal route. At this time, both, ERBD-t and P-t remained secured over the ENBD-t. After ENBD and bile collection, external-to-internal conversion was performed as follows: the fixation between ENBD-t and P-t was released and only the ENBD-t was withdrawn from the P-t. P-t was gripped so as not to be withdrawn with the ENBD-t. Then, ERBD-t was isolated from P-t and ENBD-t. Finally, we were able to leave only the ERBD-t between the duodenum and the bile duct without endoscopy or radiography.
**Study design:** We evaluated the ETI-EBD device in a preliminary, prospective feasibility study. We enrolled 18 consecutive patients with a malignant biliary stricture between January 2015 and December 2015.
**Results:** A total of 14 patients were evaluated in the present study, because we had to exclude 4 patients who failed to be passed a guide wire through the stricture. ETI-EBD was successfully completed in all 14 patients (100%). The median time of placing of this device was 20 hours (1–47 hours). The median time of placing the ERBD-t after removal of ENBD-t was 27 days (7–83 days). The reasons for discontinuation of ERBD were ERBD-t obstruction in 3 patients, conversion to a metallic stent in 6 patients, surgery for the stricture in 2 patients, and death in 3 patients. There were no significant complications associated with the use of the device.
**Conclusion:** We have introduced a new device that has shown favorable feasibility and has enabled both, external and internal biliary drainage with a single endoscopy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0076 A PROGNOSTIC MODEL ADOPTING NEW CRITERIA OF INVASION DEPTH IN DISTAL BILE DUCT CANCER: A BETTER PREDICTOR OF SURVIVAL THAN PREVIOUS METHODS

**B. Son**[1], K. Min[2], D. Kim[3], E. Kim[4]

[4]*Pathology, Eulji General Hospital, Eulji University School of Medicine, Seoul/Korea, Republic of*

**Contact E-mail Address:** sbk1026@eulji.ac.kr.
**Introduction**: The 7th AJCC staging system is well known to effectively predict the prognosis of DBD cancers. However, published data showed that AJCC staging system is not reliable to predict patient's survival in DBD cancer. The unexpected results could be related to inter-observer variation induced by confusion among pathologists in microscopic evaluation according to ambiguous description of AJCC staging system.
**Aims & Methods:** Depth of invasion (DOI) is an important prognostic factor for patients with distal bile duct (DBD) carcinoma. This study aims to identify the optimal cut-off value of DOI in relation to the prognosis in patients with DBD cancer. Data of 179 patients with DBD adenocarcinoma treated in 3 institutions in Korea were investigated. At microscopic review, DOI was measured. The relationships between clinicopathological parameters and groups based on depth of invasion ($\leq$3 mm; 3–10 mm; $>$10 mm) were evaluated, and the survival time of each group based on DOI and 7$^{th}$ AJCC T classification was compared.
**Results:** The deeply invading tumor exhibits more tendency towards infiltrative type, high histological grade, AJCC stage, and nodal metastasis, pancreatic, duodenal, lymphovascular and perineural invasions. The measured DOI was significantly correlated with worse disease-free and overall survival (all. $p < 0.05$). In multivariate analyses, after adjusting confounders, grouping based on invasion depth remained as one of the prognostic factors (all, $p < 0.05$), while that of T classification was not significant.
**Conclusion:** On basis of proposed cut-off value, the DOI could be clear and meaningful concept overcoming the vagueness of the T classification in predicting clinical outcomes in patients with DBD carcinoma. Invasion depth should be measured on histopathological assessment of DBD carcinomas.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** To assess the safety and efficacy of using air for cholangiography in patients with hilar strictures, high cholangio carcinoma in CHD and CHD strictures secondary to carcinoma gall bladder.
**Aims & Methods:** A prospective study to assess the safety and efficacy of using air for cholangiography in patients with hilar strictures, high cholangio carcinoma in CHD and CHD strictures secondary to carcinoma gall bladder. 90 patients, from 1$^{st}$ October 2010 to 31$^{st}$ October 2015, who came with obstructive jaundice for stenting with strictures at high CHD or hilum (Type 1 and Type II Strictures only) due to cholangiocarcinoma and carcinoma gall bladder were included in this study. 10 cc of air was injected slowly and the ductal anatomy outlined. Ease of identification of various segments of liver, length of stricture, proximal limit of the stricture, possibility of placing stents, risk of cholangitis and complications was studied.

**Results:** Total cases – 90. Etiology: Carcinoma GB – 59 (65.5%), Hilar Type 1 -21 (23.3%), Hilar Type II – 10 (9%). Successful normal cannulation at ERCP – 61 (67.8%), Precut Used – 29 (32.2.%). Ductal anatomy outlined – 90 (100%). Proximal end of stricture identified – 90 (100%). Classification of stricture possible – 87 (96.7%) – 3 cases had Type III and III B strictures which were not clearly outlined. Dilatation and stenting possible: 85 (94.4%), Single stent – 40 (44.4%), Double stenting -50 (44.4%). Complications: Air embolism – 0 (0%), Cholangitis – 2 (2.22%) – Non affording patients, plastic 10 Fr stents were placed. Days of hospitalization – 2.5 (1 to 5).
**Conclusion:** 1. Air cholangiography is a feasible and safe option in high CHD and Hilar bile duct malignant strictures. 2. High success of identifying ductal anatomy and successful placement of stents in the desired segment is possible. 3. Complications are very rare and no case of air embolism was noted in our study.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** With the advent of the short-type balloon-assisted endoscopes, endoscopic biliary drainage for malignant biliary obstruction (MBO) is possible in surgically altered anatomy. Moreover, self-expandable metallic stents (SEMS) with a small-diameter delivery system showed longer patency and lower incidence of stent occlusion than plastic stents, which leads to QOL improvement.
**Aims & Methods:** This study was designed to evaluate the usefulness of endoscopic metallic stenting using short-type balloon-assisted endoscopes for MBO with surgically altered anatomy. Between January 2012 and February 2016, short-type double-balloon or single-balloon endoscope-assisted ERCP for MBO was performed in 16 patients with surgically altered anatomy. SEMS with a small-diameter delivery system (5.7Fr–7.2Fr) were used. Technical success rate, clinical success rate, adverse events, and long-term outcomes were evaluated in this retrospective study. Recurrent biliary obstruction (RBO) was defined as a composite of either occlusion or migration, and time to recurrent biliary obstruction (TRBO) refers to the time from SEMS placement to the recurrence of biliary obstruction. TRBO was estimated using the Kaplan-Meier method.
**Results:** A total of 16 patients (12 male, a mean age of 68 years) were enrolled. The causes of MBO included recurrent gastric cancer after total gastrectomy with Roux-en-Y reconstruction (n = 4), recurrent perihilar cholangiocarcinoma after extended hepatic lobectomy (n = 4), recurrent distal cholangiocarcinoma after pancreaticoduodenectomy (PD) (n = 4), recurrent pancreatic cancer after PD (n = 2), recurrent diffuse cholangiocarcinoma after extended hepatic lobectomy and PD (n = 1), and lymph node metastasis of intrahepatic cholangiocarcinoma after distal gastrectomy with Roux-en-Y reconstruction (n = 1).
Technical success rate and clinical success rate were 94% and 88%, respectively. Multiple SEMS were placed using the partial-stent-in-stent method in 4 patients and side-by-side method in 1 patient. Early adverse events (< 30 days) occurred in 2 patients (13%); mild pancreatitis in 2. The median follow-up period was 165 days, the median TRBO was 272 days, and median overall survival was 255 days. The causes of RBO were biliary sludge (n = 4), tumor ingrowth (n = 2), tumor overgrowth (n = 1), and kinking (n = 1). All 8 patients required re-intervention: additional stent-in stent placement of covered SEMS in 2 patients, PTBD in 1 patient, plastic stent in 3 patients, and balloon cleaning alone in 2 patients. Internal biliary drainage could be maintained in 12 patients (75%) until death or the end of follow-up.
**Conclusion:** Endoscopic metallic stenting using short-type balloon-assisted endoscopes for MBO with surgically altered anatomy is technically feasible, safe, and effective, and can contribute to the QOL improvement.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0079 THE SEQUENCE OF BRUSH CYTOLOGY AND INTRADUCTAL BIOPSY DO NOT AFFECT THE DIAGNOSTIC YIELD IN PATIENT WITH BILIARY STRICTURE

**S.Y. Seo**, I.S. Min, D. Kim, S.B. Kim, S.H. Kim, I.H. Kim, S.W. Kim, S.T. Lee, D.G. Kim, S.O. Lee
*Internal Medicine, Biomedical Research Institute of Clinical Medicine, Chonbuk National University Medical School and Hospital, Jeonju, Jeonbuk/Korea, Republic of*

**Contact E-mail Address:** bear7905@naver.com.
**Introduction:** Confirming malignancy through cytological or tissue diagnosis is essential in patient with biliary stricture, especially considering surgical management. Brush cytology and intraductal biopsy are routinely done during endoscopic retrograde cholangiopancreatography (ERCP) to diagnose malignant biliary stricture. However, whether the sequence of two diagnostic methods affect the diagnostic yield or not is not known well.
**Aims & Methods:** This study was aimed to investigate the diagnostic efficacy according to the sequence of brush cytology and intraductal biopsy in patient with biliary stricture. From January 2010 to December 2015, a total of 364 patients who underwent brush cytology and intraductal biopsy during ERCP for suspicious malignant biliary stricture were reviwed retrospectively at Chonbuk National University Hospital. ERCP was performed by two experienced endoscopists who carried out brush cytology and intraductal biopsy in different sequence according to personal preference. The final diagnosis was confirmed by histocytologic findings or, operation or, clinical and radiologic follow-up at least 6 months.
**Results:** 154 patients underwent brush cytology first and then intraductal biopsy was done, while 210 patient underwent intraductal biopsy first and then brush cytology during ERCP. There was no significant difference in rates of diagnostic accuracy according to the sequence of brush cytology and intraductal biopsy [cytology-biopsy vs biopsy-cytology: 117/154 (76.0%) vs 156/210 (74.3%), p = 0.713]. Overall sensitivity and accuracy of brush cytology was similar with intraductal biopsy [58.8%, 63.7% vs 58.5%, 64.5%]. A combination of both diagnostic methods could increase the sensitivity and accuracy as 72.0% and 75.0%.
**Conclusion:** The sequence of brush cytology and intraductal biopsy did not affect the diagnostic yield in patient with biliary stricture in this study. A combination of both diagnostic methods could increase sensitivity and accuracy. These results suggest that endoscopist can feel free from the sequence of brush cytology and intraductal biopsy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0080 COMPARING LIQUID-BASED CYTOLOGY (CELLPREP®) METHODS WITH CONVENTIONAL SMEAR METHODS FOR ERCP GUIDED BRUSHING CYTOLOGY OF BILE DUCT

**Y. Choi**, J.H. Han, H.B. Chae, S.M. Park
*Chungbuk National Hospital, cheong-ju/Korea, Republic of*

**Contact E-mail Address:** cyongh20@hanmail.net.
**Introduction:** ERCP-guided brushing cytology has been used worldwide to diagnose bile duct cancer. Bile duct brushings have been recognized as a technique of moderate sensitivity and high specificity in identifying carcinoma of the biliary regions. In the 1990s, Liquid-based cytology (LBC) was developed as an alternative to conventional smear (CS). Recent studies suggests the Liquid-based cytology (ThinPrep) method can improve diagnostic sensitivity and accuracy than conventional smear methods in bile duct brushings. However, there is no a study comparing Cellprep® methods with CS in bile duct cancer.
**Aims & Methods:** The aim of this study was to compare the morphologic features and diagnostic efficacy of LBC with those of CS for ERCP brushing cytology. This is the prospective study. This study was done with total 32 pts who were suspected bile duct cancer. Bile duct diagnosis was used by ERCP guided brushing cytology. Brushing cytology was done more than two. The final diagnosis is done by biopsy, cellblock, and clinical follow up.
**Results:** There were performed 34 brushing cytology in our institution from 32 patients (among them, two patients, it was performed twice). The cytologic diagnoses for both CP and CS were categorized into five main groups: ① inadequate, ② negative, ③ atypical, ④ suspicious for malignancy, and ⑤ malignant. 1 case (2.9%) of CS preparations was inadequate, but 4 cases (11.8%) CP preparations were inadequate. In CP and CS, the negative: 20.6% and 11.8%, atypical cell: 11.8% and 14.7%, suspicious: 5.9% and 11.8%, and malignant: 50% and 55.8%. accuracy: 58.8% and 73.5%. The sensitivity was 57.6% for CP and 72.7% for CS. The specificity and positive predictive value was 100% for both methods.
**Conclusion:** Cellprep® methods (Liquid-based cytology) revealed lower sensitivity and accuracy than conventional smear methods. Thus, cellprep® (liquid-based cytology) methods can not be replaced by conventional smear methods.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Percutaneous cholecystostomy is an effective and safe treatment for acute cholecystitis in critically ill patients. However, it not has been established as definite management of cholecysitis instead of interval cholecystectomyespecially in patients with unresectable klatskin tumor.
**Aims & Methods:** From June 2009 to July 2015, we retrospectively reviewed 47 klatskin tumor patients who received percutaneouscholecystostomy diagnosed as acute cholecystitis. Long-term outcomes following percutaneous cholecystostomywere evaluated. In this study, we evaluated efficacy and safety of percutaneous cholecystostomy as definite management for acute cholecystitis in patients with unresectable klatskin tumor.
**Results:** 47 patients with a mean age of 74 years were identified. The technical and clinical success rates for percutaneouscholecystostomy were 100%. All patients did not receive an interval cholecystectomy. The mean maintenance period of cholecystostomy tube was about 11.5 weeks (range, 3 – 43). 2 patients (4.2%) suffered tube-related complications, including catheter displacement, bile leakage with site infection. 23 patients (48.9%) could removed the cholecystostomy tubes during the follow up period. Seven out of 23 patients (30.4%) suffered recurrent cholecystitis during the follow-up period. The mean time to re-intervention was 8.5 weeks (range, 4–20). They were treated successfully with repeated percutaneous cholecystostomy.
**Conclusion:** Although some patients had recurrent attacks, percutaneous cholecystostomy can be performed as definite treatment for the management of acute cholecystitis. It seems to be a feasible and considerable option in some patients with unresectable klatskin tumor.

[3]*Gastroenterology, West China Hospital, Sichuan University, Chengdu/China*

**Contact E-mail Address:** melody224@163.com.
**Introduction:** Alcohol-induced pancreatic disease has got much attention all over the world. Accumulating animal studies and our previous clinical research showed that long-term alcohol administration led to pancreatic steatosis. But its possible genetic background is still unclear. Alcohol-induced pancreatic steatosis is associated with alcohol metabolism in the pancreas, in which alcohol dehydrogenase (ADH) and aldehyde dehydrogenase (ALDH) are the major oxidative enzyme. And genetic polymorphism of ADH2 and ALDH2 is known to be closely related to alcohol dependence. But it is still unknown whether genetic polymorphism of them is also relevant to pancreatic steatosis in alcoholics.
**Aims & Methods:** This study aims to find out the possible genetic background of alcohol-induced pancreatic steatosis in alcoholics by analyzing genetic polymorphism in ADH2 and ALDH2. 163 alcoholic male aged 20 ~ 70 years with a normal body mass index were recruited into this study. The alcoholics were defined as the drinkers with an alcohol intake of >80 g/day, a duration of >5 years, and abstinence from alcohol within 2 years. They received magnetic resonance scanning in the epigastric region by using double-echo chemical shift magnetic resonance technique. PCR- restriction fragment length polymorphism was used for ADH2 and ALDH2 genotype detection. The drinkers with pancreatic fat content higher than ≥4.2%, ≥8.0% in alcoholics younger and older than 50 years respectively were diagnosed as alcohol-induced pancreatic steatosis. This study was approved by the Chinese Clinical Trial Registry Clinical Trial Ethics Committee (registration number:ChiCTR-CCH-00000147) and the Ethics Committee of West China Hospital of Sichuan University. And it conform to the principles of the Declaration of Helsinki of the World Medical Association. Informed consent was obtained from each participant before enrollment.
**Results:** The distribution of the different ADH2 and ALDH2 genotypes among the 163 alocholics closely conformed to expected Hardy-Weinberg frequencies ($p > 0.05$). In drinkers, compared with ADH2*2/*2 carriers, ADH2*1/*1 carriers showed a significantly elevated risk of developing pancreatic steatosis (<50 years, OR = 6.73; >50 years, OR = 5.34). No association was found between ALDH2 genotypes and risk of pancreatic steatosis.
**Conclusion:** In drinkers, ADH2*1/*1 carriers had a significantly higher risk to develop alcohol-induced pancreatic steatosis. ADH2*1/*1 genotype may be related to alcohol-induced pancreatic steatosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0083 BETAINE ATTENUATES ALCOHOLIC FATTY PANCREAS THROUGH DOWN-REGULATION OF DGAT2

W. Yang[1], **J. Li**[1], L. Huang[1], H. Tong[1], Z. Huang[1], C. Tang[2]
[1]*Department Of Gastroenterology, West China Hospital, Sichuan University, Chengdu/China*
[2]*Gastroenterology, West China Hospital, Sichuan University, Chengdu/China*

**Contact E-mail Address:** melody224@163.com.
**Introduction:** Our previous studies have shown that betaine could attenuate alcoholic fatty pancreas by down-regulation of sterol regulatory element binding protein-1 c. However, whether diacylglycerol acyltransferase (DGAT) 1/2 and peroxisome proliferator-activated receptor λ coactivator (PGC)-1α, which also play important roles in alcohol-induced disorders of lipid metabolism, are involved in the antisteatotic effects of betaine remains to be explored.
**Aims & Methods:** This study aims to explore the effect of betaine on pancreatic DGAT1/2 and PGC-1α in rats with alcoholic fatty pancreas and its possible mechanism. 36 Wistar rats were randomly divided into control, ethanol and ethanol + betaine groups and given the following as their only water source respectively: water, ethanol containing water (25%, vol/vol), or ethanol containing water (25%, vol/vol) plus betaine (1%, wt/vol) for six months. Morphological changes of the pancreas were observed by hematoxylin-eosin staining, oil red O staining and transmission electron microscope. Pancreatic triglyceride (TG) and free fatty acid (FFA) levels were assessed by enzymatic colorimetric methods. Adiponectin levels in the pancreas and serum were measured by enzyme-linked immunosorbent assay. Pancreatic adiponectin receptor (AdipoR) 1/2 protein expression were detected by immunohistochemistry and Western blot. Pancreatic mRNA expression of AdipR1/2, DGAT1/2 and PGC-1α were determined by quantitative reverse transcriptase PCR (qRT-PCR). DGAT2 expression in SW1990 pancreatic adenocarcinoma cells treated with ethanol (100 mmol/L) or ethanol (100 mmol/L) plus betaine (168 mmol/L) and/or adiponectin (0.5 μg/mL) was determined by qRT-PCR.
**Results:** Betaine significantly alleviated the alcohol-induced accumulation of lipid droplets in the pancreatic acinar cells. Pancreatic TG and FFA levels were greatly elevated by 91.2% and 92.3% in ethanol group when compared with controls ($p < 0.05$). And pancreatic TG and FFA contents were markedly reduced by 40.8% ($p < 0.05$) and 61.5% ($p < 0.01$) in ethanol + betaine group when compared with those in ethanol group and were maintained at control levels. The adiponectin levels in the pancreas and serum of ethanol-fed rats were dramatically reduced by 45.4% and 62.5% when compared with the controls ($p < 0.01$). And adiponectin levels in the pancreas and serum were elevated by 110.6% and 98.3% in ethanol + betaine group compared with those in ethanol group ($p < 0.05$) and were sustained at control levels. Compared with control group, ethanol group showed significantly down-regulated protein level of AdipoR1 and mRNA expression of AdipoR1 and PGC-1α in the pancreas ($p < 0.05$). And pancreatic AdipoR1 mRNA and protein levels were greatly enhanced in ethanol + betaine group compared with those in ethanol group ($p < 0.01$) and were similar to controls. However, pancreatic PGC-1α mRNA expression in ethanol + betaine group was still lower than that of control group ($p < 0.01$) and were similar to that of ethanol group. Moreover, pancreatic DGAT2 mRNA level was significantly elevated by ethanol consumption ($p < 0.01$) and was markedly down-regulated to control levels with the addition of betaine. However, no significant difference was observed in the expression of DGAT1 and AdipoR2 in the pancreas between the three groups. In vitro, betaine or/and adiponectin significantly suppressed alcohol-induced up-expression of DGAT2 mRNA ($p < 0.01$), whereas no difference was observed between the effects of the sole betaine, sole adiponectin and the combination of betaine and adiponectin.
**Conclusion:** Betaine attenuated alcoholic fatty pancreas probably by suppressing alcohol-induced DGAT2 up-regulation in the pancreas through both the restoration of pancreatic adiponectin signaling and the direct effect of betaine on acinar cells.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0084 EXPRESSION OF INSULIN AND GLUCAGON IN LIVER AND PANCREAS IN RAT COPPER-DEFICIENT MODEL OF INJURY

**K.N. Saifullina**[1], A. Abdulkhakova[1], A. Galyavieva[1], G. Pevnev[1], S.R. Abdulkhakov[2], A.A. Gumerova[3], A. Kiassov[4]

**Introduction:** The copper-deficient model of injury is one for studying pancreas regeneration, where we can see destruction of pancreatic parenchyma, concomitant liver injury and regeneration of both organs during the recovery phase of the experiment.

**Aims & Methods:** The aim of our work was to study the expression of insulin and glucagon in pancreas and liver tissue in rat copper-deficient model of injury. 24 white Wistar male rats (80–100 g weight) were maintained on copper-deficient diet (MP Biomedicals, USA) containing a relatively non-toxic copper-chelating agent, triethylenetetramine tetrahydrochloride in final concentration of 0.6% w/w for 8 weeks, and then returned to normal rat chow for another 8 weeks (recovery phase). Groups of 3 animals each were killed after 2, 4, 6, and 8 weeks of copper-deficient diet and 2, 4, 6, and 8 weeks of recovery phase. Paraffin sections of liver and pancreas were stained immunohistochemically using antibodies to insulin and glucagon. The level of these hormones was measured in venous blood of rats.

**Results:** After 4 weeks of copper-deficient diet we observed glucagon-positive cells in peripheral part of the islets as well as single glucagon-positive cells and their clusters resembling newly formed islets. Expression of glucagon was maximal after 8 weeks of diet and continued to be at the same level 2 and 4 weeks after rats were returned to normal rat chow. Groups of glucagon-positive hepatocyte-like cells were found in the pericentral areas of liver, solitary glucagon-positive hepatocyte-like cells in liver parenchyma during all weeks of our experiment. The maximum of glucagon expression in liver was detected 2 weeks after return to normal rat chow. Glucagon-positive cells were observed only in peripheral part of the pancreatic islets after 6 and 8 weeks of recovery phase. Expression of glucagon in liver decreased alongside; glucagon-positive cells were located predominantly in pericentral areas. Insulin-positive cells were found in central part of the pancreatic islets during the experiment. Insulin-positive hepatocyte-like cells were detected in the pericentral areas and in liver parenchyma from $4^{th}$ to $6^{th}$ weeks of diet, the number of these cells was the highest after 6 weeks of copper-deficient diet. After 8 weeks of diet we observed insulin-positive small round cells – at least 1 positive cell was around every tenth of central vein (these cells were single after 4 and 6 weeks of diet). Appearance of the insulin-positive hepatocyte-like cells was accompanied with increase of insulin level in venous blood. The maximum of insulin expression in liver coincided with the highest concentration of insulin in venous blood after 6 weeks of diet. After rats were transferred to normal rat chow, we observed solitary insulin-positive small round cells in liver tissue until $2^{th}$ week. Later positive cells were not detected in liver.

**Conclusion:** We suppose that glucagon-positive pancreatic islet cells are probably the source of pancreas regeneration in rat copper-deficient model; the appearance of glucagon- and insulin-positive cells in liver confirms common origin of these organs and can be the response reaction for the pancreatic tissue injury.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0085 A NEW ANIMAL MODEL IN PANCREATOLOGY- PANCREATIC DUCTAL FLUID AND BICARBONATE SECRETION IN WILD TYPE FERRETS

**Introduction:** Cystic fibrosis (CF) is a lethal genetic disease affecting several organs, including the pancreas. Although animal models are available to study the CF-related tissue damage they have clear limitations. Recently a cystic fibrosis transmembrane regulator (CFTR) knock out ferret model was generated. This model would be the first available one to study pharmacological prevention of the disease development.

**Aims & Methods:** We aimed to characterize the fluid and bicarbonate secretion of wild type (WT) ferret pancreatic ducts. Expression of CFTR was detected by immunohistochemistry. Intra/interlobular pancreatic ducts were isolated from the WT ferret pancreas. Resting pH, buffer capacity and $Cl^-/HCO_3$ exchange activity were evaluated by microfluorometry. Fluid secretion was examined by video microscoopy.

**Results:** CFTR was expressed on the luminal membrane of ferret pancreatic ducts. The resting intracellular pH of pancreatic epithelial cells is lower ($7.17 \pm 0.08$) in ferrets compared to mice (7.31) or to guinea pigs (7.36). Concerning the bicarbonate influx mechanisms, functionally active sodium/hydrogen exchanger and sodium/bicarbonate cotransporter were detected. Anion exchanger activity measured by $NH_4Cl^-$ technique, $Cl^-$ removal and inhibitory stop methods indicated that ferret pancreatic ducts secrete similar amount of bicarbonate as mice and guinea pigs. Video microscopy revealed a significant increase in fluid secretion to $HCO_3^-$ and to 5 μM forskolin stimulation.

**Conclusion:** Ferret pancreatic ductal epithelial cells express the major epithelial ion transporters. Our results indicate that ferret could be a suitable model organism to study the CF-related pancreatic damage. Moreover this model opens up the possibilities to test pharmacological interventions in the disease development.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Cyclic adenosine monophosphate (cAMP) and $Ca^{2+}$ signaling play central role in the regulation of the secretory functions of epithelial cells. The two signaling system have multiple synergistic interactions helping to optimize the cellular response to stimulation. One of the interferences includes the interaction between the store operated $Ca^{2+}$ entry (SOCE) channel Orai1 with adenylyl cyclase 8 (AC8) that increase cAMP production, however its exact molecular mechanism is not known.

**Aims & Methods:** In this project we wanted to characterize the interactions of cAMP and $Ca^{2+}$ signaling further focusing on the molecular components of SOCE. Human embrional kidney (HEK) cells were transfected with plasmids encoding the proteins of interest. Cellular cAMP production was measured by fluorescence resonance energy transfer (FRET) using the cAMP reporter Epac1.

**Results:** The stimulation of the cells with 5 μM forskolin and 100 μM 3-isobutyl-1-methylxanthine (IBMX) resulted in reversible elevation in cAMP production. The expression of AC8 significantly elevated the cAMP response. Whereas, Orai1 induced spontaneous cAMP production and a massive increase in the stimulated cAMP production. The effect of Orai1 was completely $Ca^{2+}$ independent. Extended synaptotagmin 1 (E-Syt1), a recently described endoplasmic reticulum-plasma membrane tethering protein, increased the cAMP response, similarly to Orai1.

**Conclusion:** Our results showed that Orai1 and E-Syt1 play an important role in the regulation of cAMP production. However further studies are required to clarify the mechanisms of the interaction.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Excessive ethanol consumption is one of the most common causes of acute and chronic pancreatitis. Earlier we showed that ethanol and ethanol metabolites cause severe damage in the function and expression of the cystic fibrosis transmembrane conductance regulator (CFTR), which increases the severity of acute ethanol-induced pancreatitis. There are new compounds available, such as lumacaftor (VX-809), to correct the impaired CFTR expression in cystic fibrosis patients, however the potential utility of this compound in pancreatitis treatment has never been investigated.

**Aims & Methods:** Our aim was to test the effect of VX-809 treatment on the CFTR expression during ethanol exposure. CFTR expression was evaluated by immunofluorescent staining in Capan-1 cells. The cells were incubated with 100 mM ethanol, 10 μM VX-809, or their combination for 24 h. Images were captured by confocal microscopy.

**Results:** As reported earlier exposure of Capan-1 cells to 100 mM ethanol for 24 hours significantly decreased the plasma membrane expression of CFTR. In parallel the cytoplasmic CFTR expression was increased. 10 μM VX-809 alone had no effect on the CFTR expression. Notably, application of 10μM VX-809 in pretreatment (treatment started 6 h prior to ethanol exposure), or post-treatment (treatment started 6 h after to ethanol exposure) significantly improved the plasma membrane expression of CFTR in Capan-1 cells.

**Conclusion:** These preliminary findings suggest that VX-809 might be able to restore the CFTR expression defect caused by alcohol. Further extended in vitro and in vivo studies need to clarify the effect of VX-809 on alcohol-induced pancreatic injury.

**Introduction:** Minimally invasive necrosectomy, as compared with open necrosectomy, may reduce death rates in patients with necrotizing pancreatitis, especially in critically ill patients.

**Aims & Methods:** We performed a registry study combining published and unpublished data from 15 cohorts of patients undergoing pancreatic necrosectomy in 65 hospitals in 8 countries. Death rates were compared in patients undergoing open necrosectomy or minimally invasive necrosectomy (i.e. minimally invasive surgical necrosectomy or endoscopic necrosectomy). We adjusted for confounding by three types of analyses: multivariable logistic regression, stratification according to the predicted risk of death at baseline (low: $<5\%$, intermediate: $\geq 5\%$ to $<15\%$, high: $\geq 15\%$ to $<35\%$ and very-high: $\geq 35\%$) and propensity-score matching.

**Results:** Among 1980 patients with necrotizing pancreatitis, 1167 underwent open necrosectomy, 467 underwent minimally invasive surgical necrosectomy and 346 underwent endoscopic necrosectomy. There was a lower risk of death for minimally invasive surgical necrosectomy (odds ratio, 0.53; 95%-CI, 0.34 to 0.84; $P=0.006$) and endoscopic necrosectomy (odds ratio, 0.19; 95%-CI, 0.06 to 0.61; $P=0.005$) as compared with open necrosectomy. After risk stratification and propensity-score matching, minimally invasive surgical necrosectomy remained associated with a lower risk of death than open necrosectomy in the very-high-risk group (risk ratio, 0.70; 95%-CI, 0.52 to 0.95; $P=0.02$). Endoscopic necrosectomy remained associated with a lower risk of death than open necrosectomy in the high-risk group (risk ratio, 0.27; 95%-CI, 0.08 to 0.88; $P=0.03$) and the very high-risk group (risk ratio, 0.43; 95%-CI, 0.24 to 0.77; $P=0.005$).

**Conclusion:** As compared with open necrosectomy, minimally invasive surgical or endoscopic necrosectomy for necrotizing pancreatitis reduces mortality among patients at high risk of death.

**Introduction:** Pancreatic fluid collections (PFC) are a common local complication of pancreatitis with incidences of 5–16% and 20–40% in acute and chronic pancreatitis respectively (1). Classification of PFC includes acute peripancreatic fluid collection, pancreatic pseudocyst, acute necrotic collection and walled-off necrosis (WON). A new lumen-opposing, covered self-expanding metal stent on a catheter-based delivery system (Hot AXIOS, Boston Scientific) may have higher technical success rates, easier deployment and lower stent migration. We present the first multicentre prospective case series from the UK and Ireland to assess success and complication rates associated with Hot AXIOS stent for the drainage of PFC.

**Aims & Methods:** All adult patients who had Hot AXIOS stent placement for PFC from July 2015-February 2016 were included. Eight centres participated (London, Glasgow, Edinburgh, Newcastle, Cambridge, Manchester, Dublin and Leeds). All patients had CT assessment of the PFC prior to placement. Data including technical success, resolution of collection, complications and stent migration were collected.

**Results:** Forty patients were treated with a single Hot AXIOS stent in each case. The median age was 57 years (range 31–78) and 25 were male (63%). The indications were WON (24), pseudocyst (15) and abcess (1). The median size of the PFC was 10.9 cm (3.9–20 cm). Thirty-eight patients (95%) had trans-gastric stents, 1 had trans-duodenal and 1 had a trans-oesophageal stent. Thirty-seven (93%) had freehand puncture into the cyst, the rest were wire guided. Procedures were technically successful in all patients. Of 21 patients with available follow-up data to date, the collection resolved in 18 (86%) and reduced in size in 3 (14%). Twelve patients (30%) had 33 necrosectomies and/or endoscopic lavage following stent insertion. Stents migrated in 3 patients (7.5%). One patient developed small bowel obstruction resulting from stent migration and this was managed surgically. There was no procedure-related or 30-day mortality (data available in 27 patients).

**Conclusion:** This multicentre case series demonstrates that the Hot AXIOS system is safe and effective in draining PFC with a technical success rate of 100% and serious adverse event rate of 2.5%. The stent migration rate was 7.5%.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0090 RED CELL DISTRIBUTION WIDTH AND RATIO RED CELL DISTRIBUTION WIDTH/TOTAL SERUM CALCIUM AS MAJOR PREDICTORS OF SEVERITY AND MORTALITY IN ACUTE PANCREATITIS

**M. Gravito-Soares**, E. Gravito-Soares, D. Gomes, S. Lopes, C. Sofia
*Gastroenterology, Coimbra Hospital, Coimbra/Portugal*

**Contact E-mail Address:** ms18498@gmail.com.

**Introduction:** Acute pancreatitis (AP) is associated with systemic inflammatory response syndrome and it has considerable mortality. The current severity scores include multiple variables, some of them only complete within 48 hours post-admission. Red cell distribution width (RDW) is a simple and routine parameter that seems to be related with inflammation.

**Aims & Methods:** To evaluate the diagnostic value of RDW in severity and mortality of AP. Retrospective case-control study of total of patients with severe AP (cases), between 2013 and 2015, who were compared with patients with mild AP (controls), in a proportion of 1:1. Additionally it was compared patients with AP that died (cases) with patients that not died (controls). The diagnosis and severity of AP were defined by modified Atlanta classification of 2012. Variables evaluated included demographics, comorbidities, laboratorial parameters, prognostic scores at the first 24 hours [Ranson, BISAP and Modified Marshall (MM)] and mortality.

**Results:** Registered 182 cases of AP. Included 91 cases of severe AP, 58.2% (n = 53) with male gender (vs 51.6%; p = 0.459) and mean age of 65.0 ± 16.3yo (vs 67.9 ± 13.7; p = 0.201). RDW was higher in patients with severe AP (14.6 ± 1.3 vs 12.7 ± 0.5; p < 0.001), as well as ratio RDW/serum calcium (1.8 ± 0.3 vs 1.3 ± 0.1; p < 0.001). After multivariate and ROC curve analysis, RDW (AUROC 0.959; p < 0.001) and RDW/serum calcium (AUROC 0.971; p < 0.001) were the major predictors of severe AP to a cut-off value of 13.0 (S-91.3%; E-95.6%) and 14.0 (S-91.3%; E-92.3%), respectively. These factors were superior to stablished prognostic scores as Ranson (AUROC 0.754; p < 0.001; cut-off: 3.0), BISAP (AUROC 0.735; p < 0.001; cut-off: 2.0) and MM (AUROC 0.772; p < 0.001; cut-off: 1.0). The mortality rate was 8.8% (16/182), all of cases associated with severe AP (17.6%; 16/91). RDW and RDW/serum calcium were superior in patients with AP that died (15.3 ± 1.4 vs 13.5 ± 1.3; p < 0.001 and 1.9 ± 0.3 vs 1.6 ± 0.3; p < 0.001, respectively). In multivariate and ROC curve analysis, the only independent risk factors mortality-associated in AP were RDW (AUROC 0.844; p < 0.001; cut-off: 14.0) and RDW/serum calcium (AUROC 0.830; p < 0.001; cut-off: 1.7).
**Conclusion:** RDW and serum calcium are simple and routine parameters, available in emergency department. This cohort showed that RDW and RDW/serum calcium are potential good predictors of severity and mortality in AP, being superior to conventional prognostic scores. RDW ≥ 13.0 and RDW/serum calcium ≥ 1.4 predict severe AP. RDW ≥ 14.0 and RDW/serum calcium ≥ 1.7 predict mortality in AP.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0091 PREVALENCE OF POST-ERCP COMPLICATIONS ACCORDING TO HOSPITAL VOLUMES AND EXPERIENCE OF OPERATORS: A PROSPECTIVE MULTICENTER STUDY

**Introduction:** Despite technical improvement and endoscopists' growing experience with ERCP procedures, the incidence of post-procedure pancreatitis has not yet dropped and efforts are still being made to identify factors associated with the risk and minimize the incidence and severity. Although patient- and procedure-related risk factors for post-ERCP pancreatitis were identified at previous studies, few studies were addressed the association between post-ERCP pancreatitis and endoscopists' experience and hospital's cases volume and showed a debate on the results.
**Aims & Methods:** The aim of our study was to evaluate the impact of endoscopist's experience and hospital's case volume on post-ERCP pancreatitis. Between January 2015 and August 2015, patients with naïve papilla who were referred for diagnostic and therapeutic ERCP were enrolled. Each endoscopist participated in the study entered the data for all consecutive ERCPs attempted and prospectively recorded details of patient- and procedure-related variables on data collection sheet at the time of ERCP. We analyzed the collected data for identifying patient- and procedure- related risk factors for post-ERCP complications and the impact of the endoscopist's experience (< 200 vs. > 200 cases of therapeutic ERCP) and the hospital's case volume (cutoff of 500 procedures per year) in a multicenter, prospective study in Daegu-Kyungpook Province.
**Results:** Data were obtained from 6 centers (four with high and two with low volume). A total of 883 patients (median age, 70 years; range, 19 ~ 101; male: female ratio, 1.34: 1) who underwent ERCP procedures were included in the study; 611 were performed in the 4 high-volume centers (69.2%) and 272 in the 2 low-volume centers (30.8%). Overall, 422 ERCPs were carried out by expert operators and 461 by less-experienced operators. Overall, post-ERCP pancreatitis occurred in 64 patients (7.3%). Post-ERCP pancreatitis was observed and classfied as mild in 56 (87.5%), moderate in 6 (9.4%) and severe in 2 (3.1%). The incidence of post-ERCP pancreatitis was lower in experienced endoscopist (3.3% vs. 10.9%, p < 0.001)). However, there was no difference according to hospital volume (high vs. low volume, 7.0% vs. 7.7%, p = 0.718).
**Conclusion:** Although our results revealed that the risk of post-ERCP pancreatitis was associated with the experience of endoscopist and not with hospital volume, further studies including larger samples and many hospitals with variable degree of case volume are needed to support our results and clarify risk factors.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0092 EUS-GUIDED INTERVENTIONS FOR WALLED-OFF PANCREATIC NECROSIS: CLINICAL OUTCOMES OF A STEP-UP APPROACH AND RISK FACTORS FOR FAILED ENDOSCOPIC TREATMENT

**M. Takenaka**[1], K. Minaga[1], M. Kitano[1], S. Oomoto[1], K. Kamata[2], T. Miyata[2], K. Yamao[2], H. Imai[2], M. Kudo[1]
[1]*Department Of Gastroentelorogy, Kinki University, Osaka-sayama/Japan*
[2]*Gastroenterology & Hepatology, Kinki University, Osaka-sayama/Japan*

**Contact E-mail Address:** mamoxyo45@gmail.com.
**Introduction:** Walled-off necrosis (WON) remains difficult to manage endoscopically because of insufficient drainage of solid necrotic debris. This study aimed to evaluate the technical/clinical success, and safety of EUS-guided treatment of WON and to ascertain factors associated with failed endoscopic treatments.
**Aims & Methods:** This retrospective study involved 70 consecutive patients who had undergone a step-up approach based on EUS-guided drainage for WON. Our treatment strategy is shown in Figure 1. Multivariable logistic regression analysis was performed to ascertain factors associated with failed endoscopic treatments.
**Results:** Seventy patients (57 men and 13 women; mean age 57.1 years) underwent EUS-guided drainage. Forty-one cases (59%) had a multilocular lesion and 13 cases (19%) had a WON cavity extending to the pelvis. The mean number of stents placed was 3.7; metal stents were deployed in 32 cases (46%). The technical success rate (successful stent deployment) of EUS-guided drainage was 97%. The clinical success rates (resolution of symptoms or inflammation) in STEP 1, 2, 3, and 4 were 40%, 69%, 76%, and 89%, respectively. Eight (11%) cases experienced adverse events related to endoscopic interventions and 10 (14%) required surgical necrosectomy; 8 (11%) patients died. The multivariable analysis for exploring factors associated with failure to manage the procedure successfully up to STEP 2 showed that ratios of patients with serious comorbidities (Charlson comorbidity index ≧ 3) and with WON cavity extending to the pelvis were the significant risk factors (odds ratio 5.3 and 4.7, P = 0.021 and 0.026, respectively).
**Conclusion:** A step-up approach based on EUS-guided drainage is an effective strategy for the management of WON, particularly in patients with serious comorbid conditions or in those with WON cavity extending to the pelvis, who are difficult to manage with endoscopy alone. More options, such as surgical necrosectomy should be considered.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0093 EVALUATION OF THE BISAP SCORE IN PREDICTING SEVERITY AND PROGNOSIS IF ACUTE PANCREATITIS

**P. Santos**[1], S.R. R. Fernandes[2], M. Moura[3], J.R. Carvalho[1], T. Antunes[3], J. Velosa[4]

[2]*Serviço De Gastrenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, Lisboa/Portugal*
[3]*Gastroenterology, Hospital de Santa Maria, Lisboa/Portugal*
[4]*Serviço De Gastrenterologia E Hepatologia, Hospital Santa Maria, Centro Hospitalar Lisboa Norte, Lisboa/Portugal*

**Contact E-mail Address:** patricia.sants@hotmail.com.
**Introduction:** Early risk stratification of acute pancreatitis (AP) is essential to optimize the approach and improve outcomes. Among the several scoring systems, the index for severity in acute pancreatitis (BISAP) stands out for its versatility, including clinical, laboratory and radiological data. Only limited data is available regarding validation among different patient populations.
**Aims & Methods:** To evaluate the accuracy of the BISAP in predicting severe clinical outcomes in AP. Retrospective and single-center study, evaluating patients with AP. Outcomes: prolonged hospitalization (≥15 d), admission to intensive care unit (ICU), organ damage (PO2 ≤ 60 mmHg or need for ventilation; creatinine ≥2 mg/dl; systolic blood pressure ≤ 90 mmHg or need for vasopressor), its persistence (≥48 h), pancreatic necrosis and early (≤7 d) and late mortality (≥8 d). Accuracy was assessed separately according to etiology (lithiasic, alcoholic and non-lithiasic). Statistical analysis: SPSSv21.0.
**Results:** 198 patients, 69.2% male, mean age 58.5 ± 19.0 years. 56 patients (28.3%) were admitted to ICU and 19 patients (9.6%) died. BISAP was accurate in predicting pancreatic necrosis (AUC 0.74, p < 0.001), prolonged hospitalization (AUC 0.70, p = 0.001), need for ICU admission (AUC 0.88, p < 0.001), organ injury (AUC 0.61, p = 0.016), its persistence (AUC 0.72, p = 0.003) and early (AUC 0.95, p < 0.001) and late mortality (AUC 0.76, p = 0.008). Best cutoff value calculated for BISAP in predicting mortality was > 2 (sensibility 78.9%; specificity 86.7%). Separately, only in lithiasic and non-lithiasic pancreatitis could BISAP predict, with fair accuracy, persistent organ dysfunction (AUC 0.725 and 0.745, p = 0.03 respectively).
**Conclusion:** Overall, BISAP demonstrated high accuracy in all outcomes. This score is simple and easily allowing for early assessment of prognosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Acute biliary pancreatitis (ABP) caused by gallstone disease is the most common form of acute pancreatitis. The role of endoscopic retrograde cholangiopancreatography (ERCP) in ABP is still controversial.
**Aims & Methods:** The study aimed to evaluate data on diagnosis, management and clinical outcome of ABP in Hungary. Retrospective clinical analysis of patients with ABP between January 2013 and August 2015 based on the National Pancreas Registry established by the Hungarian Pancreatic Study Group.
**Results:** Data of 371 patients with ABP including 210 (56.6%) females and 161 (43.4%) males with mean age of $61.7 \pm 18.1$ and $62.1 \pm 16.1$, respectively were evaluated. The diagnosis was made according to clinical symptoms, laboratory findings and/or clinical imaging. Cholelithiasis was detected in 74.1%, dilated common bile duct (CBD) in 32.6%, whereas choledocholithiasis in 5.1% by abdominal ultrasonography and/or computed tomography. According to laboratory tests biliary origin was determined in 42.3%. The majority of patients (67.7%) developed mild disease, 25.9% was identified as moderate and minority of cases (6.5%) was categorized as severe. In terms of therapy, ERCP was performed in 74.1%, in majority of patients (61.7%) during the first 24 hours after admission. During ERCP CBD stones were detected in 36.7%, CBD dilation in 45.8%. Endoscopic sphincterotomy was done in 86.5% and overall successful biliary clearance was achieved in 84.7%. According to Tokyo guidelines, definite cholangitis was assessed in 33.7%. In this group ERCP was performed in 84.8%, in 67% within 24 hours after admission. 62.3% of patients received at least 2000 ml of parenteral fluid during the first day, enteral feeding was administered in 27.8% (mostly in moderate or severe group) and antibiotics were given in 90.3%. Multimorbidity, age and length of hospital stay were associated with severity. Local complications developed overall in 29.3%, pancreatic necrosis in 12.4% and organ failure was identified in 7.8%. Mortality was 0.4%, 1.04% and 20.83%, respectively in mild, moderate and severe disease group. When ERCP was performed local or systemic complications developed in 27.6% or 6.9%, respectively compared to conservatively treated patients who developed local complications in 35.4% and systemic complications in 10.4%. Mortality was 1.5% in the ERCP treated group and 3.1% in conservatively treated group. Notable difference was assessed in patients with concomitant definite cholangitis where local complications developed in 25.5% vs. 36.8% and systemic complications in 3.8% vs. 10.5% when compared ERCP with conservative treatment. In patients where cholangitis was definitely ruled out the rate of complications and mortality was comparable between the ERCP and conservatively treated group.
**Conclusion:** ERCP is the mainstay of therapy of ABP in Hungary. The use of ERCP in ABP is associated with lower complication and mortality rate. Regardless of the treatment ABP is associated with significant morbidity and mortality. Registry provides comprehensive information which can help in further understanding and improving ABP management.

**Introduction:** Acute pancreatitis is usually a mild disease; however, some patients may develop to severe courses. It is important to identify severe cases early because it enables early intensive care and nutritional support. Fatty liver change was commonly seen in patients with acute pancreatitis; however, its clinical significance have not been well studied.
**Aims & Methods:** We aimed to investigate the relationship between fatty liver and severity of acute pancreatitis. We retrospectively analyzed data from patients who were diagnosed with acute pancreatitis from July 2009 to June 2015. The unenhanced CT images were retrospectively reviewed by a radiologist and the mean hepatic and splenic attenuations were measured in Hounsfield units (HU). Fatty liver was defined as a mean hepatic/splenic HU $< 1$. The revised Atlanta classification was adopted to define the severity of acute pancreatitis.
**Results:** Among 167 patients, fatty liver was found in 57 patients (34.8%) and non-fatty liver in 107 patients (65.2%). Fatty liver was more frequently shown in male and obese patients. Compared with patients without fatty liver, the severity of pancreatitis and serum C-reactive protein levels were higher in fatty liver patients. Prevalence of local complications including pseudocyst and walled-off necrosis and mortality were higher in the patients with fatty liver. Even after adjusting for age, sex, body mass index, and cause of pancreatitis, fatty liver was significantly associated with moderately-severe or severe acute pancreatitis (odds ratio, 4.34; 95% confidence intervals, 2.00–9.40). Fatty liver was a poor prognostic factor not only in obese or alcoholic patients but also in non-obese or non-alcoholic patients.
**Conclusion:** Fatty liver may play a prognostic role in acute pancreatitis. Fatty liver can be usefully incorporated into future predictive scoring models.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0096 MIR 210-3P AND MIR 10B-5P AS A POTENTIAL BIOMARKERS FOR DIFFERENTIATION BETWEEN CHRONIC PANCREATITIS AND PANCREATIC CANCER

**A. Madro**[1], M. Guz[2], W. Jeleniewicz[2], M. Cybulski[2], J. Kozicka[3], J. Kurzepa[4], A. Stepulak[2]

**Contact E-mail Address:** agnieszka.madro@wp.pl.
**Introduction:** Chronic pancreatitis (CP) is a chronic inflammatory disease of pancreas characterized by irreversible morphological changes providing to exocrine and endocrine dysfunction. It's known that CP is a main risk factor of pancreatic cancer (PC). A number of studies have been performed in order to identify biomarkers for this disease. Recently, microRNAs (miRNAs), short, non-coding RNAs have been proposed as possible biomarkers. Several miRNAs were found to be associated with malignant processes.
**Aims & Methods:** The aim of our study was identification of miRNAs that could be markers for differentiation between CP and PC. We assessed expression of selected miRNAs, as well as parameters in serum including lipase, amylase, bilirubin, aminotransferases activity, gamma glutamylotranspeptidase, alkaline phosphatase activity, CRP and Ca 19-9. Blood samples from patients with CP (34) and PC (26) were collected in Department of Gastroenterology with Endoscopic Unit, Medical University, Lublin. RNA was extracted from serum using miRCURY RNA Isolation Kit Biofluids and reverse transcribed using the Universal cDNa Synthesis Kit, according to the manufacturer's protocol. Diluted cDNA was mixed with microRNA LNA primers and SYBR Green Master Mix. Assay was performed in triplicate, and the expression levels of miRNAs were quantified using LightCycler 480® II following the manufacturer's instruction. We screened the expression level of five microRNAs (miR-30c, miR-103a, miR-124-3p, miR-191, miR-423-3p) and selected miR-103a as a reference gene with the minimal variation between the two groups. The relative expression of miRNAs was calculated using the comparative cycle threshold ($\Delta\Delta$CT) method. Nonparametric tests (Mann-Whitney and Spearman) were used for statistical analysis.
**Results:** We observed significantly higher expression of miR 210-3p in PC than in CP ($p = 0.015$) and lower but not statistically significant expression of miR 10b-5p. We also found statistically significant correlation between alkaline phosphatase and miR 210-3p ($p < 0.02$), between miR 210-3p and gamma glutamylotranspeptidase ($p < 0.02$), miR 10b-5p and CRP ($p < 0.04$) in patients with PC. On the other hand statistically significant difference was observed between miR 10b-5p and Ca 19-9 ($p < 0.005$) in patients with CP.
**Conclusion:** We can conclude, that two of investigated microRNAs: miR210-3p and miR 10b-5p may be take into consideration as possible biomarkers for differentiation between CP and PC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0097 PANCREATIC ENDOCRINE FUNCTION IN PATIENTS WITH CHRONIC PANCREATITIS: EVALUATION AND RELATION TO MALNUTRITION

**S. Siminkovitch**[1], M. Kovacheva-Slavova[1], B. Vladimirov[1], J. Genov[1], R. Mitova[1], P. Gecov[2], B. Golemanov[1]

[2]*Medical Imaging, University Hospital Tsarica Ioanna-ISUL, Sofia/Bulgaria*

**Contact E-mail Address:** sylvie.mitova@abv.bg.

**Introduction:** Chronic pancreatitis (CP) progression leads to pancreatic endocrine and exocrine dysfunctions. We evaluated Diabetes Mellitus type 3c (DM) presence in patients (pts) with CP and assessed the endocrine function relation with pancreatic exocrine insufficiency (PEI) and with pre-albumin (transthyretin, TTR) and retinol-binding protein (RBP) as markers for malnutrition.

**Aims & Methods:** Serum samples of 106 pts (55 male, 51 female) were collected in our centre for the period February 2014 – January 2016. We divided all patients into 3 subgroups: subgroup 1- CP without DM (68pts); subgroup 2- CP with DM (18 pts); subgroup 3- control group (20 pts). Patients were also subdivided according to Cambridge classification for CT/MRCP - grade 1–4. Serum TTR and RBP levels were measured by immunonephelometry assay. Endocrine function was evaluated using fasting levels of HBA1C, glucose (mmol/L), Insulin (method ECLIA ref. range 3–20$\mu$U/ml) and C-peptide (method ECLIA ref. range 1.1–4.4 ng/ml). Based on their results HOMA1, HOMA2[1] indices and FCGR (fasting C- peptide/ glucose ratio) were calculated for assessment of insulin secretion and insulin sensitivity. The used below HOMA1-IR and HOMA2%$S_{insulin}$ (markers for insulin sensitivity) were calculated via glucose and insulin levels, and HOMA2%$B_{c\text{-}peptide}$ (marker for insulin secretion) and FCGR- via C-peptide and glucose levels. Exocrine function was evaluated using faecal elastase-1 (FE-1: cut-off for PEI $< 200\,\mu$g/g). The statistical analysis was performed applying SPSS version 22.

**Results:** By subgroup 3 we observed glucose median 5.0, Insulin 7.2, C-peptide 1.8, HOMA1-IR 1.6, HOMA2%$S_{insulin}$ 99.7 and HOMA2%$B_{c\text{-}peptide}$ 103.9, which indicated normal insulin secretion and sensitivity. Subgroup 2 was with the lowest levels of C-peptide 0.68, HOMA2%$B_{c\text{-}peptide}$ 33.4, FCGR10.7, associated with low insulin secretion, and the highest levels of HOMA2%$S_{insulin}$ 154, related to high insulin sensitivity, with significant differences in values compared to other subgroups, $p < 0.05$. Within subgroup 1, 14 pts were with HOMA1-IR $> 2$ and their data demonstrated high insulin secretion (HOMA2%$B_{c\text{-}peptide}$ 158.5) and low insulin sensitivity (HOMA2%$S_{insulin}$51.9) with significant differences to all other subgroups, $p < 0.05$. By the rest 54 pts within subgroup 1, we observed significantly lower C-peptide, Insulin, HOMA2%$B_{c\text{-}peptide}$ and FCGR within CT/MRCP grade 3 and 4, $p < 0.05$. TTR for all pts were $0.24 \pm 0.09$ g/L and RBP $0.039 \pm 0.014$. TTR under 0.2 g/L were found in 33% in subgroup 1 and in 11 pts in subgroup 2; RBP under 0.03 g/L - in 35.3% in subgroup 1 and in 9 pts in subgroup 2, with significant differences in mean values in both subgroups, $p < 0.05$. Within both CP groups PEI was found in 30 pts. Levels of HOMA2%$B_{c\text{-}peptide,}$ reflecting insulin secretion, were lower in pts with PEI, $p < 0.05$. Within levels of C-peptide (below 1.1 ng/ml) there was a relation between TTR levels and PEI presence $\chi^2 = 4.6$, $p = 0.035$, with Odd Ratio 2.9 (95%CI 1.1–7.1).

**Conclusion:** PEI and malnutrition with lower TTR and RBP levels have closely related to the pancreatic endocrine function in CP patients which requires establishing insulin status. DM type 3c has negative impact on malnutrition in CP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** kovacheva_mila@abv.bg.

**Introduction:** Deficiency of fat-soluble vitamin D (VD) is a present complication in pancreatic disorders. Studies have demonstrated that low VD levels may be associated with increased cardiovascular risk (CVR) and adverse cardiovascular events.

**Aims & Methods:** To assess the relation between VD levels and CVR factors by patients (pts) with chronic pancreatitis (CP) and reccurent pancreatitis (RP). Study enrolled 66 pts (38 males, mean age 49.8yrs): 40 pts had CP and 26-RP. Determination of 25-hydroxyvitamin D (25OHD, sum of 25OHD3 and 25OHD2) was performed by a validated, DEQAS certified ID-LC-MS/MS method with accuracy and precision within 7.5% and linearity range 3.0–300.0 nmol/L. VD status was assessed as deficiency (25OHD $< 25$ nmol/L), severe insufficiency (25–50 nmol/L), mild insufficiency (50–80 nmol/L), and sufficiency ($> 80$ nmol/L). CVR was investigated by European SCORE chart (Systematic COronary Risk Evaluation) and was calculated as percent for the 10-year risk mortality; CVR factors- by lipid profile, apolipoproteins A and B, CRP, fasting glucose levels (FGL), diabetes mellitus (DM), blood pressure; imaging morphological data- by Cambridge classification for CT/MRCP (grade I-IV); pancreatic exocrine insufficiency (PEI)- by fecal elastase-1 (cut-off for PEI $< 200\,\mu$g/g). Statistical analysis was performed via SPSS v22.

**Results:** Total 25OHD for all pts was $41.47 \pm 26.36$ nmol/L (range 3.81–93.8 nmol/L); 23 pts (34.8%) had deficiency; profound insufficiency was found in 27.3% of pts; another 31.8% were with mild insufficiency, and only 4 pts (6.1%) were in sufficiency status. According to SCORE, 7.6% had low ($<1$%), 50%-moderate ($\geq 1$ and $<5$%), 18.2%-high ($\geq 5$% and $<10$%) and 24.2%-very high ($\geq 10$%) risk for CVD-events that eventually will occur after 10 years. Patients with PEI compared to pts without PEI had higher CVR based on SCORE chart results, $p < 0.05$. Among pts with severe morphological changes (grade III and IV, $n = 36$ pts), SCORE results were as follows: 30.6% had very high, 25%-high, 33.3%-moderate and 11.1%-low CVR, which was significantly higher compared to pts with mild structural changes (grade I and II), $p < 0.05$. VD status worsened with increasing the 10-year risk mortality (moderate, high and very high), $p < 0.05$. Lower VD levels were associated with higher FGL and DM ($22.52 \pm 13.10$ vs. $44.84 \pm 26.76$ nmol/L), $p < 0.05$. There was statistically significant correlation between VD levels and triglycerides (TG) and VLDL, $p < 0.05$. CRP correlated with increased cholesterol and decreased VD levels, which were lower by pts with RP, $p < 0.05$. We found no significant relation between VD levels and gender; systolic and diastolic blood pressure.

**Conclusion:** We confirmed a high prevalence of VD insufficiency and deficiency in CP and RP patients, related to impaired pancreatic structure and exocrine function. VD status was associated with the presence of increased CVR assessed by SCORE chart and CVR factors (DM, FGL, TG, VLDL, CRP). Further studies are required to establish CVR screening panel in this population.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0099 GENOME ANALYSIS WITH WHOLE EXOME SEQUENCING TO IDENTIFY GENETIC ALTERATIONS IN PATIENTS WITH IDIOPATHIC PANCREATITIS

**Introduction:** Idiopathic pancreatitis (IP) is designated to cases of pancreatitis wherein a diagnosis could not be made through routine evaluations including a thorough history, physical examination, laboratory studies and imaging modalities. Genetic alterations are known to be one of the most important etiologies in patients with IP. However, researches for related genes were conducted mostly in the Western countries and data is limited in the Asian population.

**Aims & Methods:** To reveal possible ethnic difference, genome analysis with whole exome sequencing was performed in Korean patients with IP. Patients who met the diagnostic criteria and provided written informed consent were enrolled consecutively at 8 university hospitals in the Metropolitan Seoul between March 2015 and February 2016. Blood samples were transferred to and analyzed at a single laboratory (the Genome Institute of MACROGEN, Inc.).

**Results:** The results from 18 patients with IP were compared with those from 7 patients with alcoholic chronic pancreatitis as the control group. In the IP group, alteration in ADRBK1 (adrenergic beta receptor kinase 1) gene was the most prevalent (12/18, 66.7%), followed by CDC34 (cell division cycle 34) (11/18, 61.1%) and CHRNA7 (cholinergic receptor nicotinic alpha 7 subunit) (11/18, 61.1%). There was no alteration for these genes in the control group. Interestingly, any alterations in established genes including PRSS1 (Protease, serine 1), PRSS2 (Protease, serine 2), SPINK1 (Serine peptidase inhibitor, Kazal type), CTRC (Chymotrypsin C), CASR (Calcium sensing receptor) and CPA1 9 Carboxypeptidase A1) were not detected in both groups.

**Conclusion:** ADRBK1, CDC34 and CHRNA7 may serve as new candidates for the hot spots in patients with IP. Also, there may be an ethnic difference in the genes associated with the heredity of pancreatitis. Further validation studies to explain the association between the genetic alterations in above genes and IP are anticipated in the future.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0100 PREVALENCE OF EXOCRINE PANCREATIC INSUFFICIENCY IN PATIENTS WITH CHRONIC PANCREATITIS WITHOUT FOLLOW-UP: NUTRITIONAL STATUS AND QUALITY OF LIFE. PANCR-EVOL STUDY

**Introduction:** Exocrine pancreatic insufficiency (EPI) is an important complication of chronic pancreatitis (CP). (1) Guidelines recommend to rule out EPI in CP, to detect those patients who would benefit from pancreatic enzyme replacement therapy. (2).

**Aims & Methods:** The aim of this study was to evaluate the prevalence of EPI in patients with CP without follow-up in the last 2 years and to describe their nutritional status and quality of life (QoL). This was a cross-sectional Spanish multicenter study. We included patients with CP, without follow-up by a gastroenterologist or surgeon in at least 2 years. The exocrine function was evaluated in these patients. EPI was defined as a fecal elastase (FE) test $<200$ mcg/g. For nutritional assessment, laboratory and anthropometric data were obtained. QoL was investigated using the EORTC QLQ-C30 questionnaire

**Table 1:** Baseline characteristics.

| | Study population (n = 64) | EPI group (N = 41) | Non-EPI group (N = 23) | P value |
|---|---|---|---|---|
| Men | 55 (85.9%) | 36 (87.8%) | 19 (82.6%) | 0.7109 |
| Caucasic Race | 63 (98.4%) | 41 (100.0%) | 22 (95.7%) | 0.3594 |
| Age (years) | 58.8 (10.3) | 58.6 (9.0) | 59.0 (12.4) | 0.8799 |
| BMI (kg/m$^2$) | 24.5 (3.3) | 23.9 (3.5) | 25.7 (2.5) | 0.0334 |
| Time since diagnosis of CP (months) | 58.7 [37.7, 95.4] | 62.1 [39.0, 104.9] | 55.8 [35.4, 78.2] | 0.7487 |
| Pancreatic calcifications | 42 (65.6%) | 27 (65.9%) | 15 (65.2%) | 1.0000 |
| Biliary duct dilation | 40 (62.5%) | 28 (68.3%) | 12 (52.2%) | 0.2142 |
| Bowel movements/day | 2.0 [1.0, 2.0] | 2.0 [1.0, 3.0] | 1.0 [1.0, 2.0] | 0.0603 |
| Diabetes | 29 (45.3%) | 25 (61%) | 4 (17.4%) | 0.0008 |
| **Smoking habit** | | | | |
| Smokers | 41 (64.1%) | 28 (68.3%) | 13 (56.5%) | 0.6937 |
| Cigarettes per day | 20 [15, 30] | 20 [13.5, 25] | 20 [20, 30] | 0.3639 |
| **Alcohol consumption** | | | | |
| Habitual | 34 (53.1%) | 23 (56.1%) | 11 (47.8%) | 0.0372 |
| Ex-alcoholic | 18 (28.1%) | 14 (34.2%) | 4 (17.4%) | |
| Grams of alcohol/day | 60 [40, 90] | 61.5 [40, 87] | 60 [30, 100] | 0.9155 |

**Results:** 64 patients (see baseline characteristic, table 1) from 10 centers were prospectively included. 64.1% patients were tested positive for EPI (FE $<200$ mcg/g) and 45.3% of them had severe EPI (FE $<100$ mcg/g). Regarding nutritional status, the following differences were observed (EPI vs. Non-EPI): BMI ($23.9 \pm 3.5$ kg/m$^2$ vs. $25.7 \pm 2.5$, $p = 0.03$); glucose (121 [96, 189] mg/dl vs. 98 [90, 116]; $p = 0.006$); HbA1c 6.6% [6.0, 8.4] vs. 5.5 [5.3, 6.0] $p = 0.0005$); Vitamin A (0.44 mg/l [0.35, 0.57] vs. 0.53 [0.47, 0.63] $p = 0.048$) and Vitamin E ($11.2 \pm 5.0$ mg/ml vs. $14.4 \pm 4.3$, $p = 0.03$). EPI group showed a worse EORTC QLQ-C30 score on physical (93.3 [66.7, 100] vs. 100 [93.3, 100], $p = 0.048$) and cognitive function (100 [83.3, 100] vs. 100 [100, 100], $p = 0.04$). Other frequent complications of CP apart from EPI were: pseudocysts, chronic abdominal pain, biliary obstruction and splenic vein thrombosis.

**Conclusion:** Prevalence of EPI is high in patients with CP without follow-up**.** EPI group vs non-EPI group had significative lower BMI, higher levels of glucose, Hba1c, lower of vitamins A, E and a worse QoL.Regular follow up should be attempted; in this study we have used fecal elastase, an easy screening method.

**Introduction:** The concept of acute obstructive suppurative pancreatic ductitis (AOSPD) has been proposed recently. It is characterized by a purulent discharge from the distal part of the duct without evidence of any infected necrotic tissue or coexisting pancreatic abscess. However, AOSPD has not been recognized sufficiently because of its rarity.

**Aims & Methods:** We aimed to clarify the clinical features of AOSPD. We retrospectively reviewed the clinical features of 20 patients with AOSPD at two tertiary referral centers between 1993 and 2012. We compared 17 AOSPD patients with chronic pancreatitis (CP) and 42 patients with acute-on-CP in terms of clinical characteristics, presentation, and laboratory and imaging findings.

**Results:** The etiology of AOSPD involved CP in 17 (85%) patients, pancreatic ductal adenocarcinoma in 2 (10%), and intraductal papillary mucinous neoplasm in 1 (5%). Endoscopic pancreatic drainage was effective in 19 (95%) patients. Body temperature was significantly higher in AOSPD with CP than acute-on-CP patients (median: 38.2 vs. 36.9°C; $p < 0.001$). Serum amylase levels at onset were significantly lower (median: 133 vs. 364.5 U/L; $p = 0.009$), and C-reactive protein was significantly higher (median: 9.42 vs. 1.06 mg/dL; $p < 0.001$) in AOSPD with CP patients. Enlargement of the pancreatic parenchyma (18% vs. 93%; $p < 0.001$) and stranding of the surrounding fat (12% vs. 93%; $p < 0.001$) on computed tomography were observed less frequently in patients with AOSPD with CP patients. The diameter of the main pancreatic duct was significantly greater in AOSPD with CP than acute-on-CP patients (median: 7 vs. 5 mm; $p = 0.006$).

**Conclusion:** The major etiology of AOSPD involved CP, and endoscopic pancreatic drainage was effective. The clinical features differ between AOSPD with CP and acute-on-CP.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Chronic pancreatitis (CP) is a continuing, inflammatory process of the pancreas, characterized by irreversible morphological changes. The identification of pancreatic stellate cells resulted in the development of research on the pathogenesis of CP. The intensity of fibrosis depends on the production of extracellular matrix components and their degradation by metalloproteinases (MMP) - zincdependent endopeptidases. Gelatinases (MMP-2 and MMP-9) play the most important role in inflammatory processes because of their ability to degrade type IV collagen. Erythropoietin (EPO) regulates the interaction between apoptosis and inflammation of the brain, kidney and heart muscle. Epo receptors were also found in the pancreas, in particular the islet cells.
**Aims & Methods:** Our objective was to evaluate the influence of erythropoetin on fibrosis and apoptosis in experimental chronic pancreatitis. The experiments were performed on 48 Male Wistar rats (250–350 g). The animals were divided into six equal groups. (I – control, II – chronic cerulein – induced pancreatitis, III - erythropoetin s.c. (5 doses - 1 ml Epo/day), IV - erythropoetin s.c. (5 doses - 0.5 ml Epo/day), V – CP treated with 1 ml Epo, VI – CP treated with 0.5 ml Epo. The animals were sacrificed after 24 hours from the administration of the last doses. The blood for gelatinases and pancreas for the morphological examinations and immunohistochemistry were collected. MMP-2 and MMP-9 activities in serum were determined with gelatin zymography. groups. Histological changes of the pancreas were classified, based on the approximate percentage of acinar cells showing vacuolization, edema, and the areas showing inflammatory cell infiltration and fibrosis: 0 = absent, 1 = < 5%, 2 = 5–25%, 3 = 25–50%, 4 = > 50%.
**Results:** In the groups receiving cerulein injections the intensification of fibrosis around the pancreatic ducts was observed. Comparably, a slight reduction of interstitial edema and less severe fibrosis were reported in the groups treated with Epo. In group II, a strong expression of $\alpha$-actin was noticed in damaged acinar cells and the cells with vacuolar degeneration. The $\alpha$-actin expression appeared focally in groups V and VI, mostly in cells with the vacuolar degeneration, and is not visible in cells with inflammatory changes. In group II there was a very weak expression of Bcl-2 in acinar cells, while in the other groups, there was no expression noted. In group II cytoplasmic expression of caspase-3 was observed in the acinar cells, especially in the inflammatory changes and the cells with vacoular degeneration. In groups V and VI a reduced expression of caspase-3 was observed in areas with inflammation. In the cells with vacuolar degeneration, a weak, focal expression was noticed. There were no statistically significant differences between the groups in the activity of gelatinases.
**Conclusion:** Conclusions: Erythropoietin seems to have the effect of reducing fibrosis and apoptosis in an experimental model of chronic pancreatitis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0103 COMPARISON OF REMNANT-INVAGINATION AND DUCT-TO-MUCOSA PANCREATICOJEJUNOSTOMY FOLLOWING WHIPPLE'S RESECTION: PROSPECTIVE RANDOMIZED TRIAL IN PATIENTS AT HIGH RISK OF POSTOPERATIVE PANCREATIC FISTULA

**Introduction:** Pancreatitis and pancreatic fistula following pancreaticoduodenectomy (POPF) are potentially lethal postoperative complications that may occur after extensive surgical manipulation of viable pancreatic parenchyma[1, 2]. The aim of this clinical trial was to evaluate the outcomes of a remnant-invaginating pancreatojejunal reconstruction technique (RI) in a patient cohort at high risk for POPF, and to compare it to the traditional duct-to-mucosa anastomosis technique (DM) regarding the risk of associated morbidity.
**Aims & Methods:** This prospective randomized clinical trial was conducted between 2012-15 in patients undergoing pancreaticoduodenectomy. Eligible candidates were identified by radiological criteria at the multidisciplinary pancreatic conference[3]. The POPF risk was estimated intraoperatively according to a previously published standardized assessment[4]. Patients who were assessed to have a high risk of POPF were included in the trial and randomized to either RI or DM. POPF and associated morbidity were classified according ISGPF[5] and Dindo-Clavién[6].
**Results:** One hundred and twenty consecutive high-risk patients were included into the analysis (60 RI, 60 DM). Pancreatic duct diameter and pancreatic gland circumference were median 2 and 80 mm, respectively. The RI and DM groups had comparable outcomes regarding duration of surgery (median 336 min) and blood loss (median 400 mL). The RI reconstruction took less time (28 min) to complete compared to the DM reconstruction (36 min; $p = 0.001$), but caused more technical problems (RI 14 patients, DM 7 patients). Severe postoperative complications were observed in 57 patients (48%; RI 25 patients, DM 32 patients; $p = 0.273$). Overall mortality was 7.5% (9 patients; RI 2 patients, DM 7 patients; $p = 0.163$), POPF-associated mortality was 5% (6 patients; RI 1 patient, DM 5 patients; $p = 0.207$). Clinically-relevant POPF (POPF B or C) was observed in both groups (RI 30 patients, DM 31 patients); however, the RI group had significantly fewer cases of severe POPF (POPF C; 2 patients; 3.3%) compared to DM (12 patients; 20%; $p = 0.008$).
**Conclusion:** The results of this prospective randomized trial indicate that the described remnant-invaginating pancreaticojejunostomy represents a suitable technique for safe pancreatojejunal reconstruction following Whipple's resection. In high-risk patients with soft pancreatic parenchyma and small pancreatic duct, the remnant-invaginating technique was associated with a lower risk of severe postoperative pancreatic fistula than the traditional duct-to-mucosa technique.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** EUS-FNA for pancreatic solid mass lesions is important because of its high diagnostic yield. Multicenter prospective studies have established the clinical efficacy of EUS-FNA for pancreatic solid mass lesions, however prospective studies in Japan are lacking.
**Aims & Methods:** The aim of the study is to evaluate the efficacy and safety of EUS-FNA for pancreatic solid mass lesions in a multicenter study based in Japan. The primary outcome measure was the diagnostic sensitivity by EUS-FNA. The secondary outcomes were specimen adequacy, diagnostic yield, adverse events and diagnostic accuracy related to the procedure. Diagnostic yield was defined by the percentage of lesions sampled for which a tissue diagnosis was obtained. Specimen adequacy was defined as the percentage of lesions sampled in which obtained material was representative of the target site and sufficient for diagnosis. Patients were prospectively enrolled and EUS-FNA was performed. All procedures were performed by experienced endoscopists who have performed at least 100 cases or by less-experienced endoscopists assisted by such experienced endoscopists. Data related to EUS guided tissue acquisition in addition to white blood cell count (WBC), hemoglobin (Hb), serum c-reactive protein (CRP) and serum pancreas-related amylase (p-AMY) between pre- and post-examination were collected. Adverse event rates were determined within 24 hours and after 7 and 28 days. After pathological evaluation, the collected specimens were interpreted as benign, malignant, or non-diagnostic specimens. Diagnostic accuracy was then determined and defined as the percentage of lesions sampled by EUS that correspond to the final histopathologic diagnosis at surgery or clinical follow up of 1 year.
**Results:** Two hundred and forty-nine patients were enrolled from November 2011 to June 2013. One patient suffered from cerebral infarction just before procedure. In 2 patients, EUS could not detect target lesions. Therefore, these 3 cases were excluded. A median of 2 passes were performed per procedure. In 99 cases (40.2%), specimens were evaluated immediately by pathologists, cyto-techinicians or endoscopists trained in cytopathology. The specimen adequacy rate was 100% in 246 cases. From these specimens, 215 cases were diagnosed as malignant lesions, 27 cases were diagnosed as benign, and 4 cases were non-diagnostic. The diagnostic yield was 98.4% (242/246). There was no significant difference in WBC, Hb, CRP, p-AMY between pre- and post-examination. The complication rates within 24 hours and after 7 and 28 days were 2.8%, 1.6% and 0% respectively. After 1-year follow up, 7 cases interpreted as malignant by EUS-FNA were lost for follow up and excluded for final evaluation. Finally, diagnostic sensitivity, specificity, accuracy, positive predictive value and negative predictive value were 97.2% (208/214), 88.0% (22/25), 96.2% (230/239), 100% (208/208), 81.4% (22/27), respectively based on final histopathology at the time of surgery or clinical follow up period of 1 year.

Pathological diagnosis and final diagnosis

| | Final diagnosis | | | | |
|---|---|---|---|---|---|
| Malignant | | Benign | Unknown | Total | |
| Pathological diagnosis | Malignant | 208 | 0 | 7 | 215 |
| | Benign | 5 | 22 | 0 | 27 |
| | Non-diagnostic | 1 | 3 | 0 | 4 |
| | Total | 214 | 25 | 7 | 246 |

**Conclusion:** EUS-FNA for pancreatic solid lesions has a high diagnostic yield and is a safe procedure in Japan consistent with previously published international studies.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0105 ECHOENDOSCOPIC ETHANOL ABLATION OF TUMOR COMBINED TO CELIAC PLEXUS NEUROLYSIS IN PATIENTS WITH PANCREATIC ADENOCARCINOMA

**A. Facciorusso**, M. Di Maso, N. Muscatiello
*Gastroenterology, University of Foggia, Foggia/Italy*

**Contact E-mail Address:** antonio.facciorusso@virgilio.it.
**Background:** Endoscopic ultrasonography (EUS) guided-celiac plexus neurolysis (EUS-CPN) has proven able to relieve pain in pancreatic cancer (PC) patients, but with often suboptimal and transient results. The study is aimed at comparing the efficacy and safety of EUS-guided tumor ethanol ablation combined to CPN with respect to EUS-CPN alone for pain management in PC patients.
**Methods:** Among 123 unresectable PC patients referred to our Institution between 2006 and 2014, 58 treated with EUS-CPN (group 1) and 65 with the combined approach (group 2) were compared. Logistic regression models were applied to identify predictors of pain relief, while time-to-event data were compared by means of log-rank test.
**Results:** The two groups presented similar baseline clinical and tumoral parameters. Pre-procedural visual analogue scale (VAS) score was 7 in both groups ($p = 0.8$) and tumor max diameter was 38 mm (range 25–59) in group 1 and 43 mm (22–59) in group 2 ($p = 0.4$). The combined treatment increased the pain relief and the complete pain response rate ($p = 0.005$ and 0.003, respectively). Median duration of pain relief was 10 (7–14) and 18 (13–20) weeks in the two groups, respectively ($p = 0.004$). At multivariate regression, initial VAS score and EUS technique adopted resulted significantly associated to pain relief. No severe treatment-related adverse events were reported. Median overall survival was 6.5 months (5.1–8.6) in group 1 and 8.3 months (6–11.4) in group 2 ($p = 0.05$).
**Conclusion:** EUS-guided tumor ablation combined to CPN appears to be superior to standard EUS-CPN in terms of pain control and overall survival.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0106 INTRAOPERATIVE US IS THE MAIN TOOL FOR MAKING DECISION ON ARTERIAL RECONSTRUCTION DURING DP-CAR. EXPERIENCE OF 20 MODIFIED APPLEBY PROCEDURES

**Introduction:** Distal pancreatectomy with celiac artery resection (DPCAR) is widely used for borderline-resectable pancreatic cancer. It is believed that considerable reduction of the liver arterial supply after DPCAR may cause severe liver dysfunction and/or gallbladder necrosis. The decision to reconstruct artery or not is still difficult.
**Aims & Methods:** To study liver collateral arterial supply after temporary occlusion of the common (CHA), right gastroepiploic (RGEA) and accessory/replaced left hepatic arteries (a/rLHA). Arterial anatomy, diameters of CHA, proper hepatic (PHA), gastroduodenal (GDA) and pancreatoduodenal arteries (PDA) were registered before surgery in 110 consecutive patients with pancreatic body/tail cancer (n35), gastric cancer with pancreatic involvement (n30) and liver tumors (n45) by CT. For DPCAR (n20) these data were obtained after surgery as well. Diameters of peripancreatic arteries and mean systolic blood velocity in hepatic arteries before and after CHA clamping were measured intraoperatively by Doppler ultrasound.
**Results:** Classical arterial anatomy was identified in 67% and replaced right hepatic artery (rRHA) from the SMA in 12.2% of cases. Pulse had disappeared in 19 (17%) cases after clamping of CHA, RGEA and aLHA/rLPA. Collateral arterial blood flow in the liver parenchyma was revealed in all cases. DPCAR led to increase of GDA, rRHA, PDA and RGEA blood flow in 0.9–2 times; visualization of PD arcades as a main and sole collateral way after DPCAR.
**Conclusion:** Doppler ultrasound is a good modality for intraoperative assessment of liver arterial blood supply after DPCAR; Hepatic artery reconstruction may be necessary after DPCAR in case of disappearance of arterial Doppler signal upon the liver parenchyma.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0107 PANCREATIC CANCER IN PATIENTS WITH AUTOIMMUNE PANCREATITIS: A SCOPING REVIEW

**P. Macinga**[1], T. Hucl[1], M. Del Chiaro[2], M. Löhr[2]
[1]*Department Of Gastroenterology And Hepatology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic*
[2]*Division Of Surgery, Clintec, Karolinska Institutet, Stockholm/Sweden*

**Contact E-mail Address:** maip@ikem.cz.
**Introduction:** Autoimmune pancreatitis (AIP) is a rare chronic inflammatory disease of the pancreas which responds well to immunosuppressive therapy. As its manifestation often mimics pancreatic cancer (PDAC), a lot of attention has been given to differentiation of the two conditions.
Chronic inflammatory process is a well-known risk factor of malignancy, as described in chronic pancreatitis and PDAC. A similar association in patients with AIP and PDAC has been suggested but not clearly demonstrated.

**Aims & Methods:** The aim of our study was to identify and analyze all published cases of AIP and PDAC co-occurrence focusing on the interval between the two diagnoses and the location of the PDAC lesions.
Studies were identified by searching MEDLINE, EMBASE, Scopus and Web of Science databases. The computer search was supplemented with manual searches for reference lists of all retrieved articles.
**Results:** Forty-five cases of PDAC in AIP patients (1 certain and 8 potential duplicates) were reported in 10 case reports, 1 case-control study, 13 retrospective and 5 prospective cohort studies. The interval between the diagnoses of AIP and PDAC was stated in 22 studies (30 unique cases, 1 duplicate). Synchronous occurrence was reported in 11 patients, metachronous in 19 patients (median time between the two diagnoses was 50 months, range 6-186, peak between 30–60 months). Gender and age (at the time of PDAC diagnosis) were noted in 21 of these 30 patients. There were 17 males and 4 females, median age 69 years (52–83).
In the metachronous group (19 cases), 7 patients were diagnosed with a focal form (6 head, 1 tail), 1 with a diffuse form, the information was not available in 11 patients. The location of PDAC was stated in 8 cases (3 in the pancreatic head, 3 in the body, 2 in the tail) and it arose in the part of the pancreas affected by AIP in only 3/8 (38%) patients (all head).
Patients with synchronous occurrence of conditions (11 cases) suffered from focal AIP in 6 cases (3 head, 2 body, 1 tail), diffuse type in 4 cases, the information was not available in 1 patient. PDAC was most often located in the head of the pancreas (4 cases), followed by the body and the tail (2 cases each). In one case PDAC affected the whole organ, the information was not available in 2 patients. Cancer occurred in the part of the pancreas affected by AIP in all (9/9) described cases.
**Conclusion:** There is a significant number of described cases of PDAC in patients with AIP in the literature. The majority of well described cases were metachronous with the tumor usually arising in the part of the pancreas affected by AIP. Although the risk of PDAC in AIP patients cannot be assessed by this review, the rather an unexpectedly high number of published cases should draw attention to a vigilant follow-up of patient with an established diagnosis of AIP.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0108 KEY ENDOSCOPIC ULTRASOUND FINDINGS USEFUL FOR DIFFERENTIATING INVASIVE CARCINOMA FROM NON-INVASIVE HIGH-GRADE DYSPLASIA IN PANCREATOBILIARY TYPE INTRADUCTAL PAPILLARY MUCINOUS NEOPLASMS OF THE PANCREAS

**T. Osoegawa**[1], A. Aso[2], K. Nakamura[1], E. Ihara[1], H. Kubo[1], A. Goto[1], Y. Minoda[1], T. Ohtsuka[3], M. Nakamura[3], T. Ito[1]

**Introduction:** Intraductal papillary mucinous neoplasm of the pancreas (IPMN) was classified into four histological subtypes: gastric, intestinal, pancreatobiliary (PB), and oncocytic. PB type IPMN is considered to have the most malignant potential and invasive carcinoma (IC) has poorer prognosis than noninvasive high-grade dysplasia (HD). It is therefore important to differentiate IC from HD. Endoscopic ultrasound (EUS) is more sensitive than other radiological methods for evaluation of intratumoral features of IPMN. In this study, we determined the key EUS findings that are useful for differentiating IC from HD in PB-type IPMN.
**Aims & Methods:** We retrospectively reviewed 124 patients with IPMN who underwent surgical resection between 2010 and 2015. Twenty-four cases were histologically classified as PB type. Two patients were excluded because of intermediate dysplasia. Twenty-two patients with PB-type IPMN, including IC ($n=11$) and HD ($n=11$), were enrolled in the present study. All patients underwent EUS before surgery. We retrospectively reviewed EUS findings to assess main pancreatic duct diameter, cyst diameter, mural nodule (MN) height, presence of ill-defined MN margin from the pancreatic parenchyma, and MN echogenicity.
**Results:** There were no significant differences in the clinical characteristics including gender and age between HD and IC. In HD/IC, the EUS findings were as follows. The number of main duct type, mixed type and branch duct type IPMN were 1/5, 4/2 and 6/4 cases, respectively. The mean diameter of the main pancreatic duct was $6.72 \pm 3.17/7.65 \pm 6.82$ mm. The mean diameter of the cyst, excluding main duct type, was $28.8 \pm 14.2/28.9 \pm 10$ mm. Definite MNs were seen in 9/11 cases. The mean height of the MNs was $20.6 \pm 9.7/10.9 \pm 9.06$ mm ($p=0.071$). Out of 9/11 definite MN cases, ill-defined MN margins from the pancreatic parenchyma were observed in 2/9 cases ($p=0.0077$). MNs with lower echogenicity than that of the pancreatic parenchyma were observed in 1/9 cases ($p=0.0017$). These two EUS findings about MNs were observed significantly more often in IC ($p=0.0010$).
**Conclusion:** In the PB-type IPMN, ill-defined MN margin from the pancreatic parenchyma and echogenicity of MN are the key EUS findings useful for distinguishing IC from HD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0109 ETHANOL VERSUS POVIDONE IODATE EUS-GUIDED FOR PANCREATIC CYSTIC LESIONS: A PROSPECTIVE AND COMPARATIVE STUDY

**Introduction:** The EUS-guided ethanol lavage is a minimally invasive treatment modality in pancreatic cystic. The most common agents used are ethanol and paclitaxel, and rarely cause systemic effects1, 2. The literature has been reporting the use of povidone iodate for treatment of renal cysts and just one case in pancreatic cyst 3, 4.
**Aims & Methods:** This study evaluated the immediate occurrence of adverse events, the cyst size three months after the injection and the need for further lavage if the cyst does not shown reduction less than 30%. The inclusion criteria were no clinical condition or refuse to surgery, unilocular pancreatic cyst (1–8 cm). The patients were aleatory treated by EUS-guided with ethanol injection or povidone iodate, been the volume dependent of the cyst size. The technique used was puncture via a transduodenal or transgastric route and cystic fluid aspiration was performed using a curvilinear array echoendoscope and 19-Gauge needle. After subtotal evacuation of cystic fluid, injection of ethanol, which equals to that of aspiration, was performed.
**Results:** The ethanol injection was performed in 14 patients, with a mean injection of 27.6 ml (10–80 ml) and povidone iodate in 6 patients with a mean injection of 25.2 ml (2–50 ml). The cyst were serous adenoma (7.1%), pseudocyst (50%) and mucinous cyst (12.8) in the ethanol group and papillary mucinous neoplasm (33.3%), serous adenoma (33.3%) and pseudocyst (33.3%) in the iodine povidone group. The average size of the cysts in the ethanol group was 4.7 cm (2.5–7.8) and in povidone group was 4.5 cm (1.2–3.6). Average sessions for ethanol group was 1.4 (1–5) and povidone iodate was 1. The only adverse events found occurred in the ethanol group and it was pain (28.5%). The ablation cyst and decreased over 50% of the initial volume after ethanol and povidone was 14.2%, 83.3% [odds ratio (OR) = 3.75], 57.1% and 16.6% [odds ratio (OR) = 1.45], respectively.
**Conclusion:** The results of this study shows that the EUS-guided lavage with povidone iodate is a method as good as ethanol in the cystic ablation with a lower incidence of adverse events. Further prospective, randomized and comparative studies are need to confirm these benefits of povidone iodate in the conservative treatment of pancreatic cyst.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0110 NONINVASIVE NOVEL THERAPY OF HIGH-INTENSITY FOCUSED ULTRASOUND (HIFU) FOR UNRESECTABLE PANCREATIC CANCER

**A. Sofuni**, M. Fujita, T. Sano, S. Asai, T. Tsuchiya, S. Tsuji, R. Tanaka, K. Kamada, R. Tonozuka, M. Honjo, S. Mukai, K. Yamamoto, Y. Matsunami, T. Itoi
*Gastroenterology & Hepatology, Tokyo Medical University, Tokyo/Japan*

**Contact E-mail Address:** a-sofuni@amy.hi-ho.ne.jp.
**Introduction:** Recently, high-intensity focused ultrasound (HIFU) is most expected as new advanced therapy for unresectable pancreatic cancer (PC). HIFU therapy with chemotherapy is being promoted as new method to control local advance by ablation tumor, and mainly achieve relief of pain caused by PC.
**Aims & Methods:** We have evaluated the therapeutic effect of HIFU therapy in locally advanced and metastatic PC. We treated PC patients by HIFU as optional local therapy as well as systemic chemo / chemo-radiotherapy, with whom an agreement was obtained in adequate IC, from the end of 2008 in our hospital. This study took approval of member of ethic society of our hospital. HIFU device used is FEP-BY02 (Yuande Bio-Medical Engineering Co.LTD., China). The subjects were 120 PC patients, i.e. 62 cases in stage III, 58 cases in

stage IV. Performance status (PS) was PS:0; 74, PS:1; 44, and PS:2; 2 cases. Mean age was 61.7 ± 10.9 years, The details of therapy before HIFU treatment (overlap) was chemo-radiotherapy in 33, chemotherapy in 74, arterial infusion chemotherapy in 5, immunotherapy in 4, operation in 12, and BSC in 6 cases.
**Results:** All tumors were visualized by HIFU monitor system. Tumor location was head in 35, uncus in 19, body in 48, body ~ tail in 5, tail in 1, and others (recurrence) in 12 cases. Treatment data was followed; mean tumor size before and after therapy was 33.6 ± 10.3 and 33.6 ± 10.7 mm, mean treatment sessions: 2.4 ± 0.6 times, mean total treatment time: 111 ± 68.2 min, mean total number of irradiation: 2107 shots. The effects of HIFU therapy were the following; the rate of complete tumor ablation was 85.8%, the rate of symptom relief effect was 68.2%, the effectiveness of primary lesion was CR:0, PR:17, SD:76, PD:27 cases, primary disease control rate (DCR) more than SD was 77.5%. The therapy after HIFU treatment was operation in 8, chemotherapy in 100, immunotherapies in 3, and best supportive care (BSC) in 11 cases. MST after diagnosis in HIFU with chemotherapy and chemotherapy alone (38 patients in our hospital) was 997.8 vs 366.6 days, respectively ($p < 0.001$). MST after HIFU therapy was 582.7 days. Combination therapy of HIFU with chemotherapy was better result than common chemotherapy alone.
**Conclusion:** This study suggested that HIFU therapy has the potential of new method of combination therapy for PC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[4]*Pathology, University Hospital Lozano Blesa, Zaragoza/Spain*

**Contact E-mail Address:** j_mibo@hotmail.com.
**Introduction:** Intraductal Papillary Mucinous Neoplasms of the pancreas are subcategorized clinically into Main Duct (MD-IPMN), Branch Duct (BD-IPMN) and Mixed Type (Mx-IPMN). MD-IPMN, Mx-IPMN and Mucinous Cystic Neoplasms (MCN) are considered lesions with malignant potential. Different International Consensus (IAP-2012, European-2013 and AGA-2015 guidelines) differ in criteria for surgical resection.
**Aims & Methods:** To analyze the suitability of a more conservative management regarding the predictive value of different risk criteria described for High Grade Displasia (HGD) or Invasive Carcinoma (IC). A retrospective multicenter study was performed, recruiting a total of 44 operated IPMN or MCN. Demographic, imaging, operative and pathological data, and outcomes were recorded.
**Results:** MD-IPMN: A total of 18 cases recruited, 89% male with a median age of 64 years old. 89% of them (16/18) showed HGD or IC in the post-surgery specimen analysis, and 81% (13/16) were symptomatic (PPV = 92.9%). One of the most frequent symptoms was jaundice (43.7% patients). And almost all symptomatic patients (except one) showed HGD or IC in the specimen analysis. Median size of lessions with any kind of malignancy (HGD or IC) was 36.7 mm (range: 15–80) while benign lesions (Low Grade Dysplasia) showed a median size of 27.5 mm (range: 20–35) ($p = 0.45$). All HGD or IC cyst presented at least one of the following criteria: size ≥ 30 mm (75%, PPV = 92.3%), Wirsung ≥ 5 mm (68.75%, PPV = 84.6), Worrisome features like intracystic mural nodules or thickened wall (68.75%, PPV = 100). BD-IPMN: A total of 10 cases recruited, 55.6% female, with a median age of 68 years old. 100% were symptomatic (probable selection bias, only operated lesions recruited) from which 50% (5/10) showed HGD or IC. Median size of lessions with any kind of malignancy was 43.8 mm (range: 22–70) while benign lessions showed a median size of 32.2 mm (range: 15–52, $p = 0.39$). Most cysts (80%) with HGD or IC presented at least one of the following criteria: Wirsung ≥ 5 mm, Worrisome features like intracystic mural nodulesor thickened wall (Sensitivity = 80%, Specificity = 100%). MCN: A total of 16 cases recruited, 87.5% female, with a median age of 50years old. 50% (8/16) were symptomatic and only 3/16 (18.75%) showed HGD or IC inthe pathologic analysis. All malignant lessions were symptomatic, with a median size of 103.7 mm (range: 35–200). Benign lessions showed a median-size of 43.7 mm (range 15–80, $p = 0.028$). Thus, size was an excellent predictor of benignity with a Negative Predictive Value for lessions under 40 mm of 85.7%, and 100% for lessions under 30 mm. No dilated Wirsung was observed and curiously, up to 30.7% of benign MCN presented orrisome features like mural nodules or peripheral calcifications (PPV = 33.3).
**Conclusion:** Our series supports the malignant rate described for MD-IPMN or BD-IPMN (88.9% vs 50%). Symptoms and morphological risk-criteria showed high specificity, but the size was not discriminant, supporting universal resection. MCN malignant rate was similar to that described in consensus (18.7%). Size was an effective discriminant factor (no malignancy in < 30 mm) supporting a more conservative management.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0112 PREDICTING FACTORS FOR UNRESECTABILITY IN PATIENTS WITH LOCALIZED PANCREATIC CANCER AND SELECTIVE USE OF STAGING LAPAROSCOPY

**H.S. Lee**, S. Bang
*Department Of Internal Medicine, Institute of Gastroenterology, Yonsei University College of Medicine, Seoul/Korea, Republic of*

**Contact E-mail Address:** lhs6865@gmail.com.
**Introduction:** The prognosis for pancreatic cancer patients is very poor. At the time of pancreatic cancer diagnosis, only 15 ~ 20% of patients have a potentially resectable disease without evidence of a major vessel involvement or extrapancreatic spread of the tumor. Despite the advances and resolution improvement of imaging technologies, surgeons sometimes encounter distant metastasis intraoperatively, including liver metastases or small amount of peritoneal metastasis.
**Aims & Methods:** The aim of the present study was to identify the predicting factors for unresectability and to evaluate who should receive staging laparoscopy in patients with radiographically resectable pancreatic cancer. From 2006 to 2015, we retrospectively reviewed the medical records of 470 patients who diagnosed with pancreatic cancer and underwent open laparotomy at Severance Hospital, Seoul, South Korea. Information on age, sex, CA 19-9, total bilirubin, albumin, cholesterol, body mass index, tumor size, tumor location, and intraoperative finding were collected.
**Results:** Of the 470 patients who underwent open laparotomy, 32 (6.8%) patients were unresectability status on intraoperative finding and underwent open & closure or palliative bypass surgery. The tumor size and CA 19-9 in unresectable group were significantly larger than that in the resectable group. After matching by age and sex, multivariate analysis showed that tumor size was independent predicting factor for unresectability in radiographically resectable pancreatic cancer (hazard ratio, 1.214; 95% confidence interval, 0.473–0.994).
**Conclusion:** The presence of high-risk fators was associated with surgical unresectability in patients with radiographically resectable pancreatic cancer. The selective use of staging laparoscopy in patients high risk factors may decrease the frequency of unnecessary laparotomy in pancreatic cancer patient.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Magnifying endoscopy with narrow-band imaging (M-NBI), a recently developed image-enhanced endoscopic technique, can reportedly help distinguishing between cancerous and non-cancerous stomach lesions. For M-NBI diagnosis of early gastric cancer, the vessel plus surface classification system (VSCS) proposed by Yao et al [1] is very useful [2], and could require fewer biopsies to diagnose each cancer [3]. However, acquiring skill at M-NBI diagnosis takes substantial effort.

**Aims & Methods:** We have developed an internet-based e-learning system to teach diagnosis of early gastric cancer using M-NBI based on VSCS. This study was designed as a randomized controlled multicenter trial (UMIN: 000008569). We recruited endoscopists as participants from all over Japan. Initially, we conducted Test-1, which consisted only of M-NBI images of 40 gastric lesions (22 cancerous and 18 non-cancerous lesions) which were taken at maximum magnification. Participants were randomly assigned to the former-learning and the latter-learning groups. Pre-adjustment strata were their institutions, their numbers of endoscopies conducted, and their Test-1 scores. The former-learning group was allowed to access the e-learning system, which consisted of video lectures on the basics of M-NBI and VSCS, and self-exercise tests consisting only of M-NBI images of 100 gastric lesions to accumulate experience. We conducted Test-2 (same as Test-1) in both groups after the learning period. Following the Test-2, the same e-learning was given only to the latter-learning group before Test-3 (same as Test-1) was conducted for both groups. The analysis set of this study was the participants who scored $< 80\%$ accuracy on Test-1. The primary endpoint of this study was to compare the changes in diagnostic accuracy on Test-2 between groups. The secondary endpoint was to investigate the improvement of the diagnostic accuracies after e-learning in both groups.

**Results:** Among the 490 endoscopists from 77 institutions assessed for eligibility, 395 participants completed Test-1 and were enrolled; 198 were allocated to the former-learning group and 197 to the latter-learning group. The analysis sets of this study, excluding the 27 participants who scored $\geq 80\%$ on Test-1, were former-learning group: $n = 184$; and latter-learning group: $n = 184$. The former-learning group scored on average 59.9%, 67.3%, 67.4% in Test-1, Test-2, and Test-3, respectively, while the latter-learning group's average scores were 61.7%, 61.8%, 68.4%, respectively. The mean change in accuracy on Test-2 was significantly higher in the former-learning group than in the latter-learning group ($7.4 \pm 8.6\%$ and $0.14 \pm 7.5\%$, $P < 0.001$), when e-learning was given only to the former-learning group. After e-learning in both groups, the mean accuracy on Test-3 in the latter-learning group improved even to that in the former-learning group ($P = 0.323$).

**Conclusion:** This study clearly demonstrated the efficacy of the e-learning system. Endoscopists can take advantage of this e-learning system at any one time to learn gastric M-NBI diagnosis using VSCS and improve their capabilities to differentiate and diagnose cancer and non-cancer using M-NBI.

Diagnostic accuracy in each tests

| | Former-learning group n = 184 | Latter-learning group n = 184 |
|---|---|---|
| Test-1, %, mean ± SD | 59.9 ± 8.2 | 61.7 ± 8.6 |
| Test-2, %, mean ± SD | 67.3 ± 8.6 | 61.8 ± 10.2 |
| Test-3, %, mean ± SD | 67.4 ± 8.5 | 68.4 ± 9.2 |

**Introduction:** Visually guided endoscopic treatment of variceal bleeding is the current standard of care. Residual blood flow in varices causes rebleeding but is not currently used for hemostasis.

**Aims & Methods:** In a RCT, our primary outcome was 30 day lesion rebleed rates of patients treated either with standard endoscopic hemostasis or DEP guided therapy. Secondary outcomes were complications, surgeries, TIPS, death, transfusions, & hospital days. Cirrhotics were resuscitated, screened, & consented before endoscopy – EGD (if they met clinical entry criteria) & had severe UGI bleeding (clinical signs, hemoglobin drop of $>2$ gms, & RBC transfusions). Randomization was during EGD for esophageal varices-EV's (with or without stigmata of hemorrhage – SRH –active bleed, platelet plug, clot, spot); gastric varices (GVs), post-rubber band ligation (RBL) ulcers, or Mallory Weiss tears (MWT) with SRH. Patients had airways protected, antibiotics & Octreotide (OCT) infusions, & RBL hemostasis (distally & on SRH & for varices or MWT- minimum 2 bands/column). Sclerotherapy was used to control severe active bleeding first; for GVs & post-RBL ulcers; & during FU for varices too small to band. For DEP patients, varices & other lesions were interrogated near SRH & distally & again after hemostasis using DEP depth settings $<4$ mm with disposable probes & FDA approved Doppler unit (Vascular Technology Inc, Nashua, NH). For residual lesion blood flow by DEP after standard treatment, more RBL &/or sclerotherapy was applied to obliterate flow, if deemed safe by endoscopists. All patients received OCT infusions (50 micrograms/hr) for 72 hours & twice daily PPIs & were managed in ICUs by physicians & nurses blinded to whether DEP was used. EGD was repeated for severe UGI rebleeding or varix surveillance in 7–14 & 30 days. For continued bleeding TIPS was performed. Research coordinators followed patients prospectively, data management was with SAS, & $p < 0.05$ was considered statistically significant.

**Results:** For 87 RCT patients, 79% had EVs & 21% other lesions. No differences were significant in lesions or baseline clinical variables for the 2 treatments. A significant difference (21.2% higher) was in 30 day rebleed rate for Standard vs. DEP patients (17/47 vs. 6/40 – $p = 0.0302$) – Odds ratio 3.21 (95%CIs 1.12, 9.2); Number Needed to Treat was 4.7. 30 day rates of surgery (OLT – 3 vs. 1), TIPS (3 vs. 4), or deaths (2 vs. 1) were not significantly different but RBC & FFP transfusions & hospital days were. No major complications occurred.

**Conclusion:** Cirrhotics with bleeding varices, post-RBL ulcers, or MWTs treated with DEP guided hemostasis had significantly lower 30 day rebleed rates, RBC or FFP transfusions, & hospital days than those treated with standard visually directed treatment without blood flow monitoring. 2. DEP was fast, safe, & easy to use. Supported by a Clinical Veterans Administration Merit Review Grant (CLIN-013-07F) and NIH NIDDK 41301 CURE DDRC Human Studies Core. Registered on ClinTrials.gov (NCT00732212).

**Contact E-mail Address:** amolbapaye@gmail.com.

**Introduction:** Sub epithelial tumors (SET's) are soft tissue tumors arising from the submucosal or muscluaris propria layers of luminal organs. Enbloc resection of these lesions is desirable; often using surgical methods. Endoscopic techniques for resection of these lesions include endoscopic submucosal dissection (ESD) for lesions originating in the sub mucosal layer or endoscopic full thickness resection (EFTR) or submucosaltunneling endoscopic resection (STER) for lesions arising in the muscularis propria layer. This study describes ourexperience of endoscopic treatment of SETs.

**Aims & Methods:** Data of all consecutive patients undergoing endoscopic resection of SET in the period 2012 –2015 was analyzed. All patients underwent pre procedure screening esophagogastroduodenoscopy (EGD) andendoscopic ultrasound (EUS) for assessment of SET and layer of origin. One of following 3 procedures – ESD, EFTR or STER was performed for resection of the SET. ESD was performed for SETs arising in sub mucosal layer whereas EFTR or STER was performed for lesions in the muscularis propria layer. All patients underwent follow up EGD at 4–6 weeks. Parameters recorded were – location of lesion, layer of origin, procedure performed (ESD, EFTR or STER), technical success, closure techniques, margin positivity on histology, complications and their management and final histopathology.
**Results:** 34 consecutive patients with sub epithelial tumors underwent endoscopic resection during study period. Mean age – 57 years (range 29–78) and 24 male patients. ESD was performed in 25 patients, EFTR in 7 and STER in 2. Endoscopic closure was performed whenever deep muscle layer was breached. Full-thickness clip was applied in 2, mucosal clip (hemoclip) with omental patch closure in 1, hemoclip approximation of full-thickness defect in 1 and hemoclip approximation of muscle defect in 12 patients. Mucosal incisions after STER were closed using hemoclips in 2 patients. Location of SETs was stomach (15), colon (6), duodenum (9), esophagus (3) and rectum (1). The mean area of sub epithelial tumors was 11.26 $cm^2$ (range 1–110). Histology was neuroendocrine tumors – 12, lipoma – 7, gastrointestinal stromal tumors – 8, leiomyoma – 5, ectopic pancreatic rest – 1 and duplication cyst – 1. Technical success of resection was 100%. 3 complications: perforation – 2 patients, 1 required surgery; bleeding – 1 patient, managed endoscopically. Histopathology of all specimens showed en-bloc excision with negative tumor margins.
**Conclusion:** Conclusions: Endoscopic en-bloc resection using ESD, EFTR or STER is a safe and effective therapy for SETs. Pre procedure EUS can determine the appropriate excision procedure to be performed. Endoscopic closure using mucosal or full-thickness clips is safe and effective.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0116 ASSESSMENT OF THE SAFETY OF ENDOSCOPIC SUBMUCOSAL DISSECTION IN VERY ELDERLY PATIENTS

**M. Nishimura**[1], J. Woo[2], Y. Fujii[1], Y. Kowazaki[3], M. Matsukawa[1], J. Matsuoka[3]

[3]*Gastroenterology, Tokyo Metropolitan Geriatric Hospital and Institute of Gerontology, Tokyo/Japan*

**Contact E-mail Address:** nimakoto@gmail.com.
**Introduction:** Since endoscopic submucosal dissection (ESD) has been developed for en bloc resection of large superficial tumors, it is widely accepted as a reliable therapeutic procedure. This recent innovation allows safe treatment in elderly patients; however, there are only few reports of ESD in very elderly patients, aged 80–90 years old or above. This study aimed to assess the safety and feasibility of ESD in the very elderly patients.
**Aims & Methods:** Between June 2013 and March 2016, patients with superficial gastrointestinal lesions at our institution were treated with ESD. A standard gastroscope (GIF-Q 260Z, Olympus) and a Dual knife (KD-650Q, Olympus) were used for ESD. All patients were treated under conscious sedation with midazolam (1–10 mg). Patients were divided to an elderly group (60–79 years of age) and a very elderly group (above 80 years of age). For both groups, lesion size, procedure time, total amounts of midazolam, and ESD-related complications (hypotension, hypertension, hypoxia, arrhythmia, and bleeding) were analyzed.
**Results:** From the database, we collected data on a total of 293 patients who underwent ESD for esophageal (39 cases), gastric (123 cases), and colorectal lesions (131 cases) more than 60 years old in our institution. In the elderly group, 161 patients were treated (89 males/ 72 females, 60–79 years of age, mean age 73.1) and in the very elderly group, 133 patients were treated (68 males / 64 females, 80–92 years of age, mean age 84.7). All patients were successfully treated with ESD in both groups. The mean resected specimen size was 34.4 mm in the elderly group and 34.3 mm in the very elderly group ($p = 0.98$). ESD time was 61.5 minutes in the elderly group and 56.1 minutes in the very elderly group ($p = 0.32$). Midazolam doses of 3.8 mg and 3.6 mg were administered ($p = 0.38$), respectively. As complications, hypoxia were 32.2% and 51.9% ($p < 0.05$), bradycardia were 12.4% and 18.0% ($p = 0.17$), tachycardia were 11.8% and 12.0% ($p = 0.45$), hypotension were 68.9% and 66.2% ($p = 0.67$), hypertension were 30.4% and 29.3% ($p = 0.86$), respectively. Based on the final pathological results, there were 2 cases on whom additional gastrectomy was performed, and 1 case of radiation in the elderly group; and no additional therapy was performed in the very elderly group.
**Conclusion:** Our data suggests that ESD is safe and feasible in very elderly patients; however, such patients tended to be more sensitive to sedation. Our data also suggests that general anesthesia might not be necessary for the elderly and very elderly patients undergoing ESD, as long as there is appropriate intraoperative management. Further investigations to evaluate various other factors including past medical history, performance status, and anticoagulant medicine are necessary.

**Introduction:** Accurate diagnosis of submucosal (SM) invasion of esophageal squamous cell carcinoma (ESCC) is difficult by conventional endoscopic examination, especially in case of slight or moderate SM invasion. Endoscopic ultrasonography (EUS) has been used for evaluation of the depth of cancer invasion worldwide[1–3], however, there is no prospective, multicenter study to evaluate the diagnostic yield of EUS for ESCC.

Correlation between clinical and pathological depth of invasion.

| | Pathological diagnosis | | | | | |
|---|---|---|---|---|---|---|
| Clinical diagnosis | pEP | pLPM | pMM | pSM1 | pSM2 | total |
| cSM1 | 3 | 28 | 44 | 14 | 25 | 114 |
| cSM2 | 0 | 3 | 11 | 3 | 44 | 61 |
| total | 3 | 31 | 55 | 17 | 69 | 175 |

**Aims & Methods:** The aim of this study is to evaluate endoscopic diagnostic yield of EUS for SM invasion as a post hoc analysis using the data of multicenter prospective study as well as to explore clinical features that influenced the clinical diagnosis. JCOG0508 was a multicenter prospective confirmatory study to evaluate the efficacy and safety of combined treatment of endoscopic resection (ER) and chemoradiotherapy for clinical (c) Stage I (cSM-slight or moderate) ESCC [4]. All lesions were evaluated with both conventional endoscopy and EUS before enrollment. If the differential diagnosis between cT1a-musclaris mucosa (MM) and cT1b-SM-slight was difficult, it was judged as cT1b-SM-slight. We compared the clinical and pathological (p) diagnosis for depth of invasion and assessed the diagnostic yield: positive predictive value (PPV) for SM (pSM/cSM), PPV for the patient diagnosed with cSM but pMM or pSM (pMM + pSM/cSM). We also investigated what factors affected the pathological depth of invasion. The factors included macroscopic type, tumor size, circumference of the lesion, and clinical evaluation of depth of invasion (cSM-slight vs cSM-moderate).
**Results:** Of 177 patients enrolled in JCOG0508, two patients were excluded because of withdrawal of consent and invasion depth of pMM with unknown vertical margin. Finally, 175 patients were analyzed. The numbers of the macroscopic type with 0-I/ 0-IIa/ 0-IIb/ 0-IIc were 18/ 30/ 4/ 123, respectively. The median size of lesion was 2.5 cm (range: 0.5–5.0). The circumference of the lesion in the esophageal lumen; $<1/2$/ $>1/2$ and $<3/4$ were 152/ 23. The number of patients with cSM-slight and cSM-moderate were 114 and 61, respectively. The number of patients with pEP/ pLPM/ pMM/ pSM1/ pSM2 were 3/ 31/ 55/ 17/ 69, respectively. The PPV for SM was 49.1% (86/175) and PPV for the patient diagnosed with cSM but pMM or pSM was 80.6% (141/175). A multivariate analysis demonstrated that clinical evaluation (cSM-slight vs cSM-moderate) was an independent factor associated with the discrimination of pM from pSM (OR 6.65, 95%CI 3.21–13.75).
**Conclusion:** The PPV of endoscopic diagnosis for submucosal invasion of ESCC was not high enough even with EUS. Especially, clinically diagnosed SM-slight ESCC is likely to be pathological mucosal cancer. Such lesions could be curatively treated by ER alone. Therefore, ER could be recommended for these lesions as an appropriate diagnostic procedure as an initial part of minimally invasive treatment strategy.

**Introduction:** Peroral endoscopic myotomy is a promising minimally invasive treatment for achalasia. It is also reported that this new therapy was effective for treating achalasia with sigmoid esophagus.
**Aims & Methods:** The aim of the study was to examine the feasibility and safety of a novel modified peroral endoscopic shorter myotomy for sigmoid-type achalasia. Between July 2011 and August 2015, 11 achalasia patients (6 male, with a mean age of 41 years) with sigmoid esophagus underwent peroral endoscopic shorter myotomy in our department. Diagnosis was based on symptoms, manometry, radiology and endoscopy. Preoperative and postoperative symptoms scores, manometry outcomes and quality of life scoring of achalasia were recorded and analyzed.
**Results:** All patients had dysphagia as their chief presenting complaint with the median duration of 21 months (range 18–36 months). Procedure was performed successfully in all patients, and the mean time required for the procedure was 56.8 minutes (range 49–70 minutes). There were no mortalities and major postoperative complications occurred. The mean length of myotomy was 5.2 cm (range 5–6 cm). During a mean follow-up period of 23 months (range 12–37.5 months), treatment success (Eckardt score $\leq 3$) was achieved in all patients. There was a significant improvement of symptoms relief, lower esophageal sphincter pressure decrease and quality of life ($P < 0.01$, $P < 0.01$, $P < 0.01$, respectively). Symptoms of gastroesophageal reflux occurred in two patient, and it was easily controlled with regular doses of proton pump inhibitors.
**Conclusion:** In this study, peroral endoscopic shorter myotomy is feasible, effective and safe in improving subjective, objective, and quality-of-life outcome measures in patients with sigmoid-type achalasia. Further studies are warranted to prove its long-term efficacy in comparison to other treatment modalities.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0120 EFFICACY, RECURRENCE AND COMPLICATION RATES OF ENDOSCOPIC MUCOSAL RESECTION VERSUS ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY BARRETTÍS NEOPLASIA: A RETROSPECTIVE GERMAN SINGLE CENTER ANALYSIS

**C. Meinhardt**[1], P. Troschel[1], A. Schütte[2], R. P. Henke[3], H. Seifert[1]

**Introduction:** Endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) are established standard treatment options for superficial Barrett's neoplasia. Whereas EMR is the most comprehensively studied method with the advantages of being effective and safe, ESD has potential advantages regarding a high en bloc resection rate and better histopathologic assessment for accurate staging, but it is technically more demanding and may cause more adverse events. So far, there are only few data comparing both endoscopic techniques for treatment of early Barrett's neoplasia in a long-term follow-up.
**Aims & Methods:** We aimed to assess EMR compared to ESD in terms of curative resection rates, complication and recurrence rates. In the retrospective single center analysis, all patients were included in which an EMR ($n = 56$) or ESD ($n = 53$) was performed between 2003 and 2015 due to a visible suspicious Barrett's lesion or a histologically confirmed Barrett's associated high-grade intraepithelial neoplasia (HGIN) or an early Barrett's carcinoma (BC). EMR was carried out in form of one or by serial endoscopic resections while ESD was performed in one session.
**Results:** In 39 of 56 patients who underwent EMR, histological assessment showed HGIN ($n = 8$) or BC ($n = 31$). 49 of 53 patients treated with ESD showed HGIEN ($n = 5$) or BC ($n = 44$). Specimen histology revealed no neoplasia in 17 and 4 patients, respectively, despite of visible suspicious Barrett's lesion or previous biopsy-proven HGIN. R0 resection defined as margins free of HGIN and BC was achieved in 76.9% (30/39) by EMR and in 81.6% (40/49) by ESD ($p = 0.6057$). Regarding a subgroup which showed an invasion less than pT1sm2, R0 resection was observed in 77.8% (28/36) and 97.3 (36/37), respectively ($p < 0.05$). After R1 resection, surgical or endoscopic resection ± ablative therapy was carried out according to the histological tumor category. EMR and ESD did not lead to complications requiring surgery. Furthermore, there were no significant differences in the risk of delayed bleeding, perforation and stricture rates when comparing EMR to ESD. Delayed major bleedings were observed in 3.6% (2/56) after EMR and 3.8% (2/53) after ESD, periinterventional perforations occurred in 1.8% (1/56) and 7.5% (4/53), respectively ($p = 0.1976$). Esophageal strictures developed in 25.0% (14/56) after EMR, partially due to serial endoscopic resections and in 18.9% (10/53) after ESD ($p = 0.4936$), all treated endoscopically. After EMR, recurrent BC was observed in 10.3% (4/39, mean endoscopic follow-up 61 ± 46 months), thereof three patients with initially mucosal and one with submucosal invasion. After ESD, recurrent BC was observed in 6.1% (3/49, mean endoscopic follow-up 26 ± 20 months), thereof one patient with initially mucosal and two with submucosal invasion ($p = 0.4578$).
**Conclusion:** EMR and ESD are both highly effective endoscopic resection options in early Barrett's neoplasia. In the analysed cohort, ESD achieves higher R0 resection rates than EMR in tumors with mucosal and superficial submucosal invasion, but not in lesions which show an invasion greater than pT1sm1. Both techniques are associated with low recurrence rates without significant differences. ESD is not associated with higher complication rates than EMR.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0121 ENDOSCOPIC HAND SUTURING FOR MUCOSAL DEFECT CLOSURE AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION IN IN VIVO ANIMAL MODELS AND CLINICAL CASES

**Introduction:** Mucosal defect closure after gastric endoscopic submucosal dissection (ESD) may prevent postoperative bleeding and delayed perforation. Although several clipping techniques have been introduced, endoclips are too weak to maintain closure and may be too small for large mucosal defect closure after ESD. Endoscopic hand suturing (EHS) was developed to provide more reliable closure without a size limitation)[1].
**Aims & Methods:** In this pilot study, we aimed to demonstrate the feasibility of EHS and possibility of permanent closure after gastric ESD in in vivo animal models and clinical cases. [Animal experiment] The institutional review board of our animal laboratory approved the study; EHS was performed in 6 live pigs. A mucosal defect (3 cm in size) was made in each pig. The mucosal layers were continuously sutured in a linear fashion using a prototype of a through-the-scope needle holder (Olympus) and an absorbable barbed suture (V-loc180; Covidien) with a haemoclip or a knot on the tail as an anchor. After suturing, the remaining part of the needle and thread was cut with scissor forceps and was retrieved transorally. Suturing sites were endoscopically observed at most on the 7th day following the procedure. The success rate of EHS and suture maintenance were investigated. [Clinical study] The institutional review board of our hospital approved the study; EHS was performed in 8 patients who underwent ESD for gastric neoplasms (3 cm or less in size) using the above-mentioned procedure. The patients were endoscopically monitored at postoperative week 1 and 4. The success rate of EHS and maintenance of the suturing were assessed, including postoperative adverse events.
**Results:** [Animal experiment] In the all 6 pigs, EHS was successfully completed (100%). However, the sutured sites collapsed in the first 3 cases on the 7th day following the procedure. In the latter 3 pigs, the sutures were reinforced with additional clipping and closely monitored endoscopically on every 2 days after the procedure; however, these also reopened in all cases on the 4th day following the procedure. [Clinical study] EHS was completed in all 8 cases (100%), and no severe adverse events occurred during the procedure and thereafter. The median diameter of the mucosal defect, procedure time and the number of stitches were 32 mm (range, 20–37 mm), 20 min (range, 13–18 min) and 7 (range, 6–10), respectively. In the first 4 cases, the sutures collapsed at postoperative week 1. Therefore, we attempted to insert the needle deeply in the horizontal direction and to pull the strings more tightly in the latter 4 cases. Consequently, sutures were successfully maintained at 1 and 4 weeks following the procedure in these cases.
**Conclusion:** EHS was feasible in both in vivo animal models and human cases, and the closure was maintained by suturing the mucosal defects deeply and tightly in clinical cases. EHS, which enables optimally designed intraluminal suturing by peroral flexible endoscopy, appears to be helpful in avoiding postoperative adverse events after gastric ESD and therefore in shortening the hospitalization period (UMIN000017125).
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic examination is essential for diagnosis of gastric cancer and atrophic gastritis. Blue laser imaging (BLI) including a brighter BLI-bright was developed as a novel image-enhanced laser endoscopy for a narrow-band light observation. Moreover, linked color imaging (LCI) was developed to recognize slight differences in mucosal color for detection of tumor and mucosal inflammation. It is unknown which is better visibility for diagnosis of early gastric cancer (EGC) and atrophic gastritis among white light imaging (WLI), BLI (BLI-bright), LCI and flexible spectral imaging color enhancement (FICE).
**Aims & Methods:** We investigated which is better visibility for diagnosis of EGC and atrophic gastritis among white light imaging (WLI), BLI (BLI-bright), LCI and flexible spectral imaging color enhancement (FICE). We recorded non-magnifying and magnifying observation videos of consecutive 40 cases with EGCs by using WLI, BLI (BLI-bright), LCI and FICE. Five endoscopists evaluated the videos in a randomized order. The visibility of EGC and atrophic border was assigned a visibility score from 4 (excellent) to 1 (poor). The visibility scores in each mode and their relationship to EGC and atrophic border were analyzed. Atrophic border was evaluated by Kimura-Takemoto classification. This study was approved by the Ethical Review Committee of the Kyoto Prefectural University of Medicine and carried out in accordance with the Helsinki Declaration of the World Medical Association.
**Results:** Six EGCs were located in upper third of stomach, 20 were in middle third, and 14 were in lower third. There were 32 well-differentiated adenocarcinoma, three moderately differentiated adenocarcinoma, and five poorly differentiated adenocarcinoma. There were six cases with mild atrophy (C-1 and C-2), 12 cases with moderate atrophy (C-3 and O-1), 22 cases with severe atrophy (O-2 and O-3). The mean tumor size was 12 mm (9–40). The mean visibility scores of BLI-bright and LCI for EGC in a distant observation were significantly higher than those of WLI and FICE (3.51, 3.34, 3.04, and 3.14; $P = 0.002$, respectively). The mean visibility scores of BLI for EGC in a magnifying observation were significantly higher than those of WLI, LCI, and FICE (3.81, 2.61, 3.28, and 3.07; $P < 0.0001$, respectively). The mean visibility scores of LCI for atrophic border in a distant observation were significantly higher than those for WLI, BLI-bright, and FICE (2.78, 2.73, 2.24, and 2.52; $P = 0.001$, respectively).
**Conclusion:** EGCs were more visible in a distant observation by using BLI-bright or LCI compared with WLI and FICE. EGCs were more visible in magnifying observation by using BLI compared with WLI, LCI, and FICE. Atrophic border was more visible by using LCI compared with WLI, BLI-bright, and FICE. Therefore, LCI was the most suitable for detection of EGC and atrophic gastritis. On the other hand, BLI was the most suitable for detailed magnifying observation of EGC.

**Introduction:** Anticoagulants are used to reduce the risk of thromboembolic events and increasing evidence support them to prevail. direct oral anticoagulants (DOAC) are our new choice, however, there is no report about the effect to endoscopic treatments.
**Aims & Methods:** This is a retrospective study of three referral institutes. We treated with ESD gastric neoplasm in 97 patients who were taking anticoagulants. We divided the patients into the two groups, warfarin group and DOAC group. We researched patients' background, treatment results, complication, and hospitalization period.
**Results:** Seventy-three patients were taking warfarin and 24 patients were taking DOAC including 12 patients on dabigatran, 11 patients on rivaroxavan, 1 patient on apixavan. In warfarin group, 78% of patients were performed heparin replacement (HR) as a bridge therapy for perioperative cessation period and delayed bleeding rate was significantly higher in patients with HR than in patients without HR (36% vs 0%, $p < 0.05$). In DOAC group delayed bleeding rate was significantly higher in patients with rivaroxavan than in patients with dabigatran (45% vs 0%, $p < 0.05$), with no relation to HR. As the number of taking antithrombotic agents increased, delayed bleeding rate became higher. Compared to warfarin, period of HR was required shorter ($p < 0.05$) in DOAC, because DOAC reach to maximum effect shortly, and hospitalization period were also shorter ($p < 0.05$). Multivariate analysis showed HR (OR 10.7), rivaroxaban (OR 6.00), and multiple antithrombotic agents (OR 4.35) were independent risk factors of delayed bleeding. Thrombotic event (cerebral infarction) was developed in one patient, who discontinued warfarin with HR.
**Conclusion:** Dabigatran was attractive alternative for warfarin to reduce the period of hospitalization and delayed bleeding rate, although rivaroxaban had significantly higher risk of delayed bleeding. The effect of DOAC differs in each agents.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0124 DETECTION OF UPPER GASTROINTESTINAL BLEEDING WITH A NOVEL TELEMETRIC SENSOR CAPSULE (HEMOPILL ACUTE) – A PROSPECTIVE PILOT STUDY

**A. Schmidt**, M. Bauder, C. Kama, A. Küllmer, B. Meier, K. Caca

**Contact E-mail Address:** arthur.schmidt@kliniken-lb.de.
**Introduction:** Due to the lack of reliable non-invasive methods to detect upper gastrointestinal bleeding (UGIB), decision on timepoint of endoscopy is usually based on clinical parameters as well as on local resources and expertise. In preclinical trials, a novel telemetric swallowable photometric sensor capsule was able to reliably detect blood in the upper GI tract.
**Aims & Methods:** The aim of this pilot study was 1) to evaluate saftey of the device and 2) to determine parameters and threshold levels of the measurement signals in a clinical real-life Setting. We conducted a prospective non-randomized cohort study at a tertiary referral center. Patients with symptoms of UGIB without evidence of hemorrhagic shock swallowed the sensor capsule immediately after presentation in the emergency department. The capsule is battery-powered and contains an optical sensor and a telemetry unit that sends measurement values in real time to an extra-corporal reciever. Independet of the measurement values, all patients recieved esphagogastroduodenoscopy (EGD) within 12 hours.
**Results:** From April 2015 to Febuary 2016, 30 patients were included in the study. Ingestion of the capsule was feasible and without adverse events in all patients. EGD showed active bleeding in 3 patients and signs of recent bleeding in 10 patients. We chose the maximal quotient (Q) of the measurement values generated within the first ten minutes after capsule ingestion as parameter for detection of blood. A threshold level of $Q = 40$ or $Q = 10$ (depending on timepoint of last meal) was defined. Using this parameter, the capsule was able to correctly detect UGIB in 12 patients. In one case, bleeding was probably generated during EGD and therefore not detected by the sensor. The correlation coefficent (Kendall Tau) was 0.727 ($p < 0.0001$). All 15 patients without endoscopic evidence of UGIB were correctly recognized as negative by the capsule. We observed one case of aspiration of gastric content during EGD, there were no adverse events related to the capsule. Capsule excretion could be documented in 25 patients, there was no evidence of capsule retention.
**Conclusion:** Non-invasive detection of UGIB with the novel telemetric sensor capsule is feasible and safe. The measurement values generated within the first ten minutes after ingestion correlated significantly with the presence or absence of UGIB. Prospective multicenter studys are required to confirm the results of this pilot study.
**Disclosure of Interest:** A. Schmidt: Dr. Schmidt has recieved lecture fees from Ovesco Endoscopy.
K. Caca: Prof. Caca has recieved lecture fees from Ovesco Endoscopy.

## P0125 OVER-THE-SCOPE CLIP SYSTEM VERSUS ENDOLOOP COMBINED WITH METAL CLIPS APPLIED TO CLOSURE OF PERFORATION IN GASTRIC ENDOSCOPIC FULL-THICKNESS RESECTION: A SINGLE-CENTER PROSPECTIVE COMPARISON STUDY

C. Zhang, J. Hu, Q. Li, **M. Xu**
*Endoscopy Center And Endoscopy Research Institute, Zhongshan Hospital of Fudan University, Shanghai/China*

**Contact E-mail Address:** xumeidong@aliyun.com.
**Introduction:** Endoscopic full-thickness resection (EFTR) is a novel endoscopic resection method based on the developed techniques of endoscopic submucosal dissection (ESD) and endoscopic submucosal excavation (ESE). EFTR without laparoscopic assistance has been deemed to be an efficacious, safe, and minimally invasive therapeutic method for the treatment of gastric submucosal tumors (SMTs). The technique makes it possible to resect deep upper gastrointestinal (GI) lesion and provide complete specimen for acquiring precise pathological diagnosis. Since EFTR leads to artificial perforation, the key stage of the

procedure is successful closure of the wall defect after resection, to prevent peritonitis and the need for surgical intervention. The use of endoloop combined with metal clips is still a widely accepted closure technique, but it is time-consuming, and the effectiveness of it is more dependent on the operators' skill. Over-the-scope clip (OTSC) system, as a novel closure technique, seems to be time-saving and make closure much easier to perform.
**Aims & Methods:** The study aimed to compare safety and efficacy of a novel closure device, OTSC system, with endoloop and metal clips, applied to gastric EFTR for SMTs. A prospective study was carried out, including a consecutive cohort of 40 patients who underwent EFTR for gastric SMTs between March 2014 and June 2014 in our center. According to the different closure methods applied to perforation resulting from EFTR, the patients were divided into two groups, OTSC group (n = 20) and endoloop and metal clips group (n = 20). The demographic and operation-related parameters of the two groups were compared used statistical approach by statistical software SPSS 20.
**Results:** EFTR and closure procedure were both performed successfully in all of the patients. R0 resection was achieved in every patient. The data, including clinicopathological characteristics of the patients and comparison of the parameters between the OTSC group and endoloop and metal clips group, is listed in Table 1. There was no significant difference in patient age, sex, tumor size and perforation size between the two groups. The operation time, closure time, total complication rate and hospital stays in OTSC group were all shorter than those in endoloop and metal clips group, but it showed no statistical difference between the two groups. The operation cost in OTSC group was significantly less than that in endoloop and metal clips group. Clip retaining rate in OTSC group was significantly higher than that in endoloop and metal clips group. There were two and four cases occurred seroperitoneum or pleural effusion in OTSC group and endoloop and metal clips group, respectively. All those complications disappeared spontaneously. Delayed bleeding and perforation were detected in one case in endoloop and metal clips group, and the patient suffered secondary surgery to stop bleeding and repair perforation. No other severe complications developed in the two groups. During the follow-up ranged from 17 to 19 months, all OTSC were proved to stay in situ by gastroscopy. No procedure-related death occurred in the study.

**Table 1:** Clinicopathological characteristics of the patients and comparison of the parameters between the over-the-scope clip (OTSC) group and endoloop and metal clips group.

| | OTSC group (n = 19) | Endoloop and metal clips group (n = 21) | P-value |
|---|---|---|---|
| Age, years, mean ± SD | 58.7 ± 14.2 | 61.8 ± 9.9 | 0.421 |
| Sex, male/female | 8/11 | 14/7 | 0.119 |
| Tumor location: GB/GF/GA | 7/9/3 | 9/9/3 | |
| Tumor size, mm, mean ± SD | 2.5 ± 0.6 | 2.0 ± 0.9 | 0.056 |
| Perforation size, mm, mean ± SD | 2.3 ± 0.6 | 1.9 ± 0.9 | 0.086 |
| Procedure time, min, mean ± SD | 45.9 ± 10.6 | 56.6 ± 41.9 | 0.286 |
| Closure time, min, mean ± SD | 14.2 ± 2.8 | 15.7 ± 9.5 | 0.508 |
| R0 resection (%) | 100 (19/19) | 100 (21/21) | |
| Success Closure procedure (%) | 100 (19/19) | 100 (21/21) | |
| Complications (%) | | | 1.000 |
| Seroperitoneum (%) | 5.3 (1/19) | 9.5 (2/21) | |
| Pleural effusion (%) | 0 | 4.8 (1/21) | |
| Delayed perforation (%) | 0 | 4.8 (1/21) | |
| Delayed bleeding (%) | 0 | 4.8 (1/21) | |
| Convertion to surgery (%) | 0 | 4.8 (1/21) | |
| Mean hospital stays, day, mean ± SD | 3.8 ± 1.2 | 5.3 ± 3.4 | 0.078 |
| Operation cost, thousand yuan, mean ± SD | 18.7 ± 0.7 | 1.9 ± 0.1 | 0.000 |
| Clip retaining rate | 89.5 (17/19) | 14.3 (3/21) | 0.000 |

**Conclusion:** The two closure methods, OTSC and endoloop combined with metal clips, both appeared to be feasible, safe and effective for repairing gastric perforations. Compared with endoloop and metal clips method, OTSC was easier to operate, more efficient and might require shorter operation time. However, OTSC required higher cost, and its rate of clip retention in the body was much higher than that of endoloop and metal clips.

## P0126 TWO DIFFERENT ENDOSCOPIC LONG INTESTINAL TUBE PLACEMENTS FOR SMALL BOWEL OBSTRUCTION: TRANSNASAL ULTRATHIN ENDOSCOPY VERSUS CONVENTIONAL ENDOSCOPY

Y. Chu, C. Zhang, **M. Xu**
*Endoscopy Center And Endoscopy Research Institute, Zhongshan Hospital of Fudan University, Shanghai/China*

**Contact E-mail Address:** xumeidong@aliyun.com.
**Introduction:** Small bowel obstruction (SBO) is a common problem in general surgery and is associated with considerable morbidity and mortality. It is commonly caused by postoperative adhesions, and sometimes by the recurrence and metastasis of the abdominal tumor. The conventional method is to intubate a common nasogastric tube, which can only suction the fluid in the stomach, and has limited effects. In recent years, the long intestinal tube has been applied for intestinal decompression and proved to be efficient and necessary for the treatment of patients who suffer the SBO, especially those with partial obstruction. The early studies reported that most long intestinal tubes are inserted only under fluoroscopy which had some disadvantages such as the long operation time and the exposure to more radiation. As the endoscopic technique develops, more investigators have tried endoscope-guide intubation to facilitate the procedure. A novel endoscopy with a transnasal ultrathin endoscopy was shown to be more convenient and better tolerated by patients. However, although there are some researches reporting the advantages of placing the long intestinal tube with the help of transnasal ultrathin endoscope over placing the tube under fluoroscopy, few investigators have compared the effects of transnasal ultrathin endoscopy and conventional endoscopy for placement of a long intestinal tube in patients with SBO.

**Table 1:** Outcomes of long-tube insertion by the transnasal ultrathin endoscopy method (Group A) and the conventional endoscopy method (Group B).

| | Group A (n = 29) | Group B (n = 32) | P value |
|---|---|---|---|
| Procedure time (Mean ± SD, min) | 15.3 ± 2.5 | 22.9 ± 2.4 | < 0.001 |
| Success rate (%) | | | |
| Total | 100 (29/29) | 93.8 (30/32) | 0.493 |
| No history of Billroth II anastomosis | 100 (25/25) | 100 (27/27) | |
| History of Billroth II anastomosis | 100 (4/4) | 60 (3/5) | 0.444 |
| Complications | | | |
| Bleeding of GI tract | 0 | 2 | 0.493 |
| Perforation | 0 | 0 | |
| Epistaxis | 8 | 7 | 0.767 |

**Aims & Methods:** To investigate and compare the effect on small bowel obstruction (SBO) of a long intestinal tube inserted by two different endoscopic placements which are transnasal ultrathin endoscopy and conventional endoscopy. Twenty-nine patients who had been diagnosed as suffering from SBO underwent long tube insertion placed by transnasal ultrathin endoscopy were included as subjects. Thirty-two patients who had undergone insertion of a long tube placed by conventional endoscopy were included as controls. The success rate of intubation of the small bowel, the time required for the procedure, and complications were compared between the subjects and controls.
**Results:** The outcomes of long-tube insertion by the transnasal ultrathin endoscopy method (Group A) and the conventional endoscopy method (Group B) are listed in table 1. The success rate of intubation was 100% (29/29) in subjects and 93.8% (30/32) in controls, without a significant difference (P = 0.493). There are 2 failed cases that the procedure was attempted near 60 min in 2 patients who had performed Billroth II anastomosis before, and the intestinal tube could not be inserted into efferent loops of jejunum in controls. The mean time required for the procedure was 15.3 min in subjects and 22.9 min in controls, respectively, and with a significant difference (P < 0.001). Epistaxis occurred in both groups, and 2 cases encountered bleeding of the gastrointestinal tract in controls.
**Conclusion:** Long tube insertion facilitated by transnasal ultrathin endoscopy takes shorter time and has a higher success rate compared with the procedure conducted with the help of conventional endoscopy. It is safe and useful to insert a long intestinal tube assisted by transnasal ultrathin endoscopy for the decompression of small bowel.

**Introduction:** Upper gastrointestinal bleeding (UGIB) is a frequent cause of hospitalization with significant morbidity.
**Aims & Methods:** The aim of this study was to evaluate the performance of Blatchford and Rockall score to predict in-hospital and post-discharge rebleeding and evaluate the clinical and laboratorial variables that are associated with a higher risk of rebleeding. We performed a retrospective observational study of patients undergoing upper gastrointestinal endoscopy for UGIB between January and December 2015.
**Results:** A total of 158 patients (92 men and 66 women) were included, with an average age of 71.8 ± 14.8 years. The most common aetiology of UGIB was peptic ulcer. Of the 158 patients, 8.3% had rebleeding during the hospitalization and 7% post-discharge. Overall, in-hospital and post-discharge mortality rate were, respectively, 10.1% and 1.3%. Hospitalized patients with shock criteria (P = 0.001), low average systolic blood pressure (103.8 vs. 120.1; P = 0.007) and

who needed more blood transfusions (4.6 vs. 1.4; $P < 0.001$) were more likely to have rebleeding. After discharge, patients with shock criteria ($P = 0.001$), diagnosis of cirrhosis ($P = 0.001$) and with comorbidities (81.8% vs. 50.3%; $P = 0.044$) were more likely to have rebleeding. In terms of in-hospital rebleeding, the area under the ROC curve was 0.680 (CI: 0.554–0.806) for Blatchford score, 0.686 (CI: 0.552 to 0.820) for admission Rockall score and 0.725 (CI: 0.612–0.839) for full Rockall score. In terms of post-discharge rebleeding, the area under the ROC curve was 0.640 (CI: 0.489–0.790) for Blatchford score, 0.629 (CI: 0.468–0.790) for admission Rockall score and 0.663 for full Rockall score (CI: 0.481–0.845).
**Conclusion:** The full Rockall score had a reasonable performance in predicting in-hospital rebleeding, compared with the remaining scores. After discharge, neither Rockall or Blatchford score were capable to predict rebleeding. The presence of shock, high number of blood transfusions and systolic blood pressure amount were clinical variables associated with higher potential of rebleeding.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The resolution of food impactions (FI) and the removal of ingested foreign bodies (IFB) is a frequent indication for esophagogastroduodenoscopy in the Emergency Department [1]. Its rapid diagnosis and proper management are crucial to minimize morbidity.
**Aims & Methods:** The aim of this study was to characterize clinically and endoscopically the patients undergoing therapy for FI and/or IFB. This a retrospective study in a single center (2010–2015) including patients undergoing esophagogastroduodenoscopy due to FI/IFB. Data related to demographic parameters, treatment choices and complications of this group of patients were evaluated. Statistics analysis were performed using IBM SPSS Statistics 22 with $p < 0.05$ deemed to be statistically significant.
**Results:** We identified 384 patients, mostly male (53.4%) with mean age of $61.5 \pm 11.4$ years. FI was diagnosed in 66% of cases, and the IFB (34%) mostly identified were: fish (18%) or animal (16%) bones. The median period between the IFB/FI and the time the patient arrived to the Emergency Department was 6 hours (IQR: 2-12). There was no correlation between the location of the IFB sensation described by the patient and the endoscopic findings (Kappa value = 0.018). In 99.2% of the cases the successful endoscopic therapy was possible, with a perforation rate of 1.0% ($n = 4$). Forty-four percent of the patients had esophageal abnormalities, the most frequent were: Schatzki ring (22.2%) and benign esophageal strictures (18.1%). Fifteen percent of the patients had more than one episode of FI and/or IFB, and the presence of structural changes was associated with more than one event with an OR = 7.790 (95% IC: 3.449-17.598). The presence of minor complications (superficial laceration, self-limiting bleeding) after FI/IFB resolution occurred in 30.3% of the patients. The presence of minor complications was higher among patients who had FI vs. IFB (52.3% vs 17.7%, $p < 0.001$). The use of foreign body grasper in comparison to roth net foreign body retrieval was associated with higher frequency of minor complications (59.1% vs. 22.5%, $p < 0.001$). However, a linear regression model concluded that the type of IFB was independent of the tool used (roth net or grasper) for the presence of minor complications.
**Conclusion:** Endoscopic resolution of FI/IFB was associated with a low rate of major complications. Regardless of the tool used for endoscopic therapy, complications were more frequent in FI than in the IFB.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0129 ENDOSCOPIC FULL-THICKNESS RESECTION OF UPPER AND LOWER GASTRO-INTESTINAL LESIONS USING A NEW, FLAT BASED OVER-THE-SCOPE-CLIP; A FEASIBILITY STUDY

**W. F. w. Kappelle**, Y. Backes, L. M. g. Moons, F.P. Vleggaar
*Gastroenterology & Hepatology, Universiteit Med. Centrum Utrecht, Utrecht/Netherlands*

**Contact E-mail Address:** w.f.w.kappelle@umcutrecht.nl.
**Introduction:** Surgical resection of subepithelial tumors (SET) in the stomach and duodenum and incompletely resected colonic adenomas is associated with significant morbidity and mortality. A new over-the-scope-clip (Padlock) mounted on a transparent cap can be used for endoscopic full-thickness resection (eFTR). The flat base of the clip is thought to facilitate full-thickness resection, obviating the need for surgery.
**Aims & Methods:** We evaluated the feasibility and safety of eFTR using the Padlock clip for gastric, duodenal and colonic lesions. After successful clip placement, lesions were removed with a snare in auto-cut mode. Patients were observed for one night after the procedure. Patients were followed for one month to assess severe adverse events (SAEs); 3–6 months after eFTR, endoscopy was performed. eFTR was performed on 22 lesions in 21 patients: 6 gastric SETs (10–18 mm) with proven histology of a gastro-intestinal stromal tumor (GIST) or inconclusive histology; 6 duodenal (suspected) subepithelial neuroendocrine tumors (4–13 mm); 10 colonic adenomas (5 incompletely resected adenomas, 4 recurrent non-lifting adenomas, and 1 adenoma in a diverticulum).
**Results:** Technical success was achieved in 19 cases (86%); 2 gastric lesions could not be positioned within the cap and in one patient, the endoscope could not pass the pharynx. In all 19 cases, histology confirmed that full-thickness resection was achieved. Histology of the gastric lesions revealed GIST ($N = 1$) and ectopic pancreas ($N = 2$). In the duodenum, gastrinoma ($N = 3$), brunneroma ($N = 1$) and ectopic pancreas ($N = 1$) were seen. Colonic specimens showed scar tissue ($N = 7$), low grade dysplasia ($N = 2$) and adenocarcinoma ($N = 1$). No SAEs were observed after resection of gastric lesions. Two resections in the cecum were complicated by (micro) perforation; one was treated conservatively with antibiotics, the other was treated with laparoscopic suturing. After duodenal resection, several SAEs were observed: perforation ($N = 2$), severe pain ($N = 2$), and hemorrhage ($N = 1$). During follow up endoscopy, the clip was no longer in situ in the majority of available patients (6/8; 75%). The mucosa was healed in all patients and no recurrence was observed in biopsies of the scars.
**Conclusion:** eFTR with this new flat-based, over-the-scope-clip is feasible and effective. Full-thickness resection was achieved in all patients, but was accompanied by a significant risk of perforation. Therefore, the design of the clip and the technique of the resection need further refinement to improve safety of resection of SET and recurrent adenoma, in particular in thin walled areas such as the duodenum and cecum.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0130 ENDOSCOPISTS' BIOPSY RATE (EBR) AS A QUALITY INDICATOR FOR DIAGNOSTIC OUTPATIENT GASTROSCOPY

**W. Januszewicz**[1], M.F. Kaminski[2], P. Wieszczy[3], J. Szlak[4], R. Serek[4], M. Rupinski[1], A. Mroz[5], L. Wyrwicz[4], J. Regula[6]

**Introduction:** Many of gastric cancers arise from precancerous lesions which are commonly missed at endoscopy. A quality indicator for detection of premalignant lesions and early cancers at gastroscopy is urgently needed. Detection of these lesions in conventional endoscopy relies on biopsy sampling of suspicious areas in the stomach. We hypothesized that the rate of biopsies at gastroscopy varies among endoscopists and this rate is associated with a likelihood of detecting premalignant lesions.
**Aims & Methods:** The aim was to investigate a variability in taking biopsies by endoscopists and to analyze association between endoscopists' biopsy rate (EBR) and detection of dysplastic lesions and all premalignant conditions (atrophic gastritis, intestinal metaplasia and dysplasia) at diagnostic outpatient gastroscopy. This was a cross-sectional study analyzing outpatient gastroscopy data and histopathology reports from a single academic endoscopy unit in Poland between years 2002 and 2010. Procedures with indications of surveillance for already known premalignant conditions (Barrett's esophagus, atrophic gastritis, gastric intestinal metaplasia and dysplasia), genetic cancer syndromes (familial adenomatous polyposis and Lynch syndromes) and history or suspicion of upper gastrointestinal (UGI) cancers at other imaging tests were excluded from analysis. We have also excluded gastroscopies performed by endoscopists who did less than 100 procedures during the study period. For each endoscopist we counted biopsy rate as a percentage of endoscopies with at least one biopsy for histopathological examination obtained (ICD-9 codes 45.14, 45.16, 42.24) to all performed gastroscopies (EBR). Biopsies for rapid urease test were not included. After setting a median value of EBR as the cut-off point we divided endoscopists

into low and high EBR groups. We analyzed association between EBR group and detection of dysplasia and premalignant conditions at gastroscopy using multivariate clustered logistic regression model adjusted for patients' age and sex.
**Results:** Of the total 17, 490 gastroscopies 4, 690 (26.8%) met exclusion criteria and the remaining 12, 800 procedures performed by 16 staff endoscopists were analyzed. The EBR varied from 19% to 62% between endoscopists with median value of 39% by which we assigned 8 endoscopists to low and 8 to high EBR groups. In total, 86 (0.7%) gastric dysplasia and 1013 (7.9%) all gastric precancerous lesions were detected. The adjusted odds ratio for detecting gastric dysplasia or any precancerous lesion in the high EBR group were 1.79 (95%CI, 1.13–2.83; $P = 0.012$) and 2.20 (95%CI, 1.91–2.53; $P < 0.001$) respectively, as compared to the low EBR group.
**Conclusion:** Biopsy rate is highly variable among endoscopists. Endoscopists with high EBR detected significantly more dysplastic lesions and over twofold more precancerous lesions in the stomach than those with low EBR. EBR is a candidate EGD quality indicator.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0131 ENDOSCOPIC ZENKER DIVERTICULOTOMY USING THE WINDOW TECHNIQUE: A TECHNICAL TRICK TO IMPROVE THE FIELD OF VIEW

**L. Calavas**[1], J. Rivory[2], S. Roman[3], J.C. Saurin[1], T. Ponchon[4], M. Pioche[1]
[1]*Gastroenterology And Endoscopy, Hospices Civils de Lyon, Lyon/France*

[3]*Digestive Physiology, Hôpital Edouard Herriot Dept. of Digestive Physiology, Lyon/France*
[4]*Dept. Of Digestive Diseases, Herriot University Hospital Dept. de Hepato-gastroenterologie, Lyon/France*

**Contact E-mail Address:** laura.calavas@chu-lyon.fr.
**Introduction:** Zenker's diverticulum is a protrusion of the hypo-pharyngeal mucosa through a weak area between the inferior pharyngeal constrictor muscle and the cricopharyngeal muscle, responsible of symptoms such as dysphagia, regurgitations, night cough and in the worst cases loss of weight and pulmonary infection. It can be treated by surgery with external myotomy of the cricopharyngeal muscle and removal of the diverticulum or by endoscopic procedure with division of the muco-muscular septum between the diverticulum and the esophagus. Endoscopic diverticulotomy is a safe, effective, and simple technique [1] and was demonstrated to be as effective as surgical external diverticulotomy in most cases and can be recommended as the first choice [2]. Diverticuloscope-assisted diverticulotomy has been demonstrated to be safer and more effective than the cap-assisted procedure [3]. The main benefit of the diverticuloscope is to improve exposure of the muscular fibers by stretching them [4]. In our practice, we additionally use a technical trick called the ''window technique'' by doing a mucosa window at the top of the septum to improve the field of view before the myotomy. We are currently studying the feasibility of this trick, the technical and clinical results, in our department.
**Aims & Methods:** Are included, retrospectively, all patients treated for symptomatic Zenker's diverticulum in our department, by endoscopic diverticulotomy using this technical trick, since december 2008. After insertion of the diverticuloscope, we initially cut a small square of mucosa to enlarge the space and expose the muscular fibers. This step usually takes 1 minute. A square, measuring approximately 5 mm, is cut on the four sides and then removed. We usually use a Hook-knife to create this window with Endocut electric current. Thanks to this mucosal window, the cricopharyngeal fibers are stretched and visible. Without the mucosal window, the two sides of the sectioned mucosa can obscure the myotomy site and prevent perfect control of the depth of cutting. In contrast, the mucosal window helps to enlarge the field of view and allows us to precisely catch the muscular layer by hooking. To evaluate long-term results, phone interview were made.
**Results:** Currently, 46 patients are included, 27 males (59%) and 19 females (41%), median age is 68 years (34-98y), and 50 endoscopic diverticulotomy were performed, by 4 different endoscopists (4 patients had 2 procedures because of recurrent or persistent symptoms). Main symptoms were dysphagia (93.5%), regurgitations (69.6%), loss of weight (34.8%), gastric reflux (34.8%), night cough (17.4%) and pulmonary infection (13%). Mean depth of diverticulum was 4.5 cm (0.5–9 cm), 37 procedures (74%) were diverticuloscope-assisted and 7 were cap-assisted (14%) (Missing data $n = 4$). Mean time of the complete procedure was 43 minutes (14–76). At the end of procedure, 1 to 3 clips were placed to prevent secondary perforation or bleeding. 35 patients (76%) could resume drinking within 24 hours and 39 (85%) mixed diet within 48 hours after procedure. Mean hospitalization time was 3, 7 days (2–13 days). One patient with anticoagulation therapy had delayed haemorrhage 2 days after procedure, treated with efficacy by endoscopic haemostasis. Two patients presented mild mediastinitis, treated by antibiotics with favourable evolution and were discharged after respectively 7 and 10 days. So far 27 patients were contacted to evaluate long term results (59%), (1–72 months), the clinical efficacy is 88.9% the first month, 85.1% the second month and 78% at the end of the actual follow up. 4 patients (8.7%) had a second procedure, for a recurrent diverticulum or persistent symptoms due to an insufficient section of the septum.
**Conclusion:** Patients are still being included and many remain to be contacted to evaluate clinical efficacy, but so far, this work indicates that endoscopic diverticulotomy is effective, safe and the window technique is a simple and feasible trick to facilitate the myotomy by enlarging the field of view and allowing us to precisely catch the muscular layer, leading to a complete section.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0132 ENDOSCOPIC DOUBLE-LAYER SUTURE FOR THE GASTROINTESTINAL WALL DEFECT AFTER FULL-THICKNESS RESECTION

**B. Liu**, J. Song, L. Tao
*Department Of Gastroenterology And Hepatology, The Second Hospital Of Harbin Medical University, Harbin/China*

**Contact E-mail Address:** 13704510648@126.com.
**Introduction:** Successful closure of gastrointestinal (GI) wall defects is the key procedure following endoscopic full-thickness resection (EFR).
**Aims & Methods:** To describe a new endoscopic closure method for gastrointestinal wall defects after EFR procedure similar to hand-sewn double-layer suture technique–endoscopic double-layer suture (EDS) and evaluated the safety and efficacy of this method. We retrospectively analyzed 15 patients who presented at our institute between April 2011 and September 2015 with GI tumors (13 of gastric subepithelial tumors, 2 of colonic lateral spreading tumors) and who underwent EFR, with the resulting full-thickness wall defects being closed using EDS technique. The seromuscular and mucosal layers of wall defects were sutured separately by using endoclips with or without endoloops assistance during EDS procedure. Tumors characteristics, en bloc resection rates, suturing procedures and complications were evaluated in all patients.
**Results:** Successful en bloc resection and closure of wall defects were achieved in 15 cases (100%). The mean maximum size of lesions was 2.4 cm (range 1.0–3.3 cm). The mean size of wall defects after EFR was 2.1 cm (range 0.8–3.5 cm, $\geq 2.5$ cm in 6 cases and $< 2.5$ cm in 9). The total mean closure time was 54.9 min (range 18–106 min), the mean closure time was 82.7 min (range 62–110 min) in $\geq 2.5$ cm group and 36.4 min (range 18–60 min) in $< 2.5$ cm group ($P = 0.01$). The mean number of endoclips during EDS was 26.7 (range 17–58) including 10.6 (range 5–26) in seromuscular closure and 16.1 (range 10–32) in mucosal closure. The suture procedure with endoloops assistance was completed in 7 patients (46.7%). Histological diagnosis was gastrointestinal stromal tumor (GIST) in 8 lesions (4 fundus, 2 bodies, 2 antrum;), schwannoma in 3 lesions (2 fundus and 1 antrum), heterotopic pancreas in 1 lesion (antrum), cystic fibroma in 1 lesion (fundus) and early colonic adenocarcinoma in 2 lesions. Five patients developed localized peritonitis after treatment, 3 cases of postoperative peritonitis resolved after antibiotic treatment and two cases required placement of an abdominal tube for continuous peritoneal lavaged 3 days without surgical intervention. No patient developed delayed hemorrhage, abdominal abscess and chronic fistula after the procedure. During the mean follow-up time of 19.1 (range 3–52) months, wounds healed in all cases and no tumor recurrence was found in any patients.
**Conclusion:** EDS is relatively safe and effective method for repairing GI wall defects resulting from EFR. The new closure method mimics hand-sewn double-layer suture technique during surgical procedure. However, EDS for closure of $\geq 2.5$ cm GI wall defect is more time consuming, further control study is required to evaluate the efficacy of this method compared with other endoscopic GI defect suture methods.

## P0133 ENDOSCOPIC SEPTOTOMY IS A NOVEL TREATMENT FOR CHRONIC LEAKS COMPLICATING LAPAROSCOPIC SLEEVE GASTRECTOMY

**S. Fishman**[1], M. Shnell[2], N. Gluck[2], E. Santo[1]

**Contact E-mail Address:** sigalf@tlvmc.gov.il.
**Introduction:** Staple-line leak following laparoscopic sleeve gastrectomy (LSG) is a dire adverse event. The leading etiology is sleeve stenosis leading to increased pressure in the proximal stomach that exceeds the burst-pressure of the staple line. While the treatment of acute and early leaks is well established, there is still dispute regarding late and chronic leaks, (6–12 and $> 12$ weeks after surgery, respectively) with paucity of data regarding endoscopic treatment. Late and chronic leaks are characterized by a well-defined, walled-off perigastric space with a feeding fistula. As a result the clinical course is usually insidious with no overt sepsis. Endoscopic treatment should address these chronic changes and the precipitating factors. We describe a novel approach combining septotomy and sleeve stricture dilatation for treating late/chronic leaks.
**Aims & Methods:** All patients with late/chronic leaks referred to our clinic during 2014–2015 were treated endoscopically. The septum separating the sleeve lumen from the perigastric cavity was progressively dissected using argon plasma coagulation. Downstream strictures underwent pneumatic dilatation. (Rigiflex 30 mm 20PSI, Boston Scientific). Success was defined as avoiding further surgical intervention, removal of external drain tubes and weaning from parenteral nutrition.
**Results:** Ten consecutive patients were treated. Average time between surgery and first endoscopic treatment was 202 days. All leaks were located at the Angle of His. Sleeve stricture was diagnosed in 8 patients, in whom a septotomy accompanied by stricture dilatation was performed. A mean of 5 sessions over the course of 43 days was needed to complete endoscopic treatment. In the remaining 2 patients a small perigastric cavity was diagnosed without downstream stricture, and the septotomy was achieved with through-the-scope balloon dilatation of the fistula. No adverse events were encountered. Nine patients (90%) were treated successfully. One patient developed recurrent leak 3 months after end of treatment and was referred to surgery.

**Conclusion:** Septotomy accompanied by pneumatic stricture dilatation seems highly effective and safe in late/chronic leaks following LSG and may prevent further major surgery with high co-morbidities rate.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0134 UPPER GASTROINTESTINAL ENDOSCOPY IN GRAFT-VERSUS-HOST DISEASE

**Introduction:** Receptors of allogeneic hematopoietic cell transplantation (alloHCT) often develop graft-versus-host disease (GVHD) with cutaneous, digestive and other manifestations.
**Aims & Methods:** The aim of this study was to analyze the role of upper endoscopy (EGD) in alloHCT patients who presented with upper gastrointestinal symptoms. Methods: retrospective study of patients undergoing alloHCT from January 2012 to December 2015 that were submitted to EGD.
**Results:** 63 patients were included among those submitted to alloHCT in our institution (n = 275), 51% male and mean age of 37 ± 18 years. All patients were on GVHD prophylaxis and 21% were already under treatment, although the majority (74%) had not previously diagnosed GVHD. The main complaints were nausea (67%) followed by vomiting (57%), anorexia (46%), dysphagia (11%) and dyspepsia (9%); diarrhoea was also present in 56% of cases. All patients underwent biopsies of at least one segment, even in the absence of endoscopic alterations (28%). The second duodenal portion was submitted to biopsies in 96% and the stomach in 85%. Although no endoscopic findings predicted the diagnosis of GVHD, an endoscopic Correa score $\geq 2$ was associated with histological confirmation of GVHD ($p < 0.001$), with 81% sensitivity and 78% specificity for diagnosis. However, in 5 cases without positive endoscopic findings, biopsies confirmed GVHD and EGD with biopsies additionally allowed the identification of 20 cases previously undiagnosed. After the EGD, 49% of patients had upgrade of therapy, with clinical improvement resulting in a similar proportion.
**Conclusion:** EGD favorably modifies the management of about half of alloHCT patients with digestive complaints, being useful not only in confirmation of the clinical diagnosis or suspicion but also for the identification of new cases.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0135 DIAGNOSIS OF TUMORS IN THE CERVICAL AND UPPER THORACIC ESOPHAGUS: EFFICACY OF ENDOSCOPIC ULTRASONOGRAPHY USING A JELLY-FILLING METHOD WITH WATER-SOLUBLE LUBRICATING JELLY; A RETROSPECTIVE SINGLE-CENTER TRIAL

**N. Matsuura**[1], N. Hanaoka[2], R. Ishihara[3], M. Kato[3], K. Hamada[1], Y. Tonai[3], Y. Yamasaki[3], T. Kanesaka[3], S. Yamamoto[3], T. Akasaka[3], Y. Takeuchi[3], K. Higashino[3], N. Uedo[3], H. Iishi[3]

**Introduction:** Endoscopic ultrasonography (EUS) is the standard modality for qualitative diagnosis of submucosal tumors (SMTs) and determining the depth of invasion of esophageal cancer. Standard EUS, however, comprises a continuous water-filling or water-filled balloon method, which creates some problems (e.g., difficulty filling the water, poor image quality because of balloon compression, water aspiration). Water aspiration is especially problematic during the diagnosis of lesions in the esophagus adjacent to the hypopharynx. Therefore some endoscopists are skeptical about performing EUS for lesions in the cervical and upper thoracic esophagus.
To resolve such disadvantages, we reported a method using probe EUS with a jelly-filling technique (EUS-J) to evaluate superficial esophageal squamous cell carcinomas (SCCs). The procedure is characterized by filling the esophageal lumen with a water-soluble lubricating jelly (K-Y lubricating jelly; Johnson & Johnson, Tokyo, Japan) that is used for routine endoscopy and is harmless to humans; this enables convenient observation without the use of a balloon. More recently, we retrospectively evaluated the usefulness of EUS-J with water-soluble lubricating jelly for lesions in the cervical and oral side of upper thoracic oesophagus.
**Aims & Methods:** Patients with an esophageal SCC or SMT in the cervical (18 cm from incisors) or oral side of upper thoracic oesophagus (18 ~ 21 cm from incisors) were included. EUS-J with water-soluble lubricating jelly was performed using a high-resolution probe. Before examination, several 5-mL syringes containing the water-soluble lubricating jelly were prepared. With the patient under conscious sedation with midazolam, an endoscope (GIF-2TQ260M; Olympus, Tokyo, Japan) was inserted into the targeted area in the esophagus. A 30- or 20-MHz miniature probe was then inserted through the left channel of the endoscope, and 40 mL of jelly was instilled through the right channel until the esophageal lumen was filled. For esophageal SCCs, the diagnostic accuracy of EUS was analyzed while the histologic diagnosis of resected specimen served as reference standard.
**Results:** From December 2010 to April 2016, we used EUS-J to evaluate 28 patients with esophageal SCCs and 10 with SMTs in the cervical or oral side of upper thoracic esophagus. There were 10 lesions in the cervical esophagus and 28 in the oral side of upper thoracic esophagus.
Among the 28 SCCs, 7 were recurrences following chemoradiotherapy. The other 19 SCCs did not undergo chemoradiotherapy. All 28 esophageal SCCs lesions were detected with EUS-J. 21 lesions treated either by esophagectomy (n = 3) or endoscopic resection (n = 18). Histologic diagnosis was T1a in 12 lesions, T1b in 9 lesions. The overall accuracy of diagnosing invasion depth was 76.2% (16/21 lesions) by EUS.
Among the 10 SMTs were seven leiomyomas derived from muscularis mucosa and one lesion due to vertebral body compression. The other two lesions were a tiny SMT (< 3 mm) and a small lesion in the cervical oesophagus adjacent to the hypopharynx. Neither was detected by EUS-J because of their small size and difficult instrumental manoeuvering. There were no adverse events with EUS-J.
**Conclusion:** EUS-J with water-soluble lubricating jelly is useful and safe for diagnosing lesions in the cervical or oral side of upper thoracic esophagus.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0136 THE STUDY OF THE RESULTS OF DUODENOSCOPE CHANNELS BY DIFFERENT DISINFECTION METHODS

**S. Ma**, H. Xi
*Digestive Endoscopy Center, Changhai Hospital, Shanghai/China*

**Contact E-mail Address:** ma00su@163.com.
**Introduction:** In China, the number of procedures involving duodenoscope use is increasing each year since ERCP is one of the best ways of resolving various problems caused by cancer, gallstones, or other conditions in the pancreatic and biliary ducts. However, physicians have not paid much attention to duodenoscope-related (especially the elevator channel and biopsy channel) infection so far. For the clinical various strains of drug-resistant strains increase, variation, cleaning and disinfection of endoscope has become a high-profile topic. Recent reports regarding duodenoscope-related infections raised many concerns to healthcare community worldwide. The purpose of this article is to compare the clump count of elevator channel and biopsy channel, to explore the situation of bacterial contamination of duodenoscope channels.
**Aims**: To study the effect of the different kinds of methods disinfecting duodenoscope channels (the biopsy channel and the elevator channel).
**Methods**: 30 samples were measured randomly from 20th Oct, 2015 to 17th Nov, 2015 in a grade A tertiary Hospital, Shanghai. Group A (N = 10), using the automatic cleaning sterilizer with OPA. Group B (N = 10), using manual cleaning and disinfection with OPA. Group C (N = 10), using the automatic cleaning sterilizer with peracetic acid. Collected and compared the data of bacterial colonies number of different groups, analyzed by SPSS19.0.
**Results:** The disinfection eligible rate of duodenoscope is 16.67%. There is no difference between the clump count of biopsy channel and elevator channel among three groups ($P > 0.05$). The elevator channels' bacterial colonies number of group A are higher than that of group C ($P < 0.05$). The elevator channels' bacterial colonies number of group A are higher than that of group B ($P < 0.05$).
**Conclusion:** The disinfection eligible rate of duodenoscope is low. There is no distinction between the clump count of biopsy channel and elevator channel with different cleaning and disinfection methods. For the elevator channel, using peracetic acid is better than OPA (in the same "automatic cleaning sterilizer" condition), and manual cleaning and disinfection is better than automatic cleaning sterilizer under the same "using OPA" condition.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** ali494@gmail.com.
**Introduction:** Gastroenterologists often experience musculoskeletal injury as a result of repetitive strain during endoscopic procedures. Survey data has reported the prevalence of musculoskeletal pain/injury among endoscopists at 29%-89%. Little information is available regarding such injuries to trainee GI fellows and their training to prevent injury due to endoscopy.
**Aims & Methods:** To ascertain GI fellow awareness of occupation injuries and the value of video training instruction of best practices to minimize injury from performing endoscopy. A written and online survey was distributed to GI fellows at 12 US training programs and an international group of fellows using an email distribution group in Spain and the UEG Young GI Fellows Facebook group. After a 30 question pre-test, a 6 minute teaching video regarding endoscopy ergonomics and practice patterns to minimize injury. This was followed by an 8-question post-test. The questionnaire evaluated knowledge of occupational injury, previous training and basic demographic information.
**Results:** 99 fellows completed the training, 63% were male. 51% (50/99) participated via lecture attendance. Fellows trained in the United States (92), Spain (7) and Romania (1). Fellows were evenly divided by level of training across first three years: first (35%), second (25%) and third (29%). European training with final year, fourth year fellows (4%) and advanced US fourth year fellowship training (4%) were a minority. A majority had performed more than 150 EGD's (68%) and 150 colonoscopies (61%). 77% (76/99) were concerned about developing musculoskeletal injury related to endoscopy but only 8% reported training as part of their curriculum, which was sporadic and more commonly in the form of individualized attending teaching during endoscopy (56%) and one-third reported no training. GI fellows reported musculoskeletal pain attributed to endoscopy at an alarmingly high rate (71%) with the most common sites being the hand (38%), wrist (37%), thumb (32%) and neck (32%). No treatment was required for 70% of the time. Only 2 fellows had to miss work due to injury, but 18% have had to reduce physical activity outside of the hospital due to an endoscopy-related injury. Post-test data after viewing a short training video demonstrated an overall 12% increase in correct responses. Over 90% of respondents felt their curriculum should incorporate endoscopic ergonomic and injury prevention training.
**Conclusion:** The majority of GI fellows reported endoscopy-related musculoskeletal injury, with nearly one-fifth requiring a reduction in physical activity. Less than 10% of the fellowship program curricula included ergonomic training; however, over 90% of fellows were in favor of inclusion. Video-based training may provide an effective resource. Further study of injury patterns in trainees and the long-term impact of endoscopic ergonomic training on occupation-related injuries is warranted.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** We demonstrated the usefulness of a simplified narrow-band imaging (NBI) classification of surface patterns in Barrett's esophagus (BE) using high-definition magnification endoscopy with NBI (HDME-NBI) (Kato M, et al. UEGW 2014). It is, however, unclear whether this classification is useful for novices. We conducted this study to validate the interpretation of the NBI classification among novices.
**Aims & Methods:** A total of 248 HDME-NBI images from non-dysplastic and flat-type dysplastic areas in 89 patients with BE were retrieved and randomized for review by eight novices (endoscopists who experienced more than 200 procedures of white-light endoscopy and none of experience of magnification endoscopy). All novices took the 1st exam before receiving the lecture about the classification, the 2nd immediately after the lecture, and the 3rd six weeks after the lecture. The primary endpoint was observer agreement of NBI surface patterns and predicted histology (dysplasia vs. non-dysplasia), and the secondary endpoint was the classification-based diagnostic accuracy values.
**Results:** The overall inter-observer agreements were all substantial for mucosal pattern ($\kappa = 0.78$), vascular pattern (0.70) and predicted histology (0.79) in the 2nd exam. The overall intra-observer agreements were almost perfect for mucosal pattern (0.81) and predicted histology (0.81) and substantial for vascular pattern (0.78) between the 2nd and 3rd exams. Although the mean values of sensitivity, specificity and overall accuracy for all novices in the 1st exam were 86.6%, 80.0% and 82.0%, respectively. The mean values of sensitivity, specificity and overall accuracy in the 2nd exam were 87.2%, 96.9% and 94.1%, respectively.
**Conclusion:** The simplified NBI classification seems to be easily understandable and reliable and to have high diagnostic accuracy for novices.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0139 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL PROXIMAL ESOPHAGEAL NEOPLASIA IS HIGHLY SUCCESSFUL

**Z. Yiqun**, L. Yao, C. Zhang, Q. Li, W. Chen, M. Cai, J. Hu, W. Qin, Y. Huang, T. Chen, P. Zhou, M. Xu
*Endoscopy Center And Endoscopy Research Institute, Zhongshan Hospital of Fudan University, Shanghai/China*

**Contact E-mail Address:** may7523@hotmail.com.
**Introduction:** Squamous-cell carcinoma accounts for about 90% of all esophageal cancer cases in China and worldwide. It is most commonly found in the upper and middle esophagus. Esophagectomy is a procedure with a high morbidity and mortality. Surgery for a tumor located in the proximal esophagus is a technically challenging procedure and carries a higher then average morbidity and mortality compared to other esophageal procedures. Following a successful esophagectomy, most patients experience disabling symptoms, such as regurgitation and dysphagia. Therefore, it is common for radiation therapy alone to be recommended for patients with the proximal carcinoma of esophagus. Endoscopic submucosal dissection (ESD) was developed in Japan by Gotoda et al to permit the en bloc resection of large flat rectal lesions. Subsequently, ESD was used for therapy of early gastric cancer and esophageal lesions. Compared to surgery, ESD is an incisionless, minimally invasive, endoscopic treatment aiming to cure early neoplasia of the gastrointestinal tract. It is performed worldwide because of its perioperative safety and excellent short and long-term outcomes. However, the narrow lumen and thin wall of the esophagus, movement caused by respiration and heartbeats make it difficult to perform ESD for the proximal esophagus. There is no publication about ESD for the treatment of superficial proximal esophageal neoplasia. The aim of our study was to assess the feasibility, safety and long-term outcome of the ESD procedure for treatment of superficial proximal esophageal neoplasia.
**Aims & Methods:** Squamous cell cancer of the esophagus accounts for 90% of malignant esophageal neoplasia cases worldwide. Superficial esophageal neoplasia located in the cervical and upper thoracic region is uncommon. The surgery for a tumor located in this region, due to a complicated anatomy, is very difficult and leads to a high morbidity and mortality. Endoscopic submucosal dissection (ESD) is a minimally invasive endoscopic treatment of superficial neoplasia of the gastrointestinal tract allowing en bloc resection with low recurrence rates. The aim of this study was to evaluate the outcomes of ESD for superficial proximal esophageal neoplasia. We retrospectively analyzed 102 consecutive patients that fit the inclusion criteria with 106 lesions who underwent ESD from February 2009 to July 2015 at the Zhongshan Hospital, Fudan University in Shanghai, China. During the study the en bloc and pathologically complete resection rates, complication rate, incidence of esophageal stricture after ESD, disease-specific and overall survival rates were evaluated.
**Results:** The mean age was 62 (45–84) years with100% en bloc resection rate. The mean operation time was 48 (10–144) minutes. The mean diameter of the resected tumors was 2.9 (1.2–6.5) cm. The pathological diagnoses were high grade intraepithelial dysplasia in 45 (42.5%) lesions, rest were squamous cell carcinoma with staging of intraepithelial in 18 (17.0%), lamina propria in 13 (12.3%), muscularis mucosa in 16 (15.1%), SM1 in 10 (9.4%) and SM2 or deeper in 4 (3.8%) of the lesions. The R0 resection rates were 94.3% (100/106). There was no delayed bleeding. Two small perforations observed were closed successfully with clips. Symptomatic esophageal strictures in 17 patients were treated by endoscopic

balloon dilation with a mean of 4 (1–14) times and 88.2% (15/17) success. Additional treatments of esophagectomy or chemoradiotherapy were recommended to patients with sm1 or deeper neoplasia or incomplete resection. Local recurrence was observed in three (2.9%) cases. 15 patients were lost to follow-up. 5-year overall survival rate was 98% and disease-specific survival rate was 100%. The mean follow-up time was 33.6 months.
**Conclusion:** ESD for the superficial proximal esophageal neoplasia is a safe and a very effective treatment method with a 100% 5 year disease specific survival rate.
**Disclosure of Interest:** All authors have declared no conflict of interest.

## P0140 DETECTION OF NEOPLASIA IN BARRETT'S DISEASE WITH IMAGE ENHANCEMENT USING OE– AN EARLY EXPERIENCE

**S. John**[1], D. Jones[1], H. Neumann[2]
[1]*Gastroenterology, Logan Hospital, Logan/Australia/QLD*
[2]*University Hospital Erlangen, Erlangen/Germany*

**Contact E-mail Address:** sneha.john@health.qld.gov.au.
**Introduction:** Barrett's esophagus (BE) is the metaplastic transformation of the esophageal squamous mucosa to intestinal columnar mucosa with the potential for malignant transformation. Current surveillance protocols recommend standard white light endoscopy and 4 quadrant biopsies every 1–2 cm. However, areas of dysplasia may not be visible on standard white-light examination. Multiple biopsies still carry a risk of sampling error and are time-consuming and costly. Recent advances in image enhancement technology have been proposed as potential alternatives to allow accurate detection and targeted biopsies. The ASGE PIVI statement states that any imaging technology for BE surveillance should achieve per- patient sensitivity >90% and a negative predictive value of 98% or greater. Most technologies that are available and have been tested in this area have struggled to achieve this high threshold. Disadvantages of existing technology include poor spatial resolution in surveying long segments of BE and the ability to combine morphological data with details of vascular architecture. OE is a new technology that combines the ability to analyse microvascular pattern using band limited light with digital chromo endoscopy. In OE1 mode spectral transmission utilises the peak wavelength of the haemoglobin absorption spectrum thereby enhancing surface vessel pattern. OE2 mode adds in the longer wavelength of red light allowing more natural and brighter illumination. It is expected that the ability to combine detailed assessment of vascular and mucosal pit patterns at the same time will enhance increased detection and characterisation of neoplasia and assessment of margins of lesions discovered. The use of this technology in BE surveillance is as yet unstudied.
**Aims & Methods:** The aim of our study was to assess the sensitivity and Negative Predictive Value of OE in detecting neoplasia within segments of Barrett's disease. 10 patients with Barrett's oesophagus were assessed as part of the study. 6 of these individuals had established long segment BE with biannual surveillance. The rest were diagnosed with short segment disease and had less frequent surveillance. No patient had previously been diagnosed with definite dysplasia or undergone endoscopic therapy. One patient had cellular atypia associated with active inflammation reported during prior endoscopy. Barrett's mucosa was examined with high definition white light followed by OE1 and OE2 mode. Biopsies from any area of neoplasia identified by OE were reviewed by 2 pathologists.
**Results:** We did not discover visible abnormalities or changes suggestive of neoplasia in 8 of the 10 cases. Histopathology from the BE segment confirmed absence of dysplasia in all these patients. In one individual with long segment BE an area of focal high grade dysplasia was predicted on the basis of vascular anomalies on magnification endoscopy with OE. Biopsies from this area were confirmed by 2 pathologists as focal high-grade dysplasia. Another individual had ulceration noted within the segment of BE with vascular and epithelial alterations suggestive of reactive changes on OE and confirmed as such on histopathology. Diagnostic sensitivity was calculated for our 10 cases as 100% and similarly Negative Predictive Value for detection of neoplasia was estimated and is 100%.
**Conclusion:** Our early experience using OE in Barrett's disease suggests that this new image enhancement technology is promising in its ability to accurately detect neoplasia. In our limited case series it has been able to achieve the thresholds set by the PIVI statement. Further prospective studies are required with larger number of patients to assess the technology further and its utilisation in day to day clinical practice.

**Introduction:** Hands-on training of advanced endoscopic procedures is of paramount importance. To date, training is mostly performed with animal models. However, due to the thickened mucosa and the diverging anatomical situation of the animal model, advanced endoscopic procedures are somehow difficult to teach and learn.
**Aims & Methods:** Primary objective was to develop and validate a new endoscopic training model designed for hands-on training of advanced and complex endoscopic procedures. In the first phase, human cadaver models were specially prepared for upper and lower gastrointestinal endoscopy. In the second phase, twelve endoscopists with different experience from seven different countries were trained in advanced endoscopic procedures, including ESD, POEM, sealing of perforations by using different types of hemoclips and the over-the-scope-clip (OTSC) and in endoscopic full thickness resection. Outcomes of endoscopic procedures performed during the study period were analyzed.
**Results:** A new interventional endoscopy training model for advanced endoscopic procedures with specially prepared human cadaver models was developed and validated in an international study. A significant improvement of the endoscopic skills was noted for all procedures performed, especially for ESD and POEM. Of note, perforations occurring during the study showed a real-life appearance and could be managed endoscopically therefore allowing completion of procedures in all cases. In addition, endoscopic full thickness resection was successfully performed by the participants. All participants rated training with the new model as significantly more effective compared to traditional training based on animal models.
**Conclusion:** The HEAT international endoscopy study was initiated to develop and validate a new endoscopic training model for advanced endoscopic procedures. Technical skills of the attending endoscopists improved rapidly and training was rated as more effective as traditional hands-on training with animal models. Based on the study results we now recommend to include the HEAT model in endoscopy training programs before advanced endoscopic procedures should be performed in living patients.

## P0142 A STUDY ON THE IMPACT FROM THE USE OF NAFAMOSTAT MESILATE, A SYNTHETIC PROTEASE INHIBITOR, AS AN ANTICOAGULANT FOR HEMODIALYSIS AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION ON POST-ESD BLEEDING IN THE PATIENTS WITH END-STAGE RENAL DISEASE

**K. Kojima**[1], N. Toda[1], S. Kurosaki[1], K. Funato[2], S. Kawamura[1], Y. Karasawa[1], S. Maeshima[1], T. Ohki[1], M. Seki[1], K. Tagawa[1]

**Introduction:** Bleeding after gastric endoscopic submucosal dissection (ESD) is one of major complications. It is reported that end-stage renal disease on hemodialysis is important as one of the risk factors of bleeding after gastric ESD, but little reported about the methods to prevent bleeding after gastric ESD among hemodialysis patients.
**Aims & Methods:** Nafamostat mesilate (FUT) is a synthetic protease inhibitor with a short half-life and used as an anticoagulant for hemodialysis in the patients at high risk for bleeding instead of heparin because it does not prolong the systemic coagulation time. We evaluated the impact from the use of FUT for hemodialysis after gastric ESD on post-ESD bleeding. The 540 patients with 584 lesions who underwent gastric ESD between April 2004 and March 2016 in our institution were retrospectively analyzed. In hemodialysis patients, we temporally used FUT or low-molecular-weight heparin (LMWH) for hemodialysis after gastric ESD instead of heparin.
**Results:** Of all the patients who underwent gastric ESD, 54 (10.0%) had chronic kidney disease and 18 (3.3%) were undergoing hemodialysis. The mean period on hemodialysis was 5.8 ± 6.0 years, and the most causative disease getting on hemodialysis was diabetic nephropathy (50.0%). In hemodialysis patients, 10 (55.6%) took anti-platelet agents and 3 (16.7%) underwent double anti-platelet therapy. Bleeding after gastric ESD occurred in 46 (8.5%) of all the patients and 8 (44.4%) of hemodialysis patients. By multivariate analysis, end-stage renal disease on hemodialysis was strong risk factor of bleeding after gastric ESD (OR 4.75 [95%CI 1.24–19.9], p = 0.02), as with procedure in the lower thirds of the stomach (OR 2.40 [95%CI 1.24–4.85], p = 0.009). FUT was used for 15 (83.3%) and LMWH for 3 (16.7%) of hemodialysis patients after gastric ESD (because of 1 procedure of an early date and 2 FUT allergy). The mean duration of FUT for hemodialysis after gastric ESD was 11.5 ± 6.2 days. Bleeding after gastric ESD occurred in 6 (40.0%) of FUT group and 2 (66.7%) of LMWH group. Adverse events due to using FUT did not occur and no significant difference was shown about another complications excluding post-ESD bleeding between hemodialysis and non-hemodialysis patients. Patients characteristics and results:

| | Non-HD (n = 522) | HD (n = 18) | p value |
|---|---|---|---|
| Sex (male) | 422 (80.8%) | 14 (77.8%) | N.S. |
| Age (>=75years) | 320 (61.3%) | 15 (83.3%) | N.S. |
| Diameter (>=4.0 cm) | 32 (6.3%) | 0 (0.0%) | N.S. |
| Location | | | |
| -Upper third | 105 (20.2%) | 4 (22.2%) | N.S. |
| -Middle third | 161 (30.9%) | 3 (16.7%) | N.S. |
| -Lower third | 255 (48.9%) | 11 (61.1%) | N.S. |
| Diagnosis | | | |
| -Carcinoma | 465 (89.1%) | 16 (88.9%) | N.S. |
| -Adenoma | 44 (8.4%) | 2 (11.1%) | N.S. |

(continued)

. C

| | Non-HD (n = 522) | HD (n = 18) | p value |
|---|---|---|---|
| Ulcer | 18/464 (3.9%) | 2/16 (12.5%) | N.S. |
| Diabetes Mellitus | 113 (21.7%) | 9 (50.0%) | p = 0.01 |
| Hypertension | 246 (47.1%) | 11 (61.1%) | N.S. |
| Cerebrovascular disease | 21 (4.0%) | 3 (16.7%) | p = 0.04 |
| Cardiovascular disease | 101 (19.4%) | 8 (44.4%) | p = 0.02 |
| Liver cirrhosis | 13 (2.5%) | 0 (0.0%) | N.S. |
| Anti-platelet therapy | 109 (20.9%) | 10 (55.6%) | p = 0.002 |
| Dual anti-platelet therapy | 20 (3.8%) | 3 (16.7%) | p = 0.04 |
| Anti-coagulant therapy | 20 (3.8%) | 0 (0.0%) | N.S. |
| Complications | | | |
| -Bleeding | 38/519 (7.3%) | 8 (44.4%) | p < 0.0001 |
| -Perforation | 13/519 (2.5%) | 1 (5.6%) | N.S. |
| -Pneumonia | 3 (0.6%) | 0 (0.0%) | N.S. |
| -Stenosis | 2 (0.4%) | 0 (0.0%) | N.S. |

**Conclusion:** In hemodialysis patients, bleeding after gastric ESD occurred at a high rate in the use of FUT, as in the case with LMWH. We thought that it needed more cases to confirm the statistical efficacy of FUT as an anticoagulant for hemodialysis after gastric ESD to prevent post-ESD bleeding.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0143 FEASIBILITY OF A STRUCTURED INTERNATIONAL ESD TRAINING PROGRAMME FOR INTERNATIONAL DOCTORS IN JAPAN

**J. Woo**[1], Y. Kowazaki[2], J. Matsuoka[2], M. Nishimura[3]
[1]*Endoscopy, Southend University Hospital, Southend On Sea/United Kingdom*

[3]*Gastrointestinal Endoscopy, Tokyo Metropolitan Geriatric Hospital and Institute of Gerontology, Tokyo/Japan*

**Contact E-mail Address:** mtjwu888@gmail.com.
**Introduction:** Endoscopic submucosal dissection (ESD) is an important procedure which is minimally invasive, safe and provides excellent en-bloc resection of superficial mucosal tumour of the gastrointestinal tract. However, ESD experience and skill is still largely limited to Japan and a few countries in Asia.[1] Dissemination of such technique to the West has been difficult due to various reasons. This situation may potentially change, as the licensing law in Japan has changed to allow international medical doctors to pursue short-term clinical and endoscopic training under the supervision of a Japanese government certified expert without subjecting to Japanese licencing examinations. We have successfully initiated the first international ESD programme in Japan to allow an international doctor to work in our hospital under the supervision of an ESD expert.
**Aims & Methods:** The programme was initiated first by consultation with different ESD experts in Japan in terms of requirements prior to ESD training, diagnostic ability, hands-on training time, haemostasis skills and polypectomy skills required. Once a structured programme is established, a UK-trained gastroenterologist who is interested in learning ESD was then invited by our hospital. The training duration is dictated by our international trainee and the programme is then modified. First step in the application was approval by the Japanese Ministry of Justice for entry clearance. After this, application to the Ministry of Health for a provisional licence to practice in 'advanced clinical training' is required. Upon clearing the necessary documents for entry and practice, the trainee must purchase Japanese indemnity insurance for the time duration of the training. There was no funding for the programme and the international trainee is required to prepare his/her own expense for the duration of training in Japan. The structured training programme was then commenced.
**Results:** The duration of our programme was only for 3 months, as this was the duration our international trainee could afford. The programme commenced with 2 weeks of narrow band imaging (NBI) diagnostic training. If an ESD case is done, the trainee is required to observe and at times begin with the assistant role in ESD. After a total of 4 weeks into observing, being an assistant and continual NBI training, the trainee is allowed to perform under supervision, part of submucosal dissections during the procedure. Into the second month, the trainee continues to either observe ESD being performed and also performs part of the procedure. Learning content for the second month involved placing markings, initial dissections with the Dual Knife and haemostasis technique during ESD. Into the third month, ESD learning is expanded into learning about spatial importance of using gravity during ESD, depth recognition to avoid perforation and further intraoperative haemostasis techniques. During the third month the trainee also has the opportunity to visit the National cancer centre, Tokyo and St Luke's international hospital to observe ESD being done by other expert Japanese centres. The advantages of this programme gained from the trainee's perspective was a step by step learning of ESD under direct supervision, opportunity to observe expert ESD cases, learning from peers and international connections. Areas that may disadvantage the programme from the trainee's perspective may include lesser time dedicated to training of the international trainee due to local trainee also training in ESD, lack of cases at times and difficulty with communication sometimes. These were however, issues that can be addressed and improved.
**Conclusion:** We describe the first international ESD training programme set up in Japan for international trainees. As this is the index case in Japan, we have also gained valuable experience in training and teaching for the potential international trainee. In the future, we hope to design a further improved international ESD training programme in collaboration with the Japanese Ministry of Health and ESD experts in Japan.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** toshiyuki.yoshio@jfcr.or.jp.
**Introduction:** Recent advances in endoscopic resection (ER) provide us increasing chances for resecting esophageal SCC with muscularis mucosae (MM) invasion. As MM invasive cancer is reported to have 8–18% of metastatic risks and is defined as relative indication for ER in guideline by Japan Esophageal Society. For them, we perform additional therapy such as chemo radiotherapy (CRT) or operation considering the risk of metastasis and patients' condition. However, there is only a few reports of long term outcome of ER comparing to operation.
**Aims & Methods:** We retrospectively studied the long-term outcome in 143 cases of esophageal SCC with pathological MM invasion resected by ER (108 cases) and operation (35 cases) from 2003 to 2013 in Cancer Institute Hospital. Median observation period was 36 months for ER cases and 50 months for operation cases.
**Results:** Median age for ER and operation cases were 66 and 64. Median lesion size in ER cases were significantly smaller than that in operation cases (23 mm vs 44 mm, $P < 0.01$). Lymphovascular invasion were observed 7.1% in ER cases and 25.7% in operation cases. It was implicated that operation cases were more advanced cancer, although pathological depth of invasion were both MM. Of 108 cases of ER, 87 cases were observed without additional treatment. Two cases had recurrence as LN metastasis. One received operation and CRT and one received CRT, surviving with no re-recurrence. The rest of 21 cases were recommended additional therapy because of lymphovascular invasion or droplet infiltration and 12 cases were performed additional therapy (operation/CRT/RT 6/5/1). Seven cases had local recurrence after ER, however they were salvaged by re-ER or argon plasma coagulation. No one died of esophageal SCC. Of 35 cases of operation, two cases had recurrence including one LN metastasis and one lung metastasis. Both of two cases were died of esophageal SCC. Overall survival rate in 3 year/5 year were 87.8%/85.5% in ER cases and 89.7%/85.4% in operation cases. Cause specific survival rate in 3 year/5 year were 100%/100% in ER cases and 96.8%/96.8% in operation cases.
**Conclusion:** The long term outcome of ER for MM invasive esophageal SCC was very good with appropriate additional therapy. ER for MM invasive esophageal SCC is feasible.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0145 DISCRIMINATING FACTORS FOR SIGNIFICANT BLEEDING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION NEEDING EMERGENT HEMOSTASIS

**J.H. Lim**[1], S.G. Kim[2], J.P. Im[2], J. Choi[3], J.S. Kim[2], H.C. Jung[2]

[3]*Department Of Internal Medicine, Inje University College of Medicine, Seoul/Korea, Republic of*

**Contact E-mail Address:** limz00@gmail.com.
**Introduction:** It is hard to decide whether to perform emergent hemostasis or not, when gastric post-endoscopic submucosal dissection (ESD) bleeding occurs.
**Aims & Methods:** To clarify discriminating factors for significant gastric post-ESD bleeding needing emergent hemostasis. We retrospectively reviewed medical records of subjects who developed bleeding after ESD for gastric neoplasms between January 2005 and February 2011. Their comorbidities, biochemical results, pathologic characteristics, previous ESD history, current medication, and clinical findings at the time of bleeding events were reviewed. Significant bleeding was defined as bleeding which needed embolization or endoscopic hemostasis for visible exposed vessels or ongoing bleeding.
**Results:** Out of the total 2, 039 ESD patients, 309 had post-ESD bleeding. Among them 113 (36.6%) underwent endoscopy and 73 (23.6%) needed embolization or endoscopic hemostasis. Overall, hypoalbuminemia (OR 19.743, 95% CI: 2.084–187.011, p = 0.003), specimen size (OR 1.252, 95% CI: 1.025–1.528,

p = 0.027), and previous adjacent ESD history (OR 6517, 95% CI: 1.593–26.669, p = 0.009) were independently related with significant bleeding. Whereas, location of the lesion, malignant pathology, and shock at the time of bleeding event were not associated with significant bleeding.
**Conclusion:** For post-ESD bleeding in those with hypoalbuminemia, large specimen size, or previous adjacent ESD history, emergent hemostasis should be considered.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0146 DIAGNOSTIC ACCURACY OF ENDOSCOPIC FORCEPS BIOPSIES FOR SUPERFICIAL GASTROINTESTINAL LESIONS

**J. Rodrigues**, L. Carvalho, M. Túlio, S. Marques, J. Carmo, P. Barreiro, C. Chagas
*Gastroenterology, Centro Hospitalar Lisboa Ocidental, Lisboa/Portugal*

**Contact E-mail Address:** jp.azevedo.rodrigues@gmail.com.
**Introduction:** The lack of diagnostic accuracy of endoscopic biopsies for superficial gastrointestinal lesions may inadequately select patients for surgery that could be treated by endoscopy and underestimate malignant lesions.
**Aims & Methods:** The authors aim to determine whether an adequate histological diagnosis of superficial gastrointestinal lesions can be attained on the basis of forceps biopsy and identify clinicopathological factors predicting reliability. Retrospective analysis of all gastrointestinal lesions treated by endoscopic submucosal dissection (ESD) in a Centre with previous histological assessment from forceps biopsies was done. Agreement between pre and post ESD histological assessment and clinicopathological factors predicting reliability (localization, tumor size and endoscopist profile) were evaluated.
**Results:** Of the 50 gastrointestinal lesions treated by ESD, 36 (6 esophageal, 22 gastric and 8 rectal) from 35 patients had previous histological evaluation from forceps biopsies. When biopsies results were compared, disagreement was found in 13 cases (36%), particularly high in rectal lesions (50%, n = 4), followed by gastric lesions (40%, n = 9). In the majority of them, forceps biopsies underestimated the final histological diagnosis (69%, n = 9) although overstaging was made in 3 cases (23%). From the analyzed clinicopathological factors, only endoscopist's ESD experience was associated with a higher agreement (p = 0.034, OR 10.83).
**Conclusion:** The disagreement between endoscopic forceps biopsies and post ESD specimen evaluation is high. Histological diagnosis from endoscopic forceps biopsies must be interpreted carefully and in the setting of a high-quality endoscopic evaluation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Gastrointestinal bleeding (GIB) can be due to a plethora of disease, such as ulcers and liver cirrhosis, or can occur as result of iatrogenic interventions. It is still a demanding indication for GI endoscopy with high morbidity and mortality rates; thus hemostatic powders such as EndoClot have been developed to improve endoscopic treatment.
**Aims & Methods:** In this study, we evaluated the application of EndoClot EndoClot Plus Inc., Santa Clara, CA, USA) during routine and emergency endoscopy over a one year period from consecutive unselected patients, arising from the real-life clinical day.
**Results:** EndoClot was applied during 25 endoscopies in 23 pts (1.08 applications/pt.; 10 male and 13 female; age 70.5 yrs, 28–90).
In 18 pts EndoClot was applied during upper GI endoscopy (81.8%) and in 5 pts during lower GI endoscopy (27.7%) with a total success rate of short-term hemostasis in 19/23 pts (82.6%).
The detailed analysis of the 18 pts with upper GIB showed that endoclot was applied for various therapeutic/prophylactic settings. Endoclot application was used for 1) ultimative emergency rescue treatment in 8/18 pts with a 100% success rate, 2) first line treatment modality before any other hemostasis technique in 4/18 pts resulting in 75% hemostasis, 3) recurrence prophylaxis after conventionally achieved endoscopic hemostasis in 4/18 pts with 75% success, and 4) primary prophylaxis of post-interventional bleeding in 2 pts avoiding bleeding in 1 (50% success).
At the lower GIT EndoClot resulted in at least short-term hemostasis in 4/5 pts (80%). Of note, over all locations endoclot induced hemostasis in 7/9 pts (77.7%) with impaired coagulation/anticoagulants. No major complications were noted, but 1/23 pts died (4.3%), unrelated to GIB.
**Conclusion:** EndoClot is a further and safe option for the treatment in GI endoscopy. It can be used as first line therapy (especially hampered coagulation), after failure of other hemostatic options or prophylactically after achieved hemostasis or interventions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0148 CLINICAL APPLICATION OF ENDOSCOPIC MINIMALLY INVASIVE THERAPEUTIC TECHNIQUES FOR UPPER GASTROINTESTINAL SUBMUCOSAL TUMORS

**X. Wang**, S. Zhang, B. Lu
*Department Of Gastroenterology, First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou/China*

**Contact E-mail Address:** rainbowlove44@126.com.
**Introduction:** Little is known about the clinical outcomes among different endoscopic minimally invasive therapeutic techniques for upper gastrointestinal submucaosal tumors (SMT).
**Aims & Methods:** To evaluate the efficacy safety and clinical application value of endoscopic minimally invasive therapeutic techniques for upper gastrointestinal submucaosal tumors, 84 patients with upper gastrointestinal submucosal tumors (SMT) underwent endoscopic submucosal excavation (ESE), endoscopic submucosal dissection (ESD), submucosal tunneling endoscopic resection (STER) and endoscopic full-thickness resection (EFTR) after the examination of endoscopy, endoscopic uhrasonography and CT at Endoscopy Center, Department of Gastroenterology, the First Affiliated Hospital of Zhejiang Chinese Medical University from March 2013 to March 2015. There were 40 males and 44 females with an age range of (51.5 ± 9.3) years. The appearances of lesions and operative complications were recorded. The specimens were definited with pathological diagnosis, and postoperative therapeutic effect and safey were followed up.
**Results:** Of the 84 SMTs, 26 SMTs were located in esophagus, 6 in cardia, 23 in fundus, 10 in gastric body, 19 in gastric antrum. The results of EUS suggested that 52 SMTs were originating from muscularis propria layer (61.9%), 23 originating from mucosal muscular layer (27.4%)) 9 originating from submucosal layer (10.7%); The appearances of lesions were regular (n = 66) and irregular (n = 18). The overall rate of complete resection was 97.6% (82/84). Among them, the complete resection rate of ESD, ESE, STER and EFTR were 97.7%, 100%, 93.8% and 100%, with a mean diameter of (1.33 ± 0.61), (1.47 ± 1.12), (1.76 ± 0.98) and (1.36 ± 0.86) cm, a mean operative duration of (46 ± 29), (39 ± 16), (53 ± 23) and (44 ± 25) min, a mean hemostatic clips amount of (4.2 ± 1.8), (7.5 ± 2.8), (6.4 ± 2.1) and (7.8 ± 3.5). 3 cases occurred perforation during operation and 3 cases of subcutaneous emphysema, 3 cases of postoperative fever associated with elevated WBC, 3 cases of pneumoperitoneum and 2 cases of delayed bleeding were occurred after procedure. Of these patients, 1 case of delayed bleeding received surgical stomach resection and others were treated conservatively. The mean hospital stays after procedure were (5.98 ± 2.11) days (range 3–12 days). Among the 84 patients, 40 cases were pathologically proved to be leiomyoma (47.6%), 29 cases to be stromal tumor (34.5%), 8 cases to be ectopic pancreas tissue (9.5%), 3 cases to be lipoma (3.6%), 2 cases to be unknown pathological type of spindle cell tumor (2.4%), 1 case to be inflammatory polyp (1.2%) and 1 case to be submucosal cyst (1.2%). During a follow-up period of 1–18 months, no recurrence or residual lesions were noted in 67 patients (67/84, 79.8%).
**Conclusion:** Clinical application of endoscopic minimally invasive therapeutic techniques including ESD, ESE, STER and EFTR has proved to be safe and effective for upper gastrointestinal submucosal tumors.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0149 INDIVIDUAL SKILLS PARAMETERS ASSOCIATED WITH COMPETENCY AT COLONOSCOPIC POLYPECTOMY: A RETROSPECTIVE ANALYSIS OF DIRECTLY OBSERVED POLYPECTOMY SKILLS (DOPYS)

**A. Rajendran**[1], S. Thomas-Gibson[2], P. Dunckley[3], N. Sevdalis[4], A. Haycock[5]

[4]*King's College, London/United Kingdom*
[5]*Wolfson Unit, St Mark's Hospital, Harrow/United Kingdom*

**Contact E-mail Address:** arunrajendran@nhs.net.
**Introduction:** The Directly Observed Polypectomy Skills (DOPyS) is a validated tool used to assess polypectomy skills in the United Kingdom. Polypectomy performed by a trainee is documented with DOPyS in an e-portfolio. DOPyS has 34 parameters of technical & non-technical skills (1) on which a trainee is scored on a grade of 1–4. Scores of 3 and 4 are accepted as being competent in a descriptor. Trainees are certified as competent in Level 1 (< 1 cm) & Level 2 (1–

2 cm) polypectomy if they achieve overall grades 3 or 4 for more than 90% of their last 4 consecutive DOPyS & a caecal intubation rate (CIR) >90% (over last 3 months). There is paucity of literature on the rate and type of skills acquisition required by trainees to achieve safe and competent polypectomy. Stable colonoscope position, tip control, CIR, variability in the endoscopists' technique & time spent to examine the polypectomy site have all been suggested as factors critical in effective polypectomy (2).

**Aims & Methods:** Retrospective data from the e-portfolio of 707 trainees (4965 DOPyS) from Jan 2009 to Sept 2015 was extracted. The low-scoring (grade 1 & 2) descriptors were identified and further analysed according to site, morphology and size of polyps removed. We also analysed a further subset of 61 trainees (749 DOPyS) & data were collected for absolute CIR at first recorded polypectomy assessment and at provisional/Full certification.

**Results:** 4965 DOPyS were analysed. 80% (3898) left sided polyps, 20% (976) right sided. 1851 (37%) stalked polyps, 3114 (63%) sessile polyps. Median size of the polyps was 6 mm & the majority (68%) <1 cm.

Trainees in UK scored grade 1 or 2 for the following parameters:

1) Preparation checks (non-technical skill): Checking for snare closure = 10% (411) & diathermy settings = 10% (474).

2) Technical skills: advancing snare sheath (8%), directing snare accurately (8%), positioning snare over the lesion (8%) and appropriate submucosal injection technique (8%) 3) Post polypectomy "Polyp retrieval" (4%).

Additionally, trainees were assessed as less competent for right-sided polyps vs left-sided polyps in skills such as choosing appropriate polypectomy technique (7%) and treating residual polyp (7%). The subset analysis of absolute CIR for 61 (749 DOPyS) trainees is shown in the table.

| | Median | n |
|---|---|---|
| **Number of lower GI procedures at first recorded DOPyS** | 137 (5-508) | 61 |
| **Absolute CIR at first recorded DOPyS (%)** | 73 (0-100) | 61 |
| **Absolute CIR at Level 1 polypectomy competency (%)** | 86 (47-94) | 42 |
| **Absolute CIR at Level 2 polypectomy competency (%)** | 88 (60-93) | 19 |

**Conclusion:** Trainees in the UK start formative assessment of polypectomy after completing >130 lower GI procedures with a CIR > 70%. Polypectomy competency in UK trainees is achieved with absolute CIR > 86%. This suggests that DOPyS competency increases with technical competence in colonoscopy and validates the assessment requirement of CIR > 90% over the last 3 months. We have identified several details of polypectomy technique (both technical & non–technical) that trainees are assessed as incompetent during the early phase of learning polypectomy, particularly for right sided polypectomy. Identification of these factors has potential to shorten the learning curve of polypectomy skills acquisition with targeted interventions like e-learning modules and specific in-vivo training.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0150 ACCURACY OF MODERN ENDOSCOPIC IMAGING TO DETERMINE THE KUDO NEOPLASTIC PIT PATTERN OF LARGE LATERALLY SPREADING COLONIC LESIONS (LSL)

**D. J. Tate**, L. Desomer, H. Awadie, M. J. Bourke

*Gastroenterology And Hepatology, Westmead Hospital, Sydney|Australia*

**Contact E-mail Address:** djtate@gmail.com.

**Introduction:** Expert opinion suggests that the discrimination of pit pattern of colorectal lesions, first described by Kudo (Kudo neoplastic pit pattern, KPP), requires a chromic dye combined with magnification endoscopy. Endoscopic imaging has become so advanced that chromendoscopy may no longer be necessary for the discrimination of the KPP.

**Aims & Methods:** The study aimed to evaluate the diagnostic accuracy of high definition white light (HD-WL) and narrow-band imaging (NBI) for the discrimination of KPP to predict lesion histopathology without magnification or chromendoscopy. Amongst a prospective observational study of patients referred for WF-EMR of laterally spreading lesions (LSL) > 20 mm, successive lesions were analysed prior to resection for KPP using HDWL and NBI including the 'near focus' magnification mode where available. Olympus H180/HQ190 endoscopes were used throughout. 10 endoscopists, experienced in advanced endoscopy at fellow or consultant level interpreted the KPP. Lesion histopathology was determined later by two expert gastrointestinal histopathologists. KPP II, III + IV and V were correlated to sessile serrated adenoma, tubular adenoma/tubulovillous adenoma and invasive cancer respectively. Since the therapeutic approach for KPP III/IV is identical these were logically grouped together. The primary outcome was congruence of endoscopic pit pattern assessment with histology.

**Results:** From January 2015 to April 2016, 162 patients (mean age 68.4 years, 53.2% male) with 173 lesions (median size 35 mm (IQR 25–50 mm), 61.5% proximal colon) were referred for WF-EMR at a single tertiary referral endoscopy centre. Analysis of Kudo pit pattern was available for 169 lesions. Endoscopic assessment of the KPP was correct in 159/169 (94.1%) of cases. The endoscopic prediction of KPP II was correct in 12/15 lesions (accuracy 80%, 95% confidence interval 51.3–94.7%). KPP III or IV was correctly predicted in 146/152 cases (accuracy 96.1% – 95% confidence interval 91.2–98.3%). Where endoscopic imaging incorrectly predicted the KPP in this group (n = 6), 2/6 (33.3%) lesions were dysplastic serrated adenomas, known to exhibit areas of KPP III/IV. KPP V was only seen in 2 lesions, one was determined as invasive adenocarcinoma at histopathology, the other tubulovillous adenoma with diffuse high grade dysplasia. Key data regarding the endoscopic prediction of kudo neoplastic pattern is presented in table 1.

**Table 1:** Correct endoscopic assessment of Kudo neoplastic pit pattern (KPP) compared to histopathology; 95% CI – 95% confidence interval, SSA-ND – sessile serrated adenoma without dysplasia, SSA-D – SSA with dysplasia, TVA – tubulovillous adenoma, HGD – high grade dysplasia.

| **Kudo Neoplastic Pattern (KPP)** | Correct Endoscopic Assessment n = 169 | Accuracy (95% CI) | Histopathology where endoscopic assessment of KPP was incorrect n = 10 |
|---|---|---|---|
| II | 12/15 | 80% (51.3-94.7) | Tubular, 1 (33%) TVA, 2 (66%) |
| III/IV | 146/152 | **96.1% (91.2-98.3)** | SSA-ND, 3 (50%) SSA-D, 2 (33.3%) Invasive Cancer, 1 (16.7%) |
| V | 1/2* | | TVA HGD, 1 |

**Conclusion:** Kudo pit pattern can be reliably determined by advanced endoscopic imaging in the majority of cases, obviating the need for chromendoscopy. In particular, KPP III and IV, suggesting endoscopic resectability, were correctly predicted in over 95% of cases.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0151 THE CLINICAL SIGNIFICANCE OF SOLITARY LARGE SESSILE SERRATED ADENOMAS

**L. Desomer**[1], D. J. Tate[1], M. Jayanna[1], N. Burgess[1], M. Pellise[1], H. Awadie[1], D. Mcleod[2], M. J. Bourke[1]

[2]*Pathology, Westmead Hospital, Westmead|Australia|NSW*

**Contact E-mail Address:** lobkedesomer@gmail.com.

**Introduction:** Serrated lesions are a heterogeneous group of polyps with variable malignant potential. Although up to 30% of CRC develop via the serrated pathway, the natural history and malignant potential of solitary large (≥20 mm) SSAs (S-SSAs) is still incompletely understood.

**Aims & Methods:** To describe the characteristics of S-SSAs in comparison to large SSAs (≥20 mm) in patients with serrated polyposis syndrome (SPS) and unravel their clinical significance. Data was collected prospectively from a single tertiary referral center between September 2008 and July 2015. Patients with one or more large (≥20 mm) SSA were eligible. Data was collected from the diagnostic procedure performed by the referring endoscopist, the EMR procedure and the first surveillance colonoscopy (SC1). Based on these 3 procedures, patients were categorised in 3 groups: the S-SSA group, SPS group and the group of patients with ≥1 SSA without fulfilling the criteria of SPS (2-4 SSAs of which 1 is ≥20 mm). The SPS group was compared to the S-SSA group and the 2-4 SSAs group for patient and lesion characteristics and polyp burden.

**Results:** 151/1027 (14.7%) lesions removed by EMR were SSAs ≥20 mm. 30/151 (19.9%) lesions were excluded as they could not be assessed for polyp burden (18/30 did not undergo SC1 and 12/30 underwent surgery). 57/121 (47.1%) of patients had SPS, 43/121 (35.5%) had only 1 large SSA and 21/121 (17.4%) belonged in the 2-4 SSA group.

In the S-SSA group the lesion size was significantly smaller (25 vs 30 mm, p = .023), showed more submucosal fibrosis (23.3% vs 5.3%, p = .008) and was more frequently located proximal to the transverse colon (79.1% vs 57.9%, p = .026) as compared to the SPS group. In terms of polyp burden, patients with SPS had more conventional adenomas (14% vs 0%, p = .010) and more

high-risk adenomas (29.8% vs 9.3%, p = .014) than the S-SSA group. The presence of dysplasia was similar in both groups and relatively high (21% in the SPS group and 17% in the S-SSA group). There were no differences noted between the group with SPS and the 2-4 SSA group. In only 5/57 (10.9%) of cases, SPS was recognized by the referrer.

**Table 1:** Comparison between SPS and S-SSA and SPS and the 2-4 SSAs group. SPS: serrated polyposis syndrome; S-SSA: solitary large sessile serrated adenoma, SD: standard deviation; Hx: history; CRC: colorectal carcinoma; IQR: interquartile range; n/a: not applicable; high-risk adenoma: presence of an advanced adenoma or ≥3 adenomas.

| | SPS n = 57 | S-SSA n = 43 | P | 2-4 SSAs n = 21 | P |
|---|---|---|---|---|---|
| **Baseline characteristics** | | | | | |
| Age (mean; SD) | 64.6 (13.5) | 66.2 (11.4) | .547 | 64.8 (9.1) | .963 |
| Male (%) | 16 (35.1) | 18 (41.9) | .490 | 8 (38.1) | .806 |
| Personal Hx CRC (%) | 9 (15.8) | 4 (9.3) | .340 | 1 (4.8) | . 272 |
| Familial Hx CRC (%) | 11 (20.8) | 7 (16.7) | .614 | 4 (20.0) | 1.000 |
| Personal Hx polyps (%) | 51 (89.5%) | 38 (88.4) | .862 | 19 (90.5) | .942 |
| SPS recognised by referrer (%) | 5 (10.9) | n/a | | n/a | |
| **Lesion** | | | | | |
| Size (mm) (median, IQR) | 30 (25-40) | 25 (20-30) | **.023** | 30 (25-35) | .705 |
| Submucosal fibrosis (%) | 3 (5.3) | 10 (23.3) | **.008** | 4 (19.0) | .080 |
| **Location** | | | | | |
| Right colon (hepatic flexure and proximal) (%) | 33 (57.9) | 34 (79.1) | **.026** | 12 (57.1) | .952 |
| **Dysplasia** | | | | | |
| None (%) | 36 (63.2) | 26 (60.5) | .919 | 14 (66.7) | 1.000 |
| Low Grade (%) | 20 (35.1) | 16 (37.2) | 7 (33.3) | | |
| High Grade (%) | 1 (1.8) | 1 (2.3) | 0 | | |
| Cancer (%) | 0 | 0 | 0 | | |
| **Follow up** | | | | | |
| Recurrence at SC1 (%) | 3 (1.8) | 3 (7.0) | .312 | 1 (4.8) | .469 |
| **Polyp burden** | | | | | |
| **≥1 High-risk adenomas (%)** | 17 (29.8) | 4 (9.3) | **0.014** | 7 (33.3) | .787 |
| **≥10 Conventional adenomas (%)** | 8 (14.0) | 0 | **.010** | 1 (4.8) | .431 |

**Conclusion:** The clinical significance of S-SSAs is unknown. There is a different colonic distribution and a lower polyp burden in patients with a S-SSA as compared to SPS. However, striking commonalties such as age and sex distribution, suggest that SPS is not an evolutionary process. Also, high rates of dysplasia were noted in all 3 groups warranting adequate surveillance of patients with large SSA/Ps given the risk of synchronous advanced neoplasia. Finally, SPS is only in the minority of cases recognised by the referring physician. This is however of paramount importance since SSA/Ps with dysplasia are thought to be largely responsible for the relatively high prevalence of proximal interval cancer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0152 IMMEDIATE AND DELAYED BLEEDING AFTER COLD SNARE POLYPECTOMY: A PROSPECTIVE SINGLE-ARM TRIAL

**N. Matsuura**[1], Y. Takeuchi[1], N. Uedo[1], M. Kato[1], K. Hamada[2], Y. Tonai[1], Y. Yamasaki[1], T. Kanesaka[1], T. Akasaka[1], N. Hanaoka[3], K. Higashino[1], R. Ishihara[1], H. Iishi[1]

**Contact E-mail Address:** ibura9@yahoo.co.jp.
**Introduction:** Cold snare polypectomy (CSP), a promising polypectomy technique without electrocautery, is generally accepted as a less invasive procedure and has little risk of delayed bleeding for subcentimetric colorectal polyps. However, the frequency of immediate bleeding and delayed bleeding after CSP for subcentimetric colorectal polyps has thus far not been reported in a prospective large cohort.
**Aims & Methods:** We conducted a prospective, single-arm trial in a tertiary cancer center to investigate the frequency of immediate and delayed bleeding after CSP. Patients with subcentimetric colorectal polyps scheduled to undergo endoscopic polypectomy were enrolled. Patients who underwent polypectomy with electrocautery were excluded after enrollment. First, CSP was performed for the detected lesions, which were predicted to be neoplastic lesions, and the resected specimens were retrieved. When immediate bleeding occurred, endoscopic hemostasis was performed. The participants were scheduled to visit our hospital within 1 month after their colonoscopy to assess post-procedural complications such as bleeding. We defined immediate bleeding as evident bleeding requiring endoscopic hemostasis just after CSP (during examination). Delayed bleeding was defined as evident bleeding requiring endoscopic hemostasis after the completion of an examination. The study protocol was approved by the institutional review board of our hospital and registered in the Clinical Trial Registry (UMIN000010879).
**Results:** A total of 434 patients were assessed for study enrollment. 7 cases refused to participate and were excluded from the study enrollment. Therefore, 427 patients were enrolled by the participating colonoscopists. Since one patient claimed to withdraw from the study enrollment before the procedure, she was excluded after enrollment. Since 72 cases had polyps larger than 10 mm, pedunclated, or depressed lesion, they were excluded from the study protocol. Finally, a total of 1312 subcentimetric polyps in 354 patients (median age; 68 y.o. male/female; 271:83) were analyzed. We performed 1312 CSPs for subcentimetric lesions (median tumor size 4 mm; 947 polypoid and 364 flat). Immediate bleeding requiring endoscopic hemostasis occurred in 41 lesions (3.1%), but all were easily managed with endoscopic clipping. Delayed bleeding requiring endoscopic intervention occurred in 5 patients (1.4%; 95% confidence interval, 0.2%–2.6%), all of which were ooze-type bleeds also easily controlled by endoscopic clipping. We encountered no perforation or fatal adverse events.
**Conclusion:** The incidence of delayed bleeding after CSP, while not nonexistent, was remarkably low. CSP has the potential to become a standard endoscopic therapy for subcentimetric polyps.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** mpisera@gmail.com.
**Introduction:** Participation in primary colonoscopy screening programs is unsatisfactory. Bowel preparation for colonoscopy is one of the key barriers to participation in screening. Low volume (LV) bowel preparation is better tolerated than standard volume (SV) bowel preparation. We hypothesized that offering LV bowel preparation will increase participation in screening colonoscopy (SC) without negative effect on bowel preparation quality.
**Aims & Methods:** This was a multicenter, randomized health services study performed within the organized Polish Colonoscopy Screening Program. Individuals aged 55–64 years who were invited for SC between March and April 2015 were randomly assigned in a 1:1 ratio to the LV bowel preparation group (0.3 L sodium picosulphate/magnesium citrate plus 2 L of water, Citrafleet®) or SV bowel preparation group (4 L polyethylene glycol, Fortrans®) and invited by invitation letter 6 week before SC then reminding letter in case of no response. Both bowel preparations were routinely administered in a split-dose regimen unless SC was scheduled for early morning hours. Bowel preparation medications were dispensed free of charge along with standardized instructions to all invitees who contacted screening centers and agreed to participate in screening. The primary outcome measure was participation rate in SC within 3 months from the date proposed in invitation letter. The secondary endpoints were compliance with the bowel preparation instructions, a quality of bowel preparation assessed with the Boston Bowel Preparation Scale (BBPS) and adenoma detection rate (ADR). The study was powered to detect 2% point difference in participation rates between study groups at a 0.05 significance level.
**Results:** Of the 13, 621 individuals invited for screening over the study period, 6, 811 were assigned to the LV group and 6, 810 to the SV group. There was no significant difference between the groups in participation rate in SC (15.8% LV vs. 14.7% SV, p = 0.067). 747/1199 (62.3%) in the LV group and 718/1154 (62.2%) in the SV group prepared using split-dose regimen. Bowel preparation was adequate (≥2 points in the BBPS in each colonic segment) significantly more often in the SV group compared to the LV group (86.3% and 78.5%, respectively; $p < 0.001$) despite the fact that more participants from the LV group complied with a full-dose of bowel preparation (98.6% and 96.9%, respectively, p = 0.05). Similarly, bowel preparation in the right colon was adequate significantly more often in the SV group compared to the LV group (91.0% and 84.2%, respectively; $p < 0.001$). There was no difference in the ADR between groups (30.4% LV vs. 29.4% SV, p = 0.60).
**Conclusion:** LV bowel preparation did not improve participation rate with screening colonoscopy compared to SV. Bowel preparation was adequate significantly more often in the SV group.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0154 NBI ENDOSCOPIC CRITERIA- A USEFULL TOOL TO CHARACTERIZE COLONIC LESIONS IN CLINICAL PRACTICE

**A. Boeriu**, O. Pascarenco, D. Onisor, O. Brusnic, E.D. Dobru
*Gastroenterology, University of Medicine Gastroenterology, Tirgu Mures/Romania*

**Contact E-mail Address:** aboeriu@gmail.com.
**Introduction:** The characterization of colonic lesions by narrow band imaging (NBI) endoscopy provides the opportunity for endoscopists to adopt a proper therapeutic and surveillance strategy. We studied the applicability of NBI endoscopic criteria in current practice for the identification and differentiation of adenomas and serrated polyps.
**Aims & Methods:** A high-definition magnification endoscope with an NBI system and dual-focus optical imaging (Evis Exera III, Olympus) was used to perform endoscopic procedures. The Workgroup serrAted polypS and Polyposis (WASP) classification, which combines NICE criteria and the Hazewinkel criteria, was used for endoscopic diagnosis. Brown color, brown vessels, oval tubular or branched surface pattern were endoscopic criteria used to diagnose adenomas. Lesions exhibiting two of the following features: clouded surface, indistinctive border, irregular shape, or dark spot inside crypts, were diagnosed as sessile serrated adenomas/ polyps (SSA/Ps). Histology was used as the reference standard.
**Results:** A total number of 275 patients were prospectively assessed and 328 lesions have been detected: 155 hyperplastic polyps (HPs), 156 adenomas, 15 SSAs, and 2 invasive cancers. A high confidence diagnosis was made in 266 (81%) of polyps. We obtained 83.8 (95%CI: 66.2–94.5) sensitivity (Se), 96.7 (95%CI: 90.6–99.3) specificity (Sp), 89.6 (95%CI: 72.6–97.8) positive predictive value (PPV) and 94.6 (95%CI: 87.9–98.2) negative predictive value (NPV) for adenomas detection in diminutive polyps (<5 mm in size); 96.6 (95%CI: 88.4–99.5) Se, 95.4 (95%CI: 77.1–99.8) Sp, 98.3 (95%CI: 90.9–99.9) PPV, 91.3 (95%CI: 71.9–98.9) NPV in small polyps (6–9 mm), and 95.2 (95%CI: 83.8–99.4) Se, 91.6 (95%CI: 61.5–99.7) Sp, 97.5 (95%CI: 87.1–99.9) PPV, 84.6 (95%CI: 54.5–98.0) NPV in large polyps (>9 mm in size), when polyps were assessed with high confidence. Specific NBI endoscopic criteria for SSA/Ps according to WASP classification were identified in 9 lesions (6 lesions were assessed with high confidence, 3 with low confidence), and histologic confirmation of SSAs was obtained in 7 of these lesions. Seven lesions diagnosed as HPs on NBI endoscopy and one adenoma (2 high confidence diagnosis, 6 low confidence diagnosis) proved to be SSAs at histology. Overall, the endoscopic criteria yielded 46.6 (95%CI: 21.2–73.4) Se, 98.7 (95%CI: 95.5–99.8) Sp, 77.7 (95%CI: 39.9–97.1) PPV, and 95.2 (95%CI: 90.7–97.9) NPV for SSAs diagnosis.
**Conclusion:** Our study proved the utility of NBI endoscopic criteria in characterization of colonic lesions. The diagnostic performance was good in high confidence predictions of histology. The detection of specific features for SSA/Ps may represent a challenge during real-time examination (7 SSAs did not meet the endoscopic criteria, and were underestimated as HPs). The implementation of a standardized classification system in clinical practice, as well as an adequate training for the identification of endoscopic criteria with high level of confidence, are mandatory for an accurate optical diagnosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0155 KNIFE-ASSISTED RESECTION OF RIGHT-SIDED COLONIC POLYPS: THE RIGHT WAY ROUND!

K. Kandiah[1], S. Thayalasekaran[1], F.J.Q. Chedgy[1], **S. Subramaniam**[1], R. Bhattacharyya[2], P. Bhandari[1]
[1]*Gastroenterology, Queen Alexandra Hospital, Portsmouth/United Kingdom*
[2]*Dept. Of Gastroenterology, Queen Alexandra Hospital Dept. of Gastroenterology, Portsmouth/United Kingdom*

**Contact E-mail Address:** shar811@googlemail.com.
**Introduction:** Endoscopic resection of right-sided colonic polyps carries an inherently higher risk of complications including bleeding and perforation. This risk is heightened in the resection of polyps that are tethered, flat or on background of colitis (complex polyps). In the West, complex polyps in the right colon are frequently managed by endoscopic mucosal resection (EMR) or surgery although recurrence rates can be as high as 20%. Endoscopic submucosal dissection (ESD) is an effective technique in the resection of complex polyps. However, ESD is technically challenging with a long learning curve and carries a significant perforation rate (6% in Eastern series and 17% in Western series) leading to a poor uptake of this technique in the West.[i], [ii].
**Aims & Methods:** We aim to examine the safety and efficacy of a novel technique of knife-assisted snare resection (KAR) in resecting complex polyps in the right colon. Data of all KARs undertaken at our institution from 2009 to 2015 were prospectively compiled in a pre-designed database. Independent researchers blinded to the technique interrogated this database. Polyps in the right colon (distal transverse to caecum) were included in the analysis. Polyp characteristics and procedure details were prospectively recorded. Endoscopic follow-up was performed to identify recurrence.
**Results:** A total of 52 patients with complex polyps 10–80 mm in size were resected by KAR. The mean follow-up time was 35 months. 42% of the polyps were >40 mm in size, and 51% were scarred from previous attempts. The majority of the polyps resected (91%) exhibited flat morphology (Paris Classification IIa, IIa + IIb, IIa + IIc). Table 1 shows the patient baseline and lesion characteristics. There were 2 cases of delayed bleeding (4%) neither of which required surgery. The endoscopic cure rate was 96% after single procedure, improving to 98% with further attempts.

**Table 1:** Patient baseline and lesion characteristics.

| | |
|---|---|
| Age, Years (Mean) | 46-83, (70) |
| Sex (M:F) | 2.7:1 |
| Mean polyp size, mm (range) | 35 (7-80) |
| En Bloc Resection, n (%) | 24 (45%) |
| Histology, n Adenoma SSP DALM Cancer | 36 12 3 4 |

**Conclusion:** This is the first reported Western series of KAR of complex polyps in the right colon. Although the en-bloc resection rate was low, our data demonstrates that this novel technique is a safe and effective technique for resection of complex polyps in the right colon. The recurrence rates are superior to EMR and complication rates are lower than ESD. As the learning curve for KAR is shorter than that for ESD, we believe that this technique is ideal for the Western setting.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** An adequate bowel preparation is an essential prerequisite for quality colonoscopy[1]. The identification of a patient's risk factors for inadequate colon cleansing and efficacy of preparation may result in the identification of personalized bowel preparation with positive impacts on both quality colonoscopy and patients' satisfaction.
**Aims & Methods:** This study was aimed at evaluating the efficacy of bowel cleansing preparation of a low-volume mixed preparation (20 mg bisacodyl plus 2 L polyethylene glycol solution with citrate and simethicone [PEG-CS + B], LOVOL-S) and a high-volume preparation (4 L polyethylene glycol solution plus simethicone [PEG-S], SELG-S) and the risk factors for inadequate cleansing in patients who were free to choose among the two types of preparations. This single-center, observer-blinded, observational trial enrolled all consecutive adult outpatients referred for colonoscopy. All subjects received a questionnaire asking on demographics (age, sex, body mass index [BMI]), clinics (Bristol stool chart, comorbidities, colonoscopy indication) and type of bowel preparation used. Patients were asked to freely choose between 4 L PEG-S one-day (subgroup A) or 2 L PEG-CS + B one-day dose (subgroup B) for morning colonoscopy, and 4 L PEG-S split-dose (subgroup C) or2 L PEG-CS plus 20 mg bisacodyl split-dose for afternoon colonoscopy. All colonoscopies were performed by experienced endoscopists (>300 colonoscopies/year), well-trained in the use of bowel preparation rating scales. Data concerning cecal intubation, Boston bowel preparation scale (BBPS) [2], Ottawa scale (OS) [2] were collected by the endoscopist, who was blinded to patient's data. The OS and BBPS scales were used as end points: a score ≤2 for each bowel segment was used as satisfactory for OS, while a score ≥2 for BBPS. Logistic regression was adjusted for sex, colonoscopy indication, Bristol stool chart, BMI, age, and number of

comorbidities in order to evaluate the association between the two bowel-cleansing preparations and the study end-points.
**Results:** Between December 2014 and March 2016, 1174 patients were enrolled; 100 of them were excluded for missing information in the questionnaire. In the remaining population, 51% were men, the mean age was 61 ys, the mean BMI 25 kg/m$^2$. 283 patients were allocated In subgroup A, 340 in subgroup B, 263 in subgroup C and 188 in subgroup D. Indications for colonoscopy were abdominal pain (10%); diarrohea (6%); constipation (6%); irregular bowel movements (3%); screening, also including post-polypectomy surveillance, proctorrhagia and anaemia (54%); inflammatory bowel disorders (9%); previous bowel surgical resection (7%); others (5%). Subgroups A-D showed an equal distribution of indications, age, sex, BMI and number of comorbidities.Data regarding the adequacy of bowel preparations are reported in the table below (table 1a). The odds of bowel cleansing observed with split regimens (either PEG-CS + B or PEG-S 4 L) are remarkably greater compared to the odds of the corresponding one-day regimens, regardless of the rating scale used, while no significant difference was observed between small or large volume preparations. Old age was the only variable significantly associated with inadequate bowel cleansing as assessed by either BBPS or OS (table 1b-f), while a trend was observed for BMI $\geq$ 30 for low BBPS.
**Conclusion:** This study confirms the efficacy of split-dose regimens with either low or high volume preparations for bowel cleansing. In patients free to choose among different preparations and regimens, we observed no relevant impact on cleansing. Our results confirm the risk of inadequate bowel cleansing in elderly and show some risk in obese subjects as well.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** jpratone@hotmail.fr.

**Introduction:** Colorectal cancer remains to this day a major public health problem. Currently, colonoscopy and polypectomy are the gold standard to prevent incident cases of colorectal cancer. This endoscopic examination can detect lesions at a curable stage and resect adenomas. Colonoscopy quality indicators have been defined by professional societies based on published studies. One of the most important is adenoma detection rate (ADR). American Society of Gastrointestinal Endoscopy (ASGE) recommend ADR of 20% or higher for female patients and 30% or high for male patients. Use of a new colonoscope with larger panoramic view up to 330° improve adenomas rate of 41% with 15% of advanced adenomas, in a tandem randomized multicenter study. Fuse® colonoscope system use three independent 170° imagers, one central and 2 laterals, each one being separately displayed on the screen. We wanted to confirm these results by producing the first French prospective observational study concerning the colonoscopy FUSE©.
The primary endpoint was potentially omitted adenomas (POA) i.e. adenomas seen on the side screens and will not appear on the central display during colonoscopy withdrawal without oriented movements. Secondary endpoints included our ADR team, FUSE© impact on ADR, time to cecal intubation and withdrawal time.
**Aims & Methods:** We did a monocentric prospective study in one french center (Paoli-Calmettes institute, Marseille, France). We enrolled patients aged over 18 years between January 2015 and March 2016 who had been referred for complete colonoscopy. We excluded individuals with a history of colonic resection, individuals with APC or MYH mutation, patients referred to endoscopic mucosal resection or endoscopic submucosal resection of a large adenoma and patients with bad bowel preparation. Informed consent was obtained from all participants.
**Results:** We included 141 patients between January 2015 and March 2016. Three patients were excluded of the final analysis on account of incomplete colonoscopies. The final analysis concerned 138 patients. Our study interested 78 men and 43 women (sex ratio = 1, 3). Mean age was 60.4 years. 130 polyps were resected without complication. Among these polyps, 88/130 were adenomas (68%). 3 CCR were found. Pathology of all adenomas was low grade dysplasia. Number of POA was estimated at 34. Therefore 34/88 adenomas (39%) were POA. Mean time to caecum was 10 minutes and mean withdrawal time was 12 minutes. 91 colonoscopies (66%) were performed by fellow under senior supervision and 34% only by senior. Global ADR was 34%. Men ADR was 35% and women ADR 31%. Estimated ADR without POA was 29% for men and 19% for women.
**Conclusion:** The results of our study support the use of FUSE© system for several reasons. First and foremost POA represented 39% of all adenomas and this

confirms our primary endpoint. Achievement time of FUSE© colonoscopy was acceptable all the more so a lot (66%) of endoscopies was performed by fellow under senior supervision. Female ADR is congruent with ASGE guidelines since it is higher than 30%. Women ADR is also in agreement with ASGE guidelines. Impact of panoramic view on ADR was considered significant given that 10% increase of either sex. After several months of use of the FUSE© colonoscope, we think that FUSE© colonoscopy is feasible and reliable. This new scope improves the vision of the colonic lumen and may reduce the rate of interval cancers.

**Contact E-mail Address:** arthur.berger.bx@gmail.com.
**Introduction:** Colonoscopy is the gold standard for colorectal cancer screening in general population. Adequate bowel preparation is important for optimal colonoscopy. The occurrence of interval cancers raises the problem of missed lesions. The rate of poorly prepared colonoscopies is established about 20 to 40%. This problem generates significant additional costs associated with colonoscopies redone, estimated at 35 million euros in 2008. It is important to identify patients at high risk of inadequate bowel preparation in this specific group.
**Aims & Methods:** To develop a prediction score to identify patients at high risk for inadequate bowel preparation evaluated by a self-administered questionnaire completed by patients during the pre - colonoscopy consultation. Main Outcome Measurements: Inadequate bowel preparation defined as Boston Bowel Preparation Scale. We performed a prospective study of 599 consecutive patients who underwent colonoscopy, from February to November 2015 at the University Hospital of Angers (France). Multivariate analysis was performed to identify factors associated with inadequate preparation, which were expressed as odds ratio (OR) and used to build a predictive model.
**Results:** A total of 599 colonoscopies were included, of which 24.5% (n = 147) had an inadequate bowel preparation (Boston Preparation score < 7). Mean age was 57.1 ± 14.3 years, 331 (55.3%) were male and indications for colonoscopy were screening and/or surveillance 320 (53.5%), abdominal symptoms and/ or blood loss and/or anemia 151 (25.3%), inflammatory bowel disease 65 (10.9%), and others (62 (10.4%), independent factors included in the prediction model were American Society of Anesthesiologists Physical Status Classification System score: ASA = 2 (OR = 1.57 [0.94–2.61]) and ASA > 3 (OR = 5.79 [3.12–10.77]), history of inadequate bowel preparation (OR = 3.86 [1.83–8.12]), and older age < 50 ans (OR = 2.89 [1.43–5.83]), older age between 50 et 70 ans (OR = 2.05 [1.12–3.75]). These factors predicted which patients would have inadequate cleansing with sensitivity 44.6 [42.8–46.4], specificity 81.1 [80.3–81.9], positive predictive value = 44.0, and negative pre- dictive value = 81.5; they had an under the receiver operating charac- teristic curve value of 0.671.
**Conclusion:** the use of this predictive score would allow the selective optimization of bowel preparation at the initial consultation to increase the percentage of colonoscopies properly prepared, and then reduce the number and the cost of rescheduled exams and the risk of interval cancers.
**Disclosure of Interest:** A. Berger: Norgine.

## P0159 EFFECTIVENESS OF ENDOSCOPIC SUBMUCOSAL DISSECTION USING THE "CLIP-FLAP METHOD" FOR SUPERFICIAL COLORECTAL TUMORS

**Introduction:** Endoscopic submucosal dissection (ESD) is technically challenging because of poor visualization and instability in the operative field. Although mucosal flap formation improves visualization of the cutting area, it is difficult to achieve, especially in colorectal ESD. To facilitate mucosal flap creation, we developed the "clip-flap method" using the endoclip as a substitute for the mucosal flap until the flap is completed (K. Yamamoto, et al. Endoscopy 20122015).
**Aims & Methods:** We retrospectively studied 407 cases, in which ESD for superficial colorectal tumors was performed between August 2008 and April 2016. The primary object lesions were laterally spreading tumor, which were suspected to be intramucoal or with slightly invaded submucosal cancers > 20 mm in diameter in the operative examinations. We compared the treatment outcomes after the adoption of the clip-flap method (Clipflap-ESD: 287 cases) with those before the adoption of the clip-flap method (Conventional-ESD: 120 cases) to evaluate the efficacy and safety of the clip-flap method. The procedure of the clip-flap method is as follows. The lesions were moved upward as far as possible against gravity following a postural change to take advantage of the counter-traction of gravity. After submucosal injection, the mucosa around the lesion on the anal side was incised with an adequate margin, and the submucosal layer was cut deeply. The edge of the exfoliated mucosa was clipped with an endoclip (EZ CLIP, HX-610-135; Olympus). The distal attachment was inserted under the endoclip, and then the submucosal layer was dissected with the endoknife. A single endoclip was generally used, and the cross pattern of endoclips, created by attaching one endoclip to another endoclip, was also used according to the situations. We predominantly used a short-needle electrosurgical endoknife with a water-jet function (FlushKnifeBT; Fujifilm), and also used other endoknives in some cases.
**Results:** Median tumor diameter, resected specimen diameter, procedure time, en bloc resection rate, and perforation rate of Conventional-ESD and Clipflap-ESD were 26 mm vs 29 mm, 32.5 mm vs 36 mm, 88.5 minutes vs 59 minutes, 90% vs 97.2%, and 4.2% vs 1.4%, respectively. The procedure time of Clipflap-ESD was statistically significantly shorter than that of Conventional-ESD ($P < 0.01$), and en bloc resection rate of Clipflap-ESD was significantly higher than that of Conventional-ESD ($P < 0.01$). In all the cases which the clip-flap method was applied, the exfoliated mucosa was lifted by the endoclip attached to the exfoliated mucosa after the distal attachment was inserted under the endoclip, allowing for clear visualization and efficient dissection of the submucosal layer, and effective creation of the mucosal flap. The clip-flap method was effective even when it was difficult to insert the distal attachment under the exfoliated mucosa due to submucosal fibrosis or vertical approach. Perforation was conservatively treated with clipping in 8 of 9 cases. In only one case of C-ESD, laparotomy was needed due to difficult situation to repair, which was caused by poor visualization of cutting area.
**Conclusion:** The clip-flap method facilitated the mucosal flap creation and allowed our treatment outcomes to be dramatically improved. The present study demonstrates that the clip-flap method is a simple, safe, and very effective option for colorectal ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic submucosal dissection (ESD) is an ideal advanced endoscopic technique for management of selected early gastrointestinal neoplasms (EGN) with low risk of lymph node involvement. Learning curve in Western setting is demanding, in particular for colorectal cases.
**Aims & Methods:** To assess therapeutic outcomes of ESD initiated in two tertiary centers in Madrid, we conducted a prospective evaluation of patients with EGN eligible for ESD. Prior intensive training program in animal model was completed by main operator (AH) from 2010 to 2012 (over 100 ESD cases completed). Clinical ESD procedures were mostly performed with Flush knife BT (Fujifilm Co.) and/or Hook knife (Olympus Co.), with 96% of patients under general anesthesia. We performed a global analysis and also time-framed analysis of the series to evaluate the ESD learning curve process, specifically assessing initial success, en-bloc & R0 resection rate, speed and complication rate.
**Results:** ESD was attempted in 118 lesions from January 2012 to April 2016. Majority of procedures were performed at Puerta de Hierro University Hospital (110/93.2%). Mean age was 65.8 years, with male proportion 58.5%. Most of the cases were colorectal (72%), with lower proportion of gastric (17.8%) and esophageal EGNs (10.2%). Initial success was achieved in 112 cases (95%), with en-bloc and R0 resection rate of 95% and 82.2% respectively. Mean lesion size was 30.5 mm (range 5–80), with median time to complete procedure 94.5 min (range 8–260). Perforation was the main complication, with a global rate of 34.7%, along with 5 cases (12.2%) requiring early surgical management. Late complications were identified in 11 patients: delayed perforation (4), bleeding (3), electrocoagulation syndrome (1), severe esophageal stricture (1), haemoperitoneum (1) and splenic rupture (1). All but 4 cases (36%) were successfully managed with medical and/or endoscopic treatment. The mean hospital stay for patients without complications was 2.5 (SD 2.1) days. Results from the learning curve progression according to 4 consecutive chronological blocs of 30 cases are summarized in table 1. Initial success increased from 86.7% to 100%, along with similar rise of en-bloc resection rate. An increasing proportion of colorectal cases up to 82–83% on the 2 final periods were noticed. Speed of ESD increased after the first 30 cases (0.14 $cm^2$/min), with a plateau of 0.22–0.26 $cm^2$/min subsequently. A high perforation rate in the first period (43%) was noteworthy, with a slight reduction to 30–35% on the following periods. It was remarkable that endoscopic treatment was successful in all cases of perforation along the final period analyzed.
**Conclusion:** High rates of success and en-bloc resection can be achieved after intensive training and learning curve progress on ESD, even in a high prevalence-based approach of colorectal EGN. Perforation in such realistic environment is still a challenge for Western endoscopists. Nevertheless, increasing experience reflects in a remarkable success in endoscopic management of perforation, which eventually can help to overcome such constrain.

**Introduction:** Fecal immunochemical tests (FITs) and flexible sigmoidoscopy (FS) are less invasive alternatives to colonoscopy in colorectal cancer (CRC) screening. FITs detect the majority of CRCs but have limited sensitivity to detect advanced adenomas (AA). FS detects neoplasms in the left colon and rectum only.
**Aims & Methods:** We aimed at assessing the expected diagnostic performance of combined use of FIT and FS. We systematically reviewed screening studies conducted in an average risk population that reported specificities and site-specific sensitivities of FITs for detection of CRC or AA. PubMed and Web of Science were searched until September 4th, 2015. Reference lists of eligible studies were also screened. Sensitivity of FS was derived from colonoscopy results, assuming

| Perforation | 13 (43.3%) | 9 (30%) | 9 (30%) | 10(35.7%) | 41(34.7%) |
| Surgery | 2/13(15.4%) | 2/9(22.2%) | 1/9(11.1%) | 0/10 (0%) | 5 (12.2%) |

0% sensitivity for right- and 100% sensitivity for left-sided neoplasms. Bivariate meta-analyses across studies were used to derive summary estimates of overall sensitivity and specificity of individual and joint application of both tests.
**Results:** Ten eligible studies were identified. Summary estimates (95% CI) of overall sensitivity for detecting CRC and AA were 64% (56–72%) and 26% (21–32%) for FIT alone, 61% (51–70%) and 59% (48–69%) for FS alone, and 86% (80–90%) and 68% (60–76%), respectively, for the combination of both tests. The pooled specificity (95% CI) of FIT alone or in combination with FS was 93% (90– 95%).
**Conclusion:** Combined use of FS and FIT would detect close to 90% of CRCs and two out of three AAs at a high specificity.

## P0162 IS HYBRID ENDOSCOPIC SUBMUCOSAL DISSECTION EFFECTIVE FOR TREATMENT OF LARGE NON-PEDUNCULATED COLORECTAL POLYPS? A SINGLE CENTER EXPERIENCE

**H.R. Cheng**[1], R.M. m. Bogie[2], C.J. Huysentruyt[3], A.A. Masclee[2], S. Sanduleanu[2], J.W.A. Straathof[2]

**Introduction:** There is wide variation in endoscopic treatment of large non-pedunculated colorectal polyps (LNPCP, Rutter et al., *Gut* 2015) among gastroenterology practices. Both endoscopic mucosal resection (EMR) and endoscopic submucosal dissection (ESD) techniques are applied. The hybrid ESD (hESD) is an alternative resection technique, though its effectiveness in the treatment of LNPCPs is unclear. Because the learning-curve of ESD is steep and lengthy, hESD could be helpful as an intermediate step in acquiring technical skills. The aim of this study was to evaluate the complete resection rate and local recurrence rate of EMR and hESD in our daily practice.
**Aims & Methods:** We prospectively included all consecutive patients who underwent endoscopic resection of LNPCPs at a community hospital from January 2008 to October 2015. Follow-up data were collected. We defined LNPCPs as large (≥20 mm) sessile, flat, and depressed colorectal neoplasms or combinations (Paris classification). Overall complete resection rate was defined as complete resection after 1, 2 or ≥3 sessions. Early local recurrence was defined as presence of residual adenoma at first follow-up examination after resection. All procedures were performed by one experienced therapeutic colonoscopist.
**Results:** Thirty-five patients (mean age 74.9 yrs, 74.3% male) with 42 LNPCPs and 56 patients (mean age 69.8 yrs, 48.2% male) with 58 LNPCPs were included in the EMR group vs hESD group, respectively. Lesion characteristics and outcomes of resection are summarized in **Table 1**. Overall complete resection rate after 1, 2 or ≥3 sessions was 76.2%, 78.6% and 85.7% for EMR vs 74.1%, 87.9% and 89.7% for hESD. En-bloc resection rate was similar in the EMR group vs hESD group. Early recurrence rate after EMR and hESD was 23.8% (95% CI 12.1–39.5%) vs 25.9% (95% CI 15.3%-39%) after a median follow-up duration of 5.2 (1.2–24.4) months and 5 (0.7–14.9) months. Referral rate to surgery was similar in both groups. Two (4.8%) and 4 (6.6%) post procedural complications requiring hospital admission occurred after EMR vs hESD, without the need for surgery.

**Table 1:** Lesion characteristics and outcomes of EMR vs hESD. CRC: colorectal cancer, EMR: endoscopic mucosal resection, hESD: hybrid endoscopic submucosal dissection, HGD: high grade dysplasia, LGD: low grade dysplasia.

| Lesion characteristics | EMR (n = 42) | | hESD (n = 58) | |
|---|---|---|---|---|
| **Location** | | | | |
| Proximal | 21 | 50% | 12 | 20.7% |
| Distal | 21 | 50% | 46 | 79.3% |
| **Mean polyp size, mm** | 25.1 | [20-53] | 29.7 | [20-60] |
| **Polyp shape** | | | | |
| Sessile | 20 | 47.6% | 12 | 20.7% |
| Flat, depressed, combinations | 22 | 52.4% | 46 | 79.3% |
| **Histopathology** | | | | |
| Adenoma with LGD | 27 | 64.3% | 26 | 44.8% |
| Adenoma with HGD | 12 | 28.5% | 25 | 43.1% |
| Early CRC | 2 | 4.8% | 7 | 12.1% |
| Sessile serrated adenoma/polyp | 1 | 2.4% | 0 | 0% |
| **Overall complete resection rate** | | | | |
| After 1 session | 32 | 76.2% | 43 | 74.1% |
| After 2 sessions | 33 | 78.6% | 51 | 87.9% |
| After ≥3 sessions | 36 | 85.7% | 52 | 89.7% |
| **En-bloc resection rate** | 19 | 45.2% | 25 | 43.1% |
| **Early recurrence rate** | 10 | 23.8% | 15 | 25.9% |
| **Referral to surgery** | 2 | 4.8% | 3 | 5.2% |
| **Complication rate** | 2 | 4.8% | 4 | 6.8% |
| Bleeding | 1 | 2.4% | 2 | 3.4% |
| Abdominal pain | 1 | 2.4% | 2 | 3.4% |

(continued)

**Table 1**. Continued

| Lesion characteristics | EMR (n = 42) | | hESD (n = 58) | |
|---|---|---|---|---|
| Perforation | 0 | 0% | 0 | 0% |

**Conclusion:** To our knowledge, this is the first study to report outcomes of hESD of LNPCPs in the Netherlands. In this single-center experience, both EMR and hESD appeared to be safe and equally effective in resecting LNPCPs, albeit some cases require multiple sessions. Larger studies are needed to investigate whether hESD can help to speed-up the learning-curve of ESD.

**Introduction:** Appropriate surveillance colonoscopy according to guidelines is crucial for optimal effectiveness of colorectal cancer (CRC) prevention. Family history (FH) of CRC has been associated with an increased use of surveillance, but it is uncertain if first degree relatives (FDRs) are at increased risk of recurrent neoplasia.
**Aims & Methods:** To evaluate the adherence, appropriateness and colorectal findings of surveillance colonoscopy in a population-based screening program (Trentino, Italy) for FDRs of CRC patients. From December 2005 to November 2009, 1252 FDRs had screening colonoscopy. They received a letter in which timing of the next examination was reported, according to the current guidelines; individuals with complex FH (one CRC at age > 60 or two or more CRC) and normal colonscopy were assigned to follow-up within 5 years; individuals with simple FH (one CRC at age > 60 years) and normal colonscopy and those with normal colonscopy and no FH were assigned to follow-up within 10 years; individuals with non advanced adenomas (nAA: 1 or 2 adenomas, size < 10 mm; low grade dysplasia; tubular histology) were assigned to follow-up within 5 years and individuals with advanced adenomas (AA: size ≥ 10 mm; high grade dysplasia; (tubulo)villous histology) or with 3 or more adenomas were assigned to follow-up within 3 years, regardless of the complexity of FH. Exclusion criteria: age > 75 years at the time of the scheduled follow up, emigration from Trentino, significant comorbidities, diagnosis of hereditary CRC syndromes. The program is ongoing; for the study's purpose FDRs were followed from baseline colonoscopy until October 2015. We calculated uptake and appropriateness of colonoscopy; the timing was considerate appropriate if surveillance has been performed a 6-month period around guidelines interval; colonoscopy was classified early (overuse) if performed 6 months before the expected date of follow-up or late (underuse) if performed 6 months after the expected date; we also calculated the yield of finding neoplastic lesions and predictive factors for them. We compared these data with those of 765 individuals without FH who underwent screening colonoscopy in the same period (controls). For the purpose of this study, patients were divided in 6 risk groups according to FH and findings at index colonoscopy: group 1 (AA and positive FH), group 2 (nAA and positive FH), group 3 (no adenomas and positive FH), group 4 (AA and no FH), group 5 (nAA and no FH) and group 6 (no adenomas and no FH). The follow-up of this study is 5 years; for uptake analysis, we considered individuals scheduled within 5 years; for appropriateness and yield of colonoscopy, we considered also individuals who underwent colonoscopy even if surveillance was recommended within 10 years.
**Results:** 722 FDRs and 232 controls were scheduled for follow up within 5 years. Adherence to colonoscopy was significantly higher among FDRs than among controls (93% vs 48%; p < 0.001). On-time colonoscopy was significantly higher in FDRs vs controls (59.6 vs. 18.8%; p < 0.0001). Overuse was observed in 37.3% of group 2 and underuse in 30% of group 1. In multivariate analysis, younger age (≤50 vs >71 yrs, OR 8.87, 95% CI: 2.80 – 28.08; 51–60 vs. >71, OR 9.33, 95% CI: 3.00 – 28.99 and 61–70 vs. >71, OR 6.75, 95% CI: 2.18–20.92) female sex (vs. male, OR 1.43, 95% CI: 1.02 – 1.98), positive FH (simple FH vs no FH, OR 2.71 95% CI: 1.68 – 4.38 and complex FH vs. no FH, OR 15.23, 95% CI: 9.01 – 25.73) and neoplasia at screening colonoscopy (AA vs. no adenomas, OR 2.88, 95% CI: 1.73 – 4.81 and nonAA vs. no adenomas, OR 3.97, 95% CI: 2.62 – 6.02) are predictors of appropriate surveillance. No differences were found in cumulative risk of AA between FDRs and controls when compared according to risk group (group 1 vs group 4: 10.8 vs 16.1% p ns; group 2 vs group 5: 4.0 vs 1.4% p ns and group 3 vs group 6: 4.8 vs 5%). In multivariate analysis AA at follow up was associated with age (HR 1.04; 95% CI 1.00–1.09) and AA at screening colonoscopy (HR 4.52; 95% CI 2.01 – 10.14).
**Conclusion:** In an organized screening program, colonoscopy uptake is high among FDRs, but in 40% of them, timing of surveillance is still inappropriate. FH of CRC does not impact on the yield of AA at surveillance colonoscopy in a 5 year follow-up.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0164 PREVALENCE AND SEX SPECIFIC DIFFERENCES IN LOCALIZATION OF SERRATED POLYPS WITHIN A LARGE AUSTRIAN COLORECTAL CANCER SCREENING COHORT

**Contact E-mail Address:** daniela.sallinger@meduniwien.ac.at.
**Introduction:** Serrated lesions, including sessile serrated polyps/adenomas (SSA) and traditional serrated adenomas (TSA) are known to follow a different histopathological pathway and show different tumor characteristics than conventional adenomas following the adenoma-carcinoma sequence. A study by Brenner et al. showed female sex and proximal localization to be associated with higher prevalence of interval cancer. We therefore analyzed prevalence rates of serrated lesions in a large colorectal cancer screening cohort with regard to gender and localization.
**Aims & Methods:** 127,421 screening colonoscopies performed by 283 endoscopists between May 2012 and April 2016 were assessed. For evaluation of localization, we limited our analyzes to colonoscopies where one lesion was detected (n = 95,211).
**Results:** Patients mean age was 60.15 (SD = 9.62). Overall polyp detection rate was 38.62% (n = 49,206) and serrated lesion detection rate 1.78% (n = 2,277). In 24.22% (n = 23,056) of patients with one lesion, polyps were detected; 27.28% (n = 12,251) of men and 21.16% (n = 10,805) of women. 3.12% (n = 719) of those polyps were serrated lesions [2.60% (n = 318) in male and 3.71% (n = 401) in female screened individuals]. Both, SSA [2.12% (n = 260) of male; 3.03% (n = 334) of female patients] and TSA [0.47% (n = 58) in male; 0.62% (n = 67) in female patients] were detected more often in women than in men. SSAs occur in both, men and women more often in the proximal [60.00% (n = 156) in male; 66.47% (n = 222) in female] than in the distal colon [40.00% (n = 104) in male and 33.53% (n = 112) in female patients]. Interestingly in women TSA were located more frequently in the proximal (62.68% n = 42) than in the distal colon (37.31% n = 25), while in male patients the distribution was the opposite [37.93% (n = 22) proximal and 62.06% (n = 36) distal].
**Conclusion:** In conclusion, serrated lesions occur in 1.78% of patients undergoing screening colonoscopy with higher prevalence in women than in men. Interestingly in women, TSA, as well as SSA were more frequently located in the proximal than in the distal colon compared to male patients, were TSAs were more often located in the distal and SSAs in the proximal colon, which could explain the higher occurrence of interval cancer in female patients and in the proximal colon.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Awareness of quality indicators and the use of international best practice standards can improve the quality of colonoscopy.[1] The European Colonoscopy Quality Investigation (ECQI) Group is a team of experienced colonoscopists, from eight European Union countries. It seeks to improve clinical practice standards by helping colonoscopists perform a self-assessment.
**Aims & Methods:** To assess the quality of colonoscopy in current clinical practice versus quality standards[2, 3] established by the European Society of Gastrointestinal Endoscopy, through the use of a novel online questionnaire.

The questionnaire was tested via 2 pilots. Issues identified in the first pilot were refined for the second which concluded in July 2015.

**Results:** A range of data for individuals, institutions and countries was analysed. Seventy-seven practitioners at 22 institutions in 9 European countries completed questionnaires for 1, 548 colonoscopies. Nine institutions (41%) reported recording adenoma detection rate. Fourteen institutions (64%) used a bowel cleansing scale. Among these, 10 (46%) used the Boston Bowel Preparation Scale and 4 (18%) used their own scale. Caecal intubation rate was used routinely by 52 (68%) practitioners. Other measured quality indicators were used only by a minority of the practitioners (Table 1). The main reasons for colonoscopy were clinical signs and symptoms 694 (45%) including altered bowel habit 264 (17%), rectal bleeding 227 (15%), pain 185 (12%), and other causes 151 (10%). Screening was also a common reason [following a positive screening test in 17%, due to familial risk 6% and without a pre-screening test 5%]. The intended endpoint (IE) was reached in 1, 419 (92%) procedures, and was most frequently the caecum 69%, ileum 27%, or anastomosis 3%; 1% not answered (NA). Reasons for not reaching IE, 72 (5%) were: technically difficult 20 (1%), insufficient preparation 18 (1%), stricture 18 (1%), and pain 11 (1%). Bowel cleansing was rated as adequate on the BBPS in 1, 180 (76%) procedures, and inadequate in 318 (21%) cases; NA 50 (3%).

**Table 1:** Recording of quality measures by practitioners.

| Do you routinely record | Yes (%) | No (%) | Not answered (NA) (%) |
|---|---|---|---|
| Adenoma detection rate? | 29 (38%) | 47 (61%) | 1 (1%) |
| Caecal intubation rate? | 52 (68%) | 25 (32%) | 0 (0%) |
| Polyp detection rate? | 29 (38%) | 48 (62%) | 0 (0%) |
| Polyp removal rate? | 31 (40%) | 44 (57%) | 2 (3%) |
| Polyp retrieval rate? | 25 (32%) | 51 (66%) | 1 (1%) |
| Retraction time? | 36 (47%) | 41 (53%) | 0 (0%) |
| Tattoo rate? | 21 (27%) | 56 (73%) | 0 (0%) |

**Conclusion:** This 2nd pilot has proven the relevance of this questionnaire, enabling colonoscopists to gather information on quality in an easy to use, yet comprehensive manner. It will now be utilised in a wider activation phase across Europe, and may provide useful information on colonoscopy, enabling the identification and improvement of quality issues.

### P0166 THERAPEUTIC STRATEGY OF ESD FOR COLORECTAL TUMORS ACCOMPANIED BY SEVERE DEGREE FIBROSIS IN THE SUBMUCOSAL LAYER

**Y. Tamegai**, H. Osumi, T. Kishihara, F. Tagao, A. Chino, S. Saito, M. Igarashi
*Dept. Of Endoscopy, Cancer Institute Hospital, Tokyo/Japan*

**Contact E-mail Address:** yoshiro.tamegai@jfcr.or.jp.

**Introduction:** The development of the ESD technique has led to changes in therapeutic strategies for early colorectal cancer. The difficulty of one-piece resection of a colorectal tumor using ESD depends on the existence of fibrosis rather than the tumor size. We examined the causes and endoscopic findings of fibrosis in the submucosal layer (SM) in order to establish an appropriate therapeutic strategy for such lesions.

**Aims & Methods:** We performed ESD on 1, 229 colorectal tumors in 1, 197 patients (male: female = 700:497; mean age, 65.9years). Among these 1, 229 cases, 278 cases were accompanied by fibrosis in the SM. These cases were divided into three groups; absence of fibrosis (type A), fibrosis due to benign causes (due to biopsy, recurrence after EMR, etc. type B), and fibrosis due to cancer invasion in the SM layer (type C). The degree of fibrosis was classified into mild (grade 1), moderate (grade 2), and severe (grade 3) degree. In this study, we analyzed these lesions in order to establish a safe and curative ESD technique.

**Results:** These 278 cases accompanied by fibrosis were including 12 withdrawal cases, 96 cases were considered related to cancer invasion (type C), and 182 cases were related to benign cause (type B). The one-piece resection rates were as follows: Type A; 925/751 (97.3%), type B-1; 84/87 (96.6%), B-2:46/52 (88.5%), B-3:25/43 (58.1%), type C-1:46/46 (100%, average SM depth:692.2$\mu$m), C-2:19/20 (95.0%, average SM depth:1, 772.7$\mu$m), C-3:18/31 (58.1%, average SM depth:2, 716.8$\mu$m). We had experienced four cases (Type A:1, Type B:3) with perforation (0.3%) and 14 cases with postoperative bleeding (1.1%). Among these cases complicated with perforation, two cases were treated with clipping conservatively and other two cases required emergent surgery due to peritonitis. The tumors accompanied by mild to moderate fibrosis should be dissected carefully just above the muscle layer. In cases accompanied by severe degree fibrosis (type B-3), ESD becomes more difficult due to the risk of perforation. From the analysis of one-piece resection cases in type B-3, we developed the safe ESD technique to break these difficulties. The feasibilities to complete one-piece resection with type B-3 were as follows: 1) recognition of the narrow translucent area just above the muscle layer, 2) identification of the dissection line by linking with the normal SM layer of both ends of fibrosis, 3) using an endo-clip on the muscle layer to prevent perforation before dissection. Other cases of type B-3 were impossible to design the dissection line due to wide and firm fibrosis. The limitation of ESD is thought to be existed in these lesions from the viewpoint of safety and curability. From these reasons, we established the laparoscopy endoscopy cooperative surgery (LECS) procedure to complete a safe one-piece resection with adequate surgical margin. Otherwise, type C-3 was showing a deep cancer invasion about 3, 000$\mu$m in the SM, and revealed very low one-piece resection rate. From these results, type C-3 endoscopic finding was thought to be an indication of laparoscopic surgery (LAC) due to the risk of lymph node metastasis.

**Conclusion:** The usefulness of ESD for lesions with fibrosis is limited from the viewpoint of safety and curability. We classified the endoscopic findings of fibrosis in order to establish a safe and curative ESD technique. The tumors accompanied by fibrosis of a mild to moderate degree become a standard indication for ESD. And the tumors accompanied by severe degree fibrosis without deep cancer invasion in the SM will become a relative indication of ESD and laparoscopy endoscopy cooperative surgery (LECS) procedure.

### P0167 "OVER-THE-SCOPE" CLIP (OTSC) DECREASES THE SURGERY RATE IN THE MANAGEMENT OF IATROGENIC PERFORATIONS OCCURRING DURING ENDOSCOPIC PROCEDURES

**S. Khater**, G. Rahmi, E. Samaha, L. Abbes, H. Benosman, G. Malamut, C. Cellier
*Hopital Europeen Georges Pompidou, Paris/France*

**Contact E-mail Address:** sherine_khater@hotmail.com.

**Introduction:** Perforation is one of the most serious complications of diagnostic and therapeutic endoscopic procedures. The over-the-scope clip (OTSC; Ovesco Endoscopy AG, Tubingen, Germany) is a relatively new endoscopic tool used for closure of luminal perforations. In contrast to through-the-scope clips, the OTSC is able to capture a larger volume of tissue with a higher compression force.

**Aims & Methods:** The aim of this study is to compare the management of iatrogenic perforations before and after the OTSC was available in our endoscopy unit. We conducted a monocentric retrospective study from June 2007 to June 2015. All iatrogenic gastrointestinal perforations occurring during an endoscopic procedure and detected during the procedure were included in the study, irrespective of the location of the perforation. The study was divided in two equal periods of time: a period before the use of the OTSC, from June 2007 to June 2011, and a period during which the OTSC was available, from June 2011 to June 2015. In both periods, all patients had a multidisciplinary management involving the gastroenterologists, the surgeons and the intensive care physicians. The primary endpoint was to compare the rate of surgery between the two groups. The secondary endpoint was to compare the mortality rates between the two groups.

**Results:** During the first period of the study (from June 2007 to June 2011), 24 perforations were recorded for 29203 endoscopies performed (18 in the colon, 5 in the duodenum and one in the stomach). 15 of the 24 perforations (62.5%) were referred for surgery, and the mortality rate during this period was 8.3% (2/24). During the second period (from June 2011 to June 2015), 16 perforations were reported for 35525 endoscopies performed (9 in the colon, 4 in the duodenum, 2 in the stomach and one in the esophagus). In eleven patients, an OTSC was used to close the perforation, with a technical success achieved in 100% since all patients had an adequate deployment of the OTSC and a complete sealing of the perforation without leakage. However two of these patients had to undergo surgery despite an adequate closure of the perforation: one because of a localized peritonitis and the other because the clip deployed in the sigmoid had captured the right ureter. The rate of surgery during this period was 12.5% (2/16) versus 62.5% ($p = 0.002$), and the mortality rate was 0% versus 8.3% but the difference was not significant ($p = 0.23$).

**Conclusion:** The OTSC system is effective for endoluminal closure of acute iatrogenic perforations and results in a significant decrease in the surgery rate. Based on our experience, all endoscopy units should have a supply of OTSC, with a proper training for endoscopists and nurses on its use.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0168 CURRENT STATUS OF ERAT IN THE MANAGEMENT OFACUTE APPENDICITIS IN CHINA

**B. Liu**, X. Ma
*Department Of Gastroenterology And Hepatology, The Second Hospital Of Harbin Medical University, Harbin/China*

**Contact E-mail Address:** 13704510648@126.com.
**Introduction:** Endoscopic retrograde appendicitis therapy (ERAT) is a new method for the treatment of acute appendicitis. The study aims to analysis the information of ERAT and to prove the safety and efficacy of this method.
**Aims & Methods:** The study was performed on patients underwent ERAT at 8 tertiary hospitals in China from 2009 to 2014. The inclusive criteria: patients clinically suspected of acute appendicitis (Alvarado scores $\geq 5$); the diagnosis can be made by ultrasonography or CT scan. The main outcome was clinical success rate. The secondary outcomes included the success rate of cannulation, time of resumption of diet, hospital stay, hospital costs, complications and recurrent rate.
**Results:** One hundred eighteen of 158 patients underwent ERAT were enrolled into the study. There were 107 of 118 patients (91%) who had successfully cannulating appendiceal orifice. One hundred of them (including 6 patients with peri-appendiceal abscess) had definite diagnosis of acute appendicitis and received ERAT. The median time of abdominal pain and abdominal tenderness relief was 12 hours (Inter quartile range, IQR = 6 hours-72 hours) and 24 hours (IQR = 24 hours -72 hours) respectively. The clinical success rate was 97%. The median time of hospital stay was 3 days (IQR = 2 days–4 days). The median of hospital costs was 8497 RMB (IQR = 5303 RMB-12358 RMB). The rate of complications was 2%. During the median time of following up (12 months, IQR = 5–24 hours), the recurrent rate was 7%.
**Conclusion:** This study confirmed the safety and utility of ERAT for the diagnosis and treatment of acute appendicitis and peri-appendiceal abscess. However, further studies need to further improve the novel method.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The postoperative surveillance of patients treated for colorectal cancer (CRC) is intended to prolong survival by diagnosing recurrent and metachronous cancers at a curable stage, and to prevent metachronous cancer by detection and removal of precancerous polyps.
**Aims & Methods:** To evaluate the rates of local relapses, synchronous and metachronous cancers and adenoma detection (AD) in surveillance colonoscopies and to identify clinical characteristics associated with AD in a cohort of patients with CRC treated with curative intent. Cohort study, single-centre. All patients with CRC, stages II and III AJCC, treated with curative intent, with at least one surveillance colonoscopy between 03/2008 and 07/2015, were included. Surveillance colonoscopies were done in the 1st (or within 3–6 months postoperatively when the baseline colonoscopy was incomplete) and 4th years after CRC resection; Tumours detected during the 1st year after CRC diagnosis were considered synchronous. Statistical analysis was performed with SPSS v20.0, using chi-square test and a multivariate regression model.
**Results:** 391 patients were evaluated; mean age was $65 \pm 10$ years; 59.8% male; tumour location: rectum-51.2%, left colon-29.9%, right colon-18.9%; Baseline colonoscopy: 34.5% had an incomplete colonoscopy, synchronous cancers in 4.3% and adenomas in 31.5%. During follow-up: 36.6% had adenomas and 2.6%: local relapse (n = 5), synchronous (n = 3) or metachronous (n = 2) cancer; 182 patients underwent two surveillance examinations. 1st year AD: 31.7%, 4th year AD: 29.7%. AD in the 1st surveillance colonoscopy was positively associated with AD on the 4th year ($p = 0.001$). After multivariate analysis, the factors associated with AD were male gender ($p = 0.01$) and left colon tumours ($p = 0.011$).
**Conclusion:** The higher adenomas' detection rate in patients with left colon tumours is likely related to the high rate of incomplete baseline colonoscopies due to malignant obstruction or inadequate cleaning. During postoperative surveillance more than one third of patients had adenomas and 2.6% local relapse or synchronous/metachronous cancers, which highlights the importance of endoscopic surveillance.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0170 BEYOND WHITE LIGHT: EMBARKING ON THE FIRST EXPERIENCE WITH THE NEW GREEN-RED-ORANGE LIGHT OPTICAL ENHANCEMENT MAGNIFICATION COLONOSCOPY TO DEFINE SUBTLE INFLAMMATORY CHANGES IN ULCERATIVE COLITIS PATIENTS

**M. Iacucci**[1], X. Gui[2], O. Akinola[3], R. Panaccione[3], S. Ghosh[3]

**Contact E-mail Address:** iacuccim@yahoo.it.
**Introduction:** The i-SCAN Optical Enhancement (OE) with CloseFocus™ (Pentax, Japan) is a recently introduced novel virtual chromoendoscopy (CE) platform which enhances the details of the surface structures of blood vessels and the glandular –crypts structures of the colonic mucosa in much higher resolution than white light. Thus, the OE-iSCAN technology with CloseFocus ™along with novel digital-based CE features (i.e., surface, contrast, tone and OE) have the potential to improve characterization of mucosal and vascular patterns and to increase the accuracy of assessing and predicting grade of inflammation and mucosal healing in ulcerative colitis (UC) patients.
**Aims & Methods:** We aimed to determine whether OE-iSCAN CloseFocus™ (Pentax, Japan) has the potential to assess more accurately the disease activity in patients with UC as compared with white light Mayo endoscopic score, relative to the recently validated Robarts Histology Index (RHI) and the newly defined histological ECAP score.[1] Consecutive patients with UC undergoing the new OE-iSCAN –EPKi 7010 with Close Focus™ (Pentax, Japan) were enrolled for assessment of the grade of inflammation and mucosal healing. Inflammation and mucosal healing in UC were recorded according to Mayo endoscopic subscore (0–3) and CE score was divided into mucosal and vascular pattern as well as overall score. Subsequently targeted endoscopic biopsies were obtained for histological analysis of disease activity (RHI) and the ECAP score. [1]

The diagnostic accuracy of OE-CE was calculated with histology as a gold standard.
**Results:** 50 consecutive patients (41 UC and 9 control) were included in the study (25 men, median age 49 y, range 24–79). The endoscopic appearance by overall OE-iSCAN score correlated with ECAP ($r = 0.70$; $p < 0.0001$) and the accuracy of OE-iSCAN to detect abnormalities by ECAP was 80% (sensitivity 77.7%; specificity 100%). The correlation between Mayo endoscopic score and ECAP score was less strong ($r = 0.432$; $p < 0.001$). Both the OE-iSCAN vascular and mucosal scores correlated with ECAP score ($r = 0.65$ and 0.71 respectively; $p < 0.001$). We also determined correlation between OE-iSCAN score and RHI ($r = 0.61$; $p < 0.01$) and the accuracy to detect abnormalities by RHI was 68% (sensitivity 78.1% specificity 50%). The RHI unlike ECAP only scores acute but not chronic histological changes.
**Conclusion:** The new OE-iSCAN with magnification may accurately reflect histologic abnormalities demonstrated by ECAP histology score which incorporates the full spectrum of acute and chronic histologic abnormalities. This demonstrates that with advanced CE technology, endoscopic assessment of UC is starting to approximate histology.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0171 REMOVAL OF DIMINUTIVE COLORECTAL POLYPS: A PROSPECTIVE RANDOMIZED COMPARATIVE STUDY BETWEEN COLD SNARE POLYPECTOMY AND HOT FORCEPS BIOPSY

**Y. Komeda**, H. Kashida, T. Sakurai, K. Okamoto, M. Kono, R. Tanaka, M. Yamada, T. Adachi, H. Mine, T. Nagai, Y. Asakuma, S. Matsui, M. Kudo
*Gastorenterology And Hepatology, Kindai University, Faculty of Medicine, Osaka/Japan*

**Contact E-mail Address:** y-komme@mvb.biglobe.ne.jp.
**Introduction:** Cold snare polypectomy (CSP) is a common method for resecting diminutive polyps without using submucosal injections or electrocautery. Hot forceps biopsy (HFB) is another method for removing diminutive polyps and is still widely used because it is comparatively easy to manipulate. However, there have been no definitive studies to compare these two techniques directly.
**Aims & Methods:** The aim of this study was to compare the efficacy and safety of CSP and HFB for the removal of colorectal diminutive polyps. The study design was a prospective, randomized, single-center comparison of two methods between CSP and HFB in patients with diminutive colorectal polyps 3–5 mm in size from December 2014 to October 2015. The consecutive patients >20 years old with polyps of target size were enrolled. Exclusion criteria were patients with inflammatory bowel disease, patients with polyposis, polyps suspicious of cancer, and hyperplastic polyps less than 5 mm in the distal colon.
**Results:** After a written informed consent was obtained, 208 patients with a total of 339 polyps were randomized into CSP group (102 people) and HBF group (106 people). After the exclusion of some polyps, 283 polyps (CSP group:148 polyps, HFB group:135 polyps) were evaluated. There was no significant difference between the groups with respect to demographic characteristics of the patients and polyps. The en-bloc resection rate was significantly higher with CSP than HFB (99.3% [147/148] vs 80.0% [108/135], $p < .0001$). The complete resection rate was significantly higher with CSP than HFB (80.4% [119/148] vs 47.4% [64/135], $p < .0001$). Immediate bleeding rate was similar (8.6% [13/148] vs 8.1% [11/135], $p = 1.000$) and hemostasis with clips was successful in all the cases. No perforation or delayed bleeding was encountered. The rate of severe tissue injury to the pathological specimen was higher in the HFB than in the CSP (52.6% [71/135] vs 1.3% [2/148], $p < .0001$). The frequency of polyp retrieval failure was higher in the CSP than in the HFB (9/183 polyps vs 0/156).
**Conclusion:** The results showed that CSP is more effective than HFB for resection of diminutive polyps. Endoscopic en-bloc resection rate and pathologic complete resection rate were both lower in HFB group as histological evaluation in HFB was difficult due to tissue injury. Serious events were not encountered in either group. A further study including long-term follow-up is required. (Clinical trial registration number: UMIN000015016).
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0172 A 5.9MM ENDOSCOPE CAN RELIEVE ABDOMINAL PAIN EFFECTIVELY IN UNSEDATED WATER-AIDED COLONOSCOPY

S. Lee, **Y. Yang**
*Digestive Department, the first affiliated hospital of Harbin Medical University, Harbin/China*

**Contact E-mail Address:** yangyoulinyyl@163.com.
**Introduction:** Although standard colonoscopy by water exchange or using an endoscope with a diameter of 9.2 mm can relatively reduce patients' abdominal pain, there are still around 5% of them who can not endure it and another 5% described the pain as moderate during the procedure.
**Aims & Methods:** Aims: To detect that if abdominal pain can be relieved effectively by using a 5.9 mm endoscope with water exchange in unsedated colonoscopy. Methods: The patients who described the abdominal pain as moderate or serious (the visual analog score > 5) during standard colonoscopy without sedatives by using water exchange were enrolled. All of them were to undergo an unsedated water-aided colonoscopy by using a 5.9 mm endoscope. The abdominal pain score (on a 10-cm unscaled visual analog; 0 = no pain, 10 = serious pain) after the cecal intubation was documented as the primary outcome.
**Results:** A total of 57 patients were enrolled. During the last standard colonoscopy, the proportions of the abdominal pain scores of 5, 6, 7, 8, 9 and 10 were 12% (7/57), 12% (7/57), 23% (13/57), 11% (6/57), 5% (3/57) and 37 (21/57), repectively. The medium pain score was 8. While in this study, the highest pain score was only 3. The proportions of the abdominal pain scores of 0, 1, 2 and 3 were 68% (39/57), 12% (7/57), 12% (7/57) and 7% (4/57), respectively. The medium pain score was 0. It was much lower when compared to before ($P < 0.001$).
**Conclusion:** In this study, only a minority of the patients described the abdominal pain as mild. Whereas the others hardly felt uncomfortable during the procedure by using a 5.9 mm endoscope.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** lmachecar@torrejonsalud.com.
**Introduction:** Gastrointestinal endoscopies are invasive, unpleasant and sometimes painful procedures. Sedation is essential to reduce the anxiety, pain and also to increase their efficacy. Various sedation and analgesia regimens can be used, such as midazolam, fentanyl and propofol. Propofol is considered the best single sedation agent for endoscopy. Our purpose was to compare propofol alone and in combination with fentanyl for sedated colonoscopies.
**Aims & Methods:** We prospectively recorded all the colonoscopies performed in our center between July 2013 and July 2015. During the first year we administered propofol at an initial dose of 0.5–1 mg/kg and a fixed dose of 50 mcg of fentanyl. The second year we only used propofol in monotherapy. Demographic data, anesthetic risk, propofol dose, adverse events, and patient and physician satisfaction (scale: 1 very good; to 4, bad) were obtained. We excluded incomplete procedures, not sedated by the endoscopist, and patients with two endoscopic procedures performed on the same day. Statistical analysis was performed with the SPSS v20.0 software.
**Results:** During the study period 4741 colonoscopies were performed. 2223 were sedated with propofol-fentanyl and 2518 with propofol. Table 1 shows the demographics, propofol dose, complications and satisfaction in both groups. There were significant differences between groups in the mean propofol dose (propofol-fentanyl group: $132.4 \pm 59.5$ mg, propofol monotherapy group: $160.2 \pm 69.1$ mg, $p < 0.05$) and in therapeutic procedures (propofol-fentanyl: 24%, propofol monotherapy: 38.8%, $p < 0.05$). When therapeutic colonoscopies were excluded, the difference in the propofol dose persisted ($154.7 \pm 59$ mg vs $129 \pm 53$ mg, $p < 0.05$). There were no differences in adverse events. No serious adverse event occurred. The satisfaction for patients and endoscopists were very good in the majority of cases.

**Table 1:** Demographic, propofol dose, adverse events, complications and satisfaction in both groups.

| CHARACTERISTICS | PROPOFOL (n = 2518) | PROPOFOL-FENTANYL (n = 2223) |
|---|---|---|
| Age | $55.2 \pm 15.1$ | $55.7 \pm 15.4$ |
| Weight | $73.9 \pm 15.3$ | $73.8 \pm 14.7$ |
| ASA I/II/III (%) | 45.7/52.3/2 | 57.3/40.9/1.8 |
| Propofol Dose | $160.2 \pm 69.1$* | $132.4 \pm 59.5$ |
| Therapeutic (polypectomy)% | 38.8* | 24 |
| Adverse events (%) Desaturation/Bradycardia/Hypotension | 0.4/0.5/0.1 | 0.6/0.6/0.1 |
| Satisfaction (very good-good) Patient/Endoscopist | 99.5/98.3 | 99.8/99.8 |

Data are presented as mean ± SD (range: 95% CI of the mean). Abbreviations:ASA (American Society of Anesthesiology). *P < .005.

**Conclusion:** In our experience, the use of propofol in monotherapy was as effective as the use of propofol plus fentanyl, without decreasing the pleasant perception for the patient and the endoscopist. Additionally, the use of a single drug simplifies the daily practice, reducing the possibility of mistakes with medications.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0174 DIAGNOSTIC ABILITY OF AUTOMATED DIAGNOSIS SYSTEM USING ENDOCYTOSCOPY FOR INVASIVE COLORECTAL CANCER

**Introduction:** Endocytoscopy (EC) enables in vivo observation of nuclei at 380-fold magnification during gastrointestinal endoscopy (1). We have developed a computer-aided diagnosis system for EC imaging (EC-CAD) that provides fully automated classification of colorectal polyps and reported its usefulness (2, 3). The aim of the present study was to evaluate the efficacy of EC-CAD system for diagnosis of invasive colorectal cancer.
**Aims & Methods:** EC-CAD comprises image acquisition, nuclear segmentation, feature extraction, and classification into three pathological groups (non-neoplastic, adenoma and invasive cancer). The classification algorithm was programmed based on 350 features of each image (e.g., area, circularity, diameter, and perimeter of nuclei, and over 300 variables calculated by texture analysis of a whole image). We used a support vector machine to help classify these many features; 5543EC images (2506 non-neoplastics, 2667 adenomatous and 370 invasive cancerous lesions) were used for machine learning in the process of construction of the model. A total of 300 EC images (100 non-neoplastic, 100 adenomatous and 100 invasive cancerous lesions that had not been used for machine learning) are used for test data.
**Results:** Of all the 300 test images, 284 images were assessable with EC-CAD system (94.7%). EC-CAD system provided sensitivity of 84.0%, specificity of 99.5%, positive predictive value of 98.8%, negative predictive value of 92.6%.
**Conclusion:** This study indicates the usefulness of EC-CAD system for diagnosing invasive colorectal cancer. The EC-CAD system has the possibility to develop its diagnosis ability as study sample of invasive cancerous lesions increase.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Colonoscopy screening with the removal of adenomas has been the preferred and most effective strategy to prevent colorectal cancer (CRC). However adenomas are often missed during colonoscopic examination, particularly on the proximal sides of folds and at the flexures. The prototype (EWAVE) Extra Wide Angle View colonoscope (Olympus, Tokyo, Japan) has a 147°- 235° angle lateral/backward view lens and a standard 140° angle forward view lens. Views from both lenses are constructed and displayed as a single image. By improving visualisation behind the folds and flexures this new scope could increase the polyp detection rate (PDR).
**Aims & Methods:** Aims To compare the polyp detection rate between EWAVE and a standard colonoscope in a colonic model with simulated polyps. **Methods** Two colorectal (Koken, Japan) rubber colon models were prepared with 18 and 20 polyps of different size (5–20 mm) at various locations. Seventeen endoscopists, 14 gastroenterology trainees and 3 nurse endoscopists with varying levels of experience performed back to back examinations with the standard colonoscope and EWAVE scope. The order which they performed the procedure (i.e. EWAVE or SD first) was randomised using concealed envelopes. In order to minimise type 2 error, on the 2nd model the endoscopists performed the procedure in reverse order.
**Results:** There was no significant difference in mean insertion time ($p = 0.8$) or withdrawal time ($p = 0.29$) between EWAVE and standard colonoscope (Figure 1). Mean simulated PDR was significantly higher with EWAVE examination when compared to standard colonoscopic examination in both models ($p = 0.026$ and $< 0.0001$). Mean simulated PDR was significantly higher with EWAVE in comparison to the standard colonoscope for polyps in the mid transverse colon (79.4% vs 32.3%, $p = 0.0002$) and mid sigmoid colon (82.3% vs 52.9%, $p = 0.0186$). When the examination was carried out with the standard colonoscope followed by EWAVE, PDR was significantly higher in both models ($p = 0.045$ for model 1 and $p < 0.0001$ for model 2). More significantly no difference was observed when the procedure was performed in the reverse order ($p = 0.28$ for model 1 and $p = 0.08$ for model 2).

| | Model I Standard | Model I EWAVE | P value | Model II Standard | Model II EWAVE | P value |
|---|---|---|---|---|---|---|
| Insertion time (mean+/- SD) | 3.7+/-1.8 | 3.74+/-1.4 | 0.89 | 3.05+/-1.7 | 2.89+/-1.7 | 0.80 |
| Withdrawal time (mean+/- SD) | 4.88+/-1.8 | 4.96+/-2.1 | 0.91 | 4.81+/-3.0 | 3.85+/-1.6 | 0.29 |
| PDR (mean+/-SD) | 14.5+/-1.8 | 15.93+/-1.3 | 0.026 | 15.8+/-1.2 | 18.13+/-1.5 | <0.0001 |

**Conclusion:** Our non-clinical study showed significantly higher polyp detection rates with the novel extra wide angle colonoscope when colonoscopy was performed by moderately experienced colonoscopists. Further clinical trials appear warranted.

## P0176 THE FREQUENCY OF THE INAPPROPRIATE CONVERSION FROM COLONOSCOPY TO SIGMOIDOSCOPY AND ITS POTENTIAL EFFECT ON QUALITY INDICATORS

**S. Beg**[1], S. Sansone[1], J. Schembri[2], J. Patel[3], M.H. Thoufeeq[2], G. Corbett[4], K. Ragunath[1]

**Contact E-mail Address:** sabinabeg@hotmail.com.
**Introduction:** A caecal intubation rate of >90% is a well-accepted quality indicator of colonoscopy and is consequently monitored within endoscopy units. Endoscopists' desire to meet this target may mean that incomplete colonoscopies are recorded as flexible-sigmoidoscopies.
**Aims & Methods:** The aim of this study was to examine whether the conversion of requested colonoscopies is a clinically significant phenomenon. A retrospective review of all flexible-sigmoidoscopies performed between 1st January 2015 and 31st December 2015 was performed across three UK teaching hospitals; Nottingham University Hospitals, Sheffield Teaching Hospitals and Cambridge University Hospitals. Where a colonoscopy was requested but a flexible sigmoidoscopy performed, the patient's records and endoscopy reports were reviewed to determine whether this conversion was appropriate.
**Results:** During the 12-month period, 6839 flexible-sigmoidoscopies were performed. 149 requests could not be retrieved and were therefore excluded from this analysis. Of the 6690 sigmoidoscopy requests reviewed, 2.8% (n = 190) procedures were originally requested as a colonoscopy, with 32 converted prior to commencing the procedure on clinical grounds. 53 of converted procedures were planned polypectomies or post polypectomy assessments in patients who had previously undergone complete visualisation of the colon, and could therefore be considered appropriate to the intended purpose. 105 conversions occurred in patients who had a valid documented indication for colonoscopy and had undergone full bowel preparation. The most common reasons cited included poor bowel preparation (n = 38), technically challenging (n = 30) or clinically inappropriate (n = 26). A clear reason for conversion was not apparent in 11 cases. During the study period 21943 colonoscopies were performed and so inappropriate conversions represent 0.48% of the total requests. This practice was observed amongst 44 endoscopists, when inappropriate conversions were included in individuals' performance data 6 endoscopists fell to ≤90% target caecal intubation target, whilst a further 9 who were already below this target demonstrated poorer performance.
**Conclusion:** A small, but significant number of colonoscopies are converted to flexible sigmoidoscopies at the time of the procedure. This study demonstrates the conversion of colonoscopy to sigmoidoscopy as being a potential limitation of relying on caecal intubation rate alone. Endoscopy units should consider monitoring the rate of inappropriate conversions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0177 CORRELATION BETWEEN ADENOMA DETECTION RATE AND SERRATED ADENOMA DETECTION RATE IN AN UNSELECTED POPULATION

**S. John**, S. Stanley, D. Jones
*Gastroenterology, Logan Hospital, Logan/Australia/QLD*

**Contact E-mail Address:** sneha.john@health.qld.gov.au.

**Introduction:** Serrated lesions of the colon and rectum are precursors of colon cancer. However, they are often difficult to detect and missed serrated lesions in the proximal colon are implicated in post colonoscopy interval cancers. Adenoma detection rate (ADR) has been established as a key quality marker in colonoscopy. Improvements in adenoma detection rates are asociated with a reduction in colorectal cancer risk. The correlation between adenoma detection rate (ADR) and serrated adenoma detection rate (SSADR) is not well established. It is postulated that serrated adenoma detection rate may be a more stringent marker of quality.

**Aims & Methods:** The aim of our study was to assess the correlation between adenoma detection rate and serrated adenoma detection rate in an unselected population. Procedures performed in our endoscopy unit over an 18 month period between July 2014 and December 2015 were considered for the retrospective analysis. ADR and SSADR were calculated for each proceduralist for all procedures they performed during the study period. ADR and SSADR were also calculated separately for all procedures for patients $>50$ years. Detection rates were expressed as number of procedures with at least one adenoma or serrated adenoma detected. Statistical anlysis was performed with Spearman's correlation co-effiecient to assess the strength of association between ADR and SSADR.

**Results:** 13 endoscopists performed 3173 procedures during the study period. 8 of them were physicians and 5 were surgeons. Individual results were as follows.

| Endoscopist | ADR | SSADR | >50yrs ADR | >50 yrs SSADR |
|---|---|---|---|---|
| 1 | 36.2% | 9.8% | 44.2% | 9.6% |
| 2 | 47.8% | 18.3% | 61.4% | 18.2% |
| 3 | 31.3% | 7.4% | 38.9% | 9.2% |
| 4 | 39.8% | 8.2% | 44.4% | 7.8% |
| 5 | 30.2% | 8.9% | 37.4% | 9.2% |
| 6 | 37.9% | 8.9% | 44.3% | 6.8% |
| 7 | 27.7% | 6.1% | 36.4% | 7.6% |
| 8 | 23.7% | 6.1% | 26.3% | 7.5% |
| 9 | 33.3% | 12.3% | 50.0% | 21.0% |
| 10 | 33.5% | 12.7% | 45.2% | 14.5% |
| 11 | 44.0% | 6.3% | 47.0% | 6.0% |
| 12 | 38.1% | 12.2% | 47.8% | 15.7% |
| 13 | 46.6% | 18.8% | 55.3% | 19.7% |

Statistical analysis suggested a positive association between ADR and SSADR ($r=0.56$, p0.04). When the analysis was performed for ADR and SSADR in the patient population $>50$ years, a stronger positive association between the 2 variables was detected ($r=0.64$, p 0.016).

**Conclusion:** Our study suggests a positive correlation between adenoma detection rate and serrated adenoma detection rate in an unselected population. A focus on improvement in quality in colonoscopy with a resultant increase in adenoma and serrated adenoma detection rate is vital in colorectal cancer prevention.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0178 RISK FACTORS FOR DELAYED BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION (ESD) FOR COLORECTAL TUMORS IN JAPANESE PATIENTS

**T. Yoshimine**[1], N. Ogasawara[2], T. Simmura[1], H. Noda[1], Y. Kondou[1], S. Izawa[2], M. Ebi[2], Y. Funaki[2], M. Sasaki[2], K. Kasugai[2]

**Contact E-mail Address:** yoshimine.takashi.363@mail.aichi-med-u.ac.jp.

**Introduction:** Endoscopic submucosal dissection (ESD) has been widely accepted as curative treatment for early gastrointestinal neoplasms. However, when performing ESD for colorectal neoplasms, the intestinal wall is relatively thin, and the lumen is narrow; therefore, the endoscopic manipulation of removing colorectal neoplasms is difficult. The main complications of colorectal ESD are intestinal perforation and delayed bleeding as well as gastric ESD. Therefore, the assessment and prediction of risk factors for complications in colorectal ESD are considered to be necessary. The risk factors for perforation during colorectal ESD have recently been investigated in several studies. However, there were few studies that assessed the risk factors for delayed bleeding after ESD for colorectal tumors. In this study, we aimed to clarify the risk factors for delayed bleeding after colorectal ESD.

**Aims & Methods:** This study included 124 consecutive colorectal neoplasms resected using ESD between April 2013 and November 2015. We classified patients and lesions into two groups on the basis of presence or absence of delayed bleeding and retrospectively compared the clinicopathological characteristics and clinical outcomes of ESD between the two groups.

**Results:** Delayed bleeding occurred in 10 (8.1%) of 124 lesions. Only one case of delayed bleeding required endoscopic hemostasis. With respect to patient-related factors, there was no significant difference between the two groups in mean age, sex, comorbidities, and current use of antithrombotic agents. With respect to lesion-related factors, there was no significant difference between the two groups in mean lesion size, growth pattern, resected tumor size, and mean procedure time. However, lesions located in the rectum (vs colon, $p<0.05$) were significantly related to delayed bleeding. The median number of occurrences of arterial bleeding during ESD was significantly higher in the delayed bleeding group (5, range: 0–20) than in the non-delayed bleeding group (1, range: 0–22) ($p<0.05$). Upon multivariate analysis, 3 and more occurrences of arterial bleeding during ESD (less than 2, odds ratio: 5.95; 95% confidence interval: 1.41–25.14; $p=0.02$) were significantly related to delayed bleeding after colorectal ESD, and lesions located in the rectum (vs colon, odds ratio: 4.54; 95% confidence interval: 0.89–23.16; $p=0.06$) were considered to relate to delayed bleeding after colorectal ESD.

**Conclusion:** This study demonstrated that frequent occurrences of arterial bleeding during ESD and location of tumors in the rectum were significant independent risk factors for delayed bleeding after ESD for colorectal neoplasms. Optimal management for patients with rectal tumors treated by ESD should be considered to avoid delayed bleeding after ESD regardless of patients' characteristics, tumor sizes, or tumor growth patterns.

## P0179 EFFICACY AND SAFETY OF THE NOVEL 1 L PEG AND ASCORBATE BOWEL PREPARATION NER1006 VERSUS STANDARD 2 L PEG WITH ASCORBATE IN OVERNIGHT OR MORNING SPLIT-DOSING ADMINISTRATION: RESULTS FROM THE PHASE 3 STUDY MORA

**R. Bisschops**[1], J. Manning[2], L. B. Clayton[3], R. Ng Kwet Shing[3], M. A. Álvarez-González[4]
[1]*Universitair Ziekenhuis, Katholieke Universiteit Leuven, Leuven/Belgium*

[3]*Clinical Development, Norgine, Harefield/United Kingdom*
[4]*Hospital del Mar, Barcelona/Spain*

**Contact E-mail Address:** raf.bisschops@uzleuven.be.

**Introduction:** Successful colon cleansing enables effective colonoscopy. PEG-based split dosing preparations are the gold standard in cleansing, but many still require a high preparation volume intake. NER1006 is the first 1 L PEG3350 and ascorbate bowel preparation in phase 3 clinical development. The low volume of NER1006 is achieved through the use of ascorbate in the second dose only.

**Aims & Methods:** This phase 3, randomised, multicentre, colonoscopist-blinded, non-inferiority study assessed the efficacy, safety and tolerability of NER1006, administered either as a 2-day overnight (N2D) or 1-day morning (N1D) split-dosing regimen versus a 2 L PEG3350 with ascorbate 2-day overnight split dosing regimen (2LPEG) in patients undergoing a colonoscopy. Two alternative primary endpoints were evaluated: overall bowel cleansing efficacy and 'Excellent plus Good' cleansing rate in the colon ascendens using the Harefield Cleansing Scale (HCS). Secondary endpoints included hierarchical evaluation of lesion detection rates (key), and cleansing assessment using the Boston Bowel Preparation Scale (BBPS; supportive). Patient tolerability, acceptability and compliance were assessed using questionnaires. Safety was monitored through adverse events and clinical laboratory evaluation. The threshold for statistical significance in this study was $P<0.025$ and a 10% margin was used to demonstrate non-inferiority vs. 2LPEG.

**Results:** Patients ($n=283$/group) were randomised to receive N2D, N1D, or 2LPEG. Each respective group had a mean age (SD) of 56.3 (12.03), 54.9 (13.21) and 54.3 (12.48) years, and 120 (42.4%), 131 (46.3%) and 144 (50.9%) males. A high successful overall bowel cleansing efficacy was achieved in all three treatment groups (Table 1). N2D and N1D demonstrated non-inferiority to 2LPEG in overall bowel cleansing efficacy. N2D and N1D showed non-inferiority and superiority vs. 2LPEG in the 'Excellent plus Good' cleansing of the colon ascendens. Both N2D and N1D were non inferior to 2LPEG in detecting adenomas and polyps in the colon ascendens and in the overall colon (Table 1). In addition, N2D showed superiority for polyp detection in the colon ascendens. There were no deaths. NER1006 was not associated with any serious treatment-emergent adverse events (TEAEs). The most frequently reported related TEAEs for NER1006 were nausea and vomiting; and for 2LPEG, nausea and abdominal pain. Compliance levels were high in all treatment groups.

**Conclusion:** When administered as either a 2-day overnight or 1-day morning split-dosing regimen, and compared with 2LPEG, NER1006 was non-inferior in overall bowel cleansing success and lesion detection. It demonstrated a superior 'Excellent plus Good' cleansing rate in the colon ascendens. The 2-day NER1006 demonstrated a superior polyp detection rate in the colon ascendens. The overall tolerability and safety profile of NER1006 was comparable to that of 2LPEG; most TEAEs were mild or moderate in severity and reflected the expected safety profile of the respective treatments. The 1 L NER1006 showed high efficacy and safety in overnight or morning split-dosing administration.

## P0180 COMBINATION ENDOSCOPIC THERAPY USING ENDOSPONGE AND OVER-THE-SCOPE-CLIP TO TREAT LARGE ENDOLUMINAL GI DEFECTS WITH INTRA-PERITONEAL OR THORACIC ABSCESSES

**J. P. Gutierrez**[1], Á. Martínez-Alcalá[2], P.T. Kroener[2], H. Neumann[3], K. Mönkemüller[1]
[1]*Gastroenterology, Basil I. Hirschowitz Endoscopic Center of Excellence, birmingham/United States of America/AL*
[2]*University of Alabama, Birmingham/United States of America/AL*
[3]*Department Of Medicine I, University Hospital Erlangen, Erlangen/Germany*

**Contact E-mail Address:** jpgutierrezaguiar@hotmail.com.
**Introduction:** Management of large gastrointestinal fistulae and perforations is challenging and usually mandates surgery. Novel endoscopic closure methods have increased our ability to successfully occlude endoluminal GI defects. Nonetheless, there still exist situations where the defects are too large to allow for a one-step endoscopic closure. Sponge has been reported to be useful for closure of anastomotic fistulae.
**Aims & Methods:** The aim of this study was to evaluate the success, safety and complications rates of a multi-modal endoscopic approach using sponge, overt-the-scope clips to close large endoluminal GI defects. This is a retrospective, observational cohort study at a single academic institution during an 18-months period evaluating patients with severe and complex of large GI defects. The following over-the-scope clips were used preferentially 12/6 t and 12/6gc. The sponge was cut, sized and then attached to nasogastric or enteric tubes using Nylon 2–0. The tube-sponge device was then introduced into the GI lumen using overtubes of various sizes and lengths, depending on the location of the fistulae.
**Results:** During the study period we treated a total of 11 patients (8 male, 3 female, mean age 57.2 years; range 38 to 73) with large fistulae or perforations. The mean ASA socre was 3.5, range 3–4. Seven patients were critically ill at the time of consultation, with large perforation or intrabadominal abscess. The etiology of the GI defects involving the esophagus (n = 3), stomach (n = 3), small bowel N = 2) and colon (n = 3) were Boerhaave's syndrome n = 2, leak after gastric sleeve n = 2, colorectal anastomotic leak n = 2, lung abscess with tracheoesophageal fistula (n = 1), combined retroperitoneal and pleural abscess (n = 1), enterocutaneous fistula in Crohn's (n = 1), radiation-induced rectovesical fistula (n = 1). The defects were treated sequentially by endoscopic lavage and debridement, followed by insertion of sponge. Once the cavity decreased in size the sponge was exchanged or removed and the smaller diameter defect was closed using one or more over-the-scope clips. In defects larger than 5 cm a stent was also inserted to bridge the lumen. Five patients also underwent placement of a direct endoscopic jejunostomy using balloon-assisted enteroscopy technique. The mean number of procedures was 3, range 2–5. Successful closure of the GI defect and resolution of the abscess was achieved in six patients (54.4%). In three patients closure failed and they underwent surgery. Two patients died from underlying sepsis without improvement of their fistula. There were no adverse events related to the multi-modal endoscopic therapy.
**Conclusion:** The use of multi-modal endoscopic therapy based on endo-sponge and over-the-scope clip appears promising for the treatment of complex GI endoluminal defects, especially when patients are poor surgical candidates and are critically ill. In up to 50% of patients the therapy was successful, suggesting that this approach should be added to the armamentarium of the advanced endoscopist. Endoscopic interventions resulted in resolution of the bariatric complication in 50% of patients, therefore representing a valid alternative to treat these complications. However, some luminal defects associated with these types of surgery are recalcitrant to endoscopic approaches and require definitive surgical intervention to solve the problem. Nevertheless, endoscopy can serve as a bridge to surgery, thus decreasing the size of GI defect and improving the patient's general status.

**Contact E-mail Address:** oconnorsama@gmail.com.
**Introduction:** The majority of polyps removed at colonoscopy are diminutive (≤5 mm) to small (≤10 mm) and there is no consensus method and limited data for the best way for these polyps to be removed.
**Aims & Methods:** We aimed to assess the effectiveness of cold biopsy forceps polypectomy with pre-lift (CBPP) for polyps ≤7 mm. Our aims were to assess completeness of histological resection of this technique, to identify factors contributing to this and assess secondary considerations such as timing, retrieval and complication rates. We conducted a prospective cohort study on consecutive patients receiving a colonoscopy on the British Bowel Cancer Screening program within the Gloucestershire National Heath Service Trust Hospital, Cheltenham General Hospital. Polyps were included if they were ≤7 mm and deemed appropriate by the colonoscopist. A maximum of 3 polyps per patient could be included for analysis. A small pre lift was used prior to complete visual removal of the polyp using cold biopsy forceps. The resected polyp was sent for standard histopathological assessment. The polypectomy site was then removed using endomucosal resection (EMR) with a margin of at least 1–2 mm. This was sent for histopathological analysis to assess completeness of resection. Polypectomy timing, tissue retrieval, number of bites required for visual resection and complications were recorded at the time of the procedure. Basic patient characteristics, colonoscopy indication, procedure time and withdrawal time were recorded.
**Results:** 64 patients were recruited and consented. Of these 42 patients had a total of 60 polyps that were included for pathological analysis after CBPP. Retrieval

was complete for all 60 polyps and there were no complications both during and after polypectomy. Three polyps were excluded from final analysis as they were inflammatory or post inflammatory polyps. Basic patient characteristics were similar in groups with and without polyps included in the study. Procedural times (36.04 vs 26.05 minutes) ($p = 0.01$) and withdrawal (25.36 vs 15.33) ($p = 0.002$) were significantly longer in those patients that had polyps included in the study. Overall CRR of polyps was 86%. Histology, polyp size, number of bites and location of resection did not significantly affect CRR and is summarised in Table 1.

**Table 1:** Complete resection rates (CRR) based on polyp characteristics.

| | Complete resection rate n/N (%) | 95% CI | P value |
|---|---|---|---|
| Overall complete resection | 49/57 (86) | 75–93 | |
| **Histology** | | | |
| Hyperplastic | 14/17 (82.4) | 60–95 | 0.61 |
| Adenomatous | 35/40 (87.5) | 75–95 | |
| **Size (mm)** | | | |
| ≤3 | 19/21 (90.5) | 73–98 | 0.26 |
| 4-5 | 14/15 (93.3) | 74–99 | |
| 6-7 | 16/21 (76.2) | 55–91 | |
| **No of bites** | | | |
| 1 | 25/30 (83.3) | 67–94 | 0.57 |
| 2-3 | 21/23 (91.3) | 75–99 | |
| ≥4 | 3/4 (75) | 27–98 | |
| **Location** | | | |
| Right colon | 20/23 (87) | 69–97 | 0.86 |
| Left colon (except rectum) | 20/24 (83.3) | 65–95 | |
| Rectum | 9/10 (90) | 63–99 | |

**Conclusion:** CBPP appears highly effective for polyps ≤5 mm with CRR >90% and a 100% retrival rate with no complications. Further studies are required to determine the optimal technique for complete histological resection of diminutive and small polyps.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0182 ASSESSMENT OF THE PATIENTS' PERCEPTIONS AFTER AN OUTPATIENT COLONOSCOPY AND THE QUALITY PROCEDURE

**M.I. Portillo Villares**[1], I. Idigoras Rubio[1], E. Arana-Arri[2], L. Bujanda Fernández De Piérola[3], I. Bilbao[1], I. Indart[1], I. Ortega[1], L. Martínez-Indart[2]

**Contact E-mail Address:** mariaisabel.portillovillares@osakdietza.eus.
**Introduction:** In the Basque Country (one of the 17 autonomous regions in Spain), with an approximate population of 2, 200, 000 inhabitants, colorectal cancer (CRC) screening—by immunochemical test (FIT) and colonoscopy under sedation as a diagnostic procedure—was introduced in 2009. Since then, the quality of the colonoscopies performed—regardless of what the reasons for the colonoscopy have been (screening/diagnostic)—has been improving by following the European and Spanish Guidelines and the continuous evaluation of the process and results. However, more than 30, 000 colonoscopies are carried out by the public health service every year and we do not know what the patient's perceptions are at the different stages of the process, disregarding the results of the procedure related to quality criteria.
**Aims & Methods:** To obtain information regarding the perceptions of the patients after a colonoscopy and to compare them with the quality indicators of the procedure based on the European Guidelines of quality assurance on colorectal cancer screening and diagnosis. Cross-sectional study. 1) Design and validation of a survey which includes questions to be asked previous to, during and after the colonoscopy. Aspects covered: waiting time, cleansing method, information provided, discomfort/pain previous, during and after the procedure, attention and global satisfaction. 2) Stratified by 12 different colonoscopy units, depending on the annual volume of colonoscopies. 3) Target population: men and women 40–75 years old, who have had a colonoscopy 24–48 hours previous to the interview. 4) All interviews were done by two trained interviewers via telephone calls and recorded after the patient gave her/his informed consent. 5) Period: November- December 2015. 6) All data related to each colonoscopy were registered including: cleansing, sedation, lesions found, tolerance and adverse effects.
**Results:** 90.8% of the 445 people selected for the sample accepted to take part in the survey. 52.0% were men and 45.6% were less than 60 years old. The main reason to perform the colonoscopy was by symptoms (33.3%), followed by screening (30.6%) with sex differences ($p = 0.02$). Waiting time was less than 30 days in 52.4% of the cases, considered too long by the 19.6% of participants. 89.7% received instructions—offered by primary-care physician or nurse (94.2%)—previous to the colonoscopy and these were considered appropriate by 87.0% of the patients. 80.3% of the cases had an adequate colonic cleansing, but more fasting hours had a significant impact on poor colonic cleansing. In 78.2% of the cases, deep sedation was registered, however only 21 patients reported pain. In 231 (51.9%) cases polyps or CRC were detected. No severe or fatal complications occurred. Global satisfaction score was above 8 (1 to 10 scale), 81.6% disregarding waiting time or pain.
**Conclusion:** The assessment of our patients' perceptions is a very useful tool to improve information to give them, as well as the colonoscopy report. Even though the global satisfaction score was high, waiting time, levels of pain, cleansing methods and the quality of the information provided during all the process should be improved.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0183 COLD SNARING POLYPECTOMY IS A BETTER PROCEDURE FOR RESECTING THE DIMINUTIVE COLON POLYP

**H. Chiba**, M. Nishimura, J. Tachikawa, D. Kurihara, T. Suto, N. Kawano, K. Ashikari, M. Kaai, S. Seki, T. Ida, T. Morohashi, T. Goto
*Dept. Of Gastroenterology, Omori Red Cross Hospital Dept. of Gastroenterology, Tokyo/Japan*

**Contact E-mail Address:** h.chiba04@gmail.com.
**Introduction:** Clinically, cold forceps polypectomy (CFP) may be more popular procedure for resecting the diminutive colon polyp because of the simplicity. However, there remain problems of CFP in regards to the piecemeal resection or a snare cost for resecting the other larger polyps in the same examination, while cold snaring polypectomy (CSP) enables resection for the small-to-large lesions (<10 mm).
**Aims & Methods:** To verify the usefulness of CSP for treatment of the diminutive polyps (<4 mm) compared to CFP, consecutive patients who underwent cold polypectomy (CP) in Omori Red Cross Hospital from 2015 January to 2015 December were retrospectively analyzed. We used 10 mm Captivator TM[II] for CSP and Radial Jaw[TM] 4 Jumbo for CFP (Boston scientific). These patients were divided in 2 groups; patients resected by CSP and patients resected by CFP. We use clips for cases with immediate bleeding or delayed bleeding more than 2 minutes after procedure. Two groups were compared with relative to the medication, tumor characteristics, the rate of complete en bloc resection and complication.
**Results:** 235 patients underwent CP; 98 patients with 175 lesions (CSP group) and 137 patients with 190 lesions (CFP group). Anticoaglant patients were 17 cases (17.3%) in CSP group and 17 cases (12.4%) in CFP group. In addition, 6 cases (35.3%) in CSP group and 8 cases (47.1%) in CFP group underwent CP without cessation of anticoaglant agents. The tumor shape (Is : Isp : Ip : IIa) was 60 : 9 : 1 : 105 in CFP group and 63 : 4 : 0 : 123 in CSP group, respectively. The rate of using clips was similar between two groups (7.4% in CSP, 3.2% in CFP). The rate of piecemeal resection in CFP group (7cases, 3.7%) was significantly higher than that of CSP group (0%) ($p = 0.010$). Cases with poor resected specimen (positive or unclear of tumor margin) in CFP group (70, 36.8%) were more than that of CSP group (46, 26.3%) ($p = 0.033$). There was no difference in complication, such as post-bleeding or perforation, between two groups (0% vs 0%).
**Conclusion:** With regards to completeness of resection or safety in CP of diminutive polyps, CSP performed better. It is difficult to predict what kind of polyps will be detected during the colonoscopy, so CSP will be a better way for treating diminutive polyps.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0184 THE ROLE OF ENDOSCOPIC SUBMUCOSAL DISSECTION IN EARLY-STAGE LOWER RECTAL TUMOUR TREATMENT

**T. Maehata**, T. Akimoto, A. Fujimoto, Y. Ochiai, T. Nishizawa, O. Goto, T. Uraoka, N. Yahagi
*Cancer Center, Keio University, School of Medicine, Tokyo/Japan*

**Contact E-mail Address:** t2maehata@keio.jp.
**Introduction:** The operative method for early stage lower rectal cancer must be selected carefully from the perspective of functional preservation. Compared with other operative techniques, endoscopic resection, especially endoscopic submucosal dissection (ESD), is a minimally invasive treatment that has a high curability rate and using which, surgical resection may be avoided. Therefore, it is also relevant for diagnostic treatment. Furthermore, ESD is considered an effective treatment for lesions close to the anal canal, residual recurrent lesions (after EMR and TEM), and large lesions (≥5 cm), which were considered difficult to resect using traditional endoscopic treatments (Endoscopic mucosal resection:EMR). Therefore, we examined the effectiveness of ESD.

**Aims & Methods:** Of the 67 patients with lower rectal lesions treated with ESD at our hospital we selected patients with: (1) lesions close to the anal canal (17 lesions), (2) residual recurrent and lesions with scaring (eight lesions), and (3) large lesions (≥5 cm) (22 lesions). We examined tumour size, operation time, en bloc resection rate, and accidental symptoms.
**Results:** (1) The size of tumour was 53.7 mm (range 12–150 mm), mean operation time was 96.6 minutes (range 15–250 minutes), curative resection rate was 94.1%, and complication included one postoperative bleeding and one stenosis. (2) The mean tumour size was 45.1 mm (range 10–100 mm), mean operation time was 93.4 minutes (range 15–250 minutes), curative resection rate was 87.5%, and no procedural accident was registered. (3) The size of tumouur was 85.8 mm (range 50–175 mm), mean operation time was 97.9 minutes (range 50–240 minutes), and curative resection rate was 81.8%; procedural accidents included two cases of postoperative bleeding and one of stenosis. En bloc resection was possible in all cases, without residual stenosis.
**Conclusion:** We demonstrated that ESD could give favourable results for lesions that were conventionally treated surgically because of endoscopic treatment difficulties. Surgical treatment could be predominantly invasive and associated with dysfunction, but with ESD, lesions could be resected with complete functional preservation. Therefore, ESD can be considered an effective, non-invasive treatment option, even for lesions that are difficult to treat with traditional endoscopic treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0185 METAL OR PLASTIC STENTS TO RELIEVE OBSTRUCTIVE JAUNDICE PRIOR TO RESECTION OF PERIAMPULLARY TUMORS RESULTS OF A PROSPECTIVE RANDOMIZED, DOUBLE BLIND CLINICAL STUDY

**Introduction:** Albeit that preoperative biliary drainage prior to pancreaticoduodenectomy has been questioned, it remains controversial and clinically most relevant, not the least in light of the emergence of novel therapeutic concepts in the form of neoadjuvant therapies. Therefore we embarked on a randomized clinical study to compare preoperative stenting by use of conventional plastic vs modern self expandable metal (SEMS) stents.
**Aims & Methods:** The sample size estimate of the study was based on a difference in enteric bacterial colonization of intrahepatic bile at the time of resection as a marker of the efficacy of the bile drainage executed by the respective stent type. 92 patients were randomized with 45 allocated to a plastic stent and 47 received a SEMS. Although all patients were originally considered to be eligible for a curative resection, eventually only 59 were found to be suitable for a resection with curative intent. Of these were 32 originally allocated to the plastic stent group and 27 to the SEMS group. Whenever a potential stent dysfunction appeared the patient remained in the originally allocated group even if replacement of the stent was required. Until the time of resection or change of stent, the group affiliation was blinded for the patient as well as the assessor.
**Results:** The patients were well matched regarding clinical and disease-specific characteristics. During the preoperative biliary drainage period more stent dysfunctions requiring stent-exchanges were recorded in the plastic stent group (19% vs 0%, $p < 0.05$). At the time of the operation we were unable to detect any important differences in the macroscopic assessment of the region for stent deployment, nor concerning the microscopic scoring of the grade of inflammation. No differences could be visualized in the amount and composition of the bacterial cultures from the aspirated intrahepatic and gallbladder bile. However, postoperative complications were more frequent in patients being treated with plastic stents (72% vs 52%, $p = 0.11$) with a numerical difference in number of clinical significant leakages (12% vs 3.7%, $p = 0.36$).
**Conclusion:** The need for preoperative biliary drainage remains in light of current development of therapies for periampullary tumors. The results of the current randomized, clinical study offer strong arguments in favor of SEMS to minimize the ensuing postoperative risk profile.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Disconnected pancreatic duct syndrome (DPDS) encountered in severe pancreatitis is characterized by complete transection of the main pancreatic duct (MPD) resulting in a variable portion of the upstream pancreatic gland becoming isolated from the MPD downstream. The upstream gland secretes pancreatic juice that results in a non-resolving percutaneous fistula or pancreatic fluid collection (PFC).
**Aims & Methods: Aim:** To study the impact of DPDS on the endoscopic management of PFCs. **Methods:** This is a retrospective study of patients undergoing endoscopic drainage of PFCs over 12-years (2003–2015). Initial treatment consisted of endoscopic or endoscopic ultrasound (EUS)-guided transmural stenting. If treatment response was suboptimal, multidisciplinary hybrid interventions included drainage by EUS-guided multi-gate technique, dual (endoscopic-radiology) modality technique and/or endoscopic/percutaneous sinus tract necrosectomy. While the transmural stents were removed after PFC resolution during the initial 5 years, they were left permanently in patients with DPDS in the later period. Main outcome measures were to evaluate the impact of DPDS on the need for hybrid treatment, re-interventions, rescue surgery, length of stay (LOS) and overall treatment success.
**Results:** Of 361 patients, 34 (9.4%) were acute collections, 178 (49.3%) pseudocysts and 149 (41.3%) walled-off necrosis (WON). DPDS was more frequent in WON compared to other PFC types (68.3% vs. 31.7%; $p < 0.001$). While there was no significant difference in overall treatment success (85 vs. 91.9%, $p = 0.07$), more DPDS patients required hybrid interventions (31.1 vs. 4.8%, $p < 0.001$), re-interventions (30 vs. 18.5%, $p = 0.03$), rescue surgery (13.2 vs. 4.8%, $p = 0.02$) and longer LOS (median days, 3 [2–10] vs. 2 [1–4], $p = 0.003$). PFC recurrence was significantly less in DPDS patients with permanent transmural stents (17.4 vs. 1.7%, $p = 0.001$). Multivariate logistic regression revealed that the presence of DPDS (OR 2.99, 95% CI 1.06–8.47, $p = 0.039$), WON (OR 3.37, 95%CI 1.41–8.06, $p = 0.006$) and multiple (OR 10.6, 95% CI 4.7–23.6, $p < 0.001$) or large (≥10 cm in size) PFCs (OR 2.66; 95% CI 1.19–5.95, $p = 0.017$) were associated with need for hybrid interventions.
**Conclusion:** DPDS has a significant impact on endoscopic management of PFCs as these patients require more multidisciplinary hybrid interventions for achieving optimal clinical outcomes.

**Introduction:** Is it well known that obstructive jaundice is a frequent cause of access in Emergency Department (ED), with or without cholangitis, and this requires a rapid management with hospitalization in surgical or gastroenterology unit to perform ERCP and to solve the problem. To reduce the problem of overcrowding and too many hospital admissions in Italian EDs were added Brief Observation Unit (BOU), small units located close to the ED in which patients are treated for 48–72 h with a significant decrease of regular admission costs. Aim of our study was evaluate the efficacy of a new model of managing acute obstructive jaundice with ERCP procedures directly from BOU, instead of admitting patients to long and unnecessary periods of hospitalization.
**Aims & Methods:** We enrolled from July 2014 to November 2015, 172 consecutive patients (102 M/70F mean age 66.7 +- 13.5) who came to our ED of Gemelli Hospital with an acute obstructive jaundice with the indication to perform ERCP Routine blood tests including LFTs, chest x-ray, EKG, abdominal ultrasound (or CT scan if needed) were performed and the patient sent urgently to perform ERCP. After ERCP patients were hospitalized for a short observation in the BOU close to the ED in which patients are treated for 48–72 h with a significant decrease of regular admission costs. Aim of our study was evaluate the efficacy of a new model of managing acute obstructive jaundice with ERCP procedures directly from BOU, instead of admitting patients to long and unnecessary periods of hospitalization.
**Results:** Indications for ERCP are summarized in the table.

| | Patients | % of patients | % of discharge after observation |
|---|---|---|---|
| **Removal of bilary stones** | 98/172 | 57% | 71.4% |
| **Bilary Stent Clogging** | 34/172 | 19.8% | 94.1% |
| **Cholangitis with incomplete drainage from other facility** | 3/172 | 1.7% | 0% |
| **Unresectable Pancreatic cancer** | 35/172 | 20.3% | 85.7% |
| **Acute biliary pancreatitis** | 2/172 | 1.2% | 0% |

Overall, 132 / 172 patients (76.7%) were discharged the day after the procedure or within 48 hours from admission ($p < 0.0001$). Biliary stent clogging, unresectable pancreatic cancer and removal of biliary stones are the diseases in which treatment determined a significantly high probability of discharge directly form BOU, differently from cholangitis with incomplete drainage from other facilities or acute biliary pancreatitis, which always require regular hospital admission ($p < 0.0001$). This model allowed to significantly reduce the total costs of management of those diseases (291 vs 1058 USD per day for each patient; $p < 0.0001$).
**Conclusion:** Our study showed the effectiveness of BOU in the managing of patients with acute obstructive jaundice who needs ERCP, especially for those who underwent for removal of biliary stones or biliary stent clogging. All of these patients were admitted to BOU, thereby reducing the cost and time of hospitalization. This approach decreases unnecessary inpatient admission, reduces timing of procedures actuation and allows a faster and appropriate managing of the patients.

**Introduction:** Cholangioscopy for diagnostic and therapeutic purposes of bile duct disorders is important to confirm pathology, assess for disease extent and provide non-surgical therapies.
**Aims & Methods:** A multicenter retrospective review of 300 patients who had SODC performed with therapeutic intent (137) and diagnostic intent (163). A single-use, multi-purpose 10.5 Fr flexible endoscope, all-inclusive design with independent irrigation and a 1.3 mm therapeutic channel (SpyGlass DS$^{tm}$, Boston Scientific, MA, USA) was used in an outpatient setting under monitored anesthesia, all with prophylactic antibiotics and biliary sphincterotomy; Standard imaging findings, endoscopic findings, treatment and pathology were reviewed.
**Results:** (* 1 not biopsied) SODC modified the extent of biliary strictures in malignant strictures in 26/102 (25.4%), all with greater extent. Three patients with OLT stricture did not have a stricture but cast stones. Of the suspected malignant strictures, 1 had portal cholangiopathy, 4 AIC, 1 post-radiation, 1 ischemia, 12 inflammatory. Biopsy performed via SODC (SpyBite$^{tm}$, Boston Scientific, MA, USA) diagnosed cancer in 83 patients with strictures, EHD 34/40 (85%) and IHD 55/62 (90%). The visual appearance by DSOC suggested cancer in 86/102 (84.3%) and benign in 15/19 (79%). In patients with filling defects, a neoplastic process was diagnosed in 5, all suspected to have stones. The majority of patients with dilated bile duct had benign disease whereas the majority presenting with hemobilia had malignant disease. There were no complications noted attributable to DSOC except for one OLT patient with transient cholangitis.
**Conclusion:** DSOC is safe and effective permitting various therapies: it is highly effective in the management of stone disease and it is of significant value in diagnosing malignant lesions, distinguishing benign from malignant strictures secondarily altering diagnosis and prognosis.

**Introduction:** The definition of ''difficult biliary cannulation'' was very heterogeneous in each study although it has been addressed by the European Society of Gastrointestinal Endoscopy (ESGE) in 2014 as any of the following factors: duration of >5 minutes, >5 attempts or >2 pancreatic guidewire passages.
**Aims & Methods:** The aim of this study was to validate the EGSE criteria and identify an optimal timing for rescue technique. Endoscopic retrograde cholangiopancreatography (ERCP) registry was prospectively maintained from November 2014 to December 2015 in six teaching hospitals, Daegu, South Korea. Decision tree analyses with CHAID (Chi-squared Automatic Interaction Detection) was conducted for external validation of the three factors (biliary access duration, attempt, pancreatic guidewire passage) for post-ERCP pancreatitis (PEP) and the cut-off time of switching to rescue biliary access technique.
**Results:** A total of 1, 067 consecutive patients with naïve papilla were included. Selective bile duct cannulation succeeded in 761 (70.4%) patients with first attempt. Overall success for the biliary cannulation was 1, 040 (97.4%) with median time of 5 minutes (range 0.5 – 59) and PEP occurred in 72 (6.7%) patients. In CHAID decision tree analyses, the duration of biliary cannulation was the most decisive factor, whereas the number of biliary attempt was not included in decision tree model. Furthermore, two cut-off times of biliary cannulation were identified, which were 2 minutes with 3.4% PEP and 5 minutes with 11.8% PEP.
**Conclusion:** The duration of biliary cannulation was the most decisive factor for PEP. And if the duration of biliary cannulation exceeds 5 minutes, the risk of PEP is expected to increase by up to 12%. Therefore, we suggest that 5 minutes could be the cut-off time for switching to other rescue technique.

## P0190 EVALUATION OF LEARNING CURVE FOR NEEDLE KNIFE PRECUT SPHINCTEROTOMY

**J. Li**[1], T. Ang[2]

[2]*Changi General Hospital, Singapore/Singapore*

**Contact E-mail Address:** james.ac2000@gmail.com.
**Introduction:** Selective deep cannulation of the common bile duct (CBD) is a crucial step for successful endoscopic retrograde cholangiopancreatography (ERCP). Precut is a technique used when standard techniques fail. It is associated with higher rates of post-ERCP complications such as pancreatitis, bleeding and perforation. These have been reported to be as high as 12–22%. There is currently no consensus on what constitutes adequate training for precut. Moreover, no studies have defined the minimum threshold needed to achieve basic competency. It is therefore relevant to examine the learning curve in precut to optimize training outcomes and patient safety.
**Aims & Methods:** Aim: To determine the number of procedures required before effective and safe precut sphincterotomy can be achieved. Methods: Retrospective observational study of efficacy and safety of needle knife precut sphincterotomy to achieve selective deep CBD cannulation. Data of all patients who underwent ERCP by an experienced Endoscopist in a tertiary centre were reviewed. These data have been maintained in a prospective registry established for quality control. All patients who underwent needle knife precut during ERCP were included. Patient demographics, co-morbidities, ASA status, indication for ERCP, success rate of index precut and complications were recorded. Success was defined as successful selective deep CBD cannulation after precut. Success rate was analysed as a function of number of procedures performed. The minimum acceptable success rate was arbitrarily predefined as 85%, as this is the rate of successful CBD cannulation achievable by most Endoscopists. We predefined a more stringent acceptable threshold for developing a complication as 10% or less in our study.
**Results:** 158 patients underwent needle knife precut sphincterotomy from December 2005 to October 2015 (male 55.1%; mean age 66.2 ± 15.8 years). Commonest indications were cholangitis and obstructive jaundice (61/158, 38.6% and 73/158, 46.2% respectively). 140/158 (88.6%) had ASA scores 2 or less, with the remaining patients having an ASA score of 3. 141/158 (89.2%) patients had a successful index ERCP. The number of procedures to achieve a probability of success of 85% was 6. A success rate of 85% and above was maintained consistently after 13 precut procedures. The exact one-sided binomial test showed that the probability of a successful precut was not statistically higher than the threshold of 85% for the first one hundred precuts. At the 125th precut, the probability of successful index ERCP was significantly higher (91%; $p = 0.029$) than the predefined threshold. However, this became insignificant at the 150th precut performed. 2/158 (1.3%) patients developed bleeding and 5/158 (3.2%) patients had pancreatitis after precut. The risk of pancreatitis was 2.0% after the 50th precut, which was significantly lower than the 10% predefined threshold ($p = 0.034$). For bleeding, the probability of developing this complication was 3.0% at the 75th precut, which was significantly lower than the 10% threshold ($p = 0.016$). Both complication rates were well-maintained below 5.0% beyond the 50th precut performed, with bleeding rates showing a continual decline to 1% at the 150th precut, while pancreatitis rates remained relatively constant between 2.0% to 4.0%. There were no patients with perforation in our study.
**Conclusion:** An experienced Endoscopist requires at least 13 precut procedures to achieve a sustained success rate of 85% or more. Significant improvements in complications below a predefined 10% threshold were achieved after 50 and 75 precuts for pancreatitis and bleeding respectively. Bleeding rates continue to improve beyond this point, but pancreatitis rates remained relatively constant.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The endoscopic treatment of bile duct stones is commonly performed worldwide and has a success rate of 90%. Endoscopic sphincterotomy (EST) is the standard method for enlarging the common bile duct (CBD) opening in the duodenum before stone removal during endoscopic retrograde cholangiopancreatography (ERCP). However, approximately 10–15% of patients present with bile duct stones that are difficult to remove using standard techniques for large or impacted stones or for stone located proximal to biliary structures. There may be technical difficulties related to peri-ampullary diverticulum, coagulopathy or Billroth II gastrectomy. Recently, Dilation Assisted Stone Extraction (DASE) alone or plus EST has been reported as another alternative technique that is more efficient than EST alone for removal of CBD stones.
**Aims & Methods:** We collected and analysed data on 194 patients from 5 centres who underwent DASE (194/3150 of all ERCP done for stone [15%]) from Jan 2013 to Dec 2015 for the treatment of common (large) bile duct stones. All patients had undergone EST**.** Some patients underwent to DASE directly, others after failure of removal stones with standard technique (basket or retrieval balloon). Cannulation of CBD took place by contrast-assisted or wireguide-assisted techniques or after papillary pre-cut. The guidewire was maintained in the CBD while diagnostic catheter was removed and exchanged with dilating balloon catheter. The dilating balloon was advanced over the guidewire and positioned in the mid-portion of the balloon across the major duodenal papilla. The balloon was then inflated gradually with diluted contrast and maintained for 30–60 sec in situ. The size of the balloon was 10–20 mm in diameter according to the diameter of the CBD. Stone extraction after DASE was performed with either stone retrieval baskets or balloon-tipped catheters.
**Results:** 110/194 pts were females (57%), with a mean age of 70.5 (SD 14.9) yrs; 69 pts (39%) had previous EST (minimal sphinterotomy in 46%, 54 (28%) periampullary diverticulum and 8 pts (4%) Billroth II gastrectomy. The wire-guide-assisted technique was used in 90%, pre-cut in 8% and contrast-assisted techniques in 2%. DASE was used as first approach in 69% and after initial failure to remove stone with standard techniques in 31%. The indication for DASE were large stones (78%), intra-diverticular papilla (22%) or coagulopathy just in one patient. DASE was used mainly as an elective (95%) procedure. Technical success (complete dilation) was reached in 94% of patients. The mean final dilation was 15 (±3.7) mm in diameter. In 183 patients (94%) stones were successful removed from the CBD (50% with retrieval balloon and 50% with Basket). Twenty-seven complications (13.9%) occurred: 15 bleeding

| Intraepithelial inflammation 0 1 | #12 33% 67% | #27 33% 67% | #13 46% 54% | #30 33% 67% |
| Papanicolau classification 1 2 3 4 | #12 17% 67% 17% 0% | #27 4% 78% 11% 7% | #13 8% 84% 8% 0% | #30 7% 73% 13% 7% |

#number of patients tested. *p = 0.028; all other variables not significant. Neutrophils, lymphocytes: 0 = absent, 1 = mild, 2 = high. Intra-epithelial inflammation: 0 = absent, 1 = present Cytology classification (Papanicolaou): 0 = no neoplasia, 1 = bening atypia, 2 = mild suspicion of neoplasia, 3 = high suspicion of neoplasia

episodes, 11 pancreatitis and 1 perforation. The majority of these complications were immediate (44%) or occurred within 24 hours (41%). Only one patient died, because of perforation despite surgical treatment. The pancreatitis prophylaxis was done by using in majority rectal indomethacin (58%) or with stent placement (9%).
**Conclusion:** Dilation Assisted Stone Extraction after EST is safe and effective in treatment of large CBD stones and might be useful in patients who have a high risk of complications associated with extensive sphincterotomy, such as diverticula or bleeding tendencies.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0192 CORRELATION OF MAGNETIC RESONANCE IMAGING WITH MARKERS OF DISEASE ACTIVITY AND PROGRESSION IN PRIMARY SCLEROSING CHOLANGITIS

**A. Tenca**[1], K. Lind[2], E. Lantto[2], H. Mustonen[3], S. Boyd[4], J. Arola[5], M.A. Färkkila[1]

**Contact E-mail Address:** ante14@hotmail.it.
**Introduction:** Primary sclerosing cholangitis (PSC) is a cholestatic chronic liver disease, associated with an increased risk of biliary dysplasia and carcinoma. Alkaline phosphatase (ALP) has been used as a marker of disease activity and progression[1], but more reliable and validated surrogate markers are needed[2]. The role of magnetic resonance imaging (MRI) and bile duct enhancement in predicting disease activity and dysplastic changes in PSC is still unclear.
**Aims & Methods:** The aim of the study was to investigate the role of MRI and biliary enhancement as a non-invasive marker of disease activity in PSC in a group of patients, who systematically underwent endoscopic retrograde cholangiography (ERC) surveillance with brush cytology and bile collection. PSC diagnosis was based on patient's history, laboratory tests, histology, cholangiographic findings and clinical follow-up. All PSC patients who underwent MRI and ERC within 3-month interval (n = 50) were retrospectively collected from PSC register of our hospital (n = 614). MRI images were reviewed by two radiologists and biliary enhancement was categorised in <2 mm and >2 mm for intra- and extra-hepatic (IH and EH) bile ducts. Serum ALP, gamma-glutamyl transpeptidase (GGT), alanine aminotransferase (ALT), aspartate aminotransferase (AST), carcinoembryonic antigen (CEA) and carbohydrate antigen 19-9 (Ca19-9) as well as biliary concentration of calprotectin were collected, when available. Brush cytology was reviewed by pathologist for inflammation and dysplasia classification (Table). Categorical and continuous variables were expressed as percentage and median (25%– 75%), respectively. Differences between enhancement and variables were tested with the Fisher's Exact Test and with the Mann Whitney test, when appropriate.
**Results:** Overall, 61 MRI (1.5 Tesla in 51 and 3 Tesla in 10; 3D in 58) and ERC have been performed (14 for diagnosis and 47 for follow-up) in 50 PSC patients (male 38, median age at diagnosis 31; 6–75, median age at MRI/ERC 38; 15–75) and included in the analysis. Table shows variables' distribution according with the different biliary enhancement. A significant difference was found only in Ca19-9 values between MRI biliary enhancement groups in IH (p = 0.028), but not for any other variables.
**Conclusion:** Although MRI is an accurate, cost-effective and non-invasive procedure for diagnosis and follow-up of PSC, its role as an accurate surrogate marker for biliary inflammation and dysplasia seems to be limited.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Management of biliary anastomotic strictures (AS) after liver transplantation remains to be defined.
**Aims & Methods:** To retrospectively report the endotherapy workload for AS and its management in Italy, a questionnaire was sent to the Endoscopy Units of Italian Liver Transplantation Centers.
**Results:** Nineteen of the total 21 Units (90%) returned the questionnaire, twelve being high-volume (>250 ERCPs/year) Units. During 2013, 248 liver-transplanted (LT) patients underwent AS endotherapy and 560 (7.3%) out of 7, 679 ERCPs (median/Center 16, range 5–204) were performed for AS. After unsuccessful ERCP, interventional radiology or surgery was used in 6% and 3.2% of patients, respectively. The ERCP selection criteria included the trend of liver tests in 84% of the Units, associated with AS as documented by non-invasive imaging in 89%. AS was treated by fully covered self expandable metal stent (SEMS) or plastic multistenting (PM) in eight Centers, only by PM in ten and by single plastic stenting in one. SEMS was used independently of the overall ERCP workload and removed after three (37%) or six (63%) months. PM was planned at three-month intervals or at stent dysfunction in 94% of the Units. The duration of endotherapy was planned up to the radiological resolution of the stricture in most Centers. Recurrent AS was treated endoscopically in 79% of Centers, by PM in most Units and by fully covered SEMS in 5%.
**Conclusion:** In Italy endotherapy is confirmed as the preferred first and second-line management option for AS and progressive plastic multi-stenting is most frequently used.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0194 COMPARISON OF ERCP SUCCESS RATE IN EST-NAÏVE PATIENTS WITH ADVANCED AND NON-ADVANCED LIVER CIRRHOSIS

**J. Lee**[1], J. Lee[2], H.W. Kim[1], J. Hwang[1], J. Kim[1]
[1]Gastroenterology, Seoul National University Bundang Hospital, Sungnam/Korea, Republic of
[2]Seoul National University Bundang Hospital, Sungnam/Korea, Republic of

**Contact E-mail Address:** ljckhsh@naver.com.
**Introduction:** Although endoscopic retrograde cholangiopancreatography (ERCP) is one of the standard pancreatobiliary interventional methods, there is limited study about ERCP in patients with liver cirrhosis. The aim of this study is to assess the ERCP success rate in endoscopic sphincterotmy (EST)-naïve patients with cirrhosis.
**Aims & Methods:** In a single tertiary teaching hospital, total 135 EST-naïve patients with cirrhosis who had undergone ERCP were identified between 2003 and 2015. The ERCP success was defined with successful deep cannulation with drainage or stone removal. Advanced liver cirrhosis was defined as Child-Pugh-Turcot classification (CPT) C.
**Results:** Proportion of male sex was 71.1 (%) and median age was 62 years. Major causes of ERCP were CBD stone (60.7%), malignant biliary obstruction (24.4%), and others (14.8%). According to CPT A, B, and C, number of patients was 33, 67 and 35, respectively. The initial ERCP success rates of each group were 93.9%, 94.0% and 80.0%, which showed lower success rate in CPT C group. (P = 0.001). However, success rates increased to 97.0%, 98.5%, and 91.4% after the repeated ERCP trial. As a result, the eventual success rates between non-advanced (97.9%) and advanced group (91.4%) were not statistically different (P = 0.132).
**Conclusion:** Compared with patient with CPT A and B, there is a significant lower success rate of initial ERCP in patients with CPT C. However, there is no difference in final success rates including re-trial of ERCP. ERCP in patients with advanced cirrhosis is feasible with a proper preparation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0195 EFFICACY AND SAFETY OF LEFT LATERAL POSITION FOR ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

**T.Y. Park**[1], J.H. Yoon[1], Y.J. Yang[1], S.P. Shin[1], C.S. Bang[2], K.T. Suk[2], G.H. Baik[2], D.J. Kim[2]
[1]Department Of Internal Medicine, Chuncheon Sacred Heart Hospital, Chuncheon/Korea, Republic of
[2]Internal Medicine, Hallym universitiy College of Medicine, Chuncheon/Korea, Republic of

**Contact E-mail Address:** ptymd@hotmail.com.
**Introduction:** Endoscopic retrograde cholangiopancreatography (ERCP) has been widely used in diagnosis and treatment of pancreaticobiliary diseases. ERCP has been usually performed in the prone position. The prone position for ERCP can facilitate selective bile duct cannulation, offer a better fluoroscopic image of pancreaticobiliary anatomy, and prevent aspiration of gastric contents. However, in cases of difficulty in the prone position, ERCP can be performed in the left lateral position. Compared with the prone position, left lateral position is more comfortable for patients, especially with limitation for cervical movement including cervical cord injury, cervical spine operation, parkinson's disease, muscle contracture due to cerebral infarction, and allow more easy passage of the scope through the pharynx, and useful to secure airway.
**Aims & Methods:** We aimed to evaluate the efficacy and safety of left lateral position for ERCP compared with prone position in this prospective, controlled study. Between August 2015 and March 2016, a total 62 patients with naïve papilla who underwent ERCP at Hallym University Chuncheon Sacred Heart Hospital in Korea, were enrolled. They were randomly assigned to the left lateral position (n = 31) and the prone position (n = 31) before procedure. Age, sex, indication for ERCP, comorbidity, anticoagulation agent, American Society of Anesthesiologists (ASA) class, dose of sedative agent, dose of analgesics, procedure time, type of periampullary diverticulum, pancreatic duct cannulation, acquisition of pancreatogram, need of precut, type of papillary sphincter therapy, success of procedure, and adverse event including pancreatitis, bleeding, infection, cardiopulmonary complication, basket impaction, mortality were analyzed.
**Results:** Demographic data, indication for ERCP, comorbidity, anticoagulation agent, and ASA class were similar in each group. There was no significant difference between the two groups in dose of sedative agent, dose of analgesics, and procedure time. The rate of pancreatic duct cannulation and acquisition of pancreatogram in the left lateral group were significantly higher than those in the prone group (9/30, 30.0% vs. 3/31, 9.7%, P = .046; 7/30, 23.3% vs. 1/31, 3.2%, P = .020). However, there was no significant difference in the rate of post-ERCP pancreatitis between the two groups (6/30, 20% vs. 5/31, 16.1%, P = .694). The rate of technical success and adverse event were similar between the two groups (96.8% and 40% in left lateral, and 100% and 32.3% in prone, respectively). There was no severe adverse event in each group.
**Conclusion:** The efficacy and safey of ERCP in the left lateral position was not inferior to those in the prone position.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0196 QUALITY OF ERCP IN A DISTRICT GENERAL HOSPITAL IN UNITED KINGDOM

**M. G. Eisa**, K. Amin, T. Thomas, I. Khan
*Gastroenterology, Northampton General Hospital, Northampton/United Kingdom*

**Contact E-mail Address:** gaforamf@hotmail.com.
**Introduction:** Endoscopic Retrograde Chlangiopancreatography (ERCP) is a procedure that combines endoscopy and fluoroscopy to visualize the bile and pancreatic ducts. ERCP can be used to diagnose, as well as treat, various conditions. Common conditions treated include gallstones, inflammatory strictures, bile leaks, and cancer. ERCP is generally considered to be a safe procedure, however like any procedure there will always be associated complications such as pancreatitis, bleeding, perforation, infections, and sedation risk. Of the aforementioned complications pancreatitis is the most frequent; occurring in about 3 to 5 percent of people undergoing ERCP.
**Aims & Methods:** The aim of the audit is to evaluate and compare our clinical practice against the recommendations and standards set by the Joint Advisory

Group on Gastrointestinal Endoscopy (JAG) and with British Society of Gastroenterology (BSG) audit of ERCP. We did a retrospective review of all ERCP performed during 12 months period between April 2015 to April 2016. The data was collected from Unisoft Endoscopy database and the Electronic Discharge Note (EdN).

**Results:** Two Gastroenterologists and one Surgeon carried out a total of 209 procedures on 177 patients during the study period. Of which 157 (75.11%) were routine procedures. The mean age was 66.92 years (range: 18–95 yrs.). 112 (63.27%) were females and 43 (24.29%) were patients over 80 years. Indication of ERCP were as follows: Choledocholithiasis/Cholelithiasis- 145 (69.37%), biliary and pancreatic ductal abnormalities (leak, strictures)- 14 (6.69%), stent removal- 8 (3.82%), stent replacement- 4 (1.91%), ampullary/papillary abnormalities (Sphincter of Oddi dysfunction)- 3 (1.43%), no indication listed- 35 (16.74%). Deep CBD cannulation with intended intervention completion was 179 (85.64%); partially/unsuccessful cannulation was 20 (9.56%). Sphincterotomy was carried out in 30 (14.35%) and stone removal in 33 (15.78%). Procedure related complication was 5 (2.39%)- of which pancreatitis 3 (3.26%) and minor bleed 2 (0.95%). 2 (0.95%) patients were given Midazolam >5 with no subsequent complication. Patient performance state (ASA) was recorded in 57 (27.27%), of which 21 (10.04%) had ASA score of 3 or more.

**Conclusion:** In this study group the primary duct cannulation rate was above the national average and to expected JAG standards. Complication rates and procedure-related, well within expected national average and JAG standards. Less than third of patients had their ASA status recorded; this requires more attention in future, as it is essential in order to determine the appropriateness of the procedure.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic papillary large balloon dilatation (EPLBD) is increasingly accepted as an appropriate option in management of difficult common bile duct (CBD) stones. Given the minor incision necessary, the short procedure time, the reduced requirement for mechanical lithotripsy (ML) and the low frequency of adverse events, EPLBD may be applied in patients who cannot tolerate wide endoscopic biliary sphincterotomy (EBS).

**Aims & Methods:** The aim of our work was to evaluate the safety and efficacy of EPLBD with a relatively large balloon (15–20 mm) in extraction of difficult CBD stones. 40 patients with calcular obstructive jaundice and dilated CBD (≥10 mm) subsequent to a single large stone (≥10 mm) or multiple stones (≥3) were recruited. All patients were subjected to endoscopic retrograde Cholangio-Pancreatography (ERCP) with limited sphincterotomy and large balloon dilatation followed by stone extraction using extraction balloon or dormia basket without lithotripsy, stenting or further ERCP sessions.

**Results:** Successful stone extraction was achieved in 34 patients (85%), while failure of stone extraction occurred in 6 patients (15%). The noted complications were minimal pancreatitis in 4 cases (10%), mild pancreatitis in 2 cases (5%), cholangitis in 2 cases (5%) and bleeding in 2 cases (5%), while no recorded cases of perforation or mortality subsequent to our procedure.

**Conclusion:** EPLBD is a safe and efficient procedure for extraction of difficult CBD stones and may be advisable in patients with high bleeding risk or abnormal papillary anatomy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0198 COST-EFFECTIVENESS OF CYANOACRYLATE GLUE INJECTIONS VERSUS ENDOSCOPIC ULTRASOUND GUIDED TREATMENT IN THE MANAGEMENT OF GASTRIC VARICES

**C. Robles-Medranda**[1], M. Valero[1], M. Puga[1], J. Ospina[1], M. Soria[2], H. Alvarado[1], H. Pitanga Lukashok[1]

**Contact E-mail Address:** carlosoakm@yahoo.es.

**Introduction:** Bleeding from gastric varices (GV) is severe and the mortality associated is high. Treatment with cyanoacrylate (CYA) glue injection has demonstrated higher hemostasis (>90%) and lower rebleeding rates compared to band ligation or sclerotherapy. However pulmonary embolism is one of its main adverse effects. It is a serious and sometimes fatal complication that is seen in 4.3% of the cases and depends on the volume of glue injected. Currently endoscopic treatments with CYA can be performed under direct visualization using a standard gastroscope or by Endoscopic Ultrasound (EUS) guidance with the injection of CYA alone or in combination with coils. Treatment under EUS guidance may improve results by precise targeting of the varix lumen and afferent feeding vein, allowing obliteration with less volume of CYA than the "blind" injection with standard endoscope. Coils are small metal devices with attached synthetic fibers that work retaining the CYA within varix lumen, reducing the volume needed for obliteration and risk of embolism. Variceal bleeding is the most costly of all digestive diseases in terms of hospitalization charges and there is little information in the literature on the economic impact of these treatments.

**Aims & Methods:** The aim of this study is to compare cost-effectiveness of GV treatment with two different techniques, CYA glue injections using a standard gastroscope vs. coils plus CYA guided by EUS. **Methods:** observational, descriptive and retrospective study with case collection from November 2014 to March 2016. Patients included had GV type GOV II or IGV I according to the to the Sarin classification. The indication of treatment was active bleeding, history of previous bleeding due to GV (secondary prophylaxis) or high-risk GV according to Baveno VI consensus (primary prophylaxis). Outcome measures included costs of the procedure, technical success, rebleed and complications rate.

**Results:** 36 patients (19 in CYA group and 17 in coils + CYA group) were included. The mean age was 61.45 (7–87) years old and 20 (55.5%) were men. 24 had GOV II GV and 12 IGV I. All patients enrolled in CYA group had active bleeding as the mean indication, unlike coils + CYA group that had active bleeding (41.2%), secondary prophylaxis (47.1%) and primary prophylaxis (11.8%) as indications. Mean varix size was 21.5 mm and mean number of procedures 1.23 (1.47 in CYA group and 1 in coils + CYA group). CYA group used more volume of glue than coils + CYA group (2.15 ml vs. 1.65 ml, p 0.018) and the mean number of coils was 2.1. There was a high technical success in both groups (CYA 84.2% vs. coils + CYA 100%) with a complication rate of 15.8% (2 pneumonia and 1 death) in CYA group; and 11.8% (1 episode of fever and 1 transient abdominal pain) in coils + CYA group (Table 1). Although mean total procedure cost was lower in CYA patients (US $1350.3 vs. US $ 2978) there was a significant difference in mean hospitalization cost (CYA = US $9710.6 vs. coils + CYA = US $70.46).

**Conclusion:** The overall cost showed that GV treatment with coils + CYA EUS-guided is more cost-effective than the use of CYA alone.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Radiation therapy (RT) has an important role in the treatment of oesophageal and rectal cancer. Delineation target of the lesion is often difficult during RT. Some series showed the potential use of fiducial markers (FM). FM has a supposed role to target the lesions, although there was no proved data in the literature.

**Aims & Methods:** Prospective registered study with inclusion from September 2014 to December 2015. Criteria for inclusion were oesophageal or rectal cancer with indication of RT, and lesions could be be crossed with EUS-scope (Slim US-scope, EG-3270UK). All patients underwent a simulation CT-scan before FMP and after FMP. All patients underwent gastroscopy, EUS, and CT-scan before the first simulation CT-scan. FM were placed under EUS and X-Ray guidance in a sedated patient. FM were gold markers of 5 mm length preloaded in a 22 G needle (Cookmedical®). FM were placed at the top and at the inferior part of the tumour. In case of visible lymph nodes, FM were placed after

CYA: cyanoacrylate, F: female, M: male, GV: gastric varix, GOV: gastro-esophageal varices, IGV: isolated gastric varices; US $: United States Dollar

confirmation of metastic lymph nodes on pathological EUS-FNA reading. Evaluation criteria for usefulness of FMP in delineation target was the variation of growth tumor volume (GTV) and clinical target volume (CTV) before and after placement of FM. The GTV contours and the CTV contours were outlined in 3 dimensions. Modifications between both CT scan were considered as significant if axial (x) or coronal (y) variation was ≥5 mm or sagittal variation was ≥10 mm, or if target volume variation was ≥20%.
**Results:** 29 patients were included. All fiducial procedures could be achieved. 2 patients were excluded. One for unavailability of FM, one because of technical problem with the simulation CT-scan before FMP. A total of 15 oesophagus cancer and 12 rectal cancer were studied (13 and 10 men respectively). No complication were reported. FM migration occurred for one FM in one patient. The GTV changed significantly in 89% of the cases (13/15 for oesophagus cancer, 11/12 for rectal cancer), mainly due a difference in sagittal dimension with a mean of 21 mm and >10 mm for 67% (18/27) of the patients. The difference in sagittal dimension was >10 mm for 80% (12/15) of oesophagus tumours and for 50% (6/12) of the rectal tumours.
6 (1 oesophagus, 5 rectum) patients had a significant movement of the isocentre with a mean of 23 mm [6–40mm]. The oesophagus tumour was not seen with TDM in one patient. One (7%) patient had a distant lymph node metastasis in oesophagus cancer not seen with CT-scan.
GTV variation had also impact on global GTV and clinical tumor volume (CTV) in respectively 96% (15/15 oesophagus cancers and 11/12 rectal cancers) and 96% also (14/15 oesophagus cancers and 12/12 rectal cancers).
**Conclusion:** Placement of FM has an impact in target delineation in RT for oesophagus and rectal cancer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0200 HIGH YIELD OF CORE TISSUE FOR HISTOLOGICAL ANALYSIS WITH HIGH DIAGNOSTIC ACCURACY OF EUS-FINE NEEDLE BIOPSY USING THE 22 G AND 25 G SHARKCORE™ NEEDLES: A MULTICENTER RETROSPECTIVE STUDY

**M. Rimbas**[1], F. Attili[2], A. Fantin[3], C. Fabbri[4], S. Carrara[5], G. Gibiino[6], L. Di Maurizio[7], A. Repici[5], A. Larghi[2]

**Contact E-mail Address:** mrimbas@gmail.com.
**Introduction:** Procurement of tissue core biopsy samples may overcome some of the limitations of endoscopic ultrasound-guided fine-needle aspiration (EUS-FNA). Novel designs of EUS-guided biopsy needles (EUS-FNB) may improve the procurement yield and the diagnostic capability.
**Aims & Methods:** We aimed to assess the safety, yield for a histological sample and diagnostic accuracy of the newly developed 25-gauge (25 G) and 22-gauge (22 G) SharkCore™ histology needles. The innovative needle tip geometry is designed with six cutting edge surfaces and an opposing bevel to acquire cohesive units of tissue with intact architecture and to minimize tissue fracturing. Data from consecutive patients with solid lesions who underwent EUS-fine needle biopsy (EUS-FNB) using the 25 G and 22 G SharkCore™ needles were retrospectively retrieved from the database of 4 tertiary care centers. A visible core was defined as an architecturally intact-looking piece of tissue deemed sufficient for histologic evaluation. Samples positive for malignancy were considered diagnostic. For patients with negative EUS-FNB, surgical specimen evaluation, results of other diagnostic investigations and/or long-term clinical follow-up (6 months) were used to establish the definitive diagnosis.
**Results:** During the study period, 147 patients underwent EUS-FNB using the SharkCore™ needles. Definitive diagnosis was available for 141 (96%) of them (M/F: 73/68; mean age 64 ± 12 years). Ten patients underwent sampling of two sites for a total of 151 solid lesions biopsied. There were 110 (72.8%) pancreatic lesions, 11 (7.3%) hepatic/bile duct lesions, 14 (9.3%) submucosal tumors, and 16 (10.6%) other lesions biopsied, with a mean diameter of 2.9 ± 1.1 cm (Table). In 80 cases the 22 G needle was used, while the 25 G needle was utilized in the remaining 71 cases. A mean of 3.5 ± 1.2 passes per lesion site was performed, without any major complications. A visible core was procured in 90.1% of cases, while in 6.0% a specimen for cytologic evaluation was obtained. In 80.1% of cases a definitive diagnosis of malignancy was made, while in 19.9% there was a benign condition. Considering malignant vs. non-malignant disease, the sensitivity, specificity, positive predictive value, negative predictive value, positive likelihood ratio, negative likelihood ratio, and diagnostic accuracy were 92.2% (95% CI, 86.1–95.8), 98.4% (95% CI, 86.3–99.8), 99.6% (95% CI, 95.9–100), 76.3% (95% CI, 61.1–86.8), 57.1 (95% CI, 3.65–844.18), 0.079 (95% CI, 0.043–0.146), and 94.0% (95% CI, 90.1–98.0), respectively. Regarding needle size, the visible core procurement yield and diagnostic accuracy (malignant vs. non-malignant disease) for the 25 G and 22 G needles were 83.1% vs. 96.3%, p < 0.001 and 90.1% vs. 97.5%, p = 0.08, respectively. 7 of the 9 non-diagnosed cases belonged to the 25 G subgroup, despite the fact that there was a tendency of performing more needle passes with the 25 G than with the 22 G needle (3.7 ± 0.2 vs. 3.4 ± 0.1, p = 0.06). The presence of a visible core was associated with a higher diagnostic accuracy for malignancy (97.1% vs. 66.7% in procedures where no

visible core has been obtained, $p < 0.01$). The core procurement yield was further influenced by the number of passes: for 3 or more passes, the core procurement yield was 95% vs. 75% for 2 or less passes ($p < 0.01$). However, this did not influence diagnostic accuracy.

| Lesion location | N | Median no. of passes (n, range) | Visible core present (%) | Diagnostic yield (%) (malignant vs. non-malignant disease) |
|---|---|---|---|---|
| **Pancreas** | 110 | 3.6 (1-7) | 90.1 | 94.6 |
| **Liver/bile ducts** | 11 | 2.5 (2-3) | 81.8 | 81.8 |
| **Submucosal tumors** | 14 | 3.9 (3-5) | 85.7 | 92.9 |
| **Other** | 16 | 3.1 (2-5) | 100 | 100 |

**Conclusion:** The 22 G and 25 G SharkCore™ needles are able to gather tissue for EUS-FNTA of solid lesions with very good procurement and diagnostic yields after a minimum number of passes. The 22 G-size needle showed superior core procurement and diagnostic capabilities. However, large prospective studies on their performances are warranted to further evaluate the use of these novel types of needles.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0201 UTILITY OF CONTRAST-ENHANCED ULTRASONOGRAPHY FOR DIFFERENTIAL DIAGNOSIS OF BILIARY TRUCT DISEASE

**H. Miwa**[1], K. Sugimori[1], K. Sanga[1], Y. Goda[1], K. Irie[1], T. Ishii[2], T. Kaneko[3], K. Numata[1], K. Tanaka[1], S. Made[1]

**Contact E-mail Address:** miwa@yokohama-cu.ac.jp.
**Introduction:** Although contrast-enhanced ultrasonography (CE-EUS) provides high spatial resolution and enable precise blood flow imaging, few study have reported its use for biliary tract disease.
**Aims & Methods:** The aim of this study is to investigate the value of CE-EUS for differential diagnosis of biliary tract disease. The present study enrolled 53 consecutive patients with confirmed biliary tract disease who underwent CE-EUS in Yokohama City University Medical Center between April 2009 and December 2015. The cohort included 36 men and 17 women, with a mean age of 61.4 years. EUS examinations were performed using UE260 and UCT260 (Olympus Medical Systems, Tokyo, Japan). Ultrasound image analyses were performed using Prosound $\alpha$10 (Hitachi Aloka Medical Systems, Tokyo, Japan). When B-mode US detected biliary tract disease, a bolus infusion of contrast agent (15 μL/kg Sonazoid (Daiichi Sankyo, Tokyo, Japan)) was administered, and contrast harmonic images were obtained for 90 s. All clips were stored on a hard disk, and blinded investigators evaluated the intensity, heterogeneity, and persistence of contrast effect retrospectively. Then, the sensitivity, specificity, and accuracy for diagnosis of malignant lesions were determined on the basis of characteristic findings.
**Results:** Final diagnoses were based on histological findings, and benign status was confirmed by follow-up for at least 1 year. Nineteen patients were found to have benign lesions (7 patients had sclerosing cholangitis and 12 had conditions), and 33 had malignant lesions (25 had extra-hepatic cholangiocarcinoma, 3 had gallbladder cancer, and 4 had other cancers). CE-EUS could detect enhancement in all lesions. After contrast infusion, 17 cases (89%) of benign lesions and 27 cases (81%) of malignancies showed hyper-enhancement in the arterial phase. Fifteen cases (79%) of benign lesions showed persistent enhancement in the venous phase, while 13 cases (61%) of malignancies showed a decrease in enhancement ($p < 0.05$). In the 39 cases in which strictures were found on B-mode EUS (12 benign lesions and 27 malignant lesions), luminal narrowing was seen on CE-EUS in 9 cases (75%) of benign lesions and but no cases of malignancy. The sensitivity, specificity, and accuracy of CE-EUS for differentiating benign lesions from malignancies using these findings were 94%, 73%, and 85%, respectively.
**Conclusion:** CE-EUS was useful to differentiate benign and malignant case of biliary tract disease in the present study. We believe this modality has clinical benefits, especially, for lesions for which are difficult to reach the pathological confirmation of diagnosis is difficult.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0202 ETOMIDATE VERSUS PROPOFOL ADMINISTRATION DURING ENDOSCOPIC ULTRASONOGRAPHIC PROCEDURES: A PROSPECTIVE DOUBLE-BLINDED RANDOMIZED CONTROLLED TRIAL

S.W. Park, **J.H. Kim**
*Department Of Internal Medicine, Hallym University College of Medicine, Gyeonggi-do/Korea, Republic of*

**Contact E-mail Address:** mdkjh@hallym.or.kr.
**Introduction:** Although a growing body of evidence demonstrates that propofol-induced deep sedation can be effective and performed safely, cardiopulmonary adverse events have been frequently observed. Etomidate is a new emerging drug that provides hemodynamic and respiratory stability, even in high-risk patient groups.
**Aims & Methods:** The objective of this study was to compare safety and efficacy profiles of etomidate and propofol for endoscopic sedation. A total of 128 patients undergoing endoscopic ultrasound were randomized to receive either etomidate or propofol blinded administered by a registered nurse. Endpoints comprised cardiopulmonary adverse events, efficacy, patient satisfaction, and sedation profiles.
**Results:** The incidence of oxygen desaturation (4/64 [6.25%] vs. 20/64 [31.25%], $P = 0.001$) and respiratory depression (5/64 [7.81%] vs. 21/64 [32.81%], $P = 0.001$) was significantly lower in the etomidate group than in the propofol group. All cardiovascular episodes were self-limited, controlled completely without special intervention, and lacked significant difference between both groups. The frequency of myoclonus was significantly higher in the etomidate group (22/64 [34.37%]) compared with the propofol group (8/64 [12.50%]) ($P = 0.012$). Repeated measure analysis of variance revealed significant effects of sedation group and time on systolic blood pressure (etomidate group > propofol group). Physician satisfaction was greater in the etomidate group than in the propofol group.
**Conclusion:** Etomidate administration resulted in fewer respiratory depression events and had a better sedative efficacy than propofol; however, it was more frequently associated with myoclonus and increased blood pressure during endoscopic procedures.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0203 ENDOSCOPIC ULTRASOUND-GUIDED INJECTION OF GEMCITABINE-LOADED IRON OXIDE NANOPARTICLES IN THE PORTAL VEIN AS A THERAPEUTIC OPTION FOR PANCREATIC CANCER METASTASES

**B. S. Ungureanu**[1], D. Pirici[2], A. Fifere[3], C. Teodorescu[4], A. Săftoiu[1]

[3]*Petru Poni Institute of Molecular Chemistry, Iasi/Romania*
[4]*National Institute of Material Physics, Magurele/Romania*

**Contact E-mail Address:** boboungureanu@gmail.com.
**Introduction:** The poor prognosis of pancreatic cancer (PAC) has developed a continuous need for new potential therapies. Because most of the times PAC is diagnosed in highly advanced stages, when hepatic metastases have occurred, chemotherapy remains the main option for cancer patients. Gemcitabine is currently used for many cancer types including PAC, however the maximum tolerated dose in humans is restricted by its side effects on healthy cells.
**Aims & Methods:** Our objective was to assess a new developed gemcitabine-loaded iron oxide nanoparticles (IONs) after portal vein injection in an experimental pig model. Six domestic pigs were used for our study design, of which three were injected under endoscopic ultrasound guidance with gemcitabine-IONs in the portal vein and other three in the jugular vein. All endoscopic equipment was intended for animal use only, while the procedures were performed according to the national and international guidelines for animal use in research. After identifying the portal vein, 2 ml of gemcitabine-IONs were injected using a 19 gauge EUS-FNA needle, with live monitoring on EUS-imaging. A day after the procedure, necropsy was performed and liver, heart, spleen, kidneys and pancreas were harvested and sent to pathologic examinations, mass spectroscopy and x-ray diffraction assessment.
**Results:** No technical difficulties were encountered, with a mean time per procedure of 5.23 minutes. The portal vein was easily identified, with no major complications or additional bleeding. Pathologic examinations with multispectral imaging assessment showed large ION deposits in all macrophages-like organs, especially in the liver ($6526.35 \pm 290.62 \mu m^2$) after portal vein injection. Liver iron concentrations were significantly higher after portal vein injection than systemic procedures. Hepatic concentrations of gemcitabine were significantly higher after portal vein injection than systemic injection.
**Conclusion:** Gemcitabine – ION levels after portal vein injection were significantly higher in the liver which indicated that the gemcitabine was still loaded on the nanoparticles and may result in a prolonged drug exposure. EUS-guided injection of gemcitabine loaded iron oxide nanoparticles may offer better outcomes on therapeutic options for hepatic metastases for PAC.

## P0204 THE HIGH DIAGNOSTIC PERFORMANCE OF EUS-ASSISTED SINGLE- INCISION NEEDLE-KNIFE (SINK) BIOPSY MAY AVOID FURTHER ENDOSCOPIC FOLLOW-UP OF SMALL UPPER SUBEPITHELIAL TUMORS

**C. De La Serna Higuera**[1], I. Peñas-Herrero[1], B. Madrigal-Rubiales[2], A. Loza[1], R. Sanchez-Ocana[1], P. Gil-Simon[1], M. Pérez-Miranda[1]
[1]*Gastroenterology, Rio Hortega Hospital, Valladolid|Spain*
[2]*Pathology, Rio Hortega Hospital, Valladolid|Spain*

**Contact E-mail Address:** csernah@hotmail.com.

**Introduction:** The optimal management strategy for small subepithelial tumors (s-SETs) is unknown. Current guidelines recommend EUS to characterize upper SETs and annual follow-up for those smaller lesions (≤2 cm). However, this approach is not evidence-based and is associated to a very poor compliance (< 50%, Kushnir et al, *GIE* 2015). EUS-guided SINK biopsy may provide and all-at-once definitive diagnosis able to save from iterative endoscopic procedures. The study is aimed at assessing the histologic/diagnostic performance and outcomes of EUS-SINK biopsy for upper s-SETs as a single procedure.

**Aims & Methods:** This is a retrospective chart review of a prospectively-mantained database from April'10 to Oct'15 including all consecutive patients with small (≤2 cm) foregut SETs referred for EUS study. They all underwent radial EUS study and then, linear EUS exploration for size/layer/morphological characterization and doppler to discard presence of vessels. Then a needle-knife sphincterotome was used in endocut mode at 30–60 W settings to perform a 6 mm linear incision over the highest convexity area of the target lesion. Finally, a conventional biopsy forceps was deeply introduced through the hole to retrieve 3 to 5 samples. Patients were discharged one hour thereafter and contacted by telephone one and seven days later to discard complications.

**Results:** 93 patients with SETs were referred (M/F: 50/43; mean age: 60.23, range 20–89) Small SETs: 42/93 (45.16%): mean diameter s-SETs: 1.19 cm (0.65–2). Organ location: Esophagus (5) Stomach (31) Duodenum (6). Echolayer: 2nd /3rd /4th: 5/24/13. Only 3 samples were non-diagnostic or included just mucosal tissue: Yield of SINK biopsies: 39/42: 92.85%. Histologic diagnoses- table 1-: Lipoma (2), leiomyoma (3), GIST (15), Abrikosoff's tumor (1), heterotopic pancreas (13), gangliocytic paraganglioma (1), Inflammatory fibroid polyp (5), duplication cyst (1), neuroendocrine tumor (1). IH analysis (CD117-CD34) was feasible in 13/15 GISTs (86.66%). There were no procedural-related complications.

**Conclusion:** SINK biopsy provides an all-in-one time, effective and safe method for accurate diagnosis of small upper SETs. This one-step technique may avoid conventional endoscopic follow-up which is hampered by costs and low compliance with standard surveillance recommendations.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0205 CLINICAL IMPACT OF EUS TREATMENT OF WOPN WITH DEDICATED DEVICES: A RETROSPECTIVE ANALYSIS

**I. Tarantino**, D. Ligresti, L. Barresi, A. Granata, G. Curcio, M. Traina
*Endoscopy Service, Department of Diagnostic and Therapeutic Services, IRCCS-ISMETT (Istituto Mediterraneo per i Trapianti e Terapie ad alta specializzazione), Palermo, Italy, Palermo|Italy*

**Contact E-mail Address:** itarantino@ismett.edu.

**Introduction:** Infected Walled-Off Pancreatic Necrosis (WOPN) is the main life-threatening complication of acute pancreatitis. Superiority of trans-gastric endoscopic necrosectomy over surgical necrosectomy was demonstrated[i]. However, standard endoscopic techniques were associated with long procedural time, stent migration and bleeding, pointing out the need of dedicated devices. Recently, a dedicated lumen apposing metal stent (LAMS) was designed to create an anastomosis between the WOPN cavity and the gut lumen in a single-step procedure.

**Aims & Methods:** The primary aim of this study was to evaluate the survival rate and clinical efficacy of EUS-guided drainage of infected WOPN with LAMS and subsequent Direct Endoscopic Necrosectomy (DEN). Survival was evaluated at 1 and 3 months after the first procedure. Clinical success was evaluated as recovery from sepsis and other WOPN-related symptoms associated with disappearance of WOPN at CT scan after LAMS removal without the need for additional endoscopic or surgical intervention. Secondary outcomes were to evaluate technical success, adverse events, procedure time, number of endoscopic procedures, and duration of hospital stay. All consecutive patients with infected WOPN who underwent LAMS placement and DEN between February 2014 and February 2016 were retrospectively reviewed. This novel device was directly advanced under EUS guidance into the cavity by using the electrocautery tip. After deployment of the LAMS, the echoendoscope was removed, and a standard gastroscope was inserted to perform immediate DEN.

**Results:** A total of 19 patients (mean age 59.8 years, female 31.5%,) underwent DEN. LAMS placement and necrosectomy (technical success) was achieved in 18 (94.9%) patients. Mean procedure time was 42.9 minutes. Mean number of sessions was 3.9 (1–9). Three patients underwent double LAMS placement, through the stomach and duodenum. Clinical success was achieved in 15/18 (83.3%) patients. Mean length of hospital stay was 19 days (3–43). Median follow up was 261 days (IQR 270). No adverse events occurred. A total of 3 patients died during the study period: the survival rate was 84.2% and 78.9% at 1 and 3 months after procedure.

**Conclusion:** This study on EUS treatment of patients with infected WOPN with dedicated LAMS demonstrates excellent efficacy and safety of the procedure with significant impact on survival in this setting of patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** laura.uribarri.gonzalez@sergas.es.

**Introduction:** Morphological evaluation of cystic pancreatic tumours (CPT) for the detection of worrisome features and high-risk stigmata is required for the correct management of these lesions. Magnetic resonance cholangio-pancreatography (MRCP) and endoscopic ultrasound (EUS) are considered the techniques of choice for the morphological evaluation and follow-up of CPT.

**Aims & Methods:** Aim of the study was to evaluate the concordance between these two techniques in this setting. Methods: Retrospective analysis of a prospectively collected database of CPT. Patients undergoing both EUS and MRCP for the study of CPT were included over a period of 5 years. Time between EUS and MRCP should be shorter than 6 months for final inclusion. EUS was performed by linear Pentax echoendoscopes (EG-3870UTK y EG-3270UK) and HITACHI-ASCENDUS and PREIRUS ultrasound equipment. MRCP was performed by SIEMENS equipment. Location, number and size of PCT, and presence of worrisome features and high-risk stigmata according to Fukuoka criteria were evaluated. Concordance between EUS and MRCP was evaluated by Kappa score.

**Results:** 97 patients fulfilled inclusion criteria (mean age 66 years, range 25–87, 64 females). Number and size of lesions were similarly evaluated by EUS and MRCP. Individual worrisome features and high-risk stigmata were present in up to 12% of patients. A poor agreement between EUS and MRCP ($k < 0.2$) was found for wall thickness, non-enhanced mural nodules, enhanced solid component, and dilatation of the main pancreatic duct (MPD) > 10 mms. Agreement was fair ($k = 0.21–0.40$) for MPD dilatation of 5–9 mms, and moderate ($k = 0.41–0.60$) for the location of the CPT and abrupt change of the MPD. There was no agreement between the two techniques in the evaluation of lymph nodes.

**Conclusion:** EUS and MRCP provide similar information about number, size and location of CPT, but the concordance between the two techniques is poor to fair for the detection of the majority of worrisome features and high-risk stigmata. These findings deserve confirmation in larger studies including a higher number of lesions with worrisome features and high-risk stigmata.

**Disclosure of Interest:** J.E. Domínguez-Muñoz: International Advisor Pentax. All other authors have declared no conflicts of interest.

## P0207 FACTORS INFLUENCING THE ACCURACY OF EUS-GUIDED TISSUE ACQUISITION FOR THE EVALUATION OF ENLARGED LYMPH NODES

S. Rebolledo Olmedo[1], **D. De La Iglesia-García**[2], J. Iglesias-García[3], L. Díaz-Hernández[1], J. Lariño-Noia[3], I. Abdulkader[4], H. Lazare Iglesias[5], J.E. Domínguez-Muñoz[1]

**Introduction:** Endoscopic ultrasound (EUS)-guided tissue acquisition is an accurate technique for the evaluation of both mediastinal and intra-abdominal enlarged lymph nodes.

**Aims & Methods:** Aim of our study was to evaluate factors associated with the diagnostic yield of EUS-guided tissue acquisition in this setting.

Methods: Retrospective analysis of a prospectively collected database of patients who underwent a EUS-guided tissue acquisition for the pathological diagnosis of enlarged lymph nodes over the last 3 years. EUS were performed under conscious sedation with Pentax linear echoendoscopes (EG-3870UTK and EG-3270UK) and the HITACHI ultrasound device. Tissue acquisition was performed with both cytological and histological EUS needles of different sizes. Samples were

processed in a cytological solution (cytolit). The impact of lymph node location and size, number of passes and type of needle used on the accuracy of EUS-guided tissue acquisition was evaluated. Final diagnosis was based on surgical histopathology or, in non-operated cases, on EUS-guided tissue acquisition, imaging assessment (CT scan and/or PET scan), with a minimum clinical follow-up of 6 months. Data are shown as percentage, median and range, and were analyzed by logistic regression. Diagnostic accuracy was also evaluated.
**Results:** 175 lymph nodes on 159 patients were sampled in the study period, with a median size of 20 mm (range 12.5–27 mm). 94 lymph nodes (53.7%) were located at mediastinum and 81 (46.3%) were intra-abdominal. Histology needles (ProcoreTM) were used in 107 (61.1%) cases, and cytology needles in the remaining 68 lymph nodes (38.9%). Final diagnosis was benign/reactive origin in 88 cases (50.3%), carcinoma in 70 cases (40%), and lymphoma in 17 (9.7%). Sensitivity, specificity, positive predictive value and negative predictive value of EUS-guided tissue acquisition for the detection of malignancy was 75.9%, 100%, 100% and 80.7%, respectively. Overall accuracy was 87.9% (95%IC 72.1–87.7). None of the factors evaluated influenced the diagnostic accuracy of EUS-guided tissue acquisition.
**Conclusion:** EUS-guided tissue acquisition is a very accurate technique for the differential diagnosis of enlarged lymph nodes. Diagnostic accuracy of this technique is not influenced by the location or size of the lymph nodes evaluated, the number of needle passes nor the type of needle used.
**Disclosure of Interest:** J.E. Domínguez-Muñoz: International advisor Pentax.
All other authors have declared no conflicts of interest.

## P0208 PREP-LESS COLON CANCER SCREENING USING A NOVEL X-RAY IMAGING CAPSULE

[7]*Department Of Interdisciplinary Endoscopy, Hospital Hamburg-Eppendorf, Hamburg/Germany*

**Contact E-mail Address:** nadira@tlvmc.gov.il.
**Introduction:** Bowel preparation is likely the most significant reason for low participation in screening colonoscopy, while poor preparation impairs adenoma detection. A CRC screening method that would generate structural data of thecolon, without cathartic cleansing or diet restrictions, would offer an attractive alternative for many patients from the target population that are not willing to undergo colonoscopy. In preliminary studies: Colon reconstructions from synthetic phantoms, bovine cadaver and live swine showed spatial resolution of 2–3 mm in colon diameter measurements, and detection of implanted polyps >= 6 mm.
**Aims & Methods: Device:** The capsule is similar in dimensions to other approved capsules. The capsule emits ultra-low dose X-rays, which are scattered by ingested contrast agent mixed with colon contents, and sensed by detectors in the capsule to generate high-resolution 3-dimensional (3D) imagery of the colon without bowel cleansing. The capsule is activated and scans the inner surface only when the capsule is propelled within the colon. **Aim:** To evaluate the safety and correlation between the capsule and colonoscopy findings **Methods and Patients:** The system performed scans upon detecting of effective capsule motion in the colon and transmitted imaging data to an external recorder unit attached to patients' lower back. Combined data from colon scans and the CPS system were used to reconstruct 3D colon segments in nonprepped colons. Total transit time and total Xray exposure were calculated to assess the safety profile of the capsules. Between 1.3.13 -9.2.16 scanning capsules were swallowed by 52 subjects, and tracked throughout the alimentary tract using an external capsule positioning system (CPS). The capsule was activated to scan only while moving in the colon, and transmitted imaging data to the CPS to reconstruct 3D colon segments. Total transit times were measured. X-ray exposure was calculated to assess safety in human subjects.
**Results:** Seventy five dummy capsules passed naturally and uneventfully confirming the safety of the capsule. Scanning capsules were swallowed uneventfully in all 52 patients, and naturally and eliminated in 51/52 patients, after 64.3 ± 36.4 hours. One capsule was extracted via colonoscopy during a planned polypectomy. The volunteers were exposed to an ultralow total radiation dose of 0.03 ± 0.0007 mSv (equivalent to 1 chest X-ray) for the entire procedure. The capsule detected polyps of different size, shape and location in the colon. Capsule routes and 3D reconstructions of colon lumen and outer surface were obtained from all participants. Both pedunculated and sessile polyps were clearly seen and validated by colonoscopy. There were no reports of capsule malfunction or damage which might have compromised the participants' safety. Fifty capsules (out of 52 that were ingested) were returned to the lab. They were all in perfect shape.
**Conclusion:** A novel X-ray imaging capsule for colorectal cancer screening appears safe and capable of prep-less colon imaging in an human study. Quantitative ultra-low dose X-ray imaging and detection of polyps of different sizes and polyp types was achieved in the colon of human subjects. Efficacy validation of this X-ray-based CRC screening technology is being conducted in a multi-center prospective study.

## P0209 CAPSULE ENDOSCOPY SCORES FOR ASSESSMENT OF INFLAMATORY ACTIVITY OF SMALL-BOWEL IN CROHN'S DISEASE

**A. Ponte**[1], R. Pinho[2], A. Rodrigues[2], J. Silva[2], J. P. Rodrigues[2], M. Sousa[2], J. Carvalho[2]
[1]*Gastroenterology, Centro Hospitalar Vila Nova Gaia/Espinho, Vila Nova Gaia/Portugal*
[2]*Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia/Portugal*

**Contact E-mail Address:** ana.ilponte@gmail.com.
**Introduction:** Capsule endoscopy (CE) represents the non-invasive method with the highest sensitivity in the evaluation of small-bowel mucosa in Crohn's disease (CD).[1] Recent recommendations advocate the employment of validated CE scores for the assessment of small-bowel inflammatory activity in CD, allowing a standardized description of lesions and an objective assessment of severity and follow-up.[1, 2] Lewis Score (LS) and Capsule Endoscopy Crohn's Disease Activity Index (CECDAI) are the two validated scores currently available, but comparative studies are scarce.[3, 4] Moreover, evidence concerning the correlation of these endoscopic scores with biomarkers and clinical activity in small-bowel CD is lacking.
**Aims & Methods:** The primary aim of this study was to compare LS with CECDAI and to determine cutoff values for CECDAI similar to those of LS (135 and 790). The second aim was to correlate LS and CECDAI with biomarkers and symptoms. All patients with CD who underwent CE between March 2010 and February 2016 were included. LS and CECDAI were determined after analysis of each CE. In patients with CD confined to the small-bowel, C-reactive protein (CRP) and Harvey-Bradshaw index (HBI) were evaluated. Statistical analysis: Spearman's correlation coefficient and linear regression analysis. Significance: $p < 0.05$.
**Results:** Fifty-three patients were included, 60.4% (n = 32) were women, with a mean age of 41.8 years. CD was restricted to the small-bowel in 64.2% (n = 34) of patients and in the remaining 35.8% (n = 19) the activity was ileocolonic. Mean values obtained for LS were 1147 (+/-1453), CECDAI 11.3 (+/-6.9), CRP 0.92 (+/-1.5) mg/dL and HBI 2.4 (+/-2.8). There was a very strong correlation between LS and CECDAI ($r_s = 0.878$; $p < 0.0001$). In linear regression analysis, thresholds values of 135–790 in LS corresponded to 7.7–10.3 cutoff values in CECDAI, respectively, with an accuracy of 62.3%. Neither CRP correlated with LS ($r_s = 0.068$; $p = 0.72$) or CECDAI ($r_s = -0.004$; $p = 0.98$), nor HBI with LS ($r_s = -0.15$; $p = 0.40$) or CECDAI ($r_s = -0.10$; $p = 0.23$).
**Conclusion:** Correlation between the two CE activity scores was very strong, with LS thresholds of 135 and 790 corresponding to CECDAI values of 7.7 and 10.3. HBI and CRP had no correlation with endoscopic activity scores in small-bowel CD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** i.steinbrueck@asklepios.com.
**Introduction:** Recently the PillCamSB3 capsule endoscopy system was introduced. In comparison to the PillCamSB2 the new capsule has a wider angle of view, an increased resolution and an adaptive frame rate from 2 to 6 frames per second depending on the speed of capsule movement. The aim of this study was to investigate if these developments lead to an increased sensitivity of the new capsule system. As the duodenal papilla is a finding that is present in everyone but only visualized in 10.4% with older capsule systems [1] it appears to be an ideal target lesion for the investigation of the diagnostic accuracy of a new capsule system.
**Aims & Methods:** The capsule endoscopy procedures between 01/2011 and 04/2015 with the PillCamSB2 and SB3 were reviewed. Exclusion criteria included endoscopic introduction of the capsule, polyposis syndromes, overt bleeding/poor visibility/gaps in the duodenum and previous surgery with alteration of the gastric and/or duodenal anatomy. The review was done by one experienced

reader frame by frame during the passage of the entire duodenum. The detection rate of the papilla and the number of frames in which the papilla was visualized were compared.
**Results:** 181 capsule procedures were included in this study, 84 with the PillcamSB3 and 97 with the Pillcam SB2 system. There were no differences in the detection rate of the papilla (11/84 vs. 12/97, p = 0.884) and the number of frames that showed the papilla (11.91 vs. 14.00, p = 0.155 (-21, 208–17, 026)).
**Conclusion:** The sensitivity of the PillCamSB3 system is not superior to the SB2 system regarding the detection of the papilla vateri.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Radiation enteritis is a radiation-induced injury of the gastrointestinal (GI) tract and a major complication of radiotherapy. Capsule endoscopy (CE) may be a useful diagnostic tool for radiation enteritis of the small intestine, which standard endoscopy cannot evaluate. However, there are few reports regarding detection of radiation enteritis by CE.
**Aims & Methods:** We aimed to assess the Clinical usefulness of classification by CE for detection of radiation enteritis. We selected patients with the possibility of radiation enteritis who had previously treated with radiotherapy on the abdomen or pelvis. To increase diagnostic the yield of radiation enteritis, CE was performed in patients having anemia or chronic abdominal pain. We used PillCam® SB and SB2 (Given Imaging Ltd.) for the CE. Lesions were described according to the Capsule Endoscopy Structured Terminology (CEST). Pathological findings were classified into three groups (modified Saurin's classification), according to their relevance to radiation enteritis. P0:no relevance, P1:potential relevance, P2:high relevance.
**Results:** Fifteen consecutive patients were enrolled between May 2011 and January 2016. The median age was 66 years (54–79). The median radiation dose was 55 Gy with range of 3671.12 Gy. In one case, bowel patency was not confirmed by patency capsule evaluation. CE diagnosed radiation enteritis occurs in 12 of 14 patients (P2: 50%, P1: 36%). Congested mucosa and Yellow villi were the most frequent abnormal lesions. Although no patient experienced capsule retention, one drawback was that the CE impacted at the stenosis. In the follow-up period ranging from 109 to 1732 days (median 1344 days), ileus occurred in 3 cases among 7 cases that have been diagnosed as P2. Correspondence between ileus and P2 classification was significantly high.
**Conclusion:** CE was shown to be useful for detecting radiation enteritis. We recommend performing CE first when radiation enteritis is suspected.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0212 SMALL INTESTINE CAPSULE ENDOSCOPY FOR THE EVALUATION OF OBSCURE GASTROINTESTINAL BLEEDING IN THE ELDERLY

**M. Ogawa**, R. Sawada, T. Nishimura, K. Tsutsui, S. Kanba, D. Ide, T. Iwasaki, Y. Arai, J. Mitobe, M. Mitsunaga, S. Arihiro, M. Matsuoka, T. Kato, M. Saruta
*Gastroenterology And Hepatology, Jikei Univesity School Of Medicine, Tokyo/Japan*

**Contact E-mail Address:** 10maimai10@gmail.com.
**Introduction:** Obscure gastrointestinal bleeding (OGIB) in the elderly is often caused by angioectasia and/or mucosal injury. We examined elderly patients (≥65 years) with OGIB, according to the World Health Organization criteria and our report (*Gastrointest Endosc* 2015;81:AB479). Cases of OGIB significantly increased with intake of oral antithrombotic agents among the elderly due to prolonged small intestine transit time. These findings also suggest the involvement of chemical mucosal disorders. In this study, we classified patients according to 10-year increments to clarify the effects of age on the occurrence of OGIB.
**Aims & Methods:** We used small intestine capsule endoscopy (CE) to examine 506 patients in this hospital between April 2004 and March 2016. We classified the patients according to age (group A, <55 years; group B, ≥55 to ≤65 years; group C, ≥65 to ≤75 years; group D, >75 years) and compared the symptoms, oral medication use, and small intestine transit times between the groups.
**Results:** A total of 506 patients were enrolled in the study, with 169, 96, 131, and 110 patients in groups A, B, C, and D, respectively. Antithrombotic drugs were administered in 4.7% (8), 15.6% (15), 20.6% (27), and 27.3% (30) of patients in groups A, B, C, and D, respectively. The use of antithrombotic drugs significantly increased with age ($P < 0.01$). Angioectasia and/or mucosal injury were demonstrated in 25% (2), 20.0% (3), 44.4% (12), and 46.7% (14) of patients in groups A, B, C, and D, respectively. Small intestine transit times were 254.5, 283.4, 301.6, and 313.5 min in groups A, B, C, and D, respectively. Although the small intestine transit time was significantly shorter in group A compared to groups C and D ($P < 0.01$ and $P < 0.01$, respectively), no significant differences were observed among the other three groups.
**Conclusion:** The use of oral antithrombotic drugs increased with age, along with the concomitant findings of angioectasia and/or mucosal injury. The small intestine transit time was significantly longer in elderly people who were at least 65 years. These findings suggest the development of OGIB in the elderly. Therefore, in cases of OGIB in the elderly, we should consider utilizing CE in monitoring for mucosal disorders related to intake of antithrombotic drugs, particularly in patients older than 65 years.

**Contact E-mail Address:** ana.ilponte@gmail.com.
**Introduction:** Capsule endoscopy (CE) represents a safe diagnostic procedure in small-bowel mucosal assessment.[1] The presence of debris and air bubbles negatively impairs the diagnostic yield of CE and the evaluation of the quality of small-bowel cleansing is necessary to assess the reliability of findings.[2] A computed assessment of cleansing (CAC) score was developed to objectively evaluate small-bowel cleansing in the PillCam® CE system and to overcome the subjectivity and complexity of previous scoring systems.[1]
**Objectives:** Adapt the CAC score to the Mirocam® system, evaluate its reliability with the Mirocam® CE system and compare it with three validated subjective grading scales.
**Methods:** Thirty CE were prospectively and independently reviewed by 2 authors (RP, AP) who classified the degree of cleanliness of the small-bowel according to a quantitative index (QI), a qualitative evaluation (QE) and an overall adequacy assessment (OAA).[2] The authors were blinded for the CAC score of each CE, which consisted of ([mean intensity of the red channel]/[mean intensity of the green channel]–1) x10. The mean intensities of the red and green channels of the small-bowel segment of the "Map View" bar of Miroview Client® were determined using the histogram option of a photo-editing software. Statistical analysis: Spearman's correlation coefficient, intraclass correlation coefficient (ICC), unweighted kappa and student's t-test. Significance: $p < 0.05$.
**Results** The mean grade for the QI was 7.47 (+/-1.74) for reader-1 and 7.9 (+/-1.67) for reader-2, resulting in an excellent inter-reader reliability with an ICC of 0.92 (CI95% = 0.84–0.96). The classification in excellent/good/fair/poor of the QE was obtained in 13.3%/53.3%/26.7%/6.7% CE for reader-1 and in 20%/46.7%/23.3%/10% for reader-2, with an excellent concordance between both readers with an ICC of 0.83 (CI95% = 0.68–0.91). The degree of cleanliness in OAA was considered adequate in 86.7% of cases by reader-1 and 90% of cases by reader-2, with an unweighted kappa of 0.84. A good correlation between the QI and the computed scores was found with a $r_s = 0.5$ ($p = 0.005$) for reader-1; $r_s = 0.48$ ($p = 0.008$) for reader-2; and $r_s = 0.49$ ($p = 0.006$) for the mean of both readers. A fair correlation between QE and the computed scores was found with an ICC of 0.43 (CI95% = 0.089–0.68, $p = 0.008$) for reader-1 and 0.45 (CI95% = 0.11–0.70, $p = 0.006$) for reader-2. The mean values of CAC for adequate/inadequate levels of cleanliness for OAA were 5.16/3.45 ($p = 0.02$) for reader-1 and 5.07/3.66 for reader-2 ($p = 0.09$).
**Conclusion:** There was a strong agreement between both CE readers for each of the three subjective scales used. The CAC score is feasible in the Mirocam® CE system and correlates with the validated subjective scales.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Small bowel capsule endoscopy (SBCE) is a diagnostic tool with increasing relevance. Pillcam® SB3 has better image resolution than PillCam® SB2 and adaptive frame rate technology, rendering it potentially more effective. **Aims & Methods:** Compare findings detection and completion rate between PillCam® SB2 and SB3. **Methods:** Retrospective single-center study including 357 consecutive SBCE, 173 SB2 and 184 SB3. Videos were reviewed and findings were recorded and classified as relevant or not.
**Results:** Patients had a mean age of 48 years with 66.9% females. The two main indications were suspicion/staging of inflammatory bowel disease (IBD) and obscure gastrointestinal bleeding (OGIB), (43.7% and 40.3%, respectively). Median small-bowel (SB) transit time was 261 minutes (IQR ± 122) and overall completion rate was 95% (339/357). Endoscopic findings were reported in 76.2% of the examinations, while relevant findings corresponded to 53.5%. The most frequently reported findings were SB ulcers, in 29.4% of patients. Findings in gastrointestinal segments other than the SB were reported in 20.4% of SBCE, most frequently in the stomach (16.8%). No significant differences were found when comparing SB2 with SB3 regarding completion rate (93.6% vs 96.2%, $p = 0.27$), overall endoscopic findings (73.4% vs 78.8%, $p = 0.23$), relevant findings (54.3% vs 52.7%, $p = 0.76$), first tercile findings (43.9% vs 48.9%, $p = 0.35$), extra-SB findings (23.7% vs 17.3%, $p = 0.14$), after-8 hours findings (8.1% vs 8.2%, $p = 0.99$), Z line and papilla detection rate (35.9% vs 35.7%, $p = 0.97$ and 27.1% vs 32.6%, $p = 0.32$, respectively). Regarding the subgroup of patients with suspicion/staging of IBD, a significant difference was found in the detection of villous edema and 3rd tercile findings, favoring SB3 (26% vs 44%, $p = 0.02$ and 47% vs 66%, $p < 0.02$, respectively). No differences were found on Lewis score classification and 3rd tercile ulcer detection. In patients with OGIB, mucosal atrophy was significantly more frequently diagnosed with the PillCam ® SB3 (0% vs 8%, $p = 0.03$).
**Conclusion:** Overall, PillCam ® SB3 didn't improve diagnostic yield nor the completion rate compared with SB2. Nevertheless, when particular indications were analyzed, significant differences in detection of villi alteration, such as atrophy and segmental villous edema, were found, which may eventually be attributable to SB3 better image resolution.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0215 WHOLE-LIVER CT TEXTURE ANALYSIS TO PREDICT THE DEVELOPMENT OF METACHRONOUS COLORECTAL LIVER METASTASES – A MULTICENTRE STUDY

**Introduction:** Texture analysis refers to a mathematical approach to quantify heterogeneity on imaging. Commonly used measures are 'entropy' (a measure of heterogeneity) and 'uniformity' (a measure of homogeneity). Previous research showed promise for texture analysis of the liver on CT in patients with colorectal cancer to assess whether or not metastases are present within the liver.[1, 2] Apparently diffuse changes in liver texture occur due to the presence of metastatatic liver disease, which are probably related to diffuse changes in liver perfusion or the presence of microscopic disease throughout the liver. The hypothesis is that such changes may already be present and detectable by texture analysis before any metastases become visible on CT and that CT-texture analysis may thus predict which patients are at risk to develop metachronous liver metastases. **Aims & Methods:** Aim of this multicenter study was to test this hypothesis and assess whether CT-texture can predict the development of metachronous metastases before they become visible on CT. To investigate this 165 patients (from 3 centres) were included and divided into three subgroups: patients [A] without metastases for >2 years after primary diagnosis (n = 57), [B] with synchronous metastases (n = 54) and [C] who developed metachronous metastases within 24 months after primary diagnosis (n = 54). Whole-liver texture analysis was performed on primary staging portal-phase CT by manual delineation of the apparently non-diseased liver parenchyma. The texture parameters mean grey-level intensity (M), entropy (E) and uniformity (U) were derived with different image filter values (unfiltered = 0.0, fine = 0.5, medium = 1.5, coarse = 2.5). Image filtration was applied to highlight structures of different size within a tissue. Univariable logistic regression analysis was performed (group A vs. B) to identify potentially predictive texture and clinical parameters (e.g. age, sex, primary tumour site, T- and N-stage and CEA). The best predictors were subsequently tested in multivariable analyses to differentiate between group A and C (i.e. predict metachronous disease). Receiver Operator Characteristics (ROC) curve analysis was performed to test the diagnostic performance of the different clinical and texture variables to predict metachronous metastases. Subgroup analyses were performed for patients with early (≤6 months), intermediate (7–12 months) and late (13–24 months) metastases.
**Results:** Univariable analysis identified $U_{0.5}$ and the clinical parameters sex, primary tumour site, N-stage and CEA as potential predictors. For the early metastases subgroup, $U_{0.5}$ remained a significant predictor in multivariable analysis (OR 0.56, $p = 0.05$), resulting in an AUC of 0.74 to predict metachronous disease within 6 months. Adding $U_{0.5}$ to the clinical parameters CEA + N-stage resulted in an AUC of 0.78 to predict early metastases, which was a tendency towards significant improvement compared to only N-stage + CEA ($P = 0.08$). None of the texture or clinical parameters were able to predict metachronous metastases within 12 or 24 months.
**Conclusion:** Whole-liver CT texture analysis may have additional value to more well-known clinical parameters such as N-stage and CEA to predict upfront which patients are at risk to develop metastases within six months after primary diagnosis. It is, however, not robust enough to predict patients at risk to develop metastases within 24 months.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Changes in diameters of the pancreaticobiliary ducts are markers of diseases including benign conditions like chronic pancreatitis, bile duct stones or pancreaticobiliary malignancies. MRCP (magnetic resonance cholangiopancreatography) is the first line, non-invasive imaging modality for duct configuration, with broad availability and ever increasing accuracy. However, the reference ranges in asymptomatic individuals and their change with age and after medical procedures have only been studied in small cohorts.
**Aims & Methods:** To define new reference values for diameters of pancreaticobiliary ducts on MRCP in the general population and to identify factors influencing duct size. Study subjects were recruited from the general population-based SHIP and had whole body MRI + MRCP (1.5 T MRI system). Diameters of pancreatic duct (PD) and common bile duct (CBD) were measured on MRCP maximal intensity projection sequence before and after administration of secretin by an investigator blinded to other subject data.
**Results:** 1385 subjects were initially scanned, 865 measured PDs and 938 CBDs were included for further analysis. Subjects were excluded for missing data or evidence of pancreaticobiliary disease (post-cholecystectomy n = 115, cholecystolithiasis n = 57, choledocholithiasis n = 8, chronical pancreatitis n = 17, pseudocysts n = 52, cholestasis n = 11, liver cirrhosis n = 1, hepatitis n = 2). Median age was 53 y (21–89 y) and 48.5% were female. The diameters increased with age (PD median (range) 1.-3. Quartile: 20–29 years 1.33 cm (1.20–1.57), >70 years 2.49 (1.85–3.01); CBD median (range) 1.-3. Quartile: 20–29 years 4.53 (3.87–5.17), >70 years 6.50 (5.10–8.23)) and the historic upper limit of normal of 3 mm for PD and 7 mm for CBD were exceeded by 11% and 18.2% respectively. Subjects that underwent cholecystectomy presented with significantly increased diameter of CBD, but not PD ($CBD_{w/oCCE}$: 5.30 mm ± 1.893 SD vs. $CBD_{w/CCE}$: 8.18 mm ± 2.841 SD, $p < 0.01$; $PD_{w/oCCE}$: 1.84 mm ± .778 SD vs. $PD_{w/CCE}$: 2.06 mm ± .868 SD, $p > 0.01$). Duct size was not correlated to liver function tests (ASAT, ALAT, γGT). Using quantile regression on the 95th percentile age and gender dependent upper limits for normal duct size were defined (<70 years PD male 3.77 cm, female 3.76 cm; CBD male 9.16 cm, female 10.70 cm; >70 years PD male 4.12 cm, female 4.35 cm; CBD male 10.32 cm, female 12.44 cm). PD but not CBD diameters significantly changed after administration of secretin. Upper limits of normal PD size after secretin were (<70 years $PD_{sec}$ male 4.33 cm, female 4.11 cm; >70 years $PD_{sec}$ male 5.95 cm, female 4.74 cm).
**Conclusion:** Up to 18% of healthy volunteers would have undergone diagnostic workup for enlarged CBD or PD above the current reference standard. The width of the pancreaticobiliary ducts increases in an age dependent manner in asymptomatic volunteers. An increase of the CBD after cholecystectomy can be observed, whereas the PD remains unaffected. In cases of no signs of cholastatic liver disease a moderately increased duct diameter is most likely non pathologic.

So to reduce healthcare expenditure and unnecessary workup age and gender-related adjustments of the reference values are suggested to avoid unnecessary diagnostic workup.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0217 A PILOT STUDY OF PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY FOR GASTROINTESTINAL NEOPLASMS: AN INITIAL EXPERIENCE IN JAPAN

**Y. Tanaka**[1], S. Abe[1], Y. Ohno[2], I. Oda[1], T. Matsuda[1], K. Kaneko[2], Y. Saito[1]

**Contact E-mail Address:** yustanak@ncc.go.jp.
**Introduction:** Probe-based confocal laser endomicroscopy (pCLE) allows real-time, in vivo high-resolution imaging of the gastrointestinal epithelium at a cellular level. There are only a few publications on pCLE in the additional diagnostic value of gastric and colorectal neoplasms. We conducted a pilot study to investigate the diagnostic yield of pCLE in the evaluation of neoplastic and non-neoplastic gastric lesions and non-invasive and invasive colorectal neoplasms. (UMIN000016557).
**Aims & Methods:** This study was conducted by two referral centers. A total of 38 patients were referred for the treatment of gastric or colorectal lesions between February and May 2015. All participating clinicians had web-based self-training of pCLE. High-definition white light endoscopy (WLE), chromoendoscopy (CE), and magnified narrow band imaging (M-NBI) were performed on all lesions. pCLE was then performed to differentiate between non-neoplastic or neoplastic gastric lesions and non-invasive or invasive colorectal neoplasms based on Miami classification (on-site diagnosis). All neoplastic lesions were treated by endoscopy or surgery. An off-line review was performed on all lesions by a separate expert endoscopist who was blinded to the clinical information. All the still images of WLE, CE, and M-NBI and the video of pCLE were reviewed. The clinician independently scored the gastric lesions as neoplastic or non-neoplastic and the colorectal lesions as adenoma/slight invasion (M-SM) or deep invasion (SM) for each endoscopic imaging modality. We then evaluated the sensitivity, specificity, accuracy of each endoscopic imaging modality and inter-observer agreement of pCLE. The histology was the gold standard.
**Results:** 17 patients had a total of 24 gastric lesions and 21 patients had 22 colorectal lesions. 14 gastric lesions were neoplastic (median tumor size: 12.5 mm (2–38), histology: differentiated-type/undifferentiated-type adenocarcinoma = 11/3, depth of invasion: mucosa/slight submucosa/deep submucosa (≥500 μm) = 10/1/3). 10 were non-neoplastic. Sensitivity/specificity/accuracy (%) of pCLE in on-site diagnosis was 79/90/83. The sensitivity/specificity/accuracy (%) for the off-line review were as follows; WLE = 50/90/67, CE = 57/70/63, M-NBI = 64/80/71, and pCLE = 79/70/75. The inter-observer agreement of pCLE between on-site diagnosis and off-line review, kappa value was 0.67 (95%C.I.:0.37–0.96). 22 colorectal lesions were characterized as follows; (adenoma/M-SM slight/SM deep: 7/10/5). The sensitivity/specificity/accuracy (%) for the on-line diagnosis were as follows; WLE = 83/100/96, M-NBI = 100/100/100, CE = 100/100/100. Either of lack of structure or thickened epithelium in pCLE findings was seen in 80% of SM deep invasion (4/5) and 12% of adenoma/M-SM slight invasion (2/17). Sensitivity/ specificity (%) was 80/88. When these pCLE findings applied for depth diagnosis in off-line review, the sensitivity/specificity/accuracy (%) of pCLE in off-line review were 60/88/82, respectively. The inter-observer agreement of pCLE between on-site diagnosis and off-line review, kappa value was 0.58 (95%C.I.:0.14–1.02).
**Conclusion:** pCLE may be useful in the differentiation between neoplastic and non-neoplastic gastric lesions and depth diagnosis for colorectal lesions. Further study should be conducted to validate these findings.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Cytoreductive surgery (CRS) is the treatment of choice for peritoneal carcinomatosis (PC). In order to achieve a significant survival gain a complete cytoreduction is essential in the surgical treatment of PC of colorectal carcinoma. In case of peritoneal PC and colon carcinoma cytoreduction is combined with hyperthermic intraperitoneal chemotherapy (HIPEC). Whether a complete cytoreduction is feasible is determined by the amount and localization of disease in the abdomen. In colorectal cancer the Dutch region count is a scoring system using surgical inspection to assess the amount and localization of disease. Currently a diagnostic laparoscopy is often used to inspect all areas in the abdomen and to predict whether a complete cytoreduction is feasible. However, with this invasive procedure it is not always feasible to inspect all relevant areas in the abdomen due to the presence of adhesions and / or tumor. It would therefore be more than helpful if a radiological diagnostic tool could accurately assess the amount and localization of peritoneal disease before any surgery in order to predict the possibility of achieving a complete cytoreduction. A better selection of the group of patients in whom a complete cytoreduction is feasible will limit the number of ineffective and expensive procedures.
**Aims & Methods:** This study aims to compare the extent of PC on computed tomography (CT) with the peroperative findings of PC and long-term survival. Preoperatieve abdominal CT scans of patients who underwent CRS-HIPEC, performed between January 2005 and September 2015, were evaluated by two experienced radiologists. The extent of PC according to the Dutch region count was scored, in which the abdominal cavity is divided into seven regions. When five or less abdominal regions were affected CRS-HIPEC was considered useful and thus executed. Peroperative region count was the reference standard. Diagnostic performance of CT was calculated and survival analyses were performed.
**Results:** Two hundred thirty-four patients were included. The accuracy for selecting PC patients with a good or bad prognosis with CT was 87%, based on a region count of five or less. Forty-nine scans were evaluated by two radiologist and inter-observer variability for a continuous region count was calculated (k = 0.139). Patients with five or less affected abdominal regions on CT imaging showed significant lower disease free survival (median 20.5 months; IQR 18.0–23.0) and overall survival (median 39.5 months; IQR 32.5–46.5) compared to patients with more affected abdominal regions (median 2.8 months; IQR 0.0–7.6 and median 9.3 months; IQR 0.0–21.7) ($p < 0.001$ and $p = 0.002$).
**Conclusion:** These results show that CT can select patients who could benefit from CRS-HIPEC. Survival rates significantly decreased when more abdominal regions on CT were affected.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0219 DIAGNOSTIC VALUE OF IMAGING FOR THE DETECTION OF PERITONEAL METASTASES: A META-ANALYSIS

**Introduction:** Peritoneal seeding is a well-known mechanism of spread in advanced gastrointestinal cancer. Peritoneal carcinomatosis (PC) has significant implications for not only treatment options but also prognosis; it is the second-most frequent cause of death in colorectal cancer patients after metastatic disease to the liver. The last few decades showed a revolution in the treatment of PC. Presently the prognosis of PC patients has dramatically improved and where once only palliative treatments and comfort measures were contemplated, nowadays selected patients benefit from a radical locoregional approach aiming at long-term disease control. That radical locoregional approach consists of cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (CRS-HIPEC). When a complete surgical cytoreduction can be achieved 5-years survival rates of up to 50% are reported after CRS-HIPEC. Therefore, it is important to detect patients with peritoneal metasasis.
**Aims & Methods:** To determine the diagnostic value of imaging in detecting peritoneal carcinomatosis in staging cancer patients. A literature search of Ovid, Embase and Pubmed was performed to identify studies reporting on the accuracy of imaging for the detection of PC for colorectal, gastric and gynaecological cancers. Data extraction was performed by two observers in consensus. The sensitivity, specificity, and diagnostic odds ratio (DOR) were calculated using a bivariate random effects model and hierarchical summary operating curves (HSROC) were generated.
**Results:** The search resulted in 4165 articles. 35 relevant studies fulfilled all the required inclusion criteria of >15 patients and surgery/histology/clinical follow-up as reference standard. From these 35 articles 42 datasets could be extracted for analysis; 21 for CT, 5 for MRI, 5 for PET and 11 for CTPET.

**Table 1:** Results meta-analysis.

| | Pooled Sensitivity | Pooled Specificity | DOR |
|---|---|---|---|
| CT | 73% (CI:60-83%) | 90% (CI:84-94%) | 25.6 (CI:13.3-49.1) |
| MRI | 78% (CI:69-85%) | 88% (CI: 83-92%) | 26.6 (CI: 14.7-48.4) |
| PET | 53% (CI: 32-75%) | 98% (CI: 94-99%) | 55.7 (CI:19.4-159.9) |
| CTPET | 87% (CI:74-94%) | 87% (CI:69-95%) | 46.0 (CI: 16.2-130.4) |

**Conclusion:** This meta-analysis shows that CTPET seems to be the most optimal imaging modality for the detection of PC. CT and MRI demonstrate similar results in detecting PC with a lower pooled sensitivity than CTPET.

## P0220 MR IMAGING FOR DEDICATED LOCAL STAGING OF COLON CANCER

E. Nerad[1], D.M. Lambregts[2], E. Kersten[3], F. Bakers[4], H. Van Den Bosch[1], H. Grabsch[5], R.G. h. Beets-Tan[2], **M. Lahaye**[6]

**Introduction:** Distant and local staging of colon cancer is currently performed with computed tomography (CT). At diagnosis, 15–23% of colorectal cancer (CRC) patients have liver metastasis detection is crucial because it entails poor prognosis and a different clinical approach and treatment. Multiple studies already demonstrated that magnetic resonance imaging (MRI) is superior to CT for the detection of liver metastasis[1]. It seems local staging of colon cancer does not need the same finesse; imaging is mostly used to assess the resectability of the colon tumor (i.e. involvement of surrounding organs). However, this might change in the near future; a large multicenter study, FOXTROT[13], is currently investigating the benefits of neo-adjuvant chemotherapy for patients with locally advanced colon cancer. If the FOXTROT trial confirms initial promising reports, neoadjuvant treatment in colon cancer patients will be adopted as standard therapy, just like in rectal cancer patients. If so, preoperative imaging will become a crucial tool to select patients for neo-adjuvant treatment. MRI is well established in local staging of rectal cancer because of its superior results compared to CT[14]. However, little is known about the local staging of colon cancer with MRI. If MRI is able to accurately stage colon tumors, it might be the ideal imaging tool for simultaneous local and distant staging.
**Aims & Methods:** The aim of this study was to evaluate the diagnostic performance of MRI for local staging of colon cancer patients. 55 colon cancer patients underwent MRI (1.5 T; T2TSE and DWI) of the abdomen and were retrospectively analysed by two blinded, independent readers. Histopathology after resection was the reference standard. Both readers evaluated tumour characteristics being; invasion through bowel wall (T3/T4 tumours), invasion beyond bowel wall of $\geq$5 mm and/or invasion of surrounding organs (T3cd/T4), serosal involvement, extramural vascular invasion (EMVI) and the presence of malignant lymph nodes (N+). Inter-observer agreement was compared using Kappa ($\kappa$) statistics.
**Results:** The sensitivity and specificity detecting T3/T4 tumours (35/55), T3cd/T4 tumours (15/55), fascia involvement (8/55), EMVI (17/55) and nodal involvement (19/55) were for reader 1; 91%/84%, 40%/88%, 88%/74%, 100%/62% and 47%/86%, 68%/64% and for reader 2: 72%/89%, 60%/75% and 75%/72% 88%/70%, respectively. Interobserver agreement between both readers were good to moderate: 0.72, 0.55, 0.62, 0.60 and 0.60 respectively.
**Conclusion:** Compared to previous literature on CT our study shows that MRI seems to perform as well as CT in local staging, with the added benefit that it has the potential to be more accurate in detecting prognostic factors such as serosal involvement and EMVI. This could have an important therapeutic impact, especially if neo-adjuvant treatment will be adopted in the treatment guidelines for advanced colon cancer (i.e. if the results of the FOXTROT trial confirm its benefit). An additional important advantage of MRI is its superiority in detecting small liver metastases with the evaluation of the colon tumor in one imaging session[1]. The most recent EURECCA expert guidelines advise MRI of the liver[2] in the preoperative staging of colorectal cancer. This would entail that the MR sequences for local staging of the colon tumor can be performed in the same MR imaging session of the liver. This combined approach could result in the most optimal abdominal staging tool for colon cancer patients.

**Introduction:** Gastrointestinal wall thickening (GWT) is a common incidental finding in abdominal computed tomography (CT). Despite uncertain clinical significance, this finding often leads to expensive evaluation, especially in the fear of cancer.
**Aims & Methods:** We assessed the utility of endoscopic investigation in patients with GWT diagnosed by CT. We retrospectively evaluated patients performing upper gastrointestinal endoscopy (UGE) and colonoscopy (CP) following a diagnosis of GWT. Age, gender, previous oncologic history and endoscopic and pathology findings were recorded.
**Results:** We included 353 patients (53.8% female, mean age 66.2 $\pm$ 15.2 years) with GWT in the stomach (183) and colon (170). 161 patients (45.6%) had a normal endoscopic examination (51.4% UGE versus 39.4% CP). 142 patients (40.2%) presented only with benign lesions (39.3% UGE versus 41.2% CP). In 49 patients (13.9%) a high grade adenoma or cancer was diagnosed (8.7% UGE versus 19.4% CP). Only age was identified as an independent risk factor for the diagnosis of malignancy (OR 1.028, 95%CI 1.005–1.052, $p = 0.015$). A cancer was more likely to be found in CP than UGE (OR 2.60 95%CI 1.37–4.94, $p = 0.004$). Even though 61 patients (17.3%) had a prior history of cancer, this was not found to be predictive of a current diagnosis of carcinoma.
**Conclusion:** In our series, over 50% of patients presented with abnormal findings during endoscopic investigation of GWT and in 13.6% a diagnosis of cancer was performed. Our results support the investigation of GWT, especially in older patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0222 TRANSPARENTIZATION TECHNOLOGY ENABLES US TO RECONSTRUCT THREE-DIMENSIONAL HISTOPATHOLOGICAL STRUCTURE OF GASTROINTESTINAL MUCOSA NON-DESTRUCTIVELY: A PORCINE MODEL STUDY

**Introduction:** There is no established method to assess three-dimensional structure of endoscopic resected gastrointestinal mucosa non-destructively.
**Aims & Methods:** This study was aimed to evaluate the feasibility of transparentization technology for three-dimensional histopathological assessment of resected gastrointestinal mucosa in a porcine model. Esophagus, stomach, and colon mucosa obtained from a sacrificed pig were prepared in the following two fashions; formalin-fixed specimen, and deparaffinized specimen after formalin-fixed paraffin-embedding. After staining with 4', 6-diamidino-2-phenylindole (DAPI) and lycopersicon esculentum lectinconjugated with DyLight 594 (tomato lectin), all specmens were transparentized by LUCID method (ilLUmination of Cleared organs to IDentify target molecules)[1] and observed by confocal laser scanning microscope (CLSM) and multiphoton-excited fluorescence microscope (MEFM). Scanned horizontal section views were evaluated after reconstruction of three-dimensional structures using image-analyzing software. After observation, all transparentized specimens were paraffin-embedded again. They were evaluated by conventional histopathological assessment including immunohistopathological staining to measure the impact of transparentization comparing to formalin-fixed paraffin-embedded specimen without transparentization.
**Results:** Degrees of transparency were increased well in all specimens, especially in deparaffinized specimens after formalin-fixed paraffin-embedding. CLSM and MEFM revealed horizontal section views of mucosa at deeper levels. MEFM enabled us to observe the whole thickness of mucosal layer and reconstruct three-dimensional structure. DAPI and tomato lectin staining revealed ductal structure and vessel structure, respectively. Paraffin-embedded specimens after transparentization were all assessed appropriately by conventional histopathological staining.
**Conclusion:** Transparentization technology enables us to observe deeper inside of endoscopic resected specimen and evaluate three-dimensional structure non-destructively.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0223 THE EVOLUTION OF THE ENDOSCOPE ASSISTED PERCUTANEOUS TRANS-ESOPHAGEAL GASTRO-TUBING AS A NEW ALTERNATIVE TO THE PERCUTANEOUS ENDOSCOPIC GASTROSTOMY: 86 SUCCESSFUL CASES

**H. Oishi**
*Division Of Gastroenterological Surgery, Department Of Surgery, Yachiyo Med Ctr, Tokyo Women's Med Univ, Chiba/Japan*

**Contact E-mail Address:** oishi.hideto@twmu.ac.jp.

**Introduction:** In 1994, percutaneous transesophageal gastrotubing (PTEG) was reported as an alternative procedure for feeding tube placement in patients for whom percutaneous endoscopic gastrostomy (PEG) is contraindicated. In 1997, the PTEG balloon was replaced with a rupture-free balloon (RFB) because the original balloon was easily punctured and could not support the esophageal lumen for guidewire insertion. In Japan, PTEG is commonly used for enteral nutrition and gastrointestinal decompression, and the standard PTEG procedure is performed under ultrasonographic and fluoroscopic guidance.
**Aims & Methods:** For safety, we began, in 2003, to perform endoscope-assisted PTEG (EA-PTEG), which has since been revised and assessed. The original RFB was used for the first 6 of 107 EA-PTEG procedures. Contact between the endoscope and the RFB was inadequate, so an endoscope-mounting RFB (EM-RFB) was devised for the tip of the endoscope. EA-PTEG was performed with the EM-RFB in 2 patients, but the balloon prevented smooth operation of the endoscope. In fact, in 1 of the 2 patients, EA-PTEG with the original RFB was necessary. The next new RFB was an overtube (OT-RFB) to allow for smooth endoscope operation. EA-PTEG with the OT-RFB was performed in 5 patients, but the OT-RFB obscured the ultrasonographic view needed for puncture. To resolve this problem, a double-layered RFB was fitted around the overtube, to which a window was added. Fluid was injected so that the outer RFB dilated the esophageal lumen and the inner RFB does so inward so that a clear ultrasonographic view could be obtained. This new RFB is referred to as the double-balloons equipped overtube type RFB (DBOt-RFB).
**Results:** The DBOt-RFB was used successfully in 86 patients—63 for enteral nutrition and 23 for gastrointestinal decompression. We had some difficulty at first: we were unable to obtain a safe puncture route in 3 patients, the endoscope caused vagus nerve hypotension in 1 patient, and hypoxia occurred in 1 patient. We resorted to using the original RFB in 1 of these patients and to standard PTEG in the other 4. We made several improvements to the DBOt-RFB, and the EA-PTEG procedure was performed with no major complications.
**Conclusion:** Because real-time assessment of the esophageal lumen is achieved endoscopically, the EA-PTEG procedure is not only safer than standard PTEG but also easier to monitor. The endoscopic view warns us of bleeding and/or mucosal injury and alerts us to contraindications. Should the endoscopic procedure prove ill-advised, we can convert to standard PTEG. EA-PTEG with DBOt-RFB is a safe, simple, minimally invasive cervical esophagostomy procedure.

**Introduction:** The number of endovascular abdominal interventions has increased over the past decades and is expected to increase even further in the near future. Examples of endovascular interventions in gastroenterology are trans-arterial chemoembolization (TACE) for hepatocellular carcinoma, mesenteric artery stent placement for occlusive chronic gastro-intestinal ischemia and embolization of hepatic artery aneurysm, hepatic adenoma or bleeding hepatocellular carcinoma. The approach for endovascular abdominal interventions is mostly trans-brachial or trans-femoral. Previous reports about trans-brachial and trans-femoral procedures for endovascular abdominal interventions report relatively high complication rates. Moons et al.[1] reported in 43 patients (trans-brachial $n = 32$) a minor complication rate of 25.6% (8 local hematoma, 1 dissection, 2 pseudo-aneurysms) and a major complication rate of 20.9% (1 pneumonia, 2 strokes, 1 spleen-infarction, 2 thrombosis, 1 AV-fistula, 2 nerve damages). In interventional cardiology nowadays, trans-radial access (TRA) is the preferred approach with low reported complication rates. Advantages of TRA compared to trans-brachial and trans-femoral access are reduced radiation exposure to the interventionalist and no requirement of ultrasound for the arterial puncture. Furthermore, no major anatomical structures with risk of damaging are nearby and collateral circulation exists via the ulnar artery. Finally, the closure device is inexpensive compared to femoral closure devices such as Angio-Seal and patients are permitted to mobilize immediately. TRA however requires longer catheters, especially in abdominal procedures, which can lead to difficulties in manipulation. Reports on endovascular abdominal interventions per TRA are lacking.
**Aims & Methods:** The aim of this study was to assess the feasibility and complication rate of TRA for endovascular abdominal interventions. We prospectively assessed the complication rates of patients who underwent endovascular abdominal intervention per TRA instead of trans-brachial or trans-femoral access between November 2014 and April 2016. All patients had a normal modified Allen test result, a simple test to assess the adequacy of blood supply through the ulnar artery to the hand.
**Results:** Forty-five patients (24 men, mean age $63.8 \pm 12.1$ years) underwent 49 trans-radial endovascular abdominal procedures. Thirty-one (63.3%) interventions concerned a mesenteric endovascular procedure, 11 (22.4%) TACE and 7 (14.3%) an endovascular procedure of the hepatic artery. The minor complication rate was 16.3% (6 local hematoma, 1 cellulitis, 1 temporary sensibility loss). There were no major complications. In 7 procedures successful execution was not achieved, in 3 out of 7 procedures possibly attributed to the radial approach. Therefore, radial technical success rate was 94%. All patients were able to mobilize directly after the intervention.
**Conclusion:** TRA for endovascular abdominal interventions showed to be a feasible and successful technique with a low complication rate. TRA may therefore be the preferred approach in endovascular abdominal interventions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Both Roux-en-Y gastric bypass (RYGB) and duodenojejunal bypass liner (DJBL) have been shown to induce significant weight loss and dramatically ameliorate type 2 diabetes mellitus (T2DM). Because DJBL implantation induces nutrient bypass of the duodenum, its mechanisms have been proposed to mimic those of the RYGB.
**Aims & Methods:** This monocentric prospective parallel group study aimed to compare the bariatric procedures DJBL and PYGB in the treatment of obesity and T2DM. Up to April 2016, a total of 54 patients were included. Twenty-five (8 male, mean age $51.1 \pm 10.9$ yrs) underwent RYGB and twenty-eight had DJBL (12 male, mean age $54.1 \pm 10.6$ yrs). Body weight, body mass index, and glycated haemoglobin A1C (HbA1C) were documented pre- and 1, 3, and 9 months postsurgery.
**Results:** Changes in metabolic parameters are shown in table 1.
**Conclusion:** This is the first study comparing the improvement in glucose metabolism following RYGB or DJBL. As expected, our preliminary data demonstrated RYGB to be superior for induction of weight loss. However, both procedures have a similar impact on diabetes remission, indicating that alteration of weight loss itself is not the main determinant of improvement in glucose homeostasis in these obesity procedures.
**Disclosure of Interest:** J. Stein: Jürgen Stein has received fees for lecturing and consultancy from GI Dynamics.

**Introduction:** Sleeve gastrectomy (SG) is one of the most performed procedure in the field of bariatric surgery. However, digestive symptoms such as gastroesophageal reflux disease (GERD), vomiting, regurgitations, food intolerance, or epigastric pain are also reported after this type of surgery. Currently, data are scarce on the exact impact of SG on esophagogastric physiology, in particular on the pathogenesis of ''de novo'' GERD.
**Aims & Methods:** We aimed to assess the impact of SG on esophageal chemical clearance and on basal impedance levels in morbidly obese without preoperative pathological GER by means of impedance-pH monitoring (MII-pH). We retrospectively reviewed data from a consecutive series of 18 women and 7 men (median age, 42 years) who underwent MII-pH before and after SG. All patients underwent a standardized questionnaire for symptom presence and severity, upper endoscopy, high resolution manometry (HRM) and MII-pH. By means of MII-pH, the following variables were assessed: distal esophageal acid exposure as percentage (AET%) of time with pH < 4 (abnormal if total time with pH < 4 was greater than 6.3%, and/or upright time with pH < 4 was greater than 4.2%, and/or recumbent time with pH < 4 was greater than 1.2%), number and quality (acid and weakly-acid) of reflux detected at MII (normal value < 73), and Symptom Association Probability (SAP). Esophageal chemical clearance was determined using the post-reflux swallow-induced peristaltic wave (PSPW). A PSPW was defined as an antegrade 50% drop in impedance relative to the pre-swallow baseline originating in the most proximal impedance site, reaching all the distal impedance sites, and followed by at least 50% return to the baseline in the distal impedance sites (bolus exit). For each impedance-pH tracing, the number of refluxes followed within 30 s by a PSPW was divided by the number of total refluxes (manual calculation) in order to obtain the PSPW index. The mean nocturnal esophageal basal impedance (MNBI) level was assessed from the most distal impedance channel during nighttime recumbent period. Three 10-minute time periods (around 1.00 am, 2.00 am, and 3.00 am) were selected and the mean baseline for each period was computed with the aid of the software. Time periods including swallows, refluxes and pH drops were avoided. The mean of the three measurements was manually calculated to obtain the MNBI. Parametric variables were summarized as mean and SD and compared using ANOVA. Nonparametric variables were summarized as median with interquartile range (IQR) and compared using Wilcoxon nonparametric tests (Kruskall–Wallis). A $p < 0.05$ was considered significant.
**Results:** The preoperative (130.8 kg (119–156), Body Mass Index (BMI) = 46.1 (38–58)) and postoperative (98 kg (72–110), BMI = 34.7 (28–46)) anthropology was statistically different with 56% excess weight loss. After surgery, the incidence of symptoms related to reflux was not modified; in particular, no increase in perception of heartburn, regurgitation, and epigastric pain was observed. The preoperative median percentage with esophageal pH < 4 was 1.47 for total time, 1.1 and 1 in the upright and recumbent positions, respectively. Postoperatively, DeMeester's score ($p = 0.041$) and the median percentage with esophageal pH < 4 in recumbent position ($p = 0.04$) significantly increased (from 1 (0–1.2) to 3.1 (0–4.2), $p = 0.04$). The SG produced an increase of total reflux episodes (33 vs. 53; $p < 0.0001$) detected at MII. Specifically, a significant increase of postoperative non-acid reflux episodes in both upright (17 vs. 28; $p < 0.0001$) and recumbent (4 vs. 8; $p < 0.0001$) position was detected. PSPW index decreased after SG (80 ± 10 vs. 50 ± 20; $p < 0.001$), as well as MNBI, that decreased (3016 ± 819 vs 1542 ± 452; $p < 0.001$). There was an inverse correlation between PSPW, MNBI and the number of reflux, and a inverse correlation between PSPW and AET ($p < 0.0001$).
**Conclusion:** SG can lead to an impairment of esophageal chemical clearance and mucosal integrity, as well as to an increase of reflux number. Due to this effect, SG should be considered only after an adequate preoperative esophageal testing to exclude an underlying GERD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0227 LONG TERM QUALITY OF LIFE AFTER ESOPHAGECTOMY WITH GASTRIC PULL-UP

**S. Mantoan**, F. Cavallin, E. Pinto, L. M. Saadeh, R. Alfieri, M. Cagol, M. C. Bellissimo, C. Castoro, M. Scarpa
*Esophageal And Digestive Tract Surgical Unit, Regional Centre For Esophageal Disease, Veneto Institute of Oncology (IOV-IRCCS), Padova/Italy*

**Contact E-mail Address:** mantoan.silvia@gmail.com.
**Introduction:** Esophageal cancer (EC) is an increasingly common cancer with a poor prognosis. Health-related quality of life (HRQL) has become an important outcome measure of surgical treatment for cancer and recent systematic reviews showed a deterioration in HRQL after esophagectomy. Data about long-term adjustment to esophagectomy are scarce.
**Aims & Methods:** The aim of this study was to analyze long term quality of life at 3 or more years after esophagectomy for cancer. Patients who had undergone esophagectomy with gastric pull-up during 2007–2013 were interviewed regarding their alimentary satisfaction and quality of life. Quality of life was evaluated using the Italian version of the European Organization for Research and Treatment of Cancer (EORTC) QLQ-C30 and OG25. Data about patients characteristics, treatment and follow-up were retrieved. Comparisons with European norms were performed. Non parametric statistics was carried on.
**Results:** We identified 65 long-term survivors after esophagectomy and gastric pull-up for cancer. The median age was 64 years (IQR 58; 70) with a median follow-up of 4 years (IQR 3; 5). Most patients reported early satiety (76.9%), whereas dysphagia (10.8%), reflux (33.8%), regurgitation (20.0%) and dumping (24.6%) were less frequently reported. The median alimentary comfort rating was 8 of 10. Patient's global quality of life was comparable to European population values (mean 74.0 vs. 75.7, $p = 0.27$). Patients reported lower physical functioning (mean 84.5 vs. 91.0, $p = 0.005$) and more insomnia (mean 19.0 vs.15.7, $p = 0.005$) and appetite loss (mean 9.7 vs. 4.8, $p = 0.01$) than European population.
**Conclusion:** Long-term survivors after esophagectomy for cancer had a global quality of life comparable to the European population. Alimentary satisfaction was good but appetite loss and early satiety were reported even at long term. Such results enhance the importance of long-term follow-up in EC evaluating alimentary and functional aspects in addition to recurrence surveillance.

## P0228 PROSPECTIVE RANDOMISED STUDY COMPARING BILLROTH II WITH BRAUN ANASTOMOSIS VERSUS ROUX-EN-Y RECONSTRUCTION AFTER RADICAL DISTAL GASTRECTOMY

**S. Gavini**, V. Vutukuru, K. Radhakrishna, S. Parthasarathy
*Gi Surgery, SVIMS, Tirupati/India*

**Contact E-mail Address:** srkgavini@gmail.com.
**Introduction:** Billroth II reconstruction is the most common method of reconstruction after distal gastrectomy because of its simplicity. However, enterogastric reflux is regarded as an unavoidable consequence of this procedure. Enterogastric reflux of bile acids leads to reflux gastritis and esophagitis. Apart from morphologic changes, enterogastric reflux causes various symptoms

**Abstract No: P0228**

| | | RY(n = 14) | BEE(n = 13) | p value |
|---|---|---|---|---|
| Residual food | Grade0 Grade1 Grade2 Grade3 Grade4 | 10(71.4%) 2(14.3%) 2(14.3%) 0 0 | 12(92.3%) 0 0 1(7.7%) 0 | 0.07 |
| Degree of gastritis | Grade0 Grade1 Grade2 Grade3 | 7(50%) 7(50%) 0 0 | 1(7.7%) 7(53.8%) 5(38.5%) 0 | **0.003** |
| Extent of gastritis | Grade0 Grade1 Grade2 Grade3 | 7(50%) 0 7(50%) 0 | 1(7.7%) 3(23.1%) 7(53.8%) 2(15.4%) | **0.008** |

$p < 0.05$ is significant

that adversely affects the quality of life of the patients after distal gastrectomy. There is still controversy regarding which is the best method of reconstruction after radical distal gastrectomy and how factors like bile reflux and other consequences of different types of reconstruction influence the postoperative quality of life. Therefore, a prospective randomized study has been undertaken to evaluate incidence of bile reflux, reflux gastritis, reflux esophagitis, postoperative quality of life according to reconstruction method after radical distal gastrectomy for gastric cancer and to find out the best method.

**Aims & Methods:** The aim of this study is to compare Billroth II with Braun anastomosis (BEE) and Roux-en-Y gastrojejunostomy (RY) after radical distal gastrectomy for gastric cancer in terms of bile reflux, endoscopic and histologic changes in the gastric remnant and postoperative outcomes in terms of morbidity, mortality and quality of life. The study was conducted from June 2012 to November 2013 at Department of Surgical Gastroenterology, Sri Venkateswara Institute of Medical Sciences, Tirupati, India.

**INCLUSION CRITERIA:** 1. Patients with histopathologically confirmed adenocarcinoma of the distal stomach suitable for radical distal gastrectomy with curative intent. 2. Age between 21–80 years.

**EXCLUSION CRITERIA:** 1. Patients not willing to participate in the study 2. Patients who have undergone previous gastric surgery. 3. Patients with previous small bowel surgery precluding construction of either form of anastomosis. 4. Patients operated for palliation of gastric outlet obstruction, bleeding and perforation. 5. Patients who underwent additional organ resection. The study was approved by the Institutional Research Approval Committee and Ethical Committee. All participants gave informed consent before enrollment in the study.

**Results:** The mean age of patients in RY group was 54.57 years and in BEE group was 54.08 years. Comparison of two groups based on reconstruction type showed significant differences in the incidence of bile reflux on endoscopy. None (0/14) of the patients who underwent RY reconstruction showed evidence of bile reflux on endoscopy. One patient (1/13) in the BEE group showed evidence of bile reflux on endoscopy. The frequency of bile reflux was significantly lower in the RY group (7.1%) than in the BEE group (46.1%) based on the hepatobiliary scintigraphy ($p = 0.03$) Two patients (2/14) in the RY group and one patient (1/13) in the BEE group were found to have stomal ulcer on follow up. The remnant stomach after Billroth II with Braun anastamosis showed significantly more severe and extensive gastritis than after Roux-en-Y gastrojejunostomy when visualised during endoscopy. None of the patients in both the groups had evidence of reflux esophagitis on endoscopy. The symptom scores based on quality of life questionnaire were comparable between the two groups at 3 months follow-up. **Comparison of endoscopic findings in remnant stomach after each type of reconstruction**.

**Conclusion:** In our study, Roux-en-Y reconstruction is superior to Billroth II with Braun anastomosis comparing reflux by endoscopy and hepatobiliary scintigraphy and endoscopic severity of gastritis. However, there is no difference in quality of life between these reconstruction methods at 3 months follow-up.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Laparoscopic-assisted distal gastrectomy (LADG) has been common procedure for early gastric cancer. And totally laparoscopic distal gastrectomy (TLDG) is regarded as a difficult method due to technical problems. However, instruments have evolved and operators have become proficient. Recently, advantage of TLDG has been reported by several institutions.

**Aims & Methods:** This study aimed to compare the short-term surgical outcomes of patients with gastric cancer undergoing TLDG to those of patients undergoing LADG. A total of 232 gastric cancer patients who underwent LADG (115 patients) or TLDG (117 patients) with lymphadenectomy from March 2010 to February 2016 were retrospectively studied from a prospectively designed database.

**Results:** Operating time for TLDG group ($245 \pm 38$ min) was significantly shorter than for LADG group ($278 \pm 70$ min) ($P < 0.001$). Blood loss during surgery was less for TLDG ($77 \pm 29$ ml) than for LADG ($128 \pm 65$, ml) ($P < 0.001$). There was no significant difference between TLDG and LADG with regard to postoperative hospital stay, first flatus passage and start of soft diet. Although number of total retrieved number was much larger in TLDG ($49 \pm 18$) than LADG ($42 \pm 15$), adequate lymphadenectomy was performed in both groups. Postoperative morbidity rates in TLDG and LADG were similar (5.9% vs 9.5%, $P = 0.757$). Postoperative pain scores were 4.2 vs 4.3, 3.4 vs 3.4 and 2.4 vs 2.5 at postoperative days 1, 3, and 5 respectively in the TLDG and LADG. ($P = 0.932$, 0.804 and 0.440).

**Conclusion:** This study suggests that TLDG is technically safe and feasible procedure as LADG and better cosmetic procedure for the treatment gastric cancer.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0230 EFFICACY OF ORAL VITAMIN B12 SUPPLEMENTATION AFTER TOTAL GASTRECTOMY – RESULTS FROM A PROSPECTIVE STUDY

**J. Moleiro**[1], S. Mão Ferro[1], S. Ferreira[1], M. Serrano[1], M. Silveira[2], A. Dias Pereira[1]

**Introduction:** Vitamin B12 (vitB12) deficiency is a common and early complication after total gastrectomy which may be associated with megaloblastic anemia and neurologic symptoms potentially irreversible. Intramuscular injection of vitB12 has been considered the standard treatment, however, it is painful, expensive and, currently, difficult to obtain in our country.

**Aims & Methods:** We performed a prospective uncontrolled study (ACTRN12614000107628) in order to evaluate the laboratorial and clinical efficacy of long-term oral vitB12 supplementation in patients who underwent total gastrectomy (primary outcome). The secondary outcome was to evaluate other nutritional deficiencies namely iron and folate deficiency. All patients received daily oral vitB12 (dosage: 1 mg/day) and were evaluated every 3 months (clinical and laboratory evaluation: haemoglobin, vitB12, total iron, ferritin and folate). Statistics: SPSS 23 (Wilcoxon test).

**Results:** A total of 26 patients were included in this study, mean age of 64 years (29–79), with the diagnosis of adenocarcinoma ($n = 25$) and MALT lymphoma ($n = 1$). Patients were included 65 months after total gastrectomy (3-309). At inclusion time, 17/25 patients were under intramuscular vitB12 and 8 had not yet started supplementation. There were normal serum levels of vitB12 in 25/26 patients (1/26 with low vitB12 levels due to non-adherence to intramuscular supplementation) - mean vitB12 level of 657 pg/ml (136–2642). During the follow-up, all patients had normal vitB12 levels, and there was no need of intramuscular therapeutic. The patient with low vitB12 serum levels had an increase to adequate levels, which maintained stable. There were no differences with statistical significance among vitB12 levels at 6 (867 pg/ml), 12 (1008 pg/ml) and e 24 (1061 pg/ml) months, although there was a progressive increase of them. Iron and folate supplementation was necessary in 12 and 7 patients, respectively.

**Conclusion:** Oral vitB12 supplementation is effective and safe in patients who underwent total gastrectomy and should be considered the preferential form of supplementation in this group of patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0231 SEXUAL DISORDERS AFTER LOW ANTERIOR RESECTION OF THE RECTUM

**Contact E-mail Address:** martynaszewczyk94@gmail.com.
**Introduction:** Low anterior resection of the rectum is a treatment of choice in patients with diagnosed low rectal cancer. Surgical resection of the rectum can result in multiple complications related to lesion of neighbouring neural structures responsible for fecal continence as well as urinary and sexual function.
**Aims & Methods:** In our study we investigate the sexual disorders in patients who underwent a low anterior resection of the rectum. The sexual activity, comfort of the experience, quality of sexual life during 3 periods: before surgery, a month after and half a year after were analyzed. Analysis of comorbidities, previous surgeries and trauma as risk factors of sexual disorders. Patients with rectal cancer who underwent low anterior resection of the rectum at the Department of General and Colorectal Surgery at the Medical University in Lodz during the period from 2003 to 2015 were asked to complete a questionnaire concerning their sexual activity before and after surgical procedure. The questionnaire was comprised of 37 closed-ended questions. Only fully completed questions (surveys) were included to further statistical analysis.
**Results:** The study analysis involved 100 fulfilled questionnaires – 43 women and 57 men. Patients mean age was $56.9 \pm 7.6$. A statistical, significant differences between the periods of time (before surgery, month after surgery and half year after surgery) and quality of sexual life was noted ($p < 0.001$). No relationship was found between the sex of patients and quality of their sexual life. However, the quality of sexual life one month after the surgery was significantly lower in patients with diagnosed hypertension ($p = 0.009$).
**Conclusion:** Low anterior resection (of rectum) significantly impairs the sexual activity of patients. However, these disorders are passing of over time. Also LAR procedures have strong negative impact on fecal, gas and urinary incontinence which may, in addition, intensify sexual discomfort.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0232 OUTCOME PREDICTORS AND TREATMENT OF BILIARY COMPLICATIONS POST LIVER TRANSPLANTATION

Y.J. Wong[1], J.H. J. Ngu[1], C.K. Tan[1], W.C. Chow[1], H.K. Tan[1], H.F. Lui[1], P.C. Cheow[2], R. Prema[3], Y.F.A. Chung[3], K.P. Brian Goh[3], H.G.R. Lo[4], F.G. Irani[4], F.G. Irani[4], **S.J. Mesenas**[1]

**Introduction:** Liver transplantation (LT) can be life saving for the patient with acute liver failure and end-stage liver disease. However, LT is associated with significant morbidity and mortality. Biliary complication (BC) is one of the major causes of morbidity among LT recipients.
**Aims & Methods:** We aim to investigate the outcome predictors and treatment of BC post LT. Patients with LT performed from 2005–2015 were prospectively monitored for BC. Diagnosis of BC was made by cholangiography (MRCP, ERC or T-tube cholangiography). Cases were censored at death or last follow up. Kaplan Meier curves were used to present survival data. Analyses were performed using Cox-regression or logistic binary regression. Statistical analysis was performed with SPSS 21.0.
**Results:** Total of 81 consecutive LT patients were included. Total follow-up duration was 4086 patient-months. Median age was 61.5 years and 69.1% were males. Etiology of underlying liver disease of LT patients included hepatitis B (42%), autoimmune liver diseases (14%), cryptogenic (12%), alcohol (10%), hepatitis C (9%) and others (13%). Deceased donor liver transplant (DDLT) and living donor liver transplant (LDLT) were 71.6% and 28.4% respectively. BC was diagnosed in 30.9% of LT patients (21 strictures, 7 leaks and 2 choledocholithiasis and 1 sphincter of Oddi dysfunction). BC was associated with worse 5-year patient survival (84% vs 58%, $p = 0.013$). Surveillance ultrasound missed 57.1% of biliary strictures, which were subsequently confirmed on MRCP or cholangiography. Among patients with biliary strictures, 81% had anastomotic strictures (AS) and 19% had non-anastomotic strictures (NAS). All AS were treated with ERC and stenting with or without balloon dilatation. Majority (80%) of AS achieved complete resolution of stricture after an average of 5.0 ERC over median intervention period of 16.8 months. Of those who had not achieved complete resolution, 3 were still undergoing 3-monthly ERC and 2 had died from non-BC-related causes prior to treatment completion. There was no recurrence of strictures in those who had achieved complete resolution. Complications from ERC were low [cholangitis (1.33%) and bleeding (1.33%)]. Factors associated with the development of BC were longer cold ischemia time of more than 6 hours ($HR = 4.45$, $p = 0.015$) and LDLT ($HR = 4.5$, $p = 0.004$). Predictors of poor outcomes in patients with biliary strictures were elevated serum alkaline phosphatase (ALP) more than 581U/L ($OR = 4.9$, $p = 0.044$) and presence of NAS ($OR = 32.5$, $p < 0.01$).
**Conclusion:** We found that factors associated with development of BC post liver transplant are LDLT and prolonged cold ischemia time. ERC with stenting is a safe, effective and durable treatment option for anastomotic strictures. Predictors of poor survival in patients with BC post LT are elevated serum ALP at diagnosis and presence of non-anastomotic strictures.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0233 EMERGENCY LAPAROTOMY: STRATEGIES TO ACHIEVE INTERNATIONAL BENCHMARKS IN LOW - MIDDLE INCOME COUNTRIES (LMIC)

[4]*Department Of Anaesthesiology, Max Super Speciality Hospital, New Delhi/India*

**Contact E-mail Address:** Nitin.vashistha@maxhealthcare.com.
**Introduction:** Advancements in surgical techniques and critical care over the last 2 decades have led to a low mortality of ≤5% for major elective digestive tract surgery. Similar results have however not been replicated for major emergency laparotomy (EL) where the current mortality ranges between 15 – 20% in best of healthcare systems.[1, 2] A recent review reported that while LMIC carry majority burden of emergency conditions they have only a limited capacity to deal with the problem.[3].
With an aim to achieve prevalent international benchmarks, we introduced a series of steps for an efficient conduct of EL. The outcome was evaluated in terms of morbidity, mortality and costs.
**Aims & Methods:** Intervention: EL.
Period: December 2012 – December 2015.
Study design: Retrospective.
Patients: >16 years, Consecutive.
Exclusions: Laparoscopic surgery.
Setting: Tertiary care referral hospital.
Modifications:.
- All patients admitted to ICU for preoperative stabilization (intravenous fluids and antibiotics) and maintained until postoperative optimization.
- Preferred radiologic investigation: Abdominal computed tomography scan.
- All imaging was evaluated by senior radiologist.
- All operations performed by team of senior digestive tract surgeons.
- A senior internist well versed with critical care issues was an integral part of the team.

Outcome measures: 30 – day mortality, morbidity, re-admission and costs.
**Results:** Of the 102 patients there were 62 males & 40 females with median age of 60 (range 16 -93) years. The indications for surgery included obstruction 30, perforation 27, acute ischemia 16, gastrointestinal bleed 10, and others 19.
There were no complications in 22 (21.5%) patients while Clavien – Dindo complications grade I & II occurred in 48 (47%) patients. Complications ≥III occurred in 31.3% patients [III (2.9%), IV (9.8%) and grade V in 19 (18.6%) respectively]. The 30 day readmission rate was 8 (7.8%). The overall median length of stay was 10 (range 2 – 72) days.
The median all inclusive cost of treatment was INR 379.255 /- (Approximately €5000). For patients with no complications or outcomes Clavien – Dindo grade I-II, the median cost was INR 318.483 (range 121.344/- to 11, 65.429/-), approximately €4201. For patients in grade III, IV & V the median cost was INR 710500/ (range 147081 – 32, 000, 00/-), approximately €9373.
At step wise logistic regression analysis serum albumin ≤2 gm% ($P < 0.0001$) and multiorgan failure ($P = 0.002$) were independent predictors of mortality.
**Conclusion:** With careful preoperative planning, optimal use of available resources and minimizing complications, EL can be performed at LMIC centers with outcomes consistent with prevalent international benchmarks and at affordable costs.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Acute gastrointestinal defects contain a high risk of morbidity and mortality and may be closed endoscopically by a full-thickness over-the-scope clip (OTSC).
**Aims & Methods:** Unselected consecutive patients presenting with acute non-surgical or postoperative perforations underwent attempted OTSC placement as primary closure method after interdisciplinary consensus in three tertiary referral centers. Their clinical data and intervention characteristics were evaluated in an intention to treat analysis during a 24 months period to assess closure rates, 30-days mortality, hospitalization and comorbidity.
**Results:** In total, 34 patients (16 female, 18 male, 69.5 years) were included with 22 non-surgical perforations and 12 postoperative perforations. Definitive closure of perforation was achieved in 26/34 patients (76.5%). Successful perforation closure resulted in a significantly shorter hospital stay (8 days, $p = 0.03$) and was significantly correlated with comorbidity ($r = 0.56$, $p = 0.005$). In the group with OTSC failure hospitalization was 18 days and 6 of 8 patients (75%) required immediate surgery. Three deaths occurred in the group with successful perforation closure due to comorbidity, while one death in the OTSC failure group was related to a refractory perforation. Favorable indications and locations for a successful OTSC procedure were identified as PEG complications, endoscopic or postoperative perforations of stomach, colon or rectum, respectively.
**Conclusion:** In unselected patients OTSC was effective for closure of acute perforations in more than 75% of all patients. Clinical success and short hospitalization were best achieved in patients without comorbidity, but perforation closure was found to be not the only parameter relevant for patient outcome and mortality.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0236 LONG TERM QOL AFTER ESOPHAGECTOMY: DO POST-OPERATIVE COMPLICATIONS MATTER?

A. E. Slaman[1], L.M. Saadeh[2], S. Mantoan[2], S. S. Gisbertz[1], F. Cavallin[2], E. Jezerskyte[1], E. Pinto[2], C. Caberlotto[2], R. Alfieri[2], M. Cagol[2], **M.I. Van Berge Henegouwen**[3], C. Castoro[2], M. Scarpa[2]

[3]*Academic Medical Center, Surgery, Academic Medical Centre, Amsterdam, Netherlands, Amsterdam/Netherlands*

**Contact E-mail Address:** m.i.vanbergehenegouwen@amc.uva.nl.
**Introduction:** Esophageal cancer (EC) is the eighth most common cancer in the world; despite new advances in neoadjuvant therapies, the outcome remains poor compared to other malignancies. The surgical resection plays a key role but it is still burdened by high rate of complications even in tertiary referral centers. Health-related quality of life (HRQL) is one of the most important outcome measure to determine how the disease and its treatment affect patient's daily life. Few data are known about the impact of surgical complications after esophagectomy on HRQL.
**Aims & Methods:** The aim of this study was to analyze the impact of surgical complications after esophagectomy for cancer on HRQL of patients with at least one year follow-up postoperatievely. Patients were prospectively enrolled in two tertiary referral centers (one in The Netherlands and one in Italy). Quality of life was evaluated using the Dutch and Italian version of the EORTC QLQ-C30 and OG25. Data about patients' characteristics, treatment and follow-up were retrieved from the centers'prospective databases. Perioperative complications were classified using the Clavien-Dindo classification of surgical complication. Patients were further matched for site of anastomosis, age, sex, AJCC stage and timing of the procedures. Non parametric statistics was carried on; data were adjusted for age, timing and center of enrollment.
**Results:** 152 patients (76 in each center) were enrolled in the outpatient clinics from October 2014 to December 2015. The median age was 62 years (IQR 55; 67); 108 (71.6%) were male and the median follow-up was 45 months (IQR 27, 58). 27 (17.8%) patients underwent esophagectomy with cervical anastomosis, 125 (82.2%) had an intrathoracic anastomosis. At univariate analysis, complication scale was directly correlated with more reflux symptom ($r = 0.185$, $p = 0.034$) and trouble with talking ($r = 0.261$, $p = 0.002$) but at multivariate analysis it did not result to be an independent predictor of worse HRQL. No differences were seen in HRQL between the two groups with the exception of anxiety which seems to affect more Italian patients than Dutch patients ($p = 0.001$).
**Conclusion:** Surgical complications after esophagectomy still affect the perioperative survival rate but, in the long run, they do not affect HRQL. Cross cultural differences showed a higher anxiety in Italian patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0237 ELECTRICAL STIMULATION THERAPY OF THE LOWER ESOGHAGEAL SPHINCTER IN TREATING GASTROESOPHAGEAL REFLUX DISEASE IN CHILDREN, OPEN LABEL PROSPECTIVE TRIAL

**Introduction:** Electrical stimulation therapy (EST) of the Lower Esophageal Sphincter (LES) is a new treatment for Gastroesophageal reflux disease (GERD) that was always used in adult patients, in this work we describe the first two cases in children with GERD, treated with EST, the device improves the pressure of the LES without interfering with its relaxation.
**Aims & Methods:** To describe the fist two cases in pediatric population with the use of ENDOSTIM, shows an alternative in the treatment of GERD by electrical stimulation. Case 1: Female, 12 years old with GERD, with chronic pain, semi choking episodes, heartburn, regurgitation which does not respond to proton pump inhibitors with abnormal esophageal pH Demeester score of 63.2, hiatal hernia less than 3 cm and esophagitis los angeles grade C evaluated by endoscopy and biopsies reporting chronic esophagitis, manometry with pressure at rest 10.1 mmHg (normal up 14), complete relaxation, the mother refused performing Nissen fundoplication, the case was evaluated and approved by the Bioethics Committee of the hospital. Case 2: Male, 2 years old with GERD, down syndrome, weight 9.1 kg, growth and with failure, aspiration pneumonia because of gastroesophageal reflux, with no response to proton pump inhibitors for about a year, endoscopy with los angeles grade c esophagitis, pathology with reflux esophagitis, pH metry with 95% acid reflux, manometry relax pressure 10 mmHg. Two Bipolar stitch electrodes were placed in the LES using laparoscopy and a dispositive was placed in a subcutaneous pocket, electrical stimulation was delivered at 20 Hz, 215 ns, 3–8 mA, in 30 minutes session, with recess of 90 minutes, without chance of this parameters, the patient was evaluated using GERD daily symptom and medication use, endoscopy, esophageal pH and high resolution manometry.
**Results:** 1 female patient, on chronic acid-suppresive therapy who underwent successful laparoscopic implantation of the LES stimulation system, 2 weeks after the surgery the patient reported better symptom control without the intake of PPI, and the absence of heartburn and regurgitation. 1 month follow-up with esophageal pH shows decrease of Demeester score to 20.2, and 3 months esophageal pH shows decrease to 3.9, manometry with primary peristalsis in 80% of swallowing, complete relaxation, pressure at rest EEI 16.9 mmHg, endoscopy with biopsies reported esophagitis los angeles grade A, 6th postsurgical month pH Demeester index 9, manometry pressure at rest EEI 33, normal endoscopy. 1 male patient, adequate laparoscopic implantation of LES stimulation system, 1 week after the surgery the patient has a normal feeding, decrease in symptoms, 3 weeks post surgical weight increase 900 grs., first post surgical month pH metry Demeester index 6, 28% of acid reflux, with improvement in their quality of life, 3rd post surgical month endoscopy los angeles grade a esophagitis, pH 12% acid reflux, manometry pressure at rest EEI 17 mmHg.
**Conclusion:** These are the first two pediatric case in the world with electrical stimulation as a treatment for GERD; the results show that electrical stimulation of the LES can improve symptoms of GERD, reduce esopagheal acid exposure by augmenting esophageal sphincter pressures and reduce the need for PPI medication without Gastro esophageal side effects typically seen with other antireflux procedures that involve mechanical alteration of the gastroesophageal junction. Formal randomized clinical trials are needed; this will test the true rate of operative complication and side effects, and the studies could assess whether the device is restricted to patients with no hernia or is suitable for use after crural repair to know the real benefit and safety of this study.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Inflammatory bowel diseases (IBDs) are a heterogeneous group of disorders which exhibit two major phenotypic forms, Crohn's disease (CD) and ulcerative colitis (UC), characterized by a cyclical nature, alternating between active and quiescent states impairing the patients' quality of life. Although progress has been made in understanding of IBD, their etiology is unknown but several factors from adipose tissue and skeletal muscles such as cytokines, adipokines and myokines were implicated in the pathogenesis of IBD. The hypertrophied mesenteric white (mWAT) adipose tissue was shown to increase the circulating proinflammatory cytokines that predisposed to development of colitis. Among therapeutic options, exercise was proposed as one of the most important lifestyle practices to adopt when considering treatment options for IBD but mechanism of this beneficial effect of voluntary endurance training in amelioration of lower bowel disorders has not been extensively studied.
**Aims & Methods:** We determined whether diet-induced obesity (DIO) augments the severity of experimental colitis in C57mice and whether moderate exercise can affect the experimental colitis induced in DIO mice. The effect of voluntary physical activity on the changes in colonic blood flow (CBF) and the plasma myokine irisin released from exercising muscles and plasma adiponectin levels from adipose tissue, and the concentrations of plasma proinflammatory cytokines in DIO mice with colitis were investigated. Ninety mice were randomized into two series A and B and fed with 70% fat diet (cholesterol up to 70%, Altromin, Lage, Germany, series A) and with normal diet (ND, series B) and subjected to the voluntary wheel running to assess the effect of physical performance and endurance on the healing of colitis. For endurance test, mice individually housed were allow to run freely on the open surface wheel placed outside a standard mouse cage. Rotations were electronically transmitted to a USB hub so that frequency and rate of running was captured via a software program for data storage and analysis for variable time periods. After 6 weeks of wheel exercise, colitis was induced in both series of mice A and B by intra-colonic administration of TNBS. The severity of colonic damage (DAI index), the alterations in the colonic blood flow (CBF) determined by $H_2$ -gas clearance technique in colonic mucosa, the plasma concentration of TNF-$\alpha$ and IL-1$\beta$, adiponectin, leptin, IL-6, TWEAK and irisin were assessed by ELISA.
**Results:** The macroscopic and microscopic colitis in sedentary ND mice was accompanied by the significant fall in the CBF, an increase in colonic tissue weight and significant increase in the plasma IL-1$\beta$ and TNF-$\alpha$ levels ($p < 0.05$). In sedentary mice fed DIO, the colonic lesions and the colonic tissue weight were aggravated and the plasma IL-1$\beta$, TNF-$\alpha$, TWEAK and leptin levels were significantly increased ($p < 0.05$) but a significant decrease in plasma irisin and adiponectin levels ($p < 0.05$) were observed comparing to non-exercising ND mice. Exercise of DIO rats significantly decreased the severity of TNBS-induced colonic damage while significantly increasing the CBF and attenuated the increase in plasma IL-1$\beta$, TNF-$\alpha$, TWEAK, and leptin levels. Wheel running significantly increased plasma levels of myokines IL-6 and irisin but this enhancement failed to reach the rise in plasma of these cytokines observed in ND fed mice ($p < 0.05$). These changes in plasma levels of proinflammatory markers IL-1$\beta$, TNF-$\alpha$, TWEAK and leptin were rather moderate in ND fed animals and further significantly decreased by exercise.
**Conclusion:** 1) The healing of experimental colitis is impaired in mice fed DIO and this effect is mediated by a fall in colonic microcirculation and an increase in plasma proinflammatory markers such as IL-1$\beta$, TNF-$\alpha$, IL-6 and TWEK; 2) voluntary physical activity can diminish of the severity of colonic damage in DIO fed mice mediated, at least in part, by a release of myokines such as protective irisin, and 3) regular voluntary exercise could exert a beneficial effect in IBD by affecting abdominal adiposity due to restoration of protective adiponectin and promotion of anti-inflammatory environment by inhibition of proinflammatory cytokines.

**Introduction:** Long-standing ulcerative colitis (UC) patients are at highrisk of developing colitis associated colorectal cancer (CAC). We have previously demonstrated that EPA-FFA protects towards CAC in the AOM-DSS mouse model through modulation of the Notch1 signaling and gut microbiota.
**Aims & Methods:** To expand our previous findings, in this study we evaluated whether the treatment with Eicosapentaenoic acid-free fatty acid (EPA-FFA) was able to affect markers associated with CAC progression in UC patients. 20 long-standing UC patients in stable clinical remission (SCCAI = 0) and with fecal calprotectin (FC) > 150 µg/g measured in stools were recruited and treated with 2 g/day of EPA-FFA (ALFA, SLA Pharma AG, Switzerland) for 90 days. Biopsies and biological samples were collected at the entry (T0) and at the end of the study (T3). Compliance was evaluated by EPA incorporation into red blood cell membranes. Protein levels of Jagged1, Hes1, Stat3, phospho-Stat3 and Klf-4 were determined by western blotting. IL-22, IL-10 and SOCS3 mRNA levels were analyzed by qRT-PCR. Goblet cells were stained by Alcian blue. Microbiota analyses were performed on fecal and biopsies DNA samples sequencing the V3-V4 region of the bacterial 16S rRNA gene; as a reference, we employed a healthy adult population previously analyzed for microbiota composition. Endoscopic and histologic disease activities were measured by Mayo and Geboes scores respectively.
**Results:** 19 patients completed the study; 17 patients resulted adherent to treatment based on EPA levels at T3 with an overall compliance of 89.5%. Patients showing clinical, histological or endoscopic reactivation at T3 (n = 3) were considered as non-responders. The per-protocol analysis, conducted on patients incorporating EPA and which did not show any sign of disease at T3 (n = 15), demonstrated that EPA-FFA treatment induced IL-10 and SOCS3, partially inhibiting STAT3 activation. Moreover, we observed a concomitant significant induction of Hes1 and Klf-4 associated with goblet cells differentiation. Importantly, some dysbioses associated with UC at T0, were partly redressed by the EPA-FFA treatment. In particular, EPA-FFA treatment increased the abundance of fecal Prevotellaceae and Porphyromonadaceae families and decreased mucolytic Bacteroides spp at mucosal level.
**Conclusion:** EPA-FFA supplementation promotes intestinal homeostasis in patients with long-standing UC inducing goblet cells differentiation, limiting STAT3 activation through the modulation of IL-10/SOCS3 axis and contributing to restore intestinal eubiosis. Overall, our data suggest a protective role of EPA-FFA on CAC onset during UC.

## P0241 ALTERATION IN MICROBIOTA COMPOSITION CONTRIBUTES TO CHRONIC INFLAMMATORY RESPONSE TRIGGERED BY CROHN'S DISEASE-ASSOCIATED AIEC INFECTION IN GCN2 DEFICIENT MICE

**Contact E-mail Address:** alexis.bretin@inserm.fr.
**Introduction:** A high prevalence of the adherent-invasive *E. coli* (AIEC) in the intestinal mucosa of Crohn's disease (CD) patients has been shown. We previously showed that AIEC persist in the intestine and induce inflammation in transgenic CEABAC10 mice expressing human CEACAM6, the receptor for AIEC. We also showed that upon infection, autophagy is induced in host cells to restrain AIEC intracellular replication and that this requires activation of the GCN2/eIF2alpha/ATF4 pathway. Autophagy response upon AIEC infection was inhibited in *gcn2*$^{-/-}$ mice, leading to increased AIEC colonization and AIEC-induced inflammation. Here, we investigated whether transient AIEC colonization of mice deficient for Gcn2 induces changes in the gut microbiota, which might contribute to the development of chronic inflammation.
**Aims & Methods:** Wild type (WT) and *gcn2*$^{-/-}$ mice, or transgenic CEABAC10 invalidated for Gcn2 (CEABAC10/*gcn2*$^{-/-}$) or not (CEABAC10/*gcn2*$^{+/+}$) were infected with the AIEC reference strain LF82 or the non-pathogenic *E. coli* MG1655 strain by gavage. Feces were collected at different time points and used to determine AIEC persistence, to quantify the amounts of the inflammatory marker lipocalin-2 and to analyse microbiota composition by 454

pyrosequencing. The microbiota analysis data were analysed using Quantitative Insights Into Microbial Ecology (QIIME) software package.
**Results:** In WT and *gcn2*$^{-/-}$ mice, LF82 colonization was higher and lasted longer compared to the colonization of MG1655. However, LF82 was undetectable in the feces of mice at day 4 post-infection, indicating that in this model of infection, in which neither a cocktail of antibiotic nor DSS was used, the gut colonization by AIEC was transient. The microbiota analyzed by UniFrac metrics and principal coordinates analysis (PCoA) did not show any pattern of clustering or significant change at the family level in WT mice upon LF82 infection. However, for the LF82-infected *gcn2*$^{-/-}$ mice, PC analysis showed a clear pattern of clustering at day 14 and 21 post-infection. This was associated with significant changes at the family level with an increase in *Bacteroidetes* and *Proteobacteria* and a decrease in *Firmicutes*. These changes are consistent with those observed in CD patients. Furthermore, lipocalin-2 levels were increased in LF82-infected *gcn2*$^{-/-}$ mice at day 21 post-infection compared to other groups of mice. These data showed that chronic intestinal inflammation was developed in *gcn2*$^{-/-}$ mice after AIEC clearance and more importantly after the modification in the microbiota composition. Finally, the results obtained for CEABAC10/*gcn2*$^{-/-}$ mice were consistent with those obtained for *gcn2*$^{-/-}$ mice.
**Conclusion:** Herein, we show that, in genetically predisposed hosts, a transient colonization of a pathobiont AIEC strain could lead to a change in the gut microbiota that persisted even after AIEC clearance. Furthermore, this change in the microbiota seems to contribute to the development of a chronic inflammation response as observed in CD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0242 ANTI-INFLAMMATORY AND ANTIBACTERIAL EFFECTS OF HUMAN CATHELICIDIN ACTIVE FRAGMENT KR-12 – A NOVEL POTENTIAL THERAPY OF INFLAMMATORY BOWEL DISEASE

**Introduction:** Inflammatory bowel diseases (IBD), which consist mainly of Crohn's disease (CD) and ulcerative colitis (UC) is a group of gastrointestinal tract diseases with uncertain etiology. Several therapeutic options are used in IBD; the choice of the treatment depends on disease activity, behavior and extent. Analogs of 5-aminosalicylic acids (5-ASA) administered orally or rectally are first-line drugs. Glucocorticoids, anti-inflammatory agents and biologicals are used when remission has not been achieved. In portion of patients none of the available therapies is effective and surgical intervention is necessary. Therefore novel pharmacological treatment options are still sought in order to avoid the disabling procedures. Cathelicidins derive from a family of antimicrobial peptides (AMPs). In addition to their potent anti-pathogenic ability, they exhibit chemotactic, immunomodulatory and angiogenic properties [1]. The sole human representative of cathelicidins, LL-37, was found to be potentially implied in the pathogenesis of IBD [2]. Currently, shorter analogues of LL-37 are under development.
**Aims & Methods:** In our study, we attempted to assess the anti-inflammatory and antibacterial actions of LL-37 and its shortest fragment, KR-12 (both 1–5 mg/kg, i.p., twice daily) in two mouse models of colitis: induced by 2, 4, 6-trinitrobenzenesulfonic acid (TNBS) and dextran sulfate sodium (DSS). The extent of inflammation was evaluated based on the macroscopic score, quantification of myeloperoxidase (MPO) activity and microbiological analysis of stool samples.
**Results:** The results of a preliminary study with low doses of LL-37 and KR-12 showed a non-significant decrease in macroscopic score and ulcer score in the acute TNBS model of colitis. Overall, the anti-inflammatory effect of KR-12 was more pronounced than that of LL-37; hence, further studies were performed exclusively with KR-12. In the semi-chronic TNBS model, the peptide at the dose of 5 mg/kg (i.p., twice daily) significantly reduced macroscopic score ($p < 0.05$) and ulcer score ($p < 0.001$). Furthermore, qualitative and quantitative changes in colonic microbiota were observed. In the semi chronic model of colitis induced by DSS, KR-12 significantly attenuated intestinal inflammation as demonstrated by a significant reduction in macroscopic score ($p < 0.05$) and a decrease in stool score and MPO activity.
**Conclusion:** We demonstrated potential ability of KR-12, a fragment of human cathelicidin LL-37 to alleviate inflammation in the mouse models of colitis. Although we did not achieve significant reduction in all parameters, we believe our research contributes to the field of IBD treatment. We conclude that KR-12 and cathelicidins as a whole are worth being considered as a potential therapeutic option in the treatment of IBD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Inflammatory Bowel Disease is linked to immune activation and increased inflammation, evidenced by increased release of TNF-a from peripheral mononuclear cells (PBMCs). This immune response is closely linked with the intensity of gastrointestinal symptoms and extra-intestinal comorbidities such as depression or anxiety. Interestingly, in a substantial proportion of patients with inflammatory bowel disease and increased TNF-a, gastrointestinal symptoms persist after lesions heal. Motivational change (decreased reward and increased loss sensitivity) is a core feature of sickness behaviour and depressive symptoms.
**Aims & Methods:** We targeted motivational brain circuitry during reinforcement learning to assess the effects of anti TNF-a therapy on depressive symptoms in patients with Crohn's Disease. We recruited 10 patients with Crohn's disease ($30.0 \pm 13.0$ yrs, 5 female, 6 ileocolonic, 2 colonic and 2 ileal disease) in stable clinical remission (CDAI < 150) following chronic anti-TNF$\alpha$ therapy (8 adalimumab/2 infliximab). 72 hours before and after anti-TNF$\alpha$ patients underwent visceral sensory testing (standardised nutrient challenge) and functional brain scanning during a reinforcement learning task, where participants experienced both rewards and losses (gaining / losing fake $10 notes). During sensory testing 600 ml of enteral feeding solution was consumed over 15 minutes while the intensity of GI symptoms was quantitated.
**Results:** Within 72 hrs after administration anti-TNF-$\alpha$ unpleasant visceral sensation during nutrient challenge (subjective fullness) was significantly reduced (22% reduction, $p < 0.031$). Motivational circuits were strongly activated by rewards and losses, including within the nucleus accumbens and primary interoceptive cortex (insula). Anti-inflammatory therapy altered activity in the brains motivational circuits during reinforcement learning, including within the nucleus accumbens and insula cortex. Importantly, across patients, depressive symptoms (Beck Depression Inventory) also correlated with drug induced changes to rewards in the right insula cortex.
**Conclusion:** Immune modulation of the gastrointestinal tract with anti-TNF$\alpha$ agents is associated with significant reduction in symptoms during a standardised nutrient challenge, and alterations in core motivational circuitry within the brain. These alterations within the right insula cortex also reflect self reported depressive symptoms before anti-TNFa. The findings suggest that systemic reductions of circulating TNF and reduced visceral hypersensitivity is translated into improved motivational functioning, improving our understanding of psychiatric comorbidities in IBD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0244 CO-ABUNDANCE OF AKKERMANSIA MUCINIPHILA AND FAECALIBACTERIUM PRAUSNITZII IN THE MUCOSA OF HEALTHY AND DISEASED GUT

**M. Lopez-Siles**[1], N. Enrich-Capó[1], M. Sabat-Mir[2], X. Aldeguer[3], S.H. Duncan[4], J. Garcia-Gil[1], M. Martinez-Medina[1]

**Contact E-mail Address:** mireia.lopezs@udg.edu.
**Introduction:** *Akkermansia muciniphila* and *Faecalibacterium prausnitzii*, co-inhabitants of the intestinal mucosa, have been associated with a healthy microbiota. Depletion of *F. prausnitzii* occurs in several intestinal disorders [1], while a reduction of *A. muciniphila* has only been reported in inflammatory bowel disease (IBD) [2, 3] as few studies determining its load and including several gut diseases have been done. No direct link between this two species has been reported yet, but it can be hypothesised that *F. prausnitzii* presence in the gut is influenced by acetate producers like *A. muciniphila*, because it is a required compound for its growth [4, 5].
**Aims & Methods:** The aim of this study is to determine the amount of *A. muciniphila* in healthy subjects (H) and patients with various gut disorders, and to establish whether or not there is correlation between the abundance of the two species. *A. muciniphila* load was determined by quantitative polymerase chain reaction targeting specific regions of the 16 S rRNA gene as reported previously [6] in colonic biopsies from 17 H, 23 patients with ulcerative colitis (UC), 31 with Crohn's disease (CD), 3 with irritable bowel disease (IBS) and 3 with colorectal cancer (CRC). Data were normalised to total bacterial counts. These values of relative abundances were compared by type of disease and considering relevant clinical characteristics of patients, by non parametric statistical tests. Relative abundance of total *F. prausnitzii* and its phylogroups for these patients, available from previous studies [7], were used to establish correlation between the two species.
**Results:** A reduction in *A. muciniphila* load was observed in CRC patients compared with H subjects ($p = 0.023$), whereas for the other intestinal disorders no statistically supported differences were found with respect to H subjects due to high variation within the data. Within IBD, CD patients had lower loads of this species than those with UC ($p < 0.05$). CD patients with colonic disease location

featured the lowest abundance of *A. muciniphila*. Abundance of this species was not affected by medication or activity of the disease at time of sampling. There is correlation between the abundance of *A. muciniphila* and total *F. prausnitzii* in patients with CD ($\rho = 0.386$) and CRC ($\rho = 1.000$). In CD patients, correlation between *F. prausnitzii* phylogroup I and *A. muciniphila* was observed ($\rho = 0.360$).
**Conclusion:** CRC patients featured a striking depletion of *A. muciniphila*, but further confirmation in a larger cohort is required. Differences in *A. muciniphila* load have been found between IBD patients, therefore its quantification in conjunction to *F. prausnitzii* may help to differentiate patients with CD from those with UC. Because abundances of these two species were correlated in CD and CRC patients, further studies to confirm whether or not they are influenced by similar factors in certain gut disorders would be of interest.

**Introduction:** Adherent-Invasive *E. coli* strains (AIEC) isolated from ileal lesions of Crohn's disease patients are flagellated bacteria able to invade intestinal epithelial cells and to survive within macrophages. Flagellin (FliC), major bacterial flagellum protein, is required for motility but is also recognized by innate immune receptors TLR5 and Naip5-Naip6/NlrC4/Caspase-1 leading to pro-inflammatory cytokines release. FlgM is a protein involved in the regulation of flagellar assembly. Its function is to associate flagellar assembly to appropriate temporal flagellar gene transcription.
**Aims & Methods:** In this work, we aim at better understanding if efficient modulation of flagellin expression is required for mucosa colonization and in vivo persistence, and allows AIEC to evade innate immune detection. For that, transgenic mouse model expressing human CEACAM6 (CEABAC10) was used in this study. Bacterial persistence in the colonic mucosa of mice, treated or not with dextran sodium sulfate (DSS) used to disrupt mucus layer, was measured after infection by wild-type AIEC LF82, AIEC-DfliC and AIEC-DflgM mutants.
**Results:** The abilities of the wild-type AIEC LF82, AIEC-DfliC and AIEC-DflgM mutants to colonize colonic mucosa in CEABAC10 mice model treated with DSS were analyzed. We observed at 4 days post-infection that AIEC-DfliC significantly better colonized colonic tissue (median of $3.3 \times 10^6$ bacteria/mg of tissue) than AIEC LF82 (median of $9.3 \times 10^5$ bacteria/mg of tissue). In contrast, we observed that LF82-DflgM overproducing flagellin presented a lower ability to colonize colonic mucosa than WT AIEC LF82 (median of $5.0 \times 10^5$ bacteria/mg of tissue). However, when the mucus layer was not altered by DSS treatment in CEABAC10 mice, the higher persistence of AIEC-DfliC was no longer observed. This indicates that flagella expression by bacteria allows the crossing of the mucus layer, but overexpression of flagellin in the contact of epithelial cells can be detrimental to the virulence by inducing acute inflammation enhancing AIEC clearance.
**Conclusion:** This work aims to better understand the pathogenicity of AIEC strains to develop specific inhibitors interfering with bacteria/cell interaction, and shows that flagella expression should be finely regulated for optimal virulence of AIEC pathobionts. Targeting FlgM bacterial factor could be an alternative strategy to control AIEC colonization on the gut mucosa.

**Introduction:** Risk stratification of subjects with inflammatory bowel disease (IBD) into those likely to relapse and those who will remain quiescent remains a significant challenge.
**Aims & Methods:** We undertook a pilot study to investigate the association of proteomic profiles during remission in ulcerative colitis (UC) and subsequent disease relapse. 61 patients with UC in clinical, endoscopic and histological remission and 17 normal controls were included. 8 UC patients had clinical relapse of UC within 6 months from the index endoscopy (Early Relapse (ER)). 43 patients had no relapse (NR) during follow-up for 3 years. Soluble protein fractions were extracted from rectal biopsies in patients with ER and NR and normal controls using an isobaric tag for relative and absolute quantitation (iTRAQ)-compatible protocol. Samples from ER ($n = 7$), NR ($n = 7$) and two separate controls (CON) ($n = 7$ in each) were pooled and labelled. Labelled peptides were analysed by hydrophilic interaction liquid chromatography coupled with tandem mass spectrometry (HILIC-MS/MS) and data reconstituted (GeneBio Phenyx). Inter-group comparisons were made using validated in-house algorithms. iTRAQ results were validated by immunoblotting on 7 pooled ER, 7 pooled and 6 external NR, and 3 external CON samples against selected target proteins following decision tree analysis (protein fold change (FC) of $\geq 2$). Relative protein expression for each dot-blotted sample was determined from its signal intensity using densitometry. Statistical significance was set as false detection rate (FDR) and p-value of $\leq 0.05$.
**Results:** 11 upregulated and 3 down-regulated proteins in ER relative to NR were identified from iTRAQ analysis. Smooth muscle contraction, cell-cell communication, signal transduction, fatty acid metabolism, lipoprotein metabolism, semaphorin interactions, EPH-ephrin signalling, and haemostasis were the possible discriminatory cellular pathways. Similarly, 7 upregulated and 3 downregulated proteins in ER relative to controls were identified from iTRAQ analysis. Metabolism of polyamines and vesicle-mediated transport were the possible discriminatory cellular pathways. Glycoprotein A33 (GPA33) ($FC = 4$, $p = .0006$ in ER vs. NR; $FC = 3.22$, $p = .0007$ in ER vs. CON) and keratin 10 (K10) ($FC = 1.94$, $p = .0002$ in ER vs. NR; $FC = 2.49$, $p < .000$ in ER vs. CON) were chosen for further orthogonal validation. Immunoblotting confirmed down-regulated GPA33 in ER vs. NR ($p = .02$) and ER vs. CON ($p = .009$), and upregulated K10 in ER vs. NR ($p = .04$), in line with iTRAQ outcomes.
**Conclusion:** Reduced GPA33 expression and increased K10 in patients with UC in remission, is associated with early relapse, compared with those who did not relapse. This has the potential for understanding the pathogenesis of UC relapse and the development of predictive tissue biomarkers.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0247 ANTIBIOTIC RESISTANCE PROFILES OF ADHERENT INVASIVE E. COLI AND NON- PATHOGENIC E. COLI ISOLATED FROM CROHN'S DISEASE PATIENTS AND CONTROLS

**M. Martinez Medina**[1], B. Ruiz Del Castillo[2], N. Serrano-Morillas[1], J. Garcia-Gil[1], L. Martínez-Martínez[2]

**Introduction:** The adherent invasive *E. coli* (AIEC) pathotype has been associated with the aetiology of Crohn's disease (CD). The use of antibiotics for the treatment of CD has shown limited efficacy. Besides, few studies have determined the susceptibility of AIEC to antimicrobials [1, 2], and one of them reported a higher frequency of multidrug resistant (MDR) strains in CD patients than in controls.
**Aims & Methods:** We aimed to compare the antimicrobial resistance profiles of AIEC and non-AIEC strains inhabiting the gut mucosa of CD patients and controls, and to depict putative mechanisms of resistance. For this purpose, we examined the resistance to 35 antimicrobials in a collection of 22 AIEC and 27 non-pathogenic *E. coli* obtained from CD patients ($N = 31$, 16 of which were AIEC) and healthy controls ($N = 18$, 6 of which were AIEC) using the Vitek®2 system, the Sensititre plates COMPAN1F, and macrodilution tests following the 'Clinical and Laboratory Standards Institute' standards. Detection of AmpC $\beta$-Lactamases was performed by disk diffusion tests and definition of plasmidic AmpC $\beta$-lactamase (pAmpC) was determined by polymerase chain reaction. Genes encoding for antimicrobial resistance were searched in the genome of 23 AIEC available in GenBank using the ARG-ANNOT tool.
**Results:** AIEC were more frequently resistant to $\beta$-lactams than non-AIEC strains, including penicillins (> 50% of AIEC were resistant), penicillins + $\beta$-lactamase inhibitors (up to 41.2%) and first and second generation cephalosporins (up to 23.5%). About the 11% of AIEC were also resistant to third and fourth generation cephalosporins whereas none of the non-AIEC was resistant. The proportion of resistant strains to other antimicrobials such as tetracyclines, aminoglycosides and quinolones was similar between AIEC and non-AIEC strains. The number of resistances to antibiotics was slightly higher in AIEC strains ($4.59 \pm 1.23$) than in non-AIEC strains ($1.93 \pm 0.68$) and AIEC were two times more frequently MDR than non-AIEC (27.3% vs 14.8%). The phenotype and genome analysis of the LF82 strain suggested the hyperproduction of the intrinsic chromosomal AmpC. The ARG-ANNOT tool allowed the identification of several genes for resistance to antimicrobial agents that included $\beta$-lactams, aminoglycosides, macrolides, phenicols, sulfonamides, tetracyclines and folate pathway inhibitors. TEM $\beta$-lactamases were detected in 7 out of 23 AIEC genomes and OXA-9 in one of them. NRG857c strain carried a plasmid with genes that confer resistance to multiple types of antibiotics (TEM-1, strA, strB, mphB, catA1, sulII, tetA, tetR, and dfrA1).
**Conclusion:** We report an association between increased antimicrobial resistance and virulence. Further studies are needed to decipher whether or not there could be a common factor implicated in AIEC phenotype and resistance to $\beta$-lactams. Antimicrobial resistance in AIEC is a matter of concern regarding the putative implication of the pathotype in CD, especially in the case of strains carrying plasmids with multiple resistances to antimicrobials.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** A novel family of proton-sensing G-protein coupled receptors (GPCRs), including ovarian cancer G-protein coupled receptor 1 (OGR1, also known as GPR68) has been identified to play an important role in pH homeostasis. Hypoxia is known to change tissue pH due to anaerobic glucose metabolism through the stabilization of hypoxia inducible factor (HIF)-1$\alpha$.
**Aims & Methods:** We investigated how hypoxia regulates the pH-sensing GPCR receptor OGR1 in the intestinal mucosa and associated cells. OGR1 mRNA expression in murine tumors, human colonic tissue and myeloid cells was determined by RT-qPCR. The influence of hypoxia on OGR1 expression was studied in human MM6 cells, in primary human intestinal macrophages and in the intestinal mucosa of healthy volunteers (HV) and inflammatory bowel disease (IBD) patients. Changes in OGR1 expression in MM6 cells under hypoxia were determined upon stimulation with tumor necrosis factor (TNF), in the presence or absence of NF-$\kappa$B inhibitors. In order to study the molecular mechanisms involved, chromatin immunoprecipitation (ChIP) analysis of the OGR1 promoter was performed.
**Results:** OGR1 expression was higher (2.8-fold) in tumor compared to normal murine colon tissue. Hypoxia positively regulated the expression of OGR1 in MM6 cells, primary human intestinal macrophages and colonic tissue from IBD patients compared to HV. Under hypoxia OGR1 expression increased in THP1 cells (4.76, 13.19 and 3.82 -fold) at 8, 16 and 24 h, respectively and HT29 cells (7.78 -fold) at 24 h. The expression of OGR1, but not TDAG8 was significantly increased under hypoxia at pH 7.7, 7.3 and 6.8, with a higher increase of OGR1 expression at acidic conditions. OGR1 expression levels of MM6 cells under hypoxia increased 3.2, 3.7 and 53.5 -fold at pH 7.7, 7.3 and 6.8 respectively compared to pH 7.7, normoxia. Under hypoxia, OGR1 expression at acidic pH increased more than 14 -fold compared to pH 7.7 and pH 7.3. The expression of OGR1 in biopsies taken one week after hypoxia showed a clear trend to increase in CD and UC patients when compared to control subjects. Conversely, mRNA levels of TDAG8 in CD patients, but not HV were significantly reduced at T2 and T3 after hypoxia when compared to T1, and a similar trend was shown in UC patients. In MM6 cells, hypoxia enhanced TNF-induced OGR1 expression was reversed by the inhibition of NF-$\kappa$B. In addition to the effect of TNF and hypoxia, OGR1 expression was further increased at low pH. ChIP analysis revealed that HIF-1$\alpha$, but not NF-$\kappa$B, binds to this promoter region of OGR1 24 h after hypoxia in THP1 cells.
**Conclusion:** The enhancement of TNF- and hypoxia-induced OGR1 expression under low pH points to a positive feed-forward regulation of OGR1 activity in acidic conditions, and supports a role for OGR1 in the pathogenesis of IBD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0249 CORRELATION BETWEEN THE PRESENCE OF BACTEROIDETES AND FAECAL CALPROTECTIN FOR THE DETECTION OF ENDOSCOPIC ACTIVITY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

**Introduction:** Faecal calprotectin (FC) levels correlate directly with the endoscopic activity of inflammatory bowel disease (IBD). Microbiota plays a role in the etio-pathogenesis of IBD. In this context, the presence of specific genotypes of bacteroidetes has been shown to be associated with the activity of the disease.
**Aims & Methods:** Aim of this study was to evaluate the correlation between the presence of genotypes of bacteroidetes and the FC levels in relation to the endoscopic activity of IBD. Methods: A single-center, observational cross-sectional study was designed. Consecutive patients with Crohn's disease (CD) and ulcerative colitis (UC) who attended the Endoscopy Unit of Santiago de Compostela for colonoscopy were included. Colonic biopsies were taken to characterize microbiota by using a restriction fragment length polymorphism (RFLP) analysis on PCR products targeting the 16SrRNA genes of Bacteroidetes digested with HinfI, PciI, DpnII and AciI. CF levels were measured in faecal samples with a quick test (Quantum blue) the day before starting colon cleansing for colonoscopy. Inactive UC was defined as a Mayo endoscopic score of 0. Inactive CD was defined as a SES-CD $<= 2$. Results are shown as prevalence and median, and they were analyzed by the Mann-Withney test, Spearman correlation test and multivariate lineal regression.
**Results:** 22 patients with IBD (12 CD and 10 UC) were included. Endoscopic activity was detected in 15 patients (9 CDa and 6 UCa). 7 different genotypes of Bacteroidetes called N1, C1-C5 and CB10 were detected. The presence of genotype N1 and C1 was constant in patients with active and inactive IBD, while genotype C4 was present in 82.35% of patients with UCa and CDa, and in 17.65% of patients with inactive IBD ($p = 0.009$). The median of FC was 48 in patients with inactive disease and 205 µg/g in patients with active IBD ($p = 0.019$). In patients with genotype C4 the median of CF was 205 µg/g, whereas in patients with other genotypes the median of FC was 48 µg/g ($p = 0.446$). A positive correlation was found between C4 genotype and FC levels ($r = 0.429$). After multivariable analysis, FC levels were associated with endoscopic activity (coef 473.88, $p = 0.018$) and the presence of genotype C4 in biopsies (coef 67.92, $P = 0.014$).
**Conclusion:** FC levels and genotype C4 of bacteroidetes in colon biopsies are associated with the endoscopic activity of IBD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0250 15-D-PGJ2 AS A NEW REGULATOR OF HEPCIDIN EXPRESSION AND ITS INVOLVEMENT IN IRON METABOLISM

**J. Martin**[1], S. Ulrich-Rueckert[1], J. Stein[2]
[1]*Institute Of Pharmaceutical Chemistry, Goethe University Frankfurt, Frankfurt/Main/Germany*

**Introduction:** The acute phase protein hepcidin, produced mainly in the liver, has been demonstrated to be a key mediator of the cytokine-induced anaemia of chronic inflammation (ACI). Prostaglandins are recognized as both pro- and anti-inflammatory lipid mediators, and have been shown to be involved in different pathogenic inflammatory pathways.
**Aims & Methods:** Our study aimed to elucidate the role of prostagladins (PGs) in iron homeostasis. Using the pro-inflammatory PGE2 and the anti-inflammatory 15-Deoxy-Delta-12-14-prostaglandin J2 (15-d-PGJ2), the latter also a known inducer of the transcription factor Nrf2, we tested whether these lipid mediators may be involved in interleukin-6 (IL-6) and oncostatin M (OSM)-induced hepcidin expression. The liver cell line HepG2 was cultivated under standard conditions and incubated for 16 hours with IL-6 (10 ng/mL) or OSM (10 ng/mL) alone or in combination with 15-d-PGJ2 (10$\mu$M). For reporter gene assays, plasmids were transfected by lipofection and luciferase activity was measured luminometrically. Quantitative real-time PCR was performed to determine mRNA expression. Proteins were detected by Western blot analysis. For gene-knockdown, HepG2 cells were transfected with Nrf2 or nontargeting siRNA duplexes according to the protocol for reversed lipofection.
**Results:** 15-d-PGJ2 (**$p < 0.01$), but not PGE2, counteracted the OSM and IL-6 induced hepcidin induction on promoter and mRNA level significantly after 16 h when coincubated with the cytokines. Treatment with 15-d-PGJ2 leads to nuclear translocation and thus activation of transcription factor Nrf2, which was confirmed by induction of Nrf2 target genes HO-1 and NQO-1 (**$p < 0.01$) on mRNA level. Compared to nontargeting siRNA transfection, a 50% Nrf2 knockdown tended to reduce the 15-d-PGJ2 inhibition of IL-6-induced hepcidin mRNA expression. In addition, 15-d-PGJ2 significantly induced ferritin and ferroportin on mRNA level in HepG2 (**$p < 0.01$), which could be significantly counteracted by knockdown of Nrf2 target gene HO-1 (*$p < 0.01$). These results points towards a key role of Nrf2-signaling in 15-d-PGJ2 mediated effects.
**Conclusion:** Our study data demonstrated an involvement of the prostaglandin 15-d-PGJ2 in the regulation of iron homeostasis. Our preliminary data also indicate that these effects may be linked, at least in part, to the transcription factor Nrf2 signaling pathway. Further research will be needed to tighten up these data.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Shift work has become increasingly prevalent across a wide range of occupations. Circadian disruption, associated with shift work, has been linked to inflammatory pathologies including inflammatory bowel disease (IBD). Circadian clock genes participate in the regulation of the integrity of the epithelial intestinal barrier, a process that is linked to IBD.
**Aims & Methods:** The aim of this study was to evaluate the effect of circadian rhythm inversion on the severity of a Dextran Sodium Sulfate (DSS)-induced colitis in mice. 25 mice were divided into 4 groups: a control group without circadian inversion (C), a control group with circadian inversion (CI), a group treated with DSS 2% (DSS) and a group treated with DSS 2% with an inverted circadian rhythm (DSSI). The fecal calprotectin (FC) and the systemic inflammatory (C-RP, IL-1ß, IL-6, TNF-$\alpha$) markers concentrations were measured in the 4 groups using the ELISA technique. RT-PCR was used to measure the expression of Per2, Claudin-1and TNF-$\alpha$ in the mice's colon in the 4 groups. Histological analysis of the extracted colon tissues was also enrolled.
**Results:** FC was significantly increased in the DSS group vs. control ($89.52 \pm 20.15$ vs $44.92 \pm 14.67$ pg/ml. $p = 0.038$), and was twofold much higher in the DSSI group vs DSS. Additionally, IL-6 ($49.99 \pm 11.44$ vs $31 \pm 9.80$ pg/ml. $p = 0.032$), TNF-$\alpha$ ($2252.5 \pm 432.08$ vs $901.67 \pm 454.67$ pg/ml. $p = 0.009$) and C-RP ($8.93 \pm 1.05$ vs $4.87 \pm 0.32$ pg/ml $p = 0.001$) plasma concentrations were more elevated in the DSSI group vs the other groups. Inverted circadian rhythm was associated with a higher expression of Per2 and a lower expression of epithelial Claudine-1 and TNF-$\alpha$ in inflamed colonic mucosa.
**Conclusion:** Disruption of circadian rhythm in mice is associated to a more severe colitis, characterized by a more severe systemic inflammation and higher concentrations of fecal calprotectin.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Inflammatory Bowel Disease (IBD) is a chronic relapsing inflammation of the digestive tract with alternative periods of exacerbation and remission. There are numerous methods to treat IBD, but medication that would ensure permanent therapeutic effect has not been found so far. Therefore, it is vital to search for the new therapeutic strategies. Ghrelin, an acylated 28-amino acid polypeptide, has been primarily shown to exhibit protective and therapeutic effect in the gut. Administration of ghrelin after induction of acute pancreatis accelerates pancreatic recovery in the course of this disease. In the stomach and duodenum, pretreatment with ghrelin reduces mucosal damage. Moreover, previous studies have suggested that ghrelin reduces colonic inflammation induced by trinitrobenzene sulfonic acid.
**Aims & Methods:** The aim of present studies was to assess the influence of ghrelin administration on the course of acetic acid-induced colitis. Moreover, we examined the role of growth hormone (GH) and insulin-like growth factor-1 (IGF-1) in ghrelin's effects in this inflammation. Materials & Methods: Studies have been performed on male Wistar rats. Before induction of colits animals were hypophysectomised or sham-operated. After two-week recovery, colitis was induced by a rectal enema of 1 ml of 3% solution of acetic acid. Saline or ghrelin (given at the dose of 8 nmol/kg/dose) were administered intraperitoneally twice a day and the first dose saline or ghrelin was given 24 h after rectal enema of acetic acid. Seven days after inductions of colitis, rats were anesthetized and colonic mucosal blood flow, and area of colonic mucosa damage were measured. Blood was taken for determination of serum concentration of GH and IGF-1. Biopsy samples of colonic mucosa were taken for biochemical examination.
**Results:** Rectal acetic acid enema induced colitis in all animals. Treatment with ghrelin for 6 days accelerated the healing of colonic mucosa. Ghrelin reduced damage of colonic wall and improved blood flow in colonic mucosa. This effect was associated with a significant reversion of the acetic acid-evoked decrease in mucosal DNA synthesis. Moreover, ghrelin administration reduced mucosal concentration of IL-1$\beta$ and activity of myeloperoxidase. Hypophysectomy increased the severity of mucosal damage and delayed the healing of the acetic acid-induced colitis. These effects were associated with additional reduction in mucosal blood follow and DNA synthesis. Mucosal concentration of IL-1$\beta$ and mucosal activity of myeloperoxidase were maximally increased. Administration of ghrelin was without any therapeutic effect in the course of the acetic acid-induced colitis in hypophysectomised rats. Treatment with ghrelin increased serum level of growth hormone and IGF-1 in pituitary-intact rats. Hypophysectomy lowered serum concentration of GH under the detection limit and reduced serum level of IGF-1 by about 90%. Administration of ghrelin failed to affect serum level of GH and IGF-1 in hypophysectomised rats.
**Conclusion:** Administration of ghrelin accelerates the healing of the acetic acid-induced colitis. Therapeutic effect of ghrelin in experimental colitis is mediated by the release of endogenous growth hormone and IGF-1.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0253 IONIZING DIAGNOSTIC RADIATION EXPOSURE IN PATIENTS WITH CROHŃS DISEASE: A RETROSPECTIVE STUDY IN A MEDIUM HOSPITAL AND ITS PREDICTIVE FACTORS

**E. Merino Rodríguez**[1], E. Carrera Alonso[1], M. Torralba González De Suso[2], S. Rebolledo Olmedo[1], M. Sánchez Da Silva[1], M. Martínez López[1], M.D. Sánchez-Tembleque Zarandona[1]
[1]*Gastroenterology, Universitary Hospital of Guadalajara, Guadalajara/Spain*
[2]*Internal Medicine, Universitary Hospital of Guadalajara, Guadalajara/Spain*

**Contact E-mail Address:** esthermerino780@hotmail.com.
**Introduction:** It is estimated that diagnostic medical radiation exposure may be responsible for up to 2% of cancers worldwide. Because of the relapsing course of Crohn's disease (CD), these patients usually require multiple ionizing radiation tests. The cumulative effective dose (CED) >50mSv is associated with an increased risk of developing certain solid tumours.
**Aims & Methods:** Our aim was to estimate the total CED and the CED due to the disease (CEDD) and to identify the risk factors associated with the exposure to a CEDD >50mSv. Design: retrospective cohort study (2001-20014). Population: patients with CD. Analysed variables: age, gender, disease duration, Montreal classification (age of onset, behaviour, location, perianal disease), history of major surgery, treatments and severity (major surgery and/or immunomodulator treatment and/or biological therapy), radiological tests, total CED and CEDD. Statistical analysis: for identifying predictive factors for receiving a CEDD

> 50mSV, an univariate and a multivariate analyses were performed using a > 50mSv dose as dependent variable.
**Results:** 297 CD patients were included, with a median disease duration time of 7 years (IQR = 4-14). 73.1% met severity criteria. The median total CED was 20.8 mSV (IQR = 5.9–48.3), being 24.6% > 50msV. The median CEDD was 10mSv (IQR = 3-31), being a 15.2% of patients > 50mSv. The more common tests were abdominal x-ray (63%), small bowel follow-through (58.95%) and abdominal computed tomography (47.9%). Patients receiving more radiation: women (median 13mSv (IQR 3-31.5)), >40 years old (median 13 mSv (IQR 3-35.3)), B2 (median 23.5mSv (IQR 5.2-53.3)) and B3 (median 40mSv (IQR 3-70)), L1 (median 20mSv (IQR 3-43), severity (median 20mSv (IQR 3-43)), major surgery (median 29.5mSv (IQR 3-56.8)), inmunomodulator (median 20msV (IQR 3-43)) and biological therapies (median 23 mSv (IQR 3-50)). Variables associated with a CEDD > 50mSv: inflammatory versus stricturing/penetrating (OR = 10.5; $IC_{95\%}$ (4.7–23.6); $p < 0.001$), major surgery (OR = 4.19; $IC_{95\%}$ (2.2–8.1); $p < 0.001$), inmunomodulator (OR = 4.5; $IC_{95\%}$ (1.7–11.9); $p < 0.001$) and biological treatments (OR = 3.6; $IC_{95\%}$ (1.9–6.9); $p < 0.001$) and severity (OR = 20.1; $IC_{95\%}$ 2.7–148.4); $p < 0.001$). In the multivariate analysis, the following variables were identified as independent predictors associated with an CEDD > 50mSv: major surgery (OR = 2.1; $IC_{95\%}$ (1.1–3.8); p = 0.019) and severity (OR = 20.6; $IC_{95\%}$ (4.5–94.8); $p < 0.01$).
**Conclusion:** Around a quarter of our patients with CD have received dangerous radiation. The severity of the disease and major surgery are predictive factors for receiving a CEDD > 50mSV. Monitoring patients' CED could be useful to reduce the exposure to potentially carcinogenic ionizing radiation. Alternative imaging tests not using ionizing radiation such as ultrasounds and abdominal magnetic resonance enterography should be considered in CD patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0254 CLAUSII IN COLITIS: ROLE AND MECHANISMS OF ACTION OF BACILLUS CLAUSII IN EXPERIMENTAL COLITIS

**Introduction:** *Bacillus clausii* is a gram-positive bacteria, used as in spore form as a probiotic. It is wide use in acute diarrhea, little is known about its ability to modify intestinal microbiota.
**Aims & Methods:** Aim of this study is to investigate the effect of *B. clausii* on mice acute DSS colitis, experimental condition mimicking human IBD and we evaluated gut microbiota modulation in this animal models. Mice were exposed to 2.5% of DSS for 5 days, with or without concomitant administration of *B. clausii* by oral gavage at two different doses. Stool samples were cultured for microbiological analysis before starting the experiments (day 0), at the end of the DSS treatment: 5 days and 14 days. Every other day, disease activity index was calculated based on body weight monitoring, fecal occult blood and type of feces. At sacrifice, histology was analyzed. The direct microbial properties of *B. clausii* were also evaluated in vitro using aerobic and anaerobic selective culture media.
**Results:** Higher dose of *B. clausii* (80 millions) significantly ameliorated mild DSS colitis in mice, according to DAI. No major changes were found on body weight in treated and untreated mice. Histology showed a lower inflammatory score for mice treated with *B. clausii* lower dose and a reduction of inflammatory total score. *B. clausii* modulates gut microbiota composition in mild DSS murine colitis in stool samples in colitic mice: colitic mice displayed lower counts of aerobic bacteria and higher anaerobes in fecal samples compared to healthy mice. The treatment with *B. clausii* associated to an increased counts of aerobes, in a dose dependent fashion. No major change were observed in anaerobic bacteria, treated or not with *B. clausii*. Finally, when used in vegetative form, *B. clausii* reduced the total count of *P. aeruginosa* in aerobic conditions, when compared to control.
**Conclusion:** As we obtained unexpected positive modulatory properties of *B. clausii* on murine colitis, in accordance with the medical advice and we concentrated on characterization of microbiota within fecal compartment of treated mice. We evaluated a histological characterization of the colonic inflammatory infiltrate within intestinal mucosa. The treatment with *B. clausii* was associated to a measurable effect on gut microbiota composition, resulting, in particular, in a reduction of *Staphilococcus aureus*, *Clostridium innocuum* and *Enterobacteriacae* like *Klebsiella oxytoca*, *Enterococcus casseliflavus* and *gallinarum*. *B. clausii* improves acute mild colitis in mice while in-vivo modulating gut microbiota by increasing total counts of aerobics.

**Contact E-mail Address:** lukasbajer1@gmail.com.
**Introduction:** Inflammatory bowel disease (IBD), Crohn's disease (CD) and ulcerative colitis (UC), is chronic idiopathic disorder of gastrointestinal tract. Although its pathogenesis is not completely understood, the inflammation in IBD is a result of an aberrant immune response to commensal microbiota in genetically susceptible individuals. Since there is a marked association of CD with gut fungal microbiota (mycobiota) we analyzed its composition in patients with CD, UC and in healthy controls.
**Aims & Methods:** We obtained stool samples from 9 CD patients, 7 UC patients and 3 healthy controls and extracted DNA using repeated bead–beating technique. Next, we analyzed mycobiota composition by sequencing internal transcribed spacer (ITS2) region of fungal DNA using Illumina MiSeq. The data were processed using standard Qiime pipeline, and the mycobiome alpha (Simpson's evenness index) and beta diversity (binary Jaccard metrics) were calculated.
**Results:** Number of detected fungal OTUs was not significantly different among groups healthy = 4.7 ± 0.6, CD = 5.9 ± 3.1 and UC = 7.6 ± 2.5). Either form of IBD clearly increased mycobiome variability, as documented by an increase in alpha diversity in CD and UC. All healthy individuals have similar fungal communities, dominated by well-adapted natural symbionts such as orders Saccharomycetales and Onygenales. In IBD, these communities were disrupted, and several other fungi were acquired from the environment. These major qualitative differences are well documented by tight clustering pattern of all three groups, as measured by binary Jaccard metrics. This was caused mainly by appearance of Davidiellaceae family and decrease in diversity within order Saccharomycetales in IBD patients.
**Conclusion:** These preliminary data show that gut mycobiota has significant pattern associated with health and disease. The high variability and presence of acquired fungi suggest that disrupted gut microbial ecology in IBD support transient fungal communities. Larger groups and more experiments are needed to confirm these interesting findings and to assess their medical relevance.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0256 HIGHER DISEASE ACTIVITY IN ULCERATIVE COLITIS PATIENTS WITH ESBL PRODUCING ENTEROBACTERIACEAE GUT COLONIZATION: PRELIMINARY STUDY RESULTS

**V. Skuja**[1], K. Pekarska[1], Z. Straume[2], E. Goida[1], H. Dauvarte[1], D. Rudzite[3], E. Lavrinovica[3], A. Derovs[3], A. Lejnieks[3], A. Krumina[3]
[1]*Riga Stradins University, Riga/Latvia*
[2]*University of Latvia, Riga/Latvia*
[3]*Riga East Clinical University Hospital, Riga/Latvia*

**Contact E-mail Address:** vita@skuja.lv.
**Introduction:** Extended-spectrum beta-lactamase (ESBL) producing Enterobacteriaceae are the most frequently found multi-drug resistant bacteria colonizing the gut of ulcerative colitis (UC) patients. Changes in the microbiome may act as a trigger in UC inflammatory process. The objective of this study was to analyze whether the gut colonization with ESBL producing Enterobacteriaceae is associated with clinically relevant disease activity increase according to Mayo score, Montreal classification, Truelove and Witt's index.
**Aims & Methods:** All consecutive patients with histologically confirmed UC, hospitalized in Riga East Clinical University Hospital 2012 – 2015 were interviewed, rectal swabs were collected, Enterobacteriaceae were cultured and analyzed for ESBL presence according to EUCAST guidelines. Patient disease activity was evaluated according to Second European evidence-based consensus on the diagnosis and management of ulcerative colitis Part 1, that recommended clinically used severity indexes: Mayo score, Montreal classification, Truelove and Witt's index.
**Results:** A total of 65 patients with ulcerative colitis were tested for gut colonization with ESBL producing Enterobacteriaceae. We found that 7 (10.8%) of the ulcerative colitis patients were colonized with ESBL producing Enterobacteriaceae. Mean disease activity according to Mayo score in patients without ESBL producing Enterobacteriaceae colonization was 3.40 (SD = 1.98),

whereas in patients with ESBL producing Enterobacteriaceae colonization it was 5.86 (SD = 3.24) (n = 0.015). Most of the patients without ESBL producing Enterobacteriaceae colonization (n = 37; 63.8%) were in clinical remission, whereas most of the patients with ESBL producing Enterobacteriaceae colonization (n = 4; 57.1%) had moderate disease activity, according to Montreal classification disease severity section (p = 0.031). Most of the patients without ESBL producing Enterobacteriaceae colonization (n = 52; 89.7%) had mild disease activity, whereas most of the patients with ESBL producing Enterobacteriaceae colonization (n = 4; 57.1%) had moderate disease activity, according to Truelove and Witt's index (p = 0.008).

**Conclusion:** Higher disease activity is found in ulcerative colitis patients with ESBL producing Enterobacteriaceae gut colonization, according to three most frequently used UC disease activity scores – Mayo score, Montreal classification and Truelove and Witt's index. Such finding could be clinically relevant, because eradication of ESBL producing bacteria might reduce UC disease activity.

## P0257 THE PROTECTIVE EFFECT OF METFORMIN ON MATAINING INTESTINAL BARRIER FUNCTION IN COLITIS

Y. Chen, **J. Deng**

*State Key Laboratory Of Organ Failure Reserach, guangdong Provincial Key Laboratory Of Gastroenterology, Department Of Gastroenterology, Nanfang Hospital, Southern Medical University, Guang Zhou/China*

**Contact E-mail Address:** dlzdj555@163.com.

**Introduction:** The intestinal epithelium serves as an important barrier to prevent intestinal penetration of liminal bacteria, toxins and antigens. The integrity of intestinal epithelial barrier is disrupted in IBD patients. Metformin, which is used in the treatment of type 2 diabetes, was show to have additional benificial effects including anti-inflammation, anti-tumor, improvement of lifespan, modulation of gut microbiota. In the current study, we explore whether metformin could matain the intestinal epithelial function in DSS-induced colitis.

**Aims & Methods:** C57BL/6 mice were given ad libitum access to 3% DSS dissolved in the drinking water 7 days to induced acute colitis. The colitis mice were gavaged with metformin (100 mg/kg/day and500mg/kg/day) or PBS daily since colitis induction. The disease activity index (DAI) was assessed daily. The severity of inflammation was assessed by histopathological analysis. The inflammatory factors IL-6, TNF-$\alpha$and IL-1$\beta$were tested by real-time PCR and Elisa. The mRNA level of tight junction proteins zo-1, occludin and Muc 2 were determined by real-time PCR. Western blot was used to test the level of zo-1 and occludin in colon. To determin the bacterial translocation, the total population of bacteria in the MLNs, liver and spleen of colitis mice were assessed by qPCR.

**Results:** Metformin can significancantly ameliorate the induction of colitis by DSS, prevnets the reduction of body weight and colon length and reduces DAI score. Metformin significancantly inhibits the production of inflammatory factors IL-6, TNF-$\alpha$and IL-1$\beta$in DSS-induced colitis. Metformin treatment reuduces the loss of globet cell in colon of colitis mice. Compared to the DSS group, the level of zo-1, occludin and Muc2 are greatly higher after metformin administration. In addition, metformin can alleviate bacterial translocation caused by DSS-induced colitis.

**Conclusion:** Metfomin can ameliorate the severity of DSS-induced colitis through the potential mechanism involving its effects on mataining intestinal barrier function.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0258 FAMILIAL AGGREGATION OF INFLAMMATORY BOWEL DISEASE ON THE FAROE ISLANDS – A FAROESE IBD COHORT STUDY

**K.R. Nielsen**[1], J. Olsen[1], G. Andorsdóttir2[2], E. Gislason[2], J. Burisch[3]

[2]*Genetic Biobank, Torshavn/Faroer Islands*

[3]*Department Of Gastroenterology, North Zealand University Hospital, Frederikssund/Denmark*

**Contact E-mail Address:** lskarni@ls.fo.

**Introduction:** Over the last two decades the incidence of inflammatory bowel disease (IBD) has increased dramatically on the Faroe Islands[1]- an archipelago located in the North Atlantic Ocean populated by an endogamous population - and is today the highest in the world[2]. This steep increase in IBD is mainly caused by ulcerative colitis (UC), since the incidence of Crohn's disease (CD) has remained stable over the last 5 decades. The reasons for these observations are unknown.

**Aims & Methods:** In this study we aimed to investigate the genetic contribution component in CD and UC patients on the Faroe Islands. The Faroese IBD cohort is a population-based, nationwide cohort of all patients diagnosed with Crohn's disease (CD), ulcerative colitis (UC), and IBD unclassified (IBDU) according to the Copenhagen diagnostic criteria from 1960 until 2014. The relationship among CD and UC patients was studied using a unique computerized nationwide genealogy registry covering pedigrees from the whole Faroese population from approx. 1650. Relative risk (RR) of kinship for patients were compared to controls (simulated as if they were probands and shown as CI93%). Controls were matched for age, gender and approximate sibship size. Pedigrees for control subjects were randomly and reiteratively sampled from the Faroese genealogic database.

**Results:** Pedigrees were available for the whole cohort consisting of 664 incident IBD patients, 113 (17%) with CD, 417 (62%) with UC, and 134 (21%) with IBDU diagnosed according to the Copenhagen Diagnostic Criteria for IBD. Average age at diagnosis was 41 years (0–86 yrs). Disease extent for UC patients at diagnosis was proctitis in 21%, left-sided colitis in 39%, and extensive colitis in 40%. For CD patients the disease behavior was nonstricturing/nonpenetrating (B1) in 65%, stricturing (B2) in 25%, and penetrating (B3) in 8% at the time of diagnosis. Only 2% of CD patients had perianal disease. Disease location for CD patients as terminal ileum (L1) in 22%, colon (L2) in 65%, ileo-colon (L3) in 10%, and upper GI (L4 (+/- L1-L3) in 3%. The RR of kinship in UC and CD patients compared to controls are shown in table 2. Overall, UC patients were more closely related than controls (RR for UC was higher than upper CI93% limit for controls), whereas no hereditary component in CD patients was found.

**Conclusion:** In this population-based, nationwide cohort of Faroese IBD patients a hereditary component was found for UC but not for CD patients. Further analyses on the impact of the genetic contribution on disease course as well as genetic and microbial analysis are ongoing.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The ECCO-EpiCom study investigates the differences in the incidence, disease characteristics and therapeutic strategy of inflammatory bowel diseases (IBD) between Eastern and Western Europe.

**Aims & Methods:** Our aim was to analyze differences in the 2-and 3-year outcomes between Eastern Europe and Western Europe/Australia in the 2011 ECCO-EpiCom cohort. Eight Western European, 5 Eastern European and one Australian center participated in the 2-and 3-year follow-up. Patients' data on medical therapy, surgery and hospitalizations were registered in the web-based ECCO-EpiCom database.

**Results:** 319 IBD patients (Crohn's disease (CD): 126, (ulcerative colitis (UC): 160, IBD unclassified: 33; 234 patients from Western Europe/Australia and 85 patients from Eastern Europe; median age at diagnosis: 38.2 years (range: 15.1–88.6); F/M: 137/182) have completed the 2-year and 269 IBD patients completed the 3-year follow-up. During the 2- and 3-year follow-up period, 24 (67%) and 24 (75%) CD patients from Eastern Europe and 54 (60%) and 56 (68%) from Western Europe/Australia received IS (immunosuppressives) ($p = NS$). Five (14%) and 5 (16%) CD patients from Eastern Europe and 27 (30%) and 29 (35%) from Western Europe/Australia received biological therapy ($p_{2\text{-year}} = 0.06$ and $p_{3\text{-year}} = 0.04$). Nine (25%) and 9 (28%) CD patients from Eastern Europe and 9 (10%) and 9 (11%) CD patients from Western Europe/Australia underwent surgery ($p_{2\text{-year}} = 0.03$ and $p_{3\text{-year}} = 0.02$). Twelve (33%) and 12 (38%) CD patients from Eastern Europe and 26 (29%) and 28 (34%) from Western Europe/Australia were hospitalized ($p_{2\text{-year}} = 0.62$ and $p_{3\text{-year}} = 0.70$). During the 2- and 3-year follow-up period, about a third of the UC patients received IS in both Eastern Europe and Western Europe/Australia 3-year follow-up: Eastern Europe: 12 (39%) Western Europe/Australia: 33 (34%) $p = NS$. No difference was found in biological use, surgery and hospitalization rates in UC patients both during the 2-and 3-year follow-up period (biological therapy: 3-year follow-up: Eastern Europe: 4 (13%), Western Europe/Australia: 15 (16%) $p = 0.72$; colectomy: 3-year follow-up: Eastern Europe: 1 (3%) Western Europe/Australia: 5 (5%) $p = 0.66$; hospitalization: 3-year follow-up: Eastern Europe: 9 (29%) Western Europe/Australia: 33 (34%) $p = NS$).

**Conclusion:** At 2 and 3 years after diagnosis, the biological use in CD patients was higher in Western Europe/Australian centers compared to Eastern Europe. The surgery rate was lower in the former, while IS use and hospitalization rates were not different. In UC, IS and biological use, colectomy and hospitalization rates remained similar between these regions.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0260 REAL-WORLD EPIDEMIOLOGY AND INITIAL TREATMENT PATTERNS OF PATIENTS NEWLY DIAGNOSED WITH INFLAMMATORY BOWEL DISEASE IN ISRAEL

C. Weil[1], G. Chodick[2], A. Yarden[3], **J.M. Khalid**[4], V. Shalev[2]
[1]Epidemiology, Maccabi Healthcare Services, Tel Aviv/Israel
[2]Sackler Faculty Of Medicine, Tel Aviv University, Tel Aviv/Israel
[3]Takeda Pharmaceuticals Israel, Tel Aviv/Israel
[4]Global Outcomes Research, Takeda Development Centre Europe Ltd, London/United Kingdom

**Contact E-mail Address:** mona.khalid@takeda.com.

**Introduction:** To describe the real-world epidemiology and treatment patterns of patients newly diagnosed with inflammatory bowel disease (IBD) in Israel, including ulcerative colitis (UC) and Crohn's disease (CD).

**Aims & Methods:** A retrospective cohort study was performed using the computerized databases of Maccabi Healthcare Services, a 2-million-member healthcare maintenance organization with similar demographic characteristics to the general population in Israel (representing 25% of the Israeli population), in a context of universal and mandatory health insurance. Patients newly diagnosed with IBD in 2010–2014 were defined by at least 2 separate diagnoses (including one from a gastroenterologist or hospital) and 12 months of enrolment prior to their first diagnosis. For the analysis of treatment patterns, patients were required to have purchased a disease-related pharmacotherapy on/after IBD diagnosis (index purchase) and have 12 months of follow up through 2015. Patients were classified by index therapy based on the first purchase after diagnosis. Excluded were patients who initiated biologics prior to IBD diagnosis. In order to group patients by unique index therapy class, 25 patients with a combined index purchase of immunomodulators (IMs) and 5- aminosalicylates (5-ASA) were also excluded. Changes from index therapy in the first 12 months were described, including discontinuation (based on an observed treatment gap $\geq$ 60 days), switching, add-on therapy and upward dose titration, assuming an induction or dose-adjustment period of 90 days for 5-ASA, IM and biologics.

**Results:** During 2010–2014, the incidence rates for newly diagnosed UC ($N = 1$, 120) and CD ($N = 1$, 704) were 11.4 and 17.3 per 100, 000 Maccabi Health Services members, respectively. A total of 1, 034 UC patients (mean age: $37.2 \pm SD$ 16.5 years) and 1, 251 CD patients ($33.0 \pm 16.9$ years) were included in the analyses of treatment patterns. In the year prior to index purchase, 179 patients (4.3% of UC and 10.8% of CD patients) had seen a gastroenterologist at least 5 times. 5-ASAs were the predominant index therapy during the study period, accounting for 90.2% and 66.4% of UC and CD patients, respectively. IMs were more frequently initiated among patients newly diagnosed with CD compared to UC (14.7% vs. 0.7%). Among 5-ASA initiators, almost half discontinued during the induction period. Add-on therapy consisted primarily of 5-ASA or CS for UC patients and of IM for CD patients. Among IM-initiating CD patients ($N = 184$), 8.7% switched directly to biological therapies within a year, accounting for the majority of switches in this sub-group. Overall, 86% and 9% of IBD patients used 5-ASAs and biologics, respectively, either at index or over the following 12 months.

**Conclusion:** Overall during the study period, high treatment uptake was observed among patients with newly diagnosed IBD, particularly with 5-ASAs and IMs. However, changes from index therapy or discontinuation were frequent within the first year, underscoring the complexity of initial treatment pathways among different patient sub-groups.

**Introduction:** At the era of early combined immunosuppressive treatment, identification of early prognostic factors of a complicated or disabling Crohn's disease course is needed for physician decision-making to minimize structural bowel damage, complications of disease and side effects related to treatment. Only population-based studies are able to assess these questions given the selection bias of referral center studies.

**Aims & Methods:** All incident cases of patients diagnosed with possible CD ($n = 370$) were registered from 1994 to 1997 in Brittany, a limited area in France. At diagnosis were recorded clinical features, endoscopic lesion per ileocolic segment (according to the CDEIS), radiologic and histologic data. All charts of patients were reviewed from the diagnosis to the last clinic in 2015. Disabling Crohn's disease course was defined according to the Saint-Antoine criteria: more than 2 steroid course or steroid dependency/resistance, hospitalization related to CD, use of immunosuppressant or anti-TNF, anal or major abdominal surgery. Bowel damage was defined according to the criteria that weight the recent Lémann Score (surgery, complicated behavior, anoperineal involvement) Independent predictors of all outcomes were identified using a Cox proportional hazards model.

**Results:** Among the 370 incident cases, 39 had not Crohn's disease and 272 of the 331 cases with CD (82%) were reviewed with a median follow-up of 12.8 years. Disease locations were broadly similar for each patient over time involving the ileon for 15% of patient, the colon for 36% of patient and ileocolic for 48% of patients. Cumulative probabilities of stricturing disease and fistulizing disease at 15 years were 35% 95%IC [29%–42%] and 17% 95%IC [12%–22%], respectively. Cumulative probabilities of complicated behavior (structuring or fistulizing disease) were at 5 years, 10 years, and 15 years, 23%, 34% and 42%, respectively. Cumulative probabilities of major abdominal surgery were at 1 year, 5 years, 10 years and 15 years, 14% [10%–19%], 29% [24%–35%], 36% [30%–42%] and 45% [38%–52%], respectively. The cumulative probabilities of the use of steroids, immunosuppressant (thiopurine and methotrexate) and TNF antagonist were 65.8% ($n = 179$), 37.5% ($n = 102$) and 22.1% ($n = 60$) at 15 years. Median disease duration before the use of immunosuppressant or TNF antagonist were 68 months and 131 months, respectively. Cumulative probabilities of disabling disease were at 1 year, 5 years, 10 years and 15 years, 35% [29%–41%], 57% [50%–63%], 67% [61%–73%] and 74% [68%–79%], respectively. Systemic manifestation at diagnosis ($HR = 1.62$ [1.09–2.39], $p = 0.02$) and perianal lesion ($HR = 4.47$ [1.80–11.08], $p = 0.001$) independently predicted a disabling disaese course. Endoscopic lesions at diagnosis were not associated with disease outcomes. Bowel damage was observed for 154 patients after

mean disease duration of 15 months. The cumulative probabilities of having bowel damage were 14%, 34%, 44% et 51%, at 1 year, 5 years, 10 years et 15 years, respectively. L1 disease (HR = 1.9, IC95 [1.2–2.9]), diagnostic delay of at least 9 months (HR = 1.7, IC95 [1.17–2.4]) and extraintestinal manifestation (HR = 1.44, IC95 [1.01–2.03]) predicted at diagnosis bowel damage in the long term.

**Conclusion:** In a population-based cohort, most patients experienced disabling disease outcomes according to the predefined Saint-Antoine criteria. Half of patients had bowel damage that occurred early in the course of CD. The high rate of disabling outcomes may underline the need to treat CD patients with effective treatment whatever the disease characteristics at diagnosis, including endoscopic lesions.

**Contact E-mail Address:** ayesha17@gmail.com.

**Introduction:** There appears to be an association between inflammatory bowel disease (IBD) and Celiac Disease (CeD). The aim of this systematic review was to assess in IBD patients the risk of CeD and in CeD the risk of IBD.

**Aims & Methods:** With the search term 'inflammatory bowel disease' & 'celiac disease', 28 studies (17 IBD in CeD, 13 CeD in IBD and 4 both) met inclusion criteria. Proportions and 95% Confidence Intervals (CI) for the prevalence of IBD in CeD patients and vice versa were compared with published prevalence rates for the respective geographic regions.

**Results:** Seventeen studies included 41, 482 adult IBD patients (20, 357 Crohn's disease (CD), 19, 797 ulcerative colitis (UC)), 459 patients with CeD. Overall, in IBD patients the prevalence of celiac disease was 1.065% (95% CI 1.065–1.2065) while the prevalence in CD and UC was 1.1888 (95% CI 1.0388–1.2288) and 1.0307 (95% CI 0.86307–1.1707). The prevalence of IBD in celiac disease was 1.6619 (95% CI 1.19–2.15). The prevalence for IBD in the respective geographic regions was 307 per 100.000 (95% CI). The expected adjusted prevalence of celiac disease in the study population was 1%. Thus our results show a 5.5 fold increase of IBD in CeD compared to the general population (6.6 fold for CD and 4.9 fold for UC).

**Conclusion:** The prevalence of IBD in CeD is increased, while the prevalence of CeD in IBD is not different from the expected prevalence in the various populations. Celiac disease is a risk factor for IBD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0263 OBJECTIVE ASSESSMENT OF PHYSICIAN TO PATIENT CONCORDANCE AND BIOPSYCHOSOCIAL IMPACT ON PERTINENT PATIENT REPORTED OUTCOMES AND MEDICATION COMPLIANCE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

**C. Chao**, W. Afif, A. Bitton, G. Wild, C. Lemieux, T. Bessissow

**Contact E-mail Address:** noidea2001@hotmail.com.

**Introduction:** Enhanced attention to patient report outcomes (PRO) and medication compliance are associated with improved holistic care of inflammatory bowel disease (IBD) patients. This study aims to evaluate physician and patient concordance on PRO and compliance as well as the potential relationship with underlying biopsychosocial factors.

**Aims & Methods:** We conducted a prospective study on patients diagnosed with Crohn's disease (CD) or ulcerative colitis (UC) presenting for evaluation at the McGill IBD center between September 2015 and March 2016. Patients were assessed for quality of life, disability and productivity using validated short IBD questionnaire (SIBDQ), IBD disability index (IBDDI) and work productivity assessment index (WPAI) respectively. Medication compliance was evaluated using the medication adherence questionnaire (MAQ) and selected psychological assessment was also performed using hospital anxiety and depression score (HADS) as well as brief COPE questionnaire for disease coping strategies. Disease activity was objectively determined by fecal calprotectin (FCP). Results were examined against the treating IBD physician's assessment on these measures, which was independently obtained using visual analogue following concurrent clinic review.

**Results:** 132 (91 CD / 41 UC) patients, with median age of 39 and 40% male, were included. The validated PRO evaluation tools correlated well with each other, despite their assessment on different outcomes (Pearson correlation coefficient r = 0.66–0.81), as well as with HADS (r = 0.62); $p < 0.001$ for all. Unexpectedly there was a strong concordance between physician perception and PRO measures of disability (r = 0.65), quality of life (r = 0.65) and productivity (r = 0.61) as well as disease activity (FCP: r = 0.64), $p < 0.001$ for all. Men were more likely to report worse disability (odd ratio [OR] 3.01, 95% confidence interval [CI] (1.21–7.49), p = 0.018) and quality of life (OR 5.63, 95% CI 2.02–15.72, p = 0.001). Disease activity (FCP > 250), high HADS and patient coping strategies did not reliably predict worse PRO on regression analysis. Medication compliance rate is poor in the study population (17% strong adherence rate) and it is inadequately identified by treating physicians (r = 0.20). Furthermore, in those asymptomatic patients (HBI ≤ 4 / partial Mayo ≤ 1) with higher risk of relapse as indicated by elevated FCP > 250, up to 43% report suboptimal compliance. Strong compliance (MAQ < 3) is independently predicted by active disease with FCP > 250 (OR 3.64, 95% CI 1.09–12.17, p = 0.036), age less than 30 (OR 3.57, 95% CI 1.53–8.34, p = 0.003) and poor quality of life (SIBDQ < 47: OR 2.70, 95% CI 1.18–6.21, p = 0.019) on univariate analysis. FCP > 250 is the only factor independently associated with compliance on multivariate analysis (OR 6.41, 95% CI 1.46–28.18, p = 0.014).

**Conclusion:** Pertinent patient-reported outcomes of disability, quality of life and productivity can be accurately and effectively identified by treating physicians in standard clinical settings without the necessary need of administering extensive qualitative questionnaires. Strong medication compliance is associated with disease activity however more emphasis needs to be made on addressing adherence issues, particularly in those with high risk of risk relapse.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0264 THE ONLINE HEALTH CARE REVOLUTION AND THE ASSOCIATION BETWEEN UNCERTAINTY AND QUALITY OF LIFE IN CROHN'S DISEASE

**Introduction:** The internet has revolutionized our daily life. Recent studies found that medical-related searches ranked third as one of the most frequent online activities.

Individuals seek information in order to understand symptoms, treatment, options, and prognosis but the benefits haven't come without consequences.

**Aims & Methods:** To examine the association between seeking health information via internet and health related quality of life (HRQOL) and uncertainty among Crohn's disease (CD) patients.

Methods: The research tool was composed of a 4 parts questionnaire; demographic and clinical information; HRQOL (The short inflammatory bowel disease questionnaire), level of certainty (the Mishel Uncertainty in Illness Scale), and information gathered via internet regarding CD questionnaire.

**Results:** 105 consecutive patients participated in the study, mean age was 34.2 ± 10.7 years. Sixty-three percent of participants reported of seeking information via internet about their disease during the last 3 months. The results show a positive significant correlation between HRQOL and certainty (P = 0.002) and a negative correlation between certainty and seeking information via internet (r = −0.19, p = 0.05). Multiple regression analysis for factors associated with HRQOL, found level of certainty, seeking information via internet, and disease activity significant factors for quality of life. Seeking information via internet was significantly associated with level of certainty.

**Conclusion:** This is the first study examined the relationship between seeking information via internet, HRQOL and level of certainty in patients with CD. Understanding factors affecting level of certainty and HRQOL can provide tools for caregivers for better treatment of CD patients, focusing on dedicated web information.

**Introduction:** Restorative proctocolectomy with ileal pouch-anal anastomosis is the standard surgical procedure for patients with ulcerative colitis (UC). Pouchitis, a non-specific inflammation of the ileal reservoir, is the most common long-term complication. MicroRNAs (miRNAs) are small, noncoding RNAs that act as potent negative regulators of gene expression and are differentially expressed in chronic inflammatory diseases, including UC. To our knowledge, little is known about the relationship between pouchitis and miRNA expression. This study was aimed to determine whether miRNA expression is altered in pouchitis.

**Aims & Methods:** Sixty-four patients were included in this study. Modified Pouch Disease Activity Index (mPDAI) was used for the diagnosis of pouchitis; an mPDAI of no less than four was indicative of pouchitis. We identified 16 pouchitis patients, and the rest were considered non-pouchitis patients. Biopsies were

obtained by pouch endoscopy, and the total RNA was extracted, reverse-transcribed, and quantified with real-time polymerase chain reaction. The relative quantification (RQ) value was calculated according to the manufacturer's instructions. Statistical analyses for qRT-PCR were performed using non-parametric Mann-Whitney test. Statistical significance was set at $p < 0.05$.
**Results:** We compared miRNA expression between samples from pouchitis and those from non-pouchitis. We have demonstrated that two miRNAs (miR-21, miR-223) increased (RQ = 1.352 (1.125–1.625), p = 0.004; and RQ = 1.371 (1.039–1.809), p = 0.014, respectively) and two miRNAs (miR-192, miR-196a) decreased (RQ = 0.611 (0.381–0.979), P = 0.036, RQ = 0.716 (0.541–0.958), p = 0.019, respectively) in the inflamed mucosa of pouchitis compared with the control. Next, we compared miRNA expression between samples from pouchitis and those from the proximal non-inflamed ileum. We found that fourteen miRNAs decreased in the inflamed mucosa of pouchitis compared with that in the proximal region without inflammation (Table). Two miRNAs (miR-192, miR-196a,) were downregulated analogously in pouchitis samples compared with samples from non-pouchitis and those from the proximal samples.

Comparison in miRNA expression between pouchitis and the proximal ileum

| MiRNA | Relative quantification | P value |
|---|---|---|
| miR-7 | 0.69 (0.54–0.89) | 0.008 |
| miR-16 | 0.79 (0.66–0.94) | 0.049 |
| miR-17 | 0.72 (0.57–0.93) | 0.045 |
| miR-29c | 0.73 (0.61–0.88) | 0.006 |
| miR-106a | 0.69 (0.54–0.89) | 0.014 |
| miR-145 | 0.65 (0.46–0.91) | 0.042 |
| miR-188 | 0.67 (0.53–0.84) | 0.037 |
| miR-192 | 0.24 (0.15–0.39) | <0.001 |
| miR-195 | 0.76 (0.62–0.93) | 0.041 |
| miR-196a | 0.60 (0.45–0.80) | 0.006 |
| miR-200b | 0.45 (.32–0.65) | <0.001 |
| miR-221 | 0.58 (0.46–0.74) | <0.001 |
| miR-422a | 0.51 (0.38–0.68) | <0.001 |
| miR-499 | 0.69 (0.53–0.90) | 0.033 |

**Conclusion:** We found a statistically significant difference in miRNA expression in pouchitis tissues. MiRNA may play a significant role in the pathogenesis of pouchitis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0266 VARIANTS OF IL23R GENE AND CROHN'S DISEASE

N. Ben Mustapha[1], **M. Hafi**[2], M. Serghini[3], A. Laabidi[2], M. Fekih[2], J. Boubaker[2], A. Filali[2]

[3]*Gastroenterology A, La Rabta Hospital Dept. of Gastroenterology, Tunis/Tunisia*

**Contact E-mail Address:** maroua.hafi@gmail.com.
**Introduction:** The pathogenesis of inflammatory bowel disease (IBD) is very complex. It is related to factors both genetic, immunological and environmental. Numerous studies have associated susceptibility genes to these diseases. Among the genes that have been recently implicated in IBD susceptibility we note the IL23R.
Its role in inflammation and in innate and adaptive immunity makes it a strong candidate involved in triggering certain autoimmune and inflammatory diseases. This locus includes many polymorphisms or SNPs including 11209026 SNP and the 7517847 SNP which are the interest of our study.
**Aims & Methods:** Our aim is to study the 11209026 SNP and the 7517847 SNP of the IL23R gene in our country's population in order to assess the involvement of these two variants in the susceptibility to Crohn's disease (CD). We began a preliminary study by seeking the presence of mutations for each SNPs of IL23R gene in the Tunisian population while relying on studies that concerned the two polymorphisms 11209026 and 7517847. Molecular analysis of IL23R gene was made on 28 patients with Crohn's disease and 37 healthy controls. We conducted a verification of the presence of the SNPs in the DNA sequences extracted from whole blood of patients and healthy controls. The extraction was made using two techniques: phenol / chloroform for healthy controls and by KIT Quiagen for patients with CD. Then, amplification of the 11209026 SNP and the 7517847 SNP is carried out using specific primers that amplify the exon 9 of IL23R gene for the first and intron 6 of the gene for the second one. The primers' design was done using a bioinformatic tool: Primer 3 software to amplify the region of interest. The primers designed to amplify the SNP 11209026 have a 298 bp band size and the SNP 7517847 provides an amplicon of 378 bp. The next step is to confirm that the amplification products correspond to the amplified regions and if they contain polymorphisms at their sequences. The technique used for this purpose is that of sequencing followed by statistical analysis of allele and genotype frequencies.
**Results:** PCR results confirmed the specificity of the primers since we obtained a 208 bp band for patients with CD. Similarly for the 2nd SNP, we had the expected band size of 378 bp for both patients and controls.
Analysis of the results showed for the SNP 11209026 the presence of the rare allelic polymorphism A in the nucleotide sequences of the DNA of patients with CD. Thus the frequency of this rare allele A is 0.08 which is close to the frequency found in other studies such as the population of Pennsylvania (1). The genotypic frequencies of the SNP12209026: GG (0.87) GA (11.9) and AA (0.8) are also acceptable on the basis of other studies that show quite similar values such as the population of New Zealand (2) and that of the German population (3). The absence of this allele in the SNP 112209026 sequence in certain populations is due to its rarity. As for the sequence analysis results for the second SNP 7517847 resulting in allelic and genotypic frequencies: It was shown that the G allele polymorphism or SNP G is found in the DNA sequence for both controls and CD patients. The frequency of the G allele was 0.17 for patients with Crohn's disease and 0.18 for healthy controls. These allele frequencies are also accepted by comparing the frequencies observed in the Polish population (4). Also, the genotypic frequencies of TT, TG and GG are present in our control population as observed in studies such as that of Rome and that of Hungary (5) with an allele and genotype frequencies close to those we found.
**Conclusion:** Our results show the presence of the rare allele A of the SNP11209026 (Arg 381Gln) in patients with CD and the G polymorphism of the 7517847 SNP in our country's population. Our study is the first studying our population by investigating a susceptibility gene as that of IL23R in CD. Further studies with largest numbers of patients are necessary to be able to study the implication of the presence of these polymorphisms on the presence and severity of CD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** In the pathogenesis of Crohn's diseases (CD) it is hypothesized that a dysregulated mucosal immune response to the intestinal environment in a genetically susceptible host. Organic cation/carnitine transporter 1 (OCTN1), one of CD associated genes, have been demonstrated that the non-synonymous variant p.L503F is associated with susceptibility to CD. However, it was reported that p.L503F is absent in Asian populations. Previously, we identified and functionally characterized that four genetic variants of the OCTN1 promoter region significantly changed a promoter activity in Koreans.
**Aims & Methods:** We examined whether four functional variants of the OCTN1 promoter play a role in the susceptibility to or clinical course of CD in Koreans. The frequencies of the four variants of the OCTN1 promoter were determined by genotyping using DNA samples from 194 patients with CD and 287 healthy controls. Then, association tests were performed between genetic variants and the susceptibility to CD or clinical course of CD.
**Results:** We identified that susceptibility to CD was not significantly associated with OCTN1 functional promoter variants or haplotypes showing altered promoter activities in in vitro assays. However, a penetrating behaviour in CD patients was significantly associated with OCTN1 functional promoter haplotypes showing decreased promoter activities (Hazards ratio = 2.428, P = 0.009).

**Table:** Clinical course of CD patients according to OCTN1 haplotypes.

| Parameter | Variant (%) | Control (%) | Hazards ratio (95% CI) | P value |
|---|---|---|---|---|
| Total number | 86 | 108 | | |
| Behavior | | | | |
| Inflammatory | 40 (46.5) | 68 (63.0) | | |
| Stricturing | 18 (20.9) | 27 (25.0) | 1.004 (0.549 – 1.837) | 0.990 |
| Penetrating | 28 (32.6) | 13 (12.0) | 2.428 (1.243 – 4.741) | 0.009 |
| Azathioprine or Anti-TNF agent use | 64 (74.4) | 81 (75.0) | 0.795 (0.566 – 1.115) | 0.184 |
| Surgery | 33 (38.4) | 32 (29.6) | 1.147 (0.702 – 1.875) | 0.584 |

**Conclusion:** Our results suggest that the OCTN1 functional promoter haplotypes can influence the penetrating behaviour of CD, although these might not be associated with susceptibility to CD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** To date, mucosal healing should be the therapeutic goal in Crohn's disease (CD) as it is associated with more favourable outcomes. However, repeating ileocolonoscopy to monitor the disease is felt as a burden by the patients and has led physicians to look for alternative noninvasive approaches. Thus, magnetic resonance imaging (MRI) has been increasingly used for the diagnosis and the monitoring of CD because of its lack of ionizing radiation, and its ability to accurately assess inflammation in CD. Recently, it has been shown that MRI is able to assess therapeutic efficacy [1]. However, whether achieving MRI remission is associated with favourable outcomes remains unknown.

**Aims & Methods:** We aimed to investigate whether MRI remission after therapeutic intervention could predict clinical corticosteroids-free remission (CFREM), hospitalization and CD related-surgery. We performed a posthoc analysis from pooled data of two prospective trials [2, 3]. Patients were excluded from this study if MRI examination was performed at diagnosis, if MRI was performed before starting/switching therapy, or if follow-up was shorter than 6 months. Objective sign of inflammation on colonoscopy, CTscan or MRI before treatment has to be available to include the patients in this study. Overall, 63 CD patients, undergoing MRI to monitor a therapeutic response, were included. All the patients underwent diffusion-weighted magnetic resonance enterocolonography with no bowel cleansing and no rectal enema. MRI evaluation was performed using 5 segments (ileum, right colon, transverse colon, left/sigmoid colon and rectum). MRI remission was defined using Clermont criteria [2, 3] (Clermont score dedicated to the ileum $< 18.9$ and no segmental apparent diffusion coefficient ADC $< 1.88$) or using Barcelona criteria [4] (no segmental MaRIA $> 11$). Deep MRI remission was defined as no segmental MaRIA $> 7$. Clinical corticosteroids-free remission was defined as absence of CD flare. CD flare was defined as reappearance or worsening of clinical manifestation leading to therapeutic modification, hospitalization or CD-related surgery. For each of the patients CFREM and hospitalization were assessed by semesters. Repeated data were analyzed using generalized linear mixed model (logistic) taking into account between and within patient variability as random-effect. Other data were analyzed with usual statistical tests.

**Results:** The characteristics of the 63 included patients were given in Table 1 with a median follow-up of 4 semesters.

Characteristics of the 63 Crohn's disease patients at inclusion (=time of MRI examination)

| Charateristics | Overall population (n = 63) |
|---|---|
| Female gender | 43 (68.3%) |
| Smokers | 32 (50.8%) |
| Age at diagnosis, years, (mean +/- sd) | 26.4 +/- 12.6 |
| Age at inclusion, years, (mean +/- sd) | 34.8+/- 14.5 |
| Disease duration, years, (mean +/- sd) | 8.7 +/- 9.5 |
| Montreal classification | |
| Location | |
| L1 | 19 (30.2%) |
| L2 | 18 (28.6%) |
| L3 | 26 (41.2%) |
| L4 | 6 (9.5%) |
| Behaviour | |
| B1 | 29 (46.0%) |
| B2 | 22 (34.9%) |
| B3 | 12 (19.0%) |
| Perianal lesions | 20 (31.7%) |
| Prior intestinal resection | 21 (33.3%) |
| CDAI, median [IQR] | 189[80-243] |
| CDAI > 150 | 39 (61.9%) |
| CRP, median [IQR] | 14.0[2.9-35.5] |
| CRP > 5 g/L | 37 (56.9%) |
| Current therapies at inclusion | |
| Corticosteroids | 25 (39.7%) |
| Thiopurines | 23 (36.5%) |
| Methotrexate | 1 (1.6%) |
| Anti-TNF | 30 (47.6%) |
| Infliximab | 12 (19.0%) |
| Adalimumab | 18 (28.6%) |
| MRI remission according Clermont criteria | 15 (23.8%) |
| MRI remission according Barcelona criteria | 14 (22.2%) |
| Deep MRI remission according Barcelona criteria | 11 (17.4%) |

Overall, 300 semesters were taken into account for the analysis. In multivariate analysis taken into account the impact of CDAI, CRP and current therapy at inclusion, deep MRI remission was associated with more time spent in CFREM (85.7% vs 44.9%, $p = 0.01$) and increased time to CD-related surgery ($p < 0.05$) compared to CD patients with persistent MRI activity. MRI remission according to Clermont criteria (67.1% vs 47.1%) and Barcelona criteria (66.7% vs 47.3%) ($p = 0.047$) were also associated with higher proportion of semester spent in CFREM. No definitions of MRI remission were associated with the percentage of semesters with hospitalization.

**Conclusion:** MRI remission after therapeutic intervention is associated with favourable outcomes and should be considered as non-invasive therapeutic endpoint in CD. A dedicated prospective trial should be led to confirm our data.

**Introduction:** Inflammatory bowel disease (IBD) is influenced by environmental and genetic factors which alter the gut microbiota. The human gut microbiota is involved in the maintenance of its host physiological functions and an imbalance in the microbial population with it's subsequent metabolic signatures may lead to disease activity and phenotypes.[1] Therapy with anti-TNF medication forms the backbone of treatment in moderate to severe Crohn's disease (CD) and is used as salvage therapy in severe acute ulcerative colitis (UC). The metabonomic approach using powerful analytical methods for metabolite detection have led to biomarker discovery and may help in differentiating IBD phenotypes and therapeutic response to medications.[2].

**Aims & Methods:** We aimed to investigate the variations occurring in polar metabolites via hydrophilic interaction liquid chromatography (HILIC) profiling between healthy, CD and ulcerative colitis cohorts in urine and faeces and response to anti-TNF therapy by profiling using a metabonomic approach. Urine and faeces were collected from 15 healthy controls, 58 patients with moderate to severe CD prior to commencement of anti- TNF and 8 patients with severe acute UC at the point of hospital admission. The samples were collected at three-monthly timepoints for 12 months at study exit or upon cessation of drug due to non-response or requirement for surgery. Metabolic profiling was performed on an Acquity UPLC system coupled to a Xevo G2 QTof mass spectrometer (Waters). Chromatography was performed using an Acquity BEH HILIC column (Waters). Separation was performed using gradient elution (20 min run) with 0.1% (v/v) formic acid and 10 mM ammonium acetate in 95/5% ACN/H2O

(A) and 0.1% (v/v) formic acid and 10 mM ammonium acetate in 50/50% ACN/H2O (B). Mass spectrometry was performed in positive ion electrospray (ESI+) modes.

**Results:** HILIC-MS metabonomic analysis was implemented on urine (n = 215) and faeces (n = 187) from healthy, CD and UC participants. Metabolite features were extracted from UPLC-MS data (urine n = 779, faeces n = 1888) and aligned across samples. Before multivariate statistical analysis, intensity coefficient of variations (CVs) of each metabolite feature were calculated and applied as filter (CV < 30%, urine n = 533 faeces n = 1065). Partial least square-discriminant analysis (PLS-DA) scores plot was performed to reduce the dimensionality of the data and to assess the relation between the participant groups. Classes for the supervised discrimination of the data were set according to each of the three groups. Various models were created; 1) healthy vs. DC, 2) healthy vs. UC and 3) CD vs. UC. For urine samples, the three models explained >90% of the variance ($R^2$) with strong predictive capacity ($Q^2$) >60–80% of the variance. For fecal samples, the three models explained >90% of the variance ($R^2$) and good predictive capacity ($Q^2$) >30–70% of the variance. On further PLS-DA, we were able to show that polar metabolities account for differences between UC and CD. PLS-DA analysis scores plot aimed also to decipher the progression of metabolic metabolism during anti-TNF treatment at 3 monthly interval (5 visits) (See Table 1). The biological effects of anti-TNF therapy on HILIC compounds can be seen by the strength of association as demonsrated by the most significant model between visit 1 and visit 3 in urine (R2 = 1, Q2 = 0.598) and falls away by visit 5 (R2 = 0.976, Q2 = 0.205). This may demonstrate that it may take approximately 6 months (at visit 3) before maximal host metabolism alterations occurs, at which time determination of response or non-response can be made. This is in contrast to faecal metabolites where there was a longer time to derivation of anti-TNF effect with maximal association at visit 5 (R2 = 0.957, Q2 = 0.494).

**Table 1:** The strength of assocation between CD patient visits.

| R2/Q2 | | V1 | V2 | V3 | V4 | V5 |
|---|---|---|---|---|---|---|
| Urine | V1 | - | 0.917/0.184 | 1/0.598 | 0.997/0.381 | 0.976/0.205 |
| | V2 | 0.917/0.184 | - | 0.968/0.119 | 0.983/0.128 | 0.955/0.116 |
| | V3 | 1/0.598 | 0.968/0.119 | - | 0.997/0.217 | 0.993/0.505 |
| | V4 | 0.997/0.381 | 0.329/0.128 | 0.997/0.217 | - | 0.997/0.252 |
| | V5 | 0.976/0.205 | 0.955/0.116 | 0.993/0.505 | 0.997/0.252 | - |
| Faeces | V1 | - | - | 0.996/0.360 | 0.906/0.421 | 0.957/0.494 |
| | V3 | 0.996/0.360 | - | - | 0.997/0.686 | 0.980/0.640 |
| | V4 | 0.906/0.421 | - | | - | 0.999/0.563 |
| | V5 | 0.957/0.494 | - | 0.980/0.640 | 0.999/0.563 | |

**Conclusion:** IBD phenotypes (UC and CD) have different polar metabolite profiles. Our data demonstrate that the biological effects of anti-TNF therapy in faecal and urine samples on host metabolism may be as late as 6 to 9 months. Identification of specific metabolites resulting in these differences will hope to develop biomarkers for future validation.

### P0271 FINGER CLUBBING: HIGH PREVALENCE IN SEVERE SMALL BOWEL CROHN'S DISEASE IN A PROSPECTIVE SINGLE-CENTER STUDY

M. Cossignani, B. Neri, S. Romeo, A. Ruffa, E. Lolli, E. Calabrese, **L. Biancone**
*Systems Medicine, University "Tor Vergata", Rome, Rome/Italy*

**Contact E-mail Address:** biancone@med.uniroma2.it.

**Introduction:** Finger clubbing has been associated with Crohn's Disease (CD) since 1960s (1, 2). However, whether finger clubbing may represent a marker of aggressive CD course is undefined.

**Aims & Methods:** In a prospective single-center study, we aimed to assess whether finger clubbing in CD is associated with clinical characteristics of the disease. In particular, we aimed to investigate whether finger clubbing may represent a non-invasive marker of severe CD: From January to April 2016, CD patients (pts.) undergoing clinical assessment were enrolled. Inclusion criteria: 1) Diagnosis of CD; 2) Regular follow up (≥2 visits/yr); 3) Scheduled visit; 4) Age >18 yrs; 5) Clinical records including detailed clinical history. For each pt., the following characteristics were recorded: 1) Date of birth and of diagnosis of CD; 2) CD site (L1-L4) (3); 3) CD pattern (B1-B3) (3); 4) CD-related surgery; 5) CD duration; 6) Current/past use of thiopurines (IS) and/or anti-TNFα; 7) Smoking habits; 8) Pulmonary diseases. Finger clubbing was assessed by ≥2 IBD-dedicated gastroenterologists, and documented by photographic verification. Results were expressed as median (range).

**Results:** During the 4 months follow-up, 114 CD pts. The median age at time of the visit was 46 (18–79), at time of diagnosis of CD was 26 (12–72) and CD duration was 12 years (1–56.). CD lesions involved the ileum in 107 pts. (93.8%) (including: the ileum only n = 61; ileum-colon n = 31; jejunum.ileum n = 6; duodenum, stomach or esophagus and ileum: n = 9), or the colon only in 7 pts. (6.2%), Perianal CD was recorded in 23 (20.1%) and previous surgery in 60 (52.6%) pts. (>1 resection: n = 23 [38.3%]). IS use was observed in 57 pts. (50%), anti-TNFα in 42 (36.4%), both IS and anti-TNFα in 27 (23.6%) pts. Pulmonary diseases were observed in 10 (8.7%) pts. Finger clubbing was detected in 20 (17.5%) pts. Among the 20 pts. with clubbing, CD involved the ileum in 19 (95%) (also including the colon in 4 [20%]; jejunum in 4 [20%], the esophagus, stomach or duodenum in 1 [5%] pt.) and the colon only in 1 (5%) pt. Among the 20 CD pts. with finger clubbing, known history of:perianal CD was observed in 6 (out of 19: 31%). CD-related surgery (≥1) was observed in 14 (70%) and ≥1 resection in 4 (20%) pts. Defined IS use was observed in 12 (63.1%) CD pts. with finger clubbing, anti- TNFα in 9 (47.3%) and both treatments in 9 (47.3%) pts. Pulmonary diseases were recorded in 1 (5%) CD pts. with finger clubbing.

**Conclusion:** In the tested population, a high prevalence of finger clubbing was observed, particularly in CD pts. with extensive small bowel lesions requiring immunomodulators, The detection of finger clubbing may represent a non invasive marker of severity of CD.

[2]*Rheumatology Unit, Second University of Naples, Naples/Italy*

**Contact E-mail Address:** dolores.sgambato@gmail.com.

**Introduction:** Spondyloarthritis (SpA) occurs in up to 20% of patients with inflammatory bowel disease (IBD) [1]. Symptomatic enthesitis is a characteristic feature of SpA and represents an early sign of SpA [2]. The prevalence of enthesitis in patients with IBD is not known.

**Aims & Methods:** This study was designed to evaluate whether patients with IBD showed an increased prevalence of entheseal involvement, even in the absence of clinical symptoms. Thirty-five IBD patients (25 M and 10 F, median age 41 yrs), 25 with Crohn's disease (CD) and 10 with ulcerative colitis (UC), all with moderate intestinal activity, and 22 (13 M and 12 F, median age 44 yrs) control subjects with irritable bowel syndrome underwent a thorough clinical evaluation followed by entheses ultrasonography of upper limb (brachial triceps) and lower limb (quadriceps, proximal and distal rotuleus, Achilles tendon and plantar fascia). The Madrid sonographic entheses index (MASEI) was used to score entheses abnormalities [thickness, enthesophytosis, bursitis, erosions with and without power doppler (PD)]. Correlation between IBD features (type, duration and activity), age, sex and MASEI score was assessed with nonlinear Spearman's rho. Significance of differences was assessed by chi-square test. The level of statistical significance of differences was set at $p < 0.05$.

**Results:** All of 35 patients with IBD presented at least one entheses alteration with a mean MASEI of 5.43 (thickness 57.1%, enthesophytosis 42.8%, bursitis 0%, erosions 0%, PD abnormalities 14.2%) vs 3 patients of control group (enthesophytosis 14%) ($p < 0.05$). MASEI significantly correlated with the age of IBD patients ($p < 0.0001$).

**Conclusion:** 1) IBD patients showed a significantly higher prevalence of early entheses involvement, even in the absence of clinical symptoms; 2) the entity of entheses alteration as assessed by MASEI did not correlate with type, duration and activity of IBD; 3) age was the only variable which significantly correlated with ultrasonographic entheses involvement.; 4) we speculate that IBD patients should undergo ultrasonography evaluation of entheses and, if any alteration, be followed up for early detection of SpA.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** j.langhorst@kliniken-essen-mitte.de.
**Introduction:** To assess the performance of combined PET/MR enterography in the assessment of inflammatory activity in Crohn's disease (CD).
**Aims & Methods:** N = 38 patients with Crohn's disease underwent PET/MR enterography with [18F]Fluorodeoxyglucose (FDG) using an integrated PET/MR scanner. For bowel distension an oral contrast solution (1500 cc of mannitol and locust bean gum) was ingested. The MR protocol comprised: 1) TrueFISP cor; 2) T2w HASTE fs cor and ax.; 3) dyn. T1w VIBE cor post gadolinium; 4) T1w FLASH 2D cor and ax post gadolinium as well as 5) EPI DWI ax (b = 0, 500, 1000). PET was acquired for 8 min per bed position. The datasets were reviewed by two readers in consensus regarding the presence of active inflammation. For each segment of the lower gastrointestinal tract SUVmax as well as SULmax (SUVmax/SUVmaxLiver) was determined. Ileocolonoscopy with a segment-based analysis served as standard of reference. ROC analysis for SUVmax and SULmax was performed to determine an optimal cutoff value. Furthermore, accuracy, sensitivity and specificity for PET, MRI and combined PET/MR were determined.
**Results:** In n = 38 pts (male n = 15; mean age: 42.4 ± 14.0; mean time since first diagnosis: 12 years; smoker n = 8), 219 ileocolonic segments were evaluated. According to the reference standard, active inflammation was present in 33 segments. A cutoff value for SULmax of >1 was associated with the highest accuracy (SULmax > 1: 0.78; SULmax > 1.5: 0.66; SULmax > 2: 0.74; SULmax > 3: 0.64) for the detection of inflammation. Using a cutoff value of SULmax < 1 sensitivity for PET was 88%, specificity 76%. MRI alone was associated with a higher specificity (sensitivity: 75%, specificity: 96%). Compared to MRI alone the combination of PET and MRI lead to an increase in sensitivity as well as decrease in specificity (sensitivity: 88%, specificity: 87%).
**Conclusion:** In combined PET/MR enterography FDG-PET as well as the MR data provide complementary information for the non-invasive assessment of inflammatory activity. In the present study the combination of PET with MRI lead to an increase in sensitivity. Combined PET/MR enterography allows for a multimodal and non-invasive assessment of inflammatory activity in Crohn's disease.

**Introduction:** Microscopic colitis (MC) is an invalidating inflammatory disorder of the colon with chronic, watery, non-bloody diarrhea being the main symptom. To date, the disease course of microscopic colitis is largely unpredictable. Small, retrospective studies point towards an intermittent or chronic disease course, with only low rates of spontaneous remission. However, prospective studies on the disease course of MC are lacking and valid markers to predict the disease course at diagnosis have not yet been identified. To adequately assess the disease course of MC, a large and preferentially non-selected patient cohort is required. Considering the variable incidence rates of MC across Europe, international collaboration is indispensable.
**Aims & Methods:** The aim of the PRO-MC Collaboration is to systematically and prospectively collect data on the long-term disease course of MC and to improve the knowledge on MC across Europe. By a systematic brainstorm and selection process within an expert panel, the outcomes of interest were formulized, i.e. the persistence, respectively recurrence of diarrhoea and health-related quality of life of incident MC cases following diagnosis, the outcome of the treatments applied, and the characteristics of budesonide non-responders. Hereafter, a consensus on a follow-up strategy was reached and case record forms (CRFs) were drafted. Based on the CRFs, a web-based registry was built. Because pathology assessment is crucial for the diagnosis of MC, a slide kit presenting the diagnostic criteria and recommended stains was developed in collaboration with members of the European Society of Pathology (ESP), in order to increase the awareness of MC among pathologists and to improve data validity. All European MC centres can participate in the project and all new cases of MC in the participating centers are eligible for inclusion.
**Results:** For follow-up, a strategy with fixed visits was preferred. Patient data will be collected at diagnosis and at follow-up. Follow-up visits are scheduled 3, 6, and 12 months after diagnosis, yearly thereafter, and in case of clinical relapse. The CRFs include variables on demographics, symptoms, medical history, drug use, endoscopy and histology, disease activity, quality of life, comorbidity, treatment, and complications. All data will be recorded in a fully customized, web-based data registry. Disease activity and quality of life scores will be documented using a one week defecation diary and the Short Health Scale questionnaire.
**Conclusion:** The PRO-MC Collaboration, initiated with support of the UEG LINK Award, used a standardized approach to develop case record forms and a follow-up strategy, incorporated in an international, web-based registry for MC patients. The registry will generate novel insight into the long-term disease course of MC, and could possibly identify markers to predict the disease course and treatment outcome. The systematic, Europe-wide data collection will enhance the applicability of the project results and increase the awareness for the disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0275 A HISTOLOGICAL APPRAISAL OF HEPATOBILIARY DISORDERS IN INFLAMMATORY BOWEL DISEASE

**P. Andrade**[1], S. Lopes[1], J. Lopes[2], G. Macedo[1]
[1]*Gastroenterology, Centro Hospitalar de São João, Porto/Portugal*
[2]*Pathology, Centro Hospitalar São João, Porto/Portugal*

**Contact E-mail Address:** anapatriciarandrade@gmail.com.
**Introduction:** Diseases of the liver and biliary tract do occur in Inflammatory Bowel Disease (IBD) patients. In fact, in the clinical management of IBD patients, liver complications are of major concern as up to 30% of patients present with abnormal liver function tests. These abnormalities may be associated with IBD itself or be secondary to metabolic/physiological changes induced by IBD or drugs used during treatment.
**Aims & Methods:** We aimed to analyse and characterize the spectrum of hepatobiliary disorders in patients with IBD who underwent liver biopsy (LB) due to sustained altered liver function tests. Retrospective study of IBD patients who underwent LB between 2010 and 2015 due to sustained altered liver function tests at our tertiary referral centre. Demographic, clinical, laboratory, imaging and histological data were collected. Sustained altered liver function tests was defined as elevation for at least 6 months of aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma glutamyl transferase (GGT), alkaline phosphatase (ALP) or total bilirubin.
**Results:** We included 54 patients (65% male, 34 with Crohn's disease) with a mean age of 43 ± 12 years. Mean time between the beginning of liver function tests abnormalities and LB was 12 ± 9 months. Eighteen percent of patients were under mesalazine, 39% under azathioprine and 43% under combination therapy (immunomodulators + anti-TNF-$\alpha$ agents). Twenty-eight patients had isolated elevation of transaminases, 11 patients cholestasis and 15 patients a mixed pattern. The aetiology of altered liver function tests was drug toxicity in 19 cases, non-alcoholic fatty liver disease (NAFLD) in 13 cases, and autoimmune hepatitis in 9 cases (66.7% induced by anti-TNF-$\alpha$ agents). We also identified 6 cases of primary sclerosing cholangitis (PSC), 2 cases of primary biliary cirrhosis (PBC) and 1 case of overlapping syndrome PSC/AIH, secondary amyloidosis, hemochromatosis, nodular regenerative hyperplasia and A1AT deficiency.
**Conclusion:** Abnormal liver function tests in IBD patients had a widely range of aetiologies and, in a significant number of cases, histology was essential for reaching a correct diagnosis. Drug toxicity, NAFLD and autoimmune hepatitis were the most common hepatobiliary disorders in this cohort of IBD patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0276 EVALUATION OF QUALITY OF LIFE AND PAIN IN PATIENTS WITH ULCERATIVE COLITIS USING IBDQ, SF-36 AND EQ-5D – FIRST STEP OF PERSONALIZATION OF TREATMENT

**A. Y. Atanassova**[1], V. Velikova[2]
[1]*Gastroenterology, Medical University of Varna, Varna/Bulgaria*
[2]*Medical University Varna, Varna/Bulgaria*

**Contact E-mail Address:** aniatanassova@abv.bg.
**Introduction:** In the last few years it was proven that the inflammatory bowel diseases (IBD) influence the quality of life (QL) of patients. Takin into account the clinical and endoscopic activity has proven insufficient. More often observation through patient report outcomes and evaluation of QL through different questionnaires are being used.
**Aims & Methods:** The aim was to evaluate the QL in patients with ulcerative colitis (UC) via - IBDQ, SF-36 and EQ-5D, and the influence of pain on this evaluation. **Material and method.** This covers 74 patients with UC, 41.9% men and 58.10% women, average age 43.9 12. All patients answered IBDQ, SF-36 and EQ-5D. We analyzed the overall evaluation of QL, the factors that influence the formation and the evaluation of pain/discomfort according the questionnaires used.
**Results:** The average QL evaluation according to IBDQ is 151.95 ± 44.15. The minimal evaluation that our patents give is 52 and the maximal 222. 37.8% of patients gave evaluation of 170 (typical of remission).

**PO276: Table 1:** Severity of the disease and QL (IBDQ).

| Severity | Total QL | Emotional state | Questions concerning the disease | Social aspects of life | General questions |
|---|---|---|---|---|---|
| **In remission** | 176.23 ± 38.39 | 61.23 ± 16.39 | 59.13 ± 12.25 | 29.42 ± 6.55 | 26.45 ± 6.02 |

The factor, that the most influences negatively all the used questionnaires for evaluation of QL - IBDQ, SF-36 and EQ-5D, is pain intensity ($p < 0.001$).

**Conclusion:** The intensity of pain, the duration and severity of UC are the main factors that influence the QL negatively. The use of questionnaires to evaluate the QL is useful in everyday practice, as they improve the complex idea on the development of UC and its effect and treatment on the patients and can help with the personalization of the UC treatment.

**Introduction:** Sex differences in the incidence and progression of inflammatory bowel diseases (IBD) have been reported in observational studies. The effect of testosterone on the pathogenesis of IBD is unknown.
**Aims & Methods:** The aim was to assess the serum concentration of testosterone in IBD male patients, to describe the prevalence of low serum concentration of testosterone and to investigate the effect of testosterone on disease activity. The cohort consisted of 113 consecutive IBD male patients (66 CD and 47 UC) examined at a tertiary IBD centre. Clinical and demographic characteristics of every patient were recorded, i.e. age, duration of the disease, clinical behaviour, location of disease according to Montreal classification, IBD related surgeries, concomitant medications. We measured the morning serum concentration of testosterone, luteinising hormone, cortisol, ACTH, CRP, vitamin D in each patient. Disease activity was assessed by Harvey-Bradshaw Index (HBI) in CD patients and by partial Mayo score in UC patients. The prevalence of low serum concentration of testosterone below the cut-offs 6 nmol/l and 10 nmol/l was assessed and risk factors analysed by univariate analysis.
**Results:** The median serum concentration of testosterone both in CD and UC male patients was 11 nmol/l. The low serum concentration of testosterone with cut-offs $\leq$6.0 nmol/l and $\leq$10.0 nmol/l was noted in 4/113 (3.5%) IBD male patients (3 CD and 1UC) and in 38/113 (33.6%) (22CD and 16UC), respectively. We found significant negative correlation between age and testosterone in all patients ($r2 = 0.067$, $p = 0.006$) and between CRP and testosterone in CD males ($r2 = 0.073$, $p = 0.028$). No similar correlation was seen in UC patients. We did not observe any significant correlation between clinical activity although there was a trend towards significance in correlation of partial Mayo score and level serum concentration of testosterone in UC males ($r2 = 0.076$, $p = 0.061$). Patients who undergone appendectomy had significantly lower serum concentrations of testosterone in comparison to those who did not with median of 11.3 vs 8.4 nmol/l ($p = 0.005$).
**Conclusion:** The prevalence of low serum concentration of testosterone was observed in 3.5% (cut-off $\leq$ 6.0 nmol/l) and 33.6% (cut-off $\leq$ 10.0 nmol/l) of IBD male patients. Serum concentration of testosterone correlated with age in all IBD patients and CRP in CD patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0278 TOWARDS A PROACTIVE THERAPEUTIC DRUG MONITORING OF INFLIXIMAB - ASSESSMENT AND VALIDATION OF A NEW POINT-OF-CARE QUANTIFICATION DEVICE

**Contact E-mail Address:** joanavafonso@gmail.com.
**Introduction:** Therapeutic drug monitoring (TDM) is a powerful strategy known to improve the clinical outcomes and to optimize the health care resources in the treatment of Inflammatory Bowel Diseases (IBD). Infliximab, a Tumour Necrosis factor (TNF) antagonist, is known to have an optimal therapeutic window of 3 to 7 $\mu$g/ml. However, most of the methods that are commercially available for the quantification of IFX are ELISA-based, and the results take approximately 8 hours to be obtained, delaying the target dosage-adjustment to the following infusion.
**Aims & Methods:** Our aim was to assess the performance and to validate the first point-of-care (POC) IFX quantification device available in the market by comparing it with two well-established ELISA methods. The POC IFX quantification device and the two established ELISA methods were used to assay the IFX concentration in the serum of 299 patients under IFX maintenance therapy. The results were statistically compared both in quantitative and qualitative terms.
**Results:** The Intraclass Correlation Coefficients (ICC) of the POC IFX assay compared with each of the two ELISA-based established methods were 0.889 and 0.939. The results were stratified according to the IFX therapeutic window ($<$3, 3–7 and $>$7), and the accuracy of the POC IFX compared with each of the two reference methods was 77% and 83%, whereas the kappa (95% CI) statistics were 0.648 (0.577–0.719) and 0.738 (0.673–0.803).
**Conclusion:** Our conclusions support that the newly launched POC IFX assay can successfully and effortlessly replace the commonly used ELISA-based IFX quantification kits. The fact that this POC IFX assay is able to deliver the results within 15 minutes makes it ideal for an immediate target concentration adjusted dosing. Moreover, it does not require specific laboratory facilities nor highly specialized personnel, being a user-friendly desktop device that holds the potential to revolutionize the TDM in IBD patients undergoing IFX therapy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0279 ADHERENCE TO RECOMMENDATIONS AND QUALITY OF ENDOSCOPIC COLORECTAL CANCER SURVEILLANCE IN LONG-STANDING ULCERATIVE COLITIS

**Introduction:** Long-standing ulcerative colitis has been associated with an increased risk of colorectal cancer (CRC). Current guidelines recommend endoscopic CRC surveillance after 8 years of disease duration and then every 1–2 years (1). Use of chromoendoscopy has been recommended in order to increase precancerous lesions detection rates (1). There are currently few studies that assess adherence of clinicians to surveillance guidelines in the context of inflammatory bowel disease. The objectives of our study were to assess the adherence to recommendations and the quality of endoscopic procedure in long-standing ulcerative colitis.
**Aims & Methods:** This is a retrospective cohort study. We selected patients included in the Swiss IBD cohort having the following characteristics: left-sided colitis or pancolitis, disease duration >= 8 years, having experienced at least one period of remission during the follow-up. Patients with PSC were excluded. Complementary medical charts review focused on endoscopy and associated histological reports. Descriptive analyses were performed by first focusing on the patients and on the history of their colonoscopies. We then focused on the colonoscopies themselves.
**Results:** 391 colonoscopies were conducted among a total of 94 patients. Characteristics of patients at 8 years of disease duration were: men (51.1%), age at diagnosis (mean = 30.5, SD = 11.9), disease location at diagnosis (pancolitis 46.8%, left-sided colitis 38.3%, proctitis 6.4%, unknown 8.5%). Explicit indication for cancer screening was mentioned in 35.6% of colonoscopies. 40.6% of patients had a first screening colonoscopy before 8 years (resp. 53.6% before 10 years). Mean (SD) time since the next screening colonoscopy was 2.4 (1.5) years. Caecal (resp. ileal) intubation was performed in 85.2% (resp. 74.9%) of cases. Bowel preparation was good to excellent in 48.6% of endoscopies. Mean withdrawal time was 15.8 (10.6) minutes. Chromoendoscopy (virtual chromoendoscopy) was used in 2.6% (10%) of cases. Mean number of colonic biopsies was 14 (SD = 9.8, interquartile range = 18-7). Dysplasia/DALM was found in 14 cases (3.6%). Histologically confirmed adenomas were found in 13 cases (3.3%).
**Conclusion:** Despite current international recommendations, a significant number of patients were not included in a surveillance program. Patients undergoing surveillance colonoscopy were often inadequately prepared and chromoendoscopy was used in a minimal number of patients. Moreover, the number of biopsies was too low given that chromoendoscopy was not used. Overall, our data suggest that adherence to surveillance guidelines and endoscopic quality should be promoted and standardized.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0281 FECAL CALPROTECTIN LEVEL LOOKS PROMISING IN IDENTIFYING ACTIVE DISEASE IN BEHÇET'S SYNDROME PATIENTS WITH GASTROINTESTINAL INVOLVEMENT: A CONTROLLED AND PILOT STUDY

**A.I. Hatemi**[1], S.N. Esatoglu[2], Y. Ozguler[2], G. Hatemi[2], A. Ferhat Çelik[1], H. Yazici[2]

**Contact E-mail Address:** ihatemi@yahoo.com.
**Introduction:** The fecal calprotectin (FC) is widely used as a non-invasive method for identifying patients with active Crohn's disease (CD) and ulcerative colitis. Gastrointestinal involvement of Behçet's syndrome (GIBS) shows clinical and endoscopic similarities to CD. A previous study in a small number of Behçet's syndrome (BS) patients with mainly mucocutaneous lesions showed serum calprotectin levels did not differ between active and inactive patients (1). Another study suggested FC may help to diagnose GIBS patients (2). We are not aware of studies addressing whether FC helps to distinguish active GIBS patients from those in remission.
**Aims & Methods:** The aim of this study is to determine whether FC helps predict active disease in GIBS patients. We collected fecal specimens from 23 GIBS (11 M, 12 F and mean age 44 ± 9 yrs) patients before colonoscopy. The reasons for colonoscopy were assessing active disease in patients presenting with abdominal pain (with or without diarrhea) (n = 9) or confirmation of a remission in asymptomatic patients (n = 16). Four symptomatic and 3 asymptomatic patients had active ulcers by endoscopy. On the other hand, 5 symptomatic and 13 asymptomatic patients did not have ulcers. We also included 22 active and 25 inactive CD patients as controls. We used 150 µg/g as the cut-off for a positive FC level. We also looked at the correlation between FC and serum CRP levels, Crohn's disease activity index (CDAI) and disease activity index for intestinal Behçet's disease (DAIBD) scores.
**Results:** FC was > 150 µg/g in all of the 7 GIBS patients with ulcers compared to 4/16 of GIBS patients without ulcers (OR, 95%CI: 42 to 888). The mean FC was 1125 ± 800 µg/g (95%CI: 341 to 1908) among symptomatic patients with ulcers (n = 4) and 209 ± 213 µg/g (95%CI: 22 to 396) among symptomatic patients without ulcers (n = 5). On the other hand, the mean FC was 243 ± 73 µg/g (95%CI: 158 to 328) among asymptomatic patients with ulcers (n = 3) and 95 ± 160 µg/g (95%CI: 0.4 to 189) among asymptomatic patients without ulcers (n = 11). Among CD patients, 16/25 active patients and 3/22 patients in remission had FC level > 150 µg/g (OR, 95%CI: 11 to 49). There was a low correlation between FC and serum CRP levels (r = 0.3, p = 0.1), a moderate correlation between FC and CDAI scores (r = 0.5, p = 0.02) and very low correlation between FC and DAIBD scores (r = 0.01, p = 0.9). Among the 4 GIBS patients who had high FC levels despite being in remission for gastrointestinal (GI) involvement, 1 had active mucocutaneous lesions, 1 had concomitant macrophage activation syndrome, and 1 had polycythemia vera with trisomy 8. None of the patients were receiving NSAIDs that could increase FC levels.
**Conclusion:** Pending the study of more number of patients, FC may turn out to be a useful non-invasive tool for ruling out active GI lesions in asymptomatic GIBS patients. A high FC level demands caution for the presence of active ulcers especially in symptomatic patients, but whether the presence of other BS manifestations can cause false positive results remains to be studied.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** sahareelmahjoubi27@gmail.com.
**Introduction:** Hepatobiliary disease is one of the most common extraintestinal manifestations of inflammatory bowel disease (IBD). However, the true prevalence of clinically significant chronic liver disease in patients with IBD is not known and could be underestimated due to reliance on abnormal liver tests and/or liver biopsies. Transient elastography, FibroScan®, is a non-invasive, safe and effective technique to evaluate liver fibrosis.
**Aims & Methods:** Our aim was to evaluate the prevalence of clinically significant liver disease in IBD patients using transient elastography. Prospective study including IBD patients between January and April 2016. Demographic, clinical and therapeutic data were obtained. Liver stiffness was assessed by transient elastography (FibroScan®), performed by a single physician. The cut-off values for advanced liver fibrosis were (according to the METAVIR scoring system): F ≥ 2: 7.1 and F ≥ 3: 9.5 kPa.
**Results:** A total of 34 patients were included, 18 women (53%), mean BMI of 18.43 ± 2.5 kg/m$^2$. The mean age was 38.5.5 ± 12.5 years. 24 patients had Crohn's disease (70.6%), 8 ulcerative colitis (23.5%) and 2 patients had indeterminate colitis (5.9%). Mean duration of disease was 4.5 years. The median value of liver stiffness was 4.5 kPa, the median IQR was 0.7 ± 0.2, with a mean success rate of 96 ± 5%. According to the cut-off value of 7.1 kPa, there were 33 patients (97%) with F < 2, and 1 patient (3%) with F ≥ 2. No patient had F ≥ 3.
**Conclusion:** Development of liver fibrosis in IBD patients is exceptional. FibroScan is a non-invasive and safe technique, which may be potentially useful for evaluation and follow-up of liver fibrosis in IBD patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0283 CORRELATION OF FECAL CALPROTECTIN AND LACTOFERRIN LEVELS WITH ULCERATIVE COLITIS ENDOSCOPIC INDEX OF SEVERITY AND MAGNIFYING ENDOSCOPIC STRATIFICATION IN PATIENTS WITH ULCERATIVE COLITIS IN CLINICAL REMISSION

**M. Shoichiro**[1], F. Takeshima[1], K. Matsushima[1], H. Minami[1], Y. Akazawa[1], N. Yamaguchi[1], K. Ohnita[1], H. Isomoto[2], K. Nakao[1]

**Introduction:** Recently, fecal markers such as calprotectin, lactoferrin, and hemoglobin have been reported to correlate well with the Mayo endoscopic subscore (MES) and expected to be used as an alternative monitoring tool to endoscopy. Ulcerative colitis endoscopic index of severity (UCEIS) is a newly proposed and more detailed endoscopic scoring system compared with MES; however, only few studies have examined the association between fecal markers and UCEIS. Recently, we proposed magnifying endoscopic stratification (ME) based on alternations in the mucosal surface pit patterns and showed its utility in predicting relapse in patients with ulcerative colitis (UC).
**Aims & Methods:** In this study, we investigated the association between the aforementioned fecal markers and MES, UCEIS, and ME in patients with UC in clinical remission. We included 39 patients with UC in clinical remission who underwent colonoscopy at the Nagasaki University Hospital between June 2015 and March 2016; their stool samples were collected on the same day as that of colonoscopy. Calprotectin and lactoferrin levels were measured using enzyme-linked immunosorbent assay. Clinical remission was defined as a partial UC-disease activity index score of ≤2 and a bloody stool score of 0. Furthermore, endoscopic remission and relapse was defined as an MES of ≤1 and ≥2, respectively.

**Results:** There were 12, 18, 9, and 0 cases with an MES score of 0, 1, 2, and 3, respectively. The endoscopic relapse rate was 23.1% (9/39 patients). A significant correlation was observed between MES and all fecal markers (Spearman's rank correlation coefficient: calprotectin 0.45, P = 0.004 lactoferrin 0.46, P = 0.003; and hemoglobin 0.41, P = 0.009) as well as between UCEIS and all fecal markers (calprotectin 0.57, P = 0.0002; lactoferrin 0.52, P = 0.0006; and hemoglobin 0.41, P = 0.01). In addition, ME correlated significantly with calprotectin and lactoferrin levels but not with hemoglobin levels (calprotectin 0.56, P = 0.0006; lactoferrin 0.49, P = 0.0017; and hemoglobin 0.31, P = 0.077). Moreover, a significant correlation was observed between ME and UCEIS (Spearman's rank correlation coefficient: 0.80, P < 0.0001).
**Conclusion:** Fecal markers correlate with not only MES but also UCEIS and ME and can be predictive of subclinical relapse in patients with UC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Due to the high cost of therapeutic drug monitoring (TDM) of infliximab (IFX) and adalimumab (ADA) in inflammatory bowel disease, many algorithms have been proposed to optimize the use of the analysis. Most of them are based on the determination of drug levels and antibodies if patients show loss of response (LOR).
Besides patients who develop drug antibodies, some patients have drug serum levels below the therapeutic range that may present a relapse without evidence of antibodies. For economic impact analysis, it is important to know the percentage of patients that are at risk of LOR due to low serum drug levels, with or without the presence of drug antibodies.
**Aims & Methods:** The aim of this study was to calculate the percentage of patients at risk of loss of response due to low concentrations of IFX or ADA, analyzing all treated patients of a population, not only those who had experienced LOR. Methods: A cross-sectional study of a cohort of patients with IBD was carried out. Patients were included consecutively through visits to the hospital to receive IFX or ADA. Serum drug concentrations and drug antibodies were measured by an ELISA technique. Patients with IFX levels < 3 mcg/mL and ADA < 5 mcg/mL were considered at risk of LOR. Usually, if IFX is present in a sample, antibodies detection could be altered. Therefore, negative antibodies results in these samples are often classified as inconclusive. Anyway, patients with low serum drug levels due to inter-individual pharmacokinetic variations or drug antibodies, are at increased risk of LOR.
**Results:** The study included 100 patients, 79 patients with Crohn's disease and 21 with ulcerative colitis, 68 treated with IFX and 32 with ADA. Mean age was 39 [17–69] years. Azathioprine immunosuppressive therapy was used by 40% of the patients.
In the IFX group, 40 patients (58.8%) were at risk of LOR and 4 (21.9%) in the ADA group. Drug antibodies were detected in 25.0% and 28.6% of the patients in IFX and ADA groups respectively.
The total number of patients with drug serum level below the cutoff without detectable antibodies was 30 in the IFX group and 5 in the ADA (75.0% and 71.4% of patients out of therapeutic range respectively). Only 2 patients with azathioprine developed antibodies.
The proportion of patients detected at risk of loss of response was high (44.1% in IFX group and 15.6% in ADA group).
**Conclusion:** The percentage of patients at risk of LOR is high, mainly those treated with Infliximab. Although not always resulting in clinical deterioration, there is a significant number of patients who could benefit from pharmacokinetic monitoring, helping to optimize dosage and prevent relapses.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0285 HOME-TESTING OF FAECAL CALPROTECTIN USING THE IBDOC™ SYSTEM: A COMPARATIVE PILOT STUDY

**Contact E-mail Address:** b.hayee@nhs.net.

**Introduction:** Faecal calprotectin (FCAL) is a useful test for monitoring of inflammatory bowel disease (IBD) activity. Providing a stool sample in person to the hospital laboratory is an anecdotally unpopular method with poor uptake. A new FCAL kit (IBDoc™, Bühlmann) enables self-testing using a proprietary collection tube, camera smartphone and app. The aim of this study was to assess patient's adherence to, and experience of, a testing regimen using IBDoc™, as well as benchmarking the assay to the standard laboratory test.
**Aims & Methods:** After focussed training, participants were asked to test using IBDoc™ once a month for four months and provide a standard stool sample which was posted to the hospital laboratory overnight and refrigerated on receipt, to be tested with standard ELISA (Bühlmann). The following questionnaires were applied before and after testing: GAD-7 (anxiety), PHQ-9 (depression), IBD-control-8, Multi-dimensional Health Locus of control (MHLC) and Cognitive Behavioural Responses to Symptoms (CBSRQ). Patients were also asked to record their experiences and preferences for testing on a proprietary questionnaire. REC reference 15/WA/0168.
**Results:** 54 consecutive patients (Crohn's: 23, UC: 31, F = 28, mean age 36.0 ± 9.2 yrs) were enrolled. Participants completed a median of 3 tests (0–4) during the study with 19/54 (35%) completing all four set time points and 17/54 (32%) returning no samples, despite active reminders. There was no difference in any of the questionnaire scores between compliant and non-compliant patients. There was moderate correlation of numerical FCAL results between the two methods (r = 0.77, 95%CI 0.68–0.84, p < 0.0001). Categorising results into disease activity categories (no inflammation, mild, moderate, severe) produced a similar result (weighted $\kappa = 0.57$, p < 0.0001). 63% of respondents stated a preference for IBDoc™, but stated that (in a routine clinical scenario) they would require timely contact from the hospital team in the event of an abnormal result (24–72 hours). A further 22% of patients preferred the IBDoc™ test, but stated that they would not require contact until their next scheduled appointment.
**Conclusion:** There was reasonable uptake and adherence to a demanding testing regimen (more frequent testing than might be required in routine clinical care) with 85% of respondents preferring the IBDoc™ test over other methods. The home testing kit results show only moderate correlation to laboratory results. While this is a promising and clearly popular technology, further studies are warranted to correlate results to clinical outcomes.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0287 TRABECULAR BONE SCORE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES

**Contact E-mail Address:** krajann@hotmail.com.

**Introduction:** Osteopenia and osteoporosis are known chronic complications of inflammatory bowel diseases (IBD). It is known that areal bone mineral density (aBMD) does not sufficiently reflect bone strength and quality. The trabecular bone score (TBS) provides an indirect measurement of bone microarchitecture, independent of aBMD.
**Aims & Methods:** The aim was to assess TBS and BMD of lumbar spine (LS) in IBD patients. Furthermore we analyzed the impact of clinical factors on TBS. The cohort consisted of consecutive IBD patients from tertiary IBD centre. Clinical characteristics i.e. age, gender, anthropometry, clinical behaviour, medication were recorded. The BMD was determined by dual-energy X-ray absorptiometry (DXA, Hologic Discovery) at the lumbar spine. TBS was determined by TBS Insight® software (Medimaps, France).
**Results:** The cohort consisted of 84 IBD patients (53 with Crohn's disease (CD) and 31 with ulcerative colitis (UC)). The mean age was 42.0 ± 14.2 years with the mean disease duration of 11.0 ± 7.0 years. There were 14% (12/84) postmenopausal women, 8 patients (9.5%) were on long term corticosteroids and 21 CD patients had prior major IBD surgery. The percentage of patients with substitution of vitamin D (800 IU) and calcium (0.5–1 g) was similar between CD and UC (24.5% vs. 29.0%), none of the patients was on anti-porothic treatment. The mean LS BMD of the cohort was 0.964 ± 0.113 g/cm$^2$ and TBS 1.36 ± 0.14. We observed significantly lower mean TBS LS in patients with fistulising CD compared to luminal CD, 1.36 ± 0.09 and 1.47 ± 0.05 (p = 0.0039) respectively. No similar finding was observed using BMD. We did not observe any significant impact of clinical characteristics nor medication in UC patients.
**Conclusion:** We observed that TBS LS might identify quality of bone mineral density better than BMD itself, mainly in CD patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0288 AN AUDIT OF ENDOSCOPY IN ULCERATIVE COLITIS; SHOULD ENDOSCOPY FOR INFLAMMATORY BOWEL DISEASE (IBD) BE PERFORMED BY AN IBD SPECIALIST?

**A. Moore**[1], M. Lythgoe[1], F. Kallon[2], J. Mawdsley[2]
[1]*Gastroenterology, West Middlesex University Hospital, London/United Kingdom*
[2]*West Middlesex University Hospital, London/United Kingdom*

**Contact E-mail Address:** malice102@hotmail.com.

**Introduction:** Endoscopy plays a vital role in the management of Ulcerative Colitis (UC), both in terms of; 1. Accurate assessment of severity (at diagnosis and response to treatment) 2. Colorectal Cancer Surveillance (CCS) Endoscopic assessment is often performed by general endoscopists, rather than those with a special interest in IBD. We assessed the quality of endoscopy performed for patients with UC. In acute UC we assessed whether severity had been accurately determined as suggested by ECCO guidelines.1 For CCS we assessed adherence to BSG guidelines.2.

**Aims & Methods:** Colonoscopy and flexible-sigmoidoscopy reports were analysed over a 6-month period (1.05.15 – 31.10.15) at a London District General Hospital. In acute UC quality of reports were assessed by classifying into either a) utilisation of a recognized scoring system b) a qualitative assessment using descriptive terms appropriate to justify grading c) a simple description as mild/moderate/severe with no other assessment d) no assessment of severity. For CCS, the quality of procedure was assesssed by classifying into a) appropriate use of dye spray b) dye spray not used but justification given c) if dye spray not used then documentation of 2–4 biopsies taken every 10 cm as per BSG guidance d) non-adherence to BSG guidelines.

**Results:** Acute UC (n = 60).

| | Physician (n = 36) | Surgeon (n = 12) | Nurse endoscopist (n = 12) | All endoscopists (n = 60) |
|---|---|---|---|---|
| a) scoring system | 11 (31%) | 0 (0%) | 0 (0%) | 11 (18%) |
| b) qualitative disease assessment | 20 (55%) | 2 (16%) | 3 (25%) | 25 (42%) |
| a) or b) | 31 (86%) | 2 (16%) | 3 (25%) | 36 (60%) |
| c) classification as mild/moderate/sever e | 4 (11%) | 5 (42%) | 9 (75%) | 18 (30%) |
| d) no severity assessment | 1 (3%) | 5 (42%) | 0 (0%) | 6 (10%) |

CCS (n = 34) Pancolonic mucosal dye spraying was used in only 11 (32%) colonoscopies. There was an appropriate justification as to why dye spray was not used in a further 8 (24%) colonoscopies, namely poor bowel prep. Of those that didn't undergo dye spray, 0% had biopsies every 10 cm. 15 (44%) colonoscopies were non-adherent to BSG guidelines. IBD endoscopists adhered to the BSG guidelines 9/11 (82%), compared to general endoscopists 13/23 (57%).

**Conclusion:** In acute UC, use of a validated scoring system is low. Use of either a validated scoring system or good description of severity is good in physicians but poor in surgical and nurse endoscopists. In CCS overall adherence to BSG guidance was low, with a low use of dye spray and large inter-operator variability suggesting dependance on operator rather than patient factors. IBD endoscopists showed greater adherence to guidelines. Our results suggest a case for patients with UC in both scenarios to have endoscopies performed by endoscopists with a special interest in IBD and appropriate endoscopic skills.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0289 THE USE OF THE WHO FACTURE RISK ASSESSMENT TOOL (FRAX) IN PREDICTING RISK OF FRACTURES IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A SYSTEMATIC REVIEW

**A. J. Lucendo**[1], B. Serrano-Montalbán[1], A.B. Friginal-Ruiz[1], Á. Arias Arias[2]
[1]*Gastroenterology, Hospital General de Tomelloso, Tomelloso/Spain*
[2]*Research Unit, Hospital La Mancha Centro, Alcazar de San Juan/Spain*

**Contact E-mail Address:** alucendo@vodafone.es.

**Introduction:** Inflammatory bowel disease (IBD), which includes Crohn's disease and ulcerative colitis, is associated with an increased prevalence of osteoporosis and osteopenia. The fracture risk assessment (FRAX®) tool is a risk-assessment survey developed by the World Health Organization (WHO) that calculates the 10-year probability of hip fracture and major osteoporosis-related fracture (including clinical spine; forearm; hip or proximal humerus fracture). The WHO FRAX® score utilizes age, sex, body mass index, clinical risk factors, and femoral neck bone mineral density (BMD) to estimate the 10-year probability (of hip fracture and major osteoporosis-related fracture – repetitive). It is composed of 11 variables: age, sex, weight, height, previous fracture as an adult, parental hip fracture, current cigarette smoking, current (or 3 months prior) use of glucocorticoids, diagnosis of rheumatoid arthritis, consumption of ≥3 units of alcohol daily, and secondary osteoporosis. It can be used with or without the addition of the bone mineral density derived T-score at the femoral neck, but conflicting results have been provided regarding the reliability of FRAX estimation without BDM measurements.

**Aims & Methods:** Our research aims to conduct a systematic review to assess the 10-year risk of fracture as determined by the FRAX® tool in patients with IBD in order to provide an up-to-date summary of the available evidence on the utility of this tool in the prediction of bone fracture risk among these patients. Electronic searches were performed with keywords relating to IBD and FRAX in the MEDLINE, EMBASE and SCOPUS databases. Summary estimates were calculated. A fixed or random-effects model was used depending on heterogeneity ($I^2$).

**Results:** The search yielded 146 references; 7 that included research carried out in adult patients, were used in the systematic review and quantitative summary. No significant publication bias was noted according to the Harbord test. The 10-year probability of hip and major osteoporotic fracture in adult IBD patients was 1.03% (95% CI, 0.37% – 2%; $I^2$ 0%) and 4.05% (95% CI, 2.61% – 5.79%; $I^2 = 49\%$), respectively. In those patients with Crohn's disease, hip and major osteoporotic fractures calculated with FRAX increased to 1.74% (95% CI, 0.42% – 3.93%; $I^2 = 37.5\%$) and 6.65% (95% IC, 2.97% – 11.66%; $I^2 = 8.7\%$), respectively. Risks of fracture in adults with ulcerative colitis were provided by a single study only.

**Conclusion:** The FRAX tool has been limited to use in patients with IBD, however the evidence currently available only shows a modest increase in the 10-year risks of bone fracture and does not support unequivocally the need for specific interventions. Further well-designed studies are needed to confirm the results obtained from this systematic review.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0290 DEVELOPMENT OF A NOVEL ENDOSCOPIC SCORING SYSTEM PREDICTING THE RELAPSE AFTER SURGERY IN INTESTINAL BEHCET'S DISEASE

**J.W. Park**, H.J. Lee, S.J. Park, S.P. Hong, T.I. Kim, W.H. Kim, J.H. Cheon
*Division Of Gastroenterology, Department Of Internal Medicine, Yonsei University College of Medicine, Seoul/Korea, Republic of*

**Contact E-mail Address:** gardenpark87@yuhs.ac.

**Introduction:** Behcet's disease (BD) is a multi-systemic vasculitic disorder featuring multi-organ involvement including gastrointestinal tract. Surgical therapy for intestinal Behcet's disease is considered for patients unresponsive to medical treatments or those with bowel complications. According to our previous studies, cumulative surgery rates of intestinal Behcet's disease is 6.7% and 15.1% after 2 and 5 years of diagnosis each, and the recurrence rate of intestinal lesions was approximately 50% at two years postoperatively. The idea is that an appropriate algorithm and scoring system involving follow-up endoscopic findings which can predict recurrence of intestinal Behcet's disease after intestinal resection needs to be developed.

**Aims & Methods:** This study aimed to establish a scoring system based on follow up endoscopic findings which can predict intestinal Behcet's disease recurrence after surgery. A total of 91 intestinal Behcet's disease patients who underwent surgical intervention due to complication of intestinal Behcet's disease in Severance hospital between March 1986 and December 2015 were identified retrospectively. Their medical records were reviewed by two physicians (JH Cheon and JW Park). Among them, 54 patients who underwent follow-up endoscopy within 5 year after surgery, regardless of clinical relapse, were selected. After selection, demographic and preoperative clinical data including follow up colonoscopic findings (ulcer location, distribution, shape, number and depth) were retrieved. Clinical relapse were defined as DAIBD over 40, existence of newly added medications or admission due to symptomatic aggravation, re-operation related to intestinal Behcet's disease. Univariate and multivariate analyses were performed to find clinically relevant factors associated with clinical relapse of intestinal Behcet's disease after surgery. Classification And Regression Tree (CART) analysis was used to discover the appropriate model of endoscopic classification which can explain the post-surgical recurrence of intestinal Behcet's disease most properly; e, 0 – no lesions; e, 1 – <20 mm sized solitary ulcer; e, 2 – 20 mm sized solitary ulcer; e, 3 – multiple ulcers regardless of size.

**Results:** Median age at diagnosis was 36 years (range 12–69) with 28 male and 26 female patients. Clinical relapse occurred in 37 patients (61.52%) and 16 patients (29.63%) underwent re-operation. 37 patients (61.52%) had colonoscopic recurrence at follow-up colonoscopy, and among these cases, only 28 cases had clinically relapsed. All colonoscopically recurred cases had ulcers located in the anastomosis site and 34 cases (91.9%) occurred in the localized area. Multivariate Cox hazard regression analysis identified younger age years) at diagnosis (HR = 0.26; 95% CI, 0.098–0.689, p = 0.007), disease duration (HR = 0.992, 95% CI, 0.984–1.0, p = 0.043), previous immunosuppressant usage such as azathioprine, 6-MP, cyclosporine (HR = 0.306; 95% CI 0.134–0.697, p < 0.001), continued immunosuppressant usage after surgery (HR = 3.678, 95% CI, 1.495–9.051, p = 0.005), higher DAIBD at colonoscopy (HR = 1.032, 95% CI, 1.019–1.045, p < 0.001) and colonoscopic recurrence (HR = 2.992, 95% CI 1.133–7.904, p = 0.027) as independent risk factors for clinical relapse in IBD. Endoscopic findings were classified in four groups, according to size and number of recurred ulcer (s), and multivariate analysis adjusting age at diagnosis, disease duration, previous surgical resection, medication and disease activity score showed that the endoscopic score was an independent risk factor of clinical relapse (p = 0.043).

**Conclusion: Conclusion** According to the results of our study, this new endoscopic scoring system could predict the clinical relapse of patients undergoing surgical resection due to complications of intestinal Behcet's disease. Nevertheless, a larger-scale prospective study is needed to validate this scoring system.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Data are few and conflicting regarding the association of serological markers to the disease behavior, medical treatment and response to therapy in patients with ulcerative colitis (UC). We aimed to determine the prognostic potential of serological antibodies regarding long-term disease course of an adult prospective UC patient cohort. The association between serological markers and requirements for immunosuppressant or anti-TNF therapy was also evaluated.

**Aims & Methods:** One hundred and eighty-seven consecutive patients (male:46.0%, median age:40 years, extensive colitis:33.3%) were studied from a single referral IBD center. Sera were tested for a panel of different IgA/IgG type autoantibodies (anti-neutrophil cytoplasmic[ANCA], anti-lactoferrin[aLFS], anti-goblet cell and anti-pancreatic [anti-GP2 and anti-CUZD1] antibodies) by IIFT and for anti-microbial antibodies (ASCA IgG/IgA and anti-OMPPlus$^{TM}$ IgA) by ELISA. Clinical data were available on unfavorable disease outcome as well as disease activity and medical treatment during the prospective follow-up (median: 104 months).

**Results:** A total of 73.6%, 62.4% and 11.2% of UC patients were positive for IgA/IgG type of pANCA, aLFS and anti-goblet cell antibodies, respectively. Both type of anti-pancreatic antibody occurred in 9% of the patients, while ASCA and anti-OMP in 17.7% and 19.8%. Serological antibody status was stable over time. There was no significant association between antibody positivity and gender, age at onset or disease extent. Presence of certain antibodies was negatively associated to the occurrence of extraintestinal manifestations: aLFS IgA/IgG to current smoking status (OR:0.26, $p = 0.01$) and ocular disease (OR:0.16, $p < 0.01$), while pANCA IgA/IgG to the arthritis (OR:0.36, $p = 0.026$). During the follow-up period, UC-related hospitalization occurred in 34.2% and requirement for colectomy was 3.7%. Exposure to steroids, azathioprine or anti-TNFs was 77.0%, 37.4% and 13.4%, respectively. IgA type ASCA and anti-CUZD1 antibody but not other serological markers were associated to an increased likelihood of requirements for immunosuppressant in Kaplan-Meier analysis (pLogRank $< 0.01$ for both), however only ASCA IgA was identified as an independent predictor in multivariate Cox- regression model (HR:2.74, 95%CI:1.46–5.14, $p < 0.01$) comprising age at onset, gender, disease extent as covariates. At the same time, clinical factors, such as extensive colitis and male gender were exclusively associated with UC related hospitalization, HR:1.8 (95%CI:1.09–2.95, $p = 0.019$) and HR:6.7 (95%CI:1.6–27.9, $p < 0.01$), respectively.

**Conclusion:** Present prospective study displays limited role of serologic markers in the prediction of disease course in UC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0292 INTER-OBSERVER AGREEMENT IN BOWEL ULTRASONOGRAPHY FOR DIAGNOSTIC ASSESSMENT IN PATIENTS WITH CROHN'S DISEASE

**Introduction:** Bowel Ultrasonography (US) constitutes an attractive imaging modality in Crohn's disease (CD) because it can be repeated frequently to assess and monitor lesions over time. Bowel US does not involve radiation and its low cost provides an alternative to other techniques, especially for children and young patients. Currently, however, a lack of standardization of the bowel US parameters commonly used in CD and the still reduced number of skilled ultrasonographers in this technique is limiting the use of this imaging modality around the world.

**Aims & Methods:** The aim of this study was to assess the interobserver agreement among different sonographers, experts in bowel US, from different centers, in the evaluation of predefined bowel US parameters commonly used in the detection and follow-up of patients with CD in order to develop an unequivocal imaging interpretation.

Fifteen patients with established CD underwent bowel US performed blindly by 6 sonographers from different IBD centers around the world, expert in bowel US (>1000 exams/year). Before the evaluation, the operators and clinical and radiological IBD experts dedicated a meeting to formally define the US parameters [site lesion, bowel wall thickness (3–7 mm vs >7 mm), bowel wall pattern (preserved vs disrupted), vascularization (absent/mild vs moderate/severe), lymph nodes, mesenteric adipose tissue alteration, stenosis, fistulas, phlegmon and abscess) that have been included in the study. Interobserver agreements were tested with Fleiss' kappa statistics.

**Results:** Fleiss' k values were moderate for bowel wall thickness ($k = 0.54$, $p = 0.01$), site lesion ($k = 0.46$, $p = 0.01$), bowel wall pattern ($k = 0.43$, $p = 0.001$), vascularization ($k = 0.59$, $p = 0.001$) and mesenteric adipose tissue alteration ($k = 0.43$, $p = 0.001$). Agreement was good and excellent for prestenotic dilation and penetrating complications ($k = 0.73$–$1$, $p = 0.001$). Fair and poor agreements were observed for stenosis, lymph nodes and lesion extent ($k < 0.3$, $p = 0.001$).

**Conclusion:** In this pilot study most of the US parameters used in CD patients showed a satisfactory reproducibility. The development of a common US imaging interpretation among bowel sonographers will allow the better comparability of US results among various centers, improve the quality of multicenter US studies and bowel US training with a further diffusion of this technique.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0293 THE BRISTOL STOOL FORM SCALE AND A VISUAL ANALOGUE SCORE FOR ABDOMINAL PAIN MAY BE USED AS PATIENT REPORTED OUTCOME MEASURES IN CROHN'S DISEASE

**Introduction:** Patient-reported outcomes are increasingly important disease measures in Crohn's disease.

**Aims & Methods:** We aimed to investigate whether (i) the Bristol Stool Form Scale (BSFS) and (ii) a visual analogue scale (VAS) for abdominal pain can be used as patient reported outcome measures in Crohn's disease. In this prospective cohort study, patients with active Crohn's disease were included before they started treatment with corticosteroids or TNF inhibitors. Patients with colectomy or stoma were excluded. The following parameters were collected prior to treatment and 10 weeks later: Harvey Bradshaw Index (HBI), Crohn's Disease Activity Index (CDAI), serum CRP and fecal calprotectin. At the same time points, participants completed a 7-day diary containing the following items for each day: BSFS (1–7) and 10 cm VAS for abdominal pain. HBI-response was defined as a reduction in HBI $\geq 3$; CDAI-response was defined as a reduction in CDAI $\geq 100$; calprotectin-response and CRP-response were defined as reduction of $\geq 50\%$ compared to baseline values. Changes in minimum, mean and maximum BSFS and changes in VAS score were evaluated in relationship to clinical and biochemical response using area under the receiver operator characteristic curve (AUROC). Guyatt's responsiveness statistic was calculated as the mean change in responders divided by the standard deviation of the change in non-responders. Test-retest reliability was evaluated using single measure intraclass correlation coefficients (ICCs).

**Results:** A total of 42 patients were included of whom 35 completed the study (31% males, mean age 41 years). Corticosteroids (6 prednisolone, 16 budesonide) were started in 63% and TNF inhibitors (6 infliximab, 7 adalimumab) in 37%. Clinical response based on HBI or CDAI was observed in respectively 38% and 24% of the patients, while CRP- and calprotectin-response was seen in 38% and 55% of patients, respectively. Change in the lowest BSFS-score and change in mean VAS-score were most strongly associated with HBI-response (respectively, AUROC 0.91, 95% CI 0.81–1.0; AUROC 0.92, 95% CI 0.82–1.0; Guyatt's statistic 1.06; 2.24) and CDAI-response (respectively, AUROC 0.90, 95% CI 0.79–1.0; AUROC 0.94, 95% CI 0.85–1.0; Guyatt's statistic 2.96; 2.24). Change in mean highest BSFS-score (AUROC 0.60, 95% CI 0.39–0.81) and change in highest VAS-score (AUROC 0.81, 95% CI 0.65–0.96) were most strongly associated with calprotectin-response; Guyatt's statistic 0.95 and 2.24, respectively. Change in mean lowest BSFS-score (AUROC 0.64, 95% CI 0.45–

0.84) and change in highest VAS-score (AUROC 0.70, 95% CI 0.50–0.90) most strongly associated with CRP-response; Guyatt's statistic 2.43 and 2.68, respectively. Test-retest reliability was moderate for VAS-score (ICC 0.70 and 0.58, before and after treatment, respectively), and moderate to strong for lowest (ICC 0.80 and 0.65), mean (ICC 0.75 and 0.52) and highest (ICC 0.51 and 0.50) BSFS-score.
**Conclusion:** The Bristol Stool Form Scale and a visual analogue scale for abdominal pain appear to be reliable, accurate and responsive instruments to evaluate the effect of treatment in patients with Crohn's disease. Future studies are required to validate whether these instruments can be used as outcome measures in Crohn's disease trials.

**Introduction:** Malnutrition and altered body composition (BC) can develop in patients with inflammatory bowel diseases for a variety of reasons.
**Aims & Methods:** Our aim was to develop a method to diagnose presarcopenia at an early stage in Crohn's disease (CD) outpatients, based on the assessment of body composition (BC) as well as using fat-free mass index (FFMI) reference values of the healthy population to prevent sarcopenia. The second aim was to establish national reference values for FFMI percentiles. 136 CD outpatients and 1752 healthy controls were included. Bioelectrical impedance analysing (BIA) method was used to measure BC. BMI and FFMI percentiles were determined within the healthy population, and cut-off point was established for the proposed presarcopenia screening method.
**Results:** BMI and FFMI were significantly different between the groups of patients and healthy subjects (median BMI: 22.0 vs 25.1 $kg/m^2$, $p < 0.0001$; FFMI: 17.3 vs 18.4 $kg/m^2$, $p = 0.0044$; respectively). Low BMI (i.e., malnutrition) was diagnosed among patients vs. healthy subjects for 32% vs. 4% for men and 33% vs. 13% for women; whereas low FFMI (i.e., presarcopenia) was diagnosed for 25% vs. 5% for men and 36% vs. 14% for women. Considering CD patients, both genders had almost the same prevalence of low BMI, but more females had low FFMI. Thus, a reasonable algorithm was suggested (based on BMI and FFMI) for nutritional intervention of CD outpatients to prevent severe malnutrition and sarcopenia.
**Conclusion:** BC assessment is essential for CD patients because of high risk for presarcopenia. Our study presents charts for BIA-determined gender-, age-, and BMI-specific percentiles for FFMI, based on healthy adults.

**Introduction:** Crohn's disease (CD) is a chronic inflammatory disorder defined as a transmural inflammation of the bowel wall, affecting the small and large intestine. The Capsule Endoscopy Crohn's Disease Activity Index (CECDAI or Niv score) was devised to measure mucosal disease activity. We extended the Niv score to the colon and have a comprehensive view of the whole intestine of CD patients.
**Aims & Methods:** To establish a new capsule endoscopy score for disease activity in Crohn's disease of the small and large intestine. We evaluated 3 parameters of intestinal pathology: A. Inflammation B. Extent of disease C. Presence of strictures, for the proximal and distal small bowel, and for the right and left colon. The scoring formula is as follows: CEDCAIic = (A1 x B1 + C1) + (A2 x B2 + C2) + (A3 x B3 + C3) + (A4 x B4 + C4) (1 = proximal small bowel, 2 = distal small bowel, 3 = right colon, 4 = left colon).
**Results:** The median CECDAIic score was 15.5 (range 0 – 42), and the mean (±SD) score was 17.2 ± 11.5. The CECDAIic scores per patient were similar among the 5 observers. Kendall's coefficient of concordance was high and significant for almost all the parameters examined but for strictures in the proximal small bowel and distal colon. Nevertheless, the coefficients for the small bowel and for the whole intestine were high, 0.85 and 0.77, $P < 0.0001$, respectively.
**Conclusion:** We established a new score, the CECDAIic of the small-bowel and colonic CD. We offer this easy, user friendly score for use in randomized controlled trials as well as in the clinical follow-up of CD patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0296 MUCOSAL HEALING: MAYO 0 VS 1 AFTER 3 YEARS

**G. Frieri**, M. Di Ruscio, A. Capannolo, G. Latella, A. Pasetti, R. Tittoni, A. Viscido
*Department Of Life, Health And Environmental Sciences, Gastroenterology Unit, L'Aquila/Italy*

**Contact E-mail Address:** gastroaq@libero.it.
**Introduction:** Mucosal endoscopic healing (MH), is considered the best prognostic factor in patients with ulcerative colitis (UC) but currently, there is no consensus regarding its definition1. Most of the studies define MH by a Mayo endoscopic score (MES) 0 or 1, others distinguish score 0 from score 1.
**Aims & Methods:** To measure the prognostic value of MES 0 and 1 in the prediction of the clinical course of patients with UC in stable clinical remission. Methods: Sixth-four patients with UC in stable clinical remission with high dosage of mesalazine were studied. All the patients underwent colonoscopy at baseline and MES was measured. Clinical course was evaluated measuring relapses needing steroids, immunosuppressants and/or biologics, after 3 years of follow-up. Statistical analysis was performed using the Kaplan-Meier life-table method, the log-rank test, the Cox's proportional hazard model, as appropriate.
**Results:** At the baseline, 36 patients (56%) showed a MES 0; 21 (33%) MES 1, 7 (11%) MES 2, none MES 3. At 3-year of follow-up, 50% of patients were still in remission. The cumulative proportion of steroid free remission at 36 months of follow-up in MES 0, 1 and 2 was 69%, 35%, and 0%, respectively ($p < 0.0001$ among all groups). Patients with MES 1 and 2, showed a hazard risk of relapse 2.86, and 15.74 times higher than those with MES 0 (table).

| MES | baseline | after 3 years | Hazard Risk |
|---|---|---|---|
| 0 | 36 | 25 | 1 |
| 1 | 21 | 7 | 2.86 |
| 2 | 7 | 0 | 15.74 |

**Conclusion:** Only the Mayo endoscopic score of 0 should be considered as mucosal healing.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** Subrata.Ghosh@albertahealthservices.ca.
**Introduction:** Ustekinumab (UST) is a well-established therapy in psoriasis (PsO) and psoriatic arthritis (PsA) with up to 5 years safety experience from psoriasis clinical trials with 3117 pts & 8998 patient years (PY) of follow-up. However, limited safety data have been presented in Crohn's disease (CD). In pts with CD, Phase 2/3 data show that UST is safe & effective. Herein we present CD safety results & compare these with the safety profile in psoriatic diseases.
**Aims & Methods:** Safety data from 5 CD (2 Ph2/3Ph3) trials were analyzed with the previously reported PsO (1 Ph2/3Ph3) & PsA (1 Ph2/2 Ph3) randomized

controlled trials. All psoriatic pts received UST 45 or 90 mg SC; Ph3 CD pts received a single IV UST induction dose of 130 mg or ~6 mg/kg followed by 90 mg SC q8 or q12 wks. In PsO trials, no concurrent treatment was permitted; concomitant MTX was permitted in PsA trials & concomitant immunomosuppressives & corticosteroids were permitted in CD trials. All pts who received ≥1 dose of UST were included. Safety outcomes are presented as events per 100 PYs.
**Results:** Through the PBO-control period across all indications, 3636 pts were treated with UST (1582 PsO, 692 PsA & 1362 CD). Treated pts with ≥1 reported event PBO vs UST in pooled indications (incidence/100 PY of f/u): AEs 556.1 vs 594.3; SAEs 19.5 vs 16.4; infections 135.8 vs 138.1; serious infections 2.9 vs 3.3; MACE 0.26 vs 0.60; malignancies 0.26 vs 0.12; deaths 0 vs 0.12. Through 1 year, 5884 pts were treated with UST (3117 PsO, 1018 PsA, & 1749 CD) with 4521 PY of follow-up. Rates of AEs, SAEs, infection/serious infection were similar between UST group and PBO (Table) across the pooled indications. Event rates in the combined CD studies were also similar between treatment groups (PBO & UST groups) with overall AEs, & infections occurring more frequently in CD pts.
**Conclusion:** UST has a favorable safety profile in CD with IV induction dosing up to 6 mg/kg & SC maintenance dosing up to 90 mg q8wks. Evaluation of the CD experience did not alter the safety profile of UST previously defined in pts with psoriatic disease treated with up to 5 years of therapy.

## P0298 SAFETY, PHARMACOKINETICS AND PHARMACODYNAMICS OF THE NOVEL ORAL PEPTIDE THERAPEUTIC PTG-100 (ALPHA4-BETA7 INTEGRIN ANTAGONIST) IN NORMAL HEALTHY VOLUNTEERS

**R. Shames**, L. Tozzi, L. Mattheakis, T. Annamalai, A. Bhandari, D. Liu
*Protagonist Therapeutics, Milpitas/United States of America/CA*

**Contact E-mail Address:** r.shames@protagonist-inc.com.
**Introduction:** PTG-100 is an orally administered, potent and highly selective $\alpha4\beta7$ antagonist peptide therapeutic that is being developed for the treatment of ulcerative colitis (UC). PTG-100 is orally stable because of its chemical and structural resistance to the acidic, reducing and proteolytic milieu of the gastrointestinal (GI) tract and was developed to have minimal systemic exposure and maximal GI tissue concentrations. Animal pharmacokinetic (PK) studies have shown that the drug is stable in the gut lumen and present in the colon, small intestine, mesenteric lymph nodes, Peyer's patches, and feces, but at very low concentrations in the blood (%F plasma < 0.5%) under normal and inflammatory conditions. In a dextran sulphate sodium (DSS)-induced colitis mouse model, PTG-100 induced a dose-dependent reduction in $\alpha4\beta7+$memory T cell homing to inflamed gut tissue and a significant improvement in mucosal damage with comparable activity to the mouse $\alpha4\beta7$ antagonist antibody DATK32. Fluorescence-activated cell sorter (FACS) analysis of whole blood from healthy cynomolgus monkeys demonstrated that blood receptor occupancy (RO) < 50% is correlated with efficacy in the mouse colitis studies. Following completion of IND-enabling studies, we conducted a phase 1 first-in-human study of orally-administered PTG-100 in normal healthy volunteers (NHVs) to assess safety/tolerability, PK and pharmacodynamic (PD) activity as measured by %RO and $\alpha4\beta7$ target expression (TE) on CD4+memory a4b7+T cells in peripheral blood.
**Aims & Methods:** We conducted a randomized, double-blinded, placebo-controlled phase 1 trial of single- (SAD) and multiple ascending dose (MAD) administration of PTG-100 in 70 male NHVs. MAD administration consisted of once daily dosing over 14 days. Subjects were monitored for safety / tolerability and underwent serial PK and PD evaluations.
**Results:** In the SAD portion of the study (n = 40), dose escalation proceeded to 1000 mg, the highest planned dose in the study. There were no serious adverse events or dose-limiting toxicities. All adverse events were of mild to moderate severity and resolved without complication. PTG-100 plasma levels were extremely low, but increased in a dose-dependent manner. There was a dose-dependent increase in blood RO of memory T cells, naïve T cells, and B cells with sustained RO beyond 24 hours following single dose exposure. Blood $\alpha4\beta7$ TE on memory T cells decreased in a dose-dependent manner consistent with internalization of the target with apparent plateauing at the 300 mg dose level. PTG-100 caused an increase in the percentage of circulating $\alpha4\beta7+$memory T cells, but not $\alpha4\beta7+$naïve T cells or $\alpha4\beta7+$B cells. MAD dosing is expected to be completed by mid-year 2016.
**Conclusion:** PTG-100 was well tolerated following single dose oral administration in NHVs with extremely low plasma exposure and evidence of target engagement and pharmacologic activity. As a novel orally-stable, GI-restricted and highly selective $\alpha4\beta7$ antagonist peptide therapeutic, PTG-100 may offer unique benefits compared to systemically administered biologics and non-specific immunomodulators. A Phase 2 study in UC patients is currently planned.

**Introduction:** Anti-tumor necrosis factor (anti-TNF) agents are an important treatment option for a variety of inflammatory diseases. Patients with a stable response to anti-TNF therapy may discontinue or switch treatments for non-medical reasons such as cost reduction. In the United States, non-medical switching (NMS) was demonstrated to be associated with increased healthcare resource utilization and cost.[1–3] The objective of this study is to estimate costs associated with NMS of anti-TNFs in a European setting.
**Aims & Methods:** We constructed a model to estimate costs associated with NMS from an originator anti-TNF to biosimilar infliximab among patients with Crohn's disease, ulcerative colitis, rheumatoid arthritis, ankylosing spondylitis, psoriasis, and psoriatic arthritis in Denmark, The Netherlands, and Norway. Differences in resource utilization over 1 year due to NMS (i.e. comparing switchers to non-switchers) were estimated to be 7.12 outpatient visits, 0.02 inpatient admissions, 0.15 emergency department (ED) visits, and 1.16 additional anti-TNF infusions per patient [1, 2]. Cost inputs were based on data from the national healthcare authorities for each country, and included both disease-specific and all-cause medical (outpatient, inpatient, and ED visit) and drug (acquisition and administration) costs. Incremental costs attributable to NMS were summarized for each country in 2013/2014 currency. Costs were expressed in Euros.
**Results:** Average yearly costs were estimated to be €2, 349 (Denmark), €2, 730 (The Netherlands), and €4, 404 (Norway) per switcher. Increased costs were

**Contact E-mail Address:** siew-hwa.ong@viforpharma.com.

**Introduction:** Patients with Inflammatory Bowel Disease (IBD) are likely to have iron deficiency with an estimated prevalence of 60–80%, whereas anaemia manifests in about one-third of patients. Iron deficiency can have a significant impact on a patient's quality of life. Intravenous iron and oral iron are indicated for patients with IBD and iron deficiency or iron deficiency anaemia.

**Aims & Methods:** The aim of this study was to compare patients with IBD and Iron Deficiency/Anaemia (ID/A) newly treated with oral or intravenous iron regarding the impact on hospitalisation in Germany. Pooled claims data from the Health Risk Institute research database were used which comprises data from 75 German health insurances on an anonymised individual level. IBD patients with ID/A were identified by ICD-10-GM codes in 2013. Type of incident iron treatment, oral/intravenous iron, were assessed via ATC codes. All patients had to be insured continuously during the individual pre-observation period of 4 quarters for the incidence assessment of iron treatment. A 1:1 propensity score matching was performed to compare patients with oral iron to patients with intravenous iron using age, gender, and the updated Charlson Comorbidity Index. Matching couples were identified applying the nearest neighbor matching and a caliper of 0.05 was used. Outcome measures focused on impact on hospitalisation. P-values were calculated applying the McNemar's test and the Wilcoxon signed rank test.

**Results:** In total, 2, 379 IBD patients had ID/A, of which 589 received oral iron treatment for the first time, 442 patients were newly treated with intravenous iron, whereas 1, 348 patients received no iron treatment in 2013. After matching oral vs. intravenous iron, 380 IBD patients remained in each treatment cohort. Mean age was balanced to 42.3 and 42.2 years for oral and intravenous iron patients and 67% vs. 61% were female, respectively. Insurance status (member, family insured, pensioner) were equally distributed in the matched cohorts. All-cause hospitalisations were reported in 48% of the oral iron patients vs. 37% of the intravenous iron patients ($p = 0.001$), and ID/A-related hospitalisations in 14% and 5%, respectively ($p < 0.001$). Mean duration of ID/A-related hospitalisations was significantly shorter for patients treated with intravenous iron (9.6 vs. 7.0 days; $p < 0.001$).

**Conclusion:** Real-world evidence suggests that IBD patients with ID/A treated with intravenous iron had fewer all-cause and ID/A-related hospitalisations, and had a shorter duration of ID/A-related hospitalisation vs. IBD patients with ID/A treated with oral iron. Further research is warranted to assess the long-term effects of iron supplement treatment.

**Introduction:** Biosimilar infliximab CT-P13 received EMA approval in June 2013 for all indications of the originator product and its use is mandatory in all anti-TNF-naïve IBD patients in Hungary since May 2014.

**Aims & Methods:** In the present study we aimed to prospectively evaluate the immunogenicity profile of the biosimilar infliximab and predictors of TDM in IBD in a nationwide, multicentre cohort. Demographic data were collected and a harmonized monitoring strategy was applied. Clinical and biochemical activity were evaluated at weeks 14, 30 and 54. Routine therapeutic drug monitoring (TDM) was applied. Trough level (TL) and anti-drug antibody (ADA) concentration were measured by ELISA (LT-005, Theradiag, France) at baseline and at 2, 6, 14, 30 and 54 weeks right before anti-TNF administration during the induction treatment.

**Results:** 291 consecutive IBD patients (184 CD patients and 107 UC patients) were included in the present cohort. 24.5% of CD patients and 14% of UC patients had received previous anti-TNF therapy. None of the patients had received infliximab within 12 months prior to initiation of the biosimilar infliximab. 60/52% of CD/UC patients received concomitant immunosuppressives at baseline. Mean TLs were 20.1, 14.7, 5.1 and 3.9 $\mu$g/ml at weeks 2, 6, 14 and 30. Early TLs were higher in CD compared to UC at weeks 2 (19.1 vs 15.1 $\mu$g/ml, $p = 0.05$) and 6 (16.7 vs. 12.1 $\mu$g/ml, $p = 0.046$) with no significant differences in TLs thereafter at week 14 and 30. ADA positivity rates were 3.8%, 16.1%, and 24.1% in naïve patients at weeks 0, 14, and 30 ($n_{total} = 229$, 192 and 143). TLs were lower at week 2 and 6 ($p = 0.02$ and $p = 0.005$), but not week 14 or 30 in patients with previous anti-TNF exposure, compared to naïve patients, coupled with higher ADA positivity. Concomitant IS use prevented early ADA formation in anti-TNF naïve patients (24.6% vs 11.2%, $p = 0.03$) by week 14, but the effect was lost by week 30 (29.8% and 21.2%, p = ns). 21 (7.2%) patients had infusion reactions during induction or maintenance treatment, of which 13 patients had received previous infliximab treatment.

**Conclusion:** Drug TLs and ADAs in IBD patients at weeks 0, 2, 14 and 30 weeks were in line with results reported for the originator in previous studies. Early TLs were slightly lower in UC compared to CD. Patients with previous exposure to anti-TNFs had lower early TL coupled with ADA positivity and were more likely

to develop infusion reactions. Concomitant IS use prevented early but not later ADA development.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0302 RATE AND PREDICTORS OF MUCOSAL HEALING IN PATIENTS WITH ULCERATIVE COLITIS TREATED WITH THIOPURINES: RESULTS OF A MULTICENTRIC COHORT STUDY

**Introduction:** Mucosal healing (MH) has become the optimal treatment goal in ulcerative colitis (UC) as it is associated with a better outcome. Thiopurines are immunosuppressants currently used in UC. However, MH rate is little known in UC patients treated with thiopurines. Our study aimed to assess rate and predictors of MH in UC patients treated with thiopurine monotherapy.
**Aims & Methods:** Patients were selected from prospective and administrative databases of 5 hospitals. Inclusion criteria were: UC, thiopurine monotherapy longer than 6 months and endoscopic evaluation before (T0) and at least 6 months after treatment initiation (T1). Exclusion criteria were: history of anti-TNF alpha, methotrexate or ciclosporin intake. Baseline characteristics of the patients (age at diagnosis, Montreal classification, complications) were collected in a standardized anonymous questionnaire (File Maker Pro v.12®). Clinical (Mayo score), biology and endoscopic (Mayo score, UCEIS) data were collected at T0, T1 and at latest news (T2). MH definition was: Mayo endoscopic score $\leq 1$ or UCEIS $\leq 2$. Patients with and without MH were compared by Mann Whitney-Wilcoxon test for non-parametric quantitative variables and by Student test for parametric variables.
**Results:** Out of 902 UC patients, 125 received at least 6 months of thiopurine monotherapy: 45 were excluded because previous ciclosporin treatment for acute severe colitis (N = 9) or lack of endoscopic evaluation (N = 36). Overall 80 patients (31 women) aged 43 (32–58), were included. Median UC duration was 10.5 (6–16) years. UC extent was E1, E2 and E3 in 8 (10%), 33 (42.5%) and 37 (47.5%) respectively. At T0, full Mayo score, endoscopic Mayo score and UCEIS were 8 (6.75–10), 3 (2–3) and 5 (3–6) respectively. At T1, after a mean of $38 \pm 31.3$ months, full Mayo score, endoscopic Mayo score, UCEIS were 3.5 (1–6), 2 (0–2.25) and 2 (0–4) respectively. Clinical remission was achieved in 62.7%, MH in 43.7% and histologic healing in 38%. Independent predictive factors of MH were: thiopurine exposure $\geq 2$ years [OR (CI95%) = 2.9 (1.1–7.6); p = 0.03] and acute severe colitis prior to thiopurine [OR (CI95%) = 5.9 (1.1–32); p = 0.04]. At T1, rectal bleeding Mayo sub-score $\leq 1$, BMI $\geq 25$ kg/m$^2$ and mean corpuscular volume (MCV) $\geq 95$ fL had a negative predictive value of 100%, 75% and 73% respectively. At T2 (N = 49), after a median of 5.9 (3.4–9.5) years follow up, 79% achieved clinical remission and 63.2% MH. Eighty percent who achieved MH at T1 had MH at T2.
**Conclusion:** This study shows that thiopurine monotherapy in UC is associated with MH in 43.7%. Independent predictive factors of MH are exposure to thiopurine $\geq 2$ years and severe acute colitis prior to thiopurine. Absence of rectal bleeding, BMI $\geq 25$ kg/m$^2$ and MCV $\geq 95$fL have good predictive value for MH.

**Introduction:** Anti-TNF$\alpha$ (Tumour necrosis factor $\alpha$) changed the way of treating Crohn's disease, including in case of fistulizing disease. To date, studies assessing the efficacy of anti-TNF$\alpha$ treatment in fistulizing CD mainly focused on perianal fistulae. Data assessing their use in case of internal fistulae are lacking. Intestinal resection is often preferred, considering the high risk of abscess for non-drained fistulae. The aim of the present study was to assess the efficacy of anti-TNF$\alpha$ treatment in a large cohort of CD patients complicated with internal fistula (excluding entero-cutaneous and perianal fistulae).
**Aims & Methods:** This was a multi-centric observational retrospective study. All CD patients who started anti-TNF$\alpha$ treatment for internal fistula were included. The primary outcome was the occurrence of intestinal resection. The secondary outcomes were the occurrence of internal fistula healing following anti-TNF$\alpha$ treatment, and the safety profile of anti-TNF$\alpha$.
**Results:** One hundred and seven (107) patients were included. After a median follow-up of 3.5 [1.6–5.6] years, 52 patients (48.6%) underwent a major abdominal surgery. Indications for surgery were the absence of fistula healing for 32 patients (61.5%), occlusion or sub-occlusion resulting from concomitant stenosis for 15 patients (28.8%), intestinal adenocarcinoma for 3 patients (5.7%), peritonitis secondary to intestinal perforation for 2 patients (3.8%). Cumulative probabilities for being free from surgery were 67%, 58% and 51% at 1, 3 and 5 years respectively. The complex characteristic of fistula (HR 3.49; 1.33 to 11.2; p = 0.01), C-reactive protein (CRP) > 18 mg/L (HR 3.63; 1.52 to 9.72; p = 0.003) and albumin < 30 g/L (HR 3.37; 1.46 to 7.70; p = 0.005) were associated with surgery. Fistula healing was obtained for 41% of patients (n = 44) with a mean duration of 12.5 [5.7 – 22.8] months. The cumulative probabilities of sustained fistula-healing were 20%, 35% and 47% at 1, 3 and 5 years after anti-TNF$\alpha$ treatment started. Only albumin $\geq 35$ g/L (HR 6.21; 2.53 to 16.73; p < 0.0001) was significantly and independently associated to fistula healing. Septic complications concerned 15 patients (14.0%), 11 patients (10.3%) developed an abscess. Four patients (3.8%) developed malignancy. Four patients (3.8%) died, 3 patients from an intestinal adenocarcinoma at 10 months, 5 et 7 years from anti-TNF$\alpha$ start; and 1 patient from a septic-shock at 3 months from anti-TNF$\alpha$ introduction.
**Conclusion:** Anti-TNF$\alpha$ treatment is useful for half of CD patients complicated with internal fistula, which has to be balanced against significant septic and malignant risks. Their use should be proposed to a selected population.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0304 DIFFERENT INDUCTION RESPONSE CRITERIA DO NOT INFLUENCE 1 YEAR RESPONSE AND REMISSION RATES OF USTEKINUMAB 90 MG Q8W IN PHASE III PROGRAM

**D. Naessens**[1], J. Johanns[2], C. Gasink[2]

**Introduction:** Crohn's disease Phase III maintenance clinical trials with biologics are typically randomized withdrawal trials, in which patients that responded after induction with a specific biologic are re-randomized to either maintenance therapy or placebo. Different response criteria have been used to qualify responders for these studies, such as CDAI 70 at week 2, 4 or 6 and CDAI 100 at week 8, but the influence of this criterion on remission results at year 1 has not been investigated. In the IM-UNITI study, patients with a CDAI 100 response 8 weeks after ustekinumab induction were re-randomized to either placebo, ustekinumab 90 mg Q12w or ustekinumab 90 mg Q8w (every 8 weeks). Non-responders to ustekinumab induction, as well as patients that received placebo for induction remained blinded in the trial. Non-responders to ustekinumab induction received ustekinumab 90 mg SC Q8w at week 0 of IM-UNITI. As a result, since both ustekinumab CDAI-100 responders and non-responders received 90 mg Q8w, remission rates at 52 weeks of total treatment can be calculated for ustekinumab 90 mg Q8w for patients with different induction response criteria.
**Aims & Methods:** Pre-specified analyses were conducted to evaluate the proportion of patients in remission and CDAI-100 response at 52 weeks of total treatment in the different arms of IM-UNITI for patients with a - 70 point CDAI response to ustekinumab at week 6 of induction. - 70 point CDAI response to ustekinumab at week 3 of induction - 100 point CDAI response to ustekinumab at week 8 of induction (original response criterion). Subsequently, the overall proportion of remitters and CDAI-100 responders at week 52 of total treatment was calculated for patients with a CDAI-70 response to ustekinumab respectively at week 3 or 6 of induction taking into account their relative distribution over the randomized or non-randomized arms receiving 90 mg Q8W.
**Results:** Remission rates after 52 weeks of total treatment in patients receiving 90 mg ustekinumab Q8w are summarized below.

**Abstract No: P0304**

| Response criterion | Randomized group (CDAI-100 responders at week 8) #patient randomized | Week 52 remission rate in 90 mg Q8w arm | Non-randomized group (no CDAI-100 at week 8) #patients at start of maintenance | Week 52 remission rate (90 mg Q8w) | Overall week 52 remission rate in responders |
|---|---|---|---|---|---|
| **CDAI 70 responder week 6** | **347** | **55.0%** | 127 | 42.5% | **51.7%** |
| **CDAI 70 responder week 3** | **283** | **60.7%** | 102 | 41.2% | **55.5%** |
| **CDAI 100 responder week 8 (original response criterion)** | 388 | 53.1% | | | **53.1%** |

Similarly, CDAI-100 response rates after 52 weeks of total treatment in patients receiving 90 mg ustekinumab Q8w were calculated for the different induction response categories. Rates were 60.8%, 58.3%, and 59.4% for CDAI-70 responders at week 3, 6, and CDAI-100 responders at week 8 respectively.
**Conclusion:** The majority of patients with CDAI-70 response at either week 3 or 6 after induction also had a CDAI-100 response at week 8. Using different qualifiers for response to ustekinumab induction did not result in different response or remission rates after 1 year of treatment in patients treated with ustekinumab 90 mg Q8w.

**Introduction:** Biosimilar infliximab CT-P13 received EMA approval in June 2013 for all indications of the originator product and its use is mandatory in all anti-TNF naïve IBD patients in Hungary since May 2014.
**Aims & Methods:** In the present study we aimed to prospectively evaluate the predictors of short and medium-term clinical outcome in patients treated with the biosimilar infliximab in two IBD centers in Hungary. Demographic data were collected and a harmonized monitoring strategy was applied. Clinical and biochemical activity were evaluated at weeks 14, 30 and 54. Therapeutic drug monitoring (TDM) was regularly used. Trough level (TL) and anti-drug antibody (ADA) concentration were measured by ELISA (LT-005, Theradiag, France) at baseline at 14, 30 and 54 weeks and in the above 2 centers at weeks 2 and 6 right before anti-TNF administration during the induction treatment.
**Results:** 291 consecutive IBD patients (184 CD patients and 107 UC patients) were included in the present cohort. 24.5/14% and 62/52% of CD and UC patients received previous anti-TNF and concomitant immunosuppressives at baseline therapy. Mean TLs were 20.1, 14.7 and 5.1 $\mu$g/ml at weeks 2, 6 and 14 (n = 124, 86 and 158). Cumulative ADA positivity rates were 8.7%, 19.3%, and 28.0% in IBD patients at weeks 0, 14, and 30 ($n_{total}$ = 229, 192 and 143). Early TLs at week 2 were predicting short term- (week 14 response/remission, $AUC_{TLweek2}$ = 0.715/0.721, p = 0.05/0.005,) but not medium-term (week 30 or 54) clinical efficacy. TLs measured at week 6/14 were not predicting either short or medium-term clinical outcome. In addition, early ADA status by week 14 (p = 0.04–0.05, OR: 2.1–2.6 for week 14 and 30), early clinical response ($p < 0.001$, OR: 7.7–42.8 for week 30/54) and normal CRP at week 14 (p = 0.005–0.0001, OR: 3.2–7.8 for week 14 and 30) and previous anti-TNF exposure (p = 0.03–0.0001, OR: 2.22–6.25, for week 14, 30 and 54) were associated with short and medium-term clinical outcomes (response and remission).
**Conclusion:** Early TLs were only associated with short-term clinical outcomes, while ADA development by week 14, early clinical response and normal CRP at week 14 and previous anti-TNF exposure were predicting medium-term clinical outcomes.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0306 TOFACITINIB FOR INDUCTION THERAPY IN PATIENTS WITH ACTIVE ULCERATIVE COLITIS IN TWO PHASE 3 CLINICAL TRIALS: RESULTS BY LOCAL AND CENTRAL ENDOSCOPIC ASSESSMENTS

**Contact E-mail Address:** reinisw@mcmaster.ca.
**Introduction:** Tofacitinib is an oral, small molecule JAK inhibitor that is being investigated for ulcerative colitis (UC). Two Phase 3 randomised placebo-controlled studies (OCTAVE Induction 1, NCT01465763; OCTAVE Induction 2, NCT01458951) demonstrated efficacy of tofacitinib 10 mg twice daily (BID) vs placebo as induction therapy for patients with moderately to severely active UC.[1].
**Aims & Methods:** We describe here the clinical efficacy endpoints assessed by local endoscopy readings along with the previously reported results assessed by central readings. Patients in OCTAVE Induction 1 and 2 were randomised (4:1) to receive treatment with tofacitinib 10 mg BID or placebo for up to 9 weeks (wks). Patients were ≥18 years old with moderately to severely active UC (baseline Mayo score ≥6, rectal bleeding subscore ≥1 and endoscopic subscore ≥2). Patient eligibility was assessed based on central endoscopic reading. Patients had previous failure or intolerance to treatment with ≥1 of corticosteroids, thiopurines, or tumour necrosis factor inhibitors. The following efficacy endpoints were assessed at Wk 8: mucosal healing (defined as Mayo endoscopic subscore ≤1), remission (study primary endpoint, defined as Mayo score ≤2, no subscore >1 and rectal bleeding subscore of 0) and clinical response (decrease from baseline Mayo score of ≥3 points and ≥30%, plus decrease in rectal bleeding subscore ≥1 or absolute subscore ≤1). Clinical outcomes were measured using both local (ie site) and central endoscopic readings at baseline and Wk 8.
**Results:** At Wk 8, significantly more patients receiving tofacitinib 10 mg BID achieved mucosal healing in both studies vs placebo as demonstrated by both central and local endoscopic readings (Table). Similar results were observed with remission and clinical response at Wk 8. The observed rates as well as the magnitude of treatment differences based on local endoscopic reading were generally higher than those assessed by central reading. There was good agreement between locally and centrally read endoscopic subscores (kappa = 0.63 (95% CI 0.58, 0.67) and 0.62 (95% CI 0.57, 0.67) in OCTAVE Induction 1 and 2, respectively).
**Conclusion:** In patients with moderately to severely active UC, who were qualified for both Phase 3 studies on central reading, treatment effects observed with local endoscopic readings were similar or slightly higher and, overall, consistent with central readings. Both methods demonstrated the significant effect of tofacitinib vs placebo for induction therapy.

**Introduction:** *Escherichia coli* Nissle (ECN) 1917 is a Gram-negative bacteria that belongs to the family of Enterobacteriaceae, and it is currently used as probiotic drug in the management of infectious gastroenteritis and in maintenance of remission in ulcerative colitis (UC) patients. ECN has been described to act also on intestinal epithelial barrier but few information exists on the influence of this probiotic on the gut microbiota composition.

**Aims & Methods:** The aim of our study was to evaluate the effect of administration of ECN in the qualitative and quantitative composition of the intestinal bacterial flora. Five patients affected by UC were treated with ECN (1 pill daily) for 10 days follwed by 2 pills per day for further 20 days. Fecal samples were collected before starting the treatment (T0), after 10 days from the beginning of the therapy (T1) and one month following the start of treatment (T2). Genomic DNA was isolated from the entire set of samples. The V1-V3 region of 16 S rRNA locus was amplified on a 454-Junior Genome Sequencer. Reads were analyzed by Quantitative Insights into Microbial Ecology (QIIME, v.1.8.0), grouped into operational taxonomic units (OTUs) by sequence matching against Greengenes database. The $\alpha$ and $\beta$ diversity and the Kruskal Wallis test were performed by QIIME software.

**Results:** The T test on good's coverage index (measure of total number of species represented in a sample) revealed that the qualitative composition of the gut microbiota between the T0 and T2 conditions resulted significantly different. Box plot of Shannon and Chao I indices revealed an increase in the median index values at the time point T1, which means an increase in the OTU total number at T1. This indicates an increase of the microbiota wellness at this time point. Post hoc analysis at phylum taxonomic level, revealed that Firmicutes relative abundance in the condition T0 versus T1 resulted significantly different, with a decrease of Firmicutes at T1. Indeed, at family taxonomic level the post hoc analysis revealed that Clostridiaceae relative abundance in the condition T0 versus T1, and also in T1 versus T2, differed significantly, with a T1 median value higher than the T0 and T2 values. At genus level, the T test confirms the variability in the two conditions (T0 and T2), with significantly differences for *Actinomyces*, *Anaerostipes*, *Bacteroides*, *Bulleidia*, *Corynebacterium*, *Dialister*, *Enterobacteriaceae*, *Erysipelotrichaceae*, *Finegoldia*, *Granulicatella*, *Lactobacillaceae*, *Peptoniphilus*, *Phascolarctobacterium*, *Roseburia*, *Serratia*, *Veillonellaceae*, *Veillonella_dispar*, *belonging to Firmicutes*, *Bacteroidetes* and *Proteobacteria phyla*.

**Conclusion:** Our data show that treatment with ECN leads to an improvement of the qualitative composition of the gut microbiota in patients affected by UC. These effects are stronger at the end of treatment in terms of wealth, with a stable variability between the genera after 1 month of treatment. Further studies should be performed to investigate the effect of this gut microbiota modulation on the history of the disease.

**Introduction:** Tumour necrosis factor antagonists (anti-TNF) have proven efficacy in Crohn's disease (CD) and Ulcerative Colitis (UC) patients, although many of them require therapy changes over time to maintain clinical benefit. Treatment modifications (i.e., dose escalation, switch to another anti-TNF, surgery, or addition of other medications) can be used as surrogate indicators of loss of response and may be considered as markers of suboptimal therapy.

**Aims & Methods:** The aim of this study was to quantify the incidence of and time to suboptimal therapy among adult patients with UC and CD using real-world clinical practices. A retrospective chart review study conducted in six countries (Canada, France, Germany, Italy, UK, and Spain) recruited CD and UC patients initiating infliximab or adalimumab between June 2009–2013 (index therapy). Indicators of suboptimal therapy were anti-TNF dose escalation (assessed >4 months after index to allow for initial dose optimizations), augmentation with aminosalicylates, immunomodulators, or corticosteroids, discontinuation of initial anti-TNF, switching to another anti-TNF, or disease-related surgery. Time to the first occurrence of the indicator of suboptimal therapy was measured using the Kaplan-Meier Method where patients were censored after discontinuation and at the end of the follow-up period.

**Results:** 657 CD (mean age of 39.2 years, 51% female) and 538 UC (mean age of 41.6 years, 47% female) patients initiating anti-TNF therapy were included. Among the CD cohort, 55.6% and 44.4% were initiated therapy with infliximab and adalimumab, respectively, whereas 92.2% of UC patients had been initiated

therapy with infliximab. Mean disease duration was longer for CD patients compared to UC [8.8 (SD = 8.6) vs. 7.1 (SD = 7.2) years]. A higher proportion of UC patients had at least one non-biologic treatment at index compared to CD patients (83.6% vs. 70.6%). Median time to at least one indicator of suboptimal therapy was 12.5 (95% CI: 10.5–15.2) and 17.5 (95% CI: 15.3–21.1) months for UC and CD patients, respectively. Within the first 12 months, the probability of discontinuation was highest indicator of suboptimal therapy (0.23 and 0.21 for UC and CD, respectively) followed by dose escalation (0.21 and 0.14 for UC and CD, respectively).
**Conclusion:** In this large multi-national cohort, the majority of patients initiating anti-TNF therapy had at least one indicator of suboptimal therapy within the first 12 months for UC and 17 months for CD. The most common indicators of suboptimal therapy were dose escalation and discontinuation with anti-TNF therapies. Future research should assess the potential for alternative therapies to improve treatment response rates among patients initiating anti-TNF therapies.

**Introduction:** Patients with active ulcerative colitis (UC) experience several symptoms that affect and reduce their work productivity.
**Aims & Methods:** The aim of this study was to assess the impact of an 8–week treatment with 3 g/day Eudragit-coated mesalazine tablets on the work productivity in patients with mild to moderate UC measured by the WPAI:UC. Data were collected from a phase III, multi-centre, double-blind, double-dummy study with mildly to moderately active UC patients receiving either the novel high-dose TID 1000 mg mesalazine tablet or the registered TID 2 × 500 mg mesalazine tablet Salofalk® for 8 weeks (SAT-25/UCA trial). The WPAI:UC is a self-report questionnaire measuring on 4 different scales the impairment of work and other activities due to symptoms of UC: 1) absenteeism (work time missed), 2) presenteeism (impairment while working), 3) overall work productivity loss (combined absenteeism and presenteeism) and 4) activity impairment (limitations of non-work activities) during the previous 7 days. During the 8-week treatment phase patients completed the WPAI:UC every other week. Clinical disease activity was measured using the Clinical Activity Index (CAI).
**Results:** Of the 306 randomised patients, only those with an impairment in WPAI:UC at baseline were used for analysis (n = 297, 97%). For absenteeism, presenteeism and overall work productivity loss only employed patients (n = 186, 61%) at baseline were evaluated. 43% of the employed patients achieved clinical remission at week 8. 89%, 74%, 76% and 76% of these patients showed an improvement in absenteeism, presenteeism, overall work productivity and activity impairment at week 8, respectively. In all four scales of the WPAI:UC, an 8-week mesalazine treatment significantly reduced impairment of work productivity ($p < 0.0001$). These changes correlated with an improvement of the clinical activity (defined as CAI improvement $\geq 3$ points) ($p < 0.0001$), except for absenteeism. Patients achieving clinical remission at week 8 (defined as CAI $\leq 4$ with normalization of stool frequency and absence of rectal bleeding at week 8) were significantly less affected in their work productivity compared to patients not achieving clinical remission ($p < 0.0001$), except for absenteeism. No statistically significant differences for all scales of the WPAI:UC were observed between the two different mesalazine formulations.
**Conclusion:** This large study demonstrates that an 8-week treatment with 3 g/day Eudragit-coated mesalazine tablets in patients with active UC leads to significant improvements in work productivity. At week 8, patients in clinical remission are significantly less affected in their work productivity than patients being not in clinical remission. Improvement of clinical activity correlates with significant improvement of work productivity as assessed with the WPAI:UC.

**Introduction:** Vedolizumab has been approved for the treatment of both Crohn's disease (CD) and ulcerative colitis (UC). However, data of the effectiveness and safety of this drug in clinical practice are scarce.
**Aims & Methods:** Aims: 1) To assess the short-term effectiveness of vedolizumab in inflammatory bowel disease (IBD) patients; 2) To identify factors associated with the response to the treatment; and 3) To evaluate the safety of this drug in clinical practice. Methods: Observational, multicenter, nationwide study. Patients treated with vedolizumab due to active IBD (UC, Partial Mayo Score $\geq 2$; CD, Harvey-Bradshaw $> 4$) were retrospectively included. Short-term response was evaluated at week 14. The variables associated with the short-term effectiveness were identified by logistic regression analysis. Adverse events during the treatment were recorded.
**Results:** Ninety-five patients were included. Mean age was 44 years (standard deviation [SD] = 14 years), mean time of evolution of the disease was 11 years (SD = 7 years), 57% were female, and 30% were current smokers. Fifty-three patients (56%) were diagnosed with CD and 42 (44%) with UC. Among CD patients, 57% had ileocolonic involvement, and 25% ileal location; 60% had inflammatory behaviour, 28% fistulizing disease, and 32% perianal disease. Among UC patients, 50% had left-sided colitis, and 47% extensive colitis. 42% suffered extraintestinal manifestations, and 34% had been operated on due to IBD: 22 patients (22%) had undergone intestinal resection and 10 patients (10.5%) had undergone surgery due to perianal disease. With respect to previous treatments, 93% patients had received azathioprine, 29% mercaptopurine, 36% methotrexate and 10% cyclosporine. Eighty-nine patients (94%) had been

refractory to biologic agents before starting vedolizumab: 5 patients (5%) had previously failed to 4 biologic agents, 26 (27%) to 3, 46 (48%) to 2, and 12 (6%) to 1 biologic agent. Overall, 40% of the patients were under concomitant immunosuppressants when they were started on vedolizumab. After the induction doses (week 14th), 75% (95%CI, 65–83%) of patients responded to the treatment (23% achieved remission and 52% partial response). The percentages of remission and response were similar between CD and UC patients: 19 vs. 30% ($p = 0.2$) for remission, and 73 vs. 75% ($p = 0.8$) for response. We could not identify any factor associated with response to vedolizumab (including the type of IBD and concomitant immunomodulators). Nine patients (9.5%) had adverse events during the treatment, all of them being mild: 2 respiratory infection, 2 dizziness, 1 fatigue, 1 herpes infection, 1 palmar erythema, 1 arthralgia and 1 infusion reaction.

**Conclusion:** In the short-term, vedolizumab seems to be effective and safe for the treatment of IBD (both CD and UC), even in refractory patients.

**Disclosure of Interest:** J.P. Gisbert: Served as a speaker, a consultant and advisory member for or has received research funding from MSD, Abbvie, Hospira, Kern Pharma, Takeda, Janssen, Pfizer, Ferring, Faes Farma, Shire, Dr Falk Pharma, Chiesi, Casen Fleet, Gebro Pharma, Otsuka, Vifor Pharma.

## P0311 EFFICACY OF EXCLUSIVE ENTERAL NUTRITION IN ADULT ACTIVE CROHN'S DISEASE WITH COMPLICATIONS OR FAILURE OF MEDICAL TREATMENT

Q. Yang[1], **X. Gao**[1], M. Zhi[1], H. Chen[2], P. Hu[1]
[1]*Gastroenterology, The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou/China*
[2]*The Sixth Affiliated Hospital of Sun Yat-sen University, Guangzhou/China*

**Contact E-mail Address:** helen818@163.com.

**Introduction:** Complicated active Crohn's disease (CD) patients may not need emergent surgery or not be suitable for surgery due to malnutrition. They may also not be appropriate for corticosteroids or biologics due to stricture, intestinal fistula and/or abdominal abscess. Some patients had poor response to medical therapy. We aim to investigate the efficacy of EEN in induction of remission in active CD patients with complications or poor response to drugs.

**Aims & Methods:** Active CD patients who had been diagnosed as complicated with stricture, intestinal fistula, abdominal abscess and no response to drugs, were recruited since July 2013 to October 2015. Patients were offered EEN for 12weeks without other drugs except patients with abscess could use antibiotic therapy with or without percutaneous drainage. Demographics and clinical variables were recorded.

**Results:** 48 patients aged 18–60 with CD were finally involved. 10 patients diagnosed as refractory CD; 10 accompanied with stenosis and 33 with intestinal fistula (4 enterocutaneous fistulas and 25 intra-abdominal abscesses). After 12 weeks EEN, the CDAI decreased obviously ($213.7 \pm 62.7$ VS $94.8 \pm 41.6$, $P = 0.000$). 4 patients only achieved partial remission, while 3 of them insisted to continue EEN except 1 patient transferred to surgery. Among patients with enterocutaneous fistula, 3 (3/4, 75%) got fistula closure after EEN. In patients with stenosis, 2/10 (20%) had no response to EEN and were transferred to surgery. 2/10 (20%) had partial remission and 6/10 (60%) achieved completely clinical remission after 12 weeks EEN. 10 (10/10, 100%) refractory CD patients all achieved clinical remission. 19 patients complicated with intra-abdominal abscess got abscess disappeared (19/25, 76%). 23 patients performed colonoscopy before and after EEN, 7 patients (7/23, 30.4%) reached mucosal healing. The inflammatory index of patients was significantly decreased (hs-CRP: $9.17 \pm 4.02$ mg/l VS $3.33 \pm 3.15$, $p = 0.00$; PLT: $321.42 \pm 105.5$*10E9/l VS $241.42 \pm 55.75$*10E9/l, $p = 0.00$). The nutritional parameters such as BMI were increased obviously ($17.09 \pm 2.26$ VS $18.41 \pm 1.93$, 0.06) and the NRS 2002 score decreased significantly ($3.35 \pm 1.58$ VS $2.19 \pm 1.45$, $P = 0.001$).

**Conclusion:** EEN is effective for inducing early clinical remission, mucosal healing, promoting fistula closure and reducing the size of abscess to adult CD patients with complications and poor response to drugs. More cases need to be enrolled for further study.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0312 THE EFFICACY OF DOSE SPLITTING THIOPURINES IN HYPERMETHYLATORS

**B. Warner**[1], S. Fong[1], E. Johnston[1], S. Mashari[1], S. Patel[1], S.H. Anderson[1], P. Irving[1], A. Marinaki[2], J. Sanderson[1]
[1]*IBD Centre, Guy's & St Thomas' NHS Foundation Trust, London/United Kingdom*
[2]*Purine Research Laboratory, Guy's and St Thomas' NHS Foundation Trust, London/United Kingdom*

**Contact E-mail Address:** Ben.Warner@gstt.nhs.uk.

**Introduction:** Hypermethylation (defined as a methylmercaptopurine to thioguanine nucleotide ratio (MeMP:TGN) of >11) is associated with a poor response to treatment and side effects such as nausea and hepatotoxicity. Conventional management is to switch to low dose thiopurine and allopurinol co-therapy (LDTA). A previous study has shown a significant reduction in MeMP levels through splitting the dose to half in the morning and half in the evening, the rationale being that the reduced dose is below the optimum substrate affinity for the enzyme thiopurine methyltransferase (TPMT).[1].

**Aims & Methods:** We performed a retrospective analysis of patients with inflammatory bowel disease (IBD) who underwent dose splitting. We analysed for: dose, IBD type, ethnicity, TPMT, MeMP:TGN ratio immediately before and after dose splitting, reasons for dose splitting and outcomes as judged by the authors based on whether LDTA was required. Statistical analysis was performed using SPSS. A paired T test was used to make comparisons between the means for TGN, MeMP and MeMP:TGN. TGNs and MeMP are measured in pmol/8 X 108 RBC.

**Results:** 25 patients were identified who underwent dose splitting. 15 were female (Mean age 35.4 years). 13 had Crohn's disease, 1 had IBD unclassified, and 11 had ulcerative colitis. 23 were on azathioprine, 2 were on mercaptopurine. Mean dose was 131 mg for azathioprine and 75 mg for mercaptopurine. 2 patients had dose splitting to 3 daily doses (morning, lunchtime and evening).
Prior to dose splitting, mean MeMP was 4486 (SD 2462), mean TGN was 233 (SD 72) and mean MeMP:TGN was 19 (SD 8.57).
22 patients were dose split due to hypermethylation of which 2 had hepatotoxicity (defined as elevated alanine transferase >45 IU/L). The remaining 3 were dose split for nausea.
9 patients (36%) were no longer hypermethylators after dose splitting. A further 6 patients (24%) had a reduction in the MeMP:TGN ratio but not to >11. 8 patients (32%) were switched to LDTA. 1 patient had no change in the ratio following dose splitting but did have an improvement in their nausea and so continued on dose splitting. 1 patient paradoxically had a higher ratio after dose splitting, but is asymptomatic and has not been switched to LDTA.
Overall, there was a significant reduction in the mean MeMP and the mean MeMP:TGN ratio after dose splitting (4487 versus 3326 ($P < 0.05$) and 19.0 versus 13.2 ($P = 0.01$) respectively). There was no significant change in mean TGN before and after (233 versus 251).
Patients who had hepatotoxicity had no improvement from dose splitting and all were switched to LDTA. There was no significant relationship between gender and TPMT on reduction in MeMP or success with dose splitting.

**Conclusion:** Dose splitting has been shown to significantly reduce both MeMP and MeMP:TGN ratio avoiding the use of LDTA in some patients. Through dose splitting, it is feasible to alter the biochemistry of thiopurine metabolism to reduce hypermethylation whilst maintaining TGNs within a therapeutic range.

**Disclosure of Interest:** P. Irving: PI has been advisor to, in receipt of educational or research grants from, or invited lecturer for Abbvie, Falk, Ferring, Genetech, Hospira, Merck, Pharmacosmos, Shire, Takeda, Tillotts, Topivert, Vifor and Warner Chilcott.

[3]*Sandoz Biopharmaceuticals, Holzkirchen/Germany*

**Contact E-mail Address:** antonio.dasilva@sandoz.com.

**Introduction:** Biosimilars are biologics that are highly similar to already marketed biopharmaceuticals which have lost exclusivity and aim to offer more affordable treatment. Anti-TNF therapeutic antibodies have been shown to be highly effective and safe for the treatment of immune mediated inflammatory diseases such as psoriasis, Crohn's disease and rheumatoid arthritis. Here we present in-vitro functional characterization data of the proposed adalimumab biosimilar GP2017 and in-vivo assessment of reduction in disease progression in homozygous human TNF (huTNF) transgenic murine models of polyarthritis driven by either soluble or membrane bound TNF. The resolution of inflammation upon multiple treatments was compared to the originator adalimumab. Inflammatory markers spanning from clinical signs to histological readouts and related biomarkers were used as endpoints.

**Aims & Methods:** In vitro functional characterization of GP2017 consisted of a cell-based TNFα neutralization potency assay, assays addressing the binding to TNFα, complement component C1q, FcγR and FcRn, as well as assays measuring antibody-dependent cell-mediated cytotoxicity (ADCC) and complement dependent cytotoxicity (CDC) to assess various mechanisms of action ascribed to adalimumab. Untreated, huTNF transgenic mice started to develop severe inflammation at 3–4 weeks of age. Shortly after the onset of disease, two groups of mice were treated twice weekly, either with GP2017 or the originator adalimumab at an intermediate most sensitive sub-therapeutic dose. Two additional groups of mice treated with either placebo or a maximal saturating effective dose of the originator adalimumab served as controls. All animals were sacrificed 3 days after last treatment for histological analysis of joints. Disease scoring system, swelling of the ankles, hind limb distortion, impaired movement as well as progressive weight loss were used as continuous readouts.

**Results:** High degree of similarity was seen in target binding affinity and functional activity for TNFα, Fc-receptors and C1q binding for both GP2017 and originator adalimumab. Correspondingly, bioassays for TNFα neutralization and for Fc dependent effector functions (ADCC and CDC) demonstrated that GP2017 was similar to the originator adalimumab. Comparable in-vivo PD effects were also demonstrated for GP2017 and the originator adalimumab in

murine models of polyarthritis. Significant efficacy in inhibiting the arthritic pathology as well as the underlying histopathology, was seen with both GP2017 and the originator adalimumab, as compared to placebo treated animals.
**Conclusion:** GP2017 and the originator adalimumab exhibited similar in vitro pharmacology and in vivo efficacy in TNF driven disease models of polyarthritis. In combination with structural and physicochemical characterization and pre-clinical pharmacokinetics and safety, similarity of GP2017 and the originator adalimumab was demonstrated at the nonclinical level. Ongoing clinical trial (s) aim to provide additional confirmatory evidence of similar efficacy and safety of GP2017 compared to the originator adalimumab, further minimizing the remaining residual uncertainty.

**Contact E-mail Address:** markasamaan@gmail.com.
**Introduction:** Vedolizumab, a selective leukocyte adhesion molecule inhibitor, has recently been granted approval for use in moderate-to-severe Crohn's disease (CD) and ulcerative colitis (UC). Novel inflammatory bowel disease (IBD) pathways agreed by our local clinical commissioning group meant that patients at Guy's & St. Thomas' (GSTT) and King's College Hospitals (KCH) had access to vedolizumab from November 2014, prior to NICE approval, which was not granted until June 2015.
**Aims & Methods:** The records of patients with IBD commencing vedolizumab at GSTT and KCH between November 2014 and November 2015 were screened and those completing at least 14 weeks of treatment were included. Outcome assessments were made by retrospective review of prospectively maintained records. Clinical disease activity was assessed using Harvey-Bradshaw Index (HBI) or Simple Clinical Colitis Activity Index (SCCAI) at baseline, 14 and 30 weeks of treatment. Response was defined as HBI/SCCAI reduction $\geq$3. Remission was defined as HBI $<$ 5 or SCCAI $<$ 3. Primary outcome:.
- Change in clinical disease activity Secondary outcomes:.
- Change in biochemical markers of disease activity (CRP and faecal calprotectin).
- Rates of corticosteroid usage and surgery Sixty-two patients received at least one infusion of vedolizumab for CD, UC or IBD-unclassified (IBD-U). Patients who had not completed at least 14 weeks of treatment (n = 5), had missing clinical disease activity data (n = 2) or a stoma (n = 5) were excluded from further analysis. Continuous data are summarised as medians followed by range. Pre- and post-induction values were compared using Wilcoxon signed-rank test.
**Results:** Primary Outcome: Of the 50 patients whose data were analysed, 27 had CD, 20 had UC and 3 had IBD-U (included in the UC group for the purpose of analysis). At baseline visit the median HBI was 8 (1–16) and SCCAI was 6 (0–15). At week 14 these values had fallen to 5 (0–15) (p = 0.117) and 4 (0–10) (p = 0.005), respectively. Additional week 30 data was available for 19 patients (9 CD, 10 UC). The clinical disease activity scores at that point were HBI 2 (0–7) and SCCAI 2 (1–10), reflecting a significant fall from baseline values and remission in both cases (p = 0.039 and p = 0.023, respectively) At baseline, 37 (74%) of the 50 patients had clinically active disease (HBI $\geq$ 5, SCCAI $\geq$ 3). Of the patients with active disease, 22 (59%) responded and 14 (38%) achieved remission. Divided by IBD-subtype, response rates were 12/19 (63%) in CD and 10/18 (55%) in UC. Remission rates were 7/19 (37%) in CD and 7/18 (39%) in UC. Divided by prior anti-TNF exposure, response rates were 5/8 (63%) in anti-TNF naïve and 17/29 (59%) in anti-TNF exposed patients. Corresponding remission rates were 5/8 (63%) and 9/29 (33%), respectively. Of the 13 patients with inactive clinical disease at baseline, 8 (62%) remained in remission at week 14.
Secondary Outcomes: Faecal calprotectin fell significantly, pre-treatment: 1076 (27-4800), post-week 14: 476 (10-3184) (p = 0.010 for n = 18). CRP remained stable, baseline: 4 (1–70), week 14: 4 (1–72) (p = 0.627 for n = 49). Rates of steroid use at each study time point were 24/50 (48%) at baseline, 16/50 (32%) at week 14 and 3/19 (16%) at week 30 (p = 0.008). Surgery was required in 4/50 (8%, 3 CD 1 UC).
**Conclusion:** Our experience mirrors a previously reported 'real-world' cohort[1] and demonstrates similar efficacy to those reported in the GEMINI trial program[2, 3]. This data demonstrates a meaningful reduction in clinical and biochemical disease activity as well as a steroid-sparing effect in patients with complex and previously refractory disease. Outcomes were more favourable amongst anti-TNF naïve patients than those with previous exposure but did not significantly differ between UC and CD.

**Introduction:** Infliximab (IFX) is used less frequently in elderly patients ($\geq$65 years) with moderate-to-severe Crohn's disease (CD) and ulcerative colitis (UC) due to lower efficacy and higher risk of adverse events compared to younger patients (1). The ageing process has been associated with physiological and immunological changes that might influence the pharmacokinetics (PK) of IFX and thereby its efficacy. However, no data are available on the IFX exposure-response relation in elderly patients with inflammatory bowel disease (IBD).

**Table 1:** Infliximab trough concentrations, mean ± standard deviation (number of patients), and patient baseline characteristics in non-elderly and elderly patients with inflammatory bowel disease.

| | Non-elderly | Elderly |
|---|---|---|
| **Trough concentrations (μg/mL)** | | |
| **Week 2** | 25.7 ± 16.0 (n = 51) | 25.6 ± 12.4 (n = 30) |
| **Week 6** | 16.8 ± 11.7 (n = 48) | 19.3 ± 14.3 (n = 26) |
| **Week 14 *** | 5.7 ± 4.8 (n = 42) | 9.5 ± 5.9 (n = 14) |
| **Baseline characteristics** | | |
| **Female, n (%)** | 24 (44) | 19 (63) |
| **Age, median [IQR], years **** | 37 [27–50] | 69 [66–74] |
| **Charlson Comorbidity Index > 0, n (%) *** | 13 (24) | 14 (47) |
| **Disease duration, median [IQR], months** | 59 [21–428] | 101 [32–270] |
| **UC/CD/IBDU, n (%) *** | 16/12/2 (80/20/0) | 43/11/0 (53/40/7) |
| **Albumin < 35 g/L, n (%) **** | 3 (9) | 11 (38) |
| **CRP > 5 mg/L, n (%)** | 29 (54) | 21 (72) |
| **Lean body mass, median [IQR], kg ***** | 52 [46–61] | 46 [40–52] |

* p < .05, ** p < .01, *** p < .001, **** p < .0001. Lean body mass calculated using James formula. Multivariate linear regression withheld age $\geq$65 years as an independent predictor of higher TC at w6 and w14, but not at w2. A serum albumin concentration (SAC) < 35 g/L at w2, w6 and w14 was identified as an independent predictor of a lower TC at the respective time point. The proportion of patients with SAC < 35 g/L at w2 was significantly higher in elderly patients (27%, 7/26) compared to non-elderly patients (4%, 2/50) (p = .006), while at w6 and w14 proportions were similar in both groups. SAC $\geq$ 35 g/L at w2 is associated with clinical response (p = .003) and biological response (p = .02). Elderly patients had a significantly lower lean body mass at w6 (46 ± 1 kg) and w14 (48 ± 2 kg) compared to the non-elderly controls (54 ± 1 kg and 56 ± 1 kg, resp.) (p = .0004 and p = .005, resp.), but when adjusted for the lean body mass, the effect of age on the TC was still significant. Using a drug tolerant assay, 7% of the elderly (1/14) and 17% of the non-elderly (7/41) patients were identified as ATI+ at w14. The proportion of short-term clinical and biological responders to IFX induction therapy was lower among elderly patients (67% and 38%, resp.) compared to non-elderly patients (85% and 71%, resp.) (p = .047 and p = .040, resp.).

**Aims & Methods:** The aim of this retrospective, tertiary single-center case-control study was to analyze the exposure-response relation to IFX during induction therapy in 30 consecutive elderly cases (16 UC, 12 CD, 2 IBD unclassified) and 54 non-elderly controls (43 UC, 11 CD) (controls matched 2:1 to cases for follow-up and disease duration). IFX trough concentrations (TC) were measured

in consecutive trough samples and antibodies towards IFX (ATI) were measured in w14 samples using in-house developed ELISAs. IFX TC and their relation to short-term clinical (based on physician global assessment) and biological response (defined as a CRP $\leq$ 5 mg/L by w14) were evaluated. Patient- and disease-related factors were analyzed in multiple linear regression (backward selection, $\alpha = 5\%$) with TC as dependent variable.
**Results:** Elderly patients did not have significantly different IFX TC at w2 and w6 compared to the respective non-elderly controls (table 1). TC at w14 were significantly higher in elderly patients compared to the non-elderly controls ($p = .02$).
**Conclusion:** Elderly age is independently associated with higher IFX TC, nonetheless, rates of short-term clinical and biological response were lower in the elderly patients.

**Introduction:** The increased use of anti-TNF$\alpha$ antibody in Inflammatory Bowel Disease (IBD) has generated interest regarding adverse events of this relatively new therapeutic option, including the paradoxical triggering of psoriatic skin lesions.
**Aims & Methods:** To determine the prevalence of psoriasis in an IBD cohort with reference to clinical characteristics and anti-TNF$\alpha$ use. Following ethical approval, a survey questionnaire that included demographic and clinical data including age, gender, smoking status, IBD type, diagnosis of psoriasis and anti-TNF$\alpha$ use was devised and posted out to all patients attending the IBD clinic in Tallaght Hospital. Incidence rates of concomitant and reactive psoriasis were calculated and compared using a students T-test. A p value of $<0.05$ was considered significant.
**Results:** In all, 905 questionnaires were posted out, 34% (n = 312) returned, 32% (n = 286) were complete. In all, 58% (n = 166) were female, 36% (n = 103) and 64% (n = 183) had UC and CD respectively, 55% (n = 157) ever smoked, 44% (n = 126) were ever on an anti-TNF$\alpha$ therapy of which 56% (n = 71) had been on Adalimumab (ADA) only, 18% (n = 23) Infliximab (IFX) only, 23% (n = 29) on ADA or IFX, and 2% (n = 3) were exposed to Symponi. In all, 55.3% (n = 57) and 54.6% (n = 100) of the UC and CD cohort smoked. The overall prevalence rate of IBD and psoriasis was 9.4% (n = 27), mean age 48 years (range 33–66) of which 30% (n = 8) had reactive psoriasis, ie psoriasis occurring after commencement anti-TNF$\alpha$ therapy. The mean duration of treatment before onset of reactive psoriasis was 2.6years. The prevalence rate of psoriasis in the non-biologic and biologic cohort was 11.9% (19 of 160) and 6.3% (8 of 126) respectively, p = 0.1, CI = 1.82 to 12.57. There was a similar rate of the overall prevalence of IBD and psoriasis 9.4% (27 of 286) compared to reactive psoriasis 6.3% (8 of 126), p = 0.31, CI = 3.52 to 8.40 in our cohort. Interestingly, all 8 patients who had reactive psoriasis had CD and were female compared to 63% (17 of 27) CD and females in the overall psoriasis group, p = 0.04, CI = 3.93 to 57.59. There was no association between the type of AntiTNF$\alpha$ prescribed with the occurrence of reactive psoriasis 6% (6 of 100) vs. 3.8% (2 of 52) ADA and IFX respectively, Odds Ratio (OR) = 1.5, p = 0.59, 95% CI 0.30 to 8.00 or smoking with any form of psoriasis in IBD, OR = 1.4, p = 0.42, CI = 0.6182 to 3.1560.
**Conclusion:** In our study, there was a similar prevalence rate of reactive psoriasis and background rate of psoriasis in the overall IBD cohort (6.3% vs 9.4%). Our study suggests that the risk factors associated with reactive psoriasis include a diagnosis of CD and female gender. Further work to elucidate the pathophysiology of this phenomenon is required.

**Introduction:** Ulcerative colitis is associated with marked impairments in all aspects of quality of life. Yoga is a mind-body practice which is used for health purposes. Various styles of yoga typically combine physical postures, breathing techniques, and meditation or relaxation.
**Aims & Methods:** Patients with ulcerative colitis in clinically remission (CAI) and impaired quality of life (Inflammatory Bowel Disease Questionnaire [IBDQ] < 170) were randomly assigned to hatha yoga (one weekly session of 90 minutes over 12 weeks) or written lifestyle advice. The primary outcome measure was disease-specific Quality of life (IBDQ). Secondary outcomes included generic quality of life (SF-36), disease ctivity (Clinical Activity Index), anxiety and depression (Hospital Anxiety and Depression Scale), positive and negative affect (Positive and Negative Affect Schedule), perceived stress (Perceived Stress Scale, Perceived Stress Questionnaire), and self-efficacy (General Self-Efficacy Scale), laboratory parameters and fecal inflammation markers (calprotectin, lactoferrin, PMN-elastase). Outcomes were assessed at week 12 and week 24 after randomization by blinded outcome assessors.
**Results:** A total of 77 patients (75% women; 45.5 ± 11.9 years; 13.4 ± 8.8 years since diagnosis; CAI = 2.2 ± 1.5; IBDQ = 144.9 ± 23.4) were randomized to yoga (YG; n = 39) or control (CG; n = 38). After 12 weeks, the yoga group had significantly higher disease-specific quality of life compared to the control group (IBDQ: YG = 158.8 ± 32.2; CG = 147.1 ± 36.0; p = 0.018). Significant group differences were also found for physical quality of life (p = 0.030), anxiety (p = 0.019), depression (p = 0.001), and self-efficacy. All effects were maintained at week 24 (IBDQ: YG = 167.8 ± 29.2; CG = 153.1 ± 35.9; p = 0.022); additionally, significant group differences at week 24 were found for disease activity (p = 0.029), mental quality of life (p = 0.009), positive affect (p = 0.020), perceived stress (p = 0.020), and self-efficacy (p = 0.019).
**Conclusion:** A 12-week yoga intervention improved quality of life and mental health in patients with ulcerative colitis. The effects persisted for at least 3 months after the end of the intervention. Yoga can thus be regarded as a complementary intervention for patients with ulcerative colitis.
**Disclosure of Interest:** J. Langhorst: Research grant: TechLab, Steigerwald, Falk Foundation lecture honorarium: Falk; MSD; Repha; Ardeypharm.

### P0318 A LOW FODMAPS DIET REDUCES FUNCTIONAL SYMPTOMS IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE WITH NO SIGNS OF ACTIVE INFLAMMATION

**A. Testa**[1], A. Rispo[1], M. Rea[1], N. Imperatore[1], O. M. Nardone[1], G. Accarino[2], L. Lucci[2], P. Gervetti[1], N. Caporaso[1], F. Castiglione[1]

**Introduction:** FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides and Polyols) indicate a series of osmotically active and rapidly fermentable compounds that may lead to functional gastrointestinal symptoms (bloating, abdominal pain, wind, diarrhoea). Patients with Inflammatory Bowel Diseases (IBD) can experience functional gastrointestinal symptoms not related to inflammation, but in literature data about the use of low FODMAPs diet in this setting are scarce.
**Aims & Methods:** The aim of our study was to evaluate the usefulness low FODMAPs diet in patients with non active IBD compared to patients with irritable bowel syndrome (IBS). From March 2015 to September 2015 we performed a dietetic interventional prospective study evaluating the effect of a low FODMAPs diet in patients with IBS and IBD with no signs of active inflammation but experiencing apparent functional symptoms (e.g. bloating, diarrhoea, flatulence). The definition of state of remission for IBD subjects was made in accordance with the ECCO guidelines (clinical remission in CD: CDAI < 150; clinical remission in patients in UC: Mayo score < 2). The diagnosis of IBS has made by using the Rome III criteria. Each subject was submitted to a diet low in FODMAPs, after filling out questionnaires on quality of life and symptoms (SF-36 and IBS-SSS). After the administration of the questionnaires, an experienced dietician explained the diet low in FODMAPs to patients. Each regimen was specific for the patient's energy requirement (calculated by BMI) and for its content in FODMAPs, realized in conformity with the food reference tables. The low FODMAPs diet was prescribed for 2–6 weeks, after which a steady re-introduction phase was followed, and closely monitored, until a balance between tolerated doses and symptom control was achieved.
**Results:** The study included 65 patients (22 with IBD and 43 with IBS). The analysis of the IBS-SSS survey showed that functional symptoms improved after 1 month and after 3 months of low FODMAPs diet, both in patients

with IBD and in those with IBS, with no statistically significant difference between the two groups (overall score IBD: 2.01 at T0, 1.23 at T1 and 1.00 at T3 ($p < 0.01$); overall score IBS: 2.37 at T0, 1.43 at T1 and 1.08 at T3 ($p < 0.01$). Furthermore, also by using the SF-36 questionnaire, we did not observe any statistically significant difference between the two groups in terms of response to diet ($p = NS$), even if a trend of clinical improvement was described at 1 month and 3 months after the start of the diet, for all 8 domains of the questionnaire. On the other hand, a statistically significant difference between the two groups was evident before starting the dietary approach. In particular, for some domains (role physical, bodily pain, social functioning, role emotional state), patients with IBD had a significantly greater perception of symptoms compared to patients with IBS. This would reinforce the concept that, in patients with CD or UC in remission, residual symptoms are attributable to the presence of functional disorders, comparable to those of IBS. These symptoms could improve by using a low FODMAPs diet.

**Conclusion:** A low FODMPs diet can improve functional symptoms in patients with IBS and in subjects with IBD that experience symptoms not due to active disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0319 FAECAL MICROBIOTA TRANSPLANTATION (FMT) AS A RESCUE THERAPY FOR STEROID-DEPENDENT AND/OR NON-RESPONSIVE PATIENTS WITH ULCERATIVE COLITIS (UC): A PILOT STUDY

**T. Karakan, M.** Ibiş, Z. Gök Sargın
*Department Of Gastroenterology, Gazi University, Ankara/Turkey*

**Contact E-mail Address:** tkarakan@gmail.com.

**Introduction:** FMT is an experimental method for restoration of dysbiosis in UC. Few studies reported improvement in clinical and endoscopical response. However, route of administration, donor and patient selection, number of FMT sessions and intervals are still obscure. Steroid failure leads the patient to a next step of drugs. Immunomodulatory or biological agents have higher costs and adverse events, potential risks of infection and malignancy. We have analysed the efficacy of rescue FMT for steroid-dependent and/or non-responsive UC patients.

**Aims & Methods:** Fourteen patients with steroid-dependent and/or non-responsive UC were enrolled, and treated with FMT. Follow-up clinical data was collected for at least 3 months (3–18 months). Donors were selected according to Amsterdam Criteria. All patients received FMT after complete colon cleansing via colon. Patient and donor clinical, demographic and laboratory data were recorded.

**Results:** Eleven of fourteen (78.5%) patients achieved clinical improvement and were able to discontinue steroids following rescue FMT. One patient was lost to follow-up. Among the 11 patients who responded, five (45.4%) received one FMT therapy, one (9.0%) received two FMTs, and three (27.2%) received four FMTs, and two (18.1%) received six FMTs. Six (54.5%) of the 11 patients who responded maintained long-term remission during follow-up (3–18 months). Three patients (21.4%) failed to meet the criteria of clinical improvement and maintained steroid dependence, though one patient experienced transient or partial improvement. Eight of 11 responders had the same blood group antigen with the corresponding donor. Patient age ($28 \pm 8$ vs $47 \pm 11$yrs, $p < 0.05$) and disease duration ($6 \pm 3$ vs $35 \pm 12$ months, $p < 0.05$) were also lower in responders. Mean body mass index ($kg/m^2$) increased in all responders (baseline: $23 \pm 3$ vs post-FMT 3 months: $26 \pm 2$, $p < 0.05$). None of the patients experienced major adverse events due to FMT.

**Conclusion:** Rescue FMT shows promise as a therapeutic strategy for patients with steroid-dependent and/or non-responsive UC, likely due to the successful restructuring of gut microbial composition. Blood group antigen-match might be a promising research area such as in other organ transplantations. Post-FMT weight gain might be due to cessation of inflammation or improved dysbiosis. Further studies are urgently needed to clarify predictive factors of success for FMT in this population.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0320 INDIGO NATURALIS ALTERS THE GUT MICROBIAL COMMUNITY AND MODIFIES COURSE OF INFLAMMATION IN THE MOUSE MODEL OF COLITIS

**S. Adachi**[1], N. Hoshi[1], J. Inoue[1], E. Yasutomi[1], D. Watanabe[1], S. Nishiumi[1], K. Yuna[1], H. Yamairi[1], M. Ooi[1], M. Yoshida[1], T. Azuma[1], Z. Wang[2], T. Otsuka[1], R. Dhakhwa[3]

**Contact E-mail Address:** so16@med.kobe-u.ac.jp.

**Introduction:** Indigo Naturalis (IND), also known as 'Qing Dai', is a herbal medicine which has been traditionally used for the treatment of inflammatory lesions including skin rush, psoriasis and ulcerative colitis in China. Especially, the effect on Ulcerative colitis (UC) has been attracting some attention due to some recently reported clinical studies showing good effect of IND on active UC. One showed that clinical response and mucosal healing reached to 72% and 61%, respectively in moderate UC patients, and another showed it helped six of seven patients to reduce and discontinue corticosteroid, which sounds promising. However, the mechanism of action or possible adverse events has not been well studied in the basic research. The aim of study was to investigate the effect of IND for the treatment of colitis and how it works.

**Aims & Methods:** A mouse model of Th2-type colitis, oxazolone (OXA) colitis, was used. OXA colitis was induced in BALB/c mice by rectal injection of 0.5% OXA one week after sensitization of OXA by skin painting. After induction of colitis, mice were fed with 5% IND-mixed chow. The severity of colitis was evaluated by body weight change, colonoscopy scoring, histology of the colonic tissues, and the gene expression levels of inflammatory cytokines in the colon were also tested by real-time PCR. To analyze whether IND can influence the composition of the gut microbiota, fecal samples from IND fed and non-fed colitic mice were collected and they were subjected to the 16 S ribosomal RNA gene sequencing.

**Results:** IND treatment significantly reduced the expression of IL-13, the cytokine shown to induce inflammation in the OXA colitis model, however, the severity of colitis was aggravated along with the upregulation of TNF$\alpha$ in the IND fed mice. We also found that the result of 16 S ribosomal RNA sequencing showed a dramatic change of the composition of gut microbiota in the IND fed mice compared to IND non-fed mice. To test whether this change conferred to the aggravation of colitis, we treated the mice with 4 antibiotics (ampicillin, vancomycin, metronidazole, and neomycin) to deplete the gut microbiota, and then OXA colitis was induced. As we expected, the aggravation of colitis was reversed and the level of colitis became similar between IND fed mice and non-fed control mice.

**Conclusion:** Needless to say, the results of experiments using animal disease model should be carefully interpreted, and obviously, should not be directly applied to human case. Furthermore, the amount of IND given to mice in our study could be too large/small than those optimal doses used for UC treatment. Therefore, further experiments with different doses of IND should be tested. However, the result of our study clearly showed that IND has an ability to change the composition of gut microbiota. With recent reports of fecal microbiota transplant expected to be a new strategy to treat UC patients in the future, it is now widely recognized that gut microbiota plays an important role in the pathogenesis of UC. Our result suggests that IND has a potential to be used for the treatment of UC, or to cause unwanted adverse events through modifying gut microbiota. Further basic research on IND would be required, and clinical trials should be carefully conducted.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Recurrence of Crohn disease (CD) after an ileo-colonic resection is predicted by the severity of endoscopic lesions during the first year after resection, hence guidelines recommend every patient to underwent endoscopy during the first year after surgery. The aim of our study was to describe the management and results of endoscopy after surgery in a population of CD patients between 2007 and 2010.

**Aims & Methods:** PRACTICROHN was a retrospective study that included patients aged ≥18 years-old from 26 Spanish hospitals who underwent CD-related ileocolonic or ileorectal resection with ileocolonicor ileorectal anastomosis between January 2007 and December 2010. Clinical data was retrospectively collected from clinical charts.Categorical variables were compared with the $\chi 2$ test or Fisher'sexact test, Kaplan-Meier method was used to assess time to clinical recurrence and a log-rank test to obtain statistical significance.

**Results:** 314 patients were analyzed (mean age 40 years [SD 13], 48% men). Of these, 52 (16.56%) had suffered previous surgeries. In 143 (46.28%) a colonoscopy was performed during the first year after surgery. In 2007, only 24/75 patients (33%) underwent endoscopy in the first year, while in 2010 endoscopy was performed in 47/79 (59.49%) $p = 0.017$. During first year after surgery, 146 (46.50%) patients presented with endoscopic recurrence without symptoms.

Along the five years follow-up 222 patients underwent colonoscopy. Rutgeerts score was ≥ 2 in 122 patients (54.9%). Rutgeerts score in patients that received prophylactic treatment was significantly lower than in patients without prophylaxis.

**Table**

| | | Prophylactic treatment Yes | No | p |
|---|---|---|---|---|
| Rutgeerts score | 0 | 54 (37.24) | 15 (20.83) | 0.005 |
| | 1i | 18 (12.41) | 11 (15.28) | 0.005 |
| | 2i | 40 (27.59) | 16 (22.22) | 0.005 |
| | 3i | 12 (8.28) | 18 (25.00) | 0.005 |
| | 4i | 21 (14.48) | 12 (16.67) | 0.005 |

**Conclusion:** In the time interval of data collection of the study there was a trend towards performing significantly more endoscopies after surgery in CD patients, as recommended by guidelines. The number of endoscopic recurrence without symptoms in our study reinforces the importance of performing colonoscopies in high risk CD patients. Prophylactic treatment after surgery is associated with lower Rutgeerts score and prevents endoscopic recurrence.

**Introduction:** It has been reported that use of anti-tumor necrosis factor (anti-TNF) agents may be associated with paradoxical dermatologic complications such as psoriasis.
**Aims & Methods:** A cross-sectional nationwide population study was performed by using the Korea National Health Insurance Claim Data. A total of 42, 165 inflammatory bowel disease (IBD) patients consisting of ulcerative colitis (UC) (n = 29, 434) and Crohn's disease (CD) (n = 12, 731) were identified between 2009 and 2013. Among them, those who were treated with any anti-TNFs more than 6 months were 1, 664 (3.9%). Thirty-three IBD patients who had co-existing psoriasis in 2009 were excluded. One-to-five age- and sex-matched controls were randomly sampled to compare incidences of psoriasis, psoriatic arthritis, and palmoplantar pustulosis (PPP) between the patients with and without anti-TNF treatment.
**Results:** Incidence of psoriasis was significantly higher in IBD with anti-TNF group (31/1, 631; 1.90%) compared with IBD without anti-TNF group (64/8, 057; 0.79%) (adjusted odds ratio [aOR] 2.44; 95% confidence interval [CI] 1.58 to 3.76; $p < 0.0001$). Psoriatic arthritis and PPP also showed higher incidence in IBD with anti-TNF group (aOR 1.71; 95% CI 0.86–3.40 and aOR 3.77; 95% CI 1.31–10.90, respectively). In subgroup analyses, aORs for psoriasis by IBD subtype were 2.03 (95% CI 0.78–5.27) in UC and 2.57 (95% CI 1.58–4.18) in CD. aORs for psoriasis by gender were 2.21 (95% CI 1.25 to 3.93) in male and 2.79 (95% CI 1.44 to 5.42) in female. aORs for psoriasis according to age groups were 2.97 (95% CI 1.07 to 8.24) under 20 years old, 2.68 (95% CI 1.57 to 4.56) between 21 to 39, and 1.47 (95% CI 0.48 to 4.51) aged 40 and over, which implies younger IBD patients have a higher risk of anti-TNF-induced psoriasis.
**Conclusion:** The risk of psoriasis is increased by anti-TNF agents in patients with IBD and higher especially in younger patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0323 COMBINATION THERAPY PREDICTS LONG-TERM MUCOSAL HEALING IN MODERATE-TO-SEVERE ULCERATIVE COLITIS TREATED WITH ANTI TNF-A

**D. Pugliese**[1], P. M. Ferraro[2], C. Felice[1], G.L. Rapaccini[1], A. Papa[1], L. Guidi[1], A. Armuzzi[1]

**Introduction:** Mucosal healing (MH) has emerged as an important treatment goal in ulcerative colitis, because can alter the course of the disease. The aim of our study was to evaluate long-term MH of a large cohort of moderately-to severely active ulcerative colitis (UC) patients treated with anti Tumor necrosis factor (TNF)-α and to explore predictors of efficacy thereof.
**Aims & Methods:** We retrospectively collected data on all consecutive outpatients with moderate-to severe UC who started anti TNF-α at our IBD center from January 2008 to June 2015. Associations between clinical and epidemiological characteristics and clinical remission and MH were analyzed with survival regression models and expressed as hazard ratios (HRs) and 95% confidence intervals (CIs). Clinical remission was defined as disappearance of diarrhoea and blood, without corticosteroids for at least 6 months. MH was defined as a Mayo endoscopy subscore of 0 or 1.[a].
**Results:** A total of 160 patients started anti TNF-α during the interval. The mean (SD) age at diagnosis was 39 (14) years and the median duration of disease was 4 years (range 2–9 years). One-hundred and four patients (65%) had pancolitis and 56 (35%) left-sided colitis. Thirty-nine patients (24%) were started on concomitant thiopurines. After a median of 9 months, 108 (68%) patients achieved clinical remission. Duration of disease (HR 0.95, 95% CI 0.90, 1.00) and anti TNF-α dose optimization (HR 0.49, 95% CI 0.26, 0.92) were inversely associated with worse clinical outcome. MH was recorded in 71 patients (55%), after a median time to endoscopy of 27 months (range 22–32). Anti TNF-α combination therapy (HR for monotherapy vs combination therapy 0.16, 95% CI 0.21, 0.87) and clinical remission (HR 0.14, 95% CI 0.07, 0.23) were inversely associated with persistent endoscopic activity.
**Conclusion:** Long-term anti TNF-α treatment is effective in inducing MH in patients with moderate-to-severe UC. Combination therapy led to significantly better MH than anti TNF-α monotherapy.

### P0324 ADSORPTIVE DEPLETION OF MYELOID LINEAGE LEUCOCYTES IN PATIENTS WITH ULCERATIVE COLITIS: BASELINE DEMOGRAPHIC FEATURES OF NON-RESPONDERS AND RESPONDERS TO THIS APHERESIS TREATMENT OPTION

**T. Tanaka**, M. Akagi, H. Goishi, T. Iiboshi, T. Kajihara, T. Miura

**Introduction:** Patients with active inflammatory bowel disease (IBD) have elevated myeloid lineage leucocytes like the CD14 (+) CD16 (+) monocyte phenotype, which is a major source of tumour necrosis factor-α (Belge, et al. *J Immunol* 2002). Hence depletion of myeloid leucocytes by adsorptive granulocyte/monocyte apheresis (GMA) with an Adacolumn is expected to promote remission or at least enhance drug efficacy. However, studies in ulcerative colitis (UC) have reported contrasting efficacy, from an 85% (Suzuki, et al. *Gastroenterology* 2005) to a statistically insignificant level (Sands, et al. *Gastroenterology* 2008). Patients' demographic variables in the aforementioned studies were different.

**Aims & Methods:** In 145 UC patients who had undergone GMA therapy at our institute over the past 10 years, we looked at baseline clinical and endoscopic features of responders and non-responders to GMA. Seventy-three patients were steroid naive, 70 were steroid dependent, and 2 were steroid refractory. Patients had received up to 11 GMA sessions over 10 weeks. At entry and week 12, patients were clinically and endoscopically evaluated, allowing each patient to serve as her or his own control. Clinical activity index (CAI) $\leq 4$ was defined as response to GMA. Biopsies from colonoscopically detectable inflamed mucosa were processed to see the impact of GMA on leucocytes within the mucosa.
**Results:** At baseline, the average CAI was 12.8, range 10–17. Ninety-three patients (64.1%) had responded to GMA, 52 of 73 steroid naïve (71.2%), 40 of 70 steroid dependent (57.1%), and 1 of the 2 steroid refractory cases. On average remission was sustained for 8.6 months in steroid naïve patients and for 10.4 months in steroid dependent cohort. Upon relapse, the majority of patients responded well to a second course of GMA. Over 1200 biopsies were processed. Infiltrating leucocytes were mostly neutrophils and monocytes. There was a marked reduction of infiltrating leucocytes in responders. Patients with extensive deep UC lesions together with loss of the mucosal tissue at the lesions were identified as non-responders. Patients with the first UC episode were identified as the best responders (100%), followed by steroid naive patients. Additionally, a short duration of active UC prior to GMA marked a patient as a likely responder.
**Conclusion:** Depleting elevated myeloid lineage leucocytes was associated with efficacy in UC patients, most notably first episode and steroid naïve cases who attained a favourable future clinical course. Additionally, GMA was more effective if applied immediately after a relapse than after a lag time. In general, GMA is very much favoured by patients for its safety profile and for being a non-drug therapeutic intervention. Patients with extensive deep ulcers, with long duration of UC refractory to multiple pharmacologicals are unlikely to benefit from GMA. In therapeutic settings, knowing baseline features, which may identify responder patients should help to stop futile use of medical resources.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0325 EFFICACY OF TUBERCULOSIS SCREENING IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

**M. Hafi**[1], N. Ben Mustapha[2], M. Amri[1], A. Laabidi[1], M. Serghini[1], M. Fekih[1], J. Boubaker[1], A. Filali[1]

**Contact E-mail Address:** maroua.hafi@gmail.com.
**Introduction:** Inflammatory bowel disease (IBD), by their own impact on the immunity of our patients, malnutrition and increased use of immunosuppressive treatments determine a group at risk of developing active tuberculosis (AT).
**Aims & Methods:** The aim of this study was to report the outcome of the screening of latent tuberculosis and the effectiveness of the latter in the prevention of AT. We collected retrospectively patients' records between January 2010 and December 2014 who underwent a tuberculosis screening including at least one Tuberculin Skin Test (TST), chest radiography (CR) (a CT scan was done when doubt on the CR) with or without a blood test: QuantiFERON®–TB Gold In-Tube test (QTF). This has occurred as part of a pre- therapeutic assessment or systematically. We also studied the appearance of a possible subsequent AT.
**Results:** We have studied 123 cases. They were 70 men and 53 women. Smokers or weaned smokers were a total of 36. The average age was 33.24 years and average BMI 20.9 kg/m$^2$. Diabetics or hypertensives numbered 4 each. 7 patients had an ulcerative colitis (UC) which was a pancolitis in all cases. 116 patients had Crohn's disease (CD). In the 6 months before screening tests: 25% of patients were under salicylates, 40.8% under corticosteroids, 44.16% azathioprine (AZA) and 10% under anti-TNF alpha. Patients were in flair-up at screening test in 67.5% of cases, it was a severe one in 36.6% of cases. Biology at the time of the tests: average CRP 71.82 mg / L, an average of 28.8 g/l albumin and hemoglobin average of 10.35 mg / dl. All patients had a TST and a CR, 99 of them (80.4%) had a QTF. 9 had a positive TST, 3 a positive CR and 7 a positive QTF. 4 patients had indeterminate QTF, they were all in severe flares of their disease, and were all under azathioprine, two under AZA and steroids. Chemoprophylaxis was prescribed in all 4 cases. No cases of AT were noted. As for the anti- tubercular chemoprophylaxis, 27 patients (22%) have benefited of it: 13 for a positive test (latent TB), 7 for an immunosuppression (drug-induced) and 7 for malnutrition (low BMI –biological findings).

AT cases under immunosuppressive therapy

| | |
|---|---|
| Number | 5 (4.1%) |
| Received treatment before AT | 3: ATF / 2: ATF + AZA |
| Average time to AT | 7 months |
| localization | 3 pulmonary-1 ganglionic-1 péritoneal |
| Positive screening | All negative including QTF. |
| Chemoprophylaxis | prescribed in 3 cases for malnutrition |

**Conclusion:** Despite pretreatment comprehensive assessment including TST, CR and QTF. And despite a relative wide prescription of anti- tubercular chemoprophylaxis, 4.1% of our patients developed active tuberculosis undergoing immunosuppressant treatment. This pre- therapeutic assessment is certainly necessary, especially in an endemic country like ours, but is still of limited effectiveness since all our patients who developed tuberculosis reactivation had a negative screening.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0326 EXCLUSIVE ENTERAL NUTRITION IN ADULTS WITH ACTIVE CROHN'S DISEASE IS ASSOCIATED WITH DEACRSE IN DISEASE ACTIVETY

**T. Pfeffer-Gik**, H. Yanai, L. Godny, Y. Ron, N. Maharshak, I. Dotan
*Inflammatory Bowel Disease Center, Department Of Gastroenterology And Liver Diseases, Tel Aviv-Sourasky Medical Center, Tel Aviv/Israel*

**Contact E-mail Address:** tamar.pg10@gmail.com.
**Introduction:** Exclusive Enteral Nutrition (EEN) for 8–12 weeks induces clinical remission in $\sim 70\%$ in children and adolescents with active Crohn's disease (CD), and is considered comparable to steroids. Nonetheless, in adults EEN has not gained acceptance. We aimed to evaluate the impact of EEN in adult patients with active CD.
**Aims & Methods:** Patients with active CD referred for nutritional intervention with EEN in a tertiary inflammatory bowel disease (IBD) center were enrolled. All patients were assessed by the centers' gastroenterologists and nutritionist. Baseline metabolic status, weight and nutritional needs were evaluated. EEN was administered either as a polymeric or a hydrolyzed formula. Patients were treated for at least three weeks and were tightly followed by the nutritionist. Physician's Global assessment (PGA), Harvey Bradshaw Index (HBI), biomarkers (blood count, C-reactive protein [CRP], albumin), weight, and body mass index (BMI) were measured and recorded at baseline and at the end of EEN treatment.
**Results:** A total of 25 patients with active CD started EEN. Demographics: The mean age was $31.7 \pm 9.4$ years; Male/female ratio 9/16. Average BMI $21.8 \pm 4.1$ kg/m$^2$; median disease duration 9.5 (IQR 1-22) years. Ten patients (40%) had newly diagnosed CD (range 3–18 months). Location: L1 (ileal)- 10/25 (40%), L3 (ileocolonic)-13/25 (52%); Behaviour: B2 (stricturing) -9/25 (36%), B3 (penetrating)- 5/25 (20%); P (perianaldisease)- 7/25 (28%). Baseline disease activity: PGA – mild-5, –moderate-13, and severe-7; mean HBI $6.95 \pm 5.3$ points; median CRP 1.75 mg/dl (IQR 1.0–3.8), and mean albumin $3.86 \pm 0.5$ mg/l. Twelve patients (48%) were on stable doses of biologics, thiopurines, corticosteroids or mesalamine, and four (16%) were treated with EEN only. Mean EEN duration was 5.75 weeks (range 3–16). PGA improved in 19/20 patients. Baseline vs. end of EEN outcomes: HBI $6.75 \pm 5.5$ vs. $2.75 \pm 3.4$ points ($p = 0.001$); median CRP 1.75 (IQR 1.0–3.8) vs. 0.53 (IQR 0.4–0.93) mg/dl ($p = 0.001$);mean albumin $3.9 \pm 0.52$ vs. $4.3 \pm 1.2$ mg/l ($p = 0.001$). No significant change in weight and BMI was observed. The improvement in most activity measures was noticed in patients with newly diagnosed, as well as long standing disease: HBI drop-$5.1 \pm 4.2$ to $1.5 \pm 1.4$ points ($p = 0.06$) and $7.8 \pm 6.2$ to $3.5 \pm 4.1$ points ($p = 0.004$), respectively; median CRP decrease-2.5 (IQR 0.8–4.8) to 0.45 (IQR 0.22–0.65) mg/dl ($p = 0.08$) and 1.5 (IQR 1.3–2.9) to 0.61 (IQR 0.5–1.1) mg/dl ($p = 0.005$), respectively; mean albumin increase - $4.1 \pm 0.5$ to $4.5 \pm 0$ mg/l ($p < 0.001$) and $3.8 \pm 0.53$ to $4.22 \pm 0.27$ mg/l ($p = 0.027$), respectively.
**Conclusion:** EEN is an effective therapeutic modality for active CD in adults. EEN therapy is associated with decreased clinical and biologic inflammatory activity, and may benefit patients with longstanding and newly diagnosed CD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0327 COST PER CLINICAL OUTCOMES WITH VEDOLIZUMAB FOR THE TREATMENT OF MODERATELY TO SEVERELY ACTIVE ULCERATIVE COLITIS IN BRAZIL

**T. Decimoni**[1], G. Muricy[1], H. Patel[2], D. Demuth[3]
[1]*Takeda Pharmaceuticals International. Inc., São Paulo/Brazil*

**Contact E-mail Address:** tassia.decimoni@takeda.com.
**Introduction:** Ulcerative colitis (UC) is a chronic condition associated with significant clinical and economic burden. Anti-tumour necrosis factor (anti-TNF) therapy has been shown to be effective in patients with UC refractory to conventional treatments. Recent research advances have led to the development of selective biologics targeting the gastrointestinal tract, such as vedolizumab (VDZ).
**Aims & Methods:** The aim of the study was to compare the cost per clinical outcomes of VDZ against infliximab (IFX) and adalimumab (ADA) for the treatment of anti-TNF-naive and anti-TNF-experienced patients with moderately to severely active UC from a private health care system perspective in Brazil. A systematic literature review identified randomized controlled trials (RCTs) for approved biologics up to February 2014. Outcomes of interest included sustained response and remission defined according to the Mayo score at 52 weeks, as reported in the individual RCTs. The treatment effect or the odds ratios with different biologics relative to placebo were estimated using Bayesian meta-analyses and were transformed into number-needed-to-treat (NNT) using the average placebo results across all trials. For the cost per outcomes analyses, it was assumed that responders to induction treatment with ADA and VDZ continued with maintenance treatment at 8 and 14 weeks respectively, based on the approved UC indication. For IFX, it was assumed that in the absence of response at 8 weeks, treatment was discontinued in line with RCT design. The time horizon was 52 weeks and no discounting was applied. Therapy costs, reported as Brazilian Real (R$), were calculated based on approved dose and frequency of administration; prices were obtained from the Brazilian official price list on 22 February 2016.
**Results:** At 52 weeks, the NNT and the cost per patient with sustained response and remission for anti-TNF-naive patients was estimated to be the lowest for VDZ versus IFX and ADA (Table 1). Among anti-TNF-experienced patients, the NNT for sustained response for VDZ and ADA was 5.1 (95% Confidence interval [CI]: 2.5–15.8) and 13.5 (4.9–80.9), respectively; and for sustained

**P0327: Table 1:** Number needed-to-treat (NNT) and cost per clinical outcomes of biologics among anti-TNF naive patients with UC.

| | Probability of induction response | | Probability of sustained response at 52 weeks | | NNT for sustained response at 52 weeks | | Cost (R$) per sustained responder at 52 weeks | |

[1]infliximab 5 mg/kg induction treatment (week 0, 2, and 6) followed by every 8 weeks as maintenance treatment; [2]adalimumab 160 mg at week 0, 80 mg at week 2 for induction treatment followed by 40 mg every other week as maintenance treatment; [3]vedolizumab 300 mg induction treatment (week 0, 2, and 6) followed by every 8 weeks as maintenance treatment. Abbreviation: mg – milligrams; kg – kilograms; CI – Confidence intervals; NNT – Number needed-to-treat.

remission was 12.0 (4.8–44.5) and 39.2 (10.9- 283.1), respectively. The cost per sustained response for anti-TNF-experienced patients was lower with VDZ (R$ 322, 882; 95% CI: 160, 901-1, 002, 376) versus ADA (R$ 663, 415; 243, 006-3, 983, 940). Similarly, the cost per patient with sustained remission was R$ 760, 358 (95% CI: 302, 364-2, 826, 726) with VDZ and R$ 1, 928, 682 (95% CI: 537, 824-13, 943, 050) with ADA.

**Conclusion:** Compared to anti-TNF therapies, VDZ had the lowest NNT and cost per outcome, for both sustained response and remission at 52 weeks, among anti-TNF-naive and anti-TNF-experienced populations. The findings suggest VDZ potentially provides better clinical and economic value relative to anti-TNFs approved for the treatment of patients with moderately to severely active UC in Brazil.

## P0328 DOSE ESCALATION OF BIOLOGICS IN CROHN'S DISEASE: CRITICAL REVIEW OF OBSERVATIONAL STUDIES

**X. Y. Lee**[1], F. Lelli[2], B. Bereza[3], T. Einarson[3]
[1]*Emea Health Economics, Market Access And Reimbursement, Janssen-Cilag A/S, Birkerod/Denmark*

[3]*Leslie Dan Faculty Of Pharmacy, University of Toronto, Toronto/Canada*

**Contact E-mail Address:** lying3@ITS.JNJ.com.

**Introduction:** Biologics used to treat Crohn's disease (CD) may lose their effect over time, requiring dose escalation. While little information is available from randomized controlled trials, observational studies provide more evidence.

**Aims & Methods:** The aim was to summarize rates of dose escalation, its duration, responses and subsequent de-escalation in observational studies of CD in adults treated with adalimumab, infliximab, and vedolizumab in Europe. Two independent investigators conducted a systematic review, searching Medline and Embase for observational studies published 1998–2015 and proceedings from 4 major scientific meetings, including United European Gastroenterology Week, Digestive Disease Week, American College of Gastroenterology, European Crohn's and Colitis Organisation. Rates were summarized descriptively.

**Results:** In total, 62 articles from 12 European countries were analyzed (51 full articles and 11 abstracts), providing data from 8567 patients of whom 57% were females and 43% males. Thirty seven papers reported on 3899 patients with adalimumab and 34 papers on 4668 patients with infliximab. The male:female ratio was similar between drugs. No papers were located for vedolizumab. Overall, 28.4% (SD = 2.5%) of patients required dose escalation, including 30.2% (SD = 4.5%) with adalimumab and 26.0% (SD = 2.5%) with infliximab (P = 0.74). Rates increased according to line of treatment: 19% for first line, 37% second and 46% third. The median time to loss of response was 7 months; the weighted average time was 6.5 months. Average time to escalation was 6.6 (SD = 4.1) months; 6.5 months for adalimumab and 6.7 for infliximab (P = 0.497). Short-term response rates to escalation were 54% for adalimumab and 45% for infliximab (P = 0.97). Short-term remission rates were 53% for adalimumab and 49% for infliximab. Approximately 38% of patients were de-escalated. Few long-term data were available for analysis. Risk factors for loss of response included smoking, extensive resections and family history of inflammatory bowel disease. The risk was lower in TNF-naïve patients and in those receiving immunomodulators such as azathioprine. Other risk factors identified as associated with dose escalation were perianal disease, prior anti-TNF treatment, higher BMI, higher baseline CDAI, and stopping azathioprine.

**Conclusion:** A substantial proportion of patients receiving adalimumab or infliximab for Crohn's disease require dose escalation after a short period of time. Effective alternatives appear to be needed, especially for those who lose response and/or do not regain remission after escalation.

**Disclosure of Interest:** X.Y. Lee: I am an employee of Janssen.

F. Lelli: I am employee of Janssen.

B. Bereza: I received funding from Janssen to undertake this research.

T. Einarson: Sponsored by Janssen. I received a consulting fee for this project.

## P0329 SELECTIVE GRANULOCYTE AND MONOCYTE APHERESIS IS EFFECTIVE AND SAFE IN GERIATRIC PATIENTS WITH ULCERATIVE COLITIS

**A. Ito**[1], B. Iizuka[2], O. Teppei[1], H. Kashiwagi[1], K. Tokushige[1], T. Hara[2]
[1]*Dept. Medicine, Inst. Gastroentelorgy, Tokyou Womens Medical University, Tokyo/Japan*

**Contact E-mail Address:** itoayumi@ige.twmu.ac.jp.

**Introduction:** Recently, the number of elderly patients with ulcerative colitis (UC) has increased in line with an increase in the number of patients developing UC. Additionally, treatment of elderly UC patients with conventional drugs, like salicylates, thiopurines, corticosteroids, or anti-cytokine biologics demands serious considerations of patients overall well-being, as immunosuppression may predispose to infection and other adverse effects. Granulocyte and monocyte apheresis (GMA) with an Adacolumn, if effective should be the treatment of choice in the elderly.

**Aims & Methods:** We were interested to evaluate efficacy and safety of the Adacolumn GMA in a geriatric setting. We retrospectively reviewed elderly and routine patients with moderate to severe UC, in whom remission was induced by GMA between April 2000 and January 2016. Any patient aged 65 years or more was regarded as an elderly, otherwise, he or she was classified as a routine patient. Of 95 patients who underwent GMA therapy in our hospital, 80 were eligible for inclusion, excluding those who had received GMA in combination with tacrolimus, prednisolone (PSL) or biologics. Lichtiger's clinical activity index (CAI) $\leq$4 meant clinical remission. To better understand the background factors, which potentially were associated with the response to GMA, we looked at gender, age at onset, duration of UC, UC location, baseline CAI, haemoglobin, albumin, C-reactive protein (CRP), estimated glomerular filtration rate (eGFR), Mayo endoscopic score and UCEIS, past PSL dose, presence of an underlying disease, drug-related complications.

**Results:** Clinical remission was achieved in 67 of the 80 patients, 78% for the geriatric group and an 85% for the routine group. Between the two groups, there were significant differences in the age at UC onset, UC duration, baseline CRP, eGFR, underlying disease, and PSL-related complications ($P < 0.05$). GMA-related transient headache was reported by 1 patient in each group, transient reduction in blood pressure and blood access failure were noted in 1 and 2 patients respectively in the elderly group, and heparin allergy in 1 patient in the routine group.

**Conclusion:** The clinical efficacy rates we achieved in these patients are very much higher than hitherto reported for GMA in UC patients, but very close to the published efficacy rates in steroid naïve patients. However, in the geriatric UC setting, drug therapy is more likely to cause adverse side effects as additional morbidity factors than in young patients. GMA monotherapy, as a non-pharmacological intervention appeared to be effective with good safety profile in all patients; a relevant option in geriatric setting.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

[3]*Department Of Surgery, University of Szeged, Szeged/Hungary*

**Contact E-mail Address:** milagn422@hotmail.com.
**Introduction:** Surgery is not curative in Crohn's disease (CD), hence postoperative recurrence still remains significant problem. Currently conflicting data are available about the role of the clinical and the histological findings in CD postoperative relapse. However according to the latest data, presence of submucosal or myenteric plexitis can be predictive for postoperative relapse. We evaluated the frequency and predictors of postoperative recurrence and the role of the presence of submucosal and myenteric plexitis in predicting postoperative recurrence on the basis of endoscopic findings and/or the need for additional surgical resection.
**Aims & Methods:** Data from all patients who underwent CD-related resection at the University of Szeged, Hungary between 2004 and 2014 were analysed retrospectively. Demographic data, smoking habits, previous resection, treatment before and after the surgery, resection margins, neural fibre hyperplasia, submucosal and myenteric plexitis were evaluated as possible predictors on postoperative recurrence. Patients were controlled by colonoscopy regularly after surgery. Postoperative recurrence was defined on the basis of the endoscopic findings and/or the need of additional surgical resection.
**Results:** One hundred and four patients were included in the study. Ileocecal, colonic and small bowel resection were performed in 66.3%, 30.7% and 3% of the cases. Mean disease duration at the time of surgery was 6.25 years. Twenty-six patients underwent previous CD-related surgery. 43.2% of the patients was on 5-aminosalicylate, 20% on corticosteroid, 68.3% on immunomodulant and 4% on anti TNF-alpha postoperative treatment. Postoperative recurrence occurred in 63.5% of the patients, from them 92% relapsed within 5 years after the resection and second surgery was needed in 38% of the cases. Mean disease duration for endoscopic relapse was 2.19 years. The severity of submucosus plexitis was a predictor for the need of second surgery. Predictors for postoperative recurrence were also female gender (OR = 2.21, 95% CI 0.2–1.02, p = 0.056), penetrating disease behaviour (OR = 9.09, 95% CI 0.01–1.09, p = 0.06) and isolated ileal localisation (OR = 6.41, 95% CI 0.024–1.0, p = 0.05). No association was revealed between postoperative recurrence and smoking status, postoperative prophylactic treatment and the presence of myenteric plexitis and relapse.
**Conclusion:** Severity of submucosus plexitis, penetrating behaviour and isolated ileal localisation proved to be predictors of postoperative recurrence of CD. Our results did not confirm the hypothesis about the predictive role of myenteric plexitis in postoperative relapse.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0331 RELATED RISK FACTORS ASSOCIATED WITH STEROID RESISTANCE IN AN IRISH IBD POPULATION

**M. Hussey**[1], G. Holleran[2], D. Keating[3], S. Whelan[3], P. Devitt[3], J. Healy[3], B. Ryan[4], D. Mcnamara[1]

**Contact E-mail Address:** mhussey@tcd.ie.
**Introduction:** Glucocorticoids (GCS) remain the gold standard for treating an acute flare of IBD & response rates are often unpredictable. Resistance rates have been estimated to range from 20–30%, however related or predictive factors associated with GCS resistance remain uncertain.
**Aims & Methods:** To estimate local steroid resistance rates amongst an Irish IBD cohort & to identify related risk factors driving resistance. **Methods:** A retrospective review of patients from HIPE data requiring hospitalisation for an acute flare of colitis from 2010–2015 was undertaken. Demographics & clinical details including phenotype, behaviour, severity, duration, therapies, CRP, rates of hypoalbuminaemia (albumin < 35 g/dl), rates of anaemia (hb < 10.5 g/l), length of stay (LOS) were all recorded. Resistance rates were determined by a lack of improvement or deterioration in day 3 CRP or a need for therapy escalation or surgery. Steroid dependence was defined as a relapse of symptoms within 3 months of stopping IV GCS. Results were compared amongst responders & non-responders using a student t-test and p value of $<0.05$ was considered significant.
**Results:** In all 473 patients requiring hospitalisation for acute colitis were identified, of which we have analysed data on 247 patients to date. A total of 74 (29%) of the 247 patients were excluded due to insufficient information. Of the remaining 173, 99 (57%) were female, mean age was 39yrs (range15–84yrs), mean disease duration was 4.5yrs (range 0–27yrs). There were statistically more patients with Crohn's disease (CD) 98 (57%) than UC 75 (43%), p = 0.009, 95% CI 0.03 to 0.24. In all 52 (30%) had severe, 87 moderate (50%), 36 mild (20%) disease. Overall the mean LOS was 10 days (range 3–49) and admission CRP 59 mg/l (range 1–307.9 mg/l). Mean day 3 CRP was 25 mg/l (range 1–260 mg/l). In all, 103 (60%) were responders, 55 (31%) were steroid resistant & 15 (9%) were steroid dependent. Overall resistant patients had more severe disease vs. responders 25 (45%) vs. 17 (17%), $p < 0.0001$, OR 4.2, 95% CI 2.00 to 8.86. Mean CRP on day 3 for responders and non-responders was 10 mg/l vs. 48 mg/l. CRP > 45 mg/l on day 3 appeared to be predictive of steroid resistance, OR 20.6, 95% CI 5.78–73.37, $p < 0.001$. Overall resistant patients had higher rates of anaemia (24%, n = 13, vs 13%, 13) and hypoalbuminaemia (29%, n = 16 vs. 23%, n = 24) on admission and on day 3 of admission ((36%, n = 20 vs 19%, n = 20 and 55%, n = 30 vs. 34%, n = 35 respectively), however day 3 hb (OR 0.42, $p \leq 0.02$ 95% CI 0.2–0.9)) and albumin (OR 0.42, $p \leq 0.01$, 95% CI 0.2–0.8) appeared to be predictive of response. Overall disease subtype, concomitant therapies or disease extent did not appear to influence resistance rates, however amongst UC patients pancolitic patients had higher resistance rates, n = 21 (28%) vs. n = 8 (7%), $p < 0.0001$, 95%CI 0.18–0.42. In all 44 (80%) of the resistant patients required surgical intervention, of which 13 (30%) had failed rescue biologic therapy.
**Conclusion:** GCS resistance rates in our cohort are similar to previously published figures and significant at 31%. A high CRP, anaemia, hypoalbuminaemia on day 3 as well as severe disease & pancolitis are predictive of GCS resistance. Further work on mechanisms of steroid resistance is needed as most required surgery and did not respond to a biologic.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0332 THE INCIDENCE OF SUBOPTIMAL THERAPY AFTER INITIATING A SECOND TUMOUR NECROSIS FACTOR ANTAGONIST IN PATIENTS WITH CROHN'S DISEASE: A MULTI-COUNTRY CHART REVIEW

**Introduction:**Patients with Crohn's disease (CD) treated with tumour necrosis factor antagonists (anti-TNF) may require treatment modifications (i.e., dose escalation, switch to another anti-TNF, surgery, or addition of other medications). Such changes can be used as surrogate of loss of response and may be considered as indicators of suboptimal therapy.
**Aims & Methods:** Our aim was to evaluate the incidence of indicators of suboptimal therapy among adult patients with CD treated with a second anti-TNF using data from real-world clinical practices. A retrospective chart review study conducted in six countries (Canada, France, Germany, Italy, UK, and Spain) recruited CD patients initiating anti-TNF therapy between June 2009-2011. We measured the incidence of suboptimal therapy over two years and time to the first indicator of suboptimal therapy among patients who switched from initial anti-TNF to a second anti-TNF. Indicators of suboptimal therapy with a second anti-TNF included anti-TNF dose escalation (assessed >4 months after index to allow for initial dose optimization), augmentation with aminosalicylates, immunomodulators, or corticosteroids, discontinuation of anti-TNF therapy, switching to another anti-TNF, and CD-related surgery. Time to the first occurrence of the indicator of suboptimal therapy was measured using the Kaplan-Meier Method, where patients were censored after discontinuation of therapy or at the end of the follow-up period.
**Results:** The study included a total of 657 anti-TNF naÿve CD patients of which 174 (26.5%) initiated a second anti-TNF during follow up [mean age (SD): 38.8 (13.3) years, 37.9% females]. Median duration of CD was 7.7 years and with first anti-TNF therapy was 12.3 months. Among patients with reported physician global assessment score (n = 123), 76.4% had moderate to severe CD. 70.1% of patients had an ongoing treatment with at least one non-biologic therapy at the time of initiation of the second anti-TNF therapy. The percentage of patients on adalimumab and infliximab as the second anti-TNF therapy was 63.2% and 36.8% respectively. Fifty-six percent of patients had at least one indicator of suboptimal therapy within two years after initiating a second anti-TNF therapy. Discontinuation (29.9%), dose escalation (16.7%) and augmentation (16.7%) were the most frequently reported indicators of suboptimal therapy. Median time to at least one of the indicators of suboptimal therapy was 13.0 months (95% CI: 10.1 - 19.8).
**Conclusion:** Over half of CD patients treated with a second anti-TNF therapy experienced at least one indicator of suboptimal therapy within 2 years of therapy. The most common indicators were discontinuation and dose escalation with anti-TNFs and augmentation with non-biologic therapies. Future research should determine the potential for alternative therapies to improve treatment response rates among patients who experience loss of response with anti-TNF therapies.

## P0333 REAL-WORLD CHARACTERISTICS OF THE FIRST USERS OF VEDOLIZUMAB IN INFLAMMATORY BOWEL DISEASE PATIENTS IN ISRAEL

C. Weil[1], G. Chodick[2], A. Yarden[3], K. Minda[4], **J.M. Khalid**[5], V. Shalev[2]
[1]*Epidemiology, Maccabi Healthcare Services, Tel Aviv/Israel*
[2]*Sackler Faculty Of Medicine, Tel Aviv University, Tel Aviv/Israel*
[3]*Takeda Pharmaceuticals Israel, Tel Aviv/Israel*
[4]*Takeda Pharmaceuticals International AG, Zurich/Switzerland*
[5]*Global Outcomes Research, Takeda Development Centre Europe Ltd, London/United Kingdom*

**Contact E-mail Address:** mona.khalid@takeda.com.
**Introduction:** To describe the real-world characteristics of patients with moderately to severely active ulcerative colitis (UC) or Crohn's disease (CD) who initiated vedolizumab (VDZ) in Israel in 2015.
**Aims & Methods:** A retrospective cohort study was performed using the computerized databases of Maccabi Healthcare Services (MHS), a 2-million-member healthcare maintenance organization representing 25% of the Israeli population. Patients with at least one dispensed prescription of VDZ in the year 2015 were included. They were classified as having UC or CD based on the last gastroenterologist diagnosis prior to treatment initiation (index). Socio-demographic and clinical characteristics were described at index, including a Deyo-Charlson comorbidity index (CCI) augmented with the MHS chronic disease registries. Baseline annual healthcare resource utilization was measured by physician visits, hospitalization and laboratory data.
**Results:** In 2015, a total of 95 patients with UC (n = 37, 39%) or CD (n = 58, 61%) initiated VDZ. The mean age (SD) of UC (56% female) and CD patients (55.2% female) was 37.0 (16.1) and 36.3 (15.1) years, respectively. The median (IQR) disease duration before VDZ initiation was 6.0 (10.1) and 9.1 (7.3) years for UC or CD patients, respectively. Among recently diagnosed (2010–2015) VDZ initiators, over two-thirds had started their initial UC or CD treatment with 5-aminosalycylates (5-ASA) and 85% were experienced with other biological therapies. Overall, a third of patients were overweight or obese and 6.3% were diabetic. The mean (SD) CCI was 0.92 (1.19) and 0.84 (1.18) for UC and CD patients, respectively. In the year prior to VDZ initiation, 30% of patients had seen a gastroenterologist more than 4 times and 38% had been hospitalized.
**Conclusion:** In the first year of licensure in Israel, results indicate that uptake of VDZ was amongst primarily anti-TNF experienced patients experiencing significant health care resource utilization. Real-world evidence on patient characteristics will inform planned studies of treatment patterns and outcomes of VDZ treatment, including longer-term comparative effectiveness and safety studies to allow assessment of appropriate place of VDZ in therapy.

## P0334 POOR TOLERABILITY PROFILE OF THIOPURINES IN INFLAMMATORY BOWEL DISEASE: A PROSPECTIVE SINGLE-CENTRE EXPERIENCE

**F.S. Macaluso**[1], M. Maida[2], S. Renna[1], M. Dimarco[1], C. Sapienza[1], M. Affronti[1], E. Orlando[1], G. Rizzuto[1], R. Orlando[1], M. Cottone[1], A. Orlando[1]
[1]*Di.bi.m.i.s., Division Of Internal Medicine, "Villa Sofia-cervello" Hospital, University of Palermo, Palermo/Italy*
[2]*Gastroenterology And Endoscopy Unit, Villa Sofia-Cervello" Hospital, Palermo, Italy, Palermo/Italy*

**Contact E-mail Address:** fsmacaluso@gmail.com.
**Introduction:** In inflammatory bowel disease (IBD) treated with thiopurines, the occurrence of adverse events (AEs) leading to discontinuation of the drug is reported in 10% to 28% of patients. However, the majority of the studies on this topic were retrospective and primarily designed to assess efficacy of thiopurines, but not safety.
**Aims & Methods:** The aim of this study was to evaluate thiopurine tolerability in patients with IBD in a real-life setting, and the factors associated with the occurrence of AEs leading to treatment withdrawal. This study was conducted at the Division of Internal Medicine of "Villa Sofia-Cervello Hospital", Palermo, a tertiary referral centre for IBD. Data collection was performed as part of a post-marketing surveillance project on the AEs of immunosuppressants and biologics granted by the Italian Medicines Agency (AIFA). All consecutive patients who started a treatment with azathioprine (AZA) from January 2010 to March 2016 were entered in a prospectively maintained database. All AEs which led to the permanent discontinuation of the drug were reported. Switch to 6-mercaptopurine (6-MP) and its related outcomes were also recorded. All variables at baseline were assessed at univariate analysis in order to identify predictive factors of AEs.
**Results:** 253 patients were included. Mean age was 40.4 years, the majority of patients were males (60.1%) and affected by Crohn's Disease (64.4%). The median total follow-up was 32 months (range: 0.2–75 months). At the end of the study, AZA was discontinued in 160 patients (63.2%). The main reason leading to drug withdrawal was the occurrence of AEs (109/160 patients [68.1%]; cumulative incidence among the entire cohort: 43.1%); in 47/160 patients (29.4%), AZA was stopped due to inefficacy, and in 3/160 patients (1.9%) after a sustained clinical remission. In two patients, discontinuation of therapy was arbitrary. Overall, the most frequent AEs leading to treatment withdrawal were nausea and/or vomit (31/253 patients, 12.3%) and subjective symptoms, i.e. nonspecific and poorly defined side effects such as fatigue, headache, and muscle pain (20/253 patients, 7.9%) (Table 1). Among the 109 patients who discontinued AZA due to AEs, an attempt to restart a thiopurine-based treatment using 6-MP was performed in 44 cases (40.4%). At the end of the follow-up, 6-MP was discontinued in 35/44 patients (79.5%), mostly due to AEs (29/35 patients, 82.8%), which were the same of those reported during treatment with AZA in nearly half of the cases. At univariate analysis, AZA-induced hepatic and pancreatic toxicity were associated with male gender ($p = 0.01$, and $p = 0.03$, respectively), occurrence of nausea with Crohn's disease ($p = 0.04$), and the concomitant use of proton pump inhibitors with the absence of development of subjective symptoms ($p = 0.04$).

| Adverse event | Cumulative Incidence, n (%) |
|---|---|
| Nausea Subjective symptoms Hepatotoxicity Pancreatic toxicity Flu-Like syndrome Leucopenia Cutaneous reactions Bone marrow failure Infections Cancer | 31 (12.3%) 20 (7.9%) 14 (5.5%) 13 (5.1%) 12 (4.7%) 6 (2.4%) 6 (2.4%) 4 (1.4%) 2 (0.8%) 1 (0.4%) |
| **Total** | **109/253 (43.1%)** |

**Conclusion:** In a real-life setting, the tolerability profile of thiopurines is poor, with a very high rate of discontinuation of therapy due to AEs.
**Disclosure of Interest:** A. Orlando: served as an advisory board member for AbbVie, MSD, Takeda Pharmaceuticals and received lecture grants for AbbVie, MSD, Sofar, Chiesi, and Takeda Pharmaceuticals.

**Contact E-mail Address:** eugenidomenech@gmail.com.
**Introduction:** Cytomegalovirus (CMV) reactivation in the colon has been involved in steroid refractoriness in patients with ulcerative colitis (UC). Its diagnosis is based on the detection of CMV by means of specific immunohistochemistry (IHC) or PCR on rectal biopsies. Although the benefit of antiviral therapy in this clinical setting is still under debate, a threshold of CMV copies by PCR has been associated with a poorer outcome.
**Aims & Methods: Aim:** To assess whether the intensity of CMV reactivation measured by the number of positive cells by IHC, is associated with the short-term prognosis in these patients. **Methods:** UC patients with IHC-CMV+ were identified in three different hospitals. The biopsies were reviewed by expert pathologist and the maximum number of cell IHQ-CMV+ in each biopsy sample was determined. Baseline and evolutive clinical variables were recorded.
**Results:** We included 48 patients, with a median age of 40 years (IQR 32-55). 67% had extensive UC, 25% presented severe activity and the median time of UC duration at the index flare was 26 months (IQR 2-73). At the moment of

**P0337: Table 1:** Characteristics of patients presenting with LGIB.

| **Mortality** (Missing data) | 51 (2.2) 34 | 33 (17.9) 1 | 85 (3.4) 36 |

§Includes 12 patients classified as 'other' and 2 with missing data. *On admission or first set of observations after developing LGIB. Shock defined as HR ≥ 100 and SBP < 100 mmHg.

CMV reactivation, 70% were receiving corticosteroids, 22% azathioprine, and 19% antiTNF agents. The median number of IHC-CMV+ cells were 2 cells/biopsy (IQR 1-5). No factors were associated with the magnitude of the reactivation. Thirty-two patients (67%) were treated with antiviral therapy. Thirteeen patients (27%) underwent colectomy; persistence of CMV was reported in 6/13 (46%) of the surgical specimens. The colectomy during admission for the index flare was significantly higher in patients with >2 cells/biopsy (50% vs. 16%, p = 0.022) and in patients with more severe activity (58% vs. 19%, p = 0.01).
**Conclusion:** The intensity of CMV colonic reactivation in patients with refractory UC, as measured by IHC, could be of prognostic relevance. Our data, together with a previous rectal PCR study, suggest that the decision to start antiviral treatment might rely on the quantitative measure of CMV reactivation.

### P0336 FIVE YEAR BUDGET IMPACT ANALYSIS OF BIOSIMILAR INFLIXIMAB (CT-P13) FOR THE TREATMENT OF CROHN'S DISEASE AND ULCERATIVE COLITIS IN SPAIN

**S. Han**, D. Kwon, S. Yoon
*Celltrion, Incheon/Korea, Republic of*

**Contact E-mail Address:** SeongHee.Han@celltrion.com.
**Introduction:** Crohn's disease (CD) and ulcerative colitis (UC) are immune-related diseases that are particularly common in the European population. Treatment with biologic drugs such as infliximab may be suitable for many patients with these diseases; however, these drugs are usually expensive and therefore access to treatment is often restricted. Biosimilar infliximab (CT-P13) has a lower cost than the infliximab reference product (RP) and has been approved for use in CD and UC in Europe, the USA and elsewhere.
**Aims & Methods:** The aim of this study was to analyse the pharmacoeconomic effects of the use of biosimilar infliximab in CD and UC in Spain. An Excel-based model was developed to apply three different price-discount scenarios (20%, 30%, and 40% discount versus RP) and to evaluate potential cost savings in Spain over five years. Total population, disease prevalence and incidence, annual prevalent population receiving RP and the public price of RP in Spain were parameters used in the model. To calculate the maximum possible cost savings associated with use of biosimilar infliximab, the analysis presumed that all RP-treated patients in Spain would switch to biosimilar infliximab.
**Results:** After applying the 20%, 30%, and 40% price-discount scenarios to the CD population, cumulative cost savings over five years were €223, 295, 625, €373, 550, 625, and €446, 591, 250, respectively. With these savings, an additional 7, 605, 15, 289, and 20, 265 CD patients, respectively, could be treated using biosimilar infliximab annually. In the UC population, total cost savings over five years with the 20%, 30% and 40% price-discount scenarios were estimated to be €247, 068, 522, €371, 431, 872, and €493, 952, 802, respectively. With these savings, an additional 8, 415, 15, 202 and 22, 414 patients with UC could access biosimilar infliximab treatment each year.
**Conclusion:** Cost savings in this study were calculated assuming that all patients being treated with RP were switched to biosimilar infliximab. Applying this assumption, this study showed that biosimilar infliximab use in CD and UC could result in significant cost savings compared with RP use. Savings generated via the use of biosimilar infliximab could help ease the economic burden of CD and UC treatment and/or allow more patients to access biologic therapy.

**Contact E-mail Address:** kathryn.oakland@nhsbt.nhs.uk.
**Introduction:** Lower gastrointestinal bleeding (LGIB) is a common indication for emergency hospitalisation. There are few data characterising its modern day epidemiology, interventions and outcomes. This study describes characteristics, aetiology and management of patients admitted to UK hospitals with LGIB.
**Aims & Methods:** Prospective national audit of consecutive presentations with LGIB from September to December 2015 in acute hospitals in the UK. Data were collected on demographics, transfusion, investigations, interventions and outcome. Cases were identified by clinical teams and data entered into a centralised website until discharge or 28 days.
**Results:** 2528 cases of LGIB were identified across 138 hospitals. Median age 74 (57–83), 1319 (52.5%) female. 1994/2521 (79.1%) patients had co-morbidities, e.g. hypertension (39.8%), diabetes (15.0%) and chronic respiratory disease (11.8%). 1075/2510 (42.8%) patients were receiving an oral anti-platelet or anticoagulant. Inpatients accounted for 185/2405 (7.3%) bleeds. Shock and anaemia were infrequent, but more common in inpatients (table 1). 666/2493 (26.7%) patients received a red cell transfusion, 258/2493 (10.3%) requiring more than 4 units. 642/2481 (25.9%) had flexible sigmoidoscopy or colonoscopy whilst admitted and 54/2450 (2.2%) received endoscopic haemostasis. 507/2452 (20.7%) underwent computed tomography (CT) of the abdomen, 149/2452 (6.1%) CT angiography, 37/2467 (1.5%) mesenteric angiography and 19/2504 (0.8%) embolization. 1213/2473 (49.0%) had no inpatient investigations. 6/2475 (0.4%) underwent laparotomy for bleeding and 5/2475 underwent transanal surgery for bleeding. 260/1993 (13.0%) were re-admitted within 28 days, 111/1993 (5.6%) due to further LGIB. Death at 30 days was 85/2492 (3.4%). The most frequent discharge diagnoses were diverticular disease (668/2528, 27.1%), benign anorectal conditions (422/2528, 17.1%) and source unidentified (576/2528, 23.4%).
**Conclusion:** LGIB is a disease of older patients, diverticular disease is the most common aetiology and a quarter receive red cell transfusion. Half of presentations had no in-patient investigations. When flexible sigmoidoscopy, colonoscopy and CT are used, they rarely lead to endoscopic haemostasis or mesenteric embolization. Surgery is rarely required and case fatality rates are low.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0338 STIGMATA OF RECENT HEMORRHAGE AND NON-ASPIRIN ANTIPLATELET DRUG ARE PREDICTIVE FACTORS FOR REFRACTORY COLONIC DIVERTICULAR HEMORRHAGE

**Y. Shimodate, M.** Mizuno, A. Doi, N. Nishimura, H. Mouri, K. Matsueda, H. Yamamoto
*Gastroenterology And Hepatology, Kurashiki Central Hospital, Kurashiki/Japan*

**Contact E-mail Address:** ys13544@kchnet.or.jp.
**Introduction:** Colonic diverticular hemorrhage is usually self-limited but is often recurrent. In some cases, radiological intervention or operation is required due to repeated rebleeding. In the present study, we investigated predictive factors for the rebleeding of colonic diverticular hemorrhage.
**Aims & Methods:** We studied 474 episodes (290 patients) of colonic diverticular hemorrhage from January 2006 to February 2016 in our hospital. The diagnosis of colonic diverticular hemorrhage was based on all of the following findings; 1. hematochezia without abdominal pain, 2. diverticulosis confirmed by colonoscopy or computed tomography, and 3. no other cause of hematochezia. Stigmata of recent hemorrhage were defined as active bleeding, non-bleeding visible vessel, or adherent clot in the diveluticulum at colonoscopy. When we found them, endoscopic hemostasis was performed. Rebleeding was defined as hematochezia requiring colonoscopy. Early and late bleeding were defined as

rebleeding within 1 week and 2–4 weeks after the first colonoscopy, respectively. In the analysis of late rebleeding, 3 episodes were excluded because hemicolectomy was performed due to rebleeding within 1 week. Using multivariate logistic regression, we analyzed the following factors to identify predictive factors for the rebleeding: age, sex, shock vital on admission, comorbidities (hypertension, hyperlipidemia, diabetes mellitus, cardiovascular disease, cerebrovascular disease, chronic liver disease, hemodialysis), current medication (low-dose aspirin, non-aspirin antiplatelet drug, anticoagulants, non-steroidal anti-inflammatory drug, corticosteroid), extravasation confirmed by contrast enhanced computed tomography, identification of bleeding spot, and stigmata of recent hemorrhage.
**Results:** Stigmata of recent hemorrhage were identified in 128 (27%) episodes including 105 active bleeding. Endoscopic hemostasis was performed in all of these episodes; clipping was used in most cases (117, 90.7%). Early and late rebleeding were observed in 59 (12.4%) and 28 (6%) episodes. Stigmata of recent hemorrhage (odds ratio, 2.30; 95% confidence interval, 1.30–4.05, $p = 0.0072$) and non-aspirin antiplatelet drug users (odds ratio, 2.42; 95% confidence interval, 1.06–5.52, $p = 0.035$) were identified as significant and independent predictive factors for early and late rebleeding, respectively. In the subgroup analysis of 117 episodes with endoscopic clipping, early rebleeding occurred more often in the diveluticulum located in the left side of the colon (14/42, 33.3%) than that in the right side (10/75, 13.3%) (odds ratio, 3.07; 95% confidence interval, 1.20–7.87, $p = 0.02$).
**Conclusion:** Stigmata of recent hemorrhage were predictive factor for early rebleeding even after endoscopic hemostasis. Endoscopic clipping may not be effective enough for the management of colonic diverticular hemorrhage especially in the left side of the colon. We should be alert to late rebleeding in non-aspirin antiplatelet drug users.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0339 COMPARISON OF CT, SIGMOIDOSCOPY AND COLONOSCOPY AS INITIAL METHODS OF EXAMINATION FOR PRESENCE OF HEMATOCHEZIA

**J.S. Joo,** K.D. Kim, S.H. Kang, H.S. Moon, E.S. Lee, S.H. Kim, J.K. Sung, B.S. Lee, H.Y. Jeong
*Internal Medicine, Chungnam National University School Of Medicine, Daejeon/Korea, Republic of*

**Contact E-mail Address:** icarus143@naver.com.
**Introduction:** The preferred method of examination of hematochezia is sigmoidoscopy and colonoscopy; However, in cases of emergencies, the bowel preparation can be poor and entry to the upper level is very difficult. On the other hand, computed tomography offer a non-invasive way to evaluate both enteric and extra enteric abnormalities. It is also efficient in verifying the point of hemorrhage.
**Aims & Methods:** The purpose of this research is to compare whether computed tomography are no more inferior than sigmoidoscopy and colonoscopy as the initial method of examination in patients who have sought medical assistance because of the presence of hematochezia. Medical records dating from January 2012 to March 2015 were retrospectively analyzed for 279 adult patients over 18 years of age who had sought medical attention and undergone computed tomography (CT), sigmoidoscopy, or colonoscopy as a result of the presence of hematochezia. Patients with hematochezia were divided into groups who underwent initial examinations via computed tomography, sigmoidoscopy, and colonoscopy. The data presents a comparison of each group by the detection rate of bleeding focus, through initial inspection, hospital stay, and period until the final diagnosis.
**Results:** Of the 279 enrolled patients with hematochezia, 91 underwent sigmoidoscopy, 58 underwent colonoscopy, and 130 initially underwent computed tomography. There were no significant differences in the figures of patients in each group when comparing the early detection rate of bleeding focus and hospital stay ($p = 0.491$). With the exception of 39 patients whose bleeding focus could not be determined through examination, there were no significant differences in the length of time required to obtain a final diagnosis when comparing the 240 target patients in each group ($p = 0.258$). In the CT treatment group, 125 patients (96.2%) subsequently underwent endoscopy. In the case of those who underwent endoscopic therapy, 15 patients (11.5%) were from the CT treatment group, and 36 (24.2%) were those who had initially undergone sigmoidoscopy and colonoscopy ($p = 0.007$). Of the CT treatment group, there were 9 patients (6.9%) who experienced extravasation, while among those who did not have extravasation, there was 1 patient (0.8%) who experienced significant bleeding (Hemoglobin $\leq 6$ g/dL, systolic blood pressure $\leq 90$ mmHg).
**Conclusion:** This study showed that CT as an initial inspection of patients with hematochezia showed no significant differences in figures related to the duration of diagnostics through initial inspection, hospital stay, and length of time required to obtain a final diagnosis when compared to patients who underwent sigmoidoscopy and colonoscopy. There were significantly more patients who underwent endoscopic therapy from the sigmoidoscopy and colonoscopy groups than from the CT group. The results suggest that CTs might be considered an alternative to sigmoidoscopy when initializing exams related to hematochezia.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** ferguschedgy@yahoo.co.uk.
**Introduction:** EMR / ESD of large lesions creates large mucosal defects and is associated with significant post-procedural bleeding. Endoclot™ is a topical hemostatic powder that rapidly absorbs water creating a high concentration of platelets, red blood cells and clotting factors – accelerating the natural coagulation cascade.
**Aims & Methods:** Routine application of Endoclot™ to ESD or EMR defects is hypothesised to reduce the risk of significant post EMR/ESD bleeding. A prospective registry was set up to record all EMR / ESD procedures since 2006. Prophylactic use of Endoclot™, following endoscopic resection of lesions $> 20$ mm, to prevent delayed bleeding was introduced in June 2014. The bleeding rate since the introduction of this strategy was compared with the bleed rate of our historic cohort since 2006. Bleeding was defined as significant if it required: readmission, transfusion or further intervention. SPSS was used for statistical analysis of data.
**Results:** Pre-Endoclot cohort: 496 patients underwent lower gastrointestinal EMR/ESD at our institution between 2006 and 2013 with a mean polyp size of 43 mm and 12% of these polyps were scarred due to previous intervention. Significant delayed bleeding was seen in 21/496 patients (4%). 264 patients underwent upper gastrointestinal EMR/ESD at our institution between 2006 and 2013. Significant delayed bleeding was seen in 9/264 patients (3%). Endoclot cohort: 71 patients have undergone colonic EMR/ESD (mean polyp size 46 mm, 38% scarred) (Table 1). 61 patients have undergone upper gastrointestinal resection (mean lesion size 33 mm, 37% scarred).
There was 1 significant delayed bleed in the colonic group (1%) requiring further endoscopic therapy. There were 2 bleeds (3%) in the upper GI group, which were managed with further endoscopic therapy without the need for blood transfusion. There have been no complications related to Endoclot™ use. Device clogging was experienced in 5% of upper gastrointestinal cases and 15% of lower gastrointestinal cases.

**Table 1:** Colonic ER Outcomes.

| | Mean Lesion Size (mm) | Scarring % | Delayed Bleeding % |
|---|---|---|---|
| Pre-Endoclot n = 496 | 43 | 12 | 4 |
| Post-Endoclot n = 71 | 46 | 38 | 1 |
| P-value | NS | <0.01 | NS |

**Conclusion:** Endoclot™ shows promise in reducing the risks of delayed bleeding following endoscopic resection of large neoplastic lesions from the gastrointestinal tract. Our data demonstrates a 75% reduction in risk of delayed bleeding following EMR/ESD for large colonic polyps in a group with a significantly higher rate of scarring and therefore bleeding risk. A randomised controlled trial is required to clarify the role of routine use of Endoclot™ following EMR/ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0341 RISK FACTORS FOR ACTIVE BLEEDING FROM COLONIC ANGIODYSPLASIA CONFIRMED UNDER COLONOSOCPIC OBSERVATION

**N. Nishimura**[1], M. Mizuno[2], Y. Shimodate[2], A. Doi[2], H. Mouri[2], K. Matsueda[2], H. Yamamoto[2]
[1]*Kurashiki Central Hospital, Kurashiki/Japan*
[2]*Gastroenterology And Hepatology, Kurashiki Central Hospital, Kurashiki/Japan*

**Contact E-mail Address:** nn13543@kchnet.or.jp.
**Introduction:** Colonic angiodysplasia is an important cause of lower gastrointestinal bleeding in the elderly, but there have been few studies on its risk factors for bleeding. Thus, we retrospectively investigated the risk factors for bleeding from colonic angiodysplasia which was confirmed under colonosocopic observation.
**Aims & Methods:** Among 24334 patients who underwent colonoscopic examination from 2006 November to 2015 November in our hospital, 435 patients with colonic angiodysplasia were studied. The following factors were analyzed to identify risk factors for active bleeding from colonic angiodysplasia at the time of colonoscopy: age, sex, co-morbidities (heart disease, liver cirrhosis, chronic kidney disease, chronic obstructive pulmonary disease, and diabetes mellitus), medications (antiplatelet drugs, anticoagulants, and non-steroidal inflammatory drugs) and endoscopic features of colonic angiodysplasia.

**Results:** Among the 435 patients with colonic angiodysplasia, active bleeding from the angiodysplasia was observed in 29 patients (6.7%). Using multivariate logistic regression analysis, we identified the following factors as independent and significant risk factors for the bleeding: age over 80 years (odds ratio (OR), 5.2; 95% confidence interval (CI), 1.6–16.5), heart disease (OR, 6.9; 95%CI, 1.04–45.5), use of anticoagulants (OR, 4.2; 95%CI, 1.2–14.9), multiple angiodysplasia (OR, 6.7; 95%CI, 1.8–25.2) and small angiodysplasia less than 5 mm (OR, 17.7; 95%CI, 4.9–64.0). With regard to characteristics of angiodysplasia, colonic angiodysplasia with active bleeding was mostly located in the right colon (90%, 26/29) and 1–2 mm in size (83%, 24/29). All patients with active bleeding from colonic angiodysplasia were successfully treated with endoscopic clipping or argon plasma coagulation. Rebleeding occurred in 9 patients (31%, 9/29) during follow-up period of a median of 16 months ranging 2–84 months. No patient required angiographic embolization, hormonal therapy or surgical resection.
**Conclusion:** Multiple or small colonic angiodysplasias in patients of advanced age, with heart disease, or under use of anticoagulants have an increased risk for bleeding. We should be alert to small colonic angiodysplasia in the right colon at colonoscopy and consider prophylactic treatment for bleeding in patients with those risk factors.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0342 PREVENTING DELAYED POST-POLYPECTOMY INDUCED ULCER HEMORRHAGE BY USING DOPPLER ENDOSCOPIC PROBE AS A GUIDE TO RISK STRATIFICATION & PROPHYLACTIC HEMOSTASIS AFTER POLYPECTOMY

**D.M. Jensen**[1], G. V. Ohning[2]

[2]*Gastroenterology/medicine, Veterans Affairs Greater West Los Angeles, Los Angeles/United States of America/CA*

**Contact E-mail Address:** djensen@mednet.ucla.edu.
**Introduction:** Delayed post-polypectomy ulcer (PPIU) bleeding is increasing in prevalence as more colorectal cancer screening is performed and large polyps are removed. A recently published large retrospective report recommended hemoclip (HC) closure of all PPIUs during screening colonoscopy of high risk patients to prevent severe delayed bleeding[1]. However, this approach may not be effective because: 1) HC closure of PPIUs > 15 mm is usually not possible with current HCs 2) a large number of HCs is required for closure of large PPIUs or multiple PPIUs in the same patient & 3) this technique covers up rather than obliterates underlying arteries which later are exposed after the HCs come off. We hypothesized that the underlying vessels in PPIUs could be localized & focally treated after polypectomy with Doppler endoscopic probe (DEP) guidance to prevent and effectively prevent delayed PPIU hemorrhage.
**Aims & Methods:** 1) to determine the prevalence of blood flow by DEP in PPIUs just after colon polypectomy, 2) in an initial cohort, to utilize DEP for risk stratification and to determine the natural history of untreated PPIUs with positive DEP, 3) in a second cohort to use DEP as a guide for focal hemostasis to obliterate the underlying blood flow, & 4) to report 30 day rates of bleeding & complications in both cohorts. In two consecutive prospective cohort studies, 62 outpatients having elective screening or surveillance colonoscopies were included. Standard colon preps & techniques for removal of benign appearing pedunculated or sessile polyps were used. Sizes of the PPIUs were estimated with accessories of known dimensions. After polypectomy, a disposable colon DEP (Vascular Technology Inc, Nashua, NH) was used to interrogate the PPIUs for superficial (<4 mm) blood flow (both arterial & venous) & to map the vessel course. The first cohort of 30 patients did not have prophylactic hemostasis and the second cohort of 32 patients with arteries detected in the PPIUs had hemostasis (HC or MPEC) until arterial blood flow was obliterated. ASGE guidelines for anti-coagulants & anti-platelet drugs were followed before & after colonoscopy.
**Results:** Patients in the 2 cohorts had similar risk factors for delayed PPIU bleeding. 30 of the 62 patients (48.4%) had arterial blood flow detected in 1 or more PPIUs with DEP - none was venous. None had visible arteries or stigmata of hemorrhage. For 120 polyps removed (range 1- 5 /patient), PPIUs were 6 – 30 mm & 37 PPIUs (30.8%) had arterial flow detected. For PPIUs < 10 mm only 3/37 (8%) had + DEP, for 10–14 mm PPIUs 15/53 (28.3%) had + DEP, & for PPIUs 15 mm or larger, 19/30 (63.5%) had + DEP, that were focal in the PPIUs & usually short in course. For the initial 30 patients not treated with hemostasis, the delayed bleeding rate was 16.7% (5/30). For the next 32 patients treated with DEP guided hemostasis, the delayed bleed rate was 0% (0/32). No other complications occurred.
**Conclusion:** 1) DEP facilitated mapping of artery location & blood flow in PPIUs. 2) Arterial blood flow was detected in increasing prevalence from < 8% in PPIUs < 10 mm; to 28% for PPIUs 10 - 14 mm in diameter; to 63% of PPIUs 15 mm or larger. 3) With focal treatment of arteries in the base of PPIUs & obliteration of blood flow as monitored by DEP, no patient had delayed PPIU bleeding. 4) In contrast 16.7% of those not treated endoscopically had delayed bleeding from PPIUs and all had positive blood flow at baseline. Disclosures – Funding. Supported in part by a VA Clinical Merit Review Research Grant and CURE DDRC NIH 41301 (Human Studies Core).

**Introduction:** Postpolypectomy bleeding (PPB) is a major complication of colorectal polypectomy and antithrombotic agents are one of the major risk factors for PPB. PPB risks have been reported for each kinds of antithrombotic and several guidelines have been published regarding possible management modalities. However, little is known about PPB risks in patients taking multiple antithrombotics. Therefore, we investigated PPB risks with regard to the use of multiple antithrombotics.
**Aims & Methods:** A total of 6, 387 colonoscopies involving polypectomy (endoscopic mucosal resection [EMR] / cold polypectomy) were performed in our hospital between September 2002 and December 2014. We retrospectively assessed these cases with respect to the following factors: patient factors which comprised age, sex, use of antithrombotics, type of antithrombotics (anticoagulant, aspirin, thienopyridine, and other antiplatelets), use of heparin bridge (HB), and total number of polyps in one examination; and lesion factors which consisted of location, gross type, size, resection method, and pathology. Antithrombotics were generally discontinued a minimum days before polypectomy. PPB was considered as hematochezia requiring emergency endoscopic hemostasis within 30 days after a polypectomy. The chi-square test was used to compare PPB rates between the groups with antithrombotics and the group without antithrombotics. The chi-squared test, Wilcoxon rank sum test, and multivariate logistic regression were used to assess factors associated with PPB (significance: $p < .01$). Statistical analysis was performed using Stata SE version 10.1.
**Results:** Among the patients who received anticoagulants, the PPB rate for HB use and nonuse was 28.6% (4/14) and 3.2% (4/127), respectively ($p < .001$). Among the patients who received anticoagulants but did not receive HB, the PPB rate for each antithrombotic was as follows: anticoagulant only, 2.3% (2/87, $p = .076$); anticoagulant + aspirin, 3.9% (1/26, $p = .054$); anticoagulant + aspirin + thienopyridine, 16.7% (1/6, $p < .001$); anticoagulant + aspirin + other antiplatelets, 0% (0/3, $p = .885$); and anticoagulant + other antiplatelets, 0% (0/5, $p = .852$). Among the patients who did not receive anticoagulants, the PPB rate for each antithrombotic was as follows: aspirin only, 0.6% (2/335, $p = .846$); thienopyridine only, 0.8% (1/121, $p = .855$); other antiplatelets only, 0% (0/244, $p = .194$); aspirin + thienopyridine, 3.9% (3/77, $p = .001$); and aspirin + other antiplatelets, 0% (0/60, $p = .519$). A multiple regression analysis of the cases that did not receive HB identified that the following patient factors: age (OR 0.95 [95%CI 0.93–0.97], $p < .001$), total lesion number per procedure (OR 1.31 [1.20–1.43], $p < .001$), and anticoagulant + antiplatelets (OR 7.94 [1.77–35.7], $p = .007$), were independent risk factors for PPB, whereas the following lesion factors: size (OR 3.05 [1.66–5.61], $p < .001$) and anticoagulant + antiplatelets (OR 9.34 [3.22–27.1], $p < .001$), were independent risk factors for PPB.
**Conclusion:** Based on our results, HB was a major risk factor for PPB. Meanwhile, of those who did not receive HB, anticoagulant + antiplatelets was a significant risk factor for PPB even after its use had ceased.

## P0345 SENTIFIT 270 SYSTEM CLINICAL PERFORMANCE EVALUATION COMPARED WITH OC SENSOR DIANA, FOR THE DETECTION OF HUMAN HAEMOGLOBIN AS FAECAL OCCULT BLOOD (FOB)

**R. Dvir**[1], M. Clementi[2]
[1]*Laboratory Of Clinical Microbiology, San Raffaele University hospital, Milan/Italy*
[2]*Vita Salute San Raffaele University, Milan/Italy*

**Contact E-mail Address:** dvir.roee@hsr.it.
**Introduction:** The SENTiFIT system (SENTiFIT assay) composed of the SENTiFIT 270 Analyser, the FOBGold reagents and the SENTiFIT pierceTube, is a specific system for the detection of human haemoglobin present in faeces, known as the FOB (faecal occult blood) test. The SENTiFIT assay is a quantitative FIT test (Faecal Immunochemical Test), highly recommended for both routine diagnostic testing and the CRC (ColoRectal Cancer) screening program. Faecal samples are collected and stabilized using the SENTiFIT pierceTube, whereas, the FOBGold latex reagent is optimized for the agglutination reaction with haemoglobin, analysed on the SENTiFIT 270 Analyser, a bench-top fully automated clinical chemistry instrument.
**Aims & Methods:** The aim of our study was to evaluate the clinical performances of the SENTiFIT FOBGold latex test using the SENTiFIT 270 system, and comparing it with the OC SENSOR DIANA system (DIANA assay), both FIT quantitative assays. Patients and Methods: Overall, 134 patients were enrolled in our prospective pilot clinical study. Patients were undergoing routine outpatient diagnostic workup and subsequent monitoring for the detection of Human Haemoglobin in the faeces. Two sets of 3 collection tubes (numbered 1 to 3), each for both assays (SENTiFIT assay and DIANA assay) were given to all patients along with detailed instructions on how to collect faecal samples. The patients were asked to collect 3 different bowel movements, using both collection tubes. A clinical provider emphasized the importance of collecting a sample from different areas of the faeces with both sticks and then after, rolling the tube sticks against each other for fecal homogenization. The initial approach for results

analyzing, for both assay, was using a cut-off level of 100 ng/mL for "positive" results.
**Results:** A total of 387 collection tubes of the DIANA assay and 387 collection tubes of the SENTiFIT assay were considered adequate for our study. The SENTiFIT assay identified 52 samples as positive (of these, the DIANA assay identified 28 samples), and 335 samples as negative (all but one were identified as negative by the DIANA assay). 25 samples were found discrepant, corresponding to 6.4% of total samples. Considering 100 ng/mL as threshold level, the total concordance percentage was 93.5%, and the AUC (Area Under the Curve) was 0.95.
**Conclusion:** Herein we report the results of a unique clinical comparison evaluation study of the SENTiFIT assay using the SENTiFIT 270 automated system. For the first time, we conducted a clinical study on a large scale of patients undergoing routine diagnostic FIT testing, using 2 different collection tubes for each of the 3 bowel movements. Our data show a significant correlation between the SENTiFIT assay and the DIANA assay, with a sensitivity of 96.6% and specificity of 93.3%. Although significant importance was given to sample collection and fecal homogenization instructions, we could assume that the possible reasons for discrepant results, as already shown by others, were due to sample collection (sampling by patient at home) and feces variability and stability. Applying higher cut-off levels (>100 ng/mL) on the SENTiFIT assay showed fewer discrepant results. According to the above, we could consider the SENTiFIT 270 system as a potential clinical assay for faecal immunochemical test.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0346 CORRELATION BETWEEN THE NATURE OF POSTPOLYPECTOMY BLOODY STOOL AND THE RISK OF POSTPOLYPECTOMY BLEEDING

**E.M. Song,** D. Yang, G.U. Kim, M.S. Seo, S.W. Hwang, S.H. Park, K. Kim, B.D. Ye, J. Byeon, S.J. Myung, S. Yang
*Department Of Gastroenterology, Asan Medical Center, University of Ulsan College of Medicine, Seoul/Korea, Republic of*

**Contact E-mail Address:** rainbowhouse135@gmail.com.
**Introduction:** Postpolypectomy bleeding (PPB) is a significant adverse event related to colonic polypectomy. However, little is known about the correlation between the nature of bloody stool within 24 hours after polypectomy and the risk of PPB. We aimed to evaluate the correlation between the nature of the bloody stools and PPB, using the photo-documented bloody stool data of the patients during immediate postpolypectomy period (<24 hours after polypectomy).
**Aims & Methods:** Between October 2015 and March 2016, 2, 514 patients underwent colonoscopic polypectomy in Asan Medical Center. In-hospital post procedural monitoring was provided for 927 of them at the specialized, short-term care unit for therapeutic colonoscopic procedures. During the in-hospital post procedural monitoring, the nurses routinely check the nature of the patients' first stools after polypectomy and take a snapshot of the stool in the toilet bowel, if it contains any bloody components. Forty-two of 927 patients (4.5%) reported that hematochezia or blood in stool. The photos were scored from 1 to 4 by three experienced endoscopists as follows: only a streak of blood or few blood clots (score 1), a handful of blood clots in the background of normal stool-colored fluid (score 2), pinkish, bloody fluid with or without clots (score 3), and moderate to large amount of fresh blood (score 4). The scoring endoscopists were blinded from the score data of other endoscopists and the patients' clinical outcomes. The score concordant in 2 or more endoscopists were confirmed as the final score for the photo (postpolypectomy bloody stool score, PBSS). Based on these scores, patients were divided into two groups based on the: high PBSS (score 3, 4) and low PBSS (score 1, 2) groups.
**Results:** Of 42 patients, 6 (14.3%), 22 (52.4%), 9 (21.4%), and 5 (11.9%) patients were scored 1, 2, 3, and 4, respectively. The PBSS scores were positively correlated with clinically significant PPB (spearman's $\rho = 0.526$). Based on the PBSS, 14 patients were categorized into the high PBSS group and 28 were into the low PBSS group. Second-look colonoscopy was performed for 5 (17.9%) of the low PBSS group and 10 (71.4%) of the high PBSS group ($P = 0.001$). Endoscopic hemostasis was required in 3 (10.7%) of the low PBSS patients and 8 (57.1%) of the high PBSS patients ($P = 0.001$). There were no significant differences in characteristics of patients and colon lesions between 2 groups. Among all the patients discharged without any treatment ($n = 27$), 2 patients in low PBSS group and 1 patient in high PBSS group developed delayed PPB. One of the 3 patients was large polyp (>20 mm) with long stalk, and the other 2 patient had multiple polyps more than 5.
**Conclusion:** The nature of bloody stool immediately after polypectomy is associated with the significant bleeding stigmata at the second-look colonoscopy and the risk of clinically significant PPB.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0347 ADENOMA RECURRENCE RATES AFTER CURATIVE RESECTION FOR RIGHT-SIDE OR LEFT-SIDE COLONIC CANCER

F. Y. Lam[1], W.L. Law[2], I. Hung[1], **W.K. Leung**[1]
[1]*Department Of Medicine, University of Hong Kong, Hong Kong/Hong Kong PRC*
[2]*Department Of Surgery, University of Hong Kong, Hong Kong/Hong Kong PRC*

**Contact E-mail Address:** waikleung@hku.hk.
**Introduction:** Patients with history of colorectal cancer (CRC) are at increased risk of developing metachronous lesions including adenoma and cancer. We aim to determine the rates of colorectal polyp and adenoma recurrence on surveillance colonoscopy in patients after colonic resection for right-side (R-CRC) and left-side CRC (L-CRC).
**Aims & Methods:** Consecutive patients with CRC who had undergone surgical resection in our hospital between January 2001 and December 2003 were identified from our colorectal cancer database. Patients were included only if they had undergone surgical resection for curative intent and had a clearing colonoscopy performed either before or within 6 months after the operation. Patients with familial colorectal cancer syndrome (familial adenomatous polyposis, hereditary non-polyposis colorectal cancer syndrome), subtotal or total colectomy, and inflammatory bowel syndrome were excluded. Findings of surveillance colonoscopy performed up to 5 years after colonic resection were included in the analysis. Patient's baseline characteristics, tumor locations, type of surgical intervention and surveillance colonoscopy findings were retrieved. R-CRC was defined as cancer at and proximal to splenic flexure and L-CRC included all other distal cancers.
**Results:** 857 patients underwent surgical resection for CRC during the study period and 430 patients (146 patients with R-CRC and 284 with L-CRC) fulfilled our inclusion criteria. Among them, 88 (60.3%) patients with R-CRC and 204 (71.8%) patients with L-CRC had at least one surveillance colonoscopy, with a total of 447 colonoscopies performed. The rates of metachronous lesions found on surveillance colonoscopy were shown in the Table. The proportion of patients who had polyp and adenoma detected on surveillance colonoscopy was higher for those who had surgery for L-CRC compared to those who had surgery for R-CRC. There was also a significant difference on the time to polyps and adenoma recurrence between the two group, with a higher rate in the L-CRC group (log rank: $p = 0.04$ and 0.03 respectively). However, there was no significant difference on the detection of serrated lesions.

Detection Rates of Adenoma and Polyp on Surveillance Colonoscopy

| | R-CRC | L-CRC | P |
|---|---|---|---|
| Any polyps | 22.7% | 35.3% | 0.04 |
| Any adenoma | 14.5% | 26.5% | 0.03 |
| Advanced adenom | 5.7% | 8.3% | 0.63 |
| Cancer | 2.3% | 0.5% | 0.90 |
| Serrated lesions | 8.0% | 8.3% | 1.0 |

**Conclusion:** Patients who had surgery for L-CRC have a higher chance of developing metachronous polyps and adenoma than those with R-CRC. Our findings may call for a different surveillance strategy for patients with L-CRC or R-CRC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0348 HOW SIGNIFICANT IS THE ASSOCIATION BETWEEN METABOLIC SYNDROME AND PREVALENCE OF COLORECTAL NEOPLASIA?

**Introduction:** The incidence and prevalence of metabolic syndrome (MS) and colorectal cancer (CRC) has been rising in developed countries. The association between these two diseases has been widely studied and published. Less evidence is available about the relation between MS and CRC precancerous lesions (adenomatous polyps, adenomas).
**Aims & Methods:** To assess the prevalence of colorectal neoplasia (adenomas, advanced adenomas) in individuals with high metabolic risk factors – type 2 diabetes mellitus (DM2) and cardiovascular risk (SCORE > 10%). Evaluate the outcomes in the CRC screening. Prospective, multicenter study was performed from January 2013 to December 2015. 2, 000 individuals aged 45–75 years were enrolled; 1, 000 in the target group (metabolic risk) and 1, 000 in the control group. All patients meet the screening population criteria (asymptomatic, without family or personal history of colorectal neoplasia) and were examined by colonoscopy at eight centers.
**Results:** 2, 071 individuals were enrolled and the first statistical analysis of 1, 500 completed records was finished. 726 persons (494 men, 68%) were enrolled in the target group (high metabolic risk) and 774 persons (353 men, 46%) in the control

group (without metabolic risk). The significantly higher prevalence of advanced adenomas was observed in the target group (18%; 95% CI 15–21%) comparing to the control group (9%; 95% CI 7–11%); OR 1.8; p = 0.002. Similarly, the prevalence of all adenomas was higher in the target group (48%; 95% CI 44–51%) than in the control group (35%, 95% CI 32–38%); OR 1.2, however the difference was not statistically significant (p = 0.179). Individuals with isolated high cardiovascular risk had higher prevalence of both, non-advanced adenomas (51%, 95% CI 46–56%; p = 0.327) and advanced adenomas (22%, 95% CI 18–26%; p = 0.049) comparing to the individuals with isolated DM2. Advanced adenomas were more likely in patients aged 65 – 75 years.

**Conclusion:** Individuals with a higher metabolic risk (cardiovascular; DM2) have two times higher risk of advanced adenomatous polyps. The individualized colorectal cancer screening should be considered namely in the individuals aged 65 – 75 years with SCORE > 10%. This project has been supported by the Czech Ministry of Health grant NT 13673.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0349 ADHERENCE TO COLORECTAL CANCER SCREENING: 4 ROUNDS OF FECAL IMMUNOCHEMICAL TEST BASED SCREENING

**Introduction:** The effectiveness of fecal immunochemical test (FIT) based screening programs is highly dependent on consistent participation over multiple rounds. Data on participation rates and characteristics of persons participating and not participating in repeated screening rounds are scarce.

**Aims & Methods:** We evaluated adherence to FIT-screening over 4 rounds and aimed to identify determinants for participation behavior. A total of 23, 339 randomly selected asymptomatic individuals aged 50–74 years were invited for biennial FIT screening from 2006 through 2014. All selected individuals were eligible and invited for every consecutive round, except for those who had moved out of the area, passed the upper age limit, or had tested positive in a previous screening round. One reminder letter was sent to non-responders after 6 weeks. For analyses of adherence, only invitees who were eligible at least for two rounds were included. Data on age, sex and socioeconomic status (SES) were recorded. Outcomes included participation rate per round, response to a reminder letter and behavioral differences in adherence to screening grouped by age, sex and SES.

**Results:** During the 4 rounds, overall participation rates remained stable at 60.4% (95% CI 59.6–61.2), 59.5% (95% CI 58.7–60.3), 61.8% (95%CI 61–62.6) and 62.5% (95% CI 61.8–63.5) respectively, with significantly higher participation rates for women across all 4 rounds (p < 0.001). Overall, 71.9% of the invitees attended at least once (12, 455 of 17, 312 invitees) and 28.1% never participated (4, 857 of 17, 312 invitees). The proportion of consistent participation (i.e. attending all rounds when eligible) was 47.8% (8, 271 of 17, 312 invitees). Consistent participation was associated with older age, female gender and a higher SES (Table 1). Offering a reminder letter in the first round increased uptake with 11.8%, during following screening rounds this resulted in an additional uptake of up to 10%.

**Table 1:** Predictors of adherence to FIT screening per category of participation behavior.

| | Consistent (n = 8271, 47.8%) | Inconsistent (n = 4184, 24.2%) | Never (n = 4857, 28.1%) | p-value |
|---|---|---|---|---|
| Age (median; (IQR)) | 57 (52-63) | 55 (51-61) | 55 (51-62) | p < 0.001 |
| Sex (male, %) | 45.4 | 50 | 54.1 | p < 0.001 |
| SES (%) -Low -Average -High | 7.4 70.5 22.1 | 10.7 72.2 17.1 | 13.9 70.4 15.7 | p < 0.001 |

**Conclusion:** In this population-based biennial FIT-screening cohort, participation over consecutive rounds was high and remained stable. Still, the substantial proportion of inconsistent participants suggest the existence of incidental barriers to participation, that, if possible, should be identified and removed.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0350 AGING, CURRENT SMOKING AND METABOLIC FACTORS ARE INDEPENDENTLY ASSOCIATED WITH THE PREVALENCE OF COLORECTAL NEOPLASIA IN JAPAN: ANALYSES OF COMPREHENSIVE HEALTH CHECKUP DATA

**N. Inoue**[1], M. Takayama[1], R. Bessho[1], T. Yoshida[1], K. Kashiwagi[1], K. Makino[1], R. Shimizu-Hirota[1], H. Hirose[1], H. Ogata[2], Y. Sugino[1], Y. Iwao[1]

[2]*Center for Diagnostic and Therapeutic Endoscopy, Keio University Hospital, Tokyo/Japan*

**Contact E-mail Address:** nagamu@z6.keio.jp.

**Introduction:** Colorectal cancer (CRC) is the third leading cause of cancer death in Japan. For the past decades, the incidence and mortality rate of CRC has been increased in Japan which corresponds with the economic development and concomitant shifts from traditional lifestyle towards a westernized lifestyle. The association of metabolic syndrome (MetS) and CRC has been reported in several studies, however, individual factors contributing to CRC occurrence have been obscure, especially in Japan.

**Aims & Methods:** In the present study, we investigated the risk factors such as metabolic and lifestyle factors for the occurrence of colorectal neoplasia (CRN) including adenomatous polyps as precancerous lesionsby using comprehensive health checkup data. We conducted a retrospective analysis in clinical practice at a single center. Among 7213 subjects who took comprehensive health checkup at our hospital between in August 2012 and July 2015, 1835 subjects who also underwent screening colonoscopy were enrolled. Sixty-three subjects were excluded for analyzes because they did not take computed tomography (CT) for visceral fat area (VFA) measurement. In the present study, CRN was defined as adenomatous polyp ≥ 5 mm in size and adenocarcinoma. A diagnosis of MetS was made by Metabolic Syndrome Diagnostic Criteria Exploratory Committee in Japan. Demographic characteristics, anthropometric measurements, VFA measured at the umbilical level by CT, hematological metabolic parameters, degree of liver fat evaluated by ultrasonography, and current smoking and drinking habits were assessed. Association between variables and CRN was evaluated by univariate analysis using t-test, $\chi 2$ test, Mann-Whitney test, and then by multivariate analysis using multiple logistic regression model. A p value < 0.05 was considered statistically significant.

**Results:** Of 1772 subjects (men: 1206, women: 566) analyzed, 195 subjects had CRN (11.0%) and 5 had invasive colorectal cancer (0.3%). Four hundred and forty-six subjects were diagnosed as MetS (25.2%; 31.3% in men, 12.0% in women) and presence of MetS was significantly associated with CRN both in men (p = 0.016) and women (p < 0.01). Univariate analysis identified significant association of age, body mass index (BMI), VFA, systolic blood pressure (SBP), low-density lipoprotein (LDL)-cholesterol, high-density lipoprotein (HDL)-cholesterol, triglycerides (TG), fasting plasma glucose, hemoglobin A1c (HbA1c), fatty liver, current smoking habits, current drinking habits and ≥10 kg weight gain compared with the body weight at the age of twenty with prevalence of CRN. Logistic regression analysis revealed that age, current smoking, BMI, SBP, LDL and HDL-cholesterol and TG were independent factors associated with CRN prevalence (Table).

Logistic regression analysis

| | OR | 95% CI | p value |
|---|---|---|---|
| Age per 1 year increment | 1.046 | 1.031–1.062 | 0.000 |
| current smoking vs non-smoker | 2.445 | 1.617–3.697 | 0.000 |
| BMI per 1 kg/m$^2$ increment | 1.068 | 1.019–1.119 | 0.006 |
| systolic blood pressure per 1 mmHg increment | 1.013 | 1.004–1.021 | 0.004 |
| LDL-cholesterol per 1 mg/dL increment | 1.009 | 1.003–1.014 | 0.001 |
| HDL-cholesterol per 1 mg/dL increment | 1.013 | 1.001–1.026 | 0.035 |
| triglyceride per 1 mg/dL increment | 1.002 | 1.000–1.003 | 0.011 |

**Conclusion:** The present study demonstrated that metabolic factors in addition to aging and current smoking might be risk factors for CRN in Japan. This may help to identify high-risk subjects in CRC screening strategies.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0351 SECOND REORGANISED CYCLE OF NATIONAL COLORECTAL CANCER SCREENING PROGRAMME IN CROATIA

**Contact E-mail Address:** mirjanakalauz1@gmail.com.

**Introduction:** Colorectal cancer (CRC) was the second leading cause of cancer mortality in both men and women in 2013. in Croatia, (1.182 males and 855 females). Incidence is also on a second place among malignant neoplasms with 3.070 cases in 2013. with crude rate 71.6/100.000 (1.837 males and 1.233 females). The National Colorectal Cancer (CRC) Screening Program was established by the Ministry of Health, and started at the beginning of 2008. The second cycle lasted from October 2013. to April 2016. and it was performed in reorganised form.

**Aims & Methods:** Invitations included average population born between 1939 and 1963. The fecal occult blood test (FOBT) was performed by guaiac Hemognost card-test (Biognost). Each participant was invited to respond to invitation letter, and test cards with return envelope were mailed to responders. They had to fill the questionnaire and to send it together with the stool specimen of three consecutive bowel movements on test cards to the county public health institute for further reading. Person was considered as positive if 1 or more out 12 windows were positive. All positive persons were invited to colonoscopy within 6 weeks, and their GP was informed about that finding. A descriptive analysis of results was performed.

**Results:** A total of 1,331,910 individuals (100% of eligible from population database) were invited to screening by the end of 2016. In total, 353,164 (26.5%) persons returned the envelope with a completed questionnaire, while 81,837 were in one of groups with reason for nontesting. According to preliminary results, 184,084 persons returned test cards with a correctly applied stool specimen on FOBT cards. Until now, 7,630 (4.1%) FOBT positive patients have been found. Colonoscopy was performed in 6,120 patients (80%), and identified colorectal cancers in 205 patients (3.3% of colonoscopied, 2.6% of FOBT-positive, and 0.11% of all screened individuals). Polyps were found and removed in 1,328 (22% of colonoscopied) patients.

**Conclusion:** Second cycle implementation characteristics are: better compliance to screening invitation, especially in some counties, but still relatively low FOBT compliance; lower number of FOBT-positive persons than in first cycle, consecutively lower number of pathologic findings (polyps and cancers). Among organisational problems we detected problems with population database, lack of gastroenterology units, connection to informatised web-based screeening registry which is connected with GPs' application. Due to that, there is possible underregistration of examined participants. These results suggest a need for continous educational activities to improve awareness of CRC screening usefulness among target population as well as included health workers. Another problem is lack of colonoscopy equipement and in few counties lack of personnel. Continous improvement of CRC screening programe is needed.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0352 EARLY PERFORMANCE INDICATORS OF THE COLORECTAL CANCER SCREENING PROGRAMME IN NAVARRA (SPAIN): HIGH PARTICIPATION AND ACCEPTANCE RATE

**M. Rullan Iriarte**[1], D. Oyon Lara[1], S. López López[1], A. Elosua[1], F. Estremera Arévalo[1], C. Saldaña Dueñas[1], L. Casanova Ortiz[1], S. Oquiñena Legaz[2], A. Pueyo Royo[1], A. Guerra Lacunza[1]

**Contact E-mail Address:** maria_rullan@hotmail.com.

**Introduction:** In Navarra colorectal cancer (CRC) represents the highest incidence of cancer, the second cause of cancer mortality in men and the first in women. This implies an important public health problem, which justifies the development of control strategies. Moreover, various studies demonstrate that CRC screening programmes are cost-effective, and a determining factor for the successful of them is the participation rate and the adherence.

**Aims & Methods:** The aim of this study was to assess the global participation, from the invitation until the confirmatory diagnostic procedure during the first fifteen months of the colorectal cancer screening programme in Navarra, started in 2013 and based on a quantitative immunochemical fecal occult blood (i-FOBT). The following indicators were analyzed:.

**1. Target population:** people born between 1.1.1944 and 31.12.1964, who reside in Navarra.

**2. Exclusion criteria:** colonoscopy performed in the previous 5 years, previous diagnosis of CRC, follow-up colonoscopies because of colon disease and severe illness that involves a contraindication for the participation.

**3. Invited population:** people who have received an invitation to participate in the CRC screening programme during the first fifteen months.

**4. Acceptance:** expression of their willingness to participate.

**5. Participation:** number of people who provide their i-FOBT sample. The reasons for non-participation were collected through randomized telephone interviews (n = 250).

**6. Rate of referral for follow-up confirmatory diagnostic procedure** (colonoscopy or virtual colonoscopy**) after a positive i-FOBT.**.

**Results:** Firstly, 10, 664 people were excluded following the criteria described above from our target population (160, 000). Invited population during the first fifteen months was composed of 46, 189 people. However, 31, 107 expressed their willingness to participate and 26.752 (65.29%) provided their i-FOBT (66.97% for women and 63.41% for invited men). The most frequent reasons for non-participation were laziness and lack of time (30%), and also lack of risk of disease perception (26%). In total, 1914 people had a positive i-FOBT and 36 (1.9%) of them refused to continue with the confirmatory diagnostic procedure. In this period, 1145 people had followed-up confirmatory diagnostic procedure, 1244 colonoscopies and 25 virtual colonoscopies were performed.

**Conclusion:** We have obtained a high rate of acceptance and participation in the colorectal cancer screening programme in Navarra with a participation rate (PR) of 65.29% and also an acceptance rate of follow-up confirmatory diagnostic procedure of 98.1%. Both values exceed quality indicators and recommended standards of the European guidelines. (1) It is important to highlight that our programme participation rate is one of the highest in Spain (PR: 21% - 64.3%) and in Europe (7 – 67.7%), with similar rates to the Basque Country (PR: 64.3%) and Finland (PR: 67.7%) programmes. (2) To conclude, further studies are required for assessing the factors that have most significant influence in the PR of the CRC screening programmes. Nevertheless, the important lack of risk of disease perception in the non-participation group from our target population is an issue to be analyzed and addressed.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Morphine is still a gold standard in the treatment of patients with malignant tumors and those suffering from severe cancer pain. Its potent antinociceptive activity improves quality of life and is an advantage over side effects caused by chronic administration. Recent studies revealed that stimulation of opioid receptors produces different effects on cancer progression depending on the cancer type, stage of disease, etc. Therefore, before deciding on the type of therapy, in order to predict the course of, and estimate the patient's response to the intended treatment, it may be useful to consider possible involvement of genetic variability in opioid system activity. An animal model based on two mouse lines, displaying high (HA) and low (LA) activity of the endogenous opioid system has recently been employed for studies on the effects of opioids in the gastrointestinal (GI) tract. So far the usefulness of the HA/LA model has been validated for investigations on the GI motility.

**Aims & Methods:** The aim of our study was to characterize the role of the endogenous opioid system in the development of colitis-associated colorectal cancer in HA and LA mouse lines. Ten-week-old male Swiss-Webster mice bred using bidirectional selection and classified as HA or LA line based on the measurement of analgesia (hot plate and tail-flick tests) were used in this study. Colitis-associated colorectal cancer was induced by a single intraperitoneal injection of azoxymethane (10 mg/kg) and subsequent addition of dextran sodium sulfate (2% w/v) into drinking water (days: 7–14, 35–42, 63–70). The body weight and clinical score (rectal bleeding, stool consistency) were controlled. After 12 weeks, the macroscopic colon damage score was assessed and the samples for biochemical, molecular and histological studies were collected.

**Results:** A significant difference in tumor development between HA and LA lines in the mouse model of colitis-associated colorectal cancer was observed. In the HA mouse line, hyperactivity of the endogenous opioid system increased two-fold the number of tumors as compared to the LA mouse line. Myeloperoxidase activity, a measure of neutrophil infiltration, was also significantly increased in HA vs. LA mouse line. Moreover, LA mice were in good general health throughout the entire experimental period comparing to HA mouse line. Hematoxylin and eosin staining confirmed a significant difference between HA and LA mouse lines as indicated by histology score (muscle thickness, damage of the intestinal wall, immune cell infiltration, invasion depth, crypt hyperplasia and disruption).

**Conclusion:** Our data suggest that hyperactivity of the endogenous opioid system may be crucial in tumor development and progression in colitis-associated colorectal cancer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0354 PROMOTER HYPOMETHYLATION AND OVEREXPRESSION OF LINC00152 LONG NON-CODING RNA DURING DEVELOPMENT AND PROGRESSION OF COLORECTAL CANCER

**Introduction:** Long non-coding RNAs (lncRNAs) contribute to the development of different cancers including colorectal cancer (CRC). LINC00152 lncRNA has an oncogenic function in gastric cancer cell lines. Expression and effects of LINC00152 during colorectal carcinogenesis and cancer progression are not well studied.
**Aims & Methods:** We aimed to analyze LINC00152 expression and promoter DNA methylation changes along the colorectal normal-adenoma-carcinoma sequence. Possible gene expression regulatory role of LINC00152 was also studied in connection with DNA methylation regulation and with microRNAs which can be targeted by LINC00152. 147 colonic biopsy samples (49 normal, 49 adenoma, 49 CRC) were analyzed using HGU133Plus2.0 microarrays (Affymetrix). Real-time PCR validation was performed on 90 colonic specimens. DNA methylation was studied in 30 colonic tissue samples (15 adenoma, 9 CRC, 6 normal) using methyl capture sequencing. Methylation status of LINC00152 promoter was validated on 90 biopsy samples by bisulfite sequencing. Parallel LINC00152, microRNA, mRNA expression analysis was carried out using Human Transcriptome Array 2.0 and miRNA 3.0 Array data of 24 colonic biopsies.
**Results:** LINC00152 (Affy ID: 225799_at) was found significantly upregulated in adenoma and CRC samples compared to normal tissue ($p < 0.001$) which was confirmed by real-time PCR. Remarkable hypomethylation of LINC00152 promoter region was detected in CRC compared to normal samples using both methyl capture sequencing and bisulfite sequencing ($p < 0.01$), which was correlated with increased LINC00152 expression ($R = 0.90$). In parallel with LINC00152 overexpression, downregulation of certain microRNAs potentially targeted by LINC00152 (including miR-195-5 p) was found in CRC, while certain validated targets (like CDK4, CCND1) of these microRNAs were significantly upregulated ($p < 0.01$). In silico analysis revealed potential interactions between LINC00152 and promoters of tumor suppressor genes such as p15 and p21.
**Conclusion:** Promoter hypomethylation and overexpression of LINC00152 lncRNA can contribute to colorectal carcinogenesis facilitating cell proliferation through downregulation of miRNAs targeting cell cycle progression genes or affecting promoter methylation of tumor suppressor genes.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0355 CONTRIBUTION OF THE MEK5/ERK5 PATHWAY TO COLON CANCER STEM-LIKE CELL PROPERTIES

**D. M. Pereira,** S.E. Gomes, A. E. s. Simões, R. E. Castro, P. M. Borralho, C. M.P. Rodrigues

**Introduction:** Cancer stem cells are currently viewed as the reservoir of cells responsible for tumour development, metastasis and drug resistance. However, the molecular players underlying cancer stem cell self-renewal and chemoresistance remain poorly understood. We have previously demonstrated that the MEK5/ERK5 signalling pathway promotes colon cancer metastasis, and that ERK5-targeted inhibition enhances the anticancer properties of 5-fluorouracil in a murine xenograft model.
**Aims & Methods:** In the present study, we aim to understand the contribution of MEK5/ERK5 signalling for the regulation of the balance between self-renewal and differentiation in colon cancer stem cells. The effect of MEK5/ERK5 signalling inhibition was investigated in human colon cancer stem-like cells using both genetic and pharmacological approaches. For this purpose, HCT116, HT29, SW480 and SW620 colon cancer cells were cultured for three generations in sphere-forming conditions. The number of tumour spheres and cells per sphere was determined for each generation. The levels of CD44/CD133 expression and aldehyde dehydrogenase 1 (ALDH1) activity were evaluated by flow cytometry. Additionally, the mRNA expression of established stemness markers was evaluated by SYBR Real-Time PCR.
**Results:** Our results demonstrate that tumour spheres enriched in colon cancer stem-like cells have significantly higher levels of MEK5 and ERK5 phosphorylation when compared with their adherent counterparts. In turn, ERK5 inhibition using the pharmacological inhibitor XMD8-92 decreased the number and size of spheres in HCT116, HT29, SW480 and SW620 cells over three generations ($p < 0.05$). Similarly, ERK5 inhibition using a dominant negative form of MEK5 decreased HCT116 sphere-forming ability, significantly reducing the number of cells per tumour sphere in third generation spheres, as compared to controls ($p < 0.01$). In addition, ERK5 pharmacological inhibition significantly reduced the proportion of CD44/CD133-positive cells ($p < 0.05$), as well as the percentage of cells with high ALDH1 activity. Finally, mRNA expression levels of stemness markers Sox2, Oct4, Lgr5 and Bmi1 were also negatively regulated by XMD8-92 in SW620 spheres ($p < 0.05$).
**Conclusion:** Our results indicate that MEK5/ERK5 pathway activation may contribute to sustained stemness in colon cancer cells, suggesting ERK5 inhibition as a potential therapeutic strategy to target colon cancer stem cells and improve colon cancer treatment. Supported by UID/DTP/04138/2013, SFRH/BD/96517/2013 and SFRH/BD/88619/2012 from FCT, Portugal.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0356 SELECTIVE INHIBITION OF FATTY ACID AMIDE HYDROLASE INHIBITOR PF-3845 DECREASES VIABILITY, MIGRATION AND INVASIVENESS OF HUMAN COLON ADENOCARCINOMA COLO-205 CELL LINE

**Introduction:** Colorectal cancer (CRC) is the third most commonly diagnosed cancer and the third leading cause of cancer death worldwide. Thus, it is clear that there is an urgent need for developing effective anti-cancer agents and promising approaches that will improve clinical outcomes in CRC patients. Earlier reports suggest that cannabinoids may inhibit tumor growth both in vitro and in animal models. The aim of our study was to characterize the influence of selected inhibitors of the enzymes involved in the synthesis and degradation of endocannabinoids on colon cancer cell viability, invasiveness and migration.
**Aims & Methods:** The human colon adenocarcinoma Colo-205 cells were incubated with PF-3845, JZL-184 and RHC-80267 (inhibitors for fatty acid amide hydrolase (FAAH), mono- (MAGL) and diacylglycerol lipase (DAGL), respectively) for 48 h. To determine cell viability, the colorimetric MTT metabolic activity assay was used. Next, Colo-205 cells were incubated with PF-3845 alone or with PF-3845 together with selected antagonists: AM 251, AM 630, SB 366791, RN 1734 and G-15 ($CB_1$, $CB_2$, TRPV1, TRPV4 and GPR30 antagonists, respectively). Furthermore, we characterized the expression of $CB_1$ and $CB_2$ receptors by Western blot analysis and assessed the effect of PF-3845 on Colo-205 cell migration and invasiveness.
**Results:** We observed that PF-3845 was the most efficient in decreasing Colo-205 cell viability ($IC_{50} = 52.55 \pm 4.75\,\mu M$). Interestingly, this effect was enhanced when Colo-205 cells were incubated with PF-3845 and RN-1734, a TRPV4 antagonist ($IC_{50} = 30.54 \pm 5.36\,\mu M$). Furthermore, we noted a significant decrease ($p < 0.05$) in the expression of $CB_1$ receptor and a significant increase ($p < 0.001$) in $CB_2$ expression levels in response to treatment with PF-3845 compared with untreated control. We also demonstrated that PF-3845 at the concentrations of 25 $\mu$M and 50 $\mu$M significantly ($p < 0.001$) reduced migration and invasiveness of Colo-205 cells (by 49.57 and 71.28% versus control, respectively).
**Conclusion:** For the first time, we report that PF-2845 may play a crucial role in inhibiting viability, migration and invasiveness of Colo-205 cell line. Thus, our studies strongly support the hypothesis that modulation of the endocannabinoid turnover through inhibition of their hydrolysis could be a potential anti-cancer strategy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0357 SECRETION PROTEIN VSTM2A IS A NOVEL TUMOR SUPPRESSOR AND ASSOCIATES WITH COLORECTAL CANCER PATIENT SURVIVAL

**Introduction:** Using genome-wide promoter CpG island screening and RNA-sequencing data, we have recently identified that V-set and transmembrane domain containing 2 A (VSTM2A) gene, which encodes a 26 kDa protein, was hypermethylated and silenced in colorectal cancer (CRC). However the role of VSTM2A in tumorigenesis has not been evaluated yet.
**Aims & Methods:** VSTM2A methylation status was evaluated by bisulfite genomic sequencing. The biological functions of VSTM2A were investigated in vitro

and in vivo. VSTM2A downstream effectors were elucidated by luciferase assay, real-time PCR and Western blot. The clinical impact of VSTM2A was assessed in 263 CRC patients.
**Results:** Full or partial methylation of VSTM2A promoter was found in CRC cell lines and tumor specimens, whilst none or low methylation was detected in the normal colon tissue specimens. Demethylation by 5-aza-2'-deoxycytidine restored VSTM2A expression in silenced CRC cell lines, indicating that promoter methylation contributed to the decrease expression of VSTM2A. VSTM2A mRNA was significantly reduced in all 8 CRC cell lines and in CRC cancer tissues compared with adjacent normal tissues ($n = 86$, $P < 0.05$). In keeping with this, VSTM2A protein expression was reduced in CRC tumors compared to their adjacent normal tissues detected by Western blot ($P < 0.05$) and immunohistochemistry analysis ($P < 0.01$). We further evaluated the association between VSTM2A protein expression level and survival of CRC patients by tissue microarray. A survival analysis of 158 CRC patients indicated that high VSTM2A protein expression was significantly correlated with longer overall survival ($P < 0.05$) and disease-free survival ($P < 0.05$). Our functional studies supported a tumor suppressive role of VSTM2A in CRC. Ectopic VSTM2A expression significantly suppressed CRC cell viability ($P < 0.01$) and reduced colony formation ($P < 0.01$). VSTM2A caused G2 phase cell cycle arrest ($P < 0.001$) and induced apoptosis ($P < 0.01$), concomitant with enhanced cell cycle regulators p21 and p27, and pro-apoptotic factors of cleaved caspase 3, caspase 8 and PARP. Subcutaneous tumor xenografts of CRC cells (HCT116 and DLD1) with stable VSTM2A expression in nude mice exhibited significant reduced tumor growth compared with the control cells ($P < 0.01$). We further investigated the molecular mechanisms of VSTM2A in CRC. VSTM2A could be detected in the cell culture supernatant. Inhibition of the cell secretion by Brefeldin A, which prevents secretory protein transport from the endoplasmic reticulum to the Golgi apparatus, inhibited VSTM2A supernatant expression and induced cytosolic accumulation, suggesting a secretory property of VSTM2A. Our results further indicated that secreted VSTM2A could attach to cell plasma membrane evidenced by Immunofluorescence and immunoprecipitation assays, inferring that VSTM2A exerted its biological function in a paracrine manner. Using luciferase reporter screening of 9 signal transduction pathways, we found that VSTM2A significantly inhibited Wnt signaling TOP-Flash luciferase reporter activity ($P < 0.01$). Moreover, VSTM2A suppresses Wnt signaling through inducing $\beta$-catenin phosphorylation and inhibiting Wnt downstream targets c-myc and cyclin D1 expression.
**Conclusion:** Secretory protein VSTM2A is a critical tumor suppressor in colorectal carcinogenesis through inhibiting Wnt signaling by suppressing $\beta$-catenin activation. High VSTM2A protein level was significantly correlated with better CRC patient outcomes.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0358 MDM2 T309G POLYMORPHISM AND RISK OF COLORECTAL CANCER

**N. Aggarwal,** N. Donald, S. Malik, S. Selvendran, M. Mcphail, K. Monahan
*Imperial College London, London/United Kingdom*

**Contact E-mail Address:** na2412@ic.ac.uk.
**Introduction:** Murine double minute 2 (MDM2) is an E3 ubiquitin-protein ligase that mediates cell cycle arrest by negatively regulating the tumour suppressor gene p53. Polymorphisms have been thought to be associated with colorectal cancer (CRC), however results have been largely inconclusive. A meta-analysis of MDM2 T309G (rs2279744) was conducted to clarify and assess whether any association could be found.
**Aims & Methods: Aim:** To perform a systematic review and meta-analysis to assess the association of MDM2 T309G polymorphism with the risk of CRC.
**Methods:** A systematic literature review of the Pubmed and HuGENet databases was conducted and studies were included/excluded based on pre-specified criteria. The per allele model was used to assess risk by calculating pooled odds ratios with 95% confidence intervals. Publication bias was investigated using a funnel plot. Statistical analysis was conducted using the R program (version 3.2.4).
**Results:** A total of 135 studies were screened and 6 case control studies were included with 3553 cases and 5781 controls. No association was found between MDM2 T309G and CRC ($OR = 1.25$; 95% CI 0.97–1.62). The funnel plot showed that publication bias was present.
**Conclusion:** This meta-analysis suggests that MDM2 T309G polymorphism is not associated with risk of CRC and should not be evaluated as part of a patient risk assessment. Future studies with larger and more varied ethnicities would allow more accurate assessment of the association between MDM2 T390G and CRC risk.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0359 UNTANGLING MOLECULAR ORIGINS OF COLORECTAL CARCINOMAS AND ASSIGNMENT OF MAJOR PATHWAYS BASED ON CIMP/MSI/BRAF/KRAS/TP53/APC PROFILES FROM ENDOSCOPIC TISSUE SAMPLING

**Introduction:** Recent advances in molecular profiling have resulted in definition of molecular types of colorectal cancer based on genetic and epigenetic aberrations. Resulting from separate developmental pathways the different types are associated with distinct prognostic features, which can be utilized in clinical practice.
**Aims & Methods:** The aim of this study was to assign molecular subtypes based on CIN/CIMP/MSI molecular phenotypes in combination with mutation status of (proto) oncogenes KRAS and BRAF and tumor suppressors TP53 and APC in large adenomas and in early and late carcinomas for assessment of patients prognosis. A prospective 3-year study has resulted in the acquisition of samples (fresh biopsies or FFPE sections from EPE or EMR) from 138 carcinomas along with associated clinical parameters including localization, grade and histological type from adenomas and localization and stage for carcinomas. A complex molecular phenotyping has been performed on endoscopic tissue specimens using methylation-specific multiplex ligation-dependent probe amplification technique (MS-MLPA) for the evaluation of CpG-island methylator phenotype (CIMP), PCR fragment analysis for detection of microsatellite instability (MSI) and high-sensitive CE melting assay for multiplex detection of somatic mutations in KRAS, BRAF, TP53 and APC genes.
**Results:** We have identified carcinomas belonging into 5 major molecular subtypes: (i) 3x serrated CIMP+/BRAF+/MSI-; (ii) 9x serrated CIMP+/BRAF+/MSI+; (iii) 2x familial CIMP+/MSI+/BRAF-, (iv) 38x Traditional CIMP-/KRAS+/APC+ and (v) 18x Traditional CIMP+/TP53+. The remaining 68 carcinomas were resulting from other combinations.
**Conclusion:** The complex molecular profiling using combination of phenotypes with somatic mutations of oncogenes and tumor supressors allows for efficient stratification of carcinomas with subsequent assignment of prognosis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Universal screening of all colon cancers for Lynch syndrome (LS) through immunohistochemistry for DNA mismatch repair proteins is currently recommended. However, there are many false positive results due to somatic methylation of MLH1. Directly analyzing the MLH1 gene for promoter methylation is ideal but is costly and not widely available. BRAF mutation status has been proposed as a surrogate marker, but the performance of BRAF testing in the setting of a large screening population has not been defined.
**Aims & Methods:** To define the correlation between BRAF mutation status and MLH1 promoter methylation in a screening program for LS. To define the correlation between BRAF mutation status and MLH1 promoter methylation in a screening program for LS. A universal screening program for LS was established in 2 medical centers. Tumors with abnormal MLH1 staining had both BRAF and MLH1 promoter methylation analysis performed. Tumors positive for both were considered to be sporadic cancers. Formal genetic testing was recommended for all other cases.
**Results:** 1011 CRC cases were screened for LS over a 4-year period, and 148 (15%) exhibited abnormal MLH1 staining. Both BRAF and MLH1 hypermethylation testing was completed in 126 of these cases. Concordant results (positive for both BRAF mutation and MLH1 hypermethylation, or negative for both) were obtained in 86 (68%) and 16 (13%) cases, respectively. The overall concordance rate between MLH1 methylation and BRAF mutation status was 81%. The PPV and NPV for a BRAF mutation in predicting MLH1 promoter methylation were 99% and 41%, respectively. In patients 70 years or older, the NPV fell to 15% (vs. NPV = 68% in patients < 70 years). This decline in NPV was observed in both male and female patients, though it was much more pronounced in females (NPV = 6% in females ≥ age 70). If BRAF mutation testing had been used as a sole test to evaluate cases with abnormal MLH1 staining, there would have been a 2.3-fold increase in the number of referrals for genetic testing compared to the use of MLH1 methylation testing. However, a 2-tier approach in which BRAF is

performed on all cases and MLH1 methylation testing is then offered only for BRAF wild type (WT) cases would result in a comparable number of referrals for genetic testing when compared to MLH1 methylation testing in all cases. By reserving MLH1 methylation testing only for BRAF WT cases, there would be a decrease of almost 70% in the number of MLH1 methylation tests performed.
**Conclusion:** In a large prospective screening program for LS, BRAF mutation status has an excellent PPV but poor NPV in predicting MLH1 promoter methylation. This low NPV is attributable to a large number of BRAF WT/MLH1 methylation-positive cases in patients ≥ 70 years old. A tiered approach in which BRAF testing is performed in all cases and more costly MLH1 methylation is reserved for BRAF WT cases may reduce costs and facilitate wider implementation of LS screening programs.

**Introduction:** Sessile serrated lesions (SSL) are suggested to be the precursors of 15–30% of colorectal cancer (CRC). Distinguishing premalignant SSL from innocuous hyperplastic polyps (HP) tends to be difficult for pathologists in daily practice. As a result, the current European Society of Gastrointestinal Endoscopy surveillance guideline does not differentiate between histopathological subtypes of serrated polyps with regard to post-polypectomy surveillance advice, resulting in both over- as well as under-treatment.
**Aims & Methods:** We aimed to evaluate nationwide variability within histopathology laboratories in the frequency of diagnosing a SSL as compared to a HP within the Dutch Faecal Immunological Test (FIT)-based population screening program for colorectal cancer and to assess the potential beneficial effect of a structured e-learning on practice variation. Data of all resected serrated polyps within the national screening program were retrieved from the Dutch Pathology Registry (PALGA) from January 2014 to December 2015. An e-learning was developed, commissioned by the National Institute for Public Health and the Environment, and implemented among screening pathologists on October first 2014. Ratio between SSL and HP diagnosis was determined per laboratory. Mixed effects logistic regression was used to calculate adjusted odds ratios (OR) for the diagnosis of a SSL per laboratory, as compared to the median reference laboratory. To evaluate the effect of the e-learning on the variability within pathology laboratories, only those laboratories that assessed at least 50 lesions both before as well as after implementation of the e-learning were selected. Difference in practice variation before and after implementation was calculated using a Wilcoxon matched-pair signed-rank test.
**Results:** In total 14, 997 individuals with 27, 879 serrated polyps were included for analysis; 9, 244 (61.6%) were male and 8, 487 (56.6%) were above 65 years of age. Of all serrated polyps, 6, 665 (23.9%) were diagnosed as SSL and 21, 214 as HP (76.1%). Number of diagnosed serrated polyps ranged from 99 to 2238 (median 533) between 44 laboratories. The ratio of diagnosing a SSL as compared to all serrated polyps ranged from 5 to 47% (median 23%). In total 22 (50%) laboratories showed a significant different adjusted OR (range 3.47–0.16) for the diagnosis of an SSL as compared to the reference laboratory. Proportion of SSL diagnosis significantly increased after implementation of the e-learning (median 18 vs 25%; $P < 0.001$). After implementation, the adjusted OR of 23 out of 33 included laboratories shifted towards the reference, while 10 laboratories shifted away from the reference laboratory. Variability between laboratories significantly decreased after implementation ($p = 0.02$).
**Conclusion:** We demonstrated a substantial inter-laboratory variability in the histopathological classification of serrated polyps, which decreased after implementation of a structured e-learning. Results from this study might contribute to more homogeneous practice among pathologists in the diagnosis of SSL, by advocating awareness and training in an overarching and structured setting.

**Introduction:** Colorectal cancers are generally recognized to develop from protruded-type "polyps". This "adenoma-carcinoma sequence" theory has been in the mainstream of development of colorectal cancers. But recently the existence of many depressed-type cancers has been revealed, which are considered to emerge directly from normal epithelium, not through the adenomatous stage. This theory is called "de novo" pathway.
**Aims & Methods:** The aim is to clarify the pathological features of depressed-type colorectal carcinomas compared with flat- and protruded -type. A total of 27599 colorectal neoplasms excluding advanced carcinomas were resected endoscopically or surgically in our Center from April 2001 to Dec 2015. Of these, 1097 lesions were T1 carcinomas. According to the morphological/development classification, 236 lesions (21.5%) were depressed-type, 373 lesions (34.0%) were flat-type and 426 lesions (44.4%) were protruded-type. We analyzed the pathological features of these lesions.
**Results:** The rate of submucosal invasion in all the lesions was 62.1% in depressed-type, 3.3% in flat-type and 2.8% in protruded-type. Within less than 5 mm in diameter, that was 10.6%, 0% and 0% respectively. Among T1 carcinomas, the rate of vessel invasion was 63.6% in depressed-type, 34.3% in flat-type and 38.7% in protruded-type, that of poorly differentiated or mucinous adenocarcinoma was 16.9%, 11.0% and 13.6%, that of massively submucosal invasion was 87.7%, 59.0% and 71.4%, and that of tumor budding was 36.9%, 16.4% and 17.3%, respectively. The rates of these pathological factors were significantly higher in the depressed-type lesions. On the other hand, the rate of adenomatous component was 5.1%, 52.5% and 50.8%, and the rate of polypoid growth was 16.1%, 53.1% and 95.3% respectively. It was significantly lower in depressed-type lesions, suggesting that they emerge directly from normal epithelium without going through the adenoma stage. The rate of lymph node metastasis was 10.2%, 3.2% and 9.1%, respectively. Among 1097 cases of T1 colorectal carcinomas, two cases showed synchronous metastasis and both were depressed-type lesions.
**Conclusion:** Depressed-type colorectal carcinomas invade massively even when they are small. They had higher risks of vascular invasion, poorly differentiated or mucinous adenocarcinoma, massive invasion, and tumor budding than flat- and protruded-types. For their rapid growth and malignant potential, whether the lesion is depressed-type or not is very important in the diagnosis of colorectal carcinomas.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0363 ELECTRONIC NOSE (AENOSE™) CAN DETECT COLORECTAL CARCINOMA IN EXHALED BREATH: A PILOT STUDY

**M. E. Jansen**[1], B. Koekoek[1], M. J.A. Mulder[1], J.J. Kolkman[2]
[1]*Gastroenterology, Medisch Spectrum Twente, Enschede/Netherlands*
[2]*Department Of Gastroenterology, University Medical Center Groningen, University of Groningen, Groningen/Netherlands*

**Contact E-mail Address:** M.jansen@mst.nl.
**Introduction:** With colorectal cancer (CRC) being the fourth leading cause of death of malignant diseases early detection in screening programs is essential. With a limited sensitivity for the most frequently used screening tool, the fecal immunochemical test (FIT), there is need for a better screening tool. We performed a first study to analyse volatile organic compound (VOC) patterns in exhaled air using an electronic nose.
**Aims & Methods:** In this proof of concept study we aimed to investigate with an electronic nose (Aenose™) whether patients with CRC have a specific VOC pattern compared to non-CRC patients. Breath samples of patients with a suspicion of CRC who were scheduled to undergo an elective colonoscopy were collected, as well as samples of patients with histologically proven CRC before undergoing surgery. The electronic nose (Aenose™) is equipped with three sensors. By using thermal cycling a four dimensional pattern (time, temperature, sensor response, sensor type) is obtained. These data were compressed using a Tucker3 algorithm, generating a 1-dimensional vector for each measurement. In this way, the electronic nose is "trained" to distinguish between healthy controls and patients with CRC. Sensitivity, specificity and the receiver operator characteristic (ROC) curves for detection of CRC were calculated.
**Results:** We obtained samples in 90 patients, mean age 65 years (range 40–85, 52% female). Of these 23 had CRC, and 67 served as controls. No differences in baseline characteristics were seen, besides a 3 years higher age in the CRC group. The colonoscopic findings in the control group encompassed normal findings ($n = 17$), hyperplasia ($n = 7$), adenomas with low ($n = 23$) and high grade dysplasia ($n = 1$), and colitis ($n = 5$). The VOC pattern from patients with CRC differed from the controls with a sensitivity of 96% and a specificity of 91%. The area under the ROC curve (AUC) was 0.93.
**Conclusion:** This study shows that patients with CRC and healthy controls have a different VOC pattern and suggests that this electronic nose is able to differentiate between these two. A validation study is needed for confirmation of these promising first results.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0364 CLINICOPATHOLOGICAL STUDY OF LATERALLY SPREADING TUMORS OF THE COLORECTUM

**M. Iwabuchi,** M. Sugimura, K. Ukai, K. Tadokoro
*Gastroenterology, Sendai Medical Center, Sendai/Japan*

**Contact E-mail Address:** s7856@snh.go.jp.
**Introduction:** Laterally spreading tumors (LSTs) of the colorectum are classified into the following four subtypes according to their morphology; granular homogeneous type (LST-GH), granular nodular mixed type (LST-GM), non-granular flat-elevated type (LST-NGF), and non-granular pseudo-depressed type (LST-NGPD). Clinical features of each subtype of LSTs have not been fully evaluated.
**Aims & Methods:** The aims of this study was to clarify the clinicopathological features of colorectal LSTs focusing on their subtypes. We reviewed clinical

charts and surgical pathology files of 4402 endoscopically resected specimens during January 2007 and December 2015 at our institution. A total of 358 LSTs were detected. We examined the clinical features (mean age, male to female ratio, size, location, Incidence of concomitant carcinoma) according to their subtypes.
**Results:** Of these 358 lesions, a total of 117 (32.7%) were LST-GH, 29 (8.1%) LST-GM, 188 (52.5%) LST-NGF, and 24 (6.7%) LST-NGPD. Mean age of patients with each subtype was 68.7 years old for LST-GH, 66.1 for LST-GM, 68.6 for LST-NGF, and 67.9 for LST-NGPD. Male to female ratio (M/F) was 1.05 for LST-GH, 2.22 for LST-GM, 1.85 for LST-NGF, and 1.40 for LST-NGPD. Mean size of LST-GH (19.4 mm) and LST-GM (24.3 mm) were significantly larger than that of LST-NGF (15.1 mm) and LST-NGPD (13.9 mm). All subtypes were located predominantly in the proximal colon. Incidences of concomitant carcinomas in LST-GH, LST-GM, LST-NGF, and LST-NGPD were 22.2% (26 out of 117), 62.1% (18 out of 29), 16.0% (30 out of 188), and 71.4% (15 out of 21), respectively. Incidences of concomitant submucosal carcinomas in LST-GH, LST-GM, LST-NGF, and LST-NGPD were 0% (0 out of 117), 17.2% (5 out of 29), 1.1% (2 out of 188), and 25.0% (6 out of 24), respectively.
**Conclusion:** Each subtype of LSTs has distinct clinical features. LST-GM and LST-NGPD have higher malignant potentials than other subtypes. Especially LST-NGPD has the highest risk of invasive carcinoma regardless of its size. Therefore we should carefully detect these lesions and choose appropriate treatment according to the subtypes.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0365 MICROVESSEL DENSITY OF NEOVASCULAR VESSELS COULD BE A PREDICTOR OF DISTANT METASTASIS OF COLORECTAL CANCER: IMMUNOHISTOCHEMICAL ASSESSMENT WITH CD105 ANTIBODY

**T. Cho**[1], E. Shiozawa[1], S. Kudo[2], F. Urushibara[3], M. Misawa[4], H. Miyachi[4], T. Yamochi[1], M. Takimoto[1]

**Introduction:** It is thought that tumor growth is dependent on angiogenesis, which may also permit metastasis. CD105 (endoglin) is an accessory receptor of transforming growth factor (TGF)-$\beta$. It has been demonstrated that anti-CD105 antibody has high affinity for activated endothelial cells. Therefore, CD105 may be a specific marker for tumor angiogenesis. The relationship between neovascularization, assessed by CD105 antibody, and metastasis has been reported. However, it is still worthwhile to investigate the relationship between distant metastasis and CD105 antibody-positive microvascular density (MVD), along with potentially confounding clinicopathological factors.
**Aims & Methods:** We aimed to establish the relationship between CD105-antibody-positive microvessels and distant metastasis. We analyzed 126 colorectal adenocarcinomas that were endoscopically or surgically resected at Showa University Northern Yokohama Hospital between January and September 2009. We assessed microvessels by staining their endothelial cells with CD105 monoclonal antibody. We defined MVD as the number of microvessels per 400× field. MVD was counted by one pathologist (T.C.). In addition, clinicopathological factors were retrospectively analyzed and multivariate logistic regression was performed to predict the independent risk factors for distant metastasis.

**Table:** Multivariate logistic regression.

| Clinicopathological factors OR (95% CI) | | Multivariate analysis P value | |
|---|---|---|---|
| Age | (≥70/<70 years) | 1.24 (0.42–3.67) | 0.6962 |
| Sex | (male/female) | 1.34 (0.46–4.03) | 0.5947 |
| Tumor size | (≥30/<30 mm) | 1.15 (0.22–7.71) | 0.8736 |
| Location | (rectum/colon) | 1.20 (0.39–3.61) | 0.7488 |
| Tumor depth | (T2–T4/T1b) | 8.32 (0.76–238.54) | 0.1266 |
| Lymphatic invasion | (+/-) | 0.54 (0.12–2.21) | 0.3912 |
| Venous invasion | (+/-) | 3.88 (0.87-23.40) | 0.0983 |
| Regional lymph node metastasis | (+/-) | 6.22 (1.73–25.99) | 0.0074 |
| Por/Muc component | (+/-) | 0.65 (0.17–2.30) | 0.5182 |
| Adjuvant chemotherapy | (+/-) | 1.69 (0.47–6.13) | 0.4147 |
| MVD | (≥10/<10 per 400× field) | 3.84 (1.30–12.31) | 0.0176 |

CI, confidence interval; OR, odds ratio; Por/Muc, poorly differentiated adenocarcinoma / Mucinous adenocarcinoma.

**Results:** At the time of resection or during follow-up, 30 lesions had distant metastasis (liver, 12; lung, 4; peritoneum, 4; liver and peritoneum, 3; lung and peritoneum, 3; liver, lung and peritoneum, 1; liver and bone, 1; liver, lung, distant lymph node and bone, 1; lung, kidney and spleen, 1). The mean ± SD CD105-antibody-positive MVD in patients with distant metastases was significantly larger than in those without distant metastasis (10.5 ± 4.9 vs 7.6 ± 3.4; $P < 0.05$, Student's t test). Multivariate logistic regression indicated that CD105-antibody-positive MVD and regional lymph node metastasis were predictors of distant metastasis (Table).
**Conclusion:** Assessment of CD105-antibody-positive MVD could contribute to selecting patients who need more intensive surveillance after surgery for colorectal cancer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0366 CLINICOPATHOLOGICAL STUDY OF SERRATED LESIONS OF THE COLORECTUM

**M. Sugimura,** M. Iwabuchi, K. Ukai, K. Tadokoro
*Gastroenterology, Sendai Medical Center Dept. of Gastroenterology, Sendai/Japan*

**Contact E-mail Address:** msugimura@snh.go.jp.
**Introduction:** Serrated lesions of the colorectum are the precursors of microsatellite unstable carcinomas. However, their clinical and pathologic features are still unclear and need further exploration.
**Aims & Methods:** The aims of this study was to clarify the clinicopathological features of colorectal serrated lesions. We reviewed clinical charts and pathology files of 4402 endoscopically resected specimens performed during January 2007 and December 2015 in our hospital. A total of 381 serrated lesions resected were classified into three categories: HP (hyperplastic polyp), SSA/P (sessile serrated adenomas/ polyps), and TSA (traditional serrated adenoma), according to the WHO criteria. We examined the features of these cases and evaluate the morphologic characteristics by using immunochemical staining for Ki-67 and the expression of MUCs (MUC2, MUC5AC and MUC6) in differentiating serrated lesions.
**Results:** Of these 381 lesions, a total of 194 (50.9%) were HP, 77 (20.2%) SSA/P, and 110 (28.9%) TSA. Male to female ratio (M/F) was 2.35 for HP, 1.02 for SSA/P, and 2.45 for TSA. Mean size of SSA/Ps (13.1 mm) and TSAs (10.4 mm) were significantly larger than that of HP (8.5 mm) ($p < 0.005$, respectively). SSA/Ps were located predominantly in the proximal colon, whereas HP and TSA were mainly located in the sigmoid colon and rectum. 85% of SSA/Ps were flat in macroscopic appearance. SSA/Ps and HPs were whitish or almost the same as adjacent mucosa in color, whereas TSAs had a tendency to be reddish. Magnified colonoscopy showed Type II open pit pattern as characteristic of SSA/Ps, whereas pinecone-shaped pit pattern as that of TSAs. Incidences of concomitant carcinomas in HP, SSA/P, and TSA were 0% (0 out of 194), 2.6% (2 out of 77), and 4.5% (5 out of 110), respectively. Ki-67 positive cells in HP showed regular, symmetric distribution, and those in SSA/P did irregular asymmetrical pattern, whereas most of those cells in TSA distributed in the so-called ectopic crypts. Expression levels of MUC2, MUC5AC and MUC6 were significantly different between serrated lesions, SSA/Ps and HPs were positive for MUC5AC in comparison with TSAs.
**Conclusion:** Our studies showed the three types of serrated lesions have their own distinct features and could be helpful to distinguish between them. SSA/P and TSA are premalignant lesions of colorectum and we should detect these lesions and completely remove endoscopically.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0367 COMPARISON OF A METHYLATED BCAT1/IKZF1 BLOOD TEST WITH CEA FOR RECURRENT COLORECTAL CANCER

**Contact E-mail Address:** graeme.young@flinders.edu.au.

**Introduction:** Recurrence will develop in 30–50% of colorectal cancer (CRC) cases despite apparent clearance following treatment. Carcinoembryonic-antigen (CEA) is the only guideline-recommended blood test for monitoring cases for recurrence, but its sensitivity and specificity are suboptimal and its survival value might be improved upon. A more sensitive test for recurrence might provide survival benefit.

**Aims & Methods:** This study compared a novel 2-gene (methylated *BCAT1 and IKZF1* DNA) blood test to CEA for detection of recurrent CRC. To do this, we conducted an observational, paired comparison of detectable methylated *BCAT1 and IKZF1* DNA with CEA (cut-off 5 ng/mL) in blood from patients in remission after treatment for primary CRC and undergoing surveillance at 3–6-monthly intervals. Blood collected in the 12-months prior to or 3 months after radiological assessment of recurrence status were assayed and the results (in the sample collected closest to ascertainment of recurrence status) compared by McNemar's test. Recurrence status was determined by a combination of radiological, pathological and endoscopic methods.

**Results:** Of 397 patients enrolled, 220 underwent satisfactory assessment for recurrence and 122 had blood testing performed within the prescribed period. In 28 cases with recurrent CRC, CEA was positive in 9 (32%; 95%CI 16–52%) compared to 19 (68%; 95%CI 48–84%) positive for methylated *BCAT1/IKZF1* ($p = 0.002$). All samples from cases with recurrence that were CEA positive were also *BCAT1/IKZF1* positive (none was positive by CEA alone). Sensitivity estimates of the methylated *BCAT1/IKZF1* test for local ($n = 4$) and distant ($n = 24$) recurrence were 75% and 66.7%, respectively, compared to 50% and 29.2% for CEA. In 94 patients without clinically-detectable recurrence, CEA was positive in 6 (6%, 95%CI 2–13%) and *BCAT1/IKZF1* in 12 (13%, 95%CI 7–21%), $p = 0.210$, with only 1 of these being positive by both tests. *BCAT1/IKZF1* test positivity was not affected by gender or age. The odds ratio of a positive CEA test for recurrence was 6.9 (95%CI 2–22) compared to 14.4 (5–39) for *BCAT1/IKZF1*. The positive predictive values of methylated *BCAT1/IKZF1* and CEA in this population were 61.3% (42.2–78.2) and 60.0% (32.3–83.7) respectively.

| Concordance between tests<br>**Recurrence, n = 28** | | CEA | CEA |
|---|---|---|---|
| | **Result** | + | - |
| *BCAT1/IKZF1* | + | 9 | 10 |
| *BCAT1/IKZF1* | - | 0 | 9 |
| **No apparent recurrence, n = 94** | | | |
| *BCAT1/IKZF1* | + | 1 | 11 |
| *BCAT1/IKZF1* | - | 5 | 77 |

**Conclusion:** The *BCAT1/IKZF1* test was more sensitive for recurrence and picks up additional cases not detected by CEA. Also, recurrence was twice as likely with a positive *BCAT1/IKZF1* test than with CEA when applied on a single occasion. This test should be considered for monitoring cases for recurrence after induction of remission.

**Introduction:** Carbonic anhydrase IX (CAIX) is a hypoxia-inducible enzyme that is overexpressed in a variety of cancers including colon cancer and plays a crucial role in maintaining favourable intracellular pH and reducing extracellular pH, thus providing a selective advantage for cancer cells. There is also evidence that extracellular vesicle (EV) production is increased in response to hypoxia and promotes adaptive response of cancer cells.

**Aims & Methods:** Within this study, we explored a possibility to use CAIX for the isolation of hypoxic exosomes from colorectal cancer (CRC) patients' plasma. Colon cancer cell lines SW480 and SW620 that are originally derived from primary and metastatic tumour from a single patient were cultured under hypoxic or normoxic conditions. Exosome-enriched EV fractions were isolated from cell culture mediums and plasma samples from 12 CRC patients and 10 healthy donors by using sequential centrifugation, filtration and size-exclusion chromatography steps.

**Results:** Nanoparticle tracking analysis (NTA) of EVs produced by SW480 and SW620 cell lines showed that SW620 cells secrete 70% more EVs than SW480 cells in normoxia and hypoxia stimulates EV secretion by 80% in SW480 cells and 449% in SW620 cells. In addition, we observed changes in the size distribution of EVs produced by SW620 cells under hypoxic conditions while no such difference was observed in SW480 cells in response to hypoxia. By measuring CAIX positive EVs in cell cultures, we concluded that the CAIX positive proportion is increased by 10% in SW480 and 15% in SW620 cells in response to hypoxia. No significant differences in the amount and size distribution of EVs were observed between healthy donors and CRC patient cohorts based on NTA data. However it seems that there is a tendency that the percentage of CAIX-positive EVs increases with the stage of CRC and is higher in stage II-IV CRC patients than in healthy controls. In addition, it is higher in patients with metastasis than without distant metastases, but does not correlates with tumour size.

**Conclusion:** CAIX can be detected on the surface of EVs and the production of CAIX positive EVs is increased under hypoxic conditions suggesting that CAIX positive EVs in patients' plasma might have diagnostic or prognostic value. However it seems that possibly there is also different source of CAIX positive EVs in human plasma beside the tumour. (Financed by Latvian council of science Collaboration project No: 625/2014).

## P0369 OPTIMAL INTAKE OF CLEAR LIQUIDS DURING PREPARATION FOR COLONOSCOPY WITH LOW VOLUME POLYETHYLENE GLYCOL PLUS ASCORBIC ACID (PEG-ASC)

**M. Tajika**[1], T. Tanaka[1], M. Ishihara[1], Y. Hirayama[1], S. Oonishi[1], N. Mizuno[2], K. Hara[2], S. Hujioka[2], H. Imaoka[2], T. Fujiyoshi[2], N. Okuno[2], N. Hieda[2], T. Yoshida[2], V. Bhatia[3], K. Yamao[2], M. Ando[4], Y. Niwa[1]

**Introduction:** Polyethylene glycol electrolyte lavage solution containing ascorbic acid (PEG-ASC) has recently become available in Japan, as a low volume lavage solution. In a previous trial[1], we found that the 1.5-L PEG-ASC regimen had higher patient acceptability than the 2-L PEG-ELS regimen. Tolerability, bowel cleansing, and safety were similar between regimens. So, the 1.5-L PEG-ASC regimen has become a standard regimen for afternoon procedures in Japan. The regimen is sequential intake of one liter of PEG-ASC, 500 mL of clear liquid, 500 mL of PEG-ASC, and finally 250 mL of clear fluids (all at rate of 250 ml every 15 min) on the day of colonoscopy. However, the regimen seems to be intolerable and complicated for many patients, especially in elderly.

**Aims & Methods:** The aim of this study was to evaluate an alternate regimen of 500 ml of PEG-ASC followed by 250 mL clear liquids, repeated 3 times compared to the standard regimen. We conducted a single-blinded, non-inferiority, randomized, controlled study. Subjects were randomized to the standard regimen or the alternate one (UMIN000014766). The Boston Bowel Preparation Scale was used to evaluate bowel cleansing, and a 3-point scale was used to assess mucosal visibility. The primary endpoint was the rate of successful bowel cleansing. The acceptability, tolerability, safety, and endoscopic findings of these two regimens were secondary endpoints.

**Results:** Four hundred and nine patients were randomized to either the standard regimen ($n = 204$, males 54.0%, mean age 65.5 years) or the alternate regimen ($n = 205$, males 54.6%, mean age 65.0 years). The rates of successful bowel cleansing were 71.1% (64.3–77.2%) in standard regimen vs. 75.1% (68.6–80.9%) in alternate regimen (95% lower confidence limit, for the difference = -4.6, non-inferiority $P < 0.05$). No significant differences were found in the rates of 100% volume intake of each regimen (94.6% vs 96.1%; $P = 0.49$), the frequency of defecation (9.4 vs 9.3; $P = 0.61$), the time to preparation (170 min vs 168 min; $P = 0.63$), feel of nausea (4.9% vs 2.0%; $P = 0.13$), distension (27.9% vs 23.4%; $P = 0.22$), cases of vomiting (3 vs 1; $P = 0.37$), the willingness to repeat the same regimen (79.0% vs 76.7%; $P = 0.71$), polyp detection rate (57.8% vs 62.4%; $P = 0.72$), and optimal visibility grades of 0/1/2 (105/68/31 vs 118/62/25; $P = 0.17$).

**Conclusion:** The alternate regimen and standard regimen are clinically equivalent, with respect to cleansing efficacy and acceptability, tolerability, safety, and endoscopic findings. These results will give good news for patients had difficulty in drinking the first liter of PEG-ASC.

**Introduction:** The development of new sequencing technologies (next generation sequencing, NGS) is a paradigm shift in the study of diseases and enabling rapid and cost - effective analysis of a substantial number of genes. This tool could improve the diagnosis of hereditary forms of cancer. A panel of genes has been designed, analyzable by NGS, in order to validate it as an alternative to the diagnosis of hereditary digestive cancer strategy based on clinical criteria.

**Aims & Methods:** Twenty-one genes involved in hereditary forms of colon, stomach and pancreatic cancer have been included in the same panel (version 1: v1DIGCUN): *APC, BMPR1A, BRCA1, BRCA2, CDH1, CDKN2A, ENG, EpCAM GREM1, MLH1, MSH2, MSH6, MUTYH, PALB2, PMS2, POLD1, POLE, PRSS1, PTEN, SMAD4, SPINK1*. The panel design was made with the SureDesign (Agilent Technologies) program with coverage of all coding exons and flanking intron of 25 nt. The libraries were developed in HaloPlex (Agilent Technologies) technology and sequenced on an Ion Torrent PGM (Thermo Fisher). NGS data were analyzed with software programs and Ion Torrent Suite Reporter ™ Software. A total of 53 patients selected in the High Risk Clinic on Digestive Tumors in our hospital have been included, 10 of them with known mutation (positive controls). The identified variants were analyzed on the basis of specific gene data, ClinVar, dbSNP, Exac Genome Browser, BIC and variants of uncertain significance (VOUS) were predicted by Asessor Mutation, Mutation Taster, PolyPhen-2 and SIFT.

**Results:** All known variants in controls have been identified and validated. Twenty-nine of the 43 cases analyzed showed no mutations or VOUS, only polymorphisms. In 14 cases, 16 variants were found: 1 mutation in *PTEN* probably pathogenic (c.507_510delCAGT / p.Ser170fs) and 15 VUS (3 *APC*, 3 *POLD1, 2 POLE, 2 MSH6, 1 BRCA1, 1 BMPR1A, 1 MSH2, 1 PMS2 and 1 PALB2*). It is currently establishing the relationship between the clinical phenotype and the possible contributor to the disease gene.

**Conclusion:** We developed the first version of a genes panel, analyzable by NGS with adequate diagnostic accuracy for known mutations. They have also identified many variants not initially suspected by phenotype genes. If the pathogenicity of those variants is confirmed, this strategy could potentially improve the diagnosis of hereditary forms of digestive cancer.

**Contact E-mail Address:** shibata200101545@yahoo.co.jp.

**Introduction:** The survival rates for colorectal cancer (CRC) patients with mucinous adenocarcinoma or signet-ring cell carcinoma (Muc/Sig) are worse than for patients with differentiated adenocarcinoma (AC). In addition, previous studies have reported that a positive lymph node ratio (LNR) is a prognostic factor in CRC. However, the clinical significance of LNR in CRC patients with Muc/Sig is unclear.

**Aims & Methods:** The aim of this study was to evaluate the prognostic impact of histologic type and LNR in patients with stage III colorectal cancer. The data for stage III CRC patients, who underwent surgical curative resection between 1997 and 2006, were retrospectively collected from 22 referral institutions of the Japanese Study Group for Postoperative Follow-up of Colorectal Cancer. The patients were divided into two groups according to histologic types: (1) Muc/Sig and (2) AC. LNR was categorized as low ($<0.25$) or high ($\geq 0.25$).

**Results:** Of the 7036 patients studied, the Muc/Sig histologic type was observed in 316 patients. The disease-specific survival (DSS) and relapse-free survival (RFS) rates were worse in the Muc/Sig group than in the AC group. A multivariate analysis revealed that the incidence of Muc/Sig and high LNR were independently associated with poor DSS and RFS. In addition, the RFS rates did not differ according to the histologic type in patients with low LNR; however, for patients with high LNR, the RFS rates were worse in the Muc/Sig group than in the AC group. Therefore, we focused on stage III CRC patients with Muc/Sig. The multivariate analysis further revealed that high LNR was independently associated with poor DSS (HR = 3.252, 95% CI: 1.971–5.383, $P < 0.001$) and was the only independent factor associated with poor RFS (HR = 2.954, 95% CI: 1.829–4.785, $P < 0.001$). Furthermore, in stage III CRC patients with low LNRs, there was no difference in RFS rate according to histologic type. However, in patients with high LNRs, the RFS rate was worse in those with Muc/Sig than in those with AC (5-year RFS rate of the patients with low LNRs: 70.8% in the Muc/Sig group vs. 72.8% in the AC group, $P = 0.08$; patients with high LNRs: 31.5% in the Muc/Sig group vs. 53.4% in the AC group, $P < 0.001$).

**Conclusion:** We found a strong correlation between high LNR and poor prognosis in stage III CRC patients with Muc/Sig. Further studies are necessary to elucidate the effects of histologic type and LNR variations in patients with CRC.

## P0372 KNIFE - ASSISTED SNARE RESECTION (KAR) PROCEDURE TIME FOR COLONIC DYSPLASTIC LESIONS AND ASSOCIATED PROGNOSTIC FACTORS

**S.P. Terzoudis**[1], S. Subramaniam[2], S. Thayalasekaran[2], K. Kandiah[2], F.J.Q. Chedgy[2], G. Longcroft-Wheaton[1], M. Abdulla[1], A. A. Alkandari[1], P. Bhandari[1]

**Contact E-mail Address:** sotiris.p.terzoudis@gmail.com.

**Introduction:** The combination of endoscopic knife and snare, known as Knife-Assisted snare Resection (KAR) is a novel technique which could be promising in the management of the colonic dysplastic lesions. KAR is a recently described effective technique to treat complex LST (Lateral Spreading Tumors). It involves knife-assisted circumferential mucosal incision followed by some submucosal (SM) dissection before snare assisted resection. Depending on the degree of SM dissection and lesion size a single or multiple piece resection is achieved. It is much safer then ESD and has better outcome than EMR in the west. However, detailed evaluation of the time spent for every part of this procedure and the possible factors which can affect it, is rather limited.

**Aims & Methods:** Aims: To establish individual component steps of KAR procedure and identify the time taken for each step of the KAR. Secondary aim was to identify factors influencing the procedure time. Patients and Methods 42 consecutive patients were enrolled in this study. All the endoscopic procedures have been performed by a single experienced endoscopist (PB), have been recorded in full on a video recorder and were analyzed by an independent researcher with experience in KAR procedure. First 50 patients who had KAR were excluded from this study as a part of learning curve and not analyzed. Lesion area was calculated based on length of the lesion and the percentage of the colonic circumference involved. Using the equation area = $2*\pi*$ r * l *% circumferential involvement / 100. Here r = radius (cm) and l = length of lesion. The following time of every part of the procedure was recorded: Lesion evaluation, suction/drying time, submucosal injection, mucosal incision, submucosal dissection, snaring, accessory change times, post resection evaluation, hemostatic (blood control) time and total procedural time.

**Results:** The mean age of the patients was 57 ± 28 years. The mean size of the lesion was 40 mm (range 15 mm -100 mm) with a mean area of 7.53 $cm^2$ (range: 4.71–14.13 $cm^2$), whereas the mean circumferential percentage was 42%. The morphology of the lesion was LST (Lateral Spreading Tumors) from which 43% was resected enbloc. Complete endoscopic resection achieved in 97.75% of the cases. The mean procedural time was 95 (±54) min, equating to 12.61 min/$cm^2$.

The time taken for each component of the procedure is shown in Table 1. The lesion resection time (mucosal incision, submucosal dissection and snaring) was just under 1/3 of the total time (30%). The submucosal injection time was 16.3% while the initial evaluation of the lesion was 6% and post resection evaluation was 14.6%. Bleeding control took 3.2% of the total time. The time recorded for accessory change, suction/drying and lumen insufflation time was 32%. Circumferential extension seemed to affect the total procedure time, with $<50\%$ circumference lesions taking 72 min versus 122 min for lesions with $>50\%$ circumferential extension. ($p = 0.0067$) Procedural time was also significantly influenced by lesion size. For colonic lesions $>40$ mm the mean time was 125.65 min whereas for the lesions $<40$ mm the mean time was 60.32 min. ($p = 0.0018$)

**Table 1. Time recorded for each component of the KAR procedure**

| Time recording | MeanTime (min) ± SD | Percentage (%) |
|---|---|---|
| Initial Lesion Evaluation | 6.28 (±4.29) | 6% |
| Submucosal Injection Time | 15.57 (± 10.38) | 16.3% |
| Resection Time (Mucosal incision, Submucosal Dissection, Snaring) | 29.35 (±29.31) | 31% |
| Post Resection Evaluation | 8.23 (± 5.46) | 8.5% |
| Accessory Change Time/ drying / Lumen Insufflation | 30.37 (± 30.39) | 31% |
| Blood Control (hemostatic) Time | 3.04 (±5.34) | 3.2% |
| Other | 4.21 (± 2.37) | 4% |
| Total | 95.27 (±54.27) | 100% |

**Conclusion:** Our data showed that it takes 12.61 min/$cm^2$ to perform KAR for LST lesions in colon. Size of the lesion as well as circumferential extent seems to

be the predictors of the procedural time. Only one third of the total procedure time was spent in lesion resection. Another third of time was spent in inflating & deflating the lumen and changing accessories. We believe that this data can help influence future research in improving KAR procedure times &comparing new devices for KAR & ESD. This data will also help clinicians allocate appropriate time for procedures and remuneration for the procedure.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Irreversible electroporation (IRE) is a promising novel technique for the ablation of tumor. IRE has an advantage over other ablation technique in its mechanism to remove undesired cells by affecting the cell membrane without thermally destructing surrounding blood vessels, nerves. There have been recent concerns regarding the potential use of IRE as an ablative modality. The aim of this study was to evaluate the effectiveness of IRE ablation according to therapeutic method in colon cancer animal model.
**Aims & Methods:** Male nude mice (6 weeks old) were introduced. Caco2 cells (ATCC) were each visually injected into both flakes. We performed in vivo IRE procedures in the tumors of nude mouse model. Electrical pulses were applied to the tumor of nude mice using a DC generator at $1 \sim 2\,kV/cm$ amplitude, $100 \sim 200$ pulses, $100 \sim 300\,\mu s$ length. A group received early ablation (0, 7 day), and the other group received continuous ablation (0, 7, 14, and 21 days). We compared the size of tumors between control and IRE ablation group.
**Results:** The size of IRE ablative tumors significantly decreased comparing with the control. ($p = 0.005$) But there was no significant difference between early ablation group and continuous ablation group. ($p = 0.972$) There was complete cell death within the IRE lesions without intervening live cells. Histologically, in each group, the IRE ablative tumors were nonviable, with a persistent tumor nodule replaced fibrosis. The tissue with H&E stain and Tunnel assay showed apoptotic cell death in the 1 days after IRE ablation. The tissues after 24 hr IRE ablation showed diffuse necrotic cell death.
**Conclusion:** The present study demonstrated that IRE ablated colon cancer tissue very effectively through the induction of cellular apoptosis in the early stage. This study suggests that IRE is the potential use of IRE in colon cancer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Rectal cancer response to neoadiuvant chemo-radiotherapy (CRT) is variable. Identifying markers of response will help select patients more likely to benefit from therapy. Objective of the study is to identify at diagnosis proteomic profiles associated with tumor regression grading (TRG) in rectal cancer.
**Aims & Methods:** This study includes 41 patients with rectal cancer treated with CRT followed by surgery. Proteins from pre-treatment tumor biopsies and control from paired normal bioptic specimens were screened for comparative proteomic approach by using 2D difference gel electrophoresis (2D-DIGE). Differential spots found with Decyder were identified by MALDI-TOF and peptide fingerprinting with Mascot search engine. Interactions among identified proteins was analysed with STRING 9.1 search tool. Pathological TRG was assessed on surgical specimens.
**Results:** A total of 30 proteins were identified as discriminators between tumor samples and controls by principal component analysis and hierarchical clustering ($p < 0.01$; spot map $> 50\%$). These proteins were already described as involved in rectal metabolic cell pathways and angiogenesis. Possible correlations between these proteins and TRG are under evaluation.
**Conclusion:** Comparative proteomics approach based on 2D-DIGE and MALDI-TOF identification succeeded in differentiating rectal tumor samples from paired normal rectal mucosa. Further analyses will unravel possible correlations between distinct protein profiles and TRG response to CRT treatment that could be used to select optimal therapy in rectal cancer patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0375 COLORECTAL CANCER IN THE ELDERLY – HOW MUCH SHOULD WE INVEST?

**F. Ávila**[1], J. Castela[1], I. Rosa[2], I. Marques[3], J. P. Da Silva[2], A. Dias Pereira[2]

[3]*Multidisciplinary Colorectal Cancer Clinic, Portuguese Oncology Institute of Lisbon, Lisboa/Portugal*

**Contact E-mail Address:** filipaavila@gmail.com.
**Introduction:** Colorectal cancer (CRC) treatment in elderly patients gains complexity due to the frequently associated comorbidities. The influence of seniority in prognosis and therapy safety is not evaluated in clinical trials, making its study in the clinical practice an essential tool.
**Aims & Methods:** To determine the impact of age $\geq 80$ years in the therapeutic management and outcome of patients with CRC. Single-center cohort study of patients aged $\geq 80$ years at CRC diagnosis, evaluated in a Multidisciplinary Group, between January/2010 and December/2012, and followed prospectively. Analysis of clinical characteristics, TNM stage, therapeutic decision and evolution. Statistics: Fisher's exact test, Kaplan-Meyer (SPSS-21).
**Results:** 108 patients were evaluated, 59.3% male, mean age $83.4 \pm 2.97$ years (80–94). Most of the patients presented a performance status 0–1 (90.7%) and a Charlson comorbidity index $2.05 \pm 2.71$. The CRC diagnosis was established in the context of symptoms in 94.4% of the patients. Location: rectum 43.5%; colon 50.9%; synchronous tumours 5.6%. Stages III-IV in 58.3%. 80.6% of patients were proposed for curative intent (CI) therapy, from which 82% (71/87) completed the treatment. The presence of stage IV disease at diagnosis was associated with palliative intent (PI) therapy decision ($p < 0.001$). There were 9 deaths secondary to therapy: 8 postoperatively; 1 by chemotherapy – significant association with PI therapy ($p = 0.037$). Postoperative mortality was significantly associated with PI therapy ($p = 0.001$) but not with age $\geq 85$ years ($p = 0.23$). Survival of patients proposed for CI therapy: 71.8% and 45.8%, in the first and third years, respectively. CI therapy was significantly associated with a higher overall survival ($p < 0.001$).
**Conclusion:** CRC among patients aged $\geq 80$ years was mainly diagnosed in advanced stages, limiting therapeutic options. Still, PI therapy was found to be associated with higher mortality from complications - therefore, the CI therapy investment should not be restricted by age.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0376 COMPARISON OF ENDOSCOPIC SUBMUCOSAL DISSECTION OUTCOME IN OUTPATIENTS VERSUS INPATIENTS

**R. Maselli,** P.A. Galtieri, S. Sferrazza, E.C. Ferrara, F. Mazza, L. Amato, A. Anderloni, S. Carrara, M. Di Leo, A. Repici
*1. department Of Gastroenterology, Digestive Endoscopy Unit, Humanitas Research Hospital, Rozzano (MI)/Italy*

**Contact E-mail Address:** roberta.maselli@humanitas.it.
**Introduction:** Endoscopic submucosal dissection (ESD) is worldwide accepted as a minimally invasive treatment for early gastrointestinal (GI) cancer but it is still considered a challenging and risky procedure in the colorectum. In both Eastern and Western settings published studies indicate that the vast majority of patients undergoing ESD are hospitalized because of the expected high risk of complications.

**Aims & Methods:** Aim of this study is to investigate the efficacy and safety of colorectal ESDs performed in outpatient setting, in a tertiary center. From May 2014 to March 2016, all consecutive patients treated at Humanitas Research Hospital, Italy for colorectal ESD were enrolled in a prospective registry. Per protocol patients > 80 years and with comorbidities (ASA III) were admitted in hospital for at least two nights, whereas ESD was performed in outpatient setting in the remaining patients. Complete resection rate (R0) and major complications (perforation, immediate bleeding - defined as a large amount of bleeding during the procedure and/or difficult hemostasis - and delayed bleeding -defined as clinical evidence of melena within 10 days after the procedure that required endoscopic treatment-) were compared using Fisher exact test for categorical variables. All differences were considered significant at two-sided p-values $< 0.05$.

**Results:** A total of 107 (M/F 71/36, mean age 66.8 years) consecutive patients were treated by ESD for 108 colorectal lesions (rectum 59.2%, left colon 13.8%, transverse colon 10.2%, right colon 16.6%). All procedures were performed under deep sedation (propofol i.v.) administered by a dedicated anaesthesiologist; none of the patients required general anaesthesia. The median operation time was 85.4 (range 15–293) minutes and the mean size of resected specimens was 39.7 mm (range 12–120 mm). Thirty-nine patients were hospitalized (36.1%) whereas 69 (63.9%) were treated as outpatients. Complete resection rate was 97.4% in inpatient group and 98.5% in outpatient group ($p = ns$). Perforations occurred in 3 cases (2.8%): 2 in the inpatient group (5.12%) and 1 in the outpatient group (1.5%) ($p = ns$). All of them were endoscopically treated. No immediate nor delayed bleeding occurred.

**Conclusion:** Endoscopic submucosal dissection is a feasible technique to treat superficial colorectal tumors with a high resection rate and low complication rate. It is safe and effective not only for hospitalized patients but also in an out-patient setting. Although a cost-effective analysis was not performed, we could speculate that outpatient setting could lead to minor costs and minor patients discomfort than inpatient setting.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0377 THE VALIDITY OF THREE STEPS LEARNING SYSTEM OF COLORECTAL ESD

**K. Ashikari**[1], H. Chiba[2], M. Nishimura[2], J. Tachikawa[2], D. Kurihara[2], T. Suto[2], N. Kawano[2], M. Kaai[2], S. Seki[2], T. Ida[2], T. Morohashi[2], T. Goto[2]

**Contact E-mail Address:** kei-pushi-1@hotmail.co.jp.

**Introduction:** Endoscopic submucosal dissection (ESD) for early colorectal tumors has become a widespread treatment, but still have technical difficulties. A standard training system for colorectal ESD remains to be established. We reported, in UEG week last year, our original training program called three steps learning system (TSLS), and the trainee has gained more experience. Now, TSLS is considered to be verified again in terms of the safety and validity.

**Aims & Methods:** TSLS consists of the following qualifications. The trainee (A) has experienced 1000 upper/300 lower endoscopy, 30 gastric ESD, and 20 colorectal ESD assistance. Colorectal ESD is performed with support by an expert (B) under the 3 steps. 1) 0–5 cases: the position is all rectum, and have no fibrosis (F0), 2) 6–20cases: tumor size is $\leq$50 mm with no or mild fibrosis (F0/F1) and the expert gives every possible advices during procedures, 3) 21cases-: The expert gives important advices or hands-on support when needed. 262 consecutive ESD procedures performed in Omori Red Cross Hospital from 2012 April to 2016 March were retrospectively analyzed. We evaluated clinical backgrounds, treatment outcomes, complications, and postoperative courses. We aimed to evaluate the safety and validity of TSLS.

**Results:** A/B performed 49/169 cases respectively (44 cases were performed by another endoscopist). The mean age, sex, comorbid diseases (hypertension, diabetes, renal dysfunction, cardiac disease), rate of having antithrombotic agents were similar between two groups. Tumor locations were C3/A7/T12/D5/S8/R14 in group A and C25/A35/T36/D18/S21/R34 in group B ($p = 0.43$). The trainee tended to perform more rectal lesion and less cecal lesions. Protruded tumors were 1 case (2.0%) in A and 12 cases (7.1%) in B. There were also no significant differences in specimen size, tumor size, en bloc resection rate, and complication: $38.3 \pm 18.1$ mm, $26.4 \pm 16.3$ mm, 100%, and 1 case (perforation) in group A and $37.8 \pm 16.5$ mm, $29.6 \pm 15.9$ mm, 99.4% (168/169), and 1 case (perforation) in group B, respectively. Only an operation time and speed of resection (specimen size ($mm^2$) / operation time (min)) in group B were much faster than group A: $59.0 \pm 43.1$ min, $17.0 \pm 8.4 mm^2$/min in group A and $35.5 \pm 36.2$ min, $33.1 \pm 17.1 mm^2$/min ($p < 0.01$). The rate of fibrosis was 12.2% (F0/F1/F2: 43/6/0) in group A, 22.5% (F0/F1/F2: 131/33/5) in group B ($p = 0.22$). Trainee's self-completion rate was 83.7% (41/49) (85% (17/20) in the initial 20 cases and 82.8% (24/29) in subsequent 29 cases). The most frequent reason for not self-completion was difficulty in technique or hemostasis. R0 resection rate were similar, 95.9% (47/49) in group A, and 95.3% (161/169) in group B. The clinical courses after procedures (fever, WBC, CRP) were also similar.

**Conclusion:** Under our training system (TSLS), through the support by an expert and selection of the lesion for the initial 20 cases, it might be possible that the trainee can gradually become able to perform colorectal ESD by himself. TSLS was considered to be an effective and safe method. We need to attempt this training system to other novices and verify the validity of our system.

## P0378 ANGIOGENESIS INHIBITOR-RELATED ANAL CANAL ULCERS IN METASTATIC COLORECTAL CANCER PATIENTS

F. Bergamo[1], S. Lonardi[1], C. Lacognata[2], B. Salmaso[3], F. Battaglin[1], L. M. Saadeh[3], A. Caruso[4], F. Cavallin[3], C. Aliberti[5], V. Zagonel[1], C. Castoro[3], **M. Scarpa**[3]

**Contact E-mail Address:** marcoscarpa73@yahoo.it.

**Introduction:** Combining conventional systemic chemotherapy with the angiogenesis inhibitor bevacizumab is now recommended as a first treatment for metastatic colorectal neoplasms. The risk for short-term postoperative complications related to bevacizumab has been assessed but anal canal ulcers related to angiogenesis inhibitors have never been described.

**Aims & Methods:** The aim of our study was to assess the prevalence of angiogenesis inhibitor-related anal canal ulcers in colorectal cancer patients and its impact on patient wellness and therapy.

We reviewed a cohort of 404 consecutive patients undergoing chemotherapy for metastatic colorectal cancer from january 2010 to december 2013. In this cohort 333 patients had at least one angiogenesis inhibitor and 71 had other chemotherapy regimens.

Details about patients history, therapy protocols, and proctology reports were retrived. Pain was graded in a semiquantitative scale (0–3) where higher is more severe.

Vascularizaton of anal canal was compared with contrast MRI in patients with angiogenesis inhibitor and in healthy controls.

Non parametric statistics was performed.

**Results:** In the study period, twenty five patients, among the 404 ones, were referred to the proctology outpatient clinic for perianal complaints. Ten patients (3.0%) experienced an anal ulcer while in therapy with angiogenesis inhibitor while only a patient (1.4%) treated with other chemoterapy regimens had one [OR = 2.1 (95% CI 0.273–17.2)]. The pain intensity was medianly severe (3 IQR:2-3). The risk of having the chemotherapy interrupted or suspended for perianal disorders was higher while on therapy with angiogenesis inhibitor [OR = 2.8 (95% CI 0.366–22.1)]. Vascularizaton of anal canal, as measured with relative contrast enhancement at MRI, was signifcantly lower in patients with angiogenesis inhibitor than in healthy controls ($p = 0.03$).

**Conclusion:** Angiogenesis inhibitors-related anal canal ulcers in colorectal cancer patients are a rare complication that can compromise the prosecution of the life saving therapy. A low vascularization of the anal canal mucosa due to angiogeneisis inhibitor subministration is possibly involved in the pathogeneisis of this complication. Adequate strategies should be implemented to prevent this complication.

## P0379 PARTHENOLIDE ENHANCES ANTI-TUMOR EFFICACY OF BALSALAZIDE IN HUMAN COLON CANCER CELLS AND COLITIS-ASSOCIATED COLORECTAL CANCER BY BLOCKADE OF NF-KB ACTIVATION

**S.Y. Seo,** I.S. Min, D. Kim, S.B. Kim, S.H. Kim, I.H. Kim, S.O. Lee, S.T. Lee, D.G. Kim, S.W. Kim
*Internal Medicine, Biomedical Research Institute of Clinical Medicine, Chonbuk National University Medical School and Hospital, Jeonju, Jeonbuk/Korea, Republic of*

**Contact E-mail Address:** bear7905@naver.com.

**Introduction:** Balsalazide is a colon-specific prodrug of 5-aminosalicylate (5-ASA) that was recently shown to be associated with a reduced risk of colon cancer in patients with ulcerative colitis. Parthenolide (PT), a strong NF-kB inhibitor, has recently been demonstrated to be a promising anticancer agent that promotes apoptosis of cancer cells.

**Aims & Methods:** In the present study, we investigated the antitumor effect of balsalazide combined with PT through inhibition of nuclear factor-kB (NF-kB) activation in human CRCs.

**Results:** Our results demonstrated that the combination of balsalazide and PT markedly suppressed proliferation, nuclear translocation of NF-$\kappa$B, I$\kappa$B-a phosphorylation, NF-kB DNA binding and expression of NF-kB target proteins. Apoptosis under NF-kB signaling was confirmed by detecting expression of caspases, p53 and PARP. Moreover, treatment of a colitis-associated colon cancer (CAC) murine model with PT and balsalazide resulted in significant recovery of body weight and improvement in histological severity. Administration of PT and balsalazide to CAC models also suppressed carcinogenesis as demonstrated by uptake of $^{18}$F-fluoro-2-deoxy-D-glucose (FDG) using micro PET/CT scans.

**Conclusion:** These results demonstrate that PT potentiates the efficacy of balsalazide through synergistic inhibition of NF-kB and the combination of dual agents prevents colon carcinogenesis from chronic inflammation. This is the first evidence that a combination of balsalazide and PT could be a new regimen for colorectal cancer treatment.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0380 EFFICACY OF PREOPERATIVE COLONOSCOPIC TATTOOING ON LYMPH NODE HARVEST

R. Daegon, D. Kang, H. Kim, C. Choi, S. Park, S. Kim, H. Nam, W. Choi, J. Cho, **J. Park**, K. Oh
*Division Of Gastroenterology, Department Of Internal Medicine, Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of*

**Contact E-mail Address:** mini3763@hotmail.com.
**Introduction:** Consensus guidelines suggest to assess at least 12 lymph nodes for adequate staging of colorectal cancer and thecorrelation between number of lymph nodes retrieved and the patient survival has been formerly reported. To facilitate the retrieval of lymph nodes, preoperative endoscopic tattooing to mark the site of the tumor has been proposed.
**Aims & Methods:** In the study, we aimed to identify the impact of preoperative colonoscopic tattooing (PCT) on lymph node harvest incolorectal cancer patients. 682 patients who underwent curative resection for colorectal cancer between 2013 and 2015 at the Pusan NationalUniversity Yangsan Hospital in Korea were retrospectively divided into the tattooing group and the non-tattooing group depending on whether preoperative indocyanine green (ICG) tattooing was done. Pathological findings and lymphnode harvest were compared between the two groups. For the same stage comparison, lymph nodes harvest of T1stage colorectal cancer patients in the two groups were compared.
**Results:** The median number of lymph nodes obtained was 20 in the tattooing group (N = 93) and 23 in the non-tattooing group (N = 589). The rate of adequate lymph node harvest (retrieval of more than 12 lymph nodes) was higher in the non-tattooing group than that in the tattooing group (93.3% vs. 89.2%). As for the same stage comparison (T1 stage) therewere 48 patients in the tattooing group and 51 patients in the non-tattooing group. The median number of lymphnodes obtained was 20 in the tattooing group and 21 in the non-tattooing group. The rate of adequate lymph nodeharvest was also higher in the non-tattooing group (89.6 vs. 86.3%).
**Conclusion:** PCT did not have any association with higher lymph node yield in colorectal cancer. Further studies are needed todetermine if preoperative colonoscopic tattooing to mark the tumor site is related to better lymph node yield.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0381 DEFECATORY SYMPTOMS IN PATIENTS WITH IRRITABLE BOWEL SYNDROME IN A PRIMARY HEALTH CARE POPULATION IN SWEDEN

**Contact E-mail Address:** jenny.sjodahl@liu.se.
**Introduction:** Irritable bowel syndrome (IBS) is a chronic disorder characterized by abdominal pain and alterations in bowel habits (diarrhoea, constipation, or both in an alternating pattern) that affects approximately 10% of the general population. IBS is associated with impaired quality of life and increased use of health care resources[1]. The majority of patients are diagnosed and treated in primary care[2]. Many IBS patients suffer from symptoms related to defecation, such as the feeling of incomplete evacuation or straining, but the prevalence of these symptoms has not yet been well described in a primary care setting.
**Aims & Methods:** The aim was to characterize and compare defecation symptoms in patients with IBS in a primary health care population. The study adopted a case-control design in a defined region in south-east Sweden (i.e., the County Council of Östergötland). Patient recruitment was accomplished in 10 Primary Health Care (PHC) centres located in the 3 major cities of the region during March 2010 and February 2014. These PHC centres are responsible for the primary care of approximately 150 000 inhabitants (≈1/3 of the region). For this study, patients within the normal working age range (18–65 years) with a clinical IBS diagnosis and active symptoms during the last 2 years, identified with ICD-10 diagnoses in the patient medical register, were invited by e-mail to participate. IBS patients meeting the ROME III criteria were included (n = 282). The control group was comprised of other patients at the selected PHC centres who were similar in terms of sex and age, and sought care for complaints not associated with gastrointestinal symptoms and with no earlier gastrointestinal diagnoses found in the patient register for the previous 2 years (n = 372). Subjects recorded their bowel habits and symptoms prospectively on validated diary cards[3] for 2 weeks. They were asked to record every single stool, stool consistency, and corresponding defecatory symptoms: urgency, straining, and feeling of incomplete evacuation. Stool consistency was defined by the Bristol Stool Form Scale. IBS and control groups were statistically compared with respect to occurrence of defecatory symptoms using unconditional logistic regression (symptom prevalence) or proportional odds models (number of simultaneous symptoms per bowel movement). All statistical tests and confidence intervals adjusted variance estimates for multiple observations per patient via the intraclass correlation.
**Results:** During the 2-week recording the total number of stools was 6785 in IBS patients and 6635 in controls. The feeling of incomplete evacuation, straining and urgency associated with defecation were more present in patients with IBS than controls ($p < 0.001$; $p = 0.002$; $p < 0.001$) (Table 1). The feeling of incomplete evacuation was present in 49% of the stools among the IBS patients and in 21% of the stools among the controls. The need of straining during defecation was reported in 41% of stools by IBS patients compared to 33% of the stools by controls. Urgency was experienced in 37% of the stools in IBS patients compared with 18% in controls. Patients with IBS experienced to a higher degree more than one defecatory symptom per stool (OR 3.51, 95% CI 2.81–4.38; $p < 0.001$) (Table 1).

**Table 1:** Logistic regression analyses comparing IBS patients with controls in terms of odds of urgency, straining and feeling of incomplete evacuation associated with defecation.

| | OR (95% CI) | p-value |
|---|---|---|
| Feeling of incomplete evacuation | 3.63 (2.81–4.69) | <0.001 |
| Need to strain during defecation | 1.45 (1.15–1.83) | 0.002 |
| Experiencing urgency | 2.77 (2.11–3.63) | <0.001 |
| Number of symptoms per bowel movement | 3.51 (2.81–4.38) | <0.001 |

OR: odds ratio; 95% CI: confidence interval.
**Conclusion:** To our knowledge this is the first time defecatory symptoms are investigated for IBS patients in a primary care setting. The IBS patients experienced more defecatory symptoms such as straining, urgency and feeling of incomplete evacuation, than the primary care patient population without IBS. Patients with IBS were also more frequently experiencing more than one defecatory symptom per stool.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Irritable bowel syndrome (IBS) is one of the most commonly diagnosed gastrointestinal disorders. IBS is subtyped based on the predominant stool pattern, with the diarrhoea-predominant subtype (IBS-D) accounting for 30–40% of all cases. IBS symptoms significantly impact patients' work productivity and activities of daily living, resulting in a substantial burden for both patients and employers. As the symptoms of IBS differ between subtypes, an understanding of the impact of each subtype is important; however, European data specific to IBS-D are lacking.
**Aims & Methods:** The objective of this study was to assess the impact of IBS-D on work productivity and daily activity impairment. Adult IBS-D patients from the EU5 (Spain, France, Italy, Germany, United Kingdom) were identified from the 2013 National Health and Wellness Survey, a self-administered, internet-based survey. Respondents were defined as diagnosed IBS-D patients if they self-reported a physician diagnosis of IBS-D, and as undiagnosed IBS-D patients if they reported experiencing IBS-D symptoms but did not self-report a physician diagnosis. Controls included all respondents without IBS (diagnosed or undiagnosed) or inflammatory bowel disease. IBS-D severity was evaluated based on a single item assessing disease severity (mild, moderate, or severe). The Work Productivity and Activity Impairment Questionnaire: General Health version assessed absenteeism, presenteeism, overall work productivity loss (absenteeism + presenteeism), and daily activity impairment in the previous 7 days. Each domain is calculated as a percentage with higher scores indicating greater impairment. Descriptive statistics were conducted to examine sample characteristics. Days of work missed annually (for employed respondents) was calculated based on reported work hours missed assuming a 40-h work week and 50 weeks worked. Bivariate analyses were used to compare work productivity and activity impairment by IBS-D severity. To assess the burden of IBS-D specifically, multivariable generalised linear models were used to compare impairment across groups, controlling for demographic and health characteristics, including age, gender, and comorbidities.
**Results:** In total, 58, 161 respondents were included (859 diagnosed IBS-D; 370 undiagnosed IBS-D; 56, 932 controls). Patients (diagnosed and undiagnosed) with severe IBS-D reported significantly greater activity impairment (n = 110; mean = 52.4%) compared with those with moderate (n = 499; mean = 38.1%) and mild (n = 620; mean = 29.5%) IBS-D ($p < 0.05$ for all). Patients with severe IBS-D also had a significantly lower rate of labour force participation (48.2%) compared with those with moderate (64.5%) or mild (67.4%) IBS-D ($p < 0.05$). After adjusting for covariates, diagnosed and undiagnosed IBS-D patients reported significantly greater lost productivity at work (presenteeism), overall work impairment, and activity impairment compared with controls (Table).

**Abstract No: P0382**
**Table.**

| Adjusted mean (SE) | Diagnosed IBS-D (n = 859) | Undiagnosed IBS-D (n = 370) | Controls (n = 56,932) | p-value: Diagnosed vs. controls | p-value: Diagnosed vs. undiagnosed | p-value: Undiagnosed vs. controls |
|---|---|---|---|---|---|---|
| Absenteeism (%) | 6.39 (1.13) | 6.01 (1.49) | 4.87 (0.10) | 0.13 | 0.40 | 0.40 |
| Presenteeism (%) | 22.45 (1.63) | 20.31 (2.09) | 15.39 (0.13) | **<0.001** | 0.43 | **0.007** |
| Overall work impairment (%) | 26.22 (1.85) | 24.33 (2.41) | 18.57 (0.15) | **<0.001** | 0.54 | **0.007** |
| Activity impairment (%) | 31.98 (1.32) | 28.47 (1.80) | 22.38 (0.11) | **<0.001** | 0.12 | **<0.001** |
| Work missed annually (days) | 15.59 (2.99) | 11.94 (3.26) | 11.25 (0.25) | 0.09 | 0.42 | 0.83 |

**Conclusion:** Compared with controls, patients with IBS-D have significantly greater impairments in work productivity and daily activities, highlighting the significant burden of illness associated with this condition. The negative impact of IBS-D on patients' daily lives is greatest for those reporting moderate or severe IBS-D.

**Introduction:** Irritable bowel syndrome (IBS) is a chronic gastrointestinal disorder characterised by recurring abdominal pain and altered bowel habits. IBS is a common disorder, affecting approximately 10–15% of adults. The symptom burden experienced by patients with IBS is associated with significant reductions in health-related quality of life (HRQoL), though information specific to the diarrhoea-predominant subtype (IBS-D) is lacking internationally.
**Aims & Methods:** The objective of this study was to assess the impact of IBS-D on HRQoL among a sample of adults in the EU5 (Spain, France, Italy, Germany, United Kingdom). IBS-D patients were identified from the 2013 National Health and Wellness Survey, a self-administered, internet-based survey. Respondents defined as diagnosed included those who reported a physician diagnosis of IBS-D; those identified as undiagnosed reported experiencing IBS-D symptoms but did not self-report a physician diagnosis. Controls included all respondents without IBS (diagnosed or undiagnosed) or inflammatory bowel disease. IBS-D severity was evaluated based on a single item assessing disease severity (mild, moderate, or severe). HRQoL was assessed via the Short Form Health Survey version 2, scored as physical and mental component summary scores (PCS, MCS; range 0–100), and the Short Form-6 Dimension (SF-6D) score, a health utility ranging from 0 (death) to 1 (perfect health). Descriptive statistics were conducted to examine sample characteristics. Bivariate analyses (one-way ANOVA for continuous variables and chi-square tests for categorical variables) were used to compare HRQoL by IBS-D severity. Multivariable generalised linear models were used to compare diagnosed and undiagnosed patients and controls, controlling for demographic and health characteristics, including age, gender, and comorbidities.
**Results:** A total of 58, 161 respondents were included: 859 diagnosed IBS-D, 370 undiagnosed IBS-D, and 56, 932 controls. Mean age was 47 years, and 52.6% of respondents were female. HRQoL differed significantly based on self-reported IBS severity. Unadjusted comparisons showed IBS-D patients (diagnosed and undiagnosed) with moderate IBS-D (n = 499) had significantly lower HRQoL compared with those with mild IBS-D (n = 620) for MCS (40.1 vs. 43.5), PCS (47.7 vs. 50.0), and SF-6D (0.64 vs. 0.68) [all $p < 0.05$]. Similarly, patients with severe IBS-D (n = 110) had significantly lower scores (MCS, 34.9; PCS, 43.1; SF-6D, 0.57) compared with patients with moderate and mild IBS-D. Compared with controls, patients with diagnosed and undiagnosed IBS-D had significantly lower HRQoL, based on MCS, PCS, and SF-6D scores, even after controlling for demographic and health characteristics (Table).

**Table.**

| Adjusted mean (SE) | Diagnosed IBS-D (n = 859) | Undiagnosed IBS-D (n = 370) | Controls (n = 56, 932) | p-value: Diagnosed vs. controls | p-value: Diagnosed vs. undiagnosed | p-value: Undiagnosed vs. controls |
|---|---|---|---|---|---|---|
| MCS | 41.98 (0.34) | 42.44 (0.52) | 46.65 (0.04) | **<0.001** | 0.454 | **<0.001** |
| PCS | 48.83 (0.27) | 50.33 (0.41) | 51.52 (0.03) | **<0.001** | **0.002** | **0.004** |
| SF-6D | 0.66 (0.004) | 0.67 (0.007) | 0.72 (0.001) | **<0.001** | 0.277 | **<0.001** |

**Conclusion:** IBS-D patients, both diagnosed and undiagnosed, had significantly lower HRQoL in comparison with controls. Notably, HRQoL scores were significantly worse for patients with moderate or severe IBS-D than for those with mild IBS-D. The significant impact of IBS-D on patients' HRQoL emphasises the need for treatments to more effectively manage IBS-D symptoms.

**Introduction:** Atopy has been associated with functional gastrointestinal disorders including irritable bowel syndrome (IBS) and functional dyspepsia (FD), implicating a shared pathophysiology.[1, 2].
**Aims & Methods:** In a population-based study we aimed to determine if allergic conditions are more common among people with FD and IBS including the subtypes of diarrhoea-predominant IBS (IBS-D) and post-infectious IBS (PI-IBS) compared with constipation-predominant IBS (IBS-C). A total of 3576 people (mean age 58.5 years, age range 18–100 years and 47.6% males) randomly selected from the Australian population returned a mail survey (response rate-= 43.6%). The survey contained self-reported questions on whether the participant had ever been told by a doctor that they had asthma, food allergy, pollen allergy and/or animal allergy. FD and IBS including constipation-predominant and diarrhoea-predominant IBS were diagnosed according to modified Rome III criteria. Post infectious IBS was defined by the history of gastroenteritis in the 3 months preceding the onset of symptoms.
**Results:** Among the general population 25.5, 4.5%, 6.7%, 2.6% and 14.6% met criteria for IBS, IBS-C, IBD-D, PI-IBS and FD respectively. One fifth of those with IBS and FD had self-reported asthma. Asthma was significantly associated with IBS (including IBS-C, IBS-D and P-IBS) and FD (Table 1). Food allergies were reported in 9% of people with IBS and 10.5% with FD and were significantly associated with IBS and FD, except PI-IBS. A pollen allergy was significantly associated with IBS including IBS-C and IBS-D but not PI-IBS or FD (Table 1). Animal allergies were less common, affecting 5.7% of people with IBS and was only significantly associated with IBS not its subgroups or with FD. In a multivariate model that included all the allergic conditions, self reporting asthma (OR = 1.45; 95%CI 1.19, 1.78, $P < 0.001$), food (OR = 1.45; 95%CI 1.08, 1.95, $P = 0.02$) and pollen (OR = 1.47; 95%CI 1.12, 1.93, $P = 0.006$) allergies were independently associated with IBS. In FD both asthma (OR = 1.46; 95%CI

1.15, 1.84, P = 0.002) and food allergies (OR = 1.79; 95%CI 1.29, 2.47, P = 0.002) were independent predictors.

Univariate associations of allergic conditions and IBS and FD.

| Self reportedallergic conditions (yes) | IBS Yes n (%) vs. No n (%) CI (95%CI) P value | FD Yes n (%) vs. No n (%) CI (95%CI) P value |
|---|---|---|
| **Asthma** | 189 (21.3)<br>373 (14.4)<br>1.61 (1.33, 1.96)<br>P < 0.001 | 112 (21.8)<br>457 (15.3)<br>1.55 (1.23, 1.95)<br>P < 0.001 |
| **Food Allergy** | 81 (9.1)<br>142 (5.5)<br>1.73 (1.31, 2.30)<br>P < 0.001 | 54 (10.5)<br>171 (5.9)<br>1.94 (1.41, 2.68)<br>P = 0.001 |
| **Pollen Allergy** | 100 (11.3)<br>172 (6.6)<br>1.79 (1.38, 2.31)<br>P < 0.001 | 49 (9.6)<br>223 (7.5)<br>1.31 (0.95, 1.81)<br>P = 0.1 |
| **Animal Allergy** | 51 (5.7)<br>87 (3.3)<br>1.81 (1.26, 2.57)<br>P < 0.001 | 23 (4.5)<br>115 (3.8)<br>1.17 (0.74, 1.86)<br>P = 0.5 |

**Conclusion:** Allergic conditions are associated with IBS including its subgroups and FD in the general population. Asthma and food allergies in particular are risk factors for these FGIDs.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0385 ARE CONDITIONS OF IMMUNE DYSREGULATION RISK FACTORS FOR FUNCTIONAL GASTROINTESTINAL DISORDERS? FINDINGS FROM A RANDOM POPULATION-BASED STUDY

**N. A. A Koloski**[1], A. V. Zala[2], M. M. Walker[3], M.P. Jones[4], L. Bunby[5], M. Veysey[6], L. Lambeth[7], L. Hayden[7], G. J. Holtmann[8], N. J. Talley[1]

**Introduction:** The prevalence of disorders of immune dysregulation is rising. [1] Inflammatory bowel disease and coeliac disease [2] as well as rheumatoid disorders [3] have been shown to be more common among patients with functional gastrointestinal disorders (FGIDs) including irritable bowel syndrome (IBS). Little is known however about whether other types of immune disorders are also associated with FGIDs in the community.
**Aims & Methods:** In a population-based study we aimed to determine whether disorders of immune dysregulation are risk factors for IBS and functional dyspepsia (FD). A total of 3576 people (mean age 58.5 years, age range 18–100 years and 47.6% males) randomly selected from the Australian population returned a mail survey (response rate = 43.6%). The survey contained self-reported questions on whether the participant had ever been told by a doctor that they had the following immune diseases including scleroderma, diabetes mellitus, rheumatoid arthritis, coeliac disease, ulcerative colitis (UC) and Crohn's disease (CD). IBS including constipation predominant (IBS-C) and diarrhoea predominant IBS (IBS-D) and FD were diagnosed according to modified Rome III criteria. Post infectious IBS (PI-IBS) was defined by the presence of gastroenteritis in the 3 months preceding the onset of symptoms. In a multivariate model these factors along with other health conditions, lifestyle (BMI, smoking, sleep problems, proton pump inhibitor usage), psychological disturbance and age and gender were evaluated.
**Results:** Among the general population 25.5%, and 14.6% met modified Rome III criteria for IBS and FD, respectively. As expected UC was significantly more common in people with IBS including IBS-D, with UC and CD remaining independent risk factors for IBS (OR = 4.46; 95%CI 2.11, 9.44, P = 0.001; OR = 3.62; 95%CI 1.12, 11.67, P = 0.03) and IBS-D (OR = 5.53; 95%CI 2.73, 11.21, P < 0.001; OR = 6.61, 95%CI 1.88, 23.23, P = 0.003) in the multivariate model respectively. Ulcerative colitis (OR = 3.01; 95%CI 1.53, 5.94, P = 0.001) and Coeliac disease (OR = 2.51; 95%CI 1.21, 5.19, P = 0.01) were also independent predictors of FD. Rheumatoid arthritis was significantly associated with IBS and PI-IBS but was not an independent risk factor for these conditions. Scleroderma and diabetes mellitus were not significantly associated with either IBS or FD (Table 1).

**Table 1:** Univariate associations of immune dysregulation disorders and IBS and FD.

| | IBS Yes n (%) vs. No n (%) CI (95%CI) P value | FD Yes n (%) vs. No n (%) CI (95%CI) P value |
|---|---|---|
| Scleroderma | 2 (0.2)<br>12 (0.5)<br>0.49 (0.11, 2.18)<br>P = 0.4 | 2 (0.4)<br>12 (0.4)<br>1.0 (0.22, 4.36)<br>P = 0.9 |
| Diabetes mellitus | 87 (9.8)<br>281 (10.8)<br>0.89 (0.69, 1.15)<br>P = 0.4 | 57 (11.1)<br>313 (10.5)<br>1.07 (0.79, 1.44)<br>P = 0.7 |
| Rheumatoid Arthritis | 74 (8.3)<br>162 (6.2)<br>1.37 (1.03, 1.82)<br>P = 0.03 | 44 (8.6)<br>191 (6.4)<br>1.38 (0.98, 1.94)<br>P = 0.07 |
| Ulcerative Colitis | 31 (3.5)<br>23 (0.9)<br>4.05 (2.35, 6.98)<br>P < 0.001 | 26 (3.5)<br>28 (0.9)<br>4.01 (2.34, 6.89)<br>P < 0.001 |
| Crohn's disease | 9 (1.0)<br>12 (0.5)<br>2.20 (0.93, 5.25)<br>P = 0.07 | 5 (0.1)<br>16 (0.5)<br>1.83 (0.67, 5.02)<br>P = 0.24 |
| Coeliac Disease | 14 (1.6)<br>34 (1.3)<br>1.21 (0.64, 2.56)<br>P = 0.6 | 16 (3.0)<br>33 (1.1)<br>2.89 (1.58, 5.29)<br>P = 0.001 |

**Conclusion:** We found evidence for an increased risk of some disorders of immune dysregulation including inflammatory bowel disease, rheumatoid arthritis and Coeliac disease and the FGIDs IBS and functional dyspepsia in the general population. Further research is needed to determine whether these conditions share a similar underlying pathophysiology or are due to other factors such as medication side effects.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[3]*Almirall, Barcelona/Spain*

**Contact E-mail Address:** jose.mira@umh.es.

**Introduction:** Irritable bowel syndrome (IBS) is a common disorder characterised by recurring abdominal pain and altered bowel movements. The pathophysiology of IBS is not fully understood, and there is no validated biological diagnostic marker. As a result, patients often feel frustrated by a lack of information and perceive a stigma associated with their symptoms. A strong healthcare provider (HCP)–patient relationship is associated with increased patient satisfaction and improved outcomes, and as such is central to the effective diagnosis and management of IBS.
**Aims & Methods:** The objective of this study was to identify potential barriers as perceived by patients with IBS in relation to the care they received in the public health system in Spain. This was a multicentre, cross-sectional observational

study. Patients (aged ≥ 18 years) who attended a private consultation with a gastroenterologist (GE) for constipation and abdominal discomfort, had no previous IBS diagnosis, and who met Rome III criteria for IBS without alarm symptoms, were included. Patients completed the IBS-Symptom Severity Score questionnaire, EuroQol five dimensions (EQ-5D) quality of life questionnaire, and the Irritable Bowel Syndrome Patient Experience questionnaire, which comprises questions relating to patient experiences with both their primary care physician (PCP) and their GE.

**Results:** A total of 707 patients completed the study; 81% were female and the mean age was 45.6 years. The majority of patients (87.1%) met the criteria for IBS with constipation (IBS-C), with 11.9% of patients having mixed or unclassified IBS. The median time elapsed since patients' first visit to a HCP for their symptoms was 2 years. The main reason patients reported visiting a private GE was to seek a second opinion (41.4%) or because they felt their public HCP had not resolved their condition (36.4%). Overall, most patients reported suffering moderately severe symptoms (68.9%). Patients reported frequently suffering from abdominal pain (90%) and abdominal distension (91.5%), and the average severity of these symptoms on a scale of 0–100 was 58.3 ± 18.3 for abdominal pain and 61.9 ± 17.9 for abdominal distension. EQ-5D survey results showed that 61.5% of IBS patients reported moderate or severe problems with pain/discomfort, and 41.9% reported mild or moderate problems with everyday activities. Patients reported that their current treatment was offering little (47%) or some (25.9%) improvement in symptoms. In general, patients' perceptions were more positive towards their GE than their PCP, with only 43.9% of patients satisfied with the care received by their PCP, compared with 62.8% for their GE (**Table**).

**Conclusion:** IBS symptoms impact patients' quality of life and many patients experience symptoms for several years before being formally diagnosed. Moreover, many IBS patients feel they are not listened to when seeing a HCP, especially in the case of primary care. These data in patients with IBS-C highlight the high unmet need for improved provider–patient communication in relation to IBS, in order to improve both diagnosis and patient outcomes.

**Disclosure of Interest:** X. Cortés Gil: Xavier Cortés Gil is an employee of Almirall.

**Table:** Summary of selected questions from the Irritable Bowel Syndrome Patient Experience questionnaire.

| Question, % | Primary care physician | | Gastroenterologist | |
|---|---|---|---|---|
| | Yes | No | Yes | No |
| Do you feel that your provider listens to you and takes into account what you are saying when you speak? | 59.4 | 40.6 | 77.4 | 22.6 |
| Does your provider give you enough time in the consultation for you to be able to properly tell them what is wrong? | 30.5 | 69.5 | 53.5 | 46.5 |
| Does your provider give you written information about, for example, diet or other instructions to help you feel better and follow the treatment correctly? | 28.9 | 71.1 | 50.1 | 49.9 |
| Do you feel you are wasting your time when you attend the consultation with your provider? | 52.4 | 47.6 | 27.8 | 72.2 |
| Do you trust that your provider is knowledgeable about what is wrong with you and chooses the appropriate treatment? | 33.7 | 66.3 | 63.6 | 36.4 |
| In general, are you satisfied with the care you receive from the provider you normally see? | 43.9 | 56.1 | 62.8 | 37.2 |

## P0388 PROTON PUMP INHIBITORS INCREASE THE RISK FOR IRRITABLE BOWEL SYNDROME - A POPULATION-BASED STUDY

**Introduction:** Proton pump inhibitors (PPIs) are widely prescribed in gastroenterology and general practice. Recent literature supports a change in the gut microbiome in patients on long term PPIs (1, 2). Irritable bowel syndrome (IBS) is a disease with unclear pathophysiology and risk factors although alterations in the microbiome have been implicated as a mechanism (3). Little is known about the link between PPI use and IBS, although a link with small intestinal bacterial overgrowth has been implicated (4).

**Aims & Methods:** In a population-based study we aimed to determine the prevalence of IBS in participants taking PPIs. A total of 3576 people (mean age 58.5 years, age range 18 to 100 years, 47.6% males) randomly selected from the Australian population returned a mail survey (response rate = 43.6%). IBS including constipation predominant and diarrhoea predominant IBS subtypes was diagnosed according to modified Rome III criteria. Post infectious IBS was defined by the presence of gastroenteritis in the 3 months preceding the onset of symptoms. The survey contained a self-reported question on whether the participant was taking PPIs.

**Results:** Amongst the general population, 25.5% met the ROME III criteria for IBS and 14.6% for functional dyspepsia (FD). A total of 631 (17.6%) subjects were taking PPIs. Of those on PPIs, 228 (36.3%) had IBS and on subtype analysis, 7.2% of people had IBS–constipation (IBS-C) and 8.8%, IBS-diarrhoea (IBS-D). Post-infectious IBS was present in only 4% of participants with IBS on PPIs. Also, 27.3% of patients on PPIs had FD as diagnosed by ROME III criteria, suggesting this was the most common indication for PPI use. In the multivariate analysis including a range of self-reported health conditions, demographic, lifestyle (smoking, BMI, sleep problems) and psychological distress, those on PPIs showed an odds ratio of 1.75 (95% CI 1.31–2.34, $p < 0.001$) for concurrent IBS and PPI use.

**Conclusion:** Based on a large population-based study, we confirm that the prevalence of IBS is higher in patients taking PPIs, in line with a previous report from the USA (4). This may be secondary to an alteration in the gut microbiome. The general notion that PPIs are harmless might not hold true and further research is needed to elucidate the complex relationship between acid suppression and gut health.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** lukas.vanoudenhove@med.kuleuven.be.

**Introduction:** Irritable Bowel Syndrome (IBS) is associated with increased symptom levels after a lactulose challenge test, compared to healthy controls (Le Nevé et al, *AJG* 2013), with psychological distress and co-morbid functional dyspepsia (FD) also being associated with symptom levels (Pohl & Van Oudenhove et al, *UEGW* 2015). However, it remains unknown whether hydrogen breath test responses and symptom responses to this test are associated.

**Aims & Methods:** 196 IBS patients (Rome III), 81 of which had co-morbid FD (43.6%), and 81 healthy volunteers (HV) consumed a 400-ml liquid breakfast (Nutridrink®) combined with 25 g of lactulose after an overnight fast. They completed visual analogue scales (0–20) assessing severity of five gastrointestinal (GI) symptoms (abdominal pain, bloating, nausea, gas, urgency) and digestive comfort before breakfast and every 15 minutes up to 240 minutes post-lactulose ingestion, and hourly for 240 more minutes after intake of a standardized lunch. Breath samples were collected and analysed at the same time points up to 240 minutes post-lactulose ingestion for hydrogen level measurement using a gas chromatograph. The relationship between peak hydrogen level (increase from baseline) and GI symptom levels over time was analyzed using linear mixed models, controlling for gender and anxiety, depression, or somatization.

**Results:** No significant main or interaction effects of delta peak hydrogen were found for bloating and urgency. For nausea, a significant main effect of delta

peak hydrogen was found ($p = 0.028$), driven by a positive association between hydrogen response and symptom level over the entire period of measurement. For gas, a significant delta peak hydrogen-by-time interaction effect was found ($p = 0.013$), driven by a positive association between hydrogen response and symptom level from 195 minutes post-lactulose ingestion on. For abdominal pain and digestive comfort, a group-by-time-by-delta peak hydrogen three-way interaction effect was found ($p = 0.003$ and $p = 0.059$, respectively), driven by a lack of association between hydrogen response and symptom levels in healthy controls, a main effect of delta peak hydrogen in IBS patients without FD, and a time-by-delta peak hydrogen interaction effect in IBS patients with FD (with the strongest relationship in the beginning of the measurement and after lunch). The effect of the psychosocial variable was significant for all symptoms, confirming earlier findings.

**Conclusion:** Increased hydrogen production during a lactulose-nutrient challenge test is associated with higher levels of nausea, gas, and abdominal pain, and lower levels of digestive comfort.

**Introduction:** Irritable Bowel Syndrome (IBS) is a heterogeneous disorder with no clear pathophysiological explanations, and therapy options are sparse. Current subgroupings are based on bowel habits and do not consider other gastrointestinal, psychological or extraintestinal symptoms. Our aim was to evaluate a subgrouping strategy based on detailed symptom profiles.

**Aims & Methods:** A mixture model analysis (latent classes) was used to identify naturally occurring subgroups of IBS patients based on GI, extraintestinal and psychological traits. Traits included the 13 single-item scores from the IBS specific Gastrointestinal Symptom Rating Scale (GSRS-IBS) to account for a profile of GI symptoms, and the average stool consistency and frequency from a six-day stool diary. Psychological symptoms included anxiety and depression from the Hospital Anxiety and Depression scale and three subscores each from the Fatique Impact Score (FIS) and the Sense of Coherence questionnaire (SOC), respectively. Extraintestinal symptoms were drawn from the Patient Health Questionnaire. From these measures we derived two latent classification systems: The first based on all 13 gastrointestinal symptoms only, and a second where we added psychological and extraintestinal symptoms. Latent classes were then compared with respect to symptom profiles using analysis of variance and pair-wise comparisons.

**Results:** We analyzed 172 well-characterized patients with IBS (Rome III criteria, 69% female; mean age 33.7 (range: 18–60 years). Rome III based subgrouping showed 20 patients with IBS-C (11.6%), 42 with IBS-D (24.4%), 107 with IBS-M (62.2%) and 3 patients with IBS-U (1.7%). Our first classification based on 15 gastrointestinal symptoms (GIM) showed an optimal solution for three subgroups. These were characterized by symptom profiles of a) constipation, abdominal distention, incomplete bowel emptying ($n = 69$), b) diarrhea, urgency, pain ($n = 72$), c) less than average symptom severity ($n = 31$) (Figure 1). We then compared these groups regarding psychological and extraintestinal symptoms. Significantly higher anxiety levels could be attributed to the diarrhea-pain group. The low-symptom group showed significantly lower levels of psychological and extraintestinal symptoms and higher levels of SOC, as well as significantly lower scores for dizziness and fainting (Figure 2 and 3). A comparison of these three groups with the Rome III subgroups showed a high overlap for IBS-C and IBS-D with the constipation-abdominal distention and diarrhea-pain group, respectively, whereas IBS-M and IBS-U where quite evenly distributed between latent classes. All Rome subgroups showed overlap with the low symptom group (Table 1). The model based on a combination of all considered symptoms showed an optimal solution for two groups, characterized by a) high overall symptom burden, b) low overall symptom burden. A comparison with Rome subgroups exhibited no clear clustering.

**Conclusion:** This model-based subgrouping partly supports the distinction of subgroups based on bowel habits, but takes other gastrointestinal symptoms and severity into account and uses a symptom profile to characterize subgroups. The association of gastrointestinal, psychological and extraintestinal symptoms is generalized across a profile and not solely focused on a single construct. As a next step we will compare these latent classes regarding underlying pathophysiological mechanisms.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0391 LABORATORY INVESTIGATIONS FOR PATIENTS MEETING DIAGNOSTIC CRITERIA FOR IRRITABLE BOWEL SYNDROME: ARE WE MEETING THE STANDARDS?

**J. Kennedy**[1], K. Wright[2], L. B. Materacki[2], S. Waterman[3], R. Makins[2], A. Di Mambro[2]

[1]*Gastreoenterology, Cheltenham General Hospital, Cheltenham/United Kingdom*

[2]*Gastroenterology, Cheltenham General Hospital, Cheltenham/United Kingdom*

[3]*Pathology, Cheltenham General Hospital, Cheltenham/United Kingdom*

**Contact E-mail Address:** James@chase23.co.uk.

**Introduction:** Alongside a thorough clinical assessment the UK National Institute for Clinical Effectiveness (NICE) clinical guideline 61 recommends that patients meeting diagnostic criteria for irritable bowel syndrome (IBS), as defined by the Rome III criteria, should undergo laboratory testing for inflammation (C-reactive peptide (CRP) and plasma viscosity (PV) or erythrocyte sedimentation rate (ESR)), full blood count (FBC) and antibody testing for coeliac disease to exclude non-organic pathology [1]. Faecal calprotectin is a reliable and cost effective adjuvant test to help differentiate between functional and inflammatory bowel disease (IBD) [2, 3].

**Aims & Methods:** Our aim was to assess local adherence to NICE guidelines on investigating patients who meet diagnostic criteria for IBS. As part of a wider study into the use of faecal calprotectin as a diagnostic tool within Gloucestershire Hospitals NHS Foundation Trust, UK, we interrogated clinic letters, endoscopy reports and pathology results for patients in whom a negative ($< 50$ mg/g faeces) or intermediate (50–150 mg/g faeces) faecal calprotectin level had been measured between September 2014 and September 2015. In patients diagnosed with IBS, we identified which of CRP, PV/ESR, FBC and antibody testing for coeliac disease had been done prior to or concurrent with faecal calprotectin measurement.

**Results:** Of the 148 patients (age range: 16–81, median age: 35; 72% female) who satisfied inclusion criteria, 63.5% ($n = 94$) had not undergone at least one of the recommended laboratory tests around the time of faecal calprotectin measurement. PV/ESR had not been checked in a majority (54.1%). Notably, 7.4% of patients had never had coeliac serology checked, 72.7% of whom presented with a change in bowel habit.

**Conclusion:** Although clear guidance exists for the investigation of patients meeting diagnostic criteria for IBS and use of faecal calprotectin as a diagnostic tool, insufficient essential accessory investigations are being completed. This risks conditions such as IBD, gastrointestinal cancer and coeliac disease being misdiagnosed as IBS with significant implications for delays in management and ongoing avoidable morbidity. We are reviewing measures to improve local adherence to NICE guidance, and call on other Trusts internationally to reflect on their own practice.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Irritable bowel syndrome (IBS) is a chronic, relapsing and often lifelong disorder. It is characterised by the presence of abdominal pain or discomfort, which may be associated with defaecation and/or accompanied by a change in bowel habit.

**Aims & Methods:** We compared the management of IBS with standards set up by NICE. Ensuring the correct management of IBS will improve the quality of life of the patients as well as being cost effective in term of avoiding unnecessary

investigations and admissions. Over a seven-month period, information was gathered retrospectively on 66 patients (18–90 year old) referred to the gastroenterology out patient clinic with a suspected diagnosis of Irritable Bowel syndrome.

**Results:** The management of those patients was assessed against NICE guidelines (NICE guidelines 61, 2008). include establishing a diagnosis; identification of 'red flags' (symptoms and/or features that may be caused by another condition that needs investigation); avoiding unnecessary investigations; providing lifestyle advice; drug and psychological interventions; and referral and follow-up. The results showed that most of the patients (85% -100%) were assessed and clinically examined for the ''red flag'' signs and symptoms like weight loss, anaemia, abdominal mass, rectal bleed, or family history of bowel or ovarian cancer. Majority of the patients (94%–100%) had the basic blood tests (Full blood count, ESR, CRP). However, only 34% were had antibody testing for coeliac disease. There was a clear insufficiency (45% -65%) in providing information about IBS explaining the importance of self-help in effectively managing their IBS including life style, diet, and physical activity. High percentage of patient with clinical diagnosis of Irritable bowel syndrome had unnecessary investigations like upper or lower endoscopy (76%) and abdominal ultrasound scan (48%).

**Conclusion:** The use of the national guidelines to make appropriate diagnosis and management for Irritable bowel syndrome can improves patients' quality of life and avoids exposing them to unnecessary tests like colonoscopy. The study showed that there is a general tendency to over investigate patient with suspected IBS despite the absence of the red flag signs and symptoms. Most of the patients did not have the appropriate information and advice regarding their disease management. National guidelines are helpful tools in management patients; however, to avoid missed diagnoses of serious disease, using the guidelines must be tailored to the specific clinical setting.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0393 PERFORMANCE EVALUATION OF DYSBIOSIS STATUS AS A TOOL FOR CLINICAL INVESTIGATION IN PATIENTS WITH FUNCTIONAL GASTROINTESTINAL DISORDERS

**Introduction:** Probiotic treatments in patients with functional gastrointestinal disorders (FGID) show promising effects. Because of a lack of tests for routine diagnosis of dysbiosis as yet bacteriotherapy cannot be targeted.

**Aims & Methods:** A commercially available stool dysbiosis test (GA-map™ Dysbiosis Test[1]) was performed in patients with FGID to analyze individual microbiota and to define goups of patients according to their symptoms and microbiota profiles. The dysbiosis test is a 16 S rRNA DNA test that utilizes DNA probes in recognizing gut bacteria profiles for identification and characterization of dysbiosis. The study took place in 7 private gastroenterology praxes all over Germany and included 99 eligible outpatients. Age of the patients ranged from 16 to 84 years (median age 44) and sex ratio was 70% females. Informed, written consent was given by each patient.

**Results:** Stool testing was feasible and complete in all included patients. A dysbiosis index score (DI) consisting of 5 levels (1–2: non dysbiotic, 3–5 dysbiotic) was defined in 99 patients. According to the cut off of the dysbiosis test, 31 patients (31%) had no dysbiosis while the majority of patients (69%) were dysbiotic. Dysbiosis was mainly associated with augmented Ruminococcus gnavus, and Proteobacteria and diminished Faecalibacterium prausnitzii. Subgroups with elevated levels of dysbiosis could be identified such as FGID after travelers' diarrhea (82% dysbiosis, 9/11 patients), as compared to diarrhea predominant FGID (69%, 42/61 patients) with dysbiosis not different from the majority of patients, and a group of 13 low-grade inflammatory patients harboring severe dysbiosis. All subgroups showed different bacterial profiles.

**Conclusion:** The dysbiosis test available for clinical routine testing is able to identify dysbiosis in symptomatic patients with FGID in a daily routine setting. Accurate diagnosis of the microbiota offers the possibility of targeted bacteriotherapy.

## P0394 NEGATIVE FAECAL CALPROTECTIN TESTING PROVIDES COST-EFFECTIVE DIAGNOSTIC REASSURANCE IN PATIENTS WITH IRRITABLE BOWEL SYNDROME

**L. B. Materacki**[1], J. Kennedy[1], K. Wright[1], S. Waterman[2], R. Makins[1], A. Di Mambro[1]
[1]*Gastroenterology, Cheltenham General Hospital, Cheltenham/United Kingdom*
[2]*Pathology, Cheltenham General Hospital, Cheltenham/United Kingdom*

**Contact E-mail Address:** LBM425@gmail.com.

**Introduction:** The diagnosis of irritable bowel syndrome (IBS) requires careful exclusion of 'red flag' clinical features and blood abnormalities which may indicate an alternative organic diagnosis such as inflammatory bowel disease (IBD).[1] The chronic, recurrent nature of the symptoms of IBS may lead to diagnostic anxiety. Faecal calprotectin (FC) is a useful non-invasive test for intestinal inflammation that can distinguish IBS from IBD when specialist referral or further investigations are being considered.[2] Confident use of FC is likely to save costs by reducing referral and endoscopy burden.

**Aims & Methods:** This retrospective, observational study investigated the management of patients diagnosed with IBS following gastroenterologist review who had negative FC (<50 µg/g faeces) tested between September 2014 and September 2015 in Gloucestershire, UK. Electronic records were interrogated for clinical letters and the results of blood (full blood count, C-reactive peptide, erythrocyte sedimentation rate/plasma viscosity and coeliac serology), stool and endoscopic investigations. Red flag indicators were defined as per NICE clinical guideline 61.[1] The cost-saving implications of negative FC testing to confirm IBS were evaluated using estimated per person costs of an ELISA test and POCT CalDetect (£22.79), outpatient gastroenterology appointment (£164.00), colonoscopy (£577.68) and flexible-sigmoidoscopy (£351.00).[2, 3].

**Results:** During the study period 173 non-IBD patients (age range: 17–81 y, median: 35 y, 72% female) were referred for gastroenterologist review and had a negative FC test. There were no documented red flag clinical features nor significant abnormalities on blood testing in 30 patients diagnosed with IBS. 23% and 17% of these patients had undergone colonoscopy and flexible sigmoidoscopy respectively. No significant abnormalities were detected. The estimated cost-saving impact of a negative FC to confirm a diagnosis of IBS and limit unnecessary referral and endoscopy was £357.29 per person.

**Conclusion:** A negative FC may provide cost-effective diagnostic reassurance in patient with suspected IBS without red flag clinical features or blood abnormalities in whom specialist referral or endoscopy is considered. There is a need for FC testing to be made available to primary care physicians with robust pathways to support decision-making.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Large numbers of referrals for specialist gastroenterology outpatient care result in long waiting lists and reduce or delay access to a diagnosis and effective management for referrals judged less ''urgent''. Many non-urgent referrals are for people with likely functional gastrointestinal disorders (FGID). Therefore, new models of care are needed to more efficiently transfer specialist-held expertise in FGIDs out to primary care practitioners.

**Aims & Methods:** This study aims to evaluate the performance of a non-specialist dependent algorithm-based approach to the diagnosis and management of FGID. Consecutive patients triaged to the 'routine waitlist' of an Australian public hospital Gastroenterology Department over 2 years, with non-specific GI symptoms (no alarms) were randomised to waitlist control or the algorithm (2:1). Algorithm patients were screened for organic disease with a standard questionnaire for alarms and a routine panel of blood/stool tests (full blood count, C-reactive protein, biochemistry, thyroid function tests, iron studies, coeliac serology, +/- *H. pylori* serology, +/- faecal calprotectin and elastase). In cases where patients had clinical alarms or abnormal tests, data were reviewed by a gastroenterologist (GE) and, if appropriate, prompt GE appointment offered. Those without screening concerns were classified according to Rome III criteria and received a letter which explained their FGID diagnosis and dietary/psychological management options. Waitlist control patients were not screened. All participants completed symptom severity, quality of life, workplace productivity and mental health surveys at baseline and 6 weeks.

**Results:** 90 algorithm patients (61% female, mean 42, [SD 14] y) and 21 control (75% female, mean 43, [SD 16] y) patients completed intake. Of the 90 patients screened with the algorithm 47 were diagnosed FGID, 34 warranted prompt GE review (diagnoses = 15 FGID, 2 IBD, 5 other, 12 pending), and 9 were excluded.

34 algorithm patients completed 6 weeks follow up and compared to controls, showed reduced GI catastrophizing cognitions [t (50) = -4.27, p < .001], anxiety [t (47) = -2.35, p = .023] and stress [t (47) = -2.41, p = .020] whilst GI symptom severity did not change [t (50) = −0.171, p = .865]. GI-specific anxiety was higher than controls at 6 weeks [t (50) = 2.46, p = .017), but unchanged from baseline [t (34) = 1.251, p = .215]. 33/34 patients had read the letter and only 1 rejected the diagnosis. Most patients found the letter useful (23/34): as it provided a diagnosis (n = 5), management options (n = 6) and reassurance (n = 7). Two felt the algorithm did not take their full situation into account (Table). Only 9/34 discussed the letter with their GP yet 23 proceeded with management options. Dietary management (14 diet only, 1 psychology only, 8 both, 11 neither) and self-help options (47% self-help only, 21% self-help/face-to-face) were preferred, with symptom improvement in 17 of the 34 respondents at 6 weeks, and the approach was acceptable to 19 of these. We postulate that the difference in GI-specific anxiety between control and algorithm group may be a side effect of monitoring, or a delay between cognition changes affecting GI-specific anxiety. However, the algorithm was able to reduce overall stress and anxiety by providing reassurance and management tools.

Patient Feedback on the Usefulness of the Diagnostic/Management Letter

| | |
|---|---|
| Useful | "It was good to know what was wrong with me and that there were options for managing it". Pt #3 |
| | "Stopped me worrying it was something serious". Pt #31 |
| | " It has help to reduce my stress level... I am able to manage my health problem better and is feeling much better" Pt #32 |
| Ambivalent | "Confirmed possible diagnosis. But would prefer to have a colonoscopy to double check all is ok" Pt #25 |
| | "I know it was meant to be reassuring that there is nothing sinister, but without definite proof I find it hard to relax" Pt #34 |
| Not Useful | "I did not find the letter and diagnosis useful, I felt that my case had not been thoroughly considered and that that I had many questions left unanswered". Pt #5 |
| | "No. All my problems were not included or asked about, fat malabsorption or floaty stool, lactose intolerance..." Pt #33 |

**Conclusion:** This novel FGID care pathway was effective at improving patient outcomes by providing a diagnosis, reassurance, and evidence-based management options without accessing face-to-face specialty care. Patient acceptability and buy-in was good, with the majority of respondents achieving symptomatic improvement and reduced stress and anxiety. Future research trialing the 'FGID Care Pathway' in either primary or tertiary care would be beneficial.
**Disclosure of Interest:** E.C. Linedale: Abbott's Pathology provided funding for the cost of routine stool tests used in this study.

**Introduction:** The aim of this exploratory study was to assess the effect of 14 days consumption of a fermented milk product with probiotics (FMPP) on gastrointestinal (GI) symptoms and exhaled $H_2$ and $CH_4$ during a combined nutrient and lactulose challenge test (Le Nevé et al, 2013) in patients with irritable bowel syndrome (IBS).
**Aims & Methods:** We screened 125 patients with IBS (Rome III) from a secondary/tertiary care center. The fasted subjects were served a test meal consisting of a 400 ml liquid breakfast (Nutridrink®, 1.5 kcal/ml) containing 25 g lactulose. The intensity of eight meal-related GI symptoms, the overall level of digestive comfort and the amount of exhaled $H_2$ and $CH_4$ were assessed before and during 4 h after meal intake. The lactulose challenge test was repeated on the same subjects after they had consumed 125 grams of FMPP (fermented milk product containing B. lactis CNCM I-2494) or a control product twice daily for 14 days in a double-blind, randomized, parallel design. Active fraction of the fecal microbiota derived from RNA was profiled using 16 S Miseq analysis targeting V3-V4 variables regions from fecal samples obtained before and after the intervention period. Measured endpoints were the intensity of eight meal-related GI symptoms and the amount of exhaled $H_2$ and $CH_4$.
**Results:** A total of 108 patients with IBS were randomized; 4 patients withdrew from each group. Analysis by intention to treat (ITT) did not show any statistically or clinically relevant difference between groups. However, a post-hoc analysis in patients stratified according to their baseline $H_2$ breath level demonstrated that the FMPP intervention significantly reduced mean $H_2$ breath level ($p = 0.01$) vs. control in high $H_2$ producers (baseline $H_2$ breath level $\geq 10$ ppm; n = 21 FMPP; n = 12 control), and tended to decrease some meal-related GI symptoms (gas, discomfort, $p = 0.09$) vs. control. Within the active microbial community, the ratio Prevotella/Bacteroides was significantly higher in high $H_2$ producers ($p < 0.05$), indicating a higher activity of Prevotella. The FMPP intervention tended to decrease the ratio Prevotella/Bacteroides vs. control in high $H_2$ producers ($p = 0.07$). No significant difference was found between high $H_2$ producers and low $H_2$ producers regarding baseline clinical parameters (IBS-SSS, HAD score, Rome III subtype).
**Conclusion:** We could not demonstrate an effect of FMPP containing B. lactis CNCM I-2494 on exhaled $H_2$ and $CH_4$ and GI symptoms in the whole IBS group. However, a subgroup of patients with high $H_2$ production and increased Prevotella/Bacteroides activity ratio at baseline appeared to respond more favorably, indicating that the degree of microbial activity in the gut may predict the symptomatic response to a FMPP intervention. Further investigations are required to confirm that subgrouping IBS patients using exhaled gas could open new opportunities in the management of IBS.

## P0397 EFFICIENCY OF FMT IN CASES OF "TREATMENT-RESISTANT" IBS

G. Syzenko[1], **L. Budovska**[2], K. Puchkov[1]
[1]*Internal Medicine № Bogomolets National Medical University, Kyiv/Ukraine*
[2]*Internal Medicine № Bogomolets National medical University, Kyiv/Ukraine*

**Contact E-mail Address:** happy_lucie@mail.ru.
**Introduction:** Abnormal microbiota has crucial role in the pathogenesis and expression of the intestinal manifestations of IBS [1]. Gut microbiota is already accepted as a therapeutic target. Regarding high efficacy faecal microbiota transplantation (FMT) in refractory *C. difficile* infection, this procedure has also been proposed for the treatment of IBS, especially in "treatment resistant" cases [2].
**Aims & Methods:** The aim of our study is to evaluate the efficiency of FMT in treatment of "treatment resistant" IBS. We enrolled 12 patients (75% women; 6 IBS-D, 5 IBS-C, and 1 IBS-M, according to the Rome III criteria), with continuous GI symptoms after adequate lifestyle modification, antibiotic, pre- and probiotic and antipsychotic drugs treatment. FMT through colonoscopy with or without consecutive enemas was performed to all patients. Quantifying severity of GI symptoms (abdominal pain, bloating, flatus) for all patients was performed by using VAS. Bowel habits evaluation was performed by Bristol stool scale and frequency assessment. Quality of life estimated with SF-36.
**Results:** Abdominal pain resolution or significant improvement ($p \leq 0.01$) was reported in 3 (25%) and 6 (50%) patients; one patient (8.3%) reported no change in pain level. Statistical significant reduction in bloating and flatus level was achieved in 2 (16.7%) and 7 (58.3%) patient, respectively. All IBS-D and IBS-M patients reported normalization of stool frequency and consistency, for all IBS-C patients was observed significant ($p \leq 0.01$) reduction in frequency of laxatives using; stool consistency was changed in 3 (60%) patients. Straining and incomplete defecation reported by 5 (41.6%) and 2 (16.6%) patients before FMT, were not observed after procedure. Quality of life was also improved in 11 (91.6%) of patient. Complete symptoms resolution or significant improvement was observed in 4 (33.3%) and 7 (58.3%) patients respectively. Adverse effects (temporary increasing in bloating intensity) was reported in 2 (16.7%) patients.
**Conclusion:** Significant rate of clinical improvement in of patient with refractory IBS symptoms after FMT and less number of adverse effects as temporary increasing in bloating intensity substantiates the possibility of its use as a therapeutic modality in such circumstances. Future studies are needed to accurate investigation of possibly adverse effects and long-term outcomes.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Linaclotide (LIN) is a guanylate cyclase-C agonist approved for the treatment of irritable bowel syndrome with constipation (IBS-C) in adults in the US, EU, Switzerland, Canada, Mexico, and Hong Kong (290 -μg dose). There is a need in China for therapy that is well tolerated and effective in treating both bowel and abdominal symptoms of IBS-C.

**Aims & Methods:** To evaluate the efficacy and safety of LIN in patients with IBS-C in China and other regions. This Phase 3, double-blind trial randomized IBS-C patients to once-daily oral LIN 290 $\mu$g or placebo (PBO). Eligible patients met Rome III criteria for IBS and, during a 2-week pretreatment period, had an average of $\leq$5 spontaneous bowel movements (SBMs)/week and $<$3 complete SBMs (CSBMs)/week, and reported abdominal pain $\geq$2 days/week with average abdominal pain score $\geq$3.0 (11-point numerical rating scale; 0 = none, 10 = very severe). Patients reported bowel habits (SBMs, CSBMs, stool consistency, and straining) and abdominal symptoms (bloating, discomfort, and pain) daily throughout the pretreatment and 12-week treatment periods. Co-primary and secondary endpoints were tested using a predefined 3-step serial gatekeeping multiple comparisons procedure (MCP). Adverse events (AEs) were monitored.

**Results:** The intent-to-treat (ITT) population included 839 patients (mean age = 41 years; 82% female; 81% Asian). The trial met all primary and secondary endpoints under the MCP (see Table). Responder criteria were met by 60.0% of LIN patients vs. 48.8% of PBO patients for $\geq$30% decrease in abdominal pain or discomfort for $\geq$6 of 12 weeks (P = 0.0010), and by 31.7% of LIN patients vs. 15.4% of PBO patients for IBS degree of relief score $\leq$2 (considerably or completely relieved) for $\geq$6 of 12 weeks ($P < 0.0001$) (co-primary endpoints). Higher weekly responder rates among LIN vs. PBO patients were seen within the first 2 weeks and sustained over 12 weeks of treatment for abdominal pain/discomfort ($P < 0.05$ at weeks 2–12) and IBS degree of relief ($P < 0.05$ at all weeks 1–12). LIN showed significant improvements vs. PBO in all secondary endpoints: 12-week change from baseline in CSBM and SBM frequency, stool consistency, straining, abdominal pain, abdominal discomfort, and abdominal bloating (all $P < 0.0001$). Diarrhea, the most common AE, was reported in 9.4% of LIN patients and 1.2% of PBO patients. Discontinuation rates due to diarrhea were low (0.7% LIN, 0.2% PBO).

**Table:** Primary and Secondary Endpoint Results (ITT Population).

| | PBO (N = 422) | LIN (N = 417) | P value[d] |
|---|---|---|---|
| **Co-primary Endpoints (% Responders)[a]** | | | |
| $\geq$30% decrease in abdominal pain or discomfort, with neither score worsening from baseline, for $\geq$6/12 weeks | 48.8 | 60.0 | 0.0010 |
| IBS degree of relief score $\leq$2 for $\geq$6/12 weeks[b] | 15.4 | 31.7 | $<$0.0001 |
| **Secondary Endpoints (LS Mean Change from Baseline)[c]** | | | |
| CSBMs/week | 1.0 | 1.9 | $<$0.0001 |
| SBMs/week | 1.5 | 3.0 | $<$0.0001 |
| Stool consistency (7-point BSFS) | 0.8 | 1.5 | $<$0.0001 |
| Straining (5-point ordinal scale) | −0.7 | −1.0 | $<$0.0001 |
| Abdominal bloating (11-point NRS) | −0.9 | −1.5 | $<$0.0001 |
| Abdominal pain (11-point NRS) | −1.1 | −1.6 | $<$0.0001 |
| Abdominal discomfort (11-point NRS) | −1.0 | −1.5 | $<$0.0001 |

BSFS= Bristol Stool Form Scale; CSBM = complete SBM; ITT = intent-to-treat; LS = least squares; NRS = numerical rating scale; SBM = spontaneous bowel movement.

[a]P values based on a comparison of LIN vs. PBO using a Cochran-Mantel-Haenszel test controlling for geographic region.

[b]IBS degree of relief score $\leq$2 (7-point balanced ordinal scale) corresponds to a response of ''Considerably relieved'' or ''Completely relieved''.

[c]P values based on a comparison of LIN vs. PBO using an analysis of covariance model with treatment group and geographic region as factors and baseline value as covariate.

[d]All P values met the criteria for statistical significance under the MCP.

**Conclusion:** These results demonstrate that LIN improves IBS-C symptoms in a predominantly Chinese IBS-C population; results support earlier trials and expand on previous results. Study sponsored by AstraZeneca AB and Ironwood Pharmaceuticals, Inc.

**Introduction:** Linaclotide, a guanylate cyclase-C agonist, has been shown in clinical trials to relieve constipation and improve abdominal pain and discomfort in patients with irritable bowel syndrome with constipation (IBS-C), but there are limited UK-specific 'real world' data to support this.

**Aims & Methods:** The aim of the present study was to describe 'real world' clinical experience of linaclotide treatment in the UK. A multi-centre, observational, uncontrolled, prospective 52-week study is ongoing in 8 specialist gastroenterology services in England and Scotland, with the primary objective to describe the change from baseline in IBS-Symptom Severity Scale (IBS-SSS) score at 12 weeks after linaclotide initiation. Consenting patients aged $\geq$18 years initiated on linaclotide for IBS-C as part of usual clinical care were recruited. Data on patient demographic and clinical characteristics, concomitant medication (any concomitant laxative use was based only on clinicians' routine advice and/or patients' personal choice), patient reported outcomes (including IBS-SSS) and adverse events (AEs) are being collected. Here we report analysis of real world clinical experience at 12 weeks following linaclotide initiation.

**Results:** 202 patients were evaluated (185 female [92%]). Patient baseline characteristics were as follows: median age 44.9 (range: 18–77) years; median time since IBS-C diagnosis 2.6 months (range: 0–68 years); 84 (42%) patients reported laxative use at baseline. Mean baseline IBS-SSS score overall was 339 (standard deviation [SD]: 92; n = 192); 128 (67%) patients had IBS-C classified as severe (scores $\geq$ 300), 54 (28%) moderate (175 $<$ 300), 9 (5%) mild (75 $<$ 175) and 1 (0.5%) in remission ($<$75). At 12 weeks, mean IBS-SSS score was 266 (SD: 119; n = 123); 50 (41%) patients had IBS-C classified as severe, 42 (34%) moderate, 22 (18%) mild, 9 (7%) in remission. There was a significant decrease in IBS-SSS scores between initiation of linaclotide treatment and the 12-week observation, with a mean decrease of 59.4 (SD: 98) points ($P < 0.001$; n = 120 patients with paired data); 67 (56%) of these patients reported responding to treatment (i.e. reduction of $\geq$50 points, OR score fell below 150 [for patients with baseline score $\geq$150]). Linaclotide treatment 12-week follow-up questionnaires were returned by 154 (76%) patients; of these, 87 (56%) remained on linaclotide (defined as $\geq$4 days treatment in last week) at 12 weeks. 67/154 patients (44%) discontinued linaclotide by 12 weeks; 44/154 (29%) cited unacceptable tolerability, mostly diarrhoea (29/154 [19%]; 15/29 [52%] were taking laxatives at baseline). Median (range) time to discontinuation for diarrhoea-related and unrelated reasons: 3.3 (0.1–11.6) and 5.1 (0.1–12.0) weeks, respectively. Overall, 127 AEs possibly related to linaclotide were reported in 74 patients (37%), with diarrhoea (n = 44 [22%]), abdominal pain/cramps (n = 19 [9%]) and inefficacy (n = 13 [6%]) being most common (see Table). AEs were reported in 41/84 patients taking laxatives at baseline (49%) and in 33/118 patients not taking laxatives at baseline (28%); there was a significant association between taking laxatives at baseline and the emergence of diarrhoea on treatment, with a higher proportion of patients experiencing diarrhoea among those taking laxatives (31% versus 15%, $P = 0.008$; see Table).

**Table:** Most common adverse events reported in patients treated with linaclotide according to baseline laxative use.

| Patients with AEs reported | No laxatives at baseline (n = 118) | Laxatives at baseline (n = 84) | Overall (n = 202) |
|---|---|---|---|
| **Diarrhoea**, n (%) | 18 (15%) | 26 (31%)** | 44 (22%) |
| **Abdominal cramps/pain**, n (%) | 8 (7%) | 11 (13%) | 19 (9%) |
| **Drug ineffective**, n (%) | 8 (7%) | 5 (6%) | 13 (6%) |

**Chi-square test $P = 0.008$.

**Conclusion:** Linaclotide significantly reduced mean IBS-SSS score at 12 weeks. Linaclotide was reasonably well tolerated; diarrhoea was the most commonly reported AE, consistent with clinical trial data and mechanism of action of linaclotide, and was more common in patients reporting laxative use at baseline compared to those not on baseline laxatives.

## P0400 POSITIVE EFFECTS FIVE YEARS AFTER A STRUCTURED PATIENT EDUCATION (IBS SCHOOL) FOR PATIENTS WITH IRRITABLE BOWEL SYNDROME (IBS)

**G. Ringström**, S. Storsrud, P. Jerlstad, H. Törnblom, M. Simrén
*Institute Of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg/Sweden*

**Contact E-mail Address:** gisela.ringstrom@vgregion.se.
**Introduction:** Treatment options for patients with IBS are limited. Information and reassurance are suggested to be important components in the management of patients with IBS. Patient education has previously been demonstrated to improve symptoms, health-related quality of life and knowledge about IBS at six and twelve months follow-up. (Ringström et al. Eur J Gastroenterol Hepatol. 2010 & 2012) but no long-term follow-up studies are available.
**Aims & Methods:** The aim was to evaluate long-term effects annually over five years after participation in an IBS school. We included 158 patients (mean age 38 (18–68) years; 135 females) with IBS according to the Rome II criteria, who had participated in the patient education, consisting of six two-hour sessions, once per week with approximately ten patients per group. Five different health care professionals were responsible for one session each. The patients completed questionnaires at baseline and thereafter annually during five years to evaluate the perceived knowledge of IBS, GI symptoms (IBS Severity Scoring System, IBS-SSS), GI-specific anxiety (Visceral Sensitivity Index, VSI), psychological symptoms (Hospital Anxiety and Depression scale, HAD) and health-related quality of life (Short Form-36, SF-36).
**Results:** The patients experienced increased knowledge of IBS ($74 \pm 12$ vs. $44 \pm 23$ (mean $\pm$ SD); $p < 0.001$), and were more satisfied with that knowledge (VAS, $69 \pm 21$ vs. $30 \pm 23$; $p < 0.001$), reduced GI symptoms (IBS-SSS, $263 \pm 103$ vs. $304 \pm 97$; $p < 0.001$), reduced GI-specific anxiety (VSI, $30 \pm 17$ vs. $38 \pm 17$; $p < 0.001$), reduced general anxiety (HAD anxiety, $6.9 \pm 4.5$ vs. $8.0 \pm 4.5$; $p < 0.001$) and improved health-related quality of life (SF-36 Mental Component Score, $39 \pm 14$ vs. $36 \pm 12$; $p < 0.001$) one year after the IBS school compared to baseline. These results were maintained throughout the five-year follow-up period. Patients who completed questionnaires at $\geq 3$ time points during the five-year follow-up tended to be more anxious, report better physical health-related quality of life and to be older compared to those who responded $\leq$ twice; otherwise, there were no significant differences between these two groups.
**Conclusion:** A structured patient education for IBS patients improves knowledge about IBS, reduces GI and psychological symptoms, and improves health-related quality of life. These positive effects are sustained for at least five years after participation in the IBS School. Therefore, this seems to be an important tool in the management of patients with IBS.

## P0401 CORRELATION BETWEEN FOOD INTAKE AND SYMPTOM SEVERITY IN IBS

**S. Störsrud**[1], B. Le Nevé[2], B. Holmes[2], H. Törnblom[1], M. Simrén[1]
[1]*Dept Of Medicine And Clinical Nutrition, Mag-tarmlab Sahlgrenska University hospita, Gothenburg/Sweden*
[2]*Palaiseau, Danone Research, Paris/France*

**Contact E-mail Address:** stine.storsrud@vgregion.se.
**Introduction:** Food consumption and diet are central issues that concerns patients with irritable bowel syndrome (IBS), and they frequently report associations between food ingestion and onset or worsening of gastrointestinal (GI) symptoms. The current understanding about the association between the intake of certain nutrients, food items and/or food groups, and the GI symptom pattern is poor.
**Aims & Methods:** The aims of this study were to determine the intake of energy and nutrients, as well as FODMAPs (Fermentable Oligo-, Di, Monosaccharides and Polyols) in patients with IBS, and to study the association between food and nutrient intake and the severity of GI symptoms. We included 116 patients who fulfilled the Rome III criteria for IBS (mean age 34 (18–60) years; 74% females). They completed a 4-day food diary, in which the quantities consumed were entered in grams or household measures. The intake of nutrients, including FODMAPs, as well as 14 different food groups, was calculated by using a dedicated software. The IBS symptom severity was assessed with the IBS severity scoring scale (IBS-SSS; range 0–500).
**Results:** The mean daily intake of energy was $2134 \pm 591$ kcal (mean $\pm$ SD); 37.6% of the energy came from fat, 16.3% and 41.2% from protein and carbohydrates respectively. The total intake of FODMAPs was $17.8 \pm 16.7$ g, of which 72.0% was lactose, 14.9% fructans, 6.3% polyols, 3.4% fructose in exess of glucose and 3.4% galacto-oligosaccharides.
According to IBS-SSS, the majority of patients reported moderate to severe IBS symptoms. The IBS symptom severity was negatively correlated with the total intake of energy ($r = -0.25$, $p = 0.007$), carbohydrates ($r = -0.24$, $p = 0.010$), vegetables ($r = -0.219$, $p = 0.019$), alcohol ($r = -0.218$, $p = 0.019$), fiber ($r = -0.239$, $p = 0.010$) and cereals ($r = -0.203$, $p = 0.029$), However, we could not show any significant correlations between the severity of IBS symptoms and intake of FODMAPs (total or FODMAP components), fat or protein, or other food groups.
**Conclusion:** In this study we demonstrate associations between the severity of IBS symptoms and intake of certain nutrients and food groups. The negative associations could potentially indicate dietary adjustments made by the patients to cope with symptoms. A relatively low intake of FODMAPs compared with other populations could also implicate that patients have restricted intake of FODMAPs to reduce symptom severity.

[5]*Dept. Of Gastroenterology, University of Michigan, Ann Arbor/United States of America/MI*

**Contact E-mail Address:** Jessica.Abel@allergan.com.
**Introduction:** Most guidelines universally recommend the use of lifestyle interventions, such as increased dietary fiber, for the treatment of irritable bowel syndrome (IBS). This analysis examines the use of lifestyle interventions (e.g., diet, exercise) to treat bowel and/or abdominal symptoms among IBS-C/CIC patients participating in the Chronic **Con**stipation and IBS-C **T**reatment and **O**utcomes **R**eal-world Research Platform (CONTOR).
**Aims & Methods:** Fully insured patients $\geq$18 years old were identified from a large, geographically diverse US health plan based on claims from December 2012 through June 2015. Identification criteria included: $\geq$1 medical claim with a diagnosis of constipation (ICD-9-CM 564.0 x), IBS (ICD-9-CM 564.1 x), or abdominal pain (ICD-9-CM 789.0 x) plus $\geq$1 pharmacy claim for a stool softener/laxative; or $\geq$1 pharmacy claim for linaclotide or lubiprostone. Study participants completed a self-administered survey that included an assessment of prescription and over-the-counter medication use and lifestyle interventions ever used to treat their bowel and/or abdominal symptoms. Respondents were stratified by patient-reported current (last 7 days) medication use, including linaclotide, other prescription medications, and over-the-counter therapies.
**Results:** Of 18, 590 patients invited to participate, 2, 052 eligible patients responded and are included in this analysis. Respondents were predominately female (94%); mean age (SD) was 47 (12) years. Nearly all respondents reported experiencing bowel/abdominal symptoms for $\geq$2 years (92%), with nearly half (44%) experiencing symptoms for over 10 years. Almost all respondents (93%) reported using diet and/or other lifestyle interventions to treat their bowel/abdominal symptoms, with nearly 85% of respondents within each subgroup reporting use of dietary changes. A majority (93%) of respondents who reported using diet and/or exercise to treat their symptoms reported current medication use (within the last 7 days). Among current linaclotide users, more than two-thirds reported using both diet and exercise to treat their symptoms (Table). About half (53%) of all respondents reported using at least 2 lifestyle interventions to treat their bowel/abdominal symptoms (diet and exercise were the most common combination); 14% reported using 3 or more lifestyle interventions (diet, exercise, other). Less than 10% of respondents reported using no lifestyle interventions.
**Conclusion:** The majority of IBS-C/CIC patients have utilized both medication and lifestyle interventions to treat their bowel/abdominal symptoms, suggesting diet/exercise alone may not be sufficient to manage the symptoms of IBS-C and CIC.
**Disclosure of Interest:** J.L. Abel: Employee, stock holder and stock options from Allergan, plc.

**Abstract No: P0402**

**Table:** Patients using Lifestyle Interventions to Treat Bowel/Abdominal Symptoms by Current Medication Use[1]

| Lifestyle Changes, n (%) | Total (N = 2,052) | Linaclotide (N = 381) | Prescription Medications other than Linaclotide (N = 471) | Over-the-counter Medications Only (N = 715) | No Current Medication (N = 485) |
|---|---|---|---|---|---|
| Diet and Exercise | 1,290 (64) | 264 (69) | 270 (58) | 468 (66) | 288 (60) |

**Introduction:** Benefits of increased fiber intake for improvement of bowel function is well accepted, however most often average fiber intake is less than half of recommended amount.

**Aims & Methods:** The aim of the study was to supplement the dietary fiber intake up to recommended amount using interventions with less rough changes of food related behavior and investigate its effects on the bowel function, general well-being and compliance of patients with constipation-predominant irritable bowel syndrome (IRS-C). In total 100 healthy women, without any clinical signs of gastrointestinal disorders and 98 women who met Rome III criteria for IBS-C were enrolled in the dietary fiber intake assessment survey. There was no significant difference in average age among the groups ($33.7 \pm 16.7$ years and $39.2 \pm 12.3$ years, $p > 0.1$ respectively). After completion of the survey the women with IBS-C were assigned to daily intake of wheat bran-enriched bread (9.5 g dietary fiber per 100 g) and muesli (22.42 g dietary fiber per 100 g). Before, on the seventh day and on the end of two weeks of observation patients completed adopted questionnaire for assessment of bowel function and general well-being. The amount of added dietary fiber was $21.32 \pm 4.9$ g/daily. It made up average 40 g/daily intake of dietary fiber in women with IBS-C - excessive amount recommended for patients with constipation.

**Results:** The dietary fiber intake was significantly lower in the group of women with IBS-C ($18.7 \pm 4.9$ g) compared with healthy population ($27.8 \pm 5.55$ g, $p = 0.0022$), however the difference in consumption of carbohydrates between the groups was not considerable ($254.2 \pm 88.6$ g and $216.3 \pm 60.7$ g, $p = 0.17$ respectively). After 14 days the bowel movement increased significantly from $0.27 \pm 0.07$ up to $1.54 \pm 0.55$ times daily ($p < 0.0001$). 82 patients from initially enrolled 98 continuously received dietary fiber rich food during 14 days of observation, consequently the compliance rate was 83.7%. Before supplement of dietary fiber stool type was hard to pass in 70 from 82 cases (85.4%). After two weeks of eating of dietary fiber added food the stool was of normal consistency (Bristol scale level 3 and 4) in 76 cases (91.7%, $p < 0.0001$ respectively). Statistically significant improvement was observed in abdominal pain, the score decreased from baseline $0.75 \pm 0.11$ to $0.07 \pm 0.05$ points ($p = 0.0026$). The score relevant for difficulty of defecation decreased from $1.57 \pm 0.18$ up to $0.11 \pm 0.08$ points ($p < 0.0001$), the sensation of incomplete evacuation was decreased from baseline $1.96 \pm 0.13$ to $0.14 \pm 0.11$ points ($p < 0.0001$). Analyses showed significant decrease of alertness related to digestive feelings after continuous consumption of dietary fiber (from $1.04 \pm 0.31$ up to $0.18 \pm 0.07$ points, $p < 0.0001$).

**Conclusion:** Supplementation of dietary fiber with broadly used food products allows avoiding the changes of food-related habits and have a high compliance, also such intervention improves the bowel function and decreases alertness related to digestive feelings.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Ischemic colitis (IC) is the most common gastrointestinal vascular disease and could be potentially lethal. Clinic (shock), biology, CT scan and/or lower GI endoscopy are usually used to appreciate the severity. However, there is no consensus regarding this evaluation and it is challenging to choose between surgical or conservative treatment. To date, no studies have evaluated the prognosis of IC according to the endoscopic stages. Consequently, we propose this study to determine outcomes of patients depending on endoscopic findings, and the impact of endoscopy on the therapeutic decision.

**Aims & Methods:** This is a retrospective study conducted in a tertiary center, in North Hospital, Marseille, France. All the files of patients who had lower GI endoscopy for suspected ischemic colitis were reviewed in our database. Patients with confirmed severe ischemic colitis were kept for analysis. The following data were collected: age, Charlson comorbidity score, vascular disease, etiology including aortic surgery, clinical symptoms, organ failures, signs of severity in CT scan (effusion, enhancing defect or perforation), endoscopic stage of Favier, surgery and findings, death. The risk factors for colectomy and death were analyzed, and the correlation between endoscopic grade and outcomes was calculated. A p-value $< 0.05$ determined as statistically significant.

**Results:** Between 2006 and 2015, 118 patients were identified and 71 patients were finally included. They were 48 men (68%), and the mean age was $71 \pm 13$ years old. The mean Charlson score was $5.1 \pm 2.2$. The most common trigger factor for IC was surgery ($n = 34$; 48%), and especially aortic surgery ($n = 26$). Hemodynamic failure was present in 29 (41%) patients at the time of endoscopy. A CT scan was performed in 48 (68%) patients and identified a sign of severity in 18 (38%) patients. Twenty-nine (41%) patients underwent surgery, and twenty-four (34%) patients died, all being hemodynamically instable, except one. The endoscopic grades (100% of patients) were: 15 grade 1 (21%), 32 grade 2 (45%) and 24 grade 3 (34%). Regarding the patients with grade 3: 12 (55%) had hemodynamic instability, 14 had severity signs at CT scan, 15 (68%) underwent surgery and 12 (55%) died. Among the patients with grade 2: 10 (32%) had hemodynamic instability, 9 (29%) had signs of severity in CT scan, 10 (32%) underwent surgery and 9 (29%) died. Among the patients with grade 1: 7 (46%) were in shock, 4 (27%) underwent surgery, 2 had a sign of severity in CT scan and 3 (20%) died. A mismatch between mucosa (aspect of necrosis) and serous (normal aspect) was noted in 13 patients (46%), 6 had a colonic resection (4 deaths among these patients). The surgical decision was made on hemodynamic status in 62% of cases ($n = 18$), endoscopic grade in 10% ($n = 3$), the CT scan severity in 14% ($n = 4$) and other in 14% ($n = 4$). Risk factors for colectomy identified in univariate analysis were: aortic aneurysm surgery, hemodynamic failure, no colic enhancement in CT scan and endoscopic grade 3. Risk factors for mortality in univariate analysis were: hemodynamic failure, endoscopic grade 3, aortic aneurysm surgery, no colic enhancement in CT scan and Charlson score $> 5$. The Pearson correlation test showed a correlation of hemodynamic status with death and colectomy ($p < 0.01$). The endoscopic grade 3 was also correlated with colectomy and death ($p < 0.05$) but not with hemodynamic status.

**Conclusion:** This study suggested that endoscopy impacted on the decision to operate in situation of IC in only 10% of cases. However, colectomy and mortality were more frequent in patients with grade 3 endoscopic. Hemodynamic instability was the most frequent indication of colectomy in patients with ischemic colitis. A mismatch between mucosa and serous was present in 50% of patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0405 COLON ISCHEMIA SEVERITY SCALE: EVALUATION AND DETERMINATION OF ADDITIONAL SEVERITY MARKERS

**J. P. Rodrigues**[1], A. Coelho[2], C. Fernandes[1], T. Freitas[1], J. Silva[1], A. Ponte[1], M. Sousa[1], J. Carvalho[1]

**Introduction:** Recent American College Of Gastroenterology guidelines (2015)[1] proposed to redefine Colon Ischemia (CI) severity stratification into mild, moderate and severe disease in order to guide treatment. This classification assumes special importance in severe disease according to its high morbidity and mortality.
**Aims & Methods:** We aimed to evaluate the clinical evolution of patients hospitalized with CI diagnosis, taking into account the disease severity, and determine risk factors for severe disease classification. This is a retrospective study of all patients with definite diagnosis of CI according to Brandt criteria, from January 2010 to December 2015. We stratified patients according to the proposed classification and evaluated their evolution and prognosis. Additional clinical, histological, endoscopic and imagiologic features and its relation with the classification were considered.
**Results:** We selected 207 patients (72.9% female; mean age $72.3 \pm 13.0$ years), 21.7% (n = 45) with mild CI, 60.9% (n = 126) moderate and 17.4% (n = 36) severe. Patients with growing severity grade, mild, moderate and severe, had longer hospitalizations (4.8 vs. 6.6 vs. 11.1 days; $p < 0.001$), more surgery requirement (0% vs. 0% vs. 5.6%; $p = 0.008$) and recurrence rate (4.4 vs. 11.0 vs. 19.4%; $p = 0.036$), respectively. Mortality rate was similar between groups ($p = 0.270$). On univariate analysis, age, disease extension, disease in the rectum, non-description of erosions by the endoscopist, identification of bleeding, purulent material or necrotic cells on histologic analysis and the presence of occlusive vascular disease on computed tomography were associated with severe disease classification; $p < 0.05$. On multivariate analysis, independent features associated with severe disease classification were disease extension ($p = 0.005$; OR 1.14) and necrotic cells identification (0.047; OR 8.91); $R^2 = 0.68$.
**Conclusion:** The proposed classification properly stratifies CI patients regarding their clinical evolution and prognosis. Disease extension and necrotic cells identification in the histology are independent risk factors for severe disease classification.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The natural history and pathogenesis of diverticular bleeding in Western population remains unclear. In Eastern population, the prevalence of right-side diverticulosis is higher than in Western one, and some Authors identified bilateral diverticulosis as a risk factor for bleeding in Eastern population.
**Aims & Methods:** The aim of this study was to evaluate whether right-side location of diverticular disease is a risk factor for bleeding also in Western world. We performed an interim analysis of a prospectively collected database; we analysed all patients admitted to Our Institution for acute diverticulitis and diverticular bleeding from January 2013 to December 2014. For each patient, age, gender, clinical presentation, concomitant medication, presence of divertula and their localization in the colon were recorded. All patient underwent computed tomography or colonoscopy during hospitalization, on the basis of clinical presentation. Patients who did not undergo endoscopic evaluation during the hospitalization, underwent complete colonoscopy or computed tomography colonoscopy within 3 months. Medacalc software was performed for statistical analysis.
**Results:** 144 patients (70 male, 48.3%; $77.4 \pm 14.0$ years-old) were prospecively enrolled. 85 patients (59.0%) were hospitalized for uncomplicated/complicated acute diverticulitis; 59 (41%) for diverticular bleeding. Among the entire study population, 112 (78.3%) patients had left-side diverticular disease, 7 (4.9%) left-side extended to trasverse colon diverticular disease and the remainig 24 (16.8%) had bilateral diverticular disease. Among patient who presented with diverticular bleeding (no. 59), 36 (61.0%) had left-side diverticular disease, 3 (5.1%) left-side extended to trasverse colon diverticular disease and remainig 20 (33.9%) had bilateral diverticular disease. On multivariate analysis, age 1.08 [1.04 – 1.12], male gender 4.80 [2.05 – 11.25] and bilateral divertcular diease 8.29 [2.38 – 28.79] were identified as risk factors independently related to dverticular bleeding. The relative risk for bleeding among patients with bilaterl diverticular disease was 2.56 [1.87 – 3.51].
**Conclusion:** Our preliminary findings suggest that bilateal diverticulosis was an independent risk factor for bleeding also in a western population.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Uncomplicated Diverticular Disease (UDD) seems to be related to impaired intestinal motility, although it is still unknown whether the abnormal colonic motor activity is the primary event or the consequence of the presence of diverticula. In a recent study it has been shown that UDD induces significant modifications of Toll-like receptor 4 (TLR4) expression on several immune cell subpopulations isolated from both peripheral blood and affected mucosa. It is well known that during sepsis the activation of TLR4 impairs intestinal motility trough activation of intestinal muscolaris macrophages.
**Aims & Methods:** Therefore the aim of this study was to evaluate the contractility patterns in vitro of colonic smooth muscles strips (MS) and cells (SMC) obtained from human circular colonic muscle layers of UDD patients and to assess expression of Toll like receptors 4. Human colonic circular smooth MS or cells were isolated from specimens of human distal colon of 17 patients undergoing surgery for non-obstructive colonic cancer, among them 9 were found to have UDD. MS and SMC were exposed, after stabilitation, for 60 min to Krebs solution (control) and afterwards stimulated with a maximally effective dose of acetylcholine ($10^{-5}$M). Spontaneous phasic contractions on strips and morpho-functional parameters on cells were evaluated in basal conditions and in response to acetylcholine (Ach). Immunohistochemical staining for TLR4 was performed with goat polyclonal anti-TLR4 (Santa Cruz Biotechnology, Santa Cruz, CA, USA).
**Results:** Colonic MS of UDD group presented a significant reduced basal tone and Ach-elicited contraction over basal, compared to the results obtained in the control group (7.16 g and 47% in the DD group and 8.82 g and 69% in the CG, $p < 0.05$). Similarly to MS, SMCs of UDD group showed a mean resting cell length statistically higher than that obtained in CG ($158.7 \pm 12.1\,\mu m$ vs $184.8 \pm 12.9\,\mu m$, $p < 0.05$) with a maximal contractile response to acetylcholine significantly reduced when compared to controls, being 8, $831\% \pm 1.8$ vs $16.49\% \pm 1.2$, $p < 0.05$. At the epithelial level, in UDD patients, TLR4 was shown to be expressed mainly by scattered cells resembling enteroendocrine cells in colonic glands and only rarely by intestinal epithelial cells on the basolateral or apical surface. In the lamina propria and among smooth muscle cells, inflammatory cells were identified as main TLR4 expressing cells.
**Conclusion:** An impaired basal tone and contractility of circular colonic MS and SMCs was observed only in UDD patients group, compared to controls. The immunohistochemical analysis confirmed the expression of TLR4 both at the epithelial and at the lamina propria level, mainly on inflammatory and enterendocrine cells. It might be reasonable to hypothesize that in UDD the activation of TLR-4 plays a crucial role in inducing intestinal dismotility through production of cytokines by intestinal inflammatory cells and mediators by enteroendocrine cells.

**Introduction:** Pathogenesis of Symptomatic Uncomplicated Diverticular Disease (SUDD) is not completely understood. Imbalance of colonic microbiota is considered a milestone in occurrence of symptoms, but whether intestinal microbiota is really altered in those patients is unknown. Metabolic profiling is a powerful exploratory tool for understanding interactions between nutrients, the intestinal metabolism and the microbiota composition in health and disease, and metabolomics technologies have been applied for the screening of different pathological conditions that are linked with a metabolic imbalance.
**Aims & Methods:** We performed a prospective study assessing fecal microbiota and metabolome in symptomatic uncomplicated diverticular disease (SUDD). Stool samples from 52 consecutive female patients (17 with SUDD, 16 with asymptomatic diverticulosis (AD), and 19 healthy), born and living in the same geographic area, were analysed. Real-time PCR was used to quantify targeted microorganisms. High-resolution proton nuclear magnetic resonance spectroscopy in combination with Multivariate Analysis with partial least square discriminant analysis (PLS-DA) were applied on the metabolite data set.
**Results:** There were no differences in the demographic characteristics among the three groups. The overall bacterial quantity did not differ among the three groups. Thus, a colonic bacterial overgrowth was absent in SUDD ($p = 0.449$). In AD group a reduction in the percentage of Bifidobacteria and Enterobacteria and an increase of Clostridia and Lactobacilli compared to total bacteria was observed. These differences were however not significant. In both AD and SUDD groups a significant increase of Akkermansia muciniphila was also observed in comparison to healthy group ($p = 0.05$ and $p = 0.02$ respectively). PLS-DA analysis of NMR-based metabolomics of fecal waters showed a good discrimination between AD and SUDD patients ($R2 = 0.69$; $Q2 = 0.35$; $p < 0.05$). Moreover, significant differences in N-Acetyl-compounds were found between AD and SUDD patients. PLS analysis showed that SUDD patients, with higher N-Acetyl-compound levels as compared to AD patients, showed higher levels in Bifidobacteria and Enterobacteria, and lower levels in Clostridia and Lactobacillus spp.
**Conclusion:** SUDD does not show colonic bacterial overgrowth, but significant qualitative alteration of the fecal microbiota. Moreover, increasing expression of some metabolites as expression of different SUDD metabolic activity was found.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## OESOPHAGEAL, GASTRIC AND DUODENAL DISORDERS I – POSTER EXHIBITION

## P0409 H19 NON CODING RNA-DERIVED MIR-675, ACTIVATED BY HELICOBACTER PYLORI, PROMOTES GASTRIC CANCER FORMATION AND RESISTANCE TO CISPLATIN BY DOWNREGULATING FADD

**J. Yan**
*Gastroenterology, The First Affiliated Hospital Of Nangjing Medical University, Nanjing/China*

**Contact E-mail Address:** jsyj0220@163.com.
**Introduction:** H19 is increasingly described to play key roles in the development of cancers from different tissue origins. In this study, we aimed to find the association of H19 and *Helicobacter pylori*. In addition, the mechanism of H19 promoting gastric cancer formation and resistance was evaluated.
**Aims & Methods:** H19 expression in GC cells and tissues was quantified by quantitative reverse transcription-PCR (qRT-PCR). The GC cell lines were transfected with pc-H19, si-H19, or their respective controls and we investigated the phenotype of GC cells and possible molecular mechanisms.
**Results:** In this study, we established H19/miR-675 ectopic expression models of gastric cancer to further investigate the underlying mechanisms of H19 oncogenic action. We showed that overexpression of H19/miR-675 enhanced the aggressive phenotype of gastric cancer cells including increased cell proliferation, increased cell migration, decreased apoptosis and cisplatin resistance. In addition, H19 is overexpressed in cells cultured with *Helicobacter pylori*. Moreover, we identified FADD as direct targets of miR-675 in gastric cancer. Using a luciferase assay, we demonstrated that H19, through its microRNA, decreased FADD expression in gastric cancer cell. Thus, by directly binding FADD mRNA, miR-675 promotes gastric cancer, inhibiting activation of caspase-8 and caspase-3.
**Conclusion:** Our findings revealed that H19 is activated by *Helicobacter pylori* and can promote tumor formation and cisplatin resistance in GC and it will be a valuable predictor for treatment and target for reversal of cisplatin resistance in human GC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0410 HYDROTALCITE PROTECTS GASTRIC EPITHELIUM FROM DICLOFENAC-INDUCED INJURY BY UPREGULATING EGF-R, IGF-1 AND SURVIVIN: NEW MECHANISMS OF HYDROTALCITE'S PROTECTIVE ACTION AND THERAPEUTIC IMPLICATIONS

**Introduction:** Diclofenac (DFN) is one of the most widely used NSAIDs worldwide. Clinical and experimental studies demonstrated that even a short term use of DFN induces gastric, duodenal and intestinal mucosal injury. Because of a wide spread use of DFN and side effects of long term PPI prophylaxis, it is very important to develop a new alternative strategy to counteract DFN's mucosal damaging actions. Hydrotalcite (HTL) - new generation antacid has been shown to protect gastric mucosa against ethanol injury, to accelerate gastric ulcer healing and is approved for clinical use in Europe, Canada and Asia. Our hypothesis was that HTL directly interacts with gastric epithelial cells, which are critical component of mucosal defense and upregulates expression of epidermal growth factor receptor (EGF-R), survivin and insulin like growth factor 1 (IGF-1), which in turn protect these cells from injury and death.
**Aims & Methods:** Our **aims** were to determine whether HTL can protect gastric epithelial cells from DFN-induced injury and to identify the underlying molecular mechanisms with focus on epidermal growth factor receptor (EGF-R), survivin (anti-apoptosis protein), and insulin like growth factor (IGF-1) – which all can potentially enhance cell survival. **Methods:** Cultures of normal rat gastric mucosal (RGM1) cells, which have many features of epithelial progenitor cells, were pretreated with placebo or HTL suspended in medium (1–5 mg/ml) for 1 - 4 hrs and then exposed to either: medium alone (controls), or sodium diclofenac (DFN; 0.5–1.0 mM) for 1–4 hrs. **Studies:** 1) cell injury under confocal microscope; 2) cell death/survival using novel Calcein AM live cell tracking dye; 3) expression of: EGF-R, survivin and IGF-1 by immunostaining and quantification of signal intensity using Metamorph 7 imaging system.
**Results:** DFN treatment of RGM1 cells caused very extensive cell injury and reduced cell viability from $95 \pm 3\%$ in controls to $12.7 \pm 4\%$; $p < 0.001$. Pretreatment of RGM1 cells with HTL significantly increased in these cells expression of EGF-R by 84%, survivin by 47% and IGF-1 by 72% (all $p < 0.001$) and significantly reduced/prevented DFN-induced RGM1 cells death; cell viability in this group was $71 \pm 6\%$, i.e. 5.7-fold higher ($p < 0.001$) than in medium + DFN treated group.
**Conclusion:** 1) Diclofenac induces extensive injury and death of gastric epithelial cells, which are critical component of gastric mucosal defense. 2) Treatment with hydrotalcite significantly upregulates in gastric epithelial RGM1 cells expression of EGF-R, survivin, and IGF-1 and protects these cells against diclofenac-induced injury. 3) These findings provide novel molecular mechanisms for DFN-induced gastric epithelial injury and HTL's protective action on gastric mucosal cells and a rationale for therapeutic use of HTL to prevent DFN-induced injury as alternative to proton-pump inhibitors.

**Introduction:** Spindle cell carcinoma (SpCC) of the esophagus is a rare malignant neoplasm composed of both carcinoma and sarcomatous elements. The pathogenesis of the sarcomatous component of the tumor has not been elucidated. On the other hand, epithelial mesenchymal transition (EMT) is a phenomenon by which epithelial cells lose their property and turn into mesenchymal cells. It is said that EMT has various biological roles in tumor budding, including invasive front formation and sarcomatous change of epithelial cells. Recent studies have shown that alpha actinin-4, which is an isoform of non-muscular a-actinin and actin-bundling protein, plays an important role in cancer invasion and metastasis by enhancing cellular motility through EMT. However, most studies about alpha actinin-4 have focused on the invasiveness of tumor cells; it is unclear whether alpha actinin-4 is involved in the pathogenesis of the sarcomatous component in SpCC of the esophagus.
**Aims & Methods:** To investigate the involvement of alpha actinin-4 in sarcomatous differentiation, we performed immunohistochemistry for alpha actinin-4 in 14 cases of SpCC of the esophagus. We also evaluated E-cadherin, whose loss of expression is considered a hallmark of EMT. The stainings of alpha actinin-4 and E-cadherin in carcinoma and sarcomatous components were scored as follows: -, 0% of positive cells; +, 1–10%; ++, 11–50%; +++, 51–80%; and ++++, >80%. In order to verify the neoplastic nature of the sarcomatous component, we examined the monoclonality between carcinoma and sarcomatous elements, comparing TP53 mutation status and protein expression of both areas by DNA sequencing and p53 immunohistochemistry, respectively.
**Results:** Cytoplasmic alpha actinin-4 expression was more extensive in the invasive front of the carcinoma component than that in the sarcomatous component ($P = 0.0101$). Membranous E-cadherin expression was mostly lost in the invasive front of carcinoma areas and sarcomatous cells in all cases ($P < 0.0001$). The p53

expression pattern was almost concordant between the two components in all cases. TP53 mutation analysis uncovered that 7 cases possessed identical mutations in both areas. One case had mutations only in the sarcomatous component.
**Conclusion:** We found that alpha actinin-4 was significantly widely expressed in the invasive front of the carcinoma component compared to that in the sarcomatous component. We also found identical TP53 mutation patterns and nuclear p53 immunohistochemical staining in both carcinoma and sarcomatous areas. These findings suggest that the two components in SpCC of the esophagus have a monoclonal origin and alpha actinin-4 is involved in acquisition of invasiveness rather than in the formation of the sarcomatous component in SpCC of the esophagus.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0412 THE ACTIVITY OF H+/ K+ -ATPASE IN BIOPSY MATERIAL OF PATIENTS WITH GASTRIC ULCER

**O. Kharchenko**[1], G. Shayakhmetova[2], O. Kostuk[1], O. Savchuk[1]
[1]*Taras Shevchenko National University Of Kyiv, The Institute Of Biology, Kyiv/Ukraine*
[2]*SI "Institute of Pharmacology and Toxicology of NAMS of Ukraine, Kyiv/Ukraine*

**Contact E-mail Address:** 77olgaz@gmail.com.
**Introduction:** It is known that origin of a peptic ulcer in the stomach and in the duodenum is associated with disorders of interaction between factors of gastric juice aggression and mucosal protective properties. Acid-peptic factor is the most important in mechanisms of the gastric ulcer development. Its aggressiveness primarily associated with hydrochloric acid ulcerogenicity. The synthesis of this compound depends on the functioning of H+/K+-ATPase (the enzyme of the stomach mucous membrane parietal cells).
**Aims & Methods:** The aim of the study was the evaluation of H+/K+-ATPase activity in gastric mucosa biopsy material of patients in exacerbation and remission phase of *H. pylori*-dependent and *H. pylori*-independent duodenal ulcer (DU). 44 patients of the Institute of Gerontology of NAMS of Ukraine clinic (gastroenterological department) took part in the study (20 men, 24 women, 18–69 years old). Diagnosis and disease stage were endoscopically and morphologically verified. The presence of *H. pylori* infection in patients was confirmed by urease and histological tests and accounted 70%: 30%. The control group consisted of 10 volunteers (4 men and 6 women of the same age) with absence of duodenal ulcer in past history. Biopsy material from the fundus of the stomach was received (parietal cells with H+/K+-ATPase are localized here). Taking into account that H+/K+-ATPase activity does not depend on gender and age of patients we divided patients into 3 groups: 1st - healthy volunteers, 2nd - patients in exacerbation phase of DU and 3rd - patients in remission phase of DU. All patients received combined therapy with proton pump inhibitors and anti-Helicobacter pylori agents.
**Results:** It has been shown that in gastric mucosa biopsy material of patients in exacerbation phase of DU the activity of H+/K+-ATPase was 2.5 folds higher than in healthy volunteers. In remission phase the enzyme activity decreased by 1.3 folds as compared with patients in exacerbation phase of DU, but in the same times it was 2 folds higher than in healthy volunteers. Thereby, in spite of reparative processes in the gastric mucosa (according to the results of endoscopic and histological examination complete epithelization of the ulcer was observed) functioning of membrane-bound enzyme of gastric glands parietal cells remained to be impaired. It should be noted that in exacerbation phase activity of H+/K+-ATPase in patients with *H. pylori*-dependent form did not differ from the activity of the enzyme in patients with *H. pylori*-independent form.
**Conclusion:** Our results confirm the lack of association between the activity of H+/K+-ATPase and *H. pylori* and suggest that regenerative processes in the gastric mucosa in remission phase of DU occur in the absence of normalization of the functioning of parietal cells' H+/K+-ATPase. This factor increases the risk of new relapses. Thereby, search of approach aimed to correct H+/K+-ATPase activity have not lost topicality.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0413 IMAGING THE GLYCOME IN RAT STOMACH MUCOSA UNDER CONDITIONS OF ULCERATION AND PRETREATMENT WITH TRIPEPTIDE T-34

**Contact E-mail Address:** nasadyukch@gmail.com.
**Introduction:** Due to their structural diversity and sensitivity to intra- and extracellular conditions, glycans are an indispensable tool for analyzing cellular transformations [1]. Glycome of rat stomach mucosa (SM) in health and ulceration leaves much to be elucidated.
**Aims & Methods:** Aim of our study was to assess changes of galactose-specific carbohydrate determinants of SM in indomethacin-induced (II) gastric lesions (GL) in rats, pretreated with tripeptide T-34 (H-Glu-Asp-Gly-OH).
Studies were conducted on white male rats due to international ethical regulars. Rats were devided into 3 groups: 1) control (n = 6); 2) intragastrically (ig) administered indomethacin (ind), (35 mg/kg, n = 6); 3) ig pretreated with T-34 (10 μg) 30 min before ind introduction (n = 6). 24 h later rats were sacrificed, SM was removed, fixed in 4% neutral formalin, and embeded in paraffin wax. SM glycome was studied by lectin-peroxidase technique. Intensity of lectin-receptor reaction was scored as follows: 0 – no reaction; 1 – weak; 2 – mild and 3 – strong reaction. Lectin panel is presented in Table 1.
**Results:** Ind caused erosive GL ($9.7 \pm 0.4$ mm$^2$), score of damage made $8.0 \pm 0.57$. T-34 effect resulted in tendency to decrease of GL area and diminished injury index ($p < 0.05$). We detected relatively faint reactivity of gastric mucosal epithelial barrier (GMEB) to HPA and PNA, whereas strong labeling by SBA-lectin. Concerning glandular cells of SM, HPA reactivity in chief cells was restricted only to T-34 –pretreated group. HPA-staining of parietal cells was evaluated as $1.83 \pm 0.34$ in control animals, $2.83 \pm 0.18$ – in II GL ($p < 0.05$) and $1.67 \pm 0.23$ in T-34-group ($p < 0.05$). Simultaneously increased number of HPA-positive cells was noted in II GL. HPA- and PNA-staining also revealed increased number of mucocytes in T-34-pretreated rats and enhanced binding affinity closer to foveola surface. Evaluation of cytotopography of receptors to PNA and SBA in glandular cells of SM showed increased reactivity to parietal cells in GL, which decreased in T-34-pretreated rats. Development of GL resulted in decreased SBA-labeling of mucocytes ($1.17 \pm 0.18$) compared to control ($1.83 \pm 0.18$, $p < 0.05$), that was not enhanced by T-34. All used lectins did not label endocrinocytes of stomach glands.

**Table 1:** Lectins and their respective carbohydrate specificities.

| № | Lectin designation, abbreviation | Specific monosaccharide | Complementary oligosaccharide/ polysaccharide |
|---|---|---|---|
| 1 | Peanut, PNA | DGal | DGal (β1-3) GalNAc |
| 2 | Soybean, SBA | αDGalNAc > βDGalNAc | GalNAc (α1-3) Gal (β1-3) GalNAc |
| 3 | Helix promatia, HPA | αDGalNAc | GalNAc (α1-3) GalNAc |

**Conclusion:** Cyclooxygenase-1/2 blockage by ind affects glycoconjugates processing in rat SM, decreasing αDGalNAc > βDGalNAc, DGal in mucocytes and increasing αNAcDGal, βDGal in parietal cells. SBA-lectin demonstrated the strongest affinity among galactose-specific lectins to GMEB. Cytoprotective effect of T-34 was accompanied by redistribution of II alterations of glucoconjugates, approaching glycome in control rats. Lectins may be used as a valuable molecular tool to explore functional peculiarities of SM cells in gastrointestinal disorders.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0414 EFFECT OF TRIPEPTIDE T-34 ON SYALO- AND FUCOSE-SPECIFIC CARBOHYDRATE DETERMINANTS OF STOMACH MUCOSA IN INDOMETHACIN-INDUCED GASTRIC LESIONS IN RATS

**C. Nasadyuk**, A. Yashchenko, E. Sogomonyan, O. Sklyarov
*Biochemistry, Lviv National Medical University Dept. of Biochemistry, Lviv/Ukraine*

**Contact E-mail Address:** nasadyukch@gmail.com.
**Introduction:** Recent research provides increasing evidence on gastroprotective effects of certain short peptides although their mechanism of action is under-investigated. Our previous studies revealed gastroprotective effects of hexapeptide thymohexin (Arg-α-Asp-Lys-Val-Tyr-Arg) and tripeptide T-34 (H-Glu-Asp-Gly-OH) in experimental gastric lesions (GL) associated with a decrease of nitrosooxidative stress in gastric mucosa (GM) [1, 2].
**Aims & Methods: Aim of research** was to assess the effect of T-34 on GM glycome. Studies were conducted on white male rats due to international ethical regulars. Rats were devided into 3 groups (n = 6 in each group): 1) control; 2) intragastrically (ig) administered indomethacin (ind), 35 mg/kg; 3) ig pretreated with T-34 (10 μg) 30 min before ind introduction. 24 h later rats were sacrificed. GM glycome was studied by lectin-peroxidase technique. Lectins panel included fucose- (Laburnum anagyroides bark agglutinin (LABA) and syalo-specific (Sambucus nigra agglutinin (SNA) and Wheat germ agglutinin (WGA). Intensity of lectin-receptor reaction was scored: 0 – no; 1 – weak; 2 – mild and 3 – strong reaction.
**Results:** We revealed strong reactivity of control animals GM both to syalo- and fucose-specific lectins although WGA/SNA-labeling was higher compared to LABA ($p < 0.05$). In intact rats expression of fucose-specific receptors was high in epitheliocytes, chief cells and mucocytes, whereas LABA-staining of parietal cells was low. In GL tendency to increased reactivity of epitheliocytes and decreased staining of chief cells and mucocytes was noted. T-34 pretreatment resulted in decrease of GL area, what was accompanied by decreased reactivity of epitheliocytes to LABA ($p < 0.05$) and interestingly reduction of fucose-specific receptors of mucocytes was even more significant ($p < 0.05$) compared to ind effect. T-34 also caused tendency to increased LABA-staining of chief and parietal cells ($p > 0.05$). No changes of epitheliocytes reactivity to WGA and SNA

were revealed between experimental groups. GM ulceration decreased affinity of chief cells and mucocytes to WGA compared to control, what was reversed by pretreatment of T-34. SNA-staining of epitheliocytes, chief cells and mucocytes in GL significantly decreased ($p < 0.05$). T-34 enhanced the reduction of syalospecific receptors of chief cells noted in ind-treated group.
**Conclusion:** Cyclooxygenase-1/-2 blockage by ind results in molecular transformation of GM glycans. The most significant changes were revealed in SNA-staining of epitheliocytes, chief cells and mucocytes of GM between experimental groups. Cytoprotective effect of T-34 reversed some ind-induced alterations of GM glycome but caused reduction of SNA-labeling of chief cells and LABA-labeling of mucocytes compared to control what may be speculated as masking of relevant receptors by other glycans. Molecular interaction between short peptides and GM glycans need deeper elucidation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The aim of this study was to determine the role of vascular endothelial growth factor (VEGF), Ki-67, Bcl-2, and endocrine cells (EC) of the gastric mucosa (GM), producing somatostatin (SS), glucagon (GL), pancreatic polypeptide (PP) in diseases associated with *Helicobacter pylori* (*H. pylori*), and to supplement on their basis the early diagnostic criteria of GM structural changes progression in patients with gastric ulcer (GU), chronic atrophic gastritis (CAG), gastric adenomatous polyps (GAP) and gastric cancer (GC) before and after surgery, and *H. pylori* eradication therapy.
**Aims & Methods:** 104 patients with *H. pylori*-associated gastric diseases were enrolled in this study: 30 patients – with GU, 30 – with CAG, 20 – with GAP combined with CAG and 24 – with non-cardiac GC II (T1N2, T2N1, all M0) and III (T2N2, T3N1, T4N0 all M0) stages. The comparison group consisted of 12 healthy subjects. The material for morphological studies was taken from the antrum and fundus of the stomach. Immunohistochemical studies were performed using mouse monoclonal antibodies to VEGF, SS, GL, PP, Ki-67, Bcl-2. The number of Ki-67, Bcl-2, VEGF, SS, GL and PP - immunopositive cell nuclei automatically counted in 10 randomized fields of view.
**Results:** For acute GU reduction of EC number that produce VEGF, GL, PP and increasing of EC number producing SS (upon activation of proliferative processes, determined by immunopositive for Ki-67 and Bcl-2 EC number) were typical. After 2 months in GU remission normalization of all studied parameters of stomach diffuse neuroendocrine system and cell proliferation indicators was observed. CAG, GAP and intestinal type GC are associated with persistent *H. pylori* infection and accompanied by hyperplasia of EC secreting VEGF, GL, PP and hypoplasia of EC secreting SS, against the background of high proliferative activity of EC, expressed in terms of Ki-67 and Bcl-2.
**Conclusion:** VEGF, GL, SS and PP realizing their pathological properties directly or indirectly by *H. pylori*, Bcl-2, Ki-67 play an important role in predicting the occurrence and course of *H. pylori*-associated diseases. Eradication of *H. pylori* in the presence of intestinal metaplasia does not lead to its disappearance, therefore, all patients in need of dynamic observation, as well as persons who have this microbial expansion.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0416 COLLAGEN PEPTIDES PREVENT THE STRESS-INDUCED ULCERATION BY REGULATING STRESS-ASSOCIATED ACTIVATION OF NEUROENDOCRINE AND IMMUNE SYSTEMS

**Introduction:** Interaction of the neuroendocrine and immune systems determines the ability of biosystems to resist the psychoemotional and physical strain. Hormones (adrenaline and cortisol in human, corticosterone in rats) enter the blood at stress. They are involved in the organism's adaptation to stress, however have ulcerogenic effect. The hormones excess in the blood causes activation of gastric secretion, HCl release, reducing the number of mucocytes and mucus production, which contributes to ulceration. Cortisol with time begins to depress the immune system and increases the risk of stomach ulcers, too. At stress is enhanced catabolism of collagen, a large number of short glycine- and proline-containing peptides fall into the blood. We showed that tripeptide Pro-Gly-Pro (PGP) and its acetylated derivative AcPGP, entered in various ways, reduce the stress-induced ulceration. But the mechanism of their gastroprotective action is not fully understood. We suggested that peptides can participate in the immune and neuroendocrine interactions.
**Aims & Methods:** I. We studied the effect of peptides - PGP and AcPGP - on the content stress hormones and the main pro-inflammatory cytokine in serum of rats after water-immersion stress (30 min, $t = 19–21^0$C). Intranasal injection of peptides (3.7 mmol/kg/40 ml) or saline solution was added 1 hour before ulceration. Blood was collected from the jugular vein of the rats to determine the production of adrenaline, corticosterone and IL-1$\beta$ by means of ELISA. II. We identify a local immune response in the stomach. Ln. gastricus caudalis of intact rats without ulcers (IR) and rats with stress ulcer (SU) were used as the source of T-lymphocytes. PGP or AcPGP ($10^{-5}$M) were added to the wells immediately after cell seeding. IL-1$\beta$ were determined in the supernatant of mononuclear cells after 24 h and 48 h.
**Results:** In serum IR were determined: adrenaline – $133.1 \pm 32.2$ ng/ml, corticosterone – $2.7 \pm 0.2$ ng/ml, IL-1$\beta$ – $22.51 \pm 5.5$ pg/ml. After stress adrenaline increased in 2 times, corticosterone in 4 times, IL-1$\beta$ in 5 times that reflects the high stress-tension of organism. Regional lymph node cells produced IL-1$\beta$ in 2 times higher at 24 hours after stress and after 48 hours less than IR cells. PGP and Acetyl-PGP prevent a sharp increase of hormones and the cytokine in the blood of rats in 1 h and in 24 h after stress in the supernatant of mononuclear cells.
**Conclusion:** Thus collagen peptides reduce of excessive stress-associated activation neuroendocrine and immune systems. Peptides regulate systemic and local immune response. Perhaps, this provides a good gastroprotection by stress-induced ulceration.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0417 HIGH DIAGNOSTIC PERFORMANCE OF A NOVEL ASSAY FOR AUTOANTIBODIES AGAINST ATP4A AND ATP4B SUBUNITS OF GASTRIC PROTON PUMP H+, K+-ATPASE IN ATROPHIC BODY GASTRITIS PATIENTS

**Introduction:** The H+, K+-ATPase 4 of the parietal cells in the gastric oxyntic mucosa is a gastric proton pump maintaining an acidic environment within the stomach (1). Circulating autoantibodies, targeting the H+/K+-ATPase alpha (ATP4A) or beta (ATP4B) subunits, are considered diagnostic markers of autoimmune gastritis, but their real diagnostic utility is unclear. Previous studies employed enzyme-linked immunosorbent or indirect immunofluorescence to detect the autoantibodies against parietal cells, but did not discriminate reactivities against either the alpha or beta subunits (2, 3). Antibodies directed towards the H+, K+-ATPase 4B subunit (4) have not been assessed so far in patients with atrophic body gastritis, the histological condition associated with autoimmune gastritis.
**Aims & Methods:** The aim of this study was to assess the presence of autoantibodies against ATP4A and ATP4B subunits of parietal cells H+, K+-ATPase in patients with atrophic body gastritis and controls. Serum samples of 100 cases with histologically proven atrophic body gastritis (female 70%, median age 55 years) and 147 controls (female 79%, median age 45 years) were assessed for autoantibodies (IgG class) specific for either the ATP4A or ATP4B subunits by luminescent Immuno Precipitation System (LIPS). Recombinant antigens fused to a luciferase reporter were expressed by in vitro transcription and translation (ATP4A) or after transfection in Expi293F cells (ATP4B), incubated with test sera, and immune complexes recovered using protein A-sepharose. After addition of the luciferase substrate light output was measured in a luminometer and converted to arbitrary units using results from a positive serum as a reference. In addition, positive sera were titrated to properly quantify ATP4A and ATP4B autoantibodies. Cut-off values were selected using a normal-quantile plot analysis (ATP4A assay: $>51$ units; ATP4B assay: $>170$ units).
**Results:** Autoantibody titers were significantly higher in cases (ATP4A antibodies: median 3003 units, range 54–47, 429; ATP4B antibodies: median 2, 762

units, range 29–19, 796) compared to controls (ATP4A antibodies median units: 1, range 1–2, 440; ATP4B antibodies median units: 2, range 1–1, 301; $p < 0.0001$ for both assays). The area under the ROC curve of ATP4A and ATP4B assays was 0.98 and 0.99 ($p < 0.0001$ for both), respectively. Concordance between the two assays was good with a Spearman's coefficient of rank correlation (rho) 0.905 (95%CI 0.880 to 0.925, $p < 0.0001$). The ATP4A antibody LIPS assay showed a 100% sensitivity and 89.1% specificity and the ATP4B LIPS assay showed a 95% sensitivity and 97.3% specificity for atrophic body gastritis. Simultaneous positivity for both ATP4A and ATP4B autoantibodies in LIPS increased specificity for atrophic body gastritis (98.9% sensitivity and 97.04% specificity).
**Conclusion:** These novel assays for autoantibodies against ATP4A and ATP4B subunits showed a high diagnostic performance in atrophic body gastritis suggesting that oxyntic mucosa damage is strictly associated with gastric autoimmunity.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Autoimmune chronic atrophic gastritis (ACAG) is often associated to the presence of other autoimmune disorders such as autoimmune thyroid disease (ATD); it has been demonstrated that this could be due to an immunological cross-reaction caused by the presence of an homologous auto-epitope between thyroperoxidase (TPO) and gastric parietal cell (PCA) antibodies.
**Aims & Methods:** To evaluate the role of predictive markers for ACAG in patients affected by ATD. A consecutive series of 1524 patients (441 males, 1083 females, mean age 44 years, range 6–89) selected from general population on the basis of dyspeptic symptoms was submitted to serum Pepsinogen I, II (PGI, PGII) and Gastrin 17 (G17) (Biohit, Plc) assays for ACAG identification. Among them, 309 patients who presented a clinical and immunological history of ATD (positivity for TPO antibodies, Siemens) were evaluated for PCA antibodies by indirect-immunofluorescence method (Menarini). Definitive diagnosis of CAG was performed by histological evaluation (OLGA Staging System).
**Results:** 39/94 (41.5%) of patients with ACAG were also affected by ATD. Table illustrates the results obtained from the following groups of patients:.

| | No ATD, No ACAG | ATD | ACAG | ATD + ACAG |
|---|---|---|---|---|
| **Patients** | 1082 | 309 | 55 | 39 |
| **Mean Age (ys)** | 42.3 | 43.7 | 57.9 | 54.3 |
| **Sex (M/F) (M:F)** (1:1.8) | 387/695 (1:1.8) 3/36 (1:12) | 298/280 (1:10) | 19/36 | |
| **PCA+** | 7 (0.7%) | 87 (28.1%) | 40 (72.7%) | 37 (94.9%) |
| **PCA-** | 1075 (99.3%) | 222 (71.9%) | 15 (27.3%) | 2 (5.1%) |
| **PGI (ug/L)** | 108.6 | 105.4 | 14.0 | 11.0 |
| **PGI/PGII (ratio)** | 12.6 | 12.0 | 2.3 | 1.5 |
| **G17 (pmol/L)** | 5.2 | 8.4 | 53.5 | 56.2 |

**Conclusion:** ATD and ACAG seem to occur in a closely linked fashion. ATD PCA negative young females have to be regularly monitored for PCA; ATD PCA positive young women should be followed up by gastric serological markers in order to early evidence a possible onset of ACAG.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0419 A POSSIBLE ROLE OF TYPE 1 INNATE LYMPHOID CELLS IN THE RECTAL MUCOSA OF PATIENTS WITH NON-CELIAC WHEAT SENSITIVITY

**Introduction:** Non-celiac wheat sensitivity (NCWS) is a ''new'' and still undefined clinical condition. Its pathogenesis is incompletely understood, we evaluated the inflammatory response in the rectal mucosa of patients with well-defined NCWS.
**Aims & Methods:** The prospective study included 22 patients with irritable bowel syndrome (IBS)-like clinical presentation, diagnosed with NCWS by double-blind placebo controlled challenge. Eight IBS patients not improving on wheat-free diet were used as controls. Two-weeks after oral challenge, cells were isolated from rectal biopsies and thoroughly characterized by FACS analysis for intracellular cytokines and surface markers.
**Results:** Rectal biopsies from wheat challenged NCWS patients showed a significant mucosal $CD45^+$ infiltrate consisted of $CD3^+$ and $CD3^-$ lymphocytes, with these latter spontaneously producing more IFN-g than IBS controls. About 30% of IFN-g-producing $CD45^+$ cells were T-$bet^+$, $CD56^-$, $NKP44^-$ and $CD117^-$, defining them as a type-1 innate lymphoid cells (ILC1). IFN-g-producing ILC1 cells significantly decreased in ten patients analyzed two weeks after they resumed a wheat-free diet.
**Conclusion:** These data indicate that in patients with active NCWS, IFN-g-producing ILC1 cells infiltrate rectal mucosa and support a role for this innate lymphoid cells population in the pathogenesis of NCWS.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0420 STUDY OF VARIATION BETWEEN THE ENDOSCOPIST, PATHOLOGIST AND THE BIOCHEMIST IN THE DIAGNOSIS OF CHRONIC FUNDAL ATROPHIC GASTRITIS: THERE IS NEED FOR DEFINITIVE GUIDELINES

**T. Mahmood**
*Mulja-e-Tariq, Ickenham, Middsx/United Kingdom*

**Contact E-mail Address:** tm123@btinternet.com.

**Introduction:** Gastritis is a common condition and is diagnosed endoscopically and /or with histology. There are also biochemical markers available to differentiate different types of gastritis. There have been different classifications of Gastritis as types A, B and C and acute or chronic. More recently Sydney classification of gastritis has been introduced. The Endoscopists recognise mucosal atrophy by thinning of the mucosa which shows underlying blood vessels. The histopathologist looks for signs of duct dilatation, fibrosis, intestinal metaplsia and crypt changes in the lamina propria. The biochemist recommend that serum Pepsinogen I levels should drop in patients with fundal atrophy due to damaged chief cells. No previous study has looked at the concordance between these three modalities of diagnosis. This study aims to look at any relationship and degree of variation amongst the endoscopists, histopathologists and the biochemists in making the diagnosis of chronic fundal atrophic gastritis.
**Aims & Methods:** Endoscopy was performed on 71 patients by an experienced consultant gastroenterologist. Pre-endoscopy fasting samples were taken for Serum Pepsinogen I levels and two biopsies were taken from the fundus. If atrophic gastritis was suspected endoscopically, then the histopathologist was advised of the diagnosis in writing. Clo test was done on all patients. Senior histopathologists reviewed the histology slides and reported their findings. Serum Pepsinogen I level was done in Finland by Biohit laboratories and the sample was either stored at -20 degree Centigrade or treated with stabilizer to ensure validity during storage and transport. The study was done with approval

of the ethics committee and patient consent was obtained for participation. Patients were either on no PPIs or were off them for one week or a correction factor was put in case of their inability to be off the PPI due to worsening symptoms.
**Results:** 65 patients had some positive findings during endoscopy. 06 patient had normal endoscopy so histology samples were not undertaken for them but serum Pepsinogen I level was still undertaken. 40 patients had no fundal atrophy while 25 were deemed by the endoscopist to have atrophy. There was total agreement between the endoscopist and histopathologist in all 40 cases with no atrophy. However the histopathologist agreed with only 04 out of 25 cases diagnosed fundal atrophy by the endoscopist (84% disagreement) p value $< 0.019$. The biochemists likewise showed normal levels of Pepsinogen I in patients without fundal atrophy diagnosed by the endoscopist and the histopathologist in 39 out of 40 cases (97.5% agreement). However in patients with chronic fundal atrophy only 1 out of 25 patients had low Pepsinogen I when matched by the endoscopist's findings (96% disagreement) p value $< 0.625$ and in 0 out of 25 of them when matched with histopathologist's diagnosis. (100% disagreement) p value $< 0.880$.
**Conclusion:** This study has demonstrated that when chronic fundal atrophic gastritis is not suspected by the endoscopist, all three modalities of diagnosis i.e the endoscopist, histopathologist and the biochemist with biomarkers get an almost complete agreement. However when atrophy is suspected there is wide variation between the endoscopist, histopathologist and the it biochemist. Early recognition of fundal atrophy is important as it indicates a higher risk of developing cancer. Therefore a co-ordinated approach by the three may enable a more definitive diagnosis. There is need for clear guidance and training on endoscopic appearances of gastritis. Sydney Classification helps the histopathologist to a certain extent. Pepsinogen I as a biomarkers of gastric fundal atrophy has been validated and can become an important tool in helping the endoscopist and the histopathologist in making a more definitive diagnosis. If normal level of serum Pepsinogen I is taken as a guide prior to endoscopy, the endoscopist and the histopathologist, both can be more sure that there is no fundal atrophy and may achieve greater concordance in their reports. Further formal guidelines on diagnosis of various types of gastritis are warranted.
**Disclosure of Interest:** T. Mahmood: Biohit transported and conducted biochemical testing free of charge to Finland.

## P0421 THE USE OF CANCER-ASSOCIATED AUTOANTIBODIES AS BIOMARKERS IN GASTRIC MALIGNANCIES

**Introduction:** According to GLOBOCAN, gastric cancer (GC) remains the third deadliest malignancy worldwide with Eastern Asia and Eastern Europe being the regions of the highest incidence and mortality. High-titer IgG class autoantibodies generated against tumor associated antigens have been demonstrated to have valuable biomarker qualities in various malignancies including GC[1] and have been used for non-invasive biomarker assay development[2].
**Aims & Methods:** In our previous study, we developed a recombinant tumor antigen microarray and data analysis algorithm suitable for robust autoantibody profiling and biomarker identification[3]. Within this study, we used these tools to reassess the diagnostic and prognostic value of 105 previously selected markers and evaluate possible inter-population differences in seroreactivity patterns by testing serum samples from GC patients and healthy controls (HC) (245 and 310 from Baltic States, and 296 and 298 from Taiwan, respectively). For prognostic analyses, autoantibody reactivity was compared in patients with available overall survival data subdividing them into long-term survival (LTS) group ($>1$ year, $n = 163$) and short-term survival (STS) group ($\leq 1$ year, $n = 28$).
**Results:** The study identified 26 and 33 autoantibody biomarker signatures in Taiwan and Baltic cohorts, respectively, capable of discriminating GC from HC in both cases with AUC of 0.6 ($p < 0.001$). Results revealed minor differences in antigen seroreactivity patterns between the Taiwan and Baltic cohorts, but indicated differences in immunodominant epitope prevalence for tumor antigens NY-ESO-1 and TP53. GC-associated serum autoantibodies were not statistically significantly associated with cancer stage, histological type, grade, *H. pylori* status, age or sex. However, a 15-autoantibody signature associated with worse prognosis was identified ($OR = 3.36$, $p = 3.3\,e\text{-}5$) and included serological responses against known tumor antigens such as MYC, MUC1, IMP1 and IMP2, while antibodies against NY-ESO-1, SSX2 and SOX2, amongst others, were found to be associated with longer overall survival.
**Conclusion:** Tumor antigen associated autoantibody repertoires show slight differences when compared between Caucasian and Asian cohorts. Although readily detectable at first stages of GC, the cancer-associated autoantibodies have limited diagnostic value, but may have possible clinical application as an independent prognostic factor.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Many studies have been shown, that $\beta$-glucans is effective as a natural immunomodulator and could be used as dietary supplement to reduce inflammation and oxidative tissue injury.
**Aims & Methods:** The aim of this study was to determine the effect of high or low molecular weight oat $\beta$-glucans on gastric mucosa histological changes in patients with chronic gastritis. Study participants were recruited from patients who underwent an elective esophagogastroduodenoscopy (EDG) due to dyspepsia. All consecutive eligible patients with initial diagnosis of gastritis within gastric antrum were invited to participate in the study. 48 patients were either randomly assigned to a placebo group, receiving an oral dose of 100 ml 3% solution of potato starch (P), or to one of the treatment groups receiving oral dose of 100 ml high molecular weight $\beta$-glucans (G1) or low molecular weight $\beta$-glucans (G2). Easily digestible diet was recommended for all groups. All participants underwent a baseline screening assessment which included a medical history and physical examination. Appearance of the mucosa of the stomach, and duodenum was evaluated and scored with the use of esophagogastroduodenoscopy scores (EGs) which were partially based on the Sydney grading/scoring system. Double biopsies for urease testing (GUT Plus, Poland) and histology were taken: pylorus, distal lesser curvature and the distal greater curvature. Endoscopy with biopsies and histological examinations were performed before treatment and the day after discontinuation of the administration the beta-glucan supplement. Plasma TNF-alpha and C-reactive protein (CRP) level was measured using ELISA kits (Merck Millipore, Germany).
**Results:** There were no statistically significant differences in CRP and TNF-alpha level as well as antral histological scores of inflammation, activity, atrophy, metaplasia and degree of *H. pylori* observed both within and between groups after 30 days of oral administration of beta-glucans.
**Conclusion:** Dietary supplementation with $\beta$-glucans did not reduce inflammation changes in patients with chronic gastritis. Although strong anti-inflammatory effect of oral $\beta$-glucans in gastrointestinal tract have been seen in animal models we could not confirm these effect in patients with chronic gastritis. Considering the underlying mechanism, the main reason could be that, in contrary to our population treated, in an animal model of GI inflammation the induced inflammatory process was rather acute with predominance of granulocyte infiltration. It would be of interest to further explore the exact effects of oral beta-glucans treatment in humans suffering from acute inflammation within GI tract like e.g. acute gastritis or ulcerative colitis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0423 THE PREVALENCE OF ANTI-PARIETAL CELL AND ANTI-INTRINSIC FACTOR ANTIBODIES, PEPSINOGENS AND GASTRIN-17 IN CORPUS-RESTRICTED GASTRITIS PATIENTS

**Introduction:** Corpus-restricted gastritis (usually of autoimmune origin) may result in pernicious anaemia as well as gastric cancer. The aim of our study was to detect the prevalence and values of anti-parietal cell antibodies (anti-PCA), anti-intrinsic factor antibodies (anti-IFA), pepsinogen ratio (PGI/II) and gastrin-17 (G-17) in corpus-restricted gastritis and control group patients.
**Aims & Methods:** This was a sub-group analysis of 1978 patients being referred for endoscopy due to dyspeptic symptoms; 5 biopsies were analysed according to updated Sydney system. ELISA method was used to measure PGI/II and G-17 (Biohit, Oyj., Finland); anti-PCA and anti-IFA (Inova Diagnostics, USA) in plasma samples. Spearman's correlation was run to assess the relationship between the biomarkers.

**Results:** 52 patients with corpus-restricted gastritis according to the morphology report were included to the study group and 104 patients without gastric atrophy in the control group. In the corpus-restricted gastritis group 59.6% and 9.6% patients were anti-PCA and anti-IFA positive with mean values of 45.0 and 13.7 units; in the control group 15.4% and 1% patients were anti-PCA and anti-IFA positive with mean values of 10.8 and 5.8 units, $p < 0.001$ and $p = 0.184$ respectively. There was a strong negative correlation between G-17 and PI/II ratio ($rs = -.731$, $p < .001$), a positive correlation between G-17 and anti-PCA ($rs = .325$, $p < .001$) and a negative correlation between PI/II ratio and anti-PCA ($rs = -.320$, $p < .001$).
**Conclusion:** Increased anti-PCA levels were observed in a significant proportion of patients with corpus-restricted gastritis. In contrast, anti-IFA levels increased in only a small proportion of patients. There was a negative correlation between G-17 and PI/II ratio and between anti-PCA and PI/II ratio, while a positive correlation between G-17 and anti-PCA values was observed.

**Contact E-mail Address:** petra.krike@gmail.com.
**Introduction:** Gastric atrophy and *H. pylori* infection are well-known risk factors of gastric adenocarcinoma, but the relevance of autoimmune gastritis in gastric adenocarcinoma development is not entirely clear.
**Aims & Methods:** We studied anti-parietal cell antibodies (anti-PCA) and anti-intrinsic factor antibodies (anti-IFA) levels and their associations with pepsinogen PgI/PgII levels in Caucasian patients with morphologically confirmed gastric adenocarcinoma. Plasma levels of anti-PCA and anti-IFA were measured by ELISA (Inova Diagnostics, USA), the cut-off value for both was ≥25 units. Plasma levels of PgI, PgII, *H. pylori* IgG were measured by ELISA (Biohit, Oyj., Finland). A cut-off value of PgI/PgII <3 was used to detect gastric atrophy. The cut-off value for *H. pylori* IgG was ≥30 units.
**Results:** A total of 229 patients (134 men, 95 women, median age 65, range: 35–86) with confirmed gastric adenocarcinoma from Riga East University Hospital in Latvia were included to the study. Positive autoantibody (either anti-PCA or anti-IFA or both) was found in 25 (11%) of the patients with adenocarcinoma, the positivity results for each subgroups are provided in the Table. Significantly, higher prevalence was found in the group with pepsinogen values characteristic for gastric atrophy.

| | *H. pylori* IgG | PgI/PgII ≥ 3 | PgI/PgII < 3 | P-value (Pg subgroups) |
|---|---|---|---|---|
| Positive anti-PCA (n = 24) | 9 (38%) | 8 (33%) | 16 (67%) | 0.0003 |
| Positive anti-IFA (n = 6) | 1 (17%) | 1 (17%) | 5 (83%) | 0.0134 |
| Positive both (n = 5) | 0 (0%) | 1 (20%) | 4 (80%) | 0.0368 |
| Positive anti-PCA or anti-IFA or both (n = 25) | 10 (50%) | 8 (32%) | 17 (68%) | 0.0002 |

**Conclusion:** Autoantibodies suggesting the presence of autoimmune gastritis were detected in only a minority of patients with gastric cancer, with only 1 of 9 (25/229) patients presenting with positive test results suggesting the presence of autoimmune gastritis. As expected, presence of autoantibodies is higher in atrophic gastritis group.
**Disclosure of Interest:** Z. Shums: Employee of Inova Diagnostics Inc, San Diego, CA, USA.
G.L. Norman: Employee of Inova Diagnostics Inc, San Diego, CA, USA.

## P0425 REDUCED 25-OH-VITAMIN D LEVELS IN PATIENTS WITH CHRONIC AUTOIMMUNE ATROPHIC GASTRITIS

F. Cavalcoli, **A. Zilli**, S. Bernasconi, D. Conte, C. Ciafardini, S. Massironi
*Gastroenterology And Endoscopy Unit, Fondazione IRCCS Ca Granda Ospedale Maggiore Policlinico, Milan/Italy*

**Contact E-mail Address:** alessandra.zilli@gmail.com.
**Introduction:** chronic atrophic autoimmune gastritis (CAAG) is an organ-specific autoimmune disease characterized by the presence of autoantibodies against gastric parietal cells or intrinsic factor. The progressive destruction of the parietal cells leads to hypo/achlorhydria and results in a reduced absorption of vitamin B12. The possible role of CAAG and gastric achlorhydria in the pathogenesis of several nutritional deficiency has already been reported. Moreover, few studies reported the possible association between CAAG and 25-OH-Vitamin D deficiency.
**Aims & Methods: Aim:** To evaluate the prevalence of 25-OH-Vitamin D deficiency in a cohort of patients affected by chronic atrophic autoimmune gastritis.
**Methods:** 25-OH-Vitamin D, PTH, calcium and ionized calcium were measured in all the patients with atrophic gastritis followed at our center from January 2012 to July 2015. Results were compared with a control group formed by 1402 subjects [1093 females, 309 males; median age 62 years (14–83)]. Patients with primary hyperparathyroidism, abnormal calcium values or renal failure were excluded.
**Results:** 86 CAAG patients (64 females; median age 65 years) were studied. Median 25-OH-vitD was significantly lower than in the control group (17.9 vs 23.9 ng/ml, $p < 0.0001$). 25-OH-VitD deficiency was observed in 57 patients (66%) considering 20 ng/ml as a cut-off and in 22 patients (26%) considering 12.5 ng/ml. In detail, 25-OH-vitD was significantly lower in CAAG patients compared with controls in decades 36–45 (17.7 vs 22 ng/ml, $p = 0.02$), 46–55 (17 vs 22.5 ng/ml, $p = 0.03$), 56–65 (18.7 vs 24.2 ng/ml, $p = 0.0043$), 66–75 (17.7 vs 24.3 ng/ml, $p < 0.0004$) and 76–85 (13.9 vs 24.3 ng/ml, $p = 0.003$). No differences were observed for decades below 35 and above 86 years probably due to the low number of patients in these groups. The two groups don't differ significantly for age and male/ female distribution.
**Conclusion:** the increased incidence of osteopenia and osteoporosis in patients with longstanding hypochlorhydria has already been reported. Moreover, few studies reported a reduction in calcium and phosphorus levels in patients with hypochlorhydria. To the best of our knowledge this is the first study aimed at evaluating 25-OH-Vitamin D levels in patients affected by CAAG. Our study, showed 25-OH-Vitamin D levels significantly reduced in patients with CAAG as compared to control group. These observations suggest a possible impairment in vitamin D absorption in CAAG's patients, which could lead to alteration in bone mineralization.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic hemostasis is the first therapeutic approach to the emergent upper gastrointestinal bleeding, which is the still serious life-threatening condition. The present study aimed to examine i) whether visiting time to the hospital influenced prognosis of the outpatients with the bleeding peptic ulcer, and ii) whether prognosis of the outpatients who received endoscopic hemostasis was different from that of the hospitalized patients.
**Aims & Methods:** Totally, 444 patients who received emergency endoscopic hemostasis from January, 2008 to December, 2014 were included in the present study. These patients were divided into two groups of hospitalized patients (137 cases) and outpatients (307 cases). The outpatients were divided into two semi-groups; the group A of 120 cases who visited the hospital in time (8:30 to 17:00 on weekdays), and the group B of 187 cases in out of the regular consultation time (17:00 to 8:30 on 0weekdays or holidays).
**Results:** Backgrounds of the outpatients including age, gender, underlying disease, and medication were not different between the groups A and B. The treatment outcomes of endoscopic hemostasis for the bleeding ulcer including primary hemostasis, re-bleeding, complications, and number of deaths within one month were not different between the groups A and B. Compared to the outpatients, mortality rate ($p < 0.01$), recurrent bleeding rate ($p < 0.01$), and procedure related accident rate after endoscopic hemostasis ($p < 0.01$) were relatively high in the hospitalized patients. The average age of the hospitalized patients was old compared to the outpatients ($p < 0.01$), and severe comorbidity was complicated in the hospitalized patients with the bleeding peptic ulcer; diabetes mellitus ($p < 0.01$), cerebrovascular disease ($p < 0.01$), and malignant neoplasm ($p < 0.01$). The significant mortality risks of the hospitalized patients compared to the outpatients were aging more than 65 year old ($p < 0.01$), and complicated malignant neoplasm ($p < 0.05$).

**Conclusion:** The present study indicated the prognosis of the patients with the bleeding peptic ulcer who were treated by the endoscopic hemostasis was better in the outpatients compared to the hospitalized patients, and the prognosis was not influenced the visiting time to the hospitals. These results suggest that prognosis of endoscopic hemostasis for the upper gastrointestinal bleeding might be dependent on the characteristics of the patients, but not on correspondence of the medical staffs including the endoscopists.

## P0427 INFORMATICS ASSESSMENT OF BURDEN OF ANAEMIA POST UPPER GI BLEEDING IN AN UNIVERSITY HOSPITAL POPULATION

**N. Bhala**[1], D. Mcnulty[2], F. Evison[3], T. Read[2], N. Sharma[4], T. Iqbal[1]

**Introduction:** Upper GI bleeding (UGIB) remains a considerable burden causing premature mortality throughout the world. Uncertainty exists about the best haemoglobin measure to aim for acutely and on discharge in order to prevent premature mortality. However, the long term effects of anaemia post-UGIB has not been evaluated in secondary care cohorts, particularly to assess associations with mortality and the potential role of risk factors.
**Aims & Methods:** In order to assess the associations of anaemia post-UGIB, we analysed the secondary care patient sample identified from University Hospital Birmingham informatics electronic patient records databases, which has a catchment population of just over half a million in South Birmingham. Demographics, clinical and follow-up information were collected on first admission per patients having: (i). an upper gastrointestinal endoscopic procedure; (ii). a haemoglobin measurement; and (iii). an admission between 1st January 2010 and 31st December 2014. Anaemia status was defined using the last haemoglobin (Hb) measurement before discharge according to high (Hb $>=$10) or low (Hb $<$ 10). Upper GI bleeding and related conditions were detected using ICD10 codes: Gastric K25, Duodenal K26, Peptic K27, GI bleeding K92, Varices I85. One year survival post discharge was collected from UHB regional databases and was analysed using log rank statistics in Kaplan Meier survival curves. A naïve analysis of all data was compared against a matched analysis where patients were matched on propensity to anaemia using risk factors in a generalised logistic model.
**Results:** There were 1304 cases of upper GI bleeding identified in the 5 year period. The median range of patients was 67 years (interquartile range 54–80 years). 38.6% (504) of patients were female. Ethnicity included: Caucasian 81.7% (1065), South Asian 9.3% (121), and Other 9.0% (118). Prevalence coding of past and current medical history was predominantly Peptic ulcer (50.3%) but also included: Liver disease (18.8%); Diabetes Mellitus (16.9%); Cancer (16.6%); Renal disease (15.5%); Myocardial Infarction (12.1%); and Congestive Cardiac Failure (9.5%). Independent risk factors for overall mortality identified included: admission method (emergency or elective; $p < 0.0001$), age ($p = 0.0005$), gender ($p < 0.001$), body mass index ($p < 0.001$) and comorbidities (liver disease, renal disease, peptic ulcer all $p < 0.001$; heart failure and diabetes $p < 0.02$). One year survival between those discharged with a Haemoglobin $>=$10 and $<$10 when adjusted for age, gender, admission method, demographics, body mass index was 85.1% versus 76.7% ($p = 0.0034$). However, when comorbidities were also adjusted for, there was limited evidence to suggest overall mortality differences between high and low Hb groups ($p = 0.31$).
**Conclusion:** This large-scale informatics study in a single centre secondary care population has identified associations post-UGIB for a 1 year mortality difference dependent on haemoglobin on discharge. However, this appears to be associated with comorbidities rather than anaemia per se. Further studies to assess the long-term effects of post-UGIB anaemia are required.

## P0428 INCIDENCE, CLINICAL CHARACTERISTICS AND RISK FACTORS OF UPPER GASTROINTESTINAL BLEEDING IN PATIENTS ON DUAL ANTI-PLATELET THERAPY AFTER PERCUTANEOUS CORONARY INTERVENTION IN SOUTH CHINA

**Z. Zhang**, W. Sha, Q. Wang
*Gi, Guangdong General Hospital, Guangzhou/China*

**Contact E-mail Address:** 503274480@qq.com.
**Introduction:** The acute coronary artery syndrome (ACS) patients should take aspirin and clopidogrel (dual anti-platelet) for at least 1 year after percutaneous coronary intervention (PCI). However, dual anti-platelet therapy in patients increases the risk of gastrointestinal bleeding (GIB), hospitalization time and costs, and adverse clinical outcomes. It has been reported that, the risk factors of GIB after PCI include old age[1], female[2], smoking[2], drinking[2], taking non steroidal anti-inflammatory[1]and anticoagulant drugs[1], with digestive tract tumors[3], congestive heart failure[3], low BMI[4], renal inadequacy[5], coronary artery bypass graft[6], previous history of peptic ulcer[1, 2] and bleeding[1, 2].Proton pump inhibitors (PPI) can prevent and treat the upper GIB (UGIB) after PCI. But there has not any statistical data about UGIB after PCI for 1 year in China, and the lifestyle and genetic characteristics are different from foreign patients; this study intends to provide help for the prevention and treatment of UGIB after PCI.
**Aims & Methods:** To investigate the incidence, clinical characteristics and risk factors of UGIB in ACS patients on aspirin with clopidogrel dual anti-platelet therapy after PCI. Clinical data of ACS patients who had undergone PCI in the cardiovascular institute of Guangdong General Hospital from Sep 2009 to Aug 2014 were reviewed. The incidence of UGIB and clinical characteristics of ACS patients on dual anti-platelet therapy for 1 year after PCI were analyzed. Risk factors of UGIB were screened by comparing the cases and controls, which were trebly matched with the same age and sex.
**Results:** 9118 ACS patients had undergone PCI and UGIB occurred in 189 patients (2.07%) totally from Sep 2009 to Aug 2014. Except those happened over one year, with digestive tumors or varices and negative results under endoscopy, UGIB occurred at a rate of 0.61% in 56 patients (0.61%) and appeared to decline year by year. Most patients (91.07%) had melena or stool occult blood positive, while others had bloody stool or haematemesis. Most UGIB were ulcer-related under endoscopy, which accounted for 67.86%, and there were 24 duodenal ulcers and 13 gastric ulcers and 1 complex ulcer, while others were gastric erosion, gastritis and duodenal bulb. The risk factors of UGIB were previous history of peptic ulcer ($P < 0.01$) and renal inadequacy ($P < 0.01$), while PPI use was a protective factor ($P < 0.05$). The incidence of new-onset ACS was 1.44% with PPI use, and 1.34% without PPI use; there was no significant difference between the two groups ($P > 0.05$). PPI use for prevention of UGIB after PCI didn't increase the incidence of ACS.
**Conclusion:** UGIB occurs at a rate of 0.61% in ACS patients on dual anti-platelet therapy (aspirin and clopidogrel) for 1 year after PCI and appears to decline year by year. PPI use after PCI contributes to preventing UGIB, especially for those who had precious history of peptic ulcer and renal inadequacy.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Ginkgo biloba (ginkgo) has been widely used to treat dementia, cognitive impairment, peripheral nerve problems and vascular tinnitus worldwide. To our knowledge, whether Ginkgo increases risk of upper gastrointestinal bleeding still remains unknown.
**Aims & Methods:** To clarify whether Ginkgo increases risk of upper gastrointestinal bleeding and identifies the risk modifiers. This was a national population-based study by using National Health Insurance database (NHIRD) of Taiwan and conducted with the case cross-over study design with time windows of 7, 14 and 28 days. According to the Taiwan National Health Insurance database, patients aged >20 year old and <95 year old and hospitalized for upper gastrointestinal hemorrhage during January 1, 2000 to December 31, 2012 were retrieved according to ICD-9-CM diagnosis codes with endoscopic therapies from inpatient claims from the one million random sample of NHIRD. Those who ever used Ginkgo (>=1 day) before admission were defined as Ginkgo-indicated patients. A conditional logistic regression model was used to estimate odds ratios (ORs) and 95% confidence intervals (CIs). Test interaction test was performed to determine the risk modifier of Ginkgo related upper gastrointestinal bleeding.
**Results:** A total of 13752 patients with upper gastrointestinal bleeding were retrieved and 1504 Ginkgo-indicated patients were analyzed. The odds ratio for the risk of upper gastrointestinal bleeding and risk of severe bleeding in need of blood transfusion after Gingko exposure were 5.21 (95% CI, 2.94–9.24) and 7.83 (95% CI, 3.35–18.32) for the 7-daywindow, 2.45 (95% CI, 1.59–3.77) and 3.39 (95% CI, 1.82–6.28) for the 14-day window, and 1.85 (95% CI, 1.31–2.63) and 1.78 (95% CI, 1.11–2.85) for the 28-day window respectively. The test of interaction showed the risk of Gingko-related UGI bleeding existed regardless of age, gender, comorbidities and concurrent medicines.
**Conclusion:** Short- term Ginkgo use increased the risk for upper gastrointestinal bleeding, especially within 7 days and had lag effect up to 28 days, regardless of age, gender, comorbidities and concurrent medication.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0430 CHADS2 SCORE IS A PREDICTOR OF DELAYED BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASMS

**T. Inoue**, S. Ito, T. Shimizu, Y. Yokoyama, S. Ishii, **A. Inoue**
*Gastroenterology, Osaka General Medical Center, Osaka/Japan*

**Contact E-mail Address:** taktaktakkun@gmail.com.
**Introduction:** Delayed bleeding is one of major complications associated with endoscopic treatment for gastrointestinal neoplasms. Some predictors are known to involve in delayed bleeding after endoscopic treatment, and however, the association between CHADS2 score and delayed bleeding after gastric ESD has not been reported.
**Aims & Methods:** The present study aimed to identify the predictors of delayed bleeding after gastric ESD. Data of consecutive inpatients who underwent ESD for gastric neoplasms in Osaka General Medical Center between January 2013 and March 2016 were retrospectively investigated. Main survey item was delayed bleeding, and we also investigated the associated factors, including age, gender, characteristics of lesion, drug utilization (antiplatelet agents, heparin bridge, non-steroid anti-inflammatory drugs (NSAIDs), and steroid), hemodialysis, CHADS2 score. The predictors of delayed bleeding were analyzed in a multivariate analysis by logistic regression model.
**Results:** A total 312 patients with gastric neoplasms were identified. The mean and median age of patients were 75.1 ± 7.8 and 76 (48–92), and male was 71.4%. Most neoplasms were located in gastric body (84.6%), and two-thirds of lesions were protruded type. The proportion of continuous antiplatelet agents, heparin bridge, NSAIDs, and steroid utilization were 8.4%, 9.2%, 3.2%, and 5.8%, respectively. Median glomerular filtration rate (GFR) was 61 (5–107), and 16 patients (5.1%) underwent hemodialysis. Delayed bleeding rate was 8.7% (27/312), and median onset of bleeding was post operation day 1 (1–16). Four patients (1.3%) encountered repeated delayed bleeding, and three of them received heparin bridge therapy. Median hospitalization was 8 days (7–24), which was significantly longer in heparin bridge cases. Delayed bleeding was associated with age (>75), lesion site (antrum), heparin bridge, hemodialysis, and CHADS2 score (>3) in a univariate analysis. A multivariate analysis showed CHADS2 score (>3) was an independent predictor of delayed bleeding after gastric ESD (Odds Ratio 3.14 [95%CI 1.17–8.22], p = 0.024).
**Conclusion:** CHADS2 score (>3) is a predictor of delayed bleeding after endoscopic submucosal dissection for gastric neoplasms.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0431 DIAGNOSTIC SCORES AS PREDICTORS OF OUTCOME IN PATIENTS WITH BLEEDING PEPTIC ULCERS

**Introduction:** The aim of this study was to compare Rockall score (RS), Baylor bleeding score (BBS) and Glasgow Blatchford score (GBS) in predicting clinical outcomes and the need for interventions in patients with bleeding peptic ulcers.
**Aims & Methods:** Between January 2008 and December 2013, 1012 consecutive hospitalized patients managed for peptic ulcer bleeding (PUB) were included into the study.For every patient we calculated preendoscopic (RS, BBS and GBS) as well as postendoscopic diagnostic scores (RS and BBS), according to urgent upper endoscopy findings. The area under the receiver-operating characteristics curve (AUROC) was calculated for predicting lethal outcome, rebleeding, predicting the need for blood transfusion and surgery.
**Results:** PUB made up 41.9% of all bleedings from upper gastrointestinal tract, 5.2% patients died and 5.4% patients underwent surgery. By comparing the AUROC curves of before mentioned preendoscopic scores, RS was the best score for predicting lethal outcome (AUROC 0.82 vs 0.67 vs 0.63, respectively). Postendoscopic RS was better than postendoscopic BBS in predicting lethal outcome in patients with peptic ulcer bleeding (AUROC 0.82 vs 0.69, resepectively). GBS was the best score in predicting rebleeding (AUROC 0.75 vs 0.61 vs 0.53, respectively), in the predicting of need for blood transfusion (AUROC 0.83 vs 0.63 vs 0.58, respectively) and surgery (0.82 vs 0.63 vs 0.52, resepectively) among this three pre-endoscopic scores.
**Conclusion:** In the group of patients with bleeding peptic ulcers RS was the best in predicting mortality, but GBS was the best in predicting rebleeding rate, in predicting the need for blood transfusion and surgery intervention.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Abstract No: P0429**

Risk of Upper gastrointestinal Bleeding of Current use of Ginkgo biloba.

| Time Window | Exposure periods (N = 1504) | Control periods (N = 1504) | Crude OR Point estimate | 95%CI | P |
|---|---|---|---|---|---|
| Total upper gastrointestinal bleeding | | | | | |
| 1-7 day window | 97 | 38 | 5.21 | 2.94-9.24 | <0.0001 |
| 1-14 day window | 111 | 69 | 2.45 | 1.59-3.77 | <0.0001 |
| 1-28 day window | 140 | 100 | 1.82 | 1.28-2.57 | 0.0008 |

**Introduction:** Acute upper Gastrointestinal (GI) Bleeding is the commonest emergency managed by Gastroenterologists. Most deaths occur in elderly patients who have significant co-morbidity and the majority are inevitable, despite improvements in medical and surgical expertise. Mortality is reported to be lower in specialist units and this is probably not related to technical developments but because of adherence to protocols and guidelines.
**Aims & Methods:** The aim of this audit was to look into the compliance with the National Guidelines which were published by the Scottish Intercollegiate Guidelines Network (SIGN) in 2008. Information was gathered retrospectively on 50 patients admitted to a district general hospital with acute upper gastrointestinal haemorrhage.
**Results:** They were 16 females and 34 males with age range of 18–90 years. Data on the date and time of admission, using Rockall scoring system, time of referral to the gastroenterologist, restoring eth circulatory volume and the time of endoscopy were collected from the case notes. These data were analysed based on SIGN national standards in managing upper gastrointestinal bleeding. Results showed that 92% of the patients were admitted under non gastroenterologist physician as part of the on call take. Majority of patients (90%) was referred to the Gastroenterologist within the first 24 hours of admission. The severity of the bleeding was assessed in only 44% of the patients using Rockall scoring system. The circulatory volume was restored in all of the patients with intravenous fluids or blood transfusion. Not all of the patients (only 44%) had an endoscopy within 24 hours and there was no out of hours endoscopists on site unless the on call physician was a gastroenterologist.
**Conclusion:** The initial management of acute upper gastrointestinal bleeding is very important. In a district general hospital, the lack of out of hour endoscopists and the long waiting time for the endoscopy list may delay the appropriate timing of endoscopy. Our study showed that we need to train junior doctors how to use the Rockall scoring system. Following this audit, a standard Performa for clerking patients with upper gastrointestinal bleeding was developed. Regarding out of hour endoscopists cover, a proposal was put forward to provide funding to ensure that patients with bleeding would have endoscopy within 24 hours of admission.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Portal hypertension is the most common complication of liver cirrhosis. (1) It may be complicated by gastrointestinal bleeding from oesophageal or gastric varices. (2) Treatment of varices can be medical by using non-selective beta blockers (as propranolol or cavedilol), or endoscopic (endoscopic variceal ligation EVL, endoscopic injection sclerotherapy EIS), or both. (3).
**Aims & Methods:** This study was conducted on 80 patients with liver cirrhosis and oesophageal varices (O.V.) grade III and IV, who were classified into five groups. Group I, 20 patients were subjected to EVL alone, group II, 20 patients received carvedilol alone (6.25 mg once daily, then increased to 6.25 mg twice daily after 1 week), group III received propranolol alone (20 mg three times daily), group IV, 20 patients who were subjected to EVL combined with carvidolol (6.25 mg once daily, then increased to 6.25 mg twice daily after 1 week) and group V, 20 patients who were subjected to EVL combined with propranolol (20 mg three times daily). All patients were followed up by doppler study of portal vein and upper G.I. endoscopy.
**Results:** Upper G.I. endoscopy was done for all patients every 3 months up to 12 months. In the 1st visit, 95% of group I patients had O.V. grade IV and 5% had grade III O.V., by the 4th visit 80% had O.V. grade I and 20% had no O.V. in the same group. In group II, in the 1st visit 90% of patients had O.V. grade IV and 10% had O.V. grade III, in the 4th visit 60% had O.V. grade I and 40% had no O.V., In group III, in the 1st visit 95% of patients had O.V. grade IV and 5% had O.V. grade III, in the 4th visit 50% had O.V. grade I and 30% had no O.V., In group IV, in the 1st visit 20% of patients had O.V. grade IV and 80% had O.V. grade III, in the 4th visit 40% had O.V. grade I and 60% had no O.V., regarding group V, in the 1st visit, 75% had grade IV O.V. and 5% had O.V. grade III, while in the 4th visit 60% had O.V. grade I and 40% had no varices.
**Conclusion:** The combination of carvedilol and EVL is more effective in treating medium and large sized O.V. than EVL alone or EVL combined to propranolol.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Acute upper gastrointestinal bleeding (UGIB) is the most common medical emergency managed by gastroenterologists. It accounts for 5% of presentations to the emergency department (ED) and 2% to 3% of hospital admissions. Overall mortality remains around 8%[1]. Several practice guidelines and risk scores, combining clinical and endoscopic parameters, have been developed to predict the outcomes of these patients. Their aim is to assist physicians in the early stages of decision making. In 2000, Blatchford developed a clinical score that predicts the need for treatment in acute UGIB[2]. The score ranges from 0 to 23 and the risk of requiring treatment increases with increasing score. Patients presenting to the ED with UGIB and a GBS score of 0 have been shown to be safe for discharge and can be managed in an outpatient setting. However, patients are routinely hospitalized.
**Aims & Methods:** We retrospectively studied all patients presenting to the emergency department with upper gastrointestinal bleeding over 3 years. We defined UGIB as hematemesis, melena, and/or rectal bleeding, the latest only if it was accompanied by anemia (haemoglobin $< 10$ g/dl) and/or syncope. Primary outcome was the need for clinical intervention: blood transfusion, endoscopic, radiological or surgical intervention. We assessed the accuracy of the Glasgow Blatchford scoring system by plotting its receiver-operating characteristic (ROC) curve.
**Results:** We included 257 patients in final analysis. A total of 50.2% patients received one or more transfusion with packed red blood cells, fresh-frozen plasma and/or platelet concentrates. Sixty three (24.5%) patients underwent endoscopic hemostasis. Six patients (2.3%) underwent emergency surgery and 7 (2.7%) received interventional radiology. Mean GBS was 9.4 ($\pm$4.1). No patient who needed clinical intervention (blood transfusion, endoscopic, surgical, or radiologic management) was not identified by the GBS. The area under ROC curve reaches 92.3%. Thirty nine (15.2%) patients had a GBS $\leq 4$. None of them needed intervention.
**Conclusion:** We validated the Glasgow Blatchford score in the setting of a Belgian university hospital. Given its high sensitivity, it is probably the safest scoring system to predict the need for treatment of patients presenting to the emergency department with symptoms of acute upper gastrointestinal bleeding. To reduce unnecessary admissions, a cut-off value of $\leq 4$ can be used safely and effectively in our institution as it predicts the need for clinical intervention with 100% sensitivity.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0435 APPROACH OF REBLEEDING IN UPPER GASTROINTESTINAL NON-VARICEAL HAEMORRHAGE

M. Ilie[1], V. Sandru[2], **A. Constantin**[3], D. Tabacelia[2], I. Moroi[2], G. Constantinescu[2]
[1]*Dept. Of Gastroenterology, Clinical Emergency Hospital Bucharest, Bucharest/Romania*
[2]*Gastroenterology, Clinical Emergency Hospital Bucharest, Bucharest/Romania*
[3]*Clinical Emergency Hospital Bucharest, Bucharest/Romania*

**Contact E-mail Address:** drconstantinalina@gmail.com.
**Introduction:** Upper gastrointestinal bleeding (UGIB) represents a common and challenging emergency for gastroenterologists. The morbidity and mortality of upper GI bleeding remains high in patients with recurrent bleeding or significant co-morbid illnesses.
**Aims & Methods:** Aim The aim of this study is to assess the factors associated with rebleeding rate in upper GI non variceal haemorrhage especially: the aetiology, presence of comorbidities, type of treatment and final outcome. Methods We have performed a retrospective analysis of the patients admitted with upper GI non-variceal haemorrhage and rebleeding between 2014–2016 in Clinical Emergency Hospital Bucharest. We have used resuscitation methods at presentation, blood transfusions, intravenous PPI, endoscopic hemostasis and surgical treatment when needed.
**Results:** We had in total 1600 cases of upper GI non-variceal haemorrhage with 71 cases of recurrence. The mean age of the patients was 60. Also, 84.5% of the patients with rebleeding presented comorbidities. The mean value of Rockall score was 6. The causes of rebleedings were represented by: duodenal ulcers in 34% of cases (size over 1 cm, active bleeding, visible vessels), gastric ulcers 17%, anastomotic ulcers 16%, Dieulafoy's lesions 13%, duodenal angiodysplasia 4%, tumors 8%, Mallory Weiss lesions 4%, esophageal ulcers 3% and post sphincterotomy 1%. The type of endoscopic hemostasis used was combined in the majority of cases: injection, bipolar coagulation and hemoclips and successful in 84.6% of the cases. The average of repeated endoscopic hemostatic procedures was 3 but the highest number (4) was represented for Dieulafoy's lesion. Surgery was required in the rest of the cases (15.4%) for giant gastric ulcers, tumors, penetrating duodenal ulcers and spurting Dieulafoy's lesions. We had a mortality of 14% for the rebleeding group, most of them because of comorbidities and only 2 cases due to postoperative complications.
**Conclusion:** Repeated endoscopic hemostatic therapy for recurrent upper GI non-variceal bleeding (after successful initial endoscopic control of haemorrhage) represents the optimal choice with favourable results (84.6%). Patients at high risk, with increased value of Rockall score should be closely monitored for rebleeding. Multidisciplinary care, including endoscopists, surgeons, anaesthesiologists represents the best approach of upper GI non-variceal bleeding especially for recurrences.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0436 AMBULATORY HIGH RESOLUTION OESOPHAGEAL MANOMETRY: A NOVEL TOOL TO INVESTIGATE NONCARDIAC CHEST PAIN

**E. Yazaki**, P. Woodland, J. Ooi, F. Hughes, S. L. Preston, D. Sifrim
*Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London/United Kingdom*

**Contact E-mail Address:** e.yazaki@qmul.ac.uk.
**Introduction:** Non-cardiac chest pain can present a clinical challenge to the gastroenterologist. Many causes remain undiagnosed and untreated.
Oesophageal spasm is frequently considered a cause of non-cardiac chest pain, but current diagnostic tools are often poor at making this diagnosis. High resolution oesophageal manometry is now the gold standard oesophageal motility test, and is a swallow-based assessment. Unfortunately most episodes of chest pain in this context are not swallowrelated, and are usually sporadic and unpredictable. Thus most manometry assessments occur in the absence of a symptom event.
We propose that prolonged, ambulatory high resolution may be a tool that can detect these sporadic chest pain events and allow correlation to symptom episodes.
**Aims & Methods:** We aimed to test the diagnostic yield of a novel, ambulatory high resolution oesophageal manometry device in the diagnosis of non-cardiac chest pain. We studied 17 patients (7 male, 10 female, age range 14 to 66) with chest pain. All had cardiac pain excluded by cardiology review, and all had been studied with normal upper GI endoscopy. All had also had major oesophageal motor disorder (including spasm) excluded by swallow-based high resolution manometry (with liquid and solid swallows). An ultra-thin high resolution solid-state catheter (Unisensor) was inserted transnasally into the oesophagus. This was connected to a small laptop and battery pack carried in a backpack (recording device an software, MMS). Patients were sent home and encouraged to mobilise. Patients were asked to keep the catheter in place at least until a symptomatic pain event was perceived. Symptom events were self-marked on a recorder device that was subsequently synchronised with the manometry output. Manometry tracings were read manually, and motor events at the time of symptoms were examined in detail.
**Results:** The median duration of recording with the system was 12 hours, 13 minutes (range 5 hours, 30 minutes to 26 hours, 40 minutes). 12 of the 17 patients perceived typical chest pain symptom during recording. Of the 12 with typical symptoms, 3 (25%) had clinically important findings that changed management. They had significant oesophageal spasm, pressurisation and shortening associated with pain events. These have been treated successfully with oesophageal body Botox injections (2 patients) and with long laparoscopic myotomy (1 patient). The remaining 9 patients either had no abnormalities, or minor abnormalities that did not correspond to symptoms.
**Conclusion:** Ambulatory high-resolution manometry is a novel tool for investigation of non-cardiac chest pain. In our series, we identified management-altering abnormalities in 3 of 17 (18%) patients who had previously been investigated with normal cardiac, endoscopic and stationary manometric evaluation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0437 HETEROGENEITY IN HIGH RESOLUTION MANOMETRY (HRM) AND AMBULATORY PH TESTING AROUND THE WORLD IN 2015

**R. Sweis**[1], M. Fox[2]
[1]*Gi Medicine, University College London Hospital, London/United Kingdom*
[2]*Department Of Gastroenterology, St. Claraspital, Basel/Switzerland*

**Contact E-mail Address:** dr.ramisweis@gmail.com.
**Introduction:** Despite advances in HRM and pH monitoring there is wide variation in technique and technology while reporting is often subjective and open to interpretation. This study assesses current practice around the world.
**Aims & Methods:** Through an on-line platform (Qualtrics LLC), a survey was distributed to unselected oesophageal units through international NGM societies. Questions explored infrastructure, technology, analysis and reporting. Results are presented as % of the total or mean ± SD.
**Results:** 91 of 102 responses from 29 countries were analysable (Table). 43 High (HVC) and 48 Low Volume Centres (LVC) were defined as more and less than 500 referrals/year. HVC employ more staff than LVC ($p = 0.02$) with more clinicians ($3.0 \pm 1.0$ vs. $2.6 \pm 1.2$; $p = 0.05$), physiologists ($1.6 \pm 1.1$ vs. $2.0 \pm 1.3$; $p = 0.07$) and nurses ($3.3 \pm 1.2$ vs. $2.4 \pm 1.1$; $p < 0.001$). Most units (63/91;69%) stop medication. 18 (20%) use $<12$ sensor manometry, 75 (82%) $>26$ sensor HRM and 53 (58%) use HRM-Impedance (some had several systems). Adjunctive testing is increasingly incorporated (Table). To define pathology, Chicago Classification is used in 65 (71%) units. 60% comment on the upper sphincter. In the presence of a hiatus hernia analysis of oesophago-gastric junction morphology varies widely (p = NS). 64% proceed with pH-monitoring despite ≥Grade B oesophagitis. If intolerant of the catheter, 45% refer for catheter-free monitoring and 16.5% for barium; 14% do nothing further. HVC are more likely to employ catheter-free systems than LVC (47% vs. 17%; $p < 0.001$). Of 86 (95%) units with Impedance-pH (Imp-pH), studies are performed on acid suppression in 54% with oesophagitis/Barrett's. Overall, 8% perform all Imp-pH studies on therapy, 9% never do. Dietary modification (acid avoidance) is always recommended in 48%. Meals/snacks are not analysed in 91% units with standard pH and 84% with Imp-pH. Overall 17% do not exclude meals with either. 75% manually analyse every Imp-reflux event while 59% only target symptoms. For symptom-association, 30% units pool symptoms while 74% analyse each separately. Therapy advice is included in 49% HVC and 31% LVC ($p = 0.044$); 40% overall.

| | Adjunctive Tests | Single Solid/ Viscous | Multiple water | Meal | Upright-seated swallows |
|---|---|---|---|---|---|
| Europe (n = 45) | 43 (96%) | 31 (69%) | 38 (42%) | 11 (24%) | 18 (40%) |
| USA (n = 14) | 10 (71%) | 6 (43%) | 7 (50%) | 3 (21%) | 6 (43%) |
| S. America (n = 8) | 9 (100%) | 5 (56%) | 7 (78%) | 0 (0%) | 5 (56%) |
| Australia/NZ (n = 12) | 11 (92%) | 10 (83%) | 8 (67%) | 2 (17%) | 6 (50%) |
| Asia (n = 5) | 6 (100%) | 3 (50%) | 6 (100%) | 1 (17%) | 2 (33%) |
| Africa/Middle East (n = 6) | 5 (100%) | 2 (40%) | 4 (80%) | 0 (0%) | 1 (20%) |
| Total (n = 91) | 84 (92%) | 57 (63%) | 70 (77%) | 16 (18%) | 38 (42%) |

**Conclusion:** There is marked heterogeneity in methodology, interpretation and presentation of HRM and pH studies around the world. This survey sets the background from which agreement of standard operating procedures can begin.
**Disclosure of Interest:** R. Sweis: Symposium funded by Given Img.

**Contact E-mail Address:** helenefoisy@yahoo.fr.

**Introduction:** Per oral endoscopic myotomy (POEM) is an emerging minimally invasive procedure for the treatment of achalasia. However the precise technique can be refined and the hook knife can be used to precise the myotomy. We evaluated its results in the 132 first patients of our institution.

**Aims & Methods:** All consecutive cases referred for POEM using the Hook Knife for the myotomy were included. The database was completed prospectively. Clinical evaluation (Eckardt score) was realized before the procedure and after procedure at 3 and 12 months. All patients underwent high-resolution manometry (HRM) before procedure and 3 months later to classify achalasia according to Chicago classification.

**Results:** 132 patients (75 men, mean age 53 years) were included. Typical achalasia represented 117 cases (type I :13, II: 81, III :23), Jackhammer esophagus 1 case, and it was not possible to pass the manometry cathter through the esophago-gastric junction (EGJ) in 13 patients. Ninety one patients did not receive any previous treatment, 23 underwent pneumatic dilation, 12 Heller myotomy, 2 botulinum toxin injection and pneumatic dilation, 1 botulinum toxin injection alone and 3 patients a previous POEM. Procedure was incomplete in 8/134 (6%) cases: 3 for several submucosal fibrosis, 2 for mucosal injury of the tunnel in the cardia, 1 for diverticulum on the tunnel way, 1 for peptic ulceration and 1 for food stasis (success during the second attempt two weeks later). Procedures were complete in 126 other cases (93.9%). Dual Knife ® (n = 115) or the water jet Nestis Enki 2 ® (n = 11) were used for the tunnel. No mucosal injury was observed with the water-jet system. Hook Knife ® was used for all the myotomies and allowed a precise circular myotomy. The average time of procedure was 76.1 min with a clear learning curve (155–23 min). A pneumoperitoneum was exsufflated with a needle during the procedure in 70 cases (53.1%), we noticed subcutaneous emphysema in 39 (29.5%) cases, without any visible perforation. The 23 first patients were explored by systematic CT scan at day 1 with a pneumomediastinum (n = 20/23), a pneumoperitoneum (n = 20/23) and/or a pneumothorax (n = 7/23). Two (1.5%) patients presented a hematoma of the tunnel, diagnosed with pain and aphagia, one at day 1 and the other at day 5 without any other bleeding. Those hematoma were treated conservatively. No sepsis was observed. Feeding was always possible with liquids at day 1. Nine patients were discharged at day 1 without any further adverse events. All patients noted a clinical improvement. Three months after POEM (available for 87 patients) mean Eckardt score was 1.3 (0–7) versus 7.2 (3–12) before ($p < 0.001$). The EGJ resting pressure significantly decreased (7.9 mmHg (0–39) versus 26.8 mmHg (2–81) before POEM, $p < 0.001$) as well as integrated relaxation pressure (7.8 mmHg (0–24) versus 23.7 mmHg (3–79) before POEM, $p = < 0.001$).

**Conclusion:** Myotomy with hook knife is very precise, safe and effective. Only 2 hematoma of the tunnel were observed on the 134 cases. Due to the low rate of adverse events, we now recommend a discharge at the day after the myotomy; CT scan is no longer peformed systematically but only in case of symptoms.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0439 ENDOSCOPIC PYLOROMYOTOMY VIA GASTRIC SUBMUCOSAL TUNNEL DISSECTION: A PROMISING TECHNIQUE FOR GASTROPARESIS

K. He, L. Liu, M. Wang, X. Wang, **Z. Fan**
*Digestive Endoscopy Center, the First Affiliated Hospital of Nanjing Medical University, Nanjing/China*

**Contact E-mail Address:** fanzhining@njmu.edu.cn.

**Introduction:** Pyloroplasty has been the most common treatment for the pyloric diseases. But it is still associated with complication of leakage, post-operational stenosis and general anesthesia. Therefore, the development of minimally invasive but reliable method is highly desired. Inspired by the peroral endoscopic myotomy to treat achalasia, the novel technique of endoscopic pyloromyotomy has been designed. The aim of this study is to investigate the feasibility and efficacy of endoscopic pyloromyotomy via gastric submucosal tunnel dissection.

**Aims & Methods:** The 5 pigs were studied for the procedure. The pyloromyotomy via the submucosal tunnel dissection was performed as the follows: (1) the incision site of mucosa was defined on the posterior gastric antral wall 5cm proximal to the pylorus; (2) saline solution mixed with norepinephrine and methylene blue was topically injected for submucosal lifting; (3) 1-2cm mucosal incision in longitudinal length was made to create the submucosal tunnel entry; (4) The submucosal layer was carefully disassociated until pyloric muscular layer was identified; (5) 1-2cm pyloromyotomy were performed; (6) After endoscope withdrawal, mucosal defect were closed with clips. Pigs were euthanized and necropsies were performed.

**Results:** Dissection of pylorus muscle was successful in the pigs. Bleeding was limited during the procedure. No complication of perforation was observed.

**Conclusion:** The endoscopic gastric submucosal tunnel dissection technique was feasible and effective for pyloromyotomy. It is also easy to perform and minimally invasive for clinical application. Further studies need to perform for confirming the safety and efficacy on the human, and the clinical advantages other than traditional techniques.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0440 OPTIMAL NUMBER OF MULTIPLE RAPID SWALLOWING DURING HIGH RESOLUTION OESOPHAGEAL MANOMETRY

**Introduction:** Low volume (10 ml) multiple rapid swallowing (MRS) has been proposed as additional test during oesophageal high resolution manometry (HRM) in order to assess pathophysiological alterations of clinical relevance. Generally one sequence is performed, however we have recently shown[1] that it is not reliable regarding presence of the after contraction and its strength.

**Aims & Methods:** To determine the optimal number of MRS in order to assess the peristaltic function. This is an interim analysis of an ongoing study. Thirty-five consecutive patients who underwent HRM were prospectively enrolled. Twenty-two had normal motility and 13 had ineffective esophageal motility (IEM) diagnosed according to Chicago 3 classification. The HRM protocol consisted in: five single five ml swallows (SS), five MRS followed by another five SS and five MRS. Measures were as follows: a) highest value of DCI (DCImax) during SS and MRS respectively, b) number of SS and MRS needed to detect DCImax, c) minimum number of MRS needed to detect MRS/SS DCI ratio > 1 (i.e. peristaltic reserve), d) minimum number of MRS needed to detect DCI > 450 mmHg.s.cm. in severe IEM (patients where all SS had a DCI < 450 mmHg.s.cm). Chi squared test and Wilcoxon test were used when appropriate.

**Results:**

| | All patients | IEM (13) | Normal motility (22) | P value * |
|---|---|---|---|---|
| Number of SS to detect DCImax | 5; 1–10 | 7; 2–10 | 5; 1–8 | 0.03 |
| Number of MRS to detect DCImax | 4; 1–10 | 4; 2–6 | 4.5; 1–10 | 0.5 |
| Number of MRS to detect MRS/SS DCI ratio > 1 | 1; 1–4 | 1; 1–4 | 1; 1–4 | 0.81 |

Data expressed as median; $10^{th}$–$90^{th}$.* IEM vs normal motility Results, median ($10^{th}$ to $90^{th}$ percentile), see table: In IEM patients DCImax during MRS was higher than during SS (1098; 657–1760 vs 741; 399–930; $p = 0.019$) whereas it was not different in patients with normal motility (2439; 1886–5002 vs 2302; 1719–5231); $p = 0.36$). A highly variable number of sequences of both MRS and SS were needed in order to identify DCImax. 12/13 IEM and 14/22 normal motility patients had a peristaltic reserve, which was detected within three and four sequences of MRS respectively ($90^{th}$ percentile). The first MRS sequence detected peristaltic reserve in seven IEM and nine normal motility patients, that is only 58% and 64% of all patients with peristaltic reserve in both groups. Patients who had severe IEM (5/13) reached a DCI > 450 mmHg.sec.cm with the first MRS (3/5) or never (2/5).

**Conclusion:** In a cohort of patients with oesophageal symptoms the number of MRS needed to reach DCImax was quite variable, however peristaltic reserve was reliably detected within three to four MRS sequences and ability to produce an effective wave (DCI > 450) in severe IEM was detected at the first MRS sequence. Our data suggest that four MRS sequences should always be performed.

## P0441 MOTILITY AND OESOPHAGEAL CLEARANCE IN BARRETT'S OESOPHAGUS

**R. Sweis**[1], A. Raeburn[2], E. Athanasakos[2], N. Zarate-Lopez[2], L.B. Lovat[1], R.J. Haidry[1], M. Banks[1], A. Emmanuel[2]

**Introduction:** It is not clear if Barrett's is a consequence of excessive reflux only or reduced clearance of refluxed materials. This study compares oesophageal reflux over 24 hours and High Resolution Manometry (HRM) response to solids in Barrett's with non-Barrett's reflux (NBR).
**Aims & Methods:** Reports for 19 consecutive patients (M58:F14) with ≥2 cm Barrett's during 2015 were compared with 25 patients with NBR (M10:F16) and 22 patient controls with normal physiology/endoscopy (M6:F16). All had at least one typical symptom of heartburn, regurgitation or chest pain. All had HRM with the intention of completing 10 × 5cc water and 5 × 1cc bread. Contractile vigour was measured with the Distal Contractile Integral (amplitude x length x contraction time); DCI > 450 mmHg.cm.s and breaks in peristalsis of < 5 cm were considered the lower limit of normal contraction as per Chicago Classification 3.0. Standard reflux and impedance parameters were assessed. 11/19 Barrett's were on while all NBR were off treatment.
**Results:** Lower oesophageal sphincter pressure was lower in Barrett's (8 vs. 14 mmHg; p = 0.009). Compared to NBR, patients with Barrett's (2–10 cm) had significantly reduced DCI for both 5 ml water (318 vs. 650 mmHg.cm.s; p = 0.007) and solid (1096 vs. 2002 mmHg.cm.s; p = 0.009). On the other hand, the likelihood of measuring a DCI of > 450 was significantly reduced in Barrett's only with solids (69% vs. 100%; p < 0.001) not water (32% vs. 54%; p = 0.224). Peristaltic effectiveness based on HRM was also reduced only for solids (44% vs. 65%; p = 0.029). All reflux parameters were similar between the two groups: total (p = 0.116), upright (p = 0.233) and supine reflux (p = 0.110), symptom index (p = 0.16), symptom association probability (p = 0.106) and total number of reflux events (p = 0.063). On the other hand, bolus clearance time (BCT) was significantly prolonged for Barrett's (13 vs. 10 s; p = 0.009) solely due to prolonged supine BCT (14 vs. 10 s; p < 0.003). Bolus exposure time (BET) was significantly prolonged for Barrett's (p = 0.011) due to both daytime (4.49% vs. 1.73%; p = 0.015) and nocturnal BET (0.75% vs. 0.24%; p = 0.002). Comparing those with prior endoscopic Barrett's therapy (n = 6) with treatment naïve (n = 13), there was no difference in any motility or pH monitoring parameter apart from BET which was greater in those who received therapy (5.87% vs. 1.99%; p = 0.046).
**Conclusion:** Solids were superior to water swallows in demonstrating ineffective contractility in Barrett's. This was associated with reduced nocturnal oesophageal clearance and increased exposure to refluxate during the day/night. These findings contribute to the theory of impaired contractility and reduced clearance despite acid-reducing medication in Barrett's.

**Contact E-mail Address:** wangkun55555@sina.com.
**Introduction:** According to the Chicago criteria version3, patients with esophageal hypertensive peristalsis of DCI between 5000 to 8000 mmHg.s.cm were definite as "normal". However, many of such patients presented symptoms such as dysphagia, chest pain, et al.
**Aims & Methods: Aims**: To compare the clinical symptoms, esophagography and esophageal motility characteristics between Jackhammer esophagus and other esophageal hypertensive peristalsis, and to analyze the clinical diagnose value of patients with EHP.
**Methods**: All patients underwent esophageal manometry were screened from Jan1st 2012 to Apr 1st 2015. The patients with esophageal hypertensive peristalsis were enrolled in the study. All enrolled subjects underwent esophageal radiography. Part of the patients fulfilled the dysphagia questionnaire. We defined the hypertensive peristalsis area (HPA) as an area in 180 mmHg isobaric contour. The patients with HPA but not reaching the Jackhammer criteria were defined as other esophageal hypertensive patients (OEHP). The data were analyzed by SPSS17.0 software.
**Results:** sixty-four in 543 patients (11.8%) were found to have HPA. Among them, 15.63% were Jackhammer esophagus, and 67.2% were OEHP patients. Esophageal radiography showed 5 patients presented esophageal spasm in 10 Jackhammer, and 30.2% (13/43) OEHP patients showed esophageal spasm. No statistical differences were found between these two groups (P > 0.05). There were no significant differences in the symptoms, esophageal forms and LES functions between Jackhammer esophagus and OEHP patients (p > 0.05), except the peristalsis amplitude. The dysphagia questionnaire investigations were completed in 34 patients. There were negative correlations between solid food dysphagia frequency and esophageal DCI, the esophageal peristaltic amplitude 3 cm above LES, the esophageal peristaltic amplitude 3–7 cm above LES (r = −0.445, P = 0.008, r = −0.354) P = 0.040, r = −0.459, P = 0.006). Negative correlations were found between solid food dysphagia extent score and average DCI, amplitude 3–7 cm above LES (r = −0.349, P = 0.043; r = −0.400, P = 0.019).
**Conclusion:** (1) Patients with HPA were not uncommon. (2) Jackhammer esophagus and OEHP were considered to be two subgroups of a spectrum. It's valuable to give the OEHP a definite diagnosis and recommended for further treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0443 DOES BALLOON DILATATION AFFECT PER-ORAL ENDOSCOPIC MYOTOMY PROCEDURE?

**Introduction:** Per oral endoscopic myotomy (POEM) is a minimally invasive endoscopic treatment option for achalasia patients. The aim of the study is to evaluate whether previous history of failed balloon dilatation has any effect over POEM procedure in our clinic.
**Aims & Methods:** Between May 2014 and March 2016, 140 patients with achalasia who were naïve or previously endoscopically treated with pneumatic balloon dilatation underwent POEM. 134 of these patients with control endoscopy and high resolution manometry results were included into the trial. The procedure was carried out at the endoscopy unite in the gastroenterology clinic under general anesthesia by an endoscopist who was experienced at endoscopic submucosal dissection (ESD) and was educated for POEM. All POEM procedures were done with a triangle knife. Demographic data was recorded before the procedure and results of the procedure were recorded prospectively. Data of POEM procedure and demographics were compared between the balloon dilatation (BD) and naïve groups.
**Results:** 47 patients in BD group and 87 patients in Naïve group underwent POEM. There was no statistical difference between the groups regarding age, gender, tunnel and myotomy lengths, preoperative and postoperative Eckardt scores, total times of the procedure, rate of complications (p > 0.05). The median age of the patients was 42 (12–73) years. Preoperative and postoperative median Eckardt scores were 8 (5–12) and 0 (0–2) respectively. The median total time of the procedure was 52 (27–153) minutes, tunnel length 17 (12–27) cm and myotomy length was 14 (9–25) cm. Postoperative oral intake started at median 1 (1–2) day and length of stay was 5 (3–7) days. Capnoperitoneum developed during the procedure in 53 (39.4%) patients and was treated with veress needle. Mucosal perforation developed in 2 patients and was treated with endoscopic hemoclips successfully. 30 patients had esophagitis (26 Grade A, 3 Grade B, 1 Grade C) at control endoscopy in third month after the procedure.
**Conclusion:** We think that previous history of failed balloon dilatation in achalasia does not affect POEM procedure performed by an endoscopist experienced in advanced endoscopic techniques such as ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0444 ESOPHAGEAL SHORTENING IN HIGH RESOLUTION MANOMETRY: DOES IT MEAN ANYTHING?

**F. Estremera Arevalo**[1], I. Aresté Anduaga[1], A. Zúñiga Ripa[2], V. Fernandez De Pinedo[3], M. Fraile González[2], H. Leon[4], R. Iglesias Picazo[2], E. Albéniz Arbizu[5], S. Oquiñena Legaz[6]

**Contact E-mail Address:** festremera15@gmail.com.
**Introduction:** Esophageal shortening is an occasional finding on HRM secondary to longitudinal muscle contraction. Fluoroscopy and magnetic field associated to HRM established physiological shortening in 1.8 cm. It is not known whether > 2 cms oesophageal shortening has clinical relevance.
**Aims & Methods:** Patients with ≥ 2 cm shortening anytime during a HRM (MMS water perfused 22 channels) were identified between 454 consecutive procedures between 2013 and march 2016. We evaluated the HRM following Chicago v.3 criteria. Symptoms, demographic and manometric patters (included multiple swallows test) were compared with patients without shortening.
**Results:** 33 (7.3%) patients with ≥ 2 cm shortening were identified between 454 HRM. 11 (33%) of shortening group were male, not finding differences with control group (41%). 51.5% (17) of shortening group had "normal" HRMs and 4 patients had a Minor Peristaltic Disorder (Ineffective Esophageal Peristalsis). 5 patients had Achalasia diagnosis (4 type II and 1 type III). 3 were diagnosed of EGJ obstruction, 2 patients were diagnosed of Distal Esophageal Spasm, two were diagnosed of Rumination Syndrome and another patient had Jackhammer esophagus. Comparing with non-shortening, Major Motility Disorders were significantly more frequent (p 0.003) in shortening patients. No statistical differences were found in symptom pattern regarding heartburn, regurgitation, abdominal pain, pharynx discomfort, chronic cough, halitosis, asthma and conditions such as Functional Dyspepsia or Irritable Bowel Syndrome. However dysphagia was more frequent in shortening patients (p

0.027). Regarding EGJ (esophageal gastric junction), no differences were found in manometric sub types I, II or III prevalence between both groups. 21 of shortening patients were studied by 24 h pH/impedance test, being 9 abnormal. No differences seem to be present with the non-shortening group (38% abnormal pH/impedance). Multiple swallow test was pathological more frequently in shortening group (p 0.0001).

**Conclusion:** A larger proportion of Motility Disorders were found in patients with $\geq$ 2 cm oesophageal shortening finding in HRM. No statistical differences were found in symptomatic patterns except for dysphagia, more frequent in shortening group. Multiple swallow test is also pathological more frequently in shortening patients, probably explained by a more prevalent dysphagia. Esophageal shortening is a phenomenon that can be found in normal HRM. However, its association with Motility Disorders invites to register this finding and to pay special attention in these patients follow up.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0445 MACROPHAGE FUNCTIONAL ACTIVITY DEPENDING ON THE REFLUXATE TYPE IN GASTROESOPHAGEAL REFLUX DISEASE

**Introduction:** Gastroesophageal reflux disease (GERD) is one of the most common clinical problems in daily practice and is associated with active mucosal inflammation including a moderate infiltration of macrophages in esophageal mucosa. The modern understanding of the cell and molecular pathogenesis of GERD-associated mucosal inflammation suggest a complex and multifactorial immune-mediated effects of the recurrent exposure of the esophagus to acidic and nonacidic refluxate of gastric contents (containing duodenal and intestinal proteases as well as acid and gastric pepsin) from the stomach.

**Aims & Methods: Aim**: to assess the change of macrophage activity inclusive of phenotype according to the refluxate type.

**Material and methods**: Macrophage phenotype activity was assessed in vitro by adding acidic and nonacidic refluxates of patients (n = 26) with different pH (4.6–6.6, n = 10; 6.7–7.2, n = 10; 7.3–8.1, n = 6) to peritoneal macrophages of C57/BL6 mice (n = 26) with the following macrophage culturing in standard conditions (10% FBS, RPMI1640) for 36 hours. Pooled analysis of macrophage phenotype included assessment of Th1/Th2 cytokine production in culture medium (Antigenix America, Mouse Th1/Th2/Th17 (18-Plex Panel)), typical M1/M2 surface macrophage CD markers (monoclonal antibodies CD25, CD80 and CD163, CD206, respectively) performed by flow cytometry (Beckman Coulter FC500).

**Results:** In groups of comparison with pH 4.6–6.6 and 6.7–7.2 analysis of cytokine production revealed the prevalence of Th1 inflammatory and Th1/Th2 bivalent cytokines production. The indices of Th1/Th2 summary cytokine production were 3.6 and 2.8, respectively. The most expressed changes were observed in the levels of IL1b, IL-8, IL-6 and TNF-a ($41.4 \pm 6.8$ vs $33.6 \pm 5.1$ pg/ml; $68.3 \pm 5.9$ vs $42.8 \pm 5.1$pg/ml; $75.4 \pm 6.9$ vs $52.1 \pm 5.6$ pg/ml; $23.5 \pm 1.8$ vs $18.7 \pm 1.6$ pg/ml, respectively; $p < 0.05$). In the group of pH 7.3–8.1 the index of Th1/Th2 cytokine production was 1.6, indicating the elevated concentrations of Th2 cytokines as compared to the other experimental groups. The most expressed changes were observed in IL-10: $27.7 \pm 2.6$ pg/ml in 7.3–8.1pH vs $16.2 \pm 1.8$ and $4.2 \pm 0.6$ pg/ml in 6.7–7.2 and 4.6–6.6 pH groups, respectively ($p < 0.05$). The expression of surface M1/M2 macrophage CD markers significantly varied. In 6.7–7.2 pH group the ratio of M1/M2 (CD25+CD80/CD163+CD206) CD markers expression was 1.9 and in 7.3–8.1 pH group M1/M2 index was 1.2.

**Conclusion:** Assessment of macrophage phenotype activity depending on pH of the GERD refluxate showed the prevalence of M1 (Th1) proinflammatory activated macrophages with increased expression of M1 surface markers (CD80, CD25) and predominantly increased production of Th1 cytokines (IL-1 b, IL-8, TNF-a) in the cells exposed to acid refluxate. The effect of mild-alkalotic refluxate also turned in M1 (Th1) macrophage phenotype but with the distinct trend of M2 (Th2) CD markers and Th2 cytokine production increasing as compared the other groups.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0446 IMPAIRED MUCOSAL INTEGRITY IS PRESENT IN SOME REFRACTORY GORD PATIENTS: THE RELEVANCE OF THE REFLUXATE

**Introduction:** Clinical manifestations of gastro-oesophageal reflux disease (GORD) are known to result from prolonged contact of gastric acid with the oesophageal epithelium. It is commonly believed that the acidity of the refluxate is the major responsible agent altering tissue integrity and provoking symptoms. Nevertheless, over 30% of patients with GORD symptoms do not have pathological reflux. Based on the current pathophysiology we believe that oesophageal integrity plays an important role in symptom perception.

**Aims & Methods:** In this study we evaluated oesophageal mucosal integrity and its interaction with different reflux parameters in patients with typical GORD symptoms refractory to proton pump inhibitor (PPI) therapy. Twenty nine patients with typical refractory GORD symptoms, off PPI treatment during 2 weeks and 20 healthy volunteers (HV) were included in the study. Endoscopy and 24 h multichannel-intraluminal impedance (MII-pH) measurements were performed in both groups. Oesophageal biopsies were collected 3–5 cm above the lower oesophageal sphincter and mounted in Ussing chambers to evaluate transepithelial electrical resistance (TEER) and passage of fluorescein (Fl) in vitro. After the endoscopy, a MII-pH catheter was placed transnasally and 24 h recordings were performed to investigate the following reflux parameters: acid exposure (% time), total number of reflux events, number of acid and non-acid reflux events and total volume exposure. Furthermore, symptom association probability (SAP) and Symptom Index (SI) were calculated. These parameters were correlated with TEER and passage values. Data are presented as mean±SD and were analyzed using t-tests, a p-value $< 0.05$ was considered statistically significant.

**Results:** Based on SAP and SI scores our cohort consisted of 7 true GORD, 6 hypersensitive and 13 functional heartburn patients. A substantial overlap and variability was found in TEER and passage values both in HV and patients. A significantly lower TEER ($182.8 \pm 79.$ 6 Ωxcm$^2$ vs $238.1 \pm 70.2$ Ωxcm$^2$, $p = 0.0069$) and higher passage ($57.01 \pm 9.3$ pmols vs $21.83 \pm 3.4$ pmols, $p = 0.0022$) was found in GORD patients compared to HV. Despite the differences in permeability measures, no correlations between oesophageal integrity (TEER and passage) and reflux parameters of interest could be found (Table 1). Based on the 95$^{th}$ percentile, subgroups of patients with normal and hyper-permeability were made. Increased permeability to Fl was found in 14/29 GORD patients. However, in these subgroups no differences were found between reflux parameters. The proportion of patients with a positive SAP and/or SI was similar in the normo- and hyperpermeability subgroups.

**Table 1:** Correlation between TEER and passage and reflux parameters in refractory GERD patients off PPI.

| | Acid exposure (% time) | Total nr of reflux | Nr of acid reflux | Nr of non-acid reflux | Total volume exposure (% time) |
|---|---|---|---|---|---|
| **TEER** | | | | | |
| r-value | 0.000305 | −0.2566 | −0.1558 | −0.2443 | −0.07 |
| p-value | 0.9988 | 0.1964 | 0.4376 | 0.2195 | 0.717 |
| **Passage** | | | | | |
| r-value | −0.2151 | 0.0992 | −0.03183 | 0.301 | −0.06 |
| p-value | 0.2913 | 0.6297 | 0.8773 | 0.1351 | 0.763 |

**Conclusion:** Despite the impaired integrity found in refractory GORD patients, none of the reflux parameters were associated with oesophageal integrity, and this was the case both in patients with normo- and hyperpermeability. The lack of association with acid reflux and other reflux parameters strongly suggest that other factors besides number and acidity of reflux events may play an important role in the pathophysiology of refractory GORD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0447 DUODENAL EOSINOPHILIA AND POSTBRANDIAL DISTRESS SYNDROME ARE ASSOCIATED WITH AN INCREASED RISK OF NEW ONSET GASTROESOPHAGEAL REFLUX IN FUNCTIONAL DYSPEPSIA: PROSPECTIVE TEN YEAR FOLLOW-UP OF THE KALIXANDA STUDY

**Introduction:** Functional dyspepsia (FD) and gastroesophageal reflux disease (GERD) overlap more than expected by chance. One subtype of FD, postprandial distress syndrome (PDS) has been linked to impaired fundic accommodation which potentially can induce increased transient lower esophageal sphincter relaxations and GERD. Also, duodenal eosinophilia has been linked to functional dyspepsia (FD).[1, 2] However, the link between FD and GERD is not fully understood.

**Aims & Methods:** Our aim was to identify if there is an association between duodenal eosinophilia and FD, the subtypes of postprandial distress syndrome (PDS) and epigastric pain syndrome (EPS) (Rome III definition) and new onset gastroesophageal reflux symptoms (GERS) in a population-based follow-up study. We also evaluated whether baseline GERS is linked to new onset FD. Methods: Participants (n = 3000) were randomly selected from the national Swedish population register and surveyed in 1998 by a validated abdominal symptom questionnaire (ASQ). 1000 individuals randomly selected completed esophagogastroduodenoscopy in 1999–2001. All eligible from the endoscoped cohort (n = 887) were invited to a follow-up study in 2010 with the ASQ. In a subsample of 175 subjects, eosinophil counts by histology[1] from the duodenum were evaluated at baseline. Data were analyzed by chi square test, Fishers exact test and logistic regression.

**Results:** Of 887 subjects at follow-up, in total 703 (79.3%) completed the questionnaire. FD was reported by 110 subjects (15.6%) at baseline (87 PDS and 35 EPS, overlap in 12) and by 93 (13.3%) at follow-up (79 PDS and 21 EPS, overlap in 7); overlap in 45 between baseline and follow-up; in total 158 subjects with FD. GERS without organic disease was reported by 185 subjects (26.3%) at baseline and by 203 subjects (28.9%) at follow-up (overlap in 128); in total 260 subjects, of whom 77 had developed new onset GERS at follow-up. PDS with no overlapping GERS (n = 34) at baseline was associated with new GERS at follow-up (13/77 vs. 21/626, $p < 0.001$, OR 5.66, 95% CI 2.68–11.98), but EPS (also without overlapping GERS, n = 13) was not (3/77 vs. 10/626, p = 0.16, OR 2.50, 95% CI 0.66–9.49), Table. Of the 127 subjects with baseline eosinophil counts from the duodenum, FD was reported by 29 subjects (22.8%, 95% CI 15.4–30.2) at baseline (24 PDS and 10 EPS, overlap in 5) and by 22 (17.3%, 95% CI 10.4–24.0) at follow-up (20 PDS and 3 EPS, overlap in 1); overlap in 10 between baseline and follow-up (41 subjects with FD). GERS (no organic disease) was reported by 19 subjects (16.2%, 95% CI 9.5–23.0) at baseline and by 36 subjects (30.8%, 95% CI 22.3–39.2) at follow-up (overlap in 14); 41 subjects, of whom 22 had developed new onset GERS at follow-up. Change from PDS with no overlapping GERS (n = 16) at baseline to new onset GERS at follow-up (8/22 vs. 8/105, p = 0.001) was associated with duodenal eosinophilia, OR 17.96; 95% CI 2.0 – 161.4, but EPS (n = 8, 3/22 vs. 5/105, p = 0.14) was not, OR 0.6; 95% CI 0.05 – 7.53. In contrast, baseline GERS without baseline FD was not associated with new onset FD (2/22 vs. 9/105, p = 1.0).

PDS at baseline and new onset reflux at 10 years, Age categorized at 60 years, PPI use during the last 3 months, *H. pylori* positive on culture/histology (n = 703)

| | OR | 95% CI |
|---|---|---|
| New onset reflux at 10 years | 5.66 | 2.68–11.98 |
| Gender | 1.04 | 0.50–2.18 |
| Age | 0.80 | 0.38–1.68 |
| PPI | 2.95 | 0.93–9.38 |
| *H. pylori* | 1.05 | 0.48–2.33 |
| Alcohol > 100 g/week | 0.55 | 0.12–2.43 |
| Smoking | 1.56 | 0.66–3.70 |

**Conclusion:** Duodenal eosinophilia is associated with an 18-fold increased risk of new onset GERS at 10 year follow-up in those with FD and PDS at baseline but not EPS. PDS but not EPS has been linked to gastric disaccommodation[3]. Duodenal eosinophilia may thus explain the link between GERD and FD via impaired gastric accommodation and increased transient lower esophageal sphincter relaxations[3], suggesting FD and GERD are part of the same disease spectrum. Our novel hypothesis that duodenal eosinophilia impairs gastric accommodation and predisposes to GERD is further supported by the fact that baseline GERS was not associated with new onset FD.

**Introduction:** High-resolution manometry (HRM) provides a better representation of the esophagogastric junction (EGJ) isolating the crural diaphragm (CD) from the lower esophageal sphincter (LES). According to the Chicago Classification (CC), three different EGJ subtypes can be detected based on the separation between the LES and the CD. However, few concerns have been raised about the possibility to describe a dynamic structure like the EGJ by a single snapshot taken at the beginning of the test.

**Aims & Methods:** We aimed to assess whether EGJ morphology may vary during the standard manometric protocol and after esophageal stimulation and body change position. Consecutive patients with esophageal symptoms presenting to different motility laboratories in Italy were enrolled. Patients underwent upper endoscopy off-therapy and solid state HRM with the following protocol: 5-min baseline recording after probe introduction, 10 single water swallows (WS, 5 mL), 2 multiple rapid swallows (MRS, five 2 mL water swallows 2–3 s apart), change of body position (seated) and multiple water swallow (MWS, 200 mL of water using 'multiple rapid swallows' without stopping). Tracings were analyzed based on CC vers. 3 and EGJ morphology was assessed after each step as: Type I, no separation between the LES and the CD; Type II, > 1 and < 2 cm of separation; Type III, > 2 cm of separation. In case of reflux symptoms, patients also underwent pH (-impedance) testing off-therapy [abnormal if acid exposure time higher than 4.2% or number of reflux episodes greater than 54 or positive symptom-reflux association using symptom association probability (SAP+ if ≥ 95%) and symptom index (SI+ if ≥50%)].

**Results:** We enrolled 89 [52M/37 F; mean age 52 (18–82); mean BMI 25 (17–35)] outpatients. Based on CC, we identified 50 (56%) patients with EGJ Type I, 18 (20%) with EGJ Type II and 6 (7%) with EGJ Type III, in whom no EGJ changes occurred during standard manometric protocol or after esophageal stimulation or body change position. In contrast, we identified 15 (17%) patients in whom EGJ morphology varied after WS (n = 6), MRS (n = 3), body change position (n = 4) or MWS (n = 4). In particular, in 2 patients there was more than one change. All patients with EGJ variation who underwent pH- (impedance) monitoring had an abnormal test (7/9, 78%), whereas this phenomenon occurred only in 13 out of 34 (38%) patients with stable EGJ (p = 0.0591). Endoscopy did not vary between the two groups [abnormal in 4/15 (33%) with changed EGJ vs. 13/74 (18%) with stable EGJ, p = 0.1745].

**Conclusion:** Esophago-gastric junction morphology varies only in a minority of patients, suggesting that the single assessment at the beginning of the test has a high per patient reproducibility. On the other hand, EGJ changes occurring during HRM testing are associated with more objective evidence of GERD, thus confirming the major role of EGJ as anti-reflux barrier.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0449 INCREASED INTRA-BOLUS PRESSURE IS MORE COMMON IN PATIENTS WITH NON-CARDIAC CHEST PAIN THAN IN THOSE WITH HEARTBURN – A STUDY USING HIGH-RESOLUTION MANOMETRY

**Introduction:** The aetiology of Non-Cardiac Chest Pain (NCCP) is poorly known and different factors including esophageal motility abnormalities have been implicated. However, previous studies with conventional manometry failed to observe specific monometric features associated to NCCP. Indeed, hypercontractility of the esophageal body or rapid propagation of peristaltic wave were also common in asymptomatic subjects. High Resolution Manometry (HRM) is actually considered the ''gold standard'' to assess esophageal peristalsis and esophago-gastric junction (EGJ) function. Based on this technology, novel metrics have been developed to define esophageal motility abnormalities. Limited data are available in patients with NCCP.

**Aims & Methods:** We aimed to investigate whether patients with NCCP and reflux-related heartburn (RH) present different HRM features. We included consecutive patients with NCCP or RH as stand-alone symptom, referring to our motility laboratory. Patients with gastro-intestinal surgery, achalasia or scleroderma were excluded. Heartburn was considered reflux-related in case of complete symptom relief after at least 8 weeks of anti-secretory therapy. All patients underwent esophagogastroduodenoscopy off-antisecretory drugs (discontinued at least 30 days before the endoscopy) to assess the presence of esophageal mucosal lesions and HRM with 5-min baseline recording and 10 single water swallows. The diagnostic criteria for manometry agreed with the Chicago Classification vers. 3. Further, a normal IBP was defined in case of a mean value lower than 17 mmHg and therefore abnormal in case of a mean value $\geq$ than 17 mmHg. Data were expressed as mean and standard deviation.

**Results:** Between March 2014 and March 2015, we included 24 patients (9 Male/15 Female, $56 \pm 15$ years) with NCCP and 47 patients ($50 \pm 13$ years; 19 M/28F) with RH. No differences were found in terms of age, sex and BMI between the two groups ($p = ns$). Patients with NCCP had a mean IBP higher than patients with RH ($18.6 \pm 6.7$ vs. $14.1 \pm 4.7$; $p = 0.02$) and had more frequently an abnormal IBP value (13 vs. 11; $p = 0.0161$). On the other hand, mean DCI ($4148 \pm 18598$ vs. $1563 \pm 1083$; $p = 0.6$) and IRP ($7 \pm 8$ vs. $4 \pm 6$; $p = 0.06$) were similar between NCCP and RH, respectively. Also no differences were found in terms of mean distal latency, mean contractile front velocity, frequency of different manometric patterns and EGJ morphologies ($p = ns$). Only 1/24 patients (4%) of the NCCP patients had endoscopic evidence of GERD, whereas in the RH group the number of patients with erosive esophagitis was higher (13/47; 28%; $p = 0.02$).

**Conclusion:** IBP is the only HRM metric that differed between patients with NCCP and those with RH suggesting that NCCP elicitation could be more associated to abnormal EGJ compliance (i.e. abnormal bolus transit and EGJ dysfunction) rather than abnormal vigor of peristalsis or contractile velocity.

## P0450 PREVALENCE RATE OF TYPE OF GASTROESOPHAGEAL JUNCTION IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE (GERD) AND PATIENTS WITHOUT GERD

**A. Zúñiga Ripa**, F. Estremera Arévalo, M. Fraile González, I. Aresté Anduaga, R. Iglesias Picazo

**Contact E-mail Address:** albazuri@hotmail.com.

**Introduction:** High Resolution Manometry (HRM) allows to identify the different morphology of the esophagogastric junction (EGJ). In type EGJ I, diaphragm and lower esophageal sphincter (LES) conform a single pressure peak. Both EGJ II and III have a double pressure peak. In EGJ type II there is a separation lower than 2cms between diaphragm and LES, and in EGJ type III the separation is larger than 2cms (hiatal hernia). Hiatal hernia is traditionally associated with GERD.

**Aims & Methods:** Aims To assess the prevalence of each subtype of EGJ in GERD and non-GERD patients. Methods Descriptive retrospective study of 296 patients who underwent HRM and 24 h pH/impedance test. GERD was diagnosed by endoscopic findings or 24 h pH/impedance results. Separate prevalence of each EGJ subtype was compared in GERD vs non-GERD. Also double pressive peak EGJ (type II and III) was compared versus EGJ type I prevalence.

**Results:** Of 296 patients, 38.04% (112) were diagnosed GERD. In this group, 33% had EGJ type I, 38.4% EGJ type II and 28.6% EGJ type III. In non-GERD patients (61.95%, n:184), EGJ subtypes prevalence was EGJ I 49.5%, EGJ II 30.4% and EGJ III 20.1%. Globally, EGJ I is observed in 33% patients with GERD and 45.9% in non-GERD, reaching significant difference (p 0.02). EGJ II is most frequent in patients with GERD (38.4% vs 30.4%) as well as EGJ type III (28.6% vs 20.1%) but with no statistical differences. Grouping double peak morphology (EGJ II and III) it is observed that in GERD patients, EGJ I is found in 33% of cases, compared to 67% of patients with double peak. In non-GERD patients, the percentage of EGJ I is 49.5% vs 50.5% double peak EGJ. Proportionally, the single pressive peak respect the double pressive peak appears with a proportion 1:2 in patients with GERD, and with a proportion 1:1 in patients without GERD, with statistical significance ($p = 0.006$).

| | | EGJ I | EGJ II | EGJ III |
|---|---|---|---|---|
| GERD | n: 112 (38.04%) | 33% | 38.4% | 28.6% |
| Non-GERD | n: 184 (61.95%) | 49.5% | 30.4% | 20.1% |
| | | EGJ I | EGJ II+III | |
| GERD | n: 112 (38.04%) | 33% | 67% | |
| Non-GERD | n: 184 (61.95%) | 49.5% | 50.5% | |

**Conclusion:** The prevalence of the different types of GEJ significantly varies depending on the existence of GERD, with lower presence of EGJ I in patients with GERD.
If we assess the different types of EGJ separately, GERD patients do not present more frequently EGJ type II and there is non-significant trend towards EGJ III morphology.
Gastroesophageal junctions formed by double pressive peak (EGJ II and III) are more prevalent than single pressive peak in patients with GERD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0451 RELATIONSHIP BETWEEN GASTRIC ACCOMMODATION AND POSTPRANDIAL TRANSIENT LOWER OESOPHAGEAL SPHINCTER RELAXATIONS AND REFLUX EVENTS IN HEALTH AND GASTRO-OESOPHAGEAL REFLUX DISEASE/FUNCTIONAL DYSPEPSIA OVERLAP

**B. Van Houtte**[1], C. Broers[1], T. Vanuytsel[1], N. Rommel[2], J. Tack[1], A. Pauwels[1]

**Introduction:** Several studies reported a high symptomatic overlap between gastro-oesophageal reflux disease (GORD) and functional dyspepsia (FD). Impaired gastric accommodation (GA) is a well-established mechanism underlying symptom generation in FD and has been suggested to provide a plausible mechanism of overlap between GORD and FD.

**Aims & Methods:** Our aim was to study the relationship between GA, transient lower oesophageal sphincter relaxations (TLOSRs) and reflux events in healthy volunteers (HV) and patients with overlapping GORD and FD symptoms. Twenty HV (10 m, 23 y (range 19–36)) with no prior history of digestive disease and 10 patients with overlapping GORD and FD symptoms (2 m, 33 y (range 20–54)) underwent combined high resolution impedance and manometry (HRiM) monitoring, with the catheter (Unisensor AG, Attikon, Switzerland) placed into the stomach. Recordings were made 30 min before and 60 min after a high carbohydrate and high fat solid meal consisting of meatloaf, mashed potatoes and apple sauce (1000 kcal). Medical Measurement System (MMS, Enschede, The Netherlands) software was used for analysis. TLESRs and reflux events were identified and quantified using established criteria. In sensors 5 cm below the lower border of the lower oesophageal sphincter (LOS), the intra-gastric pressure (IGP) before, during and after the meal was measured. Area Under the Curve (AUC) of IGP during the meal, representing GA, was calculated. The relationship between GA, TLOSRs and reflux events was analyzed using Pearson and Spearman correlation tests.

**Results:** Seven of the 10 patients had pathological reflux on ambulatory 24-h ph-impedance monitoring. During meal intake, a small drop and subsequent rise in IGP was observed, both in HV and patients, with a bigger drop ($-1.79$ mmHg vs. $-2.47$; $p = 0.041$) and a lower rise (4.68 mmHg vs. 3.53 mmHg; $p = 0.068$) in patients. 60% of patients vs. 15% of HV did not complete the meal. No difference in the number of postprandial TLOSRs (10 (8–13) vs. 9 (5–12); $p = 0.666$) and associated liquid (2 (0–5) vs. 2 (0–6); $p = 0.838$), gas (1 (0–3) vs. 0 (0–5); $p = 0.869$) or mixed (0 (0–1) vs. 0 (0–1); $p = 0.283$) reflux events could be found between HV and patients. In HV, a significant positive correlation was found between the recovery of IGP during the meal, calculated as the slope from the minimum to the maximum IGP during the meal, and the total number of postprandial TLOSRs (Pearson $r = 0.49$; $p = 0.029$). This slope was lower in patients (0.69 vs. 0.50; $p = 0.058$). Also in HV, AUC of IGP during the meal tended to be correlated to the total number of postprandial TLOSRs (Pearson $r = 0.38$; $p = 0.097$) and the total number of postprandial TLOSRs associated with liquid reflux (Spearman $r = 0.40$; $p = 0.082$). These correlations were not found in the GORD/FD overlap patient group.

**Conclusion:** These findings confirm GA as a potential determinant of TLOSR and reflux occurrence in HV. In the present cohort of GORD/FD overlap patients, no significant correlation was found, suggesting involvement of other triggering pathways. Future studies will address differences in GORD/FD overlap patients with or without pathological reflux exposure as well as pure GORD patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0452 ACID SENSING ION CHANNELS AS TARGETS FOR THE MODULATION OF PAIN SENSATIONS IN GASTROESOPHAGEAL REFLUX DISEASE

**Introduction:** We earlier demonstrated that STW5 and omeprazole affect multiple chemokine families on genome and proteome level and involve G-protein coupled receptor and MAP-kinase signaling to reduce inflammation in the esophageal tissue in our rat model for gastro-esophageal reflux disease (GERD)[1]. We further reported a simultaneous upregulation of acid sensing ion channels (ASICs), especially ASIC4 and 5-hydroxytryptamin receptor (5-HTR) subtypes in the inflamed esophageal tissue and postulated both receptor types may form a communication network involved in pain signaling[2]. Chen and Wong[3] pointed out that ASICs alone are not sufficient to reconstruct the path of pain signaling. Evidence that ASICs are mechanically sensitive needs to be provided. Proteins proposed to be involved as mechanotransducers along with ASICs include extracellular matrix (ECM) proteins (collagens), ECM-linker proteins (matrilin-2), intra-cellular linker proteins (e.g. stomatin) and cytoskeleton proteins (actin filament, microtubule)[3].
**Aims & Methods:** We analysed in our subacut GERD rat model the transcript modulation of matrilin-2, stomatin and tubulin in the esophageal tissue.
**Methods**: Rats were pretreated with either STW5 (0.5 or 2 ml/kg), a multicomponent herbal preparation, or Omeprazole (O) (30 mg/kg). Esophagitis was induced surgically followed by a further 10 d treatment. On day 10 animals were sacrificed. RNA was isolated from defined tissue areas of the esophagi for Agilent whole genome microarray (rat). Data were analysed by Ingenuity[1].
**Results:** Tissues of animals suffering from GERD showed a small, but significant increase in the expression of stomatin (3.1f,) and of tubulin 6 (2.6f) ($p < 0.0001$) compared to ''normal'' tissue. Other tubulins or matrilin-2 were not regulated. In tissues of animals treated with either STW5 (2 ml/kg) or with O (30 mg/kg) stomatin (−4.8f; −2.6f) as well as tubulin 6 (−2.8f; −2.1f) were downregulated ($p < 0.0001$) by both treatments. The magnitude of regulation corresponded with the one of ASIC4[2].
**Conclusion:** Even though we did not yet investigate the identified molecules in function, data further support our hypothesis that a central pain response in peripheral nerve tissues is activated via ASICs in the presence or absence of acidic reflux and is positively influenced by STW5 and O.

## P0453 RELEVANCE OF SLEEP DISTURBANCE TO THE INTEGRITY AND CHARACTERISTICS OF SECONDARY PERISTALSIS IN PATIENTS WITH GERD

**C. Chen**, W. Lei, C. Yi, T. Liu, J. Hung
*Department Of Medicine, Hualien Tzu Chi Hospital, Hualien/Taiwan*

**Contact E-mail Address:** harry.clchen@msa.hinet.net.
**Introduction:** Sleep disturbance is common in patients with gastroesophageal reflux disease (GERD). Secondary peristalsis is important for clearance of the refluxate from the esophagus.
**Aims & Methods:** We aimed to test the hypothesis that altered physiological characteristics of secondary peristalsis may occur in a subset of GERD patients with sleep disturbance and such alteration also correlated with the severity of sleep disturbance. Secondary peristalsis was performed with slow and rapid air injections into mid-esophagus in 8 age-matched health controls and 41 patients with GERD. Sleep disturbance was assessed by the Pittsburg Sleep Quality Index (PSQI) with >5 indicating sleep disturbance. Objective sleep measures were assessed by ambulatory actigraphy. We aimed to test the hypothesis that altered physiological characteristics of secondary peristalsis may occur in a subset of GERD patients with sleep disturbance and such alteration also correlated with the severity of sleep disturbance.
**Results:** The patient group included twenty patients with sleep disturbance and 21 patients without sleep disturbance. The threshold volume for inducing secondary peristalsis during slow air injection was significantly greater in GERD patients with sleep disturbance than healthy controls ($14.3 \pm 1.2$ vs. $8.9 \pm 0.5$ ml, $p < 0.05$). GERD patients with sleep disturbance had greater threshold volume of secondary peristalsis during rapid air injection than GERD patients without sleep disturbance ($5.1 \pm 0.4$ vs. $3.9 \pm 0.2$ ml, $p < 0.05$) and healthy controls ($5.1 \pm 0.4$ vs. $3.6 \pm 0.2$ ml, $p < 0.05$). The frequency of peristaltic response during rapid air injection was also significantly lower in GERD patients with sleep disturbance as compared with GERD patients without sleep disturbance (50% [22.5–67.5%] vs. 60% [50–90%], $p < 0.05$) and healthy controls (50% [22.5–67.5%] vs. 95% [72.5–100%], $p < 0.05$). There was a negative correlation between PSQI and peristaltic frequency during rapid air injection ($r = -0.39$, $p = 0.01$). Secondary peristaltic amplitude during rapid air injection was negatively correlated with wake after sleep onset ($r = -0.34$, $p = 0.04$).
**Conclusion:** Sleep disturbance is associated with attenuated mechanosensitivity to distension-induced secondary peristalsis and impaired secondary peristaltic competence in patients with GERD. The demonstrated relationships between sleep measures and peristaltic parameters suggest that sleep disturabnce per se may impact the effectiveness of esophageal peristaltic reflex.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0454 INFLAMMATION MIGHT HAVE A ROLE IN EROSIVE ESOPHAGITIS BUT NOT IN NON-EROSIVE REFLUX DISEASE

**Introduction:** The relationship between inflammatory activation mechanisms and acid-peptic injured esophageal tissue is not clear. We evaluated whether there are differences between inflammation and tight junctional proteins such as e-cadherine among subtypes of gastroesophageal reflux disease (GERD).
**Aims & Methods:** The aim of this study was to investigate any possible role of inflammation in pathologic mechanism of reflux disease by determining the inflammatory markers in injured esophageal tissue as well as serum of patients. Three groups (erosive-EE, n = 18; nonerosive-NERD, n = 12; healthy controls-HC, n = 13) were evaluated with high-resolution esophageal manometry, 24 h pH-intraesophageal impedance, upper gastrointestinal endoscopy and mucosal impedance measurements. The esophageal biopsies and blood samples were collected. Serum e-cadherine levels, NFkB, chitotirosidase (CHIT), myeloperoxidase (MPO) activities in serum and homogenized tissues were determined.
**Results:** NKFB levels in tissue was significantly higher in subjects with EE ($4.9 \pm 2.53$ ng/mg.prt) versus HC ($2.95 \pm 1.51$ ng/mg.prt, $p = 0.018$). MPO tissue activities in EE group were significantly lower ($0.07 \pm 0.06$ u/mg.prt) than HC ($0.23 \pm 0.22$ u/mg.prt, $p = 0.025$) while MPO serum levels were higher in EE ($1.15 \pm 1.63$ uL) versus HC ($0.56 \pm 0.69$ uL, $p = 0.045$). Tissue CHIT levels were three fold increased in EE versus HC ($p = 0.071$). None of these measurements showed any differences in NERD group. NFKB and MPO levels had a negative correlation ($r = -0.408$, $p = 0.005$) in tissue. NFKB and ECAD levels had a positive correlation in serum ($r = 0.642$, $p < 0.0001$). Mucosal impedance in EE ($1200.8 \pm 305.6$ ohms) was significantly higher than HC ($3956.7 \pm 1920.7$ ohms, $p = 0.001$) and also NERD ($2882.2 \pm 1296.0$ ohms, $p = 0.001$), while there were no significant differences between NERD and HC.
**Conclusion:** Inflammatory process might play a pivotal role in injured mechanism only in erosive esophagitis but not in NERD. The lower values of mucosal impedance measurements also support this assumption that impaired tissue integrity might be an outcome of inflammation in erosive esophagitis. Non-inflammatory mechanisms might be responsible such as hypersensitivity in patients with NERD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0455 TJ-14 (HANGESHASHINTO) IMPEDES THE DEVELOPMENT OF REFLUX-INDUCED ESOPHAGEAL CANCER IN A SURGICAL RAT MODEL

**T. Miyashita**[1], D. Matsui[1], I. Makino[1], H. Tajima[1], A. K. Ahmed[2], J. W. Harmon[3], T. Ohta[1]

**Contact E-mail Address:** tomoharumiya@gmail.com.
**Introduction:** Hangeshashinto (TJ-14), a Japanese Kampo medicine, has been reported to be effective in preventing chemotherapy-induced oral mucositis through the reduction of prostaglandin E2 (PGE2). TJ-14 has also been shown to affect cyclooxygenase activity. M2 phenotype macrophages contribute to tumor development in the immunosuppressive microenvironment. Therefore, targeting the immunosuppressive network in tumor tissues, by inhibiting PGE2, may provide an effective preventive strategy. We evaluated the effectiveness of TJ-14 as a chemoprevention agent in a surgical rat reflux model of esophageal cancer.
**Aims & Methods:** The rat reflux model was created by performing an end-to-side esophagojejunostomy on Sprague Dawley rats. The surgery promoted the reflux of gastro-duodenal contents into the esophagus. The rats were divided into 2 groups. One group was given commercial chow (control group), and the other

was given experimental chow, containing TJ-14 (TJ-14 group). All surviving animals were sacrificed 40 weeks after surgery and their esophagi were examined. The primary antibodies against CD163 (M2; AbD Serotec) were used for immunohistochemistry.

**Results:** Twenty two rats survived 40 weeks post-surgery and were included in the study. Of these, 12 were included in the control group (Figure 1a), and the remaining 10 received TJ-14 administration (Figure 1b). 67% (8/12) of the controls developed esophageal cancer (Figure 1c), but animals that received TJ-14 had a cancer incidence of 10% (1/10) (p = 0.007, Chi-squared) (Table 1). Barrett's metaplasia was found in 83% (10/12) of the rats in the control group (Figure 1d). However, only 50% (5/10) of the rats in the TJ-14 group displayed signs of Barrett's metaplasia, indicating a protective tendency of TJ-14. All of the rats in the TJ-14 and control groups developed proliferative hyperplasia. M2 phenotype macrophage decreased in the TJ-14 group compared to the control group.

**Conclusion:** TJ-14 protected against the development of esophageal cancer in a clinically relevant surgical reflux model. Further investigation is required regarding the potential clinical use of TJ-14 as a chemopreventive agent.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0456 IN VITRO AND EX-VIVO QUANTITATIVE ASSESSMENT OF LOCAL INTERACTIONS OF ANTACIDS WITH OESOPHAGEAL MUCOSA FOCUSED ON LAYER STABILITY AND RESISTANCE TO HCL PENETRATION: SIGNIFICANT THERAPEUTIC IMPLICATIONS

**B. Havertz**[1], R. Krastev[2]
[1]*Scientific Affairs, Bayer Vital GmbH, Leverkusen/Germany*

**Contact E-mail Address:** Brigitte.Havertz@Bayer.com.

**Introduction:** Liquid formulations of antacids are widely used for the treatment of heartburn and some antacids e.g, hydrotalcite was shown to protect and heal ulcerated oesophageal mucosa. Hydrotalcite (HTL) is a "layer-lattice" antacid. The liquid formulation of HTL contains 1000 mg per dose. The formation of a stable layer on top of the mucous lining and its acid penetration resistance is thought to be crucial for the liquid formulation, however these properties have not been quantitatively assessed and tested. HTL protects the stomach and oesophageal mucosa and improves the quality of mucosal repair. Its protective properties have been documented in animal and human studies*.

**Aims & Methods:** The objective of the study is to characterise the action of HTL Liquid using physicochemical model systems and compare it with three other commercially available antacids: 1) another liquid layer-lattice antacid with 1600 mg magaldrate (ANT 1) per dose; 2) with a liquid algeldrate magnesium hydroxide mixture (ANT 2) and 3) with a combination of sodium alginate, sodium hydrogen carbonate and calcium carbonate (ANT 3). The mechanical stability of the liquid antacid formulations was tested on a de-wetting model experiment. As substrates standard glass plates and ex-vivo freshly excised porcine oesophageal mucosa were used. In this model the antacids form a layer on top of the substrate. The layers show different stability. Some of the antacids dewet the substrate which means they do not form a complete layer on it. This process occurs with the formation of small holes in the homogenous layer of antacids. As the background is dark, parts of the layers with different thickness have different colour intensity. The parts of the glass substrate which are dewetted are black in reflected light. The stability of the layers of antacids was defined as the time when the first de-wetting areas appear. The acid penetration resistance of a layer of antacid was defined as the time necessary for 0.1 M HCl to penetrate through a layer of antacid with defined thickness and area. The tests were performed in micro well plates (12 wells). The bottoms of the wells contained a thin layer of the pH sensitive indicator Pentamethoxy Red which is not soluble in the antacids. It is colourless at pH higher than 3 and red in the pH range below 3. The wells were filled with equal volumes of the tested antacids. On top of the antacids equal amounts of 0.1 M HCl was added. The change in the intensity of the red color of the samples was video imaged and quantified. The images were analysed using an Image J macro. The results were obtained from at least 5 separate tests.

**Results:** The acid penetration was after 40 minutes significantly longer (lower) for HTL than for ANT 2 and ANT 3 ($p < 0.001$ with ANOVA). The mechanical stability of the tested antacids showed that ANT 1 induced dewetting almost immediately after its application to the substrate whereas the other three antacids showed stable layers for at least 30 minutes. The results were similar on glass substrates and in ex-vivo porcine oesophageal mucosa. The acid penetration resistance for the chemical (acid neutralisation capacity) and physical (thickness and stability of the layer) resistance of an antacid layer were best for HTL and ANT 1. The stability of the antacid film however was the lowest for ANT 1.

**Conclusion:** 1) We established novel methods for the quantitative assessment of antacids interaction with oesophageal mucosa. 2) From four studied antacids HTL forms the most stable antacid layer both on glass substrate and on ex-vivo porcine oesophageal mucosa and has at the same time the best acid penetration resistance which might be of particular benefit in vivo.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0457 THE EXCRETION OF PANTOPRAZOL IN HUMAN BREAST MILK

**S. Bor**[1], G. Yildiz Turkyilmaz[2], S. Karacaoglu[2], S. Kipcak[1], P. Ergun[1], E. Karasulu[2]

**Contact E-mail Address:** serhatbor@yahoo.com.

**Introduction:** Proton pump inhibitors are the most widely used medications and currently no data available about their concentrations in the human breast milk.

**Aims & Methods:** We aimed to measure the amount of pantoprazole in human milk after oral administration to a breast-feeding women and to estimate human exposure. Eight women who decided to stop breastfeeding were included. All subjects were taken 40 mg once a day of pantoprazole for 7 days. Blood and milk were collected at day 1 and 7 at 0–1.5–3–4.5–6–9–12$^{th}$ hours. A selective and rapid HPLC method was developed and validated for quantification of pantoprazol in plasma and breast milk samples using Omeprazol as internal standard. Pantoprazol was extracted from biological matrix by using Liquid-liquid extraction process. The method was validated over a linear concentration rage of 0.03–1 μg/mL and the limit of quantification (LLOQ) was 0.03 μg/mL.

**Results:** Pantoprazole was measured only in one sample of milk within 12 hours of period (7 measurements a day) at both days in all subjects. The mean concentration of pantoprazole was 54.8+24.1 (32.7–96.2) ng/ml for day 1 and 48.5+20.4 (21.7–82.9) ng/ml for day 7 in the milk. The detection of the drug in the milk was either at the time of the highest concentration of the blood or 90 minutes after the peak level. Eleven out of 16 detections in the milk were at the 3$^{rd}$ or 6$^{th}$ hour after administration of the drug.

**Conclusion:** The two compartment model was proposed to describe time profiles of pantoprazole in plasma and milk (plasma as central, milk as peripheral compartment). Pantoprazole's level of milk compartment was far less than plasma compartment. We estimate that 100 ml of milk contains about 50 mcg pantoprazole which means that the drug is minimally excreted. Since, pantoprazole is unstable in acidic pH, the systemic dose received by the infant might be even lower. Our limited data implicate that women who are breast-feeding might not stop breastfeeding when taking pantoprazole.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0458 THE USE OF NON-ABLATIVE RF ENERGY (STRETTA) FOR THE TREATMENT OF GERD. TEN YEARS FOLLOW-UP RESULTS

**Introduction:** To date, the Stretta procedure (Mederi Therapeutics Inc., Greenwich, CT, USA), which applies thermal radiofrequency energy to the LES, still remains an available technique for endoscopic treatment of GERD, with documented effectiveness on patient symptom control, quality of life (QoL), oesophageal acid exposure, and LES pressure. From June 2002 to March 2016 a cohort of 251 patients were consecutively treated with the Stretta procedure for GERD; 57 patients (36 females, 21 males) reached to date a ten year follow-up. Aim of the follow-up study is to verify durability, efficacy and safety of the procedure at this time.

**Aims & Methods:** Selection criteria for patients eligible to stretta were: hiatal hernia $<3$ cm, esophagitis not more than grade B, LES pressure not below 8 mmHg at preop manometric study, no dysmotility disorders of the esophageal body (except Ineffective Motility certainly secondary to GERD) and Barret's esophagus (except short segment BE). All patietns were under PPIs regimens, 26 out 57 of them still having ''extraesophageal'' symptoms as chronic cough, laringeal discomfort, dysphonia and nocturnal chest pain. All procedures were performed on an outpatient day-hospital basis; for deep sedation propofol (100–300 mg i.v.) and remifentanil (0.5–1 mg/kg/h i.v.) were administered with continue cardio-respiratory monitoring. The median procedure time was 40 minutes. Recovery mean time after procedure was 4, 5 hours and all patients were discharged from the hospital within the day. All patients received very detailed informations about dietary habits continued their current PPIs regimen for at least 0 days and then discontinued all antacid medications. All patients underwent to clinical interview after 6 months, 1 year, 4 years and ten years The primary outcomes of the study were heartburn (using a 6-point Likert scale ranging from no symptoms to incapacitating symptoms), GERD health-related quality of life (HRQL), using a 6-point Likert scale for multiple different symptoms, each ranging from no symptoms to incapacitating symptoms and general quality of life, using the medical outcomes 36-item Short-Form Health Survey (SF-36). GERD HRQL improvement was evaluated as a continuous variable and as a dichotomous variable (responder versus non-responder). A response was a $>50\%$ improvement compared with baseline values, as previously described.

**Results:** Out of 251 patients treated with Stretta from June 2002 to March 2016 a cohort of 178 did not reach at the date of the objective of a full 10 years follow-up, nine patients were lost to follow-up and in seven patients the RF treatment lost its efficacy. In all studied subjects there here was a significant decrease in both heartburn and GERD HRQL scores as well as a significant increase of QoL scores (mental SF-36 and physical SF-36). The Stretta procedure was very effective in patients suffering for extraesophageal symptoms, wich were resolved in 100% of them within the 6 months/one year controls. Forty-one patients out of 57 (71.9%) were completely off PPIs ten years after the Stretta procedure.

**Conclusion:** The Stretta procedure for GERD is now widely documented by experimental studies and clinical trials as effective and safe. The results of this follow-up study after 10 years confirms data published by Noar in late 2014 and further sustain the concept that Stretta might represent a viable treatment option for selected patients with symptomatic mild to moderate GERD; this suggestion has been recently stated by the SAGES Guidelines in 2013 and by the ASGE Guidelines in 2015. The Stretta RF treatment can be offered, especially to the younger GERD sufferers as a ''bridge therapy'' between the continuous medical treatment and the optimal timing for laparoscopic fundoplication and is indicated in refractory GERD and extraesophageal symptoms.

**Disclosure of Interest:** L. Dughera: I have received grants by mederi Therapeutics for training sessions.

## P0459 RESPONSE TO TREATMENT WITH PROTON PUMP INHIBITORS (PPI) OF ATYPICAL SYMPTOMS DEPENDING ON THEIR COEXISTENCE WITH TYPICAL SYMPTOMS

**A. Zúñiga Ripa**, F. Estremera Arévalo, I. Aresté Anduaga, R. Iglesias Picazo, M. Oreja Arrayago
*Gastroenterology, Complejo Hospitalario de Navarra, Pamplona/Spain*

**Contact E-mail Address:** albazuri@hotmail.com.

**Introduction:** Gastroesophageal reflux disease (GERD) is divided according to the Montreal Classification into typical symptoms (heartburn and regurgitation) and atypical (cough, asthma and/or laryngitis). Response to treatment with proton pump inhibitors (PPI) suggests the relationship of these symptoms with GERD. It is unknown which factors could predict treatment response in these patients.

**Aims & Methods:** To study if the co-existence of typical and atypical symptoms is a predictive factor of PPI treatment response in atypical GERD-related symptoms. Observational retrospective study of 109 patients evaluated with 24 h pH/impedance test due to the presence of GERD typical and/or atypical symptoms. We evaluated the response to PPIs as indicated by their referring doctor. ''Response'' is defined as complete disappearance of symptoms and ''non-response'' if there is no improvement or if it is partial. Outcomes are compared between two groups: co-existence of Typical and Atypical symptoms and no co-existence (Atypical symptoms alone).

**Results:** Globally, in patients evaluated due to extra-esophageal symptoms (n: 109), symptomatic improvement with PPI treatment was found in 20.2% (20 patients) while 79.8% did not improve. Co-existence of typical and atypical symptoms of GERD was present in 66 patients and no co-existence in 43 patients. Evaluating the response to treatment, improvement was observed in 18 patients (18/66: 27.3%) in the co-existence group, while in patients with only atypical symptoms the improvement was detected in 4 patients (4/43: 9.3%). Regarding the global PPI response (n: 22), 18 ''co-existence'' patients improved (81.8%) versus 4 patients with atypical symptoms (18.2%).

| | | Non- PPI response | PPI response | Total |
|---|---|---|---|---|
| Atypical symptoms | N | 39 | 4 | 43 |
| | % | 90.7% | 9.3% | 100% |
| Atypical + Typical symptoms | N | 48 | 18 | 66 |
| | % | 72.7% | 27.3% | 100% |
| Total | N | 87 | 22 | 109 |
| | % | 79.8% | 20.2% | 100% |

**Conclusion:** 20.2% of patients evaluated due to extra-esophageal symptoms of GERD improved after PPI treatment. Treatment response was significantly larger in patients with coexistence (typical and atypical symptoms of GERD) versus 9.3% in patients with isolated atypical symptoms (27.3% vs 9.3%). The coexistence of atypical and typical GERD-related symptoms predicts a better response to treatment with PPIs of atypical symptoms compared to patients with isolated existence of atypical symptoms.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0460 A NEW GASTRIC ACID SUPPRESSOR, "VONOPRAZAN" IS EFFECTIVE IN PROTON PUMP INHIBITOR-REFRACTORY REFLUX ESOPHAGITIS

H. Yamashita[1], **A. Kanamori**[2]
[1]*Gastroenterology, Osakafu Saiseikai Nakatsu Hospital, Osaka/Japan*
[2]*Gastroenterology & Hepatology, Osakafu Saiseikai Nakatsu, Osaka/Japan*

**Contact E-mail Address:** atsushi-vvvvv@hotmail.co.jp.

**Introduction:** Proton pump inhibitors (PPIs) are the first choice of drugs for reflux esophagitis (RE). In 10–20% of patients with RE, there is incomplete healing of the mucosal injury even after a standard 8-week regimen of PPIs (i.e. PPI-refractory RE). Vonoprazan (VPZ) belongs to a new class of gastric acid-suppressing agents developed in Japan. It has potent and long-lasting anti-secretory effects on H+, and K+-ATPase owing to its high accumulation and slow clearance from the gastric tissue, resulting in a higher mucosal healing rate for patients with RE on initial therapy than in those receiving conventional PPIs (1–2). The purpose of this study was to elucidate the effect of VPZ using pH/impedance monitoring in patients with PPI-refractory RE.

**Aims & Methods:** All patients were tested for the cytochrome P450 (CYP) 2C19 genotype and *Helicobacter pylori* infection status at baseline, and were assessed using upper endoscopy, high-resolution manometry (Starlet, Star Medical, Inc., Tokyo, Japan), and pH/impedance monitoring (Sleuth, Sandhill Scientific, Highlands Ranch, CO. USA) after being on a standard PPI dose and 4 weeks after administration of VPZ (20 mg/day). The primary end-point of this study was the comparison of the percentage time to achieve intragastric and oesophageal pH $<4$ between patients on PPIs and on VPZ.

**Results:** Six patients with PPI-refractory RE (five women: mean age, 71.4 years; mean body mass index [BMI], 22.3, LA grade A/B/C/D, 1/1/2/2) were enrolled in this study. All patients were *H. pylori*- negative, and CYP2C19 extensive metabolizer, and had hiatal hernias. Four of the six patients achieved complete mucosal healing at 4 weeks. VPZ decreased the percentage time of the 24-h intragastric pH $<4$ significantly from 76.0 to 20.3% ($p=0.03$). Although VPZ decreased the percentage time of 24-h oesophageal pH $<4$ from 8.0 to 4.1%, but the difference was not significant ($p=0.42$). The acid clearance time significantly decreased from 352.6 to 115.8 s ($p=0.02$). The impedance study revealed a significant decrease in acid reflux events (19.2 vs. 6.0, $p=0.01$). However, significant differences were not found in the total reflux, non-acidic, proximal, and distal reflux events between patients on PPIs and those on VPZ (43.4 vs. 34.3, $p=0.11$; 21.6 vs. 28.2, $p=0.79$; 15.4 vs. 14.0, $p=0.08$; and 28.0 vs. 20.2, $p=0.11$, respectively).

**Conclusion:** VPZ significantly suppressed gastric acid secretion, and thereby, reduce the percentage time of the 24-h oesophageal pH $<4$, acid reflux events, and acid clearance time for patients on PPIs with PPI-refractory RE. Therefore, VPZ could be a potential optimal therapeutic strategy for patients with PPI-refractory RE.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0461 ENDOSCOPIC NON-ABLATIVE RADIO FREQUENCY ENERGY TREATMENT (STRETTA®) FOR GASTROOESOPHAGEAL REFLUX DISEASE – THE FIRST U.K. SINGLE-CENTRE EXPERIENCE

**S. Punnoose**[1], R. Sathasivam[2], O. Reece-Bolton[2], A. Dhar[1], Y. Viswanath[2]
[1]*Gastroenterology, County Durham & Darlington NHS Foundation Trust, Darlington/United Kingdom*
[2]*Surgery, James Cook University Hospital, Middlesbrough/United Kingdom*

**Contact E-mail Address:** dr_siby@yahoo.com.

**Introduction:** Gastro-oesophageal reflux disease (GORD) is usually treated with lifestyle modifications, combined with drug therapy (antacids, alginates and acid suppression drugs such as proton pump inhibitors and H2 receptor antagonists). Patients with inadequate response to lifestyle and medical treatments, or intolerant of medical therapy, are offered anti-reflux surgery with open or laparoscopic fundoplication which remains the gold standard[1, 2]. Stretta® is a minimally-invasive endoscopic treatment that delivers non-ablative radiofrequency (NARF) energy to improve and restore the function of the lower oesophageal sphincter muscle, thereby improving symptoms of GORD. The efficacy of the Stretta® procedure in achieving symptom control of GORD has been reported in previous international publications. A systematic review involving 20 studies with 1441 patients having a mean follow-up interval of 15 months showed significant improvements in GORD symptoms including disease-specific and global quality of life[3]. UK data on the outcomes of Stretta® have not been reported, and this is the first report of the Stretta® procedure in the UK, carried out at a single centre since October 2014.

**Aims & Methods:** Patients with confirmed GORD, unresponsive to medical management with standard or double dose PPI, were offered the Stretta® procedure based on clinician and patient shared decision. Patients with an associated hiatus hernia of $\leq$2 cm on their index endoscopy were included. Patients needed to be symptomatic of reflux for at least 3 months on medication and all patients were administered a GERD Health Related Quality of Life (GERD-HRQL) questionnaire pre and post-Stretta® procedure. The Stretta® procedure was carried out either under general anaesthesia (early phase) or conscious sedation (later phase) by a single trained endoscopist using the manufacturers protocol. Up to 14 lesion sets or 56 RF applications to the lower oesophageal sphincter at 1 cm intervals were carried out using an automated generator (Mederi Therapeutics Inc, USA).

**Results:** 26 patients underwent the Stretta procedure over a period of 12 months (October 2014 - September 2015). The mean follow-up period was 3.8 months (range 10.5) and there were no recorded procedural complications. All patients completed pre and post procedure GERD-HRQL questionnaires. The median heartburn score (scale 0–30) improved from18 pre-procedure to 2.5 post-procedure. The overall median regurgitation score (scale 0–30) improved from 19 pre-procedure to 0 post procedure. The overall patient satisfaction was 78%. There was also an improvement in the median overall total GERD-HRQL score (scale 0–75) from 44 pre-procedure to 6 post-procedure. 3 patients had undergone previous anti-reflux surgery. There was again overall improvement of median heartburn scores (18 pre, 0 post), regurgitation scores (1 pre, 0 post) and total GERD-HRQL scores (27 pre, 0 post). Baseline and post-procedure GERD-HRQL scores in 26 patients, average follow-up of 3.8 months:.

| Outcome variables | Pre-Stretta | Post-Stretta |
|---|---|---|
| Heartburn score | 18 | 2.5 |
| Regurgitation score | 19 | 0 |
| Patient satisfaction with GORD | 0% | 78% |
| Total GERD-HRQL score | 44 | 6 |

**Conclusion:** In this first UK report of Stretta, we demonstrate therapeutic benefit in medically non-responsive GORD, improving patient's heartburn, regurgitation and overall satisfaction scores with low procedural risks. There is also therapeutic benefit in patients with recurrent reflux symptoms after previous anti-reflux surgery, making it a possible treatment option for this group of patients. A larger UK Study is needed to incorporate Stretta into the therapeutic pathway for GORD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0462 THE CONCEIVED LIMITATIONS OF COMMONLY PRESCRIBED PROTON PUMP INHIBITORS IN THE TREATMENT OF GASTROINTESTINAL REFLUX DISEASE

**D. Carter**[1], R. Dickman[2]

**Contact E-mail Address:** dr.dancarter@gmail.com.

**Introduction:** Gastroesophageal reflux disease (GERD) is a worldwide highly prevalent disorder. Proton pump inhibitors (PPIs) have profoundly revolutionized the treatment of GERD. However, a substantial number of patients with GERD fail to respond adequately to PPIs. Available data on local attitudes and conceived limitations of treatment options for GERD among general practitioners (GP) and gastrointestinal specialists (GS) are scarce.

**Aims & Methods:** The aim of this study was to compare the common practices of family physicians and of GI specialists in the treatment of GERD, and to examine the conceived limitations of the available treatment options.

**Methods:** We conducted an internet survey addressed for GI specialist and family physicians during January to February 2016.

**Results:** 40 GS (18%) and 132 GP (10%) returned the questionnaire. Both groups treat 13–14 GERD patients/week (mean age 41–50 years). The most common indications for referral for a GI consultation were unresponsiveness to PPIs (46%) and presence of warning signs (weight loss, anemia, dysphagia, age $>$45 years, recurrent vomiting). GSs stated that the most important considerations for the selection of therapy were high safety profile; while GPs consider a rapid symptomatic relief. The most common first and second-line drug choices among both groups were omeprazole and esomeprazole, respectively. In the case of first and second line PPI failures, GSs tended to prescribe a non-PPI treatment, while GPs restarted esomeprazole. GSs stated that the commonest conceived limitations of PPI treatment were nighttime heartburn and undesirable side effects; while GPs considered treatment inflexibility (need to take on empty stomach before meals) and drug interactions. About 88% GSs and 55% of GPs would consider prescribing a new medication, if it would be long acting (covering the nighttime), prescribed once daily and without drug interactions.

**Conclusion:** GSs and GPs hold different attitudes to and conceive differently the limitations of the available PPI therapy. Despite these differences, it seems that PPI failure may be overcome by approaching two main unmet needs: nighttime heartburn and drug inflexibility.

**Contact E-mail Address:** romeo.bardini@unipd.it.

**Introduction:** Laparoscopic Nissen fundoplication (NF) is considered the gold standard to treat gastroesophageal reflux disease (GERD) with a reported failure rate of 10–15%. In most cases, the wrap migration or disruption of hiatal repair represent the main cause of it.

**Aims & Methods:** We investigated whether a modified Nissen procedure (MNF) may reduce the failure rate of traditional Fundoplication. Between March 2011 and January 2016, we prospectively collected the clinical and pathophysiological data of consecutive GERD patients with typical symptoms who underwent MNF. Also, patients with prior surgical failure were enrolled. The surgical modification consisted of: 1) anchoring the esophagus to the diaphragmatic crura by means of two non-absorbable stitches on each side; 2) fixing the upper stitch of the valve to the diaphragm. In case of clearly weak crura, a reinforcement with dual mesh was used. Patients were evaluated before and after surgery with validated symptoms and quality of life (GERD-HRQL) questionnaires, upper endoscopy, barium-swallow, esophageal high-resolution manometry, and 24-hour impedance-pH monitoring. Surgical failure was defined in case of: (1) abnormal pH-Impedance; (2) esophagitis; (3) recurrence of hiatal hernia/slipped fundoplication; (4) persistence or early recurrence of GERD symptoms.

**Results:** Thirty-eight patients (20F/18M, mean age 56 $\pm$ 14 years) were included. Of them, 21 (55%) were refractory to PPIs, whereas 17 were on chronic treatment. In 9 cases (24%), MNF was performed as redo-surgery. The mean follow-up was 22 $\pm$ 10 months. In 28 patients surgery was completed laparoscopically;

**Abstract No: P0464**

**Table 1:** Sensitivity, specificity, positive likelihood ratios, negative likelihood ratios, positive predictive values, and negative predictive values of different combinations of DeMeester scroe, SI, and SAP for predicting response to treatment in patients with GORD.

| Test | Sensitivity (%) | Specificity (%) | Positive Likelihood Ratio | Negative Likelihood Ratio | Positive Predictive Value (%) | Negative Predictive Value (%) |
|---|---|---|---|---|---|---|
| abnormal DeMeester, SI +ve, OR SAP +ve | 80.00 (33.39–97.48) | 33.33 (11.82–61.62) | 1.20 (0.75–1.93) | 0.60 (0.14–2.51) | 44.44 (21.53–69.24) | 71.43 (29.04–96.33) |
| Abnormal DeMeester | 33.33 (7.49–70.7) | 87.50 (61.65–98.45) | 2.67 (0.54–13.10) | 0.76 (0.46–1.25) | 60.00 (14.66–94.73) | 70.00 (45.72–88.11) |
| SI +ve | 61.54 (31.58–86.14) | 58.33 (27.67–84.83) | 1.48 (0.67–3.27) | 0.66 (0.29–1.52) | 61.54 (31.58–86.14) | 58.33 (27.67–84.83) |
| SAP +ve | 77.78 (39.99–97.19) | 37.50 (15.20–64.57) | 1.24 (0.74–2.08) | 0.59 (0.15–2.35) | 41.18 (18.44–67.08) | 75.00 (34.91–96.81) |
| SI +ve AND SAP +ve | 66.67 (22.28–95.67) | 57.89 (33.50–79.75) | 1.58 (0.73–3.43) | 0.58 (0.17–1.90) | 33.33 (9.92–45.13) | 84.62 (54.55–98.08) |
| abnormal DeMeester AND SAP +ve | 60.00 (14.66–94.73) | 90.00 (68.30–98.77) | 6.00 (1.43–26.81) | 0.44 (0.15–1.31) | 60.00 (14.66–94.73) | 90.00 (68.30–98.77) |
| abnormal DeMeester AND SI +ve | 37.50 (8.52–75.51) | 93.75 (69.77–99.84) | 6.00 (0.74–48.90) | 0.67 (0.38–1.16) | 75.00 (19.51–99.37) | 75.00 (50.90–91.34) |
| abnormal DeMeester, SI +ve, AND SAP +ve | 60.00 (14.66–94.73) | 95.00 (75.13–99.87) | 12.00 (1.56–92.29) | 0.42 (0.14–1.24) | 75.00 (19.41–99.37) | 90.48 (69.62–98.83) |

conversion was necessary in 3 patients; 7 laparotomies ab initio. The median operating time was 157 ± 22 minutes. Mortality and post-operative complications were nil. All patients experienced complete symptom relief, but 2 did not improve due to dysphagia persistence (n = 1 redo) and severe dyspeptic symptoms (n = 1). Endoscopy was regular in all patients. After surgery, GERD-HRQL and symptom scores significantly decreased ($p < 0.001$), whereas pathophysiological findings significantly improved (Table).

| | **Before Surgery** | After Surgery | P value |
|---|---|---|---|
| Symptom score | 18 (14–21) | 0 (0–3) | $P < 0.001$ |
| Dysphagia score | 0 (0.5–1) | 0 (0–1) | $p = 0.88$ |
| GERD-HRQL score | 26.7 | 2.4 | $p < 0.001$ |
| LES resting pressure (mmHg) | 17.3 | 20.4 | $p = 0.67$ |
| LES residual pressure (mmHg) | 6.6 | 10.5 | $p = 0.50$ |
| LES total length (mm) | 3 | 3.3 | $p = 0.91$ |
| LES abdominal length (mm) | 0.7 | 1.5 | $p = 0.03$ |
| Acid exposure time (%) | 14.2 | 0.5 | $P < 0.001$ |
| Number reflux | 64.8 | 8.2 | $P < 0.001$ |
| Symptoms-reflux association (SI/SAP) | 16 pos | 0 pos | $P < 0.001$ |
| Antireflux medication | 17 (45%) | 2 (5%) | $P < 0.001$ |

**Conclusion:** Our data showed that the MNF was a safe and effective procedure, providing satisfactory clinical and pathophysiological outcome in the long-term (22 months), also in case of redo-surgery. In the end, in comparison to literature data, the failure rate also improved.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0464 CLINICAL YIELD OF USING COMMON REFLUX-SYMPTOM CORRELATION METHODS: A RETROSPECTIVE STUDY COMPARING THE DEMEESTER SCORE, SYMPTOM INDEX, AND SYMPTOMS ASSOCIATION PROBABILITY IN PREDICTING RESPONSE TO ANTIREFLUX TREATMENT IN PATIENTS WITH GORD

**C. Premathilaka**[1], M. Adesanya[1], J. Jafari[2], I. Miah[2], T. Wong[2]

[2]*Oesophageal Physiology Laboratory, Guy's and St Thomas' Hospitals, London/United Kingdom*

**Contact E-mail Address:** chirantha.premathilaka@kcl.ac.uk.

**Introduction:** Oesophageal pH-impedance monitoring is the gold standard for the diagnosis of gastroesophageal reflux disease (GORD). The DeMeester score is calculated using different reflux parameters and serves as a global measure of acid exposure. Symptom Index (SI) and the Symptoms Association Probability (SAP) scores are also used to correlate symptoms to episodes of gastroesophageal reflux (GOR). Currently, it is not clear which of these scoring methods are best related to the patient's response to treatment. The aim of this study is to investigate the value of these 3 metrics in predicting the clinical outcome of treatment in GORD patients.

**Aims & Methods:** We retrospectively selected patients who had 24-hour pH-impedance monitoring on suspicion of GORD during December 2014 to October 2015. Abnormal DeMeester was defined as ≥ 14.72, +ve SI as ≥ 50%, and +ve SAP as ≥ 95%. The Reflux Disease Questionnaire (RDQ) was completed by each patient before investigation. After reflux monitoring was done, patients were followed up to calculate their post-treatment RDQ at least 2 months post treatment. Sensitivity, specificity, positive and negative likelihood ratios and predictive values were calculated.

**Results:** 42 patients (11 male; total mean age 51 [25–79]) were included. 25 (59.52%) of these patients were treated. Of these, 21 patients, had medical treatment and 6 had surgical treatment (2 had both). 10/25 (40%) had a reduced RDQ score post-treatment: 8/10 (80%) having medical treatment, 1/6 (23.33%) having surgical treatment. In patients without treatment, 7/17 (41.18%) had a reduced RDQ. The two-tailed p value between those treated and untreated group was not significant (P = 1.00). Considering individual metrics, abnormal DeMeester score showed highest specificity and SAP showed the highest sensitivity in predicting lowering RDQ score post-treatment. When combining different metrics, having all three parameters positive, yielded in the highest overall clinical value: Sensitivity 60%, specificity 95%, positive likelihood ratio 12, positive predictive value 75%, negative predictive value 90% (table 1).

**Conclusion:** In patients diagnosed with GORD by pH-impedance monitoring, having all three parameters positive i.e. abnormal DeMeester score, SAP +ve and SI +ve had a high overall value in predicting the response to treatment. Nevertheless, reduction of RDQ was equally seen in untreated GORD group. A study on a larger number of patients might be required to further confirm the findings of this research.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0465 A DOUBLE-BLIND, RANDOMIZED, MULTICENTER CLINICAL TRIAL INVESTIGATING THE EFFICACY AND SAFETY OF ESOMEPRAZOLE SINGLE THERAPY VERSUS MOSAPRIDE AND ESOMEPRAZOLE COMBINED THERAPY IN PATIENTS WITH EROSIVE REFLUX DISEASE

**Introduction:** We aims to evaluate the efficacy and safety of combination therapy in ERD (erosive reflux disease) patients by comparing endoscopic healing rate according to the LA classification for esomeprazole alone and esomeprazole plus mosapride.

**Aims & Methods:** Patients complaining of reflux symptoms for the last 3 months and diagnosed with ERD according to the LA classification in an upper endoscopy were included in this study. A total of 116 patients were randomized to receive esomeprazole 40 mg once daily plus mosapride 5 mg three times daily (EM group), or esomeprazole plus placebo (E group) for 8 weeks. Patients recorded GERD symptom questionnaire at week 4 and 8. The primary endpoint was endoscopic healing rate of ERD after 8 weeks of treatment.

**Results:** The number patients showing improved endoscopic findings according to the LA classification was 32 (66.7%) in the EM group and 26 (60.5%) in the E group, but there was no statistically significant difference between the groups ($p = 0.692$). Only at 4 weeks, a total GERD symptom score changes relative to baseline significantly improved in EM group than that of E group (−13.4 ± 14.7

vs. $-8.0 \pm 12.3$, $p = 0.041$) and upper abdominal pain and belching score changes showed significantly improved in EM group than that of E group ($p = 0.018$ and $p = 0.013$, respectively).
**Conclusion:** The combination PPI with mosapride showed a tendency for upper abdominal pain, belching, and total GERD symptoms scores to improve more rapidly. This suggests that combination therapy with esomeprazole and mosapride will be useful for rapid improvement of symptoms in ERD patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0466 ANTI-REFLUX ENDOSCOPIC SURGERY FOR REFRACTORY GASTROESOPHAGEAL REFLUX DISEASE

**W.J. Ko**, G.W. Song, J.Y. Cho
*Digestive Disease Center, CHA University, Seongnam/Korea, Republic of*

**Contact E-mail Address:** gwsong@chamc.co.kr.
**Introduction:** Currently, a variety of endoscopic procedures for gastroesophageal reflux disease (GERD) have been proposed. This suggests that anti-reflux endoscopic surgery (ARES) could achieve an effective anti-reflux procedure.
**Aims & Methods:** In this pilot study, 11 patients with refractory GERD received ARES, 3 of them has sliding hiatal hernia. ARES was crescentic conducted using cap assisted endoscopic mucosal resection method.
**Results:** Reflux symptoms of GERD improved significantly after ARES. In the GERD-Q score, mean score decreased from 13.8 to 5.8 ($P = 0.0001$). At endoscopic examination, the flap valve grade decreased from 3.2 to 1.2 ($p = 0.015$). Also the EGJ distensibility that was measured endoscopic.
**Conclusion:** This initial case series demonstrated the potential anti-reflux effect of ARES, with a crescentic mucosal resection appearing adequate. Further longitudinal study will be required to establish ARES as an effective technique to control GERD in this setting.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Endoscopic treatment is a standard approach for patients with early esophageal cancer (EEC) with mucosal invasion (T1a). For patients with 'high-risk' T1a cancer (e.g. advanced grading or invasion to lymphatic vessels) and patients with any submucosal (sm) invasion (T1b), surgery has been recommended as a standard of care. Recent data suggests that endoscopic treatment might be curative also in such patients with 'high-risk' EEC.
**Aims & Methods:** To compare outcomes of endoscopic vs. surgical treatment in patients with 'high-risk' EEC. 'High-risk' cancer was defined as any cancer with sm invasion or mucosal cancer with at least one of the following: poor (G3/G4) differentiation, A+ and/or L+ (blood or lymphatic vessel invasion) and high tumor cell dissociation (TCD3). The main outcome measurement was defined as tumor-free survival after surgical/endoscopic treatment.
A single-center, prospective study. Patients with EEC underwent endoscopic resection (ER) or endoscopic submucosal dissection (ESD). Based on staging, patients with 'high-risk' EEC were referred for surgery if there were no contraindications. All other patients continued (if necessary) in endoscopic treatment which consisted of further sessions of ER and/or radiofrequency ablation (RFA). After treatment, all patients have been followed up by a median of 27 months (range 3–144).
**Results:** A total of 43 patients with 'high-risk' EEC were diagnosed: 15 patients (35%) had T1a cancer with 'high-risk' features (L+: 1; TCD3 with L+: 1; G3 with A+ and L+: 1; G3 with TCD3: 5; TCD3: 7) and 28 patients (65%) had cancer with submucosal invasion (sm1: 13; sm2: 6; sm3: 9); 37 patients had adenocarcinoma (AC) and 6 patients squamous carcinoma (SCC).
Fifteen patients (35%) were referred for esophagectomy and 28 patients (65%) continued in endoscopic treatment. In one patient, the planned esophagectomy was abandoned due to tumor generalization (AC) found during the operation, and he has since undergone chemotherapy.
Among 14 patients who underwent esophagectomy, local residua of malignancy after endoscopic treatment were present in 3 patients (21%) and lymph node (LN) metastases have not been detected in any of 210 investigated LN. During the follow-up, none of the patients has shown signs of generalization or a local tumor relapse. In patients with endoscopic treatment, a complete remission of neoplasia was achieved in 22/24 patients (93%) during a median of 2 (range 1–4) treatment sessions. Tumor-free survival has been 100% in patients treated by surgery and 92% (CI 81–100%) by endoscopic treatment (NS) vs. surgery. Cancer related mortality has been zero in both groups.
**Conclusion:** Endoscopic treatment provides a long-term remission or cure in a considerable number of patients with 'high-risk' early esophageal cancer, representing a valid alternative to surgery. The broadened indications for radical endoscopic treatment should be further defined.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0468 DEVELOPMENT AND VALIDATION OF A TRAINING MODULE ON THE USE OF ACETIC ACID CHROMOENDOSCOPY (AAC) TO DETECT BARRETT'S NEOPLASIA

**F.J.q. J. Chedgy**[1], K. Kandiah[2], G. Longcroft-Wheaton[1], P. Bhandari[1]
[1]*Endoscopy, Queen Alexandra Hospital, Portsmouth/United Kingdom*
[2]*Gastroenterology, Queen Alexandra Hospital, Portsmouth/United Kingdom*

**Contact E-mail Address:** ferguschedgy@yahoo.co.uk.
**Introduction:** AAC enhances the ability to correctly identify Barrett's neoplasia and is increasingly used by both expert and non-expert endoscopists. However, despite its increasing use, there is no validated training strategy to achieve competence.
**Aims & Methods:** The aim of our study was to develop a validated training tool in the technique of using AAC, lesion recognition and a novel acetic acid classification and evaluate its impact and effectiveness. A validated assessment of 40 images and 20 videos was developed. 13 endoscopists with experience of Barrett's endoscopy but no formal training in AAC (7 consultants, 6 nurse endoscopists) underwent training. Participants underwent: baseline assessment (1)®online training®assessment (2) ®interactive seminar®assessment (3).
**Results:** Endoscopists with vast experience in Barrett's endoscopy lack lesion recognition skills with AAC, consultants perform no better than nurse-endoscopists. There were statistically significant increases in accuracy, sensitivity, specificity, negative predictive value (NPV) and positive predictive value (PPV) following the online training module (Table 1). There was additional gain from the interactive live workshop. Improvement was also seen in inter-observer agreement.
**Conclusion:** 1. Our data demonstrate the need for training as baseline performance, even by experts, was poor 2. We were successful in developing and validating an online training and testing tool for acetic acid chromoendoscopy for Barrett's neoplasia 3. Low pre-training scores amongst users and non-users demonstrated the need for training tool 4. Training intervention with our tool improves the accuracy of endoscopists meeting the ASGE PIVI standards for sensitivity and NPV 5. The training tool increases the endoscopist's degree of confidence in the use of AAC 6. The training tool also leads to shift in attitudes of endoscopists from Seattle protocol towards AAC guided biopsy protocol for Barrett's surveillance.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Abstract No: P0468**

**Table 1:** Performance of educational intervention at each stage of training tool, *p < 0.05 The training intervention with our tool led to a significant improvement in the endoscopist confidence in AAC, with the mean pre-training confidence level rising from 2.5 (5-point scale) to 3.9 post-training (p < 0.001). The training module led to a significant shift to the willingness of the endoscopists in changing practise from Seattle protocol to AAC-targeted biopsy with mean pre-training score of 2.6 (5-point scale) rising to 3.8 post-training(p < 0.001).

**Introduction:** It is well-documented that stenting is the best palliative treatment for advanced oesophagus- and cardia-cancer when it comes to relief of dysphagia. However, which kind of stent that is most favorable has not been established. Earlier designs of fully-covered oesophageal stents had the acknowledged disadvantage of a higher risk of migration. In this study we compared a newer design of a fully-covered stent (Wallflex®) with a widely used semi-covered stent (Ultraflex®). Migration more than 20 mm was the primary outcome. Effects on dysphagia, QoL and need for re-intervention were also investigated.

**Aims & Methods:** Ninety-five patients with dysphagia secondary to a non-curable oesophagus/cardia cancer were randomized, in a prospective multi-center setting, to receive either the newer fully-covered stent (n = 48) or the conventional semi-covered stent (n = 47). The follow-up examinations were scheduled at one week, four weeks and three months, entailed a chest x-ray, dysphagia scores and QoL measurements.

**Results:** 13.9% of patients with fully covered stents experienced stent-migration compared to 25.6% with partially-covered stents at three months; a difference which was not significant. During total survival time the difference in migration were 20.1% vs 37.2% with a tendency towards significance (p = 0.068) in favor for the fully-covered group.

Dysphagia was measured with Watson and Ogilvie scores and with the dysphagia module in the quality of life measurements (QLQ OG-25). On average, there was a tendency to a better result for the fully-covered design with the two latter dysphagia instruments (p = 0.081 and p = 0.067), but only at three months. There was no significant difference in Quality of life (QLQ-C30) between groups at any time point. No difference in technical failures was detected, but a trend towards more re-interventions in the semi-covered group (p = 0.083) was seen.

**Conclusion:** This study suggests that the risk of migration is not increased when using a fully-covered stent compared to the conventional semi-covered stent. The potential benefit of the former is reflected by somewhat better effects on dysphagia relief in those with longer life expectancy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0470 LYMPHOVASCULAR INVASION MAY BE MORE RELEVANT TO NODAL METASTASES THAN SUBMUCOSAL MASSIVE INVASION IN EARLY-STAGE ESOPHAGEAL SQUAMOUS CELL CANCERS: A RETROSPECTIVE ANALYSIS IN 29 CASES

**T. Akimoto**[1], O. Goto[2], Y. Kiguchi[1], Y. Mitsunaga[1], A. Fujimoto[1], Y. Ochiai[1], T. Maehata[1], T. Nishizawa[1], T. Uraoka[1], N. Yahagi[1]

**Introduction:** Endoscopic submucosal dissection (ESD) for early-stage esophageal squamous cell cancer (ESCC) s is gaining acceptance as one of curative treatment options. With regard to the possibility of nodal metastasis, lesions invading muscularis mucosae (MM) or deeper or positive lymphovascular invasion are thought to require additional treatments even though they are completely resected endoscopically. However, which of the two factors (tumor invasion or lymphovascular involvement) contribute more to the probability of nodal metastases has not been fully investigated. Therefore, we retrospectively assessed non-curative ESCC cases after ESD to compare the potential risk of nodal metastasis between these two histological findings.

**Aims & Methods:** We identified 163 patients who underwent initial ESD from June 2010 to September 2015. Of these, the invasion depth was MM or SM in 31 lesions in 30 patients. Out of 30 patients, we assessed the clinical courses of 29 patients who could be monitored after ESD.

**Results:** The mean age was 65.5 years old. Males and females were 24 and 5, respectively. The mean size of lesions was 30.1 mm. En bloc resection rate was 100% (29/29). Complete resection rate was 96.8% (28/29). Clinical courses after ESD were observation (17), surgery (8), chemoradiotherapy (2) or chemotherapy (1), respectively. The depths of invasion were MM/SM1 in 25 and SM2 in 4, respectively. Of the 25 patients (MM/SM1) and 4 patients (SM2), 5 patients and 3 patients underwent surgery, respectively. Although there was no pathological residual cancer after surgery, lymph node metastasis rate of MM/SM1 and SM2 was 40% (2/5) and 33% (1/3), respectively (p = 0.8214). Lymphovascular involvement was positive in 6 patients (20.7%). Of these, each 4 patients with or without ductal invasion underwent surgery. There was a tendency that lymph node metastasis rate was higher (3/4, 75%) in positive ductal invasion cases than in negative cases (0/4, 0%), without significant difference (p = 0.0714). The mean observational period was 25 months. The overall survival rate was 96.8% (28/29). There was no esophageal cancer death.

**Conclusion:** Lymphovascular involvement may contribute more to the probability of nodal metastasis than the depth of invasion. Additional treatments after ESD should be considered in cases having ductal invasion. On the other hand, the data implied that no further treatment could be avoided after ESD in some non-curative cases without ductal invasion. ESD for ESCCs as a staging measure may be acceptable especially in patients who are reluctant to undergo radical treatments due to comorbidities.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0471 CLINICAL SIGNIFICANCE OF GLASGOW PROGNOSTIC SCORE FOR ESOPHAGEAL SQUAMOUS CELL CARCINOMA AFTER ESOPHAGECTOMY

**Introduction: Depth of tumor invasion and lymph node metastasis** are well-known prognostic factors in esophageal squamous cell cancer (ESCC). Inflammation-based Glasgow prognostic score (GPS), which is based on a combination of C-reactive protein (CRP) and albumin measurements, has been reported to have a prognostic value for several types of cancer, such as colorectal cancer and gastric cancer. However, the value of GPS for ESCC remains unclear.

**Aims & Methods:** The aim of this study was to investigate the prognostic value of GPS for ESCC after R0 esophagectomy. A total of 328 patients with ESCC who underwent R0 radical esophagectomy with 2- or 3- field lymphadenetomy between January 2000 and December 2014 were identified from a prospectively collected database. Prognostic factors were investigated according to the depth of tumor invasion. Patients with both an elevated CRP (≥10 mg/L) and low albumin (<35 g/L) levels were allocated a score of 2. Patients with only one of these abnormalities were allocated a score of 1, and those with normal CRP and albumin levels were allocated a score of 0.

**Results:** There were 290 males and 38 females, with a median age of 64 years (39–87 years). Of these, 112 (34%) had pT1 tumor, 53 (16%) had pT2 tumor, and 163 (50%) had pT3 tumor. The 5-year overall survival (OS) rate for the whole group was 60%, with a median follow-up of 82.2 months. The 5-year OS was 70% for pT1/2 ESCC and 50% for T3 (pT1/2 vs pT3, P = 0.0001). Two hundred thirty-seven patients had GPS 0 (72.5%), 67 had GPS 1 (20.5%), and 23 had GPS 2 (7%). 1) Prognostic factors for pT1/2 ESCC. In univariate analysis, age (<65 vs ≥65, P = 0.0008), GPS (0 vs 1/2, P = 0.0018), and other primary malignancy (no vs yes, P = 0.0388) were found to be factors affecting the survival. Other factors including gender (female vs male), tumor length (<6 cm vs ≥6 cm), tumor location (lower vs middle/upper), multifocal neoplasia (no vs yes), lymph node

metastasis (pN0 vs pN1–3), histologic grade (1 vs 2/3), lymphadnectomy (3F vs 2F), and postoperative morbidity (no vs yes) did not affect the survival. In multivariate analysis, GPS (HR: 2.814, 95%CI: 1.530–5.013, P = 0.0012) and age (HR: 2.488, 95%CI: 1.4643–4.2990, P = 0.0007) were found to be independent prognostic factors. 2) Prognostic factors for pT3 ESCC. In univariate analysis, gender (P = 0.0389), lymph node metastasis (P = 0.0054), and histologic grade (P = 0.0231) were significantly associated with OS. In multivariate analysis, only lymph node metastasis was an independent prognostic factor (HR: 1.789, 95%CI: 1.057–3.219, P = 0.0293).
**Conclusion:** Prognostic factors were different according to the depth of tumor invasion. GPS has prognostic value in patients with pT1-2 ESCC who underwent R0 esophagectomy. However, GPS does not have the prognostic significance in patients with pT3 ESCC. GPS might be more practical when used in combination with tumor-related factors.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0472 MISSED OESOPHAGOGASTRIC CANCERS AT ENDOSCOPY, WHAT CAN WE LEARN FROM RETROSPECTIVE AUDIT?

**A. Cavazza**[1], V. Karunanithi[2], A. Vaziri[2], J. Deacon[3], D.L. Morris[4]

**Introduction:** Studies based on retrospective analysis in England found 6–14% of patients with oesophagogastric malignancy had an endoscopy within the 3 previous years. This study aims to establish the incidence of oesophagogastric (OG) missed cancers during endoscopy and identify possible risk factors based from our experience in a district general hospital in the UK which serves a population of half a million patients. Possible risk factors suggested from other studies include concurrent UGI Bleeding and use of sedation.
**Aims & Methods:** This is a retrospective study of all patients diagnosed with OG cancers from March 2014–15. We identified those patients who underwent an endoscopy within 3 years before the diagnosis. The indications, findings, endoscopist seniority and type of sedation were recorded. The information was extracted from computerised endoscopy and histology records. We also compared our findings with the previous years and 2013–14.
**Results:** 71 patient were diagnosed with upper GI cancer over one year period and 5 (7%) had a previous endoscopy done within the last 3 years. 3 cases were oesophageal and 2 cases were gastric cancers. Mean age at diagnosis was 76 years (range 62–89). The endoscopy was performed mainly by Consultant in 60% of cases. Two cases needed a third endoscopy in order to diagnose the cancer. In two cases, one with Barrett's and one failed intubation, the repeated planned endoscopy did not happen in a timely manner. In one case, oesophageal cancer was mistaken for food residue in two occasions. The fourth case was a patient with Barrett's who underwent surveillance and cancer was missed on biopsy and the last case was a patient with gastric ulcer which was not initially biopsied because of dual anti-platelets therapy.
**Conclusion:** We have identified a small number (7%) of upper GI cancer missed during endoscopy in the last year audit**.** The reported incidence seem to be similar to a previous audit conducted in our hospital (9%) and to a larger English study. The presence of sedation or the level of endoscopist seniority did not seem to be related to missed cancer. We stress the importance of performing quality endoscopy, of timely follow-up endoscopies and to improve the standard of OG endoscopy nationally, with quality indicators for gastroscopy and standardised teaching as recommended by the British Society of Gastroenterology.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0473 THE OUTCOME OF ESOPHAGO-GASTRIC JUNCTIONAL ADENOCARCINOMA TREATED BY ESD AND ANALYSIS FOR THE RISK FACTOR OF LYMPH NODE METASTASIS

**A. Takahashi**[1], T. Oyama[2]
[1]*Advanced Care Center, Saku Central Hospital Gastroenterology, Nagano/Japan*
[2]*Endoscopy, Saku Central Hospital Advanced Care Center, Nagano/Japan*

**Contact E-mail Address:** aurevoireurope@yahoo.co.jp.
**Introduction:** Esophago-gastric junctional adenocarcinoma (EGJAC) has been increasing in Japan. The risk of lymph node metastasis (LNM) of gastric adenocarcinoma (GAC) and esophageal squamous cell carcinoma (ESCC) is different. That of GAC corresponds with invasion depth, histology, size, ulcer scar and vascular invasion. And, that of ESCC corresponds with only invasion depth and vascular invasion. And, that of EGJAC is still unclear.
**Aims & Methods:** The aim of this study is to investigate the outcome of superficial EGJAC treated by ESD and the risk factor of LNM in superficial EGJAC. Ninety four patients (80 males and 14 females) with EGJAC treated by ESD from Jan. 2000 to Dec. 2012 were enrolled to this retrospective study. EGJAC was defined as adenocarcinoma located between 1 cm oral and 2 cm anal from EGJ. The median age and follow up period were 74 and 73 months, respectively. The median diameter of the lesions was 18 mm. Protuberant, flat and depressed type was 44, 3 and 47 lesions, respectively. T1b was sub-classified into T1bSM1 (500 micrometer or less) and 2 (501 micrometer or bigger). T1aM, T1bSM1 and T1bSM2 were 67, 15 and 12, respectively. Dominant histology, differentiated and poorly differentiated adenocarcinoma were 90 and 4 lesions, respectively.
**Results:** 1. Complete resection rate was 100%. R0 rate resection was 99% (93/94). 2. Complications: The bleeding during ESD and delayed bleeding required blood transfusion was 0% and 1% (1/94). The perforation during ESD and delayed perforation was 1% (1/94) and 0%. Stenosis was 11% (10/94), and all of 10 cases were treated by endoscopic balloon dilatation. 3. Local recurrence rate was 0%. 4. The risk factors of LNM (Univariate analysis) a. Invasion depth; The rate of LNM was 0% (0/82) in T1aM to T1bSM1 and 8% (1/12) in T1bSM2 (p = 0.12277). b. Histological type; The rate of LNM was 0% (0/90) in well differentiated adenocarcinoma (WDA) and 25% (1/4) in poorly differentiated adenocarcinoma (PDA) (p = 0.00426). c. Histology of T1b; The rate of LNM of WDA and PDA were 0% (0/22) and 20% (1/5) in poorly differentiated adenocarcinoma (p = 0.11852). d. Lymphatic invasion; The rate of LNM was 33% (1/3) in positive and 0% (0/91) in negative (p = 0.0319). e. Tumor size, ulcer scar didn't correlate with LNM; 5. The risk factors of LNM (Multivariate analysis) Lymphatic invasion (p = 0.03) and PDA (p = 0.05) were the risk factors of LNM.
**Conclusion:** The outcome of superficial EGJAC treated by ESD was excellent. Lymphatic invasion and PDA were the risk factors of LNM of EGJAC. The guide lines of GAC rather than ESCC should be indicated for EGJAC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0474 CHARACTERISTICS AND RISK FACTORS FOR SOLITARY NON-AMPULLARY DUODENAL CARCINOMA

**Introduction:** Non-ampullary duodenal carcinoma (NADC) is rare, and its characteristics and risk factors are not well-known.
**Aims & Methods:** The aim of this study was to clarify clinical characteristics and risk factors for solitary NADC. From the cancer registry database from 2003 to 2015 in a prefectural cancer center, patients diagnosed as non-ampullary duodenal carcinoma were extracted. Patients with duodenal tumors such as neuroendocrine tumors, lymphoma, stromal tumor, metastatic tumor, ampullary tumors and familial adenomatous polyposis were excluded. For each NADC patient, 2 age/sex-matched controls were selected from medical checkup recipients in the same hospital. Smoking and drinking habits, history of colorectal adenoma/carcinoma, infection status of *Helicobacter pylori* (*H. pylori*), grade of gastric atrophy, diabetes, other malignancy and familial history were compared between the groups.
**Results:** A total of 160 NADC in 156 patients (male/female: 103/53) and 312 controls were assessed. The median age of NADC patients was 64 (range 31–90) and median body mass index was 22 (range 15–31). Most of NADC were located in the second portion (121/160, 76%), histology was mostly differentiated adenocarcinoma (144/160, 90%), the clinical/pathological depth was T1 in 99 (63%), T2 or more in 57 (37%) patients. In total, number of smoking habit (past or current), *H. pylori* infection, and moderate to severe atrophic gastritis were significantly higher in NADC patients. There was no difference among history of colorectal adenoma/carcinoma and familial history between the groups. In male NADC patients, number of past history of other malignancy was also significantly higher. In female NADC patients however, number of smoking and drinking habits were the only significant factors.
**Conclusion:** The frequency of NADC was higher in men. The common risk factor for NADC of both genders was smoking.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0475 EFFECT OF VONOPRAZAN IN ARTIFICIAL ULCER HEALING AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION

**Y. Horikawa**, H. Mizutamari, N. Mimori, Y. Kato, S. Fushimi, S. Okubo
*Gastroenterology, Hiraka General Hospital Dept. of Gastroenterology, Yokote/Japan*

**Contact E-mail Address:** horikawa_01@me.com.
**Introduction:** Anti-secretory agents, proton pump inhibitors (PPIs) and histamine H2 receptor antagonists (H2RAs), have already been the standard management for artificial gastric ulcers after endoscopic surgeries. Vonoprazan is a new type of anti-secretory drug, Potassium-Competitive Acid Blocker (P-cab). This drug could involve stronger and more rapid anti-secretory effect than common used PPIs. Vonoprazan so far indicated the equal or superior efficacy for peptic gastric or duodenal ulcer compared to the existing PPI, Lansoprazole. However, the effect of Vonoprazan for ESD-related procedure and adverse events is unclear.
**Aims & Methods:** We preliminary conducted this study to clarify the effect of Vonoprazan to the ESD-related gastric ulcer healing compared to Lansoprazole. We prospectively analyzed consecutive patients treated between April 2015 and March 2016 at Hiraka General Hospital. Patients were randomly allocated to two groups just after the ESD procedure by the following pharmacotherapy for 4 weeks: Group V (treated by Vonoprazan 20 mg) and Group L (treated by

Lansoprazole 30 mg). The primary outcome was the epithelial regeneration rate of the artificial ulcer base 2 weeks after ESD. The secondary outcomes were the diminution rate of the artificial ulcer 2 or 4 weeks after ESD and the occurrence rate of adverse events.
**Results:** A total of 60 patients were enrolled (30 cases in Group V and 30 cases in Group L). In Group V, the epithelial regeneration rate was significantly accelerated (P = 0.0007), and the diminution rate 2 or 4 weeks after ESD was significantly higher (P = 0.0060 / 0.0069) compared to Group L. There were no adverse events in both Groups.
**Conclusion:** P-CAB indicated to posses a rapid artificial ulcer healing compared to the common used PPI in this study. This suggested that P-CAB could be potential pharmaco-therapeutic choice after gastric ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0476 THE CORRELATION BETWEEN HISTOLOGICAL GASTRITIS STAGING- "OLGA/OLGIM" AND SEROLOGICAL PEPSINOGEN TEST IN RISK ASSESSMENT OF GASTRIC CANCER IN CHINA

**X. Wang**, B. Lu, S. Zhang, C. Y. Chen, M. Zhang
*Department Of Gastroenterology, First Affiliated Hospital of Zhejiang Chinese Medical University, Hangzhou/China*

**Contact E-mail Address:** rainbowlove44@126.com.
**Introduction:** The combination of serum pepsinogen (PG) level and serum anti-*Helicobacter pylori* IgG antibody, "ABC method", has been suggested to serve as a useful predictive marker for patients with gastric cancers. The available classifications of gastritis, known as the Operative Link on Gastritis Assessment (OLGA) and Operative Link on Gastritis Intestinal Metaplasia (OLGIM), have been gradually accepted and used in screening for gastric cancer in recent years.
**Aims & Methods: Aim**: To assess whether OLGA staging system and OLGIM staging system are consistently stratified patients according to the ABC method and applicable in the screening for gastric cancer. **Methods**: The OLGA or OLGIM staging system ranks the GC risk according to both the topography and the severity of gastric atrophy or intestinal metaplasia. A total of 331 enrolled consecutive patients (140 men and 191 women) who underwent endoscopy with consecutive biopsy sampling (A set of at least 5 biopsy samples) were retrieved and reassessed according to both the OLGA and the OLGIM staging systems. Serum pepsinogen tests, including the levels of PG I, PG II, PGI/PFII (PGR) and *H. pylori* antibody, were also measured to assess the presence of atrophic gastritis. Results were presented as gastritis stage serum pepsinogen level and *H. pylori* status.
**Results**:All patients were assessed applying the OLGA and OLGIM criteria with a mean age of (54.7 ± 10.8) years. Overall, 116 (27.9%) and 154 (37.1%) patients were classified as stage I-IV according to OLGA and OLGIM. Patients among OLGA or OLGIM stage III-IV were presented with a lower level of serum PGI and PGR (P < 0.05), especially for stage-IV (P = 0.01). Meanwhile, according to the result of serum pepsinogen tests, 214 (64.7%) patients were classified into group A, 106 (32.0%) patients into group B, 4 (1.2%) patients into group C and 7 (2.1%) patients into group D, respectively. There exists connections between OLGA, OLGIM stratifications and ABC method in patient stratification for gastric mucosal atrophy assessment (P = 0.002, P = 0.004).
**Conclusion:** Gastritis staging, including OLGA and OLGIM, combined with serum pepsinogen levels, provide prognostically important information on the cancer risk.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0477 UPCOMING PARADIGM SHIFT OF GASTRIC CANCER RISK: INCREASE OF H. PYLORI NEGATIVE GASTRIC CANCER AND THEIR RISK FACTORS

**S. Nam**, S.W. Jeon, H.Y. Park
*Gastroenterology, Kyungpook National University Medical Center, Daegu/Korea, Republic of*

**Contact E-mail Address:** nam20131114@gmail.com.
**Introduction:** Although the prevalence of *H. pylori* infection has gradually decreased recent two decades, the incidence of gastric cancer has not decreased. The incidence of *H. pylori* negative gastric cancer (HPNGC) has been reported as below 10% before 2010. The tumor characteristics of HPNGC have been evaluated but host habitual factors have not been known. We evaluated the incidence and host habitual factors of HPNGC in South Korea.
**Aims & Methods:** A total of 394 gastric cancer patients underwent rapid urease test and serum *H. pylori* IgG test and completed the questionnaires for personal history and diet habits from March 2014 to Oct 2015 in a single medical center. *H. pylori* positive gastric cancer (HPPGC) was defined as current *H. pylori* infection and HPNGC was defined as negative current infection and negative serum HP IgG and no history of *H. pylori* eradication. Past infection was defined as current *H. pylori* negative with presence of *H. pylori* eradication or positive serum *H. pylori* IgG.
**Results:** The portion of HPNGC, HPPGC, and past infection was 34% (n = 134), 50% (n = 198), and 16% (n = 62), respectively. HPNGC was related with old age comparing to HPPGC (64.7yr vs 61.9yr, P = 0.025) and early menopause (48.0yr vs 50.8yr, p = 0.014). Low fruit diet was higher in HPNGC than HPPGC (59.4% vs 47.9%, p = 0.041) and low soy-tofu diet was also higher in HPNGC than HPPGC (31.6% vs 19.7%, p = 0.014). In multivariate analysis, age increased the risk of HPNGC (odd ratio [OR] 1.03, 95% confidence interval [CI] 1.01–1.05), whereas high fruit diet (OR 0.58, 95% CI 0.36–0.94) and high soy-tofu diet (OR 0.60, 95% CI 0.30–0.99) decreased the risk of HPNGC.
**Conclusion:** The incidence of HPNGC was high comparing to previous reports and they are related to increasing age, low fruit diet, and low soy-tofu diet comparing to HPPGC.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0478 NEGATIVE PATHOLOGIC RESULTS AFTER GASTRIC ENDOSCOPIC SUBMUCOSAL DISSECTION

R. Daegon, D. Kang, H. Kim, C. Choi, S. Park, S. Kim, H. Nam, S. Lee, J. Cho, **J. Park, K.** Oh
*Division Of Gastroenterology, Department Of Internal Medicine, Pusan National University Yangsan Hospital, Yangsan/Korea, Republic of*

**Contact E-mail Address:** mini3763@hotmail.com.
**Introduction:** Endoscopic submucosal dissection (ESD) is largely used for gastric superficial neoplasm (gastric adenoma or EGC), although in some cases the negative results of the pathological group after ESD leads to confusion.
**Aims & Methods:** After ESD forgastric adenoma or EGC by endoscopic forceps biopsy, we evaluated the causes and factors with negative pathologicresult after ESD. Between December 2008 and July 2015, a total of 1379 patients were performed after endoscopic forceps biopsy. Weanalyzed the causes and factors that are associated with negative pathology.
**Results:** The incidence of patients with a negative pathology after ESD was 2.0% (28/1379). Factors related to negativepathologic findings were small tumor size and surface area. The reasons of negative pathologic lesions after ESDwere as follows: complete removal during endoscopic forcep biopsy, overestimation of EFB pathology and incorrectlocalization of ESD site.
**Conclusion:** Small tumor size and surface area were associated with negative pathologic result after ESD. When negativepathologic results were reported after ESD, a review of the previous endoscopic biopsy tissue pathology andcontinued observation of the lesion is needed, because of the possibility of an incorrect localization during ESD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0479 EFFICACY AND SAFETY OF A PATIENT-POSITIONING DEVICE (EZ-FIX) FOR ENDOSCOPIC SUBMUCOSAL DISSECTION OF GASTRIC EPITHELIAL NEOPLASM

**S. Pyeon**[1], D.W. Ha[2], C.J. Park[2], C.H. Park[3], B.E. Lee[4], G.H. Kim[5], G.A. Song[5]

**Contact E-mail Address:** smartpsi@hanmail.net.
**Introduction:** Endoscopic submucosal dissection (ESD) has been widely accepted as an excellent treatment for gastric epithelial neoplasm. Although ESD has its advantages, the technique of ESD is complicated and requires considerable expertise and a prolonged operation time and at least moderate to deep level of sedation. So, we think that fixing the position of patient can minimize patient movement and can achieve safe and successful ESD procedure outcomes. EZ-FIX is a patient-positioning device that uses polyethylene particles and compressed air that is expected to contribute to procedure efficacy and safety by fixing the position of the patient.

**Aims & Methods:** To assess the efficacy of a patient positioning device (EZ-FIX) during endoscopic submucosal dissection (ESD) for gastric epithelial neoplasm. In this prospective study, a total of 86 patients who had been diagnoesd with gastric adnoma or early gastric cancer were randomized to the EZ-FIX (n = 44) and non-EZ-FIX (n = 42) group. During ESD, midazolam and propofol was titrated to provide an adequate level of sedation, and patient's movement score was measured. The endoscopist completed a questionnaire after ESD, using a 10-cm visual analog scale (VAS), which assessed the level of satisfaction with sedation and overall satisfaction with the procedure. In the EZ-FIX group, a contribution of EZ-FIX to stable ESD was assessed and diviedeinto four categories of none, low, medium and high. We defined the contribition group from low to high categories. Patients also completed a questionnaire, using a 10 cm VAS, which assessedpost-ESD myalgia, overall satisfaction with procedure and an uneasiness to EZ-FIX use.
**Results:** There was no significant difference between the EZ-FIX and non-EZ-FIX groups in terms of age, gender, BMI, ASA score, lesions' endoscopic and histological findings and dose of sedatives. EZ-FIX group just took a longer procedural time than the non-EZ-FIX group (28.1 ± 24.2 minvs19.6 ± 12.0 min, p = 0.044). Clinical outcomes including an en bloc and complete resection rate, procedure related complications, endoscopistsatisfaction with sedation and overall satisfaction with procedure did not differ between the two groups. In the EZ-FIX group, 16 patients (36.4%) were a contribution group. Subgroup analysis between the contribution and non-contricution groups revealed that the contribution group had a larger lesion size (24 ± 19 mm vs 15 ± 10 mm, p = 0.043) with a longer procedural time (38.0 ± 33.9 mind vs 22.4 ± 14.2, p = 0.037), and had a higher patient's movement score (p = 0.000) with a higher dose of propofol (p = 0.004) and pethidine (p = 0.001). Endoscopist satisfaction with sedation (7.5 ± 1.0 vs 9.5 ± 0.5, p = 0.00) and overall satisfaction with the procedure (8.4 ± 1.0 vs 9.2 ± 0.8, p = 0.01) was lower in the contribution group than the non-contribution group. The results of the patients'questionaire survey did not differ significantly between the two groups.

Clinical outcomes of the ESD procedure in the EZ-FIX and non-EZ-FIX group

| | EZ-FIX (n = 44) | Non-EZ-FIX (n = 42) | P value |
|---|---|---|---|
| En bloc resection rate | 100 | 97.6 | 0.303 |
| Complete resection rate | 97.7 | 97.6 | 0.973 |
| Procedure related complications (%) | | | |
| Bleeding | 1 (2.3) | 0 (0) | 0.326 |
| Perforation | 0 (0) | 0 (0) | |
| Unstable vital sign | | | |
| Below 90% in SaO2 for ≥30 s | 0 (0) | 0 (0) | |
| ↓20 mm = Hg in BP | 0 (0) | 0 (0) | |
| ↓20% in PR | 0 (0) | 0 (0) | |
| Endoscopist satisfaction with sedation | 8.8 ± 1.2 | 8.4 ± 1.6 | 0.240 |
| Endoscopist overall satisfaction with procedure | 8.9 ± 0.9 | 8.8 ± 1.4 | 0.632 |

**Conclusion:** To achieve successful outcomes, patient's cooperation is very important during ESD. In this study, we think EZ-FIX is an effective tool for patients with incomplete sedationand who are expected to take a long procedure time with a large lesion size, especially more than 2 cm.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0480 USEFULNESS OF A NOVEL MAGNIFYING LCI WITH INDIGO CARMINE DYE IN THE DIFFERENTIAL DIAGNOSIS OF GASTRIC SMALL DEPRESSIVE LESIONS

**Y. Kitagawa**[1], T. Hara[1], T. Suzuki[1], T. Yamaguchi[2]

**Contact E-mail Address:** ykitagawa@chiba-cc.jp.

**Introduction:** Magnifying endoscopy using image-enhanced endoscopy (M-NBI or M-BLI) has been reported to be useful for the accurate diagnosis in the GI tract compared with white-light imaging (WLI) endoscopy [1, 2]. However, NBI or BLI produces monochromatic images only, thus conventional magnifying endoscopy findings are difficult to interpret in some situations. Recently, Linked Color Imaging (LCI) was developed using a laser endoscopic system, which emphasizes the contrast of reddish color. We discovered LCI with indigo carmine dye (Chromo-LCI), which can add information of color image to magnifying endoscopy. Thus, Chromo-LCI is considered a novel image-enhanced endoscopy, contributing to improve visualization of the microstructures and microvessels of the superficial gastric mucosa.
**Aims & Methods:** The aim of this retrospective, cross-sectional image evaluation study was to investigate the usefulness of M-Chromo-LCI for the differential diagnosis of gastric lesions. We collected 100 consecutive gastric small depressive lesions between December 2014 and March 2016. The inclusion criteria were as follows: lesions estimated 10 mm; lesions diagnosed as noncancerous or cancer on biopsy or endoscopic resection specimens; and endoscopic images of the same lesions taken under the same conditions using M-BLI and M-Chromo-LCI. The expert selected one endoscopic image for each modality that could adequately depict whether a lesion is cancer or noncancerous. The endoscopic images were randomly displayed for each modality, and independently reviewed by six endoscopists (3 experts and 3 non-experts) without prior knowledge of the histologic findings of the lesions. The diagnostic accuracy and interobserver agreement for WLI, M-BLI, and M-Chromo-LCI were then compared.
**Results:** For the experts, M-BLI showed a statistically significantly higher diagnostic accuracy, sensitivity, and specificity compared with WLI (82.7% vs 67.0%, $P < 0.05$, 80.6% vs 66.1%, $P < 0.05$, and 85.2% vs 68.1%, $P < 0.05$, respectively). M-Chromo-LCI showed a statistically significantly higher diagnostic specificity compared with M-BLI (95.6% vs 85.2%, $P < 0.05$), but the diagnostic accuracy of M-BLI (82.7%) and M-Chromo-LCI (87.7%) did not differ significantly. For the non-experts, M-BLI showed a statistically significantly higher diagnostic accuracy and sensitivity compared with C-WLI (69.3% vs 52.3%, $P < 0.05$, 77.6% vs 52.1%, $P < 0.05$, respectively). M-Chromo-LCI showed a statistically significantly higher diagnostic accuracy and specificity compared with M-BLI (79.7% vs 69.3%, $P < 0.05$, 74.1% vs 59.3%, $P < 0.05$, respectively). For the experts, interobserver agreement indicated fair agreement for C-WLI, moderate agreement for M-BLI, substantial agreement for M-Chromo-LCI (kappa values = 0.33, 0.52 and 0.77, respectively). For the non-experts, interobserver agreement indicated fair agreement for C-WLI and M-BLI, moderate agreement for M-Chromo-LCI (kappa values = 0.32, 0.33 and 0.43, respectively).
**Conclusion:** M-chromo-LCI enabled the accurate diagnosis of gastric small depressive lesions with good reproducibility, regardless of the reviewer's proficiency. Magnifying Chromo-LCI is expected to be powerful modality for the differential diagnosis of gastric lesions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0481 NEUTROPHIL LYMPHOCYTE RATIO VERSUS PLATELET LYMPHOCYTE RATIO IN PREDICTION OF SURVIVAL IN PATIENTS WITH GASTRIC ADENOCARCINOMA

**S. Gundogdu**, B. Yildiz, M. Tez
*General Surgery, Ankara Numune Teaching Hospital, Ankara/Turkey*

**Contact E-mail Address:** salihbg@hotmail.com.

**Introduction:** The serum neutrophil lymphocyte ratio and platelet lymphocyte ratio are considered an easily assessable prognostic factor in cancer patients. We evaluated significance of neutrophil lymphocyte ratio and platelet lymphocyte ratio in predicting survival in patients with gastric cancer who had undergone gastric resection.
**Aims & Methods:** From 2003 to 2014, 192 patients who had undergone gastrectomy with curative intent for gastric adenocarcinoma were included. Data were retrieved from a prospective collected database. Neutrophil lymphocyte ratio and platelet lymphocyte ratio were calculated from lymphocyte and neutrophil counts on routine blood tests taken before surgery. Survival analyses were generated according to the Kaplan–Meier method. Univariate and multivariate analyses were carried out by the Cox proportional hazard model.
**Results:** Mean age of patients was 59 ± 12 (26–88). There were 68 female and 124 male patients. The median follow-up time for surviving patients was 24 months (range 1 to 32 months). None of the patients received a neoadjuvant treatment modality. Median preoperative neutrophil lymphocyte ratio was 3.7 ± 3.8 (range 0.34 to 33). A cut off value for neutrophil lymphocyte ratio was identified as of

2.3 according to ROC analysis. Multivariate analysis failed to show a statistically significant relationship between the neutrophil lymphocyte ratio and the overall survival with a p value of 0.167. When platelet lymphocyte ratio was analyzed it was seen that 155 was cut off according to ROC. Median preoperative platelet lymphocyte ratio was 1.9 ± 1.12 (range 11.6 to 614). Furthermore, Kaplan Meiere analysis depicted better overall survival in patients with platelet lymphocyte ratio less than 155.
**Conclusion:** Inflammatory mediators such as lymphocytes and platelets might promote progression of tumor cells. The results suggest that the elevated preoperative neutrophil lymphocyte ratio does not predict poor overall survival following resection for gastric adenocarcinoma. But elevated platelet lymphocyte ratio migth be used a marker to predict survival for these patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** miyajimail0413@yahoo.co.jp.

**Introduction:** Endoscopic submucosal dissection (ESD) for early gastric cancer (EGC) in histology of undifferentiated-type (UD-type) adenocarcinoma is gradually prevailing from its minimally-invasive approach, though it is performed as clinical research in expanded indication of ESD according to Japanese Gastric Cancer Association (JGCA). There are still no report of multiple gastric cancers (synchronous or metachronous) comparing. The aim is to clarify the incidence of synchronous and metachronous gastric cancers after ESD for UD-type ECG.
**Aims & Methods:** We treated UD-type EGC in 237 patients by ESD which was preoperatively diagnosed as expanded indication (within 20 mm, intramucosal, without ulceration, UD-type adenocarcinoma) from May 2004 to October 2014, in Cancer Institute Hospital, Tokyo, Japan. Excluding the patients with past history of operation in stomach, 173 patients with UD-type ECG (UD group) was compared to the 173 patients with differentiated-type group (D group) treated by ESD. D group was randomly picked up matching their age and sex. Median observation period was 48.8 months. HP- was only diagnosed when the patients was HP- in 2 tests out of serum IgG, stool antigen and urease breath test and the patients didn't have gastric atrophy in endoscopy.
**Results:** We first compared the characteristics of patients and lesions between UD and D group. The ratio of male was 53%, 82% in UD and D group ($p < 0.01$). Tumor location in upper third was more frequent in UD than D group ($p < 0.01$). Tumor size was significantly smaller in UD group than in D group (10 mm vs 13 mm; $p < 0.01$). HP infection was less frequent in UD group than in D group (61% vs 100%; $p < 0.01$). The incident rate of synchronous cancer in UD and D group were 2.3% and 13.3% ($p < 0.01$). The cumulative incidence rate of metachronous cancer in UD group and D group were 0.7% and 10.5% in 3 years, 0.7% and 16.1% in 5 years, and 5.9% and 21.9% in 7 years. The incidence of metachronous cancer in UD group was significantly less frequent than D group by log-rank test ($p < 0.01$). Histology of multiple cancers were 3 D-type and 4 UD-type cancers in UD group, and 43 D-type cancers in D group ($p < 0.01$). Noteworthy, Hp- patients in UD group had only UD-type EGC, while patients in D group had only D-type EGC for synchronous and metachronous cancers.
**Conclusion:** Synchronous and metachronous cancers were less frequent in UD group than in D group. Histology of multiple cancers were different each other between D and UD group.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0483 EARLY GASTRIC CANCER WITH MIXED HISTOLOGICAL COMPONENTS IS HIGH-RISK FOR LYMPH NODE METASTASIS

**A. Shimayoshi**, S. Yamamoto, K. Kozumi, E. Kimura, E. Yoshida, F. Sano, C. Torizumi, T. Eri, M. Horie, K. Iwahashi, D. Nakamatsu, M. Murata, M. Miyazaki, E. Satoshi, M. Oshita
*Internal Medicine, Osaka Police Hospital, Osaka-shi/Japan*

**Contact E-mail Address:** simakit7@gmail.com.

**Introduction:** Endoscopic submucosal dissection (ESD) is minimally invasive therapy for early gastric cancer (EGC) and its application prevails gradually. After ESD is performed, we evaluate the obtained specimen histologically, and additional surgery becomes necessary when the lesion has the risk of lymph node metastasis. Several factors have been established as risks for lymph node metastasis. However, management of "mixed-type" lesions, which is consisted with differentiated and undifferentiated carcinoma, is still unclear.
**Aims & Methods:** The objective of the study is to clarify the clinicopathological significance of histologically mixed-type EGC. We retrospectively reviewed 593 consecutive EGC lesions in 528 subjects treated in our hospital (age (mean±SD) 69.9 ± 9.7), male/female 410/183). 362 were underwent ESD and 231 were underwent gastrectomy. We classified the obtained specimens into following four groups; purely undifferentiated type (PD, n = 471), mixed-type with predominantly differentiated part (MD, n = 34), purely undifferentiated type (PU, n = 55), and mixed-type with predominantly undifferentiated part (MU, n = 33). We examined the correlation between these types and following findings; location of the tumor, macroscopic type, tumor size, presence of lymphatic and vascular duct invasion, invasion depth of the cancer, and the existence of lymph node metastasis. Among subjects underwent gastrectomy, potential risk factor for lymph node metastasis including macroscopic type, tumor size, submucosal invasion depth, and the histological type (pure/mixed) were evaluated by multivariate logistic regression analysis.
**Results:** Subjects with PU type cancer were younger and held more female subjects than those with MU type ($p < 0.001$, $p < 0.05$). In macroscopic type, MD and PU type included more depressed lesions than PD and MU type, respectively ($p < 0.0001$, $p < 0.05$). Mean diameter of lesions of MD type were larger than that of PD type ($p < 0.0001$). MD and MU type were significantly associated with submucosal invasion than PD and PU type, respectively ($p < 0.0001$, $p < 0.001$) and this association was observed even among the lesion less than 20 mm, respectively ($p < 0.001$, $p < 0.05$). Multivariate analysis revealed that mixed-type (odds ratio (OR) = 3.1, 95% confidence interval (95%CI):1.2–8.3, $p = 0.02$) and the invasion depth (OR = 5.2, 95%CI: 1.6–2.3, $p = 0.01$) were significant risk factor for lymph node metastasis.
**Conclusion:** Regardless of tumor size, the factor of histologically mixed-type in EGC is an independent risk factor for lymph node metastasis. At evaluating the resected EGC, histological confirmation of whether the lesion is pure or mixed type should be considered.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0485 ANALYSIS OF PREDICTIVE FACTORS FOR VARIATION OF NEUTROPHIL COUNT DURING GASTROINTESTINAL CANCER CHEMOTHERAPY USING REAL WORLD DATA

**Introduction:** Variation of neutrophil count is one of the most important indicator when monitoring the efficacy and safety of chemotherapy. Physicians are always required to balance between maintaining effective drug concentrations and avoiding febrile neutropenia. We know empirically that the variation of monocyte count can predict the variation of neutrophil count; only a small number of studies with relatively small sample size reported the association between the decrease of monocyte and neutropenia during chemotherapy. We hence searched for clinical data which could serve as indicative precursor factors of changes in neutrophil count through a time series analysis of laboratory data.
**Aims & Methods:** We retrieved 22 items of laboratory data, (red blood cell count, hemoglobin estimation, platelet count, neutrophil count, lymphocyte count, monocyte count, eosinophil count, blood urea nitrogen, creatinine, albumin, aspartate aminotransferase, alanine aminotransferase, alkaline phosphatase, γ-glutamyltransferase, lactate dehydrogenase, total bilirubin, sodium, potassium, chloride, calcium, serum glucose, C-reactive protein) at 54338 time points from 1807 gastrointestinal cancer patients who received chemotherapy using our clinical database system (CyberOncology®), that is integrated in electronic medical record of Kyoto University Hospital. The patients characteristics were as follows: The median age was 65 years (Range 31−87 years), and 1166 patients (65%) were men. The most common cancer type was colorectal (n = 592, 33%), followed by pancreas (n = 454, 25%) and stomach (n = 283, 21%). We applied Vector Autoregressive (VAR) models and estimated chronological models. Furthermore, we analyzed cause-effect relationship between neutrophil count and other laboratory data by impulse response assay in based on estimated VAR model.
**Results:** VAR model showed that monocyte count is one of the most relevant factor for predicting variation of neutrophil count. In addition to red blood cell

count and serum albumin were also found to be significant relationship with variation of neutrophil count ($P < 0.001$, Z-test).
**Conclusion:** We demonstrated that monocyte count is promising indicator for predicting variation of neutrophil count analyzing Real World Data obtained in daily clinical practice.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0486 POTENTIAL ROLE OF MICRORNA-375 IN THE DIAGNOSIS OF CANCERS: A META-ANALYSIS

**J. Yan**
*Gastroenterology, the first affiliated hospital of nangjing medical university, Nanjing/China*

**Contact E-mail Address:** jsyj0220@163.com.

**Introduction:** Several studies have investigated the association between abnormal circulating microRNA-375 (miR-375) expression and cancers and identified miR-375 as diagnosis biomarker for cancer. However, the results are inconsistent. Therefore, this meta-analysis aimed to assess the potential diagnostic value of miR-375 for cancer.
**Aims & Methods:** We searched PubMed, Embase, and Web of Science for publications concerning the diagnostic value of miR-375 for cancer. The bivariate meta-analysis model was employed to summarize sensitivity, specificity, and diagnostic odds ratio (DOR) for miR-375 in the diagnosis of cancer. Summary receiver operating characteristic (SROC) curve analysis and the area under the curve (AUC) were also used to check the overall test performance.
**Results:** A total of 588 cancer patients and 393 cancer-free individuals from 11 studies were contained in this meta-analysis. The summary estimates revealed that the pooled sensitivity is 78% (95% confidence interval (CI): 62%-88%), the specificity is 75% (95% CI: 61%-85%), the DOR is 10.40 (95% CI: 5.93–18.24), and the AUC is 0.83 (95%CI: 0.79–0.86).
**Conclusion:** Our data suggest that miR-375 profiling has a potential to be used as a screening test for various cancers, and more studies on the diagnostic value of miR-375 for cancer are needed in the future.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The clinicopathologic features of gastric cancer in young patients are different from those of older patients.
**Aims & Methods:** The aim of this study was to identify the clinicopathologic features of early gastric cancer (EGC) and clinical outcomes of endoscopic submucosal dissection (ESD) in young patients (≤40). From January 2006 and June 2014, 55 patients aged 40 years old or younger with newly diagnosed EGC underwent ESD at two tertiary hospitals. Clinicopathologic features of EGC and clinical outcomes ESD in these young patients were reviewed retrospectively, compared with those of standard ESD cohort in our hospital.
**Results:** 55 patients with 57 EGC lesions underwent ESD in young patients group. Compared with older patients in our standard ESD cohort (older than 40 years old, 806 patients with 831 EGC), female patient, superficial flat or depressed lesions, undifferentiated histology, deep mucosal invasion were more common in young patients group. En-bloc resection rate and complete resection rate were not significantly different between two groups (93.0% vs. 88.1%, $p = 0.264$; 71.9% vs. 67.1%, $p = 0.456$). Although high proportion of undifferentiated cancers in young patients group, curative resection rate was not lower for the young patients groups compared with older patients groups (73.7% vs. 69.6%, $p = 0.706$). Among 16 patients with non-curative resection, 4 patients underwent additional surgery and 1 patient underwent Argon Plasma coagulation at ESD ulcer margin. 9 patients were under close surveillance examination without additional treatment and there was no recurrent tumor. Median follow-up periods was $37.20 \pm 23.6$ months in young patients group. During follow-up periods, one patient was diagnosed synchronous cancer and underwent surgery.
**Conclusion:** Different clinicopathologic features of gastric cancer in young patients did not affect short-term outcomes of ESD compared with the older patients. ESD is a feasible treatment for young patients with EGC fulfilled expanded indication of ESD. However, long-term follow-up study is needed.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0488 FEASIBILITY OF COLD SNARE POLYPECTOMY FOR MULTIPLE DUODENAL ADENOMAS IN PATIENTS WITH FAMILIAL ADENOMATOUS POLYPOSIS: A PILOT STUDY

**K. Hamada**[1], Y. Takeuchi[2], H. Ishikawa[3], Y. Tonai[2], N. Matsuura[2], Y. Ezoe[3], R. Ishihara[2], Y. Tomita[2], H. Iishi[2]

**Introduction:** Duodenal, rather than colorectal, cancer is now the main cause of death in patients with familial adenomatous polyposis (FAP) after preventive proctocolectomy[1]. Endoscopic treatment for duodenal lesions is less invasive, but carries a high risk of complications such as bleeding or perforation[2, 3]. Therefore, watchful waiting has been recommended for patients with early-stage FAP[4]. Recently, cold snare polypectomy (CSP) for small colorectal polyps was reported to be safer than conventional hot snare polypectomy and equally effective[5, 6]. Therefore, we hypothesized that CSP was also safe for small duodenal adenomas in patients with FAP.
**Aims & Methods:** The aim of this study was to assess the feasibility of CSP for multiple duodenal adenomas in patients with FAP. This was a retrospective feasibility study including four consecutive FAP patients with multiple small duodenal adenomas who underwent CSP between July and October 2015. The primary outcome was complications during the 28 days post-CSP, such as bleeding or perforation. The secondary outcome was efficacy, using the staging system developed by Spigelman et al. to assess the severity of the duodenal polyposis, and to predict the risk of developing duodenal cancer[1]. We assessed Spigelman staging before CSP, and 2–4 months after CSP.
**Results:** The median patient age (two men, two women) was 45 years (range, 22–52 years), and all four patients had multiple duodenal adenomas (2–16 mm in size) located between the superior duodenal angle and the transverse duodenum. Two patients had Spigelman stage IV disease. The remaining two patients had Spigelman stage III disease. CSP was performed for a total of 126 duodenal polyps (2–16 mm in size) in the four patients (median 30 lesions/patient). Each patient underwent CSP once during the study period. During CSP, intra-procedural oozing occurred with most polyp excisions, but stopped spontaneously without endoscopic hemostasis in all cases. No prophylactic procedure, such as suturing with hemoclips or tissue shielding with polyglycolic acid sheets and fibrin glue, was performed for any of the cases. Although a total of 126 duodenal polyps were resected in these four patients, no cases experienced severe complications requiring emergency intervention (0%; 95% confidence interval: 0.00–0.02). Follow-up endoscopy was performed in all four patients a median of 2.75 months after CSP. Spigelman stage was downstaged in all cases at follow-up endoscopy.
**Conclusion:** CSP was feasible for multiple duodenal adenomas in patients with FAP. Although this was a pilot feasibility study, our results may support changing the current management strategy of duodenal adenomas in patients with FAP from a surveillance approach to a therapeutic approach.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0489 ORAL HEALTH-RELATED BEHAVIOR AMONG CANCER SURVIVORS IN KOREA USING POPULATION-BASED NATIONWIDE SURVEY

**M.A. Han**[1], M.G. Oh[2], J. Park[1], S.Y. Ryu[1], S.W. Choi[1]
[1]*Preventive Medicine, Chosun University, Gwangju/Korea, Republic of*
[2]*Internal Medicine, Jeongup Asan Hospital, Jeongup/Korea, Republic of*

**Contact E-mail Address:** mahan@chosun.ac.kr.

**Introduction:** Cancer survivors may remain at life-long risk of developing oral complications. Despite worldwide recognition of the dangers of cancer, the oral health behavior among cancer survivors has not been fully addressed. To date, there are no data on oral health behavior among cancer survivors. In addition, few studies have investigated oral self-care and use of dental services by cancer survivors in Korea. Thus, we investigated oral health behavior among cancer survivors and compared to subjects without cancer history using nationwide survey.

**Aims & Methods:** We investigated oral health behavior among cancer survivors and compared to subjects without cancer history using nationwide survey. Data source: This study used the data from the Korea National Health and Nutrition Examination Survey conducted the Korea Centers for Disease Control and Prevention. Cancer survivors and controls Cancer survivors were defined as those who answered ''yes'' to the question, ''Have you ever been told by a doctor that you had cancer?''. Cancer survivors were asked about the site of their cancer and the age at diagnosis. The time since diagnosis was calculated as the difference between the age at the time of the survey and the age at diagnosis. Controls were defined as subjects who reported no cancer history. Oral health behavior: This study checked the tooth brushing frequency per day, the number of secondary oral products and oral health screening use. Secondary oral products included dental floss, mouthwash, interdental brush, and electric toothbrush. Statistical analysis: Oral health behavior of cancer survivors and controls were compared by chi-square tests and multiple logistic regression analysis. P values $< 0.05$ were considered statistically significant. All statistical analyses were performed with SAS software version 9.2 (SAS Institute Inc., Cary, North Carolina, USA).

**Results:** About 40.2% and 38.1% of cancer survivors and controls brushed their teeth more than 3 times a day. And 8.2% and 7.6% of cancer survivors and controls used secondary oral products. Finally, 24.9% and 23.1% of cancer survivors and controls screened oral health during the recent year. In multiple logistic regression analysis, adjusted odds ratio (aOR) for current use of secondary oral products was significantly high in cancer survivors compared to controls without cancer history (aOR = 1.30, 95% confidence interval = 1.05–1.60).

**Conclusion:** Cancer survivors reported suboptimal oral hygiene behavior. Oral health behavior excepting use of secondary oral products, was not significantly different between cancer survivor and controls. Our findings suggest that there is a significant need for increased knowledge of periodontal disease and adoption of preventive oral health behaviors that would improve oral health among cancer survivors. Furthermore, because some people with cancer do not seek regular dental care, all health care professionals should be encouraged to support efforts for more comprehensive oral health, an integral part of general health. Thus, improvement in oral health behavior among cancer survivors is essential to compensate for their higher risk of oral diseases.

**Introduction:** Gastrointestinal stromal tumors (GIST) are rare neoplasms of the gastrointestinal tract. In localized disease, surgical treatment is recommended, with association with tyrosine kinase inhibitors in local advanced disease. Adjuvant therapy is given according to the risk of recurrence.

**Aims & Methods:** To evaluate clinical features, type of treatment, relapse and overall survival (OS) of patients with localized GISTs. Retrospective evaluation of consecutive patients with GIST without metastatic disease followed in a single-centre outpatient clinic (2005–2015). Statistical analysis was performed with SPSS, V20 (Chi2, Fisher's exact test, Kaplan-Meier, logistic regression/AUROC).

**Results:** 96 patients were evaluated; mean age = 61 years (20–87), 56.3% female; 77% had symptoms at diagnosis, like abdominal pain (29.7%) and gastrointestinal bleeding (25.7%). Anatomic location of the tumor: stomach-52.2%, small bowel-24%, rectum-11.5%, colon-1%, extra-intestinal-5.2%, multifocal-3.1%. 92.7% (n = 89) of the patients underwent surgery (R0–89.6%). Twelve patients with advanced disease started cytoreductive treatment with imatinib, of which 3 are waiting surgery and 2 developed disease progression. All prognostic scores were effective in risk stratification: US National Institutes of Health (NIH): AUROC 0.73, modified NIH: AUROC 0.715, Armed Forces Institute of Pathology (AFIP): AUROC 0.725, Heat maps: AUROC 0.713. 24% started postoperative imatinib. Among patients with intermediate risk (NIH), 35.3% who did not start postoperative imatinib had relapse (6/17) vs 0% who received imatinib ($p = 0.015$). Among 18 patients with relapse 10 (20.2%) underwent further surgery. The overall 3- and 5-year survival rates were 93.7% and 81.7%, respectively (Kaplan-Meier).

**Conclusion:** In this study, 3-years OS was over 90% proving the excellent prognosis of localized disease. Post-operative treatment with imatinib in patients with intermediate risk was associated with absence of recurrence.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Widespread use of antimicrobial agents often leads to an imbalanced composition of the intestinal microbiota. *H. pylori* eradication therapy consisting of several antimicrobial drugs also sometimes leads to adverse events, such as diarrhea. Moreover, several studies have shown that *H. pylori* infection itself may lead to shifts of the composition of the normal intestinal microflora.

**Aims & Methods:** The aim of the study was to describe the gut microbiota composition in *H. pylori*-positive and *H. pylori*-negative patients, as well as to assess the effect of eradication therapy on the composition using ''shotgun'' metagenomics.

**Results:** One hundred twenty-six stool samples were used for analysis: 58 samples from *H. pylori*-positive patients before eradication therapy, 58 - from the same patients after the completion of eradication therapy, 50 samples from *H. pylori*-negative patients (control group). Total deoxyribonucleic acid (DNA) was isolated from the stool samples using phenol extraction method and subject to whole-genome sequencing on Solid 5500 Wildfire platform. Composition of intestinal microbiota community was evaluated basing on the number of species, the qualitative composition and Shannon diversity index. In general, bacterial community in all groups was quite similar. Bacteroides, Prevotella, Eubacterium, Roseburia, Faecalibacterium and Clostridium genera were predominant in all stool samples. However, the spread in variations prevailing Firmicutes and Bacteroides phyla was wider after the treatment than in the control samples. In about half of the patients, the eradication therapy led to a decrease of both the number of species and the Shannon index indicating a decrease in the overall bacterial diversity and consequently, a reduction of the stability of community, with a possible predominance of individual species. Eradication therapy led to a reduction in the representation of the Bifidobacterium, Collinsella, Coprococcus genera, increase in the number of Clostridium, Bacteroides, Coprobacillus and Flavonifractor as well as other species. Gene-centric analysis of the functional composition in paired samples taken before and after therapy showed an increase of the relative abundance of genes conferring antibiotic resistance.

**Conclusion:** Changes in the composition of intestinal microbiota after *H. pylori* eradication therapy are individual and depend on initial condition of the intestinal microbiota. We suggest that evaluation of intestinal microflora composition prior to treatment can in the prospect predict the incidence of side effects caused by changes in microbiota composition.

## P0492 HIGH DOSE CAM WITH VONOPRAZAN (P-CAB) PLUS AMX REGIMEN IS THE STRONGEST H. PYLORI ERADICATION TRIPLE THERAPY REGIMENS TO IMPROVE SUCCESS RATE OF CAM BASED REGIMENS

**T. Yamasaki**[1], M. Owari[2], Y. Tokai[2], Y. Amano[2], H. Nakashima[2], N. Sakaki[2], M. Yoshida[2]
[1]*Department Of Gastroenterology, Foundation For Detection of Early Gastric Carcinoma, Tokyo/Japan*

**Contact E-mail Address:** takusan.yamasan@gmail.com.

**Introduction:** Success or failure of Amoxicillin (AMX) and Clarithromycin (CAM) based *H. pylori* (HP) eradication therapy mainly depends on sensitivity of CAM for HP. So far now, several proton pomp inhibitors (PPIs) have been used in HP eradication therapy, most of reports said that the success rate of eradication approximated from 70 to 80% on AMX and CAM-based triple therapy regardless of CAM dose (400 or 800 mg/day) in Japan. Recently the ratio of CAM resistance in Japan comes up to over 30%, we have to overcome CAM resistance using any contrivance. On the other hand, recently it is considered that the stability of continuous gastric acid suppression is one of most important factors. At the point of gastric acid suppression, we expect stronger acid suppressive drug rather than PPIs. Since Feb. 2015 we have used **P-CAB** (Potassium-Competitive Acid Blocker) instead of PPIs in AMX and CAM-based HP eradication therapy to improve success rate.
**Aims & Methods:** The aim of this study is to elucidate effects of CAM dose on success rate of **P-CAB** Vonoprazan (VPZ) and one of PPI Rabeprazol (RPZ) based triple therapy regimens (VAC, RAC). This study is a single-center, prospective case study from Jan. 2012 to Oct. 2015. A total of 648 patients (HP positive) were enrolled. Mean age of patients was 54.4 years old. Fisher's exact test was used in all statistical analyses. Regimen of VAC (400 or 800) was VPZ (40 mg/day) b.i.d., AMX (1, 500 mg/day) b.i.d. plus CAM (400 or 800 mg/day) b.i.d. for 7 days. Regimen of RAC (400 or 800) was RPZ (20 mg/day) b.i.d., AMX (1, 500 mg/day) b.i.d. plus CAM (400 or 800 mg/day) b.i.d. for 7 days. The judgement of success or failure on eradication was done with urea breath test on 3 months later after eradication therapy to avoid false negative results.
**Results:** Success rate of VAC 800 showed significantly high (90/92 = 97.8%, PPT) rather than VAC 400 (98/113 = 86.7%, PPT). The average success rate of VAC regimens was 91.7% (188/205, PPT). On the other hand, success rate of RAC 800 showed significantly high (190/245 = 77.6%, PPT) rather than RAC 400 (140/198 = 70.7%, PPT). The average success rate of RAC regimens was 74.5% (330/443, PPT). Success rate of high dose CAM regimens (VAC 800 and RAC 800) were significantly higher than standard dose CAM 400 regimens ($p < 0.05$). These results suggest that using high dose CAM with Vonoprazan (P-CAB) plus AMX regimen might be the strongest *H. pylori* eradication triple therapy regimens to overcome CAM resistance.
**Conclusion:** In case of AMX, CAM and P-CAB based triple therapy regimens, we cloud be able to expect significantly high success rate of HP eradication. This regimen might be expected to improve success rate even if CAM resistance.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0493 EFFICACY OF VONOPRAZAN BASED NEW HELICOBACTER PYLORI ERADICATION THERAPY

**Y. Sato**, K. Yamamoto, M. Mori, A. Asakura, Y. Kawasaki, T. Tokuda, M. Matsushita, H. Saiki, Y. Tokuda, Y. Onishi, A. Ishimi, T. Kawai, M. Hamano, M. Chiba, K. Maeda, N. Tatsumi, T. Ito
*Department Of Gastroenterology, Japan Community Healthcare Organization Osaka Hospital, Osaka/Japan*

**Contact E-mail Address:** tottotto269@gmail.com.

**Introduction:** It is widely known that *Helicobacter pylori* (*H. pylori*) causes several diseases such as gastric cancers and gastroduodenal ulcer disease. Previous reports showed that *H. pylori* eradication therapy prevent recurrence of gastroduodenal ulcer or metachronous gastric carcinoma. The *H. pylori* eradication therapies with proton pump inhibitors (PPIs) are, today, widely given, but the eradication rates are not sufficient due to increase of resistant bacteria or insufficient suppression of gastric acid with PPIs. A new potassium competitive acid blocker, Vonoprazan (VPZ) has been recently developed which suppresses acid secretion more potently than PPIs. A latest clinical trial showed that the eradication rate of new anti-*H. pylori* regimen with VPZ was higher than that of a conventional *H. pylori* eradication therapy using a PPI, Lansoprazole (LPZ) (Murakami et al. Gut 2016). However, its eradication rate in clinical site and comparison with that of other PPIs are not elucidated.
**Aims & Methods:** The purpose of this study is to evaluate the efficacy of VPZ combined regimen against *H. pylori* in clinical practice. We retrospectively analyzed eradication rates of *H. pylori* positive 525 patients whom we prescribed VPZ, LPZ and Rabeprazole (RPZ) based triplet therapy from August 2014 to February 2016. Those cases include 390 cases of first line therapies; 155 cases of VPZ based first line therapy (VPZ 20 mg+Amoxiciline (AMX) 750 mg+Cratithromycine (CLR) 200 mg×7days (7 d), with all drugs given twice daily: VAC); 157 cases of LPZ based first line therapy (LPZ 30 mg+AMX 750 mg+CLR 200 mg×7d, with all drugs given twice daily: LAC); and 78 cases of RPZ based first line therapy (RPZ 10 mg+AMX 750 mg+CLR 200 mg×7d, with all drugs given twice daily: RAC). 92 patients received metronidazole (MTZ) combined second line therapy, including 30 cases of VPZ based therapy (VPZ 20 mg+AMX 750 mg+MTZ 250 mg×7d, with all drugs given twice daily: VAM); 14 cases of LPZ based therapy (LPZ 30 mg+AMX 750 mg+MTZ 250 mg×7d, with all drugs given twice daily: LAM), and 48 cases of RPZ based therapy (RPZ 10 mg+AMX 750 mg+MTZ 250 mg×7d, with all drugs given twice daily: RAM). The remaining 43 cases were excluded due to neither first line nor second line therapy, or different drug dose. The eradication rates and the incidences of drug adverse effects in those therapies were calculated. Subgroup analyses were performed to investigate the patients' backgrounds affecting the efficacy of those therapies. Statistical analyses were performed with chi-squared test.
**Results:** The *H. pylori* eradication rate with VAC in first line therapy were 82.2%, which was significantly higher than that with LAC (68.1%, $p = 0.0067$), and with RAC (61.4%, $p = 0.0013$). The incidences of drug adverse effects with VAC, LAC, and RAC were 5.9%, 4.3%, and 4.3%, respectively. There were no significant differences regarding incidences of adverse events, body mass index, and the proportion of atrophic gastritis, and the prevalence of gastroduodenal ulcers and gastric cancer among those three therapies. The second line eradication rate with VAM, LAM and RAM were 92.3%, 85.7% and 84.1%, and there were no significant difference.
**Conclusion:** The present study demonstrates that the new *H. pylori* eradication first line therapy in combination with VPZ is superior to the conventional ones with LPZ and RPZ. VPZ based second line therapy also showed higher eradication rate compared with RPZ and LPZ.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0494 HIGH-DOSE ONE-WEEK TRIPLE THERAPY FOR H.PYLORI INFECTION

**B. Porter**[1], L. Lim[2], R. Logan[1]
[1]*Department Of Gastroenterology, Kings College Hospital, London/United Kingdom*
[2]*Gastroenterology, King's College Hospital, London/United Kingdom*

**Contact E-mail Address:** benedictporter@nhs.net.

**Introduction:** Eradication of *H. pylori* infection cures duodenal ulcer disease; since our original report of a one week eradication regime[1], widespread use of eradication therapy for other indications and increasing prevalence of antibiotic resistance has resulted in efficacy of <75% for standard one week regimes[2], leading to more complex sequential, quadruple and hybrid treatment regimes[3].
**Aims & Methods:** This prospective observational cohort study aims to evaluate the efficacy of a high dose one week triple therapy regime. Patients undergoing OGD and found to be infected with *H. pylori* by CLO-test were considered for inclusion. Clinical data was extracted by review of electronic case notes. All patients were treated with omeprazole 20 mg bd, clarithromycin 500 mg tds and metronidazole 400 mg tds for 1 week by a single prescriber (RL) immediately after the end of the procedure. All patients were advised about possible side-effects and the importance of compliance in ensuring successful eradication. *H. pylori* status was confirmed prior to treatment by CLO-test +/- antral and corpus histology. Eradication was assessed by $^{13}$C-Urea Breath Test ($^{13}$C-UBT) at least 6 weeks after the end of treatment.
**Results:** From 2013–2016, ninety-three patients (male, n = 60 (65%), mean age 55 yr, range 22–76yrs) with evidence of peptic ulcer disease (n = 76 (82%)) severe oesophagitis (n = 4, (4%)) or other indication for treatment were endoscoped and found to be *H. pylori* positive. Patients were mainly Caucasian (46%) or Afro-Caribbean (34%), and non-smokers (76%). Six patients had previously received *H. pylori* eradication therapy from their GP, but remained infected. Seventeen patients did not attend for their follow-up $^{13}$C-UBT. In previously untreated patients, eradication of *H. pylori* was achieved in 67/70 (96% [95% CI 91–100%] and also in 4/6 (67%) of patients previously treated by their GP.
**Conclusion:** A high dose one week *H. pylori* eradication regime might be an alternative to current more complex lengthy treatment options, but with the advantage of maximizing the opportunity for patient compliance particularly for patients with *H. pylori* associated ulcer disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** seita1120@icloud.com.
**Introduction:** Vonoprazan (P-cab) is a novel oral potassium-competitive acid blocker, which overcomes the weaknesses of proton pump inhibitor (PPI). Unlike previous PPIs, P-cab inhibits the enzyme in a K+-competitive and reversible manner. P-cab is shown to accumulate in parietal cells with its acid-inhibitory effects as well as greater increases in gastric pH than previous PPIs as it accumulated in high concentrations and became slowly cleared from gastric glands. Therefore, P-cab is promising drug for *H. pylori* eradication therapy.
**Aims & Methods:** The aim of this study is to evaluate the effectiveness of P-cab based *H. pylori* eradication therapy compared with previous PPI based triple therapy. We treated with previous PPIs based eradication therapy from May 2012 to May 2015 and the P-cab based eradication therapy between June 2015 and February 2016. *H. pylori* eradication therapies were as follows; 1st line therapies were PPIs or P-cab, amoxicillin (AMPC), clarithromycin (CAM), 2nd line therapies were PPI or P-cab, metronidazole (MNZ), AMPC, 3rd line therapies were PPI or P-cab, AMPC, MNZ, ecabet sodium for 2 weeks, Penicillin allergy therapies were PPI or P-cab, minocycline (MINO), MNZ. We compared with eradication rates, completion rates, and adverse reaction rates between previous PPIs based eradication therapy and P-cab based eradication therapy. The *H. pylori* eradication was diagnosed based on the $^{13}$C-urea breath test performed 12 weeks after completion of the eradication therapy. Completion was defined to finish taking all medicines of these therapies.
**Results:** We enrolled 398 patients (Age Mean±SD: 61.3 years ± 11.8, Male/Female: 182/216) who treated with PPI based therapy, and 69 patients (Age Mean±SD 57.7 years±11.4, Male/Female: 39/30) who treated with P-cab based therapy in this study. Overall eradication rate was 94.2% (65/69) in the P-cab group vs 79.4% (316/398) in the PPI group ($p = 0.002$). Completion rate and adverse reaction rate were 100% (69/69) and 7.2% (5/69) in the P-cab group compared with 98% (390/398) and 4.0% (16/398) in the PPI group. The eradication rate of 1st line therapy was 92.1% (36/41) with P-cab vs 76.7% (214/279) with PPI, completion rate 100% (41/41) vs 98.2% (274/279), adverse reaction rate 2.6% (1/41) vs 2.9% (8/279). The eradication rate of 2nd line therapy was 100% (11/11) with P-cab versus 86.7% (65/75) with PPI, completion rate 100% (11/11) vs 98.7% (74/75), adverse reaction rate 0% (0/11) vs 5.3% (2/75). The eradication rate of 3rd line therapy was 80% (8/10) with P-cab versus 72% (18/25) with PPI, completion rate 100% (10/10) vs 92.0% (23/25), adverse reaction rate 40% (4/10) vs 20% (5/25). The eradication rate of penicillin allergy therapy was 100% (7/7) with P-cab vs 100% (19/19) with PPI, completion rate 100% (7/7) vs 100% (19/19), adverse reaction rate 0% (0/7) vs 5.3% (1/19).Most common adverse reaction of P-cab was diarrhea.
**Conclusion:** P-cab based *H. pylori* eradication therapy is more effective than previous PPI based *H. pylori* eradication therapy in 1st, 2nd and 3rd lines.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0496 EFFICACY OF RIFABUTIN-BASED TRIPLE THERAPY FOR HELICOBACTER PYLORI ERADICATION AS A RESCUE THERAPY

**C. Lin**, C. Kuo, C. Chiu, M. Su
*Gastroenterology And Hepatology, Linkou Chang Gung Memorial Hospital, Taoyuan/Taiwan*

**Contact E-mail Address:** 8805035@adm.cgmh.org.tw.
**Introduction:** With the rising prevalence of antimicrobial resistance, the treatment success of *Helicobacter pylori* eradication has recently declined. The Maastricht IV/Florence consensus report recommends that culture and antimicrobial sensitivity testing should be performed after one or two treatment failures with different antibiotics. Rifabutin-based triple therapy has been applied as a rescue treatment.
**Aims & Methods:** The aim of the present study was to evaluate the efficacy of rifabutin-based triple therapy for *Helicobacter pylori* eradication as a rescue therapy. Patients who experienced twice *Helicobacter pylori* eradication failure were treated with esomeprazole 40 mg twice daily, rifabutin 150 mg twice daily and amoxicillin 1 g twice daily for 7 days. Eradication status was determined by the 13 C-urea breath test performed 4 weeks later. Antibiotic susceptibility was determined by the E-test from *Helicobacter pylori* culture and real-time PCR for DNA sequencing from gastric biopsy specimens. Clarithromycin and levofloxacin phenotypic resistance were defined as a minimum inhibitory concentration (MIC) of 1 μg/mL or more. Mutations in *Helicobacter pylori* 23 S rRNA and gyrA genes associated with resistance to clarithromycin and levofloxacin, respectively, were determined, too.
**Results:** Total 33 patients were enrolled. All of them complete treatment course and had follow-up 13 C-urea breath test. The successful eradication rate was 72.2% (24/33). Antibiotic susceptibility was determined in these patients and 22 of them had clarithromycin and levofloxacin dual resistant *Helicobacter pylori* strains. The successful eradication rate was 81.8% (18/22) in patients with dual resistant strains. Another 10 days course of rifabutin-base triple therapy was prescribed for two failure subjects and one of them had successful *Helicobacter pylori* eradication.
**Conclusion:** The present study suggests that rifabutin-based triple therapy can be used for *Helicobacter pylori* eradication in clarithromycin and levofloxacin dual resistant strains.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0497 EFFICACY OF 7-DAY BISMUTH-BASED QUADRUPLE THERAPY VERSUS 14-DAY MOXIFLOXACIN-BASED TRIPLE THERAPY FOR SECOND-LINE TREATMENT OF HELICOBACTER PYLORI INFECTION

**S.E. Kim**[1], J.H. Roh[2], M.I. Park[3], S.J. Park[3], W. Moon[3], J.H. Kim[3], K. Jung[3], J. Lee[3], G.H. Jang[1]

[3]*Department of Internal Medicine, Kosin University of College of Medicine, Busan/Korea, Republic of*

**Contact E-mail Address:** solefide@hanmail.net.
**Introduction:** Moxifloxacin-based triple therapy has been suggested as second-line eradication therapy for *Helicobacter pylori* (*H. pylori*) infection.
**Aims & Methods:** The aims of this study were to evaluate the efficacy of 14-day moxifloxacin-based triple therapy in second-line *H. pylori* eradication comparing to 7-day bismuth-based quadruple therapy. From January 2011 to December 2015, a total of 569 patients who were failed to first-line triple therapy and received 7-day bismuth-based quadruple therapy or 14-day moxifloxacin-based triple therapy were retrospectively enrolled. The eradication rates of both groups were identified as intention-to-treat (ITT) and per-protocol (PP) analyses. *H. pylori* eradication was confirmed by a $^{13}$C-urea breath test or a rapid urease test at least 4 weeks after the completion of eradication therapy.
**Results:** Total of 487 and 82 patients received the 7-day bismuth-based quadruple therapy and 14-day moxifloxacin-based triple therapy, respectively. ITT eradication rates were 75.4% (367/487; 95% confidential interval (CI), 70.8%-79.3%) in the 7-day bismuth-based quadruple therapy group and 58.5% (48/82; 95% CI, 46.2%-70.8%) in the 14-day moxifloxacin-based triple therapy group ($P = 0.003$). And, PP eradication rates were 93.6% (366/391; 95% CI, 91.0%-95.9%) in the 7-day bismuth-based quadruple therapy group and 73.8% (48/65; 95% CI: 63.1%-84.6%) in the 14-day moxifloxacin-based triple therapy group ($P < 0.001$). The eradication rates in the 7-day bismuth-based quadruple therapy group were significantly higher than in the 14-day moxifloxacin-based triple therapy group according to both ITT and PP analyses. Adverse event rates were 17.1% (67/391) in the 7-day bismuth-based quadruple therapy group and 7.7% (5/65) in the 14-day moxifloxacin-based triple therapy group ($P = 0.065$).
**Conclusion:** The 7-day bismuth-based quadruple therapy is still an effective second-line therapy in patients who failed the first-line triple therapy considering the high resistance of antibiotics in Korea.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** *Helicobacter pylori* (Hp) infection has been well recognized as a major risk for gastric cancer, and most patients with gastric cancer are infected with Hp. Recently, several studies showed the existence of a small number of Hp-negative gastric cancers (HPNGC) [1, 2]. However, results were not consistent and controversy exists regarding the clinicopathological features of HPNGC.
**Aims & Methods:** This study aimed to evaluate the clinicopathological features of HPNGC compared to Hp-positive gastric cancer (HPPGC). We retrospectively analyzed 426 cases of early gastric cancer that underwent endoscopic resection at our hospital from April 2009 to January 2016. Twenty-three HPNGC cases (11 males, 12 females; mean age 62.3 y; 24 lesions) and 174 HPPGC cases except for those with past infection (151 males, 41 females; mean age 70.4 y; 192 lesions) were enrolled in this study. Hp-negative status was defined as the fulfillment of all of the following criteria: no eradication history, no mucosal atrophy in endoscopic (C-0 or 1, according to Kimura-Takemoto classification) and pathological findings, negative rapid urease test or urease breath test, serum Hp-immunoglobulin G test, or stool antigen.
**Results:** Prevalence of HPNGC was calculated as 5.4%. No significant difference was observed in macroscopic types, median depth of submucosal (SM) invasion, and the curative resection rate. There were significant differences (HPNGC vs. HPPGC) in mean age (62.3 y vs. 70.4 y, $P < 0.01$), gender (male/female = 11/12 vs. 151/41, $P < 0.01$), and tumor size ($9 \pm 4.2$ vs. $23.7 \pm 8.7$ mm, $P < 0.01$). Regarding tumor location, HPNGC was observed more often at the upper third of the stomach than HPPGC (cardia/U/M/L = 1/13/4/6 vs. 5/11/91/85, $P < 0.01$). Histologically, gastric adenocarcinoma of fundic gland type (GAFG) was observed significantly more often in HPNGC than HPPGC (58.3% vs. 0%, $P < 0.01$). There were significant differences (HPNGC vs. HPPGC) in SM invasion rate (50% vs. 11.9%, $P < 0.01$) and lymphatic and venous invasion rate (0% vs. 5.4%, $P < 0.01$).

In HPNGC, frequency according to histological type was as follows: GAFG/well-differentiated adenocarcinoma (WDA)/signet-ring cell carcinoma (Sig) = 14 (58.3%)/7 (29.2%)/3 (12.5%). GAFG tended to be observed at the upper third of the stomach (cardia/U/M/L = 0/12/2/0, $P < 0.01$) while WDA tended to be observed at the lower third of the stomach (cardia/U/M/L = 1/1/0/5, $P < 0.01$) and Sig tended to be observed at middle third of the stomach (cardia/U/M/L = 0/0/2/1, $P < 0.01$).

**Conclusion:** HPNGC is very rare but has distinct clinicopathological features, especially in terms of age, sex, size of tumor, tumor location, histological type, and low grade malignancy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0499 IMPLEMENTATION OF A CLINICAL-ENDOSCOPIC-PATHOLOGICAL -INDEX (CEPIX) FOR ESTIMATING THE RISK OF SPORADIC NON-CARDIA GASTRIC CARCINOMA IN DYSPECTIC PATIENTS AND GASTRITIS ASSOCIATED WITH INFECTION BY HELICOBACTER PYLORI IN A CLINICAL SETTING. A PROPOSAL

**Introduction:** Gastric cancer still represents a major healthcare issue; in fact, gastric malignancies are mostly diagnosed in their advanced stage, and are associated to high mortality rates. Etiologically, sporadic gastric cancer is considered a multifactorial disease. Environmental or lifestyle factors are major contributors to the etiology. *Helicobacter pylori* infection (the major oncogenic agent), age, geographic localization, gender, ethnic group, high intake of salty and smoked food, low consumption of fruits and vegetables, alcohol consumption, cigarette smoking, family history of cancer, genetics factors, some occupations, low socioeconomic status, physical activity, radiation, statins and non-steroidal anti-inflammatory drugs use, appear contribute in greater or lesser degree to gastric carcinogenesis. Some of these risk factors are well known, whereas others show no clear links. Rugge et al point out that categorizing patients in terms of their risk of developing gastric cancer should enable clinicians to provide the most appropriate patient care and it is important stratify risk in terms of reversibility or stabilization of carcinogenesis process.

**Aims & Methods:** In the clinical setting is mandatory the need to estimate the risk of developing gastric cancer in patients with gastritis associated with *Helicobacter pylori* infection. Therefore, we propose the implementation of a Clinical-Endoscopic-Pathological -Index (CEPIx). CEPIx was applied to patients with dyspeptic disease and gastritis associated with *Helicobacter pylori* infection and without *Helicobacter pylori* infection. The CEPIx includes clinical aspects (age, family history of cancer, smoking history, geographic particularities, ethnic group, dietary factors, helminths co-infection), endoscopic aspects (presence of gastric ulcer) and pathological aspects (phenotype and topography of gastritis). Sixty five patients with dyspeptic disease were studied at Gastroenterology Department of Universitary Hospital of Maracaibo, Venezuela. Forty six with gastritis associated with *Helicobacter pylori* infection and nineteen without *Helicobacter pylori* infection.

**Results:** Dyspeptic patients with gastritis associated with *Helicobacter pylori* infection displays higher general score, exhibits higher mean age, family cancer history, a more conspicuous and frequent smoking habit, higher mean score in clinical and pathological aspects, compared with dyspeptic patients without *Helicobacter pylori* infection.

**Conclusion:** The implementation of a Clinical-Endoscopic-Pathological-Index for estimating the risk of sporadic non-cardia gastric carcinoma in dyspectic patients and gastritis associated with infection by *Helicobacter pylori* in a clinical setting could be a very useful tool for a more precise and individual estimation of the risk for gastric cancer.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The recent results of a randomized controlled study and meta-analysis study have demonstrated that *Helicobacter pylori* (Hp) eradication reduces the development of gastric cancer. However, gastric cancers may still occur following successful Hp eradication. Therefore, it is important to determine the clinicopathological features of early gastric cancers after Hp eradication. Several previous studies reported that gastric cancers developing after Hp eradication display unclear demarcation in approximately 24–40% of lesions [1] [2]. However, the role of magnifying endoscopy with narrow-band imaging (ME-NBI) using the VS classification system (VSCS) has not been evaluated in tumor demarcation detection.

**Aims & Methods:** The aim of this study was to assess the clinicopathological features of early gastric cancers after Hp eradication by comparing lesions with Hp positive early gastric cancer. Additionally, we analyzed the usefulness of ME-NBI using VSCS for the detection of tumor demarcation. There were 239 patients with early gastric cancer who underwent endoscopic resection in our hospital between April 2013 and March 2016. We excluded the following cases: undifferentiated or mixed-type gastric cancer (15), special type gastric cancer (24), and cases with an unknown eradication history (96). We enrolled 34 Hp eradicated patients (28 males, 6 females; mean age 71.6 y) and 70 Hp positive patients (54 males, 16 females; mean age 72.6 y). We then evaluated tumor demarcation, using a classification system. All DL (+) tumors were defined as having a clear demarcation line present circumferentially between the lesion and non-lesion areas. The DL (-) tumors had an absent or unclear demarcation line. We then analyzed the frequency of DL (-) cases in each patient populations.

**Results:** There were no significant differences between patient groups for the following characteristics: mean age, gender, operative method, tumor location, extent of atrophic gastritis, main histological type, invasion depth, and curative resection rate. However, there were significant differences (Hp eradicated group vs. Hp positive group) in macroscopic type (elevated/flat/depressed = 9/0/25 vs. 35/1/34, $P < 0.05$), and tumor size ($11.4 \pm 13.4$ vs. $16.2 \pm 23.1$ mm, $P < 0.05$). Our analysis of tumor demarcation by ME-NBI using VSCS indicated that DL (-) cases were significantly higher in the Hp eradicated group than in the Hp positive group (11.8% (4 (absent:1, unclear:3)/34) vs. 1.4% (1 (absent:0, unclear:1)/70), $P < 0.01$). The histopathological analysis of the four DL (-) cases in the Hp eradicated group were composed of cancers with low-grade atypia or mixed with non-neoplastic epithelium in the demarcation area. The demarcation line might become unclear as a result of these findings. However, we could detect clear tumor demarcation in 88.2% of Hp eradicated cases using ME-NBI. We estimated the border between the lesion and non-lesion areas based on subtle changes of micro-vascular/surface pattern with ME-NBI in the 4 DL unclear cases. There were no cases of positive lateral margins in the DL (-) Hp eradicated group.

**Conclusion:** Several studies have reported that tumor demarcation tends to be unclear in gastric cancers developing after Hp eradication. Our results show that ME-NBI using VSCS may detect tumor demarcation in gastric cancers after Hp eradication.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

HR, hazard ratio; CI, confidence interval; BMI, body mass index; HP, Helicobacter pylori; DM, diabetes mellitus; GGT, gamma-glutamyl transpeptidase; HDL, high-density lipoprotein; TG, triglyceride.

**Aims & Methods:** This retrospective study investigated the association between HP infection and ACN in different age groups with medical records of patients who underwent a general medical examination, including colonoscopy for the first time at the Gangnam Severance hospital, Seoul, Korea. The patients with previous history of colorectal cancer were excluded. ACN was defined as the presence of colorectal cancer or at least one colorectal adenoma with at least one of the following features: ≥1 cm in size, tubulovillous or villous adenoma or high grade dysplasia. The presence of ACN was determined by reports of colonoscopy and pathology. HP infection was determined by the presence of serum anti-HP immunoglobulin G (IgG). In case of the titer of anti-HP IgG was reportedly in the borderline range, the results of the rapid urease test, if present, were alternatively adopted. Abdominal obesity was defined as waist-hip ratio above 0.9 for males and above 0.85 for females. Univariable analyses with continuous and nominal variables were performed using Student's t-test and Fisher's exact test, respectively. Multivariable analyses were performed using a binary logistic regression test.

**Results:** A total of 21, 125 patients (11, 987 male and 9, 138 female) was studied. Mean age was 49.64 years (range, 18–91 years). Among those, ACA was reported in 728 patients (3.4%). In univariable analyses, older age (mean 55.62 years [range, 31–86 years] vs. 49.43 years [range, 18–91 years] in patients with and without ACN, respectively; p <0.001), body mass index ≥23 kg/m$^2$ (64.0% vs. 55.1%; p <0.001), HP infection (60.7% vs. 56.0%; p = 0.018), male gender (69.8% vs. 56.3%; p <0.001), presence of abdominal obesity (69.4% vs. 51.8%; p <0.001), smoking history (62.2% vs. 49.1%; p <0.001), diabetes mellitus (DM) (9.2% vs. 5.3%, p <0.001), high-density lipoprotein <40 mg/dL (20.1% vs. 15.4%; p = 0.001) and triglyceride ≥200 mg/dL (16.6% vs. 12.2%; p = 0.001) were significantly associated with increasing risk of ACN. Alcohol intake (p = 0.271), hypertension (p = 0.173), use of aspirin (p = 0.667) or non-steroidal anti-inflammatory drugs (p = 0.197), family history of colorectal cancer (p = 0.448) and low-density lipoprotein ≥100 mg/dL (p = 0.820) were not significant. In multivariable analyses, older age (hazard ratio [HR], 1.058; p <0.001), male gender (HR, 1.316; p = 0.028), presence of smoking history (HR, 1.489; p <0.001) and DM (HR, 1.333; p = 0.044) showed independent significance in all age group (Table 1). In subgroup analyses, HP infection was significant only in patients with age <50 years (Table 1).

**Conclusion:** Our data suggest that HP infection is associated with increasing risk of ACN in patients with age <50 years. Older age, male gender, presence of smoking history and DM were significant risk factors for ACN in all age group.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0502 LONG-TERM FOLLOW UP OF PEPSINOGEN I/II RATIO AFTER HELICOBACTER PYLORI ERADICATION

**S. Nam**, S.W. Jeon, H.Y. Park, Y.H. Kwon
*Gastroenterology, Kyungpook National University Medical Center, Daegu/Korea, Republic of*

**Contact E-mail Address:** nam20131114@gmail.com.

**Introduction:** Although several studies regarding short term follow-up of pepsinogen I/II (PG I/II) after *H. pylori* eradication suggested recovery to normal range, long term follow-up of PG I/II is few. We evaluated the serial long-term follow-up of PG I/II.

**Aims & Methods:** Between 2007 and 2014, a total of 773 patients with gastric cancer who underwent endoscopic resection, pepsinogen test, and *H. pylori* test at baseline were enrolled. *H. pylori* eradication therapy was provided after endoscopic resection if *H. pylori* was present. Serial endoscopic and pepsinogen test were performed every year after resection. Study group was classified into non-infected group, eradication group, and non-eradication group. Low PG I/II was defined as ≤3.

**Results:** PG I/II ratio was higher in non-infected patients with *H. pylori* (n = 275, 4.99) than infected patients (n = 498, 3.53) (P < 0.05). After *H. pylori* eradication, PG I/II increased from 3.55 at diagnosis to 5.81 at 1 yr and 5.63 at 2 yr (each P < 0.05), respectively. Follow-up PG I/II is similar with that of baseline in non-infected group. However, PG I/II was 3.48 at diagnosis, 3.94 at 1year, and 2.75 at 2year in non-eradication group. The adjusted OR for low PG I/II in non-eradication group comparing to eradication group was 4.78 (95% CI 2.15–10.67) at 1 yr and 8.13 (95% CI 2.56–25.83) at 2 yr.

**Conclusion:** PG I/II was definitely low in *H. pylori* infected subjects comparing to *H. pylori* non-infected patients. After *H. pylori* eradication, PG I/II was recovered up to the level of non-infected patients and the recovered PG I/II maintained.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0503 PERSISTENT HELICOBACTER PYLORI INFECTION AND OLD AGE ARE RISK FACTORS FOR METACHRONOUS RECURRENCE AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION OF EARLY GASTRIC CANCER

**Introduction:** Although endoscopic submucosal dissection (ESD) is widely accepted as curative treatment method for early gastric cacner (EGC) worldwide, metachronous recurrence often occurs after endoscopic submucosal dissection for early gastric cancer. But, there is insufficient data about the role of *Helicobacter pylori* (*H. pylori*) infection and other risk factors for recurrence.

**Aims & Methods:** We aimed to compare the metachronous lesion in the *H. pylori* persistent group and the negative group and to identify risk factors for metachronous lesion. We retrospectively analyzed 782 patients who underwent ESD for between January 2008 and December 2013. We excluded patients with dysplasia or patients not tested for *H. pylori* infection. Patients were classified into the persistent group (n = 18) or negative group (n = 167) and the follow-up data were analyzed retrospectively.

**Results:** A total 185 patients were enrolled. Successful eradication was achieved in 167 patients (90.2%). At 61.1 months' median follow up, metachronous recurrence was diagnosed in 24 patients (12.9%), including 12 cancers and 12 dysplasias. The incidence of metachronous gastric lesions developed more in >70 year-old group (p = 0.021) and *H. pylori* persistent (non-eradicated or failed) group (p = 0.006).

**Conclusion:** *H. pylori* infection and old age were independent risk factor for metachronous gastric lesions after ESD in early gastric cancer.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Although successful eradication of *Helicobacter pylori* (HP) will decrease the risk of gastric cancer (GC), characteristics of GC that is detected after HP eradication is not fully known.

**Aims & Methods:** The aim of this study is to clarify clinicopathological characteristics of GC detected in patients after successful HP eradication. Among 888 patients who were diagnosed as GC during April to December 2015, those who had undergone successful HP eradication at least one year before were extracted. Patients who had less than 3 years after HP eradication until the diagnosis of GC were classified as early group, those who had more than 3 years were classified as late group. The clinicopathological characteristics of GC among the early and late groups were compared. Patients with a remnant stomach, those who had unsuccessful HP eradication were excluded.
**Results:** A total of 101 lesions in 79 patients (58 men) with a median age of 70 (range 27 to 89) were extracted. The reason for HP eradiation was gastritis (57%), gastric ulcer (23%) and endoscopic resection for early GC (14%). The median interval from HP eradication to the diagnosis of GC was 3 years (range 1 to 22). The location of the lesions was in the middle or lower stomach in 77% of cases. The median diameter of the lesion was 16 mm (range 2 to 235), 83% were of the differentiated type, and 10 lesions were advanced GC. Fifty lesions were detected in 37 patients in the early group. Most of the patients had extensive atrophic gastritis (78%), the lesions were red or isocolor (90%), and the pathological depth was pT1a in 80% of the lesions. Fifty-one lesions were detected in 42 patients in the late group. Half of the patients had extensive atrophic gastritis (52%), the ratio of pale-colored lesions increased (26%), and 38% of the lesions were deeper than pT1b. The number of patients receiving periodical endoscopy every one or two years was significantly larger among the early group. There were no significant differences in lesion size, location, macroscopic type and histology between the groups.
**Conclusion:** Significant difference was observed among the degree of atrophic gastritis, the color and depth of GC detected in early and late phase after HP eradication. More advanced lesions were detected in the late phase suggesting the importance of periodic surveillance after HP eradication.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0505 DOWN-REGULATION OF LNCRNA NR_033122 REPRESSES VPS11 EXPRESSION BY EPIGENETIC MODULATION IN H. PYLORI-RELATED GASTRIC CARCINOMA

**Y. Dang**, G. Zhang
*Department Of Gastroenterology, The First Affiliated Hospital of Nanjing Medical University, Najing/China*

**Contact E-mail Address:** yeani_hi@126.com.
**Introduction:** Long non-coding RNAs (lncRNAs) have been identified as key molecular players in the regulation of gene expression in multiple carcinogenic processes. They are involved in epigenetic modulation by recruiting DNA methyltransferases to promoter of certain genes. Some of these genes are supposed to be related to tumorigenesis. Although *Helicobacter pylori* is assumed to play a pathophysiological role in gastric carcinoma, little is known about its impact on the interaction between lncRNA and DNA methylation.
**Aims & Methods:** Based on comprehensive lncRNA microarray and Methylation BeadChip for Hp-related gastric cancer sample, we found lncRNA NR_033122 and VPS11 to be close in chromosome 11. Real-time PCR was used to measure level of lncRNA NR_033122 and VPS11 in 32 gastric cancer and paired adjacent nontumor tissue samples. The methylation level of VPS11 was determined by bisulfite sequencing PCR. lncRNAs and VPS11 were transferred by lentiviral vectors or down regulated with si-RNAs in MGC-803, SGC-7901 and AGS. The interaction between lncRNA NR_033122 and VPS11 was detected by RNA pulldown, RIP and ChIp.
**Results:** Expression level of lncRNA NR_033122 and VPS11 were significantly lower in Hp-related GC than neighboured nontumor tissues. Three-dimensional contours showed a relationship between NR_033122 expression, and VPS11 expression and VPS11 methylation. In ChIp assays, NR_033122 was associated with NF-KB p65, activation of which could recruit DNMT. Overexpression of NR_033122 in 3 cell lines attenuated their proliferation and ability to form colonies, and reduced the expression of VPS11, whereas down regulation of NR_033122 increased the levels of VPS11. CpG islands in POU3F3 were densely hypermethylated in cell lines after Hp stimulation. Pharmacologic inhibition of p65 increased the levels of VPS11 and significantly reduced binding of DNMT to its promoter.
**Conclusion:** lncRNA NR_033122 decreased after *H. pylori* infection and subsequent activation of NF-$\kappa$B p65 recruited DNMT, which led to VPS11 promoter methylation. Both lncRNA NR_033122 and VPS11 are potential tumor suppressors in gastric cancer.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0506 LINE-1 HYPOMETHYLATION IS A RARE EVENT IN PRENEOPLASTIC STAGES OF GASTRIC CARCINOGENESIS

**Introduction:** LINE-1 methylation is an established marker for assessment of diffuse genomic DNA methylation, which is a frequent event in carcinogenesis. The alterations in LINE-1 methylation have been suggested for gastric cancer (GC) while the data to premalignant gastric lesions remain poorly reported. The aim of the study was to evaluate the LINE-1 methylation status at different stages of gastric carcinogenesis and evaluate its prognostic potential.
**Aims & Methods:** LINE-1 methylation was analyzed in 267 tissue samples by bisulfite pyrosequencing. Overall, the study included 80 pairs of primary gastric cancer tissues (T-GC) with corresponding adjacent normal gastric mucosa (N-GC), 24 pairs of primary colorectal cancer (CRC) tissues (T-CRC) with corresponding normal mucosa (N-CRC), 19 gastric tissues from controls (N), 37 tissues from patients with chronic non-atrophic and atrophic gastritis (CG). Survival analysis was performed using Kaplan-Meier curves.
**Results:** LINE-1 methylation level was lower in both GC and CRC tumor tissues when compared to paired healthy adjacent tissues. No difference was observed for LINE-1 methylation status between patients with normal gastric mucosa, CG and N-GC. LINE-1 methylation showed no correlation between N-GC and T-GC while tended to correlate with age of the patients at the diagnosis. Subgroup stratification analysis did not reveal significant differences in LINE-1 methylation status according to tumor stage, anatomical location, histological subtype, differentiation grade or *Helicobacter pylori* status. In our cohort, we observed similar survival data between patients with high or low LINE-1 methylation.
**Conclusion:** LINE-1 hypomethylation is characteristic feature in GC tissues; however, it seems to be a rare event in early stages of gastric carcinogenesis such as preneoplastic conditions. In our population, we could not confirm the prognostic role of LINE-1 hypomethylation in GC patients.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0507 GISTAR PILOT STUDY: GROUP DESCRIPTION AND PRELIMINARY RESULTS

**M. Leja**[1], A. Rudule[1], J. Y. Park[2], R. Murillo[2], I. Liepniece-Karele[1], S. Isajevs[1], I. Kikuste[1], D. Rudzite[1], P. Krike[3], S. Parshutin[1], I. Polaka[1], A. Kirsners[1], D. Santare[4], I. Daugule[1], R. Herrero[2]

**Introduction:** Although recommended by international guidelines, limited data are available on the benefits and risks of a population-based *H. pylori* eradication ('search-and-treat') strategy from controlled clinical studies. Furthermore, the benefit of pepsinogen testing for risk stratification in Caucasian population has not been sufficiently studied.
**Aims & Methods:** GISTAR study is aimed at investigating the role of *H. pylori* eradication combined with non-invasive screening for precancerous lesions in the reduction of gastric cancer mortality in a predominantly Caucasian population in Northern and Eastern Europe. Study subject recruitment for the pilot study was conducted in Latvia.
**Results:** Altogether 3453 subjects (1826 men, 1627 women) in the age range 40–64 were recruited to the study between October, 2013 and December, 2015 in 4 different recruitment sites in Latvia: Cesis, Aluksne, Ludza and Saldus. *H. pylori* IgG seroprevalence (Biohit, Plc., Finland) was 68.3%. GastroPanel (Biohit, Plc., Finland) and Eiken (Eiken Chemical Co., Tokyo, Japan) pepsinogen tests were performed to non-invasively assess the gastric mucosal status. Over 1000 subjects have undergone upper endoscopy with an extensive biopsy work-up; all the biomarker-positive cases and a fraction of subjects with normal biomarkers were referred for endoscopy. Participants underwent a faecal immunochemical test as a benefit of study participation and all the subjects with a positive FIT were referred for colonoscopy. OC-Sensor (Eiken Chemical Co., Tokyo, Japan) FIT with cut-off 10 µg Hb/g faeces was used; the FIT positivity rate was 5.6%.
**Conclusion:** The pilot study has provided the background study population description for Latvia and will provide data on the prevalence of precancerous lesions and acceptance of participation in the interventions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0508 INFECTIOUS AGENTS AND COLORECTAL CANCER: ANY IMPLICATION OF HELICOBACTER PYLORI?

**E. Soares**, M. Gravito-Soares, C. Lérias, C. Sofia
*Gastroenterology, Coimbra University Hospital, Coimbra/Portugal*

**Contact E-mail Address:** es18497@gmail.com.

**Introduction:** *Helicobacter pylori* (Hp) is the only bacterium with a potential carcinogen in humans, already established for gastric cancer. However, systemic effects have been proposed, including colorectal carcinogenesis. The involved mechanisms remain unknown, being gastrin a candidate trophic factor.

**Aims & Methods:** To determine the Hp role in the development of adenomatous polyps and colorectal cancer (CRC). **Methods:** Retrospective case-control study of a total of 1271 routine upper GI endoscopies, performed during 6 months. Selected 306 patients with additional evaluation of gastric Hp infection and 116 with at least one total colonoscopy. There were evaluated demographic variables, classic risk factors of CRC and conditions associated with hypergastrinemia (CAH).

**Results:** Hp gastric infection occurred in 37.9% (n = 44), being moderate to severe in 61.4% (n = 27). The development of adenomatous polyps/CRC occurred in 25.9% (n = 30), being more frequent in Hp-positive patients (45.5% vs13.9%; $p < 0.001$), with a 5-fold increased risk (OR 5.167; $p < 0.001$). The moderate to severe Hp infection was associated with an 11-fold increased risk (OR 11.188; $p < 0.001$). The CAH were present in 62.1% (n = 72). The development of adenomatous polyps/CRC was more frequent in CAH (22.4% vs 3.4%; $p = 0.001$), showing a 5-fold higher risk (OR 5.652; $p = 0.001$). After multivariate analysis, the only significant risk factors for the development of adenomatous polyps/CRC were moderate to severe Hp infection (OR 17.618; $p = 0.024$) and long-term proton pump inhibitors (PPI) use (OR 31.289; $p = 0.010$). There was no association with the classic risk factors of CRC.

**Conclusion:** Hp gastric infection was associated with a higher risk of adenomatous polyps/CRC development. Hp eradication (especially in moderate to severe infection) and the rational use of PPI may reduce colorectal cancer risk. In patients with indication for long-term PPI use, a more aggressive colorectal cancer surveillance could be considered. Further studies are needed to evaluate the real impact of Hp/gastrin in colorectal carcinogenesis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Magnetic resonance enterography (MRE) is highly sensitive in revealing soft tissues inflammation. Diffusion-weighted imaging (DWI) can distinguish intestinal inflammation from a lower diffusion of water molecules giving rise to a reduced apparent diffusion coefficient. The magnetic resonance index of activity score (MaRIA) and Clermont score were recently developed for staging CD activity and bowel wall fibrosis. The aim of the study was to prospectively compare conventional MRI sequences, dynamic contrast enhanced (DCE) MRI and diffusion weighted imaging (DWI) with histopathology of surgical specimens in Crohn's disease to identifie degree of disease activity and fibrosis.

**Aims & Methods:** Thirty consecutive Crohn's disease patients undergoing surgical intestinal resection were selected. Every patient has been studied with MRE with T1, T2 and DWI sequences. Thirty patients with abdominal pain and without gross lesions undergoing MRE with the same protocol have been taken as controls. In Crohn's patients subgroup images have been analysed through quantitative (oedema, ulcers) and qualitative submucosal intensity signal (WSI), relative contrast enhancement (RCE), apparent diffusion coefficient (ADC) parameters. Tissue samples from surgical specimens have been analysed by a pathologist and have been calculated histopathological inflammatory and fibrosis scores. Correlation analysis and case-control studies were done by non-parametric tests and ROC curves has been realized to evaluate RM parameters' accuracy to predict fibrosis degree.

**Results:** None of traditional MRI parameters (%gain, wall thickness, relative contrast enhancement, ulcers or edema presence, MaRIA and Clermont agrees with the histological data of inflammation or with the fibrosis score (FS). ADC values instead inversely correlate with FS ($r = -0.517$: $p < 0.005$), amount of neutrophils ($r = -0.373$; $p = 0.045$), with the depth of neutrophilic penetration ($r = -0.428$; $p = 0.021$) and with acute inflammation score (AIS) ($r = -0.435$; $p = 0.019$). AIS and FS significantly correlate ($r = 0.431$, $p = 0.017$). An ADC value cutoff of 0.82 $10^{-3}$ $mm^2/s$ has high accuracy in predicting fibrosis with 75% sensitivity (95% CI 42.8–94.2) and 88.9% specificity (95% CI 65.2–98.3) with an AUC of 0.799. ADC can predict AIS value with an accuracy of 83.7% (95% CI 0.657–0.945) ($p < 0.0001$) for a cutoff value of 1 x $10^{-3}$ $mm^2/s$ (100% sensitivity and 63.2% specificity). A threshold value of 0.82 x $10^{-3}$ $mm^2/s$ ADC predicts the presence of neutrophils with a 83% accuracy (95% CI 0.65–0.94) ($p = 0.0001$), 100% sensitivity and 76% specificity. The depth of neutrophilic penetration is predicted with a 79% accuracy (95% CI 0.60–0.91) ($p = 0.0007$), 100% sensitivity and 60% specificity for a threshold value of 1 x $10^{-3}$ $mm^2/s$. ADC, RCE, MaRIA and Clermont were significantly different from CD patients to controls ($p = 0.019$ for RCE and $p < 0.0001$ for the others). The threshold value of 1.47 x $10^{-3}$ $mm^2/s$ is able to discriminate MC patients from healthy controls with 99.8% accuracy (95% CI 0.936–1.000), 96.7% specificity and 100% sensitivity.

**Conclusion:** MRE with DWI sequences provide important information in small bowel CD. ADC and MaRIA maps correlated with histopathological specimens and represent good predictors of both fibrosis and inflammation. In presence of a major fibrotic component ADC values tend to be low and it is possible to establish threshold values that can accurately identify patients who can be eligible for surgery.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0511 THE ROLE OF ZONULIN AND HAPTOGLOBIN GENOTYPE IN TYPE 1 DIABETES

**H. Ahmad Al-Saffar**, C. Sturgeon, R. Freire, A. Fasano
*Mucosal Immunology And Biology, MassGeneral Hospital for Children, Boston/United States of America*

**Introduction:** Haptoglobin (HP) is an acute phase protein that in its mature form scavenges hemoglobin, averting oxidative activity following hemolysis. HP has a strong relationship with the development of inflammatory and autoimmune disorders and exists as HP1 and HP2 alleles resulting in 3 HP genotypes; HP 1–1; HP 2–1 and HP 2–2. The precursor of HP2 (pHP2) has been characterized as zonulin, a protein that causes physiological reversible disassembly of intestinal tight junctions (TJ) and altering permeability by regulating the paracellular pathway. It is hypothesized that zonulin is upregulated in individuals with type-1-diabetes (T1D) who carry the HP2 allele.

**Aims & Methods:** The aim is to determine if zonulin expression is increased in T1Ds who have a higher yield of HP 2 allele by comparing HP genotype with Zonulin expression. Serum and DNA from T1D and age, race and gender matched controls were selected from our biorepository. Samples were genotyped using specific primers to HP in exon 2 and 5 in HP1 and exon 2 and 7 in HP2. The quantification of zonulin in the serum samples was done by a semi-quantitative approach using a non-denaturing gel in native western blot followed by band densitometry of zonulin.

**Results:** A total of 322 individuals were genotyped for HP and quantified for zonulin. The distribution of HP genotypes is shown in Table 1. We observed a statistical difference between T1Ds and controls ($p < 0.05$) When segregating the HP genotype distribution by gender, we observed a significant difference in males ($P < 0.0002$), but not in females ($p = 0.5059$). In comparing pediatric T1D age of onset with HP genotype, we observed a correlation ($R^2 = 0.97$) trending toward a lower age of onset related to HP2 frequency. Furthermore, we saw a significant ($P < 0.0001$) zonulin increase in T1Ds with HP 2–2 compared with HP 2–1 and HP 1–1, which was not observed in controls ($P = 0.0912$). This observed increase in zonulin levels for the HP2 alleles was more represented in male T1Ds ($p = 0.0029$) compared with the female T1Ds ($p = 0.0103$). When we compared the T1Ds with controls for each respective HP genotype, no significant increase was observed in any group.

**Table 1**

| | T1Dm, n (%) | Controls, n (%) | P value |
|---|---|---|---|
| **Total** | 215 (66.8) | 107 (33.2) | 0.0465 |
| **HP 1–1** | 35 (16.3) | 25 (23.4) | |
| **HP 2–1** | 104 (48.3) | 46 (43.0) | |
| **HP 2–2** | 74 (34.4) | 36 (33.6) | |
| | **Female T1Dm, n (%)** | **Female Controls, n (%)** | **P value** |
| **Total** | 137 (63.7) | 74 (69.2) | 0.5095 |
| **HP 1–1** | 27 (19.7) | 17 (23.0) | |
| **HP 2–1** | 64 (46.7) | 35 (47.3) | |
| **HP 2–2** | 46 (33.6) | 22 (29.7) | |
| | **Male T1Dm, n (%)** | **Male Controls, n (%)** | **P value** |
| **Total** | 78 (36.3) | 33 (30.8) | 0.0002 |
| **HP 1–1** | 8 (10.3) | 8 (24.2) | |
| **HP 2–1** | 42 (53.8) | 11 (33.3) | |
| **HP 2–2** | 28 (35.9) | 14 (42.4) | |

**Conclusion:** There is a significant difference in distribution of HP genotypes when comparing controls with T1Ds presenting male subjects as highly statistically significant compared with females. Also, a lower age of onset in T1D pediatrics is related to a higher frequency of HP 2–2 compared with HP 2–1 and HP 1–1. Moreover, there is a significant correlation between T1D serum Zonulin levels compared with HP genotypes. This significance stronger in male T1Ds compared with female T1Ds.

## P0512 WNT SIGNALING ACTIVATION IN THE GUT ANTI-INFLAMMATORY PROCESS DRIVEN BY THE HERBAL PREPARATION, STW5

**T. Bertalot**[1], S. Schrenk[1], N. Facchinello[2], T. Skobo[2], C. Cenzi[1], L. Dalla Valle[2], H. Abdel-Aziz[3], R. Di Liddo[1]

[3]*Phytomedicines Supply & Development Center, Steigerwald Arzneimittelwerk GmbH, Bayer Consumer Health, Darmstadt/Germany*

**Contact E-mail Address:** thomas.bertalot@unipd.it.

**Introduction:** In the last two decades, enormous progress has been made in the characterization of soluble and regulatory factors of gut functionality under physiological and inflamed conditions. Among signaling molecules, Wnt pathway components, including specific ligands (Wnts) and Frizzled (FZD) receptors, are reported to play a pivotal role in the homeostasis of intestine epithelium[1] and enteric neuronal surveillance from inflammatory stimuli.[2] The multi-component herbal preparation, STW5, has been effectively used clinically to treat functional gastrointestinal disorders.[3] Its mechanism of action seems to be multi-targeted, including anti-inflammatory and mucosal protective effects.[4, 5] In the present study, using in vitro models of gut inflammation, we investigated whether the activation of Wnt signaling is promoted by STW5 treatment.

**Aims & Methods:** Cells from enteric nervous system (ENSc) and epithelium (EPc) were isolated from the gut of adult Zebrafish (over 3 months of age) adapting known standardized procedures.[2, 6] After assessing in vitro-inflammatory conditions by stimulating for 24 h with 5 μg/mL lipopolysaccharide (LPS) or 0.5% dextran sodium sulfate (DSS), cell cultures were treated for 6 h and 24 h with 0.12 mg/mL lyophilized STW5. In parallel, resting cells and samples primed with only STW5 or LPS or DSS were used as controls. Thus, the analysis of Wnt signaling was performed evaluating the expression of IL1$\beta$, IL6, IL8, TNF$\alpha$, IL10 and Wnt3a by qPCR and the nuclear translocation of $\beta$-catenin and NF-$\kappa$B p50/p65 by Western blot.

**Results:** Isolation methods and in vitro culture conditions demonstrated to be effective to obtain functional ENS and EP cell cultures. Under inflammatory conditions, STW5 treatment downregulated mRNA expression of pro-inflammatory cytokines (IL1$\beta$, IL6, IL8 and TNF$\alpha$) and increased the gene expression of anti-inflammatory IL10 and Wnt3a. Interestingly, in resting and inflammatory conditions, STW5 showed to be functional to inhibit the nuclear translocation of p65, known to activate inflammatory response, while promoting a continuous nuclear shuttling of $\beta$-catenin, that, in contrast, is involved in anti-inflammatory process. Moreover, STW5 seemed to regulate NF-$\kappa$B transcriptional repression modulating the presence of NF-$\kappa$B p50 in the nucleus.

**Conclusion:** Our results provided the evidence that the activation of Wnt pathway is driven by STW5 treatment and leads to a negative regulation of NF-$\kappa$B inflammatory signaling in enteric epithelial and ENS compartments.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Gastrointestinal mucositis is a serious side effect of chemotherapy. It increases the frequency of infection, risk of bleeding, and duration of hospitalization, consequently reducing subsequent chemotherapy doses. Ursodeoxycholic acid (UDCA), which is currently used in various liver diseases, exerts direct cytoprotective effects by stabilizing membranes, inhibiting apoptosis, and acting as an antioxidant. The protective effect of UDCA against chemotherapy-induced mucositis was assessed using an in vivo animal model.

**Aims & Methods:** Female Sprague-Dawley rats were randomly assigned to the following 5 groups: non-chemotherapy and vehicle; 5-fluorouracil (5-FU) and vehicle; 5-FU and 10 mg/kg/day UDCA; 5-FU and 100 mg/kg/day UDCA; and 5-FU and 500 mg/kg/day UDCA. 5-FU (400 mg/kg) or physiological saline (control) was administered by intraperitoneal injection. UDCA was orally administered 1 day before 5-FU injection for 6 days. One day after the final UDCA dose, rats were sacrificed, and the intestines were dissected for tissue sampling and laboratory analysis.

**Results:** UDCA promoted a higher body weight recovery, decreased villus destruction, and reduced inflammatory cytokines levels, at doses of 10 and 100 mg/kg/day. Villous fusion and destruction were pronounced in the 5-FU group compared with those observed in the UDCA-treated group or controls. The jejunal villous lengths were as follows: 212.8 ± 58.0 μm, 331.3 ± 18.0 μm, and 310.0 ± 112.6 μm, in the 5-FU and vehicle, 5-FU and 10 mg/kg UDCA ($p = 0.006$), and 5-FU and 100 mg/kg UDCA groups ($p = 0.046$), respectively. Real-time polymerase chain reaction (RT-PCR) showed that IL-6 and TNF-$\alpha$ levels decreased in the 10 mg/kg and 100 mg/kg UDCA co-administration groups. Further, myeloperoxidase activity decreased in the UDCA co-administration group.

**Conclusion:** UDCA significantly attenuated the reduction of the height of small intestinal villi and reduced inflammatory cytokine levels, thus highlighting the potential of UDCA as a preventive agent against chemotherapy-induced gastrointestinal mucositis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** vijaysadashiv@yahoo.com.

**Introduction:** In acute colonic pseudoobstruction (Ogilve syndrome) there is dilation of the colon without mechanical obstruction, it may develop after surgery or with severe systemic illness. This condition is due to an acute imbalance of the normal extrinsic autonomic innervation of the bowel. Although it may resolve with conservative therapy, colonoscopic decompression is sometimes needed to prevent ischemia and perforation of the bowel. Studies suggest that neostigmine is an effective treatment. One report from our centre of Ryles tube administration of Naloxone, an opiod antagonist, which is a synthetic congener of oxymorphone, with good results. However there is no reported experience with Intravenous Injection Naloxone hydrochloride.

**Aims & Methods:** To study the efficacy of Injection Naloxone hydrochloride in patients acute colonic pseudoobstruction. We studied admitted patients fulfilling criteria of acute colonic pseudo-obstruction in the form of clinical abdominal distention and radiographic evidence of significant colonic dilation. Reversible and mechanical causes of abdominal distention ruled out. When there was no response to at least 24 hours of conservative treatment, we prospectively recruited patients to receive 0.4 mg Naloxone intravenous eight hourly. Clinical response was defined as evacuation of flatus or stool and a reduction in abdominal distention, abdominal circumference, and measurements of the colon diameter on radiographs. Patients who had no response to the initial dose were eligible to receive open-label Naloxone 24 hours later and subsequent doses 8 hrly for 24 hrs, if that fails then rescue Injection neostigmine and colonoscopic decompression were kept in treatment protocol.

**Results:** Prospectively total 25 patients were included in study since march 2015, eight patients were having pneumonia, septicaemia, three patients with chronic renal failure, septicaemia, five patient with cerebrovascular accident, two post spinal surgery, five with polytrauma due to road traffic accident, two post knee replacement. Twenty-one patients who received Naloxone had early colonic decompression in the form of passage of flatus, passage of motion, significant (more than 2 inch) decrease in abdominal girth, significant decrease in large bowel diameter on x-ray flat plate abdomen (equal or more than one cm), improvement in clinical parameters especially respiratory rate, oxygen saturation. In one patient colonoscopic decompression required, three had poor recovery. Injection Neostigmine was not used for any patient. Median time to response was 8 hours (range 3 to 28 hours). Side effects of Naloxone included mild tachycardia and rise in blood pressure in five patients, Irritability noted in 6 patients.

**Conclusion:** Our study suggests that Injection Naloxone is beneficial and safe in the treatment hospitalized patients with acute colonic pseudoobstruction. It obviates the need of Neostigmine which is associated with serious cardiac side effects and colonoscopic decompression which is not possible at every centre.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0515 ARE NUTRITIONAL BEHAVIOR, LIFESTYLE-FACTORS AND ANTIBIOTICS RISK FACTORS OF SMALL BOWEL BACTERIAL OVERGROWTH (SIBO)?

K. Gewecke[1], C. Von Castell[1], S. Nannen-Ottens[1], J. Keller[2], P. Layer[2], **V. Andresen**[2]
[1]*Life Sciences, Nutritional Science, Hochschule für Angewandte Wissenschaften, Hamburg/Germany*
[2]*Internal Medicine, Israelitisches Krankenhaus, Hamburg/Germany*

**Contact E-mail Address:** v.andresen@ik-h.de.

**Introduction:** Established risk factors of small bowel bacterial overgrowth (SIBO) include anatomical (e.g. ileocecal resection) or physiologic (e.g. gastric hypoacidity) barrier dysfunctions as well as disturbed gut motility and mucosal immune deficiency. Mucosal immunity is suggested to be modulated by gut microbiota. Gut microbiota, in turn, are influenced by nutrition and antibiotics.

**Aims & Methods:** It was therefore the aim of our study to test associations between nutritional behavior and prior antibiotic treatments with the presence of SIBO. Consecutive patients, who presented with typical abdominal symptoms and performed a glucose H2-breath test for suspected SIBO, were asked to fill in questionnaires assessing nutritional behavior (including 'food frequency'), physical exercise, prior medical history including abdominal surgery and medication (including antibiotic therapies within the past two years). Associations between the questionnaire and breath-test results (SIBO confirmation: yes/no) were analyzed with t-test and Chi-square statistics.

**Results:** In the 191 participants (69% female, mean age 48), SIBO was confirmed in 26%. There were significant differences between SIBO-positive patients compared to patients with abdominal symptoms but normal glucose H2-breath test: SIBO patients were predominantly female (84%), had a lower BMI (21.4 vs. 23.9), and exercised less (53 vs. 104 min/week) (all $p < 0.05$). SIBO patients more often followed individual diets and consumed less sugary foods and drinks, less alcohol and less stodgy foods. Moreover, prior gastrointestinal surgery and frequent antibiotic treatment were significantly associated with SIBO (all $p < 0.05$).

**Conclusion:** In patients, who perform glucose H2-breath test because of abdominal symptoms, those with confirmed SIBO differ significantly from patients with normal breath test results, particularly regarding less physical exercise, altered nutritional behavior and more frequent prior antibiotic therapies. Whether these differences can be attributed to consequences (adaptation?) or causes (risk factors?) of SIBO should be addressed and clarified in future studies.

[2]*Anestesiology Department., Hospital Clínic of Barcelona, Barcelona/Spain*

**Contact E-mail Address:** ikaraujo@clinic.ub.es.

**Introduction:** The exact length of small bowel (SB) explored during Balloon Enteroscopy and its correlation with Capsule Endoscopy (CE) is difficult to estimate. The insertion depth measurement using May's Method for Double Balloon Enteroscopy (DBE) was validated previously in animal model but there are no studies with single-balloon Enteroscopy (SBE).

**Aims & Methods:** 1. To validate the insertion distance with SBE by May's method in porcine a model. 2. To correlate the explored distance of SBE with CE time. Necropsy was used as gold standard. An oral SBE was performed during a maximum time of 120 minutes. Different marks, using colored clips, were done during the procedure every 30 minutes and, at the most distal insertion depth, an ink tattoo was injected. May's Method was used to assess the length of each insertion cycle (estimated 30–40 cm). 24 hours later, a CE was administered to the animal in order to localize the different SB marks. After euthanasia, the marks and distances were measured with a flexible ruler.

**Results:** 13 pigs were included. The average insertion depth estimated was 167.69+/-13.8 cm and 150.31+/-17.3 cm, with Maýs method and necropsy respectively; The Pearson correlation coefficient showed a good correlation between both measures ($r = 0.7$; $p = 0.004$). The average number of cycles performed during SBE was 8.29+/- 2.9. Regarding CE, average time to reach ink tattoo was 228.71+/-20.35 minutes, identifying 75% of marks previously done in SB.

**Conclusion:** 1. Maýs method is accurate to estimate depth insertion for SBE and might give approximate reference values in humans. 2. These data may help us estimate distances to reach a lesion detected by Capsule Endoscopy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0517 DIAGNOSIS OF CELIAC DISEASE WITHOUT DUODENAL BIOPSY IN ADULTS WITH POSITIVE SEROLOGY TESTING

**Introduction:** The latest ESPGHAN guidelines for the diagnosis of coeliac disease (CD) allow to avoid duodenal biopsy sampling in symptomatic children with genetic predisposition to CD who show immunoglobulin A anti-transglutaminase (IgA tTG) antibody titers >10 times the upper limit of normal range after confirmation of anti-endomysium antibodies (EMA) positivity. In adults, instead, small-bowel biopsy is still requested for the diagnosis of CD.

**Aims & Methods:** Our aim was to assess, in a large adult population with clinical suspicion of CD: 1) the PPV of specific serum antibodies (IgA EMA and IgA tTG), both alone and in combination, for histologically proven CD (Marsh-Oberhuber≥I); II) the cut-off value of IgA tTG correlated with the highest PPV for histologically proven CD in patients with positive EMA. We performed a retrospective analysis of a prospectively maintained database including all adult (age >16 year old) patients who underwent celiac serology testing between January 2004 and September 2015 at the "A. Gemelli" University Hospital. First, the electronic database of the Biochemistry Unit was searched to identify patients who resulted positive for IgA EMA and/or had IgA TTG >16 U/ml. Then, we searched the electronic database of the Histopathology Unit to determine how many of these patients underwent small bowel biopsy, and to retrieve related histology reports. Patients were excluded from the final analysis for the following reasons: pediatric age (<18 year-old); pregnancy; small bowel neoplasms; Whipple disease; Crohn's disease; duplicate testings; duodenal biopsy not performed/unavailability of histology report at our Center. The PPV of specific serum antibodies, alone and/or in combination, for histologically proven CD (Marsh-Oberhuber ≥1) was calculated. A ROC curve was generated to establish the cut-off value of IgA tTG correlated with the highest PPV for histologically proven CD in patients with positive IgA EMA. Accuracy parameters are reported as percentage [95% confidence interval].

**Results:** Between January 2004 and September 2015, a total of 57303 individuals underwent IgA EMA and/or IgA TTG; after removal of duplicate testings, we found 23531 patients who had undergone both testings; among them, 446 patients were positive for both EMA and tTG, 341 for EMA alone, and 436 patients for tTG alone, respectively. Histology reports were available for 178 patients. Of these patients, 38 (21%) had abnormal tTG alone, 19 (11%) had positive EMA alone, and 121 (68%) had positivity of both antibodies. Among the 19 subjects positive for EMA alone, 13 (68%) showed no alterations of duodenal mucosa, none showed Marsh-Oberhuber I or II lesions, and 6 (32%) showed Marsh-Oberhuber III lesions. The 38 subjects positive for tTG alone had no Marsh-Oberhuber lesions in 21 cases (55%), Marsh-Oberhuber I lesions in 1 case (3%), Marsh-Oberhuber II lesions in no cases, Marsh-Oberhuber III lesions in 16 cases (42%). Among the 121 patients with positivity of both antibodies, respectively 4 Marsh-Oberhuber I lesions (3%), 4 Marsh-Oberhuber II lesions (3%) and 113 Marsh-Oberhuber III lesions (95%) were identified. Positivity of both EMA and tTG in combination, positivity of EMA alone, and positivity of tTG alone achieved, respectively, a PPV for histologically proven CD (Marsh-Oberhuber ≥I) of 100%, 91%, and 86%. In patients with positive EMA, level of tTG ≥18 U/mL was identified as the best cut-off value for predicting Marsh-Oberhuber grade≥1, with a PPV of 100%, whereas level of tTG ≥34 U/mL was identified as the best cut-off value for predicting Marsh-Oberhuber grade≥2, with a PPV of 99.1%, and level of tTG ≥43 U/mL was identified as the best cut-off value for predicting Marsh-Oberhuber grade = 3, with a PPV of 97%.

**Conclusion:** Our preliminary findings suggest that CD can be diagnosed without the need of biopsy sampling in adult patients with positive EMA and tTG cut-off levels slightly higher than those used currently in clinical practice. Should our results be confirmed by further, larger studies, the diagnosis of CD based only on serology, without duodenal biopsy, may become a reasonable approach in a substantial subpopulation of the adult patients with clinical suspicion of CD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0518 GENETIC VARIANTS ASSOCIATED WITH ANAEMIA IN ADULT COELIAC PATIENTS: THE ROLE OF TMPRSS6 AND HFE

**N. Imperatore**[1], R. Tortora[2], L. De Falco[3], P. Capone[1], M. S. Bruno[4], N. Gerbino[1], N. Caporaso[1], A. Iolascon[5], A. Rispo[1]

**Contact E-mail Address:** nicola.imperatore@alice.it
**Introduction:** Coeliac disease (CD) is a chronic, immune-mediated disease occurring in genetically predisposed individuals who assume gluten. Iron deficiency anaemia (IDA) is very common in CD and has been reported in up to 46% of cases of subclinical CD. Even though the link between malabsorption and anaemia is well known, the role of genetic factors remain unexplored.
**Aims & Methods:** We speculated that common SNPs of iron metabolism genes would be associated with anaemia of CD patients. From October 2011 to July 2015 we prospectively assessed the frequency of TMPRSS6 variant rs855791 and HFE variants rs1800562 and rs1799945 in both anemic and non-anemic CD patients at time of CD diagnosis. We also estimated the association of these variants with some hematological and iron parameters (Hb, MCV, serum iron and serum ferritin). Statistical analysis was performed by using T-student and X-square test when indicated; all differences were considered significant when $p < 0.05$.
**Results:** Finally, 491 patients were enrolled: 266 with IDA (mean age 31.2; females 88%), 225 with non-IDA (mean age 32.4; females 65%). TMPRSS6 variant rs855791 and HFE variant rs1799945 were found higher in non-IDA than IDA CD patients (52.2% vs 47% and 27% vs 24.5%, respectively), although not statistically significance ($p = 0.1$). Conversely, HFE variant rs1800562 was found to be significantly higher in IDA than non-IDA CD patients (3.4% vs. 0.8%, $p = 0.03$). Furthermore, CD subjects with TMPRSS6 variant rs855791 showed higher Hb and serum ferritin and lower MCV and serum iron level compared to CD subject with TMPRSS6 WT variant. IDA subjects with HFE variant rs1800562 showed increased serum iron and ferritin values in comparison with CD subject carrying the wild type variant.
**Conclusion:** In CD patients, HFE variant rs1800562 appeared to be more frequent in IDA than in non-IDA and it associated with higher iron status, so conferring a protective role regarding IDA in CD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0519 FODMAPS FREE DIET: AN EFFECTIVE SOLUTION FOR SYMPTOMATIC COELIAC PATIENTS ON GLUTEN-FREE DIET

**N. Imperatore**[1], A. Rispo[1], P. Capone[1], F. Castiglione[1], N. Gerbino[1], L. Lucci[2], G. Accarino[2], N. Caporaso[1], R. Tortora[3]
[1]*Gastroenterology, Department of Clinical Medicine and Surgery, School of Medicine "Federico II" of Naples, Naples, Italy, Naples/Italy*
[2]*Nutrition, Department of Clinical Medicine and Surgery, School of Medicine "Federico II" of Naples, Naples, Italy, Naples/Italy*
[3]*Gastroenterology, Department of Clinical Medicine and Surgery, School of Medicine "Federico II" of Naples, Naples/Italy*

**Contact E-mail Address:** nicola.imperatore@alice.it
**Introduction:** Recent studies have shown high efficacy of a FODMAPs free diet (FFD) in patients suffering from non-coeliac wheat sensitive (NCWS) and irritable bowel syndrome (IBS), but data on this kind of dietary approach in coeliac disease (CD) are still scarce.
**Aims & Methods:** Aim: to establish the efficacy of FFD in symptomatic CD patients despite being on gluten-free diet (GFD), also comparing this outcome with that of subjects affected by IBS.
**Methods:** From January 2016 to September 2016 we carried out an observational prospective study including all consecutive adult CD patients (Group A) who were symptomatic (abdominal pain, diarrhoea, bloating, constipation) despite performing a strict GFD. Also, we enrolled all consecutive adult IBS patients (Group B) referred to our general Ambulatory. We administered a personalized FFD and 2 questionnaires (IBS-SSS with a pain score from 0-minimum to 3-maximum, and SF-36 with 8 different domains) at the time of the first visit (T0), 1 month after (T1) and at 3 months (T3) from the beginning of FFD. Statistical analysis included ANOVA test with and without covariates adjustment. All results were considered significant with a $p < 0.05$.
**Results:** Finally, 66 patients were enrolled (Group A: 23 vs Group B: 43). All CD patients were on GFD from at least 1 year and showed negative EMA and anti-transglutamineases. No differences were noted in terms of age and gender (P = NS). When analyzing the IBS-SSS results, the symptomatic score dropped in both Groups after starting FFD (Group A: 2.04 at T0, 1.26 at T1 and 1.09 at T3 ($P < 0.01$); Group B: 2.35 at T0, 1.42 at T1 and 1.07 at T3 ($P < 0.01$)). However, no statistically significant differences were noted between the two Groups (P = NS). When analyzing the results from SF-36, no differences were noted between the two Groups, even though both CD and IBS population significantly improved their own status with the regards of the 8 domains of SF-36, both at T1 ($P < 0.01$) and at T3 ($P < 0.01$).
**Conclusion:** FFD leads to a significant improvement of gastrointestinal symptoms in CD patients who were persistently symptomatic despite GFD. GFD in association with FFD should be considered a first-line therapy CD this population.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0520 VALUE OF FOLLOW-UP CONTROL BIOPSY AND SIGNIFICANCE OF INCOMPLETE MUCOSAL RECOVERY CELIAC DISEASE

**H. Pekki**[1], K. Kurppa[2], M. Maki[3], H. Huhtala[4], K. Laurila[5], P. Collin[5], K. Kaukinen[6]

**Contact E-mail Address:** pekki.henna.a@student.uta.fi
**Introduction:** A repeat biopsy is recommended in celiac patients on a gluten-free diet, but for variable reasons it is often omitted. We sought factors associated with lacking endoscopic follow-up and significance of this to the long-term treatment results. Furthermore, predictors and significance of histological recovery was investigated in re-biopsied patients.
**Aims & Methods:** 760 previously diagnosed patients participated to a nationwide follow-up study. A wide selection of medical data at celiac disease diagnosis and at present were gathered through interviews and via patient records and blood samples were drawn for serology. Current symptoms and quality of life were assessed by validated questionnaires. Next, all study data was compared between participants with and without a repeat biopsy, and between those with and without histological recovery in re-biopsy.
**Results:** Altogether 68% had undergone a repeat biopsy. Factors predicting this were presence of malabsorption (46% vs 33%, $p < 0.001$) and severe symptoms (24% vs 16%, $P = 0.05$) at diagnosis and concomitant gastrointestinal (40% vs 32%, $P = 0.049$) or locomotor (35% vs 27%, $p = 0.023$) disease, whereas it was less likely in subjects diagnosed in private care (11% vs 23%, $P < 0.001$) or by screening (10% vs 16%, $P = 0.010$). The groups did not differ in the current self-estimated symptoms and dietary adherence, but non-biopsied subjects were less confident of their diet (89% vs 94%, $P = 0.002$) and were more often endomysial antibody-positive (14% vs 9%, $P = 0.012$). However, they reported better SF-36 physical functioning (0.043) and pain (0.013) scores and GSRS indigestion (0.046) and total (0.052) score. Incomplete mucosal recovery in re-biopsied patients ($n = 476$) was predicted by more advanced histological ($P < 0.001$) and serological ($P = 0.001$) disease at diagnosis and presence of concomitant respiratory ($P = 0.031$) and dermatological (0.043) diseases, while the groups did not differ in the other co-morbidities and current adherence or capability to manage gluten-free diet, seropositivity, self-estimated symptoms and questionnaire scores.
**Conclusion:** Patients with more severe disease at diagnosis were more prone to undergo repeat biopsy and also not reaching full mucosal recovery if re-biopsied. However, neither lack of repeat biopsy nor incomplete histological recovery were associated with poorer long-term dietary adherence or clinical response.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0521 MARKERS OF INNATE IMMUNITY AND GUT PERMEABILITY IN COELIAC DISEASE PATIENTS WITH PERSISTENT SYMPTOMS ON A GLUTEN-FREE DIET

**P. Laurikka**[1], K. Lindfors[2], M. Oittinen[2], H. Huhtala[3], K. Kurppa[4], K. Kaukinen[1]
[1]*School Of Medicine, University of Tampere, Tampere/Finland*

[4]*Centre For Chinld Health Research, University of Tampere and Tampere University Hospital, Tampere/Finland*

**Contact E-mail Address:** laurikka.pilvi.l@student.uta.fi
**Introduction:** For unexplained reasons a part of the coeliac disease patients suffer from persistent symptoms despite a strict gluten-free diet (GFD) and lack of co-morbidities (1). We investigated the role of dietary factors, innate immunity, epithelial stress and integrity in this setting by comparing long-term treated coeliac disease patients with and without persistent symptoms.
**Aims & Methods:** Altogether 22 asymptomatic and 25 symptomatic coeliac disease patients on a GFD were enrolled. They completed a four-day food diary and clinical, serological and histological data were analyzed. Further, density of CD3+ and $\gamma\delta$+ intraepithelial lymphocytes (IELs), CD25+ and FOXP3 regulatory T cells and CD117+ mast cells, and the expression of Claudin-3 tight junction protein, heat shock protein 60 (HSP60) and interleukin 15 (IL15) were evaluated from small-bowel mucosal biopsies.
**Results:** All subjects were on a strict GFD and had negative coeliac autoantibodies and recovered mucosal villi. The groups did not differ in the use of wheat starch and purified oats, but asymptomatic patients had higher mean fiber intake than those with symptoms (20.2 vs. 15.2 g/day, $p = 0.028$), although there was wide individual variation. Asymptomatic subjects had higher density of CD3+ IELs than those with symptoms (59.3 vs. 45.0 cell/mm, $p = 0.045$) and there was

similar but non-significant trend in γδ+ IELs (17.9 vs. 13.5, p = 0.149). There were no differences between the groups in the intensity of CD25+, FOXP3, CD117+ and IL15 stainings, but some patients with persistent symptoms had weaker Claudin-3 staining and stronger HSP60 staining.
**Conclusion:** Our results indicate that some coeliac disease patients with persistent symptoms could benefit from a diet rich in fiber. Most of the study markers were not associated with the presence of symptoms, but there might be a subgroup of symptomatic patients exhibiting increased epithelial stress and compromised integrity. Somewhat surprisingly, asymptomatic patients had even higher density of mucosal IELs, suggesting that there is no direct association between these cells and persistent symptoms.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Celiac disease is an autoimmune enteropathy that may be associated with various extra-intestinal manifestations. Liver disease is one of the most frequent.
**Aims & Methods:** Clinical data of 91 patients with celiac disease associated with abnormal liver tests were retrospectively studied and analyzed, during a period of 20 years, from January 1995 to December 2015. The aim of this study is to show the different forms of liver diseases that can be associated to celiac disease ant the impact of a gluten free diet in the evolution of those liver abnormalities.
**Results:** The mean age of the patients was 34 years and they were aged between 13.5 and 61 years old. There was a feminine predominance with sex ratio women/men of 4. The discovery of the liver disease was concomitant with the diagnosis of celiac disease in 86.8% of cases, and found first, before the diagnosis of celiac disease in 13.2% of cases. The most frequent liver disase found was represented by hepatic steatosis, nonalcoholic steatohepatitis, cryptogenic hypertransaminasemia and cryptogenic cirrhosis. Celiac disease was associated with autoimmune hepatitis in 6 cases, primary biliary cirrhosis in 2 cases, idiopathic portal hypertension in 2 cases, portal vein thrombosis by hymerhomocysteneimia or prothrombotic proteins deficiency in 5 cases, sarcoidosis in 2 case and a tuberculoid granulomatous hepatitis in 3 cases and hepatocellular carcinoma in one case. All our patients taked a gluten-free diet and deficiency supplementation, The follow up was weekly to evaluate the evolution of the disease. Celiac disease evolution was favorable in 90.1% and the evolution of the liver diseases was marked by the normalization of the liver function tests in the cryptogenic hypertransaminasemia after the start of gluten diet in 100% of cases. The normalization of biologically and ultrasound features in hepatic steatosis, and the stabilization of the cryptogenic cirrhosis in 71.42% of cases. We noted the normalization of the liver tests in the autoimmune hepatitis and the primary biliary cirrhosis after specific treatment of those 2 diseases.
**Conclusion:** Liver disease is frequent in celiac disease. Therefore celiac disease should be systematically looked for in any patient with unexplained chronic liver tests abnormalities, even in the absence of any gastrointestinal symptoms.

### P0523 SERUM 25-HYDROXYCHOLECALCIFEROL LEVELS AT CELIAC DISEASE PRESENTATION PREDICT BONE MINERAL DENSITY RECOVERY AFTER GLUTEN EXSCLUSION

**K. Efthymakis**, M. Serio, R. Sanelli, A. Milano, A. Bonitatibus, F. Laterza, M. Neri
*Dept. Of Medicine And Ageing Sciences, G. D'Annunzio University and Foundation, Chieti/Italy*

**Contact E-mail Address:** efkn78@gmail.com
**Introduction:** Celiac disease (CD) patients at presentation variably show reduced bone mineral density (BMD) and altered bone-related serology, including serum 25-hydroxycholecalciferol (25[OH]-VitD). Gluten-free diet (GFD) has been shown to promote repair in children and to a smaller extent in adults[1]. However, complete bone mineral recovery is uncertain and predictive markers are lacking.
**Aims & Methods:** We aimed to evaluate the prevalence of reduced BMD (expressed as Z-score) at CD presentation, assess recovery under GFD and identify potential predictors of bone tissue recovery.
We included consecutive adult IgA anti-tTG positive, biopsy proven CD patients. BMD Z-scores were obtained by Dual Energy X-Ray Absorptiometry of the left femoral neck at diagnosis and during follow-up. GFD compliance at inclusion was assessed serologically.
**Results:** We evaluated 161 celiac adults (mean age = 39.2 years, F/M = 5:1) at diagnosis and after adequate GFD (mean duration 7.4 ± 6.8 years). Histology was graded according to the Corazza-Villanacci classification (Grade A = 10.6%, B = 50.9%, C = 38.5%). Mean IgA anti-tTG levels at onset were 73.3 ± 35.4 U/dl (mean±SD), while at inclusion 4.4 ± 2.3 U/dl. BMD Z-scores were lower at diagnosis (−1.6 ± 1.09 vs −0.9 ± 0.89, $p < 0.001$), showing no correlation with sex but moderately with age ($r = -0.221$, $p = 0.04$). Prevalence of normal vs low BMD (< −1.0 DS) at onset and inclusion was 18.6% vs 81.4%, and 27% vs 73%, respectively. Prevalence of severely reduced BMD (< −2.5 DS) at diagnosis was 14.8% vs 1.2% after GFD. Mean 25[OH]-VitD levels at inclusion were 17.07 ± 6.44 vs 26.71 ± 6.74 ng/dl after GFD ($p < 0.001$). Prevalence of deficit/insufficiency at diagnosis were 20.8%/66.7% vs 4.9%/62.3% after GFD, respectively. BMD at diagnosis did not correlate with GFD outcome ($r = -0.41$, $p = 0.581$). 25[OH]-VitD levels showed no correlation to BMD at onset. However, they correlated with BMD outcome ($r = 0.419$, $p = 0.041$). In particular, 25[OH]-VitD serum titers over a cut-off level of 20 ng/dl were significantly associated to higher BMD values after GFD (−0.24 ± 0.85 vs −1.12 ± 0.94, $p = 0.033$). Overall, mean GFD duration necessary to achieve a statistically significant BMD increase from diagnosis was 48 months (−1.46 ± 1.05 vs −1.04 ± 0.85, $p = 0.029$).
**Conclusion:** Reduced BMD is common in adult celiacs at diagnosis and generally responds slowly to GFD, potentially taking up to 4 years before significantly improving. Initial severity of BMD loss does not seem to impair recovery. Serum 25[OH]-VitD titers at onset positively correlate with outcome BMD; a cut-off of 20 ng/dl in our sample predicted an almost complete BMD recovery. Further studies are needed to confirm this potential predictor of outcome under GFD and its use as a marker for early treatment.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0524 CLINICAL OUTCOME OF PATIENTS WITH RAISED INTRAEPITHELIAL LYMPHOCYTES (IELS) WITH NORMAL VILLOUS ARCHITECTURE ON DUODENAL BIOPSY

**V. Parihar**[1], R. Stack[1], A. Alakkari[2], S. Crowther[3], D. Mcnamara[4]

**Contact E-mail Address:** vikpar37@yahoo.com
**Introduction:** Intestinal intraepithelial lymphocytes (IELs) belong to a unique T-cell population interspersed between epithelial cells of the small intestine. IELs are the first line of host immune defense and are involved in intestinal immune surveillance with levels increasing in response to antigenic stimulation. (1) The normal IEL count has been recommended to be less than 25 IELs per 100 enterocytes based on duodenal biopsies being obtained endoscopically with histology performed on sections cut at 3–4 μm. (2, 3). The finding of a raised intraepithelial lymphocytes (IEL) count with normal villous architecture is of sufficient clinical importance to be reported in routine duodenal biopsies and remains a management challenge. Raised IELs with preserved villi are a feature of latent coeliac disease (CD). However they are also seen in a number of other conditions. Follow-up data from clinical practice may help identify at risk patients.
**Aims & Methods:** To determine the long-term clinical relevance of isolated increased IELs on random duodenal biopsy in an Irish cohort, with reference to subsequent coeliac disease development. A single tertiary center retrospective observational cohort study was undertaken. Patients from 2012 to 2014, > 18 years with at least one biopsy from the second part of duodenum with increased IELs; defined as > 25IELS/100 enterocytes, with preserved villous architecture were identified from our histopathology database. Patients were excluded if they had a history of Coeliac Disease (CD). Clinical and demographic data were recorded following a chart review. CD was diagnosed by the attending Physician based on the Physician Global Assessment. Data was compared between groups using a student t-test and odds ratios were calculated as appropriate. Statistical significance was set a priori at $p < 0.05$.
**Results:** Over 24 months 6,244 patients had duodenal biopsies and 114(1.8%) had isolated increased IELs. The mean age was 50 years (19–91) and 34(30%) were male. Follow-up was available in 75(65%), with a mean duration of 22 months. CD was subsequently diagnosed in 32% (n = 24). CD was associated with female gender 22/24 v 39/51, OR 7.5, $p < 0.05$, 95%CI 0.74–0.01 and older age 55 v 41 years, $p < 0.04$, 95%CI 26.8 - 0.28, In addition, a higher IEL count was predictive of CD with an IEL of > 40 in 11/24 (46%) with CD v 12/51 (24%) without CD, $p = 0.0006$, OR 5.6, 95% CI −0.54 to –0.15. Overall raised IEL's could be attributed to CD in 24 (32%), associated conditions / medications in 21(28%), *H.Pylori* infection in 14 (19%) and no cause was found in 24 (32%).

Clinical features and subsequent coeliac disease development

| Parameter | CoeliacN = 24 | Non-Coeliac N = 51 | p-value | OR |
|---|---|---|---|---|
| Age | 55 | 41 | <0.05 | N/A |
| Female | 22 | 39 | <0.05 | 7.5 |
| Positive TTG | 14 | 0 | <0.001 | 139 |
| H.Pylori infection | 10 | 14 | 0.36 | N/A |
| Associated medical conditions | 9 | 12 | 0.12 | N/A |
| IEL>40 | 11 | 12 | <0.001 | 5.6 |

**Conclusion:** Raised IELs are a frequent non-specific but important finding. In our cohort a third of patients subsequently developed CD. Of import a negative baseline TTG does not exclude CD development, NPV 85%. Close follow up of older female patients and those with IELs > 40 is supported by this data.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0525 COMPARING DIETITIAN-LED GROUP CLINICS TO INDIVIDUAL APPOINTMENTS FOR NEWLY DIAGNOSED PATIENTS WITH COELIAC DISEASE (CD)

**M. Kurien**[1], N. Trott[1], F. Branchi[2], D. S. Sanders[1]

**Introduction:** Newly diagnosed CD patients should have a nutritional assessment and gluten-free diet (GFD) education by registered dietitians, in accordance with guidelines. Achieving these standards is problematic due to increased CD diagnosis and limited trained dietitians available to deliver these services. Locally, we have shown that patients often wait four to six weeks for a dietetic consultation following CD diagnosis, with patient feedback suggesting this is unacceptably long. This study aimed to address this concern by comparing whether dietetic consultations provided in group clinics was non-inferior to an individual appointment for newly diagnosed CD patients.
**Aims & Methods:** Between January 2015 and December 2015 newly diagnosed CD patients were seen either by a dietitian in a group clinic or in an individual appointment as part of a local service evaluation project. Group clinics were defined as having a minimum of 6 individuals, and covered the same topics as individual appointments (education on gluten-free diets, prescriptions, travelling and information on Coeliac UK). All patients had nutritional assessments at baseline and bloods performed in accordance with BSG guidelines. These were reassessed at 3-month follow-up appointments, alongside evaluation forms for clinics and assessment of GFD adherence using the Biagi score (A validated 5 point adherence score (0–4), with the highest score indicating strict GFD adherence). Comparisons between groups were made using a student t-test, with a p-value $< 0.05$ considered significant.
**Results:** 56 new CD patients were initially referred for a dietetic consultation. Eight patients (14%) did not attend first appointments and 8 failed to attend follow-up. Of the remaining 40 patients (25 F:15 M, mean age 48 years), 30 were seen in group clinics and 10 had individual appointments. There was no statistically significant difference in baseline BMI ($p = 0.57$), age ($p = 0.10$) or tissue transglutaminase antibody levels ($p = 0.54$) between group patients and individual clinic patients. At follow-up mean GFD adherence scores were similar in both groups (3.3 vs 3.1, $p = 0.51$), with paired t-tests showing significant reduction in both groups in serological markers and haematinics ($p < 0.001$). Evaluation forms supported the merits of group clinics, with 97% (29/30) of patients stating that group clinics met expectations, enhanced understanding and that they would recommend to other patients.
**Conclusion:** This study demonstrates how group dietetic clinics for newly diagnosed patients may be a resource saving intervention, which derives no detriment to patient education and GFD adherence. Findings from this work provide proof of concept for undertaking a future randomised controlled trial in this area, including health economic analysis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0526 CIRCULATING MICRORNA ASSOCIATED WITH VISCERAL OBESITY: A POSSIBLE BIOMARKER OF DIGESTIVE CANCERS

**J. Matsuzaki**[1], R. Shimizu-Hirota[2], H. Tadokoro[1], Y. Iwao[2], T. Ochiya[1]

[2]*Center For Preventive Medicine, Keio University Hospital, Tokyo/Japan*

**Contact E-mail Address:** jmatsuza@ncc.go.jp

**Introduction:** Visceral obesity is a key risk factor for the development of several digestive malignant diseases, such as esophageal adenocarcinoma, colorectal adenocarcinoma, and pancreatic ductal adenocarcinoma. Recently, circulating microRNAs (miRNAs) have been proposed as noninvasive biomarkers of diseases and potential therapeutic targets.
**Aims & Methods:** The aim of this study is to examine whether the level of visceral obesity-associated circulating miRNAs could be a novel biomarker for the presence of digestive cancers. We obtained serum samples from healthy individuals who received thorough medical examinations including the measurement of visceral fat area by abdominal computed tomography at Keio University Hospital between February 2015 and June 2015 as a training set. We also obtained serum samples from the healthy volunteers at Yokohama Minoru Clinic in 2015 as a validation set. We comprehensively evaluated serum miRNA expression profiles using microarray analysis. The training set was used to identify miRNAs which were associated with both the levels of visceral fat area (VFA) and body mass index (BMI). Subsequently, BMI-associated miRNAs were refined using the validation set. Finally, the associations between the presence of digestive cancers and the expression levels of the identified miRNAs were evaluated using a published dataset in the Gene Expression Omnibus database (GSE59856).
**Results:** A total of 83 and 1991 individuals were enrolled in the training set and the validation set, respectively. Levels of 9 miRNAs were positively correlated with both the levels of VFA and BMI in the training set. In the validation set, 2 of 9 miRNAs correlated with BMI were identified. Levels of both 2 miRNAs were also positively correlated with levels of HbA1c. Regarding one of the 2 miRNAs, the expression levels were significantly associated with the presence of pancreatic ductal adenocarcinoma (area under the ROC curve [AUC], 0.75; 95% confidence interval [CI], 0.68 to 0.81), hepatocellular carcinoma (AUC, 0.72; 95% CI, 0.64 to 0.79), colorectal adenocarcinoma (AUC, 0.69; 95% CI, 0.61 to 0.77), and biliary tract cancer (AUC, 0.67; 95% CI, 0.60 to 0.74), and were marginally associated with the presence of esophageal squamous cell carcinoma (AUC, 0.66; 95% CI, 0.58 to 0.74) and gastric adenocarcinoma (AUC, 0.65; 95% CI, 0.57 to 0.73).
**Conclusion:** We identified circulating miRNAs which were associated with visceral fat in large cohorts. Levels of a given miRNA were associated with the presence of pancreatic cancer, hepatic cancer, and colorectal cancer. This miRNA could be a biomarker of obesity-related digestive cancers, and be a target for the prevention of them.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0527 INDIVIDUALIZED RESPONSES TO LIFESTYLE INTERVENTIONS CAN BE PREDICTED BY GUT MICROBIOTA

**D. A. Muñiz-Pedrogo**[1], B. A. Schmidt[1], M. D. Jensen[2], J. A. Murray[1], P. C. Kashyap[1], V. Nehra[1]

**Contact E-mail Address:** pedrogo.david@mayo.edu

**Introduction:** Recent evidence suggests that the gut microbiota has a role in the pathophysiology of obesity by influencing host energy metabolism and adiposity. However, there is still limited evidence if pre-intervention characteristics of the gut microbiome will predict response to lifestyle interventions aimed at achieving weight loss.
**Aims & Methods:** The primary aim of this study is to determine if baseline differences in the gut microbiota are predictive of weight loss after a lifestyle intervention program in overweight and obese individuals. 27 obese and overweight individuals were recruited to participate in a lifestyle intervention program that included cognitive/behavioral therapy, a nutritional intervention, and a physical activity intervention. The nutritional intervention involved a volumetric approach that included unlimited fruits and vegetables and lower energy density foods with greater nutrient density. The physical activity intervention involved walking at least 10,000 steps per day. Subjects were followed every week during the first 3 months, every 2 weeks during the next month, and monthly thereafter. Height and weight measurements were obtained at baseline, 3 months, and 6 months after initiation of the intervention program. Percent of baseline weight loss was also calculated and a 5% weight loss was defined as success. Fecal stool samples were collected at baseline, 3 months, and 6 months. The V4 variable region of bacterial 16 S rRNA was amplified from stool DNA and sequenced with the MiSeq Illumina platform. Data analysis was done using Quantitative Insights into Microbial Ecology (QIIME 1.9.1) pipeline. The linear discriminant analysis (LDA) effect size (LEfSe) method was performed to identify significantly discriminative bacteria between subjects who failed or succeeded in achieving weight loss. An alpha of 0.05 and LDA threshold of >2.0 were used.
**Results:** 3 overweight and 24 obese individuals were included in the analysis. Mean age was 54 years (95% CI: 50.7, 57.1) and 78% were female. Average weight at baseline was 96.0 kg (95% CI: 90.4, 101.4) and average BMI at baseline was 34.1 $kg/m^2$ (95% CI: 32.8, 35.4). At 3 months, subjects achieved a mean

weight loss of 3.71 kg (95% CI: 2.31, 5.11) and a mean reduction in BMI of 0.80 (95% CI: 0.38, 1.57), with 9 subjects (33%) achieving at least a 5% weight loss. 8 of these subjects (89%) maintained a 5% weight loss at 6 months. Gut microbiota analysis showed no significant changes in alpha diversity or beta diversity after 3 months or 6 months. Subjects who achieved a 5% weight loss had baseline microbiota significantly enriched with Phascolarctobacterium, Corynebacterium, Cerasicoccaceae family, Oxalobacter, and Turicibacteraceae family bacteria. Those who failed to achieve a 5% weight loss had microbiota enriched with Veillonella and Pasteurellaceae family bacteria. Interestingly, both Phascolarctobacterium and Veillonella are members of the Veillonellaceae family and were the most discriminant taxa for each group, respectively, suggesting a potential nutrient niche competition in different states.
**Conclusion:** In this study, we identified discriminant gut microbiota that predict successful weight loss in participants of a comprehensive lifestyle intervention program. These pilot data support future developments of microbiota-based individualized strategies for weight loss.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0528 ENDOGASTRORIO CLINIC EXPERIENCE IN THE TREATMENT OF EXCESS WEIGHT USING THE SPATZ3 BALLOON

**R.J. Fittipaldi-Fernandez**[1], C.F. Diestel[2], M. Passos Galvão Neto[3]
[1]*Dept. Of Digestive Endoscopy, EndogastroRio, Rio de Janeiro/Brazil*
[2]*Nutrition Division, Rio de Janeiro State University, Rio de Janeiro/Brazil*
[3]*Gastro Obeso Center, Sao Paulo/Brazil*

**Contact E-mail Address:** ricfittipaldi@hotmail.com
**Introduction:** The intragastric balloon (IGB) is established as a safe and effective option to treat overweight/obesity, however, the balloons available untill now were not adjustable, and the maximum permanence was six months. Recently, the adjustable twelve months stay IGB Spatz3® has been approved for use in Brazil, and EndogastroRio clinic pioneered the use of this device in this country.
**Objective:** To evaluate the results and complications during the initial thirteen months of using the IGB Spatz3® in EndogastroRio clinic.
**Methods:** 155 patients were analyzed. The IGB Spatz3® was filled with a standard volume of 600 ml. The patients presented a minimum body mass index (BMI) 27 kg/m$^2$. Data were analyzed using descriptive statistic and the Student t test.
**Results:** Of 155 patients, 13 were excluded due to early IGB removal: three by intolerance and rejection of setting down the volume, one by a gastric ulcer due to non-use of proton pump inhibitor, eight for withdrawal of treatment non correlated with the adaption period sintoms, and one due to baloon ruption nine months after the implant and the not desire to replace it. The complications were: 5 (3.22%) gastric ulcers (4 observed only in the removal of the balloon, flat and asymptomatic). 1 (0.81%) case of gas production inside the balloon. Six balloon leakages: three balloons ruption due to cândida colonization, and three early leakages due to a deffective valve. One case of Mallory-Weiss syndrome. Of all patients, 9 underwent volume reduction of the balloon due to intolerance (mean 180 ml): Seven at the beginning of the treatment, and two after the upward setting, with clinical improvement and maintenance in treatment. Of the 142 remaining patients, 45 patients (33 female) have already completed the treatment and removed the balloon after a minimum period of nine months of balloon use. The final BMI ($31.88 \pm 6.38$ kg/m$^2$) was significatively lower than the initial BMI ($38.68 \pm 5.47$ kg/m2) ($p < 0.0001$). The average weight loss in kilograms was $18.84 \pm 11.21$. %TBWL was $17.65 \pm 10.02$, %EWL of $56.64 \pm 36.49$. 30 patients did the upward adjustment of the balloon during the treatment (mean 284.67 ml). There was no difference between the two groups in relation to kg weight loss ($p = 0.4144$), %TBWL ($p = 0.2754$) and %EWL ($p = 0.1739$)
**Conclusion:** Treatment with IGB Spatz3 shows to be safe (despite a higher incidence of ulcers, they are mostly asymptomatic), effective, without early removals in intolerant patients that were submitted to the down setting balloon volume.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0529 ASPIREASSIST AS A TOOL TO TREAT OBESITY: 1, 2, AND 3 YEAR RESULTS TO DATE IN 100-SUBJECT ONGOING MULTI-CENTER POST-MARKET STUDY

**E. Machytka**[1], H. Forssell[2], E. Noreen[2], R. Turro[3], T. Bammer[4], P.A. Testoni[5], V. Fehlert[6]

[6]*Herzog-Karl Klinik, Stuttgart/Germany*

**Contact E-mail Address:** evmac@seznam.cz
**Introduction:** The AspireAssist System (Aspire Bariatrics, Inc. King of Prussia, PA) is a device to help people with obesity lose weight, consisting an a customized percutaneous endoscopic gastrostomy (PEG) tube and an external device to facilitate removal of approximately 30% of ingested calories consumed in a meal, in conjunction with lifestyle (diet and exercise) counselling.
**Aims & Methods:** A total of 100 subjects were enrolled from June 2012 to December 2015 as part of a post-market study involving 6 centers: University of Ostrava, in Ostrava, Czech Republic, Blekinge County Hospital in Karlskrona, Sweden; Teknon in Barcelona, Spain; L'Ospedale San Raffaele in Milan, Italy; a private clinic in Kufstein, Austria; and Herzog-Karl Klinik in Stuggart, Germany. Mean baseline BMI of the 100 subjects was $44.9 + 8.3$ kg/m$^2$.
**Results:** As of January 5, 2016, 80, 25, and 15 patients have reached 1, 2, and 3 years of therapy, respectively. Of the 100 subjects that enrolled, 17 patients have had their gastrostomy tube removed and are no longer part of the study: 6 before 1 year, 8 between 1 and 2 years, and 3 between 2 and 3 years. Mean (±SD) %EWL for the patients that completed 1, 2, and 3 years of therapy was 46.5% (24.3%), 55.1% (25.7%), and 56.2% (29.8%), while mean (±SD) %TBL was 18.8%(8.4%), 23.5%(8.8%), and 21.0%(10.2%), respectively. The most frequently reported adverse events were abdominal pain and discomfort in the perioperative period and skin irritation around the stoma in the postoperative period. Serious adverse events were reported in 4% of participants. There was no evidence to date of the development of any metabolic abnormality, nor any abnormal eating behaviors in patients in this study.
**Conclusion:** The AspireAssist System provides an effective weight-loss therapy, with few and minimal complications, for people with Class II and Class III obesity.
**Disclosure of Interest:** E. Machytka: Aspire Bariatrics – research and travel grant, consulting

[3]*Taras Shevchenko National University Of Kyiv, Kyiv/Ukraine*
[4]*Esc "institute Of Biology", Taras Shevchenko National University of Kyiv, Kyiv/Ukraine*

**Contact E-mail Address:** nazariikobyliak@gmail.com
**Introduction:** Today probiotics have been suggested as a treatment for the prevention of NAFLD. Omega-3 fatty acid treatment may have beneficial effects in regulating hepatic lipid metabolism, adipose tissue function, and inflammation.
**Aims & Methods:** The present study was designed to determine whether probiotics plus omega-3 as adjunct are superior to probiotic alone on the monosodium glutamate (MSG) induced NAFLD model in rats.
**Methods**. We included 60 rats divided into 4 groups 15 animals in each. Rats of group I were intact. Newborns rats of groups II-IV were injected with MSG (4.0 mg/g body weight) subcutaneously at postnatal days 2, 4, 6, 8 and 10. The III (Symbiter) group received 2.5 ml/kg of multiprobiotic "Symbiter" containing concentrated biomass of 14 probiotic bacteria genera Bifidobacterium, Lactobacillus, Lactococcus, Propionibacterium. The IV (Symbiter-Omega) groups received "Symbiter Omega" combination of probiotic biomass supplemented with flax and wheat germ oil (250 mg of each, concentration of omega-3 fatty acids 1–5%). Administration was started at 4 weeks after birth and continued intermittently two-week course in 2 weeks intervals. To assess morphological changes in liver we used NAS (NAFLD activity score). Lipid extraction from liver was performed according to Folch. The content of proinflammatory cytokines (IL)-1$\beta$, IL-12Bp40, INF-$\gamma$) and anti-inflammatory cytokines (IL-4, IL-10, TGF-$\beta$) were measured by ELISA.
**Results:** In both interventional groups reduction of total NAS score as compared to MSG-obesity was observed. Supplementation of alive probiotics mixture with omega-3 leads to more pronounced reduction for steatosis degree ($0.73 \pm 0.11$ vs $0.93 \pm 0.22$, $p = 0.199$) which accompanied with significant decreasing of triglyceride $5.1 \pm 0.25$ vs $6.26 \pm 0.23$, $p < 0.05$) accumulation in liver as compared to probiotic alone. For both intervention groups similar reduction of lobular inflammation and ballooning degeneration was observed. This data accompanied with significant but more pronounced reduction of proinflammatory cytokines (IL)-1$\beta$, IL-12Bp40, INF-$\gamma$) and restoration of anti-inflammatory cytokines (IL-4, IL-10, TGF-$\beta$) levels for combination of probiotic with omega-3.
**Conclusion:** Combination of alive probiotic with omega-3 are superior in NAFLD prevention and lead to greater reduction of liver triglyceride accumulation as compared to probiotic alone.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0531 IMPACT OF BODY MASS INDEX AND BODY COMPOSITION ON LUNG FUNCTION IN ADULT PATIENTS WITH CYSTIC FIBROSIS AFTER LUNG TRANSPLANTATION

**Introduction:** Cystic fibrosis (CF) is a multisystem disease mainly affecting the gastrointestinal and respiratory tract. Nutritional status (NS) is an important prognostic factor and has been shown to correlate with lung function prior to

lung transplantation (LT). The impact of malnutrition and vitamin D deficiency on lung function after LT is unclear.
**Aims & Methods:** This study aimed at investigating the impact of body mass index (BMI), body composition (BC), and vitamin D – levels on lung function in adult CF patients after LT. Therefore, consecutive adult CF patients after LT who attended our CF outpatient service between January 2012 and July 2015 were included. Data on BC measured by 3 compartment model bioelectrical impedance analysis (BIA), general nutritional status as evaluated by BMI, as well as 25-hydroxy(OH)-vitamin D levels at initial visit and follow-ups were collected retrospectively and correlated with lung function parameters.
**Results:** In total, 58 patients (59% female, median age: 30.1 y) were included. The majority (81%) carried the F508del allele, were pancreatic insufficient (PI; 97%), diabetics (80%; CFRD or NODAT), or had reduced bone density (88%). Median BMI was 19.6 $kg/m^2$. More than a quarter of subjects (16/58; 28%) were malnourished (BMI < 18.5 $kg/m^2$), none of the patients was classified as obese. BMI significantly correlated with lung function. Malnourished patients had significantly reduced lung function compared to normal/overweight patients. BMI, as well as the single BIA parameters PA, TBW, FFM, and BCM were univariate predictors of lung function as assessed by FEV1%. 139 BIAs performed in 58 patients during longitudinal follow-up were analysed, demonstrating a steady rise in median BMI, PA and BCM. In parallel lung function fell slowly, but constantly during the same period (FEV1% from 88% to 80.5%). In malnourished patients, a dramatic reduction of −43% in FEV1% was observed in the longitudinal term, whereas the FEV1% decline in the normal/overweight patients was only −4%. Vitamin D deficiency was highly prevalent but was not associated with lung function after transplantation.
**Conclusion:** BMI, PA, TBW, FFM, and BCM in contrast to vitamin D levels are univariate predictors of lung function in adult CF patients after LT. Diabetes (CFRD or NODAT) and vitamin D deficiency are highly prevalent in post-transplant CF patients. Malnourished patients had significantly impaired lung function within the longitudinal follow – up. Continuous care by a multidisciplinary and specialized team of dietitians and gastroenterologists trained in CF care might improve nutritional status in CF patients after LT.

**Contact E-mail Address:** daniel.pohl@usz.ch
**Introduction:** Irritable Bowel Syndrome (IBS) is associated with an increased postprandial symptom response to a lactulose nutrient challenge test (LNCT) compared to healthy controls. Co-morbid Functional Dyspepsia (FD) and psychological comorbidity are highly prevalent in IBS, but are not regularly taken into account. Our aim was to investigate the association between co-morbid FD status and severity of co-morbid psychological symptoms on the one hand and the symptom response to the LNCT in IBS and healthy controls.
**Aims & Methods:** 205 IBS patients (Rome III), 94 (46%) of whom had co-morbid FD (IBS-FD, Rome III), and 83 healthy volunteers (HV) consumed a 400-ml liquid breakfast (NutridrinkÒ) combined with 25 g of lactulose after an overnight fast. They completed graded rating scales (0–20) assessing severity of gastrointestinal (GI) symptoms (abdominal pain, bloating, nausea, gas, urgency) and overall ''digestive comfort'' before breakfast and every 15 minutes up to 240 minutes, postprandially. The relationship between subject health status (HV, IBS, IBS-FD) and the course of GI symptom scores over time were analyzed using linear mixed models with level of anxiety, depressive, and somatization symptoms as continuous covariates.
**Results:** A significant main effect of group, (i.e. difference between the three groups in the average symptom level over time), was found for all symptoms (all $p < 0.0001$). Post-hoc tests showed that both IBS groups differed significantly from HV for all symptoms, whereas IBS-FD had higher levels of bloating ($p_{Tukey} = 0.004$), abdominal pain ($p_{Tukey} = 0.005$), and digestive comfort ($p_{Tukey} < 0.01$) compared to IBS. A significant group-by-time interaction effect was found for bloating ($p = 0.009$), abdominal pain ($p = 0.0006$), urgency ($p = 0.049$) and digestive comfort ($p = 0.002$). A significant difference in symptom increase from baseline between IBS-FD and IBS was found in abdominal pain ($p_{FDR} = 0.013$). In addition, anxiety levels were positively associated with symptom levels for all symptoms (all $p < 0.025$) except abdominal pain, levels of which were associated with somatization severity ($p < 0.0001$). Breath test results ($H_2$ and $CH_4$) were not different between groups, yet anxiety levels were positively associated with hydrogen levels ($p < 0.0042$).
**Conclusion:** In IBS, co-morbid FD is associated with increased GI symptom reporting, both preprandially and after a LNCT, particularly for abdominal pain, and is associated with decreased overall digestive comfort reporting. Anxiety and somatization have independent additional effects. These results indicate that the presence of co-morbid FD and levels of psychological symptoms are relevant for symptom reporting in IBS, including after a lactulose nutrient challenge test.

## P0533 PROTON PUMP INHIBITORS – A RISK FOR MICRONUTRIENT DEFICIENCY. BUT ARE WE LOOKING OUT FOR THIS?

**T. El Menabawey**, S. Dluzewski, S. Phillpotts, R. Preedy, K. Besherdas
*Gastroenterology, Barnet Hospital, Royal Free London NHS Trust, London/United Kingdom*

**Contact E-mail Address:** tareq.elmenabawey@gmail.com
**Introduction:** Proton pump inhibitors (PPIs) have long been established as an effective evidence-based therapy for many upper gastrointestinal diseases including peptic ulcer disease, gastro-oesophageal reflux disease, oesophagitis and dyspepsia. However, nonjudicious use of PPIs creates both preventable financial as well as medical concerns. There are several studies that point to potential micronutrient deficiencies including iron, vitamin B12, magnesium and calcium as a consequence of long-term PPI use. While these risks are considered to be relatively low in the general population, they may be notable in elderly and malnourished patients on PPIs. Although high-quality evidence for the true burden of deficiency is scarce, clinicians should have an awareness of the potential for these side effects in patients, particularly those on long-term PPIs.
**Aims & Methods:** We hypothesised that despite increasing evidence of micronutrient deficiency in patients on long-term PPIs, this is not assessed in clinical practice. A single-centre, retrospective analysis of all patients on long term PPIs usage in a large NHS North London trust was performed. Patients with Barrett's oesophagus were used as a database of patients on long-term PPIs. Their names were identified from the Unisoft endoscopy reporting system as undergoing endoscopic surveillance for Barrett's. We reviewed their electronic patient records to see if they had ever had their indices for B12, ferritin or magnesium tested whilst they had been undergoing outpatient clinical review.
**Results:** Of 41 patients identified, 38 (92.7%) had not had serum magnesium checked in the last 12 months including 15 (36.59%) who had never had it checked. 32 (78.1%) had not had serum ferritin or B12 checked in the past 12 months. Including 9 (21.95%) whom had never had it checked. The median magnesium level was low (0.77, range 0.76–0.89). The median ferritin was normal (106, range 13–196). There was one incidence of B12 deficiency (2.44% all patients, 31.3% of all those tested). Median serum B12 was normal (351, range 10.6–645).
**Conclusion:** Despite evidence in the literature of an association between long term PPI use and micronutrient deficiency, the investigation for this by clinicians in a high-risk group was poor and inconsistent. Even in this small cohort, magnesium and B12 deficiency was detected. We would recommend that clear guidance from national Gastroenterology bodies on micronutrient monitoring in patients on long term PPIs is required. This may improve screening of micronutrients in long term PPI usage and identify those requiring supplementation.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0534 A CROSS-SECTIONAL STUDY ON THE MILK CONSUMPTION IN SOUTHERN ITALY

**F. Zingone**, C. Bucci, P. Iovino, C. Ciacci
*Gastrointestinal Unit, Department Of Medicine And Surgery, University of Salerno, Salerno/Italy*

**Contact E-mail Address:** fabiana.zingone@outlook.com
**Introduction:** Milk consumption has had a sharp decline in the last decades, particularly in developed countries**.** One of the reasons for this decline is the diagnosis or the perception of lactose intolerance**.**
**Aims & Methods:** Our aim was to investigate average milk and dairy products consumption in Campania (Italy), one of the main producers of Italian dairy products. Subjects, aged 18–75 years and lived in Campania, were invited to answer an online questionnaire on the average milk and dairy products consumption posted on the public-access Hospital website, and on several Facebook pages

of friends and hospital personnel. The survey consisted of 16 questions and we calculated an average time of 5 minutes to complete it. Categorical variables were expressed as frequency and differences in frequencies between groups were calculated using $\chi 2$ test. Covariates included sex, age (18–35, 35–49, 50–75), body mass index (BMI kg/m$^2$), classified as underweight ($\leq$18.5), normal weight ($>$18.5–25), overweight ($>$25–30) and obese ($>$30), job type (classified as student, housewife, low, middle and high class job based on the average salary, retired and unemployed) and physical activities based on the weekly physical activity. We used logistic regression models to evaluate the influence of each covariate in the milk habit. All ORs were adjusted for sex, age, BMI, job and physical activities when not stratified for.
**Results:** We included in our analyses 1173 questionnaires. Most of the subjects were females (66%), aged 18–34 years (44.9%), had a high-class job (44.7%) which included university professors, managers and doctors and 42.4% of them did not practice any sport. We showed that 22.2% (260/1173) of responders from Campania population does not drink fluid milk, and 18.1% (213/1173) drinks lactose-free milk, mainly because of gastrointestinal symptoms. We considered two groups: group 1, people who drink fluid milk (with and without lactose) and group 2, those who do not drink milk. There were more women than men (OR 1.40, 95% CI 1.02–1.92) and less people aged 50–75 years than 18–34 years (OR 0.56, 95% CI 0.38–0.84) in group 1 compared to group 2. Moreover, a sub-analysis showed that females and underweight people drink more lactose-free milk than milk with lactose. Considering the dairy products, only 7 (0.6%) persons among our population do not regularly eat dairy products, while 86.7% of them eat these products at least once a week. Most of the people in our cohort avoid drinking fluid milk because of gastrointestinal symptoms without any doctor advice. Five subjects instead believe that milk and any dairy products are dangerous and can cause cancer; fifteen subjects do not drink fluid milk as they do not like it, eight because they are on a diet, and think that milk is a fat product.
**Conclusion:** The decrease in fluid milk consumption, a low-cost source of proteins, is considered a public health problem that deserves a strategy to raise. In fact, the trend of decreased milk consumption and the parallel increased consumption of cheese means the greater intake of cholesterol and calories. Our data support the need of a mandatory implement of the nutritional campaign to avoid unnecessary fluid milk avoidance.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Chronic atrophic autoimmune gastritis (CAAG) is characterized by the presence of autoantibodies against gastric parietal cells or intrinsic factor and a progressive destruction of the parietal cells, leading to hypo/achlorhydria responsible for a reduced absorption of vitamin B12. A possible role of CAAG and gastric achlorhydria in the pathogenesis of multiple nutritional deficiencies, including vitamin C, folic acid, vitamin D and calcium, has been reported.
**Aims & Methods:** Present series was aimed at evaluating both the prevalence of nutritional deficiencies in CAAG patients and the potential relationship with the grading of gastric atrophy or enterochromaffin-like (ECL) cells hyperplasia or body mass index (BMI). From January 2005 to January 2016 122 consecutive CAAG patients (100 F; median age 65 years, range 25–90) underwent regular follow-up with annual blood tests and upper gastrointestinal tract endoscopy every 3 years. Data about BMI, blood levels of B12, 25–OH vitamin D, folic acid, ferritin, gastrin and the grading of gastric atrophy and ECL cells hyperplasia were collected in all cases.
**Results:** Of the 122 patients with CAAG, 76 (62%) presented nutritional deficiencies, single in 24 and multiple in 52 cases. In detail, a deficiency in B12 was present in 42 patients (34%; median value 130 pg/ml, range 11–190), in folic acid in six cases (5%; median value 3.4, range 2.9–4.3 ng/ml) and in iron in 42 patients (34%; median ferritin value 14 ng/ml, range 4–30). 25–OH vitamin D deficiency was present in 76 patients (62%; median value 18 ng/ml): in detail, 17 patients had vitamin D levels $<$10 ng/ml, 35 levels between 10 and 20 ng/ml and 24 levels between 20 and 30 ng/ml). Levels of 25–OH vitamin D directly correlated with blood B12 levels (p-value $<$0.05); moreover, vitamin D levels were lower in patients with macronodular ECL cells hyperplasia than in patients with linear or micronodular hyperplasia (11.8 versus 19.8 ng/ml respectively, p-value $<$0.05). No significant correlation was observed between levels of B12, folic acid or ferritin and BMI, blood gastrin levels, the grading of gastric atrophy or ECL cells hyperplasia.
**Conclusion:** 25–OH vitamin D, vitamin B12 and iron deficiencies are frequent in CAAG patients, probably because the mucosal alteration secondary to chronic autoimmune inflammation could negatively affect the absorption of the above factors. Indeed, the correlation between 25–OH vitamin D and vitamin B12 deficiency may indicate underlying shared pathogenic mechanisms.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[2]*Medical Corps, Israel Defence Force, Ramat-Gan/Israel*

**Contact E-mail Address:** dr.amit.assa@gmail.com

**Introduction:** Celiac disease (CD) is a systemic disorder associated with various autoimmune disorders and higher prevalence of other diagnoses and complications. The prevalence of associated diseases and complications varies in different reports.
**Aims & Methods:** We aimed to investigate the association of CD with various medical conditions at late adolescence in a large cross-sectional population-based study. A total of 2,001,353 Jewish Israeli adolescents who underwent a general health examination at median age of 17.1 (16.9–17.4) years from 1988 to 2015 were included. Of these, comprehensive data regarding medical status was available for 1,588,041 (79%) subjects. A definite diagnosis of CD was based on accepted criteria. Covariate data included demographic measures, and data on associated medical conditions.
**Results:** Overall, data of 7145 subjects with CD and 1,580,896 controls were analyzed. Multivariate analyses showed that autoimmune diseases were significantly more common in subjects with CD including insulin dependent diabetes (RR = 5.5), inflammatory bowel diseases (RR = 3.8), arthritis (RR = 2.4), thyroid diseases (RR = 1.8), psoriatic skin disorders (RR = 1.6) and asthma (RR = 1.5). Further associations included bile stones (RR = 3.6), migraine (RR = 2.3), anemia (RR = 1.7), and menstrual abnormalities in females (RR = 1.5). Neither long bones fractures nor axial fractures were more common in adolescents with CD compared with controls.
**Conclusion:** Already at adolescence, CD is associated with multiple comorbidities, not limited to autoimmune disorders.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P0537 ETHNIC DISPARITIES IN PHENOTYPE AND HISTOPATHOLOGY PROFILE IN CHILDREN WITH CELIAC DISEASE

**E. Broide**[1], B. Yerushalmi[2], S. Vosco[3], S. Matalon[3], H. Shirin[3]

[3]*The Kamila Gonczarowski Institute Of Gastroenterology&liver Diseases, Assaf Harofeh Medical Center, Tel-Aviv University, Zerifin/Israel*

**Contact E-mail Address:** efratb@asaf.health.gov.il

**Introduction:** The prevalence of Celiac Disease (CD) has increased dramatically worldwide with a high variability in the clinical presentation. Despite the relationship between a common genetic heritage and the phenotype of the disease, the contribution of racial disparities in pediatric CD is unclear.
**Aims & Methods:** To investigate a possible association between ethnicity and clinical presentation, familial occurrence of CD and histological severity of the disease. Data were retrieved from questionnaires, distributed via mail by the Israeli Celiac Foundation, and medical charts in two academic medical centers in Israel. We compared demographics, clinical presentation at diagnosis, laboratory results, familial occurrence of CD, additional autoimmune diseases and histological severity of CD by Marsh classification in the four ethnic groups to determine any association between these parameters to ethnicity.
**Results:** Data from 1223 children with CD, 41% males, 237 Ashkenazi, 110 Sheparadi, 360 mixed origin and 517 Bedouins, were requited. Familial occurrence of CD and the presence of additional autoimmune diseases were similar between the four different ethnic groups. Atypical symptoms such as anemia or elevated liver enzymes were reported in 47% of children. Despite anemia at presentation that was more prevalent among Bedouin children (p = 0.01 l) clinically they had less intestinal symptoms like abdominal pain, diarrhea, vomiting or failure to thrive (P = 0.011). Histological severity of CD by Marsh classification (Marsh 3C) was higher in the Bedouin origin. Multivariate logistic regression analysis revealed that only presence of anemia and Bedouin origin were associated with more advanced disease [OR of 2.03 (95% C.I 1.31; 4.308) (p $<$ 0.009) and OR 1.78 (95% C.I 1.31; 4.308) (p $<$ 0.003) respectively].

**Conclusion:** CD in Bedouin children has different clinical phenotype with more severe histological disease at presentation. These differences might be explained by variable environmental cultural and nutritional factors in the Bedouin group.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0538 ANTHROPOMETRIC MEASURES AND PREVALENCE TRENDS IN ADOLESCENTS WITH CELIAC DISEASE: A POPULATION-BASED CROSS-SECTIONAL STUDY

**A. Assa**[1], Y. Frenkel-Nir[2], Y. Leibovici-Weissman[3], L. Katz[2], Z. Levi[4], R. Shamir[5]

[4]*Gastroenterology, Rabin Medical Center, Petach Tiqva/Israel*
[5]*Institute Of Gastroenterology, Nutrition And Liver Diseases, Schneider Children's Medical Center, Petach Tikva/Israel*

**Contact E-mail Address:** dr.amit.assa@gmail.com
**Introduction:** Celiac disease (CD) occurs in about 1%-3% of the population, in most countries, with a recent reported increase in prevalence. Data regarding anthropometric measures in adolescents with CD, particularly final adult height, is inconclusive and mostly relies on relatively small cohorts.
**Aims & Methods:** We aimed to investigate anthropometric measures including height at late adolescence in a large National cohort. In addition we assessed trends in the prevalence of diagnosed CD over time and impact of socio-demographic factors. Between 1988 and 2015, most of the Jewish population of Israeli adolescents ($n = 2{,}001{,}353$) underwent a general health examination at a median age of 17.1 (16.9–17.4) years. A definite diagnosis of CD was based on accepted criteria. Covariate data included demographic and anthropometric measures.
**Results:** Overall, 10,566 CD cases were identified and analyzed. Multivariate analysis demonstrated that males with CD are leaner (BMI $21.2 \pm 3.7$ vs. $21.7 \pm 3.8$, $p = 0.02$) while females with CD are shorter ($161.5 \pm 6$ vs. $162.1 \pm 6$, $p = 0.017$) than the general population. The prevalence of diagnosed CD increased from 0.5% to 1.1% in the last 20 years with a female predominance (0.64% vs 0.46%). CD prevalence was significantly lower in subjects of lower socioeconomic status and those of African, Asian and former Soviet Union origin ($p < 0.0001$).
**Conclusion:** Adolescent males with CD are leaner and females with CD are shorter compared with the general population. However, the clinical relevance of the small differences suggests that when CD is diagnosed during childhood, final weight and height are not severely impaired. Our cohort reinforces the observed increase in diagnosed CD.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0539 CLINICAL PRESENTATION OF CELIAC DISEASE AND ESPGHAN CELIAC DISEASE GUIDELINES RETROSPECTIVE REAL-TIME APPLICATION IN A SINGLE-CENTER EUROPEAN PEDIATRIC POPULATION: A 10 YEARS EXPERIENCE

A.R. Di Biase[1], **G. Marasco**[2], A. Colecchia[3], M.G. Berardi[1], F. Ravaioli[3], L. Iughetti[1], D. Festi[3]
[1]*Pediatrics, University of Modena, Modena/Italy*
[2]*Department Of Medical And Surgical Sciences, University Of Bologna, Bologna/Italy*
[3]*Department Of Medical And Surgical Science, University of Bologna, Bologna/Italy*

**Contact E-mail Address:** giovannimarasco89@gmail.com
**Introduction:** Celiac disease (CD) is a chronic illness characterized by an immunoreaction to gluten peptides that results in a small bowel enteropathy. Its incidence is increasing in the last decades from 1% to 3% of children (1,2). This increase may be related to different factors: the adoption of new criteria for diagnosis, a major awareness of the disease by physicians and a wider laboratory screening extended also to asymptomatic subjects that are at high-risk for CD (3–6). Besides the increasing incidence, changes in the clinical presentation have been observed since the 1980s: instead of the classical symptoms, atypical symptoms have been increasingly noticed (7).
**Aims & Methods:** The aim of the present study was to retrospectively investigate CD clinical presentation at diagnosis in a children Italian population from 2004 to 2014. We also retrospectively applied new ESPGHAN criteria to our population in order to quantify the number of endoscopy avoidable. We considered all pediatric patients referred as Gastroenterology outpatients to the Pediatric Unit of Modena Hospital with a suspicion of CD. All demographic, clinical, laboratory and endoscopy data were recorded. We searched for differences of symptoms presentation for CD in the period 2004–2009 vs 2009–2014 and if there were relationships between IgA-tTGA (tissue transglutaminase) levels and Marsh grade degree at biopsy with debut symptoms of CD. Then, we classified our patient according to the new ESPGHAN criteria for CD diagnosis in order to obtain the number of CD patients correctly identified by new criteria.
**Results:** We collected data of 360 patients: 7 patients were excluded for incomplete data, 48 patients were diagnosed of CD without biopsy according to the new ESPGHAN criteria, 43 patients had asymptomatic CD and were evaluated because at high-risk for CD. The comparison between 2004–2009 and 2009–2014 documented no difference ($p = 0.177$) as far as the frequency of either symptomatic (both classical and non-classical onset of the disease) or asymptomatic CD is concerned. In particular, at specific symptoms level, asthenia was predominantly reported in the second period (2009–2014) ($p = 0.02$), the association with atopic dermatitis in the first one ($p = 0.05$). Frequent changes in bowel habits were present more frequently in patients with a low-degree of mucosal damage (Marsh 2 vs 3) ($p = 0.30$). Lack in appetite was correlated with higher IgA-tTG levels ($p < 0.01$). IgA-tTG levels were strongly correlated with Marsh grade and the differences among Marsh grade were statistically significative ($p < 0.001$). Applying new ESPGHAN criteria to our population all patients were correctly classified and the number of endoscopy possibly avoidable was 98/353 (27.8%).
**Conclusion:** In the last decade the clinical onset of celiac disease did not change in our population. Classical gastrointestinal symptoms were correlated with the degree of bowel mucosa damage according to Marsh grade and IgA-tTG levels, that were confirmed to be related. Almost one third of endoscopy could be avoided in our population according to the new ESPGHAN criteria.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

[2]*First Pediatric Clinic, University of Medicine and Pharmacy Victor Babes, Timisoara/Romania*

**Contact E-mail Address:** oana22_99@yahoo.com
**Introduction:** Non-celiac gluten sensitivity (NCGS) is characterized by intestinal symptoms (bloating, diarrhoea and abdominal pain) compatible with irritable bowel syndrome (IBS) that occurs after ingestion of gluten in subjects in whom infectious enterocolitis, inflammatory bowel diseases, celiac disease and wheat allergy have been ruled out. Gastro-esophageal reflux disease (GERD) is mainly a functional condition often diagnosed in children and treated with proton pump inhibitors (PPI). Long term PPI can alter intestinal bacterial population by suppressing the gastric acid barrier and may cause diarrhea.
**Aims & Methods:** The aim of this study was to evaluate the incidence of small intestinal bacterial overgrowth (SIBO) assessed by glucose hydrogen breath test (GHBT) among children that received 12 weeks of PPI treatment with or without probiotics associated, compared to children with NCGS that did not received PPI and a control lot. Methods: We performed GHBT to 182 consecutive children aged 1–18 years old: 64 with GERD who received PPI for 12 weeks, 58 children with NCGS in absence of PPI treatment and 60 healthy control subjects. The children with GERD were randomized in two groups: 32 who received only PPI and 32 who received PPI and probiotics (Lactobacillus reuteri) for 12 weeks. In children with GERD, GHBT was performed before treatment and after 12 weeks of treatment for every child.
**Results:** There weren't any was no patient detected with SIBO by GHBT among children with GERD before treatment. After 12 weeks of treatment, we detected SIBO among 56% of children treated with PPI only (18/32), compared to 6% of children treated with PPI and probiotics (2/32), ($p < 0.001$). SIBO was detected in 20% of patients with NCGS (12/58) and 5% of healthy control subjects (3/60). There was a statistically significant difference regarding SIBO prevalence between children with GERD treated with PPI only and those with NCGS or healthy control subjects ($p < 0.001$). Children with GERD treated with PPI and probiotics had a significant lower prevalence of SIBO, similar to control lot.
**Conclusion:** SIBO assessed by GHBT occurred more frequently among children with GERD treated with long-term PPI compared to children with NCGS or control subjects. Association of probiotics based on Lactobacillus reuteri decreased the rate of SIBO among children with GERD treated with PPI. Being a functional disorder that request long term PPI, GERD may benefit by acid suppression inhibition combined with probiotics in order to decrease the risk of intestinal bacteria alteration.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0541 LINKED COLOR IMAGING COMBINE MAGNIFY ENDOSCOPY FOR HELICOBACTER PYLORI INFECTION AND INTESTINAL METAPLASIA: A PIONEER STUDY WITH PRELIMINARY RESULT IN TAIWAN

**T. Chen**[1], C. Chiu[2]
[1]*Department Of Gastroenterology And Hepatology, Linkou Chang Gung Memorial Hospital, Kwei-Shan/Taiwan*
[2]*Department Of Gastroenterology & Hepatology, Chang Gung University Chang Gung Memorial Hospital, Kwei-Shan/Taiwan*

**Contact E-mail Address:** itochenyu@gmail.com
**Introduction:** LCI as a novel image-enhanced endoscopy has been reported usefully in *H. pylori* infection diagnosis. Since, H. pylori is one of the carcinogen of gastric cancer and also related to gastric or duodenal ulcer. We expect that LCI combine magnify endoscopy can increase diagnosis rate of H.pylori infection
**Aims & Methods:** The aim of this study is to evaluate the usefulness of LCI combine magnify endoscopy for diagnosis of H. pylori infection. We conduct a prospective study enrolled 52 patients from June 2016 to April 2016 at Chang Gung Memorial Hospital, Linkou medical center, Taoyuan, Taiwan. We use at least 2 methods to make sure of H. pylori infection. The procedures were performed only by one experience endoscopist. The specimens are checked by two experience pathologist.
**Results:** The accuracy diagnostic rate of H. pylori infection in LCI/Magnify endoscopy/Combine group were: 78.5%/83.6%/92.3%. The accuracy diagnostic rate of intestine metaplasia was 72.4%
**Conclusion:** LCI is a useful tool for diagnosis of H. pylori infection and intestinal metaplasia when combine with magnify endoscopy. And, we can eradicate H. pylori as soon as possible once it was diagnosed. We also can arrange intensive follow up for those patients who have precancerous lesions.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0542 HELICOBACTER PYLORI VIRULENCE GENES MAY DETERMINE CLINICAL OUTCOME AND GASTRIC PATHOLGY AMONG INFECTED EGYPTIAN CHILDREN

**S. Barakat**[1], N. Baddour[2], R. Harfoush[3], A. Hasab El-Naby[1]
[1]*Pediatrics, Faculty of Medicine,Alexandria University, Alexandria/Egypt*
[2]*Pathology, Faculty of Medicine, Alexandria University, Alexandria/Egypt*
[3]*Medical Microbiology, Faculty of Medicine, Alexandria University, Alexandria/Egypt*

**Contact E-mail Address:** barakat_sana@yahoo.com
**Introduction:** Different genotypes of *H. pylori* circulate in different geographic areas; the different clinical presentations are partly attributed to this high genetic diversity; however, no studies have focused on the clinical and endoscopic findings of different genotypes among Egyptian children so far.
**Aims & Methods:** To investigate the relationship between *H. pylori* virulence genes and clinical, pathologic findings and antibiotic resistance in Egyptian children with H.pylor infection: Stomach biopsies from 50 symptomatic *H.pylori* positive children (39 with hematemesis and 11with dyspeptic symptoms) and stool samples from another 50 asymptomatic *H.pylori* positive children(-controls) were tested using PCR for the presence of cagA, vacA, babA and antibiotic resistance.
**Results:** There was a significant predominance of vacA (80% vs40%), cagA (70%vs16%), and babA2 (60%vs12%) genes among cases compared to controls. The triple genotype (babA2+ cagA+ vacAs1) and type 1 (cagA+vacAs1) were prevalent in 12% and 26%of cases and absent in controls. Significant associations were found between hematemesis and babA2, cagA, vacA,triple genes and type 1, while dyspeptic symptoms were related to babA2 and cagA genes only. CagA, vacAs1m1 and type1 were associated significantly with antral nodularity and severity of inflammation,whereas vacAs1m1 and type1 were associated with presence of deep inflammation and lymphoid follicles,and cagA and type1 with active inflammation. Resistance to metronidazole was found in 36% patients,it was significantly associated to babA2 gene.
**Conclusion:** While 82% of the cases had more than one virulence genes,92% the controls had 1 gene or lacked genes completely suggesting that the virulence genes, particulary cagA and vacAs1m1 work synergistically rather than independently in causing severe pathology and severe symtopms like hematemesis. type 1genotype could be suitable for prediction of the clinical outcomes among infected Egyptian children and may be candidate for eradication therapy to prevent severe disease.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0543 ROLE OF THE GLUTEN-FREE DIET ON NEUROLOGICAL-ELECTROENCEPHALOGRAPHY FINDINGS AND SLEEP DISORDERED BREATHING IN CHILDREN WITH CELIAC DISEASE

**C.M. Trovato**[1], P. Parisi[2], M. Montuori[1], C. Anania[1], A. Ferretti[2], M. Arena[2], F. Valitutti[1], M.P. Villa[2], S. Cucchiara[1]

**Contact E-mail Address:** chiaramariatrovato@gmail.com
**Introduction:** Celiac disease (CD) is a systemic disorder that involves a lot of tissues, among which is the nervous system. In 2013, Diaconu [1]et al. studied the incidence of neurologic manifestations in children with CD showing that one-third of children presented one or more neurologic symptoms as the onset manifestation of CD. Status epilepticus and encephalopathy in the absence of profound GI symptom can be a symptom of a celiac crisis. A meta-analysis[2] of the few evidence-based data available on these disorders in children showed that the relative risk of epilepsy in individuals with CD, and of CD in individuals with epilepsy, compared with the general population, was 2.1 and 1.7, respectively. In the vast majority of these patients, wakefulness EEGs revealed focal abnormalities, mainly localized in one or both occipital regions.
**Aims & Methods:** To assess whether celiac children are at risk for EEG- and sleep disordered breathing (SDB), and whether an appropriate gluten-free diet (GFD) may influence these disorders. We consecutively enrolled 22 children (18 females and 5 males, mean age at diagnosis $9.51 \pm 4.17$ DS years, range 3–16 years) with a new biopsy-proven celiac disease (CD) diagnosis. At CD diagnosis and after 6 months of GFD, each patient underwent a general and neurological examination, an electroencephalogram, a questionnaire investigating neurological features, and a validated questionnaire about SDB: OSA (obstructive sleep apnea) scores $< 0$ predict normality; values $> 0$ predict OSA.
**Results:** At CD diagnosis, 8 of 22 (36.4%) patients complained headache and 3 of 22 had presented febrile seizures. 21 children filled OSAS test (mean OSAS score: $3.4 \pm 2.1$ DS). Abnormal EEG findings were observed in 11 of 22 (50%) children. The electroencephalography (EEG) examinations revealed abnormal finding, such as focal or generalized sharps and/or spikes and spike-waves, in 11 children (50%). 1 child had abnormal finding in frontal region, 3 in occipital region, 2 in parietal region and 5 children showed diffuse aberration. (Table1). After 6 months of GFD, we analyzed data of 9 children: headache disappeared in 72% of children and EEG abnormalities in 78%; all children showed negative OSA score.

| | Age at CD diagnosis | EEG abnormalities (cerebral regions) |
|---|---|---|
| 1 | 7.42 | Frontal |
| 2 | 10.33 | Occipital |
| 3 | 14.16 | Diffuse |
| 4 | 3.16 | Diffuse |
| 5 | 16.16 | Diffuse |
| 6 | 8.67 | Diffuse |
| 7 | 9.75 | Occipital |
| 8 | 0.58 | Diffiuse |
| 9 | 0.25 | Parietal |
| 10 | 6.58 | Parietal |
| 11 | 2.47 | Occipital |

**Conclusion:** According to our preliminary data, in the presence of unexplained EEG abnormalities and/or other neurological disorders/SDB in newly diagnosed CD diagnosis, is likely to be disease-related and respond to GFD over 6-month time.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Scientific literature shows a high prevalence of Small Intestinal Bacterial Overgrowth (SIBO) in patients with Cystic Fibrosis (CF). The role of SIBO in nutritional status and gastrointestinal symptoms in CF is not known.
**Aims & Methods:** Our aim was to study SIBO epidemiology and clinical impact and to assess the efficacy of rifaximin in eradicating SIBO in CF patients. A symptoms questionnaire and Glucose Breath Test (GBT) were given to 79 patients (median age 19.6y 9.2–36.9) attending an Italian CF Centre. Subjects with a positive GBT were enrolled in a randomized controlled trial into two groups to receive oral rifaximin for 14 days or no treatment. Patients repeated GBT and symptoms questionnaire 1 month after withdrawal of therapy or 45 days after the first negative GBT.

**Results:** Twenty-five patients resulted affected by SIBO (31.6%) with a significant correlation with lower BMI ($p < 0.01$) and serum albumin levels ($p < 0.05$). Twenty-three patients took part in the randomized trial, 13 patients (56.5%) in rifaximin group and 10 patients (43.5%) in control group. Some patients dropped out for lung exacerbations. Eradication rate of SIBO was 9/10 (90%) in rifaximin group and 2/6 (33.3%) in control group ($p < 0.05$). In rifaximin group gastrointestinal symptom improvement was observed in 4/5 patients aged ≤14 years and in 0/5 patients aged >14 years ($p < 0.05$). In control group symptom improvement was observed in 2/6 patients.
**Conclusion:** CF patients show a high prevalence of SIBO, related to a lower BMI. Rifaximin therapy is well tolerated and the results are promising in terms of efficacy in relieving gastrointestinal symptoms.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** There are very few studies on frequency of gastritis and *H.pylori* infection in adults with celiac disease (CD).
**Aims & Methods:** We aimed to determine the frequency of both, gastritis and H.pylori infection in children with CD. This retrospective observational multicentre study included patients diagnosed with CD at 3 tertiary pediatric gastroenterology centres in Poland: Warsaw, Bydgoszcz and Gdansk from March 2003 to March 2016. Medical records of children with new diagnosed CD were reviewed. Frequency of H.pylori infection and correlation with the presence and severity of inflammation.
**Results:** A total of 408 children were diagnosed with CD (173 males). Median age at diagnosis was 8.5 y.o. (range: 4 months – 18 years). Mean time of symptoms prior to diagnosis was 27.9 months (range: 0–156 months). Gastritis was found in 25% patients. It was more common in children with more advanced villous atrophy in duodenum (Marsh 3A vs Marsch 3C) but the difference was insignificant ($p = 0.3$). Presence of H.pylori infection was found in 8% of children and it was more frequent at younger age ($p = 0.01$). The time prior to diagnosis were not correlated with the frequency of infection ($p = 0.06$).
**Conclusion:** Gastritis is common in children with newly diagnosed CD. Time prior to diagnosis and severity of villous atrophy in duodenum are not correlated with frequency of gastritis.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0546 ARE LYMPHOID FOLLICLES IN CHILDREN WITH IDIOPATHIC GASTRITIS MUCH MORE COMMON THAN PREVIOUSLY THOUGHT?

**E. Broide**[1], V. Richter[2], S. Mendlovic[3], H. Shirin[2]

**Introduction:** The rate of *Helicobacter pylori* positive (Hp+) gastritis has been declining over the years. As a result, *Helicobacter pylori* negative (Hp-) gastritis has become more prevalent. While the presence of chronic gastritis and IM in children with *H. pylori* has been well studied, there is very little data regarding the risk factors, clinical and histological characteristics of non *H. pylori* induced chronic gastritis and IM in the pediatric literature.
**Aims & Methods:** We therefore attempted to evaluate the prevalence, risk factors, and clinical correlations of chronic gastritis and IM in childhood, and it's relation to *H. pylori* infection and celiac disease in all patients who had gastric biopsies performed at our medical center over a one-year period.
The medical records of children aged between 1 and 18 years that underwent elective esophagogastroduodenoscopy at Assaf Harofeh Medical Center in Israel were retrospectively reviewed. Demographic, clinical, endoscopic and histologic features were analyzed. Gastric biopsies were taken from the antrum and from the corpus and graded using the Updated Sydney System. Hp+ gastritis was defined by the presence of *H. pylori* by histology (H&E, Gimsa or immunohistochemistry staining).
**Results:** A total of 184 children met the study criteria (61.9% girls) with a mean age of 10 years. Out of 184, 66.3% (122) had chronic gastritis; of these 60.7% (74) had Hp- gastritis. Children with Hp- gastritis were mostly not of Arabic origin ($p = 0.011$), younger ($p = 0.003$) and presented less with abdominal pain ($p = 0.02$). The majority (95.8%) of the Hp+ gastritis children had pan-gastritis compared to only 50% in the Hp- gastritis group ($p < 0.001$). Nodular gastritis, monouclear infiltrates and neutrophils were all less prominent in Hp- gastritis compared to Hp+ gastritis ($p < 0.001$). Although less typical, lymphoid follicles were demonstrated in 51.3% of the Hp- patients. The presence or absence of celiac disease in Hp- gastritis had no impact on the histological findings.
**Conclusion:** Based on the data analyzed, we conclude that lymphoid follicles in children with idiopathic gastritis are more common than previously thought, independently of their celiac disease status. Obviously, additional long term follow-up studies in those young patients should help clarify the importance of this process, facilitate identification, surveillance and treatment strategies.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0547 FRUCTOSE SENSITIVITY – AND NOT FRUCTOSE MALABSORPTION – CORRELATE WITH THE CLINICAL SYMPTOMS REPORTED BY CHILDREN WITH CHRONIC ABDOMINAL PAIN?

**V. Hammer**[1], K. Hammer[1], K. Hammer[2], J. Hammer[1]
[1]*Dept. Of Gastroenterology And Hepatology, Medical University of Vienna, Vienna/Austria*
[2]*St. Anna Kinderspital, Vienna/Austria*

**Contact E-mail Address:** veronika.ham@meduniwien.ac.at
**Introduction:** Fructose malabsorption is generally considered as a possible cause of chronic abdominal pain in children. Fructose malabsorption can be determined with the fructose breath hydrogen test (BHT). However, fructose malabsorption and abdominal symptoms do correlate poorly.
**Aims & Methods:** Our aim was to evaluate whether fructose malabsorption or rather fructose sensitivity correlates with clinical symptoms in children with chronic abdominal pain. 60 patients (age: 10–15 years; 28 male, 33 female) with chronic abdominal pain received a fructose BHT for clinical suspicion of carbohydrate induced gastrointestinal symptoms. Clinical symptoms were quantified by a faces graded scale (0 = no symptom, 5 extreme symptom) evaluating severity of pain, nausea, meteorism, flatulence and diarrhea in the 4 weeks before the BHT. An overall 4weeks symptom score was calculated by adding each single score. For the BHT subjects ingested a 20% fructose solution, 1 g/kg body weight up to a maximum of 25 g. An increase of breath hydrogen concentration by at least 20 ppm over baseline was considered to demonstrate malabsorption. Symptoms during the BHT were ascertained regularly up to 9 hours after commencing the test on a faces graded scale. Fructose sensitivity was defined as one or more symptoms increasing significantly (2 points or more) over baseline. Median ($25^{th}/75^{th}$ percentile) are given, $p < 0.05$ was considered significant.
**Results:** 23 out of 60 were fructose malabsorbers, 21 patients (13 m, 8 f) turned out to be fructose sensitive. Among the fructose malabsorbers, 11 were fructose sensitive and 12 had no increased symptoms during the BHT. Overall 4 weeks symptom score was 6.0 (3.5/8.5) in malabsorbers and 5.5 (1.75/7.5) in non-malabsorbers (NS). In contrast, the overall 4 weeks symptom score of fructose sensitive patients [9.0; (5.5/13.0)] was significantly higher than that of non-sensitive patients [4.0; (1.5/6.0)] ($p < 0.001$), independent whether they malabsorbed fructose or not. No individual symptom differed in fructose malabsorbers and absorbers in the 4 weeks before the BHT, while pain ($p < 0.01$), meteorism ($p < 0.001$), flatulence ($p < 0.001$) and diarrhea ($p < 0.001$) was significantly more severe in fructose sensitive patients as compared to non-sensitive subjects.
**Conclusion:** Fructose sensitivity, but not fructose malabsorption, correlates well with clinical symptoms in children with chronic abdominal pain.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0548 HOW DO THE MATERNAL AND NEWBORNS PARAMETERS INFLUENCE THE CHILDREN'S BIRTH WEIGHT?

**C.O. Mărginean**[1], C. Marginean[2], L. Melit[1], M.O. Marginean[1]
[1]*Pediatrics, University of Medicine and Pharmacy Tg Mures, Tirgu Mures/Romania*
[2]*Obstetrics And Gynecology, University of Medicine and Pharmacy Tg Mures, Tirgu Mures/Romania*

**Contact E-mail Address:** marginean.oana@gmail.com
**Introduction:** The birth weight is determined by maternal and neonatal factors and it influences the afterwards child's nutritional status.
**Aim** – to evaluate the maternal and neonatal factors that influence birth weight.
**Material and method** – We performed a prospective study on 151 mothers and 151 de newborns in a tertiary center maternity from Romania. We evaluated the mother's demographical factors (age, parity, smoking, educational degree); mothers' bioimpedance characteristics [Fat mass (FM), Bone mass (BM), muscle mass (MM) and total body water (TBW)]; anthropometric parameters [weight (W), height (H), body mass index (BMI), middle upper arm circumference (MUAC), tricipital skinfold thickness (TST)] and laboratory ones (cholesterol, triglyceride, ASAT, ALAT) in mothers and newborns.
**Results:** We noticed that mother's weight ($p = 0.01$), height ($p = 0.04$), gestational age ($p = 0.001$), fat mass (kg) ($27.41 \pm 6.09$, $p = 0.01$) (0.002), muscle mass (MM) ($39.09 \pm 4.87$; $p < 0.02$) and total body water ($32.48 \pm 3.82$; $p = 0.03$) influenced positively the birth weight, while mothers' smoking status was negatively correlated with birth weight ($p = 0.04$). We observed a higher incidence of mother's weight gain, and therefore a higher birth weight in the children whose mothers had superior studies ($p = 0.05$). Birth weight correlated with mother's increased TST and MUAC ($p = 0.001$). We did not identify any correlations between birth weight and laboratory parameters.
**Conclusion:** Mothers with bigger FM, MM, and TBW had children with bigger birth weight, while smoking status is negatively correlated with birth weight. Bioimpedance evaluates better pregnant women's nutritional status.
**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0549 TIMING OF SYMPTOMS DURING AND AFTER THE FRUCTOSE HYDROGEN BREATH TEST IN CHILDREN WITH CHRONIC ABDOMINAL PAIN

**K. Hammer**[1], V. Hammer[1], K. Hammer[2], J. Hammer[1]
[1]*Dept. Of Gastroenterology And Hepatology, Medical University of Vienna, Vienna/Austria*
[2]*St. Anna Kinderspital, Vienna/Austria*

**Contact E-mail Address:** kathi.ham@aon.at

**Introduction:** Carbohydrate malabsorption can cause visceral pain and non-painful symptoms such as nausea, meteorism, flatulence and diarrhea in sensitive patients. Fructose malabsorptioncan be determined with the fructose breath hydrogen test (BHT).

**AIM:** We evaluated the development of pain and non-painful symptoms over time in children who were referred to the fructose hydrogen breath test.

**METHODS:** 60 patients (age: 10–15 years; 28 male, 33 female) with chronic abdominal pain received for clinical suspicion of carbohydrate induced gastrointestinal symptoms a fructose BHT. Subjects ingested a 20% fructose solution, 1 g/kg body weight up to a maximum of 25 g. The diagnosis of fructose malabsorption was established when breath hydrogen concentration increased by at least 20 ppm over baseline. Symptoms during the BHT were ascertained regularly up to 9 hours after commencing the test on a faces visual analogue scale (0 = no symptom, 5 extreme symptom). Sensitivity was defined as one ore more symptoms increasing significantly (2 points or more) over baseline. Mean±SEM are given, $p < 0.05$ was considered significant.

**Results:** 21 patients (13 m, 8 f) turned out to be fructose sensitive, 39 were not fructose sensitive. Among the fructose sensitive subjects 11 malabsorbed fructose. In the non-sensitive group, 12 children were fructose malabsorbers and 27 absorbed fructose appropriately. Before fructose ingestion abdominal pain scores were low in both fructose sensitive patients ($0.60 \pm 0.2$) and non-sensitive patients ($0.87 \pm 0.2$)(NS). In the fructose sensitive group, pain scores stayed low for the following 120 min (NS vs. baseline) but increased significantly at 150 min ($1.33 \pm 0.3$; $p < 0.05$ vs. baseline). Pain resolved thereafter and did not recur. In contrast, nausea developed 30 min after baseline and continued until 120 min, meteorism was present between 120 and 150 min and urge to pass flatus was present 3 to 6 hours after fructose ingestion. Diarrhea did not develop in the fructose sensitive patients within the 9 hour observation period.

**Conclusion:** Paediatric patients with fructose sensitivity develop abdominal pain approximately 2½ hours after fructose ingestion. Other symptoms associated with fructose ingestion show distinct timing patterns.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P0550 FACTORS ASSOCIATED WITH SIGNIFICANT LIVER STEATOSIS AND FIBROSIS AS ASSESSED BY TRANSIENT ELASTOGRAPHY IN PATIENTS WITH ONE OR MORE COMPONENTS OF THE METABOLIC SYNDROME

**I. Mikolasevic**, L. Orlic, D. Stimac, S. Milic
*UHC Rijeka, Rijeka/Croatia*

**Contact E-mail Address:** ivana.mikolasevic@gmail.com

**Introduction:** Diet and lifestyle changes have caused a dramatic increase in the worldwide prevalence of obesity and metabolic syndrome (MetS) in parallel with an increasing incidence of non-alcoholic fatty liver disease (NAFLD). Presence of the MetS can be used for the initial risk stratification of patients, who need further evaluation of NAFLD by using either liver biopsy or other non-invasive methods, such as the FibroScan®. However, to our knowledge, the relationship between controlled attenuation parameter (CAP), liver stiffness measurement (LSM) and MetS components has been not extensively examined in large cohorts of patients. We examined the relationship between CAP and LSM, as assessed by transient elastography (TE), and different clinical and biochemical parameters in patients with one or more components of the MetS.

**Aims & Methods:** A total of 648 consecutive patients were analyzed. The MetS was defined according to the International Diabetes Federation by the presence of at least three of the following metabolic abnormalities: waist circumference > 94 cm for men and > 80 cm for women (as a pre-requisite diagnostic criterion); blood pressure ≥130/85 mmHg or anti-hypertensive treatment; previously physician-diagnosed T2DM, or use of any hypoglycemic drugs or a fasting plasma glucose level ≥5.6 mmol/L; triglyceride levels > 1.7 mmol/L and/or HDL-cholesterol < 1.04 mmol/L for men and < 1.29 mmol/L for women or lipid-lowering treatment. CAP and LSM measurements were performed using the FibroScan® (Echosens, Paris, France) by a single experienced operator. All patients were examined using either the 3.5 MHz standard M probe or the XL probe (center frequency 2.5 MHz), depending on the body mass index (BMI) level of the patients. Significant liver steatosis was defined as a CAP value≥238 dB/m, whereas significant fibrosis was defined as a LSM value > 7.0 kPa.

**Results:** Of all analyzed patients, 82.1% had hypertension, 77.9% had atherogenic dyslipidemia, 77.5% had abdominal overweight or obesity, 45.7% had dysglycemia and 67.3% of patients fulfilled the criteria for the diagnosis of the MetS. Patients with the MetS had significantly higher values of CAP ($312.9 \pm 45.1$ vs. $278.4 \pm 50.8$ dB/m; $p < 0.0001$) and LSM ($5.8 \pm 3.3$ vs. $4.9 \pm 1.6$ kPa; $p < 0.001$) than those without the MetS. Notably, in the whole cohort, the prevalence of patients with increased CAP and LSM (as defined according to widely accepted cut-off points) were 88.3% and 16.5%, respectively. Patients with CAP≥238 dB/m (n = 572) had a markedly greater prevalence of the MetS and all its individual components. Moreover, CAP measurements increased progressively with number of MetS components ($p < 0.0001$ for the trend by one-way ANOVA). Among patients with CAP≥238 dB/m, those with LSM > 7.0 kPa (n = 103) had higher liver enzymes and a greater prevalence of the MetS and its individual components than those with LSM≤7.0 kPa. Factors independently associated with elevated CAP were presence of the MetS (or its individual components), insulin resistance, increased uric acid and LSM > 7 kPa. In multivariable logistic regression analysis, the factors that remained independently associated with LSM > 7 kPa were the presence of the MetS, diabetes mellitus type 2, hypertension, abdominal obesity, elevated HOMA-IR score and serum uric acid levels.

**Conclusion:** Patients with one or more components of the MetS have a high prevalence of NAFLD defined by TE with CAP and advanced liver fibrosis. Our data further support screening for NAFLD and/or advanced fibrosis in this group of high-risk patients. Although improvements in non-invasive assessment of liver fibrosis are still needed, we believe that transiet elastography with CAP may be a reasonable initial assessment for patients with one or more components of the MetS.

**Introduction:** Metabolic syndrome such as diabetes are important pathogenetic background for the development of nonalcoholic steatohepatitis (NASH). It was reported that the expression of AGE (advanced glycation end-product) was activated in metabolic syndrome, and was also related to the development of NASH. However, precise mechanisms of AGE for the pathogenesis in NASH has not been well understood yet. We clarified the involvement of AGE-AGE receptor (RAGE) system for the development of hepatic fibrosis in NASH by RAGE gene deficient mice (RAGE KO).

**Aim:** Metabolic syndrome such as diabetes are important pathogenetic background for the development of nonalcoholic steatohepatitis (NASH). It was reported that the expression of AGE (advanced glycation end-product) was activated in metabolic syndrome, and was also related to the development of NASH. However, precise mechanisms of AGE for the pathogenesis in NASH has not been well understood yet. We clarified the involvement of AGE-AGE receptor (RAGE) system for the development of hepatic fibrosis in NASH by RAGE gene deficient mice (RAGE KO).

**Method:** Six-week-old male RAGE KO and C57BL/6 (WT) mice were fed with methionine-choline deficient (MCD) diets or control diets (NC) for 20 weeks, and evaluated the biochemical, histological and molecular analysis among these groups. In addition, signal transduction of fibrosis and AGE-RAGE system in the liver, and the crosstalk between both signals were also investigated.

**Results:** The increase of gene expression of RAGE, and remarkable hepatic steatosis and fibrosis were observed in WT mice with MCD (MCD WT). On the other hand, these phenotypes were significantly attenuated in MCD RAGE KO mice. Furthermore, hepatic triglyceride contents in MCD RAGE KO mice were significantly lower than that in MCD WT mice, even though serum triglyceride levels were not different between both groups.

Moreover, the gene expression of the fibrosis markers such as TGF-$\beta$, CTGF, $\alpha$-SMA, Type1 collagen $\alpha$1 and TIMP-1, and the inflammatory markers such as TNF $\alpha$ and NOS2 were increased in the livers in MCD WT mice. However, all of these molecules were significantly down regulated in MCD RAGE KO mice. In addition, the expression of mDia1, Egr1 and other molecules which were important downstream molecules of RAGE were increased, and ERK which was important for the activation of hepatic stellate cells was strongly phosphorylated in MCD WT mice. In contrast, the expression and the activation of these molecules were significantly attenuated in MCD RAGE KO mice.
